About This Book

The primary objective of this reference manual is to define the functionality of the MCIMX51 (i.MX51). The i.MX51 is ideal for power-thirsty applications, such as video and audio media players. The i.MX51 processor includes leading power management, security management, digital rights management, video and image processing technology, providing a formidable combination of the features OEMs desire to drive high-performance video and audio content on wireless mobile devices. The processor is designed with Freescale's Smart Speed Technology, which enables ultra low-power consumption and performance equivalent to processors with much higher MHz.

Audience

It is assumed that the reader understands operating systems, microprocessor system design, and the basic principles of RISC processing.

Organization

Following is a summary and a brief description of the major parts of this reference manual:

Book I contains information that is unique to the i.MX51. The following chapters are included:

- Chapter 1, "Introduction" provides a high-level description of features and functionality of the integrated host processor. It describes the MCIMX51, its interfaces, and its programming model. The functional operation with emphasis on peripheral functions is also described.
- Chapter 2, "Memory Map" describes the memory map. An overview of the local address map is followed by a description of how local access windows are used to define the local address map. The inbound and outbound address translation mechanisms used to map to and from external memory spaces are described next. Finally, the configuration, control, and status registers are described, including a complete listing of all memory-mapped registers with cross references to the sections detailing descriptions of each.
- Chapter 3, "Interrupts and DMA Events" provides a listing of the Interrupts and DMA Events. This chapter also provides information on the assignments of interrupts and of the DMA events.
- Chapter 4, "External Signals and Pin Multiplexing" describes the external signals and pin multiplexing. The input-output multiplexer (IOMUX) controls the pin multiplexing. The IOMUX also configures other pin characteristics, such as voltage level, drive strength, and hysteresis. This chapter organizes the signals by functional group (as defined by the top-level block diagrams) and then by subgroups (interfaces) within each functional group.
- Chapter 5, "External Memories" describes the module that controls all i.MX51 external memory accesses (read/write/erase/program) from all the masters in the system to different external memories. All accesses are arbitrated by the Multi Master Multi Memory Interface (M4IF) module and controlled by the respective memory controller. Because different modules require different pad settings (like pull up, keeper, and others), the IOMUXC controls also the pad settings parameters.
- Chapter 6, "Fuse Map" lists all fusable elements in the i.MX51.

- Chapter 7, “Clock Controller Module (CCM)” controls the clocks for the i.MX51 modules. This module uses the available clock sources to generate the clock roots.
- Chapter 8, “Debug Architecture” describes the hardware and software debug and application development features and resources of i.MX51. There are core/platform-specific resources, resources associated with some of the more complex IP blocks, and chip-wide resources.
- Chapter 9, “System Boot” describes the system boot sequence of the i.MX51 application processor and provides the details of boot options.[1]
- Chapter 10, “Multimedia” contains descriptions of the major components of the Multimedia module including the Video Processing Unit (VPU), Graphics Processing Unit (GPU): accelerating 2D/3D graphics, Image Processing Unit (IPU): providing connectivity to cameras and displays, related processing, synchronization and control.
- Chapter 11, “Power Management” describes the operation of the various power management techniques supported by the i.MX51 and the registers used to configure and control them. These power management techniques reduce active and static power consumption.
- Chapter 12, “System Security” describes the security features designed into the i.MX51.

Book II contains chapters describing modules in the i.MX51 that are common to the MX generation of ICs. The following chapters are included:

- Chapter 13, “1-Wire Module (1-Wire)” describes the 1-Wire module, which provides the communication link to a generic 1-Kbit add-only memory. The module sends or receives one bit at a time with an option for software to manage the data using bytes.
- Chapter 14, “Cortex-A8 Platform” provides an overview of the ARM Cortex-A8n platform, which includes a NEON co-processor, an L1 cache, an L2 cache, an ETM and a CTI. The platform includes the essential sub-blocks: platform control, test logic and the debug modules (CTM, ETB, and a second CTI).
- Chapter 15, “Platform Debug” provides an overview of the ARM platform debug. It will cover the modules inside the tigerp_gp_debug block and also the modules that support the platform debug within the SOC, but external to the ARM platform
- Chapter 16, “Multi-Layer AHB Crossbar Switch (MAX)” provides an overview of the MAX (Multi-Layer AHB Crossbar Switch). The purpose of the MAX is to concurrently support up to 4 simultaneous connections between master ports and slave ports.
- Chapter 17, “Digital Audio Mux (AUDMUX)” describes the AUDMUX, which provides a programmable interconnect device for voice, audio, and synchronous data routing between host serial interfaces (that is, SSI, SAP) and peripheral serial interfaces (that is, audio and voice CODECs, also known as coder-decoders).
- Chapter 18, “Configurable Serial Peripheral Interface (CSPI)” describes the Configurable Serial Peripheral Interface (CSPI) module, which allows rapid data communication with fewer software interrupts than conventional serial communications.
- Chapter 19, “Clock Amplifier (CAMP)” describes the Clock Amplifier, which converts a square wave/sinusoidal input of frequency range 8–40 MHz into a rail-to-rail square wave (CAMP supply voltage).

1. Portions of this chapter are restricted. See your Freescale representative for details.

- Chapter 20, “Central Security Unit (CSU)” describes the Central Security Unit (CSU), which enables software for setting comprehensive security policy within the platform and sharing secure information between various secure modules.
- Chapter 21, “Digital Phase Lock Loop (DPLL)” describes the three on-chip Digital Phase Lock Loops (DPLLs), which provide clock generation in digital and mixed analog/digital chips designed for wireless communication and other applicationsThis chapter provides an overview of the DPLL opertation.
- Chapter 22, “DPLL-IP Interface (DPLL-IP)” describes the DPLL-IP, which serves as an interface to the DPLL module. It generates the control signals required for the DPLL operations. In other MX ICs this used to be part of the SRC (System Reset Controller) module
- Chapter 23, “Dynamic Process and Temperature Compensation (DPTC)” describes the DPTC (Dynamic Process and Temperature Compensation) module, which is a power management module. The purpose of the DPTC module is to detect the minimum operation voltage for the IC, regarding process corner case and temperature for a given frequency
- Chapter 24, “Dynamic Voltage Frequency Scaling (DVFS)” The DVFS allows simple dynamic voltage frequency scaling. The frequency of the core clock domain and the voltage of the core power domain can be changed on the fly while all modules (including the MCU) continue their normal operation.
- Chapter 25, “Dynamic Voltage Frequency Scaling for Peripherals (DVFS_PER)” Dynamic Voltage and Frequency Scaling (DVFS) enables the frequency of the system and the voltage of the power domain to be changed on the fly while all modules continue their normal operation on reduced frequency.
- Chapter 26, “Enhanced Configurable Serial Peripheral Interface (eCSPI)” The eCSPI module allows rapid data communication with fewer software interrupts than conventional serial communications methodologies.
- Chapter 27, “External Memory Interface (EMI)” The EMI is a memory controller of memory devices in the system, both internal and external. It provides a capability for the system to control the external memory device, by preforming several type of accesses like read, write, program, and erase as well as internal memories of the system.
- Chapter 28, “Embedded Memory Periphery Power Gating Controller (EMPGC)”
- Chapter 29, “Enhanced Periodic Interrupt Timer (EPIT)” The Enhanced Periodic Interrupt Timer (EPIT) is a 32-bit set-and-forget timer which begins counting after the EPIT is enabled by software. It is capable of providing precise interrupts at regular intervals with minimal processor intervention.
- Chapter 30, “Enhanced SDRAM Controller (eSDCTL)” The Enhanced SDRAM Controller version 2 (eSDCTLV2) consists of nine major blocks, including the SDRAM command state machine controller, bank register (page and bank address comparators), Row/Column Address Multiplexer, configuration registers, refresh request counter, command sequencer, size logic (splitting access), data path (data aligner/multiplexer), LPDDR interface, and the Power Down timer.
- Chapter 31, “Enhanced Secured Digital Host Controller (eSDHC)” The eSDHC provides the interface between the host system and MMC/SD/SDIO/CE-ATA cards, including cards with reduced size or mini cards.

- Chapter 32, “Fast Ethernet Controller (FEC)” This chapter provides a feature-set overview, a functional block diagram, and transceiver connection information for both the 10 and 100 Mbps Media Independent Interface (MII), as well as the 7-wire serial interface.
- Chapter 33, “Fast Infrared Interface (FIRI)” The Fast Infrared Interface module (FIRI) is capable of establishing any of the following links: 0.576 Mbit/s, 1.152 Mbit/s, or 4 Mbit/s half duplex (using a LED and IR detector).
- Chapter 34, “General Power Controller (GPC)” GPC module controls the following Advanced Power Saving features:DVFS, DPTC, and all of the SRPG modules.
- Chapter 35, “General Purpose Input/Output (GPIO)” The General Purpose Input/Output (GPIO) module provides 32 bits of bidirectional, general-purpose input and output signals.
- Chapter 36, “General Purpose Timer (GPT)” The General purpose timer (GPT) has a 32 bit up-counter. The timer counter value can be captured in a register using an event on an external pin. The capture trigger can be programmed to be a rising or/and falling edge.
- Chapter 37, “Graphics Processing Unit 2D (GPU2D)” The GPU is an embedded 2D and vector graphics accelerator targeting the OpenVG 1.1 graphics API and feature set. It accelerates 2D bitmap graphics operations, such as BitBlt, fill and raster operations using a separate 2D graphics acceleration unit. Vector graphics rendering is accelerated by a separate anti-aliasing polygon rasterizer, which is connected to the 2D graphics acceleration unit.
- Chapter 38, “3D Graphics Accelerator (GPU3D)” The GPU3D (3D graphics processing unit) is based on the AMD Z430 (also known as ATI Yamato DX). The contains an embedded engine capable of DirectX9 Shader Model 3.0+ program execution. The module focus is on accelerating user level graphics APIs such as OpenGL ES 2.0 & 1.1, and Direct3D Mobile 1.2.
- Chapter 39, “High Speed Inter IC (HS-I^2C)” The High Speed Inter IC (HS-I^2C) is bi-directional, two wire, serial bus interface module. The HS_I^2C is designed to be compatible with the standard Philips I^2C bus protocol version 2.1.
- Chapter 40, “Inter IC (I^2C)” The Inter IC (I^2C) module provides functionality of a standard I^2C slave and master. The I^2C module is designed to be compatible with the standard Philips I^2C bus protocol.
- Chapter 42, “Image Processing Unit 3 (IPUv3EX)” The IPU is part of the video and graphics subsystem in the i.MX51. It provides comprehensive support for the flow of data from an image sensor and/or to a display device.
- Chapter 43, “Keypad Port (KPP)” The Keypad Port (KPP) is a 16-bit peripheral that can be used as a keypad matrix interface or as general purpose input/output (I/O).
- Chapter 44, “Multi Master Multi Memory Interface (i.MX51)” The Multi-Master Multi Memory Interface (M4IF) controls memory accesses (read/write/erase/program) from one or more masters through different port interfaces to different external memory controllers ESDCTL, NFC, and WEIM, as well as two internal memories in the system as well.
- Chapter 45, “NAND Flash Controller (NFC)” Composed of various control logic units, a 4.5-Kbyte internal RAM buffer and an internal ECC mechanism, the NAND Flash Controller (NFC) implements the interface to standard NAND Flash memory devices.

- Chapter 46, “Parallel Advanced Technology Attachment (P-ATA)” The ATA block is an AT attachment host interface. Its main use is to interface with hard disc drives and optical disc drives. It interfaces with the ATA device over a number of ATA signals.
- Chapter 47, “Pulse-Width Modulator (PWM)” The pulse-width modulator (PWM) has a 16-bit counter, and is optimized to generate sound from stored sample audio images and it can also generate tones. It uses 16-bit resolution and a 4×16 data FIFO to generate sound.
- Chapter 48, “Run-Time Integrity Checker (RTIC)” The Run-Time Integrity Checker (RTIC) function is to ensure the integrity of the peripheral memory contents, and assist with boot authentication. The RTIC has the ability to verify the memory contents during system boot and during run-time execution.
- Chapter 49, “Symmetric/Asymmetric Hashing and Random Accelerator (SAHARA)” The Symmetric/Asymmetric Hashing and Random Accelerator (SAHARA) is a security co-processor that can be used on cell phone baseband processors or wireless PDAs. It implements block encryption algorithms, (AES, DES, and 3DES), hashing algorithms (MD5, SHA-1, SHA-224, and SHA-256), stream cipher algorithm (ARC4), and a hardware random number generator.
- Chapter 50, “Security Controller (SCC)” The Security Controller (SCC) is composed of two sub-blocks, secure RAM and a security monitor.
- Chapter 51, “Subscriber Identification Module (SIM)” The Subscriber Identification Module (SIM) is designed to facilitate communication to SIM cards or Eurochip pre-paid phone cards. The SIM module has two ports that can be used to interface with the various cards.
- Chapter 52, “Smart Direct Memory Access (SDMA) Controller” The Smart Direct Memory Access (SDMA) controller offers highly-competitive DMA features combined with software-based virtual-DMA flexibility. It enables data transfers between peripheral I/O devices and internal/external memories.
- Chapter 53, “Sony/Philips Digital Interface Transmitter (SPDIF Tx)” The Sony/Philips Digital Interface Transmitter (SPDIF Tx) audio module is a stereo transmitter that allows the processor to transmit digital audio over it.
- Chapter 56, “Synchronous Serial Interface (SSI)” The SSI is a full-duplex, serial port that allows the chip to communicate with a variety of serial devices. These serial devices can be standard CODer-DECoder (CODECs), Digital Signal Processors (DSPs), microprocessors, peripherals, and popular industry audio CODECs that implement the inter-IC sound bus standard (I^2S) and Intel AC97 standard.
- Chapter 58, “TV Encoder (TVE)” The TV Encoder (TVE) is designed to provide direct connection between an Application Processor (AP) and a TV set via analog interfaces.
- Chapter 59, “y Universal Asynchronous Receiver/Transmitter (UART)” The UART supports serial RS-232 NRZ format, and IrDA.
- Chapter 60, “Universal Serial Bus OTG HOST (USBOH3)” The USBOH3 module contains all of the functionality required to support four independent USB ports which are compatible with the USB 2.0 specification. Three of the USB host controllers are identical. In addition to the normal USB functionality, the module also provides support for direct connections to on-board USB peripherals using serial or ULPI protocol.

- Chapter 61, “Video Processing Unit (VPU)” Video Processing Unit of the i.MX51 is a high performance multi-standard video processing unit which can perform H.264 BP/MP/HP, VC-1 SP/MP/AP, MPEG4 SP/ASP, Divx ,RV8/9,and MPEG2 MP decoding up to 1920x1088 resolution.
- Chapter 62, “Watchdog Timer (WDOG)” The Watchdog (WDOG) timer module protects against system failures by providing a method of escaping from unexpected events or programming errors.
- Chapter 63, “Wireless External Interface Module (WEIM)” The Wireless External Interface Module (IPU) handles the interface to devices external to the chip, including generation of chip selects, clock and control for external peripherals and memory. It provides asynchronous access to devices with SRAM-like interface and synchronous access to devices with NOR-Flash like or PSRAM like interface.
- Appendix A, “IOMUX Controller (IOMUXC)” The IOMUX controller (IOMUXC), together with the IOMUX, enables the IC to share one BGA contact with several functional blocks. The sharing is done by multiplexing the BGA contact input/output signals.

MCIMX51 Reference Manual
Book I

Rev. 1
2/2010

Chapter 1
Introduction

This chapter introduces the architecture of the MCIMX51 (i.MX51) Multimedia Applications Processor. The i.MX51 processor represents Freescale Semiconductor's latest achievement in multimedia integrated applications processors that are part of a growing family of multimedia-focused products offering high performance processing optimized for lowest power consumption.

A high-level description of features and functionality of the integrated host processor are provided in this chapter. The different modules are summarized and the interfaces are also described, along with the respective programming model. Functional operation with emphasis on peripheral functions is also included.

NOTE

Because the i.MX51 and i.MX51A are functionally identical, all references to the i.MX51 in this reference manual also apply to the i.MX51A.

1.1 Target Applications

The flexibility of the architecture allows it to be used in a wide variety of applications. Regardless of whether the customer is designing a smartphone, PDA, gaming console, portable media player (PMP), portable navigation device (PND), web tablets, or other portable device, the i.MX51 processor provides design with the power and flexibility necessary for today's competitive marketplace.

1.2 Features

The i.MX51 processor is based on an ARM Cortex A8™ platform, which has the following features:

- ARM Cortex A8™ Processor (with TrustZone)
- 32 Kbyte L1 Instruction Cache
- 32 Kbyte L1 Data Cache
- 256 Kbyte L2 cache
- Neon coprocessor
  - SIMD Media Processing Architecture
  - NEON register file with 32 × 64-bit general-purpose registers
  - NEON Integer execute pipeline (ALU, Shift, MAC)
  - NEON dual, single-precision floating point execute pipeline (FADD, FMUL)
  - NEON load/store and permute pipeline
  - Non-pipelined Vector Floating Point (VFP) co-processor (VFP)

The maximum frequency of the core is:

- 800 MHz (consumer version)
- 600 MHz (automotive and extended temperature version)

See respective data sheet for details about frequency, voltage, and temperature ranges.

To boost the multimedia performance, the following hardware accelerators are integrated:

- VPU—Video Processing Unit
- IPU—Image Processing Unit
- GPU 3D—Graphics Processing Unit (OpenGL ES 2.0)
- GPU 2D—Graphics Processing Unit, 2D (OpenVG 1.1)

Security functions are enabled and accelerated by the following hardware:

- ARM TrustZone including the TZ architecture (separation of interrupts, memory mapping, etc.)
- SJC—Secure JTAG Controller. Protecting JTAG from debug port attacks by regulating or blocking the access to the system debug features
- SRTC—Secure Real-Time Clock. Tamper resisted RTC with its own power domain and mechanism to detects voltage and clock glitches
- RTIC—Real-Time Integrity Checker. RTIC type 1, enhanced with SHA-256 engine
- SAHARA Lite—Cryptographic accelerator that includes true random number generator (TRNG)
- SCC—security controller type 2. Improved SCC with AES engine, Secure/Non-Secure RAM and support for multiple keys as well as TZ/non-TZ separation
- CSU—Central Security Unit. Enhancement for the IIM. Will be configured during boot and by e-fuses and will determine the security level operation mode as well as the TZ policy
- A-HAB—Advanced High Assurance Boot – HAB with the next embedded enhancements: SHA-256, 2048 bit RSA key, version control mechanism, warm boot, CSU and TZ initialization

The memory system consists of the following levels:

- Level 1 Cache
  - Instruction (32 Kbyte)
  - Data (32 Kbyte)
- Level 2 Cache
  - Unified instruction and data (256 Kbyte)
- Level 2 Memory
  - Boot ROM, including HAB (36 KB)
  - Unified Internal RAM (128 KB), including Secure/Non-Secure RAM. Support flexible allocation of secure/non-secure, at 8 KB blocks granularity. Controlled by SCC module.

The i.MX51 SoC is built around the following system buses:

- 64-bit AMBA AXI v1.0. It is referenced further as AXI and used by ARM Cortex A8™ Platform, major multimedia accelerators (VPU, IPUEX), and EMI.

- 32-bit AMBA AHB 2.0. It is referenced further as AHB and used by most of the bus master peripherals, such as SDMA, RTIC, SCC etc. (see block diagram for the complete list).
- 32-bit IP. It is used for control (and slow data traffic) of the most SoC peripheral devices.

The following interfaces are available for external devices (some are muxed and not available simultaneously):

- Hard Disk Drives
  - CE-ATA, up to 416 Mbps
  - P-ATA, up to 66 MByte/s
- Displays
  - Two display ports, each can drive displays using either (or both) of the following interfaces
    - Parallel interface: up to 24-bit data bus, up to 100 MHz
    - DSI fast serial interface: up to 2 data lanes, up to 1600 Mbps
  - NTSC/PAL TV-Out interface via integrated video encoder.
  - Pixel Color depth up to 24-bits
- Camera sensors
  - Two camera ports (each can use either parallel or serial interface)
    - Parallel Camera sensor (up to 16-bit, peak up to 120 Mpixels/sec)
- Expansion cards
  - Four SD/MMC cards , The MMC card supports operation of 416 Mbps in 8-bit mode. The SD/SDIO supports 1-bit and 4-bit modes up to 200 Mbps.
- External memory interfaces
  - 32-bit DDR2, mobile DDR - both with 200 MHz clock
  - 8/16-bit NAND SLC/MLC Flash, up to 50 MHz
  - 16-bit NOR Flash. 32-bit width is supported in multiplexed Address/Data mode. All WEIM pins are muxed on other interfaces (data with NFC pins). IO muxing logic selects WEIM port, as primary muxing at system boot.
  - PSRAM, Cellular RAM
  - MDOC NAND Flash and OneNAND
  - 32-bit is supported in Muxed mode
- USB
  - USB 2.0 OTG, up to 480 Mbps
  - Integrated High Speed USB Phy
  - 3 USB 2.0 Hosts, up to 480 Mbps each
    - Only OTG port supports overcurrent and PM signals.
  - External HS/FS Transceivers, (ULPI / Serial), at expense of functionality, due to IO muxing limitations.
- Low-Power Modes (LPM)
  - Supporting DVFS and DPTC techniques for low power modes

- Uses SRPG (State Retention Power Gating) for ARM and Neon
- Power-gating for VPU, GPU and Save & Restore (S&R) Power gating for IPU.
- Partial SRPG of EMI
- Support for various levels of system power modes
  - Peripherals are divided into 2 groups. One of the groups supports SRPG.
- Flexible clock gating control scheme

- Miscellaneous IPs and interfaces:
  - 1-Wire
  - Three (3) I^2S/SSI/AC97, up to 1.4 Mbps each
  - Three (3) UART, up to 4.0 Mbps each
    - One supports 8-bit and others supports 4-bit.
  - One CSPI
  - Two eCSPI, up to 52 Mbps each
  - One HS-I^2C, supports 3.4Mbps[1]
  - Two (2) I^2C, supports 400 kbps
  - Fast Ethernet Controller, 10/100 Mbps
  - Two Pulse Width Modulators (PWM)
  - JTAG Controller (SJC)
  - GPIO with interrupt capabilities
  - Key Pad Port (KPP)
  - One SIM, up to 33 Mbps
  - Sony Phillips Digital Interface Transmitter (SPDIF)
- Watchdog timers
- Audio MUX

1.3 Architectural Overview

This section contains a simplified block diagram of the i.MX51.

1. Not recommended for use in new designs. See i.MX51 IC errata

1.3.1 Block Diagram

Figure 1-1 shows a high-level block diagram of the i.MX51, providing a view of the major subsystems (processor domains, shared peripherals domain, memories, etc.) and logical connectivity.

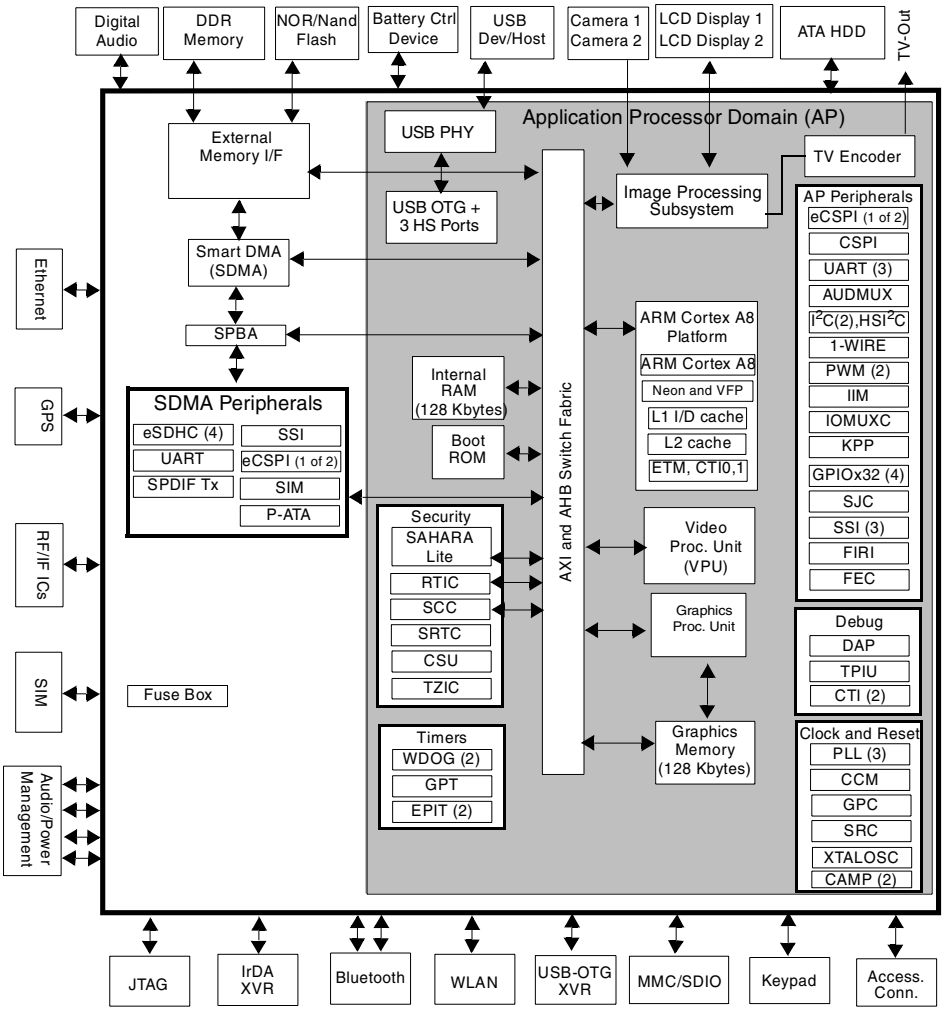

Figure 1-1. i.MX51 Simplified Block Diagram

1.3.2 Major Subsystems

The i.MX51 consists of the following major subsystems:

- Core (ARM Cortex A8™) Platform, L1/L2 memories
- SDMA controller and the shared peripheral domain
- System Control—Boot Flow control, Clocks distribution, “Reset” control and Low Power logic

- Multimedia
  - Video Processor
  - TV-Encoder (TVe-) for PAL/NTSC output
  - Image Processor
  - Graphics Processors
  - Audio—connectivity interfaces in hardware, while codecs are performed in SW by ARM core.
- Security
- Connectivity peripherals
- External Memory Interface

1.3.3 Architectural Partitioning

This paragraph defines how architecture supports the processing intensive tasks:

- ARM Cortex A8™ Platform is responsible for:
  - Operating System
  - User applications (including control over hardware accelerators and non-accelerated functions)
  - TrustZone applications
- Smart DMA enables data transfer between non-mastering peripherals and external or internal memories
- System Control is supported via:
  - Clock Control Block (CCM)
  - Three (3×) PLLs
  - XTALOSC—Crystal oscillator source support
  - Frequency Pre-multiplier (FPM)
  - System Reset Controller (SRC)
  - Global Power Controller (GPC)
  - Two (2×) CAMPs—Clock Amplifier modules on the CKIH1 and CKIH2 inputs
- Multimedia is supported with:
  - Image Processing Unit—IPUEX
    - Connectivity to displays, display controllers, and auxiliary graphics co-processors
    - Display Processing: video/graphics combining, image enhancement
    - Image conversions: resizing, rotation/inversion, color conversion
    - Synchronization and control capabilities, allowing autonomous operation
  - Video Processing Unit (VPU) (Video codecs, all in hardware unless mentioned otherwise):
    - MPEG-4 decode: 1280 × 720, 30 fps, Simple Profile and Advanced Simple Profile
    - MPEG-4 encode: D1, Simple Profile
    - H.263 decode: 1280 × 720, 30 fps, Profile 3
    - H.263 encode: D1, Profile 3

- H.264 decode: 1280 × 720, 30 fps, Baseline, Main, and High Profile
- H.264 encode: D1, Baseline Profile
- MPEG-2 decode: 1280 × 720, 30 fps, MP-ML
- MPEG-2 encode: D1, MP-ML (in Software with Partial Acceleration in Hardware)
- VC-1 decode: 1280 × 720, 30 fps, Simple, Main, and Advanced Profile
- DivX decode: 1280 × 720, 30 fps Versions 3, 4, and 5
- RV10 decode: 1280 × 720, 30 fps
- MJPEG decode: 32 MPix/s
- MJPEG encode: 64 Mpix/s

— Graphics Processing Unit (GPU), 3D graphics processing compliant with the following:
- OpenGL ES Common Profile v1.0
- OpenGL ES Common Profile v1.1/Direct3D Mobile
- OpenGL ES Profile v2.0
- OpenVG 1.0

— Graphics Processing Unit (GPU2D), 2D graphics processing

— Audio
- Audio codecs are provided by software, which runs on ARM core
- 3 × SSIs
- Audio Mux
- SPDIF

- Security is supported by:
  - — High Assurance Boot (HAB) System
  - — ARM TrustZone (TZ) Trusted Execution environment
  - — IC Identification Module (IIM) and Central Security Unit (CSU)
  - — On-chip One-Time programmable electrical fuse array (E-Fusebox)
  - — RTIC: Real-Time Integrity Checker
  - — SAHARA Lite (SAHARA-Lite) cryptographic acceleration engine
  - — SJC—Secured JTAG controller
  - — Secure Real Time Clock (SRTC)
  - — Security Controller (SCC) with secure RAM
  - — Tamper Detection
  - — TrustZone Watchdog (TZ WDOG)
- Connectivity peripherals, timers, and External Memory Interface (EMI)
  - — Low-level communication protocols
  - — Embedded DMAs
  - — 3.3-V IO voltage for seamless integration
  - — USB 2.0 with integrated PHY/Transceiver, Serial FS (requires external transceiver)

— Video encoder with NTSC/PAL output
— DDR, Nand Flash (MLC 4/8-bit ECC) memory interface via EMI
— Timers: 2 × EPIT, GPT, and Watch Dog timer (WDOG)
— Miscellaneous connectivity support—I2C, SPI, UART, PWM, and Keypad interface

1.4 i.MX51 Modules List

Table 1 lists the modules used by the various subsystems of the i.MX51.

Table 1. i.MX51 Digital and Analog Modules

Block Mnemonic	Block Name	Subsystem	Brief Description
1-WIRE	1-Wire Interface	Connectivity Peripherals	1-Wire support provided for interfacing with an on-board EEPROM, and smart battery interfaces, for example: Dallas DS2502.
ARM Cortex A8™	ARM Cortex A8™ Platform	ARM	The ARM Cortex A8™ Core Platform consists of the ARM Cortex A8™ processor version r2p5 (with TrustZone) and its essential sub-blocks. It contains the Level 2 Cache Controller, 32-Kbyte L1 instruction cache, 32-Kbyte L1 data cache, and a 256-Kbyte L2 cache. The platform also contains an Event Monitor and Debug modules. It also has a NEON co-processor with SIMD media processing architecture, register file with 32 × 64-bit general-purpose registers, an Integer execute pipeline (ALU, Shift, MAC), dual, single-precision floating point execute pipeline (FADD, FMUL), load/store and permute pipeline and a Non-Pipelined Vector Floating Point (VFP) co-processor (VFPv3).
Audio Subsystem	Audio Subsystem	Multimedia Peripherals	The elements of the audio subsystem are three Synchronous Serial Interfaces (SSI1-3), a Digital Audio Mux (AUDMUX), and Digital Audio Out (SPDIF TX). See the specific interface listings in this table.
AUDMUX	Digital Audio Mux	Multimedia Peripherals	The AUDMUX is a programmable interconnect for voice, audio, and synchronous data routing between host serial interfaces (for example, SSI1, SSI2, and SSI3) and peripheral serial interfaces (audio and voice codecs). The AUDMUX has seven ports (three internal and four external) with identical functionality and programming models. A desired connectivity is achieved by configuring two or more AUDMUX ports.
CCM GPC SRC	Clock Control Module Global Power Controller System Reset Controller	Clocks, Resets, and Power Control	These modules are responsible for clock and reset distribution in the system, and also for system power management. The modules include three PLLs and a Frequency Pre-Multiplier (FPM).
CSPI-1, eCSPI-2 eCSPI-3	Configurable SPI, Enhanced CSPI	Connectivity Peripherals	Full-duplex enhanced Synchronous Serial Interface, with data rate up to 66.5Mbit/s (for eCSPI, master mode). It is configurable to support Master/Slave modes, four chip selects to support multiple peripherals.
CSU	Central Security Unit	Security	The Central Security Unit (CSU) is responsible for setting comprehensive security policy within the i.MX51 platform, and for sharing security information between the various security modules. The Security Control Registers (SCR) of the CSU are set during boot time by the High Assurance Boot (HAB) code and are locked to prevent further writing.

Table 1. i.MX51 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
Debug System	Debug System	System Control	The Debug System provides real-time trace debug capability of both instructions and data. It supports a trace protocol that is an integral part of the ARM Real Time Debug solution (RealView). Real-time tracing is controlled by specifying a set of triggering and filtering resources, which include address and data comparators, cross-system triggers, counters, and sequencers.
EMI	External Memory Interface	Connectivity Peripherals	The EMI is an external and internal memory interface. It performs arbitration between multi-AXI masters to multi-memory controllers, divided into four major channels: fast memories (Mobile DDR, DDR2) channel, slow memories (NOR-FLASH/PSRAM/NAND-FLASH etc.) channel, internal memory (RAM, ROM) channel and graphical memory (GMEM) Channel. In order to increase the bandwidth performance, the EMI separates the buffering and the arbitration between different channels so parallel accesses can occur. By separating the channels, slow accesses do not interfere with fast accesses. EMI features: • 64-bit and 32-bit AXI ports • Enhanced arbitration scheme for fast channel, including dynamic master priority, and taking into account which pages are open or closed and what type (Read or Write) was the last access • Flexible bank interleaving • Supports 16/32-bit Mobile DDR up to 200 MHz SDCLK (mDDR400) • Supports 16/32-bit (Non-Mobile) DDR2 up to 200 MHz SDCLK (DDR2-400) • Supports up to 2 Gbit Mobile DDR memories • Supports 16-bit (in muxed mode only) PSRAM memories (sync and async operating modes), at slow frequency, for debugging purposes • Supports 32-bit NOR-Flash memories (only in muxed mode), at slow frequencies for debugging purposes • Supports 4/8-ECC, page sizes of 512 Bytes, 2 KBytes and 4 KBytes • NAND-Flash (including MLC) • Multiple chip selects • Enhanced Mobile DDR memory controller, supporting access latency hiding • Supports watermarking for security (Internal and external memories) • Supports Samsung OneNAND™ (only in muxed I/O mode)
EPIT-1 EPIT-2	Enhanced Periodic Interrupt Timer	Timer Peripherals	Each EPIT is a 32-bit “set and forget” timer that starts counting after the EPIT is enabled by software. It is capable of providing precise interrupts at regular intervals with minimal processor intervention. It has a 12-bit prescaler for division of input clock frequency to get the required time setting for the interrupts to occur, and counter values can be programmed on the fly.

Table 1. i.MX51 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
eSDHC-1 eSDHC-2 eSDHC-3	Enhanced Multi-Media Card/ Secure Digital Host Controller	Connectivity Peripherals	The features of the eSDHC module, when serving as host, include the following: • Conforms to SD Host Controller Standard Specification version 2.0 • Compatible with the MMC System Specification version 4.2 • Compatible with the SD Memory Card Specification version 2.0 • Compatible with the SDIO Card Specification version 1.2 • Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC and MMC RS cards • Configurable to work in one of the following modes: —SD/SDIO 1-bit, 4-bit —MMC 1-bit, 4-bit, 8-bit • Full-/high-speed mode • Host clock frequency variable between 32 kHz to 52 MHz • Up to 200 Mbps data transfer for SD/SDIO cards using four parallel data lines • Up to 416 Mbps data transfer for MMC cards using eight parallel data lines
eSDHC-4 (muxed with P-ATA)	Enhanced Multi-Media Card/ Secure Digital Host Controller	Connectivity Peripherals	Can be configured as eSDHC (see above) and is muxed with the P-ATA interface.
FEC	Fast Ethernet Controller	Connectivity Peripherals	The Ethernet Media Access Controller (MAC) is designed to support both 10 Mbps and 100 Mbps ethernet/IEEE Std 802.3™ networks. An external transceiver interface and transceiver function are required to complete the interface to the media.
FIRI	Fast Infra-Red Interface	Connectivity Peripherals	Fast Infra-Red Interface
GPIO-1 GPIO-2 GPIO-3 GPIO-4	General Purpose I/O Modules	System Control Peripherals	These modules are used for general purpose input/output to external ICs. Each GPIO module supports up to 32 bits of I/O.
GPT	General Purpose Timer	Timer Peripherals	Each GPT is a 32-bit “free-running” or “set and forget” mode timer with a programmable prescaler and compare and capture register. A timer counter value can be captured using an external event, and can be configured to trigger a capture event on either the leading or trailing edges of an input pulse. When the timer is configured to operate in “set and forget” mode, it is capable of providing precise interrupts at regular intervals with minimal processor intervention. The counter has output compare logic to provide the status and interrupt at comparison. This timer can be configured to run either on an external clock or on an internal clock.
GPU	Graphics Processing Unit	Multimedia Peripherals	The GPU provides hardware acceleration for 2D and 3D graphics algorithms with sufficient processor power to run desk-top quality interactive graphics applications on displays up to HD720 resolution. It supports color representation up to 32 bits per pixel. The GPU with its 128 KByte memory enables high performance mobile 3D and 2D vector graphics at rates up to 27 Mtriangles/sec, 166 M pixels/sec, 664 Mpixels/sec (Z).

Table 1. i.MX51 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
GPU2D	Graphics Processing Unit-2D Ver. 1	Multimedia Peripherals	The GPU2D provides hardware acceleration for 2D graphic algorithms with sufficient processor power to run desk-top quality interactive graphics applications on displays up to HD720 resolution.
I^2C-1 I^2C-2 HS-I^2C	I^2C Interface	Connectivity Peripherals	I^2C provides serial interface for controlling peripheral devices. Data rates of up to 400 Kbps are supported by two of the I^2C ports. Data rates of up to 3.4 Mbps (I^2C Specification v2.1) are supported by the HS-I^2C. **Note:** See the errata for the HS-I^2C in the i.MX51 Chip Errata. The two standard I^2C modules have no errata.
IIM	IC Identification Module	Security	The IC Identification Module (IIM) provides an interface for reading, programming, and/or overriding identification and control information stored in on-chip fuse elements. The module supports electrically programmable poly fuses (e-Fuses). The IIM also provides a set of volatile software-accessible signals that can be used for software control of hardware elements not requiring non-volatility. The IIM provides the primary user-visible mechanism for interfacing with on-chip fuse elements. Among the uses for the fuses are unique chip identifiers, mask revision numbers, cryptographic keys, JTAG secure mode, boot characteristics, and various control signals requiring permanent non-volatility. The IIM also provides up to 28 volatile control signals. The IIM consists of a master controller, a software fuse value shadow cache, and a set of registers to hold the values of signals visible outside the module.
IOMUXC	IOMUX Control	System Control Peripherals	This module enables flexible I/O multiplexing. Each I/O pad has default as well as several alternate functions. The alternate functions are software configurable.
IPU	Image Processing Unit	Multimedia Peripherals	IPU enables connectivity to displays and image sensors, relevant processing and synchronization. It supports two display ports and two camera ports, through the following interfaces. • Legacy Interfaces • Analog TV interfaces (through a TV encoder bridge) The processing includes: • Support for camera control • Image enhancement: color adjustment and gamut mapping, gamma correction and contrast enhancement, sharpening and noise reduction • Video/graphics combining • Support for display backlight reduction • Image conversion—resizing, rotation, inversion and color space conversion • Synchronization and control capabilities, allowing autonomous operation. • Hardware de-interlacing support
KPP	Keypad Port	Connectivity Peripherals	The KPP supports an 8×8 external keypad matrix. The KPP features are as follows: • Open drain design • Glitch suppression circuit design • Multiple keys detection • Standby key press detection

Table 1. i.MX51 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
P-ATA (Muxed with eSDHC-4	Parallel ATA	Connectivity Peripherals	The P-ATA block is an AT attachment host interface. Its main use is to interface with hard disc drives and optical disc drives. It interfaces with the ATA-5 (UDMA-4) compliant device over a number of ATA signals. It is possible to connect a bus buffer between the host side and the device side. This is muxed with eSDHC-4 interfaces.
PWM-1 PWM-2	Pulse Width Modulation	Connectivity Peripherals	The pulse-width modulator (PWM) has a 16-bit counter and is optimized to generate sound from stored sample audio images. It can also generate tones. The PWM uses 16-bit resolution and a 4x16 data FIFO to generate sound.
RAM 128 Kbytes	Internal RAM	Internal Memory	Unified RAM, can be split between Secure RAM and Non-Secure RAM
ROM 36 Kbytes	Boot ROM	Internal Memory	Supports secure and regular Boot Modes
RTIC	Real Time Integrity Checker	Security	Protecting read-only data from modification is one of the basic elements in trusted platforms. The Run-Time Integrity Checker v3 (RTICv3) module, is a data monitoring device responsible for ensuring that memory content is not corrupted during program execution. The RTICv3 mechanism periodically checks the integrity of code or data sections during normal OS run-time execution without interfering with normal operation. The RTICv3's purpose is to ensure the integrity of the peripheral memory contents, protect against unauthorized external memory elements replacement, and assist with boot authentication.
SAHARA Lite	SAHARA security accelerator Lite	Security	SAHARA (Symmetric/Asymmetric Hashing and Random Accelerator) is a security co-processor. It implements symmetric encryption algorithms, (AES, DES, 3DES, and RC4), public key algorithms, hashing algorithms (MD5, SHA-1, SHA-224, and SHA-256), and a hardware random number generator. It has a slave IP bus interface for the host to write configuration and command information, and to read status information. It also has a DMA controller, with an AHB bus interface, to reduce the burden on the host to move the required data to and from memory.
SCC	Security Controller	Security	The Security Controller is a security assurance hardware module designed to safely hold sensitive data such as encryption keys, digital right management (DRM) keys, passwords, and biometrics reference data. The SCC monitors the system's alert signal to determine if the data paths to and from it are secure—that is, cannot be accessed from outside of the defined security perimeter. If not, it erases all sensitive data on its internal RAM. The SCC also features a Key Encryption Module (KEM) that allows non-volatile (external memory) storage of any sensitive data that is temporarily not in use. The KEM utilizes a device-specific hidden secret key and a symmetric cryptographic algorithm to transform the sensitive data into encrypted data.

Table 1. i.MX51 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
SDMA	Smart Direct Memory Access	System Control Peripherals	The SDMA is multi-channel flexible DMA engine. It helps in maximizing system performance by off loading various cores in dynamic data routing. The SDMA features list is as follows: • Powered by a 16-bit instruction-set micro-RISC engine • Multi-channel DMA supports up to 32 time-division multiplexed DMA channels • 48 events with total flexibility to trigger any combination of channels • Memory accesses including linear, FIFO, and 2D addressing • Shared peripherals between ARM Cortex A8™ and SDMA • Very fast context-switching with two-level priority-based preemptive multi-tasking • DMA units with auto-flush and prefetch capability • Flexible address management for DMA transfers (increment, decrement, and no address changes on source and destination address) • DMA ports can handle unit-directional and bi-directional flows (copy mode) • Up to 8-word buffer for configurable burst transfers for EMI • Support of byte-swapping and CRC calculations • A library of scripts and API are available
SIM	Subscriber Identity Module Interface	Connectivity Peripherals	The SIM is an asynchronous interface with additional features for allowing communication with Smart Cards conforming to the ISO 7816 specification. The SIM is designed to facilitate communication to SIM cards or pre-paid phone cards.
SJC	Secure JTAG Interface	System Control Peripherals	JTAG manipulation is a known hacker's method of executing unauthorized program code, getting control over secure applications, and running code in privileged modes. The JTAG port provides a debug access to several hardware blocks including the ARM processor and the system bus. The JTAG port must be accessible during platform initial laboratory bring-up, manufacturing tests and troubleshooting, as well as for software debugging by authorized entities. However, in order to properly secure the system, unauthorized JTAG usage should be strictly forbidden. In order to prevent JTAG manipulation while allowing access for manufacturing tests and software debugging, the i.MX51 processor incorporates a mechanism for regulating JTAG access. The i.MX51Secure JTAG Controller provides four different JTAG security modes that can be selected via e-fuse configuration.
SPBA	Shared Peripheral Bus Arbiter	System Control Peripherals	SPBA (Shared Peripheral Bus Arbiter) is a two-to-one IP bus interface (IP bus) arbiter.
SPDIF	Sony Philips Digital Interface	Multimedia Peripherals	A standard digital audio transmission protocol developed jointly by the Sony and Philips corporations. Only the transmitter functionality is supported.
SRTC	Secure Real Time Clock	Security	The SRTC incorporates a special System State Retention Register (SSRR) that stores system parameters during system shutdown modes. This register and all SRTC counters are powered by dedicated supply rail NVCC_SRTC_POW. The NVCC_SRTC_POW can be energized even if all other supply rails are shut down. This register is helpful for storing warm boot parameters. The SSRR also stores the system security state. In case of a security violation, the SSRR mark the event (security violation indication).

Table 1. i.MX51 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
SSI-1 SSI-2 SSI-3	I2S/SSI/AC97 Interface	Connectivity Peripherals	The SSI is a full-duplex synchronous interface used on the i.MX51 processor to provide connectivity with off-chip audio peripherals. The SSI supports a wide variety of protocols (SSI normal, SSI network, I2S, and AC-97), bit depths (up to 24 bits per word), and clock/frame sync options. Each SSI has two pairs of 8x24 FIFOs and hardware support for an external DMA controller in order to minimize its impact on system performance. The second pair of FIFOs provides hardware interleaving of a second audio stream, which reduces CPU overhead in use cases where two timeslots are being used simultaneously.
TVE	TV Encoder	Multimedia	The TVE is implemented in conjunction with the Image Processing Unit (IPU) allowing handheld devices to display captured still images and video directly on a TV or LCD projector. It supports the following analog video outputs: composite, S-video, and component video up to HD720p/1080i.
TZIC	TrustZone Aware Interrupt Controller	ARM/Control	The TrustZone Interrupt Controller (TZIC) collects interrupt requests from all i.MX51 sources and routes them to the ARM core. Each interrupt can be configured as a normal or a secure interrupt. Software Force Registers and software Priority Masking are also supported.
UART-1 UART-2 UART-3	UART Interface	Connectivity Peripherals	Each of the UART modules supports the following serial data transmit/receive protocols and configurations: • 7 or 8 bit data words, 1 or 2 stop bits, programmable parity (even, odd, or none) • Programmable baud rates up to 4 MHz. This is a higher max baud rate relative to the 1.875 MHz, which is stated by the TIA/EIA-232-F standard and previous Freescale UART modules. • 32-byte FIFO on Tx and 32 half-word FIFO on Rx supporting auto-baud • IrDA 1.0 support (up to SIR speed of 115200 bps) • Option to operate as 8-pins full UART, DCE, or DTE
USB	USB 2.0 High-Speed OTG and 3x Hosts	Connectivity Peripherals	USB-OTG contains one high-speed OTG module, which is internally connected to the on-chip HS USB PHY. There are an additional three high-speed host modules that require external USB PHYs.
VPU	Video Processing Unit	Multimedia Peripherals	A high-performing video processing unit (VPU), which covers many SD-level video decoders and SD-level encoders as a multi-standard video codec engine as well as several important video processing such as rotation and mirroring. VPU Features: • MPEG-4 decode: 720p, 30 fps, simple profile and advanced simple profile • MPEG-4 encode: D1, 25/30 fps, simple profile • H.263 decode: 720p, 30 fps, profile 3 • H.263 encode: D1, 25/30 fps, profile 3 • H.264 decode: 720p, 30 fps, baseline, main, and high profile • H.264 encode: D1, 25/30 fps, baseline profile • MPEG-2 decode: 720p, 30 fps, MP-ML • MPEG-2 encode: D1, 25/30 fps, MP-ML (in software with partial acceleration in hardware) • VC-1 decode: 720p, 30 fps, simple, main, and advanced profile • DivX decode: 720p, 30 fps versions 3, 4, and 5 • RV10 decode: 720p, 30 fps • MJPEG decode: 32 Mpix/s • MJPEG encode: 64 Mpix/s

Table 1. i.MX51 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
WDOG-1	Watch Dog	Timer Peripherals	The Watch Dog Timer supports two comparison points during each counting period. Each of the comparison points is configurable to evoke an interrupt to the ARM core, and a second point evokes an external event on the WDOG line.
WDOG-2 (TZ)	Watch Dog (TrustZone)	Timer Peripherals	The TrustZone Watchdog (TZ WDOG) timer module protects against TrustZone starvation by providing a method of escaping normal mode and forcing a switch to the TZ mode. TZ starvation is a situation where the normal OS prevents switching to the TZ mode. This situation should be avoided, as it can compromise the system's security. Once the TZ WDOG module is activated, it must be serviced by TZ software on a periodic basis. If servicing does not take place, the timer times out. Upon a time-out, the TZ WDOG asserts a TZ mapped interrupt that forces switching to the TZ mode. If it is still not served, the TZ WDOG asserts a security violation signal to the CSU. The TZ WDOG module cannot be programmed or deactivated by a normal mode SW.
XTALOSC	Crystal Oscillator I/F	Clocking	The XTALOSC module allows connectivity to an external crystal.

1.5 Frequency Requirements

The i.MX51 datasheet lists the target system frequencies at different voltage conditions.

1.6 Memory Interfaces

The EMI supports the following memory interfaces:

- mDDR, DDR2, 32-bit, 200 MHz clock
- NAND (MLC/SLC) Flash, 8/16-bit, 40 MHz
- OneNAND, 1-2 Kbyte page size

Chapter 2
Memory Map

This chapter introduces the memory architecture of the i.MX51. The system memory high-level partition is defined below:

- Level 1 Cache
  - Instruction (32-Kbyte)
  - Data (32-Kbyte)
- Level 2 Cache
  - Unified instruction and data (256 Kbytes)
- Level 2 Memory
  - Boot ROM, including HAB (36-Kbyte)
  - Unified Internal RAM (128 Kbyte), can be split between Secure and Non-Secure RAM
- External memory interface
  - 32-bit mDDR, up to 200 MHz clock
  - 32-bit DDR2, up to 200 MHz clock
  - 8/16-bit NAND SLC/MLC Flash, up to 40 MHz
  - 8/16-bit NOR Flash.

2.1 CPU Memory Map

Table 2-1 shows the system memory map.

NOTE

User must not address reserved memory regions. Access to reserved memory regions can cause unpredictable behavior.

Table 2-1. i.MX51 System Memory Map

AP		Size	Region
Start Address	End Address		
On-Chip Memories (hardware connection via EMI)			
0000_0000	0000_8FFF	36K	Boot ROM
0000_9000	1FFD_FFFF	512M (minus 164K)	Reserved for Internal ROM aliasing
1FFE_0000	1FFF_FFFF	128K	SCC RAM
2000_0000	2001_FFFF	128K	Graphics Memory of GPU

1 The memory map of M4IF, ESDCTL, WEIM, and NFC is specified in the Section 27.4.1, External/Internal Memory Map, of Chapter 27, "External Memory Interface (EMI)."

2 Also named as AXI_BASE in Section 45.6.1, Memory Map of Chapter 45, "NAND Flash Controller (NFC)."

2.2 DMA Memory Map

The Smart DMA's memory map is defined in Table 2-2.

NOTE

User must not address reserved memory regions. Access to reserved memory regions can produce unpredictable behavior.

Table 2-2. SDMA Peripheral Memory Map

Peripheral	Base Address	Size	Comments
Reserved for SDMA internal memory	0x0000	4KB	—

Chapter 3
Interrupts and DMA Events

3.1 Overview

This chapter provides information about the assignments of interrupts in Section 3.2, AP Interrupts," and about the DMA events in Section 3.3, SDMA Event Mapping."

3.2 AP Interrupts

The TrustZone interrupt controller (TZIC) collects up to 128 interrupt requests from all i.MX51 sources and provides an interface to the core. Each interrupt can be configured as a normal or a secure interrupt. Software force registers and software priority masking are also supported.

Table 3-2 describes the ARM interrupt sources.

Table 3-2. ARM Domain Interrupt Summary

IRQ	Interrupt Source	Interrupt Description
0	Reserved	Reserved
1	eSDHC1	Enhanced SDHC Interrupt Request
2	eSDHC2	Enhanced SDHC Interrupt Request
3	eSDHC3	CE-ATA Interrupt Request based on eSDHC-3
4	eSDHC4	Enhanced SDHC Interrupt Request
5	DAP	Power-up Request
6	SDMA	"AND" of all 48 interrupts from all the channels
7	IOMUX	POWER FAIL interrupt
8	EMI (NFC)	nfc interrupt out
9	VPU	VPU Interrupt Request
10	IPUEX	IPUEX Error Interrupt
11	IPUEX	IPUEX Sync Interrupt
12	GPU3D	GPU3D Interrupt Request
13	Reserved	Reserved
14	USBOH3	USB Host 1
15	EMI	Consolidated EMI Interrupt

Table 3-2. ARM Domain Interrupt Summary (continued)

IRQ	Interrupt Source	Interrupt Description
16	USBOH3	USB Host 2
17	USBOH3	USB Host 3
18	USBOH3	USB OTG
19	SAHARA Lite	SAHARA host 0 (TrustZone) Intr
20	SAHARA Lite	SAHARA host 1 (non-TrustZone) Intr
21	SCC	Security Monitor High Priority Interrupt Request.
22	SCC	Secure (TrustZone) Interrupt Request.
23	SCC	Regular (Non-Secure) Interrupt Request.
24	SRTC	SRTC Consolidated Interrupt. Non TZ.
25	SRTC	SRTC Security Interrupt. TZ.
26	RTIC	RTIC (Trust Zone) Interrupt Request. Indicates that the RTIC has completed hashing the selected memory block(s) during single-hash/boot mode.
27	CSU	CSU Interrupt Request 1. Indicates to the processor that one or more alarm inputs were asserted
28	Reserved	Reserved
29	SSI1	SSI-1 Interrupt Request
30	SSI2	SSI-2 Interrupt Request
31	UART 1	UART-1 ORed interrupt
32	UART 2	UART-2 ORed interrupt
33	UART 3	UART-3 ORed interrupt
34	Reserved	Reserved
35	Reserved	Reserved
36	eCSPI1	eCSPI1 interrupt request line to the core.
37	eCSPI2	eCSPI2 interrupt request line to the core.
38	CSPI	CSPI interrupt request line to the core.
39	GPT	“OR” of GPT Rollover interrupt line, Input Capture 1 and 2 lines, Output Compare 1,2, and 3 Interrupt lines
40	EPIT1	EPIT1 output compare interrupt
41	EPIT2	EPIT2 output compare interrupt
42	GPIO1	Active HIGH Interrupt from INT7 from GPIO
43	GPIO1	Active HIGH Interrupt from INT6 from GPIO
44	GPIO1	Active HIGH Interrupt from INT5 from GPIO

Table 3-2. ARM Domain Interrupt Summary (continued)

IRQ	Interrupt Source	Interrupt Description
45	GPIO1	Active HIGH Interrupt from INT4 from GPIO
46	GPIO1	Active HIGH Interrupt from INT3 from GPIO
47	GPIO1	Active HIGH Interrupt from INT2 from GPIO
48	GPIO1	Active HIGH Interrupt from INT1 from GPIO
49	GPIO1	Active HIGH Interrupt from INT0 from GPIO
50	GPIO1	Combined interrupt indication for GPIO1 signal 0 throughout 15
51	GPIO1	Combined interrupt indication for GPIO1 signal 16 throughout 31
52	GPIO2	Combined interrupt indication for GPIO2 signal 0 throughout 15
53	GPIO2	Combined interrupt indication for GPIO2 signal 16 throughout 31
54	GPIO3	Combined interrupt indication for GPIO3 signal 0 throughout 15
55	GPIO3	Combined interrupt indication for GPIO3 signal 16 throughout 31
56	GPIO4	Combined interrupt indication for GPIO4 signal 0 throughout 15
57	GPIO4	Combined interrupt indication for GPIO4 signal 16 throughout 31
58	WDOG1	Watchdog Timer reset
59	WDOG2	Watchdog Timer reset
60	KPP	Keypad Interrupt
61	PWM 1	Cumulative interrupt line.“OR” of Rollover Interrupt line, Compare Interrupt line and FIFO Waterlevel crossing interrupt line.
62	I2C1	I2C-1 Interrupt
63	I2C2	I2C-2 Interrupt
64	HS-I2C	High Speed I2C Interrupt
65	Reserved	Reserved
66	Reserved	Reserved
67	SIM	SIM interrupt composed of oef, xte, sdi1, and sdi0
68	SIM	SIM interrupt composed of tc, etc, tfe, and rdrf
69	IIM	Interrupt request to the processor. Indicates to the processor that program or explicit sense cycle is completed successfully or in case of error. This signal is low-asserted.
70	PATA	Parallel ATA host controller interrupt request
71	CCM	CCM, Interrupt Request 1
72	CCM	CCM, Interrupt Request 2
73	GPC	GPC, Interrupt Request 1
74	GPC	GPC, Interrupt Request 2
75	SRC	SRC interrupt request

Table 3-2. ARM Domain Interrupt Summary (continued)

IRQ	Interrupt Source	Interrupt Description
76	TIGERP_PLATFORM_NE_32K_256K	Neon Monitor Interrupt
77	TIGERP_PLATFORM_NE_32K_256K	Performance Unit Interrupt
78	TIGERP_PLATFORM_NE_32K_256K	CTI IRQ
79	TIGERP_PLATFORM_NE_32K_256K	Debug Interrupt, from Cross-Trigger Interface 1
80	TIGERP_PLATFORM_NE_32K_256K	Debug Interrupt, from Cross-Trigger Interface 1
84	GPU2D	GPU2D (OpenVG) general interrupt
85	GPU2D	GPU2D (OpenVG) busy signal (for S/W power gating feasibility)
86	Reserved	Reserved
87	FEC	Fast Ethernet Controller Interrupt request (OR of 13 interrupt sources)
88	OWIRE	1-Wire Interrupt Request
89	TIGERP_PLATFORM_NE_32K_256K	Debug Interrupt, from Cross-Trigger Interface 2
90	SJC	—
91	SPDIF	—
92	TVE	—
93	FIRI	FIRI Intr (OR of all 4 interrupt sources)
94	PWM 2	Cumulative interrupt line.“OR” of Rollover Interrupt line, Compare Interrupt line and FIFO Waterlevel crossing interrupt line.
95	Reserved	Reserved
96	SSI3	SSI-3 Interrupt Request
97	EMI	Boot sequence completed interrupt
98	TIGERP_PLATFORM_NE_32K_256K	Debug Interrupt, from Cross-Trigger Interface 3
99	Reserved	Reserved
100	VPU	Idle interrupt from VPU (for S/W power gating)
101	EMI	Indicates all pages have been transferred to NFC during an auto program operation.
102	GPU3D	Idle interrupt from GPU3D (for S/W power gating)
103_128	Reserved	Reserved

3.3 SDMA Event Mapping

Table 3-3 shows the DMA request signals for peripherals.

Table 3-3. SDMA Event Mapping

Event Number	DMA Source	Description
0	VPU	VPU DMA request
1	GPC	Will be used for power management.
2	PATA	Rx FIFO of PATA
3	PATA	Tx FIFO of PATA
4	PATA	PATA Transfer End
5	Reserved	Reserved
6	eCSPI1	DMA Rx request
7	eCSPI1	DMA Tx request
8	eCSPI2	DMA Rx request
9	eCSPI2	DMA Tx request
10	HS-I^{2}C	HS I^{2}C DMA Tx request
11	HS-I^{2}C	HS I^{2}C DMA Rx request
12	FIRI	DMA request of receiver FIFO
13	FIRI	DMA request of transmitter FIFO
14	IOMUX	External DMA request from BGA contact GPIO1_4
15	IOMUX	External DMA request from BGA contact GPIO1_5
16	UART2	Rx FIFO of UART 2
17	UART2	Tx FIFO of UART 2
18	UART1	Rx FIFO of UART 1
19	UART1	Tx FIFO of UART 1
20	esdhc1 I^{2}C1	MMC/SDHC1 **muxed with** I^{2}C1
21	esdhc2 I^{2}C2	MMC/SDHC2 **muxed with** I^{2}C2
22	SSI2	SSI #2 receive 2 DMA request
23	SSI2 SLM	SSI #2 transmit 2 DMA request
24	SSI2 SLM	SSI #2 receive 1 DMA request
25	SSI2 SLM	SSI #2 transmit 1 DMA request
26	SSI1	SSI #1 receive 2 DMA request
27	SSI1	SSI #1 transmit 2 DMA request
28	SSI1	SSI #1 receive 1 DMA request
29	SSI1	SSI #1 transmit 1 DMA request

Table 3-3. SDMA Event Mapping (continued)

Event Number	DMA Source	Description
30	EMI	Asserts every time NFC finishes reading a page
31	CTI2	CTI2 (SDMA_CTI) trigger_out[0] connected to SDMA event.
32	EMI	Asserts at the beginning of auto-program sequence, and every time the NFC finishes transferring data from the RAM to the NAND (Meaning, the SDMA can write to the RAM the next page).
33	CTI2	CTI2 (SDMA_CTI) trigger_out[1] connected to SDMA event.
34	EPIT2	EPIT2 DMA request
35	SSI3 SLM	SSI #3 receive 2 DMA request
36	IPUEX	IPUEX DMA request
37	SSI3 SLM	SSI #3 transmit 2 DMA request
38	CSPI	DMA Rx request
39	CSPI	DMA Tx request
40	eSDHC3	MMC/SDHC3 DMA request
41	eSDHC4	MMC/SDHC4 DMA request
42	Reserved	Reserved
43	UART3	Rx FIFO of UART 3
44	UART3	Tx FIFO of UART 3
45	SPDIF	SPDIF DMA request
46	SSI3 SLM	SSI #3 receive 1 DMA request
47	SSI3 SLM	SSI #3 transmit 1 DMA request

As shown in the table, some of the events are an output of a mux of two signals or triggers. The select of this mux is controlled by general purpose register 0 in IOMUXC.

For other shared connectivity peripherals that do not have dedicated DMA request signals, the AP interrupt service routines have the option of programming the SDMA to move data between the peripheral and memory.

Chapter 4
External Signals and Pin Multiplexing

Because the IC has a limited number of pins, most pins have multiple signal options. The input-output multiplexer (IOMUX) controls the pin multiplexing. The IOMUX also configures other pin characteristics, such as voltage level, drive strength, and hysteresis.

4.1 External Signals

Table 4-1 shows the external signals of the i.MX51. Table 4-2 shows an additional view of external signals muxing. It presents the muxing options per module/instance. Table 4-3 shows IOMUX daisy chain settings.

4.1.1 I/O Configuration Parameters

In the Pad Settings column, each I/O configuration parameter uses one of the two following notations:

- A CFG (value) notation, where ‘value’ is High, Disabled, Keep, and others. The CFG notation indicates the parameter is configurable using the SW_PAD_CTL_PAD and SW_PAD_CTL_GRP registers of Appendix A, “IOMUX Controller (IOMUXC).” The value shown is the default setting, and the associated bits are shown in Appendix A, “IOMUX Controller (IOMUXC).”
- A value notation (with no CFG indicator) where ‘value’ is High, Disabled, Keep, and others indicates the parameter is not configurable. The value shown is the default setting. However, the associated bits shown in Appendix A, “IOMUX Controller (IOMUXC),” below the gray bit-location boxes (read-only) are simply the values read from that particular location and do not reflect the actual functional default.

Chapter 5
External Memories

5.1 Overview

The M4IF is the module that controls all external memory accesses (read/write/erase/program) from all the masters in the system to different external memories. All accesses are arbitrated by the Multi Master Multi Memory Interface (M4IF) module and controlled by the respective memory controller. The high level block diagram is presented in Figure 5-1.

The Masters Interface to the EMI port is a full AXI interface with separated input bus for read and write access, so master that handle separated buses for read and write access can access the EMI. The data width can be 32 or 64 bits. All ports support 32 or 64-bit IF.

5.2 External Memory Interface

The M4IF provides the ability to connect to a wide variety of memory devices. This chapter contains the technical information about the operation and configuration of the M4IF modules in the chip to allow the designer to quickly integrate external memory devices into new and existing designs. Pin sharing is done between the data bus of the WEIM and the Nand Flash Controller in order to reduce the total number of pins needed for the M4IF.

The EMI is an External Memory Interface and arbitration between multi AXI masters to multi memory controllers, divided into three major channels, fast memories (Mobile DDR SDRAM) channel, slow memories (NOR-FLASH/PSRAM/NAND-FLASH etc.) channel, Internal Memory (RAM, ROM) channel and Internal GMEM memory.

To increase the bandwidth performance, the EMI separates the buffering and the arbitration between accesses to fast channel slow channel and Internal Memory channels, so parallel accesses can occur. By separating the three channels, slow accesses do not interfere with fast accesses.

The M4IF contains the arbitration interface and different external memory controllers to support the following memory devices:

- M4IF—Multi Master Multi Memory Interface
- ESDRAMC—Enhanced Mobile LPDDR SDRAM memory controller
- NFC—NAND Flash memory controller
- WEIM—SRAM/PSRAM/NOR Flash memory controller

5.2.1 EMI i.MX51 Masters

Table 5-1 provides details on EMI masters and the EMI port associated with each master.

Table 5-1. AMXI Bus Masters

Module	Direct Bus	Master Port	Buffered	Boundary Crossing
ARM Cortex-A8	AXI	3	Y	4K
SDMA (burst)	AHB via AHBS2AXI	4	N	1K
SDMA (non-burst)	AHB via AHBMAX	2	N	1K
IPUEX	AXI	0	Y	4K
VPU	AXI	1	Y	4K
GPU3D	AXI	5	Y	4K
RTIC	AHB via AHBMAX	2	N	1K
SCC	AHB via AHBMAX	2	N	1K
USBOH3	AXI	7	N	4K
GPU2D (OpenVG)	AXI	6	Y	4K
FEC	AHB via AHBMAX	2	N	1K
SAHARA	AHB via AHBMAX	2	N	1K
eSDHC 1	AHB via AHBMAX	2	N	1K
eSDHC 2	AHB via AHBMAX	2	N	1K
eSDHC 4	AHB via AHBMAX	2	N	1K
eSDHC 3 - CE-ATA	AHB via AHBMAX	2	N	1K
DAP	AHB via AHBMAX	2	N	1K

5.2.2 Features

Each of the EMI memory controller block guides specify detailed information about the supported features, programming model. However, in i.MX51 some of those feature are disabled or not supported.

The M4IF in the i.MX51 includes these distinctive features:

- Multi Master Multi Memory Interface (M4IF)
  - — Supports multiple accesses from 8 masters through different input ports interfaces. Each port can support either of the following two data width options:
    - – ×32 AXI port.
    - – ×64 AXI port.
  - — Supports different clock domain for each AXI port master
  - — Configurable memory “snooping”
  - — Configurable memory watermark protection per CS

- Enhanced arbitration scheme for fast channel, consider page hit/miss, last access details (read/write) and fixed priority configuration

- Enhanced SDRAM Controller (ESDRAMC) or LPDDR Controller (LPDDRC)
  - Up to 2 chip selects support up to 256 MBytes each
  - ×64 AXI port
  - Supports ×16/×32 LPDDR/Non-mobile DDR1 SDRAM at clock frequency up to 200 MHz (DDR400)
  - Supports ×16/×32 DDR2 memories up to 200 MHz (400 MHz data rate)
  - Supports latency hiding logic
- NANDFlash Controller (NFC)
  - ×8/×16 NAND interface
  - Up to 8 chip selects support up to 8 Gbit in 1/2K page mode, 64 Gbit in 2K page mode and 256 Gbit in 4K page mode each.
  - 4.5K RAM Internal Buffer
  - MLC and SLC memory support.
  - Configurable operation mode—symmetric and asymmetric
  - Configurable page mode, 1/2K, 2K, or 4K
  - ECC support up to 8 bits
  - Supports up to 8 mutually exclusive, yet interleaved NAND devices.
  - Automatic Common Nand Operations
- Wireless External Interface Memory Controller (WEIM)
  - Up to 6 chip selects.
  - Supports ×32/×16 PSRAM (up to 133 MHz).
  - Supports ×32/×16 muxed mode PSRAM / NOR (up to 133 MHz).
  - Supports ×32/×16 NOR (up to 133 MHz).
- Supports DVFS, voltage and frequency change.
- Supports watermark configuration.
- Supports automatic shut-down (power saving features)
- Enhanced debug capabilities (trace mode).

5.3 M4IF Setup

The following section describes i.MX51 specific requirements in order to use the M4IF module.

5.3.1 Clock Domains

The EMI contains the following clock domains:

- EMI IPS clock
- ESDCTL main clock (up to 200 MHz)

- Slow arbitration clock (up to 133 MHz)
- Internal memory arbitration 1 and 2 clocks (up to 166 MHz)
- 8 × masters clocks, can be asynchronous to the EMI arbitration clocks (66 MHz–166 MHz)
- NFC main clock—should be integer divided from slow arbitration clock (up to 50 MHz)
- SDCLK—SDR/DDR clock to SDR/DDR SDRAM device
- BCLK—NOR Flash/PSRAM clock WEIM in synchronous mode

5.3.2 Boot Scenarios

The M4IF memory controllers allow booting from the following memories: NOR Flash devices through the WEIM and NAND Flash devices through the NAND Flash Controller. Special signals coming from the SOC define the different booting options to those memories like the memory data width, memory page size, and other specific parameters for the initial access of the boot. For more details refer to the memory controllers detailed chapters and boot chapter.

5.3.3 Watermark Ports

Watermark regions are supported in the M4IF while the configuration is handled by the CSU module. The external memory spaces have trust zone area's that only trust zone accesses are able to reach. Non-trust zone accesses are blocked. The CSU module has the registers that define those regions. It sends the indication of the region and whether the specific access is trust zone or not to the M4IF. The EMI is also capable of handling the special watermark zone for the BP domain, but this is not used for the i.MX51.

The watermark indication is dynamic and can change for each access.

For details on the watermark configuration ,refer to the CSU chapter.

5.3.4 Drive Strength Settings

The IOMUXC registers that controls the ESDRAMC relevant BGA contact drive strength are specified in Table 5-2.

Table 5-2. Drive Strength Settings

Functional Group	Signal Group		Drive Strength Mode			
	BGA Contact name	Registers settings	MAX	HIGH	MEDIUM	LOW
DATA	DRAM_D[7:0]	Address	0xIOMUXC_BASE+IOMUXC_SW_PAD_CTL_GRP_DRAM_B0			
		Value	0x0000_0006	0x0000_0004	0x0000_0002	0x0000_0000

5.3.5 M4IF I/O MUX

The M4IF provides the ability to mux some of its signals in the SOC to allow pin sharing between the different memory controllers. Muxing is possible on the slow channel only because of timing limitations.

Only shared i.MX51 PADS signals/buses are routed through the I/O MUX toward the external devices. Signals (mainly controls) that have dedicated PADS are directly routed from the memory controllers to the external devices. Table 5-3 summarizes the EMI PADS definition in i.MX51.

Table 5-3. EMI IOMUX in i.MX51

5.4 External Memory Controllers Preset Operation

This section discusses the preset operations of the following:

- NAND Flash Controller
- WEIM
- ESDRAMC
- M4IF

5.4.1 NAND Flash Controller (NFC) Preset Operation

The NFC has several inputs that defines the initial operation of this module. This information is the page size (0.5K, 2K, 4K), data size (8/16 bit), and NFC clock configuration. Those parameters are defined by fuse programing.

For initialization examples, please refer to the Nand Flash Controller specific chapter.

5.4.2 WEIM Preset Operation

The initial operation of the WEIM is defined by the memory data width, muxed/non-muxed memory, address unshift, and merged CS0 and CS1 memory space. These inputs define how the WEIM operates during direct boot to NOR Flash devices.

For an initialization example, please refer to the WEIM Controller specific chapter.

5.4.3 ESDRAMC Preset Operation

The ESDRAMC functionality depends on the register setup that defines the derive strength of the pads related to it (see Table 5-2). For the detailed needs of the DDR delay line and options for frequency changes, refer to the specific ESDCTL chapter.

Refer to the ESDCTL chapter for an example for ESDCTL initialization.

5.4.4 M4IF Preset Operation

Security levels, locking indications, and endianness define the way the M4IF works. Refer to the M4IF specific chapter for a detailed description.

Chapter 6
Fuse Map

6.1 Overview

This chapter contains the fuse map for the i.MX51. There are four fuse banks. Many fuse rows may be be locked by setting a single fuse.

6.1.1 Fuse Locks

Table 6-1 is a summary of the fuse locks used in the i.MX51.

Table 6-1. Fuse Lock Summary

Fuse Name	Fuse Bank	Rows Affected
IMEI_LOCK	0	0860–087C
BOOT_LOCK	0	0804, 080C–0818, 0840–0844, 0854
MAC_ADDR_LOCK	1	0824–0838
SRK_LOCK	1	0C04
SJC_RESP_LOCK	1	0C08–0C20
TRIM_LOCK	1	0C24–0C7C
SRK_LOCK88	3	1404–142C
SRK_LOCK160	3	1430–147C

6.1.2 Fuse Map

Table 6-2, beginning on page 6-2, is a complete listing of all user-accessible fuses.

Table 6-2. i.MX51 Fuse Map

1 Address offset from bank base address
2 Shaded areas in the table indicate fuses that have corresponding GPIO pins
3 Controls JTAG debug operating modes
4 MSB (Most Significant Byte) of 256-bit of AP SRK HASH
5 SJC_RESP fuses that have being locked for read, explicit sense, override and writting.

Chapter 7
Clock Controller Module (CCM)

The Clock Controller Module (CCM) controls the clocks for the i.MX51 modules. This module uses the available clock sources to generate the clock roots. Figure 7-1 shows the CCM block diagram.

7.1 Overview

The Clock Controller Module controls the following functions in the i.MX51:

- Uses the available clock sources to generate clock roots to various parts of the SoC.
- Programable bits are used to control frequencies of the clock roots.
- Control of the low-power mechanism.
- Provides control signals to LPCG for gating clocks.
- Provides handshake with SRC for controlling clocks during reset.
- Provides handshake with GPC for support of DVFS, DPTC, and power gating operations.

7.1.1 Features

The CCM includes the following features:

- Clock switching module to generate three source clocks using three PLLs.
- Root clocks generation—provides root clock to the i.MX51's modules based on three switchable source clocks.
- ARM core root clock generated from a dedicated switchable source clock.
- Includes separate dividers to control generation of core and bus root clocks (axi's, ahb, ipg).
- Includes separate dividers and clock sources selectors for each serial root clock.
- Option for external clock to bypass PLLs clocks.
- Selects which clocks are routed to the IOMUX signals CLKO and CLKO2 for observability.
- Controllable registers are accessible via IP bus.
- Manages the Low-Power Modes, namely RUN, WAIT, SCREEN REFRESH and STOP. The gating of the peripheral clocks is programmable in RUN and WAIT modes.
- Manages frequency scaling procedure for ARM core clock by shifting between PLL sources, without loss of clocks.
- Manages frequency scaling procedure for peripheral clock roots by programable divider. The division occurs on the fly without loss of clock signals.
- Interface for the following modules:
  - PLL_IP—Three PLL_IP interfaces for each PLL on the IC.

— LPCG—Low-Power Clock Gating unit
— SRC—System Reset Controller
— GPC—Global Power Controller

7.1.2 CCM Blocks

The CCM includes the following submodules:

CCM_CLK_IGNITION	The purpose of this module it to manage the ignition process. This module becomes active after the CCM comes out of reset. It manages the ignition process by starting the Clock Amplifiers (CAMP), the Frequency Pre-Multiplier (FPM), and the PLLs. The ignition process ends when stable root clock outputs are available.
CCM_CLK_SWITCHER	This submodule receives the clock outputs of the three PLLs, together with the bypass clocks for three PLLs, and generates three clock outputs (pll1_sw_clk, pll2_sw_clk, pll3_sw_clk) for the ccm_clk_root_gen sub module. The submodule can route any of the PLL inputs to any of the three outputs.
CCM_CLK_ROOT_GEN	This sub module receives the three main clocks (pll1_sw_clk, pll2_sw_clk, pll3_sw_clk) and generates the output root clocks. The module also includes the programable clock dividers.
CCM_CLK_LOGIC	This sub-module generates the clock enables. It generates the clock enable signals based on data from CCM_LPM and CCM_IP. The clock enables are used by the Low-Power Clock Gating (LPCG) module to gate distributed clocks on and off.
CCM_LPM	Manages the low-power modes of the IC and module handshaking associate with low-power operation.
CCM_REGS	Manages the CCM memory map containing the programable registers and the connectivity to the IP bus. This module is connected to all the sub modules that need definition of programmable bits.
CCM_CLK_SRC_DIV	This sub-module directs various internal clocks which can be selected as i.MX51 outputs (through IOMUX), CLKO and CLKO2, used for observation and debug testing. These clocks are not optimized and therefore may introduce a jitter and are not suitable for supplying a clock signal to peripheral devices.
CCM_HND_SK	Manages the handshaking for those root clock dividers that require handshaking and manages the frequency changes during DVFS events.

Figure 7-1 shows the submodules contained in the CCM.

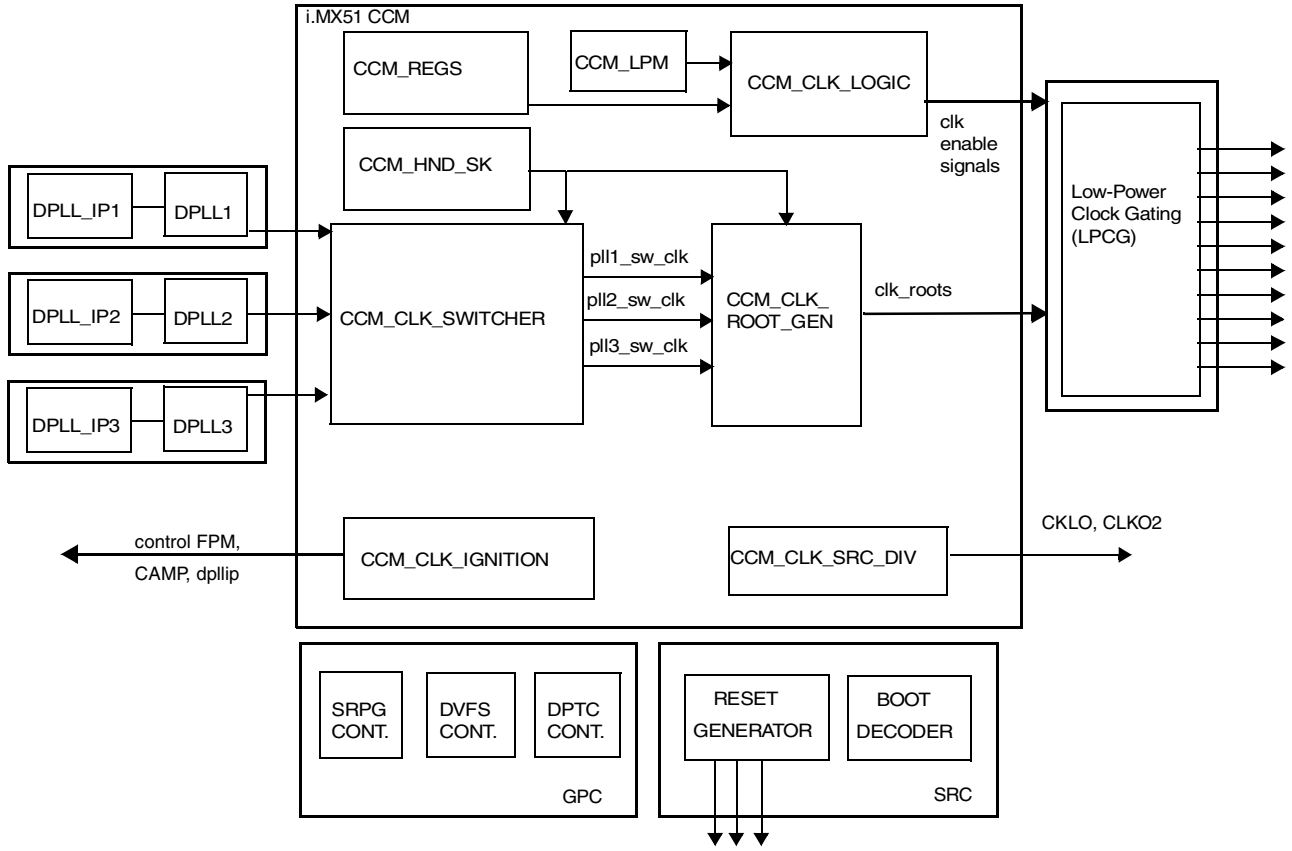

Figure 7-1. i.MX51 CCM Block Diagram

7.2 Detailed Signal Descriptions

7.2.1 External Signals Description

Table 7-1 describes the input/output signals of CCM module:

Table 7-1. CCM External Signals Description

Signal	I/O	Description
clko signals		
ipp_do_clko1	O	Clock observability 1 output
ccm_ipp_obe_clko1	O	BGA Contact output enable for Clock observability 1 output
ipp_do_clko2	O	Clock observability 2 output
ccm_ipp_obe_clko2	O	BGA Contact output enable for Clock observability 2 output
dptc_core1_clk_clko	I	DPTC core clock for observability
dptc_peripheral1_clk_clko	I	DPTC peripheral clock for observability

Table 7-1. CCM External Signals Description (continued)

Signal	I/O	Description
obs_output_0	O	Observability output
obs_output_1	O	Observability output
obs_output_2	O	Observability output
usbphy_pll_out_480	I	480MHZ USB PHY PLL clock for observability
General purpose signals		
cgpr_dout[31:0]	O	General purpose outputs
Input clocks from PADs		
ipp_di_clk	I	Reserved
ipp_ind_ckil	I	CKIL clock input
ipp_ind_clkss	I	Selects DPLL reference clock during reset
PMIC voltage control signals		
pmic_vstby_req	O	Goes to PMIC_VSTBY_REQ pin, which notifies external power management IC to move from functional voltage to standby voltage.
pmic_vfuncional_ready	I	Signal coming from PMIC to indicate that the voltage started to change as result of change in pmic_vstby_req
FPM clock		
fpm_clk	I	FPM clock input
PLL signals		
pll1_main_clk	I	PLL1 clock
pll2_main_clk	I	PLL2 clock
pll3_main_clk	I	PLL3 clock
pll1_reference_clk	I	PLL reference clock
pll1_bypass_clk	I	PLL1 bypass clock
pll2_bypass_clk	I	PLL2 bypass clock
pll3_bypass_clk	I	PLL3 bypass clock
pll_bypass_en1	I	Enable bypass of PLL 1 clock
pll_bypass_en2	I	Enable bypass of PLL 2 clock
pll_bypass_en3	I	Enable bypass of PLL 3 clock
pll_lvs	O	Goes to LVS input in DPLLIPs (switches frequencies)
pll_lrf_sticky1	I	Asserts when PLL1 output is stable (lock ready flag)
pll_lrf_sticky2	I	Asserts when PLL2 output is stable (lock ready flag)
pll_lrf_sticky3	I	Asserts when PLL3 output is stable (lock ready flag)
Ignition signals		

Table 7-1. CCM External Signals Description (continued)

Signal	I/O	Description
fpm_lrf	I	FPM output is stable (lock ready flag)
ccm_fpm_en	O	Enable FPM
fpm_mult	O	0 - FPM multiply by 512 1 - FPM multiply by 1024
osc_clk	I	Internal oscillator clock input
cosc_en	O	Enable internal oscillator
cosc_pwrdown	O	Power down internal oscillator
ckih_CAMP1_clk	I	Input from the CKIH CAMP1
ckih2_CAMP2_clk	I	Input from the CKIH CAMP2
ccm_CAMP1_dis	O	Disable CKIH CAMP1
ccm_CAMP2_dis	O	Disable CKIH2 CAMP2
ref_clk_en_dpllip	O	Enable reference clock for DPLL
dpll_en_dpllip	O	Enable DPLLs
src_clock_ready	O	Notifies reset controller that the root clocks are ready
ccm_ref_en_b	O	Enable external reference clock (CKIH)

7.3 Memory Map and Register Definition

7.3.1 Memory Map

See the system memory map for the complete listing of memory map offset addresses. Table 7-3 shows the CCM memory map.

Table 7-3. CCM Memory Map

Base Address Offset (Register Abbreviation)	Register	Access	Reset Value	Section/Page

7.3.2 Register Summary

The conventions in Figure 7-2 and Table 7-4 serve as a key for the register summary and individual register diagrams.

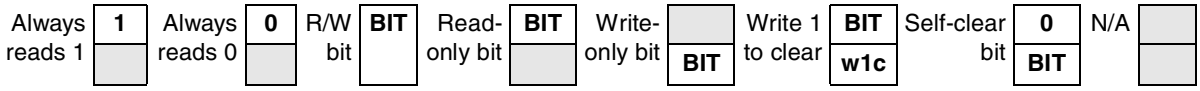

Figure 7-2. Key to Register Fields

Table 7-4 provides a key for register figures and tables and the register summary.

Table 7-4. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 7-5 shows the register summary for the CCM.

Table 7-5. i.MX51 CCM Register Summary

7.3.3 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number.

7.3.3.1 CCM Control Register (CCR)

Figure 7-3 represents the CCM Control Register (CCR), which contains bits to control general operation of CCM. Table 7-6 provides its field descriptions.

73FD_4000 (CCR) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	—	1	1	1	—	1	1	1	1	1	1	1	1

Figure 7-3. CCM Control Register (CCR)

Table 7-6. CCR Field Descriptions

Field	Description
31–13	Reserved
12 cosc_en	On-chip oscillator enable bit - this bit value is reflected on the output cosc_en. The ignition process sets this bit if the on-chip oscillator is selected as the clock source. The reset value of this bit is determined during the ignition process based on CLKSS input. In Run mode, the software controls the on-chip oscillator enable/disable through this bit. If this bit is changed from '0' to '1' then the CCM enables the on-chip oscillator and after counting the **oscnt CKIL** clock cycles it indicates the on-chip oscillator is ready by an interrupt **cosc_ready** and by the **cosc_ready** status bit. **Note:** The cosc_en bit should only be changed if the on-chip oscillator is not chosen as the clock source by the DPLL_IPs. 0 Disable the on-chip oscillator 1 Enable the on-chip oscillator
11 FPM_MULT	fpm_mult - controls the multiplicand of FPM. This bit can be changed only in case FPM is not chosen as the source of clock generation. FPM should be disabled (FPM_en=0) when changing this value. **Note:** It multiplies the CKIL (32Khz) clock. 0 FPM multiply by 512 1 FPM multiply by 1024
10 CAMP2_EN	CAMP2 Enable bit - the ignition process always setS this bit. In run mode, software can control CAMP2 enable/disable using this bit. If this bit is changed from '0' to '1' then the CCM enables the CAMP2 and after counting oscnt CKIL's it will notify that CAMP2 is ready by the CAMP2_ready interrupt (if the interrupt is not masked) and by the CAMP2_ready status bit. **Note:** The CAMP2_en bit should only be changed when CAMP2 is not chosen as a clock source. 0 disable CAMP2 1 enable CAMP2 Note: CCM has an output ccm_CAMP2_dis. this signal is inverted from the CAMP2_en bit, for example, when CAMP2_en bit is '1' the ccm_CAMP2_dis signal is '0'.

Table 7-6. CCR Field Descriptions (continued)

Field	Description
9 CAMP1_EN	CAMP1 Enable bit - the ignition process will always set this bit. In run mode, software can control CAMP1 enable/disable through this bit. If this bit is changed from '0' to '1' then CCM will enable the CAMP1 and after counting oscnt CKIL's it will notify that CAMP1 is ready by a interrupt CAMP1_ready and by status bit CAMP1_ready. The CAMP1_en bit should be changed only when CAMP1 is not chosen as a clock source. 0 disable CAMP1 1 enable CAMP1 Note: CCM has an output ccm_CAMP1_dis. this signal will be inverted from the CAMP1_en bit, that is, when CAMP1_en bit is '1' the ccm_CAMP1_dis signal is '0'.
8 FPM_EN	FPM Enable bit - the ignition process will set this bit if the FPM is chosen as the clock source, that is, the reset value of this bit is chosen from the ignition process based on CLKSS input. In run mode, software can control FPM enable/disable through this bit. If this bit is changed from '0' to '1' then CCM will enable FPM and after FPM lock ready flag is asserted it will notify that FPM is ready by a interrupt FPM_ready and by status bit FPM_ready. **Note:** The FPM_en bit should be changed only when FPM is not chosen as the clock source, that is, the DPLL_ip's are not choosing the FPM as the clock source. 0 disable FPM 1 enable FPM
7–0 OSCNT	Oscillator ready counter value. These bits define value of 32 KHz counter that serves as the counter for oscillator lock time. This is used for both the on-chip oscillator lock time and the time that CAMP1 and CAMP2 will be ready since the CAMPs receives the external oscillator clock. Current estimation is ~5ms. This counter will be used in ignition sequence and in wake from STOP sequence if sbyos bit was set , to notify that the on-chip oscillator output is ready for the DPLL_ip to use and only then the gate in DPLL_ip is enabled. 00000000 count 1 CKIL 11111111 count 256 CKIL's (Default)

7.3.3.2 CCM Control Divider Register (CCDR)

Figure 7-4 represents the CCM Control Divider Register (CCDR). The only function of this register is to control the masking of handshaking with some of the dividers.

Table 7-7 provides its field descriptions.

73FD_4004 (CCDR) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 7-4. CCM Control Divider Register (CCDR)

NOTE

The bits in the CCDR register can only be changed after a completion of the handshake.

Table 7-7. CCDR Field Descriptions

Field	Description
31–19	Reserved
18	Reserved. **Note:** Functionality is no longer supported. Bit must be set for better power saving - along with configuration of CLPCR[23] and CCGR4[13:6] bits. Please refer to description of these bits for the recommended values.
17 ipu_hs_mask	During load_dividers procedure[1] this bit allows or masks the handshake with IPU module. 0 allow handshake with IPU module 1 mask handshake with IPU module
16 emi_hs_mask	During load_dividers procedure[1] this bit allows or masks the handshake with EMI module. 0 allow handshake with EMI module 1 mask handshake with EMI module
15–0	Reserved

7.3.3.3 CCM Status Register (CSR)

Figure 7-5 represents the CCM status Register (CSR). The status bits are read only bits. Table 7-8 provides its field descriptions.

73FD_4008 (CSR) Access: User read

Figure 7-5. CCM Status Register (CSR)

Table 7-8. CSR Field Descriptions

Field	Description
31–6	Reserved
5 cosc_ready	Status indication of on-chip oscillator. This bit is asserted if the on-chip oscillator is enabled and the on-chip oscillator is not powered down, and if the oscnt counter has finished counting. 0 - on-chip oscillator is not ready. 1- on-chip oscillator is ready.
4 lvs_value	Status of the value of pll_lvs output of the CCM. For more details about the pll_lvs see the DPLL IP chapter. 0 - value of pll_lvs output is ‘0’ 1- value of pll_lvs output is ‘1’
3 CAMP2_ready	Status indication of CAMP2. This is asserted if CAMP2 is enabled and if the oscnt counter has finished counting. 0 - CAMP2 is not ready. 1- CAMP2 is ready.
2 CAMP1_ready	Status indication of CAMP1. This is asserted if CAMP1 was enabled and if oscnt counter has finished counting. 0 - CAMP1 is not ready. 1- CAMP1 is ready.

Table 7-8. CSR Field Descriptions (continued)

Field	Description
1 fpm_ready	Status indication of FPM. This will be asserted if FPM was enabled and FPM notified by asserting its ready signal. 0 - FPM is not ready. 1- FPM is ready.
0 ref_en_b	Status of the value of ref_en_b output of ccm 0 - value of ref_en_b is '0' 1- value of ref_en_b is '1'

7.3.3.4 CCM Clock Switcher Register (CCSR)

Figure 7-6 represents the CCM Clock Switcher register (CCSR). The CCSR register contains bits to control the switcher sub module dividers and multiplexers. Table 7-9 provides its field descriptions.

73FD_400c (CCSR) Access: User read-write

Figure 7-6. CCM Clock Switch Register (CCSR)

Table 7-9. CCSR Field Descriptions

Field	Description
31–9	Reserved
9 lp_apm	Selects the option to be chosen for the Low-Power Audio Playback source clock. 0 On-chip oscillator clock output 1 FPM clock output

Table 7-9. CCSR Field Descriptions (continued)

Field	Description
8–7 step_sel [1:0]	Selects the option to be chosen for the step frequency when shifting ARM frequency. This bits controls the step_clk. 00 clock source 4 - source for lp_apm. (default) 01 pll1 bypass clock 10 divided pll2 clock 11 divided pll3 clock **Note:** The mux can only be switched while the output is not being used. **Note:** To conserve power, Freescale recommends this mux not be set to the pll2 and pll3 options when not being used. When PLL2 and PLL3 are running (but not selected), a small amount of power is until consumed, but it does not enter the glitchless mux and hence less clock tree power is consumed".
6–5 pll2_div_podf [1:0]	Divider for PLL2 clock. 00 divide by 1 01 divide by 2 10 divide by 3 11 divide by 4 **Note:** This field can only be changed during the period that its output is not used.
4–3 pll3_div_podf [1:0]	Divider for PLL3 clock. 00 divide by 1 01 divide by 2 10 divide by 3 11 divide by 4 **Note:** This field can only be changed during the period that its output is not used.
2 pll1_sw_clk_sel	Selects source to generate pll1_sw_clk. 0 pll1_main_clk (default) 1 step_clk **Note:** This bit is OR'd with the pll_bypass_en1 signal and DVFS_control signal. If one of the sources requests to move to step_clk (pll1_sw_clk=1, or pll_bypass_en1=1, or DVFS_control=1) then the source clock for pll1_sw_clk will be step_clk. Only if both sources request pll1_main_clk (pll1_sw_clk=0, and pll_bypass_en1=0 and DVFS_control=0) will the pll1_sw_clk source clock be pll1_main_clk.
1 pll2_sw_clk_sel	Selects source to generate pll2_sw_clk. This bit should only be used for testing purposes. 0 pll2_main_clk(Default) 1 pll2 bypass clock **Note:** This bit is OR'd with pll_bypass_en2 signal. If one of the sources requests to move to pll2 bypass clk (pll2_sw_clk=1 or pll_bypass_en2=1) then the pll2_sw_clk will be pll2 bypass clk. Only if both sources request pll2_main_clk (pll2_sw_clk=0 and pll_bypass_en2=0) then the pll2_sw_clk will be pll2_main_clk.
0 pll3_sw_clk_sel	Selects source to generate pll3_sw_clk. This bit should only be used for testing purposes. 0 pll3_main_clk(Default) 1 pll3 bypass clock Note: this bit is OR'd with pll_bypass_en3 signal. If one of the sources requests to move to pll3 bypass clk (pll3_sw_clk=1 or pll_bypass_en3=1) then the pll3_sw_clk will be pll3 bypass clk. Only if both sources request pll3_main_clk (pll3_sw_clk=0 and pll_bypass_en3=0) then the pll3_sw_clk will be pll3_main_clk.

7.3.3.5 CCM Arm Clock Root Register (CACRR)

Figure 7-7 represents the CCM Arm Clock Root register (CACRR). The CACRR register contains bits to control the ARM clock root generation. Table 7-10 provides its field descriptions.

Figure 7-7. CCM ARM Clock Root Register (CACRR)

Table 7-10. CACRR Field Descriptions

Field	Description
31–3	Reserved
2–0 arm_podf [2:0]	Divider for ARM clock root. Note: if arm_freq_shift_divider is set to ‘1’ then any new write to arm_podf will be held until arm_clk_switch_req signal is asserted. 000 divide by 1(default) 001 divide by 2 010 divide by 3 011 divide by 4 100 divide by 5 101 divide by 6 110 divide by 7 111 divide by 8

7.3.3.6 CCM Bus Clock Divider Register(CBCDR)

Figure 7-8 represents the CCM Bus Clock Divider Register (CBCDR). The CBCDR register contains bits to control the clock generation sub module dividers. Table 7-11 provides its field descriptions.

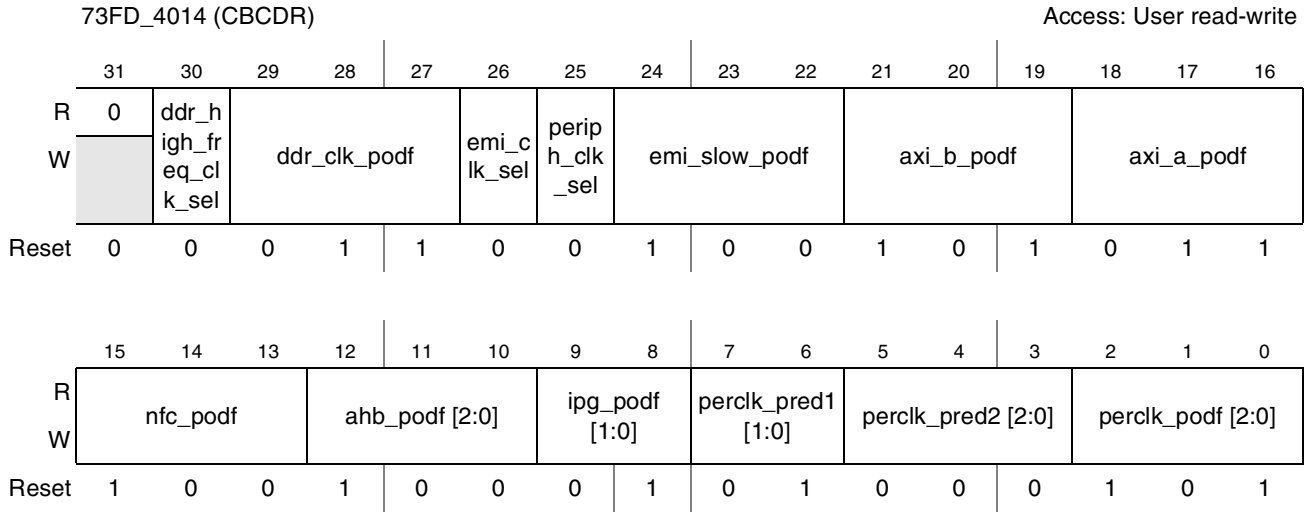

Figure 7-8. CCM Bus Clock Divider Register (CBCDR)

Table 7-11. CBCDR Field Descriptions

Field	Description
31	Reserved
30 ddr_high_freq_clk_sel	Selector for DDR main clock. 0 derive clock from DDR mux clock source. 1 derive clock from divided PLL1 clock source. **Note:** Any change of this multiplexer will involve handshake with EMI on the DDR part. The handshake can be masked by setting CCDR[16] bit. See Section 7.3.3.18, CCM Divider Handshake In-Process Register(CDHIPR) for details.
29–27 ddr_clk_podf [2:0]	Divider for DDR podf. 000 divide by 1 001 divide by 2 010 divide by 3 011 divide by 4 (default) 100 divide by 5 101 divide by 6 110 divide by 7 111 divide by 8 **Note:** Any change of this divider might involve handshake with EMI. The handshake can be masked by setting CCDR[16] bit. See Section 7.3.3.18, CCM Divider Handshake In-Process Register(CDHIPR) for details,
26 emi_clk_sel	Selector for EMI clock group 0 derive clock from DVFS divider 1 derive clock from AHB clock root **Note:** Any change of this multiplexer might involve handshake with EMI and IPU. See Section 7.3.3.18, CCM Divider Handshake In-Process Register(CDHIPR) register for the handshake busy bits.

Table 7-11. CBCDR Field Descriptions (continued)

Field	Description
25 periph_clk_sel	Selector for peripheral main clock. 0 derive clock from pll2_sw_clk clock source. 1 derive clock from periph_apm_clk clock source. **Note:** Any change of this multiplexer will involve handshake with EMI and IPU - a similar handshake to the one that is performed on peripheral DVFS. See Section 7.3.3.18, CCM Divider Handshake In-Process Register(CDHIPR)
24–22 emi_slow_podf [2:0]	Divider for EMI slow podf. 000 divide by 1 001 divide by 2 010 divide by 3 011 divide by 4 100 divide by 5(default) 101 divide by 6 110 divide by 7 111 divide by 8 **Note:** Any change of this divider might involve handshake with EMI and IPU. See CDHIPR register for the handshake busy bits. See Section 7.3.3.18, CCM Divider Handshake In-Process Register(CDHIPR) for details.
21–19 axi_b_podf [2:0]	Divider for axi b podf. 000 divide by 1 001 divide by 2 010 divide by 3 011 divide by 4 100 divide by 5 101 divide by 6 (default) 110 divide by 7 111 divide by 8 **Note:** Any change of this divider might involve handshake with EMI and IPU. See CDHIPR register for the handshake busy bits. See Section 7.3.3.18, CCM Divider Handshake In-Process Register(CDHIPR) for details.
18–16 axi_a_podf [2:0]	Divider for axi a podf. 000 divide by 1 001 divide by 2 010 divide by 3 011 divide by 4 (default) 100 divide by 5 101 divide by 6 110 divide by 7 111 divide by 8 **Note:** Any change of this divider might involve handshake with EMI and IPU. See CDHIPR register for the handshake busy bits. See Section 7.3.3.18, CCM Divider Handshake In-Process Register(CDHIPR) for details.

Table 7-11. CBCDR Field Descriptions (continued)

Field	Description
15–13 nfc_podf [2:0]	Divider for nfc podf. 000 restricted 001 divide by 2 010 divide by 3 011 divide by 4 100 divide by 5 (Default) 101 divide by 6 110 divide by 7 111 divide by 8 **Note:** Any change of this divider might involve handshake with EMI and IPU. See CDHIPR register for the handshake busy bits. See Section 7.3.3.18, CCM Divider Handshake In-Process Register(CDHIPR) for details.
12–10 ahb_podf [2:0]	Divider for ahb podf. 000 divide by 1 001 divide by 2 010 divide by 3 011 divide by 4 100 divide by 5 (Default) 101 divide by 6 110 divide by 7 111 divide by 8 **Note:** Any change of this divider might involve handshake with EMI and IPU. See CDHIPR register for the handshake busy bits. See Section 7.3.3.18, CCM Divider Handshake In-Process Register(CDHIPR) for details.
9 -8 ipg_podf [1:0]	Divider for ipg podf. 00 divide by 1 01 divide by 2 (Default) 10 divide by 3 11 divide by 4
7–6 perclk_pred1 [1:0]	Divider for perclk pred1 00 divide by 1 01 divide by 2 (default) 10 divide by 3 11 divide by 4 Note: Divider should be updated when output clock is gated.

Table 7-11. CBCDR Field Descriptions (continued)

Field	Description
5–3 perclk_pred2 [2:0]	Divider for perclk pred2. 000 divide by 1(default) 001 divide by 2 010 divide by 3 011 divide by 4 100 divide by 5 101 divide by 6 110 divide by 7 111 divide by 8 Note: Divider should be updated when output clock is gated.
2–0 perclk_podf [2:0]	Divider for perclk podf. 000 divide by 1 001 divide by 2 010 divide by 3 011 divide by 4 100 divide by 5 101 divide by 6(default) 110 divide by 7 111 divide by 8 Note: Divider should be updated when output clock is gated.

7.3.3.7 CCM Bus Clock Multiplexer Register (CBCMR)

Figure 7-9 represents the CCM Bus Clock Multiplexer Register (CBCMR). The CBCMR register contains bits to control the multiplexers that generate the bus clocks. Table 7-12 provides its field descriptions.

73FD_4018 (CBCMR) Access: User read-write

Figure 7-9. CCM Bus Clock Multiplexer Register (CBCMR)

Table 7-12. CBCMR Field Descriptions

Field	Description
31-18	Reserved
17-16 gpu2d_clk_sel [1:0]	Selector for gpu2d clock multiplexer 00 derive clock from axi a (Default) 01 derive clock from axi b 10 derive clock from emi_slow_clk_root 11 derive clock from ahb clock root
15–14 vpu_axi_clk_sel [1:0]	Selector for VPU axi clock multiplexer 00 derive clock from axi a (Default) 01 derive clock from axi b 10 derive clock from emi_slow_clk_root 11 derive clock from ahb clock root
13–12 periph_apm_sel [1:0]	Selector for peripheral clock multiplexer 00 derive clock from pll1_sw_clk 01 derive clock from pll3_sw_clk 10 lp_apm clock (default) 11 reserved
11–10 ddr_clk_sel [1:0]	Selector for DDR clock multiplexer 00 derive clock from axi a (Default) 01 derive clock from axi b 10 derive clock from emi_slow_clk_root 11 derive clock from ahb clock root
9–8 arm_axi_clk_sel [1:0]	Selector for ARM axi clock multiplexer 00 derive clock from axi a (Default) 01 derive clock from axi b 10 derive clock from emi_slow_clk_root 11 derive clock from ahb clock root
7–6 ipu_hsp_clk_sel [1:0]	Selector for IPU hsp clock multiplexer 00 derive clock from axi a 01 derive clock from axi b 10 derive clock from emi_slow_clk_root 11 derive clock from ahb clock root (Default)
5–4 gpu_clk_sel [1:0]	Selector for GPU clock multiplexer 00 derive clock from axi a (Default) 01 derive clock from axi b 10 derive clock from emi_slow_clk_root 11 derive clock from ahb clock root
3–2 debug_apb_clk_sel [1:0]	Selector for debug apb clock multiplexer 00 derive clock from axi a (Default) 01 derive clock from axi b 10 derive clock from emi_slow_clk_root 11 derive clock from ahb clock root
1 perclk_lp_apm_sel	Controls if the root clock generation of perclk will be from peripherals main clock or lp_apm source. 0 generate perclk_root from peripherals main clock source. 1 generate perclk_root from lp_apm source.
0 perclk_ipg_sel	Selector for perclk multiplexer - allows to select between ipg_clk or the division of chosen PLL. 0 select perclk generation from division of pll frequency 1 select perclk generation from ipg_clk

Note: Any change on the above multiplexer will have to be done while the module that its clock is affected is not functional and the respective clock is gated in LPCG. If the change will be done during operation of the module, then it is not guaranteed that the modules operation will not be harmed.

The change for arm_axi_clk_sel should be done through SDMA so that ARM will not use this clock during the change and the clock will be gated in LPCG.

7.3.3.8 CCM Serial Clock Multiplexer Register 1 (CSCMR1)

Figure 7-10 represents the CCM Serial Clock Multiplexer Register 1 (CSCMR1). The CSCMR1 register contains bits to control the multiplexers that generate the serial clocks. Table 7-13 provides its field descriptions.

73FD_401c (CSCMR1) Access: User read-write

Software should program this value correspondingly to the setings in the GPIO, so that the wakeup detector will be able to track the correct signals. 00 - The interrupt is low level sensitive 01 - The interrupt is high level sensitive 10 - The interrupt is rise edge sensitive 11 - The interrupt is fall edge sensitive
9–8 gpio1_8_ icr	Interrupt sensitivity configuration bits for gpio1_8. Software should program this value correspondingly to the setings in the GPIO, so that the wakeup detector will be able to track the correct signals. 00 - The interrupt is low level sensitive 01 - The interrupt is high level sensitive 10 - The interrupt is rise edge sensitive 11 - The interrupt is fall edge sensitive
7–6 gpio1_7_ icr	Interrupt sensitivity configuration bits for gpio1_7. Software should program this value correspondingly to the setings in the GPIO, so that the wakeup detector will be able to track the correct signals. 00 - The interrupt is low level sensitive 01 - The interrupt is high level sensitive 10 - The interrupt is rise edge sensitive 11 - The interrupt is fall edge sensitive
5–4 gpio1_6_ icr	Interrupt sensitivity configuration bits for gpio1_6. Software should program this value correspondingly to the setings in the GPIO, so that the wakeup detector will be able to track the correct signals. 00 - The interrupt is low level sensitive 01 - The interrupt is high level sensitive 10 - The interrupt is rise edge sensitive 11 - The interrupt is fall edge sensitive
3–2 gpio1_5_ icr	Interrupt sensitivity configuration bits for gpio1_5. Software should program this value correspondingly to the setings in the GPIO, so that the wakeup detector will be able to track the correct signals. 00 - The interrupt is low level sensitive 01 - The interrupt is high level sensitive 10 - The interrupt is rise edge sensitive 11 - The interrupt is fall edge sensitive
1–0 gpio1_4_ icr	Interrupt sensitivity configuration bits for gpio1_4. Software should program this value correspondingly to the setings in the GPIO, so that the wakeup detector will be able to track the correct signals. 00 - The interrupt is low level sensitive 01 - The interrupt is high level sensitive 10 - The interrupt is rise edge sensitive 11 - The interrupt is fall edge sensitive

7.3.3.18 CCM Divider Handshake In-Process Register(CDHIPR)

Figure 7-20 represents the CCM Divider Handshake In-Process Register (CDHIPR). The CDHIPR register contains read-only bits that indicate that ccm is in process of updating dividers or muxes that might need handshake with modules.

Bit 16 corresponds to the arm_podf divider only if ARM DVFS operation is done through arm_podf change (arm_freq_shift_divider = ‘1’). In this case, ARM divider will be updated only after assertion of arm_clk_switch_req from GPC. During this period, bit 16 (arm_podf_busy) will assert to indicate that arm_podf is during process of change. Software should not write new values to arm_podf during this period. any reads of arm_podf during this period will result the next value of arm_podf and not the actual

dividers value. To read the actual dividers value, software should wait until arm_podf_busy deasserts. Once the value of the indication bit changes from ‘1’ to ‘0’, ccm can also generate interrupt, if its not masked (refer to CIMR). This bit will not assert if its not a ARM DVFS operation, for example, if arm_freq_shift_divider = ‘0’. In this case, ARM divider will be updated once arm_podf register will be written.

The dividers in the bits 8–0 group are axi_a_podf, axi_b_podf, emi_slow_podf, ahb_podf, ddr_clk_podf and nfc_podf. The muxes control in this group are ddr_high_freq_clk_sel, periph_clk_sel and emi_clk_sel.

For each of those dividers and muxes control, CDHIPR holds a busy indication bit. If this bit is equal to 1, then ccm is in process of updating the divider or mux. The corresponding bit will assert to ‘1’ once the CBCDR register is updated and a handshake is indeed needed for the update. The corresponding bit will deassert to ‘0’ once the handshake has completed and the divider or mux is loaded with the new values. Software reads of the divider or mux control bits, during the time that these bits are 1, will represent the next value of the divider or mux to be loaded. If software wants to read the actual divider value, it should wait until the value of the indicator bit is equal 0. Once the value of the indication bit changes from ‘1’ to ‘0’, ccm can also generate interrupt, if its not masked (refer to CIMR). Table 7-23 provides its field descriptions.

The handshake bypass should be used in case that a specific module that has a handshake is disabled - in this case the module is not ready to answer for the handshake, and the handshake should be bypassed. In case of a bypass, the CCM will generate the request to the module but will not wait for the acknowledge signal.

Figure 7-20. CCM Divider Handshake In Process Register(CDHIPR)

Table 7-23. CDHIPRR Field Descriptions

Field	Description
31–10	Reserved
16 arm_podf_busy	Busy indicator for arm_podf. This bit corresponds to the arm_podf divider only if ARM DVFS operation is done through arm_podf change (arm_freq_shift_divider = '1'). 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process. The value read in the divider represents the next value that the divider will hold after the handshake with gpc (after assertion of arm_clk_switch_req and the actual write to the divider).
15–9	Reserved
8 ddr_high_freq_clk_sel_busy	Busy indicator for ddr_high_freq_clk_sel mux control. 0 mux is not busy and its value represents the actual division. 1 mux is busy with handshake process with module. The value read in the register represents the next value that the mux will hold after the handshake.
7 ddr_podf_busy	Busy indicator for ddr_podf. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with module. The value read in the regster represents the next value that the divider will hold after the handshake.
6 emi_clk_sel_busy	Busy indicator for emi_clk_sel. 0 mux is not busy and its value represents the actual division. 1 mux is busy with handshake process with module. The value read in the divider represents the next value that the divider will hold after the handshake.
5 periph_clk_sel_busy	Busy indicator for periph_clk_sel mux control. 0 mux is not busy and its value represents the actual division. 1 mux is busy with handshake process with module. The value read in the divider represents the next value that the divider will hold after the handshake.
4 nfc_podf_busy	Busy indicator for nfc_podf. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with module. The value read in the divider represents the next value that the divider will hold after the handshake.
3 ahb_podf_busy	Busy indicator for ahb_podf. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with module. The value read in the divider represents the next value that the divider will hold after the handshake.
2 emi_slow_podf_busy	Busy indicator for emi_slow_podf. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with module. The value read in the divider represents the next value that the divider will hold after the handshake.
1 axi_b_podf_busy	Busy indicator for axi_b_podf. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with module. The value read in the divider represents the next value that the divider will hold after the handshake.
0 axi_a_podf_busy	Busy indicator for axi_a_podf. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with module. The value read in the divider represents the next value that the divider will hold after the handshake.

7.3.3.19 CCM DVFS Control Register(CDCR)

Figure 7-21 represents the CCM DVFS Control Register (CDCR). The CDCR register contains bits to control the DVFS operation.Table 7-24 provides its field descriptions.

Figure 7-21. CCM DVFS Control Register (CDCR)

Table 7-24. CDCR Field Descriptions

Field	Description
31-8	Reserved
7 sw_periph_clk_div_req_status	Status bit defines the operation of DVFS driver in case of software control of DVFS divider." Set this bit to '1' to clear - after a DVFS divider switch request it will be asserted and software should write '1' to clear it and prepare it for the next DVFS divider switch request. 1 DVFS frequency switch operation finished. 0 DVFS frequency switch is not finished, or there is no frequency switch request.
6 sw_periph_clk_div_req	Start DVFS frequency division operation. This bit will affect the DVFS divider only if software_DVFS_en bit was set to '1'. 0 Remove DVFS divider operation - DVFS divider will divide by '1'. 1 enable DVFS divider operation. DVFS divider will divide by the value which is programmed in periph_clk_DVFS_podf bits.
5 software_DVFS_en	Defines if the DVFS operation will commence by software bit or by GPC signal "periph_clk_div_req". 0 DVFS operation is started by GPC signal "periph_clk_div_req" 1 DVFS operation is started by software bit sw_periph_clk_div_req
4	reserved **Note:** Functionality is no longer supported. Bit shouldn't be altered and must remain in its default value.
3	reserved **Note:** Functionality is no longer supported. Bit shouldn't be altered and must remain in its default value.

Table 7-24. CDCR Field Descriptions (continued)

Field	Description
2 arm_freq_shift_divider	Define if next DVFS of ARM domain will be through podf change or pll relock. 0 Next ARM DVFS operation is done through PLL relock. The PLL relock process will start once arm_clk_switch_req is asserted. (in this case any new writes to arm_podf will immediately change the frequency, without waiting for arm_clk_switch_req). 1 Next ARM DVFS operation is done through arm_podf change. ccm will hold updates to arm_podf until signal arm_clk_switch_req is asserted.
1–0 periph_clk_DVFS_podf[1:0]	Divider value for next operation of peripheral DVFS. This defines the value of the dividers affecting main_bus_clk. Please refer to Figure 7-40 and Figure 7-41. This divider will take place only during DVFS operation. Please refer to Section 7.4.7.2, Peripheral Clock Domain Frequency Shift for details. 00 restricted 01 divide by 2(Default) 10 divide by 3 11 divide by 4 Note: IPU will not support DVFS operation of division by 3.

7.3.3.20 CCM Testing Observability Register (CTOR)

Figure 7-22 represents the CCM Testing Observability Register (CTOR). CCM includes three muxes to mux between different critical signals for testing observability. The output of the three muxes is generated on the three output signals obs_output_0, obs_output_1 and obs_output_2. Those three output signals can be generated on the IC pads by configuring the IOMUXC. The CTOR register contains bits to control the data generated for observability on the three output signals above. Table 7-25 provides its field descriptions.

Figure 7-23. CCM Low Power Control Register (CLPCR)

Table 7-26. CLPCR Field Descriptions

Field	Description
31–24	Reserved
23	Reserved **Note:** Functionality is no longer supported. Bit must be set for better power saving - along with configuration of CCDR[18] and CCGR4[13:6]. Please refer to description of these bits for the recommended values.
22 bypass_scc_lpm_hs	Bypass handshake with scc on next entrance to STOP mode. CCM does not wait for the module's acknowledge. 0 handshake with SCC on next entrance to STOP mode will be performed. (default). 1 handshake with SCC on next entrance to STOP mode will be bypassed.
21 bypass_max_lpm_hs	Bypass handshake with max on next entrance to low power mode (wait or STOP mode). CCM does not wait for the module's acknowledge. 0 handshake with max on next entrance to low power mode will be performed. (default). 1 handshake with max on next entrance to low power mode will be bypassed.
20 bypass_sdma_lpm_hs	Bypass handshake with sdma on next entrance to low power mode (wait or STOP mode). CCM does not wait for the module's acknowledge. 0 handshake with sdma on next entrance to low power mode will be performed. (default). 1 handshake with sdma on next entrance to low power mode will be bypassed.

Table 7-26. CLPCR Field Descriptions (continued)

Field	Description
19 bypass_emi_lpm_hs	Bypass handshake with emi on next entrance to low power mode (wait or STOP mode). CCM does not wait for the module's acknowledge. 0 handshake with emi on next entrance to low power mode will be performed. (default). 1 handshake with emi on next entrance to low power mode will be bypassed.
18 bypass_ipu_lpm_hs	Bypass handshake with IPU on next entrance to low power mode (wait or STOP mode). CCM does not wait for the module's acknowledge. 0 handshake with IPU on next entrance to low power mode will be performed. (default). 1 handshake with IPU on next entrance to low power mode will be bypassed.
17 bypass_rtic_lpm_hs	Bypass handshake with rtic on next entrance to low power mode (wait or STOP mode). CCM does not wait for the module's acknowledge. 0 handshake with rtic on next entrance to low power mode will be performed. (default). 1 handshake with rtic on next entrance to low power mode will be bypassed.
16 bypass_sahara_lpm_hs	Bypass handshake with SAHARA on next entrance to low power mode (wait or STOP mode). CCM does not wait for the module's acknowledge. 0 handshake with SAHARA on next entrance to low power mode will be performed. (default). 1 handshake with SAHARA on next entrance to low power mode will be bypassed.
15–13	Reserved
12 apm_sdma_clk_gate_en_bit	This bit will allow the operation of automatic clock gating of SDMA - to be used in LP-APM mode. 1 Enable automatic clock gating of SDMA clocks. For this feature to work, the CGR bits of SDMA should be programmed to turn the clocks on in WAIT mode. 0 Disable automatic clock gating of SDMA clocks. In this case the sdma_clk_enable signal will operate as indicated by the CGR bits.
11 cosc_pwrdown	In run mode, software can manually control powering down of the on-chip oscillator, that is, generating '1' on cosc_pwrdown signal. If software manually powered down the on-chip oscillator, then sbyos functionality for on-chip oscillator will be bypassed. The manual closing of the on-chip oscillator should be performed only in case the reference oscilator is not the source of all the clocks generation. 0 On chip oscillator will not be powered down, that is, cosc_pwrdown = '0'.(default) 1 On chip oscillator will be powered down, that is, cosc_pwrdown = '1'.
9–10 stby_count	Standby counter definition. These two bits define, in the case of STOP exit (if vstby bit was set), the amount of time CCM will wait between PMIC_VSTBY_REQ negation and the check of assertion of PMIC_VFUNCIONAL_READY. If the counter is used when the handshake is bypassed, then add this here. 00 CCM will wait 2 CKIL clock cycles 01 CCM will wait 4 CKIL clock cycles 10 CCM will wait 8 CKIL clock cycles 11 CCM will wait 16 CKIL clock cycles
8 VSTBY	Voltage standby request bit. This bit defines if PMIC_VSTBY_REQ pin, which notifies external power management IC to move from functional voltage to standby voltage, will be asserted in STOP mode. 0 voltage will not be changed to standby voltage after next entrance to STOP mode. (PMIC_VSTBY_REQ will remain negated - '0') 1 voltage will be requested to change to standby voltage after next entrance to STOP mode. (PMIC_VSTBY_REQ will be asserted - '1'). Note: When returning from STOP mode, the PMIC_VSTBY_REQ will be deasserted (if it was asserted when entering STOP mode), and CCM will wait for indication that functional voltage is ready (by sampling the assertion of pmic_vfuncional_ready) before continuing the process of exiting from STOP mode. Please refer to stby_count bits.

Table 7-26. CLPCR Field Descriptions (continued)

Field	Description
7 dis_ref_osc	dis_ref_osc - in run mode, software can manually control closing of external reference oscillator clock, that is, generating '1' on ref_en_b signal. If software closed manually the external reference clock, then sbyos functionality will be bypassed. The manual closing of external reference oscilator should be performed only in case the reference oscilator is not the source of any clock generation. 0 external high frequency oscillator will be enabled, that is, ref_en_b = '0'.(default) 1 external high frequency oscillator will be disabled, that is, ref_en_b = '1'
6 SBYOS	Standby clock oscillator bit. This bit defines if REF_EN_B pin, which disables external high frequency crystal, and cosc_pwrdown, which power down the on-chip oscillator, will be asserted in STOP mode. This bit is discarded if dis_ref_osc = '1' for external oscillator, and if cosc_pwrdown='1' for the on-chip oscillator. 0 external high frequency oscillator will not be disabled and the on-chip oscillator will not be powered down, after next entrance to STOP mode. (ref_en_b will remain asserted - '0' and cosc_pwrdown will remain de asserted - '0') 1 external high frequency oscillator will be disabled and the on-chip oscillator will be powered down, after next entrance to STOP mode. (ref_en_b will be deasserted - '1' and cosc_pwrdown will be asserted - '1'). (default). When returning from STOP mode, external oscillator will be enabled again, the on-chip oscillator will return to oscillator mode, and after oscnt count ccm will continue with the exit from STOP mode process.
5 ARM_clk_dis_on_lpm	Define if ARM clocks (arm_clk, soc_mxclk, soc_pclk, soc_dbg_pclk, vl_wrck) will be disabled on wait mode. This is useful for debug mode, when the user wants to simulate entering wait mode and keep ARM clock functioning. 0 ARM clock enabled on wait mode. 1 ARM clock disabled on wait mode. (default). Note: software should not enable ARM power gating in wait mode if this bit is cleared.
4–3 lpsr_clk_sel	Controlls the mux to select the lpsr_clk_root generation. Refer to Figure 7-46 and to 7.4.8.4, "Low Power Screen Refresh Mode (LPSR) for details. 00 Reserved 01 generate clock from FPM 10 generate clock from FPM/2 11 GND - to be set when LPSR is not used, (for power consumption considerations) (default).
2 bypass_pmic_vfunctional_ready	By asserting this bit CCM will bypass waiting for pmic_vfunctional_ready signal when coming out of STOP mode. This should be used for PMIC's that don't support the pmic_vfunctional_ready signal. 0 Don't bypass the pmic_vfunctional_ready signal - CCM will wait for it's assertion during exit of low power mode if standby voltage was enabled. 1 bypass the pmic_vfunctional_ready signal - CCM will not wait for it's assertion during exit of low power mode if standby voltage was enabled.
1–0 LPM[1:0]	Setting the low power mode that system will enter on next assertion of dsm_request signal. 00 Remain in run mode 01 Transfer to wait mode 10 Transfer to STOP mode 11 Transfer to LPSR mode (Low Power Screen Refresh Mode).

7.3.3.22 CCM Interrupt Status Register(CISR)

Figure 7-24 represents the CCM Interrupt Status Register (CISR). This is a write one to clear register. Once a interrupt is generated, software should write one to clear it. Table 7-27 provides its field descriptions.

Figure 7-24. CCM Interrupt Status Register (CISR)

Table 7-27. CISR Field Descriptions

Field	Description
31–27	Reserved
26 arm_podf_loaded	Interrupt ipi_int_1 generation. due to frequency change of arm_podf. The interrupt will commence only if arm_podf is loaded during a arm DVFS operation. 0 - interrupt is not genrerated due to frequency change of arm_podf. The frequency of arm_podf is not changed, the values are changed which cause the frequency to change. The same is also relevant for next fields and for description of the interrupt mask register. 1 - interrupt genrerated due to frequency change of arm_podf
25 ddr_high_freq_clk_sel_loaded	Interrupt ipi_int_1 generation due to update of ddr_high_freq_clk_sel. 0 - interrupt is not genrerated due to update of ddr_high_freq_clk_sel. 1 - interrupt genrerated due to update of ddr_high_freq_clk_sel.
24 ddr_clk_podf_loaded	Interrupt ipi_int_1 generation due to frequency change of ddr_podf 0 - interrupt is not genrerated due to frequency change of ddr_podf 1 - interrupt genrerated due to frequency change of ddr_podf
23 emi_clk_sel_loaded	Interrupt ipi_int_1 generation due to update of emi_clk_sel. 0 - interrupt is not genrerated due to update of emi_clk_sel. 1 - interrupt genrerated due to update of emi_clk_sel.

Table 7-27. CISR Field Descriptions (continued)

Field	Description
22 periph_clk_sel_loaded	Interrupt ipi_int_1 generation due to update of periph_clk_sel. 0 - interrupt is not genrerated due to update of periph_clk_sel. 1 - interrupt genrerated due to update of periph_clk_sel.
21 nfc_podf_loaded	Interrupt ipi_int_1 generation due to frequency change of nfc_podf 0 - interrupt is not genrerated due to frequency change of nfc_podf 1 - interrupt genrerated due to frequency change of nfc_podf
20 ahb_podf_loaded	Interrupt ipi_int_1 generation due to frequency change of ahb_podf 0 - interrupt is not genrerated due to frequency change of ahb_podf 1 - interrupt genrerated due to frequency change of ahb_podf
19 emi_slow_podf_loaded	Interrupt ipi_int_1 generation due to frequency change of emi_slow_podf 0 - interrupt is not genrerated due to frequency change of emi_slow_podf 1 - interrupt genrerated due to frequency change of emi_slow_podf
18 axi_b_podf_loaded	Interrupt ipi_int_1 generation due to frequency change of axi_b_podf 0 - interrupt is not genrerated due to frequency change of axi_b_podf 1 - interrupt genrerated due to frequency change of axi_b_podf
17 axi_a_podf_loaded	Interrupt ipi_int_1 generation due to frequency change of axi_a_podf 0 - interrupt is not genrerated due to frequency change of axi_a_podf 1 - interrupt genrerated due to frequency change of axi_a_podf
16 dividers_loaded	Interrupt ipi_int_1 is generated due to frequency update which is cause by programming any of the following: axi_a_podf, axi_b_podf, emi_slow_podf, ahb_podf, nfc_podf, periph_clk_sel, emi_clk_sel. 0 - interrupt is not genrerated due to updated of axi_a_podf, axi_b_podf, emi_slow_podf, ahb_podf, nfc_podf, periph_clk_sel, emi_clk_sel. 1 - interrupt genrerated due to updated of axi_a_podf, axi_b_podf, emi_slow_podf, ahb_podf, nfc_podf, periph_clk_sel, emi_clk_sel.
15 gpio1_9_wakeup_det	Interrupt ipi_int_2 generation due to change of gpio1_9 input. 0 - interrupt is not genrerated due to change of gpio1_9 input 1 - interrupt genrerated due to change of gpio1_9 input
14 gpio1_8_wakeup_det	Interrupt ipi_int_2 generation due to change of gpio1_8 input. 0 - interrupt is not genrerated due to change of gpio1_8 input 1 - interrupt genrerated due to change of gpio1_8 input
13 gpio1_7_wakeup_det	Interrupt ipi_int_2 generation due to change of gpio1_7 input. 0 - interrupt is not genrerated due to change of gpio1_7 input 1 - interrupt genrerated due to change of gpio1_7 input
12 gpio1_6_wakeup_det	Interrupt ipi_int_2 generation due to change of gpio1_6 input. 0 - interrupt is not genrerated due to change of gpio1_6 input 1 - interrupt genrerated due to change of gpio1_6 input
11 gpio1_5_wakeup_det	Interrupt ipi_int_2 generation due to change of gpio1_5 input. 0 - interrupt is not genrerated due to change of gpio1_5 input 1 - interrupt genrerated due to change of gpio1_5 input
10 gpio1_4_wakeup_det	Interrupt ipi_int_2 generation due to change of gpio1_4 input. 0 - interrupt is not genrerated due to change of gpio1_4 input 1 - interrupt genrerated due to change of gpio1_4 input

Table 7-27. CISR Field Descriptions (continued)

Field	Description
9 sdhc2_wakeup_det	Interrupt ipi_int_2 generation due to insertion of sdhc2 card. 0 - interrupt is not genrerated due to insertion of sdhc2 card 1 - interrupt genrerated due to insertion of sdhc2 card
8 sdhc1_wakeup_det	Interrupt ipi_int_2 generation due to insertion of sdhc1 card. 0 - interrupt is not genrerated due to insertion of sdhc1 card 1 - interrupt genrerated due to insertion of sdhc1 card
7 kpp_wakeup_det	Interrupt ipi_int_2 generation due to key press detection. 0 - interrupt is not genrerated due to key press detection 1 - interrupt genrerated due to key press detection
6 cosc_ready	Interrupt ipi_int_2 generation due to on-chip oscillator ready, that is, oscnt has finished counting. 0 - interrupt is not genrerated due to on-chip oscillator ready 1 - interrupt genrerated due to on-chip oscillator ready
5 CAMP2_ready	Interrupt ipi_int_2 generation due to CAMP2 ready, that is, oscnt has finished counting. 0 - interrupt is not genrerated due to CAMP2 ready 1 - interrupt genrerated due to CAMP2 ready
4 CAMP1_ready	Interrupt ipi_int_2 generation due to CAMP1 ready, that is, oscnt has finished counting. 0 - interrupt is not genrerated due to CAMP1 ready 1 - interrupt genrerated due to CAMP1 ready
3 fpm_ready	Interrupt ipi_int_2 generation due to fpm ready 0 - interrupt is not genrerated due to FPM ready 1 - interrupt genrerated due to FPM ready
2 lrf_pll3	Interrupt ipi_int_2 generation due to lock of pll3 0 - interrupt is not genrerated due to lock ready of pll_3 1 - interrupt genrerated due to lock ready of pll_3
1 lrf_pll2	Interrupt ipi_int_2 generation due to lock of pll2 0 - interrupt is not genrerated due to lock ready of pll_2 1 - interrupt genrerated due to lock ready of pll_2
0 lrf_pll1	Interrupt ipi_int_2 generation due to lock of pll1 0 - interrupt is not genrerated due to lock ready of pll_1 1 - interrupt genrerated due to lock ready of pll_1

7.3.3.23 CCM Interrupt Mask Register(CIMR)

7.3.3.25 CCM General Purpose Register(CGPR)

Figure 7-27 represents the CCM General Purpose Register (CGPR). This is a regular read/write implemented register, which can serve for future possible usage. the respective bits are connected to cgpr_dout[31:0] output of ccm. Few bits are already in use, The other bits are free to be used in future usage. Table 7-30 provides its field descriptions.

73FD_4064 (CGPR) Access: User read-write

Figure 7-27. CCM Register (CGPR)

Table 7-30. CGPR Field Descriptions

Field	Description
31– 24	Reserved for future use. Those bits are connected to ccm output cgpr_dout[31-10]
23 arm_async_ref_en	Enable of ARM async ref circuit. This bit is connected to ccm output cgpr_dout[23]. 0 - ARM async ref circuit disabled 1- ARM async ref circuit enabled
22 arm_async_ref_sel[7]	Bit 7 of frequency select of async reference circuit. 0 frequency of async reference circuit is defined by other arm_async_ref_sel bits 1 frequency of async reference circuit is reference number 7 (this is in case all other arm_async_ref_sel are defined as ‘0’.
21 arm_async_ref_sel[6]	Bit 6 of frequency select of async reference circuit. 0 frequency of async reference circuit is defined by other arm_async_ref_sel bits 1 frequency of async reference circuit is reference number 6 (this is in case all other arm_async_ref_sel are defined as ‘0’.
20 arm_async_ref_sel[4]	Bit 4 of frequency select of async reference circuit. 0 frequency of async reference circuit is defined by other arm_async_ref_sel bits 1 frequency of async reference circuit is reference number 4 (this is in case all other arm_async_ref_sel are defined as ‘0’.

Table 7-30. CGPR Field Descriptions (continued)

Field	Description
19 arm_async_ref_sel[3]	Bit 3 of frequency select of async reference circuit. 0 frequency of async reference circuit is defined by other arm_async_ref_sel bits 1 frequency of async reference circuit is reference number 3 (this is in case all other arm_async_ref_sel are defined as ‘0’.
18 arm_async_ref_sel[2]	Bit 2 of frequency select of async reference circuit. 0 frequency of async reference circuit is defined by other arm_async_ref_sel bits 1 frequency of async reference circuit is reference number 2 (this is in case all other arm_async_ref_sel are defined as ‘0’.
17 arm_async_ref_sel[1]	Bit 1of frequency select of async reference circuit. 0 frequency of async reference circuit is defined by other arm_async_ref_sel bits 1 frequency of async reference circuit is reference number 1 (this is in case all other arm_async_ref_sel are defined as ‘0’.
16 arm_async_ref_sel[0]	Bit 0 of frequency select of async reference circuit. 0 frequency of async reference circuit is defined by other arm_async_ref_sel bits 1 frequency of async reference circuit is reference number 0 (this is in case all other arm_async_ref_sel are defined as ‘0’.
15 arm_async_ref_sel[5]	Bit 5 of frequency select of async reference circuit. 0 frequency of async reference circuit is defined by other arm_async_ref_sel bits 1 frequency of async reference circuit is reference number 5 (this is in case all other arm_async_ref_sel are defined as ‘0’.
14–6	Reserved for future use. Those bits are connected to ccm output cgpr_dout[14-6]
5 overide_apm_emi_intr_clock_gating	Defines override of the automatic clock gating control of EMI clock: aclk_intr. If this bit is defined as ‘0’, there will not be an override, and the aclk_intr will be gated each time both m3_clk_gate_en and m4_clk_gate_en are ‘0’. If this bit is ‘1’, then aclk_intr will not be gated based on the above two signals. In APM, this feature will aid consuming less power since EMI aclk_intr will be gated each time there is no access of ARM or SDMA. 1 override aclk_intr input of EMI. 0 don’t override the aclk_intr automatic control, that is, allow control of m3_clk_gate_en and m4_clk_gate_en on aclk_intr.
4 efuse_prog_supply_gate	Defines the value of the output signal cgpr_dout[4]. Gate of programming supply for efuse programing 0 fuse programing supply voltage is gated off to the efuse module 1 allow fuse programing.
3 FPM_mux_select	FPM_mux_select - Defines the value of the output signal cgpr_dout[3] going to FPM. FPM uses this signal to mux between FPM output and FPM internal oscilator. This functionality is used for testability of FPM. Refer to FPM spec for further details. 0 fpm_mux_select output is 0 1 fpm_mux_select output is 1
2–0	Reserved

NOTE

ARM_CLK_ROOT is muxed in top level between the ccm_arm_clock_root output and the clock generated by reference circuit. The frequency of the reference circuit is defined by 8 control frequency select bits of the async reference circuit. Only one single select bit should equal to '1' - all the other select bits should equal to '0'. The frequency is defined by the next table:

Table 7-31. Async Reference Circuit Settings

Field	Description
arm_async_ref_sel[7:0] = 00000001	Frequency Option 0
arm_async_ref_sel[7:0] = 00000010	Frequency Option 1
arm_async_ref_sel[7:0] = 00000100	Frequency Option 2
arm_async_ref_sel[7:0] = 00001000	Frequency Option 3
arm_async_ref_sel[7:0] = 00010000	Frequency Option 4
arm_async_ref_sel[7:0] = 00100000	Frequency Option 5
arm_async_ref_sel[7:0] = 01000000	Frequency Option 6
arm_async_ref_sel[7:0] = 10000000	Frequency Option 7

7.3.3.26 CCM Clock Gating Register(CCGR)

Figure 7-28 through Figure 7-33 represents the CCM Clock Gating Register (CCGR). The clock gating Registers define the clock gating for power reduction of each clock (CG(i) bits). There are 7 CGR registers. The number of registers required is according to the number of peripherals in the system. Table 7-32 through Table 7-38 provides its field descriptions.

Figure 7-34. CCM Clock Gating Register (CCGR6)

7.3.4 CG(i) bits

This bits are used to turn on/off the clock to each module independently. Table 7-32 details the possible clock activity conditions for each module.

Table 7-32. CG Bit Description

CGR value	Clock Activity Description
00	Clock is off during all modes. stop enter hardware handshake is disabled.
01	Clock is on in run mode, but off in WAIT and STOP modes
10	Not applicable (Reserved).
11	clock is on during all modes, except STOP mode.

Note: Stop the module before clearing its bits because clocks to the module will be stopped immediately.

The following tables show the register mappings for the different CGRs. The clock connectivity table should be used to match the “CCM output affected” to the actual clocks going into the modules.

Table 7-33. CCGR0 Register Mapping

CG bit index	Controlled Clocks	Comments	CCM output affected
0	arm_bus	to control ipg bus of arm	arm_bus_clk_enable
1	arm_axi	to control arm_axi input clock	arm_axi_clk_enable

12	hs2ic_serial clock	affects hsi2c ipg_hsi2c_clk (the serial clock)	hsi2c_serial_clk_enable
13	firi ipg clock		firi_clk_enable
14	firi serial clock		firi_serial_clk_enable
15	SCC clocks	affects scc_clk_enable. it is not possible to close SCC clocks during run mode. writting ‘00’ to this cgr will not affect the clocks of SCC. Closing the clocks of SCC will eventually block the access to the internal memory. In WAIT mode the SCC clocks can be closed only if it is guaranteed that no master will access the internal memory during the time spend in WAIT mode. The SCC clocks will be closed in WAIT mode only if SAHARA clocks were closed as well. During WAIT mode, if SCC will assert either hclk_en signal or ipg_clk_en signal, the CCM will assert scc_clk_enable and will thus enable the SCC clocks. The WAIT mode will not be exited due to this assertion.	scc_clk_enable

7.3.4.1 CCM Module Enable Override Register(CMEOR)

Figure 7-35 represents the CCM Module Enable Override Register (CMEOR). The CMEOR register contains bits to override the clock enable signal from the module. This should be used in case that it is decided to bypass the clock enable signals from the modules. In this case the word bypass is defined as the clock remaining on, unless gated by the corresponding CCGR bit. This bit will be applicable only for module that their clock enable signal is used provides its field descriptions.

7.4 Functional Description

This section describes clock generation.

7.4.1 External Low Frequency Clock—CKIL

The i.MX51 can use either a 32 kHz, 32.768 kHz, or a 38.4 kHz crystal as the external low frequency source. Throughout this chapter, the low frequency crystal is referred to as the 32 kHz crystal. CMOS input buffer with schmitt trigger feature is used as the receiver of 32 kHz clock. This clock source should be active all the time the i.MX51 is powered on.

The 32 kHz entering the CCM is referred as CKIL. It is synchronized to ipg_clk and supplied to modules that need it.

The 32 kHz clock also enters the FPM to produce the DPLL reference clock.

7.4.2 External High Frequency Clock CKIH and Internal Oscillator

An external crystal connected to the on-chip oscillator circuit is used to generate a reference for the three on-chip PLLs. The oscillator circuit frequency range is 22 to 27 MHz. For flexibility, inputs CKIH1 and CKIH2 may be used to supply special frequencies for the TV encoder, SPDIF, and others. as an alternate to the PLL-generated clocks. Because CKIH1 and CKIH2 pass through the CAMP (Clock Amplifier) modules, their frequency range is limited to the frequency range of the CAMP. See the Clock Amplifier Parameters section of the data sheet for specifications.

7.4.3 DPLLs (Digital Phase-Locked Loops) and Reference Clocks

There are three DPLLs in the i.MX51 project, as follows:

- PLL1 (typical functional frequency 800 MHz)
- PLL2 (typical functional frequency 665 MHz)
- PLL3 (typical functional frequency 216 MHz)

Each DPLL is controlled by a PLL-IP interface module, which can use the following options as DPLL reference clock:

- Output of OSC (typical functional frequency 24 MHz)
- Output of FPM (multiplied CKIL) (typical functional frequency 32.768 kHz)

7.4.4 PLL Clock Selector

A clock selector exists on each DPLL output of the 3 DPLLs. The clock selector is used to select between the gated clock output of the DPLL (dpgdck) and the divided by 2 gated clock output of the DPLL (dpgdck_2). Please refer to DPLL chapter for the description of the DPLL output and input pins.
The selection of dpgdck_2 is done by setting DPDCK02_EN bit (DPCTL[12]) in the corresponding DPLL-IP interface module.

When low range frequencies are required by the DPLL, such as 150Mhz, the divided output should be selected.

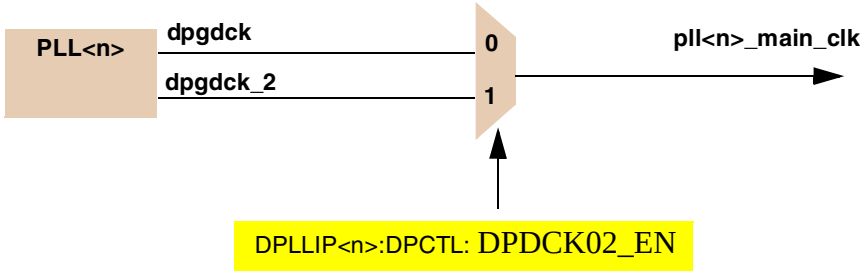

Figure 7-36. PLL clock selector

7.4.5 CLKSS Support

CLKSS input to the i.MX51 is internally connected to init_dp_ctl_dpllip[8] signal of each PLL-IP interface. This signal defines the initialization configuration of clock source to be used by PLL-IP interface:

- If CLKSS = 0, then OSC output is used as reference clock for all three DPLL_IPs.
- If CLKSS = 1, then FPM output is used as reference clock for all three DPLL_IPs.

During ignition process the value of clkss signal will be used in ccm to set either cosc_en bit or fpm_en bit, depending on which is the selected reference clock. The CAMP1_en and CAMP2_en will always be enabled when coming out of ignition process, no matter what was the value of clss. In run mode, software can control cosc_en, CAMP1_en, CAMP2_en and fpm_en by reprograming those bits.

7.4.6 CCM Internal Clock Generation

The clock generation is comprised of three submodules, as follows:

- CCM_CLK_SWITCHER
- CCM_CLK_IGNITION
- CCM_CLK_ROOT_GEN
- CCM_CLK_SWITCHER

CCM_CLK_SWITCHER sub module receives the pll output clocks and the pll bypass clocks. It generates the following three main switchable clocks to be delivered for CCM_CLK_ROOT_GEN:

- pll1_sw_clk (typical functional frequency 800Mhz - used to supply ARM platform)
- pll2_sw_clk (typical functional frequency 665Mhz - used to supply axi/ahb/ip buses clocks)
- pll3_sw_clk (typical functional frequency 216Mhz - used to supply serial clocks like usb, ssi, and so on.)

Figure 7-37 describes the generation of the three switchable clocks. It also includes the frequency switch control submodule that is responsible for the frequency change during DVFS scenario.

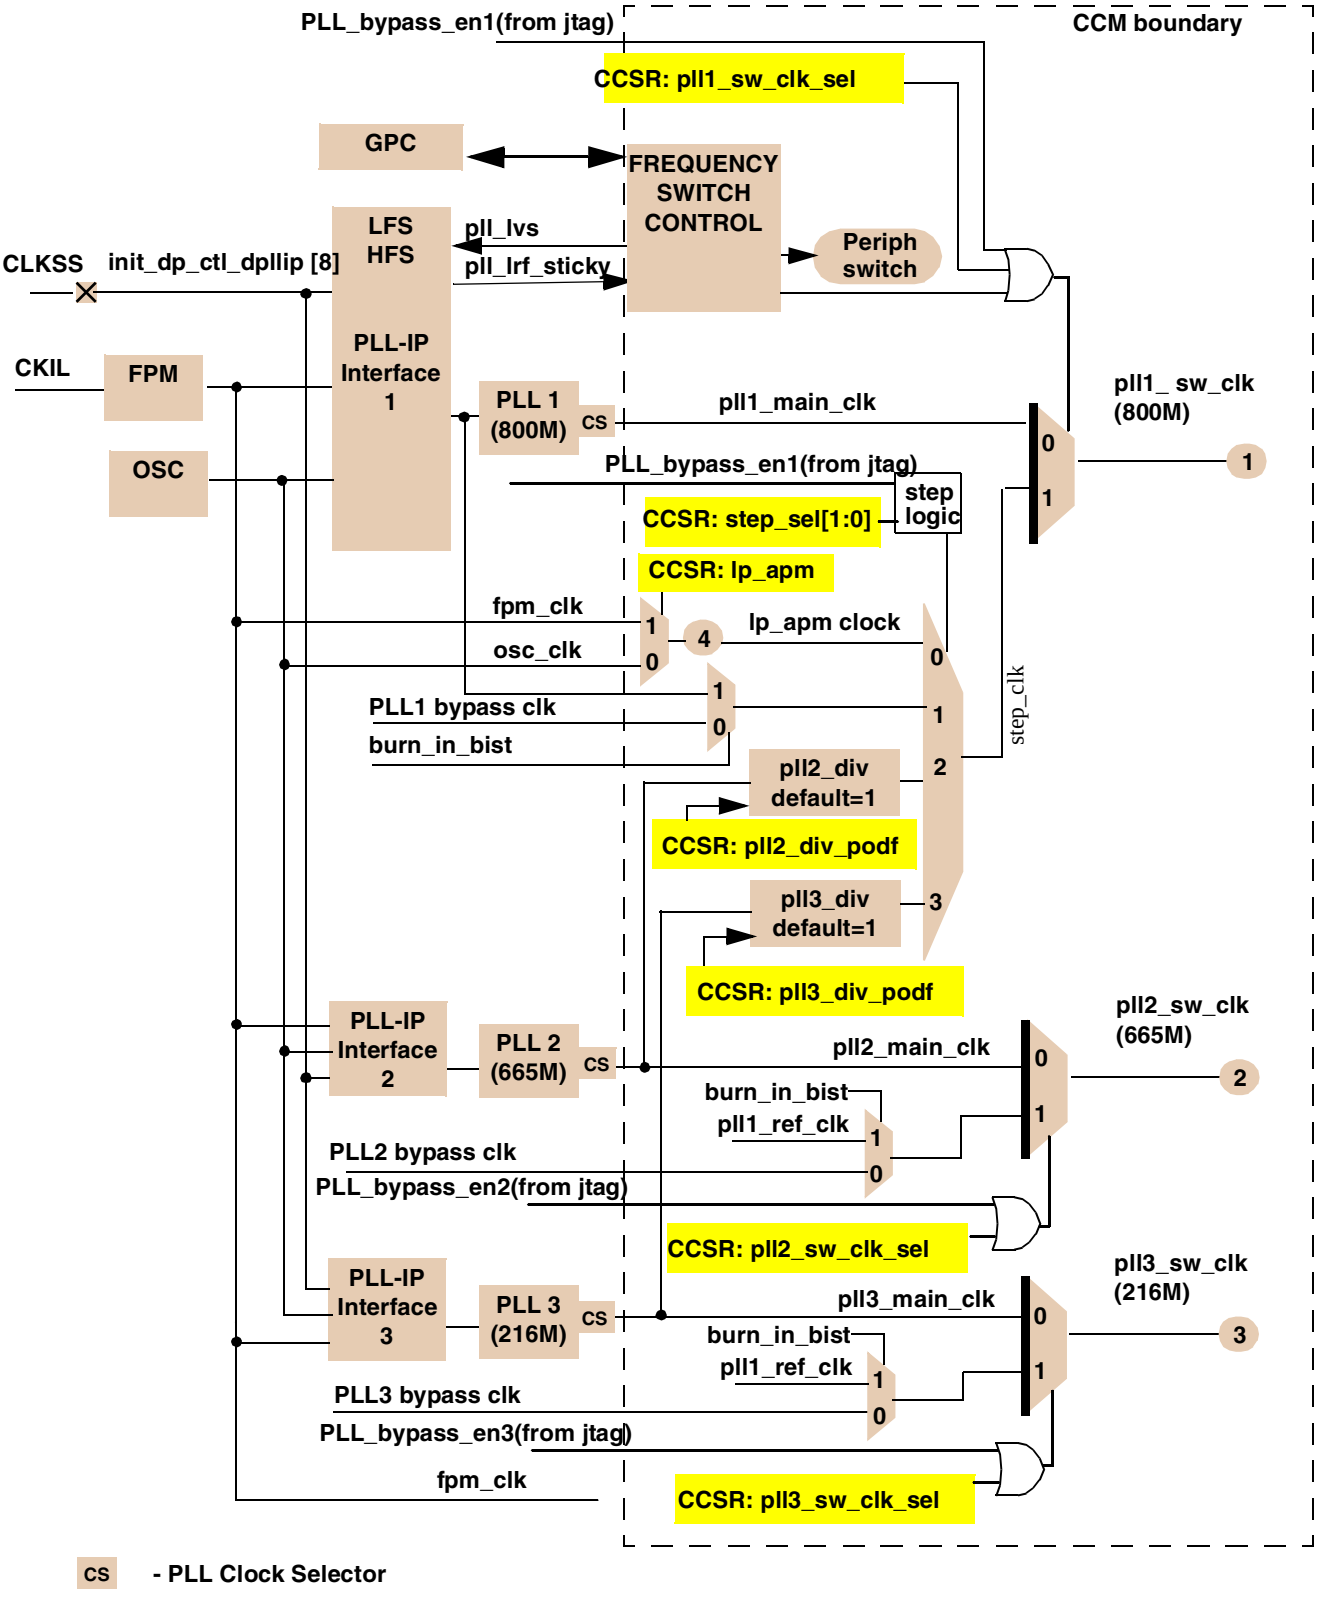

Figure 7-37. Switchable Clock Generation

7.4.6.1 PLL Bypass Procedure

CCM_CLK_SWITCHER sub module includes capability for each of the pll_main_clk's to be bypassed with an external bypass clk, and in this way supply to the three pll_sw_clk outputs a external bypass clock. In burn_in_bist mode the PLL bypass clocks for all three PLLs will be supplied from pll1_ref_clk (the output of DPLLIP1).

The decision to shift from pll_main_clk to pll_bypass_clk is done either by programable bits in CCSR or by three pll_bypass_en signals which are driven from jtag module. Since the switch between the clocks is done by a glitch less multiplexer, then both pll_main_clk and pll_bypass_clk should be running to complete the shift glitchlessly. In case the selection is done in reset, then it is not needed that both clocks will be available simultaneously.

NOTE

Since the bypass clock for pll1_sw_clk is generated from a multiplexer, the software needs to set the bypass clock via CCSR:step_sel[1:0] before shifting the glitchless mux via CCSR:pll1_sw_clk_sel. Similarly, when returning from pll_bypass, the system should first change the glitchless mux via CCSR:pll1_sw_clk_sel and only after that it is completed is change allowed to the CCSR:step_sel[1:0].

If the shift to pll_bypass for pll1_sw_clk is done via pll_bypass_en1 signal, then the pll_bypass_en1 signal should first set the step_select mux to prepare the bypass clock, and only after that to shift the glitch less mux from pll1_main_clk to the step_sel multiplexer output. This is taken care of since shift of step_sel mux is done faster than shift of the glitch less mux. When returning from pll_bypass to pll1_main_clk the step_sel mux control should be delayed until the glitch less mux has shifted back to the pll1_main_clk. This is taken care of in hardware by step_logic sub module.

7.4.6.2 Step Logic

The step logic allows the pll_bypass enable signal to bypass the step_sel bits and to set the 4x1 mux to the pll1_bypass_clk option. This sub module also delays the step_sel mux as described in PLL bypass procedure above.

7.4.6.3 DPLL-IP Reference Clock Connectivity

For all three DPLL-IPs, connections are as follows:

- The input clk2 is connected to on-chip oscillator clock output.
- The input clk3 is connected to FPM output (fpm_clkout).
- The input init_dp_ctl_dpllip [8] receives ccm_ipp_ind_clkss (this goes also to ccm).
- The input init_dp_ctl_dpllip [9] is connected to Vcc.

The above connections allows clkss to define in reset whether the FPM output or the on-chip oscillator output is chosen.

7.4.6.4 PLL Reference Clock Change

If software wants to change the PLL reference for a specific PLL, between FPM and on-chip oscillator outputs, or if software wants to stop a specific PLL, then software needs first to move all the clocks generated from this PLL to another PLL which is not changed. This should be done via the glitchless muxes for the clocks which cant be stopped (core and bus clocks). Then software should reprogram the respective dpll_ip: first configure DP_CONFIG[1], so that it will allow auto restart of the PLL on next update of the reference clock. Then software should change DP_CTL[8:9], to change the reference clock mux. In this case the respective PLL will restart and once its locked it will generate lrf_sticky signal to ccm. This signal can cause an interrupt from ccm (if configured in CIMR register). Based on this interrupt, software can be notified that the PLL is ready with the new reference clocks. Software should also take care of reprograming the PLL settings to match the new reference clock.At this point software can change the glitch less muxes to supply clock from the respective PLL that was changed.

7.4.6.5 CCM_CLK_IGNITION

The responsibility of the ccm_clk_ignition sub module is to manage the wake up after reset of the FPM, on-chip oscillator, CAMP1, CAMP2, dpll_ip and PLL modules. Its task starts with de-assertion of early_reset from the Reset controller. Its task finishes with assertion signal src_clock_ready that notifies reset controller that the root clocks are ready.

Figure 7-38 describes the connectivity of CCM clock ignition.

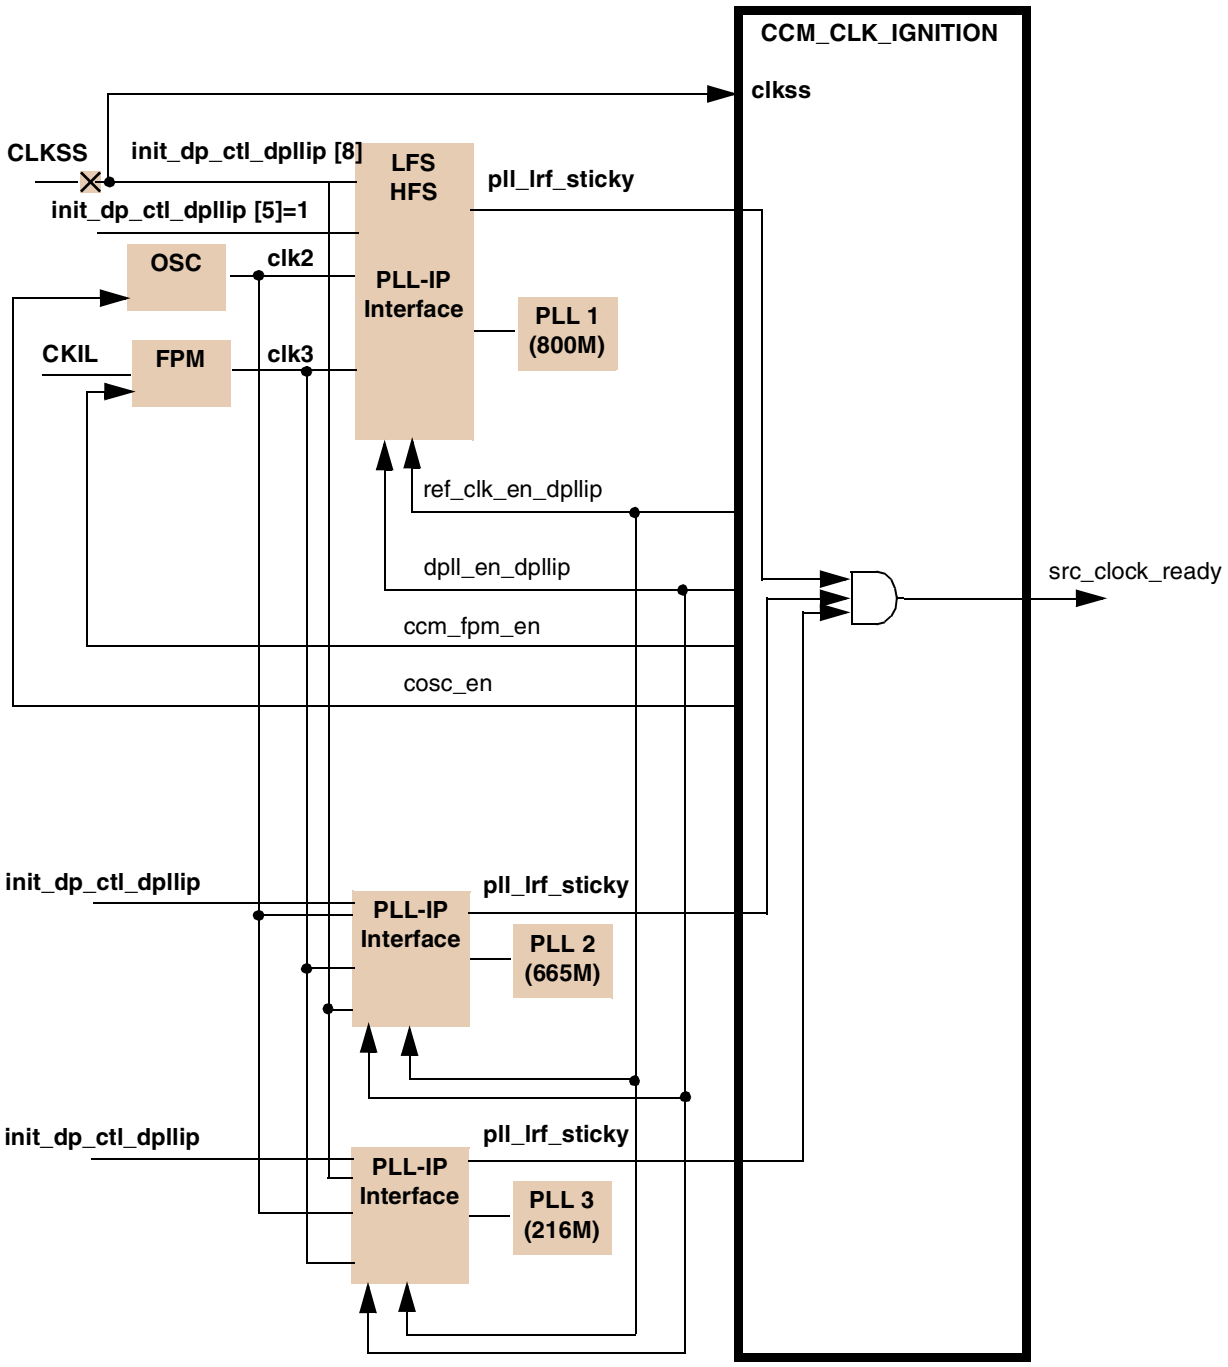

Figure 7-38. CCM Clock Ignition Connectivity

CLKSS is entering the three PLL_IP's to select upon reset which of the two clock sources to be used as reference clock for the PLL's. CLKSS is entering the init_dp_ctl_dpllip[8], while init_dp_ctl_dpllip[9] is constantly connected to '1'. This allows DPLL IP to choose between option 10 and 11 for dp_ctl[9,8]. It is not allowed to choose options 00 and 01 for dp_ctl[9,8], that is, it is not allowed to set dp_ctl[9] to '0'.

CLKSS is also entering the ccm_clk_ignition to notify which of the two sources (FPM or on-chip oscillator) is chosen as PLL source.

If FPM is chosen, fpm_en signal is asserted to start FPM. Next, ccm_clk_ignition should wait until FPM notifies by fpm_ready signal that its clock output is ready. In this stage CCM will assert the fpm_ready bit.

If the on-chip board is chosen, cosc_en signal will be asserted and cosc_pwrdown will remain deasserted to start the on-chip oscillator. Next ccm_clk_ignition will count the default number of CKIL defined in oscnt bits. Once the counter has elapsed, it is assumed that the clock output of on-chip oscillator is ready. In this stage CCM will assert the cosc_ready bit.

In both of the above cases, no matter what clkss chooses, the external oscillator and CAMPs will be enabled during ignition process: CAMP1_en=1, CAMP2_en=1 and ref_en_b=0 so that ckih_CAMP1 and ckih2_CAMP2 clocks will be started. Next, ccm_clk_ignition will count the default number of CKIL defined in oscnt bits. Once the counter has elapsed, it is assumed that the clock output of the CAMPs is ready. In this stage CCM will assert the CAMP1_ready and CAMP2_ready bit.

In case clkss defines on using the on-chip oscillator, then both oscnt counts for on-chip oscillator and external oscillator will be performed parallel, so that elapse of the count will notify that both oscillators are ready. This is done to save time during ignition process. If FPM is chosen, then both procedures of enabling FPM and counting oscnt value for the on-chip oscillator will start simultaneously.

Next, ccm_clk_ignition should assert ref_clk_en_dpllip so that reference clock to PLLs should be enabled.

Next, ccm_clk_ignition should assert dpll_en_dpllip so that dpllip_cpen will be generated by the DPLL-IP to the corresponding DPLL.

Note: For this, initial value of UPEN should be asserted 1, that is init_dp_ctl_dpllip[5] for all PLLs should be connected to 1.

Once the PLLs are locked, dpll_ip's will generate pll_lrf_sticky signal to ccm_clk_ignition.

Upon assertion of all three pll_lrf_sticky signals, ccm_clk_ignition will generate src_clock_ready signal for reset controller to indicate that PLL clocks are ready.

If pll_bypass_en is asserted, then src_clock_ready signal will be asserted as soon as exiting reset.

Upon arrival of src_clock_ready signal to reset controller, the reset sequence will continue. Please review SRC spec for details on this sequence.

7.4.6.6 Reset Values for DPLL-IP

Reset values that are hard coded to dpll-ip initialization values are as follows:

- PLL1—initial value = 262.144 MHz
- PLL2—initial value = 262.144 MHz
- PLL3—initial value = 229.376 MHz

These frequencies correspond to the reference clock source of CKIL (32 kHz), which generates a DPLL reference clock of 32.768 MHz (after multiplication of FPM by 1024).

These frequencies will be lower if the on-chip oscillator (24 MHz) is chosen as the source of DPLL. In that case the default frequencies generated are:

- PLL1—initial value = 208 MHz
- PLL2—initial value = 208 MHz
- PLL3—initial value = 182 MHz

7.4.6.7 CCM_CLK_ROOT_GEN

CCM_CLK_ROOT_GEN sub module generates the root clocks to be delivered to LPCG.

The following is a list of the root clocks generated by this module. The clocks are asynchronous unless otherwise stated.

- ARM_CLK_ROOT —generated from pll1_sw_clk.
- EMI_SLOW_CLK_ROOT
- eNFC_CLK_ROOT—generated by division of EMI_SLOW_CLK_ROOT and balanced with it.
- VPU_RCLK_ROOT
- AHB_CLK_ROOT
- IPG_CLK_ROOT—generated by division of AHB_CLK_ROOT and balanced with it.
- PERCLK_ROOT—this clock is synchronized and balanced to AHB_CLK_ROOT. For the synchronization process, perclk predivider and podf should generate clock 2.5 times lower than ahb clock. In peripheral DVFS scenario, when ahb is reduced, perclk should be configured to be lower 2.5 times the minimum value of ahb_clk (the DVFS value of ahb_clk).
- DDR_CLK_ROOT
- ARM_AXI_CLK_ROOT
- IPU_HSP_CLK_ROOT
- CKIL_SYNC_CLK_ROOT—CKIL clock synchronized to IPG_CLK_ROOT and balanced with it, when not in STOP mode. Synchronizer is bypassed, when in STOP mode.
- USBOH3_CLK_ROOT
- ESDHC1_MSPRO1_CLK_ROOT
- ESDHC2_CLK_ROOT
- ESDHC3_CLK_ROOT
- UART_CLK_ROOT
- SSI1_CLK_ROOT
- SSI2_CLK_ROOT
- SSI_EXT1_CLK—connected to external BGA contact
- SSI_EXT2_CLK—connected to external BGA contact
- USB_PHY_CLK_ROOT
- TVE_216_54_CLK_ROOT
- DI_CLK_ROOT
- SPDIF0_CLK_ROOT

- SPDIF1_CLK_ROOT
- CSPI_CLK_ROOT
- WRCK_CLK_ROOT
- LPSR_CLK_ROOT
- PGC_CLK_ROOT—generated as division of ipg_clk and balanced to it.

7.4.6.7.1 Special Considerations for Configuring PERCLK

In addition to ensuring that PERCLK remains at least 2.5 times slower than the AHB clock, certain steps need to be followed to ensure robust operation of PERCLK when reconfiguring the PERCLK clock source.

To properly configure the PERCLK clock source, the following steps are required:

1. In the CCGR registers, gate the clocks to all PERCLK-dependent modules (see Table 7-41 for a list of PERCLK-dependent modules).
2. Select the desired input clock for the PERCLK root clock (to be either source from the peripherals main source clock or the lp_apm clock source). Refer to the CMCBR register, perclk_lp_apm_sel bit.
3. Configure the perclk_pred1, perclk_pred2, and perclk_podf dividers to the desired setting. Refer to the CBCDR register for details.
4. In the CCGR registers, enable the desired clocks for the PERCLK-dependent module clocks.

Table 7-41 lists the PERCLK-dependent module clocks and the associated CCGR register.

NOTE

When configuring the PERCLK clock source, these clocks must be gated, however, other unused clock source may also be gated to minimize power consumption.

Table 7-41. PERCLK-dependent Module Clock Sources

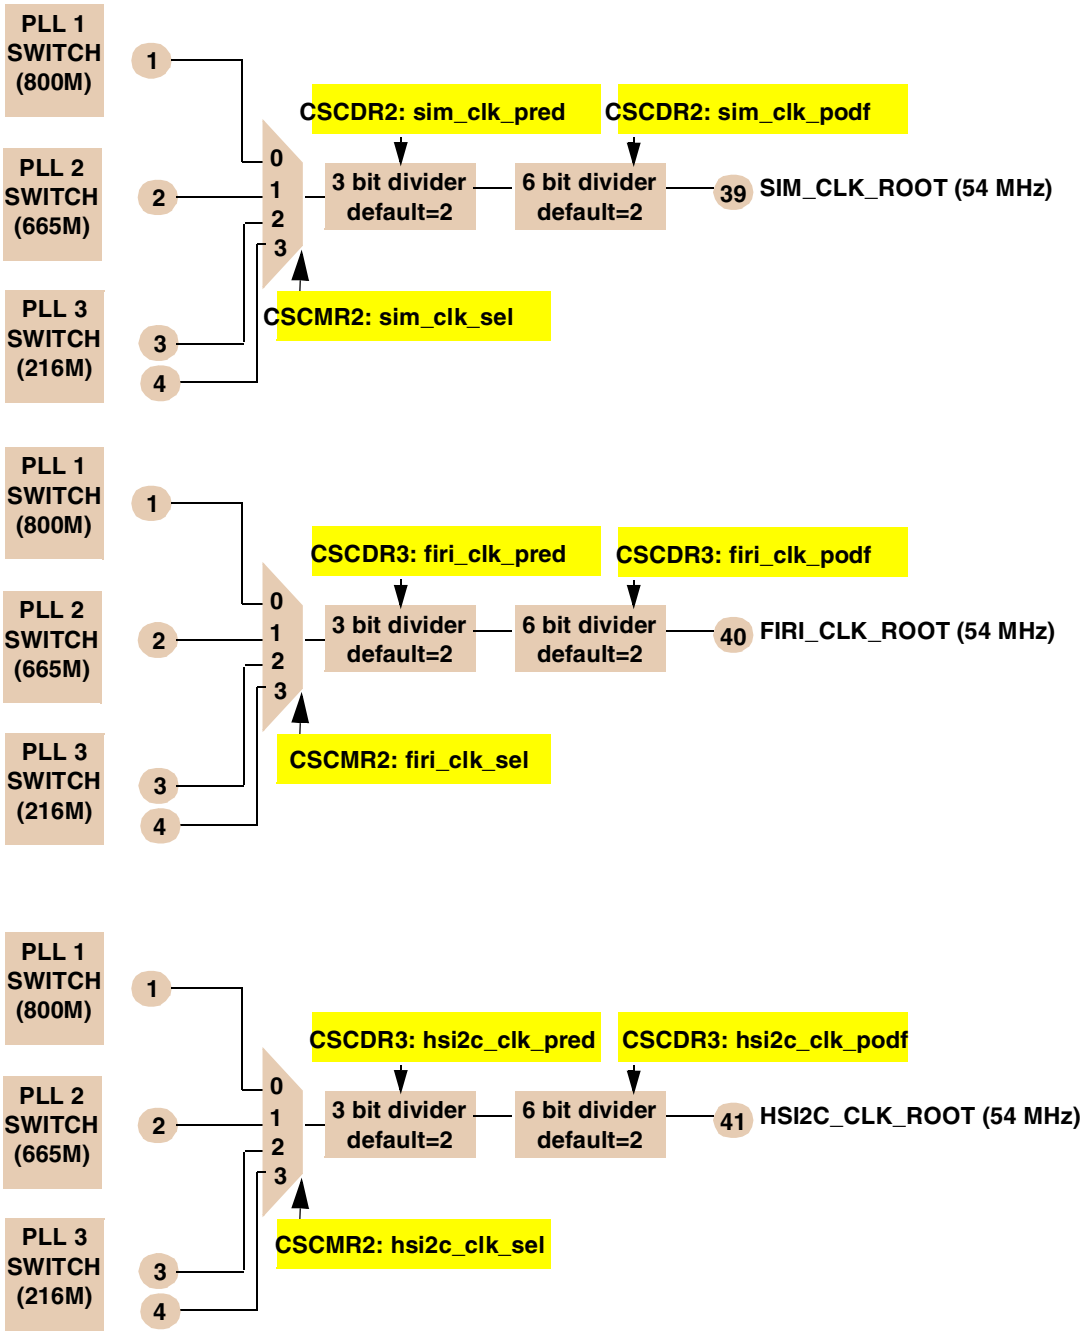

Figure 7-46. Serial Clock Generation (5 of 7)

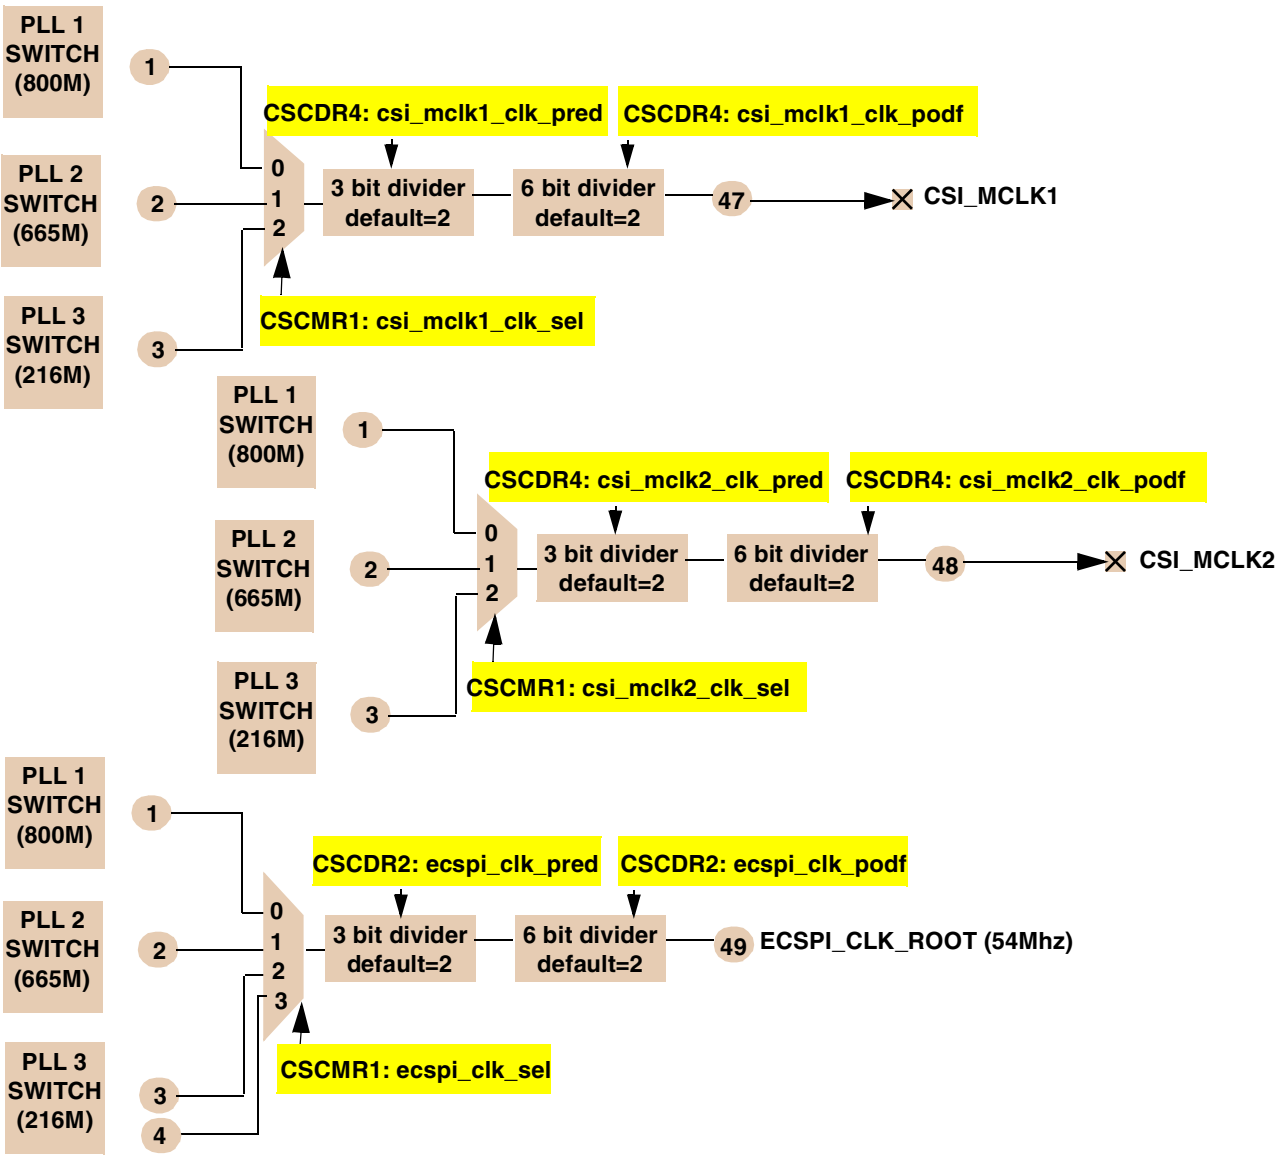

Figure 7-47. Serial Clock Generation (6 of 7)

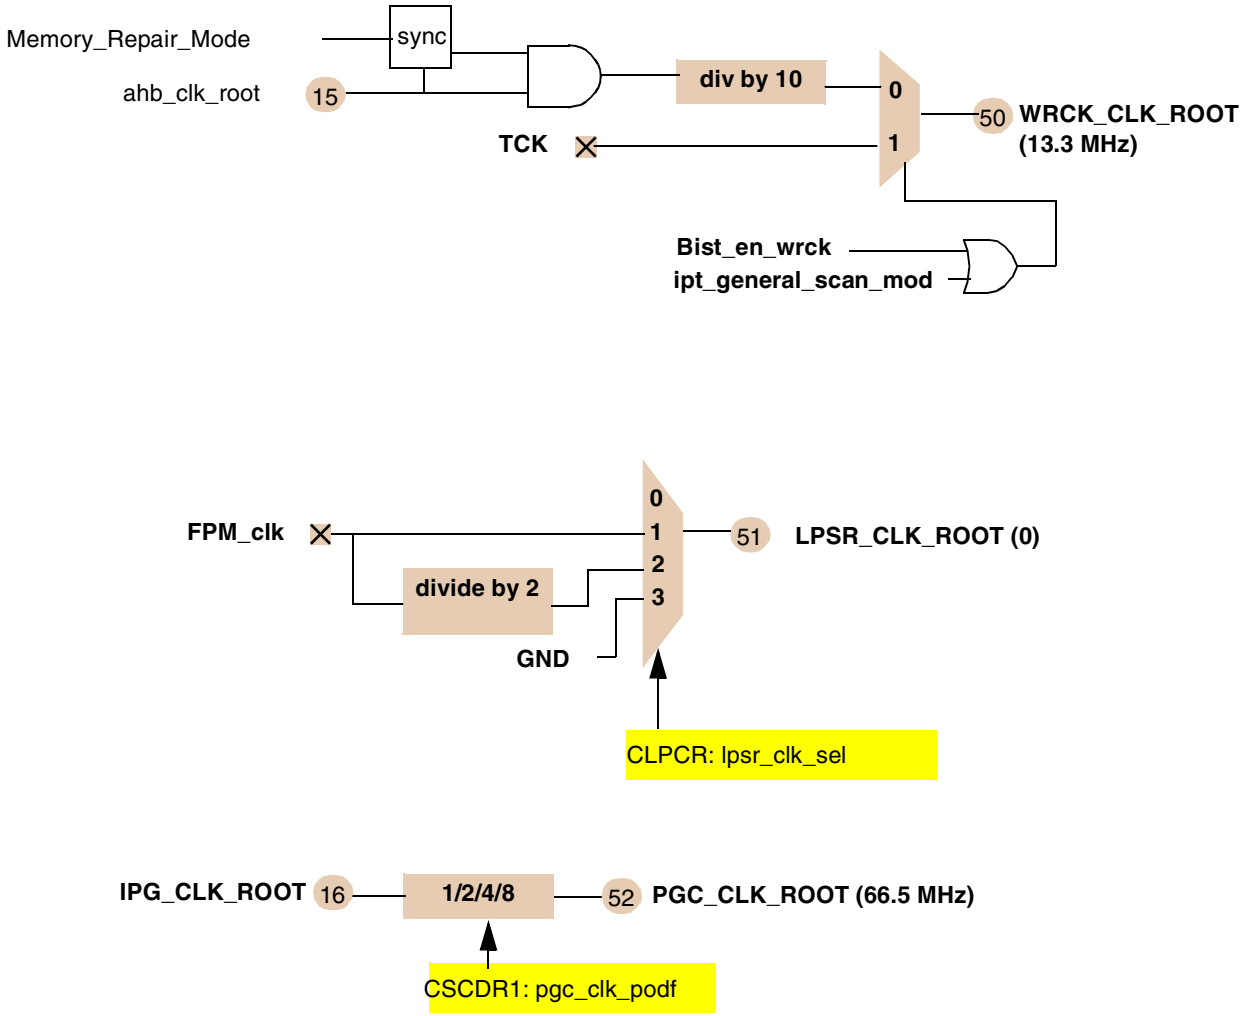

Figure 7-48. Serial Clock Generation (7 of 7)

NOTE

All 6-bit podf dividers in the previous figures are able to work on frequencies lower than the clock speeds defined in the i.MX51 datasheet. It is not allowed to insert the 6-bit divider a frequency higher than this frequency.

The following predividers should use divider values larger than ‘1’. The option ‘000’ is not allowed for them: usboh3_clk_pred, ssi1_clk_pred, ssi2_clk_pred, ssi_ext1_clk_pred, ssi_ext2_clk_pred, cspi_clk_pred.

7.4.6.7.2 Initial Values Controlled by SJC

The initial values of the following dividers and muxes can be controlled by SJC. In regular functional mode, the SJC will drive the reset values stated in the CCM register memory map. If SJC is progarmmed to change those values, then the reset value for those dividers/muxes will be taken from the SJC

programability. Software can update the changed reset value after reset sequence. The control signals and the dividers/muxes are listed below:

- init_perclk_pred1[1:0] to control reset value of perclk_pred1.
- init_perclk_pred2[2:0] to control reset value of perclk_pred2.
- init_perclk_podf[2:0] to control reset value of perclk_podf.
- init_ipg_podf[1:0] to control reset value of ipg_podf.
- init_ahb_podf[2:0] to control reset value of ahb_podf.
- init_axi_a_podf[2:0] to control reset value of axi_a_podf.
- init_axi_b_podf[2:0] to control reset value of axi_b_podf.
- init_emi_slow_podf[2:0] to control reset value of emi_slow_podf.
- init_nfc_podf[2:0] to control reset value of nfc_podf.
- init_periph_apm_sel[1:0] to control reset value of periph_apm_sel.
- init_periph_clk_sel to control reset value of periph_clk_sel.
- init_ssi_apm_clk_sel[1:0] to control reset value of ssi_apm_clk_sel.

7.4.6.7.3 Divider Change Handshake

Table 7-42 describes the dividers that may involve module handshake on every divider update. These handshakes should be bypassed if the respective module is disabled.

Table 7-42. i.MX51 Divider Handshake Summary

Divider	Handshake with module	Comment
emi_slow_podf	EMI IPU	Handshake with IPU will exist if emi_slow_podf is chosen as source to ipu_hsp_clk. Handshake with EMI will be through emi_DVFS_req_slow, emi_DVFS_req_int1,emi_DVFS_req_int2, emi_DVFS_ack_slow, emi_DVFS_ack_int1, emi_DVFS_ack_int2. If emi_slow_podf is chosen as source of gpu_clk, that is, the change of emi_slow_podf will affect gpu_clk then the handshake of emi_DVFS_req_garb, emi_DVFS_ack_garb should also commence. If this divider is chosen as source of ddr_clk,then the handshake of emi_DVFS_req_fast, emi_DVFS_ack_fast should also commence.
nfc_podf	EMI	Handshake with EMI will be through emi_DVFS_req_slow, emi_DVFS_ack_slow.
axi_a_podf	EMI IPU	Handshake with EMI will exist only if axi_a_podf is chosen as source to ddr_clk. In this case handshake with EMI will be through emi_DVFS_req_fast, emi_DVFS_ack_fast. If axi_a_podf is chosen as source of gpu_clk, that is, the change of axi_a_podf will affect gpu_clk then the handshake of emi_DVFS_req_garb, emi_DVFS_ack_garb should also commence.Handshake with IPU will exist only if axi_a_podf is chosen as source to ipu_hsp_clk.

Table 7-42. i.MX51 Divider Handshake Summary (continued)

Divider	Handshake with module	Comment
axi_b_podf	EMI IPU	Handshake with EMI will exist only if axi_b_podf is chosen as source to ddr_clk. In this case handshake with EMI will be through emi_DVFS_req_fast, emi_DVFS_ack_fast. If axi_b_podf is chosen as source of gpu_clk, that is, the change of axi_b_podf will affect gpu_clk then the handshake of emi_DVFS_req_garb, emi_DVFS_ack_garb should also commence. Handshake with IPU will exist if axi_b_podf is chosen as source to ipu_hsp_clk.
ahb_podf	EMI IPU	Handshake with EMI will exist only if ahb_podf is chosen as source to ddr_clk. In this case handshake with EMI will be through emi_DVFS_req_fast, emi_DVFS_ack_fast. If ahb_podf is chosen as source of emi_slow_clk generation, then similar handshake to the emi_slow_podf should take place. If ahb_podf is chosen as source of gpu_clk, that is, the change of ahb_podf will affect gpu_clk then the handshake of emi_DVFS_req_garb, emi_DVFS_ack_garb should also commence. Handshake with IPU will exist only if ahb_podf is chosen as source to ipu_hsp_clk.
ddr_clk_podf	EMI	Handshake is needed only if EMI's DDR (fast) clock is derived from this divider.
ddr_high_freq_clk_sel	EMI	Handshake of emi_DVFS_req_fast, emi_DVFS_ack_fast is needed.

Any update of CBCDR might involve handshake with modules based on the above table.

Once the CBCDR register is updated, CCM will check which of the above dividers was updated. For the updated dividers, CCM will check if a handshake with the respective modules is needed. If the handshake is needed, CCM will request acknowledge from the respective module for frequency change. Once the acknowledge arrives, CCM will perform the actual frequency change, and will notify the module that the frequency has changed by de asserting the request. IPU handshake also involves signal to notify it on the frequency change. This signal (periph_DVFS_sw_ack) is held for two clock cycles of ipg_clk on each change.

The handshake with the respective module will not be performed in case that the respective handshake is masked through CCDR[bits18–16]. In this case the write to the respective divider will commence immediately after the CBCDR register is updated.

Software has to make sure that the respective module is on and has the ability to acknowledge a request from the CCM. If the respective module is disabled or its clocks are gated off, then it will not have ability to support the handshake process and software should mask its handshake capability (through CCDR[bits18–16]).

Interrupts can be generated for each of the above dividers change. Please refer to CISR register for details on those interrupts.

In addition, CCM has divider handshake in process register (CDHIPR). This register has status bits for each of the above dividers that are involved in the handshake process. When the respective bit is asserted, it means that the respective dividers is being updated, and software should not attempt to write to this

divider until the respective bit is deasserted. Any reads of the respective divider during the time that the CDHIPR respective bit is asserted, will read the next value to be loaded to the divider, and not the actual dividers value. To make sure that software reads the actual dividers value, it should wait until the CDHIPR bits are desasserted.

All selections of muxes that are not glitchless should be updated only when there are no modules using their clocks, or the modules which use those clocks are disabled and their clocks are gated off.

Changing the periph_clk_sel bits in CBCDR will involve handshake with EMI and IPU - a similar handshake to the one that is performed in load dividers for EMI and IPU dividers. Those handshakes will be masked if configured to be masked in CCDR register".

Changing the ddr_high_freq_clk_sel bits in CBCDR will involve handshake with EMI - a similar handshake to the one that is performed in load dividers for EMI ddr. This handshake will be masked if configured to be masked in CCDR register.

Changing the emi_clk_sel bits in CBCDR will involve handshake with EMI and IPU - a similar handshake to the one that is performed in load dividers for EMI and IPU dividers. The IPU handshake will be performed only if IPU_HSP clock uses the emi_core_clk_root.

NOTE

In case DVFS is enabled (through GPC), it is not allowed to do any frequency changes, that is, the frequency of the system should be set prior to DVFS enable, and once the DVFS scenario is enabled, no divider of the above handshake group dividers should be changed "manually" by software since this might corrupt the handshake process.

7.4.6.7.4 CKIL Synchronizing to ipg_clk

CKIL is synchronized to ipg_clk when system is in functional mode. When system is in STOP mode, that is, when there is no ipg_clk, the CKIL synchronizer will be bypassed, and raw CKIL will be supplied to the system.

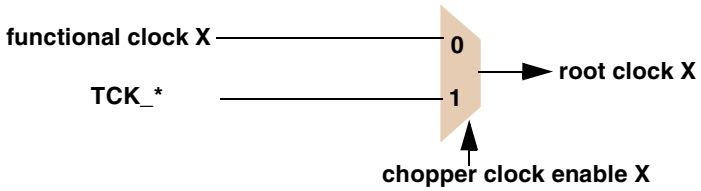

Figure 7-49. Chopper Control on Root Clocks

7.4.6.8 PLL Disabling/Enabling

PLL disabling and enabling is done via DPLL-IP module. Software should first move all the clocks generated from a specific PLL to another PLL, before disabling the PLL through DPLL-IP. This move of clocks can be done via glitch less mux for clocks which are critical to the system, that is, bus clocks. For

serial clocks, software should first disable the module and the clock generated to it, then move the mux controlling the source of the clocks to another PLL, and start back the module and its clocks. Only then it is safe to disable the PLL. The mux for the serial clocks is not glitch less hence the above procedure should be followed.

7.4.6.9 Observability Output signals

CCM has three muxes that generate critical signals to the IO PADS for observability. The three MUX outputs are connected to the three CCM outputs named obs_output_0, obs_output_1, obs_output_2. The three muxes are controlled via CTOR register of CCM.

It is possible to generate also the obs_input_0, obs_input_1, obs_input_2, obs_input_3, obs_input_4 and obs_input_5 to the external pads through the muxes controlled by CTOR. This allows to observe the signals connected to those 6 CCM input pins. Below list describes the signals connected for observability to those input pins:

- obs_input_0 connect to DPLLIP1 : dpllip_cpen
- obs_input_1 connect to DPLLIP1 : dpllip_cpres
- obs_input_2 connect to DPLLIP1 : dpllip_crstrt
- obs_input_3 connect to DPLLIP1 : dpllip_load_req
- obs_input_4 connect to DPLLIP2 : dpllip_cpen
- obs_input_5 connect to DPLLIP3 : dpllip_cpen

7.4.6.10 Low-Power Clock Gating (LPCG) Module

The LPCG module receives the root clocks and splits them to clock branches for each module. The clock branches are gated clocks. The enables for those gates can come from the following five sources:

- Clock enable signal from CCM—This signal is generated by configuration of the cgr bits in CCM. It is based on the low power mode.
- Clock enable signal from the module—This signal is generated by the module based on internal logic of the module. For clock enable signals from the module, that are used, CCM will generate override signal based on programable bit in CCM (CMEOR).
- Clock enable signal from Reset controller (SRC)—This signal will enable the clock during the reset procedure. Please refer to SRC chapter for details on the clock enable signal during reset procedure.
- Hard coded enable from fuse box.
- Enable or disable clock in BIST mode, based on bist_en signal. This will be applicable for clocks that are not functional and needed only on memory repair or bist sequence (like sms_clk’s and wrck).

The possible enable signals listed above are ANDed to generate the enable signal for the gating cell.

The enable signal for the gating cell is synchronized with the clock it needs to gate. This is done in order to prevent glitches on the gated clock.

Notifications are generated for the CCM, to indicate when to close and to open the clock roots. All notifications that correspond to the same clock root will be ORed to generate one notification signal to ccm for clock root gating.

Figure 7-50 describes the implementation for each gating cell:

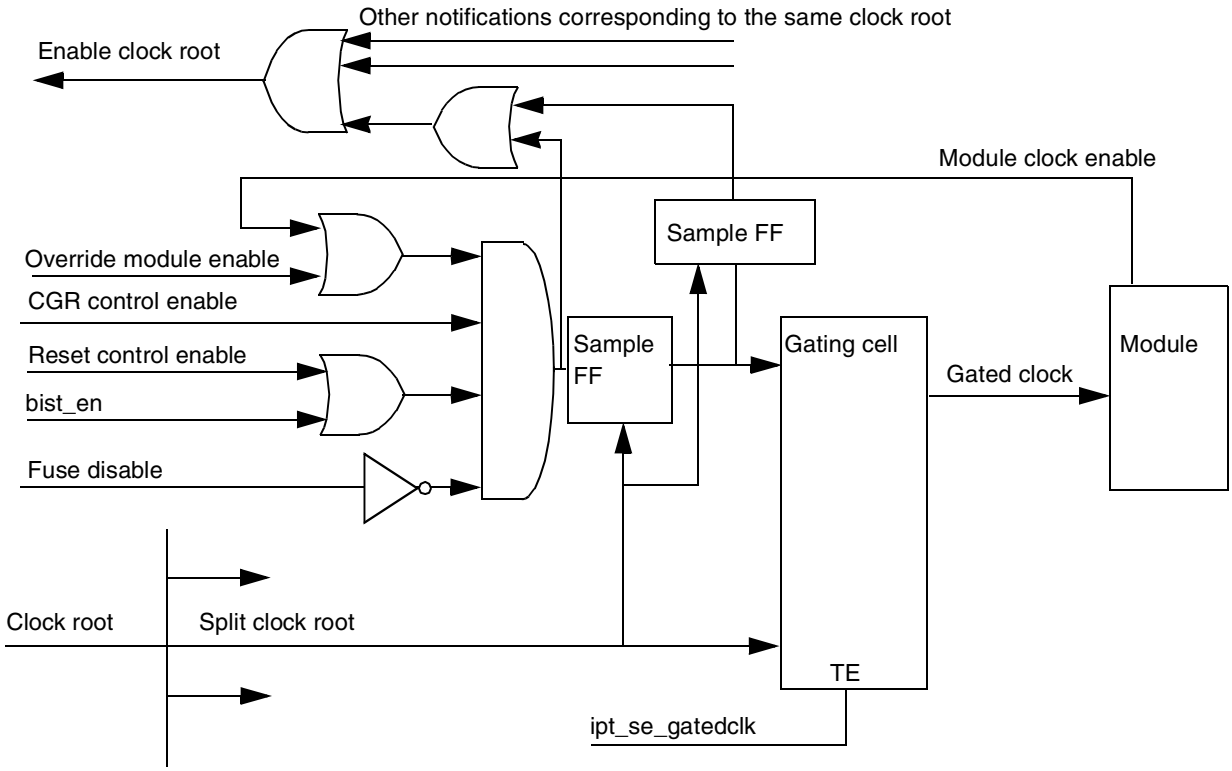

Figure 7-50. Gating Cell Implementation

Figure 7-51 describes the clock split inside LPCG module. It describes the case of two modules, one module without enable signal and one with enable signal. (SRC enable signals and sync FFs are omitted from this figure).

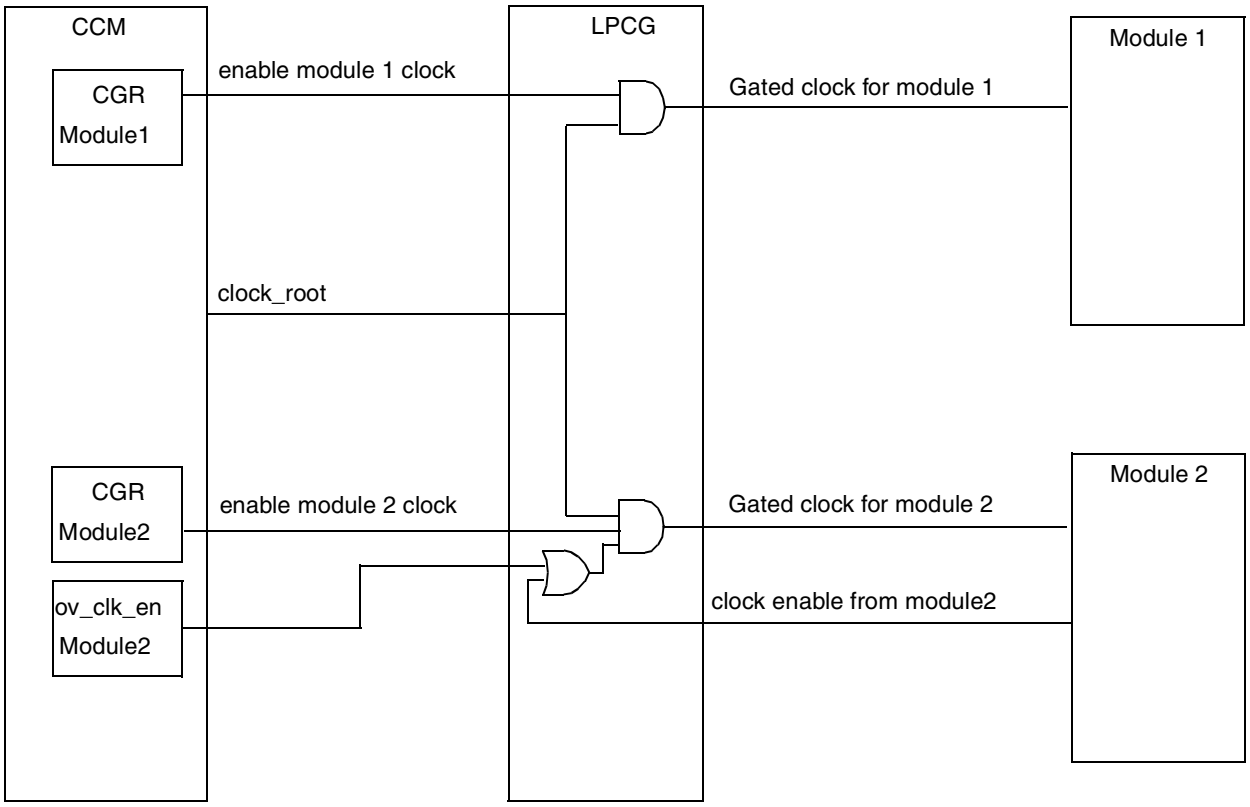

Figure 7-51. Clock Split in LPCG

7.4.7 DVFS Support

Frequency shift during DVFS procedure in the i.MX51 can be done on the following two domains:

- ARM clock domain frequency shift.
- Peripherals clock domain frequency shift (including buses).

The initiator of the frequency shift procedure is the GPC (Global Power Controller) module. It will initiate only one frequency shift at a time. There is no option to commence both of the above frequency shifts simultaneously. GPC will be aided by sdma and ccm to execute the frequency shift.

The next paragraphs explain the details of the above two frequency shift options.

7.4.7.1 ARM Clock Domain Frequency Shift

SDMA can request ARM frequency shift by using ARM clock divider or by relock of PLL1

The following steps will be configured by SDMA, (this can also be performed by ARM, but to be able to reduce load of ARM processing, it is preferable to perform it by SDMA):

1. SDMA can request ARM frequency shift by dividers, or by PLL1 relock. This request is written to CCM's arm_freq_shift_divider bit:
   - arm_freq_shift_divider = 0: PLL1 relock shift is requested.
   - arm_freq_shift_divider = 1: ARM_PODF divider shift is requested. In this case any new writes to ARM_PODF will be held until arm_clk_switch_req signal is asserted by GPC. This signal indicates that voltage is stable. The CCM holds a status bit to notify that the arm_podf divider is being in process of writing, and software should wait until the write finishes before writing any new value to arm_podf. Refer to CDHIPR register for details on the status bit. CCM can also generate interrupt once the actual arm_podf has been taken into effect in DVFS scenario. Please refer to CISR register for details.
2. Configure new ARM domain dividers (if arm_freq_shift_divider = 1: ARM_PODF divider shift is requested)

SDMA continues with the next steps only if (arm_freq_shift_divider = 0: PLL1 relock shift is requested).

3. Check which frequency mode is active in DPLLIP1, HFS or LFS: DPLLIP bit HFSM of DP_CTL register.
4. Configure the non active frequency mode (HFS or LFS) of DPLLIP1, with the new frequency needed for PLL1 to relock on: DPLLIP1 registers DP_OP, DP_MFD, DP_MFN, DP_HFS_OP, DP_HFS_MFD, DP_HFS_MFN.
5. Configure the step frequency divider: CCM CCSR register, bit pll2_div_podf or pll3_div_podf bits (depending on the decision in the step mux in step 6).
6. Configure the step frequency mux: CCM bit step_sel of CCM_CNT register.

Once those configurations are done, SDMA notifies GPC to continue with the frequency shift procedure.

The actual shift starts by assertion of arm_clk_switch_req signal from GPC to CCM.

CCM commences the following steps upon assertion of arm_clk_switch_req signal: These are hardware steps and do not require software involvement.

- If arm_freq_shift_divider = 1 dividers shift is requested):
  a) Load the ARM domain new dividers.
  b) After actual reloading of the dividers (all counters in 0), assert clk_switch_ack for 2 ipg cycles. This is done so GPC will have indication that frequency has been updated.
- If arm_freq_shift_divider = 0 (PLL1 relock shift is requested):
  a) Switch to the step frequency by a glitch less mux.
  b) After the glitchless mux has changed to the step frequency, invert pll_lvs signal to DPLLIP1 so that PLL1 will lock on the new frequency.
  c) On pll_lrf_sticky1 assertion move back to PLL1 that is locked on the new reloaded frequency by the glitch less mux.
  d) After actual shift of the mux assert clk_switch_ack for 2 ipg cycle. This is done so GPC will have indication that frequency has been updated.

Upon clk_switch_ack assertion, GPC deasserts arm_clk_switch_req signals.

At this point, ARM has changed frequency and system is ready for a new frequency switch procedure.

See Figure 7-52 for an illustration.

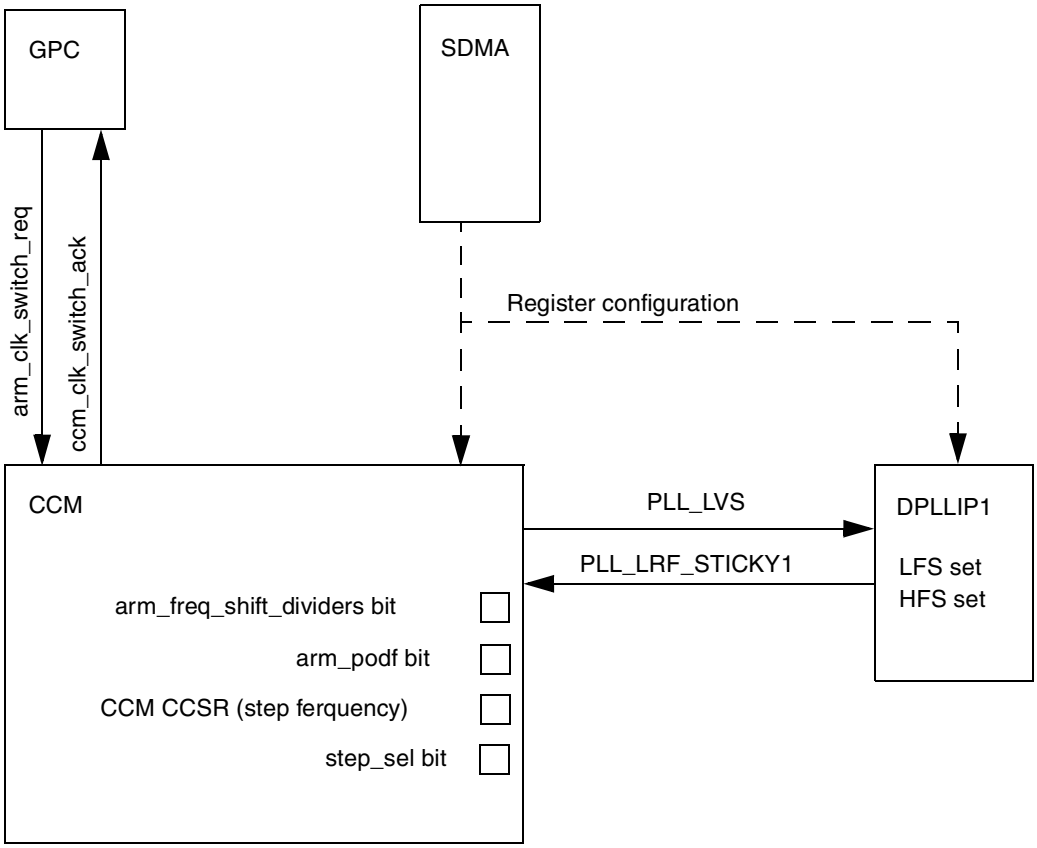

Figure 7-52. ARM DVFS Connectivity

7.4.7.2 Peripheral Clock Domain Frequency Shift

CCM includes capability to divide by 2/3/4 the root of bus clocks (ahb, axi, ipg, int_mem, ddr_clk, nfc_clk). The actual division factor is defined by bits in the ccm memory map, register CDCR [1–0]. The software is expected to set those bits prior to enabling DVFS operation. The value written to the DVFS register divider (CDCR[0–1]) will not be loaded immediately to the actual divider, but will wait until peripheral DVFS procedure will commence.

During DVFS scenario, the root clocks which are not affected by DVFS divider should be generated from a low frequency PLL. This frequency should not be higher than 240Mhz since the operating voltage is lowered in DVFS mode. Software can use the PLL3 with frequency 216Mhz for this operation. The setting for the serial clocks is done through CSCMR1 register.

The modules that their clock is about to change (IPU,EMI, and so on.) may need to be configured with values that determine the frequency of the new clock prior to the clock switch operation. Please refer to the respective module’s specification for clarification on the needed configuration.

Divide by 2/3/4 procedure (lowering frequency):

Upon assertion of periph_clk_div_req signal from GPC to CCM, the actual division procedure will take place. The periph_clk_div_req signal from GPC will remain asserted as long GPC requests a division of the peripheral clocks. This signal will be deasserted only when GPC requests to multiply the frequency and go back to the division by '1'.

Note: the DVFS operation can start also by software control using the sw_periph_clk_div_req. In that case the GPC control will be ignored and the ccm_clk_switch_ack will not be asserted.

There is no need to synchronize the three dividers change since they work on async clock domains.

Prior to the actual division there is need for acknowledge from peripherals that are sensitive to the frequency change. The modules sensitive to the frequency change are IPU and EMI. Those handshakes are described below:

- IPU handshake
  a) CCM asserts IPU_freq_change_req to request approval from IPU to commence the frequency shift.
  b) IPU asserts IPU_freq_change_ack to notify the time window that its ok from IPU point of view to change the frequency.

     Note that IPU does not support DVFS operation of division by 3.
- EMI handshake
  a) CCM asserts EMI_freq_change_req to request approval from EMI to commence the frequency shift.
  b) EMI asserts EMI_freq_change_ack to notify the time window that its ok from EMI point of view to change the frequency.

NOTE

Handshakes that are bypassed are not performed.

  c) CCM commences the actual division once all of the acknowledges (IPU_freq_change_ack, EMI_freq_change_ack) are asserted.
  d) After completing the division, CCM will notify the GPC by assertion of ccm_clk_switch_ack for 2 ipg cycles (rising on ipg_clk) and notify IPU by assertion of ipu_clk_changed for at least 2 hsp clock cycles (rising on the edge of the new hsp clock). CCM will also negate the IPU_freq_change_req and EMI_freq_change_req.

Multiply by 2/3/4 procedure (raising frequency): Upon negation of periph_clk_div_req signal from GPC to CCM, the actual multiplication procedure will take place by removing the division by 2/3/4 and returning to division by '1'.

Note: the DVFS operation can be stopped also by software control using the sw_periph_clk_div_req. In that case the GPC control will be ignored and the ccm_clk_switch_ack will not be asserted.

There is no need to synchronize the 3 dividers change since they work on async clock domains.

Prior to the actual frequency change there is need for acknowledge from peripherals that are sensitive to the frequency change. Those handshakes are described below:

- IPU Handshake
  a) CCM asserts IPU_freq_change_req.
  b) IPU asserts IPU_freq_change_ack to notify the time window if it is acceptable from the viewpoint of the IPU to change the frequency.
- EMI handshake
  a) CCM asserts EMI_freq_change_req.
  b) EMI asserts EMI_freq_change_ack to notify the time window that its ok from EMI point of view to change the frequency.

CCM performs the actual multiplication once both of the acknowledges are asserted.

After completing the frequency change, CCM notifies GPC by assertion of ccm_clk_switch_ack for 2 ipg cycles and notifies IPU by assertion of ipu_clk_changed for at least 2 hsp clock cycles. CCM also negates the IPU_freq_change_req and EMI_freq_change_req.

The following figure describes the connectivity.

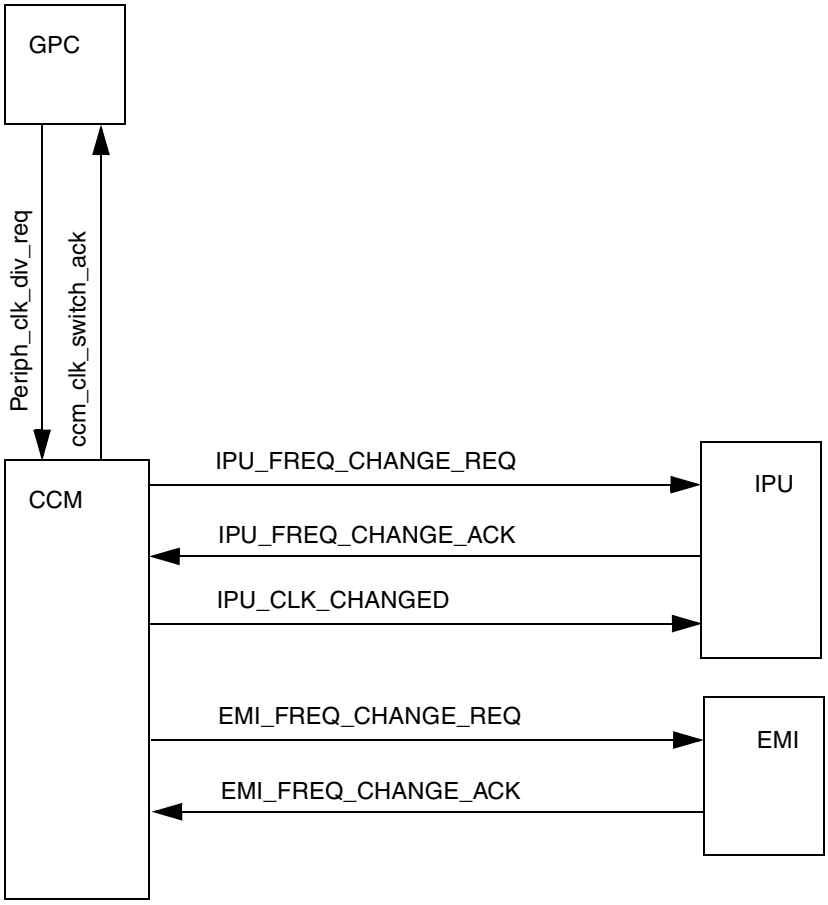

Figure 7-53. Peripheral DVFS Connectivity

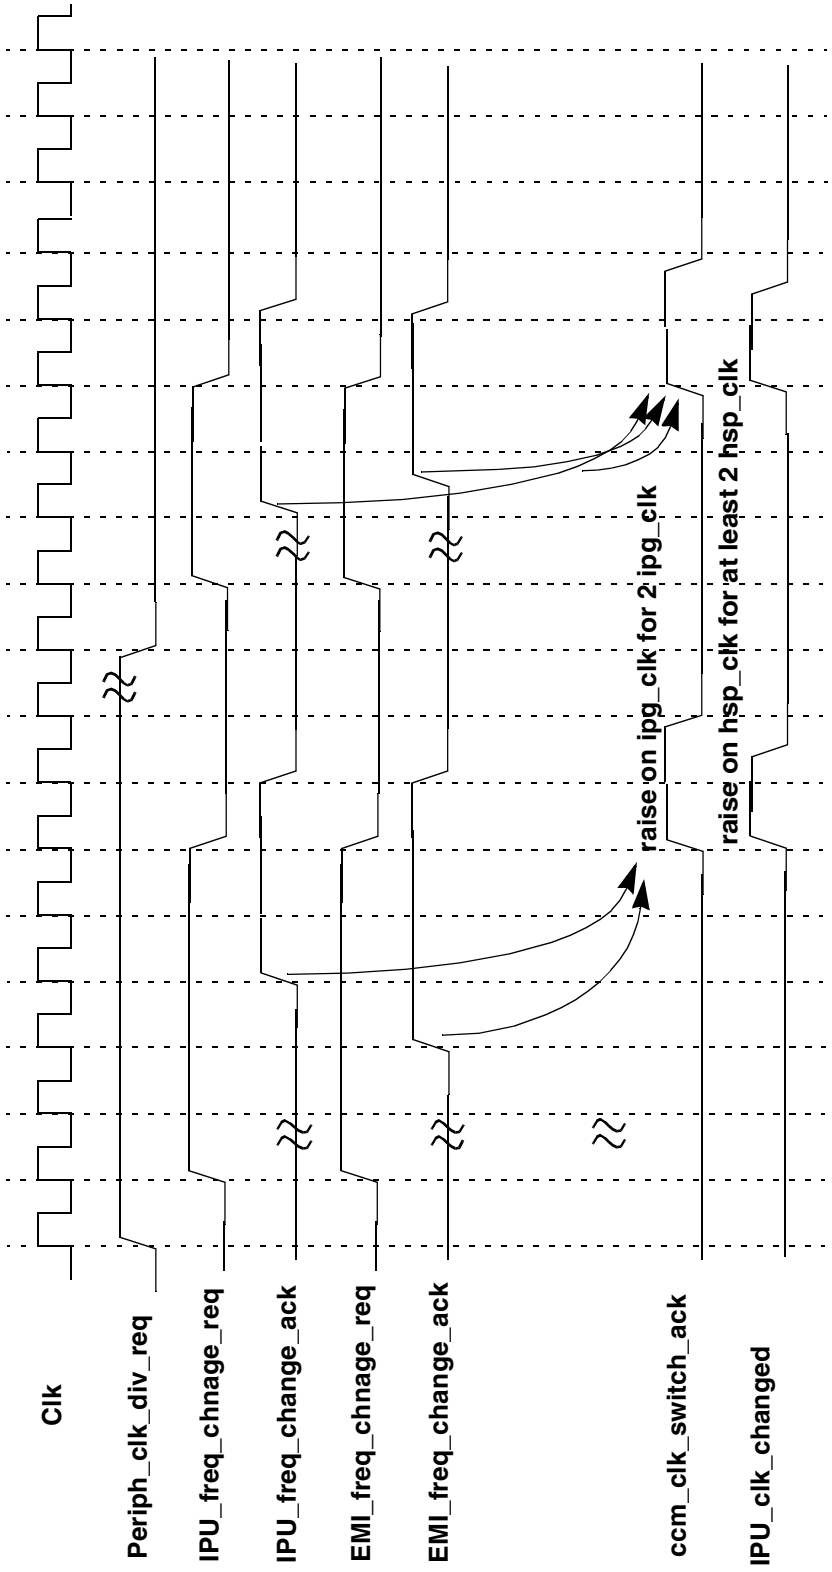

Figure 7-54. Peripheral DVFS Signals

7.4.7.3 Peripherals Restrictions in DVFS Scenario

On DVFS scenario for peripherals, IPG and AHB clocks are divided from their nominal frequency. The serial dividers in the low voltage case, should use a low frequency PLL input (below 300 Mhz) to work correctly.

Table 7-43 describes restrictions that need to be followed to support the DVFS frequency shift:

Table 7-43. DVFS Restrictions

Module	Support	Restriction
UART	R[1]	Need to configure uart rate to be lowest ipg clock frequency/16. Hence rates of 1.875M and 4M cannot be reached in DVFS scenario.
ESDHC	R	Need to configure card rate to be low_frequency_ahb_clk/2. Hence rate of 52 Mhz for SD card cannot be reached in the DVFS scenario.
MSHC	R	Need to configure card rate to be low_ipg_clk. Hence rated of 40M for card cannot be reach in DVFS scenario.
SSI	R	Master clock should be generated from ssi_ext1 and ssi_ext2 pads.
CSPI	R	Need to configure spi rate to be low ipg clk.
DDR memory	R	To be able to reach 200 Mhz on DDR, the clock can be generated from PLL1 that also supplies clock to ARM. In that case, PLL1 will have to be programmed to a multiplication of 200Mhz (200, 400, 600, 800) and the ARM DVFS should be enabled from divider change only and not from PLL change. If 166 Mhz is accepted for DDR memory, then the DDR clock should be generated from PLL2 (665 Mhz), and in that case ARM DVFS may be enabled.
USB, USB_PHY	N[2]	Needs ipg_clk>60 Mhz. Hence will not work under DVFS scenario
FEC	N	Needs ipg_clk>50 Mhz. Hence will not work under DVFS scenario
TVE	N	Is not synthesized for frequency operation
SPDIF	N	Is not synthesized for frequency operation y
P-ATA	N	Needs ipg_clk to be fixed. In case ARM core manages DVFS scenario, it can work only in times ipg_clk is fixed, that is, before and after DVFS scenario.

1 R= modules that will work with restriction

2 N = modules that will not work and need to be gated off if DVFS is used”

7.4.8 Power Modes

The i.MX51 supports four low-power modes: RUN mode, WAIT mode, STOP mode, LPSR (low power screen refresh) mode.

7.4.8.1 Run Mode

This is the normal/functional operating mode. In this mode ARM runs in its normal operational mode. The frequency and voltage can be changed upon DVFS scenario as described in Section 7.4.7, DVFS Support.” Clocks to the modules can be gated by configuring the corresponding cgr bits.

7.4.8.2 Wait Mode

In this mode the ARM clock is gated. All other clocks are functional and can be gated by programing their CGR bits. Power gating can be done on ARM platform.

7.4.8.2.1 Wait Mode Procedure

The wait mode procedure is as follows:

1. ARM writes to the LPM bit to set it for WAIT mode.
2. ARM writes to DSM_INT_HOLDOFF bit in TZIC.
3. DSM_INT_HOLDOFF assertion forces the interrupt controller to stop the synchronizer clock for incoming interrupts. Any interrupts that had previously been synchronized by the interrupt controller will remain asserted.
4. If a wakeup event occurred or an interrupt was serviced or is pending, the CPU may abort the DSM sequence by exiting the main shutdown code sequence and returning to the desired security mode.
5. If not, the software should execute the Wait For Interrupt (WFI) instruction.
6. Upon execution, the WFI instruction causes the ARM to drain its write buffers and enter a quiescent state. At this point the ARM asserts the STANDBYWFI signal.
7. The ARM platform then waits until the L2 cache controller has become inactive. Once the L2 is inactive and the CPU's STANDBYWFI output is asserted, the ARM platform asserts the ARM_DSM_REQUEST signal to the CCM.
8. The CCM continuously synchronizes both the ARM_DSM_REQUEST and TZIC_DSM_WAKEUP inputs into the clock domain used by its internal state machine.
9. If TZIC_DSM_WAKEUP is negated and ARM_DSM_REQUEST is asserted, the CCM begins the WAIT shutdown sequence:
10. CCM stops the ARM clock. (soc_mxclk input to ARM will be gated only if the respective CGR defines to gate it in WAIT mode).
11. Stop of ARM clock takes place only if CLPCR[5]=1 and debug_arm_clk_off_on_lpm=0 (connected to sjc register sjc_gpucr3_reg bit 15). If either CLPCR[5]=0 or debug_arm_clk_off_on_lpm=1 then ARM clocks will not be gated off and CCM will continue to next step.
12. CCM generates ccm_ipg_wait to indicate that it started WAIT entrance procedure.
13. CCM requests an acknowledge to close clocks of SAHARA,RTIC, IPU, SDMA, SCC, EMI and AHBMAX if their cgr bits indicate to close their clocks on WAIT mode and if their clocks was not already closed in run mode. The request is issued if the handshake is not bypassed by programing the CLPCR register bits 23–16. If the corresponding bits are set, the request signal is not issued to the corresponding module and CCM does not wait for its acknowledge in the process of entering low power mode. The requests commence via the following signals:
    - SAHARA: sahara_ipg_stop_req
    - RTIC: rtic_ipg_stop_req
    - IPU: ipu_stop_clk_at_wait_req
    - SDMA: sdma_ipg_stop_req

— SCC: scc_ipg_stop_req

— EMI: emi_lpmd, emi_lpmd_fast, emi_lpmd_int1, emi_lpmd_slow, emi_lpmd_garb - these requests will be asserted based on the definition of CCGRs. CCM will perform the appropriate EMI handshake based on the programing of the corresponding CCGR bits.

NOTE

Since EMI needs the aclk_fast (ddr clock) to be running for it to answer with emi_lpmd, then software should make sure to turn on the aclk_fast (ddr_clk) before entering any low power mode that requests the emi_lpmd.

— AHBMAX: ahbmax_halt_req

14. Once the above modules finished their operation and are ready to enter low power mode, they acknowledge CCM that its safe to turn of their clocks. The acknowledge signals are as follows:
    — SAHARA: sahara_ipg_stop_ack
    — RTIC: rtic_ipg_stop_ack
    — IPU: ipu_stop_clk_ack
    — SDMA: sdma_ipg_stop_ack
    — SCC: scc_ipg_stop_ack
    — EMI: emi_lpack, emi_lpack_fast, emi_lpack_int1, emi_lpack_slow, emi_lpack_garb
    — AHBMAX: ahbmax_halt_ack

NOTE

The SCC clocks are closed in WAIT mode only if SAHARA clocks are also closed, hence the SCC handshake is performed only if the SAHARA clocks are programmed to be closed as well.

15. The requests are generated by CCM in stages. CCM continues from stage to stage once all the acknowledgements of a present stages were received. The stages are the following:
    — Stage 1: SAHARA, RTIC, IPU, SDMA
    — Stage 2: SCC
    — Stage 3: AHBMAX
    — Stage 4: EMI
16. Once CCM receives all the acknowledge signals needed, and if at least 8 ipg_clk cycles have elapsed since the assertion of ccm_ipg_wait signal, it enters WAIT mode and does the following:.
    a) Closes the clocks to the modules which were defined to be shut at WAIT mode in the CCGR bits.
    b) Asserts system_in_wait_mode signal. This signal is connected to the IO pads for observability, to indicate of a WAIT mode.

Once CCM is in WAIT mode, it checks whether TZIC_DSM_WAKEUP signal has asserted or ARM_DSM_REQUEST has negated during the process of entering WAIT mode. If it has occurred, then CCM exits WAIT mode.

If TZIC_DSM_WAKEUP is not asserted and ARM_DSM_REQUEST is still asserted, the CCM moves to state SRPG_ARM and generates a request to GPC to power down the ARM platform, IPU, VPU,GPU, GPU2D and EMI by asserting signals ccm_pdn_4arm_req and ccm_pdn_4all_req. If in GPC those modules are defined to be powered down on WAIT mode, then GPC commences powering down for them. Please refer to CCM-GPC Connectivity diagram. The GPC sends a pdn_ack at the end of the power down sequence.

CCM's low power state machine remains in state "SRPG_ARM" until WAIT mode is exited.

Note that during WAIT mode, if SCC asserts either hclk_en signal or ipg_clk_en signal, the CCM asserts scc_clk_enable, thus enabling the SCC clocks. The WAIT mode is not exited due to this assertion.

7.4.8.2.2 Wait Mode is Exited by the Following Procedure

As soon as the synchronized TZIC_DSM_WAKEUP signal is seen as asserted or the ARM_DSM_REQUEST is negated, the CCM begins the process of exiting WAIT mode.

- Enable VPU, GPU2D and GPU clocks only.
  a) CCM requests that GPC restores power. CCM asserts ccm_pup_req to request that GPC powers up all the modules that were powered down if it was powered down on the entrance to WAIT mode.
  b) GPC notifies CCM by asserting signal PUP_ACK that power of ARM, VPU, IPU, and EMI is back on, and it's safe to exit from WAIT mode. Only then does CCM do the following:
     – Once assertion of notification from src that the resets for the power gated modules has been finished, (src_power_gating_reset_done is set) negate the low power request signals to all modules and enable all modules clocks including ARM clocks and return to run mode. (the clocks that their CCGR bits define not to be open in RUN mode will not be opened, and will continued to be gated in RUN mode).
     – Once system is in run mode, CCM will negate ccm_ipg_wait and system_in_wait_mode.
  c) Once the interrupt propagates through all the synchronization logic, the ARM CPU recognizes and services it. This forces the negation of the ARM_DSM_REQUEST output.

     Prior to this point, ARM_DSM_REQUEST and TZIC_DSM_WAKEUP were simultaneously asserted. Since TZIC_DSM_WAKEUP has top priority, the system is able to wake up.
  d) Before the ARM exits the ISR, it clears the interrupt source. This causes the TZIC_DSM_WAKEUP signal to be negated. At this point, the two low power control signals (TZIC_DSM_WAKEUP and ARM_DSM_REQUEST) are negated, and the WAIT sequence can be repeated at any time.

7.4.8.3 Stop Mode

In this mode all system clocks are stopped. PLLs are stopped. Power gating can be done on ARM platform, IPU, VPU and EMI. Synchronization of the CKIL clock is bypassed.

7.4.8.3.1 Entering Stop Mode

Stop Mode is entered by the following procedure:

1. ARM writes to LPM bit to set it for STOP mode.
2. ARM writes to DSM_INT_HOLDOFF bit in TZIC.
3. DSM_INT_HOLDOFF assertion forces the interrupt controller to stop the synchronizer clock for incoming interrupts. Any interrupts that had previously been synchronized by the interrupt controller will remain asserted.
4. If a wakeup event occurred or an interrupt was serviced or is pending, the CPU may abort the DSM sequence by exiting the main shutdown code sequence and returning to the desired security mode.

   If not the software, should execute the Wait For Interrupt (WFI) instruction.
5. Upon execution, the WFI instruction causes the ARM to drain its write buffers and enter a quiescent state. At this point the ARM asserts the STANDBYWFI signal.
6. The ARM platform waits until the L2 cache controller has become inactive. Once the L2 is inactive and the CPU's STANDBYWFI output is asserted, the ARM platform asserts the ARM_DSM_REQUEST signal to the CCM.
7. The CCM continuously synchronizes both the ARM_DSM_REQUEST and TZIC_DSM_WAKEUP inputs into the clock domain used by its internal state machine.

   The only time when those signals are not synchronized is when PLLs are closed. In this case exiting from STOP mode is done asynchronously (please refer to Section 7.4.8.3.2, Exiting Stop Mode").

If TZIC_DSM_WAKEUP is negated and ARM_DSM_REQUEST is asserted, the CCM begins the following STOP shutdown sequence:

1. CCM stops the ARM clock.
2. CCM generates ccm_ipg_stop and ccm_int_mem_ipg_stop to indicate that it started stop entrance procedure.
3. CCM requests an acknowledge to close clocks of SAHARA, RTIC, IPU, SDMA, SCC, EMI and AHBMAX if their clocks was not already closed in run mode. The request will be issued if the handshake is not bypassed by programing the CLPCR register bits 23–16. If the corresponding bits are set, then the request signal will not be issued to the corresponding module and CCM will not wait for its acknowledge in the process of entering low power mode. The requests will commence via the following signals:
   - SAHARA: sahara_ipg_stop_req
   - RTIC: rtic_ipg_stop_req
   - IPU: ipu_stop_clk_at_stop_req
   - SDMA: sdma_ipg_stop_req
   - SCC: scc_ipg_stop_req
   - EMI: emi_lpmd, emi_lpmd_fast, emi_lpmd_int1, emi_lpmd_slow, emi_lpmd_garb

NOTE

Since EMI needs the aclk_fast (ddr clock) to be running for it to answer with emi_lpmd, then software should make sure to turn on the aclk_fast (ddr_clk) before entering any low power mode that requests the emi_lpmd.

— AHBMAX: ahbmax_halt_req

Once the above modules finished their operation and are ready to enter low power mode, they acknowledge CCM that its safe to turn of their clocks. The acknowledge signals are as follows:

- SAHARA: sahara_ipg_stop_ack
- RTIC: rtic_ipg_stop_ack
- IPU: ipu_stop_clk_ack
- SDMA: sdma_ipg_stop_ack
- SCC: scc_ipg_stop_ack
- EMI: emi_lpack, emi_lpack_fast, emi_lpack_int1, emi_lpack_slow, emi_lpack_garb
- AHBMAX: ahbmax_halt_ack

The requests will be generated by CCM in stages. CCM will continue from stage to stage once all the acknowledges of a present stages were received. The stages are the following:

- Stage 1: SAHARA, RTIC, IPU, and SDMA
- Stage 2: SCC
- Stage 3: AHBMAX
- Stage 4: EMI

Once CCM receives all the acknowledge signals needed, and if at least 8 ipg_clk cycles has elapsed since the assertion of ccm_ipg_stop signal, then it will enter STOP mode and do the following tasks in the order they are written below:

1. * Close the system modules clocks, not including pgc_clk. The closing of clocks will include the ckil_sync clocks of Megamix only if the indication from GPC is that Megamix is about to be powered down (by spare_input_10 indication). The gating signal output for the CKIL sync gating cells is spare_output_0).
2. Assert system_in_stop_mode signal. This signal is connected to the IO pads for observability, to indicate of a STOP mode.

Once CCM is in STOP mode, it will check if TZIC_DSM_WAKEUP signal has asserted or if ARM_DSM_REQUEST has negated during the process of entering STOP mode. If it has occurred, then CCM will exit STOP mode.

If TZIC_DSM_WAKEUP is not asserted and ARM_DSM_REQUEST is asserted, then CCM will move to state STOP_GPC and generate a request to GPC to power down the ARM platform, IPU, VPU, GPU, GPU2D and EMI by asserting signals ccm_pdn_4arm_req and ccm_pdn_4all_req. If in GPC those modules are defined to be powered down on STOP mode then GPC will commence powering down for them.

After the GPC sends the pdn_ack signal, the following occurs:

1. Close PLLs and DPLL_ips by deasserting dpll_en_dpllip and ref_clk_en_dpllip.
2. After deassertion of lock ready flag from the PLL's, close CAMPs and FPM by deasserting ccm_CAMP1_en, ccm_CAMP2_en and ccm_fpm_en.
3. If sbyos bit was set, then de assert ref_en_b signal to close external oscillator and assert cosc_pwrdown to put on-chip oscillator in power down mode. (if they were not already closed by software. If one of them was already closed by software then discard the sbyos operation for it and perform the sbyos operation only on the one that is working. If both of them were closed in run mode, then discard sbyos operation for both of them).

   If vstby bit was set, then assert pmic_vstby_req signal, to indicate power management IC to shift voltage to standby voltage.

CCM's low power state machine will remain in state STOP_GPC until STOP mode will be exited.

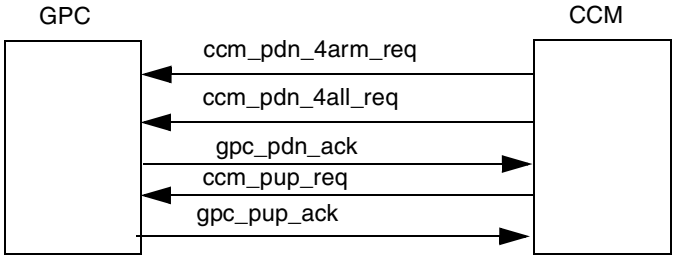

Figure 7-55. CCM-GPC Connectivity

7.4.8.3.2 Exiting Stop Mode

As soon as the unsynchronized TZIC_DSM_WAKEUP signal is seen as asserted or ARM_DSM_REQUEST is seen deasserted, the CCM exits STOP mode according to the following procedure

1. If vstby bit was set, deassert pmic_vstby_req to notify power management IC to change voltage from standby voltage to functional voltage.

   If sbyos was set, and CCM closed either external oscillator or on-chip oscillator, then CCM will start external oscillator and on-chip oscillator by asserting ref_en_b signal and deasserting cosc_pwrdown signal respectively.
2. After amount of CKIL's defined in stby_count bits, wait until pmic_vfunctional_ready signal is asserted. pmic_vfunctional_ready is used if an internal counter is not used. This is the notification from power management IC that the voltage is ready at its functional value. (Figure 7-58 describes the pmic signals connectivity.) Only then will CCM continue with the next steps:
3. Start FPM or CAMPs (based on definition of CAMP1_EN, CAMP2_EN and FPM_EN bits)
4. If any CAMP or on-chip oscillator were started, wait until oscnt has finished its counting to make sure that external oscillator, CAMPs output and on-chip oscillator are ready.
5. If FPM was selected, wait until assertion of fpm_lrf.
6. Start PLLs. Only the PLLs that were configured to be on prior to the entrance to STOP mode will be started.

7. Enable VPU, GPU2D, and GPU clocks only.

CCM will request GPC to restore power by GPC_PUP_REQ. If power was removed from the ARM platform or IPU or VPU or GPU2D or GPU, GPC will notify CCM by asserting signal GPC_PUP_ACK that power to ARM, VPU, IPU, GPU2D, GPU and EMI is back on, and its safe to exit from STOP mode. Only then CCM will do the following:

1. Once assertion of notification from SRC that the resets for the power gated modules has been finished, (src_power_gating_reset_done is set) negate the low power request signals to all modules and enable all modules clocks including ARM clocks and CKIL sync of Megamix (if it was turned off), and return to run mode. (the clocks that their CCGR bits define not to be open in RUN mode will not be opened, and will continued to be gated in RUN mode).
2. Once system is in run mode, negate signals ccm_ipg_stop and system_in_stop_mode.

Once the interrupt propagates through all the synchronization logic, the ARM CPU will recognize and service it. This will force the negation of the ARM_DSM_REQUEST output. Prior to this point, ARM_DSM_REQUEST and TZIC_DSM_WAKEUP were simultaneously asserted. Since TZIC_DSM_WAKEUP has top priority, the system is able to wake up.

Before the ARM exits the ISR, it will clear the interrupt source. This will cause the TZIC_DSM_WAKEUP signal to be negated. At this point, the two low power control signals are negated, and the STOP sequence can be repeated at any time.

Figure 7-56 describes the connectivity of ARM, CCM and TZIC.

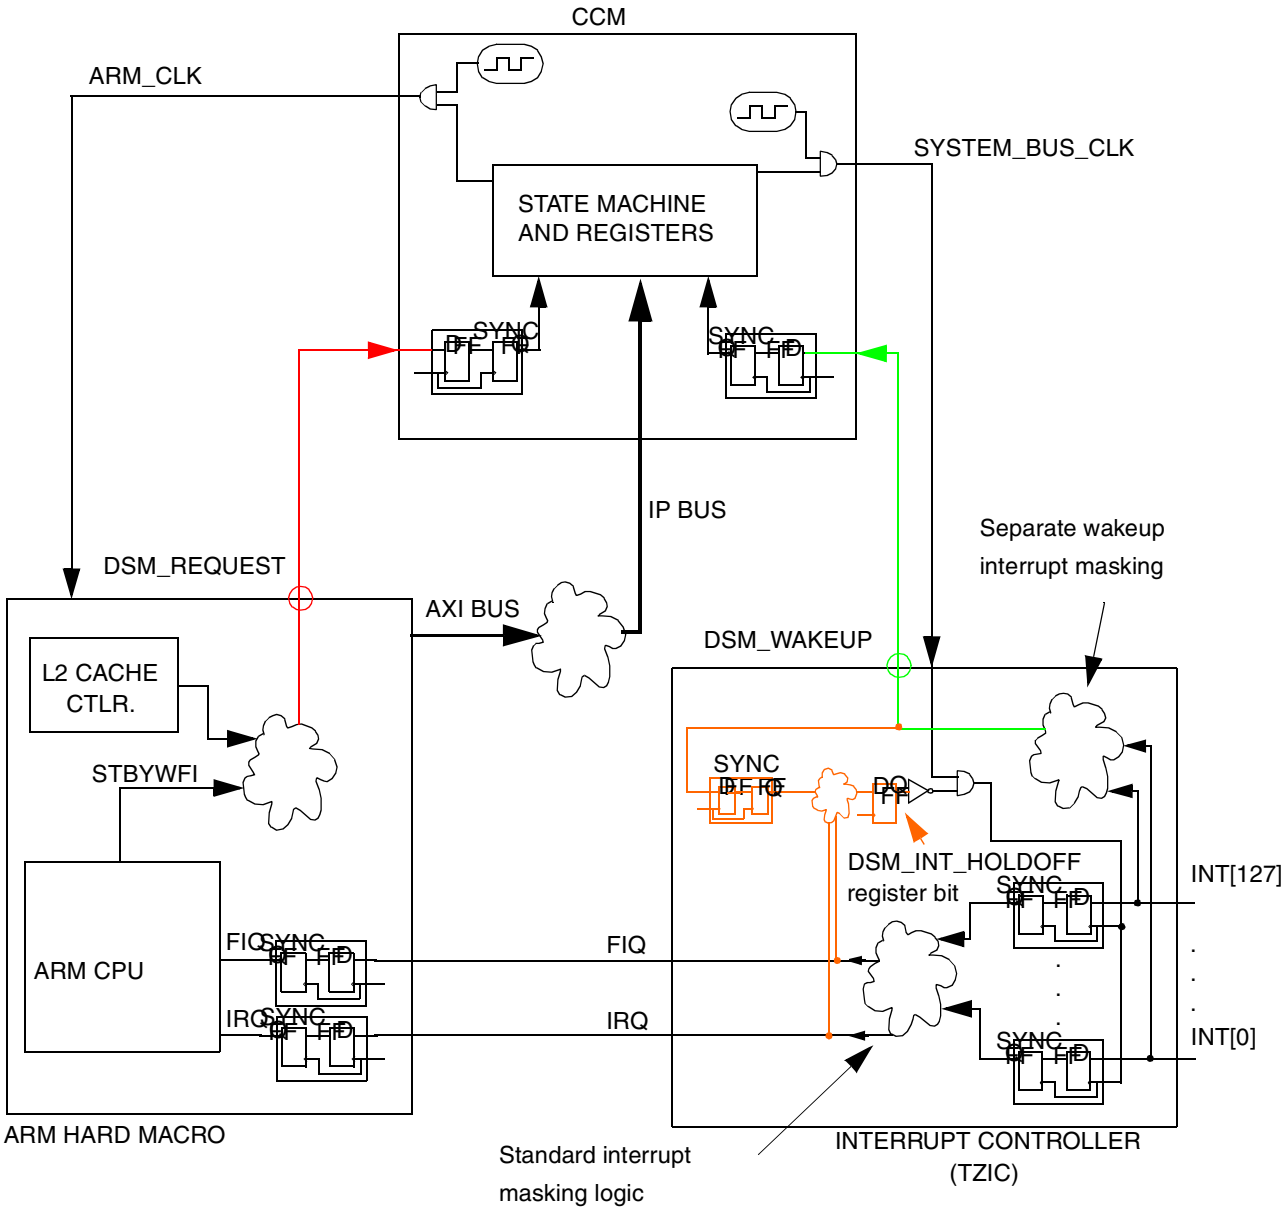

Figure 7-56. ARM Low Power Request

Figure 7-57 describes CCM's low-power state machine:

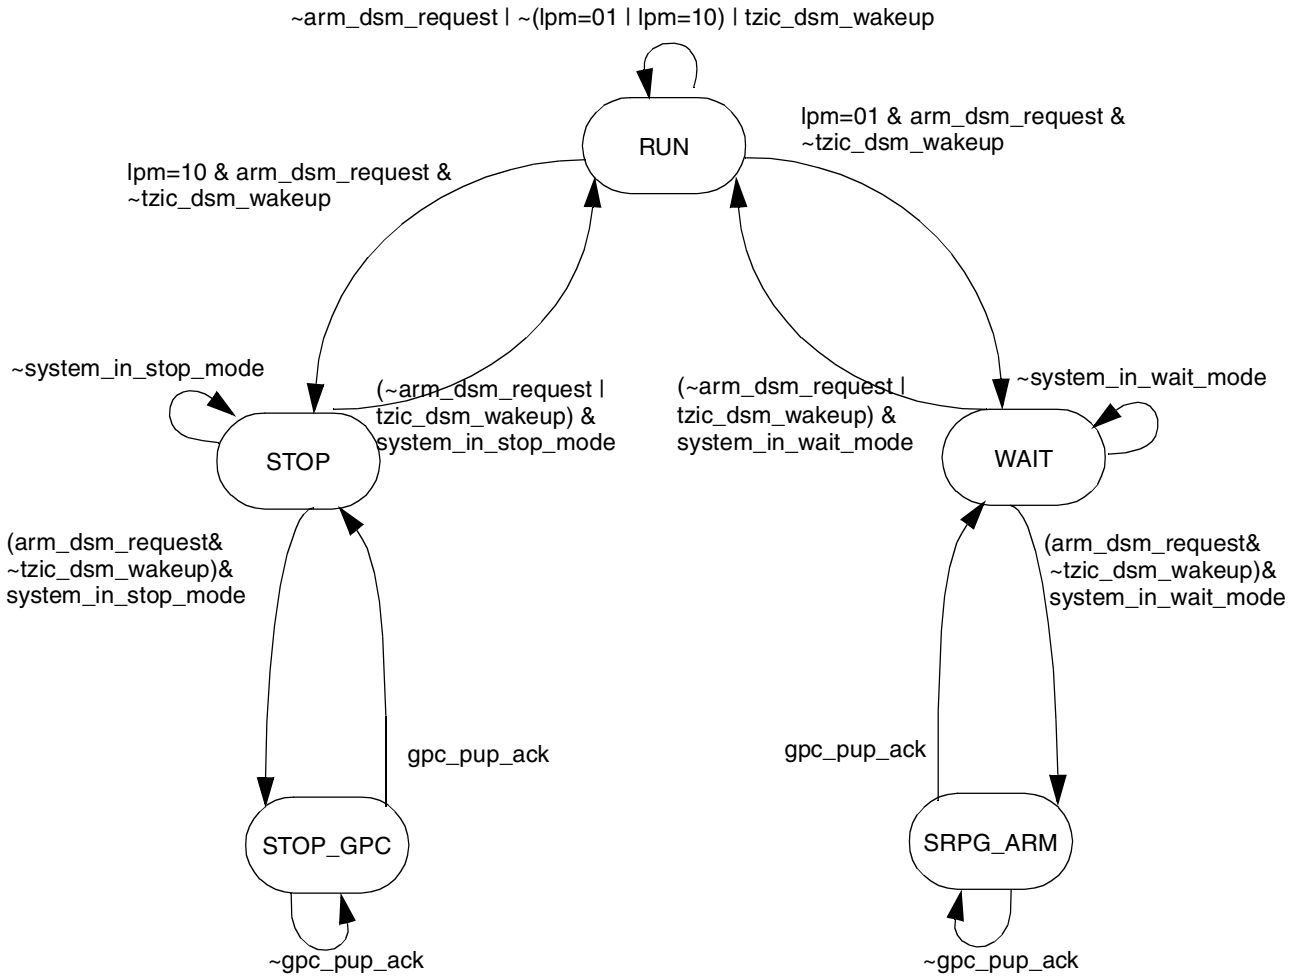

Figure 7-57. CCM Low Power State Machine

7.4.8.3.3 PMIC Signal Description

stby_count value should be larger than t1 - larger than the amount of time that it takes between CCM's negation of pmic_vstby_req, and the negation of pmic_vfuncional_ready (the signal coming back from PMIC to indicate that the voltage started to change).

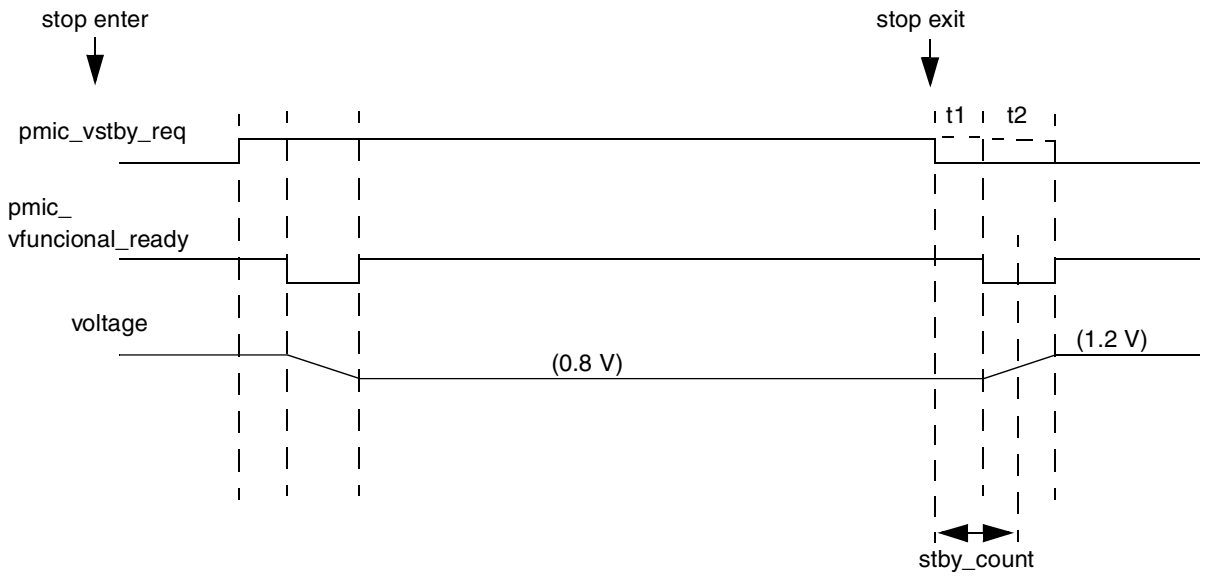

Figure 7-58. PMIC Signal Description

Note: Software should configure the IOMUXC so that pmic_vstby_req and pmic_vfuncional_ready will be operating in the correct ALT mode, so that they will be connected between CCM and the pads.

7.4.8.4 Low Power Screen Refresh Mode (LPSR)

The following section describes the solution for the low-power screen refresh support for the i.MX51. This allows the IPU to refresh the screen by reading the data from the internal RAM (incorporated in SCC module), while the system is in low-power mode by running from a low frequency clock. The low frequency clock source can be chosen from three possible options. LPSR is similar to STOP mode with the distinction that IPU can continue to access internal memory. For this capability, the clock to IPU, internal memory system, and emi master 0 should continue to function. All other clocks will be closed, including PLLs. When entering this mode, it is not allowed to configure IPU and emi to power gating / SRPG.

To be able to supply the above clocks, ccm generates lpsr_clk_root. This clock is generated from the following options:

- FPM clock output
- FPM clock output divided by 2
- GND. To reserve power, this option is to be chosen when LPSR is not used.

The lpsr_clk_root is connected to LPCG. The above clocks that need to continue to function in LPSR will have a mux in LPCG to shift between their functional clock to the lpsr_clk_root. The control of the mux comes from ccm and is named LPSR_mode_clk_en.When this signal is ‘0’ the mux will choose the functional clock for the above modules. When this signal is ‘1’ the mux will choose the lpsr_clk_root as the fed clock for the above modules. Figure 7-59 describes the LPCG part implemented for those clocks:

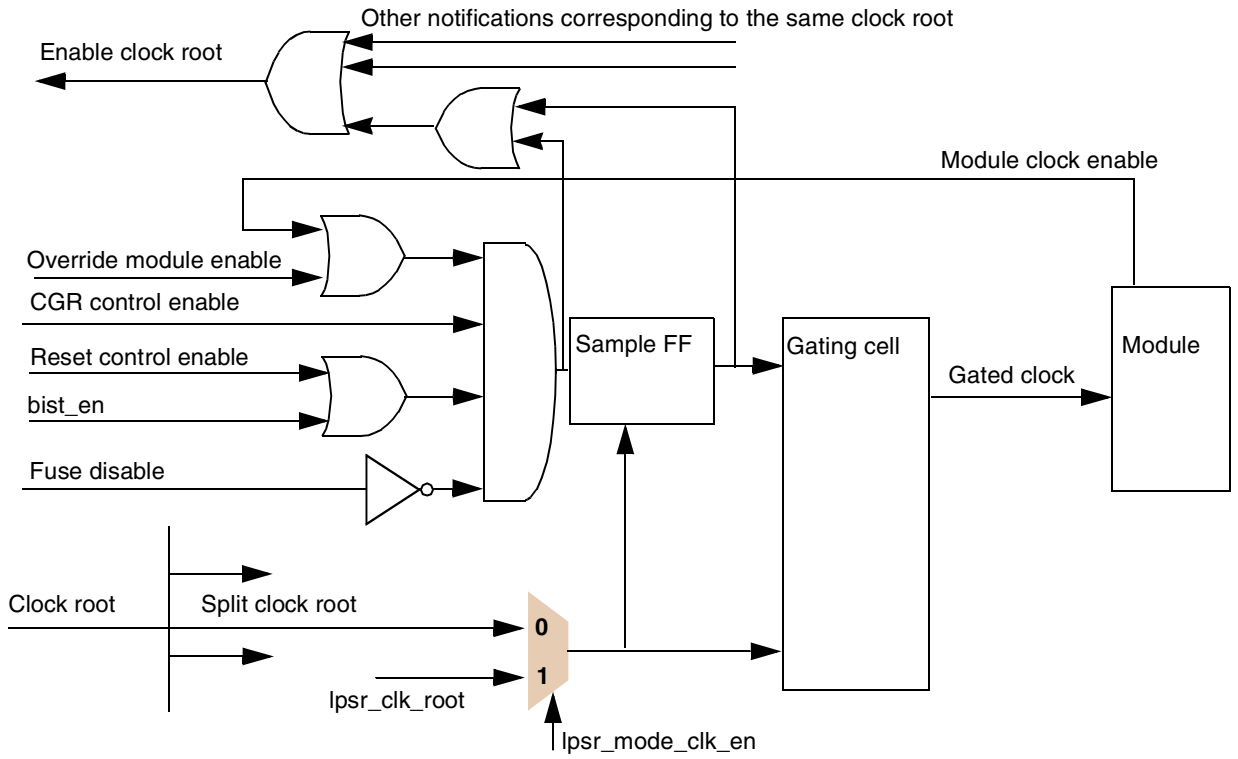

Figure 7-59. LPCG Part Implementation

Note: the IPU module expects specific configuration prior entering LPSR mode—please refer to IPU chapter for details.

7.4.8.4.1 LPSR Mode

LPSR mode uses the following procedure:

1. ARM will write to LPM bit to set it for LPSR mode.
2. ARM will write to DSM_INT_HOLDOFF bit in TZIC.
3. DSM_INT_HOLDOFF assertion forces the interrupt controller to stop the synchronizer clock for incoming interrupts. Any interrupts that had previously been synchronized by the interrupt controller will remain asserted.
4. If a wakeup event occurred or an interrupt was serviced or is pending, the CPU may abort the DSM sequence by exiting the main shutdown code sequence and returning to the desired security mode.

   If no wakeup event has occurred the software should execute the Wait For Interrupt (WFI) instruction.
5. Upon execution, the WFI instruction will cause the ARM to drain its write buffers and enter a quiescent state. At this point the ARM will assert the STANDBYWFI signal.

6. The ARM platform will then wait until the L2 cache controller has become inactive. Once the L2 is inactive and the CPU's STANDBYWFI output is asserted, the ARM platform will assert the ARM_DSM_REQUEST signal to the CCM.
7. The CCM will continuously synchronize both the ARM_DSM_REQUEST and TZIC_DSM_WAKEUP inputs into the clock domain used by its internal state machine.The only time when those signals will not be synchronized is, when PLLs will be closed. In this case the exiting from LPSR mode will be done asynchronously (please refer to the section below describing the exiting from STOP mode).
8. If TZIC_DSM_WAKEUP is negated and ARM_DSM_REQUEST is asserted, the CCM will begin the LPSR shutdown sequence:
   a) CCM will prepare the LPSR root clock - if FPM was chosen, it will start FPM and wait until FPM_lrf is asserted.
   b) CCM will stop ARM clock. ARM clock can be stopped even before FPM_lrf is asserted.
   c) CCM will assert ccm_ipg_stop and ccm_int_mem_ipg_stop to indicate that it has started the STOP entrance procedure.
9. CCM will request an acknowledge to close clocks of SAHARA, RTIC, IPU, SDMA, SCC, EMI and AHBMAX if their clocks was not already closed in run mode. The requests will commence via the following signals:
   — SAHARA: sahara_ipg_stop_req
   — RTIC: rtic_ipg_stop_req
   — IPU: ipu_stop_clk_at_stop_req
   — SDMA: sdma_ipg_stop_req
   — SCC : scc_ipg_stop_req
   — EMI: emi_lpmd, emi_lpmd_fast, emi_lpmd_int1, emi_lpmd_slow, emi_lpmd_garb

   NOTE

   Since EMI needs the aclk_fast (ddr clock) to be running for it to answer with emi_lpmd, software should make sure to turn on the aclk_fast (ddr_clk) before entering any low power mode that requests the emi_lpmd.

   — AHBMAX: ahbmax_halt_req
10. Once the above modules finished their operation and are ready to enter low power mode, they acknowledge CCM that its safe to turn of their clocks. The acknowledge signals are as follows:
   — SAHARA: sahara_ipg_stop_ack
   — RTIC: rtic_ipg_stop_ack
   — IPU: ipu_stop_clk_ack
   — SDMA: sdma_ipg_stop_ack
   — SCC: scc_ipg_stop_ack
   — EMI: emi_lpack, emi_lpack_fast, emi_lpack_int1, emi_lpack_slow, emi_lpmd_garb
   — AHBMAX: ahbmax_halt_ack

11. The requests will be generated by CCM in stages. CCM will continue from stage to stage once all the acknowledges of a present stages were received. The stages are as follows:
    - Stage 1: SAHARA, RTIC, IPU, SDMA
    - Stage 2: SCC
    - Stage 3: AHBMAX
    - Stage 4: EMI

Once CCM receives all the acknowledge signals needed, and if at least 8 ipg_clk cycles has elapsed since the assertion of ccm_ipg_stop signal, then it will enter STOP mode and does the following tasks in the order they are written below:

1. Close the system modules clocks, not including pgc_clk.
2. Assert system_in_stop_mode signal.

Once CCM is in STOP mode, it will check if TZIC_DSM_WAKEUP signal has asserted or if ARM_DSM_REQUEST has negated during the process of entering STOP mode. If it has occurred, then CCM will exit STOP mode.

If TZIC_DSM_WAKEUP is not asserted and ARM_DSM_REQUEST is asserted, then CCM will move to state STOP_GPC and generate a request to GPC to power down the ARM platform, GPU, GPU2D and VPU by asserting signals ccm_pdn_4arm_req and ccm_pdn_4all_req. If in GPC those modules are defined to be powered down on STOP mode then GPC will commence powering down for them.

NOTE

IPU is not allowed to be powered down in LPSR mode. When finished, the GPC sends the pdn_ack signal.

In parallel to the request to GPC to power down the needed modules, the following takes place:

1. Assert lpsr_mode_clock_en to shift the lpcg mux to the lpsr_clk_root.
2. Open the clocks of the modules involved in LPSR, that is, IPU and emi aclk_m3 (ipu_clk_enable), emi (emi_int1_clk_enable), downsizer, axi2ahb, regslice, ahbmux (ahbmux2_clk_enable), scc (scc_clk_enable).
3. Deassert ccm_int_mem_ipg_stop and scc_ipg_stop_req (connected to scc to notify it to exit STOP mode).
4. Deassert emi_lpmd, emi_lpmd_int1 (connected to emi to notify it to exit low power mode on int1 and on master side).
5. Assert ccm_lpsr_ipu to notify IPU to enter LPSR mode.

After the GPC sends the pdn_ack signal, the following takes place:

1. Close PLLs and dpll_ips by deasserting dpll_en_dpllip and ref_clk_en_dpllip.
2. Close CAMPs and FPM (only if FPM is not the source for lpsr_clk_root) by de asserting ccm_CAMP1_en, ccm_CAMP2_en and ccm_fpm_en.

3. If sbyos bit was set, then de assert ref_en_b signal to close external oscillator and assert cosc_pwrdown to put on-chip oscillator in power down mode. (if they were not already closed by software. If one of them was already closed by software then discard the sbyos operation for it and perform the sbyos operation only on the one that is working. If both of them were closed in run mode, then discard sbyos operation for both of them).
4. If vstby bit was set, then assert pmic_vstby_req signal, to indicate power management IC to shift voltage to standby voltage.

CCM's low power state machine will remain in state "STOP_GPC" until LPSR mode is exited.

7.4.8.4.2 Exiting LPSR Mode

As soon as the unsynchronized TZIC_DSM_WAKEUP signal is seen as asserted or the ARM_DSM_REQUEST is negated, the CCM begins the process of exiting LPSR mode, according to the following procedure:

1. If vstby bit was set, deassert pmic_vstby_req to notify power management IC to change voltage from standby voltage to functional voltage.

   If sbyos was set and CCM closed either external oscillator or on-chip oscillator, the CCM will start external oscillator depending on the configuration of the on-chip oscillator by asserting ref_en_b signal and deasserting cosc_pwrdown signal respectively.
2. After amount of CKILs defined in stby_count bits, wait until pmic_vfunctional_ready signal is asserted. This is the notification from power management IC that the voltage is ready at its functional value. (Figure 7-58 describes the pmic signals connectivity.) Only then will CCM continue with the next steps.
3. Start FPM (if not already working) or CAMPs (based on definition of CAMP1_EN, CAMP2_EN and FPM_EN bits).
4. If any CAMP or on-chip oscillator were started, wait until oscnt has finished its counting to make sure that external oscillator, CAMPs output and on-chip oscillator are ready.
5. If FPM was selected, wait until assertion of fpm_lrf (if its not already working).
6. Start PLLs. Only the PLLs that were configured to be on prior to the entrance to LPSR mode will be started.
7. Enable VPU, GPU2d and GPU clocks only.

CCM requests that GPC restores power by GPC_PUP_REQ. If power was removed from the ARM platform or IPU, VPU, GPU2D, GPU, GPC notifies CCM by asserting signal GPC_PUP_ACK that power to ARM, IPU, VPU, GPU2D, GPU and EMI is back on, and it is safe to exit from LPSR mode. Only then does CCM do the following:

1. Once assertion of notification from src that the resets for the power gated modules has been finished, (src_power_gating_reset_done is set) deassert ccm_lpsr_ipu.
2. Once ipu_lpsr_wakeup_ack is asserted, assert emi_lpmd, emi_lpmd_int1 (connected to EMI to notify it to enter low power mode on int1 and on master side), and ccm_int_mem_ipg_stop and scc_ipg_stop_req (connected to scc to notify it to enter STOP mode).

3. Once emi_lpack_int1 and scc_ipg_stop_ack are received, close the clocks of the modules involved in LPSR, that is, IPU and emi aclk_m3 (ipu_clk_enable), emi (emi_int1_clk_enable), downsizer, axi2ahb, regslice, ahbmux (ahbmux2_clk_enable), scc (scc_clk_enable). emi_lpack is ignored since it willl not be received - the fast clock is not available in this state, hence emi will not be able to generate the emi_lpack. The emi_lpack_int is an enough indication that emi has finished its function, since IPU has already stopped.
4. Deassert lpsr_mode_clock_en to shift the lpcg mux from the lpsr_clk_root to the functional root clock.
5. Enable all modules clocks including ARM clocks and return to run mode.
6. Once system is in run mode, negate signals ccm_ipg_stop and system_in_stop_mode and all low power requests (emi_lpmd, emi_lpmd_int1, emi_lpmd_fast, emi_lpmd_slow, scc_ipg_stop_req, and so on.).

Once the interrupt propagates through all the synchronization logic, the ARM CPU will recognize and service it. This will force the negation of the ARM_DSM_REQUEST output. Prior to this point, ARM_DSM_REQUEST and TZIC_DSM_WAKEUP were simultaneously asserted. Since TZIC_DSM_WAKEUP has top priority, the system is able to wake up.

Before the ARM exits the ISR, it will clear the interrupt source. This will cause the TZIC_DSM_WAKEUP signal to be negated. At this point, the two low power control signals are negated, and the STOP sequence can be repeated at any time

7.4.8.5 LPMD Request from SRC (Reset Controller)

SRC generates a signal named emi_DVFS_req. This signal will be asserted in case of WARM reset to request emi to enter sdram into selfrefresh. Since CCM is also a generator for the request to emi for entering sdram to selfrefresh, then the SRC request will be connected to CCM, and CCM will generate one common request to emi for sdram selfrefresh. This common request will assert either if CCM is the originator of the request or if the SRC is the originator of the request. The SRC request (named emi_DVFS_req) is connected to CCM's input src_warm_DVFS_req. CCM generates the request to EMI via DVFS request signal. This signal generation will be combined with the signal coming from SRC (src_warm_DVFS_req) to generate one DVFS request signal to EMI.

The acknowledge from emi regarding the self-refresh of EMI is connected to both CCM and SRC.

7.4.8.6 Low Power Audio Playback Mode (LP-APM)

Low Power Audio Playback mode (APM) defines special low power mode, dedicated for Audio only playback mode. It involves PLL on/off and frequency settings, as well as voltage and clock gating aspects, to enable lowest possible power consumption.

This section covers APM, as well as assumptions, and enter/exit flows from the APM mode.

7.4.8.6.1 Low Power APM Mode Definition

APM can be entered by DVFS settings or by manual clock configuration.

Only one PLL of i.MX51 is running—ARM PLL. This PLL is set to the maximal frequency that ARM can run at that lowest point, while still ensuring ARM and bus system processing needs. .

The peripherals will also work on low voltage. The peripherals work on a frequency suitable for this low voltage (about third of the nominal frequency). For information regarding voltages at low performance operating mode, please refer to the i.MX51 Datasheet.

For i.MX51 used as master on SSI clocks, the MCU PLL frequency must be set to an integer multiplication of SSI clock

7.4.8.6.2 LP-APM Mode Restrictions

The following restrictions apply to LP-APM mode restrictions.

- Enter and exist to/from Low Power APM mode has effect on Display and SSI clocks. If i.MX51 is master on SSI clocks, audio playback will be interrupted during the switch, and as such - it is not recommended to switch modes during audio playback.
- Due to impact to Display controller clock, switch to/from LP-APM, SW should take that into consideration. This is not applicable when using Smart Display.

Figure 7-60 describes the sequence to be performed to switch from a high power settings (3 PLLs, high voltage) to the low power APM.

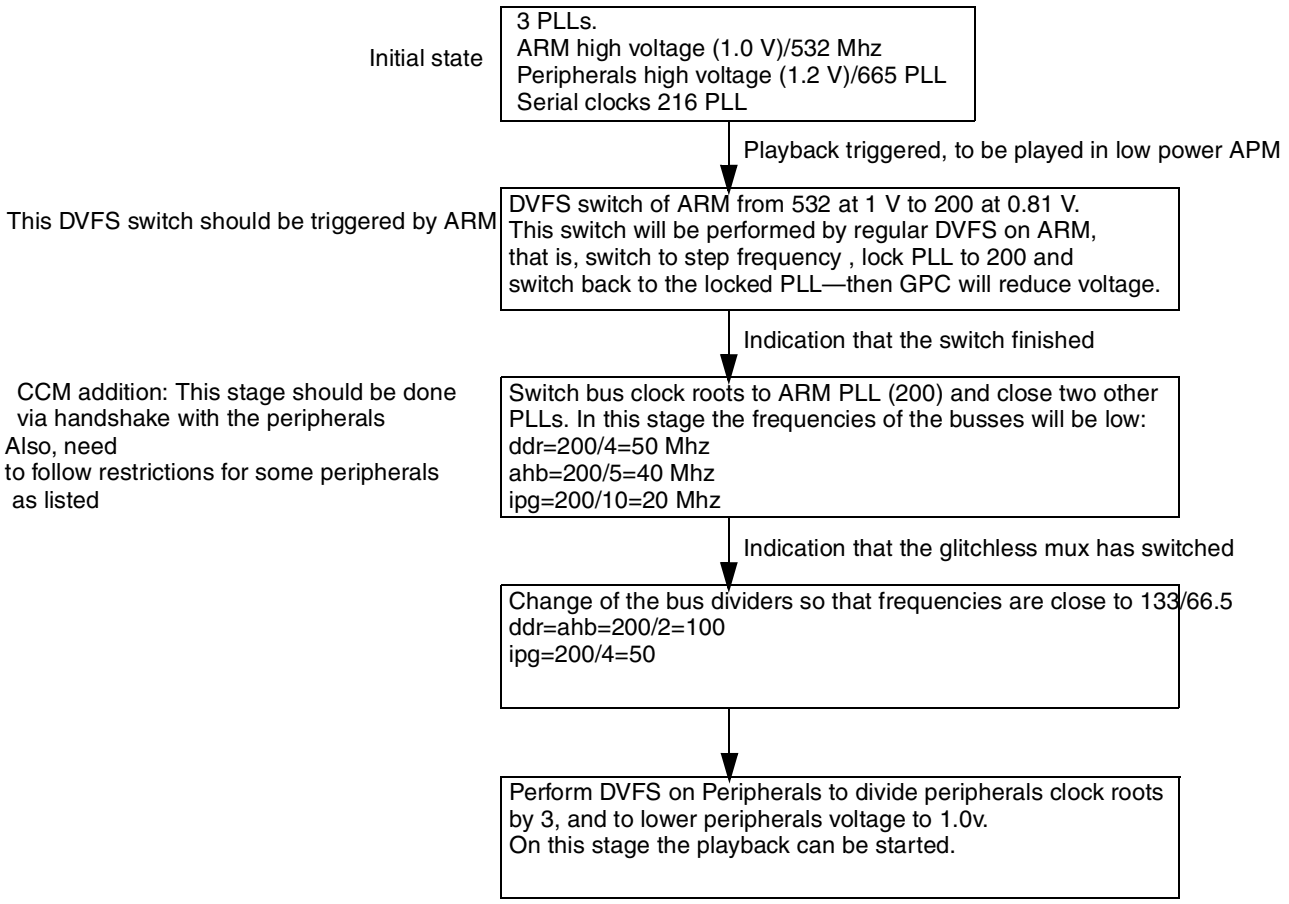

Figure 7-60. Flow of Entering Low Power APM on i.MX51

Table 7-44 shows the LP-APM flow frequencies.

Table 7-44. LP-APM Flow Frequencies

Stage	Farm [Mhz]	Varm [v]	Fahb [Mhz]	Fipg [Mhz[	Vper [v]	Comments
Initial state	532	1.0	133	66.5	1.2	run system from 3 PLLs: ARM PLL = 532 Mhz supplying ARM PERIPH PLL = 665 Mhz supplying busses (ahb, ipg). Serial PLL = 216 Mhz supplying USB, TVE, and so on.
DVFS on ARM	200	0.81	133	66.5	1.2	GPC operation triggered by software
Switch bus clocks to ARM PLL	200	0.81	40	20	1.2	Peripheral dividers are not changed during the shift. The shift should involve EMI handshake
Change bus dividers	200	0.81	100	50	1.2	—

Figure 7-62 shows the frequency and voltage flow

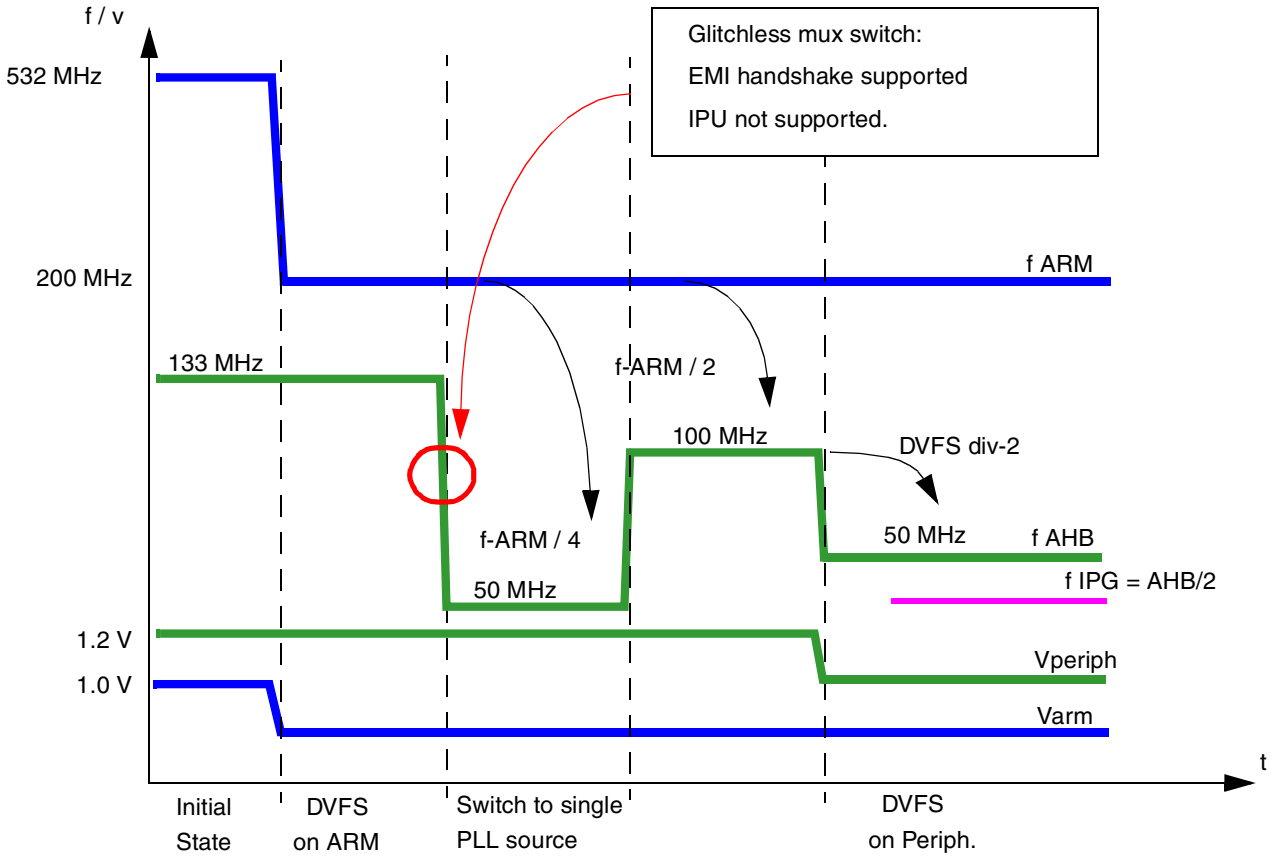

Figure 7-61. Frequency and Voltage Flow

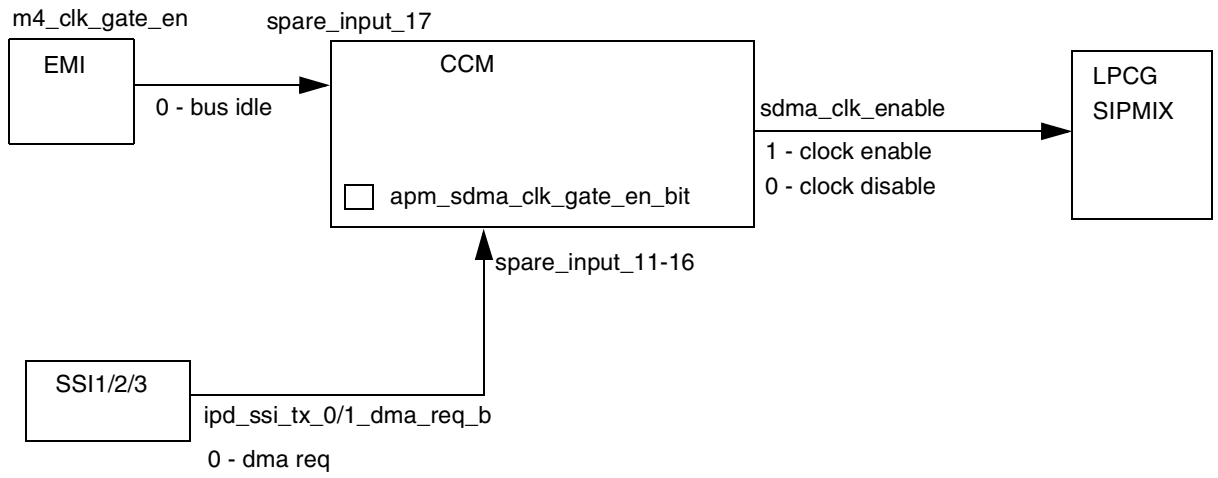
7.4.8.7 SDMA Clock Gating in APM Scenario

In LP-APM scenario, SDMA accesses EMI through master 4. Once EMI notifies that master 4 is idle (based on auto clock gating of EMI), then we can assume that all the data needed was transferred to SDMA, and SDMa clocks can be gated off. The SDMA clocks should be turned on, once SSI requests the next data from SDMA. Between those two indications, SDMA clocks can be gated off, by using sdma_clk_enable output of CCM. All this operation will be masked by apm_sdma_clk_gate_en_bit. If this

bit is not enabled, then the SDMA clock gating operation will not be based on m4_clk_gate signal. Figure 7-62 describes the design implementation.



CCM logic:
EMI bus idle → sdma_clk_enable = 0 (disable SDMA clock).
Upon SSI request (any of ipd_ssi_* = 0) → sdma_clk_enable = 1 (enable SDMA clock).
Wait for EMI bus idle to assert (m4_clk_gate_en = 1) → start from begining to look for bus idle.
The above should be masekd if the apm_sdma_clk_gate_en_bit is deasserted, (sdma clk enable).

Figure 7-62. Design Implementation Scheme

7.4.8.8 Wake Up Detector

When the MEGAMIX is in SRPG mode, all the modules in the MEGAMIX do not receive clock and power; hence they cannot wake up the system from external interrupts. The Wake Up Detector allows the reception of the following external interrupts when the MEGAMIX is SRPGed:

- KPP
- SDHC 1/2 Detection
- GPIO1_4, GPIO1_5, GPIO1_6, GPIO1_7, GPIO1_8, GPIO1_9

The Wake Up detector catches interrupts only when the clocks are stopped, that is, upon dpll_en_dpllip signal deassertion. In order to receive an interrupt, a corresponding pin has to be configured at IOMUX controller as described below.

7.4.8.8.1 KPP Interrupt

Interrupt occurs when key pressed. To enable the interrupt set corresponding bit at CCM_CIMR register to zero.

7.4.8.8.2 SDHC Interrupts

Interrupt occurs when SD card is inserted. To enable the interrupt set corresponding bit at CCM_CIMR register to zero. Each SD has separate enable and status bit.

7.4.8.8.3 GPIO Interrupts

The i.MX51 can wake up from STOP mode with MEGAMIX at SRPG state by one of the six GPIO interrupt described above.

Each interrupt can be masked at CCM_CIMR register. GPIO direction and interrupt type have to be configured for each GPIO at CCM_CR2 register, as it is configured at GPIO module.

7.4.8.9 Recommendations for Using Low Power Consumption from CCM

In addition to using APM mode for low power, here are the recommendations for configuring CCM so that it consumes less power. These recommendations should be followed when applicable:

- Use the AHB clock source as the source of all AXI buses and VPU core clkin - this case the power of the AXI dividers will be preserved.
- Work from one PLL and disable the other two PLLs.
- Generate SSI external clocks from SSI clock roots—in this case the SSI external clocks dividers power will be preserved.
- Generate SPDIF clocks from SSI clock roots—in this case the SPDIF clocks dividers power will be preserved. Gate debug clocks (arm debug clock, CTIs, DAP,...) and functional clocks that are not required for operation by CCGR registers. If a whole root clock is not required and gated by CCGR bits, it will gate the clock entering the divider.
- Shut external oscillator when not required.
- Lower the voltage and frequency (DVFS) when possible.
- Enable dynamic clock gating (enables from modules) so the clocks will be gated automatically when not used.
- Use the lowest possible frequencies of the PLLs to generate low frequencies that will enter the clock dividers and as a result save power consumed by the CCM.

Chapter 8
Debug Architecture

8.1 Overview

This chapter describes the debug architecture.

8.1.1 Introduction

This chapter describes the hardware and software debug and application development features and resources of i.MX51. There are core/platform-specific resources, resources associated with some of the more complex IP blocks, and chip-wide resources. Also discussed is the interface to external debug and development tools.

The debug architecture of i.MX51 is based on that of previous members of the i.MX application processor family.

An overview of the primary debug capabilities and features includes:

- JTAG-based access (control, monitoring), built around the Secure Controller (SJC)
- Trace Port
- Real-time and Halt-mode debug and profiling capabilities of the Cortex-A8 core platform
- Real-time and Halt-mode debug capabilities of the SDMA core
- An SOC-wide cross-trigger system built around ARM's Embedded Cross Trigger (ECT)
- Visibility of pre-selected critical internal signals via pin muxing
- External memory interface/controller arbitration profiling

Each of these features will be described in detail in the following sections of this chapter. The i.MX51 also supports ARM CoreSight architecture for system debug and trace capabilities.

8.1.2 Debug Strategy

The following features form the building blocks of the i.MX51 Debug design:

- Software debug (MSFT kernel)
- Trace the CPU activity via ETM trace port or ETB (ARM only)
- Control and monitor via JTAG
- Monitor preselected critical internal signals via pin muxing - scope

8.2 System Secure Controller—SJC

The SJC module is the bridge between external development and test instrumentation and the internal JTAG-accessible debug and test resources. It implements and manages the daisy-chained topology consisting of it's own TAP and those of the SDMA, the ARM core, and the ARM Debug Access Port (DAP). The ARM core is not part of a daisy chain.

8.2.1 JTAG Topology

Figure 8-1 shows a high level block diagram of the i.MX51 JTAG connectivity.

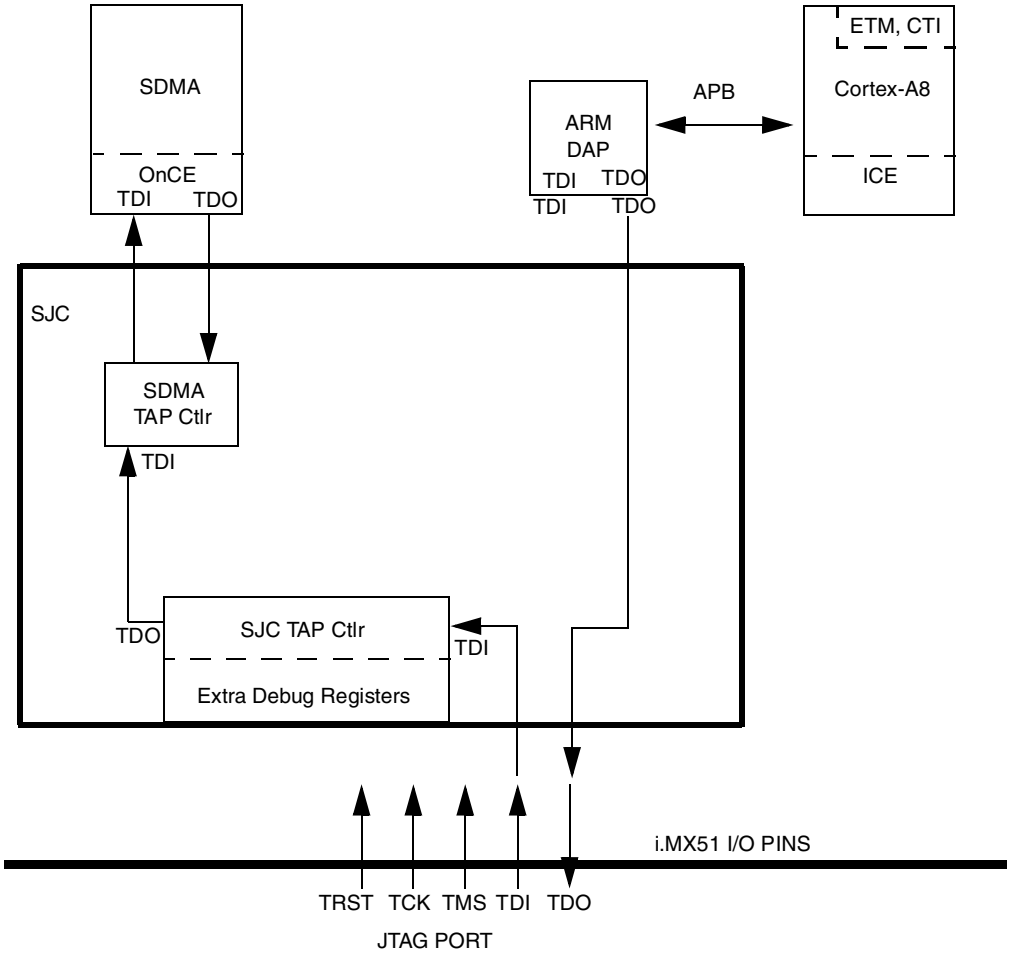


Figure 8-1. JTAG Connectivity

8.2.2 Secure JTAG Controller Main Feature

The secure JTAG controller main features are as follows:

- IEEE 1149.1 (standard JTAG) interface to off-chip test and development equipment

— Includes an SJC-only mode for true IEEE 1149.1 compliance, used primarily for board-level implementation of boundary scan.

- Debug-related control and status, such as putting selected cores into reset and/or debug mode and the ability to monitor individual core status signals via JTAG.
- System status, such as the state of the PLLs (locked or not locked)
- Generic status and control, defined on a per-SOC basis by the architecture team
- Factory test related control/status such as PLL bypass and memory BIST
- Four levels of security, ranging from no security to no JTAG accessibility to the chip.

8.2.3 SCJ TAP Port

The SJC in the i.MX51 supports the following standard JTAG pins: TRSTB, TDI, TDO, TCK, and TMS.

8.2.4 SJC Main Blocks

- Interface to the outside world via the standard JTAG pins
- Interface to the external Debug_Event pin
- A master TAP controller, which implements the standard JTAG state machine.
- Implementation of the mandatory and optional IEEE P1149.1 (JTAG) instructions
  — Mandatory: “EXTEST”, “SAMPLE/PRELOAD,” and “BYPASS”
  — Optional: “ID_CODE” (SOC JTAG ID register), “HIGHZ”
- Supports the SDMA’s DR-path-only JTAG architecture by implementing the controller portion of its TAP (including “BYPASS” as the default state) within the SJC
- Provides the serial interfaces to various DSP-domain JTAG resources (not implemented on i.MX51)
- The ExtraDebug registers, which implement a variety of control and status features
  — Three 32-bit insecure general purpose status registers
  — Two 32-bit secure status registers - one predefined, one general purpose.
  — Control and status registers for debug, core, charge pump, PLL, and BIST related functions
  — Control bits for memory timing control (not used on i.MX51)
- Four levels of fuse-defined security, ranging from no security to no access.

8.2.5 SJC Features—JTAG Disable Mode

In addition to four different JTAG security modes that are implemented internally in the Secure JTAG Controller (SJC), there is an option to disable the SJC functionality by e-FUSE configuration. This creates an additional JTAG mode, JTAG Disabled, with the highest level of JTAG protection. In this mode, all JTAG features are disabled. Specifically, the following debug features are disabled in addition to the features that were already disabled in “No Debug” JTAG mode:

- Memory BIST
- Boundary scan register (BSR)

- Non-Secure JTAG control registers (PLL configuration, Deterministic Reset, PLL bypass)
- Non-Secure JTAG status registers (Core status)
- Chip Identification Code (IDCODE)

8.2.6 SJC Registers Summary

The following is a summary of the SJC registers.

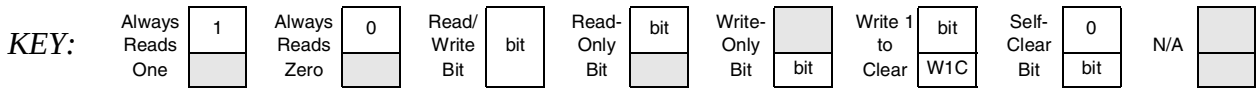

Table 8-1. SJC Registers Summary

Name		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8.2.7 SJC Registers Description

The following registers are accessed using the extra debug register.

8.2.7.1 General Purpose Unsecured Status Registers 1,2,3 (Three Registers)

The General Purpose Unsecured Status Register 1 is a read-only register used to check the status of the different cores and the PLL. The rest of its bits are for general purpose use.

GPUSR1 — **General Purpose Unsecured Status Register 1** — **Addr $BASE + 0x00**

8.2.7.3 Product ID and JTAG ID

i.MX51 PROD_ID = 11110010 and JTAG_ID = 0x0190_C01D. Product revision (hw_rev[7:4] in IIM) is = 4’b0000 accordingly.

8.3 CoreSight Design Kit

The i.MX51 includes an ARM CoreSight component for multicore debug and trace solution. CoreSight component can be found in the following hierarchy levels: ARM core, ARM platform, and top level.

- ARM core—include the following CoreSight components: ETM, CTI0
- ARM platform—include the following CoreSight components: ETB, ATB Replicator, CTI1, CTM
- Top level—include the following CoreSight components: DAP, CTI2, CTI3, TPIU

8.3.1 Memory Map and Register Definition

Each CSDK component has a 4 Kbyte location block in the CoreSight memory map. The base address of the CoreSight location block is not fixed but the address offsets are fixed. Each CSDK component has a 4-Kbyte memory map, that is, 1 Kbyte words.

Components connected to the DAP internal bus appear as part of a memory mapped structure with parallel address and two data buses, read data and write data. The bus master, JTAG-DP, uses normal bus transactions to control the various APs, in this structure the slaves. The JTAG-DP reads and writes registers within this bus.

8.3.2 CoreSight Clock Enable

By default the CoreSight component clocks are enabled when the system exists from reset with all clocks enabled. The CoreSight clocks' gating is controlled by programmable CCM registers and DBGEN. The CCM allows control of each CoreSight component separately (by default) and the DBGEN controls all debug clocks. DBGEN is raised when detecting activity on JTAG ports (TMS) and descend on reset (by dap_sys) or controlled by ARM. Only if both CCM registers bits and DBGEN are high the clock will be propagate to CoreSight component.

8.3.3 CoreSight Debug Access Port (DAP) and DAP_SYS

ARM's Debug Access Port (DAP) has several functions. DAP_SYS is a wrapper around DAP and is the FSL block that is actually instantiated in a design (DAP is contained within DAP_SYS). The following list summarizes the features provided by DAP_SYS.

- Enables debug-related communication between various parts of the system
  - It is a modular block.
  - It has slave-side support for JTAG and APB (ARM Peripheral Bus) protocols.
  - The Debug master can access many debug resources in real time without having to halt the core.
  - It can enable system access to anything connected to the Debug-APB via the APB multiplexor.
- ROM Table provides a list of memory locations of CoreSight components connected to the Debug APB. Visible from both tools and system access.
- AHB to APB gasket to translate System AHB accesses to APB (input as system APB to the DAP).
- APB Decode to issue select signals to CoreSight components on APB, and handle the PSLVERR and PREADY signals from the components to the DAP.
- AHB-Lite to AHB converter, to translate DAP's AHB-lite accesses to system's AHB protocol.

Debug and Reset logic generate DBGEN signal and reset signals. The CoreSight components that reside on the Debug-APB include all Embedded Cross Trigger blocks, the ETM, and the ETB.

8.3.4 Embedded Cross Trigger (ECT)

System events, such as a debug request, a core entering or exiting debug mode, the occurrence of a breakpoint or watchpoint, the occurrence of a particular error, the state of a buffer, etc., can be useful or even essential for debugging or profiling system performance. Whatever the source of the event, the embedded cross trigger implements a flexible, programmable mechanism to transport these events from a source to one or multiple destinations. This includes handling handshake requirements with both the source and the destination as needed and synchronization of signals from different clock domains. The end result is that events of interest that occur in one domain, such as in the Cortex-A8 domain, can be recognized and responded to be a destination domain, such as the SDMA.

The i.MX51 uses the CoreSight ECT (provided by ARM as part of their full CoreSight Debug Support package) and a custom wrapper to accommodate the various necessary interface scenarios. The ECT (as delivered by ARM) consists of two major blocks—a central Cross Trigger Matrix (CTM) and a Cross Trigger Interface (CTI) block. A Freescale-custom wrapper is added to the CTI to accommodate a variety

of different input and output interface scenarios. The wrapped CTI is called the Extended CTI and is configured on a signal by signal basis with port tie-off's.

i.MX51's ECT architecture consists of a single CTM and three wrapped CTI's covering three basic groups of functionality as follows:

- CTI0 is in the ARM Cortex A8 core.
- CTI1 is in the Cortex-A8 core platform, with two triggers in and two triggers out used by the platform and the others by the device peripherals.
- CTI2 is in the SOC level and is SDMA.
- CTI3 is in the SOC level and is used by MCU peripherals (IPU, GPU, VPU).

A detailed CTI pin assignment can be found in on page 8-21.

Figure 8-10 is a simple illustration of the relationship between the two processor domains, the SJC and peripherals, and the ARM CoreSight DAP. APB is an AMBA bus used for debugging. It defines what debug and trace components are required and how they are connected. The DAP is the Debug-APB master for the following debug units: ETM, ETB, TPIU, and the ARM Cortex A8 debug unit, which are four CTI blocks. The Debug-APB bus differs from system-level APBs in that it can be directly accessed via JTAG as well as from the ARM core. Module selects for each slave module on the Debug-APB are generated by the DAP_SYS.

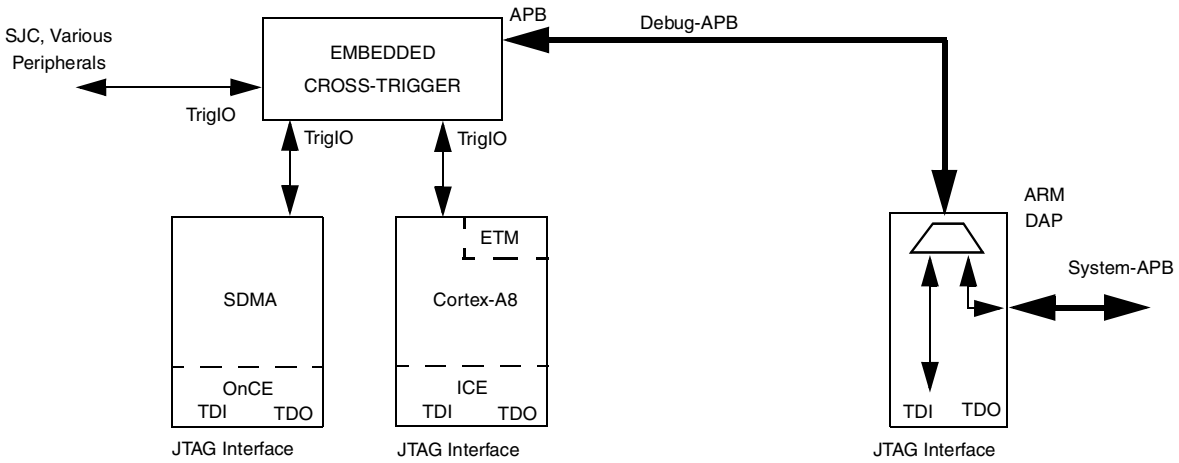

Figure 8-10. Embedded Cross Trigger Topology

Figure 8-11 illustrates the connectivity between the CTM and CTIO components of the CoreSight ECT.

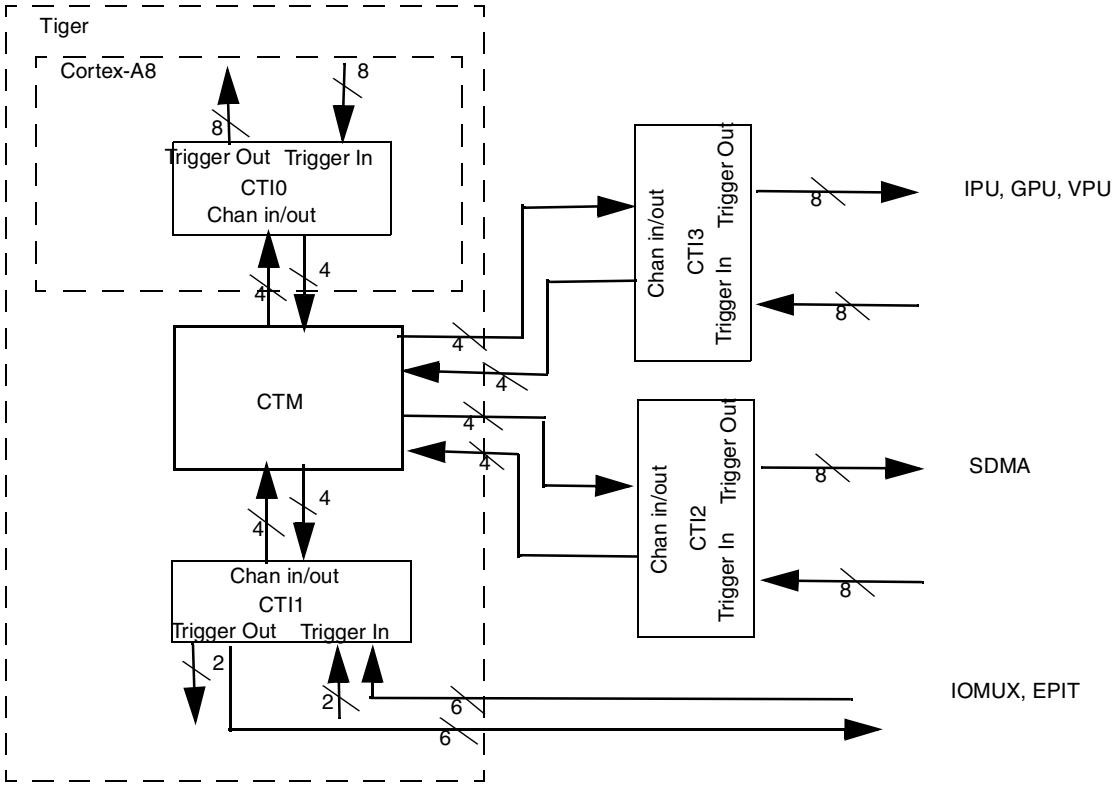

Figure 8-11. Embedded Cross Trigger - Basic Architecture

8.3.4.1 CoreSight CTM

The CTM (Cross Trigger Matrix) is provided by ARM. The CTM is a relatively simple block with no programmability. On i.MX51, it is configured to have four input and four output channels. Whatever comes in on an input channel is routed to all corresponding output channels. For instance, if a trigger input comes in on input channel 0 from CTI0, it is routed to output channel 0 to CTI1, CTI2, and CTI3. All selection of drivers and receivers for an event is done in the individual CTI blocks.

The final feature provided by the CTM is handshake with each CTI. This insures that as trigger signals cross different clock domain boundaries, they will not be lost due to slower downstream sampling frequencies. It is a simple mechanism in which a CTI holds an output until it receives the acknowledgement from the CTM. Handshake is also implemented in the reverse direction, insuring that a trigger signal propagating from the CTM to a CTI is not missed by the CTI.

8.3.4.2 CoreSight CTI

The CTI (Cross Trigger Interface) is also provided by ARM. A summary description of the CTI is provided here, but please refer to ARM documentation for detailed information. As mentioned earlier, there are three CTIs. Each of these has eight trigger inputs and eight trigger outputs that connect to logic in the domain to be debugged or profiled. Each CTI also includes a 4-channel interface to the CTM (four inputs

and four outputs). The CTIs are wrapped with additional logic to from the Extended CTI, which is described in the next section.

8.3.4.3 Extended CTI (CTI Wrapper)

This wrapper consists of additional logic for each input and each output trigger to implement several features that can be selected or enabled with hard tie-off’s on the module’s boundary. It is combined with ARM’s CTI block to form the CTI_Extended block. A summary of the extended input features implemented by logic in the wrapper is as follows:

- Invert the incoming signal
  - The ARM CTI assumes all inputs are active-high. An active-low input must first be inverted before going into the ARM CTI
- Sample the incoming trigger signal with a clock synchronous to the incoming signal
  - Samples the incoming trigger with its own clock
- Convert the incoming signal to a pulse
  - Used when an input trigger has a long assertion time. Destinations may be sensitive to a long assertion time and may see it as multiple input triggers.
- Implement holding logic to insure that the ARM CTI captures and acknowledges the incoming signal. The holding logic clock must be synchronous to the clock that generated the input trigger.

- Provides a synchronized or asynchronous acknowledge signal back to the origin of the trigger.
  - If the asynchronous trigger source requires an ACK signal back from the CTI, but a clock from that source is not available to the CTI, the source must first synchronize the received ACK before using it in the trigger source logic.

8.3.5 CoreSight Trace Port Interface (TPIU)

The TPIU is one of the CoreSight trace sink components it acts as a bridge between the on-chip trace data to a data stream that is then driven out the trace port. ATB interface is used by the TPIU accepts trace data from a trace source, either direct from a trace source or using a Trace Funnel. The TPIU has 32 bit connected to the chip BGA contact. The APB interface is the programming interface for the TPIU configuration.

8.4 ARM Cortex A8 Core and Platform

ARM Cortex A8 Debug architecture includes support for TrustZone and CoreSight. The memory-mapped external debug interface replaces the coprocessor interface defined in the previous version of the Debug architecture. A full access to the processor debug capability available by ARM Cortex A8 debug register map through the *Advanced Peripheral Bus* (APB) slave port. The core includes Processor Debug Unit allow: stop program execution, examine and alter processor and coprocessor state, examine and alter memory and input/output peripheral state, and restart the processor core.

8.4.1 ARM Cortex A8 Core Debug Support Features

The ARM Cortex A8 core debug support features are as follows:

- CoreSight Embedded Trace Macro (ETM11)—trace generator for the ARM Cortex A8 core
- Support for a TrustZone-relateyd 3-level debug scheme:
  - Debug everywhere
  - Debug in Non-Secure privileged and user and Secure user
  - Debug in Non-Secure only
- EmbeddedICE-RT logic
  - Support for both monitor-mode and halt-mode debugging.
  - Core run/halt control, debug status/control
  - Breakpoint/watchpoint control
  - Core- and memory-mapped resource examination/modification
- Data communication channel between ARM core and host debugger via JTAG
- PMU—Performance Metrics Unit used for system profiling and debug.
- CP15 register for debugging the MMU, I and D L1 cache, and TLB
- EVTMON-L2 Event Monitor—Supports debug and profiling of the ARM’s L2 cache activity

8.4.2 Additional Platform Debug Functionality

- CoreSight Embedded Trace Buffer (ETB11)—4-Kbyte RAM array to be used for on-chip capture of trace data output from the ETM11
- ATB Replicator to connect the trace data to TPIU (Trace Port Interface) and ETB (Embedded Trace Buffer).
- Debug Visibility—select critical signals routed to the I/O pads as alternate outputs for external visibility

8.5 Smart DMA (SDMA) Core

The SDMA is a dedicated, programmable DMA engine. It is an integration of a 32-bit RISC core and DMA-specific hardware, and it includes ports for the AP domain and a peripheral domain, along with a burst-capable port for direct external memory access. The SDMA and its integration in the i.MX51 is unchanged from previous SOCs.

The main SDMA debug features are as follows:

- OnCEOn Chip Emulator, provides the following capabilities:
  - SDMA core control - run/halt/single-step
  - SDMA core register/memory-map access
  - Event detection, watchpoints, and hardware breakpoints
  - Real time buffer and PC trace buffer capability
- Trace buffer
  - Contains information to identify the 32 last changes of flow detected during a program execution
- Context dump
  - include information about all the channel dump activity
  - Current contents of SDMA RAM
- ROMPATCH

8.5.1 SDMA On Chip Emulation Module (OnCE) Feature Summary

The SDMA debug features are primarily defined by the OnCE portion of its design, which are summarized as follows:

- Memory And Register Access—dedicated logic enables user-access to SDMA memory and register locations. These accesses are supported only when the processor is in debug mode.
- Event Detection Unit—watches signals from the data memory bus (DMBus) which is used by the RISC core to access its RAM, ROM, and memory-mapped registers
- Watchpoints—one output signal is available to watch event matching conditions at the chip level. Match conditions are defined by programming memory-mapped registers.
- Hardware Breakpoint—a counter is decremented after an event detection. A debug request is sent to the SDMA core only when the counter reaches the value of zero. It is possible to program the

initial value of the counter or to disable the use of the counter if a debug request must be generated after each event detection.

- Real Time Buffer—The Real Time Buffer Register (RTB) is a single 32-bit memory-mapped register which can be accessed as a regular memory location during program execution. It is used to store and retrieve run time information without putting the SDMA in debug mode. Each write to this register causes an event. This register is, in fact, located in the OnCE. Executing through JTAG, a buffer command exports the content of this register through the JTAG port.
- Core Control (Core Status/Single Stepping)—Commands are provided to monitor and control processor activity. The commands can halt the core, rerun the core from another address location, and get processor status.
- Trace Buffer—a 32 × 32 buffer that records the last 32 changes of flow during program execution. The buffer stores data in a modulo fashion (i.e. the 33rd instruction change replaces the 1st). Captured trace information is retrieved via reads to the Trace Buffer Register.

8.5.2 Other SDMA Debug Functionality

Other SDMA debug functionalisty is as follows:

- Core Trace—basic core trace capability is available through debug visibility functionality only. ETM/Nexus trace capability does not exist.
- ROM Patch—can be accomplished by manipulating the CHN0ADDR register through JTAG or via the MCU's ability to write to SDMA OnCE registers. This must be done right after reset and before the SDMA core is enabled to begin processing events.
- Additional debug control/status interaction with the SJC module
  - SJC-controlled Debug Request
  - SJC-readable Debug Acknowledge (in debug mode)
  - Debug clock control - allows SJC to force clocks on for debug purposes
  - Debug core state (SDMA RISC Core State) - 4 bits accessible from the SJC via JTAG
- Debug Visibility—observable outputs as alternate (programmable) output functions of I/O pins
  - Debug Request, Debug Mode
  - Debug Yield
  - Debug Event Channel[5:0] (indicates requesting event or channel being processed)
  - Debug PC [13:0] (for SDMA core trace)
  - Debug core state [3:0]
  - Debug Real-time Buffer write
  - Debug Addr/Data match
  - Debug bus error
  - Debug bus device
  - Debug bus r/w
  - Debug Event Channels[7:0]
  - Debug Core Run (active when core is running)

8.5.3 Embedded Cross Trigger Interface

Please refer to the Embedded Cross Trigger section of this chapter for detailed information about the SDMA interface to that subsystem.

8.6 External Memory Interface (EMI)

The second-generation EMI contains an arbitration profiling unit. This can be used to monitor and profile the dynamic arbitration behavior during operation. Several internal signals would be routed out by EMI debug unit to give SoC the capability to track the internal logic mainly for the arbitration mechanism and memory served accesses. In addition, the debug unit gives the ability to profile a master connected to EMI and get the bus performance of the arbitration.

Signals routed to 51 bit **ipp_do_emi_debug** bus are routed to the BGA contact.

The Profiling unit includes the following:

- A register that saves the maximal time that a selected master was pending without getting the bus (MDSR0)
- The maximum value of the dynamic priority which was selected (MDSR0)
- Counters to record the number of access that each master performed through each channel (MDSR2–5)
- Counter of the total number of accesses a specific request (or type of request) has accessed the bus can be fast, slow or intr (MDSR6)
- A register that sums of "time for bus" the time it took a specified request (or type of request) to get the bus (MDSR7)
- A register that sums the time it took each access to get the bus (pending time) (MDSR8)
- Ability to reset all the counters

The EMI profiling logic includes a START signal, which comes from the ECT. Thus, any definable ECT condition can be used to initiate profiling.

8.7 Debug Visibility—IOMUX

Certain predefined, internal signals can be viewed at the package pins. The BGA contact logic for most pins includes an IOMUX, allowing that BGA contact to be shared across multiple functions. Each BGA contact has a primary function that is selected at reset. The alternate functions, such as displaying the state of an internal signal for debug purposes, is selected by reprogramming the IOMUX.

Table 8-16 shows the debug visibility.

Table 8-16. Debug Visibility

Module	Signals
SDMA	debug_mode, debug_bus_error, debug_bus_device[4:0], debug_bus_rwb, debug_matched_dmbus, debug_rtbuffer_write, debug_evt_chn_lines[7:0]
EMI	ipp_do_emi_debug[50:0]
IPU	ipu_diagbus[15:0]
GPU	SYS_GC_debug_out[16:0]
TPIU	TRACEDATA[31:0]

8.8 MCU Peripherals

This section discusses the following MCU peripherals:

- Section 8.8.1, Image Processing Unit (IPU)”
- Section 8.8.2, Video Processing Unit (VPU)”
- Section 8.8.3, Graphics Processing Unit (GPU)”

8.8.1 Image Processing Unit (IPU)

The IPU include debug unit that allow routing of its signals to the SoC level. The signals muxing to be routed to top are controlled by DP Debug Control register (DP_DEBUG_CNT) and are connected to 16 bit diagnostic bus (ipu_diagbus). The IPU also include status register (DP_DEBUG_STAT) that can be used for debug.

The IPU can enter the system into debug mode by the cross trigger system. Three of the IPU signals are input to ETC: IPU general interrupt, IPU error interrupt, and IPU end of frame. These inputs can trigger the system to enter debug mode.

More details on signal muxing and IPU debug registers can be found in IPU chapter.

8.8.2 Video Processing Unit (VPU)

The VPU can enter the system into debug mode by the cross trigger system. Three of the VPU signals are input to ETC: VPU idle, VPU interrupt, and VPU underrun. Those signals can trigger the system to enter debug mode.

VPU internal register can access the AHB bus for further analysis.

8.8.3 Graphics Processing Unit (GPU)

The GPU supports propagating debug information from the core over a 32-bit wide debug bus. The debug outputs are directed to only 16 visible ports. GPU includes debug control bus SYS_GC_gpio[15:0] that selects which debug signals are exposed on the debug out bus GC_SYS_debug_out[31:0].

GPU can enter the system into debug mode by the cross trigger system. Two of the GPU signals are input to ETC: GPU error interrupt and GPU end of frame. Those signals can trigger the system to enter debug mode.

8.9 Supported Tools

The i.MX51 supports RealView™ ARM Debugger, the debugger should be connect to i.MX51 from host by RealView ICE protocol converter.

8.10 Interrupt Visibility

Similar to debug visibility, the i.MX51 includes multiplexors that allow users to view selected internal interrupts. Up to five pads support this as alternate BGA contact output functions, allowing the user to view up to five different interrupt sources simultaneously. These five signals also route to ECT inputs, allowing them to generate ECT trigger events as desired.

8.11 Miscellaneous

This section discusses the SOC-level bus trace and clock/reset/power block interactions.

8.11.1 SOC-level Bus Trace

There is no SOC-level bus trace capability on i.MX51

8.11.2 Clock/Reset/Power

The interactions between the debug system and the system clock, reset, and power control blocks include enhancements to insure that status of critical system components can be monitored at all times and that a debugger can insure that all critical clocks and power are enabled when needed. Specifically, a master signal coming from an SJC control bit and going to the Clock/PLL logic is implemented for each major clock domain. The same is done for each power domain. Historically, JTAG based operations have not been possible under certain system conditions. For the i.MX51, the debugger must have the ability to determine the status of all critical system elements and to override any condition that would prevent the desired debug resources from operating properly.

Chapter 9
System Boot

9.1 Introduction

The i.MX51 allows the user to configure a wide variety of boot configurations for both engineering development and production. The boot ROM logic supports features such as booting from various external memory devices, support for downloading code through a serial downloader, boot device configuration, and secure boot. This chapter describes how the boot process works and how to program it.

The boot process begins at Power On Reset (POR). The boot ROM logic reads hardware inputs such as the boot pins on the IC, eFUSEs, and/or GPIO settings to determine the boot flow behavior of the i.MX51.

The default out-of-reset boot sequence is a High Assurance Boot (HAB) secure boot environment. The HAB is a combination of hardware and software combined with a PKI (Public Key Infrastructure) protocol to protect the system from executing unauthorized images or programs. Before the HAB allows the user's boot code to execute, the code must be signed by the private key holder, which is then compared with the public key on i.MX51. The HAB library in the i.MX51 boot ROM also provides a number of API functions allowing the user to authenticate any defined region and signature at run-time.

For non-secure operations and testing, the i.MX51 also allows the HAB to be bypassed while reading the internal ROM or using a direct external boot allowing the processor to boot directly from external memory, as done by traditional microprocessors.

The boot ROM logic also allows the downloading of and the ability to flash new ROM code via a serial connection. Typically, the serial downloader application is downloaded to internal RAM, which facilitates the ROM Flash programming. The download uses either a high-speed USB in nonstream mode or a UART connection.

The boot capabilities can differ substantially depending on the HAB type security configuration being employed and the other boot configuration settings.

The i.MX51 supports two general configuration environments. Full boot flexibility is supported in the development (or engineering) configuration but in the production (or secure) configuration significant limitations on the boot process exist. The remainder of this chapter provides the details about how to configure and use the boot features of the i.MX51.

9.2 Boot Module Activation

The i.MX51 boot logic affects up to 17 different hardware modules, which are activated and play a vital role in the boot flow. The processor configures and uses the following modules (listed in alphabetical order) during the boot process:

- CCM—Clock Control Module

- CSU—Central Security Unit. The Security Control Registers (SCR) of the CSU are set during boot time by the High Assurance Boot (HAB) code and are locked to prevent further writing.
- eCSPI—enhanced Configurable Serial Peripheral Interface
- EMI[1] (WEIM/NFC/ESDCTL)—External Memory Interface
- eSDHC—enhanced Secure Digital Host Controller
- HS-I^{2}C—High Speed Inter IC
- I^{2}C—Inter IC
- IIM—IC Identification Module. The IIM contains the eFUSEs.
- IOMUX—I/O Multiplexor allows using the GPIO to override eFUSE boot settings.
- PLL—Phase Locked Loop. Also called Digital Phase Locked Loop (DPLL)
- RTIC—Run Time Integrity Checker. The RTIC's purpose is to ensure the integrity of the peripheral memory contents, protect against unauthorized external memory elements replacement, and assist with boot authentication.
- SAHARA—Symmetric/Asymmetric Hash And Random Accelerator
- SCC—Security Controller
- SRC—System Reset Controller. The SRTC incorporates a special System State Retention Register (SSRR) that stores system parameters during system shutdown modes including the value of the BMOD pins
- SRTC—Secure Real Time Clock
- UART and USB—used for serial download of new ROM code to Flash the Boot ROM
- WDOG—Watchdog Timer

1. Only used for booting from an external memory device using the WEIM, NFC, or eSDCTL.

9.3 Internal ROM /RAM Memory Map

Figure 9-1 shows the internal ROM/RAM memory map.

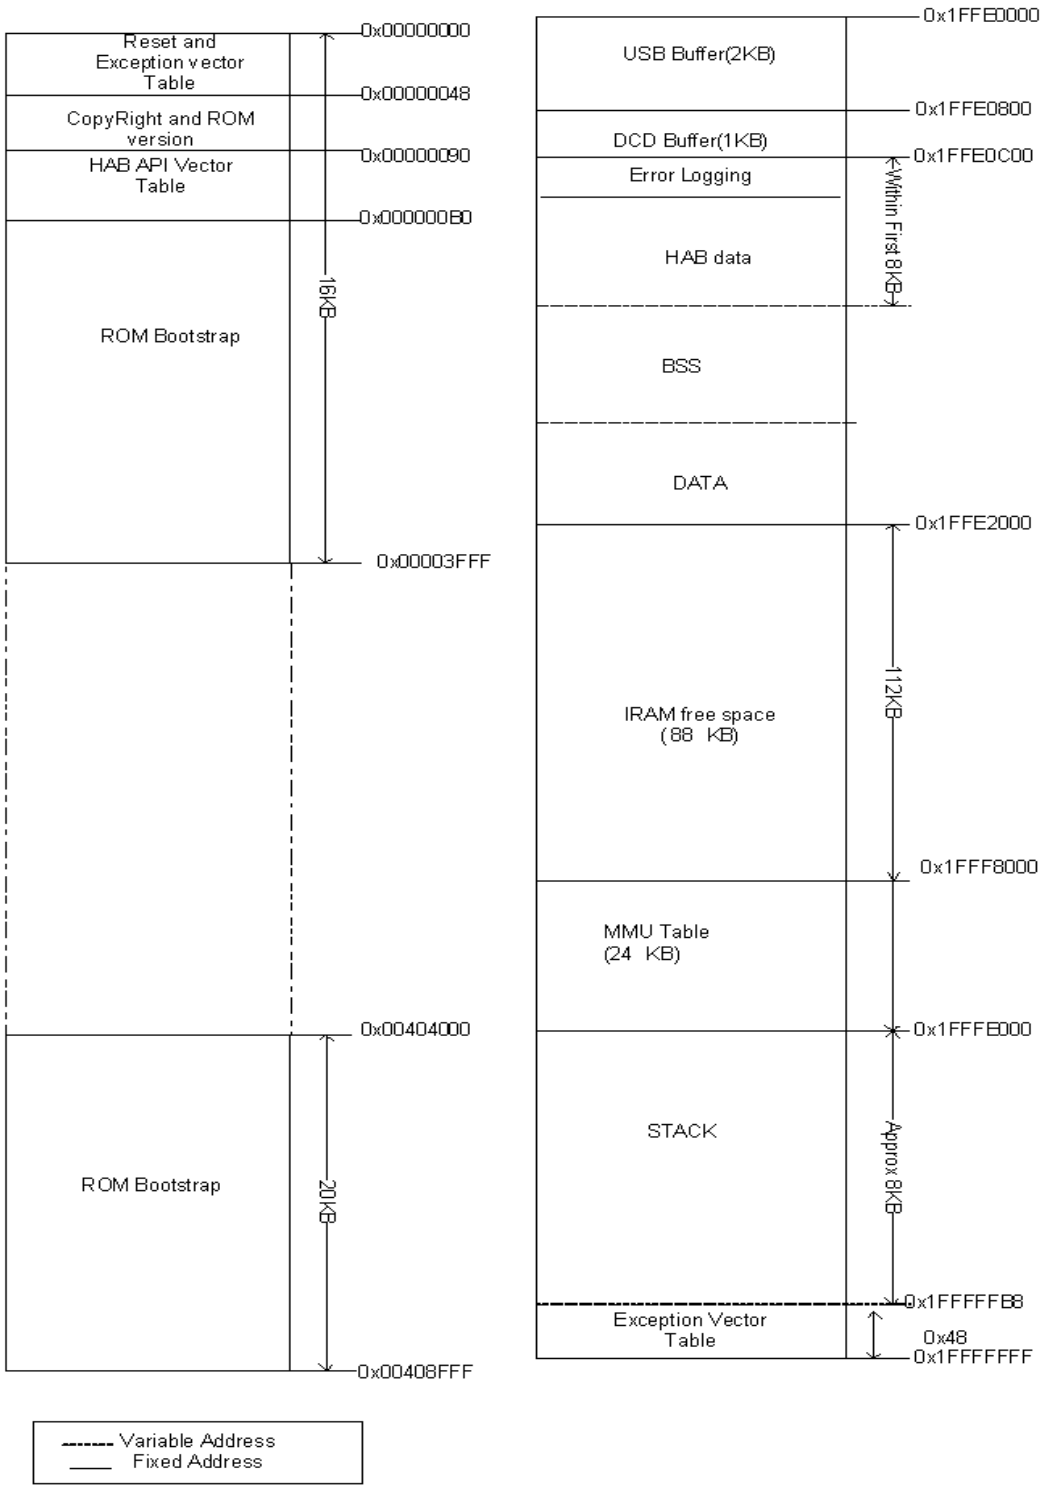

Figure 9-1. Internal ROM and RAM Memory Map

9.4 Boot Modes

The i.MX51 has four boot modes (one is reserved for internal use) that are selected by the two boot mode contacts on the IC package (BOOT_MODE0/1]). The settings of these two contacts are sampled upon exit of reset and stored in the BMOD[1:0] field of the SRC Boot Mode Register (SBMR) register in the SRC (System Reset Controller) module. Connecting the Boot Mode contacts to GND reads as a logic 0. For logic 1, Freescale recommends tying the contact to NVCC_PER3

The boot modes are: internal, internal boot with fuses, and serial boot via USB/UART. Refer to Table 9-1 for settings.

Table 9-1. Boot Mode Contact Settings

BMOD[1:0]	Boot Type
00	Internal Boot
01	Reserved
10	Internal Boot – ROM Select
11	Serial Downloader

9.4.1 Internal Boot (BMODE = 00)

Internal boot mode is selected by a value of ‘00’ on the BMOD[1:0] pins, at device power up. In this mode the processor boots from internal ROM. The boot code performs HW initialization, application image validation using the HAB library, and then jumps to an address derived from the application image. If any error occurs during internal boot the boot code jumps to the serial downloader. Internal boot mode is the only mode in which a secure boot of the i.MX51 is possible.

When set to Internal Boot (BMOD[1:0] = 00) the boot flow is controlled by a combination of eFUSE settings with the option of overriding the fuse setting using GPIO. The selection between these two boot modes is controlled by the GPIO Boot Select (GPIO_BT_SEL) fuse.

- If the GPIO_BT_SEL fuse is blown, all boot options are controlled by the eFUSEs described in Table 9-2 on page 9-5. The boot ROM software may read the value of BMOD[1:0] in theSBMR, or read the eFUSEs directly via the IIM module.
- If the GPIO_BT_SEL fuse is intact, the boot options are determined by the settings of the SBMR register. Some fuse options can be overridden in this mode. The fuses that can be overridden in GPIO mode are indicated by a YES in the GPIO column. See Table 9-4 on page 9-10 for details about the boot GPIO pins. In this mode the options’ values can only be read from the SBMR register.

The use of GPIO overrides is intended for development board work because those pads are used for other purposes in normal mode. Freescale recommends controlling the boot configuration by eFUSEs (GPIO_BT_SEL fuse blown) for deployed products and reserve the use of the GPIO mode (GPIO_BT_SEL fuse intact) for testing purposes. On production board GPIOs are not required—the customer can burn the fuses and not use the GPIO signals.

9.4.2 Internal Boot—ROM Select (BMODE = 10)

Internal boot (from only boot fuses) is selected by driving value of ‘10’ on the BOOT_MODE[1:0] pins, at device power up. This mode is equivalent to the Internal boot BOOT_MODE[1:0] = 00, with the only difference being that GPIO boot override pins are ignored, regardless of the BT_GPIO_SEL setting. The boot program only uses the boot eFUSE settings. This allows the user to burn fuses on the closed production device, with no external muxes on BOOT_MODE, pull ups/pull downs, and with no uncertainty that the serial downloader will be invoked by unknown boot pin values during the initial boot of the product device.

If set to Internal Boot ROM Select, the boot flow can be redirected if the BT_BLANK fuse is not blown (indicating that the ROM has not yet been programmed). This causes the boot flow to jump to the serial downloader. If the BT_BLANK fuse is blown the boot flow is normal and controlled by the eFUSE settings.

The first time a boad is used, when no fuses have been burnt yet, the device connected to BT GPIO pads can drive some values that will be incorrectly interpreted by ROM code. In such case the ROM code may try performing boot from not existing device. This may cause electrical/logic violation on some pads. Internal Mode—ROM Select (BMOD = 10) solves this problem. The first time the BT_BLANK fuse is encountered it is not burnt and therefore the ROM code jumps to the serial downloader. The next time BT_BLANK is burnt and therefore ROM code will perform internal boot according to the fuse settings.

The user can set BOOT_MODE[1:0] = 10 on a production device and burn fuses on the same device (by falling back to serial downloader), without changing value of BOOT_MODE[1:0] or pull ups/pull downs on the boot pins.

For cleaner jumping to serial downloader during initial fuse burning, the BT_BLANK fuse was introduced. If BOOT_MODE[1:0] = 10 and BT_BLANK = 0, then the ROM code jumps directly to the serial downloader, without trying other interfaces. BT_BLANK is designed to be blown by the user during initial fuse burning.

Table 9-2 shows the boot eFUSE descriptions.

Table 9-2. Boot eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Settings[2]
DIR_BT_DIS	OEM	Direct External Memory Boot Disabled	NA	0 Direct boot to external memory is allowed 1 Direct boot to external memory is not allowed
BT_MEM_CTL[1:0]	OEM	Boot Memory Control Type used to select one of the following: • EIM (NOR, OneNAND) • NAND flash • Expansion devices such as SD/MMC or EEPROM.	Yes	00 WEIM 01 NAND Flash 10 Reserved 11 Expansion Device (SD/MMC, support high storage, EEPROMs. The fuse BT_MEM_TYPE[1:0] defines Expansion Device settings.

Table 9-2. Boot eFUSE Descriptions (continued)

Fuse	Config	Definition	GPIO[1]	Settings[2]
BT_PAGE_SIZE[1:0]	OEM	NAND Flash Page Size. This field is used in conjunction with the BT_MEM_CTL[1:0] setting to set page size of NAND flash device.[3] **Note:** BT_MEM_CTL must be set to NAND Flash for these settings to be used.	Yes	00 512 bytes 01 2 Kbytes 10 4 Kbytes 11 Reserved
BT_SPARE_SIZE	OEM	Specifies the size of spare bytes for 4Kbyte page size NAND Flash devices. **Note:** The spare size setting is only applicable when used with 4Kbyte page size devices. This fuse can also be used as a “fast boot” mode indication for use with eSD 2.10 protocol devices.	Yes	0 128 bytes spare (Samsung) 1 218 bytes spare (Micron, Toshiba) If the bootable device is SD then: 0 “FAST_BOOT” bit 29 in ACMD41 argument is 0 1 “FAST_BOOT” bit 29 in ACMD41 argument is 1
BT_BUS_WIDTH[1:0]	OEM	NAND/NOR Bus Width. **Note:** OneNAND devices can only use a 16-bit bus width,	Yes	BT_MEM_CTL[1:0] = NAND Flash 00 8-bit 01 16-bit BT_MEM_CTL[1:0] = WEIM (NOR) 00 16-bit data bus 01 32-bit data bus BT_MEM_CTL[1:0] = Expansion Device (SPI) 00 2-Address word SPI device (16-bit) 01 3-Address word SPI device (24-bit)
BT_MEM_TYPE[1:0]	OEM	Boot Memory Type. Selects memory card options. Available settings are defined by the memory type selected using **BT_MEM_CTL**	Yes	BT_MEM_CTL = 00 (WEIM) 00 NOR 01 Reserved 10 OneNand 11 Reserved BT_MEM_CTL = 01 (NAND Flash) 00 3 address cycles 01 4 address cycles 10 5 address cycles 11 reserved BT_MEM_CTL = 11 (Expansion Card) 00 SD/MMC/eMMC/eSD 01 Reserved 10 Serial ROM via I^2C 11 Serial ROM via SPI

SRTC_SECMODE[1:0]	OEM	Security Mode for Secure RTC. Determines the level of security of the Secure Real Time Clock (SRTC) module	No	00 Low Security 01 Medium Security 10 High Security 11 Reserved
BT_LPB_FREQ[2:0]	OEM	Low-Power Boot Mode (LPBM) ARM core frequency.	Yes	000 192 MHz (Default - out of reset), 001 133 Mhz 010 55.33 MHz 011 200 MHz 100 220 MHz 101 166 MHz 110 266 MHz 111 Normal boot frequency (400 MHz)
BT_BLANK	OEM	Indicates that the boot area has not yet been burned. **Note:** This fuse is only read when BOOT_MODE[1:0]=10	No	0 BOOT area is unprogrammed. Boot flow jumps to serial downloader. 1 BOOT area is programmed. Regular boot flow is performed.

Table 9-2. Boot eFUSE Descriptions (continued)

Fuse	Config	Definition	GPIO[1]	Settings[2]
MMU_EN	OEM	MMU/d-cache enable bit used by boot ROM for fast HAB processing	No	0 MMU/d-cache is disabled by ROM during the boot 1 MMU/d-cache is enabled by ROM during the boot
BT_LPB[1:0]	OEM	Options for Low-Power Boot Mode (LPBM).	No	00 LPBM disabled 01 Generic PMIC and one GPIO input (Low battery) 10 Generic PMIC and two GPIO inputs (Low battery and Charger detect) 11 Atlas AP Power Management IC.

1 Setting can be overridden by GPIO settings when GPIO_BT_SEL fuse is intact. See Table 9-4 for corresponding GPIO pin.

2 0 = intact fuse and 1= blown fuse

3 The Page-Per-Block settings may not always exhibit a “one to one” relationship to the block size; however, most devices exhibit the relationships listed in Table 9-3:

4 eMMC4.3 fastboot is supported

Table 9-3. Page-Per-Block Relationships

Page Size	Page-per-Block
512 Bytes	32
2 Kbytes SLC	64
2 Kbytes MLC	128
4 Kbytes	128

9.4.2.1 GPIO Boot Overrides

Table 9-4 on page 9-10 provides a listing of GPIO boot overrides. These input pins are sampled at boot and can be used to override corresponding fuse values, depending on the setting of the GPIO_BT_SEL fuse. The boot GPIO override options are only in effect when GPIO_BT_SEL is ‘0’ (intact fuse) and BOOTM[1:] = 10.

Table 9-4. GPIO Override Contact Assignments

Contact	eFUSE	Details
DISP1_DAT[21:20]	BT_MEM_TYPE[1:0]	GPIO Boot pin overrides fuse settings if the following conditions apply: • Internal Boot mode (BMODE[0:1]=00) • GPIO_BT_SEL = 0
DISP1_DAT[19:18]	BT_WEIM_MUXED[1:0]	
DISP1_DAT[17:16]	BT_PAGE_SIZE[1:0]	
DISP1_DAT[15]	BT_BUS_WIDTH	
DISP1_DAT[14:13]	BT_MEM_CTL[1:0]

DISP1_DAT[11,23,22]	BT_LPB_FREQ[2:0]	
DISP1_DAT[10]	BT_SPARE_SIZE	
DISP1_DAT[9:8]	BT_SRC[1:0]	
DISP1_DAT[7]	BT_EEPROM_CFG	
DISP1_DAT[6]	BT_USB_SRC	
EIM_A[23]	BT_HPN_EN	
EIM_A[21:20]	BT_UART_SRC[1:0]	
EIM_A[19:18]	BT_LPB[1:0]	
EIM_A[17:16]	OSC_FREQ_SEL[1:0]	

9.4.3 Serial Downloader (BMOD[1:0] = 11)

The serial downloader is invoked if the external Flash device is not programmed, when a failure is encountered during the boot flow process or any of the following conditions are met:

- BMOD[1:0] = 11 (serial downloader mode)
- BMOD[1:0] = 10 (internal boot with fuses) and the eFUSE BT_BLANK = 0
- BMOD[1:0] = 10 (internal boot with fuses) but the fuses are not set properly.
- BMOD[1:0] = 00 or 10 (internal or internal boot with fuses) and there is not a valid image in the Flash device
- Security hardware failure
- Runtime exception occurs
- Error returned by the HAB functions while in production mode. Errors are ignored in engineering mode)

To determine the active serial port, either UART or USB, the processor ROM program polls the UART and USB status register for approximately 32 seconds. If there is no activity on either port within the predefined polling time, the ROM program powers down the IC using WDOG. When the serial downloader is active, the WDOG is serviced periodically. If the communication between the serial host

and the i.MX51 hangs for more than 32 seconds or the processor enters an endless loop, the WDOG expires and powers down the device.

NOTE

For detailed information about the boot module contact your Freescale representative.

Chapter 10
Multimedia

10.1 Video Subsystem

The video subsystem includes the following dedicated modules:

- Video Processing Unit (VPU): a multi-standard video
- Image Processing Unit (IPU): providing connectivity to displays, related processing, synchronization, and control
- TV encoder (TVE) bridge: providing optional translation from the digital display interface supported by the IPU to SDTV analog and some HDTV interfaces

These modules are connected to the other parts of the system as follows:

- IPU has two display ports, used to connect to relevant external devices.
- The VPU and IPU have a master AXI port, providing access to system memory. The IPU provides different IDs for accesses related to real-time and non-real-time flows (real-time flows being screen refresh) to allow allocating a higher priority to the real-time flows, reducing the risk of their starvation.
- All modules have a host interface, used to configure and control them (by the ARM MCU or the SDMA). For the VPU and the TVE, this is a slave IP port. For the IPU, this is a slave AHB port.
- The slave AHB port of the IPU also provides direct access from the ARM MCU and SDMA to an external display controller or graphics accelerator, connected to the display port.

10.1.1 Image Processing Unit (IPU)

Table 10-1 shows the IPU IP parametric table.

Table 10-1. IPU IP Parametric Table

Name	IPU
Function	Connectivity to displays; related processing; synchronization and control
External I/O Pins Notes: This is the pinout of the IPU module At chip level, some of the pins are muxed and some are omitted. Additional GPIO pins are required to construct the connection. This is not included in this list.	Parallel Display port: 32 bit data, ~18 clocks and controls. Regular CMOS IO type, 133 MHz max. May be also connected to the TVE internal connectivity bridge.

Table 10-1. IPU IP Parametric Table (continued)

Name	IPU
SoC Buses	AXI master—for accessing the memory AHB slave—for programming, control and direct access of the MCU to the display
Interrupts	Two interrupts: functional and error
DMA Requests	Includes an integral DMA controller, with an AXI master port Also one DMA request to the SDMA
Number of instantiations	1
Clock sources and range	HSP_CLK—Internal high-speed processing clock: up to 133 MHz DI_CLK—Display interface clock: up to 80 MHz

The goal of the IPU is to provide comprehensive support for the flow of data to a display device. This support covers all aspects of these activities:

- Connectivity to relevant devices—displays, graphics accelerators, TV encoders
- Related image processing and manipulation: image enhancements and conversions, etc.
- Synchronization and control capabilities (for example, to avoid tearing artifacts)

This integrative approach leads to several significant advantages:

- Automation
  The involvement of the MCU (Main Control Unit) in image management is minimized. In particular, display refresh/update can be performed completely autonomously. The resulting benefits are reducing the overhead due to software-hardware synchronization, freeing the MCU to perform other tasks and reduced power consumption (when the MCU is idle and can be powered down).
- Optimal data path
  Access to system memory is minimized. In particular, significant processing can be performed on-the-fly while sending data to a display. System memory is used essentially only when a change in pixel order or frame rate is needed. The resulting benefits are reduced load on the system bus and further reduction of power consumption.
- Resource sharing
  Maximal hardware reuse for different applications, resulting with the support of a wide range of requirements with minimal hardware

The hardware reuse mentioned above is enabled by a sophisticated configurability of each hardware block. This configurability also allows the support of a wide range of external devices, data formats and operation modes. The resulting flexibility is important because the support requirements are evolving significantly; expected future changes need to be anticipated and accounted for.

10.1.1.1 External Ports

The IPU has the following ports:

- Two display ports—each controlled by a DI module—providing a connection to displays and related devices.
- Memory port—AXI (AHB V3.0) master, controlled by the IDMAC—providing connection to the system memory.
- AHB-lite slave port, providing connection to the ARM MCU (and to any other master connected to the ARM's cross-bar switch)
- Additional ports for control and debug

10.1.1.1.1 Display Ports

The role of these ports is to communicate with a display device, either directly or through a controller (for example, graphics accelerator) or a bridge (for example, TV encoder).

Two access modes are supported: synchronous access and asynchronous access.

In synchronous access mode, the IPU transfers a two-dimensional block of pixels to the display device, in synchronization with the screen refresh cycle.

This mode has a dual role:

- For a RAM-less display or a TV screen, this mode is used to perform the screen refresh process from a display buffer in system memory.
- For a "smart" display, this mode is used to transfer a rectangular block of pixels to the display's screen and, in some cases, also to the display buffer

In both cases, the IPU sends to the display all the synchronization signals controlling the screen refresh and the block transfer is synchronized with these signals. This synchronization means that tearing effects are avoided when using this mode.

Asynchronous access is the main mode used for communicating with an external display controller (possibly in a smart display or a graphics accelerator). In this mode, the IPU performs random access—read/write—to the memory and registers of controller.

The following access types are provided:

- Data transfer to the external device, after on-the-fly processing in the IPU.
- Data transfer (DMA)—read/write—between the host's system memory and the external device, through the IPU's memory port (controlled by the IDMAC); for example, transfer of a rectangular block of pixels (possibly full screen).
- Host access—read/write—to an external device, through the AHB-slave port
  - Access types
    - Direct access—emulating a directly-addressed access (see below)
      This includes burst access (incremental; up to 8 words/burst)
    - Low-level access—leaving to the host the explicit generation of the access protocol

— The possible accessing modules include the MCU and the system DMA controller (as well as any other AHB master connected to the MCU's cross-bar switch).

Asynchronous access requires the specification of an address. The display interface uses indirect addressing, meaning there is no address bus and the address, control commands, and configuration commands, are embedded in the data stream. The access procedure, including writing addresses and commands, can be managed autonomously by the interface, using an access template generated by the MCU.

10.1.1.1.2 The Interface

The display interface is very flexible and supports a wide variety of devices from major manufacturers. The following interface types are provided (in each of the two display ports).

- A parallel video interface (for synchronous access)—up to 24-bit data bus.
- A parallel bidirectional bus interface (for asynchronous access)—up to 32-bit data bus.

The supported formats for pixel data are: RGB and YUV 4:2:2 (for TV encoder).

The transfer rate supported is at least 100 MHz (for all interfaces)

- For synchronous access with one cycle/pixel, this enables, e.g (including 35% blocking intervals)
  - XGA (1024 × 768) at 100 fps
  - 720p (1280 × 720) at 60 fps
  - 1080i (1920 × 1080) at 30 fps
- When two (or more) display devices are used simultaneously, the total rate supported is as above.

Simultaneous functionality of the above devices is possible in each of the following ways:

- Two devices can be accessed independently, each through a different port.
- Two devices can time-share asynchronous accesses, using the CS signals.
- An asynchronous access can be performed during vertical blanking intervals of a synchronous access.

10.1.1.2 Processing

The IPU processes rectangular blocks of pixels. The processing is performed in modules: DP, IC, and IRT. Several time-shared data flows are supported, as described in Table 10-2.

Table 10-2. Time-Shared Data Flows Through The IPU

Name	Number	Type	Flow	Target	Restrictions
Display Refresh/ Update	5 flows (at most two of them of type DS1)	DS1	Fmem → DP → Display	Synchronous Access (for example, display refresh; controlled by the DI)	—
		DS2	Fmem → DP → Display	Asynchronous Access (for example, display update)	—
		DS3	Fmem ↔ Display	Generic Data Transfer	—
	1 flow	DS4	MCU ↔ Display	Direct Access	—

Table 10-2. Time-Shared Data Flows Through The IPU (continued)

Name	Number	Type	Flow	Target	Restrictions
Video Playback	flow	PL1	Bmem → IC → Bmem → IRT → Fmem + DSx	Main option	—
		PL2	Fmem → IRT→ Bmem → IC → DP	Low power (branching to DSx, as a video plane)	Large enough window No other video flows
Graphic Overlays	2 flows	GF1	Fmem → IC	(combining with the main flow)	—
	2 flows	GF2	Fmem → DP		—

Comments

- System memory usage–legend
  - — Fmem: frame double-buffer (page-flip) in system memory (typically external)
  - — Bmem: two possibilities
    - – A frame double buffer, as above
    - – A band (4–256 rows) double-buffer (page-flip) in system memory (could be internal)
  - — Direct arrow between two processing stages represents an internal pipelining
- Time-sharing
  - — DP can time-share one DS1 flow and a one DS2 flow (each with different destinations and independent processing parameters)
  - — Direct access to display (DS4) time-shares tightly the display port with other active DSx flows.
  - — Other time-sharing (between PLx, between DS2 and DS3, in IRT) is frame-by-frame

Any of the processing stages in the above flows can be skipped.

10.1.1.2.1 Display Processor (DP)

The display processor performs processing required for output to a display:

- Combining two video/graphics planes
- Overlaying a simple hardware cursor
  32×32 pixels, uniform color, may be combined logically with the background.
- Color conversion/correction—linear (multiplicative and additive)
  Programmable; including:
  - — YUV ↔ RGB, YUV ↔ YUV conversions
    where YUV stands for any one of the color formats defined in the MPEG-4 standard
  - — Adjustments: brightness, contrast, color saturation...
  - — Special effects: gray-scale, color inversion, sepia, blue-tone...
  - — Hue-preserving clipping, for gamut mapping
  - — Applied to the output of combining or to one of the inputs
- Gamma correction and contrast stretching—programmable piecewise-linear map

The DP processes a single data flow at any given time, but it supports up to three data flows, by time sharing, one of them may be synchronous.

The data throughput is up to 110M pixels/sec (peak; including blanking intervals)

10.1.1.2.2 Image Converter (IC)

The Image Converter performs various operations on a video stream. The operations performed are:

- Resizing
  - Fully flexible resizing ratio
    Maximal downsizing ratio: 8:1
    Subject to this limitation, any N→M resizing can be performed
  - Independent horizontal and vertical resizing ratios.
- Color conversion/correction - linear (multiplicative and additive)
  Programmable; including:
  - YUV ↔ RGB, YUV ↔ YUV conversions
    where YUV stands for any one of the color formats defined in the MPEG-4 standard
  - Adjustments: brightness, contrast, color saturation...
  - Special effects: gray-scale, color inversion, sepia, blue-tone
- Combining with a graphics plane (for example, application-specific overlay)
- Horizontal inversion

The IC supports three time-shared data flows share a common input).

The frame resolution supported is up to 4096 × 4096 for input and up to 1024 × 1024 for output. Wider frames can be processed by the IC by splitting them to vertical stripes.

The data throughput is up to 100 M pixels/sec for input and up to 50 M pixels/sec for output.

10.1.1.2.3 Image Rotator (IRT)

The Image Rotator performs any combination of the following:

- 90-degree rotation
- Horizontal inversion
- Vertical inversion

The data throughput is up to 50 M pixels/sec.

10.1.1.3 Automatic Procedures

The IPU is equipped with powerful control and synchronization capabilities to perform its tasks with minimal involvement of ARM and minimal use of memory. In particular, it includes the following:

- An integrated DMA controller with an AXI master port, allowing autonomous access to the system memory
- An integrated display controller, performing screen refresh of a RAM-less display.

- A page-flip double buffering mechanism, synchronizing read and write access to system memory, to prevent tearing effects.
- Internal synchronization

As a result, in most cases, the MCU is involved only when it also performs part of the processing (for example, video coding). In particular, the following procedures are performed by the IPU completely autonomously:

- Screen refresh for RAM-less displays
- Update of the (foreground) display buffer used for screen refresh (located either in system memory or in an external display controller, for example, of a smart display or graphics accelerator) when the content is generated in a different (background) buffer.

Typically, there are extended periods of time in which there is no other activity in the system. The MCU being idle can be put into a low-power mode, reducing the power consumption and significantly extending the battery life.

The IPU supports the following techniques that further reduce the power consumption of the display system:

- Optimized update of the display buffer, using a snooping signal from the ISM (IPU Snooping Module), indicating a modification of the source buffer.
- Dynamic backlight control, with low-light compensation by image enhancement (contrast and brightness adjustment)

Further features and capabilities of the automatic procedures include the following:

- Automatic display of a changing image (animation) or moving image (scrolling).
- The timing of the display update can be adjusted to avoid tearing.

The IPUE supports direct frame synchronization with the GPU, using either two or three frames, as follows:

- The GPU instructs the IPU which frame should be transferred to the display.
- The IPU notifies the GPU which frame is currently transferred to the display.
- The IPU provides to the GPU an end-of-frame trigger (after which it switches to the frame indicated by the GPU).

This mechanism is provided for the main plane of the primary flow to the DP.

The clock sources received by the IPU are listed in Table 10-3.

Table 10-3. IPU Clock Sources

Name	Symbol	Source	Rate	Comments
High-Speed Processing Clock	HSP_CLK	Clock control Module	Up to 133 MHz	—
Display Interface Clock	DI_CLK	Clock control Module or an external PLL	up to 80 MHz	Optional For example, for synchronization with a TV encoder

10.2 Video Processing Unit (VPU)

The VPU is a multistandard video codec (encoder/decoder) capable of handling up to four simultaneous multiple streams using time multiplexing. The VPU is a very flexible block consisting of hardwired accelerators surrounding a programmable core. The VPU presents to system a register mapped interface that is controlled by the embedded processor. Because this interface can be updated by the firmware, it is not documented in this document. Instead, the designer should consult the documentation released with the firmware used. End users should only interface with the VPU using the API that is also released with each firmware release. This API isolates the user from possible changes in the register level interface.

Table 10-4 shows a summary of the VPU specs. The VPU has its own DMA driven AXI masters that allow it to retrieve the required data directly from system memory. The load in the host is negligible because it only needs to interact with the VPU at the frame level.

Table 10-4. A Brief Summary of VPU Specification

Name	VPU
Function	Decode video streams including optional video processing such as rotation, deringing and mirroring.
Supported encoders	MPEG-4 SP H.263 V2 + Annex J, K (RS = 0 and ASO = 0), and T H.264 BP MJPEG Baseline
Supported decoders	MPEG-2 MP VC-1 SP, MP, HP MPEG-4 SP, ASP H.263 V2 + Annex J, K (RS = 0 and ASO = 0), and T H.264 BP, MP, HP DivX v3,4,5 Real Video 10 MJPEG Baseline
External I/O Pins (List, Type, Schmidt Trigger, Speed)	No external I/O pins are needed
SoC Buses (List, Type, Bandwidth)	64 bit AXI master for accessing the system memory and search RAM IPBus slave for host control
Interrupts	one interrupt
DMA Requests	Integrated DMA controller on the AXI master port
Endianness	64 and 32 bit BE/LE
Number of instantiations	1
Clock sources and range	Core clock: up to 133 MHz AXI bus clock: up to 166 MHz IP bus clock: up to 66.5 MHz

Chapter 11
Power Management

The i.MX51 supports several power management techniques to reduce active and static power consumption. This chapter describes the operation of these features and the registers used to configure and control them.

11.1 Power Saving Methodology

This section discusses active power savings and leakage power savings.

11.1.1 Active Power Savings

Active power saving methods include the following:

- Dynamic voltage frequency scaling (DVFS)

  This reduces active power consumption by scaling voltage and frequency. There are two DVFS engines in the i.MX51: one is used by the peripherals and the other by the ARM platform.
- Dynamic process temperature compensation (DPTC)

  This reduces active power consumption by adjusting supply voltage according to the individual device's characteristics and ambient temperature. There are two DPTC engines: one is used by the peripherals and the other by the ARM platform.
- Clock gating

  This reduces active power consumption by gating the clock to each module while the module is in idle state. The i.MX51 implements three levels of clock gating as follows:
  - Clock tree roots in the Clock Control Module (CCM)
  - Clock tree branches in the Low Power Clock Gating unit (LPCG)
  - Clock tree leaf nodes in the individual modules

11.1.2 Controlling Leakage

The primary leakage control mechanisms are reduced voltage (STOP mode) and power gating. There are three types of power gating, as follows:

- State retention power gating (SRPG)
- Power gating (PG)
- PG with Save and Restore

The three types of power gating work in the following ways. When SRPG is applied, the state of the flip flops is preserved to internal switch cells (powered by a continuously powered supply) at the time the combinatorial logic between the flip flops is powered down. Using PG removes power from the selected

module, resulting in the loss of all data in three affected modules: the VPU, GPU2D, and GPU3D. When PG with Save and Restore is used, the state of the block is saved into its constantly powered memory before the power to the block is removed. Once power is reapplied, the state of the block is reloaded from memory, and the block continues in the same state as it was in before it was powered down. This type of power gating is accomplished by hardware in the IC. IPUEX supports PG with Save and Restore.

11.2 Power Gating Sequences

The following order is recommended when powering up the modules in the i.MX51:

1. SoG—After the SoG has powered up, move to the next power-up stage.
2. IPUEX—After the IPUEX has powered up, move to the next power-up stage.
3. VPU—After the VPU has powered up, move to the next power-up stage.
4. GPU3D—After the GPU3D has powered up, move to the next power-up stage.
5. GPU2D—After the GPU2D has powered up, move to the next power-up stage.
6. EMI—After the EMI has powered up, an acknowledgement the power-up is complete is generated.

11.2.1 Power Gating Options

The sequence of power gating is controlled by the Global Power Controller (GPC) modules on the i.MX51. The following power gating options exist:

- SRPG of the Cortex_A8 platform in WAIT mode.
- SRPG of the Cortex_A8 platform in STOP mode.
- SRPG of the NEON floating unit when it’s not needed, by software control.
- Partial SRPG of the EMI block during WAIT mode.
- Partial SRPG of the EMI block during STOP mode.
- Power gating of one or more of the following blocks during WAIT mode: VPU, GPU3D and GPU2D.
- Power gating of one or more of the following blocks during STOP mode: VPU, GPU3D and GPU2D.
- Power gating of one or more of the following blocks during RUN mode: VPU, GPU3D and GPU2D.
- Power gating with PG with Save and Restore of IPUEX during WAIT.
- Power gating with PG with Save and Restore of IPUEX during STOP.

11.3 Low-Power Modes

The i.MX51 can operate in several different low-power modes. Some low-power modes are module specific. The four low-power modes as follows:

- RUN

The ARM core is active; its clocks are on; and the peripheral modules needed for a specific task are active. Software is used to gate off clocks from modules that are not in use. The CCM can enable power gating of the modules described above.

- WAIT

  The ARM core is disabled; its clocks are gated off; and the bus clocks to peripherals are gated on as required. The power gating modes PG and SRPG can be applied to Cortex_A8 and the different blocks as described in Chapter 7, "Clock Controller Module (CCM)," Section 11.4, Module Specific Power Modes."

- STOP

  The ARM core is disabled; peripherals are disabled; bus clocks are off; and clock PLLs are off. The power gating modes PG and SRPG can be applied to Cortex_A8 and the different blocks as described in Chapter 7, "Clock Controller Module (CCM)," Section 11.4, Module Specific Power Modes."

- LPSR—Low Power Screen Refresh

  This is a subset of the STOP mode. The ARM core is disabled; all peripherals but the ones needed for LPSR are disabled; and clock PLLs are off. PG and SRPG can be applied to the Cortex_A8 and the peripherals that are not needed for LPSR. In this mode, the clocks are supplied by either FPM or CKIH. The peripherals that are required for LPSR mode are as follows:

  — IPU EX

  — EMI—only the internal memory arbitration is needed.

  — SCC and its internal memory

  — All translators between the EMI to the SCC.

11.4 Module Specific Power Modes

The power modes of the individual modules are as follows:

- Active—Operational with clocks on.
- Idle—Not operational but the clocks are on.
- Disabled—Not operational and the clocks are off.

The module modes can be mapped onto the domain modes as shown in Table 11-1

Table 11-1. Low-Power Modes

Mode	ARM Platform	Modules	PLL	CKIH/FPM	CKIL
RUN	Active	Active, Idle, or Disabled[1]	On	On	On
WAIT	Disabled	Active, Idle, or Disabled[1]	On	On	On
STOP	Disabled	Disabled[2]	Off	Off	On
LPSR	Disabled	Disabled[3]	Off	On	On[4]

1 During RUN and WAIT modes, the peripherals can be active, but not all must be active. The modules that are not needed can be Idle or Disabled in the RUN and WAIT modes.

2 Some modules can operate using CKIL in STOP mode.

[3] Some blocks need to operate using CKIH or FPM in LPSR mode.

[4] If the FPM is selected then CKIL needs to be left on.

11.4.1 Power Down Sequence

The power-down sequence is as follows:

1. The software configures the LPM bits in the CCM (see CCM chapter) as well as the power gate bits in the GPC. The information (if a peripheral or the ARM platform can be power gated) is stored in the GPC module.
2. The ARM platform starts the LPM sequence, resulting in the CCM raising a power-down request for ARM and the peripherals.
3. The power-down sequence occurs in parallel on all peripherals and the ARM platform.
4. A combined power-down acknowledge signal is issued to the CCM from the GPC module.

11.4.2 Power Up Sequence

The power-up sequence is as follows:

1. After an interrupt is received and the clocks resume operation, a power-up request signal is issued from the CCM to the GPC.
2. The power-up of the ARM core and the other peripherals occur in parallel.
3. The power-up of the peripherals is done one after the other in order to prevent excessive current drain during the power up.
4. The power-up request of the CCM module is connected to the power-up request of the first PGC block and its power-up acknowledge is connected to the power-up request of the next PGC blocks.
5. Each of the PGC modules sends a reset request to the SRC module. This initiates the reset sequence to the needed module as described in the SRC chapter.

11.4.3 IPU Save and Restore Sequence

The IPU save and restore sequence is as follows:

1. If the power gating bit of the IPU EX is selected, a signal (gpc_ipu_stat_pg) stating that IPU EX will be power gated in the next LPM is sent to the IPU EX.
2. In the process of entering low power mode, the IPU EX needs to approve the entrance to LPM (refer to the CCM chapter). If it sees the gpc_ipu_stat_pg, it goes through the process of Save in the IPU EX memories so that their arrays will always be powered. Only after the Save is complete does it return an acknowledge of the power-down to the CCM. The CCM then continues the LPM sequence.
3. In the process of exiting low-power mode, the IPU EX checks to see if the gpc_ipu_pg_event signal is active (meaning a power gate has occurred). Then the IPU EX restores all the required data from the memories.
4. The IPU EX sends a signal called ipu_stby_ack indicating it has completed the process. This signal clears the gpc_ipu_pg_event signal in the GPC.

11.5 RAM Memory Supplies

Refer to the Operating Ranges table in the i.MX51 data sheet.

11.6 Fusebox Supplies

Refer to the Operating Ranges table in the i.MX51 data sheet.

11.7 Dynamic Voltage and Frequency Scaling

The i.MX51 uses DVFS as one of its active power saving methodologies. The ARM core (VDDGP) and peripheral core (VCC) supply voltage ranges are stated in the Operating Ranges table of the i.MX51 data sheet.

DVFS is supported on both the ARM platform and the peripherals using the following two different load monitors:

- DVFS_Core
  - Monitors by weighing signals relevant to the ARM platform
  - Affects only the ARM platform.
- DVFS_Per
  - Monitors by weighing signal relevant to the i.MX51 peripherals
  - Affects only the peripherals.
  - While in DVFS mode each clock is divided by 2, 3, or 4 across all of the peripheral domain, depending on the configuration in the CCM.

Chapter 12
System Security

12.1 Introduction

Security is an increasingly important feature of handheld devices such as cell phones, ultra-portable computers, and integrated media players. Instances of hackers and pirates breaking into portable devices and stealing private information or copyrighted content are becoming more and more common. As such, security is a high priority for the i.MX51.

To address the potential security risks and to provide an extensible platform for addressing future security needs, the i.MX51 incorporates the following advanced hardware blocks and architectural features:

- High Assurance Boot (HAB) System
- Memory Management Unit (MMU)
- Trusted Execution Environment (ARM's TrustZone, Virtualization)
- TrustZone Interrupt Controller (TZIC) and TrustZone Watchdog (TZ WDOG)
- EMI WaterMark (WM) mechanism
- Central Security Unit (CSU)
- IC Identification Module (IIM) with On-chip One Time Programmable Electrical Fuse Array
- Security Controller (SCC) with 128KByte of secure RAM
- Cryptographic Accelerator (SAHARA4LT)
- Run-Time Integrity Checker (RTIC)
- Secure JTAG Controller (SJC)
- Secure Real Time Clock (SRTC)
- Physical Tamper Detectors
- Security Services and Protocols

For detailed information about the operation of the security features, contact your Freescale representative.

Chapter 13
1-Wire Module (1-Wire)

13.1 Overview

The 1-Wire module provides the communication link to a generic 1-Kbit add-only memory. The module sends or receives one bit at a time. The required protocol for accessing the generic 1-Wire device is defined by Maxim. The generic 1-Wire device holds battery characteristics information.

Figure 13-2 shows a block diagram of the 1-Wire module.

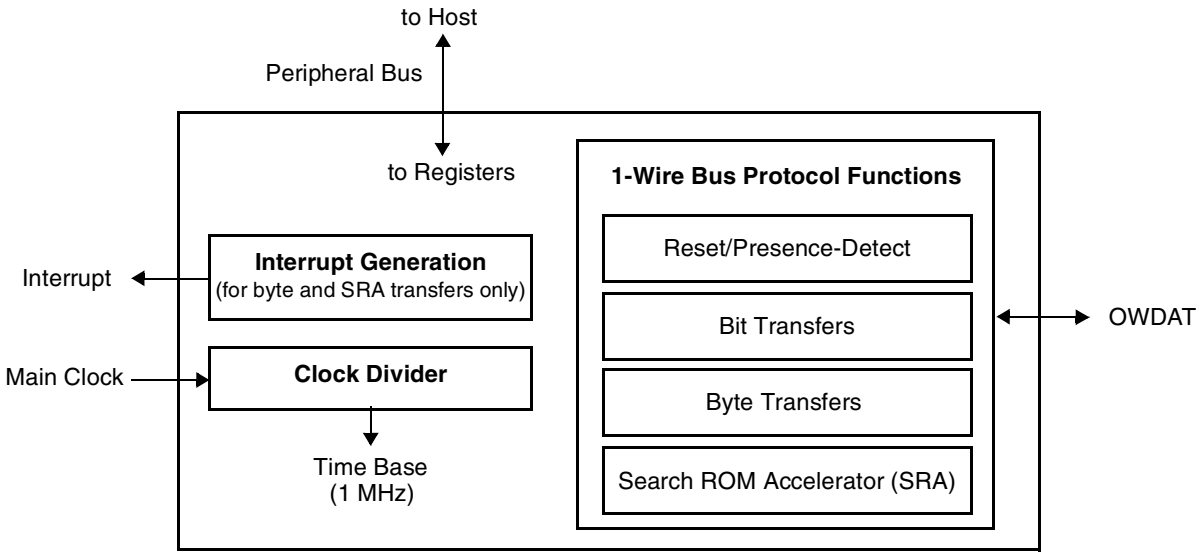

Figure 13-1. 1-Wire Module Block Diagram

13.1.1 Features

The 1-Wire module includes the following features:

- Performs the 1-Wire bus protocol to communicate with an external 1-Wire device.
- Provides a clock divider to generate a 1-Wire bus reference clock (derived from the main clock provided internally to the module).

13.1.2 Modes of Operation

The 1-Wire module supports the following operations:

- Normal Operating Modes (See Section 13.4.1, Normal Operating Modes")
  - — Bit Transfers
  - — Reset/Presence-detect Pulse
- Low-Power Mode (See Section 13.4.2, Low Power Mode")

13.2 External Signals

Table 13-1 shows the signal that interfaces with a generic 1-Wire device.

Table 13-1. 1-Wire Module Signal

Signal	I/O	Function
OWDAT	I/O	1-Wire bus Requires an external pull-up resistor. The recommended resistor value is specified by the generic 1-Wire device used in a given system.

13.3 Memory Map and Register Definition

This section provides the module memory map and detailed descriptions of all registers.

13.3.1 Memory Map

Table 13-2 shows the 1-Wire memory map.

Table 13-2. 1-Wire Memory Map

Base Address	Register	Access	Reset Value	Section/Page
0x83FA_4000 (CONTROL)	Control register	R/W	0x0000	13.3.2.1/13-2
0x83FA_4002 (TIME_DIVIDER)	Time Divider register	R/W	0x0000	13.3.2.2/13-4
0x83FA_4004 (RESET)	Reset register	R/W	0x0000	13.3.2.3/13-4

13.3.2 Register Descriptions

This section provides the detailed descriptions for the registers. All registers are byte-addressable.

13.3.2.1 Control Register (CONTROL)

The control register is used to initiate the reset/presence-detect sequence and bit transfers. The register also provides the presence-detect status and bit-read status.

Figure 13-2 shows the register. Table 13-3 describes the register fields.

Address 0x83FA_4000 (CONTROL) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 13-3. Control Register Field Descriptions

Field	Description
15–8	Reserved
7 RPP	Reset/Presence-detect Pulse. This bit is self-clearing and is cleared after the presence or absence of an external device is determined. See Section 13.4.1.1, Reset/Presence-detect Pulse." When writing: 0 Do nothing. 1 Generate Reset Pulse and sample the bus for the presence pulse from the external device. When reading: 0 Reset pulse complete. 1 Sequence not complete.
6 PST	Presence Status. This bit is valid after the RPP bit is self-cleared. 0 Device is not present. 1 Device is present.
5 WR0	Write 0. This bit is self-clearing and is cleared when the write of the bit is complete. See Section 13.4.1.2.1, Write-0 Sequence." When writing: 0 Do nothing. 1 Write a 0 bit to the interface. When reading: 0 Write sequence complete. 1 Sequence not complete.
4 WR1	Write 1/Read. This bit is self-clearing and is cleared when the write sequence is complete. See Section 13.4.1.2.2, Write-1/Read Sequence." When writing: 0 Do nothing 1 Write a 1 bit to the interface and sample the bus. When reading: 0 Sequence complete. 1 Sequence not complete.
3 RDST	Read Status. This bit is valid after the WR1 bit is self cleared. 0 A 0 has been sampled. 1 A 1 has been sampled.
2–0	Reserved

13.3.2.2 Time Divider Register (TIME_DIVIDER)

The time divider register is used for dividing the main clock (ipg_clk) input down to 1 MHz to generate the module's time base.

Figure 13-3 shows the register. Table 13-4 describes the register fields.

Address 0x83FA_4002 (TIME_DIVIDER) Access: User read/write

Field	Description
15–1	Reserved
0 RST	Software Reset. See Section 13.4.4.2, Software Reset." 0 Do not perform a software reset. 1 Initiate a software reset and hold the module in the software-reset state.

13.4 Functional Description

The 1-Wire module interfaces with a generic 1-Kbit add-only memory, through a simple 1-bit bus. Software uses the 1-Wire bus to program and read the 1-Kbyte memory.

The protocol involves first issuing one of four ROM function commands before the EPROM is accessible:

- Read ROM
- Match ROM

Through the 1-Wire bus, the host software interfaces with the generic 1-Wire device and allows the required commands to be issued to control the EPROM of a generic 1-Wire device. The host (through the 1-Wire interface) is the bus master, and the generic 1-Wire device(s) are the slave(s).

13.4.1 Normal Operating Modes

The 1-Wire module supports the following 1-Wire bus protocol functions:

- Reset/Presence-detect pulse using the control register (See Section 13.4.1.1, Reset/Presence-detect Pulse")
- Bit Transfers using the control register (See Section 13.4.1.2, Bit Transfers")

13.4.1.1 Reset/Presence-detect Pulse

The 1-Wire module provides for an automated initialization sequence for the 1-Wire bus. Software initiates the initialization sequence by setting CONTROL[RPP]. The automated initialization sequence is as follows:

1. Generate a reset pulse.
2. Listen for a response from an external device by sampling for the 1-Wire device presence bit.
3. After an amount of time determined by the 1-Wire standard, latch the presence bit (true or false) in CONTROL[PST].

If an external device is detected (PST = 1), software can begin communications on the 1-Wire bus.

The presence pulse is used by the 1-Wire to determine if at least one generic 1-Wire device is connected. Software determines if more than one generic 1-Wire device exists.

13.4.1.2 Bit Transfers

After the initialization sequence (see Section 13.4.1.1, Reset/Presence-detect Pulse"), software can write and read one bit at a time using the control register.

13.4.1.2.1 Write-0 Sequence

The Write-0 sequence writes a zero bit to the generic 1-Wire device. Setting the CONTROL[WR0] initiates the Write-0 pulse sequence. Once the write is complete, the WR0 bit is automatically cleared.

13.4.1.2.2 Write-1/Read Sequence

The Write-1 sequence writes a one bit to the generic 1-Wire device. Setting the CONTROL[WR1] bit initiates the Write-1 pulse sequence. Once the write is complete, the WR1 bit is automatically cleared.

Because the Write-1 and Read timings are identical, this sequence also reads a bit from the bus. The sampled value is stored in the read status bit CONTROL[RDST] and is valid after the WR1 bit is self-cleared.

The host transmits the 16-byte search value based on the last ROM value found. These 16 bytes are 0x00 for the first run. The 16 bytes returned contain the new ROM code and are also used to generate the next 16 bytes to transmit. This process is repeated until serial numbers duplicate to find all devices.

13.4.2 Low Power Mode

The 1-Wire module automatically goes into low-power mode whenever it is not communicating with a generic 1-Wire device. The main clock is gated off in low-power mode.

As soon as software writes to any register, the 1-Wire module exits low-power mode.

13.4.3 Clocks

The 1-Wire module takes a main clock as a module input and passes it through a clock divider. (See the block diagram in Figure 13-1.) Software must program the divider factor to generate a 1-MHz clock that is used as an internal time base for the module, as given by Equation 13-1.

$$\text{time\_base} = \text{main\_clock} \div (\text{TIME\_DIVIDER[DVDR]} + 1) \qquad \textit{Eqn. 13-1}$$

For example, if the main clock frequency is 30 MHz, the value to write to the divider register is 29. If the main clock input frequency is not an integer, the programmer must ensure the time base frequency is within the range given by Equation 13-2.

Eqn. 13-2

$$0.98\ \text{MHz} \leq \text{time\_base} \leq 1.02\ \text{MHz}$$

NOTE

A main clock frequency below 10 MHz causes improper function of the module.

13.4.4 Reset

The 1-Wire module supports two levels of reset: hardware and software.

13.4.4.1 Hardware Reset

Whenever a device reset occurs, a hard reset is performed on the 1-Wire module, clearing all values written to all registers.

13.4.4.2 Software Reset

Software initiates a software reset by setting the reset bit RESET[RST]. A software reset clears all data written to the registers.

Note that the reset register (RESET) itself is not cleared during a software reset. Software must clear the RST bit to release the software reset.

Chapter 14
Cortex-A8 Platform

14.1 Overview

A block diagram of the Cortex-A8n Core Platform is shown in Figure 14-1. The platform consists of the ARM Ltd. Cortex-A8n processor which includes a NEON co-processor, an L1 cache, an L2 cache, an ETM, and a CTI. The platform includes the essential sub-blocks: platform control, test logic, and the debug modules (CTM, ETB, and a second CTI).

The Cortex-A8n processor instruction and data read/write AXI master port is connected from the non-CPU side of the Level 2 Cache. The L2 can in turn can access L3 memory via this port.

The core platform supports static debug through the debug logic to SOC. This includes the capability of real time trace via ARM's Coresight ETM, ETB, and CTM modules. The second CTI module allows cross triggering of internal and external trigger sources.

The Cortex-A8n platform has two power domains (LP and GP), which are separated by level shifters. The LP power domain serves as an interface to the rest of the SoC. The GP power domain is completely contained within the platform and allows the Cortex-A8n core and subsystem to run at much higher frequencies than the rest of the SoC.

The boundary of the two power domains is also an asynchronous boundary between the Cortex-A8n platform and the rest of the SoC. Synchronizers in both the GP and LP power domains of the platform allow the Cortex-A8n core and subsystem to run asynchronously from the rest of the SoC.

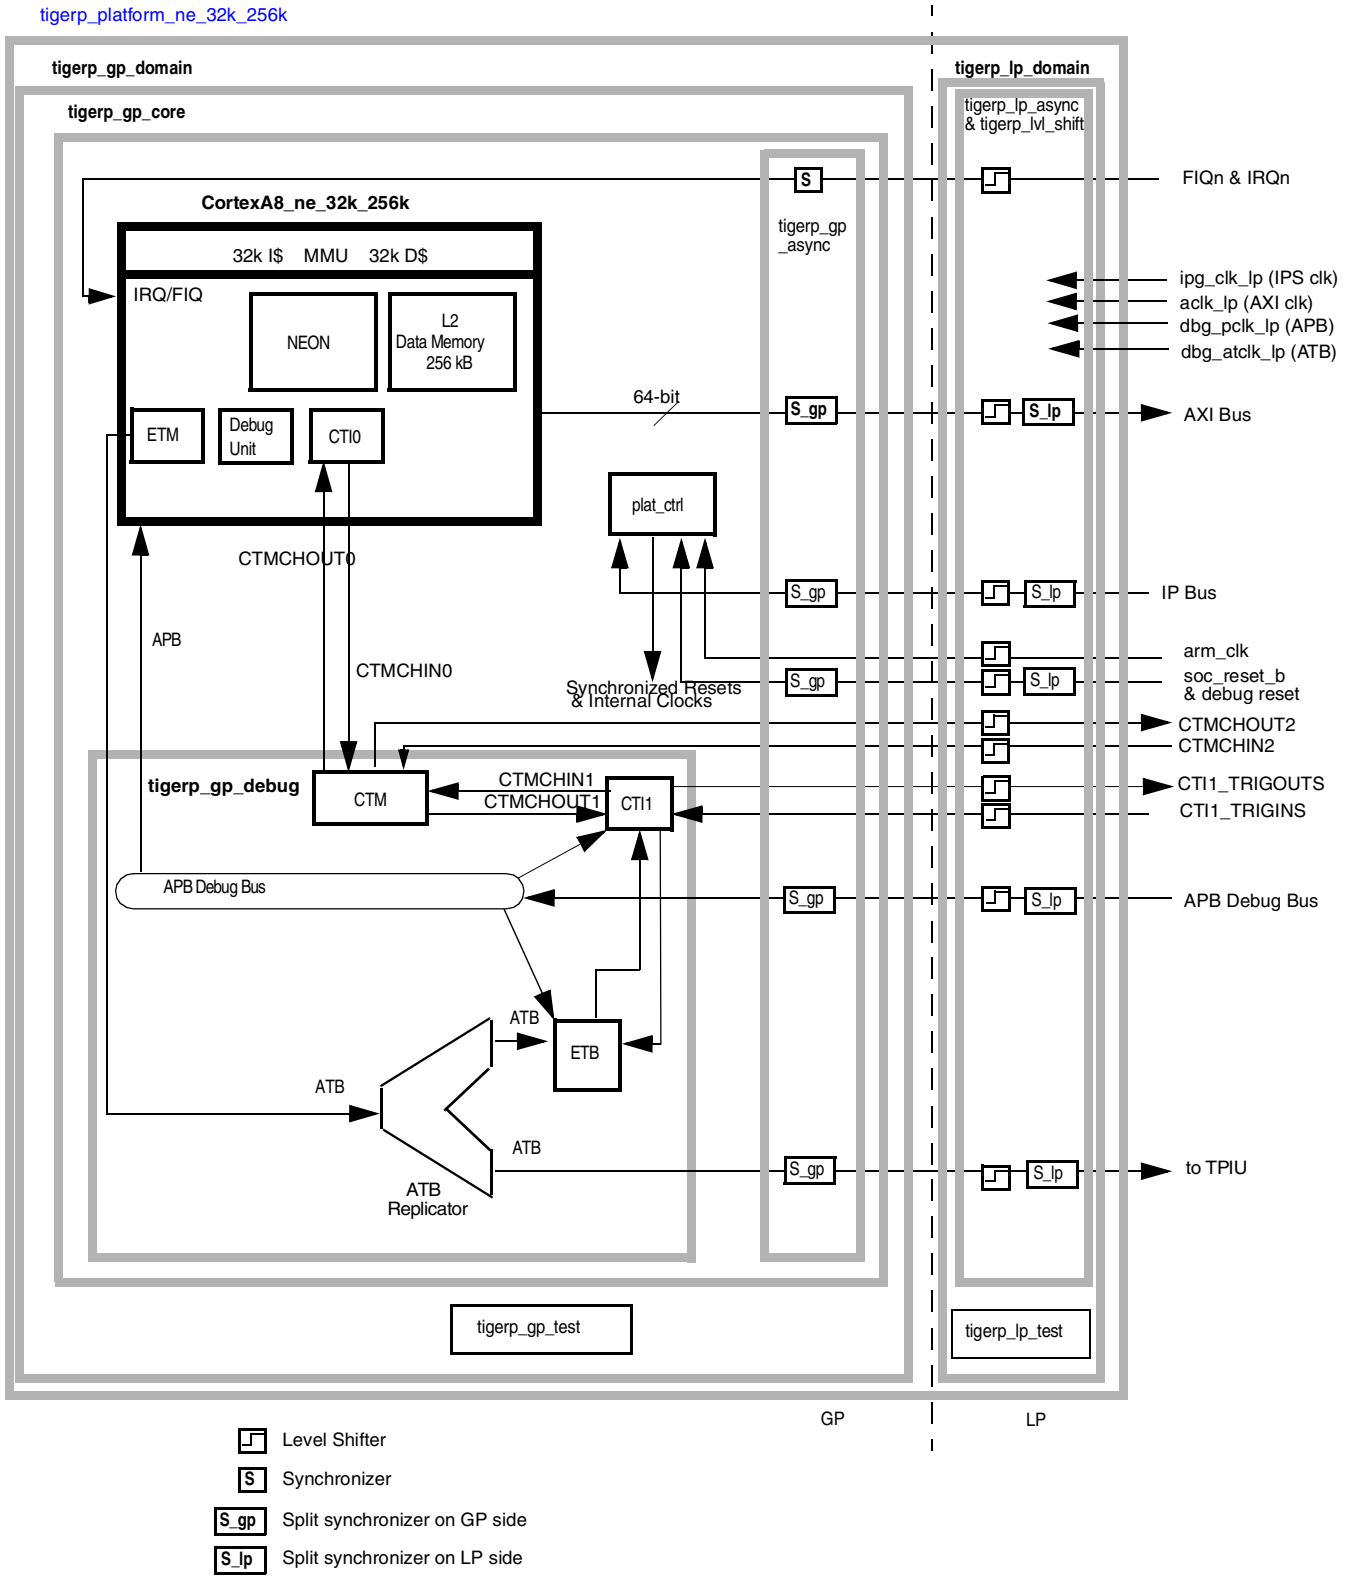

Figure 14-1. Cortex-A8n Core Platform Block Diagram

14.2 Core Platform Sub-blocks

This section discusses the core platform sub-blocks.

14.2.1 Cortex-A8n Processor

The information presented in this section focuses on design aspects of the Cortex-A8n Processor in the AP subsystem. The Cortex-A8n Processor is ARM's first superscalar processor featuring technology for enhanced code density and performance, NEON technology for multimedia and signal processing, and Jazelle RRCT (Runtime Compilation Target) technology for efficient support of ahead-of-time and just-in-time compilation of Java and other bytecode languages.

The Cortex-A8n Processor incorporates an integer core that implements the ARMv7-A architecture instruction set. It supports the ARMv7 and Thumb-2 instruction sets. A NEON module is included to accelerate the performance of multimedia applications. The included Vector Floating Point v3 architecture complies with the IEEE 754 standard. The processor includes an AMBA® 3 AXI high-performance 64-bit SoC interconnect.

14.2.1.1 Features

The following list discusses the main features.

- The ARM Cortex-A8n Processor's sophisticated pipeline architecture is based on dual, symmetric, in-order issue, 13-stage pipelines with advanced dynamic branch prediction achieving 2.0 DMIPS/MHz. The instruction execute unit consists of two symmetric *Arithmetic Logical Unit* (ALU) pipelines and the multiply pipeline.
  - In-order, dual-issue, superscalar microprocessor core
  - 13-stage main integer pipeline
  - 10-stage NEON media pipeline for executing NEON and VFP instruction sets
  - Dedicated L2 cache with programmable wait states
  - Global history based branch prediction
- Works in conjunction with a power optimized load store pipeline to deliver 2.0 DMIPS/MHz for power sensitive applications
- ARMv7 architecture compliant including:
  - Thumb®-2 technology for greater performance, energy efficiency, and code density
  - NEON signal processing extensions to accelerate media codecs such as H.264 and MP3
  - Jazelle RCT Java-acceleration technology to optimize Just In Time (JIT) and Dynamic Adaptive Compilation (DAC), and reduce memory footprint by up to three times
  - TrustZone™ technology for secure transactions and Digital Rights Management (DRM)
- Integrated Level 2 Cache
  - Built using standard compiled LP RAMs
  - Sized at 256 Kb
  - Programmable delay

- Optimized Level 1 Caches
  - Customized design for performance and power optimization
  - Sized at 32 Kb Instruction and 32 Kb Data
  - Combine minimal access latency with hash way determination to maximize performance and minimize power consumption.
- Dynamic Branch Prediction
  - Enabled by branch target and global history buffers
  - Achieves 95% accuracy across industry benchmarks.
  - Replay mechanism minimizes miss-predict penalty
- Memory System
  - Single-cycle load-use penalty for access to the L1 cache
  - Hash array in the L1 cache limits activation of the memories to when they are likely to be needed.
  - Direct interface between the integrated, configurable L2 cache and the NEON media unit for data streaming
  - Banked L2 cache design that enables only one bank at a time
- Memory Management Unit (MMU) and separate instruction and data Translation Look-aside Buffers (TLBs) of 32 entries each
- Embedded Trace Macrocell (ETM) support for non-intrusive debug
- ARMv7 debug with watchpoint and breakpoint registers and a 32-bit Advanced Peripheral Bus (APB) interface to the CoreSight debug system.

14.2.1.2 Instruction Fetch

The instruction fetch unit predicts the instruction stream, fetches instructions from the L1 instruction cache, and places the fetched instructions into a buffer for consumption by the decode pipeline. The instruction fetch unit also includes the L1 instruction cache.

14.2.1.3 Instruction Decode

The instruction decode unit decodes and sequences all ARM and Thumb-2 instructions including the debug control coprocessor, CP14, and the system control coprocessor, CP15 instructions.

The instruction decode unit handles the sequencing of the following:

- Exceptions
- Debug events
- Reset initialization
- *Memory Built-In Self Test* (MBIST) for L1 cache
- Wait-for-interrupt
- Other unusual events
- *Instruction Cycle Timing*

14.2.1.4 Instruction Execute

The instruction execute unit consists of two symmetric Arithmetic Logical Unit (ALU) pipelines and the multiply pipeline. The execute pipelines also perform register write back.

The instruction execute unit performs the following tasks:

- Executes all integer ALU and multiply operations including flag generation
- Generates the virtual addresses for loads and stores and the base write-back value, when required
- Supplies formatted data for stores and also forwards data and flags
- Processes branches and other changes of instruction stream and evaluates instruction condition codes.

14.2.1.5 Load/Store

The load/store unit encompasses the entire L1 data side memory system and the integer load/store pipeline. This includes the following:

- L1 data cache
- Data side TLB
- Integer store buffer
- NEON store buffer
- Integer load data alignment and formatting
- Integer store data alignment and formatting.

The pipeline accepts one load or store per cycle that can be present in either pipeline 0 or pipeline 1. This gives the processor flexibility when scheduling load and store instructions.

14.2.1.6 L2 Cache

The L2 cache unit includes the L2 cache and the Buffer Interface Unit (BIU). It services L1 cache misses from both the instruction fetch unit and the load/store unit.

14.2.1.7 NEON

The NEON unit includes the full 10-stage NEON pipeline that decodes and executes the NEON media instruction set. The NEON unit includes the following:

- NEON instruction queue
- NEON load data queue
- Two pipelines of NEON decode logic
- Three execution pipelines for NEON integer instructions
- Two execution pipelines for NEON floating-point instructions
- One execution pipeline for NEON and VFP load/store instructions
- VFP engine for full execution of the VFPv3 data-processing instruction set.

14.2.1.8 Processor Debug Unit

The processor debug unit assists in debugging software running on the processor. In combination with a software debugger program, the debug unit enables debugging the following:

- Application software
- Operating systems
- Hardware systems based on an ARM processor

The debug unit enables the following:

- Stopping program execution
- Examining and altering processor and coprocessor states
- Examining and altering memory and input/output peripheral states
- Restarting the processor core

14.2.1.9 Embedded Trace Macrocell (ETM)

The ETMv3.3 unit is a nonintrusive trace macrocell that filters and compresses an instruction and data trace for use in system debugging and system profiling. The ETM unit has an external interface outside of the processor called the Advanced Trace Bus (ATB) interface.

The Cortex-A8n Processor ETM provides real time instruction trace for the Cortex-A8n Processor. It is designed to be used with the CoreSight Design Kit. Unlike previous versions of the ARM platforms, this ETM is embedded inside the Processor Core.

Real time tracing is controlled by specifying a set of filtering and triggering resources which include address and data comparators, counters and sequencers. Note that although data trace cannot be enabled, the ETM can still trigger based on data values. Also, the ETM can trace data address values.

The Cortex-A8n Processor ETM contains the following main components:

- Core interface
- Trace generation
- Filtering and triggering resources
- Main FIFO
- AMBA 3 ATB interface
- AMBA 3 APB interface

14.2.1.10 Cross Trigger Interface 0 (CTI0)

This block controls the Trigger Interface (TI). The CTI combines and maps the trigger requests, and broadcasts them to all other interfaces on the ECT as channel events. When the CTI receives a channel event it maps this onto a trigger output. This enables subsystems to cross trigger with each other. The receiving and transmitting of triggers is performed through the TI.

Each CTI has eight trigger inputs, eight trigger outputs, and four sets of 4-channel I/O(s).

14.3 Summary of Remaining Platform Components

This section provides a summary of the platform components that have not been previously discussed.

14.3.1 Platform Controller

The Platform Control contains all the miscellaneous logic required for the platform. The main purpose of the Platform Control module within the Cortex-A8n Core Platform is to implement a set of control and/or status registers and associated logic for the management of certain platform functions such as internally generated clocks, debug enable/status, low-power control, platform version ID, and others.

The Platform Control Module provides these main features:

- Simple IPbus interface with TrustZone type security to all registers.
- Internal clock generation with the ability to programatically set the frequency (divide-by) for each clock independently.
- Ability to force (down-counter) preload for any one or more clocks at anytime independent of preload set.
- Provides a gated clock for the IPbus asynchronous bridge for power savings.
- Provides 16 bits of General Purpose register bits for routing out to Platform boundary.
- Provides 8 bits of Platform Internal Control register bits for external Platform (SoC) use.
- Provides a set of Low Power control and status bits.
- Control bit to enable Debug along with Debug active status bit.
- NEON activity monitor which can be used in determining when to disable NEON thus saving power.

14.3.1.1 Debug Sub-Blocks

The Cortex-A8n Core Platform debug blocks are part of the overall Coresight debug system, which includes the ETB, CTM, CTI1, ATB replicator, and APB address decode. It is expected that a DAP module and one or more additional CTI will be included at the SoC level. This section gives a brief overview of the modules that are implemented within the Cortex-A8n Core Platform platform. For details of the full Coresight debug subsystem, please refer to the SoC debug section.

14.3.1.1.1 Embedded Trace Buffer (ETB)

The ETB provides on-chip storage of trace data using 32-bit RAM. The ETB accepts trace data from the Cortex-A8n ETM via an ATB port (passing through a replicator in between). Providing an on-chip buffer alleviates the pin count, bandwidth, and pad design requirements associated with sending trace data to a debugger directly through package pins in a real-time fashion.

The features are as follows:

- 4kB compiled memory for the trace buffer and optionally can be used as a general purpose memory
- Only 32-bit accesses to the 4kB buffer is supported
- AMBA Peripheral Bus programming interface for configuration and memory access

14.3.1.1.2 AMBA Trace Bus (ATB) Replicator

The ATB Replicator enables two trace sinks (ETB and an off platform port generally connected to a Trace Port Interface Unit—TPIU) to be wired together and receive ATB trace data from the same trace source (ETM). There are no programmable registers. It takes incoming trace data from a single source (ETM) and replicates it as multiple masters.

The CSREPLICATOR is part of the ARM platform. Two output master ports are required for this design—one for the on-platform ETB and one for the off-platform TPIU. Placing the TPIU off platform allows future debug trace sources to connect to the TPIU via a FUNNEL without the need to modify the ARM platform.

14.3.1.1.3 Cross Trigger Interface 1 (CTI1)

This block controls the Trigger Interface (TI). The CTI combines and maps the trigger requests as well as broadcasts them to all other interfaces on the ECT as channel events. When the CTI receives a channel event, it maps this onto a trigger output. This enables subsystems to cross trigger with each other. The receiving and transmitting of triggers is performed through the TI.

Each CTI has eight trigger inputs, eight trigger outputs, and four sets of 4-channel I/O(s).

14.3.1.1.4 Cross Trigger Matrix—CTM

The CTM controls the distribution of channel events. It provides channel interfaces to the CTIs. The CTM can also connect to another CTM via a channel interface. This allows multiple CTMs to be connected.

The Cortex-A8n Core Platform has one CTM inside the platform to handle events between the platform's CTI, the processor's CTI and the rest of the ECT system outside the platform. Placing a CSCTM on platform minimizes the event cycle time between the ETB and the ETM. The handshaking between the CTIs on-platform and the on-platform CTM are not enabled. This requires the Cortex-A8n's CTI, the on-platform CTI1, and the on-platform CTM to all be in the same clock domain. The on-platform CTM connects to the ECT system via an off-platform CTM and the respective channels require synchronizing and handshaking enabled.

14.3.1.1.5 Advanced Peripheral Bus—APB Debug Bus

The APB originates off platform generally from a Debug Access Port—DAP block. This bus allows access to the registers in all of the debug modules that have addressable registers.

14.3.1.2 Asynchronous Wrapper

The Cortex-A8n Core Platform hard macro contains synchronizers for most signals into and out of the platform where synchronization is required. This means the Cortex-A8n Core Platform can function asynchronously from the rest of the SoC.

14.3.2 Configuration

There are several configuration options associated with the Cortex-A8n Processor. These are determined at the platform level and selected as follows:

- The L1 cache size is 32 Kb instruction and 32 Kb data
- There is parity on the L1 cache
- There is no error correction on the L1 cache
- The L2 cache size is 256 Kb
- There is no parity on the L2 cache
- There is no error correction on the L2 cache
- There are 2 L2 tag banks and 4 data banks per tag bank
- The AXI data bus width out of the platform is 64-bit

14.3.3 Endian Modes

The Cortex-A8n Core Platform only supports little-endian mode.

14.3.4 Bus Interfaces

This section discusses the major bus interfaces of the Cortex-A8n Core Platform. The Cortex-A8n Processor has the following bus interfaces:

- AMBA AXI interface
- APB CoreSight interface
- ATB CoreSight interface
- Peripheral Interface (IP Bus)

14.3.4.1 AMBA AXI Interface

The AXI bus interface is the main interface to the system bus. It performs L2 cache fills and non-cacheable accesses for both instructions and data. The AXI interface utilizes a 64-bit wide input and output data buses. It also supports multiple outstanding requests on the AXI bus. The AXI bus is allowed to be asynchronous between the platform and SoC domains. This provides maximum flexibility at the SoC level.

14.3.4.2 APB CoreSight Interface

The APB is an AMBA bus used for debugging. The CoreSight interface is the ARM architecture for multi-processor trace and debug. It defines what debug and trace components are required and how they are connected. The platform Debug APB should be connected to the SoC Debug Access Port (DAP) APB mux. The APB is allowed to be asynchronous between the platform and SoC domains. This provides maximum flexibility at the SoC level.

14.3.4.3 ATB CoreSight interface

The ATB is a trace output bus used for debugging. The CoreSight components are programmed with the *Debug Access Port* (DAP) using the APB programming bus. Trace is output over the ATB trace bus. The ATB is allowed to be asynchronous between the platform and SoC domains. This provides maximum flexibility at the SoC level.

14.3.4.4 Peripheral Interface (IP Bus)

The IP Bus interface to the platform connects the on-chip registers to the memory map and internal buses at the SoC level. Location (addresses of the registers) is determined at the SoC level. The platform acts as a slave to an SoC-based IP Bus controller.

14.4 Memory Map and Register Definition

This section provides a register memory map and register summary.

14.4.1 Register Memory Map

The memory map for Cortex-A8n Core Platform specific registers is shown in Table 14-1. This does not include the co-processor registers contained in the ARM Cortex-A8n Processor or the ARM Coresight Debug. For documentation of registers contained in those modules, please refer to the appropriate technical reference manual.

This register block address space uses 5 address lines which are fully decoded. The space includes 9 registers and 23 unimplemented locations. The unimplemented locations return an error if they are accessed. Depending on how the SoC decodes the register block, the entire 32-word register block could alias in the larger memory space.

Table 14-1. Block Memory Map

Address	**Register**	Access	Reset Value	Section/Page
General Registers

14.4.2 Register Summary

The conventions in Figure 14-2 and Table 14-2 serve as a key for the register summary and individual register diagrams.

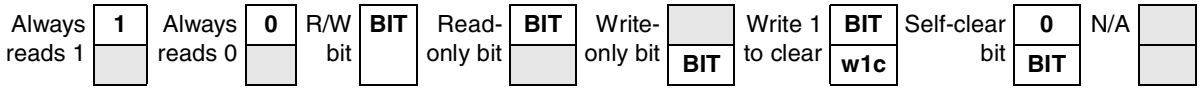

Figure 14-2. Key to Register Fields

Table 14-2. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
?	Unknown at publication time and subject to change.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

NOTE

All registers are zero wait-state and all accesses must use a 32-bit word size. Any other transaction sizes produce a zero wait-state error response.

14.4.3.1 Platform Version ID Register

The platform version ID register (PVID) contains a 32-bit version ID which can be used to link the silicon to a specific version of the platform database. The version ID should match our release label applied to the platform database.

The release label uses the following convention:

TIGERP.C65GP.XX.XX.XX.XX.

This register can be accessed by a 32-bit secure/non-secure, user/supervisor, read transaction. Writes return an error.

0xBASE_0000 (PVID)

Access: User/Supv, Secure/non-Secure Read

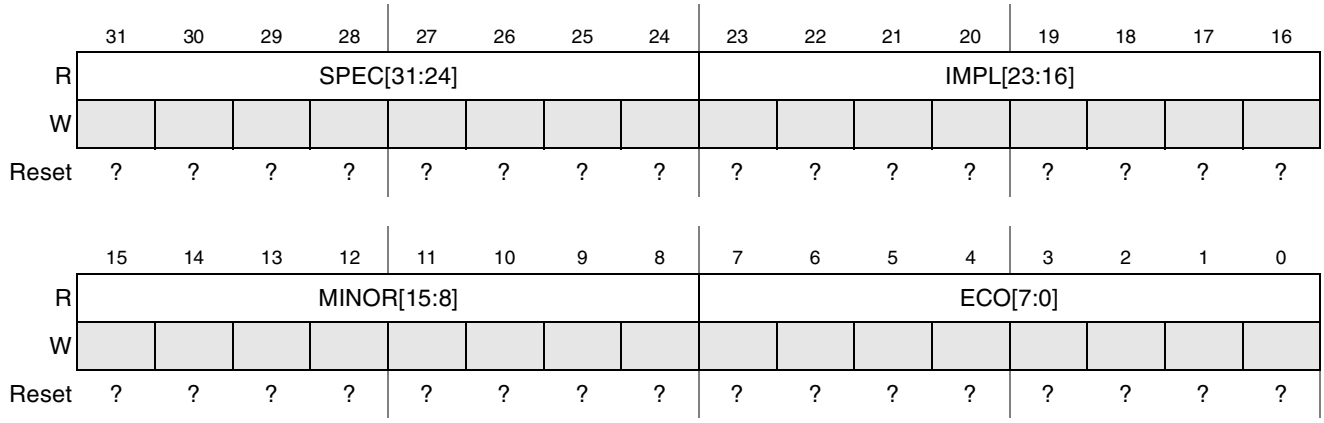

Figure 14-3. Platform Version ID Register

Table 14-4. PVID Field Descriptions

Field	Description
31–24	SPEC[31:24] = Major architectural or significant spec changes The reset value is unknown at publication of this document and is also subject to change.
23–16	IMPL[23:16] = Implementation changes The reset value is unknown at publication of this document and is also subject to change.
15–8	MINOR[15:8] = Minor changes (bug fixes, I/O changes) The reset value is unknown at publication of this document and is also subject to change.
7–0	ECO[7:0] = ECO changes The reset value is unknown at publication of this document and is also subject to change.

14.4.3.2 General Purpose Control Register

This register contains 16 bits of general purpose control which drive core platform outputs that can be used within the SoC for general purpose control. This register also contains the DBG_ACTIVE status bit and DBG_EN control bit for entering Debug mode via a software access to this register.

This register can only be accessed by 32-bit secure supervisor transactions.

0xBASE_0004 (GPC)

Access: Secure, Privileged
Read-Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0

Figure 14-4. General Purpose Control Register

Table 14-5. GPC Field Descriptions

Field	Description
31	DBGACTIVE - This bit indicates the status of debug. This allows the user to determine if debug has been enabled either from off platform, via the external DAP_SYS JTAG interface (dbgen_in platform input), or via software accesses to the DBGEN bit in this register. If 0, debug is not enabled. Debug clocks are off and debug registers are inaccessible. If 1, debug is enabled. Debug clocks are on and the debug system is ready to be used.
30–19	Reserved
18	NOCLKSTP - This bit is used to control clock-gating within the CORTEX-A8n. Note that this is distinctly different than the higher-level (platform-level) clock-gating/low-power control afforded by the other Plat_Ctrl low-power functionality (i.e. **dsm_request** along with the **DSM** and **DBG_DSM** control bits within the **Low Power Control** register). If 1 (reset state), then all normal clock-gating activity (WFI, NEON, etc.) is overridden and no clock gating occurs within the CORTEX-A8n. **NOCLKSTP**, however, has no affect on the higher-level platform clock-gating, and the low-power functions discussed in the **LPC** register work as architected. if 0, then clock-gating within the CORTEX-A8n is enabled. This is the recommended setting in order to reduce run mode power consumed by the clocking network within the Integer core as well as the Neon co-processor.
17	ATRDY - If 1, this bit disables the platform boundary ATB interface. In most SoCs, this is connected to a TPIU. This prevents traces to the ETB from stalling due to the ASYNCATB FIFO overflowing. If 0, this bit allows the platform boundary ATB interface to be active. In this case, traces to the ETB could stall due to ASYNCATB FIFO becoming full. This may cause the ETM data loss.
16	DBGEN - Debug enable. This allows the user to manually activate clocks within the debug system. This register bit directly controls the platform's dbgen_out output signal which connects to the DAP_SYS to enable all debug clocks. Once enabled, the clocks cannot be disabled except by asserting the disable_trace input of the DAP_SYS.
15-0	Reserved

14.4.3.3 Platform Internal Control Register

This register contains eight bits that drive internal signals which can be used within the platform for general purpose control. Currently, none of the PIC bits are being utilized.

This register can only be accessed by 32-bit secure supervisor transactions.

0xBASE_0008 (PIC)

Access: Secure, Privileged Read-Write

Reset	0	0	0	0	0	0	0	0	1	1	1	1	0	0	0	0

Figure 14-5. Platform Internal Control Register

14.4.3.4 Low-Power Control Register

This register is used to control entry to low-power mode and can only be accessed by 32-bit secure supervisor transactions.

There exists a platform output, **dsm_request**, that when asserted, requests the SoC to turn off clocks to the platform, and optionally deactivate one or more power supplies. DSM can only be entered after the CPU has executed a WFI instruction, completed all outstanding bus transactions, and all activity at the L2 level has completed. Assertion of either **irq_b**, **fiq_b**, or **dbg_edbgrq** platform inputs cause the CPU to complete the WFI instruction and result in the negation of **dsm_request**.

The DSM bit configures the platform to either: block deep sleep mode entry (default), or allow DSM entry when requested.

The DBG_DSM bit configures the platform to block deep sleep mode entry when debug mode is enabled (dbgen_in platform input is asserted high). This allows the user to ensure deep sleep mode is not entered when debug is enabled.

The NEON_RST bit is used for placing the Cortex-A8n NEON processor into, or releasing it from, reset.

This register can only be accessed by 32-bit secure supervisor transactions.

0xBASE_000C (LPC)

Access: Secure, Privileged Read-Write

Table 14-6. LPC Field Descriptions

Field	Description
31–2	Reserved
1	DBGDSM - Debug Deep Sleep Mode Enable If 1, DSM can be entered (dsm_request will not be blocked) regardless if debug is enabled or not. If 0, DSM can NOT be entered (dsm_request will be blocked) if debug is enabled
0	DSM - Deep Sleep Mode Enable is used to gate the platform's dsm_request signal, therefore preventing the platform from issuing a deep sleep mode request. If 1, DSM can be entered (dsm_request will not be blocked). If 0, DSM can NOT be entered (dsm_request will be blocked).

14.4.3.5 NEON Low-Power Control Register

This register is used to place the Cortex-A8n NEON processor into, or release it from, reset. Refer to Table 14-7 for a description of this control bit.

This register can only be accessed by 32-bit secure supervisor transactions.

0xBASE_0010 (NLPC) — Access: Secure, Privileged Read-Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 14-7. NLPC Field Descriptions

Field	Description
31-1	Reserved
0	NEONRST - Hold the Cortex-A8n NEON in it's reset state in preparation for a low-power mode. • If 1, the ARESETNEONn input to the Cortex-A8n is driven low - placing NEON into reset. • If 0, the ARESETNEONn input to the Cortex-A8n is driven high - releasing NEON from reset.

14.4.3.6 Internal Clock Generation Control Register

This register is used to control the clock generation circuitry for all derived clocks used within the ARM platform (**ipg_clk**, **aclk**, **dbg_atclk**, and **dbg_pclk**). The **dbg_pclk** clock is generated as a straight divide-by-2 of **dbg_atclk**.

NOTE

At reset, all generated clocks are edge aligned and are generated at 8:1. The **dbg_pclk** signal requires 1 **dbg_atclk** clock cycle before it begins clocking as a divided **dbg_atclk**.

This register can only be accessed by 32-bit secure supervisor transactions.

Figure 14-8. Internal Clock Generation Control Register

Table 14-8. ICGC Field Descriptions

Field	Description
31-12	Reserved
11	DT_PRLD - Debug AMBA Trace Bus Clock Down Counter Preload Reads always return 0 A write of 0 has no effect. If preload is 0 during a write of a new divide ratio, the down counteris not loaded with the new value until it reaches 0 (i.e. rolls over). A write of 1 forces the DBG_ATCLK down counter to preload on the next arm_clk.
10-8	DT_CLK_DIVR[2:0] - Debug AMBA Trace Bus Clock Divide Ratio These bits control the clock divide ratio for the debug AMBA trace bus (ATB) and GP async interface clocks. The ATB bus is used to transfer trace messages from the ETM to the ETB or TPIU. When ETM trace data is being transferred over the ATB to the embedded trace buffer (ETB), the ATB is capable of running up to half the CPU frequency. However, when ETM trace data is being transferred to the TPIU to be sent out the trace port, the ATB should be slowed to some appropriate SoC frequency. DT_CLK_DIVR[2:0] = 0b000 results in a 1:1 clock ratio DT_CLK_DIVR[2:0] = 0b001 results in a 2:1 clock ratio DT_CLK_DIVR[2:0] = 0b010 results in a 3:1 clock ratio DT_CLK_DIVR[2:0] = 0b011 results in a 4:1 clock ratio DT_CLK_DIVR[2:0] = 0b100 results in a 5:1 clock ratio DT_CLK_DIVR[2:0] = 0b101 results in a 6:1 clock ratio DT_CLK_DIVR[2:0] = 0b110 results in a 7:1 clock ratio DT_CLK_DIVR[2:0] = 0b111 results in a 8:1 clock ratio
7	ACLK_PRLD - AXI Master Port Clock Down Counter Preload Reads always return 0 A write of 0 has no effect. If preload is 0 during a write of a new divide ratio, the down counter is not loaded with the new value until it reaches 0 (i.e. rolls over). A write of 1 forces the ACLK down counter to preload on the next arm_clk.

Table 14-8. ICGC Field Descriptions (continued)

Field	Description
6-4	ACLK_DIVR[2:0] - AXI Master Port Clock Divide Ratio Controls the clock divide ratio for the Tiger CPU AXI bus and GP AXI async interface clocks and clock enable. The ratio of clock cycles generated for arm_clk to aclk is: ACLK[2:0] +1 : 1 ACLK_DIVR[2:0] = 0b000 results in a 1:1 clock ratio ACLK_DIVR[2:0] = 0b001 results in a 2:1 clock ratio ACLK_DIVR[2:0] = 0b010 results in a 3:1 clock ratio ACLK_DIVR[2:0] = 0b011 results in a 4:1 clock ratio ACLK_DIVR[2:0] = 0b100 results in a 5:1 clock ratio ACLK_DIVR[2:0] = 0b101 results in a 6:1 clock ratio ACLK_DIVR[2:0] = 0b110 results in a 7:1 clock ratio ACLK_DIVR[2:0] = 0b111 results in a 8:1 clock ratio
3	IPG_PRLD - Platform IP-Bus Port Clock Down Counter Preload Reads always return 0 A write of 0 has no effect. If preload is 0 during a write of a new divide ratio, the down counter is not loaded with the new value until it reaches 0 (i.e. rolls over). A write of 1 forces the IPG_CLK down counter to preload on the next arm_clk.
2-0	IPG_CLK_DIVR[2:0] - Platform IP-Bus Port Clock Divide Ratio Controls the clock divide ratio for the Platform Controller and GP async IP-Bus clock and clock enable. The ratio of clock cycles generated for arm_clk to ipg_clk is: IPG_CLK[2:0] +1 : 1 IPG_CLK_DIVR[2:0] = 0b000 results in a 1:1 clock ratio IPG_CLK_DIVR[2:0] = 0b001 results in a 2:1 clock ratio IPG_CLK_DIVR[2:0] = 0b010 results in a 3:1 clock ratio IPG_CLK_DIVR[2:0] = 0b011 results in a 4:1 clock ratio IPG_CLK_DIVR[2:0] = 0b100 results in a 5:1 clock ratio IPG_CLK_DIVR[2:0] = 0b101 results in a 6:1 clock ratio IPG_CLK_DIVR[2:0] = 0b110 results in a 7:1 clock ratio IPG_CLK_DIVR[2:0] = 0b111 results in a 8:1 clock ratio

14.4.3.7 ARM Memory Configuration Register

This register is used to configure the ALP inputs to the ARM platform memories. These bits are used to set the leakage configuration bits on the memories.

This register can only be accessed by 32-bit secure supervisor transactions.

0xBASE_0018 (AMC)

Field	Description
31	NI - NEON Idle Status • 1 - Indicates that the NEON activity counter has expired. plat_ctrl_nm_irq_b asserts if the IE bit is set. • 0 - Indicates that the NEON activity counter has not expired.
30-0	Reserved

14.5 Platform Clocks

The clocking strategy of the Cortex-A8n Core Platform can be summarized as follows:

- The Cortex-A8n Core Platform receives one functional clock from the CCM, **arm_clk**, and several SoC clocks for boundary synchronization purposes (**arm_clk** can be completely asynchronous from any other SoC clocks).
- The Cortex-A8n Core Platform, in conjunction with an external Clock Control Module (CCM), supports dynamic clock frequency scaling.
- Divided clocks based on **arm_clk** are generated within the platform for clocking buses which cannot operate at the high **arm_clk** frequencies. These divided clock ratios can be configured by on-platform registers.
  - Derived Clocks:
    - ipg_clk: This clock is used for IP bus logic.
    - aclk: This clock is used for AXI bus logic.
    - dbg_atclk: This clock is used for the Debug AMBA Trace logic.
    - dbg_pclk: This clock is used for the Debug synchronizer logic.
- Two-level clock gating is employed.
  - Module level clock gating is used when possible. A specific module's clock is gated off when the module is not in use.
  - Register level clock gating is used throughout the platform via power design tools.
- **arm_clk** may be turned off for various low-power use cases by an external clock control module that monitors the **DSM_request** output.

14.6 Platform Power Management

The Cortex-A8n Core Platform contains low voltage logic elements, an asynchronous and level shifted interface, state retention latches, low leakage power switches, and floating node isolation circuits. These elements each serves a specific purpose in the power management scheme implemented in the Cortex-A8n Core Platform. The power management capabilities of the Cortex-A8n Core Platform are summarized in this section.

14.6.1 Voltage and Frequency Scaling

The Cortex-A8n Core Platform contains structures necessary for the independent voltage scaling of the GP supply. Voltage and frequency scaling control systems are implemented at the chip level with the Cortex-A8n Core Platform acting as an object of the control. Asynchronous Interface Logic and Level-shifting between SOC-logic and ARM-logic have been implemented in the Cortex-A8n Core Platform to support the voltage and frequency scaling capabilities of the integrated system.

14.6.1.1 Asynchronous Interface Logic

Voltage and frequency scaling is most effective when there is a continuum of available frequencies at which the Cortex-A8n Processor may be clocked. Asynchronous Interface Logic removes the clock ratio dependencies between the Cortex-A8n Processor and the system in which it operates.

14.6.1.2 Level Shifting between SOC-logic and ARM-logic

Independent voltage scaling of the Cortex-A8n Processor requires a distinct power supply for the GP logic. Level shifters exist at the interface of the SOC logic and the ARM logic to allow independent voltage control of the SOC power supply and the ARM power supply.

14.6.2 Power Gating in the Cortex-A8n Core Platform

To reduce standby leakage power consumption, the Cortex-A8n Core Platform contains internal power supplies that may be completely power gated during wait for interrupt modes. Entry and exit sequences of power gating modes are completely controlled by programmed operation of the General Power Controller, so this section only describes what is possible in terms of how the Cortex-A8n Core Platform may be powered down during wait for interrupt modes.

14.6.2.1 Isolation Circuitry at the Cortex-A8n Core Platform Interface

To power down digital logic correctly, a special interface must exist that protects the system from floating signals. Such isolation circuitry has been carefully designed in order to allow glitch-free power down modes of the Cortex-A8n Core Platform.

14.6.2.2 Power Gating the Memory Peripheries

Once the STANDBYWFI mode has been invoked, all of the Cortex-A8n Core Platform memory peripheries may be power gated by the assertion of both the l1_pwrdwn and the l2_pwrdwn signals. This significantly reduces the amount of leakage from the GP supply.

14.6.2.3 Retaining the State of the Cortex-A8n Core Platform Registers

The Cortex-A8n Core Platform has been implemented using State Retention Power Gating (SRPG) register elements. In order to safely enter a power gated mode that includes power gating of the Cortex-A8n Core Platform high performance logic gates, a sequenced assertion of the srpg_pgrst and srpg_pg{0-17} signals must occur. Similarly, a sequenced deassertion is necessary when emerging from power gated states. The required sequences are automatically provided to the Cortex-A8n Core Platform by the General Power Controller.

14.6.2.4 Power Gating the Cortex-A8n Core Platform High Performance Logic Gates

Once the STANDBYWFI mode has been invoked, the Cortex-A8n Core Platform high performance logic gates may be power gated by the assertion of the cpu_powerdown signal and the negation of the vdd_short_b signal. This turns off a portion of the leakage from the GP supply.

14.6.2.5 Power Gating the L2 Bit Arrays

If the L2 cache has been flushed, the L2 bit array may be power gated during the subsequent STANDBYWFI mode. Once the STANDBYWFI mode has been invoked, the L2 memory bit arrays may be power gated by the assertion of the l2bits_powerdown signal. This turns off a portion of the leakage from the LP supply.

14.6.2.6 Controlling Power Gating using the General Power Controller (GPC)

Specific details concerning the power gating entry and exit sequence may be obtained from the block guide of the General Power Controller (GPC). This high level summary is intended to provide some overview.

Code must be formed that takes advantage of low workloads by putting the Cortex-A8n Core Platform into a STANDBYWFI state whenever possible. Prior to entering the STANDBYWFI state, the code should assess several things about the workload and the battery conservation requirements:

- What is the maximum acceptable interrupt service latency?
- What is the expected time to be spent in STANDBYWFI?

Once these time requirements are understood, then Table 14-12 can be used to determine the appropriate STANDBYWFI mode to invoke. The GPC registers can be programmed with the appropriate values to invoke the appropriate STANDBYWFI mode. After GPC programming is complete, the code should execute the STANDBYWFI instruction.

The GPC enforces the appropriate sequence for entering and exiting the programmed power gated modes.

14.6.2.7 Power Gating the NEON Block

The NEON co-processor in the Cortex-A8n Processor can be put into a state retention mode and powered down to reduce current consumption when it is not needed. The sequence is shown in the flow diagram of Figure 14-12. Each box in the diagram is numbered to correspond to the following more thorough description:

1. User Selects NEON to be Powered Down

   The NEON Coprocessor is enabled out of reset and remains powered up unless the user decides to power it down. This method power downs NEON after a user programmable time of NEON inactivity. The current state of the NEON is held in SRPG flops. To select this operation:

   a) The user code programs the amount of time that the NEON needs to be inactive before power down in the NEON Monitor Control Register. Effectively, the user programs the upper 8 bits of a 20-bit counter. This counter runs at the arm_clk rate and so the user can program a timeout from 4K to 1M arm_clk rising edges.

   b) In the same register, the user code enables the NEON Monitor and enables the NEON Monitor Interrupt.

2. Pre-Set Timer Count

   The timer is loaded (automatically by hardware) with the count value chosen by the user.

3. Decision: NEON Instruction Encountered?

If a NEON instruction is encountered the sequence is aborted until the NEON is no longer in use. As long as NEON Instructions are executing, the NEON status bit will remain in the active state and the counter gets forced with the pre-set count.

4. Decrement Timer

   When no NEON instructions are encountered, the timer counts towards the timeout.

5. Decision: Timed Out?

   If the user selected time has lapsed without any NEON activity, then the hardware generates an interrupt.

6. Exception Sequence: Power Down NEON

   The interrupt service routine disables the NEON module with the following sequence:

   a) Software must disable access to the NEON unit using the Coprocessor Access Control Register, see *c1, Coprocessor Access Control Register* on page 3-64 of the Cortex-A8n TRM. All outstanding NEON instructions retire and all subsequent NEON instruction cause an Undefined instruction exception.

```
MRC p15, 0, <Rd>, c1, c0, 2; Read Coprocessor Access Control Register
BIC <Rd>, <Rd>, #0xF00000; Disable access to CP10 and CP11
MCR p15, 0, <Rd>, c1, c0, 2; Write Coprocessor Access Control Register
```

   b) Activate the NEON output clamps.

   c) Place NEON into state retention.

   d) Prepare the NEON memory for power down keeping the state of it’s bits.

   e) Separate the NEON power supplies so that the ones that retain state can continue to have power.

   f) Remove power from the NEON power domain.

7. Decision: NEON Instruction Attempted

   The part continues running regular CPU instructions with the NEON in low power state as long as no NEON instructions are attempted. When a NEON instruction is attempted, an unimplemented instruction exception occurs.

8. Exception Sequence: Power Up NEON

   An exception is taken when a NEON instruction is attempted with the NEON is disabled. The exception routine determines that this is indeed what occurred, enables the NEON module, and waits for the NEON to power up. Returning from the exception causes the NEON instruction to be restarted and run successfully. This is a more detailed description of the sequence:

   a) Power is turned on to the NEON power domain.

   b) Reconnect the NEON power supplies together.

   c) Restore the NEON memory power maintaining the state of it’s saved bits.

   d) Reload the flops with the SRPG saved contents.

   e) Release the NEON output clamps.

   f) Software must enable access to the NEON unit using the Coprocessor Access Control Register, see *c1, Coprocessor Access Control Register* on page 3-64 of the Cortex-A8n TRM.

```
MRC p15, 0, <Rd>, c1, c0, 2; Read Coprocessor Access Control Register
ORR <Rd>, <Rd>, #0xF00000; Enable access to CP10 and CP11
MCR p15, 0, <Rd>, c1, c0, 2; Write Coprocessor Access Control Register
```

g) Return from the exception causing the NEON instruction to be reloaded and executed.

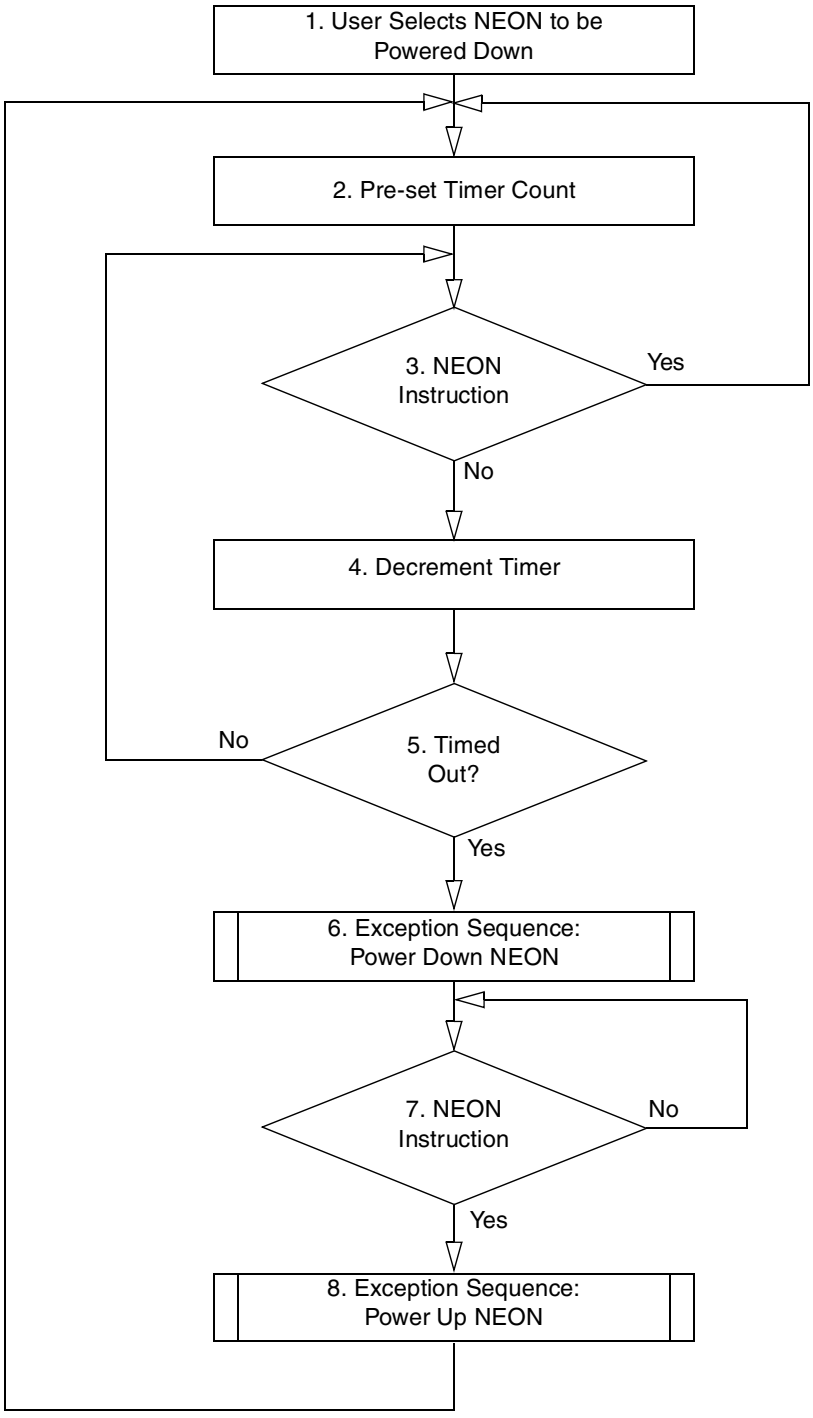

Figure 14-12. Flow Diagram of NEON Power Down Sequence

14.6.3 Modes of Operation

There are several basic low-power modes of the Cortex-A8n Core Platform, as presented in Table 14-12.

Table 14-12. Modes of Operation of the Cortex-A8n Core Platform

MODE	Description
RUN	ARM_CLK running, code executing
CLOCKED_WAIT	ARM_CLK running, STANDBYWFI=TRUE
UNCLOCKED_WAIT	ARM_CLK off, STANDBYWFI=TRUE
STOP1	UNCLOCKED_WAIT plus L1 and L2 peripheries power gated
STOP2	UNCLOCKED_WAIT plus L1 and L2 peripheries power gated, ARM_HiP_logic power gated
STOP3	UNCLOCKED_WAIT plus L1 and L2 peripheries power gated, ARM_HiP_logic power gated, L2 cache flushed, and L2 bit arrays power gated

There are several combinations of reduced power in which one of more portions of the platform are in a power saving mode. This is shown in Table 13.

Table 13. Platform Power Modes

Core and Platform	NEON	L1	L2
Powered Up	Powered Up	Powered Up	Powered Up
Powered Up	Reset (ARM Mode)	Powered Up	Powered Up
State Retention	State Retention	State Retention	State Retention
State Retention	State Retention	Powered Down	State Retention
State Retention	State Retention	State Retention	Powered Down
State Retention	State Retention	Powered Down	Powered Down

Chapter 15
Platform Debug

15.1 Introduction

This chapter provides an overview of the ARM platform debug. It covers the modules inside the tigerp_gp_debug block and the modules that support the platform debug within the SOC, but external to the ARM platform.

Debug for the ARM platform uses ARM's DK11 CoreSight Debug Kit. The following CoreSight modules are used: DAP, ETM, CSREPLICATOR, CSTPIU, CSETB, CSCTI, and the CSCTM. This introduction provides a brief description of each module. For more in-depth information, please refer to the CoreSight_DK_TRM and other relative documentation from ARM.

15.1.1 Overview

ARM's CoreSight Design Kit (CSDK) provides a single solution for multi core and bus trace. The CSDK provides the following capabilities for system-wide trace:

- Debug and trace visibility of the entire system
- Cross-triggering support between SOC subsystems
- Multisource trace in a single stream
- Higher data compression than previous solutions
- Standard programmer's models for standard tools solutions

The CoreSight Design Kit comprises the following main components: control and access, sources, links, and sinks.

- Control and access components configure, access, and control the generation of trace. They neither generate nor process trace data. Examples include the DAP (debug access port) and the ECT (embedded cross trigger interface).
- Source components generate trace data. Example source components are the ETM (embedded trace macrocell) and the future XTM (AXI trace macrocell).
- Link components provide connection, triggering and flow of trace data. Link examples include the ATB replicator and the CoreSight Trace funnel.
- Sink components are the end point for trace data on an SOC. Example sinks are the TPIU (trace port interface unit) and the ETB (embedded trace buffer).

Figure 15-1. shows the ARM Platform debug block diagram. Further detail of the modules shown in the diagram are given in the next sections.

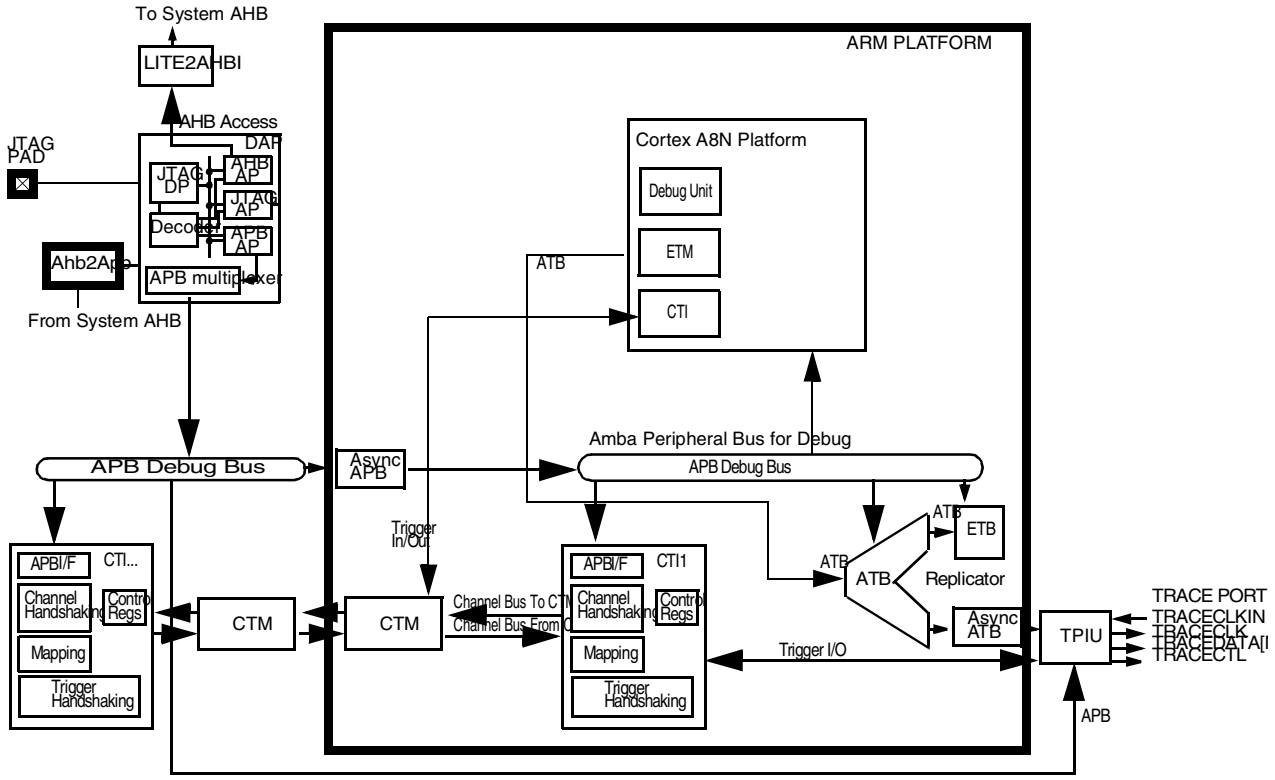

Figure 15-1. ARM Platform Debug Block Diagram

15.1.2 ARM Debug Modules

This section provides an overview of the Debug modules used in the ARM platform and also the modules outside the platform that are included in the CoreSight debug system.

The following modules are included in the ARM platform debug block: CSETB, CSCTI, CSCTM, CSREPLICATOR, and APB address decode logic.

The following modules are part of the ARM platform, outside the debug block: ETMv3.3 (embedded in the Cortex), CTI (also embedded in the Cortex), the Processor Debug Unit, and two asynchronous bridges: the asyncapb and the asyncatb.

Also included in this block guide is an overview of the DAP and TPIU that reside outside the ARM platform, yet are key components to the debug system.

15.1.2.1 Processor Debug Unit

The processor debug unit assists in debugging software running on the processor. In combination with a software debugger program, the debug unit enables debugging the following:

- Application software
- Operating systems
- Hardware systems based on an ARM processor

The debug unit enables the following:

- Stopping program execution
- Examining and altering processor and coprocessor states
- Examining and altering memory and input/output peripheral states
- Restarting the processor core

There are three ways to debug software running on the processor, as follows:

- Halt debug-mode debugging
- Monitor debug-mode debugging
- Trace debugging (ETM) (covered in a different section)

15.1.2.1.1 Halting Debug Mode Debugging

Halting debug-mode debugging is invasive. The processor halts when a debug event, such as a break point, occurs. An external debugger can examine and modify the processor state via the APB while the processor is halted.

15.1.2.1.2 Monitor Debug Mode Debugging

When a debug event occurs during monitor debug-mode debugging, instead of halting the processor, the processor takes an exception. Special software can then take control to examine or alter the processor state. When execution of a monitor target starts, the state of the processor is preserved in the same manner as all ARM exceptions.

15.1.2.1.3 Programming the Debug Unit

The processor unit is programmed using the APB slave port. Features that can be accessed using the memory-mapped APB registers are as follows:

- Instruction address comparators for triggering break points
- Data address comparators for triggering watchpoints
- A bidirectional Debug Communication Channel (DCC)
- All other state information associated with the debug unit

15.1.2.2 ARM Platform ETM

The ETM provides real time instruction trace for the Cortex A8N processor. It is designed to be used with the CoreSight Design Kit. Unlike previous versions of the ARM platforms, this ETM is embedded inside the Core.

Real time tracing is controlled by specifying a set of filtering and triggering resources which include address and data comparators, counters, and sequencers. Note that although data trace cannot be enabled, the ETM can still trigger based on data values. Also, the ETM can trace data address values.

The ETM contains the following main components:

- Core interface
- Trace generation
- Filtering and triggering resources
- Main FIFO
- AMBA 3 ATB interface
- AMBA 3 APB interface

The ETM provides a number of configurations. Table 15-1 shows the options implemented in the ETM.

Table 15-1. ETMv3.3 Configurations

Resource Description	Configuration
Instruction trace	Yes
Data address trace	Yes
Data value trace	No
Jazelle trace	-
Address comparator pairs	2
Data comparator	4
Context ID comparators	1
Sequencer	Yes
Start/stop block	Yes
Embedded ICE comparators	0
External inputs	4
External outputs	2
Extended external inputs	49
Extended external input selectors	2
Instrumentation resources	4
FIFO full	No
FIFO full level setting	N/A
Branch broadcasting	Yes

Resource Description	Configuration
ASIC control register (bits)	8
Data suppression	Yes
Software access to registers	Memory
Readable registers	Yes
FIFO size	128 bytes
Minimum port size	32
Maximum port size	32
Port modes	Dynamic
Asynchronous ATB	Yes
Load pc first	No
Fetch comparisons	No

15.1.2.3 CSETB

The ETB provides on chip storage of trace data. The ARM platform implements a 32-bit 4K RAM.

The ETB accepts trace data from a CoreSight replicator via an ATB write port. The ETB is configurable through an APB port.

Features are as follows:

- 4-Kbyte compiled memory for the trace buffer. Note: It can no longer be used as a general purpose memory.
- Only 32-bit accesses to the 4-Kbyte buffer is supported (Note: RAM size is 4K “bytes”— i.e. $1K \times 32$)
- Amba Peripheral Bus interface for configuration and memory access

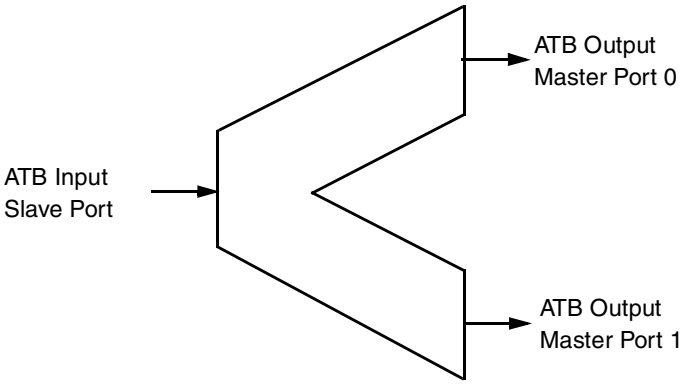
15.1.2.4 CSREPLICATOR

The ATB Replicator enables two trace sinks (TPIU and ETB) to be wired together and receive ATB trace data from the same trace source (ETM). There are no programmable registers. It takes incoming trace data from a single source (ETM) and replicates it to two master ports.

The CSREPLICATOR is part of the tigerp_gp_debug block. Two output master ports are required for this design: one for the on-platform ETB and one for the off-platform TPIU. Placing the TPIU off platform

allows future debug trace sources to connect to the TPIU via a FUNNEL, without the need to modify the ARM platform. Figure 15-2 shows a block diagram for the CSREPLICATOR.

Figure 15-2. CSREPLICATOR Block Diagram



15.1.2.5 CSTPIU

The TPIU acts as a bridge between on-chip trace data, ID distinguishable, and a TPA. It receives ATB trace data and sends it off chip via ARM's standard trace signals TRACECLK, TRACEDATA, and TRACECTL. The following submodules are included in the TPIU (see Figure 15-3): ATB interface, APB interface, Formatter, Asynchronous FIFO, Register bank, Trace out serializer, and a Pattern generator. Further information on the TPIU can be found in ARM's technical reference manuals.

The TPIU is not on the ARM platform and is configurable via the APB.

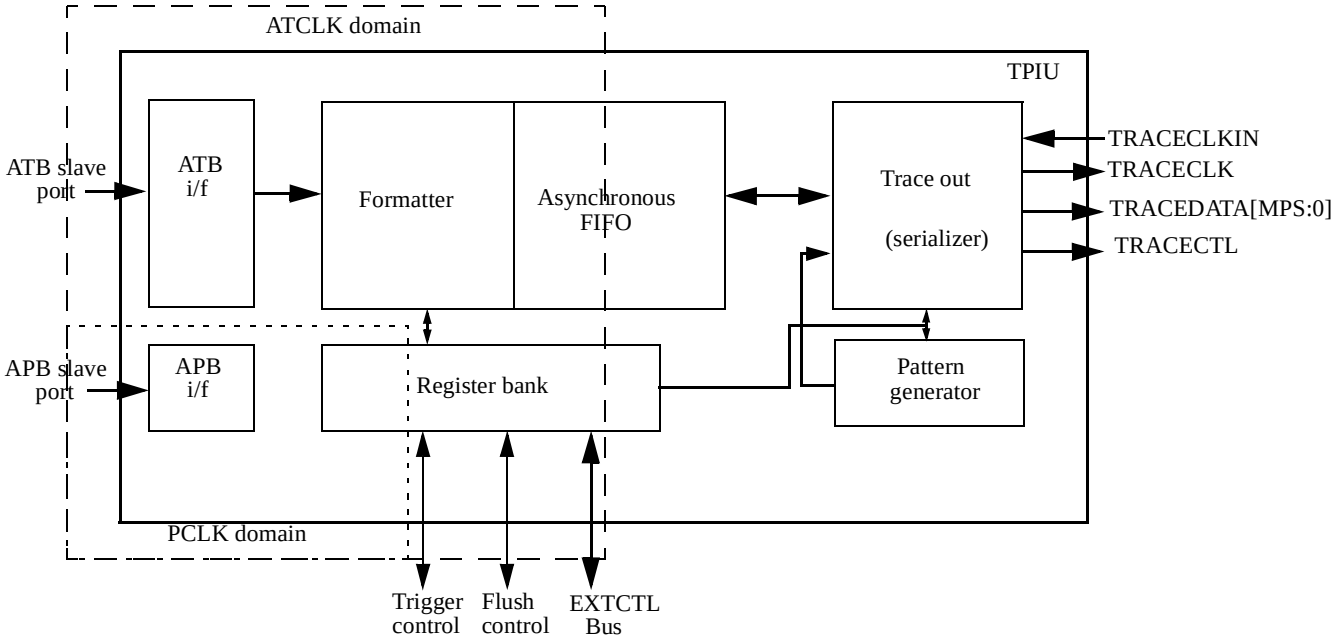


Figure 15-3. TPIU Block Diagram

All signal paths to the pads are subject to wire delays. Special consideration should be taken to re-balance the paths, removing the relative skews between the signals. An extra delay must be added on the TRACECLK path to ensure its rising and falling edge are during the stable part of TRACEDATA and TRACECTL.

15.1.2.6 CSCTI

The CSCTI is the CoreSight Cross Trigger Interface component of a ECT (Embedded Cross Trigger) system. The CSCTI combines and maps trigger requests and broadcast them to all other interfaces on the ECT as channel events. This enables subsystems to cross trigger with each other.

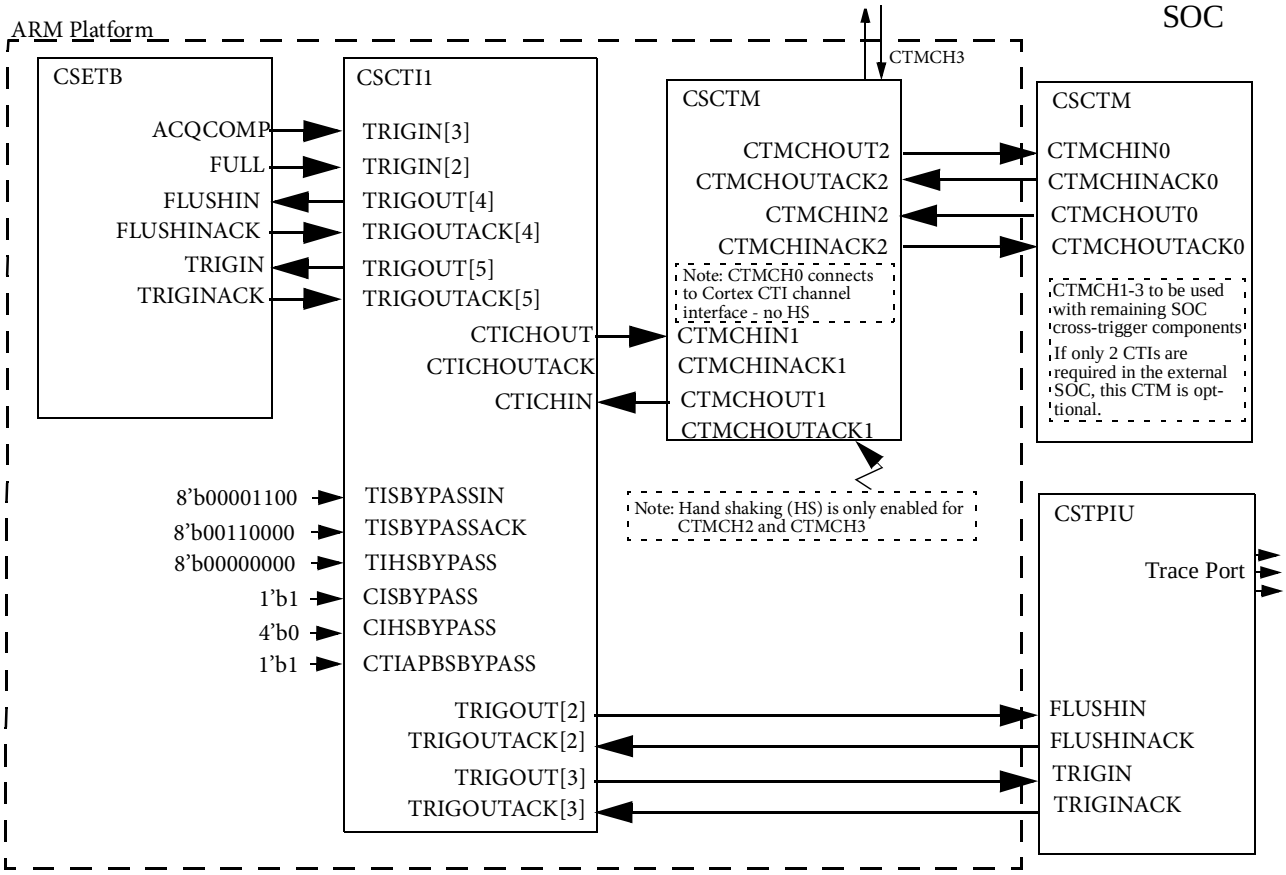
Each CTI has eight trigger inputs, eight trigger outputs, and four sets of 4-channel I/O(s). There are also acknowledge signals, configurable on/off, for the trigger and channel outputs. The channels connect to a CSCTM (CoreSight Cross Trigger Matrix). The CSCTM is off platform so special consideration should be taken for enabling the synchronizers and handshaking features on both the CSCTI and the CSCTM.

The platform requires one CTI module in addition to the embedded CTI in the ARM core. CTI0 resides in the Core and handles triggers/events from the CSETM and the CORE. Where as CTI1 handles the trigger/events for the TPIU (off platform) and the CSETB. Because the TPIU is outside the platform (asynchronous), the TRIGIN synchronizers are enabled and handshaking is turned on.

The on-platform CTI1 is synchronous and at the same clock speed as the on-platform CTM. This allows the channel handshaking and channel synchronizers to be bypassed.

Figure 15-4 shows the recommended connections for CSCTI1

Figure 15-4. CSCTI1 Connections



The SOC CTIs require additional logic to support asynchronous trigger source/destinations. The cscti_extended module includes logic, in addition to the CSCTI module, to support triggering across asynchronous boundaries where the source/destination might not have the necessary logic to support asynchronous boundaries.

15.1.2.7 CSCTM

This block controls the distribution of channel events. It provides channel interfaces to the CSCTIs. The CSCTM can also connect to another CSCTM via a channel interface. This allows multiple CSCTMs to be connected.

The platform has one CSCTM inside the platform to handle events between the platform's CSCTIs and the rest of the ECT system outside the platform. Placing a CSCTM on platform minimizes the event cycle time between the ETB and the ETM. The handshaking between the CTIs on-platform and the on-platform CTM are not enabled. This requires the Cortex's CTI, the on-platform CTI1 and the on-platform CTM to all be in the same clock domain. The on-platform CTM connects to the ECT system via an off-platform CTM and the respective channels require synchronizing and handshaking enabled.

If only two CTIs are required in the SOC, they can be connected directly to the on-platform CTM eliminating the need for a CTM outside the platform.

More information on the CoreSight ECT system can be found in ARM's Technical Reference manuals.

15.1.2.8 DAP

The DAP provides multiple master driving ports, all accessible via a single external interface port. Components that access the DAP are called Debug Ports (DP) and components that access internal interfaces are called Access Ports (AP).

The DAP provides real-time access for the debugger without halting the core to the following:

- All debug configuration registers
- AMBA system memory and peripheral registers.

The DAP enables debug access to the complete SOC via a number of access ports. Access to the CoreSight Debug APB is enabled through the APB access port (APB-AP). System access can be accomplished via an AHB access port (AHB-AP). An APB multiplexor allows system accesses to debug CoreSight components connected to the APB.

There is also a JTAG access port (JTAG-AP) providing accesses to on-chip JTAG components. The DAP acts as a JTAG master. This feature is not used for the ARM platform because the core's debug logic is now accessible via the APB.

Figure 15-5 shows a block diagram of the DAP.

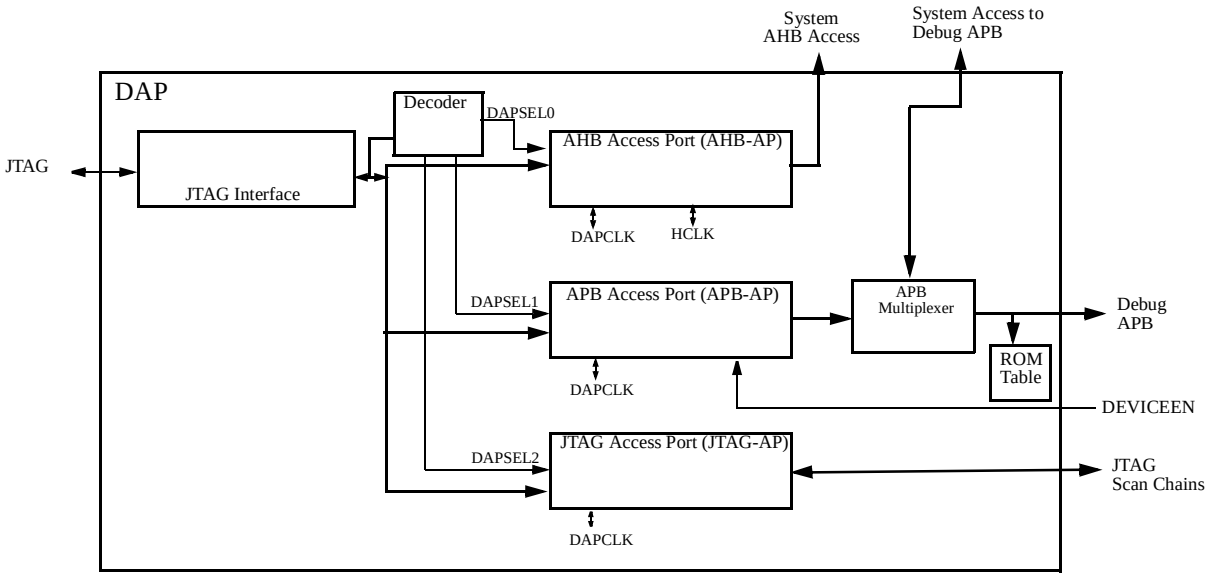


Figure 15-5. DAP Block Diagram

15.1.2.8.1 DAP_SYS

The DAP also requires decode logic for the CoreSight component PSEL signals, an AHB to APB bridge, an AHB lite to AHB bridge, detect logic to enable debug and reset synchronization logic. The dap_sys module wraps these components with the DAP. Figure 15-6 shows a block diagram of the DAP_SYS.

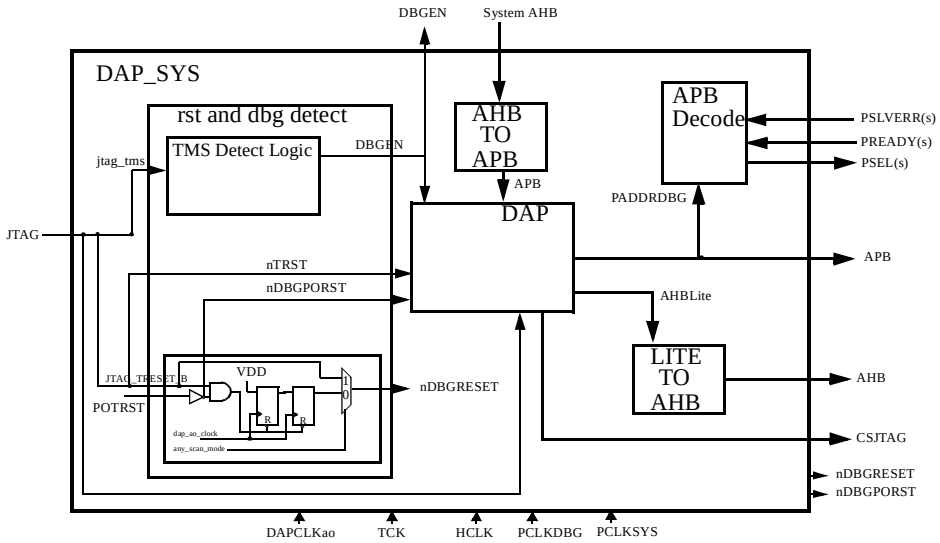

Figure 15-6. DAP_SYS Block Diagram

15.1.3 Modes of Operation

15.1.3.1 ARM Invasive Debug Mode

ARM Invasive Debug mode is usually entered via the JTAG port. Inside the dap_sys there is logic to assert DBGEN high when jtag_tms is active. The user can also invoke DBGEN by writing to a register inside the tiger plat_ctrl module.

It is required that NIDEN is asserted while DBGEN is asserted. Otherwise, CTI functionality is limited when TINIDENSEL is tied to 0. Due to this requirement, NIDEN into the Core and the Debug block is a combination of dbg_niden ored with dbgen_in.

15.1.3.2 ARM Non-Invasive Debug Mode (Real-Time Trace)

There are two methods to enter non-invasive debug mode: through JTAG or via memory mapped accesses. For memory mapped accesses, non-invasive debug can be enabled by writing to two secure supervisor registers, one within the CSU and one within the ARM platform.

15.1.3.3 Normal-Operating Modes

During normal operating mode, debug is not enabled.

15.1.3.4 Low-Power Modes

During deep sleep mode (DSM) all debug is disabled. The platform_ctl module has a bit allocated to overriding DSM when debug is enabled. This bit currently resets to a state disabling DSM while debug is enabled. For more information, refer to the platform control block guide.

The core has an input, DBGNOCLKSTOP, allowing the core's debug clocks to stay on while in WFI. The same bit used to override DSM should be connected to DBGNOCLKSTOP (inverted).

15.2 Memory Map and Register Definition

Each CoreSight component has an allocated 4K. CoreSight components are part of either CoreSight Class or ROM Class. Figure shows the CoreSight class layout for a 4-Kbyte block.

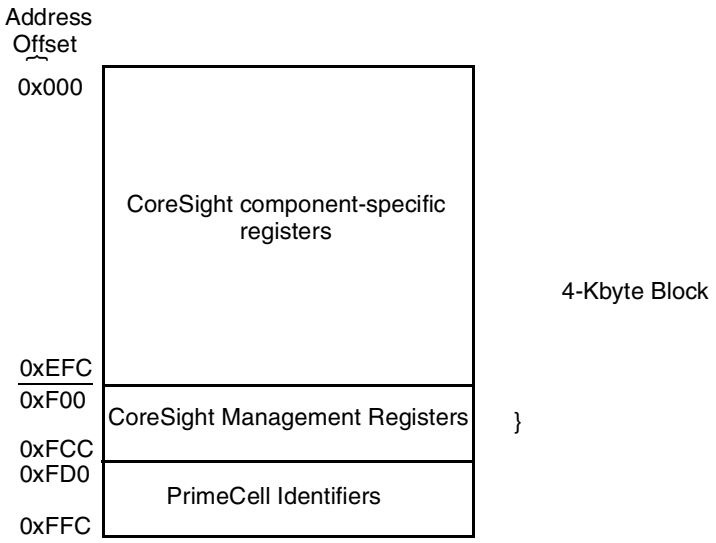

Figure 15-7. CoreSight Component Memory Map

Table 15-2 shows an example Debug memory map. The most significant half word of the address changes based on the chip-level memory map.

Table 15-2. Block Memory Map

Start Address	End Address	Size	Target IP	Comments
B0C00000	B0C00FFF	4K	Debug ROM	Located inside DAP
B0C01000	B0C01FFF	4K	ETB	—
B0C02000	B0C02FFF	4K	ETM	—
B0C03000	B0C03FFF	4K	TPIU	—
B0C04000	B0C04FFF	4K	CTI0	On platform
B0C05000	B0C05FFF	4K	CTI1	On platform

Table 15-2. Block Memory Map (continued)

Start Address	End Address	Size	Target IP	Comments

B0C07000	B0C07FFF	4K	CTI3	Off platform

15.2.1 Register Summary

This section summarizes the CoreSight Component registers in a table format. The tables are divided by Components. For a more detailed description of each register, refer to the CoreSight_DK_TRM.

The conventions in Table 15-3 serve as a key for the register summary.

Table 15-3. Register Conventions

Register Field Types	
RO	Read only. Writing this bit has no effect.
WO	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
RAZ	Read-as-zero
WI	Writes ignored
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)

15.2.1.1 DAP JTAG DP Registers

Accessing a JTAG DP register depends on both the instruction register (IR) value of the DAP access and the address field of the DAP access.

Table 15-4 shows a register summary table for the DAP DP. Detailed register descriptions can be found inside the CoreSight_DK_TRM provided by ARM.

Table 15-4. DAP JTAG DP Registers

Address Field	IR Contents	Type	Register Name
[1]	IDCODE	RO	Identification Control Register
0x0	DAPACC	RAZ/WI	Reserved
0x4	DAPACC	R/W[3]	DP Control/Status Register
0x8	DAPACC	R/W	Select Register
0x0	ABORT	WO[2]	DAP Abort Register
0x4-0xC	ABORT	[2]	Reserved

[1] There is no address associated with the ID code register. For more information, see the CoreSight_DK_TRM.

[2] The value read on the abort scan chain is unpredictable. The result of accessing the abort scan chain without the address set to 0x0 is unpredictable.

15.2.1.2 DAP ROM Register Summary

The ROM table stores the locations of components on the debug APB. The DAP ROM is read only and configurable through the DAPROM.v and DapRomDefs.v RTL files. Writes are ignored.

Table 15-5 shows a register summary table for the DAP Rom. Detailed descriptions can be found inside the CoreSight_DK_TRM provided by ARM.

Table 15-5. DAP ROM Registers

Offset	Name	Type	Description
0xFD0	Peripheral ID4	RO	See CoreSight_DK_TRM
0xFD4	Peripheral ID5	RAZ	Reserved
0xFD8	Peripheral ID6	RAZ	Reserved
0xFDC	Peripheral ID7	RAZ	Reserved
0xFE0	Peripheral ID0	RO	See CoreSight_DK_TRM
0xFE4	Peripheral ID1	RO	See CoreSight_DK_TRM
0xFE8	Peripheral ID2	RO	See CoreSight_DK_TRM
0xFEC	Peripheral ID3	RO	See CoreSight_DK_TRM
0xFF0	Component ID0	RO	Set to 0x0D
0xFF4	Component ID1	RO	Set to 0x10
0xFF8	Component ID2	RO	Set to 0x05
0xFFC	Component ID3	RO	Set to 0xB1

15.2.1.3 Processor Debug Unit Register Summary

Most of the debug unit registers are accessible through the APB. There are some registers that can also be accessed through the coprocessor interface CP14.

By default, CP14 registers can be accessed from a non-privileged mode. However, the processor can be programmed to disable user access modes using bit [12] of the Debug Status and Control Register (DSCR). For more information on the DSCR and access to CP14 registers, refer to the CortexA8 TRM document.

15.2.1.3.1 Coprocessor Registers Summary

Table 15-6 shows the valid debug instructions for accessing the debug registers.

Table 15-6. CP14 Debug Registers Summary

Instruction	Mnemonic	Description
MRC p14, 0, <Rd>, c0, c0, 0	DIDR	Debug Identification Register
MRC p14, 0, <Rd>, c1, c0, 0	DRAR	Debug ROM Address Register

Table 15-6. CP14 Debug Registers Summary

Instruction	Mnemonic	Description
MRC p14, 0, <Rd>, c2, c0, 0	DSAR	Debug Self Address Register
MRC p14, 0, <Rd>, c0, c5, 0 STC p14, c5, <addressing mode>	DTRRX	Data Transfer Register - Receive
MCR p14, 0, <Rd>, c0, c5, 0 LDC p14, c5, <addressing mode>	DTRTX	Data Transfer Register - Transmit
MRC p14, 0, <Rd>, c0, c1, 0 MRC p14, 0, PC, c0, c1, 0	DSCR	Debug Status and Control Register

15.2.1.3.2 Memory-Mapped Registers Summary

Table 15-7 shows a complete list of memory mapped registers accessible using the APB slave port.

Table 15-7. Debug Unit APB Accessible Registers Summary

Offset	Register Number	Mnemonic	Type	Description
0x000	c0	DIDR	R	CP14 c0, Debug ID Register
0x004–0x014	c1–c5	—	R	RAZ
0x018	c6	WFAR	R/W	Watchpoint Fault Address Register
0x01C	c7	VCR	R/W	Vector Catch Register
0x020	c8	—	R	RAZ
0x024	c9	ECR	R/W	Event Catch Register
0x028	c10	DSCCR	R/W	Debug State Cache Control Register
0x02C	c11	—	R	RAZ
0x030–0x07C	c12–c31	—	R	RAZ
0x080	c32	DTRRX	R/W	Data Transfer Register—Receive
0x084	c33	ITR	W	Instruction Transfer Register
0x088	c34	DSCR	R/W	CP14 c1, Debug Status and Control Register
0x08C	c35	DTRTX	R/W	Data Transfer Register—Transmit
0x090	c36	DRCR	W	Debug Run Control Register
0x094–0x09C	c37–c63	—	R	RAZ
0x100–0x114	c64–c69	BVR	R/W	Breakpoint Value Registers
0x118–0x13c	c70–c79	—	R	RAZ
0x140–0x154	c80–c85	BCR	R/W	Breakpoint Control Register
0x158–0x17C	c86–c95	—	R	RAZ
0x180–0x184	c96–c97	WVR	R/W	Watchpoint Value Register
0x188–0x1BC	c97–c111	—	R	RAZ
0x1C0–0x1C4	c112–c113	WCR	R/W	Watchpoint Control Registers

Table 15-7. Debug Unit APB Accessible Registers Summary (continued)

Offset	Register Number	Mnemonic	Type	Description
0x1C8-0x1FC	c114-c127	—	R	RAZ
0x200-0x2FC	c128-c191	—	R	RAZ
0x300	c192	OSLAR	W	Operating System Lock Access Register
0x304	c193	OSLSR	R	Operating System Lock Status Register
0x308	c194	OSSRR	R/W	Operating System Save and Restore Register
0x30C	c195	—	R	RAZ
0x310	c196	PRCR	R/W	Device Power Down and Reset Control Register
0x314	c197	PRSR	R	Device Power Down and Reset Status Register
0x318-0x7FC	c198-c511	—	R	RAZ
0x800-0x8FC	c512-575	—	R	RAZ

15.2.2 Clocks

The list below describes the Debug clocks within the ARM platform.

- ATCLK

  This is the AMBA Trace Bus (ATB) clock. This clock is also used to clock the on-platform CTICLK and on-platform CTMCLK. ATCLK needs to be synchronous (equivalent or faster) to PCLKDBG.
- CTICLK

  This is the main clock for the CTI module. The current platform configuration requires this clock to be synchronous to the on-platform CTM clock.
- PCLKDBG

  This is the Debug APB clock. It must be synchronous (equivalent or slower) to the ATCLK.
- TRACECLKIN

  This is the Trace Port Interface Unit trace clock input. Since the trace port pads are limited to 133 MHz, TRACECLKIN is pad limited to less than or equal to 266 MHz.
- TRACECLK

  This is the clock for the external trace port. It is a DDR clock and runs at ½ the speed of TRACECLKIN.

The platform control module generates the debug clocks from the arm clock. The requirement above states that the PCLKDBG needs to be synchronous to the ATCLK. When configuring the divide by settings, make sure this requirement is followed. PCLKDBG is a divide by two of ATCLK.

15.2.3 Reset

All debug resets are derived from JTAG_TRST_B and POR. These two resets go into the DAP_SYS to be combined and de-asserted synchronously to the DAPCLKao (always on clock). They also go into the platform, being synchronously de-asserted inside the plat_cntrl module, generating resets for the debug logic inside the platform. Debug resets that do not require synchronous de-assertion are routed directly to

their destination, such as por for the Core and ETM. Figure 15-8 shows a diagram of the platform debug reset strategy.

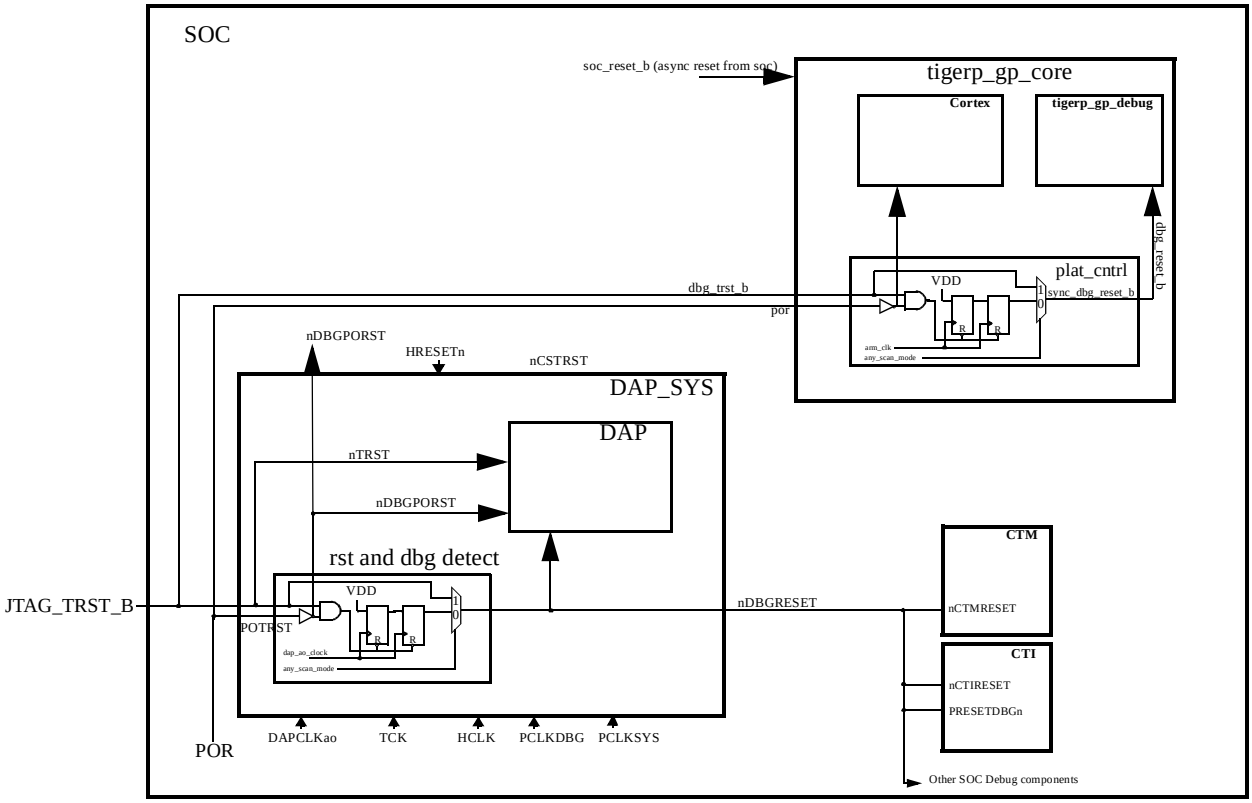

Figure 15-8. Platform Debug Reset Strategy

15.2.4 Endianness

Little endianness is supported; big endianness is not supported.

Chapter 16
Multi-Layer AHB Crossbar Switch (MAX)

This chapter provides an overview of the MAX (Multi-Layer AHB Crossbar Switch). The purpose of the MAX is to concurrently support up to 4 simultaneous connections between master ports and slave ports. The MAX supports a 32-bit address bus width and a 32-bit data bus width at all master and slave ports. A simplified block diagram is shown in Figure 16-1.

NOTE

The MAX implements a 7 master by 4 slave configuration.

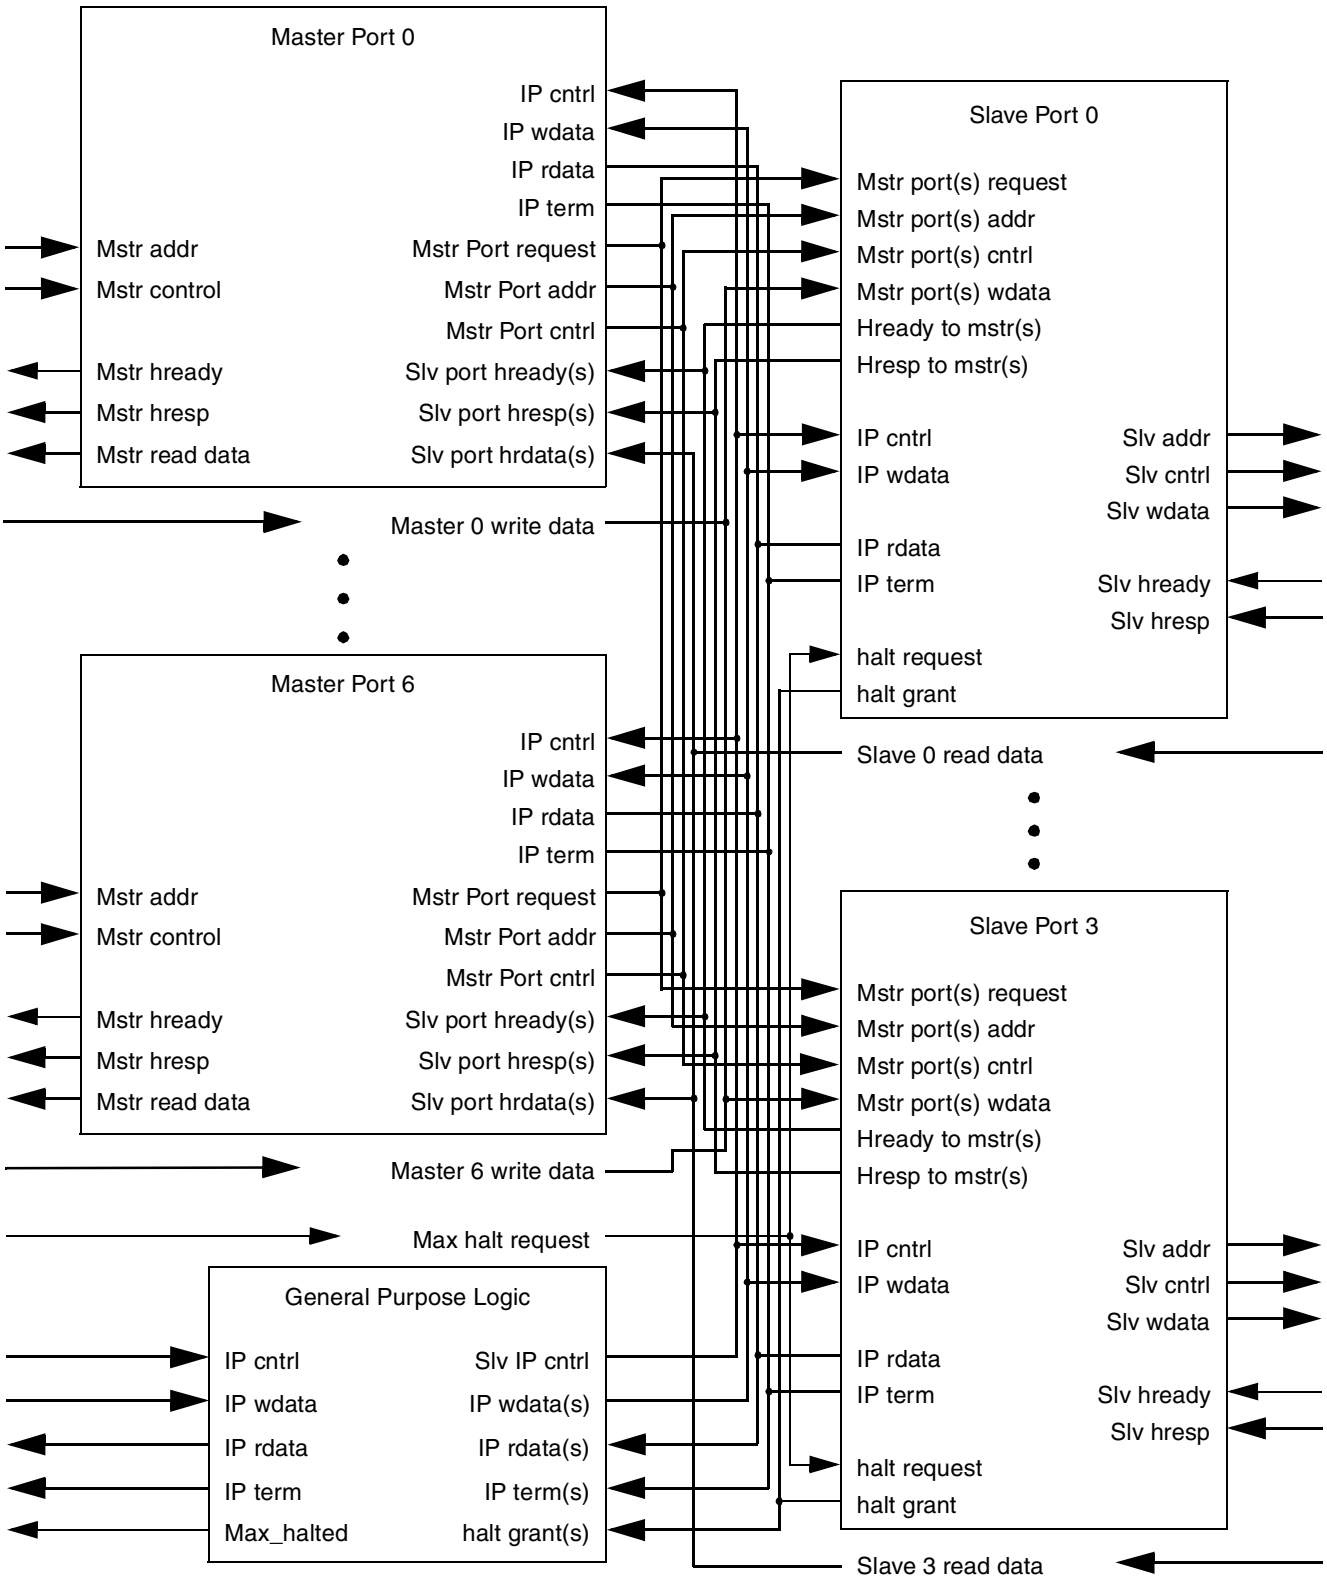

Figure 16-1. MAX Block Diagram

16.1 Features

The MAX has the ability to gain control of all the slave ports and prevent any masters from making accesses to the slave ports. This feature is useful when the user wishes to turn off the clocks to the system and needs to ensure that no bus activity is interrupted.

The MAX can put each slave port into a low-power park mode so that the slave port does not dissipate any power transitioning address, control, or data signals when not being actively accessed by a master port.

Each slave port can also support multiple master priority schemes. Each slave port has a hardware input which selects the master priority scheme so the user can dynamically change master priority levels on a slave port by slave port basis.

The MAX allows concurrent transactions to occur from any master port to any slave port. It is possible for four master ports and all slave ports to be in use at the same time as a result of independent master requests. If a slave port is simultaneously requested by more than one master port, arbitration logic selects the higher priority master and grant it ownership of the slave port. All other masters requesting that slave port are stalled until the higher priority master completes its transactions.

16.1.1 Limitations

The MAX routes bus transactions initiated on the master ports to the appropriate slave ports. There is no provision included to route transactions initiated on the slave ports to other slave ports or to master ports. Simply put, the slave ports do not support the bus request/bus grant protocol, the MAX assumes it is the sole master of each slave port.

Because the MAX does not support the bus request/bus grant protocol, an external arbiter needs to be used if multiple masters are to be connected to a single master port. In the case of a single master connecting to a master port, the single master's bus grant signal must be tied off in the asserted state.

Each master and slave port is fully AHB-Lite + AMBA V6 extensions compliant. The ports are not fully AHB compliant because the MAX does not support SPLITs or RETRYs.

16.1.2 General Operation

When a master makes an access to the MAX, the access is immediately taken by the MAX. If the targeted slave port of the access is available, the access is immediately presented on the slave port. It is possible to make single clock (zero wait state) accesses through the MAX. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted (**hready** held negated) until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding peripheral's access time.

Since the MAX appears to be just another slave to the master device, the master device has no knowledge of whether or not it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it is simply wait stated.

A master is given control of the targeted slave port only after a previous access to a different slave port has completed, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when a master has an outstanding request to one slave port that has a long response time, has a

pending access to a different slave port, and a lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

Once the master has control of the slave port it is targeting the master remains in control of that slave port until it gives up the slave port by running an IDLE cycle or by leaving that slave port for its next access. The master could also lose control of the slave port if another higher priority master makes a request to the slave port; however, if the master is running a locked or fixed length burst transfer it retains control of the slave port until that transfer is completed. Based on the AULB bit in the MGPCR (Master General Purpose Control Register) the master either retains control of the slave port when doing undefined length incrementing burst transfers or loses the bus to a higher priority master.

The MAX terminates all master IDLE transfers (as opposed to allowing the termination to come from one of the slave busses). Additionally, when no master is requesting access to a slave port the MAX drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port. When the MAX is controlling the slave bus (i.e. during low power park or halt mode) the **hmaster** field indicates 4'b0000.

When a slave bus is being IDLEd by the MAX, it can park the slave port on the master port indicated by the PARK bits in the SGPCR (Slave General Purpose Control Register). This can be done in an attempt to save the initial clock of arbitration delay that would otherwise be seen if the master had to arbitrate to gain control of the slave port. The slave port can also be put into low power park mode in attempt to save power.

16.2 MAX Interface Signals

This section provides information on MAX interface signals, including AHB master and slave interface signals as well as IP bus interface signals.

16.2.1 MAX Signal Descriptions

Please reference the AMBA Specification Rev 2.0 for a description of the AHB signals in the MAX and the IP Bus Specification Rev 2.0 for a description of the IP Bus signals in the MAX.

16.2.1.1 max_halt_request

This input signal is a request to halt all slave port bus activity (run MAX originated IDLE cycles on each slave port bus, blocking all master port accesses). This signal can be used to gracefully shut down the MAX so the system clock can be stopped for low power mode. This signal is captured by a flop inside the MAX before use.

Once the MAX is halted, it remains halted until **max_halt_request** is negated.

16.2.1.2 max_halted

This output is asserted once the MAX is in control and running IDLE cycles on each slave port.

16.3 Memory Map and Register Definition

There are four registers that reside in each slave port of the MAX and one register that resides in each master port of the MAX. These registers are IP bus compliant registers. Read and write transfers both require two IP bus clock cycles. The registers can only be read from and written to in supervisor mode. Additionally, these registers can only be read from or written to by 32-bit accesses. Section 16.3.3, MAX Register Descriptions," provides the detailed descriptions for all of the MAX registers.

The registers are fully decoded and an error response is returned if an unimplemented location is accessed within the MAX.

The slave registers also feature a bit, which when written with a 1 prevents the registers from being written to again. The registers are still readable, but future write attempts have no effect on the registers and will be terminated with an error response.

16.3.1 Memory Map

Table 16-1 shows the MAX memory map.

Table 16-1. MAX Memory Map

16.3.2 Register Summary

Figure 16-2 shows the key to the register fields and Table 16-2 shows the register figure conventions.

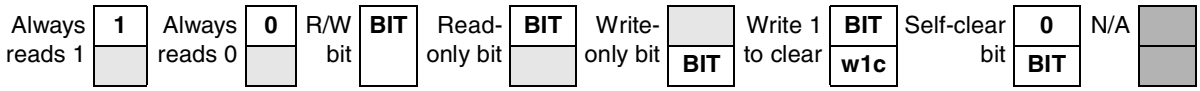

Figure 16-2. Key to Register Fields

Table 16-2. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 16-3 shows the MAX register summary.

16.3.3 MAX Register Descriptions

This section contains the detailed register descriptions for the MAX registers.

16.3.3.1 Master Priority Register (MPR0-MPR3)

The Master Priority Register (MPR) sets the priority of each master port on a per slave port basis and resides in each slave port. See Figure 16-3 for illustration of valid bits in the MPR and Table 16-4 for description of the bit fields.

0x43F0_4000(MPR0)
0x43F0_4100(MPR1)
0x43F0_4200(MPR2)
0x43F0_4300(MPR3)

Access: Supervisor read-write

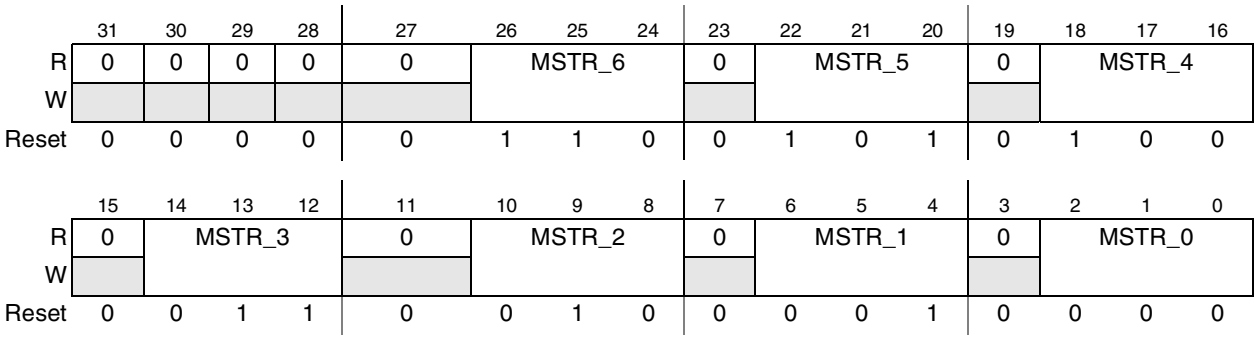

Figure 16-3. Master Priority Register (MPR0 - MPR3)

Table 16-4. Master Priority Register Descriptions

Field	Description
31–27	Reserved. They are read as zero and should be written with zero for upward compatibility.
26–24 MSTR_6	Master 6Priority. These bits set the arbitration priority for master port 6 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
23	Reserved. They are read as zero and should be written with zero for upward compatibility.
22–20 MSTR_5	Master 5 Priority. These bits set the arbitration priority for master port 5 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
19	Reserved. They are read as zero and should be written with zero for upward compatibility.
18–16 MSTR_4	Master 4 Priority. These bits set the arbitration priority for master port 4 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
15	Reserved. They are read as zero and should be written with zero for upward compatibility.

Table 16-4. Master Priority Register Descriptions (continued)

Field	Description
14–12 MSTR_3	Master 3 Priority. These bits set the arbitration priority for master port 3 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
11	Reserved. They are read as zero and should be written with zero for upward compatibility.
10–8 MSTR_2	Master 2 Priority. These bits set the arbitration priority for master port 2 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
7	Reserved. They are read as zero and should be written with zero for upward compatibility.
6–4 MSTR_1	Master 1 Priority. These bits set the arbitration priority for master port 1 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
3	Reserved. They are read as zero and should be written with zero for upward compatibility.
2–0 MSTR_0	Master 0 Priority. These bits set the arbitration priority for master port 0 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111This master has the lowest priority when accessing the slave port.

The Master Priority Register can only be accessed in supervisor mode with 32-bit accesses. Once the RO (Read Only) bit has been set in the Slave General Purpose Control Register, the Master Priority Register can only be read from. Attempts to write to it have no effect on the MPR and result in an error response.

Additionally, no two available master ports may be programmed with the same priority level. Attempts to program two or more available masters with the same priority level results in an error response, and the MPR is not updated.

16.3.3.2 Slave General Purpose Control Register (SGPCR0-SGPCR3)

The Slave General Purpose Control Register (SGPCR) controls several features of each slave port.

The Read Only (RO) bit prevents any registers associated with this slave port from being written to once set. This bit may be written with 0 as many times as the user desires, but once it is written to a 1 only a reset condition allows it to be written again.

The Halt Low Priority (HLP) bit sets the priority of the **max_halt_request** input to the lowest possible priority for initial arbitration of the slave ports. By default it is the highest priority. Please note, setting this bit does not affect the **max_halt_request** from attaining highest priority once it has control of the slave ports.

The PCTL bits determine how the slave port parks when no master is actively making a request. The available options are to park on the master defined by the PARK bits, park on the last master to use the slave port, or go into a low-power park mode that forces all the outputs of the slave port to inactive states when no master is requesting an access. The low-power park feature can result in an overall power savings

if a the slave port is not saturated; however, it forces an extra clock of latency whenever any master tries to access it when it is not in use because it is not parked on any master.

The PARK bits determine which master the slave parks on when no master is making an active request and the **max_halt_request** input is negated. Please use caution to only select master ports that are actually present in the design. If the user programs the PARK bits to a master not present in the current design implementation, undefined behavior results.

See Figure 16-4 for illustration of valid bits in the SGPCR, and Table 16-5 for description of the bit fields.

Figure 16-4. Slave General Purpose Control Register *n*

Table 16-5. Slave General Purpose Control Register Descriptions

Field	Description
31 RO	Read Only This bit is used to force all of a slave port's registers to be read only. Once written to 1 it can only be cleared by hardware reset. This bit is initialized by hardware reset. 0 All this slave port's registers can be written. 1 All this slave port's registers are read only and cannot be written (attempted writes have no effect and result in an error response).
30 HLP	Halt Low Priority This bit is used to set the initial arbitration priority of the max_halt_request input. This bit is initialized by hardware reset. 0 The max_halt_request input has the highest priority for arbitration on this slave port 1 The max_halt_request input has the lowest initial priority for arbitration on this slave port.
29–10	Reserved. They read as zero and should be written with zero for upward compatibility.
9–8 ARB	Arbitration Mode These bits are used to select the arbitration policy for the slave port. These bits are initialized by hardware reset. 00 Fixed Priority. 01 Round Robin (rotating) Priority. 10 Reserved 11 Reserved
7–6	Reserved. They read as zero and should be written with zero for upward compatibility.

Table 16-5. Slave General Purpose Control Register Descriptions (continued)

Field	Description
5–4 PCTL	Parking Control These bits determine the parking control used by this slave port. These bits are initialized by hardware reset. 00 When no master is making a request, the arbiter parks the slave port on the master port defined by the PARK bit field. 01 When no master is making a request, the arbiter parks the slave port on the last master to be in control of the slave port. 10 When no master is making a request, the arbiter parks the slave port on no master and will drive all outputs to a constant safe state. 11 Reserved
3	Reserved. They read as zero and should be written with zero for upward compatibility.
2–0 PARK	PARK These bits are used to determine which master port this slave port parks on when no masters are actively making requests and the PCTL bits are set to 00. These bits are initialized by hardware reset. 000 Park on Master Port 0 001 Park on Master Port 1 010 Park on Master Port 2 011 Park on Master Port 3 100 Park on Master Port 4 101 Park on Master Port 5 110 Park on Master Port 6 111 Reserved

The SGPCR can only be accessed in supervisor mode with 32-bit accesses. Once the RO (Read Only) bit has been set in the SGPCR the SGPCR can only be read, attempts to write to it have no effect on the SGPCR and result in an error response.

16.3.3.3 Master General Purpose Control Register

The Master General Purpose Control Register (MGPCR) presently controls only whether or not the master's undefined length burst accesses are allowed to complete uninterrupted or whether they can be broken by requests from higher priority masters.

The AULB (Arbitrate on Undefined Length Bursts) bit field determines whether (and when) the MAX arbitrates away the slave port the master owns when the master is performing undefined length burst accesses.

Figure 16-5. Master General Purpose Control Register *n*

Table 16-6. Master General Purpose Control Register Descriptions

Name	Description
31 - 3	Reserved. They read as zero and should be written with zero for upward compatibility.
2 - 0 AULB	Arbitrate on Undefined Length Bursts. These bits are used to select the arbitration policy during undefined length bursts by this master. These bits are initialized by hardware reset. 000 No arbitration is allowed during an undefined length burst. 001 Arbitration is allowed at any time during an undefined length burst. 010 Arbitration is allowed after four beats of an undefined length burst. 011 Arbitration is allowed after eight beats of an undefined length burst. 100 Arbitration is allowed after 16 beats of an undefined length burst. 101 Reserved 110 Reserved 111 Reserved

The MGPCR can only be accessed in supervisor mode with 32-bit accesses.

16.3.4 Coherency

Since the content of the registers has a real time effect on the operation of the MAX it is important for the user to understand that any register modifications take effect as soon as the register is written. The values of the registers do not track with slave port related AHB accesses but instead track only with IP bus accesses.

The exception to this rule are the AULB bits in the MGPCR. The update of these bits is only recognized when the master on that master port runs an IDLE cycle, even though the IP bus cycle to write them will have long since terminated successfully. If the AULB bits in the MGPCR are written in between two burst

accesses, the new AULB encodings does not take effect until an IDLE cycle has been initiated by the master on that master port.

16.4 Detailed Functional Description

This section describes the functionality of the MAX in greater detail.

16.4.1 Arbitration

The MAX supports two arbitration schemes; a simple fixed-priority comparison algorithm, and a simple round-robin fairness algorithm. The arbitration scheme is independently programmable for each slave port.

16.4.1.1 Arbitration During Undefined Length Bursts

Arbitration points during an undefined length burst are defined by the current master's MGPCR AULB field setting. When a defined length is imposed on the burst via the AULB bits, the undefined length burst is treated as a single or series of single back to back fixed length burst accesses. For example, a master runs an undefined length burst and the AULB bits in the MGPCR indicate arbitration occurs after the fourth beat of the burst. The master runs two sequential beats and then starts a 12-beat, undefined length burst access to a new address within the same slave port region as the previous access. The MAX does not allow an arbitration point until the fourth overall access (second beat of the second burst). At that point all remaining accesses are open for arbitration until the master loses control of the slave port.

Assume the master loses control of the slave port after the fifth beat of the second burst. Once the master regains control of the slave port, no arbitration point will be available until after the master has run four more beats of its burst. After the fourth beat of the (now continued) burst (ninth beat of the second burst from the master's perspective) is taken, all beats of the burst will once again be open for arbitration until the master loses control of the slave port.

Assume the master again loses control of the slave port on the fifth beat of the third (now continued) burst (10th beat of the second burst from the master's perspective). Once the master regains control of the slave port, it will be allowed to complete its final two beats of its burst without facing arbitration.

Note that fixed-length burst accesses arenot be affected by the AULB bits. All fixed- length burst accesses lock out arbitration until the last beat of the fixed-length burst.

16.4.1.2 Fixed Priority Operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the MPR (Master Priority Register). If two masters both request access to a slave port, the master with the highest priority in the selected priority register gains control over the slave port.

Any time a master makes a request to a slave port, the slave port checks to see if the new requesting master's priority level is higher than that of the master that currently has control over the slave port (unless the slave port is in a parked state). The slave port does an arbitration check at every clock edge to ensure that the proper master (if any) has control of the slave port.

If the new requesting master's priority level is higher than that of the master that currently has control of the slave port the new requesting master is granted control over the slave port at the next clock edge. The exception to this rule is if the master that currently has control over the slave port is running a fixed length burst transfer or a locked transfer. In this case the new requesting master must wait until the end of the burst transfer or locked transfer before it will be granted control of the slave port. If the master is running an undefined length burst transfer the new requesting master must wait until an arbitration point for the undefined length burst transfer before it will be granted control of the slave port. Arbitration points for an undefined length burst are defined in the MGPCR for each master.

If the new requesting master's priority level is lower than that of the master that currently has control of the slave port, the new requesting master is forced to wait until the master that currently has control of the slave port either runs an IDLE cycle or runs a non IDLE cycle to a location other than the current slave port.

16.4.1.3 Round-Robin Priority Operation

When operating in round-robin mode, each master is assigned a relative priority based on the master number. This relative priority is compared to the ID of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus as the next transfer boundary (accounting for locked and fixed-length burst transfers). Priority is based on how far ahead the ID of the requesting master is to the ID of the last master (ID is defined by master port number, not the **hmaster** field).

Once granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next assertion of **sX_hready**, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the MAX is implemented with master ports 0, 1, 2, 3, 4 and 5. If the last master of the slave port was master 1, and master 0, 4 and 5 make simultaneous requests, (master ports 2 and 3 make no requests), they are serviced in the order 4, 5, and then 0.

Parking may still be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff to the next master in line occurs after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

16.4.2 Priority Assignment

Each master port needs to be assigned a unique 3 bit priority level. If an attempt is made to program multiple master ports with the same priority level within a register (MPR), the MAX responds with an error and the registers are not updated.

16.4.3 Master Port Functionality

This section discusses the master port functionality.

16.4.3.1 General

Each master port consists of two decoders, a capture unit, a register slice, a mux, and a small state machine.

The first decoder is used to decode the **haddr** and control signals coming directly from the master, telling the state machine where the master's next access will be and if it is in fact a legal access. The second decoder gets its input from the capture unit, so it may be looking directly at the signals coming from the master or it may be looking at captured signals coming from the master, depending entirely on the state of the targeted slave port. The second decoder is then used to generate the access requests that go to the slave ports.

The capture unit is used to capture the address and control information coming from the master in the event that the targeted slave port cannot immediately service the master. The capture unit is controlled by outputs from the state machine which tell it to either pass through the original master signals or the captured signals.

The register slice contains the registers associated with the specific master port. The registers have a quasi-IP bus interface at this level for reads and writes and the outputs feed directly into the state machine.

The mux is used simply to select which slave's read data is sent back to the master. The mux is controlled by the state machine.

The state machine controls all aspects of the master port. It knows which slave port the master wants to make a request to and controls when that request is made. It also has knowledge of each slave port, knowing whether or not the slave port is ready to accept an access from the master port. This determines whether or not the master may immediately have its request taken by the slave port or whether the master port must capture the master's request and queue it at the slave port boundary.

For a block diagram of a master port see Figure 16-6.

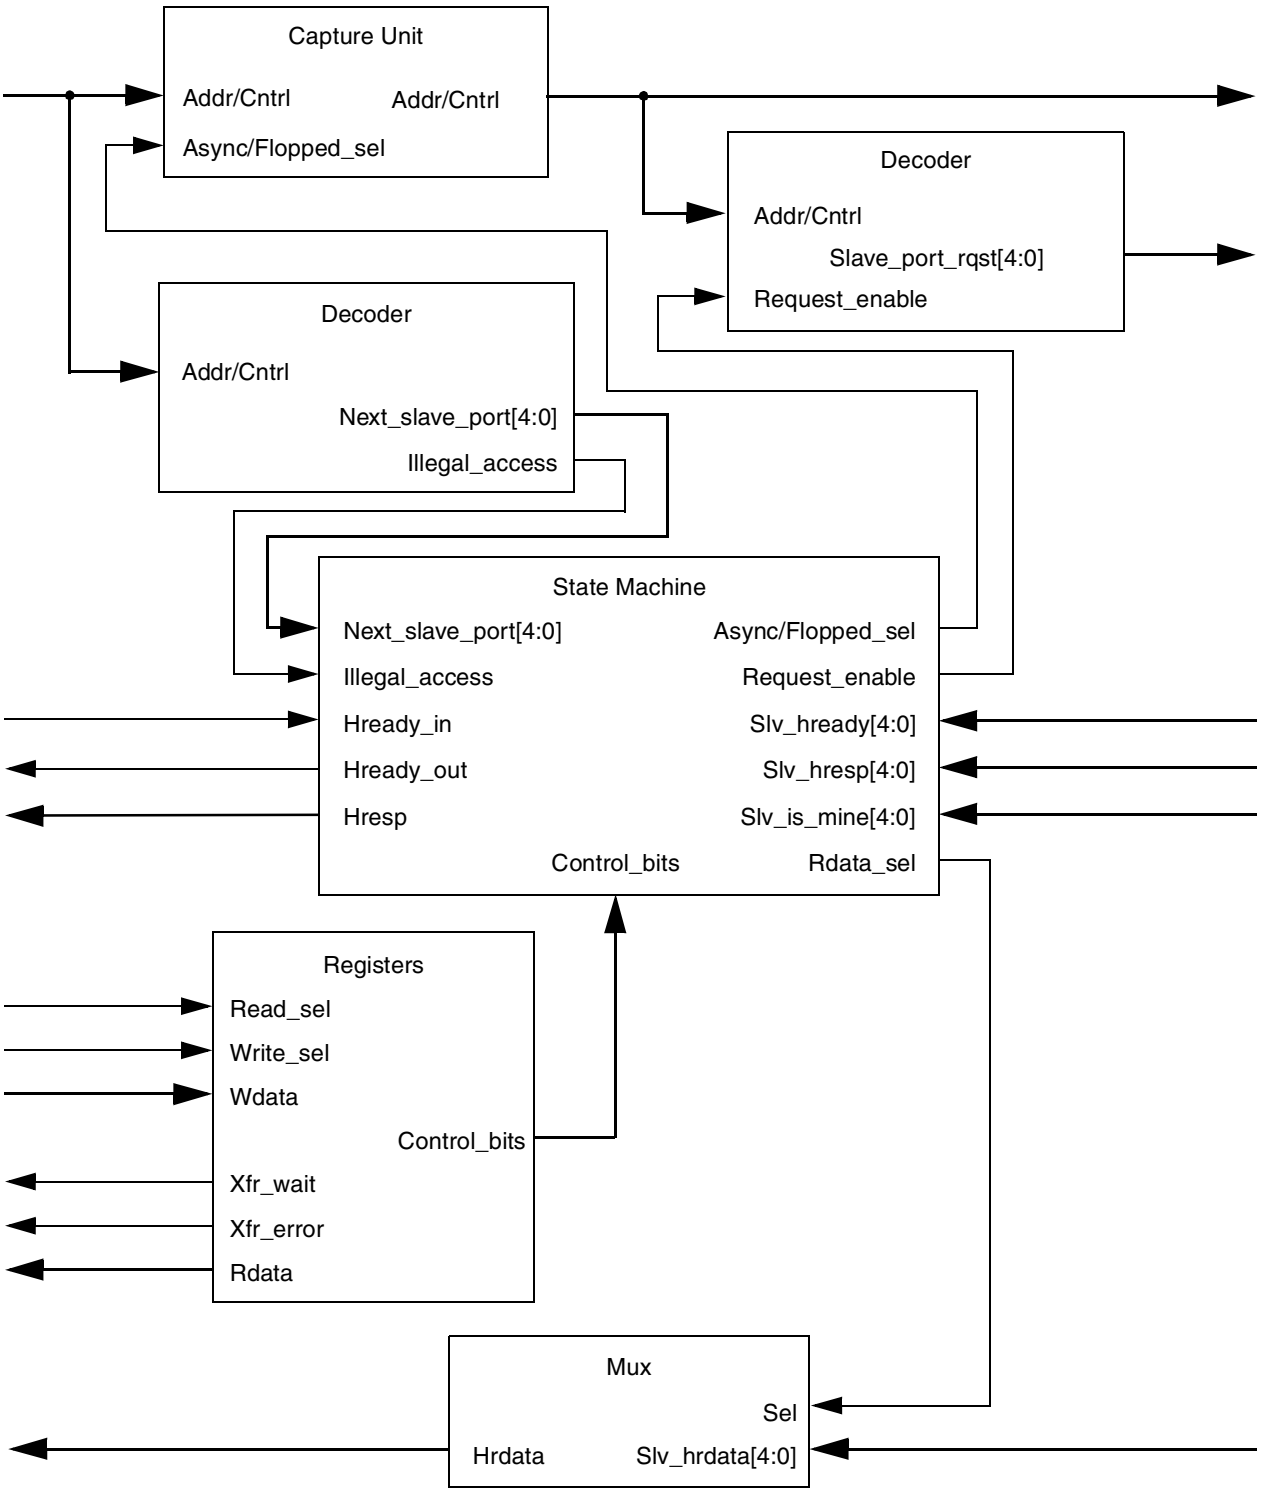

Figure 16-6. MAX Master Port Block Diagram

16.4.3.2 Master Port Decoders

The decoders are very simple as they ensure an access request is allowed to be made and that the slave port targeted is actually present in the design. The decoders feeding the state machine are always enabled. The decoders that select the slave are enabled only when the master port controlling state machine wants to make a request to a slave port. This is necessary so that if a master port is making an access to a slave port and is being wait stated, and its next access is to a different slave port, the request to the second slave port can be held off until the access to the first slave port is terminated.

The decoders also output a “hole decode” or illegal access signal which tells the state machine that the master is trying to access a slave port that does not exist.

16.4.3.3 Master Port Capture Unit

The capture unit simply captures the state of the master’s address and control signals if the MAX cannot immediately pass the master’s request through to the proper slave port. The capture unit consists of a set of flops and a mux which selects either the asynchronous path from address and control or the flopped (captured) address and control information.

16.4.3.4 Master Port Registers

The registers in the master port are only those registers associated with this particular master port. The read and write interface for the registers is a quasi-IP bus interface. It is not a full IP bus interface at this level because not all the IP bus signals are routed this deep in the design.

There is a register control block at the same level of the master port and slave port instantiations in the MAX. This control block ensures that all accesses are 32-bit supervisor accesses before passing them on to the master ports.

The register outputs are connected directly to the state machine.

16.4.3.5 Master Port State Machine

This section describes the master port state machine states and state swapping.

16.4.3.5.1 Master Port State Machine States

The master side state machine’s main function is to monitor the activities of the master port. The state machine has six states: **busy**, **idle**, **stalled**, **steady state**, **first cycle error response** and **second cycle error response**.

The **busy** state is used when the master runs a BUSY cycle to the master port. The master port maintains its request to the slave port if it currently owns the slave port; however, if it loses control of the slave port it no longer maintains its request. If the master port loses control of the slave port, it is not allowed to make another request to the slave port until it runs a NSEQ or SEQ cycle.

The **idle** state is used when the master runs a valid IDLE cycle to the master port. The master port makes no requests to the slave ports (disables the slave port decoder) and terminates the IDLE cycle.

The **stalled** state is used when the master makes a request to a slave port that is not immediately ready to receive the request. In this case the state machine directs the capture unit to send out the captured address and control signals and enables the slave port decoder to indicate a pending request to the appropriate slave port.

The **steady state** is used when the master port and slave port are in fully asynchronous mode, making the MAX completely transparent in the access. The state machine selects the appropriate slave's **hresp0, hready** and **hrdata** to pass back to the master.

The **first cycle error response** and **second cycle error response** states are self explanatory. The MAX responds with an error response to the master if the master tries to access an unimplemented memory location through the MAX (i.e. a slave port that does not exist).

16.4.3.5.2 Master Port State Machine Slave Swapping

The design of the master side state machine is fairly straight forward. The one real decision to be made is how to handle the master moving from one slave port access to another slave port access. The approach that was taken was to minimize or eliminate, when possible, any bubbles that would get inserted into the access due to switching slave ports.

The state machine does not allow the master to request access to another slave port until the current access being made is terminated. This prevents a single master from owning two slave ports at the same time (the slave port it is currently accessing and the slave port it wishes to access next).

The state machine also maintains watch on the slave port the master is accessing as well as the slave port the master wishes to switch to. If the new slave port is parked on the master, the master is able to make the switch without incurring any delays. The termination of the current access also acts as the launch of the new access on the new slave port. If the new slave port is not parked on the master, the master incurs a minimum one-clock delay before it can launch its access on the new slave port.

This is the same for switching from the **busy** or **idle** state to actively accessing a slave port. If the slave port is parked on the master, the state machine goes to the **steady state** and the access begins immediately. If the slave port is not parked on the master (serving another master, parked on another master or in low power park mode), the state machine transitions to the **stalled** state and at least a one-clock penalty is paid.

16.4.4 Slave Port Functionality

This section discusses the slave port functionality.

16.4.4.1 General

Each slave port consists of a register slice, a bank of muxes and a state machine.

The register slice contains the registers associated with the specific slave port. The registers have a quasi-IP bus interface at this level for reads and writes and the outputs feed directly into the state machine.

The muxes are a series of 6 to 1 muxes that take in all the address, control and write data information from each of the master ports and then pass the correct master's signals to the slave port. The state machine controls all the muxes.

The state machine is where the main slave port arbitration occurs, it decides which master is in control of the slave port and which master will be in control of the slave port in the next bus cycle.

For a block diagram of a slave port see Figure 16-7.

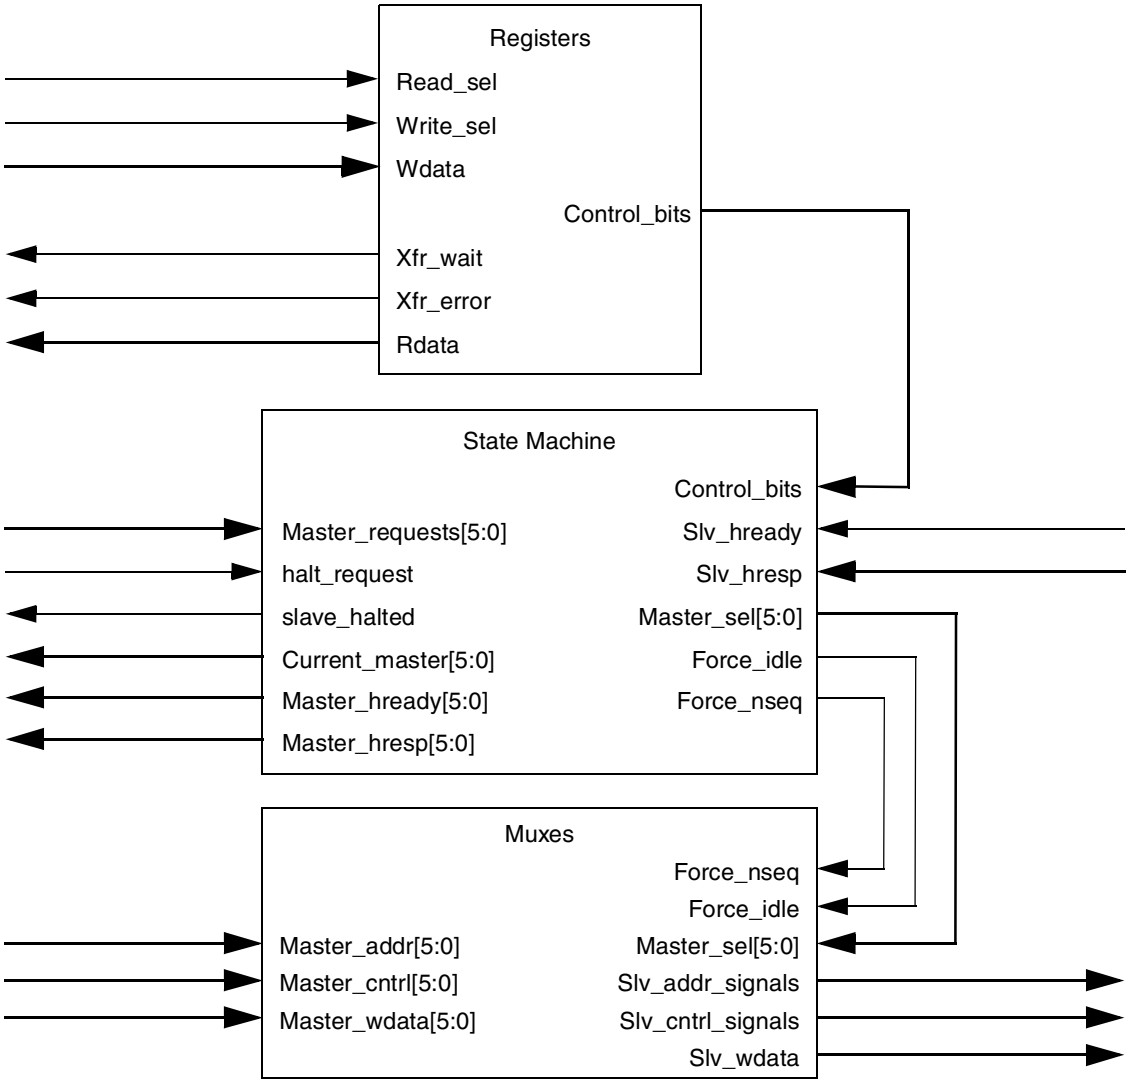

Figure 16-7. MAX Slave Port Block Diagram

16.4.4.2 Slave Port Muxes

The block diagram (Figure 16-7) shows only one block for all the muxes. In reality that block instantiates many 6 to 1 muxes, one for each master-to-slave signal in fact. All the muxes are designed in an AND-OR fashion, so that if no master is selected, the output of the muxes is zero. (This is an important feature for low-power park mode.)

The muxes also have an override signal which is used by the slave port to asynchronously force IDLE cycles onto the slave bus. When the state machine forces an IDLE cycle it zeros out **htrans** and **hmastlock**, making sure the slave bus sees a valid IDLE cycle being run by the MAX.

The enable to the mux controlling **htrans** also contains an additional control signal from the state machine so that a NSEQ transaction can be forced. This is done any time the slave port switches masters to ensure that no IDLE-SEQ, BUSY-SEQ or NSEQ-SEQ transactions are seen on the slave port when they should not be. If the state machine indicates to run both an IDLE and an NSEQ cycle, the IDLE directive has priority.

NOTE

IDLE-SEQ is in fact an illegal access, but a possible scenario given the multimaster environment in the MAX unless corrected by the MAX.

16.4.4.3 Slave Port Registers

There is a register control block at the same level of the master port and slave port instantiations in the MAX. This control block ensures that all accesses are 32-bit supervisor accesses before passing them on to the master and slave ports.

The registers in the slave port are only those registers associated with this particular slave port. The read and write interface for the registers is a quasi-IP bus interface. It is not a full IP bus interface at this level because not all the IP bus signals are routed this deep in the design.

The register outputs are connected directly to the slave state machine. The registers can be read from an unlimited number of times. The registers can only be written to as long as the RO bit is written to 0 in the SGPCR, once it is written to a 1 only a hardware reset allows the registers to be written again.

16.4.4.4 Slave Port State Machine

This section discusses the slave port state machine states, arbitration, master handoff, machine parking, and halt mode.

16.4.4.4.1 Slave Port State Machine States

At the heart of the slave port is the state machine. The state machine is simplicity itself, requiring only four states - **steady state**, **transition state, transition hold state,** and **hold state**. Either the slave port is owned by the same master it was in the last clock cycle (either by active use or by parking), it is transitioning to a new master (either for active use or parking), it is transitioning to a new master during wait states or it is being held on the same master pending a transition to a new master.

16.4.4.4.2 Slave Port State Machine Arbitration

The real work in the state machine is determining which master port will be in control of the slave port in the next clock cycle, the arbitration. Each master is programmed with a fixed 3 bit priority level. The MAX uses these bits in determining priority levels when programmed for fixed priority mode of operation.

Arbitration always occurs on a clock edge, but only occurs on edges when a change in mastership will not violate AHB-Lite protocols. Valid arbitrations points include any clock cycle in which **sX_hready** is asserted (provide the master is not performing a burst or locked cycle) and any wait state in which the master owning the bus indicates a transfer type of IDLE (provided the master is not performing a locked cycle).

Since arbitration can occur on every clock cycle the slave port masks off all master requests if the current master is performing a locked transfer or a protected burst transfer, guaranteeing that no matter how low its priority level, it will be allowed to finish its locked or protected portion of a burst sequence.

16.4.4.4.3 Slave Port State Machine Master Handoff

The only times the slave port switches masters when programmed for fixed priority mode of operation is when a higher priority master makes a request or when the current master is the highest priority and it gives up the slave port by either running and IDLE cycle to the slave port or running a valid access to a location other than the slave port.

If the current master loses control of the slave port because a higher priority master takes it away, the slave port does not incur any wasted cycles. The current master has its current cycle terminated by the slave port at the same time as the new master's address and control information is recognized by the slave port. This looks like a seamless transition on the slave port.

If the current master is being wait stated when the higher priority master makes its request, the current master is allowed to make one more transaction on the slave bus before giving it up to the new master. Figure 16-8 illustrates the effect of a higher priority master taking control of the bus when the slave port is programmed for a fixed priority mode of operation.

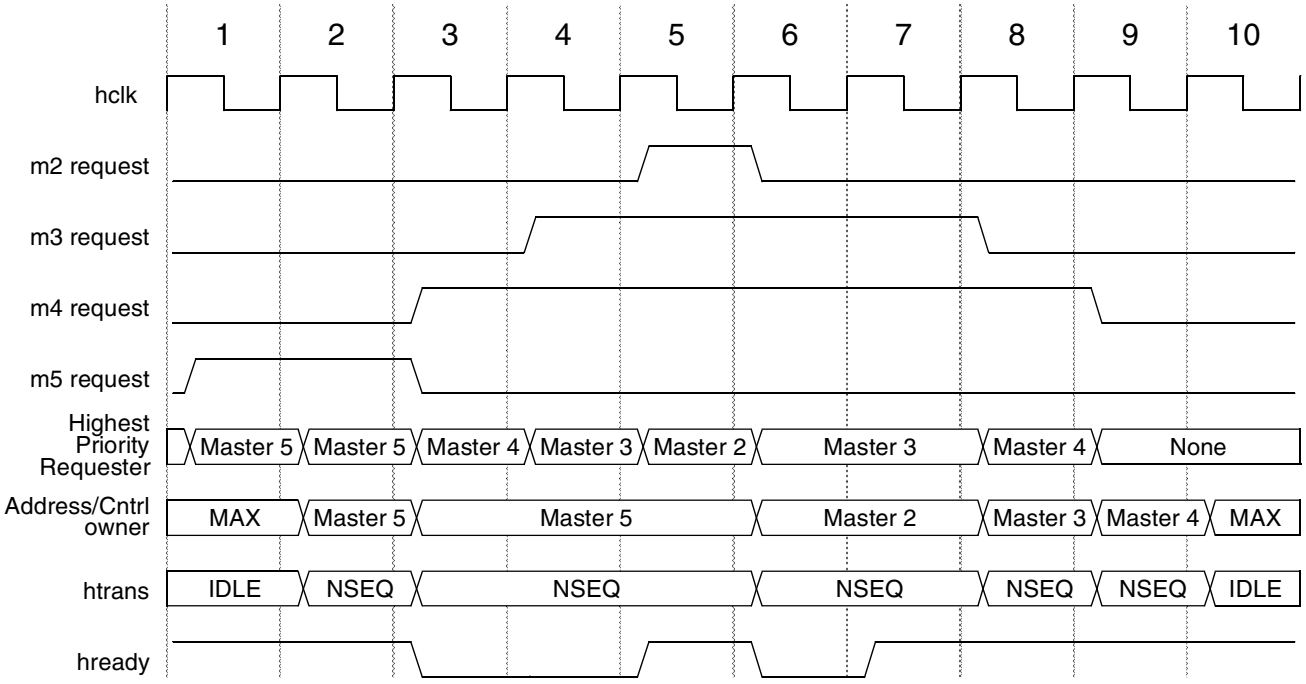

Figure 16-8. Low to High Priority Mastership Change

If the current master is the highest priority master and it gives up the slave port by running an IDLE cycle or by running a valid cycle to another location other than the slave port, the next highest priority master gains control of the slave port. If the current access incurs any wait states, the transition is seamless and no bandwidth will be lost. However, if the current transaction is terminated without wait states, one IDLE

cycle is forced onto the slave bus by the MAX before the new master is able to take control of the slave port. If no other master is requesting the bus, IDLE cycles are run by the MAX. However, no bandwidth is truly lost because no master is making a request.

Figure 16-9 illustrates the effect of a higher priority master giving up control of the bus.

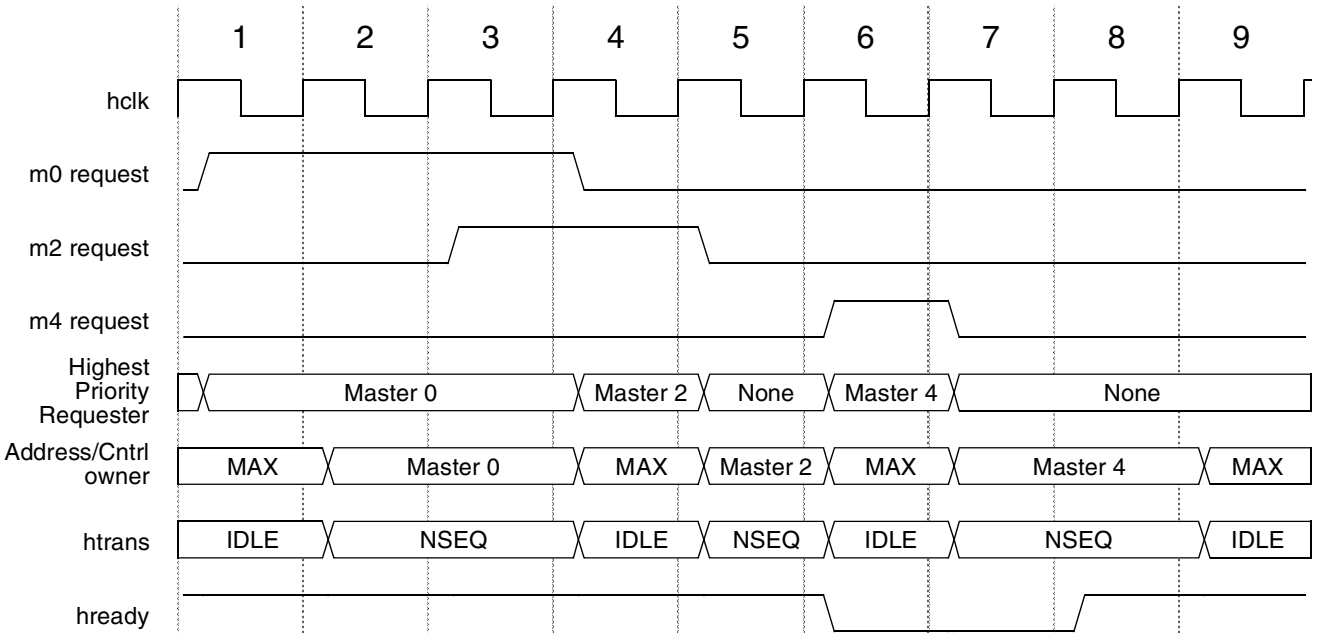

Figure 16-9. High to Low Priority Mastership Change

When the slave port is programmed for round-robin mode of arbitration, the slave port switches masters any time there is more than one master actively making a request to the slave port. This happens because

any master other than the one which presently owns the bus is considered to have higher priority. Figure 16-10 shows an example of round-robin mode of operation.

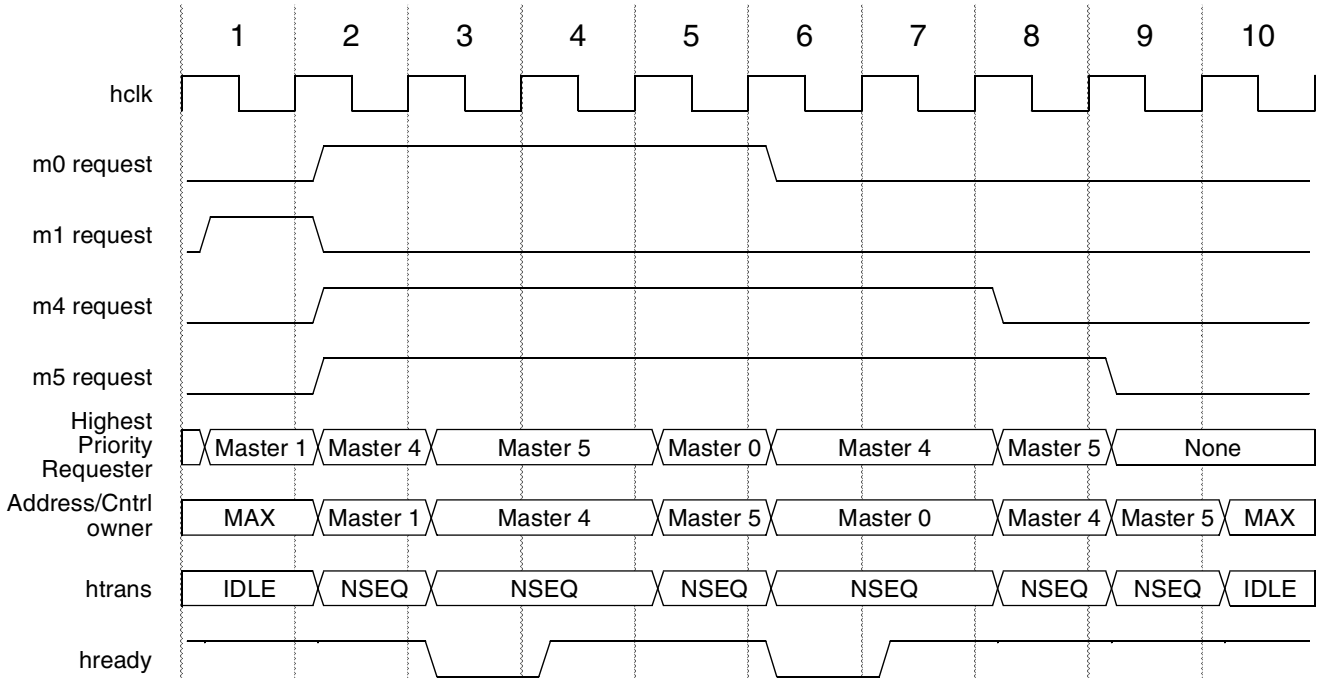

Figure 16-10. Round-Robin Mastership Change

16.4.4.4.4 Slave Port State Machine Parking

If no master is currently making a request to the slave port, the slave port parks in one of four places as dictated by the PCTL and PARK bits in the SGPCR and the locked state of the last master to access it.

If the last master to access the slave port ran a locked cycle and continues to run locked cycles even after leaving the slave port, the slave port parks on that master without regard to the bit settings in the SGPCR and without regard to pending requests from other masters. This is done so a master can run a locked transfer to the slave port, leave it, return to it, and be guaranteed that no other master has had access to it (provided the master maintains all transfers are locked transfers). If locking is not an issue for parking, the SGPCR bits dictate the parking method.

If the PCTL bits are set for low-power park mode, the slave port enters low-power park mode. It does not recognize any master as being in control of it, and it does not select any master's signals to pass through to the slave bus. In this case all slave bus activity effectively halts because all slave bus signals being driven from the MAX are 0. This of course can save quite a bit of power if the slave port is not in use for some time. The down side is that when a master does make a request to the slave port, it is delayed by one clock because it has to arbitrate to acquire ownership of the slave port.

If the PCTL bits are set to "park on last" mode, the slave port parks on the last master to access it, passing all that masters signals through to the slave bus. The MAX asynchronously forces **htrans[1:0]**, **hmaster[3:0]**, **hburst[2:0],** and **hmastlock** to 0 for all access that the master does not run to the slave port.

When that master accesses the slave port again, it does not pay any arbitration penalty; however, if any other master wishes to access the slave port, a one-clock arbitration penalty will be imposed.

If the PCTL bits are set to use PARK mode, the slave port parks on the master designated by the PARK bits. The behavior here is the same as for the park on last mode with the exception that a specific master is parked on instead of the last master to access the slave port. If the master designated by the PARK bits tries to access the slave port, it does not pay an arbitration penalty while any other master pays a one-clock penalty. Figure 16-11 illustrates parking on a specific master.

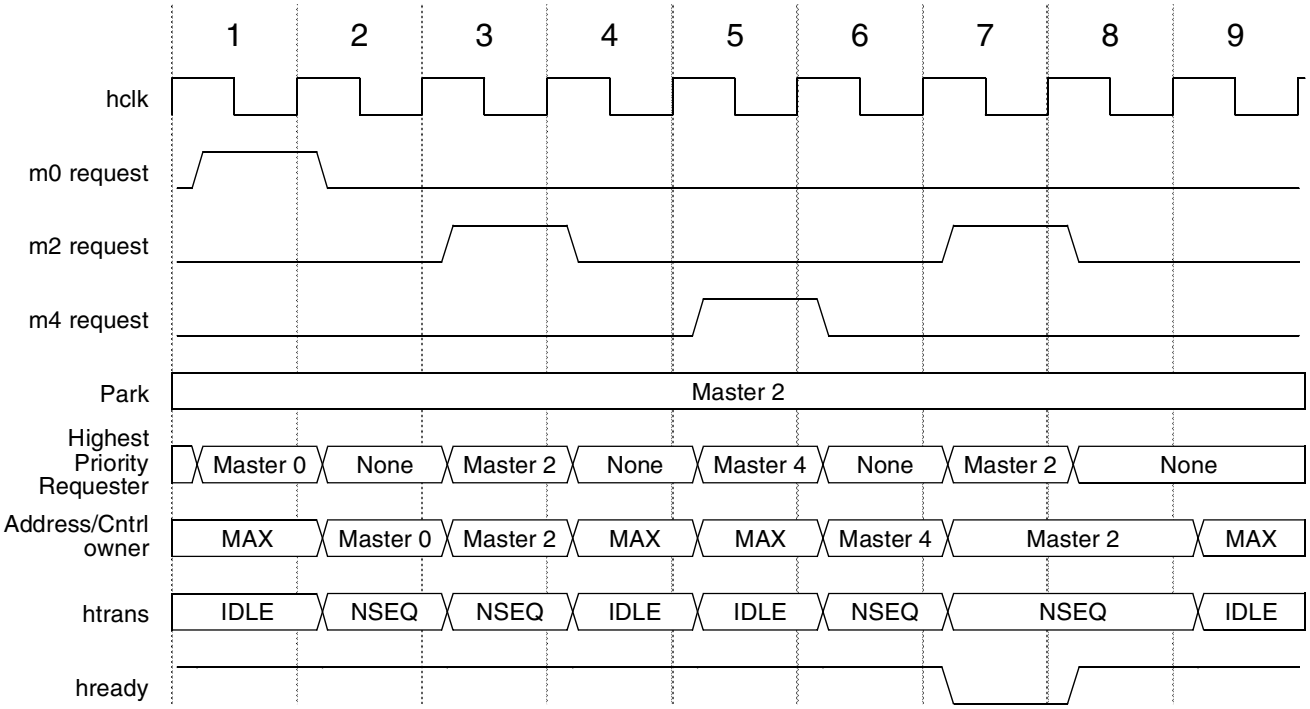

Figure 16-11. Parking on a Specific Master

Figure 16-12 illustrates parking on the last master. Note that in cycle 6 simultaneous requests are made by master 2 and master 4. Although master 2 has higher priority, the slave bus is parked on master 4 so master

4’s access is taken first. The slave port parks on master 2 once it has given control to master 2. This same situation can occur when parking on a specific master as well.

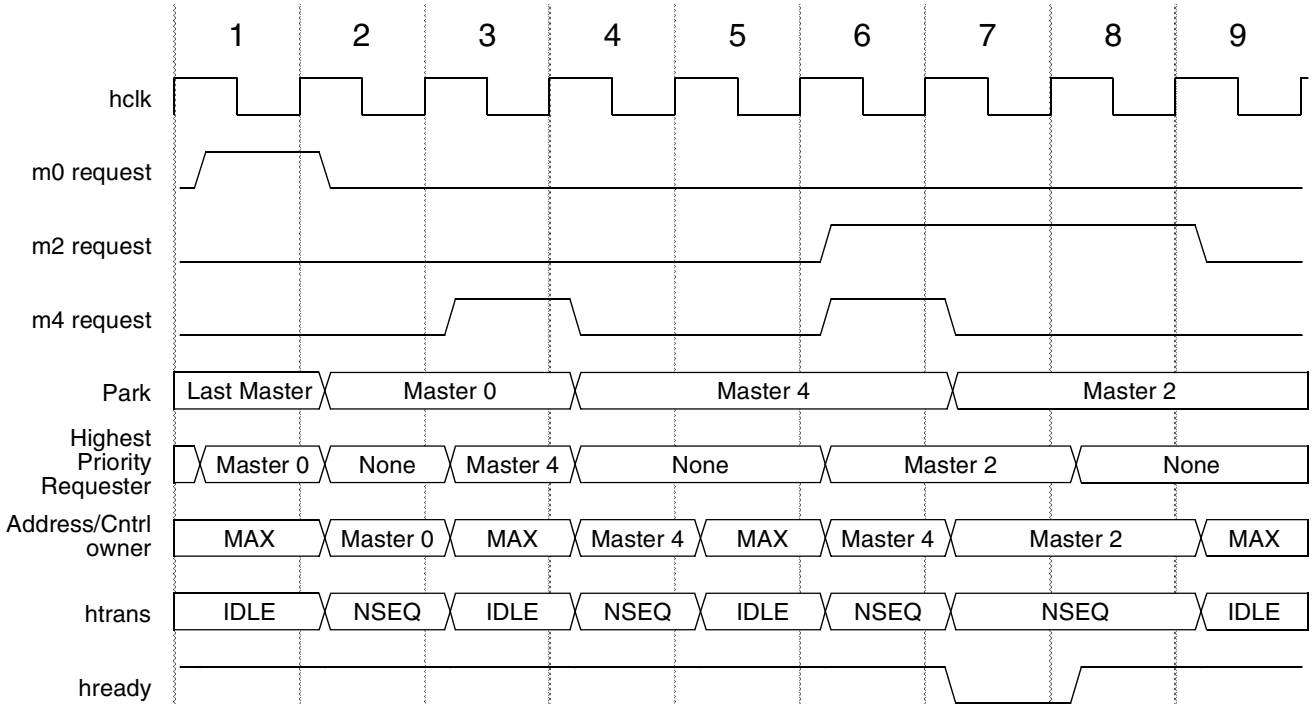

Figure 16-12. Parking on Last Master

16.4.4.4.5 Slave Port State Machine Halt Mode

If the **max_halt_request** input is asserted, the slave port eventually halts all slave bus activity and go into halt mode, which is almost identical to low power park mode. The HLP bit in the SGPCR controls the priority level of the **max_halt_request** in the arbitration algorithm. If the HLP bit is cleared, the **max_halt_request** has the highest priority of any master and gains control of the slave port at the next arbitration point (most likely the next bus cycle, unless the current master is running a locked or fixed length burst transfer). If the HLP bit is set, the slave port waits until no masters are actively making requests before moving to halt mode.

Regardless of the state of the HLP bit, once the slave port has gone into halt mode as a result of **max_halt_request** being asserted, it remains in halt mode until **max_halt_request** is negated, regardless of the priority level of any masters that may make requests.

In halt mode no master is selected to own the slave port so all the outputs of the slave port are set to 0.

16.5 Initialization/Application Information

No initialization is required by or for the MAX. Hardware reset ensures all the register bits used by the MAX are properly initialized.

16.6 MAX Interface

This section provides information on the MAX interface.

16.6.1 Overview

The main goal of the MAX is to increase overall system performance by allowing multiple masters to communicate in parallel with multiple slaves. In order to maximize data throughput it is essential to keep arbitration delays to a minimum.

This section examines data throughput from the point of view of masters and slaves, detailing when the MAX stalls the masters or inserts bubbles on the slave side.

16.6.2 Master Ports

Master accesses receive one of four responses from the MAX. They are either terminated, taken, stalled, or responded to with an error.

16.6.2.1 Terminated Accesses

A master access is terminated if the transfer type is IDLE. The MAX terminates the access, so it is not allowed to pass through the MAX.

16.6.2.2 Taken Accesses

A master access is taken if the transfer type is non IDLE and the slave port to which the access decodes is either currently servicing the master or is parked on the master. In this case the MAX is completely transparent, the master’s access is immediately seen on the slave bus, and no arbitration delays are incurred.

16.6.2.3 Stalled Accesses

A master access is stalled if the transfer type is non IDLE and the access decodes to a slave port that is busy serving another master, parked on another master or is in low power park mode. The MAX indicates to the master that the address phase of the access has been taken but then queues the access to the appropriate slave port to enter into arbitration for access to that slave port.

If the slave port is currently parked on another master or is in low power park mode and no other master is requesting access to the slave port then only one clock of arbitration is incurred. If the slave port is currently serving another master of a lower priority and the master has a higher priority than all other requesting masters then the master gains control over the slave port as soon as the data phase of the current access is completed (burst and locked transfers excluded). If the slave port is currently servicing another master of a higher priority then the master gains control of the slave port once the other master releases control of the slave port if no other higher priority master is also waiting for the slave port.

16.6.2.4 Error Response Terminated Accesses

A master access is responded to with an error if the transfer type is non-IDLE and the access decodes to a location not occupied by a slave port. Please refer to Section 16.6.3, Slave Ports," for information on locations that are not occupied by a slave port.

16.6.3 Slave Ports

The goal of the MAX with respect to the slave ports is to keep them 100% saturated when masters are actively making requests. In order to do this the MAX must not insert any bubbles onto the slave bus unless absolutely necessary.

There is only one instance when the MAX forces a bubble onto the slave bus when a master is actively making a request. This occurs when a higher priority master has control of the slave port and is running single clock (zero wait state) accesses while a lower priority master is stalled waiting for control of the slave port. When the higher priority master either leaves the slave port or runs an IDLE cycle to the slave port the MAX takes control of the slave bus and run a single IDLE cycle before giving the slave port to the lower priority master that was waiting for control of the slave port.

The only other times the MAX has control of the slave port is when the MAX is halting or when no masters are making access requests to the slave port and the MAX is forced to either park the slave port on a specific master or put the slave port into low power park mode.

In most instances when the MAX has control of the slave port, it indicates IDLE for the transfer type, negates all control signals, and indicates ownership of the slave bus via the **hmaster** encoding of 4'b0000. One exception to this rule is when a master running locked cycles has left the slave port but continues to run locked cycles. In this case the MAX controls the slave port and indicate sIDLE for the transfer type but it does not affect any other signals.

NOTE

When a master runs a locked cycle through the MAX, the master is guaranteed ownership of all slave ports it accesses while running locked cycles for one cycle beyond when the master finishes running locked cycles.

Chapter 17
Digital Audio Mux (AUDMUX)

The Digital Audio Mux (AUDMUX) provides a programmable interconnect device for voice, audio, and synchronous data routing between host serial interfaces (that is, SSI) and peripheral serial interfaces (that is, audio and voice codecs, also known as coder-decoders).

The AUDMUX allows the audio system connectivity to be modified through programming (as opposed to altering the PCB schematics of the system). Figure 17-1 and Figure 17-2 show the block diagram of the AUDMUX (Figure 17-2 is an extension of Figure 17-1).

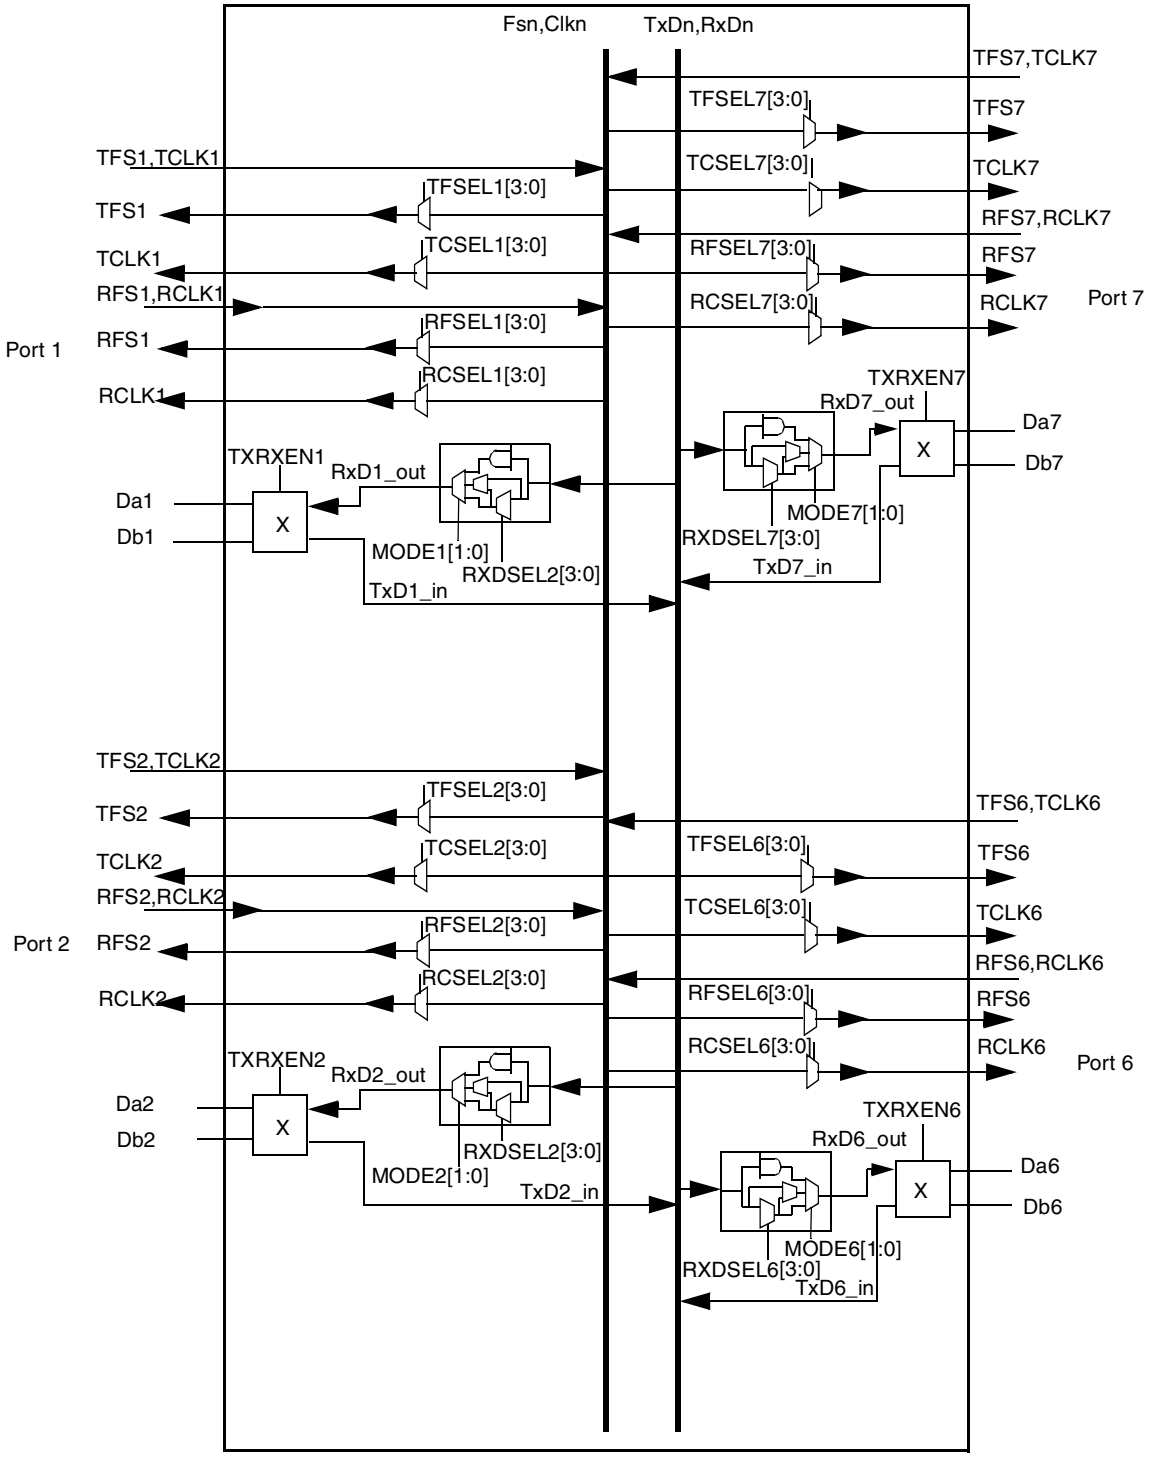

Figure 17-1. AUDMUX Block Diagram A

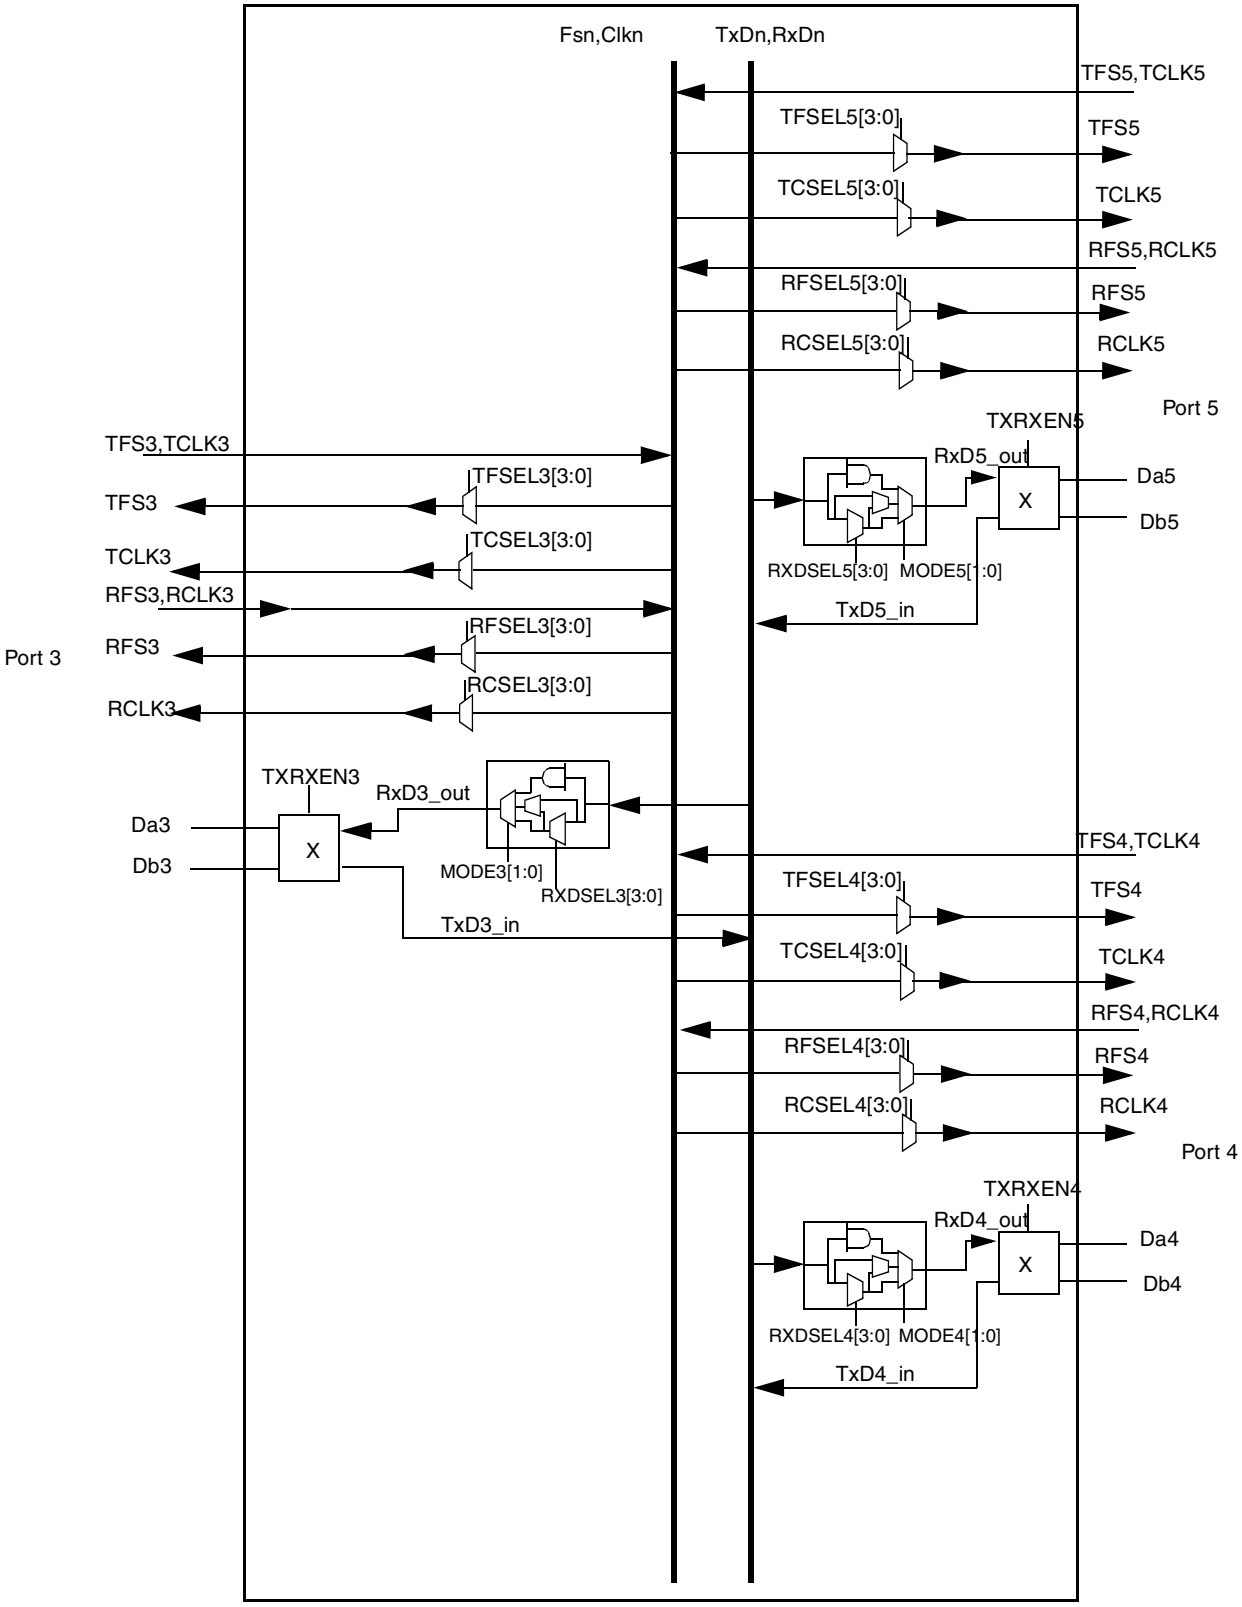

Figure 17-2. AUDMUX Block Diagram B

17.1 Introduction

With the AUDMUX, resources do not need to be hard-wired and can be effectively shared in different configurations. The AUDMUX interconnections allow multiple, simultaneous audio/voice/data flows between the ports in point-to-point or point-to-multipoint configurations.

The AUDMUX includes two types of interfaces. Internal ports connect to the processor serial interfaces and external ports connect to off-chip audio devices and serial interfaces of other processors. A desired connectivity is achieved by configuring the appropriate internal and external ports.

17.1.1 Features

- Four external ports
- Full 6-wire SSI interfaces for asynchronous receive and transmit
- Configurable 4-wire (synchronous) or 6-wire (asynchronous) peripheral interfaces
- Independent Tx/Rx Frame sync and clock direction selection for host or peripheral
- Each host interface's capability to connect to any other host or peripheral interface in a point-to-point or point-to-multipoint (network mode)
- Transmit and Receive Data switching to support external network mode

17.1.2 Modes of Operation

Figure 17-1 and Figure 17-2 show the AUDMUX block diagram.

All the ports are basically identical. The major difference is whether a port is connected to an on-chip serial interface (for example, SSI) or connected to the chip's pads to connect to off-chip serial devices (that is, any 4-wire or 6-wire external SSI, voice, I2S, or AC97 CODEC).

Port 7 can be physically connected to any of the peripherals previously mentioned. There is no functional difference among Ports 1 through 7.

All ports can be configured as four- or six-wire interfaces. When configured as a six-wire interface, the additional RFS and RCLK signals of the interface enable the serial interface to be used in asynchronous mode with separate receive and transmit clocks.

All ports have a Tx/Rx switch to provide flexibility in supporting network mode configurations. The Tx/Rx switch enables the transmit and receive data lines to be swapped so that mastership of the serial bus can be passed among multiple external devices connected to a single port.

All ports, in addition to supporting the default external network mode, support —internal network mode. With internal network mode, a point-to-multipoint network configuration with an arbitrary number of slaves can be supported if the external slaves are put into the high-impedance state (as defined in the SSI network mode protocol) and have pull-up resistors on their TxD pins. (Alternatively, this can be viewed as requiring a pull-up resistor on the corresponding AUDMUX RxD pin.)

Bit clock direction selection enables each port to be configured as a master or slave in the flow.

Possible scenarios include:

- SSI1 (internal port) drives a voice CODEC and a BT CODEC (both on external Port 6) and the Bottom Connector (on external Port 7) simultaneously using network mode. SSI1 is the master.
- An external processor (external port - Port 5) drives a voice CODEC and a BT CODEC (both on external Port 6) and the Bottom Connector (on Port 7) simultaneously using network mode. SAP is the master.

NOTE

SSI1 (internal port), which is the master, drives a voice CODEC and a BT CODEC (both on external Port 6) and the bottom connector (on external Port 7) simultaneously using network mode.

An external processor (external port - Port 5), which is the master, drives a voice CODEC and a BT CODEC (both on external Port 6) and the bottom connector (on Port 7) simultaneously using network mode.

17.1.2.1 Port Receive Data Modes

Each port has logic to select which data lines are used to create the RxD line for the corresponding host interface. Figure 17-3 shows the logic used to create the RxD line for Port 1. This logic has the following modes of operation (as determined by MODE0):

- Normal
- Internal network mode

The subsequent sections describe the various modes of the port receive data logic. The following terms are used to define the operation of the AUDMUX:

Network mode— Time-Division Multiplexed protocol for sending unique data to multiple devices on a serial bus.

Internal network mode—Physical bus configuration where multiple serial buses are effectively connected within the AUDMUX via digital logic to create point-to-multipoint connectivity. An arbitrary number of devices are supported. Devices must be put into the high-impedance state as specified by the network mode protocol. TxDATA lines of devices must be pulled high.

External network mode—Physical bus configuration where multiple serial buses are electrically connected together on a printed circuit board (that is, external to the AUDMUX). Devices must put their TxDATA lines into the high-impedance state as specified by the network mode protocol.

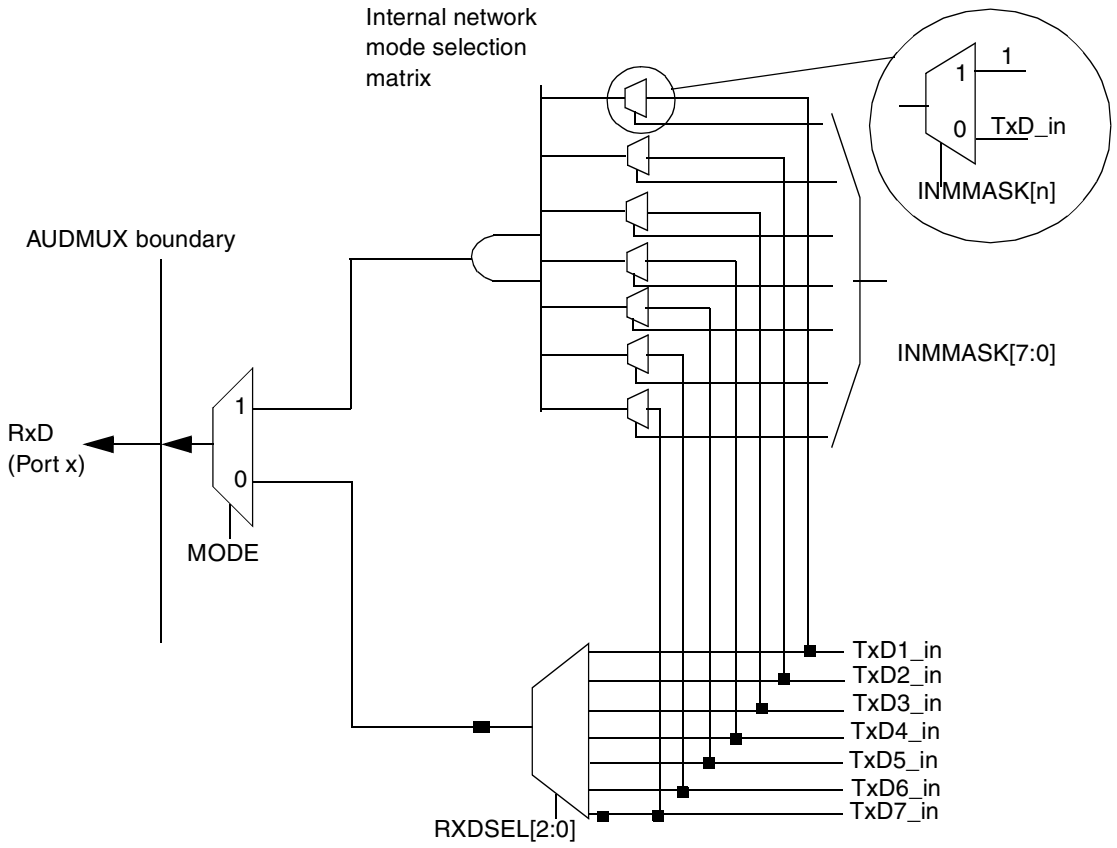

Figure 17-3. Receive Data Logic for Port x

17.1.2.1.1 Normal Mode

In normal mode (MODE0=0), the port is connected in a point-to-point configuration (as a master or a slave) and the RXDSEL[2:0] setting selects the transmit signal from any port. In normal mode, any data format can be used (that is, SSI normal mode, SSI network mode, AC-97, and others.

17.1.2.1.2 Internal Network Mode

In internal network mode (MODE0 = 1), the output of the AND gate is routed (via the output of the port) to the RxD signal of the corresponding host interface. The INMMASK bit vector selects the transmit signals of the ports that are to be connected in network mode. The transmit signals received at the AUDMUX ports (TxDn_in) are ANDed together to form the output. In internal network mode, only one device can be transmitting in its predesignated timeslot and all other transmit signals must remain high (be in high-impedance state and pulled-up). Therefore, non-active signals in the selection will be high and do not influence the output of the AND gate.

Network mode is a protocol where a master SSI is connected to more than one slave SSI device and communication occurs on a time-slotted frame. Though network mode can allow master-slave and slave-slave communication, internal network mode supports only master-slave communication.

There are two scenarios where internal network mode can be used with external network mode:

1. Slave-only devices are attached to an external port.
2. A master device is attached to an external port and all slave devices connected to the same external port are disabled.

NOTE

When internal network mode is enabled at an external port, RXDSEL[3:0] for RxDn_obe selection is ignored and RxD_obe is always driven high (that is, asserted for all timeslots). All slave devices connected to the same port must be disabled.

Internal Network Mode Example 1

SSI1 and SSI2 are used with Port 4 in internal network mode as shown in Figure 17-4. No pull-up resistors are required, since all the interfaces combined in internal network mode are on-chip interfaces. The on-chip interfaces drive a logic ‘1’ when their output enables are logic ‘0’.

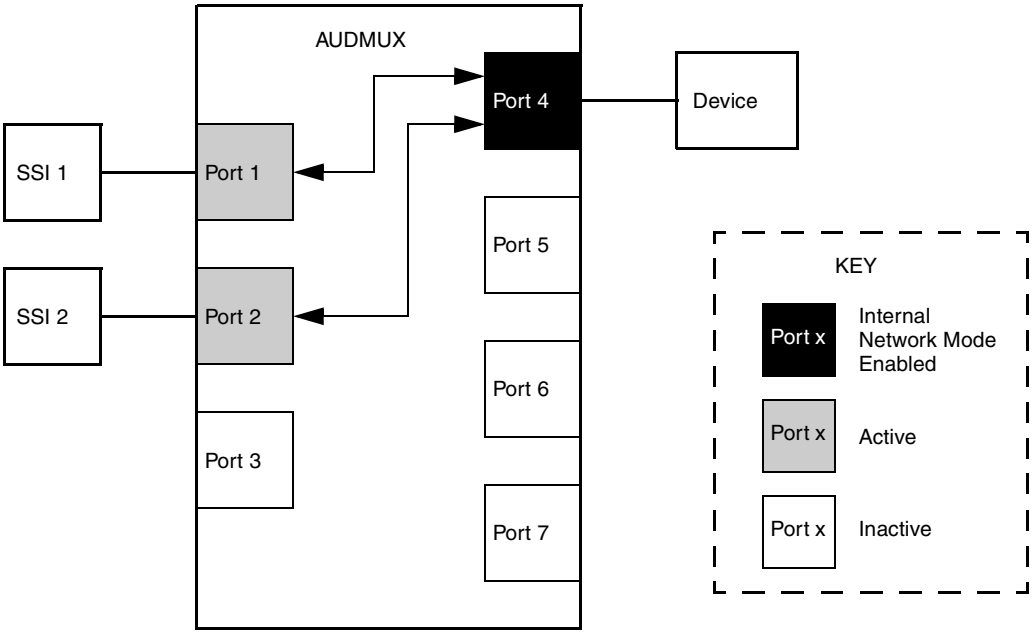

Figure 17-4. Block Diagram For Example 1

See Figure 17-5 for the timing diagram of Example 1. The clock and frame sync signals show the bit and frame timing for the serial bus. The vertical dashed lines divide the frame into four timeslots.

The data lines for SSI1 and SSI2 (as well as their output enables) are shown. Note that the SSI transmits a logic ‘1’ when its corresponding output enable is a logic ‘0’. The combined TxDATA line, which is the logical AND of SSI1 and SSI2’s TxDATA lines, is used for Port 4’s TxDATA line.

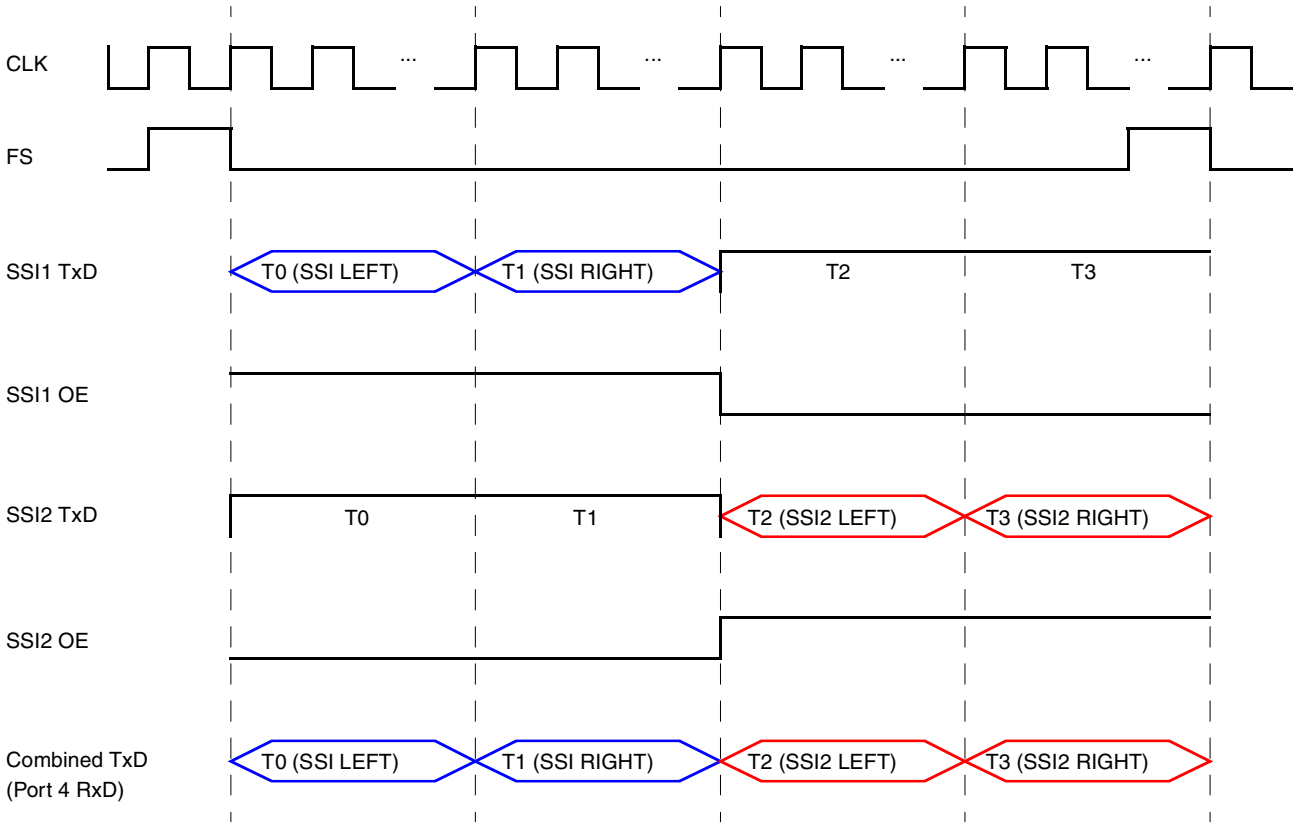

Figure 17-5. Example Using All Internal Ports For Transmit Data

Internal Network Mode Example 2

The SSI, Port 4, and Port 5 are used with Port 6 in internal network mode, as shown in Figure 17-6. Note that Port 4 and Port 5 are external ports. Therefore, pull-up resistors are required on the Port 4 RxDATA and Port 5 RxDATA pins. This example shows the timing associated with using adjacent timeslots for the SSI, Port 4, and Port 5.

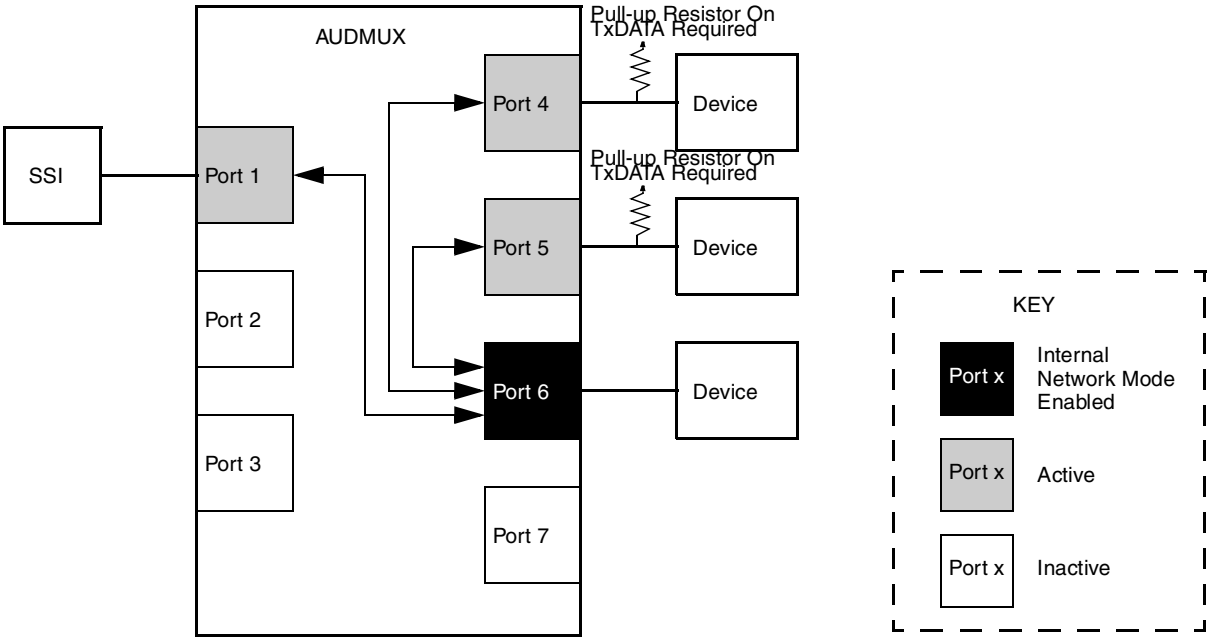

Figure 17-6. Block Diagram For Example 2

The resistance value of the pull-up resistors must be sufficiently high such that a value of ‘0’ can be pulled up to logic ‘1’ within half of a period of the bitclock. The required resistance must be no larger than:

Rmax = $1 \div (2 \times f_{bc} \times C)$ where:

f_{bc} is the frequency of the bitclock

C is the total system capacitance (ICs, board traces, and so on)

Figure 17-7 shows the timing diagram for this example. The clock and frame sync signals show the bit and frame timing for the serial bus. The vertical dashed lines divide the frame into four timeslots.

The data lines for the SSI, Port 4, and Port 5 are shown. Note that the SSI transmits a logic ‘1’ when its corresponding output enable is a logic ‘0’. The data lines from Port 4 and Port 5 *at the pad* are pulled high by pull-up resistors when they are in the high-impedance state. The data lines from Port 4 and Port 5 *at the AUDMUX* are pure digital signals and are constantly driven. The combined TxDATA line, which is the logical AND of the SSI, Port 4, and Port 5’s TxDATA lines, is used for Port 6’s TxDATA line.

Note the highlighted areas in Figure 17-7. This shows the transition time that occurs while a TxDATA line is being pulled high. In this example, this transition time is a maximum of 1/2 the period of the serial bitclock. This prevents corruption of the first data bit of the next timeslot. It is critical that the pull-up resistance is sufficient for the given bitclock frequency and system capacitance.

Note that hysteresis should be enabled at Port 4’s RxDATA pad and Port 5’s RxDATA pad to prevent the digital signals created by the pad from toggling rapidly during the pull-up period. The pads typically require a transition within 25 ns unless hysteresis is enabled. Instead of using hysteresis, one could select a pull-up resistor sufficiently high to pull-up the signal at the pad within 25 ns; however, that would result in a higher resistance value and higher current drain.

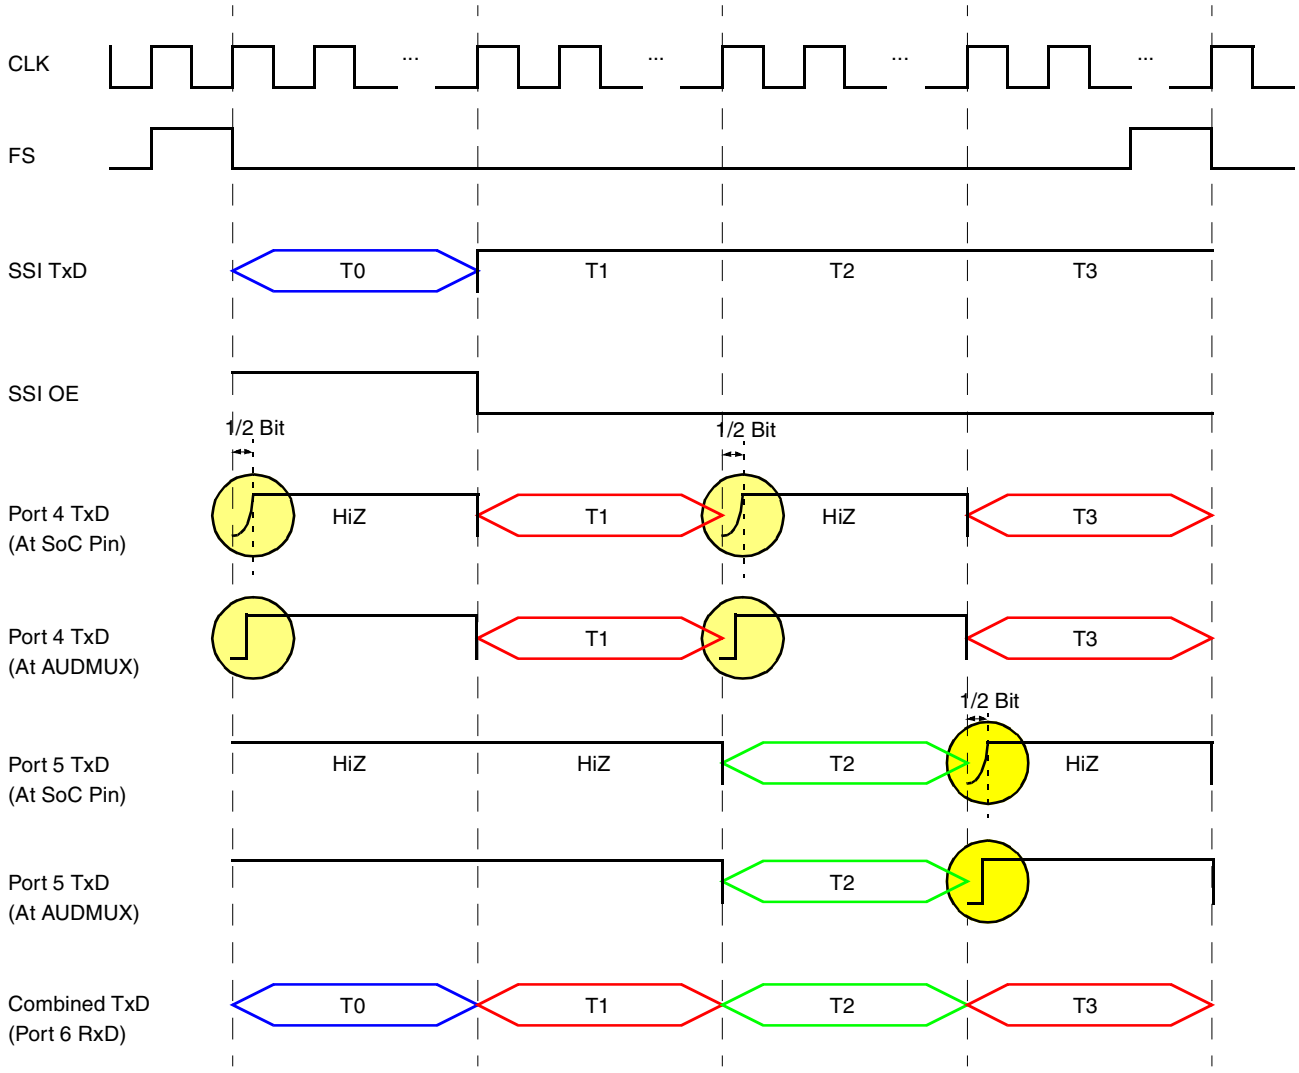

Figure 17-7. Example Using External Ports for Transmit Data in Consecutive Timeslots

Internal Network Mode Example 3

The SSI and Port 4 are used with Port 6 in internal network mode as shown in Figure 17-8. Note that Port 4 is an external port. Therefore, a pull-up resistor is required on the Port 4 TxDATA pin. This example shows the timing associated with inserting empty timeslots after the timeslots have been used by external ports.

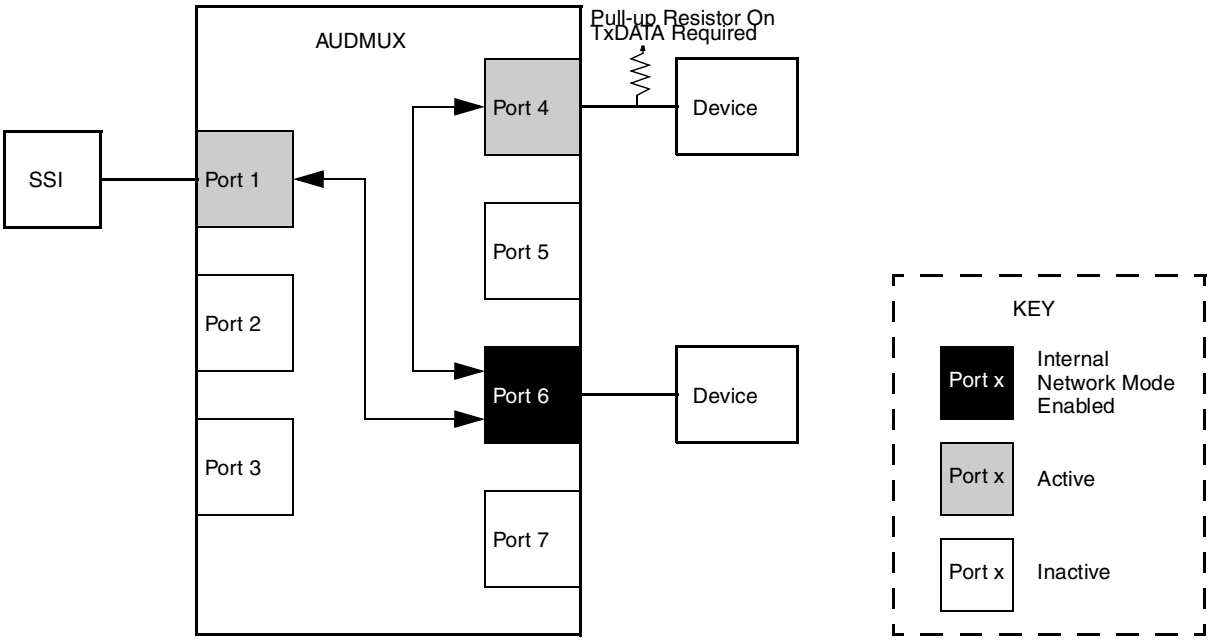

Figure 17-8. Block Diagram For Example 3

The resistance value of the pull-up resistors must be sufficiently high such that a value of ‘0’ can be pulled up to logic ‘1’ by the time that the next occupied timeslot occurs. This allows a much weaker pull-up to be used as compared to Example 2. The required resistance must be no larger than:

$Rmax = (4 \times n + 1) \div (2 \times f_{bc} \times C)$ where:

n is the number of bits per timeslot

f_{bc} is the frequency of the bitclock

C is the total system capacitance (ICs, board traces, and so on)

Figure 17-9 shows the timing diagram for this example. The clock and frame sync signals show the bit and frame timing for the serial bus. The vertical dashed lines divide the frame into four timeslots.

The data lines for the SSI and Port 4 are shown. Note that the SSI transmits a logic ‘1’ when its corresponding output enable is a logic ‘0’. The data line from Port 4 *at the pad* is pulled high by a pull-up resistor when they are in the high-impedance state. The data line from Port 4 *at the AUDMUX* is a pure digital signal and is constantly driven. The combined TxDATA line, which is the logical AND of the SSI and Port 4’s TxDATA lines, is used for Port 6’s RxDATA line.

Note the highlighted area in Figure 17-9. This shows the transition time that occurs while Port 4’s TxDATA line is being pulled high. In this example, this transition time is a maximum of two timeslots plus 1/2 the period of the serial bitclock. This prevents corruption of the first data bit of the next timeslot. It is critical that the pull-up resistance is sufficient for the given bitclock frequency and system capacitance.

Note that hysteresis must be enabled at Port 4’s RxDATA pad to prevent the digital signal created by the pad from toggling rapidly during the extended pull-up period. The pads typically require a transition within 25 ns unless hysteresis is enabled.

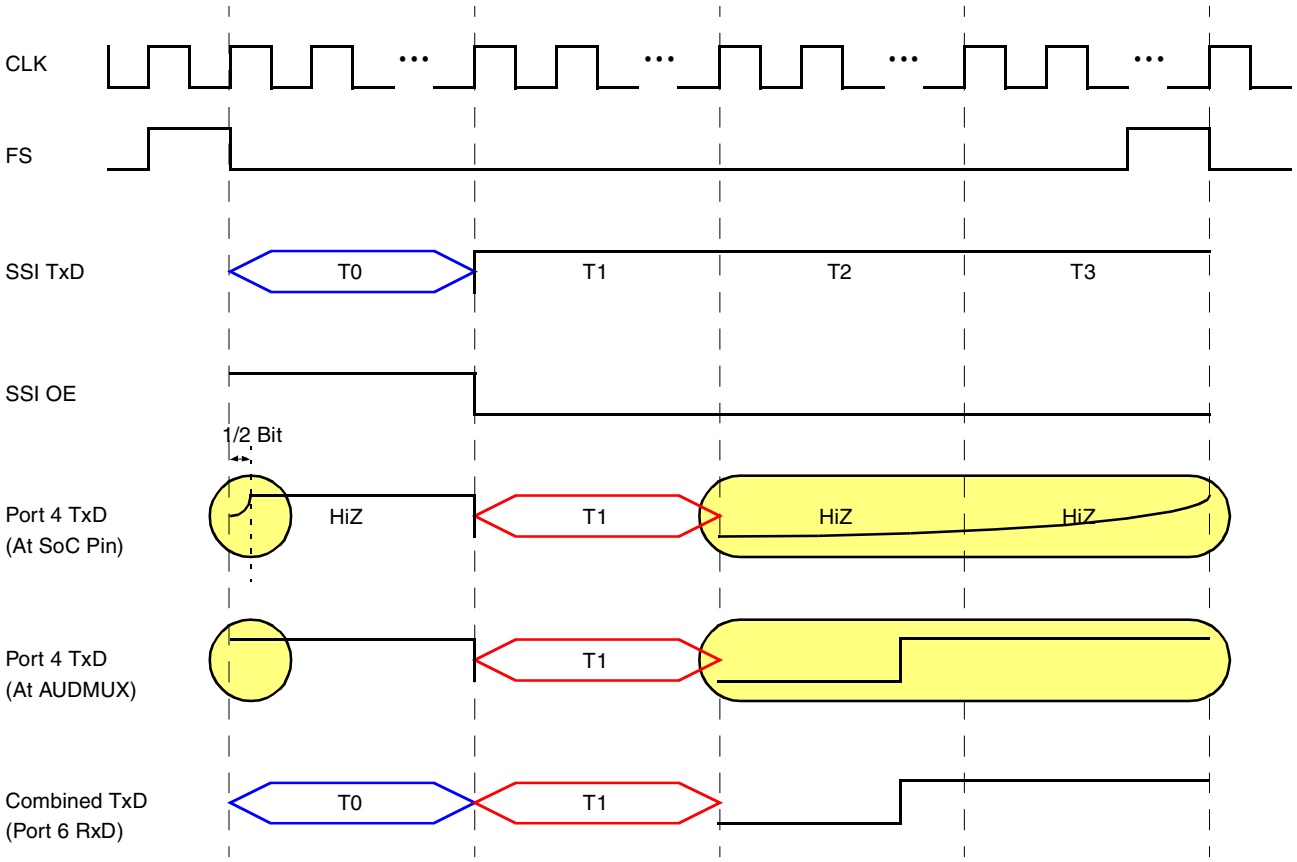

Figure 17-9. Example Using External Ports For Transmit Data In Nonconsecutive Timeslots

17.1.2.1.3 Transmit Data Output Enable Assertion

The TxDATA line from the internal network mode master (connected at any internal port) is put into the high-impedance state at the pad depending upon the assertion or deassertion of TxD_obe, its corresponding output enable generated by the network mode master.

In the case of an external network mode master (connected at an external port), the corresponding TxD_obe is always asserted after the port data register configuration.

17.1.2.2 Tx/Rx Switch and External Network Mode

External network mode is the traditional network mode connection. It is called external network mode to differentiate from the internal network mode. In external network mode, devices are connected to a single external port in a star or multi-drop configuration.

In network mode, there can be only one master (driving the frame sync and clock source) with the other devices configured in normal slave mode or network slave mode. Unlike internal network mode, both master-slave and slave-slave communication can take place in external network mode. CODEC devices transmit on a single timeslot while processor serial interfaces (that is, SSI, SAP) can process more than one timeslot of data while in network master or slave mode.

Figure 17-10 shows the Tx/Rx data switch. RxD_obe is the output buffer enable signal and RxD_out is the data transmit signal from the serial interface. The TxD_in signal is the receive data signal going towards the RXDSEL muxes of all ports.

D_TxRx is the data pin which serves as the chip-level transmit data pin when the TxRx switch is not enabled. D_RxTx is the data pin which serves as the chip-level receive data pin when the TxRx switch is not enabled. The roles of these pins are reversed when the TxRx switch is enabled.

When TXRXEN is disabled (TXRXEN = 0), RxD_out is routed to D_TxRx and D_RxTx is routed to TxD_in. The output buffer enable, selected by RXDSEL[2:0], is routed to Db_obe.

When the Tx/Rx switch is enabled (TXRXEN = 1), RxD_out is routed to D_RxTx and D_TxRx is routed to TxD_in. The output buffer enable, selected by RXDSEL[2:0], is routed to Da_obe.

If the RXDSELn[2:0] field for any Port *n* is configured to select data from an internal port, the output buffer enable is selected by RXDSELn[2:0] and is routed to Dan_obe/Dbn_obe. In the case when the RXDSELn[2:0] field for Port *n* is configured to select data from an external port, the output buffer enable is always high and routed to Dan_obe/Dbn_obe, depending on the TXRXENn switch configuration.

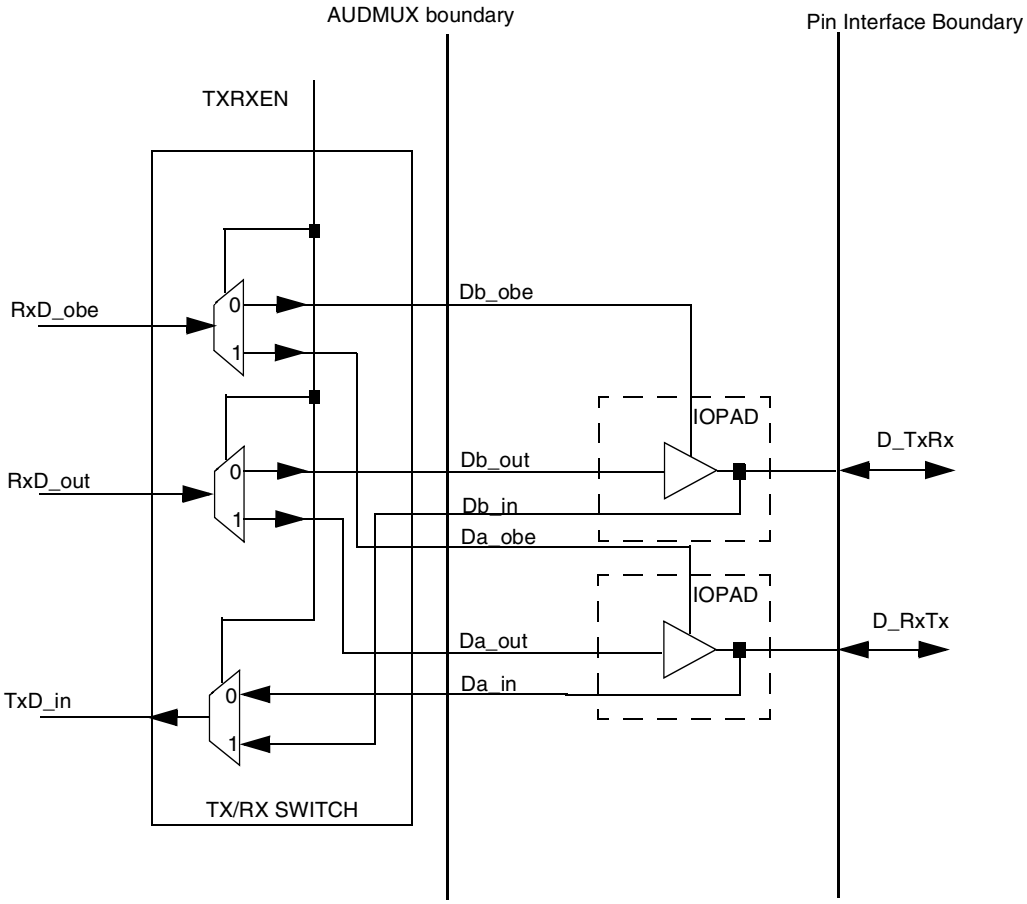

Figure 17-10. Tx/Rx Switch

17.1.2.3 Timing Modes

The AUDMUX ports are constructed as 6-wire interfaces. However, they can be used either in synchronous or asynchronous modes as determined by the SYN bit.

17.1.2.3.1 Synchronous Mode (4-wire Interface)

In Synchronous mode, the port has a 4-wire interface (that is, RxD, TxD, TxCLK, TxFS). The receive data timing is determined by TxCLK and TxFS.

As shown in Figure 17-11, Port x signals can be routed to Port y, producing 6-wire to 4-wire port connectivity.

TFS_in, RFS_in, TCLK_in, and RCLK_in are the input frame sync and bit clocks from the serial interface (Port x) with their corresponding output buffer enable signals (_obe). TFS_out, RFS_out, TCLK_out, and RCLK_out are the frame sync and bit clocks that are transmitted to the serial interface from the other ports.

The TFS_out and TCLK_out are selected at Port x by the TFSEL and TCSEL mux settings, respectively. RFS_out and RCLK_out are selected at Port x by the RFSEL and RCSEL mux settings, respectively. Similarly, in the external direction, Port y is configured as a 4-wire port; TFSEL selects the FS_obe and FS_out signals. In this mode, the configuration of RFSEL and RCSEL is not used, since the RFS_out and RCLK_out pins at Port y are not available.

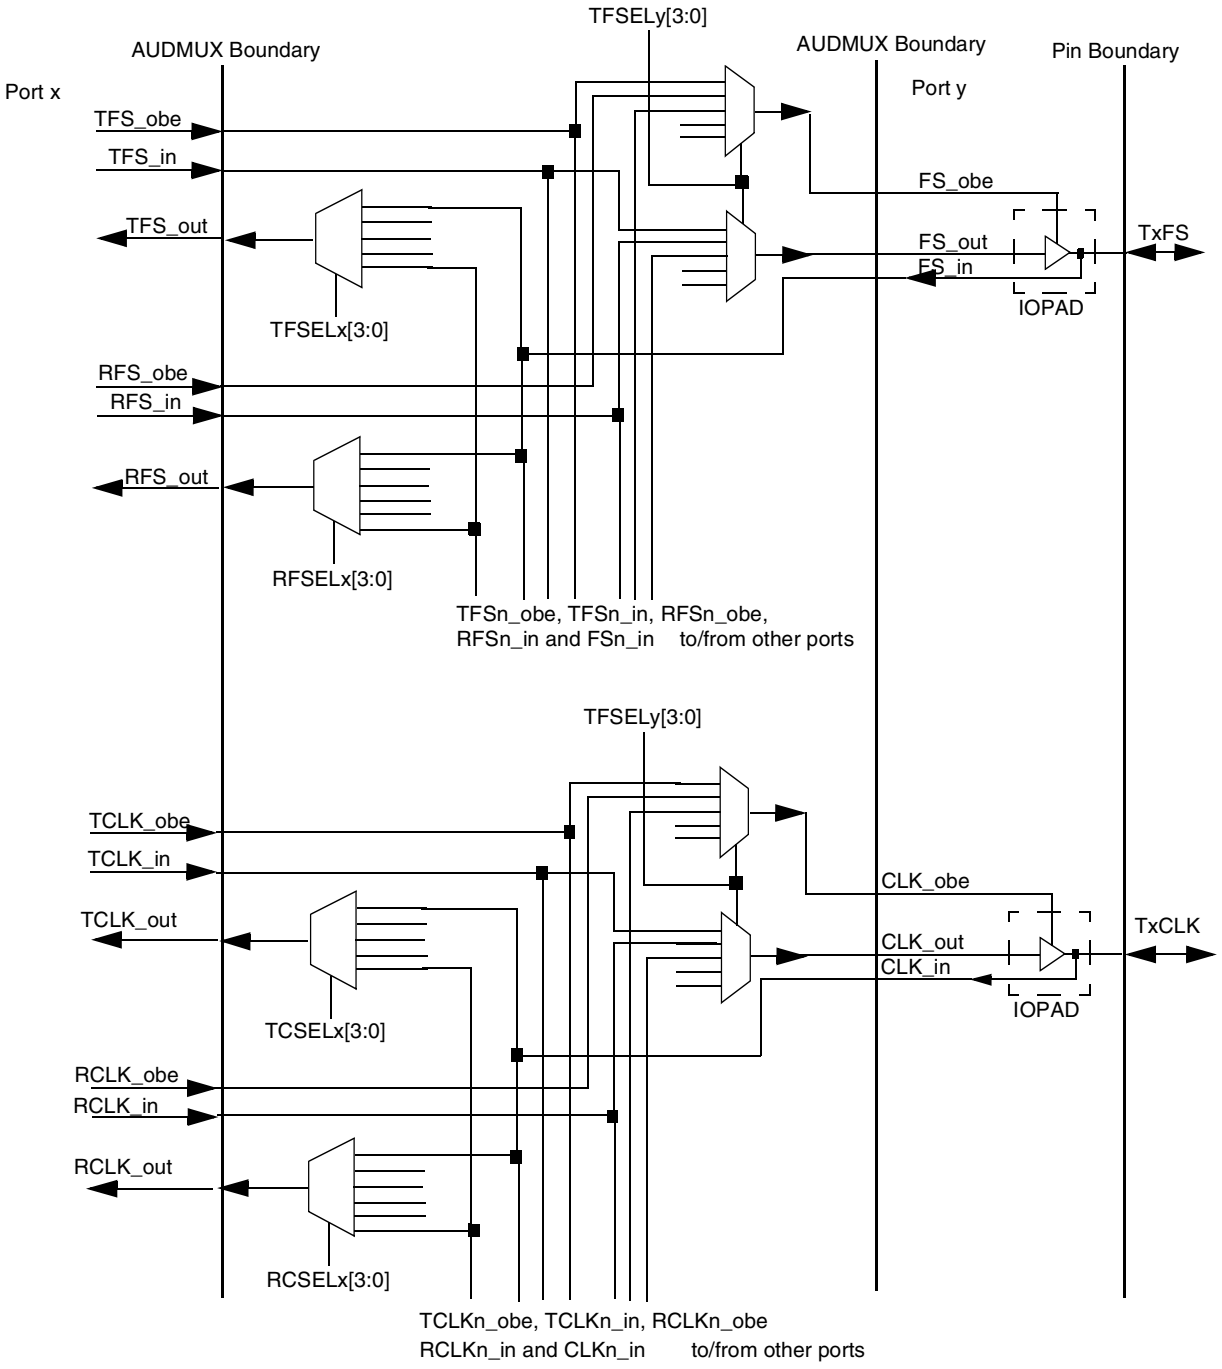

Figure 17-11. Frame Sync and Clock Routing When External Port Is 4-wire

17.1.2.3.2 Asynchronous Mode (6-wire Interface)

In Asynchronous mode, the port has a 6-wire interface (meaning RxD, TxD, TxCLK, TxFS, RxCLK, RxFS). This mode has additional receive clock (RxCLK) and frame sync (RxFS) signals as compared to the synchronous or 4-wire interface.

As shown in Figure 17-12 and Figure 17-13, Port x signals can be routed to Port y, producing 6-wire to 6-wire port connectivity.

TFS_in, RFS_in, TCLK_in, and RCLK_in are input frame sync and bit clocks from the serial interface (Port x) with their corresponding output buffer enable signals (_obe). TFS_out, RFS_out, TCLK_out, and RCLK_out are the frame sync and bit clocks that are transmitted to the serial interface from the other ports.

TFS_out and TCLK_out are selected by the TFSEL and TCSEL mux settings, respectively. RFS_out and RCLK_out are selected by the RFSEL and RCSEL mux settings, respectively. Similarly, in the external direction, the TFSEL selects the TxFS_obe and TxFS_out signals and TCSEL selects the TxCLK_obe and TxClk_out signals. The RFSEL selects the RxFS_obe and RxFS_out signals and RCSEL selects the RxCLK_obe and RxCLK_out signals.

NOTE

Since FS_in and CLK_in from external interfaces are also routed to the TFSEL and TCSEL muxes of the external ports, respectively, these signals do not have corresponding buffer enable signals. Consequently, their corresponding inputs to the TFSEL and TCSEL mux of the external ports have to be tied high.

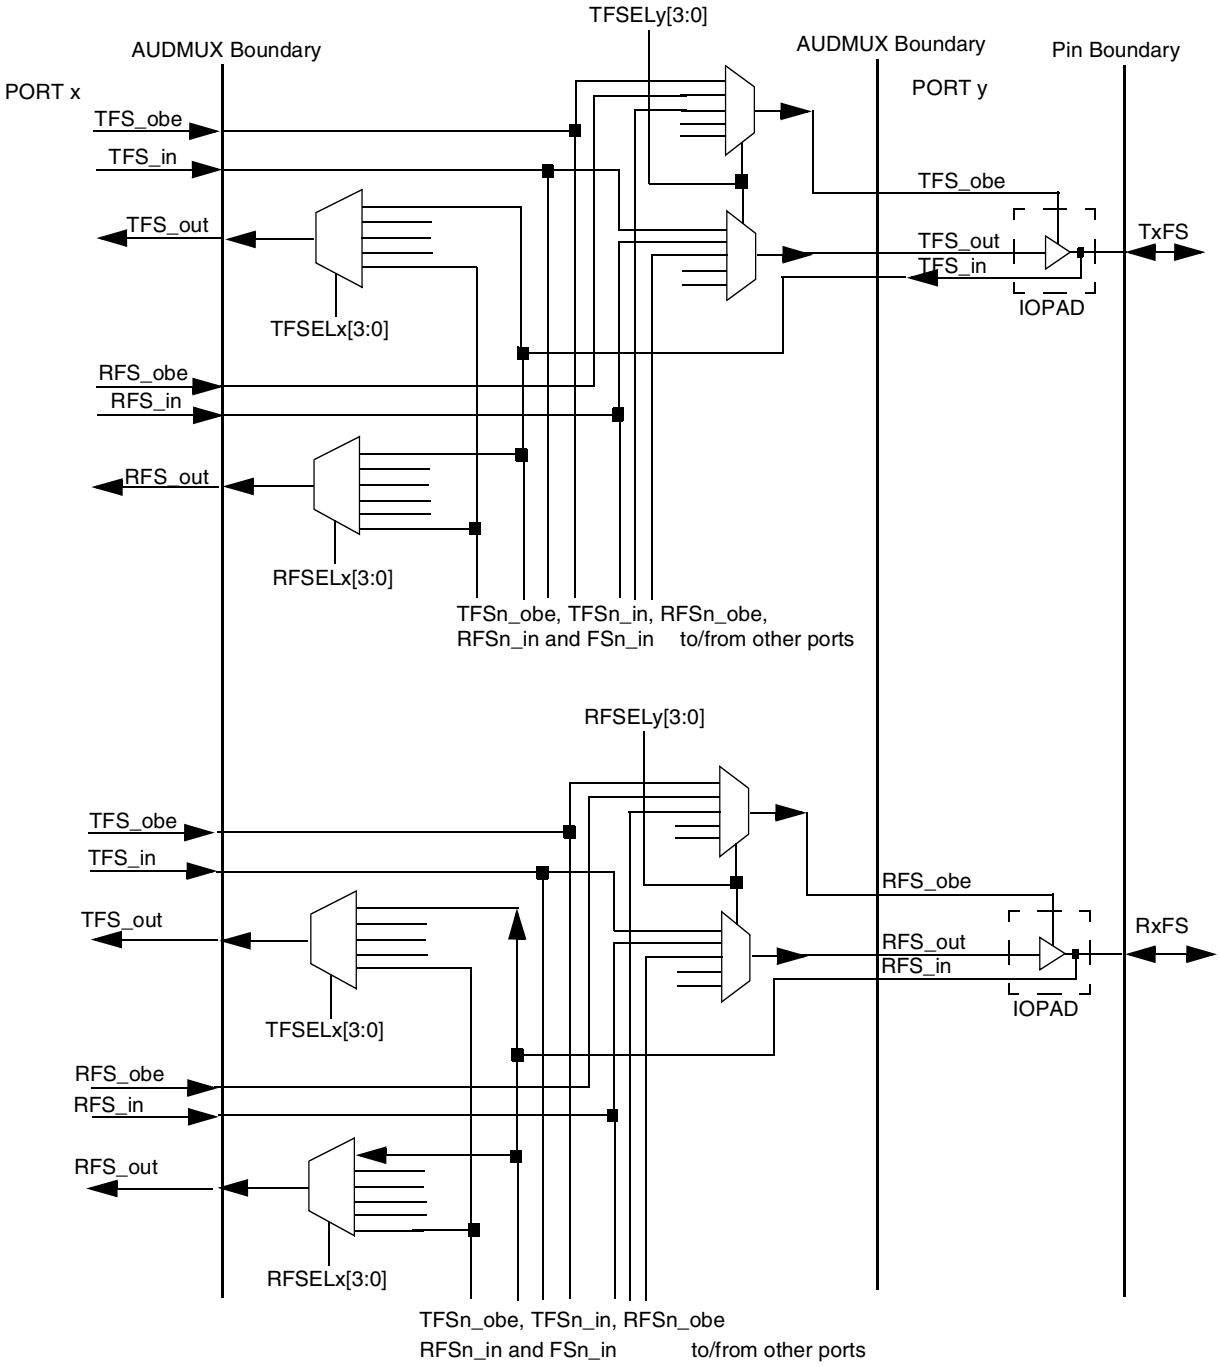

Figure 17-12. Frame Sync Routing When External Port Is 6-wire

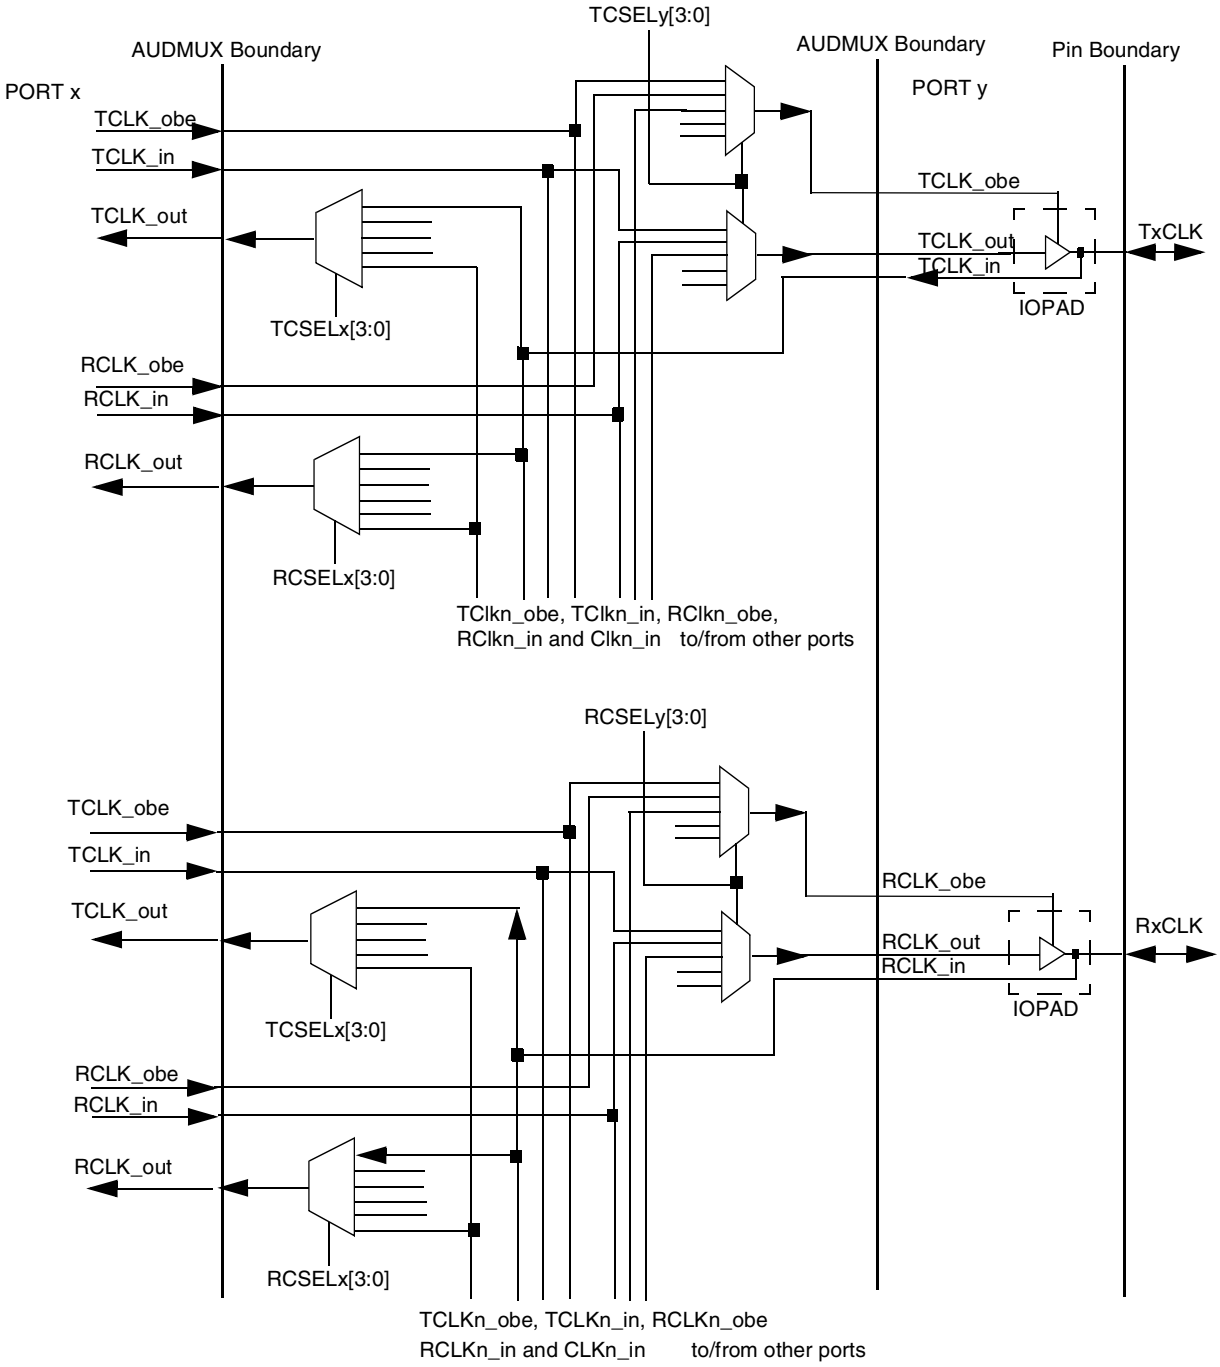

Figure 17-13. Clock Routing When External Port Is 6-wire

17.1.3 Connectivity Between Ports

Four basic types of connections are provided by the AUDMUX:

- Internal port to external port
- External port to external port

- Internal port to internal port
- Loopback

The corresponding data connections are described in the following sections.

17.1.3.1 Internal Port to External Port Connectivity

Figure 17-14 shows the data path connections between an internal port and an external port. The internal port is connected to a processor's serial interface. TxD_obe is the buffer enable signal from the serial interface, TxD_in is the input transmit data from the serial interface to the AUDMUX, and RxD_out is the receive data output from the AUDMUX to the serial interface.

RXDSEL[2:0] of the external port selects the buffer enable signal (TxD_obe) and transmit data output (TxD_out) signal from the TxD_obe and RxD_in signals. RXDSEL[2:0] is a common signal to both selection muxes.

NOTE

Since buffer TxD_in signals from external interfaces do not have corresponding buffer enable signals, their buffer enable signals into the selection mux are tied high. This will ensure that selection of TxD_in, as RxD_out will also drive the RxD_obe output high.

Transmit Data from the serial interface goes into the RXDSEL data mux and comes out as RxD_out. RxD_out is routed to Da_TxRx when TXRXEN is disabled and to D_RxTx when TXRXEN is enabled. Similarly, D_RxTx is routed to TxD_in when TXRXEN is disabled and D_TxRx is routed to TxD_in when TXRXEN is enabled. The routing of frame syncs is shown in Figure 17-12 and the routing of interface clocks is shown in Figure 17-13.

If internal network mode is disabled, then RXDSEL selects the TxD_in, which is sent from the AUDMUX to the serial interface connected at Port x. When the internal network mode is selected, RxD_out is constructed by ANDing selected TxD_in signals from the ports (as determined by INMMASK).

If there is more than one device attached to the external port at D_TxRx and D_RxTx and one of the devices is a network master, then two conditions must be noted:

1. When the external master is enabled in network mode, then the serial interface at Port x must be configured as a slave (normal or network mode). No Tx/Rx switching is required.
2. When the external master is disabled and the serial interface at Port x and other slave devices must communicate, then the serial interface at Port x must be configured as a network mode master and the Tx/Rx switch at Port y must be enabled (TXRXEN = 1). This will ensure that the transmit and receive paths are connected appropriately.

To communicate with more than one port, internal network mode can be enabled at Port x. In internal network mode, it is possible to communicate with any device attached to the other ports. Internal network mode shall be enabled at the port that is the SSI network mode master.

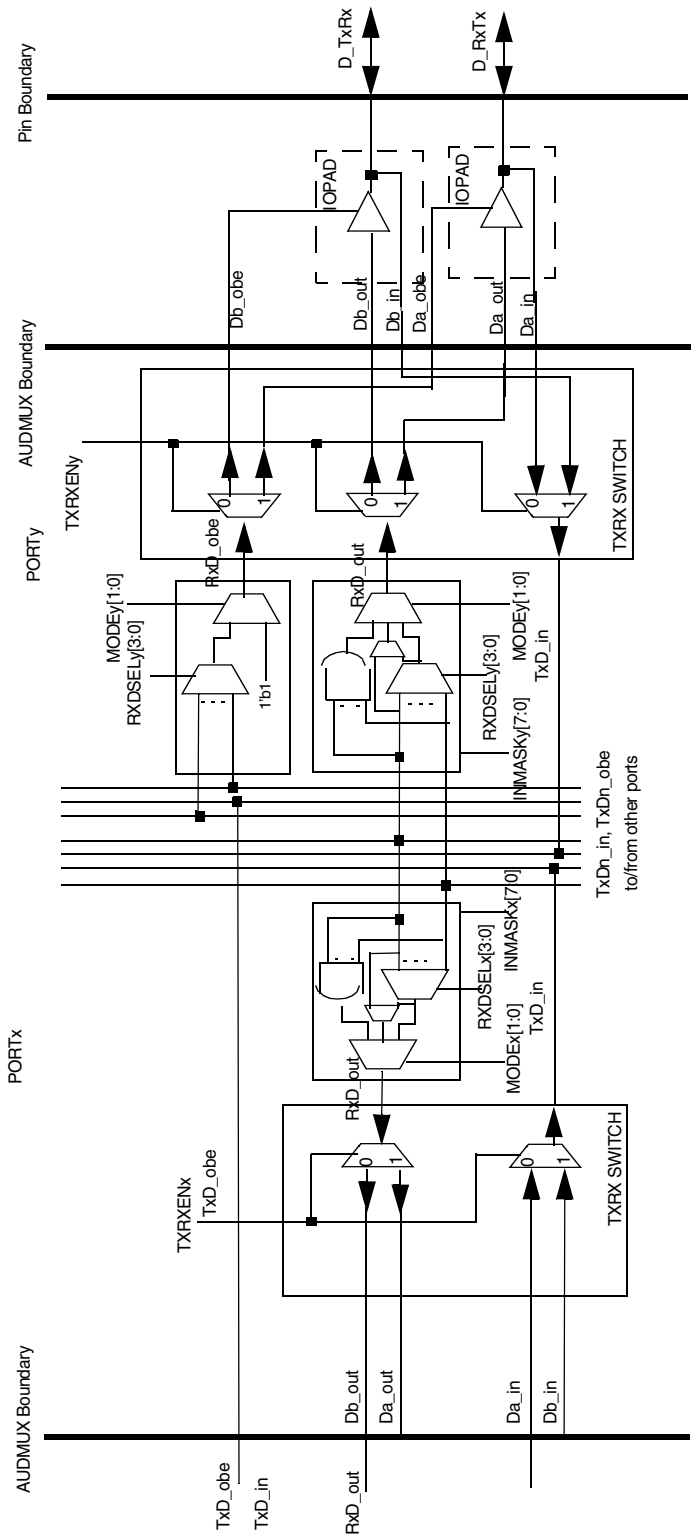

Figure 17-14. Internal to External Port Interconnection

17.1.3.2 External Port to External Port Connectivity

External ports can communicate with external ports directly. External ports can communicate together in three ways:

1. Each port's receive logic is configured in normal mode (MODE[0:1] = 00). Each port's RXDSEL[2:0] field is configured to select the other port's transmit data. Bit fields associated with clock/frame sync selection and direction are configured for each port. Either port can be the master.
2. One port is configured in internal network mode (MODE[0:1] = 01). All desired data lines are combined by the AND gate as determined by INMMASK[7:0]. Since an external port is being used as the internal network mode master, all other devices on the same AUDMUX port as the internal network mode master must be disabled. This configuration can be used with a combination of internal and external ports. All external ports must have a pull-up resistor on its RxDATA pin. Bit fields associated with clock/frame sync selection and direction are configured for each port. Any port can be the master.

17.1.3.3 Internal Port to Internal Port Connectivity

Internal ports can communicate with other internal ports directly. Internal ports can communicate together in three ways:

1. Each port's receive logic is configured in normal mode (MODE[0:1] = 00). Each port's RXDSEL[2:0] field is configured to select the other port's transmit data. Bit fields associated with clock/frame sync selection and direction are configured for each port. Either port can be the master.
2. One port is configured in internal network mode (MODE[0:1] = 01). All desired data lines are combined by the AND gate as determined by INMMASK[7:0]. This configuration can be used with a combination of internal and external ports. All external ports must have a pull-up resistor on its RxDATA pin. Bit fields associated with clock/frame sync selection and direction are configured for each port. Any port can be the master.

17.1.3.4 Loopback Connectivity

AUDMUX ports can communicate with themselves in order to provide loopback functionality. Port x can route its TxDATA signal to its own RxD_out signal by setting RXDSELx[2:0] to its own port number. This is supported by all ports in the AUDMUX.

In addition, ports can provide loopback support in internal network mode. With internal network mode, the internal network mode master can loop its TxDATA signal (combined with those of other ports, if desired) back into its RxD_out signal. Port x's INMMASK should be set such that bit (x - 1) is clear in order to enable the loopback.

17.2 External Signal Description

The following section provides the external signal descriptions for AUDMUX.

17.2.1 Overview

Table 17-1 lists pad-level signals of the AUDMUX for the external ports, where P*n* is P, to P7 and m = n -.The port is configured as an external port by a static system level signal input p*n*_int_ext_select.

Table 17-1. Signal Properties

Name	Port	I/O	Function	Reset State	Pull-up
ADm_TXD	P*n*	**I/O**	Transmitted Data from Pn	1	Active
ADm_RXD	P*n*	I/O	Received Data at Pn	1	Active
ADm_TXC	P*n*	I/O	Transmit Clock input/output at Pn	1	-
ADm_RXC	P*n*	I/O	Receive Clock input/output at Pn	1	-
ADm_TXFS	P*n*	I/O	Transmit Frame sync input/output at Pn	1	-
ADm_RXFS	P*n*	I/O	Receive Frame sync input/output at Pn	1	-

17.3 Memory Map and Register Definition

The AUDMUX memory map is shown in Table 17-2.

Table 17-2. AUDMUX Memory Map

17.3.1 Register Summary

Table 17-4 shows the control register and address mapping for the AUDMUX. Figure 17-5 shows the register fields key. Table 17-3 shows the register figure conventions.

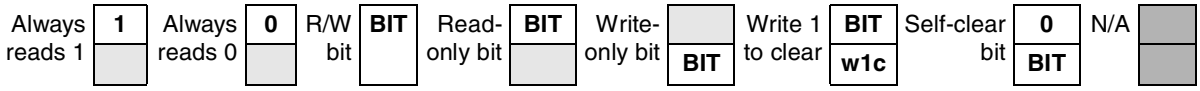

Figure 17-15. Key to Register Fields

Table 17-3. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

17.3.2 Register Descriptions

There are two configuration registers for each port. There are a total of 15 configuration registers.

17.3.2.1 Port Timing Control Register 1 (PTCR1)

PTCR1 is the Port Timing Control Register for Port 1.

0x53FC_4000 (PTCR1) Access: User read/write

Figure 17-16. Port Timing Control Register for Port 1

Table 17-5. Register Field Descriptions

Field	Description
31 TFS DIR	Transmit Frame Sync Direction Control. This bit sets the direction of the TxFS pin of the interface as an output or input. When set as an input, the TFSEL settings are ignored. When set as an output, the TFSEL settings determine the source port of the frame sync. 0 TxFS is an input. 1 TxFS is an output.
30–27 TFSEL[3:0]	Transmit Frame Sync Select. Selects the source port from which TxFS is sourced. 0xxx Selects TxFS from port. 1xxx Selects RxFS from port. x000 Port 1 . . . x110 Port 7 x111 Reserved
26 TCLKDIR	Transmit Clock Direction Control. This bit sets the direction of the TxClk pin of the interface as an output or input. When set as an input, the TCSEL settings are ignored. When set as an output, the TCSEL settings determine the source port of the clock. 0 TxClk is an input. 1 TxClk is an output.
25–22 TCSEL[3:0]	Transmit Clock Select. Selects the source port from which TxClk is sourced. 0xxx Selects TxClk from port. 1xxx Selects RxClk from port. x000 Port 1 . . . x110 Port 7 x111 Reserved
21 RFS DIR	Receive Frame Sync Direction Control. This bit sets the direction of the RxFS pin of the interface as an output or input. When set as an input, the RFSEL settings are ignored. When set as an output, the RFSEL settings determine the source port of the frame sync. 0 RxFS is an input. 1 RxFS is an output.
20–17 RFSEL[3:0]	Receive Frame Sync Select. Selects the source port from which RxFS is sourced. RxFS can be sourced from TxFS and RxFS from other ports. 0xxx Selects TxFS from port. 1xxx Selects RxFS from port. x000 Port 1 . . . x110 Port 7 x111 Reserved
16 RCLKDIR	Receive Clock Direction Control. This bit sets the direction of the RxClk pin of the interface as an output or input. When set as an input, the RCSEL settings are ignored. When set as an output, the RCSEL settings determine the source port of the clock. 0 RxClk is an input. 1 RxClk is an output.

Table 17-5. Register Field Descriptions (continued)

Field	Description
15–12 RCSEL[3:0]	Receive Clock Select. Selects the source port from which RxClk is sourced. RxClk can be sourced from TxClk and RxClk from other ports. 0xxx Selects TxClk from port. 1xxx Selects RxClk from port. x000 Port 1 . . . x110 Port 7 x111 Reserved
11 SYN	Synchronous/Asynchronous Select. When SYN is set, synchronous mode is chosen and the transmit and receive sections use common clock and frame sync signals (that is, the port is a 4-wire interface). When SYN is cleared, asynchronous mode is chosen and separate clock and frame sync signals are used for the transmit and receive sections (that is, the port is a 6-wire interface). 0 Asynchronous mode 1 Synchronous mode (default)
10–0	Reserved

17.3.2.2 Port Data Control Register 1 (PDCR1)

PDCR1 is the Port Data Control Register for Port 1.

The modes of operation include the following: • Normal mode, in which the RxD from the port selected by RXDSEL is routed to the port. • Internal Network mode in which RxD from other ports are ANDed together. RXDSEL is ignored. INMMASK determines which RxD signals are ANDed together. 0 Normal mode 1 Internal Network mode
7–0 INMMASK[7:0]	Internal Network Mode Mask. Bit mask that selects the ports from which of the RxD signals are to be ANDed together for internal network mode. Bit 6 represents RxD from Port 7 and bit0 represents RxD from Port 1. 0 Includes RxDn for ANDing 1 Excludes RxDn from ANDing

17.3.3 AUDMUX Default Configuration

The AUDMUX reverts back to its default settings following a reset. Section 17.3.3.1, Default Port Configuration," describe the default configuration of the ports.

17.3.3.1 Default Port Configuration

The AUDMUX's default port configuration after reset is as follows:

- Port 1 connected to Port 6
  - Port 6 provides the clock and frame sync.
  - Synchronous mode is enabled.
  - Normal mode is selected.
- Port 2 connected to Port 5
  - Port 5 provides the clock and frame sync.
  - Synchronous mode is enabled.
  - Normal mode is selected.
- Port 3 connected to Port 4
  - Port 4 provides the clock and frame sync.
  - Synchronous mode is enabled.
  - Normal mode is selected.
- Port 7 in data loopback mode
  - Clock and frame syncs are inputs.
  - Synchronous mode is enabled.
  - Normal mode is selected.

17.4 AUDMUX Clocking

This section provides information about AUDMUX clocking including clock inputs and the clock diagram.

17.4.1 AUDMUX Clock Inputs

The IP Bus read/write clock—ipg_clk_s—is an input to the AUDMUX. It is used for all AUDMUX register accesses. It is driven only when there is an AUDMUX access on the IP Bus.

) or external CODECs. The clock used for CE Bus Network mode is determined by PTCR7. Refer to Section Section , "CE_Bus_dis Signal Generation," for more details of the clock selection for CE Bus Network mode.

17.4.2 AUDMUX Clock Diagram

Figure 17-30 shows the clocking used in the AUDMUX.

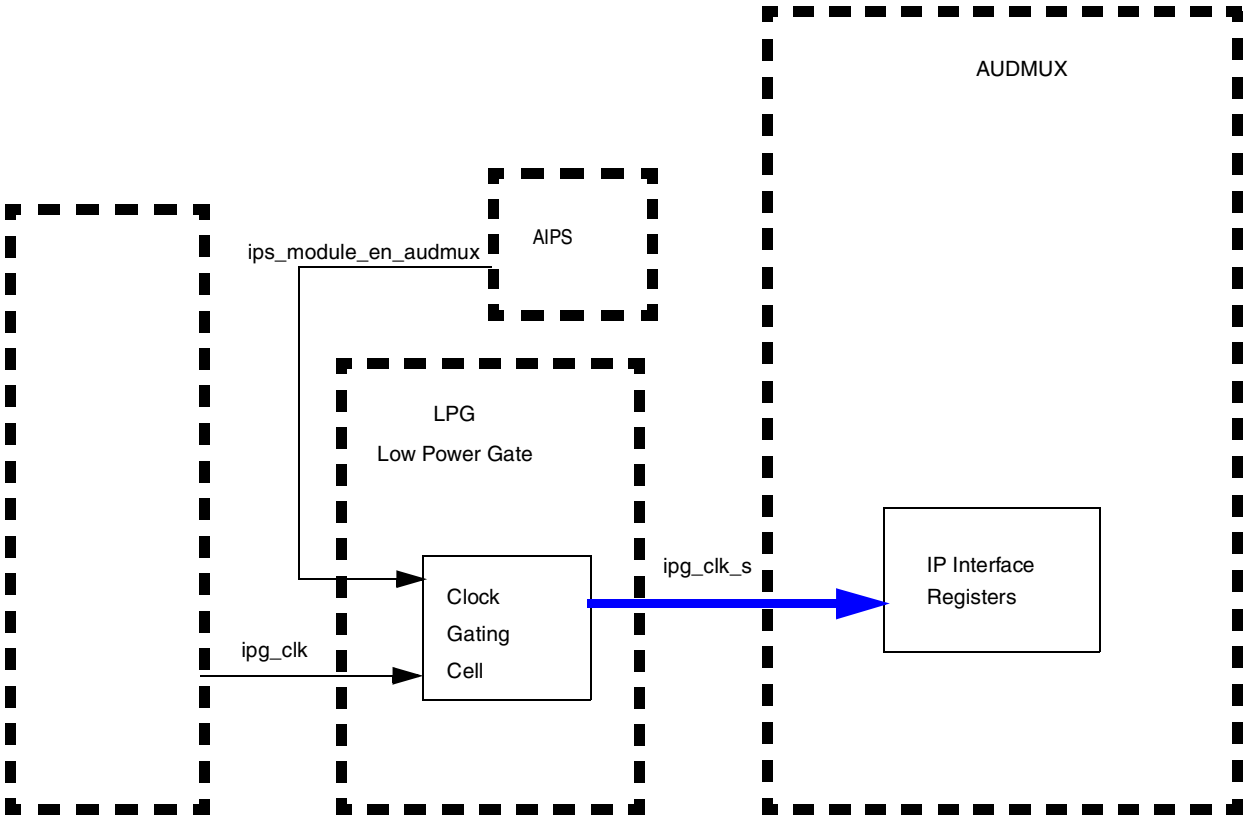

Figure 17-30. AUDMUX Clocking Scheme

17.4.3 Clocking Restrictions

- Since the AUDMUX requires only ipg_clk_s, the AUDMUX places no restrictions on the bus frequency.
- All registers in the AUDMUX are control registers so their values will not change frequently. Their values will be programmed when changing between use cases (not during use cases).

17.5 Initialization/Application Information

This section provides initialization and application information for AUDMUX.

Chapter 18
Configurable Serial Peripheral Interface (CSPI)

The Configurable Serial Peripheral Interface (CSPI) module allows rapid data communication with fewer software interrupts than conventional serial communications. The i.MX51 module contains one 8 × 32 receive buffer (RXFIFO) and one 8 × 32 transmit buffer (TXFIFO). Figure 18-1 shows the i.MX51 block diagram.

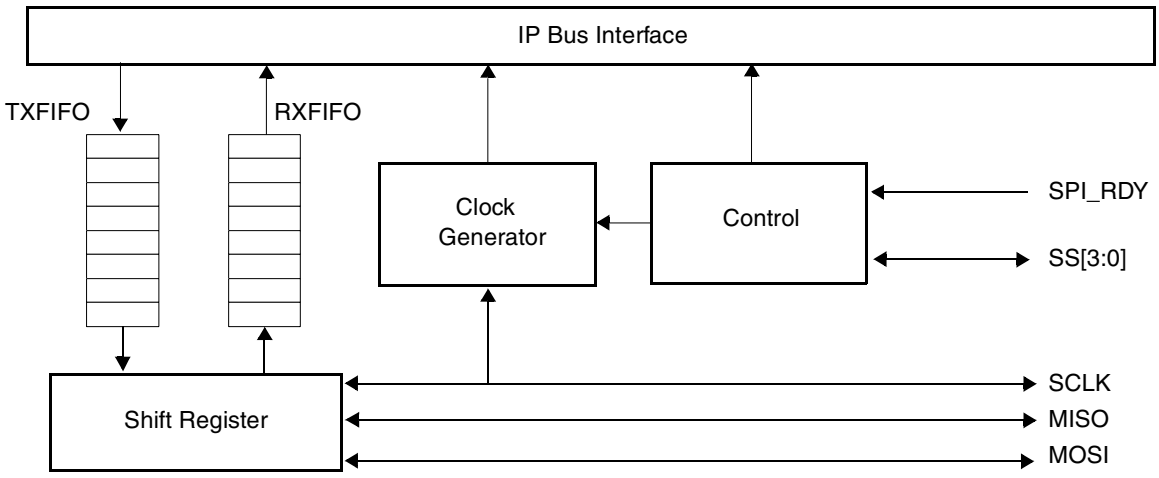

Figure 18-1. i.MX51 Block Diagram

18.1 Overview

The i.MX51 is equipped with data FIFOs and is a master/slave configurable serial peripheral interface module, capable of interfacing to both SPI master and slave devices. The i.MX51 Ready ($\overline{\text{SPI\_RDY}}$) and Chip Select ($\overline{\text{SS}}$) control signals enable fast data communication with fewer software interrupts.

This chapter describes the configuration and operation of the CSPI. Information such as base addresses and features that are unique to the multiple devices is described as appropriate.

18.1.1 Features

The i.MX51 is used for fast data communication with fewer software interrupts. It includes the following features:

- Full-duplex synchronous serial interface
- Master/Slave configurable
- Four chip selects to support multiple peripherals

- Transfer continuation function allows unlimited length data transfers
- 32-bit wide by 8-entry FIFO for both transmit and receive data
- Polarity and phase of the Chip Select ($\overline{SS}$) and SPI Clock (SCLK) are configurable
- DMA support

18.1.2 Modes of Operation

This module can be configured for master and slave modes. The details of each mode are as follows:

- Master Mode

  When the CSPI module is configured as a master, it uses a serial link to transfer data between the CSPI and an external device. A chip-enable signal and a clock signal are used to transfer data between these two devices. If the external device is a transmit-only device, the CSPI master's output port can be ignored and used for other purposes. In order to use the internal TXFIFO and RXFIFO, two auxiliary output signals, $\overline{SS}$ and $\overline{SPI\_RDY}$, are used for data transfer rate control. The user can also program the sample period control register to a fixed data transfer rate.

- Slave Mode

  When the CSPI module is configured as a slave, the user can configure the CSPI Control register to match the external SPI master's timing. In this configuration, $\overline{SS}$ becomes an input signal and is used to control data transfers through the Shift register as well as to load/store the data FIFO.

18.2 External Signal Description

The following signals shown in Table 18-1 are used to control the serial peripheral interface.

Table 18-1. CSPI Signal Properties

Name	Function	I/O	Reset	Pull-up
$\overline{SS}$[3:0]	Chip selects	I/O	1	—
SCLK	SPI clock	I/O	0	Active
MISO	Master data in; slave data out	I/O	0	Passive
MOSI	Master data out; slave data in	I/O	0	—
$\overline{SPI\_RDY}$	SPI data ready in Master mode	I	1	Active

Table 18-2 provides a detailed description of the CSPI signals.

Table 18-2. CSPI – Detailed Signal Descriptions

Signal	I/O	Description	
MOSI	I/O	Master Out Slave In. In Master mode, this bidirectional signal is a TX output signal from the Data Shift register. In Slave mode, it is an RX input from external SPI device.	
		State Meaning	Asserted—Indicates a 1 is transmitted. Negated—Indicates a 0 is transmitted.
		Timing	Asserted Negated
MISO	I/O	Master In Slave Out – In Master mode, this bidirectional signal is an RX input signal to the Data Shift register. In Slave mode, it is a TX output to external SPI device.	
		State Meaning	Asserted—Indicates a 1 is transmitted. Negated—Indicates a 0 is transmitted.
		Timing	Asserted Negated
SCLK	I/O	SPI Clock – In Master mode, this bidirectional signal is a SPI clock output. In Slave mode, it is a SPI clock input.	
		State Meaning	Asserted—Clock is high. Negated—Clock is low.
		Timing	Asserted Negated
$\overline{SS}$[3:0]	I/O	Chip selects – In Master mode, these bidirectional signals are outputs. In Slave mode, these are inputs. These signals are selected in/out by Chip Select bits in the CSPI Control register.	
		State Meaning	Asserted—When SSPOL is set, device is selected, otherwise device is de-selected. Negated—When SSPOL is set, device is de-selected, otherwise device is selected.
		Timing	Asserted Negated
$\overline{SPI\_RDY}$	I	SPI Ready – It is an input from an external SPI slave device. This signal triggers the CSPI to start a burst. Edge-trigger or level-trigger can be configured in the CSPI Control register.	
		State Meaning	Asserted—External SPI device is not ready. Negated—External SPI device is ready.
		Timing	Asserted Negated

18.3 Memory Map and Register Definition

The i.MX51 contains one CSPI module, which includes eight 32-bit registers. Section 18.3.3, Register Descriptions” provides the detailed descriptions for the CSPI registers.

18.3.1 Memory Map

Table 18-3 shows the CSPI memory map.

Table 18-3. i.MX51 CSPI Memory Map[1]

Address	Register	Access	Reset Value	Section/Page
General Registers				
0xBASE+0x000 (RXDATA)	Receive Data Register (RXDATA)	Read-only	0x0000_0000	18.3.3.1/18-6
0xBASE+0x004 (TXDATA)	Transmit Data Register (TXDATA)	Write-only	0x0000_0000	18.3.3.2/18-7
0xBASE+0x008 (CONREG)	Control Register (CONREG)	R/W	0x0000_0000	18.3.3.3/18-8
0xBASE+0x00C (INTREG)	Interrupt Control Register (INTREG)	R/W	0x0000_0000	18.3.3.4/18-11
0xBASE+0x010 (DMAREG)	DMA Control Register (DMAREG)	R/W	0x0000_0000	18.3.3.5/18-12
0xBASE+0x014 (STATREG)	Status Register (STATREG)	R/W	0x0000_0003	18.3.3.6/18-13
0xBASE+0x018 (PERIODREG)	Sample Period Control Register (PERIODREG)	R/W	0x0000_0000	18.3.3.7/18-14
0xBASE+0x01C (TESTREG)	Test Control Register (TESTREG)	R/W	0x0000_0000	18.3.3.8/18-15

1 See Chapter 2, “Memory Map,” for the value of base address of CSPI.

18.3.2 Register Summary

Figure 18-2 shows the key to the register fields and Table 18-4 shows the register figure conventions.

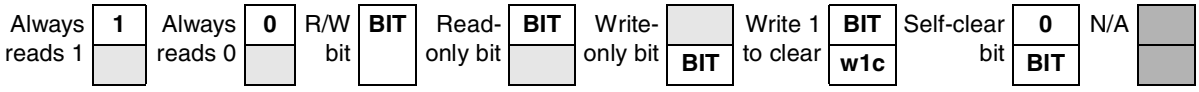

Figure 18-2. Key to Register Fields

Table 18-4. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit’s value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	

Table 18-4. Register Figure Conventions (continued)

Convention	Description
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 18-5 shows the i.MX51 register summary.

18.3.3 Register Descriptions

The following section describes the detailed register descriptions for the CSPI registers.

18.3.3.1 Receive Data Register (RXDATA)

The Receive Data register (RXDATA) is a read-only register that forms the top word of the 8×32 receive FIFO. This register holds the data received from an external SPI device during a data transaction. Only word-sized read operations are allowed. Figure 18-3 shows the RXDATA register and Table 18-6 shows the register's field descriptions.

0xBASE+0x000 (RXDATA) Access: User read-only

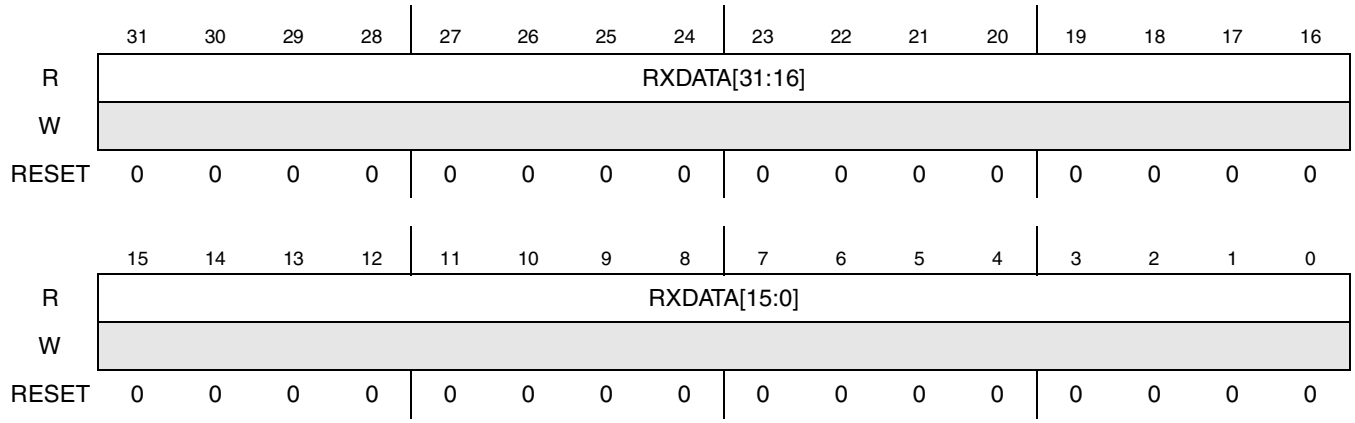

Figure 18-3. RXDATA Register Diagram

Table 18-6. RXDATA Register Field Description

Field	Description
31–0 RXDATA	Receive Data This register holds the top word of the receive data FIFO. The FIFO is advanced for each read of this register. The data read is undefined when the Receive Data Ready (RR) bit in the Interrupt Control/Status register is cleared. Zeros are read when CSPI is disabled.

18.3.3.2 Transmit Data Register (TXDATA)

The Transmit Data (TXDATA) register is a write-only data register that forms the top word of the 8×32 TXFIFO. The TXFIFO can be written to as long as it is not full, even when the XCH bit in CONREG is set. This allows the user write access to the TXFIFO during a SPI data exchange process. Writes to this register are ignored when the i.MX51 module is disabled (EN bit of i.MX51 CONREG is cleared). Figure 18-4 shows the CNTRL register and Table 18-7 shows the register's field descriptions.

0xBASE+0x004 (TXDATA) Access: User write-only

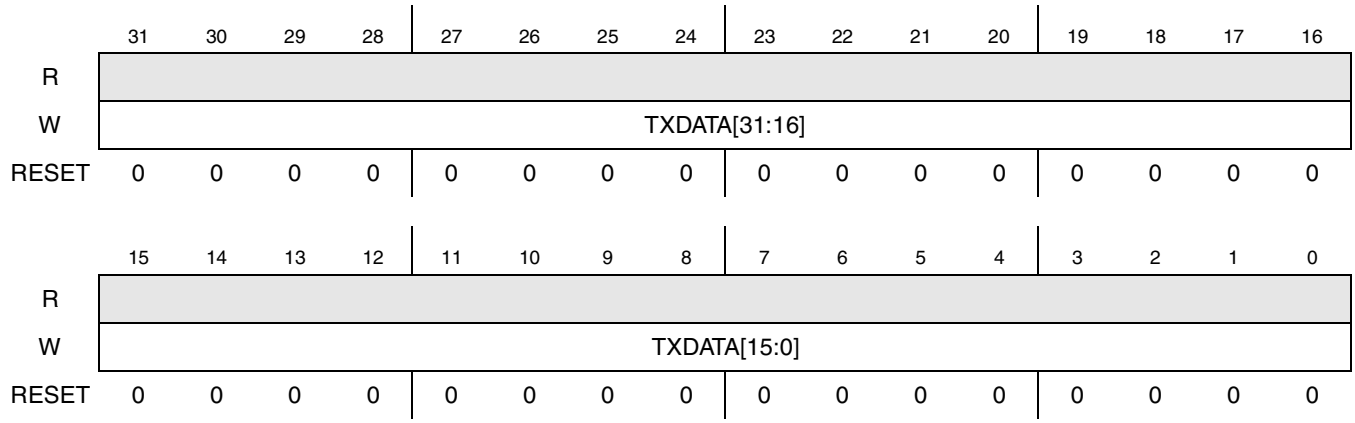

Figure 18-4. TXDATA Register Diagram

Table 18-7. TXDATA Register Field Description

Field	Description
31–0 TXDATA	Transmit Data This register holds the top word of data loaded into the FIFO. Data written to this register must be a word operation. The number of bits actually transmitted is determined by the BIT_COUNT field of the corresponding SPI Control register. If this field contains more bits than the number specified by BIT_COUNT, the extra bits are ignored. For example, to transfer 10 bits of data, a 32-bit word must be written to this register. Bits 9-0 are shifted out and bits 31-10 are ignored. When the CSPI module is operating in Slave mode, zeros are shifted out when the FIFO is empty. Zeros are read when CSPI is disabled.

18.3.3.3 Control Register (CONREG)

The Control Register (CONREG) allows the user to enable the i.MX51 module, configure its operating modes, specify the divider value, phase, and polarity of the clock, configure the $\overline{SS}$ and $\overline{SPI\_RDY}$ control signal, and define the transfer length. The reserved bits are always read as 0. Figure 18-5 shows the CNTRL register and Table 18-8 shows the register's field descriptions.

0xBASE+0x008 (CONREG) Access: User read/write

Figure 18-5. CSPI Control Register

Table 18-8. CONREG Register Field Description

Field	Description
31–20 BURST LENGTH	Burst Length. This field defines the length of a SPI burst to be transferred. $\overline{SS}$ remains asserted until all bits in a SPI burst are shifted out. A maximum of 2^12 bits can be transferred in a single SPI burst. In master mode, it controls the number of bits per SPI burst. Since the shift register always loads 32-bit data from transmit FIFO, only the n least-significant (n = BURST LENGTH + 1) are shifted out. The remaining bits are ignored. In slave mode, only when SSCTL is cleared, this field takes effect in SPI transfer. Number of Valid Bits in a SPI burst. 0x000 A SPI burst contains least 1 bit in a word. 0x001 A SPI burst contains least 2 bit in a word. 0x010 A SPI burst contains least 3 bit in a word. ..... 0x01F A SPI burst contains all 32 bits in a word. 0x020 A SPI burst contains least 1 bit in first word and all 32 bits in second word. 0x021 A SPI burst contains least 2 bit in first word and all 32 bits in second word. ..... 0xFFE A SPI burst contains least 31 bits in first word and 2^7 -1 words. 0xFFF A SPI burst contains 2^7 words.
19	Reserved, all bits should read zero.
18–16 DATA RATE	SPI Data Rate Control This three-bit field selects the baud rate of the SCLK based on a division of the ipg_clk. These bits allow CSPI to synchronize with different external SPI devices. The max frequency is one quarter of ipg_clk. The divide ratio is determined according to the following table using the equation: $2^{(n+2)}$. SPI Data Rate Control (Master Mode only) 000 Divide by 4. 001 Divide by 8. 010 Divide by 16. 011 Divide by 32. 100 Divide by 64. 101 Divide by 128. 110 Divide by 256. 111 Divide by 512.
15 –14	Reserved, all bits should read zero.
13 –12 CHIP SELECT	CHIP SELECT Selects one of four external SPI Master/Slave Devices. In master mode, these two bits select the external slave devices by asserting the $\overline{SS}$n outputs. Only the selected $\overline{SS}$n signal are active while the remaining 3 signals are negated. Chip Select 00 $\overline{SS}$0 is asserted. 01 $\overline{SS}$1 is asserted. 10 $\overline{SS}$2 is asserted. 11 $\overline{SS}$3 is asserted.
11–10	Reserved, all bits should read zero.

Table 18-8. CONREG Register Field Description (continued)

Field	Description
9–8 DRCTL	SPI Data Ready Control This 2-bit field selects the utilization of the $\overline{\text{SPI\_RDY}}$ in master mode. CSPI checks this fields before it start a SPI burst. 00 Don't care $\overline{\text{SPI\_RDY}}$ 01 Burst are triggered by failing edge of $\overline{\text{SPI\_RDY}}$. 10 Burst are triggered by low level of $\overline{\text{SPI\_RDY}}$. 11 $\overline{\text{RSV}}$.
7 SSPOL	SPI SS Polarity Select In both Master and Slave mode, this bit selects the polarity of the $\overline{\text{SS}}$ signal. 0 Active low. 1 Active high.
6 SSCTL	SPI SS Wave Form Select In master mode, this bit controls the output wave form of $\overline{\text{SS}}$ signal when SMC is cleared, and it is ignored when SMC is set. 0 Only one SPI bursts is transmitted. 1 Negate $\overline{\text{SS}}$ between SPI bursts. Multiple SPI bursts are transmitted. CSPI transfer is stopped when TXFIFO is empty. In slave mode, this bit controls when a SPI burst is completed. 0 A SPI burst is completed when number of bits received in shifter register is equal to BURST LENGTH + 1. Only n least-significant bits (n = BURST LENGTH[4:0] + 1) of first received word are valid. And all bits in following words received in RXFIFO are valid. 1 A SPI burst is completed by $\overline{\text{SS}}$ edges. (SSPOL = 0: rising edge; SSPOL = 1: falling edge) RXFIFO is advanced whenever a $\overline{\text{SS}}$ edge is detected or shifter register contains 32-bits valid data.
5 PHA	SPI Clock/Data Phase Contro This bit controls the clock/data phase relationship. Refer to Figure 18-18, SPI Burst with Different POL and PHA Configuration, for description. 0 Phase 0 operation. 1 Phase 1 operation.
4 POL	SPI Clock Polarity Control This bit controls the polarity of the SCLK signal. Refer to Figure 18-18, SPI Burst with Different POL and PHA Configuration, for description. 0 Active high polarity (0 = Idle). 1 Active low polarity (1 = Idle).
3 SMC	Start Mode Control This bit is used in master mode only and it controls how CSPI start a SPI burst. 0 XCH bit controls when a SPI burst can start. Write a 1 to XCH bit starts a SPI burst or multiple bursts. (controlled by SSCTL) 1 Immediately start a SPI burst when data is written in TXFIFO.
2 XCH	SPI Exchange Bit If the SMC bit is cleared, writing a 1 to this bit starts one SPI bursts/multiple SPI bursts according to SSCTL bit. This bit remains set while either the exchange is in progress, or the i.MX51 is waiting for active input if $\overline{\text{SPIRDY}}$ is enabled through DRCTL. This bit is cleared automatically when all data in the TXFIFO and Shift register have been shifted out. In Slave mode, this bit is ignored. 0 Idle. 1 Initiates exchange (write) or busy (read).

Table 18-8. CONREG Register Field Description (continued)

Field	Description
1 MODE	SPI Function Mode Selec This bit selects the operating mode of the i.MX51. 0 Slave Mode. 1 Master Mode.
0 EN	SPI Module Enable Control This bit enables the i.MX51. This bit must be asserted before writing to other registers or initiating an exchange. Writing zero to this bit disables the module and resets the internal logic with the exception of the CONREG. The module's internal clocks are gated off whenever the module is disabled. 1 i.MX51 is enabled. 0 i.MX51 is disabled.

18.3.3.4 Interrupt Control Register (INTREG)

The 32-bit Interrupt Control Register (INTREG) enables the generation of interrupts to the MCU. The reserved bits cannot be written and always read as 0. If CSPI is disabled, this register reads zero. Figure 18-6 shows the CNTRL register and Figure 18-9 shows the register's field descriptions.

18.3.3.5 DMA Control Register (DMAREG)

The DMA Control Register (DMAREG) provides the user a way to use the CSPI in DMA. Direct Memory Access (DMA) allows transfer of data between device and memory. Peripherals such as the CSPI supporting DMA use DMA request and acknowledge signals. The CSPI sends out DMA requests when the appropriate FIFO conditions are matched. The reserved bits cannot be written to and are always read as 0. If the CSPI is disabled, this register is also read as 0. Figure 18-7 shows the CNTRL register and Figure 18-10 shows the register's field descriptions.

0 TEDEN	TXFIFO Empty DMA Request Enable. This bit enables/disables the TXFIFO Empty DMA Request. 0 Disable 1 Enable

18.3.3.6 Status Register (STATREG)

The i.MX51 Status Register (STATREG) reflects the status of the CSPI module operating condition. The reserved bits cannot be written and always read as 0. If the CSPI is disabled, this register reads 0x0000_0003. Figure 18-8 shows the CNTRL register and Figure 18-11 shows the register's field descriptions.

0xBASE+0x014 (STATREG) Access: User read/write

Figure 18-8. Status Register Diagram

Table 18-11. STATREG Register Field Description

Field	Description
31–8	Reserved, should be cleared.
7 TC	Transfer Completed. When set, this bit indicates that all the data in TXFIFO has been loaded in the Shift register and Shift register has shifted out all the bits. Writing 1 to this bit clears it. 0 Busy. 1 Transfer Completed.
6 RO	RXFIFO Overflow. When set, this bit indicates that RXFIFO has overflowed. 0 RXFIFO is available. 1 RXFIFO has overflowed.
5 RF	RXFIFO Full. This bit is set when the RXFIFO is full (8 words). 0 Not Full. 1 Full.
4 RH	RXFIFO Half Full. This bit is set if the RXFIFO is half full (≥ 4 words in RXFIFO). 0 Less than 4 words are stored in RXFIFO. 1 Four or more words are available in RXFIFO.
3 RR	RXFIFO Ready. This bit is set any time there is one or more words stored in RXFIFO (≥ 1 words). 0 No valid data in RXFIFO. 1 More than 1 word in RXFIFO.
2 TF	TXFIFO Full. This bit is set when if the TXFIFO is full (8 words). 0 TXFIFO is not Full. 1 TXFIFO is Full.
1 TH	TXFIFO Half empty. This bit is set if the TXFIFO is more than half empty (≤ 4 words in TXFIFO). 0 TXFIFO holds more than 4 words. 1 TXFIFO holds 4 or fewer words.
0 TE	TXFIFO Empty. This bit is set if the TXFIFO is empty. 0 TXFIFO contains one or more words. 1 TXFIFO is empty.

18.3.3.7 Sample Period Control Register (PERIODREG)

The Sample Period Control Register (PERIODREG) provides the user a way to insert delays (wait states) between consecutive SPI transfers. Control bits in this register select the clock source for the sample period counter and the delay count indicating the number of wait states to be inserted between data transfers. Delay counts are only applicable when the i.MX51 module is operating in master mode. Figure 18-9 shows the CNTRL register and Figure 18-12 shows the register's field descriptions.

0xBASE+0x018 (PERIODREG) Access: User read/write

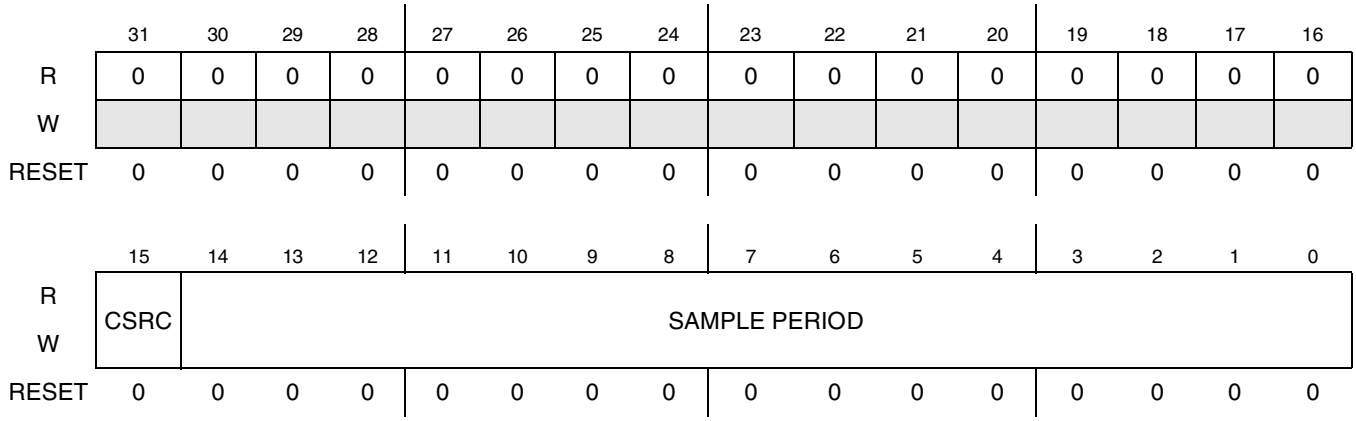

Figure 18-9. Sample Period Control Register Diagram

Table 18-12. PERIODREG Register Field Description

Field	Description
31–16	Reserved, all bits should read zero.
15 CSRC	Clock Source Control. This bit selects the clock source for the sample period counter. 0 SPI Clock (SCLK) 1 CKIL (32.768 KHz)
14–0 SAMPLE PERIOD	Sample Period Control. These bits control the number of wait states to be inserted in data transfers. During the idle clocks, the state of the $\overline{SS}$ output operates according to the SSCTL control field in CONREG. 0x0000 0 wait states inserted 0x0001 1 wait state inserted .... 0x7FFE 32766 wait states inserted 0x7FFF 32767 wait states inserted

18.3.3.8 Test Control Register (TESTREG)

The Test Control Register (TESTREG) provides the user a mechanism to internally connect the receive and transmit devices of the CSPI module, display the status of the state machine, monitor the contents of the receive and transmit FIFO, and debug the i.MX51. Figure 18-10 shows the CNTRL register and Figure 18-13 shows the register's field descriptions.

0xBASE+0x01C (TESTREG) Access: User read/write

Figure 18-10. Test Control Register Diagram

Table 18-13. TESTREG Register Field Description

Field	Description
31–16	Reserved, All bits should be read as zero.
15 SWAP	Data Swap. This bit is used to swap data as it is read from the RXFIFO. When this bit is set, data read from RXFIFO is swapped. RXDATA[31:0] is swapped as follows: {RXDATA[7:0],RXDATA[15:8], RXDATA[23:16],RXDATA[31:24]} 0 Data read from RXFIFO is unchanged. 1 Data read from RXFIFO is swapped.
14 LBC	Loop Back Control. This bit is used in Master mode only. When this bit is set, the CSPI module connects the transmitter and receiver sections internally, and the data shifted out from the most-significant bit of the Shift register is looped back into the least-significant bit of the Shift register. In this way, a self-test of the complete transmit/receive path can be made. The output pins are not affected, and the input pins are ignored. 0 Not connected. 1 Internally connected.
13–12	Reserved, all bits should read zero.
11–8 SMSTATUS	State Machine Status. These bits indicate status of the state machine for test purpose.

Table 18-13. TESTREG Register Field Description (continued)

Field	Description
7–4 RXCNT	RXFIFO Counter. These bits indicate the number of words in RXFIFO. RXFIFO Counter 0000 0 word in RXFIFO 0001 1 word in RXFIFO .... 0111 7 words in RXFIFO 1000 8 words in RXFIFO
3–0 TXCNT	TXFIFO Counter. These bits indicate the number of words in TXFIFO. TXFIFO Counter 0000 0 word in TXFIFO 0001 1 word in TXFIFO .... 0111 7 words in TXFIFO 1000 8 words in TXFIFO

18.4 Functional Description

This section describes the timings for the CSPI. Figure 18-11 shows the generic CSPI timing.

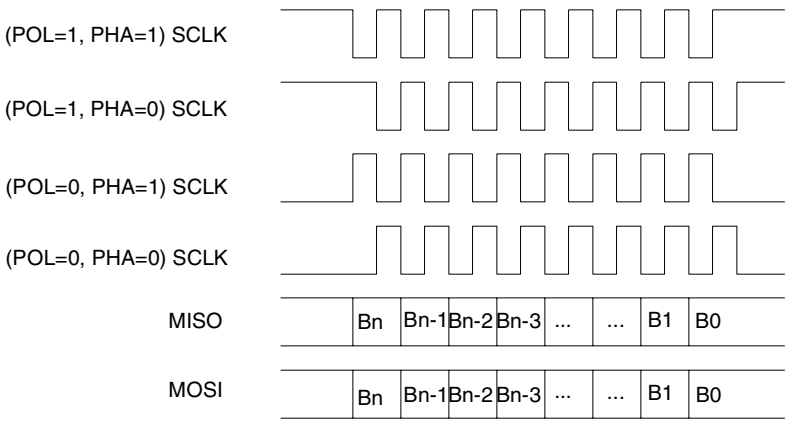

Figure 18-11. CSPI Generic Timing

18.4.1 Master Mode

The i.MX51 master uses the $\overline{SS}$ signal to enable an external SPI device and uses SPICLK to transfer data in and out of the Shift register. The $\overline{SPI\_RDY}$ enables fast data communication with fewer software interrupts. By using PERIODREG, the CSPI can be used for a fixed data transfer rate.

When CSPI is in Master mode the $\overline{SS}$, SCLK, and MOSI are output signals and the MISO is an input. Figure 18-12 shows a typical SPI burst.

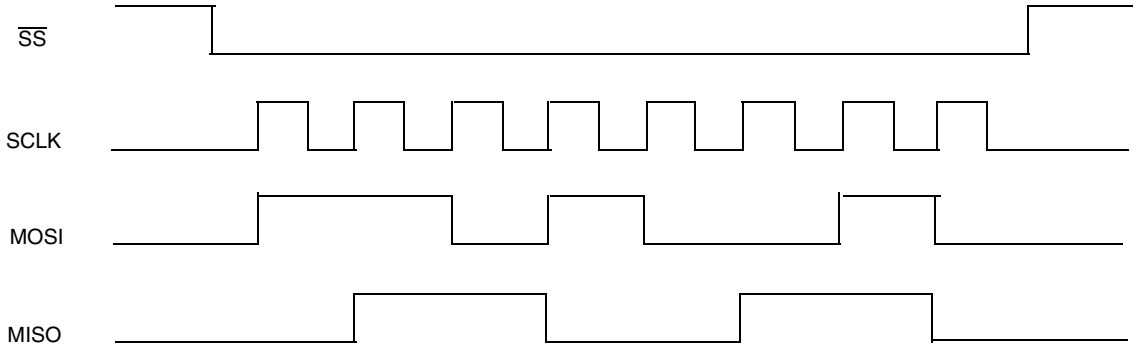

Figure 18-12. Typical SPI Burst (8-bit transfer)

In Figure 18-12, the SS signal enables the selected external SPI device and the SCLK synchronizes data transfer. MOSI and MISO change on rising edge of SCLK and the MISO is latched on the falling edge of the SLCK clock. The data shifted out is 0xD2, and the data shifted in is 0x66.

18.4.1.1 Master Mode with SPI_RDY

By default, the CSPI does not use SPI_RDY in master mode. a SPI burst begins when the following events happen: the CSPI is enabled, TXFIFO has data in it, and CONREG[XCH] or CONREG[SMC] is set. When CONREG[DRCTL] contains either 01 or 10, the SPI_RDY controls when a SPI burst starts.

If CONREG[DRCTL] is set to 01, the SPI burst can be triggered only if a falling edge of SPI_RDY has been detected. Figure 18-13 shows the relationship between a SPI burst and the falling edge of SPI_RDY.

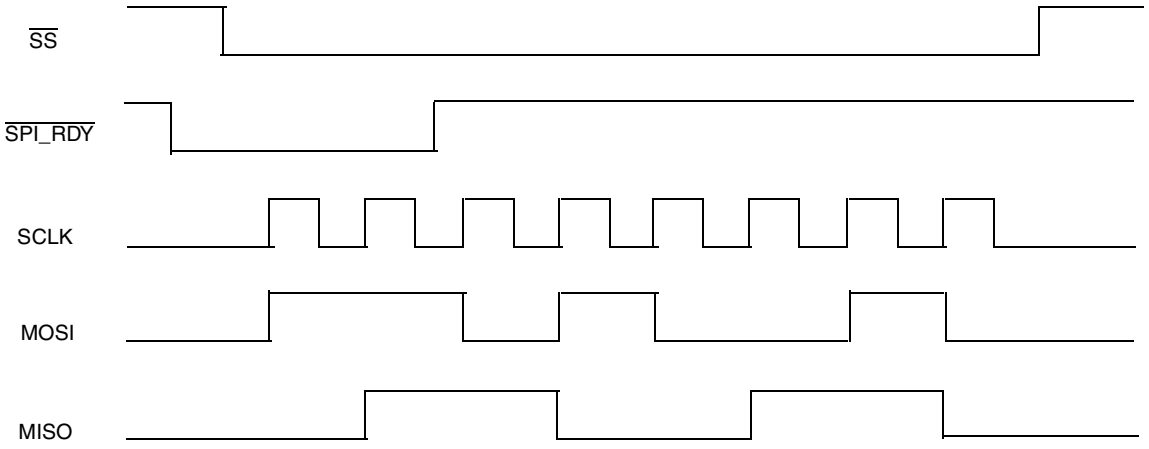

Figure 18-13. Relationship between a SPI Burst and the Falling Edge of SPI_RDY

A SPI burst does not start until the falling edge of SPI_RDY is detected. The next SPI burst starts when the next SPI_RDY falling edge is detected, after the last burst has finished.

If CONREG[DRCTL] is set to 10, the SPI burst can be triggered only if $\overline{\text{SPI\_RDY}}$ is low. Figure 18-14 shows the relationship between a SPI burst and $\overline{\text{SPI\_RDY}}$. The SPI burst does not begin until $\overline{\text{SPI\_RDY}}$ goes low. The next SPI burst begins after the last burst has finished if $\overline{\text{SPI\_RDY}}$ remains low.

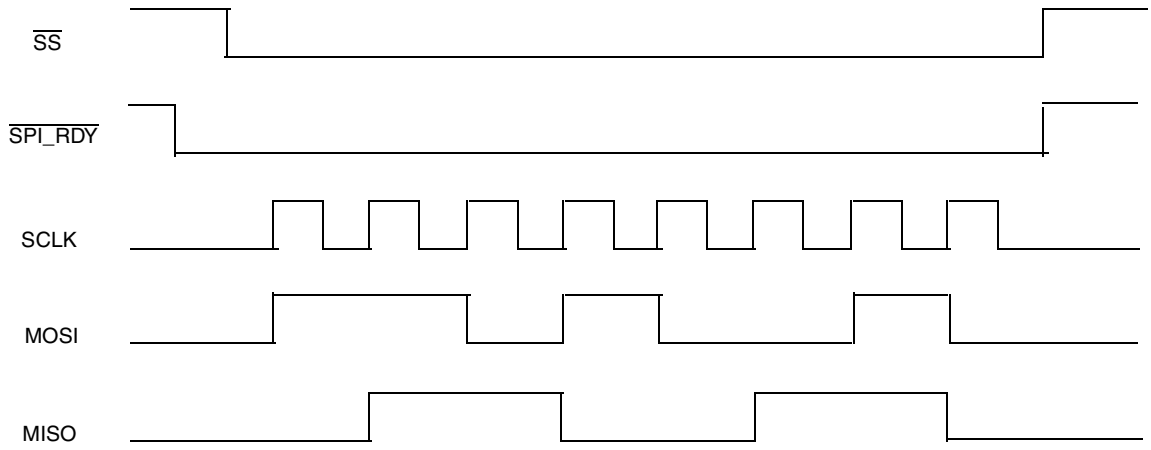

Figure 18-14. Relationship between a SPI Burst and $\overline{\text{SPI\_RDY}}$

18.4.1.2 Master Mode with Wait States

Wait states can be inserted between SPI bursts. This provides a way for the user to slow down the SPI burst to meet the timing requirements of a slower SPI device. Figure 18-15 shows wait states inserted between SPI bursts.

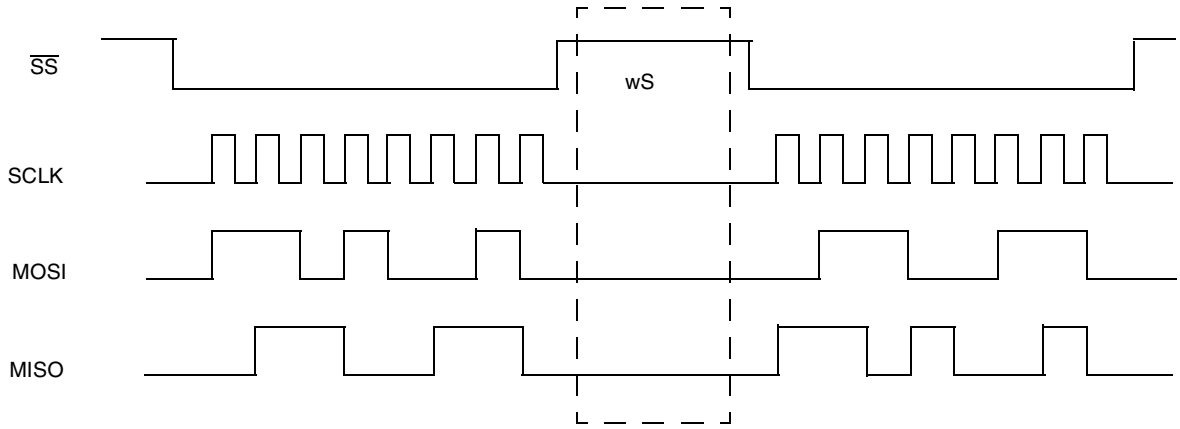

Figure 18-15. SPI Bursts with Wait States

In this case, the number of wait states is controlled by PERIODREG[SAMPLE PERIOD] and the wait states' clock source is selected by PERIODREG[CSRC].

18.4.1.3 Master Mode with SSCTL Control

SSCTL controls whether current operation is single burst or multiple bursts. When SSCTL is set, current operation is multiple bursts transfer. When SSCTL is cleared, current operation is single burst transfer. A SPI burst can contains multiple words as defined in BURST LENGTH.

Figure 18-16 shows one SPI burst while SSCTL is clear.

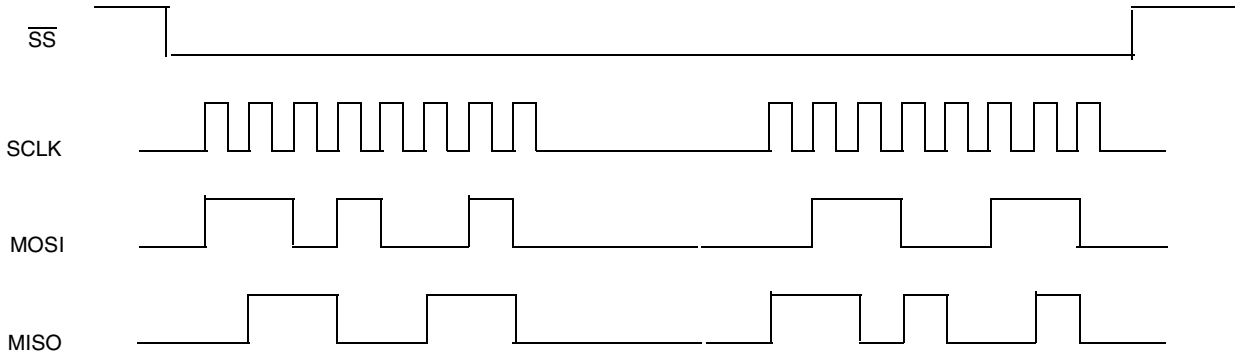

Figure 18-16. SPI Burst while SSCTL is Clear

In this case, two words in RXFIFO have been combined and transmitted in one SPI burst. The maximum length of a single SPI burst is defined in BURST LENGTH field in CONREG. This provides a way for transferring a longer SPI burst by writing data into TXFIFO while CSPI is transmitting.

Figure 18-17 shows two SPI bursts are transmitted while SSCTL is set.

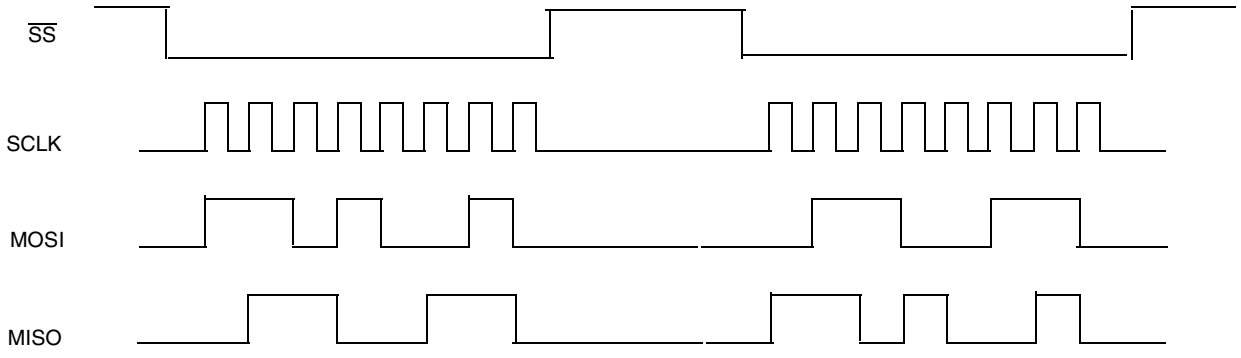

Figure 18-17. SPI Bursts while SSCTL is Set

In this case, two words are transmitted, one word per SPI burst. The CSPI continues transmitting SPI bursts until the TXFIFO is empty. When wait states can be inserted between SPI bursts, the $\overline{SS}$ negates between SPI bursts until the wait states finish.

18.4.1.4 Master Mode with PHA Control

CONREG[PHA] controls how the transmit data shifts out and the receive data shifts in.

When CONREG[PHA] is set, the transmit data shifts out on the rising edge of SCLK, and the receive data is latched on the falling edge of SCLK. The most-significant bit is output on the first rising SPICLK edge.

When CONREG[PHA] is cleared, the transmit data is shifted out on the falling edge of SCLK and the receive data is latched on the rising edge of SCLK. The most-significant bit is output when the CPU loads the transmitted data.

Inverting the SPICLK polarity does not impact the edge-triggered operations because they are internal to the serial peripheral interface master. Figure 18-18 shows a SPI burst using different POL and PHA configurations.

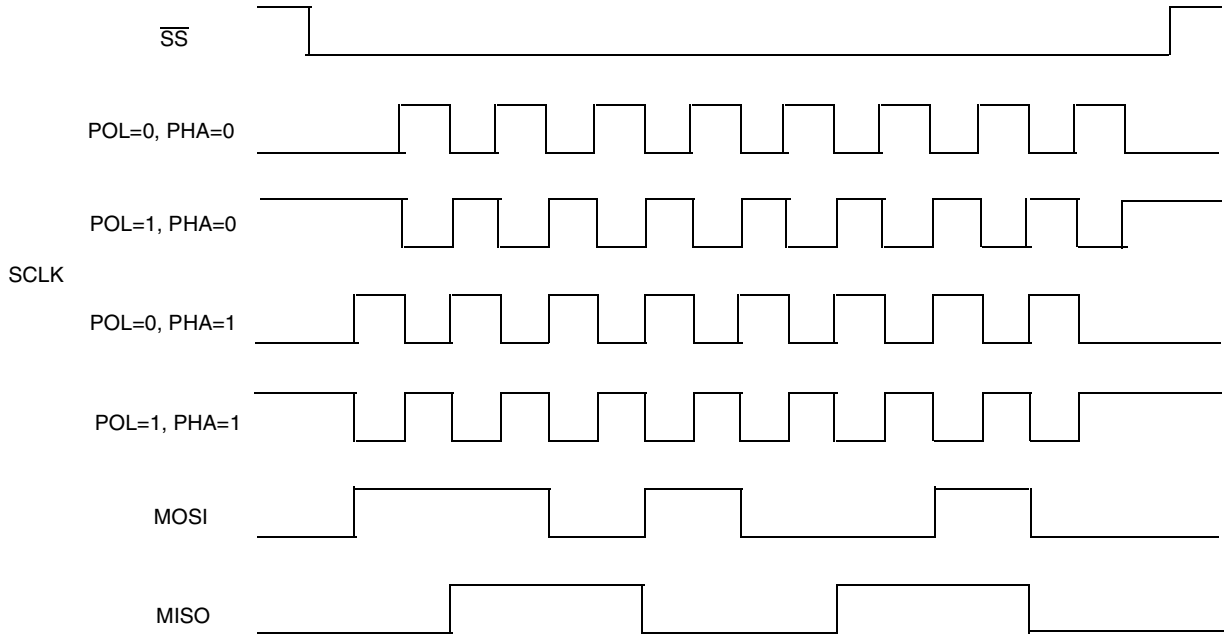

Figure 18-18. SPI Burst with Different POL and PHA Configuration

18.4.2 Slave Mode

When the CSPI module is configured as a slave, the user can configure the CSPI Control register to match the external SPI master's timing. In this configuration, $\overline{SS}$ becomes an input signal, and is used to latch data into or load data out to the internal data Shift registers, as well as to increment the data FIFO.

The $\overline{SS}$, SCLK, and MOSI are inputs and MISO is output. Most of their timing diagrams are the same as in Master mode, because the inputs come from a SPI master device.

However, it is different when $\overline{SS}$ is used to increment data FIFO. When the SSCTL is set while CSPI is in Slave mode, the data FIFO increments at $\overline{SS}$ rising edge (when SSPOL = 1, should be falling edge).

Figure 18-19 shows a SPI burst in which data FIFO is incremented by $\overline{SS}$ rising edge.

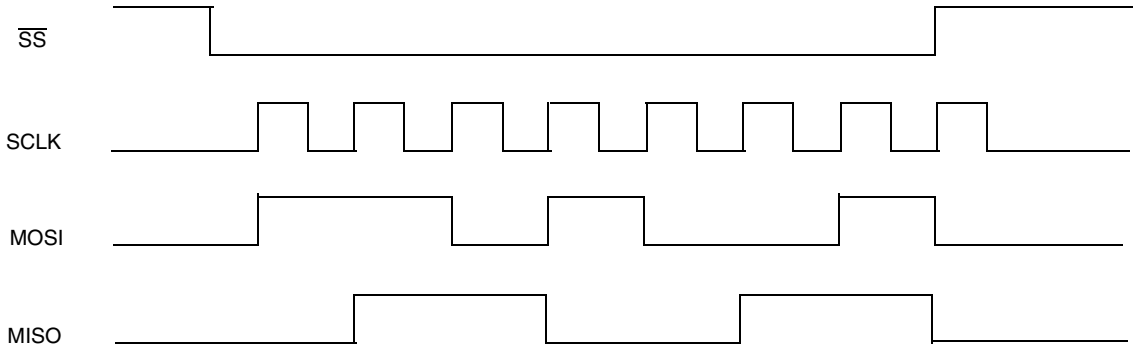

Figure 18-19. Increment Data FIFO by $\overline{SS}$ Rising Edge

In this case, the data received is not 0xD2 but 0x69. Only the most significant 7 bits are loaded to RXFIFO.

18.4.3 Interrupt Control

Interrupt control is not a specific mode of operation; however, it provides a basic method to utilize the CSPI FIFOs.

You can program the CSPI to enable the TXFIFO empty, TXFIFO half, and TXFIFO full interrupt. You can also use the interrupt service routine to fill the TXFIFO with data to be transferred. Furthermore, you can also enable RXFIFO ready, RXFIFO half, and RXFIFO full to retrieve data from RXFIFO by using the interrupt service routine.

Three other interrupt sources can be used to control/debug the SPI bursts. The transfer-completed interrupt tells the user that there is not data left in TXFIFO and the data in the Shift register is shifted out. The bit counter overflow interrupt tells the user that the CSPI received more than 32 bits in a SPI burst and the remaining bits will be lost. (Only in Slave mode does using $\overline{SS}$ increment the data FIFO.) The RXFIFO

overflow interrupt tells the user that the RXFIFO received more than 8 words and will not accept any other word. Figure 18-20 shows a program sequence of SPI bursts using interrupt.

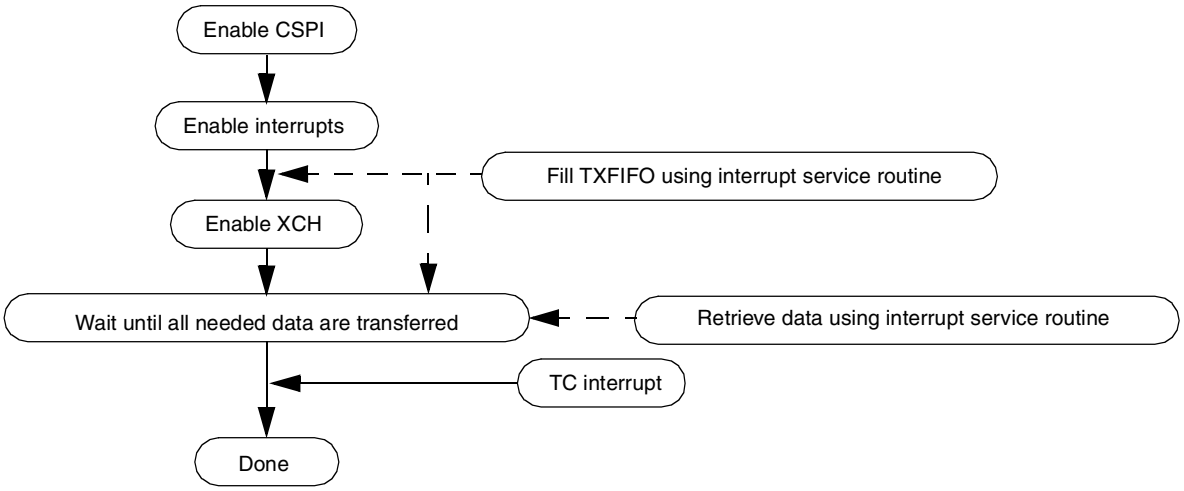

Figure 18-20. Program Sequence of SPI Burst Using Interrupt

18.4.4 DMA Control

DMA control provides another way to utilize the FIFOs in the CSPI module. Peripherals such as the CSPI which support DMA, use DMA request and acknowledge signals. Larger amounts of data can be transferred using DMA control, thereby reducing interrupts and CPU loading. When the appropriate conditions are matched, the module sends out a DMA request. The DMA deals with the following cases: TXFIFO empty, TXFIFO half, RXFIFO half, and RXFIFO full.

Figure 18-21 shows a program sequence of SPI bursts using the DMA.

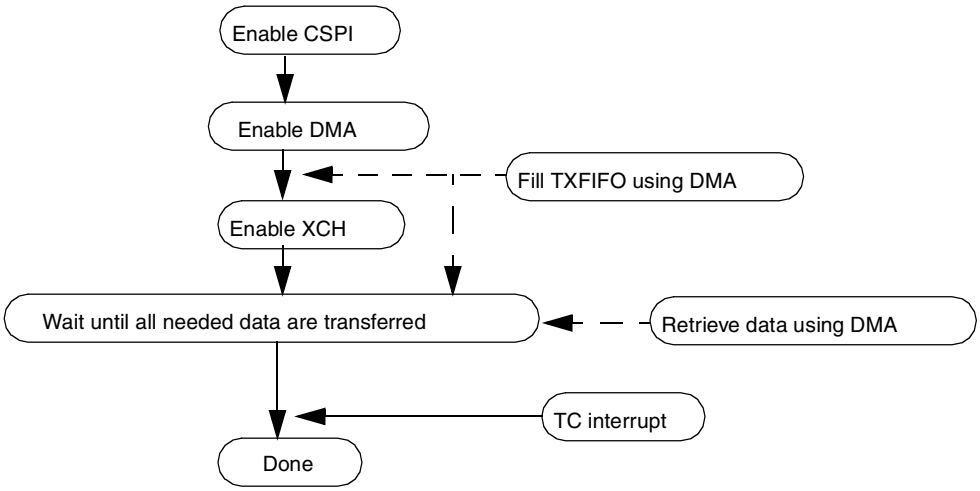

Figure 18-21. Program Sequence of SPI Burst Using DMA

18.5 Initialization/Application Information

This section provides initialization and application information for CSPI.

Figure 18-22 shows two flow charts for the master and slave mode of operations supported by the CSPI.

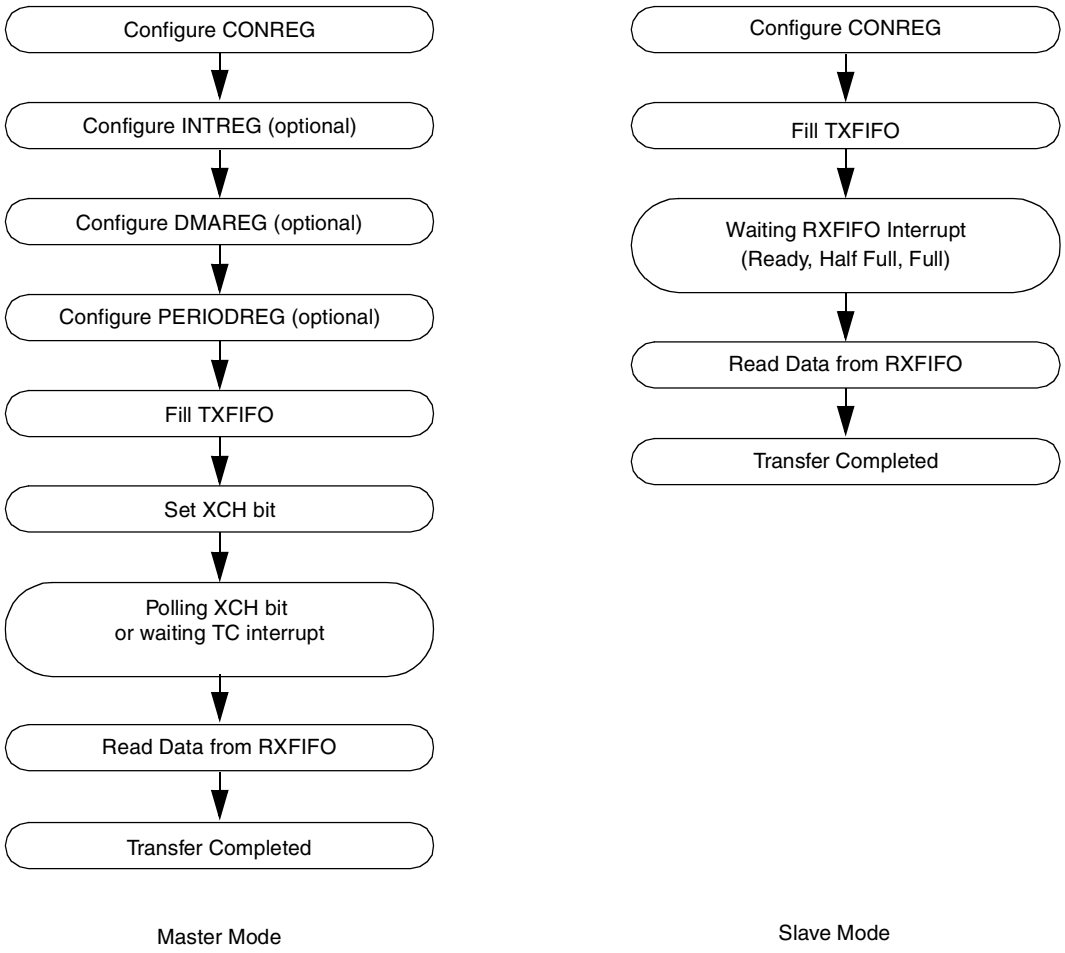

Figure 18-22. Flow Chart of CSPI Operation

Example 18-1 shows normal example code for CSPI operation using ARM instructions.

Example 18-1. CSPI Operation using ARM Instructions

Chapter 19
Clock Amplifier (CAMP)

19.1 Overview

The Clock Amplifier converts a square wave/sinusoidal input of frequency range 8–40 MHz into a rail-to-rail square wave (camp supply voltage).

The input of the CAMP block is CKIH and the output is CAMP_OUT. The input to CAMP is internally AC coupled (in normal mode); no external coupling is required.

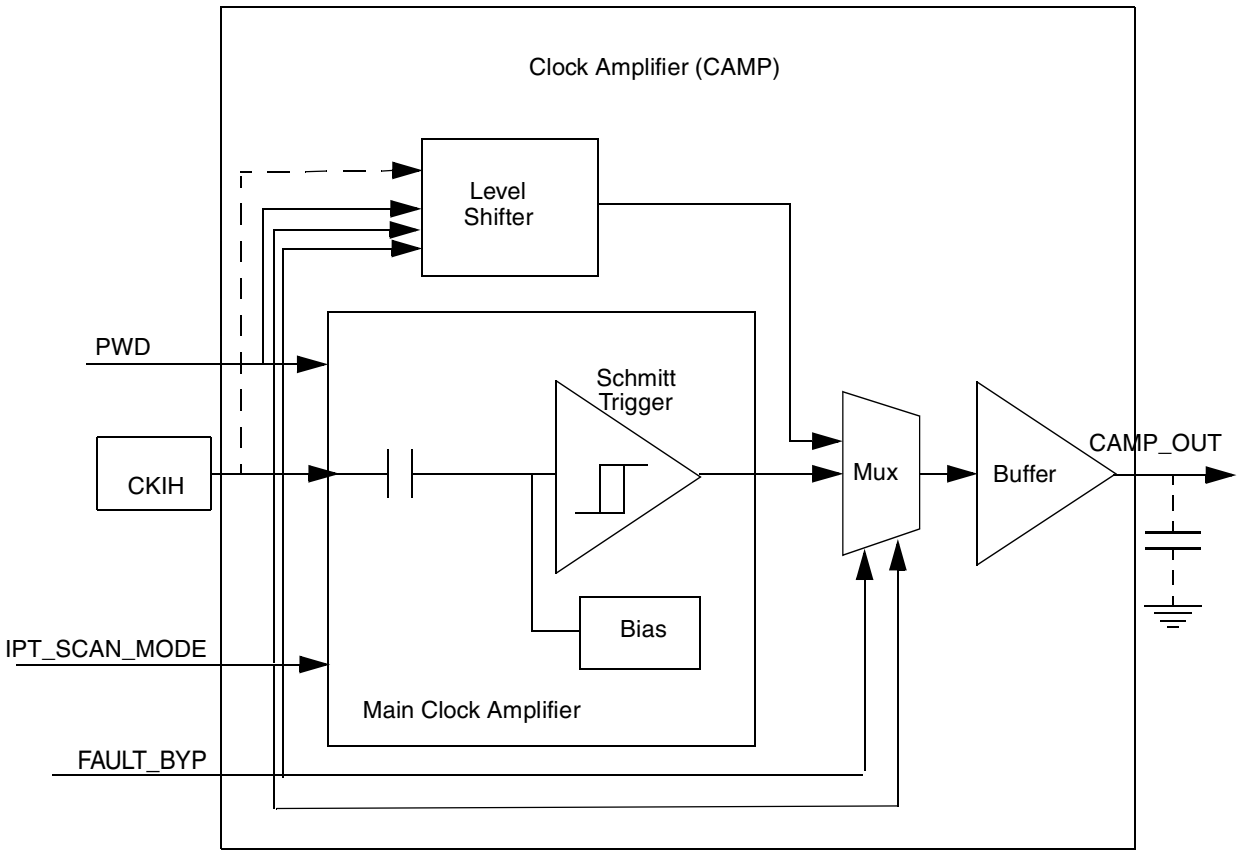

Figure 19-1. Clock Amplifier Block Diagram

19.1.1 Features

The CAMP includes the following features:

- Converts sinusoidal input to square wave.
- Can accept a square wave of amplitude greater than the supply voltage of the module.

19.1.2 Modes of Operation

The CAMP supports two modes of operation: normal and power down.

19.1.2.1 Normal Mode

In this mode of operation, the Clock Amplifier accepts a sinusodial/square wave as input and gives a rail to rail square wave output.

19.1.2.2 Power-Down Mode

In this mode the CAMP is disabled and put in the low-power state. CAMP_OUT remains at logic ’0’ level during power down.

19.2 External Signal Description

19.2.1 Overview

Table 19-1 shows the CAMP external signal properties.

Table 19-1. CAMP External Signal Properties

Name	Direction	Function
CKIH	Input	Input clock

Table 19-2 shows the CAMP interface signal properties.

Table 19-2. CAMP Interface Signal Properties

Name	Direction	Function
VDD	Input	Power supply
VSS	Input	Ground
PWD	Input	Power down signal
FAULT_BYP	Input	Test mode control signal
IPT_SCAN_MODE	Input	Scan mode signal
CAMP_OUT	Output	Output clock from CAMP

19.2.2 Detailed Signal Description

This section provides detailed signal descriptions.

19.2.2.1 CKIH—External clock input

The signal CKIH is the clock input signal to the CAMP. It can be a sinusoidal input with a minimum swing of 400 mV p-p or a square wave. It comes directly from the pad.

19.2.2.2 VDD—Power supply

The VDD is the power supply for the CAMP module. It supplies the main clock amplifier, buffer, and level shifter.

19.2.2.3 VSS—Ground

The VSS input is the ground for the CAMP.

19.2.2.4 IPT_SCAN_MODE—Scan Signal

This signal is active high. When this signal is asserted CAMP is forced to “Test Mode” irrespective of states of fault_byp or pwd signals.

19.2.2.5 PWD—Power Down Signal

This signal when asserted (and ipt_scan_mode = 0) puts the CAMP module in the low-power mode. This signal is active high.

19.2.2.6 FAULT_BYP—Control Signal for Test Mode

This signal when asserted puts CAMP in test mode. This signal is active high. When this signal is low (and ipt_scan_mode = 0) CAMP works in normal mode.

19.2.2.7 CAMP_OUT—Clock Output from CAMP

This signal is the output of the CAMP module.

19.2.3 Memory Map/Register Definition

The CAMP module obtains its control signals PWD and FAULT_BYP from registers residing in the CRM.

Chapter 20
Central Security Unit (CSU)

20.1 Overview

Security is an increasingly important feature of wireless mobile devices such as cell phones, ultra-portable computers and integrated media players. Instances of hackers and pirates breaking into portable devices and stealing private information and copyright content are becoming increasingly common. As such, security is a high priority for most high-tier architectures. To address the potential security risks and to provide an extensible platform for addressing future security needs, these designs incorporate a number of advanced hardware blocks and architectural features targeted at securing the platform. The Central Security Unit is one of them.

The Central Security Unit (CSU) enables software for setting comprehensive security policy within the platform and sharing secure information between various secure modules.

20.1.1 Features

The CSU has following security related features:

- System alarm routing policy
  - — Type of alarm triggered by the different system security violation indications
  - — Type of system event generated by each of the system alarms
  - — Security violation indication (SRTC) clearance (fuse driven)
- Setting emergency reset policy
- Execution mode access policy—Which peripheral resources can be accessed by what master privileges.
- Masters privilege policy—CSU helps those masters that cannot generate their own user/supervisor secure/non-secure signals to assert these signals.
- Special logic to prevent scan-in and scan-out of sensitive data

NOTE

For detailed information about the CSU module, contact your Freescale representative.

Chapter 21
Digital Phase Lock Loop (DPLL)

21.1 Introduction

The DPLL functional block diagram is shown in Figure 21-1. The external interface of the DPLL (I/O diagram) is shown in Figure 21-2.

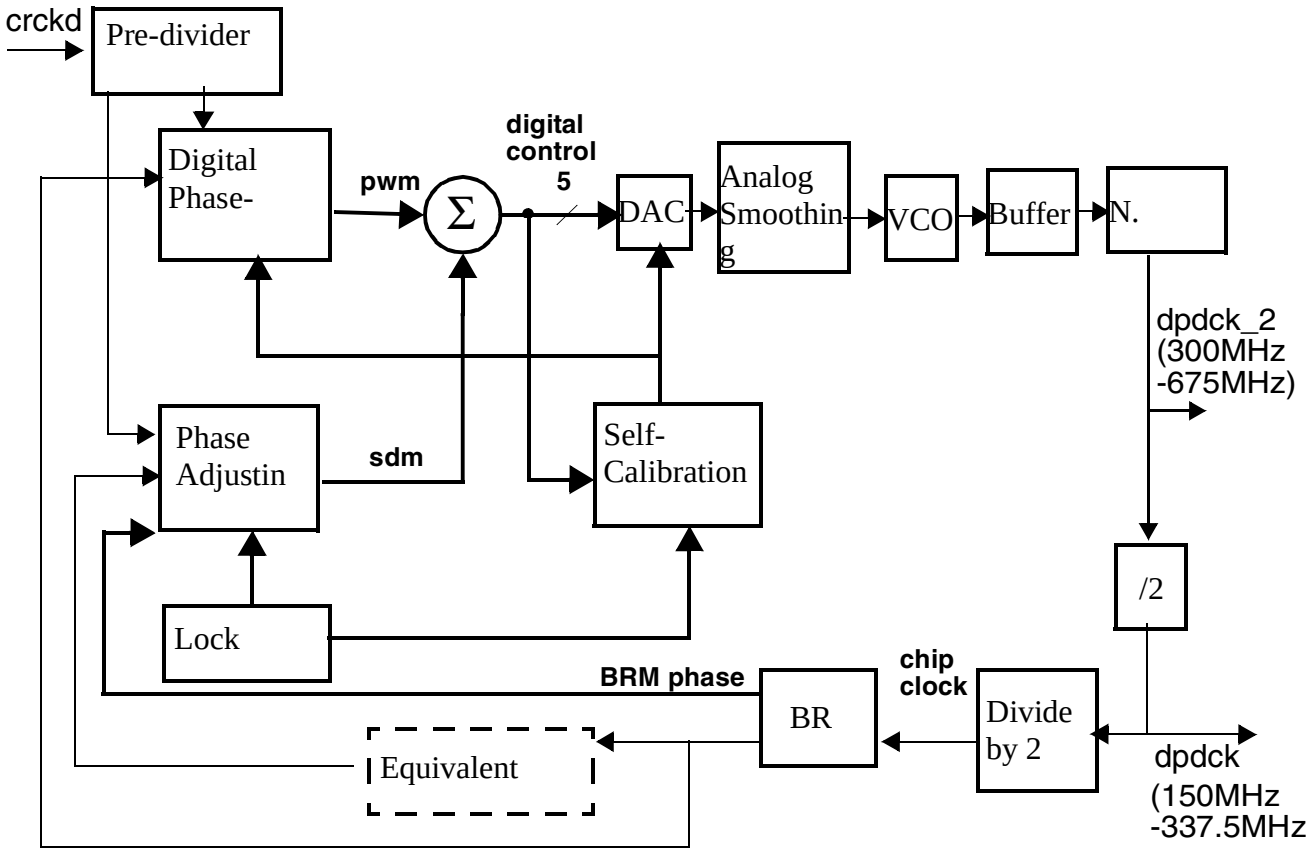

Figure 21-1. DPLL Block Diagram

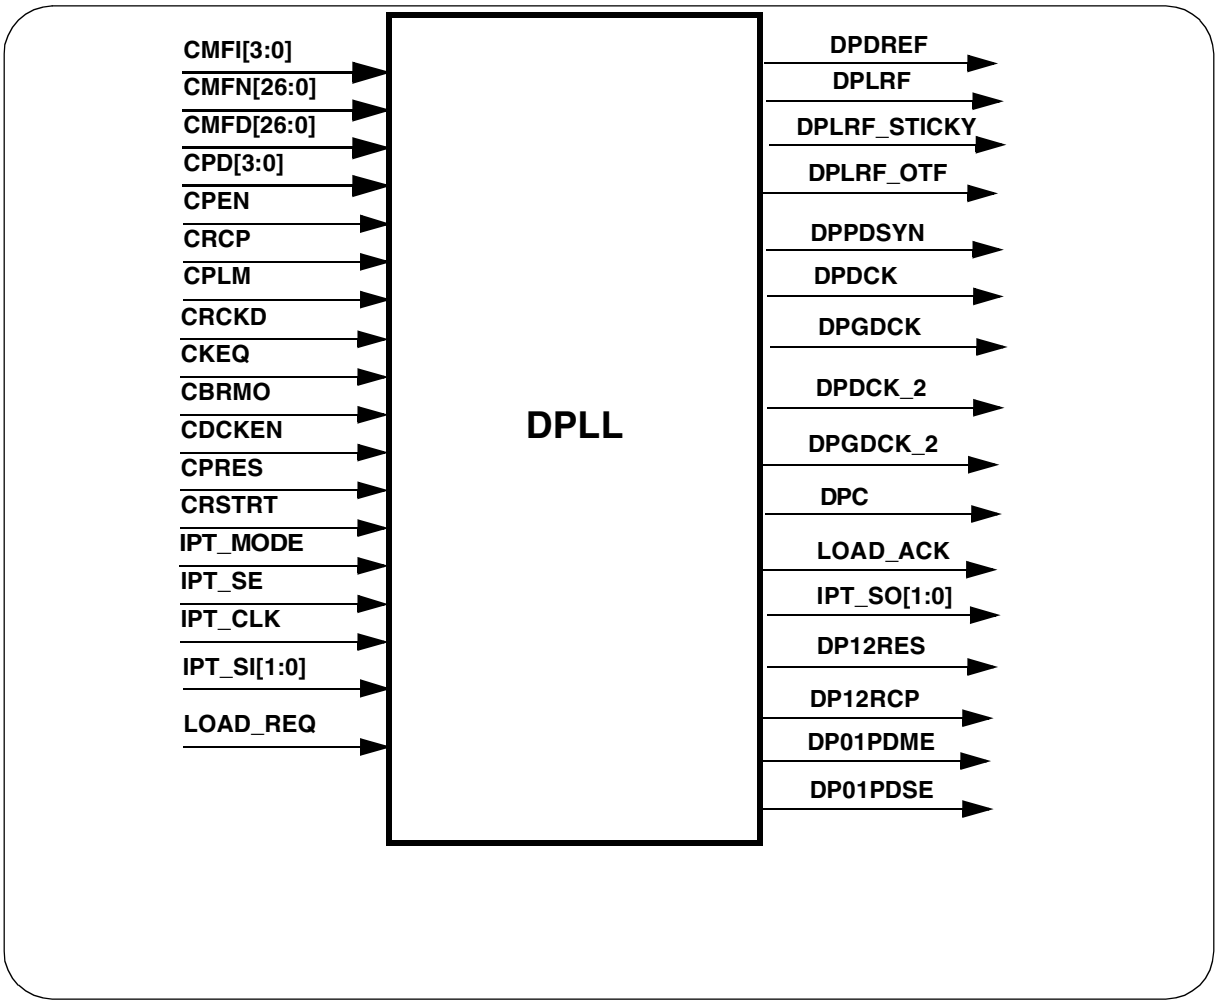

Figure 21-2. DPLL I/O Diagram

21.1.1 Overview

An on-chip Digital Phase Lock Loop (DPLL) provides clock generation in digital and mixed analog/digital chips designed for wireless communication and other applications. The DPLL produces a high-frequency chip clock with a low frequency and phase jitter.

21.1.2 Features

The DPLL includes the following features:

- A digital phase-frequency detection technique
- Fractional frequency multiplication method
- Digital control of an oscillator frequency
- Optional phase adjusting with digital phase loop filtering
- Areduced multiplication factor range

- Compensation of parameter variations by means of self-calibration

Digital implementation of frequency control and loop filtering functions allows the following new features:

- Eliminating an on-board loop filter capacitor, minimization of internal capacitor value, selection of frequency and phase/frequency operation modes
- An improved noise immunity, eliminating additional supply and ground pins
- A high frequency resolution with a reduced lock time
- Reduced sensitivity to parameter variations caused by temperature and process

The DPLL reference is an external system clock frequency. For wireless communication systems, the reference frequency is standardized. Most of the standard reference frequencies are located in the range of 10...100 MHz. The DPLL produces output clock (dpdck_2) at the frequency:

Eqn. 21-1

$$f_{dck\_2} = 4 \cdot f_{ref} \cdot \frac{MF_I + MF_N / MF_D}{PDF}$$

where f_{ref} is the reference frequency

MF_I is an integer part of a multiplication factor (MF)

MF_N and MF_D is the numerator and denominator of the MF fractional part

PDF is the predivision factor

Spectral purity of the DPLL output clock is characterized by phase and frequency jitter. Phase jitter is the magnitude of clock phase fluctuations relative to an ideal clock phase. Along with phase jitter, the output clock may be skewed relative to the reference clock. Frequency jitter is defined as magnitude of clock period fluctuation relative to an ideal clock period. Obviously, frequency jitter may be calculated as a difference of phase jitter values for adjacent clocks.

The DPLL communicates with the Clock Control Module (CCM)/DPLL-IP module. This CCM/DPLL-IP block contains a control register and provides an interface between the DPLL and various cores used in the SOC.

21.1.3 Modes of Operation

The DPLL operates in the following two modes: Frequency Only Lock mode and Phase Lock mode.

21.1.3.1 Frequency Only Lock Mode

For many stand-alone processors and asynchronous multiprocessor applications, only a frequency jitter value is important, and slow phase jitter and clock skew do not affect system performance. In such

systems, it is not necessary to adjust an output clock phase with a phase of input clock. A clock generation mode, for which the slow phase fluctuations are permissible, is named in this document as the Frequency Only Lock (FOL) mode. The DPLL operates in FOL mode when CPLM bit is made LOW.

21.1.3.2 Phase Lock Mode

A phase error can be important for synchronous applications and sampling A/D and D/A precision converters. The DPLL mode providing minimal phase jitter and skew elimination is mentioned as the Frequency and Phase Lock (FPL) mode. The DPLL operates in FPL mode when CPLM bit is HIGH & total multiplication factor is integer (ie. multiplication factor numerator is zero).

21.2 External Signal Description

This section provides and overview and list of properties for the external signals.

21.2.1 Overview

The DPLL I/O signals can be divided into the following categories:

- Reset signals
- Static control signals
- Clocks and other dynamic signals and
- Test mode signals (Freescale internal use only)
- BIST signals (Freescale internal use only)
- Supply signals

Table 21-1 gives the names and other properties of the DPLL I/O signals.

Table 21-1. DPLL I/O List

Signal	Dir.	Description	Reset State*	Default* Value
Reset signals				
cpres	I	Power up reset	1	1
cpen	I	DPLL enable	0	0
crstrt	I	Restart	N/A	N/A
Static control signals				
cmfi	I	Multiplication factor integer part	N/A	N/A
cmfd	I	Multiplication factor fractional part denominator	N/A	N/A
cpd	I	Predivision factor	N/A	N/A
crcp	I	Reference clock polarity bit	N/A	N/A
cplm	I	Phase lock mode bit (0 - FOL, 1 - FPL)	N/A	N/A
cbrmo	I	BRM order bit (0 - first, 1 - second)	N/A	N/A

Table 21-1. DPLL I/O List (continued)

Signal	Dir.	Description	Reset State*	Default* Value
Clocks and other dynamic signals				
cmfn	I	Multiplication factor fractional part numerator	N/A	N/A
crckd	I	Reference clock frequency	N/A	N/A
ckeq	I	Clock delayed by equivalent delay	N/A	N/A
cdcken	I	Gated output clock enable signal	N/A	N/A
load_req	I	Load request for on the fly change of cmfn	N/A	N/A
dplrf	O	Lock ready flag	1'b0	N/A
dplrf_sticky	O	Sticky lock ready flag	1'b0	N/A
dplrf_otf	O	On the fly lock ready flag	1'b0	N/A
dpdref	O	Divided reference clock	1'b0	N/A
dppdsyn	O	Post-divider synchronization signal	1'b1	N/A
dpdck	O	Output clock divide by 2	1'b0	N/A
dpdck_2	O	Output clock	1'b0	N/A
dpgdck	O	Gated output clock divide by 2	1'b0	N/A
dpgdck_2	O	Gated output clock	1'b0	N/A
dpc	O	Clock before the equivalent delay	1'b0	N/A
load_ack	O	On the fly cmfn change acknowledgement	1'b0	N/A

21.2.2 Detailed Signal Descriptions

This section provides detailed signal descriptions.

21.2.2.1 Reset Signals: cpres, cpen, and crstrt

There are three reset signals for the DPLL: the power-up reset CPRES, DPLL enable CPEN, and restart CRSTRT signals.

The DPLL is operating when CPRES and CRSTRT are '0' and CPEN is '1'; otherwise it is disabled.

21.2.2.1.1 cpres

This is the power up reset signal. The DPLL is reset when cpres = 1'b1

21.2.2.1.2 cpen

This is the DPLL enable signal. The DPLL is reset when cpen = 1’b0

21.2.2.1.3 crstrt

This is the DPLL restart signal. When crstrt = 1’b1, all DPLL module are reset, excluding the current reference.

The DPLL states are given in Table 21-1.

Table 21-2. DPLL Reset States

CPRES	CPEN	CRSTRT	State
1	X	X	All DPLL modules are reset
X	0	X	
0	1	1	All DPLL modules are reset excluding the current reference
0	1	0	DPLL is operating

After the CPRES signal has been set, the entire DPLL module is immediately reset. When the DPLL is powered on at chip start up, CPRES must be asserted (ie. made "1") and then de-asserted (ie. made "0"). This ensures that all the internal registers are set/reset at their desired values. During normal operation, the DPLL can be reset using CPEN or CRSTRT signals. Reset caused by the CPEN and CRSTRT signals creates a delay of three/four output clock (dpdck) cycles for dpgdck and three/four output clock (dpdck_2) cycles for dpgdck_2. It stops the output clock series synchronously as shown in Figure 21-3.

NOTE

The DPLL must be reset using "cpen" or "cpres" signal instead of restarting by "crstrt" signal when it is desired to be locked according to new DPLL settings (modes).

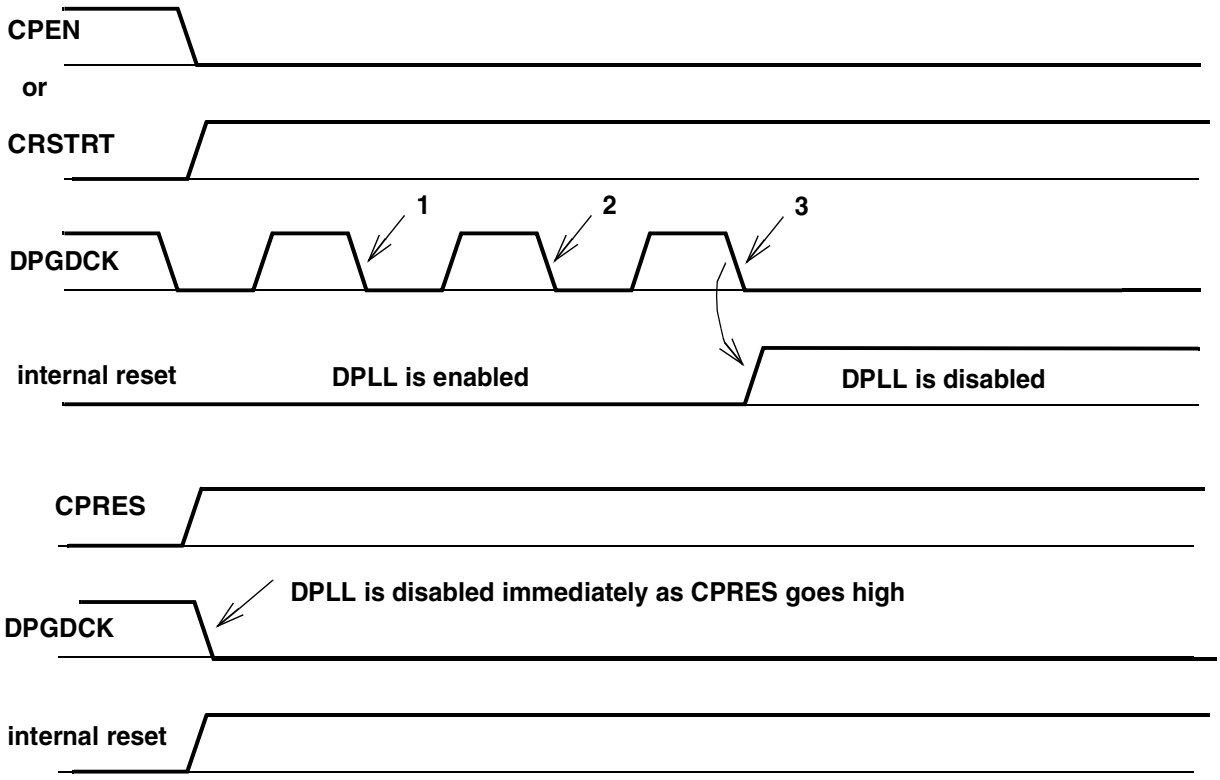

Figure 21-3. Timing diagram for DPLL stop

The DPLL starts after three reference clock periods as shown in Figure 21-4. This is provided by a synchronizer. The VCO is enabled simultaneously by enabling all the DPLL logic, but oscillation starts after settling the internal current reference. If the DPLL was disabled using only the CRSTRT signal (**partial reset**), the lock-in time is reduced by 128 divided reference clocks.

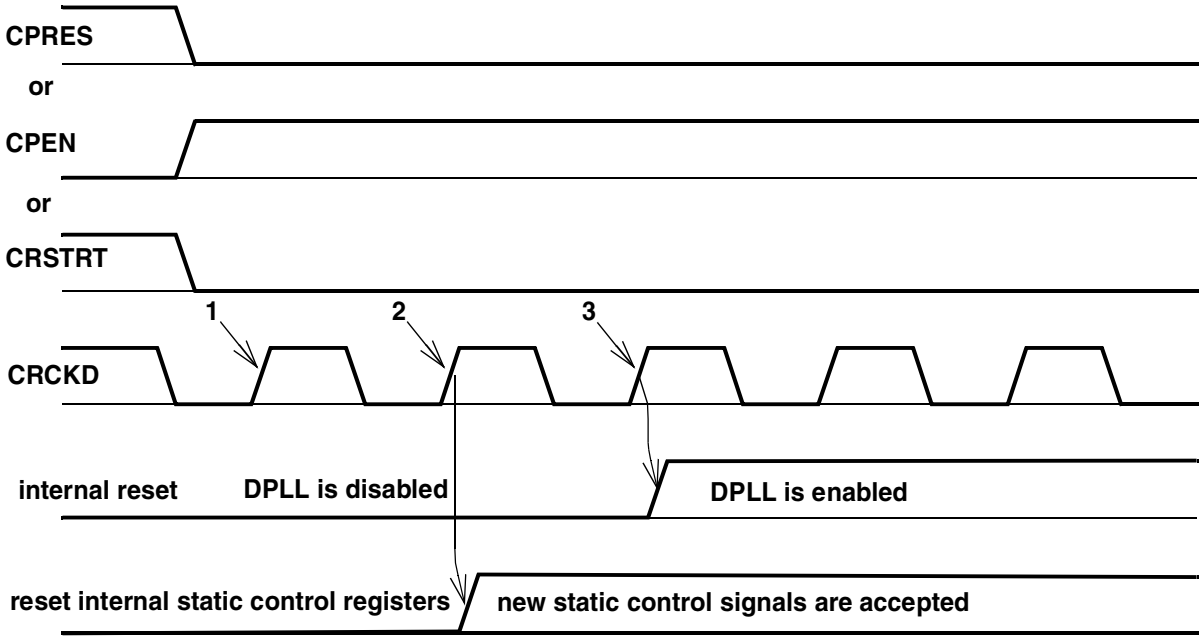

Figure 21-4. Timing diagram for DPLL start

21.2.2.2 Static Control Signals: cmfi, cmfd, cpd, crcp, cplm, cbrmo

The static control signals are discussed in the following subsections.

21.2.2.2.1 cmfi

Multiplication Factor Integer Part bits (cmfi[3:0]).

The multiplication factor integer part. cmfi[3:0] bits should be in a range from 5 to 15. If it is less than 5, the DPLL accepts 5.

21.2.2.2.2 cmfd

Multiplication Factor Fractional Part Denominator bits (cmfd[26:0])

The cmfd[26:0] bits, in a 2’s compliment format, give the denominator (bit 26 is always zero). Internal to DPLL, the cmfd[26:0] number should be in a range from 1 to 67,108,863; otherwise, the output clock frequency will differ from the desired frequency. The cmfd bits are ignored if the MF numerator (cmfn) is zero. Internal to the DPLL, a “1” is added to the CMFD number supplied by the user. For user, the CMFD range will be from 0 to 67108862.

21.2.2.2.3 cpd

Predivision Factor Minus One (cpd[3:0])

The cpd[3:0] bits give the predivision factor minus 1. The cpd[3:0] number should be in a range from 0 to 15.

21.2.2.2.4 crcp

Reference Clock Polarity bit.

If the crcp bit is cleared, the chip clock (dp08c0) is adjusted with a positive edge of the reference clock. If the bit is set, the chip clock is adjusted with its negative edge.

21.2.2.2.5 cplm

Phase Lock Mode bit.

The DPLL operates in the Frequency Only Lock (FOL) mode, when the cplm bit is cleared (1’b0), and in Frequency and Phase Lock mode (FPL), when the bit is set (1’b1). The FPL mode can be used for both an integer and fractional multiplication factor, but phase skew elimination is accomplished only for the integer MF.

21.2.2.2.6 cbrmo

BRM order bit

When the cbrmo bit is cleared (cbrmo=1’b0), the BRM has first order, otherwise the BRM order is 2. The first-order BRM should be used only if the MF fractional part denominator is less than 8. In other cases, the BRM order should be 2. This bit is ignored if the MF numerator is zero.

21.2.2.3 Clocks and Other Dynamic Signals

The clocks and dynamic siglans are as follows: cmfn, crckd, cdcken, load_req, dplrf, dpdref, dppdsyn, dpdck, dpdck_2, dpgdck, dpgdck_2, dpc, load_ack, dplrf_sticky, and dplrf_otf. They are discussed in the following subsections.

21.2.2.3.1 cmfn

Multiplication Factor Fractional Part Numerator bits (cmfn[26:0])

The cmfn[26:0] bits, in a 2’s compliment format, give the numerator. The cmfn[26:0] bits are the only bits in the DPLL that can be changed after the DPLL was locked without resetting the DPLL (on the fly MFN change). The cmfn[26:0] number should be in a range from —67108862 to 67108862. Bit 26 is the sign bit.If the absolute value of the numerator is larger than denominator (i.e. |numerator| > denominator), the output clock frequency will differ from the desired frequency. If the numerator is zero, the circuitry for fractional division is disabled to save power.

21.2.2.3.2 crckd

reference clock

The reference clock frequency can be in a range from 10 to 100MHz. The reference clock duty cycle should be 50 ± 20%.

21.2.2.3.3 ckeq

The CKEQ signal is fedback to DPLL and is a delayed copy of DPC after equivalent delay.

21.2.2.3.4 cdcken

Gated output clock enable signal.When cdcken = 1’b1, dpgdck and dpgdck_2 are enabled.

The dpgdck and dpgdck_2(gated output clocks) output signal are obtained from the output clock (dpdck and dpdck_2 respectively) by gating with the cdcken input signal. Because cdcken is synchronized in the DPLL, no spikes or shorted phases take place. Figure 21-5 shows the gating timing diagrams.

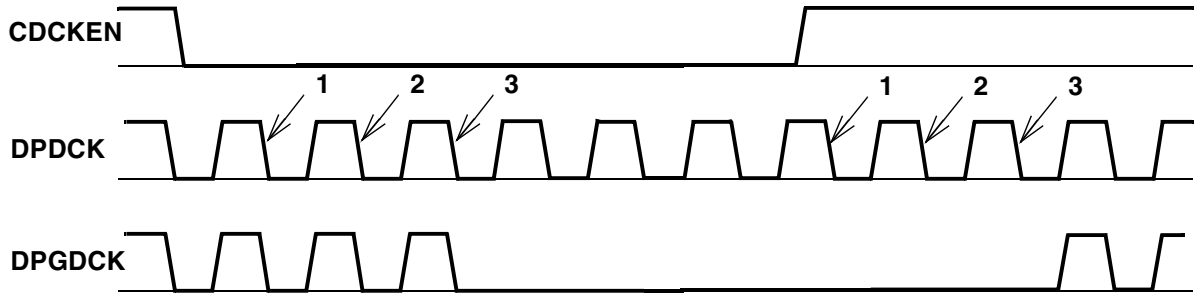

Figure 21-5. Clock Gating Timing Diagram

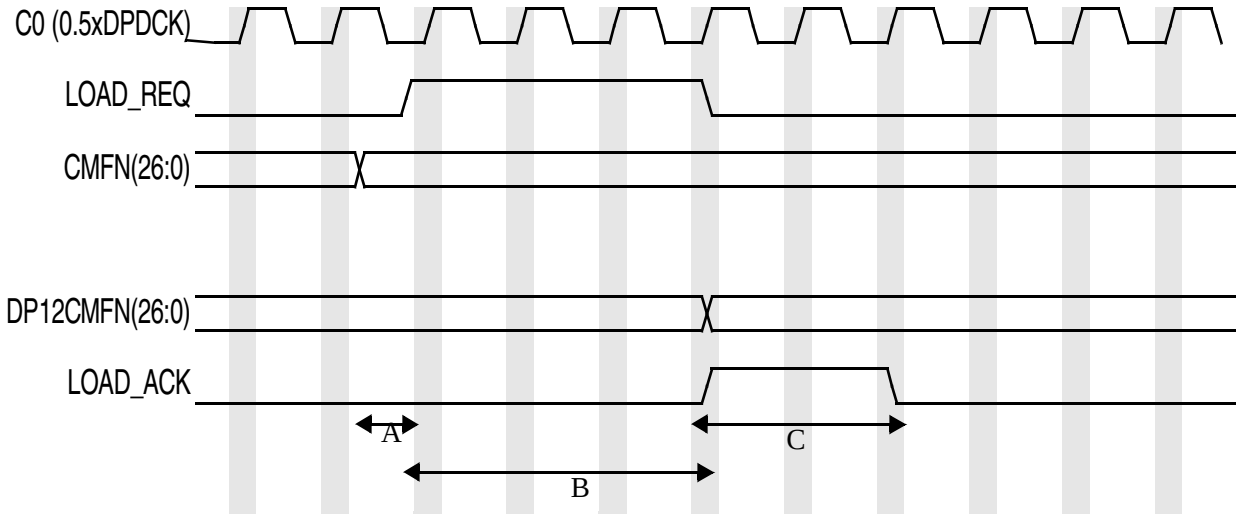
Both dpgdck and dpgdck_2 start/stop synchronously with delay of three/four cycles of dpdck and dpdck_2 respectively.

21.2.2.3.5 load_req

Load request for on the fly change of cmfn.

When on the fly cmfn value change is required, load_req should be made high. Figure 21-6 provides the timing diagram for this.



1 DP12CMFN represents the latched value of CMFN.
2 Load Request should be asserted after CMFN change

Figure 21-6. Timing diagram for CMFN

- A —The time difference between LOAD_REQ and the new value of CMFN should be greater than or equal to zero.
- B—The duration from posedge LOAD_REQ to the actual loading of the CMFN new value to the PLL is atleast three clock cycles of dp08c0 clock which has half the frequency of DPLL output clocks, dpdck/dpgdck.Thus, in terms of dpdck/dpgdck, the minimum duration of LOAD_REQ is atleast six clock cycles of dpdck/dpgdck.
- C—LOAD_ACK signal duration is two clocks.

Minimum frequency resolution will be achieved with minimum CMFN(ie equal to 1 or -1) and maximum CMFD (ie equal to 67108863). For dpdck_2 clock, the minimum frequency resolution will be twice that of dpdck clcok.

21.2.2.3.6 dplrf

Lock ready flag.

This output signal, when set, indicates that the DPLL is in lock.

21.2.2.3.7 dpdref

Divided reference clock.

This is the divided reference clock signal. Its frequency is given as

Eqn. 21-2

$$f_{dpdref} = \frac{f_{ref}}{PDF}$$

21.2.2.3.8 dppdsyn

Post divider synchronization. The dppdsyn signal is the DPLL output intended for synchronization of a post-divider that can follow the DPLL. Synchronization ensures a constant and minimal phase offset between the reference and post-divider output clocks. The dppdsyn signal is used only for an integer MF (Figure 21-7). When MF is non-integer, dppdsyn is zero.

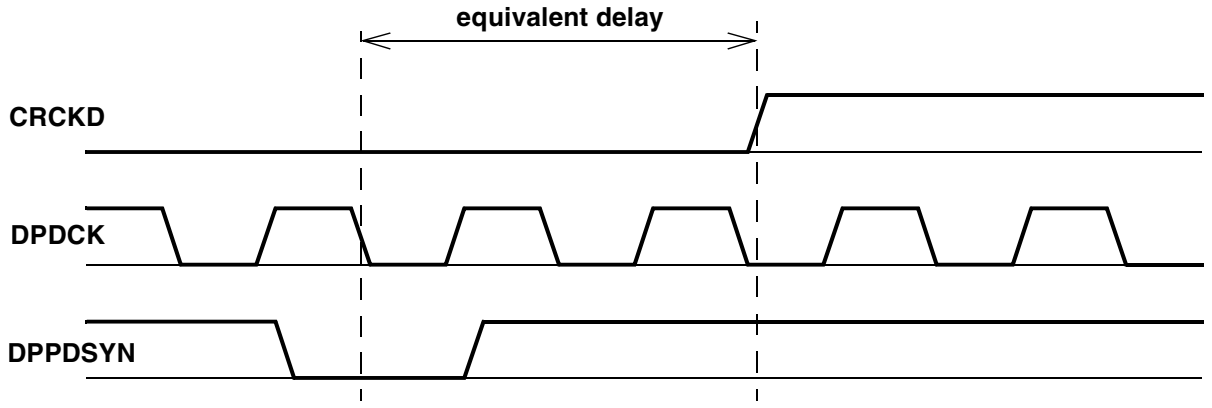


Figure 21-7. Timing diagram for DPPDSYN signal

21.2.2.3.9 dpdck

Output clock divide by 2 (ungated)

dpdck clock is the DPLL output clock divided by 2 and has 50 ± 1.5% duty cycle. This signal is zero during reset.

21.2.2.3.10 dpdck_2

Output clock (ungated)

dpdck_2 clock is the DPLL output clock and has 50% ± 1.5% duty cycle. This signal is zero during reset.

21.2.2.3.11 dpgdck

Gated output clock divide by 2. The frequency will be half the frequency of gated output clock.This signal is zero during reset.Pl. Refer to Figure 21-6 on page 21-11 for more details.

21.2.2.3.12 dpgdck_2

Gated output clock. This signal is zero during reset.

21.2.2.3.13 dpc

Clock before the equivalent delay. The output of the equivalent delay is CKEQ signal.

21.2.2.3.14 load_ack

On the fly CMFN change acknowledgement signal. This is an output of the DPLL. When the changed value of CMFN is registered in the DPLL, this signal goes high.Pl. Refer toFigure 21-7 on page 21-12 for more details.

21.2.2.3.15 dplrf_sticky

This is the sticky bit implementation of dplrf signal. In FPL mode, dplrf goes high when DPLL meets its lock criteria and goes low when DPLL looses lock. The dplrf_sticky will remain high even if dplrf goes low.

21.2.2.3.16 dplrf_otf

On the fly lock ready flag. This signal goes high after TBD number of divided reference clock cycles after load_ack goes high.

21.2.2.4 Supply Pins

The supply pins are as follows:

- avdd—DPLL analog section power supply.
- avss—DPLL analog section ground supply.
- dvdd—DPLL digital section power supply.
- dvss—DPLL digital section ground supply.
- sub—P substrate connection for guard ring only.

Chapter 22
DPLL-IP Interface (DPLL-IP)

22.1 Overview

This module serves as an interface to the DPLL module. It generates the control signals required for the DPLL operations. In other MX ICs this used to be part of the SRC (System Reset Controller) module. The separation of the DPLL from the SRC allows the flexibility for DPLL to be controlled by any of the processors that have ownership of it.

22.1.1 Feature Description

Key features of this module include:

- Maintains control/operation registers for DPLLs
- Uses a 32-bit IP bus interface, with all its registers byte, half word, and word accessible
- Provides controlled phase modulation of clocks to reduce receiver desensitization using desense circuit for DPLLs
- Generates DPLL-Enable signal (**dpllip_cpen**) depending upon both the **dpll_en_dpllip** signal (coming from SRC) as well as the internal register UPEN bit
- Selects the reference clock for DPLL (also goes to SRC) from **clock0, clock1, clock2,** and **clock3** depending upon the **ref_clk_sel** bits (bit-8 and bit-9) of the DP_CTL register
- If auto restart is enabled (**AREN** bit is ‘1’), a restart sequence is issued automatically whenever one of the DPLL registers (CTL, OP, MFD or HFS_OP, HFS_MFD) is written. Otherwise, software needs to set the restart bit manually.
- Allows SJC to control pll-enable, restart and MFI values through inputs from SJC
- Provides multiple options for Controlling DPLL On/Off independently by software as well as by DSM (Deep Sleep Mode)

22.1.2 Modes of Operation

The DPLL interface supports the following modes of operation:

- Normal Mode—supports low-frequency settings.
- HFS Mode—supports high-frequency settings
- Desense Mode—provides controlled phase modulation of clocks to reduce receiver desensitization using desense circuit for DPLL.

22.2 Memory Map/Register Definition

22.2.1 Register Summary

The register summary lists all registers of the module. The absolute address of each register is given, and the value of each bit for reads and writes is given using the conventions in the legend.

22.2.2 Detailed Register Descriptions

The figures and associated text in the subsequent sections provide detailed descriptions of the clock control registers. The following definitions serve as a key for these figures:

- **Grey bit**: unimplemented bit. Always reads as zero; Writing has no effect.
- **TYPE**: Type of register bit. Defines register bit's behavior. Possible values:
  - **r**: read only. Writing this bit has no effect.
  - **w**: write only.
  - **rw**: Standard read/write bit. Only software can change bit's value (other than a hardware reset).
  - **rwm**: A read/write bit that may be modified by a hardware in some fashion other than reset.
  - **w1c**: A status bit that can be read, and it cleared by writing a logic 1.
  - **slfclr**: Self clearing bit. Writing a one has some effect on module, but it always reads as 0.
- **RESET**: Gives the reset value of the bit. Possible values:
  - **0**: Will reset to a logic 0
  - **1**: Will reset to a logic 1
  - **?**: The reset state is unknown.
  - **u**: Unaffected by reset

22.2.2.1 DPLL Control Register (DP_CTL)

Figure 22-2 shows the DP_CTL register diagram and the field descriptions are found in Table 22-2.

0xBASE+0x000 (DP_CTL) Access: User read/write

Figure 22-2. DPLL Control Register Diagram

Table 22-2. DP_CTL Field Descriptions

Field	Description
31–14	Reserved
13 MUL_CTRL	Multiple Control. This is a self-clearing bit. and is cleared on the next posedge of PLL reference clock. Setting this bit deasserts the enable signal to the DPLL. Using this bit instead of UPEN to disable the DPLL gives DSM the control to independently switch on the DPLL. Details on the usage of this bit are given in Section 22.3.4, "Multiple Options for DPLL Control" on page 22-19. 0 No Effect. 1 DPLL disabled.
12 DPDCK0_2_EN	dpdck0_2 Enable. This bit enables the PLL output before the divide-by-2 flip-flop. It enables clock dpdck0_2 whose output is double the frequency of dpdck/dpgdck clock. 0 dpdck0_2 disable 1 dpdck0_2 enable
11	Reserved
10 REF_CLK_DIV	Ref Clk Division factor. Determines if the selected reference clock input is divided by a factor of two or one. Reset value of this bit is controlled by the init_dp_ctl_dpllip[10] bit. 0 divide by 1 1 divide by 2
9–8 REF_CLK_SEL[1:0]	Reference Clock Select:- This field selects one of the four clocks for reference clock for DPLL as listed next. Reset value of this bit is determined by the setting of init_dp_ctl_dpllip[9:8]. For all three DPLL-IP's: - clk 0 is not connected - clk 1 is not connected. - clk 2 is COSC (internal oscillator) - clk 3 is FPM. 00 clock0 is selected 01 clock1 is selected 10 clock2 is selected 11 clock3 is selected
7 HFSM	HFS-Mode Status bit. This read-only bit is a status bit that indicates which frequency mode of operation is active. In HFS mode all the shadow registers (DP_HFS_OP, DP_HFS_MFD, DP_HFS_MFN) are used whereas in LFS mode the normal registers are used. The reset value of this bit it ‘0’. 0 LFS mode, normal registers are read. 1 HFS mode is active
6 PRE	Power Up Reset. Asserts a hard reset to the DPLL. 0 reset cleared. 1 reset asserted
5 UPEN	PLL Enable. Enables DPLL operation. 0 PLL disabled. 1 DPLL enabled.
4 RST	Restart. Restarts the DPLL. It should not be used as a status bit. 0 DPLL not in restart. 1 DPLL restarted.
3 RCP	Reference Clock Polarity. Selects which edge the chip clock is adjusted to. 0 positive edge of reference clock. 1 negative edge of reference clock.

Table 22-2. DP_CTL Field Descriptions (continued)

Field	Description
2 PLM	Phase Lock Mode. Selects if phase is to be considered (in addition to frequency) during lock-in. 0 DPLL set to frequency only lock mode. 1 DPLL in frequency and phase lock mode.
1 BRMO	BRM Order Bit. Binary Rate Modulator order. 0 BRM in first order. 1 BRM in second order.
0 LRF	Lock Ready Flag. This bit indicates when the DPLL is in lock. This is a sticky bit. The reset value of this bit is '0'. The following events will break the already established lock. • DP_CTL, DP_OP, DP_MFD, DP_HFS_OP, or DP_HFS_MFD is written • Hard reset • pll_lvs toggle • DPLL enable 0 DPLL not locked. 1 DPLL locked.

22.2.2.2 DPLL Configuration Register (DP_CONFIG)

Figure 22-3 shows the DP_CONFIG register diagram, and Table 22-3 provides the field descriptions.

0xBASE+0x004 (DP_CONFIG) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 22-3. DPLL Configuration Register Diagram

Table 22-3. DP_CONFIG Field Descriptions

Field	Description
31–2	Reserved
1 AREN	Auto Restart Enable. If auto restart is enabled, then a restart sequence is issued automatically whenever a write is performed to one of the DPLL registers (DP_CTL, DP_OP, DP_MFD) in normal mode. In HFS mode, the same is true if a write is performed to one of the HFS mode registers (DP_CTL, DP_HFS_OP, or DP_HFS_MFD). Otherwise, software will need to set the restart bit manually. 0 Auto-restart is disabled 1 Auto-restart is enabled (Default Value of this bit is '1')
0 LDREQ	Load Request. Setting this bit notifies the DPLL that the numerator factor of the fractional part (MFN) has changed. This bit is cleared by an acknowledge from the DPLL. Writing a '0' to this bit has no effect. 0 DPLL has finished updating MFN. 1 request the DPLL update MFN. (Default Value of this bit is '0')

NOTE

Writing to the DP_CONFIG register does not generate an automatic 'restart'.

22.2.2.3 DPLL Operation Register (DP_OP)

Figure 22-4 shows the DP_OP register diagram and Table 22-4 provides the field descriptions. The MFI and PDF fields represent the decimal value of MFI and PDF respectively, which is output to the DPLL module by the DPLL-IP.

0xBASE+0x008 (DP_OP) Access: User read/write

Figure 22-4. DPLL Operation Register Diagram

Table 22-4. DP_OP Description

Field	Description
31–8	Reserved
7–4 MFI	Multiplication Factor Integer. This field defines the integer portion of the multiplication factor (MFI) If MFI is written with a value of less than 5,then MFI defaults to 5. 0000 5 ... 0101 5 0110 6 ... 1111 15
3–0 PDF	Predivision Factor (PDF). The value written to PDF[3:0] is equal to the Predivider Factor minus one. 0000 0 0001 1 0010 2 ... 1110 14 1111 15

Registers DP_OP, DP_MFN, and DP_MFD calculate the output frequency by the formula shown in Equation 22-1:

Eqn. 22-1

$$f_{dck} = 4 \cdot f_{ref} \cdot \left[\frac{MF}{PDF + 1}\right] \qquad \text{Where: } MF = MF_I + \frac{MF_N}{MF_D + 1}$$

22.2.2.4 DPLL MFD Register (DP_MFD)

Figure 22-5 shows the DP_MFD register diagram and Table 22-5 provides the field descriptions. The MFD is the decimal value of MFD[26:0] which is provided to DPLL by DPLL-IP module. Inside the DPLL, MFD is incremented by 1.

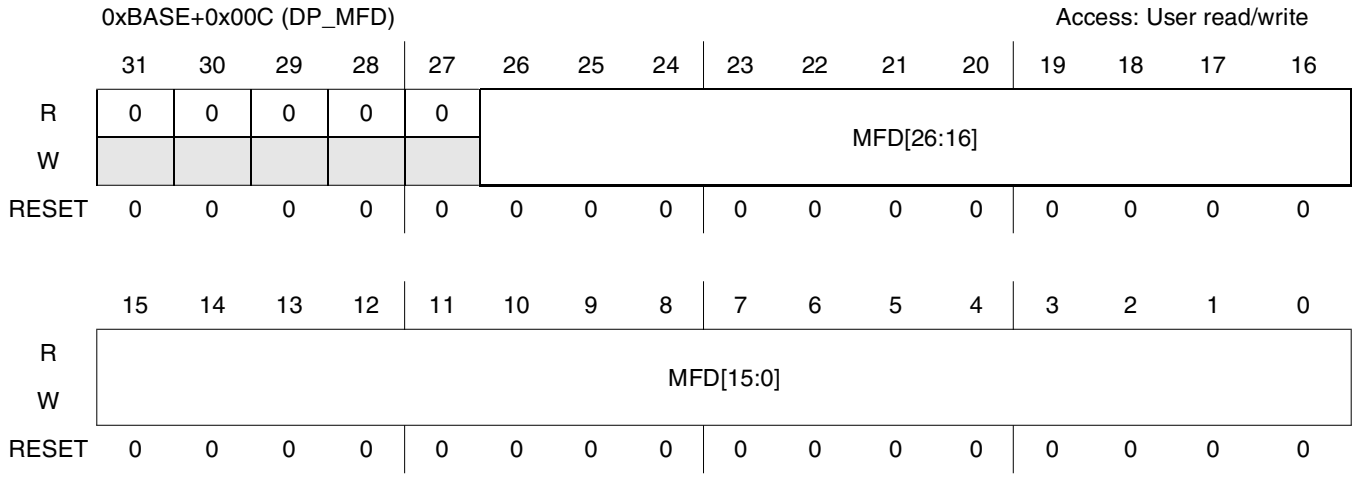

Figure 22-5. DPLL MFD Register Diagram

Table 22-5. DP_MFD Field Description

Field	Description
31–27	Reserved
26–0 MFD[26:0]	Multiplication Factor Denominator Bits. The bits in the MFD[26:0] field contain the denominator of the fractional part in a 2's compliment format. The range of the MFD is from 0 to 67108863. Settings outside of this range cause the output clock frequency to differ from the desired frequency. **Note:** Bit 26 is always 0. Settings (Hex) 000000 0 000001 1 000002 2 ... 3FFFFE 67108862 3FFFFF 67108863

22.2.2.5 DPLL MFNnnn Registers (DP_MFN, DP_MFNMINUS, and DP_MFNPLUS)

Figure 22-6 shows the DP_MFDnnn register diagram and Table 22-6 provides the field descriptions. MFNnn denotes MFN, MFNPLUS and MFNMINUS registers. The MFNPLUS and MFNMINUS

registers are part of the Desense logic. The MFN field contains the decimal value of MFN[26:0], which is output to the DPLL module by DPLL-IP.

0xBASE+0x010 (DP_MFN) Access: User read/write

30–27	Reserved
26–0 TOG_MFN [26:0]	This field contains the MFN value that is sent to the DPLL when the desense logic is active.

22.3 Functional Description

22.3.1 Clock Muxing and Gating/div Circuitry

Of the four clocks **clock0**, **clock1**, **clock2** and **clock3** one is selected depending upon the status of **ref_clk_sel**[1:0] signals (bit-8 and bit-9) of the DP_CTL register.

This is followed by a div circuitry and then by a gating circuitry as shown below. If **ref_clk_en_dpllip** signal is HIGH, the clock is passed, else it is gated to a value’1’.

Figure 22-13 illustrates the clock MUXing gating/div circuitry.

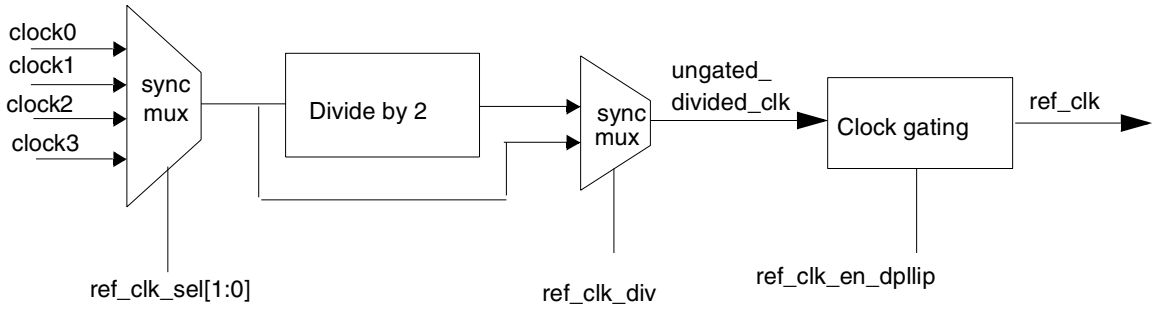

Figure 22-13. Clock MUXing and gating/div Circuitry

22.3.2 DVFS Support: HFS Mode

DPLL supports DVFS settings through an alternate set of registers which can be used to store high frequency settings corresponding to high voltage. This alternate set of HFS registers is used to restart the PLL with high frequency settings stored in HFS registers whenever system detects a voltage change from low to high level. Figure 22-14 describes this configuration.

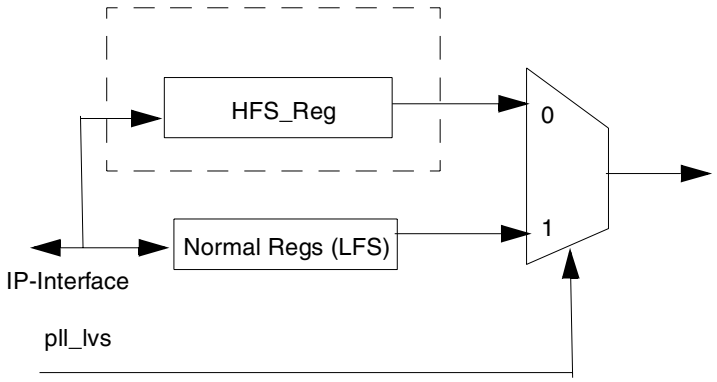

Figure 22-14. DVFS Support for High freq settings

22.3.3 DPLL Control and Port Updating

This section discusses DPLL control and port updating for the DPLL control registers, shadow registers, and DP_MFN register.

22.3.3.1 DP_CTL, DP_OP, DP_MFD Register Update

The DPLLs require special timing considerations when updating their ports. Whenever one of the DPLL control registers DP_CTL, DP_OP, or DP_MFD, or the shadow registers DP_HFS_OP or DP_HFS_MFD is written (even if the bits do not change), a restart is issued to the dpll before the actual control bits are sent to the DPLL. The restart assertion and port update will be synchronous to the reference input clock of the dpll. Writing to any of these registers causes following the procedure to come into effect:

1. Register is written

2. One clock cycle later restart (crstrt) is asserted
3. One clock cycle later the appropriate port is updated
4. Four clock cycles later restart is released

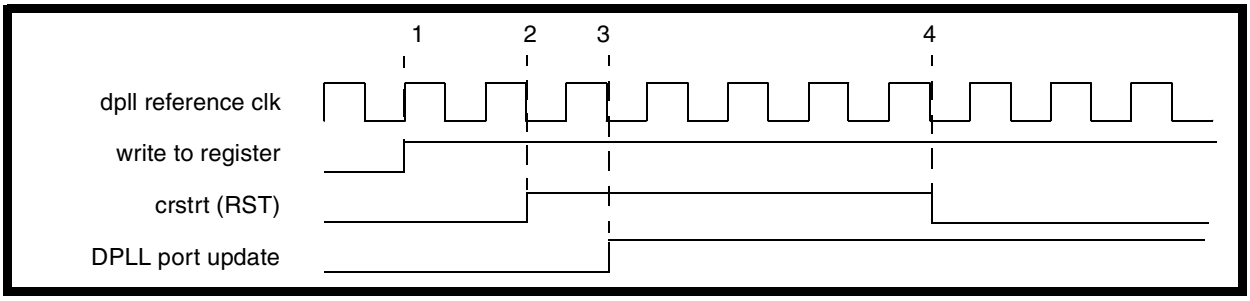

Figure 22-15. DPLL Port Timing

NOTE

Setting the RST bit causes the crstrt signal to immediately assert.

In case of AREN bit is LOW, the programmer will have to take care of restart of dpll by setting the RST bit of DP_CTL register appropriately.

22.3.3.2 DP_MFN Register Update

The MFN bits (in register DP_MFN) are the only bits in the DPLL that can be changed after the DPLL was locked without restart. As shown in Figure 22-16, after writing a new value to MFN, the procedure to update the DPLL is as follows:

1. The control bit LDREQ in DP_CONFIG is set. This sends a request signal to the DPLL.
2. When the DPLL loads the new MFN, its sends an acknowledge signal back to the Interface and clears the write value of LDREQ. At this point LDREQ becomes a status bit, reflecting the state of the acknowledge signal. NOTE: This write value of LDREQ is a “sticky” bit. When set, it will remain at ‘1’ until a load_ack pulse is received.
3. The read value of LDREQ is automatically cleared when the DPLL has completed updating MFN and has removed the acknowledge signal, allowing the next load request to take place.

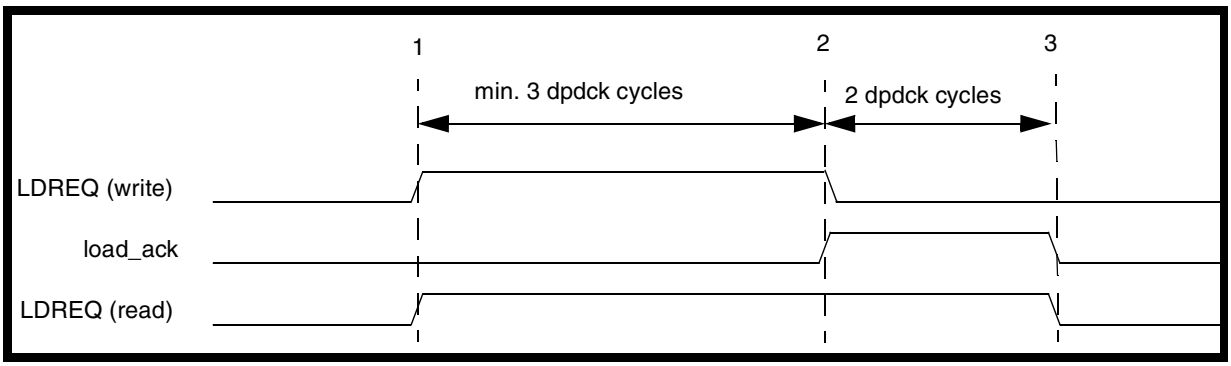

Figure 22-16. MFN Load Request Timing

22.3.4 Multiple Options for DPLL Control

The PLL interface provides multiple options for controlling the ON/OFF logic of the DPLLs from the Core and the DSM, making it possible to switch off the PLL by software and still be able to switch it on by DSM. Mul_ctrl (Bit [13]) of DP_CTL register provides this flexibility as shown in the following table:

Table 22-13. Options for DPLL Control

dpll_en_dpllip	UPEN bit	mul_ctrl bit (Self Clearing)	dpllip_cpen
X	X	1	0
X	0	X	0
posedge	1	0	1
0	X	X	0

X = Don't Care

As shown in Table 22-3, once the DPLL is switched off by Software using the Mul_ctrl bit, the software cannot turn the PLL on thereafter,unless there is a posedge on the dpll_en_dpllip signal, for example during the DSM entry sequence.

The dpllip_cpen signal shown above is the internally generated cpen signal which is then muxed with external signals to generate the final enable signal to the DPLL,

22.4 Initialization/Application Information

DPLL programming codes are shown below. In the examples, DPLL has been programmed to output frequency at 156 MHz (Example 22-1), 208 MHz (Example 22-2), and 400 MHz (Example 22-3).

Example 22-1. Example Code for DPLL Output = 156 MHz, with Reference Clock = 26 MHz:

```
// ***** Transfer ownership by writing to RAR[2:0] bits in SPBA PRR register
        // Write RAR as 111 giving access permission to all 3 masters(AP, BP, SDMA)
        mem32_write(SPBA_PLL1_PRR, 0x00000007);

         // It can then read back the RMO, RAR, ROI bits to make sure RMO returns the right
value, ROI bits contain its ID and RAR bits are correctly asserted.
         // The value should be 0xc0010007 (for ARM Access) and 0xc0020007(for DSP Access)
        if (mem32_read(SPBA_PLL1_PRR) == 0xc0020007)
                    {verilog_trigger(vt_pass);}
            else {verilog_trigger(vt_fail);}

//***** Program the PLL1 to lock at 156 MHz

Chapter 23
Dynamic Process and Temperature Compensation (DPTC)

23.1 Introduction

The DPTC (Dynamic Process and Temperature Compensation) module is a power management module. The purpose of the DPTC module is to detect the minimum operation voltage for the IC, regarding the process corner case and temperature for a given frequency. It obtains predefined values for process speed performance measurement and generates interrupt, if supply voltage value update is required.

NOTE

DPTC is a monitor that only provides an interrupt when counting exceeds a predefined value and does not actually send requests to change the voltage. This can be done by the user in the interrupt routine or SDMA code by using GPC or CCM.

23.1.1 Features

The DPTC features include the following:

- Interrupt generation on performance limit violation. Such an interrupt causes voltage value update.
- DPTC disabling at interrupt routine execution (by DPNVCR bit)
- DPTC auto re-enabling when requested voltage achieved (by PMIC_RDY signal posedge)
- DPTC disabling/enabling when DSM mode is active/ended.
- Four reference circuits support

23.1.2 Debug Mode

The debug mode is activated by writing ‘1’ to the RCLKON bit. The first activated reference circuit continues to run endlessly. DPTC interrupt should be masked.

23.2 Memory Map and Register Definition

23.2.1 DPTC Memory Map

The addresses are staring [11:2] = 01_0000_0000 value.

Table 23-1. AP Memory Map

Address	Register	Access	Reset Value	Section/Page
0xBASE_$0000 (DPTCCR)	DPTC Control Register (DPTCCR)	R/W	0x0004_0038	23.2.4.1/23-4

23.2.2 Register Summary

The conventions in Figure 1-1 and Table 1-7 serve as a key for the register summary and individual register diagrams.

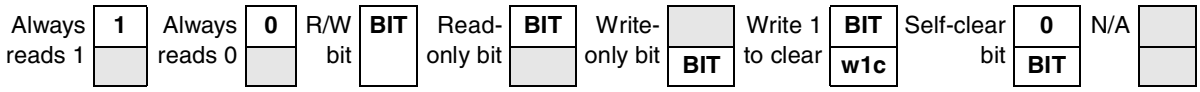

Figure 23-1. Key to Register Fields

Table 1-7 provides a key for register figures and tables and the register summary.

Table 23-2. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.

Table 23-2. Register Conventions (continued)

Convention	Description
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

23.2.3 DPTC Register Summary

Table 23-3 shows the DPTC register summary.

RESET:										0	1	1	1			0

Figure 23-2. DPTC Control Register (DPTCCR)

Table 23-4. Register Field Descriptions

Field	Description
DRCE3	DPTC reference circuit 3 enable bits. This bit defines whether reference circuit 3 is enabled during DPTC operation. 1 DPTC reference circuit 3 enabled. 0 DPTC reference circuit 3 disabled. **Note:** Write to this bit is permitted only when DPTC is disabled.
DRCE2	DPTC reference circuit 2 enable bits. This bit defines whether reference circuit 2 is enabled during DPTC operation. 1 DPTC reference circuit 2 enabled. 0 DPTC reference circuit 2 disabled. **Note:** Write to this bit is permitted only when DPTC is disabled.

Table 23-4. Register Field Descriptions (continued)

Field	Description
DRCE1	DPTC reference circuit 1 enable bits. This bit defines whether reference circuit 1 is enabled during DPTC operation. 1 DPTC reference circuit 1 enabled. 0 DPTC reference circuit 1 disabled. **Note:** Write to this bit is permitted only when DPTC is disabled.
DRCE0	DPTC reference circuit 0 enable bits. This bit defines whether reference circuit 0 is enabled during DPTC operation. 1 DPTC reference circuit 0 enabled. 0 DPTC reference circuit 0 disabled. **Note:** Write to this bit is permitted only when DPTC is disabled.
DCR	DPTC counting range. This bit configures a number of system clocks, during which the reference circuits will be active (and their output signals will be counted). Value of '1' causes 256 system clock count. Value of '0' causes 128 system clock count. 11 256 system clock count 10 128 system clock count 01 64 system clock count 00 32 system clock count **Note:** Write to this bit is permitted only when DPTC is disabled.
DSMM	IPG_STOP input masking. This masking prevents DPTC disabling when 'ipg_stop' signal goes high. 'ipg_stop' signal goes low at system entering DSM mode (sys_clk of DPTC will disappear). 1 IPG_STOP is masked 0 IPG_STOP is not masked
DPNVCR	DPTC No Voltage Change request. Bit is written by SW only. 1 DPTC enabled 0 DPTC disabled
DPVV	DPTC voltage valid edge detect. Can be overwritten by SW. Bit is cleared when DPNVCR is cleared (upon its negedge) or when 'pmic_rdy' input goes low (upon its negedge). Bit is set when 'pmic_rdy' goes high (upon its posedge). 1 Received a voltage valid acknowledge 0 Voltage is not valid
VAIM	Voltage adjustment interrupt mask. This bit masks voltage adjustment interrupt. VAI status bits will be still asserted in relevant case. 1 Interrupt is masked. 0 Interrupt is enabled.
VAI [1:0]	Voltage adjustment status. This status bits indicate, that supply voltage should change. Bits are cleared when DPTC is disabled or if limits are not violated. Read only. 00 No interrupt 01 High-limit indication. Voltage should be decreased. Interrupt is asserted, if VAIM=0 10 Low-limit indication. Voltage should be increased. Interrupt is asserted, if VAIM=0 11 Emergency-limit indication. Voltage should be increased immediately. Interrupt is asserted if VAIM=0.
DEN	DPTC enable. This bit enables DPTC block, starts reference circuit counting and compares results to the look-up table values. DPTC is enabled only if DEN = 1, DPVV = 1, DPNVCR = 1, IPG_STOP = 0 (or masked). 1 DPTC is enabled. 0 DPTC is disabled.

23.2.4.2 DPTC Debug Register (DPTCDBG)

Figure 23-3 shows the DPTC debug register, and Table 23-5 describes its fields.

0xBASE_$004 (DPTCDBG) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
RESET:																

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	RCLKON	0	RCCR											RC-CRV
W																
RESET:			0													

Figure 23-3. DPTC Debug Register (DPTCDBG)

Table 23-5. Register Field Descriptions

Field	Description
RCLKON	Reference circuit clock on. Used for DPTC debugging for viewing on CKO2 pin. If bit is set, DPTC interrupt has to be masked. 1 DPTC Debug mode—first selected reference circuit clock is always running, and other reference circuits are not selected. 0 Normal operation of DPTC. **Note:** Write to this bit is permitted only when DPTC is disabled.
RCCR	Reference Circuit Counter Result. Holds first result that was read from selected reference circuit. Bits are cleared when DPTC is disabled (DEN=0). Read-only bits.
RCCRV	Reference Circuit Counter Result Valid. Indicates that result in RCCR bits is valid. Bit is cleared when DPTC is disabled (DEN=0). Read-only status bit. 1 Result in RCCR is valid 0 Result in RCCR is not valid.

23.2.4.3 DPTC Comparator Value Registers 0–3 (DCVR0–3)

Figure 23-4 shows the DPTC comparator value registers 0–3, and Table 23-6 describes their fields.

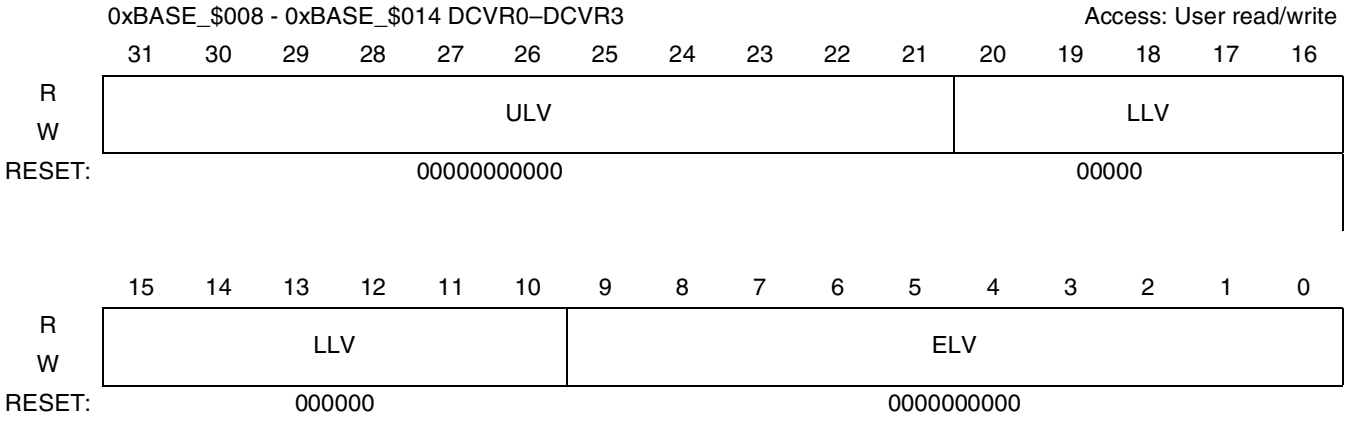

Figure 23-4. DPTC Comparator Value Registers 0–3 (DCVR0–3)

Table 23-6. Register Field Descriptions

Field	Description
ULV	Upper Limit Value (11 bits)—value of reference circuit clock counts for upper performance limit
LLV	Lower Limit Value (11 bits)—value of reference circuit clock counts for lower performance limit.
ELV	Emergency Limit Value (10 bits)—value of reference circuit clock counts for lower emergency performance limit. Emergency Limit Value should be less than Lower Limit Value. **Note:** For ELV field, Bit 9 is used as MSBit in DPTC (b10). Bit 0 is extended for LSBit in DPTC. Full emergency limit value (11 bit) should be less than lower limit value.

These registers contain relevant DPTC Look-up table values. Each register hold the limit values for the corresponding reference circuit (for example, DCVR0 corresponds to reference circuit 0). Upper limit should be always higher than lower limit. Lower limit should be always higher than emergency limit.

Chapter 24
Dynamic Voltage Frequency Scaling (DVFS)

24.1 Introduction

The DVFS allows simple dynamic voltage frequency scaling. The frequency of the core clock domain and the voltage of the core power domain can be changed on the fly while all modules (including the MCU) continue their normal operation. The frequency of the core clock domain can be changed by switching temporally to an alternate PLL clock, and then return to the updated PLL, already locked at a specific frequency, or by merely changing the post dividers division factors.

The DVFS load tracking block allows hardware tracking on the core load and a generation of an interrupt when a frequency change is requested.

NOTE

DVFS is a monitor that only provides an interrupt when counting exceeds the predefined value and does not actually send the request to make a change of voltage and frequency. This can be done by the user in the interrupt routine or SDMA code by using GPC or CCM (relocking the PLL or changing the post dividers at the CCM).

24.1.1 Overview

Figure 24-1 shows the block diagram.

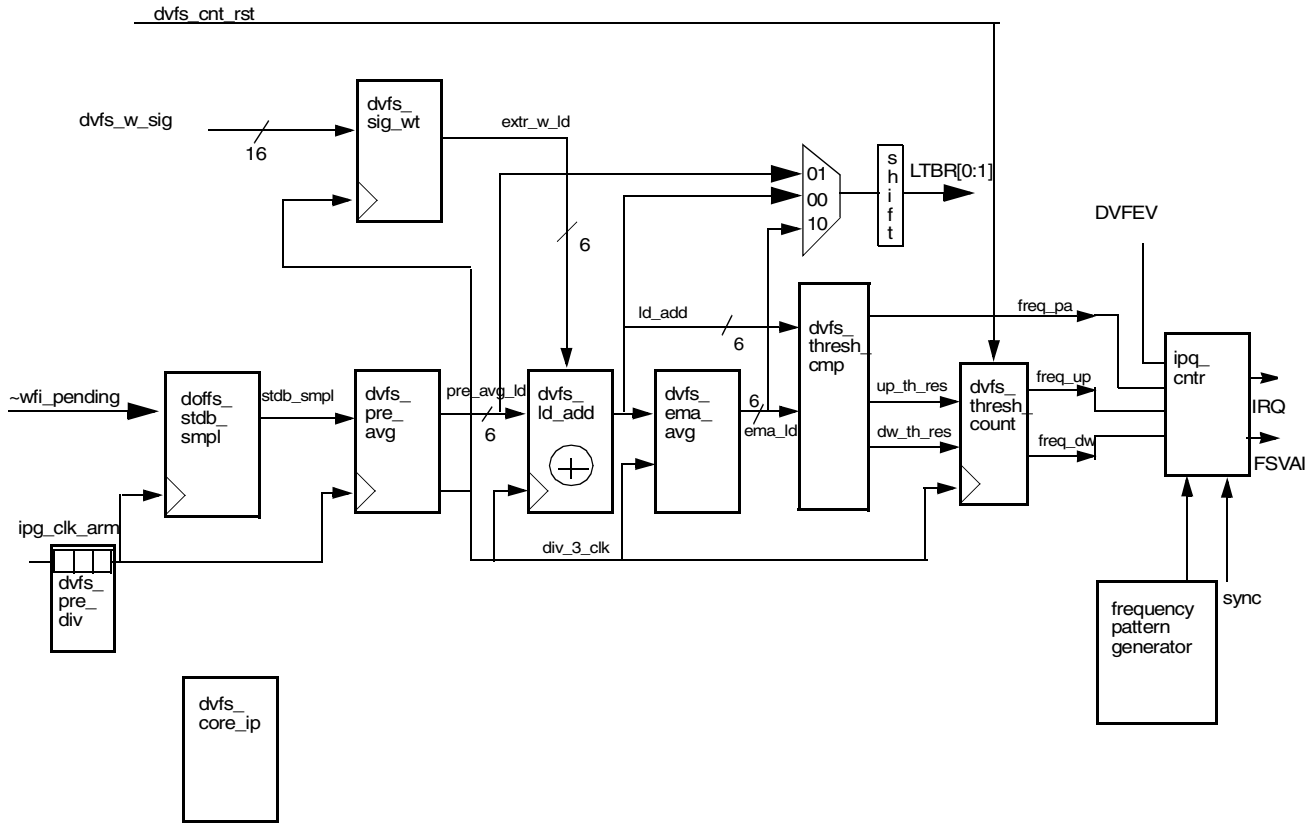

Figure 24-1. Block Diagram

24.1.2 Features

The DVFS load tracking block includes the following features:

- Configurable include/exclude of input signals:
  - — ARM standby signal (idle / non-idle)
  - — 16 general-purpose bits
    - – Configurable weight of each bit.
- Configurable generated clocks and averaging time slicing (respond time).
- Configurable panic mode respond logic (for frequency up).
- Programmable buffer for last 4,8,12, or 16 load tracking samples. Based on value in LBCF in DVFSCNTR. There is also a buffer full signal, LBFL.

24.2 Memory Map and Register Definition

This section provides a memory map, register summary, and register definitions.

24.2.1 Memory Map

Table 24-3 shows the memory map.

24.2.3 Register Descriptions

This section provides detailed descriptions of the DVFS registers. The descriptions are in address order.

24.2.3.1 DVFSTHRS Register

Figure 24-3 shows the DVFSTHRS register, and Table 24-6 describes the register fields.

Address 0xBASE_0000 (DVFSTHRS) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	UPTHR						DNTHR					
W																
Reset	0	0	0	0	1	1	1	1	1	0	1	0	1	1	1	1

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	C	0	0	0	0	0	0	0	0	PNCTHR					
W																
Reset	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	0

Figure 24-7. DVFS General Purpose Bits Weight Counter

Table 24-10. DVFSGPC0 Register Field Descriptions

Field	Description
31 C0STRT	C0STRT—Counter 0 start Setting of this bit will initialize down counting of the GPC0 value. Bit is self-cleared next cycle after setting. Any setting of this bit will re-start GPC0 counter to the GPC0 value. GPB0 bit disables (overrides) GPC0 counter - WSW0 weight is applicable continuously
30 C0ACT	C0ACT—Counter 0 active indicator 1 General Purpose bit0 counter didn't reach value of "0"—the WSW0 is provided to DVFS calculation 0 General Purpose bit0 counter reached value of "0" - the instead of WSW0, "0" (zero) is provided to DVFS calculation
29–17	Reserved
16–0 GPBC0	GPBC0—General Purpose bits counter 0 During the period of this counter, the GeP bit 0 is set and WSW0 is added to the calculations.

24.2.3.6 DVFSGPC1 Register

Figure 24-8 shows the DVFSGPC1 register, and Table 24-11 describes its register fields.

Address 0xBASE_0014 (DVFSGPC1) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0

Figure 24-11. DVFSCNTR Register

Table 24-14. DVFSCNTR Register Field Descriptions

Field	Description
31–29 DIV3CK	DIV3CK - div_3_clk division ratio inside the DVFS module. According to the Table 24-15
28 DVFEV	Always give a DVFS event. 0 - Do not give an event always. 1- Always give event.
27 LBMI	Load buffer full mask interrupt. This bit masks the generation of this interrupt. 1 = Load buffer full interrupt is masked (LBFL0 and LBFL1 bits still are updated, but interrupt won't be generated) 0 = Load buffer full interrupt is enabled.
26 LBFL1	Load buffer 1 - full status bit. This bit indicates that log buffer registers are full. The bit is set to 1 automatically. An interrupt will be generated if LBMI bit is set to "0" 1 = Load buffer0 is full. 0 = Load buffer0 is not full. Write '1' to clear. (write '0' leaves bit unchanged)
25 LBFL0	Load buffer 0 - full status bit. This bit indicates that log buffer registers are full. The bit is set to 1 automatically. An interrupt will be generated if LBMI bit is set to "0" 1 = Load buffer1 is full. 0 = Load buffer1 is not full. Write '1' to clear. (write '0' leaves bit unchanged)
24 DVFIS	DVFS Interrupt select. These bits define destination of DVFS interrupts. 1 = MCU interrupt will be generated for DVFS events. 0 = SDMA interrupt will be generated for DVFS events.

Table 24-14. DVFSCNTR Register Field Descriptions (continued)

Field	Description
23 PIRQS	PIRQS - Pattern IRQ Source * write '1' to clear. Writing '1' will clear interrupt if interrupt was from pattern 1 = DVFS IRQ source was from pattern 0 = DVFS IRQ source was not from pattern
22 FSVAIM	DVFS Frequency adjustment interrupt mask. This bit masks the DVFS frequency adjustment interrupt. FSVAI status bits are still asserted in relevant cases. 1 = interrupt is masked. 0 = interrupt is enabled.
21–20 FSVAI[1:0]	**FSVAI** DVFS Frequency adjustment interrupt. These status bits indicate that the system frequency should be changed. 00 = no interrupt 01 = frequency should be increased. Low priority interrupt. Interrupt is asserted, if FSVAIM=0. Interrupt is masked if MAXF = 1 (highest frequency). 10 = frequency should be decreased. Interrupt is asserted, if FSVAIM=0. Interrupt is masked if MINF= 1 (lowest frequency). 11 = frequency should be increased immediately. High priority interrupt. Interrupt is asserted, if FSVAIM=0. Interrupt is masked if MAXF = 1 (highest frequency).
19 WFIM	DVFS Wait for Interrupt mask bit 0 - Wait for interrupt not masked 1 - Wait for interrupt masked.
18 MAXF	Maximum frequency reached. Interrupt will not be created in maximum frequency reached and frequency increase required. 1 - max frequency reached 0 - max frequency not reached
17 MINF	Minimum frequency reached. Interrupt will not be created in minimum frequency reached and frequency decrease required. 1 - min frequency reached 0 - min frequency not reached
16–11 DIV_RATIO	DIV_RATIO—Divider value. Divider divides the input ARM clock, following Table 24-16.
10	Reserved
9 PFUE	PFUE - Period Frequency Update Enable 1 - enabled 0 - disabled
8-6 PFUS	PFUS - Periodic Frequency Update Status 000 - no update 100 - DVFSPT0 period, previous finished(can be performance level decrease) 101 - DVFSPT1 period, previous finished(can be EMA-detected performance level) 110 - DVFSPT2 period, previous finished(can be performance level increase) 111 - DVFSPT3 period, previous finished (can be EMA-detected performance level)
5 LTBRSH	LTBRSH - Load Tracking Buffer Register Shift: 0 = values of [5:2] of the selected input are saving in Load Tracking Buffer 1 = values of [4:1] of the selected input are saving in Load Tracking Buffer

Table 24-14. DVFSCNTR Register Field Descriptions (continued)

Field	Description
4–3 LTBRSR	LTBRSR - Load Tracking Buffer Register Source: 00 = pre_ld_add 01 = ld_add 10 = after ema 11 = reserved
2–1	reserved
0 DVFEN	DVFEN DVFS enable. This bit enables the DVFS block. 1 = DVFS enabled. 0 = DVFS disabled. NOTE: Between disable and enable there has to be at least 3 cycles of div_3_clk.

Table 24-15. DIV3CK Division

DIV3CK Setting	Dividing Ratio	sum_3 Passing Bits	div_1_clk Cumulative Divider
00	1	4-0	1*512=512
001	4	6-2	4*512=2048
010	16	8-4	16*512=8192
011	64	10-6	64*512=32768
100	256	12-8	256*512=131072
101	1024	16-10	1024*512=524288

Table 24-16. Preliminary Divider definition

DIV_RATIO value	ARM clk division ratio
000000	1
000001	2
000010	3
...	...

24.2.3.10 DVFSLTR0_0 Register

Figure 24-12 shows the DVFSLTR0_0 register, and Table 24-17 describes its register fields.

24.3 Functional Description of DVFS Core Load Tracking

The DVFS load tracking block includes the following features:

Configurable include/exclude of input signals:

- ARM standby signal (idle/non-idle)
- 16 general purpose load tracking signals
- Configurable weight and (level-sensitive) of GeP signals.
- Configurable generated clocks and averaging time slicing (respond time).
- Configurable panic mode respond logic (for frequency up).
- Programmable buffer for last 4,8,12, or 16 load tracking samples. Two Load Tracking Buffers are working in ping-pong mode with two buffer full signals: LBFL1, LBFL0.

24.4 Component Blocks Description

This section provides descriptions and block diagrams for the component blocks.

24.4.1 dvfs_stdb_smpl block

This block samples the ccm_arm_stdb signal (ARM11 STANDBYWFI signal—idle state indicating) according to the edge of the ipg_clk_arm (ARM11 system clock) signal.

Figure 24-20 shows the dvfs_stdb_smpl block diagram.

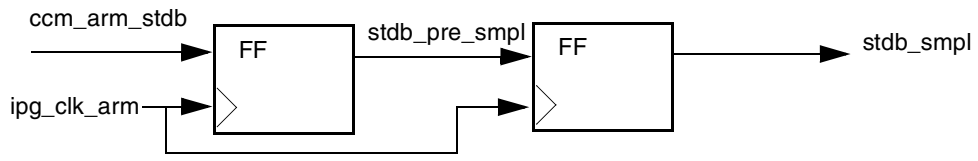

Figure 24-20. dvfs_stdb_smpl Block Diagram

This block synchronizes the ccm_arm_stdb signal with the ipg_clk_arm clock. The two signals enter the Flip-Flops (twice), and by doing so, are synchronized. The resulting synchronized signal is stdb_smpl.

24.4.2 dvfs_sig_wt block

The purpose of this block is to sample the 16 GeP (general purpose) load signals, multiply each one of them by the appropriate weight and sum products. The sampling is done by the slow clock div_3_clk.

These signals have the only one option of detection: level sampling. Figure 24-21 shows the block diagram.

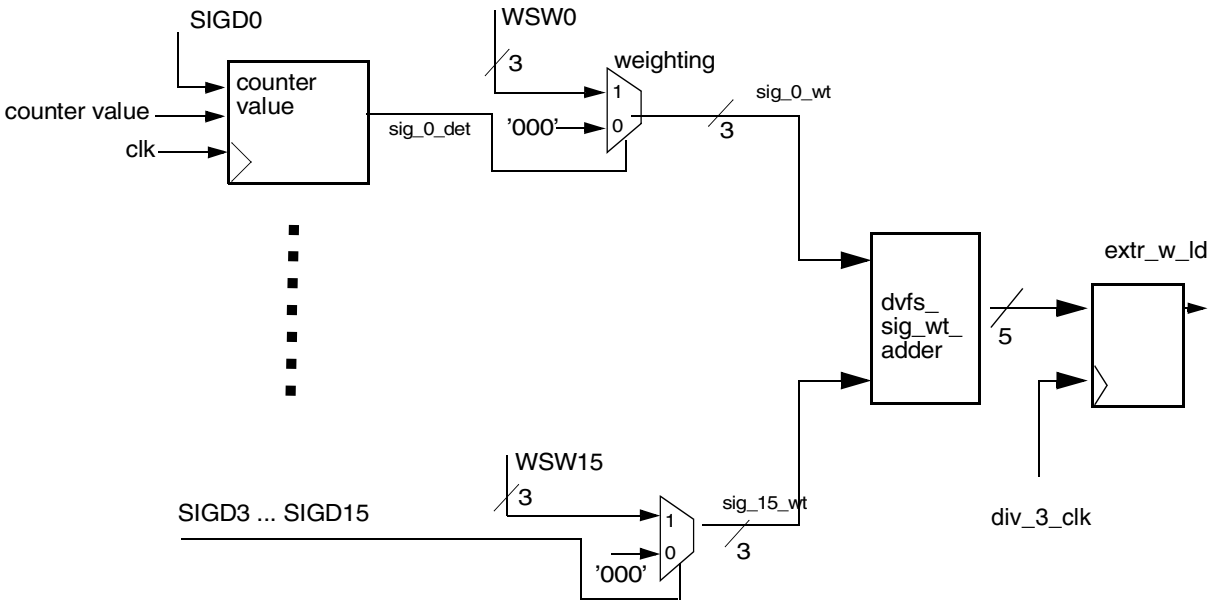

Figure 24-21. dvfs_sig_wt Block Diagram

There are two paths for general purpose bits weight.

24.4.3 dvfs_pre_avg block

The purpose of the dvfs_pre_avg block is to perform simple, non-overlapping averaging, reducing the sampling clock frequency and providing a level-based average index of the tracked CPU load.

External signals:

- stdb_sampl - (input) sampled ARM11 standby signal
- ipg_clk_arm - (input) ARM11 system clk
- pre_avg_ld[4..0] - (output) averaged load
- div_3_clk - (ouput) clock, generated (reduced) from div_2_clk
- div_2_clk - (output) clock, generated (reduced) from div_1_clk
- div_1_clk - (output) clock, generated (reduced) from ipg_clk_arm

In the current implementation, the averaging is performed in three stages:

1. The first stage !IDLE is sampled by divided sys_clock.

2. The second stage (counter2) performs an averaging operation with constant parameters. The counter is an nine (9) bit adder whose output is sampled by the div_2_clk clock. Five (5) highest bits of the sum_2 signal are passed to counter3 (equal to shift right operation).
3. The third (last) stage (counter3) performs an averaging operation with configurable parameters, set by the DIV3CK. The counter3 cell is a fifteen(15) bit adder with output sampled by div_3_clk. The Pre_avg_shifter_5 cell passes configurable bits from the sum_3 signal (see table1_3).

The output 5 bits avg_load signal provides a result with a tolerance of ~3%. (supported values range is 0–0.97)

Figure 24-22 shows the block diagram.

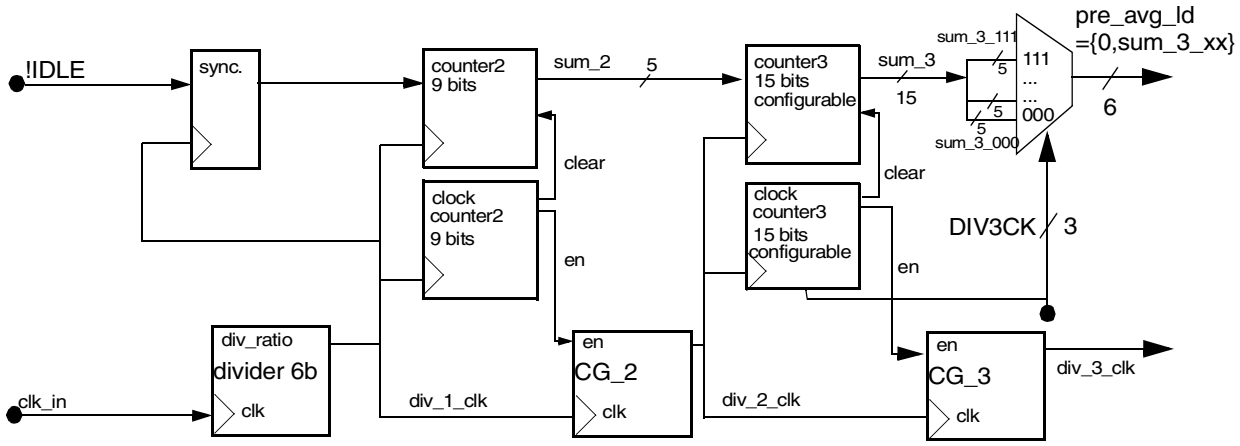

Figure 24-22. dvfs_pre_avg Block Diagram

Figure 24-23 shows the clocks.

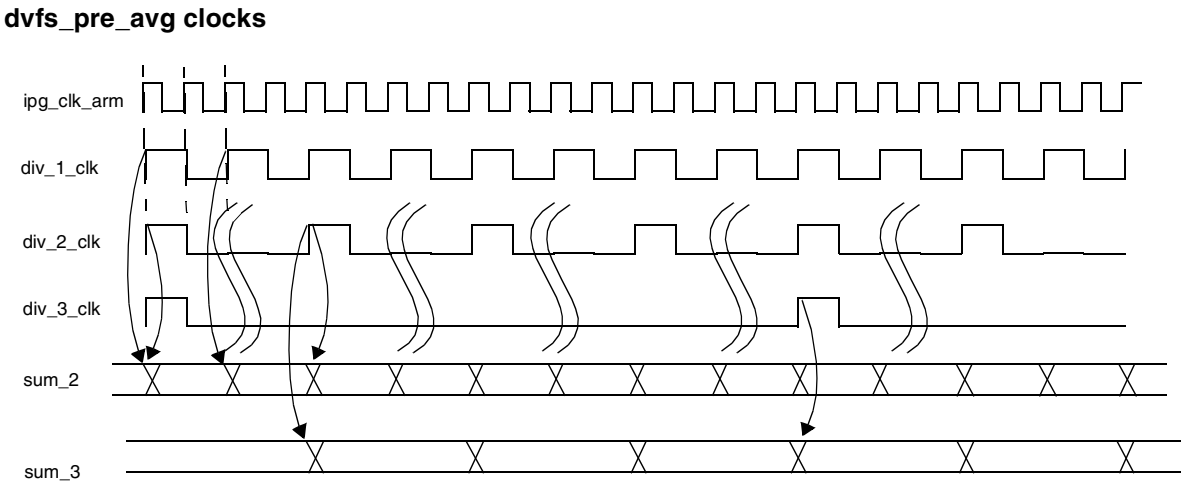

Figure 24-23. dvfs_pre_avg Clocks

The internal clocks in dvfs_avg_pre block are generated from ipg_clk_arm. See Table 24-24–Table 24-26 for details.

Table 24-24. dvfs_pre_avg Signals and its Values

Signal	Binary Max Value	Binary Min Value	Decimal Max Value	Decimal Min Value
sum_2	11111	0000	31	0
sum_3	111'1100'0000'0000	000'0000'0000'0000	31744	0
pre_avg_load	11111	0000	31	0

Table 24-25. dvfs_pre_avg Generated Clocks

Clock Name	Generated From	Ratio To Source	Ratio To lpg_clk_arm	Max Clk Freq.	Note

div_1_clk	ipg_clk_arm	configurable	configurable	66MHz	configurable
div_2_clk (gated)	div_1_clk	512	configurable	128KHz	none
div_3_clk (gated)	div_2_clk	configurable	configurable	128KHz	configurable

Table 24-26. div_3_clk Configurable Averaging

DIV3CK Setting	Dividing Ratio	sum_3 Passing Bits	div_1_clk Cumulative Divider
00	1	4–0	$1 \times 512 = 512$
001	4	6–2	$4 \times 512 = 2048$
010	16	8–4	$16 \times 512 = 8192$
011	64	10–6	$64 \times 512 = 32768$

Table 24-26. div_3_clk Configurable Averaging (continued)

DIV3CK Setting	Dividing Ratio	sum_3 Passing Bits	div_1_clk Cumulative Divider
100	256	12–8	256 × 512 = 131072
101	1024	16–10	1024 × 512 = 524288

24.4.4 dvfs_ld_add Block

The dvfs_ld_add block sums the CPU load, tracked by idle/non-idle signal and the load, detected from the additional load signals, weighted by signal_weighting block.

The adder should perform the following operation:

extr_w_ld[4..0] + pre_avg_ld[4..0]

The input signals of five (5) bits produce output signal of six (6) bits, providing 3% resolution in the range of 0–1.97 of load indication. (1 is equal to 100% load tracking with no additional signals include).

The output ld_add[5..0] is sampled by div_3_clk signal.

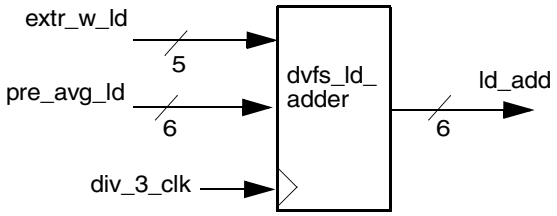

Figure 24-24. dvfs_ld_add Block Diagram

24.4.5 dvfs_ema_avg Block

The purpose of dvfs_ema_avg (EMA—Exponential Moving Average) block is to calculate an exponential moving average of the tracked CPU load. The parameters of EMA are defined by EMAC bits inside LTR2, bits ema_conf. These parameters set how many samples of simple average will be taken into account.

The EMA formula is: $EMA(i) = a \times X(i) + (1 - a) \times EMA(i - 1)$

where:

$a = 2 \div (N+1)$

N is the number of samples taken into account.

X(i) = current input sample

EMA(i – 1) = previous value of EMA

By setting the value of "a" , the behavior of EMA is defined.

In Table 24-27, the parameter "a" is listed relatively to the amount of the X(i) samples taken into account ("N") in the equation above: (the resolution of the digital multiplier is limited, hence the lowest values of the "a" can be linked to a range of included samples in EMA instead of single number).

In Table 24-27, there is also the amount of cycles in which the lower frequency is masked from the moment that DVFS is enabled (and not between frequency switches), so that enough information about the history can be gained before the frequency is lowered.

Table 24-27. EMA settings

Samples Included In Ema Calculation (N)	Number Of Cycles While Lower Frequency Interrupt Is Masked	"A" Value (Decimal)	"A" Value, Adjusted By Binary Resolution	"A" Value (Binary)

dvfs_ema_avg block diagram

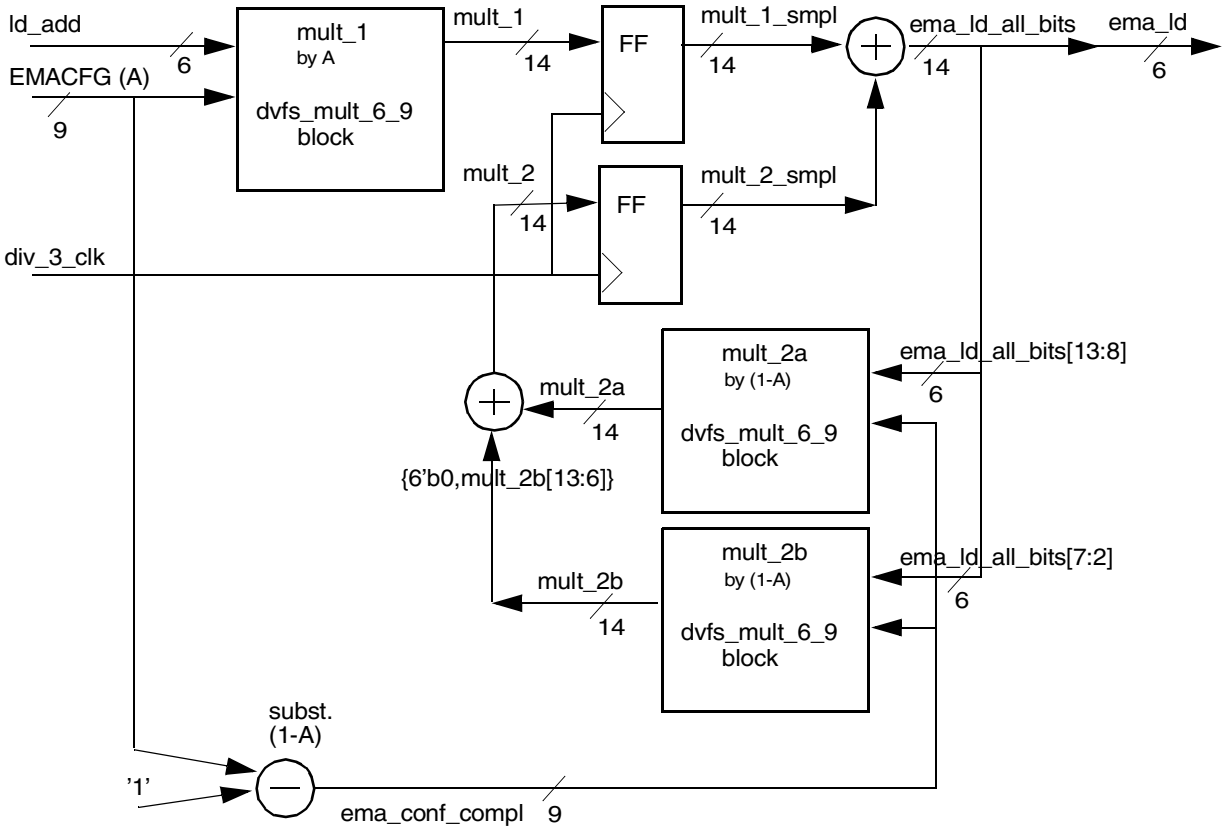

Figure 24-25. dvfs_ema_avg Block Diagram

The EMA block inputs are as follows:

- ld_add[5..0]—load level
- EMACFG[8..0]—"a" parameter of EMA algorithm
- div_2_clk—fast clock does not see this in the diagram
- div_3_clk—slow clock

The EMA block outputs the following:

- ema_ld[5..0] - result of EMA algorithm (by div_3_clk)

The mult_a block provides multiplying between comp_load (6 bits) and EMACFG (9 bits). For the multiply operation, a faster clock (for internal sum) is required- this is provided by div_2_clk. Div_2_clk is faster than the div_3_clk by a factor of at least 16, which is enough for 6×9 or 9×6 operations. Only the highest 6 bits are taken from the result of mult_a.

The mult_b block operates in a similar manner.

The adder block's output is sampled with div_3_clk clock.

24.4.6 dvfs_thres_cmp block

The dvfs_thres_cmp block compares the CPU load value to programmable threshold levels. The comparators as shown in Figure 24-26 are used:

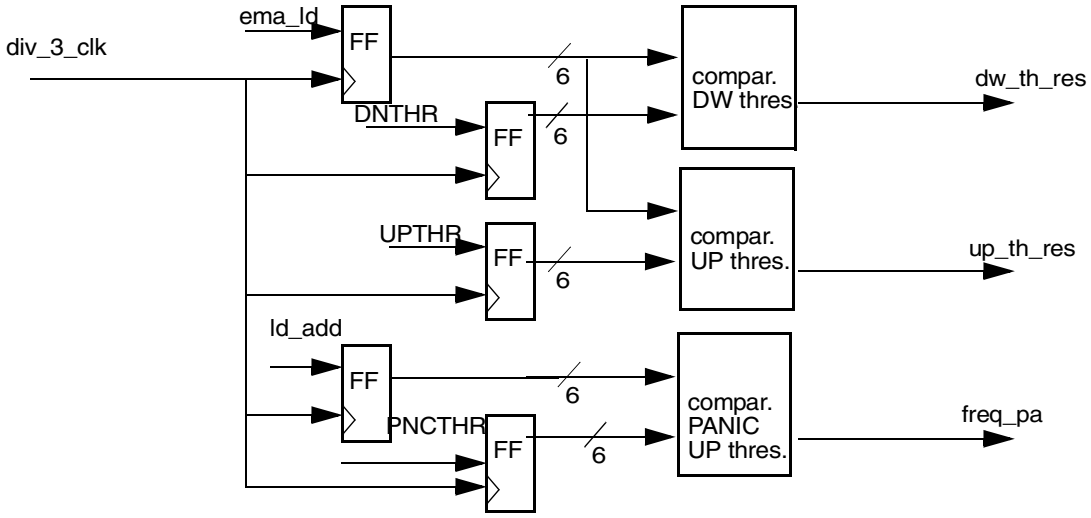

Figure 24-26. dvfs_tresh_cmp Diagram

The block is composed of three comparators:

- compar_dw_thres comparator, which compares between ema_ld signal (output of EMA block) and DNTHR signal (taken from config register, bits DNTHR).
- compar_up_thres comparator, which compares between ema_ld signal (output of EMA block) and UPTHR signal (taken from config register, bits UPTHR).
- compar_panic_up_thres comparator, which compares between ld_add signal (output of load_adder block) and PNCTHR signal (taken from config register, bits PNCTHR).

NOTE

The current implementation of this block enables step-by-step down frequency change. For more advanced option, the number of the DW threshold comparators should be increased (up to three for four-level DVFS).

24.4.7 dvfs_thresh_count block

The purpose of the dvfs_thres_count block is to count consecutive threshold overcomes of dw_th_res and up_th_res (outputs of threshold_comp block). If any of the counters (see Figure 24-27 below) receives a null (zero) input synchronous with the clk3 signal, the counter is reset.

If the counter reaches a user defined value, its output is set to an active level. These counters are reset each time frequency scaling occurs or if the threshold overcomes are consecutive.

This block's output signals are saved in configuration register 0, bits [3,2].

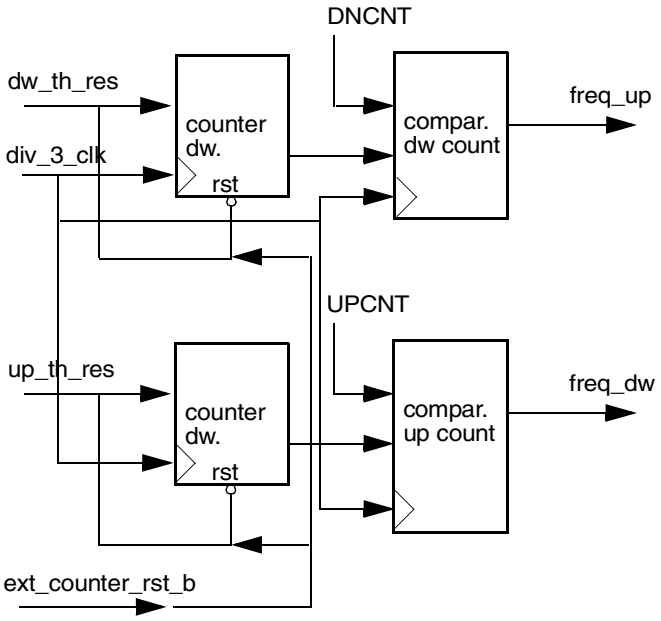

Figure 24-27. Thresh_counters Block Diagram

24.4.8 Load Tracking Buffer Register

The purpose of the load tracking buffer register is to save last 16 samples of the tracked load (before EMA operation). Hence, the 4 bits of ld_add signal (depending on the LTBRSH) are saved continuously, overwriting each time the latest sample. Each save is carried upon detecting an edge of the div_3_clk signal.

24.4.9 Frequency Pattern Generator

Frequency pattern generator is able to manage the frequency update requests periodically, additionally to main frequency update requests (if bit FPUE is set). The periodic requests are created following the DVFSPT0, DVFSPT1, DVFSPT2 and DVFSPT3 register values, as described in Figure 24-28.

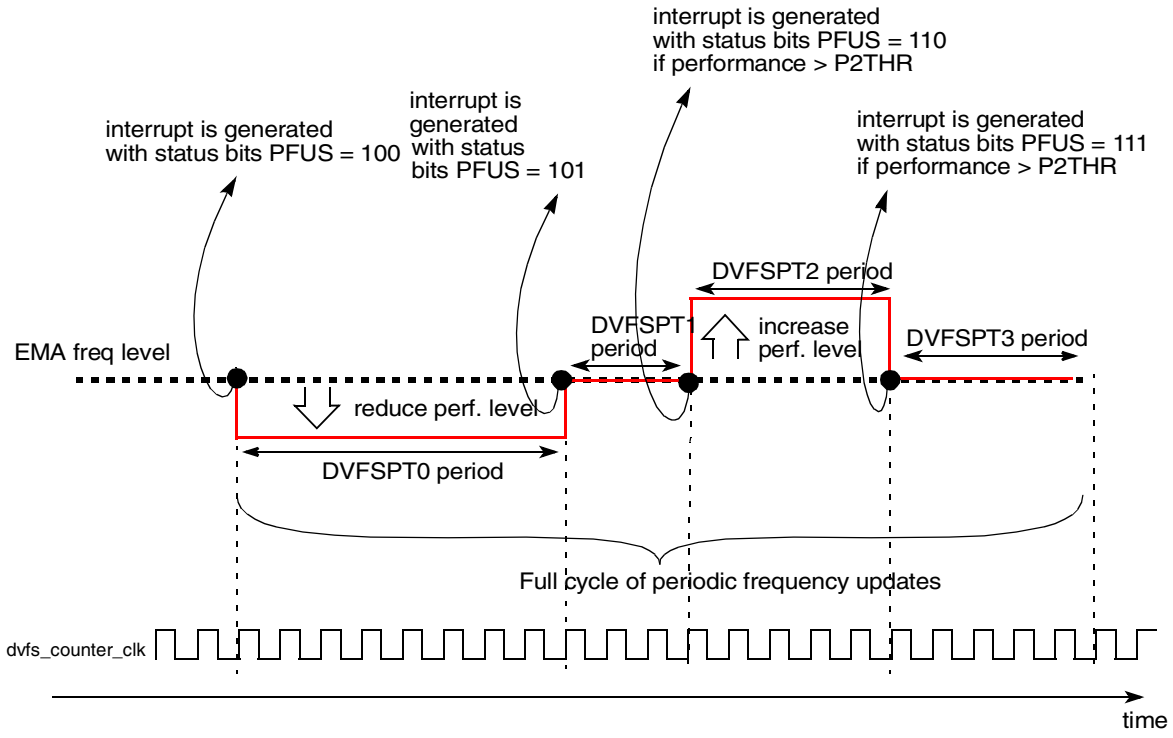

Figure 24-28. DVFS Periodic Frequency Update Requests

In case that one of the DVSPT0-DVFSPT3 period is set to “0”, such frequency update will be skipped.

The periodic frequency update status is reflected in PFUS bits (reduce/increase performance request is an example - the actual steps taken upon period expiration are defined by s/w routine).

Dvfs_counter_clk is ckih divided 64: 26MHz/64=0.40625MHz. The DVFSPT0, DVFSPT1, DVFSPT2 and DVFSPT3 counter are selected for 17 bits each to provide delay of 2^{18}-1=262143 counts, that are equal to 645ms. On the other hand, clk cycle of 0.40625MHz is ~2.46us, that is fast enough to provide high resolution for frequency management for tasks.

The DVFSPT2 and DVFSPT3 begin indication (interrupt) are conditional; only if the current performance is greater than P2THR bits at DVFSPT2 start, the interrupts will be created. Otherwise, the pattern delay will be counted, but without interrupt generation.

24.5 DVFS Output Event/interrupt Configuration

Event/Interrupt will be always high as long as LBFL is ’1’ and was not cleared by software. Unless DVFEV (always event) is asserted. Then the event/interruped will be toggled up and down every toggle of div_3_clk.

24.5.1 Interrupts

DVFS generates an interrupt that indicates that frequency and voltage update is needed. The user has to read the FSVAIM bits in order to know which change needs to be done.

24.6 Initialization Information

The user has to configure threshold values for load tracking and for counters and then enable the DVFS. When an interrupt is received, the user will change the frequency and the voltage in the interrupt handler.

NOTE

DVFS is a monitor that only provides an interrupt when counting exceeds the predefined value and does not actually send request to make a change a change of voltage and frequency. This can be done by the user in the interrupt routine or SDMA code by using GPC or CCM (relocking the PLL or changing the post dividers at the CCM).

Chapter 25
Dynamic Voltage Frequency Scaling for Peripherals (DVFS_PER)

25.1 Overview

Dynamic Voltage and Frequency Scaling (DVFS) enables the frequency of the system and the voltage of the power domain to be changed on the fly while all modules continue their normal operation on reduced frequency. The frequency of the clock domain is changed by dividing the clock source by DVFS divider. Serial clocks will remain the same.

The DVFS load tracking block allows hardware tracking on the system load and a generation of an interrupt when a frequency change is requested. The statistics for DVFS_PER are done on peripherals such as EMI (PER1), accelerators such as IPU, and so on.

NOTE

DVFS is a monitor that provides an interrupt when a count exceeds a predefined value. It does not request a change of voltage and frequency. This can be done by the user in the interrupt routine or SDMA code by using GPC or CCM (by locking the PLL or changing the post dividers at the CCM).

A diagram of the DVFS_PER module is shown in Figure 25-1.

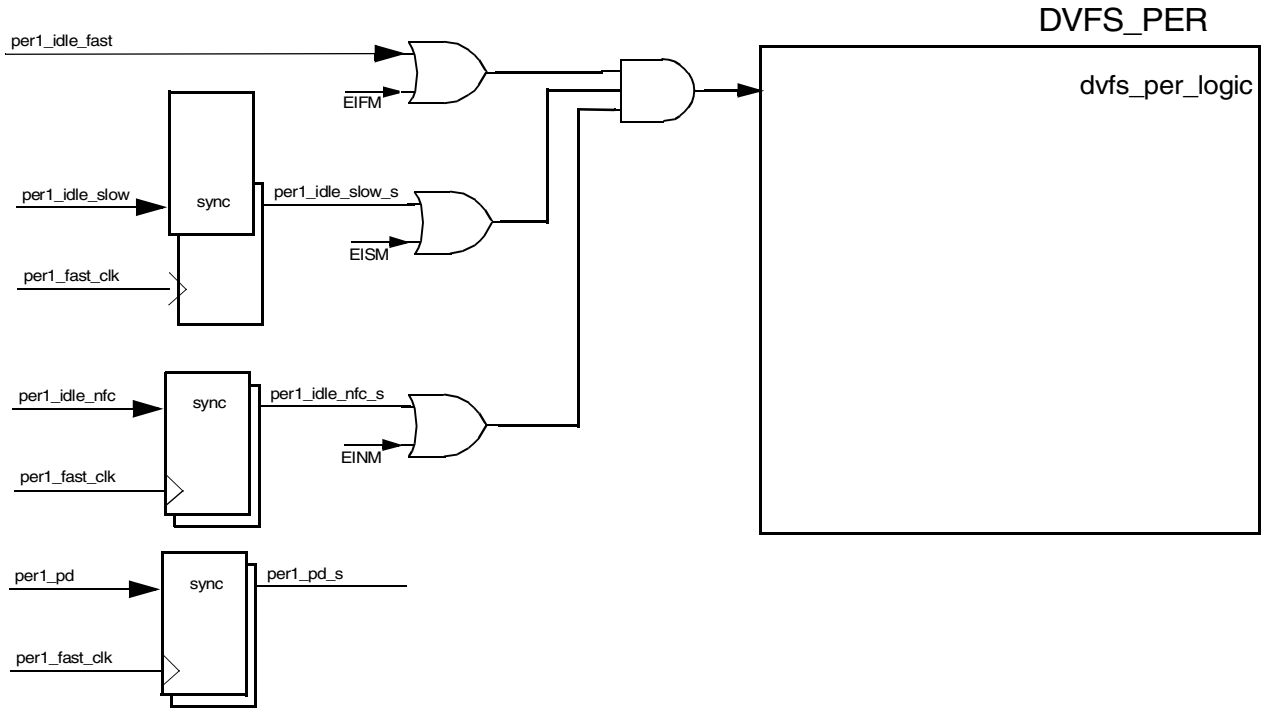

Figure 25-1. DVFS_PER Block Diagram

The DVFS_PER logic is shown in Figure 25-2.

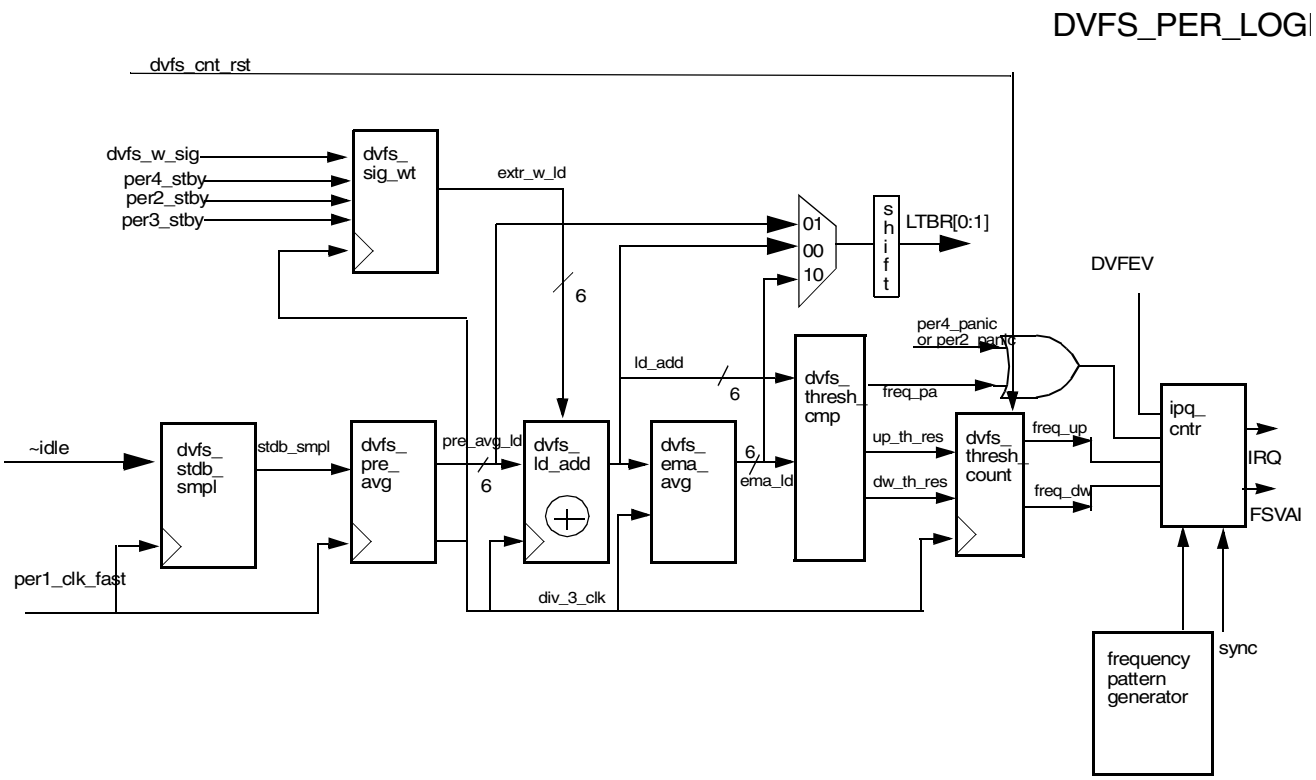

Figure 25-2. DVFS_PER_LOGIC Block Diagram

25.1.1 Features

The DVFS load tracking block includes the following features:

- Configurable include/exclude of input signals:
  - — Peripheral_1 (PER1) standby signal (idle/non-idle)
  - — 10 general purpose bits
  - — Peripheral_2 (PER2) standby
  - — Peripheral_3 (PER3) standby
  - — Peripheral_4 (PER4) standby
    - – Configurable weight of each bit.
- Configurable generated clocks and averaging time slicing (respond time).
- Configurable panic mode respond logic (for frequency up).
- Programmable buffer for last 4,8,12, or 16 load tracking samples based on value in LBCF in PMCR0. There is also a buffer full signal, LBFL.

25.2 Memory Map and Register Definition

This section provides a memory map, register figure key, and a register summary.

25.2.1 Memory Map

This DVFS_PER memory map is shown in Table 25-2.

25.2.2 Register Summary

The conventions in Figure 25-3 and Table 25-3 serve as a key for the register summary and individual register diagrams.

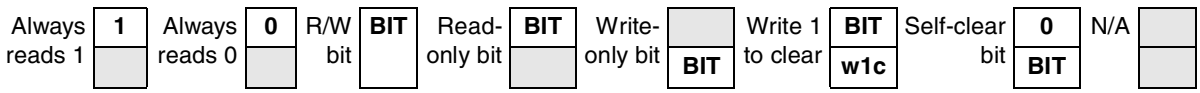

Figure 25-3. Key to Register Fields

Table 25-3 provides a key for register figures and tables and the register summary.

Table 25-3. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.

Table 25-3. Register Conventions (continued)

Convention	Description
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

The DVFS_PER registers are summarized in Table 25-4.

Table 25-4. DVFS_PER Registers Summary

Figure 25-4. LTR0 Register

The LTR0 fields are described in Table 25-10.

Table 25-5. LTR0 Register Field Descriptions

Field	Description
31 SIGD15	Detect way of general signal #15 (per2_not_idle): 1= edge, 0 = level
30 SIGD14	Detect way of general signal #14 (per2_not_idle): 1 = edge, 0 = level
29 SIGD13	Detect way of general signal #13 (per3_not_idle): 1 = edge, 0 = level
28	Reserved
27–22 UPTHR	Upper threshold for load tracking
21–16 DWTHR	Down threshold for load tracking
15 SIGD12	Detect way of general signal #12 (per3_not_idle): 1 = edge, 0 = level
14 SIGD11	Detect way of general signal #11 (per4_not_idle): 1 = edge, 0 = level
13 SIGD10	Detect way of general signal #10 (per4_not_idle): 1 = edge, 0 = level

Table 25-5. LTR0 Register Field Descriptions (continued)

Field	Description
12 SIGD9 ... 3 SIGD0	Detect way of general signal #9 ... #0(register): 1=edge, 0=level
2–0 DIV3CK	DIV3CK - div_3_clk division ratio inside the DVFS module. See Table 25-10 for the significance of different field values.

DIV3CK setting	dividing ratio	sum_3 passing bits	div_1_clk cumulative divider
00	1	4-0	1*512=512
001	4	6-2	4*512=2048
010	16	8-4	16*512=8192
011	64	10-6	64*512=32768
100	256	12-8	256*512=131072
101	1024	16-10	1024*512=524288

25.2.3.2 LTR1 Register

The LTR1 register fields are shown in Figure 25-5., and the fields are described in Table 25-11.

Address 0xBASE_0008 (LTR1) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

16

Figure 25-10. PMCR0 Register

Table 25-11. PMCR0 Register Field Descriptions

Field	Description
31–28	Reserved
27 UDSC	Up-down scaling. This bit indicates the direction of current frequency scaling. 1 = Frequency is increased. 0 = Frequency is decreased.
26–24	Reserved
23 DVFEV	Always give a DVFS event. 0 - Do not always give event. 1- Always give event.
22 DVFIS	DVFS Interrupt select. These bits define destination of DVFS interrupts. 1 = MCU interrupt will be generated for DVFS events. 0 = SDMA interrupt will be generated for DVFS events.
21 LBMI	Load buffer full mask interrupt. This bit masks the generation of this interrupt. 1 = Load buffer full interrupt is masked. 0 = Load buffer full interrupt is enabled.
20 LBFL	Load buffer - full status bit. This bit indicates that log buffer registers are full. The bit is set to 1 automatically. An interrupt will be generated if LBMI bit is set to "0" 1 = Load buffer is full. 0 = Load buffer is not full.
19–18 LBCF	load tracking configuration: 00 = 4 samples, 01 = 8 samples, 10 = 12 samples, 11 = 16 samples
17–16	Reserved
15 FSVAIM	DVFS Frequency adjustment interrupt mask. This bit masks the DVFS frequency adjustment interrupt. FSVAI status bits are still asserted in relevant cases. 1 = interrupt is masked. 0 = interrupt is enabled.
14–13 FSVAI [1:0]	**FSVAI** DVFS Frequency adjustment interrupt. These status bits indicate that the system frequency should be changed. 00 = no interrupt 01 = frequency should be increased. Low priority interrupt. Interrupt is asserted, if FSVAIM=0. Interrupt is masked if MAXF = 1 (highest frequency). 10 = frequency should be decreased. Interrupt is asserted, if FSVAIM=0. Interrupt is masked if MINF= 1 (lowest frequency). 11 = frequency should be increased immediately. High priority interrupt. Interrupt is asserted, if FSVAIM=0. Interrupt is masked if MAXF = 1 (highest frequency).
12–11	reserved
10	WFIM - WFI ARM signal masking. 1 = WFI ARM is masked 0 = WFI ARM is not masked
9–5	Rreserved

Table 25-11. PMCR0 Register Field Descriptions (continued)

Field	Description
4 DVFEN	DVFEN DVFS enable. This bit enables the DVFS block. 1 = DVFS enabled. 0 = DVFS disabled. NOTE: Between disable and enable there has to be at least 3 cycles of div_3_clk.
3–0	reserved

25.2.3.8 PMCR1 register

16 P2PM	PER2 panic mask 1= PER2 panic input is masked
15–0 DVGP	General purpose bits, used for WSW

25.3 Functional Description of DVFS Core Load Tracking

The DVFS load tracking block includes the following features:

Configurable include/exclude of input signals:

- PER1 standby signal (idle/non-idle)
- 10 general purpose load tracking signals
- per2 idle
- per3 idle
- per4 idle
- per2 panic
- per4 panic
- Configurable weight and (level-sensitive) of GeP signals.
- Configurable generated clocks and averaging time slicing (respond time).
- Configurable panic mode respond logic (for frequency up).
- Programmable buffer for last 4, 8, 12, or 16 load tracking samples.

Chapter 26
Enhanced Configurable Serial Peripheral Interface (eCSPI)

26.1 Introduction

The eCSPI module allows rapid data communication with fewer software interrupts than conventional serial communications. The eCSPI module contains one 64 × 32 receive buffer (RXFIFO) and one 64 × 32 transmit buffer (TXFIFO). Figure 26-1 shows the eCSPI block diagram.

26.1.1 Overview

The eCSPI is equipped with data FIFOs and is a master/slave configurable serial peripheral interface module, capable of interfacing to both SPI master and slave devices. The eCSPI Ready ($\overline{\text{SPI\_RDY}}$) and Chip Select ($\overline{\text{SS}}$) control signals enable fast data communication with fewer software interrupts.

There are two identical eCSPI modules in the IC. This chapter describes the configuration and operation of the eCSPI. Information such as base addresses and features that are unique to the multiple devices is described as appropriate.

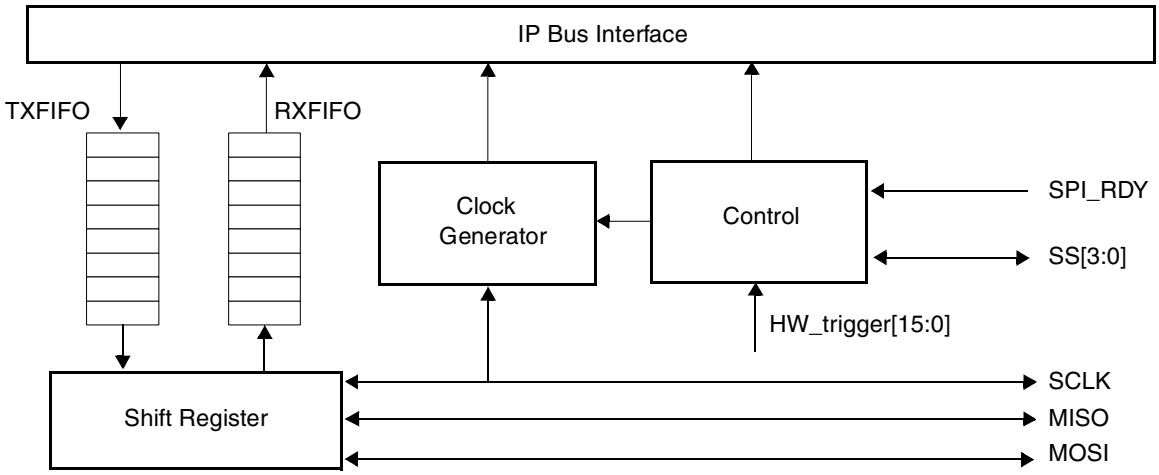

Figure 26-1. eCSPI Block Diagram

26.1.2 Features

The eCSPI is used for fast data communication with fewer software interrupts. It includes the following features:

- Four SPI channel with separate configuration bits and signals to support Multiple peripherals.
- Full-duplex synchronous serial interface

- Master/Slave configurable
- Support SPI clock up to 66MHz in both Master and Slave mode
- Transfer continuation function allows unlimited length data transfers
- 32-bit wide by 64-entry FIFO for both transmit and receive data
- 32-bit wide by 16-entry FIFO for HT message data
- Polarity and phase of the Chip Select ($\overline{SS}$) and SPI Clock (SCLK) are configurable
- DMA support
- Support hardware Trigger Mode (HT Mode).

26.1.3 Modes of Operation

eCSPI has three normal operating modes: master mode, slave mode and HT mode. It can be worked under low-power mode by enabling clock inputs to eCSPI.

eCSPI also provides some test register bits for debug purpose.

26.1.3.1 Normal Operating Modes

The normal operating modes are as follows:

- Master Mode

  When the eCSPI module is configured as a master, it uses a serial link to transfer data between the eCSPI and an external device. A chip-enable signal and a clock signal are used to transfer data between these two devices. If the external device is a transmit-only device, the eCSPI master's output port can be ignored and used for other purposes. In order to use the internal TXFIFO and RXFIFO, two auxiliary output signals, $\overline{SS}$ and $\overline{SPI\_RDY}$, are used for data transfer rate control. The user can also program the sample period control register to a fixed data transfer rate.
- Slave Mode

  When the eCSPI module is configured as a slave, the user can configure the eCSPI Control register to match the external SPI master's timing. In this configuration, $\overline{SS}$ becomes an input signal, and is used to control data transfers through the Shift register, as well as to load/store the data FIFO.
- HT Mode

  In this mode, all 16 message contents are stored in MSG Data FIFO inside the eCSPI which are associated with a set of input strobe signals. This mode is typically used to enable efficient PMIC control (via eCSPI) by GPC module, to support DVFS/DPTC with minimal CPU intervention.
  - Support up to 16 sets of 32-bit HT Message contents. And the length of HT Message contents can be programmed from 1 to 32.
  - Each HT Message content is associated with a Hardware Trigger input strobe signal and is triggered on rising edge of this signal.
  - HT Mode is valid with eCSPI Master Mode and only CS0 is available for HT mode.
  - Multiple simultaneous Hardware Triggers are not supported. If they appear, a single Hardware Trigger of highest priority is serviced. The priority of Hardware Triggers decreases with increase of their number, such as HT 0 has highest priority and HT 15 has lowest priority.

— If eCSPI transactions are requested simultaneously by CPU and Hardware Trigger, HT Mode has highest priority. If Hardware Trigger or CPU request arrive while the other one is serviced, it will be pending for the previous transaction completion.

26.1.3.2 Low Power Modes

eCSPI needs both ipg_clk and ipg_clk_per for its normal operations, so in low-power mode eCSPI works only if all these clock inputs are enabled.

26.1.3.3 Debug Mode

eCSPI provides the following test register bits for debug purposes.

- LBC bit in Test Register—provides a way to shift data out from TXFIFO and then loop back them into RXFIFO.
- CL bits in Test Register—provides a way to latch data in time when path delay is large.
- TXCNT bits in Test Register—provides a way to determine how many data are there in TXFIFO.
- RXCNT bits in Test Register—provides a way to determine how many data are there in RXFIFO.

26.2 External Signal Description

The following signals shown in Table 26-1 are used to control the serial peripheral interface.

Table 26-1. eCSPI Signal Properties

Name	Function	I/O	Reset	Pull-up
MOS	Master data out; slave data in	I/O	1’b0	—
MISO	Master data in; slave data out	I/O	1’b0	—
SCLK	SPI clock	I/O	1’b0	—
$\overline{SS}$[3:0]	Chip selects	I/O	4’b1111	Active
SPI_RDY	SPI data ready in Master mode	I	1’b1	Active
ipp_obe_mosi	Output enable for ipp_do_mosi, ipp_cspi_clk_out, ipp_do_ss_b	O	1’b0	—
ipp_obe_miso	Output enable for ipp_do_miso	O	1’b1	—

Table 26-2 provides a detailed description of all eCSPI external signals.

Table 26-2. eCSPI – Detailed External Signal Descriptions

Signal	I/O	Description	
MOSI	I/O	Master Out Slave In. In Master mode, this bidirectional signal is a TX output signal from the Data Shift register. In Slave mode, it is an RX input from external SPI device.	
		State Meaning	Asserted—Indicates a 1 is transmitted. Negated—Indicates a 0 is transmitted.
		Timing	Assertion—May occur at any edge of the SPI clocks according to configuration of eCSPI. Negation— May occur at any edge of the SPI clocks according to configuration of eCSPI.
MISO	I/O	Master In Slave Out – In Master mode, this bidirectional signal is an RX input signal to the Data Shift register. In Slave mode, it is a TX output to external SPI device.	
		State Meaning	Asserted—Indicates a 1 is transmitted. Negated—Indicates a 0 is transmitted.
		Timing	Assertion—May occur at any edge of the SPI clocks according to configuration of eCSPI. Negation— May occur at any edge of the SPI clocks according to configuration of eCSPI.
SCLK	I/O	SPI Clock – In Master mode, this bidirectional signal is a SPI clock output. In Slave mode, it is a SPI clock input.	
		State Meaning	Asserted—Clock is high. Negated—Clock is low.
		Timing	Assertion—May occur at any time. Negation— May occur at any time
$\overline{SS}$[3:0]	I/O	Chip selects – In Master mode, these bidirectional signals are outputs. In Slave mode, these are inputs. These signals are selected in/out by Chip Select bits in the eCSPI Control register.	
		State Meaning	Asserted—When SSPOL is set, device is selected, otherwise device is de-selected. Negated—When SSPOL is set, device is de-selected, otherwise device is selected.
		Timing	Assertion—May occur at any edge of the SPI clocks according to configuration of eCSPI. Negation— May occur at any edge of the SPI clocks according to configuration of eCSPI.
SPI_RDY	I	SPI Ready – It is an input from an external SPI slave device. This signal triggers the eCSPI to start a burst. Edge-trigger or level-trigger can be configured in the eCSPI Control register.	
		State Meaning	Asserted—External SPI device is not ready. Negated—External SPI device is ready.
		Timing	Assertion—May occur at any time. Negation— May occur at any time.

26.3 Memory Map and Register Definition

The eCSPI includes twenty-five 32-bit registers. Section 26.3.3, Register Descriptions,” provides detailed descriptions for the eCSPI registers.

26.3.1 Memory Map

There are two eCSPI modules in the i.MX51. Table 26-3 shows the eCSPI memory map for eCSPI1. The offsets for eCSPI2 are 0xBASE+0x000 through 0xBASE+0x040.

Table 26-3. eCSPI Memory Map[1]

Address	Register	Access	Reset Value	Section/Page
General Registers				
0xBASE+0x000 (RXDATA)	RXFIFO DATA Register (RXDATA)	R	0x0000_0000	26.3.3.1/26-7
0xBASE+0x004 (TXDATA)	TXFIFO DATA Register (TXDATA)	W	0x0000_0000	26.3.3.2/26-8
0xBASE+0x008 (CONTROLREG)	Control Register (CONTROLEG)	R/W	0x0000_0000	26.3.3.3/26-9
0xBASE+0x00C (CONFIGREG)	Config Register (CONFIGREG)	R/W	0x0000_0000	26.3.3.4/26-11
0xBASE+0x010 (INTREG)	Interrupt Control Register (INTREG)	R/W	0x0000_0000	26.3.3.5/26-13
0xBASE+0x014 (DMAREG)	DMA Control Register (DMAREG)	R/W	0x0000_0000	26.3.3.6/26-14
0xBASE+0x018 (STATUSREG)	Status Register (STATREG)	R/W	0x0000_0003	26.3.3.7/26-16
0xBASE+0x01C (PERIODREG)	Sample Period Control Register (PERIODREG)	R/W	0x0000_0000	26.3.3.8/26-17
0xBASE+0x020 (TESTREG)	Test Control Register (TESTREG)	R/W	0x0000_0000	26.3.3.9/26-18
0xBASE+0x040 (MSGDATA)	Message Data Register (MSGDATA)	R/W	0x0000_0000	26.3.3.10/26-19

[1] See Chapter 2, "Memory Map," for the value of base address of eCSPI1 and eCSPI2.

26.3.2 Register Summary

The conventions in Figure 26-2 and Table 26-4 serve as a key for the register summary and individual register diagrams.

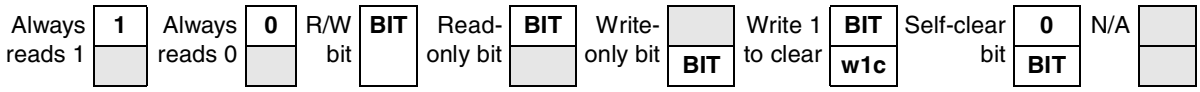

Figure 26-2. Key to Register Fields

Table 26-4 provides a key for register figures and tables and the register summary.

Table 26-4. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).

Table 26-4. Register Conventions (continued)

Convention	Description
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 26-5 shows the eCSPI register summary.

Table 26-5. eCSPI Register Summary

26.3.3 Register Descriptions

This section provides detailed descriptions of the eCSPI registers in address order.

26.3.3.1 RXFIFO DATA Register (RXDATA)

The RXFIFO Data register (RXDATA) forms the top word of 64 × 32 RXFIFO. Only word size operation is allowed for this register. Write to this register will be ignored, and read this register will get return value

from RXFIFO. Figure 26-3 shows the RXDATA Data register and Table 26-6 shows the register's field descriptions.

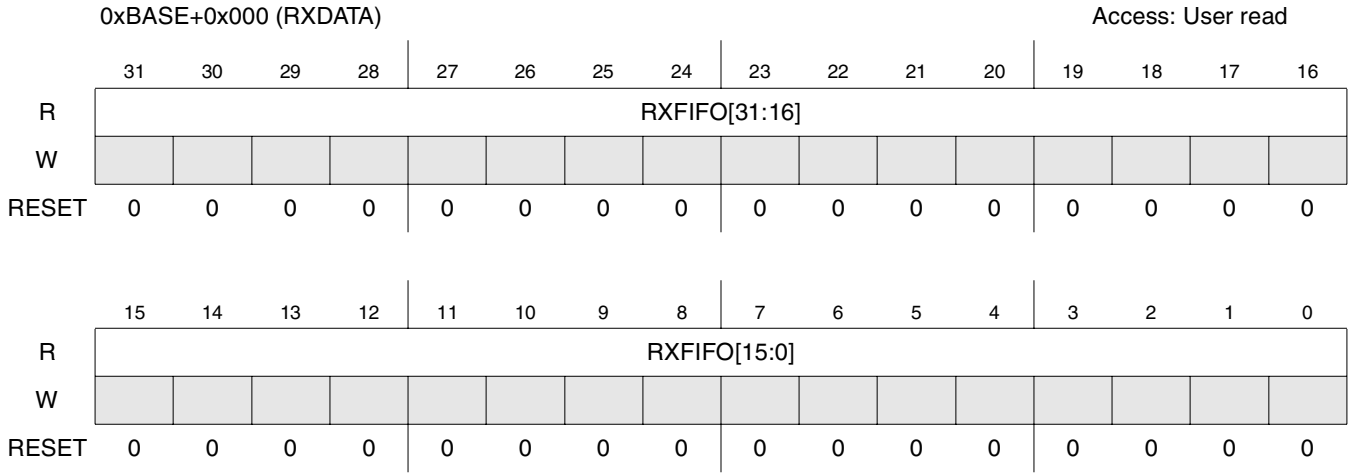

Figure 26-3. RXDATA Data Register Diagram

Table 26-6. RXDATA Data Register Field Description

Field	Description
31–0 RXDATA	RXDATA holds the top word of RXFIFO. The RXFIFO is advanced for each read of this register. The data read is zero when the Receive Data Ready (RR) bit in the Interrupt Control/Status register is cleared. The data write to this register will be ignored.

26.3.3.2 TXFIFO DATA Register (TXDATA)

The TXFIFO Data register (TXDATA) forms the top word of 64 × 32 TXFIFO. Only word size operation is allowed for this register. Read to this register will result zero, and write this register will store data into TXFIFO. Figure 26-4 shows the TXDATA Data register and Table 26-7 shows the register's field descriptions.

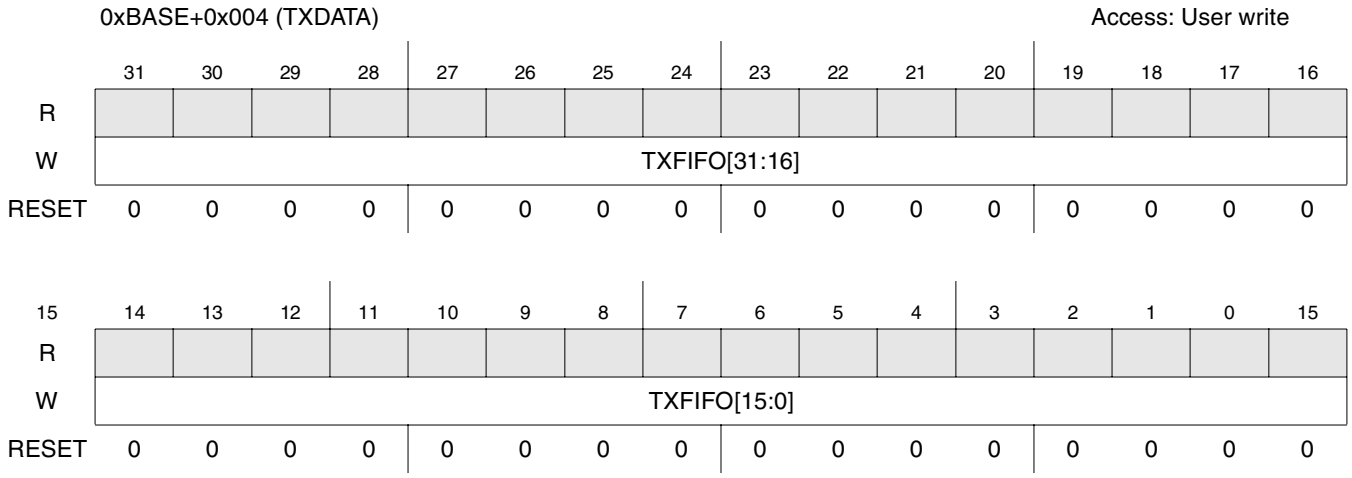

Figure 26-4. TXDATA Data Register Diagram

Table 26-7. TXDATA Data Register Field Description

Field	Description
31–0 TXDATA	TXDATA holds the top word of TXFIFO. The TXFIFO is advanced for each write of this register. The data read is zero. The data write to this register will be stored into TXFIFO.

26.3.3.3 Control Register (CONTROLEG)

The Control Register (CONTROLREG) allows the user to enable the eCSPI module, specify the clock divider value, select the SPI channel, configure $\overline{\text{SPI\_RDY}}$ control mode, and define the transfer length, etc. Figure 26-5 shows the Control register and Table 26-8 shows the register's field descriptions.

0xBASE+0x008 (CONTROLREG) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BURST LENGTH												CHANNEL SELECT		DRCTL	
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PRE DIVIDER				POST DIVIDER				CHANNEL MODE				SMC	XCH	HW	EN
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 26-5. eCSPI Control Register Diagram

Table 26-8. eCSPI Control Register Field Description

Field	Description
31–20 BURST LENGTH	Burst Length. This field defines number of bits to be transferred in one SPI burst. $\overline{SS}$ will remain asserted until all bits in a SPI burst are shifted out. A maximum of 2^12 bits can be transferred in a single SPI burst. In master mode, it controls the number of bits per SPI burst. Since the shift register always loads 32-bit data from TXFIFO, only the n least-significant (n = BURST LENGTH[4:0] + 1) bits in the first word will be shifted out. The remaining bits in first word will be ignored. All bits in other words will be shifted out. In slave mode, only when SSCTL is cleared, this field will take effect in SPI transfer. Number of Valid Bits in a SPI burst. 0x000 A SPI burst contains least 1 bit in a TXFIFO word. 0x001 A SPI burst contains least 2 bit in a TXFIFO word. 0x002 A SPI burst contains least 3 bit in a TXFIFO word. ..... 0x01F A SPI burst contains all 32 bits in a TXFIFO word. 0x020 A SPI burst contains least 1 bit in first TXFIFO word and all 32 bits in second TXFIFO word. 0x021 A SPI burst contains least 2 bits in first TXFIFO word and all 32 bits in second TXFIFO word. ..... 0xFFE A SPI burst contains least 31 bits in first TXFIFO word and 2^7 -1 TXFIFO words. 0xFFF A SPI burst contains 2^7 TXFIFO words.
19–18 CHANNEL SELECT	SPI CHANNEL SELECT bits. It selects which SPI channel is selected to be active. 00 SPI Channel 0 is selected. 01 SPI Channel 1 is selected. 10 SPI Channel 2 is selected. 11 SPI Channel 3 is selected.
17–16 DRCTL	SPI Data Ready Control. This 2-bit field selects the utilization of the $\overline{SPI\_RDY}$ in master mode. eCSPI will check this fields before it start a SPI burst. 00 Don't care $\overline{SPI\_RDY}$ 01 Burst will be triggered by falling edge of $\overline{SPI\_RDY}$. 10 Burst will be triggered by low level of $\overline{SPI\_RDY}$. 11 $\overline{RSV}$.
15–12 PRE DIVIDER	SPI Pre Divider bits. eCSPI uses a two stages divider structure to generated the SPI clock. This four-bit field defines the ipg_clk 4-bit pre-divider. 0000Divide by 1. 0001Divide by 2. 0010Divide by 3. ..... 1101Divide by 14. 1110Divide by 15. 1111Divide by 16.
11 –8 POST DIVIDER	SPI Post Divider bits. eCSPI uses a two stages divider structure to generated the SPI clock. This four-bit field defines the 4-bit post-divider. 0000Divide by 1. 0001Divide by 2. 0010Divide by 4. ..... 1110Divide by 2^14. 1111Divide by 2^15.

Table 26-8. eCSPI Control Register Field Description (continued)

Field	Description
7–4 CHANNEL MODE	SPI CHANNEL MODE defines mode of each SPI channel. CHANNEL MODE[0] defines the mode of SPI channel 0. CHANNEL MODE[1] defines the mode of SPI channel 1. CHANNEL MODE[2] defines the mode of SPI channel 2. CHANNEL MODE[3] defines the mode of SPI channel 3. 0 Slave Mode. 1 Master Mode.
3 SMC	Start Mode Control. This bit is used in master mode only and it controls how eCSPI start a SPI burst. 0 Normal mode, the XCH bit controls when a SPI burst can start. Write a 1 to XCH bit will start a SPI burst or multiple bursts. (controlled by SSCTL) 1 Automatic Mode, start a SPI burst when a data is written in TXFIFO immediately.
2 XCH	SPI Exchange Bit. If the SMC bit is cleared, writing a 1 to this bit starts one SPI bursts/multiple SPI bursts according to SSCTL bit. This bit remains set while either the exchange is in progress, or the eCSPI is waiting for active input if $\overline{\text{SPIRDY}}$ is enabled through DRCTL. This bit is cleared automatically when one SPI burst has been done (SSCTL is clear) or TXFIFO is empty (SSCTL is set). In Slave mode, this bit is ignored. 0 Idle. 1 Initiates exchange (write) or busy (read).
1 HW	HW Trigger Enable. This bit is used in master mode only and it enables hardware trigger mode. 0 HT Mode is disabled. 1 HT Mode is enabled.
0 EN	SPI Module Enable Control. This bit enables the eCSPI. This bit must be asserted before writing to other registers or initiating an exchange. Writing zero to this bit disables the module and resets the internal logic with the exception of the CONTROLREG. The module's internal clocks are gated off whenever the module is disabled. 1 eCSPI is enabled. 0 eCSPI is disabled.

26.3.3.4 Config Register (CONFIGREG)

The Config Register (CONFIGREG) allows the user to configure each channel of the eCSPI module, configure its operating modes, phase, and polarity of the clock, configure the $\overline{\text{SS}}$. The reserved bits are always read as zero.

Figure 26-6 shows the CONFIGREG register and Table 26-9 shows the register's field descriptions.

0xBASE+0x00C (CONFIGREG) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	HT LENGTH					SCLK CTL				DATA CTL			
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SSB POL				SSB CTL				SCLK POL				SCLK PHA			
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 26-6. eCSPI Config Register Diagram

Table 26-9. eCSPI Config Register Field Description

Field	Description
31–29	Reserved, all bits can be read/write, but have no meaning.
28–24 HT LENGTH	The HT LENGTH defines the length of message content in HT Mode. The number of bits of one message content is HT LENGTH + 1;
23–20 SCLK CTL	The SCLK CTL control inactive state of SCLK line for each SPI channel. Bit 27 controls the SCLK inactive state of SPI channel 3. Bit 26 controls the SCLK inactive state of SPI channel 2. Bit 25 controls the SCLK inactive state of SPI channel 1. Bit 24 controls the SCLK inactive state of SPI channel 0. 0 stay high. 1 stay low.
19–16 DATA CTL	The Data CTL control inactive state of Data line for each SPI channel. Bit 23 controls the data polarity of SPI channel 3. Bit 22 controls the data polarity of SPI channel 2. Bit 21 controls the data polarity of SPI channel 1. Bit 20 controls the data polarity of SPI channel 0. 0 stay high. 1 stay low.
15–12 SSB POL	The SSB POL control polarity of SSB for each SPI channel. Bit 15 controls the SSB Polarity of SPI channel 3. Bit 14 controls the SSB Polarity of SPI channel 2. Bit 13 controls the SSB Polarity of SPI channel 1. Bit 12 controls the SSB Polarity of SPI channel 0. 0 Active Low. 1 Active High.

Table 26-9. eCSPI Config Register Field Description (continued)

Field	Description
11–8 SSB CTRL	The SSB CTL control behavior of SSB for each SPI channel. Bit 11 controls the SSB behavior of SPI channel 3. Bit 10 controls the SSB behavior of SPI channel 2. Bit 9 controls the SSB behavior of SPI channel 1. Bit 8 controls the SSB behavior of SPI channel 0. In Master mode, this bit defines if it is in multiple burst mode when SMC bit is cleared. When SMC bit is set, this bit will be ignored. 0 Single burst Mode. 1 Multiple bursts Mode. In Slave mode, this bit controls when a SPI burst is completed. 0 SPI burst completed when (BURST_LENGTH + 1) bits are received. 1 SPI burst completed when SSB input negated.
7–4 SCLK POL	The SCLK POL control polarity of SCLK for each SPI channel. Bit 7 controls the SCLK Polarity of SPI channel 3. Bit 6 controls the SCLK Polarity of SPI channel 2. Bit 5 controls the SCLK Polarity of SPI channel 1. Bit 4 controls the SCLK Polarity of SPI channel 0. 0 Active high polarity (0 = Idle). 1 Active low polarity (1 = Idle).
3–0 SCLK PHA	The SCLK PHA control data phase of SCLK for each SPI channel. Bit 3 controls the SSB Polarity of SPI channel 3. Bit 2 controls the SSB Polarity of SPI channel 2. Bit 1 controls the SSB Polarity of SPI channel 1. Bit 0 controls the SSB Polarity of SPI channel 0. 0 Phase 0 operation. 1 Phase 1 operation.

26.3.3.5 Interrupt Control Register (INTREG)

The Interrupt Control Register (INTREG) enables the generation of interrupts to the MCU. The reserved bits are always read as zero. Figure 26-7 shows the Interrupt Control register and Table 26-10 shows the register's field descriptions.

0xBASE+0x010 (INTREG) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	TCEN	ROEN	RFEN	RDREN	RREN	TFEN	TDREN	TEEN
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 26-7. Interrupt Control Register Diagram

Table 26-10. Interrupt Control Register Field Descriptions

Field	Description
31–8	Reserved, all bits should read zero.
7 TCEN	Transfer Completed Interrupt enable. This bit enables the Transfer Completed Interrupt. 0 Disable 1 Enable
6 ROEN	RXFIFO Overflow Interrupt enable. The bit enables the RXFIFO Overflow Interrupt. 0 Disable 1 Enable
5 RFEN	RXFIFO Full Interrupt enable. The bit enables the RXFIFO Full Interrupt. 0 Disable 1 Enable
4 RDREN	RXFIFO Data Request Interrupt enable. The bit enables the RXFIFO Data Request Interrupt when number of data in RXFIFO is great than RX WATER MARK when RXTDEN is clear. When RXTDEN is set, it will active as description in Table 26-11. 0 Disable 1 Enable
3 RREN	RXFIFO Ready Interrupt enable. The bit enables the RXFIFO Ready Interrupt. 0 Disable 1 Enable
2 TFEN	TXFIFO Full Interrupt enable. The bit enables the TXFIFO Full Interrupt. 0 Disable 1 Enable
1 TDREN	TXFIFO Data Request Interrupt enable. The bit enables the TXFIFO Data Request Interrupt when number of data in TXFIFO is no more than TX WATER MARK. 0 Disable 1 Enable
0 TEEN	TXFIFO Empty Interrupt enable. The bit enables the TXFIFO Empty Interrupt. 0 Disable 1 Enable

26.3.3.6 DMA Control Register (DMAREG)

The DMA Control Register (DMAREG) provides the user a way to access eCSPI with DMA. The eCSPI sends out DMA requests when the appropriate FIFO conditions are matched. The reserved bits are always read as zero.

Figure 26-8 shows the CNTRL register and Table 26-11 shows the register's field descriptions.

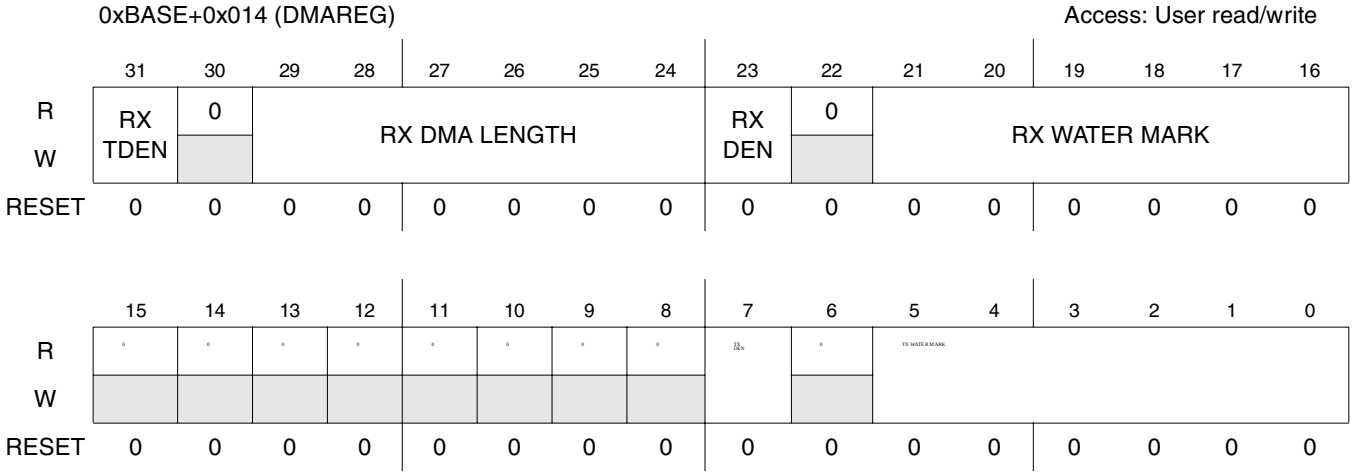

Figure 26-8. DMA Control Register Diagram

Table 26-11. DMA Control Register Field Description

Field	Description
31 RXTDEN	RXFIFO TAIL DMA Request Enable. When this bit is set, a internal counter is enabled and is increased at each read of RXFIFO. The counter will be cleared automatically when it reach RX DMA LENGTH. If number of words remained in RXFIFO is great or equal to RX DMA LENGTH - content of the counter, a DMA request will be generated even if it is less than RX WATER MARK. 0 Disable 1 Enable
30–27	Reserved, all bits should read zero.
26–24 RX DMA LENGTH	RX DMA LENGTH. These bits define how many words will be retrieved in one DMA access cycle. (Only used when RXTDEN is set.)
24 RXDEN	RXFIFO DMA Request Enable. This bit enables/disables the RXFIFO DMA Request. 0 Disable 1 Enable
23–22	Reserved, should be cleared.
21–16 RX WATER MARK	RX WATER MARK. These bits control when eCSPI issue a RX DMA request. A RX DMA/Interrupt request will be issued when number of data in RXFIFO is great than RX WATER MARK.
15–9	Reserved, should be cleared.
8 TXDEN	TXFIFO DMA Request Enable. This bit enables/disables the TXFIFO DMA Request. 0 Disable 1 Enable
7–6	Reserved, should be cleared.
5–0 TX WATER MARK	TX WATER MARK. These bits control when eCSPI issue a TX DMA request. A DMA/Interrupt request will be issued when number of data in TXFIFO is no more than TX WATER MARK.

26.3.3.7 Status Register (STATREG)

The eCSPI Status Register (STATUSREG) reflects the status of the eCSPI module operating condition. The reserved bits are always read as 0. If the eCSPI is disabled, this register reads 0x0000_0003. Figure 26-9 shows the Status register and Table 26-12 shows the register's field descriptions.

0xBASE+0x018 (STATUSREG) Access: User read

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	TC	RO	RF	RDR	RR	TF	TDR	TE
W									w1c	w1c						
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Figure 26-9. Status Register Diagram

Table 26-12. Status Register Field Description

Field	Description
31–8	Reserved, should be cleared.
7 TC	Transfer Completed. When set, this bit indicates current transmission is completed. Writing 1 to this bit clears it. 0 Busy. 1 Transfer Completed.
6 RO	RXFIFO Overflow. When set, this bit indicates that RXFIFO has overflowed.Writing 1 to this bit clears it. 0 RXFIFO is available. 1 RXFIFO has overflowed.
5 RF	RXFIFO Full. This bit is set when the RXFIFO is full (64 words). 0 Not Full. 1 RXFIFO is Full. (64 words)
4 RDR	RXFIFO Data Request. When RXTDE is set, 0 Number of data in RXFIFO is less than RX DMA WATER MARK. 1 Number of data in RXFIFO is great than RX DMA WATER MARK or a DMA TAIL DMA condition is match. When RXTDE is clear, 0 Number of data in RXFIFO is less than RX DMA WATER MARK. 1 Number of data in RXFIFO is great than RX DMA WATER MARK.
3 RR	RXFIFO Ready. This bit is set any time there is one or more words stored in RXFIFO (≥ 1 words). 0 No valid data in RXFIFO. 1 At least 1 word in RXFIFO.
2 TF	TXFIFO Full. This bit is set when if the TXFIFO is full (64 words). 0 TXFIFO is not Full. 1 TXFIFO is Full.

Table 26-12. Status Register Field Description (continued)

Field	Description
1 TDR	TXFIFO Data Request. 0 Number of empty slots in TXFIFO is great than TX DMA WATER MARK. 1 Number of empty slots in TXFIFO is no more than TX DMA WATER MARK.
0 TE	TXFIFO Empty. This bit is set if the TXFIFO is empty. 0 TXFIFO contains one or more words. 1 TXFIFO is empty.

26.3.3.8 Sample Period Control Register (PERIODREG)

The Sample Period Control Register (PERIODREG) provides the user a way to insert delays (wait states) between consecutive SPI transfers. Control bits in this register select the clock source for the sample period counter and the delay count indicating the number of wait states to be inserted between data transfers. Delay counts are only applicable when the eCSPI module is operating in master mode. Also it contains CSD CTRL which is used to insert delay between Chip Select active edge and first SPI Clock edge.

Figure 26-10 shows the Sample Period Control register and Table 26-13 shows the register's field descriptions.

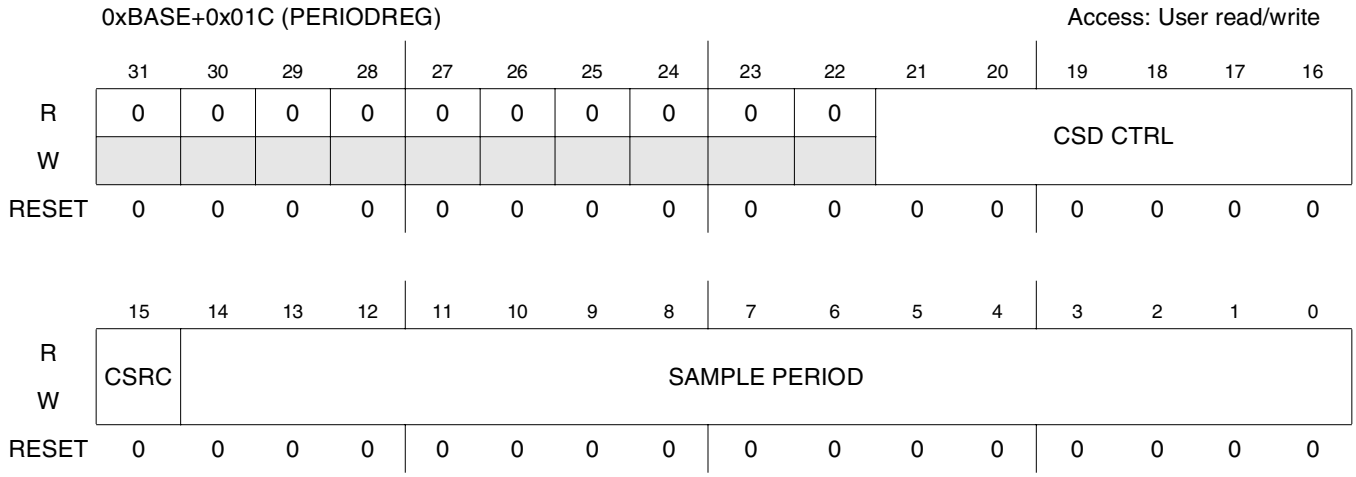

Figure 26-10. Sample Period Control Register Diagram

Table 26-13. Sample Period Control Register Field Description

Field	Description
31–22	Reserved, all bits should read zero.
21-16 CSD CTRL	Chip Select Delay Control bits. These bits define how many SPI clocks will be inserted between chip select active edge and first SPI clock edge.
15 CSRC	Clock Source Control. This bit selects the clock source for the sample period counter. 0 SPI Clock (SCLK) 1 CKIL (32.768 KHz)
14–0 SAMPLE PERIOD	Sample Period Control. These bits define the number of wait states to be inserted between data transfers.

26.3.3.9 Test Control Register (TESTREG)

The Test Control Register (TESTREG) provides the user a mechanism to internally connect the receive and transmit devices of the eCSPI module, display the status of the state machine, monitor the contents of the receive and transmit FIFO, and debug the eCSPI.

Figure 26-11 shows the Test Control register and Table 26-14 shows the register's field descriptions.

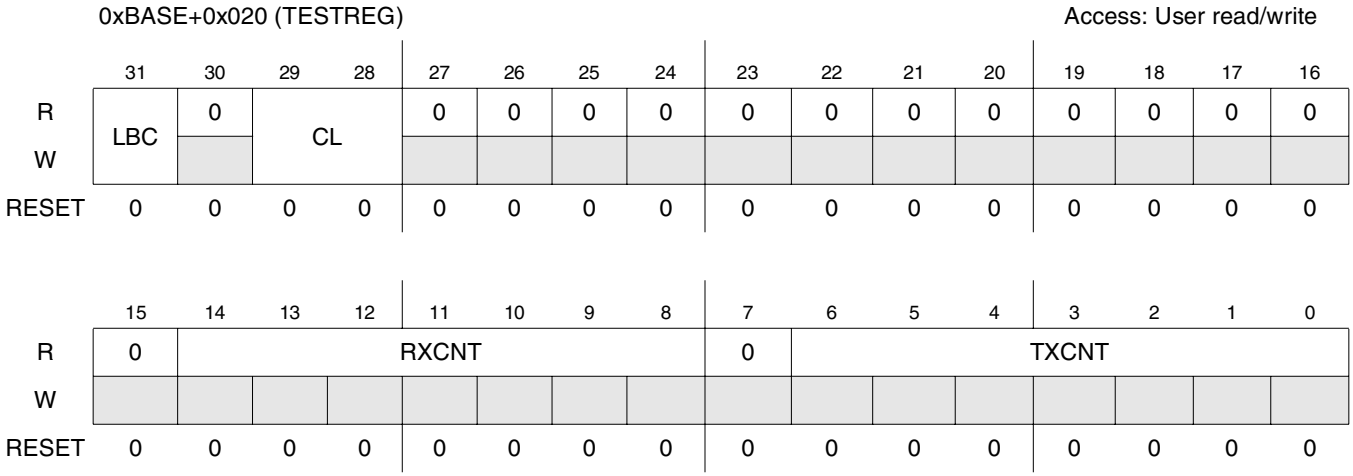

Figure 26-11. Test Control Register Diagram

Table 26-14. Test Control Register Field Description

Field	Description
31 LBC	Loop Back Control. This bit is used in Master mode only. When this bit is set, the eCSPI module connects the transmitter and receiver sections internally, and the data shifted out from the most-significant bit of the Shift register is looped back into the least-significant bit of the Shift register. In this way, a self-test of the complete transmit/receive path can be made. The output pins are not affected, and the input pins are ignored. 0 Not connected. 1 Internally connected.
30	Reserved, all bits should read zero.

Table 26-14. Test Control Register Field Description (continued)

Field	Description
29–28 CL	Catch Latency bits. These bits define the catch latency mode which will give more time on path delay between chip and external Slave devices. 00 Normal mode. 01 The data latch event will be delayed for half SPI clock cycle. 10 The data latch event will be delayed for one SPI clock cycle. 11 The data latch event will be delayed for one and half SPI clock cycle.
27–15	Reserved, all bits should read zero.
14–8 RXCNT	RXFIFO Counter. These bits indicate the number of words in RXFIFO.
7	Reserved, all bits should read zero.
6–0 TXCNT	TXFIFO Counter. These bits indicate the number of words in TXFIFO.

26.3.3.10 Message Data Register (MSGDATA)

The Message Data Register (MSGDATA) forms the top word of 16 × 32 MSG Data FIFO. Only word size operation is allowed for this register. Read to this register will result zero, and write this register will store data into MSGFIFO. Figure 26-12 shows the Message Data Register and Table 26-15 shows the register's field descriptions.The Message DATA FIFO contains message contents that are associated with HT input strobe signals. The content in each slot of MSG Data FIFO will be send out via eCSPI Channel 0 once a pulse edge of associated HT input signal is detected. First slot will be associated with HT input signal 0, the second will be associated with HT input signal1, etc.

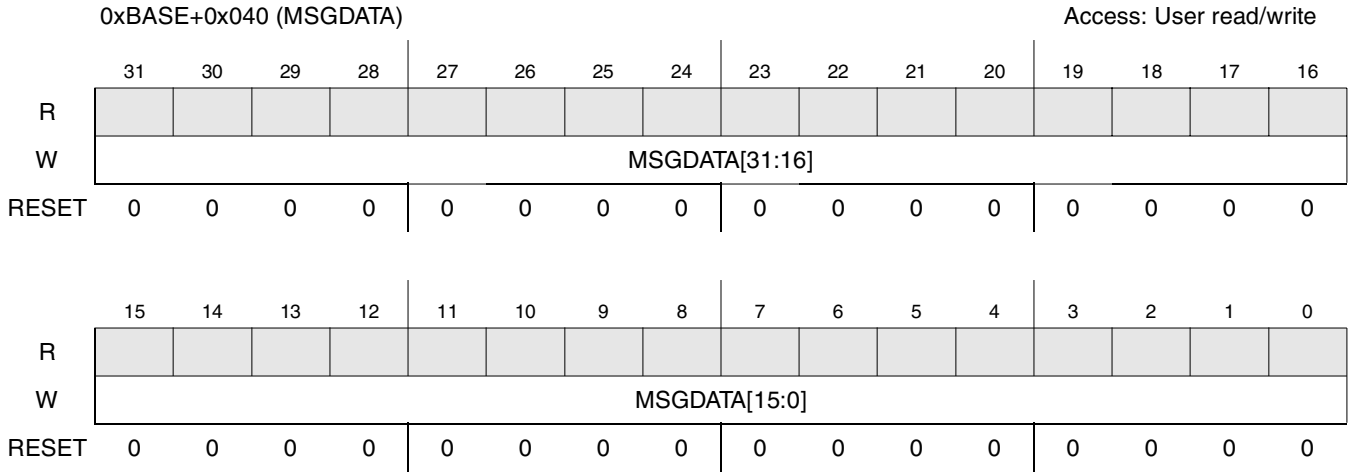

Figure 26-12. Message Data FIFO Diagram

Table 26-15. Message Data FIFO Field Description

Field	Description
31–0 MSGDATA	MSGDATA holds the top word of MSG Data FIFO. The MSG Data FIFO is advanced for each write of this register. The data read is zero. The data write to this register will be stored into MSG Data FIFO.

26.4 Functional Description

This section describes eCSPI module's functionality.

26.4.1 Clocks

There are total four clock sources in eCSPI, as follows:

- ipg_clk_s: used for IP bus read/write operations.
- ipg_clk: used for synchronize signals from ipg_clk_per domain.
- ipg_clk_per: used for baud clock generation and eCSPI operation clock.
- ipg_clk_32k: used for inserting wait states between SPI bursts when CSCR bit is set.

26.4.2 Reset

eCSPI can be reset by either a system (hard reset) or a software reset, as follows:

- For a system (hard) reset, reset eCSPI by asserting ipg_hard_neg_async_reset_b.
- For a software reset, reset eCSPI by clearing CSPI_EN bit in the control register. All registers except the control and config registers reset.

26.4.3 Interrupts

The following three kinds of conditions cause eCSPI to generate an interrupt:

- FIFO status—eCSPI will generate an interrupt which is associated with status of FIFOs. (Enable by set related bits in INT Register and DMA Register.)
- Transmit status—eCSPI will generate an interrupt when SPI bursts are finished.
- Error detected—eCSPI will generate an interrupt when RXFIFO is overflowed.

26.4.4 Endianness

eCSPI only supports little-endian mode.

26.4.5 eCSPI Timing Diagram

Figure 26-13 and Figure 26-14 show the generic eCSPI timing.

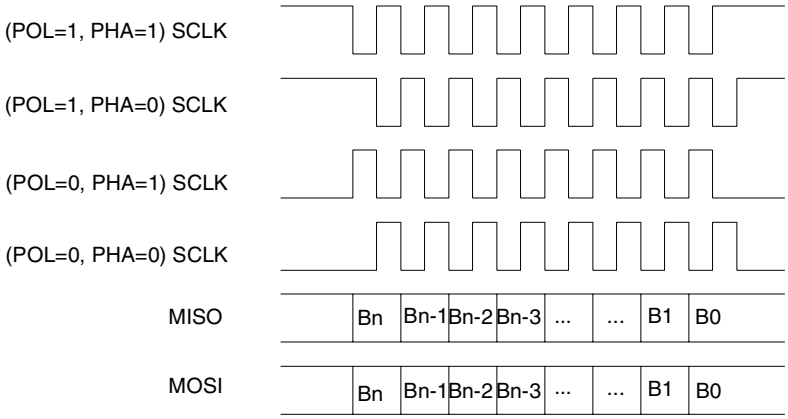

Figure 26-13. eCSPI Generic Timing

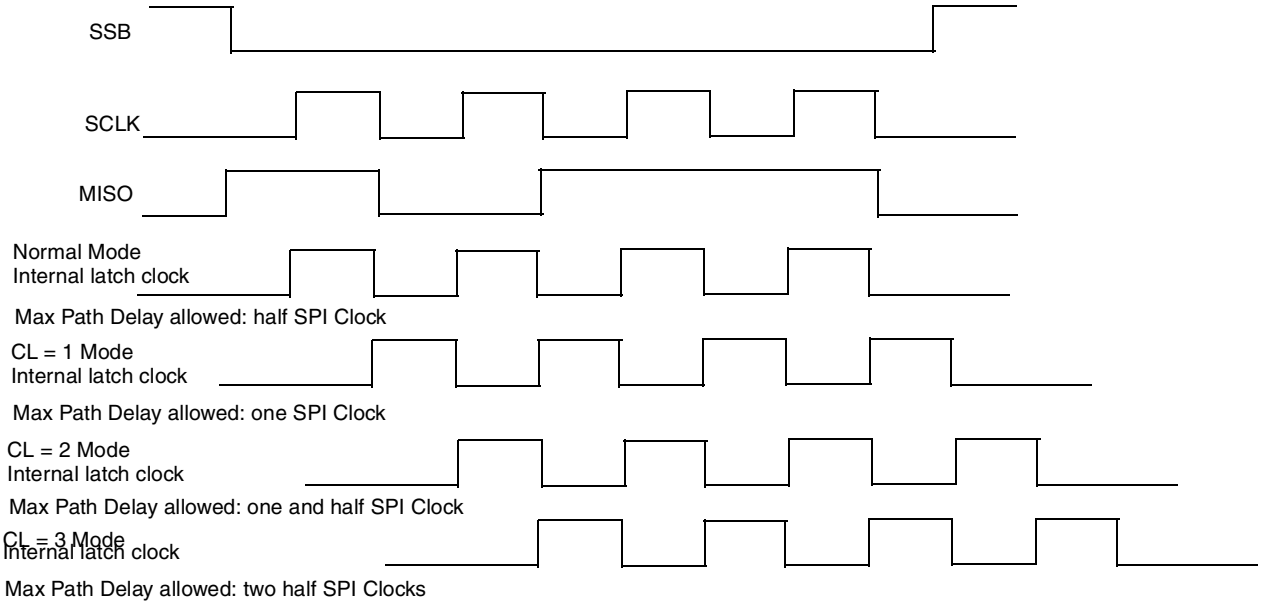

Figure 26-14. eCSPI Catch Latency Control Timing Diagram

26.4.6 Master Mode

The eCSPI master uses the $\overline{SS}$ signal to enable an external SPI device and uses SPICLK to transfer data in and out of the Shift register. The $\overline{SPI\_RDY}$ enables fast data communication with fewer software interrupts. By using PERIODREG, the eCSPI can be used for a fixed data transfer rate.

A SPI burst is defined as a bus transaction that starts when the slave select is asserted and ends when the slave select is deasserted. The SPI clock may not run continuously during the burst depends on status of TXFIFO.

When eCSPI is in Master mode the $\overline{SS}$, SCLK, and MOSI are output signals and the MISO is an input.

Figure 26-15 shows a typical SPI burst.

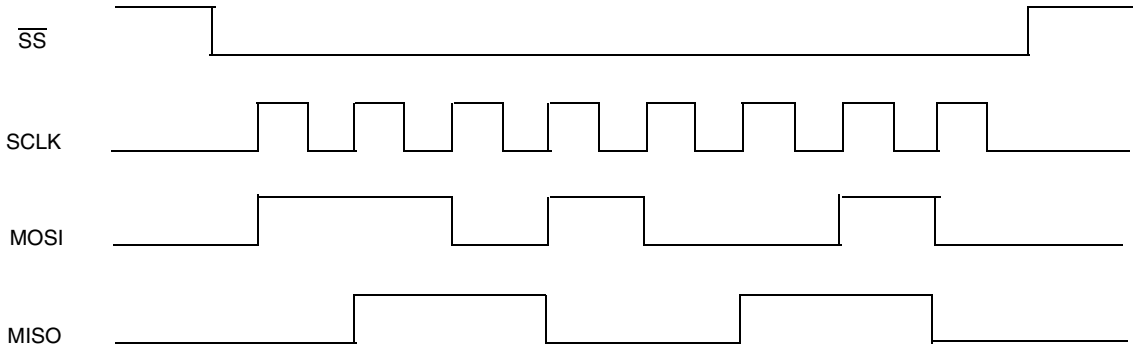

Figure 26-15. Typical SPI Burst (8-bit transfer)

In Figure 26-15, the $\overline{SS}$ signal enables the selected external SPI device and the SCLK synchronizes data transfer. MOSI and MISO are changed on rising edge of SCLK and the MISO is latched on the falling edge of the SLCK clock. The data shifted out is 0xD2, and the data shifted in is 0x66.

26.4.6.1 Master Mode with $\overline{SPI\_RDY}$

A SPI burst begins in master mode when following conditions have been satisfied:

1. When CONTROLREG[DRCTL] is 00 or 11, eCSPI is enabled, TXFIFO contains data, then CONTROLREG[XCH] or CONTROLREG[SMC] is set.
2. When CONTROLREG[DRCTL] is set to 01, a SPI burst will be triggered when a falling edge of $\overline{SPI\_RDY}$ has been detected. (Also condition 1 must be satisfied). Figure 26-16 shows the relationship between a SPI burst and the falling edge of $\overline{SPI\_RDY}$.

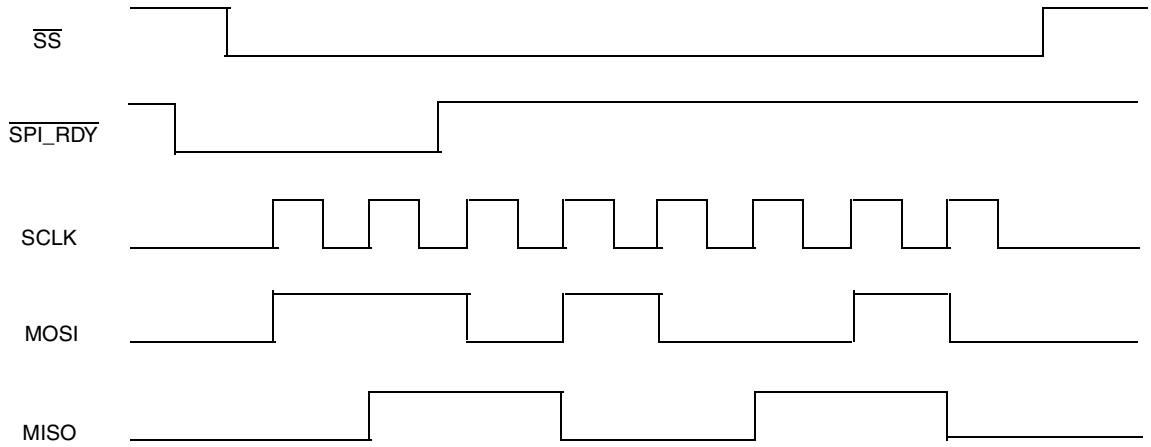

Figure 26-16. Relationship between a SPI Burst and the Falling Edge of SPI_RDY

The next SPI burst does not start until another falling edge of SPI_RDY is detected after the last burst has finished.

3. When CONTROLREG[DRCTL] is set to 10, a SPI burst will be triggered when SPI_RDY is low.(Also condition 1 must be satisfied). Figure 26-17 shows the relationship between a SPI burst and SPI_RDY. The SPI burst does not begin until SPI_RDY goes low. The next SPI burst begins after the last burst has finished if SPI_RDY remains low.

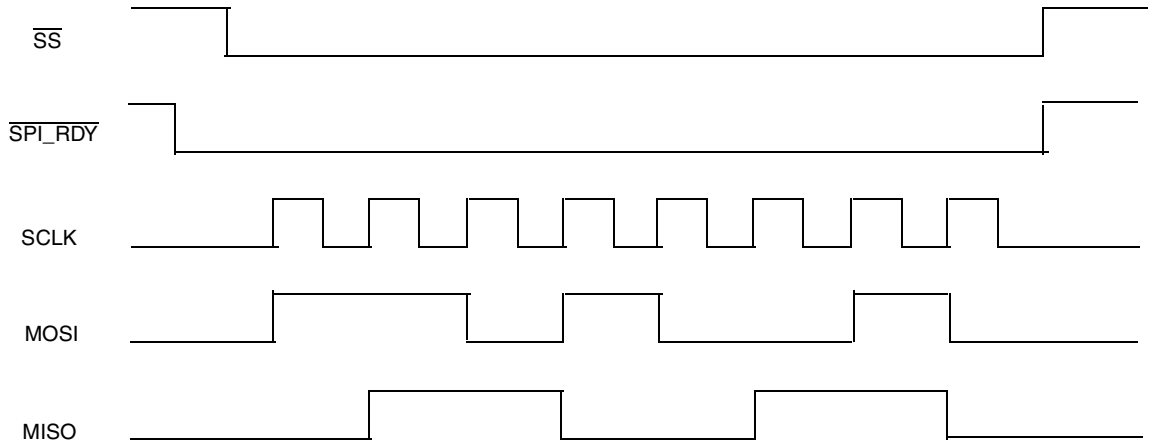

Figure 26-17. Relationship between a SPI Burst and SPI_RDY

26.4.6.2 Master Mode with Wait States

Wait states can be inserted between SPI bursts. This provides a way for the user to slow down the SPI burst to meet the timing requirements of a slower SPI device. Figure 26-18 shows wait states inserted between SPI bursts.

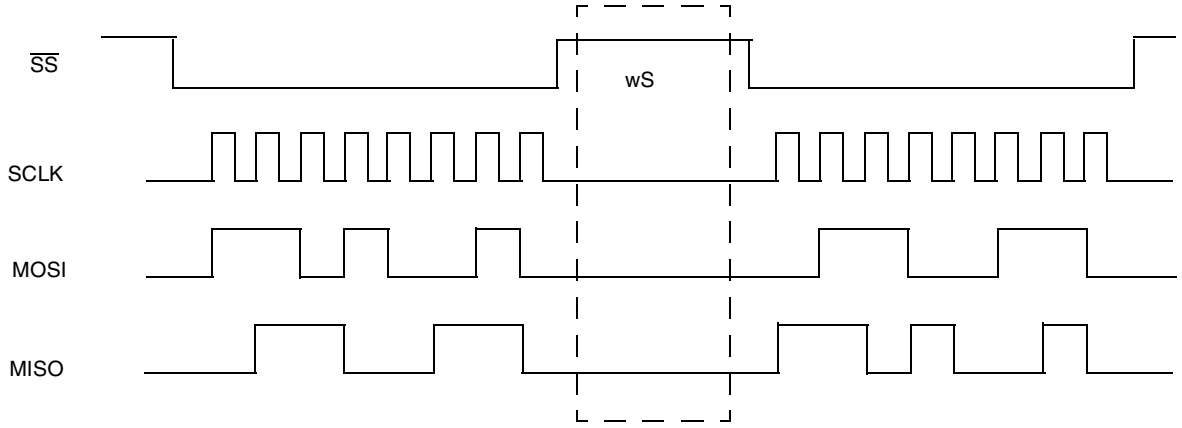

Figure 26-18. SPI Bursts with Wait States

In this case, the number of wait states is controlled by PERIODREG[SAMPLE PERIOD] and the wait states' clock source is selected by PERIODREG[CSRC].

26.4.6.3 Master Mode with CSD

Wait states can be inserted between SSB active and first SPI clock edge. This provides a way for the user to slow down the SPI burst to meet the timing requirements of a slower SPI device. Figure 26-19 shows the detail timing.

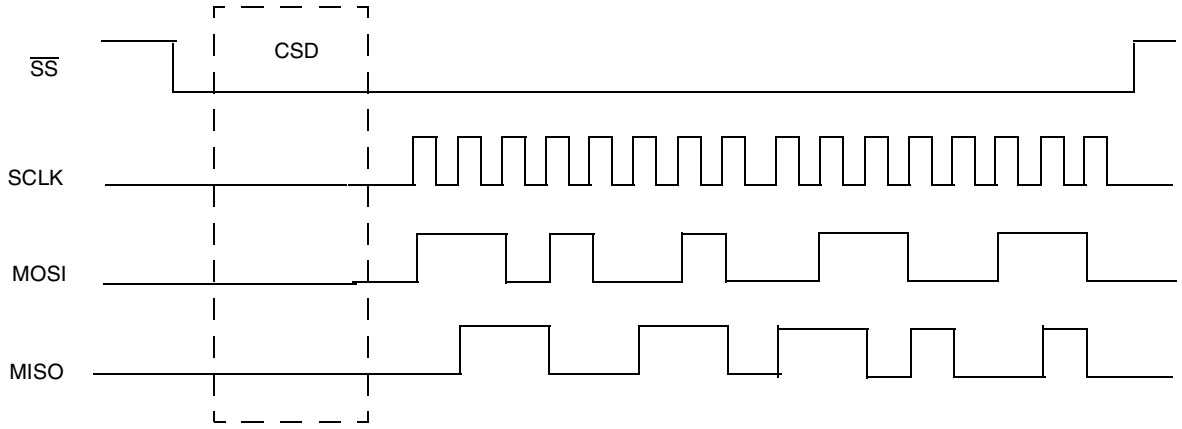

Figure 26-19. SPI Bursts with CSD

In this case, the number of wait states is controlled by PERIODREG[CSD] and the wait states are countered by SPI Clock.

26.4.6.4 Master Mode with SSCTL Control

SSCTL controls whether current operation is a single burst or multiple bursts in master mode. This bit will be ignored when SMC bit is also set. When SSCTL is set, current operation is multiple bursts transfer. When SSCTL is cleared, current operation is single burst transfer. The length of a SPI burst is defined in BURST LENGTH.

Figure 26-20 shows one SPI burst while SSCTL is clear.

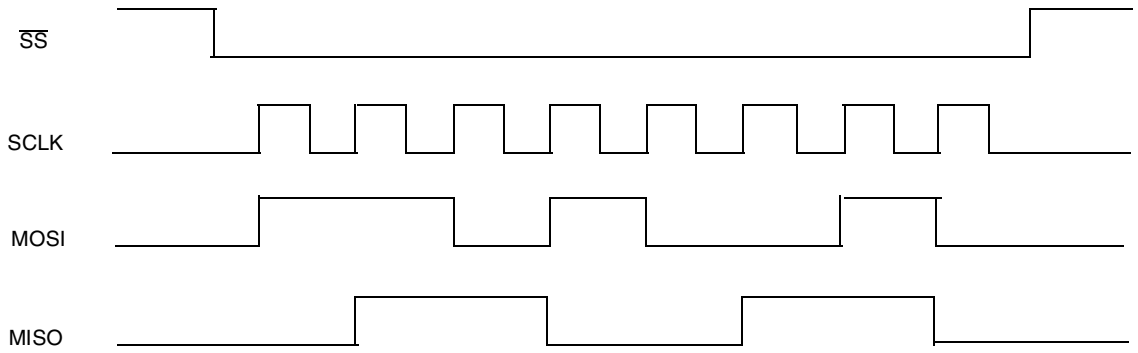

Figure 26-20. SPI Burst while SSCTL is Clear (One Burst)

In this case, two words are combined in one SPI burst and have been transmitted when CONTROLREG[XCH] is set. And CONTROLREG[XCH] is cleared after this SPI burst is completed.

Figure 26-21 shows two SPI bursts are transmitted while SSCTL is set.

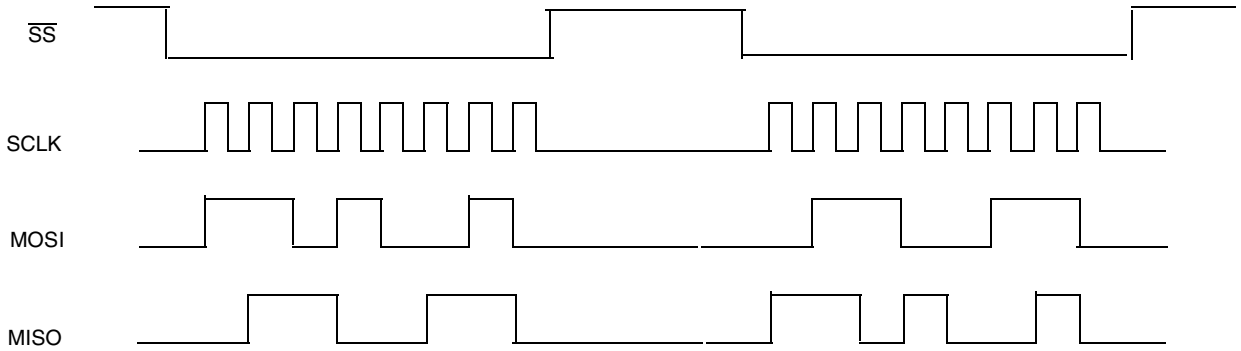

Figure 26-21. SPI Bursts while SSCTL is Set (Multiple Burst)

In this case, two SPI Bursts have been transmitted. When CONTROLREG[XCH] is set, eCSPI starts to transmit data between external device. Since the SSCTL is set, eCSPI will continue the transmission until the TXFIFO is empty. The CONTROLREG[XCH] will also keep set until TXFIFO is empty. If the wait states are inserted between SPI bursts, the SS will negate until the wait states finished. If there is no wait states inserted, the minimum width of SS pulse is 3 SPI clocks.

26.4.6.5 Master Mode with PHA Control

CONTROLREG[PHA] controls how the transmit data shifts out and the receive data shifts in.

When CONTROLREG[PHA] is set, the transmit data will shift out on the rising edge of SCLK, and the receive data is latched on the falling edge of SCLK. The most-significant bit is output on the first rising SPICLK edge.

When CONTROLREG[PHA] is cleared, the transmit data is shifted out on the falling edge of SCLK and the receive data is latched on the rising edge of SCLK. The most-significant bit is output when the CPU loads the transmitted data.

Inverting the SPICLK polarity does not impact the edge-triggered operations because they are internal to the serial peripheral interface master. Figure 26-22 shows a SPI burst using different POL and PHA configurations.

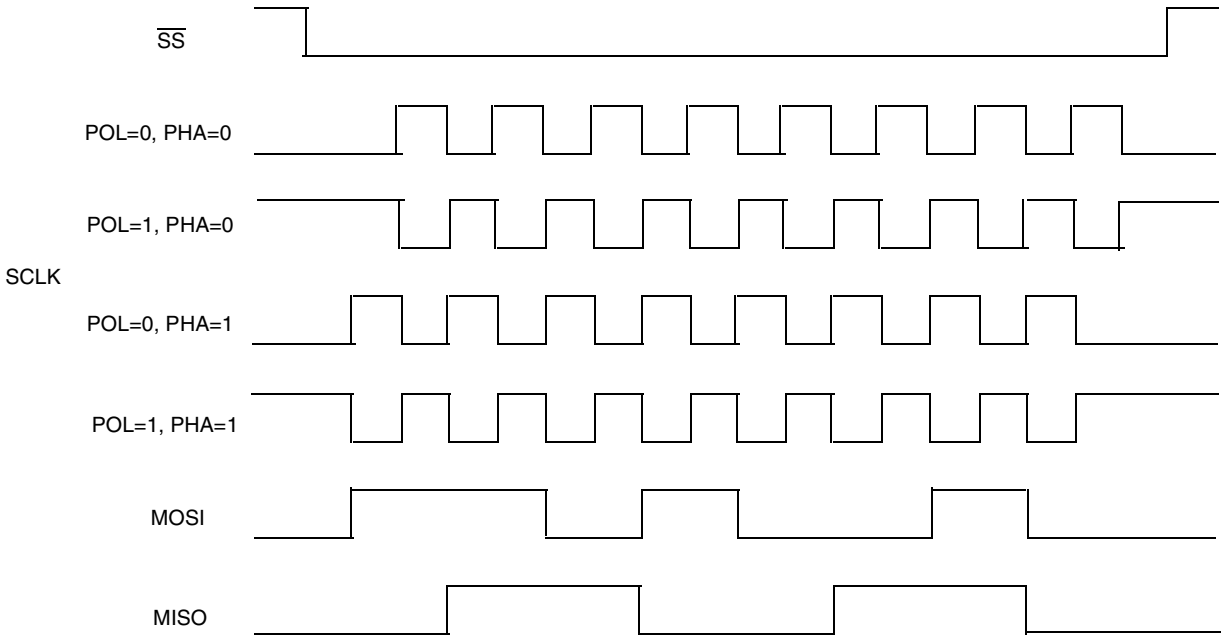

Figure 26-22. SPI Burst with Different POL and PHA Configuration.

26.4.7 Slave Mode

When the eCSPI module is configured as a slave, the user can configure the eCSPI Control register to match the external SPI master's timing. And the frequency of SPI clock input must no higher than quarter of ipg_clk_per's. In this configuration, $\overline{SS}$ becomes an input signal, and is used to latch data into or load data out to the internal data Shift registers, as well as to increment the data FIFO.

The $\overline{SS}$, SCLK, and MOSI are inputs and MISO is output. Most of their timing diagrams are the same as in Master mode, because the inputs come from a SPI master device.

However, it is different when $\overline{SS}$ is used to increment data FIFO. When the SSCTL is set while eCSPI is in Slave mode, the data FIFO will increment at $\overline{SS}$ rising edge (when SSPOL = 1, should be falling edge).

Figure 26-23 shows a SPI burst in which data FIFO is advanced by $\overline{SS}$ rising edge.

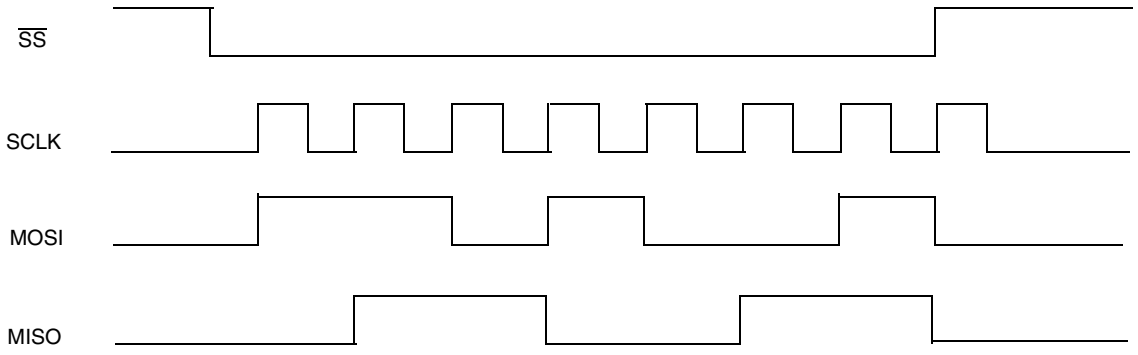

Figure 26-23. Increment Data FIFO by $\overline{SS}$ Rising Edge

In this case, the data received is not 0xD2 but 0x69. Only the most significant 7 bits are loaded to RXFIFO.

26.4.8 Hardware Trigger Mode

When CONTROLREG[HT] is set, eCSPI is enabled with HT Mode. This mode is similar with other master modes. In this mode, the burst length is limited in 32-bit. (Configurable from 1-bit to 32-bit). Also only SPI channel 0 can be used in HT mode. The main difference between HT Mode and other master modes is it's trigger mode. A SPI burst in HT Mode is triggered by HT input strobe signal other than a write to eCSPI register. So the SPI burst can be started with minimal CPU intervention for some timing critical case. In this mode, eCSPI must be configured as master mode. User must store message contents before enable this mode. Also only write operation is supported. Each message content associated with one hardware trigger input signal. Hardware trigger input signal 0 has the highest priority and hardware trigger input signal 15 has lowest priority. For example, in a write operation (16-bit command/data), the Burst Length bit in COFIGREG[HT LENGTH] should be set to 15, and effect data should be stored at least-significant 16-bit of Message Content n Register. CONTROLREG[HT] is set. After a hardware trigger has been detected, a 16-bit SPI Burst will be sent out to external device.

26.5 Initialization Information

This section provides initialization and application information for eCSPI.

Figure 26-24 shows two flow charts for the master and slave mode of operations supported by the eCSPI.

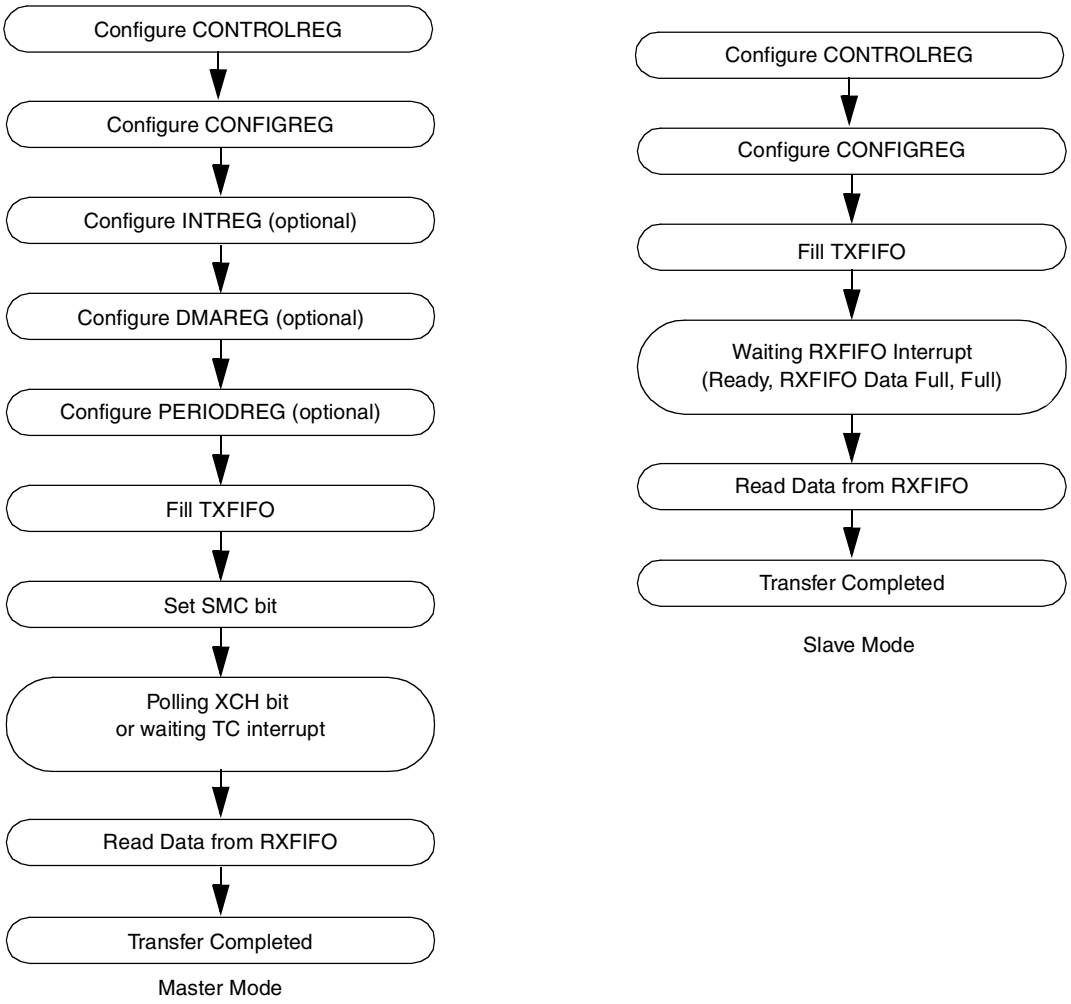

Figure 26-24. Flow Chart of eCSPI Operation

Example 26-1 shows a normal example code of eCSPI operation using C instructions.

Example 26-1. eCSPI Operation using C Instructions

```
//32bit burst, channel 0 is in master mode
mem32_write (eCSPI_CONTROL, 0x01F00011);
//Configure channel 0 to default configuration
mem32_write (eCSPI_CONFIG, 0x00000000);
//Enable interrupt if needed.
mem32_write (eCSPI_INT, 0x00000000);
//Enable DMA if needed
mem32_write (eCSPI_DMA, 0x00000000);
//Enable inserting wait states if needed
mem32_write (eCSPI_PERIOD, 0x00000000);
//Fill data into TXFIFO by instruction
for (i = 0; i <= 7; i = i + 1) {
 mem32_write (eCSPI_TXFIFO, 0x12345678 + i * 0x11223344);
}
```

```
//Set SMC bit to start transfer
mem32_write (eCSPI_CONTROL, 0x01F00019);
//Polling TC bit
while ((mem32_read (eCSPI_STATUS) & 0x80) == 0);
for (i = 0; i <= 7, i = i + 1) {
 mem32_read (eCSPI_RXFIFO);
.....                                  //Compare with expected value.
}
```

26.6 Application Information

This section discusses the following: interrupt control and DMA control.

26.6.1 Interrupt Control

Interrupt control is not a specific mode of operation; however, it provides a basic method to utilize the eCSPI FIFOs.

The eCSPI can be programmed to enable the TXFIFO empty, TXFIFO Data Request, and TXFIFO full interrupt. The interrupt service routine can also be used to fill the TXFIFO with data to be transferred. Furthermore, RXFIFO ready, RXFIFO Data Request, and RXFIFO full can be enabled to retrieve data from RXFIFO by using the interrupt service routine.

Three other interrupt sources can be used to control/debug the SPI bursts. The transfer-completed interrupt tells the user that there is no data left in TXFIFO and the data in the Shift register is shifted out. The RXFIFO overflow interrupt tells the user that the RXFIFO received more than 64 words and will not accept any other word.

Figure 26-25 shows a program sequence of SPI bursts using interrupt.

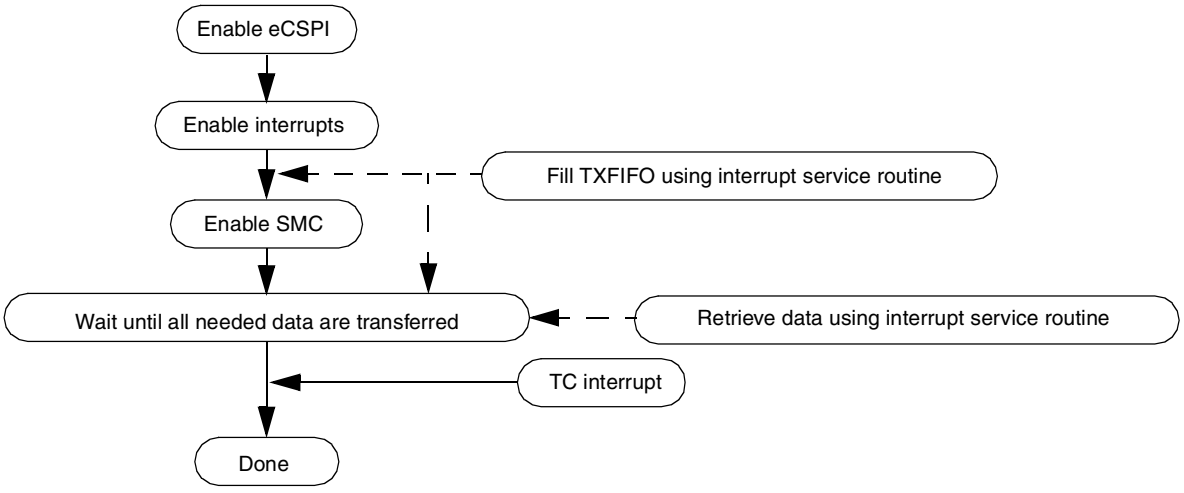

Figure 26-25. Program Sequence of SPI Burst Using Interrupt

26.6.2 DMA Control

DMA control provides another way to utilize the FIFOs in the eCSPI module. Peripherals that support DMA, such as the eCSPI, use DMA request and acknowledge signals. Larger amounts of data can be transferred using DMA control, thereby reducing interrupts and CPU loading. When the appropriate conditions are matched, the module sends out a DMA request, and the DMA deals with the following cases: TXFIFO empty, TXFIFO Data Request, RXFIFO Data Request, and RXFIFO full.

Figure 26-26 shows a program sequence of SPI bursts using the DMA.

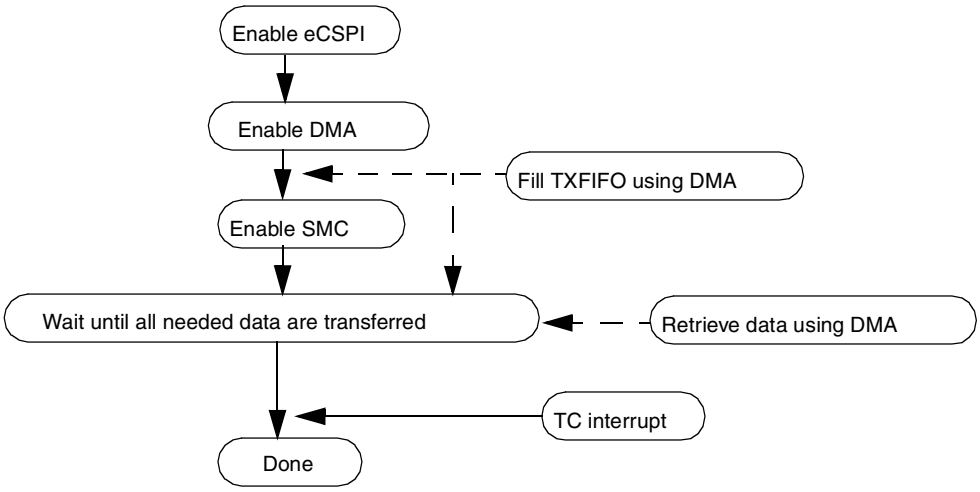

Figure 26-26. Program Sequence of SPI Burst Using DMA

Chapter 27
External Memory Interface (EMI)

27.1 Introduction

The EMI is a memory controller of memory devices in the system, both internal and external. It provides a capability for the system to control the external memory device, by preforming several type of accesses like read, write, program, and erase as well as internal memories of the system. All access from the system to a memory device are arbitrated inside EMI by M4IF submodule to the correct memory controller to perform the access. The high-level block diagram is presented in Figure 27-1.

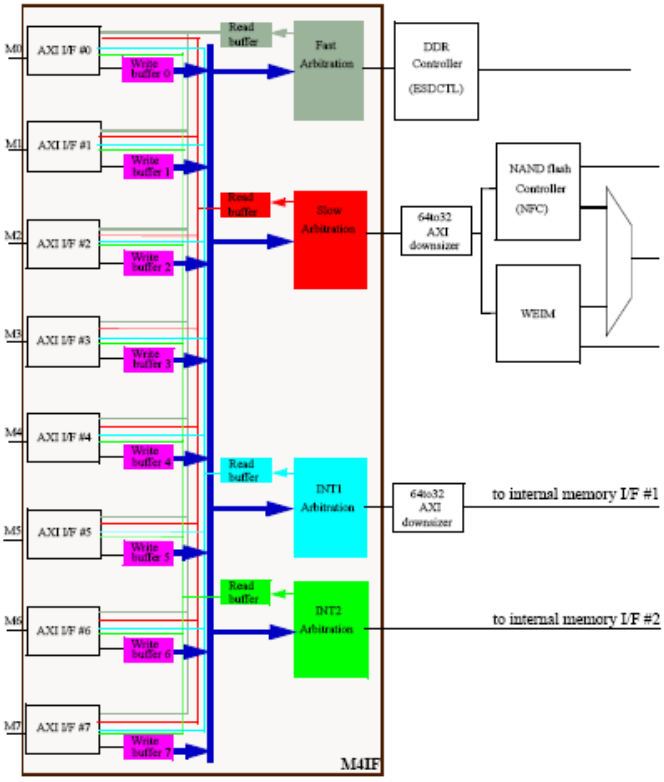

Figure 27-1. EMI Block Diagram

27.1.1 Overview

The EMI is an external memory interface with arbitration logic between multiple AXI masters to multiple memory controllers. It is divided into four major channels: a fast memories channel (Mobile SDR/DDR

SDRAM), a slow memories channel (NOR-FLASH/PSRAM/NAND-FLASH, and others.), and two internal memory channels (RAM, ROM).

To increase performance, the EMI separates the buffering and arbitration between accesses to fast channel slow channel and internal memory channels. Therefore, parallel accesses can occur. By separating these three channels, slow accesses do not interfere with fast accesses. EMI has been designed so that accesses by a slow master with a narrow bus do not block the access by a fast master with a wide bus.

27.1.2 Features

The EMI module includes the following features:

- Multi Master Multi Memory Interface (M4IF)
  - Supports multiple accesses from 8 masters through different input ports interfaces. Each port can support either of the following two data width options:
    - ×32 AXI port.
    - ×64 AXI port.
  - Supports different clock domains for each AXI port master.
  - Configurable memory snooping.
  - Configurable memory watermark protection per CS
  - Enhanced arbitration scheme for fast channel, consider page hit/miss, last access details(read/write), and fixed priority configuration.
- Enhanced SDRAM Controller (ESDRAMC) or LPDDR Controller (LPDDRC)
  - Up to 2 chip selects supporting up to 256 MByte each.
  - ×64 AXI port.
  - Support for ×16/×32 SDR SDRAM at clock frequencies up to 133 MHz.
  - Support for ×16/×32 LPDDR/Non-mobile DDR1 SDRAM at clock frequencies up to 166 MHz (DDR333).
  - Supports latency hiding logic.
- NANDFlash Controller—(NFC)
  - Supported pages sizes are ½ Kbyte, 2 Kbytes, and 4 Kbytes
  - Pages per blocks supported are 32, 64, 128, and 256
  - Up to 6 address cycles
  - 4.5K RAM Internal Buffer
  - MLC and SLC memory support.
  - Configurable operation mode - symmetric and asymmetric.
  - Configurable page mode, ½ Kbyte, 2 Kbytes, and 4 Kbytes
  - ECC support up to 8 bit.
  - Support of up to 8 mutually exclusive, yet interleaved..
- Wireless External Interface Memory Controller—(WEIM)
  - Up to 6 chip selects.

- Support ×32/×16 PSRAM (up to 133 MHz).
- support ×32/×16 muxed mode PSRAM/NOR (up to 133 MHz).
- Support ×32/×16 NOR (up to 133 MHz).

- Support DVFS, voltage, and frequency change.
- Support watermark configuration.
- Enhanced debug capability

27.1.3 Modes of Operation

The following sub sections describes several operation modes of EMI. For more information about the operation modes of each submodule in EMI, please refer to the “Modes of Operation” section in each submodule chapter.

27.1.3.1 Low-Power Modes

SoC system control provides an LPM request signal to EMI in order to let EMI enter into low-power mode. At the end of low-power mode sequence, EMI sends back an acknowledge signal to inform the system it entered into low-power mode.

In this mode, all internal clocks in EMI and its submodules are disabled by the system clock controller. Low-power mode definition is described in more details in each submodule separately.

27.1.3.2 Debug Mode

Several internal signals are routed out by the EMI debug unit to give the SoC the capability to track the internal logic mainly for the arbitration mechanism and memory served accesses. The debug unit and its debug signals are described in the M4IF chapter.

27.1.3.3 DVFS Support

EMI provides a real-time support of voltage and/or frequency change to its memory controllers. There is a handshake mechanism between EMI and the system so that the EMI is informed of any frequency change that is to be made in the system. When this handshake signal is sent to EMI, it stops all access to the external/internal memories controllers (READY signal of the memory controller will be set to LOW) and finishes any served access in the memory controller.

After that, the frequency change routine inside EMI is active so that at the end of the routine an acknowledge would be sent to inform a change clock frequency is allowed. At the moment the frequency was changed, the system should lower the handshake signal to EMI which means the frequency change is done. EMI would force a new measure in the delay line and move back to idle after the measure unit is updated with the new value (ready signals of the memory controlers will return to HIGH).

Please refer to each EMI submodule for detailed description of DVFS support.

Voltage change should be supported on the fly based on trigger signal from the system that inform EMI on a voltage change in the system. As a result, EMI would higher the measurement rate to allow better tracking of the voltage change and to allow system functionality in parallel to voltage change. When the

voltage change is done, the system lowers the trigger to EMI so that the measurement rate can be changed back to its default mode.

More details on delay line and measurement unit can be found in the “ESDCTL Spec” chapter.

27.1.3.4 Power Saving Mode

The EMI design supports few power saving modes other than LPMD. The M4IF module provides information about whether there are or are not pending requests on a certain arbitration when was the last request in this arbitration etc. Based on that info, both the specific arbitration and its correspond memory controller, would be able to enter power saving modes like Self refresh and Auto Self refresh in ESDCTL memory controller.
In this mode, each arbitration path is considered as a separate domain so that in a certain time internal memory path can be in power saving mode while DDR memory path will continue to work. It is important to mention that each power saving mode would leave an active logic to be able to get out of this mode whenever a new access arrives. In this case it would take few more cycles to serve the request since getting out of power saving mode routine is taking place first.

A quiet similar to that mechanism there is a similar mechanism on each of M4IF gaskets. M4IF can automatically shut off the clock of a specific gasket based on internal timer that counts a certain number of idle cycle.

Please refer to M4IF Chapter for more details on Power Saving mode.

27.1.3.5 SRPG Mode

EMI support SR Power gating mode. In this mode even when the power is gated off, several registers configuration in the memory controllers module will be kept so that when getting out of this mode the controller will be configured with the same values as it was before gating off the power. The following section list the register names that will be of SRPG type.

27.1.3.5.1 SRPG Register List

The following registers in ESDCTL module will be of SRPG type:

- ESDCTL0
- ESDCTG0
- ESDMISC

This configuration will give the ability to keep CS0 configuration as it was before gating off the power. Other CS will be disabled and will return to reset state.

The following registers in WEIM module will be of SRPG type:

- CS0GCR1
- CS0GCR2
- CS0RCR1
- CS0RCR2
- CS0WCR

- WIAR
- CS0WCR2

This configuration will give the ability to keep CS0 configuration as it was before gating off the power. Other CS will be disabled and will return to reset state.

Entering into SRPG mode should go through LPMD mode first, this is essential to the memory controller for right operation.

There are several registers in M4If which are SRPG type as well, mainly to support correct functionality after power gating.

27.2 Sharing of I/O Pins

The EMI module does not contain any I/O pins sharing or muxing between different arbitration paths. The only I/O sharing is done inside each arbitration/memory controller path, such as DDR and SDR I/O pin sharing or WEIM and NFC I/O pin sharing.

DDR and SDR I/O pin sharing is described in the ESDCTL chapter. WEIM and NFC I/O pin sharing is described below.

27.2.1 WEIM and NFC I/O Pin Sharing

The EMI contains an IOMUX submodule to be able to share 16-bits DATA pins of WEIM and NFC (slow arbitration). In order to be able to share data bus between these two memory controllers, data_dir signals areas are also muxed. The IOMUX module muxs between data BGA contacts of WEIM and NFC on the output path only, based on which memory controller owns the bus for the specific transaction.

WEIM's CRE signal is muxed inside the WEIM with one of the 24th–27th bits of the WEIM address, but only with the one that must be the highest available bit of the address and that is defined by the value of 4 vias bit_24_cre_via...bit_27_cre_via). For additional details on the WEIM_CRE signal, please refer to the WEIM Chapter.

Figure 27-2 shows data BGA contact sharing functionality between WEIM and NFC.

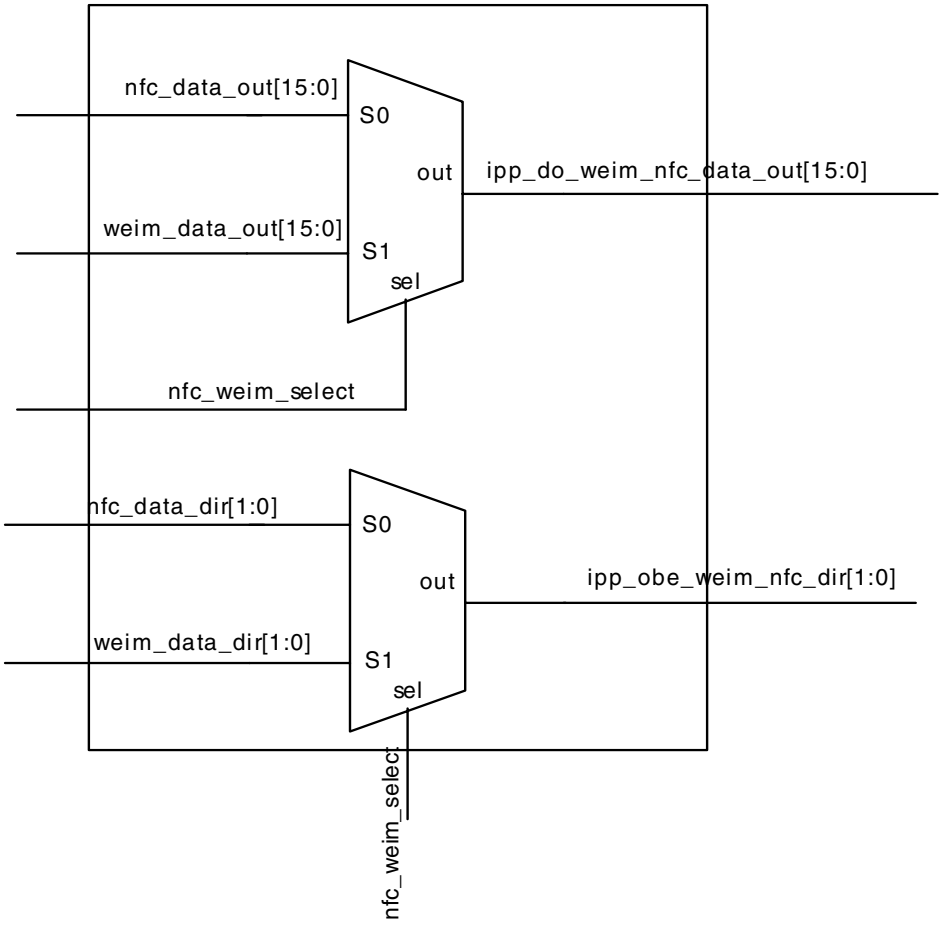

Figure 27-2. EMI IOMUX

The sharing control logic is based on the fix priority arbitrating between WEIM and NFC. WEIM has the priority on the external bus whenever there is a conflict between WEIM and NFC. However, when NFC is using the bus and WEIM access is issued in parallel, NFC frees up the bus after number of clock cycles depend on the specific command/access type is currently served in NFC. No specific time period is guaranteed for NFC to free up the bus for WEIM pending access.

27.2.2 WEIM/NFC Arbitration Logic

As was mentioned above there is a fixed priority between WEIM and NFC. The arbitration between these modules is done by a request and acknowledge signals from both modules.

NFC has two signals, a request signal from WEIM and an acknowledge signal to WEIM. Whenever NFC uses the bus it leaves the ack signal low until it finishes the transaction. If NFC does not use the bus, its ack signal will be high.

On the other side, WEIM has two signals as well, weim_grant and weim_busy. Whenever WEIM issues an access on the external bus, it needs to get weim_grant signal as high to enable its priority on the bus. If weim_grant is high, WEIM can issue the access and it is guaranteed NFC is not using the bus. Whenever WEIM gets an AXI access request it must assert weim_busy. weim-busy must remain asserted as long as the transaction isn't completed (also during the time the WEIM is waiting for weim_grant to be asserted).

Figure 27-3 is an high level scheme of the sub modules connectivity in EMI.

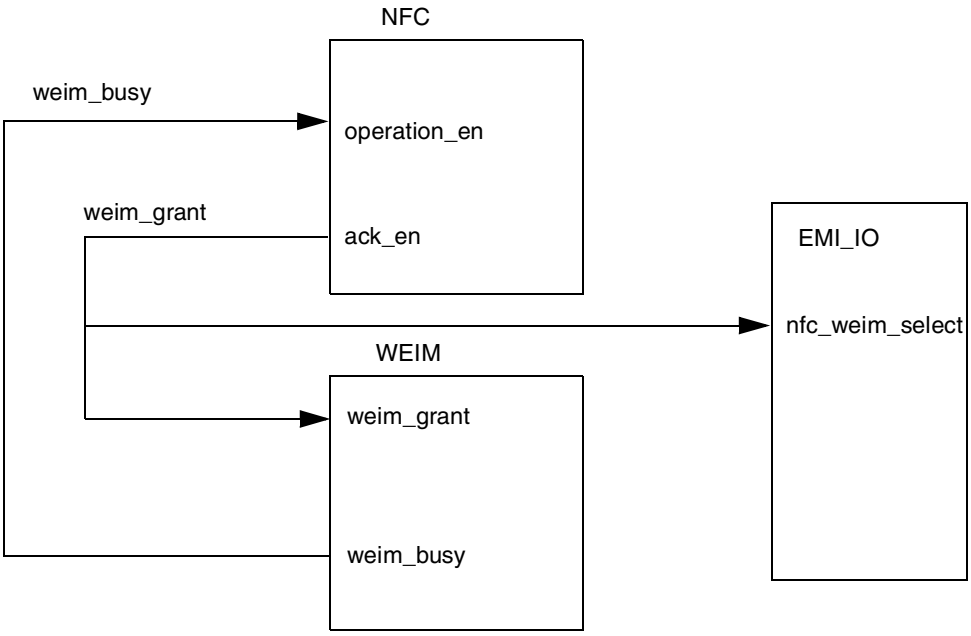

Figure 27-3. WEIM/NFC Arbitration Signals

27.3 External Signal Description

This section describes the signals that do, or may, connect off chip, and use a BGA contact. Table 27-2 describes the signal list of EMI off chip interface.

Table 27-1. EMI Signal Properties

awsize_m4[1:0]	Master axi write burst size	Input

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
awsize_m5[1:0]	Master axi write burst size	Input
awsize_m6[1:0]	Master axi write burst size	Input
awsize_m7[1:0]	Master axi write burst size	Input
awvalid_m0	Master axi write addr valid	Input
awvalid_m1	Master axi write addr valid	Input
awvalid_m2	Master axi write addr valid	Input
awvalid_m3	Master axi write addr valid	Input
awvalid_m4	Master axi write addr valid	Input
awvalid_m5	Master axi write addr valid	Input
awvalid_m6	Master axi write addr valid	Input
awvalid_m7	Master axi write addr valid	Input
bist_clk_en	NFC bist clock enable	Input
bit_24_cre_via	CRE on 24th weim's address bit	Input
bit_25_cre_via	CRE on 25th weim's address bit	Input
bit_26_cre_via	CRE on 26th weim's address bit	Input
bit_27_cre_via	CRE on 27th weim's address bit	Input
boot_cnfg[11:0]	weim via	Input
bp_via[4:0]	EMI IPMUX dsp via	Input
bready_m0	Master axi response ready	Input
bready_m1	Master axi response ready	Input
bready_m2	Master axi response ready	Input
bready_m3	Master axi response ready	Input
bready_m4	Master axi response ready	Input
bready_m5	Master axi response ready	Input
bready_m6	Master axi response ready	Input
bready_m7	Master axi response ready	Input
clk32	32 KHz clock in	Input
dftrst_as_528x32_b	NFC bist signal	Input
dvfs_req	emi dvfs req. from sys.	Input
dvfs_req_fast	emi dvfs req - fast arbitration	Input
dvfs_req_int2	emi dvfs req - internal2 arbitration	Input
dvfs_req_intr	emi dvfs req - internal arbitration	Input
dvfs_req_slow	emi dvfs req - slow arbitration	Input

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
ect_out	external debug enable in the M4IF	Input
edt_clock	Test Kompress signal - added manually to EMI.v	Input
edt_update	Test Kompress signal - added manually to EMI.v	Input
edt_reset	Test Kompress signal - added manually to EMI.v	Input
edt_bypass	Test Kompress signal - added manually to EMI.v	Input
emi_iso	SRPG signals	Input
emi_pd	SRPG signals	Input
emi_pgrst	SRPG signals	Input
emi_short_b	SRPG signals	Input
EMI_spare_ports_in[49:0]	Spare Input ports	Input
endianess_m0	Master Endian	Input
endianess_m1	Master Endian	Input
endianess_m2	Master Endian	Input
endianess_m3	Master Endian	Input
endianess_m4	Master Endian	Input
endianess_m5	Master Endian	Input
endianess_m6	Master Endian	Input
endianess_m7	Master Endian	Input
esdctl_base[3:0]	ESDCTL base address	Input
esdctl_warm_reset	warm reset req. for esdctl	Input
int_mem_arready_1	internal mem read addr ready	Input
int_mem_awready_1	internal mem write addr ready	Input
int_mem_arready_2	internal2 mem read addr ready	Input
int_mem_awready_2	internal2 mem write addr ready	Input
int_mem_base_a[3:0]	internal memory base address a area	Input
int_mem_base_b[3:0]	internal memory base address b area	Input
int_mem_bid_1[3:0]	Internal Mem response id	Input
int_mem_bid_2[3:0]	Internal2 Mem response id	Input
int_mem_bresp_1[1:0]	internal mem write response	Input
int_mem_bresp_2[1:0]	internal mem write response	Input
int_mem_bvalid_1	internal mem response valid	Input
int_mem_bvalid_2	internal2 mem response valid	Input
int_mem_end_a[3:0]	internal memory end a address	Input

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
int_mem_end_b[3:0]	internal memory end b address	Input
int_mem_rid_1[3:0]	internal mem read id 1	Input
int_mem_rid_2[3:0]	internal mem read id 2	Input
int_mem_rlast_1	internal mem read last	Input
int_mem_rvalid_1	internal mem read valid	Input
int_mem_rlast_2	internal2 mem read last	Input
int_mem_rvalid_2	internal2 mem read valid	Input
int_mem_wready_1	internal mem write ready	Input
int_mem_wready_2	internal2 mem write ready	Input
int2_mem_arready	internal2 mem read addr ready	Input
int2_mem_awready	internal2 mem write addr ready	Input
int2_mem_base[3:0]	internal memory base address area	Input
int2_mem_bid3:0]	Internal2 Mem response id	Input
int2_mem_bresp[1:0]	internal2 mem write response	Input
int2_mem_bvalid	internal2 mem response valid	Input
int2_mem_end[3:0]	internal2 memory end a address	Input
int2_mem_rid[3:0]	internal2 mem read id	Input
int2_mem_rlast	internal2 mem read last	Input
int2_mem_rvalid	internal2 mem read valid	Input
int2_mem_wready	internal2 mem write ready	Input
ipg_clk_s	IP Clock in.	Input
ipp_flash_clk	flash clock	Input
ipp_ind_dtack_b	WEIM dtack signal	Input
ipp_ind_emi_dqs[3:0]	esdctl dqs_in	Input
ipp_ind_esdctl_data[31:0]	esdctl data in	Input
ipp_ind_esdctl_scan_address[14:0]	scan signal	Input
ipp_ind_esdctl_scan_cas_b	scan signal	Input
ipp_ind_esdctl_scan_csd0	scan signal	Input
ipp_ind_esdctl_scan_csd1	scan signal	Input
ipp_ind_esdctl_scan_dqm[3:0]	scan signal	Input
ipp_ind_esdctl_scan_ras_b	scan signal	Input
ipp_ind_esdctl_scan_sdba	scan signal	Input
ipp_ind_esdctl_scan_sdcke[1:0]	scan signal	Input

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
ipp_ind_esdctl_scan_sdclk	scan signal	Input
ipp_ind_esdctl_scan_we_b	scan signal	Input
ipp_ind_esdctl_sdclk_fb	esdctl feedback clk	Input
ipp_ind_fb_bclk	weim feedback clk	Input
ipp_ind_rdy_int	weim rdy	Input
ipp_ind_read_data[31:0]	weim input data	Input
ipp_ind_read_maddr_data[15:0]	upper 16 bits of muxed mode read data	Input
ipp_ind_wait_b	weim wait signal	Input
ipp_nfc_rb0_in	nfc NF_RB0	Input
ipp_nfc_rb1_in	nfc NF_RB1	Input
ipp_nfc_rb2_in	nfc NF_RB2	Input
ipp_nfc_rb3_in	nfc NF_RB3	Input
ipp_nfc_rb4_in	nfc NF_RB4	Input
ipp_nfc_rb5_in	nfc NF_RB5	Input
ipp_nfc_rb6_in	nfc NF_RB6	Input
ipp_nfc_rb7_in	nfc NF_RB7	Input
ipp_nfc_read_data_in[15:0]	nfc data in	Input
ipp_nfc_reset_b	NFC POR	Input
ips_addr[15:2]	IP Address	Input
ips_master_id[4:0]	Master ID for IP access	Input
ips_module_en	IP module enable	Input
ips_rwb	IP read/write command	Input
ips_wdata[31:0]	IP write data	Input
ipt_last_shift_en	enable support for last-shift	Input
ipt_mode	scan mode	Input
ipt_port_sel	scan signal to emi io muxing	Input
ipt_ram_se	NFC membist signal	Input
ipt_se	scan enable	Input
ipt_se_async	scan enable async mode	Input
ipt_se_gatedclk	scan enable gated clock	Input
ipt_si[19:0]	scan in bus	Input
lpack_int_mem_1	Low Power acknowledge from internal reg. 1	Input
lpack_int_mem_2	Low Power acknowledge from internal reg. 2	Input

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
lpack_int2_mem	Low Power acknowledge from internal2	Input
lpmd	EMI low power mode req	Input
lpmd_fast	Fast arbit. low power mode req	Input
lpmd_int2	Internal2 mem arbit. arbit. low power mode req	Input
lpmd_intr	Internal mem arbit. arbit. low power mode req	Input
lpmd_slow	Slow arbit. low power mode req	Input
nf16boot_b	Boot from 16 bit NAND Flash	Input
nf8boot_b	Boot from 8 bit NAND Flash	Input
nf_16bit_sel	Use 8 or 16 bits Nand Flash	Input
nf_boot_with_reset	selects first command in boot sequence (reset command or read command)	Input
nfc_fms[1:0]	Flash Memory Select (512B/2KB/4KB page size)	Input
nfc_mem_pd	NFC internal RAM power down	Input
nfc_warm_reset	NFC warm reset signal	Input
rm_def_as_528x32_b[3:0]	NFC bist signal	Input
rready_m0	Master's Axi read ready.	Input
rready_m1	Master's Axi read ready.	Input
rready_m2	Master's Axi read ready.	Input
rready_m3	Master's Axi read ready.	Input
rready_m4	Master's Axi read ready.	Input
rready_m5	Master's Axi read ready.	Input
rready_m6	Master's Axi read ready.	Input
rready_m7	Master's Axi read ready.	Input
rresp_in_intr[1:0]	rresp from axi to m4if	Input
se_as_528x32_b	NFC bist signal	Input
si_as_528x32_b	NFC bist signal	Input
vl_sms_proc_emi_sms_1_capture_wr	bist signals	Input
vl_sms_proc_emi_sms_1_dm0	bist signals	Input
vl_sms_proc_emi_sms_1_dm1	bist signals	Input
vl_sms_proc_emi_sms_1_rst_sms_n	bist signals	Input
vl_sms_proc_emi_sms_1_run_bist	bist signals	Input
vl_sms_proc_emi_sms_1_select_wir	bist signals	Input
vl_sms_proc_emi_sms_1_shift_wr	bist signals	Input

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
vl_sms_proc_emi_sms_1_smart	bist signals	Input
vl_sms_proc_emi_sms_1_update_wr	bist signals	Input
vl_sms_proc_emi_sms_1_wrck	bist signals	Input
vl_sms_proc_emi_sms_1_wrstn	bist signals	Input
vl_sms_proc_emi_sms_1_wsi	bist signals	Input
volt_chng	Voltage change input to esdctl	Input
wdata_fast[63:0]	Fast arbit. wdata bus from m4if buffers to EMI	Input
wdata_intr[63:0]	Internl arbit. wdata bus from m4if buffers to EMI	Input
wdata_slow[63:0]	write data from EMI (slow) to m4if buffers	Input
weim_nfc_base[3:0]	Slow arbitration base address	Input
weim_warm_reset	weim warm reset signal	Input
wid_m0[3:0]	Master's axi write ID	Input
wid_m1[3:0]	Master's axi write ID	Input
wid_m2[3:0]	Master's axi write ID	Input
wid_m3[3:0]	Master's axi write ID	Input
wid_m4[3:0]	Master's axi write ID	Input
wid_m5[3:0]	Master's axi write ID	Input
wid_m6[3:0]	Master's axi write ID	Input
wid_m7[3:0]	Master's axi write ID	Input
wlast_m0	Master's axi write last	Input
wlast_m1	Master's axi write last	Input
wlast_m2	Master's axi write last	Input
wlast_m3	Master's axi write last	Input
wlast_m4	Master's axi write last	Input
wlast_m5	Master's axi write last	Input
wlast_m6	Master's axi write last	Input
wlast_m7	Master's axi write last	Input
wstrb_in_int2[7:0]	Internal2 arbit. write byte strobe from m4if_buffers to EMI	Input
wstrb_in_intr[7:0]	Internal arbit. write byte strobe from m4if_buffers to EMI	Input
wstrb_intr[7:0]	internal arbit. write byte strobe from m4if_buffers to EMI	Input
wstrb_fast[7:0]	fast arbit. write byte strobe from m4if_buffers to EMI	Input
wstrb_slow[7:0]	Slow arbit. write byte strobe from m4if_buffers to EMI	Input
wvalid_m0	Master's axi wdata valid	Input

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
wvalid_m1	Master's axi wdata valid	Input
wvalid_m2	Master's axi wdata valid	Input
wvalid_m3	Master's axi wdata valid	Input
wvalid_m4	Master's axi wdata valid	Input
wvalid_m5	Master's axi wdata valid	Input
wvalid_m6	Master's axi wdata valid	Input
wvalid_m7	Master's axi wdata valid	Input
m0_fast_bypass_via	master fast mem sync bypass	Input
m0_int2_bypass_via	master internal mem sync bypass	Input
m0_intr_bypass_via	master internal mem sync bypass	Input
m0_intrlvd_bypass_via	master interleaved bypass	Input
m0_slow_bypass_via	master slow mem sync bypass	Input
m0_wtrmrk_ap_rd	AP watermark at read	Input
m0_wtrmrk_ap_wr	AP watermark at write	Input
m0_wtrmrk_bp_rd	BP watermark at read	Input
m0_wtrmrk_bp_wr	BP watermark at write	Input
m1_fast_bypass_via	master fast mem sync bypass	Input
m1_int2_bypass_via	master internal mem sync bypass	Input
m1_intr_bypass_via	master internal mem sync bypass	Input
m1_intrlvd_bypass_via	master interleaved bypass	Input
m1_slow_bypass_via	master slow mem sync bypass	Input
m1_wtrmrk_ap_rd	AP watermark at read	Input
m1_wtrmrk_ap_wr	AP watermark at write	Input
m1_wtrmrk_bp_rd	BP watermark at read	Input
m1_wtrmrk_bp_wr	BP watermark at write	Input
m2_fast_bypass_via	master fast mem sync bypass	Input
m2_int2_bypass_via	master internal mem sync bypass	Input
m2_intr_bypass_via	master internal mem sync bypass	Input
m2_intrlvd_bypass_via	master interleaved bypass	Input
m2_slow_bypass_via	master slow mem sync bypass	Input
m2_wtrmrk_ap_rd	AP watermark at read	Input
m2_wtrmrk_ap_wr	AP watermark at write	Input
m2_wtrmrk_bp_rd	BP watermark at read	Input

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
m2_wtrmrk_bp_wr	BP watermark at write	Input
m3_fast_bypass_via	master fast mem sync bypass	Input
m3_int2_bypass_via	master internal mem sync bypass	Input
m3_intr_bypass_via	master internal mem sync bypass	Input
m3_intrlvd_bypass_via	master interleaved bypass	Input
m3_slow_bypass_via	master slow mem sync bypass	Input
m3_wtrmrk_ap_rd	AP watermark at read	Input
m3_wtrmrk_ap_wr	AP watermark at write	Input
m3_wtrmrk_bp_rd	BP watermark at read	Input
m3_wtrmrk_bp_wr	BP watermark at write	Input
m4_fast_bypass_via	master fast mem sync bypass	Input
m4_int2_bypass_via	master internal mem sync bypass	Input
m4_intr_bypass_via	master internal mem sync bypass	Input
m4_intrlvd_bypass_via	master interleaved bypass	Input
m4_slow_bypass_via	master slow mem sync bypass	Input
m4_wtrmrk_ap_rd	AP watermark at read	Input
m4_wtrmrk_ap_wr	AP watermark at write	Input
m4_wtrmrk_bp_rd	BP watermark at read	Input
m4_wtrmrk_bp_wr	BP watermark at write	Input
m5_fast_bypass_via	master fast mem sync bypass	Input
m5_int2_bypass_via	master internal mem sync bypass	Input
m5_intr_bypass_via	master internal mem sync bypass	Input
m5_intrlvd_bypass_via	master interleaved bypass	Input
m5_slow_bypass_via	master slow mem sync bypass	Input
m5_wtrmrk_ap_rd	AP watermark at read	Input
m5_wtrmrk_ap_wr	AP watermark at write	Input
m5_wtrmrk_bp_rd	BP watermark at read	Input
m5_wtrmrk_bp_wr	BP watermark at write	Input
m6_fast_bypass_via	master fast mem sync bypass	Input
m6_int2_bypass_via	master internal mem sync bypass	Input
m6_intr_bypass_via	master internal mem sync bypass	Input
m6_intrlvd_bypass_via	master interleaved bypass	Input
m6_slow_bypass_via	master slow mem sync bypass	Input

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
m6_wtrmrk_ap_rd	AP watermark at read	Input
m6_wtrmrk_ap_wr	AP watermark at write	Input
m6_wtrmrk_bp_rd	BP watermark at read	Input
m6_wtrmrk_bp_wr	BP watermark at write	Input
m7_fast_bypass_via	master fast mem sync bypass	Input
m7_int2_bypass_via	master internal mem sync bypass	Input
m7_intr_bypass_via	master internal mem sync bypass	Input
m7_intrlvd_bypass_via	master interleaved bypass	Input
m7_slow_bypass_via	master slow mem sync bypass	Input
m7_wtrmrk_ap_rd	AP watermark at read	Input
m7_wtrmrk_ap_wr	AP watermark at write	Input
m7_wtrmrk_bp_rd	BP watermark at read	Input
m7_wtrmrk_bp_wr	BP watermark at write	Input
aclk_int2_gated	AXI internal2 memory clock - gated	Output
aclk_intr_gated	AXI internal memory clock - gated	Output
arcache_int2[3:0]	AXI arcache to internal memory	Output
arcache_intr_1[3:0]	AXI arcache to internal memory	Output
arcache_intr_2[3:0]	AXI arcache to internal memory	Output
arcache_m0[3:0]	AXI master arcache	Input
arcache_m1[3:0]	AXI master arcache	Input
arcache_m2[3:0]	AXI master arcache	Input
arcache_m3[3:0]	AXI master arcache	Input
arcache_m4[3:0]	AXI master arcache	Input
arcache_m5[3:0]	AXI master arcache	Input
arcache_m6[3:0]	AXI master arcache	Input
arcache_m7[3:0]	AXI master arcache	Input
armaster_int2[3:0]	Master ID. read - internal memory	Output
armaster_intr_1[3:0]	Master ID. read - internal memory	Output
armaster_intr_2[3:0]	Master ID. read - internal memory	Output
arready_fast	AXI arready - fast arbitration	Output
arready_m0	Master addr.read ready	Output
arready_m1	Master addr.read ready	Output
arready_m2	Master addr.read ready	Output

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
arready_m3	Master addr.read ready	Output
arready_m4	Master addr.read ready	Output
arready_m5	Master addr.read ready	Output
arready_m6	Master addr.read ready	Output
arready_m7	Master addr.read ready	Output
arready_nfc	AXI arready of NFC	Output
arready_weim	AXI arready of WEIM	Output
awmaster_int2[3:0]	Master ID - write - internal memory	Output
awmaster_intr_1[3:0]	Master ID - write - internal memory	Output
awmaster_intr_2[3:0]	Master ID - write - internal memory	Output
awready_fast	AXI awready - fast arbitration	Output
awready_m0	Master axi write addr ready	Output
awready_m1	Master axi write addr ready	Output
awready_m2	Master axi write addr ready	Output
awready_m3	Master axi write addr ready	Output
awready_m4	Master axi write addr ready	Output
awready_m5	Master axi write addr ready	Output
awready_m6	Master axi write addr ready	Output
awready_m7	Master axi write addr ready	Output
awready_nfc	AXI awready of NFC	Output
awready_weim	AXI awready of WEIM	Output
bid_m0[3:0]	Master axi response id	Output
bid_m1[3:0]	Master axi response id	Output
bid_m2[3:0]	Master axi response id	Output
bid_m3[3:0]	Master axi response id	Output
bid_m4[3:0]	Master axi response id	Output
bid_m5[3:0]	Master axi response id	Output
bid_m6[3:0]	Master axi response id	Output
bid_m7[3:0]	Master axi response id	Output
boot_done	NFC boot done	Output
bresp_m0[1:0]	Master axi write resp.	Output
bresp_m1[1:0]	Master axi write resp.	Output
bresp_m2[1:0]	Master axi write resp.	Output

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
bresp_m3[1:0]	Master axi write resp.	Output
bresp_m4[1:0]	Master axi write resp.	Output
bresp_m5[1:0]	Master axi write resp.	Output
bresp_m6[1:0]	Master axi write resp.	Output
bresp_m7[1:0]	Master axi write resp.	Output
bvalid_m0	Master axi write resp. valid	Output
bvalid_m1	Master axi write resp. valid	Output
bvalid_m2	Master axi write resp. valid	Output
bvalid_m3	Master axi write resp. valid	Output
bvalid_m4	Master axi write resp. valid	Output
bvalid_m5	Master axi write resp. valid	Output
bvalid_m6	Master axi write resp. valid	Output
bvalid_m7	Master axi write resp. valid	Output
chosen_data_master_fast[2:0]	Chosen master for fast arbit. data	Output
chosen_data_master_int2[2:0]	Chosen master for internal2 arbit. data	Output
chosen_data_master_intr[2:0]	Chosen master for internal arbit. data	Output
chosen_data_master_slow[2:0]	Chosen master for inter mem. arbit. data	Output
data_buf_sel_fast[5:0]	fast arbit. data buffer pointer (arbit side)	Output
data_buf_sel_int2[5:0]	slow arbit. data buffer pointer (arbit side)	Output
data_buf_sel_intr[5:0]	slow arbit. data buffer pointer (arbit side)	Output
data_buf_sel_slow[5:0]	inter. arbit. data buffer pointer (arbit side)	Output
delay_line_significant_change	ESDCTL note of delay line change	Output
dma_access0	M4IF dma access	Output
dma_access1	M4IF dma access	Output
dvfs_ack	emi dvfs ack to sys.	Output
dvfs_ack_fast	emi dvfs ack - fast arbitration	Output
dvfs_ack_int2	emi dvfs ack - internal arbitration	Output
dvfs_ack_intr	emi dvfs ack - internal arbitration	Output
dvfs_ack_slow	emi dvfs ack - slow arbitration	Output
EMI_spare_ports_out[49:0]	Spare output ports	Output
endianess_int2	Internal mem. endian	Output
endianess_intr_1	Internal mem. endian	Output
endianess_intr_2	Internal mem. endian	Output

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
esdctl_idle	ESDCTL in idle mode, no access are served or waiting	Output
fast_clk_gate_en	fast arbitration clock - gated	Output
int_mem_araddr_1[31:0]	internal mem read addr.	Output
int_mem_arburst_1[1:0]	internal mem read burst type	Output
int_mem_arid_1[3:0]	internal mem read address id	Output
int_mem_arlen_1[2:0]	internal mem read burst length	Output
int_mem_arlock[_11:0]	internal mem read lock type	Output
int_mem_arprot_1[2:0]	internal mem read protection type	Output
int_mem_arsize_1[1:0]	internal mem read burst size	Output
int_mem_arvalid_1	internal mem read address valid	Output
int_mem_awaddr_1[31:0]	internal mem write address	Output
int_mem_awburst_1[1:0]	internal mem write burst type	Output
int_mem_awcache_1[3:0]	internal mem write cache type	Output
int_mem_awid_1[3:0]	internal mem write address id	Output
int_mem_araddr_2[31:0]	internal mem read addr.	Output
int_mem_arburst_2[1:0]	internal mem read burst type	Output
int_mem_arid_2[3:0]	internal mem read address id	Output
int_mem_arlen_2[2:0]	internal mem read burst length	Output
int_mem_arlock[_21:0]	internal mem read lock type	Output
int_mem_arprot_2[2:0]	internal mem read protection type	Output
int_mem_arsize_2[1:0]	internal mem read burst size	Output
int_mem_arvalid_2	internal mem read address valid	Output
int_mem_awaddr_2[31:0]	internal mem write address	Output
int_mem_awburst_2[1:0]	internal mem write burst type	Output
int_mem_awcache_2[3:0]	internal mem write cache type	Output
int_mem_awid_1[3:0]	internal mem write address id	Output
int_mem_awlen_1[2:0]	internal mem write burst length	Output
int_mem_awlock_1[1:0]	internal mem write lock type	Output
int_mem_awprot_1[2:0]	internal mem write protection type	Output
int_mem_awsize_1[1:0]	internal mem write burst size	Output
int_mem_awvalid_1	internal mem write address valid	Output
int_mem_bready_1	internal mem response ready	Output
int_mem_rready_1	internal mem read ready	Output

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
int_mem_wid_1[3:0]	internal mem write id	Output
int_mem_wlast_1	internal mem write last	Output
int_mem_wvalid_intr_1	internal mem write valid	Output
int_mem_awid_2[3:0]	internal mem write address id	Output
int_mem_awlen_2[2:0]	internal mem write burst length	Output
int_mem_awlock_2[1:0]	internal mem write lock type	Output
int_mem_awprot_2[2:0]	internal mem write protection type	Output
int_mem_awsize_2[1:0]	internal mem write burst size	Output
int_mem_awvalid_2	internal mem write address valid	Output
int_mem_bready_2	internal mem response ready	Output
int_mem_rready_2	internal mem read ready	Output
int_mem_wid_2[3:0]	internal mem write id	Output
int_mem_wlast_2	internal mem write last	Output
int_mem_wvalid_intr_2	internal mem write valid	Output
int2_clk_gate_en	internal clock gating enable	Output
intr_clk_gate_en	internal clock gating enable	Output
int2_mem_araddr[31:0]	internal2 mem read addr.	Output
int2_mem_arburst[1:0]	internal2 mem read burst type	Output
int2_mem_arid[3:0]	internal2 mem read address id	Output
int2_mem_arlen[2:0]	internal2 mem read burst length	Output
int2_mem_arlock[1:0]	internal2 mem read lock type	Output
int2_mem_arprot[2:0]	internal2 mem read protection type	Output
int2_mem_arsize[1:0]	internal2 mem read burst size	Output
int2_mem_arvalid	internal2 mem read address valid	Output
int2_mem_awaddr[31:0]	internal2 mem write address	Output
int2_mem_awburst[1:0]	internal2 mem write burst type	Output
int2_mem_awcache[3:0]	internal2 mem write cache type	Output
int2_mem_awid[3:0]	internal2 mem write address id	Output
int2_mem_awlen[2:0]	internal2 mem write burst length	Output
int2_mem_awlock[1:0]	internal2 mem write lock type	Output
int2_mem_awprot[2:0]	internal2 mem write protection type	Output
int2_mem_awsize[1:0]	internal2 mem write burst size	Output
int2_mem_awvalid	internal2 mem write address valid	Output

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
int2_mem_bready	internal2 mem response ready	Output
int2_mem_rready	internal2 mem read ready	Output
int2_mem_wid[3:0]	internal2 mem write id	Output
int2_mem_wlast	internal2 mem write last	Output
int2_mem_wvalid_intr	internal2 mem write valid	Output
ipi_emi_ap_int_b	Interrupts first OR in IPMUX	Output
ipi_emi_bp_int_b	interrupts second OR in IPMUX	Output
ipi_int_nfc_b	nfc interrupt out	Output
ipi_m4if_ap_int_b	m4if arm interrupt out	Output
ipi_m4if_bp_int_b	m4if dsp interrupt out	Output
ipi_weim_int_b	weim interrupt out	Output
ipp_do_addr_out_27_16[27:16]	WEIM addr out (bits 16-27)	Output
ipp_do_adv_b	weim adv output	Output
ipp_do_bclk	weim bclk out	Output
ipp_do_be_b[3:0]	weim be_b	Output
ipp_do_cre	weim cre bit	Output
ipp_do_cre_sel	weim cre select	Output
ipp_do_cs_b[5:0]	weim cs	Output
ipp_do_emi_debug[50:0]	debug bus	Output
ipp_do_emi_dqm[3:0]	esdctl dqm_x	Output
ipp_do_emi_dqs[3:0]	esdctl dqs	Output
ipp_do_esdctl_addr[14:0]	esdctl ma (address)	Output
ipp_do_esdctl_cas_b	esdctl cas_b	Output
ipp_do_esdctl_csd0	esdctl csd0	Output
ipp_do_esdctl_csd1	esdctl csd1	Output
ipp_do_esdctl_data[31:0]	esdctl data out	Output

ipt_emi_d12_in	Scan signal - data bit 12	Output
ipt_emi_d13_in	Scan signal - data bit 13	Output
ipt_emi_d14_in	Scan signal - data bit 14	Output
ipt_emi_d15_in	Scan signal - data bit 15	Output
ipt_so[19:0]	scan out bus	Output
lpack	EMI low power mode ack	Output
lpack_fast	Fast arbit. low power mode ack	Output
lpack_int2	Internal2 mem. arbit. low power mode ack	Output
lpack_intr	Internal mem. arbit. low power mode ack	Output
lpack_slow	Slow arbit. low power mode ack	Output
lpmd_int_mem_1	Low Power mode to internal memory reg. 1	Output
lpmd_int_mem_2	Low Power mode to internal memoryreg. 2	Output
lpmd_int2_mem	Low Power mode to internal2 memory	Output
nfc_idle	NFC in idle mode, no access are served or waiting	Output
m0_clk_gate_en	master 0 clock gating enable signal for power saving	Output
m1_clk_gate_en	master 1 clock gating enable signal for power saving	Output
m2_clk_gate_en	master 2 clock gating enable signal for power saving	Output

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
m3_clk_gate_en	master 3 clock gating enable signal for power saving	Output
m4_clk_gate_en	master 4 clock gating enable signal for power saving	Output
m5_clk_gate_en	master 5 clock gating enable signal for power saving	Output
m6_clk_gate_en	master 6 clock gating enable signal for power saving	Output
m7_clk_gate_en	master 7 clock gating enable signal for power saving	Output
nfc_dma_rd_req	NFC dma req.	Output
nfc_dma_wr_req	NFC dma req.	Output
one_hot_wr_sel_fast[23:0]	M4IF one hot write - fast arbitration	Output
one_hot_wr_sel_intr[23:0]	M4IF one hot write - internal arbitration	Output
one_hot_wr_sel_slow[23:0]	M4IF one hot write - slow arbitration	Output
rdata_fast[63:0]	read data from EMI to m4if buffers (fast)	Output
rdata_intr[63:0]	read data from EMI to m4if buffers (internal)	Output
rdata_sel_m0[4:0]	Master's read data buffer pointer	Output
rdata_sel_m1[4:0]	Master's read data buffer pointer	Output
rdata_sel_m2[4:0]	Master's read data buffer pointer	Output
rdata_sel_m3[4:0]	Master's read data buffer pointer	Output
rdata_sel_m4[4:0]	Master's read data buffer pointer	Output
rdata_sel_m5[4:0]	Master's read data buffer pointer	Output
rdata_sel_m6[4:0]	Master's read data buffer pointer	Output
rdata_sel_m7[4:0]	Master's read data buffer pointer	Output
rdata_slow[31:0]	read data from EMI to m4if buffers (slow)	Output
read_arbit_buf_m0[1:0]	Master's chosen buffer for read action	Output
read_arbit_buf_m1[1:0]	Master's chosen buffer for read action	Output
read_arbit_buf_m2[1:0]	Master's chosen buffer for read action	Output
read_arbit_buf_m3[1:0]	Master's chosen buffer for read action	Output
read_arbit_buf_m4[1:0]	Master's chosen buffer for read action	Output
read_arbit_buf_m5[1:0]	Master's chosen buffer for read action	Output
read_arbit_buf_m6[1:0]	Master's chosen buffer for read action	Output
read_arbit_buf_m7[1:0]	Master's chosen buffer for read action	Output
rid_m0[3:0]	Master's Axi read id	Output
rid_m1[3:0]	Master's Axi read id	Output
rid_m2[3:0]	Master's Axi read id	Output
rid_m3[3:0]	Master's Axi read id	Output

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
rid_m4[3:0]	Master's Axi read id	Output
rid_m5[3:0]	Master's Axi read id	Output
rid_m6[3:0]	Master's Axi read id	Output
rid_m7[3:0]	Master's Axi read id	Output
rlast_m0	Master's Axi last read	Output
rlast_m1	Master's Axi last read	Output
rlast_m2	Master's Axi last read	Output
rlast_m3	Master's Axi last read	Output
rlast_m4	Master's Axi last read	Output
rlast_m5	Master's Axi last read	Output
rlast_m6	Master's Axi last read	Output
rlast_m7	Master's Axi last read	Output
rready_fast	AXI rready - of fast arbitrarion	Output
rready_nfc	AXI rready - of NFC	Output
rready_weim	AXI rready - of WEIM	Output
rresp_fast[1:0]	fast arbit read response to m4if buffers	Output
rresp_out_int2[1:0]	internal memory rresp to m4if_buffers	Output
rresp_out_intr[1:0]	internal memory rresp to m4if_buffers	Output
rresp_slow[1:0]	slow arbit read response to m4if buffers	Output
rvalid_buf_fast	read data valid to fast buffer	Output
rvalid_buf_int2	read data valid to internal mem buffer	Output
rvalid_buf_intr	read data valid to internal mem buffer	Output
rvalid_buf_slow	read data valid to slow buffer	Output
rvalid_m0	Master's Axi read data valid	Output
rvalid_m1	Master's Axi read data valid	Output
rvalid_m2	Master's Axi read data valid	Output
rvalid_m3	Master's Axi read data valid	Output
rvalid_m4	Master's Axi read data valid	Output
rvalid_m5	Master's Axi read data valid	Output
rvalid_m6	Master's Axi read data valid	Output
rvalid_m7	Master's Axi read data valid	Output
size_to_int2_buf[1:0]	size to read buffer	Output
size_to_intr_buf[1:0]	size to read buffer	Output

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
slow_clk_gate_en	slow arbitration clock - gating enable	Output
so_as_528x32_b	NFC bist signal	Output
upper_to_intr_buf	M4IF to M4IF buffers	Output
vl_sms_proc_emi_sms_1_curr_err	NFC bist signal	Output
vl_sms_proc_emi_sms_1_fail_sms	NFC bist signal	Output
vl_sms_proc_emi_sms_1_ready_sms	NFC bist signal	Output
vl_sms_proc_emi_sms_1_wso	NFC bist signal	Output
vl_sms_proc_emi_sms_1_wsor	NFC bist signal	Output
wdata_sel_m0[4:0]	Master's write data buffer pointer	Output
wdata_sel_m1[4:0]	Master's write data buffer pointer	Output
wdata_sel_m2[4:0]	Master's write data buffer pointer	Output
wdata_sel_m3[4:0]	Master's write data buffer pointer	Output
wdata_sel_m4[4:0]	Master's write data buffer pointer	Output
wdata_sel_m5[4:0]	Master's write data buffer pointer	Output
wdata_sel_m6[4:0]	Master's write data buffer pointer	Output
wdata_sel_m7[4:0]	Master's write data buffer pointer	Output
weim_idle	WEIM in idle mode, no access are served or waiting	Output
wready_fast	AXI wready - of fast arbitration	Output
wready_nfc	AXI wready - of NFC	Output
wready_weim	AXI wready - of WEIM	Output
wready_m0	Master's axi write data ready	Output
wready_m1	Master's axi write data ready	Output
wready_m2	Master's axi write data ready	Output
wready_m3	Master's axi write data ready	Output
wready_m4	Master's axi write data ready	Output
wready_m5	Master's axi write data ready	Output
wready_m6	Master's axi write data ready	Output
wready_m7	Master's axi write data ready	Output
wstrb_intr_1[3:0]	Internal arbit. write strobe signal to internal mem.	Output
wstrb_intr_2[3:0]	Internal arbit. write strobe signal to internal mem.	Output
wvalid_buf_m0	Master's wdata valid from EMI to m4if buffers	Output
wvalid_buf_m1	Master's wdata valid from EMI to m4if buffers	Output
wvalid_buf_m2	Master's wdata valid from EMI to m4if buffers	Output

Table 27-1. EMI Signal Properties (continued)

Pin	Description	I/O
wvalid_buf_m3	Master's wdata valid from EMI to m4if buffers	Output
wvalid_buf_m4	Master's wdata valid from EMI to m4if buffers	Output
wvalid_buf_m5	Master's wdata valid from EMI to m4if buffers	Output
wvalid_buf_m6	Master's wdata valid from EMI to m4if buffers	Output
wvalid_buf_m7	Master's wdata valid from EMI to m4if buffers	Output

27.3.1 Detailed Signal Descriptions

Detailed description of any of EMI signals can be found in each of its sub module Chapter.

27.4 Memory Map and Register Definition

This section contains the EMI external/internal memory map, a register figure key, and a register summary.

27.4.1 External/Internal Memory Map

See Chapter 2, "Memory Map," to map the external and internal memories accessible by the EMI.

27.4.2 IPS Memory Map

EMI registers are mapped to IPS bus memory area and contain 16 Kbytes of space for all EMI registers. For more details on the IP registers, please refer to each EMI submodule specification.

Table 27-2 describes the IP memory space of each sub module of EMI. 0xBASE in Table 27-2 represents bits [31–14] of the IP address, whereas the rest of the address (bits [13–0]) is the EMI ips_address.

Table 27-2. EMI IP Memory Map[1]

Start ADDR	End ADDR	Module Name
0xBASE+0x0000	0xBASE+0x0FFF	M4IF
0xBASE+0x1000	0xBASE+0x1FFF	ESDCTL
0xBASE+0x2000	0xBASE+0x2FFF	WEIM
0xBASE+0x3000	0xBASE+0x3EFF	NFC
0xBASE+0x3F00	0xBASE+0x3FFF	EMI

1 0xBASE is the EMI base address as defined in the Chapter 2, "Memory Map".

27.4.3 Register Summary

The conventions in Figure 27-4 and Table 27-3 serve as a key for the register summary and individual register diagrams.

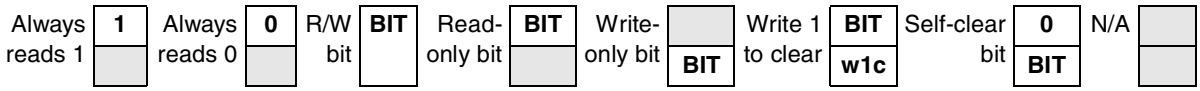

Figure 27-4. Key to M4IF Register Fields

Table 27-3 provides a key for register figures and tables and the register summary.

Table 27-3. M4IF Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 27-4 shows the M4IF register summary table.

Table 27-4. EMI Register Summary

Name		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0xBASE+0x3F00 (IPLCK)	R																
	W																
	R								Reserved			XFR_ERR_EN	Lock_all	M4IF_lock	ESDC_lock	WEIM_lock	NFC_lock

27.4.4 Register Descriptions

This section consists of M4IF register descriptions in address order. Please refer to the next sections for detailed descriptions of each register.

27.4.4.1 IP Lock Register

IPLCK register contains the locking configuration bits of each IP registers region in EMI submodules. This register is accessible by the AP privilege master only as defined at the SoC level. Other non-privilege masters can only read the content of this register.

Address 0xBASE+0x3F00 (IPLCK) Access: User read-write

Figure 27-5. IP Lock Register Description

Detailed description of IP Lock Register is shown in Table 27-5.

Table 27-5. IP Lock Register Field Descriptions

Field	Description
31–9	N/A.
8–6	Reserved.
5 XFR_ERR_EN	EMI's ips_xfr_err enable bit. 0 ips_xfr_err is disabled (always equal to 0). 1 ips_xfr_err is enabled.

Table 27-5. IP Lock Register Field Descriptions (continued)

Field	Description
4 Lock_all	Lock all EMI registers from being configured by non privilidge masters. 0 register is unlocked. 1 register is locked.
3 M4IF_lock	Lock M4IF registers from being configured by non privilege masters (except BP privilege registers). 0 register is unlocked. 1 register is locked.
2 ESDC_lock	Lock ESDCTL registers from being configured by non privilege masters. 0 register is unlocked. 1 register is locked.
1 WEIM_lock	Lock WEIM registers from being configured by non privilege masters. 0 register is unlocked. 1 register is locked.
0 NFC_lock	Lock NFC register from being configured by non privilege masters. 0 register is unlocked. 1 register is locked.

27.4.4.2 EMI Interrupt Control and Status Register

EICS register confgured the ORed interrupt scheme. It contains a masking bit for the ORed interrupt as well. EICS is a general type register. When the Lock_all bit in IPLCK register is high, only the AP master can to write to EICS register. When the Lock_all bit is low, all other masters as well as AP can write to it.

Address 0xBASE+0x3F04 (EICS) Access: User read-write

Figure 27-6. EMI Interrupt Control and Status Register Description

A detailed description of the EMI Interrupt Control and Status Register is shown in Table 27-5.

Table 27-6. EMI Interrupt Control and Status Register Field Descriptions

Field	Description
31 EAOIE	EMI AP_ORed Interrupt Enable. This bit enables the AP_ORed interrupt generation of EMI. For example, if EAOIE bit is set and one of EMI sub-module interrupt is generated, AP_ORed interrupt based on its configuration is generated as well. 0 EMI AP_ORed interrupt is disabled. 1 EMI AP_ORed interrupt is enabled. (default)
30 EBOIE	EMI BP_ORed Interrupt Enable. This bit enables the BP_ORed interrupt generation of EMI. For example, if EBOIE bit is set and one of EMI sub-module interrupt is generated, BP_ORed interrupt based on its configuration is generated as well. 0 EMI BP_ORed interrupt is disabled. 1 EMI BP_ORed interrupt is enabled. (default)
29-12	Reserved.
11 BM4IF_AP_int	BP M4IF_AP_int This bit defines whether M4IF AP interrupt is included in the EMI BP_ORed interrupt or not. 0 interrupt is not included in BP_ORed.(default) 1 interrupt is included in BP_ORed.
10 BM4IF_BP_int	BP M4IF_BP_int This bit defines whether M4IF BP interrupt is included in the EMI BP_ORed interrupt or not. 0 interrupt is not included in BP_ORed. 1 interrupt is included in BP_ORed. (default)
9 BWEIM_int	BP WEIM_int This bit defines whether WEIM interrupt is included in the EMI BP_ORed interrupt or not. 0 interrupt is not included in BP_ORed. 1 interrupt is included in BP_ORed. (default)
8 BNFC_int	BP NFC_int This bit defines whether NFC interrupt is included in the EMI BP_ORed interrupt or not.. 0 interrupt is not included in BP_ORed. 1 interrupt is included in BP_ORed. (default)
7 MAIS	M4IF AP interrupt status. This bit indicates if M4IF AP interrupt had occurred. MAIS is updated in the first positive edge of ipg_clk_s in an IP read access to EICS. 0 M4IF AP interrupt did not occur. 1 M4IF AP interrupt had occurred.
6 MBIS	M4IF BP interrupt status. This bit indicates if M4IF BP interrupt had occurred. MBIS is updated in the first positive edge of ipg_clk_s in an IP read access to EICS. 0 M4IF BP interrupt did not occur. 1 M4IF BP interrupt had occurred.
5 WIS	WEIM interrupt status. This bit indicates if WEIM interrupt had occurred. WIS is updated in the first positive edge of ipg_clk_s in an IP read access to EICS. 0 WEIM interrupt did not occur. 1 WEIM interrupt had occurred.

Table 27-6. EMI Interrupt Control and Status Register Field Descriptions (continued)

Field	Description
4 NIS	NFC interrupt status. This bit indicates if NFC interrupt had occurred. NIS is updated in the first positive edge of ipg_clk_s in an IP read access to EICS. 0 NFC interrupt did not occur. 1 NFC interrupt had occurred.
3 AM4IF_AP_int	AP M4IF_AP_int This bit defines whether M4IF AP interrupt is included in the EMI AP_ORed interrupt or not. 0 interrupt is not included in AP_ORed. 1 interrupt is included in AP_ORed. (default)
2 AM4IF_BP_int	AP M4IF_BP_int This bit defines whether M4IF BP interrupt is included in the EMI AP_ORed interrupt or not. 0 interrupt is not included in AP_ORed.(default) 1 interrupt is included in AP_ORed.
1 AWEIM_int	AP WEIM_int This bit defines whether WEIM interrupt is included in the EMI AP_ORed interrupt or not. 0 interrupt is not included in AP_ORed. 1 interrupt is included in AP_ORed. (default)
0 ANFC_int	AP NFC_int This bit defines whether NFC interrupt is included in the EMI AP_ORed interrupt or not.. 0 interrupt is not included in AP_ORed. 1 interrupt is included in AP_ORed. (default)

27.5 Functional Description

As was described above, EMI is the external memory arbitration and controller, and the internal memory arbitration of the system. Each master access to the internal or external memory region would be routed out through EMI. The EMI is based on AXI pipeline separate read and write buses and therefore it can reorder the access of the masters inside the arbitration to provide the highest throughput on the external memory bus.

EMI has separate arbitration control modules for fast and slow external/internal interfaces, therefore, an access to the slow interface can be served in parallel to an access of the fast interface without any interference between them.

In addition EMI interface support asynchronous master interface, Therefore, a slow master would be able to read/write data in parallel to other fast master accesses. The arbitration logic would optimize the access between the masters to the memory controller to provide maximum throughput on the external memory bus and in the same time a minimum latency for pending access in the arbitration.

In order to provide high performance on the fast memory channel, it was decided to separate the buses of the memory controllers and to share only between several memory controllers located on the same arbitration. In EMI case, SDR and DDR SDRAM memory controller shared the same bus as well as NFC and WEIM. However, I/O pin sharing between WEIM and SDR SDRAM controller is not supported.

Many changes were done in order to reduce power in idle and low power mode. Power saving modes were added to provide automatic capability of reducing the power consumption without any special user configuration.

DVFS is supported for both frequency and voltage changes based on improved handshake mechanism between EMI and the system.

A detailed functional description on the sub module functionality can be found in each module Chapter. Please refer to module specific spec Chapter for more details.

27.5.1 Clocks

EMI contains the following clock domains:

- EMI IPS clock.
- ESDCTL main clock, up to 166 MHz
- Slow arbitration clock, up to 133 MHz
- Internal memory arbitration 1 and 2 clocks, up to 133 MHz
- 8 × master clocks that can be asynchronous to EMI arbitration clocks (66 MHz–133 MHz).
- NFC main clock, should be integer divided from slow arbitration clock. (up to 50 MHz)
- SDCLK—SDR/DDR clock to SDR/DDR SDRAM device.
- BCLK—NOR Flash/PSRAM clock WEIM in synchronous mode.

The EMI arbitrator (M4IF) assumes all of its three main clocks—ESDCTL main clock(aclk_fast) , sSlow arbitration clock (aclk_slow), and internal memory arbitration clock (aclk_intr)—are on by default after reset. If the system wishes to turn one of the clocks off, it must do so by going through the specific lpmd sequence. For example, if the system wishes to turn off "aclk_fast", it must wake up with this clock on, send an "lpmd_fast" request, wait for "lpack_fast" acknowledge, and only then turn off "aclk_fast." "lpmd_fast" must be asserted for the whole duration of "aclk_fast" being off.

27.5.2 Reset

In general EMI supports POR reset, cold reset, and warm reset.

27.5.2.1 Power On Reset

Power on reset is a reset which interfaces with the NFC memory controller. Please refer to the NFC chapter for a detailed description on POR reset functionality.

27.5.2.2 Cold Reset

Cold Reset is the general ARESET signal that enters EMI. It generates a hardware reset to all submodules of EMI. All logic is being reset when cold reset is asserted besides the POR reset logic.

27.5.2.3 Warm Reset

Warm reset is supported for the ESDCTL module only. In this mode, the data outside in the external device is kept during warm reset so that it is eady for use as soon as the device exits warm reset. Please refer to the ESDCRTL chapter for more details.

27.5.3 Interrupts

The following interrupts are supported in EMI:

- Watermark violation AP interrupt
- Watermark violation BP interrupt
- NFC interrupt
- WEIM int for OneNand and MDOC support
- Configurable AP_ORed interrupt of all EMI interrupts
- Configurable BP_ORed interrupt of all EMI interrupts

27.5.4 Endianness

EMI supports both little- and big-endian modes (LE, BE32, and BE8). The memory controllers take care on the right storage location in the memory, based on Endianness mode and memory data bus size. Endian consideration supported is byte invariant within 32 bits word only. Byte invariant within 64 bits is not allowed. A detailed description of EMI endianess can be found in Section 27.7, EMI Endianess.”

27.5.5 IPS Interface

All EMI registers are IPS memory mapped. The registers are configurable read/write via IPS bus interface only. It is recommended that the EMI IP interface be connected on the shared peripheral bus in order to allow all IP masters to configure EMI registers.

The IPS interface unit inside EMI would combined all IPS interfaces from EMI sub modules as appears in Table 27-2. The IPS IF unit would route the access to the right sub module based on ips_module_en signal and address decoding.

EMI registers uses an accessibility policy as described here below.

Based on the fact the EMI IPS interface is located on the shared bus, only the master which owns EMI IPS IF as defined in shared peripheral bus arbiter module (SPBA) can configure EMI. Please refer to SPBA module spec for more details about ownership limitations and configurations.

In addition to that, EMI decodes ips_master_id of each IP access. At the boundary level of EMI, SoC integration would predefine by via the master ID that correspond to the privilege master and by another sets of vias the BP master ID. The privilege master has the capability to lock or unlock any register from being configured by any other master but the BP Watermark registers. Therefore, the system can ensure that when there is a lock on the registers, any register will not be changed by other master than the privilege master. In a similar way, the BP master is the only master that can lock and configure BP Watermark

registers so that even the privilege master can not changed its values. In a case of a non privilege master that tries to access a lock register, EMI does not response in error, no error signal is sent back on the bus.

Please refer to Register Definition section in this document for more details on the lock mechanism.

All EMI registers are 32bit width. Only IP accesses of 32bit data width are supported.

NOTE

There is no special mechanism inside EMI to privent IP register config while other operation on AXI taking place. Therefore, system should controll IP configuration and prevent a conflict in that case.
When the access is done to a valid address location but no register is mapped to that location, an ips_xfr_err will be generated as long as the XFR_ERR_EN bit in the IPLCK register is high. If XFR_ERR_EN bit is low the ips_xfr_err signal is disabled and remains low.

27.6 Application Information

Each submodule has application notes according to its module definition and Freescale's past experience with customer needs.

NOTE

Further refining of the spec may occur in the future, as the design, modeling, and simulations are progressing.

27.7 EMI Endianess

This section provides a detailed description of the EMI module's support for the following endian modes: LE, BE8, and BE32. The chapter describes the data arrangement on the data bus in all stages inside EMI, starting with the AXI interface at M4IF toward the external memory bus at the different memory controllers.

27.7.1 AXI Endianess Support

EMI supports AXI masters with bus width of ×64 and ×32. The following sections apply to these bus width only.

27.7.2 AXI Master ×64

This section shows the data location on AXI bus as it entered into EMI on M4IF AXI gaskets. In the next section we will show the data byte locations inside EMI toward the external bus and the storage at external memory devices.

27.7.2.1 Little-Endian Mode

Figure 27-7 shows the data byte location relative to the data bus indexes in little-endian (LE) mode.

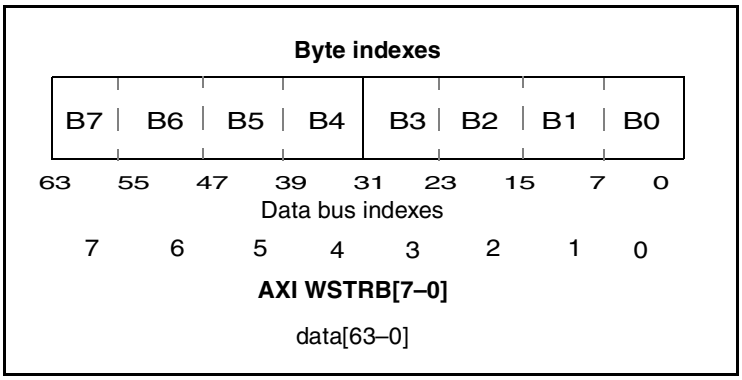

Figure 27-7. Little-Endian Byte Placement on AXI ×64

It can be seen from this illustration that the data byte with index 0 uses byte lane 0 (data[7–0]), and the data byte with index 7 uses byte lane 7 (data[63–56]).

27.7.2.2 Big-Endian Mode

The EMI module has two different big-endian modes: BE32 and BE8.

27.7.2.2.1 BE32 Mode

Figure 27-8 shows the data byte location relative to the data bus indexes in big-endian (BE32) mode.

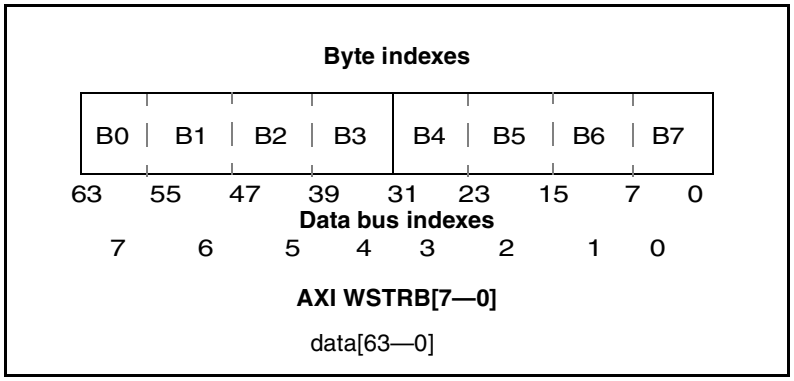

Figure 27-8. Big-Endian Byte Placement on AXI ×64 (BE32)

It can be seen from the illustration that the data byte with index 0 (least significant) uses byte lane 7 (data[63–56]), and the data byte with index 2 uses byte lane 5 (data[47–40]).

27.7.2.2.2 BE8 Mode

Figure 27-9 shows the data byte location relative to the data bus indexes in big-endian (BE8) mode.

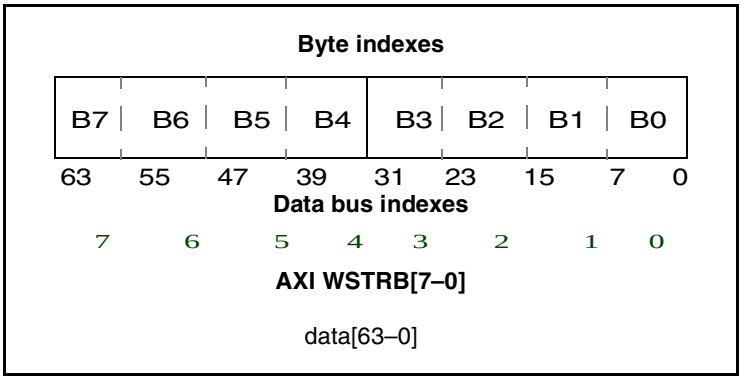

Figure 27-9. Big-Endian Byte Placement on AXI ×64 (BE8)

It can be seen from the illustration that the data byte with index 0 (least significant) uses byte lane 0 (data[7–0]), and the data byte with index 2 uses byte lane 2 (data[23–16]).This data arrangement is similar to LE mode.

The example figures below (Figure 27-10–Figure 27-13) are to show how to find which bytes are valid for each address/access size combination. Note that the example figures use the same data as their little-endian examples:

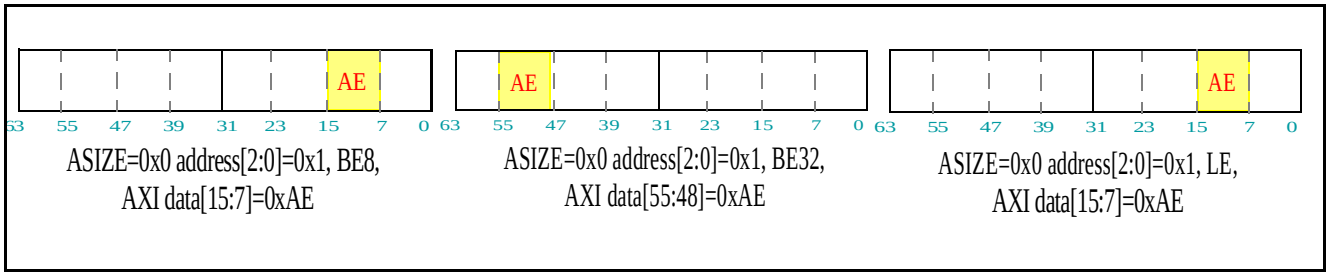

Figure 27-10. Byte Access for AXI ×64

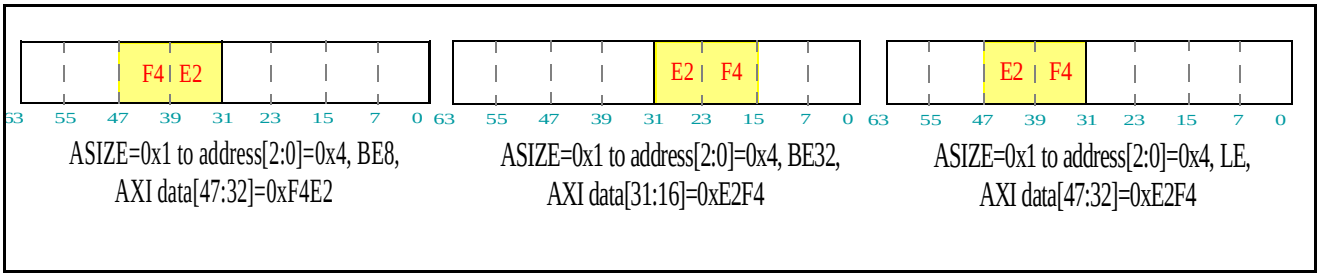

Figure 27-11. Half-Word Access for AXI ×64

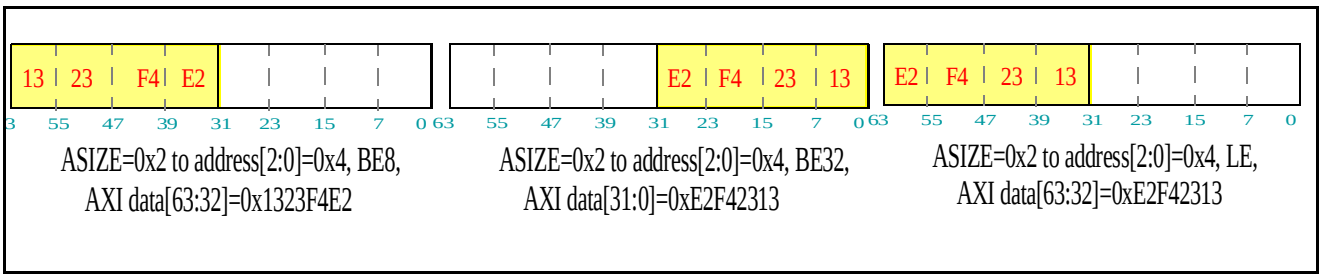

Figure 27-12. Word Access for AXI ×64

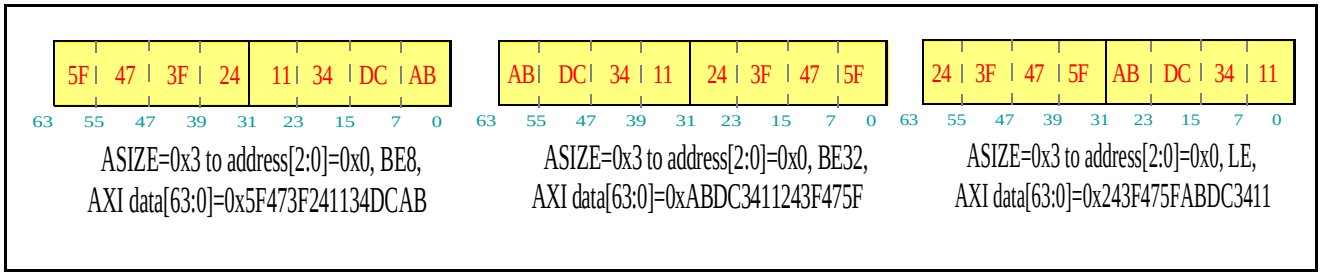

Figure 27-13. Double-Word Access for AXI ×64

27.7.3 AXI Master ×32

This section shows the data location on AXI bus as it is entered into EMI on M4IF AXI gaskets. The next section shows the data byte locations inside EMI toward the external bus and the storage at external memory devices.

27.7.3.1 Little-Endian Mode

Figure 27-14 shows the data byte location relative to the data bus indexes in little-endian mode.

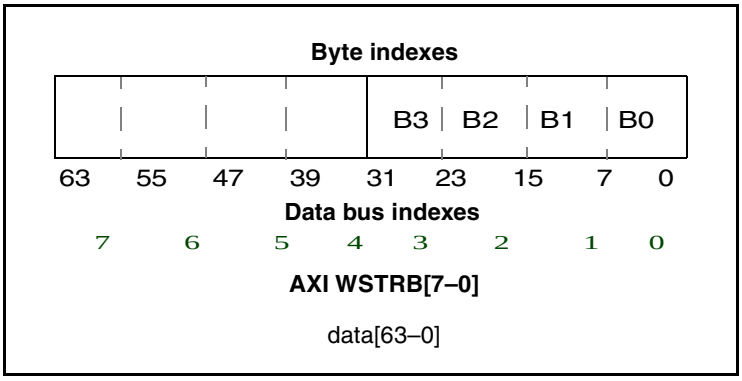

Figure 27-14. Little Endian Bytes Placement on AXI ×32

It can be seen from this illustration that the data byte with index 0 uses byte lane 0 (data[7–0]), and the data byte with index 3 uses byte lane 3 (data[31–24]).

27.7.3.2 Big-Endian Mode

The EMI module has two different big-endian modes: BE32 and BE8.

27.7.3.2.1 BE32 Mode

Figure 27-15 shows the data byte location relative to the data bus indexes in big-endian (BE32) mode.

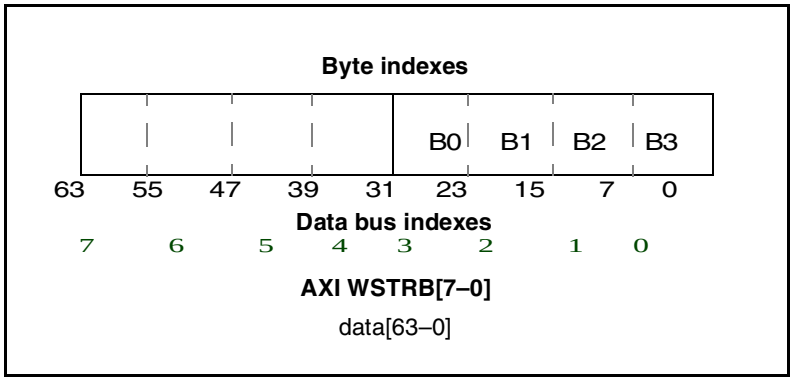

Figure 27-15. Big Endian Bytes Placement on AXI ×32 (BE32)

It can be seen from the illustration that the data byte with index 0 (least significant) uses byte lane 3 (data[31–24]), and the data byte with index 2 uses byte lane 1 (data[15–8]).

27.7.3.2.2 BE8 Mode

Figure 27-16 shows the data byte location relative to the data bus indexes in big-endian (BE8) mode.

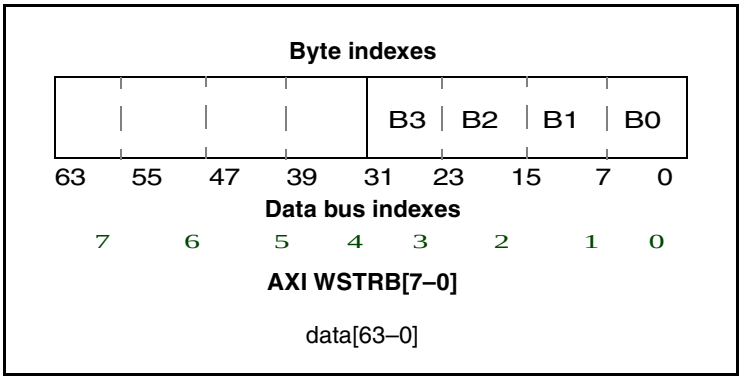

Figure 27-16. Big Endian Bytes Placement on AXI ×64 (BE8)

It can be seen from the illustration that data byte with index 0 (least significant) uses byte lane 0 (data[7–0]) and data byte with index 2 uses byte lane 2 (data[23–16]).This data arrangement is similar to LE mode.

The following examples (Figure 27-17–Figure 27-19) show the data location on AXI bus in the different modes:

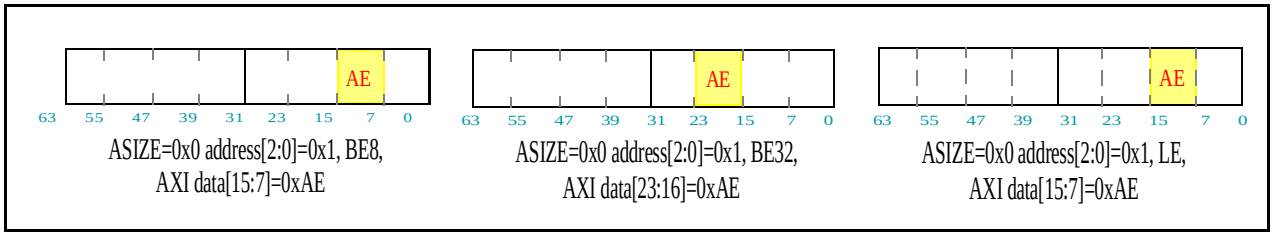

Figure 27-17. Byte Access for AXI ×32

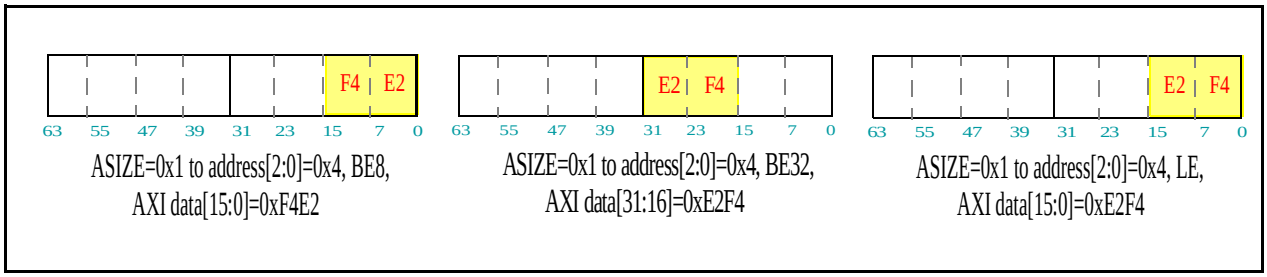

Figure 27-18. Half-Word Access for AXI ×32

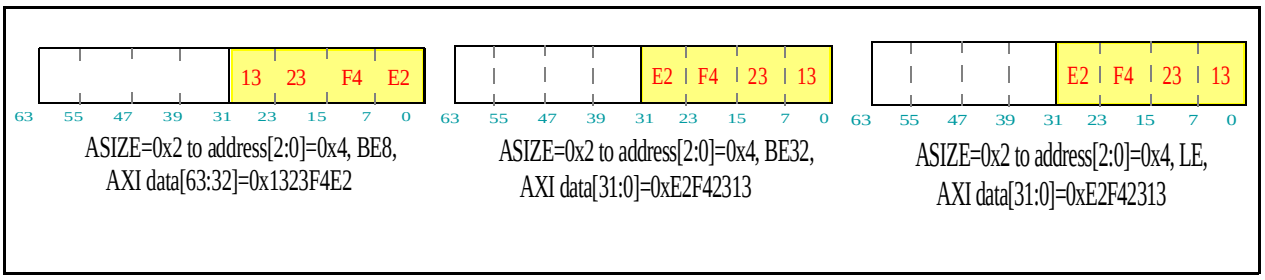

Figure 27-19. Word Access for AXI ×32

27.7.4 EMI Endianess Support

The following sections describe the endianess support in each of the EMI submodules. In general, EMI supports LE and BE32, and no special support is required for BE8.

Note that ×64 master and ×32 master can be connected to EMI. Therefore in a ×32 master case, it is required that the data bus connection be duplicated on the write bus while M4IF duplicates the data on the read bus in case of word access.

Figure 27-20 shows how a ×32 master should be connected to EMI. A ×64 master should be connected like a ×64 AXI bus regular definition.

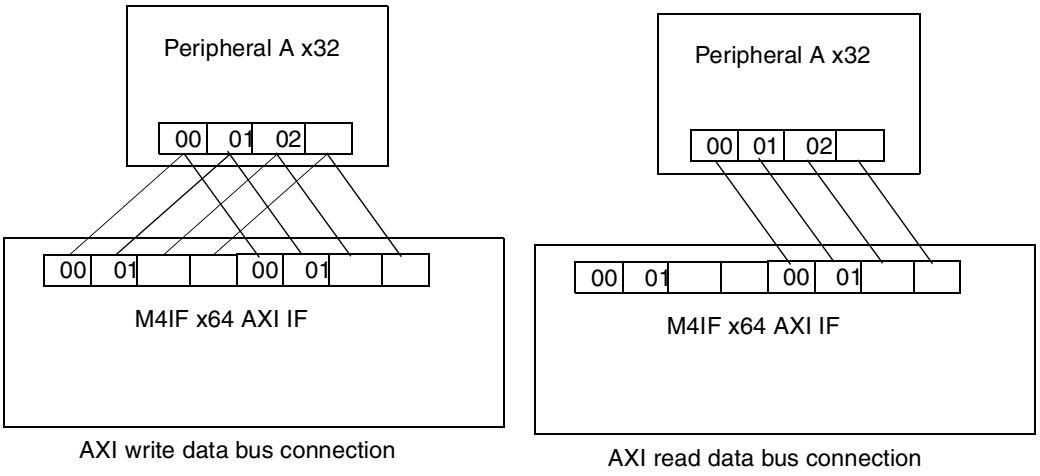

Figure 27-20. EMI Connection to AXI ×32

27.7.5 M4IF Endianess Support

This section discusses how M4IF handles the different endian modes. In general, M4IF has two different operation modes regardless of endian mode. It changes its operation logic based on fast, slow, and internal. Because the fast and internal arbitration paths are ×64 while slow arbitration is ×32, the way M4IF should provide the data to the memory controller is different.

27.7.5.1 M4IF Behavior for ×64 Arbitration

In LE or BE modes, M4IF provides the data on the bus the way it was provided from the masters in the system without any change.

27.7.5.2 M4IF Behavior for ×32 Arbitration

In LE mode, M4IF provides the data on the ×32 bus according to the byte lanes. If the access is between B0 to B3, it provides lower 32 word (byte 0–3), and when the access is between B4 to B7, it provides higher 32 word (byte 4–7).

Figure 27-21–Figure 27-23 show examples in LE mode for ×32 arbitration:

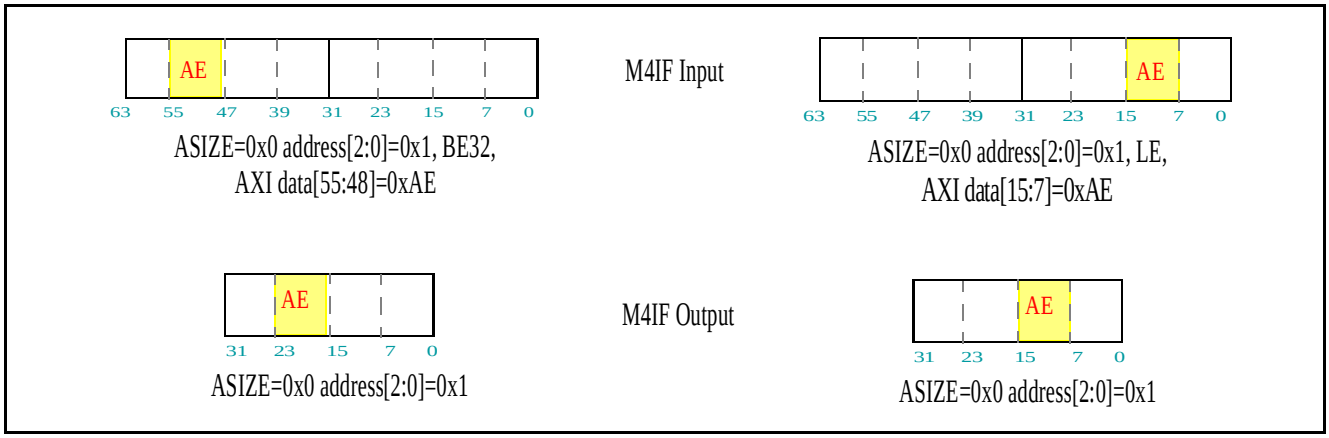

Figure 27-21. Byte Access for AXI ×64 Master and ×32 Arbitration Slave

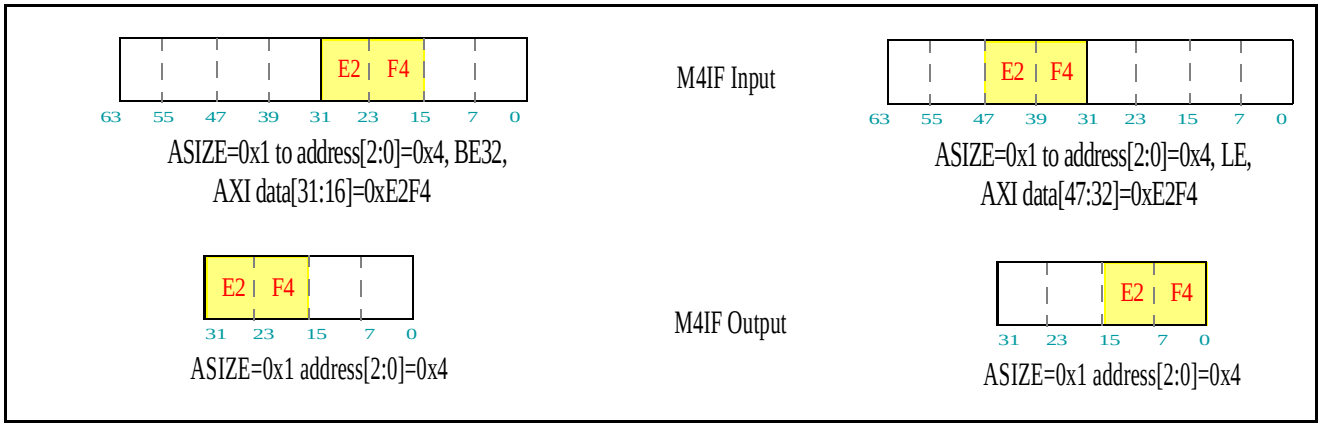

Figure 27-22. Half-Word Access for AXI ×64 Master and ×32 Arbitration Slave

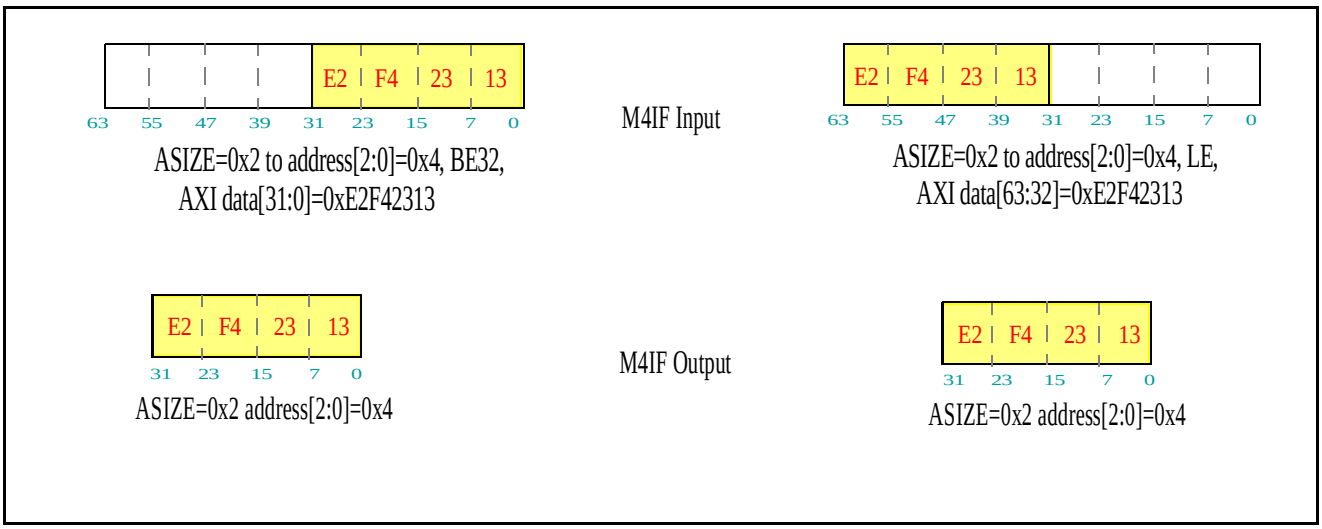

Figure 27-23. Word Access for AXI ×64 Master and ×32 Arbitration Slave

27.8 Data Storage Arrangement

This section describes how various memory controllers in EMI arrange the data in the external memory device. The section describes only ×32 and ×16 external memory devices because ×8 devices are not supported in EMI.

Figure 27-24–Figure 27-29 describe the data storage location in the external memory devices.

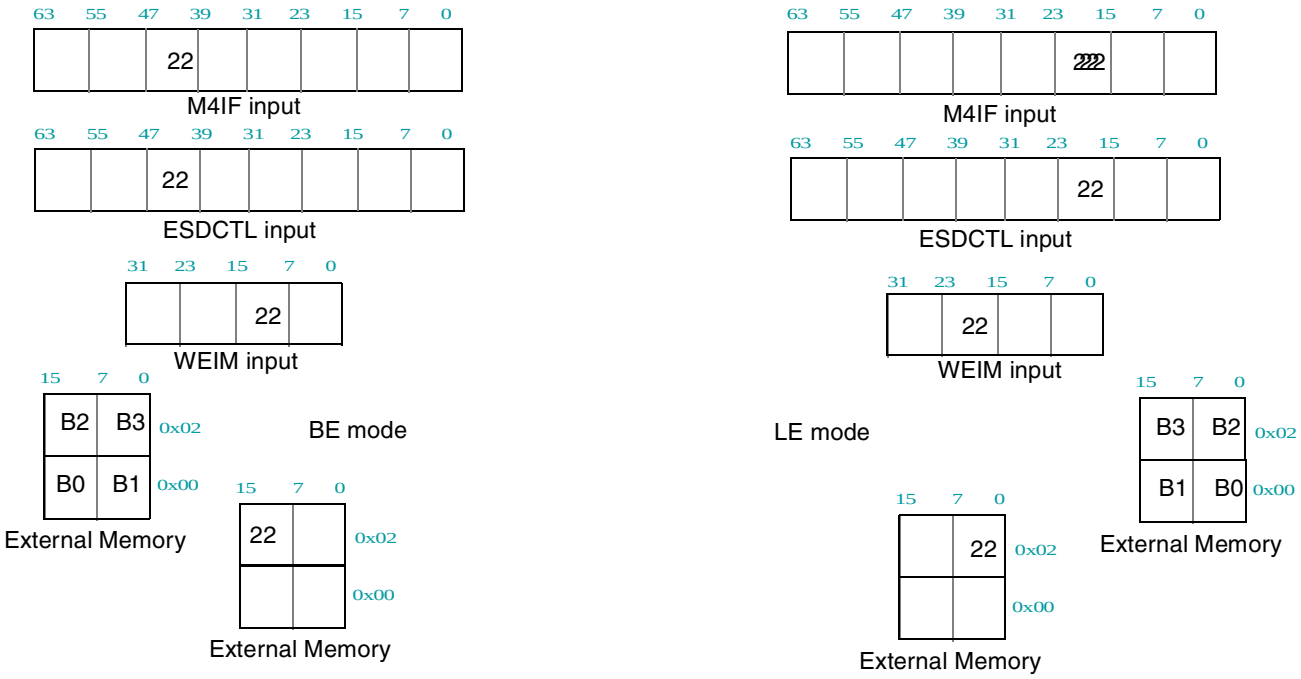

Figure 27-24. Byte Access, ASIZE = 0x0, External Memory x16

Chapter 28
Embedded Memory Periphery Power Gating Controller (EMPGC)

28.1 Introduction

The EMPGC controller controls the power to embedded memory periphery logic.

28.1.1 Features

The EMPG controller features include the following:

- Provide an option to switch off power to an embedded memory periphery.
- Generates power-up and power-down control sequences.
- Programmable registers to stage the power control signal.
- 32-bit IP bus interface, and all its registers are byte-accessible.

28.1.2 Modes of Operation

In functional mode, the EMPG Controller provides an option to switch off power to an embedded memory. The various power sequence control registers should be programmed to the desired value before power down.

28.2 Memory Map and Register Definition

This section provides a memory map, register key, and register summary.

28.2.1 EMPG Controller Memory Map

Table 28-1. EMPG Controller Memory Map

Address	Register	Access	Reset Value	Section/Page
0xBASE+0x000 (EMPGCR)	EMPG Control Register (EMPGCR)	R/W	0x0000_0000	28.2.3.1/28-4
0xBASE+0x004 (PUPSCR)	Power-up Sequence Control Register (PUPSCR)	R/W	0x0000_0001	28.2.3.2/28-4

Table 28-1. EMPG Controller Memory Map (continued)

Address	Register	Access	Reset Value	Section/Page
0xBASE+0x008 (PDNSCR))	Power-down Sequence Control Register (PDNSCR)	R/W	0x0000_0001	28.2.3.3/28-5
0xBASE+0x00C (EMPGSR)	EMPG Status Register (EMPGSR)	R/W	0x0000_0000	28.2.3.4/28-5

28.2.2 Register Summary

The conventions in Figure 1-1 and Table 1-7 serve as a key for the register summary and individual register diagrams.

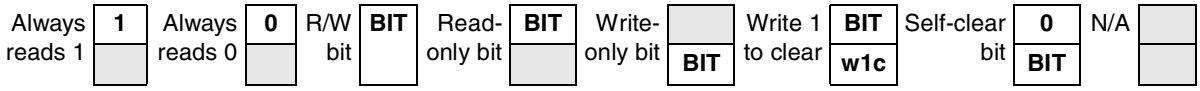

Figure 28-1. Key to Register Fields

Table 1-7 provides a key for register figures and tables and the register summary.

Table 28-2. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

28.2.2.1 EMPG Controller Register Summary

Table 28-3 shows the EMPG controller register summary.

Table 28-3. EMPG Controller Register Summary

Field	Description
0 PSR	Power status. Write 1 to clear this bit. User should clear this bit after power-up, otherwise this bit will continue to reflect the power status of the very first power down. 0 was NOT powered down in previous power down request 1 was powered down in previous power down request.

28.2.4 Power-down Sequence (EMPG Entry Sequence)

Power-down sequence control register (PDNSCR) and power-up sequence control register (PUPSCR) must be programmed to the desired value before initiating the “pdn_req” and must not be changed until power up is completed. The EMPG entry sequence is outlined in the following list of steps:

1. Software program PCR bit in the EMPG control register (EMPGCR).
2. Clocks are stopped to the powering down Embedded Memory.
3. pdn_req is asserted to EMPG controller.
4. Upon detecting the pdn_req assertion, EMPG controller asserts “empgc_enable_clk”.
5. EMPG Controller asserts “empgc_pd” to isolate the outputs, based on the programming of PDNSCR[7:0].
6. EMPG controller de-asserts “empgc_enable_clk”.

28.2.4.1 Power-down Sequence Timing Waveforms

Figure 28-6 shows the power-down sequence timing waveforms.

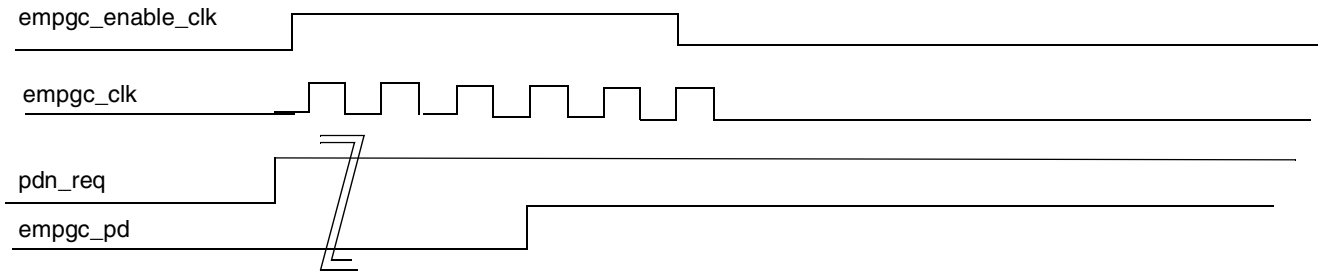

Figure 28-6. Power-down Sequence Timing Waveforms

28.2.5 Power-up Sequence (EMPG Exit Sequence)

The EMPG exit sequence is outlined in the following list of steps:

1. pup_req is asserted to EMPG Controller.
2. EMPG Controller asserts “empgc_enable_clk” to enable the clock.
3. EMPG Controller asserts “empgc_pd”, based on the programming of PUPSCR[7:0].
4. EMPG Controller de-asserts “empgc_enable_clk”.
5. “pup_req” is de-asserted to EMPG Controller.

NOTE

If pup_req is asserted before “empgc_pd” assertion then EMPG controller exits the power down sequence.

28.2.5.1 Power-up Sequence Timing Waveforms

Figure 28-7 shows the power-up sequence timing waveforms.

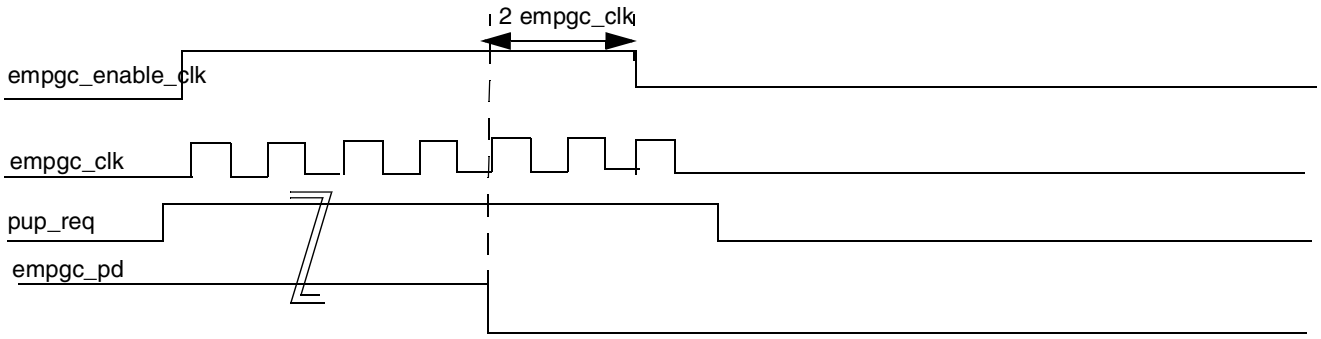

Figure 28-7. Power-up Sequence Timing Waveforms

Chapter 29
Enhanced Periodic Interrupt Timer (EPIT)

29.1 Introduction

Figure 29-1 illustrates the block diagram of the Enhanced Periodic Interrupt Timer (EPIT).

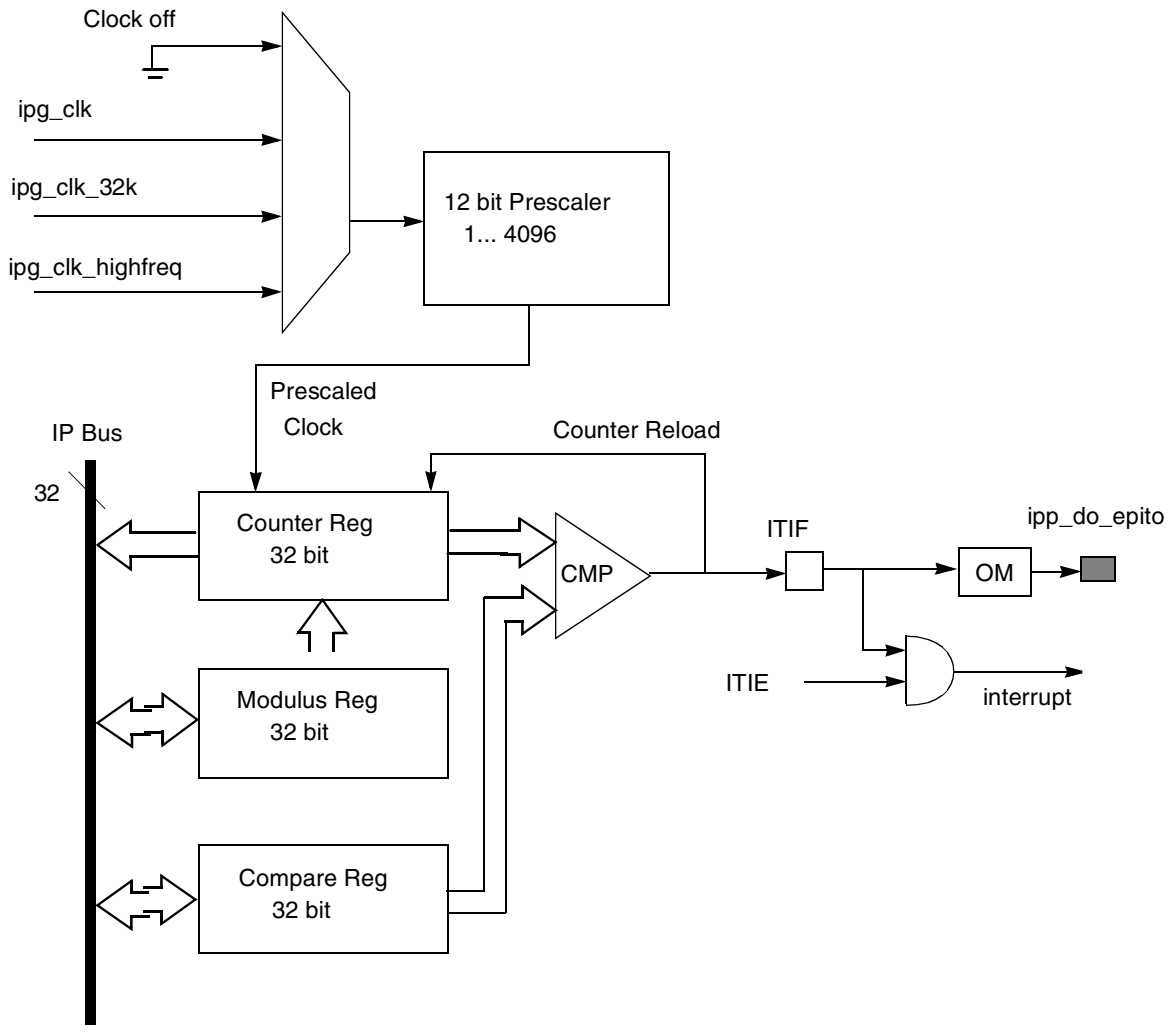

Figure 29-1. Enhanced Periodic Interrupt Timer Block Diagram

29.1.1 Overview

The Enhanced Periodic Interrupt Timer (EPIT) is a 32-bit set-and-forget timer that starts counting after the EPIT is enabled by software. It is capable of providing precise interrupts at regular intervals with minimal processor intervention.

29.1.2 Features

The following features characterize the EPIT:

- 32-bit down counter with clock source selection
- 12-bit prescaler for division of input clock frequency
- Counter value can be programmed on the fly
- Can be programmed to be active in low power and debug modes
- Interrupt generation when counter reaches the Compare value

29.1.3 Modes of Operation

The EPIT can be programmed to function in set-and-forget or free-running modes.

- Set-and-Forget mode

  This mode of operation is selected when the RLD bit in control register (EPITCR) is set to a value of one. The counter is not directly writable from the module data bus. Instead, it gets its data from the load register (EPITLR). Whenever the counter reaches a count of zero, the value in EPITLR is loaded into the counter to be decremented toward zero. The counter may by directly initialized, without having to wait for the count to reach zero, when the EPITLR is written with the IOVW bit in EPITCR set.

- Free-Running mode

  This mode of operation is selected when the RLD bit is cleared to a value of zero. In this mode, the counter rolls over from $0000_0000 to $FFFF_FFFF without reloading from the modulus register and continues counting down. In this mode, the counter can also be directly initialized by writing to EPITLR with the required initialization value after having set the IOVW bit.

29.2 External Signal Description

Table 29-1 shows the external signal properties.

Table 29-1. EPIT External Signal Properties

Name	Function	I/O	Reset	Pull Up
ipp_do_epito	Output pin at chip boundary for indication of occurrence of output compare event through a specified transition.	O	0	—

29.3 Register Definition and Memory Map

The EPIT module includes 5 user-accessible 32-bit registers. The table below summarizes these registers and their addresses.

IP Bus Write access to EPIT Control Register (EPITCR) & EPIT Load Register (EPITLR) results in one cycle of wait state (ips_xfr_wait high for 1 cycle), while other valid IP bus accesses are with 0 wait state.

Irrespective of resp_sel signal value, Write access to EPIT Counter Register EPITCNR (Read only register) will generate the bus exception (ips_xfr_err signal will be asserted). If resp_sel is driven low then Read/Write access to the unimplemented address space of EPIT (ips_addr greater than or equal to $BASE + $014) will generate the bus exception (ips_xfr_err signal will be asserted). If resp_sel is driven high then Read/Write access to the unimplemented address space of EPIT will not create any error response.

Table 29-2 shows the memory map.

Table 29-2. EPIT Memory Map

Address	Register	Access	Reset Value	Section/Page

29.3.2 Detailed Register Descriptions

Table 29-4 shows the register terms.

Table 29-4. Register Terms

Term	Description
Grey bit	Unimplemented bit; always reads as zero; writing has no effect.
Access	—
S	Supervisor mode only
—	Supervisor or user mode
R	—
0	Always read 0.
W	—
w1c	A status bit that can be read and cleared by writing a logic 1.
Reset	—
0	Resets to a logic 0.
1	Resets to a logic 1.
u	Unaffected by reset
?	Reset state is unknown.

29.3.2.1 EPIT Control Register

The EPIT control register (EPITCR), shown in Figure 29-3, is used to configure the operating settings of the EPIT. It contains the clock division prescaler value and also the interrupt enable bit. Additionally it contains other control bit which are outlined below.

IP Bus Write access to EPIT Control Register (EPITCR) results in one cycle of wait state (ips_xfr_wait high for 1 cycle), while other valid IP bus accesses are with 0 wait state.

Address 0xBASE+0x0000 Access: User read/write

Figure 29-3. EPIT Control Register

Table 29-5 shows the EPIT control register field descriptions.

Table 29-5. Register Field Descriptions

Field	Description
31–26 Reserved	These are reserved bits and writing a value will not affect the functionality of EPIT. These reserved bits are always read as zero.
25–24 CLKSRC	Select clock source These bits determine which clock input will be selected for running the counter. This field value should only be changed when the EPIT is disabled by clearing the EN bit in this register. For other programming requirements for changing the clock source, refer to Section 29.5, Initialization/Application Information.” 00 Clock is off 01 ipg_clk 10 ipg_clk_highfreq 11 ipg_clk_32k
23–22 OM	EPIT output configuration.This bit field determines the mode of EPIT output on the output pi 00 EPIT output is disconnected from pad 01 Toggle output pin 10 Clear output pin 11 Set output pin
21 STOPEN	EPIT Stop Mode enable. This read/write control bit enables the operation of the EPIT during stop mode. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 EPIT is disabled in stop mode 1 EPIT is enabled in stop mode

Table 29-5. Register Field Descriptions (continued)

Field	Description
20 RESERVED	These are reserved bits and writing a value will not affect the functionality of EPIT. These reserved bits are always read as zero.
19 WAITEN	This read/write control bit enables the operation of the EPIT during wait mode. This bit is reset by a hardware reset. A software reset doesn't affect this bit. 0 EPIT is disabled in wait mode 1 EPIT is enabled in wait mode
18 DBGEN	This bit is used to keep the EPIT functional in debug mode. When this bit is cleared, the input clock is gated off in debug mode. This bit is reset by hardware reset. A software reset doesn't affect this bit. 0 Inactive in debug mode 1 Active in debug mode
17 IOVW	EPIT Counter Overwrite Enable. This bit controls the counter data when the modulus register is written. When this bit is set, all writes to the load register will overwrite the counter contents and the counter will subsequently start counting down from the programmed value. 0 Write to load register doesn't result in counter value being overwritten. 1 Write to load register results in immediate overwriting of counter value.
16 SWR	Software Reset. The EPIT module is reset when this bit is set to 1. It is a self clearing bit. This bit is set when the module is in reset state and is cleared when the reset procedure is over. Setting this bit resets all the registers to their reset values, except for the EN, ENMOD, STOPEN, WAITEN and DBGEN bits in this control register 0 EPIT is out of reset 1 EPIT is undergoing reset
15–4 PRESCALAR	Counter clock prescaler value. This bit field determines the prescaler value by which the clock will be divided before it goes to the counter 0x000 Divide by 1 0x001 Divide by 2 . . 0xfff Divide by 4096
3 RLD	Counter Reload control This bit is cleared by hardware reset. It decides the counter functionality, whether to run in "free running mode" OR "set and forget mode". 1 When the counter reaches zero it reloads from the modulus register (Set and Forget Mode) 0 When the counter reaches zero it rolls over to 0xffffffff (Free running mode)
2 OCIEN	Output Compare Interrupt Enable This bit enables the generation of interrupt on occurrence of compare event. 0 Compare interrupt disabled 1 Compare interrupt enabled

Table 29-5. Register Field Descriptions (continued)

Field	Description
1 ENMOD	EPIT Enable Mode When EPIT is disabled (EN=0), then both Main Counter and Prescaler Counter freeze their count at current count values. ENMOD bit is a r/w bit which decides the counter value when the EPIT is enabled again by setting EN bit. If ENMOD bit is set, then Main Counter is loaded with the load value (If RLD=1)/ 0xffffffff (If RLD=0) and Prescaler Counter is reset, when EPIT is enabled (EN=1). If ENMOD is programmed to 0 then both Main Counter & Prescaler Counter restart counting from their frozen values, when EPIT is enabled (EN=1). If EPIT is programmed to be disabled in a low power mode (STOP/WAIT), then both the main counter and the prescaler counter freeze at their current count values when EPIT enters low power mode. When EPIT exits the low power mode, both main counter and prescaler counter start counting from their frozen values irrespective of the ENMOD bit. This bit is reset by a hardware reset. A software reset doesn't affect this bit. 0 Counter will start counting from the value it had when it was disabled. 1 Counter will start count from load value (RLD=1) or 0xffffffff (If RLD=0)
0 EN	This bit enables the EPIT. EPIT Counter and Prescaler value when EPIT is enabled (EN =1), is dependent upon ENMOD & RLD bit as described for ENMOD bit. It is recommended that all registers be properly programmed before setting this bit. This bit is reset by a hardware reset. A software reset doesn't affect this bit. 0 EPIT is disabled 1 EPIT is enabled

29.3.2.2 EPIT Status Register

The EPIT status register (EPITSR), shown in Figure 29-4, has a single status bit for the output compare event. It is a write 1 to clear bit.

Address 0xBASE+0x0004 Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	OCIF
W																w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 29-4. EPIT Status Register

Table 29-6 shows the EPIT status register field descriptions.

Table 29-6. Register Field Descriptions

Field	Description
31–1 RESERVED	These are reserved bits and writing a value will not affect the functionality of EPIT. These reserved bits are always read as zero.
0 OCIF	Output Compare Interrupt Flag. This bit is the interrupt flag that is set when the content of counter equals the content of the compare register (EPITCMPR). This is write one to clear bit. 0 Compare event hasn't occurred 1 Compare event occurred

29.3.2.3 EPIT Load Register

The EPIT load register (EPITLR), shown in Figure 29-5, contains the value that will be loaded into the counter when EPIT counter reaches zero if the RLD bit in EPITCR is set. If the IOVW bit in the EPITCR is set then a write to this register will overwrite the value of the EPIT counter register in addition to updating this registers value. This overwrite feature is active even if the RLD bit is not set.

IP Bus Write access to EPIT load register (EPITLR) results in one cycle of wait state (ips_xfr_wait high for 1 cycle), while other valid IP bus accesses are with 0 wait state.

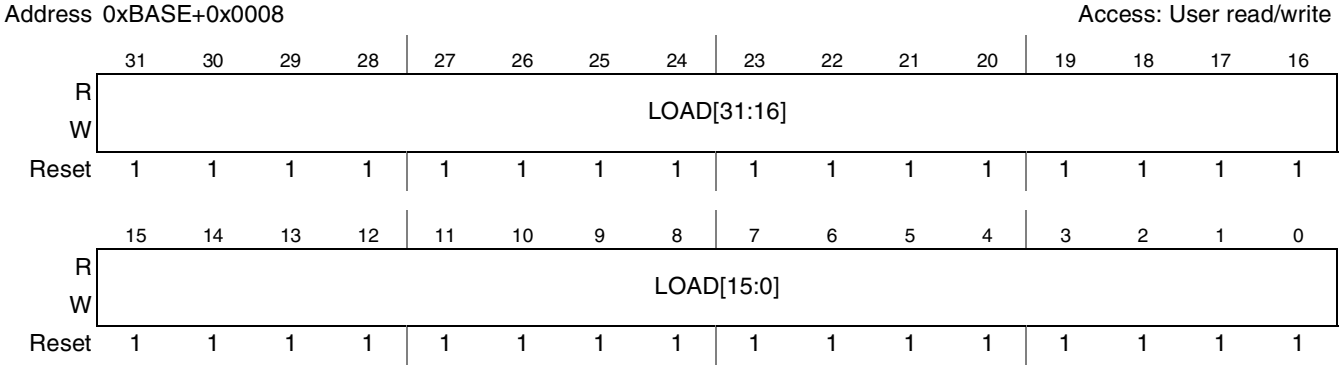

Figure 29-5. EPIT Load Register

Table 29-7 shows the EPIT load register field description.

Table 29-7. Register Field Descriptions

Field	Description
31–0 LOAD	Load Value. Value that is loaded into the counter at the start of each count cycle.

29.3.2.4 EPIT Compare Register

The EPIT compare register (EPITCMPR), shown in Figure 29-6, holds the value that determines when a compare event will be generated.

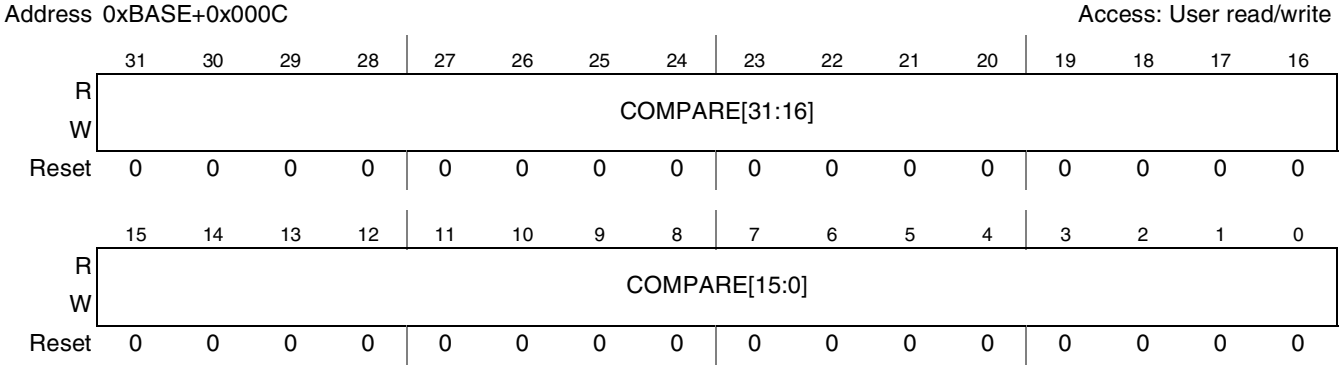

Figure 29-6. EPIT Compare Register

Table 29-8 shows the EPIT compare register field description.

Table 29-8. Register Field Descriptions

Field	Description
31–0 COMPARE	Compare Value. When the counter value equals this bit field value a compare event is generated.

29.3.2.5 EPIT Counter Register

The EPIT counter register (EPITCNR), shown in Figure 29-7, contains the current count value and can be read at any time without disturbing the counter. This is a read only register and any attempt to write into it will generate a transfer error. But if the IOVW bit in EPITCR is set, the value of this register can be overwritten with a write to EPITLR. This change is reflected when this register is read subsequently.

Address 0xBASE+0x0010 Access: User read only

Table 29-9. Register Field Descriptions

Field	Description
31–0 COUNT	Counter Value. This is the counter register value and denotes the current count state the counter register is in.

29.4 Functional Description

This section discusses the following:

- Section 29.4.1, Operation”
- Section 29.4.2, Clocks”
- Section 29.4.3, Compare Event”

29.4.1 Operation

The EPIT has a single 32-bit down counter, which starts counting when the module is enabled by software. The start value of the counter is loaded from the EPIT Load Register which can be written to at any time by the processor. The value in the compare register determines the time of occurrence of the interrupt.

When EPIT is disabled (EN = 0), then both Main Counter and Prescaler Counter freeze their count at current count values. ENMOD bit is a r/w bit which decides the counter value when the EPIT is enabled again by setting EN bit. If ENMOD bit is set, then Main Counter is loaded with the load value (If RLD = 1)/0xFFFF_FFFF (If RLD = 0) and Prescaler Counter is reset, when EPIT is enabled (EN = 1). If ENMOD is programmed to 0 then both Main Counter & Prescaler Counter restart counting from their frozen values, when EPIT is enabled (EN = 1). If EPIT is programmed to be disabled in a low power mode (STOP/WAIT), then both the main counter and the prescaler counter freeze at their current count values when EPIT enters low power mode. When EPIT exits the low power mode, both main counter and prescaler counter start counting from their frozen values irrespective of the ENMOD bit.

A hardware reset resets all EPIT registers to their respective reset values. There is a software reset which has the same effect on all registers except for the EN, ENMOD, STOPEN, and WAITEN bits in the control register. The state of these bits are not affected by software reset. Software reset can be asserted even when the EPIT is disabled.

29.4.2 Clocks

The clock that feeds the prescaler can be selected from among the following options:

- High frequency Clock (ipg_clk_highfreq)

  This is a high freq clock which is provided by the Clock Controller module (CCM). This clock is supposed to be on in low power mode when ipg_clk is turned off and thus EPIT can be run on this clock in low power mode. The CCM is expected to provide this clock after synchronizing it to ahb_clk in normal functional mode and switch to the unsynchronized version in low power mode.

- Low Reference Clock (ipg_clk_32k)

  This is the 32Khz low reference clock which is provided by the CCM. This clock is supposed to be on in low power mode when ipg_clk is turned off and thus EPIT can be run on this clock in low power mode. The CCM is expected to provide this clock after synchronizing it to ahb_clk in normal functional mode and switch to the unsynchronized version in low power mode.

- Global Functional Clock (ipg_clk)

  This clock is supposed to be on in normal operations, if ipg_clk is selected (CLKSRC= 01) as Clock Source. In low power modes, if EPIT is programmed to be disabled (STOPEN or WAITEN), then ipg_clk can be switched off.

The clock input source is determined by the clock source (CLKSRC) field in the control register. The clock input to the prescaler can also be disabled by programming the CLKSRC bits of control register to 00. **This field value should be changed only after disabling the EPIT by clearing the EN bit in the EPITCR**. For other programming requirements while changing clock source, refer to Section 29.5, Initialization/Application Information.”

The PRESCALER field is used to select the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by a value between 1 and 4096. A change in the value of the PRESCALER field is immediately reflected on its output clock frequency.

Figure 29-8 shows the prescaler value change diagram.

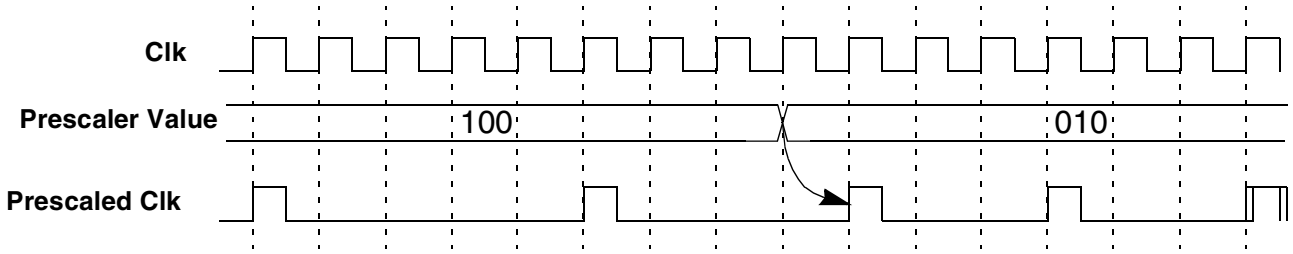

Figure 29-8. Prescaler Value Change Diagram

Whenever ipg_clk is not selected, the ipg_enable_clk is de asserted to turnoff ipg_clk to EPIT.

29.4.3 Compare Event

When the programmed content of EPITCMPR matches the value in EPITCNR, a compare status flag is set and an interrupt is generated if the corresponding bit is set in the control register. Consequently, the compare output pin will be set, cleared, toggled or not affected at all according to how the mode bits are programmed. If an interrupt is required at rollover (when counter value reaches 0x0000_0000 and new value is loaded) compare register value should be made equal to load register value in set-and-forget mode or equal to 0xFFFF_FFFF in free-running mode.

Figure 29-9 shows the compare event and interrupt timer diagram.

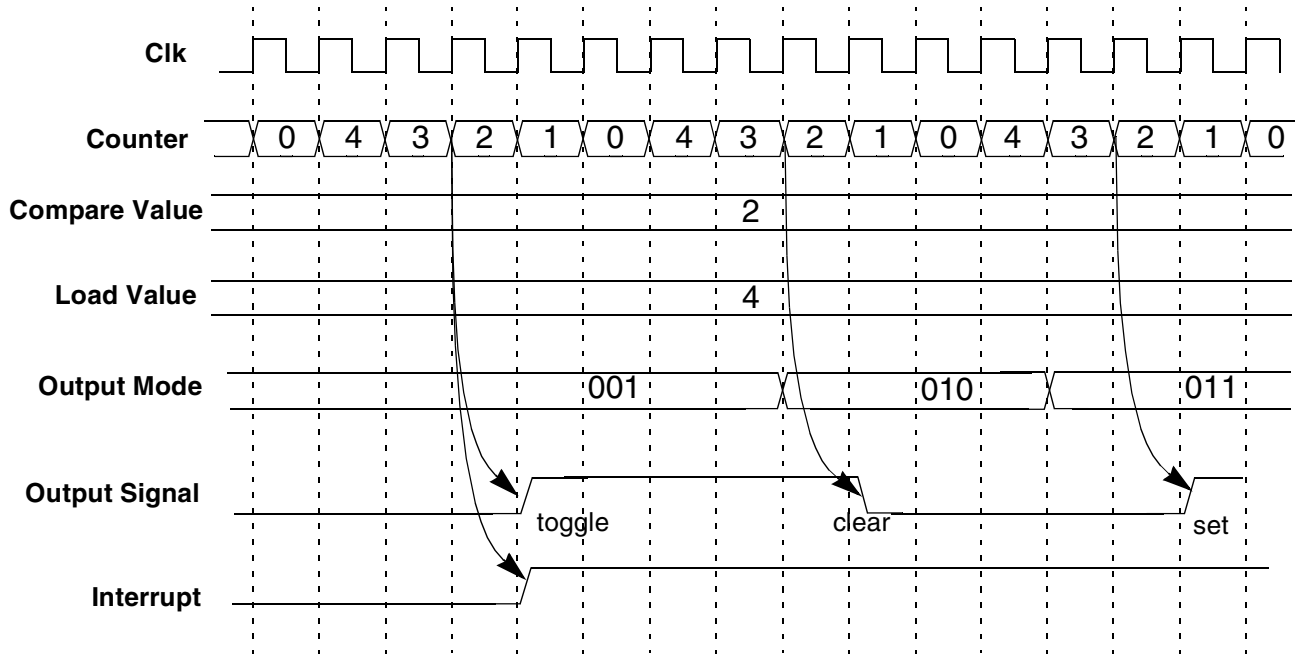

Figure 29-9. Compare Event and Interrupt Timing Diagram

29.4.3.1 Counter Value Overwrite

The EPIT counter value can be overwritten to acquire a desired value at any point of time. The procedure for this is to set the IOVW bit in the control register and then write the desired value into the load register. This will result in the load register acquiring that value and also the counter being overwritten with it. If the EPIT is running the counter resumes counting from the overwritten value.

29.4.3.2 Low Power Mode Behavior

The EPIT timer's behavior in low power modes depends on the clock source that it runs with. If the selected clock source is available and the corresponding low power enable bit is set, then the EPIT continues to function in the low power mode. If EPIT is programmed to be disabled in a low power mode (STOP/WAIT), then main counter and the prescaler counter freeze at the current count values when EPIT enters low power mode. When EPIT exits the low power mode, both main counter and prescaler counter start counting from their frozen values irrespective of the ENMOD bit.

Care should be taken that in the low power mode, any register read/ write operations should only be done if the selected clock running the counter is synchronous to ipg_clk_s. If the clock selected is not available or the enable bit is not set then the counter value freezes at its current value and resumes counting once the low power mode is excited.

29.4.3.3 Debug Mode Behavior

In debug mode, the EPIT timers have the option of continuing to run or be halted. If the DBGEN bit is reset in the EPIT control Register, the timer is halted. When debug mode is exited, the timer operation reverts to what it was prior to entering debug mode.

29.5 Initialization/Application Information

The CLKSRC field in EPITCR determines the clock source. This field value should be changed only after disabling the EPIT (EN = 0). The following software sequence must be used when changing the clock source.

1. Disable EPIT by setting EN = 0 in EPITCR.
2. Program OM = 00 in EPITCR.
3. Disable EPIT interrupts.
4. Program CLKSRC to desired clock source in EPITCR.
5. Clear EPIT status register (EPITSR) i.e. (w1c).
6. Enable EPIT interrupts.
7. Set ENMOD = 1 in EPITCR, to bring EPIT Counter to defined state (EPITLR value or 0xFFFF_FFFF).
8. Enable EPIT (EN = 1) in EPITCR.

Chapter 30
Enhanced SDRAM Controller (eSDCTL)

30.1 Introduction

ESDCTL is a DDR controller used for controlling DDR2 and mDDR memories. The controller sub blocks are as follows:

- Address Decoder—Used for interpreting the AXI address to the used device domain (chip select, bank, row and column)
- Config Register—For configuring the controller registers through IP accesses and storing registers values.
- Bank Model—Stores memory banks status.
- Size Logic—Used for breaking an incoming access to the required set of accesses to the memory device.
- Command Sequencer—Used to decide which command is required next from the memory.
- Command Control—Execute the chosen command when it can and control the process each command execution initiation.
- LPDDR Interface—Contain the Delay Lines and special logic for working with DDR devices which send/receive data in posedge and negedge.
- Data Path—Sort the outgoing data in Write and the incoming data in Read.

30.2 Block Diagram

Figure 30-1 shows the block diagram.

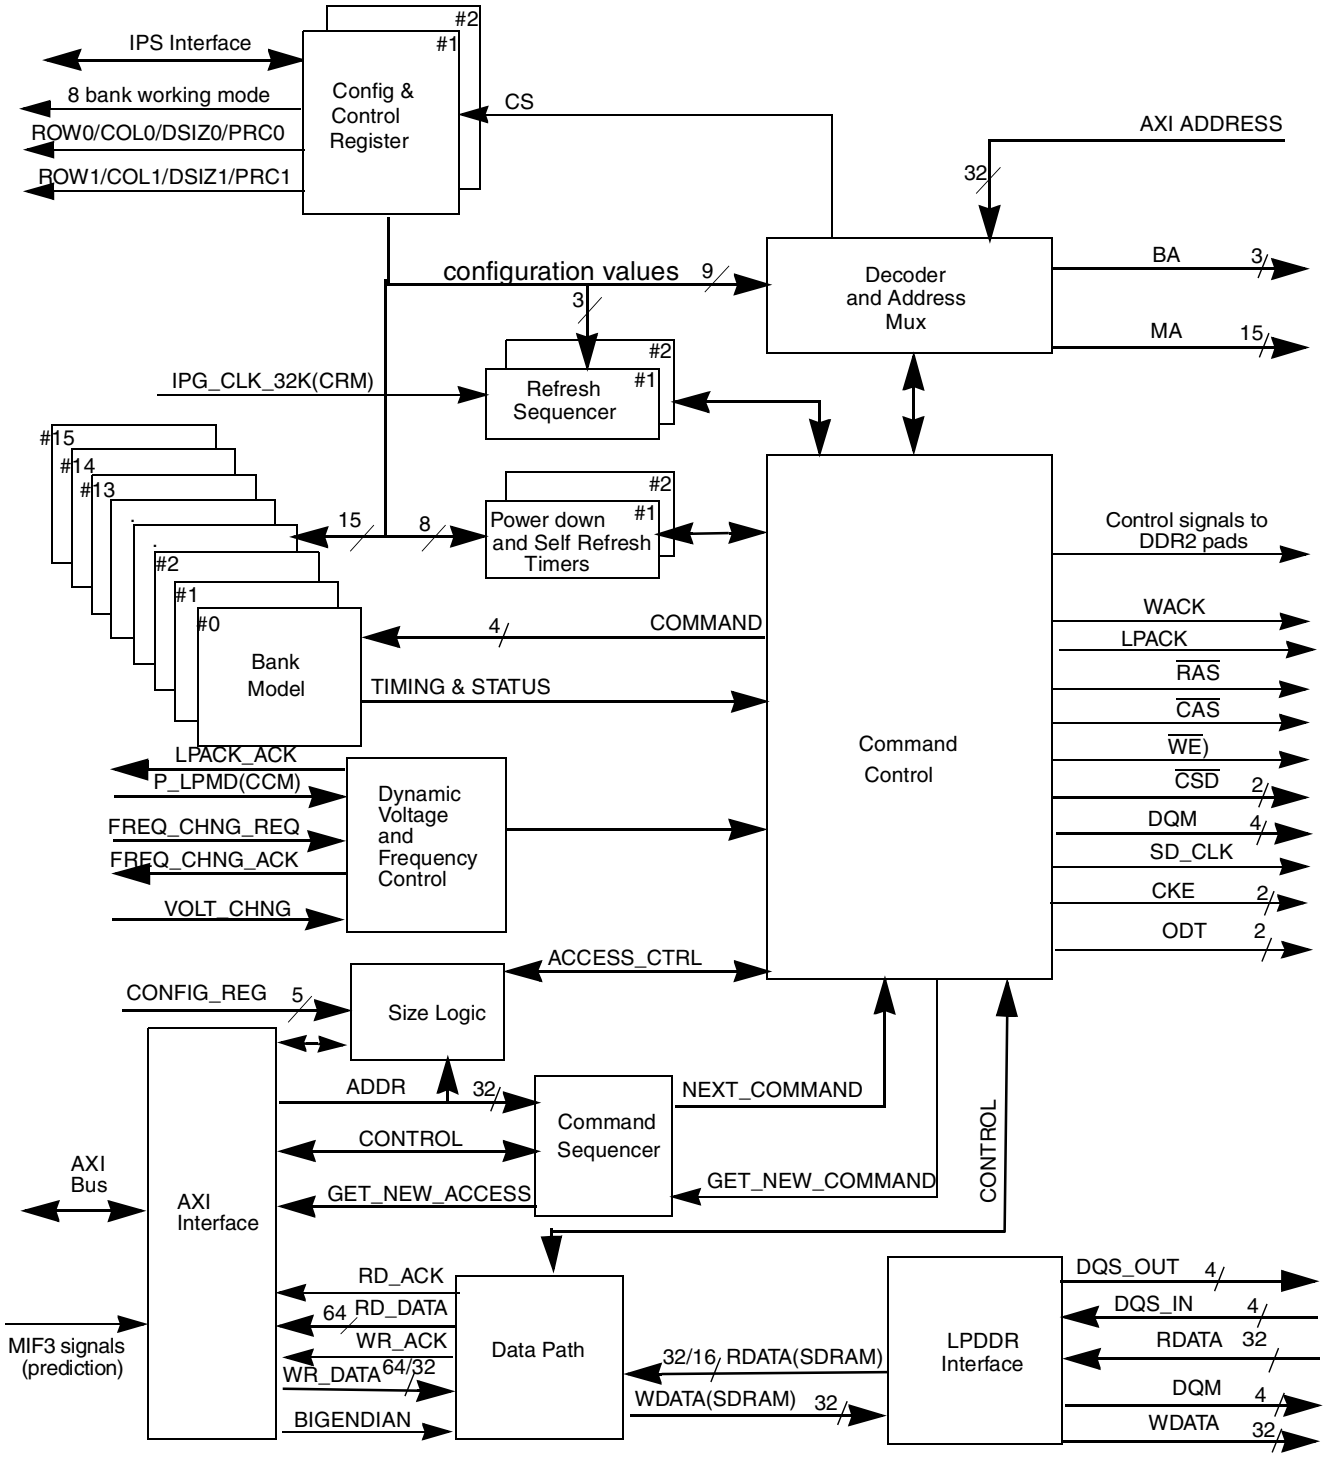

Figure 30-1. Enhanced LPDDR/DDR2 SDRAM Controller Block Diagram

30.3 Overview

The Enhanced SDRAM Controller consists of nine major blocks, including the SDRAM command state machine controller, bank register (page and bank address comparators), row/column address multiplexer, configuration registers, refresh request counter, command sequencer, size logic (splitting access), data path (data aligner/multiplexer), LPDDR interface, and the Power Down timer.

30.3.1 Features

The ESDRAMC includes the following features:

- Full support of Dynamic frequency change and voltage change for both MDDR and DDR2 modes.
  - Negotiation for frequency change with the system.
  - Constant delay line re-measuring for voltage change is supported to allow voltage change.
- Optimization of consecutive memory accesses through memory command anticipation (latency hiding)
  - Hiding latency by optimization the commands to both CS connected-command anticipation.
  - Preparation of valid waiting AXI access, in terms of ACT,PRE commands while serving another access.
  - Preparation of predicted next miss access, in term of ACT, PRE commands while serving another access.
  - Keeping track of open memory pages
  - Bank-wise memory address mapping
  - MDDR burst length configuration of 8.
  - DDR2 burst length configuration of 4.
  - AXI bus compliant
  - Shared Address and command bus to memory devices.
- Supports 64-Mbyte, 128-Mbyte, 256-Mbyte, 512-Mbyte, 4-bank, 8-bank, LPDDR or DDR2.
  - Two independent chip selects.
  - Up to 256-Mbyte per chip select.
  - Up to eight banks active simultaneously per chip select for DDR2.
  - Up to four banks active simultaneously per chip select for MDDR.
  - Support only CAS 3 devices.
  - JEDEC standard pinout/operation.
- Support for ×16/×32 mDDR/DD2 DDR400 devices.
- Support on die termination (ODT) for DDR2 devices.
- Support both differential DQS and single ended DQS modes.
- Software configurable for different system and memory devices requirements.
  - x16/x32 memory data bus width.
  - number of row and column addresses.
  - row cycle delay (t_{RC})

- auto-refresh cycle delay (t_{RFC})
- row precharge delay (t_{RP})
- row to column delay (t_{RCD})
- load mode register to active command (t_{MRD})
- write to precharge (t_{WR})
- write to read (t_{WTR}) for LPDDR memories only
- LPDDR exit power down to next valid command delay (t_{XP})
- active to precharge (t_{RAS})
- active to active (t_{RRD})
- Exit self refresh to any command (t_{XSR}/t_{XSRD} / t_{SRFX})

- Built in auto-refresh timer and state machine
- Hardware and software supported self-refresh entry and exit
  - Keeps data valid during system reset and low power modes
  - Auto Power Down timer (one per Chip Select)
  - Automatic Self Refresh timer (one per Chip Select)
  - Auto Precharge timer (one per bank in each chip select)
- Supports Deep power down enter and exit in software for LPDDR.
- Supports AXI bursts of up to 8
  - Supports bus transfers of 32 and 64 bit.
  - 8 and 16 bit transfers are supported for single accesses only.
  - Fixed burst type is not supported, other then bursts of length 1.
- Page boundary crossing support, up to 4-Kbyte boundary in AXI address.
  - Automatically generates precharge and active the next row when crossing page boundary on the AXI bus.

30.3.2 AXI Interface

The AXI interface interfaces between any AXI bus master and the ESDCTL controller. The ESDCTL supports the following features and restrictions:

Supports one AXI ×64 bus width.

- Supports clock frequency of up to 200 MHz for the AXI port.
- Out of order accesses are not supported. That means that data interleaving of two different IDs is not allowed in write cycles.
- The controller will not provide data interleaving in the AXI read data bus.
- Exclusive AXI accesses are not supported by the ESDCTL. Exclusive AXI accesses should be handled by the ESDCTL bus master.
- Atomic/Locked access are ignored. Atomic/Locked access should be handeled by the ESDCTL bus master.

- All accesses are treated as non-bufferable and non-cachable accesses. Bufferable and cachable accesses should be handeled by the ESDCTL bus master.
- The ID bus is 8 bit long.
- Bursts of up to 8 double-words (64 bits), will be supported, for incr and wrap burst types. AWSIZE/ARSIZE are 2 bits wide. AWLEN/ARLEN are 3 bits wide.
- ARRAEDY and AWREADY are all defaulted to high in idle state. Accepting a read or a write will lower the other ready as well until the controller is ready for another address for latency hiding. If both a read and a write are valid at the same cycle, the read will be serviced first, then the write, and only after the write is done the readies will go back up.
- The controller BRESP and RRESP signals are returning OKAY by default, even for exclusive access (and not EXOKAY). For accesses that are out of the memory space a DECERR will be returned, and for an access to a chip select which is not enabled, a SLVERR will be issued on bus.

NOTE

M4IF is used as ESDCTL arbirtation to buffer and manage incoming AXI accesses. Please refer to M4IF spec for more detail.

30.4 External Signal Description

This section discusses input and output signals between the Enhanced SDRAM Controller and the external memory devices. Other than the chip select outputs ($\overline{\text{CSD}}$0 and $\overline{\text{CSD}}$1), on die termination outputs (ODT0 and ODT1) and clock enables (CKE0 and CKE1), all signals are shared between the two chip select regions.

Table 30-1 summarizes the interface signals.

Table 30-1. ESDRAMC Signal Properties

Name	Function	Reset State	Direction
warm_reset	Warm synchronious Reset to ESDCTL	0	Input
reset_b	Cold Asynchronious Reset to ESDCTL	0	Input
sdclk_out	Clock to SDRAM (up to 200MHz)	1	Output
cke[0]	Clock enable to CS0	0	Output
cke[1]	Clock enable to CS1	0	Output
cs_b[0]	Chip select to CS0	1	Output
cs_b[1]	Chip select to CS1	1	Output
rd_data[31:0]	Read Data from memories	0	Input
wr_data[31:0]	Write data to memories	0	Output
out_en[3:0]	Output buffer enable for DQ pad. (bit per byte)	0	Output
ma[14:0]	Col/row addresses	0	Output
ba[2:0]	Bank address	0	Output

Table 30-1. ESDRAMC Signal Properties (continued)

Name	Function	Reset State	Direction
dqm_x[3:0]	Data Qualifier Mask (bit per byte)	0	Output
we_b	Write Enable	1	Output
ras_b	Row Address Strobe	1	Output
cas_b	Column Address Strobe	1	Output
lpack	Low Power Mode Acknowledge	1	Output
awbigend	Big endian signal for the current write transaction.	0	Input
arbigend	Big endian signal for the current read transaction.	0	Input
row0[2:0]	Number of rows as was programed for chip select number 0	0	Output
col0[1:0]	Number of columns as was programed for chip select number 0	0	Output
dsiz0[1:0]	SDRAM bus width as was programed for chip select number 0	0	Output
prc0[7:0]	Precharge bank indication for 8 banks of CS0.	0	Output
row1[2:0]	Number of rows as was programed for chip select number 1	0	Output
col1[1:0]	Number of columns as was programed for chip select number 1	0	Output
dsiz1[1:0]	SDRAM bus width as was programed for chip select number 1	0	Output
prc1[7:0]	Precharge bank indication for 8 banks of CS1.	0	Output
ddr2_8_bank	Number of banks in device(4 or 8).	0	Output
dvfs_req	Frequency change Request	0	Output
dvfs_grant	Frequency change Acknowledge	0	Input
p_lpmd	Low Power Mode Entry Request	0	Input
bi_on	Address Interleaving indication to arbiter	0	Output
volt_chng	Voltage change indication.	0	Input
freerun_clk	Free Running clock - not gated by lpmd	0	Input
clk32	32KHz clock	0	Input
emi_pd	Power down indication for SRPG cells	0	Input
sdram_base_via[3:0]	4 msb bits of CS0 in memory map.	0	Input
MIF3 signals			
mif3_p1_valid	Valid rd/wr access exist.	0	Input
mif3_p1_cs	Chip select of valid access	0	Input

Table 30-1. ESDRAMC Signal Properties (continued)

Name	Function	Reset State	Direction
mif3_p1_ba[2:0]	Bank of valid access	0	Input
mif3_p1_row[14:0]	Row of valid access	0	Input
mif3_p2_valid	Next rd/wr miss access	0	Input
mif3_p2_cs	Chip select of next miss access	0	Input
mif3_p2_ba[2:0]	Bank of next miss access	0	Input
mif3_p2_row[14:0]	Row of next miss access	0	Input
mif3_p2_ack	Bank/row of next miss access is now open, and the access is hit.	0	Output
DDR2 signals			
odt[0]	On die termination to CS0	0	Output
odt[1]	On die termination to CS1	0	Output
term_ctl0[1:0]	Termination control to DQS[0]/DQ[31:24] pads	0	Output
term_ctl1[1:0]	Termination control to DQS[1]/DQ[23:16] pads	0	Output
term_ctl2[1:0]	Termination control to DQS[2]/DQ[15:8] pads	0	Output
term_ctl3[1:0]	Termination control to DQS[3]/DQ[7:0] pads	0	Output
diff_dqs_en	Differential DQS indication to DQS[3:0] pads	0	Output
Mobile LPDDR signals			
dqs_out3	Data strobe byte 3 (D[31:24])	0	Output
dqs_out2	Data strobe byte 2 (D[23:16])	0	Output
dqs_out1	Data strobe byte 1 (D[15:8])	0	Output
dqs_out0	Data strobe byte 0 (D[7:0])	0	Output
dqs_in3	Data strobe byte 3 (D[31:24])	0	Input
dqs_in2	Data strobe byte 2 (D[23:16])	0	Input
dqs_in1	Data strobe byte 1 (D[15:8])	0	Input
dqs_in0	Data strobe byte 0 (D[7:0])	0	Input
dqs_out_en_x	Output buffer_enable for DQS pads. (bit per DQS line)	0	Output
AXI protocol signals			
ARADDR[31:0]	Read address	0	Input
ARBURST[1:0]	Read transaction burst type	0	Input
ARID[7:0]	Read address ID	0	Input
ARLEN[2:0]	Read transaction burst length	0	Input
ARSIZE[1:0]	Read transaction data size	0	Input

Table 30-1. ESDRAMC Signal Properties (continued)

Name	Function	Reset State	Direction
AWADDR[31:0]	Write address	0	Input
AWBURST[1:0]	Write transaction burst type	0	Input
AWID[7:0]	Write address ID	0	Input
AWLEN[2:0]	Write transaction burst length	0	Input
AWSIZE[1:0]	Write transaction data size	0	Input
WDATA[63:0]	Write data	0	Input
WSTRB[7:0]	Write data strobe	0	Input
ARVALID	Read address valid	0	Input
AWVALID	Write address valid	0	Input
BREADY	Response channel ready	1	Input
RREADY	Read data channel ready	1	Input
WLAST	Last write data indication	0	Input
WVALID	Write data valid	0	Input
WID[7:0]	Write data ID	0	Input
BID[7:0]	Response ID	0	Output
BRESP[1:0]	Response	0	Output
RDATA[63:0]	Read data	0	Output
RID[7:0]	Read data ID	0	Output
RRESP[1:0]	Read response	0	Output
ARREADY	Read address channel ready	1	Output
AWREADY	Write address channel ready	1	Output
BVALID	Response valid	0	Output
RLAST	Last read data indication	0	Output
RVALID	Read data valid	0	Output
WREADY	Write data channel ready	1	Output
CLK	AXI clock	0	Input
IPS protocol signals			
ips_module_en	Register interface enable	0	Input
ips_wdata[31:0]	Register interface write data	0	Input
ipg_clk	Register interface clock	0	Input
ips_addr[11:2]	Register interface address	0	Input
ips_rwb	Register interface read/write bit	0	Input
ips_rdata[31:0]	Register interface read data	0	Output

Table 30-1. ESDRAMC Signal Properties (continued)

Name	Function	Reset State	Direction
ips_xfr_wait	Register interface wait state bit	0	Output
ips_xfr_err	Register interface error state bit	0	Output
Debug signals			
delay_line_significant_change	A signal to indicate a significant change was made to the delay line measurement	0	Output

30.5 Memory Map and Register Definition

The Enhanced SDRAM Controller programming model consists of control and configuration registers (32-bit length) for each chip select and a miscellaneous register, as shown in Table 30-2. The control register maintain system dependent information, while the configuration register maintain memory device dependent information. ESDCFG0 defines the operating characteristics for the region selected by $\overline{CSD0}$, and ESDCFG1 does the same for the $\overline{CSD1}$ region. Bit field assignments within the registers are identical, so a single description will apply to both registers.

Both the control and configuration registers are 32 bits in length with bit fields defined in Figure 30-4 through Figure 30-7 respectively. All implemented bits are fully readable and writable. Reserved bit locations are unaffected by writes and always read back as zero. All register accesses must be SINGLE word (32-bit) operations through the IPS bus protocol. Accesses of any other size will have indeterminate results.

The reset state of each bit is shown underneath the bit field name. An asterisk indicates that the value is dependent on the operating mode selected during reset. Details are provided in the following bit field descriptions.

30.6 Memory Map

The ESDRAMC supports 64, 128, 256, 512 -Mb, 1 -Gb and 2 -Gb, 4 bank,8 bank, single and double data rate, synchronous DRAMs on two independent chip selects. Each chip selects defines a specific memory address mapped as shown in Table 30-3.

Table 30-2 shows the ESDRAMC memory map and Table 30-5 shows the ESDRAMC register definition.

Table 30-2. ESDRAMC Memory Map

Address	Register	Access	Reset	Section/Page
0x83FD_9000 (ESDCTL0)	Enhanced SDRAM Control Register 0	R/W	0x0111_0000	30.7.1.1/30-15

Table 30-3. Chip selects memory region

Address	Use	Access
0x{base_via,000_0000}–0x{base_via,FFF_FFFF}	CSD0 memory region (256MB)	Read/Write
0x{base_bia+1,000_0000}–0x{base_via+1,FFF_FFFF}	CSD1 memory region (256MB)	Read/Write

30.7 Register Summary

Figure 30-2 shows the key to the register fields and Table 30-4 shows the register figure conventions.

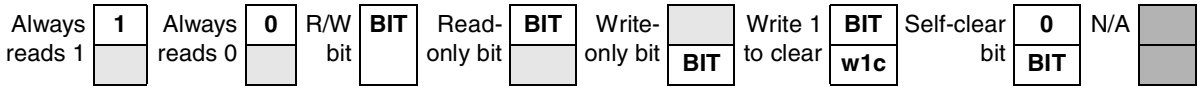

Figure 30-2. Key to Register Fields

Table 30-4. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read-only. Writing this bit has no effect.

Table 30-4. Register Figure Conventions (continued)

Convention	Description
W	Write-only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 30-5 shows the ESDRAMC register summary.

30.7.1 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of the register bit and field function follow the register diagrams, in bit order.

NOTE

Memory may be viewed from either a big-endian or little-endian byte ordering perspective depending on the processor configuration (see Figure 30-3). In big-endian mode (the typical default operating mode), the most significant byte (byte 0) of word 0 is located at address 0. For little-endian mode, the most significant byte of word 0 is located at address 3. Within registers, bits are numbered within a word starting with bit 31 as the most significant bit. By convention, byte 0 of a register is the most significant byte regardless of endian mode.

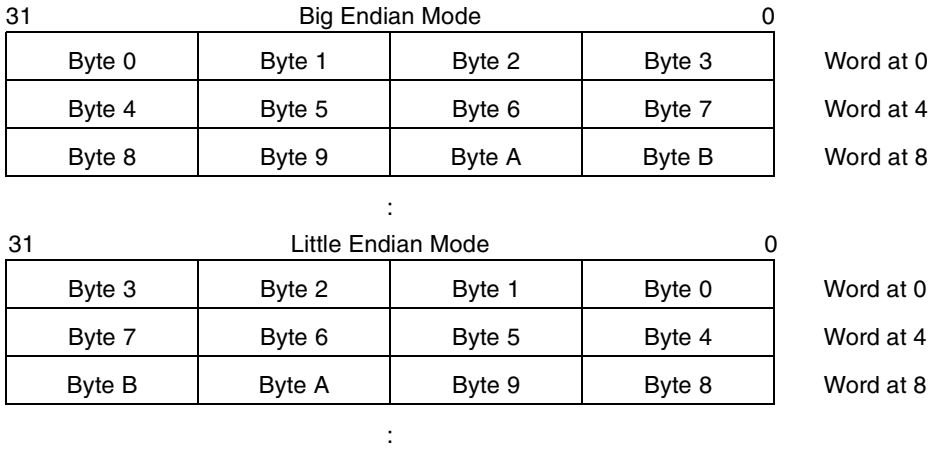

Figure 30-3. Data Organization in Memory

30.7.1.1 ESDCTL0 and ESDCTL1 Control Registers

This register contains the controlling various memory and control settings for the ESDRAMC. The bit assignments for the register are shown in Figure 30-4 and Figure 30-5. The field descriptions for the bit assignments are listed in Table 30-6.

Figure 30-5. Enhanced SDRAM Control Register (ESDCTL1)

Table 30-6. Enhanced SDRAM Control Register (ESDCTL0/1) Field Descriptions

Field	Description
31 SDE	Enhanced SDRAM Controller Enable This control bit enables/disables the Enhanced SDRAM controller. The reset value of this bit is “0”. No clocks and clock enable will be sent to memory. Writing one to those control bits enables the module, for both chip selects. Init sequence of 400 µs will pass from the enable time until the memory will be accessible. Clearing those bits disables the module. By disabling both bits (SDE0 and SDE1) all clocks within the module shuts off (with the exception of register accesses). 0 Disabled 1 Enabled
30–28 SREFR	SDRAM Refresh Rate This control bit field enables/disables SDRAM refresh cycles and controls the refresh rate. Refresh cycles are referenced to a 32 kHz clock. At each falling edge 1, 2, 4, 8 or 16 rows are refreshed as determined by this bit field. Multiple refresh cycles will be separated by the row cycle delay specified in the SRC control field. Refresh is disabled by hardware reset. SREFR Bit Field Encoding settings are listed in Table 30-7.
27	Reserved
26–24 ROW	Row Address Width This control field specifies the number of row addresses used by the memory array. It will affect the way an incoming address will be decoded. 000 11 Row Addresses 001 12 Row Addresses 010 13 Row Addresses 011 14 Row Addresses 100 through 111 are reserved
23 DBL_tRFC	Double tRFC value that was chosen in bits [31–28] of ESDCFG register. 0 tRFC value that will be used will be as shown in tRFC field description. 1 tRFC value that will be used will be double than the value that is shown in tRFC field description.
22	Reserved
21–20 COL	Column Address Width The COL control field is used to specify the number of column addresses in the memory array. It will determine how an incoming address will be decoded. 00 8 bits 01 9 bits 10 10 bits 11 Reserved
19–18	Reserved
17–16 DSIZ	SDRAM Memory Data Width This field defines the width of the SDRAM memory and its alignment on the external data bus. 16-bit ports may be aligned to either the high or low half word to equalize capacitive loading on the bus. Data qualifier mask control outputs must be matched to the selected data bus alignment. Memories aligned to D[31:16] use DQM2 and DQM3. Memories aligned to D[15:0] use DQM0 and DQM1. 00 16-bit memory width aligned to D[31:16] 01 16-bit memory width aligned to D[15:0] (reset value for CSD0) 10 32-bit memory width (reset value for CSD1) 11 reserved

Table 30-6. Enhanced SDRAM Control Register (ESDCTL0/1) Field Descriptions (continued)

Field	Description
15–14 SRT	Self Refresh Timer This field determines whether the SDRAM will be placed in a Self Refresh condition after a selectable delay from the last access. The Self Refresh time-out can be triggered on either the absence of an active bank (SRT=01) or a clock (ESDCTL_CLK) count from the last access (SRT=10 or 11). Count based time-outs do not force the SDRAM into an idle condition (for example, any active banks remain open). The Self Refresh timers feature is disabled by hardware reset. A listing of the SRT Bit Field Encoding is shown in Table 30-9.
13–12 PWDT	Power Down Timer This field determines whether the SDRAM will be placed in a Power Down condition after a selectable delay from the last access. The Power Down time-out can be triggered on either the absence of an active bank (PWDT=01) or a clock (ESDCTL_CLK) count from the last access (PWDT=10 or 11). Count based time-outs performed Precharge all to the SDRAM. The Power Down timer feature is disabled by hardware reset. See sections Section 30.8.3.3, Precharge Power-Down Mode" and Section 30.8.3.4, Active Power-Down Mode" for a comprehensive description of this operating mode. A listing of the PWDT Bit Field Encoding is shown in Table 30-8.
11-0	Reserved

Table 30-7. SREFR Bit Field Encoding

SREFR[2:0]	Rows Each Refresh Clock	# Rows / 64 mS at 32 kHz	Row Rate at 32 kHz
000	Refresh Disabled (bit field reset value)		
001	1	2048	31.25 µs
010	2	4096	15.62 µs
011	4	8192	7.81 µs
100	8	16384	3.91µs
101	16	32768	1.95 µs
110	Reserved		
111	Reserved		

Table 30-8. PWDT Bit Field Encoding

PWDT[1:0]	Power Down Time-out	Memory Device Operating Mode
00	Disabled (bit field reset value)	Run Mode
01	Any time no banks are active [2]	Precharge Power Down
10	64 clocks (ESDCTL_CLK) after completion of last access[1]	Active Power Down
11	128 clocks (ESDCTL_CLK) after completion of last access[1]	Active Power Down

[1] This setting can't be used if the PRCT (precharge timer) or SRT (Self Refresh timer) is enabled.

[2] This is mutually exclusive with setting 01 of SRT field

NOTE

When PWDT is enabled and **lpmd** or **dvfs** requests are required by system, PWDT must be disabled before the requests are granted. PWDT can only be re-enabled after these modes have been exited.

Table 30-9. SRT Bit Field Encoding

SRT[1:0]	Self Refresh Time-out	Memory Device Operating Mode
00	Disabled (bit field reset value)	Run Mode
01	Any time no banks are active [2]	Self-Refresh
10	256 clocks (ESDCTL_CLK) after completion of last access[1]	Precharge all and then self-refresh
11	512 clocks (ESDCTL_CLK) after completion of last access[1]	Precharge all and then self-refresh

[1]This setting ca no't be used if the PRCT (precharge timer) or PWDT (Power Down Timer) is enabled.
[2] This is mutually exclusive with setting 01 of PWDT field
Note: SRT is not supported in DDR2.

30.7.1.2 ESDRAMC Configuration Registers (ESDCFG0/ESDCFG1)

The bit assignments for the configuration registers are shown in Figure 30-6 and Figure 30-7. The field descriptions for the registers is listed in Table 30-10.

Address 0x83FD_9004 (ESDCFG0) Access: User read-write

Figure 30-7. Enhanced SDRAM Configuration Register 1 (ESDCFG1)

Table 30-10. ESDCFG0/ESDCFG1 Field Descriptions

Field	Description
31–28 t_{RFC}	Auto refresh to any command. This is the idle delay after auto refresh command until another command can be issued. In DDR2 this is the idle delay after auto refresh command until non read command can be issued. Figure 30-16. 0000 10 clock 0001 11 clock 0010 12 clock 0011 13 clock 0100 14 clock 0101 15 clock 0110 16 clock 0111 17 clock 1000 18 clock 1001 19 clock 1010 20 clock 1011 21 clock 1100 22 clock 1101 23 clock 1110 24 clock 1111 25 clock **Note:** If bit "*DBL_tRFC*" in register "*ESDCTL*" is high, that value that will be chosen in this field will cause double delay. For example, setting tRFC = 0xA and DBL_tRFC = 1 will cause 40 cycles delay.
27–24 t_{XSR}	Exit self refresh to any command. This control field determines the minimum delay between a valid command is issued to the SDRAM after exiting sel-refresh mode. The value programmed in t_{XSR} is the number of clocks inserted after exiting self-refresh mode and any subsequent new valid command. An example timing diagram for t_{XSR} can be found in Figure 30-17. 0000 25 clock 0001 26 clock. 0010 27 clock 0011 28 clock 0100 29 clock 0101 30 clock 0110 31 clock 0111 32 clock 1000 33 clock 1001 34 clock 1010 35 clock 1011 36 clock 1100 37 clock 1101 38 clock 1110 39 clock 1111 40 clock

Table 30-10. ESDCFG0/ESDCFG1 Field Descriptions (continued)

Field	Description
23–21 t_{XP}	Exit power down to next valid command delay This control field determines the minimum delay between a valid command is issued to the memory device after exiting power down mode. The value programmed in t_{XP} is the number of clocks inserted after exiting power down mode and any subsequent new valid command. An example timing diagram for t_{XP} can be found in Figure 30-15. 000 1 cycle delay before new COMMAND issued to LPDDR after power down mode exit 001 2 cycle delay before new COMMAND issued to LPDDR after power down mode exit 010 3 cycle delay before new COMMAND issued to LPDDR after power down mode exit 011 4 cycle delay before new COMMAND issued to LPDDR after power down mode exit 100 5 cycle delay before new COMMAND issued to LPDDR after power down mode exit 101 6 cycle delay before new COMMAND issued to LPDDR after power down mode exit 110 7 cycle delay before new COMMAND issued to LPDDR after power down mode exit 111 8 cycle delay before new COMMAND issued to LPDDR after power down mode exit
20 t_{WTR}	WRITE to READ Command Delay Data for any WRITE burst may be followed by a subsequent READ command. To follow a WRITE without truncating the WRITE burst, t_{WTR} should be set as shown in Figure 30-8. The t_{WTR} should be configured according to the memory device being used. 0 1 clock 1 2 clocks
19–18 t_{RP}	Row Precharge Delay This control bit determines the number of idle clocks inserted between a precharge command and the next row activate command to the same bank.See Figure 30-9. 00 2 clock 01 3 clocks 10 4 clocks 11 5 clocks
17–16 t_{MRD}	Load Mode Register command cycle time This control bits determines the minimum number of idle clocks required after a Load-Mode-Register (LMR). See Figure 30-10. 00 1 clock 01 2 clocks 10 3 clocks 11 4 clocks

Table 30-10. ESDCFG0/ESDCFG1 Field Descriptions (continued)

Field	Description
15–12 t_{RAS}	ACTIVE to PRECHARGE Command These control bits determine the minimum number of clocks required between a ACTIVE to PRECHARGE command to the same bank. See Figure 30-12. 0000 1 clock 0001 2 clocks 0010 3 clocks 0011 4 clocks 0100 5 clocks 0101 6 clocks 0110 7 clocks 0111 8 clocks 1000 9 clock 1001 10 clocks 1010 11 clocks 1011 12 clocks 1100 13 clocks 1101 14 clocks 1110 15 clocks 1111 16 clocks
11–10 t_{RRD}	ACTIVE Bank A to ACTIVE Bank B Command A subsequent ACTIVE command to a different row in the same bank can only be issued after the previous active row has been “closed” (precharged). A subsequent ACTIVE command to another bank can be issued while the first bank is being accessed, which results in a reduction of total row-access overhead. The minimum interval between successive ACTIVE commands to different banks is defined by t_{RRD} as shown in Figure 30-13 (for t_{RRD}=3). The t_{RRD} bits field encoding is listed below and it determines the number of idle clocks inserted between consecutive ACTIVE commands to different banks. 00 1 clock active to active (different banks) 01 2 clocks active to active (different banks) 10 3 clocks active to active (different banks) 11 4 clocks active to active (different banks)
9–8	Reserved.
7 t_{WR}	WRITE to PRECHARGE Command Data for a fixed length WRITE burst may be followed by, or truncated with, a PRECHARGE command to the same bank (provided that auto precharge was not activated). The PRECHARGE command should be issued t_{WR} after the clock edge at which the last desired input data element is registered. t_{WR} control bit determines the number of idle clocks inserted between the last desired input data element and the next PRECHARGE command, as shown in Figure 30-11. 0 2 clocks 1 3 clocks

Table 30-10. ESDCFG0/ESDCFG1 Field Descriptions (continued)

Field	Description
6–4 t_{RCD}	SDRAM Row to Column Delay This field determines the number of clocks inserted between a row activate command and a subsequent read or write command to the same bank.See Figure 30-14. 000 1 clock row to column delay 001 2 clocks row to column delay 010 3 clocks row to column delay 011 4 clocks row to column delay 100 5 clocks row to column delay 101 6 clocks row to column delay 110 7 clocks row to column delay 111 8 clocks row to column delay
3–0 t_{RC}	ACTIVE to ACTIVE, same bank, command delay. 0000 20 clock 0001 2 clocks 0010 3 clocks 0011 4 clocks 0100 5 clocks 0101 6 clocks 0110 7 clocks 0111 8 clocks 1000 9 clocks 1001 10 clocks 1010 11 clocks 1011 12 clocks 1100 13 clocks 1101 14 clocks 1110 15 clocks 1111 16 clocks

Table 30-11 lists and summarizes the Enhanced SDRAM Controller configurable set of timing parameters.

Table 30-11. Configurable Timing Parameters

Symbol	Description	Relevancy
t_{MRD}	Load Mode Register command to ACTIVE or REFRESH command	always
t_{WR}	Write recovery time (write to precharge)	commands to same bank
t_{RAS}	ACTIVE to PRECHARGE command	commands to same bank
t_{RRD}	ACTIVE bank A to ACTIVE bank B command	commands to different banks
t_{RP}	PRECHARGE command period	commands to same bank
t_{RCD}	ACTIVE to READ or WRITE delay	commands to same bank
t_{RC}	ACTIVE to ACTIVE command period	commands to same bank
t_{WTR}	LPDDR READ to WRITE command delay	command to same bank
t_{XP}	LPDDR EXIT power down to next valid command delay	always

Table 30-11. Configurable Timing Parameters (continued)

Symbol	Description	Relevancy
t_{RFC}	Auto refresh to ACTIVE or to another auto refresh command interval.	always
t_{XSR}	SDRAM EXIT self refresh to next valid command delay	always

30.7.1.3 ESDMISC Miscellaneous Register (ESDMISC)

This register contains the controlling various memory and control settings for the ESDRAMC. The bit assignments for the register are shown in Figure 30-18, and the field descriptions for the bit assignments are listed in Table 30-12.

Address: 0x83FD_9010 (ESDMISC) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 30-18. ESDRAMC Miscellaneous Register (ESDMISC)

Table 30-12. Enhanced SDRAM Miscellaneous Register (ESDCTMISC) Field Descriptions

Field	Description
31 CS0_RDY	External status device on CS0. This is a read-only status bit, that indicates the state of the external memory device(s). This bit is cleared at reset or at deep power down entry for DDR. This bit is set after 400 µs of external memory wakeup period. 0 Device in wakeup period. 1 Device is ready for initialization.
30 CS1_RDY	External status device on CS1. This is a read-only status bit, that indicates the state of the external memory device(s). This bit is cleared at reset or at deep power down entry for DDR. This bit is set after 400 µs of external memory wakeup period. 0 Device in wakeup period. 1 Device is ready for initialization.
29 ODT_IDLE_ON	ODT behavior in IDLE mode: 0 Internal and external ODT will keep its last value and will not turn off. 1 internal and external ODT will be turned off when controller is IDLE.
28 SDCLK EXT	SDCLK extension. In cases that requires shutting off SDCLK, setting this bit will keep SDCLK working two extra clocks after CKE gets low. 0 No extension of SDCLK. 1 SDCLK will continue working 2 extra clocks after cke required to get low.
26–27 TERM_CTL3	For DDR2, when working in ODT mode these two bits determine the termination resistor of the DQS[3] and DQ[31–24] pads when making READ operations. 00 No termination 01 150 Ω 10 75 Ω 11 50 Ω
24–25 TERM_CTL2	For DDR2, when working in ODT mode these two bits determine the termination resistor of the DQS[2] and DQ[23–16] pads when making READ operations. 00 No termination 01 150 Ω 10 75 Ω 11 50Ω
22–23 TERM_CTL1	For DDR2, when working in ODT mode these two bits determine the termination resistor of the DQS[1] and DQ[15–8] pads when making READ operations. 00 No termination 01 150 Ω 10 75 Ω 11 50 Ω
21–20 TERM_CTL0	For DDR2, when working in ODT mode these two bits determine the termination resistor of the DQS[0] and DQ[7–0] pads when making READ operations. 00 No termination 01 150 Ω 10 75 Ω 11 50 Ω

Table 30-12. Enhanced SDRAM Miscellaneous Register (ESDCTMISC) Field Descriptions (continued)

Field	Description
19–16 AP bit	Auto Precharge bit location. This is the bit in the device that when driven high it signals a PRECHARGE command is actually a PRECHARGE ALL command and relevant to all banks. JEDEC standard defines this bit to be bit 10 of the address, and this is the default value for this register. If the device is not JEDEC complaint, then this field needs to be set to match the device requirement. 0000 - address bit 0 is the AP bit 0001 - address bit 1 is the AP bit ... 1111 - address bit 15 is the AP bit
15 DIFF_DQS_EN	Enables differential DQS mode when working with DDR2 device: 0 Differential DQS disabled. 1 Differential DQS enabled. **Note:** On initialization, memory has to be configured as well for this mode.
14 AUTO_DLL_PAUSE	Enable auto pause of 200 cycles after issuing DLL reset at startup (For DDR2 devices) until first READ command. The controller will realize a DLL reset use asserted if a LMR command use issued with “BA=0” and A8 high. 0 AUTO_DLL_PAUSE is disabled, in this case a manual pause can be issued when needed via the SCR register. 1 AUTO_DLL_PAUSE in enabled.
13 ODT_EN	For DDR2 devices, enable the use of the ODT control output bits to the memory. 0 The use of ODT is disabled and a constant ‘0’ will be issued in this outputs. 1 The use of ODT is enabled. **Note:** This bit configuration is common to both CS0 and CS1.
12 BI_ON	Bank interleaving bit. This bit indicates whether the system is interleaving the address or not. 0 Banks are not interleaved, and address will be decoded as bank-row-column 1 Banks are interleaved, and address will be decoded as row-bank-column Example: For an external memory with 8 bit column width and 12 bit row, the address 0x80000100 would decode to bank 0 row 1 col 0 for non interleaved system, but to bank 1 row 0 and col 0 for interleaved system. The address 0x80100000 would be directed to bank 1 row 0 col 0 for the non interleaved system, and to bank 0 row 400 and col 0 for the interleaved configuration.
11 FRC_MSR	Force measurement. When this bit is set the measurement unit will start a new measurement over and over again until this bit will be cleared.
10–9 MIF3_MODE	Controlling the MIF3 mechanism. 00 Disable MIF3. 01 Enable treatment for pending access only. 10 Enable treatment for pending access only. 11 Enable treatment for both pending and predicted accesses.
8–7 RALAT	Read Additional Latency, which determines when the contoller will retrieve the data from the ESDCTL internal fifo. Using this field to compensate on board/chip delays even in slow/fast frequencies. 00 The data will be retrieved from the fifo at the earliest step possible. 01 The data will be retrieved from the fifo one clock later than in RALAT==0. 10 The data will be retrieved from the fifo one clock later than in RALAT==1. 11 Reserved

Table 30-12. Enhanced SDRAM Miscellaneous Register (ESDCTMISC) Field Descriptions (continued)

Field	Description
6 DDR2_8_BANK	DDR2 device with 8 bank is in use. This bit is common for both chip selects. 0 The controller works with 4 bank device. 1 The controller works with 8 bank device.
5 LHD	Latency Hiding Disable for read operations. When setting this bit and making a read access, the next read access will be allowed only after the last data of the first read was sent to arbitration. 0 Latency Hiding Enable. 1 Latency Hiding Disable
4 DDR2_EN	Regular (non mobile DDR2) device. This bit is common for both chip selects. 0 DDR2 Disabled. (If DDR_EN is also disabled the controller will be in Mobile DDR mode) 1 DDR2 Enabled. (DDR_EN bit should be disabled for this option)
3 DDR_EN	Regular (non mobile) DDR1 device is connected. This bit is common for both chip selects. 0 DDR1 Disabled.(If DDR2_EN is also disabled the controller will be in Mobile DDR mode) 1 DDR1 Enabled. (DDR2_EN bit should be disabled for this option)
2	Reserved
1 RST	Software Initiated Local Module Reset. This bit generate local module reset to the ESDRAMC. Writing a 1 to RST bit will put the controller in reset. All ESDRAMC registers are not affected by the software reset, in order to keep the REFRESH mechanism active as initially configured, so the data is not violated. A burst terminate command is issued to the memory after the soft reset (to terminate any active bursts, in order to prevent potential contention on the DATA pads). **Note:** After soft reset, a Precharge all command must be issued prior to normal usage of the ESDRAMC. 0 Soft Reset disabled. 1 Controller is held in reset.
0	Reserved

30.7.1.4 SDRAM Special Command Register

This register is used to issue special commands on the external device bus (such as load mode register, manual self refresh, manual precharge etc.). Every write to this register is interpreted as a command, and a read from this register shows the last command executed.

Every write to this register results in one special command, and the IP bus asserts ips_xfr_wait as long as the special command is being carried out, thus introducing wait states for the next IP write.

Address 0x83FD_9014 (ESDSCR) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 30-19. ESDRAMC Special Command Register (ESDSCR)

Table 30-13. Enhanced SDRAM Special Command Register (ESDSCR) Field Descriptions

Field	Description
31	Reserved
30–16 PSEUDO_ADDR	Pseudo Address. This field is only considered for LMR and precharge commands, and determines the value on the address bus for the load mode register and if its a precharge all or not.
15 CON_REQ	Configuration request. When this bit is set it tells the controller the user would like to configure the IP registers, so in order to prevent a clash with the AXI bus, the controller holds the aready and awready signals at low, and will not accept LPMD request. This bit is high out of reset, meaning the controller is waiting on configuration and initialization of external memory before accepting any AXI accesses. Note that this bit should be held high during subsequent accesses to this register if AXI readies in low state are to be maintained. 1 AXI address readies are being held low 0 AXI address readies are operating normally
14 CON_ACK	Configuration acknowledge. This read only bit indicates that the controller is idle and no AXI accesses are pending execution. It is recommended that the master will wait until both CON_REQ and CON_ACK are 1 before preforming any writes on the IP bus. 1 AXI channels state machines are all idle 0 At least one of the AXI state machines is not idle
13–7	Reserved
6 MAN_DLL_PAUSE	In the case that AUTO_DLL_PAUSE is disabled, there is an option to issue manual dll pause with this bit. This pause of 200 cycles until next READ command will by issued if this bit is high when making LMR command, the delay will be issued to the CS selected in the LMR command. 0 MANUAL DLL PAUSE is disabled. 1 MANUAL DLL PAUSE is enabled.

Table 30-13. Enhanced SDRAM Special Command Register (ESDSCR) Field Descriptions (continued)

Field	Description
5–3 CMD	Command. This field contains the command to be executed: 000 No command / Exit low power mode. this value should be used when writing to this register (for con_req for example) but no command is needed, or when exiting manual self refresh or deep power down (CS will be considered). 001 Precharge (CS, BA and PSEUDO_ADDR fields used. for precharge all use pseudo address with bit 10 high, such as 0x400) 010 Auto-Refresh Command (Only CS) 011 Load Mode Register Command (CS, BA, and PSEUDO_ADDR fields used) 100 Manual Self Refresh (only CS) 101 Deep power down (Only CS) (Relevant for DDR mode only) 110 Reserved 111 Reserved
2 CS	Chip Select. This field determines which chip select the command is directed at.
1–0 BA	Bank Address. This field determines which bank within the chip select the command is directed at. Only used by the Precharge command or to denote a Load mode register as an Extended mode register set.

30.7.1.5 SDRAM Debug Address Register

This debug register holds the full address of the last access to return an error response (DECERR or SLVERR). This is a read-only register.

Address 0x83FD_9018 (ESDDAR) Access: User read only

Table 30-14. Enhanced SDRAM Debug Address Register (ESDDAR) Field Descriptions

Field	Description
31–0 DEBUG_ADDR	This field holds the full address of the last access to return an error response (DECERR or SLVERR). this is a read-only field.

30.7.1.6 SDRAM Delay Line 1 Configuration Debug Register

This debug register controls delay line 1 functionality, i.e., DQS[0] delay used during READ cycles. It allows to override/manually set the delay of DQS[0] line, that is used during READ cycles of BYTE[0]. The delay line compensates for process variations, and produces a constant delay regardless of the process, temperature and voltage. The bit assignments for the register are shown in Figure 30-21 and the field descriptions for the bit assignments are listed in Table 30-15.

Address 0x83FD_9020 (ESDCDLY1) Access: User read-write

Figure 30-21. SDRAM Delay Line 1 Configuration Debug Register

Table 30-15. Enhanced SDRAM Delay Line 1 Control Register (ESDCDLY1) Field Descriptions

Field	Description
31 SEL_DLY_REG_1	SEL_DLY_REG_1 bit selects the delay used by delay line 1. It selects between a quarter of a cycle (measured) plus or minus the delay line 1 offset field (DLY_OFFSET_1) and delay line 1 register value (DLY_REG_1). 0 Delay line 1 value is a quarter of a cycle (measured) plus or minus the delay line 1 correction factor field. 1 Bypass mode: Delay line 1 value is the value of delay line 1 register field (skipping the measurement).
30–24	Reserved
23–16 DLY_OFFSET_1	This field is the delay line 1 offset value. The offset value is used only if SEL_DLY_REG_1 is cleared. The offset value is used to compensate process dependent unalignments between dqs signal and the corresponding read data (in number of small delay units). The field represents positive and negative numbers using two's compliment representation. This allows positive and negative offsets from the quarter cycle measured value. For example, to add 3 delay units to the measured delay, this field should be 00000011, to subtract 3 delay units, it will be set to 11111101.

Table 30-15. Enhanced SDRAM Delay Line 1 Control Register (ESDCDLY1) Field Descriptions (continued)

Field	Description
15–8 DLY_ABS_OFFSET_1	Absolute delay offset. This field decides the specific delay line absolute delay in fraction of a cycle terms. The fraction is process and frequency independent. The delay for the delay line would be (DLY_ABS_OFFSET ÷ 512) × tCK. So for the default value of 128 we get a quarter cycle delay. In Bypass mode (SEL_DLY_REG = 1), this register has no effect on the delay. **Note:** Not all changes will have effect on the actual delay. If the requested change is smaller then the delay line resolution (1 delay unit, which varies between 20 pSec in best case to 50 in worst case), then no change will occur.
7–0 DLY_REG_1	This field is the delay (in number of buffer units) that will be used by delay line 1, if the SEL_DLY_REG1 bit is set. Since the delay is process, temperature and voltage dependent, for a given value of this filed we get different delay values. The SoC team should provide the equivalent delay of 1 buffer. This field contains only positive numbers.

30.7.1.7 SDRAM Delay Line 2 Configuration Debug Register

This debug register controls delay line 2 functionality, i.e., DQS[1] delay used during READ cycles. It allows to override/manually set the delay of DQS[1] line, that is used during READ cycles of BYTE[1]. The bit assignments for the register are shown in Figure 30-22 and the field descriptions for the bit assignments are listed in Table 30-16.

Field	Description
31 SEL_DLY_REG_2	SEL_DLY_REG_2 bit selects the delay used by delay line 1. It selects between a quarter of a cycle (measured) plus or minus the delay line 1 offset field (DLY_OFFSET_2) and delay line 1 register value (DLY_REG_2). 0 Delay line 2 value is a quarter of a cycle (measured) plus or minus the delay line 2 correction factor field. 1 Bypass mode: Delay line 2 value is the value of delay line 2 register field (skipping the measurement).
30-24	Reserved

Table 30-16. Enhanced SDRAM Delay Line 2 Control Register (ESDCDLY2) Field Descriptions (continued)

Field	Description
23-16 DLY_OFFSET_2	This field is the delay line 2 offset value. The offset value is used only if SEL_DLY_REG_2 is cleared. The offset value is used to compensate process dependent unalignments between dqs signal and the corresponding read data (in number of small delay units). The field represents positive and negative numbers using twos compliment representation. This allows positive and negative offsets from the quarter cycle measured value. For example, to add 3 delay units to the measured delay, this field should be 00000011, to subtract 3 delay units, it will be set to 11111101.
15-8 DLY_ABS_OFFSET_2	Absolute delay offset. This field decides the specific delay line absolute delay in fraction of a cycle terms. The fraction is process and frequency independent. The delay for the delay line would be (DLY_ABS_OFFSET / 512) * tCK. So for the default value of 128 we get a quarter cycle delay. In Bypass mode (SEL_DLY_REG = 1), this register has no effect on the delay. Note that not all changes will have effect on the actual delay. If the requested change is smaller then the delay line resolution (1 delay unit, which varies between 20 pSec in best case to 50 in worst case), then no change will occur.
7-0 DLY_REG_2	This field is the delay (in number of buffer units) that will be used by delay line 1, if the SEL_DLY_REG2 bit is set. Since the delay is process, temperature and voltage dependent, for a given value of this filed we get different delay values. The SoC team should provide the equivalent delay of 1 buffer. This field contains only positive numbers.

30.7.1.8 SDRAM Delay Line 3 Configuration Debug Register

This debug register controls delay line 3 functionality, i.e., DQS[2] delay used during READ cycles. It allows to override/manually set the delay of DQS[2] line, that is used during READ cycles of BYTE[2]. The bit assignments for the register are shown in Figure 30-23 and the field descriptions for the bit assignments are listed in Table 30-17.

Field	Description
31 SEL_DLY_REG_3	SEL_DLY_REG_3 bit selects the delay used by delay line 3. It selects between a quarter of a cycle (measured) plus or minus the delay line 3 offset field (DLY_OFFSET_3) and delay line 3 register value (DLY_REG_3). 0 Delay line 3 value is a quarter of a cycle (measured) plus or minus the delay line 3 correction factor field. 1 Bypass mode: Delay line 3 value is the value of delay line 3 register field (skipping the measurement).
30–24	Reserved
23–16 DLY_OFFSET_3	This field is the delay line 3 offset value. The offset value is used only if SEL_DLY_REG_3 is cleared. The offset value is used to compensate process dependent unalignments between dqs signal and the corresponding read data (in number of small delay units). The field represents positive and negative numbers using twos compliment representation. This allows positive and negative offsets from the quarter cycle measured value. For example, to add 3 delay units to the measured delay, this field should be 00000011, to subtract 3 delay units, it will be set to 11111101.
15–8 DLY_ABS_OFFSET_3	Absolute delay offset. This field decides the specific delay line absolute delay in fraction of a cycle terms. The fraction is process and frequency independent. The delay for the delay line would be (DLY_ABS_OFFSET / 512) * tCK. So for the default value of 128 we get a quarter cycle delay. In Bypass mode (SEL_DLY_REG = 1), this register has no effect on the delay. **Note:** Not all changes affect the actual delay. If the requested change is smaller than the delay line resolution (1 delay unit, which varies between 20 pSec in best case to 50 in worst case), then no change occurs.
7–0 DLY_REG_3	This field is the delay (in number of buffer units) that will be used by delay line 3, if the SEL_DLY_REG3 bit is set. Since the delay is process, temperature and voltage dependent, for a given value of this filed we get different delay values. The SoC team should provide the equivalent delay of 1 buffer. This field contains only positive numbers.

30.7.1.9 SDRAM Delay Line 4 Configuration Debug Register

This debug register controls delay line 4 functionality, i.e., DQS[3] delay used during READ cycles. It allows to override/manually set the delay of DQS[3] line, that is used during READ cycles of BYTE[3].

The bit assignments for the register are shown in Figure 30-24 and the field descriptions for the bit assignments are listed in Table 30-18.

Field	Description
31 SEL_DLY_REG_4	SEL_DLY_REG_4 bit selects the delay used by delay line 4. It selects between a quarter of a cycle (measured) plus or minus the delay line 4 offset field (DLY_OFFSET_4) and delay line 4 register value (DLY_REG_4). 0 Delay line 4 value is a quarter of a cycle (measured) plus or minus the delay line 4 correction factor field. 1 Bypass mode: Delay line 4 value is the value of delay line 4 register field (skipping the measurement).
30–24	Reserved
23–16 DLY_OFFSET_4	This field is the delay line 4 offset value. The offset value is used only if SEL_DLY_REG_4 is cleared. The offset value is used to compensate process dependent unalignments between dqs signal and the corresponding read data (in number of small delay units). The field represents positive and negative numbers using twos compliment representation. This allows positive and negative offsets from the quarter cycle measured value. For example, to add 3 delay units to the measured delay, this field should be 00000011, to subtract 3 delay units, it will be set to 11111101.
15–8 DLY_ABS_OFFSET_4	Absolute delay offset. This field decides the specific delay line absolute delay in fraction of a cycle terms. The fraction is process and frequency independent. The delay for the delay line would be (DLY_ABS_OFFSET / 512) * tCK. So for the default value of 128 we get a quarter cycle delay. In Bypass mode (SEL_DLY_REG = 1), this register has no effect on the delay. **Note:** Not all changes affect the actual delay. If the requested change is smaller than the delay line resolution (1 delay unit, which varies between 20 pSec in best case to 50 in worst case), then no change occurs.
7–0 DLY_REG_4	This field is the delay (in number of buffer units) that will be used by delay line 4, if the SEL_DLY_REG4 bit is set. Since the delay is process, temperature and voltage dependent, for a given value of this filed we get different delay values. The SoC team should provide the equivalent delay of 1 buffer. This field contains only positive numbers.

30.7.1.10 SDRAM Delay Line 5 Configuration Debug Register

This debug register controls delay line 5 functionality, i.e., data bus delay used during write cycles. It allows override and manual set for the delay of the data bus during write cycles.

The bit assignments for the register are shown in Figure 30-25 and the field descriptions for the bit assignments are listed in Table 30-19.

Field	Description
31 SEL_DLY_REG_5	SEL_DLY_REG_5 bit selects the delay used by delay line 5. It selects between a quarter of a cycle (measured) plus or minus the delay line 5 offset field (DLY_OFFSET_5) and delay line 5 register value (DLY_REG_5). 0 Delay line 5 value is a quarter of a cycle (measured) plus or minus the delay line 5 correction factor field. 1 Bypass mode: Delay line 5 value is the value of delay line 5 register field (skipping the measurement).
30–24	Reserved
23–16 DLY_OFFSET_5	This field is the delay line 5 offset value. The offset value is used only if SEL_DLY_REG_5 is cleared. The offset value is used to compensate process dependent unalignments between dqs signal and the corresponding read data (in number of small delay units). The field represents positive and negative numbers using twos compliment representation. This allows positive and negative offsets from the quarter cycle measured value. For example, to add 3 delay units to the measured delay, this field should be 00000011, to subtract 3 delay units, it will be set to 11111101.

Table 30-19. Enhanced SDRAM Delay Line 5 Control Register (ESDCDLY5) Field Descriptions (continued)

Field	Description
15–8 DLY_ABS_OFFSET_5	Absolute delay offset. This field decides the specific delay line absolute delay in fraction of a cycle terms. The fraction is process and frequency independent. The delay for the delay line would be (DLY_ABS_OFFSET / 512) * tCK. So for the default value of 128 we get a quarter cycle delay. In Bypass mode (SEL_DLY_REG = 1), this register has no effect on the delay. **Note:** Not all changes affect the actual delay. If the requested change is smaller than the delay line resolution (1 delay unit, which varies between 20 pSec in best case to 50 in worst case), then no change occurs.
7–0 DLY_REG_5	This field is the delay (in number of buffer units) that will be used by delay line 5, if the SEL_DLY_REG5 bit is set. Since the delay is process, temperature and voltage dependent, for a given value of this filed we get different delay values. The SoC team should provide the equivalent delay of 1 buffer. This field contains only positive numbers.

30.7.1.11 General-Purpose Register

The general-purpose register is a register that shows the number of delay units that fit in a cycle. It is also responsible for the delay_line_significant_change debug signal. The reset value for the QTR_CYCLE field is unknown because the register value is updated from the measured delay after reset. The register value represents the number of delay units required to achieve a delay of 1 clock cycle, as a function of the IC conditions (temperature, voltage, frequency, process).

The other field defines a significant change to the delay measurement. It can be set to 2 delay units (any change which is not a glitch) or a half/quarter/eighth of the measured quarter cycle, to a minimum of two, according to the user's needs.

In addition, it controls the DQS-IN gating logic. This logic is necessary when no pull down/up is placed on the DQS,DQS_B signals. A separate technical note explains how to calibrate these values.

The bit assignments for the register are shown in Figure 30-26 and the field descriptions for the bit assignments are listed in Table 30-20. Bits 31 – 19 are write-only, meaning the user can write to these bits but not cannot read their value.

Figure 30-28. CS1 precharge counter register (ESDPRC1)

Table 30-21. Precharge Counter Register Field Description

Field	Description
31–24	Reserved.
23–21 PRCT7	Precharge Timer for bank 7 Precharges bank 7 after 2^PRCT clocks of no activity. Table 30-22 illustrates the PRCT bit field encoding. “Closing” (due to precharge command) the last used/open row in any non active bank within a chip select reduces the power consumption of the external memory device. The power saving is device dependent, and one should consult/examine the external memory device specification for more details on power consumption reduction. If PRCT is enabled, a PRECHARGE command is issued after approximately number of cycles (as shown in Table 30-22) of non activity to one of the SDRAM/LPDDR banks. The number of cycles before the PRECHARGE command is issued depends on command bus (WE, RAS, CAS and CSD) availability (means there is no active access to other bank) and the memory timing parameters.
20–18 PRCT_B6	Same as PRCT7 but for bank 6.
17–15 PRCT_B5	Same as PRCT7 but for bank 5.
14–12 PRCT_B4	Same as PRCT7 but for bank 4.
11–9 PRCT_B3	Same as PRCT7 but for bank 3.
8–6 PRCT_B2	Same as PRCT7 but for bank 2.
5–3 PRCT_B1	Same as PRCT7 but for bank 1.
2–0 PRCT_B0	Same as PRCT7 but for bank 0.

Table 30-22. PRCT Field Encoding

101	32 clocks to precharge
110	64 clocks to precharge
111	128 clocks to precharge

1 The PRCT can be used only if PWDT/SRT is disabled (“00”) or set to “any time no banks are active (“01”)”. PRCT can’t be used with any other PWDT/SRT settings.

2 The number of clocks is approximate and it depends on the external bus availability

30.8 Functional Description

This section addresses General Enhanced SDRAM Controller operating characteristics. The discussion starts with the optimization strategy and continues with the address decoding, one of the most basic of all DRAM controller features. The following subsections explain operation out of reset, hardware refresh, and the low-power modes. Each of the Enhanced SDRAM Controller operating modes are also described.

The Enhanced SDRAM Controller is designed to support a broad range of JEDEC standard DDR2/LPDDR configurations, including devices of 64-, 128-, 256-, 512-Mbyte, 1- and 2-Gbyte densities. Due to the physical size constraints of the target applications, the design support memory devices with data widths of 16 and 32 bits. The controller supports mDDR memory devices of 4 banks and DDR2 memory devices of 4 or 8 banks.The controller supports memory devices of up to 200 MHz, which work in CAS latency of 3.

30.8.1 Enhanced SDRAM Controller Optimization Strategy

The ESDCL receives read and write accesses through its AXI channels. When an access is accepted, the controller lowers its aready and awready signals until the last command for the accepted access is sent to the memory. Then, the aready and awready signals rise again so that they can accept the next access.

The controller can be configured to prepare for next incoming accesses. This configuration increases the chances that the next incoming access will be accepted in hit state. Hit accesses can be treated more quickly than miss accesses because no active or precharge commands are needed.

The controller optimizes through the use of the two sideband signal channels: mif3_p1 and mif3_p2.

- mif3_p1 provides the chip select, bank, and row information of the waiting access on AXI channel.
- mif3_p2 provides the chip select, bank, and row information of the next incoming miss access, based of M4IF prediction mechanism.

The controller uses every NOP cycle in its working mode to prepare the two sideband signal channels. It prepares mif3_p1 first, followed by mif3_p2. This increases the probability that the accepted accesses will be hit accesses.

For maximum performance, set the MIF3_MODE field in the ESDMISC register to 3.

30.8.1.1 Multiplexed Address Bus

Table 30-23 illustrates how a CPU address is scrambled by the Enhanced SDRAM Controller to implement a contiguous address space.

Table 30-23. CPU to memory Translation

CPU ADDRESS	16-bit SDRAM[1]	32-bit SDRAM[1]

A4	C3	C2
A3	C2	C1
A2	C1	C0

Table 30-23. CPU to memory Translation (continued)

CPU ADDRESS	16-bit SDRAM[1]	32-bit SDRAM[1]
A1[2]	C0	-
A0[3]	—	-

1 For this example a memory configuration with 10 columns and 12 rows is illustrated. The address translation is based on the following concept, COLUMN - ROW - BANK.

2 CPU A1 defines how the data masks are driven, i.e., it is used as the byte enable for non word accesses. This bit has a regular/normal use only in case of 16-bit memory, while CPU A0 defines the 2 bytes (low and high) in the 16-bit word.

3 CPU A0 defines how the data masks are driven, i.e., it is used as the byte enable for non word accesses to 32-bit memory device. Both CPU A0 and A1 defines the 4 bytes in the 32-bit word.

Note: C=COLUMN, R=ROW, BA=BANK

The Enhanced SDRAM Controller multiplexed address bus is aligned to the column addresses so that address line A1 always appears on pin MA0 for 16-bit memory devices and A2 always appears on MA0 for 32-bit memory devices. With this alignment, the “folding point” in the multiplexor is driven solely by the number of column address bits. Column bus widths of 8 to 11 bits are supported.

Table 30-24 summarizes the multiplex options supported by the controller for 16 and 32-bit devices respectively. Column addresses through A10 are driven regardless of the multiplexor configuration, although some of the lines will be unused for the smaller page sizes.

Table 30-24. Address Multiplexing by Column/Row Width for 16-bit Devices

30.8.1.1.1 Bank Interleaving

The controller supports bank interleaving mode. This mode can be enabled through a configuration bit in the ESDMISC register. In this mode, the address decoding is different because the row and bank location in the AXI address switch. The affect of this change is that when the end of a certain row in write or read operation is reached, the next row is from another bank. Therefore, the controller can prepare the new row earlier, which increases performance.

30.8.1.2 Bank Addresses

The controller supports either 4 or 8 bank devices. All connected devices should be either 4 or 8 banks devices, but not mixed. A configuration bit exist for these two modes in ESDMISC register.

The bank decoding from the AXI address depends on various values, as follows:

- Device width ×16/×32
- Column size
- Row size, for bank interleaving off mode.

See Table 30-23 for adecoding example (for bank interleaving off mode).

30.8.2 Refresh

Enhanced SDRAM Controller hardware satisfies all refresh requirements after an initial configuration by the user software. Zero, 1, 2, 4, 8, or 16 refresh cycles are scheduled at 31.25 µs (nominal 32 kHz clock) intervals, providing 0, 2048, 4096, 8192, 16384, or 32768 refresh cycles every 64 ms. The refresh rate is programmed through the REFR field in the ESDCTL0 and ESDCTL1 registers. Each array can have a different rate, allowing a mix of SDRAM/LPDDR devices, or different SDRAMs density. Refresh is disabled by hardware reset.

A refresh request is made pending at each rising edge on the 32 kHz clock. In response to this request, the hardware gains control of the memory device as soon as any in-process bus cycle completes. Once it has gained control of the memory, commands are issued to precharge all banks. Following a row precharge delay (t_{RP}), an auto-refresh command is issued. At t_{RFC} intervals, additional auto-refresh cycles are issued until the specified number of cycles have been run.

Figure 30-29 illustrates a 2 refresh sequence. Burst transfers in progress when the refresh request arrives are allowed to complete prior to the refresh operation. Memory device bus accesses queued after the refresh request are held off until the refresh completes.

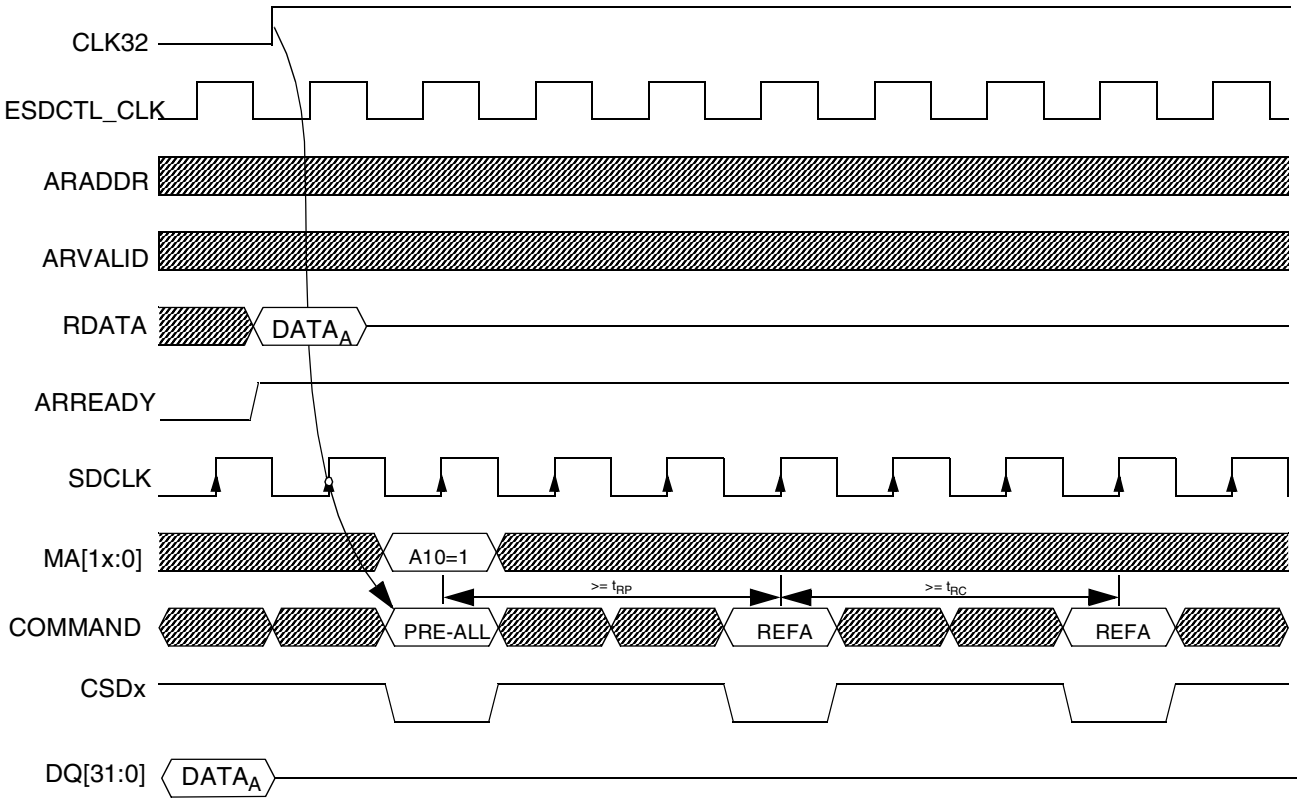

Figure 30-29. Hardware Refresh Timing Diagram

In Figure 30-30, an access is queued just as the refresh begins. This cycle is delayed until the precharge and single refresh (REFR=01) cycles are run. Bus cycles targeted to other memory or peripheral devices are allowed to progress normally while the refresh is in progress. None of the pins shared between the SDRAM and other devices are required for the refresh operation.

NOTE

Since REFRESH commands (requires all banks to be in IDLE state, achieved by PRECHARGE ALL) are issued automatically by the Enhanced SDRAM Controller at each 32 kHz clock, address bits A10 (for both 16 and 32-bit devices) cannot be shared with another peripheral's address bus in the system.

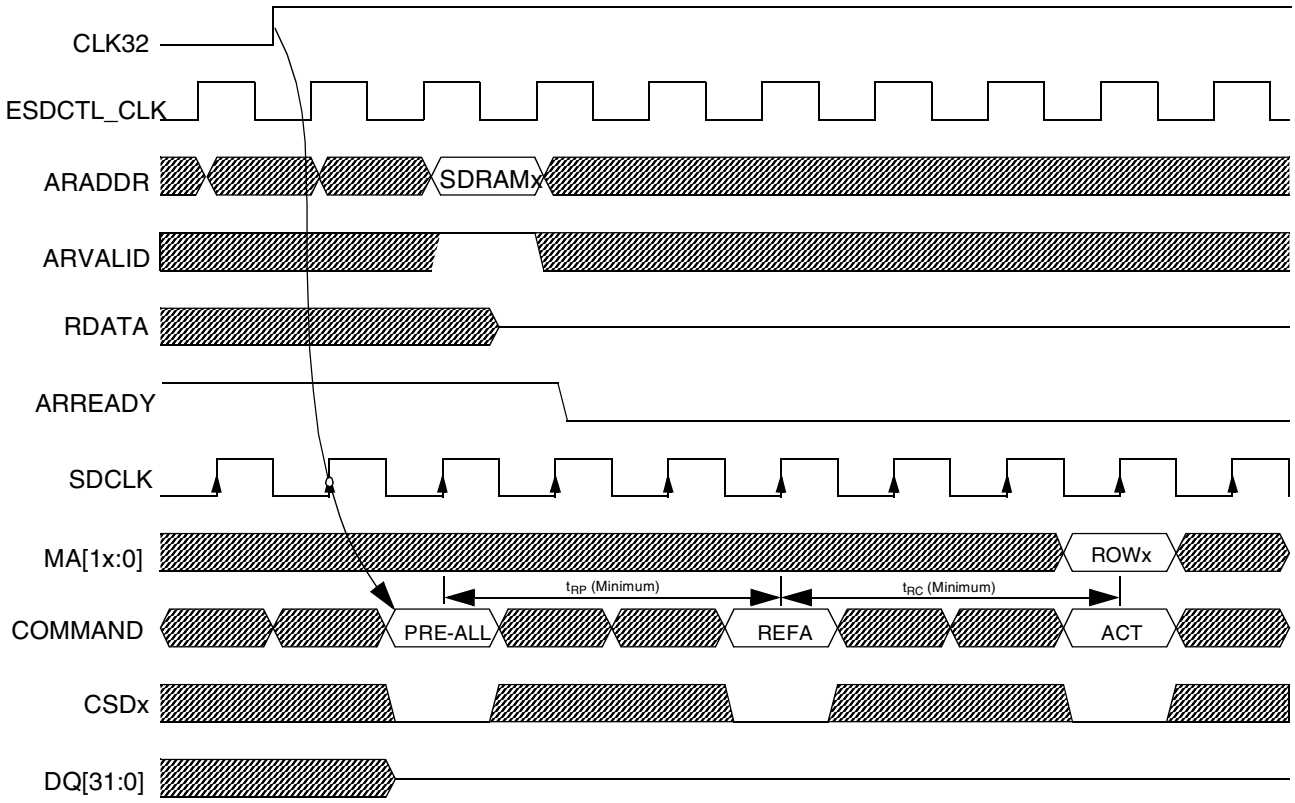

Figure 30-30. Hardware Refresh with Pending Bus Cycle Timing Diagram

30.8.3 Low-Power Operating Modes

This section describes the low-power operating modes of the Enhanced SDRAM Controller as a functions of the various memory devices. Table 30-26 lists and summarizes the low power modes supported by the Enhanced SDRAM Controller.

Table 30-26. ESDRAMC Low Power Operating Modes

System Operating Mode	Memory Device Low Power Operating Mode	WakeUp Penalty
RUN	POWER DOWN MODE	tXP
RUN	PRECHARGE Banks	1 clock cycle
RUN	MANUAL SELF REFRESH MODE	tXS + 2 Refresh Period
STOP	SELF REFRESH MODE	tXS + 2 Refresh Period

30.8.3.1 Self-Refresh Mode for DDR2/LPDDR Devices

This operating mode (see Figure 30-31 and Figure 30-32) allows the software/user to control a self-refresh mode entry of the external memory device if refresh has been enabled, during system run mode. When this mode is selected (using the special command register) and refresh is enabled, the Enhanced SDRAM Controller completes any active access, and a self-refresh command to the external device is issued. No

access is allowed to the respective CSD during manual self-refresh mode. If refresh has not been enabled, the Enhanced SDRAM Controller places the memory in a low-power consumption mode known as power down. The LPACK signal (low-power mode acknowledge) is not asserted if only one CSD enters manual self-refresh mode.

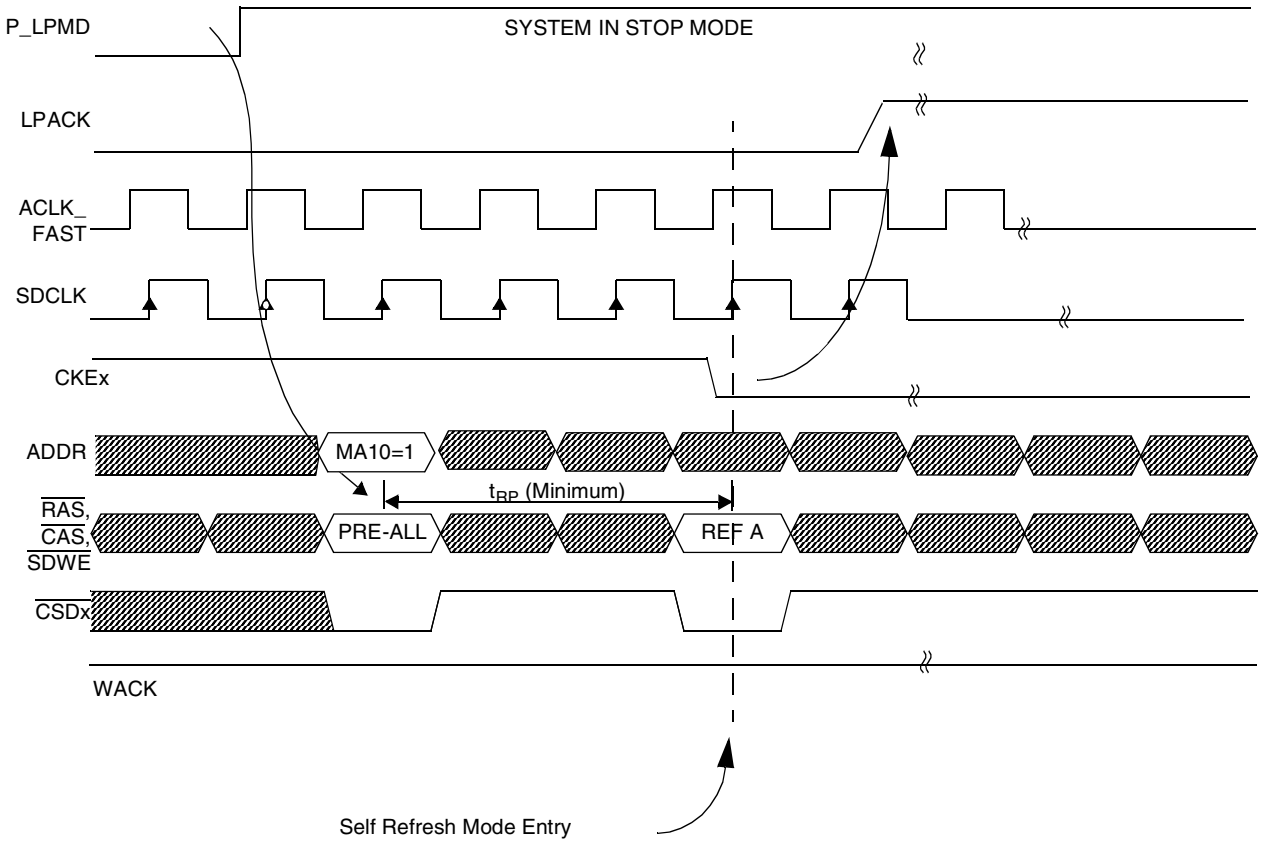

Figure 30-31. Enter Self-Refresh Mode during System Stop Mode

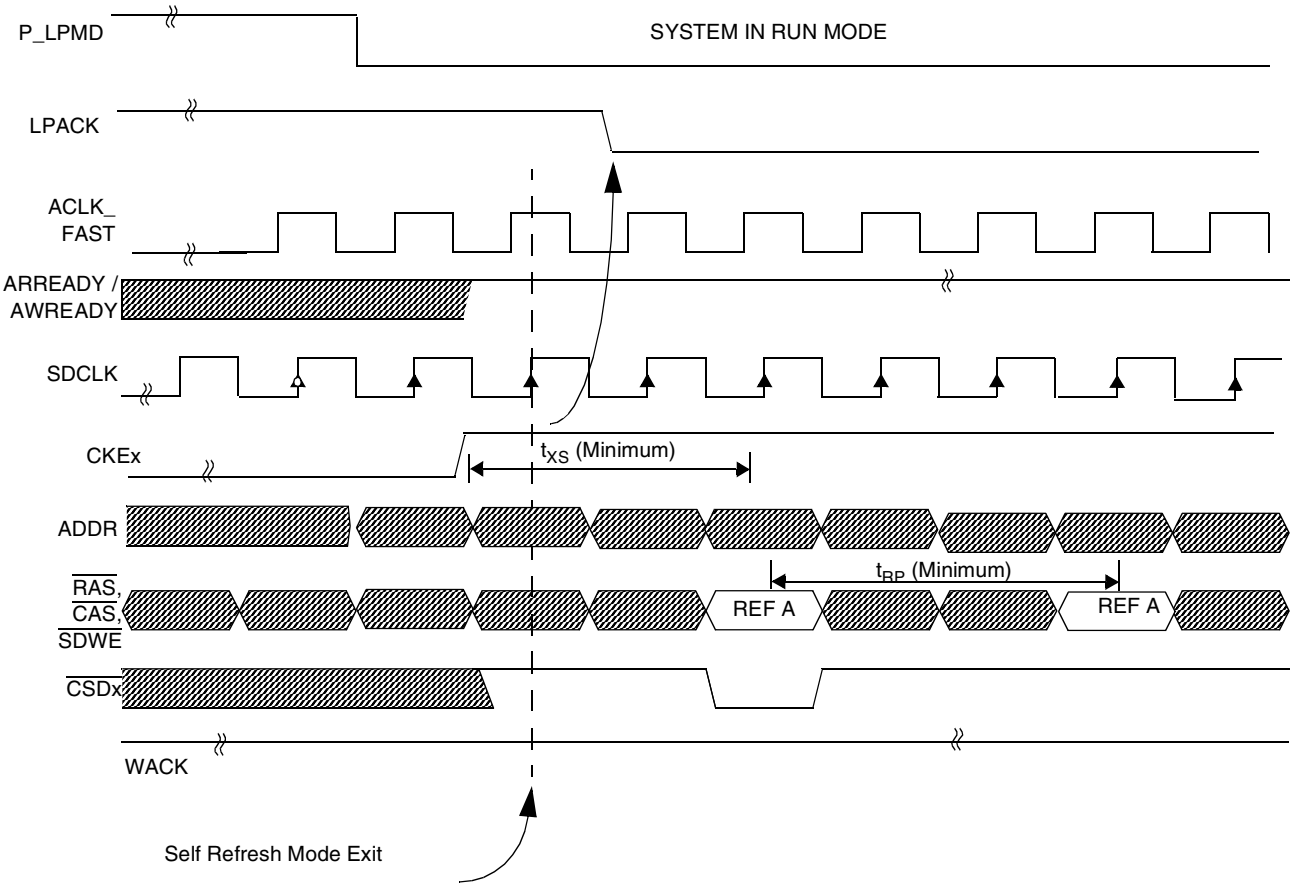

Figure 30-32. Exit Self-Refresh Mode during System StOP Mode

30.8.3.2 Manual Self-Refresh Mode for DDR2/LPDDR Devices

This operating mode allows the software/user to control a self-refresh mode entry of the external DDR2/LPDDR device if refresh has been enabled, during system run mode. When this mode is selected (using the special command register) and refresh is enabled the Enhanced SDRAM Controller will complete any active access and a self-refresh command to the external device will be issued. No access is allowed to the respective CSD during manual self-refresh mode. If refresh has not been enabled, the Enhanced SDRAM Controller places the memory in a low-power consumption mode known as power down. The LPACK signal (low-power mode acknowledge) will not be asserted if only one CSD enters manual self refresh mode.

NOTE

A manual precharge all should be initiated by the user before a manual self refresh.

To exit manual self-refresh mode, a “resume normal operation” command must be issued in the special command register. When the command is issued, the controller exits the SDRAM device from self-refresh mode and issues auto-refresh cycles (if the refresh has been enabled).

Figure 30-33 and Figure 30-34 show the timing information.

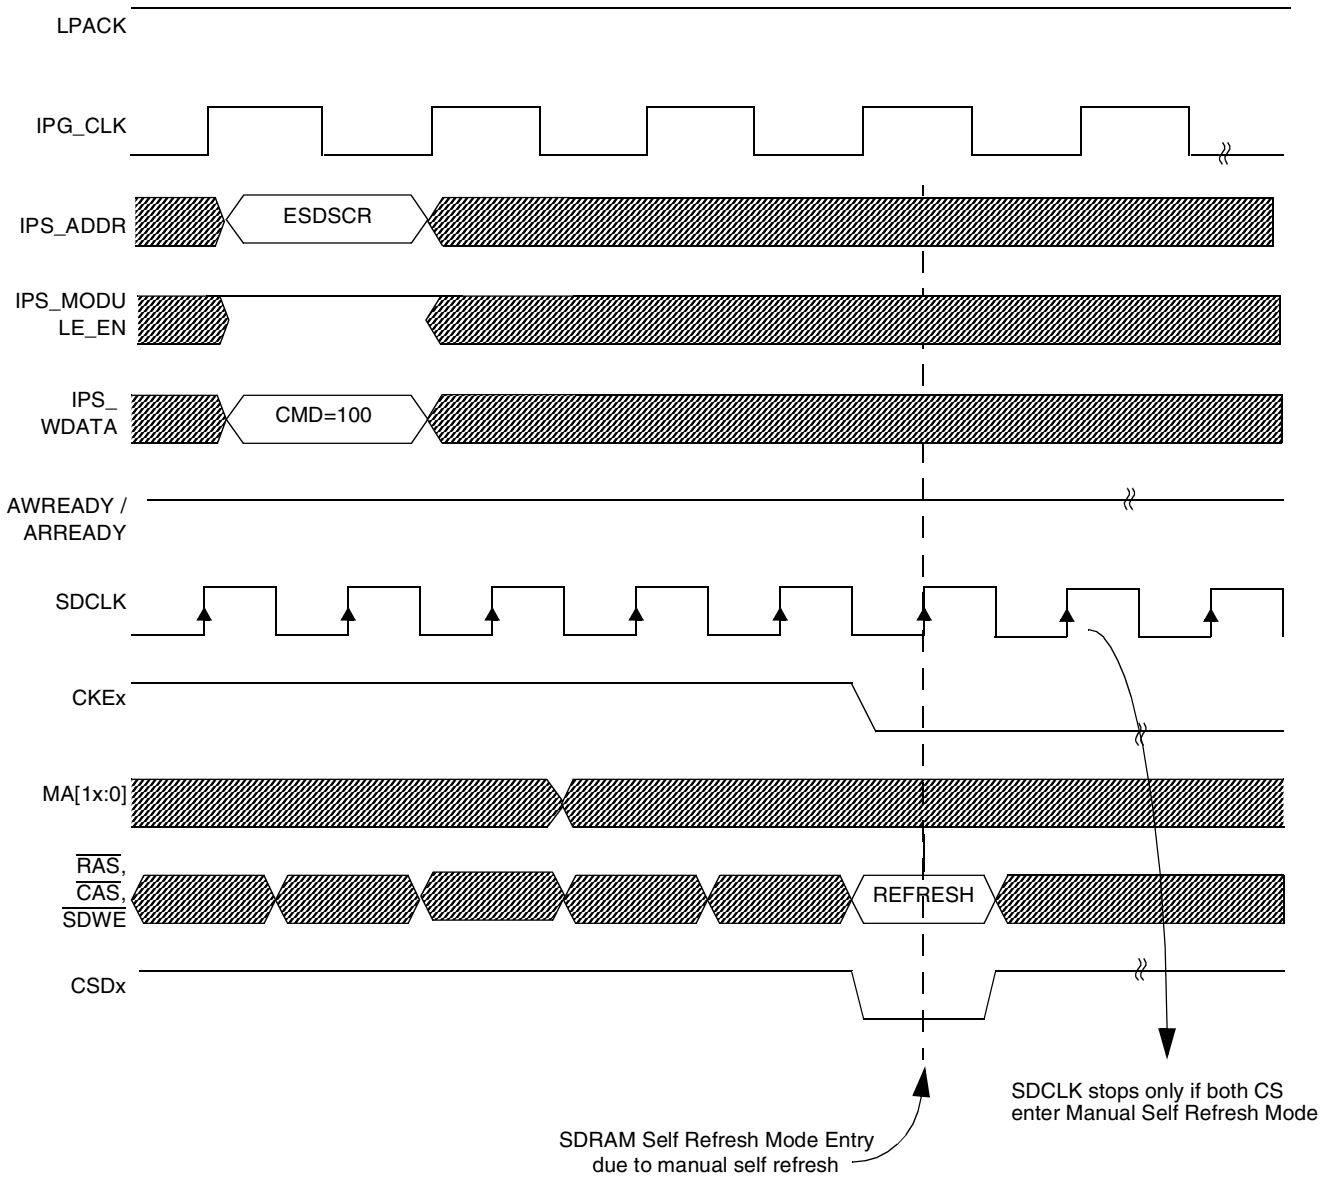

Figure 30-33. Manual Self Refresh Entry Timing Diagram

NOTE

SDCLK stops, only if both chip selects are in manual self-refresh. This allows the usage of one chip select while the other is in manual self-refresh (in case both chip selects are in use).

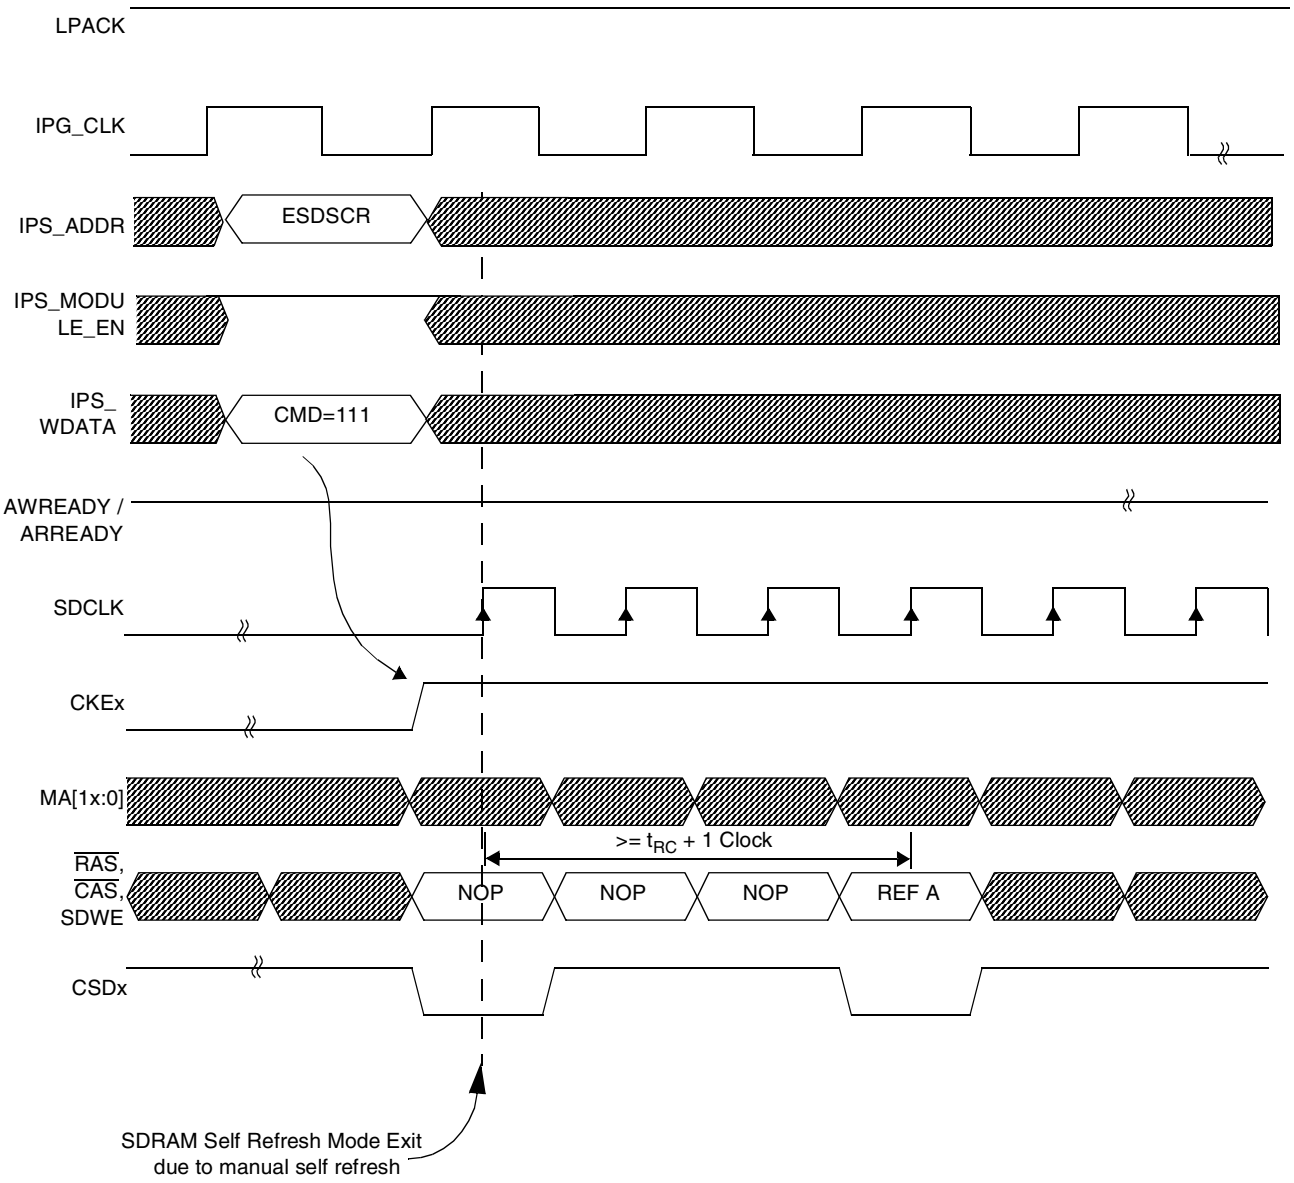

Figure 30-34. Manual Self -Refresh Exit Timing Diagram

30.8.3.3 Precharge Power-Down Mode

All the low power operating mode described in the above paragraphs will be activated only if the system enters low power operating mode, for example, stop mode. The Enhanced SDRAM Controller has the capability to reduce power consumption if the DDR2/LPDDR memory utilization is low, by setting the SDRAM device in power-down mode. This mode is activated through the PWDT bits in the ESDCTL0 and/or ESDCTL1 registers. During this operating mode the ESDRAMC automatically issues the REFRESH commands toward the LPDDR memories at the rate defined by the SREFR bits in the ESDCTL0 and/or ESDCTL1 registers.

Programming PWDT[1:0] = 01 causes the Enhanced SDRAM Controller to place the memories in power down mode anytime the controller detects that no banks are active. This mode is useful in applications where a memory array is accessed infrequently and the chances of another access to the same page are minimal.

Reading or writing to memory activates a page within the addressed bank. Reset, software generated precharge, and hardware initiated refresh are three ways to close an active bank. The periodically occurring refresh will be the normal means that invokes the power down mode. At each refresh interval, all banks will be closed by a precharge-all command, followed by the refresh operation. The controller will then issue the power down command to the memories. A few cycle delay is incurred with the first read or write cycle in order to restart the clocks, but only on the first cycle. After that, the clocks will continue to run until the next refresh operation or until any active banks are manually precharged.

Page misses on read and write cycles cause the addressed bank to be closed (precharged) and a new page opened within the bank. This operation does not cause the clocks to stop, nor does manually precharging only a single bank within the memory. All banks within the memory must be inactive before the power down mode is invoked.

Power-down mode occurs if CKE is registered low coincident with a NOP or command inhibit when no accesses are in progress. Entering power down deactivates the input and output buffers (excluding CKE) of the device. Power-down modee is exited by registering a NOP or command inhibit and CKE high at the desired clock edge.

For LPDDR SDRAM, Figure 30-35 and Figure 30-36 illustrate the power-down mode entry and exit respectively.

NOTE

Since the ESDRAMC does npt issue AUTO PRECHARGE commands toward the SDRAM, the software must issue a PRECHARGE ALL command in order to enter Precharge Low Power Down Mode, to wait for the PRECHARGE timer (PRCT) to close/precharge all active banks, or to wait for the next REFRESH cycle in order to enter this low-power mode. (During the REFRESH cycle, the ESDRAMC automatically issues the PRECHARGE ALL command).

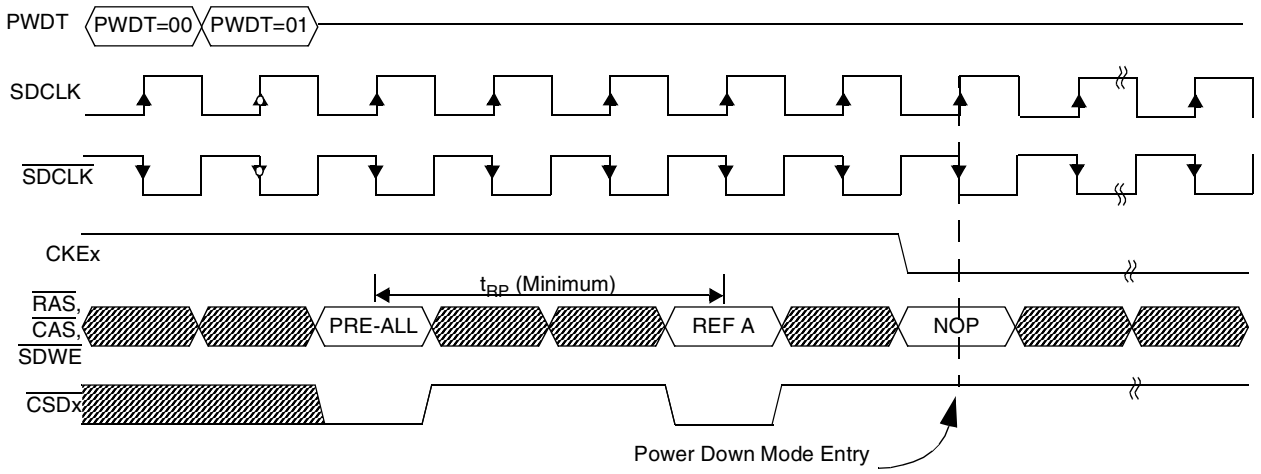

Figure 30-35. Mobile DDR SDRAM Precharge Power Down Mode Entry Timing Diagram

Power-down mode for several mobile/low-power DDRs requires that the clock CK (and $\overline{CK}$) continue running. The PWR CK EN (power down clock enable for mobile/low power DDR SDRAM) should be set to 1 to enable this option.

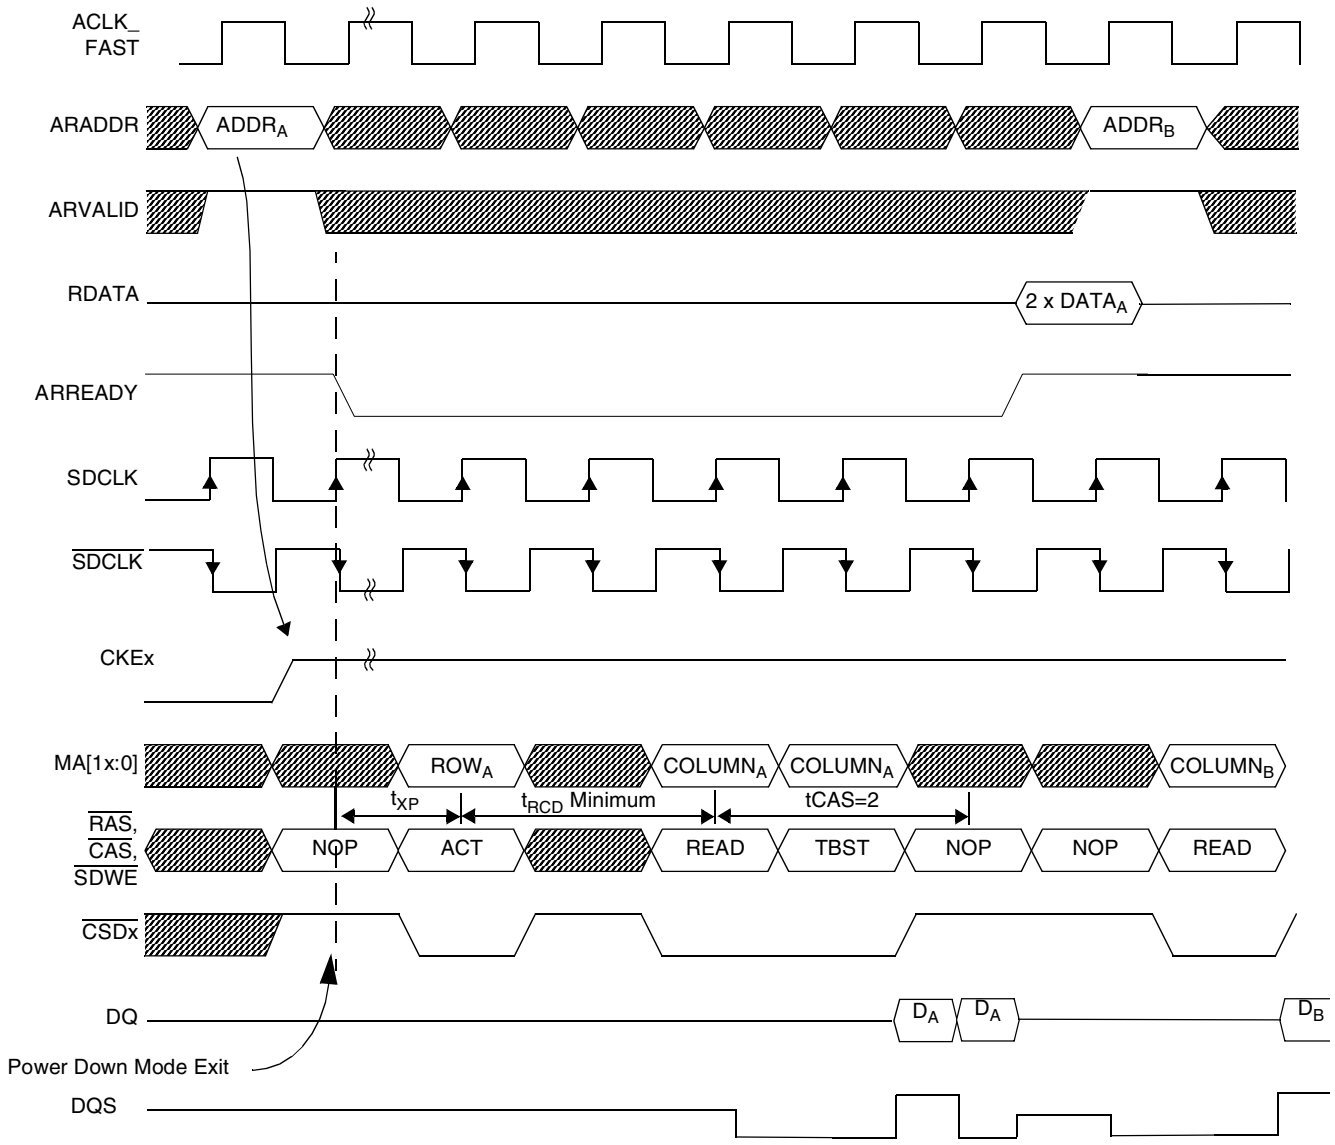

Figure 30-36. Mobile DDR SDRAM Precharge Power Down Mode Exit Timing Diagram

30.8.3.4 Active Power-Down Mode

The second clock suspend mode is selected whenever PWDT[1:0] = 1x. In this mode the SDCLK is stopped after a selectable delay from the last access to the array. Active banks are not closed prior to disabling the LPDDR clock. Either 64 (PWDT[1:0] = 10) or 128 (PWDT[1:0] = 11) cycle delays are possible. LPDDR clocks are counted from the end of the last read or write access. Subsequent read or write accesses and self-refresh modes reset the counter. Auto-refresh cycles do not affect the counter; however, if the counter expires during a refresh operation the clock will be disabled immediately following the refresh.

The distinguishing factor between precharge power-down mode and active power-down mode is whether banks remain active while the clock is stopped. Active power-down allows banks to remain activated while precharge power-down does not.

Figure 30-37 illustrates LPDDR SDRAM Active Power Down Mode entry and exit timing diagram.

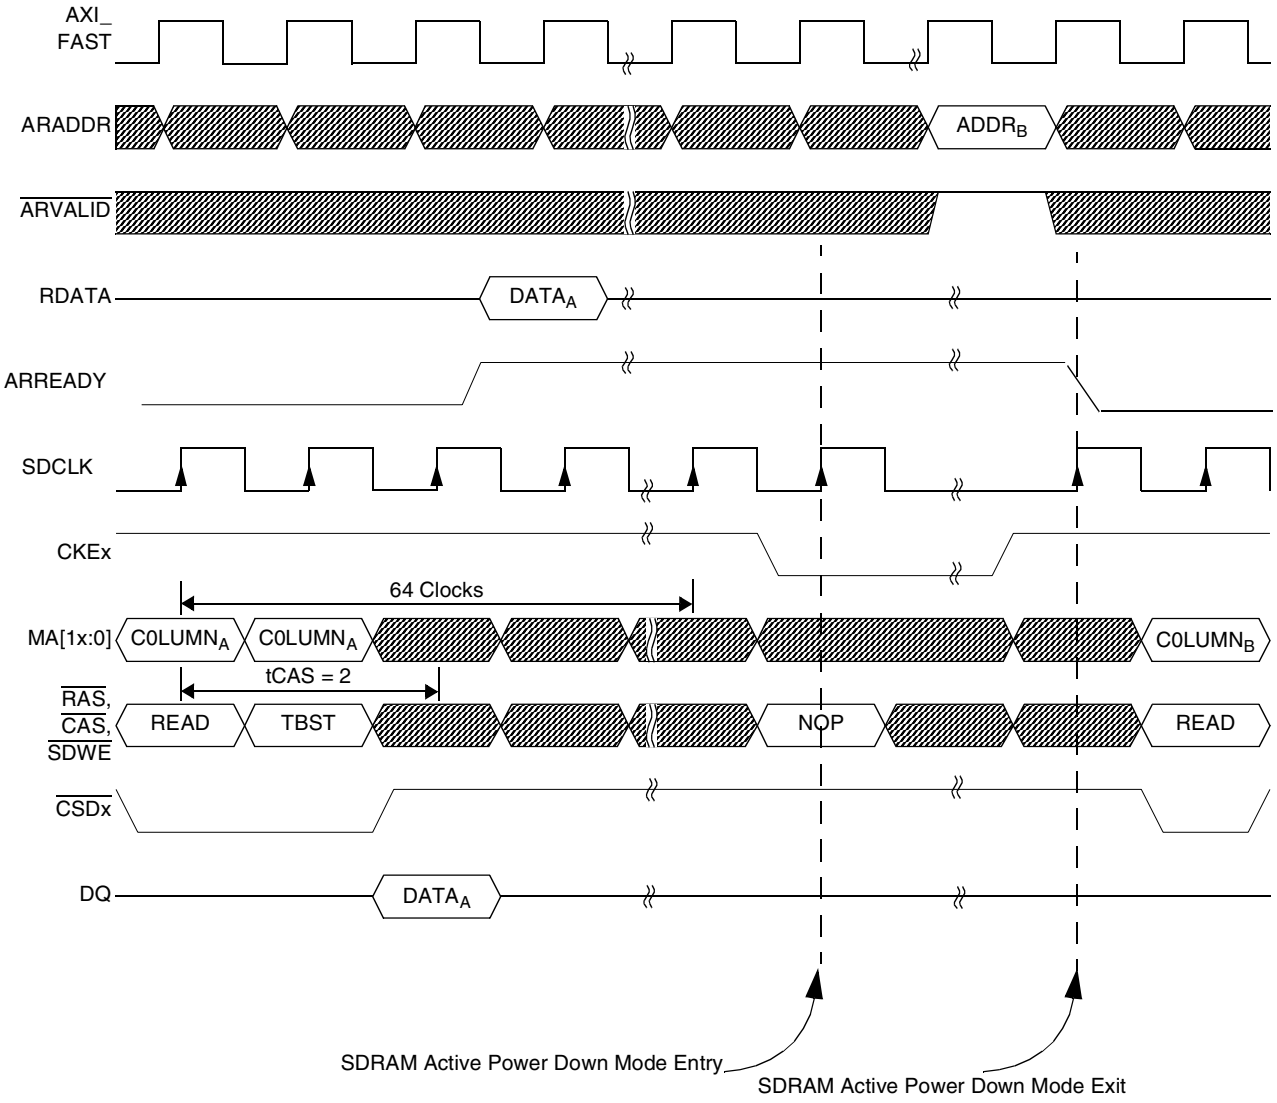

Figure 30-37. Mobile DDR SDRAM Active Power Down Mode Timing Diagram

Power-down mode for several mobile DDRs require that the clock CK (and $\overline{CK}$) continue running. The PWR CK EN (power-down clock enable for mobile DDR SDRAM) should be set to “1” to enable this option.

30.8.3.5 Precharge Bank(s)—Low Power Mode

Closing (due to precharge command) the last used/open row in any non-active bank within a chip select reduces the power consumption of the external memory device. The power saving is device dependent,

and one should consult/examine the external memory device specification for more details on power consumption reduction.

The precharge bank is activated if PRCT is enabled. A precharge command is issued after 2 × PRCT clocks (ESDCTL_CLK, up to 200 MHz) of no activity (as shown in Table 30-22) to one of the banks. The number of cycles before the precharge command is issued depends on command bus (WE, RAS, CAS and CSD) availability (meaning there is no active access to other bank) and the memory timing parameters.

30.8.3.6 LPDDR Frequency Change

The following steps need to be performed prior to a frequency change in a LPDDR based system, in order for the DDRC delay line recalibration locking.

The frequency change request signal (from system) indicates that the ESDCTL clock is about to change. This signal is considered asynchronous and is synchronized internally. When this signal is asserted, the current ongoing accesses finish and all pending accesses are put on hold. Then the ESDCTL performs self-refresh enter to the DDR SDRAM memory and finally asserts the FREQ_CHNG_ACK signal, indicating the frequency is allowed to change. The FREQ_CHNG_REQ should be negated only after the frequency change was applied. The ESDCTL performs self-refresh exit to the DDR memory. In DDR mode, the ESDCTL also updates the delay lines to the new frequency that is used to capture the DDR data.

30.8.4 Command Encoding

Table 30-27 summarizes the command encoding utilized by this controller. These commands represent a subset of the commands defined by the JEDEC standard.

Table 30-27. LPDDR Command Encoding

Function	Symbol	CKE n-1	CKE n	CS	RAS	CAS	WE	A11	A10	BA[1:0]	A[13:0]
Deselect	DSEL	H	X	H	X	X	X	X	X	X	X

Power-Down Entry	PWRDN	H	L	X	X	X	X	X	X	X	X
Power-Down Exit	PWRDNX	L	H	H	X	X	X	X	X	X	X
Mode Register Set[2]	MRS	H	X	L	L	L	L	L	L	V	V

[1]For Mobile DDR, applies only to read bursts (with auto precharge disabled).
[2]BA0-BA1 select either the mode register, the extended mode register or the LOW POWER extended mode register.

The unsupported JEDEC commands are read and write with auto precharge (when once the read/write is complete the active row in the used bank is precharged automatically).

30.8.4.1 Reset

Assertion of the $\overline{\text{RST}}$ signal initializes the controller into the idle state and disables the module. While disabled, the controller remains in the idle state with the internal clocks stopped. The reset state of the control register allows for basic read/write operations sufficient to fetch the reset vector and execute the initialization code. A complete initialization of the controller should be performed as part of the start-up code sequence.

Read/write cycles, refresh, and low-power mode requests as well as power-down time-outs all trigger transitions out of the idle state. As shown in the simplified enhanced SDRAM controller state diagram pictured in Figure 30-38, state transitions due to a read or write request depend on the operating mode. Other transitions require the corresponding function to be enabled in the ESDCTL registers. Some state transitions have been removed from the figure to minimize complexity and allow an easier understanding of the basic controller operation.

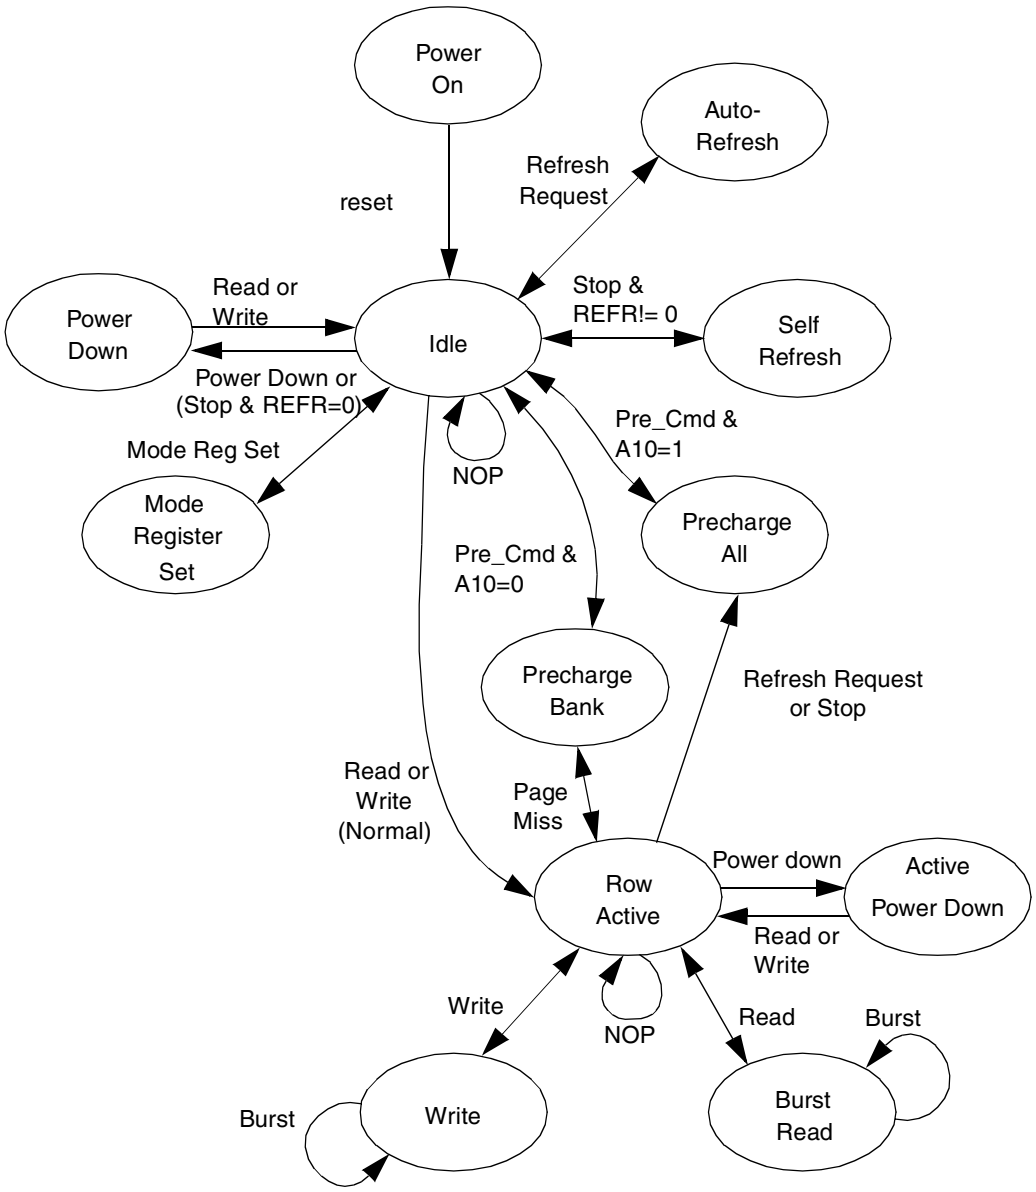

Figure 30-38. Simplified Enhanced SDRAM Controller State Diagram

The following subsections document the operation of each of the operating modes.

30.8.4.2 Warm Reset

This section describes the flow of getting into self-refresh mode before and during warm reset, as well as configuration that is needed to be made to ESDCTL when getting out of warm reset.

Please note that after issuing a precharge all via special command register in the exit warm reset, it is recommended by devices to issue a manual auto refresh command, but not necessary.

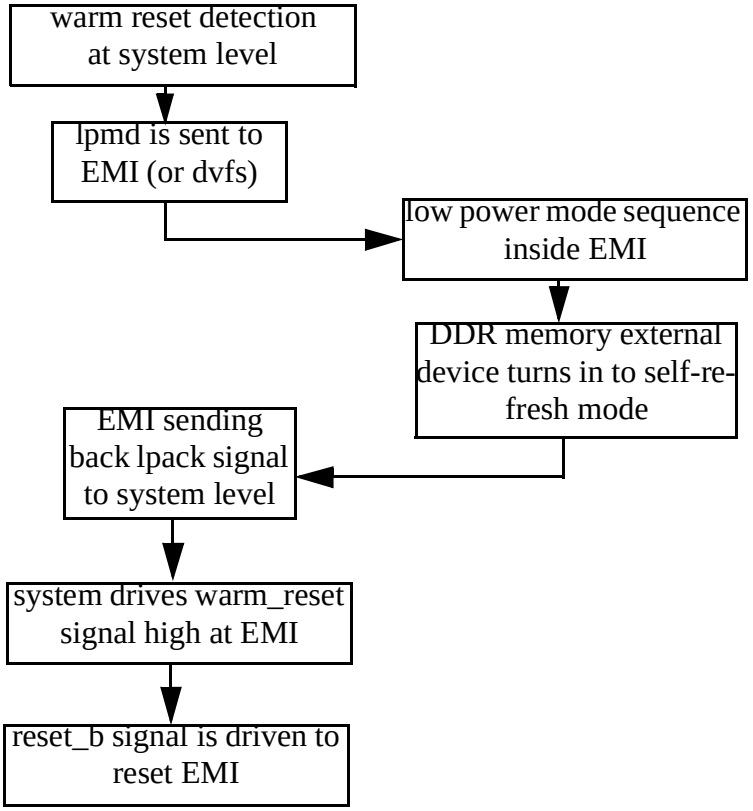

Figure 30-39. Entering into Self-Refresh before warm_reset Assertion

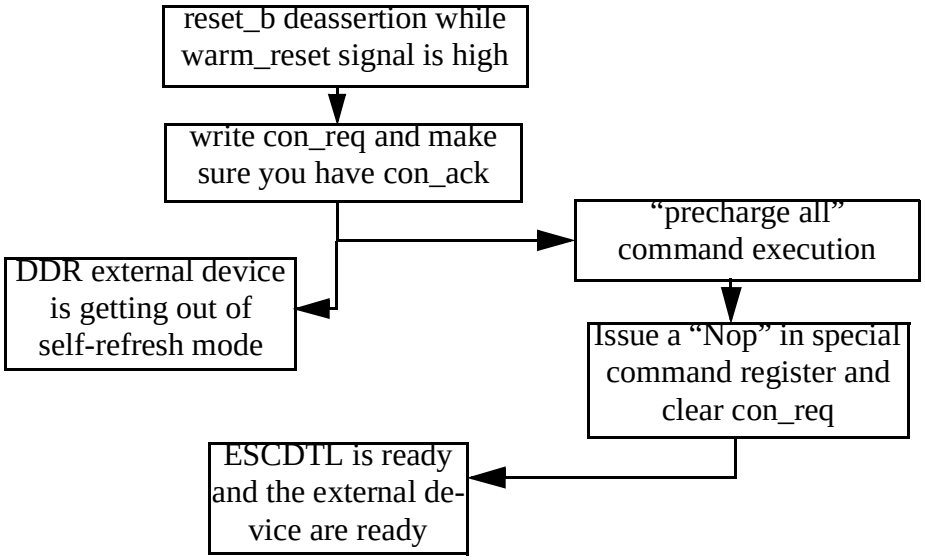

Figure 30-40. Sequence of Exiting Self-Refresh after Warm Reset

30.8.5 ODT behavior

The two type of terminations are as follows:

- Termination to the DQS/DQ I/O pads—this is controlled through the TERM_CTL configuration fields in ESDMISC register. This termination is working while there are no write accesses. It is turned off when write to external DRAM is done. Through its configuration fields it is possible to disable it or change termination resistance. This is done per byte lane.
- Termination to external DRAM. This can be enabled through ODT_EN bit in ESDMISC register.

When enabled the controller enables the termination in the DRAM that is not being accesses.

30.9 Initialization Information

The following paragraphs provide details on selecting compatible SDRAM memories and configuring the controller to work with the memory system.

30.9.1 Memory Device Selection

Many DDR2/mDDR memory devices types are supported by the Enhanced SDRAM Controller. Important characteristics to consider when choosing a memory device are as follows:

- Device size limit is 256 Mbytes per chip select
- Support 4 banks mDDR memory devices
- Support 4 or 8 banks DDR2 memory devices
- Support memory devices of up to 200 MHz
- Support memory devices with CAS latency of 3
- Support data width of ×16 or ×32

NOTE

Some DDR2 devices support higher frequency than 200 MHz and require higher CAS latency than 3. But this devices most often support CAS 3 latency when lowering the frequency to 200 MHz. The CAS latency is configurable in memory devices.

30.9.2 CAS Latency

The controller supports only CAS latency of 3 cycles. This is the required latency for DDR2-400 and LPDDR-400 devices.

30.9.3 LPDDR/DDR2 Initialization Sequence

On power up ESDCTL is disabled. The SDE bit must then be enabled first, and it keeps 400 µs of idle period. During the first 200 µs ‘CKE’ signal to memory is low, and during the second 200 µs ‘CKE’ signal to memory is high. This is to comply with both the DDR2 and mDDR initialization sequence.

The initialization of the memory device should be done according to JEDEC standard or specific memory device requirement.

Memory device initialization is done via ESDSCR register (see Table 30-13) by choosing desired command and selecting what chip select, bank, and address is to be sent to memory device.

For example, to issue precharge-all command to CS0, set the following values on the ESDSCR register:

- CON_REQ = 1 (this is required through all the init sequence).
- BA= 0x0
- CS = 0x0
- CMD = 0x1
- PSEUDO_ADDR = 0x400

In DDR2 there is a 200 cycle delay that is required after resetting memory device DLL. This delay can be done automatically or manually, as follows.

- For automatic delay, select ‘AUTO_DLL_PAUSE’ (see Table 30-12). The controller identifies the DLL reset that was sent to the memory and keeps the needed delay. This is the default option.
- For manual delay, select ‘MAN_DLL_PAUSE’ (see Table 30-13) along with the needed ‘LMR’ command selection.

Other guidelines are as follows:

- CON_REQ bit on ESDSCR register should remain high until all initialization is over. Lowering it is allowed only in the last initialization command.
- The following functions should not be enabled before the memory initialization is over.
  - SREFR field on ESDCTL0 and ESDCTL1 register
  - PWDT and SRT fields on ESDCTL0 and ESDCTL1 registers
  - PRCTn field on ESDPRCT0 and ESDPRCT1 registers
  - ODT_EN field on ESDMISC registers

The init sequence structure uses the following steps:

1. Enable the SDE bit on the ESDCTL register.
2. If using DDR2, enable the DDR2_EN bit in the ESDMISC register.
3. Make a sequence of commands to initialize the external memory. Every command is issued though the ESDSCR register. The user must set the required command and the matching values on the CS, BA, and MA signals.
4. The controller issues the selected command and signal values to the external memory. Note that the CON_REQ bit must be kept high during this process.
5. At this point, perform all remaining desired configurations to the controller.

30.9.3.1 mDDR Initialization Example

The following example code demonstrates how to initialize chip select 0 and 1.:

Example 30-1. Initializing Chip Select 0 and 1

```
setmem ESDCTL0 = 0x83220000  // ESDCTL0: Enable controller
// Init DRAM on CS0
setmem ESDSCR = 0x04008008  // ESDSCR: Precharge command
setmem ESDSCR= 0x00008010  // ESDSCR: Refresh command
setmem ESDSCR= 0x00008010  // ESDSCR: Refresh command
setmem ESDSCR= 0x00338018  // ESDSCR: LMR with CAS=3 and BL=3 (Burst Length = 8)
setmem ESDSCR= 0x0020801a  // ESDSCR: EMR with half Drive strength
setmem ESDCTL0 = 0xC3220000  // ESDCTL0: 14 ROW, 10 COL, 32Bit, SREF=8
// ESDCFG0: tRFC:22clks, tXSR:28clks, tXP:2clks, tWTR:2clk, tRP:3clks, tMRD:2clks
//          tRAS:8clks, tRRD:2clks, tWR:3clks, tRCD:3clks, tRC:11clks
setmem ESDCFG0 = 0xC33574AA
setmem ESDMISC = 0x000a1700  // ESDMISC: AP=10, Bank interleaving on, MIF3 en, RALAT=2
setmem ESDCTL1 = 0x83220000  // ESDCTL1: Enable controller
//// Init DRAM on CS1
setmem ESDSCR = 0x0400800c  // ESDSCR: Precharge command
setmem ESDSCR= 0x00008014  // ESDSCR: Refresh command
setmem ESDSCR = 0x00008014  // ESDSCR: Refresh command
setmem ESDSCR = 0x0033801c  // ESDSCR: LMR with CAS=3 and BL=3 (Burst Length = 8)
setmem ESDSCR = 0x0020801e  // ESDSCR: EMR with half Drive strength
setmem ESDCTL1= 0xC3220000  // ESDCTL1: 14 ROW, 10 COL, 32Bit, SREF=8
//// ESDCFG1: tRFC:21clks, tXSR:28clks, tXP:2clks, tWTR:2clk, tRP:3clks, tMRD:2clks
////          tRAS:8clks, tRRD:2clks, tWR:3clks, tRCD:3clks, tRC:11clks
setmem ESDCFG1 = 0xC33574AA
setmem ESDSCR = 0x00000000 // ESDSCR - clear "configuration request" bit
```

Chapter 31
Enhanced Secured Digital Host Controller (eSDHC)

31.1 Overview

The eSDHC provides the interface between the host system and MMC/SD/SDIO/CE-ATA cards, including cards with reduced size or mini cards.

Figure 31-1 shows the eSDHC and its connections within the device. The eSDHC acts as a bridge, passing host bus transactions to the MMC/SD/SDIO/CE-ATA cards by sending commands and performing data accesses to and from the cards. It handles the MMC/SD/SDIO/CE-ATA protocols at the transmission level.

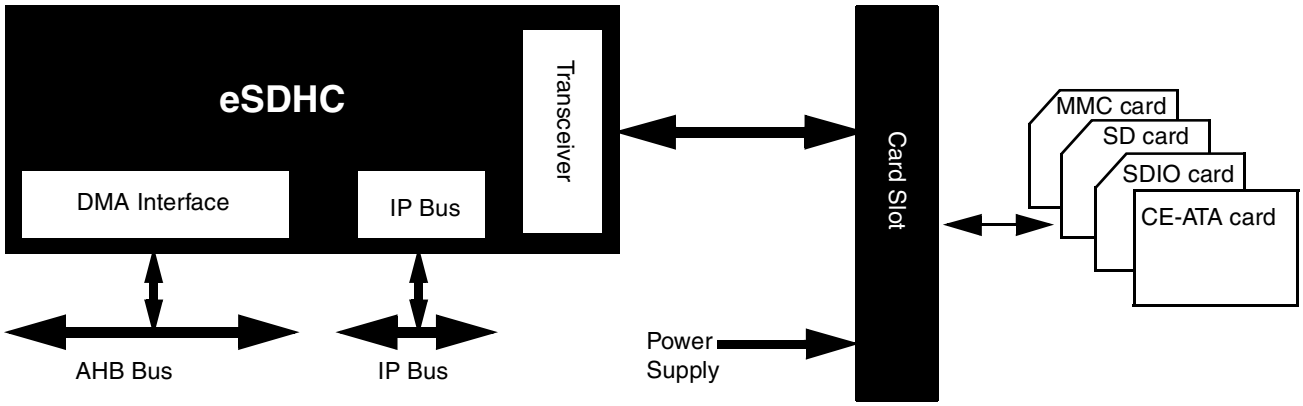

Figure 31-1. eSDHC System Connection

The different cards supported by the eSDHC are described as follows:

- MultiMediaCard (MMC)

  This is a universal low-cost data storage and communication media that is designed to cover a wide area of applications including mobile video and gaming both on pre-loaded MMC cards and downloadable from cellular phone, WLAN or other wireless networks. Old MMC cards are based on 7-pin serial bus with a single data pin, while the newer high-speed MMC communication is based on an advanced 11-pin serial bus designed to operate at lower voltage.
- Secure Digital (SD) card

  This is an evolution of earlier MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward compatible with MMC, with some additions. Under the SD protocol, an SD card can be categorized as memory card, I/O card, or combo card (having both memory and I/O functions). The memory card invokes a copyright protection mechanism that complies with the SDMI security

standard. The I/O card provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, Figure 31-1 does not show cards with reduced size or mini cards.

- Consumer electronics ATA (CE-ATA)

  This is a hard drive interface that is optimized for embedded applications. The device is layered on the top of the MMC protocol stack using the same physical interface. The interface electrical and signaling definition follows the MMC specification. For more details, see the CE-ATA Specification.

31.1.1 Features

The features of the eSDHC module include the following:

- Designed to work with MMC, MMC plus, MMC RS, SD memory, miniSD memory, SDIO, miniSDIO, SD Combo, and CE-ATA cards. Compatible with the following specifications:
  - MMC System Specification Version 4.2
  - SD Host Controller Standard Specification Version 2.0, including test event register support
  - SD Memory Card Specification Version 2.0: supports High-Capacity SD Memory Cards
  - SDIO Card Specification Version 2.0
  - CE-ATA Card Specification Version 1.0
- Supports 1, 4, or 8 bit MMC modes, 1bit or 4 bit SD and SDIO modes, and 1, 4, or 8 bit CE-ATA devices
  - Card bus clock frequency up to 52 MHz
  - Up to 416 Mbps of data transfer for MMC cards in 8-bit mode
  - Up to 200 Mbps of data transfer for SD/SDIO cards in 4-bit mode
  - Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Supports single-block and multi-block read and write
  - Block sizes of 1–4096 bytes
  - Supports pause during the data transfer at block gap
  - Supports Auto CMD12 for multi-block transfer
- Supports read/write features:
  - Write protection switch for write operations
  - SDIO read wait and suspend/resume operations
  - Includes a fully configurable 128 × 32-bit FIFO for read/write data
- Supports internal and external DMA capabilities
  - Supports Advanced DMA to perform linked memory access
- Supports both synchronous and asynchronous abort
- Host can initiate non-data transfer command while data transfer is in progress

31.1.2 Modes of Operation—Data Transfer Modes

The eSDHC can select the following modes for data transfer:

- MMC 1-, 4-, or 8-bit transfers in full-speed mode (up to 20 MHz) or high-speed mode (up to 52 MHz)
- SD 1- or 4-bit transfers in full-speed mode (up to 25 MHz) or high-speed mode (up to 50 MHz)
- CE-ATA 1-, 4-, or 8-bit transfers
- Identification Mode (up to 400 kHz)

31.2 External Signals

This section provides an overview of the external signals, including a block diagram and a table of the I/O signal properties.

31.2.1 Overview

Figure 31-2 shows the eSDHC I/O signals:

- SD_CLK is an internally-generated clock used to drive the MMC, SD, SDIO, or CE-ATA cards.
- CMD I/O is used to send commands and receive responses to/from the card.
- Eight data lines (DAT7–DAT0) are used to perform data transfers between the eSDHC and the card.
- SD_CD# and SD_WP are card-detection and write-protection signals directly routed from the socket. A low on SD_CD# indicates that a card is inserted, and a high on SD_WP indicates that the write-protect switch is active.
- SD_OD is an output signal generated at the SoC level outside eSDHC, and is used to select the external open-drain resistor.
- SD_LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.
- SD_VS is used to control the voltage at the SD_ pins listed above. When asserted, voltage is high (around 3.0V); when negated, voltage is low (around 1.8 V).

SD_CD#, SD_WP, SD_OD, SD_LCTL, and SD_VS are all optional for system implementation. If the eSDHC is desired to support a 4-bit data transfer, DAT7–DAT4 are optional and can be tied to high.

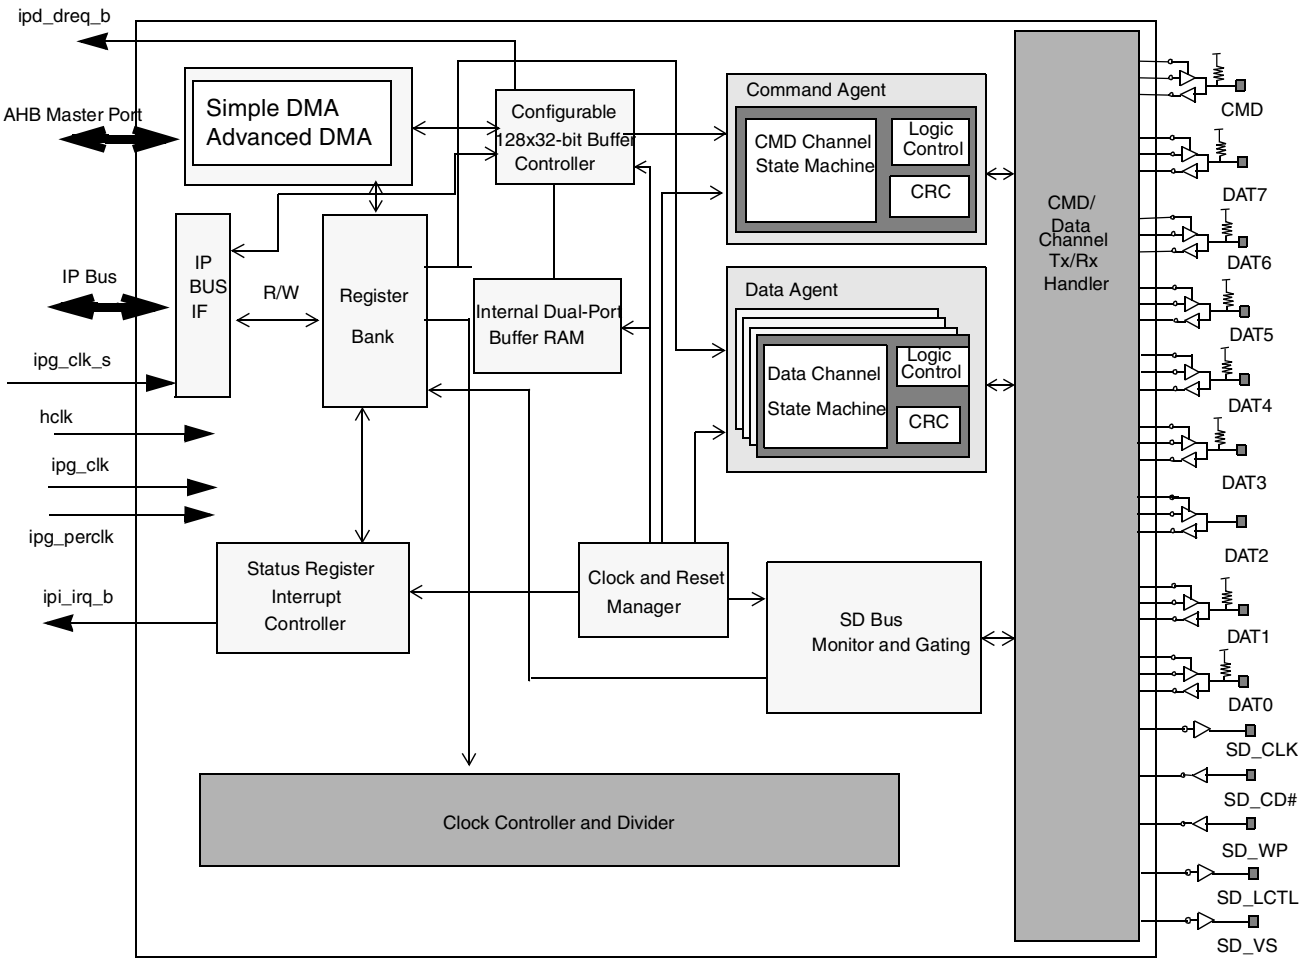

Figure 31-2. enhanced Secure Digital Host Controller (eSDHC) Block Diagram

31.2.2 Signal Descriptions

Table 31-1 shows properties of the I/O signals.

Table 31-1. Properties of I/O Signals

Name	Port	Function	Reset State	Pull up
SD_CLK	O	Clock for MMC/SD/SDIO card	0	N/A
SD_CMD	I/O	CMD line connected to card	1	Pull up
SD_DAT7	I/O	DAT7 line (MSB) in 8-bit mode Not used in other modes	1	Pull up
SD_DAT6	I/O	DAT6 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT5	I/O	DAT5 line in 8-bit mode Not used in other modes	1	Pull up

Table 31-1. Properties of I/O Signals (continued)

Name	Port	Function	Reset State	Pull up
SD_DAT4	I/O	DAT4 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT3	I/O	DAT3 line in 4/8-bit mode or configured as card detection pin May be configured as card detection pin in 1-bit mode	0	Pull-up/pull-down configurable
SD_DAT2	I/O	DAT2 line or read wait in 4-bit mode Read Wait in 1-bit mode	1	Pull up
SD_DAT1	I/O	DAT1 line in 4/8-bit mode Also used to detect interrupt in 1/4-bit mode	1	Pull up
SD_DAT0	I/O	DAT0 (LSB) line in all modes Also used to detect busy state	1	Pull up
SD_CD#	I	Card detection signal If not used tie high	N/A	N/A
SD_WP	I	Card write protect detect If not used tie low	N/A	N/A
SD_OD	O	Open drain select (not generated within the eSDHC). Optional output	N/A	N/A
SD_LCTL	O	LED control used to drive an external LED Active high Fully controlled by the driver Optional output	0	N/A
SD_VS	O	Controls the voltage at SD_ pins. When asserted, voltage is high (around 3.0V); when negated, voltage is low (around 1.8V) Optional output	0	N/A

31.3 Memory Map and Register Definition

This section includes the module memory map and detailed descriptions of all registers.

31.3.1 Memory Map

Table 31-2 shows the eSDHC memory map. For the base address of a particular module instantiation, see the system memory map.

All registers support 32-bit accesses only.Addresses greater than 0x0044, except for 0x0050, 0x0054, 0x0058, and 0x00FC, are reserved and read as all zeros. Writes to these registers are ignored.

Table 31-2. eSDHC Memory Map [1]

Address (Register Abbreviation)	Register	Access	Section
0xBASE+0x000 (DSADDR)	DMA system address register	R/W	31.3.3.1/31-12
0xBASE+0x004 (BLKATTR)	Block attributes register	R/W	31.3.3.2/31-13

31.3.3 Register Descriptions

This section provides detailed descriptions of the module's registers.

Figure 31-3 and Table 31-4 explain the conventions used in register diagrams and tables.

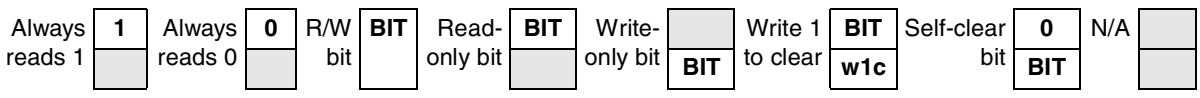

Figure 31-3. Register Field Conventions

Table 31-4. General Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can correspondingly be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that can be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to 0 (zero).
1	Resets to 1 (one).
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

NOTE

The term reset refers to power-on-reset (POR). The reset values given are POR reset values: these may differ from software reset values.

31.3.3.1 DMA System Address Register (DSADDR)

The DSADDR register contains the physical system memory address used for DMA transfers. Figure 31-4 shows the register. Table 31-5 describes the register fields.

Address 0xBASE+0x000 (DSADDR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DS_ADDR[31:16]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DS_ADDR[15:2]														0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

Figure 31-4. DMA System Address Register Diagram (DSADDR)

Table 31-5. DMA System Address Register Field Descriptions

Field	Description
31–2 DS_ADDR[31:2]	DMA system address. This register contains the 32-bit system memory address for a DMA transfer. Since the address must be (4-byte) word-aligned, the last 2 bits are always read as 0. When the eSDHC stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value. The host driver initializes this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, writes to this register are ignored. The host driver waits until the DLA bit in the present state register is cleared before writing to this register. The eSDHC internal DMA only supports continuous physical memory access, and does not support a virtual memory system. Due to AHB burst limitations, if a burst of type SEQ crosses the 1 KB boundary, eSDHC I automatically changes the burst type to NSEQ. This register supports dynamic address reflection: when TC bit is set, it automatically alters the value of internal address counter. Software cannot change this register when TC bit is set.
1–0	Reserved, read as 0

31.3.3.2 Block Attributes Register (BLKATTR)

This register is used to configure the number of data blocks and the number of bytes in each block.

Figure 31-5 shows the register. Table 31-6 describes the register fields.

Address 0xBASE+0x004 (BLKATTR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-5. Block Attributes Register (BLKATTR)

Table 31-6. Block Attributes Register Field Descriptions

Field	Description
31–16 BLKCNT	Block count for current transfer. This field is enabled when the block count enable (BCEN) bit in the transfer mode register is set to 1, and is valid only for multi-block transfers. For single block transfers, the register always reads as 1. For multi-block transfers, the host driver sets this register to a value between 1 and the maximum block count. The eSDHC decrements the block count after each block transfer, and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. This register should be accessed only when no transaction is executing (that is, after transactions are stopped). Read operations on this register during data transfers can return an invalid value, and write operations are ignored. When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register after transfer is paused by a stop at block gap operation, and before sending the Suspend command. After the Suspend command is sent the eSDHC regards the current transfer as aborted and changes the BLKCNT register back to its original value. When restoring transfer content prior to issuing a Resume command, the host driver is responsible to restore the previously-saved block count. 0x0000Stop count 0x0001 1 block 0x0002 2 blocks ..... 0xFFFF 65535 blocks **Note:** Although the BLKCNT field is 0 after reset, the read value after reset is 0x0001. This is because reset clears the MSBSEL bit to indicate a single-block transfer, so that BLKCNT reads as 0x0001.

Table 31-6. Block Attributes Register Field Descriptions (continued)

Field	Description
15–13	Reserved, read as 0
12–0 BLKSIZE[12:0]	Transfer block size. This register specifies the block size (in bytes) for block data transfers. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations are ignored. 0x000) No data transfer 0x001) 1 Byte 0x002) 2 Bytes … 0x1000) 4096 Bytes 0x1001–0xFFFF Reserved

31.3.3.3 Command Argument Register (CMDARG)

Figure 31-6 shows the register. Table 31-7 describes the register fields.

Figure 31-6. Command Argument Register (CMDARG)

Table 31-7. Command Argument Register Field Descriptions

Field	Description
31–0 CMDARG[31:0]	Command argument. The SD/MMC command argument is specified as bits 39–8 of the command format in the SD and MMC specifications.This register is write-protected when the CIHB bit is set in the present state register.

31.3.3.4 Transfer Type Register (XFERTYP)

The XFERTFYP register is used to control the operation of data transfers. The host driver is responsible to set this register before issuing a command followed by a data transfer, or before issuing a Resume command. During data transfers, to prevent data loss the eSDHC prevents writing to the following bits: DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.

The host driver is responsible to check the command inhibit bits (CDIHB and CIHB) in the present state register before writing to this register. When the CDIHB bit is set, any attempt to send a command with data transfer by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

When sending commands followed by data transfer, the command is ignored unless the following conditions are met:

- Block size is nonzero (specified by the BLKSIZE field in the BLKATTR register).
- At least one of the following conditions holds:
  - Block count is nonzero (specified by the BLKCNT field in the BLKATTR register).
  - Single-block transfer is indicated (MSBSEL bit in XFERTYP register is cleared)
  - Block count is disabled (BCEN bit in XFERTYP register is cleared)
- (Write commands only) Write protect switch is inactive (WPSPL bit in present state register is set to 1).

After the command followed by data transfer is sent, if no response is received within 64 clock cycles (the response timeout period) then the eSDHC aborts the data transfer. Response timeout occurs for instance in the following cases:

- The card responds to the command, but eSDHC does not receive the response
- An internal DMA (either simple DMA or ADMA) read operation occurs, so that external system memory is overwritten by the internal DMA with data sent back from the card.

If the command times out, the driver is responsible to reissue the command.

Figure 31-7 shows the register. Table 31-8 describes the register fields.

Address 0xBASE+0x00C (XFERTYP) Access: User read/write

Figure 31-7. Transfer Type Register (XFERTYP)

Table 31-8. Transfer Type Register Field Descriptions

Field	Description
31–30	Reserved, read as 0
29–24 CMDINX[5:0]	Command index. These bits are set to the command number that is specified in bits 45-40 of the command format in the SD Memory Card Physical Layer Specification and the SDIO Card Specification.
23–22 CMDTYP[1:0]	Command type. There are three types of special commands: Suspend, Resume and Abort (for all other commands, CMDTYP is set to 0b00). The three special commands are described as follows: • Suspend command: If a Suspend command is sent, the eSDHC assumes that the card bus has been released and that it can issue the next command which uses the DAT line. However, the eSDHC does not monitor the content of command response, so it does not know if the Suspend command succeeds or not. It is the host driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform the eSDHC that a Suspend command was successfully issued. Refer to Section 31.5.3.3.1, Suspend Operation" for more details. After the end bit of the command is sent, the eSDHC negates read wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the eSDHC maintains its current state, and the host driver restarts the transfer by setting the continue request bit in the protocol control register. • Resume command: The host driver restarts the data transfer by restoring the registers saved before sending the Suspend command and then sends the Resume command. The eSDHC checks for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, the eSDHC stops reads to the buffer. If this command is set when executing a write transfer, the eSDHC stops driving the DAT line. After issuing the Abort command, the host driver should issue a software reset (Abort transaction). 00 Normal— all other commands 01 Suspend CMD52 for writing bus suspend in CCCR 10 Resume CMD52 for writing function select in CCCR 11 Abort CMD12, CMD52 for writing I/O Abort in CCCR
21 DPSEL	Data present select. This bit is set to 1 to indicate that data is ready to be transferred using the DAT line. It is set to 0 in the following cases: • Commands using only the CMD line (such as CMD52). • Commands that transfer no data but use the busy signal on DAT[0] line (R1b or R5b, such as CMD38) 0 No data present 1 Data present **Note:** • The Resume command requires this bit be set to 1, while the other XFERTYP fields (except for CMDTYP) are the same as when the transfer was initially launched. • When the write protect switch is on, (WPSPL bit is cleared in the present state register), all writes to the transfer type register with DTDSEL = 0 and DPSEL = 1 are ignored.
20 CICEN	Command index check enable. When this bit is set to 1, the eSDHC checks the index field in the response to see if it has the same value as the command index. If not, the eSDHC reports a command index error. The Index field is not checked if the bit is cleared. 0 Disable command index check 1 Enable command index check
19 CCCEN	Command CRC check enable. If this bit is set to 1, the eSDHC checks the CRC field in the response. If an error is detected, the eSDHC reports a command CRC error. The CRC field is not checked if this bit is cleared. The number of bits checked by the CRC field value changes according to the length of the response. (Refer to RSPTYP[1:0] and Table 31-10.) 0 Disable command CRC check 1 Enable command CRC check

Table 31-8. Transfer Type Register Field Descriptions (continued)

Field	Description
18	Reserved
17–16 RSPTYP[1:0]	Response type select: 00 No response 01 Response length 136 10 Response length 48 11 Response length 48, check busy after response
15–6	Reserved, read as 0
5 MSBSEL	Multi / single-block select: This bit enables multi-block DAT line data transfers. For any other commands, this bit is set to 0. If this bit is 0, it is not necessary to set the block count register. Table 31-9 shows MSBSEL settings corresponding to different transfer types. 0 Single-block transfer 1 Multi-block transfer
4 DTDSEL	Data transfer direction select. This bit defines the direction of DAT line data transfers. The host driver sets this bit to 1 to transfer data from the SD card to the eSDHC. This bit is cleared for all other commands. 0 Write (host to card) 1 Read (card to host)
3	Reserved, read as 0
2 AC12EN	Auto CMD12 enable. Multi-block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the eSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver does not set this bit to issue commands that do not require CMD12 to stop a multi-block data transfer. In particular, secure commands defined in the file security specification do not require CMD12. In single-block transfers, the eSDHC ignores this bit. 0 Disable auto CMD12 1 Enable auto CMD12
1 BCEN	Block count enable. This bit enables the block count register, which is only relevant for multi-block transfers. When this bit is cleared, the internal block counter is disabled: this setting is used for infinite transfers.Table 31-9 shows BCEN settings corresponding to different transfer types. 0 Disable block count register 1 Enable block count register
0 DMAEN	DMA enable. This bit enables internal DMA functionality. If this bit is set to 1, an internal DMA operation begins when the host driver sets the DPSEL bit of this register. Whether the simple DMA, or the advanced DMA, is active depends on the DMA select field of the protocol control register. 0 Disable DMA 1 Enable DMA

Table 31-9 shows multi/single-block select (MSBSEL) and block count enable (BCEN) settings for different data transfer types.

Table 31-9. MSBSEL and BCEN Bit Settings for Different Transfer Types

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don’t Care	Don’t Care	Single Transfer
1	0	Don’t Care	Infinite Transfer

Table 31-9. MSBSEL and BCEN Bit Settings for Different Transfer Types (continued)

Multi/Single Block Select	Block Count Enable	Block Count	Function
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

Table 31-10 shows the settings for responses type select (RSPTYP), index check enable (CICEN), and command CRC check enable (CCCEN) fields in the XFERTYP register corresponding to different response types.

Table 31-10. RSPTYP, CICEN, and CCCEN Settings for Different Response Types

Response Type Select (RSPTYP)	Index Check Enable (CICEN)	CRC Check Enable (CCCEN)	Response Type
00	0	0	No response
01	0	1	R2
10	0	0[1]	R3,R4
10	1	1	R1,R5,R6
11	1	1	R1b,R5b[2]

[1] The CRC field for R3 and R4 is expected to be all 1's. The CRC check is disabled for these response types.

[2] The SDIO Specification does not distinguish between R5 and R5b. The notation R5b here indicates the case where eSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command is used with R5b.

31.3.3.5 Command Response *n* Register (CMDRSP0–CMDRSP3)

The CMDRSP*n* registers are used to store parts *n* of the response bits from the card (*n* = 0,1,2,3).

Figure 31-8 shows the register. Table 31-11 describes the register fields.

Address 0xBASE+0x010 (CMDRSP0)
0xBASE+0x014 (CMDRSP1)
0xBASE+0x018 (CMDRSP2)
0xBASE+0x01C (CMDRSP3)

Access: User read

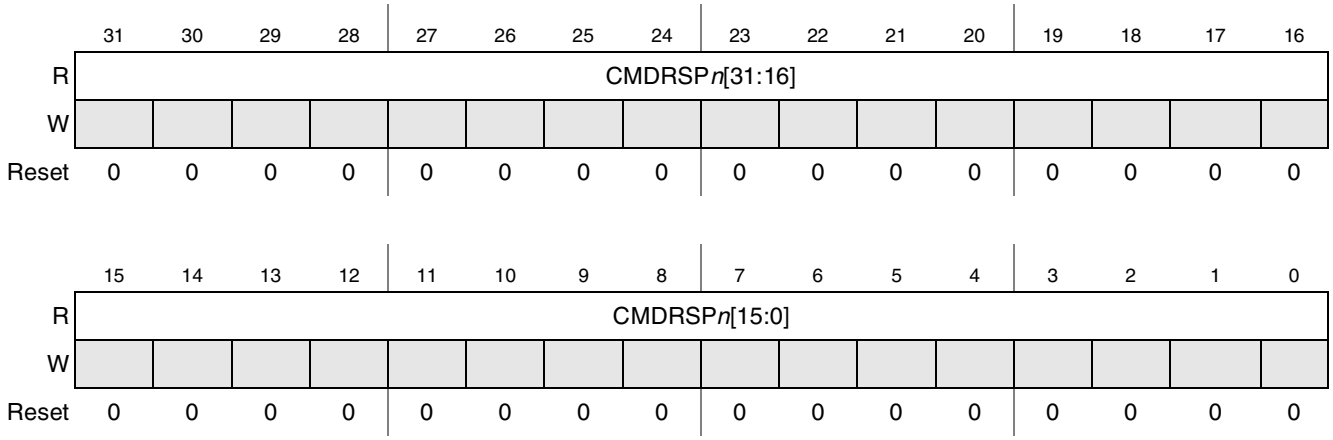

Figure 31-8. Command Response *n* Register (CMDRSP0-CMDRSP3)

Table 31-11. Command Response *n* Register Field Description

Field	Description
31–0 CMDRSP*n*[31:0]	Command response *n*. Refer to Table 31-12 for the mapping of command responses from the SD bus to this register for each response type.

Table 31-12 describes the mapping of command responses from the SD bus to command response registers for each response type. In the table, R[*x*:*y*] refers to a bit range within the response data as transmitted on the SD bus.

Table 31-12. Response Field Definitions for Each Response Type

Response Type	Meaning of Response	Response Field	Response Register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O and others	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (Publish RCA)	New Published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

The eSDHC only stores part of the response data in the command response registers. This enables the host driver to efficiently read 32 bits of response data in one read cycle on a 32-bit bus system.The eSDHC checks the response data's index field and the CRC (as specified by the command index check enable and the command CRC check enable bits in the transfer type register) and generates an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the eSDHC checks R[47:1], and if the response length is 136 the eSDHC checks R[119:1].

Table 31-12 shows that the auto CMD12 and CMD_wo_DAT responses are stored in the CMDRSP3 and CMDRSP0 registers, respectively. This prevents overwriting of the auto CMD12 response with the CMD_wo_DAT (or vice versa) when the corresponding commands are executed concurrently. When the eSDHC modifies part of the command response registers as shown in Table 31-12, it preserves the unmodified bits.

31.3.3.6 Buffer Data Port Register (DATPORT)

This register contains the buffer data port. Figure 31-9 shows the register. Table 31-13 describes the register fields. The 32-bit DATPORT register is used for CPU or external DMA access the internal buffer. When the internal DMA is enabled, writes to this register is ignored, and the register is read as 0.

Address 0xBASE+0x020 (DATPORT) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-9. Buffer Data Port Register (DATPORT)

Table 31-13. Buffer Data Port Register Field Descriptions

Field	Description
31–0 DATCONT[31:0]	Data content. When the internal DMA is enabled, writes to this register are ignored, and the register is read as 0.

31.3.3.7 Present State Register (PRSSTAT)

The 32-bit read-only PRSSTAT register provides the host driver with the eSDHC status.

Figure 31-10 shows the register. Table 31-14 describes the register fields.

Address 0xBASE+0x024 (PRSSTAT) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	DLSL[7:0]								CLSL	0	0	0	WPSPL	CDPL	0	CINS
W																
Reset	1	1	1	1	*n*[1]	1	1	1	1	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	BREN	BWEN	RTA	WTA	SDOFF	PEROFF	HCKOFF	IPGOFF	SDSTB	DLA	CDIHB	CIHB
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1 The reset value of DLSL [3] depends on the pull-up/pull-down configuration of DAT[3] (see Table 31-1). If DAT[3] is pulled down, then DLSL[3] resets to 0; if DAT[3] is pulled up, then DLSL[3] resets to 1.

Figure 31-10. Present State Register (PRSSTAT)

Table 31-14. Present State Register Field Descriptions

Field	Description
31–24 DLSL[7:0]	DAT[7:0] line signal level. These status bits are used to check the DAT line levels to recover from errors, and for debugging.DLSL[0] is especially useful for detecting the busy signal level. The reset value is affected by the external pull-up / pull-down resistors. These bits all reset to 1 except for DLSL[3], whose reset value depends on the pull-up / pull-down configuration of DAT[3]. If DAT[3] is pulled down, then DLSL[3] resets to 0; if DAT[3] is pulled up, then DLSL[3] resets to 1. DAT[*n*]: Data *n* line signal level (*n* = 7…0)
23 CLSL	CMD line signal level. This status bit is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up/pull-down resistor—by default, the read value of this bit after reset is 0b1.
22–20	Reserved, read as 0
19 WPSPL	Write protect switch pin level. The write protect switch is supported for memory and combo cards.This bit reflects the inverted value of the SD_WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the SD_WP pin is not used, it should be tied low, so that the reset value of this bit is high and write is enabled. 0 Write protected (SD_WP=1) 1 Write enabled (SD_WP=0)

Table 31-14. Present State Register Field Descriptions (continued)

Field	Description
18 CDPL	Card detect pin level. This bit reflects the inverse value of the SD_CD# signal for the card socket: for instance, when a card is inserted in the socket the SD_CD# input signal is negated, and the CDPL bit is set to 1. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed because of propagation delay. Use of this bit is limited to testing since it must be debounced by software. A software reset does not effect this bit. A write to the force event register does not effect this bit. The reset value is effected by the external card detection pin. 0 No card present (SD_CD# = 1) 1 Card present (SD_CD# = 0)
17	Reserved, read as 0
16 CINS	Card inserted. This bit indicates whether a card has been inserted. The eSDHC debounces this signal so that the host driver does not need to wait for it to stabilize. Changing from a 0 to 1 generates a card insertion interrupt in the interrupt status register. Changing from a 1 to 0 generates a card removal interrupt in the interrupt status register. A write to the force event register does not effect this bit. Setting the software reset for all (RSTA) bit in the system control register does not effect this bit. A software reset does not effect this bit. 0 Power on reset or no card 1 Card inserted
15–12	Reserved, read as 0
11 BREN	Buffer read enable. This read-only flag indicates that valid data exists in the host-side buffer.When this bit is set to 1, valid data in the buffer meets or exceeds the read watermark level. This bit changes from 1 to 0 whenever data is read from the buffer. This bit changes from 0 to1 when valid data in the buffer meets or exceeds the watermark level, and the buffer read ready interrupt has been generated and enabled. 0 Read disable 1 Read enable This status bit is used for non-DMA read transfers. The eSDHC may implement multiple buffers to transfer data efficiently.
10 BWEN	Buffer write enable. This read-only flag indicates that space is available for write data. If this bit is set to 1, available space in the buffer meets or exceeds the write watermark level]. This bit changes from 1 to 0 when data is written to the buffer. This bit changes from 0 to 1 when the available space in the buffer meets or exceeds the write watermark level, and the buffer write ready interrupt is generated and enabled. 0 Write disable 1 Write enable This status bit is used for non-DMA write transfers. The eSDHC can implement multiple buffers to transfer data efficiently.
9 RTA	Read transfer active. This status bit is used to detect completion of a read transfer. This bit is set in either of the following two cases: • After the end bit of the read command. • When the continue request bit in the protocol control register is set to 1 to restart a read transfer. A transfer complete interrupt is generated when the RTA bit is cleared. The bit is cleared in either of the following two cases: • When the last data block as specified by the block size is transferred to the system, so that all data are read from the eSDHC internal buffer. • When all valid data blocks have been transferred from eSDHC internal buffer to the system and no current block transfers are being sent because the stop at block gap request is set to 1. 0 No valid data 1 Transferring data

Table 31-14. Present State Register Field Descriptions (continued)

Field	Description
8 WTA	Write transfer active. This status bit indicates a write transfer is active. If this bit is cleared, it means no valid write data exists in the eSDHC. This bit is set in either of the following cases: • After the end bit of the write command. • When the continue request bit in the protocol control register is set to 1 to restart a write transfer. This bit is cleared in either of the following cases: • After receiving the CRC status of the last data block as specified by the transfer count (single-block or multi-block). • After receiving the CRC status of the current block, when data transmission is about to be stopped by a stop at block gap request. A block gap event interrupt is generated when this bit is cleared as result of a stop at block gap request during a write transaction. The host driver can use this status bit to determine when to issue commands during write busy state. 0 No valid data 1 Transferring data
7 SDOFF	SD clock gated off internally. This status bit indicates that the SD clock is internally gated off due to one of the following causes: • Buffer overrun or underrun • Read pause without read wait assertion • The driver has cleared the SDCLKEN bit to stop the SD clock. The host driver can use this bit to debug data transactions on the SD bus. 0 SD clock is active. 1 SD clock is gated off.
6 PEROFF	Peripheral source clock (ipg_perclk) gated off internally. This status bit indicates that the ipg_perclk is internally gated off. The host driver can use this bit for debug purposes during transactions on the SD bus. 0 ipg_perclk is active. 1 ipg_perclk is gated off.
5 HCKOFF	Master clock (hclk) gated off internally. This status bit indicates that the hclk is internally gated off. The host driver can use this bit for debug purposes during data transfers. 0 hclk is active. 1 hclk is gated off.
4 IPGOFF	ipg_clk gated off internally. This status bit indicates that the ipg_clk is internally gated off. The host driver can use this bit for debug purposes. 0 ipg_clk is active. 1 ipg_clk is gated off.
3 SDSTB	SD clock stable. This status bit indicates that the internal card clock is stable. This bit is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear SDCLKEN bit in system control register to remove glitches on the card clock when the frequency is changing. 0 Clock is changing frequency and not stable. 1 Clock is stable.

Table 31-14. Present State Register Field Descriptions (continued)

Field	Description
2 DLA	Data line active. This status bit indicates whether one of the DAT lines on the SD bus is in use. In the case of read transactions: This bit indicates if a read transfer is executing on the SD bus. A change in this bit from 1 to 0 between data blocks generates a block gap event interrupt in the interrupt status register. This bit is set in either of the following cases: • After the end bit of the read command. • When writing a 1 to the continue request bit in the protocol control register to restart a read transfer. This bit is cleared in either of the following cases: • When the end bit of the last data block is sent from the SD bus to the eSDHC. • When the read wait state is stopped by a suspend command and the DAT2 line is released. The eSDHC waits at the next block gap by driving a read wait signal at the start of the interrupt cycle. If the read wait signal is already driven (indicating that the data buffer cannot receive data), the eSDHC can wait for a current block gap by continuing to drive the read wait signal. It is necessary to support read wait in order to use the suspend / resume function. This bit remains set to 1 during read wait. In the case of write transactions: This bit indicates that a write transfer is executing on the SD bus. Changes in this bit from 1 to 0 generate a transfer complete interrupt in the interrupt status register. This bit is set in either of the following cases: • After the end bit of the write command. • When writing to 1 to the continue request bit in the protocol control register to continue a write transfer. This bit is cleared in either of the following cases: • When the SD card releases write busy of the last data block, the eSDHC also detects if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the eSDHC assumes the card drives the not busy signal. • When the SD card releases write busy, prior to waiting for write transfer, and as a result of a stop at block gap request. In the case of command with busy pending: This status bit indicates that a busy state follows the command and the data line is in use. This bit is cleared when the DAT0 line is released. 0 DAT line inactive 1 DAT line active

Table 31-14. Present State Register Field Descriptions (continued)

Field	Description
1 CDIHB	Command inhibit (DAT). This status bit is generated if either the DAT line active (DLA) bit or the read transfer active (RTA) bit in this register is set to 1. If this bit is cleared, it indicates that the eSDHC can issue the next SD/MMC command. Commands with a busy signal (for example, R1b, R5b type) belong to command inhibit (DAT). Except in the case when the command busy is finished, changing this bit from 1 to 0 generates a transfer complete interrupt in the interrupt status register. **Note:** The SD host driver can save registers for a suspend transaction after this bit has changed from 1 to 0. 0 Can issue command which uses the DAT line 1 Cannot issue command which uses the DAT line
0 CIHB	Command inhibit (CMD). This status bit is cleared when the CMD line is not in use, indicating that the eSDHC can issue a SD/MMC command using the CMD line. This bit is set immediately after the transfer type register is written. This bit is cleared when the command response is received. Changing this bit from 1 to 0 sets the command complete (CC) bit in the interrupt status register, which generates an interrupt if the CCIEN bit is set in the interrupt signal enable register. Commands using only the CMD line can be issued if this bit is cleared, even when CDIHB (bit 1 of this register) is set. Examples of commands using only the CMD line include CMD0, CMD12, CMD13 (for memory cards) and CMD52 (for SDIO). This bit is remains set (and the CC bit in the interrupt status register remains cleared) in either of the following two cases: • If the eSDHC detects a CMD line conflict when the command is issued (eSDHC drives the CMD line to 1, but detects a 0 at the next SD_CLK edge). In this case, command CRC error and command timeout error bits in the interrupt status register are set to 1. • If the command is not issued due to an auto CMD12 error. 0 Can issue command using only the CMD line 1 Cannot issue command

31.3.3.8 Protocol Control Register (PROCTL)

Figure 31-11 shows the register. Table 31-15 describes the register fields.

Address 0xBASE+0x028 (PROCTL) Access: User read/write

Figure 31-11. Protocol Control Register (PROCTL)

Table 31-15. Protocol Control Register Field Descriptions

Field	Description
31–27	Reserved, read as 0
26 WECRM	Wakeup event enable on SD card removal. This bit enables a wakeup event (via a card removal) in the interrupt status register. FN_WUS (wakeup support) in CIS does not effect this bit. When this bit is set, the card removal status and the eSDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the card removal status and assert the eSDHC interrupt. 0 Disable 1 Enable
25 WECINS	Wakeup event enable on SD card insertion. This bit enables a wakeup event, via a card insertion, in the interrupt status register. FN_WUS (wakeup support) in CIS does not effect this bit. When this bit is set, the card insertion status and the eSDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the card insertion status and assert the eSDHC interrupt. 0 Disable 1 Enable
24 WECINT	Wakeup event enable on card interrupt. This bit enables a wakeup event, via a card interrupt, in the interrupt status register. This bit can be set to 1 if FN_WUS (wakeup support) in CIS is set to 1. When this bit is set, the card interrupt status and the eSDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the card interrupt status and assert the eSDHC interrupt. 0 Disable 1 Enable
23–20	Reserved
19 IABG	Interrupt at block gap. This bit is only valid for SDIO cards in 4-bit mode. It selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multi-block transfer. Clearing the bit disables interrupt detection during a multi-block transfer. If the SDIO card cannot signal an interrupt during a multi-block transfer, this bit should be cleared to avoid an inadvertent interrupt. When the host driver detects an SDIO card insertion, it sets this bit according to the CCCR of the card. 0 Disabled 1 Enabled
18 RWCTL	Read wait control. The read wait function is optional for SDIO cards. If the card supports read wait, setting this bit enables the read wait protocol to stop read data using the DAT[2] line. Otherwise the eSDHC has to stop the SD clock to hold read data, which restricts commands generation. When the host driver detects an SDIO card insertion, it sets this bit according to the CCCR of the card. If the card does not support read wait, this bit is never set to 1—otherwise DAT line conflicts may occur. If this bit is cleared and the stop at block gap request (SABGREQ) bit is set, the eSDHC stops the SD clock to pause the read operation. 0 Disable read wait control, and stop SD Clock at block gap when SABGREQ bit is set 1 Enable read wait control, and assert read wait without stopping SD clock at block gap when SABGREQ bit is set
17 CREQ	Continue request. When a Suspend operation is not accepted by the card, setting this bit restarts the paused transfer. This bit is also used to restart a transaction that was stopped using the stop at block gap request (SABGREQ). To cancel the stop at block gap, the host driver clears the SABGREQ bit and sets this bit to 1 to restart the transfer. If both the SABGREQ bit and this bit are set to 1, the continue request is ignored. The eSDHC automatically clears this bit: the host driver does not need to clear it. 0 No effect 1 Restart

Table 31-15. Protocol Control Register Field Descriptions (continued)

Field	Description
16 SABGREQ	Stop at block gap request. This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. In the case of read transfers, setting the SABREQ bit stops the transaction at the next block gap only if the SDIO card supports read wait, and the read wait control bit (RWCTL) in this register is set to 1. Otherwise, the read operation can be paused at the next block gap by stopping the SD bus clock. In the case of write transfers in which the host driver writes data to the data port register, the host driver sets this bit after all block data is written. If this bit is set to 1, the host driver does not write data to the data port register after a block is sent. If the host driver clears this bit before the transfer complete bit in interrupt status register is set:, then the eSDHC's behavior is unpredictable. Clearing both SABGREQ and CREQ bits does not cause the transaction to restart. This bit affects the read transfer active, write transfer active, DAT line active and command inhibit (DAT) bits in the present state register. 0 Transfer 1 Stop
15–10	Reserved, read as 0
9–8 DMAS	DMA select. This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00 No DMA or simple DMA is selected 01 ADMA1 is selected 10 ADMA2 is selected 11 Reserved
7 CDSS	Card detect signal selection. This bit selects the source for the card detection. 0 Card detection level is selected (for normal purposes) 1 Card detection test level is selected (for test purposes)
6 CDTL	Card detect test level. This is bit is enabled while the card detection signal selection is set to 1 and it indicates card insertion. 0 Card detect test level is 0, no card inserted 1 Card detect test level is 1, card inserted
5–4 EMODE	Endian mode. The eSDHC supports all four endian modes in data transfer. Refer to Section 31.4.1, Data Buffer" for more details. 00 Big-endian mode 01 Halfword big-endian mode 10 Little-endian mode 11 Reserved
3 D3CD	DAT3 as card detection pin. If this bit is set, DAT3 should be pulled down to act as a card detection pin. 0 DAT3 does not monitor card insertion 1 DAT3 as card detection pin **Note:** Since DAT3 is also a chip select for SPI mode, a pull-down on this pin and CMD0 may set the card into the SPI mode. eSDHC does not support SPI mode.

Table 31-15. Protocol Control Register Field Descriptions (continued)

Field	Description
2–1 DTW[1:0]	Data transfer width. This bit selects the data width of the SD bus for a data transfer. The host driver sets it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits. 00 1-bit mode 01 4-bit mode 10 8-bit mode 11 Reserved
0 LCTL	LED control. This bit, fully controlled by the host driver, is used to caution the user not to remove the card while the card is being accessed. When the software issues multiple SD commands, setting the bit once before the first command is sufficient: it is not necessary to reset the bit between commands. 0 LED off 1 LED on

There are three ways to restart the transfer after stop at the block gap, depending on the status of the Suspend command.

- If the host driver does not issue a Suspend command, the continue request is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card accepts it, a Resume command is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card does not accept it, the continue request is used to restart the transfer.

When a stop at block gap request stops the data transfer, the host driver waits for the transfer complete bit (interrupt status register) to be set before attempting to restart the transfer. When restarting the data transfer by continue request, the host driver clears the stop at block gap request before, or simultaneously with, issuing the continue request.

31.3.3.9 System Control Register (SYSCTL)

Figure 31-12 shows the register. Table 31-16 describes the register fields.

Address 0xBASE+0x02C (SYSCTL) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-12. System Control Register (SYSCTL)

Table 31-16. System Control Register Field Descriptions

Field	Description
31–28	Reserved, read as 0
27 INITA	Initialization active. When this bit is set, 80 SD clocks are sent to the card. After the 80 clocks are sent, this bit self clears. This bit is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the CIHB and CDIHB bits in the present state register are set, writes to this bit is ignored (when the command or data lines are active, writes to this bit is not allowed). However, when this bit is set to 1 (that is, during the initialization active period), it is still possible to issue a command—the command bit stream appears on the CMD signal after the 80 clock cycles are completed. In this way, the driver can ensure that 80 clock cycles have completed before the command is sent out. This is a useful feature in the case where the driver needs to send 80 cycles to the card and does not want to wait until this bit is self-cleared.
26 RSTD	Software reset for DAT line. Resets part of the data circuit and the DMA circuit. Setting this bit clears and initializes the buffer, and also clears the following bits: • Data port register: all bits • Present state register: buffer read enable, buffer write enable, read transfer active, write transfer active, data line active, command inhibit (DAT) • Protocol control register: Continue request, Stop at block gap request • Interrupt status register: buffer read ready, buffer write ready, DMA interrupt, block gap event, transfer complete 0 No reset 1 Reset
25 RSTC	Software reset for CMD line. Resets part of the command circuit. The following bits are cleared by this bit: • Command inhibit (CMD) bit in present state register • Command complete (CC) bit in interrupt status register 0 No reset 1 Reset
24 RSTA	Software reset for all. This reset effects the entire host controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During initialization, the host driver sets this bit to 1 to reset the eSDHC. The eSDHC resets this bit to 0 when the capabilities registers are valid and the host driver can read them. Additional use of software reset for all does not affect the value of the capabilities registers. After this bit is set, it is recommended that the host driver reset and reinitialize the external card. 0 No Reset 1 Reset
23–20	Reserved, read as 0

Table 31-16. System Control Register Field Descriptions (continued)

Field	Description
19–16 DTOCV	Data timeout counter value. This value determines the interval by which DAT line timeouts are detected. Refer to the data timeout error bit in the interrupt status register for information on factors that dictate time-out generation. Time-out clock frequency is generated by dividing the base clock SD_CLK frequency by this value. The host driver can clear the data timeout error status enable (in the interrupt status enable register) to prevent inadvertent time-out events. 0000 SD_CLK x 2^{13} 0001 SD_CLK x 2^{14} ..... 1110 SD_CLK x 2^{27} 1111 Reserved
15–8 SDCLKFS	SD clock (SD_CLK) frequency prescale select. This register is used to select the prescaler of the SD_CLK signal. The frequency of the SD clock is set based on SD_CLKF and DVS settings according to the following formula: SD clock frequency = (peripheral source clock frequency) / (SDCLKF x DVS) See Section 31.4.6, SD Clock Generator" for more information about SD clock generation. Multiple bits in this field must not be set, or the behavior of the prescaler is undefined. 0x00 Base clock (10–63 MHz) divided by 1 0x01 Base clock divided by 2 0x02 Base clock divided by 4 0x04 Base clock divided by 8 0x08 Base clock divided by 16 0x10 Base clock divided by 32 0x20 Base clock divided by 64 0x40 Base clock divided by 128 0x80 Base clock divided by 256 (reset value) Other settings Reserved, not allowed
7–4 DVS[3:0]	Frequency divisor. The frequency of the SD clock is set based on SDCLKF and DVS settings according to the following formula: SD clock frequency = (peripheral source clock frequency) / (SDCLKF x DVS) DVS provides a finer granularity for the available frequencies. Odd divisors are supported without deterioration of the duty cycle. See Section 31.4.6, SD Clock Generator" for more information about SD clock generation. 0x0 Divide by 1 0x1 Divide by 2 ... 0xE Divide by 15 0xF Divide by 16
3 SDCLKEN	SD clock (SD_CLK) enable. The host controller stops SD_CLK when this bit is cleared. The SD_CLK frequency can only be changed when this bit is cleared. If the card inserted bit in the present state register is cleared, the host driver saves power by clearing this bit. 0 SD clock is stopped 1 SD clock is enabled

Table 31-16. System Control Register Field Descriptions (continued)

Field	Description
2 PEREN	Peripheral source clock (ipg_perclk) enable. When this bit is set, ipg_perclk is always active and no automatic gating is applied. In this case SD_CLK is active except during auto gating-off in case of buffer danger (pending underrun or overrun).When this bit is cleared, the ipg_perclk is automatically gated off when there is no transaction on the SD bus, and when none of the following conditions are met: • The cmd part is reset • Data part is reset • A soft reset • The cmd is about to be sent • Clock divisor is just updated • Continue request is just set • Card insertion is detected • Card removal is detected • Card external interrupt is detected • 80 clocks for initialization phase is ongoing Since this bit is only a feature-enabling bit, clearing this bit does not stop SD_CLK immediately. 0 ipg_perclk is internally gated off. 1 ipg_perclk is not automatically gated off and is active.
1 HCKEN	Master clock (hclk) enable. If this bit is set, hclk is always active and no automatic gating is applied. When this bit is cleared, hclk is automatically off when no data transfer is active on the SD bus. 0 hclk is internally gated off 1 hclk is not automatically gated off
0 IPGEN	ipg_clk enable. If this bit is set, ipg_clk is always active and no automatic gating is applied. When this bit is cleared, the ipg_clk is internally gated off if none of the following conditions is met: • The cmd part is reset • Data part is reset • Soft reset • The cmd is about to be sent • Clock divisor is just updated • Continue request is just set • Card insertion is detected • Card removal is detected • Card external interrupt is detected • The ipg_perclk is not gated off (thus clearing this bit has no effect unless the PEREN bit is also cleared) 0 ipg_clk is internally gated off 1 ipg_clk is not automatically gated off

31.3.3.10 Interrupt Status Register (IRQSTAT)

An interrupt is generated when at least one of the status bits in this register is set to 1, and the corresponding interrupt enable bit is set in the interrupt signal enable register. All bits are write 1 to clear: writing zeros has no effect. More than one status bit can be cleared with a single register write.

Figure 31-13 shows the register. Table 31-17 describes the register fields.

Address 0xBASE+0x030 (IRQSTAT) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-13. Interrupt Status Register (IRQSTAT)

Table 31-17. Interrupt Status Register Field Descriptions

Field	Description
31–29	Reserved, read as 0
28 DMAE	DMA error. This bit is set to 1, when some error occurs in the internal DMA data transfer. This error can be caused by either simple DMA or ADMA, depending on which DMA is in use. The value in DMA system address register is the next fetch address where the error occurs. Since any error corrupts the whole data block, the host driver re-starts the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 0 No DMA error 1 DMA error
27–25	Reserved, read as 0
24 AC12E	Auto CMD12 error. This bit is set to 1 when the eSDHC detects that one of the bits in the auto CMD12 error status register has changed from 0 to 1. This bit is set either when the errors in auto CMD12 occur, or when the auto CMD12 is not executed due to an error in the previous command. 0 No auto CMD12 error 1 Auto CMD12 error
23	Reserved, read as 0
22 DEBE	Data end bit error. Occurs either when the eSDHC detects 0 at the end bit position of read data, which uses the DAT line, or at the end bit position of the CRC. 0 No data end bit error 1 Data end bit error
21 DCE	Data CRC error. Occurs when detecting a CRC error when transferring read data, which uses the DAT line, or when detecting the write CRC status having a value other than 010. 0 No data CRC error 1 Data CRC error

Table 31-17. Interrupt Status Register Field Descriptions (continued)

Field	Description
20 DTOE	Data timeout error. Occurs when detecting one of following time-out conditions. • Busy time-out for R1b,R5b response types • Busy time-out after write CRC status • Read data time-out. 0 No data timeout error 1 Data timeout error
19 CIE	Command index error. Occurs if a command index error occurs in the command response. 0 No command index error 1 Command index error
18 CEBE	Command end bit error. Occurs when detecting that the end bit of a command response is 0. 0 No command end error 1 End bit error generated
17 CCE	Command CRC error. A command CRC error is generated in two cases. • If a CRC error is detected in the command response. In this case, the command timeout error bit in this register remains cleared (indicating no timeout) • If the eSDHC detects a CMD line conflict when the command is issued. This occurs when the eSDHC drives the CMD line to 1, but detects a 0 on the CMD line at the next SD_CLK edge. In this case, the eSDHC aborts the command (stops driving the CMD line), and sets the command timeout error bit in this register to 1. 0 No command CRC error 1 Command CRC error generated.
16 CTOE	Command timeout error. This bit is set if no response is returned within 64 SD_CLK cycles from the end bit of the command. If the eSDHC detects a CMD line conflict this bit is set without waiting for 64 SD_CLK cycles (the command CRC error bit (CCE) bit is also set, as shown in Table 31-20). 0 No command timeout error 1 Command timeout error
15–9	Reserved, read as 0
8 CINT	Card interrupt. This status bit is set when an interrupt signal is detected from the external card. Wakeup is supported: in 1-bit mode, the eSDHC detects the card interrupt without the SD clock. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, which may introducing some delay between the interrupt signal from the SDIO card and the interrupt to the host system. Writing 1 to this bit clears it, but if the interrupt factor from the SDIO card is not cleared then the bit is immediately set again. When CINT has been set to 1, it is the host driver's responsibility to clear the card interrupt signal enable bit in the interrupt signal enable register, so that the eSDHC stops driving the interrupt while it is being serviced. After the card interrupt service is completed, and the interrupt factors in the SDIO card have been reset, then the host driver can write 1 to clear this bit and set the card interrupt signal enable to 1. This causes the eSDHC to restart sampling the interrupt signal. 0 No card interrupt 1 Generate card interrupt
7 CRM	Card removal. This status bit is set if the card inserted bit in the present state register changes from 1 to 0. When writing 1 to this bit to clear it, the host driver is responsible to confirm the value of the card inserted bit in the present state register. This is necessary because it is possible for the card state to change while the host driver clears this bit, and the interrupt event may not be generated. When the CRM bit is cleared, if no card is inserted it is immediately set again: this can be prevented by clearing the card removal status enable bit in interrupt status enable register. 0 Card state unstable or inserted 1 Card removed

Table 31-17. Interrupt Status Register Field Descriptions (continued)

Field	Description
6 CINS	Card insertion. This status bit is set when the card inserted bit in the present state register changes from 0 to 1. When writing 1 to this bit to clear it, the host driver is responsible to confirm the value of the card inserted bit in the present state register. This is necessary because it is possible for the card state to change while the host driver clears this bit, and the interrupt event may not be generated. When the CIN bit is cleared, if a card is inserted it is immediately set again: this can be prevented by clearing the card inserted status enable bit in interrupt status enable register. 0 Card state unstable or removed 1 Card inserted
5 BRR	Buffer read ready. This status bit is set when the buffer read enable bit changes from 0 to 1. Refer to the buffer read enable bit in the present state register description for additional information. 0 Not ready to read buffer 1 Ready to read buffer
4 BWR	Buffer write ready. This status bit is set when the buffer write enable bit changes from 0 to 1. Refer to the buffer write enable bit in the present state register description for additional information. 0 Not ready to write buffer 1 Ready to write buffer:
3 DINT	DMA interrupt. Occurs only when the internal DMA (simple DMA or ADMA) finishes the data transfer successfully. When errors occur during data transfer, this bit is not set: the DMAE bit is set instead. 0 No DMA interrupt 1 DMA interrupt is generated
2 BGE	Block gap event. If the stop at block gap request bit in the protocol control register is set to 1, this bit is set when a read or write transaction is stopped at a block gap. If the stop at block gap request is not set to 1, this bit is not set to 1. For read transactions, this bit is set at the falling edge of the DAT line active status signal (when the transaction is stopped at SD bus timing). Read wait must be supported in order to use this function. For write transactions, this bit is set at the falling edge of the write transfer active status signal (after getting CRC status at SD bus timing). 0 No block gap event 1 Transaction stopped at block gap

Table 31-17. Interrupt Status Register Field Descriptions (continued)

Field	Description
1 TC	Transfer complete. This bit is set when a read or write transfer is completed. For read transactions, this bit is set at the falling edge of the read transfer active status signal. There are two cases in which the transfer complete interrupt is generated: • When a data transfer is completed as specified by the data length (after the last data has been read to the host system). • When data has stopped at the block gap and completed the data transfer by setting the stop at block gap request bit in the Protocol Control register (after valid data has been read to the host system). For write transactions, this bit is set at the falling edge of the DAT line active status signal. There are two cases in which this interrupt is generated: • When the last data is written to the SD card as specified by the data length and the busy signal is released. • When data transfers are stopped at the block gap, by setting the stop at block gap request bit in the protocol control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released). 0 Transfer not complete 1 Transfer complete
0 CC	Command complete. This bit is set when the end bit of the command response is received (except auto CMD12). This bit is set to 1 when the command inhibit (CMD) bit in the present state register is cleared. 0 Command not complete 1 Command complete

Table 31-18 shows the eSDHC status associated with different settings of the command timeout error and command complete bits.

Table 31-18. eSDHC Status for Command Timeout Error/Command Complete Bit Combinations

Command Complete Bit	Command Timeout Error Bit	eSDHC Status
0	0	—
0 or 1	1	Response not received within 64 SD_CLK cycles
1	0	Response received

Table 31-19 shows the eSDHC status associated with different settings of the transfer complete and the data timeout error bits.

Table 31-19. eSDHC Status for Data Timeout Error/Transfer Complete Bit Combinations

Transfer Complete Bit	Data Timeout Error Bit	eSDHC Status
0	0	—
0	1	Timeout occurred during transfer
1	0 or 1	Data transfer complete

Table 31-20 shows the eSDHC status associated with different settings of the command CRC error and command timeout error bits.

Table 31-20. eSDHC Status for Command CRC Error/Command Timeout Error Bit Combinations

Command CCR Error Bit	Command Timeout Error Bit	eSDHC Status
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

31.3.3.11 Interrupt Status Enable Register (IRQSTATEN)

Setting bits in this register to 1 enables the corresponding interrupt status register bits to be set by the specified event. If any bit is cleared, the corresponding interrupt status bit is cleared and remains 0.

Figure 31-14 shows the register. Table 31-21 describes the register fields.

Address 0xBASE+0x034 (IRQSTATEN) Access: User read/write

17 CCESEN	Command CRC error status enable 0 Masked 1 Enabled
16 CTOESEN	Command timeout error status enable 0 Masked 1 Enabled
15–9	Reserved, read as 0
8 CINTSEN	Card interrupt status enable. If this bit is set to 0, the eSDHC clears the interrupt request to the system. the card interrupt detection is stopped when this bit is cleared, and restarted when this bit is set to 1. The host driver is responsible to clear this bit before servicing interrupts, to prevent inadvertent interrupts. After servicing the interrupt, the host driver is responsible to set this bit to 1. 0 Masked 1 Enabled
7 CRMSEN	Card removal status enable 0 Masked 1 Enabled
6 CINSEN	Card insertion status enable 0 Masked 1 Enabled
5 BRRSEN	Buffer read ready status enable 0 Masked 1 Enabled
4 BWRSEN	Buffer write ready status enable 0 Masked 1 Enabled
3 DINTSEN	DMA interrupt status enable 0 Masked 1 Enabled
2 BGESEN	Block gap event status enable 0 Masked 1 Enabled

Table 31-21. Interrupt Status Enable Register Field Descriptions (continued)

Field	Description
1 TCSEN	Transfer complete status enable 0 Masked 1 Enabled
0 CCSEN	Command complete status enable 0 Masked 1 Enabled

NOTE

Depending on the setting of the IABG bit in the protocol control register, eSDHC may be programmed to sample the card interrupt signal during the interrupt period and hold this value in the flip-flop. This can cause a delay between the assertion of the card interrupt signal and notification of the host system.

To detect a CMD line conflict, the host driver sets both the command timeout error status enable bit and the command CRC error status enable bit to 1.

31.3.3.12 Interrupt Signal Enable Register (IRQSIGEN)

This register is used to select the events which are signaled to the host system as interrupts (these status bits all share the same interrupt line). When a bit in this register is set to 1, then setting the corresponding interrupt status register bit to 1 generates an interrupt.

Figure 31-15 shows the register. Table 31-22 describes the register fields.

Address 0xBASE+0x038 (IRQSIGEN) Access: User read/write

31.3.3.13 Auto CMD12 Error Status Register (AUTOC12ERR)

When the auto CMD12 error status bit in the status register is set to 1, the host driver checks this register to identify the source of auto CMD12 errors. This register is valid only when the auto CMD12 error status bit in the status register is set to 1.

Figure 31-16 shows the register. Table 31-23 describes the register fields.

Address 0xBASE+0x03C (AUTOC12ERR) Access: User read

Figure 31-16. Auto CMD12 Error Status Register (AUTOC12ERR)

Table 31-23. Auto CMD12 Error Status Register Field Descriptions

Field	Description
31–8	Reserved, read as 0
7 CNIBAC12E	Command not issued by auto CMD12 error. This bit is set to 1 when CMD_wo_DAT is not executed due to an auto CMD12 error (D04–D01) in this register. 0 No error 1 Not issued
6–5	Reserved, read as 0
4 AC12IE	Auto CMD12 index error. Indicates that a command index error occurred in response to a command. 0 No error 1 Error, the CMD index in response is not CMD12
3 AC12CE	Auto CMD12 CRC error. Indicates a CRC error in the command response. 0 No CRC error 1 CRC Error Met in auto CMD12 Response
2 AC12EBE	Auto CMD12 end bit error. indicates the end bit of command response is 0 which should be 1. 0 No error 1 End Bit Error Generated
1 AC12TOE	Auto CMD12 timeout error. Indicates that no response is returned within 64 SD_CLK cycles after the end bit of the command. If this bit is set to1, then the other error status bits (2–4) are not valid. 0 No error 1 Time out
0 AC12NE	Auto CMD12 not executed. This bit is set to 1 when the eSDHC cannot issue the auto CMD12 to stop a memory multi-block data transfer due to some error. In case the memory multi-block data transfer is not started due to a command error, this bit is not set because it is not necessary to issue an auto CMD12. If this bit is set to 1, other error status bits (1-4) have no meaning. 0 Executed 1 Not executed

Table 31-24 shows error types associated with different auto CMD12 CRC error and auto CMD12 command timeout error bit settings.

Table 31-24. Command CRC Error and Command Timeout Error Bit Settings and Error Types

Auto CMD12 CRC Error Bit	Auto CMD12 Timeout Error Bit	Type of Error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

When issuing auto CMD12 commands, the eSDHC sets bits in the auto CMD12 error status register according to the following steps:

1. Before issuing an auto CMD12 command, the eSDHC sets the auto CMD12 not executed bit (bit 0) of the auto CMD12 error status register if the auto CMD12 cannot be issued due to an error in the previous command.
2. If the auto CMD12 is issued, then the auto CMD12 not executed bit (bit 0) is cleared.

3. At the end bit of an auto CMD12 response, the eSDHC checks errors corresponding to bits 0–4 (AC12IE, AC12CE, AC12EBE, and AC12TOE) and sets the bit if the corresponding error is detected.
4. Before reading the command not issued by auto CMD12 error bit (bit 7) the eSDHC sets bit 7 to 1 if there is a command that cannot be issued, and clears bit 7 if there is no command to issue.

Auto CMD12 errors and writes to the command register are asynchronous. After an auto CMD12 command, bit 7 is sampled when the driver is not writing to the command register. The driver can avoid problems by setting the AC12E bit in the interrupt status register before reading this register. An auto CMD12 error interrupt is generated when one of the error bits (0-4) is set to 1. The command not issued by auto CMD12 error does not generate an interrupt.

31.3.3.14 Host Controller Capabilities Register (HOSTCAPBLT)

This register provides the host driver with information specific to the eSDHC implementation. The value in this register is the same as at power-on reset, and does not change during a software reset. Any write to this register is ignored.

Figure 31-17 shows the register. Table 31-25 describes the register fields.

Address 0xBASE+0x040 (HOSTCAPBL1T) Access: User read

Field	Description
31–27	Reserved, read as 0
26 VS18	Voltage support 1.8 V. This bit's setting depends on the host system ability. 0 1.8V not supported 1 1.8V supported
25 VS30	Voltage support 3.0 V. This bit's setting depends on the host system ability. 0 3.0 V not supported 1 3.0 V supported

Table 31-25. Host Capabilities Register Field Descriptions (continued)

Field	Description
24 VS33	Voltage support 3.3 V. This bit's setting depends on the host system ability. 0 3.3 V not supported 1 3.3 V supported
23 SRS	Suspend/Resume support. This bit indicates whether the eSDHC supports Suspend/Resume functionality. If this bit is 0, the Suspend and Resume mechanism, as well as the Read Wait, are not supported, and the host driver does not issue either Suspend or Resume commands. 0 Not supported 1 Supported
22 DMAS	DMA support. This bit indicates whether the eSDHC is capable of using the internal DMA to transfer data between system memory and the data buffer directly. 0 DMA not supported 1 DMA supported
21 HSS	High-speed mode support. This bit indicates whether the eSDHC supports High-speed mode and the Host System can supply a SD clock frequency from 25 MHz to 50 MHz. 0 High-speed not supported 1 High-speed supported
20 ADMAS	ADMA support. This bit indicates whether the eSDHC supports the ADMA feature. 0 Advanced DMA not supported 1 Advanced DMA supported
19	Reserved, read as 0
18–16 MBL[2:0]	Maximum block length. This value indicates the maximum block size that the host driver can read and write to the eSDHC's buffer. The buffer transfers blocks up to this size without wait cycles. 000 512 bytes 001 1024 bytes 010 2048 bytes 011 4096 bytes
15–0	Reserved, read as 0

31.3.3.15 Watermark Level Register (WML)

This register configures watermark levels (FIFO thresholds) and burst lengths for write and read. Watermark levels can range from 1–128 words; burst lengths can range from 1–31 words.

Figure 31-18 shows the register. Table 31-26 describes the register fields.

Address 0xBASE+0x044 (WML) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-18. Watermark Level Register (WML)

Table 31-26. Watermark Level Register Field Descriptions

Field	Description
31–29	Reserved, read as 0
28–24 WR_BRST_LEN[4:0]	Write burst length. The number of words the eSDHC writes in a single burst. The write burst length must not exceed the write watermark level, and all bursts within a watermark level transfer are in back-to-back mode. This field resets to 0b01000. The field cannot be cleared: writing 0 to this field results in the reset value 0b01000. **Note:** Due to system restrictions, the actual burst length does not exceed 16.
23–16 WR_WML[7:0]	Write watermark level. The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words in a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128. The reset write watermark level is 16.
15–13	Reserved, read as 0
12–8 RD_BRST_LEN[4:0]	Read burst length. The number of words the eSDHC reads in a single burst. The read burst length must not exceed the read watermark level, and all bursts within a watermark level transfer are in back-to-back mode. This field resets to 0b01000. The field cannot be cleared: writing 0 to this field results in the reset value 0b01000. **Note:** Due to system restrictions, the actual burst length does not exceed 16.
7–0 RD_WML[7:0]	Read watermark level. The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words in a sequence of read bursts in back-to-back mode. The maximum legal value for the read watermark level is 128. The reset read watermark level is 16.

31.3.3.16 Force Event Register (FEVT)

The force event register is not a physically-implemented register, but rather an address where the interrupt status register can be written if the corresponding bit of the interrupt status enable register is set. Writing 1’s to this register sets the corresponding bits in the interrupt status register. This register is a write-only register: reads always return zero. Writing zero to the register has no effect.

When writing to this register to change status bits in the interrupt status register, the driver is responsible to ensure that the ipg_clk is active by setting the IPGEN bit in the system control register.

Figure 31-19 shows the register. Table 31-27 describes the register fields.

Address 0xBASE+0x050 (FEVT) Access: User write

17 FEVTCCE	Force event command CRC error. Forces the CCE bit of interrupt status register to be set
16 FEVTCCE	Force event command time out error. Forces the CTOE bit of interrupt status register to be set
15–8	Reserved, read as 0
7 FEVTCNIBAC12E	Force event command not executed by auto CMD12 error. Forces the CNIBAC12E bit in the Auto CMD12 Error Status Register to be set.
6–5	Reserved, read as 0
4 FEVTAC12IE	Force event auto CMD12 Index error. Forces the AC12IE bit in the auto CMD12 error status register to be set.
3 FEVTAC12EBE	Force event auto CMD12 end bit error. Forces the AC12EBE bit in the auto CMD12 error status register to be set.
2 FEVTAC12CE	Force event auto CMD12 CRC error. Forces the AC12CE bit in the auto CMD12 error status register to be set.
1 FEVTAC12TOE	Force event auto CMD12 time out error. Forces the AC12TOE bit in the auto CMD12 error status register to be set.
0 FEVTAC12NE	Force event auto CMD12 not executed. Forces the AC12NE bit in the auto CMD12 error status register to be set.

31.3.3.17 ADMA Error Status Register (ADMAES

When an ADMA error interrupt occurs, the ADMA error status (ADMAES) field in this register indicates the ADMA error state. To recover from the error, the ADMAES field together with the system address register can be used to determine the address of the error descriptor (see the ADMAES field description in Table 31-28).

In case of a write operation, the host driver should use the ACMD22 to get the number of the written blocks, rather than using this information, since unwritten data may exist in the host controller.

The host controller generates the ADMA error interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The host driver can distinguish this error by reading the valid bit of the error descriptor.

Figure 31-20 shows the register. Table 31-28 describes the register fields

Address 0xBASE+0x054 (ADMAES) Access: User read

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-20. ADMA Error Status Register (ADMAES)

Table 31-28. ADMA Error Status Register Field Descriptions

Field	Description
31–4	Reserved, read as 0
3 ADMADCE	ADMA Descriptor Error. This error occurs when an invalid descriptor is fetched by ADMA: 0 No Error 1 Error
2 ADMALME	ADMA length mismatch error. This error occurs in the following two cases: • The block count enable bit (BCEN) in the transfer type register is set, and the total data length specified by the descriptor table is different from that specified by the block count and block size. • The BCEN bit is cleared, and the total data length is not a multiple of the block size 0 No error 1 Error
1–0 ADMAES	ADMA error state. This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. ADMAES settings and corresponding error states and ADMA system address register contents are shown in the following table.

ADMAE Setting	ADMA Error State	ADMA System Address Register Contents
00	ST_STOP (stop DMA)	Holds the address of the next executable descriptor command
01	ST_FDS (fetch descriptor)	Holds the valid descriptor address
10	ST_CADR (change address)	No ADMA error is generated
11	ST_TFR (transfer data)	Holds the address of the next executable descriptor command

31.3.3.18 ADMA System Address Register (ADSADDR)

This register contains the physical system memory address used for ADMA transfers. Figure 31-21 shows the register. Table 31-29 describes the register fields.

Address 0xBASE+0x058 (ADSADDR) Access: User read/write

Figure 31-21. ADMA System Address Register (ADSADDR)

Table 31-29. ADMA System Address Register Field Descriptions

Field	Description
31–2 ADS_ADDR[31:0]	ADMA system address. This register holds the address of the executing command word in the descriptor table. At the start of ADMA transfer, the host driver sets the start address of the descriptor table. The ADMA engine increments this register address every fetch of a descriptor command. When the ADMA is stopped at the block gap, this register indicates the address of the next executable descriptor command. When the ADMA error interrupt is generated, this register holds the valid descriptor address or the next executable descriptor command, depending on the ADMA state (see Table 31-28). The lower 2 bits of this register are tied to '0' so the ADMA address is always word aligned. This register supports dynamic address reflection: when the transfer complete (TC) bit is set in the interrupt status register it automatically alters the value of internal address counter, so software cannot change this register when TC bit is set. Additional software restrictions are listed in Section 31.7, Software Restrictions."
1–0	Reserved, read as 0

31.3.3.19 Vendor Specific Register (VENDOR)

This register contains the vendor-specific control/status settings.

Figure 31-22 shows the register. Table 31-30 describes the register fields.

Address 0xBASE+0x0C0 (VENDOR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-22. Vendor Specific Register (VENDOR)

Table 31-30. Vendor Specific Register Field Descriptions

Field	Description
31–28	Reserved, read as 0
27–24 DBG_SEL[3:0]	Debug select. Select the internal submodule to show its internal state value.
23–16 INT_ST_VAL[7:0]	Internal state value. Internal state value, reflecting the corresponding state value selected by Debug Select field. This field is read-only and write to this field does not have effect.
15–1	Reserved, read as 0
0 EXT_DMA_EN	External DMA request enable. Enables requests to external DMA. When the internal DMA (either simple DMA or advanced DMA) is not in use and this bit is set to 1, then the eSDHC sends out a DMA request when the internal buffer is ready. Clearing this bit disables the external DMA request: this can be useful in CPU polling mode. By default, this bit is set. 0 In any scenario, eSDHC does not send out external DMA request. 1 When internal DMA is not active, an external DMA request is sent out (reset value)

31.3.3.20 Host Controller Version (HOSTVER)

This register contains the vendor host controller version information. All bits are read-only with the same value as on power-on reset.

Figure 31-23 shows the register. Table 31-31 describes the register fields.

Offset 0xBASE+0x0FC (HOSTVER) Access: User read

31.4 Functional Description

The following subsections provide a brief functional description of the major system blocks, including the data buffer, DMA AHB interface, register bank and IP bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

31.4.1 Data Buffer

The eSDHC uses a configurable data buffer to optimize data transfer between the system bus (IP Bus or AHB bus) in the master clock (hclk) domain, and the SD card in the IP peripheral source clock (ipg_perclk) domain

Figure 31-24 shows the buffer scheme. The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable, from 1–128 words inclusive. The burst lengths for read and write are also configurable, from 1–16 words

inclusive (the burst length field of the watermark level register can range from 1–31, but actual burst lengths greater than 16 are not supported).

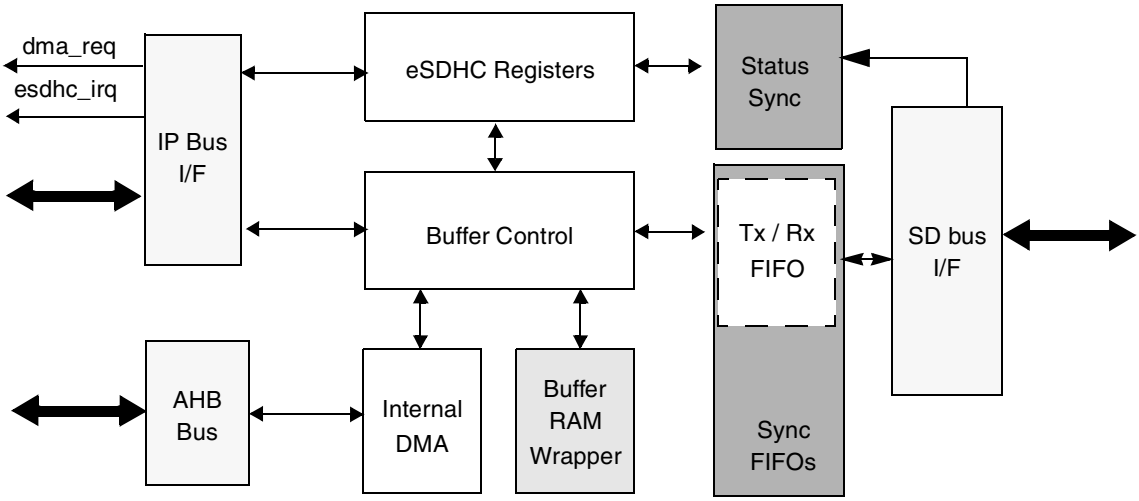

Figure 31-24. eSDHC Buffer Scheme

31.4.1.1 Data Buffer Transfer Modes

There are three transfer modes to access the data buffer:

- External DMA mode
- CPU polling mode
- Internal DMA mode (includes simple and advanced DMA accesses)

These transfer modes are explained in the following subsections

31.4.1.1.1 External DMA Mode

External DMA uses the IP bus. Using external DMA requires that DMAEN bit in the transfer type register be cleared when the DMA request is sent.

For read operations, the eSDHC sends an external DMA request (by asserting the signal esdhc_dreq_b to 0) when the number of words received in the buffer meets or exceeds the read watermark value (RD_WML in the watermark level register). The request is immediately negated when there is an access on the buffer data port register. If the number of words in the buffer after the current burst still meets or exceeds RD_WML value, the DMA request is reasserted, with one idle cycle between successive requests.

Write operations in external DMA mode are similar to read operations, except the write watermark value WR_WML is used instead of RD_WML to determine whether there are sufficiently many empty words in the buffer before the eSDHC sends the external DMA request.

31.4.1.1.2 CPU Polling Mode

CPU polling mode is similar to external DMA mode in that it uses the IP bus, and requires the DMAEN bit in the transfer type register be cleared.

CPU polling mode requires that the BRRIEN bit be set to 1 in the interrupt signal enable register. It differs from external DMA mode in that rather than relying on an external DMA request the host driver polls the BRR bit in the interrupt status register, as follows:

For read operations, when the number of words received in the buffer meets or exceeds the read watermark value (RD_WML field in the watermark level register) the eSDHC sets the BRR bit in the interrupt status register to 1 (this occurs simultaneously with sending the external DMA request). The host driver is responsible to poll the BRR bit, and when it detects that BRR is set it reads the buffer data port register to fetch RD_WML words from the buffer.

Write operation in CPU polling mode requires setting the BWRIEN to 1 in the interrupt signal enable register. Write operations are similar to read operations, except that the write watermark level WR_WML is used instead of RD_WML to determine whether there are sufficiently many empty words in the buffer, and the BWR bit is polled instead of BRR.

31.4.1.1.3 Internal DMA Mode

Internal DMA accesses utilize the AHB bus, and requires that the DMAEN bit in the transfer type register be set to 1 when the DMA request is sent. Unlike external DMA or CPU polling mode, the external DMA request is never sent out.

Internal DMA Read Operations

For internal DMA read operations, when the number of words in the buffer meets or exceeds the watermark level (RD_WML field in the watermark level register) the internal DMA starts fetching data over the AHB bus. The burst type is always INCR mode, and the burst length depends on the shortest of following factors:

- Burst length, configured in the burst length field of the watermark level register
- Watermark level boundary
- Remaining number of words in the current block
- Data boundary, configured in the current descriptor (if the ADMA is active)
- 1 Kbyte address boundary defined in the AHB protocol

When internal DMA is used, if no error is encountered the eSDHC does not inform the system before the required number of bytes are transferred. When an error occurs during the data transfer, the eSDHC aborts the data transfer and abandon the current block. The host driver is responsible to read the contents of the DMA system address register to find the starting address of the abandoned data block. If the current data transfer is in multi block mode, the eSDHC does not automatically send CMD12, even though the AC12EN bit in the transfer type register is set. Instead, it is the host drivers responsibility to send CMD12 and restart the read operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted after error recovery.

The eSDHC does not start data transmission until the number of words in the buffer meets or exceeds the read watermark level RD_WML. If the buffer is full and the host system does not read data in time, the eSDHC stops SD_CLK to avoid a data buffer overrun.

Internal DMA Write Operations

Write operations in internal DMA mode are similar to read operations, except that the write watermark level WR_WML is used to determine whether there are sufficiently many empty words in the buffer.The eSDHC does not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the host system does not write data in time, the eSDHC stops SD_CLK to avoid a data buffer under-run situation.

31.4.1.2 Data Addressing and Byte Ordering

Sequential and contiguous access is necessary to update the pointer address value correctly. Random or skipped access is not possible. On reset, byte ordering is set to little endian mode. The actually byte order is swapped inside the buffer according to the endian mode configured by software, as shown in Figure 31-25 and Figure 31-26. For a host write operation, byte order is swapped after data is fetched from the buffer and before it is sent to the SD bus. For a host read operation, byte order is swapped before the data is stored into the buffer.

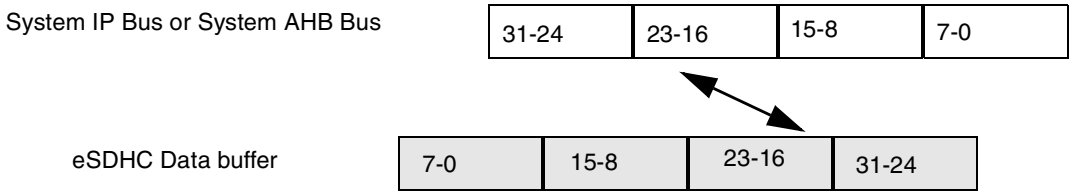

Figure 31-25. Data Swap between System Bus and eSDHC Data Buffer in Byte Little Endian Mode

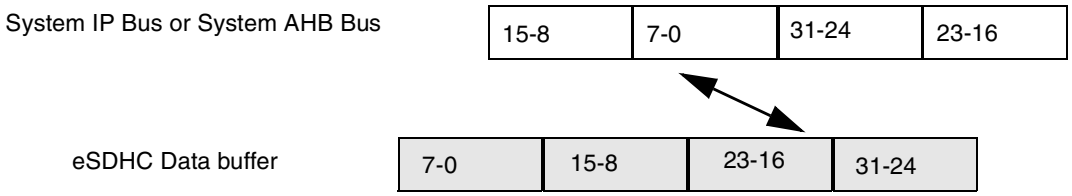

Figure 31-26. Data Swap Between System Bus and eSDHC Data Buffer in Half Word Big Endian Mode

31.4.1.3 Data Transfer Parameter Settings

In the eSDHC, the data buffer holds up to 128 4-byte words. The watermark levels for write and read can be configured from 1–128 words inclusive. For both read and write, the burst length, can be from 1–16 words inclusive (the burst length field in the watermark level ranges from 1–31, but actual burst lengths greater than 16 are not supported). The host driver is responsible to configure these values according to the system situation and requirements.

During a multi-block data transfer, the block size may be set to any value between 1 and 4096 bytes. However, additional restrictions may be imposed by the external card, which may not support large block sizes and/or partial block accesses.

31.4.1.3.1 Dividing Large Data Transfers

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multi-block transfer must be an integer multiple of the block size. If the total data length is not a multiple of the block size then there are two ways to transfer the data, depending on the function and the card design:

- The host driver splits the transaction, and fractional block portion of data is transferred using a second (single block) transfer.
- Dummy data is added to fill the last block. In this case, the card must manage the removal of the dummy data.

Figure 31-27 shows an example of a large data transfer using a WLAN SDIO card that only supports block sizes up to 64 bytes. In this case, 544 bytes are divided into eight 64-byte blocks plus 32 bytes, which are transferred using two separate CMD53 commands.

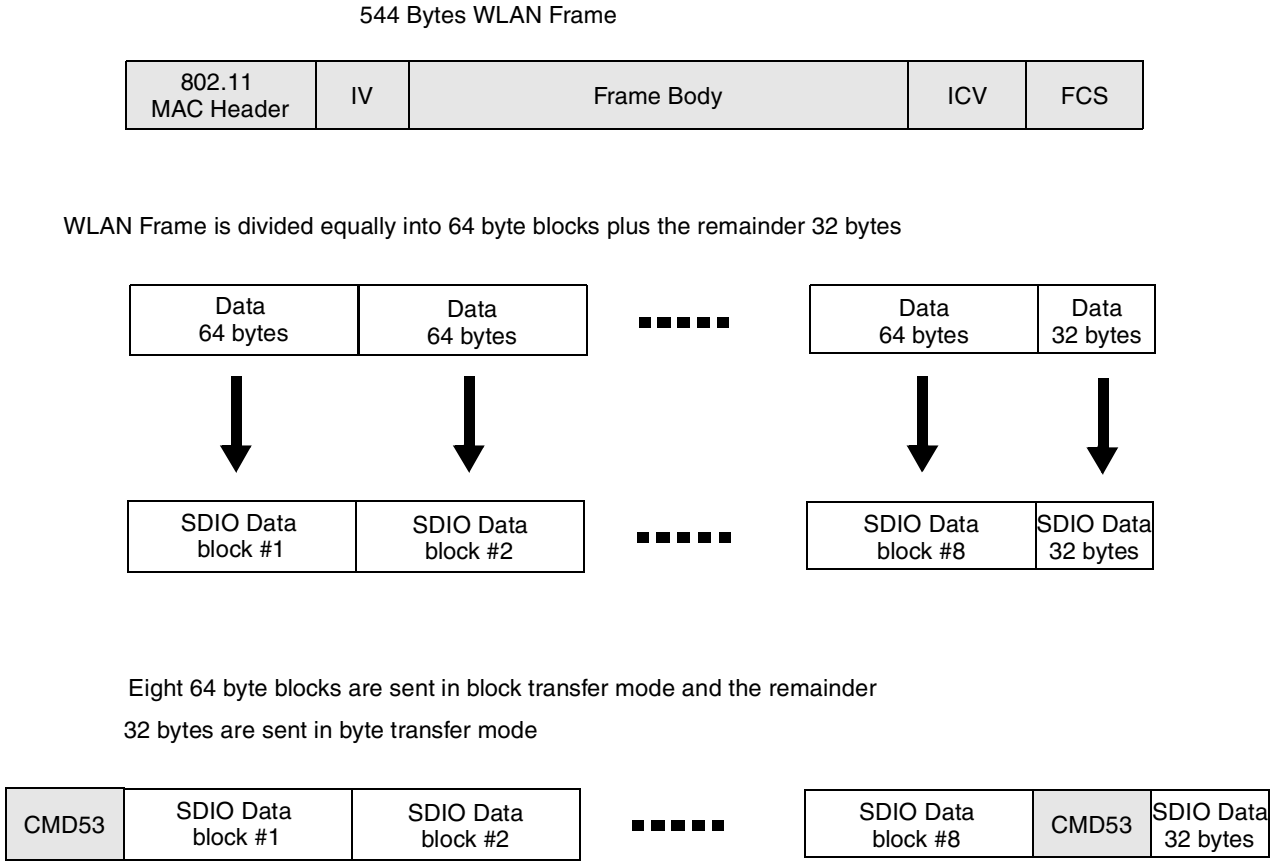

Figure 31-27. Example for Dividing Large Data Transfers

31.4.1.4 Data Transfer Parameters for External DMA Requests

[In external DMA transfer mode, since the DMA burst length cannot change during a data transfer it is necessary that the watermark level (read or write) must be a divisor of the block size (in word units): otherwise, transferring of the block may cause buffer underrun (for reads) or overrun (for writes). This implies for example that a block size of 512 bytes (128 words) requires that read and write watermark levels must be a power of two between 1 and 128 inclusive.

In CPU polling mode there are no such restrictions on the watermark levels, because the last access in the block transfer can be controlled by software. The watermark levels can even be larger than the block size (but no greater than 128 words). The actual number of bytes in each transfer is controlled by software, and does not exceed the block size.

Non-word–aligned block sizes are supported in CPU polling mode, as long as the card supports that block size. For example, the block size can be set at 31 bytes (if supported by the card), and the watermark level and burst length can take any allowed value. This is because the software transfers 8 words, and the eSDHC also sets the BRR or BWR bits (for reads or writes, respectively) when the remaining data satisfies watermark level conditions. Even though 8 words are transferred via the data port register, the eSDHC transfers only 31 bytes over the SD bus, as required by the BLKSIZE bits. In data transfers with non-word aligned block sizes, the endian mode should be set carefully, or invalid data can be transferred to/from the card.

31.4.1.5 Data Transfer Parameters for Internal DMA Requests

Internal DMA data transfers are in block units, and the host driver is responsible to set the watermark level as the minimum remaining number of words remaining in a block following a series of burst transfers. For instance, consider a multi-block read with block size 31 bytes and burst length set to 6 (4-byte) words. After the first burst transfer, there are 7 (= 31 – 4 × 6) bytes remaining to be read from the first block: the remaining data occupies 2 words. The host driver sets the read watermark level as 2 words, so that another DMA request is sent if there are 2 or more words in the buffer (which might contain some data from the next block). The eSDHC reads 2 words out of the buffer, which include 7 valid bytes and 1 stuff byte.

The DMA burst length for the internal DMA engine can be from 1 to 16 words inclusive, just as in CPU polling mode. The actual burst length for the DMA depends on the smaller of the configured burst length and the remaining words of the current block. In the above example with block size 31 bytes and burst length set to 6, the actual burst lengths alternate between 6 and 2 words. The host driver is responsible to take this variable burst length into account. One option is to configure the burst length as a divisor of the block size, so that the burst length does not need to vary.

31.4.2 DMA AHB Interface

Figure 31-28 shows the DMA AHB interface block. The internal DMA AHB interface includes a DMA engine and the AHB master.

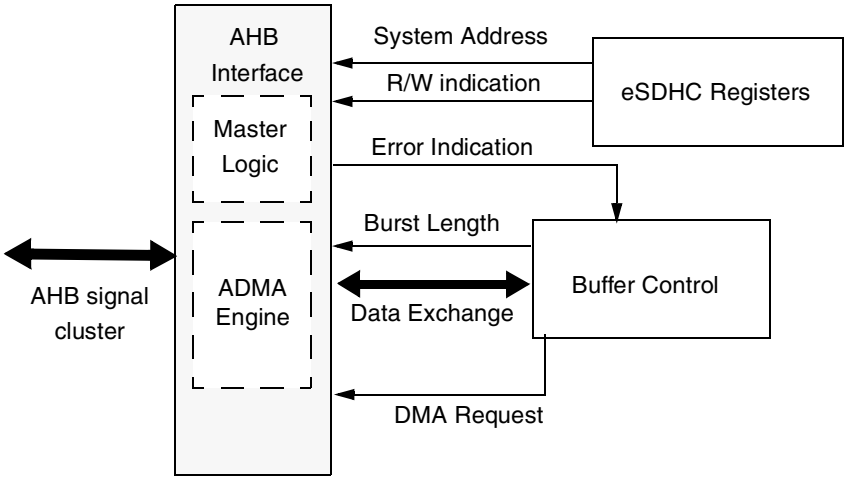

Figure 31-28. DMA AHB Interface Block

31.4.2.1 Internal DMA Requests

Internal DMA transfers are enabled by setting the DMAEN bit in the transfer type register. The external DMA request signal (esdhc_dreq_b) is disabled: however, the BRR and BWR bits in the interrupt status register are still valid, as long as the BRRSEN and BWRSEN bits have been set in the interrupt status enable register. See Section 31.4.1.1.3, Internal DMA Mode," for more details about internal DMA transfers.

If the watermark level requirement is met, the data buffer block sends a DMA request to the AHB interface. There is a delay in the internal DMA engine's response that depends on the system AHB bus loading and the priority assigned to the eSDHC. The DMA engine does not respond to a request during burst transfers, but is ready to serve as soon as the burst is over. The data buffer negates the request after the buffer is accessed. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and if the watermark level requirement is satisfied another DMA request is sent.

31.4.2.2 AHB Master Interface

If the internal AHB DMA engine fails during the data transfer, the following actions occur:

1. The DMA engine stops the transfer and goes to the idle state
2. The internal data buffer stops accepting incoming data.
3. The DMAE bit in the interrupt status register is set to inform the driver.

After the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and reads the DS_ADDR bits of the DMA system address register to get the starting address of the corrupted block. After the DMA error is fixed, the software applies a data reset and restarts the transfer from this address to recover the corrupted block.

31.4.2.3 ADMA Engine

The ADMA (Advanced DMA) transfer algorithm is defined in the SD Host Controller Standard. In contrast with simple DMA transfers, which generate a DMA interrupt at each page boundary so that the host driver can program a new system address, ADMA transfers define a programmable descriptor table in the system memory. The host driver can then calculate the system address at the page boundary and program the descriptor table before executing ADMA. This enables higher speed DMA transfers, because host intervention is not needed during long DMA-based data transfers.

The eSDHC implements two types of ADMA: ADMA1 and ADMA2. ADMA1 supports data transfers of 4-KB–aligned data in system memory. ADMA2 supports data transfers of any size from any location in system memory. ADMA1 and ADMA2 have different descriptor table formats, which are described in Section 31.4.2.3.1, ADMA1 Descriptor Tables".

The ADMA engine recognizes all descriptor types defined in the SD Host Controller Standard. The ADMA1 and ADMA2 descriptors are described in Section 31.4.2.3.1, ADMA1 Descriptor Tables" and Section 31.4.2.3.2, ADMA2 Descriptor Tables," respectively.

31.4.2.3.1 ADMA1 Descriptor Tables

ADMA1 includes the following descriptor types:

- No operation (Nop): No operation is performed, pointer passes to the next descriptor
- Set data length (Set): Specifies data length for the next data transfer
- Transfer data (Tran): Initiates data transfer
- Link descriptor (Link): Links to the next descriptor in the table, at a non-consecutive location in system memory

Descriptors also contain interrupt, end, and valid/invalid flag bits which inform the ADMA engine of the descriptor's status.

Figure 31-29 shows the ADMA1 descriptor format. Table 31-32 describes the ADMA1 field settings corresponding to each descriptor type, and Table 31-33 describes the interrupt, end, and valid/invalid flag bits.

Address/Page Field		Address/Page Field		Attribute Fields					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act2	Act1	0	Int	End	Valid

Figure 31-29. ADMA1 Descriptor Format

Table 31-32. ADMA1 Descriptor Type Field Settings

Descriptor Type Abbreviation	Descriptor Type Name	Descriptor Field Settings			
		31:12 Address/Page	27:12 Address/Page	5 Act2	4 Act1
Nop	No Operation	Don't Care		0	0
Set	Set Data Length	0000	Data Length	0	1
Tran	Transfer Data	Data Address		1	0
Link	Link Descriptor	Descriptor Address		1	1

Table 31-33. ADMA1 Descriptor Flag Bit Descriptions

Flag Bit	Description
Int (Bit 2)	Int =1 generates a DMA interrupt when this descriptor is processed.
End (Bit 1)	End = 1 indicates current descriptor is the last one in the table.
Valid (Bit 0)	Valid =1 indicates the descriptor is effective. If Valid = 0, the ADMA engine generates an ADMA error interrupt and stops the ADMA.

Figure 31-30 shows the ADMA1 descriptor table structure and its accesses by the ADMA engine. Every Tran type descriptor triggers a data transfer, with data length specified by the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length from the previous transfer is used. If no Set descriptor has been read, the data length is 0.

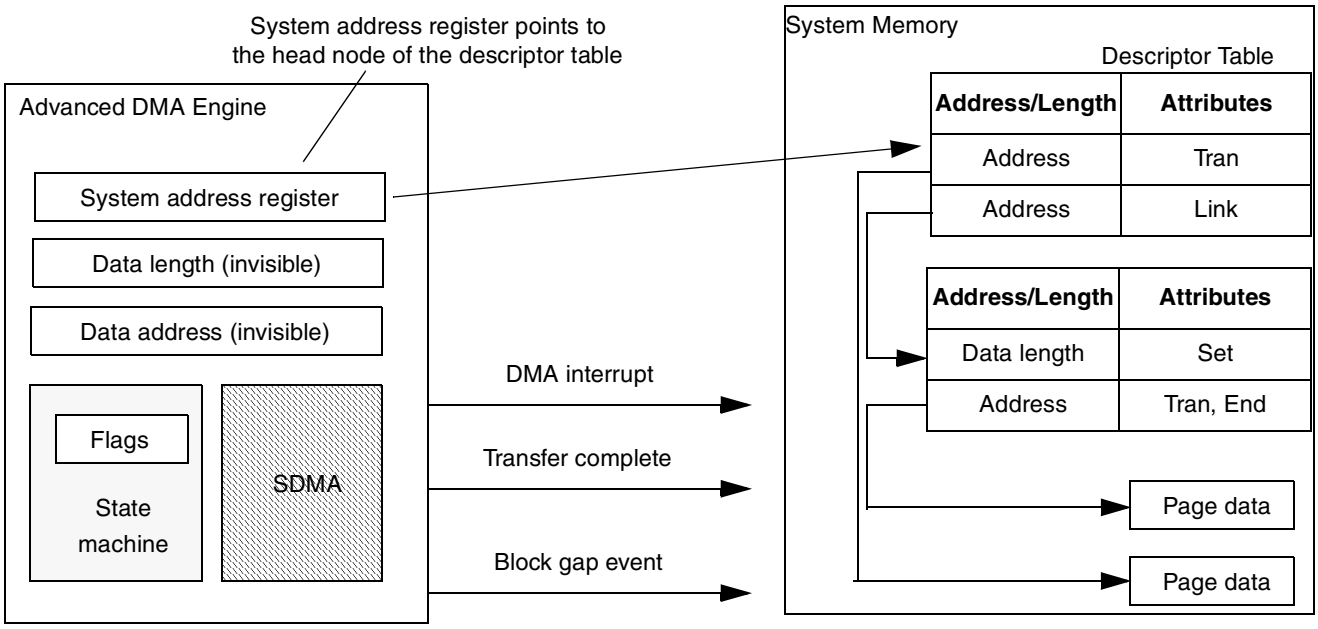

Figure 31-30. ADMA1 Descriptor Table and Access by the ADMA Engine

31.4.2.3.2 ADMA2 Descriptor Tables

ADMA2 includes the following descriptor types:

- No operation (Nop): No operation is performed, pointer passes to the next descriptor
- Reserved (Rsv): No operation is performed, passes to the next descriptor (same as Nop)
- Transfer data (Tran): Transfers data with address and length set in this descriptor line
- Link descriptor (Link): Links to the next descriptor in the table, at a non-consecutive location in system memory

Descriptors also contain interrupt, end and valid/invalid flag bits which inform the ADMA engine of the descriptor's status.

Figure 31-31 shows the ADMA2 descriptor format. Table 31-32 describes the ADMA2 Act*n* bit settings corresponding to each descriptor type, and Table 31-33 describes the interrupt, end, and valid/invalid flag bits.

Address Field		Length Field		Reserved		Attribute Fields					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit address		16-bit length		0000000000		Act2	Act1	0	Int	End	Valid

Figure 31-31. ADMA2 Descriptor Format

Table 31-34. ADMA2 Descriptor Type Field Settings

Descriptor Type Abbreviation	Descriptor Type Name	Act*n* Bit Settings		Descriptor Operation
		5 Act2	4 Act1	
Nop	No Operation	0	0	No operation: read this line and go on to the next
Rsv	Reserved	0	1	No operation: read this line and go on to the next
Tran	Transfer data	1	0	Transfer data with address and length set in this descriptor line
Link	Link descriptor	1	1	Links to the next descriptor in the table, at a non-consecutive location in system memory

Table 31-35. ADMA2 Descriptor Flag Bit Descriptions

Flag Bit	Description
Int (Bit 2)	Int =1 generates a DMA interrupt when this descriptor is processed.
End (Bit 1)	End = 1 indicates current descriptor is the last one in the table.
Valid (Bit 0)	Valid =1 indicates the descriptor is effective. If Valid = 0, the ADMA engine generates an ADMA error interrupt and stops the ADMA.

Figure 31-32 shows the ADMA2 descriptor table structure and its accesses by the ADMA engine. The ADMA engine first processes the descriptor's lower 32 bits, before reading the upper 32 bits. If the Valid flag (bit 0) of the descriptor is 0, the upper 32 bits are ignored. The address field contains word-aligned addresses, so the lowest 2 bits are always set to 0. The data length is specified in bytes.

ADMA2 read/write operations are initiated by Tran descriptors, and use the data length and address specified in the descriptor itself.

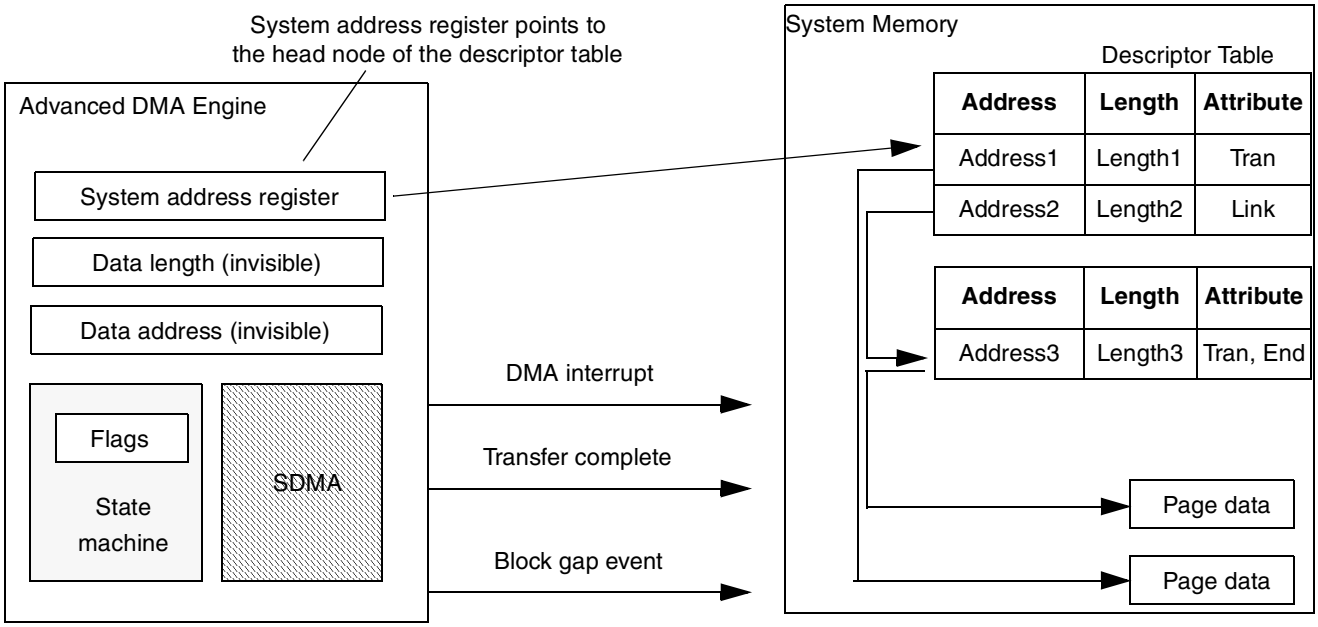

Figure 31-32. ADMA2 Descriptor Table and Access by the ADMA Engine

31.4.2.3.3 ADMA Interrupts

If the Interrupt flag (bit 2) of a descriptor is set, the ADMA engine generates an interrupt according to descriptor type, as follows:

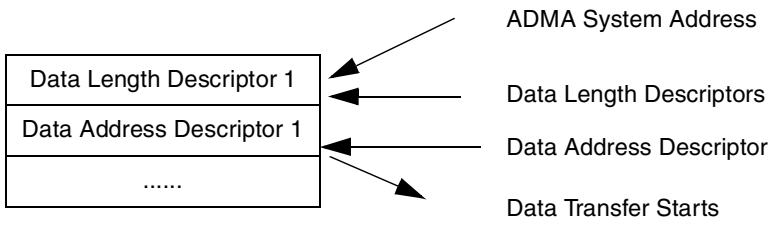
- Nop descriptor: interrupt is generated after the descriptor is fetched
- Rsv descriptor (ADMA2 only): interrupt is generated after the descriptor is fetched
- Set descriptor (ADMA1 only): interrupt is generated after the data length is set
- Tran descriptor: interrupt is generated after this transfer is completed
- Link descriptor: interrupt is generated after the new descriptor address is set.

31.4.2.3.4 ADMA Errors

The ADMA stops execution when the following errors are encountered:

- Descriptor error, generated when the valid flag in the descriptor is cleared. If an ADMA descriptor error occurs, no interrupt is generated, even if the Interrupt flag of this descriptor is set.
- AHB response error
- Data length mismatch error, generated under either of the following conditions:
  - The block count enable bit (BCEN) in the transfer type register is set, and the total data length specified by the descriptor table is different from that specified by the block count and block size.
  - The BCEN bit is cleared, and the total data length is not a multiple of the block size

31.4.3 Register Bank Access Via IP Bus Interface



The IP bus-accessible registers are contained in the register bank. Figure 31-33 is a block diagram of the register bank. Only 32-bit accesses are allowed, and no partial read/writes are supported. All accesses are word aligned (the lowest two address bits are tied to 0).

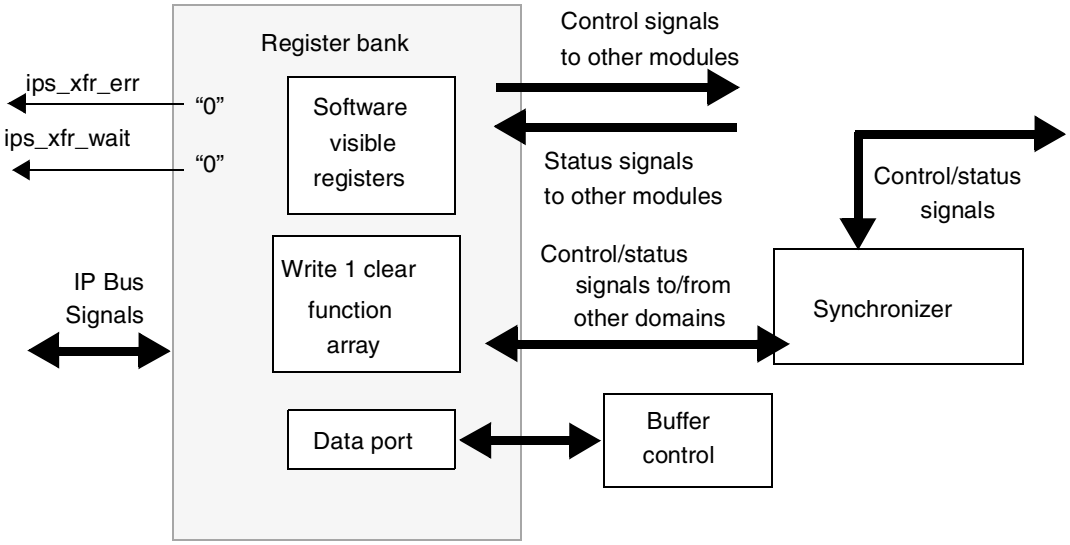


Figure 31-33. Register Bank Diagram

31.4.4 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs, and performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the DAT[0] line
- Monitors interrupts from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when the buffer announces danger status
- Detects the write-protect state

The SD protocol unit consists of four submodules:

- SD transceiver
- SD clock and monitor
- Command agent
- Data agent

31.4.4.1 SD Transceiver

The transceiver is the main control submodule in the SD protocol unit. It consists of a finite state machine (FSM) and a control module, from which the control signals for the other three submodules are generated.

31.4.4.2 SD Clock and Monitor

This submodule monitors the signal level on all 8 data lines and the command lines, and directly routes the level values into the register bank. The driver can use these values for debug purposes.

This submodule detects the card detection (CD) line as well as the DAT[3] line. The transceiver reports the card insertion state according to the CD state, or the signal level on the DAT[3] line, when the D3CD bit in the protocol control register is set.

In addition this submodule detects the write protect (WP) line, and informs the register bank when the WP switch is on. When the WP switch is on, the register bank ignores commands involving a write operation.

If the internal data buffer is in danger of overrun or underrun, this submodule asserts the gates off the SD clock. The SD clock is gated on again when the system access of the buffer catches up.

This submodule also drives the LED control output signal (SD_LCTL) when the LCTL bit is set by the driver.

31.4.4.3 Command Agent

The command agent deals with the transactions on the CMD line. Figure 31-34 shows the command CRC shift register.

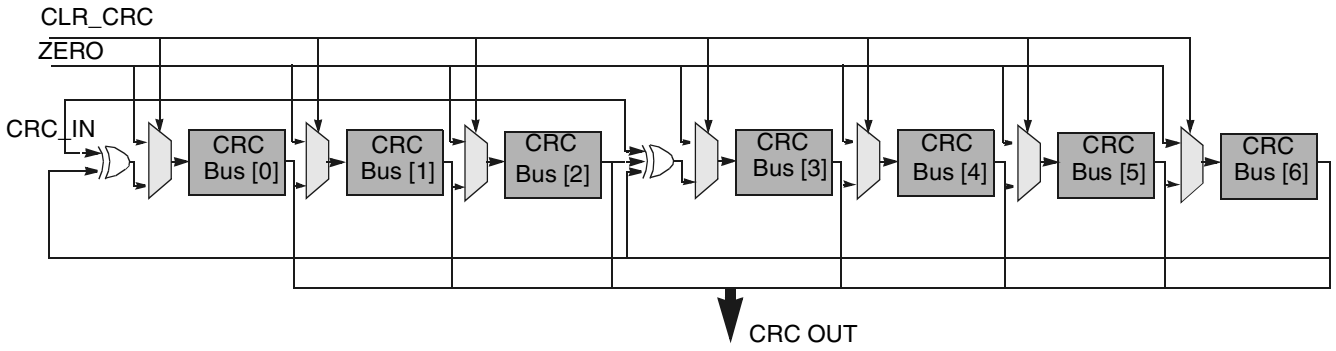

Figure 31-34. Command CRC Shift Register

The CRC polynomial for CMD is computed as follows:

```
Generator polynomial: G(x) = x^7 + x^3 + 1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[6:0] = Remainder [(M(x) * x^7) / G(x)]
```

31.4.4.4 Data Agent

The data agent deals with the transactions on the eight data lines. This module also detects the busy state from the DAT[0] line, and generates the read wait state when requested by the transceiver.

The CRC polynomials for DAT are computed as follows:

```
Generator polynomial: G(x) = x^16 + x^12 + x^5 +1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[15:0] = Remainder [(M(x) * x^16) / G(x)]
```

31.4.5 Clock and Reset Manager Submodule (CRM)

The CRM controls all the reset signals within the eSDHC, which can be classified as four types:

- Hardware reset
- Software reset for all
- Software reset for the data part
- Software reset for the command part

Reset signals are fed into the CRM, and stable signals are generated inside the CRM to reset all other modules.

The CRM also monitors the activities of all other eSDHC submodules, supplies the clocks for them and (when enabled) automatically gates off the corresponding clocks. Clocks used by the eSDHC include IPG clock (ipg_clk), peripheral source clock (ipg_perclk), and master clock (hclk).

31.4.6 SD Clock Generator

The SD clock generator generates the SD clock (SD_CLK) signal from the peripheral source clock by dividing in two stages. Refer to Figure 31-35 for the structure of the divider.

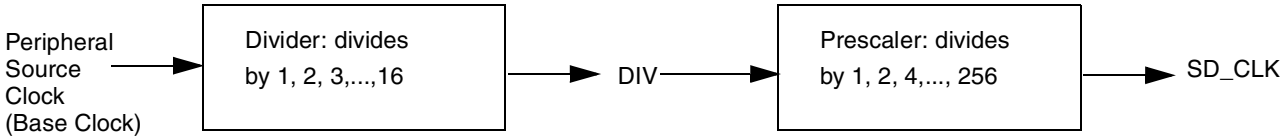

Figure 31-35. Two Stages of the Clock Divider

The SD_CLK signal which is output from the clock divider drives the clocks for all submodules of the SD protocol unit, and for the sync FIFOs to synchronize with the data rate in the internal data buffer (see Figure 31-24).

The divider and prescaler values are determined by the DVS and the SDCLKF bits in the system control register. For example, if the peripheral source clock frequency (ipg_perclk) is 96 MHz and the target SD_CLK frequency is 25 MHz, then choosing SDCLKF as 0x01 (divide by 2) and DVS as

0x1 (divide by 2) yields an SD_CLK frequency of 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to obtain a SD_CLK frequency of 400 kHz, SDCLKF = 0x08 and DVS = 0xE yields the exact clock value of 400 kHz. The highest SD_CLK frequency is equal to the base clock's (peripheral source clock); the second highest frequency is base/2; the lowest frequency is base/4096. The ipg_perclk is about 96 MHz: the reset values of SDCLKFS and DVS correspond to divides of 256 and 1 respectively, so the SD clock frequency after reset is 375 kHz.

According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD clock frequency is 50 MHz and must never exceed this limit.

If the peripheral source clock has duty cycle of 50% (which is usually true), then the duty cycle of SD_CLK is also 50%.

31.4.7 SDIO Card Interrupts

This section discusses SDIO card interrupts in the following modes: 1 bit and 4 bit.

31.4.7.1 Interrupts in 1-Bit Mode

In 1-bit mode the DAT[1] signal is dedicated to providing the interrupt function. An interrupt is asserted by pulling DAT[1] low from the SDIO card, until the interrupt service routine clears the interrupt.

31.4.7.2 Interrupts in 4-Bit Mode

In 4-bit mode the interrupt and data line 1 share pin 8. To accommodate this sharing, the eSDHC treats pin 8 as an interrupt only during specified time intervals known as interrupt periods. At all other times, the level on pin 8, is treated as a data signal.

The definition of the interrupt period is different for single-block and multi-block data transfers:

- For single-block transfers, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until the card has received the end bit of the next command that has a data block transfer associated with it.
- For multiblock data transfers, the interrupt period is limited to two clock cycles, due to the limited time between blocks. The interrupt period begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DAT[1] line is held low for one clock cycle with the last clock cycle pulling DAT[1] high. On completion of the interrupt period, the card releases the DAT[1] line into the high-Z state. The eSDHC samples the DAT[1] during the interrupt period when the IABG bit in the protocol control register is set.

Refer to SDIO Card Specification v1.10f for further information about SDIO card interrupts.

31.4.7.3 Card Interrupt Handling

Before servicing a card interrupt, the host driver is responsible to clear the card interrupt interrupt enable (CINTIEN) bit in the interrupt signal enable register. This prevents inadvertent interrupts from occurring while the interrupt is being serviced. After all interrupt requests from the card are cleared, it is the host driver's responsibility to reset this bit to 1.

The SDIO status bit is cleared by resetting the SDIO interrupt. Writing to this bit would have no effects. In 1-bit mode, the eSDHC will detect the SDIO interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status has been set, and the host driver needs to start the interrupt service routine, the SDIO bit in the Interrupt Control Register of SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the eSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO interrupt enable bit is set to 1, and the eSDHC starts sampling the interrupt signal again.

Figure 31-36 shows the system's interrupt-handling features, and also shows a flowchart that summarizes the interrupt detection and handling procedure.

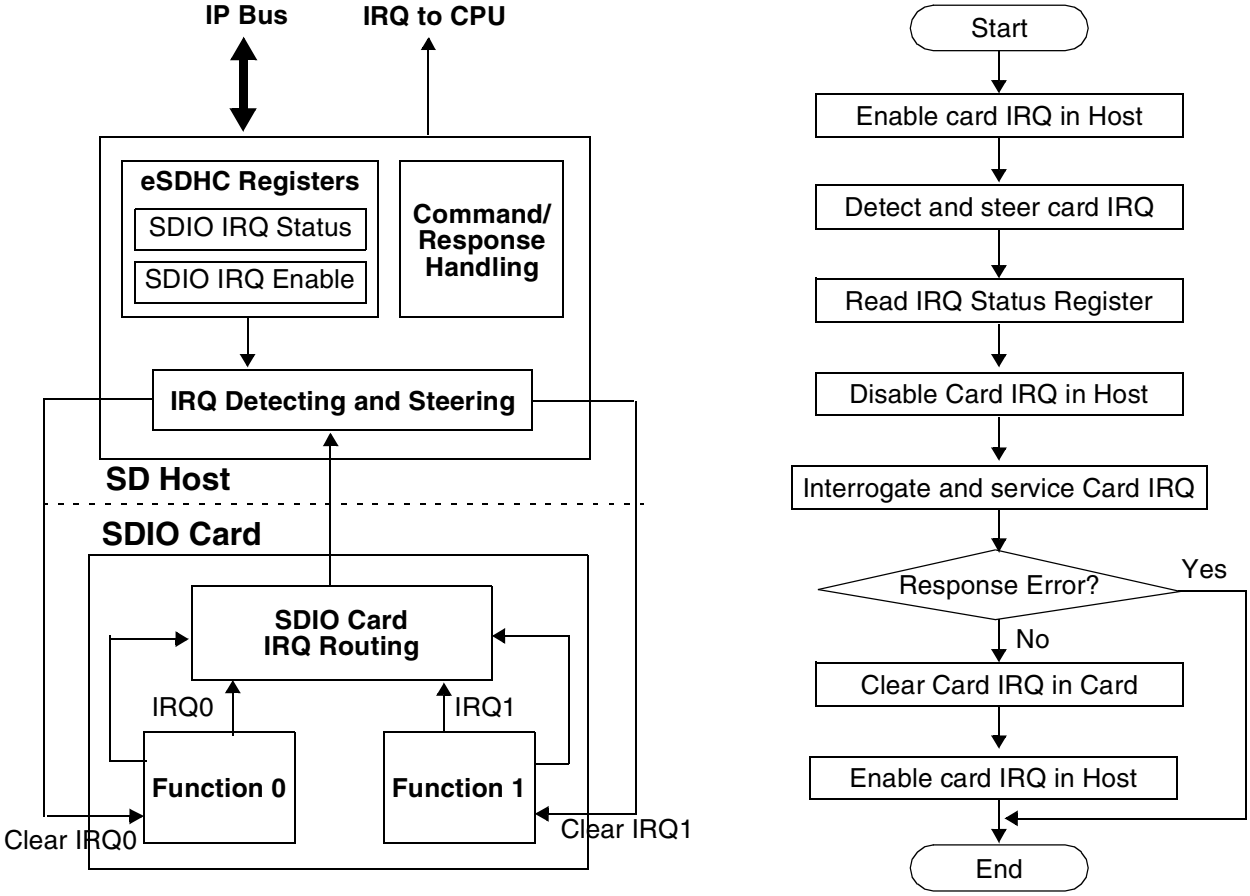

Figure 31-36. Card Interrupt-Handling Features and Card Interrupt-Detection and Handling Procedure

31.4.8 Card Insertion and Removal Detection

The eSDHC uses either the DAT[3] or the SD_CD signal to detect card insertion or removal. When there is no card on the MMC/SD bus, the DAT[3] is pulled to a low voltage level by default. When any card is inserted to or removed from the socket, the eSDHC detects the logic value changes on the DAT[3] pin and

generates an interrupt. Whether DAT[3] signal is used for card detection or not, the SD_CD pin must be connected for card detection. It may be implemented by a GPIO. The SD_CD pin is always used as a reference for card detection. If either the DAT[3] or SD_CD signal reports card inserted, the eSDHC informs the host system that a card is inserted and an interrupt is sent if it is enabled.

31.4.9 Power Management and Wakeup Events

The eSDHC offers a power management feature: by clearing the PEREN, HCKEN or IPGEN bits in the system control register, the peripheral source clock, master clock, or IPG clocks are gated in the low position to the eSDHC. For maximum power saving, the user can disable all the clocks to the eSDHC when no operation is in progress.

Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- The internal data buffer is empty

Even when the system is in low power mode and the clocks to the eSDHC are disabled, there are some events for which the clocks must be enabled to handle the event. There are three events (denoted as wakeup events or wakeup interrupts) that can be used to wake up the eSDHC by re-enabling the clocks, even if there are no clocks enabled. These three wakeup interrupts are:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from the SDIO card

In order to enable these interrupts to wake up the eSDHC, the corresponding wakeup enabled bits need to be set in the protocol control register, before the CPU enters sleep mode. See Section 31.3.3.8, Protocol Control Register (PROCTL)” for more details.

31.5 Initialization/Application Information

All communication between system and cards is controlled by the host. See Section 31.6, MMC/SD/SDIO/CE-ATA Card Commands for a complete list of the commands that the host can issue. There are two types of commands:

- Broadcast commands are intended for all cards: examples include “GO_IDLE_STATE”, “SEND_OP_COND”, “ALL_SEND_CID” and so on. In broadcast mode, all cards are in open-drain mode to avoid bus contention.
- Addressed commands can be issued after the broadcast command CMD3 has been sent, causing the cards to enter standby mode. In standby mode, the CMD and DAT I/O pads are in push-pull mode, which provides the driving capability for maximum frequency operation.

31.5.1 Command Send and Response Receive Basic Operation

The following pseudocode indicates the procedure for sending a command to the card(s). The data type WORD here denotes unsigned 32-bit integer.

Example 31-1. Pseudocode for Sending a Command to the Card(s)

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into transfer type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as ‘00’+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
         set MSBSEL bit;
         if (finite block number) {
                  set BCEN bit;
                  if (auto12 command is to use) set AC12EN bit;
         }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set transfer type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

In this example, the function wait_for_response is implemented by means of polling for the sake of simplicity. For an effective and formal way, the response is checked after the command complete interrupt is received. By doing this, the corresponding interrupt status bits are verified.

In some scenarios, a response timeout is expected after a command is issued. For example, after the host issues a CMD3 command and all cards enter the standby state, then when CMD2 is sent the cards send no response to the host. The host driver is responsible to deal with these ‘fake’ errors.

31.5.2 Card Identification Mode

When a card is inserted into the socket, or when the card is reset by the host, the host is responsible for performing a sequence of operations on the card including the following:

- Card detection (when the card is inserted) or card reset (when the card is reset by the host)
- Voltage validation (also determines whether the card is MMC, SD, SDIO, or CE-ATA)
- Card registration (including card identification and determination of relative card address (RCA))

31.5.2.1 Card Detection

Figure 31-37 shows a flowchart for the detection of MMC, SD and SDIO cards using the eSDHC.

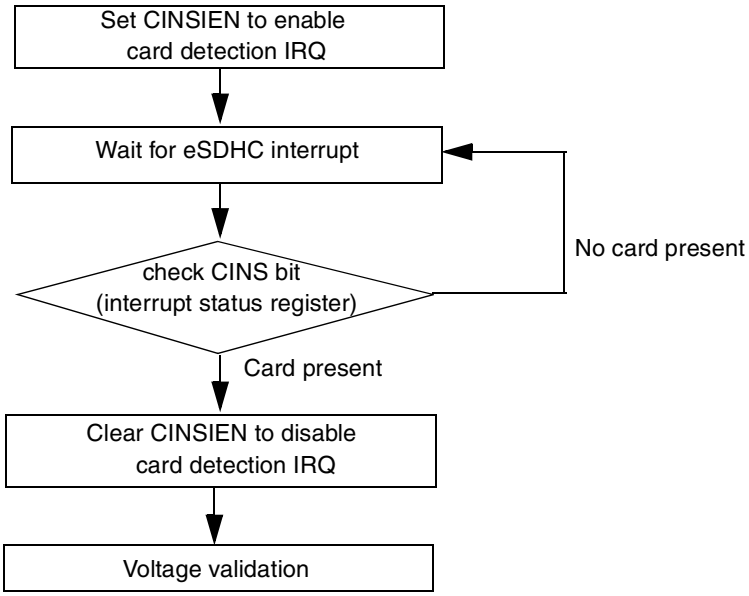

Figure 31-37. Flow Diagram for Card Detection

31.5.2.2 Reset

There are three types of resets involving the eSDHC:

- Hardware reset (card and host), which is driven by POR (power on reset)
- Software reset (host only). There are three types of software reset, which are effected by writes to bits in the system controller register as follows:
  - — Setting the RSTD bit to 1 resets the data part of the eSDHC
  - — Setting the RSTC bit to 1 resets the command part of the eSDHC
  - — Setting the RSTA bit to 1 resets all parts of the eSDHC.
- Card reset (Card Only). The command, “Go_Idle_State” (CMD0), is the software reset command for all types of MMC, SD Memory, and CE-ATA cards. This command sets each card into the idle state regardless of the current card state. For SD I/O Cards, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host is responsible to validate the voltage range of the card. See Figure 31-38 for a pseudocode to reset both the eSDHC and the card.

For CE-ATA devices that support ATA mode, two CMD39 commands should be issued back-to-back to the ATA control register before issuing CMD0 to reset the MMC layer. The first CMD39 has the SRST bit set to one, and the second has the SRST bit cleared.

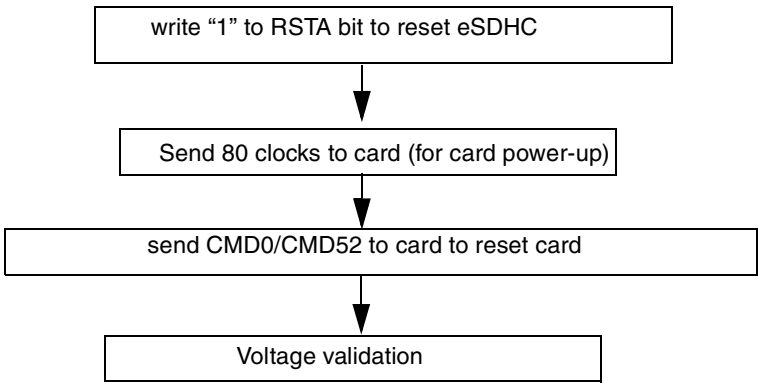

Figure 31-38. Flowchart for Reset of the eSDHC and SD I/O Card

Example 31-2. Pseudocode for Resetting eSDHC and Card

```
software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the host
set DTOCV and SDCLKFS bit fields to get the SD_CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

31.5.2.3 Voltage Validation

The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host.

A card’s supported minimum and maximum values for Vdd are defined in the card’s operating conditions register (OCR).The supported range may not cover the maximum allowed voltage range specified in the card specification. Cards that store the card identification (CID) and card-specific data (CSD) in preloaded memory are only able to communicate this information under data transfer Vdd conditions: so if the host and card have non-overlapping Vdd ranges, then the card is not able to complete the identification cycle, nor is it be able to send CSD data.

Voltage validation makes use of the special commands listed in Table 31-36 as follows:

- The host can send a command in Table 31-36 with the desired Vdd voltage window as operand. Then cards of the corresponding type that cannot perform the data transfer in the specified range disqualify themselves from further bus operations, and go into the inactive state.
- Alternatively, the host can send a command in Table 31-36 and omits the voltage range in the command. By this means the host can query each card and determine the common voltage range before sending out-of-range cards into the inactive state. This query can be used to enable the host

to select a common voltage range, or to enable notification of the system when an unusable card is detected in the stack.

Table 31-36. Voltage Validation Commands for Different Card Types

Card Type	Command Name	CMD #
MMC, CE-ATA	Send_Op_Cont	CMD1
SD	SD_Send_Op_Cont	ACMD41
SDIO	IO_Send_Op_Cont	CMD5

The following pseudocode outlines the voltage validation procedure when a card is inserted:

Example 31-3. Pseudocode for Voltage Validation Procedure Upon Card Insertion

```
voltage_validation(voltage_range_argument)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operating voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
        if (0 < number of IO functions) {
                label the card as SDIO;
                IORDY = 0;
                while (!(IORDY in IO OCR response)) { // set voltage range for each IO function
                        send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
                        wait_for_response(IO_SEND_OP_COND);
                } // end of while ...
        } // end of if (0 < ...
        if (memory part is present inside SDIO card) Label the card as SDCombo; // this is an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
        send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range
for memory part or SD card
        wait_for_response(SD_APP_OP_COND); // voltage range is set
        if (card type is UNKNOWN) label the card as SD;
        return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
        deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refused, it must be MMC card or CE-ATA card
        if (card is already labelled as SDCombo) { // change label
                re-label the card as SDIO;
                ignore the error or report it;
                return; // card is identified as SDIO card
        } // of if (card is ...
        send_command(SEND_OP_COND, <voltage range>, <...>);
        if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted, either
                label the card as UNKNOWN;
```

```
                return;
        } // of if (RESP_TIMEOUT ...
        if (check for CE-ATA signature succeeded) { // the card is CE-ATA
                store CE-ATA specific info from the signature;
                label the card as CE-ATA;
        } // of if (check for CE-ATA ...
        else label the card as MMC;
} // of else
}
```

The host detects a CE-ATA device by issuing a CMD 60 to check for a CE-ATA signature, after completing all other MMC voltage validation and identification steps. If the device responds to CMD 60 with the CE-ATA signature, then a CE-ATA device has been found.

It is possible that the CE-ATA device does not support the ATA mode, so the driver cannot issue ATA command to the device. In order to check this, the driver queries the EXT_CSD register byte 504 (S_CMD_SET) in the MMC register space. If the ATA bit (bit 4) is set, then ATA commands are supported, and the driver sets the ATA bit (bit 4) of the EXT_CSD register byte 191 (CMD_SET) to activate the ATA command set for use. To choose the ATA command set, the driver issues CMD6.

31.5.2.4 Card Identification and Registration

The card identification and registration process establishes a relative card address (RCA), which is used to address the card for future data transfer operations. The registration processes for different card types are described in the following sections:

- Section 31.5.2.4.1, Card Identification and Registration for MMC Cards”
- Section 31.5.2.4.2, Card Registration for SD, SDIO, and SD Combo Cards”
- Section 31.5.2.4.3, Card Identification and Registration for CE-ATA Cards”

A pseudocode that outlines the entire registration process is given in Section 31.5.2.4.4, Card Registration Pseudocode.”

31.5.2.4.1 Card Identification and Registration for MMC Cards

For MMC cards, the relative card address (RCA) is set by the host. The procedure for identifying the cards and setting their RCAs is described below.

Card identification mode for MMC cards uses a clock frequency of less than 400 kHz and a power voltage greater than 2.7 V. The process begins in open-drain mode: the open-drain driver stages on the CMD line allow parallel card operation during card identification. The host sends the following sequence of commands:

1. After the bus is activated, the host broadcasts a CMD1 command requesting the cards to send their valid operating conditions. The response to CMD1 is the “wired OR” operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the inactive state.
2. The host then broadcasts an All_Send_CID (CMD2) command, asking all cards for their unique card identification (CID) number. All unidentified cards (in ready state) simultaneously start sending their CID numbers serially, while bitwise monitoring their outgoing bit stream. Those

cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods stop sending their CID immediately, and must wait for the next identification cycle. Since the CID is unique for each card, only one card can successfully send its full CID to the host. This card then goes into the identification state.

3. Next, the host issues a point-to-point Set_Relative_Addr command (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received, the card state changes to the standby state, and the card does not participate in further identification cycles. The card's output driver switches from open-drain to push-pull.
4. The host repeats steps 2 and 3 above until the host sends a CMD2 which times out, signifying the completion of the identification process.

31.5.2.4.2 Card Registration for SD, SDIO, and SD Combo Cards

For SD, SDIO, and SD Combo cards, the RCA is published by the cards at the host's request. The procedure for identifying the cards and setting their RCAs is described below.

Card identification mode for SD cards uses a clock frequency of less than 400 kHz and a power voltage greater than 2.7 V (as defined in the SD card specification). The CMD line output drivers are in push-pull mode. The host sends the following sequence of commands:

1. After the bus is activated, the host broadcasts a ACMD41 (for SD) or CMD5 (for SDIO) command to all new cards in the system, requesting them to send their valid operating conditions. The card responds by sending the contents of its operating conditions register. Incompatible cards are put into the inactive state.
2. The host then broadcasts an All_Send_CID (CMD2) command, asking all cards for their unique card identification (CID) number. All unidentified cards (in ready state) simultaneously start sending their CID numbers serially, while bitwise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods stop sending their CID immediately, and must wait for the next identification cycle. Since the CID is unique for each card, only one card can successfully send its full CID to the host. This card then goes into the identification state.
3. Next, the host issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. Once the RCA is received, the card changes its state to the standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.
4. The host repeats steps 2 and 3 above until the host sends a CMD2 which times out, signifying the completion of the identification process.

31.5.2.4.3 Card Identification and Registration for CE-ATA Cards

CE-ATA operation has the same interface as MMC cards. However, CE-ATA devices are connected in a point-to-point manner, and no RCA is needed. All data communications in card identification mode use the command line (CMD) only. See CE-ATA Digital Protocol, Revision 1.1 for more details.

CE-ATA enters the tran state after reset is completed.

31.5.2.4.4 Card Registration Pseudocode

The following pseudocode outlines the card registration process for all cards (corresponding to steps 2 through 4 in the procedures shown in Section 31.5.2.4.1, Card Identification and Registration for MMC Cards" and Section 31.5.2.4.2, Card Registration for SD, SDIO, and SD Combo Cards").

Example 31-4. Pseudocode for Card Registration Process—All Cards

```
card_registry()
{
do { // decide RCA for each card until response time-out
        if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
                send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to publish its
RCA
                retrieve RCA from response;
        } // end if (card is labelled as SDCombo ...
        else if (card is labelled as SD) { // for SD card
                send_command(ALL_SEND_CID, <...>);
                if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
                send_command(SET_RELATIVE_ADDR, <...>);
                retrieve RCA from response;
        } // else if (card is labelled as SD ...
        else if (card is labelled as MMC or CE-ATA) { // treat CE-ATA as MMC
                send_command(ALL_SEND_CID, <...>);
                rca = 0x1; // arbitrarily set RCA, 1 here for example, this RCA is also the
relative address to access the CE-ATA card
                send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16
bits
        } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

31.5.3 Card Accesses

This section describes write, read, suspend/resume, and ADMA card accesses.

31.5.3.1 Block Write

Normal writes and writes with pause are described in Section 31.5.3.1.1, Normal Write" and Section 31.5.3.1.2, Write with Pause," respectively.

31.5.3.1.1 Normal Write

During a block write (CMD24–27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card indicates the failure on the DAT line. The transferred data is discarded and not written, and all further transmitted blocks (in multi-block write mode) is ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set, and the CE-ATA card does not support partial block write, either), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the

status register, while ignoring all further data transfer, waits in the Receive-data-State for a stop command. For a CE-ATA card, check the CE-ATA card specification for its behavior in block misalignment. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block size setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and not change any register contents.

Different cards may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the DAT line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO and CE-ATA cards at any time, and the card responds with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DAT line without interrupting the write operation. When re-selecting the card, it reactivates the busy indication by pulling DAT to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   a) For SD/MMC cards, use SET_BLOCKLEN (CMD16)
   b) For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1–7)
   c) For CE-ATA cards, configure bits 1~0 in the scrControl register
3. Set the eSDHC block size register to be the same as the block size set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the eSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the transfer complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

31.5.3.1.2 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the SD_CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out

condition during a write operation to the data blocks, a write to all types of cards can be paused in this way, and if the DAT0 line is not required to negate to release the busy state, no suspend command is needed.

Like in the flow described in Section 31.5.3.1.1, Normal Write," the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a) For SD/MMC, use SET_BLOCKLEN (CMD16)
   b) For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1–7)
   c) For CE-ATA cards, configure bits 1:0 in the scrControl register
3. Set the eSDHC block size register to be the same as the block size set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the eSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the transfer complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the transfer complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. The data transfer and the setting of the SABGREQ bit are concurrent, and the delay of the register read and writing, the actual number of blocks left may not be exactly the value read earlier. The driver reads the value of BLKCNT after the transfer is paused and the transfer complete interrupt is received.

It is also possible the last block has begun when the stop at block gap request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card. This is because when such a command is sent, the eSDHC thinks the System switches to another function on the SDIO card, and flush the data buffer. The eSDHC takes the Resume Command as a normal command with data transfer, and it is left for the driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the transfer type register are set as well as the AC12EN bit. However, the eSDHC automatically sends a CMD12 to mark the end of the multi-block transfer.

31.5.3.2 Block Read

Normal reads and reads with pause are described in Section 31.5.3.2.1, Normal Read" and Section 31.5.3.2.2, Read with Pause," respectively.

31.5.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi-block read, data blocks is continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA, and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfers, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a) For SD/MMC, use SET_BLOCKLEN (CMD16)
   b) For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1–7)
   c) For CE-ATA cards, configure bits 1:0 in the scrControl register
3. Set the eSDHC block size register to be the same as the block size set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the eSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set:
6. Wait for the transfer complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

31.5.3.2.2 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the read wait feature can pause during the read operation. If the SDIO card supports read wait (SRW bit in CCCR register is 1), the driver can set the SABGREQ bit in the protocol control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, make sure the RWCTL bit in the protocol control register is set, otherwise the eSDHC does not assert the read wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit once the Read Wait capability of the SDIO card is recognized.

As in the flow described in Section 31.5.3.2.1, Normal Read," the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports read wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   a) For SD/MMC, use SET_BLOCKLEN (CMD16)
   b) For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1–7)
   c) For CE-ATA cards, configure bits 1~0 in the scrControl register
5. Set the eSDHC block size register to be the same as the block size set for the card in Step 2.
6. Set the eSDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the eSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set
8. Set the SABGREQ bit.
9. Wait for the transfer complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the transfer complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the eSDHC ignores the stop at block gap request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause is transferred to the host system. Whether the Suspend command is sent or not, the internal data buffer is not flushed.

If the Suspend command is sent and the transfer is later resumed by means of a Resume command, the eSDHC takes the command as a normal one accompanied with data transfer. It is left for the driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the transfer type register are set, as well as the AC12EN bit. However, the eSDHC automatically sends the CMD12 to mark the end of multi-block transfer.

31.5.3.3 Suspend/Resume Operations

The eSDHC supports suspend and resume operations for SDIO cards, although the implementation of suspend is slightly different than that suggested in the SDIO Card Specification.

31.5.3.3.1 Suspend Operation

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of the SDIO card. The eSDHC does not monitor the content of the response, so it doesn't know if the Suspend command succeeded or not. Accordingly, it does not negate read wait for a read pause. To solve this problem, the driver first sends the command as if it were a normal command (CMDTYP = 01). After the command succeeds, and the BS bit is set to 1 in the response, the driver then sends another command marked as Suspend to inform the eSDHC that the current transfer is suspended. The following sequence is used for the Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field is set as 0b00.
3. Check the BS bit of the CCCR in the response. If it is set, repeat this step until the BS bit is cleared or abandon the Suspend operation according to the driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 0b01, to inform the eSDHC that the paused operation has successfully suspended. If the paused transfer is a read operation, the eSDHC stops driving DAT2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA system address register (for internal DMA operation), and the block attribute register.
6. Begin operation for another function on the SDIO card.

31.5.3.3.2 Resume Operation

Data transfer is resumed following a Suspend command according to the following procedure:

1. Resume the suspended function by restoring the context register with the value saved in step #5 of the Suspend operation (see Section 31.5.3.3.1, Suspend Operation").
2. Send the Resume command. In the transfer type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP field is set to 0b10).
3. If the Resume command has responded, the data transfer is resumed.

31.5.3.4 ADMA Usage

To use the ADMA in a data transfer, the host driver prepares the correct descriptor chain prior to sending the read/write command. The steps to accomplish this are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length must be a multiple of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4 KB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1–3.
4. Repeat steps 1–3 until all descriptors are created.

5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the block attribute register.
6. Set the ADMA system address register to the address of the first descriptor and set the DMAS field in the protocol control register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the transfer type register.

Steps 1–5 are independent of step 6, so step 6 can finish before steps 1–5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

31.5.3.5 Handling Transfer Errors

This section discusses the following transfer errors: CRC, internal DMA, ADMA, and Auto CMD12.

31.5.3.5.1 CRC Error

It is possible that at the end of a block transfer, a write CRC status error or read CRC error occurs. For this type of error the last block received is discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the host driver issues a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even if AC12EN and BCEND bits are set, the eSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 is sent by the eSDHC. In this case, the driver resends or re-obtains the last block with a single-block transfer.

31.5.3.5.2 Internal DMA Error

During the data transfer with internal simple DMA, if the DMA engine encounters some error on the AHB bus, the DMA operation is aborted and DMA error interrupt is sent to the Host System. When acknowledged by such an interrupt, the driver calculates the start address of data block in which the error occurs. The start address can be calculated by either of the following methods:

1. Read the DMA system address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the next burst transfer into account, it is straightforward to obtain the start address of the corrupted block.
2. Read the BLKCNT field of the block attribute register. By the number of blocks left, the total number of blocks to transfer, the start address of transfer, and the size of each block, the start address of the corrupted block can be obtained. When the BCEN bit is not set, the contents of the block attribute register do not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

31.5.3.5.3 ADMA Error

There are three types of ADMA errors: AHB transfer, invalid descriptor, and data length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set. For

acknowledging the status, the host driver should recover the error as shown below and retransfer from the place of interruption.

- AHB transfer error

  Such errors can occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and retransfer the block that was corrupted, or the next block if no block is corrupted.
- Invalid descriptor error

  For such errors, it is recommended to retrieve the transfer context, reset for the data part and recreate the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- Data length mismatch error

  Recovery from data length mismatch is similar to recovery from an invalid descriptor error. The host driver polls relating registers to retrieve the transfer context, applies a reset for the data part, configures a new descriptor chain, and makes another transfer if there is data left. As in the case of invalid descriptor error, the data length must match the new transfer.

31.5.3.5.4 Auto CMD12 Error

If the AC12EN bit is set when a multi-block data transfer is initiated by the data command, then the eSDHC automatically sends a CMD12 to the card to stop the transfer after the last block of the transfer is sent or received. It is recommended that the driver respond to errors in the auto CMD12 command as follows:

1. If the error is an auto CMD12 response timeout (indicated by bit 1 of the auto CMD12 error status register (AUTOC12ERR), then it is not certain whether the command has been accepted by the card or not. In this case, the driver can clear the AUTOC12ERR status bits and resend the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error (indicated by bit 3 of AUTOC12ERR). Since the card responds to CMD12, the card aborts the transfer. In this case, the driver can ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The CMD12 command s not sent. In this case, the driver can send a CMD12 manually.

31.5.3.6 Card Interrupts

The external cards can inform the host controller by means of some special signals. For the SDIO card, it can be the low level on the DAT[1] line during some special period. For the CE-ATA card, it can be a pulse on the CMD line to inform the host controller that the command and its response is finished, and it is possible that some additional external interrupt behaviors are defined. The eSDHC only monitors the DAT[1] line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the eSDHC, and the host system is informed by the eSDHC asserting the eSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt factor is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by writing 1. Refer to Section 31.4.7.3, Card Interrupt Handling" for the card interrupt handling flow.

31.5.4 Switch Function

MMC cards transferring data at bus widths other than 1-bit is a new feature added to the MMC spec. High-speed timing mode for all card devices, is also a recent addition to the various card specifications. To enable these new features in cards of different types the host driver issues commands as follows:

- For MMC cards (and CE-ATA over MMC interface), the high-speed mode is queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol SWITCH). 4-bit and 8-bit MMC bus widths are also enabled by SWITCH commands, but with a different argument.
- For SD cards, the high-speed mode is queried and enabled by a CMD6 (with the mnemonic symbol SWITCH_FUNC).
- For SDIO cards, the high-speed mode is enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed.

These new functions can be disabled by a software reset. For SDIO cards this can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

The following subsections provide pseudocodes for enabling/disabling high-speed mode for various card types and for setting MMC bus width. For the sake of simplicity, the pseudocodes do not show current capability check, which is recommended in the function switch process.

31.5.4.1 Query, Enable, and Disable SDIO High-Speed Mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is ‘0’) report the SDIO card does not support high-speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is cleared;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

31.5.4.2 Query, Enable and Disable SD High-Speed Mode

```
enable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
```

```
send CMD6, with argument 0xFFFFF1 and read 64 bytes of data accompanying the R1 response;
wait data transfer done bit is set;
check if the bit 401 of received 512 bit is set;
if (bit 401 is ‘0’) report the SD card does not support high-speed mode and return;
send CMD6, with argument 0x80FFFFF1 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

31.5.4.3 Query, Enable and Disable MMC High-Speed Mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high-speed mode and return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the ‘high-speed mode’ in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high-speed mode failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

31.5.4.4 Set MMC Bus Width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and return;
send CMD6 with argument 0x3B70x00; (8-bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

31.5.5 ADMA Operation

Pseudocodes for ADMA1 and ADMA2 operation are provided in Section 31.5.5.1, ADMA1 Operation" and Section 31.5.5.2, ADMA2 Operation" respectively.

31.5.5.1 ADMA1 Operation

```
Set_adma1_descriptor
{
      if (to start data transfer) {
          // Make sure the address is 4KB align.
          Set ‘Set’ type descriptor;
          {
               Set Act bits to 01;
               Set [31:12] bits data length (byte unit);
          }
          Set ‘Tran’ type descriptor;
          {
               Set Act bits to 10;
               Set [31:12] bits address (4KB align);
          }
      }
      else if (to fetch descriptor at non-continuous address) {
          Set Act bits to 11;
          Set [31:12] bits the next descriptor address (4KB align);
      }
      else { // other types of descriptor
          Set Act bits accordingly
      }
      if (this descriptor is the last one) {
          Set End bit to 1;
      }
      if (to generate interrupt for this descriptor) {
          Set Int bit to 1;
      }
      Set Valid bit to 1;
}
```

31.5.5.2 ADMA2 Operation

```
Set_adma2_descriptor
{
      if (to start data transfer) {
          // Make sure the address is 32-bit boundary (lower 2-bit are always '00').
```

```
            Set higher 32-bit of descriptor for this data transfer initial address;
            Set [31:16] bits data length (byte unit);
            Set Act bits to '10';
        }
        else if (to fetch descriptor at non-continuous address) {
            Set Act bits to '11';
            // Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
            Set higher 32-bit of descriptor for the next descriptor address;
        }
        else { // other types of descriptor
            Set Act bits accordingly
        }
        if (this descriptor is the last one) {
            Set 'End' bit '1';
        }
        if (to generate interrupt for this descriptor) {
            Set 'Int' bit '1';
        }
        Set the 'Valid' bit to '1';
}
```

31.6 MMC/SD/SDIO/CE-ATA Card Commands

There are four kinds of commands defined to control multimedia cards:

- Broadcast commands (bc), which elicit no response from the cards
- Broadcast commands with response (bcr), which elicit responses from all cards simultaneously
- Addressed (point-to-point) commands (ac), which do not involve data transfer on the DAT lines
- Addressed (point-to-point) data transfer commands (adtc), which involve data transfer

Table 31-37 lists commands for MMC/SD/SDIO/CE-ATA cards. Refer to the corresponding specifications for more details about these commands.

Table 31-37. Commands for MMC/SD/SDIO/CE-ATA Cards

CMD INDEX	Type	Argument	Response	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	—	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	—	SET_DSR	Programs the DSR of all cards.

Table 31-37. Commands for MMC/SD/SDIO/CE-ATA Cards (continued)

CMD INDEX	Type	Argument	Response	Abbreviation	Description
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operating conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to “SD Physical Specification V1.1” for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to “The MultiMediaCard System Specification Version 4.0 Final draft 2” for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/DESELECT_CARD	Toggles a card between the standby and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				

Table 31-37. Commands for MMC/SD/SDIO/CE-ATA Cards (continued)

CMD INDEX	Type	Argument	Response	Abbreviation	Description
CMD15	ac	[31:6] RCA [15:0] stuff bits	—	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	Reserved				
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command is issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.

Table 31-37. Commands for MMC/SD/SDIO/CE-ATA Cards (continued)

CMD INDEX	Type	Argument	Response	Abbreviation	Description
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				

Table 31-37. Commands for MMC/SD/SDIO/CE-ATA Cards (continued)

CMD INDEX	Type	Argument	Response	Abbreviation	Description
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather that a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57~59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	CE-ATA devices contain a set of Status and Control registers that begin at register offset 80h. These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 is used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer for the ATA command.
CMD62~63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width (‘00’=1bit or ‘10’=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.

Table 31-37. Commands for MMC/SD/SDIO/CE-ATA Cards (continued)

CMD INDEX	Type	Argument	Response	Abbreviation	Description
ACMD23[4]	ac	—	R1	SET_WR_BLK_ERASE_COUNT	—
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating conditions register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	—	R1	SET_CLR_CARD_DETECT	—
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1 CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).

2 CMD6 differs completely between high-speed MMC cards and high-speed SD cards. Command SWITCH_FUNC is for high-speed SD cards.

3 Command SWITCH is for high-speed MMC cards as well as for CE-ATA cards over the MMC interface. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 31-38.

4 ACMDs is preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The access bits for the EXT_CSD Access Modes are shown in Table 31-38.

Table 31-38. EXT_CSD Access Modes

Bits	Access Name	Operation
00	Command Set	The command set is changed according to the Cmd Set field of the argument
01	Set Bits	The bits in the pointed byte are set, according to the 1 bits in the Value field.
10	Clear Bits	The bits in the pointed byte are cleared, according to the 1 bits in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

31.7 Software Restrictions

This section describes the software restrictions.

31.7.1 Initialization Active

The driver cannot set the INITA bit in the system control register when either of the command line or data lines is active, so the driver is responsible to ensure both CDIHB and CIHB bits are cleared. In order to auto clear the INITA bit, the SDCLKEN bit must be 1, otherwise no clock signal goes out to the card and INITA never clears.

31.7.1.1 Software Polling Procedure

For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the watermark level register; moreover, if the block size is not the times of the value in watermark level register (read and write respectively), the software must access exactly the remained number of words at the end of each block. For example, for read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

31.7.1.2 Suspend Operation

In order to suspend the data transfer, the software must inform eSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform eSDHC that the transfer is suspended.

If the software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remained number of blocks before sending the normal command marked as suspend, otherwise on sending such 'suspend' command, eSDHC regards that the current transfer is aborted and changes BLKCNT register to its original value, instead of keeping the remained number of blocks.

31.7.1.3 Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be times of 4.

31.7.1.4 (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register always updates itself with the internal address value to support dynamic address synchronization, so software must make sure TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

31.7.1.5 Data Port Access

Data Port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the Data Port by CPU; or during a CPU read operation, it is also prohibited to write any data to the Data Port, by either CPU or external DMA. Otherwise the data would be corrupted inside the eSDHC buffer.

31.7.1.6 Change Clock Frequency

eSDHC does not automatically gates off the card clock when the host driver changes the clock frequency. To remove possible glitch on the card clock, clear SDCLKEN bit when changing clock divisor value and set SDCLKEN bit to '1' after SDSTB bit is '1' again.

Chapter 32
Fast Ethernet Controller (FEC)

32.1 Introduction

This chapter provides a feature-set overview, a functional block diagram, and transceiver connection information for both the 10 and 100 Mbps Media Independent Interface (MII), as well as the 7-wire serial interface. Additionally, detailed descriptions of operation and the programming model are included.

32.2 Overview

The Fast Ethernet Controller (FEC) is designed to support both 10 and 100 Mbps Ethernet/IEEE 802.3 networks. An external transceiver interface and transceiver function are required to complete the interface to the media. The FEC supports three different standard physical interfaces (MAC-PHY) for connection to an external Ethernet transceiver.

32.2.1 Features

The FEC incorporates the following features:

- Support for three different Ethernet physical interfaces:
  - 100-Mbps IEEE 802.3 MII
  - 10-Mbps IEEE 802.3 MII
  - 10-Mbps 7-wire interface (industry standard)
- IEEE 802.3 full duplex flow control
- Programmable max frame length supports IEEE 802.1 VLAN tags and priority
- Support for full-duplex operation (200 Mbps throughput) with a minimum system clock rate of 50 MHz
- Support for half-duplex operation (100 Mbps throughput) with a minimum system clock rate of 25 MHz
- Retransmission from transmit FIFO following a collision (no processor bus utilization)
- Automatic internal flushing of the receive FIFO for runts (collision fragments) and address recognition rejects (no processor bus utilization)
- Address recognition
  - Frames with broadcast address may be always accepted or always rejected
  - Exact match for single 48-bit individual (unicast) address
  - Hash (64-bit hash) check of individual (unicast) addresses

— Hash (64-bit hash) check of group (multicast) addresses
— Promiscuous mode

32.3 Modes of Operation

The primary operational modes are described in this section.

32.3.1 Full- and Half-Duplex Operation

Full-duplex mode is intended for use on point to point links between switches or end node to switch. Half-duplex mode is used in connections between an end node and a repeater or between repeaters. Selection of the duplex mode is controlled by the TCR[FDEN] bit. When configured for full-duplex mode, flow control may be enabled, which is affected by the TCR[RFC_PAUSE], TCR[TFC_PAUSE], and RCR[FCE] bits. See Section 32.5.7, Full-Duplex Flow Control," for more details.

32.3.2 Interface Options

The following interface options are supported. A detailed discussion of the interface configurations is provided in Section 32.5.2, Network Interface Options."

32.3.2.1 10 Mbps and 100 Mbps MII Interface

MII is the Media Independent Interface defined by the IEEE 802.3 standard for 10/100 Mbps operation. The MAC-PHY interface may be configured to operate in MII mode by asserting RCR[MII_MODE].

The speed of operation is determined by the FEC_TX_CLK and FEC_RX_CLK pins which are driven by the external transceiver. The transceiver will either autonegotiate the speed or control by software via the serial management interface (FEC_MDC/FEC_MDIO) pins to the transceiver. See the descriptions in Section 32.6.4.6, MII Management Frame Register (MMFR)" and Section 32.6.4.7, MII Speed Control Register (MSCR)" respectively, as well as the section on the MII for a description of how to read and write registers in the transceiver via this interface.

32.3.2.2 10 Mbps 7-Wire Interface Operation

The FEC supports a 7-wire interface as used by many 10 Mbps ethernet transceivers. The RCR[MII_MODE] bit controls this functionality. If this bit is deasserted, the MII mode is disabled and the 10 Mbps, 7-wire mode is enabled.

32.3.3 Address Recognition Options

The address options supported are promiscuous, broadcast reject, individual address (hash or exact match), and multicast hash match. Address recognition options are discussed in detail in Section 32.5.5, Ethernet Address Recognition."

32.3.4 Internal Loopback

Internal loopback mode is selected via RCR[LOOP]. Loopback mode is discussed in detail in Section 32.5.10, Internal and External Loopback."

32.4 FEC Top-Level Functional Diagram

The block diagram of the FEC is shown below. The FEC is implemented with a combination of hardware and microcode. The off-chip (Ethernet) interfaces are compliant with industry and IEEE 802.3 standards.

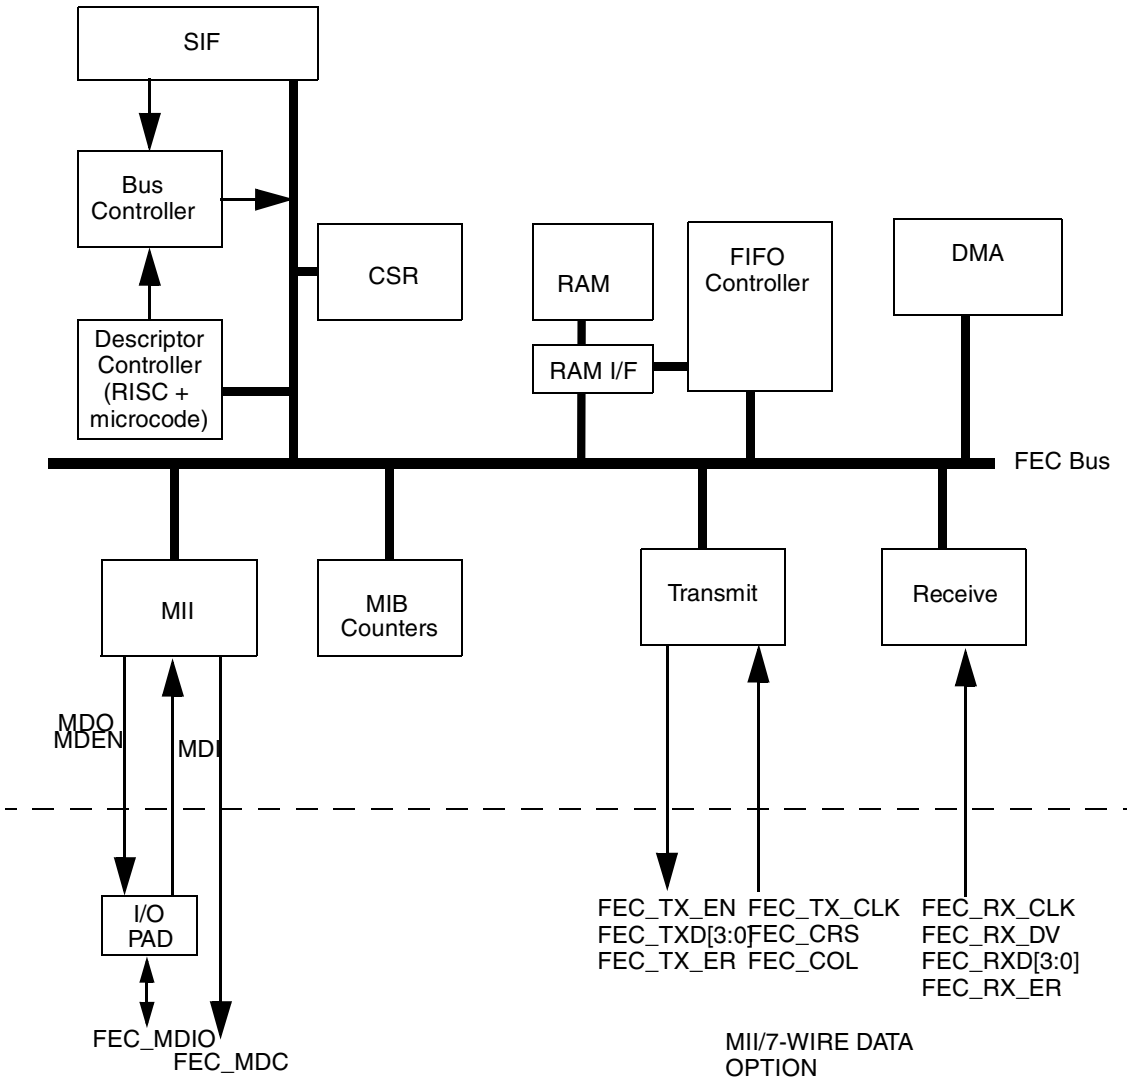

Figure 32-1. FEC Block Diagram

The descriptor controller is a RISC-based controller that provides the following functions in the FEC:

- Initialization (those internal registers not initialized by the user or hardware)
- High level control of the DMA channels (initiating DMA transfers)
- Interpreting buffer descriptors

- Address recognition for receive frames
- Random number generation for transmit collision backoff timer

NOTE

DMA references in this section refer to the FEC's DMA engine. This DMA engine is for the transfer of FEC data only, and is not related to the system DMA controller.

The RAM is the focal point of all data flow in the Fast Ethernet Controller and is divided into transmit and receive FIFOs. The FIFO boundaries are programmable using the FRSR register. User data flows to/from the DMA block from/to the receive/transmit FIFOs. Transmit data flows from the transmit FIFO into the transmit block and receive data flows from the receive block into the receive FIFO.

The user controls the FEC by writing, through the Slave Interface (SIF) module, into control registers located in each block. The Control and Status Register (CSR) block provides global control (for example, Ethernet reset and enable) and interrupt handling registers.

The MII block provides a serial channel for control/status communication with the external physical layer device (transceiver). This serial channel consists of the FEC_MDC (Management Data Clock) and FEC_MDIO (Management Data Input/Output) lines of the MII interface.

The DMA block provides multiple channels allowing transmit data, transmit descriptor, receive data and receive descriptor accesses to run independently.

The Transmit and Receive blocks provide the Ethernet MAC functionality (with some assist from microcode).

The Message Information Block (MIB) maintains counters for a variety of network events and statistics. It is not necessary for operation of the FEC but provides valuable counters for network management. The counters supported are the RMON (RFC 1757) Ethernet Statistics group and some of the IEEE 802.3 counters. See Section 32.6.3, MIB Block Counters Memory Map," for more information.

32.5 Functional Description

This section describes the operation of the FEC, beginning with the hardware and software initialization sequence, followed by a detailed description of the functions of the FEC.

32.5.1 Initialization Sequence

This section describes which registers are reset due to hardware reset, which are reset by the FEC RISC, and which locations the user must initialize prior to enabling the FEC.

32.5.1.1 Hardware Controlled Initialization

In the FEC, registers and control logic that generate interrupts are reset by hardware. A hardware reset deasserts output signals and resets general configuration bits.

Other registers are reset when the ECR[ETHER_EN] bit is cleared, as indicated in Table 32-1. ECR[ETHER_EN] is deasserted by a hard reset or may be deasserted by software to halt operation. By

deasserting ECR[ETHER_EN], the configuration control registers such as the TCR and RCR will not be reset, but the entire data path will be reset.

Table 32-1. ECR[ETHER_EN] De-Assertion Effect on FEC

Register/Machine	Reset Value
XMIT block	Transmission is aborted (bad CRC appended)
RECV block	Receive activity is aborted
DMA block	All DMA activity is terminated
RDAR	Cleared
TDAR	Cleared
Descriptor Controller block	Halt operation

32.5.1.2 User Initialization (Prior to Asserting ECR[ETHER_EN])

The user needs to initialize portions the FEC prior to setting the ECR[ETHER_EN] bit. The exact values will depend on the particular application. The order of initializations is not important.

FEC registers requiring initialization are defined in Table 32-2.

Table 32-2. User Initialization (Before ECR[ETHER_EN])

Description
Initialize EIMR
Clear EIR (write 0xFFFF_FFFF)
TFWR (optional)
IALR / IAUR
GAUR / GALR
PALR / PAUR
OPD (only needed for full duplex flow control)
RCR
TCR
MSCR (optional)
Clear MIB_RAM (locations 0xC003_8000 + 0x200-0x2FC)

FEC FIFO/DMA registers that require initialization are defined in Table 32-3.

Table 32-3. FEC User Initialization (Before ECR[ETHER_EN])

Description
Initialize FRSR (optional)
Initialize EMRBR
Initialize ERDSR
Initialize ETDSR
Initialize (Empty) Transmit Descriptor ring
Initialize (Empty) Receive Descriptor ring

32.5.1.3 Microcontroller Initialization

In the FEC, the descriptor control RISC initializes some registers after ECR[ETHER_EN] is asserted. After the microcontroller initialization sequence is complete, the hardware is ready for operation.

Table 32-4 shows microcontroller initialization operations.

Table 32-4. Microcontroller Initialization

Description
Initialize BackOff Random Number Seed
Activate Receiver
Activate Transmitter
Clear Transmit FIFO
Clear Receive FIFO
Initialize Transmit Ring Pointer
Initialize Receive Ring Pointer
Initialize FIFO Count Registers

32.5.1.4 User Initialization (After Asserting ECR[ETHER_EN])

After asserting ECR[ETHER_EN], the user can set up the buffer/frame descriptors and write to the TDAR and RDAR. See Section 32.6.5, Buffer Descriptors," for more details.

32.5.2 Network Interface Options

The FEC supports both an MII interface for 10/100 Mbps Ethernet and a 7-wire serial interface for 10 Mbps Ethernet. The interface mode is selected by the RCR[MII_MODE] bit. In MII mode (RCR[MII_MODE] = 1), there are 18 signals defined by the IEEE 802.3 standard and supported by the FEC. These signals are shown in Table 32-5 below.

Table 32-5. MII Mode

Signal Description	FEC pin	Direction
Transmit Clock	FEC_TX_CLK	In
Transmit Enable	FEC_TX_EN	Out
Transmit Data	FEC_TXD[3:0]	Out
Transmit Error	FEC_TX_ER	Out
Collision	FEC_COL	In
Carrier Sense	FEC_CRS	In
Receive Clock	FEC_RX_CLK	In
Receive Data Valid	FEC_RX_DV	In
Receive Data	FEC_RXD[3:0]	In

Table 32-5. MII Mode (continued)

Signal Description	FEC pin	Direction
Receive Error	FEC_RX_ER	In
Management Data Clock	FEC_MDC	Out
Management Data Input/Output	FEC_MDIO	I/O

The 7-wire serial mode interface (RCR[MII_MODE] = 0) operates in what is generally referred to as the "AMD" mode. 7-wire mode connections to the external transceiver are shown in Table 32-6.

Table 32-6. 7-Wire Mode Configuration

Signal description	FEC Pin	Direction
Transmit Clock	FEC_TX_CLK	In
Transmit Enable	FEC_TX_EN	Out
Transmit Data	FEC_TXD[0]	Out
Collision	FEC_COL	In
Receive Clock	FEC_RX_CLK	In
Receive Data Valid	FEC_RX_DV	In
Receive Data	FEC_RXD[0]	In

32.5.3 FEC Frame Transmission

The Ethernet transmitter is designed to work with almost no intervention from software. Once ECR[ETHER_EN] is asserted and data appears in the transmit FIFO, the FEC is able to transmit onto the network.

When the transmit FIFO fills to the watermark (defined by the TFWR register), the FEC transmit logic will assert FEC_TX_EN and start transmitting the preamble (PA) sequence, the start frame delimiter (SFD), and then the frame information from the FIFO. However, the controller defers the transmission if the network is busy (FEC_CRS asserts). Before transmitting, the controller waits for carrier sense to become inactive, then determines if carrier sense stays inactive for 60 bit times. If so, the transmission begins after waiting an additional 36 bit times (96 bit times after carrier sense originally became inactive). See Section 32.5.11.1, Transmission Errors" for more details.

If a collision occurs during transmission of the frame (half duplex mode), the Ethernet controller follows the specified backoff procedures and attempts to retransmit the frame until the retry limit is reached. The transmit FIFO stores at least the first 64 bytes of the transmit frame, so that they do not have to be retrieved from system memory in case of a collision. This improves bus utilization and latency in case immediate retransmission is necessary.

When all the frame data has been transmitted, the FCS (Frame Check Sequence or 32-bit Cyclic Redundancy Check, CRC) bytes are appended if the TC bit is set in the transmit frame control word. If the ABC bit is set in the transmit frame control word, a bad CRC will be appended to the frame data regardless of the TC bit value. Following the transmission of the CRC, the Ethernet controller writes the frame status

information to the MIB block. Short frames are automatically padded by the transmit logic (if the TC bit in the transmit buffer descriptor for the end of frame buffer = 1).

Both buffer (TXB) and frame (TXF) interrupts may be generated as determined by the settings in the EIMR.

The transmit error interrupts are HBERR, BABT, LATE_COL, COL_RETRY_LIM, and XFIFO_UN. If the transmit frame length exceeds MAX_FL bytes the BABT interrupt will be asserted, however the entire frame will be transmitted (no truncation).

To pause transmission, set the GTS (graceful transmit stop) bit in the TCR register. When the TCR[GTS] is set, the FEC transmitter stops immediately if transmission is not in progress; otherwise, it continues transmission until the current frame either finishes or terminates with a collision. After the transmitter has stopped the GRA (graceful stop complete) interrupt is asserted. If TCR[GTS] is cleared, the FEC resumes transmission with the next frame.

The Ethernet controller transmits bytes least significant bit first.

32.5.4 FEC Frame Reception

The FEC receiver is designed to work with almost no intervention from the host and can perform address recognition, CRC checking, short frame checking, and maximum frame length checking.

When the driver enables the FEC receiver by asserting ECR[ETHER_EN], it will immediately start processing receive frames. When FEC_RX_DV asserts, the receiver will first check for a valid PA/SFD header. If the PA/SFD is valid, it will be stripped and the frame will be processed by the receiver. If a valid PA/SFD is not found, the frame will be ignored.

In serial mode, the first 16 bit times of RX_D0 following assertion of FEC_RX_DV are ignored. Following the first 16 bit times the data sequence is checked for alternating 1/0s. If a 11 or 00 data sequence is detected during bit times 17 to 21, the remainder of the frame is ignored. After bit time 21, the data sequence is monitored for a valid SFD (11). If a 00 is detected, the frame is rejected. When a 11 is detected, the PA/SFD sequence is complete.

In MII mode, the receiver checks for at least one byte matching the SFD. Zero or more PA bytes may occur, but if a 00 bit sequence is detected prior to the SFD byte, the frame is ignored.

After the first 6 bytes of the frame have been received, the FEC performs address recognition on the frame.

Once a collision window (64 bytes) of data has been received and if address recognition has not rejected the frame, the receive FIFO is signalled that the frame is “accepted” and may be passed on to the DMA. If the frame is a runt (due to collision) or is rejected by address recognition, the receive FIFO is notified to “reject” the frame. Thus, no collision fragments are presented to the user except late collisions, which indicate serious LAN problems.

During reception, the Ethernet controller checks for various error conditions and once the entire frame is written into the FIFO, a 32-bit frame status word is written into the FIFO. This status word contains the M, BC, MC, LG, NO, CR, OV and TR status bits, and the frame length. See Section 32.5.11.2, Reception Errors,” for more details.

Receive Buffer (RXB) and Frame Interrupts (RXF) may be generated if enabled by the EIMR register. A receive error interrupt is babbling receiver error (BABR). Receive frames are not truncated if they exceed the max frame length (MAX_FL); however, the BABR interrupt will occur and the LG bit in the Receive Buffer Descriptor (RxBD) will be set. See Section 32.6.5.2, Ethernet Receive Buffer Descriptor (RxBD)," for more details.

When the receive frame is complete, the FEC sets the L-bit in the RxBD, writes the other frame status bits into the RxBD, and clears the E-bit. The Ethernet controller next generates a maskable interrupt (RXF bit in EIR, maskable by RXF bit in EIMR), indicating that a frame has been received and is in memory. The Ethernet controller then waits for a new frame.

The Ethernet controller receives serial data LSB first.

32.5.5 Ethernet Address Recognition

The FEC filters the received frames based on Destination Address (DA) type — individual (unicast), group (multicast), or broadcast (all-ones group address). The difference between an individual address and a group address is determined by the I/G bit in the destination address field. A flowchart for address recognition on received frames is illustrated in the figures below.

Address recognition is accomplished through the use of the receive block and microcode running on the microcontroller. The flowchart shown in Figure 32-2 illustrates the address recognition decisions made by the receive block, while Figure 32-3 illustrates the decisions made by the microcontroller.

If the DA is a broadcast address and broadcast reject (RCR[BC_REJ]) is deasserted, then the frame will be accepted unconditionally, as shown in Figure 32-2. Otherwise, if the DA is not a broadcast address, then the microcontroller runs the address recognition subroutine, as shown in Figure 32-3.

If the DA is a group (multicast) address and flow control is disabled, then the microcontroller will perform a group hash table lookup using the 64-entry hash table programmed in GAUR and GALR. If a hash match occurs, the receiver accepts the frame.

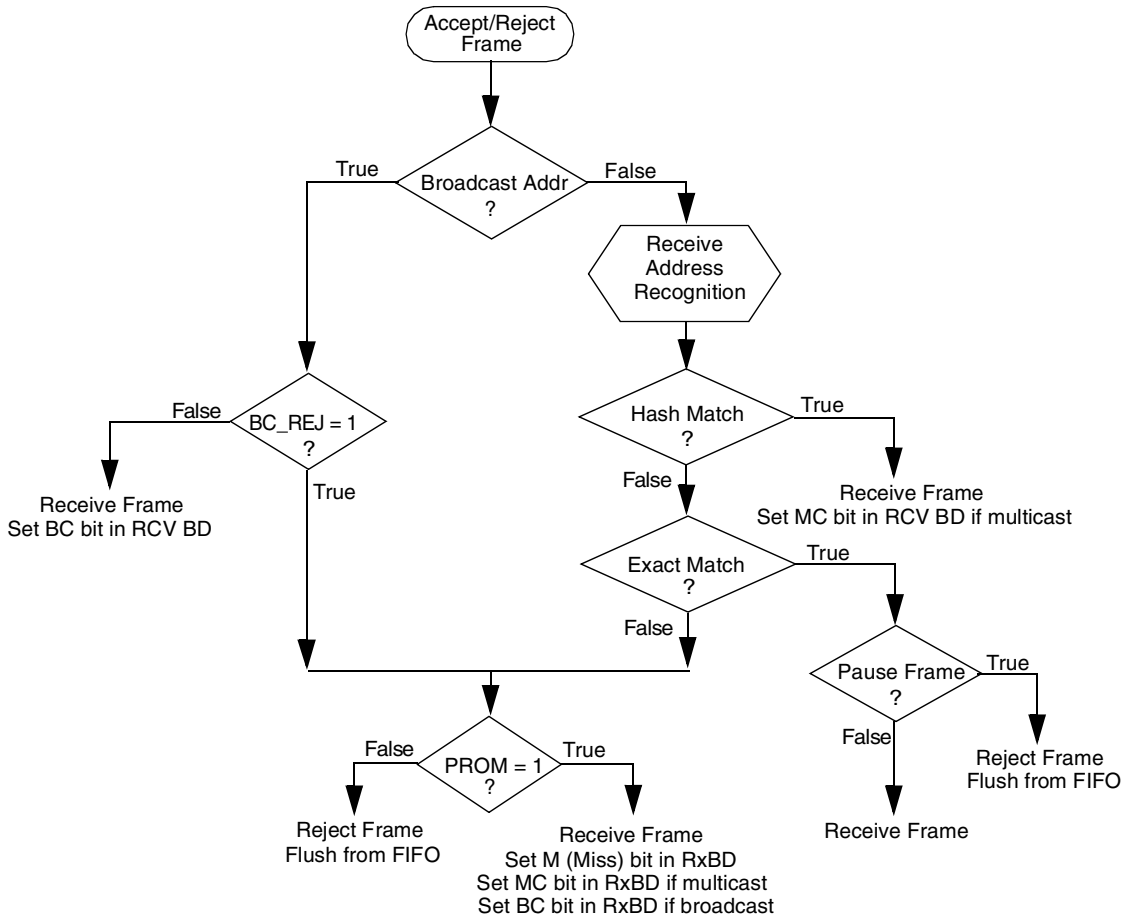
If flow control is enabled, the microcontroller will do an exact address match check between the DA and the designated PAUSE DA (01:80:C2:00:00:01). If the receive block determines that the received frame is a valid PAUSE frame, then the frame will be rejected. Note the receiver will detect a PAUSE frame with the DA field set to either the designated PAUSE DA or the unicast physical address.

If the DA is the individual (unicast) address, the microcontroller performs an individual exact match comparison between the DA and 48-bit physical address that the user programs in the PALR and PAUR registers. If an exact match occurs, the frame is accepted; otherwise, the microcontroller does an individual hash table lookup using the 64-entry hash table programmed in registers, IAUR and IALR. In the case of an individual hash match, the frame is accepted. Again, the receiver will accept or reject the frame based on PAUSE frame detection, shown in Figure 32-2.

If neither a hash match (group or individual), nor an exact match occur, then if promiscuous mode is enabled (RCR[PROM] = 1), then the frame will be accepted and the MISS bit in the receive buffer descriptor is set; otherwise, the frame will be rejected.

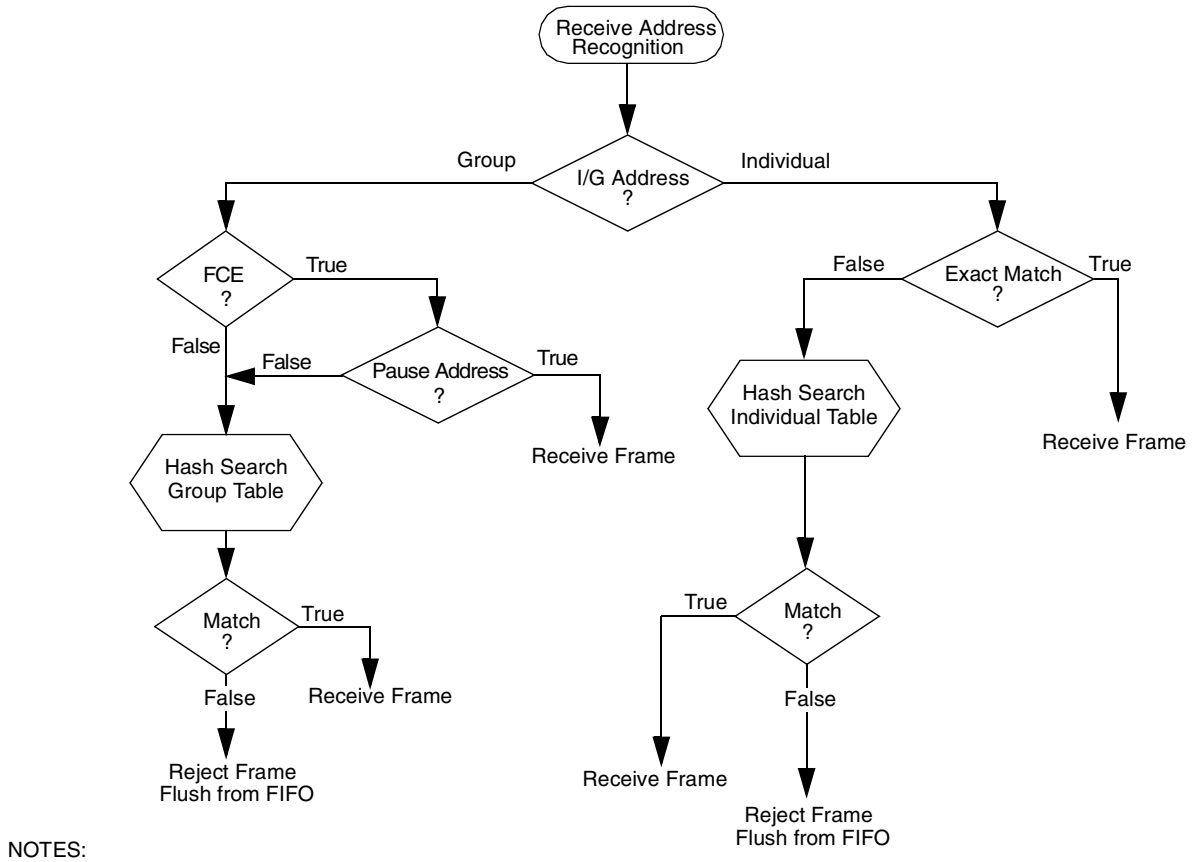
Similarly, if the DA is a broadcast address, broadcast reject (RCR[BC_REJ]) is asserted, and promiscuous mode is enabled, then the frame will be accepted and the MISS bit in the receive buffer descriptor is set; otherwise, the frame will be rejected.

In general, when a frame is rejected, it is flushed from the FIFO.



NOTES:
BC_REJ—Field in RCR register (BroadCast REJect)
PROM—Field in RCR register (PROMiscuous mode)
Pause Frame—Valid PAUSE frame received

Figure 32-2. Ethernet Address Recognition—Receive Block Decisions



NOTES:
FCE - field in RCR register (Flow Control Enable)
I/G - Individual/Group bit in Destination Address (least significant bit in first byte received in MAC frame)

Figure 32-3. Ethernet Address Recognition—Microcode Decisions

32.5.6 Hash Algorithm

The hash table algorithm used in the group and individual hash filtering operates as follows. The 48-bit destination address is mapped into one of 64 bits, which are represented by 64 bits stored in GAUR, GALR (group address hash match) or IAUR, IALR (individual address hash match). This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the 6 most significant bits of the CRC-encoded result to generate a number between 0 and 63. The MSB of the CRC result selects GAUR (MSB = 1) or GALR (MSB = 0). The least significant 5 bits of the hash result select the bit within the selected register. If the CRC generator selects a bit that is set in the hash table, the frame is accepted; otherwise, it is rejected.For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The hash table registers must be initialized by the user. The CRC32 polynomial to use in computing the hash is:

$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$

A table of example Destination Addresses and corresponding hash values is included below for reference.

Table 32-7. Destination Address to 6-Bit Hash

48-bit DA	6-bit Hash (in hex)	Hash Decimal Value
65:FF:FF:FF:FF:FF	0x0	0

32.5.7 Full-Duplex Flow Control

Full-duplex flow control allows the user to transmit pause frames and to detect received pause frames. Upon detection of a pause frame, FEC data frame transmission stops for a given pause duration.

To enable pause frame detection, the FEC must operate in full-duplex mode (TCR[FDEN] asserted) and flow control enable (RCR[FCE]) must be asserted. The FEC detects a pause frame when the fields of the incoming frame match the pause frame specifications, as shown Table 32-8. In addition, the receive status associated with the frame should indicate that the frame is valid.

Table 32-8. PAUSE Frame Field Specification

48-bit Destination Address	0x0180_c200_0001 or Physical Address
48-bit Source Address	Any
16-bit Type	0x8808
16-bit Opcode	0x0001
16-bit PAUSE Duration	0x0000 to 0xFFFF

Pause frame detection is performed by the receiver and microcontroller modules. The microcontroller runs an address recognition subroutine to detect the specified pause frame destination address, while the receiver detects the type and opcode pause frame fields. On detection of a pause frame, TCR[GTS] is asserted by the FEC internally. When transmission has paused, the EIR[GRA] interrupt is asserted and the pause timer begins to increment. Note that the pause timer makes use of the transmit backoff timer hardware, which is used for tracking the appropriate collision backoff time in half-duplex mode. The pause timer increments once every slot time, until OPD[PAUSE_DUR] slot times have expired. On OPD[PAUSE_DUR] expiration, TCR[GTS] is deasserted allowing FEC data frame transmission to resume. Note that the receive flow control pause (TCR[RFC_PAUSE]) status bit is asserted while the transmitter is paused due to reception of a pause frame.

To transmit a pause frame, the FEC must operate in full-duplex mode and the user must assert flow control pause (TCR[TFC_PAUSE]). On assertion of transmit flow control pause (TCR[TFC_PAUSE]), the transmitter asserts TCR[GTS] internally. When the transmission of data frames stops, the EIR[GRA] (graceful stop complete) interrupt asserts. Following EIR[GRA] assertion, the pause frame is transmitted. On completion of pause frame transmission, flow control pause (TCR[TFC_PAUSE]) and TCR[GTS] are deasserted internally.

The user must specify the desired pause duration in the OPD register.

Note that when the transmitter is paused due to receiver/microcontroller pause frame detection, transmit flow control pause (TCR[TFC_PAUSE]) still may be asserted, which causes the transmission of a single pause frame. In this case, the EIR[GRA] interrupt is not asserted.

32.5.8 Interpacket Gap (IPG) Time

The minimum interpacket gap (IPG) time for back-to-back transmission is 96 bit times. After completing a transmission or after the backoff algorithm completes, the transmitter waits for carrier sense to be negated before starting its 96 bit time IPG counter. Frame transmission may begin 96 bit times after carrier sense is negated if it stays negated for at least 60 bit times. If carrier sense asserts during the last 36 bit times, it will be ignored and a collision will occur.

The receiver receives back-to-back frames with a minimum spacing of at least 28 bit times. If an interpacket gap between receive frames is less than 28 bit times, the following frame may be discarded by the receiver.

32.5.9 Collision Handling

If a collision occurs during frame transmission, the Ethernet controller will continue the transmission for at least 32 bit times, transmitting a JAM pattern consisting of 32 ones. If the collision occurs during the preamble sequence, the JAM pattern will be sent after the end of the preamble sequence.

If a collision occurs within 512 bit times, the retry process is initiated. The transmitter waits a random number of slot times, where one slot time is 512 bit times. If a collision occurs after 512 bit times, then no retransmission is performed and the end of frame buffer is closed with a Late Collision (LC) error indication.

32.5.10 Internal and External Loopback

Both internal and external loopback are supported by the Ethernet controller. In loopback mode, both of the FIFOs are used and the FEC actually operates in a full-duplex fashion. Both internal and external loopback are configured using combinations of the LOOP and DRT bits in the RCR register and the FDEN bit in the TCR register.

For both internal and external loopback set FDEN = 1.

For internal loopback set RCR[LOOP] = 1 and RCR[DRT] = 0. FEC_TX_EN and FEC_TX_ER will not assert during internal loopback. During internal loopback, the transmit/receive data rate is higher than in normal operation because the internal system clock is used by the transmit and receive blocks instead of the clocks from the external transceiver. This causes an increase in the required system bus bandwidth for transmit and receive data being transferred to and from external memory via DMA. It may be necessary to pace the frames on the transmit side and/or limit the size of the frames to prevent transmit FIFO underrun and receive FIFO overflow.

For external loopback set RCR[LOOP] = 0, RCR[DRT] = 0 and configure the external transceiver for loopback.

32.5.11 Ethernet Error-Handling Procedure

The Ethernet controller reports frame reception and transmission error conditions using the FEC RxBDs, the EIR register, and the MIB block counters.

32.5.11.1 Transmission Errors

There are four types of transmission errors:

- Transmitter underrun
- Retransmission attempts limit expired
- Late collision
- Heartbeat

32.5.11.1.1 Transmitter Underrun

If this error occurs, the FEC sends 32 bits that ensure a CRC error and stops transmitting. All remaining buffers for that frame are then flushed and closed. The UN bit is set in the EIR. The FEC will then continue to the next transmit buffer descriptor and begin transmitting the next frame.

The “UN” interrupt will be asserted if enabled in the EIMR register.

32.5.11.1.2 Retransmission Attempts Limit Expired

When this error occurs, the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and the RL bit is set in the EIR. The FEC will then continue to the next transmit buffer descriptor and begin transmitting the next frame.

The “RL” interrupt will be asserted if enabled in the EIMR register.

32.5.11.1.3 Late Collision

When a collision occurs after the slot time (512 bits starting at the Preamble), the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and the LC bit is set in the EIR register. The FEC will then continue to the next transmit buffer descriptor and begin transmitting the next frame.

The LC interrupt is asserted if enabled in the EIMR register.

32.5.11.1.4 Heartbeat

Some transceivers have a self-test feature called “heartbeat” or “signal quality error.” To signify a good self-test, the transceiver indicates a collision to the FEC within 4 microseconds after completion of a frame transmitted by the Ethernet controller. This indication of a collision does not imply a real collision error on the network, but is rather an indication that the transceiver still seems to be functioning properly. This is called the heartbeat condition.

If the HBC bit is set in the TCR register and the heartbeat condition is not detected by the FEC after a frame transmission, then a heartbeat error occurs. When this error occurs, the FEC closes the buffer, sets the HB bit in the EIR register, and generates the HBERR interrupt if it is enabled.

32.5.11.2 Reception Errors

There are five types of reception errors:

- Overrun
- Non-octet (dribbling bits)
- CRC
- Frame-length violation
- Truncation

32.5.11.2.1 Overrun

If the receive block has data to put into the receive FIFO and the receive FIFO is full, the FEC sets the OV bit in the RxBD. All subsequent data in the frame will be discarded and subsequent frames may also be discarded until the receive FIFO is serviced by the DMA and space is made available. At this point the receive frame/status word is written into the FIFO with the OV bit set. This frame must be discarded by the driver.

32.5.11.2.2 Non-Octet (Dribbling Bits)

The Ethernet controller handles up to seven dribbling bits when the receive frame terminates past an non-octet aligned boundary. Dribbling bits are not used in the CRC calculation. If there is a CRC error, then the frame non-octet aligned (NO) error is reported in the RxBD. If there is no CRC error, then no error is reported.

32.5.11.2.3 CRC

When a CRC error occurs with no dribble bits, the FEC closes the buffer and sets the CR bit in the RxBD. CRC checking cannot be disabled, but the CRC error can be ignored if checking is not required.

32.5.11.2.4 Frame Length Violation

When the receive frame length exceeds MAX_FL bytes the BABR interrupt will be generated, and the LG bit in the end of frame RxBD will be set. The frame is not truncated unless the frame length exceeds 2047 bytes).

32.5.11.2.5 Truncation

When the receive frame length exceeds 2047 bytes, the frame is truncated and the TR bit is set in the RxBD.

32.6 Programming Model

This section provides an overview of the registers, followed by a description of the buffers.

The FEC is programmed by a combination of control and status registers (CSRs) and buffer descriptors. The CSRs are used for mode control and to extract global status information. The descriptors are used to pass data buffers and related buffer information between the hardware and software.

32.6.1 Top Level Module Memory Map

The FEC implementation requires a 1Kbyte memory map space. This is divided into 2 sections of 512 bytes each. The first is used for control/status registers. The second contains event/statistic counters held in the MIB block. Table 32-9 defines the top level memory map.

Table 32-9. Module Memory Map[1]

Address	Function
0xBASE + 0x000-1FF	Control/Status Registers
0xBASE + 0x200-3FF	MIB Block Counters

[1] See Chapter 2, "Memory Map,"for the value of BASE - FEC base address.

32.6.2 Detailed Memory Map (Control/Status Registers)

Table 32-10 shows the FEC register memory map with each register address, name, and a brief description.

Table 32-10. FEC Register Memory Map

Offset	Name	Width	Description
0x004	EIR	32	Interrupt Event Register
0x008	EIMR	32	Interrupt Mask Register
0x010	RDAR	32	Receive Descriptor Active Register
0x014	TDAR	32	Transmit Descriptor Active Register

0x124	GALR	32	Lower 32 bits of Group Hash Table
0x144	TFWR	32	Transmit FIFO Watermark
0x14C	FRBR	32	FIFO Receive Bound Register
0x150	FRSR	32	FIFO Receive FIFO Start Registers
0x180	ERDSR	32	Pointer to Receive Descriptor Ring

Table 32-10. FEC Register Memory Map (continued)

Offset	Name	Width	Description
0x184	ETDSR	32	Pointer to Transmit Descriptor Ring
0x188	EMRBR	32	Maximum Receive Buffer Size

32.6.3 MIB Block Counters Memory Map

Table 32-11 defines the MIB Counters memory map which defines the locations in the MIB RAM space where hardware maintained counters reside. It is the responsibility of software to poll the counters often enough to ensure that rollover is detected. For example, on a 100 Mbps channel an octets counter could roll over every 5.7 minutes.

These counters fall in the 0x200-0x3FF address offset range, and are divided into RMON counters and IEEE counters, as follows

RMON counters are included which cover the Ethernet Statistics counters defined in RFC 1757. In addition to the counters defined in the Ethernet Statistics group, a counter is included to count truncated frames as the FEC only supports frame lengths up to 2047 bytes. The RMON counters are implemented independently for transmit and receive to insure accurate network statistics when operating in full duplex mode.

IEEE counters are included which support the Mandatory and Recommended counter packages defined in section 5 of ANSI/IEEE Std. 802.3 (1998 edition). The IEEE Basic Package objects are supported by the FEC but do not require counters in the MIB block. In addition, some of the recommended package objects which are supported do not require MIB counters. Counters for transmit and receive full duplex flow control frames are included as well.

Table 32-11. MIB Counters Memory Map

Offset	Mnemonic	Description
0x200	RMON_T_DROP	Count of frames not counted correctly
0x204	RMON_T_PACKETS	RMON Tx packet count
0x208	RMON_T_BC_PKT	RMON Tx Broadcast Packets
0x20C	RMON_T_MC_PKT	RMON Tx Multicast Packets
0x210	RMON_T_CRC_ALIGN	RMON Tx Packets w CRC/Align error
0x214	RMON_T_UNDERSIZE	RMON Tx Packets < 64 bytes, good crc
0x218	RMON_T_OVERSIZE	RMON Tx Packets > MAX_FL bytes, good crc
0x21C	RMON_T_FRAG	RMON Tx Packets < 64 bytes, bad crc
0x220	RMON_T_JAB	RMON Tx Packets > MAX_FL bytes, bad crc
0x224	RMON_T_COL	RMON Tx collision count
0x228	RMON_T_P64	RMON Tx 64 byte packets
0x22C	RMON_T_P65TO127	RMON Tx 65 to 127 byte packets

Table 32-11. MIB Counters Memory Map (continued)

Offset	Mnemonic	Description
0x230	RMON_T_P128TO255	RMON Tx 128 to 255 byte packets
0x234	RMON_T_P256TO511	RMON Tx 256 to 511 byte packets
0x238	RMON_T_P512TO1023	RMON Tx 512 to 1023 byte packets
0x23C	RMON_T_P1024TO2047	RMON Tx 1024 to 2047 byte packets
0x240	RMON_T_P_GTE2048	RMON Tx packets w > 2048 bytes
0x244	RMON_T_OCTETS	RMON Tx Octets
0x248	IEEE_T_DROP	Count of frames not counted correctly
0x24C	IEEE_T_FRAME_OK	Frames Transmitted OK
0x250	IEEE_T_1COL	Frames Transmitted with Single Collision
0x254	IEEE_T_MCOL	Frames Transmitted with Multiple Collisions
0x258	IEEE_T_DEF	Frames Transmitted after Deferral Delay
0x25C	IEEE_T_LCOL	Frames Transmitted with Late Collision
0x260	IEEE_T_EXCOL	Frames Transmitted with Excessive Collisions
0x264	IEEE_T_MACERR	Frames Transmitted with Tx FIFO Underrun
0x268	IEEE_T_CSERR	Frames Transmitted with Carrier Sense Error
0x26C	IEEE_T_SQE	Frames Transmitted with SQE Error
0x270	IEEE_T_FDXFC	Flow Control Pause frames transmitted
0x274	IEEE_T_OCTETS_OK	Octet count for Frames Transmitted w/o Error
0x284	RMON_R_PACKETS	RMON Rx packet count
0x288	RMON_R_BC_PKT	RMON Rx Broadcast Packets
0x28C	RMON_R_MC_PKT	RMON Rx Multicast Packets
0x290	RMON_R_CRC_ALIGN	RMON Rx Packets w CRC/Align error
0x294	RMON_R_UNDERSIZE	RMON Rx Packets < 64 bytes, good crc
0x298	RMON_R_OVERSIZE	RMON Rx Packets > MAX_FL bytes, good crc
0x29C	RMON_R_FRAG	RMON Rx Packets < 64 bytes, bad crc
0x2A0	RMON_R_JAB	RMON Rx Packets > MAX_FL bytes, bad crc
0x2A4	RMON_R_RESVD_0	—
0x2A8	RMON_R_P64	RMON Rx 64 byte packets
0x2AC	RMON_R_P65TO127	RMON Rx 65 to 127 byte packets
0x2B0	RMON_R_P128TO255	RMON Rx 128 to 255 byte packets
0x2B4	RMON_R_P256TO511	RMON Rx 256 to 511 byte packets
0x2B8	RMON_R_P512TO1023	RMON Rx 512 to 1023 byte packets
0x2BC	RMON_R_P1024TO2047	RMON Rx 1024 to 2047 byte packets

Table 32-11. MIB Counters Memory Map (continued)

Offset	Mnemonic	Description
0x2C0	RMON_R_P_GTE2048	RMON Rx packets w > 2048 bytes
0x2C4	RMON_R_OCTETS	RMON Rx Octets
0x2C8	IEEE_R_DROP	Count of frames not counted correctly
0x2CC	IEEE_R_FRAME_OK	Frames Received OK
0x2D0	IEEE_R_CRC	Frames Received with CRC Error
0x2D4	IEEE_R_ALIGN	Frames Received with Alignment Error
0x2D8	IEEE_R_MACERR	Receive FIFO Overflow count
0x2DC	IEEE_R_FDXFC	Flow Control Pause frames received
0x2E0	IEEE_R_OCTETS_OK	Octet count for Frames received w/o Error

32.6.4 Register Descriptions

The following sections describe each register in detail.

32.6.4.1 Ethernet Interrupt Event Register (EIR)

The correspondence between interrupts and EIR bits is shown in Figure 32-4 and Table 32-13 below. When an event occurs that sets a bit in the EIR, an interrupt will be generated if the corresponding bit in the interrupt mask register (EIMR) is also set. The bit in the EIR is cleared if a one is written to that bit position; writing zero has no effect. This register is cleared upon hardware reset.

Interrupts can be divided into operational interrupts, transceiver/network error interrupts, and internal error interrupts. Interrupts which may occur in normal operation are GRA, TXF, TXB, RXF, RXB, and MII. Interrupts resulting from errors/problems detected in the network or transceiver are HBERR, BABR, BABT, LC and RL. Interrupts resulting from internal errors are EBERR and UN.

Some of the error interrupts are independently counted in the MIB block counters. The correspondence between interrupts and counters is shown in Table 32-12. Software may choose to mask off the interrupts since these errors will be visible to network management via the MIB counters.

Table 32-12. Error Interrupts and Block Counters

Interrupt	Counter(s)
HBERR	IEEE_T_SQE
BABR	RMON_R_OVERSIZE (good CRC) RMON_R_JAB (bad CRC)
BABT	RMON_T_OVERSIZE (good CRC), RMON_T_JAB (bad CRC)
LATE_COL	IEEE_T_LCOL
COL_RETRY_LIM	IEEE_T_EXCOL
XFIFO_UN	IEEE_T_MACERR

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	16
Field	HBERR	BABR	BABT	GRA	TXF	TXB	RXF	RXB	MII	EBERR	LC	RL	UN	—	
Reset	0000_0000_0000_0000														
R/W	R/W														

	15	0
Field	—	
Reset	0000_0000_0000_0000	
R/W	R/W	
Address	0xC003_8004	

Figure 32-4. Ethernet Interrupt Event Register (EIR)

Table 32-13. EIR Field Descriptions

Bits	Name	Description
31	HBERR	Heartbeat error. This interrupt indicates that HBC is set in the TCR register and that the COL input was not asserted within the Heartbeat window following a transmission.
30	BABR	Babbling receive error. This bit indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
29	BABT	Babbling transmit error. This bit indicates that the transmitted frame length has exceeded RCR[MAX_FL] bytes. This condition is usually caused by a frame that is too long being placed into the transmit data buffer(s). Truncation does not occur.
28	GRA	Graceful stop complete. This interrupt will be asserted for one of three reasons. Graceful stop means that the transmitter is put into a pause state after completion of the frame currently being transmitted. 1) A graceful stop, which was initiated by the setting of the TCR[GTS] bit is now complete. 2) A graceful stop, which was initiated by the setting of the TCR[TFC_PAUSE] bit is now complete. 3) A graceful stop, which was initiated by the reception of a valid full duplex flow control “pause” frame is now complete. See the “Full Duplex Flow Control” section of the Functional Description chapter.
27	TXF	Transmit frame interrupt. This bit indicates that a frame has been transmitted and that the last corresponding buffer descriptor has been updated.
26	TXB	Transmit buffer interrupt. This bit indicates that a transmit buffer descriptor has been updated.
25	RXF	Receive frame interrupt. This bit indicates that a frame has been received and that the last corresponding buffer descriptor has been updated.
24	RXB	Receive buffer interrupt. This bit indicates that a receive buffer descriptor has been updated that was not the last in the frame.
23	MII	MII interrupt. This bit indicates that the MII has completed the data transfer requested.
22	EBERR	Ethernet bus error. This bit indicates that a system bus error occurred when a DMA transaction was underway. When the EBERR bit is set, ECR[ETHER_EN] will be cleared, halting frame processing by the FEC. When this occurs software will need to insure that the FIFO controller and DMA are also soft reset.

Table 32-13. EIR Field Descriptions (continued)

Bits	Name	Description
21	LC	Late collison. This bit indicates that a collision occurred beyond the collision window (slot time) in half duplex mode. The frame is truncated with a bad CRC and the remainder of the frame is discarded.
20	RL	Collision retry limit. This bit indicates that a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame will commence. Can only occur in half duplex mode.
19	UN	Transmit FIFO underrun. This bit indicates that the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.
18–0	—	Reserved, should be cleared.

32.6.4.2 Interrupt Mask Register (EIMR)

The EIMR controls which interrupt events are allowed to generate actual interrupts. All implemented bits in this CSR are read/write. This register is cleared upon a hardware reset. If the corresponding bits in both the EIR and EIMR are set, the interrupt will be signalled to the CPU. The interrupt signal will remain asserted until a 1 is written to the EIR bit (write 1 to clear) or a 0 is written to the EIMR bit.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	16

R/W	R/W														

	15	0
Field	—	
Reset	0000_0000_0000_0000	
R/W	R/W	
Address	0xC003_8008	

Figure 32-5. Interrupt Mask Register (EIMR)

Table 32-14. EIMR Field Descriptions

Bits	Name	Description
31–19	See Figure 32-5 and Table 32-13.	Interrupt Mask. Each bit corresponds to an interrupt source defined by the EIR register. The corresponding EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR bit reflects the state of the interrupt signal even if the corresponding EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
18–0	—	Reserved, should be cleared.

32.6.4.3 Receive Descriptor Active Register (RDAR)

RDAR is a command register, written to by the user, which indicates that the receive descriptor ring has been updated (empty receive buffers have been produced by the driver with the empty bit set).

The RDAR bit is set whenever the register is written, independent of the data actually written by the user. When set, the FEC polls the receive descriptor ring and process receive frames (provided ECR[ETHER_EN] is also set). Once the FEC polls a receive descriptor whose empty bit is not set, then the FEC will clear the RDAR bit and cease receive descriptor ring polling until the user sets the bit again, signifying that additional descriptors have been placed into the receive descriptor ring.

The RDAR is cleared at reset, and when ECR[ETHER_EN] is cleared.

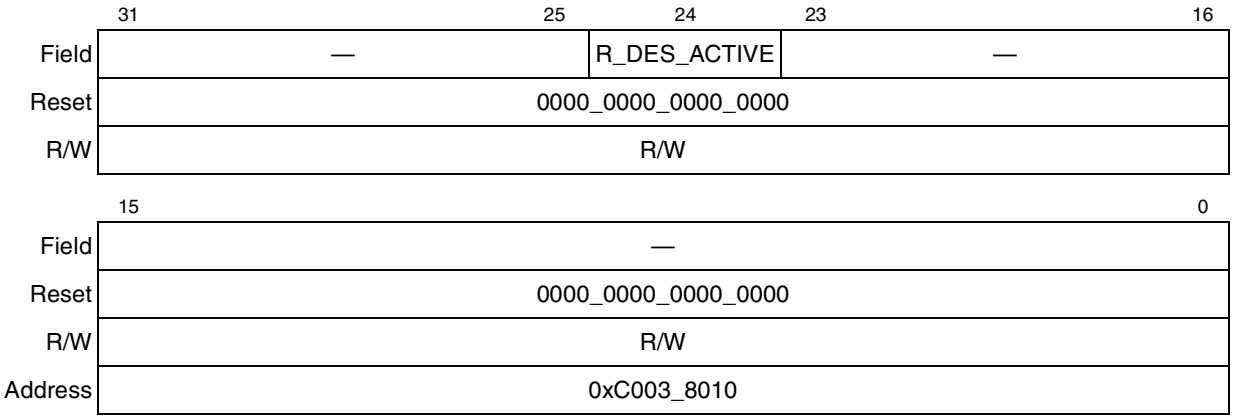

Figure 32-6. Receive Descriptor Active Register (RDAR)

Table 32-15. RDAR Field Descriptions

Bits	Name	Description
31–25	—	Reserved, should be cleared.
24	R_DES_ACTIVE	Set to one when this register is written, regardless of the value written. Cleared by the FEC device whenever no additional “empty” descriptors remain in the receive ring. Also cleared when ECR[ETHER_EN] is cleared.
23–0	—	Reserved, should be cleared.

32.6.4.4 Transmit Descriptor Active Register (TDAR)

The TDAR is a command register, written to by the user, to indicate that the transmit descriptor ring has been updated (transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor).

Whenever the register is written the TDAR bit is set, independent of the data actually written by the user. When set, the FEC will poll the transmit descriptor ring and process transmit frames (provided ECR[ETHER_EN] is also set). Once the FEC polls a transmit descriptor whose ready bit is not set[, then the FEC will clear the TDAR bit and cease transmit descriptor ring polling until the user sets the bit again, signifying additional descriptors have been placed into the transmit descriptor ring.

The TDAR is cleared at reset, when ECR[ETHER_EN] is cleared, or when ECR[RESET] is set.

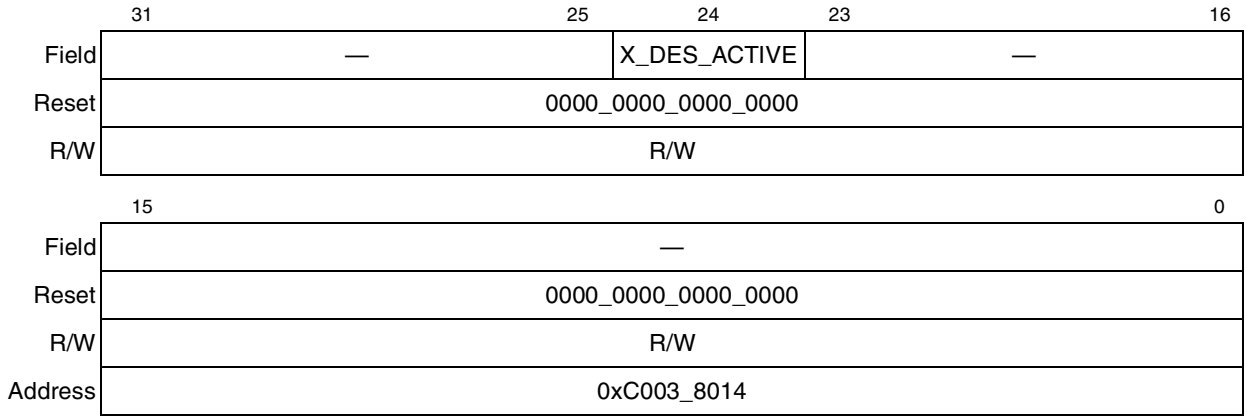

Figure 32-7. Transmit Descriptor Active Register (TDAR)

Table 32-16. TDAR Field Descriptions

Bits	Name	Description
31–25	—	Reserved, should be cleared.
24	X_DES_ACTIVE	Set to one when this register is written, regardless of the value written. Cleared by the FEC device whenever no additional “ready” descriptors remain in the transmit ring. Also cleared when ECR[ETHER_EN] is cleared.
23–0	—	Reserved, should be cleared.

32.6.4.5 Ethernet Control Register (ECR)

The ECR is used to enable/disable the FEC. ECR is a read/write user register, though both fields in this register may be altered by hardware as well.

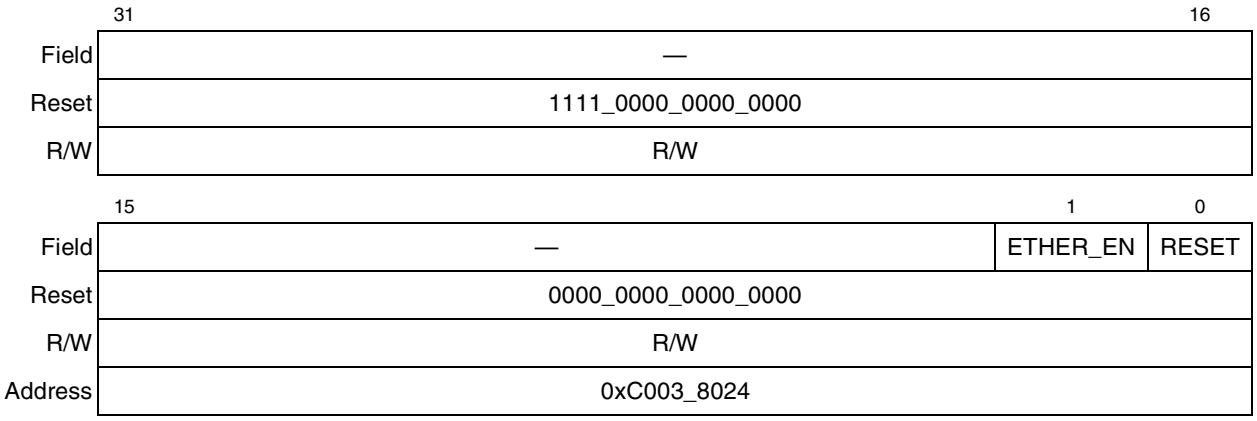

Figure 32-8. Ethernet Control Register (ECR)

Table 32-17. ECR Field Descriptions

Bits	Name	Description
31–2	—	Reserved.
1	ETHER_EN	When this bit is set, the FEC is enabled, and reception and transmission are possible. When this bit is cleared, reception is immediately stopped and transmission is stopped after a bad CRC is appended to any currently transmitted frame. The buffer descriptor(s) for an aborted transmit frame are not updated after clearing this bit. When ETHER_EN is deasserted, the DMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. The ETHER_EN bit is altered by hardware under the following conditions: • ECR[RESET] is set by software, in which case ETHER_EN will be cleared • an error condition causes the EIR[EBERR] bit to set, in which case ETHER_EN will be cleared
0	RESET	When this bit is set, the equivalent of a hardware reset is performed but it is local to the FEC. ETHER_EN is cleared and all other FEC registers take their reset values. Also, any transmission/reception currently in progress is abruptly aborted. This bit is automatically cleared by hardware during the reset sequence. The reset sequence takes approximately 8 system clock cycles after RESET is written with a 1.

32.6.4.6 MII Management Frame Register (MMFR)

The MMFR is accessed by the user and does not reset to a defined value. The MMFR is used to communicate with the attached MII compatible PHY device(s), providing read/write access to their MII registers. Performing a write to MMFR will cause a management frame to be sourced unless the MII-SPEED field of the MSCR has been set to 0, in which case MSCR is set to a non-zero value and an MII frame is generated with the data previously written to MMFR. This allows MMFR and MSCR to be programmed in either order if the MII-SPEED field of MSCR is currently zero (for further details on MSCR, see Section 32.6.4.7, MII Speed Control Register (MSCR)").

Figure 32-9. MII Management Frame Register (MMFR)

Table 32-18. MMFR Field Descriptions

Bit	Name	Description
31–30	ST	Start of frame delimiter. These bits must be programmed to 01 for a valid MII management frame.
29–28	OP	Operation code. This field must be programmed to 10 (read) or 01 (write) to generate a valid MII management frame. A value of 11 will produce “read” frame operation while a value of 00 will produce “write” frame operation, but these frames will not be MII compliant.
27–23	PA	PHY address. This field specifies one of up to 32 attached PHY devices.
22–18	RA	Register address. This field specifies one of up to 32 registers within the specified PHY device.
17–16	TA	Turn around. This field must be programmed to 10 to generate a valid MII management frame.
15–0	DATA	Management frame data. This is the field for data to be written to or read from the PHY register.

To perform a read or write operation on the MII Management Interface, the MMFR must be written to by the user. To generate a valid read or write management frame, the ST field must be written with a 01 pattern, and the TA field must be written with a 10. If other patterns are written to these fields, a frame will be generated but will not comply with the IEEE 802.3 MII definition.

To generate an IEEE 802.3-compliant MII Management Interface write frame (write to a PHY register), the user must write {01 01 PHYAD REGAD 10 DATA} to the bit fields of the MMFR, as shown in Table 32-18. Writing this pattern will cause the control logic to shift out the data in the MMFR following a preamble generated by the control state machine. During this time the contents of the MMFR will be altered as the contents are serially shifted and will be unpredictable if read by the user. Once the write management frame operation has completed, the MII interrupt will be generated. At this time the contents of the MMFR will match the original value written.

To generate an MII Management Interface read frame (read a PHY register) the user must write {01 10 PHYAD REGAD 10 XXXX} to the bit fields of the MMFR shown in Table 32-18 (the contents of the 4-bit DATA field are arbitrary). Writing this pattern will cause the control logic to shift out the data in the MMFR following a preamble generated by the control state machine. During this time the contents of the MMFR will be altered as the contents are serially shifted, and will be unpredictable if read by the user. Once the read management frame operation has completed, the MII interrupt will be generated. At this time the contents of the MMFR will match the original value written except for the DATA field whose contents have been replaced by the value read from the PHY register.

If the MMFR is written to while frame generation is in progress, the frame contents will be altered. Software should use the MII interrupt to avoid writing to the MMFR while frame generation is in progress.

32.6.4.7 MII Speed Control Register (MSCR)

The MSCR provides control of the MII clock (FEC_MDC pin) frequency, and allows a preamble drop on the MII management frame.

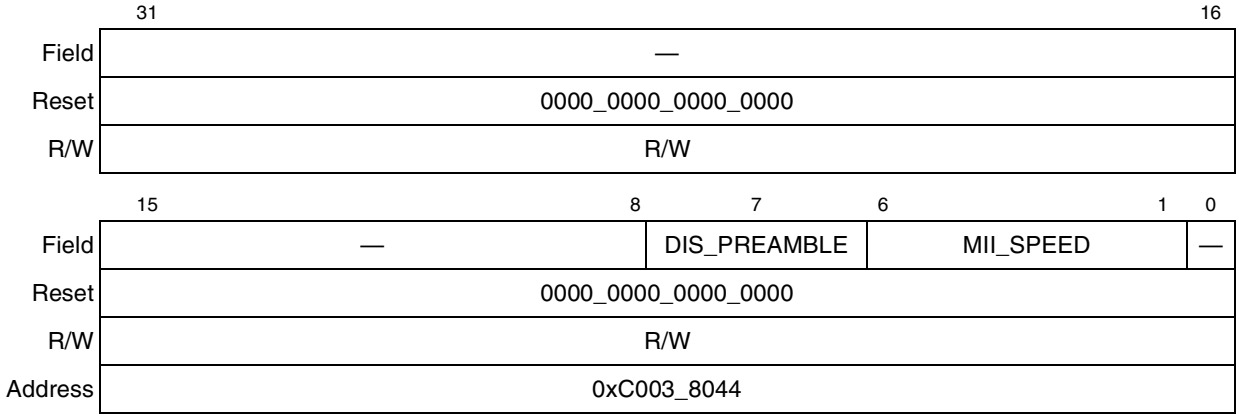

Figure 32-10. MII Speed Control Register (MSCR)

Table 32-19. MSCR Field Descriptions

Bits	Name	Description
31–8	—	Reserved, should be cleared.
7	DIS_PREAMBLE	Asserting this bit will cause preamble (32 1's) not to be prepended to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY device(s) does not require it.
6–1	MII_SPEED	MII_SPEED controls the frequency of the MII management interface clock (FEC_MDC) relative to the system clock. A value of 0 in this field will "turn off" the FEC_MDC and leave it in low voltage state. Any non-zero value will result in the FEC_MDC frequency of 1/(MII_SPEED*2) of the system clock frequency.
0	—	Reserved, should be cleared.

The MII_SPEED field must be programmed with a value to provide an FEC_MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value in order to source a read or write management frame. After the management frame is complete the MSCR may optionally be set to zero to turn off the FEC_MDC. The FEC_MDC generated will have a 50% duty cycle except when MII_SPEED is changed during operation (change will take effect following either a rising or falling edge of FEC_MDC).

The FEC_MDC frequency depends on both the system clock frequency and the MII_SPEED register. If the system clock is 25 MHz, programming the MII_SPEED register to 0x0000_0005 results in an

FEC_MDC frequency of 25 MHz × 1/10 = 2.5 MHz. Table 32-20 shows the optimum values for MII_SPEED for different system clock frequencies.

Table 32-20. Programming Examples for MSCR

System Clock Frequency	MII_SPEED (field in reg)	FEC_MDC frequency
25 MHz	0x5	2.5 MHz
33 MHz	0x7	2.36 MHz
40 MHz	0x8	2.5 MHz
50 MHz	0xA	2.5 MHz
66 MHz	0xD	2.54 MHz

32.6.4.8 MIB Control Register (MIBC)

The MIB control register is a read/write register used to provide control of and to observe the state of the Message Information Block (MIB). This register is accessed by user software if there is a need to disable the MIB operation. For example, in order to clear all MIB counters in RAM the user should disable the MIB, then clear all the MIB RAM locations, then enable the MIB. The MIB_DISABLE bit is reset to 1. See Table 32-11 for the locations of the MIB counters.

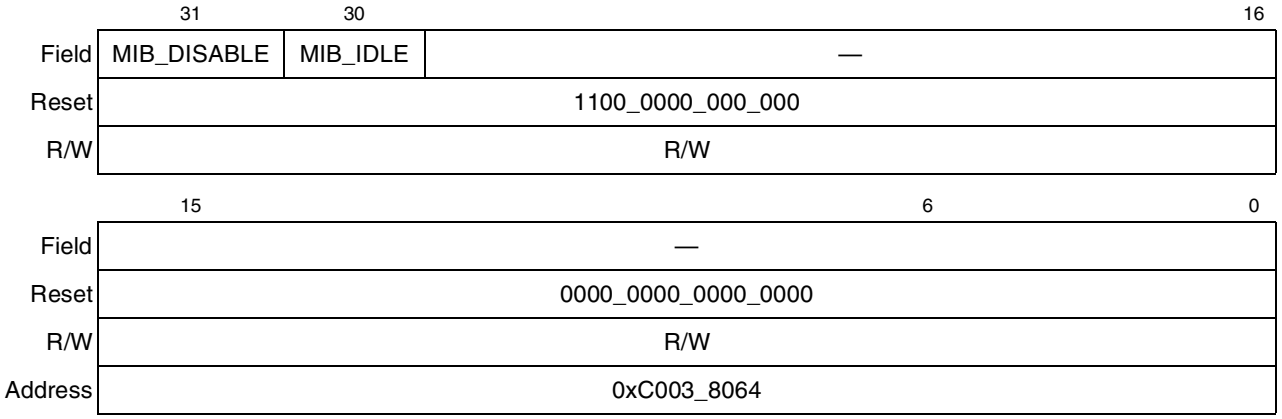

Figure 32-11. MIB Control Register (MIBC)

Table 32-21. MIBC Field Descriptions

Bits	Name	Description
31	MIB_DISABLE	A read/write control bit. If set, the MIB logic will halt and not update any MIB counters.
30	MB_IDLE	A read-only status bit. If set the MIB block is not currently updating any MIB counters.
29–0	—	Reserved.

32.6.4.9 Receive Control Register (RCR)

The RCR is programmed by the user, and controls the operational mode of the receive block. It should be written to only when ECR[ETHER_EN] = 0 (initialization time).

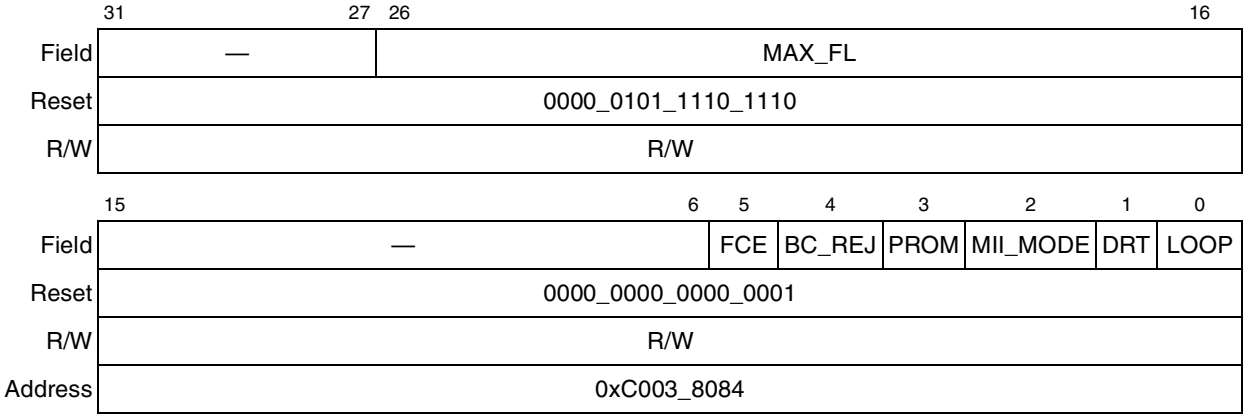

Figure 32-12. Receive Control Register (RCR)

Table 32-22. RCR Field Descriptions

Bits	Name	Description
31–27	—	Reserved, should be cleared.
26–16	MAX_FL	Maximum frame length. Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL will cause the BABT interrupt to occur. Receive Frames longer than MAX_FL will cause the BABR interrupt to occur and will set the LG bit in the end of frame receive buffer descriptor. The recommended default value to be programmed by the user is 1518 or 1522 (if VLAN Tags are supported).
15–6	—	Reserved, should be cleared.
5	FCE	Flow control enable. If asserted, the receiver will detect PAUSE frames. Upon PAUSE frame detection, the transmitter will stop transmitting data frames for a given duration.
4	BC_REJ	Broadcast frame reject. If asserted, frames with DA (destination address) = FF_FF_FF_FF_FF_FF will be rejected unless the PROM bit is set. If both BC_REJ and PROM = 1, then frames with broadcast DA will be accepted and the M (MISS) bit will be set in the receive buffer descriptor.
3	PROM	Promiscuous mode. All frames are accepted regardless of address matching.
2	MII_MODE	Media independent interface mode. Selects external interface mode. Setting this bit to one selects MII mode, setting this bit equal to zero selects 7-wire mode (used only for serial 10 Mbps). This bit controls the interface mode for both transmit and receive blocks.
1	DRT	Disable receive on transmit. 0 Receive path operates independently of transmit (use for full duplex or to monitor transmit activity in half duplex mode). 1 Disable reception of frames while transmitting (normally used for half duplex mode).
0	LOOP	Internal loopback. If set, transmitted frames are looped back internal to the device and the transmit output signals are not asserted. The system clock is substituted for the FEC_TX_CLK when LOOP is asserted. DRT must be set to zero when asserting LOOP.

32.6.4.10 Transmit Control Register (TCR)

This register is read/write, and is written by the user to configure the transmit block. This register is cleared at system reset. Bits 2 and 1 should be modified only when ECR[ETHER_EN] = 0.

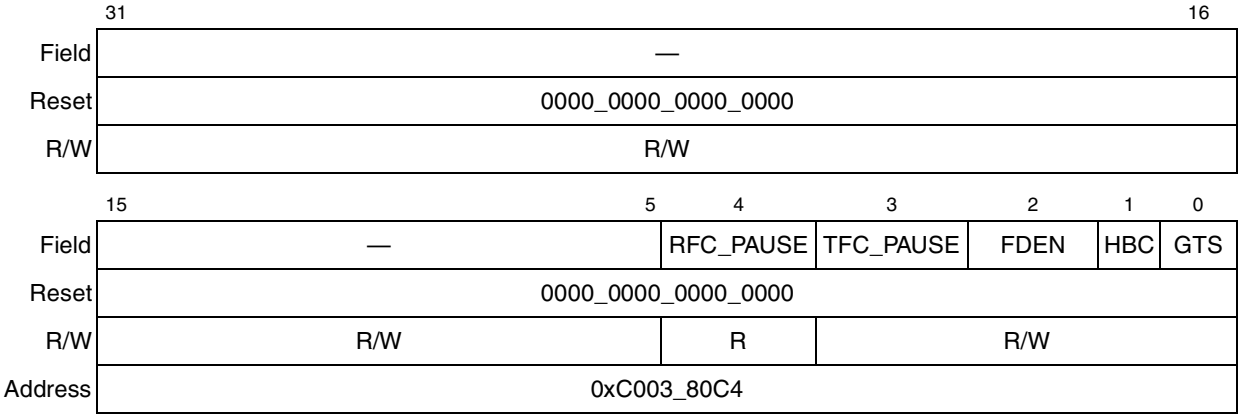

Figure 32-13. Transmit Control Register (TCR)

Table 32-23. TCR Field Descriptions

Bits	Name	Description
31–5	—	Reserved, should be cleared.
4	RFC_PAUSE	Receive frame control pause. This read-only status bit will be asserted when a full duplex flow control pause frame has been received and the transmitter is paused for the duration defined in this pause frame. This bit will automatically clear when the pause duration is complete.
3	TFC_PAUSE	Transmit frame control pause. Transmits a PAUSE frame when asserted. When this bit is set, the FEC will stop transmission of data frames after the current transmission is complete. At this time, the GRA interrupt in the EIR register will be asserted. With transmission of data frames stopped, the FEC will transmit a MAC Control PAUSE frame. Next, the FEC will clear the TFC_PAUSE bit and resume transmitting data frames. Note that if the transmitter is paused due to user assertion of GTS or reception of a PAUSE frame, the FEC may still transmit a MAC Control PAUSE frame.
2	FDEN	Full duplex enable. If set, frames are transmitted independent of carrier sense and collision inputs. This bit should only be modified when ETHER_EN is deasserted.
1	HBC	Heartbeat control. If set, the heartbeat check is performed following end of transmission and the HB bit in the status register will be set if the collision input does not assert within the heartbeat window. This bit should only be modified when ETHER_EN is deasserted.
0	GTS	Graceful transmit stop. When this bit is set, the FEC will stop transmission after any frame that is currently being transmitted is complete and the GRA interrupt in the EIR register will be asserted. If frame transmission is not currently underway, the GRA interrupt will be asserted immediately. Once transmission has completed, a “restart” can be accomplished by clearing the GTS bit. The next frame in the transmit FIFO will then be transmitted. If an early collision occurs during transmission when GTS = 1, transmission will stop after the collision. The frame will be transmitted again once GTS is cleared. Note that there may be old frames in the transmit FIFO that will be transmitted when GTS is reasserted. To avoid this deassert ECR[ETHER_EN] following the GRA interrupt.

32.6.4.11 Physical Address Low Register (PALR)

The PALR is written by the user. This register contains the lower 32 bits (bytes 0,1,2,3) of the 48-bit address used in the address recognition process to check for possible match between the DA field of receive frames and an individual DA. This register is also used for bytes 0 through 3 of the 6-byte Source Address field when transmitting PAUSE frames. This register is not reset and must be initialized by the user.

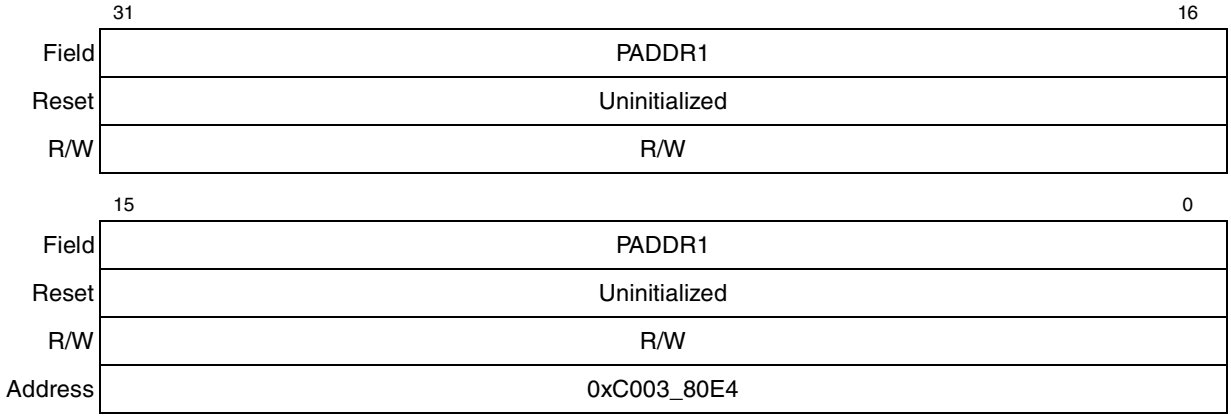

Figure 32-14. Physical Address Low Register (PALR)

Table 32-24. PALR Field Descriptions

Bits	Name	Description
31–0	PADDR1	Bytes 0 (bits 31–24), 1 (bits 23–16), 2 (bits 15–8) and 3 (bits 7–0) of the 6-byte individual address to be used for exact match, and the Source Address field in PAUSE frames.

32.6.4.12 Physical Address High Register (PAUR)

The PAUR is written by the user. This register contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to check for possible match between the DA field of receive frames and an individual DA. In addition, this register is used in bytes 4 and 5 of the 6-byte Source Address field when transmitting PAUSE frames. Bits 15–0 of PAUR contain a constant type field (0x8808)

used for transmission of PAUSE frames. This register is not reset, and bits 31–16 must be initialized by the user.

15–0	TYPE	Type field in PAUSE frames. These 16-bits are a constant value of 0x8808.

32.6.4.13 Opcode/Pause Duration Register (OPD)

The OPD register is read/write accessible. This register contains the 16-bit Opcode, and 16-bit pause duration fields used in transmission of a PAUSE frame. The Opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node will pause transmission for the duration specified in the pause duration field. This register is not reset and must be initialized by the user.

32.6.4.18 Transmit FIFO Watermark Register (TFWR)

The TFWR is a 2-bit read/write register programmed by the user to control the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows the user to minimize transmit latency (TFWR = 0x) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value will minimize the risk of transmit FIFO underrun due to

contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement (worst case bus access latency by the transmit data DMA channel).

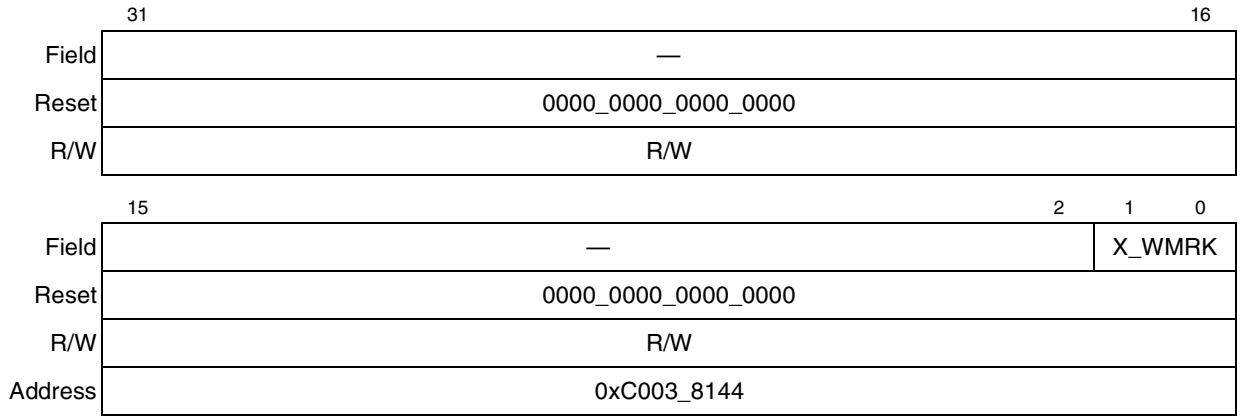

Figure 32-21. FIFO Transmit FIFO Watermark Register (TFWR)

Table 32-31. TFWR Field Descriptions

Bits	Name	Description
31–2	—	Reserved, should be cleared.
1–0	X_WMRK	Number of bytes written to transmit FIFO before transmission of a frame begins 0x 64 bytes written 10 128 bytes written 11 192 bytes written

32.6.4.19 FIFO Receive Bound Register (FRBR)

The FRBR is an 8-bit register that the user can read to determine the upper address bound of the FIFO RAM. Drivers can use this value, along with the FRSR to appropriately divide the available FIFO RAM between the transmit and receive data paths.

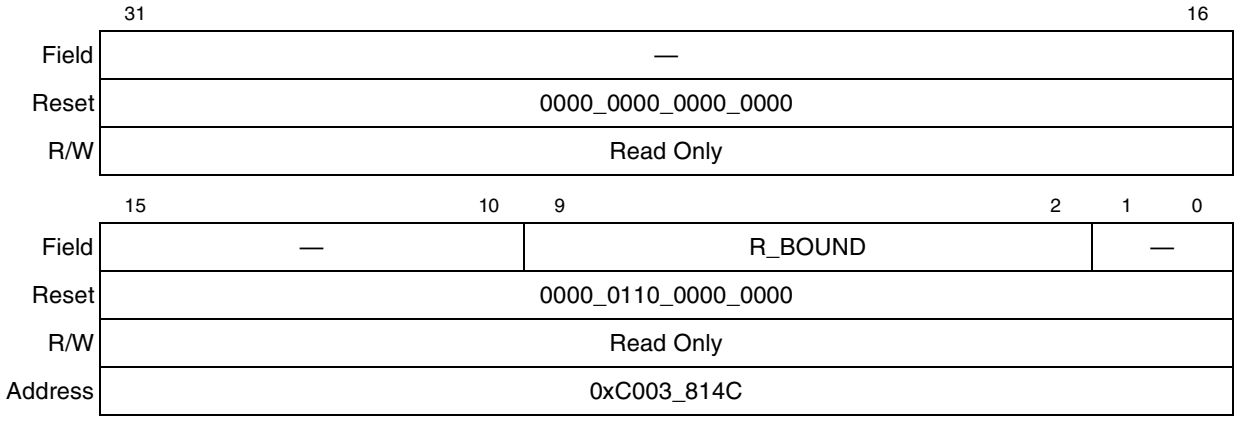

Figure 32-22. FIFO Receive Bound Register (FRBR)

Table 32-32. FRBR Field Descriptions

Bits	Name	Description
31–10	—	Reserved, read as 0 (except bit 10, which is read as 1).
9–2	R_BOUND	Read-only. Highest valid FIFO RAM address.
1–0	—	Reserved, should be cleared.

32.6.4.20 FIFO Receive Start Register (FRSR)

The FRSR, shown in Figure 32-23 and Table 32-33, is an 8-bit register programmed by the user to indicate the starting address of the receive FIFO. FRSR marks the boundary between the transmit and receive FIFOs. The transmit FIFO uses addresses from the start of the FIFO to the location four bytes before the address programmed into the FRSR. The receive FIFO uses addresses from FRSR to FRBR inclusive.

The FRSR is initialized by hardware at reset. FRSR only needs to be written to change the default value.

9–2	R_FSTART	Address of first receive FIFO location. Acts as delimiter between receive and transmit FIFOs.
1–0	—	Reserved, read as 0.

32.6.4.21 Receive Buffer Descriptor Ring Start Register (ERDSR)

The ERDSR, shown in Figure 32-24 and Table 32-34, is written by the user. It provides a pointer to the start of the circular receive buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16).

This register is not reset and must be initialized by the user prior to operation.

Bits	Name	Description
31–2	R_DES_START	Pointer to start of receive buffer descriptor queue.
1–0	—	Reserved, should be cleared.

32.6.4.22 Transmit Buffer Descriptor Ring Start Register (ETDSR)

The ETDSR, shown in Figure 32-25 and Table 32-35, is written by the user. It provides a pointer to the start of the circular transmit buffer descriptor queue in external memory. This pointer must be 32-bit

aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16). Bits 1 and 0 should be written to 0 by the user. Non-zero values in these two bit positions are ignored by the hardware.

This register is not reset and must be initialized by the user prior to operation.

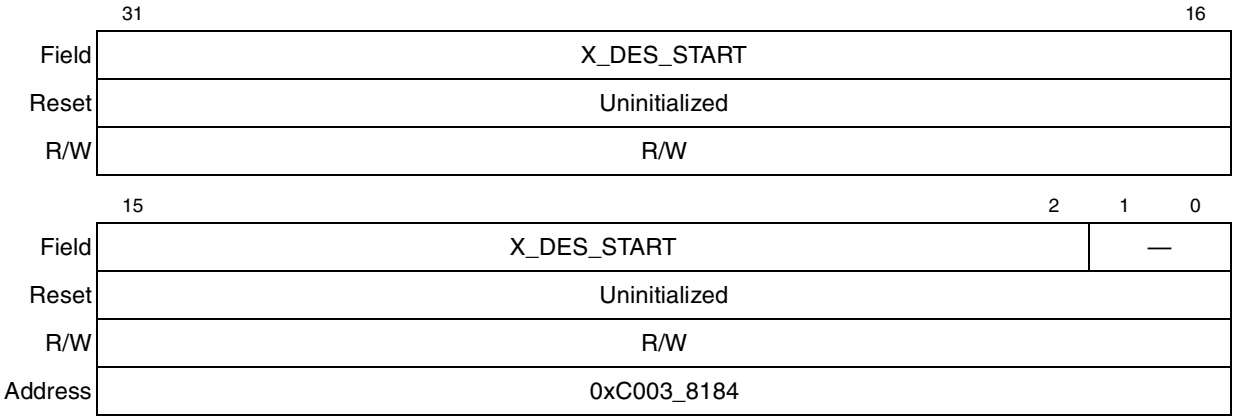

Figure 32-25. Transmit Buffer Descriptor Ring Start Register (ETDSR)

Table 32-35. ETDSR Field Descriptions

Bits	Name	Description
31–2	X_DES_START	Pointer to start of transmit buffer descriptor queue.
1–0	—	Reserved, should be cleared.

32.6.4.23 Receive Buffer Size Register (EMRBR)

The EMRBR, shown in Figure 32-26 and Table 32-36, is a 9-bit register programmed by the user. The EMRBR dictates the maximum size of all receive buffers. Note that because receive frames will be truncated at 2k-1(2047) bytes, bits 31-11 are not used. The programmed value should account for the fact that the receive CRC is always written into the last receive buffer. To allow one maximum size frame per buffer, EMRBR must be set to RCR[MAX_FL] or larger. The EMRBR must be evenly divisible by 16. To

ensure this, bits 3-0 are forced low, and hence only bits 10-4 are actually used. To minimize bus utilization (descriptor fetches) it is recommended that EMRBR be greater than or equal to 256 bytes.

The EMRBR does not reset, and must be initialized by the user.

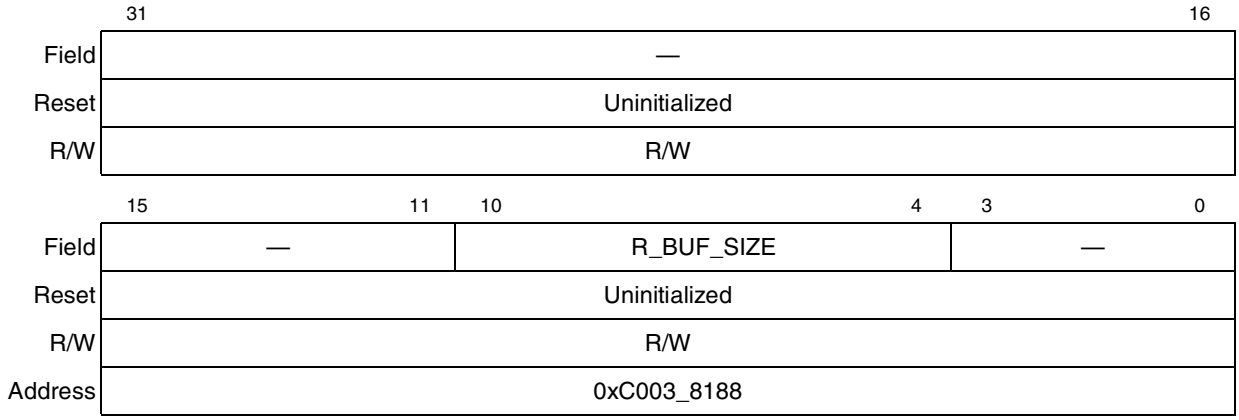

Figure 32-26. Receive Buffer Size Register (EMRBR)

Table 32-36. EMRBR Field Descriptions

Bits	Name	Description
30–11	—	Reserved, should be written to 0 by the host processor.
10–4	R_BUF_SIZE	Receive buffer size.
3–0	—	Reserved, should be written to 0 by the host processor.

32.6.5 Buffer Descriptors

This section provides a description of the operation of the driver/DMA via the buffer descriptors. It is followed by a detailed description of the receive and transmit descriptor fields.

32.6.5.1 Driver/DMA Operation with Buffer Descriptors

The data for the FEC frames must reside in memory external to the FEC. The data for a frame is placed in one or more buffers. Associated with each buffer is a buffer descriptor (BD) which contains a starting address (pointer), data length, and status/control information (which contains the current state for the buffer). To permit maximum user flexibility, the BDs are also located in external memory and are read in by the FEC DMA engine.

Software “produces” buffers by allocating/initializing memory and initializing buffer descriptors. Setting the RxBD[E] or TxBD[R] bit “produces” the buffer. Software writing to either the TDAR or RDAR tells the FEC that a buffer has been placed in external memory for the transmit or receive data traffic, respectively. The hardware reads the BDs and “consumes” the buffers after they have been produced. After the data DMA is complete and the buffer descriptor status bits have been written by the DMA engine, the RxBD[E] or TxBD[R] bit will be cleared by hardware to signal the buffer has been “consumed.” Software may poll the BDs to detect when the buffers have been consumed or may rely on the buffer/frame interrupts. These buffers may then be processed by the driver and returned to the free list.

The ECR[ETHER_EN] signal operates as a reset to the BD/DMA logic. When ECR[ETHER_EN] is deasserted the DMA engine BD pointers are reset to point to the starting transmit and receive BDs. The buffer descriptors are not initialized by hardware during reset. At least one transmit and receive buffer descriptor must be initialized by software before the ECR[ETHER_EN] bit is set.

The buffer descriptors operate as two separate rings. ERDSR defines the starting address for receive BDs and ETDSR defines the starting address for transmit BDs. The last buffer descriptor in each ring is defined by the Wrap (W) bit. When set, W indicates that the next descriptor in the ring is at the location pointed to by ERDSR and ETDSR for the receive and transmit rings, respectively.

NOTE

Buffer descriptor rings must start on a 128-bit boundary.

32.6.5.1.1 Driver/DMA Operation with Transmit BDs

Typically a transmit frame will be divided between multiple buffers. An example is to have an application payload in one buffer, TCP header in a 2nd buffer, IP header in a 3rd buffer, Ethernet/IEEE 802.3 header in a 4th buffer. The FEC does not prepend the Ethernet header (Destination Address, Source Address, Length/Type field(s)), so this must be provided by the driver in one of the transmit buffers. The FEC can append the Ethernet CRC to the frame. Whether the CRC is appended by the FEC or by the driver is determined by the TC bit in the transmit BD which must be set by the driver.

The driver (TxBD software producer) should set up Tx BDs in such a way that a complete transmit frame is given to the hardware at once. If a transmit frame consists of three buffers, the BDs should be initialized with pointer, length and control (W, L, TC, ABC) and then the TxBD[R] bits should be set = 1 in reverse order (3rd, 2nd, 1st BD) to insure that the complete frame is ready in memory before the DMA begins. If the TxBDs are set up in order, the DMA Controller could DMA the first BD before the 2nd was made available, potentially causing a transmit FIFO underrun.

In the FEC, the DMA is notified by the driver that new transmit frame(s) are available by writing to the TDAR register. When this register is written to (data value is not significant) the FEC RISC will tell the DMA to read the next transmit BD in the ring. Once started, the RISC + DMA will continue to read and interpret transmit BDs in order and DMA the associated buffers, until a transmit BD is encountered with the R bit = 0. At this point the FEC will poll this BD one more time. If the R bit = 0 the second time, then the RISC will stop the transmit descriptor read process until software sets up another transmit frame and writes to TDAR.

When the DMA of each transmit buffer is complete, the DMA writes back to the BD to clear the R bit, indicating that the hardware consumer is finished with the buffer.

32.6.5.1.2 Driver/DMA Operation with Receive BDs

Unlike the transmit case, the length of the receive frame is unknown by the driver ahead of time. Therefore the driver must set a variable to define the length of all receive buffers. In the FEC, this variable is written to the EMRBR register.

The driver (RxBD software producer) should set up some number of “empty” buffers for the Ethernet by initializing the address field and the E and W bits of the associated receive BDs. The hardware (receive

DMA) will consume these buffers by filling them with data as frames are received and clearing the E bit and writing to the L (1 indicates last buffer in frame) bit, the frame status bits (if L = 1) and the length field.

If a receive frame spans multiple receive buffers, the L bit is only set for the last buffer in the frame. For non-last buffers, the length field in the receive BD will be written by the DMA (at the same time the E bit is cleared) with the default receive buffer length value. For end of frame buffers the receive BD will be written with L = 1 and information written to the status bits (M, BC, MC, LG, NO, CR, OV, TR). Some of the status bits are error indicators which, if set, indicate the receive frame should be discarded and not given to higher layers. The frame status/length information is written into the receive FIFO following the end of the frame (as a single 32-bit word) by the receive logic. The length field for the end of frame buffer will be written with the length of the entire frame, not just the length of the last buffer.

For simplicity the driver may assign the default receive buffer length to be large enough to contain an entire frame, keeping in mind that a malfunction on the network or out-of-specification implementation could result in giant frames. Frames of 2k (2048) bytes or larger are truncated by the FEC at 2047 bytes so software never sees a receive frame larger than 2047 bytes.

Similar to transmit, the FEC will poll the receive descriptor ring after the driver sets up receive BDs and writes to the RDAR register. As frames are received the FEC will fill receive buffers and update the associated BDs, then read the next BD in the receive descriptor ring. If the FEC reads a receive BD and finds the E bit = 0, it will poll this BD once more. If the BD = 0 a second time the FEC will stop reading receive BDs until the driver writes to RDAR.

32.6.5.2 Ethernet Receive Buffer Descriptor (RxBD)

In the RxBD, the user initializes the E and W bits in the first longword and the pointer in second longword. When the buffer has been DMA'd, the Ethernet controller will modify the E, L, M, BC, MC, LG, NO, CR, OV, and TR bits and write the length of the used portion of the buffer in the first longword. The M, BC,

MC, LG, NO, CR, OV and TR bits in the first longword of the buffer descriptor are only modified by the Ethernet controller when the L bit is set.

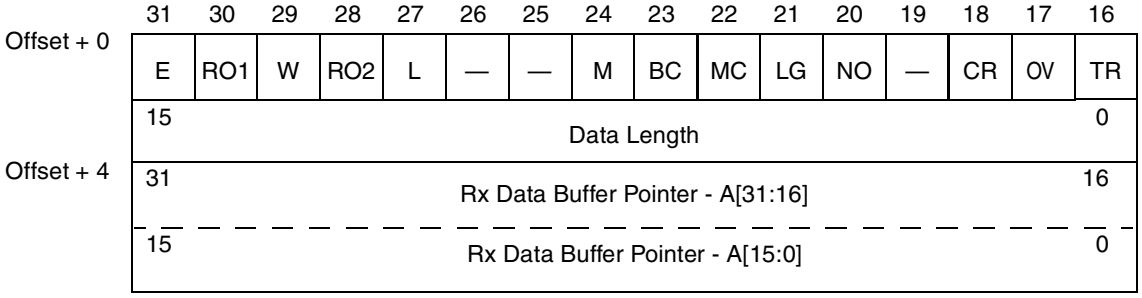

Figure 32-27. Receive Buffer Descriptor (RxBD)

Table 32-37. Receive Buffer Descriptor Field Definitions

Word	Location	Field Name	Description
Offset + 0	Bit 31	E	Empty. Written by the FEC (=0) and user (=1). 0 The data buffer associated with this BD has been filled with received data, or data reception has been aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 0	Bit 30	RO1	Receive software ownership. This field is reserved for use by software. This read/write bit will not be modified by hardware, nor will its value affect hardware.
Offset + 0	Bit 29	W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ERDSR.
Offset + 0	Bit 28	RO2	Receive software ownership. This field is reserved for use by software. This read/write bit will not be modified by hardware, nor will its value affect hardware.
Offset + 0	Bit 27	L	Last in frame. Written by the FEC. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
Offset + 0	Bits 26-25	—	Reserved.
Offset + 0	Bit 24	M	Miss. Written by the FEC. This bit is set by the FEC for frames that were accepted in promiscuous mode, but were flagged as a “miss” by the internal address recognition. Thus, while in promiscuous mode, the user can use the M-bit to quickly determine whether the frame was destined to this station. This bit is valid only if the L-bit is set and the PROM bit is set. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode.
Offset + 0	Bit 23	BC	Will be set if the DA is broadcast (FF-FF-FF-FF-FF-FF).
Offset + 0	Bit 22	MC	Will be set if the DA is multicast and not BC.

Table 32-37. Receive Buffer Descriptor Field Definitions (continued)

Word	Location	Field Name	Description
Offset + 0	Bit 21	LG	Rx frame length violation. Written by the FEC. A frame length greater than RCR[MAX_FL] was recognized. This bit is valid only if the L-bit is set. The receive data is not altered in any way unless the length exceeds 2047 bytes.
Offset + 0	Bit 20	NO	Receive non-octet aligned frame. Written by the FEC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error. This bit is valid only if the L-bit is set. If this bit is set the CR bit will not be set.
Offset + 0	Bit 19	—	Reserved.
Offset + 0	Bit 18	CR	Receive CRC error. Written by the FEC. This frame contains a CRC error and is an integral number of octets in length. This bit is valid only if the L-bit is set.
Offset + 0	Bit 17	OV	Overrun. Written by the FEC. A receive FIFO overrun occurred during frame reception. If this bit is set, the other status bits, M, LG, NO, CR, and CL lose their normal meaning and will be zero. This bit is valid only if the L-bit is set.
Offset + 0	Bit 16	TR	Will be set if the receive frame is truncated (frame length > 2047 bytes). If the TR bit is set the frame should be discarded and the other error bits should be ignored as they may be incorrect.
Offset + 0	Bits [15:0]	Data Length	Data length. Written by the FEC. Data length is the number of octets written by the FEC into this BD's data buffer if L = 0 (the value will be equal to EMRBR), or the length of the frame including CRC if L = 1. It is written by the FEC once as the BD is closed.
Offset + 4	Bits [31:16]	A[31:16]	RX data buffer pointer, bits [31:16][1]
Offset + 4	Bits [15:0]	A[15:0]	RX data buffer pointer, bits [15:0]

[1] The receive buffer pointer, which contains the address of the associated data buffer, must always be divisible by 16. The buffer must reside in memory external to the FEC. This value is never modified by the Ethernet controller.

NOTE

Whenever the software driver sets an E bit in one or more receive descriptors, the driver should follow that with a write to RDAR.

32.6.5.3 Ethernet Transmit Buffer Descriptor (TxBD)

Data is presented to the FEC for transmission by arranging it in buffers referenced by the channel's TxBDs. The Ethernet controller confirms transmission by clearing the ready bit (R bit) when DMA of the buffer is complete. In the TxBD the user initializes the R, W, L, and TC bits and the length (in bytes) in the first longword, and the buffer pointer in the second longword.

The FEC will set the R bit = 0 in the first longword of the BD when the buffer has been DMA'd. Status bits for the buffer/frame are not included in the transmit buffer descriptors. Transmit frame status is

indicated via individual interrupt bits (error conditions) and in statistic counters in the MIB block. See Section 32.6.3, MIB Block Counters Memory Map,” for more details.

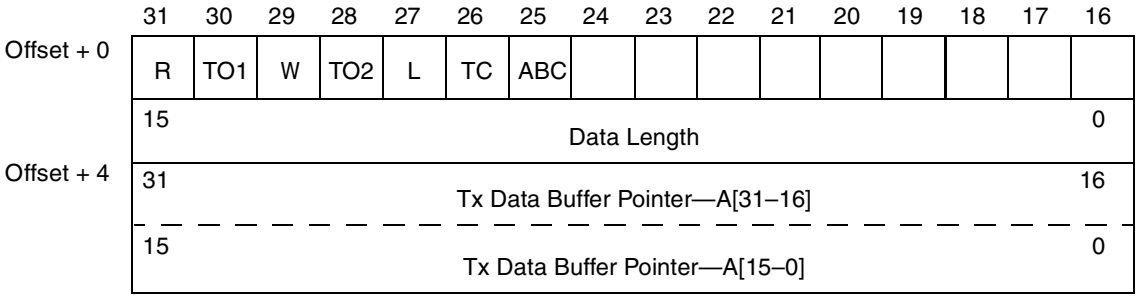

Figure 32-28. Transmit Buffer Descriptor (TxBD)

Table 32-38. Transmit Buffer Descriptor Field Definitions

Word	Location	Field Name	Description
Offset + 0	Bit 31	R	Ready. Written by the FEC and the user. 0 The data buffer associated with this BD is not ready for transmission. The user is free to manipulate this BD or its associated data buffer. The FEC clears this bit after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, which has been prepared for transmission by the user, has not been transmitted or is currently being transmitted. No fields of this BD may be written by the user once this bit is set.
Offset + 0	Bit 30	TO1	Transmit software ownership. This field is reserved for software use. This read/write bit will not be modified by hardware, nor will its value affect hardware.
Offset + 0	Bit 29	W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ETDSR.
Offset + 0	BIt 28	TO2	Transmit software ownership. This field is reserved for use by software. This read/write bit will not be modified by hardware, nor will its value affect hardware.
Offset + 0	Bit 27	L	Last in frame. Written by user. 0 The buffer is not the last in the transmit frame. 1 The buffer is the last in the transmit frame.
Offset + 0	Bit 26	TC	Tx CRC. Written by user (only valid if L = 1). 0 End transmission immediately after the last data byte. 1 Transmit the CRC sequence after the last data byte.
Offset + 0	Bit 25	ABC	Append bad CRC. Written by user (only valid if L = 1). 0 No effect 1 Transmit the CRC sequence inverted after the last data byte (regardless of TC value).
Offset + 0	Bits [24:16]	—	Reserved.
Offset + 0	Bits [15:0]	Data Length	Data Length, written by user. Data length is the number of octets the FEC should transmit from this BD’s data buffer. It is never modified by the FEC. Bits [10–0] are used by the DMA engine, bits[15–11] are ignored.

Table 32-38. Transmit Buffer Descriptor Field Definitions (continued)

Word	Location	Field Name	Description
Offset + 4	Bits [31:16]	A[31:16]	Tx data buffer pointer, bits [31–16][1]
Offset + 4	Bits [15:0]	A[15:0]	Tx data buffer pointer, bits [15–0].

[1] The transmit buffer pointer, which contains the address of the associated data buffer, must always be divisible by 16. The buffer must reside in memory external to the FEC. This value is never modified by the Ethernet controller.

NOTE

Once the software driver has set up the buffers for a frame, it should set up the corresponding BDs. The last step in setting up the BDs for a transmit frame should be to set the R bit in the first BD for the frame. The driver should follow that with a write to TDAR which will trigger the FEC to poll the next BD in the ring.

Chapter 33
Fast Infrared Interface (FIRI)

The Fast Infrared Interface module (FIRI) is capable of establishing any of the following links:

- 0.576 Mbit/s
- 1.152 Mbit/s
- 4 Mbit/s half duplex (using a LED and IR detector)

The FIRI supports these links:

- 0.576 Mbit/s
- 1.152 Mbit/s Medium InfraRed (MIR) physical layer protocol
- 4 Mbit/s Fast InfraRed (FIR) physical layer protocol (defined by IrDA, version 1.4)

FIRI interface signals are multiplexed with UART counterpart signals using a GPIO configuration for a complete infrared interface that supports SIR, MIR, and FIR modes, as illustrated in Figure 33-1. In addition, the Serial InfraRed (SIR) protocol, which supports data rate 115.2 kbps or lower, is implemented in the UART module.

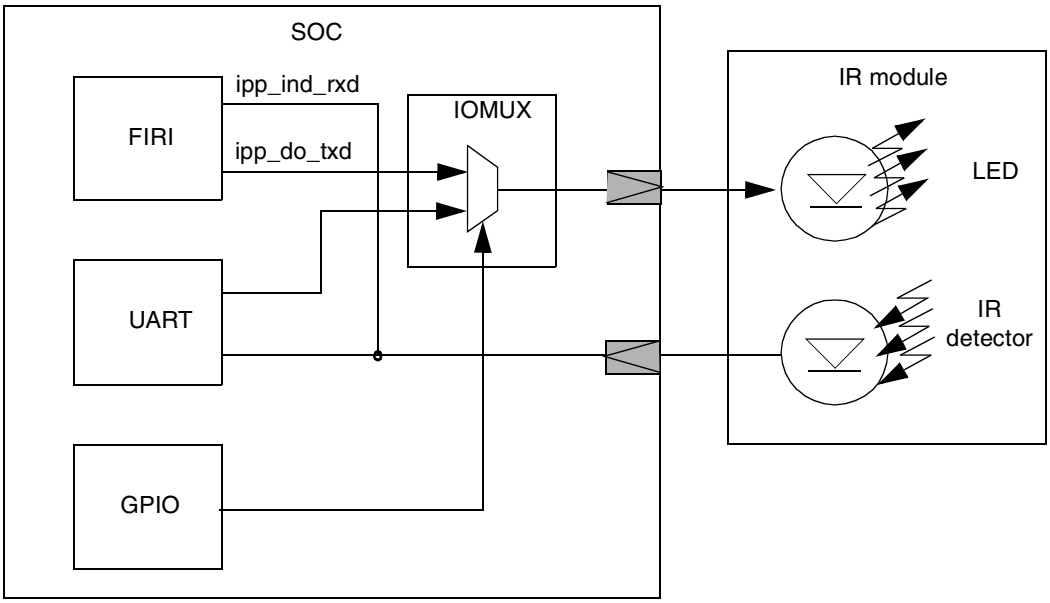

Figure 33-1. FIRI Integration Diagram

33.1 Overview

See Figure 33-2 for an illustration of the hardware components that comprise the FIRI controller.

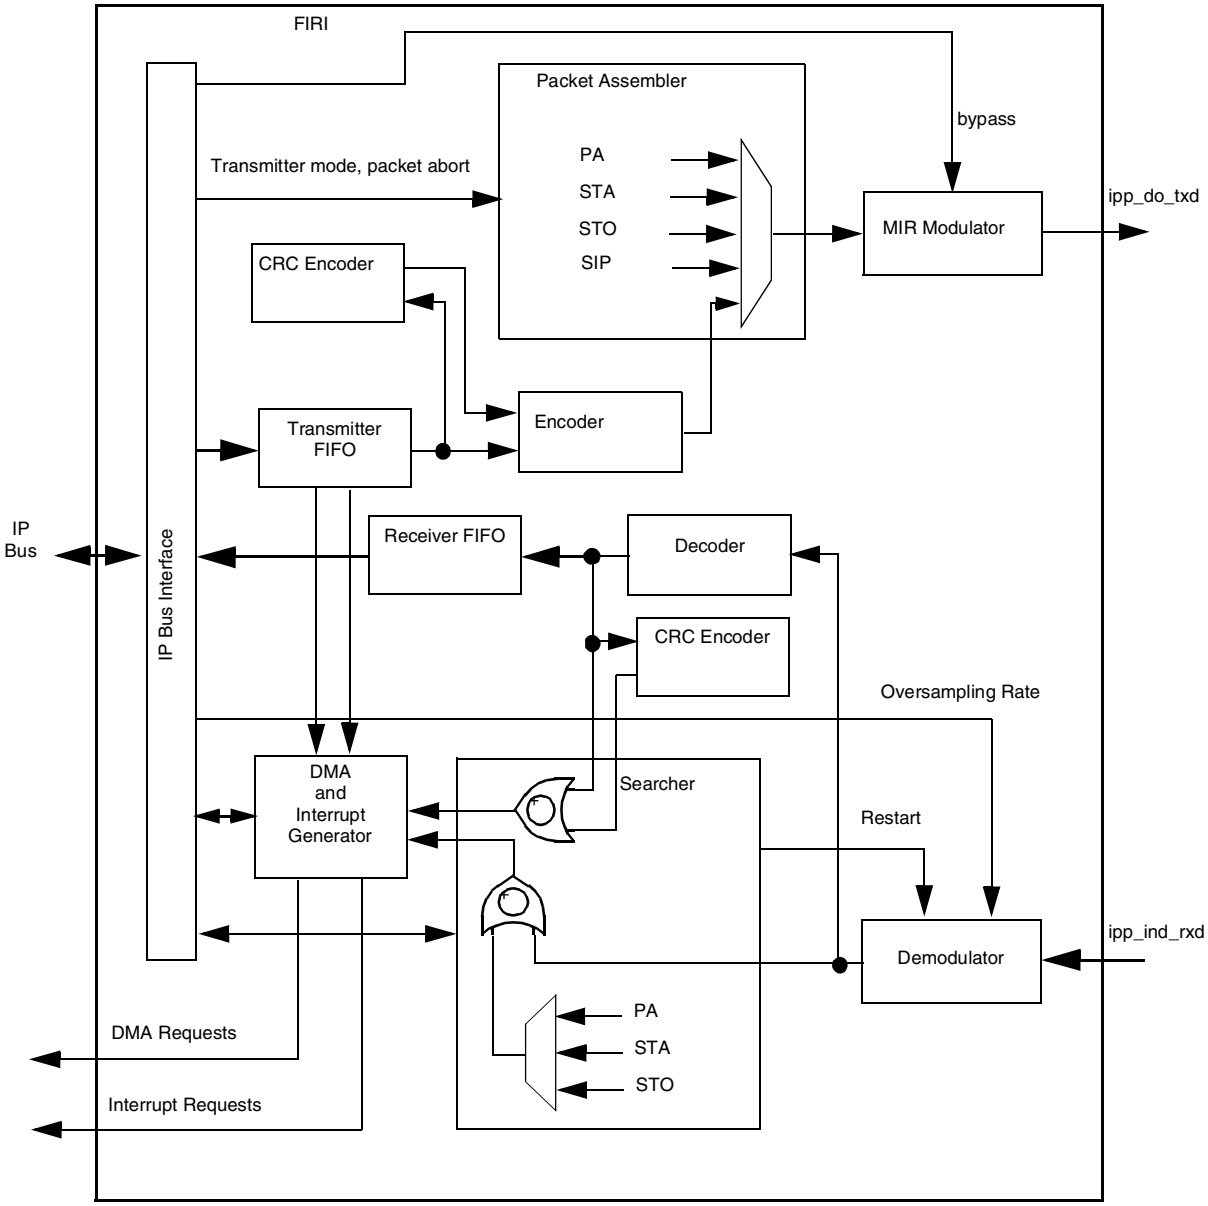

Figure 33-2. FIRI Block Diagram

The FIRI is divided into these four major functional components:

- Transmitter
- Receiver
- FIFO
- IP interface

Each of the four components that make up the FIRI is further made up of individual blocks. The transmitter consists of these blocks:

- Packet Assembler
- CRC Encoder
- MIR Modulator

The receiver consists of these blocks:

- Searcher
- CRC Encoder
- Decoder
- Demodulator

33.1.1 Overview of IrDA Medium InfraRed and Fast InfraRed Standards

The FIRI supports:

- MIR (0.576 Mbit/s, 1.152 Mbit/s)
- FIR (4 Mbit/s) physical layer protocols

This subsection provides a brief overview of the MIR and FIR standards.

33.1.1.1 MIR Packet Structure

The MIR packet format follows the standard high-level data link control (HDLC) format, except that it requires two beginning flags.

The MIR packet consists of:

- Two beginning flags (STA)
- An address
- Control fields
- Data fields
- A frame check sequence (CRC) field
- A minimum of one ending flag (STO)

See Table 33-1 for an illustration of the MIR packet structure, where STA (start flag) and STO (stop flag) are equal, predefined sequences (the left symbol is transmitted/received first).

Table 33-1. MIR Packet Structure

STA	STA	Address	Control & Data	CRC	STO

The fields in Table 33-1 are defined as follows:

- STA, STO

  The MIR links use the same physical layer flag, b’0111,1110, for both STA and STO.
- 8-bit Address Field

- 8-bit Control Field plus up to 2045 bytes in the information field
- CRC field

  The MIR links use a 16-bit CRC-CCITT to check received frames for errors. The CRC is computed from the ADDR and Data fields.

The address, control, data, and CRC fields are not transmitted in original form. They are first converted according to the MIR standards described in the next sections.

33.1.1.2 FIR Packet Structure

See Table 33-2 for an illustration of the 4 Mbit/s FIR data packet format. The chip patterns and symbols for PA, STA, CRC field, and STO are listed in Table 33-2, where PA (preamble), STA, and STO are a predefined sequence (left symbol transmitted/received first).

Table 33-2. FIR Packet Structure

PA	STA	Address & Control & Data	CRC32	STO

The fields in Table 33-2 are defined as follows:

- PA—The preamble field is used by the receiver to establish phase lock. The preamble field consists of exactly sixteen repeated transmissions of the following stream of symbols:

  b’1000,0000,1010,1000
- STA—The STA consists of exactly one transmission of the following stream of symbols:

  b’0000,1100,0000,1100,0110,0000,0110,0000
- STO—The STO consists of exactly one transmission of a stream of symbols:

  b’0000,1100,0000,1100,0000,0110,0000,0110
- ACD—The payload data is encoded as described in the 4 PPM encoding in Table 33-2. The encoded symbols reside in the ACD field and can be up to 2048 bytes long.
- CRC32—The CRC field consists of the 4 PPM encoded data, resulting from the IEEE 802 CRC32 algorithm for cyclic redundancy check as applied to the payload data contained in the packet.

33.1.1.3 MIR CRC

The CRC field is 16 bits long and generated according to the CRC-CCITT algorithm. The CRC polynomial is defined as follows:

Eqn. 33-1

$$CRC(x) = x^{16} + x^{12} + x^5 + 1$$

The CRC(x) value is inverted prior to transmission.

33.1.1.4 FIR CRC

The CRC32 field is 32 bits long and generated according to IEEE 802 CRC32 algorithm. The CRC32 polynomial is defined as follows:

Eqn. 33-2

$$CRC32(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The CRC(x) value is inverted prior to transmission.

33.1.1.5 MIR Modulation

For MIR data rates, the NZR modulation scheme is used. A “0” is represented by a light pulse. The optical pulse duration is nominally 1/4 of a bit duration. The LED is off when a “1” is transmitted.

Table 33-3. MIR Modulation

Data Bit	Data Symbol (Address, Control, and Data)
0	1000
1	0000

NOTE

Tolerance of bit rate according to the standard must not exceed ±0.1%.

33.1.1.6 FIR Modulation

For 4.0 Mbit/s, the modulation scheme is 4 PPM. In the modulation scheme, a pair of bits is taken together and called a data symbol. A data symbol is divided into four chips, only one of which contains an optical pulse. The nominal pulse duration is 125 ns. A “1” is represented by a light pulse.

Table 33-4. 4 PPM Mapping

Data Bit Pair	4 PPM Data Symbol
00	1000
01	0100
10	0010
11	0001

Verify that the tolerance of chip rate according to the standard does not exceed ±0.01%. The pulse width tolerance of an electrical signal driven by an IR detector (photodiode) can be greater than the tolerance of the optical signal defined by IrDA and can depend on the LED and IR devices used with the FIRI.

33.1.2 Features

The FIRI includes the following distinctive features:

- 0.576 Mbit/s, MIR protocol
- 1.152 Mbit/s, MIR protocol
- 4 Mbit/s, 4 PPM, FIR protocol
- Device Destination Detection Hardware Support
- Interrupt generation
- DMA capability
- SIP generation for collision avoidance

33.1.3 Modes of Operation

The FIRI supports the following modes:

- Hardware packet assembly:
  - FIR mode
  - 0.576 Mbps MIR mode
  - 1.152 Mbps MIR mode
  - Serial Infrared Interaction Pulse (SIP) generation
- Hardware packet search:
  - FIR mode
  - 0.576 Mbps MIR mode
  - 1.152 Mbps MIR mode
- Software packet assembling
- Software packet search

33.2 External Signal Description

See Table 33-5 for the list of signals used to control the FIR.

Table 33-5. Signal Properties

Name	Direction	Port	Function	Reset State	Pull up
Signals Connecting To IC IO					
LED and IR Detector Interface					
IPP_DO_TXD	Output	ipp_do_txd	Data transmit signal. Active high.	1	—
IPP_IND_RXD	Input	ipp_ind_rxd	Data receive signal. Active high.	NA	At top level IO ring, if necessary

33.2.1 Detailed Signal Descriptions

The following list describes the data transmit signal and the data receive signal.

- IPP_DO_TXD (Data Transmit Signal)
  - Output signal from the Packet Assembler module
  - Must be connected to an LED through the IOMUX, as shown in Figure 33-1.
  - A DC-level translator off-chip can be added, if necessary.
- IPP_IND_RXD (Data Receive Signal)
  - Driven by the IR detector
  - Input to the Demodulator module
  - A DC-level translator off-chip can be added, if necessary.

33.3 Memory Map and Register Definition

The FIRI includes six 32-bit registers, a transmit FIFO, and a receive FIFO. Section 33.3.3, Register Descriptions," provides detailed descriptions for all of the FIRI registers.

33.3.1 FIRI Memory Map

Table 33-6 shows the FIRI memory map.

Table 33-6. FIRI Memory Map

Address	Register	Reset Value	Access	Section/Page
0xBASE+0x000 (FIRITCR)	FIRI Transmit Control Register	0x0000_0000	R/W	33.3.3.1/33-9
0xBASE+0x004 (FIRITCTR)	FIRI Transmit Count Register	0x0000_0000	R/W	33.3.3.2/33-11
0xBASE+0x008 (FIRIRCR)	FIRI Receive Control Register	0x0000_0000	R/W	33.3.3.3/33-12
0xBASE+0x00C (FIRITSR)	FIRI Transmit Status Register	0x0000_0000	R/Write one to clear	33.3.3.4/33-14
0xBASE+0x010 (FIRIRSR)	FIRI Receive Status Register	0x0000_0000	R/Write one to clear	33.3.3.5/33-15
0xBASE+0x014	Transmitter FIFO	—	W	33.4.2/33-18
0xBASE+0x018	Receiver FIFO	—	R	33.4.4/33-19
0xBASE+0x01C (FIRICR)	FIRI Control Register	0x0000_0000	R/W	33.3.3.6/33-16

33.3.2 Register Summary

Figure 33-3 shows the key to the register fields and Table 33-7 shows the register figure conventions.

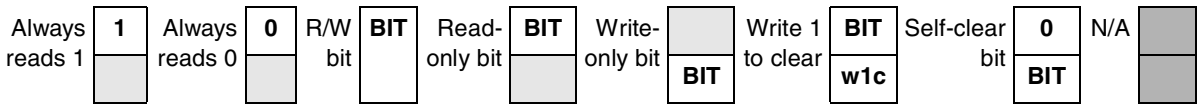

Figure 33-3. Key to Register Fields

Table 33-7. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 33-8 shows the FIRI register summary.

33.3.3 Register Descriptions

This section contains the detailed register descriptions for the FIRI registers.

33.3.3.1 FIRI Transmitter Control Register (FIRITCR)

The Transmitter Control Register is a 32-bit, read-write register that controls transmitter operation. Figure 33-4 shows the register; Table 33-9 shows its field descriptions.

0xBASE+0x000 (FIRITCR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 33-4. FIRI Transmitter Control Register

Table 33-9. FIRI Transmitter Control Register Field Descriptions

Field	Description
31–25	Reserved
24 HAG	Hardware Address Generator. When this bit is set, the content of the TPA bits is transmitted as a packet address. When the bit is cleared, the packet address is read from TX FIFO. 0 Read packet address from TX FIFO 1 Use TPA bits as packet address
23–16 TPA	Transmit Packet Address. This field contains the 8-bit Transmit Packet Address. If the HAG bit is cleared, the TPA bits have no effect.
15	Reserved
14–13 SRF	Start Field Repeat Factor. This field contains the number of PA or STA fields transmitted in the beginning of the packet for FIR and MIR mode, respectively. In FIR mode, only the 00 value should be used. 00 16 PA or 2 STA fields is transmitted. 01 32 PA or 4 STA fields is transmitted. 10 64 PA or 8 STA fields is transmitted. 11 128 PA or 16 STA fields is transmitted.
12–10 TDT	This field controls the TX FIFO depth that triggers a DMA request. Refer to Section 33.4.2, Transmitter FIFO," for details. **Note:** To avoid TX FIFO overflow, verify that the sum of TDT level and burst length (set by BL bits in the FIRICR register) does not exceed TX FIFO size, which is 128 bytes. 0 DMA request generated when TX FIFO is empty 1 DMA request generated when TX FIFO contain 16 bytes of data 2 DMA request generated when TX FIFO contain 32 bytes of data 3 DMA request generated when TX FIFO contain 48 bytes of data ... ... 7 DMA request generated when TX FIFO contains 112 bytes of data
9 TCIE	Transmit Complete Interrupt Enable. This bit enables the TC status bits of the FIRITSR register to generate a Transmit Complete Interrupt. 0 Transmit Complete Interrupt is not triggered by TC bit. 1 Transmit Complete Interrupt is triggered by TC bit.
8 TPEIE	Transmitter Packet End Interrupt Enable. This bit enables the TPE and SIPE status bits of the FIRITSR register to generate a Packet End Interrupt. 0 PEI interrupt is not triggered by TPE or SIPE bits. 1 PEI interrupt is triggered by TPE or SIPE bits.
7 TFUIE	Transmitter FIFO Underrun Interrupt Enable. This bit enables the TFU status bit of the FIRITSR register to generate a TFU interrupt. 0 TFU interrupt disabled 1 TFU interrupt enabled
6 PCF	Packet Complete by FIFO. This bit determines how a packet is completed if a TX FIFO underrun event occurs. Do not write software intentionally to cause underrun events. However, if it is done due to erroneous conditions, the value of this PC bit selects between two recovery modes. Set the PCF based on system and upper layer IrDA protocol requirements. 0 Send CRC and STO fields 1 Send packet abort symbol

Table 33-9. FIRI Transmitter Control Register Field Descriptions (continued)

Field	Description
5 PC	Packet Complete. This bit determines how a packet is completed when the TE bit is cleared or when the SIP bit is set in the middle of the transfer. Do not write software intentionally to clear the TE bit or to set the SIP bit in the middle of the transfer. However, if it is done due to erroneous conditions, the value of this PC bit selects between two recovery modes. Set PC based on system and upper layer IrDA protocols requirements. 0 Send CRC and STO fields 1 Send packet abort symbol
4 SIP	Transmit Enable of SIP. Writing “1” to this bit produces a “Serial InfraRed Interaction Pulse” transmission. Writing a “0” to this bit is ignored. This bit is always read as “0”. If this bit is set while in the middle of the transfer, the packet will be completed according to the setting of the PC bit.
3 TPP	Transmitter Pulse Polarity bit. 0 Transmitted pulse is not inverted. 1 Transmitted pulse is inverted.
2–1 TM	Transmitter Mode. This bits controls the transmission mode. 00 4 Mbps FIR Mode 01 0.576 Mbps MIR Mode 10 1.152 Mbps MIR Mode 11 Software Packet Assembling
0 TE	Transmitter Enable. This bit controls the FIRI transmitter. If this bit is cleared in the middle of the transfer, the packet will be completed according to the setting of the PC bit. When the packet is completed, the transmitter clocks are then gated OFF. 0 Transmitter Disabled 1 Transmitter Enabled

33.3.3.2 FIRI Transmitter Count Register (FIRITCTR)

The Transmitter Count Register is 32-bit, read-write register that controls the packet size. Figure 33-5 shows the register; Table 33-10 shows its field descriptions.

0xBASE+0x004 (FIRITCTR) Access: User read/write

Figure 33-6. FIRI Receiver Control Register

Table 33-11. FIRI Receiver Control Register Field Descriptions

Field	Description
31–26	Reserved
25–24 RAM	Address Match bit. The value of this bit can be changed when the RE bit is cleared. 00 Does not match address 01 Match packet address to RA bits 10 Match packet address to Broadcast address 11 Match packet address to RA bits and to broadcast address
23–16 RA	Receiver Address. Determines Receiver Packet Address. If the RAM bit value is 00 or 10, the RA bit has no effect. The value of this bit can be changed when the RE bit is cleared.
15–12	Reserved

Table 33-11. FIRI Receiver Control Register Field Descriptions (continued)

Field	Description
11 RPEDE	Receiver Packet End DMA Request Enable bit; Enable DMA request generation at the end of the packet. If this bit is set, verify that the BL value in the FIRICR register is not greater than the sum of the address, control, data, and CRC field length. 0 DMA request is not affected by the end of packet. 1 DMA request is generated at the end of packet.
10–8 RDT	Receiver DMA Request Trigger level. Sets minimum Rx FIFO depth, which triggers a DMA request. For more details, refer to Section 33.4.4, Receiver FIFO." **Note:** To avoid Rx FIFO underflow, set the RDT level to greater than or equal value of the burst length (set by the BL bit in the FIRICR register). 0 Reserved 1 DMA request generated when Rx FIFO contains 16 bytes of data 2 DMA request generated when Rx FIFO contains 32 bytes of data 3 DMA request generated when Rx FIFO contains 48 bytes of data ... 7 DMA request generated when Rx FIFO contains 112 bytes of data
7 RPA	Receiver Packet Abort bit. Determines behavior of the Rx FIFO upon detection of an illegal symbol. When an illegal symbol is detected, the DDE or CRCE bit in the FIRIRSR register is set. If the RPA bit is set, the Rx FIFO pointers are cleared and the receiver starts to search for the PA or STA fields for FIR and MIR mode, respectively. If RPA is cleared, the receiver continues to write to the Rx FIFO. 0 Does not clear the Rx FIFO upon detection of an illegal symbol 1 Clears the Rx FIFO upon detection of illegal symbol
6 RPEIE	Receiver Packet End Interrupt Enable bit. Enables the RPE status bit in the FIRIRSR register to assert the Packet End Interrupt. 0 PEI interrupt is not triggered by RPE bit. 1 PEI interrupt is triggered by RPE bit.
5 PAIE	Packet Abort Interrupt Enable bit. Enables the DDE, CRCE status bits in the FIRIRSR register to cause a PAI interrupt. 0 PAI interrupt is disabled. 1 PAI interrupt is enabled.
4 RFOIE	Receiver FIFO Overrun Interrupt Enable bit. Enables the RFO status bit in the FIRIRSR register to cause a RFOI interrupt. 0 RFOI interrupt is disabled. 1 RFOI interrupt is enabled.
3 RPP	Receiver Pulse Polarity bit. 0 Receiver signal is not inverted. 1 Received signal is inverted.
2–1 RM	Receiver Mode bits. 00 FIR Mode 01 0.576 Mbps MIR Mode 10 1.152 Mbps MIR Mode 11 Software Packet Assembling
0 RE	Receiver enable bit. When this bit is cleared, the receiver clocks are gated OFF. 0 Receiver is disabled. 1 Receiver is enabled.

33.3.3.4 FIRI Transmit Status Register (FIRITSR)

The Transmit Status Register is 32-bit register that reflects the status of the transmitter and the TX FIFO. The FIRITSR contains read-only and write-one-to-clear bits. Figure 33-7 shows the register; Table 33-12 shows its field descriptions.

0xBASE+0x00C (FIRITSR) Access: User read/write one to clear

Figure 33-7. FIRI Transmit Status Register

Table 33-12. FIRI Transmit Status Register Descriptions

Field	Description
31–16	Reserved
15–8 TFP	Transmitter FIFO Pointer bits. The value of the TFP bits represent the number of available bytes in TX FIFO (read-only bits).
7–4	Reserved
3 TC	Transmit Complete bit. Indicates that the transmission is completed (including the CRC and STO fields), and the transmitter FIFO is empty. This bit is cleared by writing a “1”. 0 Transmitting is not completed. 1 Transmitting is completed.
2 SIPE	SIP End bit. Indicates that “Serial InfraRed Interaction Pulse” has been transmitted. This bit is cleared by writing a “1”. 0 SIP transmission is not completed. 1 SIP had been transmitted.
1 TPE	Transmitter Packet End bit. Indicates that the TPS bytes of data (address, control, and data fields) have been transmitted. This bit is cleared by writing a “1”. 0 Transmissions of address, control, and data fields are not completed. 1 Address, control, and data fields had been transmitted.
0 TXU	Transmitter FIFO Underrun bit. Indicates the occurrence of a TX FIFO underrun. A TX FIFO underrun occurred if the transmitter attempted to read from the TX FIFO when the TX FIFO is empty. This bit is cleared by writing a “1”. 0 No transmitter FIFO underrun 1 Transmitter FIFO is underrun

33.3.3.5 FIRI Receive Status Register (FIRIRSR)

The Receive Status Register is 32-bit register that reflects the status of the receiver and the FIFO. It contains read-only and write-one-to-clear bits. Figure 33-8 shows the register; Table 33-13 shows its field descriptions.

0xBASE+0x010 (FIRIRSR) Access: User read/write one to clear

Figure 33-8. FIRI Receive Status Register

Table 33-13. FIRI Receive Status Register Field Descriptions

Field	Description
31–16	Reserved
15–8 RFP	Receiver FIFO Pointer bits. The value of the RFP bits represent the number of available bytes in the Rx FIFO (read-only bits).
7–6	Reserved
5 PAS	Preamble Search bit. Indicates that the receiver is searching for PA+STA, or STA fields for FIR and MIR modes, respectively (read-only bit). 0 Receiver does not search for the PA or STA field. 1 Receiver searches for the PA or STA field.
4 RPE	Receiver Packet End bit. Indicates that the STO field or packet abort symbol (b'0000,000 and b'0000,0000 for MIR and FIR, respectively) is detected. This bit is cleared by writing a "1". 0 STO was not detected. 1 STO field is detected.
3 RFO	Receiver FIFO Overrun bit. Indicates that the receiver attempted to write to the Rx FIFO when the Rx FIFO is full. This bit is cleared by writing a "1". 0 Receiver FIFO is not overrun. 1 Receiver FIFO is overrun.
2 BAM	Broadcast Address Match bit. Indicates that the address field of the packet matches the Broadcast Address 0xFF. This bit is cleared by writing a "1". 0 No Broadcast 1 Broadcast packet

Table 33-13. FIRI Receive Status Register Field Descriptions (continued)

Field	Description
1 CRCE	CRC Error bit. Indicates that the CRC check failed. This bit is cleared by writing a “1”. 0 No CRC check failure 1 CRC check failure
0 DDE	Address, Control, or Data Field Error bit. Indicates that an illegal symbol has been detected in the address, control, data, or CRC32/CRC fields. This bit is cleared by writing a “1”. 0 No illegal symbols in address, control, data, or CRC field 1 Illegal symbol in address, control, data, or CRC field

33.3.3.6 FIRI Control Register (FIRICR)

The Control Register is a 32-bit, read-write register that is shared by receiver and transmitter. Figure 33-9 shows the register; Table 33-14 shows its field descriptions.

0xBASE+0x01C (FIRICR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 33-9. FIRI Control Register

Table 33-14. FIRI Control Register Field Descriptions

Field	Description
31–12	Reserved
11–5 BL	Burst Length. Used to prevent an overrun of the TX FIFO and an underrun of the Rx FIFO. The DMA request of the transmitter deasserts when the number of vacant bytes in the TX FIFO is less than the burst length settings specified by the BL bits. The DMA request of the receiver deasserts when the number of available bytes in the Rx FIFO is less than the burst length settings specified by the BL bits. 1 1 byte 2 2 bytes 3 3 bytes ... 127 127 bytes 0 128 bytes

Table 33-14. FIRI Control Register Field Descriptions (continued)

Field	Description
4	Reserved
3–0 OSF	Over Sampling Factor. This field controls the oversampling factor of the “chip” on the IPP_IND_RXD signal if the RE bit in the FIRIRCR register is set, or the prescaling factor of the IPG_CLK_FIRI_BAUD signal if the TE bit in the FIRITCR register is set. **Note:** The “chip” rate is 4 and 2 times greater than the bit rate for MIR and FIR, respectively. 0 Does not oversample 1 Oversamples by 2 2 Oversamples by 3 ... ... 15 Oversamples by 16

To enable proper receive operations, the period of the divided clock must be four or more times shorter than the pulse width of the IPP_IND_RXD signal, and one or more times shorter than the gap between two consecutive pulses.

NOTE

The pulse width of the IPP_IND_RXD signal is dependent upon the characteristics of the LED and the Photo Diode used with the FIRI, and is different from the pulse width defined by IrDA for the optical signal. The value of the OSF bits must be adjusted accordingly. A greater OSF value leads to a better SNR on the expense of an increase in the power consumption.

33.4 Functional Description

This section details the FIRI functional description.

33.4.1 Transmitter Overview

The transmitter has three modes of operation:

- MIR
- FIR
- Software Packet Assembly

33.4.1.1 MIR Mode

In MIR mode, the following sequence occurs:

1. The Packet Assembler block sends the STA sequences (two or more times) to the MIR Modulator block.
2. The Encoder block accesses the TX FIFO, aligns the data, and sends the ACD (Address, Control, and Data) fields to the Packet Assembler block.

3. The CRC field calculated by CRC block follows the ACD field; after which, the STO bits are sent to the Modulator.

33.4.1.2 FIR Mode

In FIR mode, the following sequence occurs:

1. The Packet Assembler block sends the predefined PA (16 or more times) and STA sequences to the LED.
2. The Encoder block accesses the TX FIFO, encodes the data (4 PPM), and sends the ACD (Address, Control and Data) to the Packet Assembler block.
3. The CRC32 field calculated by CRC block follows the ACD field; after which, the STO bits are sent to the Modulator.

NOTE

The MIR Modulator block is not operable in FIR mode.

If the DMA request is not served during MIR or FIR modes, and there is no valid data to transmit, the Assembler Module terminates the packet using the packet-abort symbol (with CRC/CRC32 and STO fields [see the PCF bit description]), and a TFUI interrupt is generated. The packet can also be aborted by the packet length counter or by the software (see PC bit description).

33.4.1.3 Serial Infrared Interaction Pulse

The transmitter must send the “Serial Infrared Interaction Pulse” (SIP) at 500 ms to guarantee that low speed IR devices will not interfere with its pulses. The pulse must be 8.7 µs wide; and positive phase must be 1.6 µs wide.

33.4.1.4 Software Packet Assembly Mode

In Software Packet Assembly mode, the entire packet is read from the TX FIFO, including the PA, STA, and STO bits. The MIR modulator and Encoder blocks are disabled. This mode is used for debug purposes and can be used for testing compatibility with future IrDA protocols, if appropriate.

33.4.2 Transmitter FIFO

The transmitter FIFO is a 128-byte FIFO used for holding transmit data. The TX FIFO gets filled by the accesses to the Transmitter FIFO address (by core or DMA) and is emptied by the transmitter. When the DMA is used, a pre-programmed FIFO trigger level controls the triggering of the DMA request. When the TX FIFO is emptied below the trigger-level, a DMA request signal is asserted. The DMA request gets deasserted when the number of vacant bytes in the TX FIFO is less than the burst length settings specified by the BL bits in the FIRICR register. If the DMA request was not serviced and, as a result, there are no more data in the TX FIFO, the TFU bit in the FIRITSR register sets, and the $\overline{\text{IPI\_INT\_FIFO}}$ interrupt signal asserts depending on TFOIE bit in the FIRITCR register. During the transmit operation, the TFP bit value in the FIRITSR register reflects the amount of available bytes in the TX FIFO.

33.4.3 Receiver Overview

The receiver has three modes of operation:

- MIR
- FIR
- Software Packet Disassembly Modes

In MIR and FIR modes, each incoming pulse is oversampled by the programmable factor in the Demodulator block. Next, the Demodulator block detects the edges of the pulses and synchronizes to the phase of the transmitted pulse. Phase correction is performed until the end of the packet because the bit rate tolerance accumulates to very large values for long packets.

33.4.3.1 MIR Mode

In MIR mode, the Searcher block searches for the STA field. If the sequence is matched, the data stream following the STA field is sent to the Decoder block. The Decoder block searches for five consecutive “1”s and skips next the “zero” bit inserted by the transceiver for phase synchronization. The data is then written to the Rx FIFO. In parallel, the Searcher Module searches for the STO field. When the STO field is detected, a PEI interrupt is generated together with a DMA request, and the corresponding flag is set in the status register. The Searcher module continuously searches for illegal symbols (seven or more consecutive “1”s). If an illegal symbol is detected, the PAI interrupt is generated and the corresponding flag is set in the status register.

33.4.3.2 FIR Mode

In FIR mode, the Searcher Module searches for the PA field and then for the STA field. If found, the “chip” stream is converted to a data stream by the Decoder block and then it is written to the Rx FIFO. In a parallel operation, the Searcher Module searches for the STO field. When the STO field is detected, a PEI interrupt can be generated together with a DMA request. While receiving, the Searcher module continuously searches the PA, STA, ACD, CRC32, and STO fields for illegal symbols. In addition, the Searcher module looks for a packet abort symbol. On detection of an illegal symbol, a PAI interrupt is generated and the corresponding flag is set in the status register.

In MIR and FIR modes, the “Address” bits can be compared to a predefined value or/and to the broadcast value 0xFF (see the description of RAM bits). If the CRC field value does not match an expected value calculated by the CRC Encoder block, a PAI interrupt is generated. The CRC field sends the Rx FIFO, irrespective of a comparison result.

33.4.3.3 Software Packet Disassembly Mode

In Software Packet Disassembly mode, the entire packet is sent to the Rx FIFO, even if illegal symbols have been detected.

33.4.4 Receiver FIFO

The receiver FIFO is a 128-byte FIFO, used for holding received data. Rx FIFO gets filled by incoming data and emptied by excess Rx FIFO (by the core or DMA). When DMA is used, a pre-programmed FIFO

trigger level controls the triggering of the DMA request. When Rx FIFO is filled beyond the trigger level, a DMA request signal is asserted. The DMA request gets deasserted when the number of available bytes in Rx FIFO is less than the burst length settings specified by the BL bits in the FIRICR register. If the DMA request was not serviced and, as a result, there are no vacant bytes in the Rx FIFO for receive data, the RFO bit in the FIRIRSR register is set and the IPI_INT_FIFO interrupt signal is asserted depending on RFOIE bit in the FIRIRCR register. During a receive operation, the RFP bits' value in the FIRIRSR register reflects the amount of available bytes in the Rx FIFO.

33.5 Initialization/Application Information

This section provides the following two examples of FIRI programming: a transmitter programming scenario and a receiver programming scenario.

33.5.1 Transmitter Programming Scenario

The purpose of this scenario is to transmit 1024 bytes in FIR mode using an infrared link. Verify that the packet length is 512 bytes, and then use the following steps.

1. Configure the clock controller. For this example, the frequency of the IPG_CLK_FIRI_BAUD clock is 48 MHz.
2. Configure the DMA module for DMA-service FIRI transactions. A DMA transaction is requested by the negative edge of DMA_REQ[1]. The DMA access size is 4 bytes. For this example, the burst length is 4 accesses.
3. Configure the FIRI to work with a 32-byte burst (FIRICR.BL bits).

NOTE

Observe the burst length of the DMA and the burst length selected by FIRICR. The BL bits are not necessarily equal.

4. Set the FIRI Oversampling Factor (FIRICR.OSF bits) to 6 to achieve a 4-Mbit rate with the IPG_CLK_FIRI_BAUD clock.
5. Configure the FIRI to transmit 512-byte long packets (FIRITCTR.TPL bits).
6. Set the DMA trigger level to 16 (FIRITCR.TDT bits). A DMA request is generated when there are only 16 bytes remaining in the TX FIFO. Select FIR mode (FIRITCR.TM bits).
7. Finally, enable the transmitter (FIRITCT.TE bit). The FIRI immediately asserts a DMA request because the TX FIFO is empty. The DMA controller delivers a first burst to the FIRI. The FIRI starts the transmission.

33.5.1.1 Receiver Programming Scenario

Fort the receiver programming scenario, the data is transmitted in FIR mode. An interrupt should be generated at the end of each packet.

1. Configure the clock controller. For this example, the frequency of the IPG_CLK_FIRI_BAUD clock is 48 MHz.

2. Configure the DMA module for the FIRI to DMA transactions. The DMA transaction is requested by the negative edge of $\overline{\text{DMA\_REQ}}$[0]. DMA access size is 4 bytes. For this example, burst length is 4 accesses.
3. Configure the FIRI to work with 16-byte burst (FIRICR.BL bits). Set the FIRI Oversampling Factor (FIRICR.OSF bits) to 6 to achieve a 4-Mbit rate with the IPG_CLK_FIRI_BAUD clock.
4. Set the DMA trigger level to 16 (FIRIRCR.RDT bits). A DMA request is generated when there are 16 bytes in Rx FIFO. Select FIR mode (FIRIRCR.RM bits). Enable Packet End Interrupt.
5. Finally, enable the receiver (FIRIRCR.RE bit). The receiver searches for the PA and STA fields. When a PEI interrupt is generated, verify that the software clears the FIRIRSR.RPE bit.

Chapter 34
General Power Controller (GPC)

34.1 Introduction

GPC is a general power control module. The GPC block includes the following subblocks of advanced power saving techniques:

- Two DVFS subblocks (CPU and peripherals clock/power domains)
- Two DPTC subblocks (CPU and peripherals power domains)
- SRPG subblock for all SRPG-ed modules: CPU, VPU, GPU, IPU, EMI, LPMIX, and SIPMIX

Each of the subblocks has its own IP registers. GPC also includes an arbitration block for DVFS and DPTC voltage/frequency updates.

Figure 34-1 shows the GPC block diagram.

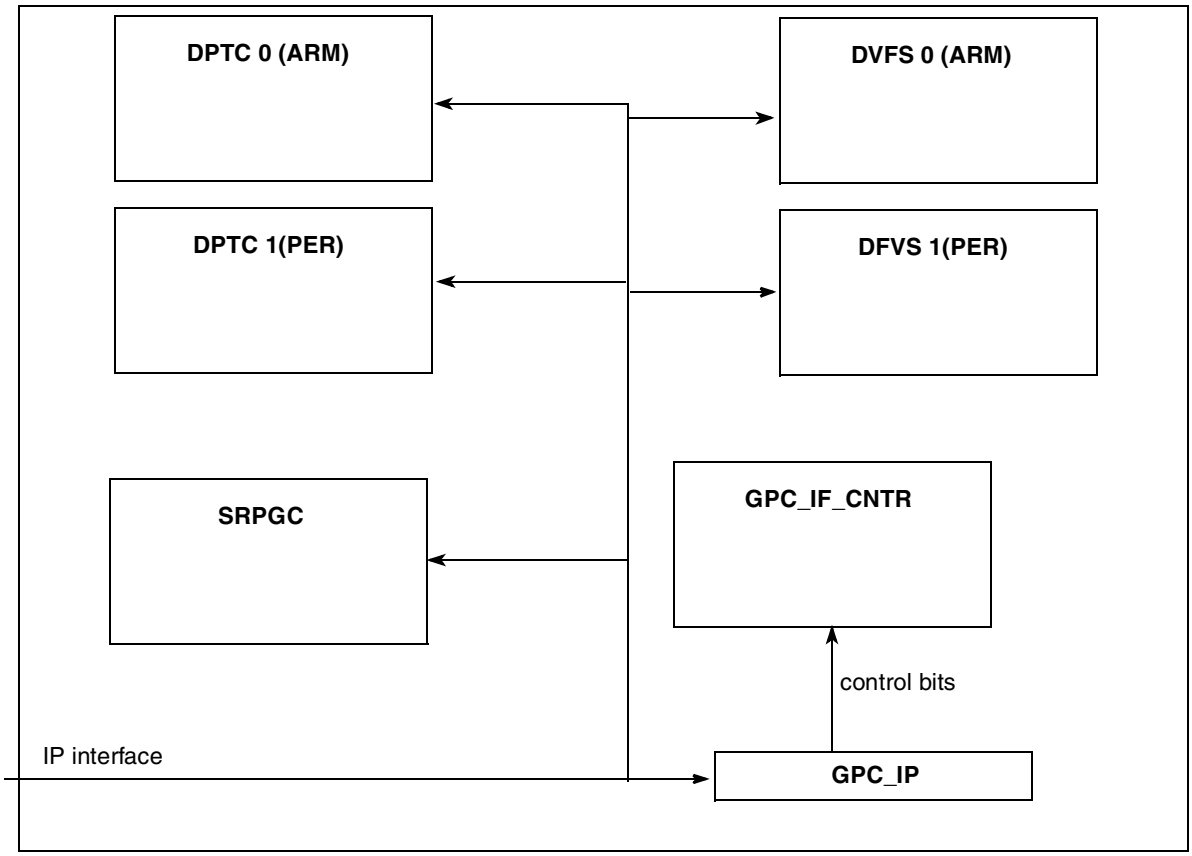

Figure 34-1. GPC Block Diagram

34.1.1 Features

The main features are as follows:

- Simultaneous usage of DVFS and DPTC of each domain.
- Internal counter for bypass of voltage_ready signal
- Possibility of switching between CSPI usage and I2C.

34.2 Memory Map and Register Definition

This section provides a memory map, a key to register conventions, and detailed descriptions of all registers.

34.2.1 Memory Map

Table 34-1 shows the memory map.

Table 34-1. Memory Map [1]

34.2.2 Register Summary

The conventions in Figure 34-2 and Table 34-2 serve as a key for the register summary and individual register diagrams.

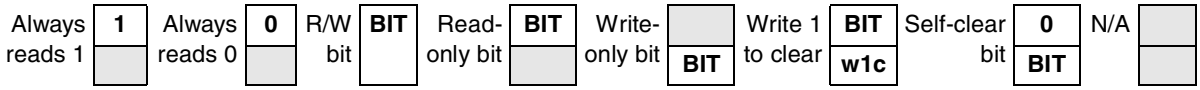

Figure 34-2. Key to Register Fields

Table 34-2 provides a key for register figures and tables and the register summary.

Table 34-2. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.

Table 34-2. Register Conventions (continued)

Convention	Description
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 34-3 shows the GPC register summary.

Figure 34-3.

Describe register functions in tables, as shown in Table 34-4.

Table 34-4. Register Field Descriptions

Field[1]	Description
31-27	reserved
26	CSPI - CSPI or I2C is used (hw trigger will be generated or irq2 will be sent for PMIC) 0 - default - I2C is in use 1 - CSPI is in use
25	IRQ2M - int2 (for I2C) masking 0 - int2 will be sent by GPC FSM if CSPI is ‘0’ (I2C is in use) 1 - default - int2 is masked, but GPC FSM will wait for INT2 bit to be negated by writing ‘1’, if CSPI is ‘0’.

Table 34-4. Register Field Descriptions (continued)

Field[1]	Description
24	IRQ2 - status bit, write 1 to clear.
23-22	Reserved
21	GPCIRQM - GPC interrupt/event masking 1 - interrupt/event is masked 0 - not masked
20	GPCIRQ - GPC will generate ARM IRQ or SDMA event, as a result of DVFS or DPTC change requests 1 - GPC will generate ARM IRQ 0 - GPC will generate SDMA event
19	DPTC1CR - DPTC1 (PER) Change request (bit is read-only) 1 - DPTC1 is requesting for voltage update 0 - DPTC1 has no request
18	DPTC0CR - DPTC0 (ARM) Change request (bit is read-only) 1 - DPTC0 is requesting for voltage update 0 - DPTC0 has no request
17	DVFS1CR - DVFS1 (PER) Change request (bit is read-only) 1 - DVFS1 is requesting for frequency/voltage update 0 - DVFS1 has no request
16	DVFS0CR - DVFS0 (ARM) Change request (bit is read-only) 1 - DVFS0 is requesting for frequency/voltage update 0 - DVFS0 has no request
15	ADU - ARM domain freq/voltage update needed 1 - ARM domain frequency and/or voltage update needed 0 - PER domain frequency and/or voltage update needed
14	STRT - Controller start Controller operation will be started when bit set to “1”. Bit will be set automatically to “0” when frequency / voltage change finished. There is still a possibility to write “0” by s/w. 1 - Controller operation in progress. No IRQ is allowed during voltage update procedure (IRQ will be masked) 0 - Controller operation finished. New freq/voltage change request is available
13	FUPD - frequency update needed 1 - frequency update needed 0 - frequency updated is not needed
12-4	Reserved
3-0	HTRI - Hardware Triggering Register Index Indicates which one of the CSPI h/t register will be written to the PMIC. 0000 - register #0 will be triggered, 0001 - register #1 will be triggered, 0010 - register #3 will be triggered...

3-2	Reserved
1	NEONPUR - NEON Power Up Request. Assertion causes Neon PowerDown state machine to change state from PowerDown to PowerUp request. Will clear itself after a single clock.
0	NEONPDR - NEON Power Down Request. Assertion starts Neon PowerDown state machine. Will clear itself after a single clock.

1 This footnote applies to the entire column. Field columns in a register field description table should use TBItem_C paragraph format.

34.3 Functional Description

GPC block includes the following sub-blocks of Advanced Power Saving techniques:

- 2 DVFS sub-blocks (CPU and peripherals clock/power domains)
- 2 DPTC sub-blocks (CPU and peripherals power domains)
- SRPG sub-block for all SRPG-ed modules: CPU, VPU, GPU, IPUv3, EMIv2, LPMIX and SIPMIX

Each of sub-blocks has its own IP registers. As well, GPC includes an arbitration block of DVFS and DPTC voltage/frequency updates.

In the following sections the global operation of the sub-blocks is described. For further details of DPTC, DVFS and SRPG refer appropriate sub-block Block Guide document.

34.3.1 DVFS — Dynamic Voltage & Frequency Scaling

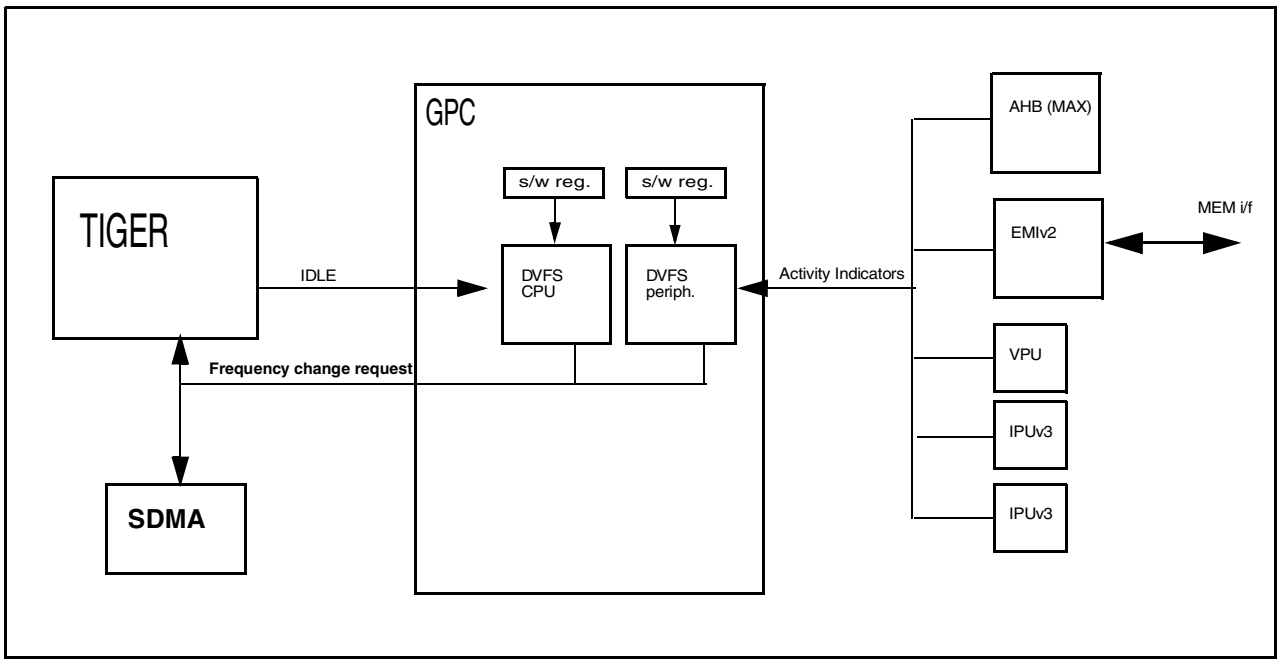
Dynamic Voltage & Frequency Scaling is a well-known technique to reduce power consumption in mobile devices.

In order to improve power saving efficiency, DVFS is applied both on CPU domain and peripherals domain. CPU-domain DVFS uses mainly ARM's IDLE signal for load monitoring, but also uses s/w writable info as secondary inputs. Peripherals-domain DVFS uses hardware accelerators activity signals, bus activity signals and memory activity indicators for load monitoring. Both DVFS load tracking controllers are h/w implemeted, providing: high resolution of load tracking (for higher efficiency), no MIPS requirements from CPU for continuous operation (more power saving, no additional CPU load).

Voltage update requests (to PMIC, via CSPI) may be served in one of the following ways:

- Hardware triggering of CSPI, by GPC
- ARM interrupts serving CSPI

Figure 34-8. DVFS System High Level Diagram



34.3.2 DPTC — Dynamic Process and Temperature Compensation

Dynamic process and temperature compensation is an advanced power saving technique that allows dynamic adjustment of the supply voltage relative to the process corner case and temperature of the chip.

While design of an IC is always done for the worst case process and hot temperature assumptions, in most cases IC will be manufactured in typical process case and will function in room temperature. Better speed performance of the chip in typical conditions allows reducing the supply voltage without impact on chip performance.

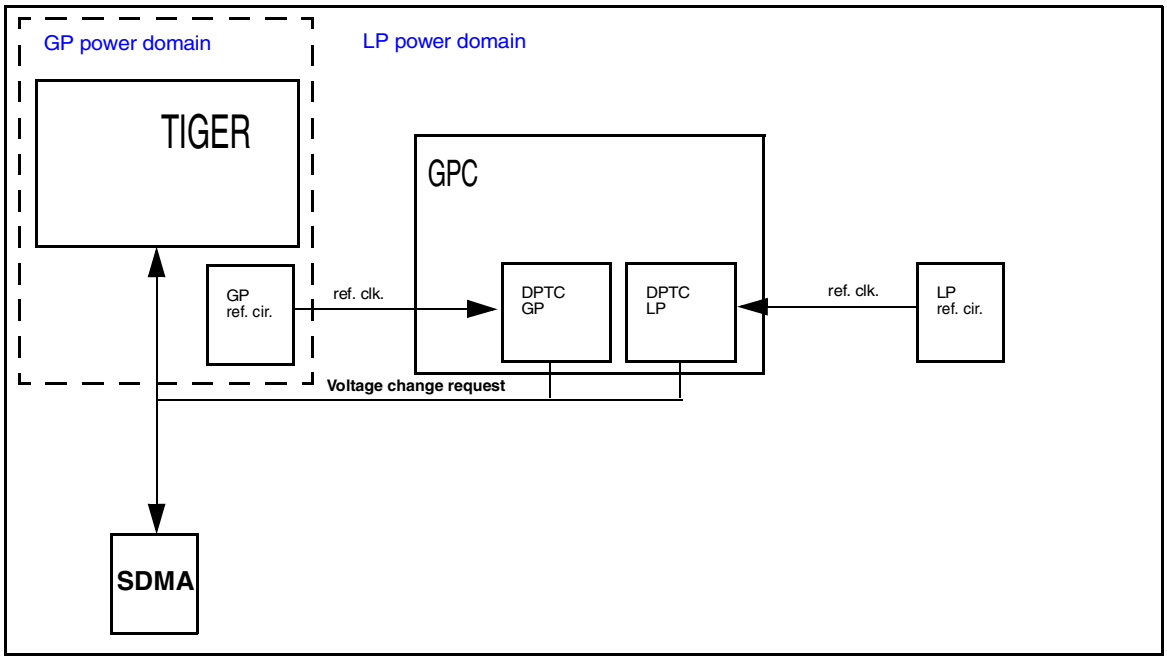
Considering different process flavors for CPU and peripheral power domains of the design, each of the domains will have dedicated DPTC engine, with relevant reference circuits connected.

Voltage update requests (to PMIC, via CSPI or using I2C) may be served in one of the following ways:

- Hardware triggering of CSPI, by GPC
- ARM interrupts serving CSPI
- ARM interrupts serving GPC int2 for I2C

The same engine, but with different reference circuits will be used to detect minimum opertaing voltage for logic part. The same can be used to define minimum operating or/and standby voltage for memory array .

Figure 34-9. DPTC System High Level Diagram



The DPTC spec describes the sequence of DPTC voltage change.

34.3.3 DVFS and DPTC Change Request Sequence Diagrams

Figure and Figure describe the sequence on DVFS or/and DPTC interrupt.

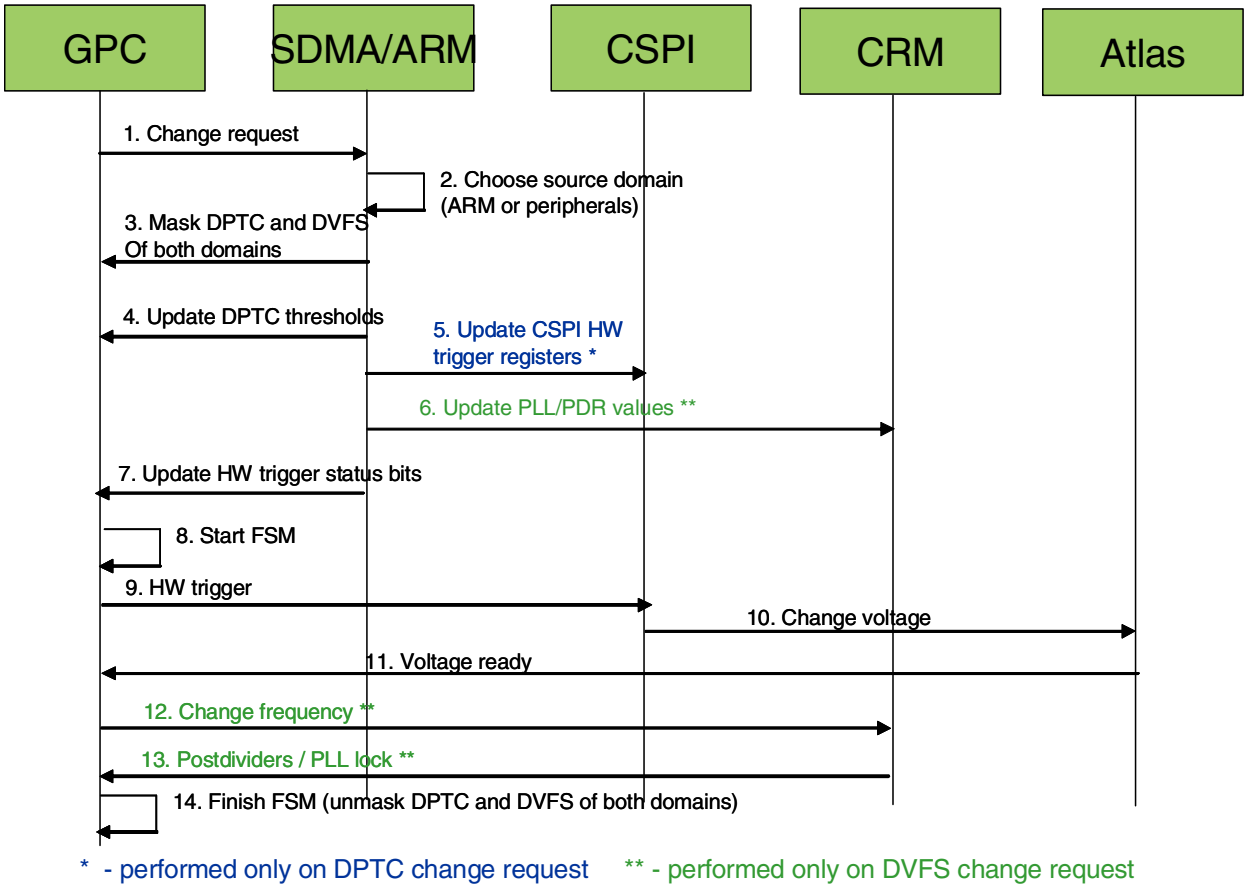


Figure 34-10. DVFS or/and DPTC Interrupt - Frequency Increase full_memories.csv

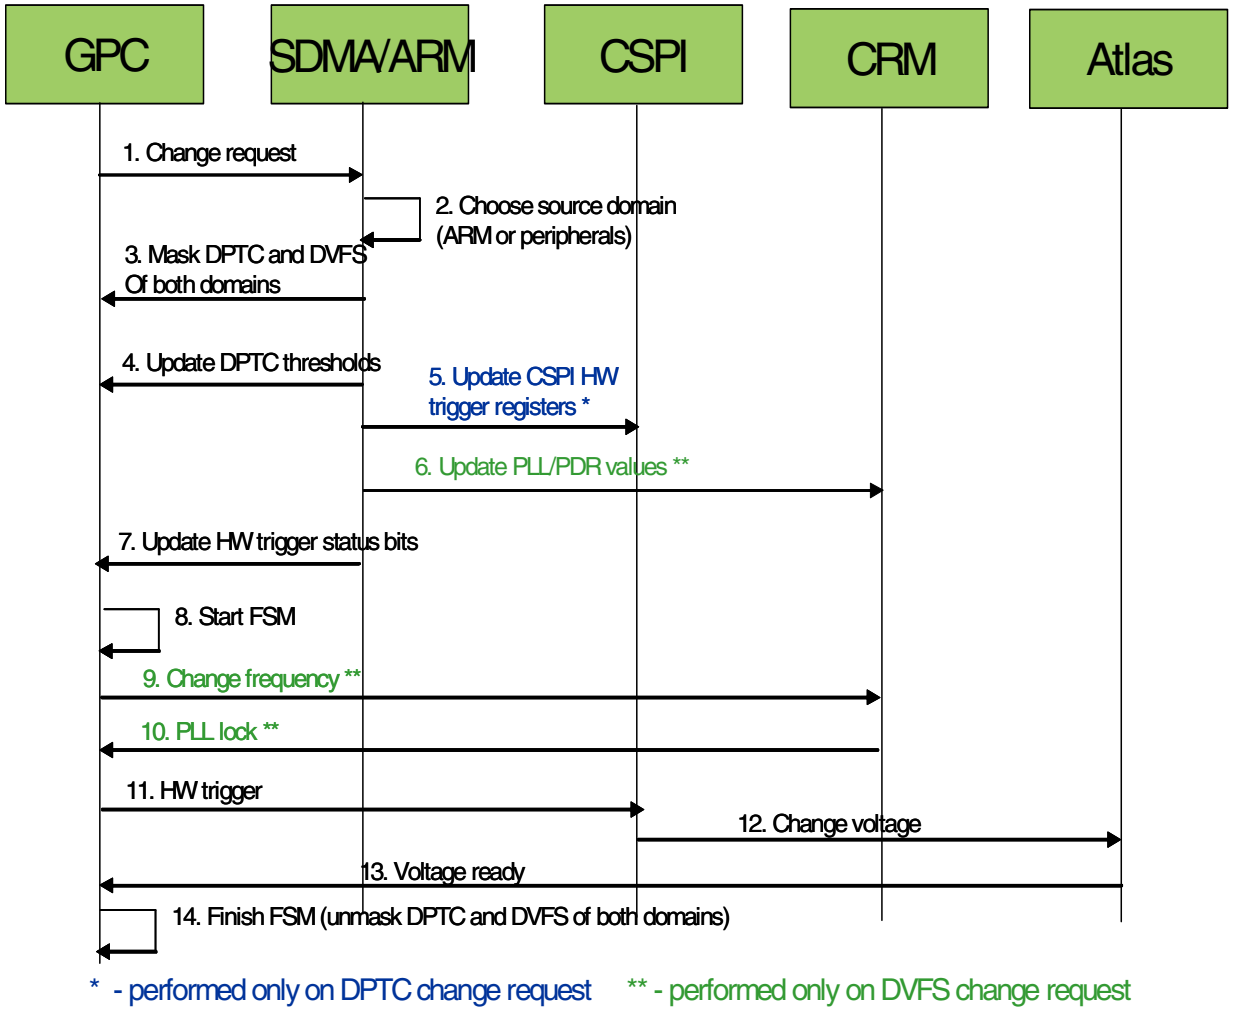

Figure 34-11. DVFS or/and DPTC Interrupt - frequency decrease

DPTC and DVFS modules of CPU and peripheral domains will have one common interrupt line to ARM and DMA request to SDMA. SDMA (or ARM) will choose only one domain to serve. If DPTC and/or DPTC interrupt of the other domainis pending, it will be triggered after the end of the first domain sequence.

Peripherals DVFS frequency change will be performed with post-dividers values update only.

CPU DVFS frequency change can be performed in 2 ways:

- PLL and post-dividers values update
- post-dividers values only update

When PLL update is required, Controller will switch CPU clock to another PLL, will wait until the previous PLL is locked on the required frequency, and then will switch the CPU clock back to the first PLL.

34.3.4 Frequency / Voltage change Controller description

Controller is responsible of correct frequency and voltage update flow.

34.3.4.1 GPC Controller Description

Table 34-12 and Table 34-10 describe the **GPC DVFS/DPTC state machine and the transition conditions.**

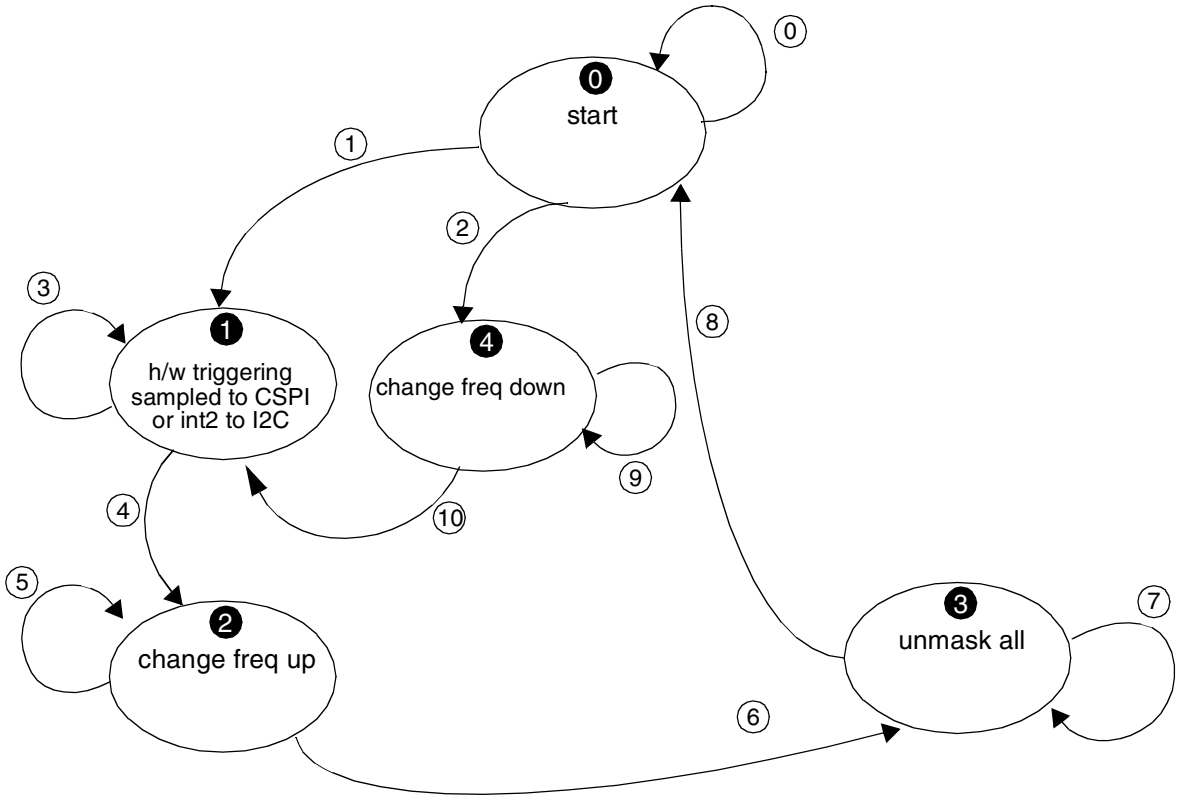

Figure 34-12. GPC DVFS/DPTC State machine

Table 34-10. GPC Transition Conditions

Transition	Transition condition	Output

9	not (10)	1. if (dvfs update dw), trigger freq. change 2. IRQ masked: IRQM=1
10	(dvfs update dw& clk change ack) | !(dvfs update dw) | !freq_update	—

34.3.4.2 CCM Frequency Update Controller Description

Additional State Machine is required in CCM to take care about frequency update sequence, as desribed in Figure 34-13. Table 34-11 lists the CCM Frequency Update Controller transition conditions.

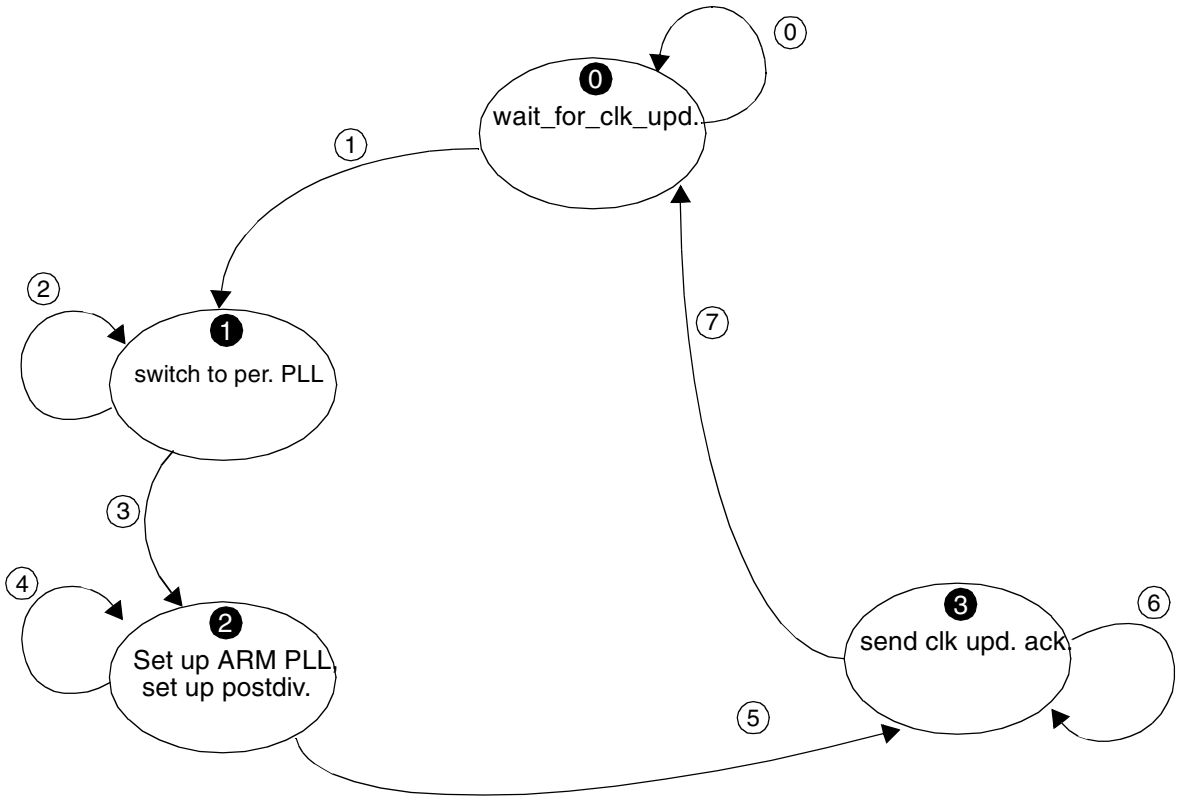

Figure 34-13. CCM Frequency Update Controller State Machine

Table 34-11. CCM Frequency Update Controller Transition Conditions

Transition	Transition condition	Output
0	not (1)	clk upd ack negated
1	clk update request	
2	not (3)	switch ARM clk to per. PLL
3	clk switched to per. PLL	
4	not (5)	apply new PLL settings, if needed apply new postdiv settings if needed
5	ARM PLL & postdiv upd ack.	
6	1 clk	clk update ack to GPC asserted.

Table 34-11. CCM Frequency Update Controller Transition Conditions

Transition	Transition condition	Output
7	not (6)	

34.3.5 State Retention Power Gating (SRPG)

State Retention Power Gating (SRPG) is an advanced power saving technique - the values of FFs are saved, while the supply for the combinational logic is gated. Such special power gating allows significant power saving during low-power (stand-by) states, when no logical operation is needed. Relatively the simple Power Gating techniques, SRPG allows to restore the state very quickly and continue the processing from the state, sampled before stand-by period.

SRPG Controller manages all the related signals for entering and exiting SRPG state of relevant modules. Not all the modules have SRPG design.

SRPG power down sequence:

All the modules except MEGAMIX get power down request, only after all the modules acknowledge received, and only if CTA8 was power downed, MEGAMIX receives power down request. The power to MEGAMIX is turned off only after the lock ready flags of all three PLLs are down.

SRPG power up sequence:

The modules receive power up request in following order:

MEGAMIX, IPU, VPU, GPU, EMI, (NEON and CTA8).

See Chapter 11, “Power Management,” for more information.

34.3.6 PMIC Interface Requirements for APM Support

PMIC APM interface is done through SPI protocol by enhanced CSPI module with HW triggering. Below is the description of modules requirements for APM support.

- CSPI
  - Will have 16 HW trigger registers.
  - Each register will be 32 bits:
    - 1 bits read/write (always write)
    - 6 bits address
    - 1 bit not used
    - 24 bits data
  - Each register will have an associated signal that starts the transaction to Atlas
- SDMA/ARM
  - will update the values of the registers on DPTC interrupt for future DVFS frequencies (up to 14 on ARM domain, 2 on peripheral domain).

- GPC
  - will have a 4-bit select register to select one of 16 HW trigger signals, if CSPI is used.
  - will trigger the signals during DPTC/DVFS state machine according to select register value.
- PMIC
  - Only one 24-bit register should be updated for voltage change. One CSPI HW trigger will be able to make the change, or I2C will get int2.

Ability to use SDMA for h/w controllers inputs analysis and/or CSPI programming will provide high level of s/w flexibility and will be kept for backup.

Chapter 35
General Purpose Input/Output (GPIO)

The General Purpose Input/Output (GPIO) module provides 32 bits of bidirectional, general-purpose input and output signals. Figure 35-1 is a block diagram of the GPIO.

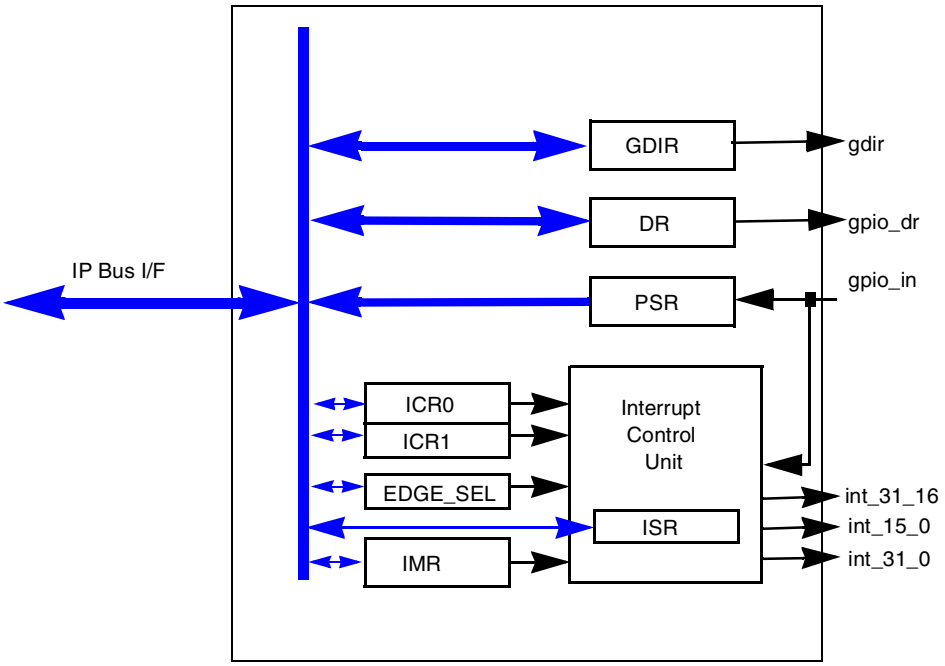

Figure 35-1. GPIO Block Diagram

35.1 Overview

The GPIO peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs. When GPIO is configured as an output, users can write to an internal register to control the state driven on the output pin. When GPIO is configured as an input, users can detect the state of the input by reading the state of an internal register.

The GPIO module is one of the modules controlling the IOMUX of the SoC (System on a Chip). Figure 35-2 shows the SoC muxing scheme.

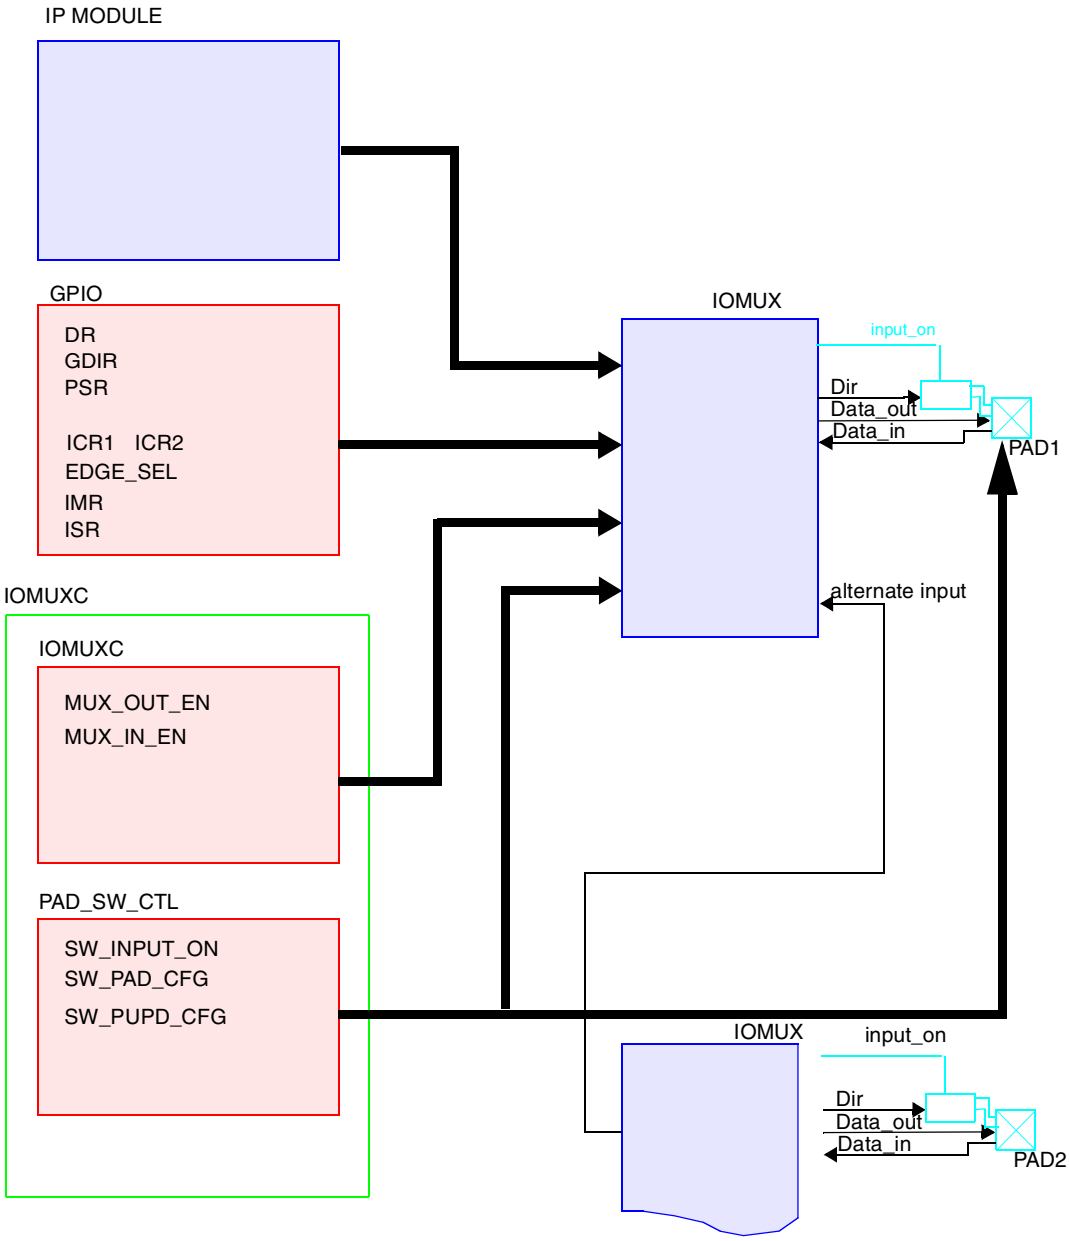

Figure 35-2. SoC IOMUX scheme

The functionality is provided through eight registers, an edge-detect circuit, and an interrupt generation logic.

The eight registers are as follows:

- DR—Data Register (32 bit)
- GDIR—Data Direction Register (32 bit)
- PSR—Pad Sample Register (32 bit)

- ICR (ICR1, ICR2)—Two Interrupt Control Registers (2 × 32 bit)
- EDGE_SEL—Edge Select register, selects edge detection.
- IMR—Interrupt Mask Register (32 bit)
- ISR—Interrupt Status Register (32 bit)

The data register is used to drive data from this register to I/O pins. Read access to the data register returns the value stored in the register or the value of the pad depending on the corresponding GDIR bit.

The data direction register controls the direction of the pin through the I/O multiplexer. Writing a one to this register configures the pin as an output, while a zero configures it as an input.

Each GPIO input has a dedicated edge-detect circuit that can be configured through software to detect rising edges, falling edges, a logic low-level, or a logic high-level on the input pin. Thirty two interrupts are supported. Two registers are used for this configuration, the interrupt configuration register (ICR1 and ICR2). Two bits are assigned to each GPIO pin, selecting one of the four possible detection methods. The EDGE_SEL register can override the ICR selection which forces edge detect (falling or rising edge).

The outputs of the edge detect circuits are optionally masked by setting the corresponding bit in the interrupt mask register (IMR). These qualified outputs are ORed together to generate three interrupt lines:

- interrupt_or_31_16 : 1One-bit interrupt OR of 16 high interrupts.
- interrupt_or_15_0 : 1One-bit interrupt OR of 16 low interrupts.
- ipi_gpio_int : One-bit interrupt OR of 32 interrupts.
- ipi_gpio_int32 : 32 bit, All Interrupts Out.

35.1.1 Features

The GPIO includes the following features:

- General purpose input/output logic supports the following:
  - Ability to drive a specific data to the pad using DR register
  - Ability to control the direction of the pad using the GDIR register
  - The core has the ability to sample the status of the corresponding pads by reading the PSR register.
- GPIO interrupts support the following:
  - Ability to support up to 32 interrupts
  - Ability to identify interrupt edges
  - Generation of three active high interrupts to the SoC interrupt controller

35.2 External Signal Description

In addition to the IP bus interface, the GPIO has the signals listed in Table 35-1.

Table 35-1. Signal Properties

Name	Port	Function	Reset	Pull Up
ipp_do_gpio_gdir	—	GPIO direction. This is the GPIO direction signal that controls the direction of the pad if the IOMUX is in GPIO mode. 0 GPIO is configured as input. 1 GPIO is configured as output.	0	—
ipp_do_gpio_dr	—	GPIO Data Register. This is the GPIO data signal. If the IOMUX is in GPIO mode and the corresponding direction bit is set to output, this signal will be driven to the pad.	0	—
ipp_ind_g_in	—	GPIO Input. This is the input line coming from the IOMUX, so the core can read the status of the pad.	0	—
ipi_gpio_int31_16	—	GPIO outputs functioning as interrupt—MSB ORed interrupts. One-bit interrupt OR of 16 high interrupts.	0	—
ipi_gpio_int15_0	—	GPIO outputs functioning as interrupt—LSB ORed interrupts. One-bit interrupt OR of 16 low interrupts.	0	—
ipi_gpio_int	—	GPIO outputs functioning as interrupt—ORed interrupts. One-bit interrupt OR of 32 interrupts.	0	—
ipi_gpio_int32	—	GPIO outputs functioning as interrupt—32-bit, All Interrupt Out.	0	—
ipg_clk_s	—	The only input clock—ipg_clk, gated by the module module_en signal. The clock is working only when GPIO is accessed.	—	—
ips_rdata	—	Read data bus.	—	—
ips_xfr_wait	—	Wait cycle. This signal indicates GPIO does not wish to complete transfer in the current cycle.	—	—
$\overline{\text{ipg\_hard\_async\_reset}}$	—	Hardware reset signal.	—	—
ips_module_en	—	Module enable input.	—	—
ips_addr	—	IP address bus.	—	—
ips_wdata	—	Write data bus. Data to write into target	—	—
ips_rwb	—	This signal is the read/write control signal. This signal Indicates a read transfer when asserted and a write transfer when negated.	—	—
ips_byte_31_24	—	These signals are byte enables 31 to 24 only—32-bit access available.	—	—
ips_byte_23_16	—	These signals are byte enables 23 to 16 only—32-bit access available.	—	—
ips_byte_15_8	—	These signals are byte enables 15 to 8 only—32-bit access available.	—	—
ips_byte_7_0	—	These signals are byte enables 7 to 0 only—32-bit access available.	—	—
ipt_test_mode	—	This signal is the scan mode signal.	—	—
ipt_test_async_se	—	This signal enables the bypass reset.	—	—
ipt_test_clk_se	—	This signal enables the clock (clk) in scan mode.	—	—

35.3 Memory Map and Register Definition

There are eight GPIO registers. All registers are accessible from the IP interface. Only 32-bit access is supported.

35.3.1 Memory Map

Table 35-2 shows the GPIO memory map.

Table 35-2. GPIO Memory Map [1]

Address	Register	Access	Reset Value	Section/Page
0xBASE+0x000 (DR)	GPIO Data	R/W	0X0000_0000	35.3.3.1/35-7

35.3.2 Register Summary

The following definitions serve as a key for the WMSG register summary and individual register diagrams.

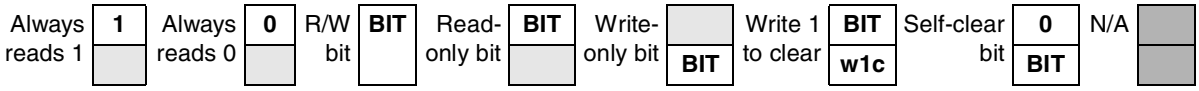

Figure 35-3. Key to Register Fields

Table 35-3 provides a key for register figures and the register summary table.

Table 35-3. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).

Table 35-3. Register Conventions (continued)

Convention	Description
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero (previously labeled slfclr).
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 35-4 shows the GPIO register summary.

35.3.3 Register Descriptions

This section contains the detailed register descriptions for the GPIO registers.

35.3.3.1 GPIO Data Register (DR)

The GPIO DR register is a 32-bit register. Each bit stores a data to be driven to the pad at all times. If the IOMUX is in GPIO mode and the direction is output, this data will be driven there. If the direction is input, a read action to DR bit reflects the value on the corresponded pad. Two wait states are required in read access for synchronization.

The data returned when reading the DR register is a function of the IOMUX input mode settings and the corresponding GDIR bit, as follows.

- If GDIR == 1 && IOMUX input mode == GPIO, reading DR returns the content of the DR register
- If GDIR == 0 && IOMUX input mode == GPIO, reading DR returns the pad's value
- If GDIR == 1 && IOMUX input mode != GPIO, reading DR returns the content of the DR register
- If GDIR == 0 && IOMUX input mode != GPIO, reading DR returns zero.

Figure 35-4 shows the DR register and Table 35-5 shows the register's field descriptions.

0xBASE+0x000 (DR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DR[31:16]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DR[15:0]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Figure 35-4. GPIO Data Register (DR)

Table 35-5. DR Field Descriptions

Field	Description
31–0 DR	Data bits. This register defines the value of the GPIO output when the pin is configured as an output (GDIR[n]=1). Writes to this register are stored in a register. Reading DR returns the value stored in the register if the pin is configured as an output (GDIR=1), or the state of the I/O pin if configured as an input (GDIR[n]=0). Settings: The I/O multiplexer associated with each bit must be configured for GPIO for the function to affect the state of the pin. Reading the data register with the input path disabled will always return a zero value.

35.3.3.2 GPIO Direction Register (GDIR)

The GPIO GDIR register is a 32-bit register that functions as direction control when the IOMUX direction is controlled by this bit. Each bit specifies the direction of a specific pad. The mapping of each DIR bit to a corresponding pad is determined on the SoC's pin assignment and IOMUX table. Figure 35-5 shows the GDIR register and Table 35-6 shows the register's field descriptions.

0xBASE+0x004 (GDIR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	GDIR[31:16]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	GDIR[15:0]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Figure 35-5. GPIO Direction Register (GDIR)

Table 35-6. GDIR Field Descriptions

Field	Description
31–0 GDIR	GPIO Direction bits. Bit i of this register defines the direction of the GPIO[i] signal. 0 GPIO is configured as input. 1 GPIO is configured as output. **Note:** GDIR affects only the direction of the I/O pin when the corresponding bit in the I/O MUX is configured for GPIO.

35.3.3.3 GPIO Pad Status Register (PSR)

The GPIO PSR register is a 32-bit read-only register. Each bit stores the value of the corresponding pad. This register is clocked with the ipg_clk_s clock, meaning that the value on the pad is sampled only when accessing this location. Two wait states are required any time this register is accessed for synchronization. Figure 35-6 shows the PSR register and Table 35-7 shows the register's field descriptions.

NOTE

PSR[i]—pad sample

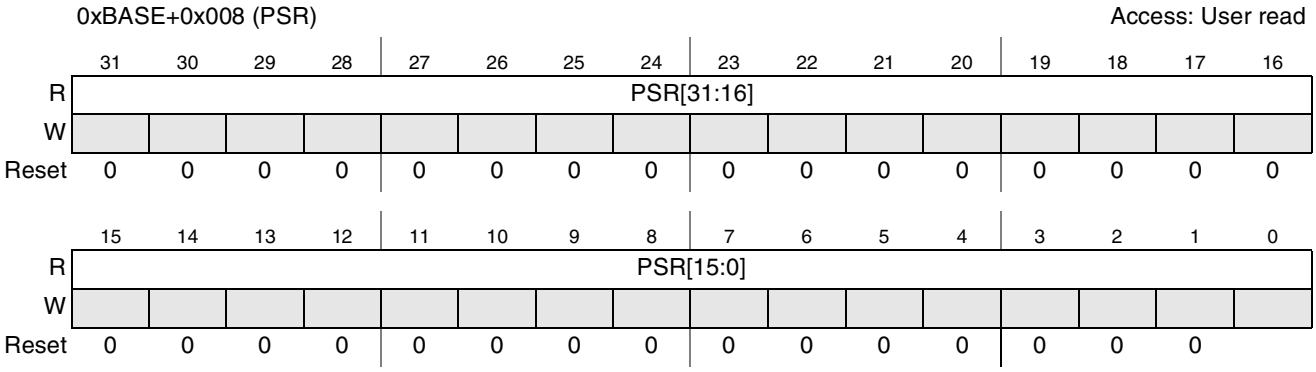

Figure 35-6. GPIO Pad Status Register (PSR)

Table 35-7. PSR Field Descriptions

Field	Description
31–0 PSR	GPIO Pad Status bits (status bits). Reading PSR returns the state of the corresponding pad. Settings: The I/O multiplexer associated with each bit must be configured for GPIO for the function to affect the state of the pin.

35.3.3.4 GPIO Interrupt Configuration Register1 (ICR1)

The GPIO ICR1 register is a 32-bit register. Each set of 2 bits specifies the interrupt configuration for each corresponding interrupt line. There is total support for 16 interrupts. Figure 35-7 shows the ICR1 register, and Table 35-8 shows the register's field descriptions.

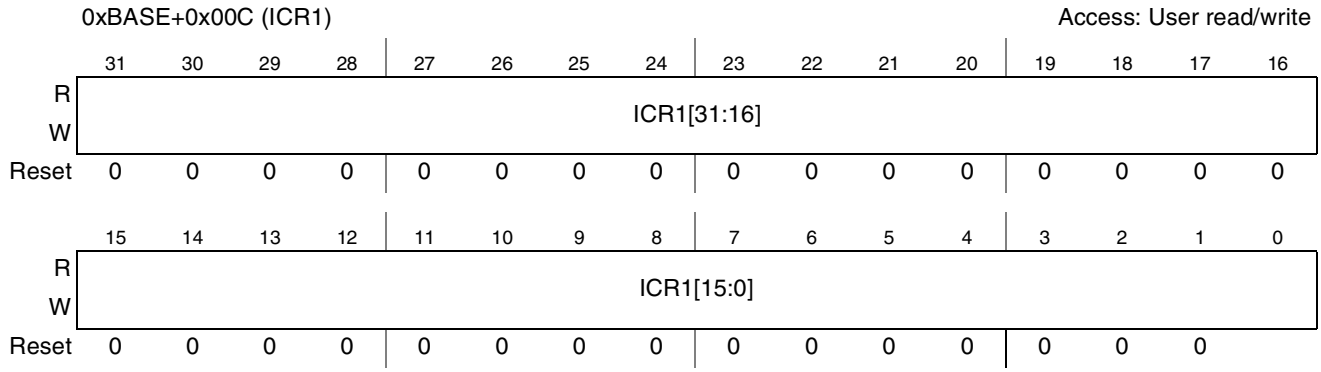

Figure 35-7. GPIO Interrupt Configuration Register1 (ICR1)

Table 35-8. ICR1 Field Descriptions

Field	Description
31–0 ICR1	Interrupt Configuration 1 bits. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: interrupts (i) 0 to 15, when bits {ICR1[2*i+1],ICR1[2*i]} are: 00 The interrupt i is low-level sensitive. 01 The interrupt i is high-level sensitive. 10 The interrupt i is rise-edge sensitive. 11 The interrupt i is fall-edge sensitive.

35.3.3.5 GPIO Interrupt Configuration Register2 (ICR2)

The GPIO ICR2 register is a 32-bit register. Each set of 2 bits specifies the interrupt configuration for each corresponding interrupt line. There is total support for 16 interrupts. Figure 35-8 shows the ICR2 register and Table 35-9 shows the register's field descriptions.

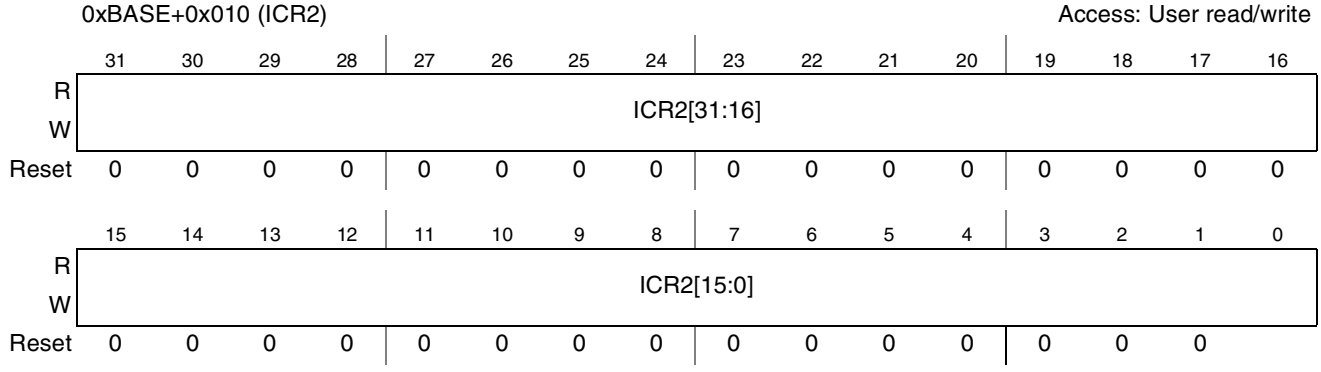

Figure 35-8. GPIO Interrupt Configuration Register2 (ICR2)

Table 35-9. ICR2 Field Descriptions

Field	Description
31–0 ICR2	Interrupt Configuration 2 bits. This register controls the active condition of the interrupt function for lines 31 to 15. Settings: interrupts (i) 0 to 15, when bits {ICR2[2*i+1],ICR2[2*i]} are: 00 The interrupt i+16 is low-level sensitive. 01 The interrupt i+16 is high-level sensitive. 10 The interrupt i+16 is rise-edge sensitive. 11 The interrupt i+16 is fall-edge sensitive.

35.3.3.6 GPIO Interrupt Mask Register (IMR)

The GPIO IMR is a 32 bit register. Each bit is the interrupt masking bit for each interrupt line. Figure 35-9 shows the IMR register and Table 35-10 shows the register's field descriptions.

0xBASE+0x014 (IMR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	IMR[31:16]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	IMR[15:0]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Figure 35-9. GPIO Interrupt Mask Register (IMR)

Table 35-10. IMR Field Descriptions

Field	Description
31–0 IMR	Interrupt Mask bits. This register is used to enable/disable the interrupt function on each of the 32 GPIO pins. Settings: For i from 0 to 31, when IMR[i] is: 0 The interrupt i is disabled. 1 The interrupt i is enabled.

35.3.3.7 GPIO Interrupt Status Register (ISR)

The GPIO ISR is a 32- bit register that functions as interrupt. Each bit indicates whether an interrupt has occurred. When an interrupt event occurs, the bit in this register is set. The condition for setting of the bit is determined by the Interrupt Configuration Register (ICR) and the input that satisfies the configuration.

Two wait states are required in read access for synchronization. One wait state is required for reset. Figure 35-10 shows the ISR register and Table 35-11 shows the register's field descriptions.

0xBASE+0x018 (ISR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	ISR[31:16]															
W	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ISR[15:0]															
W	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Figure 35-10. GPIO Interrupt Status Register (ISR)

Table 35-11. ISR Field Descriptions

Field	Description
31–0 IMR	Interrupt Status bits — Bit i of this register is asserted (active high) when the active condition is detected on the GPIO input and is waiting for service. The value of this register is independent of the value in the IMR register. When the active condition has been detected, the corresponding bit remains set until cleared by software. Status flags are cleared by writing a 1 to the corresponding bit position.

35.3.3.8 GPIO Edge Select Register (EDGE_SEL)

The GPIO EDGE_SEL register is a 32-bit register. There is total support for 32 interrupts. Figure 35-8 shows the EDGE_SEL register and Table 35-9 shows the register's field descriptions. This register overrides the ICR registers configuration to select edge detection rising edge or falling edge. This register was added for backward compatibility reasons, its reset value is set to disregard its functionality.

Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	EDGE_SEL[31:16]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	EDGE_SEL[15:0]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Figure 35-11. GPIO Interrupt Configuration Register2 (ICR2)

Table 35-12. ICR2 Field Descriptions

Field	Description
31–0 EDGE_SEL	When bit[n] is set, the GPIO disregards ICR functionality and detects any edge on the corresponding interrupt input bit.

35.4 Functional Description

This section describes the GPIO function and programming.

35.4.1 GPIO Function

A GPIO pin can operate as a general-purpose input/output when the IOMUX functions in GPIO mode. Each GPIO pin can be independently configured as either an input or an output using the GPIO Direction Register (GDIR). When configured as an output (GDIR bit = 1), the value in the data bit in the GPIO Data Register (DR) is driven on the corresponding GPn pin. When configured as an input (GDIR bit = 0), the state of the input can be read from the corresponding PSR bit.

35.4.2 GPIO Programming

This section explains the programming sequence for reading and writing values from pad.

35.4.2.1 Read Value from Pad

The programming sequence should be as follows:

1. Configure IOMUX to select GPIO mode (Via IOMUXC).
2. Configure GPIO Direction Register to input.
3. Read value from Data register/Pad Status register.

The pseudocode description for reading [pad3:pad0] values is as follows:

```
write sw_mux_ctl_<pad0>_<pad1>_<pad2>_<pad3> , 32'h00000000          // SET PADS TO GPIO MODE.
write GDIR[31:4,pad3_bit,pad2_bit, pad1_bit, pad0_bit,] 32'hxxxxxxx0 // SET GDIR TO INPUT.
read DR                                                              // READ PAD VALUE FROM DR.
read PSR                                                             // READ PAD VALUE FROM PSR.
```

NOTE

While GPIO direction is set to input (GDIR = 0), a read access to DR does not return DR data. Instead, it returns the PSR data, which is the corresponding pad value.

35.4.2.2 Write Value to Pad

The programming sequence should be as follows:

1. Configure IOMUXto select GPIO mode (Via IOMUXC).

2. Configure GPIO Direction Register to output.
3. Write value to Data Register (DR).

The pseudocode description to drive 4’b0101 on [pad3:pad0] is as follows:

```
write sw_mux_ctl_<pad0>_<pad1>_<pad2>_<pad3> , 32’h00000000          // SET PADS TO GPIO MODE.
write GDIR[31:4,pad3_bit,pad2_bit, pad1_bit, pad0_bit,] 32’hxxxxxxxF // SET GDIR TO OUTPUT.
write DR, 32’hxxxxxxx5                                               // WRITE PAD VALUE TO DR.
read_cmp PSR, 32’hxxxxxxx5                                     // READ PAD VALUE FROM PSR ONLY.
```

NOTE

While GPIO direction is set to output, real pad value can only be verified through PSR.

35.4.3 Interrupt Control Unit

In addition to the general-purpose input/output function, the edge-detect logic in the GPIO peripheral reflects whether a transition has occurred on a given GPIO signal that is configured as an input (GDIR bit = 0). The GPIO signal transition is reflected in the GPIO ICR registers. The GPIO ICR registers enables to configure each interrupt input to its sensitivity case (low-to-high transition; high-to-low transition; low; high).

The interrupt control unit is built of 32 interrupt control sub units. Each sub unit handles a single interrupt line.

.

Chapter 36
General Purpose Timer (GPT)

36.1 Introduction

A block diagram of the General Purpose Timer (GPT) outlining its basic functionality is shown in Figure 36-1.

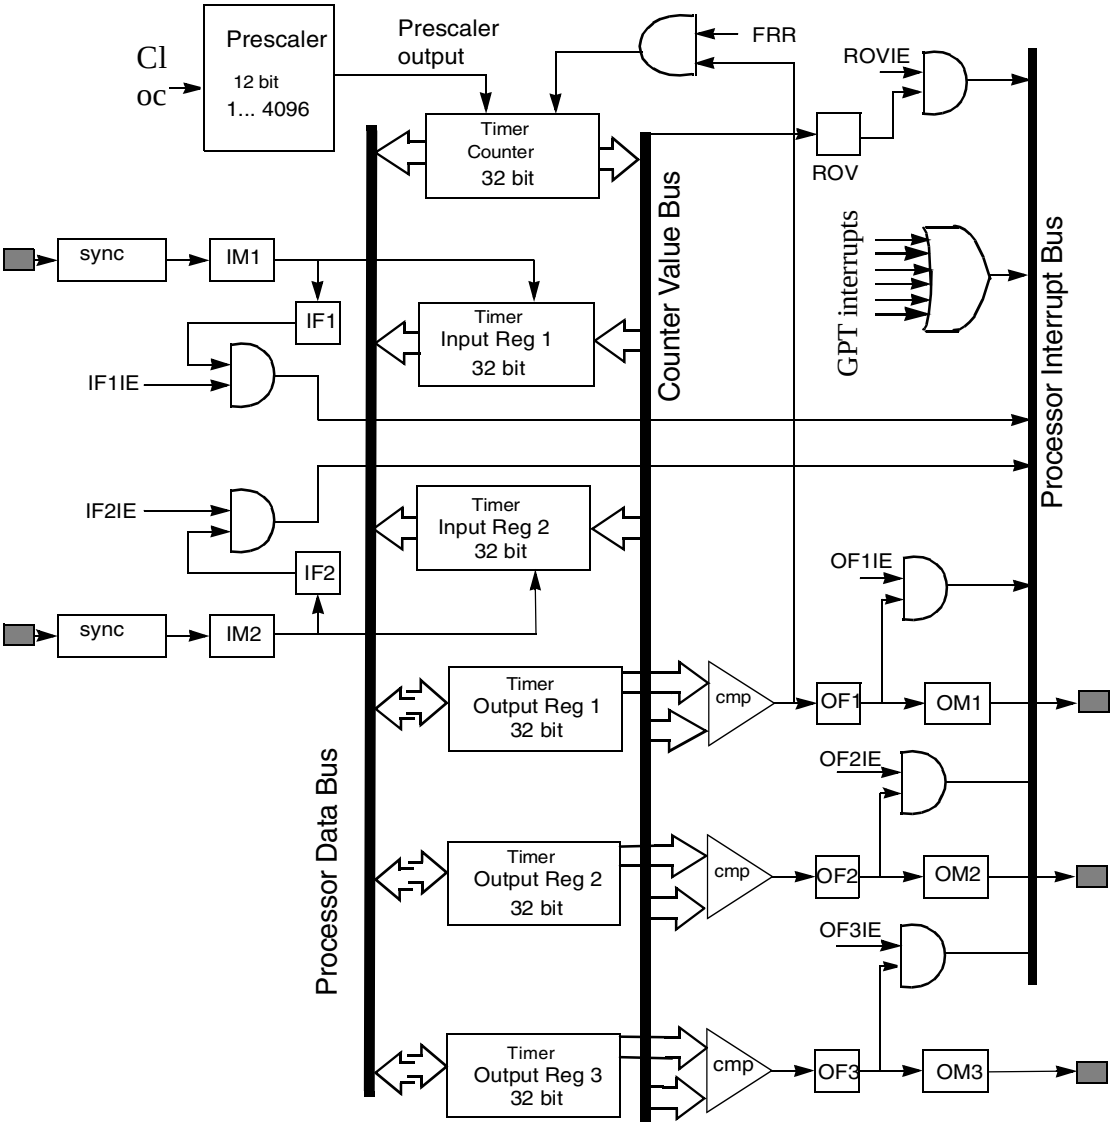

Figure 36-1. General Purpose Timer (GPT) Block Diagram

Figure 36-2 shows the GPT functional clocking scheme

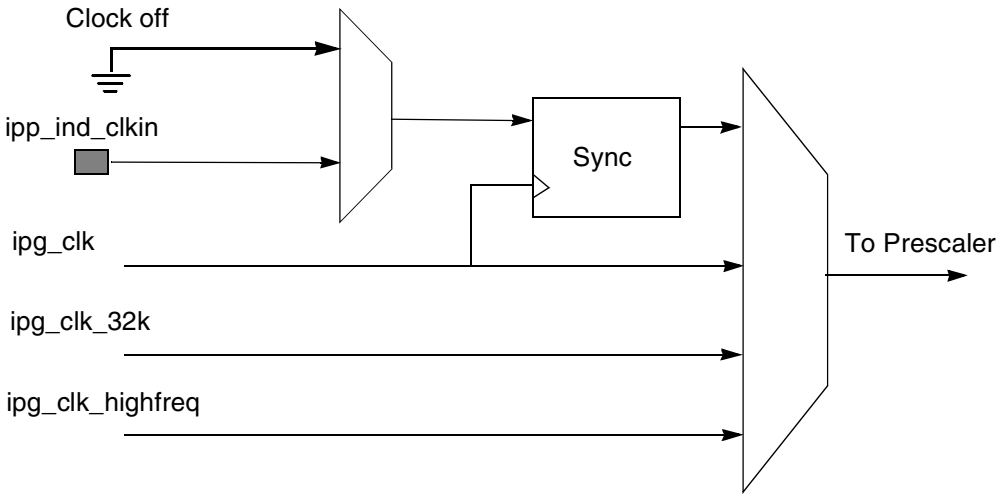

Figure 36-2. GPT Counter Clocks Diagram

36.1.1 Overview

The General purpose timer (GPT) has a 32 bit up-counter. The timer counter value can be captured in a register using an event on an external pin. The capture trigger can be programmed to be a rising or/and falling edge. The GPT can also generate an event on ipp_do_cmpout pins and an interrupt when the timer reaches a programmed value. It has a 12 bit prescaler providing a programmable clock frequency derived from multiple clock sources.

36.1.2 Features

The features are as follows:

- One 32 bit up-counter with clock source selection, including external clock.
- Two input capture channels with programmable trigger edge.
- Three output compare channels with programmable output mode. Forced compare feature also available.
- Can be programmed to be active in low power and debug modes
- Interrupt generation at capture, compare, rollover events.
- Restart or free-run modes for counter operation.

36.1.3 Modes of Operation

The GPT can be programmed to run in Free-run or Restart modes.

In restart mode, (selectable through control register), compare channel 1 behaves differently than the other two compare channels. For compare channel 1, every time the counter reaches the compared value, it resets and starts again from 0x0000_0000. Any write access to the compare register of channel 1 results in the GPT counter being reset. This is to avoid possible missing of compare event when compare value is

changed from a higher to lower value while counting is going on. For the other two compare channels, the compare event occurs, but the counter is not reset.

In free-run mode, the compare event occurs for all three channels, and the counter value is not reset. The counter continues to count until 0xFFFF_FFFF and rolls over to 0x0000_0000.

36.2 Signal Description

The GPT follows IP Bus protocol for interfacing with the Processor core. It does not have any interface signals with any other module inside the chip except for the clock and reset inputs from the Clock and Reset Controller module and the interrupt signals to the processor interrupt handler.

There are functional and clock inputs and functional output signals going outside the chip boundary. Table 36-1 outlines these signals.

Table 36-1. External Signal Description

Name	Direction	Function	Reset State	Pull up
ipp_ind_clkin	Input	Input pin for external clock on which counter can be run	—	Passive Hysteresis
ipp_ind_capin1	Input	Input pin for capture event for capture channel 1	—	Passive
ipp_ind_capin2	Input	Input pin for capture event for capture channel 2	—	Passive
ipp_do_cmpout1	Output	Output pin for indication of compare event occurrence in compare channel 1	0	Passive
ipp_do_cmpout2	Output	Output pin for indication of compare event occurrence in compare channel 2	0	Passive
ipp_do_cmpout3	Output	Output pin for indication of compare event occurrence in compare channel 3	0	Passive

36.2.1 External Signals

This section describes the six signals (three input and three output) in the GPT module that are to be connected to the chip pads.

36.2.2 ipp_ind_clkin — External Clock Input

The GPT counter can be run on external clock from outside the chip and this is the input pin on which this clock is available. This clock is treated as asynchronous to ipg_clk. Its frequency should be less than 1/4 of frequency of ipg_clk for proper functioning of GPT. Hysteresis characteristics on this pad will be required as this is a clock input.

36.2.3 ipp_ind_capin1, ipp_ind_capin2 — Input Capture Trigger Signals

The GPT counter value can be stored into a register with an event from outside the chip. A positive or/and negative edge on these signals can trigger this capture event. These signals are treated as asynchronous to

ipg_clk. Only those transitions which occur at least a single clock cycle (clock selected to run the counter) after the previous recorded transition will be guaranteed to trigger a capture event.

36.2.4 ipp_do_cmpout1, ipp_do_cmpout2, ipp_do_cmpout3—Output Compare Signals

These signals show the occurrence of output compare event through a specified transition.

36.3 Register Definition and Memory Map

The GPT has 10 user-accessible 32-bit registers. These registers are used to configure, operate, and monitor the state of the GPT.

IP Bus Write access to GPT Control Register (GPTCR) and GPT Output Compare Register1 (GPTOCR1) results in one cycle of wait state (ips_xfr_wait high for 1 cycle), while other valid IP bus accesses are with 0 wait state.

Irrespective of resp_sel signal value, Write access to GPT Status Registers (Read only registers GPTICR1, GPTICR2, GPTCNT) will generate the bus exception (ips_xfr_err signal will be asserted). If resp_sel is driven low then Read/Write access to the unimplemented address space of GPT (ips_addr greater than or equal to $BASE + $028) will generate the bus exception (ips_xfr_err signal will be asserted). If resp_sel is driven high then Read/Write access to the unimplemented address space of GPT will not create any error response.

Table 36-2 shows the register memory map.

Table 36-2. Block Memory Map

Address	Register	Access	Reset Value	Section/Page
0xBASE+0x0000 (GPTCR)	GPT Control Register	32-bit R/W	0x0000_0000	36.3.2.1/36-6

36.3.2 Detailed Register Descriptions

Table 36-4 shows the register terms.

Table 36-4. Register Terms

Term	Description
Grey bit	Unimplemented bit; always reads as zero; writing has no effect.
Access	
S	Supervisor mode only
—	Supervisor or user mode
R	
0	Always read 0.
W	
w1c	A status bit that can be read and cleared by writing a logic 1.
Reset	
0	Resets to a logic 0.
1	Resets to a logic 1.
u	Unaffected by reset.
?	Reset state is unknown.

36.3.2.1 GPT Control Register (GPTCR)

The GPT Control Register (GPTCR) is used to program and configure the GPT for appropriate operation and use of its features. IP Bus Write access to GPT Control Register (GPTCR) results in one cycle of wait state (ips_xfr_wait high for 1 cycle), while IP Bus Read access is with 0 wait state.

Address 0xBASE+0x0000 Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 36-3. GPT Control Register (GPTCR)

Table 36-5. GPT Control Register Field Descriptions

Field	Description
31 FO3	Force Output compare channel 3. The bit causes the pin action programmed for the timer output compare 3 pin (according to the bits OM3 in this register). The OF3 flag in the status register is not affected. This bit is self negating and always read as zero. 0 Writing a 0 has no effect. 1 Causes pin action on timer output compare 3 pin, OF3 flag is not set
30 FO2	Force Output compare channel 2. The bit causes the pin action programmed for the timer output compare 2 pin (according to the bits OM3 in this register). The OF2 flag in the status register is not affected. This bit is self negating and always read as zero. 0 Writing a 0 has no effect 1 Causes pin action on timer output compare 2 pin, OF2 flag is not set
29 FO1	Force Output compare channel 1. The bit causes the pin action programmed for the timer output compare 1pin (according to the bits OM1 in this register). The OF1 flag in the status register is not affected. This bit is self negating and always read as zero. 0 Writing a 0 has no effect 1 Causes pin action on timer output compare 1pin, OF1 flag is not set
28–26 OM3	Output compare channel 3 operating Mode. This bit field specifies the response that a compare event will generate on the output pin of Output Compare channel 3. The toggle, clear and set options cause a change in the output pin only on occurrence of a compare event. When OM3 is programmed as 1xx (active low pulse), the output pin is set to one, immediately on the next input clock, and the low pulse occurs when there is a compare event. This low pulse width is input clock wide. Here input clock means clock selected by CLKSRC bits of GPT Control Register 000 Output disconnected. No response on pin 001 Toggle output pin 010 Clear output pin 011 Set output pin 1xx Generate a active low pulse of one input clock wide on output

Table 36-5. GPT Control Register Field Descriptions (continued)

Field	Description
25–23 OM2	Output compare channel 2 operating Mode. This bit field specifies the response that a compare event will generate on the output pin of Output Compare channel 2. The toggle, clear and set options cause a change in the output pin only on occurrence of a compare event. When OM2 is programmed as 1xx (active low pulse), the output pin is set to one, immediately on the next input clock, and the low pulse occurs when there is a compare event. This low pulse width is input clock wide. Here input clock means clock selected by CLKSRC bits of GPT Control Register. 000 Output disconnected. No response on pin 001 Toggle output pin 010 Clear output pin 011 Set output pin 1xx Generate a active low pulse of one input clock wide on output
22–20 OM1	Output compare channel 1 operating Mode. This bit field specifies the response that a compare event will generate on the output pin of Output Compare channel 1. The toggle, clear and set options cause a change in the output pin only on occurrence of a compare event. When OM1 is programmed as 1xx (active low pulse), the output pin is set to one, immediately on the next input clock, and the low pulse occurs when there is a compare event. This low pulse width is input clock wide. Here input clock means clock selected by CLKSRC bits of GPT Control Register. 000 Output disconnected. No response on pin 001 Toggle output pin 010 Clear output pin 011 Set output pin 1xx Generate a active low pulse of one input clock wide on output
19–18 IM2	Input capture channel 2 operating Mode. This bit field determines the transition on the input pin for Input capture channel 2 which will trigger a capture event. 00 capture disabled 01 capture on rising edge only 10 capture on falling edge only 11 capture on both edges
17–16 IM1	Input capture channel 1 operating Mode. This bit field determines the transition on the input pin for Input capture channel 1 which will trigger a capture event. 00 capture disabled 01 capture on rising edge only 10 capture on falling edge only 11 capture on both edges
15 SWR	Software reset. This is the software reset of the GPT module. It is a self clearing bit. This bit is set when the module is in reset state and is cleared when the reset procedure is over. Setting this bit resets all the registers to their default reset values except for the EN, ENMOD, STOPEN, WAITEN and DBGEN bits in this control register. 0 GPT is not in reset state 1 GPT is in reset state
14–10	Reserved bits. These are reserved bits and writing a value will not affect the functionality of GPT. These reserved bits are always read as zero. It is recommended that all writes to these bits be 0 for forward compatibility.
9 FRR	Freerun or Restart mode. This bit determines the behavior of the GPT on compare event in channel 1. In restart mode the counter resets to 0x0000_0000 and resumes counting after the occurrence of a compare event. In freerun mode, after a compare event the counter continues counting until 0xFFFF_FFFF and then rolls over to 0. 0 Restart mode 1 Freerun mode

Table 36-5. GPT Control Register Field Descriptions (continued)

Field	Description
8–6 CLKSRC	Clock Source select. These bits selects which clock will go to the prescaler and subsequently be used to run the GPT counter. This bit field value should only be changed after disabling the GPT by clearing the EN bit in this register. For other programming requirements while changing clock source, refer section 20.6.1/20-30 000 No clock 001 ipg_clk 010 ipg_clk_highfreq 011 ipp_ind_clkin (external clock from pad) 1xx ipg_clk_32k
5 STOPEN	GPT Stop Mode enable. This read/write control bit enables the operation of the GPT during stop mode. This bit is reset by a hardware reset. A software reset doesn't affect this bit. 0 GPT is disabled in stop mode 1 GPT is enabled in stop mode
4 RESERVED	Reserved bits This is reserved bit and writing a value will not affect the functionality of GPT. Reading this bit will return the last written value.
3 WAITEN	GPT Wait Mode enable. This read/write control bit enables the operation of the GPT during wait mode. This bit is reset by a hardware reset. A software reset doesn't affect this bit. 0 GPT is disabled in wait mode 1 GPT is enabled in wait mode
2 DBGEN	GPT debug mode enable. This read/write control bit enables the operation of the GPT during debug mode. This bit is reset by a hardware reset. A software reset doesn't affect this bit. 0 GPT is disabled in debug mode 1 GPT is enabled in debug mode
1 ENMOD	GPT Enable mode. When GPT is disabled(EN=0), then both Main Counter and Prescaler Counter freeze their current count values. ENMOD bit determines the value of GPT counter when EN bit is set and Counter is enabled again. If ENMOD bit is set, then both the Main Counter and Prescaler Counter value is reset to 0 on enabling GPT again (EN=1). If ENMOD bit is programmed to 0, then both the Main Counter & Prescaler Counter restart counting from their frozen values on enabling GPT again (EN=1). If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then both the main counter and the prescaler counter freeze at their current count values when GPT enters low power mode. When GPT exits the low power mode, both main counter and prescaler counter start counting from their frozen values irrespective of the ENMOD bit. Setting the SWR bit will clear the counter value regardless of the value of EN or ENMOD bits. This bit is reset by a hardware reset. A software reset doesn't affect this bit. 0 GPT counter retain its value when it is disabled 1 GPT counter value is reset to 0 when it is disabled
0 EN	GPT Enable. This bit is the module enable bit. It is recommended that all registers be properly programmed before setting this bit. This bit is reset by a hardware reset. A software reset doesn't affect this bit. 0 GPT is disabled 1 GPT is enabled

36.3.2.2 GPT Prescaler Register (GPTPR)

The GPT Prescaler Register (GPTPR) contains bits that determine the divide value of the clock that runs the counter.

Address 0xBASE+0x0004 Access: User read/write

Table 36-6. Register Field Descriptions

Field	Description
31–12 RESERVED	Reserved bits. These are reserved bits and writing a value will not affect the functionality of GPT. These reserved bits are always read as zero.
11–0 PRESCALER	Prescaler bits. The clock selected by the CLKSRC field is divided by [PRESCALER + 1] and then used to run the counter. A change in the value of the PRESCALER bits result in Prescaler counter to reset & new count period to start immediately. See Figure 1-13.for timing diagram. 0x000 Divide by 1 0x001 Divide by 2 .... 0xFFF Divide by 4096

36.3.2.3 GPT Status Register (GPTSR)

The GPT Status Register (GPTSR) contains bits that indicate the occurrence of rollover of the counter and any event on input capture and output compare channels. The bits are write one to clear.

Address 0xBASE+0x0008 Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
31–6	Reserved bits. These are reserved bits and writing a value will not affect the functionality of GPT. These reserved bits are always read as zero.
5 ROV	Rollover Flag. This bit indicates that the counter has reached its maximum possible value and rolled over to 0 from which it continues counting. This bit is only set if the counter has reached 0xffffffff in both restart and freerun modes. 0 Rollover not occurred 1 Rollover occurred
4 IF2	Input capture 2 Flag. This bit indicates that a capture event has occurred on Input Capture channel 2. 0 Capture event not occurred 1 Capture event occurred
3 IF1	Input capture 1 Flag. This bit indicates that a capture event has occurred on Input Capture channel 1. 0 Capture event not occurred 1 Capture event occurred
2 OF3	Output Compare 3 Flag. This bit indicates that a compare event has occurred on Output Compare channel 3. 0 Compare event not occurred 1 Compare event occurred
1 OF2	Output Compare 2 Flag. This bit indicates that a compare event has occurred on Output Compare channel 2. 0 Compare event not occurred 1 Compare event occurred
0 OF1	Output Compare 1 Flag. This bit indicates that a compare event has occurred on Output Compare channel 1. 0 Compare event not occurred 1 Compare event occurred

36.3.2.4 GPT Interrupt Register (GPTIR)

The GPT Interrupt Register (GPTIR) contains bits that control the generation of interrupt on rollover, input capture and output compare events.

Address 0xBASE+0x000C Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
31–6 RESERVED	Reserved bits. These are reserved bits and writing a value will not affect the functionality of GPT. These reserved bits are always read as zero.
5 ROVIE	Rollover Interrupt Enable. This bit controls the occurrence of rollover interrupt. 0 Interrupt disabled 1 Interrupt enabled
4 IF2IE	Input capture 2 Interrupt Enable. This bit controls the occurrence of input capture channel 2 interrupt. 0 Interrupt disabled 1 Interrupt enabled
3 IF1IE	Input capture 1 Interrupt Enable. This bit controls the occurrence of input capture channel 1 interrupt. 0 Interrupt disabled 1 Interrupt enabled
2 OF3IE	Output Compare 3 Interrupt Enable. This bit controls the occurrence of output compare channel 3 interrupt. 0 Interrupt disabled 1 Interrupt enabled
1 OF2IE	Output Compare 2 Interrupt Enable. This bit controls the occurrence of output compare channel 2 interrupt. 0 Interrupt disabled 1 Interrupt enabled
0 OF1IE	Output Compare 1 Interrupt Enable. This bit controls the occurrence of output compare channel 1 interrupt. 0 Interrupt disabled 1 Interrupt enabled

36.3.2.5 GPT Output Compare Register 1 (GPTOCR1)

The GPT Compare Register 1 (GPTOCR1) holds the value that determines when a compare event will be generated on output compare channel 1. Any write access to the compare register of channel 1 while in restart mode (FRR=0) will result in the GPT counter being reset.

IP Bus Write access to GPT Output Compare Register1 (GPTOCR1) results in one cycle of wait state (ips_xfr_wait high for 1 cycle), while IP Bus Read access is with 0 wait state.

Address 0xBASE+0x0010 Access: User read/write

Figure 36-12. GPT Counter Register (GPTCNT)

Table 36-14. GPT Counter Register Field Description

Field	Description
31–0 COUNT	Counter Value. These bits show the current count value in the counter register.

36.4 Functional Description

The General Purpose Timer (GPT) has a single counter (GPTCNT). It is a 32-bit free-running up counter which starts counting after it is enabled by software (EN = 1). The counters clock source is the output of the prescaler labelled “Prescaler output” in Figure 36-13. If the GPT is programmed to be disabled in a low power mode (STOP/WAIT), then both the main counter and the prescaler counter freeze at their current count values when GPT enters low power mode. When GPT exits the low power mode, both main counter and prescaler counter start counting from their frozen values irrespective of the ENMOD bit. GPTCNT can be read at any time by the processor. Both input capture channels use the same counter (GPTCNT).

A hardware reset resets all the GPT registers to their respective reset values. All registers except the output compare registers (GPTOCR1,GPTOCR2, and GPTOCR3) obtain a value of 0x0. The compare registers are reset to 0xFFFF_FFFF. There is a software reset available (SWR bit in control register) which can reset all the register bits except the EN, ENMOD, STOPEN, WAITEN and DBGEN bits. The state of these bits are not affected by a software reset. Software reset can be given even when the GPT is disabled.

36.4.1 Clocks

The clock that feeds the prescaler can be selected from the following clock inputs

- **High frequency Clock** (ipg_clk_highfreq)

  This is a high frequency clock which is provided by the Clock Controller Module (CCM). This clock is supposed to be on in low power mode when the ipg_clk is turned off. Thus the GPT can be run on this clock in low power mode. The CCM is expected to provide this clock after synchronizing it to ahb_clk in normal functional mode and switch to the unsynchronized version in the low power mode.

- **Low Reference Clock** (ipg_clk_32k)

  This is the 32 kHz low reference clock which is provided by the CCM. This clock is supposed to be on in low power mode when the ipg_clk is turned off. Thus the GPT can be run on this clock in low power mode. The CCM is expected to provide this clock after synchronizing it to ahb_clk in normal functional mode and switch to the unsynchronized version in the low power mode.

- **External Clock** (ipp_ind_clkin)

  This is the external clock from outside the chip which can be used to run the counter. This clock is treated as asynchronous to ipg_clk and synchronized to ipg_clk inside the module. Thus its frequency is limited to < 1/4 frequency of ipg_clk for proper functioning of the GPT. Also in low power modes if ipg_clk is not available it cannot be used to run the counter.

- **Global Functional Clock** (ipg_clk)

  This clock is supposed to be on in normal operations, if ipg_clk or ipp_ind_clkin is selected(CLKSRC=001 or 011) as Clock Source. In low power modes, if GPT is programmed to be disabled (STOPEN or WAITEN or DOZEN=0), then ipg_clk can be switched off.

  The clock input source is determined by the clock source (CLKSRC) field in the control register. The clock input to the prescaler can also be disabled by programming the CLKSRC bits of control register to 000. **This field (CLKSRC) value should be changed only after disabling the GPT by setting the EN bit in the GPTCR to 0.** For other programming requirements when changing clock source, see Section 36.5, Initialization/Application Information.”

  The PRESCALER field is used to select the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by a value from 1 to 4096 and can be changed any time. A change in the value of the PRESCALER field is immediately reflected on its output clock frequency.

Figure 36-13 shows the prescalar value change diagram.

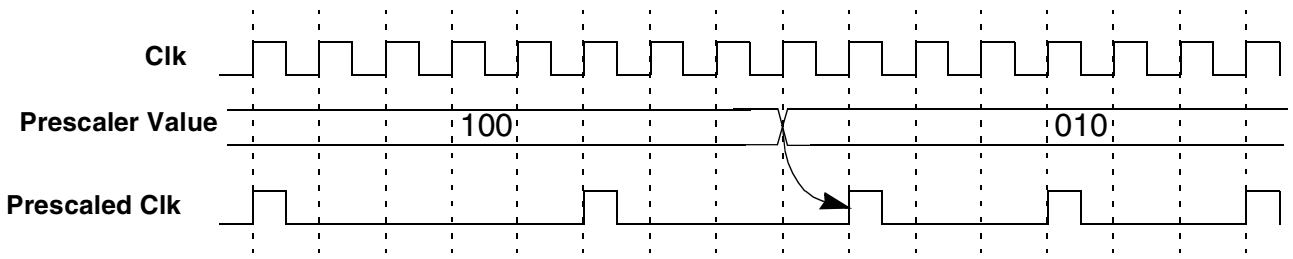

Figure 36-13. Prescaler value change diagram

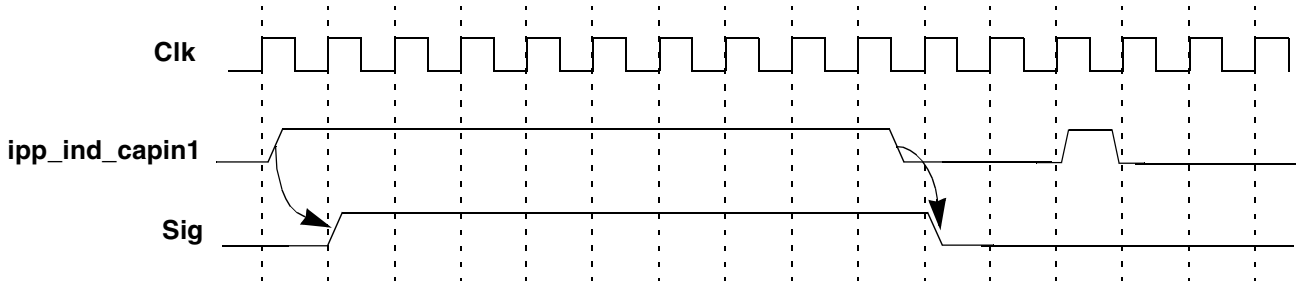
36.4.2 Input Capture

There are two input capture channels and each input capture channel has a dedicated capture pin, capture register and input edge detection/selection logic. Each input capture function has an associated status flag, and can cause the processor to make an interrupt service request. When a selected edge transition occurs on an input capture pin, the contents of the GPTCNT is captured on the corresponding capture register and sets the appropriate interrupt status flag. An interrupt request can be generated when the transition is detected if its corresponding enable bit is set in the Interrupt Register. The capture can be programmed to occur on the input pin rising edge, falling edge, on both edges or can be disabled completely. The events are synchronized with the clock selected to run the counter. Only those transitions which occur at least a single clock cycle (clock selected to run the counter) after the previous recorded transition will be guaranteed to trigger a capture event. There can be up to one clock cycle of uncertainty in latching of the input transition. The input capture registers can be read at any time without affecting their values.

Figure 36-14 shows the input capture event timing diagram.



Clk - The clock selected from CLKSRC bit field setting
ipp_ind_capin1 - Pad signal for capture channel 1
Sig - Capture signal as sensed by the module

Figure 36-14. Input Capture Event Timing Diagram

36.4.3 Output Compare

The three output compare channels use the same counter (GPTCNT) as the input capture channels. When the programmed content of an output compare register matches the value in GPTCNT, an output compare status flag is set and an interrupt is generated if the corresponding bit is set in the interrupt register. Consequently, the output compare timer pin will be set, cleared, toggled, not affected at all or provide an active-low pulse for one input clock period (this is subject to the restriction on the maximum frequency allowed on the pad) according to the mode bits programmed. There also exists a forced-compare feature allowing the software to generate compare event when required without the condition of the counter value being equal to the compare value. The action taken as a result of a forced compare is the same as when an output compare match occurs, except that the status flags are not set and no interrupt can be generated. Forced channels take programmed action immediately after the write to the force-compare bits. These bits are self-negating and always read as zeros.

Figure 36-15 shows the output compare and interrupt timing diagram.

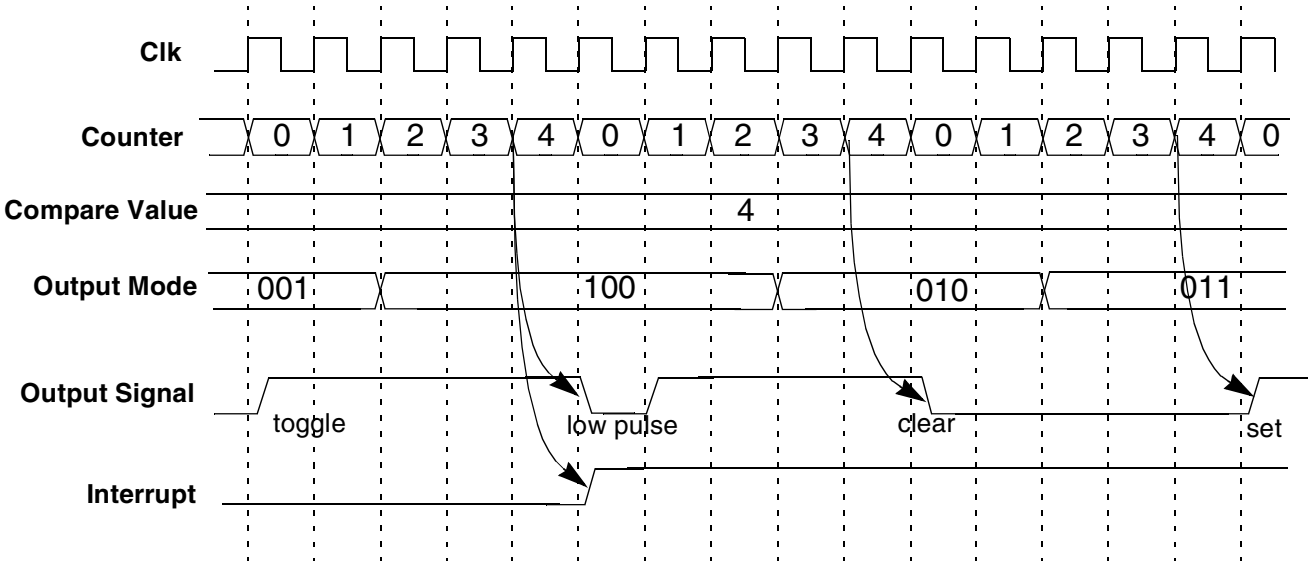


Figure 36-15. Output Compare and Interrupt Timing Diagram

36.4.4 Interrupts

There are six different interrupts that are generated by the GPT. All interrupts can be generated in low power and debug modes if the selected clock for running the counter is available.

- Rollover Interrupt

  This interrupt is generated when the GPT counter reaches 0xFFFF_FFFF and resets to 0x0000_0000 and continues counting. The interrupt is enabled by the ROVIE bit in GPTIR register and its associated status bit is ROV bit in GPTSR register.

- Input Capture Interrupt 1 and 2

  On occurrence of a capture event, interrupts can be generated by each input capture channel. These interrupts are enabled by IF2IE and IF1IE bits in GPTIR register and their associated status bits are IF2 and IF1 in GPTSR register. The capture of the counter value due to a capture event is not affected by a pending capture interrupt. Capture register is updated with new counter value on occurrence of capture event irrespective of that capture channels interrupt has been serviced or not.

- Output Compare Interrupt 1, 2, and 3

  On occurrence of a compare event, interrupts can be generated by each output compare channel. These interrupts are enabled by OF3IE,OF2IE and OF1IE bits in GPTIR register and their associated status bits are OF3,OF2 and OF1 in GPTSR register. No interrupt is generated due to a forced compare.

  An cumulative interrupt line is also present which is asserted whenever any of the above interrupts are posted. This has no associated enables or status bits.

36.4.5 Low-Power Mode (LPM) Behavior

In low power modes if the clock from the selected clock source is available (except ipp_ind_clkin which can be used only if ipg_clk is available), the counter continues to run depending on whether the control bit for that mode is set. In absence of the clock itself or the corresponding low power bit in control register being 0, the main counter and the prescaler counter freeze at their current values and resume counting from their frozen values when the low power mode is exited.

36.4.6 Debug Mode Behavior

In debug mode, the modules have the option of continuing to run or be halted. If the DBGEN bit is not set in the GPTCR, the GPT timer is halted. If the DBGEN bit is set, then the GPT timer will continue to run in debug mode.

36.5 Initialization/Application Information

This section describes how to change the clock source.

The CLKSRC field in GPTCR determines the clock source. This field value should be changed only after GPT has been disabled (EN=0). Use the following software sequence when changing the clock source.

1. Disable GPT by setting EN=0 in GPTCR.
2. Disable GPT interrupt register (GPTIR).
3. Program OM3,OM2,OM1 to 00 in GPTCR.
4. Change clock source CLKSRC to desired value in GPTCR.
5. Clear GPT status register (GPTSR) i.e. (w1c).
6. Enable GPT interrupt register (GPTIR).
7. Set ENMOD=1 in GPTCR, to bring GPT counter to 0x00000000.
8. ENABLE GPT (EN=1) in GPTCR.

Chapter 37
Graphics Processing Unit 2D (GPU2D)

37.1 Overview

The GPU is an embedded 2D and vector graphics accelerator targeting the OpenVG 1.1 graphics API and feature set. It accelerates 2D bitmap graphics operations, such as BitBlt, fill and raster operations, using a separate 2D graphics acceleration unit. Vector graphics rendering is accelerated by a separate anti-aliasing polygon rasterizer, which is connected to the 2D graphics acceleration unit. The core has a rich and well-chosen set of features that emphasize very high image quality and low memory bandwidth consumption.

The GPU top level block diagram is presented in Section 37.3, GPU2D Block Diagram."

37.2 GPU Feature List

The following sections describe the functional features of the graphics processor.

37.2.1 Frame Buffer

Frame buffer features are as follows:

- Frame buffer sizes supported up to 2048 × 2048
- ARGB4444, RGB565, ARGB1555, ARGB5551, ARGB8888 frame buffer modes
- Configurable ARGB order in frame buffer: ARGB, BGRA, ABGR, RGBA
- Linear and block-based (4 × 4 pixels) frame buffer modes
- Fast buffer clears
- Support for OpenVG render to Image

37.2.2 2D Bitmap Graphics (Separate 2D Unit)

The 2D bitmap graphics features are as follows:

- Parallel operation with the 3D pipeline, independent command input
- BitBlt (surface-to-surface copy)
- Format conversion from monochrome/ARGB/YUV to ARGB during BitBlt
- Block fill
- Internal 32-bit color precision

The source bitmap format is as follows:

- 1/4/8-bit monochrome
- ARGB4444, RGB565, ARGB1555, ARGB5551, ARGB8888
- Configurable ARGB order: ARGB, BGRA, ABGR, RGBA
- Packed YUV 4:2:2 formats (FOURCC codes YUY2, UYVY, YVYU), two pixels per 32 bits of data
- 1-bit bitmap maps to foreground and background colors
- 4-bit bitmap is optionally gamma corrected to 8-bit alpha values and can be combined with foreground color to draw anti-aliased fonts

The destination bitmap format is as follows:

- ARGB4444, RGB565, ARGB1555, ARGB5551, ARGB8888, B8, A8, AB88
- Configurable ARGB order: ARGB, BGRA, ABGR, RGBA
- Supports three source bitmaps for separate mask/pattern/alpha bitmap support plus reading destination for ROP, blend and color key operations
- Supports masking source coordinates for wrapping patterns
- Supports ROP4 (ROP3 with separate ROPs for masked and unmasked pixels) logical operations
- Supports inverting mask and alpha values from source
- Supports destination rotation by 0/90/180/270 degrees
- Supports programmable blending with optional alpha un-premultiply
- Supports per pixel and constant alpha with optional modulation by source color alpha for OpenVG alpha masking
- Supports color keying by source and destination colors, with optional ignoring of alpha channel
- Supports one scissor rectangle for destination coordinates
- Dithering (ordered)
- Color component masking
- sRGB reads and writes
- Non-power of two source and destination bitmap sizes supported (stride must be a multiple of 32-bits)
- BitBlt with scaling implemented with the 3D rendering pipeline, bilinear filtering with texture lookups, programmable filter kernels possible with the programmable Pixel processor

Vector Graphics

Vector graphic features are as follows:

- Parallel operation with the 3D pipeline, independent command input
- Rasterization of convex and concave polygons with anti-aliasing
- Efficient native polygon rendering (no tessellation to triangles)
- Non-zero and odd-even fill rules
- Primitives supported:

- Polygons
- OpenVG path primitives (except Elliptical Arcs): Horizontal/vertical lines, generic lines, curves, smooth curves, move to, path closing
- Curve types supported: cubic and quadratic BÈzier
- Strokes with thickness, joints and end caps, unlimited stroke thickness
- Special case handling of singularities for thick strokes
- Supports paths with a maximum of 256 crossings along a horizontal or a vertical line

- Input coordinates
  - Absolute and relative coordinate input in floating point
  - Fixed-point (byte, short, int) and floating-point coordinate input - 0.8, 0.16, 16.16 formats
  - Little- and Big-endian support separately selectable for command stream and data.
- Geometry
  - User to surface transform for vertices and stroke shape
  - Hardware curve tessellation
  - Adjustable accuracy for curve and round cap splitting
  - OpenVG/SVG join types: Miter (with miter limit), round, bevel
  - OpenVG/SVG cap types: Butt, round, square
- Pixel processing
  - Programmable gradient and texturing processor
  - Linear and radial gradients (with focal point)
  - Perspective texture mapping with filtering
  - Two textures supported
  - sRGB and pre-multiply support for textures
  - 16-sample anti-aliasing
  - 4x RGSS AA (Rotated Grid Super Sample)
  - Per-pixel alpha-masking
  - Maximum texture size: 1024x1024 pixels
- Vector graphics rendering system CPU load:
- Display list generation during path creation ñ commands and vertices are stored to an internal format/buffer, no format conversion is performed
- Filling or stroking a path only requires a few register writes to start the operation in hardware
- Display lists are transferred to the vector graphics rasterizer using DMA without CPU interaction

37.3 GPU2D Block Diagram

Figure 37-1 shows the GPU top-level block diagram.

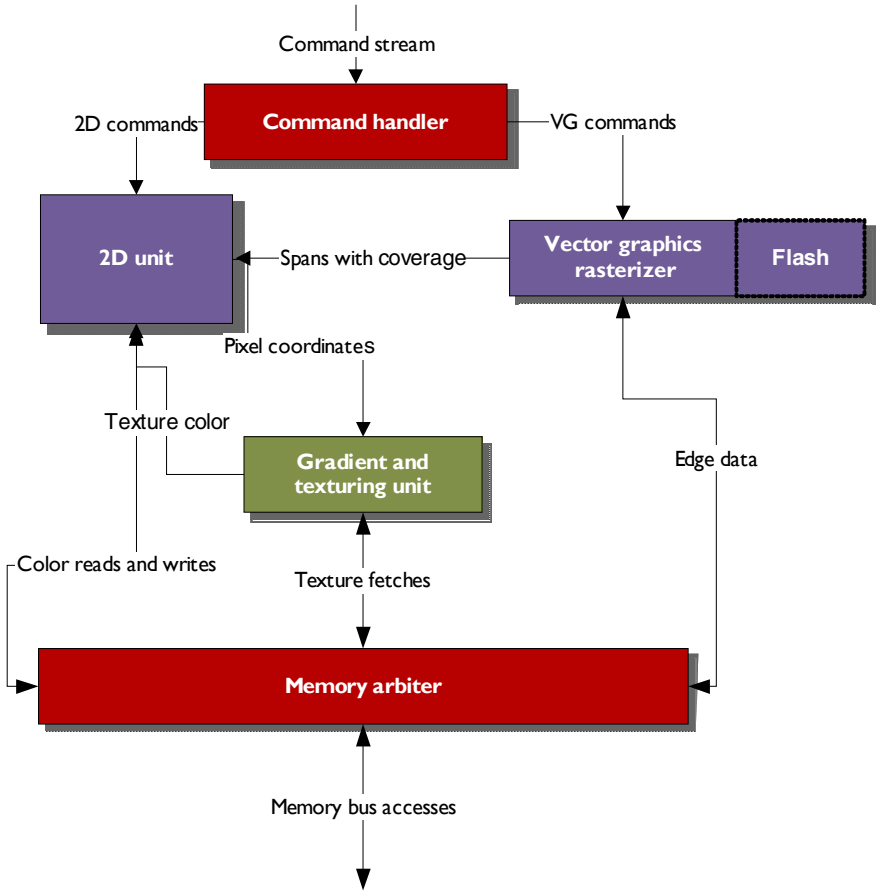

Figure 37-1. GPU Top-Level Block Diagram

37.4 Modes of Operation

The GPU supports the following:

- 2D bitmap acceleration mode
- Vector Graphic acceleration mode
- Low-power mode

37.5 Reset

The GPU2D uses one reset port, which is named HRESET*n*. The internal Z160 core (G12) contains asynchronous reset signals for each corresponding clock domain that is directly connected to HRESET*n*, namely rst_n for the clk clocks and bus_rst_n for the busclk clock.

Resets are active low. The reset signals asynchronously reset all of the DFFs in the design.

37.6 Interrupts

The Z160 Core (G12) generates individual interrupts internally. Each interrupt can be enabled or disabled by changing its own enable bit. Setting the enable bit high enables the corresponding interrupt.

The interrupts from all sources in the Z160 Core (G12) are combined (ORed) and output as the active low **gpu2d_int_b** interrupt.

37.7 DMA

GPU2D is a DMA master. It reads commands and writes data to system memory through EMI. GPU2D can also be fed by DMA through MAX slave port 0.

37.8 Memory Map

The Z160 Graphics Core (G12) memory map is described in the following sections:

- AHB slave interface
- AXI master memory interface (EMI port)

37.8.1 AHB Slave Interface

Table 37-1 shows the memory map for the AHB Slave Interface port of the GPU. This is based on the GPU occupying slave port 0 of the crossbar, whose base address is 0x2000_0000. GPU2D has two kinds of registers: interface registers, which can be read/write accessible, and internal registers, which can only be written through Z160's slave ports.

Table 37-1. GPU2D memory map

Description	Memory Address Base	Memory Address End
Registers	0xD000_0000	0xD000_07FC

A description of all user-accessible registers in the design can be found from regs.html.

Interface registers can only be accessed via the status read/write channel directly through the slave port, which is mapped to 0x400–0x7FC address range. These registers are used to read and clear interrupts by the CPU.

Internal 2/VG registers are write only. They can only be accessed via two writing commands through the slave port (GPU2D's base address). The first command is register address write, and the second command is flowing a data write. This means that the command stream, which is prepared by the software driver, is written through the 0x000–0x3ff address range either directly or through DMA operation by the core. These registers are not accessible directly by slave port channels just as the interface registers are not accessible through this channel.

37.8.2 AXI Master Memory Interface (EMI port)

The Z160 Graphics Core (G12 or GPU2D) can access memory with or without a memory management unit (MMU).

Translation is performed using a table with 8-Kbyte entries, one for each 4-Kbyte page in a 32-Mbyte linear address space. For further information, please refer to “Yamato_MMU” released by AMD.

Chapter 38
3D Graphics Accelerator (GPU3D)

38.1 Overview

The GPU3D (3D graphics processing unit) is based on the AMD Z430 (also known as ATI Yamato DX). The contains an embedded engine capable of DirectX9 Shader Model 3.0+ program execution. The module focus is on accelerating user level graphics APIs, such as OpenGL ES 2.0 and 1.1, and Direct3D Mobile 1.2.

38.1.1 IGPU3D Features

The GPU3D has the following high-level features:

- Built to accelerate OpenGL ES 2.0 and Direct3D Mobile 1.2
- Unified Shader Architecture
  - Uses dynamically shared shader ALU/memory resources between vertex and pixel shaders.
- General purpose exports to system memory from Vertex & Pixel Shaders
- Supports 2- and 4- sample MSAA
- Command Processor:
  - As a DMA master, support advanced packet based command stream manager allowing for efficient and flexible transfer of graphics commands and host data from the host system to the graphics processor core
- Graphics Memory Controller and Graphics Memory (GMEM)
  - Customer configurable on-chip memory used to accelerate 3D rendering using a binning architecture significantly reducing external system bandwidth requirements. The i.MX51 uses a 128 Kbyte internal GMEM.
- Integrated Power Management
  - Block-level clock gating managed automatically in the IP.

38.2 Capabilities and Performance

Its capabilities and performance features are as follows:

- 32-bit FP internal shader precision
- Supports general purpose exports to system memory from vertex and pixel shaders.
- Uses indexed vertex data fetches from the vertex shader as a high-bandwidth vertex data path.

- Latency hiding via FIFOs and multi-threading
- Sophisticated shader support
  - 512 4-component constants
  - 1024 shader instructions
  - 16 textures
  - 16 4-component interpolants
  - 64 general-purpose registers
- Rich texture format and types
  - Compressed
  - 16-bit Floating point
  - Cube map
  - Volume textures
  - Non power-of-2
  - Anisotropic
- 1 primitive (triangle/line/point) every 6 clocks and 1 vertex every 6 clocks the lower rate element limited by the ratio
- 2 vector (4 component) and 1 scalar (single component) ALU instruction per clock
- 1 control flow instructions (jumps, loops) per clock
- 1 export per clock
- 14 component pixel shader input interpolant per clock
- Early-Z testing at up to 4 pixels per clock
- 1 pixel (at 4 sample MSAA) per clock with alpha blending and depth test

38.3 GPU3D Block Diagram

The GPU3D contains three primary blocks:

- Graphics Core (GC)
  - Programmable graphics engine that performs all of the data processing and memory transactions
- Graphics Arbiter (GARB)
  - Controls the GMEM and arbitrates between requests from the GC and the system
- Graphics Memory (GMEM)
  - Local SRAM buffers (4x32KB buffers) that are used for the tile/bin of pixels when the GC is working.

Figure 38-1 shows the GPU3D top-level block diagram.

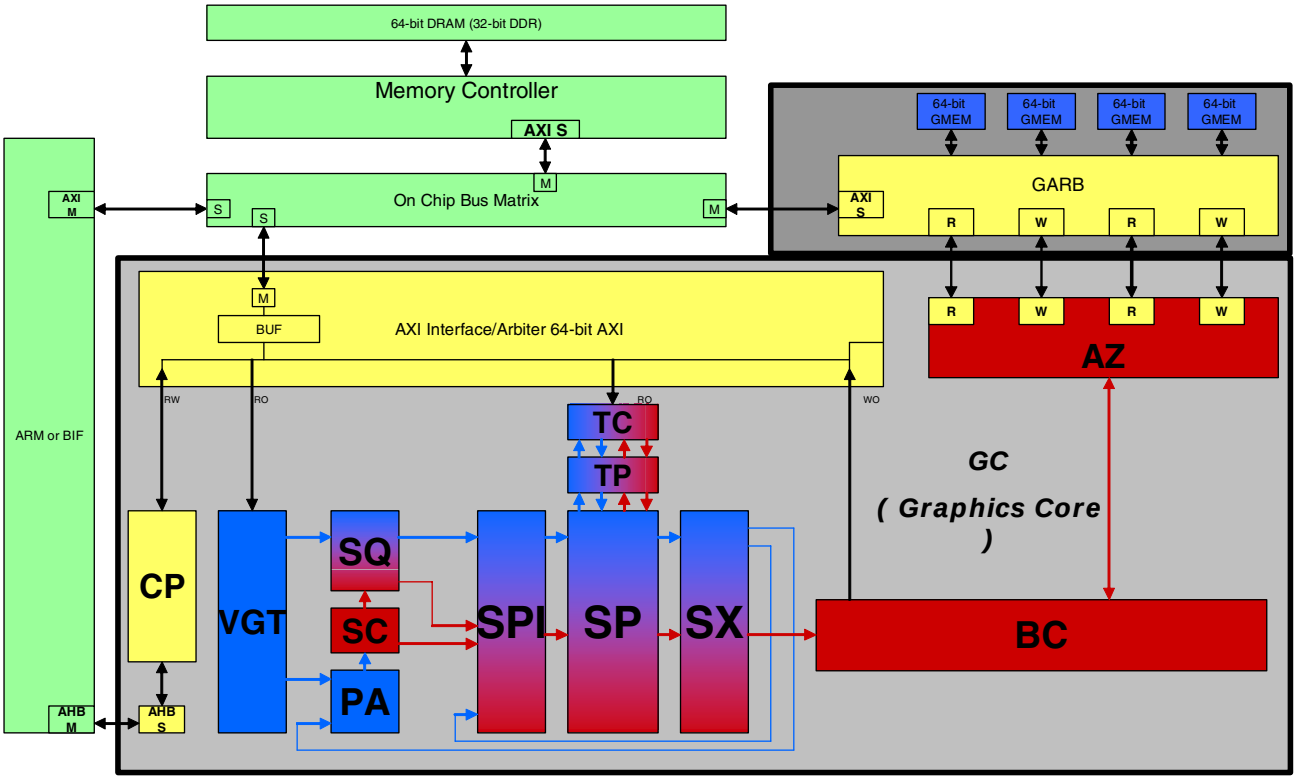

Figure 38-1. GPU3D Top-Level Block Diagram

38.4 GPU3D SoC Interface

38.4.1 GPU3D SoC Integration Top Level Diagram

Figure 38-2 shows the GPU3D graphics core connection in the i.MX51 system.

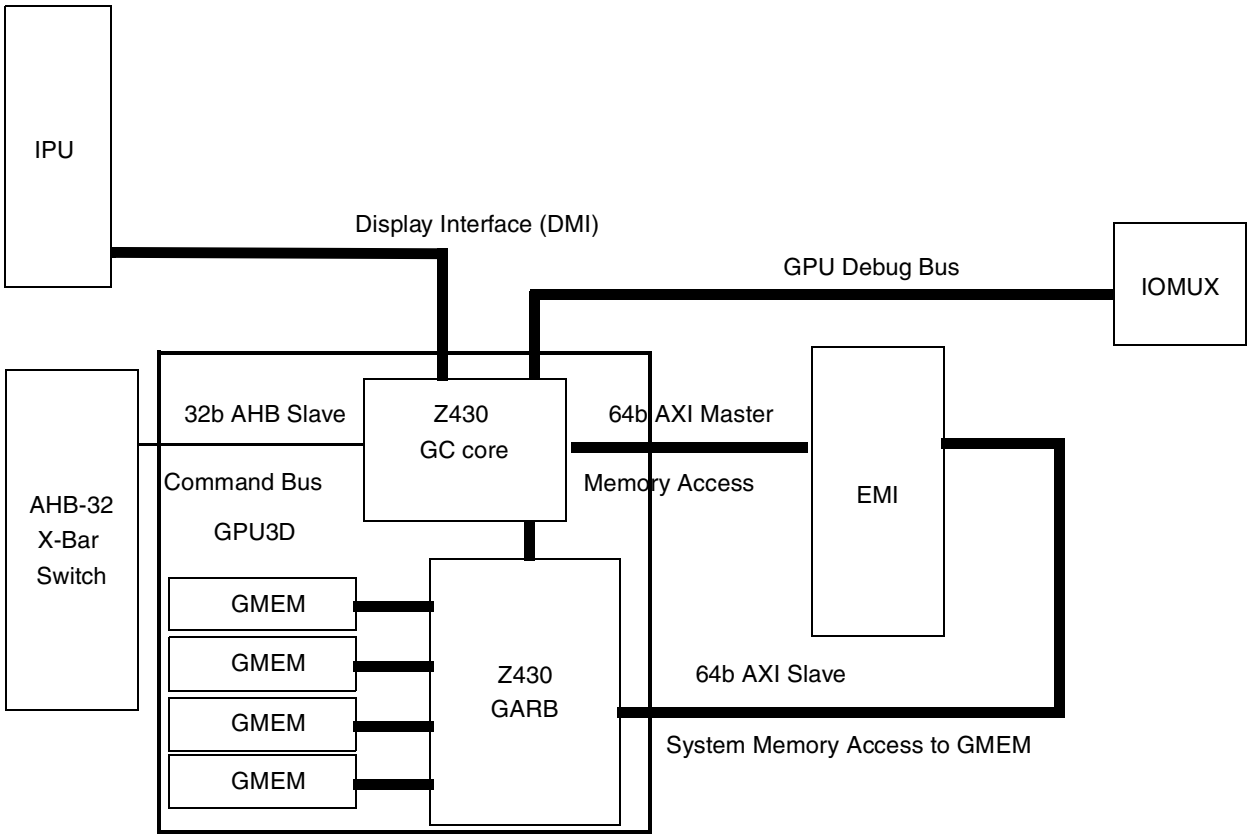

Figure 38-2. GPU3D System Connectivity

38.4.2 SoC Interface Summary

Key features of the SOC interface are as follows:

- Slave Interface to CPU or controller interface
  - — Peripheral AMBA 2.0 AHB-Lite Host Interface
  - — Provides host access to graphics core from the system processor.
  - — 32b wide, synchronous with core.
  - — Support for clock gating for phase removal on AHB clock.
- AXI Master Interface into memory system (AXI V1.0)
  - — 64b wide, synchronous
  - — Provides access to system memory from the graphics core.
  - — Programmable number of read and write requests to the memory system

- Number of outstanding request limited by system resources.

- AXI slave interface for system access to graphics memory (though GARB to GMEM)
  - 64b wide, synchronous interface
  - 1 outstanding read and write request
- Display Module Interface (DMI)
  - For synchronization with the display processor (IPU)
  - Provides indication to display processor from graphics core that a newly rendered frame is ready and that the display must perform a buffer flip at the next vertical blank.
  - Provides indication to graphics core from the display processor that the buffer identified by buffer ID has been displayed at least once..
- Control Interface Block (CIB on AHB slave bus)
  - Holding block for clock gating, reset etc.
  - Interrupt Interface (INT)
  - Error and status interrupts to the controller.
- Design For Test Interface (DFT)
  - Memory test collar access.
  - Scan/BIST access.
- Debug bus
  - GPIO register as control functions
  - Set of signals OR chained between internal masters for debug purposes
  - 32b bus muxed to 16b output to pad

38.4.3 Memory Interface Detail

This section provides a more detailed explanation of the memory interface.

38.4.3.1 Access type

The GPU3D core generates 128 and 256 bit bursts to external memory from its internal masters, which are arbitrated by a Memory Hub (MH). The MH supports up to 64 outstanding transactions, 8 AXI IDs, and contains a MMU.

Typical graphics use cases (usually games) will utilize approximately 400 to 500 MB/s and require a memory latency of less that 90ns (70ns is preferred).

The Memory Hub selects between the following clients in the graphics core:

- CP—(Command Processor) Read/Write
- VGT—(Vertex Grouper and Tesselator) Read Only
- TC—(Texture Cache) Read only
- RB—(Render Block) Write Only

Sub-Client	Sub-Client Designation	AXI ID	Operation	Transaction Size (Bytes)	Sub-Client Outstanding Transaction Limit
Ring Buffer	CPr0	0	Read	32	Programmable (Note 1)
Indirect Buffer #1	CPr1	1	Read	32	Programmable (Note 1)
Indirect Buffer #2	CPr2	2	Read	32	Programmable (Note 1)
State Sub-Block, Constant, & Shader Instruction Data	CPr3	3	Read	32	Programmable (Note 1)
Micro-Engine & Write Pointer Polling	CPr4	4	Read	32	1 Micro-engine read & 1 write pointer read
VGT Indices	VGTr0	5	Read	32	5 (Note 2)
VGT Bin ID	VGTr1	6	Read	32	8
Texture/Vertex Read	TCr	7	Read	16/32	9
Synchronization Semaphores, Micro-Engine Semaphores, Constant State Data	CPw	Programmable	Write	16/32	8 Unconfirmed writes, unlimited writes past point of confirmation
RB Copy	RBw	Programmable	Write	32	No client limit
PA	PAw	Programmable	Write	32	1
MMU TLB Miss	MMUr	Programmable	Read	32	1

All transactions are incrementing address bursts, as follows.

- The starting address is always aligned to the burst size, meaning that all 16-Byte bursts start at a 16-Byte aligned address, and all 32 Byte bursts start at a 32-Byte aligned address.
- Command stream and vertex data is read in bursts of 256 bits.
- The burst cache combines color accesses from several smaller objects to 4×4 pixel (16 bit), or 4×2 pixel (3 bit), which are transferred to memory in bursts of 256 bits.
- Color writes use byte enables when incomplete pixel blocks are written to the memory

38.4.3.2 Memory Management

The GPU3D GC core includes a memory management unit (MMU) capable of remapping a programmably sized region of the 32 bit GC memory space. This unit uses a single-level mapping table, with each 32 bit table entry mapping a 4 Kbyte region. Hence to map a 1 Mbyte region requires 256 table entries or a table 1K in size.

To make the remapping more efficient, the GC includes a translation lookaside buffer (TLB), which acts as a cache of translations. This cache holds a total of 128 translations organized as 16 lines of 8 translations each. Each of the 16 lines is fully associative, allowing translations for sections of up to 16 different surfaces to be simultaneously stored in the TLB.

Each client within the GC can be selected whether or not to use the MMU remapping function. Any accesses that do not use the MMU may be limited to a programmable range of physical address space, with accesses outside of that region resulting in a page fault fatal error. For more information, please refer to AMD's "ATI Yamato MMU."

When the driver requests memory from the OS, the virtual to physical translation is stored in the GPU3D's page table. The page table is a contiguous physical chunk of memory whose starting address is defined as the page table base (PTB) and whose extent depends on the amount of virtual memory required by the

driver. For example, if supporting 4-KByte pages and each page table entry is 32b, a virtual address range of 64 MB available to the driver would require 16K entries or 64KB of page table storage.

Note that the page table used by the graphics is not the same as the page table used by the ARM processor. Specifically, the GPU page table is a single level page table, and not all access control mechanisms are implemented.

In its simplest form, using a 4-KByte page, bits [11–0] of the virtual address can be the same as the physical address[11–0] and can be used as an index into the page. Bits [31–12] of the virtual address, in conjunction with the Virtual Address Base register, can be used as an index into the page table to find the address of the relevant page table entry (PTE).

Figure 38-3 and Figure 38-4 show the basic concept of the GPU3D MMU page table.

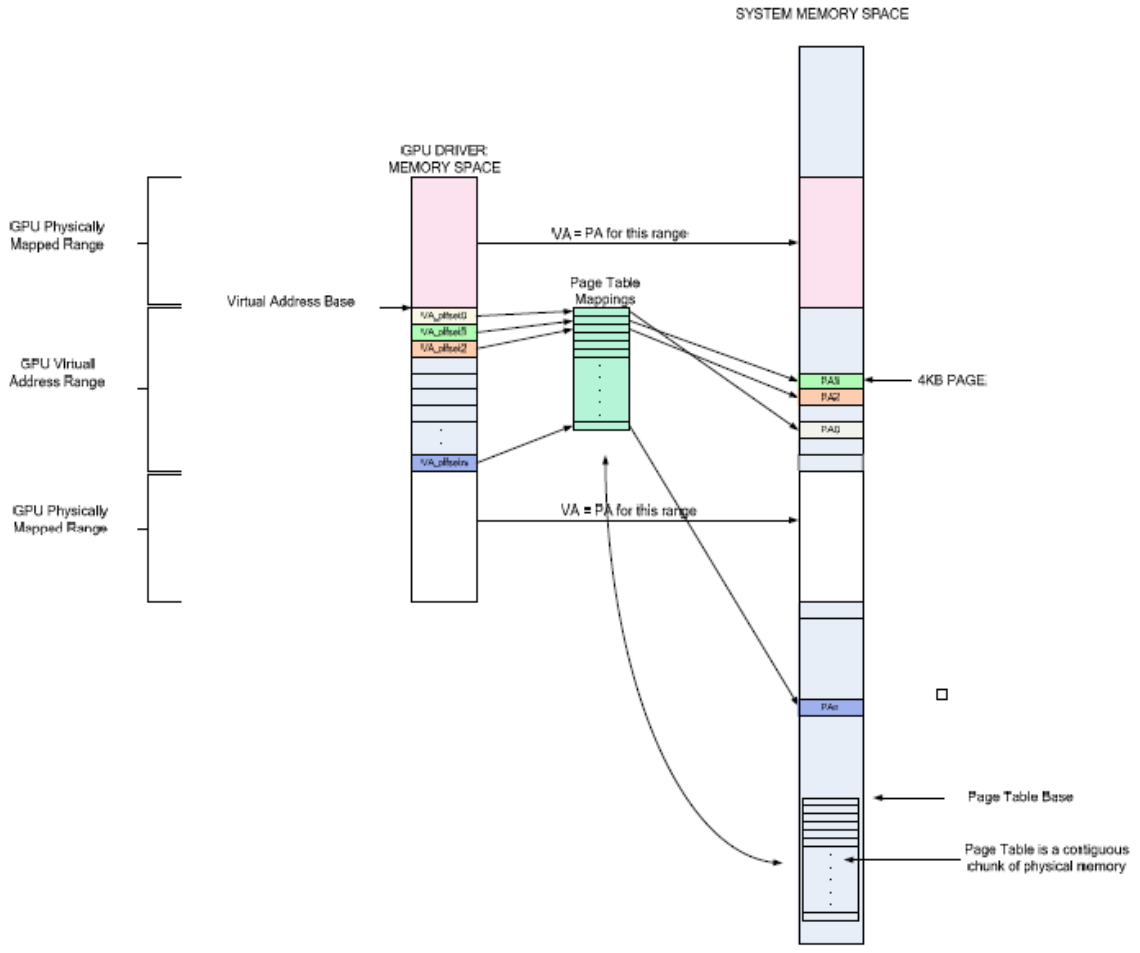

Figure 38-3. GPU3D Memory Mapping Concept

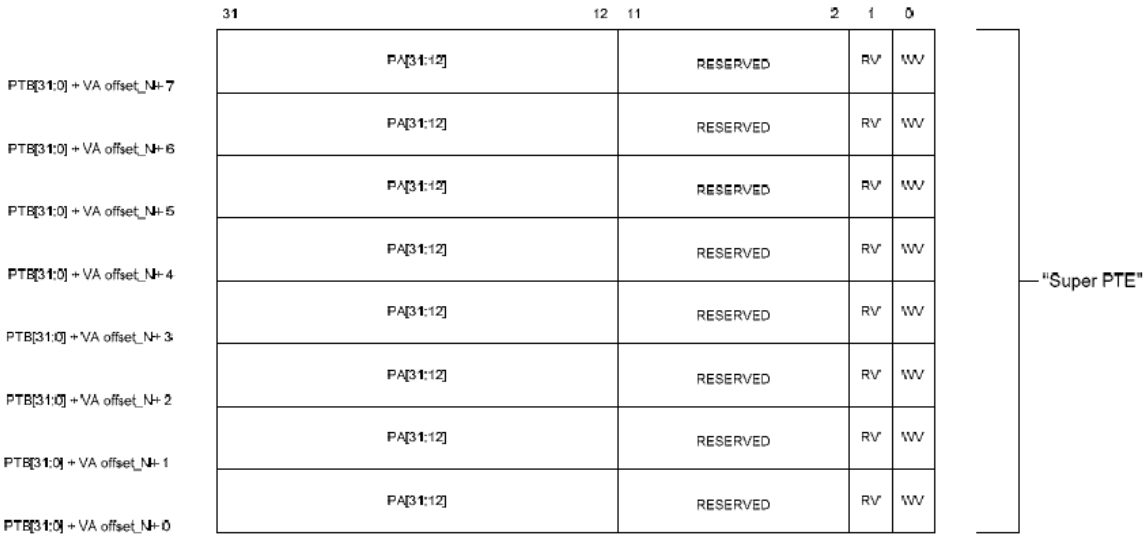

Figure 38-4. Page Table Entry Format in External Memory

38.4.4 DMI Interface Detail

Table 38-1 list the DMI handshake ports between GPU3D and IPU.

Table 38-1. GPU3D DMI Ports

Name	Type	Source	Description
gpu_use_bufid[2:0]	Output	GPU3D	Tell IPU which buffer can be displayed, one-hot coded
ipu_vsync_valid	Input	IPU	Tell GPU3D one frame is finished, high in vertical blank period
ipu_active_bufid[2:0]	Input	IPU	Tell GPU3D which frame is free to be overwritten, one-hot coded

The vertical sync (VSYNC) from the display controller occurs after each frame is displayed, during the vertical blanking period.

One-hot encoded USE_BUFID signals are updated by GPU3D whenever there is a new rendered buffer available (and the previous value of USE_BUFID has already been sampled by the IPU/display controller), so it can change anywhere in the frame. It is resynchronized and sampled at the start of the vertical blanking period (rising edge of VSYNC) in display controller, while the currently finished buffer (ACTIVE_BUFID signals) is updated by display controller at the rising edge of VSYNC, ACTIVE_BUFID are then resynchronized and sampled by GPU3D after synchronizing to VSYNC rising edge.

38.4.5 Debug Bus and GPIO

This section describes the debug bug and GPIO.

38.4.5.1 Debug Bus

The GPU3D has a 32b debug bus output that is controlled by a 18b GPIO register. The 32b debug bus should be mapped to system GPIO. In i.MX51, this 32b bus is MUXed to 16b to reduce the number of external pins required. The MUXing of these pins is controlled by 2 bits in the GPIO register.

38.4.5.2 GPIO Register

The GPU3D supports 16 general-purpose input pins that can be configured as soft reset, debug mux select bits etc. The bus is implemented as a system register (whose offset is 0x2_FFFC from GPU3D base address) along with 2_bit debug bus control information. The registered inputs are semistatic and have no timing constraints associated with them.

Table 38-2 shows the GPIO register implementation.

Table 38-2. GPIO Register-—R/W 18 Bit (0x2_FFFC)

Field Name	Bits	Default	Description
Debug Bus Control	17–16	0x0	00 Output lower 16 bits 01 Output upper 16 bits 10 Toggle between outputting lower and upper 16 bits per 83 MHz clock 11 Unused
GPU3D GPIO Bus	15–0	0x0000	Debug Bus Control

Table 38-3 lists the GPU3D GPIO bus functions:

Table 38-3. GPU3D GPIO Bus Function

GPIO BIT	Debug Function	Reset/Misc Function
15	1’b0	Ignore SQ RTR for AHB
14	1’b0	Ignore VGT RTR for AHB
13	1’b0	Ignore CP RTR for AHB
12	1’b0	Ignore RTR for AHB
11	Sub-Block Select[3]	Ignore RTR
10	Sub-Block Select[2]	VGT Soft Reset
9	Sub-Block Select[1]	SC Soft Reset
8	Sub-Block Select[0]	CIB Soft Reset
7	1’b0	1’b0
6	1’b0	1’b1
5	Sub-Block Addr[5]	SX Soft Reset

Table 38-3. GPU3D GPIO Bus Function (continued)

GPIO BIT	Debug Function	Reset/Misc Function
4	Sub-Block Addr[4]	SQ Soft Reset
3	Sub-Block Addr[3]	RB Soft Reset
2	Sub-Block Addr[2]	MH Soft Reset
1	Sub-Block Addr[1]	PA Soft Reset
0	Sub-Block Addr[0]	CP Soft Reset

The functionality in the Reset/Misc Function is the same as the functionality in the RBBM_SOFT_RESET register and the RBBM_DEBUG register. Please see the AMD's "ATI Yamato Register Spec" for more details on this functionality. The bits are logically OR'd together.

There is latency built into the debug bus due to the registered daisy chain nature of the debug bus. From the time GPU3D GPIO is registered (count this as clock 1), it can take up to 10 clock cycles before valid debug bus data is resident in the debug bus register. This latency applies any time the state of GPU3D GPIO is changed.

38.5 Clocking Architecture

This section describes clock input and gating.

38.5.1 Clock input

The GPU3D design has twp clocks at top level: ***aclk_gpu*** for the graphics core and ***aclk_garb*** for the graphic memory (GMEM) and its arbiter (GARB). These two clocks are synchronous, meaning that they are in a single domain. No multicycle paths, latches, or negative edge flops are used in the design. (The CKGATER uses a negative latch, but that is a special cell.)

Both ***aclk_gpu*** and ***aclk_garb*** are synchronous and in phase with the core clock. They come from one source in CCM, but have a separate gating cell so that ***aclk_gpu,*** the clock to the graphics core can be removed independently of ***aclk_garb***, which keeps graphic memory accessible when the graphics core is shut down.

Both ***aclk_gpu*** and ***aclk_garb*** should be implemented with programmable dividers to run at full speed, synchronous-bus speed, and half-bus speed to meet system power use cases.

38.5.2 Clock Gating

GPU3D graphics core (GC) supports the following three levels of clock gating:

- Explicit removal of clocks to the GC core by the system under software control
- Designer controlled removal of clocks to logic blocks (controlled by internal CIB module)
- Instantiated clock gating by synthesis tool.

Explicit clock gating is invoked under system control and as such is transparent to the GPU3D. All clocks (***aclk_gpu*** and ***aclk_garb***) are removed. Prior to clock removal, the system should ensure that the GPU3D is idle (no outstanding bus traffic, no outstanding command activity in command buffer). Removing the clocks to the GPU3D does not impact internal state (unless power is also removed).

Designers can chose to remove clocks to blocks or sections of blocks based on those functions becoming idle. Power Management Override bits are supported which selectively disable designer instantiated clock gating. The GC powers up with the clock gating disabled with the exception of the AHB busclock and the GMEM clocks which power up with clock gating enabled. It is the responsibility of the driver to enable the clock gating functionality by disabling (clearing) the power management override bits (by setting 2 registers RBBM_PM_OVERRIDE1 and RBBM_PM_OVERRIDE2). The GARB instantiate default enabled clock gaters for GMEM clock for power saving, which can be overridden (dibbled) by pm_override[3:0] from the GC to the GARB (by register RBBM_PM_OVERRIDE2).

In particular, the output ‘idle’ signal (gpu_idle, active high) signal from the CIB should be used to clock gate the core clock signals (***aclk_gpu***) to reduce power consumption.

38.6 Reset

GPU3D has only an asynchronous reset port named hresetn at top level. This port is active low and resets the graphics core, graphic memory, and its arbiter.

CAUTION

The internal graphics core uses synchronous reset, which is propagated through the design as a standard synchronous signal. Therefore the clocks (**ack_gc** and **aclk_garb**) must be turned on when hard reset (hresetn) is asserted.

The supplied reset (hresetn) is passed through a reset conditioning circuit in the CIB. This conditioning circuit extends reset assertion long enough to guarantee that all internal circuits are reset correctly. This circuit counts 64 bus cycles after the de-assertion of reset so GPU3D need 64 bus cycles to complete a reset.

In addition to the top level hard reset (hresetn), there are soft resets for each internal block. These resets can be controlled by software (by register RBBM_SOFT_RESET).

38.7 Interrupts

The graphics core provides a single interrupt pin to the system (gpu_int_b). Once asserted the interrupt pin remains asserted (active low) until the CPU clears the IRQ bit in the RBBM_IRQ register.

In general interrupts are used to signal error conditions or to support frame buffer swap.

38.8 Memory Map

The GPU3D memory map is shown in Table 38-4. There are two memory ranges:

- AHB slave interface (graphics core space)
- AXI slave memory interface (graphics memory space).

Table 38-4. . GPU3D Memory Map

Description	Memory Address Base	Memory Address End
GC space (register, instruction)	0x3000_0000	0x3002_FFFF
GMEM space (128 Kbytes)	0x2000_0000	0x2002_0000

Chapter 39
High Speed Inter IC (HS-I^{2}C)

39.1 Introduction

The High Speed Inter IC (HS-I^{2}C) is bidirectional, two wire, serial bus interface module. The HS_I^{2}C is designed to be compatible with the standard Philips I^{2}C bus protocol, version 2.1. Refer to Figure 39-1 for the HS_I^{2}C module block diagram.

NOTE

Due to limited functionality, Freescale does not recommend users incorporate the HS-I2C module in future designs. For details on the limitations, refer to the i.MX51 IC Errata. Users should consider using the two standard I2C modules, which have no errata.

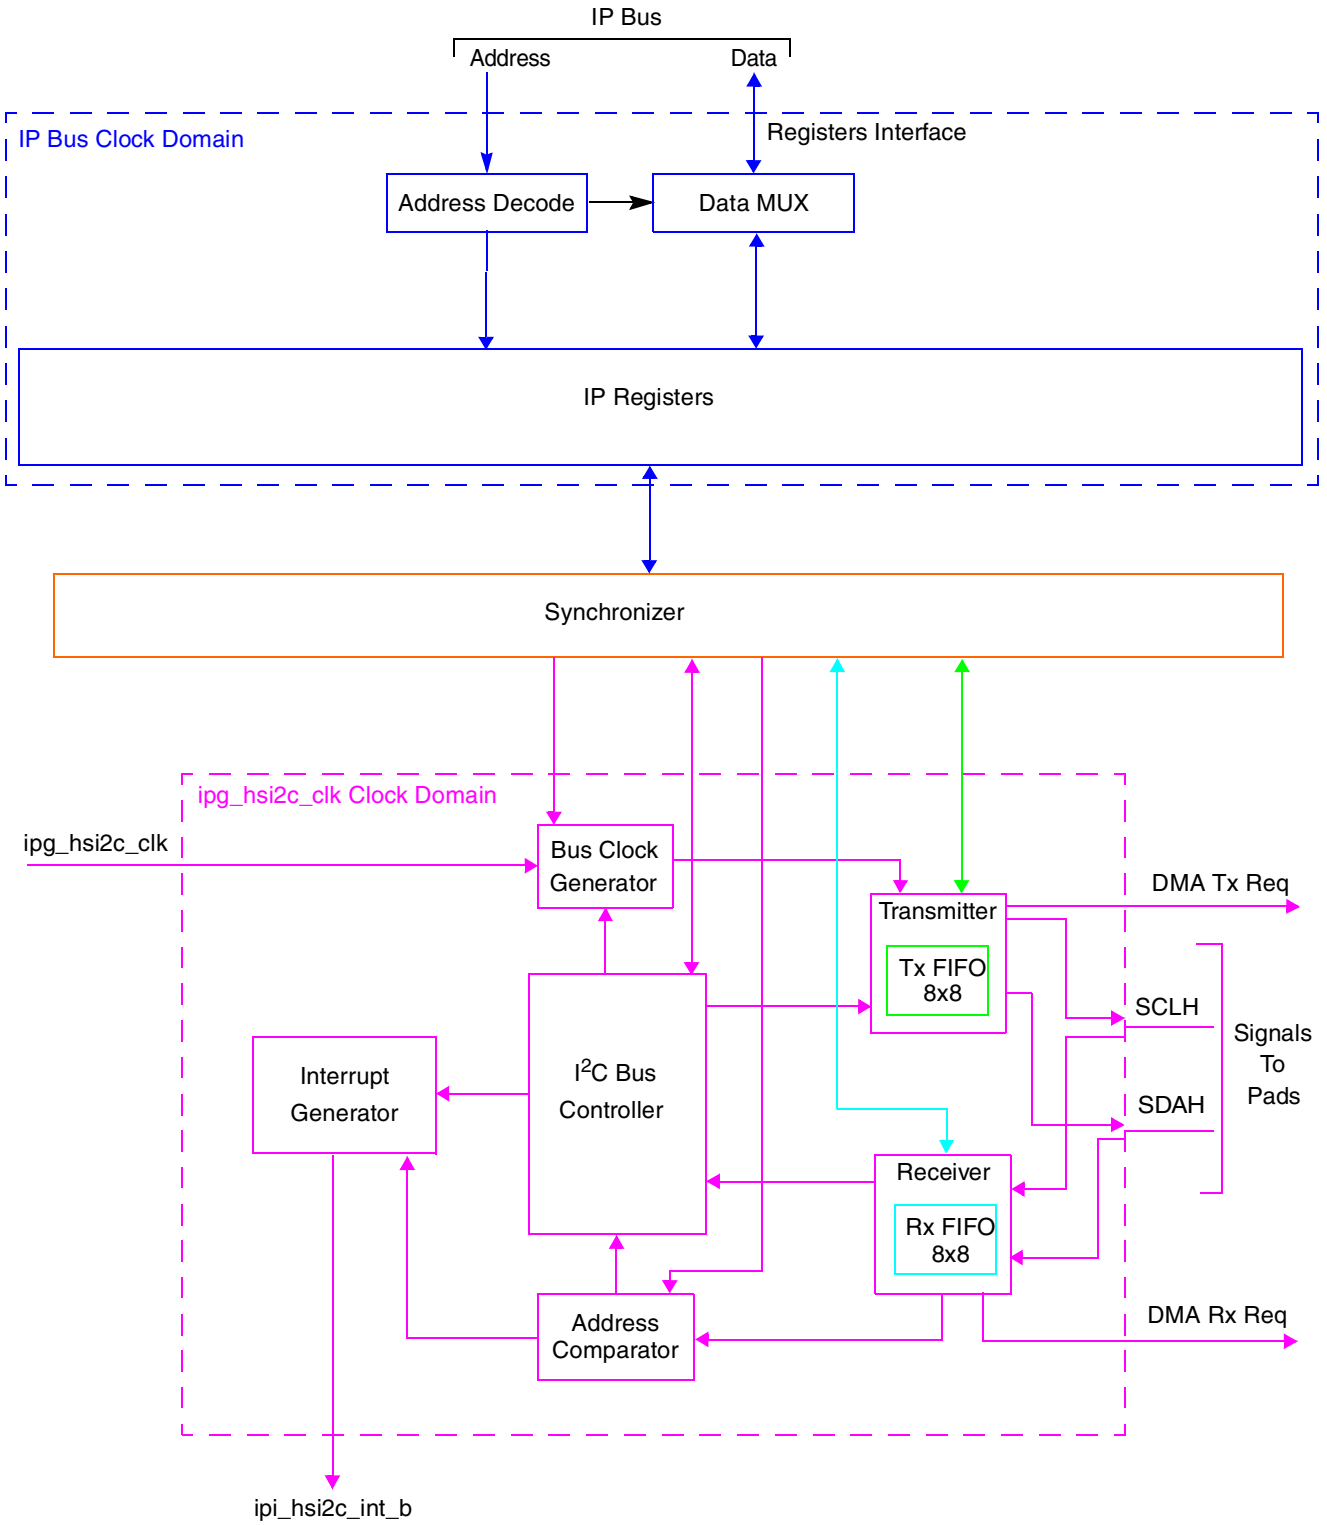

Figure 39-1. HS_I^{2}C Block Diagram

39.1.1 Overview

The HS_I^{2}C module provides simple and efficient way of 8-bit data transfers between I^{2}C bus compatible devices. The two bus lines: a serial data line (SDAH) and serial clock line (SCLH) provide data transfer rates upto 100 Kbits/s in Standard Mode, data rates upto 400 Kbits/s in Fast Mode and data rates upto 3.4 Mbits/s in High-Speed Mode. However, the data transfer rate depends upon the pad loading. The HS_I^{2}C module allows additional devices to be connected to the bus for system expansion and development. Refer to Figure 39-2 for connection of devices to the I^{2}C bus.

The HS_I^{2}C module provides a true multiple-master bus interface including arbitration and collision detection that prevents data corruption if multiple devices attempt to control the bus simultaneously.

The HS_I^{2}C incorporates 8x8 FIFO for transmit and 8x8 FIFO for receive purpose. The module IP interface supports the DMA data transfer operation to or from the HS_I^{2}C.

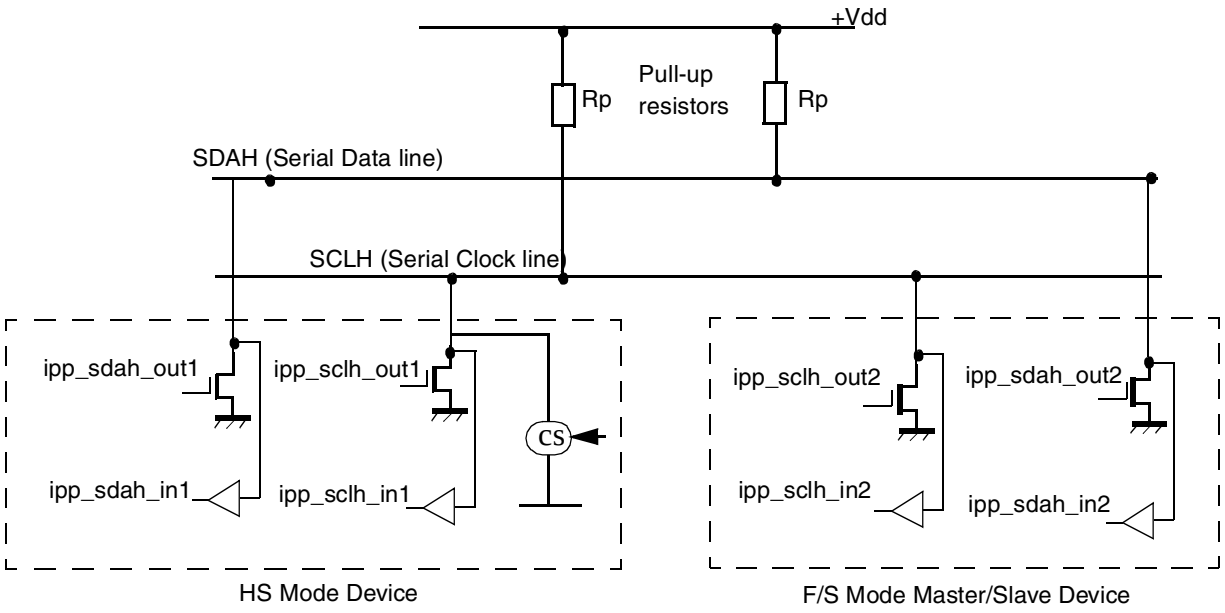

Figure 39-2. Connection of Devices to I^{2}C Bus

39.1.2 Features

The HS_I^{2}C module has the following key features.

- Compatible with the Philips I^{2}C bus standard version 2.1.
  - — Supports 7 and 10 bit addressing.
  - — Supports Standard Mode, Fast Mode and High-Speed Modes.
- Supports multiple master operation.
- Software programmable serial clock frequencies for Standard/Fast Mode and HS-Mode data transfer.

- Software option to select between High-Speed mode and Standard/Fast mode.
- Interrupt-driven, byte-by-byte data transfer
- Arbitration-lost interrupt with automatic mode switching from master to slave
- Slave address match interrupt
- Bus-busy detection
- Acknowledge bit generation/detection
- Supports DMA interface.
- Two 8x8 FIFO, one for Tx and one for Rx.

39.1.3 Modes of Operation

The HS_I^{2}C module primarily operates in 3 different functional modes.

39.1.3.1 Standard Mode

In this mode, HS_I^{2}C module supports the data transfer rates upto 100 Kbits/s.

39.1.3.2 Fast Mode

In Fast Mode data transfer rates of the order 400Kbits/s can be achieved. As per module operation, there is no special configuration required for Fast and Standard mode. It is the data transfer rate which distinguishes Standard and Fast mode.

39.1.3.3 High-Speed Mode

The data transfer rate as high as 3.4 Mbits/s can be achieved in this mode.

39.2 External Signal Description

There are two pins for HS_I^{2}C operation.

HS_I^{2}C module pins:

- SCLH—Bidirectional Clock Pin.
- SDAH—Bidirectional Data Pin.

For standard I^{2}C bus compliance, all devices connected to the SCLH and SDAH signals must have open-drain outputs. The logic AND function is exercised on both lines with external pull-up resistors in Standard/Fast mode operation. The resistor and CS pull up is used for SCLH line for HS-mode operation.

The module port signals that are connected to the pads are tabulated in Table 39-1, with relevant details.

Table 39-1. Pad Signal Properties

Name	Function	I/O	Reset	Pull Up
ipp_sclh_in	Serial Clock input	I	1	—
ipp_sclh_out	Serial Clock output	O	1	CS/Resister -Active
ipp_sclh_out_en	Serial Clock output enable	O	0	—
ipp_sdah_in	Serial Data input	I	1	—
ipp_sdah_out	Serial Data output	O	1	Resistor-Active
ipp_sdah_out_en	Serial Data output enable	O	0	—
ipp_hs_cs_cntrl	HS Mode current source pull up control	O	0	—
ipp_hs_cntrl	1) To adapt SDAH and SCLH input filters according to spike suppression requirement in HS 2) Slope control of SDLH and SCLH output stages in HS Mode	O	0	—

39.3 Memory Map and Register Definition

39.3.1 Memory Map

Table 39-2 is the memory map for the module.

39.3.2 Register Summary

Table 39-2. Block Memory Map

Address	Register	Access	Reset Value	Section/Page
General Registers				
0xBASE+0x0000(HISADR)	HS_I^{2}C Slave Address Register	R/W	0X0000	39.3.3.1/39-8
0xBASE+0x0004(HIMADR)	HS_I^{2}C Master Address Register	R/W	0x0000	39.3.3.2/39-9
0xBASE+0x0008(HICR)	HS_I^{2}C Control Register	R/W	0x0000	39.3.3.3/39-9

0xBASE+0x001C(HIFSFDR)	HS_I^{2}C F/S-Mode Frequency Divider Register	R/W	0x0000	39.3.3.8/39-16
0xBASE+0x0020(HIHSFDR)	HS_I^{2}C HS-Mode Frequency Divider Register	R/W	0X0000	39.3.3.9/39-17
0xBASE+0x0024(HITFR)	HS_I^{2}C Tx FIFO Control/Status Register	R/W	0x0000	39.3.3.10/39-18
0xBASE+0x0028(HIRFR)	HS_I^{2}C Rx FIFO Control/Status Register	R/W	0x0000	39.3.3.11/39-20
0xBASE+0x002C(HITDCR)	HS_I^{2}C Transmit Data Count register	R/W	0x00FF	39.3.3.12/39-21
0xBASE+0x0030(HIRDCR)	HS_I^{2}C Receive Data Count register	R/W	0x00FF	39.3.3.13/39-22

The conventions in Figure 39-3 and Table 39-3 serve as a key for the register summary and individual register diagrams.

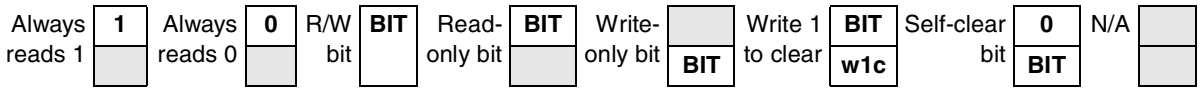

Figure 39-3. Key to Register Fields

Table 39-3 provides a key for register figures and tables and the register summary.

Table 39-3. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	

Table 39-3. Register Conventions (continued)

Convention	Description
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 39-4 shows the HS_I^{2}C register summary table.

39.3.3 Register Descriptions

This section contains the detailed register descriptions for the HS_I^{2}C registers in address order.

39.3.3.1 HS_I^{2}C Slave Address Register (HISADR)

Figure 39-4 shows the HS_I^{2}C Slave Address Register; Table 39-5 provide its field descriptions.

0xBASE+0x00(HISADR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	MSB_ADR			LSB_ADR							0
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 39-4. HS_I^{2}C Slave Address Register

The HISADR contains the 7 and 10 bit slave addresses of the HS_I^{2}C module.The module responds to this address when addressed as a slave in either 7 or 10 bit addressing mode.The HISADR can be programmed only when HICR[HIEN] bit is set to 0.The register is not reset by a software reset.

NOTE

The slave address is not the address sent on the bus during the address transfer.

Table 39-5. HS_I²C Slave Address Register Field Descriptions

Field	Description
15–11	Reserved
10-8 MSB_ADR	MSB of 10 bit slave address: Contains the three MSB bits of the 10 bit slave address
7–1 LSB_ADR	LSB of the 10 bit slave address: Contains the LSB of the slave address in 10 bit addressing mode. This bit also serves as the 7 bit slave address when the module is selected for slave mode in 7 bit addressing mode. Slave mode is the default HS_I²C mode for an address match on the bus.
0	Reserved

39.3.3.2 HS_I²C Master Address Register (HIMADR)

Figure 39-5 shows the HS_I²C Master Address Register; Table 39-6 provide its field descriptions.

0xBASE+0x04(HIMADR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	MSB_ADR			LSB_ADR							0
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 39-5. HS_I²C Master Address Register

The HIMADR contains the address of the slave to be addressed when HS_I²C is configured as master in 7 and 10 bit addressing modes. The module sends out this address on the I²C bus during address transfer for 7 and 10 bit addressing modes. The register is not reset by a software reset.

Table 39-6. HS_I²C Master Address Register Field Description

Field	Description
15–11	Reserved
10-8 MSB_ADR	MSB of 10 bit master address: Contains the three MSB bits of the 10 bit master address.
7–1 LSB_ADR	LSB of the 10 bit master address: Contains the LSB of the master address in 10 bit addressing mode. This bit also serves as the 7 bit master address when the module is bus master in 7 bit addressing mode.
0	Reserved

39.3.3.3 HS_I²C Control Register (HICR)

The HICR is used to enable the HS_I²C module and the HS_I²C interrupt. It also contains bits that govern module operation as a slave or a master. Figure 39-6 shows the HS_I²C Control Register; Table 39-7 provides its field descriptions.

0xBASE+0x08(HICR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	AUTO_RSTA	SAMC		HSM_EN	HS_MST_CODE			ADDR_MODE	HIIEN	MSTA	MTX	TXAK	RSTA	DMA_EN_TX	DMA_EN_RX	HIEN
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 39-6. HS_I^{2}C Control Register

Table 39-7. HS_I^{2}C Control Register Field Description

Field	Description
15 AUTO_RSTA	Auto Repeated Start: This bit will control whether auto repeated start is generated or not when HS_I^{2}C is configured for master transmit operation and DMA and FIFO or only FIFO is enabled and ACK is not received for particular address or data phase. If this bit is set auto repeated start is generated when no ACK is received. 0 Auto repeated start is not generated. (Default) 1 Auto repeated start is generated.
14-13 SAMC	Slave Address Mode Control: These bits control whether the HS_I^{2}C will respond to 7 or 10 bit addressing or both when configured as slave. These bits can be programmed only when HICR[HIEN] is 0. 00 - HS_I^{2}C can be selected in both 7 and 10 bit addressing mode.(Default) 01 - HS_I^{2}C can be selected in 7 bit addressing mode only 10 - HS_I^{2}C can be selected in 10 bit addressing mode only 11 - Reserved
12 HSM_EN	High Speed Mode Enable: Selects the High Speed mode or Fast/Standard mode operation for the module in master mode. The HSM_EN bit should be set to select the High Speed mode operation. After the transmission of the master code in F/S mode and the HS_I^{2}C does not loose the arbitration, automatic switching from F/S to HS mode takes place. 0 Fast/Standard mode operation. (Default) 1 High Speed mode operation.
11-9 HS_MST_CODE	High Speed Master Code: Controls the master code for high-speed mode data transfer. These bits get appended to MSB five bits of the HS master code 00001 and final 8 bit code is sent as the high speed master code. Possible value range for these bits is 001-111. These bits can be programmed only when HICR[MSTA] is 0. **Note:** Combination 00001000 is reserved for the test and debug purposes.
8 ADDR_MODE	Address Mode select: This bit controls the address mode selected for the data transfer in master mode. 0 7 bit addressing is selected (Default) 1 10 bit addressing mode is selected.
7 HIIEN	HS_I^{2}C interrupt enable. 0 HS_I^{2}C module interrupt is disabled.(Default) 1 HS_I^{2}C module interrupt is enabled. An interrupt is generated whenever any one of the following status flags are set and corresponding mask bits in Interrupt Mask Register (i.e. HIIMR) are cleared. • One byte transfer is completed either in receive or transmit mode. (the interrupt is set at the falling edge of the ninth clock). • An address is received that matches its own specific address in slave-receive mode. • Arbitration is lost. • Tx FIFO transmit data empty • RX FIFO receive data full

Table 39-7. HS_I²C Control Register Field Description (continued)

Field	Description
6 MSTA	Master/slave mode select bit. This bit controls whether the HS_I²C is in master or slave mode. For master mode operation this bit should be set to 1. Changing MSTA from 1 to 0 generates a STOP condition on the bus and selects slave mode. If MSTA is changed from 0 to 1, the module generates START condition on the bus and selects master mode. When HS_I²C is configured as master and looses bus arbitration, MSTA is cleared automatically without generating a STOP signal on the bus. If MSTA bit is cleared while data transfer is going on, stop will be generated at byte boundary only. **Note:** Module ipg_hsi2c_clk clock should be ON for writing to the MSTA bit. 0 Slave mode.(Default) 1 Master mode.
5 MTX	Transmit/receive mode select bit. Selects the direction of master and slave transfers. 0 Receive.(Default) When a slave is addressed, the software should set MTX according to the slave read/write bit in the HS_I²C status register (HISR[SRW]). 1 Transmit. In master mode, MTX should be set according to the type of transfer required.
4 TXAK	Transmit acknowledge enable. Specifies the value driven onto SDAH during acknowledge cycles for both master and slave receivers. **Note:** This bit is effective only when HS_I²C module act as a receiver. 0 An acknowledge signal is sent to the bus at the ninth clock bit after receiving one byte of data.(Default) 1 No acknowledge signal response is sent (that is, the acknowledge bit = 1).
3 RSTA	Repeated start. Initiates the repeated start on the I²C bus in master mode. The RSTA is self clearing bit which gets cleared at the data or address byte boundary. The core needs to read this bit before programming it again. **Note:** Attempting a repeated start without bus mastership causes loss of arbitration 0 No repeated start.(Default) 1 Generates a repeated START condition
2 DMA_EN_TX	DMA Enable for TX. DMA_EN_TX specifies whether the data transfer is through the core or the DMA. If enabled, DMA Tx request is generated which initiates the DMA write cycle for HITDR register. When disabled, only the core can access HITDR data register and DMA Tx request is not generated. Hardware or software reset clears this bit. 0 DMA data interface disabled (Default) 1 DMA data interface enabled
1 DMA_EN_RX	DMA Enable for RX. DMA_EN_RX specifies whether the data transfer is through the core or DMA. If enabled, DMA Rx request is generated which initiates DMA read cycle for HIRDR register. When disabled, only the core can access data register or RX FIFO and DMA Rx request is not generated. Hardware or software reset clears this bit. 0 DMA data interface disabled (Default) 1 DMA data interface enabled
0 HIEN	HS_I²C enable. This bit controls the software reset of the entire HS_I²C module. Resetting the bit generates an internal reset to the module. If the module is enabled in between a byte transfer on the I²C bus, slave mode ignores the current bus transfer and starts operating when the next start condition is detected. Master mode is not aware that the bus is busy; so initiating a start cycle may corrupt the current bus cycle, ultimately causing either the current master or the HS_I²C module to lose arbitration. After which, bus operation returns to normal. This bit must be set before proceeding to programming of the other bits/registers. 0 The module is disabled (Default) 1 The HS_I²C module is enabled

39.3.3.4 HS_I²C Status Register (HISR)

The HISR contains bits that indicate transaction direction and status. Figure 39-7 shows the HS_I²C Status Register; and Table 39-8 provides its field descriptions.

Access: User read/write

0xBASE+0x0C(HISR)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	SHS_MODE	SADDR_MODE	SRW	HIBB	RXAK	TDC_ZERO	RDC_ZERO	BTD	HIAL	HIAAS	TDE	RDF
W									w1c	w1c	w1c	w1c	w1c	w1c		
RESET	0	0	1	0	0	0	0	0	0	0	0	0	0	0	1	0

Figure 39-7. HS_I²C Status Register

Table 39-8. HS_I²C Status Register Field Description

Field	Description
15–12	Reserved
11 SHS_MODE	Slave high speed mode. When HS_I²C is selected as slave, this bit indicates whether the module is selected for High-Speed mode or Fast/Standard mode data transfer. 0 HS_I²C is selected for Fast/Standard data transfer (Default). 1 HS_I²C is selected for High-Speed mode data transfer.
10 SADDR_MODE	Slave address mode. When HS_I²C is selected as slave, this bit indicates whether 7 or 10 bit addressing is used. 0 7 bit addressing is used (Default). 1 10 bit addressing is used.
9 SRW	Slave read/write. When the HS_I²C is addressed as a slave, HIAAS is set, and the slave read/write bit (SRW) indicates the value of the R/W command bit of the calling address sent from the master. SRW is valid only when a complete transfer has occurred, no other transfers have been initiated, and the HS_I²C module is a slave and has an address match. 0 Slave receive, master writing to slave (Default) 1 Slave transmit, master reading from slave
8 HIBB	HS_I²C bus busy. Indicates the status of the bus. 0 Bus is idle. When STOP condition is detected, HIBB is cleared (Default) 1 Bus is busy. When START condition is detected, HIBB is set.
7 RXAK	Received acknowledge. This bit is set when a NOACK value is received from the SDAH input for the acknowledge for the acknowledge cycle on I²C bus. This bit should be cleared by writing 1 to it.When HS_I²C is generating ACK or NOACK, this bit is invalid. 0 No “NOT ACK” bit received (Default) 1 A “No acknowledge” signal was detected at the ninth clock
6 TDC_ZERO	Transmit Data Counter Zero. This bit is set when HITDCR[TDC_EN] =1 and the TX data count HITDCR[TDC_ZERO] reaches 0. The TDC_ZERO bit must be cleared by software by writing a “1” to it 0 Transmit data counter (HITDCR[TDC]) is not zero (Default) 1 Transmit data counter (HITDCR[TDC]) is zero

Table 39-8. HS_I^{2}C Status Register Field Description (continued)

Field	Description
5 RDC_ZERO	Receive Data Counter Zero. This bit is set when HIRDCR[RDC_EN] =1 and the RX data count HIRDCR[RDC] reaches 0.The RDC_ZERO bit must be cleared by software by writing a “1” to it 0 Receive data counter (HIRDCR[RDC]) is not zero (Default) 1 Receive data counter (HIRDCR[RDC]) is zero
4 BTD	Byte transfer done. This bit is set when a byte of address/data has been transferred on the I^{2}C bus. The BTD bit must be cleared by software by writing a “1” to it. 0 Byte Transfer not Complete (Default) 1 Byte Transfer is complete, and set by the falling edge of the ninth clock of a byte transfer
3 HIAL	HS_I^{2}C Arbitration lost. This bit is set by HS_I^{2}C in the following circumstances (This bit must be cleared by writing a “1” to it): • SDAH input sampled low when the master drives high during an address or data-transmit cycle. • SDAH input sampled low when the master drives high during the acknowledge bit of a data-receive cycle. For the above two cases, the bit is set at the falling edge of 9th SCLH clock during the ACK cycle. • A start cycle is attempted when the bus is busy. • A repeated start cycle is requested in slave mode. • A stop condition is detected when the master did not request it. **Note:** Software cannot set the bit. 0 No arbitration lost (Default) 1 Arbitration is lost.
2 HIAAS	HS_I^{2}C addressed as a slave bit. The CPU is interrupted if the interrupt enable (HICR[HIIEN]) is set. The core must check the slave read/write bit (SRW) and set its TX/RX mode accordingly. This Bit must be cleared by writing a 1 to it. 0 Not addressed (Default) 1 Addressed as a slave. Set when its own address (HISADR) matches the calling address on I^{2}C bus.
1 TDE	Transmit Data Empty: TDE flag is set when the data level in TX FIFO is less than or equal to the transmit FIFO empty watermark value. When set, TDE indicates that data should be written to the TX FIFO. If HICR[HIIEN] bit is set and HIIMR[TDE] bit is zero, transmit data interrupt will be generated. TDE flag is cleared automatically when the data level in the TX FIFO becomes more than the transmit FIFO empty watermark level. Hardware reset, software reset, and Transmit FIFO flush operation set TDE. 0 Data level in TX FIFO is above transmit FIFO empty watermark level 1 Data level in TX FIFO is less than or equal to the transmit FIFO empty watermark value (Default)
0 RDF	Receive Data Full: RDF flag is set whenever the data level in RX FIFO equals or exceeds the selected watermark threshold. If HICR[HIIEN] bit is set and HIIMR[RDF] bit is zero, receive data interrupt will be generated. This bit is cleared automatically whenever the data level in RX FIFO is below the watermark threshold. Hardware reset, software reset, and Receive FIFO flush operation clears this flag. 0 data level in RX FIFO is below the selected watermark threshold (Default) 1 data level in RX FIFO has reached the selected watermark threshold

39.3.3.5 HS_I^{2}C Interrupt Mask Register (HIIMR)

The HIIMR contains the interrupt mask bits for various HS_I^{2}C interrupt conditions. Figure 39-8 shows the register: Table 39-9 describes the HIIMR fields.

Access: User Read/Write

0xBASE+0x10 (HIIMR)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

Figure 39-8. HS_I^{2}C Interrupt Mask Register (HIIMR)

Table 39-9. HS_I^{2}C Interrupt Mask Register Field Descriptions

Field	Description
15–8	Reserved
7 MASK_RXAK	Mask Received Acknowledge Interrupt: This bit masks the received acknowledge interrupt. If this bit is cleared and HICR[HIIEN] is set and whenever acknowledge is not received, interrupt is generated. 0 Received Acknowledge interrupt generated if HICR[HIIEN] is set 1 Mask received acknowledge interrupt (Default)
6 MASK_TDC	Mask Transmit Data Count Zero Interrupt: This bit masks transmit data count zero interrupt. If this bit is cleared and HICR[HIIEN] is set and whenever transmit data count is zero, interrupt is generated. 0 Transmit data count interrupt generated if HICR[HIIEN] is set 1 Mask transmit data count interrupt (Default)
5 MASK_RDC	Mask Receive Data Count Zero Interrupt: This bit masks receive data count zero interrupt. If this bit is cleared and HICR[HIIEN] is set and whenever receive data count is zero, interrupt is generated. 0 Receive data count interrupt generated if HICR[HIIEN] is set 1 Mask receive data count interrupt (Default)
4 MASK_BTD	Mask Data Transfer Interrupt. This bit masks byte transfer done interrupt. If this bit is cleared and HICR[HIIEN] is set and whenever one byte transfer is completed either in receive or transmit mode, interrupt is generated at the falling edge of the ninth clock. 0 Data transfer interrupt generated if HICR[HIIEN] is set. 1 Mask data transfer interrupt (Default)
3 MASK_AL	Mask Arbitration Lost Interrupt. This bit masks the arbitration lost interrupt. If this bit is cleared and HS_I^{2}C module looses bus arbitration (i.e HISR[HIAL] is set) and HICR[HIIEN] is set, interrupt will be generated. 0 Arbitration lost interrupt is generated if HICR[HIIEN] is set. 1 Mask arbitration lost interrupt (Default)
2 MASK_AAS	Mask Addressed As Slave Interrupt. This bit masks the HS_I^{2}C addressed as slave interrupt. If a address is received that matches its own specific address in slave-receive mode (i.e. HISR[HIAAS] is set) and HICR[HIIEN] is set and HIIMR[MASK_AAS] is cleared, interrupt will be generated. 0 HS_I^{2}C addressed as slave interrupt is generated if HICR[HIIEN] is set 1 Mask addressed as slave interrupt (Default).

Table 39-9. HS_I²C Interrupt Mask Register Field Descriptions (continued)

Field	Description
1 MASK_TDE	Mask Transmit Data Empty Interrupt. This bit masks the Tx FIFO transmit data empty interrupt. If this bit is cleared and HISR[TDE] is set and HICR[HIIEN] bit is set, interrupt will be generated. 0 Transmit data empty interrupt is generated if HICR[HIIEN] is set 1 Mask transmit data empty interrupt (Default)
0 MASK_RDF	Mask Receive Data Full Interrupt. This bit masks the Rx FIFO receive data full interrupt. If this bit cleared and HISR[RDF] is set and HICR[HIIEN] bit is set, interrupt will be generated. 0 Receive data full interrupt generated if HICR[HIIEN] is set 1 Mast receive data full interrupt (Default)

39.3.3.6 HS_I²C Tx Data Register (HITDR)

The HITDR register serves as the transmit data register in transmit mode. This register in write only register. Figure 39-9 shows the HS_I²C Tx Data Register; Table 39-10 provides its field descriptions.

0xBASE+0x14(HITDR) Access: User Write-only

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7–0 RX_DATA	RX Data Byte. Holds the last data byte received. Software should read the data byte received if Rx FIFO is disabled.

39.3.3.8 HS_I²C F/S-Mode Frequency Divide Register (HIFSFDR)

The HIFSFDR provides a programmable prescaler to configure the clock for bit-rate selection for Fast/Standard mode HS_I²C operation. The register does not get reset by software reset. Figure 39-11 shows the HS_I²C F/S-Mode Frequency Register; Table 39-12 provides its field descriptions.

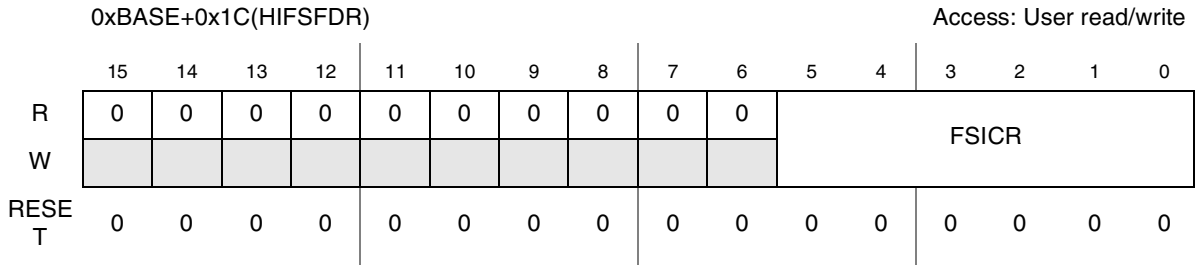

Figure 39-11. HS_I²C F/S Mode Frequency Divide Register

Table 39-12. HS_I²C F/S-Mode Frequency Divide Register Field Descriptions

Field	Description
15–6	Reserved
5–0 FSICR	F/S-Mode I²C clock rate. Prescales the clock for bit-rate selection. Due to potentially slow SCLH and SDAH rise and fall times, bus signals are sampled at the prescaler input frequency. The serial bit clock or prescaler output frequency is equal to module input ipg_hsi2c_clk clock divided by the divider shown in Table 39-13. **Note:** I²C protocol supports bit rates up to 400 Kbits/s in F/S-Mode. The FSICR bits need to be programmed in accordance with this constraint. The FSICR divider value will be used to generate the start and master code transmission in the beginning HS-Mode operation.

Table 39-16. HS_I²C Tx FIFO Register Field Descriptions

Field	Description
15–12	Reserved
11–8 TFC	Transmit FIFO Counter. These bits indicate the number of data words in the Transmit FIFO. Hardware reset, software reset or Transmit FIFO flush operation clears TFC bits. 0000 = 0 byte in transmit FIFO (Default) 0001 = 1 byte in transmit FIFO 0010 = 2 bytes in transmit FIFO .... 0111 = 7 bytes in transmit FIFO 1000 = 8 bytes in transmit FIFO 1001 to 1111 = Reserved
7 – 5	Reserved
4 - 2 TFWM	Transmit FIFO Empty WaterMark. These bits control the threshold at which the HISR[TDE] bit is set when TX FIFO is enabled. The TDE flag is set whenever the data level in the TX FIFO is less than or equal to the selected threshold. Hardware or software reset clears these bits. 000 = TDE is set, when the TX FIFO has 0 data word. (Default) 001 = TDE is set, when the TX FIFO has less than or equal to 1 data byte. 010 = TDE is set, when the TX FIFO has less than or equal to 2 data bytes. .... 111 = TDE is set, when the TX FIFO has less than or equal to 7 data bytes.
1 TFLSH	Transmit FIFO Flush. This bit controls the Transmit FIFO flush operation. Writing this bit as 1 would reset all the TX FIFO logic and hence reset the TX FIFO if enabled. Writing this bit as 0 has no effect. Once set, this bit would get cleared automatically when the TX FIFO logic is completely reset. After TX FIFO flush operation, the software should ensure that this bit is cleared before starting any operation involving TX FIFO. TFLSH bit should only be set when HS_I²C is not in transmit mode. Hardware or software reset clears this bit. 0 No action (Default) 1 TX FIFO logic is reset
0 TFEN	Transmit FIFO Enable. This bit enables the transmit FIFO. Hardware or software reset clears this bit. 0 Transmit FIFO disabled (Default) 1 Transmit FIFO enabled

39.3.3.11 HS_I²C Rx FIFO Register (HIRFR)

This bit will come into effect only when HS_I²C is in master mode and HIRDCR[RDC_EN] bit is set. 0 STOP condition would be initiated on the I²C bus. The module would switch to slave mode clearing the HICR[MSTA] bit (Default). 1 Repeated Start condition would be initiated on I²C bus

Table 39-19. HS_I^{2}C Rx Data Count Register Field Description

Field	Description
8 RDC_EN	Receive Data Counter Enable: This bit enables the receive data counter operation. The RDC_EN should only be set, when HS_I^{2}C is configured for master Rx operation. 0 Rx data counter is disabled (Default) 1 Rx data counter is enabled
7–0 RDC	Receive Data Counter: These bits contain the number of data to be received. It is a down counter and upon reaching zero, HISR[RDC_ZERO] status flag will be set. Rx data counter values should only be set once for the required number of data receive. 00000000 = All the bytes have been received. 00000001 = 1 byte needs to be received 00000010 = 2 bytes need to be received .... 11111110 = 254 bytes needs to be received 11111111 = 255 bytes needs to be received (Default)

39.4 Functional Description

39.4.1 HS_I^{2}C System Configuration

After completion of reset, the HS_I^{2}C module defaults to slave receive mode. When HS_I^{2}C module is not operating as a master or responding to a slave transmit address, the module will default to the slave receiver state.

39.4.2 I^{2}C Protocol

The I^{2}C communication protocol consists of six components, as follows:

- START
- Data Source/Recipient
- Data Direction
- Slave Acknowledge
- Data Acknowledge
- STOP

Refer to Figure 39-17 for the I^{2}C standard communication protocol, as defined in the following sections.

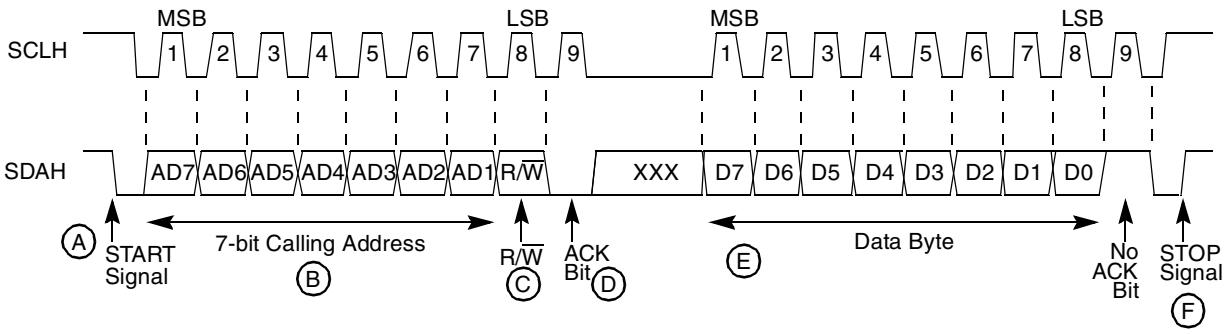

Figure 39-17. I²C Standard Communication Protocol

39.4.2.1 START Signal

When no other device is a bus master (both SCLH and SDAH lines are at logic high), a device can initiate communication by sending a START signal (Refer to A in Figure 39-17). A START signal is defined as a high-to-low transition of SDAH while SCLH is high. This signal denotes the beginning of a data transfer (each data transfer can be several bytes long) and awakens all slaves.

39.4.2.2 Slave Address Transmission

The master sends the slave address in the first byte after the START signal (B). After the seven-bit calling address, it sends the R/$\overline{W}$ bit (C), which decides the slave data transfer direction.

39.4.2.2.1 7-bit Addressing

The first seven bits of the first byte make up the slave address. The eighth bit is the LSB (least significant bit). It determines the direction of the message. A ‘0’ in the least significant position of the first byte means that the master will write information to a selected slave. A ‘1’ in this position means that the master will read information from the slave.

When an address is sent, each device in a system compares the first seven bits after the START condition with its address. If they match, the device considers itself addressed by the master as a slave-receiver or slave-transmitter, depending on the R/$\overline{W}$ bit.

Each slave must have a unique address. An I²C master must not transmit an address that is the same as its slave address; it cannot be master and slave at the same time.

The slave whose address matches with the address sent by the master pulls SDAH low at the ninth clock (D) to return an acknowledge bit.

39.4.2.3 Data Transfer

When successful slave addressing is achieved, the data transfer can proceed (E) on a byte-by-byte basis in the direction specified by the R/$\overline{W}$ bit sent by the calling master.

Data can be changed only while SCLH is low and must be held stable while SCLH is high, as shown in Figure 39-17. SCLH is pulsed once for each data bit, with the MSB being sent first. The receiving device

must acknowledge each byte by pulling SDAH low at the ninth clock; therefore, a data byte transfer takes nine clock pulses.

If the slave device does not acknowledge the master, it must leave SDAH high. The master can then generate a STOP signal to abort the data transfer or generate a START signal (a repeated start, as shown in Figure 39-18) to start a new calling sequence.

If the master receiver does not acknowledge the slave transmitter after a byte transmission, it means end-of-data to the slave. The slave releases SDAH for the master to generate a STOP or START signal.

39.4.2.4 STOP Signal

The master can terminate communication by generating a STOP signal to free the bus. A STOP signal is defined as a low-to-high transition of SDAH while SCLH is at logical high (F).

NOTE

A master can generate a STOP even if the slave has made an acknowledgment; at that point, the slave must release the bus.

39.4.2.5 Repeated Start

Instead of signalling a STOP, the master can repeat the START signal, followed by a calling command (Refer to A in Figure 39-18). A repeated START occurs when a START signal is generated without first generating a STOP signal to end the communication. The master uses a repeated START to communicate with another slave or with the same slave in a different mode (transmit/receive mode) without releasing the bus.

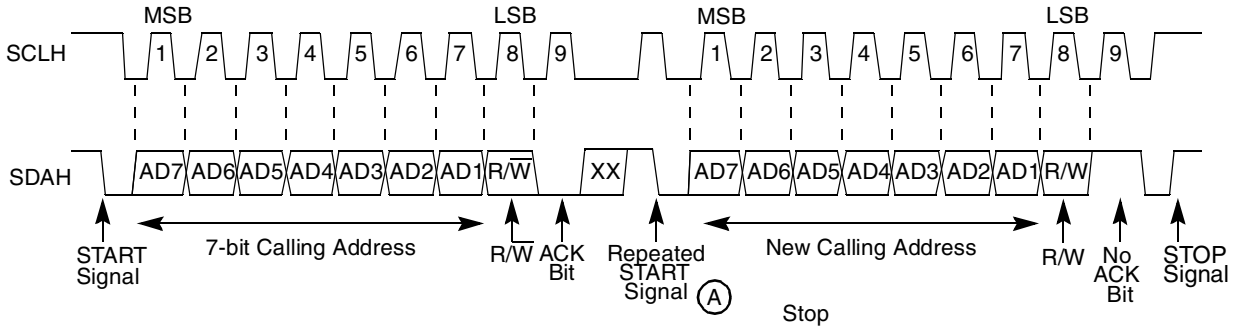

Figure 39-18. Repeated START

39.4.3 Arbitration Procedure

If multiple devices simultaneously request the bus, the bus clock is determined by a synchronization procedure in which the low period equals the longest clock-low period among the devices, and the high period equals the shortest. A data arbitration procedure determines the relative priority of competing devices. A device loses arbitration if it sends logic high while another sends logic low; it immediately switches to slave-receive mode and stops driving SDAH. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, hardware sets the arbitration lost bit in the HS_I^{2}C Status register (HISR[HIAL] to indicate loss of arbitration.

39.4.4 Clock Synchronization

As wire-AND logic is used, a high-to-low transition on SCLH affects devices connected to the bus. Devices start counting their low period when the master drives SCLH low. When a device clock goes low, it holds SCLH low until the clock high state is reached. However, the low-to-high change in this device clock may not change the state of SCLH if another device clock is still in its low period. Therefore, the device with the longest low period holds the synchronized clock SCLH low. Devices with shorter low periods enter a high wait state during this time (refer to Figure 39-19). When all devices involved have counted off their low period, the synchronized clock SCLH is released and pulled high. There is then no difference between device clocks and the state of SCLH, so all of the devices start counting their high periods. The first device to complete its high period pulls SCLH low again.

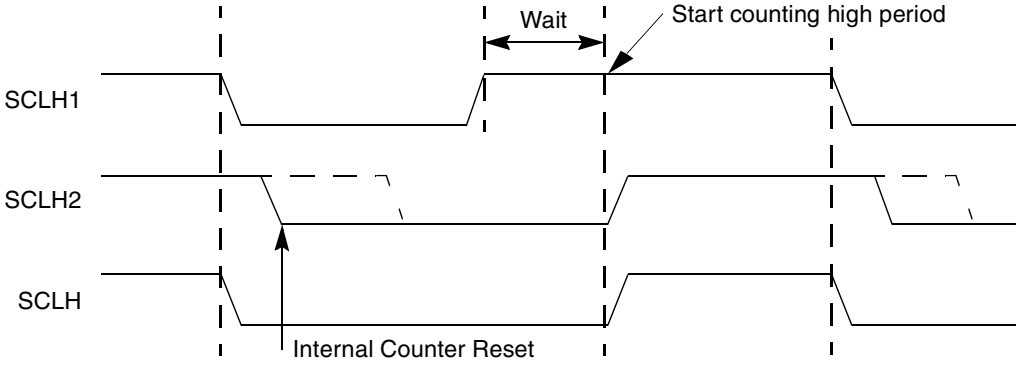

Figure 39-19. Synchronized Clock SCLH

39.4.5 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. Slave devices can hold SCLH low after completing one byte transfer (9 bits). In such a case, the clock mechanism halts the bus clock and forces the master clock into a wait state until the slave releases SCLH.

39.4.6 Clock Stretching

Slaves can use the clock synchronization mechanism to slow down the transfer bit rate. After the master has driven SCLH low, the slave can drive SCLH low for the required period and then release it. If the slave SCLH low period is longer than the master SCLH low period, the resulting SCLH bus signal low period is stretched according to slave SCLH low period.

39.4.7 High-Speed Mode Operation

The HS_I^{2}C module can transfer information at bit rates of up to 3.4 Mbits/s in HS-mode, yet it remains fully downward compatible with Fast or Standard-mode (F/S-mode) devices for bi-directional communication in a mixed-speed bus system. With the exception that arbitration and clock synchronization is not performed during the HS-mode transfer, the same serial bus protocol and data format is maintained as with the F/S-mode system.

Serial data transfer format in HS-mode meets the Standard-mode I^2C-bus specification. HS-mode can only commence after the following conditions are met (all of which occur while in F/S-mode):

1. START condition (S)
2. 8-bit master code (00001XXX)
3. not-acknowledge bit ($\overline{A}$)

Figure 39-20 and Figure 39-21 show this in more detail. The HS master code has two main functions:

1. It allows arbitration and synchronization between competing masters at F/S-mode speeds, resulting in one winning master.
2. It indicates the beginning of an HS-mode transfer.

HS-mode master codes are reserved 8-bit codes, which are not used for slave addressing or other purposes. Furthermore, as each master has its own unique master code, up to eight HS-mode masters can be present on the one I^2C-bus system (although master code 0000 1000 should be reserved for test and diagnostic purposes). The master code for an HS_I^2C module is software programmable in HICR[11-9]. Arbitration and clock synchronization only take place during the transmission of the master code and not-acknowledge bit ($\overline{A}$), after which one winning master remains active. The master code indicates to other devices that an HS-mode transfer is to begin and the connected devices must meet the HS-mode specification. As no device is allowed to acknowledge the master code, the master code is followed by a not-acknowledge ($\overline{A}$). After the not-acknowledge bit ($\overline{A}$), and the SCLH line has been pulled-up to a HIGH level, the active master switches to HS-mode and enables (at time tH, refer to Figure 39-21) the current-source pull-up circuit for the SCLH signal. As other devices can delay the serial transfer before tH by stretching the LOW period of the SCLH signal, the active master will enable its current-source pull-up circuit when all devices have released the SCLH line and the SCLH signal has reached a HIGH level, thus speeding up the last part of the rise time of the SCLH signal. The active master then sends a repeated START condition (Sr) followed by a 7-bit slave address (or 10-bit slave address, refer to Section 39.4.8, 10-Bit Addressing") with a R/$\overline{W}$ bit address, and receives an acknowledge bit (A) from the selected slave.

After a repeated START condition and after each acknowledge bit (A) or not-acknowledge bit ($\overline{A}$), the active master disables its current-source pull-up circuit. This enables other devices to delay the serial transfer by stretching the LOW period of the SCLH signal. The active master re-enables its current-source pull-up circuit again when all devices have released and the SCLH signal reaches a HIGH level, and so speeds up the last part of the SCLH signal s rise time.

Data transfer continues in HS-mode after the next repeated START (Sr), and only switches back to F/S-mode after a STOP condition (P). To reduce the overhead of the master code, it s possible that a master links a number of HS-mode transfers, separated by repeated START conditions (Sr).

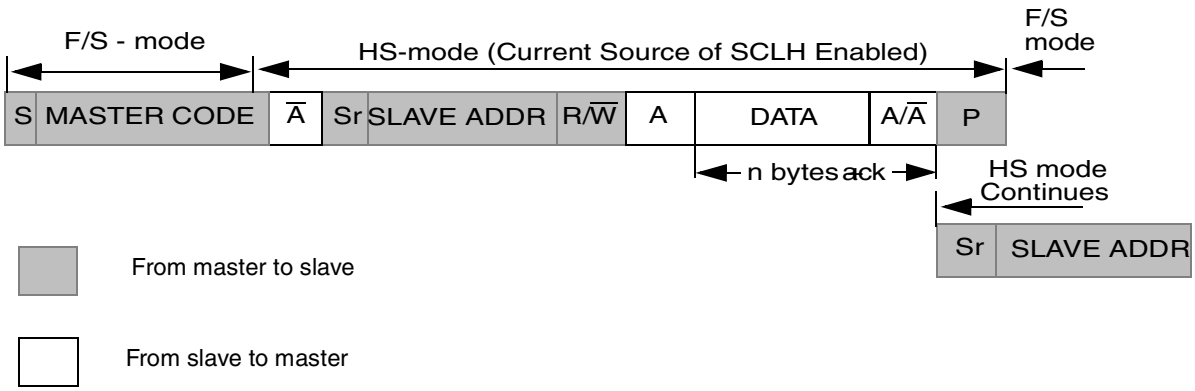

Figure 39-20. Data Transfer Format in HS-Mode

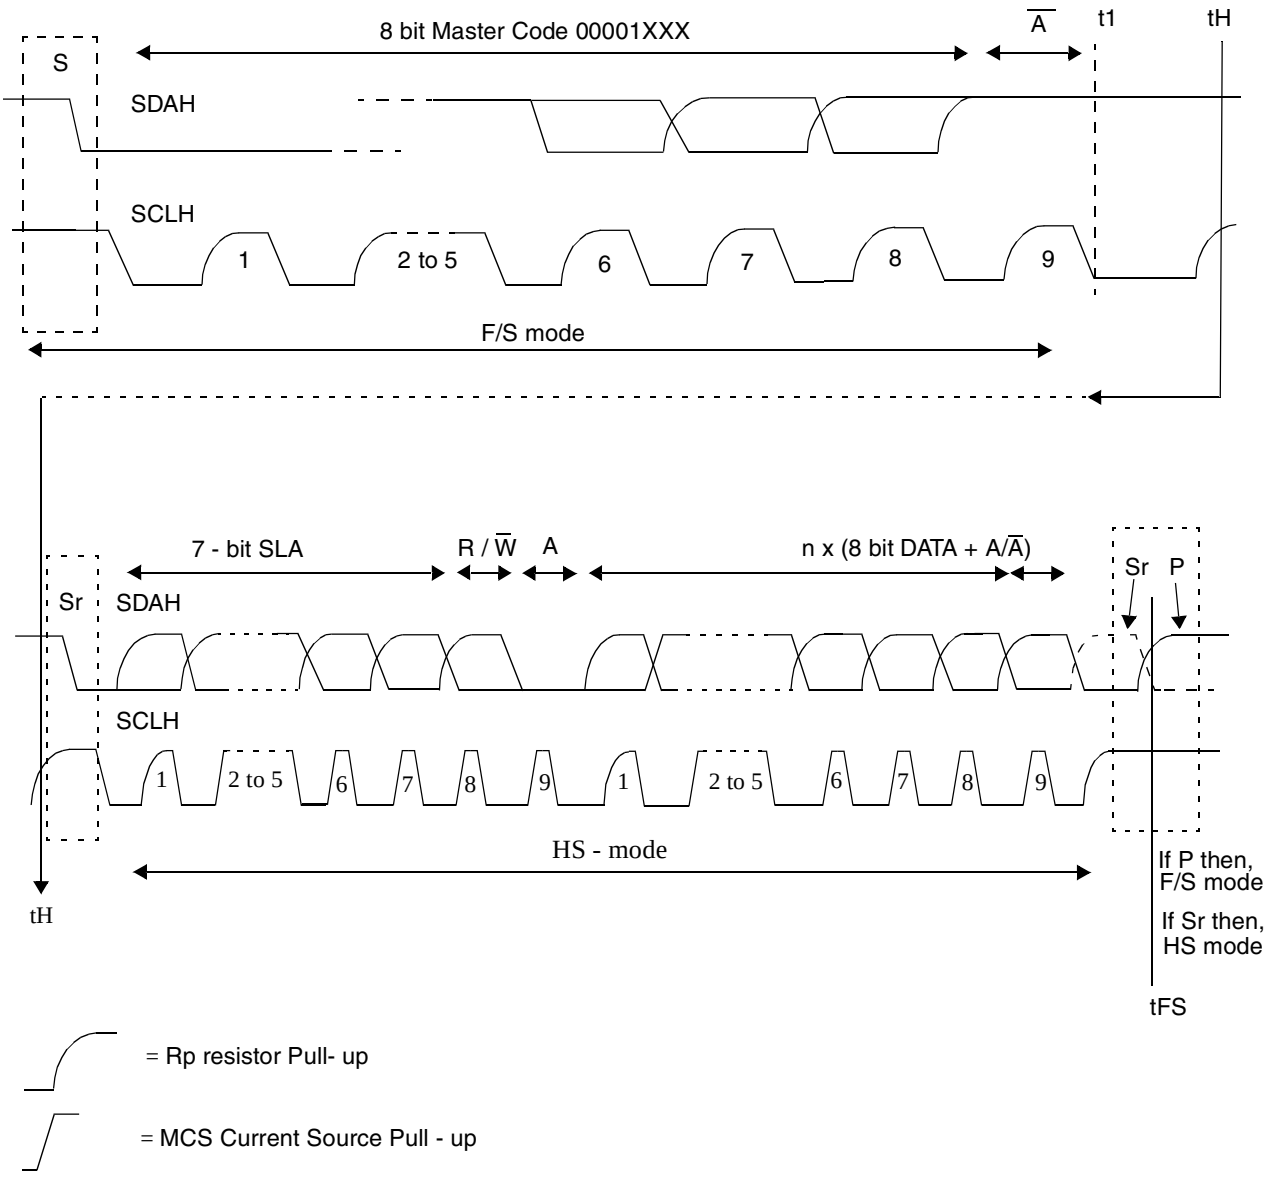

Figure 39-21. A Complete HS-Mode Transfer

39.4.8 10-Bit Addressing

The 10 bit addressing scheme, exploits the reserved combination of 1111XXX. Although there are eight possible combinations of the reserved address bits 1111XXX, only four combinations 11110XX are used for 10-bit addressing. The remaining four combinations of 11111XX are reserved for future I^2C-bus enhancements.

The 10-bit slave address is formed from the first two bytes following a START condition (S) or a repeated START condition (Sr). The first seven bits of the first byte are the combination 11110XX of which the last two bits (XX) are the two most-significant bits (MSBs) of the 10-bit address; the eighth bit of the first byte is the R/$\overline{W}$ bit that determines the direction of the message. A zero in the least significant position of the first byte means that the master will write information to a selected slave. A one in this position means that the master will read information from the slave. If the R/$\overline{W}$ bit is zero, then the second byte contains the remaining 8 bits (XXXXXXXX) of the 10-bit address. If the R/$\overline{W}$ bit is one, then the next byte contains data transmitted from a slave to a master.

Various combinations of read/write formats are possible within a transfer that includes 10-bit addressing. Possible data transfer formats are:

39.4.8.1 Master-Transmitter Transmits to Slave-receiver With a 10-Bit Slave Address.

The Figure 39-22 shows a master transmitter transmits to slave receiver using 10 bit addressing. When a 10-bit address follows a START condition, each slave compares the first seven bits of the first byte of the slave address (11110XX) with its own address and tests if the eighth bit (R/$\overline{W}$ direction bit) is 0. It is possible that more than one device will find a match and generate an acknowledge (A1). All slaves that found a match will compare the eight bits of the second byte of the slave address (XXXXXXXX) with their own addresses, but only one slave will find a match and generate an acknowledge (A2). The matching slave will remain addressed by the master until it receives a STOP condition (P) or a repeated START condition (Sr) followed by a different slave address.

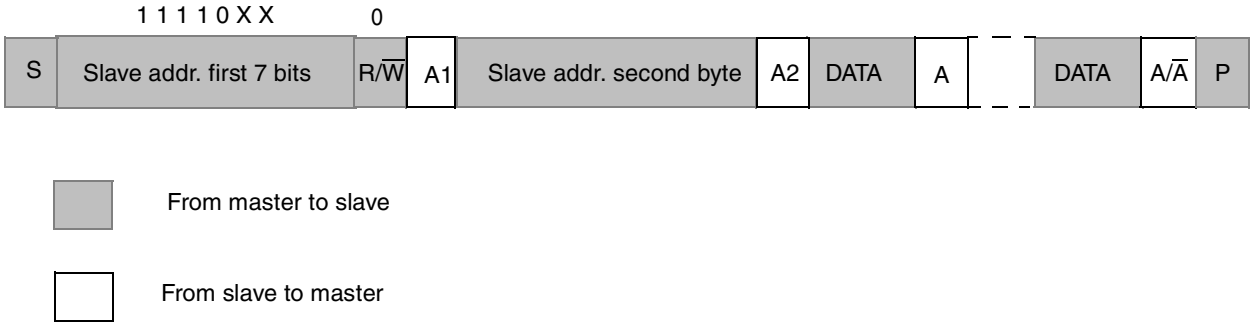

Figure 39-22. Master Transmitter Addresses a Slave Receiver with 10-Bit Address.

39.4.8.2 Master-Receiver Reads Slave-Transmitter With a 10-Bit Slave Address.

The transfer direction is changed after the second R/$\overline{W}$ bit (Refer to Figure 39-23). Up to and including acknowledge bit A2, the procedure is the same as that described for a master-transmitter addressing a slave-receiver. After the repeated START condition (Sr), a matching slave remembers that it was addressed before. This slave then checks if the first seven bits of the first byte of the slave address following Sr are the same as they were after the START condition (S), and tests if the eighth (R/$\overline{W}$) bit is 1. If there is a

match, the slave considers that it has been addressed as a transmitter and generates acknowledge A3. The slave-transmitter remains addressed until it receives a STOP condition (P) or until it receives another repeated START condition (Sr) followed by a different slave address. After a repeated START condition (Sr), all the other slave devices will also compare the first seven bits of the first byte of the slave address (11110XX) with their own addresses and test the eighth (R/$\overline{W}$) bit. However, none of them will be addressed because R/$\overline{W}$ = 1 (for 10-bit devices), or the 11110XX slave address (for 7-bit devices) does not match.

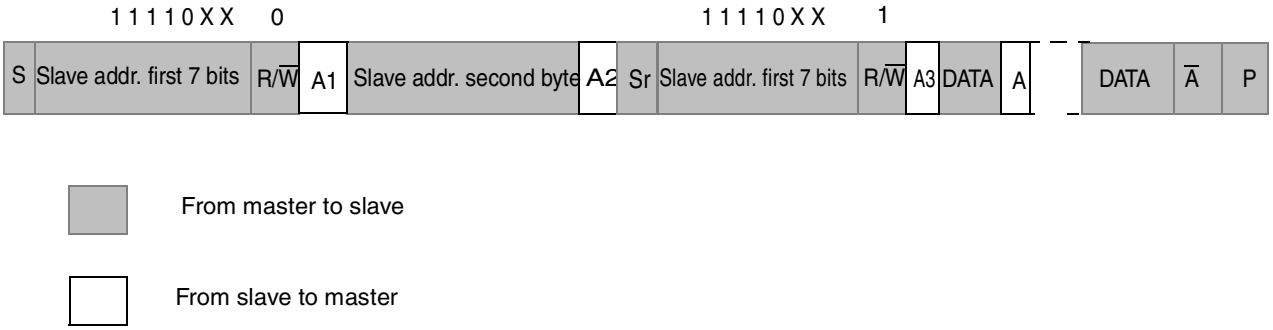

Figure 39-23. A Master-receiver Addresses a Slave-Transmitter With a 10-bit Address.

39.4.8.3 Combined Format

The combined formats like, a master transmits data to one slave and then transmits data to another slave is also possible. Another combined format where 10-bit and 7-bit addressing combined in one serial transfer is also possible. In this case the same master occupies the bus all the time.

39.4.9 DMA Bus Interface

The IP bus interface is used for both HS_I^{2}C registers read/write operation as well as DMA transfer. The core can program the HS_I^{2}C to transfer data to or from memory through the DMA controller. The interface uses two DMA channels: one to write transmit data to the HS_I^{2}C, and one to read the received data from the HS_I^{2}C module. In each case, a transfer is initiated by a dedicated DMA receive or transmit request from the HS_I^{2}C. Figure 39-24 shows the DMA interface operation of HS_I^{2}C.

The DMA will be used for data transfer operation only. The address register, HIMADR is used for slave address transfer in master mode and HISADR is used for slave address comparison for slave mode. If the DMA and FIFO are enabled, and HS_I^{2}C is in master mode and looses bus arbitration, software needs to re-configure the module for master mode operation if the module needs to be operated in master mode.

When HS_I^{2}C is configured for master transmit operation, DMA and FIFO are enabled and for a particular data or address cycle ACK is not received and HICR[AUTO_RSTA] bit is set, HS_I^{2}C will generate the repeated operation and mean time interrupt will be generated to indicate the ACK has not been received. After the address phase the same data will be transmitted again for which ACK is not received so that there is no loss of data.

39.4.9.1 DMA Transmit Request

If the TX FIFO is enabled and DMA_EN_TX is set, the DMA transmit request is generated when the data level in the TX FIFO is less than or equal to the programmable Transmit FIFO Empty WaterMark (TFWM[4:0]).

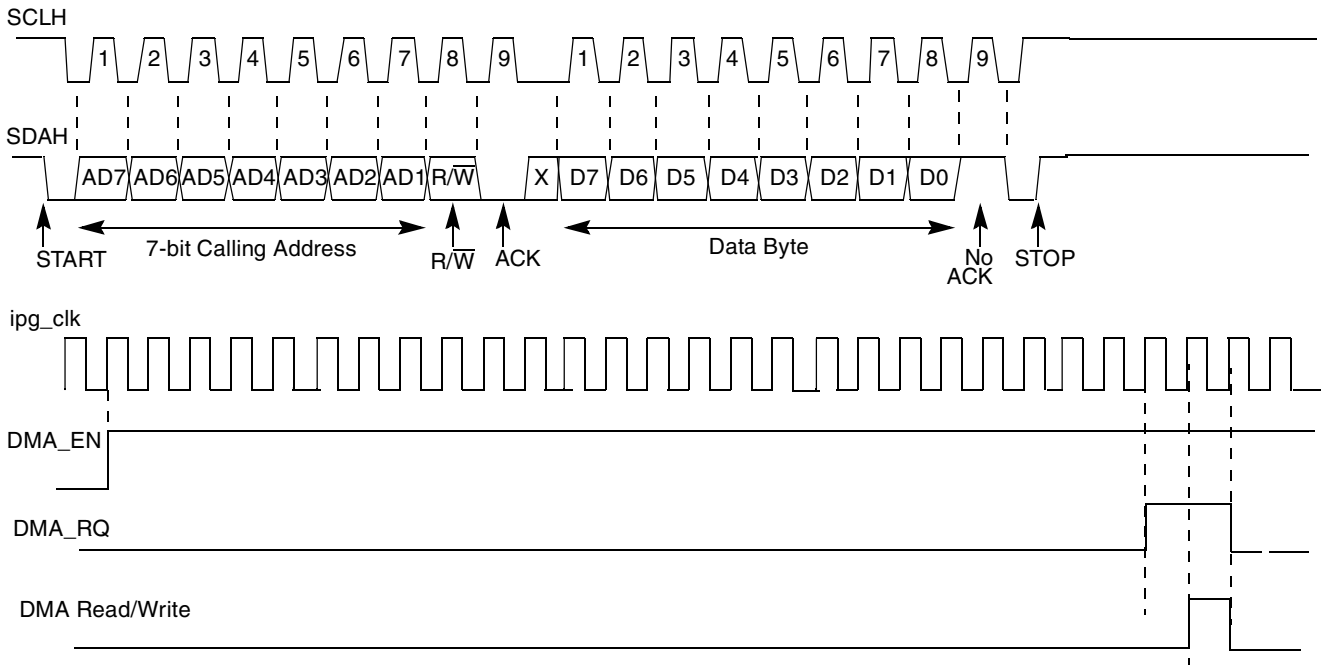

Figure 39-24. DMA Interface Operation of HS_I^{2}C

39.4.9.2 DMA Receive Request

If the RX FIFO is enabled and DMA_EN_RX is set, the DMA receive request is generated when the data level in the RX FIFO is greater than or equal to the programmable Receive FIFO Full WaterMark (RFWM[5:0]).

39.4.10 Receive and Transmit FIFOs

A 8 × 8 Tx FIFO and a 8 × 8 Rx FIFO are present to buffer HS_I^{2}C Tx and Rx data respectively. Figure 39-25 shows a high level block diagram of FIFOs and associated control registers in the HS_I^{2}C.

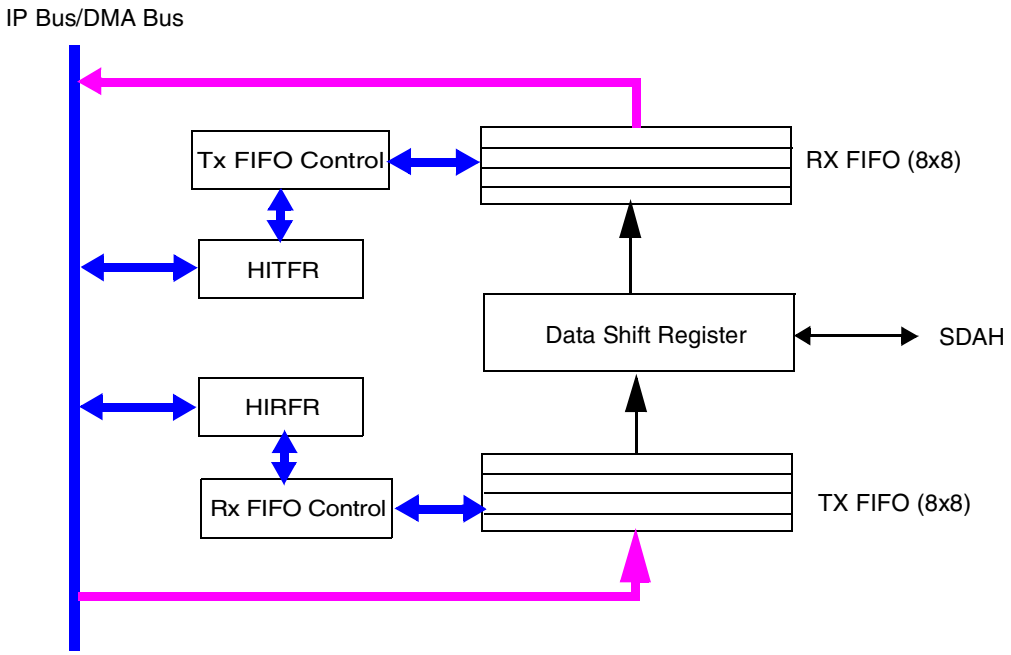

Figure 39-25. Block Diagram of FIFOs and its Control Registers in HS_I^{2}C

39.4.11 FIFO Flush Operation

The RX and TX FIFOs are reset by a Hardware or software reset. To reset only the FIFOs without affecting the HS_I^{2}C data transfer configuration, there are control bits provided in the HITFR and HIRFR registers for Tx and Rx FIFO respectively. The RFLSH bit is used to reset the RX FIFO and TFLSH bit is used to reset the TX FIFO. This RX FIFO/ TX FIFO reset using these control bits is referred to as RX FIFO/ TX FIFO flush operation. The ipg_hsi2c_clk should be ON for Tx/Rx FIFO flush operation.

39.4.12 IP Bus Accesses

HS_I^{2}C is a 32-bit IP module. Only 16 bit and 8 bit accesses should be performed to the module.

39.4.13 Generation of Transfer Error on IP Bus

If an address is received on the IP slave bus interface that is not implemented, an access error is generated (ips_xfr_err is asserted). The input pin resp_sel provides the configuration capability to generate this response. The resp_sel pin must be asserted to enable the ips_xfr_err signal.

39.4.14 Clocks

There are two clock sources for HS_I^{2}C module as follows.

- ipg_clk_s—The clock is used for IP bus register read/writes.
- ipg_hsi2c_clk—This is the functional clock of the HS_I^{2}C module. The serial bit clock frequency is derived from the ipg_hsi2c_clk. The ipg_hsi2c_clk and ipg_clk_s clocks are asynchronous to each other. The minimum frequency of this clock should be 66.66 MHz for HS-mode operation.

39.4.15 Reset

The HS_I^{2}C module can be reset in two ways.

- Global reset: It is a global reset (ipg_hard_async_reset_b) and resets the whole HS_I^{2}C module.
- Software reset: The HICR[HIEN] bit when de-asserted will generate an internal reset which will reset part of the module.

39.4.16 Interrupts

There is only one interrupt line from the module. Interrupt is enabled by setting the HICR[HIIEN] bit. The interrupt is generated in any one of the following conditions.

- One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock).
- An address is received that matches its own specific address in slave-receive mode.
- Arbitration is lost.
- Tx FIFO Transmit data empty
- Rx FIFO Receive data full

There are separate interrupt mask bits in HIIMR register for each individual interrupt condition.

39.4.17 Endianness

The module only supports the little endian mode.

39.5 Initialization Information

The HS_I^{2}C needs to be initialized before the data transfer can take place. The initialization sequence for DMA and FIFO disabled condition is as follows:

1. Set the data sampling rate (HIFSFDR[FSICR]) to obtain SCLH frequency from the ipg_hsi2c_clk clock for F/S-Mode operation. Program the HIHSFDR[HSICR] to obtain the HS-Mode operating frequency.
2. Update the address in the (HISADR and HIMADR) to define its slave and master address for both 7 and 10 bit addressing.
3. Set the I^{2}C enable bit (HICR[HIEN]) to enable the HS_I^{2}C bus interface system.
4. Modify the bits in the HICR to select master/slave mode, transmit/receive mode, high-speed or F/S mode, 7 or 10 bit addressing and interrupt-enable or not.

39.5.1 Generation of START

After completion of the initialization procedure, serial data can be transmitted by selecting the master transmitter mode. In multi-master bus system, the busy bus (HISR[HIBB]) must be tested to determine whether the serial bus is free. If the bus is free (HIBB = 0), the START signal and the first byte (the slave address for 7-bit addressing or 10-bit address code for 10 bit addressing or HS mode code) can be sent. The data written to the data register comprises the address of the desired slave and the LSB indicates the transfer direction in case of 7-bit addressing mode. For 10-bit addressing mode, the first byte contains the 10 bit address code and the MSB two bits of the 10 bit address. The second byte contains the remaining 8 bits of the 10 bit address. Refer to Section 39.4.8, 10-Bit Addressing for more details on 10-bit addressing mode. The status bit HISR[SADDR_MODE] indicates whether 7/10-bit addressing mode is used when HS_I2C is selected as slave.

For High-Speed mode, the first byte after start/repeated start condition is 8 bit master code (the value in the HICR[HS_MST_CODE] for master mode). When HS_I^2C is configured as slave, the status bit HISR[SHS_MODE] indicates whether the module is selected for HS or F/S mode.

39.5.2 Post-Transfer Software Response

Sending or receiving a byte sets the byte transfer done bit (HISR[BTD]), which indicates one byte communication is finished. Upon data transfer completion and if HIIMR[MASK_BTD] is cleared and interrupt enable (HICR[HIIEN]) is set, an external interrupt is generated. The byte transfer done bit (HISR[BTD]) is cleared by writing 1 to this bit.

During slave-mode address cycles (HISR[HIAAS] = 1), the slave read/write bit HISR[SRW] is read to determine the direction of the next transfer. For slave-mode data cycles (HISR[HIAAS] = 0), HISR[SRW] is invalid.

39.5.3 Generation of STOP

A data transfer ends when the master signals a STOP, which can occur after all data is sent.

For a master receiver to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last data byte. This is done by setting the transmit acknowledge bit (HICR[TXAK]) before reading the next-to-last byte. Before the last byte is read, a STOP signal must be generated.

39.5.4 Generation of Repeated START

After the data transfer, if the master still wants the bus, it can signal another START followed by another slave address without signalling a STOP. Repeated start can be programmed by setting HICR[RSTA] bit.

39.5.5 Slave Mode

In the slave interrupt service routine (Refer to flow chart Figure 39-26), the module addressed as slave bit (HIAAS) should be tested to check if a calling of its own address has just been received. The only time HIAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred.

To clear the HISR[HIAAS], software should write 1 to this bit. A data transfer can now be initiated by writing information to HITDR for slave transmits, or read from HIRDR in slave-receive mode.

In the slave transmitter routine, the receive acknowledge bit (HISR[RXAK]) must be tested before sending the next byte of data. Setting of HISR[RXAK] means an end-of-data signal from the master receiver.

39.5.6 Arbitration Lost

If several devices try to engage the bus at the same time, one becomes master. Hardware immediately switches devices that lose arbitration to slave receive mode. Data output to SDAH stops, but SCLH is still generated until the end of the byte during which arbitration is lost. An interrupt occurs if the arbitration is lost (HISR[HIAL] = 1), and the slave mode is selected (HICR[MSTA] = 0). Refer to flow chart in Figure 39-26.

If the HS_I2C module is not a master and tries to transmit or does a START, hardware inhibits the transmission, clears MSTA without signalling a STOP, generates an interrupt to the CPU, and sets HISR[HIAL] to indicate a failed attempt to engage the bus. When considering these cases, the slave service routine should first test HISR[HIAL], and the software should clear it if it is set.

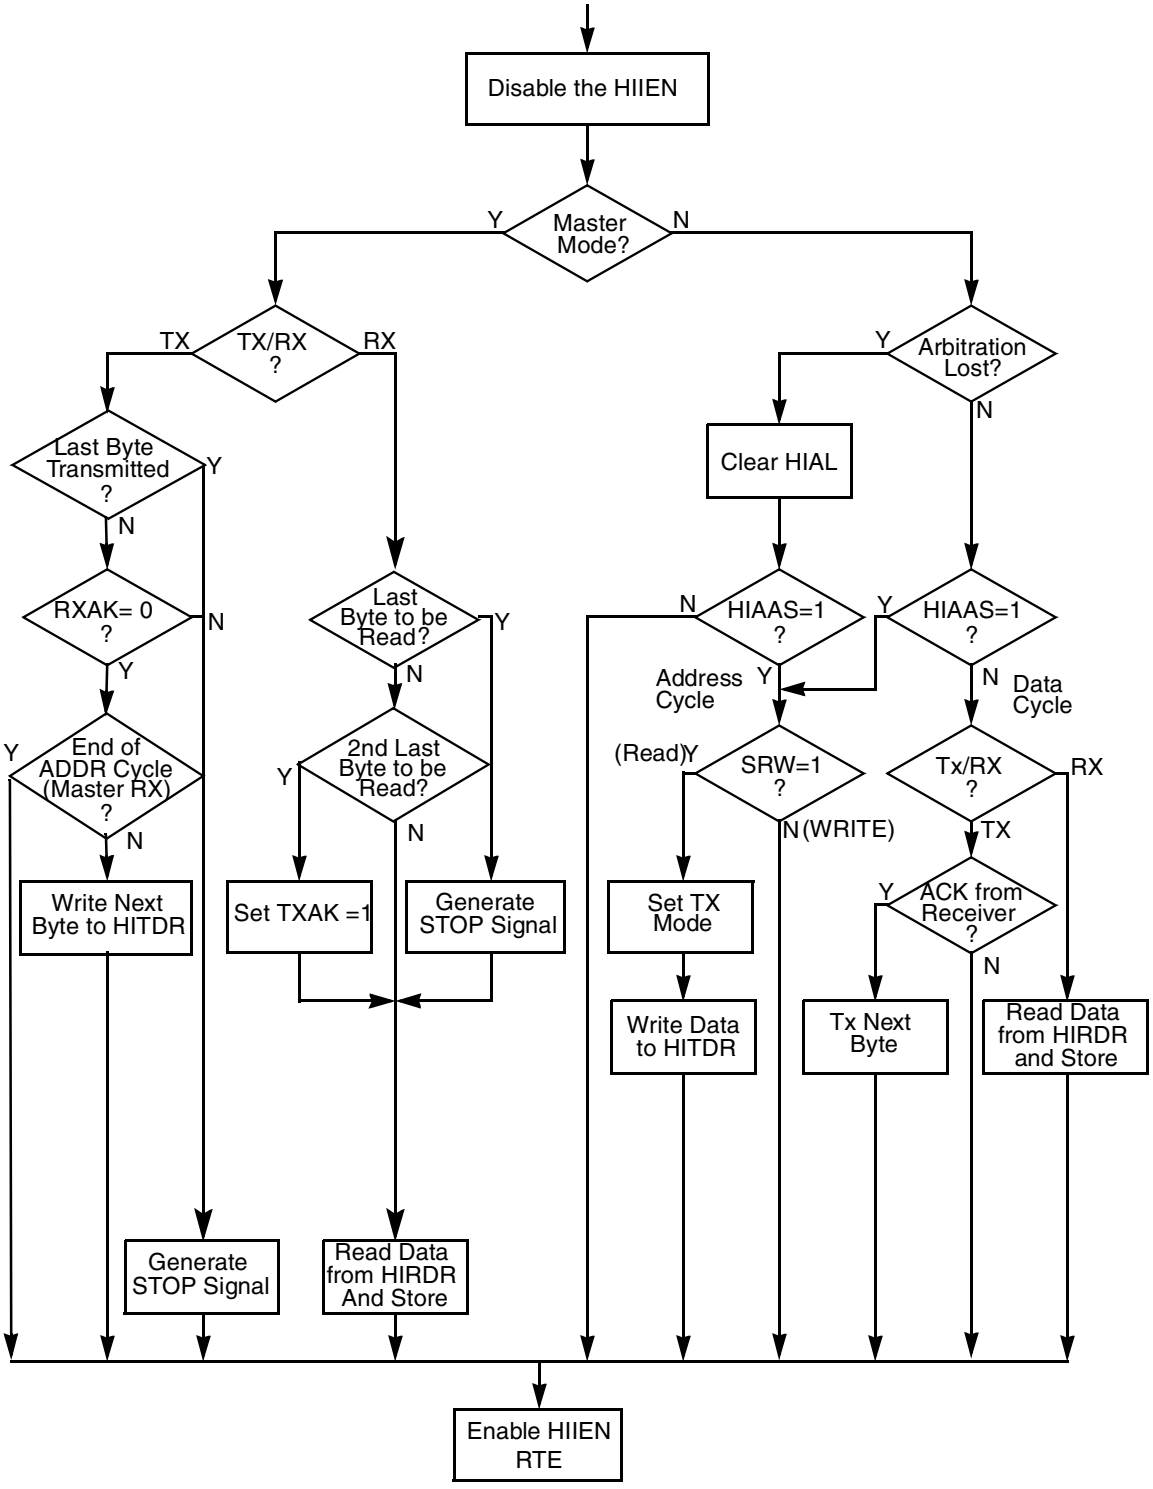

Figure 39-26. Flow-Chart of Typical HS_I^{2}C Interrupt Routine when Tx/Rx FIFO disabled

39.6 Application Information

39.6.1 Programming Sequence:

39.6.1.1 7Bit/10Bit Address Master Transmit:

39.6.1.1.1 DMA_EN = 0 and FIFO_EN = 0

1. Program HIFSFDR[FSICR] register to set SCLH frequency for F/S-Mode operation. Similarly program HIHSFDR[HSICR] register to set HS-Mode operating frequency.
2. Enable HS_I^{2}C by setting HICR[HIEN] to 1.
3. Program the HICR[ADDR_MODE] bit for selecting between 7 bit and 10 bit addressing mode. Program the LSB/MSB address of the slave to be transmitted to HIMADR.
4. Program the HICR[HS_MST_CODE] in case of High Speed transfer. Set the HICR[MTX] bit to indicate transmit operation.
5. Enable HS_I^{2}C interrupt by setting HICR[HIIEN] bit and the HIIMR[MSK_BTD] bit to interrupt the core when a byte transfer is complete.
6. Write one Byte of DATA to be transmitted to HITDR.
7. Read HISR[HIBB] to bit to make sure I^{2}C bus is free and initiate Master mode transmit/receive by setting HICR[MSTA] bit.
8. Wait until the core is interrupted by HS_I^{2}C interrupt when BTD is set for the second time at which time the first data would have been transmitted.
9. Program the next byte of data to be transmitted in HITDR. Clear the HS_I^{2}C interrupt by writing 1 to HISR[BTD].
10. Continue steps 8-9 until transmit is required to that Slave.
11. In order to initiate a repeated start, program the next slave address to HIMADR register. Then set HICR[RSTA] bit to initiate the repeated start at the end of current byte transfer.
12. Complete the transmit by Clearing the HICR[MSTA] which would initiate a STOP condition on I^{2}C bus.

39.6.1.1.2 DMA_EN = 1 and FIFO_EN = 1

Follow Steps 1 to 5, similar to DMA=0 and FIFO_EN=0 condition above and

1. Program the HITFR[TFWM] field with appropriate value for transmit. Set the HITFR[TFEN] bit to enable the TX FIFO. Flush the TX FIFO by setting the HITFR[TFLSH] bit.
2. Program system's DMA for appropriate Data Transmit to HS_I^{2}C. Set the HICR[DMA_EN_TX] bit to enable DMA requests for TX FIFO.
3. Initiate Master mode transmit/receive by setting HICR[MSTA] bit.
4. Data Transmit would be continued as long as there is valid data in the TXFIFO.
5. In order to initiate a repeated start, program the next slave address to HIMADR register. Then set HICR[RSTA] bit to initiate the repeated start at the end of current byte transfer.

6. Master mode transmit can be stopped by Clearing the HICR[MSTA] which would initiate a STOP condition on I^2C bus.
7. The DMA request generation should be disabled by clearing the HICR[DMA_EN_TX] bit.

39.6.1.2 7Bit/10Bit Address Master Receive:

39.6.1.2.1 DMA_EN = 0 and FIFO_EN = 0

1. Program HIFSFDR[FSICR] register to set SCLH frequency for F/S-Mode operation. Similarly program HIHSFDR[HSICR] register to set HS-Mode operating frequency.
2. Enable HS_I^2C by setting HICR[HIEN] to 1.
3. Program the HICR[ADDR_MODE] bit for selecting between 7 bit and 10 bit addressing mode. Program the LSB/MSB address of the slave to receive from, in the HIMADR register.
4. Program the HICR[HS_MST_CODE] in case for High Speed transfer. Set the HICR[MTX] bit to indicate a receive operation. Also program the HICR[TXACK] bit accordingly.
5. Enable HS_I^2C interrupt by setting HICR[HIIEN] bit and the HIIMR[MSK_BTD] bit to interrupt the core when a byte transfer is complete.
6. Initiate the Master mode Receive by setting HICR[MSTA] bit.
7. Wait until the core is interrupted by the HS_I^2C interrupt when BTD is set.
8. Fetch the data received from the slave by reading HIRDR register. Clear the HS_I^2C interrupt by writing 1 to HISR[BTD].
9. Continue steps 7-8 until receive operation is required to be continued.
10. In order to initiate a repeated start, program the next slave address to be addressed in the HIMADR register. Then set HICR[RSTA] bit to initiate a repeated start at the end of current byte transfer.
11. Complete the transmit by Clearing the HICR[MSTA] which would initiate a STOP condition on I^2C bus.

39.6.1.2.2 DMA_EN = 1 and FIFO_EN = 1

Follow Steps 1 to 5, similar to DMA=0 and FIFO_EN=0 condition above and

1. Program the HIRFR[RFWM] field with appropriate value to interrupt the DMA. Set the HIRFR[RFEN] bit to enable the RX FIFO. Flush the RX FIFO by setting the HIRFR[RFLSH] bit.
2. Program the system's DMA for appropriate Data Receive from HS_I^2C. Set the HICR[DMA_EN_RX] bit to enable DMA requests from HS_I^2C to the system's DMA.
3. Initiate Master mode transmit/receive by setting HICR[MSTA] bit.
4. RX DMA requests would be generated whenever DATA in RX FIFO equals/exceeds RX watermark value.
5. In order to initiate a repeated start, program the next slave address to HIMADR register. Then set HICR[RSTA] bit to initiate the repeated start at the end of current byte transfer.
6. Data Receive would be continued until the master mode receive operation is stopped by Clearing the HICR[MSTA] which would initiate a STOP condition on I^2C bus.

7. The DMA request generation should be disabled by clearing the HICR[DMA_EN_RX] bit.

39.6.1.3 7Bit/10Bit Address Slave Transmit:

39.6.1.3.1 DMA_EN = 0 and FIFO_EN = 0

1. Program HIFSFDR[FSICR] register to set SCLH frequency for F/S-Mode operation. Similarly program HIHSFDR[HSICR] register to set HS-Mode operating frequency.
2. Program the Slave Address to which HS_I^{2}C should respond as slave to HISADR register. Also program the HICR[SAMC] field to indicate the addressing mode to which HS_I^{2}C should respond.
3. Enable HS_I^{2}C by setting HICR[HIEN] to 1.
4. Enable HS_I^{2}C interrupt by setting HICR[HIIEN] bit and the HIIMR[HIAAS] bit to interrupt the core whenever HS_I^{2}C is addressed as slave.
5. When HS_I^{2}C interrupt is asserted and HIAAS bit is set, read the HISR[SRW] bit and write the corresponding value to the HICR[MTX] bit.
6. If HS_I^{2}C has been addressed to Transmit, write a Byte of data into HITDR register. Clear the interrupt by writing i to HISR[HIAAS] bit. Enable the BTD interrupt and RXACK interrupt by setting HIIMR[BTD] and HIIMR[RXACK] bits.
7. Wait until the core is interrupted by the HS_I^{2}C interrupt when HISR[BTD] is set.
8. Program the next byte of data to be transmitted in HITDR. Clear the HS_I^{2}C interrupt by writing 1 to HISR[BTD].
9. Continue steps 8-9 until a NOT ACK interrupt is received from the master or a STOP condition is detected which would clear the HISR[HIBB] bit. Clear the HS_I^{2}C interrupt by writing 1 to HISR[RXACK].
10. If repeated Start is detected on the I^{2}C bus, the procedure would follow from step 5.

39.6.1.3.2 DMA_EN = 1 and FIFO_EN = 1

Follow Steps 1 to 4, similar to DMA=0 and FIFO_EN=0 condition above and

1. Program the HITFR[TFWM] field with appropriate value for transmit. Set the HITFR[TFEN] bit to enable the TX FIFO. Flush the TX FIFO by setting the HITFR[TFLSH] bit.
2. Program system's DMA for appropriate Data Transmit to HS_I^{2}C. Set the HICR[DMA_EN_TX] bit to enable DMA requests for TX FIFO.
3. When HS_I^{2}C interrupt is asserted and HIAAS bit is set, read the HISR[SRW] bit and write the corresponding value to the HICR[MTX] bit. Enable the RXACK interrupt by setting HIIMR[RXACK] bits.
4. If HS_I^{2}C has been addressed to Transmit, data Transmit would be continued to the master as long as there is valid data in the TXFIFO or until a NOT ACK interrupt is received from the master or a STOP condition is detected which would clear the HISR[HIBB] bit. Clear the HS_I^{2}C interrupt by writing 1 to HISR[RXACK].
5. If repeated Start is detected on the I^{2}C bus, the procedure would follow from step 3.
6. The DMA request generation should be disabled by clearing the HICR[DMA_EN_TX] bit.

39.6.2 Programming Restrictions

Programming restrictions are as follows:

1. The HIFSFDR register and HIHSFDR register can be programmed only when HICR[HIEN] is 0.
2. The HISADR register and HICR[SAMC] field can be programmed only when HICR[HIEN] is 0.
3. The HICR[HS_MST_CODE] field can be programmed only when HICR[MSTA] bit is 0.
4. The HIMADR register can be programmed only when
   - HICR[MSTA] bit is 0. After HICR[MSTA] bit is set to 1, HIMADR should not be programmed for 4 cycles of ipg_hsi2c_clk.
   - HICR[RSTA] bit is 0. After HICR[RSTA] is set the HIMADR register should not be programmed until RSTA bit is cleared.
5. All other Control Registers can be programmed only when HICR[HIEN] is 1.
6. The HITDCR[TDC] field can be programmed only when HITDCR[TDC_EN] = 0 and similarly HIRDCR[RDC] field can be programmed only when HIRDCR[RDC_EN] = 0.
7. When changing from FIFO enable to disable mode, FIFO flush should be done.
8. The HITDCR[TDC_RSTA] and HIRDCR[RDC_RSTA] bits repeat start functionality should not be used for switching the configuration from master Tx to master Rx and vice versa. HITDCR[TDC_RSTA] and HIRDCR[RDC_RSTA] bits repeat start functionality is meant for data transfer to different slave devices for Tx only and Rx only cases.

39.6.3 Timing Section

Refer to Electrical Specification document for the HS_I^2C module timing characteristics.

Chapter 40
Inter IC (I^2C)

40.1 Introduction

The Inter IC (I^2C) module provides functionality of a standard I^2C slave and master. The I^2C module is designed to be compatible with the standard Philips I^2C bus protocol. See the I^2C block diagram in Figure 40-1.

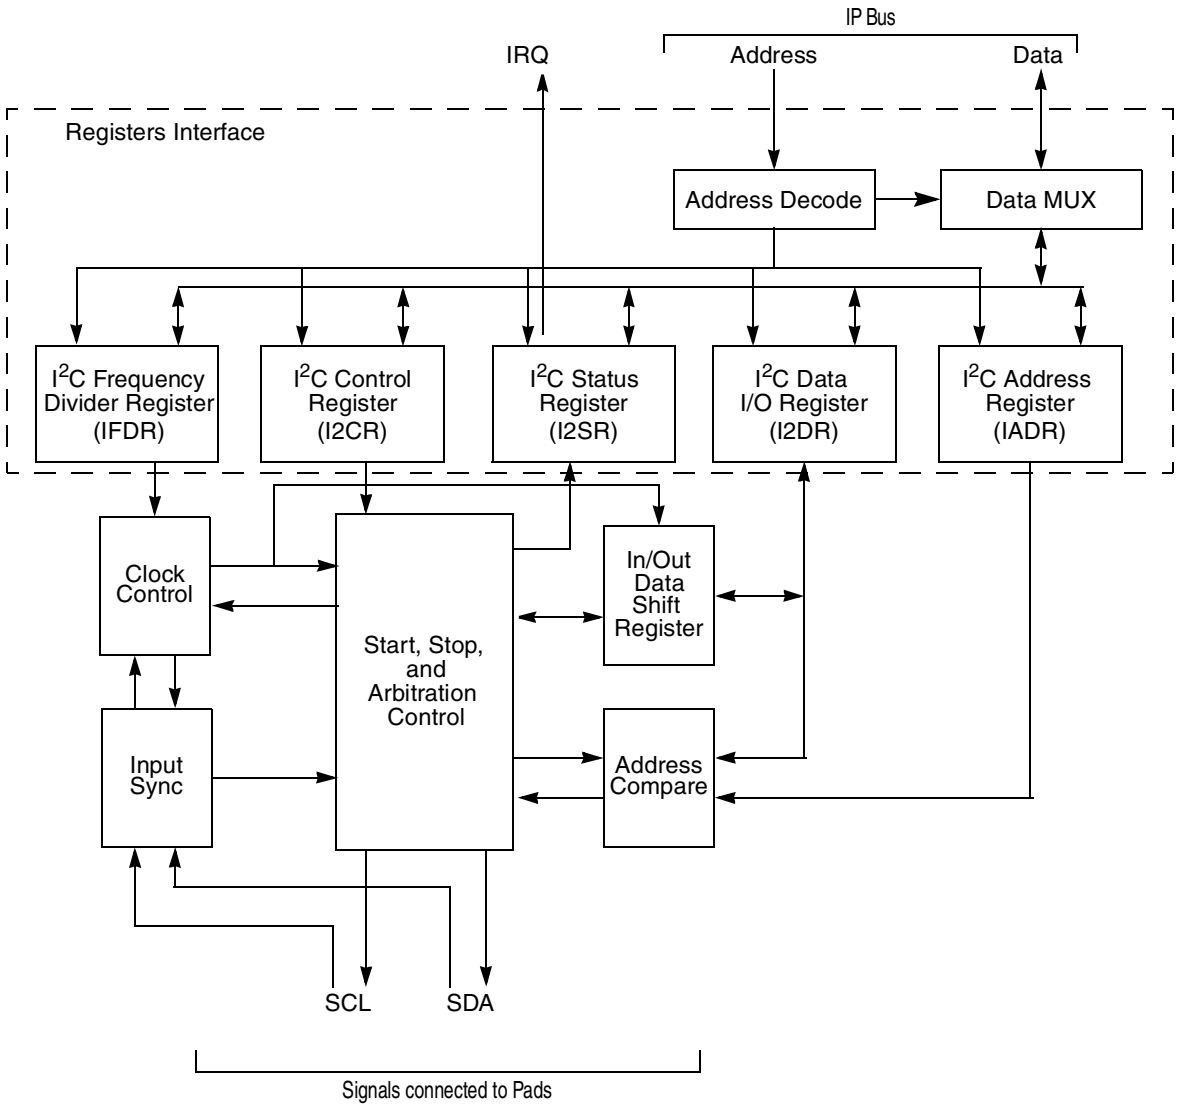

Figure 40-1. I^2C Block Diagram

40.1.1 Overview

I^{2}C is a two-wire, bidirectional serial bus that provides a simple, efficient method of data exchange, minimizing the interconnection between devices. This bus is suitable for applications requiring occasional communications over a short distance between many devices. The flexible I^{2}C allows additional devices to be connected to the bus for expansion and system development. See the connection diagram in Figure 40-2.

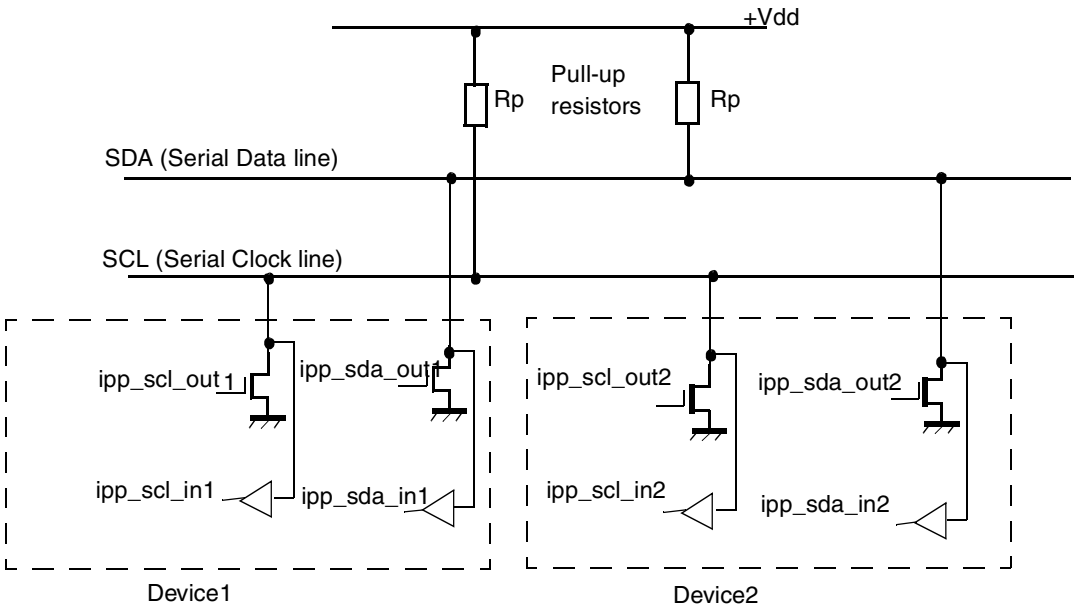

Figure 40-2. Connection of Devices to I^{2}C Bus

The I^{2}C operates up to 400 kbps, but it depends on the pad loading and timing. For pad requirement details, refer to Philips I^{2}C Bus Specification, Version 2.1. The I^{2}C system is a true multiple-master bus including arbitration and collision detection that prevents data corruption if multiple devices attempt to control the bus simultaneously. This feature supports complex applications with multiprocessor control and can be used for rapid testing and alignment of end products through external connections to an assembly-line computer.

40.1.2 Features

The I^{2}C module has the following key features:

- Compatibility with I^{2}C bus standard
- Multiple-master operation
- Software-programmable for one of 64 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven, byte-by-byte data transfer
- Arbitration-lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt

- Start and stop signal generation/detection
- Repeated START signal generation
- Acknowledge bit generation/detection
- Bus-busy detection

40.2 External Signal Description

Two pins are required for I^2C:

- I2C_SCL Bidirectional Clock Pin
- I2C_SDA Bidirectional Data Pin

For I^2C compliance, all devices connected to the SCL and SDA signals must have open-drain or open-collector outputs. The logic AND function is exercised on both lines with external pull-up resistors.

The module port signals going to the pad are tabulated in Table 40-2:

Table 40-2. Signal Properties

Name	Port	Function	Reset State	Pull up
ipp_scl_in	—	Serial Clock input	1	—
ipp_scl_out	—	Serial Clock output	1	Active
ipp_scl_out_en	—	Serial Clock output enable	0	—
ipp_sda_in	—	Serial Data input	1	—
ipp_sda_out	—	Serial Data output	1	Active
ipp_sda_out_en	—	Serial Data output enable	0	—

40.2.1 Detailed External Signal Descriptions

The following three signals are connected to the bidirectional driver for the SCL I/O Pad (through the IOMUX module):

- ipp_scl_in—Serial Input Clock
- ipp_scl_out—Serial Output Clock
- ipp_scl_out_en—Serial Output Clock Enable

The pad needs to have open-drain connectivity.
The ipp_scl_in will be the input signal from the pad. The ipp_scl_out will be the output to the pad from the module. The ipp_scl_out_en will act as the output enable.

The following three signals are connected to the bidirectional driver for the SDA I/O Pad (through the IOMUX module):

- ipp_sda_in—Serial Input Data
- ipp_sda_out—Serial Output Data
- ipp_sda_out_en—Serial Output Data Enable

The pad should have open-drain connectivity. The ipp_sda_in will be the input signal from the pad. The ipp_sda_out will be the output to the pad from module. The ipp_sda_out_en will act as the output enable.

40.3 Memory Map and Register Definition

The I^{2}C module contains five 16-bit registers. Section 40.3.3, Register Descriptions" on page 40-6 provides the detailed descriptions for all of the I^{2}C registers.

40.3.1 I^{2}C Memory Map

Table 40-3 shows the I^{2}C memory map.

Table 40-3. I^{2}C Memory Map

Address	Register	Access	Reset Value	Section/Page
0xBASE+0x000(IADR)	I^{2}C Address Register	R/W	0x0000	40.3.3.1/40-6
0xBASE+0x004(IFDR)	I^{2}C Frequency Divider Register	R/W	0x0000	40.3.3.2/40-6
0xBASE+0x008(I2CR)	I^{2}C Control Register	R/W	0x0000	40.3.3.3/40-8
0xBASE+0x00C(I2SR)	I^{2}C Status Register	R/W	0x0081	40.3.3.4/40-9
0xBASE+0x010(I2DR)	I^{2}C Data I/O Register	R/W	0x0000	40.3.3.5/40-10

NOTE

Registers at addresses 0xBASE_02, 0xBASE_06, 0xBASE_a, 0xBASE_0e are reserved for future additions.

40.3.2 Register Summary

Figure 40-3 shows the key to the register fields and Table 40-5 shows the register figure conventions.

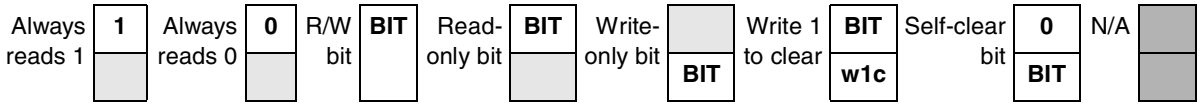

Figure 40-3. Key to Register Fields

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 40-5. Register Figure Conventions

Table 40-4 shows the I^{2}C register summary.

40.3.3 Register Descriptions

This section contains the detailed register descriptions for the I^{2}C registers in address order.

40.3.3.1 I^{2}C Address Register (IADR)

Figure 40-6 shows the I^{2}C Address Register; Table 40-5 provides its field descriptions.

0xBASE+0x000(IADR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	ADR							0
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 40-6. I^{2}C Address Register

The IADR holds the address the I^{2}C responds to when addressed as a slave.

NOTE

The slave address is not the address sent on the bus during the address transfer. The register is not reset by a software reset.

Table 40-5. I^{2}C Address Register Field Descriptions

Field	Description
15–8	Reserved
7–1 ADR	Slave address. Contains the specific slave address to be used by the I^{2}C module. Slave mode is the default I^{2}C mode for an address match on the bus.
0	Reserved

40.3.3.2 I^{2}C Frequency Register (IFDR)

The IFDR provides a programmable prescaler to configure the clock for bit-rate selection. The register does not get reset by software reset. Figure 40-7 shows the I^{2}C frequency register; Table 40-6 provides its field descriptions.

0xBASE+0x004(IFDR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Figure 40-7. I^{2}C Frequency Register

Table 40-6. I²C Frequency Register Field Descriptions

Field	Description
15–6	Reserved
5–0 IC	I²C clock rate. Pre scales the clock for bit-rate selection. Due to potentially slow SCL and SDA rise and fall times, bus signals are sampled at the prescaler frequency. The serial bit clock frequency is equal to IPG_CLK_PATREF divided by the divider shown in Table 40-7. **Note:** The IC can be changed anywhere in a program. I²C protocol supports bit rates up to 400 kbps. The IC bits need to be programmed in accordance with this constraint.

Table 40-7. IFDR Register Field Values

IC	Divider	IC	Divider	IC	Divider	IC	Divider

40.3.3.3 I²C Control Register (I2CR)

The I2CR is used to enable the I²C module and the I²C interrupt. It also contains bits that govern operation as a slave or a master. Figure 40-8 shows the I²C Control Register; Table 40-8 provides its field descriptions.

0xBASE+0x008(I2CR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	IEN	IIEN	MSTA	MTX	TXAK	0	0	0
W														RSTA		
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 40-8. I²C Control Register

Table 40-8. I²C Control Register Field Descriptions

Field	Description
15–8	Reserved
7 IEN	I²C enable. Also controls the software reset of the entire I²C module. Resetting the bit generates an internal reset to the module. If the module is enabled in the middle of a byte transfer, slave mode ignores the current bus transfer and starts operating when the next start condition is detected. Master mode is not aware that the bus is busy; so initiating a start cycle may corrupt the current bus cycle, ultimately causing either the current master or the I²C module to lose arbitration. After which, bus operation returns to normal. 0 The module is disabled, but registers can still be accessed. 1 The I²C module is enabled. This bit must be set before any other I2CR bits have any effect.
6 IIEN	I²C interrupt enable. 0 I²C module interrupts are disabled, but the status flag I2SR[IIF] continues to be set when an interrupt condition occurs. 1 I²C module interrupts are enabled. An I2C interrupt occurs if I2SR[IIF] is also set.
5 MSTA	Master/slave mode select bit. If the master loses arbitration, MSTA is cleared without generating a STOP signal. **Note:** Module clock should be on for writing to the MSTA bit. 0 Slave mode. Changing MSTA from 1 to 0 generates a STOP and selects slave mode. 1 Master mode. Changing MSTA from 0 to 1 signals a START on the bus and selects master mode.
4 MTX	Transmit/receive mode select bit. Selects the direction of master and slave transfers. 0 Receive. When a slave is addressed, the software should set MTX according to the slave read/write bit in the I²C status register (I2SR[SRW]). 1 Transmit. In master mode, MTX should be set according to the type of transfer required. Therefore, for address cycles, MTX is always 1.
3 TXAK	Transmit acknowledge enable. Specifies the value driven onto SDA during acknowledge cycles for both master and slave receivers. **Note:** Writing TXAK applies only when the I²C bus is a receiver. 0 An acknowledge signal is sent to the bus at the ninth clock bit after receiving one byte of data. 1 No acknowledge signal response is sent (that is, the acknowledge bit = 1).

Table 40-8. I²C Control Register Field Descriptions

Field	Description
2 RSTA	Repeat start. Always reads as 0. Attempting a repeat start without bus mastership causes loss of arbitration. 0 No repeat start 1 Generates a repeated START condition
1–0	Reserved

40.3.3.4 I²C Status Register (I2SR)

The I2SR contains bits that indicate transaction direction and status. Figure 40-9 shows the I²C Address Register; and Table 40-10 provides its field descriptions.

0xBASE+0x00C(I2SR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	ICF	IAAS	IBB	IAL	0	SRW	IIF	RXAK
W																
RESET	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	1

Figure 40-9. I²C Status Register

Table 40-10. I²C Status Register Field Descriptions

Field	Description
15–8	Reserved
7 ICF	Data transferring bit. While one byte of data is transferred, ICF is cleared. 0 Transfer is in progress. 1 Transfer is complete, and set by the falling edge of the ninth clock of a byte transfer.
6 IAAS	I²C addressed as a slave bit. The CPU is interrupted if the interrupt enable (I2CR[IIEN]) is set. The CPU must check the slave read/write bit (SRW) and set its TX/RX mode accordingly. Writing to I2CR clears this bit. 0 Not addressed 1 Addressed as a slave. Set when its own address (IADR) matches the calling address.
5 IBB	I²C bus busy bit. Indicates the status of the bus. 0 Bus is idle. If a STOP signal is detected, IBB is cleared. 1 Bus is busy. When START is detected, IBB is set.
4 IAL	Arbitration lost. Set by hardware in the following circumstances (IAL must be cleared by software by writing a “0” to it): • SDA input sampled low when the master drives high during an address or data-transmit cycle. • SDA input sampled low when the master drives high during the acknowledge bit of a data-receive cycle. For the above two cases, the bit is set at the falling edge of 9th SCL clock during the ACK cycle. • A start cycle is attempted when the bus is busy. • A repeated start cycle is requested in slave mode. • A stop condition is detected when the master did not request it. **Note:** Software cannot set the bit. 0 No arbitration lost. 1 Arbitration is lost.

Table 40-10. I²C Status Register Field Descriptions

Field	Description
3	Reserved
2 SRW	Slave read/write. When the I²C is addressed as a slave, IAAS is set, and the slave read/write bit (SRW) indicates the value of the R/W command bit of the calling address sent from the master. SRW is valid only when a complete transfer has occurred, no other transfers have been initiated, and the I²C module is a slave and has an address match. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave
1 IIF	I²C interrupt. Must be cleared by the software by writing a “0” to it in the interrupt routine. **Note:** The software cannot set the bit. 0 No I²C interrupt pending. 1 An interrupt is pending. This causes a processor interrupt request (if the interrupt enable is asserted [IIEN = 1]). The interrupt is set when one of the following occurs: • One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock). • An address is received that matches its own specific address in slave-receive mode. • Arbitration is lost.
0 RXAK	Received acknowledge. This is the value received of the SDA input for the acknowledge bit during a bus cycle. 0 An “acknowledge” signal was received after the completion of an 8-bit data transmission on the bus. 1 A “No acknowledge” signal was detected at the ninth clock.

40.3.3.5 I²C Data Register (I2DR)

In master-receive mode, reading the data register (I2DR) allows a read to occur and initiates the next byte to be received. In slave mode, the same function is available after it is addressed. Figure 40-11 shows the I²C Data Register; Table 40-9 provides its field descriptions.

0xBASE+0x010(I2DR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	DATA							
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 40-11. I²C Data Register

Table 40-9. I²C Data Register Field Descriptions

Field	Description
15–8	Reserved
7–0 DATA	Data Byte. Holds the last data byte received or the next data byte to be transferred. Software writes the next data byte to be transmitted or reads the data byte received.

NOTE

The core-written value in I2DR cannot be read back by the core: Only data written by the I²C bus side can be read.

40.4 Functional Description

This contains the following subsections:

- Section 40.4.1, I^{2}C System Configuration”
- Section 40.4.2, I^{2}C Protocol”
- Section 40.4.3, Arbitration Procedure”
- Section 40.4.4, Clock Synchronization”
- Section 40.4.5, Handshaking”
- Section 40.4.6, Clock Stretching”
- Section 40.4.7, IP Bus Accesses”
- Section 40.4.8, Generation of Transfer Error on IP Bus”

40.4.1 I^{2}C System Configuration

Out of a reset, the I^{2}C module defaults to slave receive operations. Thus, when not operating as a master or responding to a slave transmit address, the I^{2}C module defaults to the slave receiver state. For exceptions, see Section 40.5, Initialization/Application Information.”

NOTE

The I^{2}C module is designed to be compatible with the Philips I^{2}C bus protocol. For information on system configuration, protocol, and restrictions, refer to the I^{2}C Bus Specification, Version 2.1. The I^{2}C module supports Standard and Fast modes only.

40.4.2 I^{2}C Protocol

The I^{2}C communication protocol consists of six components, as follows:

- START
- Data Source/Recipient
- Data Direction
- Slave Acknowledge
- Data Acknowledge
- STOP

See Figure 40-12 for the I^{2}C standard communication protocol, as defined in the following sections.

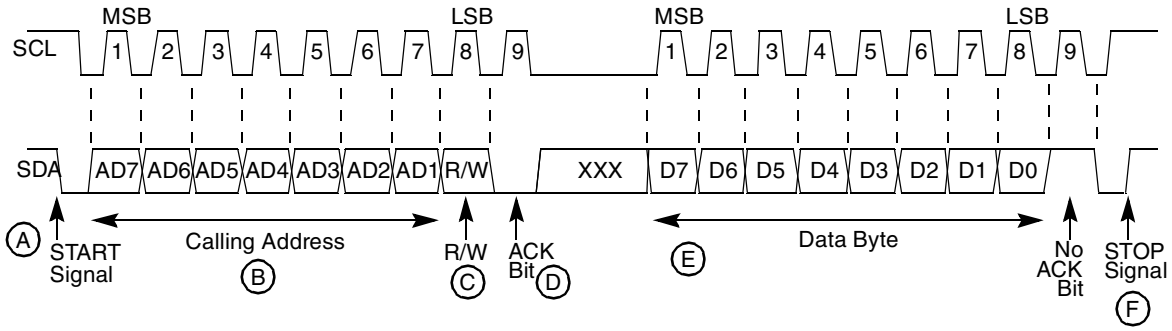

Figure 40-12. I^{2}C Standard Communication Protocol

40.4.2.1 START Signal

When no other device is a bus master (both SCL and SDA lines are at logic high), a device can initiate communication by sending a START signal (see A in Figure 40-12). A START signal is defined as a high-to-low transition of SDA while SCL is high. This signal denotes the beginning of a data transfer (each data transfer can be several bytes long) and awakens all slaves.

40.4.2.2 Slave Address Transmission

The master sends the slave address in the first byte after the START signal (B). After the seven-bit calling address, it sends the R/W bit (C), which tells the slave data transfer direction.

Each slave must have a unique address. An I^{2}C master must not transmit an address that is the same as its slave address; it cannot be master and slave at the same time.

The slave whose address matches that sent by the master pulls SDA low at the ninth clock (D) to return an acknowledge bit.

40.4.2.3 Data Transfer

When successful slave addressing is achieved, the data transfer can proceed (E) on a byte-by-byte basis in the direction specified by the R/W bit sent by the calling master.

Data can be changed only while SCL is low and must be held stable while SCL is high, as shown in Figure 40-12. SCL is pulsed once for each data bit, with the mishap being sent first. The receiving device must acknowledge each byte by pulling SDA low at the ninth clock; therefore, a data byte transfer takes nine clock pulses.

If it does not acknowledge the master, the slave receiver must leave SDA high. The master can then generate a STOP signal to abort the data transfer or generate a START signal (a repeated start, as shown in Figure 40-13) to start a new calling sequence.

If the master receiver does not acknowledge the slave transmitter after a byte transmission, it means end-of-data to the slave. The slave releases SDA for the master to generate a STOP or START signal.

40.4.2.4 STOP Signal

The master can terminate communication by generating a STOP signal to free the bus. A STOP signal is defined as a low-to-high transition of SDA while SCL is at logical high (F).

NOTE

A master can generate a STOP even if the slave has made an acknowledgment; at which point, the slave must release the bus.

40.4.2.5 Repeat Start

Instead of signalling a STOP, the master can repeat the START signal, followed by a calling command (see A in Figure 40-13). A repeated START occurs when a START signal is generated without first generating a STOP signal to end the communication. The master uses a repeated START to communicate with another slave or with the same slave in a different mode (transmit/receive mode) without releasing the bus.

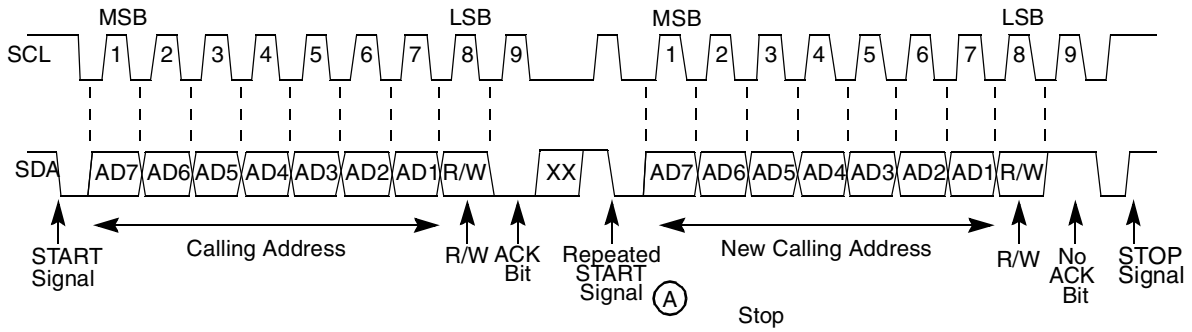

Figure 40-13. Repeated START

40.4.3 Arbitration Procedure

If multiple devices simultaneously request the bus, the bus clock is determined by a synchronization procedure in which the low period equals the longest clock-low period among the devices, and the high period equals the shortest. A data arbitration procedure determines the relative priority of competing devices. A device loses arbitration if it sends logic high while another sends logic low; it immediately switches to slave-receive mode and stops driving SDA. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, hardware sets the arbitration lost bit in the I^2C Status register (I2SR[IAL] to indicate loss of arbitration.

40.4.4 Clock Synchronization

Because wire-AND logic is used, a high-to-low transition on SCL affects devices connected to the bus. Devices start counting their low period when the master drives SCL low. When a device clock goes low, it holds SCL low until the clock high state is reached. However, the low-to-high change in this device clock may not change the state of SCL if another device clock is still in its low period. Therefore, the device with the longest low period holds the synchronized clock SCL low. Devices with shorter low periods enter a high wait state during this time (see Figure 40-14). When all devices involved have counted off their low period, the synchronized clock SCL is released and pulled high. There is then no difference between device

clocks and the state of SCL, so all of the devices start counting their high periods. The first device to complete its high period pulls SCL low again.

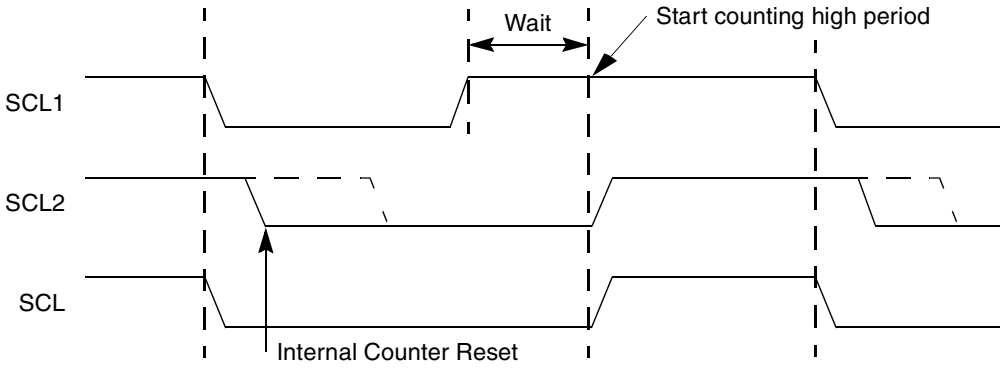

Figure 40-14. Synchronized Clock SCL

40.4.5 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. Slave devices can hold SCL low after completing one byte transfer (9 bits). In such a case, the clock mechanism halts the bus clock and forces the master clock into a wait state until the slave releases SCL.

40.4.6 Clock Stretching

Slaves can use the clock synchronization mechanism to slow down the transfer bit rate. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is longer than the master SCL low period, the resulting SCL bus signal low period is stretched.

40.4.7 IP Bus Accesses

I^2C is a 16-bit IP module. Only half-word accesses should be performed to the module.

40.4.8 Generation of Transfer Error on IP Bus

If an address is received on the IP slave bus interface that is not implemented, an access error is generated (ips_xfr_err is asserted). The input pin resp_sel provides the configuration capability to generate this response. The resp_sel pin must be asserted to enable the ips_xfr_err signal.

40.5 Initialization/Application Information

Before the interface can transfer serial data, registers must be initialized, as follows:

1. Set the data sampling rate (IFDR[IC] to obtain SCL frequency from the system bus clock.
2. Update the address in the (IADR) to define its slave address (address can range from 0 to 0x7f).
3. Set the I^2C enable bit (I2CR[IEN]) to enable the I^2C bus interface system.

4. Modify the bits in the I^2CR to select master/slave mode, transmit/receive mode, and interrupt-enable or not.

40.5.1 Generation of START

After completion of the initialization procedure, serial data can be transmitted by selecting the master transmitter mode. On a multiple-master bus system, the busy bus (I2SR[IBB]) must be tested to determine whether the serial bus is free. If the bus is free (IBB = 0), the START signal and the first byte (the slave address) can be sent. The data written to the data register comprises the address of the desired slave and the LSB indicates the transfer direction.

The free time between a STOP and the next START condition is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I^2C is busy after writing the calling address to the data register (I2DR) before proceeding to load data into the data register (I2DR).

40.5.2 Post-Transfer Software Response

Sending or receiving a byte sets the data transferring bit (I2SR[ICF]), which indicates one byte communication is finished. Upon completion, the interrupt status (I2SR[IIF]) is also set. An external interrupt is generated if the interrupt enable (I2CR[IIEN]) is set. The software must first clear the interrupt status (I2SR[IIF]) in the interrupt routine. (See the flow chart in Figure 40-15.) The data transferring bit (I2SR[ICF]) is cleared either by reading from I2DR in receive mode or by writing to this register in transmit mode.

The software can service the I^2C I/O in the main program by monitoring the interrupt status (I2SR[IIF]) if the interrupt enable is de-asserted. In this case, the interrupt status should be polled of the data transferring bit (I2SR[ICF]) because the operation is different when arbitration is lost.

When an interrupt occurs at the end of the address cycle, the master is always in transmit mode; that is, the address is sent. If master receive mode is required, then (I2DR[R/W], I2CR[MTX] should be toggled.

During slave-mode address cycles (I2SR[IAAS] = 1), the slave read/write bit I2SR[SRW] is read to determine the direction of the next transfer. The transmit/receive bit (I2CR[MTX]) should also be programmed accordingly. For slave-mode data cycles (IAAS = 0), SRW is invalid. MTX should be read to determine the current transfer direction.

40.5.3 Generation of STOP

A data transfer ends when the master signals a STOP, which can occur after all data is sent.

For a master receiver to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last data byte. This is done by setting the transmit acknowledge bit (I2CR[TXAK]) before reading the next-to-last byte. Before the last byte is read, a STOP signal must be generated.

40.5.4 Generation of Repeated START

After the data transfer, if the master still wants the bus, it can signal another START followed by another slave address without signalling a STOP.

40.5.5 Slave Mode

In the slave interrupt service routine (see Figure 40-15), the module addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (I2CR[MTX]) according to the I2SR[SRW]. Writing to the I2CR clears the IAAS automatically. The only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred; interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer can now be initiated by writing information to I2DR for slave transmits, or read from I2DR in slave-receive mode. A dummy read of I2DR in slave/receive mode releases SCL, allowing the master to send data.

In the slave transmitter routine, the receive acknowledge bit (I2SR[RXAK]) must be tested before sending the next byte of data. Setting RXAK means an end-of-data signal from the master receiver, after which the software must switch it from transmitter to receiver mode. Reading the data register (I2DR) then releases SCL so that the master can generate a STOP signal.

40.5.6 Arbitration Lost

If several devices try to engage the bus at the same time, one becomes master. Hardware immediately switches devices that lose arbitration to slave receive mode. Data output to SDA stops, but SCL is still generated until the end of the byte during which arbitration is lost. An interrupt occurs at the falling edge of the ninth clock of this transfer if the arbitration is lost (I2SR[IAL] = 1), and the slave mode is selected (I2CR[MSTA] = 0). See the flow chart in Figure 40-15.

If a device that is not a master tries to transmit or do a START, hardware inhibits the transmission, clears MSTA without signalling a STOP, generates an interrupt to the CPU, and sets IAL to indicate a failed attempt to engage the bus. When considering these cases, the slave service routine should first test IAL, and the software should clear it if it is set.

For Multi-master mode, when an I^2C module is enabled when the bus is busy and asserts START, the IAL bit gets set only for SDA=0, SCL=0/1, SDA=1, and SCL=0, but not for SDA=1 and SCA=1, which is the same as bus idle state.

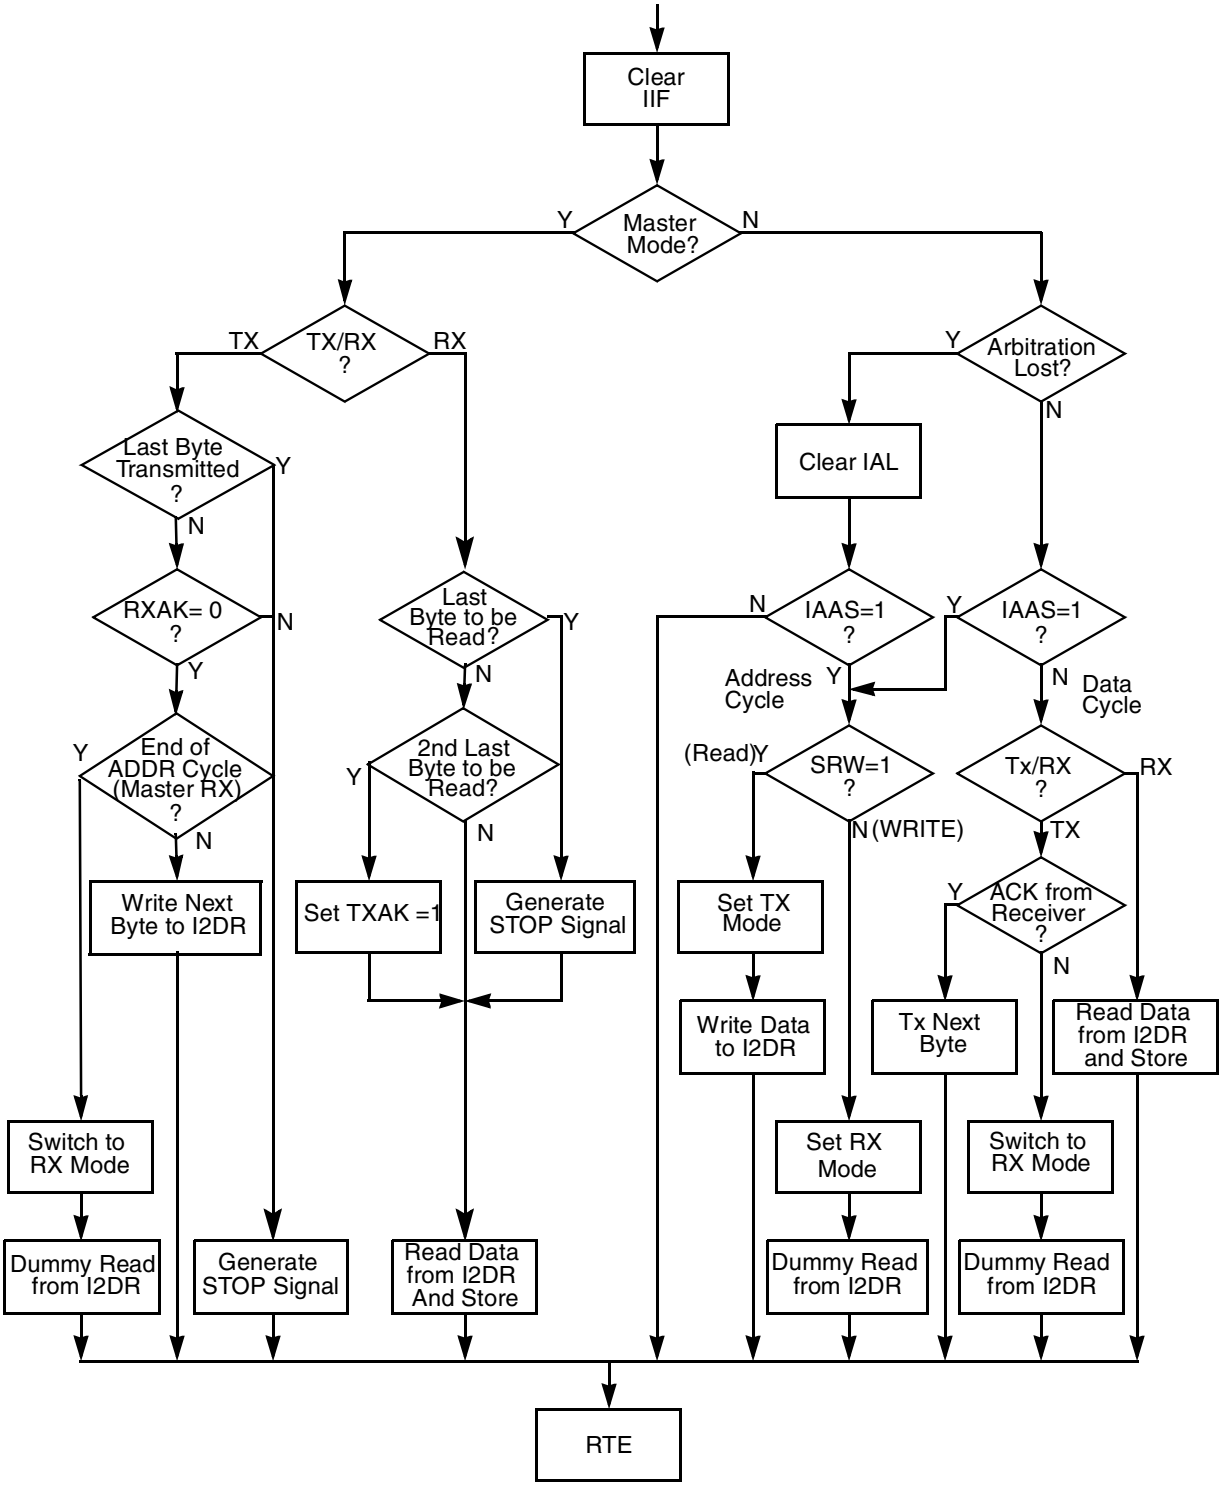

Figure 40-15. Flow-Chart of Typical I^2C Interrupt Routine

NOTE

For a repeated start-only, the stop generation stage will not occur in master mode. A loop will repeat itself without stopping for the next start.

40.5.7 Timing Section

Please refer to I^2C module electrical specification document for the I^2C module timing characteristics.

40.5.8 Software Restrictions

Software should take care that there is a delay of at least 2 ipg_clk_patref cycles after it sets the RSTA bit of I^2C control register before writing to the I^2C data register. The maximum possible clock period of ipg_clk_patref is 78 ns.

Chapter 41
IC Identification (IIM)

The IIM provides an interface for reading and in some cases programming and/or overriding identification and control information stored in on-chip fuse elements. The module supports electrically-programmable poly fuses (e-Fuses).

The IIM also provides a set of volatile software-accessible signals which can be used for software control of hardware elements, not requiring non-volatility.

41.1 Overview

The IIM provides the primary user-visible mechanism for interfacing with on-chip fuse elements. Among the uses for the fuses are unique chip identifiers, mask revision numbers, cryptographic keys, and various control signals requiring permanent non-volatility. The IIM also provides up to 28 volatile control signals

41.1.1 Modes of Operation

The IIM is in its functional mode (all specified functionality available) any time it is out of reset and supplied with the proper clocks.

41.2 Memory Map and Register Definition

Section 41.2.3, Register Descriptions," provides the detailed register descriptions for all of the IIM registers

41.2.1 Memory Map

All registers are 8-bit wide, but addressable on 32-bit boundaries. Only the bottom 8 bits (the usable bits) of each register are shown in the following diagrams. The top 24 bits always read as 0 and writes to them are ignored. Table 41-7 shows the IIM memory map. For a description of all of the addressable fuses, please refer to Chapter 6, "Fuse Map in Book I.

All IIM registers can be accessed in the user mode, except FCTL, which controls programming functions and can be accessed in supervisor mode only.

Table 41-2. IIM Memory Map

Address	Register	Access	Reset Value	Section/Page
0xBASE+0x000 (STAT)	Status register	R/W	— —	41.2.3.1/41-4
0xBASE+0x004 (STATM)	Status IRQ Mask register	R/W	00	41.2.3.2/41-5

41.2.3 Register Descriptions

This section contains the detailed register descriptions for the IIM registers.

41.2.3.1 Status Register (STAT)

All module status information is read using the STAT register.

See Figure 41-2 for illustration of valid bits in the Status Register and Table 41-4 for description of the bit fields.

0xBASE+0x000 (STAT) Access: Supervisor read-only

	7	6	5	4	3	2	1	0
R	BUSY						PRGD	SNSD
W							w1c	w1c
RESET	0	0	—	—	—	—	0	0

Figure 41-2. Status Register

Table 41-4. Status Register Field Descriptions

Field	Description
7 BUSY	Indicates whether the IIM is busy with a program or sense cycle. Any attempt to access the IIM registers other than STAT while it is busy with a program or sense cycle (BUSY asserted) results in a bus error. 0 The IIM is not busy with a program or sense cycle 1 The IIM is busy with a program or sense cycle
6–2	N/A
1 PRGD	Program Done. Indicates an e-Fuse program operation is done. Assertion causes an interrupt request (irq_b signal asserted) if PRGD_M is set in the Status IRQ Mask Register. This bit is automatically set by hardware upon completion of an e-Fuse program cycle; software must clear the bit by writing 1 to it. 0 Program operation has not finished (read); no meaning (write) 1 Program operation has finished (read); clear bit (write)
0 SNSD	Explicit Sense Cycle Done. Indicates that an explicit fuse sense cycle is done, and the data is available in SDAT. Assertion causes an interrupt request if SNSD_M is set in the Status IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 No explicit sense cycle has finished (read); no meaning (write) 1 An explicit sense cycle has finished (read); clear bit (write)

41.2.3.2 Status IRQ Mask (STATM)

See Figure 41-3 for illustration of valid bits in the Status IRQ Mask Register and Table 41-5 for description of the bit fields.

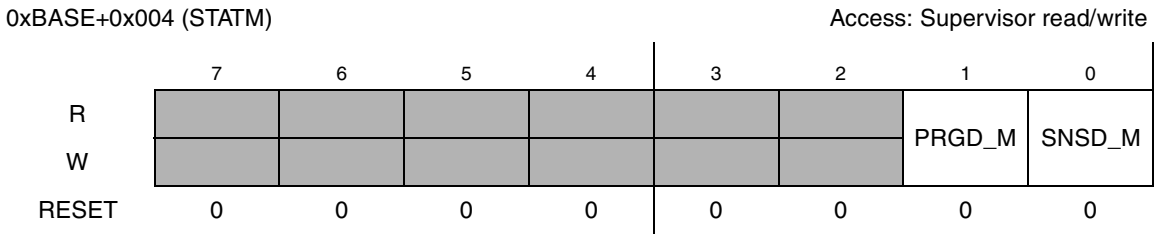

Figure 41-3. Status IRQ Mask Register

Table 41-5. Status IRQ Mask Register Field Descriptions

Field	Description
7–2	N/A
1 PRGD_M	Program Mask. Masks or unmasks IRQ generation due to PRGD events. 0 PRGD events do not cause an IRQ 1 PRGD events cause an IRQ
0 SNSD_M	Explicitly Sense Cycle Done Mask. Masks or unmasks IRQ generation due to SNSD events. 0 SNSD events do not cause an IRQ 1 SNSD events cause an IRQ

41.2.3.3 Module Errors Register (ERR)

See Figure 41-4 for illustration of valid bits in the Module Errors Register and Table 41-6 for description of the bit fields.

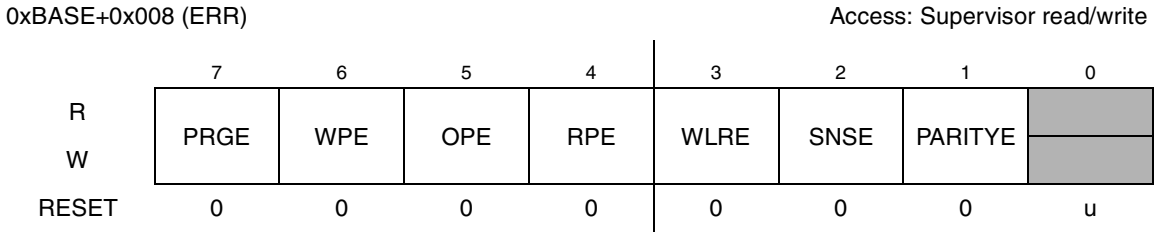

Figure 41-4. Module Errors Register

Table 41-6. Module Errors Register Field Descriptions

Field	Description
7 PRGE	Program Error. Indicates an e-Fuse program operation ended in failure. Assertion causes an interrupt request if PRGE_M is set in the Errors IRQ Mask Register. A program failure occurs when an attempt is made to program laser fuses. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 Program operation has not finished with error (read); no meaning (write) 1 Program operation has finished with an error (read); clear bit (write)
6 WPE	Write Protect Error. Indicates an e-Fuse program operation was attempted to a write-protected fuse bank, or a locked words, or when the value of PRG_P is not 8'hAA. Assertion causes an interrupt request if WPE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no write-protect error (read); no meaning (write) 1 There was a write-protect error (read); clear bit (write)
5 OPE	Override Protect Error. Indicates an attempt was made to override the values in an override-protected fuse bank, or a locked words. Assertion causes an interrupt request if OPE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no override-protect error (read); no meaning (write) 1 There was an override-protect error (read); clear bit (write)
4 RPE	Read Protect Error. Indicates an attempt was made to read values from a read-protected fuse bank or SCC. Assertion causes an interrupt request if RPE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no read-protect error (read); no meaning (write) 1 There was a read-protect error (read); clear bit (write)
3 WLRE	Write to Locked Register Error. Indicates an attempt was made to write to a locked SCS register. Assertion causes an interrupt request if WLRE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no write-to-locked-register error (read); no meaning (write) 1 There was a write-to-locked-register error (read); clear bit (write)
2 SNSE	Explicit Sense Cycle Error. Indicates that an explicit fuse sense was refused, because FBESP is set to 1, or more than two bits of SNS_N, SNS_1, SNS_0, PRG are asserted at the same moment. Assertion causes an interrupt request if SNSE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no explicit sense error (read); no meaning (write) 1 There was an explicit sense error (read); clear bit (write)
1 PARITYE	Parity Error of Cache. Indicate that an parity error was detected in hardware fuse cache or software fuse cache. Assertion causes an interrupt request if PARITYE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no explicit sense error (read); no meaning (write) 1 There was an explicit sense error (read); clear bit (write)
0	N/A

41.2.3.4 Error IRQ Mask Register (EMASK)

See Figure 41-5 for illustration of valid bits in the Error IRQ Mask Register and Table 41-7 for description of the bit fields.

0xBASE+0x00C (EMASK) Access: Supervisor read/write

	7	6	5	4	3	2	1	0
R	PRGE_M	WPE_M	OPE_M	RPE_M	WLRE_M	SNSE_M	PARITYE_M	
W								
RESET	0	0	0	0	0	0	0	u

Figure 41-5. Error IRQ Mask Register

Table 41-7. Error IRQ Mask Register Field Descriptions

Field	Description
7 PRGE_M	Program Error Mask. Masks or unmasks IRQ generation due to PRGE events. 0 PRGE events do not cause an IRQ 1 PRGE events cause an IRQ
6 WPE_M	Write Protect Error Mask. Masks or unmasks IRQ generation due to WPE events. 0 WPE events do not cause an IRQ 1 WPE events cause an IRQ
5 OPE_M	Override Protect Error Mask. Masks or unmasks IRQ generation due to OPE events. 0 OPE events do not cause an IRQ 1 OPE events cause an IRQ
4 RPE_M	Read Protect Error Mask. Masks or unmasks IRQ generation due to RPE events. 0 RPE events do not cause an IRQ 1 RPE events cause an IRQ
3 WLRE_M	Write to Locked Register Error Mask. Masks or unmasks IRQ generation due to WLRE events. 0 WLRE events do not cause an IRQ 1 WLRE events cause an IRQ
2 SNSE_M	Explicit Sense Cycle Error Mask. Masks or unmasks IRQ generation due to SNSE events. 0 SNSE events do not cause an IRQ 1 SNSE events cause an IRQ
1 PARITYE_M	Parity Error of Cache Mask. Masks or unmasks IRQ generation due to PARITYE events. 0 PARITYE events do not cause an IRQ 1 PARITYE events cause an IRQ
0	N/A

41.2.3.5 Fuse Control Register (FCTL)

See Figure 41-6 for illustration of valid bits in the Fuse Control Register and Table 41-8 for description of the bit fields.

0xBASE+0x010 (FCTL) Access: Supervisor read/write

	7	6	5	4	3	2	1	0
R W	DPC	PRG_LENGTH[2:0]			ESNS_N	ESNS_0	ESNS_1	PRG
RESET	0	0	1	1	0	0	0	0

Figure 41-6. Fuse Control Register

Table 41-8. Fuse Control Register Field Descriptions

Field	Description
7 DPC	Delayed Program Cycle. This bit is a control bit, selecting immediate or delayed program. When this bit is cleared, program cycles start immediately upon setting of PRG bit. When this bit is asserted, program cycles is delayed until input signal delayed_pgm_start is asserted. 0 Program cycles begin immediately upon setting of the PRG bit 1 Program cycles are delayed; they do not begin until delayed_pgm_start signal is asserted
6–4 PRG_LENGTH[2:0]	Program Length. This 3 bits define the length of program pulse PRG_LENGTH*(period of 32k clock) Setting is unknown.
3 ESNS_N	Explicit Sense - Normal. Writing 1 to this bit initiate an unstressed (normal) explicit sense cycle. Read of this bit always returns zero. FSM generate a “done” signal when the operation complete. This bit is cleared automatically by hardware when sense operation completed. Only one of ESNS_N, ESNS_0, ESNS_1, PRG can be asserted, otherwise ESNS_E will be asserted to indicate this error. 0 Return 0 for all read (read); No meaning (write) 1 Initiate an unstressed explicit sense cycle (write)
2 ESNS_0	Explicit Sense - 0-stressed. Writing 1 to this bit initiate a 0-stressed explicit sense cycle. Read of this bit always returns zero.FSM generate a “done” signal when the operation complete. This bit is cleared automatically by hardware when sense operation completed. During 0-stressed explicit sense cycles, the **epm_readsense0** signal is asserted to the fuse banks. Only one of ESNS_N, ESNS_0, ESNS_1, PRG can be asserted, otherwise ESNS_E will be asserted to indicate this error. 0 Return 0 for all read (read); No meaning (write) 1 Initiate a 0-stressed explicit sense cycle (write)

Table 41-8. Fuse Control Register Field Descriptions (continued)

Field	Description
1 ESNS_1	Explicit Sense - 1-stressed. Writing 1 to this bit initiate a 1-stressed explicit sense cycle. Read of this bit always returns zero. FSM generate a “done” signal when the operation complete. This bit is cleared automatically by hardware when sense operation completed. During 1-stressed explicit sense cycles, the **epm_readsense1** signal is asserted to the fuse banks. Only one of ESNS_N, ESNS_0, ESNS_1, PRG can be asserted, otherwise ESNS_E will be asserted to indicate this error. Only one of ESNS_N, ESNS_0, ESNS_1, PRG can be asserted, otherwise ESNS_E will be asserted to indicate this error. 0 Return 0 for all read (read); No meaning (write) 1 Initiate a 1-stressed explicit sense cycle (write)
0 PRG	Program. Writing 1 to this bit initiate a fuse program cycle. Read of this bit always returns zero. FSM generate a “done” signal when the operation complete. This bit is cleared automatically by hardware when program operation completed. Only one of ESNS_N, ESNS_0, ESNS_1, PRG can be asserted, otherwise ESNS_E will be asserted to indicate this error. 0 Return 0 for all read (read); No meaning (write) 1 Initiate a program cycle (write)

41.2.3.6 Upper Address (UA)

The top part of the address of the e-Fuse bit to be programmed or the word to be sensed in an explicit sense cycle. Note that programming is done by bit, so the program address is a full-bit address. Sensing is done on 8-bit words, so the bottom three bits of the address are ignored.

See Figure 41-7 for illustration of valid bits in the Upper Address Register and Table 41-9 for description of the bit fields.

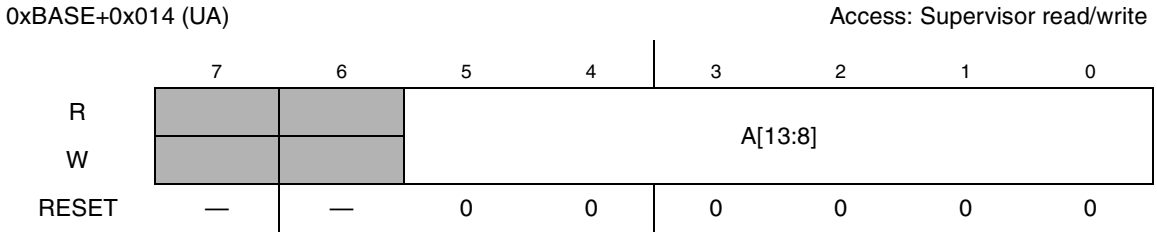

Figure 41-7. Upper Address Register

Table 41-9. Upper Address Register Field Descriptions

Field	Description
7–6	N/A
5–0 A[13–8]	The top six bits of the address of the e-Fuse bit to be programmed or the word to be sensed explicitly. The address must be written prior to setting the PRG or ESNS_x bit in FCTL to initiate the program/sense operation. A[13–11] select the Fuse bank. A[10–8] provide the most significant portion of the row address within the bank.

41.2.3.7 Lower Address (LA)

The bottom 8 bits of the address of the e-Fuse bit to be programmed or word to be explicitly sensed.

See Figure 41-8 for illustration of valid bits in the Lower Address Register and Table 41-10 for description of the bit fields.

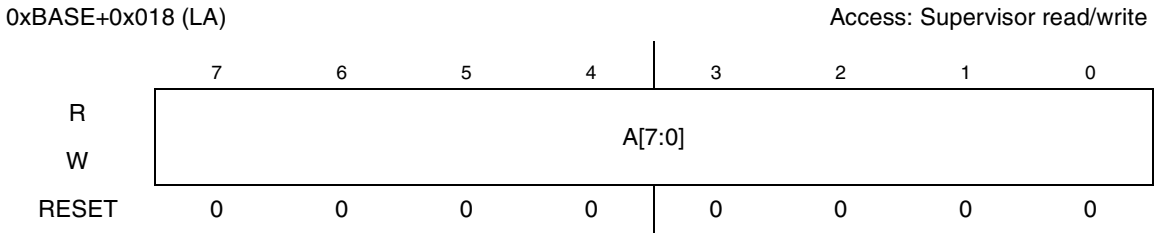

Figure 41-8. Lower Address Register

Table 41-10. Lower Address Register Field Descriptions

Field	Description
7–0 A	The bottom eight bits of the address of the e-Fuse bit to be programmed or word to be sensed explicitly. The address must be written prior to setting the PRG or ESNS_x bit in FCTL to initiate a program or sense operation. A[7:3] provides the least significant portion of the row address. A[2:0] select the bit position within the selected row.

41.2.3.8 Explicit Sense Data (SDAT)

See Figure 41-9 for illustration of valid bits in the Explicit Sense Data Register and Table 41-11 for description of the bit fields.

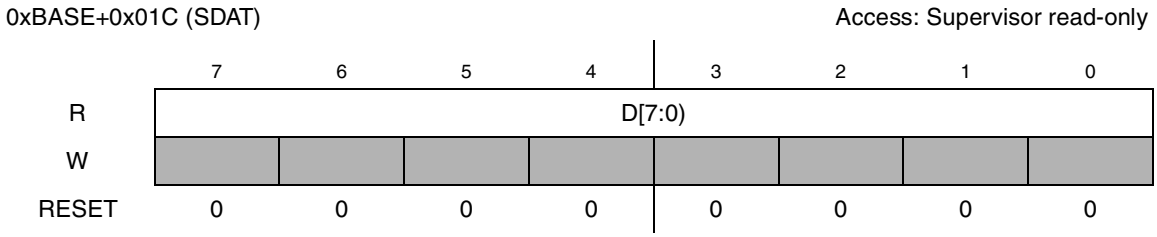

Figure 41-9. Explicit Sense Data Register

On an explicit sense cycle, the data sensed from the fuses is placed in this register at the conclusion of the sense cycle. Software can recognize the conclusion of the sense cycle by the assertion of SNSD in STAT.

Table 41-11. Explicit Sense Data Register Field Descriptions

Field	Description
7–0 D	The data sensed from the fuses. Setting is unknown.

41.2.3.9 Product Revision (PREV)

The product revision. This corresponds to the top eight bits of the deprecated HW_REV register.

See Figure 41-10 for illustration of valid bits in the Product Revision Register and Table 41-12 for description of the bit fields.

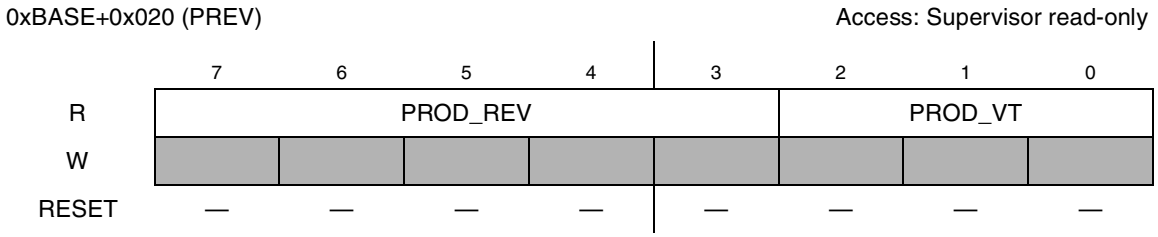

Figure 41-10. Product Revision Register

Table 41-12. Product Revision Register Field Descriptions

Field	Description
7–3 PROD_REV	Product Revision. The product revision (specific to the product or product family). Setting according to product revision.
2–0 PROD_VT	Product vendor or technology. The product vendor and/or technology (specific to the product or product family). Setting according to product vendor/technology.

41.2.3.10 Silicon Revision (SREV)

The silicon revision (that is, mask revision). This corresponds to the bottom 8 bits of the deprecated HW_REV register.

See Figure 41-11 for illustration of valid bits in the Silicon Revision Register and Table 41-13 for description of the bit fields.

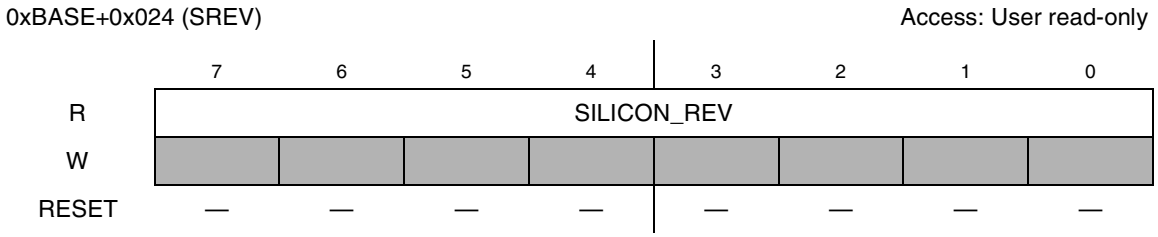

Figure 41-11. Silicon Revision Register

Table 41-13. Silicon Revision Register Field Descriptions

Field	Description
7–0 SILICON_REV	Mask Set Revision. The mask set revision used in fabrication of the part. The value changes with each change to the mask set. Setting according to mask set revision.

41.2.3.11 Program Protection Register (PRG_P)

This register is used to against accidental fuse programming. The fuses can be blown only when the value of this register is 8'hAA. Software should only program this register to 8'hAA while actively blowing fuses. After the program operation is complete, this register should be immediately reprogrammed to a different value.

See Figure 41-12 for illustration of valid bits in the Program Protection Register and Table 41-14 for description of the bit fields.

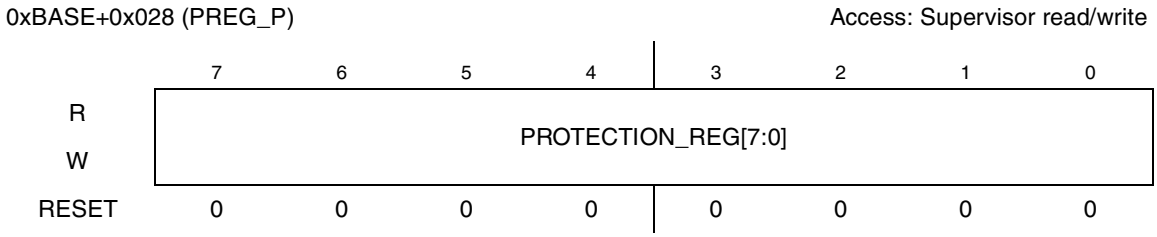

Figure 41-12. Program Protection Register

Table 41-14. Program Protection Register Field Descriptions

Field	Description
7–0 PROTECTION_REG	The fuses can be blown only when the value of this register is 8'hAA. Any attempt to program the fuse while the value is other than 8'hAA will be terminated with error. WPE bit will be asserted. Setting is undefined.

41.2.3.12 Software-Controllable Signals Register 0 (SCS0)

This register is physically located in the hardware-visible signals sub-module. It implements software-controlled, volatile signals which can drive SoC-level nets for feature enabling.

See Figure 41-13 for illustration of valid bits in the Software-Controllable Signals Register 0 and Table 41-15 for description of the bit fields.

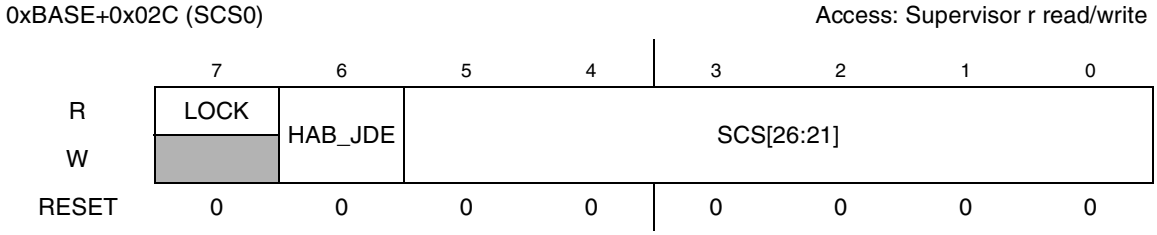

Figure 41-13. Software Controllable Signals Register 0

Table 41-15. Software Controllable Signals Register 0 Field Descriptions

Field	Description
7 LOCK	Lock this register. This bit is used to lock the contents of this register until the next reset. The intended usage is to have trusted software program the register as desired and lock it before allowing distrusted software to run. This bit is write only, read of this bit return 0. 0 The register is not locked, it may be modified 1 The register is locked, all attempts to modify it are ignored
6 HAB_JDE	HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properly signed command to do so is found and validated by the HAB. The HAB musts lock the register before passing control to the OS whether or not JTAG debugging has been enabled. Once JTAG is enabled by HAB_JDE bit, it can not be disabled unless the system is reset by POR. 0 JTAG debugging is not enabled by the HAB (it may still be enabled by other mechanisms) 1 JTAG debugging is enabled by the HAB (though this signal may be gated off)
5–0 SCS[26:21]	These bits may be used in an implementation-defined way.

41.2.3.13 Software-Controllable Signals Registers 1

This register has been dedicated for ROM boot interface with an upper SW. It is physically located in the hardware-visible signals sub-module.

0xBASE+0x030 (SCS1) Access: Supervisor read/write

	7	6	5	4	3	2	1	0
R W	LOCK	SCS[x:y]						LPB_ENABLED_STATUS
RESET	0	0	0	0	0	0	0	0

Table 41-16. Software Controllable Signals Register 1

Field	Description
7 LOCK	Lock this register. 0 The register is not locked, it may be modified 1 The register is locked, all attempts to modify it are ignored
6–1 SCS[x:y]	These bits may be used in an implementation-defined way
0 LPB_ENABLED_STATUS	0 – no LPB 1 – LPB

41.2.3.14 Software-Controllable Signals Registers 2–3 (SCS2–SCS3)

These registers are physically located in the hardware-visible signals submodule. They implement software-controlled, volatile signals that can drive SoC-level nets for feature enabling.

Each IIM fuse bank include a read protection bit to inhibit software fuses read and sense and to support secure computing environments. When a fuse bank's read protection bit is set (i.e.'1'), the bank's fuses cannot be read or sensed by software. The read protection bit cannot be changed if the sticky lock bit was asserted.

41.2.3.14.1 Read Lock Register on SCS2

This is the fuse bank read lock register. This corresponds to four iMX51 fuse banks.

See Figure 41-5 for illustration of valid bits in the Read Lock Register and Figure 41-17 for description of the bit fields.

0xBASE+0x034 (SCS2) Access: User read/write

Field	Description
7–0 SaharaEn[23–16]	third register out of 6 registers. assert proper value is necessary condition for blow up SAHRA_EN fuse.

41.2.3.18 Sahara Enable 3 (SaharaEn3)

This is the fourth register out of the six registers that serve as a necessary condition for blowing up SAHRA_EN fuse.

See Figure 41-20 for illustration of valid bits in the Sahara Enable 3 Register and Table 41-22 for description of the bit fields.

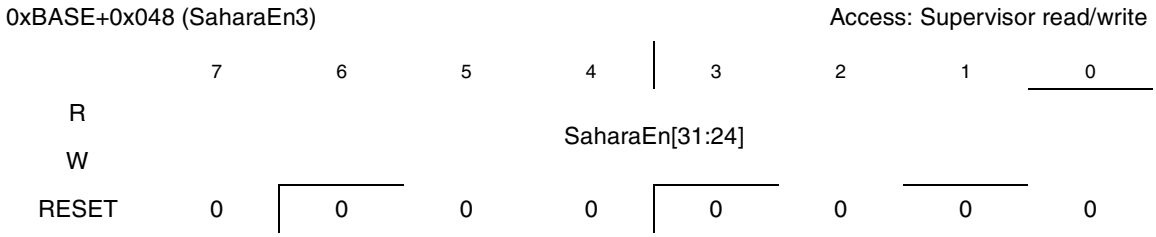

Figure 41-20. Sahara Enable 3 Register

Table 41-22. Sahara Enable 3 Register Field Descriptions

Field	Description
7–0 SaharaEn[31-24]	fourth register out of 6 registers. assert proper value is necessary condition for blow up SAHRA_EN fuse.

41.2.3.19 Sahara Enable 4 (SaharaEn4)

This is the fifth register out of the six registers that serve as a necessary condition for blowing up SAHRA_EN fuse.

See Figure 41-21 for illustration of valid bits in the Sahara Enable 4 Register and Table 41-23 for description of the bit fields.

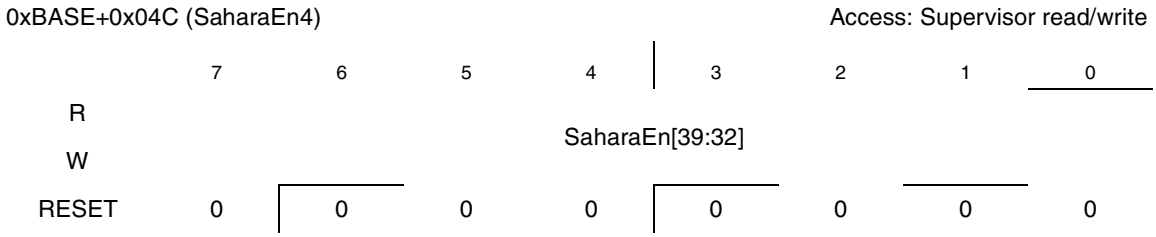

Figure 41-21. Sahara Enable 4 Register

Table 41-23. Sahara Enable 4 Register Field Descriptions

Field	Description
7–0 SaharaEn[39-32]	fifth register out of 6 registers. assert proper value is necessary condition for blow up SAHRA_EN fuse.

41.2.3.20 Sahara Enable 5 (SaharaEn5)

This is the sixth register out of the six registers that serve as a necessary condition for blowing up SAHRA_EN fuse.

See Figure 41-22 for illustration of valid bits in the Sahara Enable 5 Register and Table 41-24 for description of the bit fields.

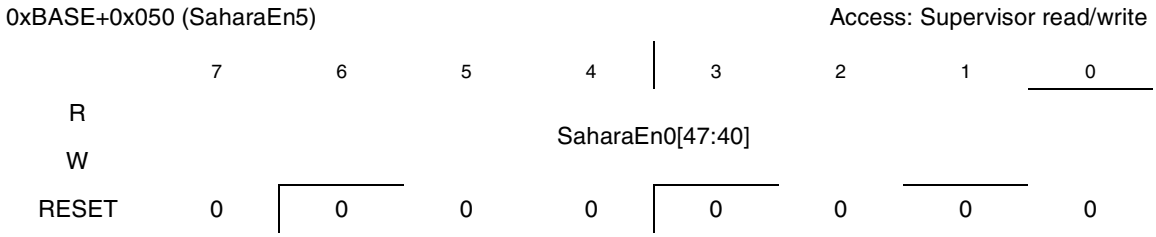

Figure 41-22. Sahara Enable 5 Register

Table 41-24. Sahara Enable 5 Register Field Descriptions

Field	Description
7–0 SaharaEn[47–40]	sixth register out of 6 registers. assert proper value is necessary condition for blow up SAHRA_EN fuse.

41.3 Functional Description

The IIM is an 8-bit IP Bus peripheral which implements interfaces for laser fuses and/or e-Fuses, as well as the hardware revision codes, cryptographic keys, and miscellaneous system-level feature enabling circuitry. Up to eight banks, each with up to 2048 fuses, are supported. Laser fuse banks and e-Fuse banks may be mixed.

41.3.1 Signal Groups

Listed below are the intended uses for the four fuse banks. Each fuse bank may contain up to 2048 fuses, and the unspecified fuses in each bank below may be used for implementation-specific purposes. However, access protection is specified on a per-bank basis; this may limit the use of the unspecified fuses.

The IIM implements non-volatile “Hardware-Visible” control signals. These are all capable of driving SoC-level nets to allow them to permanently enable or disable features in the system.

41.3.1.1 Secure JTAG Control

Among the hardware control signals implemented in Fuse Bank 0 are the Secure JTAG control bits. These fuses are used to allow or disallow JTAG access to secured resources.

Three JTAG security levels are envisioned, as shown in Table 41-25.

Table 41-25. JTAG Security Level Control Bits

Security Mode	JTAG_SMODE	JTAG_SCC_DIS	Description
No Debug	2'b11	x	The highest security level.
Secure JTAG	2'b01	x	Limit the JTAG access by using key based authentication mechanism.
JTAG Enable	2'b00	1'b1	Low Security, all JTAG features are enabled.
SCC JTAG	2'b00	1'b0	No security.

JTAG debug access may be semipermanently enabled by blowing the jtag_bp bit (JTAG Bypass Security). This, however, can be overridden by blowing the jtag_re bit (JTAG Security Re-enable). Blowing the jtag_bp bit effectively changes the security level from 'Secure JTAG' to 'JTAG Enable', without actually modifying the JTAG_SMODE fuses.

NOTE

The IIM must only allow the jtag_bp fuse to be blown if the JTAG debug security level is "Secure JTAG" (JTAG_SMODE = 2'b01) and ipt_response_in = 1, ipt_secur_block = 0. This indicates that the SJC has processed a valid response in its challenge/response protocol, and the JTAG security bypass functionality should be allowed. JTAG security is re-instated to the "Secure JTAG" level by blowing the jtag_re bit.

In addition to the three JTAG security levels, the JTAG debug notification normally passed to the Security Controller (SCC), which causes it to transition out of the secure state when debugging has become active, can be gated off using the jtag_scc fuse in JAC. If jtag_scc is left unblown, the debug active signals are masked, and do not propagate to the SCC. If jtag_scc is blown, the debug active signals propagate to the SCC as normal.

NOTE

Leaving the jtag_scc fuse unblown represents a very significant security risk, and should only be done in as few parts as possible to debug secure operation of the SCC. Once SCC debugging is complete, the jtag_scc fuse should immediately be blown. The reason for including this functionality in a fuse is to avoid the need to modify parts using FIB for SCC debugging, but the convenience afforded by the fuse must not be allowed to foster an unguarded attitude toward the dangers such insecure parts would pose.

41.3.1.2 Fuse Bank 0

Fuse Bank 0 contains manufacturing information such as Unique ID (UID), consists of fab ID, lot and wafer number, and die coordinates. These bits are usable by OS's such Microsoft PocketPC, which require a unique device ID. It also contains JTAG and debug features controls, IMEI information, and 24 bits for user purpose.

41.3.1.3 Fuse Bank 1

Fuse Bank 1 contains response reference value for the secure JTAG controller, memories information and 40 bits for user purposes.

41.3.1.4 Fuse Bank 2

Fuse Bank 2 contains the 256-bit SCC key.

41.3.1.4.1 SCC Key Format

The-256 bit keys derived from Fuse Bank 2 are used as the secret keys for the Secure RAM controller in the SCC(s). Each key actually consists of three 56-bit keys. Each of the three 56-bit keys corresponds to a 64-bit DES key with the parity bits removed, and processed through the key permutation.

The value in Fuse Bank 1includes 159 random bits and 9 Hamming Code bits. The Hamming Code will detect all 1, 2, and 3 bit errors in the codeword. It will also detect most (though not all) multiple bit errors. Numbering the bits in the key from 0 to 167, the code bits are bits 0, 1, 2, 4, 8, 16, 32, 64, and 128. All of the remaining bits are data bits. Each of the code bits is the modulo 2 sum (i.e XOR or parity) of a subset of the bits in the entire word, as described below.

To determine which bits are used to form each code bit, first look at the binary representation of the bit position of each code bit (ignoring bit 0 for the time being) as shown in Table 41-26.

Table 41-26. Binary Representation of Bit Position

Code Bit	Binary Representation
0	0b00000000
1	0b00000001
2	0b00000010
4	0b00000100
8	0b00001000
16	0b00010000
32	0b00100000
64	0b01000000
128	0b10000000

For code bit number 1, there is a single '1' bit in its binary representation. This code bit is the modulo 2 sum (XOR) of all bit positions which also have a '1' in this same point in their binary representation (that

is, all odd bit positions). Alternatively, if we bitwise AND code bit 1's bit number with a data bit's bit number, and the result is not zero, then that bit gets XOR'ed into code bit 1. The same is true for the other code bits, excepting code bit 0. For example, code bit 2 is the XOR of bits 3, 6, 7, 10, 11, 14, 15 ...254,255. Code bit 128 is the XOR of all bits from 129 through 255 inclusive. After all of the other code bits have been calculated, code bit 0 is simply the XOR of all of the other bits, including the other code bits.

Another way to look at this is to ask which code bits a data bit affects. If we look at the binary representation of the bit position of a data bit, the 1's represent the code bits that this data bit affects. For example, data bit 99 (0b01100011) is XOR'ed into code bits 1, 2, 32, and 64.

41.3.1.4.2 SCC Key Checking

The SCC checks the key using the Hamming Code. If there are any errors in the key, the SCC refuses to use it. In addition, the SCC checks the key against several known weak keys, which it will also refuse to use. Figure 41-23 shows a list of hexadecimal key patterns that are checked (x means don't care); no key matching any of these patterns should be programmed into Fuse Bank 1.

```

Figure 41-23. Known Weak SCC Key Patterns

41.3.1.5 Fuse Bank 3

Fuse Bank 3 is intended to hold data relevant to the Super-Root Key (SRK) of DSP domain. It may hold an entire SRK (that is, an up to 1024-bit RSA public key), a hash of an SRK (that is, a 160-bit SHA-1 hash), or an SRK one-of-many selector. The boot code for a specific product must know where to find and validate the SRK.

41.3.1.6 Software-Controllable Volatile Signals

The IIM implements up to 28 software-controllable, HW-Visible, volatile control signals. These are implemented in four 8-bit registers, each with a lock bit to inhibit modification of the associated register until the IIM is reset. These 28 signals may all drive SoC-level nets. They are always software-readable,

but can only be modified by software if the Lock bit (bit 7) is not set in the register. The sequence for modifying these bits is shown in Figure 41-24.

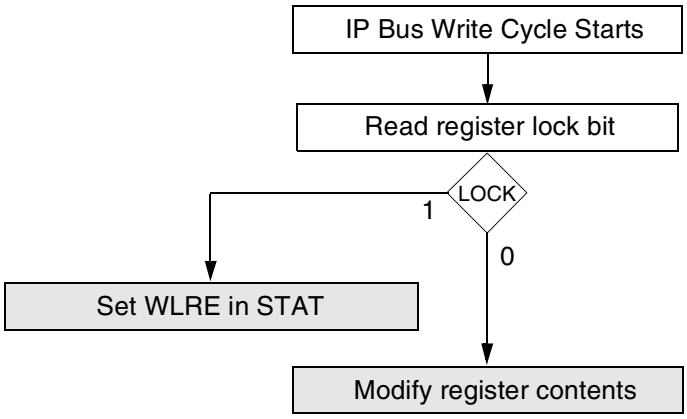

Figure 41-24. SCS Register Write Sequence

41.3.2 Fuse Box Signals

Figure 41-24 shows the fuse box interface.

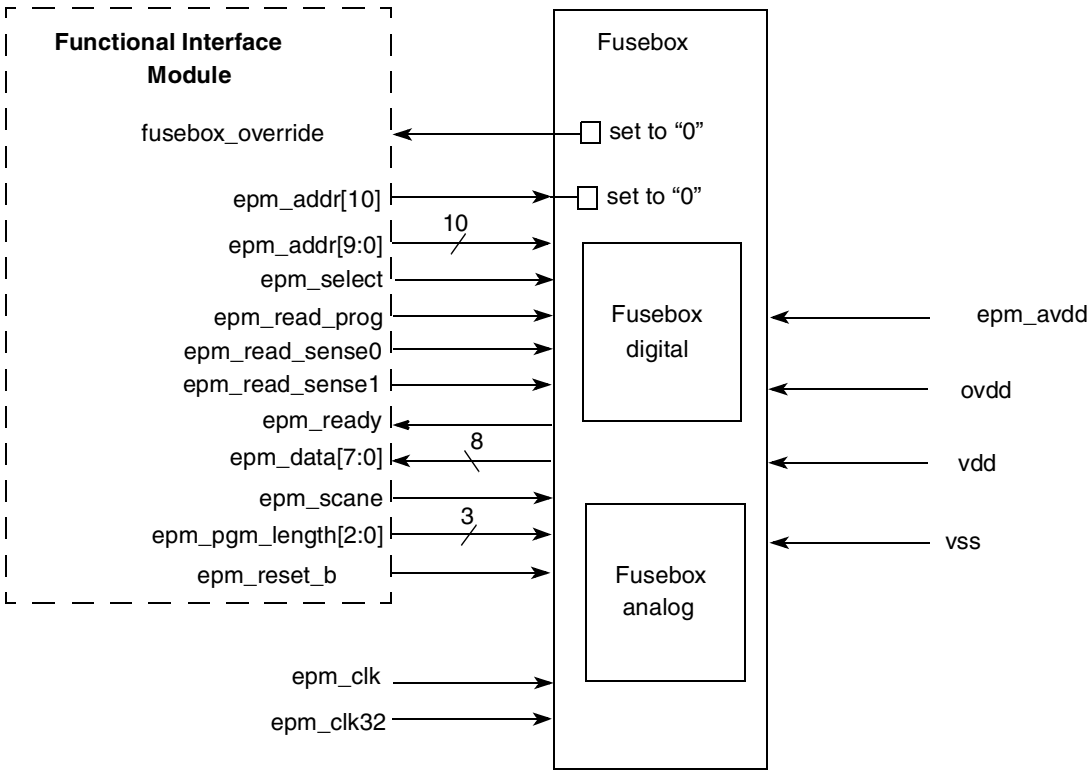

Figure 41-25. Fuse Box Interface

The signals are summarized from the fuse box's perspective in Table 41-27.

Table 41-27. Fuse Box Signal Overview

Signal Name	Signal Type	Signal Description
EPM_ADDR[10:0]	I	This bus provides the address for a read or program operation. Read operations are done on a word (8-bit) basis, so the word address is carried on address[10:3]. Program operations are done on a bit-basis, so the bit address is carried on address[10:0]. Address bits l2:0] carry the bit location in a byte, epm_addr[10] is set to "0" for 1024 bit digital block.
		State Meaning
		Timing Needs to be held to desired value at least 2 nS before and after asserting epm_select in both program and read operation.
EPM_CLK	I	Local clock used for synchronization of signals between FI and Fusebox. It is the clock used by a Fusebox Interface Module for creating Fusebox interface signals. The max. read clock is 166Mhz with worst 40%-60% duty cycle.
EPM_CLK32	I	The 32.768 KHz clock used in the Fusebox to time the program operation in read operation. This clock does not need to be utilized in the FI module.
EPM_DATA[7:0]	O	This bus carries the read data from the Fusebox during a read cycle.
		State Meaning
		Timing
EPM_PGM_LENGTH [2:0]	I	These signals define the length of the program pulse.
		State Meaning
		Timing
EPM_READY	I	This signal indicates the progress of the current read/program cycle. New commands should only be issued by the FI module while epm_ready is asserted.
		State Meaning Asserted -- The fuse is blown. Negated -- The fuse is not blown.
		Timing Latched at the rise edge of epm_clk half clock cycle ahead of epm_ready
EPM_READ_PROG	I	This signal selects whether the current operation is a read or program cycle. This signal is latched into the Fusebox on the rising edge of epm_select.
		State Meaning Assertion— Fusebox is in read operation. Negation— Fusebox is in program operation.
		Timing Needs to be held to desired value at least 2nS before and after asserting epm_select in both program and read operation.

Table 41-27. Fuse Box Signal Overview (continued)

Signal Name	Signal Type	Signal Description
EPM_READ_SENSE0	I	This signal allows sensing of the 0 (unblown) state to be stressed. This can be useful in detecting marginally blown fuses.
		State Meaning Assertion—When asserted (high), the sense circuitry is configured to stress the sensing of the 0 (unblown) state. Negation— No stress is added.
		Timing This signal is latched by the Fusebox on the rising edge of epm_select. It needs to be set to desired value at least 2nS before epm_select is asserted an to be held until epm_select is negated.
EPM_READ_SENSE1	I	This signal allows sensing of the 1 (blown) state to be stressed. This can be useful in detecting marginally blown fuses.
		State Meaning Assertion—When asserted (high), the sense circuitry is configured to stress the sensing of the 1 (blown) state. Negation— No stress is added.
		Timing This signal is latched by the Fusebox on the rising edge of epm_select. It needs to be set to desired value at least 2nS before epm_select is asserted and to be held until epm_select is negated.
$\overline{\text{EPM\_RESET\_B}}$	I	Reset Fusebox digital signals during power up. This signal needs to be connected to a early system reset. The signal is active low.
EPM_SCANE	I	This signal indicates whether the Fusebox is scannable via JTAG. It shall be always de-asserted because the JTAG function is disabled inside Fusebox in cmos065 design.
EPM_SELECT	I	This signal starts a read/program operation and epm_select rising edge needs to be synchronized with the rising edge of epm_clk. There is no restriction for epm_select falling edge to be synchronized with epm_clk. The Fusebox senses the rising edge of this signal to start the operation. On the rising edge of epm_select, the address, operation to perform and program data are latched. There is one select signal for each fuse bank.
		State Meaning Assertion— In Read/program operation. Negation— Not in read/program operation.
		Timing This signal must remain asserted throughout the read/program operation.
FUSEBOX_OVERRIDE	O	Fusebox override signal to the Functional Interface module. It is connected to VSS by default. It can be re-connected to core VDD via Metal 6 layer change.
		State Meaning Assertion— The Fusebox is bypassed. All outputs are set to 0. Negation— The Fusebox outputs are sent to FI modules.
		Timing

41.3.2.1 Fuse Box Operations

All Fusebox operations are self-timed and begin relative to the rising edge on the epm_select line. Most interface signals are shared by all Fuseboxes. Only the Fusebox selects (epm_select), read data (epm_data) and ready status (epm_ready) signals are unique to each Fusebox. The 32 KHz clock is not used within the IIM, but may be used with other FI modules. It is passed through to the Fusebox to time program operations. The 32 KHz clock distributed to the Fuseboxes should be on during Fusebox program operations and should be gated off during read operation. The epm_clk is used to sample the epm_select, epm_ready and epm_data signals in order to synchronize these signals with the Functional Interface inside a Fusebox. This epm_clk is a gated clock used by the local FI modules.

41.3.2.1.1 Word Read

Read operations are done on a word (8-bit) basis. The target word is specified by the address lines epm_addr[9:3]. The bottom three address lines (bit-select lines) are ignored in a read operation.

The timing for fuse word read cycles is shown in Figure 41-26. This timing diagram shows one read cycle followed by the start of a second read, demonstrating how quickly one read can follow another. Each read command is registered on the rising edge of epm_select. The address (epm_addr[9:3]) and read command (epm_read_prog) must be stable tsels before the rising edge of epm_select and must remain stable at least tselh hold time beyond the rising edge. epm_ready is negated immediately after the command is registered, indicating that the Fusebox is busy. After a tdv delay from the active edge of epm_select, the data is made available on blr by the analog Fusebox. The epm_ready acknowledge signal is asserted tready after the initial assertion of epm_select and the data is available on the epm_data. The Fusebox synchronizes epm_ready and the data to the epm_clk clock and drives the synchronized data onto the IP bus. The time between the valid epm_data and epm_ready is signified by tsync in Figure 41-26 and is one-half of one epm_clk cycle. Once the read data has been latched, epm_select is negated by the Functional Interface module. epm_select must remain negated a minimum cycle to cycle delay of tccd before the next cycle (read or program) may begin. epm_data remains at a steady state until replaced by data from a subsequent read cycle.

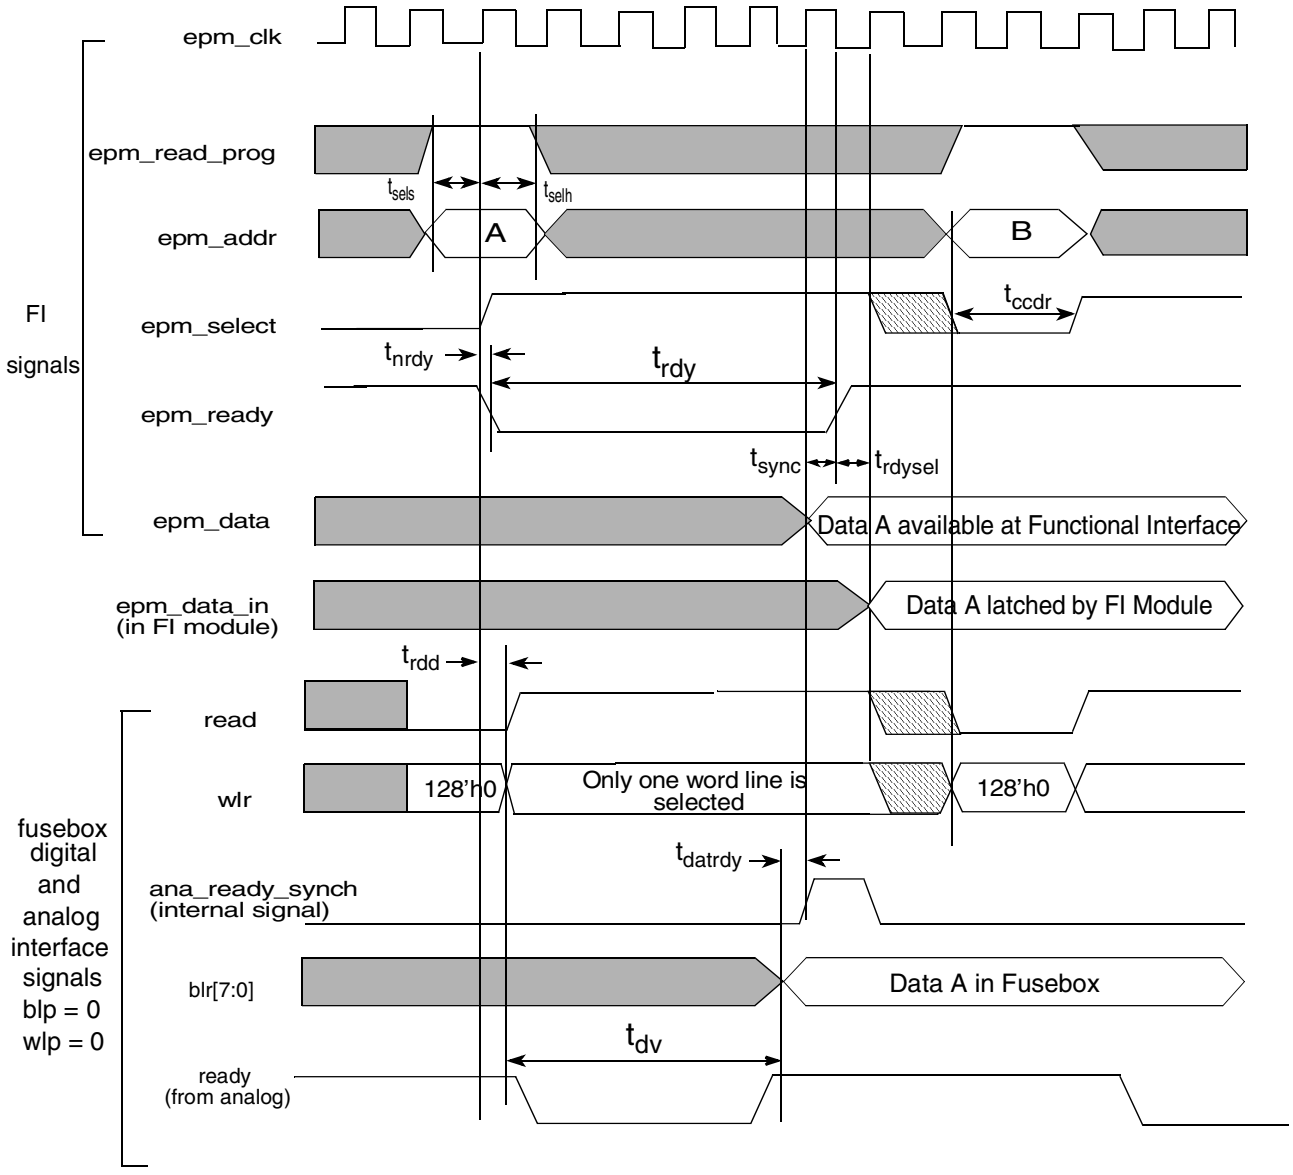

Figure 41-26. Fuse Box Read Cycle Timing

41.3.2.1.2 Bit Program

Program operations are done on a bit-basis. The target bit is specified by the full address bus (epm_addr[10:0]). Program operations can only blow fuses (change them from logic 0 to logic 1), so there is no program data bus associated with the Fusebox. The timing for a program operation is shown in Figure 41-27.

As in the read cycle, the address and program command are latched on the rising edge of epm_select. The address must be setup tsels ahead of the rising edge and remain held tselh past the edge of epm_select. Once the program command is registered, on the next rising edge of the 32 KHz clock, the Fusebox

initiates the program operation. An internal counter starts to count the number of 32K clock cycles, and the epm_ready signal is de-asserted.

After the specified number of 32 KHz clocks (determined by epm_pgm_length[2:0]), the Fusebox completes the program operation and asserts the epm_ready signal. epm_pgm_length[2:0] needs to be set tsels ahead of the rising edge of epm_select and needs to be held until the completion of the internal counter. Consult Table 41-28 for specific timing values. The Functional Interface module synchronizes the epm_ready response to the epm_clk during the period tsync. After recognizing that the program operation has completed, the Functional Interface module negates the epm_select line. To avoid accidental selection of more than one bit line at a time, the 8 bit de-coded bit-line-program (BLP) needs to be checked before generate blp[7:0].

Table 41-28. Timing Values

Designator	Timing Value	Description
t_{sels}	2 nS	Setup time to epm_select active edge
t_{selh}	2 nS	Hold time after epm_select active edge
t_{nrdy}	200 pS –1000 pS	Delay from epm_select to epm_ready negation (read). Delay from the rise edge of 32 Khz clock to epm_ready (program).
t_{rdd}	1 nS–4 nS	Assert time from epm_select active edge to negation of read from digital
t_{dv}	30 nS–100 nS	Data valid after epm_select active edge
t_{rdy}	≤ (t_{dv} + 1.5 epm_clk)	Epm_ready signal asserted after epm_select active edge (read only)
t_{ready}	(epm_pgm_length) * $period_{32KHz}$	Epm_ready signal asserted after epm_select active edge (program only)
t_{datrdy}	0–1 epm_clk	Data driven out to bus after analog ready signal asserts (read only)
t_{sync}	one-half of 1 epm_clk cycle (rising edge to falling edge) > 3nS if epm_clk duty cycle is not 50%	epm_data to epm_ready synchronization delay (read). epm_ready to negation of epm_select (program)
t_{rdysel}	> 2nS typically one-half of 1 epm_clk cycle (falling edge to rising edge)	rising-edge of epm_ready to negative-edge of epm_select (read only)
t_{ccdr}	5 nS	Minimum cycle to cycle delay (Consecutive Read)
t_{ccdp}	0.5 uS	Minimum cycle to cycle delay (Consecutive program)
t_{sels}	2 nS	Setup time to epm_select active edge
t_{selh}	2 nS	Hold time after epm_select active edge
t_{nrdy}	200 pS –1000 pS	Delay from epm_select to epm_ready negation (read). Delay from the rise edge of 32 Khz clock to epm_ready (program).

See the timing diagram of the fuse program in Figure 41-27.

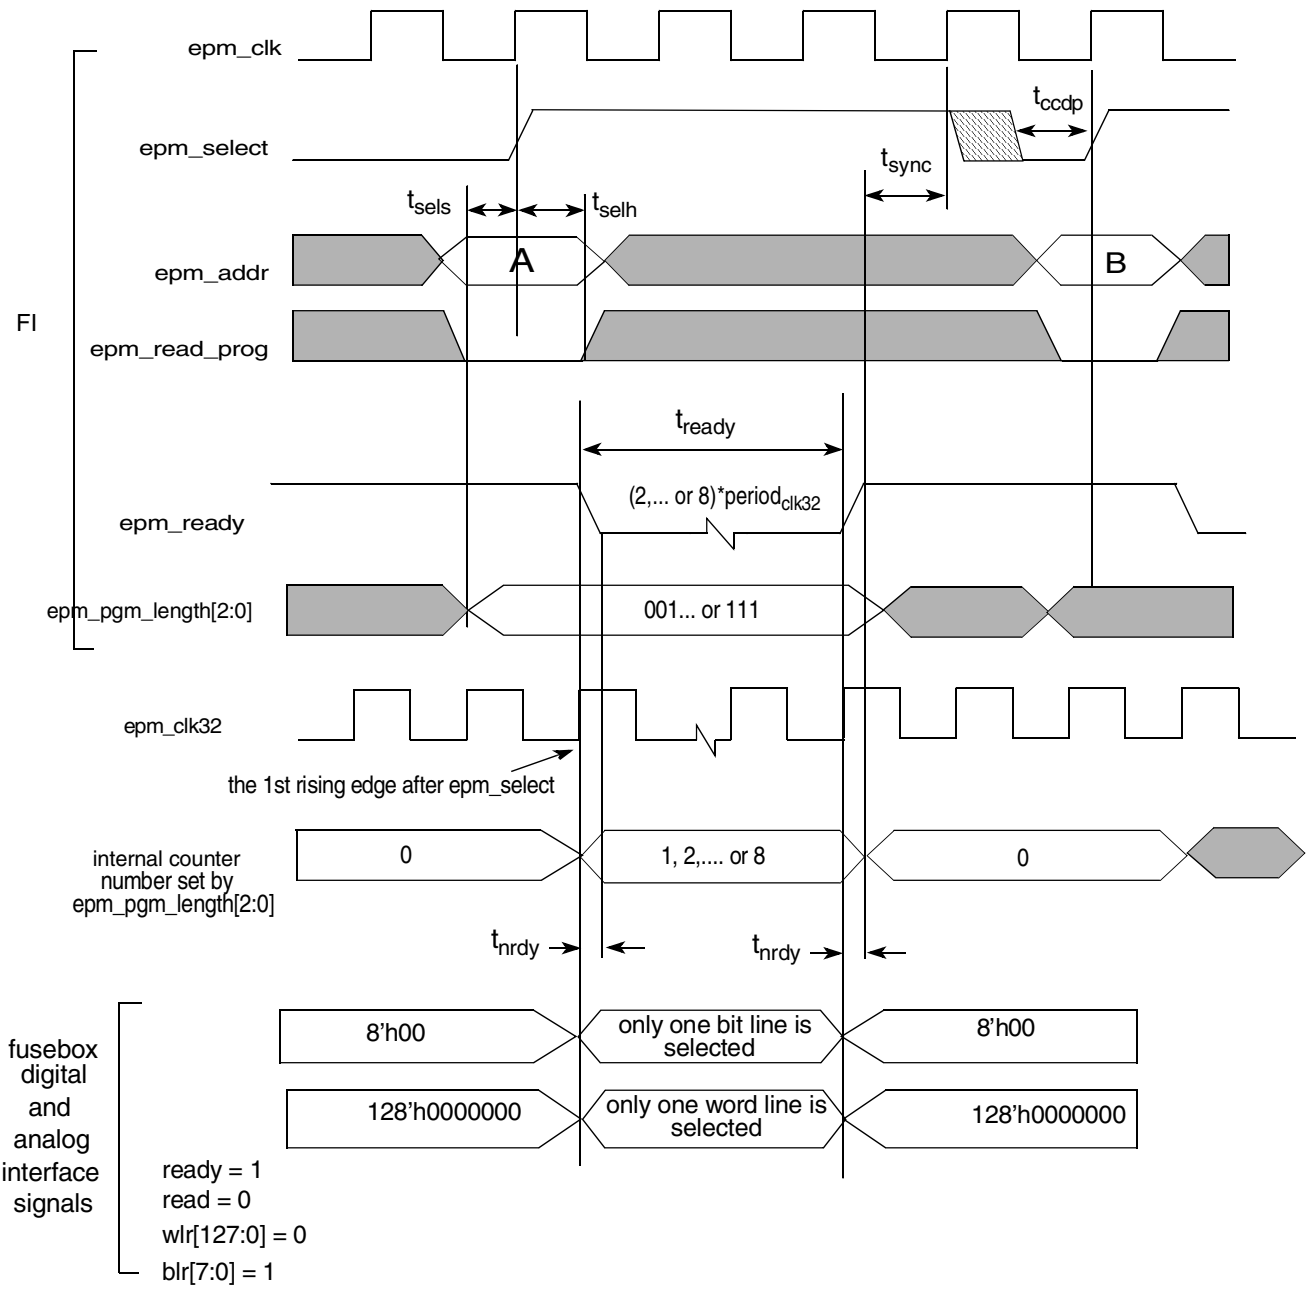

Figure 41-27. Fuse Program Cycle Timing

NOTE

The IIM controller must determine that the target fuse bank is indeed an e-Fuse bank (not a laser fuse bank) before allowing the program cycle to proceed. This is determined by examining the appropriate fuse_type signal, which is fixed at SoC integration time.

41.3.3 Fuse Value Storage

The values of fuses may be read from one of the following three places:

- Software fuse value shadow cache
- Hardware-visible fuse value shadow cache, driving SOC nets
- Fuse elements themselves

The reasons for caching the fuse values are to reduce the risk of accidental programming of e-Fuses due to repeated reads and to reduce power consumption associated with sense cycles.

41.3.3.1 Software Fuse Value Shadow Cache

Each word in the cache RAM includes a valid bit and a parity bit, as shown in Figure 41-28. The valid bit is set if the data bits and parity bit have been set according to the sensed state of the corresponding fuses, Odd parity is used across the data bits only (that is, the valid bit is not included in the parity calculation).

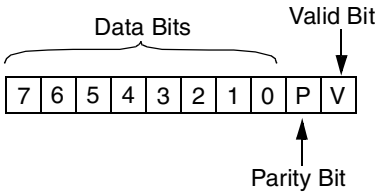

Figure 41-28. Software Cache Word Format

All bits are set to 0 when IIM comes out of reset. When a fuse word is read, the IIM will first attempt to read it from the cache (except for the hardware-visible fuses; see Section 41.3.3.2, Hardware-Visible Fuse Shadow Cache"). A sense cycle will only be run to the fuses if the cached word is invalid or the parity is incorrect. The overall cached fuse word read sequence is shown in Section 41.3.5.1, Read Sequence." The cache words and fuse words is one to one mapped.

41.3.3.2 Hardware-Visible Fuse Shadow Cache

The hardware-visible fuse include fuses in bank0 and bank1, and FBAC words of each bank.The IIM must sense these fuses and write their values to the appropriate registers when it comes out of reset, and must ensure than any change to the fuses is also immediately reflected in the registers. The overall hardware-visible word read sequence is shown in Section 41.3.5.1, Read Sequence." Each word has a parity bit as shown in Figure 41-29.

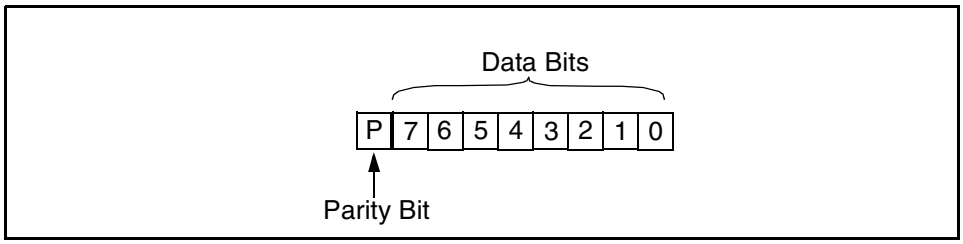

Figure 41-29. Hardware Cache Word Format

If parity error detected on shadow cache, IIM will set error bit PARITYE, and re initialize cache from fuses.

41.3.4 Fuse Protection

There are some fuses used as protection bit.

41.3.4.1 Fuse Box Bank Protection Fuse

FBWP of each bank control whether this bank can be programed. FBOP of each bank control whether this bank can be overridden. FBRP of each bank control whether this bank can be read. FBSP control whether this bank can be scanned. FBESP control whether this bank can be explicitly sensed.

41.3.4.2 Word Lock Bit

Refer to Chapter 6, “Fuse Map,” for word locks, the type of protection they provide, and words they lock.

41.3.4.3 Scan Out Protection

To prevent the secret keys scanned out by hacker, specific logic is added (shown in Figure 41-30). It resets all flip-flops in IIM before entering scan mode.

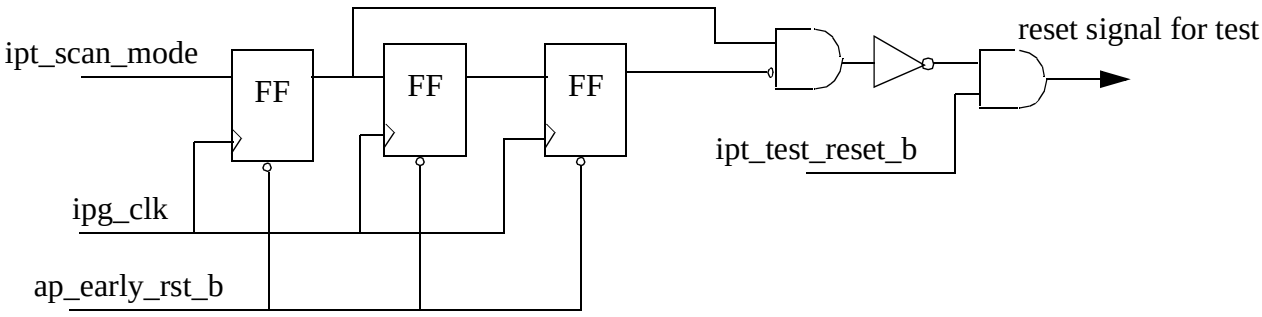

Figure 41-30. Scan Out Protection Circuit

41.3.5 Fuse Bank Operations

This section discusses the following sequences:

- Section 41.3.5.1, Read Sequence”
- Section 41.3.5.2, Explicit Sense Sequence”
- Section 41.3.5.3, Programming Sequence”
- Section 41.3.5.4, Override Sequence”

41.3.5.1 Read Sequence

Fuses may be read using the IP bus interface from any bank which is not read-inhibited (that is, FBACx[FBRP] is unblown). The read sequence from a hardware-visible signals word is shown in Figure 41-31.

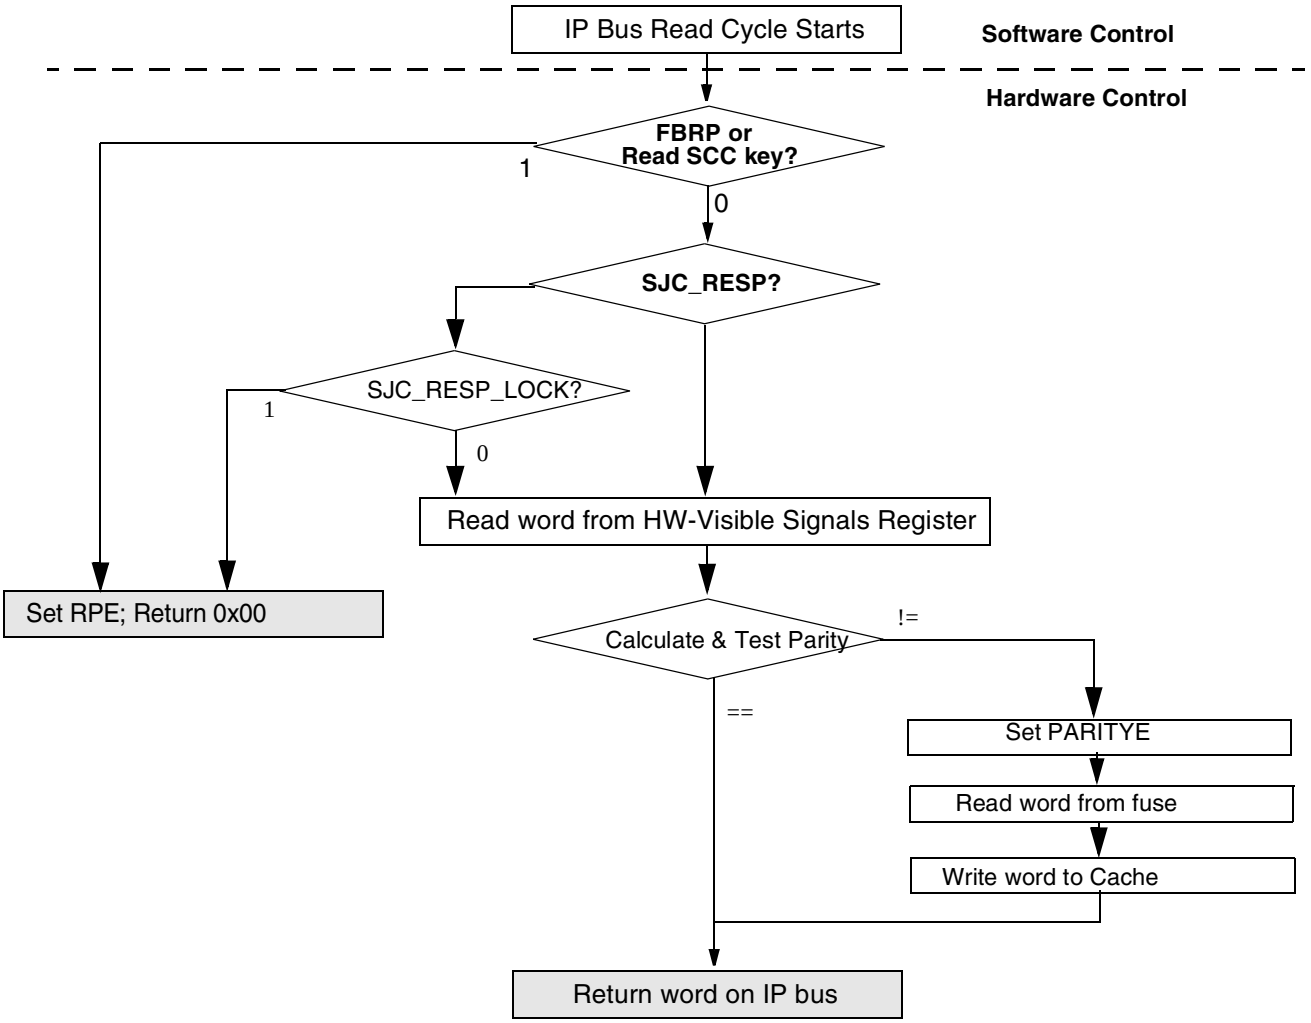

Figure 41-31. Hardware Visible Fuse Read

The read sequence to a cacheable fuse word is shown in Figure 41-32.

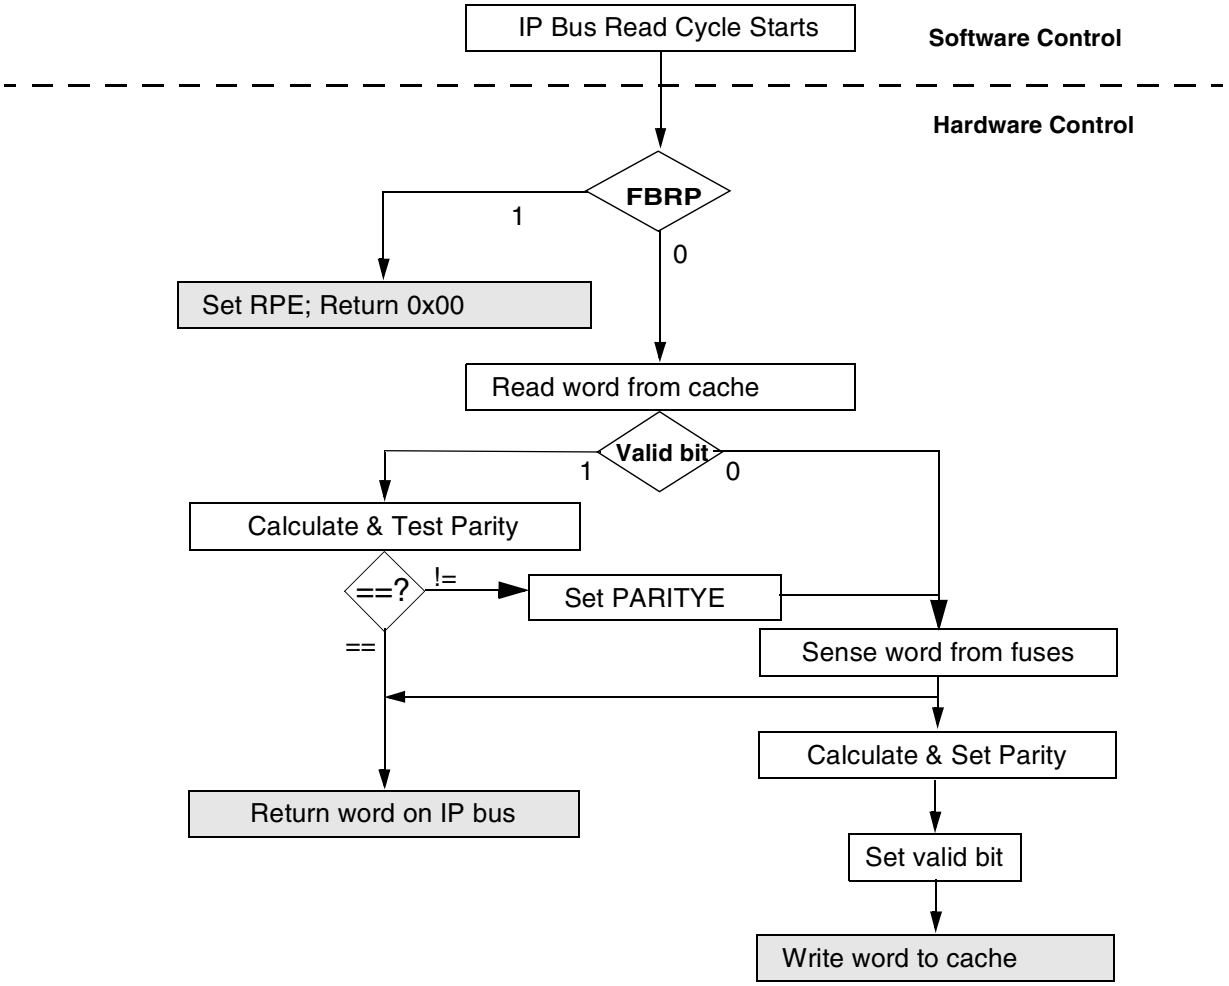

Figure 41-32. Software Fuse Read

41.3.5.2 Explicit Sense Sequence

The explicit sense sequence using IP bus is depicted in Figure 41-33.

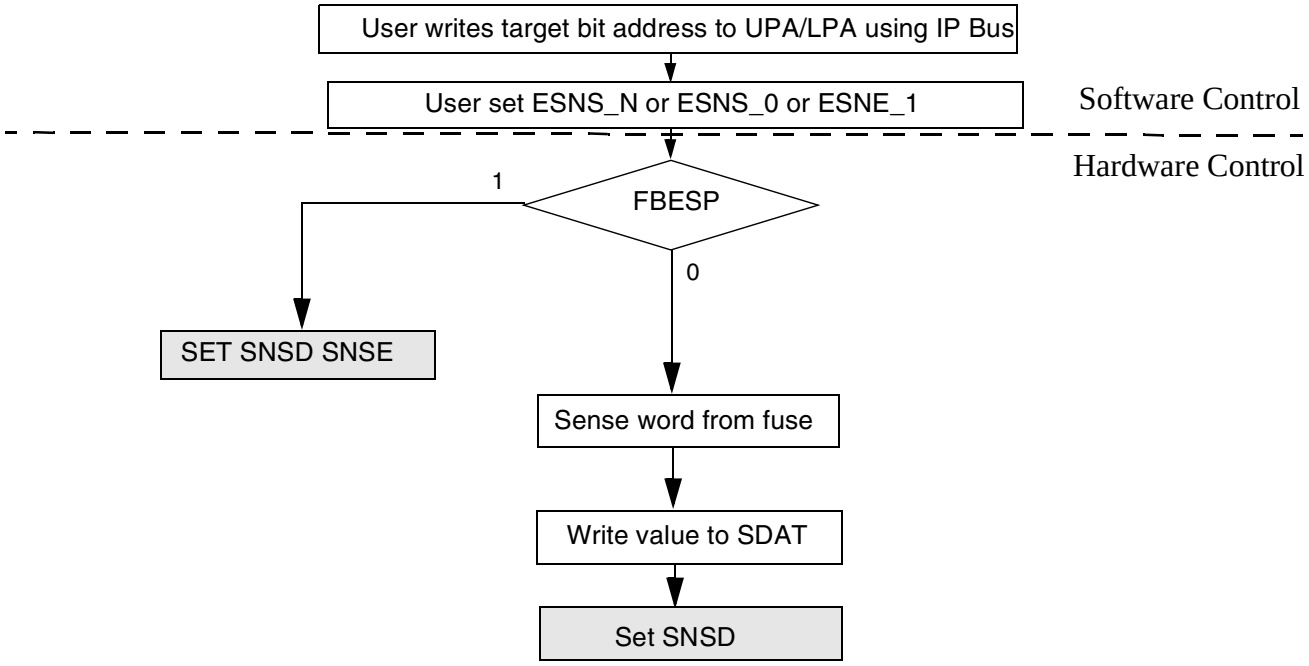

Figure 41-33. Explicit Sense Sequence

41.3.5.3 Programming Sequence

The software-controlled e-Fuse programming sequence using the IP bus is depicted in Figure 41-34.

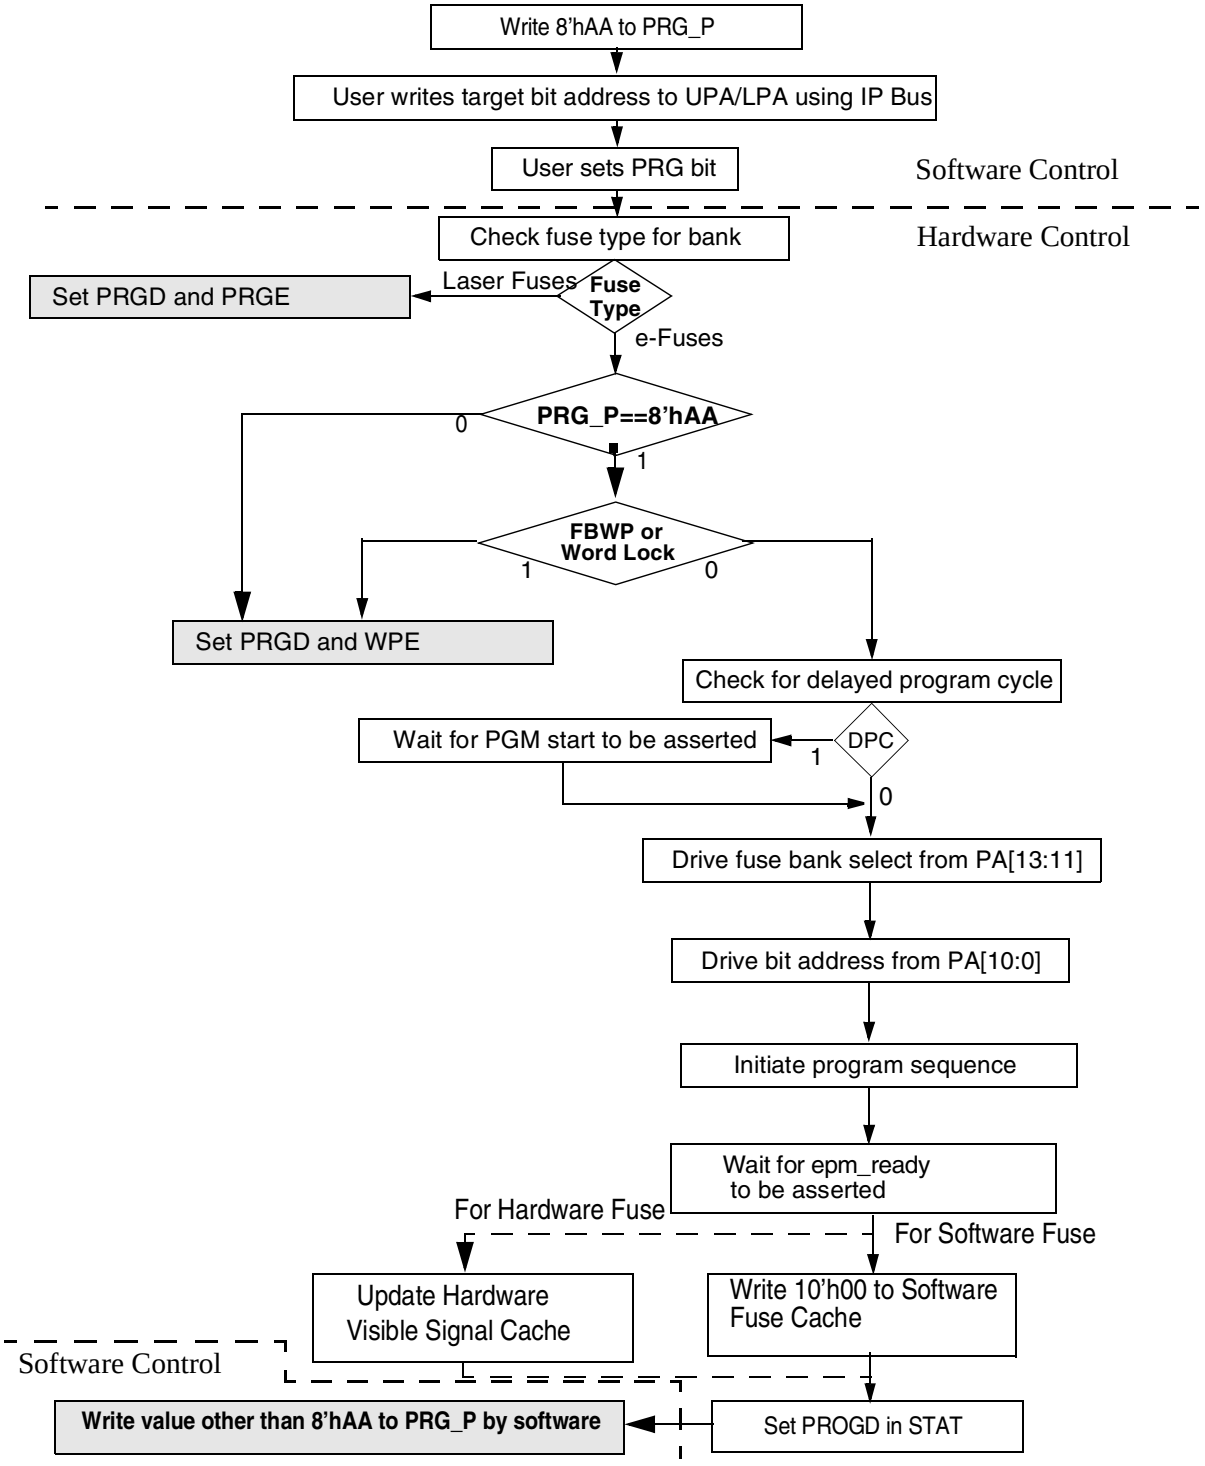

Figure 41-34. e-Fuse Program Sequence

Fuses may also be programmed directly using the JTAG interface, so long as the IIM asserts the appropriate epm_scane signal. The IIM is not involved in this programming sequence aside from allowing or disallowing it using the epm_scane signal.

Note that minimum program voltage is 2.775 V, maximum program voltage is 3.3 V. This must be taken into account when designing the architecture of an IC which includes e-Fuses. For complete parametric specifications, refer to the fuse box specification.

41.3.5.4 Override Sequence

The override sequence is depicted in Figure 41-35.

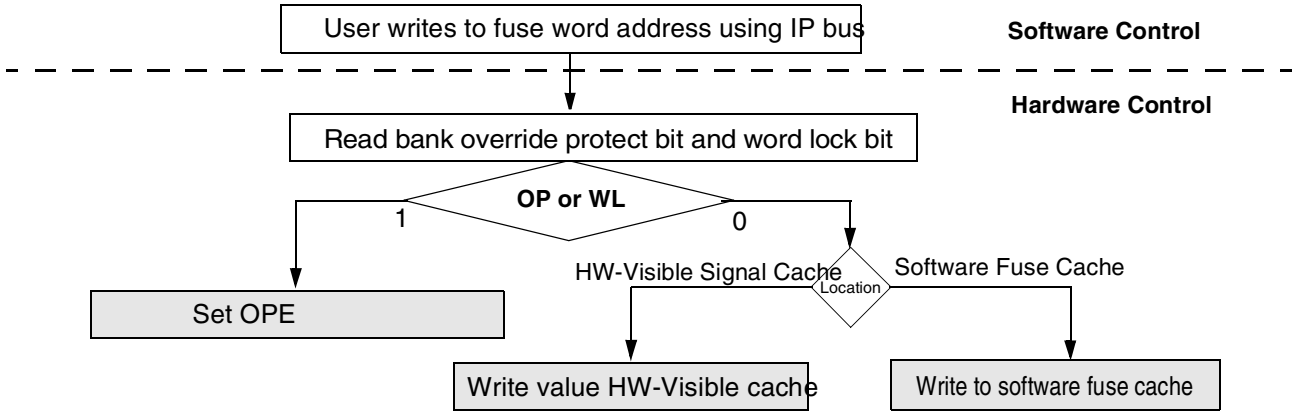

Figure 41-35. Fuse Value Override Sequence

41.4 Initialization/Application Information

41.4.1 Initialization

When the IIM come out of reset, IIM automatically senses the hardware-visible fuses and writes their values into the appropriate registers. IIM also senses the fuse access control word from each of the fuse banks, and set epm_scane according to the values of fbsp bits. Software fuses are not sensed until software has made a read request for them. Software cache will be set to 0 on reset.

After the IIM come out of reset, all the hardware visible fuses must be read out to hardware visible cache within 200us, to ensure the hardware visible fuses are loaded before the second reset at system level. IIM reads HWV2 first. iim_boot_int_ready is asserted after this read to indicate hardware visible fuse value of BOOT_INT is valid. Then FBAC words of all banks are sensed out, the sequence of sensing of other fuses depends on the parameter definition, which will be elaborated in Section 41.4.3, Parameter Definition.” The initialization time depends on the number of hardware visible fuses.

Initialization time = (number of hardware visible fuse word) × (100 ns + 4 ipg_clk cycles)

After the initialization is complete, fuse_latched will be asserted, as shown in Figure 41-36.

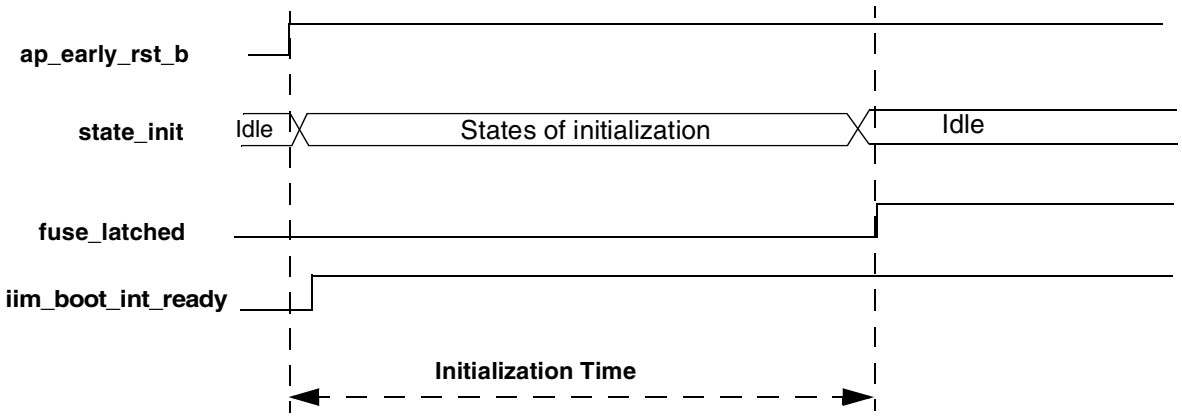

Figure 41-36. Timing Diagram of Initialization

41.4.2 Program

After JATG programming, reset must be applied to synchronize the fuse value to hardware visible signal cache.

A wait period is required between program and read operation.

41.4.3 Parameter Definition

This section for the hardware design. Each project should generate parameter file according to this section.

The RTL design can be parameterized. The maximum number of fuse bank is 8. Maximum usable fuse bank size are 2048 bits. All the parameter are defined in file iim_para. The following parameters need to be defined.

41.4.3.1 Parameter for Number

The parameters for number are as follows:

- num_bank defines the number of fuse bank.
- num_ram_block defines the number of blocks of software fuses.
- num_ram defines the number of words in software fuses cache.
- num_hwv_block defines the number of blocks of hardware visible fuses.
- num_hwv defines the number of words in hardware visible fuses cache.

41.4.3.2 Parameter for Address

This section discusses the parameter for address.

41.4.3.2.1 Address Boundary of Fuse Bank

al_bankx defines the low boundary of fuse bank x. au_bankx defines the up boundary of fuse bank x. The maximum number of fuse bank is 8. Assign 0 to unused banks.

Example 41-1. Address Boundary of Fuse Bank

```
parameter  [31:0]  num_bank= 5;
parameter [13:0] al_bank0=14'h0800;
parameter [13:0] au_bank0=14'h087C;
parameter [13:0] al_bank1=14'h0c00;
parameter [13:0] au_bank1=14'h0c3C;
parameter [13:0] al_bank2=14'h1000;
parameter [13:0] au_bank2=14'h107C;
parameter [13:0] al_bank3=14'h1400;
parameter [13:0] au_bank3=14'h147C;
parameter [13:0] al_bank4=14'h4;
parameter [13:0] au_bank4=14'h0;
parameter [13:0] al_bank5=14'h4;
parameter [13:0] au_bank5=14'h0;
parameter [13:0] al_bank6=14'h4;
parameter [13:0] au_bank6=14'h0;
parameter [13:0] al_bank7=14'h4;
parameter [13:0] au_bank7=14'h0;
```

41.4.3.2.2 Address Boundary of Software Fuse Block

al_ram_blockx defines the low boundary of software fuse block x. au_ram_blockx defines the up boundary of software fuse block x. The fuse block which is defined in this section will be mapped to Software Fuse Cache.The maximum number of blocks is 16. Assign 0 to unused blocks. If there is no fuse to be mapped to Software Fuse Cache, num_ram should be defined to 1 to avoid Verilog syntax error.

Example 41-2. Address Boundary of Software Fuse Block

```
parameter [31:0] num_ram = 32'd31;
parameter [31:0] ram_addr_width = 5;
parameter [13:0] al_ram_block0=14'h1404;
parameter [13:0] au_ram_block0=14'h147C;
parameter [13:0] al_ram_block1=14'h4;
parameter [13:0] au_ram_block1=14'h0;
```

```
parameter [13:0] al_ram_block2=14’h0;
parameter [13:0] au_ram_block2=14’h0;
parameter [13:0] al_ram_block3=14’h0;
```

41.4.3.2.3 Address Boundary of Hardware Visible Signal Block

al_hwv_blockx defines the low boundary of hardware visible Signal block x. au_hwv_blockx defines the up boundary of hardware visible fuse block x. The fuse block which is defined in this section will be mapped to Hardware Visible Signal Cache. The maximum number of blocks is 16. Assign 0 to unused block. Please note SCS0~SCS3 are assigned in block0

Example 41-3. Address Boundary of hardware Visible Signal Block

```
parameter [31:0] num_hwv = 32’d86;
parameter [31:0] hwv_addr_width = 7;
parameter [13:0] al_hwv_block0=14’h002C;
parameter [13:0] au_hwv_block0=14’h0038;
parameter [13:0] al_hwv_block1=14’h0800;
parameter [13:0] au_hwv_block1=14’h0800;
parameter [13:0] al_hwv_block2=14’h0c00;
parameter [13:0] au_hwv_block2=14’h0c00;
parameter [13:0] al_hwv_block3=14’h1000;
parameter [13:0] au_hwv_block3=14’h1000;
parameter [13:0] al_hwv_block4=14’h1400;
parameter [13:0] au_hwv_block4=14’h1400;
parameter [13:0] al_hwv_block5=14’h0;
parameter [13:0] au_hwv_block5=14’h0;
parameter [13:0] al_hwv_block6=14’h0844;
parameter [13:0] au_hwv_block6=14’h0844;
parameter [13:0] al_hwv_block7=14’h0804;
parameter [13:0] au_hwv_block7=14’h0840;
parameter [13:0] al_hwv_block8=14’h0848;
parameter [13:0] au_hwv_block8=14’h087c;
parameter [13:0] al_hwv_block9=14’h0c04;
parameter [13:0] au_hwv_block9=14’h0c3c;
parameter [13:0] al_hwv_block10=14’h1004;
parameter [13:0] au_hwv_block10=14’h107c;
parameter [13:0] al_hwv_block11=14’h0;
parameter [13:0] au_hwv_block11=14’h0;
parameter [13:0] al_hwv_block12=14’h0;
parameter [13:0] au_hwv_block12=14’h0;
parameter [13:0] al_hwv_block13=14’h0;
parameter [13:0] au_hwv_block13=14’h0;
parameter [13:0] al_hwv_block14=14’h0;
parameter [13:0] au_hwv_block14=14’h0;
```

The sequence of the definition defined the sequence of initialization. When IIM come out of reset, it initialize block1 first, then block2, block3, and so on. The sequence of the parameter definition is the same as the sequence of the fuse in hardware visible signal cache. But please note that changing of the sequence of blocks which belong to first two banks need some changes in RTL(iim_hwv_reg.v). FBAC words of all banks must be placed together.

In ZATs, Fuses in Bank0, Bank1 and FBAC words of all banks are forced to be Hardware Visible Fuses, so they must be defined in hardware visible signal block. that is, al_hwv_blockx, au_hwv_blockx.

41.4.3.3 Other Parameters

The other parameters are as follows:

- chl_size defines the size of sjc_challenge, resp_size defines the size of sjc_response.
- hwv_addr_width defines the width of hardware visible signal cache.
- ram_addr_width defines the width of software fuse cache.

If the size of bank0 is larger than 128 fuses(16 words), the following statement should be added in the iim_para.

```
‘define bank0_para_size
‘define bank0_size_para
```

Chapter 42
Image Processing Unit 3 (IPUv3EX)

42.1 Introduction

42.1.1 Overview

The goal of the IPUv3EX is to provide comprehensive support for the flow of data from an image sensor and/or to a display device. This support covers all aspects of these activities:

- Connectivity to relevant devices - cameras, displays, graphics accelerators, TV encoders and decoders.
- Related image processing and manipulation: sensor image signal processing, display processing, image conversions, etc.
- Synchronization and control capabilities (for example, to avoid tearing artifacts)

This integrative approach leads to several significant advantages:

- Automation:
  The involvement of the MCU (Main Control Unit) in image management is minimized. In particular, display refresh/update and a camera preview (displaying the input from an image sensor) can be performed completely autonomously. The resulting benefits are reducing the overhead due to SW-HW synchronization, freeing the MCU to perform other tasks and reduced power consumption (when the MCU is idle and can be powered down).
- Optimal data path:
  Access to system memory is minimized. In particular, significant processing can be performed on-the-fly while receiving data from an image sensor and/or sending data to a display. System memory is used essentially only when a change in pixel order or frame rate is needed. The resulting benefits are reduced load on the system bus and further reduction of power consumption.
- Resource sharing:
  Maximal HW reuse for different applications, resulting with the support of a wide range of requirements with minimal HW

The HW reuse mentioned above is enabled by a sophisticated configurability of each HW block. This configurability also allows the support of a wide range of external devices, data formats and operation modes. The resulting flexibility is important also because the support requirements are evolving significantly, so expected future changes need to be anticipated and accounted for.

The following further principles guided the choice of support provided by the IPUv3EX:

- For key applications that DESERVE and NEED HW support (for acceleration or low power), provide the best support (leading to an optimal implementation)
- For additional applications that can benefit from the HW, consider cost vs. benefit of making minor modifications/extensions to support them
- For all other relevant applications (to be supported by SW), verify that their support is not degraded.
- Whenever possible, let the operating system (and its windowing system) act as it would without the IPUv3EX.

42.1.2 Architecture

A simplified block diagram of the IPUv3EX is given in Figure 42-1. The role of each block is described in Table 42-1.

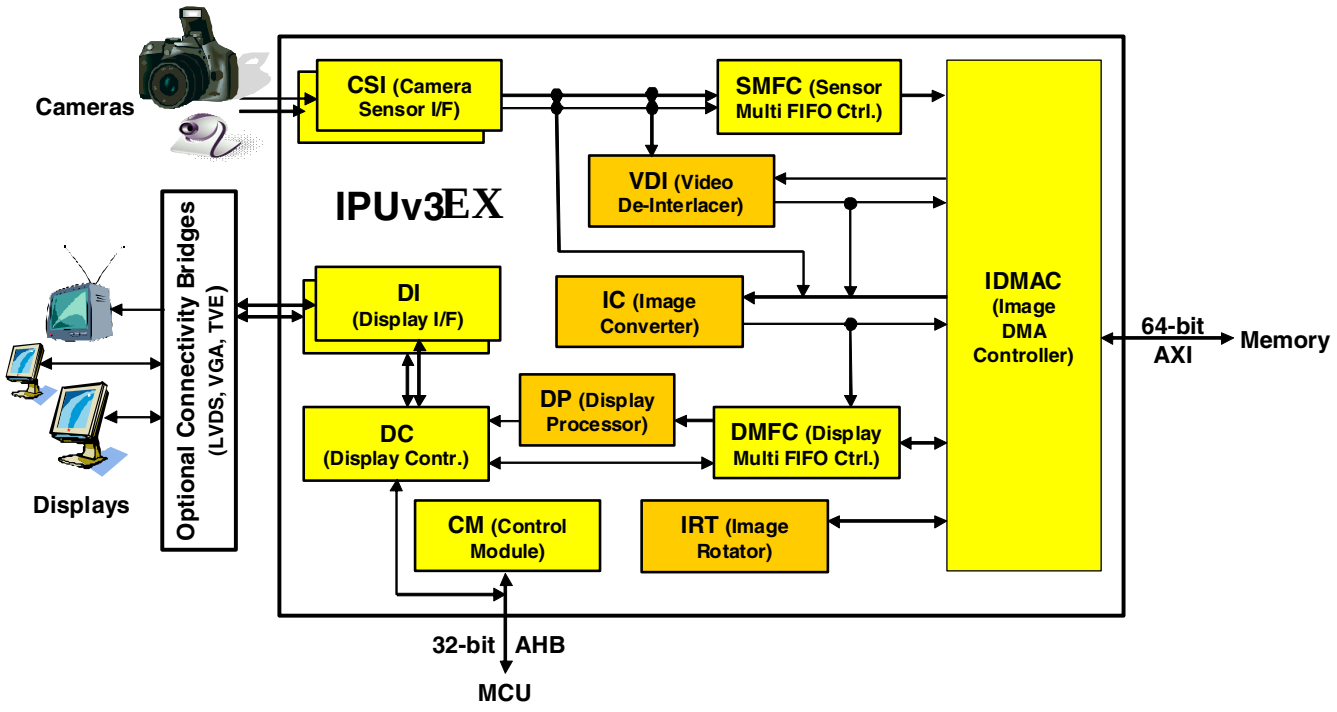

Figure 42-1. IPUv3EX - Simplified Block Diagram

Table 42-1. IPUv3EX - Block Description

Block	Description
CSI - Camera Sensor Interface	Controls a camera port; provides interface to an image sensor or a related device. IPUv3EX includes 2 such blocks
DI - Display Interface	Provides interface to displays, display controllers and related devices. IPUv3EX includes 2 such blocks
DC - Display Controller	Controls the display ports.

Table 42-1. IPUv3EX - Block Description

Block	Description
DP - Display Processor	Performs the processing required for data sent to display
IC - Image Converter	Performs resizing, color conversion/correction, combining with graphics, and horizontal inversion
VDI - Video De Interlacer	Performs video de interlacing (Interlaced -> progressive)
IRT - Image Rotator	Performs rotation (90 or 180 degrees) and inversion (vertical/horizontal)
IDMAC - Image DMA Controller	Controls the memory port; transfers data to/from system memory
SMFC - Sensor Multi FIFO Controller	Controls FIFO's for output from the CSI's to system memory
DMFC - Display Multi FIFO Controller	Controls FIFO's for IDMAC channels related to the display system
CM - Control Module	Provides control and synchronization.

42.1.3 Features And Functionality

42.1.3.1 External Ports

The IPUv3EX has the following ports:

- Two camera ports - each controlled by a CSI module - providing a connection to image sensors and related devices.
- Two display ports - each controlled by a DI module - providing a connection to displays and related devices.
- Memory port - AXI (AHB V3.0) master, controlled by the IDMAC - providing connection to the system memory.
- AHB-lite slave port, providing connection to the ARM MCU (and to any other master connected to the ARM's cross-bar switch)
- Additional ports for control and debug

42.1.3.1.1 Camera Ports

The role of these ports is to receive input from image sensors (or TV decoders) and to provide support for time-sensitive control signals to the camera. (non-time-sensitive controls - for example, configuration, reset - are performed by the MCU, through an I2C I/F or GPIO signals).

Each of the camera ports includes the following features:

- Direct connectivity to most relevant image sensors and to TV decoders.
- Interface types
  - Parallel interface
    - Up to 20-bit input data bus.
    - A single value in each cycle, except for special cases listed in Table 42-2 (comments column)
    - Programmable polarity

- The data formats
  - Interleaved color components, up to 16 bits per value (component)
  - The supported formats are listed in Table 42-2.

Table 42-2. Data Formats Supported By The Camera Port

Format	Resolution	On-The-Fly Processing	Direct path to memory	Comments
Bayer RGB	8 bits/value	Yes	Yes	
	9-10 bits/value	Yes, starting with companding to 8 bits	Written to the MSB of a 16-bit word	
	11-16 bits/value	Yes, for parallel I/F only starting with companding/reduction to 8 bits		
Full RGB or YUV 4:4:4	444/555 mode	Yes, starting with color extension to 8 bits/sample	Yes	In parallel I/F: through an 8-bit or 16-bit bus
	565 mode			In parallel I/F: through an 8-bit or 16-bit bus
	8 bits/value (888 mode)	Yes	Yes	
	8-16 bits/value	Yes, starting with companding/reduction to 8 bits	8- or 16 bit components are written to the MSB of a 16-bit word 10 bits/value can also be packed in a 32-bit word	
YUV 4:2:2 Component order: UY1VY2... or Y1UY2V...	8 bits/value	Yes	Yes	In parallel I/F: through an 8-bit bus (e.g, BT.656) or 16-bit bus (for example, BT.1120)
	10 bits/value	Yes - for parallel I/F only; starting with companding to 8 bits	Written to the MSB of a 16-bit word	In parallel I/F: through a 10-bit bus (for example, BT.656) or 20-bit bus (for example, BT.1120)
	11-16 bits/value	Yes, starting with reduction to 8 bits	Written to the MSB of a 16-bit word	
Gray scale	8 bits/value	Yes	Yes	
	9-16 bits/value	Yes, starting with companding/reduction to 8 bits	Written to the MSB of a 16-bit word	
Generic data		No	Yes In a parallel I/F, if wider than 8 bits, each bus word is written to the MSB of a 16-bit word	May be used for any other formant, for example, JPEG/MPEG4

- Scan order: progressive or interlaced
  Interlaced data (expected only for YUV 4:2:2) is sent directly to system memory, from where it can be read back for further processing.
- Frame size: up to 8192 x 4096 pixels

- Synchronization - video mode
  - The sensor is the master of the pixel clock (PIXCLK) & synchronization signals
  - Synchronization signals are received using either of the following methods:
    - Dedicated control signals -VSYNC, HSYNC - with programmable pulse width & polarity
    - Controls embedded in the data stream, following loosely the BT.656 protocol , with flexibility in code values and location.
- Synchronization - still image capture
  - The image capture is triggered by the MCU or by an external signal (for example, a mechanical shutter)
  - Synchronized strobes are generated for up to 6 outputs - the sensor and camera peripherals (flash, mechanical shutter...)
- Additional features
  - Frame rate reduction, by periodic skipping of frames
    - The supported reduction ratios are: m:n, where m,n<=5
    - This is supported independently for the different destinations - IC, SMFC.
  - Window-of-interest selection
  - Color depth reduction
    - From up to 16 bits down to 10 bits: by truncating LSBs
    - From 10 bits to 8 bits: companding - programmable piecewise-linear map (may incorporate color gain corrections)
  - Pre-flash - for red-eye reduction and for measurements (for example, focus) in low-light conditions

Several sensors can be connected to each of the CSI's. Simultaneous functionality (sending data) is supported as follows:

- Two sensors can send data independently, each through a different port.
- Only one of the (non-generic) streams can be transferred to the , VDI or IC for on-the-fly processing, while the other ones are sent directly to system memory.

The input rate supported by the camera port is as follows:

- Parallel interface:
  - Average: up to 90M values/sec
    Bayer - 90 M pixels/sec (for example, 6M pixels @ 15 fps)
    YUV 4:2:2 - 45 M pixels/sec (for example, 3M pixels @ 15 fps)
    YUV 4:4:4 or RGB - 30 M pixels/sec (for example, 3M pixels @ 10 fps)
  - Peak: up to 120M values/sec
    (to account for up to 35% blanking intervals)
- Fast serial interface:
  - Average: up to 120M values/sec, 1.44 Gbps
    Bayer - 120M pixels/sec (for example, 8M pixels @ 15 fps, 12 bits per value)

YUV 4:2:2 - 60M pixels/sec (for example, 4M pixels @ 15 fps, 12 bits per value)
YUV 4:4:4 or RGB - 40M pixels/sec (e.g., 4 pixels @ 10 fps, 12 bits per value)

  - Peak: up to 160 values/sec, 1.92 Gbps
    (to account for up to 35% blanking intervals)
- When two (or more) sensors are used simultaneously, the total rate supported is as above.
- On-the-fly processing (as listed in Table 42-2) may be restricted to a lower input rate - see Section 42.1.3.2 for further details.
- I/O pads may also be restricted to a lower input rate

42.1.3.1.2 Display Ports

The role of these ports is to communicate with display devices, either directly or through a controller (e.g. graphics accelerator) or a bridge (e.g. TV encoder).

Access Modes

Two access modes are supported.

Synchronous access:

In this mode, the IPUv3EX transfers a two-dimensional block of pixels to the display device, in synchronization with the screen refresh cycle.

This mode has a dual role:

- For a RAM-less display or a TV screen, this mode is used to perform the screen refresh process from a display buffer in system memory.
- For a “smart” display, this mode is used to transfer a rectangular block of pixels to the display’s screen and, in some cases, also to the display buffer
  - The transferred block may be only part of the screen (the rest of the screen being refreshed by the integrated controller, from the internal buffer). Moreover, a mask can be used to transfer to the display only parts of the block, e.g., a window partly hidden by other windows.
  - If the block is transferred only to the screen, the transfer rate must be equal to the refresh rate. If, however, the transfer is also to the display’s memory, the rate can be reduced to the rate at which the input buffer is updated.

In all cases (including the last one), the IPUv3EX sends to the display all the synchronization signals controlling the screen refresh and the block transfer is synchronized with these signals. This synchronization means that tearing effects are avoided when using this mode.

Asynchronous Access:

This is the main mode used for communicating with an external display controller (possibly in a smart display or a graphics accelerator). In this mode, the IPUv3EX performs random access - read/write - to the memory and registers of the controller.

Two types of addressing methods are supported

- Generic linear addressing of pixels and generic data

- 2-dimensional (X/Y) addressing of pixels

The following access types are provided:

- Data transfer to the external device, after on-the-fly processing in the IPUv3EX.
- Data transfer (DMA) - read/write - between the host's system memory and the external device, through the IPUv3EX's memory port (controlled by the IDMAC); e.g. transfer of a rectangular block of pixels (possibly full screen).
- Host access - read/write - to an external device, through the AHB-slave port
  - Access types
    - Direct access - emulating a directly-addressed access (see below)
      This includes burst access (incremental; up to 8 words/burst)
    - Low-level access - leaving to the host the explicit generation of the access protocol
  - The possible accessing modules include the MCU and the system DMA controller (as well as any other AHB master connected to the MCU's cross-bar switch).

Transfer of video/graphics data stream to controller's display buffer is performed using one of the first two modes above. Unlike in the synchronous mode, this process is not tightly-synchronized with the screen refresh cycle. However, a loose synchronization - to avoid tearing - is still possible: the appropriate timing for the transfer can be derived from the VSYNC signal of the screen refresh - either generated by the IPUv3EX's display controller or received from the external controller.

The asynchronous access requires the specification of an address. The display interface uses "indirect addressing", namely, there is no address bus, and the address, as well as control and configuration commands, are embedded in the data stream. The access procedure - including writing addresses and commands - is managed autonomously by the interface, in one of two ways:

- Automatic emulation of transparent access, following microcode ("access template") generated by the MCU. This mechanism is very flexible, supporting a wide variety of devices.
- Streaming commands/addresses from a buffer stored (by the MCU) in system memory.

Note that direct access requires the use of the first method - automatic emulation.

The Interface

The display interface is very flexible and supports a wide variety of devices from major manufacturers. The following interface types are provided (in each of the two display ports)

- Parallel video interface (for synchronous access) - up to 24-bit data bus.
  - Control protocol - follows Sharp HR and generic TFT definitions
  - Supports BT.656 (8-bit) and BT.1120 (16-bit) protocols
  - Supports HDTV standards SMPTE274 (1080i/p) and SMPTE296 (720p)
- A parallel bidirectional bus interface (for asynchronous access) - up to 32-bit data bus.
  - Compatible with MIPI-DBI standard .
  - Control protocol - either system-80 or system-68K
    The timing and polarity of the signals are programmable.
  - Byte-enable - optional, for a 16-bit interface

— Burst access
For direct access, the burst is determined by the corresponding signal in the AHB interface.

- A serial interface - 3-wire, 4-wire and 5-wire (two flavors) (for asynchronous access)

The supported formats for pixel data are

- RGB - color depth fully configurable; up to 8 bits/value (color component)
- YUV 4:2:2, 8 bits/value (for TV encoder)

In the parallel interfaces, the data bus has up to 32 bits. Non-trivial mapping of pixels to the bus is restricted to the 24 LSB's. This mapping is fully configurable and very flexible. In the serial interfaces, the data is mapped in the same way as in the parallel interfaces and then serialized.

The interface also supports "generic data". Such data is transferred - byte-by-byte, without modification - between the system memory and the display device (through a serial interface or 8/16-bit parallel interface). Non-conventional pixel formats can be supported by considering them as "generic data".

For the interface clock, there are the following options (independently for each port)

- Derived from the IPUv3EX internal clock (master mode)
- Provided by an external source (slave mode)

The transfer rate supported:

- For single port (for all interfaces):
  - 110 Mega-Accesses/Sec if the DI clock is derived from an external to IPUv3EX source (like another PLL)
  - 120 Mega-Accesses/Sec if the DI clock is derived from the IPUv3EX clock (HSP_CLK)

For synchronous access with one cycle/pixel, this enables, e.g (including 35% blanking intervals)

— XGA (1024x768) @ 100 fps
— 720p (1280x720) @ 60 fps
— 1080i (1920x1080) @ 30 fps
—

- The combined rate for the two ports is up to 120 MP/sec

The interface includes the following additional features:

- Screen size: up to 4096 x 2048 pixels, programmable by software.
- Scan Order: progressive or interlaced
- Synchronization
  — Programmable horizontal and vertical synchronization output signals (for synchronous access)
  — Data enabling output signal
- Software contrast control using 8-bit programmable pulse-width modulation (PWM)
  Two dedicated PWM outputs are provided

Connecting To Display Devices

IPUv3EX allows the connectivity to multiple display devices. In particular, it supports the following setup:

- Primary LCD display; can be smart, dumb (RAM-less) or dual-port; may use the parallel interface.
- Second LCD display; can be smart or dumb (RAM-less); may use parallel or serial interface .
- TV Output: either digital parallel output, or (through an integrated TV encoder bridge) analog output..

Each of the above connections has independent settings - interface timing, access template, chip-select, etc.

Simultaneous functionality of the above devices is possible in each of the following ways:

- Two devices can be accessed (synchronously or asynchronously) independently, each through a different port: each using any of the available interfaces.
- Two devices can time-share asynchronous accesses through the legacy serial & parallel interfaces, using the CS signals.
- An asynchronous access can be performed during vertical blanking intervals of a synchronous access (screen refresh; to the same or other device).

The possibilities for simultaneous functionality by time-sharing the legacy interfaces in a single port are summarized in Table 42-3

Table 42-3. Simultaneous Functionality of Display Port By Time-Sharing Legacy Interfaces

	Second/Third Display Type		
Primary Display Type	**Smart Display Serial Interface**	**Smart Display Parallel Interface Asynchronous access**	**RAM-less display or TV screen**
Smart Display Parallel Interface Asynchronous access	Yes	Yes	Yes; access to the smart display is restricted to blanking intervals
Dual Port Smart Display Synchronous access	Yes	Yes, access to the secondary display is restricted to blanking intervals	Not Available
TFT RAM-less Display Or TV screen	Yes	Yes, access to the smart display is restricted to blanking intervals	Not Available
Graphics Accelerator	Yes	Yes, if the accelerator supports a chip select functionality	Not Available

42.1.3.1.3 Memory Port

The memory port is an AXI (AHB V3.0) master port, used to read/write data - typically two-dimensional blocks from/to system memory.

The interface supports the following features

- Clock rate up to 133 MHz (equal to the internal clock)
- 64-bit data bus

- The supported data formats are listed in Table 42-4.

Table 42-4. Data Formats Supported By The Memory Interface

Format	Resolution	Input/Output	Comments
Non-interleaved YUV (in three separate buffers)	8 bits/value	both	4:4:4, 4:2:2, 4:2:0 formats
Partially-interleaved YUV (in two separate buffers)	8 bits/value	both	4:2:2, 4:2:0 formats Y buffer and UV buffer
Interleaved YUV (all color components in a single buffer)	8 bits/value	both	4:4:4 format (YUV...) 4:2:2 format (UY1VY2... or UY2VY1... or Y1UY2V...or Y2UY1V...)
Interleaved true color	8, 12,16, 18, 24, 32 bits/pixel 0 - 8 bits per R/G/B/A value	both	Flexible component location A: translucency value (only in input)
Coded color (using a palette)	4,8 bits/pixel	input only	
Gray scale	8 bits/pixel	both	
	4 bits/pixel	input only	Transferred to display port
Generic data (Transparent M)	8 bits/unit	both	E.g.: From CSI; to DI; Compressed data to/from DP Translucency for combining

  - The pixel formats are translated to/from a uniform internal format: RGBA/YUVA 8:8:8:8
- The supported ordering of bytes and pixels is little endian. For 4 bits/pixel, big endian is also supported.
- Addressing modes include:
  - Sequential access (to a contiguous memory buffer) - for generic data.
  - Raster-scan within a two-dimensional window of a video/display buffer - for both pixel and generic data.
  - Raster-scan of two-dimensional blocks within a two-dimensional window (for rotation of pixel data)
- Additional features
  - Scan order: progressive or interlaced
    Interlaced access is supported for fields which are stored either in separate memory buffers or with rows interleaved in a single buffer.
  - Reordered scan, implementing inversion and rotation.
    - Rotation and horizontal inversion - only when transferring two-dimensional blocks (to/from the IRT)
    - Vertical inversion - also in row-by-row raster-scan
  - Scrolling

– Applications
Panning within a frame
Frame scrolling
– Not supported for non-interleaved and partially-interleaved formats
– Resolution
Vertical: single pixel
Horizontal: 18 BPP - 4 pixels; 12, 4 BPP or YUV 422 - 2 pixels; other formats - one pixel

— Conditional read (for combining): fully-transparent or hidden pixels are not read.
– This is supported, for graphics. by reading the transparency (alpha) from a separate buffer

— Input/output FIFOs (in the SMFC, DMFC and in the processing modules) - size adjusted to provide resilience for latency of up to 1500 cycles.

42.1.3.2 Processing

The IPUv3EX processes rectangular blocks of pixels. The processing is performed in these modules - , VDI, DP, IC and IRT (see Figure 42-1 and Table 42-1).

42.1.3.2.1 Processing flows

Several time-shared data flows are supported, as described in Table 42-5.

Table 42-5. Time-Shared Data Flows Through The IPUv3EX

Name	Number	Type	Flow	Target	Restrictions
Display Refresh/ Update	5 flows (at most two of them of type DS1)	DS1	Fmem -> DP -> Display	Synchronous Access (e.g. display refresh; controlled by the DI)	
		DS2	Fmem -> DP -> Display	Asynchronous Access (e.g. display update)	
		DS3	Fmem <-> Display	Generic Data Transfer	
	1 flow	DS4	MCU <-> Display	Direct Access	
Video Playback	3 flows	PL1	Bmem -> VDI -> IC -> Bmem -> IRT -> Fmem + DSx	Main option	
		PL2	Fmem -> IRT -> Bmem -> IC -> DP	Low power (branching to DSx, as a video plane)	Large enough window No other video flows
		PL3	Fmem -> VDI -> IC -> DP	Low power (branching to DSx, as a video plane)	Interlaced source Large enough window No other video flows

Table 42-5. Time-Shared Data Flows Through The IPUv3EX

Name	Number	Type	Flow	Target	Restrictions
Camera Pre-view	2 flows (VF2 may be used also as a playback flow)	VF1	Sensor -> IC -> Bmem -> IRT -> Fmem + DSx	main option	Single progressive input
		VF2	Sensor -> Fmem -> /VDI -> IC -> Bmem -> IRT -> Fmem + DSx	two inputs and/or interlaced input	When the VDI is used, one of the three input fields can go directly from the sensor to the VDI. In that case the sensor output goes to the memory via the VDI and not the SMFC.
		VF3	Sensor -> IC -> DP	Low power Smart Display Tearing-less (branching to DS2, as a video plane)	Single progressive input Refresh rate = 2x sensor frame rate Large enough window No other video flows
		VF4	Sensor -> IC -> Fmem + DS1	Low power RAM-less Display Single Display Buffer (in internal memory) Tearing-less	Single progressive input Refresh rate = 2x sensor frame rate Large enough window No other video flows
Video Record	2 flows	RCx	IC -> Bmem -> IRT -> Fmem	(branching from VFx)	
Graphic Overlays	2 flows	GF1	Fmem -> IC	(combining with the main flow	
	2 flow	GF2	Fmem -> DP		

Comments

- System memory usage - legend
  - Fmem: frame double-buffer (page-flip) in system memory (typically external)
  - Bmem: two possibilities
    - A frame double buffer, as above
    - A band (4-256 rows) double-buffer (page-flip) in system memory (could be internal)
  - Direct arrow between two processing stages represents an internal pipeline
- Time-sharing
  - IC can time-share tightly three flows: one VFx, one RCx and one PLx (with independent processing parameters)
    –
  - DP can time-share one DS1 flow and a one DS2 flow (each with different destinations and independent processing parameters)
  - Direct access to display (DS4) time-shares tightly the display port with other active DSx flows.
  - Other time-sharing (between PLx; between DS2&DS3; in IRT) is frame-by-frame

- Any of the processing stages in the above flows can be skipped.
- Triggering and synchronization
  - Flow segments starting from a sensor are triggered and synchronized by input from the sensor
  - Flow segments ending with display refresh are triggered and synchronized by the refresh control mechanism in the DI.
  - Flow segments starting and ending in system memory, are triggered either by the double buffering mechanism or by explicit configuration and are processed continuously without delay, at a rate determined by the available resources. These flow segments have a lower priority than the sensor/display-driven flows.

The functionality of each of the processing blocks is described below.

42.1.3.2.2 Display Processor (DP)

The Display Processor performs all the processing required for data sent to a display.

- Input: from the IC and/or from system memory
  - Order: rows, progressive or interlaced
  - Format: YUVA/RGBA, non-decimated, 8 bits/value
- Processing chain
  - Combining 2 video/graphics planes
  - Overlaying a simple HW cursor
    32 x 32 pixels, uniform color; may be combined logically with the full plane.
  - Color conversion/correction - linear (multiplicative & additive)
    Programmable; including:
    - YUV <-> RGB, YUV<->YUV conversions
      where YUV stands for any one of the color formats defined in the MPEG-4 standard
    - Adjustments: brightness, contrast, color saturation...
    - Special effects: gray-scale, color inversion, sephia, blue-tone...
    - Color-preserving clipping, for gamut mapping
    - Hue-preserving gamut mapping - for minimal color distortion
    - Applied to the output of combining or to one of the inputs
  - Gamma correction and contrast stretching - programmable piecewise-linear map
- Output: to display (through the DC)
  - Rate: up to 120M pixels/sec (e.g., WXGA (1366x768) @ 85 fps + 35% blanking intervals)
  - Format: YUV/RGB, non-decimated, 8 bits/value

The DP processes a single data flow at any given time, but it supports up to three data flows, by time sharing

- A Primary flow:
  - The input is loaded periodically - using a timer (as required, e.g. for a synchronous access)

— Optionally, frames are skipped if the content has not changed (as appropriate for a smart display)

- Two secondary flows:
  — Asynchronous; processed when the DP is not needed for the primary flow (during blanking intervals or when a primary frame is skipped).
  — The two secondary flows are switched frame-by-frame.

42.1.3.3 Video De-Interlacer (VDI)

The Video De-Interlacer converts an interlaced video stream to progressive order, using a high-quality 3-field motion-adaptive filter.

- Video source - SDTV: 480i30 (720x480 @ 30 fps) or 576i25 (720x576 @ 25 fps)
- Input: - three consecutive fields
  — Source
    – The most recent field may come from the CSI or from system memory
    – The other two fields are read from memory
  — Field size: up to 720x512 pixels
  — Pixel format: YUV 4:2:2/4:2:0, 8 bits/value
- Output: progressive frame
  — Destination: to system memory or to the Image Converter.
  — Frame size: up to 720x1024 pixels
  — Rate: up to 60 MP/sec (e.g., 720x576 @ 120 fps + 10% vertical blanking overhead)
  — Format: same as input format

The de-interlacing is performed using a high-quality 3-field filter which is motion adaptive:

- For slow motion - retains the full resolution (of both top and bottom fields)
- For fast motion - prevents motion artifacts

The VDI supports a single video stream at any given time.

42.1.3.3.1 Image Converter (IC)

The Image Converter performs various operations on a video stream.

- Input: from sensor or from system memory
  — Frame size: up to 4096x4096 pixels
  — Rate: up to 100M pixels/sec (e.g., 2.5 MP @ 30 fps + 35% blanking intervals)
  — Order: rows, progressive.
  If resizing is not used, interlaced order is also acceptable.
  — Pixel format: YUV/RGB, 8 bits/value
- Processing chain:
  — Resizing

  - Fully flexible resizing ratio
    Maximal downsizing ratio: 16:1
    Subject to this limitation, any N->M resizing can be performed
  - Independent horizontal and vertical resizing ratios.
- Color conversion/correction - linear (multiplicative & additive)
  Programmable; including:
  - YUV <-> RGB, YUV<->YUV conversions
    where YUV stands for any one of the color formats defined in the MPEG-4 standard
  - Adjustments: brightness, contrast, color saturation...
  - Special effects: gray-scale, color inversion, sephia, blue-tone...
- Combining with a graphics plane (e.g. application-specific overlay)
- Horizontal inversion

- Output: to system memory or (for a single active flow) to a display device (through the DP).
  - Frame size: up to 1024x1024 pixels
  - Rate: up to 50M pixels/sec (e.g., SVGA (800x600) @ 75 fps + 35% blanking intervals)
  - Rate: up to 50M pixels/sec (e.g., SVGA (800x600) @ 75 fps + 35% blanking intervals)
  - Order: rows, progressive.
    If resizing is not used, interlaced order is also acceptable.
  - Format: YUV/RGB, 8 bits/value

The IC supports three time-shared data flows: record, camera preview and playback (the first two share a common input).

42.1.3.3.2 Image Rotator (IRT)

- Input/output: from/to system memory
  - Rate: up to 50M pixels/sec
  - Order: raster scan of 8x8-pixel blocks
  - Format: YUV/RGB, non-decimated, 8 bits/value
- Transformation: combination of the following
  - 90-degree rotation
  - Horizontal inversion
  - Vertical inversion

42.1.3.4 Automatic Procedures

The IPUv3EX is equipped with powerful control and synchronization capabilities to perform its tasks with minimal involvement of ARM and minimal use of memory. In particular, it includes:

- An integrated DMA controller with an AXI master port, allowing autonomous access to the system memory.
- An integrated display controller, performing screen refresh of a RAM-less display.

- A page-flip double buffering mechanism, synchronizing read and write access to system memory, to prevent tearing effects.
- A double/triple buffer synchronization mechanism with a video/graphics source.
- Internal synchronization, e.g., between input from sensor and output to display

As a result, in most cases, the MCU is involved only when it also performs part of the processing (e.g. video coding). In particular, the following procedures are performed by the IPUv3EX completely autonomously:

- Screen refresh for RAM-less displays
- Update of the ("partial plane") display buffer used for screen refresh (located either in system memory or in an external display controller, e.g. of a smart display or graphics accelerator), when the content is generated in a different ("full plane") buffer.
- Camera preview (displaying a view finder - a video-stream from the image sensor to the display) is autonomous except for minimum MCU involvement (~one time per frame or less) in camera input control (exposure, white balance, focus and flicker reduction)

Typically, there are extended periods of times in which there is no other activity in the system. The MCU - being idle - can be put to a low-power mode, reducing the power consumption and extending significantly the battery life.

The IPUv3EX supports several techniques to reduce further the power consumption of the display system:

- Dynamically optimized screen refresh rate (see Section 42.1.3.4.1 below)
- Optimized update of the display buffer (see Section 42.1.3.4.2 below)
- Dynamic backlight control, with low-light compensation by image enhancement

Further features and capabilities of the automatic procedures are outlined below

42.1.3.4.1 Screen Refresh

- The refresh rate may vary within a predefined range. Within this range, the rate is dynamically adjusted to the content update rate.

  An indication about the availability of new content is obtained as follows

  — If the page-flip double buffering is used, the mechanism provides this indication

  — If only a single buffer is used (and incrementally updated), the IPUv3EX can receive an indication of a modification, either through a dedicated external "snooping" signal (e.g. from the EMI), or from the MCU (by setting an internal flag).
- The IPUv3EX counts the refresh cycles: the total and those with new content. The MCU can use these counters to optimize display management (e.g. switching display buffer compression on/off). The counters are reset by the MCU.
- The transferred data may be processed on the way, using the IC and DP.

42.1.3.4.2 Update Of The Display Buffer

- Conditional update
  The IPUv3EX can receive an external "snooping" signal indicating a modification of the full plane

buffer (as during screen refresh above). It monitors the signal and, upon detection, it performs one of the following:

— Performs an update, without any SW intervention

— Interrupts the MCU, that can initiate some more involved procedure (e.g. selective update)

- Automatic display of a changing image (animation) or moving image (scrolling)
  This is implemented by reading frames (from a full plane buffer) with incremental offset. When the IPUv3EX reaches the last programmed frame, it can perform one of the following:
  — Return to the first frame, without any SW intervention
  — Interrupt the MCU, to generate the next content.
- The timing of the update can be adjusted to avoid tearing.
- The transferred data may be processed on the way, using the IC and DP

42.1.3.4.3 Camera Preview

- Tearing artifacts can be prevented by (automatic) page-flip double buffering in system memory
- Alternatively, the video stream from an image sensor can be sent directly to the display buffer used for screen refresh. The significance of this option is that only a single frame buffer is needed (and not two). This buffer may be located either in system memory or in an external display controller.
  — This option is useful, e.g., in a low frame rate, when tearing is not visible.
  — When tearing must be prevented, the refresh cycle in the display can be synchronized with the timing signals from the sensor (two refresh cycles for each input frame): the IPUv3EX receives a VSYNC signal from the sensor and generates from it synchronization signals for the display.

42.1.4 .Modes of Operation

42.1.4.1 Normal Operating Modes

42.1.4.2 Low Power Modes

See 42.3.12.10, “Low Power Modes - Stop, PG and LPSR modes

42.1.4.3 Debug Mode

42.2 Memory Map and Register Definition

The address space for accesses through the AHB-lite slave port is 512 MB and it is split internally (with 32MB resolution) according to bits [28:25] of the address. Using the following notation

Address = (IPU_ID[31:29], MSB[28:25], LSB[24:0]) ***Eqn. 42-1***

the address is used as follows ("T" is a configurable integer between 0 and 13 by configuring the MCU_T parameter):

1. MSB<T: access to an external device, with address = (MSB, LSB)
2. T<=MSB<14: access to an external device, with address (MSB-T, LSB)
3. MSB=14: Low-level access to an external device, with LSB[3:0] = (Lock, CS, RS[1:0])
   - LSB[5:4] = RS[1:0] (the address on the display interface)
   - LSB[6] = Choice of display's channel (0=channel 8, 1=channel 9)
   - LSB[7] = Lock (Lock=1 prevents the use of the display port until the next MCU access)
4. MSB=15: access to internal IPUv3EX registers, with address LSB

The display port has 2 channels dedicated for MCU accesses via the AHB bus. Channel 8 is dedicated to the accesses where MSB<T. Channel 9 is dedicated to the accesses where MSB>T. When only a single channel is used, channel 8 should be used. The usage of channel 9 requires the usage of channel 8 as well.

The table below shows the register file of the module (addresses 0x1E000000 to 0x1FFFFFFF) and how the memory space allocation for each sub module of the IPUv3.

NOTE

The addresses given in Table 42-5 are relative to the IPUv3 base address defined at SoC's level.

42.2.2 Register Summary

The conventions in Figure 42-2 and Table 42-2 serve as a key for the register summary and individual register diagrams.

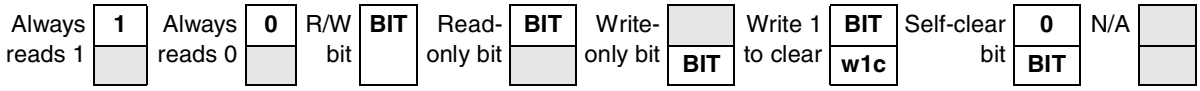

Figure 42-2. Key to Register Fields

Table 42-2 provides a key for register figures and tables and the register summary.

Table 42-2. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).

Table 42-2. Register Conventions (continued)

Convention	Description
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

42.2.3 Register Descriptions

Figure 42-3. Configuration Register (IPU_CONF)

Table 42-3. Register Field Descriptions

Field	Description
31 CSI_SEL	CSI select bit; This bit selects manually between the 2 CSIs. This bit defines which CSI is the input to the IC. This bit is effective only if IC_INPUT is bit cleared 0 - CSI0 is selected 1 - CSI1 is selected
30 IC_INPUT	IC Input select bit; This bit selects manually between the 2 inputs to the IC 0 - CSI0/1 is selected; In order to select between the CSIs use the CSI_SEL bit. 1 - VDI is selected
29 CSI1_DATA_SOURCE	0
28 CSI0_DATA_SOURCE	0
27 VDI_DMFC_SYNC	This bit enables the direct path VDI -> IC_VF -> DMFC for sync flow. If this bit is set IC_DMFC_SEL must be set. 0 - the flow is disabled 1 - the flow is enabled
26 IC_DMFC_SYNC	IC to DMFC Sync flow This bit defines if the direct flow between IC to DMFC is synchronous or asynchronous 0 - async flow 1 - Sync flow
25 IC_DMFC_SEL	IC to DMFC select Selects the DMAIC_1 (channel 21) channel's connectivity between the IC and the DMFC 0 DMAIC_1 (channel 21) is routed to the IDMAC 1 DMAIC_1 (channel 21) is routed to DMFC In case DMFC was selected the IDMAC_CH_EN[21] must be clear.
24	
23	Reserved, should be cleared.
22 IDMAC_DISABLE	Image DMA controller (IDMAC) disable bit. This bit allows the user to turn off the clock of the IDMAC if the use case permits it. By default the IDMAC is enabled. 0 - IDMAC is enabled 1 - IDMAC is disabled
21 IPU_DIAGBUS_ON	IPUv3EX Diagnostics bus on This bit is connected to the IPUv3EX's output. it can be used by the SoC in order to control the iomux and bring the IPUv3EX's diagnostics bus to the SoC's pins. 1 - diagnostics bus is on 0 - diagnostics bus is off

Table 42-3. Register Field Descriptions (continued)

Field	Description
20–16 IPU_DIAGBUS_MODE	IPUv3EX diagnostic bus mode. This 5 bits select one of 16 groups of signals to be routed to the IPUv3EX's diagnostics bus 00000 - Route group 0 to the IPUv3EX's diagnostics bus 00001 - Route group 1 to the IPUv3EX's diagnostics bus ... 01111 - Route group 15 to the IPUv3EX's diagnostics bus 10000 - Route group 16 to the IPUv3EX's diagnostics bus 10001 - Route group 17 to the IPUv3EX's diagnostics bus 10010 - 11111 Reserved
15-13	Reserved, should be cleared.
12 VDI_EN	VDI enable bit.This bit must be cleared if the ISP_EN bit is set. 0 - VDI is disabled 1 - VDI is enabled
11 SISG_EN	Still Image Synchronization Generator (SISG) Enable bit 0 - SISG is disabled 1 - SISG is enabled
10 DMFC_EN	Display's Multi FIFO Controller Module (DMFC) Enable bit 0 - DMFC is disabled 1 - DMFC is enabled
9 DC_EN	Display Controller Module (DC) Enable bit 0 - DC is disabled 1 - DC is enabled
8 SMFC_EN	Sensor's Multi FIFO Controller Module (SMFC) Enable bit 0 - SMFC is disabled 1 - SMFC is enabled
7 DI1_EN	Display Interface Module 1 Enable bit 0 - DI1 is disabled 1 - DI1 is enabled
6 DI0_EN	Display interface Module 0 Enable bit 0 - DI0 is disabled 1 - DI0 is enabled
5 DP_EN	Display processor Module Enable bit 0 - DP is disabled 1 - DP is enabled

Field	Description
31 DI1_CNT_EN_PRE_8_EN	This bit enables the interrupt that is a result of a trigger generated by counter #8 of DI1 0 Interrupt is disabled. 1 Interrupt is enabled.
30 DI1_CNT_EN_PRE_3_EN	This bit enables the interrupt that is a result of a trigger generated by counter #3 of DI1 0 Interrupt is disabled. 1 Interrupt is enabled.
29 DI1_DISP_CLK_EN_PRE_EN	0 Interrupt is disabled. 1 Interrupt is enabled.

Table 42-22. IPU_INT_CTRL_15 Field Descriptions (continued)

Field	Description
28 DI0_CNT_EN_PRE_10_EN	This bit enables the interrupt that is a result of a trigger generated by counter #10 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
27 DI0_CNT_EN_PRE_9_EN	This bit enables the interrupt that is a result of a trigger generated by counter #9 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
26 DI0_CNT_EN_PRE_8_EN	This bit enables the interrupt that is a result of a trigger generated by counter #8 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
25 DI0_CNT_EN_PRE_7_EN	This bit enables the interrupt that is a result of a trigger generated by counter #7 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
24 DI0_CNT_EN_PRE_6_EN	This bit enables the interrupt that is a result of a trigger generated by counter #6 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
23 DI0_CNT_EN_PRE_5_EN	This bit enables the interrupt that is a result of a trigger generated by counter #5 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
22 DI0_CNT_EN_PRE_4_EN	This bit enables the interrupt that is a result of a trigger generated by counter #4 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
21 DI0_CNT_EN_PRE_3_EN	This bit enables the interrupt that is a result of a trigger generated by counter #3 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
20 DI0_CNT_EN_PRE_2_EN	This bit enables the interrupt that is a result of a trigger generated by counter #2 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
19 DI0_CNT_EN_PRE_1_EN	This bit enables the interrupt that is a result of a trigger generated by counter #1 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
18 DI0_CNT_EN_PRE_0_EN	This bit enables the interrupt that is a result of a trigger generated by counter #0 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.

Table 42-22. IPU_INT_CTRL_15 Field Descriptions (continued)

Field	Description
17 DC_ASYNC_STOP_EN	This bit enables the interrupt asserted anytime the DP stops an async flow and moves to a sync flow 0 Interrupt is disabled. 1 Interrupt is enabled.
16 DC_DP_START_EN	This bit enables the interrupt asserted anytime the DP start a new sync or async flow or when an async flow is interrupted by a sync flow 0 Interrupt is disabled. 1 Interrupt is enabled.
15 DI_VSYNC_PRE_1_EN	This bit enables the DI1 interrupt indicating of a VSYNC signal asserted 2 rows before the VSYNC sent to the display 0 Interrupt is disabled. 1 Interrupt is enabled.
14 DI_VSYNC_PRE_0_EN	This bit enables the DI0 interrupt indicating of a VSYNC signal asserted 2 rows before the VSYNC sent to the display 0 Interrupt is disabled. 1 Interrupt is enabled.
13 DC_FC_6_EN	This bit enables the DC Frame Complete on channel #6 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
12 DC_FC_4_EN	This bit enables the DC Frame Complete on channel #4 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
11 DC_FC_3_EN	This bit enables the DC Frame Complete on channel #3 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
10 DC_FC_2_EN	This bit enables the DC Frame Complete on channel #2 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
9 DC_FC_1_EN	This bit enables they'd Frame Complete on channel #1 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
8 DC_FC_0_EN	This bit enables they'd Frame Complete on channel #0 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
7 DP_ASF_BRAKE_EN	DP Async Flow Brake enable bit. This bit enables the interrupt that is a result of the async flow brake at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
6 DP_SF_BRAKE_EN	DP Sync Flow Brake enable bit. This bit enables the interrupt that is a result of the Sync flow brake at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
5 DP_ASF_END_EN	DP Async Flow End enable bit. This bit enables the interrupt that is a result of the Async flow end at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.

Table 42-22. IPU_INT_CTRL_15 Field Descriptions (continued)

Field	Description
4 DP_ASF_START_EN	DP Async Flow Start enable bit. This bit enables the interrupt that is a result of the Async flow start at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
3 DP_SF_END_EN	DP Sync Flow End enable bit. This bit enables the interrupt that is a result of the Sync flow end at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
2 DP_SF_START_EN	DP Sync Flow Start enable bit. This bit enables the interrupt that is a result of the Sync flow start at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
1 IPU_SNOOPING2_INT_EN	IPUv3EX snooping 2 interrupt enable bit. This bit enables the interrupt that is a result of the detection of a snooping 2 signal assertion coming to the IPUv3EX 0 Interrupt is disabled. 1 Interrupt is enabled.
0 IPU_SNOOPING1_INT_EN	IPUv3EX snooping 1 interrupt enable bit. This bit enables the interrupt that is a result of the detection of a snooping 1 signal assertion coming to the IPUv3EX 0 Interrupt is disabled. 1 Interrupt is enabled.

42.2.3.1.21 SDMA Event Control Register 1 (IPU_SDMA_EVENT_1)

This register contains part of IPUv3EX SDMA events controls. The controls of EOF (end of frame) of DMA Channels SDMA events[31:0] can be found in this register.

Address 0xBASE+0xE000078 (IPU_SDMA_EVENT_1) Access: User read-write

15-13	Reserved
12-11 CSI0_SRM_MODE	CSI0 SRM Mode This field controls the SRM logic that handles the CSI0 registers 00 - Automatic swapping is disabled; MCU is allowed to access the CSI1's region in the RAM 01 - The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 - The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 - Update now. The SRM is controlled by the MCU. The Register will be update now
10-8 CSI0_SRM_PRI	CSI0 SRM priority This bits define the priority of the CSI1 module
7-5	Reserved

Table 42-33. IPU_SRM_PRI1 Field Descriptions (continued)

Field	Description
4-3 CSI1_SRM_MODE	CSI1 SRM Mode This field controls the SRM logic that handles the CSI1 registers 00 - Automatic swapping is disabled; MCU is allowed to access the CSI0's region in the RAM 01 - The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 - The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 - Update now. The SRM is controlled by the MCU. The Register will be update now
2-0 CSI1_SRM_PRI	CSI1 SRM priority This bits define the priority of the CSI0 module

42.2.3.1.32 IPU Shadow Registers Memory Priority 2 Register (IPU_SRM_PRI2)

The register controls the priority of SRM updates. The priority level for each module that has a shadow of its registers in the SRM should be unique. The priority level defines the order of SRM updates. a module with priority set to 010 will be updated before a module with priority set to 001.

Address 0xBASE+0xE0000A4 (IPU_SRM_PRI2) Access: User read-write

Figure 42-37. IPU Shadow Registers Memory Priority 2 Register (IPU_SRM_PRI2)

Table 42-34. IPU_SRM_PRI2 Field Descriptions

Field	Description
31-29	Reserved
28-27 DI1_SRM_MODE	DCI1 SRM Mode This field controls the SRM logic that handles the DI1 registers 00 - Automatic swapping is disabled; MCU is allowed to access the DI1 region in the RAM 01 - The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 - The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 - Update now. The SRM is controlled by the MCU. The Register will be update now
26-24 DI1_SRM_PRI	DI1 SRM priority This bits define the priority of the DI1 module
23-21	Reserved
20-19 DI0_SRM_MCU_USE	DI0 SRM is used by MCU This bit indicates that the registers of the DI0 are currently being updated by the MCU. The MCU should set this bit before accessing the SRM part that is relevant to the DI0. The MCU should clear this bit when the update procedure is finished. When this bit is set the SRM mechanism will not update the DI0's registers to avoid data coherency problems. 1 DI0 SRM is currently updated by the MCU 0 DI0 SRM s currently not updated by the MCU
18-16 DI0_SRM_PRI	DI0 SRM priority This bits define the priority of the DI0 module
15-14 DC_6_SRM_MODE	DC Group #6 SRM Mode This field controls the SRM logic that handles the DC Group #6 registers 00 - Automatic swapping is disabled; MCU is allowed to access the DC Group #6's region in the RAM 01 - The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 - The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 - Update now. The SRM is controlled by the MCU. The Register will be update now
13-12 DC_2_SRM_MODE	DC Group #2 SRM Mode This field controls the SRM logic that handles the DC Group #2 registers 00 - Automatic swapping is disabled; MCU is allowed to access the DC Group #2's region in the RAM 01 - The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 - The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 - Update now. The SRM is controlled by the MCU. The Register will be update now
11-9 DC_SRM_PRI	DC SRM priority This bits define the priority of the DC module
7-5	Reserved

Table 42-34. IPU_SRM_PRI2 Field Descriptions (continued)

Field	Description
8-7 DP_A1_SRM_MODE	DP Async flow #1 SRM Mode This field controls the SRM logic that handles the DP Async flow #1 registers 00 - Automatic swapping is disabled; MCU is allowed to access the DP Async flow #1 region in the RAM 01 - The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 - The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 - Update now. The SRM is controlled by the MCU. The Register will be update now
6-5 DP_A0_SRM_MODE	DP Async flow #0 SRM Mode This field controls the SRM logic that handles the DP Async flow #0 registers 00 - Automatic swapping is disabled; MCU is allowed to access the DP Async flow #0 region in the RAM 01 - The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 - The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 - Update now. The SRM is controlled by the MCU. The Register will be update now
4-3 DP_S_SRM_MODE	DP sync flow SRM Mode This field controls the SRM logic that handles the DP sync flow registers 00 - Automatic swapping is disabled; MCU is allowed to access the DP sync flow region in the RAM 01 - The SRM logic is controlled by the FSU. The update will be done on the next frame. 10 - Reserved 11 - Update now. The SRM is controlled by the MCU. The Register will be update now
2-0 DP_SRM_PRI	DP SRM priority This bits define the priority of the DP module

42.2.3.1.33 FSU Processing Flow 1 Register (IPU_FS_PROC_FLOW1)

42.2.3.1.38 IPU SKIP Register (IPU_SKIP)

This register controls the different frame skipping supported by the IPUv3EX.

Address 0xBASE+0xE0000BC (IPU_SKIP) Access: User read-write

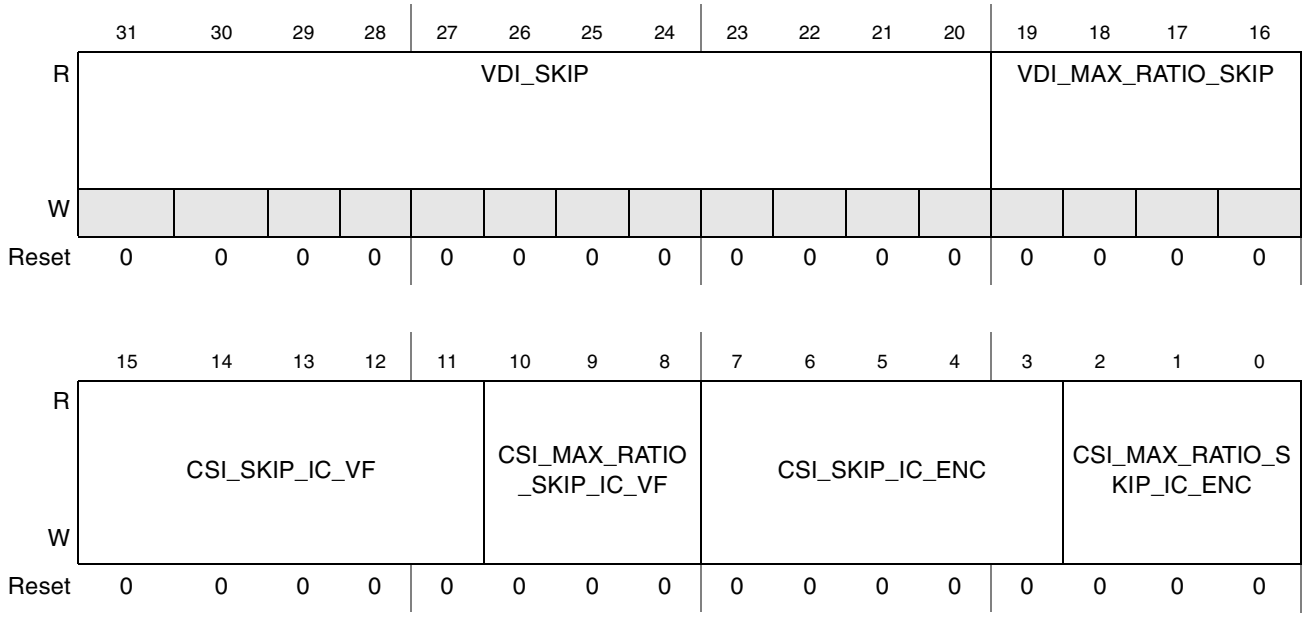

Figure 42-44. IPU SKIP Register (IPU_SKIP)

Table 42-40. IPU_SKIP Field Descriptions

Field	Description
31–20 VDI_SKIP	VDI_SKIP These 12 bits define the skipping pattern of the frames send from the VDI. The VDI avoides reading fields from the memory if the output frame is skipped. Skipping is relevant only if the source to the VDI is coming from the CSI. Skipping is done for a set of frames. The number of frames in a set is defined at VDI_MAX_RATIO_SKIP. when VDI_MAX_RATIO_SKIP = 1 => VDI_SKIP[1:0] is used; other bits are ignored when VDI_MAX_RATIO_SKIP = 2 => VDI_SKIP[2:0] are used; other bits are ignored .. .. when VDI_MAX_RATIO_SKIP = 11 => VDI_SKIP[11:0] are used;
19–16 VDI_MAX_RATIO_SKIP	Maximum Ratio Skip for VDI These bits define the number of frames in a skipping set. The maximum value of this bits is 11. When set to 0 the skipping is disabled.

Table 42-40. IPU_SKIP Field Descriptions (continued)

Field	Description
15–11 CSI_SKIP_IC_VF	CSI SKIP IC_VF These 5 bits define the skipping pattern of the frames send to the IC for view finder task from one of the CSIs as defined on the CSI_SEL and IC_INPUT bits Skipping is done for a set of frames. The number of frames in a set is defined at CSI_MAX_RATIO_SKIP_IC_VF. when CSI_MAX_RATIO_SKIP_IC_VF = 1 => CSI_SKIP_IC_VF[1:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_VF = 2 => CSI_SKIP_IC_VF[2:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_VF =3 => CSI_SKIP_IC_VF[3:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_VF = 4 => CSI_SKIP_IC_VF[4:0] are used; Setting bit #n of CSI_SKIP_IC_VF means that the #n frame in the set is skipped. For example: if CSI_MAX_RATIO_SKIP_IC_VF = 4 and CSI_SKIP_IC_VF = 11010 Frames #0 & Frame #2 will not be skipped as bit0 and bit2 are cleared Frames #1 & Frame #3 will be skipped as bit1 and bit3 are set bit #4 is ignored as CSI_MAX_RATIO_SKIP_IC_VF is set to 4
10–8 CSI_MAX_RATIO_SKIP_IC_VF	CSI Maximum Ratio Skip for IC (view finder task) These bits define the number of frames in a skipping set. The maximum value of this bits is 4. When set to 0 the skipping is disabled.
7–3 CSI_SKIP_IC_ENC	CSI SKIP IC_ENC These 5 bits define the skipping pattern of the frames send to the IC for encoding task from one of the CSIs as defined on the CSI_SEL and IC_INPUT bits Skipping is done for a set of frames. The number of frames in a set is defined at CSI_MAX_RATIO_SKIP_IC_ENC. when CSI_MAX_RATIO_SKIP_IC_ENC = 1 => CSI_SKIP_IC_ENC[1:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_ENC = 2 => CSI_SKIP_IC_ENC[2:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_ENC = 3 => CSI_SKIP_IC_ENC[3:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_ENC = 4 => CSI_SKIP_IC_ENC[4:0] are used; Setting bit #n of CSI_SKIP_IC_ENC means that the #n frame in the set is skipped. For example: if CSI_MAX_RATIO_SKIP_IC_ENC = 4 and CSI_SKIP_IC_ENC = 11010 Frames #0 & Frame #2 will not be skipped as bit0 and bit2 are cleared Frames #1 & Frame #3 will be skipped as bit1 and bit3 are set bit #4 is ignored as CSI_MAX_RATIO_SKIP_IC_ENC is set to 4
2–0 CSI_MAX_RATIO_SKIP_IC_ENC	CSI Maximum Ratio Skip for IC (encoding task) These bits define the number of frames in a skipping set. The maximum value of this bits is 4. When set to 0 the skipping is disabled.

42.2.3.1.39 IPU Display Alternate Configuration Register (IPU_DISP_ALT_CONF)

This register controls various parameters that are used for alternate flows related to the display modules.

Table 42-42. DP_DISP_GEN Field Descriptions

Field	Description
31–8	Reserved
25 DI1_COUNTER_RELEASE	DI1 Counter release By default the DI0 counters responsible for waveform generation for sync flow are frozen. For the first attempt to use the DI in sync flow the user should set this bit 1 -counter is released and running 0 - counter is cleared and stopped
24 DI0_COUNTER_RELEASE	DI1 Counter release By default the DI0 counters responsible for waveform generation for sync flow are frozen. For the first attempt to use the DI in sync flow the user should set this bit 1 -counter is released and running 0 - counter is cleared and stopped

Table 42-42. DP_DISP_GEN Field Descriptions (continued)

Field	Description
23 CSI_VSYNC_DEST	CSI_VSYNC destination This bit defines the destination of the VSYNC coming from the CSI's 1 - csi1_vsync is connected to DI0; csi0_vsync is connected to DI1 0 - csi0_vsync is connected to DI0; csi1_vsync is connected to DI1
22 MCU_MAX_BURST_STOP	MCU Maximal burst This bit limit the maximal unspecified length burst. 1 - The maximum unspecified burst length is 8-beat 0 - The unspecified burst length is unlimited
21-18 MCU_T	The address space for accesses through the AHB-lite slave port is 512 MB and it is split internally (with 32MB resolution) according to bits [28:25] of the address. Using the following notation: Address = (IPU_ID[31:29], MSB[28:25], LSB[24:0]) The address is used as follows ("T" is a configurable integer between 0 and 13): MSB<T: access to an external device, with address = (MSB, LSB) T<=MSB<14: access to an external device, with address (MSB-T, LSB)
17 MCU_DI_ID_9	MCU_DI_ID_9 - DI ID via DC channel 9. This bit defines the DI that the MCU DC's access via channel #9 1 MCU accesses DC's channel #9 via DI1. 0 MCU accesses DC's channel #9 via DI0.
16 MCU_DI_ID_8	MCU_DI_ID_8 - DI ID via DC channel 8. This bit defines the DI that the MCU DC's access via channel #8 1 MCU accesses DC's channel #8 via DI1. 0 MCU accesses DC's channel #8 via DI0.
15–7	Reserved
6 DP_PIPE_CLR	DP Pipe Clear This bit clears the internal pipe of the DP. The user may use this bit in case of an error condition This is a self clear bit 1 - Clear the internal pipe of the DP 0 - Idle - does nothing
5 DP_FG_EN_ASYNC1	FG_EN - partial plane Enable for async flow 1. This bit enables the partial plane channel. 1 partial plane channel is enabled. 0 partial plane channel is disabled.
4 DP_FG_EN_ASYNC0	FG_EN - partial plane Enable for async flow 0. This bit enables the partial plane channel. 1 partial plane channel is enabled. 0 partial plane channel is disabled.
3 DP_ASYNC_DOUBLE_FLOW	DP Async Double Flow. This bit define how many async flows are currently handles via DP channel (ch24+29) 1 2 flows are handled via DP 0 single flow is handled via DP

Table 42-42. DP_DISP_GEN Field Descriptions (continued)

Field	Description
2 DC2_DOUBLE_FLOW	DC2 Double Flow. This bit define how many flows are currently handles via DC2 channel (ch41) 11 2 flows are handled via DC2 0 single flow is handled via DC2
1 DI1_DUAL_MODE	DI1 dual mode control 1 DI1 operates in dual mode 0 DI1 is not in dual mode
0 DI0_DUAL_MODE	DI0 dual mode control 1 DI0 operates in dual mode 0 DI0 is not in dual mode

42.2.3.1.41 Display Alternate flow control Register 1 (IPU_DISP_ALT1)

Table 42-47. IPU_SNOOP Field Descriptions

Field	Description
31-17	Reserved
16 SNOOP2_SYNC_BYP	This bits control the bypass of the synchronizer on emi_snooping2 signal. This bit is for test purposes only. The user should not set this bit 1- bypass the emi_snooping2 synchronizer 0 - normal mode emi_snooping2 is internally synchronized
15-10	Reserved
9–0 AUTOREF_PER	Autorefresh period minus 1. The actual value of autorefresh period is equal to the high speed clock (HSP_CLK) period multiplied by 2^17*(AUTO_REF_PER+1).

42.2.3.1.46 IPU Memory Reset Control Register (IPU_MEM_RST)

This register controls the memory reset mechanism. IPUv3EX has a hardware mechanism for clearing the content of the internal memories. This allows the user to clear the content of or more of the internal memories without the need to perform write accesses to the memories.

Address 0xBASE+0xE0000DC (IPU_MEM_RST) Access: User read/write

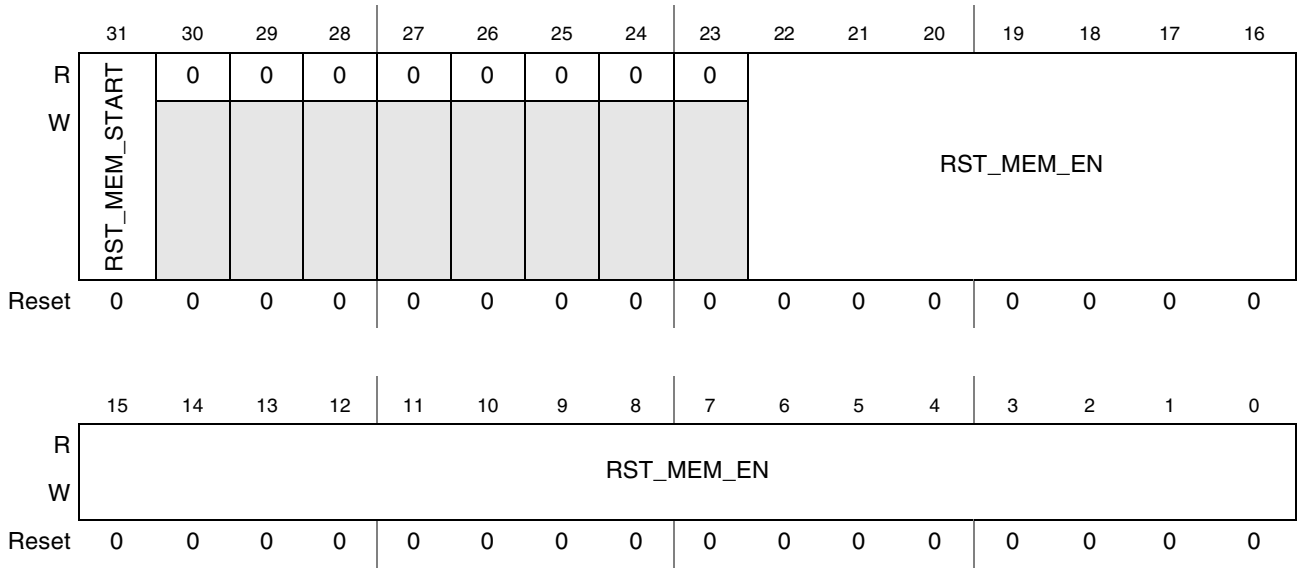

Figure 42-52. IPU Memory Reset Control Register (IPU_MEM_RST)

Table 42-48. IPU_MEM_RST Field Descriptions

Field	Description
31 RST_MEM_START	Memory Reset Start Writing one to this bit activate the memory reset mechanism. The memories that their corresponding RST_MEM_EN bit is set will be cleared. When the memory reset mechanism completes the memory clearing procedure this bit will be automatically cleared. 1 The memory reset mechanism is activated and busy 0 Idle, the memory reset mechanism is not working.
22–0 RST_MEM_EN	Reset Memory Enable Each bit on this field enables the memory reset mechanism for a specific memory. The user should set the relevant bits for the memories that need to be cleared. Below is the list of memories and their corresponding bit. srm = rst_mem_en[0] alpha = rst_mem_en[1] cpmem = rst_mem_en[2] tpm = rst_mem_en[3] mpm = rst_mem_en[4] bm = rst_mem_en[5] rm = rst_mem_en[6] dstm = rst_mem_en[7] dsom = rst_mem_en[8] lut0 = rst_mem_en[9] lut1 = rst_mem_en[10] ram_smfc = rst_mem_en[11] isp_st = rst_mem_en[12] isp_hist= rst_mem_en[13] ram_pp1= rst_mem_en[14] ram_mix1 = rst_mem_en[15] ram_pp0 = rst_mem_en[16] ram_mix0 = rst_mem_en[17] fifo_ram = rst_mem_en[18] isp_tbpr = rst_mem_en[19] dc_template = rst_mem_en[20] dmfc_rd = rst_mem_en[21] dmfc_wr = rst_mem_en[22]

42.2.3.1.47 IPU Power modes Control Register (IPU_PM)

This register controls the automatic transitions of the IPUv3EX between different power modes of the SoC and handles the clock change modes.

Address 0xBASE+0xE0000E0 (IPU_PM) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 42-53. IPU Power modes Control Register (IPU_PM)

Table 42-49. IPU_PM Field Descriptions

Field	Description
31 LPSR_MODE	LPSR Mode This bit indicates that the next attempt for entering low power mode is an attempt to move to LPST mode. Setting this bit by the user is essential in order to assure proper response of the IPUv3EX to the assertion of the stop request from the CCM. 1 - Next low power mode will be LPSR 0 - Next low power mode is not LPSR
30 DI1_SRM_CLOCK_CHANGE_MODE	SRM clock change mode When the clock is going to be changed to any new ratio other then 1:1, 1:2. 1:4. The user needs to prepare an alternate set of DI setting in the SRM. This bit enable this mode. This bit is self cleared. 1 - SRM clock change mode is enabled; the next clock change will be done by updating the DI settings from the SRM 0 - SRM clock change mode is disabled.
29-23 DI1_CLK_PERIOD_1	DI1_CLK period option 1. This parameter defines the period of the clock that the DI1 works with. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]). Setting this value to 1.0 (default) means that the DI1 works on the fastest possible clock. Setting a value smaller than 1.0 is not allowed. The value to be programmed to the DI1_CLK_PERIOD_1 field is equal to: Fast_freq/Target_freq Where: Target_freq = The frequency that the DI clock works with Fast_freq = fastest possible clock that the DI can work with
22-16 DI1_CLK_PERIOD_0	DI1_CLK period option 0. This parameter defines the period of the clock that the DI1 works with. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]). Setting this value to 1.0 (default) means that the DI1 works on the fastest possible clock. Setting a value smaller than 1.0 is not allowed. The value to be programmed to the DI1_CLK_PERIOD_1 field is equal to: Fast_freq/Target_freq Where: Target_freq = The frequency that the DI clock works with Fast_freq = fastest possible clock that the DI can work with
15 CLCOK_MODE_STAT	Clock mode status This is a read only bit indicating what is the current clock mode 1 - current clock mode is 1 0 - current clock mode is 0
14 DI0_SRM_CLOCK_CHANGE_MODE	SRM clock change mode When the clock is going to be changed to any new ratio other then 1:1, 1:2. 1:4. The user needs to prepare an alternate set of DI setting in the SRM. This bit enable this mode. This bit is self cleared. 1 - SRM clock change mode is enabled; the next clock change will be done by updating the DI settings from the SRM 0 - SRM clock change mode is disabled.

Table 42-49. IPU_PM Field Descriptions (continued)

Field	Description
13-7 DI0_CLK_PERIOD_1	DI0_CLK period option 1. This parameter defines the period of the clock that the DI0 works with. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]). Setting this value to 1.0 (default) means that the DI0 works on the fastest possible clock. Setting a value smaller than 1.0 is not allowed. The value to be programmed to the DI0_CLK_PERIOD_1 field is equal to: Fast_freq/Target_freq Where: Target_freq = The frequency that the DI clock works with Fast_freq = fastest possible clock that the DI can work with
6-0 DI0_CLK_PERIOD_0	DI0_CLK period option 0. This parameter defines the period of the clock that the DI0 works with. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]). Setting this value to 1.0 (default) means that the DI0 works on the fastest possible clock. Setting a value smaller than 1.0 is not allowed. The value to be programmed to the DI0_CLK_PERIOD_1 field is equal to: Fast_freq/Target_freq Where: Target_freq = The frequency that the DI clock works with Fast_freq = fastest possible clock that the DI can work with

42.2.3.1.48 IPU General Purpose Register (IPU_GPR)

The register contains general purpose bits.

Address 0xBASE+0xE0000E4 (IPU_GPR) Access: User read-write

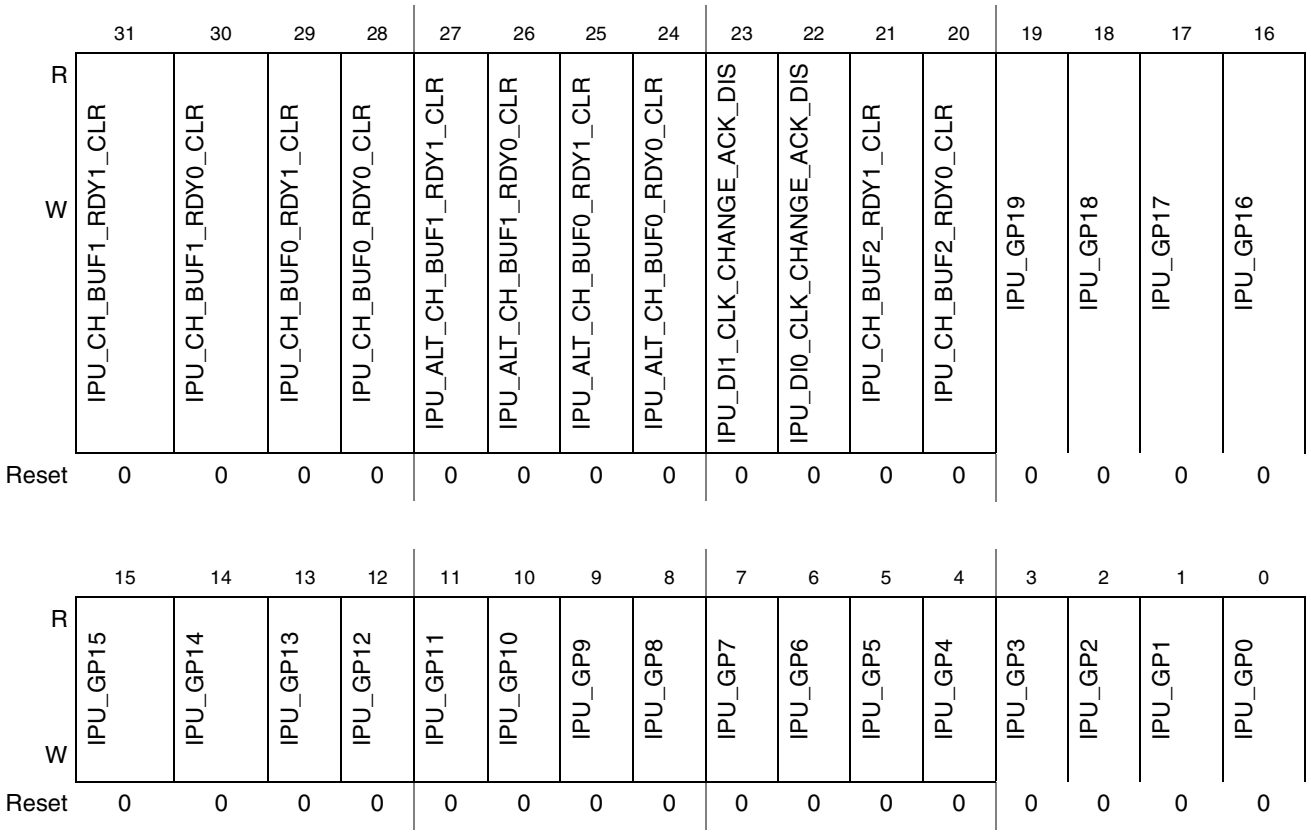

Figure 42-54. IPU General Purpose Register (IPU_GPR)

Table 42-50. IPU_GPR Field Descriptions

Field	Description
31 IPU_CH_BUF1_RDY1_CLR	This bit defines the IPU_CH_BUF1_RDY1 properties. This register can be a write one to clear OR write one to set. 1 writing one to a bit of this register clears this bit; IPU_CH_BUF1_RDY1 is w1c register 0 writing one to a bit of this register sets this bit IPU_CH_BUF1_RDY1 is w1s register
30 IPU_CH_BUF1_RDY0_CLR	This bit defines the IPU_CH_BUF1_RDY0 properties. This register can be a write one to clear OR write one to set. 1 writing one to a bit of this register clears this bit; IPU_CH_BUF1_RDY0 is w1c register 0 writing one to a bit of this register sets this bit IPU_CH_BUF1_RDY0 is w1s register

Table 42-50. IPU_GPR Field Descriptions (continued)

Field	Description
29 IPU_CH_BUF0_RDY1_CLR	This bit defines the IPU_CH_BUF0_RDY1 properties. This register can be a write one to clear OR write one to set. 1 writing one to a bit of this register clears this bit; IPU_CH_BUF0_RDY1 is w1c register 0 writing one to a bit of this register sets this bit IPU_CH_BUF0_RDY1 is w1s register
28 IPU_CH_BUF0_RDY0_CLR	This bit defines the IPU_CH_BUF0_RDY0 properties. This register can be a write one to clear OR write one to set. 1 writing one to a bit of this register clears this bit; IPU_CH_BUF0_RDY0 is w1c register 0 writing one to a bit of this register sets this bit IPU_CH_BUF0_RDY0 is w1s register
27 IPU_ALT_CH_BUF1_RDY1_CLR	This bit defines the IPU_ALT_CH_BUF1_RDY1 properties. This register can be a write one to clear OR write one to set. 1 writing one to a bit of this register clears this bit; IPU_ALT_CH_BUF1_RDY1 is w1c register 0 writing one to a bit of this register sets this bit IPU_ALT_CH_BUF1_RDY1 is w1s register
26 IPU_ALT_CH_BUF1_RDY0_CLR	This bit defines the IPU_ALT_CH_BUF1_RDY0 properties. This register can be a write one to clear OR write one to set. 1 writing one to a bit of this register clears this bit; IPU_ALT_CH_BUF1_RDY0 is w1c register 0 writing one to a bit of this register sets this bit IPU_ALT_CH_BUF1_RDY0 is w1s register
25 IPU_ALT_CH_BUF0_RDY1_CLR	This bit defines the IPU_ALT_CH_BUF0_RDY1 properties. This register can be a write one to clear OR write one to set. 1 writing one to a bit of this register clears this bit; IPU_ALT_CH_BUF0_RDY1 is w1c register 0 writing one to a bit of this register sets this bit IPU_ALT_CH_BUF0_RDY1 is w1s register
24 IPU_ALT_CH_BUF0_RDY0_CLR	This bit defines the IPU_ALT_CH_BUF0_RDY0 properties. This register can be a write one to clear OR write one to set. 1 writing one to a bit of this register clears this bit; IPU_ALT_CH_BUF0_RDY0 is w1c register 0 writing one to a bit of this register sets this bit IPU_ALT_CH_BUF0_RDY0 is w1s register
23 IPU_DI1_CLK_CHANGE_ACK_DIS	Disable DI1's clock change mechanism. 1- clock change mechanism is disabled. DI automatically acknowledges a clock change request 0 - clock change mechanism is disabled. DI performs the clock change procedure
22 IPU_DI0_CLK_CHANGE_ACK_DIS	Disable DI0's clock change mechanism. 1- clock change mechanism is disabled. DI automatically acknowledges a clock change request 0 - clock change mechanism is disabled. DI performs the clock change procedure

Figure 42-69. IPU Interrupt Status Register 9 (IPU_INT_STAT_9)

Table 42-66. IPU_INT_STAT_9 Field Descriptions

Field	Description
31 CSI1_PUPE	CSI1_PUPE - CSI1 parameters update error interrupt. This bit indicates on an interrupt that is a result of an error generated by the CSI1. The error is generated in case where new frame arrived from the CSI1 before the completion of the CSI1's parameters update by the SRM 0 Interrupt is cleared. 1 Interrupt is requested.
30 CSI0_PUPE	CSI0_PUPE - CSI0 parameters update error interrupt. This bit indicates on an interrupt that is a result of an error generated by the CSI0. The error is generated in case where new frame arrived from the CSI0 before the completion of the CSI0's parameters update by the SRM 0 Interrupt is cleared. 1 Interrupt is requested.
28 IC_VF_BUF_OVF	This bit indicates on an interrupt that is a result of the IC Buffer overflow for view finder coming from the IC. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is cleared. 1 Interrupt is requested.

Table 42-66. IPU_INT_STAT_9 Field Descriptions

Field	Description
27 IC_ENC_BUF_OVF	This bit indicates on an interrupt that is a result of the IC Buffer overflow for encoding coming from the IC. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is cleared. 1 Interrupt is requested.
26 IC_BAYER_BUF_OVF	This bit indicates on an interrupt that is a result of the IC Buffer overflow for Bayer coming from the IC. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is cleared. 1 Interrupt is requested.
25-1	Reserved
0 VDI_FIFO1_OVF	FIFO1 overflow Interrupt1 The VDI generate FIFO1 overflow interrupt1 when write pointer of FIFO1 overrun read pointer. 0 Interrupt is cleared. 1 Interrupt is requested.

42.2.3.2.10 IPU Interrupt Status Register 10 (IPU_INT_STAT_10)

This register contains part of IPUv3EX interrupts status bits. This register holds error interrupt indications coming from different modules within IPUv3EX. All the bits in this register are write one to clear.

Address 0xBASE+0xE000224 (IPU_INT_STAT_10) Access: User read-write

Field	Description
31	Reserved
30 AXIR_ERR	This bit indicates on an interrupt that is a result of AXI read access resulted with error response. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is cleared. 1 Interrupt is requested.
29 AXIW_ERR	This bit indicates on an interrupt that is a result of AXI write access resulted with error response. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is cleared. 1 Interrupt is requested.
28 NON_PRIVILEGED_ACC_ERR	Non Privileged Access Error interrupt. This bit indicates on an interrupt that is a result of access the CPMEM or the DP memory in user mode 0 Interrupt is cleared. 1 Interrupt is requested.
27	Reserved

Table 42-67. IPU_INT_STAT_10 Field Descriptions

Field	Description
26 IC_BAYER_FRM_LOST_ERR	This bit indicates on an interrupt that is a result of IC's Bayer frame lost. 0 Interrupt is disabled. 1 Interrupt is enabled.
25 IC_ENC_FRM_LOST_ERR	This bit indicates on an interrupt that is a result of IC's encoding frame lost. 0 Interrupt is disabled. 1 Interrupt is enabled.
24 IC_VF_FRM_LOST_ERR	This bit indicates on an interrupt that is a result of IC's view finder frame lost. 0 Interrupt is disabled. 1 Interrupt is enabled.
23	Reserved
22 DI1_TIME_OUT_ERR	DI1 time out error interrupt This bit indicates on the interrupt that is a result of a time out error during a read access via DI1
21 DI0_TIME_OUT_ERR	DI0 time out error interrupt This bit indicates on the interrupt that is a result of a time out error during a read access via DI0
20 DI1_SYNC_DISP_ERR	DI1 Synchronous display error interrupt This bit indicates on the interrupt that is a result of an error during access to a synchronous display via DI1
19 DI0_SYNC_DISP_ERR	DI0 Synchronous display error interrupt This bit indicates on the interrupt that is a result of an error during access to a synchronous display via DI0
18 DC_TEARING_ERR_6	Tearing Error #6 interrupt This bit indicates on the interrupt that is a result of tearing error while the anti tearing mechanism is activated for DC channel 6
17 DC_TEARING_ERR_2	Tearing Error #2 interrupt This bit indicates on the interrupt that is a result of tearing error while the anti tearing mechanism is activated for DC channel 2
16 DC_TEARING_ERR_1	Tearing Error #1 interrupt This bit indicates on the interrupt that is a result of tearing error while the anti tearing mechanism is activated for DC channel 1
15–6	Reserved
5 ISP_RAM_HIST_OF	Histogram RAM overflow/underun Interrupt This bit indicates on an interrupt that is a result of over flow or under run in the Histogram FIFO 0 Interrupt is cleared. 1 Interrupt is requested.
4 ISP_RAM_ST_OF	Statistics RAM overflow/underun Interrupt This bit enables the interrupt that is a result of over flow or under run in the statistics FIFO 0 Interrupt is cleared. 1 Interrupt is requested.

Table 42-67. IPU_INT_STAT_10 Field Descriptions

Field	Description
3 SMFC3_FRM_LOST	Frame Lost of SMFC channel 3 interrupt. This bit indicates on an interrupt that is a result of a result of a Frame Lost of SMFC channel 3 0 Interrupt is cleared. 1 Interrupt is requested.
2 SMFC2_FRM_LOST	Frame Lost of SMFC channel 2 interrupt. This bit indicates on an interrupt that is a result of a result of a Frame Lost of SMFC channel 2 0 Interrupt is cleared. 1 Interrupt is requested.
1 SMFC1_FRM_LOST	Frame Lost of SMFC channel 1 interrupt. This bit indicates on an interrupt that is a result of a result of a Frame Lost of SMFC channel 1 0 Interrupt is cleared. 1 Interrupt is requested.
0 SMFC0_FRM_LOST	Frame Lost of SMFC channel 0 interrupt. This bit indicates on an interrupt that is a result of a result of a Frame Lost of SMFC channel 0 0 Interrupt is cleared. 1 Interrupt is requested.

42.2.3.2.11 IPU Interrupt Status Register 11 (IPU_INT_STAT_11)

This register contains part of IPUv3EX interrupts status bits. The status bits of the end-of-band indication (EOBND) of DMA Channels interrupts [31:0] can be found in this register.

Address 0xBASE+0xE000228 (IPU_INT_STAT_11) Access: User read-write

Field	Description
31 DI1_CNT_EN_PRE_8	This bit indicates on the interrupt that is a result of a trigger generated by counter #8 of DI1 0 Interrupt is cleared. 1 Interrupt is requested.
30 DI1_CNT_EN_PRE_3	This bit indicates on the interrupt that is a result of a trigger generated by counter #3 of DI1 0 Interrupt is cleared. 1 Interrupt is requested.
29 DI1_DISP_CLK_EN_PRE	0 Interrupt is cleared. 1 Interrupt is requested.
28 DI0_CNT_EN_PRE_10	This bit indicates on the interrupt that is a result of a trigger generated by counter #10 of DI0 0 Interrupt is cleared. 1 Interrupt is requested.

Table 42-72. IPU_INT_STAT_15 Field Descriptions (continued)

Field	Description
27 DI0_CNT_EN_PRE_9	This bit indicates on the interrupt that is a result of a trigger generated by counter #9 of DI0 0 Interrupt is cleared. 1 Interrupt is requested.
26 DI0_CNT_EN_PRE_8	This bit indicates on the interrupt that is a result of a trigger generated by counter #8 of DI0 0 Interrupt is cleared. 1 Interrupt is requested.
25 DI0_CNT_EN_PRE_7	This bit indicates on the interrupt that is a result of a trigger generated by counter #7 of DI0 0 Interrupt is cleared. 1 Interrupt is requested.
24 DI0_CNT_EN_PRE_6	This bit indicates on the interrupt that is a result of a trigger generated by counter #6 of DI0 0 Interrupt is cleared. 1 Interrupt is requested.
23 DI0_CNT_EN_PRE_5	This bit indicates on the interrupt that is a result of a trigger generated by counter #5 of DI0 0 Interrupt is cleared. 1 Interrupt is requested.
22 DI0_CNT_EN_PRE_4	This bit indicates on the interrupt that is a result of a trigger generated by counter #4 of DI0 0 Interrupt is cleared. 1 Interrupt is requested.
21 DI0_CNT_EN_PRE_3	This bit indicates on the interrupt that is a result of a trigger generated by counter #3 of DI0 0 Interrupt is cleared. 1 Interrupt is requested.
20 DI0_CNT_EN_PRE_2	This bit indicates on the interrupt that is a result of a trigger generated by counter #2 of DI0 0 Interrupt is cleared. 1 Interrupt is requested.
19 DI0_CNT_EN_PRE_1	This bit indicates on the interrupt that is a result of a trigger generated by counter #1 of DI0 0 Interrupt is cleared. 1 Interrupt is requested.
18 DI0_CNT_EN_PRE_0	This bit indicates on the interrupt that is a result of a trigger generated by counter #0 of DI0 0 Interrupt is cleared. 1 Interrupt is requested.
17 DC_ASYNC_STOP	This bit indicates on an interrupt asserted anytime the DP stops an async flow and moves to a sync flow 0 Interrupt is cleared. 1 Interrupt is requested.

Table 42-72. IPU_INT_STAT_15 Field Descriptions (continued)

Field	Description
16 DC_DP_START	This bit indicates on an interrupt asserted anytime the DP start a new sync or async flow or when an async flow is interrupted by a sync flow 0 Interrupt is cleared. 1 Interrupt is requested.
15 DI_VSYNC_PRE_1	DI1 interrupt indicating of a VSYNC signal asserted 2 rows before the VSYNC sent to the display 0 Interrupt is cleared. 1 Interrupt is requested.
14 DI_VSYNC_PRE_0	DI0 interrupt indicating of a VSYNC signal asserted 2 rows before the VSYNC sent to the display 0 Interrupt is cleared. 1 Interrupt is requested.
13 DC_FC_6	DC Frame Complete on channel #6 interrupt indication 0 Interrupt is cleared. 1 Interrupt is requested.
12 DC_FC_4	DC Frame Complete on channel #4 interrupt indication 0 Interrupt is cleared. 1 Interrupt is requested.
11 DC_FC_3	DC Frame Complete on channel #3 interrupt indication 0 Interrupt is cleared. 1 Interrupt is requested.
10 DC_FC_2	DC Frame Complete on channel #2 interrupt indication 0 Interrupt is cleared. 1 Interrupt is requested.
9 DC_FC_1	DC Frame Complete on channel #1 interrupt indication 0 Interrupt is cleared. 1 Interrupt is requested.
8 DC_FC_0	DC Frame Complete on channel #0 interrupt indication 0 Interrupt is cleared. 1 Interrupt is requested.
7 DP_ASF_BRAKE	DP Async Flow Brake indication interrupt. This bit indicates on the interrupt that is a result of the async flow brake at the DP 0 Interrupt is cleared. 1 Interrupt is requested.
6 DP_SF_BRAKE	DP Sync Flow Brake indication interrupt. This bit indicates on the interrupt that is a result of the Sync flow brake at the DP 0 Interrupt is cleared. 1 Interrupt is requested.
5 DP_SF_END	DP Async Flow End indication interrupt. This bit indicates on the interrupt that is a result of the Async flow end at the DP 0 Interrupt is cleared. 1 Interrupt is requested.
4 DP_ASF_START	DP Async Flow Start indication interrupt. This bit indicates on the interrupt that is a result of the Async flow start at the DP 0 Interrupt is cleared. 1 Interrupt is requested.

Table 42-72. IPU_INT_STAT_15 Field Descriptions (continued)

Field	Description
3 DP_SF_END	DP Sync Flow End indication interrupt. This bit indicates on the interrupt that is a result of the Sync flow end at the DP 0 Interrupt is cleared. 1 Interrupt is requested.
2 DP_SF_START	DP Sync Flow Start indication interrupt. This bit indicates on the interrupt that is a result of the Sync flow start at the DP 0 Interrupt is cleared. 1 Interrupt is requested.
1 IPU_SNOOPING2_INT	IPUv3EX snooping 2 event indication interrupt. This bit indicates on the interrupt that is a result of the detection of a snooping 2 signal assertion coming to the IPUv3EX. 0 Interrupt is cleared. 1 Interrupt is requested.
0 IPU_SNOOPING1_INT	IPUv3EX snooping 1 event indication interrupt. This bit indicates on the interrupt that is a result of the detection of a snooping 1 signal assertion coming to the IPUv3EX. 0 Interrupt is cleared. 1 Interrupt is requested.

42.2.3.2.16 IPU Current Buffer Register 0 (IPU_CUR_BUF_0)

This register contains the current buffer status information bit for each DMA channel.

The register is shown in Figure 42-76, and the register fields are described in Table 42-73.

Address 0xBASE+0xE00023C (IPU_CUR_BUF_0) Access: User read-only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

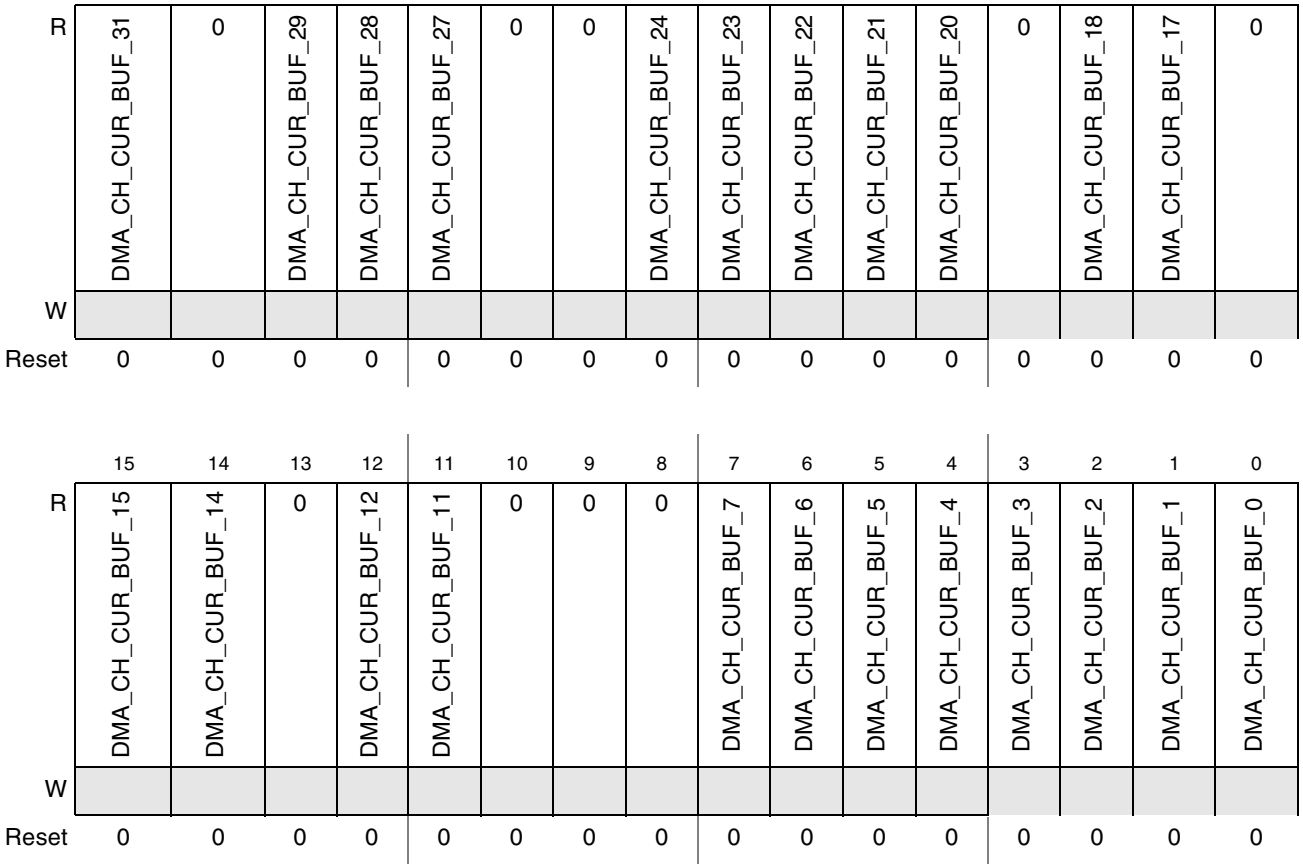

Figure 42-76. IPU Current Buffer Register 0 (IPU_CUR_BUF_0)

Table 42-73. IPU_CUR_BUF_0 Field Descriptions

Field	Description
31–0 DMA_CH_CUR_BUF_*[1]	Current buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.

[1] Indicates the corresponding DMA channel number.

42.2.3.2.17 IPU Current Buffer Register 1 (IPU_CUR_BUF_1)

This register contains the current buffer status information bit for each DMA channel.
