9 TUE1	Transmitter Underrun Error 1. This flag is set when the TXSR is empty (no data to be transmitted), the TDE1 flag is set, a transmit time slot occurs and the SSI is in Two-Channel mode. When a transmit underrun error occurs, the previous data is retransmitted. In Network mode, each time slot requires data transmission (unless masked through STMSK register), when the transmitter is enabled (TE is set). The TUE1 flag causes an interrupt if TIE and TUE1_EN are set. The TUE1 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit. 0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.
8 TUE0	Transmitter Underrun Error 0. This flag is set when the TXSR is empty (no data to be transmitted), the TDE0 flag is set and a transmit time slot occurs. When a transmit underrun error occurs, the previous data is retransmitted. In Network mode, each time slot requires data transmission (unless masked through STMSK register), when the transmitter is enabled (TE is set). The TUE0 flag causes an interrupt if TIE and TUE0_EN are set. The TUE0 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit. 0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.
7 TFS	Transmit Frame Sync. This flag indicates the occurrence of transmit frame sync. Data written to the STX registers during the time slot when the TFS flag is set, is sent during the second time slot (in Network mode) or in the next first time slot (in Normal mode). In Network mode, the TFS bit is set during transmission of the first time slot of the frame and is then cleared when starting transmission of the next time slot. In Normal mode, this bit is high for the first time slot. This flag causes an interrupt if TIE and TFS_EN are set. The TFS bit is cleared by POR and SSI reset. 0 No Occurrence of Transmit frame sync. 1 Transmit frame sync occurred during transmission of last word written to STX registers.
6 RFS	Receive Frame Sync. This flag indicates the occurrence of receive frame sync. In Network mode, the RFS bit is set when the first slot of the frame is being received. It is cleared when the next slot begins to be received. In Normal mode, this bit is always high. This flag causes an interrupt if RIE and RFS_EN are set. The RFS bit is cleared by POR and SSI reset. 0 No Occurrence of Receive frame sync. 1 Receive frame sync occurred during reception of next word in SRX registers.
5 TLS	Transmit Last Time Slot. This flag indicates the last time slot in a frame. When set, it indicates that the current time slot is the last time slot of the frame. TLS is set at the start of the last transmit time slot and causes the SSI to issue an interrupt (if TIE and TLS_EN are set). TLS is not generated when frame rate is 1 in normal mode of operation. TLS is cleared when the SISR is read with this bit set. The TLS bit is cleared by POR and SSI reset. 0 Current time slot is not last time slot of frame. 1 Current time slot is the last transmit time slot of frame.

Table 56-13. SSI Interrupt Status Register Field Descriptions (continued)

Field	Description
4 RLS	Receive Last Time Slot. This flag indicates the last time slot in a frame. When set, it indicates that the current time slot is the last receive time slot of the frame. RLS is set at the end of the last time slot and causes the SSI to issue an interrupt (if RIE and RLS_EN are set). RLS is cleared when the SISR is read with this bit set. The RLS bit is cleared by POR and SSI reset. 0 Current time slot is not last time slot of frame. 1 Current time slot is the last receive time slot of frame.
3 RFF1	Receive FIFO Full 1. This flag is set when Rx FIFO1 is enabled, the data level in Rx FIFO1 reaches the selected Rx FIFO WaterMark 1 (RFWM1) threshold and the SSI is in Two-Channel mode. The setting of RFF1 only causes an interrupt when RIE and RFF1_EN are set, Rx FIFO1 is enabled and the Two-Channel mode is selected. RFF1 is automatically cleared when the amount of data in Rx FIFO1 falls below the threshold. The RFF1 bit is cleared by POR and SSI reset. When Rx FIFO1 contains 15 words, the maximum it can hold, all further data received (for storage in this FIFO) is ignored until the FIFO contents are read. 0 Space available in Receive FIFO1. 1 Receive FIFO1 is full.
2 RFF0	Receive FIFO Full 0. This flag is set when Rx FIFO0 is enabled and the data level in Rx FIFO0 reaches the selected Rx FIFO WaterMark 0 (RFWM0) threshold. The setting of RFF0 only causes an interrupt when RIE and RFF0_EN are set and Rx FIFO0 is enabled. RFF0 is automatically cleared when the amount of data in Rx FIFO0 falls below the threshold. The RFF0 bit is cleared by POR and SSI reset. When Rx FIFO0 contains 15 words, the maximum it can hold, all further data received (for storage in this FIFO) is ignored until the FIFO contents are read. 0 Space available in Receive FIFO0. 1 Receive FIFO0 is full.
1 TFE1	Transmit FIFO Empty 1. This flag is set when the empty slots in Tx FIFO exceed or are equal to the selected Tx FIFO WaterMark 1 (TFWM1) threshold and the Two-Channel mode is selected. The setting of TFE1 only causes an interrupt when TIE and TFE1_EN are set, Tx FIFO1 is enabled and Two-Channel mode is selected. The TFE1 bit is automatically cleared when the data level in Tx FIFO1 becomes more than the amount specified by the watermark bits. The TFE1 bit is set by POR and SSI reset. 0 Transmit FIFO1 has data for transmission. 1 Transmit FIFO1 is empty.
0 TFE0	Transmit FIFO Empty 0. This flag is set when the empty slots in Tx FIFO exceed or are equal to the selected Tx FIFO WaterMark 0 (TFWM0) threshold. The setting of TFE0 only causes an interrupt when TIE and TFE0_EN are set and Tx FIFO0 is enabled. The TFE0 bit is automatically cleared when the data level in Tx FIFO0 becomes more than the amount specified by the watermark bits. The TFE0 bit is set by POR and SSI reset. 0 Transmit FIFO0 has data for transmission. 1 Transmit FIFO0 is empty.

56.3.3.9 SSI Interrupt Enable Register (SIER)

The SSI Interrupt Enable Register (SIER) is a 25-bit register used to set up the SSI interrupts and DMA requests. See Figure 56-29 for illustration of valid bits in SSI Interrupt Enable Register and Table 56-14 for description of the bit fields in the register.

Figure 56-29. SSI Interrupt Enable Register

Table 56-14. SSI Interrupt Enable Register Field Descriptions

Field	Description
31–23	Reserved
24-23 Enable Bits	Enable Bit. Each bit controls whether the corresponding status bit in SISR can issue an interrupt to the Core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
22 RDMAE	Receive DMA Enable. This bit allows SSI to request for DMA transfers. When enabled, DMA requests are generated when any of the RFF0/1 bits in the SISR are set and if the corresponding RFEN bit is also set. If the corresponding FIFO is disabled, a DMA request is generated when the corresponding RDR bit is set. 0 SSI Receiver DMA requests disabled. 1 SSI Receiver DMA requests enabled.
21 RIE	Receive Interrupt Enable. This control bit allows the SSI to issue receiver related interrupts to the Core. Refer to Section 56.4.3 for a detailed description of this bit. 0 SSI Receiver Interrupt requests disabled. 1 SSI Receiver Interrupt requests enabled.
20 TDMAE	Transmit DMA Enable. This bit allows SSI to request for DMA transfers. When enabled, DMA requests are generated when any of the TFE0/1 bits in the SISR are set and if the corresponding TFEN bit is also set. If the corresponding FIFO is disabled, a DMA request is generated when the corresponding TDE bit is set. 0 SSI Transmitter DMA requests disabled. 1 SSI Transmitter DMA requests enabled.

Table 56-14. SSI Interrupt Enable Register Field Descriptions (continued)

Field	Description
19 TIE	Transmit Interrupt Enable. This control bit allows the SSI to issue transmitter data related interrupts to the Core. Refer to Section 56.4.4 for a detailed description of this bit. 0 SSI Transmitter Interrupt requests disabled. 1 SSI Transmitter Interrupt requests enabled.
18–0 Enable Bits	Enable Bit. Each bit controls whether the corresponding status bit in SISR can issue an interrupt to the Core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.

56.3.3.10 SSI Transmit Configuration Register (STCR)

The SSI Transmit Configuration Register (STCR) is a read/write control registers used to direct the transmit operation of the SSI. STCR controls the direction of the bit clock and frame sync ports, STCK and STFS. Interrupt enable bit for the transmit sections is provided in this control register. The Power-on reset clears all STCR bits. However, SSI reset does not affect the STCR bits. The STCR bits are described in the following paragraphs. See Table 56-7 for the programming model of the SSI. The SSI Control Register (SCR) must first be set to enable interrupts. Next, the SSI interrupt bit in the Interrupt Enable Register (SIER) must be set to enable the interrupt. Finally, the interrupt can be enabled from within the SSI.

See Figure 56-30 for illustration of valid bits in SSI Transmit Configuration Register and Table 56-15 for description of the bit fields in the register.

Figure 56-30. SSI Transmit Configuration Register

Table 56-15. SSI Transmit Configuration Register Field Descriptions

Field	Description
31–10	Reserved
9 TXBIT0	Transmit Bit 0. This control bit allows SSI to transmit the data word from bit position 0 or 15/31 in the transmit shift register. The shifting data direction can be MSB or LSB first, controlled by the TSHFD bit. 0 Shifting with respect to bit 31 (if word length = 16, 18, 20, 22 or 24) or bit 15 (if word length = 8, 10 or 12) of transmit shift register (MSB aligned). 1 Shifting with respect to bit 0 of transmit shift register (LSB aligned).
8 TFEN1	Transmit FIFO Enable 1. This bit enables transmit FIFO 1. When enabled, the FIFO allows 15 samples to be transmitted by the SSI (per channel) (a 9th sample can be shifting out) before TDE1 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is transferred to the transmit shift register (provided the interrupt is enabled). 0 Transmit FIFO 1 disabled. 1 Transmit FIFO 1 enabled.
7 TFEN0	Transmit FIFO Enable 0. This bit enables transmit FIFO 0. When enabled, the FIFO allows 15 samples to be transmitted by the SSI per channel (a 9th sample can be shifting out) before TDE0 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is transferred to the transmit shift register (provided the interrupt is enabled). 0 Transmit FIFO 0 disabled. 1 Transmit FIFO 0 enabled.
6 TFDIR	Transmit Frame Direction. This bit controls the direction and source of the transmit frame sync signal. Internally generated frame sync signal is sent out through the STFS port and external frame sync is taken from the same port. 0 Frame Sync is external. 1 Frame Sync generated internally.
5 TXDIR	Transmit Clock Direction. This bit controls the direction and source of the clock signal used to clock the TXSR. Internally generated clock is output through the STCK port. External clock is taken from this port. Refer to Table 56-5 for details of clock pin configurations 0 Transmit Clock is external. 1 Transmit Clock generated internally.
4 TSHFD	Transmit Shift Direction. This bit controls whether the MSB or LSB will be transmitted first in a sample. **Note:** The CODEC device labels the MSB as bit 0, whereas the Core labels the LSB as bit 0. Therefore, when using a standard CODEC, Core MSB (CODEC LSB) is shifted in first (TSHFD cleared). 0 Data transmitted MSB first. 1 Data transmitted LSB first.
3 TSCKP	Transmit Clock Polarity. This bit controls which bit clock edge is used to clock out data for the transmit section. 0 Data clocked out on rising edge of bit clock. 1 Data clocked out on falling edge of bit clock. Note: TSCKP is 0 CLK_IST = 1; TSCKP is 1CLK_IST = 0
2 TFSI	Transmit Frame Sync Invert. This bit controls the active state of the frame sync I/O signal for the transmit section of SSI. 0 Transmit frame sync is active high. 1 Transmit frame sync is active low.

Table 56-15. SSI Transmit Configuration Register Field Descriptions (continued)

Field	Description
1 TFSL	Transmit Frame Sync Length. This bit controls the length of the frame sync signal to be generated or recognized for the transmit section. The length of a word-long frame sync is same as the length of the data word selected by WL[3:0]. 0 Transmit frame sync is one-word long. 1 Transmit frame sync is one-clock-bit long.
0 TEFS	Transmit Early Frame Sync. This bit controls when the frame sync is initiated for the transmit section. The frame sync signal is deasserted after one bit-for-bit length frame sync and after one word-for-word length frame sync. In case of synchronous operation, the frame sync can also be initiated on receiving the first bit of data. 0 Transmit frame sync initiated as the first bit of data is transmitted. 1 Transmit frame sync is initiated one bit before the data is transmitted.

56.3.3.11 SSI Receive Configuration Register (SRCR)

The SSI Receive Configuration Register (SRCR) is a read/write control registers used to direct the receive operation of the SSI. SRCR controls the direction of the bit clock and frame sync ports, SRCK and SRFS. Interrupt enable bit for the transmit sections is provided in this control register. The Power-on reset clears all SRCR bits. However, SSI reset does not affect the SRCR bits. See Figure 56-31 for illustration of valid bits in SSI Receive Configuration Register and Table 56-16 for description of the bit fields in the register.

Figure 56-31. SSI Receive Configuration Register

Table 56-16. SSI Receive Configuration Register Field Descriptions

Field	Description
31–11	Reserved
10 RXEXT	Receive Data Extension. This control bit allows SSI to store the received data word in sign extended form. This bit affects data storage only in case received data is LSB aligned (SRCR[9]=1) 0 Sign extension turned off. 1 Sign extension turned on.

Table 56-16. SSI Receive Configuration Register Field Descriptions (continued)

Field	Description
9 RXBIT0	Receive Bit 0. This control bit allows SSI to receive the data word at bit position 0 or 15/31 in the receive shift register. The shifting data direction can be MSB or LSB first, controlled by the RSHFD bit. 0 Shifting with respect to bit 31 (if word length = 16, 18, 20, 22 or 24) or bit 15 (if word length = 8, 10 or 12) of receive shift register (MSB aligned). 1 Shifting with respect to bit 0 of receive shift register (LSB aligned).
8 RFEN1	Receive FIFO Enable 1. This bit enables receive FIFO 1. When enabled, the FIFO allows 15 samples to be received by the SSI per channel (a 16th sample can be shifting in) before RDR1 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is received by the SSI (provided the interrupt is enabled). 0 Receive FIFO 1 disabled. 1 Receive FIFO 1 enabled.
7 RFEN0	Receive FIFO Enable 0. This bit enables receive FIFO 0. When enabled, the FIFO allows 15 samples to be received by the SSI (per channel) (a 16th sample can be shifting in) before RDR0 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is received by the SSI (provided the interrupt is enabled). 0 Receive FIFO 0 disabled. 1 Receive FIFO 0 enabled.
6 RFDIR	Receive Frame Direction. This bit controls the direction and source of the receive frame sync signal. Internally generated frame sync signal is sent out through the SRFS port and external frame sync is taken from the same port. 0 Frame Sync is external. 1 Frame Sync generated internally.
5 RXDIR	Receive Clock Direction. This bit controls the direction and source of the clock signal used to clock the RXSR. Internally generated clock is output through the SRCK port. External clock is taken from this port. Refer to Table 56-5 for details on clock pin configurations. 0 Receive Clock is external. 1 Receive Clock generated internally.
4 RSHFD	Receive Shift Direction. This bit controls whether the MSB or LSB will be received first in a sample. **Note:** The CODEC device labels the MSB as bit 0, whereas the Core labels the LSB as bit 0. Therefore, when using a standard CODEC, Core MSB (CODEC LSB) is shifted in first (RSHFD cleared). 0 Data received MSB first. 1 Data received LSB first.
3 RSCKP	Receive Clock Polarity. This bit controls which bit clock edge is used to latch in data for the receive section. 0 Data latched on rising edge of bit clock. 1 Data latched on falling edge of bit clock.
2 RFSI	Receive Frame Sync Invert. This bit controls the active state of the frame sync I/O signal for the receive section of SSI. 0 Receive frame sync is active high. 1 Receive frame sync is active low.

Table 56-16. SSI Receive Configuration Register Field Descriptions (continued)

Field	Description
1 RFSL	Receive Frame Sync Length. This bit controls the length of the frame sync signal to be generated or recognized for the receive section. The length of a word-long frame sync is same as the length of the data word selected by WL[3:0]. 0 Receive frame sync is one-word long. 1 Receive frame sync is one-clock-bit long.
0 REFS	Receive Early Frame Sync. This bit controls when the frame sync is initiated for the receive section. The frame sync is disabled after one bit-for-bit length frame sync and after one word-for-word length frame sync. 0 Receive frame sync initiated as the first bit of data is received. 1 Receive frame sync is initiated one bit before the data is received.

56.3.3.12 SSI Transmit and Receive Clock Control Registers (STCCR & SRCCR)

The SSI Transmit and Receive Control (STCCR and SRCCR) registers are 19-bit, read/write control registers used to direct the operation of the SSI. The Clock and Reset Module (CRM) can source the SSI clock (ccm_ssi_clk) from multiple sources and perform fractional division to support commonly used audio bit rates. The CRM can maintain the ccm_ssi_clk frequency at a constant rate even in cases where the ipg_clk frequency changes. These registers control the SSI clock generator, bit and frame sync rates, word length, and number of words per frame for the serial data. The STCCR register is dedicated to the transmit section, and the SRCCR register is dedicated to the receive section except in Synchronous mode, in which the STCCR register controls both the receive and transmit sections. Power-on reset clears all STCCR and SRCCR bits. SSI reset does not affect the STCCR and SRCCR bits. The control bits are described in the following paragraphs. Although the bit patterns of the STCCR and SRCCR registers are the same, the contents of these two registers can be programmed differently.

See Figure 56-32 for illustration of valid bits in SSI Transmit Clock Control Register and Table 56-17 for description of the bit fields for both SSI Transmit and Receive Clock Control registers.

Figure 56-33. SSI Receive Clock Control Register

Table 56-17. SSI Transmit and Receive Clock Control Register Field Descriptions

Field	Description
31–19	Reserved
18 DIV2	Divide By 2. This bit controls a divide-by-two divider in series with the rest of the prescalers. 0 Divider bypassed. 1 Divider used to divide clock by 2.
17 PSR	Prescaler Range. This bit controls a fixed divide-by-eight prescaler in series with the variable prescaler. It extends the range of the prescaler for those cases where a slower bit clock is required. 0 Prescaler bypassed. 1 Prescaler used to divide clock by 8.
16–13 WL3–WL0	Word Length Control. These bits are used to control the length of the data words being transferred by the SSI. These bits control the Word Length Divider in the Clock Generator. They also control the frame sync pulse length when the FSL bit is cleared. In I2S Master mode, the SSI works with a fixed word length of 32, and the WL bits are used to control the amount of valid data in those 32 bits. Refer to Table 56-18 for details about the data word lengths supported by SSI. In AC97 Mode of operation, if word length is set to any value other than 16 bits, it will result in a word length of 20 bits.
12–8 DC4–DC0	Frame Rate Divider Control. These bits are used to control the divide ratio for the programmable frame rate dividers. The divide ratio works on the word clock. In Normal mode, this ratio determines the word transfer rate. In Network mode, this ratio sets the number of words per frame. The divide ratio ranges from 1 to 32 in Normal mode and from 2 to 32 in Network mode. In Normal mode, a divide ratio of 1 (DC=00000) provides continuous periodic data word transfer. A bit-length frame sync must be used in this case. These bits can be programmed with values ranging from “00000” to “11111” to control the number of words in a frame.
7–0 PM7–PM0	Prescaler Modulus Select. These bits control the prescale divider in the clock generator. This prescaler is used only in Internal Clock mode to divide the internal clock (ccm_ssi_clk). The bit clock output is available at the clock port. A divide ratio from 1 to 256 (PM[7:0] = 0x00 to 0xFF) can be selected. Refer to Section 56.4.2.2 for details regarding settings.

The details regarding the settings for transmit FIFO counter bits are as follows: 0000 0 data word in transmit FIFO 0001 1 data word in transmit FIFO 0010 2 data word in transmit FIFO 0011 3 data word in transmit FIFO 0100 4 data word in transmit FIFO 0101 5 data word in transmit FIFO 0110 6 data word in transmit FIFO 0111 7 data word in transmit FIFO 1000 8 data word in transmit FIFO 1001 9 data word in transmit FIFO 1010 10 data word in transmit FIFO 1011 11 data word in transmit FIFO 1100 12 data word in transmit FIFO 1101 13 data word in transmit FIFO 1110 14 data word in transmit FIFO 1111 15 data word in transmit FIFO

Table 56-20. SSI FIFO Control/Status Register Field Descriptions (continued)

Field	Description
23–20 RFWM1[3–0]	Receive FIFO Full WaterMark 1. These bits control the threshold at which the RFF1 flag will be set. The RFF1 flag is set whenever the data level in Rx FIFO 1 reaches the selected threshold. The details regarding the settings for receive FIFO watermark bits are as follows: 0000 Reserved 0001 RFF set when at least one data word have been written to the Receive FIFO Set when RxFIFO = 1,2.....15 data words 0010 RFF set when more than or equal to 2 data word have been written to the Receive FIFO. Set when RxFIFO = 2,3.....15 data words 0011 RFF set when more than or equal to 3 data word have been written to the Receive FIFO. Set when RxFIFO = 3,4.....15 data words 0100 RFF set when more than or equal to 4 data word have been written to the Receive FIFO. Set when RxFIFO = 4,5.....15 data words 0101 RFF set when more than or equal to 5 data word have been written to the Receive FIFO. Set when RxFIFO = 5,6.....15 data words 0110 RFF set when more than or equal to 6 data word have been written to the Receive. Set when RxFIFO = 6,7.....15 data words 0111 RFF set when more than or equal to 7 data word have been written to the Receive FIFO. Set when RxFIFO = 7,8.....15 data words 1000 RFF set when more than or equal to 8 data word have been written to the Receive FIFO. Set when RxFIFO = 8,9.....15 data words 1001 RFF set when more than or equal to 9 data word have been written to the Receive FIFO. Set when RxFIFO = 9,10.....15 data words 1010 RFF set when more than or equal to 10 data word have been written to the Receive FIFO. Set when RxFIFO = 10,11.....15 data words 1011 RFF set when more than or equal to 11 data word have been written to the Receive FIFO. Set when RxFIFO = 11,12.....15 data words 1100 RFF set when more than or equal to 12 data word have been written to the Receive FIFO. Set when RxFIFO = 12,13.....15 data words 1101 RFF set when more than or equal to 13 data word have been written to the Receive FIFO. Set when RxFIFO = 13,14,15data words 1110 RFF set when more than or equal to 14 data word have been written to the Receive FIFO. Set when RxFIFO = 14,15 data words 1111 RFF set when 15 data word have been written to the Receive FIFO (default). Set when RxFIFO = 15 data words

Table 56-20. SSI FIFO Control/Status Register Field Descriptions (continued)

Field	Description
19–16 TFWM1[3–0]	Transmit FIFO Empty WaterMark 1. These bits control the threshold at which the TFE1 flag will be set. The TFE1 flag is set whenever the empty slots in Tx FIFO exceed or are equal to the selected threshold. The details regarding the settings for transmit FIFO watermark bits are as follows: 0000 Reserved 0001 TFE set when there are more than or equal to 1 empty slots in Transmit FIFO. (default) Transmit FIFO empty is set when TxFIFO ≤ 14 data. 0010 TFE set when there are more than or equal to 2 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO ≤ 13 data. 0011 TFE set when there are more than or equal to 3 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO ≤ 12 data. 0100 TFE set when there are more than or equal to 4 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO ≤ 11 data. 0101 TFE set when there are more than or equal to 5 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO ≤ 10 data. 0110 TFE set when there are more than or equal to 6 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO ≤ 9 data. 0111 TFE set when there are more than or equal to 7 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO ≤ 8 data. 1000 TFE set when there are more than or equal to 8 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO ≤ 7 data. 1001 TFE set when there are more than or equal to 9 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO ≤ 6 data. 1010 TFE set when there are more than or equal to 10 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO ≤ 5 data. 1011 TFE set when there are more than or equal to 11 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO ≤ 4 data. 1100 TFE set when there are more than or equal to 12 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO ≤ 3 data. 1101 TFE set when there are more than or equal to 13 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO ≤ 2 data. 1110 TFE set when there are more than or equal to 14 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO ≤ 1 data. 1111 TFE set when there are 15 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO = 0 data.
15–12 RFCNT0[3–0]	Receive FIFO Counter 0 These bits indicate the number of data words in Receive FIFO 0. Refer to the Receive FIFO Counter 1 bit field description for details regarding the settings for the receive FIFO counter bits.
11–8 TFCNT0[3–0]	Transmit FIFO Counter 0 These bits indicate the number of data words in Transmit FIFO 0. Refer to the Transmit FIFO Counter 1 bit field description for details regarding settings for transmit FIFO counter bits.
7–4 RFWM0[3–0]	Receive FIFO Full WaterMark 0 These bits control the threshold at which the RFF0 flag will be set. The RFF0 flag is set whenever the data level in Rx FIFO 0 reaches the selected threshold. Refer to the Receive FIFO full WaterMark 1 bit field description for details regarding settings for receive FIFO watermark bits.
3–0 TFWM0[3–0]	Transmit FIFO Empty WaterMark 0 These bits control the threshold at which the TFE0 flag will be set. The TFE0 flag is set whenever the empty slots in Tx FIFO exceed or are equal to the selected threshold. Refer to the Transmit FIFO Empty WaterMark 1 bit field description for details regarding settings for transmit FIFO watermark bits.

Table 56-19 indicates the status of the Transmit FIFO Empty flag, with different settings of the Transmit FIFO WaterMark bits and varying amounts of data in the Tx FIFO.

Table 56-19. Status of Transmit FIFO Empty Flag

Transmit FIFO Watermark (TFWM)	Number of data in Tx-Fifo														
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0

Figure 56-21. SSI Test Register

Table 56-20. SSI Test Register Field Descriptions

Field	Description
31–16	Reserved
15 TEST	Test Mode. This bit enables the test features of SSI. When set, the RXSTATE and TXSTATE bit values get transferred to the state machine. When in test mode, the user can read the contents of a specific FIFO by writing an appropriate value to the RFCNT0/1 or TFCNT 0/1 bits (in SFCSR). 0 No effect on SSI operation. 1 SSI in Test Mode.
14 RCK2TCK	Receive Clock to Transmit Clock Loop Back. This bit connects SRCK (used as output) to STCK (used as input). 0 No effect on SSI operation. 1 SRCK to STCK loop back enabled.
13 RFS2TFS	Receive Frame to Transmit Frame Loop Back. This bit connects SRFS (used as output) to STFS (used as input). 0 No effect on SSI operation. 1 SRFS to STFS loop back enabled.
12–8 RXSTATE[4:0]	Receiver State Machine Status. These bits indicate the current status of the Receive State Machine.
7 TXD2RXD	Transmit Data to Receive Data Loop Back. This bit connects STXD to SRXD. 0 No effect on SSI operation. 1 STXD to SRXD loop back enabled.

Table 56-20. SSI Test Register Field Descriptions (continued)

Field	Description
6 TCK2RCK	Transmit Clock to Receive Clock Loop Back. This bit connects STCK (used as output) to SRCK (used as input). 0 No effect on SSI operation. 1 STCK to SRCK loop back enabled.
5 TFS2RFS	Transmit Frame to Receive Frame Loop Back. This bit connects STFS (used as output) to SRFS (used as input). 0 No effect on SSI operation. 1 STFS to SRFS loop back enabled.
4–0 TXSTATE	Transmitter State Machine Status. These bits indicate the current status of the Transmit State Machine.

56.3.3.15 SSI Option Register (SOR)

See Figure 56-22 for illustration of valid bits in SSI Option Register and Table 56-21 for description of the bit fields for the register.

NOTE

SSI Option Register is designed for debugging purpose only and is not intended for general user access.

0x43FA+0x0034 (SOR) Access: User read/write

Table 56-21. SSI Option Register Field Descriptions

Field	Description
31–7	Reserved
6 CLKOFF	Clock Off. This bit is used to turn off the ipg_clk to further reduce power consumption. 0 No effect on SSI operation. 1 Turn off ipg_clk.

Table 56-21. SSI Option Register Field Descriptions (continued)

Field	Description
5 RX_CLR	Receiver Clear. This bit flushes the contents of Rx FIFOs. It is always read as cleared (‘0’). 0 No effect on SSI operation. 1 Flush Rx FIFOs.
4 TX_CLR	Transmitter Clear This bit flushes the contents of Tx FIFOs. It is always read as cleared (‘0’). 0 No effect on SSI operation. 1 Flush Tx FIFOs. **It is recommended that we flush Tx-FIFOs after re-enabling Transmission.
3 INIT	Initialize. The setting of this bit causes the SSI state machine to reset. 0 No effect on SSI operation. 1 Initialize SSI state machine.
2–1 WAIT[1:0]	Wait. These bits control the number wait states to be added to all transactions between the Core and SSI. The value of these bits ranges from ‘00’ (no wait states) to ‘11’ (three wait states).
0 SYNRST	Frame Sync Reset. This bit automatically resets the accumulation of data in Receive Data Registers (SRX0/1) and Receive FIFOs (RXFIFO 0/1) on the next frame synchronization. 0 Data accumulation not affected. 1 Reset data accumulation on Frame Synchronization.

56.3.3.16 SSI AC97 Control Register (SACNT)

See Figure 56-23 for illustration of valid bits in SSI AC97 Control Register and Table 56-22 for description of the bit fields for the register.

Figure 56-23. SSI AC97 Control Register

Table 56-22. SSI AC97 Control Register Field Descriptions

Field	Description
31–11	Reserved
10–5 FRDIV[5:0]	Frame Rate Divider. These bits control the frequency of AC97 data transmission/reception. They are programmed with the number of frames for which the SSI should be idle, after operating in one frame. Through these bits, AC97 frequency of operation, from 48 KHz (000000) to 1 KHz (101111) can be achieved. Sample Value: 001010 (10 Decimal) = SSI will operate once every 11 frames.
4 WR	Write Command. This bit specifies whether the next frame will carry an AC97 Write Command or not. The programmer should take care that only one of the bits (WR or RD) is set at a time. When this bit is set, the corresponding tag bits (corresponding to Command Address and Command Data slots of the next Tx frame) are automatically set. This bit is automatically cleared by the SSI after completing transmission of a frame. 0 Next frame will not have a Write Command. 1 Next frame will have a Write Command.
3 RD	Read Command. This bit specifies whether the next frame will carry an AC97 Read Command or not. The programmer should take care that only one of the bits (WR or RD) is set at a time. When this bit is set, the corresponding tag bit (corresponding to Command Address slot of the next Tx frame) is automatically set. This bit is automatically cleared by the SSI after completing transmission of a frame. 0 Next frame will not have a Read Command. 1 Next frame will have a Read Command.
2 TIF	Tag in FIFO. This bit controls the destination of the information received in AC97 tag slot (Slot #0). 0 Tag info stored in SATAG register. 1 Tag info stored in Rx FIFO 0.
1 FV	Fixed/Variable Operation. This bit selects whether the SSI is in AC97 Fixed mode or AC97 Variable mode. 0 AC97 Fixed Mode. 1 AC97 Variable Mode.
0 AC97EN	AC97 Mode Enable. This bit is used to enable SSI AC97 operation. Refer to Section 56.1.2.5 for details of AC97 operation. 0 AC97 mode disabled. 1 SSI in AC97 mode.

56.3.3.17 SSI AC97 Command Address Register (SACADD)

See Figure 56-24 for illustration of valid bits in SSI AC97 Command Address Register and Table 56-23 for description of the bit fields for the register.

0x43FA+0x003C (SACADD) Access: User read/write

Figure 56-24. SSI AC97 Command Address Register

Table 56-23. SSI AC97 Command Address Register Field Descriptions

Field	Description
31–19	Reserved
18–0 SACADD	AC97 Command Address. These bits store the Command Address Slot information (bit 19 of the slot is sent in accordance with the Read and Write Command bits in SACNT register). These bits can be updated by a direct write from the Core. They are also updated with the information received in the incoming Command Address Slot. If the contents of these bits change due to an update, the CMDAU bit in SISR is set.

56.3.3.18 SSI AC97 Command Data Register (SACDAT)

See Figure 56-25 for illustration of valid bits in SSI AC97 Command Data Register and Table 56-24 for description of the bit fields for the register.

0x43FA+0x0040 (SACDAT) Access: User read/write

Figure 56-25. SSI AC97 Command Data Register

Table 56-24. SSI AC97 Command Data Register

Field	Description
31–20	Reserved
19–0 SACDAT	AC97 Command Data. The outgoing Command Data Slot carries the information contained in these bits. These bits can be updated by a direct write from the Core. They are also updated with the information received in the incoming Command Data Slot. If the contents of these bits change due to an update, the CMDDU bit in SISR is set. These bits are transmitted only during AC97 Write Command. During AC97 Read Command, 0x00000 is transmitted in time slot #2.

56.3.3.19 SSI AC97 Tag Register (SATAG)

See Figure 56-26 for illustration of valid bits in SSI AC97 Tag Register and Table 56-25 for description of the bit fields for the register.

0x43FA+0x0044 (SATAG) Access: User read/write

Figure 56-26. SSI AC97 Tag Register

Table 56-25. SSI AC97 Tag Register Field Descriptions

Field	Description
31–16	Reserved
15–0 SATAG	AC97 Tag Value. Writing to this register (by the Core) sets the value of the Tx-Tag in AC97 fixed mode of operation. On a read, the Core gets the Rx-Tag Value received (in the last frame) from the Codec. If TIF bit in SACNT register is set, the TAG value is also stored in Rx-FIFO in addition to SATAG register. When the received Tag value changes, the RXT bit in SISR register is set. Bits SATAG[1:0] convey the Codec -ID. In current implementation only Primary Codecs are supported. Thus writing value 2'b00 to this field is mandatory.

56.3.3.20 SSI Transmit Time Slot Mask Register (STMSK)

See Figure 56-27 for illustration of valid bits in SSI Transmit Time Slot Register and Table 56-26 for description of the bit fields for the register.

0x43FA+0x0048 (STMSK) Access: User read/write

Figure 56-27. SSI Transmit Time Slot Mask Register

Table 56-26. SSI Transmit Time Slot Mask Register Field Descriptions

Field	Description
31–0 STMSK	Transmit Mask. These bits indicate which slot has been masked in the current frame. The Core can write to this register to control the time slots in which the SSI transmits data. Each bit has info corresponding to the respective time slot in the frame. Transmit mask bits should not be used in I2S Slave mode of operation. STMSK register value must be set before enabling transmission. 0 Valid Time Slot. 1 Time Slot masked (no data transmitted in this time slot).

56.3.3.21 SSI Receive Time Slot Mask Register (SRMSK)

See Figure 56-28 for illustration of valid bits in SSI Receive Time Slot Mask Register and Table 56-27 for description of the bit fields for the register.

Figure 56-28. SSI Receive Time Slot Mask Register

Table 56-27. SSI Receive Time Slot Mask Register Field Descriptions

Field	Description
31–0 SRMSK	Receive Mask. These bits indicate which slot has been masked in the current frame. The core can write to this register to control the time slots in which the SSI receives data. Each bit has info corresponding to the respective time slot in the frame. SRMSK register value must be set before enabing the receiver. Receive mask bits should not be used in I2S Slave mode of operation. 0 Valid Time Slot. 1 Time Slot masked (no data received in this time slot).

56.3.3.22 SSI AC97 Channel Status Register (SACCST)

See Figure 56-29 for illustration of valid bits in SSI AC97 Channel Status Register and Table 56-28 for description of the bit fields for the register.

0x43FA+0x0050 (SACCST) Access: User read

Figure 56-29. SSI AC97 Channel Status Register

Table 56-28. SSI AC97 Channel Status Register Field Descriptions

Field	Description
31–10	Reserved
9–0 SACCST	AC97 Channel Status. These bits indicate which data slot has been enabled in AC97 variable mode operation. This register is updated in case the core enables/disables a channel through a write to SACCEN/SACCDIS register or the external codec enables a channel by sending a ‘1’ in the corresponding SLOTREQ bit. Bit [0] corresponds to the first data slot in an AC97 frame (Slot #3) and Bit [9] corresponds to the tenth data slot (slot #12). The contents of this register only have relevance while the SSI is operating in AC97 variable mode. Writes to this register result in an error response on the IP interface. 0 Data channel disabled. 1 Data channel enabled.

56.3.3.23 SSI AC97 Channel Enable Register (SACCEN)

See Figure 56-30 for illustration of valid bits in SSI AC97 Channel Enable Register and Table 56-29 for description of the bit fields for the register.

0x43FA+0x0054 (SACCEN) Access: User write

Table 56-30. SSI AC97 Channel Disable Register Field Descriptions

Field	Description
31–10	Reserved
9–0 SACCDIS	AC97 Channel Disable. The Core writes a ‘1’ to these bits to disable an AC97 data channel. Writing a ‘0’ has no effect. Bit [0] corresponds to the first data slot in an AC97 frame (Slot #3) and Bit [9] corresponds to the tenth data slot (slot #12). Writes to these bits only have effect in the AC97 Variable mode of operation. These bits are always read as ‘0’ by the Core. 0 Write Has no effect. 1 Write Disables the corresponding data channel.

56.4 Functional Description

This section describes the following:

- Section 56.4.1, SSI Architecture”
- Section 56.4.2, SSI Clocking”
- Section 56.4.3, Receive Interrupt Enable Bit Description”
- Section 56.4.4, Transmit Interrupt Enable Bit Description”
- Section 56.4.5, Internal Frame and Clock Shutdown”
- Section 56.4.6, IP Bus Interface”

56.4.1 SSI Architecture

The Synchronous Serial Interface (SSI) is connected to chip pads through the Digital Audio Mux (AUDMUX) module or directly as well. The AUDMUX can be configured to connect the SSI module to the chip pads in various ways. Refer to Figure 56-1 for a block diagram of the SSI.

56.4.2 SSI Clocking

The SSI uses the following clocks:

- Bit clock—Used to serially clock the data bits in and out of the SSI port. This clock is either generated internally (from ccm_ssi_clk) or taken from external clock source (through the Tx/Rx clock ports).
- Word clock—Used to count the number of data bits per word (8, 10, 12, 16, 18, 20, 22 or 24 bits). This clock is generated internally from the bit clock.
- Frame clock (Frame Sync)—Used to count the number of words in a frame. This signal can be generated internally from the bit clock, or taken from external source (from the Tx/Rx frame sync ports).
- Sys clock—In master mode, this is an integer multiple of frame clock. This is ccm_ssi_clk. It is used in cases when SSI has to provide the clock.

Care should be taken to ensure that the bit clock frequency (either internally generated by dividing the ccm_ssi_clk or sourced from external device through Tx/Rx clock ports) is never greater than 1/5 of the ipg_clk frequency.

In Normal mode (SCR[6:5]=00), the bit clock, used to serially clock the data, is visible on the Serial Transmit Clock (STCK) and Serial Receive Clock (SRCK) ports. The word clock is an internal clock used to determine when transmission of an 8, 10, 12, 16, 18, 20, 22, or 24 bit word has completed. The word clock in turn then clocks the frame clock, which counts the number of words in the frame. The frame clock can be viewed on the STFS and SRFS frame sync ports, because a frame sync is generated after the correct number of words in the frame have passed. In master and synchronous mode, the unused port SRCK is used as Serial Oversampling Clock (ccm_ssi_clk) enabled by the SCR register bit 15, SYS_CLK_EN. This Serial System Clock is an oversampling clock of the frame sync clock (STFS). In this mode, the word length (WL), Prescaler Range (PSR), Prescaler Modulus (PM) and Frame rate (DC) selects the ratio of ccm_ssi_clk to sampling clock STFS. In case of I2S mode, the oversampling clock ccm_ssi_clk can be made available on this port if the SYS_CLK_EN bit is set. The relationship between the clocks and the dividers is shown in Figure 56-32 (“SSI Clocking”). The bit clock can be received from an SSI clock port or can be generated from the ccm_ssi_clk through a divider, as shown in Figure 56-33 (“SSI Transmit Clock Generator Block Diagram”).

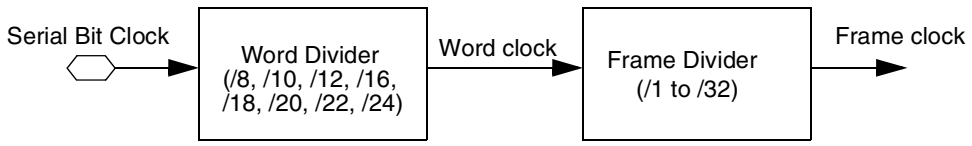

Figure 56-32. SSI Clocking

56.4.2.1 SSI Clock and Frame Sync Generation

Data clock and frame sync signals can be generated internally, or can be obtained from external sources. If internally generated, the SSI clock generator is used to derive bit clock and frame sync signals from the ccm_ssi_clk clock. The SSI clock generator consists of a selectable, fixed prescaler and a programmable prescaler for bit rate clock generation. In Gated Clock mode, the data clock is valid only when data is being transmitted. Otherwise the clock port is pulled to the inactive state. A programmable frame rate divider and a word length divider are used for frame rate sync signal generation.

Figure 56-33 shows a block diagram of the clock generator for the transmit section. The serial bit clock can be internal or external, depending on the Transmit Direction (TXDIR) bit in the SSI Transmit Configuration Register (STCR). The receive section contains an equivalent clock generator circuit.

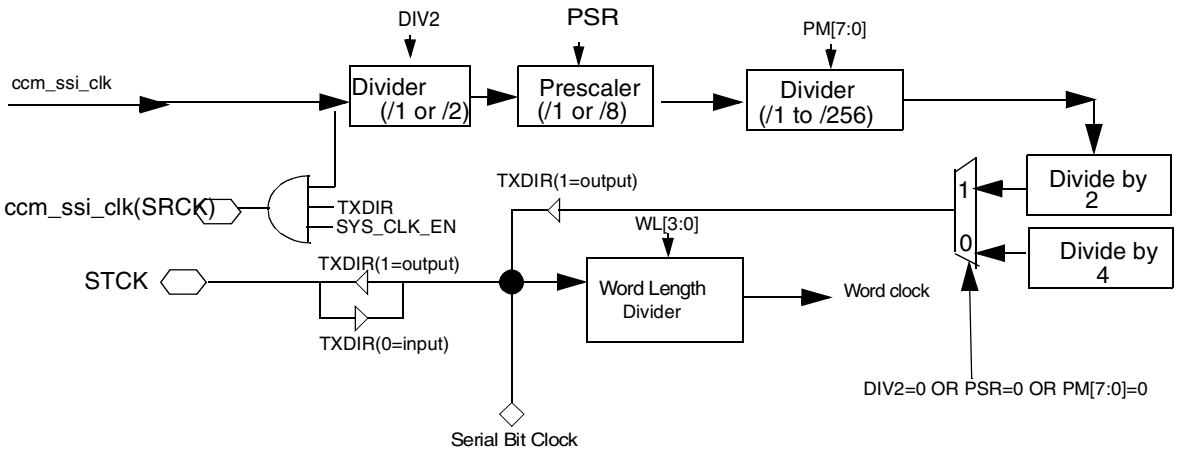

Figure 56-33. SSI Transmit Clock Generator Block Diagram

See Figure 56-34 shows the Frame Sync Generator block for the transmit section. When internally generated, both receive and transmit frame sync are generated from the word clock and are defined by the Frame Rate Divider (DC[4:0]) bits and the Word Length (WL[3:0]) bits of the SSI Transmit Clock Control Register (STCCR). The receive section contains an equivalent circuit for the Frame Sync Generator.

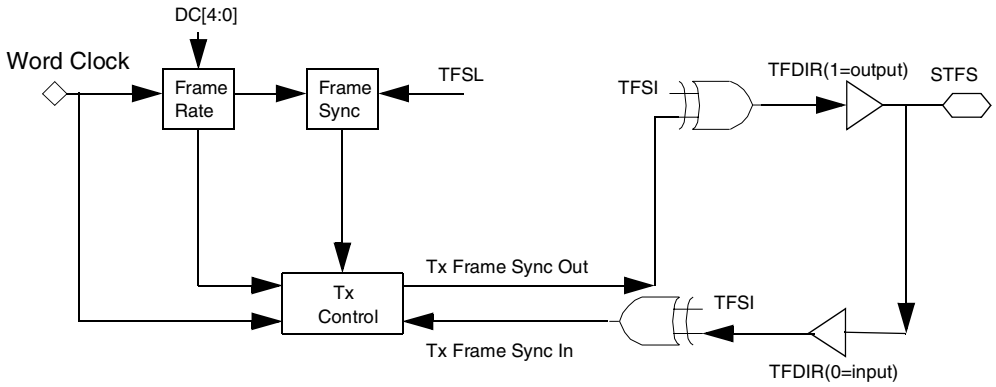

Figure 56-34. SSI Transmit Frame Sync Generator Block Diagram

56.4.2.2 DIV2, PSR and PM Bit Description

The bit clock frequency can be calculated from the SSI Serial System Clock (ccm_ssi_clk) using the equation in Figure 56-35.

NOTE

Ensure that the bit-clock frequency must be 5 times the ipg_clk frequency. The oversampling clock frequency can go up to ipg_clk frequency. Bits DIV2, PSR, and PM should not be all set to zero at the same time.

$$f_{INT\_BIT\_CLK} = f_{ccm\_ssi\_clk} / [(DIV2 + 1) \times (7 \times PSR + 1) \times (PM + 1) \times 2]$$

where PM=PM[7–0]

$$f_{FRAME\_SYN\_CLK} = (f_{INT\_BIT\_CLK}) / [(DC + 1) \times WL]$$

where DC = DC[4:0] and WL = 8, 10, 12, 16, 18, 20, 22, 24

Note: When DIV2 =0 and PSR = 0 and PM= 0, Frequency of bit_clk will be calculated as :-

$$f_{INT\_BIT\_CLK} = f_{ccm\_ssi\_clk} / 4$$

Figure 56-35. SSI Bit Clock Equation

For example, if the SSI oversampling clock (ccm_ssi_clk) is 12.288, in 8-bit word Normal mode with DC[4:0] set to 1 (00001), PM[7:0] set to 47 (0010 1111), the PSR bit cleared, DIV2 bit set to 1, a bit clock rate of 12.288 Mhz ÷ [1 × 4 × 48] = 64 kHz is generated. Since the 8-bit word rate is equal to one (i.e. normal mode), the sampling rate (FS rate) would then be 64 kHz ÷ [1 × 8] = 8 kHz.

In next example, the oversampling clock (ccm_ssi_clk) clock is 11.2896 Mhz. A 16-bit word Network mode with DC[4:0] set to 1 (00001), PM[7:0] set to 3 (0000 0011), the PSR bit is set to 0, DIV2 bit set to 0, and a 11.2896 MHz oversampling clock, a bit clock rate of 11.2896 Mhz ÷ [1 × 2 × 4] = 1.4112 MHz is generated. Since the 16-bit word rate is equal to two, the sampling rate (FS rate) would be 1.4112 MHz ÷ [2 × 16] = 44.1 kHz.

Table 56-31 shows programming examples for the clock dividers in the CRM and the SSI to support various bit clock (STCK) frequencies.

Table 56-31. SSI Bit Clock and Frame Rate as a Function of PSR, PM, and DIV2

16	4	44.1	270.9504	48	11.2896	0	0	1	7	3	2822.4	2822.4	0

NOTE

Table 56-31 describes how various frame rates can be achieved with the PLL0/1 supplying a frequency of 294.912 MHz and 270.9504 MHz (with WL and DC settings as shown). Using PLL2 requires that these input frequencies be lowered by a factor of 2 (and the dividers be changed accordingly).

Note that using the MRCG allows the input frequency to be lowered by a factor of 4 (provided the dividers are changed accordingly). These clocks are recommended as convenient starting points, but the system allows other input clock frequencies as well.

Table 56-31 below shows programming of the CRM and SSI dividers in order to generate the appropriate oversampling clock and BIT_CLK frequencies for various sampling rates. In these examples, the master mode is selected either by setting I2S master bit (SCR[6:5]=01) or individually programming the SSI in network, synchronous, transmit internal mode (the table specifically illustrates the I2S mode frequencies/sample rates). The oversampling clock is ccm_ssi_clk.

Note that the I2S master mode requires that a word length of 32 bits be used (regardless of the actual data type). Consequently, the fixed I2S frame rate of 64 bits per frame (word length (WL) can be any value) and DC of 1 are assumed.

56.4.3 Receive Interrupt Enable Bit Description

When the RIE and RE bit are set, the processor is interrupted when either of the SSI Receive FIFO Full (RFF0/1) bits in SISR is set (if the corresponding Receive FIFO is enabled). If the Receive FIFO is not enabled, the interrupt is generated when the corresponding SSI Receive Data Ready (RDR0/1) bit in the SISR is set. When the receive FIFO is enabled, a maximum of 15 values are available to be read (15 values per channel in Two-Channel mode). If not enabled, then one value can be read from the SRX register (one each in case of Two-Channel mode). If the RIE bit is cleared, these interrupts are disabled. However, the RFF0/1 and RDR0/1 bits still indicate the receive data register full condition. Reading the SRX registers clears the RDR bits, thus clearing the pending interrupt. Two receive data interrupts (two per channel in case of Two-Channel mode) are available: receive data with exception status and receive data without exception. Table 56-32 and Table 56-33 show the conditions under which these interrupts are generated.

Table 56-32. SSI Receive Data 1 Interrupts

Interrupt	RIE	ROE0	RFF0/RDR0
Receive Data 1(with Exception Status)	1	1	1
Receive Data 1(without exception)	1	0	1

Table 56-33. SSI Receive Data 0 Interrupts

Interrupt	RIE	ROE1	RFF1/RDR1
Receive Data 0 (with Exception Status)	1	1	1
Receive Data 0 (without exception)	1	0	1

56.4.4 Transmit Interrupt Enable Bit Description

The SSI Transmit Interrupt Enable (TIE) control bit determines whether the processor is interrupted when the SSI transmitter needs to be serviced. When the TIE and TE bits are set, the program controller is interrupted when either of the SSI Transmit FIFO Empty (TFE0/1) flags in SISR are set (if corresponding Transmit FIFO is enabled). If the corresponding Transmit FIFO is not enabled, an interrupt is generated when the corresponding SSI Transmit Data Register Empty (TDE0/1) flag in the SISR is set and Transmit Enable (TE) bit is set.

When Transmit FIFO 0 is enabled, a maximum of 15 values can be written to the SSI (15 per channel in case of Two-Channel mode, using Tx FIFO 1). If not enabled, then one value can be written to the STX0 register (one per channel in case of Two-Channel mode using STX1). When the TIE bit is cleared, all transmit interrupts are disabled. However, the TDE0/1 bits always indicate the corresponding STX register empty condition, even when the transmitter is disabled by the Transmit Enable (TE) bit (in the SCR). Writing data to the STX clears the corresponding TDE bit, thus clearing the interrupt. Two transmit data interrupts are available (four in case of Two-Channel mode, two per channel): transmit data with exception

status and transmit data without exceptions. Table 56-34 and Table 56-35 show the conditions under which these interrupts are generated.

Table 56-34. SSI Transmit Data 1 Interrupts

Interrupt	TIE	TUE1	TFE1/TDE1
Transmit Data 1 (with Exception Status)	1	1	1
Transmit Data 1 (without exception)	1	0	1

Table 56-35. SSI Transmit Data 0 Interrupts

Interrupt	TIE	TUE0	TFE0/TDE0
Transmit Data 0 (with Exception Status)	1	1	1
Transmit Data 0 (without exception)	1	0	1

56.4.5 Internal Frame and Clock Shutdown

During transmit/receive operation, disabling TE/RE will ensure that data transmission/reception stops after current frame ends following which TFRC/RFRC Status bits will get set to indicate the Frame Completion State. If TE is disabled 4 clock cycles before the next frame, extra frame generated are invalid frames. TFR_CLK_DIS/RFR_CLK_DIS bit is set in the current or any of the previous frames, SSI will stop driving the STFS/SRFS and STCK/SRCK signals after the current frame ends.

If TFR_CLK_DIS/RFR_CLK_DIS bit is not set, SSI will continue generating STFS/SRFS and STCK/SRCK signals (in case direction is from SSI), which then can be disabled by writing ‘1’ to TFS_CLK_DIS/RFR_CLK_DIS bit. SSI will then stop driving these signals after end of frame is reached following which TFRC/RFRC status bits will get set to indicate the Frame Completion State.

Figure 56-36 is an illustration of transmission case where TXDIR and TFDIR are both set to ‘1’. In this case TE is disabled with TFS_CLK_DIS bit set in current or any of the previous frames.

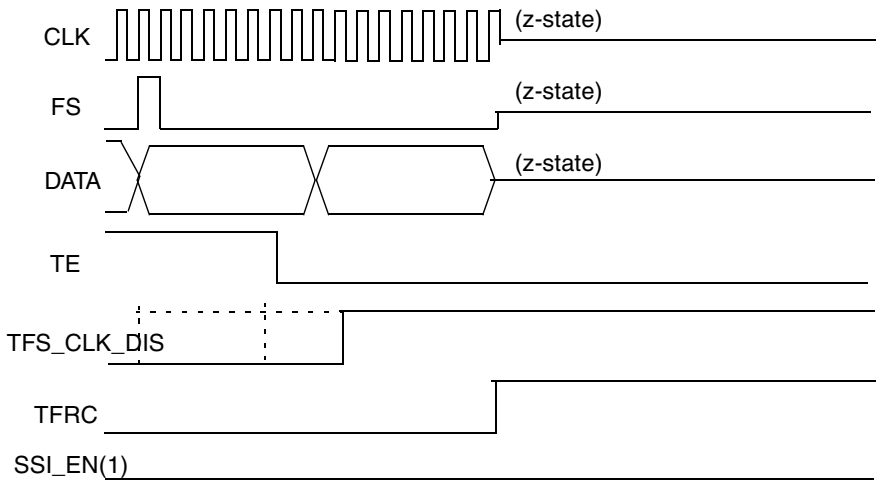

Figure 56-36. TFS_CLK_DIS assertion in current or previous frame as TE disable

Figure 56-37 is an illustration of transmission case where TXDIR and TFDIR are both set to ‘1’. In this case TFS_CLK_DIS bit is set after few frames of disabling TE. TFRC (Transmit Frame Complete) is set at frame boundary after TE is cleared. Once software services this interrupt and sets TFR_CLK_DIS bit later, TFRC bit is again set at next frame boundary.

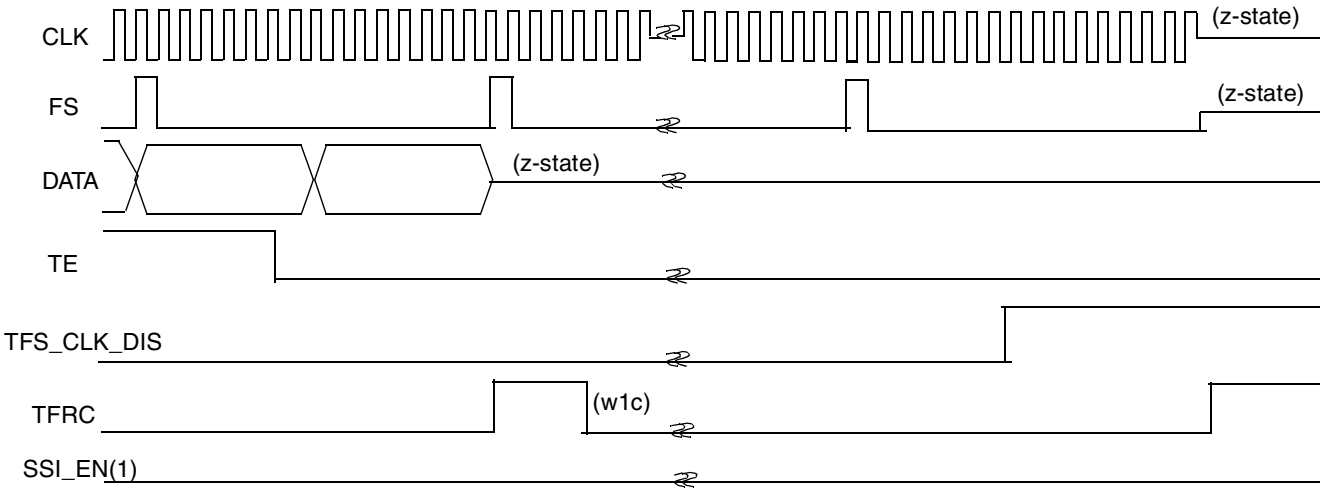

Figure 56-37. TFS_CLK_DIS assertion in subsequent frame after disabling TE

56.4.6 IP Bus Interface

The SSI has an IP Bus interface compliant with SRS 3.0.2 in order to provide a control and data interface. This interface is used by both the processor and DMA controller.

56.4.6.1 Transfer Lengths Supported

The IP Bus interface of the SSI only supports 32-bit transfers with all SSI registers other than STX0, STX1, SRX0, and SRX1 (that is, the data registers). With the exception of the data registers, using 8-bit and 16-bit transactions could result in undesired behavior but will not result in a transfer bus error. The data registers (STX0, STX1, SRX0, and SRX1) support 8-bit, 16-bit, and 32-bit transfer lengths without restrictions.

56.4.6.2 Transfer Bus Errors

Transfer bus errors are generated upon response to the following:

- Write transfer to a read-only register.
- Read or write access to a register space beyond the last populated register of the SSI in its memory map (up until the end of the allocated memory address range of the SSI).

56.4.6.3 Clock Rate

The IP Bus clock frequency must be at least five times the serial bit clock frequency.

56.5 Initialization/Application Information

The SSI is affected by the following types of reset:

- Power-on Reset—The Power-on reset is generated by asserting the RESET port. The Power-on reset clears the SSIEN bit in SCR, which disables the SSI. All other status and control bits in the SSI are affected as described in SSI Programming Model in Section 56.3.
- SSI Reset—The SSI reset is generated when the SSIEN bit in the SCR is cleared. The SSI status bits are preset to the same state produced by the Power-on reset. The SSI control bits are unaffected. The control bits in the SCR are also unaffected. The SSI reset is useful for selective reset of the SSI without changing the present SSI control bits and without affecting the other peripherals.

The correct sequence to initialize the SSI is as follows:

1. Issue a Power-on or SSI reset (SCR[SSIEN]=0).
2. Disable SSI clocks (ipg_clk, ccm_ssi_clk).
3. Set all control bits for configuring the SSI (see Table 56-36 for the list of “SSI Control Bits Requiring SSI to be Disabled Before Change”).
4. Enable appropriate interrupts/DMA requests through SIER.
5. Set the SCR[SSIEN] bit (=1) to enable the SSI.
6. Enable SSI clocks (ipg_clk, ccm_ssi_clk), as required.
7. In case of AC97 mode, set the SACNT[AC97EN] bit after programming the SATAG register (if needed, for AC97 Fixed mode).
8. In case of gated mode of operation refer Table 56-5.
9. Set SCR[TE/RE] bits.
10. To ensure proper operation of the SSI, use the “Power-on or SSI reset before changing any of the SSI Control” bits listed in Table 56-36).

NOTE

These control bits should not be changed when SSI is enabled

Chapter 57
TrustZone Interrupt Controller (TZIC)

57.1 Introduction

The TZIC is a TrustZone enabled interrupt controller with an AXI interface. It allows complete and independent control over every interrupt connected to the controller, including enable, security, and priority functionality. It provides secure and non-secure transaction access to those interrupts, restricting non-secure read and write transactions to only those interrupts configured as non-secure and allowing secure transactions read and write capability to all interrupts regardless of security configuration. It supports priority masking, overall enable/disable of secure or nonsecure interrupts, and access to raw interrupt state and pending transactions.

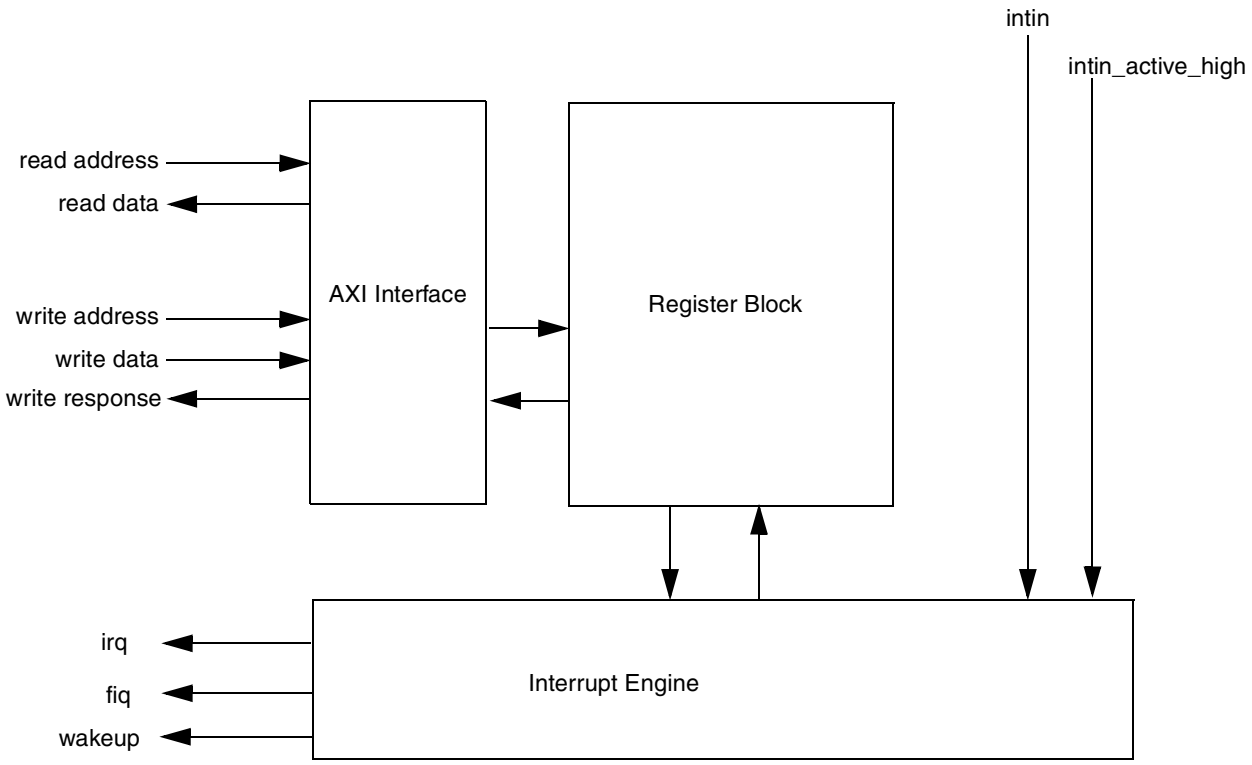

Figure 57-1. Block Diagram

57.1.1 Features

The following features are included in the TZIC:

- AXI interface
- Support for up to 128 interrupts
- Secure configuration available on all interrupts
- Software triggered interrupts supported
- High priority pending registers for autovectored interrupt service routines
- Set/Clear registers for interrupt enable, force, and secure registers
- 16/32 programmable priority levels (nonsecure/secure)
- Wakeup configuration available on all interrupts

57.1.2 Modes of Operation

The TZIC has one mode of operation. Out of reset all configurations are available.

57.2 External Signal Description

The TZIC has no external signals.

57.3 Memory Map and Register Definition

This section contains a memory map, register key, table of register conventions, and register summary.

57.3.1 TZIC Register Memory Map

Table 57-1 shows the memory map for all possible registers in the TZIC. The presence of some registers is dependent upon the implementation configuration. Unspecified address spaces are reserved.

Table 57-1. TZIC Memory Map

57.3.2 Register Summary

The conventions in Figure 57-2 and Table 57-2 serve as a key for the register summary and individual register diagrams.

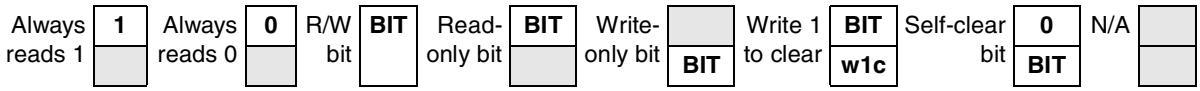

Figure 57-2. Key to Register Fields

Table 57-2 provides a key for register figures and tables and the register summary.

Table 57-2. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.

Table 57-2. Register Conventions (continued)

Convention	Description
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 57-3 shows the register summary for the TZIC.

57.3.3 Register Descriptions

This section contains the detailed register descriptions for the TZIC registers.

The read and write behavior of many of the TZIC registers is impacted by the security configuration of each individual interrupt, as determined by the INTSEC registers. In all cases, non-secure transactions will only read back information about interrupts configured as non-secure and writes will have no effect on secure interrupts. Secure transactions will have full read and write access to all interrupt bits.

Write bursts are taken with one clock per write data after an initial one clock delay. Read bursts are returned with two clocks per read data.

The specific behavior for each register set is described in the field descriptions. In some cases where the register described spans multiple 32-bit addressable locations, the variable X is used to denote which particular register corresponds to which interrupts. For instance, a register with 1 bit associated with each interrupt will have one 32-bit register for each set of 32 interrupts. The registers can be numbered such that REGISTER0 corresponds to interrupts 0–31, REGISTER1 corresponds to interrupts 32–63, and so on. This relationship can be expressed using the following equation:

REGISTER(X)[Y] corresponds to interrupt $(32 \times (X))+Y$

Such that if X is 2 and Y is 17:

REGISTER(2)[17] $\rightarrow (32 \times (2))+17 = 81$

The interrupt would be number 81.

This terminology is used to express the location and relationship for several registers in this section.

57.3.3.1 Supported Register Transaction Types

All registers are accessible with 32-bit accesses. The PRIOMASK register and PRIORITY registers support 8-bit transactions; all others are not supported and yield unpredictable results. 16-bit transactions

are not supported to any registers and result in a slave error. Any access larger than 32-bit also results in an error.

All registers are bufferable, non-cacheable, data, supervisor only. Transactions marked as cacheable, allocate, user, or instruction result in error responses.

57.3.3.2 Control Register

The interrupt control register (INTCTRL), shown in Figure 57-3, can enable or disable all normal or secure interrupts to the CPU, depending on the state of the write transaction used. A secure read or write accesses the enable bit for secure interrupts, and a non-secure read or write accesses the enable bit for non-secure interrupts. This only affects the outputs to the core; it has no impact on which interrupts are pending in the PND and HIPND registers.

A secure read can access the non-secure enable through bit 16, which is only written if bit 31 is written at the same time. This allows secure software to ignore the non-secure enable bit and update the secure enable bit without a read-modify-write sequence.

This register can only be accessed by a 32-bit supervisor transaction.

0xBASE+0x0000 (INTCTRL)

Access: Privileged Read-Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 57-3. Interrupt Control Register

Table 57-4 shows the INTCTRL field descriptions.

Table 57-4. INTCTRL Field Descriptions

Field	Description
31 NSEN MASK	Non-Secure Enable Mask This bit indicates the secure write transaction is updating the NSEN bit. When written as 1'b0 the NSEN bit will not be updated. When written as 1'b1 the NSEN bit will be updated. This allows the secure software to ignore the NSEN bit and update only the Secure EN bit without requiring a read/modify/write to determine the current state of the NSEN. If written with AWPROT[1] == 1'b0: 0 NSEN bit unaffected 1 NSEN bit updated If written with AWPROT[0[== 1'b1: no effect **Note:** Available for secure transactions only.
30–17	Reserved
16 NSEN	Non-Secure Enable This bit is available in secure mode only to enable/disable nonsecure interrupts. This allows for using both security levels in a single security level system where only secure transactions are available. A secure write to this bit will only take effect if the NSEN MASK bit is also set. If written or read with AxPROT[1] == 1'b0: 0 Non-Secure interrupts disabled 1 Non-Secure interrupts enabled If written or read with AxPROT[1] == 1'b1: On reads: 1'b0 On writes: no effect **Note:** Available for secure transactions only.
15–1	Reserved
0 EN	Interrupt Enable. This bit, when set, enables normal or secure interrupts, depending on the secure state of the transaction. If written or read with AxPROT[1] == 1'b0: 0 Secure interrupts disabled 1 Secure interrupts enabled If written or read with AxPROT[1] == 1'b1: 0 Non-secure interrupts disabled 1 Non-secure interrupts enabled

57.3.3.3 Interrupt Controller Type Register

The interrupt controller type register (INTTYPE), shown in Figure 57-4, contains information about the type of interrupt controller that has been implemented. It can be used to determine the number of interrupts, CPUs, and security domains enabled for a given instantiation.

The current version only supports configurations with one CPU and two security domains.

This register can only be accessed by a 32-bit supervisor read transaction.

0xBASE+0x0004 (INTTYPE) Access: Privileged Read Only

Field	Description
7–5 CPUS	CPU Count. This field indicates the number of CPUs supported by the current configuration. Currently only 1 CPU is supported, this field is specified for future compatability. 000 Supports 1 CPU 001 Supports 2 CPUs 010 Supports 3 CPUs ... 111 Supports 8 CPUs
4–0 ITLINES	Interrupt Lines. This field indicates the total number of interrupt lines supported by the current configuration. 00000 up to 32 interrupt lines supported 00001 up to 64 interrupt lines supported 00010 up to 96 interrupt lines supported ... 11110 up to 992 interrupt lines supported 11111 up to 1020 interrupt lines supported

57.3.3.4 Priority Mask Register

The Priority Mask Register (PRIOMASK), shown in Figure 57-5, is a single register used to mask both secure and non-secure interrupts based on their priority configuration. The CPU will only receive an interrupt if there is a pending interrupt with a priority higher than the value in this register. If an interrupt source asserts and its priority is equal to or lower than the priority mask value, it will not cause an interrupt to the CPU.

The lowest priority the priority mask value can be set to is the lowest priority level in the controller. Therefore any interrupt set to the lowest allowed priority will never cause an interrupt since it is not possible for its priority to be greater than the mask value.

This register is affected by an integration parameter which varies the available resolution of priority values. The number of bits available can vary from four to eight, with the lowest resolution only implementing bits [7:4], and the highest resolution implementing bits [7:0]. Which bits are implemented can be determined by writing 8’hFF to bits [7:0] and reading back the result. The bits set high will indicate which register bits are implemented in this register as well as the PRIORITY registers.

Secure and non-secure transactions to this register will have different behaviors. A secure write will result in the register receiving the write data bits as written. A non-secure write will results in wdata bits [7:1] being shifted to the right one bit and bit [7] being set to 1’b1. A secure read will return the actual value stored in the register while a non-secure read will return the register value shifted to the left one bit and bit [0] being filled with a 1’b0. This is subject to the actual register bits implemented according to the integration parameter.

For more information regarding priorities, see Section 57.4.1.1, TrustZone and Interrupt Priority”.

This register can only be accessed by 8-bit or 32-bit supervisor transactions.

57.3.3.5 Synchronizer Control

The Synchronizer Control Register (SYNCCTRL), shown in Figure 57-6, is used to control latency and power usage in the interrupt synchronizers. There are three configurations for synchronization:

- Low Latency—The synchronizer is clocked continuously and interrupts are synchronized as they arrive.
- Low Power—The synchronizer is not clocked until a difference is detected between the inputs and outputs of the synchronizer. When a difference is detected, the detection result is synchronized and used as a clock enable for the synchronizer, which introduces additional latency. Total latency is four clocks—two for the enable and two for the interrupt.

This register can only be accessed by 32-bit secure supervisor transactions.

57.3.3.6 DSM Interrupt Holdoff Register

The DSM Interrupt Holdoff Register (DSMINT), shown in Figure 57-7, is used to stop interrupts to the CPU from occurring until a wakeup signal occurs. This is used for entering Deep Sleep Mode. When written, the DSM bit will cause the interrupt synchronizer to stop updating. If an interrupt occurs while this register is being written the bit will not be set and the CPU will have to try to write again. If no interrupt to the CPU occurs while the register is being written the write will succeed and the interrupt synchronizers

will not update until the DSM bit clears. The DSM bit is cleared by either a write to the DSMINT register or assertion of the dsm_wakeup_request output of the TZIC. When a wakeup request is asserted, the TZIC will remove the DSM interrupt holdoff bit and interrupts will resume.

This register can only be accessed by 32-bit secure supervisor transactions.

57.3.3.7 Interrupt Security Registers

The Interrupt Security Registers (INTSEC), shown in Figure 57-8, are used to set interrupts as secure or non-secure. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, if its secure bit is set to 1’b0, the interrupt is secure and will cause a secure interrupt to the CPU. When set as secure, a particular interrupt will also be invisible to non-secure accesses, its configuration hidden during non-secure reads. If its bit is set to 1’b1, the interrupt is non-secure and will cause a non-secure interrupt to the CPU.

The values read in the INTSEC register represent the interrupts currently set as non-secure. Out of reset, all interrupts are configured as secure, the intention being that when the TZIC is used in a system that does

not use TrustZone, the secure bit of ARPROT/AWPROT will be tied to secure and the TZIC will act as always in secure mode.

These registers can only be accessed by 32-bit secure supervisor transactions.

31–0 SECURE	Interrupt Secure Status. When read, this register returns the secure bit values of the associated interrupts. When written, this register sets the configuration for the associated interrupts. The corresponding interrupts for register INTSECX are determined through the following formula: SECUREX[31] → (32 × X) + 31 SECUREX[0] → (32 × X) + 0 0 Interrupt is secure 1 Interrupt is non-secure

57.3.3.8 Enable Set Registers

The Enable Set Registers (ENSET), shown in Figure 57-9, are used to enable interrupt requests to the core. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, when read, if its enable bit is set to 1’b1, the interrupt is enabled and will be transmitted to the CPU. If its bit is set to 1’b0, any activity on that interrupt will have no effect.

Writing a bit to 1’b1 in this register will enable the interrupt associated with that bit. Writing a bit to 1’b0 will have no effect. To clear an enable bit, the Enable Clear Registers must be used.

The values read in the ENSET register represent the currently enabled interrupts.

These registers can only be accessed by 32-bit supervisor transactions.

0xBASE+0x0100 (ENSET0)
0xBASE+0x0104 (ENSET1)
0xBASE+0x0108 (ENSET2)

Access: Privileged Read-Write

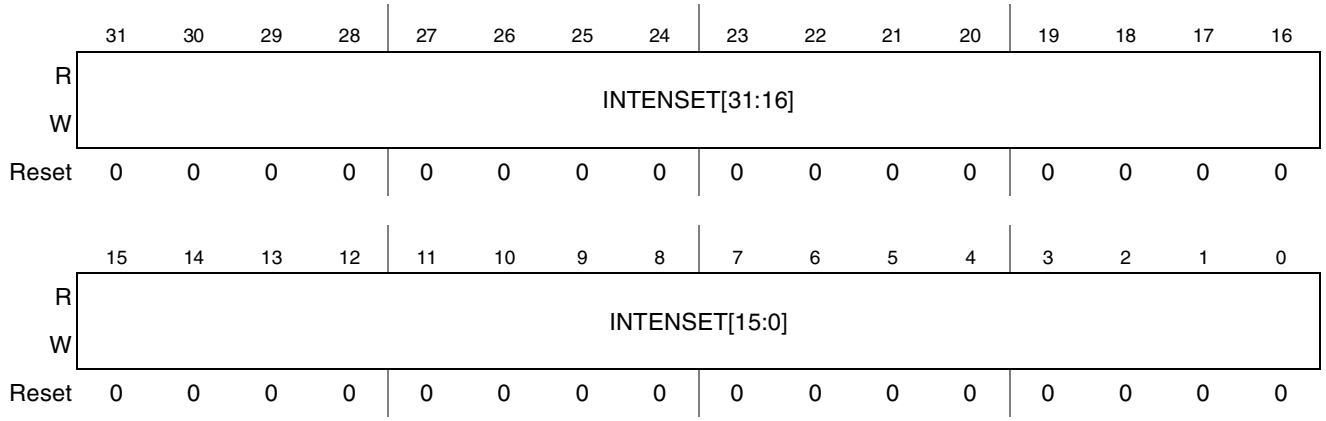

Figure 57-9. Interrupt Enable Set Registers

Table 57-10 shows the ENSET field descriptions.

Table 57-10. ENSET Field Descriptions

Field	Description
31–0 INTENSET	Interrupt Enable Set. When written, this register sets the enable bits of the associated interrupts. When read, this register returns the enable bit values of the associated interrupts. The corresponding interrupts for register ENSETX are determined through the following formula: INTENSET[31] → (32 × X) + 31 INTENSET[0] → (32 × X) + 0 If ARPROT[1] == 1'b0 (secure) 0 Interrupt is disabled 1 Interrupt is enabled If ARPROT[1] == 1'b1 (nonsecure) 0 Interrupt is disabled or configured as secure 1 Interrupt is enabled If AWPROT[1] == 1'b0 (secure) 0 no effect 1 Interrupt enable bit set If AWPROT[1] == 1'b1 (nonsecure) 0 no effect 1 Interrupt enable bit set if bit is configured as non-secure

57.3.3.9 Enable Clear Registers

The Enable Clear Registers (ENCLEAR), shown in Figure 57-10, are used to disable interrupt requests to the core. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, when read, if its enable bit is set to 1'b1, the interrupt is enabled and will be transmitted to the CPU. If its bit is set to 1'b0, any activity on that interrupt will have no effect.

Writing a bit to 1’b1 in this register will disable the interrupt associated with that bit. Writing a bit to 1’b0 will have no effect. To set an enable bit, the Enable Set Registers must be used.

The values read in the ENCLEAR register represent the currently enabled interrupts.

These registers can only be accessed by 32-bit supervisor accesses.

Table 57-11 shows the ENCLEAR field descriptions.

Table 57-11. ENCLEAR Field Descriptions

Field	Description
31-0 INTENCLEAR	Interrupt Enable Cleared. When written, this register clears the enable bits of the associated interrupts. When read, this register returns the enable bit values of the associated interrupts. The corresponding interrupts for register ENCLEARX are determined through the following formula: INTENCLEAR[31] → (32 × X) + 31 INTENCLEAR[0] → (32 × X) + 0 If ARPROT[1] == 1’b0 (secure) 0 Interrupt is disabled 1 Interrupt is enabled If ARPROT[1] == 1’b1 (nonsecure) 0 Interrupt is disabled or configured as secure 1 Interrupt is enabled If AWPROT[1] == 1’b0 (secure) 0 no effect 1 Interrupt enable bit cleared If AWPROT[1] == 1’b1 (nonsecure) 0 no effect 1 Interrupt enable bit cleared if bit is configured as non-secure

57.3.3.10 Source Set Registers

The Source Set Registers (SRCSET), shown in Figure 57-11, are used to determine which interrupts are currently asserted and to force interrupts to an asserted state regardless of activity on the interrupt lines.

Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, when read, if its source bit is set to 1’b1, the interrupt is asserted and pending action from the CPU. If its bit is set to 1’b0, the interrupt is not asserted.

Writing a bit to 1’b1 in this register will override the interrupt line and force the corresponding interrupt to assert. Writing a bit to 1’b0 will have no effect. To clear a source bit, the Source Clear Registers or SWINT must be used.

If a source bit is set which corresponds to an interrupt not enabled in the ENSET/ENCLEAR registers, the source bit will be 1’b1 but will not be considered pending and will not cause an interrupt to the core.

The values read in the SRCSET register represent the currently asserted interrupts.

These registers can only be accessed by 32-bit supervisor accesses.

Table 57-12. SRCSET Field Descriptions

Field	Description
31–0 SRCSET	Interrupt Source Set. When written, this register forces the source bits of the associated interrupts. When read, this register returns the source bit values of the associated interrupts. The corresponding interrupts for register SRCSETX are determined through the following formula: SRCSET[31] → (32 × X) + 31 SRCSET[0] → (32 × X) + 0 If ARPROT[1] == 1'b0 (secure) 0 Interrupt is not asserted 1 Interrupt is asserted If ARPROT[1] == 1'b1 (nonsecure) 0 Interrupt is not asserted or configured as secure 1 Interrupt is asserted If AWPROT[1] == 1'b0 (secure) 0 no effect 1 Interrupt source bit set If AWPROT[1] == 1'b1 (nonsecure) 0 no effect 1 Interrupt source bit set if bit is configured as non-secure

57.3.3.11 Source Clear Registers

The Source Clear Registers (SRCCLEAR), shown in Figure 57-12, are used to determine which interrupts are currently asserted and to clear interrupts from the asserted state that were triggered by software, either through the SRCSET or SWINT registers. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, when read, if its source bit is set to 1'b1, the interrupt is asserted and is pending action from the CPU. If its bit is set to 1'b0, the interrupt is not asserted.

Writing a bit to 1'b1 in this register will clear an asserted interrupt that was triggered by software. Writing a bit to 1'b0 will have no effect. To set a source bit, the Source Set Registers or Software Triggered Interrupt Register must be used.

The values read in the SRCCLEAR register represent the currently asserted interrupts.

These registers can only be accessed by 32-bit supervisor accesses.

The corresponding interrupts for register SRCCLEARX are determined through the following formula: SRCCLEAR[31] → (32 × X) + 31 SRCCLEAR[0] → (32 × X) + 0 If ARPROT[1] == 1'b0 (secure) 0 Interrupt is not asserted 1 Interrupt is asserted If ARPROT[1] == 1'b1 (nonsecure) 0 Interrupt is not asserted or configured as secure 1 Interrupt is asserted If AWPROT[1] == 1'b0 (secure) 0 no effect 1 Interrupt source bit cleared If AWPROT[1] == 1'b1 (nonsecure) 0 no effect 1 Interrupt source bit cleared if bit is configured as non-secure

57.3.3.12 Priority Registers

The Priority Registers (PRIORITY), shown in Figure 57-13, are used to configure the priority of each interrupt for masking purposes.

Each eight bit priority field is affected by an integration parameter which determines the available resolution of priority levels. The number of bits available can vary from four to eight, with the lowest resolution only implementing bits [7–4], and the highest resolution implementing bits [7–0]. The

implemented number of bits can be found in a manner similar to that described in Section 57.3.3.4, Priority Mask Register."

The priority scheme used is such that an interrupt assigned to 0 has the highest priority.

These registers can only be accessed by 32-bit or 8-bit supervisor transactions.

Field	Description
31-24 PRIO3 23-16 PRIO2 15-8 PRIO1 7-0 PRIO0	Interrupt Priority. This field stores the priority value for its corresponding interrupt. The interrupts for register PRIORITYX are determined through the following formula: PRIO3 → (4 × X) + 3 PRIO2 → (4 × X) + 2 PRIO1 → (4 × X) + 1 PRIO0 → (4 × X) + 0 If ARPROT[1] == 1'b0 (secure) 00000000 Interrupt priority is set to 0 00000001 Interrupt priority is set to 1 ... 11111111 Interrupt priority is set to 255 If ARPROT[1] == 1'b1 (nonsecure) 00000000 Interrupt priority is set to 128 or interrupt is configured as secure 00000010 Interrupt priority is set to 129 ... 11111110 Interrupt priority is set to 255 If AWPROT[1] == 1'b0 (secure) 00000000 Interrupt priority is set to 0 00000001 Interrupt priority is set to 1 ... 11111111 Interrupt priority is set to 255 If AWPROT[1] == 1'b1 (nonsecure) 00000000 Interrupt priority is set to 128 if interrupt is configured as non-secure 00000001 Interrupt priority is set to 128 if interrupt is configured as non-secure 00000010 Interrupt priority is set to 129 if interrupt is configured as non-secure ... 11111110 Interrupt priority is set to 255 if interrupt is configured as non-secure 11111111 Interrupt priority is set to 255 if interrupt is configured as non-secure

57.3.3.13 Pending Registers

The Pending Registers (PND), shown in Figure 57-14, are used to determine which interrupts are currently pending action from the CPU. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, if its pending bit is set to 1'b1, the interrupt is enabled in the ENSET/ENCLEAR registers and asserted either on the interrupt inputs or in the SRCSET/SRCCLEAR registers, and therefore is pending action from the CPU. Priority values have no effect on whether an interrupt is pending.

This is a read-only register, writes will be ignored.

These registers can only be accessed by 32-bit supervisor transactions.

Field	Description
31–0 PND	Interrupt Pending Status. When read, this register returns the pending bit values of the associated interrupts, indicating which interrupts are enabled and asserted. The corresponding interrupts for register PNDX are determined through the following formula: PND[31] → (32 × X) + 31 PND[0] → (32 × X) + 0 If ARPROT[1] == 1'b0 (secure) 0 Interrupt is not pending 1 Interrupt is pending If ARPROT[1] == 1'b1 (nonsecure) 0 Interrupt is not pending or configured as secure 1 Interrupt is pending

57.3.3.14 High Priority Pending Registers

The High Priority Pending Registers (HIPND), shown in Figure 57-15, are used to determine which interrupts are currently pending at the highest active priority. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, if its pending bit is set to 1'b1, the interrupt is pending action from the CPU and its priority is the highest level amongst all pending enabled interrupts. See Section 57.3.3.13, Pending Registers" for more information about pending interrupts.

The highest active priority is determined based on the security state of the read transaction. If the register is read by a non-secure transaction, the pending interrupts returned are those non-secure interrupts that are pending and set to the highest priority of any currently pending non-secure interrupts. If the register is read by a secure transaction, the pending interrupts returned are those interrupts, secure or non-secure, that are

pending and set to the highest priority of any currently pending interrupts regardless of security configuration.

This is a read-only register, writes will be ignored.

These registers can only be accessed by 32-bit supervisor transactions.

The corresponding interrupts for register HIPNDX are determined through the following formula: HIPND[31] → (32 × X) + 31 HIPND[0] → (32 × X) + 0 If ARPROT[1] == 1'b0 (secure) 0 Interrupt is not pending at the highest priority level 1 Interrupt is pending at the highest priority level If ARPROT[1] == 1'b1 (nonsecure) 0 Interrupt is not pending at the highest priority level or configured as secure 1 Interrupt is pending at the highest priority level

57.3.3.15 Wakeup Configuration Registers

The Wakeup Configuration Registers (WAKEUP), shown in Figure 57-16, are used to set which interrupts will assert the tzic_wakeup_request signal. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, if its wakeup bit is set to 1'b1 assertion of the interrupt will cause the wakeup request signal to assert combinationally. When its wakeup bit is set to 1'b0, the interrupt will not assert the wakeup request signal.

The values read in the WAKEUP register represent interrupts currently set to wake up the system. Out of reset, all interrupts are configured not to wake up the system. Non-secure transactions can only enable or

disable wakeup configuration of interrupts configured as non-secure. Secure transactions can enable or disable wakeup configuration of any interrupts.

These registers can only be accessed by 32-bit supervisor transactions.

Table 57-17. WAKEUP Field Descriptions

Field	Description
31–0 WAKEUP	Wakeup Configuration. When read, this register returns the wakeup bit values of the associated interrupts. When written, this register sets the configuration for the associated interrupts. The corresponding interrupts for register WAKEUPX are determined through the following formula: WAKEUP[31] → (32 × X) + 31 WAKEUP[0] → (32 × X) + 0 If AxPROT[1] == 1'b0 0 Interrupt will not assert tzic_wakeup_request 1 Interrupt will assert tzic_wakeup_request If AxPROT[1] == 1'b1 0 Interrupt will not assert tzic_wakeup_request or is configured as secure and not accessible 1 Interrupt will assert tzic_wakeup_request

57.3.3.16 Software Interrupt Register

The interrupt controller software interrupt register (SWINT), shown in Figure 57-17, can be used by software to assert or negate an interrupt at a specific interrupt number. Writing the number of the desired interrupt will either trigger an interrupt to assert if not already asserted by hardware, or negate an interrupt that was originally asserted by software. An interrupt asserted by hardware cannot be negated by this register. Triggering an interrupt with the SWINT is equivalent to asserting the associated interrupt input pin, except regarding the tzic_wakeup_request output. It will be asserted in the SRCSET/SRCCLEAR registers, but will not be pending unless the interrupt is enabled. A software interrupt will not cause a wakeup request.

A secure write can trigger any enabled interrupt. A non-secure write can only trigger non-secure interrupts, an attempt to trigger a secure interrupt with a non-secure write will be ignored. If wbstrb[3] is not asserted to indicate whether asserting or negating an interrupt, the write will be ignored.

This register can only be accessed by 32-bit supervisor transactions.

Figure 57-17. Software Interrupt Trigger Register

Table 57-18 shows the SWTRIG field descriptions.

Table 57-18. SWTRIG Field Descriptions

Field	Description
31 INTNEG	Interrupt Negate. This bit indicates whether the interrupt ID in the INTID field is being asserted or negated. Assuming the interrupt is not being asserted by hardware, when 1'b0, an interrupt is asserted, when 1'b1, an interrupt is negated.
30–10	Reserved
9–0 INTID	Interrupt ID. This field indicates the number of the interrupt to be triggered (asserted or negated). Triggering an interrupt outside of the maximum number of interrupts will result in UPREDICTABLE behavior. Triggering a secure interrupt with a non-secure write will have no effect.

57.4 Functional Description

The TZIC is a trustzone compatible interrupt controller. This implementation supports up to 128 interrupts. It supports autovectoring solutions and provides a high priority pending register for software to directly access the interrupts currently pending at the highest active priority level (based on security configuration).

The TZIC is made up of three primary components:

1. The AXI Interface
2. The Register Block
3. The Interrupt Engine

These three components handle all functionality of the TZIC.

57.4.1 Security Configurability

The TZIC is designed to handle two levels of secure interrupts using trustzone functionality included in the AXI spec. It is also possible to use it in a single security level, non-trustzone aware system. At integration the TZIC can be connected such that all transactions are treated as secure, providing the CPU with full access to all registers. The INTSEC registers reset to all interrupts being secure, which translates to all interrupts being available to the system without needing to be configured, therefore the non-secure software running as secure does not need to be aware of the security registers for configuration.

The INTSEC registers determine which interrupts are accessible by non-secure transactions. Interrupts configured as secure are not accessible or configurable by non-secure transactions. Any information associated with an interrupt configured as secure is not accessible by non-secure transactions. Read transactions will return reset values for any bits tied to a secure interrupt, writes to these bits will be ignored. This includes all registers. The INTSEC registers are not visible to non-secure transactions.

57.4.1.1 TrustZone and Interrupt Priority

The priority scheme implemented in the TZIC allows for flexible prioritization of secure and non-secure interrupts, and ease of use with legacy software.

Each interrupt can be assigned a priority value up to 8 bits (depending on the PRIORITY_MASK parameter). The highest priority value is 0, the next is 1, and so on. For designs where not all 8 bits are used, the lower bits are masked off, such that an implementation with only 5 bits would use values 0 (8’h00), 8 (8’h08), 16 (8’h10), 24 (8’h18), and so on. The number of bits available can be discovered by software through writing 8’hFF to a priority register and reading back the resulting value actually stored in the register.

Secure and non-secure transactions have different views of the priority registers. A secure transaction can see all implemented bits and has access to the full range of priority values. A non-secure transaction is limited to the lower half of the possible priorities. This is accomplished through shifting the values written and read during a non-secure transaction.

Table 57-19. Valid Priority Values Based on Transaction Security

Priority Value	Non-Secure Transaction	Secure Transaction
0 127	No Access	Recommended Values
128 255	Accessible Values	Not Recommended

A non-secure write to a priority register is automatically shifted one bit to the right, with the MSB assigned 1’b1. This shift is reversed when read, with the priority value shifted one bit to the left and the LSB assigned 1’b0. This is shown in the following equations:

Non-Secure write to priority register: priority_reg[7:0] = {1’b1, wdata[7:1]} ***Eqn. 57-1***

Non-Secure read from priority register: rdata[7:0] = {priority_reg[6:0], 1’b0} ***Eqn. 57-2***

This guarantees the highest priority a non-secure transaction can write is 128 (8’h80), which is the highest priority of the lower half of possible priorities. It also shows the non-secure software will not be aware of this limitation, since reading back a priority register with a value of 128 will result in a read data value of 0.

This scheme will allow for non-secure interrupts to function in their own priority scheme without knowledge of secure interrupt priorities while allowing secure interrupts to guarantee priority over non-secure interrupts. If all secure interrupts are assigned priorities in the upper half of the possible priorities, secure interrupts will always be of higher priority than non-secure interrupts.

Note that this priority value shifting is determined by the security of the transaction, not the security of the interrupt whose priority is being configured. A non-secure transaction will only have access to non-secure interrupt priority values, but a secure transaction will have access to secure and non-secure priority values, and will be accessing the actual value, not the shifted value. This means it is possible for a secure transaction to configure a non-secure interrupt priority to be in the upper half of the priority levels, or to configure a secure interrupt priority to be below a non-secure interrupt. In the first case, the non-secure interrupt priority will remain set until written again by another secure transaction or a non-secure transaction (which would automatically limit the priority level to 128 or lower). A non-secure read will shift the value as specified above but would not alter the value. This is not recommended since it could impact the non-secure software in an unpredictable manner. In the second case, it may be desirable to configure a secure interrupt to be of lower priority than some non-secure interrupts, although such behavior should be used with care.

57.4.2 AXI Interface

The AXI interface allows access to all functionality of the TZIC. It is fully compatible with the AMBA 3 AXI specification from ARM.

Read transactions are generally returned with one initial wait state and two clock cycles per read data. All registers can be read with 32-bit transactions, the priority registers allow 8-bit transactions. 16-bit transactions are not supported and will result in an error. Exclusive reads are not supported. The TZIC will accept one read address at a time. If a second read transaction is valid before completion of the previous read, it will be held off until the TZIC is finished returning data from the first read.

Write transactions are generally accepted with one initial wait state, the one clock cycle per write data. Registers are word writeable only with the exception of the priority and priority mask registers which support byte writes. Exclusive writes are not supported. The TZIC will accept one write address at a time. If a second write transaction is valid before completion of the previous write, it will be held off until the TZIC is finished returning the write response from the first write. The TZIC will also hold off the write data bus until it receives a write address. It follows that any interconnect port the TZIC is connected to must be configured for an interleave depth of 1.

57.4.3 Register Block

The Register Block handles all register related behavior for the TZIC. It contains programmable registers for enabling interrupts, setting priority levels, configuring security settings, etc. It also collects current interrupt activity data from the Interrupt Engine and presents it as readable registers.

The number of flops required to handle all the programmable registers is minimized using parameters. The total number of interrupts the controller can handle is controlled by a parameter set by the integrator. Based on that number of interrupts, the Register Block will reduce the number of flops to the minimum needed, with all remaining bits returning 1’b0 when read.

The Register Block provides enable and configuration information to the Interrupt Engine, and receives all information from the Interrupt Engine relating to the SRCSET/SRCCLEAR, PND, and HIPND registers.

57.4.4 Interrupt Engine

The interrupt engine performs all processing on the raw interrupt information. It receives configuration information from the Register Block, interrupts from the system, and based on that information determines when to assert interrupts to the core.

An interrupt is asserted to the core (irq_b or fiq_b) when all criteria are met as follows:

- The EN bit in the INTCTRL register is enabled, secure for fiq_b or non-secure for irq_b.
- An interrupt is asserted, either on the input intin_b or by writing the SRCSET or SWINT registers.
- The interrupt is configured appropriately for the desired interrupt in the INTSEC register, set as secure for fiq_b or non-secure for irq_b.
- The asserted interrupt is enabled in the ENSET/ENCLEAR register.
- The priority of the asserted interrupt is greater than the PRIOMASK register value. Note: this requires the actual priority value to be greater than the PRIOMASK register value, after taking into account shifting for non-secure transactions.

This TZIC implementation can handle up to 128 interrupts. Each interrupt has an associated interrupt ID number 0–127.

The interrupt synchronizers are part of the interrupt engine. A two-flop synchronizer is implemented for each interrupt input. Clock gating is available for the synchronizers and is configured through the Synchronizer Control (SYNCCTRL) Register. For more information, see Section 57.3.3.5, Synchronizer Control.”

The interrupt engine handles the wakeup functionality of the TZIC, processing the dsm_int_holdoff input and asserting tzic_wakeup_request as necessary.

tzic_wakeup_request is an asynchronous, combinational output determined by the asynchronous intin_b input and the WAKEUP registers. It asserts when any interrupt is asserted on the intin_b input while configured for wakeup. It negates when there are no more interrupts asserted that are configured for wakeup. A software interrupt will not assert this output, since a software interrupt would require a clock to be triggered and the tzic_wakeup_request is intended for enabling clocks and/or power during low power states.

dsm_int_holdoff causes the interrupt synchronizers to stop updating. This is for shutting down clocks in the system. While preparing for low power modes, the CPU may be in a position where it expects no more interrupts to be occuring, but has not yet executed a standby-wait-for-interrupt. The CPU must write to the dsm_int_holdoff bit, then read it back to verify that it was successfully set. If not set, an interrupt occurred during the process before the synchronizers could be stopped and the CPU must process the interrupt and write to the dsm_int_holdoff bit again.

57.4.5 Auto-Vectored Interrupt Handling

The TZIC is intended to be used with auto-vectored interrupt service routines. Once interrupts have been enabled using the ENSET/ENCLEAR registers and the INTCTRL register, the interrupt engine is live and will signal an interrupt to the CPU when an enabled interrupt is asserted. Once the CPU interrupt is triggered, a read to the PND or HIPND registers will determine which interrupts are currently pending.

The PND registers will contain information on every interrupt currently pending, whether asserted by the interrupt input or forced by software. This includes interrupts of priority lower than the PRIOMASK value. The PRIOMASK register limits the assertion of the irq_b/fiq_b signal based on priority, it does not affect which interrupts are visible in the pending registers.

The HIPND registers will contain information on which interrupts are currently pending at the highest pending priority, allowing autovectoring software to choose between the highest priority interrupts without having to process such information on its own. As with the PND register, the HIPND register will return pending values even if the highest pending priority is of equal or lower priority than the PRIOMASK value, although in such a case the interrupt signals will not be asserted.

After choosing a pending interrupt to service, writing the priority of the interrupt being serviced to the PRIOMASK register will allow for interrupt preemption by a higher priority interrupt being asserted later.

57.4.6 Integration Options

The following TZIC configuration parameters are available at integration and impact TZIC's functionality.

- NUMBER_OF_INTS

  This parameter determines the number of interrupts the TZIC will handle. This parameter must be a multiple of 32. Software can determine the maximum number of interrupts by reading the HWCONFIG register. Any multiple of 32 less than 1024 is possible, although if configured for 1024, there will only be 1020 actual interrupts available, interrupt ID numbers 1020–1023 are reserved. As integrated, this implementation of the TZIC supports 128 interrupts, and no interrupts are reserved.
- PRIORITY_MASK

  This parameter determines the number of bits used to specify the priority of an interrupt. The minimum allowed is four bits for non-secure interrupts, which requires at least five bits for a dual security configuration. In the minimum dual security configuration, bits [7–3] are usable and bits [2–0] are always 3'b0. As integrated, this implementation of the TZIC has a total of 5 bits. It supports the minimum dual security configuration described above.

57.4.7 Clocks

The TZIC has one clock input, ACLK. The ACLK input must receive a clock signal at all times for interrupt synchronization purposes. Internal clock gating is used to reduce power consumption. If system clocks are to be shut down for power conservation, it is recommended that ACLK receive a clock whenever the CPU is clocked. If the CPU is clocked and the TZIC is not transactions from the CPU to the TZIC could be missed by the TZIC while the CPU thinks it is being received and processed.

57.4.8 Reset

The TZIC is reset by asserting the areset_b input. Resetting the block will zero out almost all registers, the INTSEC registers will reset to all interrupts secure. Coming out of reset, all interrupts are configured as secure, disabled, and set to priority level 0. Also, the INTCTRL register is set to disable all secure and non-secure interrupts.

57.4.9 Endianness

The TZIC data buses are little endian.

57.5 Initialization Information

Initialization procedures will vary based on whether the TZIC is set up in a single vs. dual security level configuration. This description will handle the case where the TZIC is set up to take advantage of both secure and non-secure interrupts, the single security level case is a subset of this scenario.

Note: When writing to any registers affecting the interrupt outputs to the CPU it is recommended the CPU interrupt inputs be masked to prevent interrupts asserting and negating due to register writes.

When the TZIC comes out of reset, all interrupts are disabled and set as secure. It is advised that the INTCTRL register enables are not activated until all other configuration options have been set up. To set up the TZIC for autovectoring functionality:

1. Secure software sets INTSEC registers appropriately.

   This configures all interrupts as either secure or non-secure, allowing the non-secure software to configure the non-secure interrupts. Until these registers are configured, non-secure software will not be able to configure any registers.

   At this point secure and non-secure software are free to configure their associated interrupts with minimal conflict. Non-secure software cannot affect any register bits associated with secure interrupts. It is the responsibility of the secure software not to overwrite any non-secure interrupt configuration bits.
2. Configure ENSET/ENCLEAR.

   Both secure and non-secure software must enable all interrupts needed. At this point interrupt functionality has yet to be enabled in the INTCTRL register so this will not cause interrupts to occur during initialization.

3. Configure PRIORITY.

   Both secure and non-secure software must set PRIORITY registers to appropriate levels, otherwise all interrupts are set to the lowest priority level as determined by the PRIORITY_MASK parameter.

4. Set PRIOMASK.

   The PRIOMASK register must be set to allow interrupts to occur, out of reset it is set to the lowest priority level which masks all priority levels.

5. Set INTCTRL.

   Both secure and non-secure software must enable interrupt functionality in the INTCTRL register. This will enable the TZIC interrupt output to the CPU.

At this point, the TZIC generates interrupt signals to the CPU. The CPU itself must enable interrupts as well. In this configuration the TZIC is enabled for autovectoring software to access the PND or HIPND registers and determine which interrupt to service.

Chapter 58
TV Encoder (TVE)

58.1 Introduction

The TV Encoder (TVE) is designed to provide direct connection between an Application Processor (AP) and a TV set via analog interfaces. The AP may be both a standalone product and a part of a Wireless Baseband Platform (WBP). Integration of the TVE into the AP and the WBP allows minimizing system complexity and cost. The TV Encoder supports different standard-definition (SD) and high-definition (HD) television standards.

The module is based on mixed (digital and analog) signal processing. It includes three main components:

- TV Signal Processor (TVSP) is a digital module which is responsible for modulation, filtering, generation synchronization signals, upsampling, cable detection control, copy protection and other processing tasks.
- Triple Video Digital-to-Analog Converter (TVDAC) is an analog module which is designed to convert up to three digital video signals to a current.
- Cable Detection Circuit (CDC) is an analog module which provides monitoring of TVDAC output signals for Cable Detection (CD).

58.1.1 Features

The main features of the TVE are as follows:

- SD Mode Features
  - Supported TV standards:
    - NTSC
    - PAL B, D, G, H, and I/M/N
    - 480i
    - 576i
  - Supported output formats:
    - Composite video (CVBS) - up to two simultaneous identical outputs are supported
    - S-video (Y/C), composite video and S-video signals may be output simultaneously
    - YPrPb component
    - RGB component
  - Programmable notch/pre-comb filter for CVBS
  - Switchable pedestal
  - Copy Generation Management System (CGMS) support according to

  - EIA-608b
  - IEC 61880-1
  - EIA-J CPR-1204-1
- Wide-Screen Signaling (WSS) support according to ITU-R BT.1119, ETSI EN 300 294
- Closed Caption insertion capability according to EIA-608b
- Macrovision™ 7.1 copy protection
- Output oversampling up to ×16 for elimination of external analog filters

- HD Mode features
  - Supported TV standards:
    - 720p, 60 Hz
    - 720p, 50 Hz
    - 720p, 30 Hz
    - 720p, 25 Hz
    - 720p, 24 Hz
    - 1080i, 60 Hz
    - 1080i, 50 Hz
    - 1035i, 60 Hz (1920 x1035)
    - 1080p, 30 Hz
    - 1080p, 25 Hz
    - 1080p, 24 Hz
  - Supported output formats:
    - YPrPb component
    - RGB component
  - CGMS support according to
    - EIAJ CPR-1204-2 (CGMS)
    - CEA-805-A (CGMS type B)
  - Output oversampling up to x4 for elimination of external analog filters
- Common SD/HD Mode features
  - Flexible timing and gain control mechanism allowing non-standard parameters (“user mode”)
  - Programmable Chroma digital filters
  - Programmable adaptive Luma digital filters for
    - horizontal and vertical sharpening
    - horizontal and vertical noise reduction
    - de-flickering in interlaced modes
  - Programmable YCrCb to RGB color matrix
  - Output resolution—10 bits (single-ended analog output loaded by a double terminated 75-Ohm cable)

— Cable Detection functionality including
  – Separate cable connection monitoring separately for each TVDAC channel both during normal operation and in standby mode
  – Automatic TVE power on when a TV cable has been connected
  – Detection of connection type (composite, S-video, component)
  – Detection of cable short to the ground

Figure 58-1 depicts the integration of the TVE module in the i.MX51.

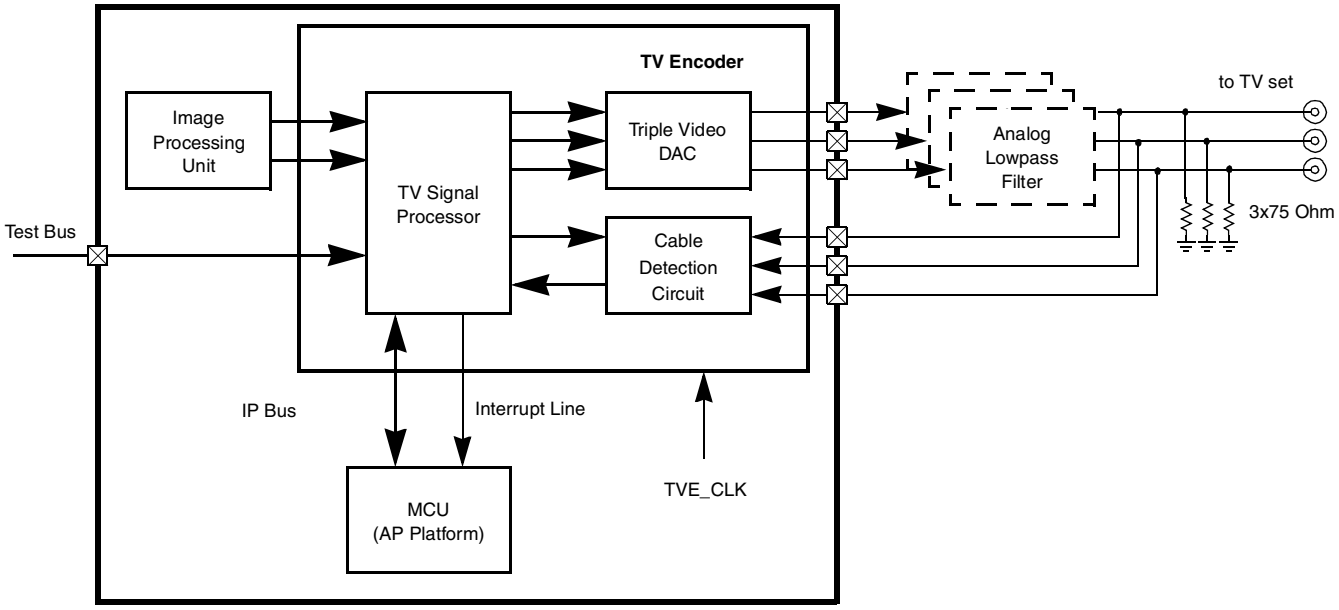

Figure 58-1. i.MX51 TVE Integration Block Diagram

The TVE receives a 30-bit video data stream either via the VIDEO_DATA_IN_1 bus or via the VIDEO_DATA_IN_2 bus from the Image Processing Unit (IPU). In functional mode, only 24-bits are used to transfer the video data in the YCbCr 4:2:2 or YCbCr 4:4:4 formats. Each of YCrCb components is represented by an 8-bit word. In test mode, all 30-bits are used to drive the test data to the TVDAC (10 bits for each TVDAC channel). There is also an option to only drive the 10 least significant bits to all channels when in test mode.

The IPU also provides the sampling clocks VIDEO_DATA_CLK_1 and VIDEO_DATA_CLK_2 for each of the data buses. The clock frequency depends on the mode being used.

In SD mode, the TVE output is always in interlaced format. For some TVE configurations, the TVE performs inter-field vertical filtering for de-flickering, fine sharpening and high frequency noise reduction. In this case, the input data is in progressive format at double the pixel frequency (Fsx). Fsx2 = 27 MHz, where Fs = 13.5 MHz is the pixel frequency for the interlaced format.

In HD mode the input data rate is always Fs = 74.25 MHz or Fs = 74.25/1.001 = 74.1758 MHz. The Y component is sampled at the VIDEO_DATA_CLK_1(2) frequency. For the YCbCr 4:2:2 input format, the

Cb/Cr components are sampled at a half of the VIDEO_DATA_CLK_1(2) frequency. For the YCbCr 4:4:4 input format, the Cb/Cr components are sampled at the VIDEO_DATA_CLK_1(2) frequency.

The stream is also accompanied by two separated signals for horizontal synchronization (HSYNC_1 and HSYNC_2 respectively) and vertical synchronization (VSYNC_1 and VSYNC_2 respectively) and by data valid indicators (VIDEO_DATA_EN_1 and VIDEO_DATA_EN_2 respectively). The timings of the video data stream and the synchronization signals should correspond the ITU-R BT.601 (SD) and SMPTE 296M/274M (HD) requirements.

The second alternative for the TVE input source is the test bus driven by an external device through the chip pins. The test bus can be used for both in functional mode testing or in TVDAC testing. In both cases, the test bus replaces the IPU output.

The TVE generates a TV signal in one of the formats specified above. The signal is oversampled before digital-to-analog conversion. The oversampling factor is programmable and can vary from 2× to 16× in SD mode and from ×2 to ×4 in HD mode. In primary operation mode with maximal output oversampling, the TVDAC sampling frequency is 216 MHz for SD, and 297 MHz or 297/1.001 MHz for HD.

For SD, there are also two additional modes when the TVDAC sampling frequency is 108 or 54 MHz. For HD, there is one additional mode with the TVDAC sampling frequency of 148.5 MHz or 148.5/1.001 MHz. These modes should be used as a reserved option in case the performance of the selected TVDAC degrades at the higher sampling frequency.

The TVDAC is able to directly drive a 75 Ω double terminated cable (the equivalent load is 37.5 Ω). Another option is filtering the TV signal by external Analog Lowpass Filters. The Analog Lowpass Filters may have high (100 Ω) or low (37.5 Ω) input impedance. If 16× oversampling is used, no external analog lowpass filters are required.

The TVE is sampled by the TVE_CLK clock. The clock frequency is equal to the TVDAC sampling rate. All required internal clocks are produced by division of the TVE_CLK inside the TVE. An output voltage of each TVE channel is monitored by Cable Detection (CD) system. The CD is able to distinguish between the following cases:

- Normal load impedance which is equal to 37.5 Ω when the TVE drives directly a 75 Ω double terminated cable
- Double load impedance (75 Ω) when the cable is disconnected
- Zero load impedance when the output is shorted to the ground

The CD monitors each of the output channels separately. The monitoring result is sent to the MCU which determines the TV output mode corresponding to the connected cable type. The TVE is controlled by the ARM platform via the IP interface. The TVE generates interrupts for the ARM platform via a singe interrupt line corresponding to the Indigo IP Interface.

58.1.2 Overview

The TVE block diagram is shown in Figure 58-2. The TVE consists of three modules: the TV Signal Processor (TVSP), the Triple Video DAC (TVDAC) and the Cable Detection Circuit (CDC).

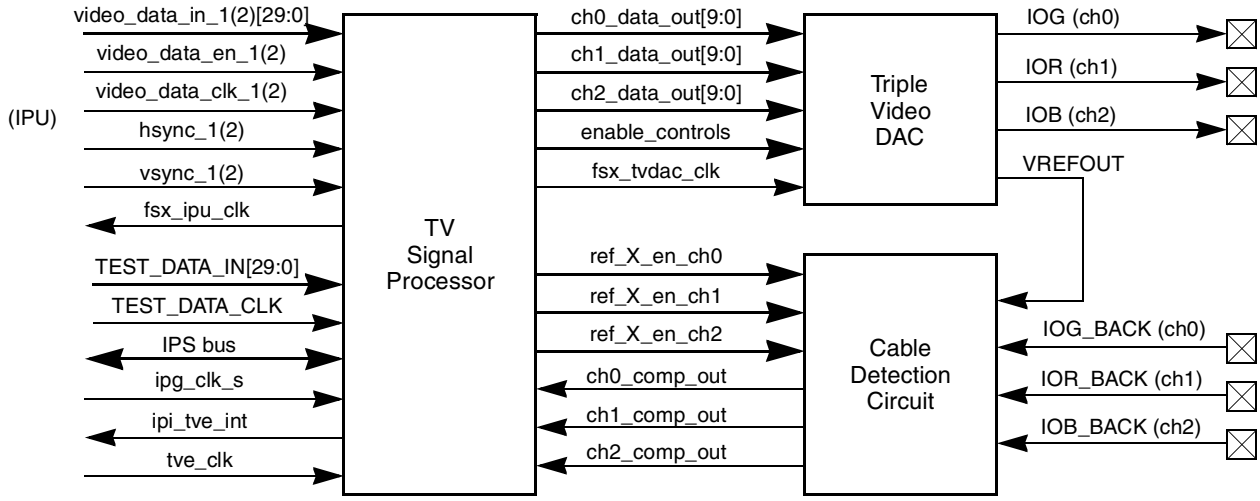

Figure 58-2. TVE Block Diagram

The TVDAC converts an input 10-bit code in the unsigned format to the output current. The DAC is able to directly drive a double terminated 75 Ω cable. The full scale output current is controlled by an external resistor that develops the required full-scale voltage of the video signal on the output load. The nominal sampling rate of the TVDAC is 216 MHz in SD mode and 297 MHz or 297/1.001 MHz in HD mode.

The CDC is an analog module which includes a reference voltage divider and three comparators (one for each TVDAC output). The reference voltage for the CDC is taken from the TVDAC VREFOUT pin. The CDC compares the TVDAC output voltage with the different reference levels derived from the VREFOUT voltage. The result is sent to the TVSP which determines whether or not a cable is connected.

The TVSP is a digital part of the TVE. Figure 58-3 shows the TVSP block diagram.

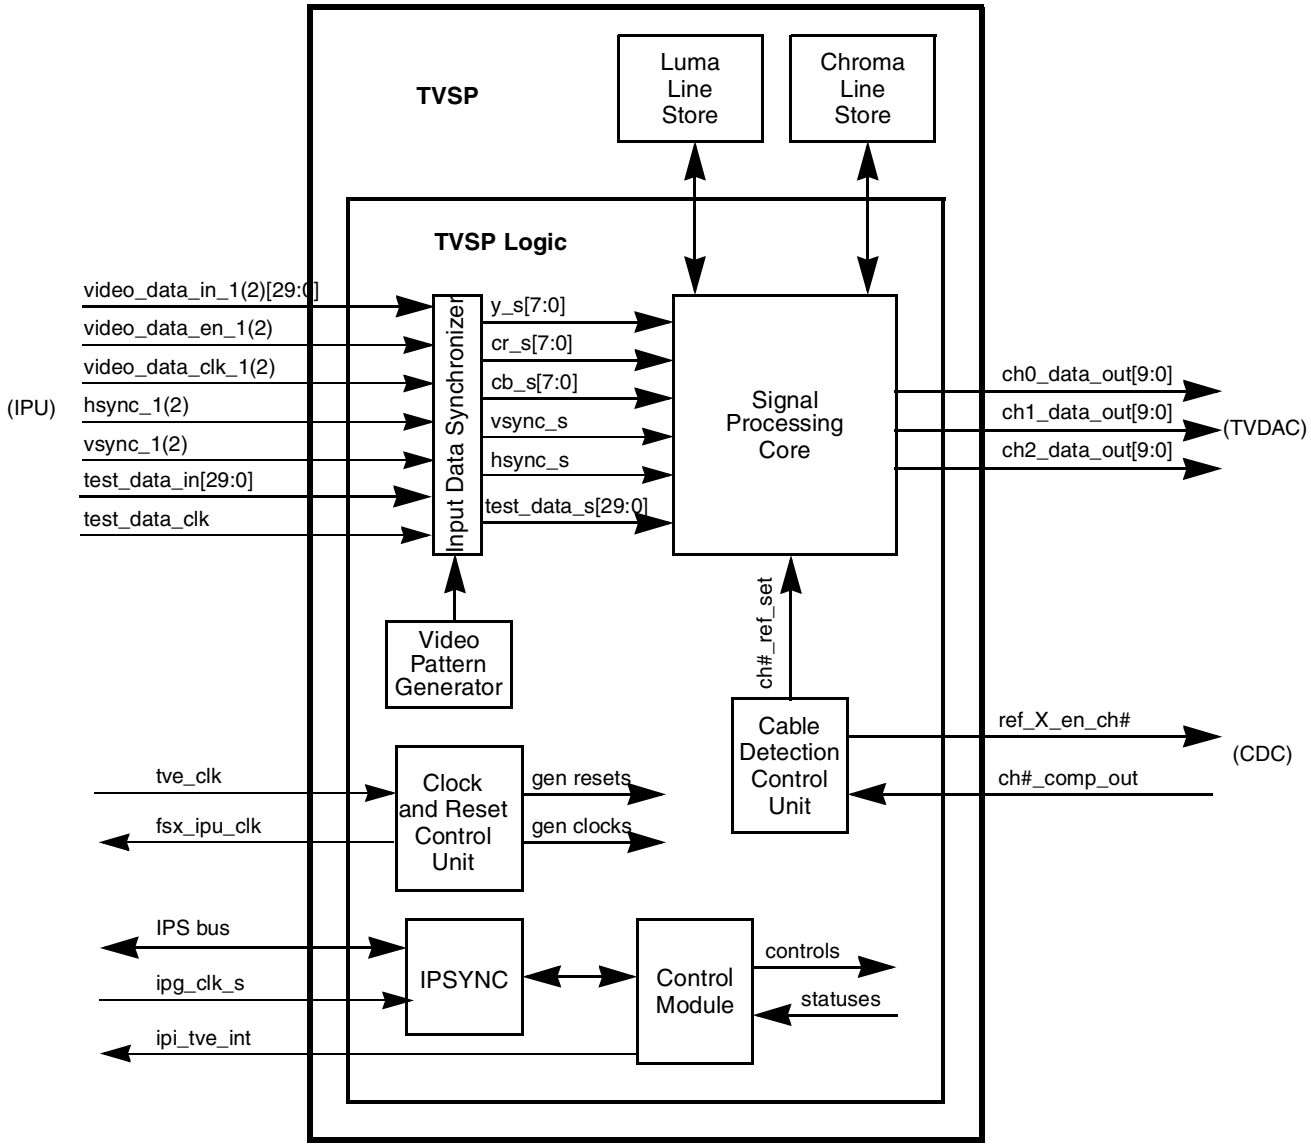

Figure 58-3. TVSP Block Diagram

The TVSP includes two parts: the memory-less TVSP Logic and two memories - the Luma Line Store and the Chroma Line Store.

The central submodule of the TVSP is based on the Signal Processing Core (SPC) which is responsible for the following TV encoding tasks:

- Synchronization signal generation as determined by the TV standard being used
- Digital non-adaptive and adaptive filtering of video signals
- Sampling rate conversion (upsampling)

- Color conversion (YCrCb to RGB) and color adjustment
- Color modulation in composite and S-video output modes as required by the supported SD standards
- VBI data insertion
- Macrovision signal generation for copy protection in SD mode

The SPC receives the input data from the Input Data Synchronizer (IDS) in the YCrCb 4:2:2 or the YCrCb 4:4:4 formats. The IDS is designed to synchronize the IPU output data to the TVE clock. According to the IPU type used, there are two possible synchronization modes.

- If the IPU supports output data synchronization to an external clock, the TVE provides the FSx_IPU_CLK clock (27 MHz in SD mode and 74.25 MHz or 74.25/1.001 MHz in HD mode) to the IPU. The IPU uses this clock to generate the output data stream. The IDS is transparent in this case.
  In functional mode, the sampling rate is 13.5 MHz in SD mode and 74.25 MHz or 74.25/1.001 MHz in HD mode (for the YCrCb 4:2:2 format, the Cb and Cr samples are repeated twice).
  In TVDAC test mode, the data sampling rate is correspondingly 27 MHz and 74.25 MHz or 74.25/1.001 MHz.
- If the IPU does not support output data synchronization to an external clock, it should provide the sampling rates mentioned above (for example, to generate the display clock using fractional frequency division). The frequencies of the IPU output and TVE input clocks must be equal, but a phase jitter between two clocks is allowed. The maximal value of this jitter should be less than one period of one pixel clock and the initial phase difference between two clocks may be unspecified. The IDS is designed to eliminate phase uncertainty and phase jitter between two clocks.

The IDS receives a 30-bit input data from the IPU. In functional mode, the least significant byte of the data bus includes the Y component and the next two bytes are the Cr and Cb components correspondingly. The six most significant bits are unused in functional mode. In TVDAC test mode 1, each ten bits are fed to the corresponding TVDAC channel. In TVDAC test mode 2, only 10 least significant bits are fed to all TVDAC channels and 20 most significant bits are unused.

In addition to the data, the IDS resamples the vertical (VSYNC_1(2)) and horizontal (HSYNC_1(2)) synchronization signals from the IPU. It also gates off the invalid IPU output data according to the VIDEO_DATA_EN_1(2) data enable signal from the IPU.

The SPC has three output channels. Each channel is represented by 10 bits. The outputs can be in composite (CVBS), S-video, YCrCb and RGB component formats according to the TV_OUT_MODE control parameter (see Table 58-1).

Table 58-1. TVEv2 Output Data Formats

Output Channel	Output Data Format (TV_OUT_MODE)							
	Composite (CVBS)				S-video (Y/C)	CVBS and Y/C	YCrCb Component	RGB Component
	(0)	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Channel #0	0	CVBS	0	CVBS	Y	Y	Y	G
Channel #1	0	0	0	0	C	C	Cr	R
Channel #2	0	0	CVBS	CVBS	0	CVBS	Cb	B

The Cable Detection Control Unit (CDCU) is a digital component of the CD system. It sends periodic requests to the CDC to monitor the TVDAC output voltage. The CDC returns the results of load resistance measurement and ground short detection for each of the monitored channels. For TVE channels that are inactive for the selected TV_OUT_MODE setting (as indicated by zeros in Table 58-1), the CDCU forces the output current to the value required for the measurement.

The Clock and Reset Control Unit (CRCU) produces internally generated clocks by division of the TVE_CLK clock. The CRCU also asserts reset signals to sub-modules that are unused in the currently selected configuration and enable signals for the TVDAC channels.

The Control Module (CM) is responsible for IP bus interface and interrupt generation support. It contains a set of control and status registers. Because the CM is sampled by the 27 MHz clock in SD mode and by the 74.25-MHz or 74.25/1.001-MHz clock in HD mode, the IP Synchronizer (IPSYNC) is used to synchronize the frequency of the IP bus interface (typically, 66 MHz) to the CM clock frequency.

The SPC block diagram is depicted in Figure 58-4.

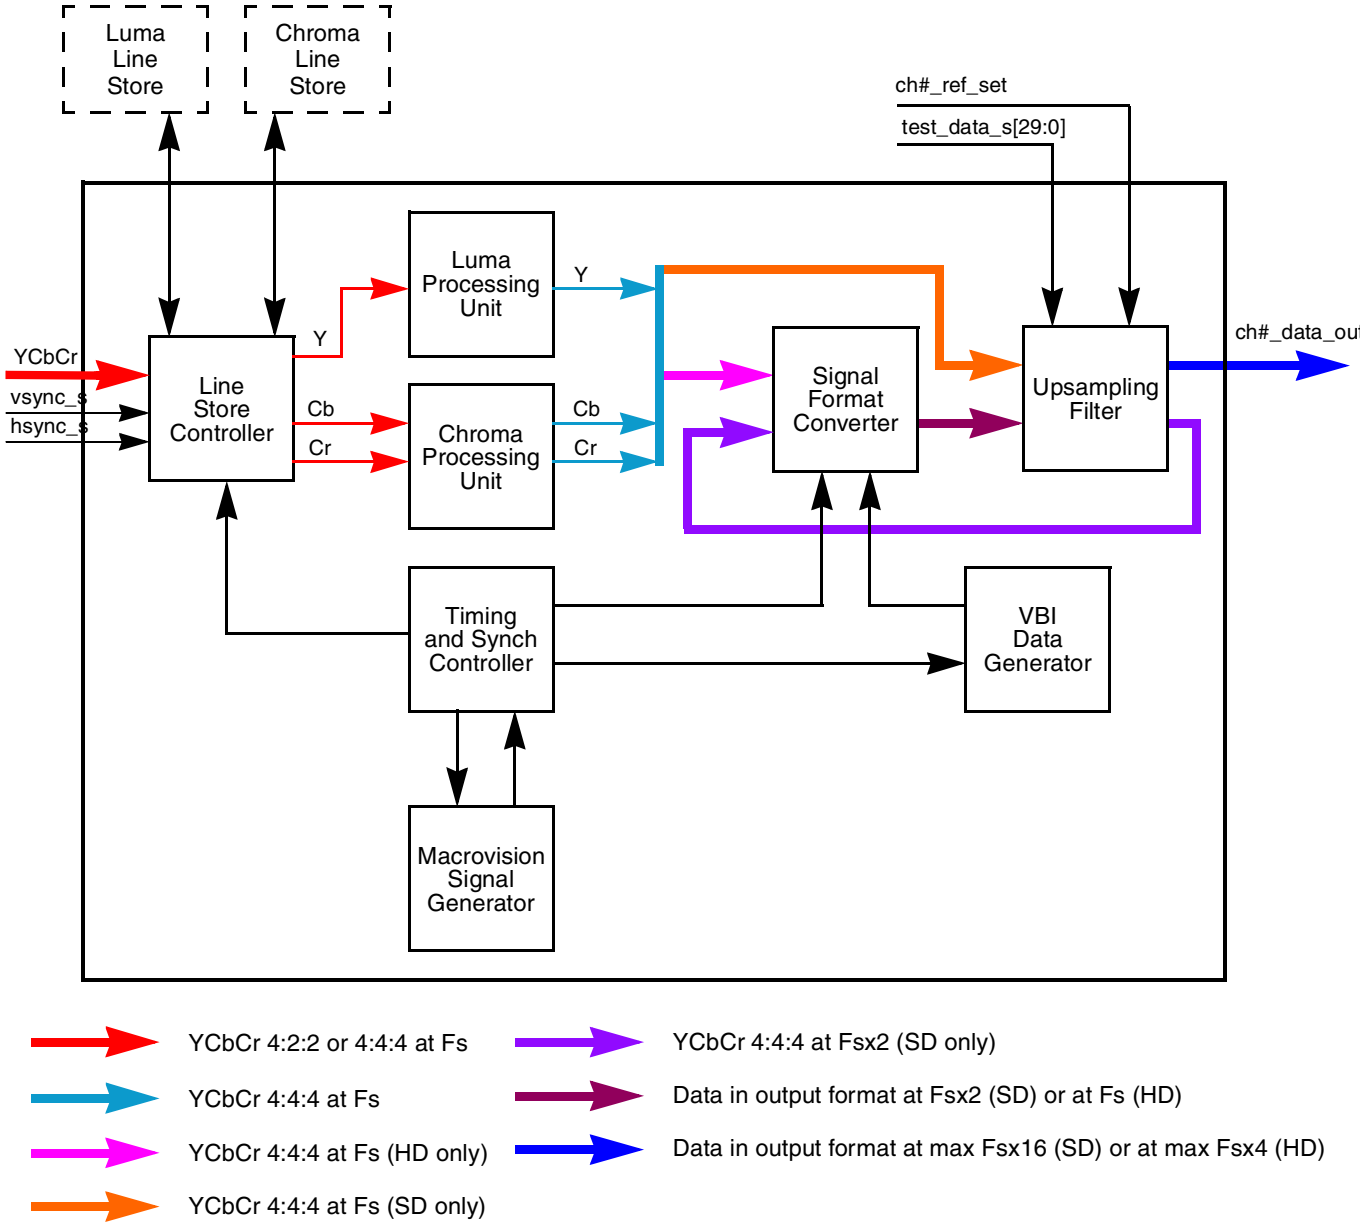

Figure 58-4. SPC Block Diagram

The SPC (shown in Figure 58-4) includes the Line Store Controller (LSC), The Luma Processing Unit (LPU), the Chroma Processing Unit (CPU), the Signal Format Converter (SFC), the Upsampling Filter (UF), The Timing and Synchronization Controller (TSC), the Macrovision signal generator and the VBI Data Generator (VDG).

The LSC receives the data in the YCbCr 4:0:0 or 4:4:4 format from the IDS. The data is written to the LLS (Y) and the CLS (Cb/Cr) line-by-line. The LLS size is 5 lines of 1920 Y samples. The CLS size is 4 lines of 1920 Cb/Cr pairs. The LSC reads 5-sample columns of the Y component from the LLS and sends it to

the LPU. In parallel, the LSC reads 4-sample columns of the Cb/Cr component from the CLS and sends it to the CPU.The columns are read sequentially so for generation of one output line, the whole line of pixel columns is read from the line stores.

The LPU contains a set of filters including:

- 5-tap vertical adaptive filter designed for
  - vertical coarse and fine sharpening
  - vertical mid-frequency and high-frequency noise reduction
  - de-flickering (required only for interlaced TV formats)
- 5-tap horizontal adaptive filter designed for
  - horizontal coarse and fine sharpening
  - horizontal mid-frequency and high-frequency noise reduction
  - horizontal de-ringing
- Notch filter for better Luma/Chroma separation in SD composite mode
- Lowpass filter for reducing out-of-band noise (it may enabled instead of the notch filter because both filters are implemented by the same hardware).

The adaptive filters boost (for sharpening) or suppress (for noise reduction, de-ringing and de-flickering) mid and high frequency components in the Luma spectrum. The filter operation (boost or suppression) depends on the Luma gradient in the corresponding spatial direction. The filters behavior is fully programmable. If the filter for vertical fine sharpening /vertical high-frequency noise reduction/de-flickering is enabled, the input data from the IPU is in the progressive format.

The CPU performs the following operation on the Chroma samples from the CLS:

- Upsampling from Fs/2 to Fs (if the input data format is YCbCr 4:2:2)
- Lowpass filtering for reducing color noise and improving Luma/Chroma separation in SD composite mode
- Comb filtering for improving Luma/Chroma separation in SD composite mode.

The CPU produces the filtered Cb and Cr components sampled at Fs.

The following processing path of the LPU and CPU output samples depends on the mode. In SD mode, the samples are fed to the UF. The UF performs upsampling the data to Fsx2 = 27 MHz. The upsampled data enters the SFC. In HD mode, the LPU and CPU outputs sampled at Fs = 74.25 or 74.25/1.001 MHz are sent directly to the SFC.

The SFC is responsible for the following functions:

- Conversion the YCbCr data to the RGB format for RGB component output
- Subcarrier generation and chroma modulation according to NTSC and PAL standards in SD composite and S-video modes
- Adjustment of brightness, saturation, and hue (in user mode)
- Signal level normalization to the desired values
- Combining the synchronization signals and the VBI data with the video signal
- Composing three output streams according to Table 58-1.

Signal formats and waveforms on three SFC outputs correspond to the final TV signals. The UF provides upsampling of these SFC outputs. The UF consists of three identical channels. Each channel includes the following elements:

- The Gain and Offset Correction (GOC) block is designed to compensate the TVDAC gain and offset deviation from the nominal values. The gain and the offset are adjusted in the range ±25% and ±12.5% of the full scale separately for each channel. The TVDAC_#_GAIN and TVDAC_#_OFFSET parameters are responsible for gain and offset control. The GOC includes an input mux used for selection between the functional mode data, the test data and the CD reference levels.
- The Drop Correction Filter (DCF) provides compensation of the gain drop introduced by the TVDAC at high frequencies. The drop compensation factor is programmable via the TVDAC_#_DROP_COMP parameter separately for each channel.
- The Halfband Upsampling Filter 1 (HUF1) performs upsampling from Fs to Fsx2 (27 MHz in SD mode and 148.5 MHz or 148.5/1.001 MHz in HD mode). In SD mode, the HUF1 input is muxed to the LPU and CPU outputs and the HUF1 output is muxed to the SFC input, so the first upsampling is done before processing in the SFC.
- The Halfband Upsampling Filter 2 (HUF2) performs upsampling from Fsx2 to Fsx4 (54 MHz in SD mode and 297 MHz or 297/1.001 MHz in HD mode). The HUF2 may be bypassed in HD mode if the output sampling frequency is set to Fsx2 via the TVDAC_SAMP_RATE control parameter.
- The 3rd order Interpolation Comb Filter (ICF) performs upsampling from Fsx4 to Fsx8 or Fsx16 in SD mode. The upsampling factor is controlled by the TVDAC_SAMP_RATE parameter. The ICF may be bypassed also in SD mode if the TVDAC_SAMP_RATE sets the output sampling frequency to 54 MHz.

In test mode, a test data is fed directly to the TVDAC (without upsampling) or through the UF.

The TSC is responsible for the following functions:

- Maintenance vertical and horizontal timing specified by the selected TV standard
- Generation of the synchronization signals, the color burst envelope, the active video data enable signal, and the pedestal
- Control of the blanking level for each of three output channels
- Insertion of the Macrovision signal distortions
- Edge shaping for all generated signals
- Delays between the synchronization signals

The TSC is triggered by the VSYNC and HSYNC signals from the IPU. The TSC provides flexible control on horizontal timings in user mode. It also allows non-standard timing modes in addition to the standard configurations (including square pixel operation in SD mode). The MSG controls the insertion of Macrovision signal distortions in the TSC. The MSG receives all necessary triggers from the TSC and returns Macrovision controls to the TSC.

The VDG generates the following VBI control sequences:

- Closed Caption
- CGMS

- WSS

The VDG can be configured only to one of them at the moment because a common hardware is used for generation of all these sequences.

58.1.3 Features

Common TVE features in both SD and HD modes are shown in Table 58-2.

Table 58-2. Common TVE Features in SD and HD Modes

Parameter	Value	Comments
Input data format	YCrCb 4:2:2 YCrCb 4:4:4	The IPU should support 24-bit/pixel parallel data output format
Input interface format and synchronization	Parallel interface with separate HSYNC and VSYNC	Two inputs from the IPU are available to allow transferring video data from one of two IPU display interfaces
Input data resolution	8 bits/component	—
Output data resolution	10 bits	—
Output interface format	Parallel	—
Non-standard horizontal timings support	Yes	Supported in user mode
Programmable adaptive Luma digital filter	Yes. The 5x5 adaptive filter is used for • horizontal and vertical sharpening • horizontal and vertical noise reduction • de-flickering in interlaced modes	The filter is fully programmable. The filter algorithm can be altered in user mode.
Programmable YCrCb to RGB color matrix	Yes	Five matrix coefficients are programmable. The can be also used for brightness, saturation and hue adjustment in user mode.
Cable Detection functionality	Supported. It includes • separate cable connection monitoring separately for each TVDAC channel both during normal operation and in standby mode • automatic TVE power on when a TV cable has been connected • detection of connection type (composite, S-video, component) • detection of cable short to the ground	—

Main parameters of the TVE in SD mode are given in Table 58-3.

Table 58-3. TVE Features in SD Mode

Parameter	Value	Comments
Supported color standards	PAL (B,D,G,H, I/M/N), NTSC	—
Supported TV standards	480i (29.97 Hz), 576i (25 Hz)	—

Table 58-3. TVE Features in SD Mode (continued)

Parameter	Value	Comments
Input frame format	Interlaced if no inter-field filtering is performed. Progressive otherwise.	Inter-field filtering is used for vertical fine sharpening, vertical high-frequency noise reduction and deflickering
Input sampling frequency	If no inter-field filtering is performed: Y - 13.5 MHz Cb/Cr - 6.75 MHz for YCbCr 4:2:2 format, Cb/Cr - 13.5 MHz for YCbCr 4:4:4 format. If inter-field filtering is performed: Y - 27 MHz Cb/Cr - 13.5 MHz for YCbCr 4:2:2 format, Cb/Cr - 27 MHz for YCbCr 4:4:4 format.	—
Square pixel operation	Yes	Also other non-standard timings can be supported in user mode
Output data format	Composite (CVBS) or S-video (Y/C) or component (YPrPb or RGB)	Simultaneous output of two identical CVBS as well as CVBS and Y/C is possible
Output sampling frequency	216/108/54 MHz	Lower sampling frequencies should be used if the TVDAC performance degrades at high sampling frequencies
Macrovision support	Yes. According to Macrovision 7.1	—
Programmable chroma bandwidth	Yes. The possible bandwidth values are: • for YCbCr 4:2:2 input - 0.6, 1.3, 2 and 3 MHz • for YCbCr 4:4:4 input - 1.3, 2.7, 4 and 5.4 MHz	—
Switchable pedestal	Yes	—
Copy generation management system (CGMS) support	Yes. According to EIA-608b, IEC 61880-1, EIA-J CPR-1204-1	—
Closed Caption support	Yes. According to EIA-608b	—
Wide Screen Signaling (WSS) support	Yes. According to ITU-R BT.1119, ETSI EN 300 294	—
Luma notch filter	Yes	For better Luma/Chroma separation in composite mode
Chroma comb filter	Yes	For better Luma/Chroma separation in composite mode

Main parameters of the TVE in HD mode are given in Table 58-4.

Table 58-4. TVE Features in HD Mode

Parameter	Value	Comments
Supported HD TV standards	720p 60 Hz 720p 50 Hz 720p 30 Hz 720p 25 Hz 720p 24 Hz 1080i 60 Hz 1080i 50 Hz 1035i 60 Hz (1920 × 1035) 1080p 30 Hz 1080p 25 Hz 1080p 24 Hz	—
Input frame format	Interlaced for 1080i. Progressive otherwise.	No interfield filtering is available for 1080i
Input sampling frequency	74.25 MHz –for 25/30/60 Hz modes 74.176 MHz - for 29.97/59.94 Hz modes	—
Output data format	Component (YCrCb or RGB)	—
Output sampling frequency	297 MHz –for 25/30/60 Hz modes 296.704 MHz - for 29.97/59.94 Hz modes	—
Programmable chroma bandwidth	Yes. The possible bandwidth values are: • for YCbCr 4:2:2 input—3.3, 7.1, 11 and 16.5 MHz • for YCbCr 4:4:4 input —6.7, 14.3, 22 and 29.7 MHz	—
Copy generation management system (CGMS) support	Yes. According to EIAJ CPR-1204-2 (CGMS) and CEA-805-A (CGMS type B)	—

Main parameters of the TVDAC are given in Table 58-5.

Table 58-5. TVDAC Features

Parameter	Value	Comments
Video signal formats	Composite (CVBS) or S-Video (Y/C) or component (YPrPb or RGB)	—
Resolution	10 bits	—
Signal bandwidth	From 0 to 30 MHz	—
Sampling rate	From 54 to 300 MHz	—
Digital input	Parallel 10x3 bits in unsigned format	—
Output type	Single-end current output	—
Output drive characteristics	Full drive - double-terminated 75 Ohm load (equivalent to 37.5 Ohm) Low drive – 100 Ohm load	Drive with standard output video levels
Output Drive Range	Controllable full-scale current	Controlled by an external resistor
Channel enable control	Separate for each channel and common control enabling the voltage reference	—

Table 58-5. TVDAC Features (continued)

Parameter	Value	Comments
Voltage reference	Build-in bandgap reference	—
Maximal gain mismatch	2%	Between any DAC
Maximal Integral Nonlinearity (INL)	±2 LSB	—
Maximal Differential Nonlinearity (DNL)	±1 LSB	—
Spurious-free Dynamic Range	> 50 dBc at F=1 5 MHz, Fs = 300 MHz	—
Power Supplies	Analog: 2.5–2.75 V Digital: 1.2 V	—

58.1.4 Modes of Operation

This section discusses the following modes of operation:

- Section 58.1.4.1, Normal Operation Mode”
- Section 58.1.4.2, Standby Mode”
- Section 58.1.4.3, Cable Detection Modes”
- Section 58.1.4.4, Test Modes”

58.1.4.1 Normal Operation Mode

In Normal Operation Mode, the TVE converts the input YCrCb 4:2:2 or 4:4:4 video stream to an analog TV signal. The TVE is in Normal Operation Mode, if the TV_OUT_MODE control parameter is in the range from 1 to 7 (see Table 58-1). This parameter also specifies the output TV signal type. During Normal Operation Mode, the inactive TVDAC and UF channels—whose outputs should be 0 according to Table 58-1—are disabled to save power.

The TV standard supported is specified by the TV_STAND control parameter as described in Table 58-6.

Table 58-6. TV_STAND Parameter

TV_STAND	Standard
0000	SD NTSC
0001	SD PALM
0010	SD Combination PALN
0011	SD PAL (B,D,G,H,I)
0100	HD 720p60
0101	HD 720p50
0110	HD 720p30
0111	HD 720p25

Table 58-6. TV_STAND Parameter (continued)

TV_STAND	Standard
1000	HD 720p24
1001	HD 1080i60
1010	HD 1080i50
1011	HD 1035i60 (1920 × 1035)
1100	HD 1080p30
1101	HD 1080p25
1110	HD 1080p24
1111	Reserved

For the TV_STAND values corresponding to HD modes, only the YPbPr and RGB output formats are valid. For SD modes, the input data from the IPU can be in interlaced or progressive formats.

The progressive format is used in the cases when vertical filtering is required for vertical sharpening, noise reduction and de-flickering. The P2I_CONV_EN control bit when set indicates that the input format is progressive. In this case, the IPU should provide progressive frames at the frame rate of 50 fps for PAL and Combinational PALN or at the frame rate of 60/1.001 fps for NTSC and PALM. For all modes, the pixel clock frequency is 27 MHz. The TVE performs vertical filtering of each progressive frame. After that interlacing is done by selection of odd or even lines. Vertical timing relations between input and output video frames for NTSC and PALM are shown in Figure 58-5. Vertical timing relations between input and output video frames for PAL are shown in Figure 58-6. Horizontal timing relations between input and output video lines are shown in Figure 58-7.

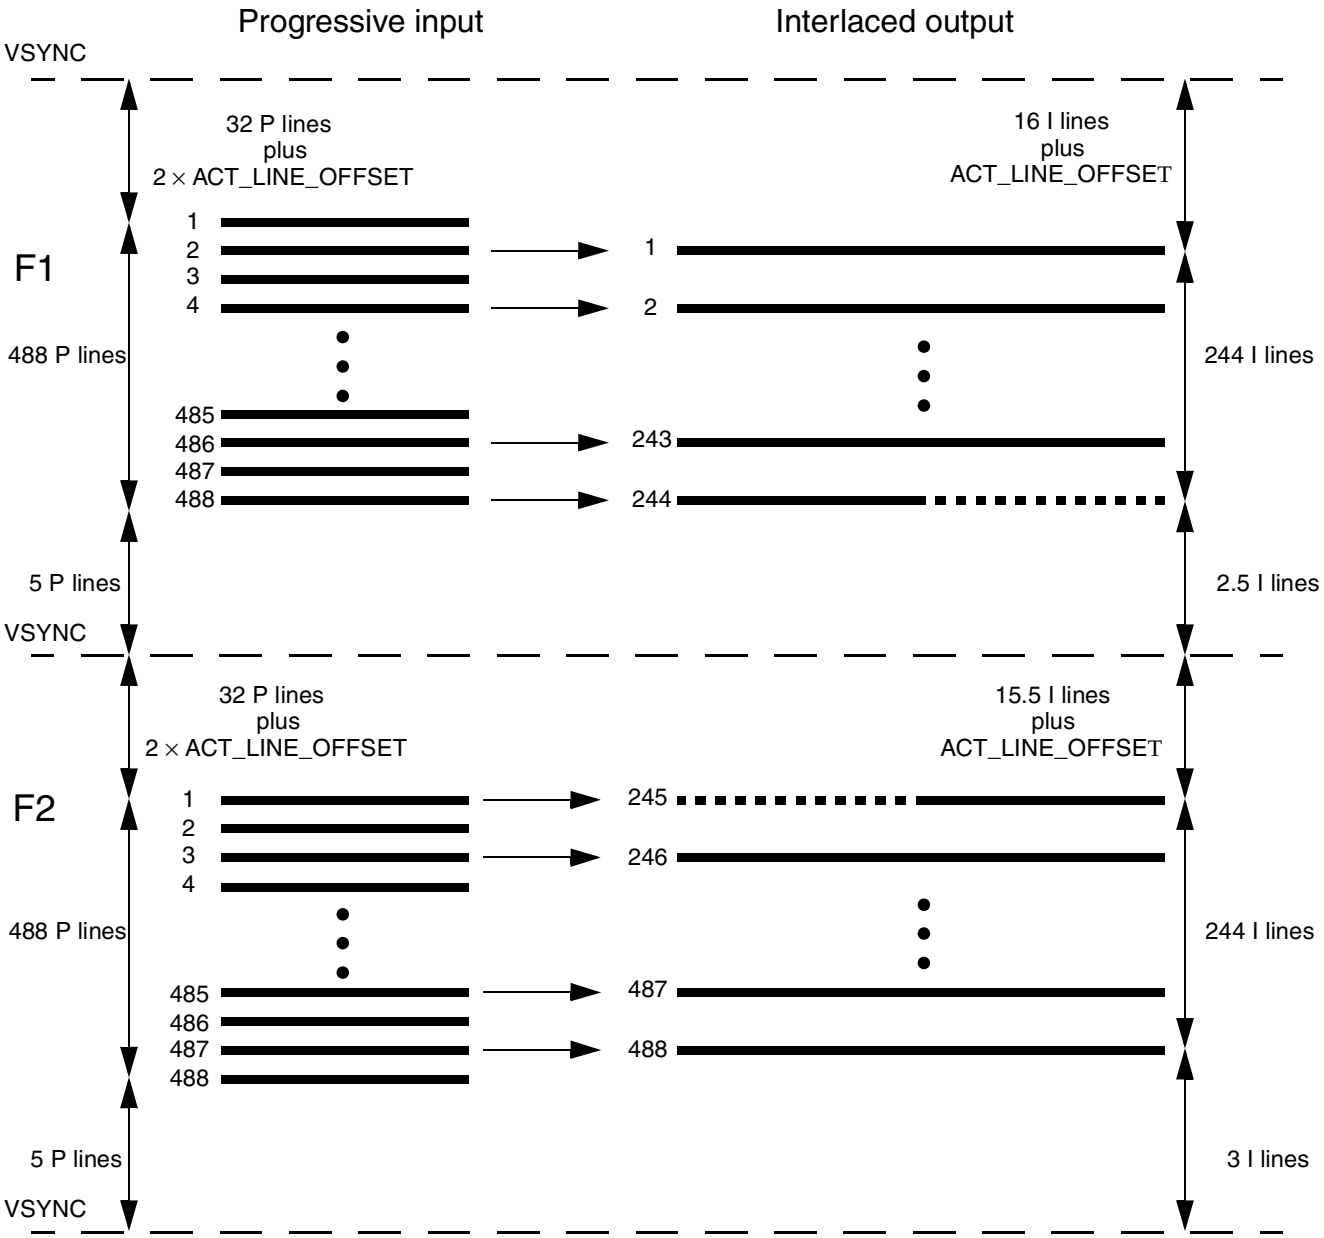

Figure 58-5. NTSC and PALM Vertical Timing Relations for Progressive-to-Interlaced Mode

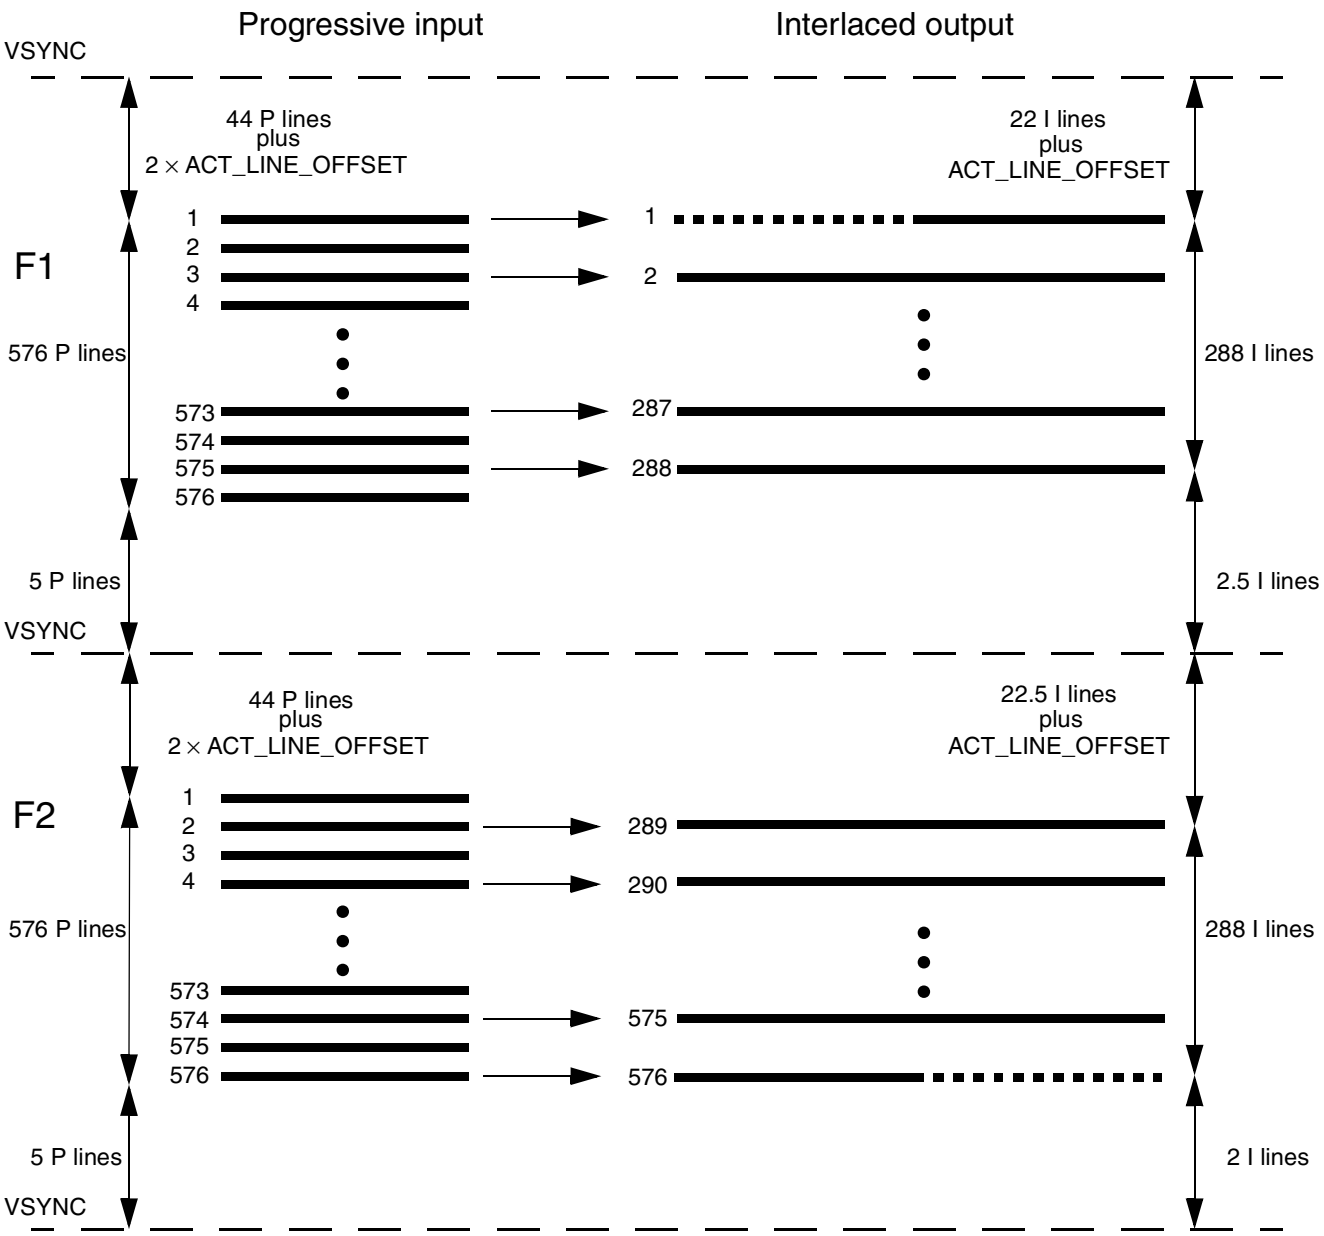

Figure 58-6. PAL Vertical Timing Relations for Progressive-to-Interlaced Mode

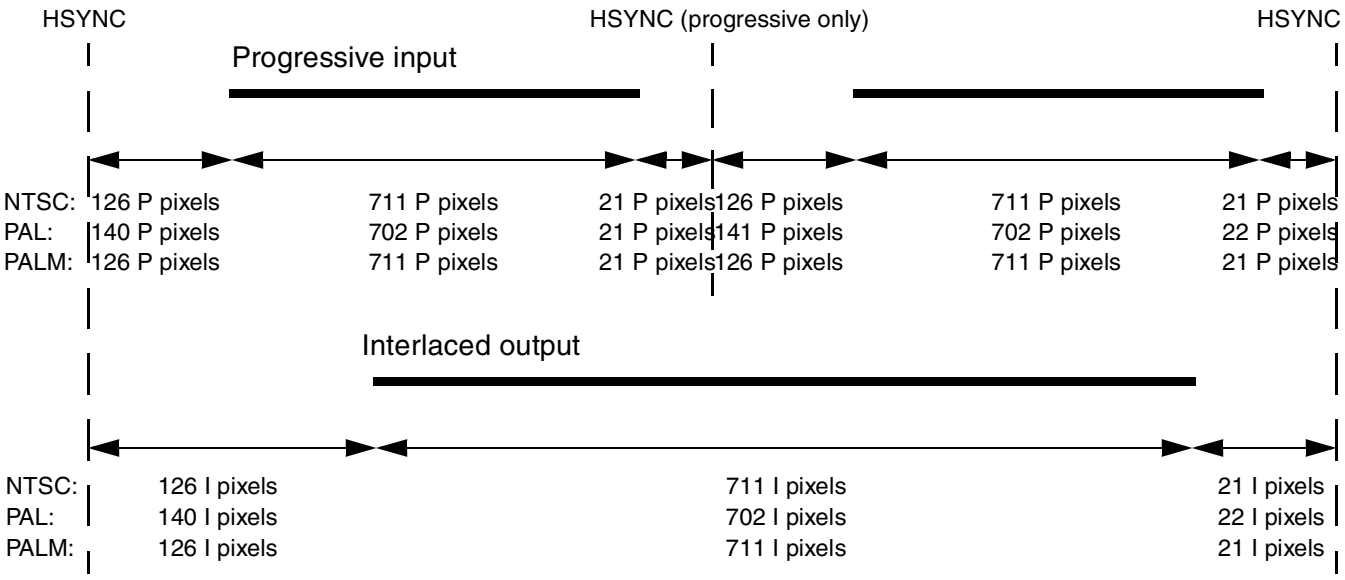

Figure 58-7. Horizontal Timing Relations for Progressive-to-Interlaced Mode

Vertical and horizontal blanking intervals shown in Figure 58-5–Figure 58-7 are minimal. If the IPU is configured to smaller blanking intervals, the TVE cuts a part of image which is outside the minimal blanking intervals. If the IPU is configured to larger blanking intervals, the TVE pads the missing image part between the actual and minimal blanking intervals by black pixels. For progressive-to-interlaced mode, the horizontal blanking interval (the timing interval between the HSYNC and the start of active data) must be an even number of pixels. The minimal vertical blanking interval between the VSYNC and the first active data line may be increased via the ACT_LINE_OFFSET control parameter. This feature may be used for disabling both the data and the pedestal on ACT_LINE_OFFSET first lines in NTSC mode.

If progressive-to-interlaced conversion is disabled, the IPU should provide interlaced vertical timings according the right parts of Figure 58-5 and Figure 58-6 and interlaced horizontal timings according to the bottom part of Figure 58-7. In cases when the IPU blanking intervals differ from those shown in these figures, the TVE cuts the image or pads it with black pixels as described above.

58.1.4.2 Standby Mode

The TVE is in Standby Mode, if the TV_OUT_MODE control parameter is 0. In this case, the most of internally generated clocks are gated off and internal resets are generated for the TVE sub-modules. The TVDAC is disabled. If the CD is enabled, the UF, the CDC and the TVDAC are periodically turned on for a short time to monitor cable connection.

58.1.4.3 Cable Detection Modes

The CD operation is supported with both hardware and software involvement. Different types of the TV connection are distinguished by a number of cable lines connected to the TV output. If one or several cable lines are connected, the equivalent load impedance for these outputs is close to 37.5 Ω and the voltage on

them matches the nominal video levels. If no cable is connected, the load impedance is elevated to 75 Ω. In this case, the output voltage is higher than the nominal video levels.

An additional feature of the CD system is detection of output line short to the ground. The short may appear if a headphone jack is plugged into the A/V connector and shorts the CVBS output to the ground.

Some natural limitations exist for CD operation. It is impossible to differentiate the mixed CVBS/S-video, the component YPrPb and the component RGB connections because in all these three cases a three-wire cable is used. So for these cases the software should set a default option or allow user choosing the interface type.

The CD is supported in both full-drive output mode (when the TV cable is connected directly to the TVDAC outputs) and low-drive output mode (when the TVDAC drives a high-resistance load and a buffer/filter is located between the TVDAC output and the TV connector). In both cases, three monitoring input pins should be connected on a board directly to the cable plug.

There are three CD modes:

- Monitoring the current cable connection when the TVE is in Normal Operation Mode. The mode is enabled if TV_OUT_MODE is not 000 and the CD_TRIG_MODE is 0.
- Periodical automatic pending the cable connection when the TVE is in Standby Mode. The mode is enabled if TV_OUT_MODE is 000 and the CD_TRIG_MODE is 0.
- Checking the cable connection ‘on demand’ (on the trigger control generated by software). The mode is enabled if the CD_TRIG_MODE is 1.

In modes 1 and 2, the CDCU periodically initiates monitoring the output voltage. In mode 3, the MCU should set the CD_MAN_TRIG bit.

The CDC measures the voltage in two steps. At the first step, cable connection is checked. The voltage comparison results obtained at the first step are compared with the current TV output mode specified by the TV_OUT_MODE parameter. If the results do not match the current output mode, an interrupt to the MCU is generated. At the second step, output short to ground is checked. If short has been detected, an interrupt to the MCU is generated.

The software is able to control for which output channels cable connection and/or output short should be checked. The CD_CH_#_LM_EN and CD_CH_#_SM_EN control bits are used for this. If an output load for one of the channels for which the CD_CH_#_LM_EN=1 is different from the value defined the TV_OUT_MODE, the load monitoring interrupt status bit (CD_LM_INT) is set and the corresponding interrupt is generated. If the output of one of the channels for which the CD_CH_#_SM_EN=1 is shorted to the ground, the short monitoring interrupt status bit (CD_SM_INT) is set and the corresponding interrupt is generated.

In the first CD mode, the monitoring period is a multiple of a TV field duration (for SD mode) or a TV frame duration (for HD mode). It is specified by the CD_MON_PER control parameter. The measurement is performed during the first half-line of the pre-equalization pulse in the vertical blanking period.

In the second CD mode, the monitoring period is a multiple of 0.31 sec. It is also specified by the CD_MON_PER control parameter. For output monitoring, the CDCU enables the monitored channels for a measurement time and forces its input to the desired value.

The reference voltage level used for comparison in the CDC can be equal to the Luma blanking level (about 320 mV) or to the Chroma blanking level (about 670 mV). The specific values of the reference levels depend on the CD_REF_MODE and the CD_CH_2_REF_LVL and the current TV output mode specified by the TV_OUT_MODE parameter.

Table 58-7 shows the CD reference levels depending on these control parameters.

Table 58-7. CD Reference Level

Output channel	CD_REF_MODE	CD Reference Level[1] (TV_OUT_MODE)							
		Composite (CVBS)				S-video (Y/C)	CVBS and Y/C	YCrCb component	RGB component
		(0)	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Channel #0	0	CD_CH_0_REF_LVL	0	CD_CH_0_REF_LVL	0	0	0	0	0
	1	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL
Channel #1	0	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	1	1	CD_CH_1_REF_LVL	0
	1	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL
Channel #2	0	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	0	0	CD_CH_2_REF_LVL	0	CD_CH_2_REF_LVL	0
	1	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL

[1] Luma Reference Level is 0, Chroma Reference Level is 1

58.1.4.4 Test Modes

There are two groups of TVE test modes: the whole TVE is tested or just the TVDAC is tested.

To invoke the test mode wherein the whole TVE is tested, the TVDAC_TEST_MODE control parameter should be 0. The TVE input data, VSYNC and HSYNC are produced by an internal colorbar generator located in the VPG or received from the external test bus. Selection between these two options is done via the DATA_SOURCE_SEL control parameter. The internal generator produces the colorbar according to the selected TVE operational mode defined by the TV_STAND, P2I_CONV_EN and INP_VIDEO_FORM control parameters. The rest of control parameters should be configured as for regular functional mode.

To involve the TVDAC test mode, the TVDAC_TEST_MODE should be set from 1 to 5. TVDAC test modes are designed for TVDAC characterization and production testing. For these modes, the most part of the TVSP processing section is bypassed. The 30-bit input test data may be received either from one of two IPU buses or from the external test bus. The data sampling ate should be 27 MHz for testing the TVDAC in SD mode or 74.25 MHz for testing the TVDAC in HD mode. The IDS output is fed directly to the UF. There are five modification of TVDAC Test Mode selected by the TVDAC_TEST_MODE. In

TVDAC Test Modes 1 and 3, the 30-bit TVE input data is separated into three 10-bit words. Each word is fed via the UF to the corresponding TVDAC channel. In TVDAC Test Modes 2 and 4, only 10 least significant bits of the input data word are sent to all UF and TVDAC channels in parallel. In TVDAC Test Modes 1 and 2, the UF is used to interpolate the test data before driving it to the TVDAC. In TVDAC Test Modes 3 and 4, the UF is bypassed. In TVDAC Test Mode 5, the VPG drives a sine wave signal with programmable frequency and amplitude to the TVDAC inputs. Independently on the TVDAC_TEST_MODE setting, the input of each TVDAC channel can be forced to a programmable constant code defined via the BLANKING_CH_#_USR control parameters. Forcing is done when the corresponding TVDAC_#_DATA_FORCE bit is set.

58.2 External Signal Description

The MMT pins are described in Table 58-8.

Table 58-8. Detailed Signal Descriptions

Signal	I/O	Description	
Clocks and resets			
tve_clk	I	High speed clock input	
		State Meaning	Asserted/Negated—Samples TVE flip-flops on positive edge
		Timing	Assertion/Negation - According to the required operation frequency. The allowed frequencies for SD are 216, 108, 54 MHz, for HD - 297 (297/1.001), 148.5 (148.5/1.001) MHz
ipg_clk_s	I	IPI Green Line gated clock for IP bus	
		State Meaning	According to the Green Line SRS protocol
		Timing	According to the Green Line SRS protocol. May be asynchronous with the tve_clk clock
fsx_ipu_clk	O	Internally generated clock fed to the IPU	
		State Meaning	Used for sampling of the output data interface in the IPU
		Timing	Derived by division of the TVE_CLK clock. Edge-synchronized with TVE_CLK
ipg_hard_async_reset_b	I	System HW reset	
		State Meaning	According to the Green Line SRS protocol
		Timing	According to the Green Line SRS protocol

Table 58-8. Detailed Signal Descriptions (continued)

Signal	I/O	Description	
ipg_soft_reset_b	I	System SW reset	
		State Meaning	According to the Green Line SRS protocol
		Timing	According to the Green Line SRS protocol
Input Data Interface			
video_data_clk_1	I	Clocking signal for input video data bus 1 from the IPU	
		State Meaning	Negative edge — Indicates that the IPU has updated the video_data_in_1 bus Positive edge — Indicates that the TVE can sample the video_data_in_1 bus
		Timing	The clock frequency is 13.5 MHz or 27 MHz in functional SD mode, 74.25 (74.25/1.001) MHz in functional HD mode. The clock frequency is 27 MHz (SD) and 74.25 (74.25/1.001) MHz (HD) in TVDAC test modes. The clock may be asynchronous with the TVE_CLK but the phase jitter between this clock and the clock generated in the TVE must be less than a half of video_data_clk cycle.
video_data_in_1[29:0]	I	Video data input bus 1 from the IPU	
		State Meaning	In functional mode - video_data_in_1[7:0]: Y video_data_in_1[15:8]: Cr video_data_in_1[23:16]: Cb video_data_in_1[29:24]: unused In TVDAC test modes 1 and 3 - video_data_in_1[9:0]: test data for TVDAC channel #0 video_data_in_1[19:10]: test data for TVDAC channel #1 video_data_in_1[29:20]: test data for TVDAC channel #2 In TVDAC test modes 2 and 4 - video_data_in_1[9:0]: test data for TVDAC channels #0 - #2 video_data_in_1[29:10]: unused
		Timing	The bus is sampled by negative edges of the video_data_clk_1 clock
video_data_en_1	I	Enable signal for input video data bus 1 from the IPU. In TVDAC test modes, the signal is unused.	
		State Meaning	Asserted—Indicates valid input video data on the bus 1 Negated— Indicates no valid input video data on the bus 1
		Timing	Assertion/Negation — Synchronized to negative edges of the video_data_clk_1 clock.

Table 58-8. Detailed Signal Descriptions (continued)

Signal	I/O	Description	
vsync_1	I	Vertical synchronization signal for input video data bus 1 from the IPU. In TVDAC test modes, the signal is unused.	
		State Meaning	Asserted—Indicates video frame start Negated— Indicates no video frame start
		Timing	Assertion/Negation— Synchronized to negative edges of the video_data_clk_1 clock. Remains asserted for one clock cycle
hsync_1	I	Horizontal synchronization signal for input video data bus 1 from the IPU. In TVDAC test modes, the signal is unused.	
		State Meaning	Asserted—Indicates video line start Negated— Indicates no video line start
		Timing	Assertion/Negation — Synchronized to negative edges of the video_data_clk_1 clock. Remains asserted for one clock cycle
video_data_clk_2	I	Clocking signal for input video data bus 2 from the IPU	
		State Meaning	Negative edge — Indicates that the IPU has updated the video_data_in_2 bus Positive edge — Indicates that the TVE can sample the video_data_in_2 bus
		Timing	The clock frequency is 13.5 MHz or 27 MHz in functional SD mode, 74.25 (74.25/1.001) MHz in functional HD mode. The clock frequency is 27 MHz (SD) and 74.25 (74.25/1.001) MHz (HD) in TVDAC test modes. The clock may be asynchronous with the TVE_CLK but the phase jitter between this clock and the clock generated in the TVE must be less than a half of video_data_clk cycle.
video_data_in_2[29:0]	I	Video data input bus 2 from the IPU	
		State Meaning	In functional mode - video_data_in_2[7:0]: Y video_data_in_2[15:8]: Cr video_data_in_2[23:16]: Cb video_data_in_2[29:24]: unused In TVDAC test modes 1 and 3 - video_data_in_2[9:0]: test data for TVDAC channel #0 video_data_in_2[19:10]: test data for TVDAC channel #1 video_data_in_2[29:20]: test data for TVDAC channel #2 In TVDAC test modes 2 and 4 - video_data_in_2[9:0]: test data for TVDAC channels #0 - #2 video_data_in_2[29:10]: unused
		Timing	The bus is sampled by negative edges of the video_data_clk_2 clock

Table 58-8. Detailed Signal Descriptions (continued)

Signal	I/O	Description	
video_data_en_2	I	Enable signal for input video data bus 2 from the IPU. In TVDAC test modes, the signal is unused.	
		State Meaning	Asserted—Indicates valid input video data on the bus 2 Negated— Indicates no valid input video data on the bus 2
		Timing	Assertion/Negation — Synchronized to negative edges of the video_data_clk_2 clock.
vsync_2	I	Vertical synchronization signal for input video data bus 2 from the IPU. In TVDAC test modes, the signal is unused.	
		State Meaning	Asserted—Indicates video frame start Negated— Indicates no video frame start
		Timing	Assertion/Negation— Synchronized to negative edges of the video_data_clk_2 clock. Remains asserted for one clock cycle
hsync_2	I	Horizontal synchronization signal for input video data bus 2 from the IPU. In TVDAC test modes, the signal is unused.	
		State Meaning	Asserted—Indicates video line start Negated— Indicates no video line start
		Timing	Assertion/Negation — Synchronized to negative edges of the video_data_clk_2 clock. Remains asserted for one clock cycle
External Test Data Interface			
IPP_IND_TEST_DATA_CLK	I	Clocking signal for input data from the external test bus	
		State Meaning	Negative edge — Indicates that an external source has updated the IPP_IND_TEST_DATA_IN bus Positive edge — Indicates that the TVE can sample the IPP_IND_TEST_DATA_IN bus
		Timing	The clock frequency is 13.5 or 27 MHz (SD) and 74.25 (74.25/1.001) MHz (HD) in TVE test mode. The clock frequency is 27-MHz (SD) and 74.25 (74.25/1.001) MHz (HD) in TVDAC test modes. The clock may be asynchronous with the TVE_CLK but the phase jitter between this clock and the clock generated in the TVE must be less than a half the clock cycle.

Table 58-8. Detailed Signal Descriptions (continued)

Signal	I/O	Description	
IPP_IND_TEST_DATA_IN[29:0]	I	Test data input from an external source	
		State Meaning	In TVE test mode - IPP_IND_TEST_DATA_IN[7:0]: Y IPP_IND_TEST_DATA_IN[15:8]: Cr IPP_IND_TEST_DATA_IN[23:16]: Cb IPP_IND_TEST_DATA_IN[24]: data enable IPP_IND_TEST_DATA_IN[25]: hsync IPP_IND_TEST_DATA_IN[26]: vsync IPP_IND_TEST_DATA_IN[29:27]: unused In TVDAC test modes 1 and 3 - IPP_IND_TEST_DATA_IN[9:0]: test data for TVDAC channel #0 IPP_IND_TEST_DATA_IN[19:10]: test data for TVDAC channel #1 IPP_IND_TEST_DATA_IN[29:20]: test data for TVDAC channel #2 In TVDAC test modes 2 and 4 - IPP_IND_TEST_DATA_IN[9:0]: test data for TVDAC channels #0 - #2 IPP_IND_TEST_DATA_IN[29:10]: unused
		Timing	The bus is sampled by negative edges of the IPP_IND_TEST_DATA_CLK clock
IPP_IBE_TEST_DATA_IN	O	Test data bus and clock pins direction control	
		State Meaning	Asserted - Indicates that the test data bus and clock pins direction should be set for test data input from an external source (the external test data is used) Negated - Indicates that the test data bus and clock pins direction should be set according to alternate functions of these pins (the external test data is unused)
		Timing	The signal is sampled by positive edges of the TVE clock
Output Analog Interface and Other Analog Pins			
IPP_ANALOGIO_TVCDC_IOG_BACK	I	Cable detection channel #0 (green) input	
		State Meaning	Voltage range is according to TVDAC specifications
		Timing	na
IPP_ANALOGIO_TVCDC_IOR_BACK	I	Cable detection channel #1 (red) input	
		State Meaning	Voltage range is according to TVDAC specifications
		Timing	na

58.3.2 Register Summary

The conventions in Figure 58-10 and Table 58-10 serve as a key for the register summary and individual register diagrams.

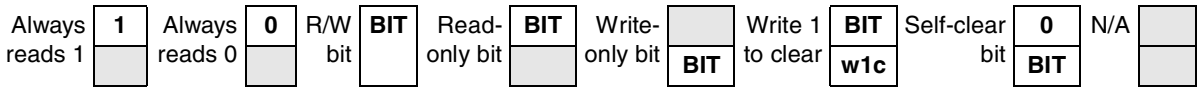

Figure 58-10. Key to Register Fields

Table 58-10 provides a key for register figures and tables and the register summary.

Table 58-10. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.

Table 58-10. Register Conventions (continued)

Convention	Description
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 58-11 is the register summary table.

W								
Reset	0	0	0	0	0	0	0	0

3

Figure 58-11. Common Configuration Register (COM_CONF_REG)

Register fields are described in Table 58-12.

Table 58-12. Register Field Descriptions

Field	Description
27–31	Reserved.
24–26 ACT_LINE_OFFSET	Offset of the first active video data line relative to a standard value. Defined in lines. 000 No offset 001 1-line offset 010 2-line offset 011 3-line offset 100 3-line offset 101 4-line offset 110 5-line offset 111 7-line offset
23	Reserved.
22 SYNC_CH_2_EN	Enable sync on output channel 2. 0 Disable 1 Enable
21 SYNC_CH_1_EN	Enable sync on output channel 1. 0 Disable 1 Enable
20 SYNC_CH_0_EN	Enable sync on output channel 0. 0 Disable 1 Enable
18–19	Reserved.
16–17 SD_PED_AMP_CONT	Control pedestal, Y/R/G/B black-to-white and sync output amplitude. 00 714 mV (black-to-white)/286 mV (sync), no pedestal 01 714 mV (black-to-white)/286 mV (sync), with pedestal 10 700 mV (black-to-white)/300 mV (sync), no pedestal 11 Reserved
15	Reserved.
12–14 TV_OUT_MODE	Select TV output mode. For HD TV standards, only YPbPr and RGB operation modes are valid. 000 Disable output 001 CVBS on channel #0 010 CVBS on channel #2 011 CVBS on both channels #0 and #2 100 S-video on channels #0 and #1 101 S-video on channels #0 and #1 and CVBS on channel #2 110 YPbPr component 111 RGB component

Table 58-12. Register Field Descriptions (continued)

Field	Description
8–11 TV_STAND	Select TV standard. 0000 SD NTSC 0001 SD PALM 0010 SD Combination PALN 0011 SD PAL (B,D,G,H,I) 0100 HD 720p60 0101 HD 720p50 0110 HD 720p30 0111 HD 720p25 1000 HD 720p24 1001 HD 1080i60 1010 HD 1080i50 1011 HD 1035i60 (1920x1035) 1100 HD 1080p30 1101 HD 1080p25 1110 HD 1080p24 1111 Reserved
7 P2I_CONV_EN	Enable progressive to interlaced conversion. Valid only in for SD TV standards. Must be 0 for HD TV standards. 0 Disable 1 Enable
6 INP_VIDEO_FORM	Select input video format. 0 YCbCr 4:2:2 1 YCbCr 4:4:4
4–5 DATA_SOURCE_SEL	Select data source. 00 Video data bus 1 from the IPU 01 Video data bus 2 from the IPU 10 External test data bus 11 Internal Color Bar Generator
3 IPU_CLK_EN	Enable clock output for the IPU. 0 Disable 1 Enable
1–2 TVDAC_SAMP_RATE	Select TVDAC sampling rate. Must match the TVE_CLK clock frequency. 00 216 MHz (SD mode) or 297 MHz (HD mode) 01 108 MHz (SD mode) or 148.5 MHz (HD mode) 10 54 MHz (SD mode) or reserved (HD mode) 11 Reserved
0 TVE_EN	Enable the TVE. When low, resets all internal registers excluding the IPS registers and gates off internal clocks. 0 Disable 1 Enable

58.3.3.2 Luma Filter Control Register 0 (LUMA_FILT_CONT_REG_0)

Figure 58-12 shows the luma filter control register 0.

Figure 58-17. Luma Statistic Analysis Control Register 1 (LUMA_SA_CONT_REG_1)

Register fields are described in Table 58-18.

Table 58-18. Register Field Descriptions

Field	Description
24–31 SA_WIN_V_OFFSET	Statistic analysis window vertical offset relative to start of an input active video data frame/field. A sum of this parameter and SA_WIN_HEIGHT should not exceed the height of the input video data frame/field. 000000000 lines 000000018 lines ..... 111111112040 lines
16–23 SA_WIN_H_OFFSET	Statistic analysis window horizontal offset relative to start of an input active video data line. A sum of this parameter and SA_WIN_WIDTH should not exceed the length of the input video data line. 000000000 pixels 000000018 pixels ..... 111111112040 pixels
8–15 SA_WIN_HEIGHT	Statistic analysis window height. 000000000 lines 000000018 lines ..... 111111112040 lines
0–7 SA_WIN_WIDTH	Statistic analysis window width. 000000000 pixels 000000018 pixels ..... 111111112040 pixels

58.3.3.8 Luma Statistic Analysis Status Register 0 (LUMA_SA_STAT_REG_0)

Figure 58-18 shows the luma static analysis status register 0.

Address 0xBASE+0x001C (LUMA_SA_STAT_REG_0) Access: User read

Figure 58-24. Cable Detection Control Register (CD_CONT_REG)

Register fields are described in Table 58-25.

Table 58-25. Register Field Descriptions

Field	Description
23–31	Reserved.
22 CD_CH_2_SM_EN	TVDAC channel #2 short monitoring enable. 0 Disable 1 Enable
21 CD_CH_1_SM_EN	TVDAC channel #1 short monitoring enable. 0 Disable 1 Enable
20 CD_CH_2_SM_EN	TVDAC channel #0 short monitoring enable. 0 Disable 1 Enable
19	Reserved.
18 CD_CH_2_LM_EN	TVDAC channel #2 load impedance monitoring enable. 0 Disable 1 Enable

Table 58-25. Register Field Descriptions (continued)

Field	Description
17 CD_CH_1_LM_EN	TVDAC channel #1 load impedance monitoring enable. 0 Disable 1 Enable
16 CD_CH_2_LM_EN	TVDAC channel #0 load impedance monitoring enable. 0 Disable 1 Enable
12–15	Reserved.
11 CD_REF_MODE	CD reference mode. Specifies how the reference voltage level for CD comparators is set for active TVDAC channels. The bit is ignored for inactive channels or in standby mode (manual mode assumed). The bit is also ignored for channels# 1 and #2 in YPrPb mode (TV_OUT_MODE=110). 0 Automatic mode when the reference voltage is set according to the channel signal type defined by the TV_OUT_MODE 1 Manual mode when the reference voltage is set according to the CD_CH_#_REF_LVL
10 CD_CH_2_REF_LVL	CD reference level for TVDAC channel #2. Specified the expected level of the channel output voltage when the output is loaded by nominal 37.5-Ohm impedance. This bit is ignored if the channel is active and CD_REF_MODE is 0 excluding YPrPb mode (TV_OUT_MODE=110). 0 The reference level corresponds to the Luma blanking level 1 The reference level corresponds to the Chroma blanking level
8 CD_CH_1_REF_LVL	CD reference level for TVDAC channel #1. Specified the expected level of the channel output voltage when the output is loaded by nominal 37.5-Ohm impedance. This bit is ignored if the channel is active and CD_REF_MODE is 0 excluding YPrPb mode (TV_OUT_MODE=110). 0 The reference level corresponds to the Luma blanking level 1 The reference level corresponds to the Chroma blanking level
8 CD_CH_0_REF_LVL	CD reference level for TVDAC channel #0. Specified the expected level of the channel output voltage when the output is loaded by nominal 37.5-Ohm impedance. This bit is ignored if the channel is active and CD_REF_MODE is 0. 0 The reference level corresponds to the Luma blanking level 1 The reference level corresponds to the Chroma blanking level
4–7 CD_MON_PER	Cable detection monitoring period. If TV_OUT_MODE is not 000 (during normal operation), specified in TV fields for SD or in TV frames for HD. If TV_OUT_MODE is 000 (standby mode), specified in 0.31-sec units. 0000 1 field (SD) or 1 frame (HD) for normal operation or 0.31 sec for standby mode 0001 2 fields (SD) or 2 frames (HD) for normal operation or 0.62 sec for standby mode ..... 1111 16 fields (SD) or 16 frames (HD) for normal operation or 4.96 sec for standby mode
2–3	Reserved.
0 CD_TRIG_MODE	CD trigger mode. 0 Automatic (periodical) trigger 1 Manual (single shot) trigger
0 CD_EN	Enable cable detection. When low, resets the CD Control Unit and the CD Circuit. 0 Disable 1 Enable

Figure 58-37. Status Register (STAT_REG)

Register fields are described in Table 58-25.

Table 58-38. Register Field Descriptions

Field	Description
26–31	Reserved.
25 BG_READY	Status bit of bandgap reference of the TVDAC. The ready time is set by the BG_RDY_TIME parameter. 0 Bandgap reference is not ready. 1 Bandgap reference is ready
24 CD_MAN_TRIG	Control/status bit for manual (single shot) trigger of CD monitors. Set by the MCU, cleared by the TVE. Has no effect if CD_TRIG_MODE is 0. This bit can be set only if CD_EN=1. 0 No CD trigger 1 Trigger CD
23	Reserved.

Table 58-38. Register Field Descriptions (continued)

Field	Description
22 CD_CH_2_SM_ST	Status bit of TVDAC channel #2 short monitoring by CD. Valid only if CD_CH_2_SM_EN is set. 0 Short detected 1 No short detected
21 CD_CH_1_SM_ST	Status bit of TVDAC channel #1 short monitoring by CD. Valid only if CD_CH_1_SM_EN is set. 0 Short detected 1 No short detected
20 CD_CH_0_SM_ST	Status bit of TVDAC channel #0 short monitoring by CD. Valid only if CD_CH_0_SM_EN is set. 0 Short detected 1 No short detected
19	Reserved.
18 CD_CH_2_LM_ST	Status bit of TVDAC channel #2 load impedance monitoring by CD. Valid only if CD_CH_2_LM_EN is set. 0 Cable detected 1 No cable detected
17 CD_CH_1_LM_ST	Status bit of TVDAC channel #1 load impedance monitoring by CD. Valid only if CD_CH_1_LM_EN is set. 0 Cable detected 1 No cable detected
16 CD_CH_0_LM_ST	Status bit of TVDAC channel #0 load impedance monitoring by CD. Valid only if CD_CH_0_LM_EN is set. 0 Cable detected 1 No cable detected
15	Reserved.
14 SA_MEAS_END_INT	Status bit of the Luma statistic measurement end interrupt. 0 No statistic measurement end event has occurred 1 Statistic measurement end event has occurred
13 TVE_FRAME_END_INT	Status bit of the end-of-frame interrupt. 0 No end-of-frame event has occurred 1 End-of-frame event has occurred
12 TVE_FIELD_END_INT	Status bit of the end-of-field interrupt. 0 No end-of-field event has occurred 1 End-of-field event has occurred
11 CGMS_HD_B_F2_DONE_IEN	Status bit of the HD CGMS Type B done interrupt for field 2. 0 No HD CGMS Type B done 1 HD CGMS Type B done
10 CGMS_HD_B_F1_DONE_IEN	Status bit of the HD CGMS Type B done interrupt for field 1. 0 No HD CGMS Type B done 1 HD CGMS Type B done
9 CGMS_HD_A_F2_DONE_IEN	Status bit of the HD CGMS Type A done interrupt for field 2. 0 No HD CGMS Type B done 1 HD CGMS Type B done
8 CGMS_HD_A_F1_DONE_IEN	Status bit of the HD CGMS Type A done interrupt for field 1. 0 No HD CGMS Type B done 1 HD CGMS Type B done
7 WSS_SD_DONE_IEN	Status bit of the SD WSS done interrupt. 0 No SD WSS done 1 SD WSS done

Table 58-38. Register Field Descriptions (continued)

Field	Description
6 CGMS_SD_F2_DONE_IEN	Status bit of the SD CGMS done interrupt for field 2. 0 No SD CGMS done 1 SD CGMS done
5 CGMS_SD_F1_DONE_IEN	Status bit of the SD CGMS done interrupt for field 1. 0 No SD CGMS done 1 SD CGMS done
4 CC_SD_F2_DONE_IEN	Status bit of the SD Closed Caption done interrupt for field 2. 0 No SD Closed Caption done 1 SD Closed Caption done
3 CC_SD_F1_DONE_IEN	Status bit of the SD Closed Caption done interrupt for field 1. 0 No SD Closed Caption done 1 SD Closed Caption done
2 CD_MON_END_INT	Status bit of the end-of-monitoring interrupt by CD. 0 No end-of-monitoring event has occurred 1 End-of-monitoring event has occurred
1 CD_SM_INT	Status bit of the short monitoring interrupt by CD. 0 No short detected 1 Short detected
0 CD_LM_INT	Status bit of the load impedance monitoring interrupt by CD. 0 No mismatch between current output mode and real output load configuration 1 Current output mode does not match real output load configuration

Chapter 59
Universal Asynchronous Receiver/Transmitter (UART)

59.1 Overview

This section briefly introduces the universal asynchronous receiver/transmitter (UART) module by showing a top-level diagram of the functional organization of the module, including all off-chip signals. The full description of the module is in Section 59.4, Functional Description."

Figure 59-1 shows the block diagram.

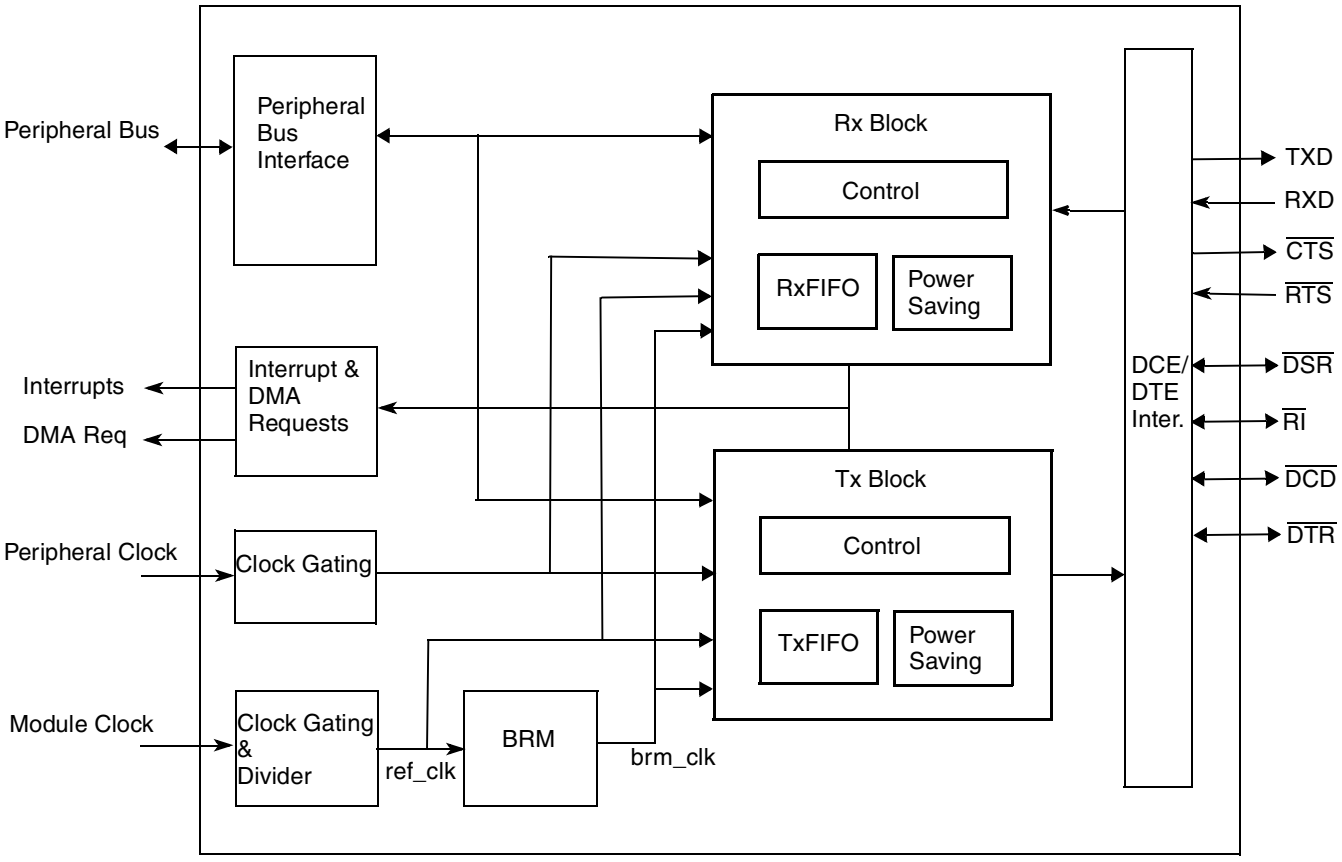

Figure 59-1. UART Block Diagram

59.1.1 Features

The UART includes the following features:

- High-speed TIA/EIA-232-F compatible
- 7 or 8 data bits
- 1 or 2 stop bits
- Programmable parity (even, odd, and no parity)
- Hardware flow control support for request to send ($\overline{\text{RTS}}$) and clear to send ($\overline{\text{CTS}}$) signals
- Edge-selectable $\overline{\text{RTS}}$ and edge-detect interrupts
- Status flags for various flow control and FIFO states
- Serial IR interface low-speed, IrDA-compatible (up to 115.2 Kbit/s).
- Voting logic for improved noise immunity (16× oversampling)
- Transmitter FIFO empty interrupt suppression
- UART internal clocks enable/disable
- Auto baud rate detection (up to 115.2 Kbit/s)
- Receiver and transmitter enable/disable for power saving
- DCE/DTE capability
- $\overline{\text{RTS}}$, IrDA asynchronous wake (AIRINT), receive asynchronous wake (AWAKE), $\overline{\text{RI}}$ (DTE only), $\overline{\text{DCD}}$ (DTE only), $\overline{\text{DTR}}$ (DCE only) and $\overline{\text{DSR}}$ (DTE only) interrupts wake the processor from STOP mode
- Maskable interrupts
- Two DMA Requests (TxFIFO DMA Request and RxFIFO DMA Request)
- Escape character sequence detection
- Software reset ($\overline{\text{SRST}}$)
- Two independent, 32-entry FIFOs for transmit and receive
- The peripheral clock can be totally asynchronous with the module clock. The module clock determines baud rate. This allows frequency scaling on peripheral clock (such as during DVFS mode) while remaining the module clock frequency and baud rate.

59.1.2 Modes of Operation

The UART uses the following modes of operation:

- Serial RS-232 NRZ format
- IrDA

59.2 External Signals

Table 59-1 lists the conventions for representing signals.

Table 59-1. Module Signal Conventions

Category	Convention	Example(s)
Off-chip signal	Uppercase (all capital letters)	TXD
Internal signal[1]	Lowercase italics	*core_int*
Active low signal	_B (_b) suffix or overbar	RESET_EN_B or $\overline{\text{RESET\_EN}}$
Range of bussed or commonly named signals	Beginning and end points of the range are: • Separated by a colon. • Surrounded by square brackets.	ADDR[31:0] CSE_B[7:0] or $\overline{\text{CSE}}$[7:0]
Individual signal in a range of bussed or commonly named signals	Individual number in the range appears without a colon or square brackets	ADDR31 CSE0_B or $\overline{\text{CSE0}}$

1 Internal signals are for reference only in descriptions of internal module or SoC functionality.

59.2.1 Detailed Signal Descriptions

Table 59-2 describes all UART signals that connect off-chip.

Table 59-2. Off-Chip Module Signals

Signal name	I/O	Active state	Description	Reset state
Serial/IrDA Signals				
RXD	I		Serial / infrared data receive	—
TXD	O		Serial/infrared data transmit	High
Modem Control Signals				
$\overline{\text{CTS}}$	O	Low	Clear to send	High
$\overline{\text{RTS}}$	I	Low	Request to send	
$\overline{\text{DSR}}$	I/O	Low	Data set ready	High
$\overline{\text{DCD}}$	I/O	Low	Data carrier detected	High
$\overline{\text{DTR}}$	I/O	Low	Data terminal ready	
$\overline{\text{RI}}$	I/O	Low	Ring indicator	High
Interrupts				
$\overline{\textit{interrupt\_uart}}$	O	Low	UART interrupt	High
DMA Requests				
$\overline{\textit{dma\_req\_rx}}$	O	Low	Receiver DMA request	High
$\overline{\textit{dma\_req\_tx}}$	O	Low	Transmitter DMA request	High

Table 59-2. Off-Chip Module Signals (continued)

Signal name	I/O	Active state	Description	Reset state
Clocks				
peripheral_clock	I		Peripheral clock	—
module_clock	I		Clock source for the module's logic	—
Special Signals				
stop_req	I	High	Module stop mode	—
doze_req	I	High	Module doze mode	—

59.2.1.1 Serial/IrDA Signals

The serial/IrDA signals are as follows:

- RXD (Data Receive)—Input asynchronous data receive in Serial and IrDA modes.
- TXD (Data Transmit)—Output asynchronous data transmit in Serial and IrDA modes.

59.2.1.2 Modem Control Signals

The modem control signals are as follows:

- $\overline{\text{CTS}}$ (Clear To Send)
  - — Output in DCE and DTE mode
  - — Informs the remote modem that UART is ready to receive data
- $\overline{\text{RTS}}$ (Request To Send)
  - — Input in DCE and DTE mode
  - — Informs UART that remote modem is ready to receive data
- $\overline{\text{DSR}}$ (Data Set Ready)
  - — Input in DTE mode. Indicates to UART that remote modem is operational.
  - — Output in DCE mode. Indicates to remote modem that UART is operational.
- $\overline{\text{DCD}}$ (Data Carrier Detected)
  - — Input in DTE mode. Indicates to UART that a good carrier is being received from the remote modem.
  - — Output in DCE mode. Indicates to remote device that a good carrier is being received from the UART.
- $\overline{\text{DTR}}$ (Data Terminal Ready)
  - — Input in DCE mode. Indicates to UART (in DCE mode) that remote device (in DTE mode) is operational.
  - — Output in DTE mode. Indicates to remote modem (in DCE mode) that UART (in DTE mode) is operational.

- $\overline{RI}$ (Ring Indicator)
  - Input in DTE mode. Indicates to UART that remote modem is detecting a ringing tone.
  - Output in DCE mode. Indicates to remote device that UART is detecting a ringing tone.

59.2.1.3 Interrupt Signals

UART Interrupt, $\overline{interrupt\_uart}$, is the interrupt signal for the output interrupt request.

59.2.1.4 DMA Request Signals

The DMA request signals are as follows:

- $\overline{dma\_req\_rx}$ (Receiver DMA Request)—Output DMA Request signal for receiver interface.
- $\overline{dma\_req\_tx}$ (Transmitter DMA Request)—Output DMA Request signal for transmitter interface. Set at 0 when TXDMAEN (UCR1[3]) is at 1 and TRDY (USR1[13]) is also at 1.

59.2.1.5 Clock Signals

The clock signals are as follows:

- *peripheral_clock* (Peripheral Clock)—See Section 59.4.2, Clocks" for more information about *peripheral_clock*.
- *module_clock* (Module Clock)—See Section 59.4.2, Clocks" for more information about *module_clock*.

59.2.1.6 Special Signals

Special signals are as follows:

- *stop_req* (Stop Mode)
  - Input stop mode
  - Indicates UART that MCU is going to enter in Stop Mode and clocks are going to stop running
  - See Section 59.4.8, Low Power Modes" for more information about Stop Mode.
- *doze_req* (Doze Mode)
  - Input doze mode
  - MCU requests UART to switch in doze mode (power saving mode)
  - See Section 59.4.8, Low Power Modes" for more information about Doze Mode.

59.3 Memory Map and Register Definition

This section includes the module memory map and detailed descriptions of all registers.

59.3.1 Memory Map

Table 59-3 is the UART memory map.

Table 59-3. UART Memory Map

Offset Address (Register Abbreviation)	Register	Access	Reset Value	Section/Page
0x0000 (URXD)	UART Receiver Register	R	00– –	59.3.3.1/59-10

0x00ac (UBRC)	UART Baud Rate Count Register	R	0004	59.3.3.14/59-30
0x00b0 (ONEMS)	UART One Millisecond Register	R/W	000000	59.3.3.15/59-31
0x00b4 (UTS)	UART Test Register	R/W	0060	59.3.3.16/59-32

59.3.2 Register Summary

Table 59-5 is the register summary table.

The UART supports 8-bit, 16-bit and 32-bit accesses to 32-bit memory-mapped addresses. Any access to unmapped memory location yields a transfer error.

All the memory mapped registers are 32 bits wide. However, the 16 MSB are not used for all of the registers except the ONEMS register:

- For 32-bits write access, the 16 MSB is not taken into account for all of the registers except the ONEMS.
- For 32-bits read access the 16 MSB is read as 0 for all of the registers except the ONEMS.

The ONEMS register is expanded from 16 bits to 24 bits in order to support the high frequency of the BRM internal clock *ref_clk* (*module_clock* after divider). The ONEMS register can be accessed in the way of 8-bits, 16-bits or 32-bits.

- For 32-bits write access, the 8 MSB of the ONEMS will not be taken into account.
- For 32-bits read access, the 8 MSB of the ONEMS will be read as 0.

All registers except the ONEMS described in this section are for 16 LSB. The ONEMS register is for 24 LSB.

Figure 59-2 shows the key to the register fields and Table 59-4 shows the register figure conventions.

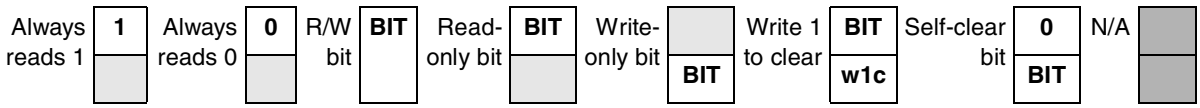

Figure 59-2. Key to Register Fields

Table 59-4. Register Figure Convention

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 59-5 shows the UART register summary.

59.3.3 Register Descriptions

This section provides detailed descriptions of the UART registers.

59.3.3.1 UART Receiver Register (URXD)

See Figure 59-3 for illustration of valid bits in the UART Receiver Register and Table 59-6 for description of the bit fields.

0x0000 (URXD) Access: User read

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 59-3. UART Receiver Register

Table 59-6. UART Receiver Register Field Descriptions

Field	Description
31–16	Reserved
15 CHARRDY	Character Ready. This read-only bit indicates an invalid read when the FIFO becomes empty and software tries to read the same old data. This bit should not be used for polling for data written to the RX FIFO. 0 Character in RX_DATA field and associated flags are invalid. 1 Character in RX_DATA field and associated flags valid and ready for reading.
14 ERR	Error Detect. Indicates whether the character present in the RX_DATA field has an error (OVRRUN, FRMERR, BRK or PRERR) status. The ERR bit is updated and valid for each received character. 0 No error status was detected 1 An error status was detected
13 OVRRUN	Receiver Overrun. This read-only bit, when HIGH, indicates that the corresponding character was stored in the last position (32nd) of the Rx FIFO. Even if a 33rd character has not been detected, this bit will be set to ‘1’ for the 32nd character. 0 No RxFIFO overrun was detected 1 A RxFIFO overrun was detected
12 FRMERR	Frame Error. Indicates whether the current character had a framing error (a missing stop bit) and is possibly corrupted. FRMERR is updated for each character read from the RxFIFO. 0 The current character has no framing error 1 The current character has a framing error
11 BRK	BREAK Detect. Indicates whether the current character was detected as a BREAK character. The data bits and the stop bit are all 0. The FRMERR bit is set when BRK is set. When odd parity is selected, PRERR is also set when BRK is set. BRK is valid for each character read from the RxFIFO. 0 The current character is not a BREAK character 1 The current character is a BREAK character
10 PRERR	Parity Error. Indicates whether the current character was detected with a parity error and is possibly corrupted. PRERR is updated for each character read from the RxFIFO. When parity is disabled, PRERR always reads as 0. 0 = No parity error was detected for data in the RX_DATA field 1 = A parity error was detected for data in the RX_DATA field
9–8	Reserved
7–0 RX_DATA	Received Data. Holds the received character. In 7-bit mode, the most significant bit (MSB) is forced to 0. In 8-bit mode, all bits are active.

NOTE

The UART will yield a transfer error on the peripheral bus when core is reading URXD register with receive interface disabled (RXEN = 0 or UARTEN = 0).

59.3.3.2 UART Transmitter Register (UTXD)

See Figure 59-4 for illustration of valid bits in the UART Transmitter Register and Table 59-7 for description of the bit fields.

0x0040 (UTXD) Access: User write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0	0	0	0	0	0	0	0								
W									TX_DATA							
RESET	0	0	0	0	0	0	0	0	—	—	—	—	—	—	—	—

Figure 59-4. UART Transmitter Register

Table 59-7. UART Transmitter Register Field Descriptions

Field	Description
31–16	Reserved
15–8	Reserved
7–0 TX_DATA	Transmit Data. Holds the parallel transmit data inputs. In 7-bit mode, D7 is ignored. In 8-bit mode, all bits are used. Data is transmitted least significant bit (LSB) first. A new character is transmitted when the TX_DATA field is written. The TX_DATA field must be written only when the TRDY bit is high to ensure that corrupted data is not sent.

NOTE

The UART will yield a transfer error on the peripheral bus when core is writing into URXD register with transmit interface disabled (TXEN=0 or UARTEN=0).

Memory space between URXD and UTXD registers is reserved. Any read or write access to this space will be considered as an invalid access and yield a transfer error.

59.3.3.3 UART Control Register 1 (UCR1)

See Figure 59-5 for illustration of valid bits in the UART Control Register 1 and Table 59-8 for description of the bit fields.

0x0080 (UCR1) Access: User read/write

Figure 59-5. UART Control Register 1

Table 59-8. UART Control Register 1 Field Descriptions

Field	Description
31–16	Reserved
15 ADEN	Automatic Baud Rate Detection Interrupt Enable. Enables/Disables the automatic baud rate detect complete (ADET) bit to generate an interrupt ($\overline{interrupt\_uart}$ = 0). 0 Disable the automatic baud rate detection interrupt 1 Enable the automatic baud rate detection interrupt
14 ADBR	Automatic Detection of Baud Rate. Enables/Disables automatic baud rate detection. When the ADBR bit is set and the ADET bit is cleared, the receiver detects the incoming baud rate automatically. The ADET flag is set when the receiver verifies that the incoming baud rate is detected properly by detecting an ASCII character “A” or “a” (0x61 or 0x41). 0 Disable automatic detection of baud rate 1 Enable automatic detection of baud rate
13 TRDYEN	Transmitter Ready Interrupt Enable. Enables/Disables the transmitter Ready Interrupt (TRDY) when the transmitter has one or more slots available in the TxFIFO. The fill level in the TXFIFO at which an interrupt is generated is controlled by TxTL bits. When TRDYEN is negated, the transmitter ready interrupt is disabled. **Note:** An interrupt will be issued as long as TRDYEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TRDY interrupt. 0 Disable the transmitter ready interrupt 1 Enable the transmitter ready interrupt
12 IDEN	Idle Condition Detected Interrupt Enable. Enables/Disables the IDLE bit to generate an interrupt ($\overline{interrupt\_uart}$ = 0). 0 Disable the IDLE interrupt 1 Enable the IDLE interrupt

Table 59-8. UART Control Register 1 Field Descriptions (continued)

Field	Description
11–10 ICD	Idle Condition Detect. Controls the number of frames RXD is allowed to be idle before an idle condition is reported. 00 Idle for more than 4 frames 01 Idle for more than 8 frames 10 Idle for more than 16 frames 11 Idle for more than 32 frames
9 RRDYEN	Receiver Ready Interrupt Enable. Enables/Disables the RRDY interrupt when the RxFIFO contains data. The fill level in the RxFIFO at which an interrupt is generated is controlled by the RXTL bits. When RRDYEN is negated, the receiver ready interrupt is disabled. 0 Disables the RRDY interrupt 1 Enables the RRDY interrupt
8 RXDMAEN	Receive Ready DMA Enable. Enables/Disables the receive DMA request $\overline{dma\_req\_rx}$ when the receiver has data in the RxFIFO. The fill level in the RxFIFO at which a DMA request is generated is controlled by the RXTL bits. When negated, the receive DMA request is disabled. 0 Disable DMA request 1 Enable DMA request
7 IREN	Infrared Interface Enable. Enables/Disables the IR interface. Refer to the IR interface description in Section 59.4.7, Infrared Interface," for more information. 0 Disable the IR interface 1 Enable the IR interface
6 TXMPTYEN	Transmitter Empty Interrupt Enable. Enables/Disables the transmitter FIFO empty (TXFE) interrupt. $\overline{interrupt\_uart}$. When negated, the TXFE interrupt is disabled. **Note:** An interrupt will be issued as long as TXMPTYEN and TXFE are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXFE interrupt. 0 Disable the transmitter FIFO empty interrupt 1 Enable the transmitter FIFO empty interrupt
5 RTSDEN	RTS Delta Interrupt Enable. Enables/Disables the RTSD interrupt. The current status of the $\overline{RTS}$ pin is read in the RTSS bit. 0 Disable RTSD interrupt 1 Enable RTSD interrupt
4 SNDBRK	Send BREAK. Forces the transmitter to send a BREAK character. The transmitter finishes sending the character in progress (if any) and sends BREAK characters until SNDBRK is reset. Because the transmitter samples SNDBRK after every bit is transmitted, it is important that SNDBRK is asserted high for a sufficient period of time to generate a valid BREAK. After the BREAK transmission completes, the UART transmits 2 mark bits. The user can continue to fill the TxFIFO and any characters remaining are transmitted when the BREAK is terminated. 0 Do not send a BREAK character 1 Send a BREAK character (continuous 0s)
3 TXDMAEN	Transmitter Ready DMA Enable. Enables/Disables the transmit DMA request $\overline{dma\_req\_tx}$ when the transmitter has one or more slots available in the TxFIFO. The fill level in the TxFIFO that generates the $\overline{dma\_req\_tx}$ is controlled by the TXTL bits. **Note:** A DMA request will be issued as long as TXDMAEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the transmit DMA request. 0 Disable transmit DMA request 1 Enable transmit DMA request

Table 59-8. UART Control Register 1 Field Descriptions (continued)

Field	Description
2 ATDMAEN	Aging DMA Timer Enable. Enables/Disables the receive DMA request *dma_req_rx* for the aging timer interrupt (triggered with AGTIM flag in USR1[8]). 0 Disable AGTIM DMA request 1 Enable AGTIM DMA request
1 DOZE	DOZE. Determines the UART enable condition in the DOZE state. When *doze_req* input pin is at '1', (the CPU executes a doze instruction and the system is placed in the Doze State), the DOZE bit affects operation of the UART. While in the Doze State, if this bit is asserted, the UART is disabled. Refer to the description in Section 59.4.8, Low Power Modes." 0 The UART is enabled when in DOZE state 1 The UART is disabled when in DOZE state
0 UARTEN	UART Enable. Enables/Disables the UART. If UARTEN is negated in the middle of a transmission, the transmitter stops and pulls the TXD line to a logic 1. UARTEN must be set to 1 before any access to UTXD and URXD registers, otherwise a transfer error is returned. This bit can be set to 1 along with other bits in this register. There is no restriction to the sequence of programing this bit and other control registers. 0 Disable the UART 1 Enable the UART

59.3.3.4 UART Control Register 2 (UCR2)

See Figure 59-6 for illustration of valid bits in the UART Control Register 2 and Table 59-9 for description of the bit fields.

0x0084 (UCR2) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	ESCI	IRTS	CTSC	CTS	ESCEN	RTEC		PREN	PROE	STPB	WS	RTSEN	ATEN	TXEN	RXEN	SRST
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 59-6. UART Control Register 2

Table 59-9. UART Control Register 2 Field Descriptions

Name	Description
31–16	Reserved
15 ESCI	Escape Sequence Interrupt Enable. Enables/Disables the ESCF bit to generate an interrupt. 0 Disable the escape sequence interrupt 1 Enable the escape sequence interrupt

Table 59-9. UART Control Register 2 Field Descriptions (continued)

Name	Description
14 IRTS	Ignore RTS Pin. Forces the RTS input signal presented to the transmitter to always be asserted (set to low), effectively ignoring the external pin. When in this mode, the RTS pin serves as a general purpose input. 0 Transmit only when the RTS pin is asserted 1 Ignore the RTS pin
13 CTSC	CTS Pin Control. Controls the operation of the $\overline{CTS}$ output pin. When CTSC is asserted, the $\overline{CTS}$ output pin is controlled by the receiver. When the RxFIFO is filled to the level of the programmed trigger level and the start bit of the overflowing character (TRIGGER LEVEL + 1) is validated, the $\overline{CTS}$ output pin is negated to indicate to the far-end transmitter to stop transmitting. When the trigger level is programmed for less than 32, the receiver continues to receive data until the RxFIFO is full. When the CTSC bit is negated, the $\overline{CTS}$ output pin is controlled by the CTS bit. On reset, because CTSC is cleared to 0, the $\overline{CTS}$ pin is controlled by the CTS bit, which again is cleared to 0 on reset. This means that on reset the $\overline{CTS}$ signal is negated. 0 The $\overline{CTS}$ pin is controlled by the CTS bit 1 The $\overline{CTS}$ pin is controlled by the receiver
12 CTS	Clear to Send. Controls the $\overline{CTS}$ pin when the CTSC bit is negated. CTS has no function when CTSC is asserted. 0 The $\overline{CTS}$ pin is high (inactive) 1 The $\overline{CTS}$ pin is low (active)
11 ESCEN	Escape Enable. Enables/Disables the escape sequence detection logic. 0 Disable escape sequence detection 1 Enable escape sequence detection
10-9 RTEC	Request to Send Edge Control. Selects the edge that triggers the RTS interrupt. This has no effect on the RTS delta interrupt. RTEC has an effect only when RTSEN = 1 (see Table 59-23). 00 Trigger interrupt on a rising edge 01 Trigger interrupt on a falling edge 1X Trigger interrupt on any edge
8 PREN	Parity Enable. Enables/Disables the parity generator in the transmitter and parity checker in the receiver. When PREN is asserted, the parity generator and checker are enabled, and disabled when PREN is negated. 0 Disable parity generator and checker 1 Enable parity generator and checker
7 PROE	Parity Odd/Even. Controls the sense of the parity generator and checker. When PROE is high, odd parity is generated and expected. When PROE is low, even parity is generated and expected. PROE has no function if PREN is low. 0 Even parity 1 Odd parity
6 STPB	Stop. Controls the number of stop bits after a character. When STPB is low, 1 stop bit is sent. When STPB is high, 2 stop bits are sent. STPB also affects the receiver. 0 The transmitter sends 1 stop bit. The receiver expects 1 or more stop bits. 1 The transmitter sends 2 stop bits. The receiver expects 2 or more stop bits.
5 WS	Word Size. Controls the character length. When WS is high, the transmitter and receiver are in 8-bit mode. When WS is low, they are in 7-bit mode. The transmitter ignores bit 7 and the receiver sets bit 7 to 0. WS can be changed in-between transmission (reception) of characters, however not when a transmission (reception) is in progress, in which case the length of the current character being transmitted (received) is unpredictable. 0 7-bit transmit and receive character length (not including START, STOP or PARITY bits) 1 8-bit transmit and receive character length (not including START, STOP or PARITY bits)

Table 59-9. UART Control Register 2 Field Descriptions (continued)

Name	Description
4 RTSEN	Request to Send Interrupt Enable. Controls the RTS edge sensitive interrupt. When RTSEN is asserted and the programmed edge is detected on the $\overline{RTS}$ pin (the RTSF bit is asserted), an interrupt will be generated on the *interrupt_uart* pin. (see Table 59-23). 0 Disable request to send interrupt 1 Enable request to send interrupt
3 ATEN	Aging Timer Enable. This bit is used to enable the aging timer interrupt (triggered with AGTIM) 0 AGTIM interrupt disabled 1 AGTIM interrupt enabled
2 TXEN	Transmitter Enable. Enables/Disables the transmitter. When TXEN is negated the transmitter is disabled and idle. When the UARTEN and TXEN bits are set the transmitter is enabled. If TXEN is negated in the middle of a transmission, the UART disables the transmitter immediately, and starts marking 1s. The transmitter FIFO cannot be written when this bit is cleared. 0 Disable the transmitter 1 Enable the transmitter
1 RXEN	Receiver Enable. Enables/Disables the receiver. When the receiver is enabled, if the RXD input is already low, the receiver does not recognize BREAK characters, because it requires a valid 1-to-0 transition before it can accept any character. 0 Disable the receiver 1 Enable the receiver
0 $\overline{SRST}$	Software Reset. Once the software writes 0 to $\overline{SRST}$, the software reset remains active for 4 *module_clock* cycles before the hardware deasserts $\overline{SRST}$. The software can only write 0 to $\overline{SRST}$. Writing 1 to $\overline{SRST}$ is ignored. 0 Reset the transmit and receive state machines, all FIFOs and register USR1, USR2, UBIR, UBMR, UBRC , URXD, UTXD and UTS[6–3]. 1 No reset

59.3.3.5 UART Control Register 3 (UCR3)

See Figure 59-7 for illustration of valid bits in the UART Control Register 3 and Table 59-10 for description of the bit fields.

0x0088 (UCR3) Access: User read/write

Figure 59-7. UART Control Register 3

Table 59-10. UART Control Register 3 Field Descriptions

Name	Description
31–16	Reserved
15–14 DPEC	DTR/DSR Interrupt Edge Control. These bits control the edge of $\overline{\text{DTR}}$ (DCE) or $\overline{\text{DSR}}$ (DTE) on which an interrupt will be generated. An interrupt will only be generated if the DTREN bit is set. 00 interrupt generated on rising edge 01 interrupt generated on falling edge 1X interrupt generated on either edge
13 DTREN	Data Terminal Ready Interrupt Enable. When this bit is set, it will enable the status bit DTRF (USR2 [13]) (DTR/DSR edge sensitive interrupt) to cause an interrupt. 0 Data Terminal Ready Interrupt Disabled 1 Data Terminal Ready Interrupt Enabled
12 PARERREN	Parity Error Interrupt Enable. Enables/Disables the interrupt. When asserted, PARERREN causes the PARITYERR bit to generate an interrupt. 0 Disable the parity error interrupt 1 Enable the parity error interrupt
11 FRAERREN	Frame Error Interrupt Enable. Enables/Disables the interrupt. When asserted, FRAERREN causes the FRAMERR bit to generate an interrupt. 0 Disable the frame error interrupt 1 Enable the frame error interrupt
10 DSR	Data Set Ready. This bit is used by software to control the DSR/DTR output pin for the modem interface. In DCE mode it applies to $\overline{\text{DSR}}$ and in DTE mode it applies to $\overline{\text{DTR}}$. 0 DSR/ DTR pin is logic zero 1 DSR/ DTR pin is logic one
9 DCD	Data Carrier Detect. In DCE mode this bit is used by software to control the $\overline{\text{DCD}}$ output pin for the modem interface. In DTE mode, when this bit is set, it will enable the status bit DCDDELT (USR2 (6)) to cause an interrupt. 0 $\overline{\text{DCD}}$ pin is logic zero (DCE mode) 1 $\overline{\text{DCD}}$ pin is logic one (DCE mode) 0 DCDDELT interrupt disabled (DTE mode) 1 DCDDELT interrupt enabled (DTE mode)
8 RI	Ring Indicator. In DCE mode this bit is used by software to control the $\overline{\text{RI}}$ output pin for the modem interface. In DTE mode, when this bit is set, it will enable the status bit RIDELT (USR2 (10)) to cause an interrupt. 0 $\overline{\text{RI}}$ pin is logic zero (DCE mode) 1 $\overline{\text{RI}}$ pin is logic one (DCE mode) 0 RIDELT interrupt disabled (DTE mode) 1 RIDELT interrupt enabled (DTE mode)
7 ADNIMP	Autobaud Detection Not Improved—. Disables new features of autobaud detection (refer to Section 59.4.5.6.2, Baud Rate Automatic Detection Protocol Improved," for more details). 0 Autobaud detection new features selected 1 Keep old autobaud detection mechanism
6 RXDSEN	Receive Status Interrupt Enable. Controls the receive status interrupt ($\overline{\textit{interrupt\_uart}}$). When this bit is enabled and RXDS status bit is set, the interrupt $\overline{\textit{interrupt\_uart}}$ will be generated. 0 Disable the RXDS interrupt 1 Enable the RXDS interrupt
5 AIRINTEN	Asynchronous IR WAKE Interrupt Enable. Controls the asynchronous IR WAKE interrupt. An interrupt is generated when AIRINTEN is asserted and a pulse is detected on the RXD pin. 0 Disable the AIRINT interrupt 1 Enable the AIRINT interrupt

Table 59-10. UART Control Register 3 Field Descriptions (continued)

Name	Description
4 AWAKEN	Asynchronous WAKE Interrupt Enable. Controls the asynchronous WAKE interrupt. An interrupt is generated when AWAKEN is asserted and a falling edge is detected on the RXD pin. 0 Disable the AWAKE interrupt 1 Enable the AWAKE interrupt
3 DTRDEN	Data Terminal Ready Delta Enable. Enables / Disables the asynchronous DTRD interrupt. When DTRDEN is asserted and an edge (rising or falling) is detected on $\overline{\text{DTR}}$ (in DCE mode) or on $\overline{\text{DSR}}$ (in DTE mode), then an interrupt is generated. 0 Disable DTRD interrupt 1 Enable DTRD interrupt
2 RXDMUXSEL	RXD Muxed Input Selected. Selects proper input pins for serial and Infrared input signal. **Note:** In this chip, UARTs are used in MUXED mode, so that this bit should always be set. 0 Input pin RXD is not used for serial and IR interfaces 1 Input pin RXD is used for serial and IR interfaces
1 INVT	Inverted Infrared Transmission. Sets the active level for the transmission. When INVT is cleared, the infrared logic block transmits a positive IR 3/16 pulse for all 0s and 0s are transmitted for 1s. When INVT is set (INVT = 1), the infrared logic block transmits an active low or negative infrared 3/16 pulse for all 0s and 1s are transmitted for 1s. 0 Active low transmission 1 Active high transmission.
0 ACIEN	Autobaud Counter Interrupt Enable. This bit is used to enable the autobaud counter stopped interrupt (triggered with ACST (USR2[11]). 0 ACST interrupt disabled 1 ACST interrupt enabled

59.3.3.6 UART Control Register 4 (UCR4)

See Figure 59-8 for illustration of valid bits in the UART Control Register 4 and Table 59-11 for description of the bit fields.

0x008c (UCR4) Access: User read/write

Figure 59-8. UART Control Register 4

Table 59-11. UART Control Register 4 Field Descriptions

Name	Description
31–16	Reserved
15–10 CTSTL	CTS Trigger Level. Controls the threshold at which the $\overline{CTS}$ pin is deasserted by the RxFIFO. After the trigger level is reached and the $\overline{CTS}$ pin is deasserted, the RxFIFO continues to receive data until it is full. The CTSTL bits are encoded as shown in the Settings column. 000000 0 characters received 000001 1 characters in the RxFIFO ... ... 100000 32 characters in the RxFIFO (maximum) All Other Settings Reserved
9 INVR	Inverted Infrared Reception. Determines the logic level for the detection. When cleared, the infrared logic block expects an active low or negative IR 3/16 pulse for 0s and 1s are expected for 1s. When INVR is set (INVR1), the infrared logic block expects an active high or positive IR 3/16 pulse for 0s and 0s are expected for 1s. 0 Active low detection 1 Active high detection
8 ENIRI	Serial Infrared Interrupt Enable. Enables/Disables the serial infrared interrupt. 0 Serial infrared Interrupt disabled 1 Serial infrared Interrupt enabled
7 WKEN	WAKE Interrupt Enable. Enables/Disables the WAKE bit to generate an interrupt. The WAKE bit is set at the detection of a start bit by the receiver. 0 Disable the WAKE interrupt 1 Enable the WAKE interrupt
6 IDDMAEN	DMA IDLE Condition Detected Interrupt Enable Enables/Disables the receive DMA request $\overline{dma\_req\_rx}$ for the IDLE interrupt (triggered with IDLE flag in USR2[12]). 0 DMA IDLE interrupt disabled 1 DMA IDLE interrupt enabled
5 IRSC	IR Special Case. Selects the clock for the vote logic. When set, IRSC switches the vote logic clock from the sampling clock to the UART reference clock. The IR pulses are counted a predetermined amount of time depending on the reference frequency. Refer to Section 59.4.7.3, InfraRed Special Case (IRSC) Bit. 0 The vote logic uses the sampling clock (16x baud rate) for normal operation 1 The vote logic uses the UART reference clock
4 LPBYP	Low Power Bypass. Allows to bypass the low power new features in UART. To use during debug phase. 0 Low power features enabled 1 Low power features disabled
3 TCEN	Transmit Complete Interrupt Enable. Enables/Disables the TXDC bit to generate an interrupt ($\overline{interrupt\_uart}$ = 0) **Note:** An interrupt will be issued as long as TCEN and TXDC are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXDC interrupt. 0 Disable TXDC interrupt 1 Enable TXDC interrupt
2 BKEN	BREAK Condition Detected Interrupt Enable. Enables/Disables the BRCD bit to generate an interrupt. 0 Disable the BRCD interrupt 1 Enable the BRCD interrupt

Table 59-11. UART Control Register 4 Field Descriptions (continued)

Name	Description
1 OREN	Receiver Overrun Interrupt Enable. Enables/Disables the ORE bit to generate an interrupt. 0 Disable ORE interrupt 1 Enable ORE interrupt
0 DREN	Receive Data Ready Interrupt Enable. Enables/Disables the RDR bit to generate an interrupt. 0 Disable RDR interrupt 1 Enable RDR interrupt

59.3.3.7 UART FIFO Control Register (UFCR)

See Figure 59-9 for illustration of valid bits in the UART FIFO Control Register and Table 59-12 for description of the bit fields.

Figure 59-9. UART FIFO Control Register

Table 59-12. UART FIFO Control Register Field Descriptions

Name	Description
31–16	Reserved
15–10 TXTL	Transmitter Trigger Level. Controls the threshold at which a maskable interrupt is generated by the TxFIFO. A maskable interrupt is generated whenever the data level in the TxFIFO falls below the selected threshold. The bits are encoded as shown in the Settings column. 000000 Reserved 000001 Reserved 000010 TxFIFO has 2 or fewer characters ... ... 011111 TxFIFO has 31 or fewer characters 100000 TxFIFO has 32 characters (maximum) All Other Settings Reserved

Table 59-12. UART FIFO Control Register Field Descriptions (continued)

Name	Description
9–7 RFDIV	Reference Frequency Divider. Controls the divide ratio for the reference clock. The input clock is *module_clock*. The output from the divider is *ref_clk* which is used by BRM to create the 16x baud rate oversampling clock (*brm_clk*). 000 Divide input clock by 6 001 Divide input clock by 5 010 Divide input clock by 4 011 Divide input clock by 3 100 Divide input clock by 2 101 Divide input clock by 1 110 Divide input clock by 7 111 Reserved
6 DCEDTE	DCE/DTE mode select. Selects data communication equipment (DCE) or data terminal equipment (DTE) mode. This bit controls the pin direction of the bidirectional modem pins DSR, DCD, DTR and RI. 0 DCE mode selected 1 DTE mode selected
5–0 RXTL	Receiver Trigger Level. Controls the threshold at which a maskable interrupt is generated by the RxFIFO. A maskable interrupt is generated whenever the data level in the RxFIFO reaches the selected threshold. The RXTL bits are encoded as shown in the Settings column. 000000 0 characters received 000001 RxFIFO has 1 character ... ... 011111 RxFIFO has 31 characters 100000 RxFIFO has 32 characters (maximum) All Other Settings Reserved

59.3.3.8 UART Status Register 1 (USR1)

See Figure 59-10 for illustration of valid bits in the UART Status Register 1 and Table 59-13 for description of the bit fields.

Figure 59-10. UART Status Register 1

Table 59-13. UART Status Register 1 Field Descriptions

Name	Description
31–16	Reserved
15 PARITYERR	Parity Error Interrupt Flag. Indicates a parity error is detected. PARITYERR is cleared by writing 1 to it. Writing 0 to PARITYERR has no effect. When parity is disabled, PARITYERR always reads 0. At reset, PARITYERR is set to 0. 0 No parity error detected 1 Parity error detected (write 1 to clear)
14 RTSS	$\overline{\text{RTS}}$ Pin Status. Indicates the current status of the $\overline{\text{RTS}}$ pin. A “snapshot” of the pin is taken immediately before RTSS is presented to the data bus. RTSS cannot be cleared because all writes to RTSS are ignored. At reset, RTSS is set to 0. 0 The $\overline{\text{RTS}}$ pin is high (inactive) 1 The $\overline{\text{RTS}}$ pin is low (active)
13 TRDY	Transmitter Ready Interrupt / DMA Flag. Indicates that the TxFIFO emptied below its target threshold and requires data. TRDY is automatically cleared when the data level in the TxFIFO exceeds the threshold set by TXTL bits. At reset, TRDY is set to 1. 0 The transmitter does not require data 1 The transmitter requires data (interrupt posted)
12 RTSD	RTS Delta. Indicates whether the $\overline{\text{RTS}}$ pin changed state. It (RTSD) generates a maskable interrupt. When in STOP mode, RTS assertion sets RTSD and can be used to wake the processor. The current state of the $\overline{\text{RTS}}$ pin is available on the RTSS bit. Clear RTSD by writing 1 to it. Writing 0 to RTSD has no effect. At reset, RTSD is set to 0. 0 $\overline{\text{RTS}}$ pin did not change state since last cleared 1 $\overline{\text{RTS}}$ pin changed state (write 1 to clear)
11 ESCF	Escape Sequence Interrupt Flag. Indicates if an escape sequence was detected. ESCF is asserted when the ESCEN bit is set and an escape sequence is detected in the RxFIFO. Clear ESCF by writing 1 to it. Writing 0 to ESCF has no effect. 0 No escape sequence detected 1 Escape sequence detected (write 1 to clear).
10 FRAMERR	Frame Error Interrupt Flag. Indicates that a frame error is detected. The $\overline{\textit{interrupt\_uart}}$ interrupt will be generated if a frame error is detected and the interrupt is enabled. Clear FRAMERR by writing 1 to it. Writing 0 to FRAMERR has no effect. 0 No frame error detected 1 Frame error detected (write 1 to clear)
9 RRDY	Receiver Ready Interrupt / DMA Flag. Indicates that the RxFIFO data level is above the threshold set by the RXFL bits. (See the RXFL bits description in Table 59-12 for setting the interrupt threshold.) When asserted, RRDY generates a maskable interrupt or DMA request. RRDY is automatically cleared when data level in the RxFIFO goes below the set threshold level. At reset, RRDY is set to 0. 0 No character ready 1 Character(s) ready (interrupt posted)
8 AGTIM	Ageing Timer Interrupt Flag. Indicates that data in the RxFIFO has been idle for a time of 8 character lengths (where a character length consists of 7 or 8 bits, depending on the setting of the WS bit in UCR2, with the bit time corresponding to the baud rate setting) and FIFO data level is less than RxFIFO threshold level (RXTL in the UFCR). Clear by writing a 1 to it. 0 AGTIM is not active 1 AGTIM is active (write 1 to clear)

Table 59-13. UART Status Register 1 Field Descriptions (continued)

Name	Description
7 DTRD	DTR Delta. Indicates whether $\overline{\text{DTR}}$ (in DCE mode) or $\overline{\text{DSR}}$ (in DTE mode) pins changed state. DTRD generates a maskable interrupt if DTRDEN (UCR3[3]) is set. Clear DTRD by writing 1 to it. Writing 0 to DTRD has no effect. 0 $\overline{\text{DTR}}$ (DCE) or $\overline{\text{DSR}}$ (DTE) pin did not change state since last cleared 1 $\overline{\text{DTR}}$ (DCE) or $\overline{\text{DSR}}$ (DTE) pin changed state (write 1 to clear)
6 RXDS	Receiver IDLE Interrupt Flag. Indicates that the receiver state machine is in an IDLE state, the next state is IDLE, and the receive pin is high. RXDS is automatically cleared when a character is received. RXDS is active only when the receiver is enabled. 0 Receive in progress 1 Receiver is IDLE
5 AIRINT	Asynchronous IR WAKE Interrupt Flag. Indicates that the IR WAKE pulse was detected on the RXD pin. Clear AIRINT by writing 1 to it. Writing 0 to AIRINT has no effect. Caution: AIRINT Interrupt flag cannot be used in loopback mode (UTS[12] = 1'b1) as RXD pin will be ignored (see Table 59-21). 0 No pulse was detected on the RXD IrDA pin 1 A pulse was detected on the RXD IrDA pin
4 AWAKE	Asynchronous WAKE Interrupt Flag. Indicates that a falling edge was detected on the RXD pin. Clear AWAKE by writing 1 to it. Writing 0 to AWAKE has no effect. Caution: AWAKE Interrupt flag cannot be used in loopback mode (UTS[12] = 1'b1) as RXD pin will be ignored (see Table 59-21). 0 No falling edge was detected on the RXD Serial pin 1 A falling edge was detected on the RXD Serial pin
3–0	Reserved

59.3.3.9 UART Status Register 2 (USR2)

See Figure 59-11 for illustration of valid bits in the UART Status Register 2 and Table 59-14 for description of the bit fields.

Figure 59-11. UART Status Register 2

Table 59-14. UART Status Register 2 Field Descriptions

Name	Description
31–16	Reserved
15 ADET	Automatic Baud Rate Detect Complete. Indicates that an “A” or “a” was received and that the receiver detected and verified the incoming baud rate. Clear ADET by writing 1 to it. Writing 0 to ADET has no effect. 0 ASCII “A” or “a” was not received 1 ASCII “A” or “a” was received (write 1 to clear)
14 TXFE	Transmit Buffer FIFO Empty. Indicates that the transmit buffer (TxFIFO) is empty. TXFE is cleared automatically when data is written to the TxFIFO. Even though TXFE is high, the transmission might still be in progress. 0 The transmit buffer (TxFIFO) is not empty 1 The transmit buffer (TxFIFO) is empty
13 DTRF	DTR edge triggered interrupt flag. This bit is asserted, when the programmed edge is detected on the $\overline{\text{DTR}}$ pin (DCE mode). or on $\overline{\text{DSR}}$ (DTE mode). This flag can cause an interrupt if DTREN (UCR3[13]) is enabled. 0 Programmed edge not detected on DTR/DSR 1 Programmed edge detected on DTR/DSR (write 1 to clear)
12 IDLE	Idle Condition. Indicates that an idle condition has existed for more than a programmed amount frame (refer to Section 59.4.5.1, Idle Line Detect”). An interrupt can be generated by this IDLE bit if IDEN (UCR1[12]) is enabled. IDLE is cleared by writing 1 to it. Writing 0 to IDLE has no effect. 0 No idle condition detected 1 Idle condition detected (write 1 to clear)
11 ACST	Autobaud Counter Stopped. In autobaud detection (ADBR=1), indicates the counter which determines the baud rate was running and is now stopped. This means either START bit is finished (if ADNIMP=1), or Bit 0 is finished (if ADNIMP=0). Refer to Section , New Autobaud Counter Stopped bit and Interrupt,” for more details. An interrupt can be flagged on $\overline{\textit{interrupt\_uart}}$ if ACIEN=1. 0 Measurement of bit length not finished (in autobaud) 1 Measurement of bit length finished (in autobaud). (write 1 to clear)
10 RIDELT	Ring Indicator Delta. This bit is used in DTE mode to indicate that the Ring Indicator input ($\overline{\text{RI}}$) has changed state. This flag can generate an interrupt if RI (UCR3[8]) is enabled. RIDELT is cleared by writing 1 to it. Writing 0 to RIDELT has no effect. 0 Ring Indicator input has not changed state 1 Ring Indicator input has changed state (write 1 to clear)
9 RIIN	Ring Indicator Input. This bit is used in DTE mode to reflect the status if the Ring Indicator input ($\overline{\text{RI}}$). The Ring Indicator input is used to indicate that a ring has occurred. In DCE mode this bit is always zero. 0 Ring Detected 1 No Ring Detected
8 IRINT	Serial Infrared Interrupt Flag. When an edge is detected on the RXD pin during SIR Mode, this flag will be asserted. This flag can cause an interrupt which can be masked using the control bit ENIRI: UCR4 [8]. 0 no edge detected 1 valid edge detected (write 1 to clear)
7 WAKE	Wake. Indicates the start bit is detected. WAKE can generate an interrupt that can be masked using the WKEN bit. Clear WAKE by writing 1 to it. Writing 0 to WAKE has no effect. 0 start bit not detected 1 start bit detected (write 1 to clear)
6 DCDDELT	Data Carrier Detect Delta. This bit is used in DTE mode to indicate that the Data Carrier Detect input ($\overline{\text{DCD}}$) has changed state. This flag can cause an interrupt if DCD (UCR3[9]) is enabled. When in STOP mode, this bit can be used to wake the processor. In DCE mode this bit is always zero. 0 Data Carrier Detect input has not changed state 1 Data Carrier Detect input has changed state (write 1 to clear)

Table 59-14. UART Status Register 2 Field Descriptions (continued)

Name	Description
5 DCDIN	Data Carrier Detect Input. This bit is used in DTE mode reflect the status of the Data Carrier Detect input ($\overline{DCD}$). The Data Carrier Detect input is used to indicate that a carrier signal has been detected. In DCE mode this bit is always zero. 0 Carrier signal Detected 1 No Carrier signal Detected
4 RTSF	RTS Edge Triggered Interrupt Flag. Indicates if a programmed edge is detected on the $\overline{RTS}$ pin. The RTEC bits select the edge that generates an interrupt (see Table 59-23). RTSF can generate an interrupt that can be masked using the RTSEN bit. Clear RTSF by writing 1 to it. Writing 0 to RTSF has no effect. 0 Programmed edge not detected on $\overline{RTS}$ 1 Programmed edge detected on $\overline{RTS}$ (write 1 to clear)
3 TXDC	Transmitter Complete. Indicates that the transmit buffer (TxFIFO) and Shift Register is empty; therefore the transmission is complete. TXDC is cleared automatically when data is written to the TxFIFO. 0 Transmit is incomplete 1 Transmit is complete
2 BRCD	BREAK Condition Detected. Indicates that a BREAK condition was detected by the receiver. Clear BRCD by writing 1 to it. Writing 0 to BRCD has no effect. 0 No BREAK condition was detected 1 A BREAK condition was detected (write 1 to clear)
1 ORE	Overrun Error. When set to 1, ORE indicates that the receive buffer (RxFIFO) was full (32 chars inside), and a 33rd character has been fully received. This 33rd character has been discarded. Clear ORE by writing 1 to it. Writing 0 to ORE has no effect. 0 No overrun error 1 Overrun error (write 1 to clear)
0 RDR	Receive Data Ready—Indicates that at least 1 character is received and written to the RxFIFO. If the URXD register is read and there is only 1 character in the RxFIFO, RDR is automatically cleared. 0 No receive data ready 1 Receive data ready

59.3.3.10 UART Escape Character Register (UESC)

Figure 59-13. UART Escape Timer Register

Table 59-16. UART Escape Timer Register Field Descriptions

Name	Description
31–12	Reserved
11–0 TIM	UART Escape Timer. Holds the maximum time interval (in ms) allowed between escape characters. The escape timer register is programmable in intervals of 2 ms. Refer to Section 59.4.5.7, Escape Sequence Detection" and Table 59-28 for more information on the UART escape sequence detection. Reset value 0x000 = 2 ms up to 0xFFF = 8.192 s.

59.3.3.12 UART BRM Incremental Register (UBIR)

See Figure 59-14 for illustration of valid bits in the UART BRM Incremental Register and Table 59-17 for description of the bit fields.

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write 0x000F value into the UBIR after finishing detecting baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle[1].

Please note software reset will reset the register to its reset value.

0x00a4 (UBIR) Access: User read/write

Figure 59-14. UART BRM Incremental Register

Table 59-17. UART BRM Incremental Register Field Descriptions

Name	Description
31–16	Reserved
15–0 INC	Incremental Numerator. Holds the numerator value minus one of the BRM ratio (refer to Section 59.4.6, Binary Rate Multiplier (BRM)"). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM will ignore this data until the other register is written to by software. Updating this field using byte accesses is not recommended and is undefined.

1. Note: The write priority in the new design is not same as the original UART. In the original design, software has higher priotiry than hardware when writing this register at the same time.

59.3.3.13 UART BRM Modulator Register (UBMR)

See Figure 59-15 for illustration of valid bits in the UART BRM Modulator Register and Table 59-18 for description of the bit fields.

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write a proper value into the UBMR based on detected baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle[1].

Please note software reset will reset the register to its reset value.

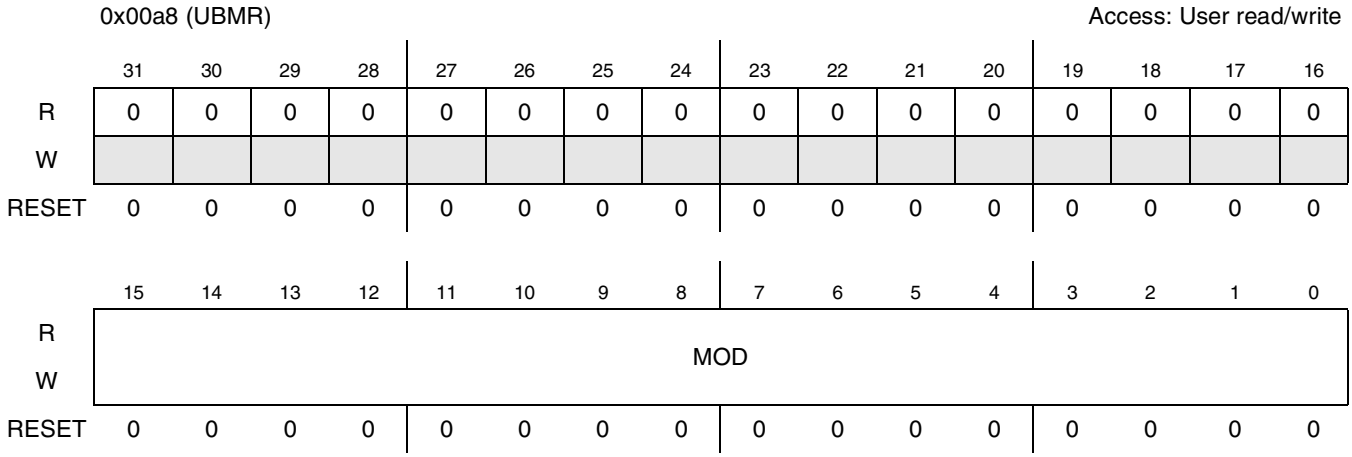

Figure 59-15. UART BRM Modulator Register

Table 59-18. UART BRM Modulator Register Field Descriptions

Name	Description
31–16	Reserved
15–0 MOD	Modulator Denominator. Holds the value of the denominator minus one of the BRM ratio (refer to Section 59.4.6, Binary Rate Multiplier (BRM)"). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM will ignore this data until the other register is written to by software. Updating this register using byte accesses is not recommended and undefined.

1. Note: The write priority in the new design is not same as the original UART. In the orginal design, software has higher priotiry than hardware when writing this register at the same time.

59.3.3.14 UART Baud Rate Count Register (UBRC)

See Figure 59-16 for illustration of valid bits in the UART Baud Rate Count Register and Table 59-19 for description of the bit fields.

Figure 59-16. UART Baud Rate Count Register

Table 59-19. UART Baud Rate Count Register Field Descriptions

Name	Description
31–16	Reserved
15–0 BCNT	Baud Rate Count Register. This read only register is used to count the start bit of the incoming baud rate (if ADNIMP=1), or start bit + bit0 (if ADNIMP=0). When the measurement is done, the Baud Rate Count Register contains the number of UART internal clock cycles (clock after divider) present in an incoming bit. BCNT retains its value until the next Automatic Baud Rate Detection sequence has been initiated. The 16 bit Baud Rate Count register is reset to 4 and stays at hex FFFF in the case of an overflow.

59.3.3.15 UART One Millisecond Register (ONEMS)

See Figure 59-17 for illustration of valid bits in the UART One Millisecond Register and Table 59-20 for description of the bit fields.

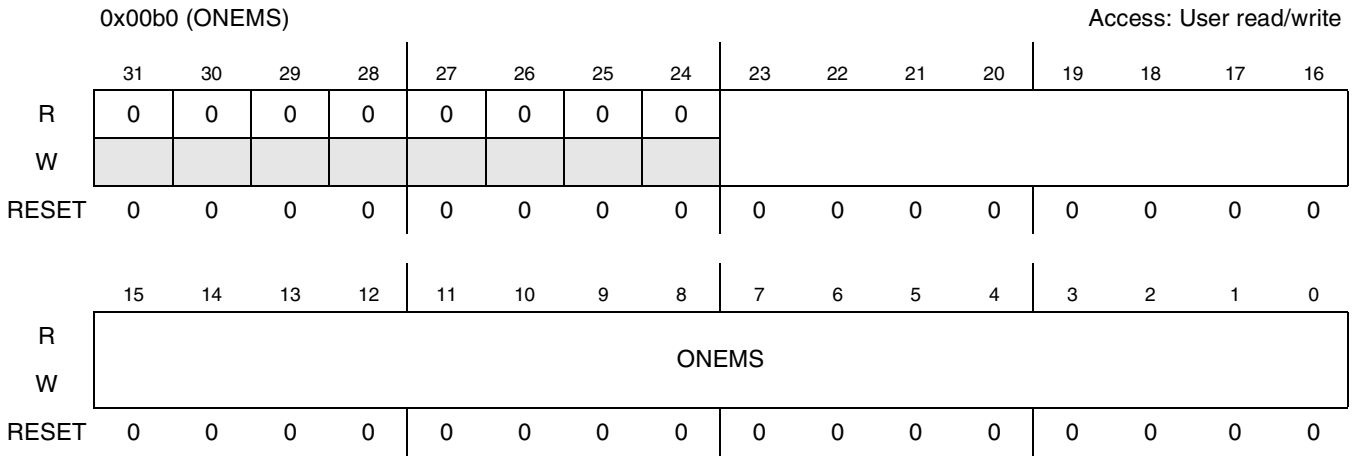

Figure 59-17. UART One Millisecond Register

Table 59-20. UART One Millisecond Register Field Descriptions

Name	Description
31–24	Reserved
23–0 ONEMS	One Millisecond Register. This 24-bit register must contain the value of the UART internal frequency (*ref_clk* in Figure 59-1) divided by 1000. The internal frequency is obtained after the UART BRM internal divider (F(*ref_clk*) = F(*module_clock*) / RFDIV). In fact this register contains the value corresponding to the number of UART BRM internal clock cycles present in one millisecond. The ONEMS (and UTIM) registers value are used in the escape character detection feature (Section 59.4.5.7, Escape Sequence Detection") to count the number of clock cycles left between two escape characters. The ONEMS register is also used in infrared special case mode (IRSC = UCR4[5] = 1'b1), refer to Section 59.4.7.3, InfraRed Special Case (IRSC) Bit."

NOTE

This register has been expanded from 16 bits to 24 bits. In previous versions, the 16-bit ONEMS can only support the maximum 65.535 MHz (0xFFFFx1000) *ref_clk*. To support 4 Mbps Bluetooth application with 66.5 MHz *module_clock*, the value 0x103C4 (66.5M/1000) should be written into this register. In this case, the 16 bits are not enough to contain the 0x103C4. So this register was expanded to 24 bits to support high frequency of the *ref_clk*.

59.3.3.16 UART Test Register (UTS)

See Figure 59-18 for illustration of valid bits in the UART Test Register and Table 59-21 for description of the bit fields.

0x00b4 (UTS) Access: User read/write

Figure 59-18. UART Test Register

Table 59-21. UART Test Register Field Descriptions

Name	Description
31–14	Reserved
13 FRCPERR	Force Parity Error. Forces the transmitter to generate a parity error if parity is enabled. FRCPERR is provided for system debugging. 0 Generate normal parity 1 Generate inverted parity (error)
12 LOOP	Loop TX and RX for Test. Controls loopback for test purposes. When LOOP is high, the receiver input is internally connected to the transmitter and ignores the RXD pin. The transmitter is unaffected by LOOP. If RXDMUXSEL (UCR3[2]) is set to 1, the loopback is applied on serial and IrDA signals. If RXDMUXSEL is set to 0, the loopback is only applied on serial signals. 0 Normal receiver operation 1 Internally connect the transmitter output to the receiver input
11 DBGEN	
10 LOOPIR	Loop TX and RX for IR Test (LOOPIR). This bit controls loopback from transmitter to receiver in the InfraRed interface. 0 No IR loop 1 Connect IR transmitter to IR receiver
9 RXDBG	
8–7	Reserved
6 TXEMPTY	TxFIFO Empty. Indicates that the TxFIFO is empty. 0 The TxFIFO is not empty 1 The TxFIFO is empty

Table 59-21. UART Test Register Field Descriptions (continued)

Name	Description
5 RXEMPTY	RxFIFO Empty. Indicates the RxFIFO is empty. 0 The RxFIFO is not empty 1 The RxFIFO is empty
4 TXFULL	TxFIFO FULL. Indicates the TxFIFO is full. 0 The TxFIFO is not full 1 The TxFIFO is full
3 RXFULL	RxFIFO FULL. Indicates the RxFIFO is full. 0 The RxFIFO is not full 1 The RxFIFO is full
2–1	Reserved
0 SOFTRST	Software Reset. Indicates the status of the software reset ($\overline{\text{SRST}}$ bit of UCR2). 0 Software reset inactive 1 Software reset active

59.4 Functional Description

This section provides a complete functional description of the module.

59.4.1 Interrupts and DMA Requests

See Table 59-22 for the lists of all interrupt and DMA signals and associated interrupt and DMA sources of the UART. See register description section for explanation of interrupt/DMA enable and status.

Table 59-22. Interrupts and DMA

59.4.2 Clocks

This section describes clocks and special clocking requirements of the UART.

59.4.2.1 Clock Requirements

UART module receives two clocks, *peripheral_clock* and *module_clock*. The *peripheral_clock* is used as write clock of the TxFIFO, read clock of the RxFIFO and synchronization of the modem control input pins. It must always be running when UART is enabled. There is an exception in stop mode (see Section 59.4.2.3, Clocking in Low-Power Modes").

The *module_clock* is for all the state machines, writing RxFIFO, reading TxFIFO, etc. It must always be running when UART is sending or receiving characters.This clock is used in order to allow frequency scaling on *peripheral_clock* without changing configuration of baud rate (*module_clock* staying at a fixed frequency).

The constraints on *peripheral_clock* and *module_clock* are as follows:

- *peripheral_clock* and *module_clock* can totally be asynchronous. Off course, they can also be synchronous.
- Due to the 16× oversampling of the incoming characters, *module_clock* frequency must always be greater or equal to 16× the maximum baud rate. For example, if max baud rate is 4 Mbit/s, *module_clock* must be greater or equal to 4 M × 16 = 64 MHz.

NOTE

The restriction that *peripheral_clock* frequency must be higher or equal to 16x baud rate has been removed. There is no limitation on *peripheral_clock* frequency to baud rate.

59.4.2.2 Maximum Baud Rate

The max baud rate the UART can support is determined by the max frequency of the *module_clock* and logic synthesis results. For example, if SoC can provide the fastest *module_clock* 66.5 MHz and the UART synthesis timing is OK under this constraint, the UART can transmit and receive serial data with the max baud rate 66.5M/16 = 4.15 Mbit/s.

The UART supports serial IR interface low speed. In the low speed IrDA mode, the max baud rate is 115.2 Kbit/s. To support the 115.2 Kbit/s, *module_clock* frequency must be higher or equal to 1.8432 MHz.

59.4.2.3 Clocking in Low-Power Modes

The UART supports 2 low-power modes: DOZE and STOP.

In STOP mode (input pin *stop_req* is at '1'), the UART doesn't need any clock. In this mode the UART can wake-up the MCU with the asynchronous interrupts (refer to Section 59.4.8, Low Power Modes"). An application of this feature is when the system must be waken-up by the arrival of a frame of characters.

- If before entering in Stop mode the software has enabled RTSDEN interrupt, then when RTS will change state (put at '0' by external device started to send), the asynchronous interrupt will wake-up the system, *peripheral_clock* and *module_clock* will be provided to the UART before first start bit, so that no data will be lost.
- If RTS doesn't change state (already at '0' before entering in Stop mode), then wake-up interrupt (AWAKE) will be sent at the arrival of first Start bit (on falling edge). In this case, the UART must receive the *peripheral_clock* and *module_clock* during the first half of start bit to correctly receive this character (for example, at 115.2 Kbit/s, UART must receive *peripheral_clock* and *module_clock* at maximum 4.3 microseconds after falling edge of Start bit). If the UART receives *peripheral_clock* and *module_clock* too late, first character will be lost, and so should be dropped. Also, if autobaud detection is enabled, the first character won't be correctly received and another autobaud detection will need to be initiated.

In Doze mode, UART behavior is programmable through DOZE bit (UCR1[1]). If DOZE bit is set to '1', then UART is disabled in Doze mode, and in consequence, UART clocks can be switched-off (after being sure UART is not transmitting nor receiving). On the contrary, if DOZE bit is set to '0', UART is enabled and it must receive *peripheral_clock* and *module_clock*.

59.4.3 General UART Definitions

The following list defines the general UART terms that occur in the subsequent sections.

Bit Time — The period of time required to serially transmit or receive 1 bit of data (1 cycle of the baud rate frequency).

Start bit	The bit time of a logic 0 that indicates the beginning of a data frame. A start bit begins with a 1-to-0 transition, and is preceded by at least 1 bit time of logic 1.
Stop bit	1 bit time of logic 1 that indicates the end of a data frame.
BREAK	A frame in which all of the data bits, including the stop bit, are logic 0. This type of frame is usually sent to signal the end of a message or the beginning of a new message.
Mark	When no data is being sent, the serial port's transmit pin's voltage is 1 and is said to be in a MARK state.
Space	The serial port can also be forced to keep the transmit pin at a 0 and is said to be the SPACE or BREAK state.
Frame	A start bit followed by a specified number of data or information bits and terminated by a stop bit. The number of data or information bits depends on the format specified and must be the same for the transmitting device and the receiving device. The most common frame format is 1 start bit followed by 8 data bits (least significant bit first) and terminated by 1 stop bit. An additional stop bit and a parity bit also can be included.
Framing Error	An error condition that occurs when the stop bit of a received frame is missing, usually when the frame boundaries in the received bit stream are not synchronized with the receiver bit counter. Framing errors can go undetected if a data bit in the expected stop bit time happens to be a logic 1. A framing error is always present on the receiver side when the transmitter is sending BREAKs. However, when the UART is programmed to expect two stop bits and only the first stop bit is received, this is not a framing error by definition.
Parity Error	An error condition that occurs when the calculated parity of the received data bits in a frame does not match the parity bit received on the RXD input. Parity error is calculated only after an entire frame is received.
Idle	One in NRZ encoding format and selectable polarity in IrDA mode.
Overrun Error	An error condition that occurs when the latest character received is ignored to prevent overwriting a character already present in the UART receive buffer (RxFIFO). An overrun error indicates that the software reading the buffer (RxFIFO) is not keeping up with the actual reception of characters on the RXD input.

59.4.3.1 $\overline{\text{RTS}}$—UART Request To Send

The UART Request To Send input controls the transmitter. The modem or other terminal equipment signals the UART when it is ready to receive by setting '0' on the $\overline{\text{RTS}}$ pin. Normally, the transmitter waits until this signal is active (low) before transmitting a character, however when the Ignore RTS (IRTS) bit is set, the transmitter sends a character as soon as it is ready to transmit. An interrupt (RTSD) can be posted on any transition of this pin and can wake the MCU from STOP mode on its assertion. When $\overline{\text{RTS}}$ is set to '1' during a transmission, the UART transmitter finishes transmitting the current character and shuts off. The contents of the TxFIFO (characters to be transmitted) remain undisturbed. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode.

59.4.3.2 $\overline{\text{RTS}}$ Edge Triggered Interrupt

The input to the $\overline{\text{RTS}}$ pin can be programmed to generate an interrupt on a selectable edge. See Table 59-23 for summary of the operation of the $\overline{\text{RTS}}$ edge triggered interrupt (RTSF).

To enable the $\overline{\text{RTS}}$ pin to generate an interrupt, set the request to send interrupt enable (RTSEN) bit (UCR2[4]) to 1. Writing 1 to the $\overline{\text{RTS}}$ edge triggered interrupt flag (RTSF) bit (USR2[4]) clears the interrupt flag. The interrupt can occur on the rising edge, falling edge, or either edge of the $\overline{\text{RTS}}$ input. The request to send edge control (RTEC) field (UCR2[10:9]) programs the edge that generates the interrupt. When RTEC is set to 0x00 and RTSEN = 1, the interrupt occurs on the rising edge (default). When RTEC is set to 0x01 and RTSEN = 1, the interrupt occurs on the falling edge. When RTEC is set to 0x1X and RTSEN = 1, the interrupt occurs on either edge. This is a synchronous interrupt. The RTSF bit is cleared by writing 1 to it. Writing 0 to RTSF has no effect.

Table 59-23. $\overline{\text{RTS}}$ Edge Triggered Interrupt Truth Table

$\overline{\text{RTS}}$	RTSEN	RTEC [1]	RTEC [0]	RTSF	Interrupt Occurs On…	$\overline{\textit{interrupt\_uart}}$
X	0	X	X	0	Interrupt disabled	1
1–>0	1	0	0	0	Rising edge	1
0–>1	1	0	0	1	Rising edge	0
1–>0	1	0	1	1	Falling edge	0
0–>1	1	0	1	0	Falling edge	1
1–>0	1	1	X	1	Either edge	0
0–>1	1	1	X	1	Either edge	0

There is another $\overline{\text{RTS}}$ interrupt that is not programmable. The status bit RTSD asserts the $\overline{\textit{interrupt\_uart}}$ interrupt when the $\overline{\text{RTS}}$ delta interrupt enable = 1. This is an asynchronous interrupt. The RTSD bit is cleared by writing 1 to it. Writing 0 to the RTSD bit has no effect.

59.4.3.3 $\overline{\text{DTR}}$—Data Terminal Ready

This signal indicates the general readiness of the Data Terminal Equipment (DTE). This signal is an input in DCE mode and an output in DTE mode. If the connection between the DCE and the DTE is established once, the $\overline{\text{DTR}}$ signal must remain active throughout the whole connection time. In general the $\overline{\text{DTR}}$ and $\overline{\text{DSR}}$ signals are responsible for establishing the connection. $\overline{\text{RTS}}$ and $\overline{\text{CTS}}$ are responsible for the data transfer and the transfer direction in the case of a half-duplex configuration. The $\overline{\text{DTR}}$ signal is like a “main switch”. If the $\overline{\text{DTR}}$ signal is inactive the $\overline{\text{RTS}}$ and $\overline{\text{CTS}}$ signals have no effect. In DCE mode, an interrupt (DTRD) can be posted on any transition of this pin and can wake the MCU from STOP mode on its assertion.

59.4.3.4 $\overline{\text{DSR}}$—Data Set Ready

This signal indicates the general readiness of the DCE. This signal is an output in DCE mode and an input in DTE mode. The DCE uses this signal to inform the DTE that it is switched on, has completed all preparations and can communicate with the DTE. In DTE mode, an interrupt (DTRD) can be posted on any transition of this pin and can wake the MCU from STOP mode on its assertion.

59.4.3.5 $\overline{\text{DTR/DSR}}$ Edge Triggered Interrupt

The $\overline{\text{DTR}}$ input pin (DCE mode) or $\overline{\text{DSR}}$ input pin (DTE mode) can be configured to cause an interrupt on a selectable edge. See Table 59-24 for summary of the operation of the $\overline{\text{DTR/DSR}}$ edge triggered interrupt. To enable the interrupt, set the DTREN bit (UCR3[13]) to '1'. Write a "one" to the DTRF bit (USR2[13]) to clear the interrupt flag.

The interrupt can be configured to occur on either the rising, falling, or either edge of the $\overline{\text{DTR/DSR}}$ input. Write to the DPEC[1:0] bits (UCR3[15:14]) to program which edge will cause an interrupt. If the bits are set to 00b and DTREN = 1, the interrupt will occur on the rising edge (default). If the bits are set to 01b and DTREN = 1, the interrupt will occur on the falling edge. If the bits are set to 1Xb and DTREN = 1, the interrupt will occur on either edge.

Table 59-24. $\overline{\text{DTR/DSR}}$ Edge Triggered Interrupt Truth Table

$\overline{\text{DTR}}$/$\overline{\text{DSR}}$	DTREN	DPEC[1]	DPEC[0]	DTRF	Interrupt occurs on:	*interrupt_uart*
X	0	X	X	0	Turned Off	1
1->0	1	0	0	0	Rising Edge	1
0->1	1	0	0	1	Rising Edge	0
1->0	1	0	1	1	Falling Edge	0
0->1	1	0	1	0	Falling Edge	1
1->0	1	1	X	1	Either Edge	0
0->1	1	1	X	1	Either Edge	0

59.4.3.6 $\overline{\text{DCD}}$—Data Carrier Detect

This signal is an output in DCE mode and an input in DTE mode. If used, the DCE device uses this signal to inform the DTE it has detected the carrier signal and the connection will be set up. This signal remains active while the connection remains established. In DTE mode this input can trigger an interrupt on changing state. This is achieved by setting to '1' the interrupt enable bit (DCD, UCR3[9]). The change state is reflected in DCDDELT (USR2[6]). Also, the state of the Data Carrier Detect input is mirrored in the status register DCDIN (USR2[5]).

59.4.3.7 $\overline{\text{RI}}$—Ring Indicator

This signal is an output in DCE mode and an input in DTE mode. If used, the DCE device uses this signal to inform the DTE that a ring just occurred. In DTE mode this input can trigger an interrupt on changing state. This is achieved by setting to '1' the interrupt enable bit (RI, UCR3[8]). The change state is reflected in RIDELT (USR2[10]). Also, the state of the Ring Indicator input is mirrored in the status register RIIN (USR2[9]).

59.4.3.8 $\overline{\text{CTS}}$—Clear To Send

This output pin serves two purposes. Normally, the receiver indicates that it is ready to receive data by asserting this pin (low). When the $\overline{\text{CTS}}$ trigger level is programmed to trigger at 32 characters received and

the receiver detects the valid start bit of the 33 character, it de-asserts this pin. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode.

59.4.3.9 Programmable $\overline{\text{CTS}}$ Deassertion

The $\overline{\text{CTS}}$ output can also be programmed to deassert when the RxFIFO reaches a certain level. Setting the CTS trigger level (UCR4[15:10]) at any value less than 32 deasserts the $\overline{\text{CTS}}$ pin on detection of the valid start bit of the N + 1 character (where N is the trigger level setting). However, the receiver continues to receive characters until the RxFIFO is full.

59.4.3.10 TXD—UART Transmit

This is the transmitter serial output. When operating in normal mode, NRZ encoded data is output. When operating in infrared mode, a 3/16 bit-period pulse is output for each 0 bit transmitted, and no pulse is output for each 1 bit transmitted. For RS-232 applications, this pin must be connected to an RS-232 transmitter. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode. See Figure 59-19.

59.4.3.11 RXD—UART Receive

This is the receiver serial input. When operating in normal mode, NRZ encoded data is expected. When operating in infrared mode, a narrow pulse is expected for each 0 bit received and no pulse is expected for each 1 bit received. External circuitry must convert the IR signal to an electrical signal. RS-232 applications require an external RS-232 receiver to convert voltage levels. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode. See Figure 59-19.

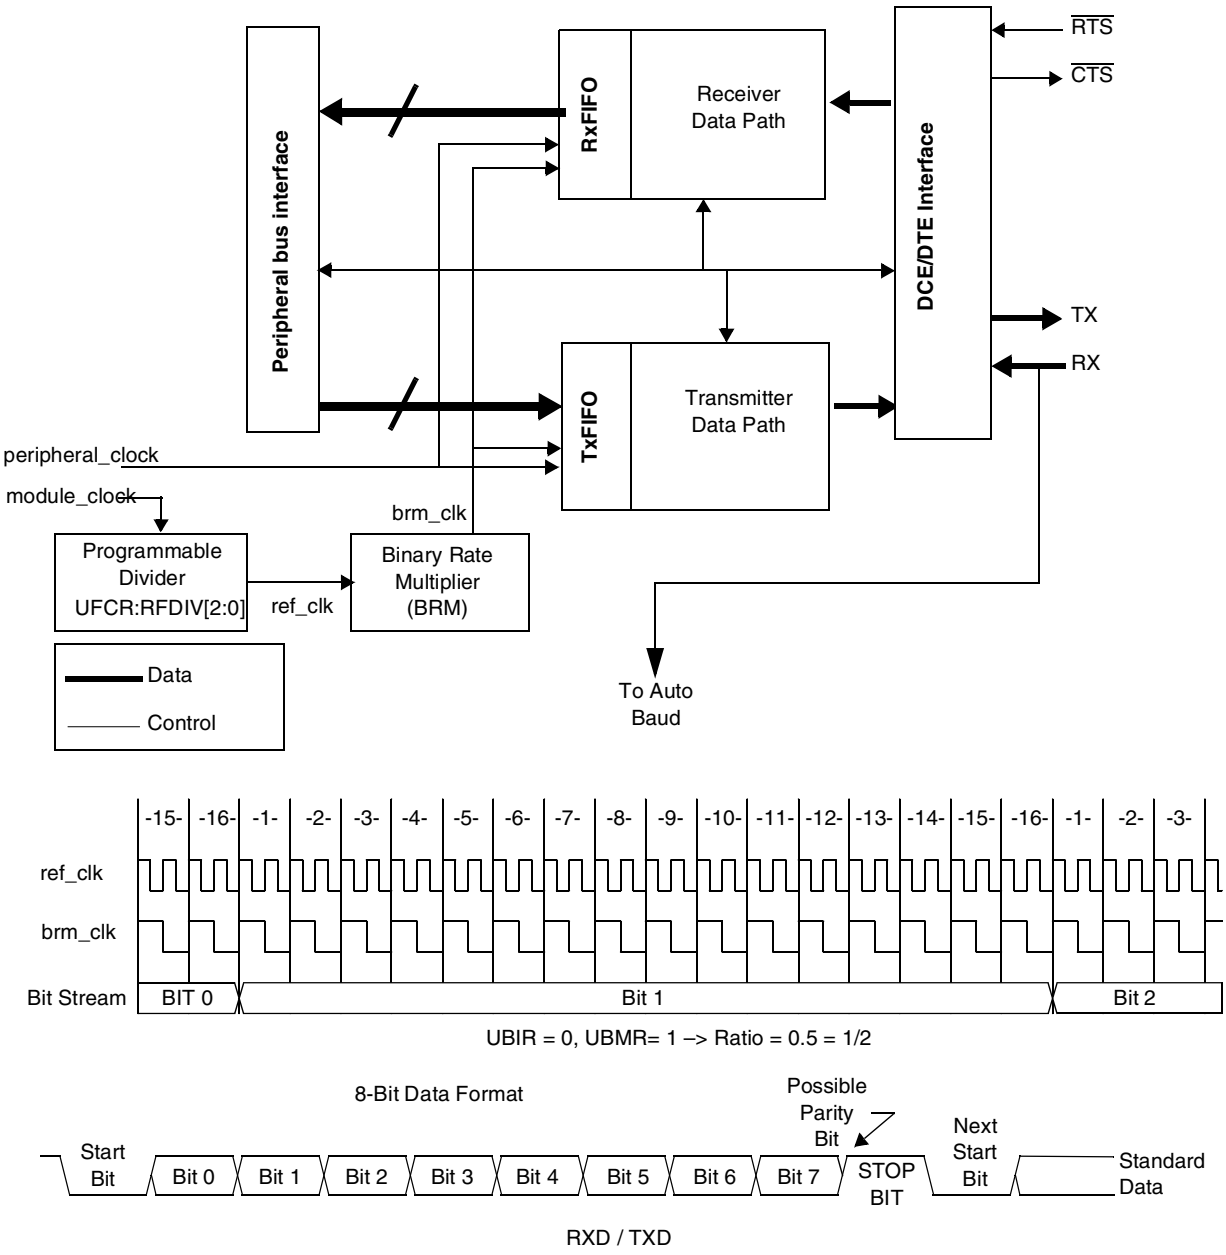

Figure 59-19. UART Simplified Block and Clock Generation Diagrams

59.4.4 Transmitter

The transmitter accepts a parallel character from the MCU and transmits it serially. The start, stop, and parity (when enabled) bits are added to the character. When the ignore RTS bit (IRTS) is set, the transmitter sends a character as soon as it is ready to transmit. $\overline{\text{RTS}}$ can be used to provide flow-control of the serial data. When $\overline{\text{RTS}}$ is set to '1', the transmitter finishes sending the character in progress (if any), stops, and waits for $\overline{\text{RTS}}$ to be set to '0' again. Generation of BREAK characters and parity errors (for debugging

purposes) is supported. The transmitter operates from the clock provided by the BRM. Normal NRZ encoded data is transmitted when the IR interface is disabled.

The transmitter FIFO (TxFIFO) contains 32 bytes. The data is written to TxFIFO by writing to the UTXD register with the byte data to the [7:0] bits. The data is written consecutively if the TxFIFO is not full. It is read (internally) consecutively if the TxFIFO is not empty. TXFULL bit (UTS[4]) can be used to control whether TXFIFO is full or not. The TxFIFO can be written regardless of the transmitter is disabled or enabled. If the UART is disabled, user can write data into the TxFIFO correctly. But in this case the write access will yield to a transfer error if the signal resp_sel is tied to 0.

59.4.4.1 Transmitter FIFO Empty Interrupt Suppression

The transmitter FIFO empty interrupt suppression logic suppresses the TXFE interrupt between writes to the TxFIFO. When TxFIFO is empty, the software can either send one or several characters. If the software sends one character, it would write the character into the UTXD register, then that character is immediately transferred to the transmitter shift register, assuming the transmitter is already enabled. Without interrupt suppression logic, the TXFE interrupt flag would be set immediately. But, with this logic, the interrupt flag is set when the last bit of the character has been transmitted, for example, before the transmission of the parity bit (if exists) and the stop bit(s).

So, the suppression logic doesn't immediately send the TXFE interrupt flag. It allows the software to write another character to the TxFIFO before the interrupt flag is asserted.

When the transmitter shift register empties before another character is written to the TxFIFO, the interrupt flag is asserted. Writing data to the TxFIFO would release the interrupt flag. The interrupt flag is asserted on the following conditions:

- System Reset
- UART software reset
- When a single character has been written to Transmitter FIFO and then the Transmitter FIFO and the Transmitter Shift Register become empty until another character is written to the Transmitter FIFO
- The last character in the TxFIFO is transferred to the shift register, when TxFIFO contains two or more characters. See Figure 59-20.

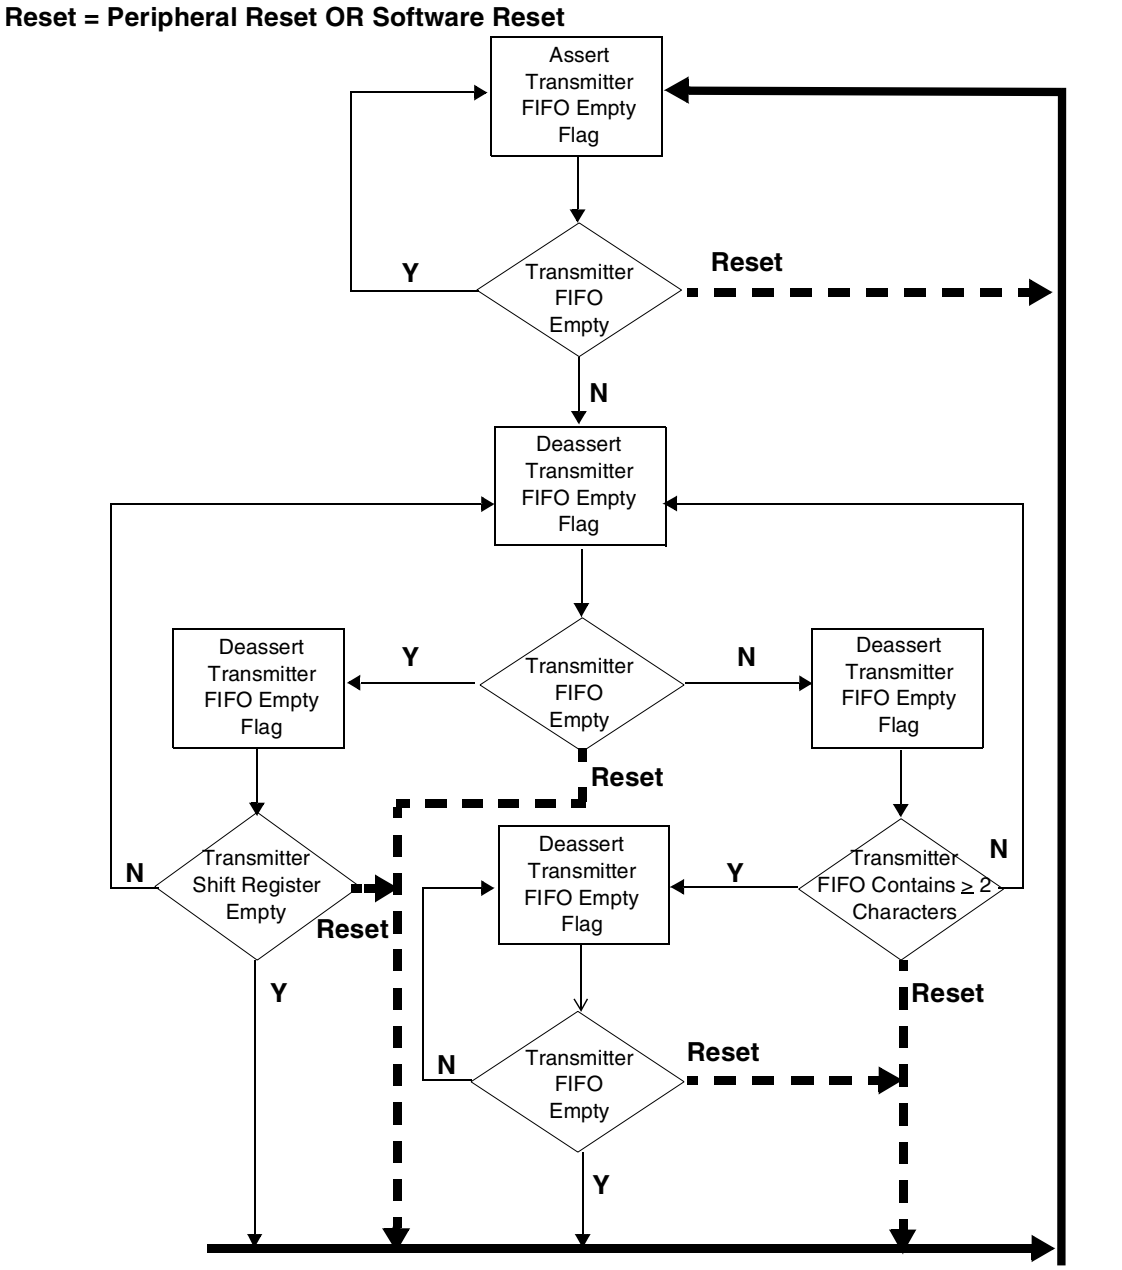

Figure 59-20. Transmitter FIFO Empty Interrupt Suppression Flow Chart

59.4.4.2 Transmitting a Break Condition

Asserting SNDBRK bit of the UCR1 Register forces the transmitter to send a break character (continuous zeros). The transmitter will finish sending the character in progress (if any) before sending break until this bit is reset. The user is responsible to ensure that this bit is high for long enough to generate a valid BREAK. The transmitter samples SNDBRK after every bit is transmitted. Following completion of the BREAK transmission, the UART will transmit two mark bits. The user can continue to fill the FIFO and any character remaining will be transmitted when the break is terminated.

59.4.5 Receiver

See Figure 59-21 for the receiver flow chart. The receiver accepts a serial data stream and converts it into parallel characters. When enabled, it searches for a start bit, qualifies it, and samples the following data bits at the bit-center. Jitter tolerance and noise immunity are provided by sampling at a 16x rate and using voting techniques to clean up the samples. Once the start bit is found, the data bits, parity bit (if enabled), and stop bits (either 1 or 2 depending on user selection) are shifted in. Parity is checked and its status reported in the URXD register when parity is enabled. Frame errors and BREAKs are also checked and reported. When a new character is ready to be read by the MCU from the RxFIFO, the receive data ready (RDR = USR2[0]) bit is asserted and an interrupt is posted (if DREN = UCR4[0] = 1). If the receiver trigger level is set to 2 (RXTL[5:0] = UFCR[5:0] = 2), and 2 chars have been received into RxFIFO, the receiver ready interrupt flag (RRDY = USR1[9]) is asserted and an interrupt is posted if the receiver ready interrupt enable bit is set (RRDYEN = UCR1[9] = 1). If the UART Receiver Register (URXD) is read once, and in consequence there is only 1 character in the RxFIFO, the interrupt generated by the RDR bit is automatically cleared. The RRDY bit is cleared when the data in the RxFIFO falls below the programmed trigger level.

Normal NRZ encoded data is expected when the IR interface is disabled. The RxFIFO contains 32 half-word entries. Characters received are written consecutively into this FIFO. If the FIFO is full and a 33rd characters is received, this character will be ignored and the USR2[ORE] bit will be set.

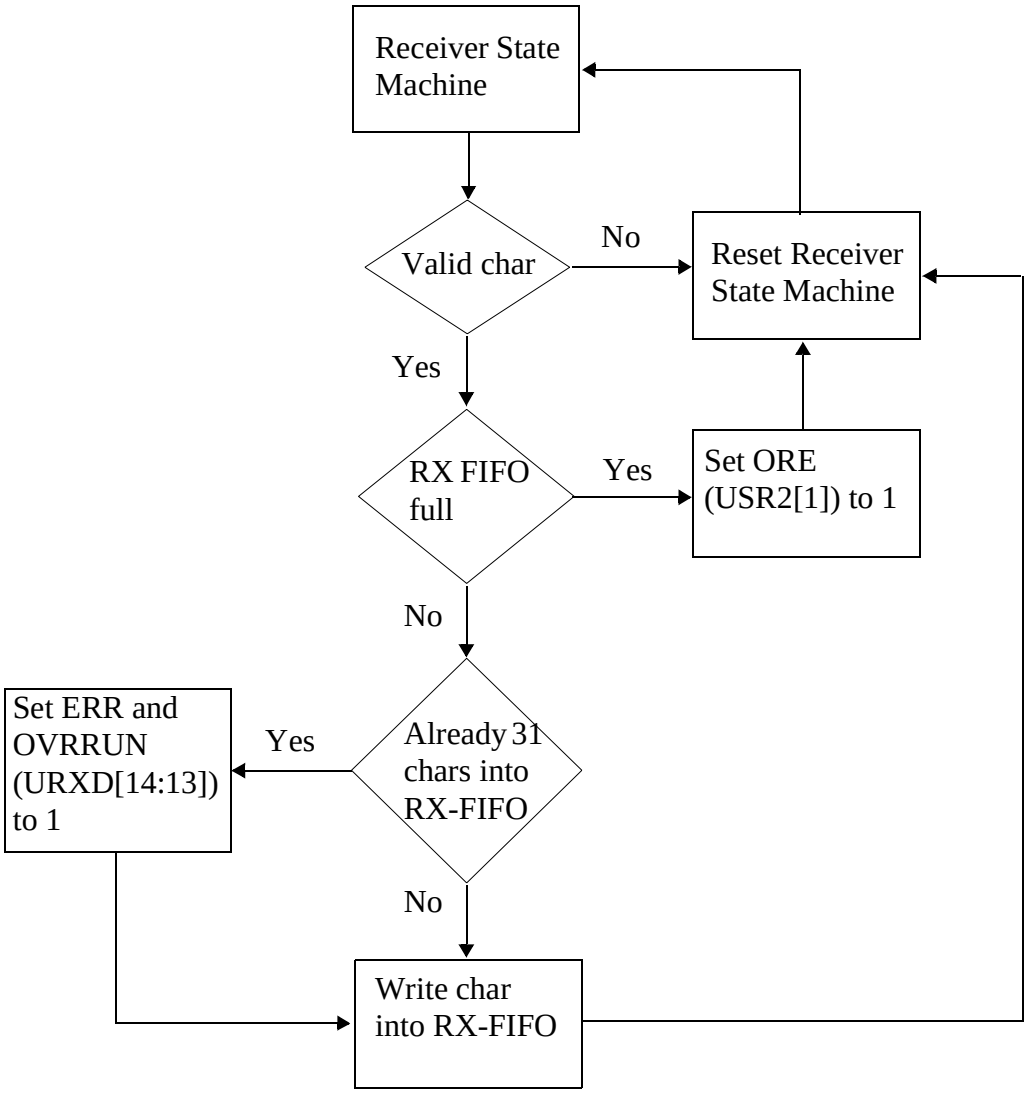

Figure 59-21. Receiver Flow Chart

59.4.5.1 Idle Line Detect

The receiver logic block includes the ability to detect an idle line. Idle lines indicate the end or the beginning of a message.

For an idle condition to occur, the following conditions must be met:

- RxFIFO must be empty
- RXD pin must be idle for more than a configured number of frames (ICD[1:0] = UCR1[11:10]).

When the idle condition detected interrupt enable (IDEN = UCR1[12]) is set and the line is idle for 4 (default), 8, 16, or 32 (maximum) frames, the detection of an idle condition flags an interrupt (see

Table 59-25). When an idle condition is detected, the IDLE (USR2[12]) bit is set. Clear the IDLE bit by writing 1 to it. Writing 0 to the IDLE bit has no effect.

Table 59-25. Detection Truth Table

IDEN	ICD [1]	ICD [0]	IDLE	*interrupt_uart*
0	X	X	0	1
1	0	0	asserted after 4 idle frames	asserted after 4 idle frames
1	0	1	asserted after 8 idle frames	asserted after 8 idle frames
1	1	0	asserted after 16 idle frames	asserted after 16 idle frames
1	1	1	asserted after 32 idle frames	asserted after 32 idle frames

Note: This table assumes that no other interrupt is set at the same time this interrupt is set for the *interrupt_uart* signal. This table shows how this interrupt affects the *interrupt_uart* signal.

During a normal message there is no idle time between frames. When all of the information bits in a frame are logic 1s, the start bit ensures that at least one logic 0 bit time occurs for each frame so that the IDLE bit is not asserted.

59.4.5.2 Ageing Character Detect

The receiver block also includes the possibility to detect when at least one character has been sitting into the RxFIFO for a time corresponding to 8 characters. This ageing character capability allows the UART to inform the MCU that there is less character into the RxFIFO than the Rx trigger and, no new character has been detected on the RXD line. The ageing capability is a timer which starts to count as soon as the RxFIFO is not empty and its trigger level is not reached (RRDY=0). This counter is reset when either a RxFIFO read is performed or another character starts to present on the RXD line. If none of those two events occurs, the bit AGTIM (USR1[8]) is set when the counter has measured a time corresponding to 8 characters. AGTIM is cleared by writing a 1 to it. AGTIM can flag an interrupt to MCU on *interrupt_uart* if ATEN (UCR2[3]) has been set.

To summarize, AGTIM is set when the following conditions are met:

- There is at least one character into RxFIFO.
- No read has occurred on RxFIFO and RXD line has stayed high, for a time corresponding to 8 characters.
- The RxFIFO trigger is not reached (RRDY=0)

59.4.5.3 Receiver Wake

The WAKE bit (USR2[7]) is set when the receiver detects a qualified Start bit. For this, two conditions must be fulfilled, firstly a falling edge on RXD line must be detected and secondly the RXD line must stays at low level for more than a half-bit duration. When the wake interrupt enable WKEN (UCR4[7]) bit is enabled, the receiver flags an interrupt (*interrupt_uart*) if the WAKE status bit is set. The WAKE bit is cleared by writing 1 to it. Writing 0 to the WAKE bit has no effect. The WAKE status bit can be asserted in either serial RS-232 mode or IR mode. The generation of the WAKE interrupt needs the clock *module_clock*.

When the asynchronous wake interrupt (AWAKE) is enabled (AWAKEN = UCR3[4] = 1), and the MCU is in STOP mode, and UART clocks have been shut-off, then a falling edge detected on the receive pin (RXD) asserts the AWAKE bit (USR1[4]) and the *interrupt_uart* interrupt to wake the MCU from STOP mode. Re-enable UART clocks and clear the AWAKE bit by writing 1 to it. Writing 0 to the AWAKE bit has no effect. When IR interface is enabled (UCR1[7]=1), the AWAKE bit is always not asserted. The generation of the asynchronous AWAKE interrupt does not need any clocks.

In IR mode, if the asynchronous IR WAKE interrupt is enabled (AIRINTEN = UCR3[5] = 1), and if MCU is in STOP mode (UART clocks are off when MCU in STOP mode), then the detection of a falling edge on the receive pin (RXD_IR), asserts the AIRINT bit (USR1[5]), and the *interrupt_uart* interrupt. This interrupt wakes the MCU from STOP mode. Software re-enables UART clocks and clear the AIRINT bit by writing 1 to it. Writing 0 to the AIRINT bit has no effect. When IR interface is disabled (UCR1[7]=0), the AIRINT bit is always not asserted. The generation of the asynchronous AIRINT interrupt does not need any clocks.

Recommended procedure for programming the asynchronous interrupts is to first clear them by writing 1 to the appropriate bit in the UART Status Register 1 (USR1). Poll or enable the interrupt for the Receiver IDLE Interrupt Flag (RXDS) in the USR1. When asserted, the RXDS bit indicates to the software that the receiver state machine is in the idle state, the next state is idle, and the RXD pin is idle (high). After following this procedure, enable the asynchronous interrupt and enter STOP mode.

59.4.5.4 Receiving a BREAK Condition

A BREAK condition is received when the receiver detects all 0s (including a 0 during the bit time of the stop bit) in a frame. The BREAK condition asserts the BRCD bit (USR2[2]) and writes only the first BREAK character to the RxFIFO. Clear the BRCD bit by writing 1 to it. Writing 0 to the BRCD bit has no effect.

Asserting BRCD would generate an interrupt on *interrupt_uart*. The interrupt generation can be masked using the control bit BKEN (UCR4[2]). Receiving a break condition will also effect the following bits in the receiver register URXD:

- URXD(11) = BRK. While high this bit indicates that the current char was detected as a break.
- URXD(12) = FRMERR. The frame error bit will always be set when BRK is set.
- URXD(10) = PRERR. If odd parity was selected the parity error bit will also be set when BRK is set.
- URXD(14) = ERR. The error detect bit indicates that the character present in the rx data field has an error status. This can be asserted by a break.

59.4.5.5 Vote Logic

The vote logic block provides jitter tolerance and noise immunity by sampling with respect to a 16x clock (*brm_clk*) and using voting techniques to clean up the samples. The voting is implemented by sampling the incoming signal constantly on the rising edge of the *brm_clk*. See Figure 59-22. The receiver is

provided with the majority vote value, which is 2 out of the 3 samples. For examples of the majority vote results of the vote logic, see Table 59-26.

Table 59-26. Majority Vote Results

Samples	Vote
000	0
101	1
001	0
111	1

The vote logic captures a sample on every rising edge of *brm_clk*, however the receiver uses 16x oversampling to take its value in the middle of the sample character.

The receiver starts to count when the Start bit is set however it does not capture the contents of the RxFIFO at the time the Start bit is set. The start bit is validated when 0s are received for 7 consecutive 1/16 of bit times following the 1-to-0 transition. Once the counter reaches 0xF, it starts counting on the next bit and captures it in the middle of the sampling frame (see Table 59-26). All data bits are captured in the same manner. Once the stop bit is detected, the receiver shift register (SIPO_OUT) data is parallel shifted to the RxFIFO.

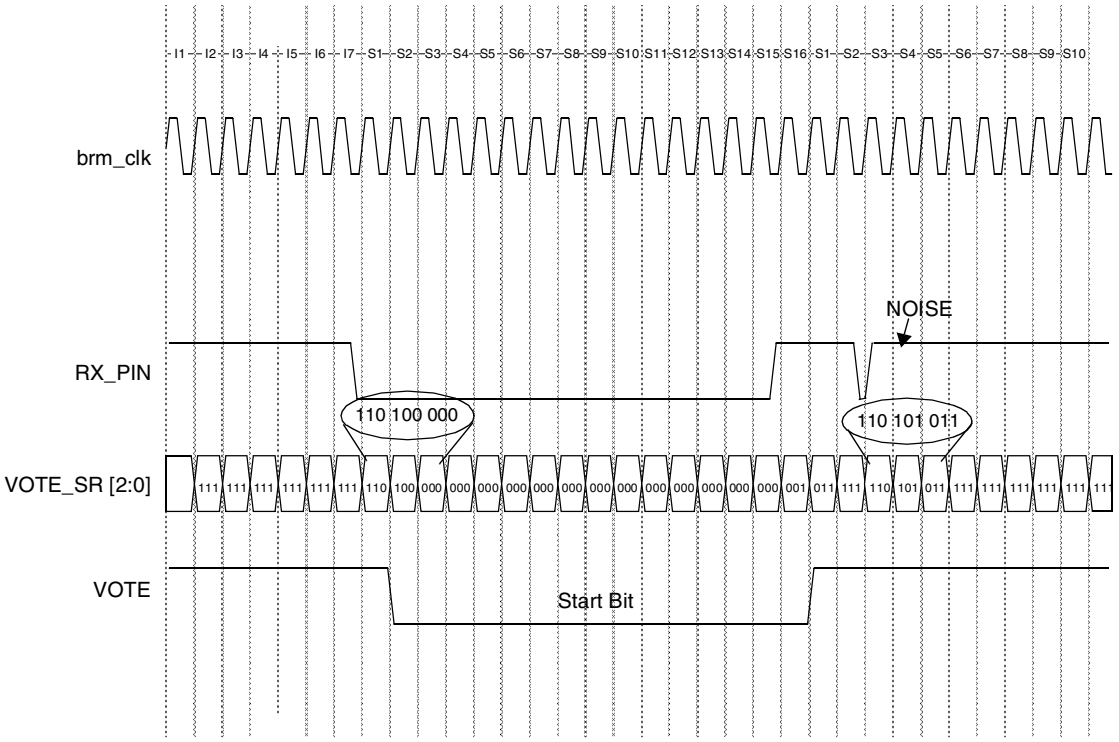

Figure 59-22. Majority Vote Results

A new feature has been recently implemented, it allows to re-synchronize the counter on each edge of RXD line. This is automatic and allows to improve the immunity of UART against signal distortion.

There is a special case when the *brm_clk* frequency is too low and is unable to capture a 0 pulse in IrDA. In this case, the software must set the IRSC (UCR4[5]) bit so that the reference clock (after internal divider) is used for the voting logic. The pulse is validated by counting the length of the pulse.

Refer to Section 59.4.7, Infrared Interface" for more details.

59.4.5.6 Baud Rate Automatic Detection Logic

When the baud rate automatic detection logic is enabled, the UART locks onto the incoming baud rate. To enable this feature, set the automatic detection of baud rate bit (ADBR = UCR1[14] = 1) and write 1 to the ADET bit (USR2[15]) to clear it. When ADET=0 and ADBR =1, the detection starts. Then, once the beginning of start bit (transition from 1-to-0 of RXD) has been detected, UART start a counter (UBRC) working at reference frequency. Once the end of start bit is detected (transition from 0-to-1 of RXD), the value of UBRC - 1 is directly copied into UBMR register. UBIR register is filled with 0x000F.

So, at the end of start bit, registers gets following values:

```
UBRC = number of reference clock periods (after divider) during Start bit.

UBIR = 0x000F

UBMR = UBRC - 1
```

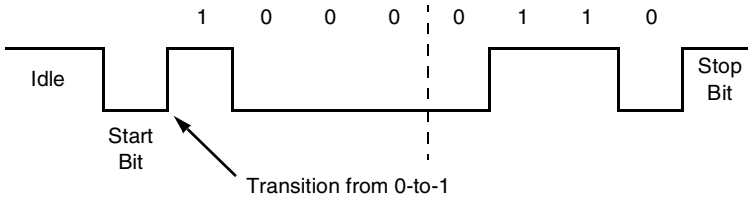
The updated values of the 3 registers can be read.

See Table 59-27 for list of parameters for baud rate detection and Figure 59-23 for baud rate detection protocol diagram.

If any of the UART BRM registers are simultaneously written by the baud rate automatic detection logic and by the peripheral data bus, the peripheral data bus would have lower priority.

Table 59-27. Baud Rate Automatic Detection

ADBR	ADET	Baud Rate Detection	$\overline{\textit{interrupt\_uart}}$
0	X	Manual Configuration	1
1	0	Auto Detection Started	1
1	1	Auto Detection Complete	0
Note: This table assumes that no other interrupt is set at the same time this interrupt is set for the $\overline{\textit{interrupt\_uart}}$ signal.			



Note: LSB transmitted first.

Figure 59-23. Baud Rate Detection Protocol Diagram

59.4.5.6.1 Baud Rate Automatic Detection Protocol

The receiver must receive an ASCII character “A” or “a” to verify proper detection of the incoming baud rate. When an ASCII character “A” (0x41) or “a” (0x61) is received and no error occurs, the Automatic Detect baud rate bit is set (ADET=1) and if the interrupt is enabled (ADEN=UCR1[15]=1), an interrupt $\overline{interrupt\_uart}$ is generated.

When an ASCII character “A” or “a” is not received (because of a bit error or the reception of another character), the auto detection sequence restarts and waits for another 1-to-0 transition.

As long as ADET = 0 and ADBR = 1, the UART continues to try to lock onto the incoming baud rate. Once the ASCII character “A” or “a” is detected and the ADET bit is set, the receiver ignores the ADBR bit and continues normal operation with the calculated baud rate.

The UART interrupt is active ($\overline{interrupt\_uart}$ = 0) as long as ADET = 1 and ADBR = 1. This can be disabled by clearing the automatic baud rate detection interrupt enable bit (ADEN = 0). Before starting an automatic baud rate detection sequence, set ADET = 0 and ADBR = 1.

The RxFIFO must contain the ASCII character “A” or “a” following the automatic baud rate detection interrupt.

The 16-bit UART Baud Rate Count Register (UBRC) is reset to 4 and stays at 0xFFFF when an overflow occurs. The UBRC register counts (measures) the duration of start bit. When the start bit is detected and counted, the UART Baud Rate Count Register retains its value until the next automatic baud rate detection sequence is initiated.

The Baud Rate Count Register counts only when auto detection is enabled.

59.4.5.6.2 Baud Rate Automatic Detection Protocol Improved

This protocol has been improved to address issues that have been reported for ICs using the existing autobaud protocol, especially for 57.6 Kbit/s and 115.2 Kbit/s. However, the old protocol is still available in the current UART IP, and several modifications can be used to make this autobaud detection more reliable. Users who wish to maintain the old method must set the bit ADNIMP (UCR3[7]) to 1. If this bit is not set (default), the autobaud improvements will be used.

The autobaud improvements are grouped in two categories: the new baud rate measurement and the new ACST bit (and associated interrupt). They are described in the following subsections.

New Baud Rate Determination

In order to fight against the problems caused by the distortion and the noise on the RXD line, the duration of the baud rate measurement has been extended. Previously, as described above, this determination was based on the measurement of the START bit duration. Now, this measurement is based on the duration of START bit + bit0. Bit0 is the first bit following the START bit. In fact, the counter which is started at the falling edge of START bit is no longer stopped at next rising edge (end of START bit), but it is stopped at the next falling edge (end of bit0). As the character sent is always a “A” (41h) or a “a” (61h), this second falling edge will always be present and it will indicate the end of bit0. Once this counter is stopped, the result is divided by 2 and used by the BRM to determine the incoming baud rate.

NOTE

UBRC register contains the result of this division by two, in consequence it reflects the measurement of the duration of one bit.

New Autobaud Counter Stopped bit and Interrupt

A new bit has been added in USR2 register: ACST (USR2[11]). This bit is set immediately after the determination of the baud rate. Settings are as follows:

- If ADNIMP is not set (default), ACST is set to 1 after the end of bit0,
- If ADNIMP is set to 1, ACST is set to 1 at the end of START bit.

If ACIEN (UCR3[0]) is set to 1, ACST flags an interrupt on $\overline{interrupt\_uart}$ signal. This interrupt informs the MCU the BRM has just been set with the result of the bit length measurement. If needed, the MCU can perform a read of UBMR (or UBRC) register and determine by itself the baud rate measured. Then the MCU has the possibility to correct the BRM registers with the nearest standardized baud rate.

NOTE

- ACST is set only if ADBR is set to 1, for example, the UART is autobauding.
- Clear the ACST bit by writing 1 to it. Writing 0 to the ACST bit has no effect.

59.4.5.7 Escape Sequence Detection

An escape sequence typically consists of 3 characters entered in rapid succession (such as +++). Because these are valid characters by themselves, the time between characters determines if it is a valid escape sequence. Too much time between two of the “+” characters is interpreted as two “+” characters, and not part of an escape sequence.

The software chooses the escape character and writes its value to the UART Escape Character Register (UESC). The software must also enable escape detection feature by setting ESCEN (UCR2[11]) to 1. The hardware compares this value to incoming characters in the RxFIFO. When an escape character is detected, the internal escape timer starts to count. The software specifies a time-out value for the maximum

allowable time between 2 successive escape characters (see Table 59-28). The escape timer is programmable in intervals of 2 ms to a maximum interval of 8.192 seconds.

Table 59-28. Escape Timer Scaling

UTIM Register	Maximum Time Between Specified Escape Characters
0x000	2 ms
0x001	4 ms
0x002	6 ms
0x003	8 ms
0x004	10 ms
…	…
0F8	498 ms
0F9	500 ms
…	…
9C3	5 s
…	…
FFD	8.188 s
FFE	8.190 s
FFF	8.192 s
Note: To calculate the time interval: (UTIM_Value + 1) × 0.002 = Time_Interval Example: (09C3 + 1) × 0.002 = 5 s.	

The escape sequence detection feature is available for all the reference frequencies. Before using the escape sequence detection, the user must fill the ONEMS register. This 24-bit register must contain the value of the UART internal frequency divided by 1000. The internal frequency is obtained after the UART internal divider which is applied on *module_clock* clock.

See the following two examples for an illustration.

Example 59-1. Example I

If the input clock *module_clock* frequency is 66.5 MHz, and if the input clock *module_clock* is divided by 2 with the internal divider UFCR[9:7] = 3’b100, the following equation is used to calculate the frequency for the ONEMS register.

Calculation of Frequency for ONEMS Register ***Eqn. 59-1***

$$ONEMS = \frac{66.5 \times 10^6}{2 \times 1000} = 33250 = 81E2h$$

Example 59-2. Example II

If the input clock *module_clock* frequency is 66.5 MHz, and if the input clock *module_clock* is divided by 1 with the internal divider: UFCR[9:7] = 3'b101, the following equation is used to calculate the frequency for the ONEMS register.

Calculation of Frequency for ONEMS Register ***Eqn. 59-2***

$$ONEMS = \frac{66.5 \times 10^6}{1000} = 66500 = 103C4h$$

The escape sequence detection interrupt is asserted when the escape sequence interrupt enable (ESCI) bit is set and an escape sequence is detected (ESCF set). Clear the ESCF bit by writing 1 to it. Writing 0 to the ESCF bit has no effect.

59.4.6 Binary Rate Multiplier (BRM)

The BRM sub-module receives *ref_clk* (*module_clock* clock after divider). From this clock, and with integer and non-integer division, BRM generates a 16x baud rate clock whose frequency is 16 times of baud rate. The uart transmitter will shift data out based on this 16x baud rate clock. The uart receiver will sample the serial data line based on this 16x baud rate clock. The input and output frequency ratio is programmed in the UART BRM Incremental Register (UBIR) and UART BRM MOD Register (UBMR). The output frequency is divided by the input frequency to produce this ratio. For integer division, set the UBIR = 0x000F and write the divisor to the UBMR register. All values written to these registers must be one less than the actual value to eliminate division by 0 (undefined), and to increase the maximum range of the registers.

Updating the BRM registers requires writing to both registers. The UBIR register must be written before writing to the UBMR register. If only one register is written to by the software, the BRM continues to use the previous values.

The following examples show how to determine what values are to be programmed into UBIR and UBMR for a given reference frequency and desired baud rate. The following equation can be used to help determine these values:

Frequency and Baud Rate for UBIR and UBMR ***Eqn. 59-3***

$$BaudRate = \frac{RefFreq}{\left(16 \times \frac{UBMR + 1}{UBIR + 1}\right)}$$

Where:

- Reference Frequency (Hz): UART Reference Frequency (*module_clock* after RFDIV divider)
- Baud Rate (bit/s): Desired baud rate.

Example 59-3. Integer Division ÷ 21

```
Reference Frequency = 19.44 MHz
UBIR = 0x000F
UBMR = 0x0014
Baud Rate = 925.7 kbit/s
```

NOTE

Observe that each value written to the registers is one less than the actual value.

Example 59-4. Non-Integer Division

```
Reference Frequency = 16 MHz
Desired Baud Rate = 920 Kbits/s
```

$$\frac{UBMR+1}{UBIR+1} = \frac{RefFreq}{16 \times BaudRate} = \frac{16 \times 10^6}{16 \times 920 \times 10^3} = 1.087$$

```
Ratio = 1.087 = 1087 / 1000
UBIR = 999 (decimal)= 0x3E7
UBMR = 1086 (decimal)= 0x43E
Non-Integer Division
Reference Frequency = 25 MHz
Desired Baud Rate = 920 kbit/s
Ratio = 1.69837 = 625 / 368
UBIR = 367 (decimal)= 0x16F
UBMR = 624 (decimal)= 0x270
```

Example 59-5. Non-Integer Division

```
Reference Frequency: 30 MHz
Desired Baud Rate = 115.2 kbit/s
Ratio = 16.276043 = 65153 / 4003
UBIR = 4002 (decimal) = 0x0FA2
UBMR = 65152 (decimal) = 0xFE80
```

59.4.7 Infrared Interface

This section discusses the infrared interface.

59.4.7.1 Generalities

The Infrared interface is selected when IREN (UCR1[7]) is set to 1.

The Infrared Interface is compatible with IrDA Serial Infrared Physical Layer Specification. In this specification, a zero is represented by a positive pulse, and a one is represented by no pulse (line remains low).

In the UART, the following is expected:

- In Tx
  - For each zero transmitted, a narrow positive pulse which is 3/16 of a bit time is generated.
  - For each one transmitted no pulse is generated (output is low). External circuitry has to be provided to drive an Infrared LED.
- In Rx
  - A narrow negative pulse is expected for each zero transmitted.
  - No pulse is expected for each one transmitted (input is high).

NOTE

The Rx part of the IR block expects to receive an inverted signal compared to IrDA specification. Circuitry external to the IC transforms the infrared signal to an electrical signal.

The IR interface has an edge triggered interrupt (IRINT). This interrupt validates a zero bit being received. This interrupt is enabled by writing a “one” to ENIRI bit.

The behavior of Infrared Interface is determined by 3 bits INVT (UCR3[1]), INVR (UCR4[9]) and IRSC (UCR4[5]).

59.4.7.2 Inverted Transmission and Reception bits (INVT and INVR)

The values of INVT and INVR depend of the IrDA transceiver connected on the TXD_IR and RXD_IR pins of the UART. If this transceiver is not inverting on both paths Tx and Rx, a zero is represented by a positive pulse and a one is represented by no pulse (line remains low). In this case, the bit INVT must be set to 0 and the bit INVR must be set to 1 (because Rx IR block expects an inverted signal).

On the contrary user must set INVT=1 and INVR=0 if both paths of the transceiver are inverting, that is, a Zero is represented as a negative pulse and a One is represented by no pulse (line remains high). The transceiver can also be inverting on only one path (Tx or Rx), in this case INVT and INVR must be together equal to 1 or to 0, depending on which path is inverted.

59.4.7.3 InfraRed Special Case (IRSC) Bit

The value to apply to IRSC bit is based on 2 parameters: the baud rate and the Minimum Pulse Duration (MPD) of the transceiver. According to IrDA Standard Specification, for SIR (Serial IR) baud rates from 2.4 Kbit/s to 115.2 Kbit/s this nominal pulse duration is equal to 3/16 of a bit duration (at the selected baud rate). But, for all the baud rates a Minimum Pulse Duration is also specified. According to IrDA Standard, a Zero is represented by a light pulse, so the IrDA transceiver can’t emit a light pulse shorter than the MPD. For SIR, the MPD is constant and equal to 1.41 us.

But user must take into account the electrical MPD associated to the transceiver on the receiver path. Typically this value is 2.0 us, but for some manufacturers MPD can go down to 1.0 us.

In order to understand the meaning of IRSC bit, one must understand how the RX path work in IrDA mode.

When UART is in IrDA mode, a Zero is not only detected by the state of the RXD_IR line, but also with the duration of the pulse. This pulse duration can be measured with two different clocks. In this case, clock is selected with the IRSC bit, as follows.

- If IRSC = 0, the clock used is the BRM clock.
- If IRSC = 1, the clock used is the UART internal clock (UART clock after the divider (RFDIV)).

In normal operation, IRSC=0. This means at any time, the user must insure the frequency of BRM_clock is high enough to measure the pulse. In the UART and for IRSC=0, the pulse must last at least 2 BRM clock cycles.

If this condition is not fulfilled, IRSC must be set to 1.

The following two examples, with the Minimum Pulse Duration equals to the MPD of the IrDA specification (in SIR), illustrate this.

Example 59-6. Calculation of BRM Clock Period (Clock Period < 1.41 µs)

The user wants to receive IrDA data at 115.2 Kbit/s. The UBIR and UBMR registers are set in order to create the BRM_clock with a frequency of 16 × baud rate = 16 × 115.2 = 1.843 MHz. But at the same time, in order to correctly detect the pulse, the user must be sure that 2 × BRM_clock period is lower than 1.41 µs.

This is checked as follows:

BRM_clock period = 1/1843000 = 542 ns

2 × BRM_clock period = 1.09 µs < 1.41 µs

Therefore, it is fine.

Example 59-7. Calculation of BRM Clock Period (Clock Period > 1.41 µs)

This time the user wants to receive at 19.2 Kbit/s. Therefore, the BRM_clock is set to 16 × 19200 = 307.2 kHz. Check whether 2 × BRM_clock period < 1.41 us as follows:

BRM_clock period =1/307200 = 3.25 µs

2 × BRM_clock period = 6.50 µs > 1.41 µs

Therefore, it does not work.

In this case, the BRM clock cannot be used to measure the pulse duration. The user must select the UART internal clock by setting IRSC = 1.

NOTE

Like for Escape character detection, when IR Special Case is enabled (IRSC=1), the UART must measure a duration. In order to do that, the user must fill the ONEMS register. Refer to Section 59.4.5.7, Escape Sequence Detection.”

59.4.7.4 IrDA interrupt

Serial infrared mode (SIR) uses an edge triggered interrupt flag IRINT (USR2[8]). When INVR =0, detection of a falling edge on the RXD pin asserts the IRINT bit. When INVR=1, detection of a rising edge on the RXD pin asserts the IRINT bit. When IRINT and ENIRI bits are both asserted, the *interrupt_uart* interrupt is asserted. Clear the IRINT bit by writing 1 to it. Writing 0 to the IRINT bit has no effect.

59.4.7.5 Conclusion about IrDA

Before using the UART in IrDA, the baud rate limit must be calculated. This baud rate limit will inform the user if IRSC bit has to be set or not.

Let's determine this limit:

As already described, if IRSC = 0, the following condition must always be fulfilled

Calculation of Baud Rate: ***Eqn. 59-4***

$$2 \times \text{BRMClockPeriod} < \text{MinPulseDuration}$$

Therefore,

$$\text{BRMClockFrequency} > \frac{2}{\text{MPD}}$$

Lnowing BRM_clock frequency = 16 × Baud Rate, we obtain:

$$\text{BaudRate} > \frac{1}{8 \times \text{MinPulseDuration}}$$

So, the user needs to set IRSC = 0 according to the following conditions:

- If Minimum Pulse Duration = 2.5 us and Baud Rate > 50 Kbit/s.
- If Minimum Pulse Duration = 2.0 us and Baud Rate > 62.5 Kbit/s.
- If Minimum Pulse Duration = 1.41 us and Baud Rate > 88.6 Kbit/s.

NOTE

For baud rates lower than the limit, IRSC must be set to 1.

59.4.7.6 Programming IrDA Interface

This section discusses the following:

- Section 59.4.7.6.1, High Speed"
- Section 59.4.7.6.2, Low Speed"

59.4.7.6.1 High Speed

The following example sequence can be used to program the IrDA interface in order to send and receive characters at 115.2 Kbit/s.

The assumptions are as follows:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 115.2 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to MCU when 1 char is received into the Rx FIFO (RDR)

Registers values and programming orders are as follows:

- UCR1 = 0x0085
  - UCR1[7] = IREN = 1: Enable IR interface
  - UCR1[0] = UARTEN = 1: Enable UART
- UTS = 0x0000
- UFCR = 0x0981
  - TXTL[5:0] = 0x02: Default value
  - RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock is 30 MHz)
  - RXTL[5:0] = 0x01: Default value
- UBIR = 0x0202
- UBMR = 0x20BE, Baud rate = 115.2 kbit/s with internal clock = 30 MHz
- UCR2 = 0x4027
  - UCR2[14] = IRTS = 1: Ignore level of RTS input signal
  - UCR2[5] = WS = 1: Characters are 8-bit length
  - UCR2[2] = TXEN = 1: Enable Rx path
  - UCR2 [1] = RXEN = 1: Enable Tx path
  - UCR2[0] = SRST_B = 1: No software reset
- UCR3 = 0x0000
- UCR4 = 0x8201
  - CTSTL[5:0] = 0x20: Default value
  - UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
  - UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)

The UART is ready to send a character as soon as there is a write into UTXD register. An interrupt will be sent to MCU when a character is received.

59.4.7.6.2 Low Speed

This example sequence uses the same assumptions as in Section 59.4.7.6.1, High Speed, ″ but the speed is now 9.6 Kbit/s. This baud rate is below the limit (even with a minimum pulse duration of 2.5 µs); thus IRSC must be set to 1.

The assumptions are as follows:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 9.6 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to MCU when 1 char is received into the Rx FIFO (RDR).

Registers values and programming orders are as follows:

- UCR1 = 0x0085
  - UCR1[7] = IREN = 1: Enable IR interface
  - UCR1[0] = UARTEN = 1: Enable UART
- UFCR = 0x0981
  - UFCR[15:10] = TXTL[5:0] = 0x02: Default value
  - RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock is 30 MHz)
  - UFCR[5:0] = RXTL[5:0] = 0x01: Default value
- UBIR = 0x00FF
- UBMR = 0xC354 Baud rate = 9.6 kbit/s with internal clock = 30 MHz
- UCR2 = 0x4027
  - UCR2[14] = IRTS = 1: Ignore level of RTS input signal
  - UCR2[5] = WS = 1: Characters are 8-bit length
  - UCR2[2] = TXEN = 1: Enable Rx path
  - UCR2 [1] = RXEN = 1: Enable Tx path
  - UCR2[0] = SRST_B = 1: No software reset
- UCR3 = 0x0000
  - UCR3[1] = INVT = 0: Positive pulse represents 0.
- UCR4 = 0x8221
  - UCR4[15:10] = CTSTL[5:0] = 0x20: Default value
  - UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
  - UCR4[5] = IRSC = 1: Because data rate is below the limit and thus the UART internal clock is used to measure the pulse duration.
  - UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)

The UART is now ready to send a character as soon as there is a write into UTXD register. An interrupt will be sent to MCU when a character is received.

59.4.8 Low Power Modes

Table 59-29 shows the UART functionality while in hardware controlled low-power modes. These modes are controlled by the signals *doze_req* and *stop_req*. The control/status/data registers do not change when entering or exiting low power modes.

Table 59-29. UART Low Power State Operation

	Normal State (*doze_req* = 1'b0 & *stop_req* = 1'b0)	Doze State (*doze_req* = 1'b1)		Stop State (*stop_req* = 1'b1)
		DOZE bit = 0	DOZE bit = 1	
UART-Clock	ON	ON	ON	OFF
UART Serial / IrDA	ON	ON	OFF	OFF

59.4.8.1 UART Operation in System Doze Mode

While in Doze State (when *doze_req* input pin is set to 1'b1), the UART behavior depends on the DOZE (UCR1[1]) control bit. While the DOZE bit is negated, the UART serial interface is enabled. While the system is in the Doze State, and the DOZE bit is asserted, the UART is disabled. If the Doze State is entered with the DOZE bit asserted while the UART serial interface was receiving or transmitting data, it will complete the receive/transmit of the current character and signal to the far-end transmitter/receiver to stop sending/receiving.

59.4.8.2 UART Operation in System Stop Mode

The internal baud rate clocks of the transmitter and receiver are gated off if the *stop_req* signal to UART is asserted. Even though the clocks at the input of UART module continue to run during system Stop mode the UART will not do any transmission or reception.

The following UART interrupts wake the MCU processor from STOP mode:

- RTS (RTSD)
- IrDA Asynchronous WAKE (AIRINT)
- Asynchronous WAKE (AWAKE)
- RI (RIDELT in DTE mode only)
- DCD (DCDDELT in DTE mode only)
- DTR (DTRD in DCE mode only)
- DSR (DTRD in DTE mode only)

When an asynchronous WAKE (awake) interrupt exits the MCU from STOP mode, make sure that a dummy character is sent first because the first character may not be received correctly.

59.4.8.3 Power Saving Method in UART

The RXEN (UCR2[1]), TXEN (UCR2[2]) and UARTEN (UCR1[0]) bits are set by the user and provide software control of low-power modes.

Setting the UARTEN (UCR1[0]) bit to 0 shuts off the receiver and transmitter logic and the associated clocks.

If the UART is used only in transmit mode, UARTEN and TXEN must be set to 1. If the UART is used only in receive mode, UARTEN and RXEN must be set to 1. Setting TXEN or RXEN to 0 allows to save a lot of power.

59.4.9 Reset

This section describes how to reset the module and explains special requirements related to reset.

59.4.9.1 Hardware reset

All of registers, FIFOs, state machines, and sequential elements can be reset to their initial values by hardware reset or power on reset.

59.4.9.2 Software reset

The status registers USR1 and USR2, BRM registers UBIR and UBMR, TxFIFO and RxFIFO, and transmitter and receiver state machines can be reset by software reset. Internal logic will remain the software reset signal at active for about 4 *module_clock* cycles. Programmer can follow the following software reset sequence:

1. Clear the $\overline{\text{SRST}}$ bit (UCR2[0])
2. Wait for software reset complete: poll SOFTRST bit (UTS[0]) until it is 0.
3. Re-program baud rate registers: Re-write UBIR and UBMR.

59.4.10 Transfer Error

The UART can generate a transfer error on the peripheral bus in the following cases:

- Core is writing into a read-only register.
- Core is accessing (read or write) an unused location within the assigned address space reserved to UART.
- Core is writing into UTXD register with transmit interface disabled (TXEN=0 or UARTEN=0)
- Core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0)

59.4.11 Functional Timing

This section includes timing diagrams for functional signaling.

59.4.11.1 RS-232 Mode

When transmitting a byte, the UART first sends a Start Bit which is logic 0, followed by the data (general 8 bits, but could be 7 bits) followed by patity bit (optional) and one or two Stop Bits which is logic 1. The

sequence is repeated for each byte sent. Figure 59-24 shows a diagram of a what a byte transmission would look like.The receiver also sample data according to this format.

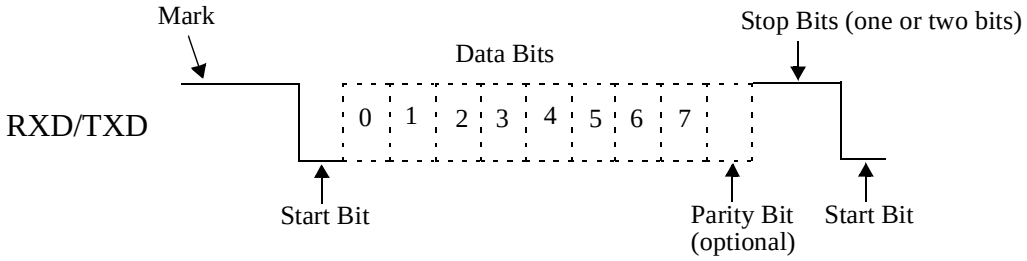


Figure 59-24. Timing Diagram of RS-232 Serial Data Line

59.4.11.2 IrDA Mode

According to IrDA specification, the low speed (115.2 Kbit/s and below) IR frame format is compatible with UART frame. Figure 59-25 shows the timing of IR data line and corresponding UART frame. In this figure, an example data 0x65 is used.

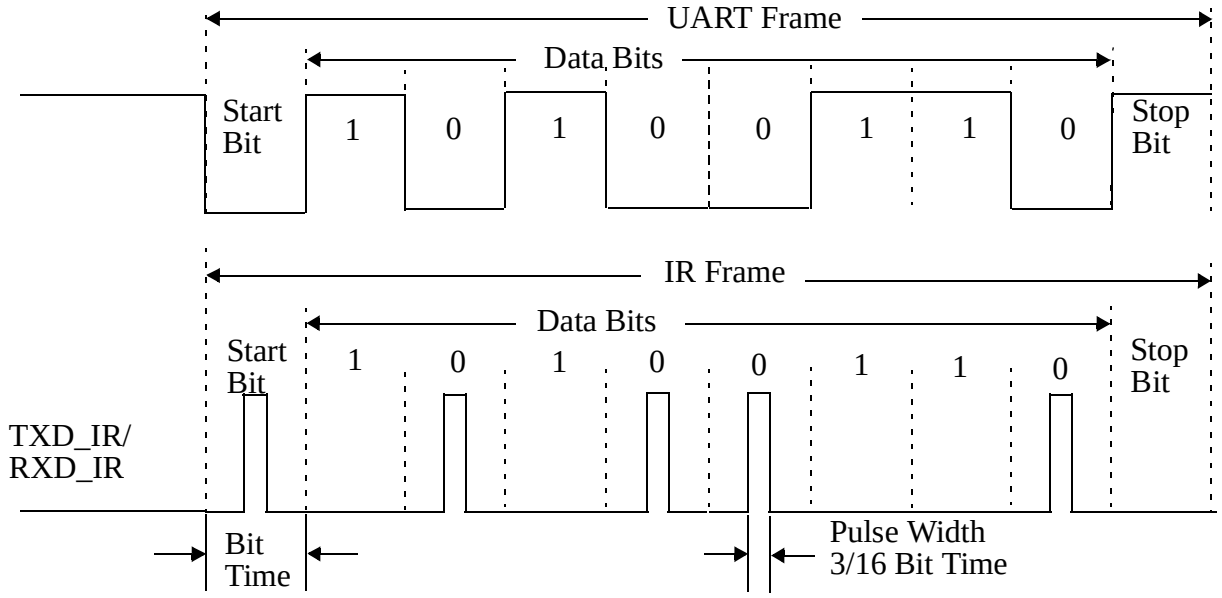

Figure 59-25. Timing diagram of Low Speed IR (≤115.2 Kbit/s) Data Line

59.5 Initialization

The following example sequence can be used to program the UART in order to send and receive characters in RS-232 mode.

The assumptions are as follows:

- Input UART clock = 100 MHz
- Baud rate = 921.6 Kbps
- Data bits = 8 bits
- Parity = Even
- Stop bits = 1 bit
- Flow control = Hardware

Main program:

1. UCR1 = 0x0001

Enable the UART.

2. UCR2 = 0x2127

Set hardware flow control, data format and enable transmitter and receiver.

3. UCR3 = 0x0704

Set UCR3[RXDMUXSEL] = 1.

4. UCR4 = 0x7C

Set CTS trigger level to 31,

5. UFCR = 0x089E

Set internal clock divider = 5 (divide input UART clock by 5). So the reference clock is 100 MHz ÷ 5 = 20 MHz.

Set TXTL = 2 and RXTL = 30.

6. UBIR = 0x08FF
7. UBMR = 0x0C34

In the above two steps, set baud rate to 921.6 Kbps based on the 20 MHz reference clock.

8. UCR1 = 0x2201

Enable the TRDY and RRDY interrupts.

Interrupt service routine for the transmitter:

- Write characters into UTXD

The TRDY interrupt is automatically de-asserted when the data level of the TxFIFO exceeds the TXTL = 2. Note that the first time, the interrupt may be de-asserted after four characters are written into the TxFIFO because of the shift register.

Interrupt service routine for the receiver:

- Read characters from URXD

The RRDY interrupt will be automatically de-asserted when the data level of the RxFIFO is below the RXTL = 30.

Chapter 60
Universal Serial Bus OTG HOST (USBOH3)

60.1 Introduction

The USBOH3 module provides high performance USB On-The-Go (OTG) functionality that conforms to the USB 2.0 specification, the OTG supplement, and the ULPI specification. The module consists of four independent USB cores, each with serial and ULPI USB ports. Three of the USB host controllers are identical.

In addition to the normal USB functionality, the module also supports direct connections to on-board USB peripherals using serial or ULPI protocol. It also has serial/ULPI bypass mode connection and support for multiple interface types of ULPI and serial transceivers.

It provides for Full-Speed Transceiverless Link (FS-TLL) operation on host port 1, port 2, and port 3. High-Speed Transceiverless Link (HS-TLL) operation is possible on all four ports and the IC-USB interface on host ports 1, 2, and 3, which permits routing of the OTG transceiver interface to host port 1. This allows this transceiver to be used to communicate with a USB peripheral connected to host port 1.

Figure 60-1 shows a block diagram of USBOH3.

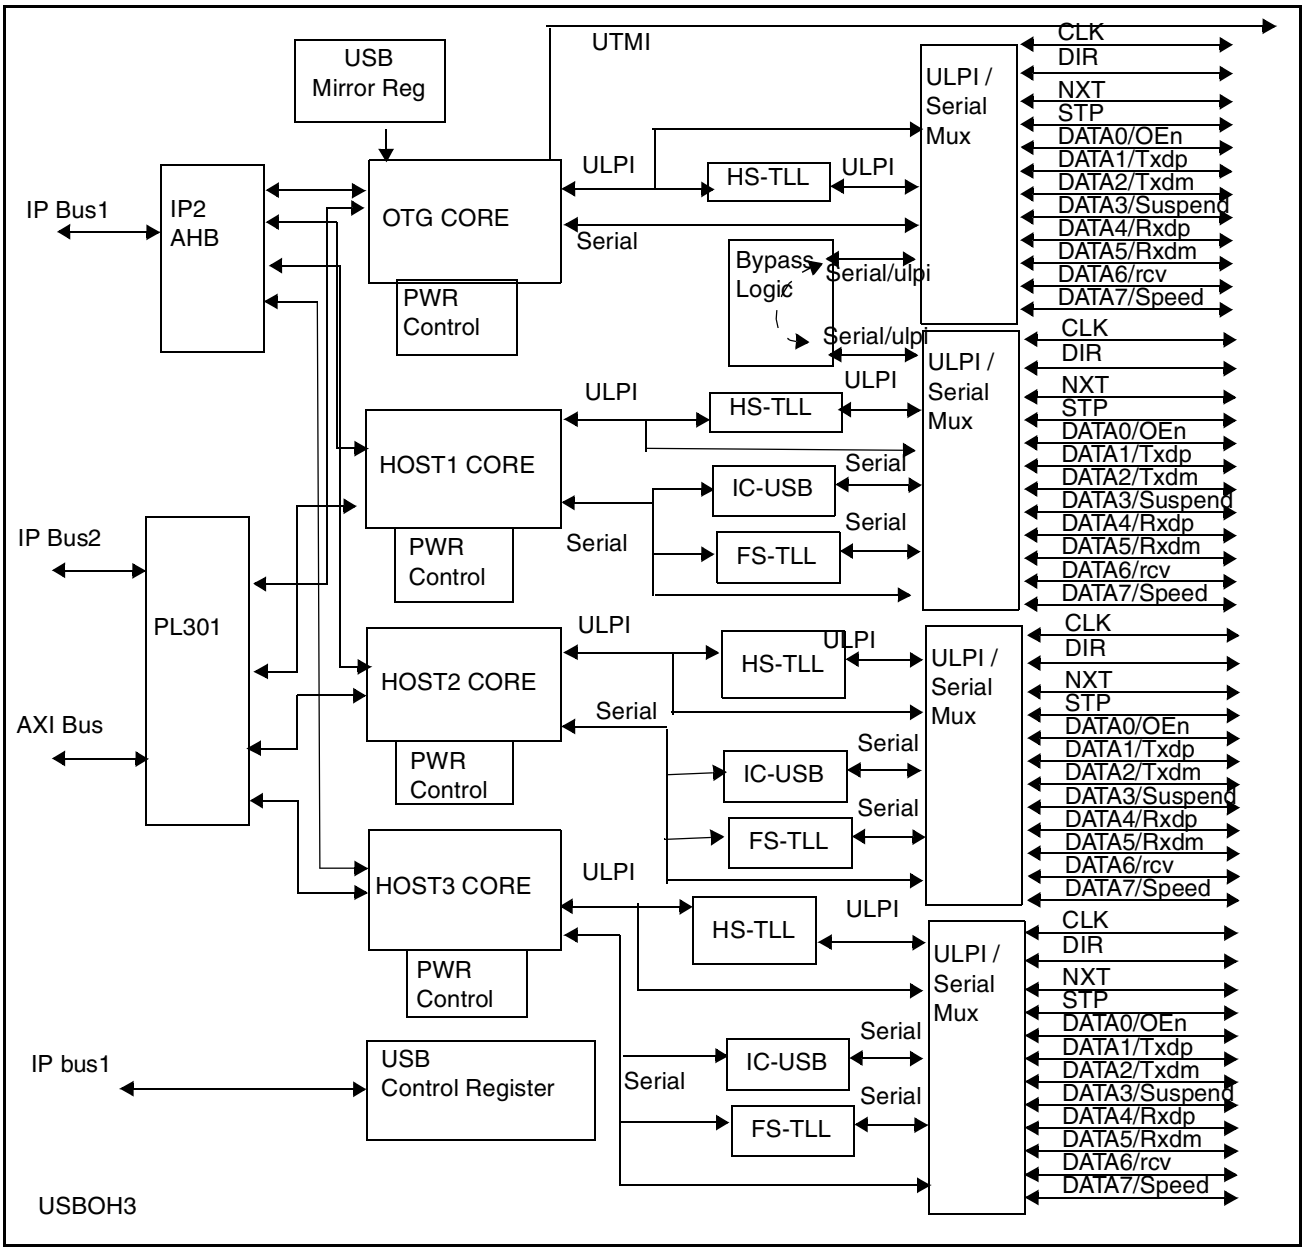

Figure 60-1. USBOH3 Block Diagram

60.1.1 Features

The USBOH3 module includes the following features:

- High-speed/full-speed/low-speed host only core (HOST 1)
  - — HS/FS ULPI compliant interface
  - — Software configurable for full-speed/low-speed interface for serial transceiver

- Full-Speed transceiverless link logic (FS-TLL) for onboard connection to a FS/LS USB peripheral
- High-speed ULPI transceiverless link logic (HS-TLL) for onboard connection to a high-speed ULPI interface USB peripheral (ULPI Link)
- Bypass mode to route host port 1 signals to OTG I/O port by Serial or ULPI mode

- High-speed/full-speed/low-speed host only core (HOST2)
  - HS/FS ULPI compliant interface
  - Software configurable for full speed/low speed interface for serial transceiver
  - Full-speed transceiverless link logic (FS-TLL) for on board connection to a FS/LS USB peripheral
  - High-speed ULPI transceiverless link logic (HS-TLL) for on board connection to a high-speed ULPI interface USB peripheral
- High-speed/full-speed/low-speed Host Only core (HOST3)
  - HS/FS ULPI compliant interface
  - Software configurable for full-speed/low-speed interface for serial transceiver
  - Full-speed transceiverless link logic (FS-TLL) for on board connection to a FS/LS USB peripheral
  - High-speed ULPI transceiverless link logic (HS-TLL) for onboard connection to a high-speed ULPI interface USB peripheral
- High-speed OTG core
  - HS/FS ULPI compliant interface
  - Software configurable for ULPI or serial transceiver interface
  - High-speed (with ULPI transceiver), full-speed, and low-speed operation in host mode
  - High-speed (with ULPI transceiver), and full-speed operation in peripheral mode
  - Hardware support for OTG signaling, session request protocol, and host negotiation protocol
  - Up to 8 bidirectional endpoints
- Low-power mode with local and remote wake-up capability
- Serial PHY interfaces configurable for bidirectional/unidirectional and differential/single ended
- Embedded DMA controller

60.1.2 Modes of Operation

The USBOH3 module has two main modes of operation: normal mode and bypass mode. Furthermore, each USB core interface can be configured for high-speed operation (480 Mbps) and/or full-/low-speed operation (12/1.5 Mbps).

60.1.2.1 Operational Modes

The following subsections describe the configuration options in greater detail.

60.1.2.1.1 Normal Mode

In normal mode, each USB core controls its corresponding port. Each port can work in one or more modes.

- Host Ports 1, 2, and 3

  Each port supports ULPI and serial transceivers.

  — Serial interface mode

  PHY mode—for connections using transceivers.

  TLL mode—for direct onboard connections to FS USB peripherals.

  — ULPI interface mode

  ULPI is the low-pin count standard for connecting off-chip high-speed USB transceivers to a USB device. When the port is configured for ULPI mode, only a ULPI compatible transceiver can be used

  — IC-USB mode

  Host can connect with IC-USB device

  — HS/FS TLL mode

  In TLL mode, internal logic is enabled to emulate the functionality of two back-to-back connected transceivers. The HS-TLL is used in ULPI interface for high speed transfer. and the FS-TLL is used in serial interface for full/low speed transfer. These two modes are typically used for on-board USB connections to USB-capable peripherals

- OTG port

  This Port requires a transceiver and is intended for off-board USB connections.

  — Serial Interface mode

  In serial mode, a serial OTG transceiver must be connected. The port does not support dedicated signals for OTG signaling. Instead, a transceiver with built-in OTG registers must be used. Typically, the transceiver registers are accessible over an I^2C or SPI interface

  — ULPI Mode

  It this mode, a ULPI transceiver is connected to the port pins to support High-speed off-chip USB connections. The ULPI mode is activated by writing to the appropriate register

  — HS TLL mode

  In HS-TLL mode, internal logic is enabled to emulate the functionality of two back-to-back connected transceivers. The OTG port can only support HS-TLL

NOTE

Since ULPI and Serial mode do not operate at the same time they share the ULPI_DATA[7:0] signals as the serial interface signals. Table 60-1 shows the signal mapping for serial interface in four different serial modes.

Table 60-1. ULPI_DATA[7:0] Signal Mapping

	Unidirectional Differential	Unidirectional Single-End	Bidirectional Differential	Bidirectional Single-End
ulpi_data[0]	oen	oen	oen	oen

Table 60-1. ULPI_DATA[7:0] Signal Mapping

ulpi_data[1]	txdp	tx_dat	dp	dat
ulpi_data[2]	txdm	tx_se0	dm	se0
ulpi_data[3]	suspend	suspend	suspend	suspend
ulpi_data[4]	rxdp	rxdp	/	/
ulpi_data[5]	rxdm	rxdm	/	/
ulpi_data[6]	rcv	rcv	rcv	/
ulpi_data[7]	speed	speed	speed	speed

60.1.2.1.2 Bypass Mode

Bypass mode affects the operation of the OTG port and host port 1. This mode is only available when a serial/ULPI transceiver is used on the OTG port and the peripheral device on host 1 port is using a TLL connection with same type port.

Bypass mode is activated by setting the bypass bit in the USBCONTROL register. In this mode, the USB OTG port connections are internally routed to the USB HOST 1 port, such that the transceiver on the OTG port connects to a peripheral USB device attached to the HOST 1 port. The OTG core and the HOST 1 core are disconnected from their ports when bypass is active. When in serial bypass mode, the status of the DM and DP inputs for the cores is programmable in the USB Control Register (Table 60-2).

60.1.2.1.3 Low-Power Mode

Each of the three USB cores has an associated power control module that is controlled by the USB core and clocked using a 32 kHz clock. When a USB bus is idle, the transceiver can be placed in low-power mode (suspend), after which the clocks to the USB core can be stopped. The 32 kHz low-power clock must remain active as it is needed for wakeup detection.

Either the local CPU or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication.

60.2 Memory Map/Register Definition

Table 60-2 shows the USBOH3 module memory map.

60.2.1 Register Descriptions

This section describes only the registers that are additional to the HS-USB Core register set.

60.2.1.1 USB_CTRL — USB Control Register

The USB control register controls the integration specific features of the USB module. These features are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wake-up functionality.

Figure 60-2 shows the USB_CTRL registe.

Figure 60-2. USB_CTRL Register

Table 60-3 describes the USB_CTRL register fields.

Table 60-3. USB_CTRL Register Field Descriptions

Field	Description
31 OWIR	OTG Wake up Interrupt Request This bit indicates that a wake-up interrupt request is received on the OTG port. This bit is cleared by disabling the wake-up interrupt. 1 Wake-up Interrupt Request received 0 No Wake-up detected
30–29 OSIC	OTG Serial Interface Configuration Controls the interface type of the OTG port when used with a serial transceiver. This bit field allows for configuring the serial interface for single-ended or differential operation combined with bidirectional or unidirectional operation. The available settings are described below. **Note:** When using bidirectional mode, the IOMUX must be configured to place the DP/DM pad into loopback mode. • Bit 30's settings are as follows: 0 Differential/unidirectional (6-wire) 0 Differential/bidirectional (4-wire) 1 Single ended/unidirectional (6-wire) (Default) 1 Single ended/unidirectional (6-wire) (Default) • Bit 29's settings are as follows 0 Differential/unidirectional (6-wire) 1 Differential/bidirectional (4-wire) 0 Single ended/unidirectional (6-wire) (Default) 1 Single ended/unidirectional (6-wire) (Default)
28 OUIE	OTG ULPI interrupt enable Controls whether or not interrupts from the ULPI transceiver will trigger the wake-up logic. This bit is only meaningful when a ULPI transceiver is selected. 1 ULPI transceiver interrupts activate the wake-up logic 0 ULPI transceiver interrupts are ignored by the wakeup logic.
27 OWIE	OTG Wake-up Interrupt Enable This bit enables or disables the OTG wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit. Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to going in suspend mode 1 Interrupt Enabled 0 Interrupt Disabled
26–25 OBPVAL	OTG Bypass Value This field contains the status of the RxDp and RxDm inputs to the OTG core when Bypass mode is enabled. Bit 26 controls RxDp, bit 25 controls RxDm.
24 OPM	OTG Power Mask The power mask bit controls whether or not the external Vbus Power and OverCurrent detection are active for the OTG port. 1 The USBPWR and OC pins are not used by the OTG core. 0 The USBPWR pin will assert with the OTG core's Vbus power Enable and the assertion of the OC input will be reported to the OTG core.
23 ICVOL	Host1 IC-USB voltage status Indicates the voltage status of IC-USB 1 3.0 V class 0 1.8 V class
22–20	Reserved

Table 60-3. USB_CTRL Register Field Descriptions (continued)

Field	Description
19 ICTPIE	IC USB TP interrupt enable 1 IC USB TP interrupt enable 0 IC USB TP interrupt disable
18 UBPCKE	Bypass clock enable 1 Bypass Host1 ulpi clock to OTG port 0 Bypass OTG ulpi clock to Host1 port
17 H1TCKOEN	Host1 ULPI PHY clock output enablej 1 CLK output disable 0 CLK output enable
16 ICTPC	Clear IC TP interrupt flag 1 Clear IC TP interrupt flag 0 Not clear IC TP interrupt
15 H1WIR	Host 1 Wake-up Interrupt Request Indicates a pending Wake-up request on Host port 1. This bit is cleared by disabling the interrupt. The interrupt must be disabled for at least 2 clock cycles of the standby clock. 1 Wake-up interrupt received 0 No Wake-up interrupt received
14–13 H1SIC	Host 1 Serial Interface Configuration Controls the interface type of the Host 1 port when used with a serial transceiver. This bit field allows for configuring the serial interface for single-ended or differential operation combined with bidirectional or unidirectional operation. The available settings are described below. **Note:** In bidirectional mode, IOMUX must set the DP/DM pad into loopback mode. • Bit 14's settings are as follows: 0 Differential/unidirectional (6-wire) 0 Differential/bidirectional (4-wire) 1 Single ended/unidirectional (6-wire) (Default) 1 Single ended/biidirectional (3-wire) (Default) • Bit 13's settings are as follows 0 Differential/unidirectional (6-wire) 1 Differential/bidirectional (4-wire) 0 Single ended/unidirectional (6-wire) (Default) 1 Single ended/biidirectional (3-wire) (Default)
12 H1UIE	Host 1 ULPI interrupt enable Controls whether or not interrupts from the ULPI transceiver will trigger the wake-up logic. This bit is only meaningful when a ULPI transceiver is selected. 1 ULPI transceiver interrupts activate the wake-up logic. 0 ULPI transceiver interrupts are ignored by the wakeup logic.
11 H1WIE	Host 1 Wake-up Interrupt Enable This bit enables or disables the Host 1 wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit. Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to going in suspend mode 1 Interrupt Enabled 0 Interrupt Disabled
10–9 H1BPVAL	HOST 1 Bypass Value This field contains the status of the RxDp and RxDm inputs to the HOST1 core when Bypass mode is enabled. Bit 10 controls RxDp, bit 9 controls RxDm.

Table 60-3. USB_CTRL Register Field Descriptions (continued)

Field	Description
8 H1PM	Host 1 Power Mask Used to mask the Host1 USB VBUS enable function. 1 Host 1 VBUS enable is controlled by the Host 1 controller (PORTSC.PP bit) 0 Host 1 VBUS enable is always inactive
7 OHSTLL	OTG ULPI TLL Enable 1 ULPI TLL is Enabled 0 ULPI TLL is Disabled (Default)
6 H1HSTLL	Host 1 ULPI TLL Enable 1 ULPI TLL is Enabled 0 ULPI TLL is Disabled (Default)
5	Reserved
4 H1DISFSTLL	Host 1 Serial TLL disable This bit controls the Serial TLL logic (FS-TLL) for Host Port 1 1 Serial TLL is disabled 0 Serial TLL is enabled (Default)
3–2	Reserved
1 OTCKOEN	OTG ULPI PHY clock output enablej 1 CLK output disable 0 CLK output enable
0 BPE	Bypass Enable This bit enables/disables the USB Bypass function. 1 Bypass active—USB signals from Host port 1 are routed to the OTG port. 0 Bypass inactive—Normal mode operation (Default).

60.2.1.2 USB_OTG_MIRROR—OTG Port Mirror Register

The OTG port is designed for operation with an external OTG transceiver. When a ULPI transceiver is in use, all OTG signaling is communicated over the ULPI data bus as described in the ULPI specification. However, when a serial transceiver is used, the interface for OTG signaling is not standardized. Most OTG transceivers use a serial interface like I^2C or SPI to transfer the OTG signaling back to the CPU and/or USB core. In this case, the USB CORE has no direct connection the OTG signals in the transceiver.

The OTGMIRROR register, shown in Figure 60-3, provides a soft interface between the OTG signals in the transceiver and the OTG signal inputs to the USB core. The USB driver software is responsible for reading the OTG status registers in the transceiver over the serial interface and set the bits accordingly in the OTGMIRROR register (see Figure 60-6), such that the USB controller knows the status of the transceiver.

The USB driver should be designed such that the latency requirements as defined in the USB 2.0 OTG supplement specification are met.

Figure 60-3. OTG Mirror Register (OTGMIRROR)

Table 60-4 shows the OTG mirror register field descriptions.

Table 60-4. OTG Mirror Register Field Descriptions

Field	Description
8 UTMIPHYCLK	OTG UTMI PHY Clock on detection This is a read-only status bit, indicating the external USB UTMI PHY clock is on and sent to USB controller. 1 The OTG ULPI input clock is on 0 The OTG ULPI input clock is off
7 ULPIPHYCLK	OTG ULPI PHY Clock on detection This is a read-only status bit, indicating the external USB ULPI PHY clock is on and sent to USB controller. 1 The OTG ULPI input clock is on 0 The OTG ULPI input clock is off
6–5	Reserved
4 SESEND	B device Session End This bit is set by the USB driver when the PHY reports a Session End condition. 1 Session end (0.2 V < Vbus < 0.8 V) 0 Session active
3 VBUSVLD	Vbus Valid The USB driver sets this bit when the transceiver reports Vbus Valid. 1 Vbus is valid (Vbus > 4.4 V) 0 Vbus Invalid (Vbus < 4.4 V)
2 BSESVLD	B Session Valid B session valid should be set when the transceiver reports B-session Valid. 1 B Session is valid (0.8 V < Vbus < 4.0 V) 0 B Session is not valid (Vbus < 0.8 V)
1 ASESVLD	A session Valid This bit must be set when a valid ‘A-Session’ level is detected on Vbus. 1 A Session is valid (0.8 V < Vbus < 2.0 V) 0 Session is not valid for A-device.
0 IDIDG	OTG ID-Pin Status This bit indicates to the USB core whether it should operate as A-device or as B-device 1 ID pin is high—Operate as B-device 0 ID pin is low —Operate as A-device

60.2.1.3 PHY_CTRL_0/1—UTMI PHY Control Register 0/1(Base + 0x808/0x80c)

PHY Control Registers 0/1, shown in Figure 60-4 and Figure 60-5, are used to control the internal UTMI PHY.

18 ICVOL	Host1 IC-USB voltage status Indicates the voltage status of IC-USB 1 3.0 V class 0 1.8 V class
17 H3WIR	Host 3 Wake-up Interrupt Request Indicates a pending wake-up request on Host port 3. This bit is cleared by disabling the interrupt. The interrupt must be disabled for at least 2 clock cycles of the standby clock. 1 Wake-up interrupt received 0 No Wake-up interrupt received
16–14	Reserved
13 ICTPIE	IC USB TP interrupt enable 1 IC USB TP interrupt enable 0 IC USB TP interrupt disable
12 H3TCKOEN	Host3 ULPI PHY clock output enable 1 CLK output disable 0 CLK output enable
11 ICTPC	IC USB TP interrupt clear 1Clear IC USB TP interrupt 0not clear
10–9 H3SIC	Host 1 Serial Interface Configuration Controls the interface type of the Host 3 port when used with a serial transceiver. This bit field allows for configuring the serial interface for single-ended or differential operation combined with bidirectional or unidirectional operation. The available settings are described below. **Note:** In bidirectional mode, IOMUX must set the DP/DM pad into loopback mode. • Bit 10's settings are as follows: 0 Differential/unidirectional (6-wire) 0 Differential/bidirectional (4-wire) 1 Single ended/unidirectional (6-wire) (Default) 1 Single ended/biidirectional (3-wire) • Bit 9's settings are as follows 0 Differential/unidirectional (6-wire) 1 Differential/bidirectional (4-wire) 0 Single ended/unidirectional (6-wire) (Default) 1 Single ended/biidirectional (3-wire)

Table 60-9. USB_UH3_CTRL Register Field Descriptions (continued)

Field	Description
8 H3UIE	Host 3 ULPI interrupt enable Controls whether or not interrupts from the ULPI transceiver will trigger the wake-up logic. This bit is only meaningful when a ULPI transceiver is selected. 1 ULPI transceiver interrupts activate the wake-up logic 0 ULPI transceiver interrupts are ignored by the wakeup logic.
7 H3WIE	Host 3 Wake-up Interrupt Enable This bit enables or disables the Host 3 wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit. Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to going in suspend mode. 1 Interrupt Enabled 0 Interrupt Disabled
6–5 H3BPVAL	HOST 3 Bypass Value This field contains the status of the RxDp and RxDm inputs to the HOST3 core when Bypass mode is enabled. Bit 6 controls RxDp, and bit 5 controls RxDm.
4 H3PM	Host 3 Power Mask The power mask bit controls whether or not the external Vbus Power and Over Current detection are active for the Host 3 port. 1 The USBPWR and OC pins are not used by the Host 3 core. 0 The USBPWR pin asserts with the Host 1core's Vbus power Enable and the assertion of the OC input is reported to the Host 3 core.
3 H3HSTLL	Host3 ULPI TLL Enable 1 ULPI TLL is Enabled 0 ULPI TLL is Disabled (Default)
2	Reserved
1 H3DISFSTLL	Host 3 Serial TLL disable This bit controls the Serial TLL logic (FS-TLL) for Host Port 3 1 Serial TLL is disabled 0 Serial TLL is enabled (Default)
0	Reserved

60.2.1.7 USB Core Register

For detailed descriptions of the OTG Controller, Host 1, and Host 2 Controller registers, refer to Section 60.4.2, Register Interface." The value of registers that depend on implementation can be found in the core configuration parameter file (for the OTG Controller refer to Section 60.3.4.1, OTG Controller Configuration Parameter," for the Host1 Controller refer to Section 60.3.1.1, Host Controller 1 Configuration Parameter," and for the Host2 Controller refer to Section 60.3.2.1, Host Controller 2 Configuration Parameter."

60.3 Functional Description

This section describes the functionality and the topology of the different building blocks of the USB module.

60.3.1 USB HOST Controller 1

Host Controller 1 is an instantiation of the core. The core is configured for high-speed/full-speed/low-speed operation.

60.3.1.1 Host Controller 1 Configuration Parameter

Host controller 1 is configured for high-speed/full-speed/low-speed operation and supports serial transceiver interface and ULPI interface. The parameters in Example 60-1 are set for the implementation of the host controller core.

Example 60-1. Host Controller Implementation

```
// ------------------------------------------------------------------------
// ------------------------------------------------------------------------
//  System Configuration Options
// ------------------------------------------------------------------------
//
//  The VUSB_HS_RESET_TYPE constant determines the reset type used in the core.
//    0 = Use Synchronous Resets
//    1 = Use Asynchronous Resets
//
//  The VUSB_HS_RESET_OPTIONAL constant determines if various register files
//  are connected to the main reset.
//
//  0 = Reset all flops except those listed above.
//  1 = Reset 100% of flops.
//
parameter VUSB_HS_RESET_TYPE = 1; //  [0,1]
parameter VUSB_HS_RESET_OPTIONAL = 0; //  [0,1]
//
//  The VUSB_HS_CLOCK_CONFIGURATION constant determines the clocking used in the core
//  See reference manual for a description of the clocking modes available.
//
//    0 = xcvr_clk_0 = pe_clk = clk (do not select for multi-port host product)
//    1 = xcvr_clk_0 < pe_clk = clk
//    2 = xcvr_clk_0 = pe_clk <> clk (do not select for multi-port host product)
//    3 = xcvr_clk_0 < pe_clk <> clk
parameter VUSB_HS_CLOCK_CONFIGURATION = 2; //  [0,1,2,3]
//
//  phy size (UTMI Only)
//  Set according to the data width of the transciever connected to the core.
//    0 = 8 bit wide data bus [60MHz clock from the transciever]
//    1 = 16 bit wide data bus [30MHZ clock from the transciever]
//    2 = software programmable reset to 8-bit width
//    3 = software programmable reset to 16-bit width
//  NOTE: options 2,3 are not recommended when VUSB_HS_CLOCK_CONFIGURATION = 0
parameter VUSB_HS_PHY16_8 = 0; //  [0,1,2,3]
//  This constant selects which phy is being used
//  0 = UTMI/UMTI+
```

```
//  1 = Philips legacy style
//  2 = ULPI ** Must have purchased the ULPI Option **
//  3 = Serial Only
//  4 = Software programmable - reset to UTMI
//  5 = Software programmable - reset to Philips legacy style
//  6 = Software programmable - reset to ULPI ** Must have purchased the ULPI Option **
//  7 = Software programmable - reset to Serial
//  NOTE: options 4,5,6,7 are not recommended when VUSB_HS_CLOCK_CONFIGURATION = 0
//  NOTE: undefined results if ULPI is selected (#2,6) and the ULPI option was not purchased &
installed.
parameter VUSB_HS_PHY_TYPE = 7; //  [0,1,2,3,4,5,6,7]
//  derived constants ; must set to match VUSB_HS_PHY_TYPE above according the attached
instructions.
parameter VUSB_HS_PHY_UTMI = 0; //  [0,1] ; set to 0 if VUSB_HS_PHY_TYPE=1,2,3       else 1

//  Host Configuration
// ------------------------------------------------------------------------
//  The VUSB_HS_NUM_PORT constant specifies the number of downstream ports
//  supported by the host controller.  This constant is only relevant for
//  for the multi-port host product.  Leave 1 for device, otg, and single port host
//  products.
//
//  Maximum: 8 downstream ports.
//
parameter VUSB_HS_NUM_PORT = 1; //  [1,2,...,8]
// ------------------------------------------------------------------------
//  Host Configuration - Internal Transaction Translator
// ------------------------------------------------------------------------
//  These constants define how many periodic contexts the internal TT can support.
//
//  Note1: These constants are only relevent for the multi-port host product.
//  Note2: The number of async. contexts should not be adjusted.
//
```

```
//  USB 2.0 spec requires 16 periodic contexts for a hub TT although this seems unncessarily
//  big for an embedded application where limits can be imposed on the downstream applications.
//  Changing the  number from 16 to 4 will significantly reduce gate count but be cautioned
//  that this will impose limits on the number of downstream periodic (ISO/Interrupt)
transactions.
//
//  The simplifying limit imposed when the number of periodic contexts is reduced to 4 is
//  that the application can send no more than 4 periodic (ISO/Interrupt) packets per
//  frame to the downstream Full and Low-Speed devices. Whereas, when the number
//  of periodic contexts are 16, its possible to pipeline packets accross the
//  microframes and send as many periodic packets per frame as can be scheduled (> 16).
//
parameter VUSB_HS_TT_ASYNC_CONTEXTS = 2; //  DO NOT CHANGE

parameter VUSB_HS_TX_CHAN_STATE = 4; //  DO NOT CHANGE
parameter VUSB_HS_TX_CHAN_STATE_ADD = 2; //  DO NOT CHANGE
parameter VUSB_HS_TX_CHAN_DATA = VUSB_HS_TX_CHAN - VUSB_HS_TX_CHAN_STATE; //  DO NOT CHANGE
//  Depth & Number Of Address Bits For TX Buffer
//  ** NOTE ** : VUSB_HS_TX_DEPTH and VUSB_HS_TX_ADD must be updated when either
//               VUSB_HS_TX_CHAN or VUSB_HS_DEV_EP are changed.
```

```
//  Host Only : VUSB_HS_TX_DEPTH = VUSB_HS_TX_CHAN
//  Device    : VUSB_HS_TX_DEPTH = (VUSB_HS_TX_CHAN)*min(1,VUSB_DEV_EP)
//          : VUSB_HS_TX_DEPTH <--> ** Power of 2 not necessary ** ; integer multiple of power
of 2 acceptable;
//                                    ie. 2**X * VUSB_HS_DEV_EP.
//                              (verify code exists for chosen TX_DEPTH in graycode package file)
parameter VUSB_HS_TX_DEPTH = 128; //  (VUSB_HS_TX_CHAN)*max_int(1,VUSB_HS_DEV_EP);
parameter VUSB_HS_TX_ADD = 7; //  log2(VUSB_HS_TX_DEPTH);
parameter VUSB_HS_TX_BURST = 8; //  Burst size for Memory To TX Buffer Transfers
//  Minimum : 2
//  Maximum : 128
//  Recommended : >= 4
//
//  Device/OTG : This constant determines if the device endpoint
//  context data used for rapid transmit response (reduced latency) and
//  double buffering tracking is stored in the TX-FIFO or if it is held
//  in registers.  There are advantages and disadvantages to each configuration:
//
//  = 0 (context in FIFO)
//     advantage    : smaller gate count & power (less 126 registers + misc. per endpoint)
//    disadvantage : actual latency buffer size is smaller because 4 words are used for context
(ie. actual VUSB_HS_TX_CHAN-4 words)
//                   FIFO interface is 2 read ports / 1 write port***
//
//  = 1 (context is registers)
//     advantage    : latency buffer uses full VUSB_HS_TX_CHAN words for data
//                   FIFO interface is 1 read port / 1 write port***
//     disadvantage : larger gate count & power (adds 144 registers + misc.)
//
//  *** this difference MAY be significant with some technologies and MAY offset the gate count
and power difference.
//
parameter VUSB_HS_TX_LOCAL_CONTEXT_REGISTERS = 1; //  [0 - context in FIFO, 1 - context in
registers]
// ------------------------------------------------------------------------
//  Device Version Number
// ------------------------------------------------------------------------
parameter VUSB_HS_DCIVERSION = 16'b 0000000000000001;
parameter VUSB_HS_HCIVERSION = 16'b 0000000100000000; //  EHCI 1.00
```

60.3.1.2 Host Controller 1 to Host Port 1 Interface

Host 1 core USB signals do not connect directly to the HOST1 I/O pins. Instead, the signals pass through the bypass mux and serial and ULPI mux, which allows additional functionality on Host Port1. The module defaults to serial mode. See Section 60.3.7, USB Bypass Mode," for Bypass Mux details.

Table 60-10 details the I/O pad connections for the USB Host Port 1. The direction control is logic 1 for output.

Table 60-10. Host Port 1 Signal Connections

I/O PAD	Type	Input	Output	Direction Control
USB1_ULPI_CLK	I/O	ipp_ind_uh1_clk	ipp_do_uh1_clk	ipp_obe_uh1_clk
USB1_ULPI_DIR	I/O	ipp_ind_uh1_dir	ipp_do_uh1_dir	ipp_obe_uh1_dir

Table 60-10. Host Port 1 Signal Connections (continued)

I/O PAD	Type	Input	Output	Direction Control
USB1_ULPI_STP	I/O	ipp_ind_uh1_stp	ipp_do_uh1_stp	ipp_obe_uh1_stp
USB1_ULPI_NXT	I/O	ipp_ind_uh1_nxt	ipp_do_uh1_nxt	ipp_obe_uh1_nxt
USB1_ULPI_DATA0	I/O	ipp_ind_uh1_data0	ipp_do_uh1_data0	ipp_obe_uh1_data0
USB1_ULPI_DATA1	I/O	ipp_ind_uh1_data1	ipp_do_uh1_data1	ipp_obe_uh1_data1
USB1_ULPI_DATA2	I/O	ipp_ind_uh1_data2	ipp_do_uh1_data2	ipp_obe_uh1_data2
USB1_ULPI_DATA3	I/O	ipp_ind_uh1_data3	ipp_do_uh1_data3	ipp_obe_uh1_data3
USB1_ULPI_DATA4	I/O	ipp_ind_uh1_data4	ipp_do_uh1_data4	ipp_obe_uh1_data4
USB1_ULPI_DATA5	I/O	ipp_ind_uh1_data5	ipp_do_uh1_data5	ipp_obe_uh1_data5
USB1_ULPI_DATA6	I/O	ipp_ind_uh1_data6	ipp_do_uh1_data6	ipp_obe_uh1_data6
USB1_ULPI_DATA7	I/O	ipp_ind_uh1_data7	ipp_do_uh1_data7	ipp_obe_uh1_data7

Host port 1can support either a ULPI transceiver or a Serial Transceiver (FS/LS). Depending on the selected type, signaling for one or the other is available at the top level. Table 60-13 gives the relation between the top level signal and the USB core signal in both modes.

Table 60-11. / Serial Muxing

60.3.2 USB Host Controller 2

The host 2 core USB signals do not connect directly to the HOST2 I/O pins. Instead, the signals pass through the HS-ULPI TLL and serial and ULPI mux, which allows additional functionality on Host Port2. Host controller 2 is configured for operation with a FS/LS serial transceiver or a parallel ULPI transceiver (HS/FS/LS). The selection between transceiver type is software programmable. The module defaults to serial mode.

60.3.2.1 Host Controller 2 Configuration Parameter

Host Controller 2 is configured for high-speed/full-speed/low-speed operation and supports serial transceiver interface and ULPI interface. Example 60-2 shows sample code used to set the host controller core implementation.

Example 60-2. Host Controller 2 Core Implementation

```
// ------------------------------------------------------------------------
// ------------------------------------------------------------------------
//  System Configuration Options
// ------------------------------------------------------------------------
//
//  The VUSB_HS_RESET_TYPE constant determines the reset type used in the core.
//    0 = Use Synchronous Resets
//    1 = Use Asynchronous Resets

60.3.3 USB Host Controller 3

The Host 3 core USB signals do not connect directly to the HOST3 I/O pins. Instead, the signals pass through the HS-ULPI TLL and serial and ULPI mux, which allows additional functionality on Host Port3. Host controller 3 is configured for operation with a FS/LS serial transceiver or a parallel ULPI transceiver (HS/FS/LS). The selection between transceiver type is software programmable. The module defaults to serial mode.

60.3.3.1 Host Controller 3 Configuration Parameter

Host Controller 3 is configured for high-speed/full-speed/low-speed operation and supports serial transceiver interface and ULPI interface. The parameters shown in Example 60-3 are used to set Host Controller 3 core implementation.

Example 60-3. Host Controller 3 Core Implementation

```
// ------------------------------------------------------------------
// ------------------------------------------------------------------------
//  System Configuration Options
// ------------------------------------------------------------------------
//
//  The VUSB_HS_RESET_TYPE constant determines the reset type used in the core.
//    0 = Use Synchronous Resets
//    1 = Use Asynchronous Resets
//
//  The VUSB_HS_RESET_OPTIONAL constant determines if various register files
//  are connected to the main reset.
//
//  0 = Reset all flops except those listed above.
//  1 = Reset 100% of flops.
//
parameter VUSB_HS_RESET_TYPE = 1; //  [0,1]
parameter VUSB_HS_RESET_OPTIONAL = 0; //  [0,1]
//
//  The VUSB_HS_CLOCK_CONFIGURATION constant determines the clocking used in the core
//  See reference manual for a description of the clocking modes available.
//
//    0 = xcvr_clk_0 = pe_clk = clk (do not select for multi-port host product)
//    1 = xcvr_clk_0 < pe_clk = clk
//    2 = xcvr_clk_0 = pe_clk <> clk (do not select for multi-port host product)
//    3 = xcvr_clk_0 < pe_clk <> clk
parameter VUSB_HS_CLOCK_CONFIGURATION = 2; //  [0,1,2,3]
//
//  phy size (UTMI Only)
//  Set according to the data width of the transciever connected to the core.
//    0 = 8 bit wide data bus [60MHz clock from the transciever]
//    1 = 16 bit wide data bus [30MHZ clock from the transciever]
//    2 = software programmable reset to 8-bit width
//    3 = software programmable reset to 16-bit width
//  NOTE: options 2,3 are not recommended when VUSB_HS_CLOCK_CONFIGURATION = 0
parameter VUSB_HS_PHY16_8 = 0; //  [0,1,2,3]
//  This constant selects which phy is being used
//  0 = UTMI/UMTI+
//  1 = Philips legacy style
//  2 = ULPI ** Must have purchased the ULPI Option **
//  3 = Serial Only
//  4 = Software programmable - reset to UTMI
//  5 = Software programmable - reset to Philips legacy style
//  6 = Software programmable - reset to ULPI ** Must have purchased the ULPI Option **
//  7 = Software programmable - reset to Serial
//  NOTE: options 4,5,6,7 are not recommended when VUSB_HS_CLOCK_CONFIGURATION = 0
//  NOTE: undefined results if ULPI is selected (#2,6) and the ULPI option was not purchased &
installed.
parameter VUSB_HS_PHY_TYPE = 7; //  [0,1,2,3,4,5,6,7]

60.3.4 USB OTG Controller

The OTG controller offers HS/FS/LS capabilities in Host mode and HS/FS in device mode.

60.3.4.1 OTG Controller Configuration Parameter

OTG Controller is configured for high-speed/full-speed/low-speed operation and supports serial transceiver interface and ULPI interface. The parameters shown in Example 60-4 show how to set the OTG Controller core implementation.

Example 60-4. OTG Controller Core Implementation

```
// ------------------------------------------------------------------------
//  System Configuration Options
// ------------------------------------------------------------------------
//
//  The VUSB_HS_RESET_TYPE constant determines the reset type used in the core.
//    0 = Use Synchronous Resets
//    1 = Use Asynchronous Resets
//
//  The VUSB_HS_RESET_OPTIONAL constant determines if various register files
//  are connected to the main reset.
//
//  0 = Reset all flops except those listed above.
//  1 = Reset 100% of flops.
//
parameter VUSB_HS_RESET_TYPE = 1; //  [0,1]
parameter VUSB_HS_RESET_OPTIONAL = 0; //  [0,1]
//
//  The VUSB_HS_CLOCK_CONFIGURATION constant determines the clocking used in the core
//  See reference manual for a description of the clocking modes available.
//
//    0 = xcvr_clk_0 = pe_clk = clk (do not select for multi-port host product)
//    1 = xcvr_clk_0 < pe_clk = clk
//    2 = xcvr_clk_0 = pe_clk <> clk (do not select for multi-port host product)
//    3 = xcvr_clk_0 < pe_clk <> clk
parameter VUSB_HS_CLOCK_CONFIGURATION = 2; //  [0,1,2,3]
//
//  phy size (UTMI Only)
//  Set according to the data width of the transciever connected to the core.
//    0 = 8 bit wide data bus [60MHz clock from the transciever]
//    1 = 16 bit wide data bus [30MHZ clock from the transciever]
//    2 = software programmable reset to 8-bit width
//    3 = software programmable reset to 16-bit width
//  NOTE: options 2,3 are not recommended when VUSB_HS_CLOCK_CONFIGURATION = 0
parameter VUSB_HS_PHY16_8 = 0; //  [0,1,2,3]
//  This constant selects which phy is being used
//  0 = UTMI/UMTI+
//  1 = Philips legacy style
//  2 = ULPI ** Must have purchased the ULPI Option **
//  3 = Serial Only
//  4 = Software programmable - reset to UTMI
//  5 = Software programmable - reset to Philips legacy style
//  6 = Software programmable - reset to ULPI ** Must have purchased the ULPI Option **
//  7 = Software programmable - reset to Serial
//  NOTE: options 4,5,6,7 are not recommended when VUSB_HS_CLOCK_CONFIGURATION = 0
```

```
//  NOTE: undefined results if ULPI is selected (#2,6) and the ULPI option was not purchased &
installed.
parameter VUSB_HS_PHY_TYPE = 7; //  [0,1,2,3,4,5,6,7]
//  derived constants ; must set to match VUSB_HS_PHY_TYPE above according the attached
instructions.
parameter VUSB_HS_PHY_UTMI = 0; //  [0,1] ; set to 0 if VUSB_HS_PHY_TYPE=1,2,3       else 1
parameter VUSB_HS_PHY_PHIL = 0; //  [0,1] ; set to 0 if VUSB_HS_PHY_TYPE=0,2,3       else 1
parameter VUSB_HS_PHY_ULPI = 1; //  [0,1] ; set to 0 if VUSB_HS_PHY_TYPE=0,1,3       else 1
//  This constant selects that the serial engine is used in place of the
//  parallel signalling for UTMI+,Philips, and ULPI.
//  0 - No Serial Engine      - Always use parallel signalling
//  1 - Serial Engine Present - Always use serial signalling for FS/LS
//  2 - Software programmable - Reset to use parallel signalling for FS/LS
//  3 - Software programmable - Reset to use serial signalling for FS/LS
//  NOTE: Must set to 1 if PHY_TYPE=1 or 3
//  NOTE: Must set to 1 or 3 is PHY_TYPE=6
//  NOTE: option 0 slims gate count by removing all logic necessary in the serial engine
parameter VUSB_HS_PHY_SERIAL = 2;
// ------------------------------------------------------------------------
//  Device Configuration
// ------------------------------------------------------------------------
//
//  The VUSB_HS_DEV_EP constant represents the total number of endpoints.
//
//  ** NOTE ** : VUSB_HS_DEV_EP should be set to 1 for host only implementations,
//  ** NOTE ** : VUSB_HS_DEV_EP_ADD must be updated when the VUSB_HS_DEV_EP is changed.
//
parameter VUSB_HS_DEV_EP = 8; //  [2,3,...,16]
//  set the VUSB_HS_DEV_EP_ADD equal to max(1, log2(VUSB_HS_DEV_EP))
parameter VUSB_HS_DEV_EP_ADD = 3;
// ------------------------------------------------------------------------
//  Host Configuration
// ------------------------------------------------------------------------
//  The VUSB_HS_NUM_PORT constant specifies the number of downstream ports
//  supported by the host controller.  This constant is only relevant for
//  for the multi-port host product.  Leave 1 for device, otg, and single port host
//  products.
//
//  Maximum: 8 downstream ports.
//
parameter VUSB_HS_NUM_PORT = 1; //  [1,2,...,8]
// ------------------------------------------------------------------------
//  Host Configuration - Internal Transaction Translator
// ------------------------------------------------------------------------
//  These constants define how many periodic contexts the internal TT can support.
//
//  Note1: These constants are only relevent for the multi-port host product.
//  Note2: The number of async. contexts should not be adjusted.
//
//  USB 2.0 spec requires 16 periodic contexts for a hub TT although this seems unncessarily
//  big for an embedded application where limits can be imposed on the downstream applications.
//  Changing the  number from 16 to 4 will significantly reduce gate count but be cautioned
//  that this will impose limits on the number of downstream periodic (ISO/Interrupt)
transactions.
//
//  The simplifying limit imposed when the number of periodic contexts is reduced to 4 is
//  that the application can send no more than 4 periodic (ISO/Interrupt) packets per
```

```
//  frame to the downstream Full and Low-Speed devices. Whereas, when the number
//  of periodic contexts are 16, its possible to pipeline packets accross the
//  microframes and send as many periodic packets per frame as can be scheduled (> 16).
//
parameter VUSB_HS_TT_ASYNC_CONTEXTS = 2; //  DO NOT CHANGE
parameter VUSB_HS_TT_ASYNC_CONTEXTS_ADDR = 1; //  DO NOT CHANGE ;
max(1,log2(VUSB_HS_TT_ASYNC_CONTEXTS))
parameter VUSB_HS_TT_PERIODIC_CONTEXTS = 16; //  [4,16 Only] ; Caution (see note above)
//  if this is changed to 4 then change the following constants:
//     VUSB_HS_TT_PERIODIC_CONTEXT_ADDR=2
//     VUSB_HS_TT_CONTEXTS_ADDR=2
parameter VUSB_HS_TT_PERIODIC_CONTEXTS_ADDR = 4; //  max(1,log2(VUSB_HS_TT_PERIODIC_CONTEXTS))
parameter VUSB_HS_TT_CONTEXTS_ADDR = 4; //  max(VUSB_HS_TT_ASYNC_CONTEXTS_ADDR,
VUSB_HS_TT_PERIODIC_CONTEXTS_ADDR)
// ------------------------------------------------------------------------
//  RX Buffer Constants
// ------------------------------------------------------------------------
//  Depth & Number Of Address Bits For RX Buffer
//  ** NOTE ** : VUSB_HS_RX_ADD must be updated when VUSB_HS_RX_DEPTH is changed.
parameter VUSB_HS_RX_DEPTH = 123; //  Must be power of 2! (ie. 2**j)
//  Minimum : >= 8
//  Minimum : >= 3*VUSB_HS_RX_BURST/2
//  Maximum : <= 2048
//  Recommended : > 2*VUSB_HS_RX_BURST
parameter VUSB_HS_RX_ADD = 7; //  log2(VUSB_HS_RX_DEPTH)
parameter VUSB_HS_RX_BURST = 8; //  Burst size for RX Buffer To Memory Transfers
//  Minimum : 2
//  Maximum : 128
//  Recommended : >= 4
// ------------------------------------------------------------------------
//  TX Buffer Constants
// ------------------------------------------------------------------------
//  Depth & Number Of Address Bits For TX Channel
//  The Channel constants control the size of the buffer associated with each TX
//  endpoint channel.  All of the channel buffers are combined into a single
//  TX Buffer using the TX Buffer constants.
//  ** NOTE ** : VUSB_HS_TX_CHAN_ADD must be updated when VUSB_HS_TX_CHAN is changed.
parameter VUSB_HS_TX_CHAN = 128; //  Must be power of 2 (ie. 2**k)
//  Minimum : >= 16
//  Minimum : >= 3*VUSB_HS_TX_BURST/2+4
//  Maximum : <= 128
//  Recommended : > 2*VUSB_HS_TX_BURST+4
parameter VUSB_HS_TX_CHAN_ADD = 7; //  log2(VUSB_HS_TX_CHAN);
parameter VUSB_HS_TX_CHAN_STATE = 4; //  DO NOT CHANGE
parameter VUSB_HS_TX_CHAN_STATE_ADD = 2; //  DO NOT CHANGE
parameter VUSB_HS_TX_CHAN_DATA = VUSB_HS_TX_CHAN - VUSB_HS_TX_CHAN_STATE; //  DO NOT CHANGE
//  Depth & Number Of Address Bits For TX Buffer
//  ** NOTE ** : VUSB_HS_TX_DEPTH and VUSB_HS_TX_ADD must be updated when either
//               VUSB_HS_TX_CHAN or VUSB_HS_DEV_EP are changed.
//  Host Only : VUSB_HS_TX_DEPTH = VUSB_HS_TX_CHAN
//  Device    : VUSB_HS_TX_DEPTH = (VUSB_HS_TX_CHAN)*min(1,VUSB_DEV_EP)
//          : VUSB_HS_TX_DEPTH <--> ** Power of 2 not necessary ** ; integer multiple of power
of 2 acceptable;
//                                    ie. 2**X * VUSB_HS_DEV_EP.
//                              (verify code exists for chosen TX_DEPTH in graycode package file)
parameter VUSB_HS_TX_DEPTH = 1024; //  (VUSB_HS_TX_CHAN)*max_int(1,VUSB_HS_DEV_EP);
parameter VUSB_HS_TX_ADD = 10; //  log2(VUSB_HS_TX_DEPTH);
```

```
parameter VUSB_HS_TX_BURST = 8; //  Burst size for Memory To TX Buffer Transfers
//  Minimum : 2
//  Maximum : 128
//  Recommended : >= 4
//
//  Device/OTG : This constant determines if the device endpoint
//  context data used for rapid transmit response (reduced latency) and
//  double buffering tracking is stored in the TX-FIFO or if it is held
//  in registers.  There are advantages and disadvantages to each configuration:
//
//  = 0 (context in FIFO)
//     advantage    : smaller gate count & power (less 126 registers + misc. per endpoint)
//    disadvantage : actual latency buffer size is smaller because 4 words are used for context
(ie. actual VUSB_HS_TX_CHAN-4 words)
//                   FIFO interface is 2 read ports / 1 write port***
//
//  = 1 (context is registers)
//     advantage    : latency buffer uses full VUSB_HS_TX_CHAN words for data
//                   FIFO interface is 1 read port / 1 write port***
//     disadvantage : larger gate count & power (adds 144 registers + misc.)
//
//  *** this difference MAY be significant with some technologies and MAY offset the gate count
and power difference.
//
parameter VUSB_HS_TX_LOCAL_CONTEXT_REGISTERS = 1; //  [0 - context in FIFO, 1 - context in
registers]
// ------------------------------------------------------------------------
//  Device Version Number
// ------------------------------------------------------------------------
parameter VUSB_HS_DCIVERSION = 16'b 0000000000000001;
parameter VUSB_HS_HCIVERSION = 16'b 0000000100000000; //  EHCI 1.00
```

60.3.4.2 Host Mode

The controller supports direct connection of a FS/LS device (without external hub) with external serial transceiver and HS/FS device with external ULPI transceiver. Although there is no separate Transaction Translator block in the system. The transaction translator function normally associated with a USB 2.0 high speed hub has been implemented within the DMA and Protocol engine blocks to support connection to full and low speed devices.

60.3.4.3 Peripheral (Device) Mode Features

The peripheral device mode features are as follows:

- Up to 8 bidirectional endpoints
- High/Full speed operation
- Supports HNP, SRP.
- Remote wakeup capable

60.3.4.4 Special Considerations

The OTG port functions as gateway between the Host 1 Port and the OTG transceiver when in Bypass mode.

60.3.4.5 OTG Port Signal Connections and Signal Muxing

Table 60-16 describes the Signal connections from the USB core to the OTG port OUTPUT PADS.

Table 60-16. Connections

60.3.5 USB Power Control Module

The HS-USB module supports suspend and wakeup functionality, but the circuit is considered application specific and therefore not part of the IP. An external circuit has been designed to place external transceivers in suspend mode, and wake them up either on a local request (CPU initiated) or on remote request by detecting activity on the USB line. The wake-up logic can optionally wake the CPU when it is in sleep mode at the time of the request. The power control mechanism is described in the VUSB-HS-SPH and VUSB-HS-OTG reference manuals. For details on the power control module, please refer to the Power Module creation guide.

60.3.5.1 Entering Suspend Mode

Suspend mode is always entered under the control of driver software by setting the appropriate bit in PORTSC register. Once the controller is suspended, the clocks to the USB block can be stopped.

60.3.5.2 Wake-up Events

The power control module monitors the USB bus when the USB core is in the suspend state. Depending on whether the core is in host or device mode, a number of wakeup conditions are detected. Upon detection of a wakeup condition, an interrupt (asynchronous) is generated on the CPU complex. This interrupt also re-activates the clocks if these were stopped during the suspend.

60.3.5.2.1 Host Mode Events

The host controller wakes-up on the following events:

- Remote wakeup request—A peripheral can request the host to re-activate the bus by driving wake-up signaling on the Dm/Dp lines. The power control module detects a J-K transition on the Dm/Dp lines and signals the wakeup request to the core.
- Wake on overcurrent—If wake on overcurrent is enabled in the PORTSC registers, the power control module signals a wakeup condition to the USB core.

- Wake on disconnect—The power control module detects disconnect events by monitoring the Dp/Dm lines. When a disconnect event is detected (Dm = Dp = 0) and the wake on disconnect is enabled in the PORTSC register, the core is notified.
- Wake on Connect—Similar to wake on disconnect, the power control module detects a connect event (Dm or Dp High) and signals this to the USB core by setting the pwrctl_wakeup signal if enabled in the PORTSC register.

60.3.5.2.2 Device Mode Events

When the OTG controller is configured for peripheral operation, the power control module detects bus activity. Any non-idle condition on the USB bus activates the wakeup output of the power control module to notify the USB core of the wakeup event.

60.3.6 Transceiverless Link Logic (HS/FS-TLL) Module

The transceiverless link logic circuit allows two microcontrollers to use USB for an interprocessor communication link (ICL) without using conventional USB transceivers. The TLL muxes support ULPI (HS-TLL) and serial (FS-TLL) type interfacing and are available on Host Port 1 and Host Port 2.

60.3.6.1 TLL Mode Features

The features of this TLL mode include the following:

- HS/FS-TLL. HS-TLL and FS-TLL are selectable based on the type of USB peripheral. HS-TLL support HS-ULPI interface protocol, and FS-TLL support FS/LS serial interface protocol.
- TLL logic can be bypassed. When the bypass bit in the USB CONTROL register is enabled, the TLL module is bypassed and host USB core works in conventional USB mode.
- TLL meets the timing requirements of both host and device.

60.3.6.2 Serial FS-TLL Functional Description

The Serial FS-TLL logic is a logic representation of two serial transceivers connected by a USB cable. The USB bus DM/DP states are modeled internally in the FS-TLL function, such that the USB I/O port acts as if it were a transceiver.

In a regular USB implementation with serial PHYs, the speed selection on the USB bus is done by means of a pull-up resistor on the peripheral side either on the DM (low speed) or the DP (full Speed) line. This pull-up pulls one of the USB lines high when the bus is idle.

This option cannot be modeled in logic as the serial USB interface does not provide for such a signal. The FS-TLL mux is therefore configured for Full Speed only operation.

The IDLE condition of the bus is determined by the OEn signals and suspend signals on both sides of the mux. When both OEn signals are high, or when one or both suspend signals are high, the idle condition is assumed. The FS-TLL block then drives TxDp high and TxDm low on both sides of the block.

Figure 60-9 shows the FS-TLL mux functional diagram.

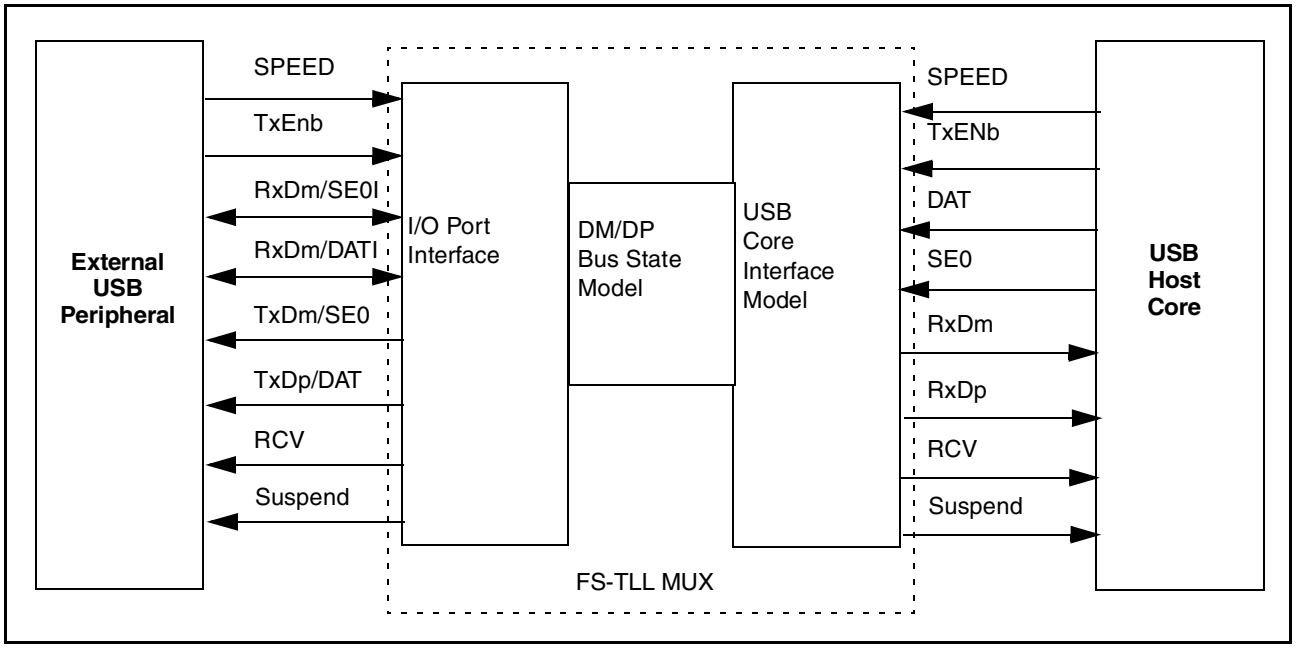

Figure 60-9. FS-TLL Mux Functional Diagram

60.3.6.3 ULPI HS-TLL Functional Description

ULPI HS-TLL module is an additional logic for the Host USB core with ULPI interface. It allows a HS-USB host communication with on-board HS-USB device (on-platform processors and modems) directly without ULPI PHY. Figure 60-10 show the functional diagram of ULPI HS-TLL.

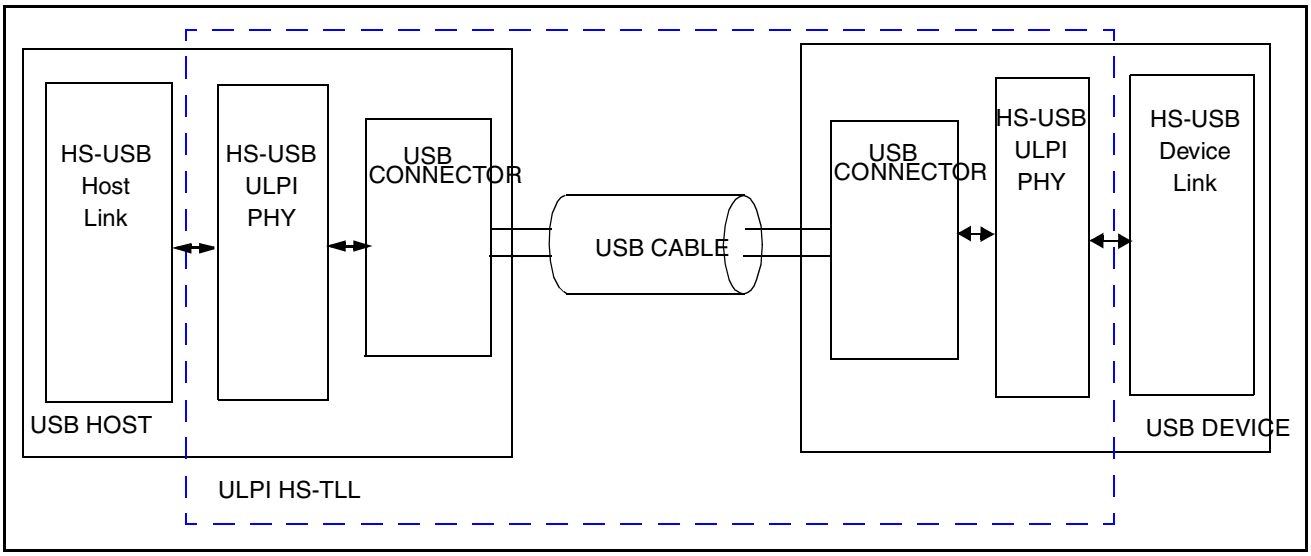

Figure 60-10. HS-TLL Functional Diagram

Figure 60-11 shows the block diagram combining ULPI interface and HS_TLL.

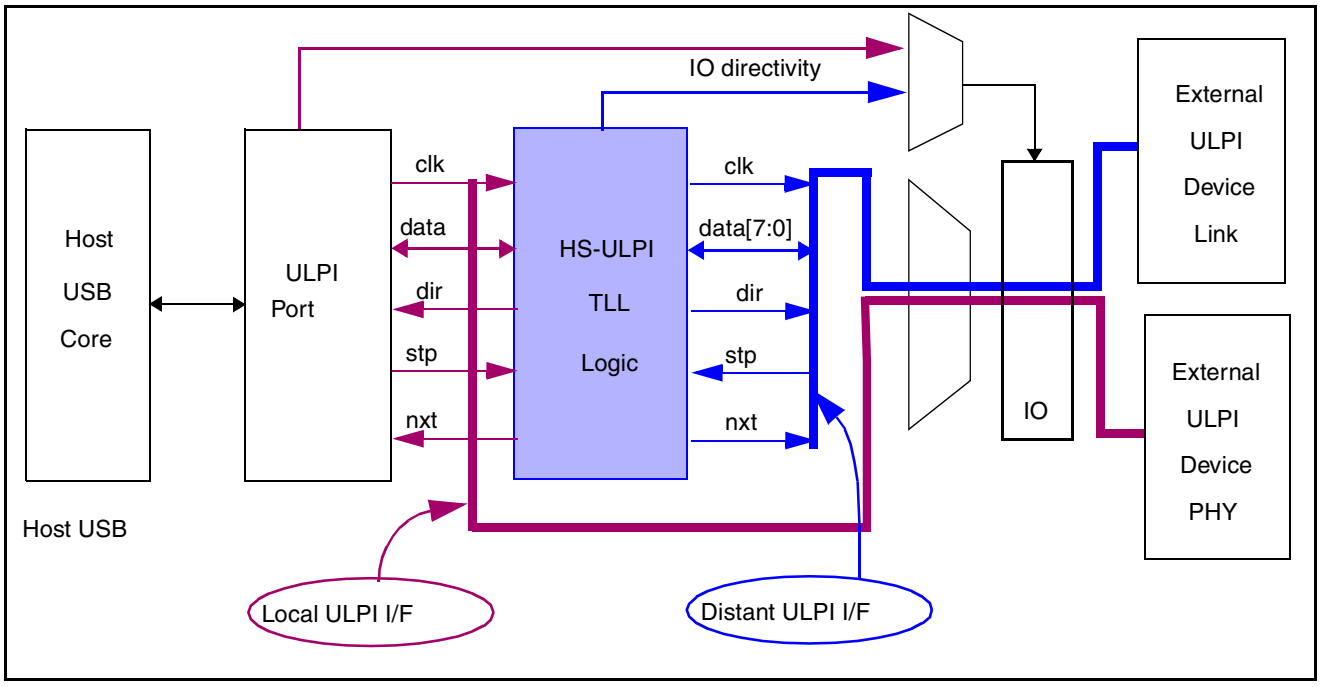

Figure 60-11. Block Diagram Combining ULPI Interface and HS-TLL

ULPI HS-TLL is designed to complied with the ULPI specification V1.1. Figure 60-12 shows a detailed block diagram of this module in USBOH3.

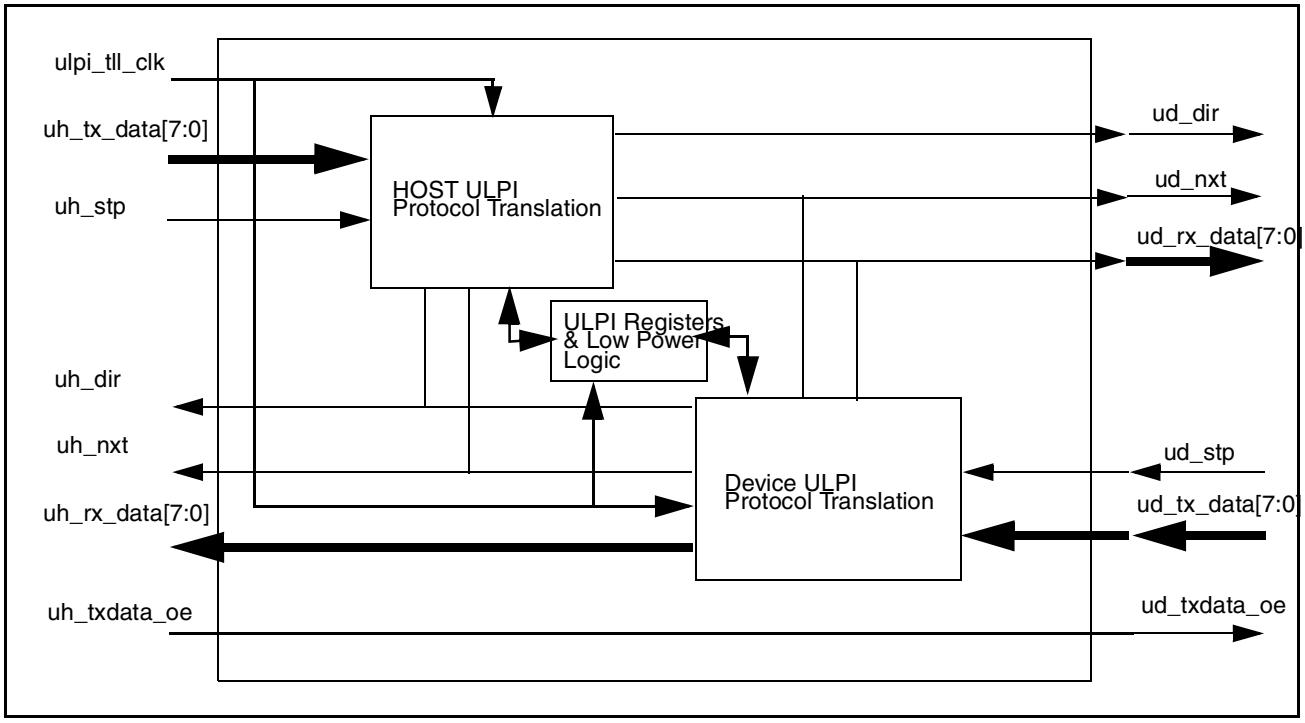

Figure 60-12. ULPI HS-TLL Detail Block Diagram

60.3.6.4 HS-TLL Detailed Features Definition

This section discusses the following:

- Section 60.3.6.4.1, General”
- Section 60.3.6.4.2, HS-TLL Data Transfer Protocol”
- Section 60.3.6.4.3, HS-TLL Modes Function”
- Section 60.3.6.4.4, Timing Requirements”
- Section 60.3.6.4.5, HS-TLL Programming Model”

60.3.6.4.1 General

In general HS-TLL imitates a host-side ULPI I/F to the local link layer, and a device-side ULPI I/F towards a link layer of a distant device. Unless otherwise said in the following sections, these two ports of the HS-TLL meet the full requirements of the ULPI specification[9].

However, several modes and features of the ULPI are not required, as discussed in the following sections. These modes and features are removed for the following reasons:

- On-board USB applications is the only use case of the TLL. No hot-insertion, plug-and-play scenarios are expected.
- There is no real analog PHY in between.

- Trial to keep HS-TLL definition compact.
- No OTG scenarios. Local processor is always a host, and distant processor is always a peripheral.

60.3.6.4.2 HS-TLL Data Transfer Protocol

HS-TLL supports ULPI protocol toward both local and distant links. This includes bus ownership, data transfer and abort protocols, as described by section 2.3 of ULPI Specification V1.1[9]. Within HS-TLL protocols of both sides are tied together such that data-transfer protocols are simultaneously operating to create a flowing link-to-link data transfer. Similarly, data abortion initiated by one of the links is translated by the HS-TLL to a PHY-like initiated data abortion in the other ULPI side.

Figure 60-13 shows the HS-USB packets data transmit from Host Link to Device Link through HS-TLL module. The packets data transmit from Device Link to Host Link through HS-TLL is the same.

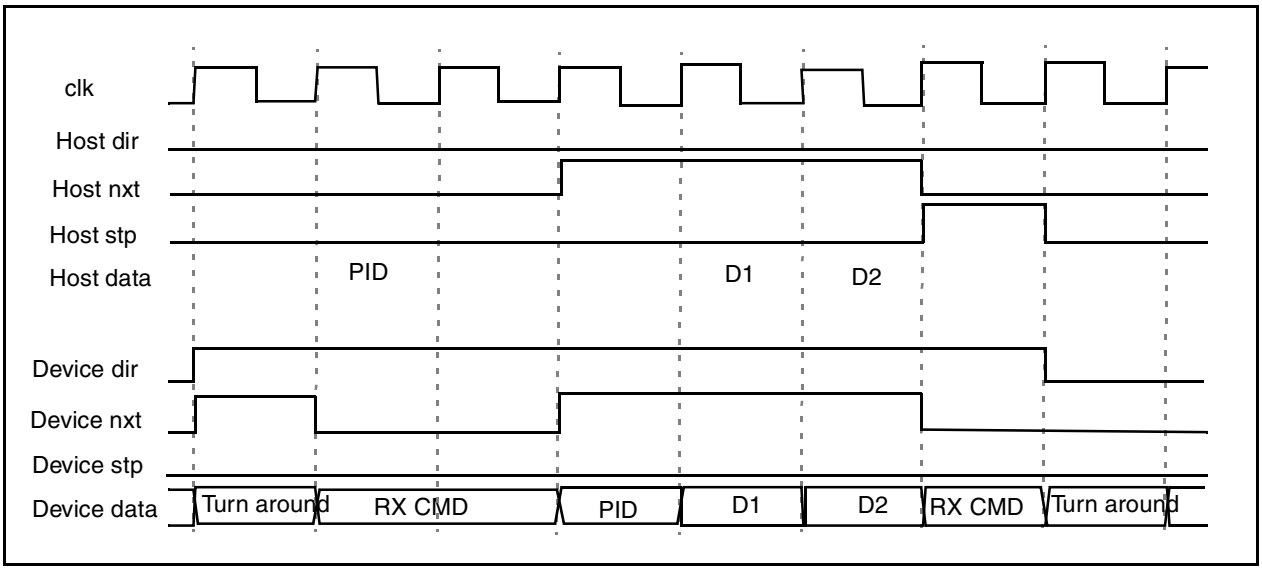

Figure 60-13. Data transmit(PID) from Host to Device through HS-TLL waveform

60.3.6.4.3 HS-TLL Modes Function

ULPI TLL supports only the basic synchronous mode and low-power mode. The trials of link side to change HS-TLL to one of the unsupported modes are ignored and generate a non-supported exception in the HS-TLL status register.

Preamble mode is not supported in the HS-TLL. The HS-TLL only operates in high speed ULPI mode; it does not support full-speed and low-speed mode. Only 8-bit mode within synchronous mode is supported at the local side and distant side ULPI I/F in this HS-TLL implementation. “6-pin”, “3-pin,” and “carkit” modes are not supported by current design, as they can by achieved by the non-TLL ULPI and FS-TLL functions of the USBOH3.

This implementation does support the following:

- High-speed chirp-like activities, as described in chapter 3.8.5 of ULPI Specification V1.1[9]
- High-Speed Remote wake up

- Resume

PID and non PID data streams from the USBHO2 core path through HS-TLL and are reflected to an external peripheral link according to the description in section 3.8.2 of ULPI Specification V1.1[9].

60.3.6.4.4 Timing Requirements

HS-TLL meets PHY-side timing requirements toward ULPI I/Fs of both local a distant links, as it is specified in Section 3.7 of ULPI Specification V1.1[9].

60.3.6.4.5 HS-TLL Programming Model

HS-TLL module supports function control and interface control registers access for ULPI control and status, but does not support other registers defined in ULPI description. During write, the unsupported register are ignored and during read, these register return the default value.

The ULPI standard defines a register set for the PHY side of the ULPI connection. The following subsections describe this part of the PHY register as implemented and reflect meaningful values of both the local and distant link layers:

Function Control Register (0x4–0x6)

Implementation is as follows:

- Bit 5—Reset

  This bit, and the related ULPI signals and protocol, is fully implemented for both distant and local links.
- Bit 6—SuspendM

  This bit, and the related ULPI signals and protocol, is fully implemented for both distant and local links. A careful design definition combines SuspendM from local link, SuspendM from distant link, and the HS-TLL own enable bit to define HS-TLL logic activity.

Interface Control Register (0x7–0x9):

Implementation is as follows:

- bit 4—AutoResume

  This bit, and the related ULPI signals and protocol, is not implemented for both distant and local links.
- USB Interrupt Enable Rising/Enable Falling/Status/Latch (0xD–0x14), bit 2,3—SessEnd, SessValid

  The 2 bits of each of these registers are supported to emulate session status as in a real PHY device for both distant and local links.
- Transmit and Receive Command bytes

  HS-TLL supports all commands to write and read the registers. For some unsupported registers, the write operation is ignored and the read operation returns the default value.

Tx CMD

Implementation is as follows:

- Reception of TX CMDs from local & distant ULPI I/Fs are supported:
- Special, Transmit (including PID codes), RegWrite, and RegRead command types are decoded and respond as defined in ULPI Specification V1.1[9].

Rx CMD

Implementation is as follows:

- Sending of RX CMDs to local and distant ULPI I/Fs are supported:
- LineState and RxEvent fields of the command are active and reflect relevant values according to data stream and protocol.
- VbusState, alt_int, and ID fields of the command are not supported and constantly reflect their inactive values.

Clock

Implementation is as follows:

- HS-TLL is always set to receive clk for local links (“Input Clock Mode” in 3.7.1.2 of ULPI Specification V1.1) and send clk for distant links (“Output Clock Mode”).
- Output Clock Mode at local ULPI and “Input Clock Mode” at distant ULPI are not supported. This is the CLK signal directivity also described at Figure 60-11.

Low-Power Modes

HS-TLL supports low-power mode entering and exiting, with local and distant link devices, independently. Low-power status change in one side of the TLL is reflected as linestate[1:0] and int changes in the other side of the TLL.

When in low-power mode, DATA[3:0] signals reflects the relevant state towards the link.

There are two ways to exit low-power mode when USB system is in suspend mode. When the host side is suspended and enters low-power mode, it can set the register bit in USB Control to cause the host to exit low-power mode and then resume the device. The peripheral side can also do remote wakeup by setting the PORTSC1 register soft wakeup bit to let the system exit suspend mode.

HS-TLL USB Operations

Figure 60-14 shows the sequence of HS-TLL USB Operations.

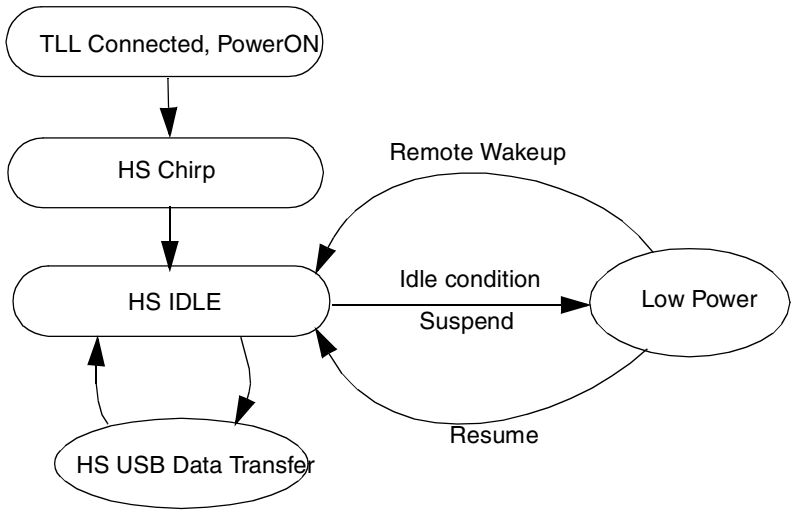

Figure 60-14. HS-TLL USB Operations

60.3.6.5 Host Port 1

On Host Port1, the FS-TLL function is integrated with the bypass function (see Section 60.3.7, USB Bypass Mode") and the transceiver type conversion logic. FS-TLL mode is disabled for this port as default. It can be enabled by setting bit 4 in the USBCONTROL register.

Table 60-18 shows the pin connections for FS-TLL mode and normal mode.

Table 60-18. Port 1 FS-TLL and PHY Mode Pin Connections

	FS-TLL mode		PHY Mode	
Pin	**I/O**	**External Device Pin**	**I/O**	**External PHY Pin**
SPEED	I	speed	O	speed
TxEnb	I	TxEnb	O	TxEnb
RxVm	I	TxDm	I	RxVm
RxVp	I	TxDp	I	RxVp
TxDm	O	RxDm	O	TxDm
TxDp	O	RxDp	O	TxDp
RCV	O	RCV	I	RCV
Suspend	I	suspend	O	SuspendM

The HS-TLL is only used in ULPI PHY. When in ULPI mode and TLL enable, the TLL function is enabled. Table 60-19 shows the HS-TLL pin connections.

Table 60-19. HS-TLL Pin Connection

	HS-TLL mode		PHY Mode	
Pin	**I/O**	**External Device Pin**	**I/O**	**External PHY Pin**
DIR	O	DIR	I	DIR
NXT	O	NXT	I	NXT
STP	I	STP	O	STP
DATA[7:0]	I/O	DATA[7:0]	I/O	DATA[7:0]

60.3.6.6 Host Port 2

The FS-TLL module on Host Port 2 contains the FS-TLL logic and the Serial Transceiver Type conversion logic. The interface type conversion is available in both TLL and Non TLL modes.

FS-TLL operation is disabled as the default mode. It can be turned on for operation with an external transceiver by setting bit 1 in th USB_UH2_CTRL register.

Table 60-20 shows the Port 2 FS-TLL and PHY mode pin connections.

Table 60-20. Port 2 FS-TLL and PHY Mode Pin Connections

	FS-TLL mode		PHY Mode	
Pin	**I/O**	**External Device Pin**	**I/O**	**External PHY Pin**
SPEED	I	speed	O	speed
TxEnb	I	TxEnb	O	TxEnb
RxVm	I	TxDm	I	RxVm
RxVp/	I	TxDp	O	RxVp
TxDm	O	RxDm	O	TxDm
TxDp	O	RxDp	O	TxDp
RCV	O	RCV	I	RCV
Suspend	I	suspend	O	SuspendM

The HS-TLL is only used in ULPI PHY, is the same as Host1. When in ULPI mode and TLL enable, the TLL function is enabled. Table 60-21 shows the HS-TLL pin connection.

Table 60-21. HS-TLL Pin Connection

	HS-TLL mode		PHY Mode	
Pin	**I/O**	**External Device Pin**	**I/O**	**External PHY Pin**
DIR	O	DIR	I	DIR
NXT	O	NXT	I	NXT
STP	I	STP	O	STP
DATA[7:0]	I/O	DATA[7:0]	I/O	DATA[7:0]

60.3.6.7 Host Port 3

The FS-TLL module on Host Port 3 contains the FS-TLL logic and the Serial Transceiver Type conversion logic. The interface type conversion is available in both TLL and Non TLL modes.

FS-TLL operation is disabled as the default mode. It can be turned on for operation with an external transceiver by setting bit 1 in th USB_UH3_CTRL register.

Table 60-22 shows the Port 3 FS-TLL and PHY mode pin connections.

Table 60-22. Port 3 FS-TLL and PHY Mode Pin Connections

	FS-TLL mode		PHY Mode	
Pin	**I/O**	**External Device Pin**	**I/O**	**External PHY Pin**
SPEED	I	speed	O	speed
TxEnb	I	TxEnb	O	TxEnb
RxVm	I	TxDm	I	RxVm
RxVp/	I	TxDp	O	RxVp
TxDm	O	RxDm	O	TxDm
TxDp	O	RxDp	O	TxDp
RCV	O	RCV	I	RCV
Suspend	I	suspend	O	SuspendM

The HS-TLL is only used in ULPI PHY, which is the same as Host1. When in ULPI mode and TLL enable, the TLL function is enabled.

Table 60-23 shows the HS-TLL mode pin connections.

Table 60-23. HS-TLL Pin Connection

	HS-TLL mode		PHY Mode	
Pin	**I/O**	**External Device Pin**	**I/O**	**External PHY Pin**
DIR	O	DIR	I	DIR
NXT	O	NXT	I	NXT
STP	I	STP	O	STP
DATA[7:0]	I/O	DATA[7:0]	I/O	DATA[7:0]

60.3.7 USB Bypass Mode

The USB Bypass mode is a special mode that allows for the transceiver on the OTG port to be used as transceiver for a USB peripheral device connected to host port 1. This mode is available for full-/low-speed serial and high-speed ULPI transceivers.

The bypass module is a combination of the following:

- The bypass function (Host Port1—OTG port pass through)
- FS-TLL function for Host Port 1
- Full-/low-bypass route with serial transceiver
- High-speed bypass route with ULPI transceiver
- Serial Transceiver Interface Conversion

60.3.7.1 Bypass Mode Operation

Bypass mode is enabled by writing a 1 to bit 0, as shown in Figure 60-2. Bypass mode supports serial or ULPI mode according to on-board peripheral and OTG external transceiver type.

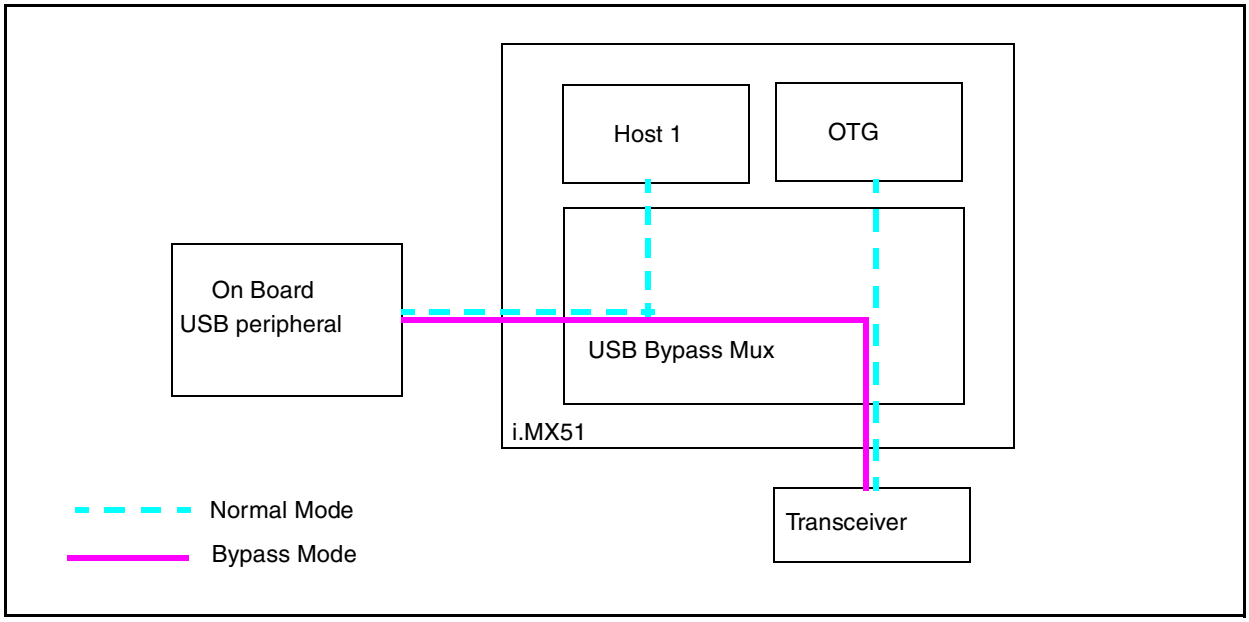

Figure 60-15. USB Bypass Mux Functional Diagram

In bypass mode, the interface signals (Serial/ULPI) from Host Port 1 are routed to the interface pins Serial/ULPI) of the OTG port such that an external USB Peripheral device can use the OTG transceiver (Serial/ULPI) to connect to an external USB Host. As this function only works with USB peripherals directly connected to Host Port 1, the port is automatically set for TLL mode. Transceiver Interface Type conversion is available in Bypass mode such that the interface type of the OTG transceiver can be different from the Host 1 interface type.

60.3.7.1.1 Serial Bypass mode

The USB HOST1 core is disconnected from the port and the inputs RxDp, RCV and RxDm from the core are driven by bits 9 and 10 (H1BPVAL) in Figure 60-2. The OTG core is also disconnected from its port and inputs RxDp, RCV, and RxDm are driven by bits 25 and 26 (OBPVAL) from Figure 60-2.

Transceiver Interface Type conversion is available in Bypass mode such that the interface type of the OTG transceiver can be different from the Host 1 interface type.

Table 60-24 list the pin functions of the Host 1 port when serial bypass mode is enabled and the associated OTG pin. The pin functions of the OTG port are not affected by serial bypass mode.

Table 60-24. HOST1/OTG Serial Bypass Mode Pin functions

	Unidirectional				Bidirectional				OTG PORT	
Pin	I/O	Single-Ended	I/O	Differential	I/O	Single- Ended	I/O	Differential	I/O	Pin
RxDm	I	RxDm	I	RxDm	I/O	SEOI/SE0O	I/O	RxDm/TxDm	O	TxDm
RxDp	I	RxDp	I	RxDp	I/O	DATI/DATO	I/O	RxDp/TxDP	O	TxDP
RCV	O	RCV	O	RCV		-	O	RCV	I	RCV
TxDm	O	SE0	O	TxDM		-		-	I	RxDM
TxDp	O	DAT	O	TxDP		-		-		RxDp
OEb	I	OEn	I	OEb	I	OEn	I	OEn		OEb
FS	I	Speed	I	FS	I	Speed	I	Speed		Speed
Suspend	I	Suspend	I	Suspend	I	Suspend	I	Suspend		Suspend

60.3.7.1.2 ULPI Bypass mode

The Host1 core is disconnected from the port and the OTG core is also disconnected from its port, then the external on-board USB peripheral with ULPI interface can route to the OTG side ULPI PHY transceiver, and the both USB USB peripheral and ULPI PHY clock are allowed and can configure by the USB Control register. Table 60-25 shows the Host1 and OTG ULPI bypass pin functions.

Table 60-25. HOST1/OTG ULPI Bypass Mode Pin functions

Signal Name	Host1 HS-TLL side pin		OTG side pin	
Data[7:0]	I/O	ipp_ind_uh1_data_tll[7:0] ipp_do_uh1_data_tll[7:0] ipp_obe_uh1_data_tll[7:0]	I/O	ipp_ind_otg_data[7:0] ipp_do_otg_data[7:0] ipp_obe_otg_data[7:0]
clock	I/O	ipp_ind_uh1_clk_tll ipp_do_uh1_clk_tll ipp_obe_uh1_clk_tll	I/O	ipp_ind_otg_clk ipp_do_otg_clk ipp_obe_otg_clk
dir	O	ipp_do_uh1_dir	I	ipp_ind_otg_dir
nxt	O	ipp_do_uh1_nxt	I	ipp_ind_otg_nxt
stp	I	ipp_ind_uh1_stp	O	ipp_do_otg_stp

Figure 60-16 shows the ULPI bypass mode Host1 and OTG pins route diagram.

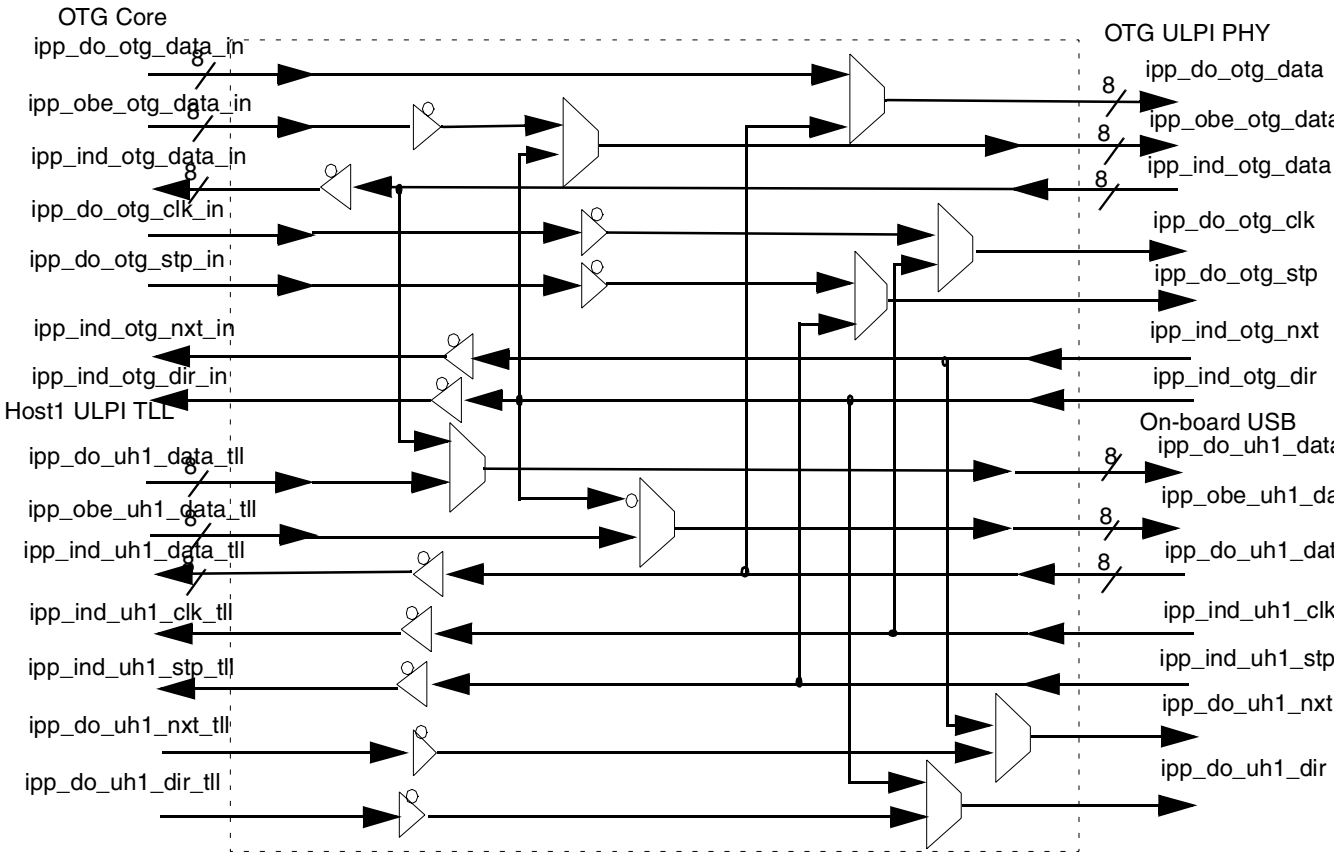

Figure 60-16. ULPI Bypass Pin Route Function Diagram

60.3.8 ULPI/Serial MUX

Host1, Host2, and OTG cores can be configured by software for ULPI or Serial PHY operation. The ULPI/Serial mux selects between ULPI interface signals and Serial PHY interface signals. The mux is controlled by the PHY Select signals from the USB core and is switched when the software selects the interface mode.

The default configuration for the mux is Serial mode. Switching to ULPI mode is done by writing the Parallel Transceiver Select (PTS) bits in the PORTSC register with 0b10.

60.3.9 Interrupts

This section discusses the USB core and wake-up interrupts.

60.3.9.1 USB Core interrupts

Each USB core uses one dedicated vector in the interrupt table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB Cores. Please refer to the USB Core documentation for details.

60.3.9.2 USB Wake-Up Interrupts

Each USB core has an associated wake-up interrupt. The wake-up interrupts are generated outside the USB cores' but use the same vector as the corresponding cores' interrupt. These interrupt are generated by the Power Control Modules which run on the 32 KHz standby clock. The wake-up interrupt is designed to work even when the USB and CPU clocks are disabled, such that a wake-up condition on the USB bus can re-activate the CPU clocks. Therefore, this interrupt request propagates thru combinational logic to the CPU's interrupt module.

Because the wake-up interrupt is generated and cleared on a 32 KHz clock, this interrupt request will respond very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt will mask the request instantaneously as this is clocked by the CPU clock. The software should than wait for at least three 32-KHz clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. As this interrupt is only used during low-power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to enter USB suspend mode.

60.4 Initialization/Application Information

This section described the detailed application knowledge for Host1, Host2 and OTG ports. It can be generally divided in two parts, one is for host and the other is for device. Host part is applied to three ports; device part is only applied to OTG port. In the following register description, device-related content is for OTG and host-related content is for all three ports.

60.4.1 Software Model

The Device API provides a framework of routines to control the USB-HS OTG High-Speed USB On-The-Go peripheral in USB device applications. It includes an application to respond to the Chapter 9 device framework commands issued by a USB host.

The USB-HS OTG High-Speed USB On-The-Go Device API is designed to significantly simplify the software tasks required to develop a USB device application. The API presents a high-level data transfer interface to the user's application code. All the register, interrupt and DMA interactions with the USB-HS OTG High-Speed USB On-The-Go core are managed by the API. The API also includes routines that handle all the USB device framework commands that are required for all USB devices.

The Host Stack provides a layered software architecture to control all aspects of a USB bus system. The Host Controller Device (HCD) interface controls the functions of an embedded EHCI host controller. The USB driver layer provides all the USB driver functions to enumerate, manage and schedule a USB bus system, while the upper layers of the stack support standard USB device class interfaces to the device drives running on the embedded system.

For details on the HS-USB OTG High-Speed USB On-The-Go Software Stack refer to following the documentation provided with the software products.

- **ANSI-C OTG software Stack provides Host and Device application support.** USB software included with the HS-USB OTG High-Speed USB On-The-Go core is tested with the hardware.
- **OTG Application Program Interface (API) handles OTG protocols.** Connect and disconnect events are handled as well as the OTG Host Negotiation Protocol (HNP) and Session Request Protocol (SRP) state machines. The OTG code calls the Host or Device API functions based on the connection state of the OTG state machines.
- **Host API to speed up Host software development.** Simple API calls allow direct interaction with USB pipes. Additional layers support bus enumeration, bus management and a growing set of supported USB classes.
- **Device API to speed up peripheral development.** USB peripheral characteristics such as endpoints, configurations, interfaces, and alternate settings are controlled by supplied ANSI-C firmware. Chapter 9 Device Frame work command set reduces software development time. Simple API interface allows quick coding of USB device applications.

60.4.1.1 Device Data Structure

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus, as shown in Figure 60-17. Using a set of linked list **transfer descriptors**, pointed to by a **queue head**, the device controller will perform the data transfers.

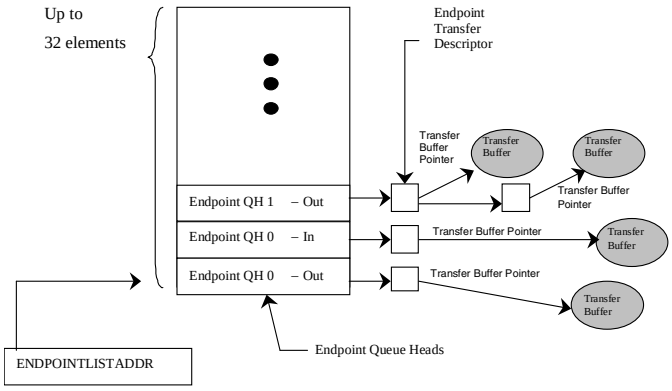

Figure 60-17. End Point Queue Head Organization

The HS-USB OTG High-Speed USB On-The-Go Device API incorporates and abstracts for the application developer all of the information contained in the device operational model.

60.4.1.2 Host Data Structure

The host data structures are used to communicate control, status, and data between software and the Host Controller, as shown in Figure 60-18 and Figure 60-19. The **Periodic Frame List** is an array of pointers for the periodic schedule. A sliding window on the Periodic Frame List is used. The **Isochronous Transfer List** is where all the control and bulk transfers are managed. The HS-USB OTG High-Speed USB On-The-Go Host API incorporates and abstracts for the application developer all of the information contained in the host operational model.

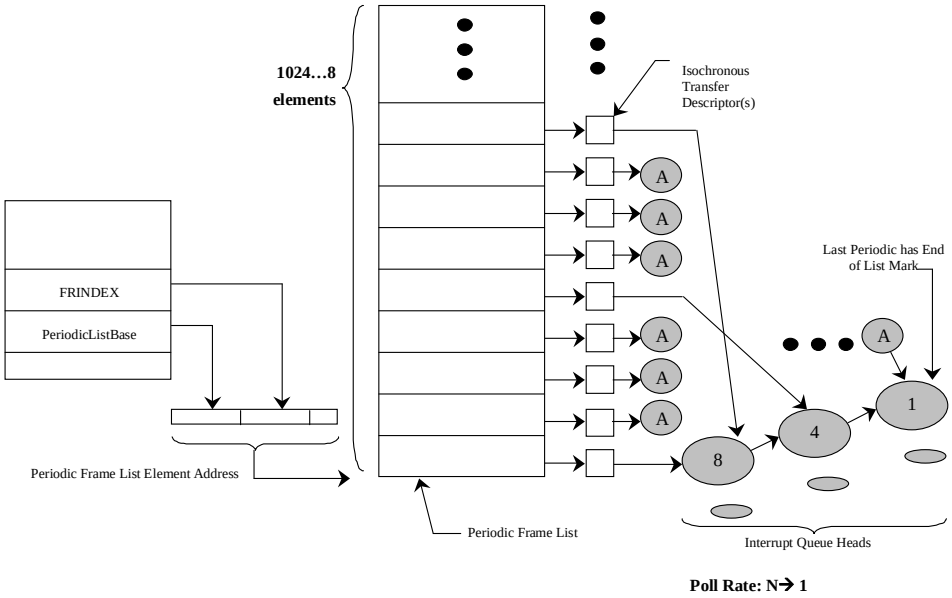

Figure 60-18. Periodic Schedule Organization

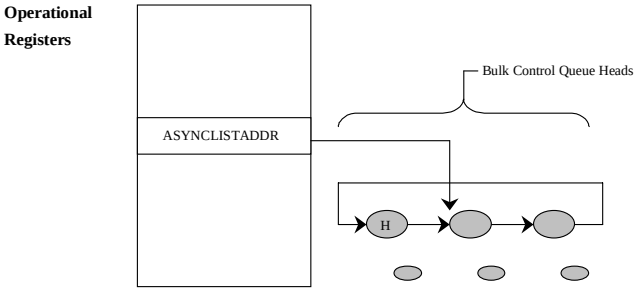

Figure 60-19. Asynchronous Schedule Organization

60.4.2 Register Interface

Slave accesses from the controlling processor enables access to the configuration, control, and status registers. One function of the system address map is the registers base address, which must begin on a **DWord** (32-bit) boundary. Register offset definitions are listed in Table 60-26.

Configuration, control and status registers are divided into three categories, identification, capability and operational registers.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are comprised of dynamic control or status registers that may be read only, read/write, or read/write to clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

NOTE

Host mode EHCI compatibility begins at offset 0x100. If it is necessary to begin the EHCI register set at offset 0x000, the identification registers are disabled from the address map by connecting the upper most address bit of the slave interface to a logic level '1' and adjusting the offsets below accordingly.

Table 60-26. Interface Register Sets

Offset	Register Set	Explanation
000h to 0FCh	Identification Registers	Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.
100h to 124h	Capability Registers	Capability registers specify the limits, restrictions, and capabilities of a host/device controller implementation. These values are used as parameters to the host/device controller driver.
140h to 1FCh	Operational Registers	Operational registers are used by the system software to control and monitor the operational state of the host/device controller.

60.4.2.1 Configuration, Control and Status Register Set

60.4.2.3 Identification Registers

Identification registers are used to declare the slave interface presence and to include a table of the hardware configuration parameters.

60.4.2.3.1 ID

The Identification register (ID) provides a simple way to determine if the USB-HS OTG High-Speed USB On-The-Go USB 2.0 core is provided in the system. The ID register identifies the USB-HS OTG High-Speed USB On-The-Go USB 2.0 core and its revision.

Figure 60-20 shows the identification register.

Address: Base + 000h

Default Value: Implementation Dependent

Attribute: Read Only

Size: 32 bits

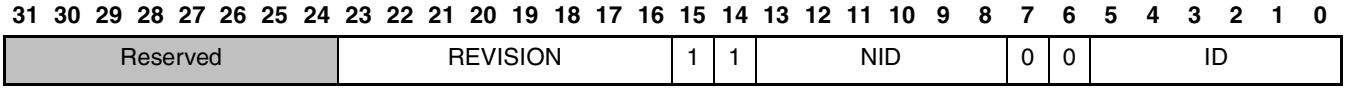

Figure 60-20. ID—Identification Register

The register fields are described in Table 60-29.

Table 60-29. Identification Register Field Descriptions

Field	Description
ID[5:0]	**Configuration number.** This number is set to 0x05 and indicates that the peripheral is the USB-HS OTG High-Speed USB On-The-Go USB 2.0 core.
NID[5:0]	Ones complement version of ID[5:0].
REVISION[7:0]	Revision number of the core
Reserved	These bits are reserved and should be set to zero

60.4.2.3.2 HWGENERAL

The HWGeneral register, shown in Figure 60-21, is for the general hardware parameters as defined in system-level issues and core configuration.

Address: Base + 004h

Default Value: Implementation Dependent

Attribute: Read Only

Size: 32 bits

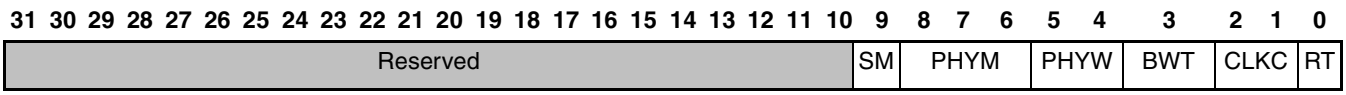

Figure 60-21. HWGENERAL—General Hardware Parameters

The register fields are described in Table 60-30.

Table 60-30. HWGeneral Field Descriptions

Field	Description
Reserved	**Reserved.** These bits are reserved and should be set to zero.
SM	VUSB_HS_PHY_SERIAL
PHYM	VUSB_HS_PHY_TYPE
PHYW	VUSB_HS_PHY16_8
BWT	Reserved for internal testing.
CLKC	VUSB_HS_CLOCK_CONFIGURATION
RT	VUSB_HS_RESET_TYPE

60.4.2.3.3 HWHOST

Host hardware parameters as defined in system-level issues and core configuration.

Address: Base + 008h

Default Value: Implementation Dependent

Attribute: Read Only

Size: 32 bits

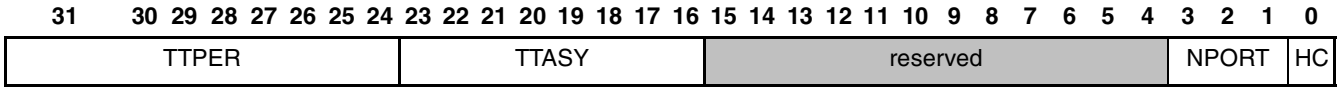

Figure 60-22. HWHOST–Host Hardware Parameters

The register fields are described in Table 60-31.

Table 60-31. HWHost Field Descriptions

Field	Description
TTPER	VUSB_HS_TT_PERIODIC_CONTEXTS
TTASY	VUSB_HS_TT_ASYNC_CONTEXTS
reserved	**Reserved.** These bits are reserved and should be set to zero.
NPORT	VUSB_HS_NUM_PORT-1
HC	VUSB_HS_HOST

60.4.2.3.4 HWDEVICE

Device hardware parameters as defined in System Level Issues and Core Configuration.

Address: Base + 00Ch

Default Value: Implementation Dependent

Attribute: Read Only

Size: 32 bits

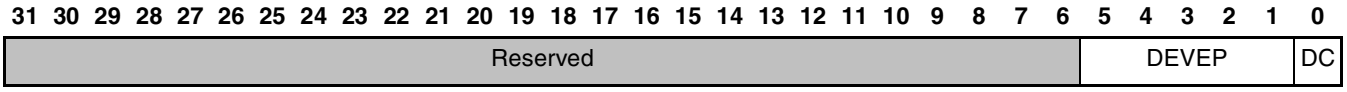

Figure 60-23. HWDEVICE – Device Hardware Parameters

The register fields are described in Table 60-32.

Table 60-32. HWDevice Field Descriptions

Field	Description
Reserved	**Reserved.** These bits are reserved and should be set to zero.
DEVEP	VUSB_HS_DEV_EP
DC	device capable; [VUSB_HS_DEV /= 0]

60.4.2.3.5 HWTXBUF

TX buffer hardware parameters as defined in system-level issues and core configuration.

Address: Base + 010h

Default Value: Implementation Dependent

Attribute: Read Only

Size: 32 bits

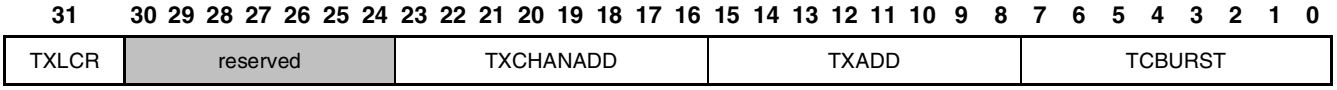

Figure 60-24. HWTXBUF – TX Buffer Hardware Parameters

The register fields are described in Table 60-33.

Table 60-33. HWTXBUF Field Descriptions

Field	Description
TXLC	VUSB_HS_TX_LOCAL_CONTEXT_REGISTERS
reserved	**Reserved.** These bits are reserved and should be set to zero.
TXCHANADD	VUSB_HS_TX_CHAN_ADD
TXADD	VUSB_HS_TX_ADD
TCBURST	VUSB_HS_TX_BURST

60.4.2.3.6 HWRXBUF

RX buffer hardware parameters as defined in System Level Issues and Core Configuration.

Address: Base + 014h

Default Value: Implementation Dependent

Attribute: Read Only

Size: 32 bits

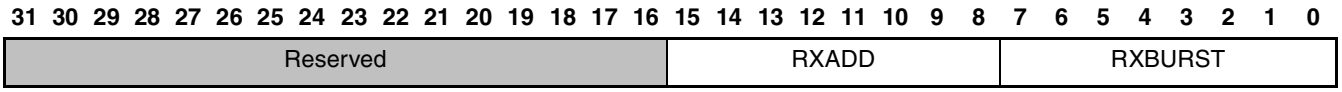

Figure 60-25. WRXBUF – RX Buffer Hardware Parameters

The register fields are described in Table 60-34.

Table 60-34. WRXBUF Field Descriptions

Field	Description
reserved	**Reserved.** These bits are reserved and should be set to zero.
RXADD	VUSB_HS_RX_ADD
RXBURST	VUSB_HS_RX_BURST

60.4.2.4 Device/Host Capability Registers

Device/Host capability registers specify the software limits, restrictions, and capabilities of the host/device controller implementation.

60.4.2.4.1 CAPLENGTH – EHCI Compliant

This register is used to indicate which offset to add to the register base address at the beginning of the Operational Register.

Address: Base + 100h

Default Value: 40h

Attribute: Read Only

Size: 8 bits

Figure 60-26. CAPLENGTH – Capability Register Length

60.4.2.4.2 HCIVERSION – EHCI Compliant

This is a two-byte register containing a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision.

Address: Base + 102h

Default Value: 0100h

Attribute: Read Only

Size: 16 bits

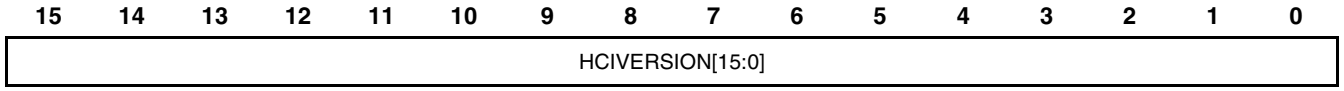

Figure 60-27. HCIVERSION – Host Interface version number

60.4.2.4.3 HCSPARAMS – EHCI Compliant with extensions

Port steering logic capabilities are described in this register.

Address: Base + 104h

Default Value: Implementation Dependent

Attribute: Read Only

Size: 32 bits

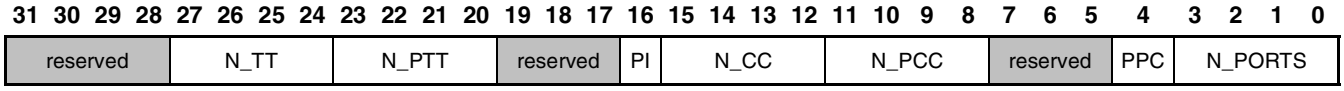

Figure 60-28. HCSPARAMS – Host Control Structural Parameters

The register fields are described in Table 60-35.

Table 60-35. HCSPARAMS Field Descriptions

Field	Description
Reserved	**Reserved.** These bits are reserved and should be set to zero.
PI	**Port Indicators (P INDICATOR).** This bit indicates whether the ports support port indicator control. When set to one, the port status and control registers include a read/writeable field for controlling the state of the port indicator. This field will always be "1".
N_TT[3:0]	**Number of Transaction Translators (N_TT).** This field indicates the number of embedded transaction translators associated with the USB2.0 host controller. For Multi-Port Host this field will always equal “0001”. For all other implementations, N_TT = “0000”. This in a non-EHCI field to support embedded TT.
N_PTT[3:0]	**Number of Ports per Transaction Translator (N_PTT).** This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. For Multi-Port Host this field will always equal N_PORTS. For all other implementations, N_PTT = “0000”. This in a non-EHCI field to support embedded TT.
N_CC[3:0]	**Number of Companion Controller (N_CC).** This field indicates the number of companion controllers associated with this USB2.0 host controller. A zero in this field indicates there are no internal Companion Controllers. Port-ownership hand-off is not supported. A value larger than zero in this field indicates there are companion USB1.1 host controller(s). Port-ownership hand-offs are supported. High, Full- and Low-speed devices are supported on the host controller root ports. In this implementation this field will always be "0".

Table 60-35. HCSPARAMS Field Descriptions

N_PCC[3:0]	**Number of Ports per Companion Controller.** This field indicates the number of ports supported per internal Companion Controller. It is used to indicate the port routing configuration to the system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC. In this implementation this field will always be "0".
PPC	**Port Power Control.** This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register. This field will always be "0" for a device only implementation.
N_PORTS[3:0]	**Number of downstream ports.** This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register. Valid values are in the range of 1h to Fh. A zero in this field is undefined. The number of ports for a host implementation is parameterizable from 1 to 8. This field will always be 1 for device only implementation.

60.4.2.4.4 HCCPARAMS – EHCI Compliant

This register identifies multiple mode control (time-base bit functionality) addressing capability.

Address: Base + 108h

Default Value: 0006h

Attribute: Read Only

Size: 32 bits

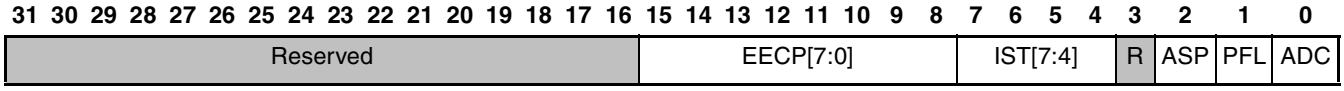

Figure 60-29. HCCPARAMS – Host Control Capability Parameters

The register fields are described in Table 60-36.

Table 60-36. HCCPARAMS Field Descriptions

Field	Description
reserved	**reserved.** These bits are reserved and should be set to zero.
EECP[7:0]	**EHCI Extended Capabilities Pointer.** Default = 0. This optional field indicates the existence of a capabilities list. A value of 00h indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. The pointer value must be 40h or greater if implemented to maintain the consistency of the PCI header defined for this class of device. For this implementation this field is always "0".

Table 60-36. HCCPARAMS Field Descriptions

IST[7:4]	**Isochronous Scheduling Threshold.** Default = implementation dependent. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. This field will always be "0".
R	**Reserved.** These bits are reserved and should be set to zero.
ASP	**Asynchronous Schedule Park Capability.** Default = 1. If this bit is set to a one, then the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USBCMD register. This field will always be "1"
PFL	**Programmable Frame List Flag.** If this bit is set to zero, then the system software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. If set to a one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This field will always be "1".
ADC	64-bit Addressing Capability. This field will always be "0". No 64-bit addressing capability is supported.

60.4.2.4.5 DCIVERSION (Non-EHCI)

The device controller interface conforms to the two-byte BCD encoding of the interface version number contained in this register.

Address: Base + 120h

Default Value: Implementation Dependent

Attribute: Read Only

Size: 16 bits

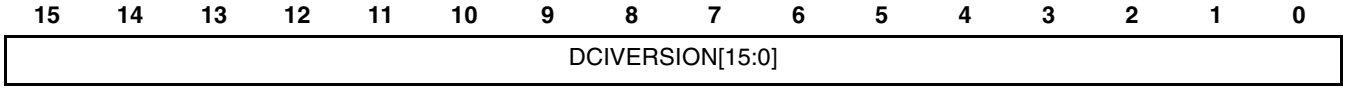

Figure 60-30. DCIVERSION – Device Interface Version Number

60.4.2.4.6 DCCPARAMS (Non-EHCI)

These fields describe the overall host/device capability of the controller.

Address: Base + 124h

Default Value: Implementation Dependant

Attribute: Read Only

Size: 32 bits

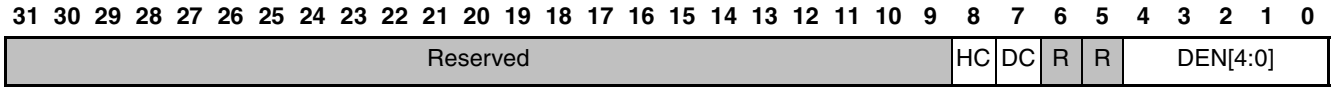

Figure 60-31. DCCPARAMS - Device Control Capability Parameters

The register fields are described in Table 60-37.

Table 60-37. DCCPARAMS Field Descriptions

Field	Description
Reserved	**Reserved.** These bits are reserved and should be set to zero.
HC	**Host Capable.** When this bit is 1, this controller is capable of operating as an EHCI compatible USB 2.0 host controller.
DC	**Device Capable.** When this bit is 1, this controller is capable of operating as a USB 2.0 device.
R	**Reserved.** These bits are reserved and should be set to zero.
DEN[4:0]	**Device Endpoint Number.** This field indicates the number of endpoints built into the device controller. If this controller is not device capable, then this field will be zero. Valid values are 0–16.

60.4.2.5 Device/Host Timer Registers (Non-EHCI)

The host/device controller drivers can measure time related activities using these timer registers. These registers are not part of the standard EHCI controller.

60.4.2.5.1 GPTIMER0LD (Non-EHCI)

This register contains the timer duration or load value. See the GPTIMER0CTRL (Non-EHCI) for a description of the timer functions.

Address: Base + 80h

Default Value: 00000000h

Attribute: Read/Write

Size: 32 bits

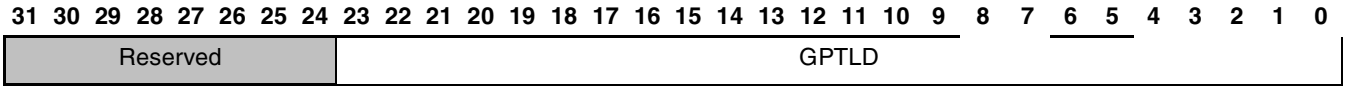

Figure 60-32. GPTIMER0LD-General Purpose Timer #0 Load Register

The register fields are described in Table 60-38.

Table 60-38. GPTIMER0LD Field Descriptions

Field	Description
Reserved	**Reserved.** These bits are reserved and should be set to zero.
H\GPTLD	**General Purpose Timer Load Value.** This field is the value to be loaded into the GPTCNT countdown timer on a reset action. This value represents the time in microseconds minus 1 for the timer duration.

60.4.2.5.2 GPTIMER0CTRL (Non-EHCI)

This register contains the control for the timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two modes supported by this timer, the first is a one shot and the second is a looped count which is described in the register table below. When the timer counter value transitions to zero, an interrupt can be generated though the use of the timer interrupts in the USBSTS and USBINTR registers.

Address: Base + 84h

Default Value: 00000000h

Attribute: Read Only, Write Only, Read/Write

Size: 32 bits

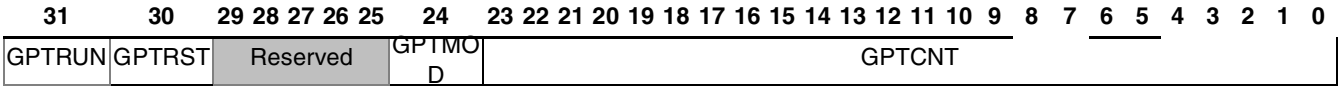

Figure 60-33. GPTIMER0LD—General Purpose Timer #0 Controller

The register fields are described in Table 60-39.

Table 60-39. GPTIMER0LD

Field	Description
GPTRUN	**General Purpose Timer Run (0)-Timer Stop; (1)-Timer Run.** This bit enable the GPT to run. Setting or Clearing this bit will not have an effect on the GPTCNT except.
GPTRST	**General Purpose Timer Reset (0)-No action; (1)-Load Counter Value**. This bit will reload the GPTCNT with the value in GPTLD.
Reserved	**Reserved.** These bits are reserved and should be set to zero.
GPTMOD	**General Purpose Timer Mode.** (0)-One Shot; (1)-Repeat.In one-shot mode the timer will count to zero, generate an interrupt and stop until the timer is reset by software. In repeat mode the timer will count to zero, generate an interrupt and automatically reload the counter to begin again.
GPTCNT	**General Purpose Timer Counter**. This field is the value of running timer.

60.4.2.5.3 GPTIMER1LD (Non-EHCI)

Same as GPTIMER0LD.

Address: Base + 88h

Default Value: 00000000h

High-Speed USB Controller Core Reference

Attribute: Read/Write

Size: 32 bits

60.4.2.5.4 GPTIMER1CTRL (Non-EHCI)

Same as GPTIMER0CTRL.

Address: Base + 8Ch

Default Value: 00000000h

Attribute: Read Only, Write Only, Read/Write

Size: 32 bits

60.4.2.6 Device/Host Operational Registers

Operational registers are comprised of dynamic control or status registers that may be read only, read/write, or read/write to clear. The following sections define the use of these registers.

60.4.2.6.1 USBCMD

The serial bus host/device controller executes the command indicated in this register.

Address: Base + 140h

Default Value: 00080B00h (host mode)

00080000h (device mode)

Attribute: Read Only, Read/Write, Write Only (field dependent)

Size: 32 bits

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Figure 60-34. USBCMD – USB Command Register

The register fields are described in Table 60-40.

Table 60-40. USBCMD Field Descriptions

Field	Description
R, reserved	**Reserved.** These bits are reserved and should be set to zero.
ITC[7:0]	**Interrupt Threshold Control —Read/Write.** Default 08h. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 00h Immediate (no threshold) 01h 1 micro-frame 02h 2 micro-frames 04h 4 micro-frames 08h 8 micro-frames 10h 16 micro-frames 20h 32 micro-frames 40h 64 micro-frames

Table 60-40. USBCMD Field Descriptions (continued)

SUTW	**Setup TripWire – Read/Write.** [device mode only] This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (See USBCMD) then there exists a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software and will be cleared by hardware when a hazard exists. For more information on the use of this bit, see the Device Operational Model section of the USB-HS OTG High-Speed USB On-The-Go DEV reference manual.
ATDTW	**Add dTD TripWire – Read/Write.** [device mode only] This bit is used as a semaphore to ensure the to proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software. This bit shall also be cleared by hardware when is state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized. For more information on the use of this bit, see the Device Operational Model section of the USB-HS OTG High-Speed USB On-The-Go DEV reference manual.
ASPE	**Asynchronous Schedule Park Mode Enable (OPTIONAL)** — **Read/Write.** If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. This field is set to "1" in this implementation.
ASP[1:0]	**Asynchronous Schedule Park Mode Count (OPTIONAL)** — **Read/Write**. If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is RO. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. See Section 4.10.3.2 for full operational details. Valid values are 1h to 3h. Software must not write a zero to this bit when *Park Mode Enable* is a one as this will result in undefined behavior. This field is set to 3h in this implementation.
LR	**Light Host/Device Controller Reset (OPTIONAL) — Read Only.** Not Implemented. This field will always be "0".
IAA	**Interrupt on Async Advance Doorbell — Read/Write.** This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results.
ASE	**Asynchronous Schedule Enable — Read/Write.** Default 0b. This bit controls whether the host controller skips processing the Asynchronous Schedule. Valuesmeaning 0 Do not process the Asynchronous Schedule. 1 Use the ASYNCLISTADDR register to access theAsynchronous Schedule. Only the host controller uses this bit.
PSE	**Periodic Schedule Enable— Read/Write.** Default 0b. This bit controls whether the host controller skips processing the Periodic Schedule. Values meaning 0 Do not process the Periodic Schedule 1 Use the PERIODICLISTBASE register to access the PeriodicSchedule. Only the host controller uses this bit.

Table 60-40. USBCMD Field Descriptions (continued)

FS[2:0]	**Frame List Size — (Read/Write or Read Only).** Default 000b. This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. Note that this field is made up from USBCMD bits 15, 3 and 2. Values meaning 000 1024 elements (4096 bytes) Default value 001 512 elements (2048 bytes) 010 256 elements (1024 bytes) 011 128 elements (512 bytes) 100 64 elements (256 bytes) 101 32 elements (128 bytes) 110 16 elements (64 bytes) 111 8 elements (32 bytes) Only the host controller uses this field.
RST	**Controller Reset (RESET) — Read/Write.** Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host Controller: When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. Device Controller: When software writes a one to this bit, the Device Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, since the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.
RS	**Run/Stop (RS) – Read/Write.** Default 0b. 1=Run. 0=Stop. Host Controller: When set to a 1, the Host Controller proceeds with the execution of the schedule. The Host Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Host Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the host controller is in the Halted state (i.e. HCHalted in the USBSTS register is a one). Device Controller: Writing a one to this bit will cause the device controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the device controller has been properly initialized. Writing a 0 to this will cause a detach event.

60.4.2.6.2 USBSTS

This register indicates various states of the Host/Device Controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus. Software clears certain bits in this register by writing a 1 to them.

Address: Base + 144h

Default Value: 00001000h (host mode)

00000000h (device mode)

Attribute: Read Only, Read/Write, Read/Write-Clear (field dependant)

Size: 32 bits

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Figure 60-35. USBSTS – USB Status

The register fields are described in Table 60-41.

Table 60-41. USBSTS Field Descriptions

Field	Description
Reserved	Reserved. These bits are reserved and should be set to zero.
TI1	General Purpose Timer Interrupt 1(GPTINT1)--R/WC. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero, writing a one to this bit will clear it.
TI0	General Purpose Timer Interrupt 0(GPTINT0)--R/WC. This bit is set when the counter in the GPTIMER0CTRL register transitions to zero, writing a one to this bit will clear it.
Reserved	**Reserved.** These bits are reserved and should be set to zero.
AS	**Asynchronous Schedule Status — Read Only.** 0=Default. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). Only used by the host controller.
PS	**Periodic Schedule Status — Read Only.** 0=Default. This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0). Only used by the host controller.
RCL	**Reclamation — Read Only.** 0=Default. This is a read-only status bit used to detect an empty asynchronous schedule. Only used by the host controller.
HCH	**HCHalted — Read Only.** 1=Default. This bit is a zero whenever the Run/Stop bit is a one. The Host Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Host Controller hardware (for example, internal error). Only used by the host controller.

Table 60-41. USBSTS Field Descriptions (continued)

R	**Reserved.** These bits are reserved and should be set to zero.
ULPII	**ULPI Interrupt – R/WC.** 0=Default. When the ULPI Viewport is present in the design, an event completion will set this interrupt. Used by both host & device controller. Only present in designs where configuration constant VUSB_HS_PHY_ULPI = 1.
R	**Reserved.** These bits are reserved and should be set to zero.
SLI	**DCSuspend – R/WC.** 0=Default. When a device controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state. Only used by the device controller.
SRI	**SOF Received – R/WC.** 0=Default. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125ms in HS mode and will be synchronized to the actual SOF that is received. Since the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp. In host mode, this bit will be set every 125us and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it. This is a non-EHCI status bit.
URI	**USB Reset Received – R/WC.** 0=Default. When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used by the device controller.
AAI	**Interrupt on Async Advance — R/WC.** 0=Default. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source. Only used by the host controller.
SEI	**System Error— R/WC.** This bit is will be set to "1" when an Error response is seen to a read on the system interface.
FRI	**Frame List Rollover — R/WC.** The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [1 3] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles. Only used by the host controller.
PCI	**Port Change Detect — R/WC.** The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively. This bit is not EHCI compatible.

Table 60-41. USBSTS Field Descriptions (continued)

UEI	**USB Error Interrupt (USBERRINT) — R/WC.** When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set See Section (Reference Host Operation Model: Transfer/Transaction Based Interrupt – i.e. 4.15.1 in EHCI Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com) for a complete list of host error interrupt conditions. See section Device Error Matrix in the USB-HS OTG High-Speed USB On-The-Go DEV reference manual. The device controller detects resume signaling only.
UI	**USB Interrupt (USBINT) — R/WC.** This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.

60.4.2.6.3 USBINTR

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt is active. The USB Status register (USBSTS) still shows interrupt sources even if they are disabled by the USBINTR register, allowing polling of interrupt events by the software.

Address: Base + 148h

Default Value: 00000000h

Attribute: Read/Write

Size: 32 bits

Figure 60-36. USBINTR – USB Interrupt Enable

The register fields are described in Table 60-42.

Table 60-42. USBINTR Field Descriptions

Field	Interrupt Source	Description
reserved	Reserved.	These bits are reserved and should be set to zero.
TIE1	GPT Interrupt Enable1	When this bit is one and the GPTINT1 in USBSTS register is a one the controller will issue an interrupt. The interrupt is acknowledge by software clear the GPTINT1 bit.
TIE0	GPT Interrupt Enable0	When this bit is one and the GPTINT0 in USBSTS register is a one the controller will issue an interrupt. The interrupt is acknowledge by software clear the GPTINT0 bit.
reserved	Reserved.	These bits are reserved and should be set to zero.
ULPIE	ULPI Enable	When this bit is a one, and the ULPI Interrupt bit in the USBSTS register transitions, the controller will issue and interrupt. The interrupt is acknowledged by software writing a one to the ULPI Interrupt bit. Used by both host & device controller. Only present in designs where configuration constant VUSB_HS_PHY_ULPI = 1.
reserved	Reserved.	These bits are reserved and should be set to zero.

Table 60-42. USBINTR Field Descriptions (continued)

SLE	Sleep Enable	When this bit is a one, and the *DCSuspend* bit in the USBSTS register transitions, the device controller will issue an interrupt. The interrupt is acknowledged by software writing a one to the *DCSuspend* bit. Only used by the device controller.
SRE	SOF Received Enable	When this bit is a one, and the *SOF Received* bit in the USBSTS register is a one, the device controller will issue an interrupt. The interrupt is acknowledged by software clearing the *SOF Received* bit.
URE	USB Reset Enable	When this bit is a one, and the *USB Reset Received* bit in the USBSTS register is a one, the device controller will issue an interrupt. The interrupt is acknowledged by software clearing the *USB Reset Received* bit. Only used by the device controller.
AAE	Interrupt on Async Advance Enable	When this bit is a one, and the Interrupt on *Async Advance* bit in the USBSTS register is a one, the host controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the Interrupt on *Async Advance* bit. Only used by the host controller.
SEE	System Error Enable	When this bit is a one, and the *System Error* bit in the USBSTS register is a one, the host/device controller will issue an interrupt. The interrupt is acknowledged by software clearing the *System Error* bit.
FRE	**Frame List Rollover Enable**	When this bit is a one, and the *Frame List Rollover* bit in the USBSTS register is a one, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the *Frame List Rollover* bit. Only used by the host controller.
PCE	Port Change Detect Enable	When this bit is a one, and the *Port Change Detect* bit in the USBSTS register is a one, the host/device controller will issue an interrupt. The interrupt is acknowledged by software clearing the *Port Change Detect* bit.
UEE	USB Error Interrupt Enable	When this bit is a one, and the *USBERRINT* bit in the USBSTS register is a one, the host controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the *USBERRINT* bit in the USBSTS register.
UE	USB Interrupt Enable	When this bit is a one, and the *USBINT* bit in the USBSTS register is a one, the host/device controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the *USBINT* bit.

60.4.2.6.4 FRINDEX

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the USBCMD register.

This register must be written as a DWord. Byte writes produce-undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop hit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (i.e. SOF

for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (i.e. SOF for 125 us micro-frame.)

Address: Base + 14Ch

Default Value: Undefined (free running counter)

Attribute: Read/Write in host mode, Read in device mode

Size: 32 bits

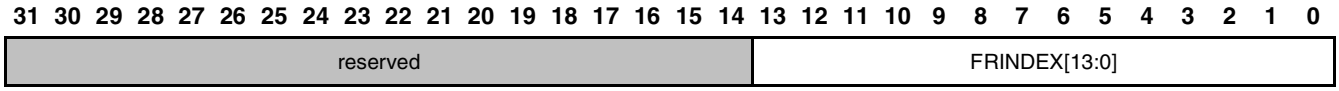

Figure 60-37. FRINDEX – USB Frame Index

The register fields are described in Table 60-43.

Table 60-43. FRINDEX Register Description

Field	Description
reserved	**Reserved.** These bits are reserved and should be set to zero.
FRINDEX	**Frame Index**. The value, in this register, increments at the end of each time frame (for example, micro-frame). Bits [N: 3] are used for the Frame List current index. This means that each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD[Frame List Size] Number Elements N 000b (1024)12 001b (512)11 010b (256)10 011b (128)9 100b (64)8 101b (32)7 110b (16)6 111b (8)5 In device mode the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode bits 2:0 indicate the current microframe.

60.4.2.6.5 CTRLDSSEGMENT

This register is not used in this implementation.

Address: Base + 150h

Default Value: 00000000h

Attribute: Read Only

Size: 32 bits

60.4.2.6.6 PERIODICLISTBASE; DEVICEADDR

This register is shared between the host controller and the device controller operation.

Address: Base + 154h

Default Value: 00000000h

Attribute: Read/Write (Writes must be DWord Writes)

Size: 32 bits

Host Controller (PERIODICLISTBASE)

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

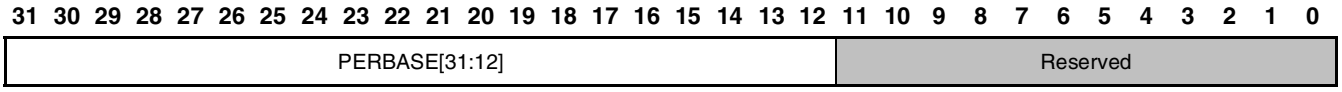

Figure 60-38. PERIODICLISTBASE—Host Controller Frame List Base Address

The register fields are described in Table 60-44.

Table 60-44. PERIODICLISTBASE Register Description

Field	Description
BASEADR	**Base Address (Low).** These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.
reserved	**Reserved.** Must be written as zeros. During runtime, the values of these bits are undefined.

Device Controller (USB DEVICEADDR)

The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS descriptor.

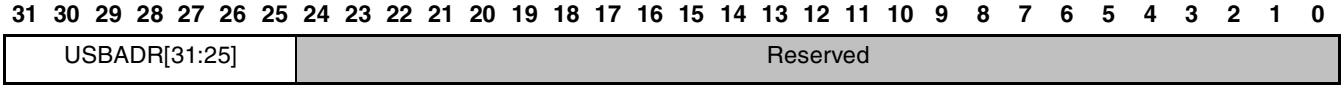

Figure 60-39. DEVICEADDR - Device Controller USB Device Address

The register fields are described in Table 60-45.

Table 60-45. DEVICEADDR Field Descriptions

Field	Description
USBADR	**Device Address.** These bits correspond to the USB device address
reserved	**Reserved.** Must be written as zeros. During runtime, the values of these bits are undefined.

60.4.2.6.7 ASYNCLISTADDR;ENDPOINTLISTADDR

This register is shared between the host controller and the device controller operation.

Address: Base + 158h

Default Value: 00000000h

Attribute: Read/Write (Writes must be DWord Writes)

Size: 32 bits

Host Controller (ASYNCLISTADDR)

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits [4:0] of this register cannot be modified by the system software and will always return a zero when read.

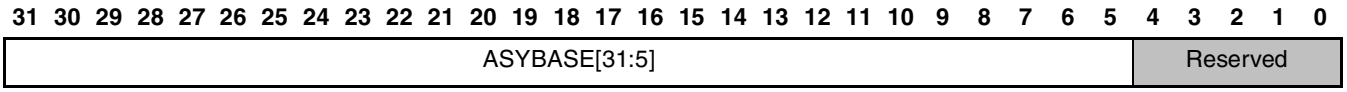

Figure 60-40. ASYNCLISTADDR - Host Controller Next Asynch. Address

The register fields are described in Table 60-46.

Table 60-46. ASYNCLISTADDR Field Descriptions

Field	Description
ASYBASE[31:5]	**Link Pointer Low (LPL).** These bits correspond to memory address signals [31:5], respectively. This field may only reference a Queue Head (OH). Only used by the host controller.
Reserved	**Reserved.** These bits are reserved and their value has no effect on operation.

Device Controller (ENDPOINTLISTADDR)

In device mode, this register contains the address of the top of the endpoint list in system memory. Bits [10:0] of this register cannot be modified by the system software and will always return a zero when read.

The memory structure referenced by this physical memory pointer is assumed 64-byte.

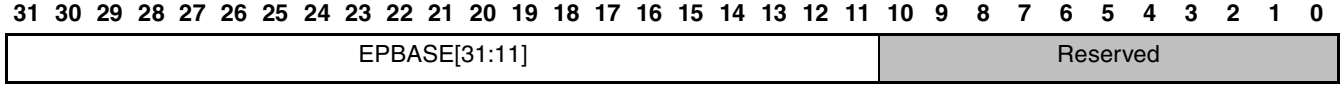

Figure 60-41. ENDPOINTLISTADDR - Device Controller Endpoint List Address

The register fields are described in Table 60-47.

Table 60-47. ENDPOINT Field Descriptions

Field	Description
EPBASE[31:11]	**Endpoint List Pointer(Low).** These bits correspond to memory address signals [31:11], respectively. This field will reference a list of up to 32 Queue Head (OH). (i.e. one queue head per endpoint & direction.)
reserved	**Reserved.** These bits are reserved and their value has no effect on operation.

60.4.2.6.8 BURSTSIZE

This register is used to control dynamically change the burst size used during data movement on the initiator (master) interface.

Address: Base + 160h

Default Value: Implementation Dependent

Attribute: Read/Write (Writes must be DWord Writes)

Size: 32 bits

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															TXPBURST									RXPBURST							

Figure 60-42. BURSTSIZE—Host Controller Embedded TT Async. Buffer Status

The register fields are described in Table 60-48.

Table 60-48. BURSTSIZE Field Descriptions

Field	Description
Reserved	**Reserved.** These bits are reserved and their value has no effect on operation.
TXPBURST	**Programmable TX Burst Length. (Read/Write)** Default is the constant VUSB_HS_TX_BURST. This register represents the maximum length of a the burst in 32-bit words while moving data from system memory to the USB bus.
RXPBURST	**Programmable RX Burst Length. (Read/Write)** Default is the constant VUSB_HS_RX_BURST. This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory.

60.4.2.6.9 TXFILLTUNING

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_{ff} = Time to fetch packet into TX FIFO up to specified level.

T_s = Total Packet Flight Time (send-only) packet

$T_s = T_0 + T_1$

T_p = Total Packet Time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure T_p remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is < T_s then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a mark will be made the scheduler health counter to note the occurrence of a “back-off” event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the TSCHHEALTH (T_{ff}) described below.

Address: Base + 164h

Default Value: 00020000h

Attribute: Read/Write (Writes must be DWord Writes)

Size: 32 bits

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16	15 14 13	12 11 10 9 8	7 6 5 4 3 2 1 0
Reserved	TXFIFOTHRES	Reserved	TXSCHEALTH	TXSCHOH

Figure 60-43. TXFILLTUNING

The register fields are described in Table 60-49.

Table 60-49. TXFILLTUNING Field Descriptions

Field	TXFILLTUNING Description
Reserved	**Reserved.** These bits are reserved and their value has no effect on operation.
TXFIFOTHRES	**FIFO Burst Threshold. (Read/Write) [Default = 2]** This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USBMODE register is set.
TXSCHHEALTH	**Scheduler Health Counter. (Read/Write To Clear) [Default = 0]** This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31.

Table 60-49. TXFILLTUNING Field Descriptions (continued)

reserved	**Reserved.** These bits are reserved and their value has no effect on operation.
TXSCHOH	**Scheduler Overhead. (Read/Write) [Default = 0]** This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267 µs when a device is connected in High-Speed Mode for OTG & SPH. The time unit represented in this register is 6.333 µs when a device is connected in Low/Full Speed Mode for OTG and SPH. The time unit represented in this register is always 1.267 the MPH product.

60.4.2.6.10 IC_USB

This register enables and controls the IC_USB FS/LS transceiver.

Address: Base + 16Ch

Default Value: 0000h

Attribute: Read/Write

Size: 32 bits

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IC8	IC_VDD8			IC7	IC_VDD7			IC6	IC_VDD6			IC5	IC_VDD5			IC4	IC_VDD4			IC3	IC_VDD_3			IC2	IC_VDD2			IC1	IC_VDD1		

Figure 60-44. IC_USB—IC_USB Enable and Voltage Negotiation

The register fields are described in Table 60-50.

Table 60-50. IC_USB Field Descriptions

Field	Description
IC8, IC7,... IC1	**Inter-Chip transceiver enable.** These bits enables the Inter-Chip transceiver for each port (for MPH case). To enable the interface, the bits PTS must be set to 11 in the PORTSCx. Writing a ‘1’ to each bit selects the IC_USB interface for that port. If the Controller is not MultiPort, IC8 to IC2 will be ‘0’ and Read-Only. If ICx is enabled, IOMUX must set the DP/DM pad into loopback mode.
IC_VDDx	**PIt selects which voltage is being supplied to the peripheral through each port (MPH case)** 000 → No voltage 001 → 1.0 V 010 → 1.2 V 011 → 1.5 V 100 → 1.8 V 101 → 3.0 V 110 → Reserved 111 → Reserved This field is read only and set to ’000’ in case of a device controller. IC_VDD8 to IC_VDD2 are read only and set to ’000’ in case the controller is not

60.4.2.6.11 ULPI VIEWPORT (optional)

The register provides indirect access to the ULPI PHY register set. Although the core performs access to the ULPI PHY register set, there may be extraordinary circumstances where software may need direct access.

CAUTION

Writes to the ULPI through the VIEWPORT can substantially harm standard USB operations. currently no usage model has been defined where software should need to execute writes directly to the ULPI.

NOTES

Executing read operations though the ULPI Viewport should have no harmful side effects to standard USB operations.

The ULPI Viewport is only synthesized in the design if the ULPI option has been purchased and installed, and the constant `VUSB_HS_PHY_ULPI` is set to `1`. If the ULPI interface is not enabled, this register always reads zeros.

There are two operations that can be performed with the ULPI Viewport, wakeup and read /write operations. The wakeup operation is used to put the ULPI interface into normal operation mode and re-enable the clock if necessary. A wakeup operation is required before accessing the registers when the ULPI interface is operating in low power mode, serial mode, or carkit mode. The ULPI state can be determined by reading the sync. state bit (ULPISS). If this bit is a one, then ULPI interface is running in normal operation mode and can accept read/write operations. If the ULPISS indicates a ‘0’ then read/write operations will not be able execute. Undefined behavior will result if ULPISS = 0 and a read or write operation is performed. To execute a wakeup operation, write all 32-bits of the ULPI Viewport where ULPIPORT is constructed appropriately and the ULPIWU bit is a ‘1’ and ULPIRUN bit is a ‘0’. Poll the ULPI Viewport until ULPIWU is zero for the operation to complete.

To execute a read or write operation, write all 32-bits of the ULPI Viewport where ULPIDATWR, ULPIADDR, ULPIPORT, ULPIRW are constructed appropriately and the ULPIRUN bit is a ‘1’. Poll the ULPI Viewport until ULPIRUN is zero for the operation to complete. Once ULPIRUN is zero, the ULPIDATRD will be valid if the operation was a read.

The polling method above could also be replaced and interrupt driven using the ULPI interrupt defined in the USBSTS and USBINTR registers. When a wakeup or read/write operation complete, the ULPI interrupt will be set.

Address: Base + 170h

Default Value: 00000000h

Attribute: Read/Write

Size: 32 bits

31	30	29	28	27	26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0
ULPIWU	ULPIRUN	ULPIRW	R	ULPISS	ULPIPORT	ULPIADDR	ULPIDATRD	ULPIDATWR

Figure 60-45. ULPI VIEWPORT

Table 60-51 shows the ULPI VIEWPORT field descriptions.

Table 60-51. ULPI VIEWPORT

Field	Description
ULPIWU	**ULPI Wakeup – Read/Write.** Writing the '1' to this bit will begin the wakeup operation. The bit will automatically transition to 0 after the wakeup is complete. Once this bit is set, the driver can not set it back to '0'. Note: The driver must never execute a wakeup and a read/write operation at the same time.
ULPIRUN	**ULPI Read/Write Run – Read/Write.** Writing the '1' to this bit will begin the read/write operation. The bit will automatically transition to 0 after the read/write is complete. Once this bit is set, the driver can not set it back to '0'. Note: The driver must never execute a wakeup and a read/write operation at the same time.
ULPIRW	**ULPI Read/Write Control – Read/Write.** (0) – Read; (1) – Write. This bit selects between running a read or write operation.
reserved	**Reserved.** This bit is reserved and its value has no effect on operation.
ULPISS	**ULPI Sync State – Read Only.** (1) – Normal Sync. State. (0) In another state (i.e. carkit, serial, low power) This bit represents the state of the ULPI interface. Before reading this bit, the ULPIPORT field should be set accordingly if used with the multi-port host. Otherwise, this field should always remain 0.
ULPIPORT	**ULPI Port Number – Read/Write.** For the wakeup or read/write operation to be executed, this value selects the port number the ULPI PHY is attached to in the multi-port host. The range is 0 to 7. This field should always be written as a 0 for the non-multi port products.
ULPIADDR	**ULPI Data Address – Read/Write.** When a read or write operation is commanded, the address of the operation is written to this field.
ULPIDATRD	**ULPI Data Read – Read Only.** After a read operation completes, the result is placed in this field.
ULPIDATWR	**ULPI Data Write – Read/Write**. When a write operation is commanded, the data to be sent is written to this field.

60.4.2.6.12 CONFIGFLAG

This register is not used in this implementation. A read from this register returns a constant of a 00000001h to indicate that all port routines default to this host controller.

Address: Base + 180h

Default Value: 00000001h

Attribute: Read Only

Size: 32 bits

60.4.2.6.13 PORTSCx

Address: Base + 184h + (4 × (Port Number – 1))

where Port Number = 1, 2, 3, …8

Default Value:

IIII00000000000000XX0000000000b (host mode)

IIII00000000000001XX0000000100b (device mode)

I	Implementation dependent
X	Unknown
Attribute:	RO, Read/Write, R/WC (field dependent)
Size:	32 bits

Host Controller

A host controller must implement one to eight port registers. The number of port registers implemented by a particular instantiation of a host controller is documented in the HCSPARAMs register. Software uses this information as an input parameter to determine how many ports need service.

This register is only reset when power is initially applied or in response to a controller reset. The initial conditions of a port are:

No device connected

Port disabled

If the port has port power control, this state remains until software applies power to the port by setting port power to one.

Device Controller

A device controller must implement only port register one and it does not support power control. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

Figure 60-46. PORTSCx—Port Status Control[1:8]

The register fields are described in Table 60-52.

Table 60-52. PORTSCx Field Descriptions

Field	Description
PTS	**Parallel Transceiver Select – Read/Write**. This register bit pair is used in conjunction with the configuration constant VUSB_HS_PHY_TYPE to control which parallel transceiver interface is selected. If VUSB_HS_PHY_TYPE is set for 0,1,2, or 3 then this bit is read only. If VUSB_HS_PHY_TYPE is 3,4,5, or 6 then this bit is read/write. This field is reset to: “00” if VUSB_HS_PHY_TYPE = 0,4 – UTMI/UTMI+ “01” if VUSB_HS_PHY_TYPE = 1,5 – Reserved “10” if VUSB_HS_PHY_TYPE = 2,6 – ULPI “11” if VUSB_HS_PHY_TYPE = 3,7 – Serial/1.1 PHY/IC USB(FS Only) This bit is not defined in the EHCI specification.

Table 60-52. PORTSCx Field Descriptions (continued)

STS	**Serial Transceiver Select – Read/Write**. This register bit is used in conjunction with the configuration constant VUSB_HS_PHY_SERIAL to control whether the parallel or serial transceiver interface is selected for FS and LS operation. The Serial Interface Engine can be used in combination with the UTMI+ or ULPI physical interface to provide FS/LS signaling instead of the parallel interface. If VUSB_HS_PHY_SERIAL is set for 0 or 1 then this bit is read only. If VUSB_HS_PHY_SERIAL is 3 or 4 then this bit is read/write. This bit has no effect unless Parallel Transceiver Select is set to UTMI+ or ULPI. The Serial/1.1 physical interface will use the Serial Interface Engine for FS/LS signaling regardless of this bit value. Note: This bit is reserved for future operation and is a placeholder adding dynamic use of the serial engine in accord with UMTI+ and ULPI characterization logic. This bit is not defined in the EHCI specification.
PTW	**Parallel Transceiver Width – Read/Write**. This register bit is used in conjunction with the configuration constant VUSB_HS_PHY8_16 to control whether the data bus width of the UTMI transceiver interface. If VUSB_HS_PHY8_16 is set for 0 or 1 then this bit is read only. If VUSB_HS_PHY8_16 is 2 or 3 then this bit is read/write. This bit is reset to 1 if VUSB_HS_PHY8_16 selects a default UTMI interface width of 16-bits else it is reset to 0. Writing this bit to 0 selects the 8-bit [60MHz] UTMI interface. Writing this bit to 1 selects the 16-bit [30MHz] UTMI interface. This bit has no effect if the Serial interfaces are selected. This bit is not defined in the EHCI specification.
PSPD	**Port Speed – Read Only.** This register field indicates the speed at which the port is operating. For HS mode operation in the host controller and HS/FS operation in the device controller the port routing steers data to the Protocol engine. For FS and LS mode operation in the host controller, the port routing steers data to the Protocol Engine w/ Embedded Transaction Translator. 00 Full Speed 01 Low Speed 10 High Speed This bit is not defined in the EHCI specification.
PFSC	**Port Force Full Speed Connect – Read/Write.** Default = 0b. Writing this bit to a 1b will force the port to only connect at Full Speed. It disables the chirp sequence that allows the port to identify itself as High Speed. This is useful for testing FS configurations with a HS host, hub or device. This bit is not defined in the EHCI specification. This bit is for debugging purposes.
PHCD	**PHY Low Power Suspend - Clock Disable (PLPSCD) – Read/Write.** Default = 0b. Writing this bit to a 1b will disable the PHY clock. Writing a 0b enables it. Reading this bit will indicate the status of the PHY clock. NOTE: The PHY clock cannot be disabled if it is being used as the system clock. In device mode, The PHY can be put into Low Power Suspend – Clock Disable when the device is not running (USBCMD Run/Stop=0b) or the host has signaled suspend (PORTSC SUSPEND=1b). Low power suspend will be cleared automatically when the host has signaled resume if using a circuit similar to that in. Before forcing a resume from the device, the device controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend – Clock Disable when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software. See for more discussion on clock disable and power down issues. This bit is not defined in the EHCI specification.
WKOC	**Wake on Over-current Enable (WKOC_E) — Read/Write.** Default = 0b. Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if *Port Power(PP)* is zero. This bit is output from the controller as signal **pwrctl_wake_ovrcurr_en** (OTG/host core only) for use by an external power control circuit.

Table 60-52. PORTSCx Field Descriptions (continued)

WKDC	**Wake on Disconnect Enable (WKDSCNNT_E) — Read/Write.** Default=0b. Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if *Port Power(PP)* is zero or in device mode. This bit is output from the controller as signal **pwrctl_wake_dscnnt_en** (OTG/host core only) for use by an external power control circuit.
WKCN	**Wake on Connect Enable (WKCNNT_E) — Read/Write.** Default=0b. Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if *Port Power(PP)* is zero or in device mode. This bit is output from the controller as signal **pwrctl_wake_dscnnt_en** (OTG/host core only) for use by an external power control circuit.
PTC[3:0]	**Port Test Control — Read/Write.** Default = 0000b. Any other value than zero indicates that the port is operating in test mode. **ValueSpecific Test** 0000b TEST_MODE_DISABLE 0001b J_ STATE 0010b K_STATE 0011b SE0 (host) / NAK (device) 0100b Packet 0101b FORCE_ENABLE_HS 0110b FORCE_ENABLE_FS 0111b FORCE_ENABLE_LS 1000b to 1111bReserved Refer to Chapter 7 of the USB Specification Revision 2.0 Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org for details on each test mode. The FORCE_ENABLE_FS and FORCE ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point. *Note: Low speed operations are not supported as a peripheral device.*
PIC[1:0]	**Port Indicator Control — Read/Write.** Default = Ob. Writing to this field has no effect if the P_INDICATOR bit in the HCSPARAMS register is a zero. If P_INDICATOR bit is a one, then the bit is: Bit ValueMeaning 00b Port indicators are off 01b Amber 10b Green 11b Undefined Refer to the USB Specification Revision 2.0 Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org for a description on how these bits are to be used. This field is output from the controller as signals **port_ind_ctl_1 & port_ind_ctl_0** for use by an external led driving circuit.
PO	**Port Owner—Read/Write**. Default = 0. This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port. Port owner handoff is not implemented in this design, therefore this bit will always be 0.

Table 60-52. PORTSCx Field Descriptions (continued)

PP	**Port Power (PP)—Read/Write or Read Only.** The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0b 0b Read Only— A device controller with no OTG capability does not have port power control switches. 1b 1b/0b – RW. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (i.e. PP equals a 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port). This feature is implemented in the host/OTG controller (PPC = 1). In a device only implementation port power control is not necessary, thus PPC and PP = 0.
LS[1:0]	**Line Status—Read Only.** These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. The encoding of the bits are: Bits [11:10]Meaning 00b SE0 10b J-state 01b K-state 11b Undefined In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of linestate by the device controller driver is not necessary.
HSP	**High-Speed Port — Read Only.** Default = 0b. When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode. Note: HSP is redundant with PSPD(27:26) but will remain in the design for compatibility. This bit is not defined in the EHCI specification.
PR	**Port Reset** This field is zero if *Port Power(PP)* is zero. **In Host Mode:** Read/Write. 1=Port is in Reset. 0=Port is not in Reset. Default 0. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. *This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.* **In Device Mode:** This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register.

Table 60-52. PORTSCx Field Descriptions (continued)

SUSP	Suspend **In Host Mode: Read/Write.** 1=Port in suspend state. 0=Port not in suspend state. Default=0. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend]Port State 0x Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the *Force Port Resume* bit to zero. The host controller ignores a write of zero to this bit. If host software sets this bit to a one when the port is not enabled (i.e. *Port enabled* bit is a zero) the results are undefined. This field is zero if *Port Power(PP)* is zero in host mode. **In Device Mode: Read Only.** 1=Port in suspend state. 0=Port not in suspend state. Default=0. In device mode this bit is a read only status bit.
FPR	**Force Port Resume —Read/Write.** 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. Default = 0. **In Host Mode:** Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the *Port Change Detect* bit in the USBSTS register is also set to one. *This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.* Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no affect because the port controller will time the resume operation clear the bit the port control state switches to HS or FS idle. This field is zero if *Port Power(PP)* is zero in host mode. This bit is not-EHCI compatible. **In Device mode:** After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition detected, the *Port Change Detect* bit in the USBSTS register is also set to one.
OCC	**Overcurrent Change—R/WC**. Default=0. 1=This bit gets set to one when there is a change to Over-current Active. Software clears this bit by writing a one to this bit position. For host/OTG implementations the user can provide over-current detection to the vbus_pwr_fault input for this condition. For device-only implementations this bit shall always be 0.
OCA	**Overcurrent Active—Read Only.** Default 0. 1=This port currently has an over-current condition. 0=This port does not have an over-current condition. This bit will automatically transition from one to zero when the over current condition is removed. For host/OTG implementations the user can provide over-current detection to the vbus_pwr_fault input for this condition. For device-only implementations this bit shall always be 0.

Table 60-52. PORTSCx Field Descriptions (continued)

PEC	**Port Enable/Disable Change—R/WC.** 1=Port enabled/disabled status has changed. 0=No change. Default = 0. **In Host Mode:** For the root hub, this bit gets set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if *Port Power(PP)* is zero. **In Device mode:** The device port is always enabled. (This bit will be zero)
PE	**Port Enabled/Disabled—Read/Write.** 1=Enable. 0=Disable. Default 0. In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if *Port Power(PP)* is zero in host mode. **In Device Mode:** The device port is always enabled. (This bit will be one)
CSC	**Connect Status Change—R/WC.** 1 =Change in Current Connect Status. 0=No change. Default 0. **In Host Mode:** Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software clears this bit by writing a one to it. This field is zero if *Port Power(PP)* is zero in host mode. In Device Mode: This bit is undefined in device controller mode.
CCS	**Current Connect Status—Read Only**. **In Host Mode:** 1=Device is present on port. 0=No device is present. Default = 0. This value reflects the current state of the port, and may not correspond directly to the event that caused the *Connect Status Change* bit (Bit 1) to be set. This field is zero if *Port Power(PP)* is zero in host mode. **In Device Mode:** 1=Attached. 0=Not Attached. Default=0. A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended.

60.4.2.6.14 OTGSC

Address: Base + 1A4h

Default Value: 00000020h

Attribute: RO, Read/Write, R/WC (field dependent)

Size: 32 bits

Host Controller

A host controller implements one On-The-Go (OTG) Status and Control register corresponding to Port 0 of the host controller.

The OTGSC register has four sections

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 Msec time constant. Values on the status inputs that do not persist for more than 1 Msec will not cause an update of the status input register, or cause an OTG interrupt.

See also USBMODE register.

Figure 60-47. OTGSC—OTG Status Control

The register fields are described in Table 60-53.

Table 60-53. OTGSC Field Descriptions

Field	Description
DPIE	Data Pulse Interrupt Enable
1msE	1 millisecond timer Interrupt Enable – Read/Write
BSEIE	B Session End Interrupt Enable – Read/Write. Setting this bit enables the B session end interrupt.
BSVIE	B Session Valid Interrupt Enable – Read/Write. Setting this bit enables the B session valid interrupt.
ASVIE	A Session Valid Interrupt Enable – Read/Write. Setting this bit enables the A session valid interrupt.
AVVIE	A VBus Valid Interrupt Enable – Read/Write. Setting this bit enables the A VBus valid interrupt.
IDIE	USB ID Interrupt Enable – Read/Write. Setting this bit enables the USB ID interrupt.

Table 60-53. OTGSC Field Descriptions (continued)

DPIS	Data Pulse Interrupt Status – Read/Write to Clear. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC(0).PortPower = Off (0). Software must write a one to clear this bit.
1msS	1 millisecond timer Interrupt Status – Read/Write to Clear. This bit is set once every millisecond. Software must write a one to clear this bit.
BSEIS	B Session End Interrupt Status – Read/Write to Clear. This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit
BSVIS	**B Session Valid Interrupt Status – Read/Write to Clear**. This bit is set when VBus has either risen above or fallen below the B session valid threshold (0.8 VDC). Software must write a one to clear this bit.
ASVIS	**A Session Valid Interrupt Status – Read/Write to Clear**. This bit is set when VBus has either risen above or fallen below the A session valid threshold (0.8 VDC). Software must write a one to clear this bit.
AVVIS	**A VBus Valid Interrupt Status – Read/Write to Clear**. This bit is set when VBus has either risen above or fallen below the VBus valid threshold (4.4 VDC) on an A device. Software must write a one to clear this bit.
IDIS	USB ID Interrupt Status – Read/Write. This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.
DPS	Data Bus Pulsing Status – Read Only. A '1' indicates data bus pulsing is being detected on the port.
1msT	1 millisecond timer toggle - Read Only. This bit toggles once per millisecond.
BSE	B Session End – Read Only. Indicates VBus is below the B session end threshold.
BSV	B Session Valid – Read Only. Indicates VBus is above the B session valid threshold.
ASV	A Session Valid – Read Only. Indicates VBus is above the A session valid threshold.
AVV	A VBus Valid – Read Only. Indicates VBus is above the A VBus valid threshold.
ID	USB ID – Read Only. 0 = A device, 1 = B device
IDPU	ID Pullup – Read/Write This bit provide control over the ID pull-up resister; 0 = off, 1 = on [default]. When this bit is 0, the ID input will not be sampled.
DP	Data Pulsing – Read/Write. Setting this bit causes the pullup on DP to be asserted for data pulsing during SRP.
OT	OTG Termination – Read/Write. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.

Table 60-53. OTGSC Field Descriptions (continued)

VC	VBUS Charge – Read/Write. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP.
VD	VBUS_Discharge – Read/Write. Setting this bit causes VBus to discharge through a resistor.

60.4.2.6.15 USBMODE

Address: Base + 1A8h

Default Value: 00000000h (otg implementation – mode not selected)
00000003h (host mode)
00000002h (device mode))

Attribute: R/WO, Read Only

Size: 32 bits

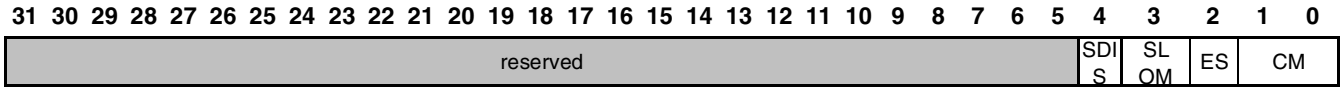

Figure 60-48. USBMODE—USB Device Mode

The register fields are described in Table 60-54.

Table 60-54. USBMODE Field Descriptions

Field	Description
Reserved	**Reserved.** These bits are reserved and should be set to zero.
SDIS	Stream Disable Mode. (0 – Inactive [default]; 1 – Active) **Device Mode:** Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received will be responded to with a NYET handshake when stream disable is active. **Host Mode:** Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB. Note: Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TXFILLTUNING and TXTTFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature. Note: The use of this feature substantially limits of the overall USB performance that can be achieved.
SLOM	**Setup Lockout Mode.** In device mode, this bit controls behavior of the setup lock mechanism. See Control Endpoint Operation Model. 0 – Setup Lockouts On (default); 1 – Setup Lockouts Off (DCD requires use of Setup Data Buffer Tripwire in USBCMD)

Table 60-54. USBMODE Field Descriptions (continued)

ES	**Endian Select – Read/Write.** This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The bit fields in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word. **Bit** **Meaning** 0 Little Endian [Default] 1 Big Endian
CM[1:0]	**Controller Mode – R/WO.** Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host & device capability, the controller will default to an idle state and will need to be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the *RESET* bit in the USBCMD register before reprogramming this register. **Bit** **Meaning** 00 Idle [Default for combination host/device] 01 Reserved 10 Device Controller [Default for device only controller] 11 Host Controller [Default for host only controller]

60.4.2.6.16 ENDPTSETUPSTAT

Address: Base + 1ACh

Default Value: 00000000h

Attribute: R/WC

Size: 32 bits

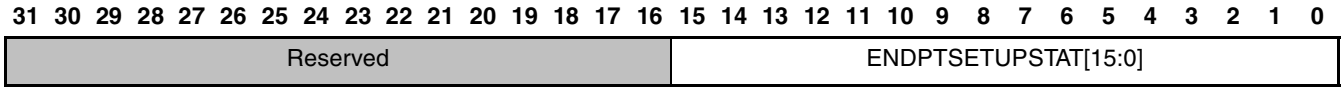

Figure 60-49. ENDPTSETUPSTAT—Endpoint Setup Status

The register fields are described in Table 60-55.

Table 60-55. ENDPTSETUPSTAT Field Descriptions

Field	Description
Reserved	**Reserved.** These bits are reserved and should be set to zero.
ENDPTSETUPSTAT [15:0]	**Setup Endpoint Status.** For every setup transaction that is received, a corresponding bit in this register is set to one. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from Queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lock our mechanism is engaged. See Managing Endpoints in the Device Operational Model. This register is only used in device mode.

60.4.2.6.17 ENDPTPRIME

Address: Base + 1B0h

Default Value: 00000000h

Attribute: R/WS

Size: 32 bits

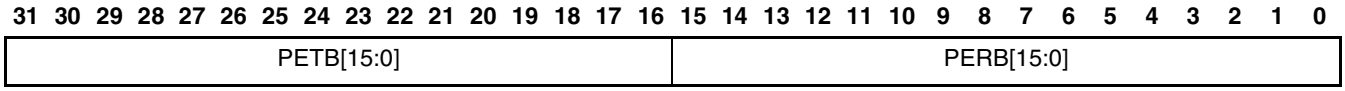

Figure 60-50. ENDPTPRIME—Endpoint Initialization

This register is only used in device mode. The register fields are described in Table 60-56.

Table 60-56. ENDPTPRIME Field Descriptions

Field	Description
PETB [15:0]	**Prime Endpoint Transmit Buffer – R/WS.** For each endpoint a corresponding bit is used to request that a buffer prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction. Software should write a one to the corresponding bit when posting a new transfer descriptor to an endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware will clear this bit when the associated endpoint(s) is (are) successfully primed. Note: These bits will be momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PETB[15] – Endpoint #15 PETB[1] – Endpoint #1 PETB[0] – Endpoint #0
PERB [15:0]	**Prime Endpoint Receive Buffer – R/WS.** For each endpoint, a corresponding bit is used to request a buffer prepare for a receive operation for when a USB host initiates a USB OUT transaction. Software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware will clear this bit when the associated endpoint(s) is (are) successfully primed. Note: These bits will be momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. Bit 15 – Endpoint #15 Bit 1 – Endpoint #1 Bit 0 – Endpoint #0

60.4.2.6.18 ENDPTFLUSH

Address: Base + 1B4h

Default Value: 00000000h

Attribute: R/WS

Size: 32 bits

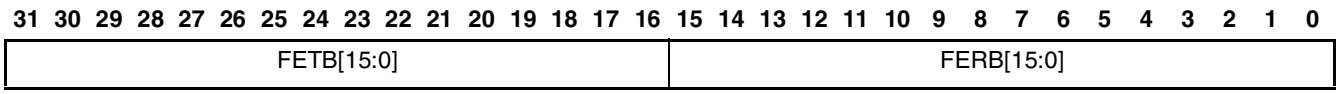

Figure 60-51. ENDPTFLUSH—Endpoint De-Initialize

This register is only used in device mode. The register fields are described in Table 60-57.

Table 60-57. ENDPTFLUSH Field Descriptions

Field	Description
FETB [15:0]	**Flush Endpoint Transmit Buffer – R/WS.** Writing a one to a bit(s) in this register will cause the associated endpoint(s) to clear any primed buffers. If a packet is in progress for one of the associated endpoints, then that transfer will continue until completion. Hardware will clear this register after the endpoint flush operation is successful. FETB[15] – Endpoint #15 FETB[1] – Endpoint #1 FETB[0] – Endpoint #0
FERB [15:0]	**Flush Endpoint Receive Buffer – R/WS.** Writing a one to a bit(s) will cause the associated endpoint(s) to clear any primed buffers. If a packet is in progress for one of the associated endpoints, then that transfer will continue until completion. Hardware will clear this register after the endpoint flush operation is successful. Bit 15 – Endpoint #15 Bit 1 – Endpoint #1 Bit 0 – Endpoint #0

60.4.2.6.19 ENDPTSTAT

Address: Base + 1B8h

Default Value: 00000000h

Attribute: Read Only

Size: 32 bits

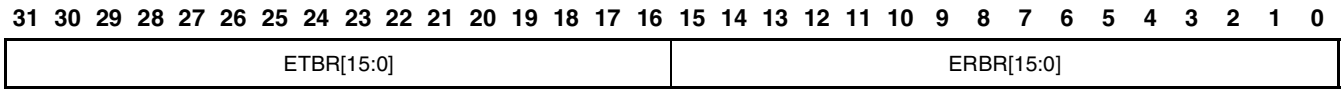

Figure 60-52. ENDPTSTAT—Endpoint Status

This register is only used in device mode. The register fields are described in Table 60-57.

Table 60-58. ENDPTSTAT Field Descriptions

Field	Description
ETBR [15:0]	**Endpoint Transmit Buffer Ready—Read Only.** One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. Note: These bits will be momentarily cleared by hardware during hardware endpoint re-priming operations when a dTD is retired, and the dQH is updated. ETBR[15]– Endpoint #15 ETBR[1]– Endpoint #1 ETBR[0]– Endpoint #0
ERBR [15:0]	**Endpoint Receive Buffer Ready—Read Only.** One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. Note: These bits will be momentarily cleared by hardware during hardware endpoint re-priming operations when a dTD is retired, and the dQH is updated. ERBR[15]– Endpoint #15 ERBR[1]– Endpoint #1 ERBR[0]– Endpoint #0

60.4.2.6.20 ENDPTCOMPLETE

Address: Base + 1BCh

Figure 60-53. ENDPTCOMPLETE—Endpoint Compete

This register is only used in device mode. The register fields are described in Table 60-57.

Table 60-59. ENDPTCOMPLETE Field Descriptions

Field	Description
ETCE [15:0]	**Endpoint Transmit Complete Event – R/WC.** Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the *USBINT*. Writing a one will clear the corresponding bit in this register. ETCE[15]– Endpoint #15 ETCE[1]– Endpoint #1 ETCE[0]– Endpoint #0
ERCE [15:0]	**Endpoint Receive Complete Event – RW/C.** Each bit indicates a received event (OUT/SETUP) occurred and software should read the corresponding endpoint queue to determine the transfer status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the *USBINT*. Writing a one will clear the corresponding bit in this register. ERCE[15]– Endpoint #15 ERCE[1]– Endpoint #1 ERCE[0]– Endpoint #0

60.4.2.6.21 ENDPTCTRL0

Address: Base + 1C0h

Default Value: 0080008h

Attribute: Read Only, Read/Write, R/WC (field dependent)

Size: 32 bits

Every device implements Endpoint0 as a control endpoint.

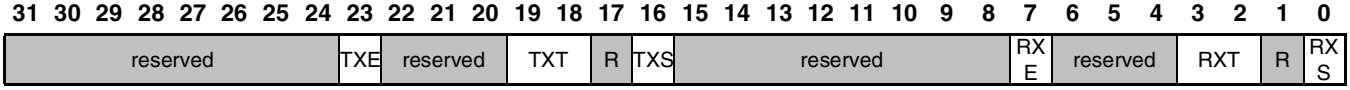

Figure 60-54. ENDPTCTRL0—Endpoint Control 0

The register fields are described in the following table.

Table 60-60. ENDPTCTRL0 Field Descriptions

Field	Description
Reserved	**Reserved.** These bits are reserved and should be set to zero.
TXE	**TX Endpoint Enable** 1 – Enabled Endpoint0 is always enabled.
TXT[1:0]	**TX Endpoint Type – Read/Write** 00 – Control Endpoint0 is fixed as a Control End Point.
R	**Reserved.** Bit reserved and should be set to zero.

Table 60-60. ENDPTCTRL0 Field Descriptions (continued)

TXS	**TX Endpoint Stall – Read/Write** 0 – End Point OK [Default] 1 – End Point Stalled Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue returning STALL until the bit is cleared by software or it will automatically be cleared upon receipt of a new SETUP request.
RXE	**RX Endpoint Enable** 1 – Enabled Endpoint0 is always enabled.
RXT[1:0]	**RX Endpoint Type – Read/Write** 00 – Control Endpoint0 is fixed as a Control End Point.
RXS	**RX Endpoint Stall – Read/Write** 0 – End Point OK. [Default] 1 – End Point Stalled Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue returning STALL until the bit is cleared by software or it will automatically be cleared upon receipt of a new SETUP request.

60.4.2.6.22 ENDPTCTRL1 – ENDPTCTRL15

There is an ENDPTCTRLx register for each endpoint in a device.

Address: Base + 1C0h+(4*(EndPoint Number))

Default Value: 00000000h

Attribute: Read/Write

Size: 32 bits

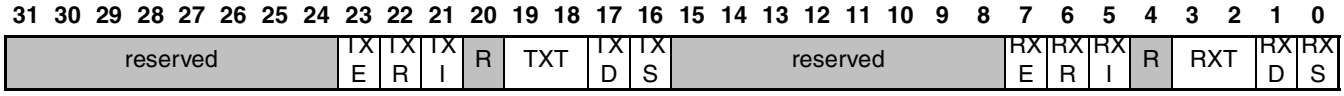

Figure 60-55. ENDPTCTRL1–15—Endpoint Control 1 to 15

CAUTION

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (IE. Bulk-type). leaving an unconfigured endpoint control will cause undefined behavior for the data pid tracking on the active endpoint/direction.

The register fields are described in Table 60-61.

Table 60-61. Endpoint Control*x* Field Descriptions

Field	Description
Reserved	**Reserved.** These bits are reserved and should be set to zero.

Table 60-61. Endpoint Control*x* Field Descriptions *(continued)*

TXE	**TX Endpoint Enable** 0 – Disabled [Default] 1 – Enabled An Endpoint should be enabled only after it has been configured.
TXR	**TX Data Toggle Reset (WS)** Write 1 – Reset PID Sequence Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the Host and device.
TXI	**TX Data Toggle Inhibit** 0 – PID Sequencing Enabled. [Default] 1 – PID Sequencing Disabled. This bit is only used for test and should always be written as zero. Writing a one to this bit will cause this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet.
R	**Reserved.** Bit reserved and should be set to zero.
TXT[1:0]	**TX Endpoint Type – Read/Write** 00 – Control 01 – Isochronous 10 – Bulk 11 – Interrupt
TXD	**TX Endpoint Data Source – Read/Write** 0 – Dual Port Memory Buffer/DMA Engine [DEFAULT] Should always be written as 0.
TXS	**TX Endpoint Stall – Read/Write** 0 – End Point OK 1 – End Point Stalled This bit will be set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It will be cleared automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue to returning STALL until this bit is either cleared by software or automatically cleared as above.
RXE	**RX Endpoint Enable** 0 – Disabled [Default] 1 – Enabled An Endpoint should be enabled only after it has been configured.
RXR	**RX Data Toggle Reset (WS)** Write 1 – Reset PID Sequence Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the host and device.
RXI	**RX Data Toggle Inhibit** 0 – Disabled [Default] 1 – Enabled This bit is only used for test and should always be written as zero. Writing a one to this bit will cause this endpoint to ignore the data toggle sequence and always accept data packet regardless of their data PID.
RXT[1:0]	**RX Endpoint Type – Read/Write** 00 – Control 01 – Isochronous 10 – Bulk 11 – Reserved

Table 60-61. Endpoint Control*x* Field Descriptions *(continued)*

RXD	**RX Endpoint Data Sink – Read/Write – TBD** 0 – Dual Port Memory Buffer/DMA Engine [Default] Should always be written as zero.
RXS	**RX Endpoint Stall – Read/Write** 0 – End Point OK. [Default] 1 – End Point Stalled This bit will be set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It will be cleared automatically upon receipt a SETUP request if this Endpoint is configured as a Control Endpoint, Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue to returning STALL until this bit is either cleared by software or automatically cleared as above,

60.4.2.7 OTG Operations

This section discusses the following:

- Section 60.4.2.7.1, Register Bits”
- Section 60.4.2.7.2, Hardware Assist”

60.4.2.7.1 Register Bits

In the previous section, the register interface has behaviors described for device mode and behaviors described for host mode. However, during OTG operations it is necessary to perform tasks independent of the controller mode.

Note also from Section 60.4.2.6.22, ENDPTCTRL1 – ENDPTCTRL15,” that the only way to transition the controller mode out of host or device mode is with the controller reset bit. Therefore, it is also necessary for the OTG tasks to be performed independent of a controller reset as well as independent of the controller mode.

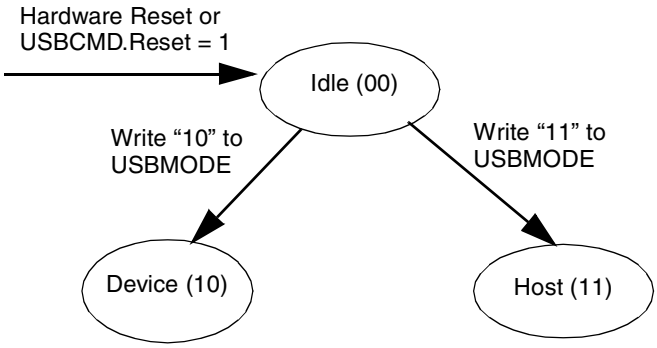

Figure 60-56. Controller Mode

To this end, the following list shows the register bits that are used for OTG operations, which are independent of the controller mode. They are also not affected by a write to the reset bit in the USBCMD register:

- All Identification Registers

- All Device/Host Capability Registers
- OTGSC—All bits
- PORTSC
  - Physical Interface Select
  - Physical Interface Serial Select
  - Physical Interface Data Width
  - Physical Interface Low Power
  - Physical Interface Wake Signals
  - Port Indicators
  - Port Power

60.4.2.7.2 Hardware Assist

The hardware assist provides automated response and sequencing that may not be possible to software with significant interrupt latency response times. The use of this additional circuitry is optional and can be used to assist the three sequences below.

Auto-Reset

When the HAAR is set to one, the host will automatically start a reset after a connect event. This shortcuts the normal process where software is notified of the connect event and starts the reset. Software will still receive notification of the connect event but should not write the reset bit when the HAAR is set. Software will be notified again after the reset is complete via the enable change bit in the PORTSC register which cause a port change interrupt.

This assist will ensure the OTG parameter TB_ACON_BSE0_MAX = 1ms is met.

Data-Pulse

Writing a one to HADP will start a data pulse of approximately 7ms in duration and then automatically cease the data pulsing. During the data pulse, the DP will be set and then cleared. This automation relieves software from accurately controlling the data-pulse duration. During the data pulse, the HCD can poll to see that the HADP and DP bit have returned low to recognize the completion or simply launch the data pulse and wait to see if a VBUS Valid interrupt occurs when the A-side supplies bus power.

This assist will ensure data pulsing meets the OTG requirement of > 5ms and < 10ms.

B-Disconnect to A-Connect

During HNP, the B-disconnect occurs from the OTG A_suspend state and within 3 ms, the A device must enable the pullup on the DP leg in the A-peripheral state. When HABA is set, the Host Controller port is in suspend mode, and the device disconnects, then this hardware assist begins.

1. Reset the OTG core.
2. Write the OTG core into device mode.
3. Write the device run bit to a 1 and enable necessary interrupts including:

- USB Reset Enable (URE) ; enables interrupt on usb bus reset to device
- Sleep Enable (SLE) ; enables interrupt on device suspend
- Port Change Detect Enable (PCE) ; enables interrupt on device connect

When software has enabled this hardware assist, it must not interfere during the transition and should not write any register in the core until it gets an interrupt from the device controller signifying that a reset interrupt has occurred or at least first verify that the core has entered device mode. HCD/DCD must not activate the core soft reset at any time since this action is performed by hardware. During the transition, the software may see an interrupt from the disconnect and/or other spurious interrupts (ie. SOF/etc.) that may or may not cascade and my be cleared by the soft reset depending on the software response time.

After the core has entered device mode by the hardware assist, the DCD must ensure that the ENDPTLISTADDR is programmed properly before the host sends a setup packet. Since the end of the reset duration, which may be initiated quickly (a few microseconds) after connect, will require at a minimum 50 ms, this is the time for which the DCD must be ready to accept setup packets after having received notification that the reset has been detected or simply that the OTG is in device mode which ever occurs first.

In the case where the A-peripheral fails to see a reset after the controller enters device mode and engages the DP-pullup, the device controller interrupt the DCD signifying that a suspend has occurred.

This assist will ensure the parameter TA_BDIS_ACON_MAX = 3ms is met.

60.4.3 Host Data Structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the Enhanced Host Controller (hardware). The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of a Periodic Schedule, Periodic Frame List, Asynchronous Schedule, Isochronous Transaction Descriptors, Split-transaction Isochronous Transfer Descriptors, Queue Heads, and Queue Element Transfer Descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) support for the host controller interface. The asynchronous list is the root for all the bulk and control transfer type support. Isochronous data streams are managed using Isochronous Transaction Descriptors. Isochronous split-transaction data streams are managed with Split-transaction Isochronous Transfer Descriptors. All Interrupt, Control, and Bulk data streams are managed via queue heads and Queue Element Transfer Descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI host controller spans a 4K-page boundary.

The data structures defined in this section are (from the host controller’s perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

60.4.3.1 Periodic Frame List

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the *PERIODICLISTBASE* address register and the *FRINDEX* register. The periodic schedule is based on an array of pointers called the Periodic Frame List. The *PERIODICLISTBASE* address register is combined with the *FRINDEX* register to produce a memory pointer into the frame list. The Periodic Frame List implements a *sliding window* of work over time.

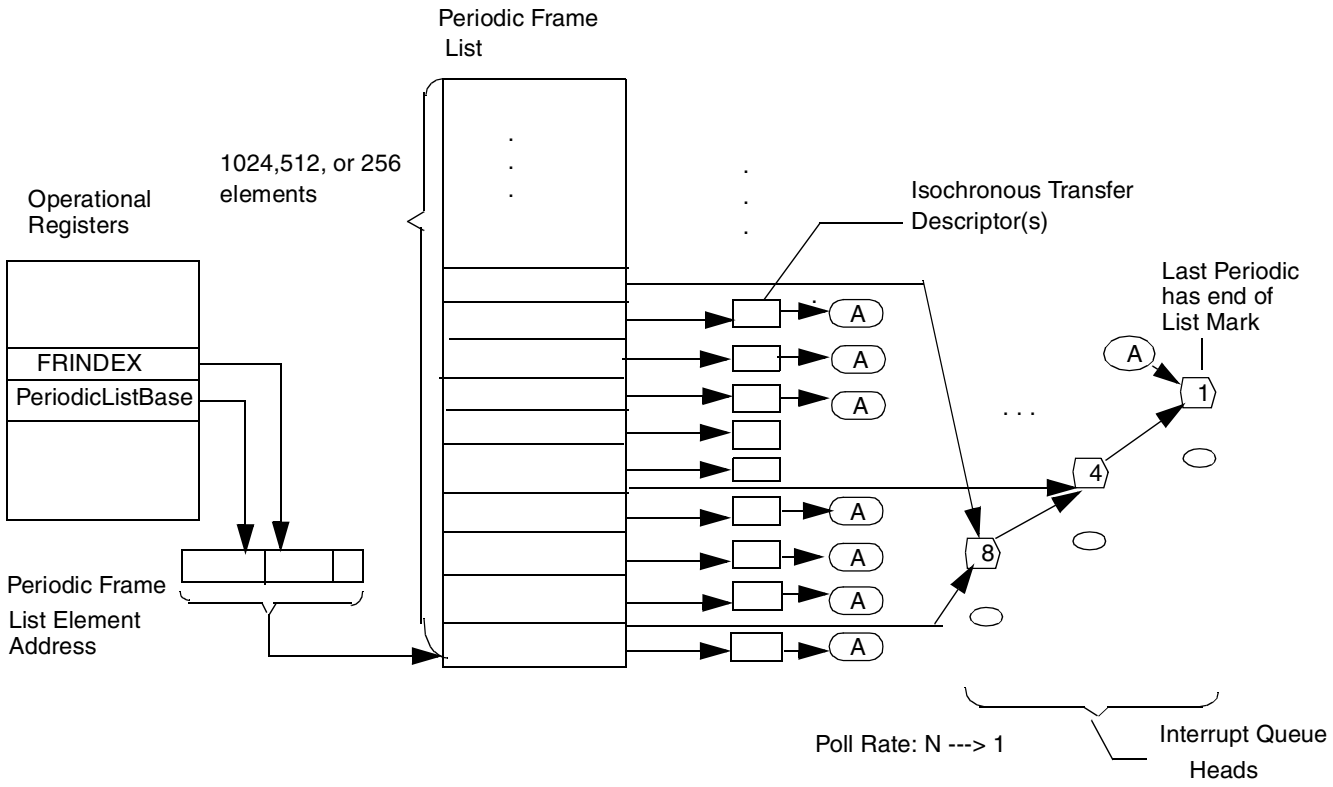

Figure 60-57. Periodic Schedule Organization

[1] Split transaction Interrupt, Bulk and Control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4K-page aligned array of Frame List Link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to system software via the HCCPARAMS register. If non-programmable, the length is 1024 elements. If programmable, the length can be selected by system software as one of 256, 512, or 1024 elements. An implementation must support all three sizes. Programming the size (i.e. the number of elements) is accomplished by system software writing the appropriate value into *Frame List Size* field in the USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current micro-frame. The link pointers are aligned on DWord boundaries within the Frame List.

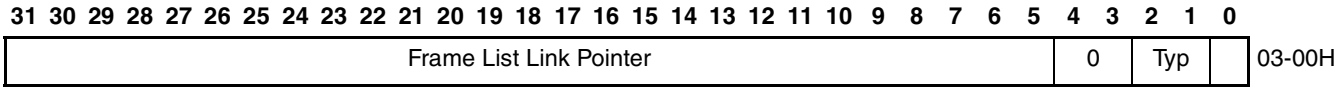

Figure 60-58. Format of Frame List Element Pointer

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing.

The least significant bit is the *T-Bit* (bit 0). When this bit is set to a one, the host controller will never use the value of the frame list pointer as a physical memory pointer. The *Typ* field is used to indicate the exact type of data structure being referenced by this pointer. The value encodings are shown in Table 60-62.

Table 60-62. Typ Field Value Definitions

Value	Meaning
00b	Isochronous Transfer Descriptor
01b	Queue Head
10b	Split Transaction Isochronous Transfer Descriptor.
11b	Frame Span Traversal Node.

60.4.3.2 Asynchronous List Queue Head Pointer

The Asychronous Transfer List (based at the ASYNCLISTADDR register) is where all the control and bulk transfers are managed. Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty.

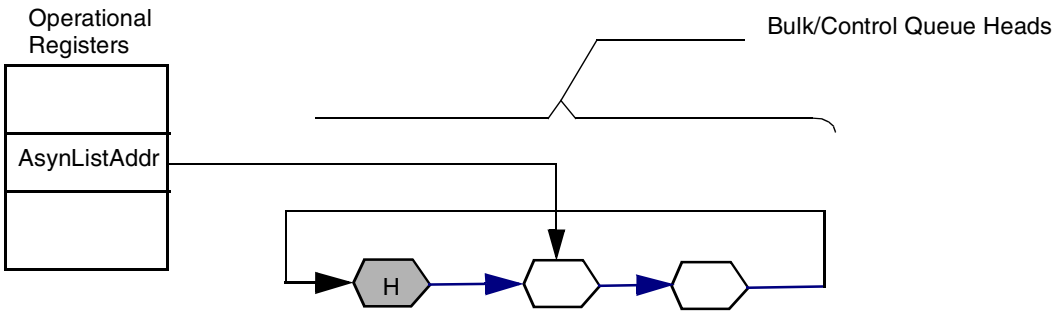

Figure 60-59. Asynchronous Schedule Organization

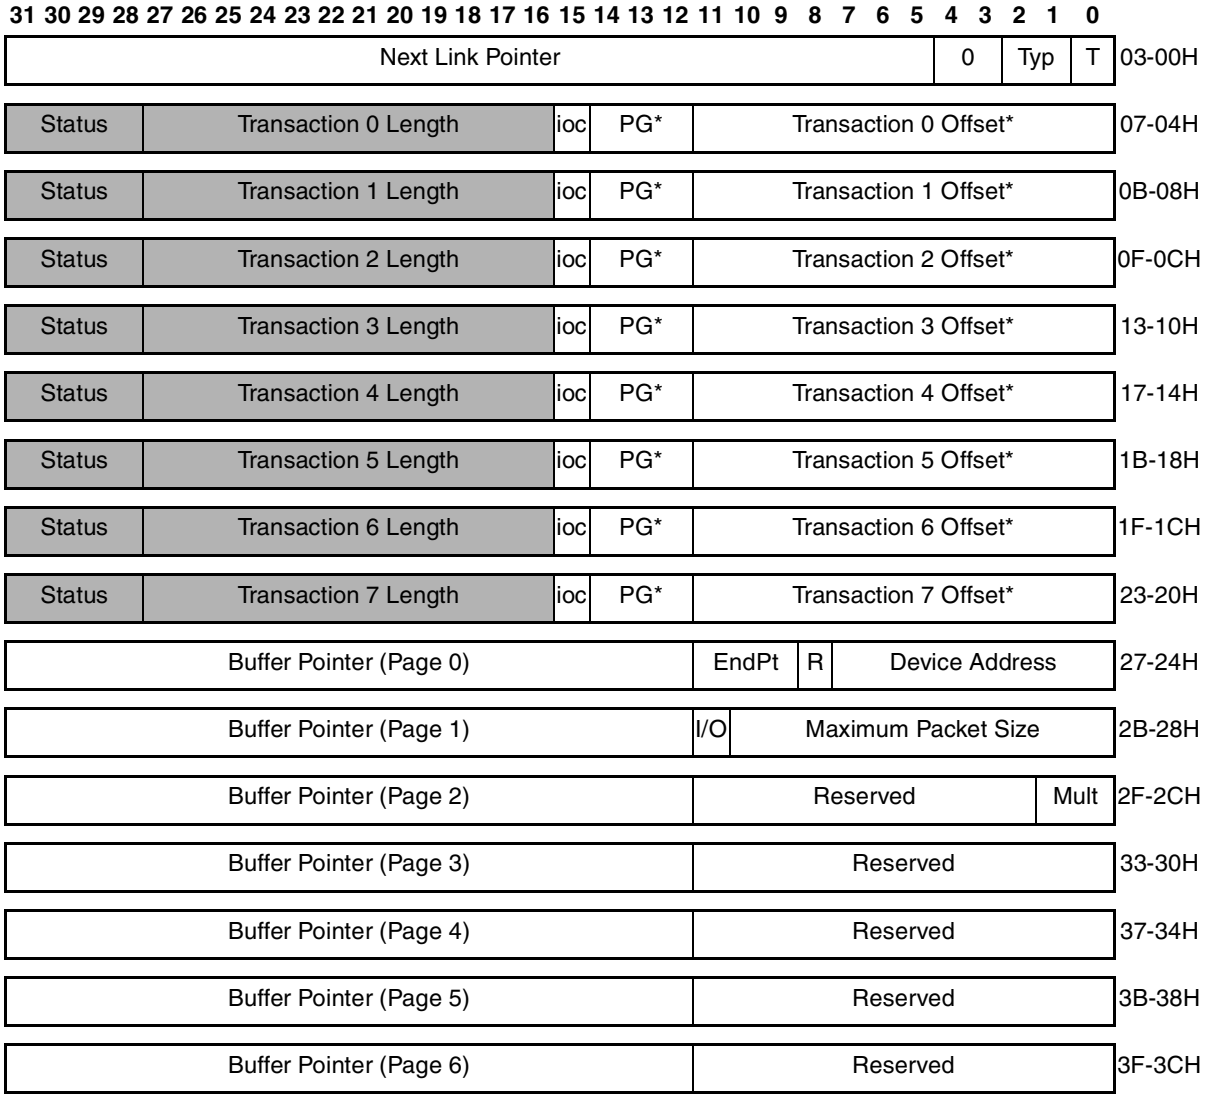
The Asynchronous list is a simple circular list of queue heads. The ASYNCLISTADDR register is simply pointer to the *next* queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

60.4.3.3 Isochronous (High-Speed) Transfer Descriptor (iTD)

The format of an isochronous transfer descriptor is illustrated in Figure 60-60. This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.



Host Controller Read/Write Host Controller Read Only.

Note: These fields may be modified by the host controller if the I/O field indicates an OUT.

Figure 60-60. Isochronous Transaction Descriptor (iTD)

60.4.3.3.1 Next Link Pointer

The first DWord of an iTD is a pointer to the next schedule data structure, as shown in Table 60-63.

Table 60-63. Next Schedule Element Pointer

Bit	Description
31–5	**Link Pointer (LP).** These bits correspond to memory address signals [31:5], respectively. This field points to another Isochronous Transaction Descriptor (iTD/siTD) or Queue Head (QH).
4–3	**Reserved.** These bits are reserved and their value has no effect on operation. Software should initialize this field to zero.
2–1	**QH/(s)iTD Select (Typ).** This field indicates to the Host Controller whether the item referenced is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: ValueMeaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0	Terminate (T). 1= Link Pointer field is not valid. 0= Link Pointer field is valid.

60.4.3.3.2 iTD Transaction Status and Control List

DWords 1 through 8 are eight slots of transaction control and status. Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The *PG* and *Transaction X Offset* fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list, to execute a transaction on the USB.

Table 60-64. iTD Transaction Status and Control Field Descriptions

Bit	Description
31–28	**Status.** This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding: 31 **Active.** Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule. 30 **Data Buffer Error.** Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary 29 **Babble Detected.** Set to one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor. 28 **Transaction Error (XactErr).** Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.

Table 60-64. iTD Transaction Status and Control Field Descriptions (continued)

27–16	**Transaction X Length**. For an OUT, this field is the number of data bytes the host controller will send during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (for example, 0‡zero length data, 1‡one byte, 2‡two bytes, etc.). The maximum value this field may contain is 0xC00 (3072).
15	**Interrupt On Complete (IOC).** If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.
14–12	**Page Select (PG).** These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.
11–0	**Transaction X Offset**. This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent *PG* field to produce the starting buffer address for this transaction.

60.4.3.3.3 iTD Buffer Page Pointer List (Plus)

DWords 9–-15 of an isochronous transaction descriptor are nominally page pointers (4K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous. Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) × 1024 (maximum packet size) × 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Since each pointer is a 4K aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

Table 60-65. iTD Buffer Pointer Page 0 (Plus)

Bit	Description
31–12	**Buffer Pointer (Page 0).** This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11–8	**Endpoint Number (Endpt).** This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	**Reserved.** Bit reserved for future use and should be initialized by software to zero.
6–0	**Device Address.** This field selects the specific device serving as the data source or sink.

Table 60-66. iTD Buffer Pointer Page 1 (Plus)

Bit	Description
31–12	**Buffer Pointer (Page 1).** This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].

Table 60-66. iTD Buffer Pointer Page 1 (Plus) (continued)

11	**Direction (I/O). 0 = OUT; 1 = IN.** This field encodes whether the high-speed transaction should use an IN or OUT PID.
10–0	**Maximum Packet Size.** This directly corresponds to the maximum packet size of the associated endpoint (*wMaxPacketSize*). This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (for example, per micro-frame). This field is used with the *Multi* field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (400h). Any value larger yields undefined results.

Table 60-67.
Table 60-68. iTD Buffer Pointer Page 2 (Plus)

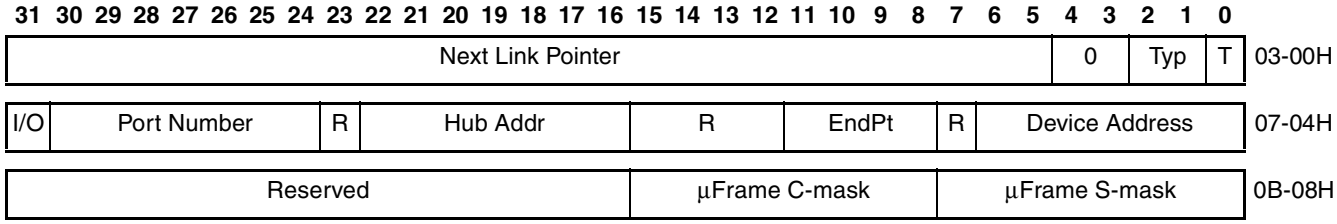
Bit	Description
31–12	**Buffer Pointer.** This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11–2	**Reserved.** This bit reserved for future use and should be set to zero.
1–0	**Multi.** This field is used to indicate to the host controller the number of transactions that should be executed per transaction description (for example, per micro-frame). The valid values are: ValueMeaning 00bReserved. A zero in this field yields undefined results. 01bOne transaction to be issued for this endpoint per micro-frame 10bTwo transactions to be issued for this endpoint per micro-frame 11bThree transactions to be issued for this endpoint per micro-frame

Table 60-69.
Table 60-70. iTD Buffer Pointer Page 3–6

Bit	Description
31–12	**Buffer Pointer.** This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11–0	**Reserved.** These bits reserved for future use and should be set to zero.

60.4.3.4 Split Transaction Isochronous Transfer Descriptor (siTD)

All full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure. This data structure satisfies the operational requirements for managing the split transaction protocol.



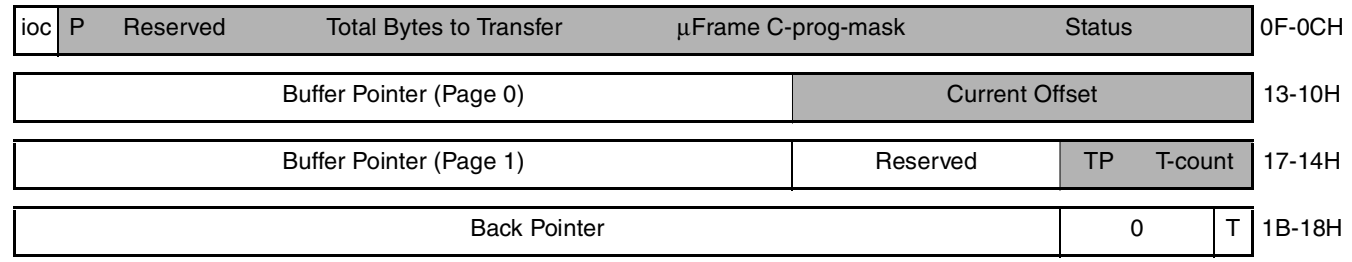


Figure 60-61. Split-transaction Isochronous Transaction Descriptor (siTD)

60.4.3.4.1 Next Link Pointer

DWord0 of a siTD is a pointer to the next schedule data structure.

Table 60-71. Next Link Pointer

Bit	Description
31–5	**Next Link Pointer (LP).** This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4–3	**Reserved.** These bits must be written as zeros.
2–1	**QH/(s)iTD Select (Typ).** This field indicates to the Host Controller whether the item referenced is an iTD/siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: ValueMeaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0	**Terminate (T).** 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

60.4.3.4.2 siTD Endpoint Capabilities/Characteristics

DWords 1 and 2 specify static information about the full-speed endpoint, the addressing of the parent Companion Controller, and micro-frame scheduling control.

Table 60-72. Endpoint and Transaction Translator Characteristics

Bit	Description
31	**Direction (I/O).0 = OUT; 1 = IN.** This field encodes whether the full-speed transaction should be an IN or OUT.
30–24	**Port Number.** This field is the port number of the recipient Transaction Translator.
23	**Reserved.** Bit reserved and should be set to zero.
22–16	**Hub Address.** This field holds the device address of the Companion Controllers' hub.
15–12	**Reserved.** Field reserved and should be set to zero.
11–8	**Endpoint Number (Endpt).** This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.

Table 60-72. Endpoint and Transaction Translator Characteristics (continued)

7	**Reserved.** Bit is reserved for future use. It should be set to zero.
6–0	**Device Address.** This field selects the specific device serving as the data source or sink.

Table 60-73. Microframe Schedule Control

Bit	Description
31–16	**Reserved.** This field reserved for future use. It should be set to zero.
15–8	**Split Completion Mask (μFrame C-Mask).** This field (along with the *Active* and *SplitX- state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute complete-split transactions. When the criteria for using this field is met, an all zeros value has undefined behavior. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the μ*Frame C-Mask* field is a one, then this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7–0	**Split Start Mask (μFrame S-mask).** This field (along with the *Active* and *SplitX-state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the μ*Frame S-mask* field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

60.4.3.4.3 siTD Transfer State

DWords 3–6 are used to manage the state of the transfer.

Table 60-74. siTD Transfer Status and Control

<table>
<tr><th>Bit</th><th colspan="2">Description</th></tr>
<tr><td>31</td><td colspan="2">Interrupt On Complete (ioc). 0 = Do not interrupt when transaction is complete. 1 = Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it will assert a hardware interrupt at the next interrupt threshold.</td></tr>
<tr><td>30</td><td colspan="2">Page Select (P). Used to indicate which data page pointer should be concatenated with the CurrentOffset field to construct a data buffer pointer (0 selects Page 0 pointer and 1 selects Page 1). The host controller is not required to write this field back when the siTD is retired (Active bit transitioned from a one to a zero).</td></tr>
<tr><td>29–26</td><td colspan="2">Reserved. This field reserved for future use and should be set to zero.</td></tr>
<tr><td>25–16</td><td colspan="2">Total Bytes To Transfer. This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)</td></tr>
<tr><td>15–8</td><td colspan="2">μFrame Complete-split Progress Mask (C-prog-Mask). This field is used by the host controller to record which split-completes has been executed.</td></tr>
<tr><td>7–0</td><td colspan="2">Status. This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:</td></tr>
<tr><td></td><td>Bit</td><td>Definition</td></tr>
<tr><td></td><td>7</td><td>Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.</td></tr>
<tr><td></td><td>6</td><td>ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.</td></tr>
</table>

Table 60-74. siTD Transfer Status and Control

	5	**Data Buffer Error**. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller will transmit an incorrect CRC (thus invalidating the data at the endpoint). If an overrun condition occurs, no action is necessary.
	4	**Babble Detected.** Set to a one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.
	3	**Transaction Error (XactErr).** Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit will only be set for IN transactions.
	2	**Missed Micro-Frame.** The host controller detected that a host-induced hold- off caused the host controller to miss a required complete-split transaction.
	1	**Split Transaction State (SplitXstate).** The bit encodings are: Value Meaning 00b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint when a match is encountered in the S-mask. 01b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint when a match is encountered in the C-mask.
	0	**Reserved.** Bit reserved for future use and should be set to zero.

60.4.3.4.4 siTD Buffer Pointer List (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4K (page) aligned buffer pointers. The least significant 12 bits of each DWord are used as additional transfer state.

Table 60-75. Buffer Page Pointer List (plus)

Bit	Description
31–12	**Buffer Pointer List.** Bits [31–12] of DWords 4 and 5 are 4K paged aligned, physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field *P* specifies the *current* active pointer
11–0	Page 0: **Current Offset.** The 12 least significant bits of the Page 0 pointer is the current byte offset for the current page pointer (as selected with the page indicator bit (*P* field)). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero). The least significant bits of Page 1 pointer is split into three sub-fields Page 1:

	Bits	Description	
	11:5	Reserved.	

Table 60-75. Buffer Page Pointer List (plus)

	4:3	**Transaction position (TP).** This field is used with T-count to determine whether to send *all*, *first*, *middle*, or *last* with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are: Value Meaning 00b All. The entire full-speed transaction data payload is in this transaction (i.e. less than or equal to 188 bytes). 01b Begin. This is the first data payload for a full-speed that is greater than 188 bytes.transaction 10B Mid. This is the *middle* payload for a full-speed OUT transaction that is larger than 188 bytes. 11b End. This is the *last* payload for a full-speed OUT transaction that was larger than 188 bytes.
	2:0	**Transaction count (T-Count).** Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

60.4.3.4.5 siTD Back Link Pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD. This pointer cannot reference any other schedule data structure.

Table 60-76. siTD Back Link Pointer

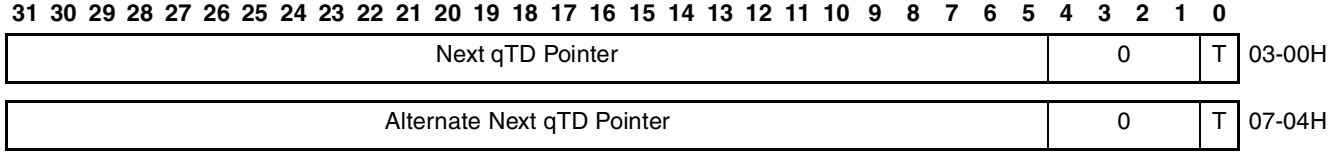
Bit	Description
31–5	**siTD Back Pointer.** This field is a physical memory pointer to a siTD.
4–1	**Reserved.** This field is reserved for future use. It should be set to zero.
0	**Terminate (T).** 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.

60.4.3.5 Queue Element Transfer Descriptor (qTD)

This data structure is only used with a queue head. This data structure is used for one or more USB transactions. This data structure is used to transfer up to 20480 (5*4096) bytes. The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers. This structure is 32 bytes (or one 32-byte cache line). This data structure must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a queue head.



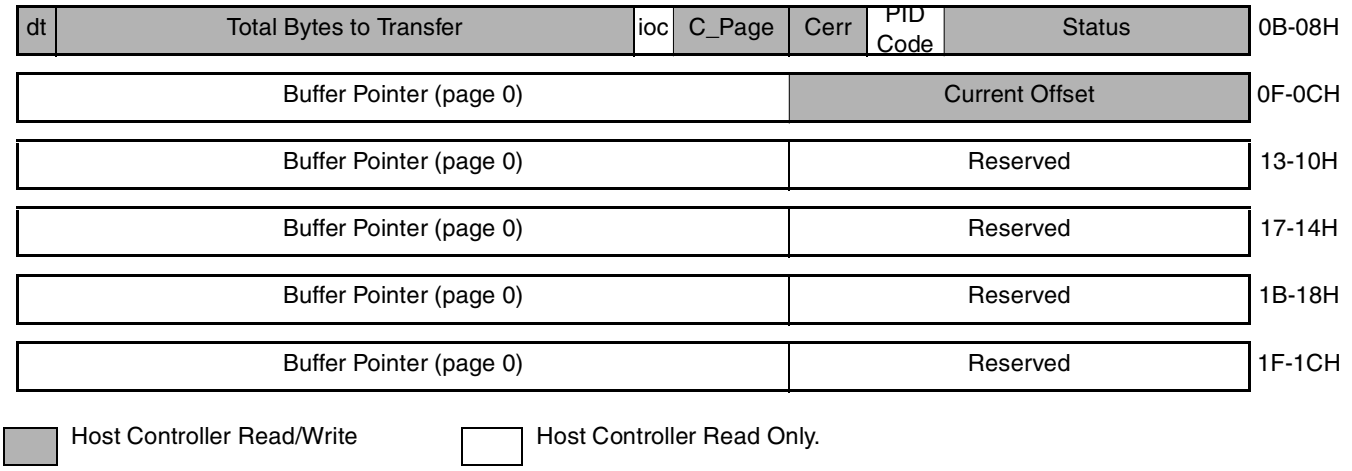


Figure 60-62. Queue Element Transfer Descriptor Block Diagram

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

60.4.3.5.1 Next qTD Pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor.

Table 60-77. qTD Next Element Transfer Pointer (DWord 0)

Bit	Description
31–5	**Next Transfer Element Pointer.** This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.
4–1	**Reserved.** These bits are reserved and their value has no effect on operation.
0	**Terminate (T).** 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

60.4.3.5.2 Alternate Next qTD Pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next client buffer on short packet. To be more explicit the host controller always uses this pointer when the current qTD is retired due to short packet.

Table 60-78. TD Alternate Next Element Transfer Pointer (DWord 1)

Bit	Description
31–5	**Alternate Next Transfer Element Pointer.** This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31–5], respectively.
4–1	**Reserved.** These bits are reserved and their value has no effect on operation.
0	**Terminate (T).** 1= pointer is invalid. 0 = Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

60.4.3.5.3 qTD Token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

NOTE

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

Table 60-79. qTD Token (DWord 2)

Bit	Description
31	**Data Toggle.** This is the data toggle sequence bit. The use of this bit depends on the setting of the *Data Toggle Control* bit in the queue head.
30–16	**Total Bytes to Transfer.** This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 * 4K (5000H). This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that *Total Bytes To Transfer* be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction will always be less than QHD.Maximum Packet Length. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. **Therefore, the maximum recommended transfer is 16K(4000H).**
15	**Interrupt On Complete (IOC).** If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.
14–12	**Current Page (C_Page).** This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0H to 4H. The host controller is not required to write this field back when the qTD is retired.
11–10	**Error Counter (CERR).** This field is a 2-bit down counter that keeps track of the number of consecutive Errors detected while executing this qTD. If this field is programmed with a non-zero value during set-up, the Host Controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the *Halted* bit to a one, and error status bit for the error that caused *CERR* to decrement to zero. An interrupt will be generated if the *USB Error Interrupt Enable* bit in the USBINTR register is set to a one. If HCD programs this field to zero during set-up, the Host Controller will not count errors for this qTD and there will be no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD. **Error Decrement Counter** Transaction Error Yes Data Buffer Error No[3] Stalled No[1] Babble Detected No[1] No Error No[2]
	Error: Decrement Counter Error Decrement Counter
	1: Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented

Table 60-79. qTD Token (DWord 2)

	2	If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and *PIDCode* indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset *CERR* to extend the total number of errors for this transaction. For example, *CERR* should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b. See section Split Transaction Interrupt for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See section Asynchronous—Do Complete Split for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the *PIDCode* indicates a SETUP.
	3	Data buffer errors are host problems. They don't count against the device's retries.
	Note: Software must not program CERR to a value of zero when the EPS field is programmed with a value indicating a Full- or Low-speed device. This combination could result in undefined behavior.	
9:8	**PID Code.** This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. Encodings are:	
	00b	OUT Token generates token (E1H)
	01b	IN Token generates token (69H)
	10b	SETUP Token generates token (2DH) (undefined if endpoint is an Interrupt the queue head is non-zero.) transfer type, for example, µ*Frame S-mask* field in
	11b	Reserved
7:0	**Status.** This field is used by the Host Controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. The bit encodings are:	
	Bit	Status Field Description
	7	**Active.** Set to one by software to enable the execution of transactions by the Host Controller.
	6	**Halted.** Set to a one by the Host Controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set to a one, the Active bit is also set to zero.
	5	**Data Buffer Error.** Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, the Host Controller will force a timeout condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	4	**Babble Detected.** Set to a one by the Host Controller during status update when" babble" is detected during the transaction. In addition to setting this bit, the Host Controller also sets the *Halted* bit to a one. Since "babble" is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
	3	**Transaction Error (XactErr).** Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.

Table 60-79. qTD Token (DWord 2)

	2	**Missed Micro-Frame.** This bit is ignored unless the *QH.EPS* field indicates a full- or low-speed endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	1	**Split Transaction State (SplitXstate).** This bit is ignored by the host controller unless the *QH.EPS* field indicates a full- or low-speed endpoint. When a Full- or Low-speed device, the host controller uses this bit to track the state of the split- transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the endpoint is in the periodic or asynchronous schedule. The bit encodings are: ValueMeaning 0b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint. 1b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint.
	0	**Ping State (P)/ERR.** If the *QH.EPS* field indicates a High-speed device and the *PID_Code* indicates an OUT endpoint, then this is the state bit for the Ping protocol. The bit encodings are: ValueMeaning 0b Do OUT. This value directs the host controller to issue an OUT PID to the endpoint. 1b Do Ping. This value directs the host controller to issue a PING PID to the endpoint. If the *QH.EPS* field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.

60.4.3.5.4 qTD Buffer Page Pointer List

The last five DWords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

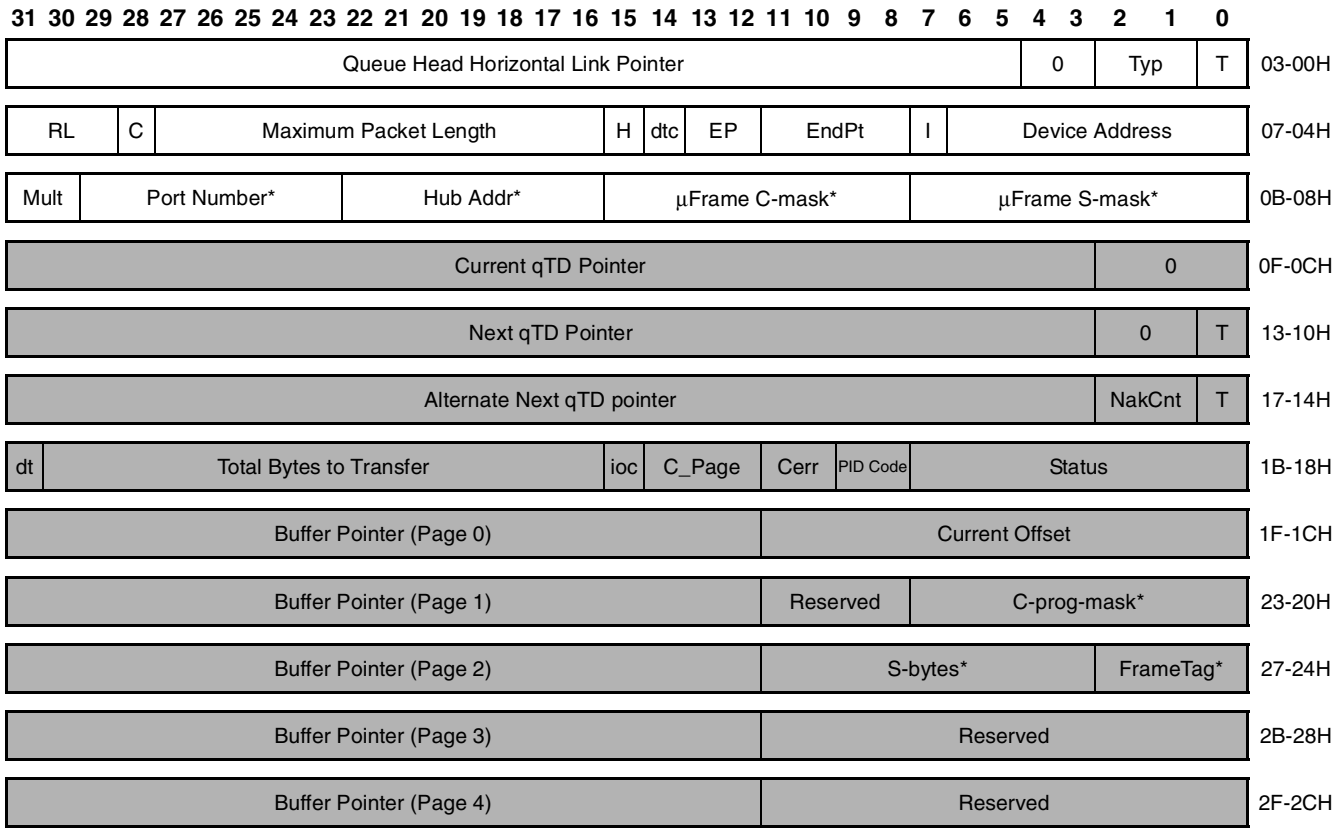
System software initializes *Current Offset* field to the starting offset into the current page, where current page is selected via the value in the *C_Page* field.

Table 60-80. qTD Buffer Pointer(s) (DWords 3–7)

Bit	Description
31–12	**Buffer Pointer List.** Each element in the list is a 4K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4K page. The field C_Page specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using C_Page (similar to an array index to select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment C_Page and advance to the next buffer pointer in the list, and conclude the transaction via the new buffer pointer.
11–0	**Current Offset (Reserved).** This field is reserved in all pointers except the first one (for example, Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by C_Page). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zeros.

60.4.3.6 Queue Head

Figure 60-63 shows the queue head structure layout.



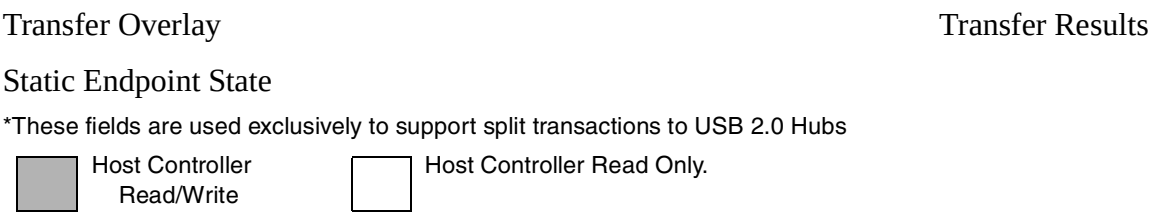


Figure 60-63. Queue Head Structure Layout

Queue Head Horizontal Link Pointer

The first DWord of a Queue Head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

Table 60-81. Queue Head DWord 0

Bit	Description
31–5	**Queue Head Horizontal Link Pointer (QHLP).** This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4–3	**Reserved.** These bits must be written as zeros.
2–1	**QH/(s)iTD Select (Typ).** This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: ValueMeaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	**Terminate (T).** 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

60.4.3.6.1 Endpoint Capabilities/Characteristics

The second and third DWords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint. There are three types of information in this region:

- Endpoint Characteristics. These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.
- Endpoint Capabilities. These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- Split Transaction Characteristics. This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

Table 60-82. Endpoint Characteristics: Queue Head DWord 1

Bit	Description
31–28	**Nak Count Reload (RL).** This field contains a value, which is used by the host controller to reload the Nak Counter field.
27	**Control Endpoint Flag (C).** If the *QH.EPS* field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to a zero.
26–16	**Maximum Packet Length.** This directly corresponds to the maximum packet size of the associated endpoint (*wMaxPacketSize*). The maximum value this field may contain is 0x400 (1024).
15	**Head of Reclamation List Flag (H).** This bit is set by System Software to mark a queue head as being the head of the reclamation list.
14	**Data Toggle Control (DTC).** This bit specifies where the host controller should get the initial data toggle on an overlay transition. 0b Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head. 1b Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD.
13–12	Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are: Value – Meaning 00b – Full-Speed (12Mbs) 01b – Low-Speed (1.5Mbs) 10b – High-Speed (480 Mb/s) 11b – Reserved This field must not be modified by the host controller.
11–8	**Endpoint Number (Endpt).** This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	**Inactivate on Next Transaction (I).** This bit is used by system software to request that the host controller set the Active bit to zero. See Section Rebalancing the Periodic Schedule for full operational details. This field is only valid when the queue head is in the Periodic Schedule and the *EPS* field indicates a Full or Low-speed endpoint. Setting this bit to a one when the queue head is in the Asynchronous Schedule or the *EPS* field indicates a high-speed device yields undefined results.
6–0	**Device Address.** This field selects the specific device serving as the data source or sink.

Table 60-83. Endpoint Capabilities: Queue Head DWord 2

Bit	Description
31–30	**High-Bandwidth Pipe Multiplier (Mult).** This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). The valid values are: ValueMeaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro-frame 10b Two transactions to be issued for this endpoint per micro-frame 11b Three transactions to be issued for this endpoint per micro-frame
29–23	**Port Number.** This field is ignored by the host controller unless the *EPS* field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address *Hub Addr* below), below which the full- or low-speed device associated with this endpoint is attached. This information is used in the split-transaction protocol.
22–16	**Hub Addr.** This field is ignored by the host controller unless the *EPS* field indicates a full-or low-speed device. The value is the USB device address of the USB 2.0 Hub below which the full- or low-speed device associated with this endpoint is attached. This field is used in the split-transaction protocol.
15–8	**Split Completion Mask (μFrame C-Mask).** This field is ignored by the host controller unless the *EPS* field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the *Active* and *SplitX-state* fields) is used to determine during which micro-frames the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the μ*Frame C- Mask* field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.
7–0	**Interrupt Schedule Mask (μFrame S-mask).** This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the μ*Frame S-mask* field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the *EPS* field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the *PID_Code* field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the *EPS* field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.

60.4.3.6.2 Transfer Overlay

The nine DWords in this area represent a *transaction working space* for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the *Queue Head Horizontal Link Pointer* to the next queue head. The host controller will never follow the *Next Transfer Queue Element or Alternate Queue Element* pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

Table 60-84. Current qTD Link Pointer

Bit	Description
31–5	**Current Element Transaction Descriptor Link Pointer.** This field contains the address Of the current transaction being processed in this queue and corresponds to memory address signals [31–5], respectively.
4–0	**Reserved (R).** These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4–11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an *overlay* because when the queue is advanced to the next queue element, the source queue element is *merged* onto this area. This area serves an execution cache for the transfer.

Table 60-85. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9)

DWord	Bit	Description
5	4:1	**Nak Counter (NakCnt)µRW**. This field is a counter the host controller decrements whenever a transaction for the endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from *RL* before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from RL during an overlay.
6	31	**Data Toggle.** The *Data Toggle Control* controls whether the host controller preserves this bit when an overlay operation is performed.
6	15	**Interrupt On Complete (IOC).** The IOC control bit is always inherited from the source qTD when the overlay operation is performed.
6	11:10	**Error Counter (C_ERR).** This two-bit field is copied from the qTD during the overlay and written back during queue advancement.
6	0	**Ping State (P)/ERR.** If the *EPS* field indicates a high-speed endpoint, then this field should be preserved during the overlay operation.
8	7:0	**Split-transaction Complete-split Progress (C-prog-mask).** This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4:0	**Split-transaction Frame Tag (Frame Tag).** This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	11:5	**S-bytes.** Software must ensure that the *S-bytes* field in a *qTD* is zero before activating the *qTD*. This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.

60.4.3.7 Periodic Frame Span Traversal Node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary. See section Host Controller Operational Model for FSTNs for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use will yield undefined results.

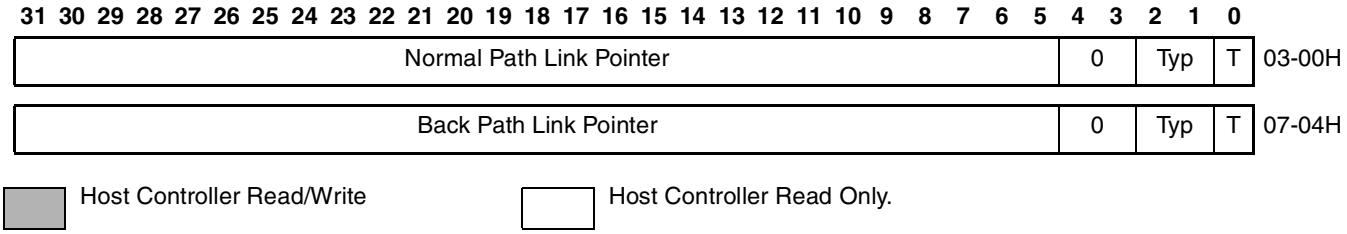

Figure 60-64. Frame Span Traversal Node Structure Layout

60.4.3.7.1 FSTN Normal Path Pointer

The first DWord of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

Bit	Description
31:5	**Normal Path Link Pointer (NPLP).** This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4:3	Reserved. These bits must be written as 0s.
2:1	**QH/(s)iTD/FSTN Select (Typ).** This field indicates to the Host Controller whether the item referenced is a iTD/siTD, a QH or an FSTN. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: **ValueMeaning** 00biTD (isochronous transfer descriptor) 01bQH (queue head) 10bsiTD (split transaction isochronous transfer descriptor) 11bFSTN (Frame Span Traversal Node)
0	**Terminate (T).** 1=Link Pointer field is not valid. 0=Link Pointer is valid.

60.4.3.7.2 FSTN Back Path Link Pointer

The second DWord of an FTSN node contains a link pointer to a queue head. If the *T-bit* in this pointer is a zero, then this FSTN is a *Save-Place* indicator. Its *Typ* field must be set by software to indicate the target

data structure is a queue head. If the *T-bit* in this pointer is set to a one, then this FSTN is the *Restore* indicator. When the *T-bit* is a one, the host controller ignores the *Typ* field.

Table 60-86. FSTN Back Path Link Pointer Field Descriptions

Bit	Description
31–5	**Back Path Link Pointer (BPLP).** This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.
4–3	**Reserved.** These bits must be written as 0s.
2–1	**Typ.** Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.
0	**Terminate (T).** 1 Link Pointer field is not valid (i.e. the host controller must not use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Restore indicator. 0 Link Pointer is valid (i.e. the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.

60.4.4 Host Operational Model

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (generally referred to as system software). Each significant operational feature of the EHCI host controller is discussed in a separate section. Each section presents the operational model requirements for the host controller hardware. Where appropriate, recommended system software operational models for features are also presented.

60.4.4.1 Host Controller Initialization

When the system boots, the host controller is enumerated, assigned a base address for the register space and BIOS sets the FLADJ register to a system-specific value. After initial power-on or *HCReset* (hardware or via *HCReset* bit in the USBCMD register), all of the operational registers will be at their default values, as illustrated in Table 60-87. After a hardware reset, only the operational registers not contained in the Auxiliary power well will be at their default values.

Table 60-87. Default Values of Operational Register Space

Operational Register	Default Value (after Reset)
USBCMD	00080000h (00080B00h if *Asynchronous Schedule Park Capability* is a one)
USBSTS	00001000h
USBINTR	00000000h
FRINDEX	00000000h
CTRLDSSEGMENT	00000000h
PERIODICLISTBASE	Undefined
ASYNCLISTADDR	Undefined

Table 60-87. Default Values of Operational Register Space (continued)

CONFIGFLAG	00000000h
PORTSC	00002000h (w/*PPC* set to one); 00003000h (w/*PPC* set to a zero)

In order to initialize the host controller, software should perform the following steps

- Program the CTRLDSSEGMENT register with 4-Gigabyte segment where all of the interface data structures are allocated.
- Write the appropriate value to the USBINTR register to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to the PERIODICLIST BASE register. If there are no work items in the periodic schedule, all elements of the Periodic Frame List should have their *T-Bits* set to a one.
- Write the USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller *ON* via setting the *Run/Stop* bit.
- Write a 1 to CONFIGFLAG register to route all ports to the EHCI controller.

At this point, the host controller is up and running and the port registers will begin reporting device connects, etc. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled port enabled High-speed ports, but the schedules have not yet been enabled. The EHCI Host controller will not transmit SOFs to enabled Full- or Low-speed ports. In order to communicate with devices via the asynchronous schedule, system software must write the ASYNDLISTADDR register with the address of a control or bulk queue head. Software must then enable the asynchronous schedule by writing a one to the *Asynchronous Schedule Enable* bit in the USBCMD register. In order to communicate with devices via the periodic schedule, system software must enable the periodic schedule by writing a one to the *Periodic Schedule Enable* bit in the USBCMD register. Note that the schedules can be turned on before the first port is reset (and enabled).

Any time the USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

60.4.4.2 Port Routing and Control

A USB 2.0 Host controller is comprised of one high-speed host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion host controllers. Companion host controllers (cHCs) may be implementations of either Universal or Open host controller specifications. This configuration is used to deliver the required full USB 2.0-defined port capability; for example, Low-, Full-, and High-speed capability for every port. Figure 60-65 illustrates a simple block diagram of the port

routing logic and its relationship to the high-speed and companion host controllers within a USB 2.0 host controller.

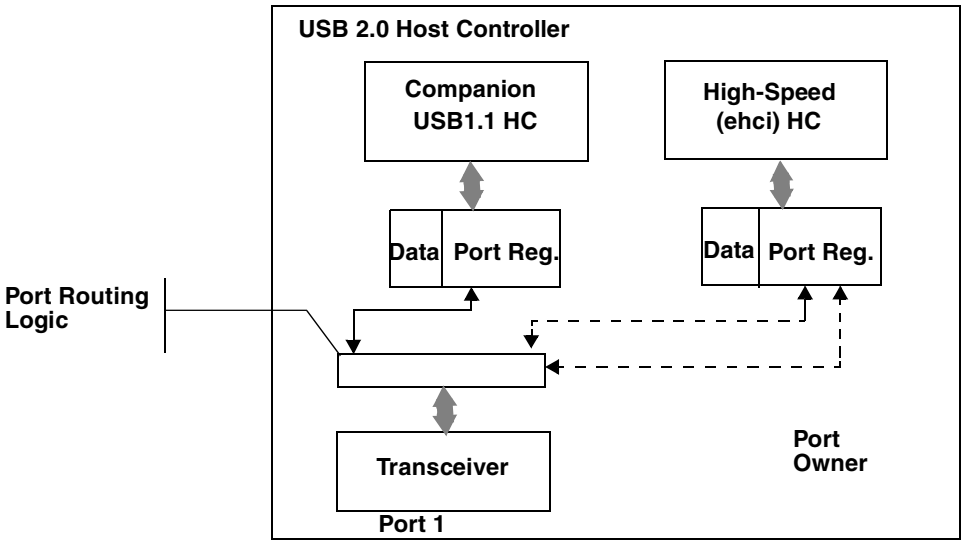

Figure 60-65. Example USB 2.0 Host Controller Port Routing Block Diagram

There exists one transceiver per physical port and each host controller module has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each companion host controller has only the port control and status registers it is required to operate. Each transceiver can be controlled by either the EHCI host controller or one companion host controller. Routing logic lies between the transceiver and the port status and control registers.

NOTE

The routing logic should not be implemented in the 480 MHz clock domain of the transceiver.

The port routing logic is controlled from signals originating in the EHCI host controller. The EHCI host controller has a *global* routing policy control field and per-port *ownership* control fields. The *Configured Flag* (*CF*) bit (defined in section BURSTSIZE) is the global routing policy control. At power-on or reset, the default routing policy is to the companion controllers (if they exist). If the system does not include a driver for the EHCI host controller and the host controller includes Companion Controllers, then the ports will still work in Full- and Low-speed mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the companion host controllers' port registers do not see a connect indication from the transceiver. Similarly, when a companion host controller owns a port, the EHCI controller's port registers do not see a connect indication from the transceiver. The details on the rules for the port routing logic are described in the following sections. The USB 2.0 host controller must be implemented as a multi-function PCI device if the implementation includes companion controllers. The companion host controllers' function numbers must be less than the EHCI host controller function number. The EHCI host controller must be a larger function number with respect to the companion host controllers associated with this EHCI host controller. If a PCI device implementation contains only an EHCI controller (i.e. no companion controllers or other PCI functions), then the EHCI host controller must be function zero, in accordance with the PCI Specification. The *N_CC* field in the Structural Parameter

register (*HCSPARAMS*) indicates whether the controller implementation includes companion host controllers. When *N_CC* has a non-zero value there exists companion host controllers. If N_CC has a value of zero, then the host controller implementation does not include companion host controllers. If the host controller root ports are exposed to attachment of full- or low-speed devices, the ports will always fail the high-speed chirp during reset and the ports will not be enabled. System software can notify the user of the illegal condition. This type of implementation requires a USB 2.0 hub be connected to a root port to provide full and low-speed device connectivity.

System software uses information in the host controller capability registers to determine how the ports are routed to the companion host controllers. See Section 60.4.2.4.3, HCSPARAMS – EHCI Compliant with extensions."

NOTE

If an implementation includes more than one set of companion and EHCI host controllers, they are organized as groups of companion host controllers with intermixed EHCI controllers.

60.4.4.2.1 Port Routing Control via EHCI *Configured* (*CF*) Bit

Each port in the USB 2.0 host controller can be routed either to a single companion host controller or to the EHCI host controller. The port routing logic is controlled by two mechanisms in the EHCI HC: a host controller global flag and per-port control. The *Configured Flag* (*CF*) bit (defined in Section BURSTSIZE), is used to globally set the policy of the routing logic. Each port register has a *Port Owner* control bit which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever the *CF bit* transitions from a zero to a one (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all *Port Owner* bits go to zero). While the *CF-bit* is a one, the EHCI Driver can control individual ports' routing via the *Port Owner* control bit. Likewise, whenever the *CF bit* transitions from a one to a zero (as a result of Aux power application, *HCRESET*, or software writing a zero to *CF-bit*), the port routing unconditionally routes all of the port registers to the appropriate companion HC. The default value for the EHCI HC's *CF bit* (after Aux power

application or *HCRESET*) is zero. Table 60-88 summarizes the default routing for all the ports, based on the value of the EHCI HC's *CF bit*.

The *view* of the port depends on the current owner. A Universal or Open companion host controller will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI host controllers are not visible to companion host controllers.

Table 60-88. Default Port Routing Depending on EHCI HC CF Bit

HS CF Bit	Default Port Ownership	Explanation
0B	Companion HCs	The companion host controllers own the ports and only Full- and Low-speed devices are supported in the system. The exact port assignments are implementation dependent. The ports behave only as Full- and Low-speed ports in this configuration
1B	EHCI HC	The EHCI host controller has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs' port status and control registers when the port owner is the EHCI HC.The EHCI HC has access to the additional port status and control bits defined in this specification (see Section PORTSCx—Port Status Control[1:8]). The EHCI HC can temporarily release control of the port to a companion HC by setting the *PortOwner* bit in the PORTSC register to a one.

60.4.4.2.2 Port Routing Control via *PortOwner* and Disconnect Event

Manipulating the port routing via the *CF-bit* is an extreme process and not intended to be used during normal operation. The normal mode of port ownership transferal is on the granularity of individual ports using the *Port Owner* bit in the EHCI HC's PORTSC register (for hand-offs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI *CF-bit* is set to a one), the typical port enumeration sequence proceeds as illustrated below:

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.
- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the *LineStatus* bits in the PORTSC register. If they indicate the attached device is a full-speed device (for example, D+ is asserted), then the EHCI Driver sets the *PortReset* control bit to a one (and sets the *PortEnable* bit to a zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing a zero to the port reset bit. The reset process is actually complete when software reads a zero in the *PortReset* bit. The EHCI Driver checks the PortOwner bit in the PORTSC register. If set to a one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.

- At the time the EHCI Driver receives the port reset and enable request the *LineStatus* bits might indicate a low-speed device. Additionally, when the port reset process is complete, the *PortEnable* field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the PORTSC register to a one to release port ownership to a companion host controller.
- When the EHCI Driver sets *PortOwner* bit to a one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The EHCI PORTSC register observes and reports a disconnect event via the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to a one, a connect change set to a one and a connect status set to a zero. This information is derived directly from the EHCI port register. This will allow the hub driver to assume the device was disconnected during reset. It will acknowledge the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's *CF-bit* transitions from a 1b to a 0b). When a disconnect occurs, the disconnect event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects will be detected by the EHCI port register and the process will repeat.

60.4.4.2.3 Example Port Routing State Machine

Figure 60-66 illustrates an example of how the port ownership should be managed. The following sections describe the entry conditions to each state.

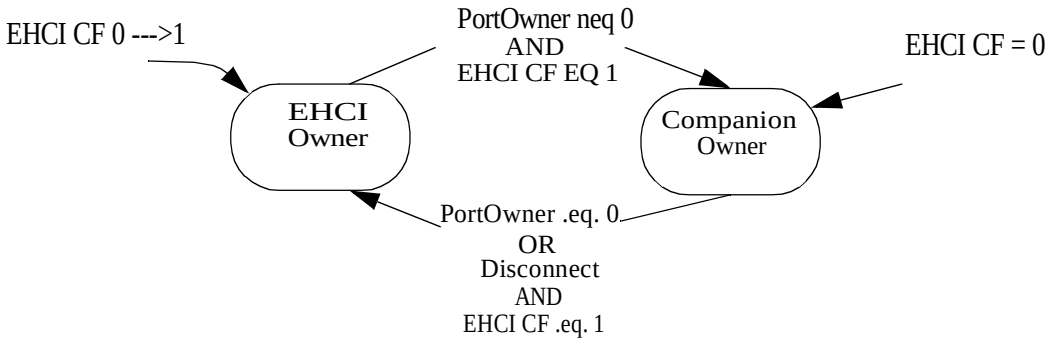

Figure 60-66. Port Owner Handoff State Machine

EHCI HC Owner

Entry to this state occurs whenever one of the following events occur:

- When the EHCI HC's *Configure Flag* (*CF*) bit in the CONFIGFLAG register transitions from a zero to a one. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.
- When the port is owned by a companion HC and the device is disconnected from the port. The EHCI port routing control logic is notified of the disconnect, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver will acknowledge the disconnect by setting the connect status change bit to a zero. This allows the companion HC's driver to interact with the port completely through the disconnect process.
- When system software writes a zero to the *PortOwner* bit in the PORTSC register. This allows software to take ownership of a port from a companion host controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.

Companion HC Owner

Entry to this state occurs whenever one of the following events occur:

- When the *Port Owner* field transitions from a zero to a one.
- When the HS-mode HC's *Configure Flag* (*CF*) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

60.4.4.2.4 Port Power

The *Port Power Control* (*PPC*) bit in the HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (See section HCSPARAMS – EHCI Compliant with extensions). When this bit is a zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the *PPC* bit is a one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is referred to in this discussion as *PortPowerOutputEnable* (*PPE*). *PPE* is controlled based on the

state of the combination bits *PPC* bit, EHCI *Configured* (*CF*)-bit and individual *Port Power* (*PP*) bits. Table 60-89 illustrates the summary behavioral model.

Table 60-89. Port Power Enable Control Rules

CF	CHC[2] (PP)	EHC[3] (PP)	Owner	PPE[1]	Description
0	0	X	CHC	0	When the EHCI controller has not been configured, the port is owned by the companion host controller. When the companion HC's port power select is off, then the port power is off.
0	1	X	CHC	1	Similar to previous entry. When the companion HC's port power select is on, then the port power is on.
1	0	0	CHC	0	Port owner has port power turned off, the power to port is off.
1	0	0	EHC	0	Port owner has port power turned off, the power to port is off.
1	0	1	EHC	1	Port owner has port power on, so power to port is on.
1	0	1	CHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	EHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	EHC	1	Port owner has port power on, so power to port is on.

[1]PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists).
[2]CHC (Companion Host Controller).
[3]EHC (EHCI Host Controller).

60.4.4.2.5 Port Reporting Over-Current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI PORTSC register has an over-current status and over-current change bit. The functionality of these bits is specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document. The over-current condition effects the following bits in the PORTSC register on the EHCI port:

- *Over-current Active* bits are set to a one. When the over-current condition goes away, the *Over-current Active* bit will transition from a one to a zero.
- *Over-current Change* bits are set to a one. On every transition of the *Over-current Active* bit the host controller will set the *Over-current Change* bit to a one. Software sets the *Over-current Change* bit to a zero by writing a one to this bit.
- *Port Enabled/Disabled* bit is set to a zero. When this change bit gets set to a one, then the *Port Change Detect* bit in the USBSTS register is set to a one.

- *Port Power (PP)* bits may optionally be set to a zero. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to *limit* the current and leave power applied. When the *Over-current Change* bit transitions from a zero to a one, the host controller also sets the *Port Change Detect* bit in the USBSTS register to a one. In addition, if the *Port Change Interrupt Enable* bit in the USBINTR register is a one, then the host controller will issue an interrupt to the system. Refer to Table 60-90 for summary behavior for over-current detection when the host controller is halted (suspended from a device component point of view).

60.4.4.3 Suspend/Resume

The EHCI host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub. Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely via software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wake-up events. The classes of wakeup events are:

- Remote-wakeup enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the PORTSC registers.

Selective suspend is a feature supported by every PORTSC register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the *Run/Stop* bit in the USBCMD register to a zero. The EHCI module can then be placed into a lower device state via the PCI power management interface (See Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com).

When a wake event occurs the system will resume operation and system software will eventually set the *Run/Stop* bit to a one and resume the suspended ports. Software must not set the *Run/Stop* bit to a one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the CPU is restarted. So, by definition, if software is running, clocks in the system are stable and the *Run/Stop* bit in the USBCMD register can be set to a one. There are also minimum system software delays defined in the PCI Power Management Specification. Refer to this specification for more information.

60.4.4.3.1 Port Suspend/Resume

System software places individual ports into suspend mode by writing a one into the appropriate PORTSC *Suspend* bit. Software must only set the *Suspend* bit when the port is in the enabled state (*Port Enabled* bit is a one) and the EHCI is the port owner (*Port Owner* bit is a zero).

The host controller may evaluate the *Suspend* bit immediately or wait until a micro-frame or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several micro-frames of activity on the port until the host controller evaluates the *Suspend* bit. The host controller must evaluate the *Suspend* bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing a one to the *Force Port Resume* bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see Section PORTSCx). If system software sets *Force Port Resume* bit to a one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 milliseconds after a port indicates that it is suspended (*Suspend* bit is a one) before initiating a port resume via the *Force Port Resume* bit. When *Force Port Resume* bit is a one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 milliseconds) then sets the *Force Port Resume* bit to a zero. When the host controller receives the write to transition *Force Port Resume* to zero, it completes the resume sequence as defined in the USB specification, and sets both the *Force Port Resume* and *Suspend* bits to zero. Software-initiated port resumes do not affect the *Port Change Detect* bit in the USBSTS register nor do they cause an interrupt if the *Port Change Interrupt Enable* bit in the USBINTR register is a one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100 µsec. The port's *Force Port Resume* bit is set to a one and the *Port Change Detect* bit in the USBSTS register is set to a one. If the *Port Change Interrupt Enable* bit in the USBINTR register is a one the host controller will issue a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 msec), then terminates the resume sequence by writing zero to the *Force Port Resume* bit in the port. The host controller receives the write of zero to *Force Port Resume*, terminates the resume sequence and sets *Force Port Resume* and *Suspend* port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the PORTSC register and observing that the *Suspend* and *Force Port Resume* bits are zero. Software must ensure that the host controller is running (i.e. *HCHalted* bit in the USBSTS register is a zero), before terminating a resume by writing a zero to a port's *Force Port Resume* bit. If *HCHalted* is a one when *Force Port Resume* is set to a zero, then SOFs will not occur down the enabled port and the device will return to suspend mode in a maximum of 10 milliseconds.

Table 60-90 summarizes the wake-up events. Whenever a resume event is detected, the *Port Change Detect* bit in the USBSTS register is set to a one. If the *Port Change Interrupt Enable* bit is a one in the USBINTR register, the host controller will also generate an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the *Port Change Detect* status bit in the USBSTS register.

Table 60-90. Behavior During Wake-up Events

Port Status and Signaling Type	Signaled Port Response	Device State	
		D0	not D0
Port disabled, resume K-State received	No Effect	N/A	N/A

Table 60-90. Behavior During Wake-up Events (continued)

Port suspended, Resume K-State received	Resume reflected downstream on signaled port. Force Port Resume status bit in PORTSC register is set to a one. Port Change Detect bit in USBSTS register set to a one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is a one. A disconnect is detected.	Depending in the initial port state, the PORTSC Connected Enable status bits are set to zero, and the Connect Change status bit is set to a one. Port Change Detect bit in the USBSTS register is set to a one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is a zero. A disconnect is detected.	Depending on the initial port state, the PORTSC Connect and Enable status bits are set to zero, and the Connect Change status bit is set to a one. Port Change Detect bit in the USBSTS register is set to a one.	[1], [3]	[3]
Port is not connected and the port's WKCNNT_E bit is a one. A connect is detected.	PORTSC Connect Status and Connect Status Change bits are set to a one. Port Change Detect bit in the USBSTS register is set to a one.	[1], [2]	[2]
Port is not connected and the port's WKCNNT_E bit is a zero. A connect is detected.	PORTSC Connect Status and Connect Status Change bits are set to a one. Port Change Detect bit in the USBSTS register is set to a one.	[1], [3]	[3]
Port is connected and the port's WKOC_E bit is a one. An over-current condition occurs.	PORTSC Over-current Active, Over-current Change bits are set to a one. If Port Enable/Disable bit is a one, it is set to a zero. Port Change Detect bit in the USBSTS register is set to a one	[1], [2]	[2]
Port is connected and the port's WKOC_E bit is a zero. An over-current condition occurs.	PORTSC Over-current Active, Over-current Change bits are set to a one. If Port Enable/Disable bit is a one, it is set to a zero. Port Change Detect bit in the USBSTS register is set to a one.	[1], [3]	[3]

[1] Hardware interrupt issued if Port Change Interrupt Enable bit in the USBINTR register is a one.
[2] PME# asserted if enabled (Note: PME Status must always be set to a one).
[3] PME# not asserted.

60.4.4.4 Schedule Traversal Rules

The host controller executes transactions for devices using a simple, shared-memory schedule. The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the *PERIODICLISTBASE* register (see Section PERIODICLISTBASE; DEVICEADDR). The *PERIODICLISTBASE* register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in Host Data Structure. In each micro-frame, if the periodic schedule is enabled (see Section Periodic Scheduling Threshold) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It will only execute from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset

reference from the *PERIODICLISTBASE* and the *FRINDEX* registers (see Figure 60-67). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a *next* link pointer of a schedule data structure having its *T-bit* set to a one. When the host controller encounters a *T-Bit* set to a one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic schedule and transitions immediately to traversing the asynchronous schedule. Once this transition is made, the host controller executes from the asynchronous schedule until the end of the micro-frame.

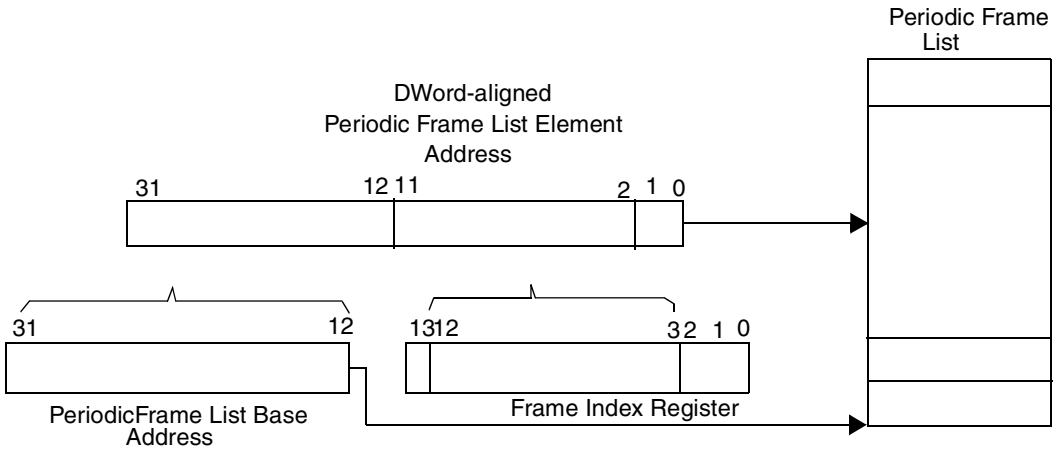

Figure 60-67. Derivation of Pointer into Frame List Array

When the host controller determines that it is time to execute from the asynchronous list, it uses the operational register *ASYNCLISTADDR* to access the asynchronous schedule, see Figure 60-68.

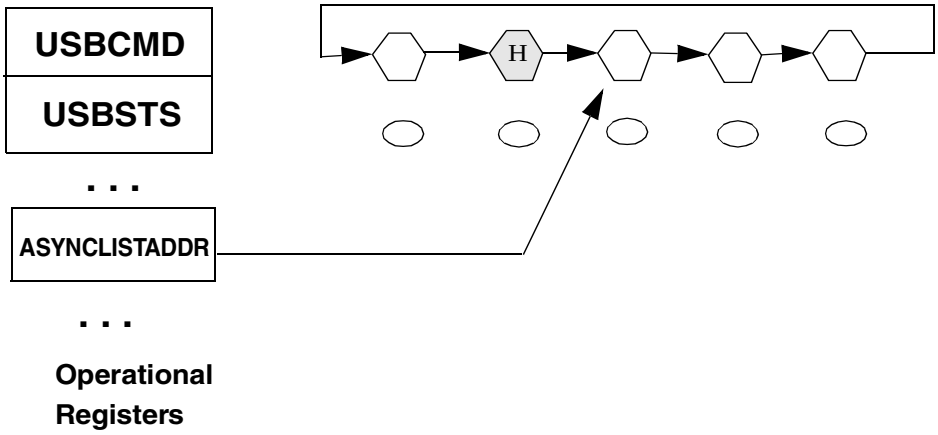

Figure 60-68. General Format of Asynchronous Schedule List

The *ASYNCLISTADDR* register contains a physical memory pointer to the *next* queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head

referenced by the *ASYNCLISTADDR* register. Software must set queue head *horizontal* pointer *T-bits* to a zero for queue heads in the asynchronous schedule. See Section Asynchronous Schedule for complete operational details.

60.4.4.4.1 Example—Preserving Micro-Frame Integrity

One of the requirements of a USB host controller is to maintain *Frame Integrity.* This means that the HC must preserve the micro-frame boundaries. For example: SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of micro-frame timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One implication of this responsibility is that the HC must ensure that it does not start transactions that will not be completed before the end of the micro-frame. More precisely, no transactions should be started by the host controller, which cannot be completed in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it will complete before the end of the micro-frame.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction will take. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch *all* of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers could allow the host controller to know exactly whether there was enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the micro-frame. It is a reasonable assumption that software will never over-commit the micro-frame to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some circumstances a transaction will not be executed that *could* have been executed. However, under all circumstances, a transaction will never be started unless there is enough time in the frame to complete the transaction.

Transaction Fit—A Best-Fit Approximation Algorithm

A curve is calculated which represents the *latest* start time for every packet size, at which software will schedule the start of a periodic transaction. This curve is the 80% bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each packet size can be started and completed, in the micro-frame. A plot of these two curves is illustrated in Figure 60-69. The plot Y-axis represents the number of byte-times left in a frame.

The space between the *80%* and the *Last Start* plots is bandwidth reclamation area. In this algorithm the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function ($f(x)$) between the 80% and *Last Start* curves. The function $f(x)$ adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land *above* the function curve. The host controller will not start transactions whose results land below the function curve.

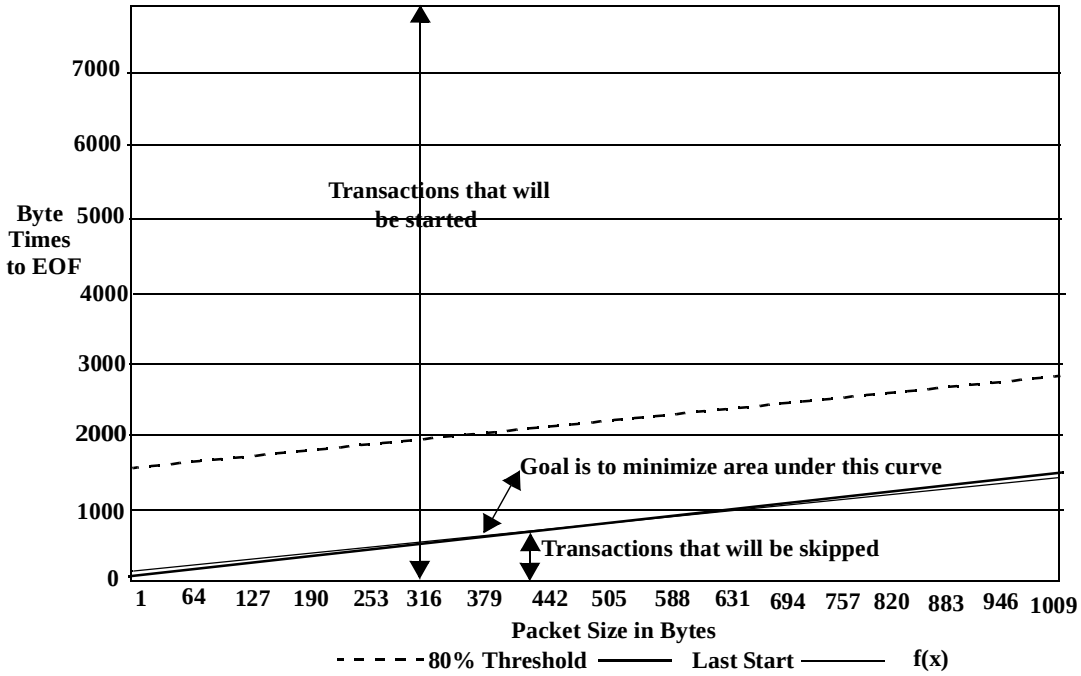

Figure 60-69. Best Fit Approximation

The *LastStart* line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used was a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in Table 60-91. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

Table 60-91. Example Worse-case Transaction Timing Components

Component	Bit time	Byte Time	Explanation
Split Token	76	9.5	Split token as defined in USB core specification. Includes sync, token, eop, etc.
Host 2 Host IPG	88	11	Number of bit times required between consecutive host packets.
Token	67	8.375	Token as defined in USB core specification. Includessync, token, eop, etc.
Host 2 Host IPG	88	11	Same as above

Table 60-91. Example Worse-case Transaction Timing Components (continued)

Data Packet (0 data bytes)	66.7	8.34	Zero-length data packet. Includes sync, PID, crc16, eop, etc.
Turnaround time	721	90.125	Time for packet initiator (Host) to see the beginning of a response to a transmitted packet.
Handshake packet	48	6	Handshake packet as defined in USB core specification. Includes sync, PID, eop, etc.
		144	Total

The exact details of the function (f(x)) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the *Last Start* curve, without dipping below the *LastStart* line, while at the same time keeping the check as simple as possible for hardware implementation. The f(x) in Figure 60-69 was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```
Alorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)

Begin

        Local Temp = MaximumPacketSize + 192

        Local rvalue = TRUE

        If MaximumPacketSize >= 128 then

                Temp += 128

        End If

        If Temp > HC_BytesLeftInFrame then

                Rvalue = FALSE

        End If

        Return rvalue

End
```

This algorithm takes two inputs, the current maximum packet size of the transaction and a hardware counter of the number of bytes left in the current micro-frame. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is greater than or equal to 128 bytes, then an additional constant of 128 is added to the running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the *f*(*x*) plot was getting *close* to the *LastStart* line.

60.4.4.5 Periodic Schedule Frame Boundaries vs Bus Frame Boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned. Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions via a micro-frame pipeline (see start- (SS) and complete- (CS) splits illustrated in Figure 60-70). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

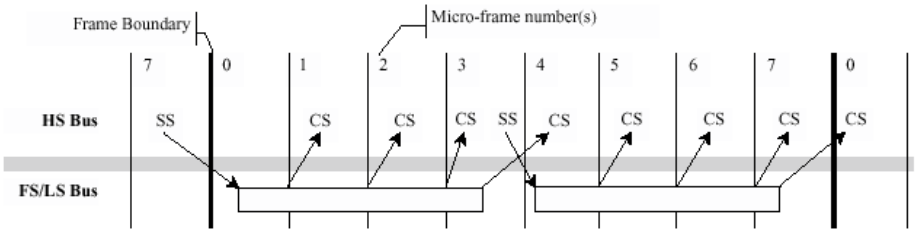

Figure 60-70. Frame Boundary Relationship between HS bus and FS/LS Bus

The simple projection, as Figure 60-70 illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement a one micro-frame phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed via the Frame List Index Register (FRINDEX) documented in Section FRINDEX and initially illustrated in Section Schedule Traversal Rules . Bits FRINDEX[2:0], represent the micro-frame number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and the SOF value are increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one micro-frame. The one micro-frame delay yields host controller periodic schedule and bus frame boundary relationship as illustrated in Figure 60-71. This adjustment allows software to trivially schedule the periodic start and complete-split transactions for full-and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

Figure 60-71 illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined. The host controller's view of the

1-millisecond boundaries is called *H-Frames*. The high-speed bus's view of the 1-millisecond boundaries is called *B-Frames.*

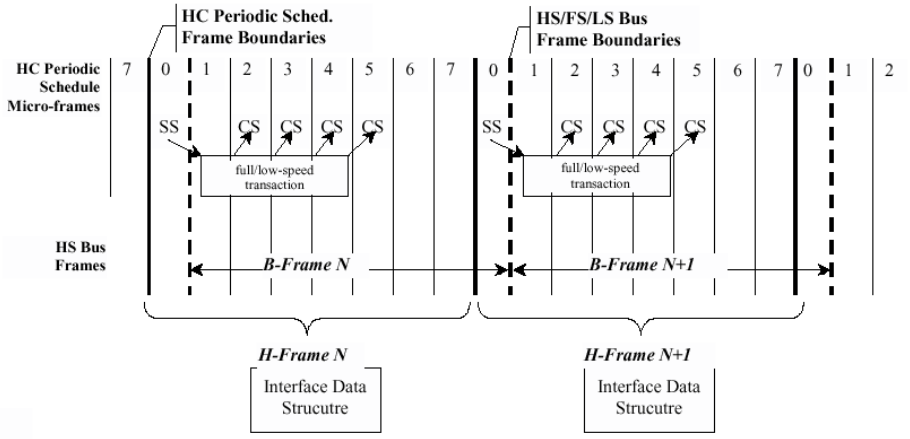

Figure 60-71. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries

H-Frame boundaries for the host controller correspond to increments of FRINDEX[13:3]. Micro-frame numbers for the *H-Frame* are tracked by FRINDEX[2:0]. *B-Frame* boundaries are visible on the high-speed bus via changes in the SOF token's frame number. Micro-frame numbers on the high-speed bus are only derived from the SOF token's frame number (i.e. the high-speed bus will see eight SOFs with the same frame number value). *H-Frames* and *B-Frames* have the fixed relationship (i.e. *B-Frames* lag *H-Frames* by one micro-frame time) illustrated in Figure 60-71. The host controller's periodic schedule is naturally aligned to *H-Frames*. Software schedules transactions for full- and low-speed periodic endpoints relative the *H-Frames*. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in Section FRINDEX, the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the FRINDEX register bits [13:3] by one micro-frame count.

Table 60-92 illustrates the required relationship between the value of FRINDEX and the value of SOFV. This lag behavior can be accomplished by incrementing FRINDEX[13:3] based on carry-out on the 7 to 0 increment of FRINDEX[2:0] and incrementing SOFV based on the transition of 0 to 1 of FRINDEX[2:0].

Software is allowed to write to FRINDEX. Section FRINDEX provides the requirements that software should adhere when writing a new value in FRINDEX.

Table 60-92. Operation of FRINDEX and SOFV (SOF Value Register)

	Current			Next	
FRINDEX[F]	SOFV	FRINDEX[mF]	FRINDEX[F]	SOFV	FRINDEX[mF]

N+1	N+1	110b	N+1	N+1	111b

Where [F] = [13:3]; [µF] = [2:0]

60.4.4.6 Periodic Schedule

The periodic schedule traversal is enabled or disabled via the *Periodic Schedule Enable* bit in the USBCMD register. If the *Periodic Schedule Enable* bit is set to a zero, then the host controller simply does not try to access the periodic frame list via the *PERIODICLISTBASE* register. Likewise, when the *Periodic Schedule Enable* bit is a one, then the host controller does use the *PERIODICLISTBASE* register to traverse the periodic schedule. The host controller will not react to modifications to the *Periodic Schedule Enable* immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the *Periodic Schedule Enable* bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b micro-frame. These work items must be removed from the schedule before the *Periodic Schedule Enable* bit is written to a zero. The *Periodic Schedule Status* bit in the USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing a one (or zero) to the *Periodic Schedule Enable* bit in the USBCMD register. Software then can poll the *Periodic Schedule Status* bit to determine when the periodic schedule has made the desired transition. Software must not modify the *Periodic Schedule Enable* bit unless the value of the *Periodic Schedule Enable* bit equals that of the *Periodic Schedule Status* bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions on the USB. Figure 60-72 illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are

linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

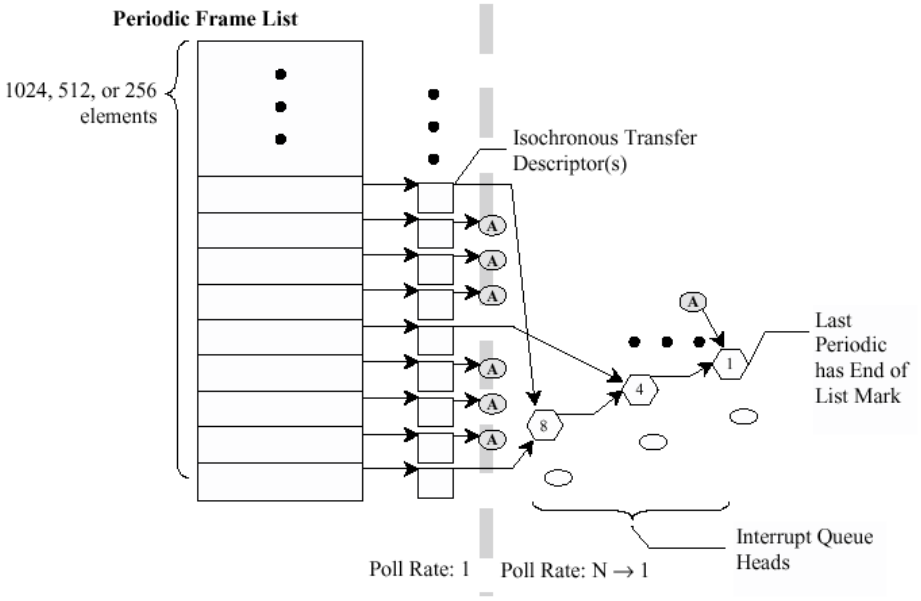

Figure 60-72. Example Periodic Schedule

60.4.4.7 Managing Isochronous Transfers Using iTDs

The structure of an iTD is presented in Isochronous (High-Speed) Transfer Descriptor (iTD). There are four distinct sections to an iTD:

- The first field is the *Next Link Pointer.* This field is for schedule linkage purposes only;
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one micro-frame's worth of transactions for a single high-speed isochronous endpoint.
- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4K aligned pointers to physical memory.
- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

60.4.4.7.1 Host Controller Operational Model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Each iTD can span 8 micro-frames worth of transactions. When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array. If the *active* bit in the *Status* field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the *Next* pointer to the next schedule data structure.

When the indexed *active* bit is a one the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, etc.). It also uses the *Page Select (PG)* field to index the *buffer pointer* array, storing the selected *buffer pointer* and the next sequential *buffer pointer*. For example, if *PG* field is a 0, then the host controller will store Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's *PG* field) and the transaction description's *Transaction Offset* field. The host controller uses the endpoint addressing information and *I/O-bit* to execute a transaction to the appropriate endpoint. When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the *Status* field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (example: page 0 pointer) selected by the active transaction descriptions' *PG* (example value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer will cross a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (example: page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the *Maximum Packet Size* field. An iTD supports high-bandwidth pipes via the *Mult* (multiplier) field. When the *Mult* field is 1, 2, or 3, the host controller executes the specified number of *Maximum Packet* sized bus transactions for the endpoint in the current micro-frame. In other words, the *Mult* field represents a transaction count for the endpoint in the current micro-frame. If the *Mult* field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the *Mult* field.

For OUT transfers, the value of the *Transaction X Length* field represents the total bytes to be sent during the micro-frame. The *Mult* field must be set by software to be consistent with *Transaction X Length* and *Maximum Packet Sixe.* The host controller will send the bytes in *Maximum Packet Size*'d portions. After each transaction, the host controller decrements it's local copy of *Transaction X Length* by *Maximum Packet Size*. The number of bytes the host controller sends is always *Maximum Packet Size* or *Transaction X Length*, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3×1024 bytes.

For IN transfers, the host controller issues *Mult* transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use *Maximum Packet Size* to detect packet babble errors. The host controller keeps the sum of bytes received in the *Transaction X Length* field. After all transactions for the endpoint have completed for the micro-frame, *Transaction X Length* contains the total bytes received. If the final value of *Transaction X Length* is less than the value of *Maximum Packet Size*, then less data than was allowed for was received from the associated endpoint. This *short packet* condition does not set the *USBINT* bit in the USBSTS register to a one. The host controller will not detect this condition. If the device sends more than *Transaction X Length* or *Maximum Packet Size* bytes (whichever is less), then the host controller will set the *Babble Detected* bit to a one and set the *Active* bit to a zero. Note, that the host controller is not required

to update the iTD field *Transaction X Length* in this error scenario. If the *Mult* field is greater than one, then the host controller will automatically execute the value of *Mult* transactions. The host controller will not execute all *Mult* transactions if any of the following occurs:

- The endpoint is an OUT and *Transaction X Length* goes to zero before all the *Mult* transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before *Mult* transactions have been executed. The end of micro-frame may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next micro-frame. Refer to Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

60.4.4.7.2 Software Operational Model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N micro-frames. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

Figure 60-73 illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (i.e. the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one micro-frame's worth of transactions. The EHCI controller does not provide per-transaction results within a micro-frame. It treats the per-micro-frame transactions as a single logical transfer. On the left is the host controller’s frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs

to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

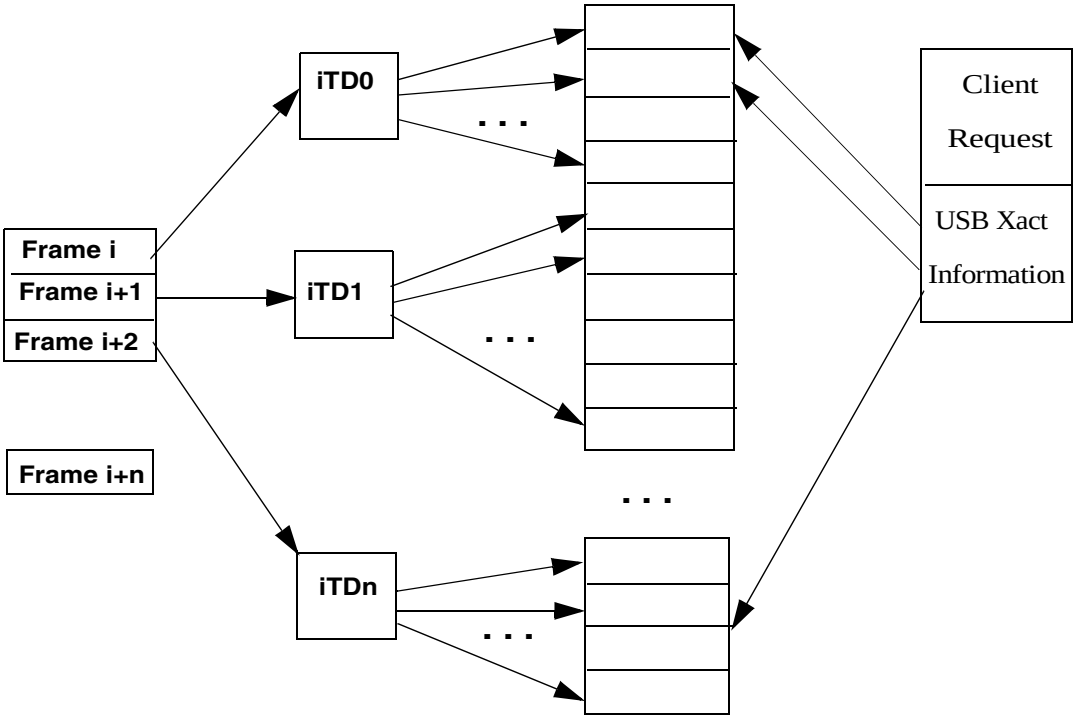

Figure 60-73. Example Association of iTDs to Client Request Buffer

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the *PG* field is set to index the correct physical buffer page pointer and the *Transaction Offset* field is set relative to the correct buffer pointer page (for example, the same one referenced by the *PG* field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current *Page Buffer Pointer* (as selected by the *PG* field) and concatenates to the *transaction offset* field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available *Page Buffer Pointer*. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer will wrap a page boundary. Doing so will yield undefined behavior. The host controller hardware is not required to 'alias' the page selector to page zero. USB 2.0 isochronous endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to a one.

Periodic Scheduling Threshold

The *Isochronous Scheduling Threshold* field in the HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures. It is used by system software when adding isochronous work items to the periodic schedule. The value of

this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 micro-frames worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. There are three basic caching models that account for the fact the isochronous data structures span 8 micro-frames. The three caching models are: no caching, micro-frame caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the FRINDEX register to determine the current frame and micro-frame the host controller is currently executing. Of course, there is no information about where in the micro-frame the host controller is, so a constant uncertainty-factor of one micro-frame has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the *Isochronous Scheduling Threshold* field. The host controller may pre-fetch data structures during a periodic schedule traversal (per micro-frame) but will always dump any accumulated schedule state at the end of the micro-frame. At the appropriate time relative to the beginning of every micro-frame, the host controller always begins schedule traversal from the frame list. Software can use the value of the FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 micro-frames in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the *Isochronous Scheduling Threshold* field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 micro-frames). Software uses the value of the FRINDEX register (plus the constant 1 uncertainty) to determine the *current* micro-frame/frame (assume modulo 8 arithmetic in adding the constant 1 to the micro-frame number). For any current frame N, if the current micro-frame is 0 to 6, then software can safely add isochronous transactions to Frame N + 1. If the current micro-frame is 7, then software can add isochronous transactions to Frame N + 2.

Micro-frame caching is indicated with a non-zero value in the least-significant 3 bits of the *Isochronous Scheduling Threshold* field. System software assumes the host controller caches one or more periodic data structures for the number of micro-frames indicated in the *Isochronous Scheduling Threshold* field. For example, if the count value were 2, then the host controller keeps a *window* of 2 micro-frames worth of state (current micro-frame, plus the next) on-chip. On each micro-frame boundary, the host controller releases the current micro-frame state and begins accumulating the next micro-frame state.

60.4.4.8 Asynchronous Schedule

The Asynchronous schedule traversal is enabled or disabled via the *Asynchronous Schedule Enable* bit in the USBCMD register. If the *Asynchronous Schedule Enable* bit is set to a zero, then the host controller simply does not try to access the asynchronous schedule via the *ASYNCLISTADDR* register. Likewise, when the *Asynchronous Schedule Enable* bit is a one, then the host controller does use the *ASYNCLISTADDR* register to traverse the asynchronous schedule. Modifications to the *Asynchronous Schedule Enable* bit are not necessarily immediate. Rather the new value of the bit will only be taken into

consideration the next time the host controller needs to use the value of the *ASYNCLISTADDR* register to get the next queue head.

The *Asynchronous Schedule Status* bit in the USBSTS register indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing a one (or zero) to the *Asynchronous Schedule Enable* bit in the USBCMD register. Software then can poll the *Asynchronous Schedule Status* bit to determine when the asynchronous schedule has made the desired transition. Software must not modify the *Asynchronous Schedule Enable* bit unless the value of the *Asynchronous Schedule Enable* bit equals that of the *Asynchronous Schedule Status* bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the *ASYNCLISTADDR* register. The default value of the *ASYNCLISTADDR* register after reset is undefined and the schedule is disabled when the *Asynchronous Schedule Enable* bit is a zero.

Software may only write this register with defined results when the schedule is disabled. for example, *Asynchronous Schedule Enable* bit in the USBCMD and the *Asynchronous Schedule Status* bit in the USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asychronous schedule by setting the *Asynchronous Schedule Enable* bit is set to one. The asynchronous schedule is actually enabled when the *Asynchronous Schedule Status* bit is a one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the *ASYNCLISTADDR* register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller "completes" processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the *ASYNCLISTADDR* register. Next time the asynchronous schedule is accessed, this is the first data structure that will be serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller "completes" processing the asynchronous schedule when one of the following events occur:

- The end of a micro-frame occurs.
- The host controller detects an empty list condition (i.e. see Section Empty Asynchronous Schedule Detection)
- The schedule has been disabled via the *Asynchronous Schedule Enable* bit in the USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in Figure 60-68. Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iTD or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

60.4.4.8.1 Adding Queue Heads to Asynchronous Schedule

This is a software requirement section. There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the *ASYNCLISTADDR* register, then enables the list by setting the *Asynchronous Schedule Enable* bit in the USBCMD register to a one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example qTD pointers have *T-Bit*s set to a one or reference valid qTDs and the *Horizontal Pointer* references a valid queue head data structure. The following algorithm represents the functional requirements:

```
InsertQueueHead (pQHeadCurrent, pQueueHeadNew)

        --
        -- Requirement: all inputs must be properly initialized.
        --
        -- pQHeadCurrent is a pointer to a queue head that is
        -- already in the active list
        -- pQHeadNew is a pointer to the queue head to be added
        --
        -- This algorithm links a new queue head into a existing
        -- list
        --
        pQueueHeadNew.HorizontalPointer = pQueueHeadCurrent.HorizontalPointer

        pQueueHeadCurrent.HorizontalPointer = physicalAddressOf(pQueueHeadNew)

End InsertQueueHead
```

60.4.4.8.2 Removing Queue Heads from Asynchronous Schedule

This is a software requirement section. There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list. Software deactivates the asynchronous schedule by setting the *Asynchronous Schedule Enable* bit in the USBCMD register to a zero. Software can determine when the list is idle when the *Asynchronous Schedule Status* bit in the USBSTS register is a zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first

deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list via the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```
UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)

        --

        -- Requirement: all inputs must be properly initialized.

        --

        -- pQHeadPrevious is a pointer to a queue head that

        -- references the queue head to remove

        -- pQHeadToUnlink is a pointer to the queue head to be

        -- removed

        -- pQheadNext is a pointer to a queue head still in the

        -- schedule. Software provides this pointer with the

        -- following strict rules:

        --      if the host software is one queue head, then

        --      pQHeadNext must be the same as

        --      QueueheadToUnlink.HorizontalPointer. If the host

        --      software is unlinking a consecutive series of

        --      queue heads, QHeadNext must be set by software to

        --      the  queue head remaining in the schedule.

        --

        -- This algorithm unlinks a queue head from a circular list

        --

        pQueueHeadPrevious.HorizontalPointer = pQueueHeadToUnlink.HorizontalPointer
pQueueHeadToUnlink.HorizontalPointer = pQHeadNext

End UnlinkQueueHead
```

If software removes the queue head with the *H-bit* set to a one, it must select another queue head still linked into the schedule and set its *H-bit* to a one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its *H-bit* set to a one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, etc.). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (*Interrupt on Async Advance Doorbell* bit in the USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (*Interrupt on Async Advance* bit in the USBSTS register) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to a one, it also sets the command bit to a zero. The third bit is an interrupt enable (*Interrupt on Async Advance* bit in the USBINTR register) that is matched with the status bit. If the status bit is a one and the interrupt enable bit is a one, then the host controller will assert a hardware interrupt.

Figure 60-74 illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that will remain in the asynchronous schedule.

When the host controller observes that doorbell bit being set to a one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A and B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (i.e. traversed beyond queue head (B) in this example).

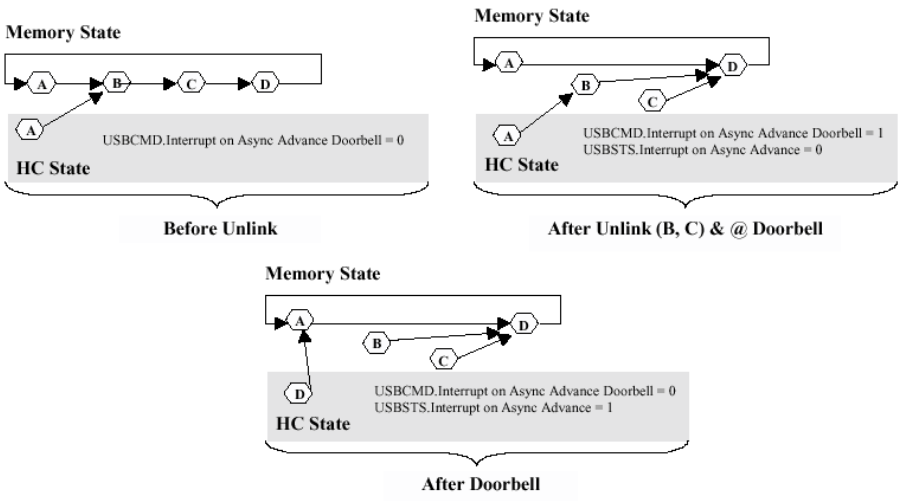

Figure 60-74. Generic Queue Head Unlink Scenario

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting the *Advance on Async* status bit to a one.

Software may re-use the memory associated with the removed queue heads after it observes the *Interrupt on Async Advance* status bit is set to a one, following assertion of the doorbell. Software should acknowledge the *Interrupt on Async Advance* status as indicated in the USBSTS register, before using the doorbell handshake again.

60.4.4.8.3 Empty Asynchronous Schedule Detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty. The queue head data structure (see Figure 60-63) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USBSTS register (*Reclamation*) that is set to a zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to a one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see Section Asynchronous Schedule Traversal: Start Event).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is illustrated in Figure 60-75

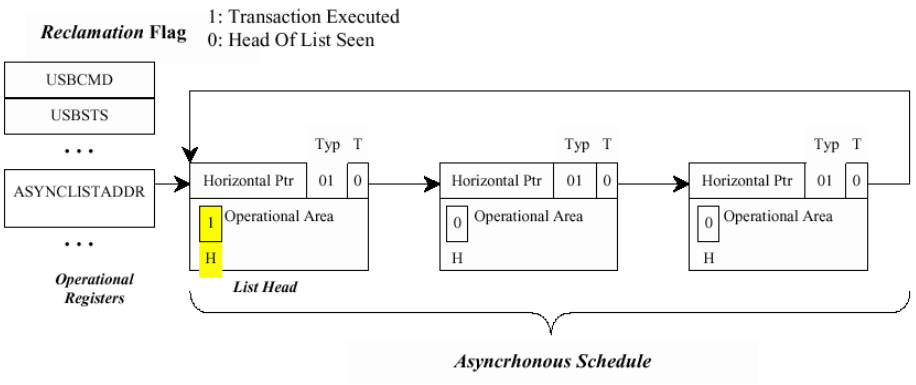

Figure 60-75. Asynchronous Schedule List with Annotation to Mark Head of List

Software must ensure there is at most one queue head with the *H-bit* set to a one, and that it is always coherent with respect to the schedule.

60.4.4.8.4 Restarting Asynchronous Schedule Before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the micro-frame. It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the micro-frame. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the host controller will cease traversal of the Asynchronous schedule very early in the micro-frame. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current micro-frame, instead of waiting until the next micro-frame. When the reason for host controller idling asynchronous

schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

Example Method for Restarting Asynchronous Schedule Traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: *how long should the host controller stay idle before restarting*?

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called *AsyncSchedSleepTime*, and has a value of 10µsec. The value is derived based on the analysis in Section Section , Example Derivation for AsyncSchedSleepTime," The traversal algorithm is as follows:

- Traverse the Asynchronous schedule until the either an End-Of-micro-Frame event occurs, or an empty list is detected. If the event is an End-of-micro-Frame, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a *schedule sleep* state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to *schedule active* state. The start context allows the HC to reload *Nakcnt* fields, etc. so the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each micro-frame. Figure 60-76 illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.

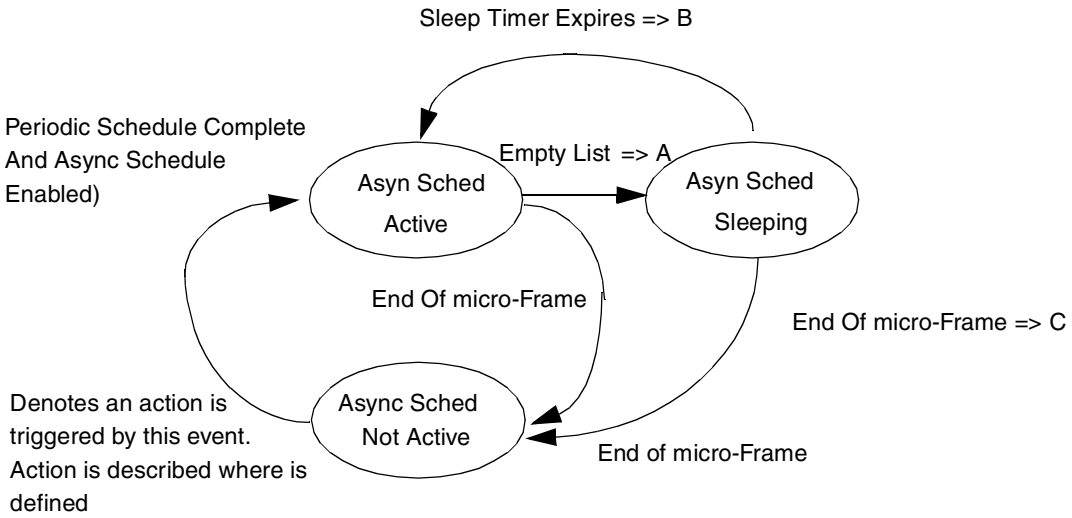

Figure 60-76. Example State Machine for Managing Asynchronous Schedule Traversal

The actions referred to in Figure 60-76 are defined in Table 60-93.

Table 60-93. Asynchronous Schedule SM Transition Actions

Action	Action Description Label
A	On detection of the empty list, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.
B	When the *AsynchronousTraversalSleepTimer* expires, the host controller sets the *Reclamation* bit in the USBSTS register to a one and moves the Nak Counter reload state machine to WaitForListHead (see Section Nak Count Reload Control).
C	The host controller cancels the sleep timer (*AsynchronousTraversalSleepTimer*).

Async Sched Not Active

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine will not leave this state when the *Asynchronous Schedule Enable* bit in the USBCMD register is a zero.

This state is entered from **Async Sched Active** or **Async Sched Sleeping** states when the end-of-micro-frame event is detected.

Async Sched Active

This state is entered from the **Async Sched Not Active** state when the periodic schedule is not active. It is also entered from the **Async Sched Sleeping** states when the *AsyncrhonousTraversalSleepTimer* expires. On every transition into this state, the host controller sets the *Reclamation* bit in the USBSTS register to a one.

While in this state, the host controller will continually traverse the asynchronous schedule until either the end of micro-frame or an empty list condition is detected.

Async Sched Sleeping

The state is entered from the **Async Sched Active** state when a schedule empty condition is detected. On entry to this state, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.

Example Derivation for *AsyncSchedSleepTime*

The derivation is based on analysis of what work the host controller could be doing next. It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests. Table 60-94 summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (for example, *footprint*, or *wall clock*) the transaction will take to complete.

Table 60-94. Typical Low-/Full-speed Transaction Times

Transaction Attributes		Footprint (time)	Description
Speed	HS	11.9 ms	Maximum foot print for a worst-case, full-sized bulk data transaction.

Table 60-94. Typical Low-/Full-speed Transaction Times

Size	512	9.45 ms	Maximum footprint for an approximate best-case, full-sized bulk data transaction.
Type	Bulk		
Speed	FS	~50 ms	Approximate typical for full-sized bulk data. An 8-byte low-speed is about 2x, or between 90 and 100 ms.
Size	64		
Type	Bulk		
Speed	FS	~12 ms	Approximate typical for 8-byte bulk/control (i.e. setup)
Size	8		
Type	Cntrl		

A *AsyncSchedSleepTime* value of 10 µs provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller will get the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10µs sleep period would allow the host controller to get the NAK results on the first complete-split.

60.4.4.8.5 Asynchronous Schedule Traversal: *Start Event*

Once the HC has *idled* itself via the empty schedule detection (Section 0), it will naturally *activate* and begin processing from the Periodic Schedule at the beginning of each micro-frame. In addition, it may have idled itself early in a micro-frame. When this occurs (idles early in the micro-frame) the HC must occasionally *re-activate* during the micro-frame and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in Section Restarting Asynchronous Schedule Before EOF . Asynchronous schedule *Start Event*s are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the micro-frame is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state (see Section Restarting Asynchronous Schedule Before EOF).

60.4.4.8.6 Reclamation Status Bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (Section Empty Asynchronous Schedule Detection) depends on the proper management of the *Reclamation* bit in the USBSTS register. The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (See Section Fetch Queue Head).

It is required that the host controller sets the *Reclamation* bit to a one whenever an asynchronous schedule traversal *Start Event*, as documented in Section Asynchronous Schedule Traversal: Start Event , occurs. The *Reclamation* bit is also set to a one whenever the host controller executes a transaction while traversing the asynchronous schedule (see Section Execute Transaction). The host controller sets the

Reclamation bit to a zero whenever it finds a queue head with its *H-bit* set to a one. Software should only set a queue head's *H-bit* if the queue head is in the asynchronous schedule. If software sets the *H-bit* in an interrupt queue head to a one, the resulting behavior is undefined. The host controller may set the *Reclamation* bit to a zero when executing from the periodic schedule.

60.4.4.9 Operational Model for Nak Counter

This section describes the operational model for the *NakCnt* field defined in a queue head (see Section Queue Head Initialization). Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control via the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced via the same asynchronous schedule. The time between the *Start-split* transaction and the first *Complete-split* transaction could be very short (i.e. like when the endpoint is the only one in the asynchronous schedule). The hub NYETs (effectively Naks) the *Complete-split* transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which will not complete until after the transaction on the classic bus completes.

There are two component fields in a queue head to support the throttling feature: a counter field (*NakCnt*), and a counter reload field (*RL*). *NakCnt* is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. There are two operational modes associated with this counter:

- **Not Used.** This mode is set when the *RL* field is zero. The host controller ignores the *NakCnt* field for any execution of transactions through a queue head with an *RL* field of zero. Software must use this selection for interrupt endpoints.
- **Nak Throttle Mode.** This mode is selected when the *RL* field is non-zero. In this mode, the value in the *NakCnt* field represents the maximum number of Nak or Nyet responses the host controller will tolerate on each endpoint. In this mode, the HC will decrement the *NakCnt* field based on the token/handshake criteria listed in Table 60-95 The host controller must reload *NakCnt* when the endpoint successfully moves data (for example, policy to reward device for moving data).

Table 60-95. NakCnt Field Adjustment Rules

Token	Handshake	
	Handshake NAK	NYET
IN/PING	decrement *NakCnt*	N/A (protocol error)
OUT	decrement *NakCnt*	No Action[1]Start
Split	decrement *NakCnt*	N/A (protocol error)
Complete Split	No Action	Decrement *NakCnt*

[1] Recommended behavior on this response is to reload *NakCnt*

In summary, system software enables the counter by setting the reload field (*RL*) to a non-zero value. The host controller may execute a transaction if *NakCnt* is non-zero. The host controller will not execute a transaction if *NakCnt* is zero. The reload mechanism is described in detail in Section Nak Count Reload Control .

Note that when all queue heads in the Asynchronous Schedule either exhausts all transfers or all NakCnt's go to zero, then the host controller will detect an empty Asynchronous Schedule and idle schedule traversal (see Section Empty Asynchronous Schedule Detection).

Any time the host controller begins a new traversal of the Asynchronous Schedule, a *Start Event* is assumed, see Section Asynchronous Schedule Traversal: Start Event . Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

60.4.4.9.1 Nak Count Reload Control

When the host controller reaches the *Execute Transaction* state for a queue head (meaning that it has an active operational state), it checks to determine whether the *NakCnt* field should be reloaded from *RL* (see Section Execute Transaction). If the answer is yes, then *RL* is copied into *NakCnt*. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (*NakCnt* see Figure 60-63) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see Section Asynchronous Schedule Traversal: Start Event for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see Figure 60-75). Figure 60-77 illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: **Execute Transaction** (Figure 60-77). The host controller does not perform the nak counter reload operation if the RL field (see Figure 60-63) is set to zero.

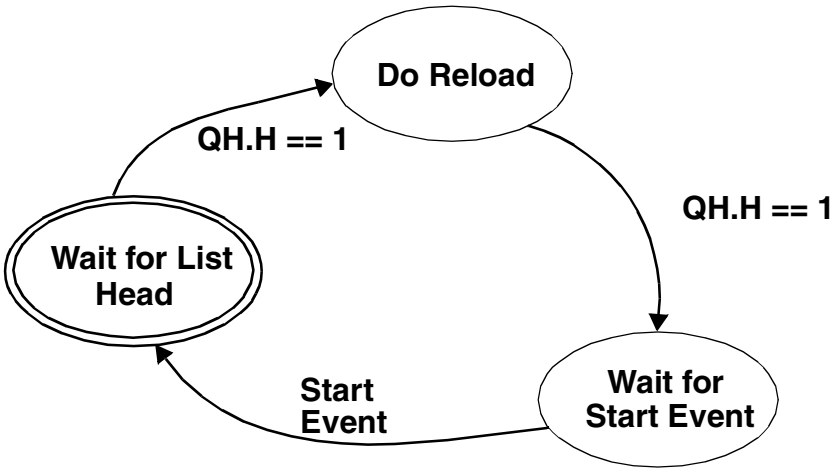

Figure 60-77. Example HC State Machine for Controlling Nak Counter Reloads

Wait for List Head

This is the initial state. The state machine enters this state from **Wait for Start Event** when a start event as defined in Section Asynchronous Schedule Traversal: Start Event occurs. The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule. This occurs when the host controller fetches a queue head whose *H-bit* is set to a one.

Do Reload

This state is entered from the **Wait for List Head** state when the host controller fetches a queue head with the *H-bit* set to a one. While in this state, the host controller will perform nak counter reloads for every queue head visited that has a non-zero nak reload value (*RL*) field.

Wait for Start Event

This state is entered from the *Do Reload* state when a queue head with the *H-bit* set to a one is fetched. While in this state, the host controller will not perform nak counter reloads.

60.4.4.10 Managing Control/Bulk/Interrupt Transfers via Queue Heads

This section presents an overview of how the host controller interacts with queuing data structures.

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in Figure 60-63). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a *transfer.*

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,
- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller will set one (or more) of the error reporting bits in the queue head's *Status* field. The *Status* field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the queue head *Status* field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions will occur for the endpoint and the host controller will not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in Figure 60-78. This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the *Fetch QH* state in order to avoid all

hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and *activate* them, then the host controller will always *find* them if/when they are reachable.

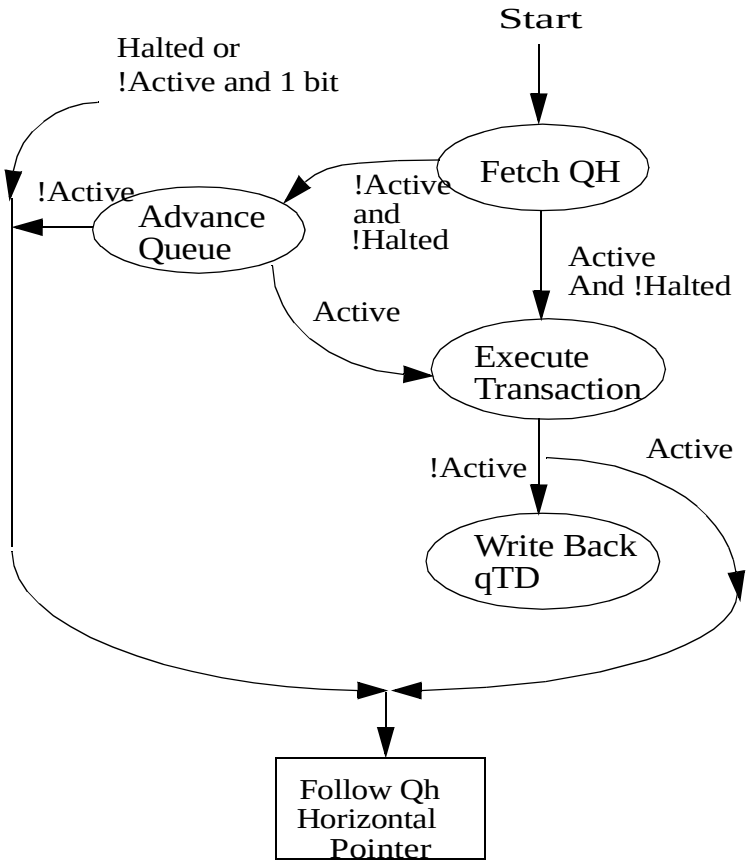

Figure 60-78. Host Controller Queue Head Traversal State Machine

This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The **Execute Transaction** state (Section Execute Transaction) describes the basic requirements for all endpoints. Sections Split Transactions for Asynchronous Transfers and Split Transaction Interrupt describe details of the required extensions to the **Execute Transaction** state for endpoints requiring split transactions.

Note: Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see SectionQueue Head for layout of a queue head):

- Valid static endpoint state
- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the *Next qTD Pointer* field value to reference a valid qTD.

60.4.4.10.1 Fetch Queue Head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register (Section ASYNCLISTADDR;ENDPOINTLISTADDR). Additionally, it may be referenced from the *Next Link Pointer* field of an iTD, siTD, FSTN or another Queue Head. If the referencing link pointer has the *Typ* field set to indicate a queue head, it is assumed to reference a queue head structure as defined in Figure 60-63.

While in this state, the host controller performs operations to implement empty schedule detection (Section Empty Asynchronous Schedule Detection) and Nak Counter reloads (Section Operational Model for Nak Counter). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (i.e. *S-mask* is a zero), and
- The *H-bit* is a one, and
- The *Reclamation* bit in the USBSTS register is a zero.

When these criteria are met, the host controller will stop traversing the asynchronous list (as described in Section Empty Asynchronous Schedule Detection). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the *H-bit* is a one and the *Reclamation* bit is a one, then the host controller sets the *Reclamation* bit in the USBSTS register to a zero before completing this state. The operations for reloading of the Nak Counter are described in detail in Section Operational Model for Nak Counter.

This state is complete when the queue head has been read on-chip.

60.4.4.10.2 Advance Queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the **FetchQHD** state if the overlay *Active* and *Halt* bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and determines whether or not to perform an overlay. Note that if the *I-bit* is a one and the *Active* bit is a zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field *Bytes to Transfer* is not zero and the *T-bit* in the *Alternate Next qTD Pointer* is set to zero, then the host controller uses the *Alternate Next qTD Pointer.* Otherwise, the host controller uses the *Next qTD Pointer.* If *Next qTD Pointer*'s *T-bit* is set to a one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has it's *Active* bit set to a one, the host controller moves the pointer value used to reach the qTD (*Next* or *Alternate Next*) to the *Current qTD Pointer* field, then performs the overlay. If the fetched qTD has its *Active* bit set to a zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure. The host controller performs the overlay based on the following rules:

- The value of the data toggle (*dt*) field in the overlay area depends on the value of the *data toggle control* (*dtc*) bit (see Table 60-82).

- If the *EPS* field indicates the endpoint is a high-speed endpoint, the *Ping* state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- *C-prog-mask* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *Frame Tag* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *NakCnt* field in the overlay area is loaded from the *RL* field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.

60.4.4.10.3 Execute Transaction

The host controller enters this state from the **Fetch Queue Head** state only if the *Active* bit in *Status* field of the queue head is set to a one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's *S-mask* field contains a non-zero value. It is the responsibility of software to ensure the *S-mask* field is appropriately initialized based on the transfer type. There are other criteria that must be met if the *EPS* field indicates that the endpoint is a low- or full-speed endpoint, see Sections Split Transactions for Asynchronous Transfers and Split Transaction Interrupt .

Interrupt Transfer Pre-condition Criteria

If the queue head is for an interrupt endpoint (for example, non-zero *S-mask* field), then the FRINDEX[2:0] field must identify a bit in the *S-mask* field that has a one in it. For example, an *S-mask* value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction**.**

Asynchronous Transfer Pre-operations and Pre-condition Criteria

If the queue head is not for an interrupt endpoint (for example, a zero *S-mask* field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria: The pre-operation is:

Checks the Nak counter reload state (Section Operational Model for Nak Counter). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the *NakCnt* field has been reloaded, the host controller checks the value of the *NakCnt* field in the queue head. If *NakCnt* is non-zero, or if the *Reload Nak Counter* field is zero, then the host controller considers this queue head for a transaction.

Transfer Type Independent Pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter *qHTransactionCounter* is loaded from the queue head's *Mult* field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the *Mult* field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the micro-frame to complete this transaction (see Section Transaction Fit—A Best-Fit Approximation Algorithm for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of *qHTransactionCounter* for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the *Reclamation* bit in the USBSTS register to a one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates *qHTransactionCounter* times in this state executing transactions. After each transaction is executed, *qHTransactionCounter* is decremented by one. The host controller will exit this state when one of the following events occurs:

- The *qHTransactionCounter* decrements to zero
- The endpoint responds to the transaction with any handshake other than an ACK

NOTE

Note that for a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

- The transaction experiences a transaction error
- The *Active* bit in the queue head goes to a zero
- There is not enough time in the micro-frame left to execute the next transaction (see Section , Transaction Fit—A Best-Fit Approximation Algorithm" for example method for implementing the frame boundary test).

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the *Total Bytes to Transfer* field is decremented by the number of bytes moved in the transaction, the data toggle bit (*dt*) is toggled, the current page offset is advanced to the next appropriate value (for example, advanced by the number of bytes successfully moved), and the *C_Page* field is updated to the appropriate value (if necessary). See Section Buffer Pointer List Use for Data Streaming with qTDs .

Note that the *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller will execute a zero-length transaction to the endpoint. If the *PID_Code* field indicates an IN transaction and the device delivers data, the host controller will detect a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to a zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example, not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement *qHTransactionCounter*). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of *qHTransactionCounter* is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and *RL* is non-zero, *NakCnt* is decremented by one. If *RL* is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of *CErr* did not change). Software should set the *RL* field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly *NakCnt*, the host controller writes back the results of the transaction to the queue head's overlay area in main memory.

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *Maximum Packet Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The *CErr* field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in Section Transaction Error .

The following events will cause the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from a one to a zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to zero. When this occurs the *Halted* bit is set to a one and *Active* is set to a zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to a one and the *Active* bit is set to a zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The *Total Bytes to Transfer* field is zero after the transaction completes. Note that for a zero length transaction, it was zero before the transaction was started. When this condition occurs, the *Active* bit is set to zero.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to zero and a short packet condition exists. The short-packet condition is detected during the **Advance Queue** state. Refer to Section Split Transactions for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (e.g.

Maximum Packet Length or *Total Bytes to Transfer* bytes, whichever is less) (e.g. a packet babble). This results in the host controller setting the *Halted* bit to a one.

- NakCnt, dt, Total Bytes to Transfer, C_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

Halting a Queue Head

A halted endpoint is defined only for the transfer types that are managed via queue heads (control, bulk and interrupt). The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USBSTS register to a one. To halt the queue head, the *Active* bit is set to a zero and the *Halted* bit is set to a one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller will not advance the transfer state on a transaction that results in a *Halt* condition (e.g. no updates necessary for *Total Bytes to Transfer*, *C_Page*, *Current Offset*, and *dt*). The host controller must update *CErr* as appropriate. When a queue head is halted, the *USB Error Interrupt* bit in the USBSTS register is set to a one. If the *USB Error Interrupt Enable* bit in the USBINTR register is set to a one, a hardware interrupt is generated at the next interrupt threshold.

Asynchronous Schedule Park Mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule. This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the *Mult* feature that is used in the Periodic schedule. Where-as the *Mult* feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in Section Execute Transaction apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the *Asynchronous Schedule Park Capability* bit in the HCCPARAMs register to a one. This information keys system software that the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USBCMD register are modifiable. System software enables the feature by writing a one to the *Asynchronous Schedule Park Mode Enable* bit.

When park-mode is not enabled (e.g. *Asynchronous Schedule Park Mode Enable* bit in the USBCMD register is a zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose *EPS* field indicates a Low/Full-speed device (i.e. only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose *EPS* field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose *EPS* field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the *Asynchronous Schedule Park Mode Count* field in the USBCMD register. Software must not set *Asynchronous Schedule Park Mode Enable* bit to a one and also set *Asynchronous Schedule Park Mode Count* field to a zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in Section Execute Transaction . It only effects how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the *Mult* field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter *PM-Count* from *Asynchronous Schedule Park Mode Count* when *Asyncrhonous Schedule Park Mode Enable* bit is a one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, *PM-Count* is decremented. The host controller may continue to execute bus transactions from the current queue head until *PM-Count* goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake. Table 60-96 summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

Table 60-96. Actions for Park Mode, based on Endpoint Response and Residual Transfer State

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	
IN	DATA[0,1] w/Maximum Packet sized data	Not zero	Not Zero	Allowed to perform another bus transaction.[1,2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.
	DATA[0,1] w/short packet	Don't care	Don't care	Retire qTD and move to next QH.
	NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH.

Table 60-96. Actions for Park Mode, based on Endpoint Response and Residual Transfer State (continued)

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	
OUT	ACK	Not zero	Not Zero	Allowed to perform another bus transaction. [2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't' care	Move to next QH.
	NYET, NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not Zero	Not Zero	Allowed to perform another bus transaction. [2]
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

[1] Note, the host controller may continue to execute bus transactions from the current high-speed queue head (if PM-Count is not equal to zero), if a PID mismatch is detected (e.g. expected DATA1 and received DATA0, or visa-versa).

[2] Note, this specification does not require that the host controller execute another bus transaction when PM-Count is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

60.4.4.10.4 Write Back qTD

This state is entered from the **Execute Transaction** state when the *Active* bit is set to a zero. The source data for the write-back is the transfer results area of the queue head overlay area (see Table 60-96). The host controller uses the *Current qTD Pointer* field as the target address for the qTD. The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include *Total Bytes to Transfer*, *Cerr*, and *Status*.

The duration of this state depends on when the qTD write-back has been committed.

60.4.4.10.5 Follow Queue Head Horizontal Pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the *Active* bit is a one on exit from the **Execute Transaction** state, or
- When the host controller exits the **Write Back qTD** state, or
- If the **Advance Queue** state fails to advance the queue because the target qTD is not active, or
- If the *Halted* bit is a one on exit from the **Fetch QH** state.

There is no functional requirement that the host controller wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

60.4.4.10.6 Buffer Pointer List Use for Data Streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be *virtually contiguous*. This means: if the buffer spans more than one physical page, it must obey the following rules (Figure 60-79 illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4K chunk beyond the first page, each buffer portion matches to a full 4K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20K bytes. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16Kbyte buffer with any starting buffer alignment.

The host controller uses the field *C_Page* field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction will span a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing *C_Page* and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the *Bytes to Transfer* field.

Figure 60-79 illustrates a nominal example of how System software would initialize the buffer pointers list and the *C_Page* field for a transfer size of 16383 bytes. *C_Page* is set to zero. The upper 20-bits of Page 0 references the start of the physical page. *Current Offset* (the lower 12-bits of queue head Dword 7) holds

the offset in the page e.g. 2049 (e.g. 4096–2047). The remaining page pointers are set to reference the beginning of each subsequent 4K page.

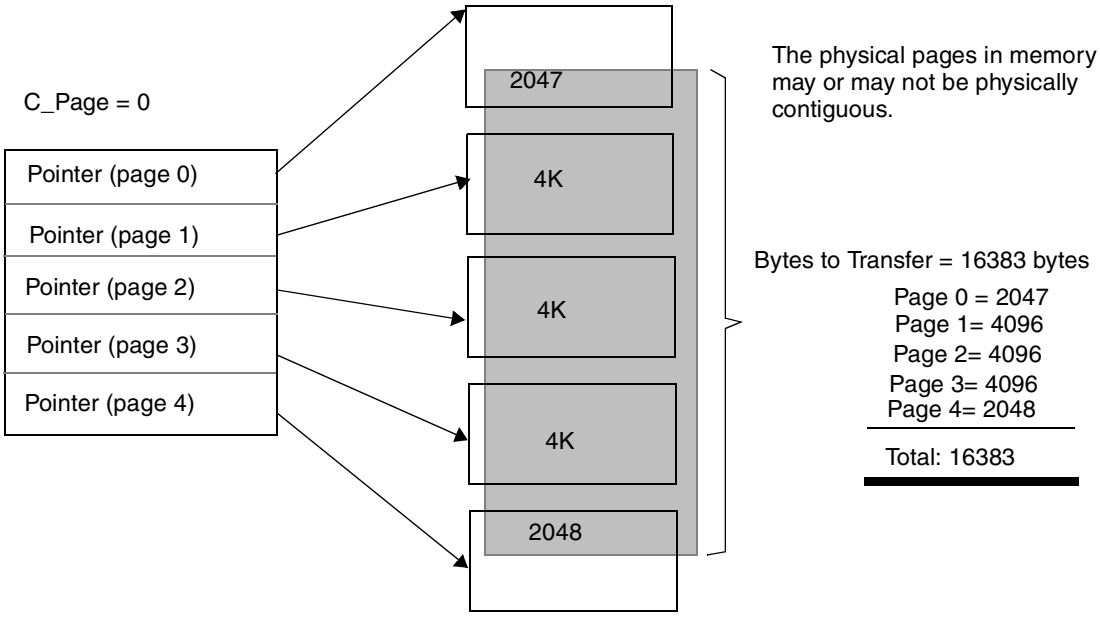

Figure 60-79. Example Mapping of qTD Buffer Pointers to Buffer Pages

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because *C_Page* is set to zero) and concatenates the *Current Offset* field. The 512 bytes are moved during the transaction, the *Current Offset* and *Total Bytes to Transfer* are adjusted by 512 and written back to the queue head working area.

During the 4th transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller will increment *C_Page* (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4th transaction, the active page pointer is the page 1 pointer and *Current Offset* has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (i.e. *C_Page*) when necessary. There are three conditions for how the host controller handles *C_Page*.

- The current transaction does not span a page boundary. The value of *C_Page* is not adjusted by the host controller.
- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (i.e. the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment *C_Page* before writing back status for the transaction.

Note that the only valid adjustment the host controller may make to *C_Page* is to increment by one.

60.4.4.10.7 Adding Interrupt Queue Heads to the Periodic Schedule

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate. System software sets a bit in a queue head's *S-Mask* to indicate which micro-frame with-in a 1 millisecond period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have *S-Mask* set to a non-zero value. An *S-mask* with a zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and *S-Mask* values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in Table 60-97.

Table 60-97. Example Periodic Reference Patterns for Interrupt Transfers with 2ms Poll Rate

Frame # Reference Sequence	Description
0, 2, 4, 6, 8, etc. *S-Mask* = 01h	A queue head for the *bInterval* of 2 milliseconds (16 micro-frames) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the *S-Mask* field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during micro-frame 0 of the frame.
0, 2, 4, 6, 8, etc. *S-Mask* = 02h	Another example of a queue head with a *bInterval* of 2 milliseconds is linked into the periodic frame list at exactly the same interval as the previous example. However, the *S-Mask* is set to 02h indicating that the transaction for the endpoint should be executed on the bus during micro-frame 1 of the frame.

60.4.4.10.8 Managing Transfer Complete Interrupts from Queue Heads

The host controller will set an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an *Interrupt on Complete* (*IOC*) bit set to a one, or whenever a transfer (qTD) completes with a short packet. If system software needs multiple qTDs to complete a client request (i.e. like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

60.4.4.11 Ping Control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints. Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The *Status* field has a *Ping State* bit, which the host controller uses to determine the *next* actual PID it will use in the next transaction to the endpoint (see Table 60-79). The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt
- *EPS* field equals High-Speed
- *PIDCode* field equals OUT

Table 60-98 illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

Table 60-98. Ping Control State Transition Table

	Event		
Current	**Host**	**Device**	**Next**
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr[1]	Do Ping
Do Ping	PING	Stall	N/C[2] Do
OUT	OUT	Nak	Do Ping
Do OUT	OUT	Nyet	Do Ping
Do OUT	OUT	Ack	Do OUT
Do OUT	OUT	XactErr[1]	Do Ping
Do OUT	OUT	Stall	N/C[2]

1 Transaction Error (XactErr) is any time the host misses the handshake.

2 No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (e.g. Active set to zero and Halt set to a one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to **Do Ping**. The Ping State bit has the following encoding:

Value	Meaning
0B	Do OUT The host controller will use an OUT PID during the next bus transaction to this endpoint.
1B	Do Ping The host controller will use a PING PID during the next bus transaction to this endpoint.

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (i.e. start in *Do OUT* when we don't know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

60.4.4.12 Split Transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs. This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol. Refer to USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed

wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.

The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see Section Split Transaction Isochronous Transfer Descriptor (siTD)). Control, Bulk and Interrupt are managed using the queuing data structures (see Sections Queue Head). The interface data structures need to be programmed with the device address and the Transaction Translator number of the USB 2.0 Hub operating as the Low-/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

60.4.4.12.1 Split Transactions for Asynchronous Transfers

A queue head in the asynchronous schedule with an *EPS* field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head. All full-speed bulk and full-, low-speed control are managed via queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit (*SplitXState*) to **Do-Start-Split**. Finally, if the endpoint is a control endpoint, then system software must set the *Control Transfer Type* (*C*) bit in the queue head to a one. If this is not a control transfer type endpoint, the *C* bit must be initialized by software to be a zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the *C* bit is a zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the *C* bit is a one, the split transaction token's ET field is set to indicate a control endpoint. Refer to Chapter 8 of USB Specification Revision 2.0 for details.

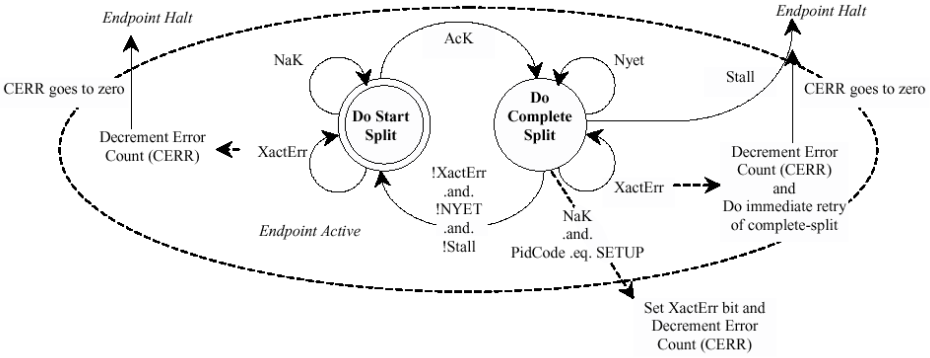

Figure 60-80. Host Controller Asynchronous Schedule Split-Transaction State Machine

Asynchronous - Do Start Split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the **Do Complete Split** state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller will execute a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and *PidCode* indicates an IN or OUT transaction, then the host controller will reload the error counter (*CErr*). If it is a successful bus

transaction and the *PidCode* indicates a SETUP, the host controller will not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements *Cerr* and proceeds to the next queue head in the asynchronous schedule.

Asynchronous—Do Complete Split

This state is entered from the **Do Start Split** state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller will execute a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's *PidCode* indicates an IN or OUT, the host controller will reload the error counter (*CErr*). When a Nyet handshake is received for a complete-split bus transaction where the queue head's *PidCode* indicates a SETUP, the host controller must not adjust the value of *CErr.*

Independent of *PIDCode*, the following responses have the effects:

- Transaction Error (XactErr). Timeout or data CRC failure, etc. The error counter (*Cerr*) is decremented by one and the complete split transaction is *immediately* retried (if possible). If there is not enough time in the micro-frame to execute the retry, the host controller MUST ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to accomplish this behavior is to not advance the asynchronous schedule. When the host controller returns to the asynchronous schedule in the next micro-frame, the first transaction from the schedule will be the retry for this endpoint. If *Cerr* went to zero, the host controller must halt the queue.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the *PidCode* is a SETUP, then the Nak response is a protocol error. The *XactErr* status bit is set to a one and the *CErr* field is decremented.
- STALL. The target endpoint responded with a STALL handshake. The host controller sets the *halt* bit in the status byte, retires the qTD but does not attempt to advance the queue.
- If the *PidCode* indicates an IN, then any of following responses are expected:
- DATA0/1. On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is *good*, the host controller will advance the state of the transfer, e.g. move the data pointer by the number of bytes received, decrement *BytesToTransfer* field by the number of bytes received, and toggle the *dt* bit. The host controller will then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

- If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the *PidCode* indicates an OUT/SETUP, then any of following responses are expected:
- ACK. The target endpoint accepted the data, so the host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount and the data toggle bit (*dt*) is toggled. The host controller will then exit this state.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers via Queue Heads).

60.4.4.12.2 Split Transaction Interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed via the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule. Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller will visit a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the *execution* phase are different (i.e. takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, etc. occurs as defined in Section Managing Control/Bulk/Interrupt Transfers via Queue Heads, but only occurs on the completion of a split transaction.

Split Transaction Scheduling Mechanisms for Interrupt

Full- and low-speed Interrupt queue heads have an *EPS* field indicating full- or low-speed and have a non-zero *S-mask* field. The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each endpoint will occur. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit micro-frames, or the data or response information in the pipeline is lost. Figure 60-81 illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule

and queue head data structure. The **S** and ^{C}x labels indicate micro-frames where software can schedule start-splits and complete splits (respectively).

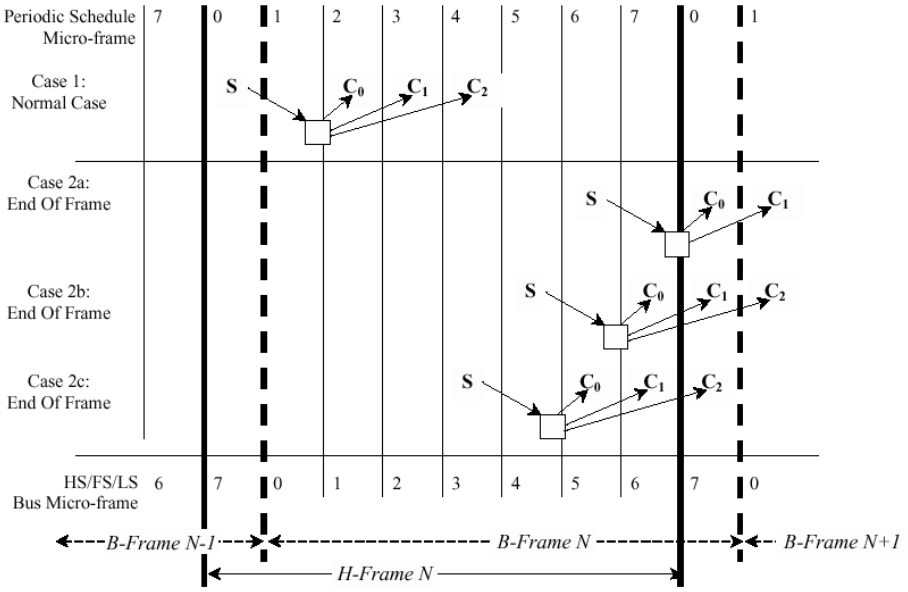

Figure 60-81. Split Transaction, Interrupt Scheduling Boundary Conditions

The scheduling cases are as follows:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in micro-frame 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs. Figure 60-82 illustrates the general layout of the periodic schedule.

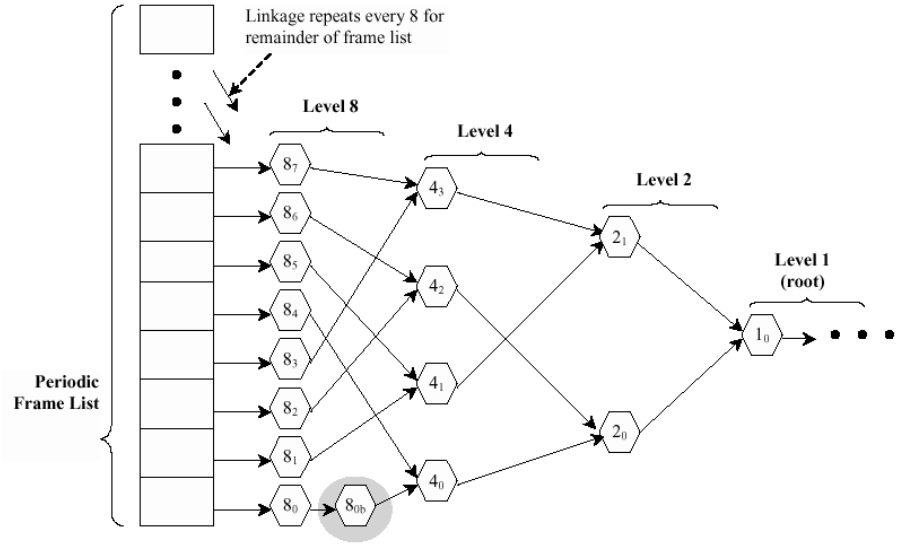

Figure 60-82. General Structure of EHCI Periodic Schedule Utilizing Interrupt Spreading

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a 2^N poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if 8_{0b} where such an endpoint. Without additional support on the interface, to get 8_{0b} reachable at the correct time, software would have to link 8_1 to 8_{0b}. It would then have to move 4_1 and everything linked after into the same path as 4_0. This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. Section Host Controller Operational Model for FSTNs defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of a queue head (see Table 60-79). This bit is used to track the current state of the split transaction.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 60-81, case one, the *S-mask* would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates **Do_Start**, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.

- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 60-81, case one, the *C-mask* would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates **Do_Complete**, and the current micro-frame as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between *H-Frames* and *B-Frames* is correctly performed when setting bits in *S-mask* and *C-mask*

Host Controller Operational Model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (i.e. boundary cases 2a through 2c). An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see Section siTD Back Link Pointer).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

There are four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its *Back Path Link Pointer. T-bit* set to zero.
- A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to a one.
- Host controller FSTN traversal rules.

Host Controller Operational Model for FSTNs

When the host controller encounters an FSTN during micro-frames 2 through 7 it simply follows the node's *Normal Path Link Pointer* to access the next schedule data structure. Note that the FSTN's *Normal Path Link Pointer.T-bit* may set to a one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in micro-frames 0 or 1, it will save the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller's rules for how it traverses the schedule and limits which data structures will be considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the micro-frame (see details in the list below).

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

- Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN's *Back Path Link Pointer.*
- Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer.*

- Do not process a QH (Queue Head) whose *EPS* field indicates a high-speed device. Simply follow its *Horizontal Link Pointer.*
- When a QH's *EPS* field indicates a Full/Low-speed device, the host controller will only consider it for execution if its *SplitXState* is **DoComplete** (note: this applies whether the *PID Code* indicates an IN or an OUT). See Sections Execute Transaction and Tracking Split Transaction Progress for Interrupt Transfers for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction. Note that the host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See Section Periodic Isochronous—Do Complete Split for special handling when in *Recovery Path* mode.
- Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The host controller must clear the context of executing a *Recovery Path* when it restores schedule traversal to the *Save-Place* FSTN's *Normal Path Link Pointer.*
- If the host controller determines that there is not enough time left in the micro-frame to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive micro-frame, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in Figure 60-83.

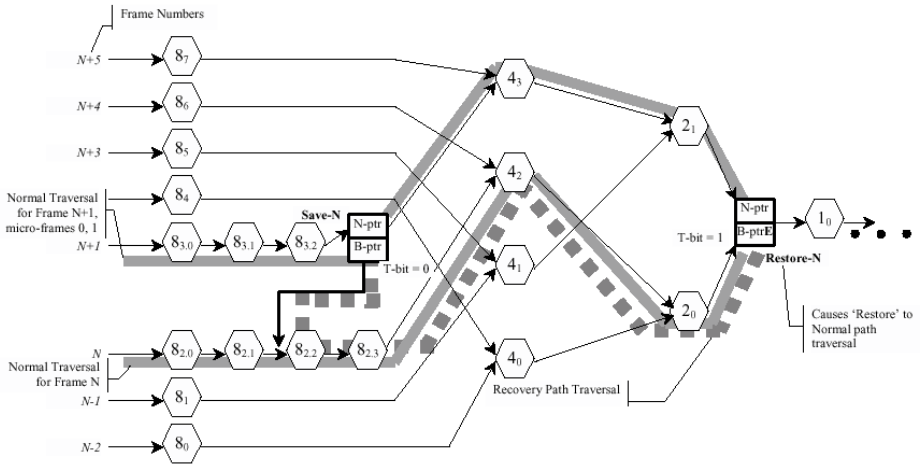

Figure 60-83. Example Host Controller Traversal of Recovery Path via FSTNs

In frame N+1 (micro-frames 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in *Recovery Path* mode (the recovery path is annotated in Figure 60-83 with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to a one (definition of a Restore indicator), so the host controller exits *Recovery Path* mode by clearing the internal *Recovery Path* mode flag and commences (restores) schedule traversal using the

saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* (e.g. Save-N.Normal Path Link Pointer). The nodes traversed during these micro-frames include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, **$8_{2.2}$**, **$8_{2.3}$**, **4_2**, **2_0**, **Restore-N**, 4_3, 2_1, Restore-N, 1_0 …}. The nodes on the recovery-path are bolded.In frame N (micro-frames 0-7), for this example, the host controller will traverse all of the schedule data structures utilizing the *Normal Path Link Pointers* in any FSTNs it encounters. This is because the host controller has not yet encountered a *Save-Place* FSTN so it not executing in *Recovery Path* mode. When it encounters the *Restore* FSTN, (Restore-N), during micro-frames 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (i.e. normal schedule traversal). This is because the host controller must use a Restore FSTN's *Normal Path Link Pointer* when not executing in a *Recovery-Path* mode. The nodes traversed during frame N include: {$8_{2.0}$, $8_{2.1}$, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 1_0 …}.

In frame N+1 (micro-frames 2-7), when the host controller encounters Save-Path FSTN Save-N, it will unconditionally follow Save-N.Normal Path Link Pointer. The nodes traversed during these micro-frames include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, 4_3, 2_1, Restore-N, 1_0 …}.

Software Operational Model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse. When using FSTNs, system software must adhere to the following rules:

- Each *Save-Place* indicator requires a matching *Restore* indicator.
  - The *Save-Place* indicator is an FSTN with a valid *Back Path Link Pointer and T-bit* equal to zero. Note that *Back Path Link Pointer.Typ* field must be set to indicate the referenced data structure is a queue head. The *Restore* indicator is an FSTN with its *Back Path Link Pointer.T-bit* set to a one.
  - A *Restore* FSTN may be matched to one or more *Save-Place* FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a *Restore* FSTN at the beginning of this list in order to match all possible *Save-Place* FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more *Save-Place* FSTNs are used, then System Software must ensure the *Restore* FSTN's *Normal Path Link Pointer*'s *T-bit* is set to a one, as this will be use to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a *Restore* FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that *Recovery Path* mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A *Save-Place* FSTN's *Back Path Link Pointer* must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list location. In other words, if the *Save-Place* FSTN is reachable from frame list offset N, then the FSTN's *Back Path Link Pointer* must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one *Save-Place* FSTN reachable in any single frame. Note there will be times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth rebalance causes system software to move the *Save-Place* FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

Tracking Split Transaction Progress for Interrupt Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost. For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline. When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets one of the *C-prog*-mask bits for each complete-split executed. The bit position is determined by the micro-frame number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.
- *FrameTag*. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame* number) when the next complete split must be executed.
- *S-bytes*. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

Split Transaction Execution State Machine for Interrupt

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence. Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- *cMicroFrameBit*. This is a single-bit encoding of the current micro-frame number. It is an eight-bit value calculated by the host controller at the beginning of every micro-frame. It is calculated from the three least significant bits of the *FRINDEX* register (i.e. *cMicroFrameBit* = (1

shifted-left(*FRINDEX*[2:0]))). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current micro-frame number. For example, if the current micro-frame is 0, then *cMicroFrameBit* will equal 00000001b. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start- or complete-split transaction for the current micro-frame.

Figure 60-84 illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at **Do_Start** and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to **Do_Complete**. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the **Do_Complete** state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the **Do_Complete** state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (e.g. after the host tries the same transaction three times, and each encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

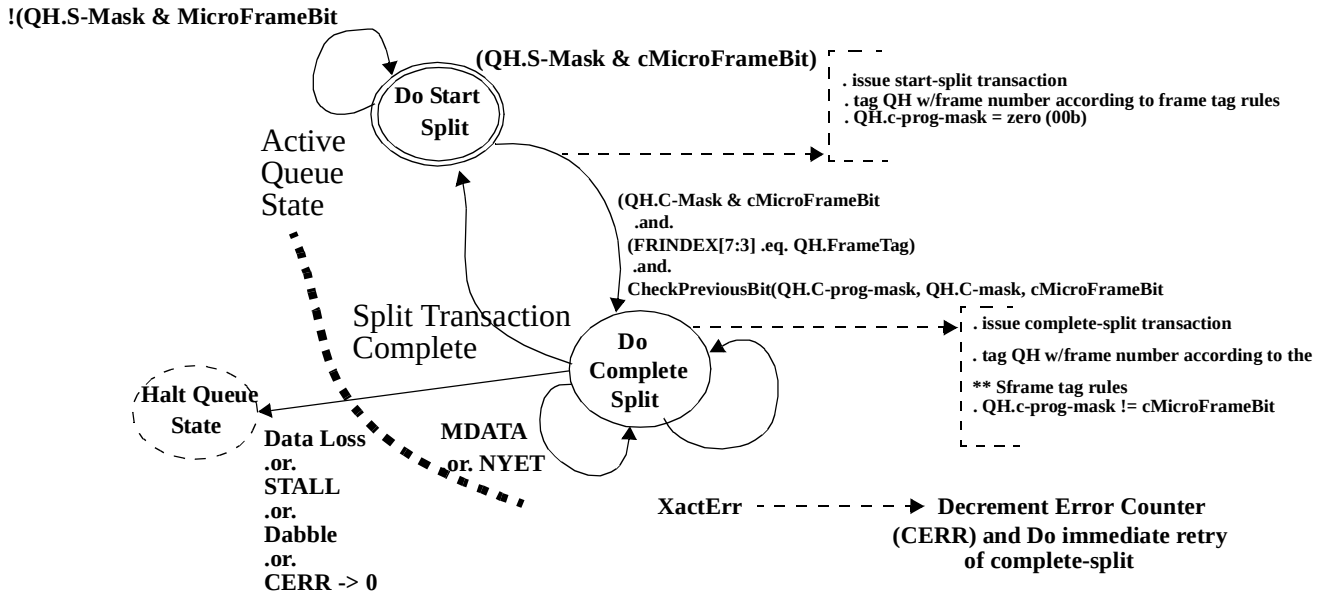

Figure 60-84. Split Transaction State Machine for Interrupt

See Previous Section for the frame tag management rules.

Periodic Interrupt—Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head *StartXState* bit. This state is entered from the **Do_Complete Split** state only after the split transaction is complete. This occurs when

one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- NAK. A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- ACK. An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- DATA 0/1. Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- ERR. The transaction on the low-/full-speed link below the transaction translator had a failure (e.g. timeout, bad CRC, etc.).
- NYET (and Last). The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section Periodic Isochronous—Do Complete Split for the definition of ‘Last’.

Each time the host controller visits a queue head in this state (once within the **Execute Transaction** state), it performs the following test to determine whether to execute a start-split.

- *QH.S-mask* is bit-wise anded with *cMicroFrameBit*.

If the result is non-zero, then the host controller will issue a start-split transaction. If the *PIDCode* field indicates an IN transaction, the host controller must zero-out the *QH.S-bytes* field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into *QH.FrameTag* field (see Section), set *C-prog-mask* to zero (00h), and exits this state. Note that the host controller must not adjust the value of *CErr* as a result of completion of a start-split transaction.

Periodic Interrupt - Do Complete Split

This state is entered unconditionally from the **Do Start Split** state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the **Execute Transaction** state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- **Test A**. *cMicroFrameBit* is bit-wise anded with *QH.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame.
- **Test B**. *QH.FrameTag* is compared with the current contents of *FRINDEX*[7:3]. An equal indicates a match.
- **Test C**. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)

Begin

-- Return values:

-- TRUE - no error

-- FALSE - error
```

```
--
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous micro-frame. So,
-- if the
-- 'previous bit' is set in C-mask, check C-prog-mask to
-- make sure it
-- happened.
If (previousBit bitAND QH.C-mask)then
                          If not(previousBit bitAND QH.C-prog-mask) then
                 rvalue = FALSE;
         End if
End If
-- If the C-prog-mask already has a one in this bit position,
-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
 rvalue = FALSE;
End if
return (rvalue)
End Algorithm
```

- **Test D.** Check to see if a start-split should be executed in this micro-frame. Note this is the same test performed in the **Do Start Split** state (see Section Periodic Isochronous - Do Start Split). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a *Recovery Path* mode, it means a start-split should occur in this micro-frame. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. On completion of the complete-split transaction, the host controller

records the result of the transaction in the queue head and sets *QH.FrameTag* to the expected *H-Frame* number (see Section). The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the *CErr* will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the clompete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the **Last** complete split can be performed by XOR *QH.C-mask* with *QH.C-prog-mask*. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the *XactErr* status bit is set to a one and the *CErr* field is decremented.
- NYET (and not Last). See above description for testing for **Last**. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask* and *FrameTag*) and stay in this state. The host controller must not adjust *CErr* on this response.
- Transaction Error (XactErr). Timeout, data CRC failure, etc. The *CErr* field is decremented and the *XactErr* bit in the *Status* field is set to a one. The complete split transaction is *immediately* retried (if *Cerr* is non-zero).If there is not enough time in the micro-frame to complete the retry and the endpoint is an IN, or *CErr* is decremented to a zero from a one, the queue is halted. If there is not enough time in the micro-frame to complete the retry and the endpoint is an OUT and *CErr* is not zero, then this state is exited (i.e. return to **Do Start Split**). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section full- and low-speed Interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.
- ACK. This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount. And the data toggle bit (*dt*) is toggled. The host controller will then exit this state for this queue head. The host controller must reload *CErr* with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers via Queue Heads).
- MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in *QH.S-bytes*. The host controller must not adjust *CErr* on this response.
- DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in *QH.S-bytes*. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.

- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers via Queue Heads).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload *CErr* with maximum value on this response.
- ERR. There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, *Cerr* is decremented, the state of the transfer is not advanced, and this state is exited.
- STALL. The queue is halted (an exit condition of the **Execute Transaction** state). The status field bits: *Active* bit is set to zero and the *Halted* bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. Table 60-99 lists the possible combinations and the appropriate action.

Table 60-99. Interrupt IN/OUT Do Complete Split State Execution Criteria

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current micro-frame.Host controller should continue walking the schedule.
A not(C)	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	Progress bit check failed. These means a complete-split has been missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (e.g. start-split is retried). This is a host-induced error and does not effect *CERR*. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A not(B) C	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	*QH.FrameTag* test failed. This means that exactly one or more *H-Frames* have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (e.g. start-split is retried). This is a host-induced error and does not effect *CERR*. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.
D	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (e.g. start-split is retried). This is a host-induced error and does not effect *CERR*. In either case, set the *Missed Micro-frame* bit in the status field to a one. Note: When executing in the context of a *Recovery Path* mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a *Recovery Path* mode.

Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- **Rule 1:** If transitioning from **Do Start Split** to **Do Complete Split** and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see Figure 60-81).
- **Rule 2:** If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in **Do Complete Split** for cases 2a, 2b, and 2c (Figure 60-81).
- **Rule 3:** If transitioning from **Do_Start Split** to **Do Complete Split** and the current value of *FRINDEX*[2:0] is not 6, or currently in **Do Complete Split** and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases (Figure 60-81).

Rebalancing the Periodic Schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation. This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (i.e. new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction* (*I*) bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.
- If the *Active* bit is a one and the *SplitXState* is **DoStart** (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed it's final bus-transaction and set *Active* to a zero.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Since the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

1. Set the *Halted* bit to a one.
2. Set the *I-bit* to a zero.
3. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

60.4.4.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions. This data structure uses the scheduling model of isochronous TDs (iTD, Section Isochronous (High-Speed) Transfer Descriptor (iTD)) (see Section Managing Isochronous Transfers Using iTDs for the operational model of iTDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur. The requirements described in Section Split Transaction Scheduling Mechanisms for Interrupt apply. Figure 60-85 illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The ^{s}x and ^{c}x labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

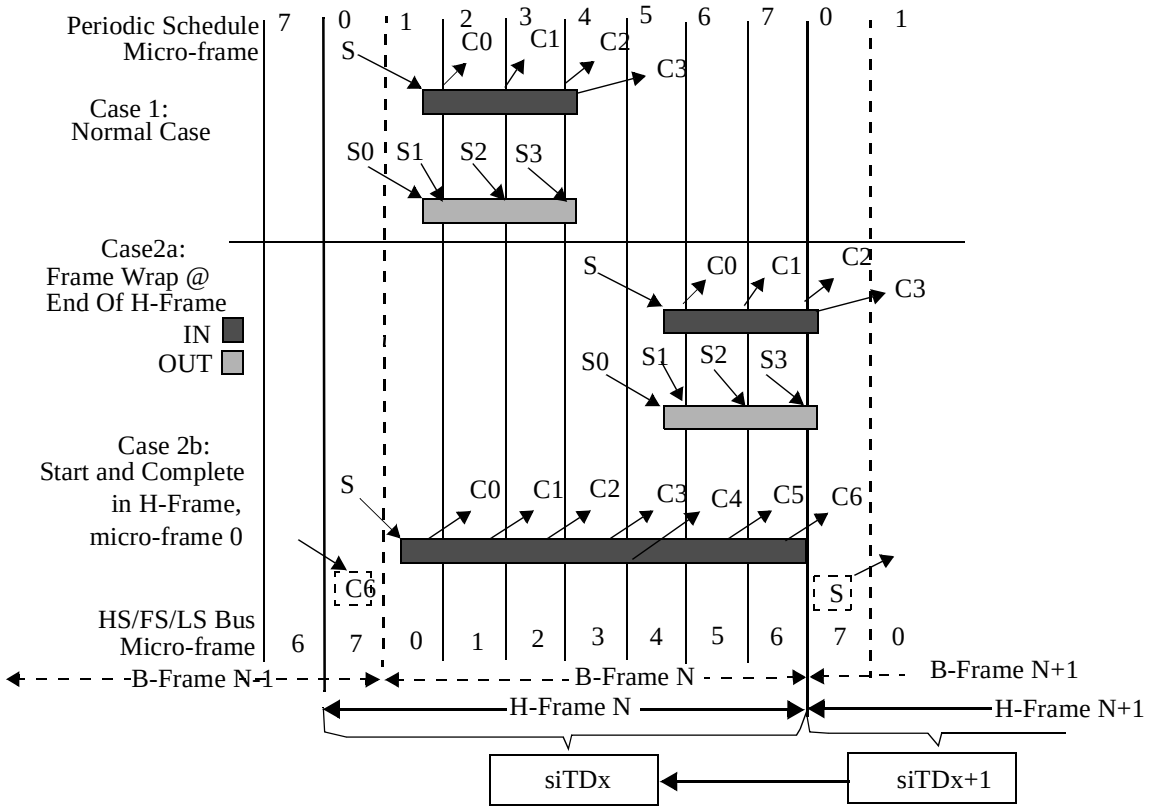

Figure 60-85. Split Transaction, Isochronous Scheduling Boundary Conditions

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to *N* complete-splits. The scheduling boundary cases are:

- *Case 1*: The entire split transaction is completely bounded by an *H-Frame*. For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.
- *Case 2a*: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame*, micro-frames 6 or 7 (*H-Frame* micro-frame 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list.(e.g. it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction).
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see Table 60-74). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in Section Split Transaction Execution State Machine for Interrupt .
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 60-85, case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates **Do Start Split**, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 60-85, case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates **Do Complete Split**, and the current micro-frame as indicated by *FRINDEX*[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.
- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN an OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. Figure 60-86 illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

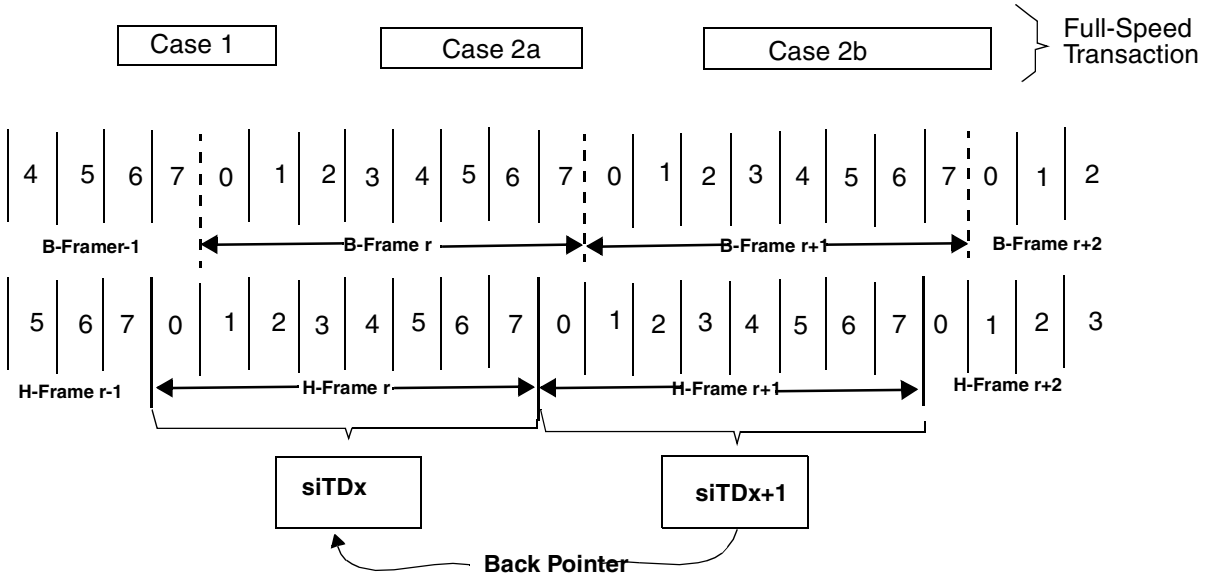

Figure 60-86. siTD Scheduling Boundary Examples

Each case is described below:

- *Case 1*: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.
- *Case 2a, 2b*: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction. $siTD_X$ is used to always issue the start-split and the first *N* complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of *H-Frame*$_{Y+1}$, or micro-frame 0 of *H-Frame*$_{Y+2}$. The complete splits are scheduled using $siTD_{X+2}$ (not shown). The complete-splits to extract this data must use the buffer pointer from $siTD_{X+1}$. The only way for the host controller to reach $siTD_{X+1}$ from *H-Frame*$_{Y+2}$ is to use $siTD_{X+2}$'s back pointer. The host controller rules for when to use the back pointer are described is Section Periodic Isochronous—Do Complete Split.

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, micro-frame 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of *H-Frame* N and the last complete-split would need to occur in micro-frame 1 of H-Frame N+1. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction N are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields *Transaction Position* (*TP*) and *Transaction Count* (*T-count*). If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section Periodic Isochronous - Do Start Split for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the micro-frame (FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section Asynchronous—Do Complete Split for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (e.g. high-speed data streams through queue heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement it's *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (e.g. a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (e.g. state not advanced) and report the appropriate error to the client driver.

Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section Tracking Split Transaction Progress for Interrupt Transfers , plus the variable *cMicroFrameBit* defined in Section Split Transaction Execution State Machine for Interrupt to track the progress of an isochronous split transaction. Figure 60-87 illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states.

Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

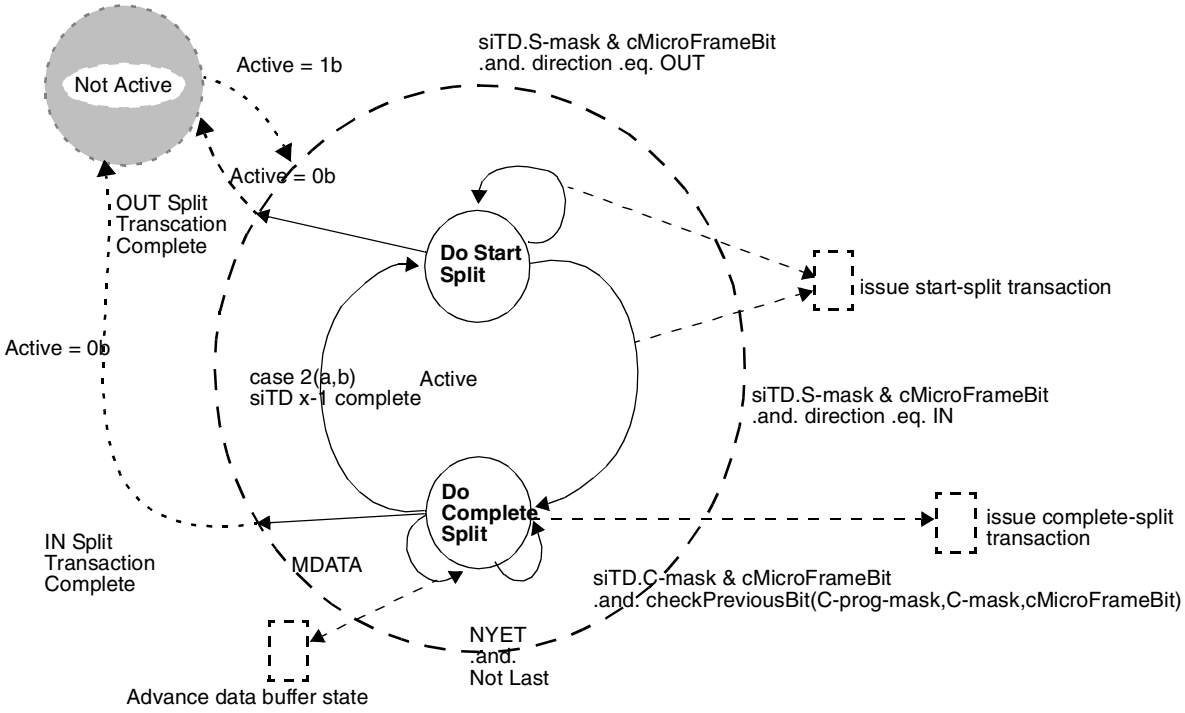

Figure 60-87. Split Transaction State Machine for Isochronous

Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state. An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from **Do Complete Split** when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the siTD will execute a start-split transaction. By definition, the host controller cannot *reach* an siTD at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (i.e. the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory buffer address for the data payload is constructed by concatenating *siTD.Current Offset* with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer

crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

T-Count is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see Figure 60-86) is used to determine the initial value of *TP*. The initial cases are summarized in Table 60-100.

Table 60-100. Initial Conditions for OUT siTD's TP and T-count Fields

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated. Table 60-101 illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

Table 60-101. Transaction Position (TP)/Transaction Count (T-Count) Transition Table

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when *T-count* starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when *T-count* starts at greater than 2.
MID	!=1	MID	*TP* stays at MID while *T-count* is not equal to 1 (e.g. greater than 1). This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in Table 60-101.

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to

a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count* and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (i.e. the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in Section Split Transaction for Isochronous—Processing Examples.

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit*() algorithm defined in Section Periodic Isochronous—Do Complete Split can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

Periodic Isochronous—Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint. This state is entered unconditionally from the **Do Start State** after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- **Test A**. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- **Test B**. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section Periodic Isochronous—Do Complete Split). The sequence in which this test is applied depends on the current value of FRINDEX[2:0]. If FRINDEX[2:0] is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

Algorithm Boolean CheckPreviousBit(`siTD.C-prog-mask, siTD.C-mask, cMicroFrameBi`**t)**

```
Begin

        Boolean rvalue = TRUE;

        previousBit = cMicroFrameBit rotate-right(1)

        -- Bit-wise anding previousBit with C-mask indicates whether there was an intent

        -- to send a complete split in the previous micro-frame. So, if the
```

```
        -- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
        -- happened.
        if previousBit bitAND siTD.C-mask then
                if not (previousBit bitAND siTD.C-prog-mask) then
                        rvalue = FALSE
                End if
        End if
        Return rvalue
End Algorithm
```

If Test A is true and FRINDEX[2:0] is zero or one, then this is a case 2a or 2b scheduling boundary (see Figure 60-85). See Section , Periodic Isochronous—Do Complete Split," for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must do the following:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer,*
- Adjust *siTD.Current Offset* by the number of bytes received,
- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives and MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, etc. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry

more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the *Active* bit is set to zero.

- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section Periodic Isochronous—Do Complete Split. If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled clompete-splits with NYETs, meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.
- MDATA (and Last). See above description for testing for **Last**. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-mask*s incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- NYET (and not Last). See above description for testing for **Last**. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- MDATA (and not Last). The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame X to X+1 and during micro-frame X, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the *Active* bit to a zero.

Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see Figure 60-85) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. Table 60-102 enumerates the transaction state fields.

Table 60-102. Summary siTD Split Transaction State

Buffer State	Status	Execution Progress
Total Bytes To Transfer P (page select) Current Offset TP (transaction position) T-count (transaction count)	All bits in the status field	C-prog-mask
Note: *TP* and *T-count* are used only for Host to Device (OUT) endpoints.		

If software has budgeted the schedule of this data stream with a frame wrap case, it must initialize the *siTD.Back Pointer* field to reference a valid siTD and have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is **Do Complete Split**.

- When cMicroFrameBit is a 1h and the siTDX.Back Pointer.T-bit is a zero
- If cMicroFrameBit is a 2h and siTDX.S-mask[0] is a zero

When either of these conditions apply, the host controller must use the transaction state from $siTD_{X-1}$.

To access $siTD_{X-1}$, the host controller reads on-chip the siTD referenced from $siTD_X$*.Back Pointer.*

The host controller must save the entire state from $siTD_X$ while processing $siTD_{X-1}$. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers.*

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is **Do Complete Split**), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see Table 60-102) of $siTD_{X-1}$ is appropriately advanced based on the results and written back to memory. If the resultant state of $siTD_{X-1}$'s *Active* bit is a one, then the host controller returns to the context of $siTD_X$, and follows its next pointer to the next schedule item. No updates to $siTD_X$ are necessary.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is **Do Start Split**), then the host controller must set *Active* bit to a zero and *Missed Micro-Frame* status bit to a one and the resultant status written back to memory.

If $siTD_{X-1}$'s *Active* bit is a zero, (because it was zero when the host controller first visited $siTD_{X-1}$ via $siTD_X$'s back pointer, it transitioned to zero as a result of a detected error, or the results of $siTD_{X-1}$'s complete-split transaction transitioned it to zero), then the host controller returns to the context of $siTD_X$ and transitions its *SplitXState* to **Do Start Split**. The host controller then determines whether the case 2b

start split boundary condition exists (i.e. if *cMicroframeBit* is a 1b and $siTD_X$.*S-mask*[0] is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of $siTD_X$, then follows $siTD_X$.*Next Pointer* to the next schedule item. If the criterion is not met, the host controller simply follows $siTD_X$.*Next Pointer* to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of $siTD_{X-1}$ will have its *Active* bit set to zero when the host controller returns to the context of $siTD_X$. Also, note that software should not initialize an siTD with *C-mask* bits 0 and 1 set to a one and an *S-mask* with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

Split Transaction for Isochronous—Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines. The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the **Execute Transaction** queue head traversal state machine (see Figure 60-78).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, Table 60-103 illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

Table 60-103. Example Case 2a - Software Scheduling siTDs for an IN Endpoint

siTDx		Micro-Frames								Initial SplitXState
#	Masks	0	1	2	3	4	5	6	7	
X	S-Mask					1				Do Start Split
	C-Mask	1	1					1	1	
X+1	S-Mask					1				Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask					1				Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Since this is the case-2a frame-wrap case, *S-mask*s of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and *C-mask* value of C3h (one-bits in micro-frames 0,1, 6 and 7). Additionally, sofware ensures that the *Back Pointer*

field of each siTD references the appropriate siTD data structure (and the *Back Pointer T-bits* are set to zero).

The initial *SplitXState* of the first siTD is **Do Start Split**. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is **Do Start Split**. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to **Do Complete Split**. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has it's *SplitXState* initialized to **Do Complete Split**. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, micro-frame 0, the host controller detects that $siTD_{X+1}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+1}$ and fetches $siTD_X$. It executes the complete split transaction using the transaction state of $siTD_X$. If the $siTD_X$ split transaction is complete, siTD's *Active* bit is set to zero and results written back to $siTD_X$. The host controller retains the fact that $siTD_X$ is retired and transitions the *SplitXState* in the $siTD_{X+1}$ to **Do Start Split.** At this point, the host controller is prepared to execute the start-split for $siTD_{X+1}$ when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section Periodic Isochronous—Do Complete Split), i.e. before all the scheduled complete-splits have been executed, the host controller will transition $siTD_X$*.SplitXState* to **Do Start Split** early and naturally skip the remaining scheduled complete-split transactions. For this example, $siTD_{X+1}$ does not receive a DATA0 response until *H-Frame* X+2, micro-frame 1.

During *H-Frame X+2,* micro-frame 0, the host controller detects that $siTD_{X+2}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the *Active* bit. The host controller returns to the context of $siTD_{X+2}$, and traverses it's next pointer without any state change updates to $siTD_{X+2}$. S

During *H-Frame X+2*, micro-frame 1, the host controller detects $siTD_{X+2}$'s *S-mask[0]* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of $siTD_{X+2}$ and changes its *SplitXState* to **Do Start Split**. At this point, the host controller is prepared to execute start-splits for $siTD_{X+2}$ when it reaches micro-frame 4. <TBD… describe how software detects that there was missing micro-frames (don't think we care about missing out micro-frames. There is enough residual state to identify than not all transactions were executed.).

60.4.4.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports. When the schedules are enabled, the EHCI host controller will access the schedules in main memory each micro-frame. This constant pinging of main memory is known to create CPU power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the CPU, based on recent history usage. In the more aggressive power saving modes, the CPU can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the CPU power management software can detect this activity over time and inhibit the transition of the CPU into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they

access their memory-based schedules keeps the CPU power management software from placing the CPU into its lowest power savings state.

USB Host controllers don't access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the CPU power management to get the CPU into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the CPU to reach it's low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the CPU will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing it's shared memory based data structures (schedule lists or otherwise).

60.4.4.14 Port Test Modes

EHCI host controllers must implement the port test modes **Test J_State**, **Test K_State**, **Test_Packet**, **Test Force_Enable**, and **Test SE0_NAK** as described in the USB Specification Revision 2.0. The system is only allowed to test ports that are owned by the EHCI controller (e.g. *CF-bit* is a one and *PortOwner* bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is as follows (assuming the *CF-bit* in the CONFIGFLAG register is a one):

1. Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
2. Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate PORTSC register to a one.
3. Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
4. Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is **Test_Force_Enable**, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
5. When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting *HCReset* to a one.

60.4.4.15 Interrupts

The EHCI Host Controller hardware provides interrupt capability based on a number of sources. There are several general groups of interrupt sources, as follows:

- Interrupts as a result of executing transactions from the schedule (success and error conditions)
- Host controller events (Port change events, etc.)
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR, see Section USBINTR). Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight microframes. This means that the host controller will not generate interrupts any more frequently than once every eight microframes.

See Section , Host System Error," for details about the effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, CPU control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to reads the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINR register, see Section USBINTR) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register (Section USBSTS) from a one to a zero.

60.4.4.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully. Table 60-104 lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

Table 60-104. Summary of Transaction Errors

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1[1]
Timeout	-1	XactErr set to a one.	1[1]
Bad PID[2]	-1	XactErr set to a one.	1[1]
Babble	N/A	Section Serial Bus Babble	1
Buffer Error	N/A	Section Data Buffer Error	

1 If it occurs in a queue head, *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted. See Section , Halting a Queue Head ."

2 The host controller received a response from the device, but it could not recognize the PID as a valid PID.

Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*. When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see Section Section , Halting a Queue Head "). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the USBSTS register is set to a one and if the *USB Error Interrupt Enable* bit in the USBINTR register is a one, then a hardware interrupt is signaled to the system at the next interrupt

threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

NOTE

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (e.g. expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction. This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

USB Interrupt (Interrupt on Completion (IOC))

Transfer Descriptors (iTDs, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USBSTS register to be set to a one. In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USBINTR register is set to a one, a hardware interrupt

is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USBSTS register is also set to a one.

Short Packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USBSTS register is set to a one. If the *USB Interrupt Enable* bit is set in the USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

60.4.4.15.2 Host Controller Event Interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section Interrupt on Async Advance).

Port Change Events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one. If the *Port Change Interrupt Enable* bit in the USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

Frame List Rollover

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs. If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

Interrupt on Async Advance

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USBCMD register. If it is a one, it sets the *Interrupt on Async Advance* bit in the USBSTS register to a one. If the *Interrupt on Async Advance Enable* bit in the USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section Removing Queue Heads from Asynchronous Schedule .

Host System Error

The host controller is a bus master and any interaction between the host controller and the system may experience errors. The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to continue in a coherent fashion. In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USBCMD register is set to a zero.
- The following bits in the USBSTS register are set:
  - *Host System Error* bit is to a one.
  - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. Table 60-105 summarizes the required actions taken on the various host errors.

Table 60-105. Summary Behavior of EHCI Host Controller on Host System Errors

Cycle Type	Master Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]
iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

[o] Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

NOTE

After a Host System Error, Software must reset the host controller via HCReset in the USBCMD register before re-initializing and restarting the host controller.

60.4.5 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specificationEnhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com. Device operation and On-The-Go operation are not specified in the EHCI and thus the implementation supported

in this core is proprietary. The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized as follows:

- Embedded Transaction Translator—Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation—In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface—This core does not a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation—This design includes an On-The-Go controller for Port #1.

60.4.5.1 Embedded Transaction Translator Function

The ARC USB-HS OTG High-Speed USB On-The-Go OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction trasnslator. Although there is no separate Tranaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator fuction is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

60.4.5.1.1 Capability Registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N_TT added to HCSPARAMS—Host Control Structural Parameters
- N_PTT added toHCSPARAMS—Host Control Structural Parameters

60.4.5.1.2 Operational Registers

The following additions have been added to the operational registers to support the embedded TT:

- A new register.
- Addition of two-bit Port Speed (PSPD) to the PORTSCx register.

60.4.5.1.3 Discovery

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation. The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (i.e. Chirp completes successfully).

Since this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in Table 60-106:

Table 60-106. Summary of EHCI

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. **[where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (ie. Split target hub)]**	FS and LS device can be either downstream from a HS hub with HubAddr = X **[HubAddr > 0]** or directly attached **[where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (ie. Split target hub is the root hub)]**

60.4.5.1.4 Data Structures

The same data structures used for FS/LS transactions though a HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator. The following sequence demonstrates how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) – Async. (Bulk/Control Endpoints) Periodic (Interrupt)
   - Hub Address = 0
   - Transactions to direct attached device/hub.
     - QH.EPS = Port Speed
   - Transactions to a device downstream from direct attached FS hub.
     - QH.EPS = Downstream Device Speed

NOTE

When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

Maximum packet size must be less than or equal 64 or undefined behaviour may result.

2. siTD (for direct attach FS) – Periodic (ISO Endpoint)
   - All FS ISO transactions:
     - Hub Address = 0
     - siTD.EPS = 00 (full speed) (maximum packet size must less than or equal to 1023 or undefined behaviour may result.)

60.4.5.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specificationUniversal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org) and for the EHCI controller moving packets between system memory and a USB-HS hub. Since the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

Micro- frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

Split State Machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator. Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. Table 60-107 summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 60-107. Summary of the Handshake Conditions

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)

Table 60-107. Summary of the Handshake Conditions (continued)

Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

Note: The unshaded cells represent Start-Splits and the shaded cells represent Complete-Splits.

Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- USB 2.0 – 11.17.3—Sequencing is provided and a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.
- USB 2.0 – 11.17.4—Transaction tracking for 2 data pipes.
- USB 2.0 – 11.17.5—Clear_TT_Buffer capability provided though the use of the register.

Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- USB 2.0 – 11.18.6.[1–2]
  - — Abort of pending start-splits
    - – EOF (and not started in micro-frames 6)
    - – Idle for more than 4 micro-frames
  - — Abort of pending complete-splits
    - – EOF
    - – Idle for more than 4 micro-frames
- USB 2.0 – 11.18.[7–8]
  - — Transaction tracking for up to 16 data pipes.
  - — Some applications may not require transaction tracking up to a maximum of 16 periodic data pipes. The option to limit tracking to only 4 periodic data pipes is chosen by changing the

configuration constant VUSB_HS_TT_PERIODIC_CONTEXTS to 4. The result is a significant gate count savings to the core given the limitations implied.

CAUTION

Limiting the number of tracking pipes in the EMBedded –TT to four (4) will impose the restriction that no more than 4 periodic transactions (INTERRUPT/ISOCHRONOUS) can be scheduled through the embedded-tt per frame. the number 16 was chosen in the USB specification because it is sufficient to ensure that the high-speed to full-speed periodic pipeline can remain full. keeping the pipeline full puts no constraint on the number of periodic transactions that can be scheduled in a frame and the only limit becomes the flight time of the packets on the bus.

— Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

Multiple Transaction Translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N_TT field in the HCSPARAMS—EHCI Compliant with extensions register.

60.4.5.2 Device Operation

The coexistence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

60.4.5.3 USBMODE Register

Given that the dual-role controller is initialized in neither host nor device mode, the USBMODE register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

60.4.5.3.1 Non-Zero Fields the register file.

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode .

60.4.5.3.2 SOF Interrupt

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode. EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See USBSTS and USBINTR registers.

60.4.5.4 Embedded Design Interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

60.4.5.4.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. i.e. 60 Mhz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

60.4.5.5 Miscellaneous Variations from EHCI

60.4.5.5.1 Programmable Physical Interface Behaviour

This design supports multiple physical interfaces which can operate in differing modes when the core is configured with software programmable physical interface modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the PORTSCx register providing a capability that is not defined by EHCI.

60.4.5.5.2 Discovery

Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the PORTSCx register for a duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a ‘1’ to the reset the device.
- Software shall write a ‘0’ to the reset the device after 10 ms.
  - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a ‘0’ to the reset bit while a reset is in progress the write will simple be ignored and the reset will continue until completion.

- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device in now operational and at this point the port speed has been determined.

Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices. Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed – *This information is redundant with the 2-bit Port Speed indicator above.*

60.4.5.5.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI since the release of revision 3.2.1. In earlier product revisions, the test packet mode was not EHCI compatible. An alternate host controller driver procedure is no longer necessary or supported.

60.4.6 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller. The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/writeable fields. The device controller must preserve the read-only fields on all data structure writes.

The ARC USB-HS OTG High-Speed USB On-The-Go core includes DCD Software called the USB 2.0 device API. The device API provides an easy to use Application Program Interface for developing device (peripheral) applications using the ARC USB-HS OTG High-Speed USB On-The-Go core. The device API incorporates and abstracts for the application developer all of the elements of the program interface.

Figure 60-88 shows the endpoint queue head organization.

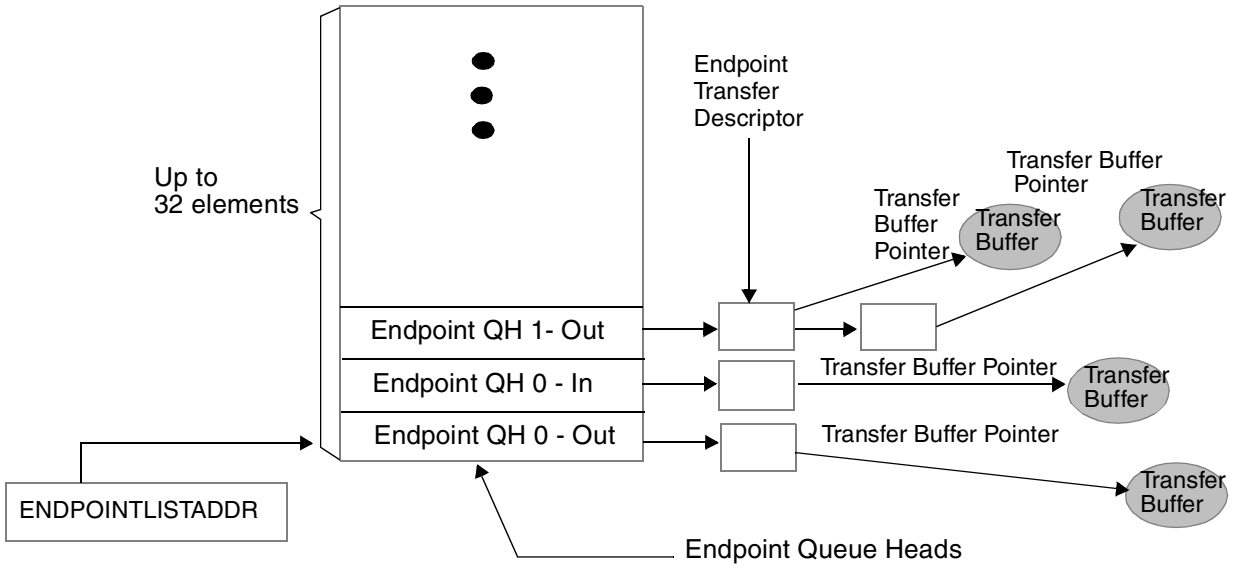

Figure 60-88. Endpoint Queue Head Organization

Device queue heads are arranged in an array in a continuous area of memory pointed to by the *ENDPOINTLISTADDR* pointer. The even –numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

NOTE

The Endpoint Queue Head List must be aligned to a 2k boundary.

60.4.6.1 Endpoint Queue Head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries. During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Mult		zlt		0				Maximum Packet Length								ios								0							
Current dTD Pointer																														0	

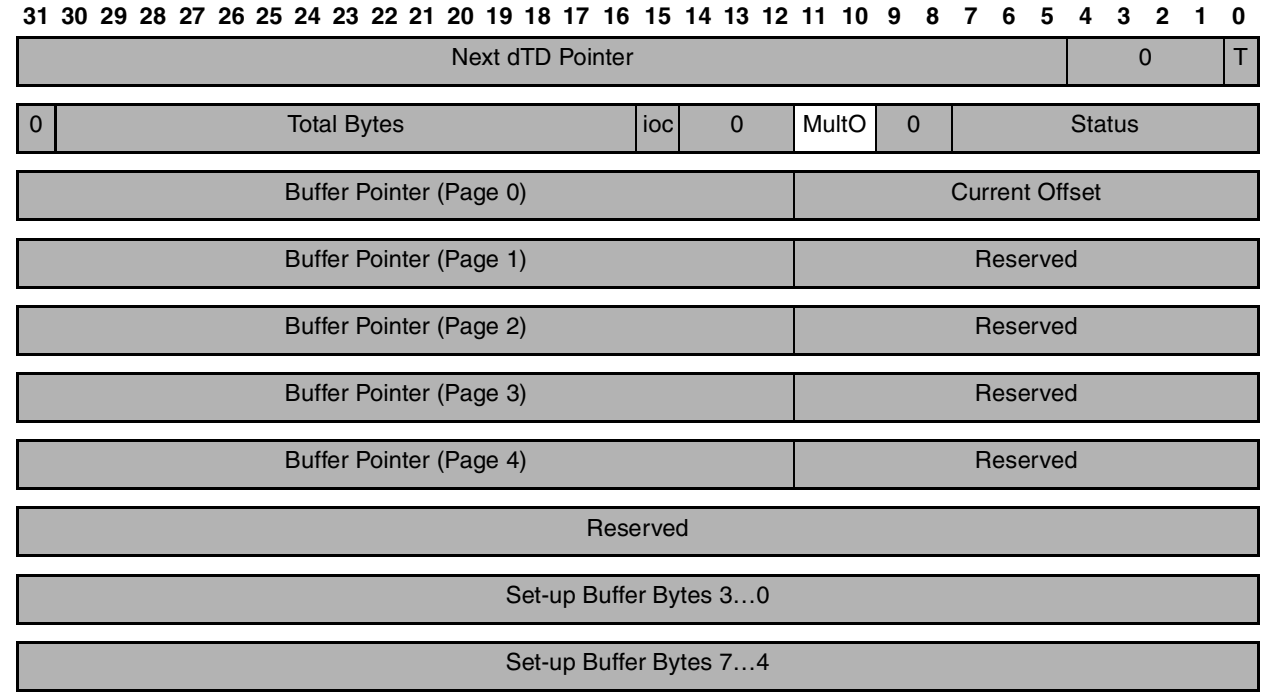

Figure 60-89. Endpoint Queue Head (dQH)

60.4.6.1.1 Endpoint Capabilities/Characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

Table 60-108 shows the endpoint capabilities and characteristics.

Table 60-108. Endpoint Capabilities/Characteristics

Bit	Description
31–30	**Mult.** This field is used to indicate the number of packets executed per transaction description as given by the following: 00 – Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD) 01 – Execute 1 Transaction. 10 – Execute 2 Transactions. 11 – Execute 3 Transactions. Note: Non-ISO endpoints must set Mult=”00”. Note: ISO endpoints must set Mult=”01”, “10”, or “11” as needed.
29	**Zero Length Termination Select.** This bit is used to indicate when a zero length packet is used to terminate transfers where to total transfer length is a multiple . This bit is not relevant for Isochronous 0 – Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default). 1 – Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28–27	**Reserved.** These bit reserved for future use and should be set to zero.

Table 60-108. Endpoint Capabilities/Characteristics (continued)

26–16	**Maximum Packet Length.** This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	**Interrupt On Setup (IOS).** This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14–0	**Reserved.** Bits reserved for future use and should be set to zero.

60.4.6.1.2 Transfer Overlay

The seven DWords in the overlay area represent a transaction working space for the device controller. The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

60.4.6.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

Table 60-109. Next dTD Pointer

Bit	Description
31–5	**Current dTD.** This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4–0	**Reserved.** Bit reserved for future use and should be set to zero.

60.4.6.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

Table 60-110. Multiple Mode Control (HCCPARAMS)

DWord	Bits	Description
1	31–0	**Setup Buffer 0.** This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31–0	**Setup Buffer 1.** This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

60.4.6.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/received for given transfer. The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in Section 60.4.7.5, Managing Transfers with Transfer Descriptors.”

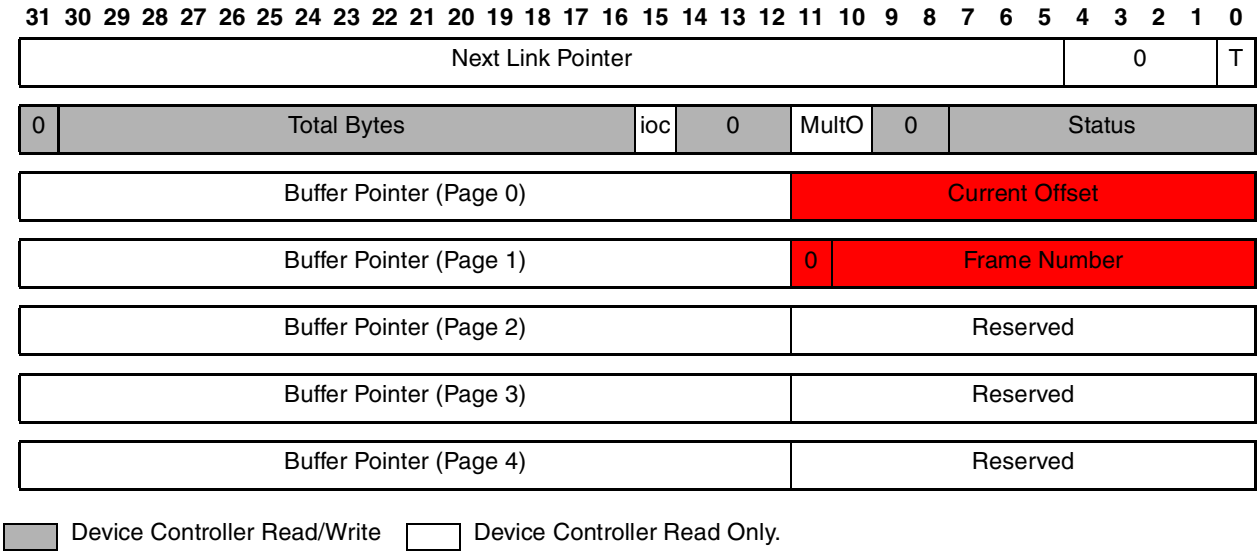

Figure 60-90. Endpoint Transfer Descriptor (dTD)

Table 60-111. Next dTD Pointer

Bit	Description
31–5	**Next Transfer Element Pointer.** This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4–1	**Reserved.** Bits reserved for future use and should be set to zero.
0	**Terminate (T).** 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

Table 60-112. dTD Token

Bit	Description
31	**Reserved.** Bit reserved for future use and should be set to zero.
30–16	**Total Bytes.** This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction. The maximum value software may store in the field is 5 × 4K(5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. **Therefore, the maximum recommended transfer is 16K(4000H).** If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of *Maximum Packet Length*. If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less that *Maximum Packet Length*.
15	**Interrupt On Complete (IOC).** This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14–12	**Reserved**. Bits reserved for future use and should be set to zero.
11–10	**Multiplier Override (MultO).** This field can be used for transmit ISO's (ie. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO. Example: if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default] Three packets are sent: {Data2(8); Data1(7); Data0(0)} if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2 Two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, software should compute MultO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultO should be 1. Note: Non-ISO and Non-TX endpoints must set MultO="00".
9–8	**Reserved**. Bits reserved for future use and should be set to zero.
7–0	**Status.** This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are: Bit Status Field Description 7 Active. 6 Halted. 5 Data Buffer Error. 3 Transaction Error. 4,2,0 Reserved.

Table 60-113. dTD Buffer Page Pointer List

Bit	Description
31–12	**Buffer Pointer.** Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0;11–0	**Current Offset.** Offset into the 4kb buffer where the packet is to begin.
1;10–0	**Frame Number.** Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

60.4.7 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus. Using a set of linked list **transfer descriptors**, pointed to by a **queue head**, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

The ARC USB-HS OTG High-Speed USB On-The-Go is shipped with a DCD called the ARC USB-HS OTG High-Speed USB On-The-Go Device API. The ARC USB-HS OTG High-Speed USB On-The-Go Device API provides an easy to use application interface for developing USB device (peripheral) applications. The ARC USB-HS OTG High-Speed USB On-The-Go Device API incorporates and abstracts for the application developer all of the information contained in the device operational model. For more information on the ARC USB-HS OTG High-Speed USB On-The-Go Device API, refer to the "Software Design document for the Precise USB 2.0 Device API".

60.4.7.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs. Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

1. Set Controller Mode in the USBMODE register to device mode.
2. Allocate and Initialize device queue heads in system memory. Note that Transitioning from host mode to device mode requires a device controller reset before modifying USBMODE.
   - Minimum: Initialize device queue heads 0 Tx and 0 Rx.
   - For information on device queue heads, refer to Section 60.4.6, Device Data Structures."

NOTE

All device queue heads must be initialized for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

3. Configure ENDPOINTLISTADDR Pointer.
   - For additional information on ENDPOINTLISTADDR, refer to the register table.
4. Enable the microprocessor interrupt associated with the ARC USB-HS OTG High-Speed USB On-The-Go core.
   - Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
   - For a list of available interrupts refer to the USBINTR and the USBSTS register tables.

5. Set Run/Stop bit to Run Mode.
   — After the Run bit is set, a device reset will occur. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the following Port State and Control section below.

NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to initially prime Endpoint 0 because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

60.4.7.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'. After receiving a reset on the bus, the port enters the *defaultFS or defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0. Figure 60-91 depicts the state of a USB 2.0 device.

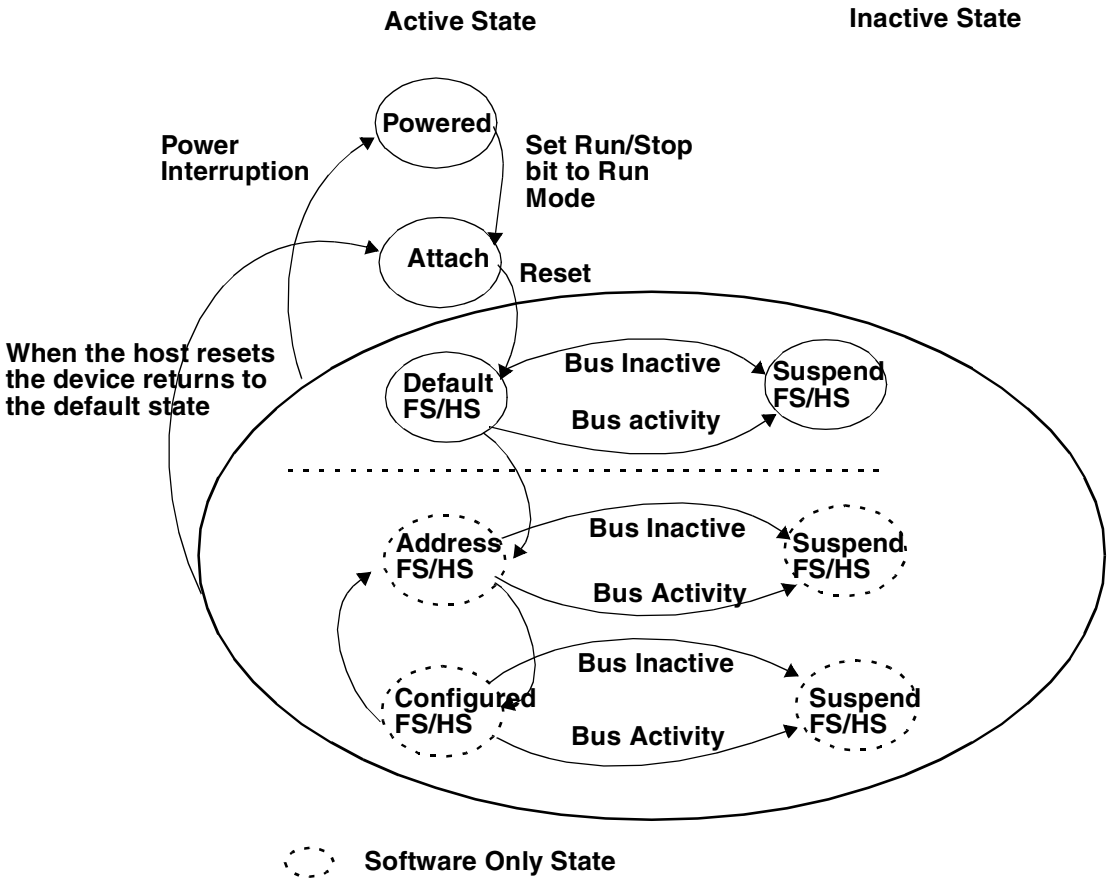

Figure 60-91. Device State Diagram

States *powered, attach, defaultFS/HS, suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits as shown in Table 60-114:

Table 60-114. Device Controller State Information Bits

Bit	Register
DCSuspend	USBSTS
USB Reset Received	USBSTS
Port Change Detect	USBSTS
High-Speed Port	PORTSCx

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the ENDPTCTRLx registers and initializing the associated queue heads.

60.4.7.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices. When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the ENDPTSETUPSTAT register and writing the same value back to the ENDPTSETUPSTAT register.

Clear all the endpoint complete status bits by reading the ENDPTCOMPLETE register and writing the same value back to the ENDPTCOMPLETE register.

Cancel all primed status by waiting until all bits in the ENDPTPRIME are 0 and then writing 0xFFFFFFFF to ENDPTFLUSH.

Read the reset bit in the PORTSCx register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the PORTSCx to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device.

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

60.4.7.2.2 Suspend

This section provides a general description of suspend and details about the operational mode.

Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the PORTSCx is set to a ‘1’, the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

NOTE

Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

60.4.7.2.3 Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port. Resume signaling is sent upstream by writing a '1' to the Resume bit in the in the PORTSCx while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

NOTE

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in the device framework chapter of the USB 2.0 Specification.

60.4.7.2.4 Port Test Modes

Contact ARC International for port test mode capabilities.

60.4.7.2.5 Managing Endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device. The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk, interrupt*, and *isochronous*. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The ARC USB-HS OTG High-Speed USB On-The-Go device controller hardware supports up to the USB 2.0 maximum of 32 endpoint specified numbers. Each additional endpoint beyond the required endpoint position adds additional hardware logic. The maximum number of endpoint numbers available to the DCD is configured at hardware synthesis timer. After synthesis, the DCD can enable, disable and configure endpoint type up to the maximum selected during synthesis.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. If the maximum of 16 endpoint numbers, one for each endpoint direction are being used by the device controller, then 32 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

60.4.7.2.6 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the ENDPTCTRLx register. Each 32-bit ENDPTCTRLx is split into an upper and lower half. The lower half of ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the ENDPTCTRLx register otherwise the behavior is undefined.

Table 60-115 shows how to construct a configuration word for endpoint initialization.

Table 60-115. Device Controller Endpoint Initialization

Field	Value
Data Toggle Reset	'1'
Data Toggle Inhibit	'0'
Endpoint Type	"00" – Control "01" – Isochronous "10" – Bulk "11" – Interrupt
Endpoint Stall	'0'

60.4.7.2.7 Stalling

There are two occasions where the device controller may need to return to the host a STALL

The first occasion is the **functional stall**, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A **protocol stall**, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

NOTE

Any write to the ENDPTCTRLx register during operational mode must preserve the endpoint type field (i.e. perform a read-modify-write).

Table 60-116. Device Controller Stall Response Matrix

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL
IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET

60.4.7.2.8 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe. For more information on data toggle, refer to the USB 2.0 specification.

Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the ENDPTCTRLx register. This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

Data Toggle Inhibit

NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

60.4.7.3 Operational Model For Packet Transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification. At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "**priming**" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "**flushing**" is used to describe the action of clearing a packet that was queued for execution.

Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH). After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Since only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section .

Priming Receive Endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

60.4.7.3.1 Interrupt/Bulk Endpoint Operational Model

The behaviors of the device controller for interrupt and bulk endpoints are identical. All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

```
N = INT(Number Of Bytes/Max. Packet Length) + 1
```

With Zero Length Termination (ZLT) = 1

```
N = MAXINT(Number Of Bytes/Max. Packet Length)
```

Table 60-117. Variable Length Transfer Protocol Example (ZLT = 0)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	—
512	256	3	256	256	0
512	512	2	512	0	—

Table 60-118. Variable Length Transfer Protocol Example (ZLT = 1)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	—
512	256	2	256	256	—
512	512	1	512	—	—

NOTE

The MULT field in the dQH must be set to “00” for bulk, interrupt, and control endpoints.

TX-dTD is complete when all packets described dTD were successfully transmitted. The total bytes in dTD equals zero when this occurs.

RX-dTD is complete when the following occurs.

- All packets described in dTD were successfully received. Total bytes in dTD equals zero when this occurs.

- A short packet (number of bytes < maximum packet length) was received. This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). This is an error condition. The device controller discards the remaining packet and sets the Buffer Error bit in the dTD. In addition, the endpoint is flushed and the USBERR interrupt becomes active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

NOTE

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

Interrupt/Bulk Endpoint Bus Response Matrix

Table 60-119 shows the interrupt/bulk endpoint bus response matrix.

Table 60-119. Interrupt/Bulk Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error	Force Bit Stuff Error
NYET/ACK	NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.
SYSERR	System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

60.4.7.3.2 Control Endpoint Operation Model

This section discusses the setup phase, data phase, status phase, and control endpoint bus response matrix.

Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

In hardware versions 2.3 and later, the setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted be an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

- Setup Packet Handling (Pre-2.3 hardware)

  After receiving an interrupt and inspecting USBMODE to determine that a setup packet was received on a particular pipe. perform the following steps:

  — 1. Duplicate contents of dQH.SsetupBuffer into local software byte array.

  — 2. Write 1 to clear corresponding ENDPTSETUPSTAT bit and thereby disable Setup Lockout. (i.e. the Setup Lockout activates as soon as a setup arrives. By writing to the ENDPTSETUPSTAT, the device controller accepts new setup packets.)

  — 3. Process setup packet using local software byte array copy and execute status/handshake phases.

  NOTE

  After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed and deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

  To limit the exposure of setup packets to the setup lockout mechanism (if used), the DCD should designate the priority of responding to setup packets above responding to other packet completions.

- Setup Packet Handling (2.3 hardware and later)

  a) Disable Setup Lockout by writing ‘1’ to Setup Lockout Mode (SLOM) in USBMODE. (once at initialization). Setup lockout is not necessary when using the tripwire as described below. Not that leaving the setup lockout mode as 0 results in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting ENDPTSETUPSTAT to determine that a setup packet was received on a particular pipe:

  a) Write '1' to clear corresponding bit ENDPTSETUPSTAT.

  b) Write ‘1’ to Setup Tripwire (SUTW) in USBCMD register.

c) Duplicate contents of dQH.SetupBuffer into local software byte array.

d) Read Setup TripWire (SUTW) in USBCMD register. (if set - continue; if cleared - goto 2)

e) Clear Setup Tripwire (SUTW) in USBCMD register.

f) Process setup packet using local software byte array copy and execute status/handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the ENDPTPRIME register is zero and the associated bit in the ENDPTSTAT register is a one. If a prime fails, ie. The ENDPTPRIME bit goes to zero and the ENDPTSTAT bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status (ENDPTSTAT) to enforce data coherency with the setup packet.

NOTE

The MULT field in the dQH must be set to “00” for bulk, interrupt, and control endpoints.

Error handling of data phase packets is the same as bulk packets described previously.

Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase. The DCD must also perform the same checks of the ENDPTSETUPSTAT as described above in the data phase.

Note: The MULT field in the dQH must be set to “00” for bulk, interrupt, and control endpoints.

Note: Error handling of data phase packets is the same as bulk packets described previously.

Control Endpoint Bus Response Matrix

Table 60-120 shows the device controller response to packets on a control endpoint according to the device controller state.

Table 60-120. Control Endpoint Bus Response Matrix

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error — Force Bit Stuff Error

NYET/ACK — NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR — System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

60.4.7.3.3 Isochronous Endpoint Operational Model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes. Real time delivery by the device controller will is accomplished by the following:

- Exactly MULT Packets per (micro)Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets and sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro)frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes

the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
  - MULT counter reaches zero.
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT

NOTE

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
  - MULT counter reaches zero.
  - Non-MDATA Data PID is received
    - Exit criteria are only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
  - Overflow Error:
    - Packet received is > maximum packet length. [*Buffer Error* bit is set]
    - Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT
  - CRC Error [*Transaction Error* bit is set

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

Isochronous Pipe Synchronization

When it is necessary to synchronize an isochroous data pipe to the host, the (micro)frame number (FRINDEX register) can be used as a marker. To cause a packet transfer to occur at a specific (micro)frame number [N], the DCD should interrupt on SOF during frame N-1. When the FRINDEX=N–1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro)frame N–1 so that the device controller will execute delivery during (micro)frame N.

CAUTION

Priming an endpoint towards the end of (micro)frame N-1 will not guarantee delivery in (micro)frame N. The delivery may actually occur in (micro)frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

Isochronous Endpoint Bus Response Matrix

Table 60-121 shows the isochronous endpoint bus response matrix.

Table 60-121. Isochronous Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error Force Bit Stuff Error

NULL Packet Zero Length Packet

60.4.7.4 Managing Queue Heads

Figure 60-92 shows the endpoint queue head diagram.

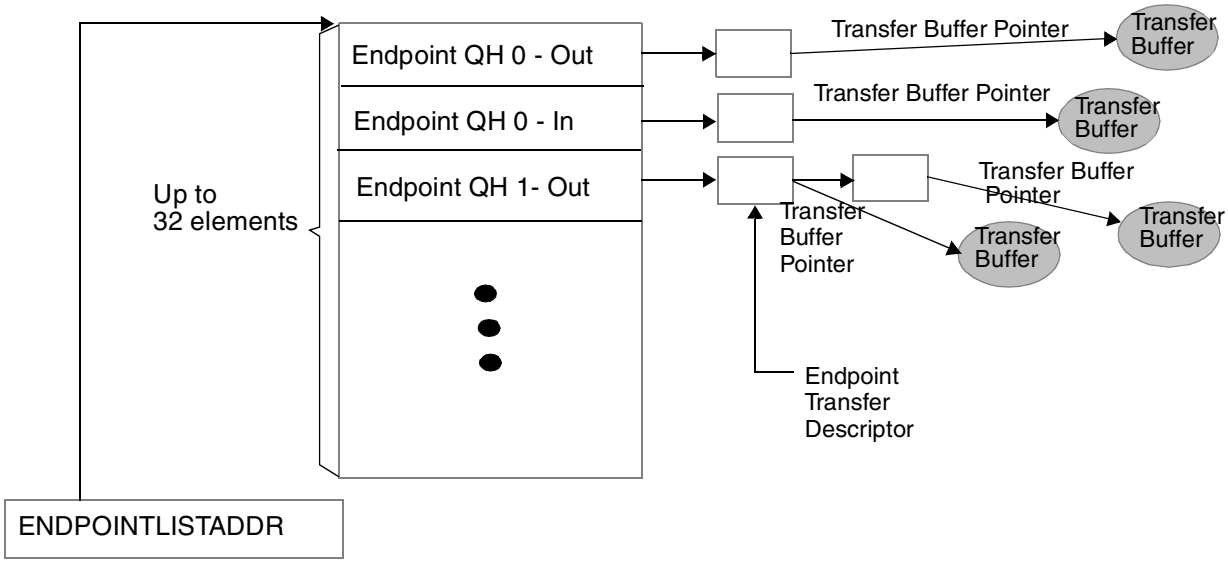

Figure 60-92. Endpoint Queue Head Diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by ENDPOINTLISTADDR contains a group of all dQH's in a sequential list as shown in Figure 60-92. The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors since pointers will no longer exist within the queue head once the dTD is retired (see section Software Link Pointers).

In addition to the current and next pointers and the dTD overlay examined in section Operational Model For Packet Transfers, the dQH also contains the following parameters for the associated endpoint: Multipler, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

60.4.7.4.1 Queue Head Initialization

One pair of device queue heads must be initialized for each active endpoint. To initialize a device queue head, use the following sequence:

1. Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
2. Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1,2, or 3 as required bandwidth an in conjuction with the USB Chapter 9 protocol. *Note: In FS mode, the multiplier field can only be 1 for ISO endpoints.*
3. Write the next dTD Terminate bit field to "1".
4. Write the Active bit in the status field to "0".

5. Write the Halt bit in the status field to “0”.

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTDs.

60.4.7.4.2 Operational Model For Setup Transfers

As discussed in section Control Endpoint Operation Model, setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a “1” to the corresponding bit in ENDPTSETUPSTAT.

NOTE

The acknowledge must occur before continuing to process the setup packet.

After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH – RX. Only the local software copy should be examined.

3. Check for pending data or status dTD’s from previous control transfers and flush if any exist as discussed in section Flushing/De-priming an Endpoint.
4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

60.4.7.5 Managing Transfers with Transfer Descriptors

This section explains how to use transfer descriptors to manage transfers.

60.4.7.5.1 Software Link Pointers

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head. This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in the next section for managing dTD assumes the DCD can use reference the head and tail of the dTD linked list.

Figure 60-93 shows the software link pointers.

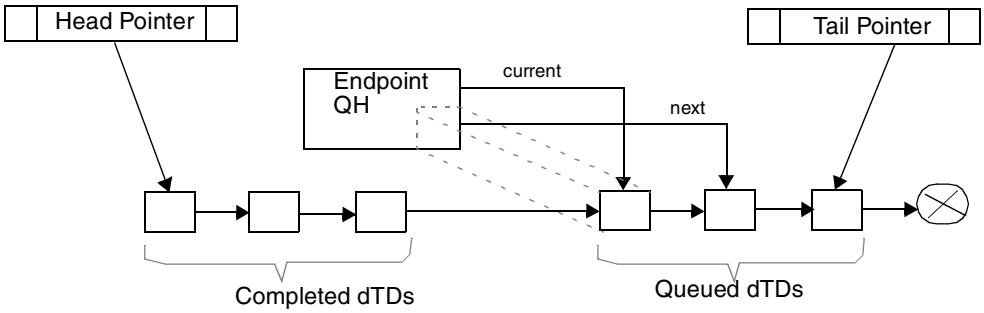

Figure 60-93. Software Link Pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers but it still remains the responsibility of the DCD to maintain the pointers.

60.4.7.5.2 Building a Transfer Descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer. Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to “00000”

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to “1”.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to “1” and all remaining status bits set to “0”.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

60.4.7.5.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must be follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty:

— Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding)

- Case 1: Link list is empty

- 1. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
- 2. Clear active & halt bit in dQH (in case set from a previous error).
- 3. Prime endpoint by writing ‘1’ to correct bit position in ENDPTPRIME.

- Case 2: Link list is not empty
  - 1. Add dTD to end of linked list.
  - 2. Read correct prime bit in ENDPTPRIME – if ‘1’ DONE.
  - 3. Set ATDTW bit in USBCMD register to ‘1’.
  - 4. Read correct tatus bit in ENDPTSTAT. (store in tmp. variable for later)
  - 5. Read ATDTW bit in USBCMD register.
  - If ‘0’ goto 3.
  - If ‘1’ continue to 6.
  - 6. Write ATDTW bit in USBCMD register to ‘0’.
  - 7. If status bit read in (3) is ‘1’ DONE.
  - 8. If status bit read in (3) is ‘0’ then Goto Case 1: Step 1.

60.4.7.5.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

CAUTION

Multiple dTDs can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the Device Error Matrix.

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

60.4.7.5.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to deprime one more endpoint on a USB device reset or during a broken control transfer. There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in ENDPTFLUSH.
2. Wait until all bits in ENDPTFLUSH are '0'.
   - Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read ENDPTSTAT to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
   - Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using ENDPTFLUSH. A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush be repeating steps 1-3 until each endpoint is successfully flushed.

60.4.7.5.6 Device Error Matrix

Table 60-122 summarizes packet errors that are not automatically handled by the Device Controller.

Table 60-122. Device Error Matrix

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated.

Table 60-123 shows the error descriptions.

Table 60-123. Error Descriptions

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length. This error also sets the halt bit in the dQH. If there are dTDs remaining in the linked list for the endpoint, those will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Hst failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

60.4.7.6 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

60.4.7.6.1 High-Frequency Interrupts

High-frequency interrupts in particular should be handed in the order shown in Table 60-124. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

Table 60-124. High-Frequency Interrupt Events

Execution Order	Interrupt	Action
1a	USB Interrupt[1]—**ENDPTSETUPSTATUS**	Copy contents of setup buffer and acknowledge setup packet (as indicated in section). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt[1]—**ENDPTCOMPLETE**	Handle completion of dTD as indicated in section .
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

[1] It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

60.4.7.6.2 Low-Frequency Interrupts

The low frequency events can be handled in any order because they do not occur often in comparison to the high-frequency interrupts. Table 60-125 shows the low-frequency interrupt events.

Table 60-125. Low Frequency Interrupt Events

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

60.4.7.6.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine. Table 60-126 shows the error interrupt events.

Table 60-126. Error Interrupt Events

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines **USB Interrupt** and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of **USB Interrupt (w/ ENDPTCOMPLETE).**
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

Chapter 61
Video Processing Unit (VPU)

61.1 Introduction

The video processing unit (VPU) is the multimedia video processing module in the i.MX51. Figure 61-1 shows the VPU top-level diagram.

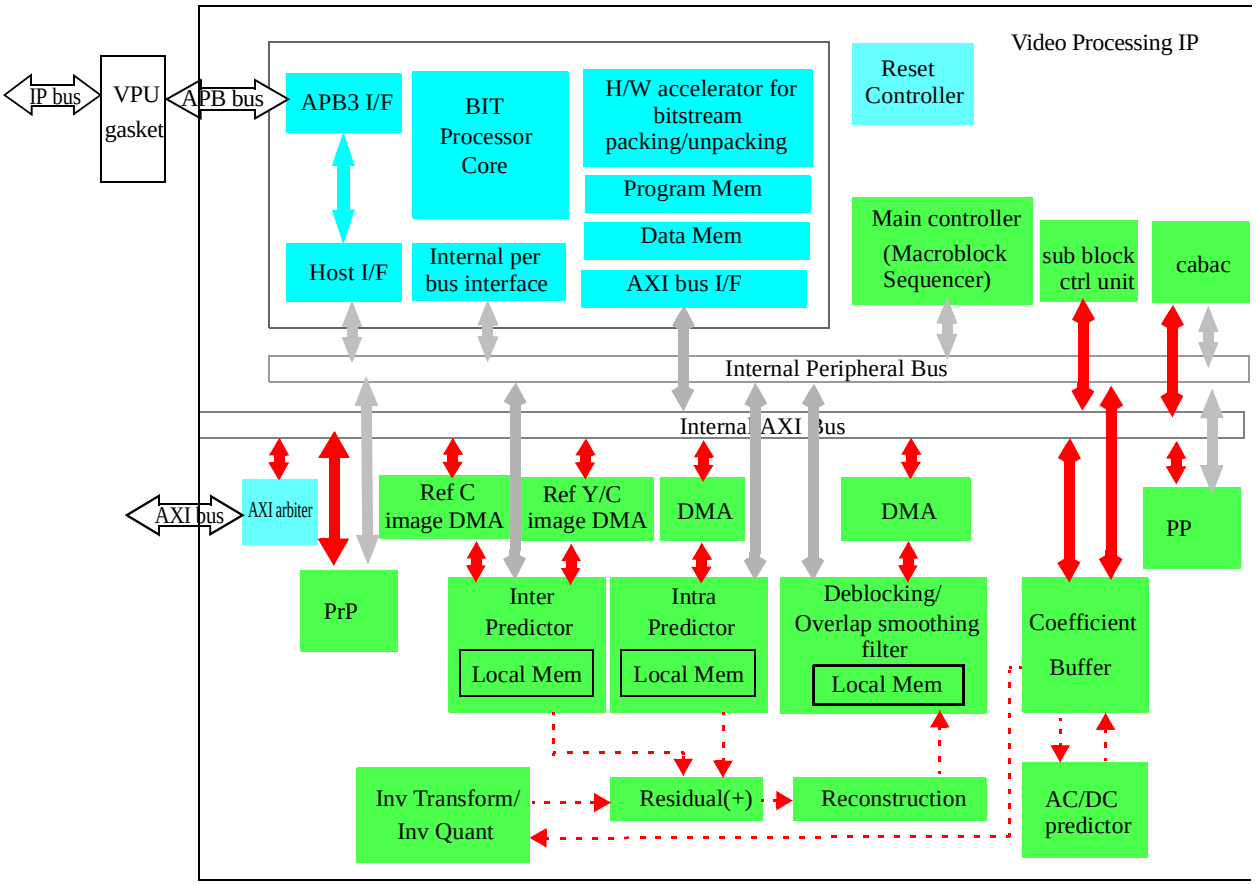

Figure 61-1. VPU Block Diagram

61.1.1 Overview

The video processing unit of the i.MX51 is a high performance, multistandard video processing unit that can perform H.264 BP/MP/HP, VC-1 SP/MP/AP, MPEG4 SP/ASP, Divx, RV8/9, and MPEG2 MP decoding up to 1920 × 1088 resolution. It supports multiple video codecs simultaneously.

The VPU has two bus interfaces: IP bus for register access controlling and AXI bus for data throughput. It makes use of external memory space for working buffer, frame buffer, parameter buffer, BIT processor program buffer and bitstream buffer. The VPU has 51 Kbyte internal memories to achieve high performance decoding.

The VPU's embedded BIT processor controls internal video processing subblocks and communicates with the host processor through host interface. The host CPU has a very low resource requirement for VPU support: it only needs to access VPU registers to initialize the VPU or to set parameters during frame gap. Applications are done through a VPU API called by host processor. A large part of the video codec (except BIT processor) is shared optimally, which achieves low power and a low gate count.

In combination with the processing capabilities of the image processing unit (IPU), the VPU can support high-quality video processing applications for the i.MX51.

61.1.2 Features

The main features of VPU are fully compliant with H.264 BP/MP/HP, VC-1 SP/MP/AP, MPEG-4 SP/ASP except GMC, Divx (Xvid), MPEG-1/2, and RV-8/9/10. The image size up to 1080p (1920 × 1088) is supported in decoding and SD (720 × 576) is supported for encoding. The VPU can support various error resilience tools and also supports multiple decoding and full duplex multi-party-call simultaneously.

The VPU is easy to integrate into the system because its interface is composed of general and simple AXI/APB. The VPU provides programmability, flexibility and ease of upgrading decoding/encoding or host interface because all the controls in decoding/encoding process and host interface are implemented as firmware in a programmable BIT processor.

Note that the capabilities of VPU are also depends on the system. For example, in the i.MX51, the maximum resolution of decoder should be 720p for all standards except MJPEG. This is mainly because of the busloading of the system.

Figure 61-2 shows a feature summary.

	Standard	Profile	Level	Resolution
Encoder	H.264	Baseline	3.0	720x576
	MPEG-4	SP		720x576
	H.263	Profile 3		720x576
	MJPEG	Baseline		8192x8192
Decoder	H.264	BP/MP/HP	4.0	1920x1088
	MPEG-4	ASP		1280x720
	H.263	Profile 3		1280x720
	VC-1	SP/MP/AP		1920x1088
	MPEG-2	Main	High	1920x1088
	Divx(Xvid)	Home theater		800x600
	RV	8/9/10		1920x1088
	MJPEG	Baseline		8192x8192

Figure 61-2. Feature Summary

The detailed features of the VPU are as follows:

- Multi-standard video codec
  - H.264/AVC decoder for baseline profile, main profile and high profile
  - VC-1 decoder for simple profile, main profile and advanced profile
  - MPEG-4 decoder for simple profile, advanced simple profile except GMC
  - H.263 decoder for baseline profile
  - Divx home theater decoder for profile (version 3.x, 4.x, 5.x, 6.x) and Xvid
  - MPEG-2 decoder for main profile @ high level
  - RV decoder for profile 8/9/10
  - H.264/AVC encoder for baseline profile
  - MPEG-4 encoder for simple profile
  - H.263 encoder for baseline profile
  - MJPEG encoder for baseline profile
  - Multiple codec: supports up to 4 decoding/encoding processes simultaneously, each process can have a different format.
- Other features
  - Supports rotating and mirroring simultaneously.
  - Built-in de-ringing filter.
  - Built-in de-blocking filter for MPEG-2/MPEG-4/Divx.
  - Simultaneous multi-stream and multi-standard processing capability.
  - Robust error detection/concelmenet.

- Programmability
  - Embeds 16-bit BIT processor that is dedicated to processing bitstream and controlling the hardware.
  - General purpose registers and interrupt generation for communication between host processor and VPU.

61.1.3 Modes of Operation

The VPU has two kinds of operating modes: normal operating mode and low power mode.

61.1.3.1 Normal Operating Mode

Normal operating mode is the video codec processing mode, which might be MPEG-4 encoding/decoding, Divx decoding, H.264 encoding/decoding, VC-1 decoding, or multiple bitstream encoding/decoding in multiple standards simultaneously. The host processor create and execute specified process by sending parameters and commands to the BIT processor through VPU API.

61.1.3.2 Low Power Mode

When VPU is in idle state, VPU interface signal vpu_busy is de-asserted and system can gate off its clock source according to this signal. If the clock source is gated off and system wants to wake it up, it reenables the clock and sends a command to VPU. If power is off when the system wants to wake it up, VPU has to be re-initialized. Refer to Section 61.2.1, Detailed Signal Descriptions," for a detailed description of the vpu_busy signal.

61.2 External Signal Description

The VPU has no external signals connecting off-chip. Table 61-1 lists the interface signals of VPU.

Table 61-1. Signal Interface List

Name	Function	Type	Reset	Comment
IP green-line clock and reset				
ipg_clk_s	IP green-line gated clock for the bus interface	input	—	—
ipg_hard_pos_async_reset_b	IP green-line hardware asynchronous reset	input	—	Active low
IP bus signals				
ips_addr[11:0]	IP bus address	input	—	—
ips_module_en	IP bus VPU module enable	input	—	Active high
ips_rwb	IP bus read/write (read if 1'b1)	input	—	—
ips_wdata[31:0]	IP bus write data	input	—	—
ips_rdata[31:0]	IP bus read data	output	32'h0	—
ips_xfr_err	IP bus transfer error	output	1'b0	Active high

Table 61-1. Signal Interface List (continued)

Name	Function	Type	Reset	Comment
ips_xfr_wait	IP bus transfer wait	output	1'b0	Active high
AXI signals - clock and reset				
aclk	AXI bus clock	input	—	—
areset_b	AXI bus reset signal	input	—	Active low
AXI first write address channel Interface				
o_pri_awid [3:0]	AXI write address ID	output	4'h0	—
o_pri_awaddr [31:0]	AXI write address	output	32'h0	—
o_pri_awlen [3:0]	AXI write burst length	output	4'h0	—
o_pri_awsize [2:0]	AXI write burst size	output	3'b011	always be 3'b011
o_pri_awburst [1:0]	AXI write burst type	output	2'b01	always be 2'b01
o_pri_awlock [1:0]	AXI write lock type	output	2'b00	always be 2'b00
o_pri_awcache [3:0]	AXI write cache type	output	4'h0	always be 4'h0
o_pri_awprot [2:0]	AXI write protection type	output	3'b010	always be 3'b010
o_pri_awvalid	AXI write address valid	output	1'b1	—
oi_pri_awready	AXI write address ready	input	—	—
AXI first write data channel Interface				
o_pri_wid [3:0]	AXI write data ID	output	4'h0	—
o_pri_wdata [63:0]	AXI write data	output	64'h0	—
o_pri_wstrb [7:0]	AXI write data stobes	output	8'hff	always be 8'hff
o_pri_wlast	AXI write last data	output	1'b0	—
o_pri_wvalid	AXI write data valid	output	1'b1	—
i_pri_wready	AXI write data ready	input	—	—
AXI first write response channel Interface				
i_pri_bid [3:0]	AXI write response ID	input	—	—
i_pri_bresp [1:0]	AXI write response	input	—	—
i_pri_bvalid	AXI write response valid	input	—	—
o_pri_bready	AXI write response ready	output	1'b1	—
AXI first read address channel Interface				
o_pri_arid [3:0]	AXI read address ID	output	4'h0	—
o_pri_araddr [31:0]	AXI read address	output	32'h0	—
o_pri_arlen [3:0]	AXI read burst length	output	4'h0	—
o_pri_arsize [2:0]	AXI read burst size	output	3'b011	always be 3'b011
o_pri_arburst [1:0]	AXI read burst type	output	2'b01	always be 2'b01

Table 61-1. Signal Interface List (continued)

Name	Function	Type	Reset	Comment
o_pri_arlock [1:0]	AXI read lock type	output	2'b00	always be 2'b00
o_pri_arcache [3:0]	AXI read cache type	output	4'h0	always be 4'h0
o_pri_arprot [2:0]	AXI read protection type	output	3'b010	always be 3'b010
o_pri_arvalid	AXI read address valid	output	1'b1	—
i_pri_arready	AXI read address ready	input	—	—
AXI first read data channel Interface				
i_pri_rid [3:0]	AXI read data ID	input	—	—
i_pri_rdata [63:0]	AXI read data	input	—	—
i_pri_rresp[1:0]	AXI read data response	input	—	—
i_pri_rlast	AXI read last data	input	—	—
i_pri_rvalid	AXI read data valid	input	—	—
o_pri_rready	AXI read data ready	output	1'b1	always be 1'b1
VPU core clock				
cclk	VPU core clock	input	—	—
creset_n	VPU core reset	input	—	—
IP Indigo Line IF				
ipi_int_vpu	signal to interrupt controller	output	1'b0	active high
Other control signal				
rclk	VPU reference clock	input	—	—
rreset_n	VPU reference reset	input	—	—
vpu_idle	VPU idle state signal	output	1'b1	—
vpu_underrun	VPU under running signal	output	1'b0	—

61.2.1 Detailed Signal Descriptions

All VPU input clock and reset sources come from the i.MX51 CCM module. The VPU does not do clock gating internally.

VPU uses one 64-bit AMBA3 AXI bus interface for data transfer from/to external memory. The VPU gasket module is responsible for transferring AMBA APB bus to IPS bus protocol.

The interrupt signal ipi_int_vpu is VPU module interrupt signal, active high. When VPU interrupt is enabled in system, its corresponding interrupt service routine is called when ipi_int_vpu signal raised. This signal is retained until host processor clear it. This signal is synchronized to the positive edge of the aclk.

The vpu_idle signal is used for VPU Clock gating control, active high. It indicates whether VPU is busy or idle. If vpu_idle is high, VPU is not running and the system can cut off the clock source. If VPU clock is off, wake up the VPU by turning on the clock and running the VPU through BIT processor command.

61.3 Memory Map and Register Definition

VPU registers are all 32-bit wide, and only support 32-bit aligned read/write operation. VPU registers are grouped into several regions corresponding to different decoding process step. They are used for decoding process configuration and control. They can only be accessed through IP bus interface.

61.3.1 Memory Map

Please note that there are some undefined address space in VPU memory map, any read/write accessing to this register address space is ignored in the VPU. Read accessing to write only register returns ZERO value. Write accessing to read only register is ignored.

The BIT processor registers' memory map in VPU is 0xBASE+0x0000~0xBASE+0x01D0. The BIT processor registers are divided into two categories.

- Address 0xBASE+0x0000~0xBASE+0x00FC (64 registers address space) are hardware registers. These registers have reset values and their functions are fixed (not configurable).
- Address 0xBASE+0x0100~0xBASE+0x01FC (64 registers address space) are software registers. They have no reset values and can be configured by internal BIT processor. Their definitions may change for different firmware version, so they are not provided here. This type of registers can be used as general parameter registers between host processor and BIT processor.
  - The first 32 parameter registers (address 0xBASE+0x0100~0xBASE+0x017C) are used as static parameters. Definition and functions of those registers are same for all kinds of run commands.
  - The second 32 parameter registers (address 0xBASE+0x0180~0xBASE+0x01DC) are used as temporal parameters. The definition and functions of those registers may differ in different run commands.

The memory map for the hardware registers of VPU is shown in Table 61-2.

Table 61-2. VPU Hardware Register Memory Map

Address	Register	Access	Reset Value	Section/Page
General Registers				
0xBASE+0x0000 (CodeRun)	BIT Processor run start	W	0x0000_0000	61.3.3.1/61-10
0xBASE+0x0004 (CodeDown)	BIT Boot Code Download Data register	W	0x0000_0000	61.3.3.2/61-10
0xBASE+0x0008 (HostIntReq)	Host Interrupt Request to BIT	W	0x0000_0000	61.3.3.3/61-11
0xBASE+0x000C (BitIntClear)	BIT Interrupt Clear	W	0x0000_0000	61.3.3.4/61-11
0xBASE+0x0010 (BitIntSts)	BIT Interrupt Status	R	0x0000_0000	**61.3.3.5/61-12**
0xBASE+0x0014 (BitCodeReset)	BIT Code Reset	W	0x0000_0000	**61.3.3.6/61-12**
0xBASE+0x0018 (BitCurPc)	BIT Current PC	R	0x0000_0000	**61.3.3.7/61-13**

Table 61-2. VPU Hardware Register Memory Map (continued)

Address	Register	Access	Reset Value	Section/Page
0xBASE_0020 (BitCodecBusy)	BIT CODEC Busy	R/W	0x0000_0000	61.3.3.8/61-13
0xBASE+0x001C ~ 0xBASE+0x00FC	Reserved	—	—	—

Please refer to the VPU API document for descriptions on software registers access.

61.3.2 Register Summary

The conventions in Figure 61-3 and Figure 61-3 serve as a key for the register summary and individual register diagrams.

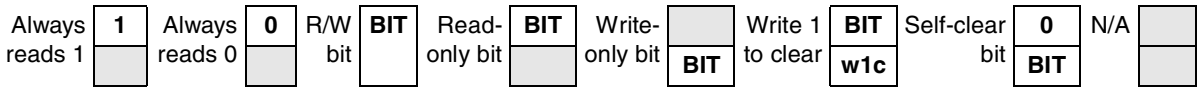

Figure 61-3. Key to Register Fields

Table 61-3 provides a key for register figures and tables and the register summary.

Table 61-3. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

The brief VPU hardware register summary is shown in Table 61-4.

Table 61-4. VPU Hardware Register Summary

Name		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

61.3.3 Register Descriptions

This section consists of VPU hardware register descriptions in address order. Each description includes a standard register diagram. A table containing the register bit and field function follows the register diagrams.

61.3.3.1 VPU Code Run Register (CodeRun)

See Figure 61-4 for illustration of valid bits in VPU Code Run Register and Table 61-5 for description of the bit fields in the register.

Address 0xBASE+0x0000 (CodeRun)

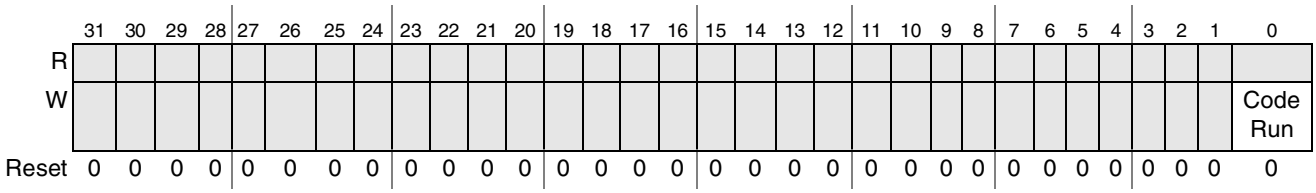

Figure 61-4. VPU Code Run Register

Table 61-5. VPU Code Run Register Field Descriptions

Field	Description
31–1	Reserved
0	CodeRun. BIT processor run start bit. 0 BIT Processor stop execution. 1 BIT Processor start execution.

61.3.3.2 VPU BIT Boot Code Download Data Register (CodeDown)

See Figure 61-5 for illustration of valid bits in VPU BIT Boot Code Download Data Register and Table 61-6 for description of the bit fields in the register.

Address 0xBASE+0x0004 (CodeDown)

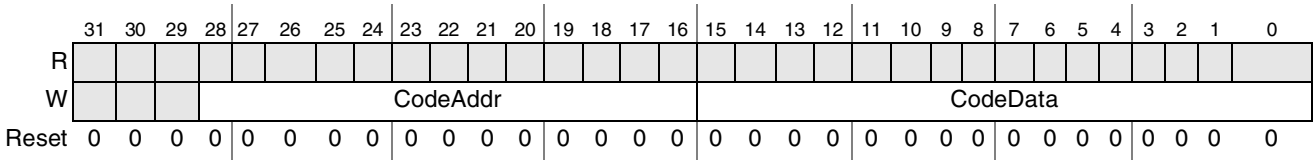

Figure 61-5. VPU BIT Boot Code Download Data Register

Table 61-6. VPU BIT Boot Code Download Data Register Field Descriptions

Field	Description
31–29	Reserved

Table 61-6. VPU BIT Boot Code Download Data Register Field Descriptions (continued)

Field	Description
28–16	CodeAddr[12:0] Download address of VPU BIT boot code, which is VPU internal address of BIT processor.
15–0	CodeData[15:0] Download data of VPU BIT boot code.

61.3.3.3 VPU Host Interrupt Request Register (HostIntReq)

See Figure 61-6 for illustration of valid bits in VPU Host Interrupt Request Register and Table 61-7 for description of the bit fields in the register.

Address 0xBASE+0x0008 (HostIntReq)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																IntReq
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 61-6. VPU Host Interrupt Request Register

Table 61-7. VPU Host Interrupt Request Register Field Descriptions

Field	Description
31–1	Reserved
0	IntReq. The host interrupt request bit. 0 No host interrupt is requested. 1 The host processor request interrupt to the BIT processor.

61.3.3.4 VPU BIT Interrupt Clear Register (BitIntClear)

See Figure 61-7 for illustration of valid bits in VPU BIT Interrupt Clear Register and Table 61-8 for description of the bit fields in the register.

Address 0xBASE+0x000C (BitIntClear)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																IntClear
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 61-7. VPU BIT Interrupt Clear Register

Table 61-8. VPU BIT Interrupt Clear Register Field Descriptions

Field	Description
31–1	Reserved
0	IntClear. BIT interrupt clear bit. 0 No operation is issued. 1 Clear the BIT interrupt to the host.

61.3.3.5 VPU BIT Interrupt Status Register (BitIntSts)

See Figure 61-8 for illustration of valid bits in VPU BIT Interrupt Status Register and Table 61-9 for description of the bit fields in the register.

Address 0xBASE+0x0010 (BitIntSts)

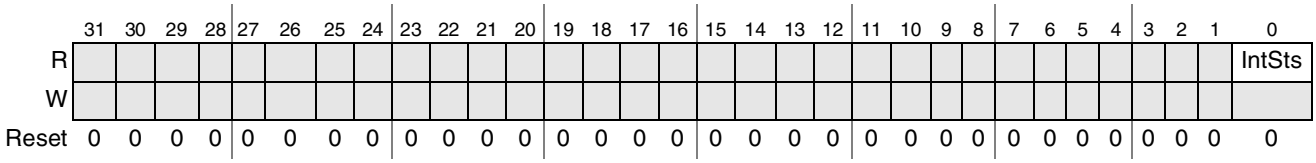

Figure 61-8. VPU BIT Interrupt Status Register

Table 61-9. VPU BIT Interrupt Status Register Field Descriptions

Field	Description
31–1	Reserved
0	IntSts. BIT interrupt status bit. 0 No BIT interrupt is asserted. 1 The BIT interrupt is asserted to the host. It is cleared when the host processor write “1” to BitIntClear register.

61.3.3.6 VPU BIT Code Reset Register (BitCodeReset)

See Figure 61-9 for illustration of valid bits in VPU BIT Code Reset Register and Table 61-10 for description of the bit fields in the register.

Address 0xBASE+0x0014 (BitCodeReset)

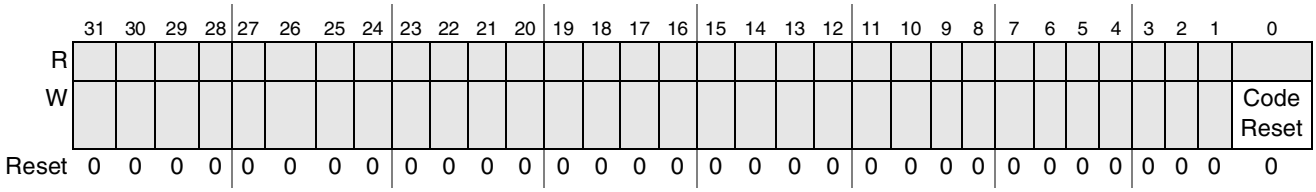

Figure 61-9. VPU BIT Code Reset Register

Table 61-10. VPU BIT Code Reset Register Field Descriptions

Field	Description
31–1	Reserved
0	CodeReset. BIT code reset bit. 0 No operation is issued. 1 The program counter of BIT processor is set to “0”, BIT processor restart at initial routine.

61.3.3.7 VPU BIT Current PC Register (BitCurPc)

See Figure 61-10 for illustration of valid bits in VPU BIT Current PC Register and Table 61-11 for description of the bit fields in the register.

Address 0xBASE+0x0018 (BitCurPc)

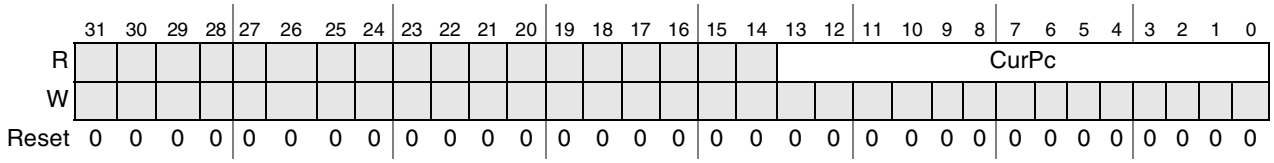

Figure 61-10. VPU BIT Current PC Register

Table 61-11. VPU BIT Current PC Register Field Descriptions

Field	Description
31–14	Reserved
13–0	CurPc[13:0]. BIT current PC value. Returns the current program counter of BIT processor by reading this register.

61.3.3.8 VPU BIT Busy Register (BitCodecBusy)

See Figure 61-10 for illustration of valid bits in VPU BIT Codec Busy Register and Table 61-11 for description of the bit fields in the register

Address 0xBASE+0x0020 (BitCodecBusy)

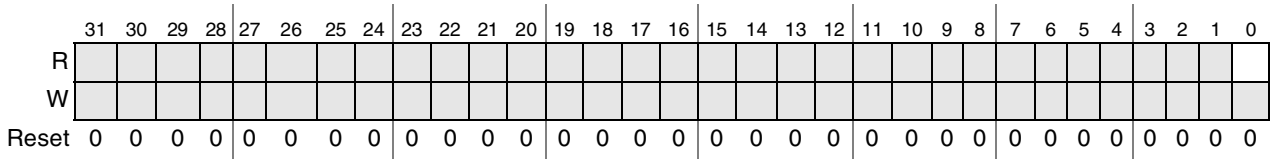

Figure 61-11. VPU BIT Busy Flag Register

Table 61-12.

field	Description
31–1	Reserved
0	Codec busy flag for Bit processor. BIT processor write “1”to this register when the processor is running.”0”means processor is waiting for a command. This value is connected to the o_vpu_idle.

61.4 Functional Description

VPU is a high-performance, multistandard video processing module in the i.MX51 that supports H.264 BP/MP/HP, VC-1 SP/MP/AP, MPEG4 SP/ASP, Divx and MPEG2 MP decoding up to 1920 × 1088 resolution.

61.4.1 VPU Architecture

The VPU is a high performance multi-standard video codec IP that can perform the H.264 BP/MP/HP, VC-1 SP/MP/AP, MPEG-4 SP/ASP, Divx, MPEG-1/2, RV-8/9/10, and MJPEG decoding and encoding. The VPU supports up to HD (1920 × 1088) decoding and SD (720 × 576) encoding. It can encode or decode multiple video clips with multiple standards simultaneously.

It connects with the system via the 32-bit AMBA 3 APB bus for system control and 64-bit AMBA3 AXI for data throughput, and takes advantage of on-chip memories to achieve high performance. The CodaHx14 has a 16-bit DSP, called as BIT processor. The BIT processor controls the internal video codec sub blocks and communicates with a host processor through the host interface. The required resource for the host CPU to control the VPU is very low, under 1 MIPS, because all functions such as rate control, FMO, ASO, video codec control, and error resilience are implemented in the BIT processor. The majority of the subblocks in the CodaHx14 is optimally shared, which achieves the ultra low power and low gate count.

VPU mainly includes two components: Video CODEC Processing IP and VPU gasket. Video CODEC Processing IP is the heart of the VPU. It is responsible for encoding/decoding. It mainly consists of an embedded 16-bit BIT processor, video codec hardware, and bus arbiter/interface. VPU gasket is in charge of converting AMBA APB3 bus to IP bus. Refer to Figure 61-1 for the block diagram of VPU. The following sections describe the main function of Video CODEC Processing IP components.

61.4.1.1 Embedded BIT processor

The embedded BIT processor is used for parsing or forming bitstreams. It includes some hardware accelerators to speed up bitstream processing. In addition to handling bitstreams, the BIT processor controls the video decoding hardware and communicates with host processor through IP bus and AXI bus interface.

61.4.1.2 Video CODEC Hardware

All video decoding processing, except handling coefficients for VLD, are implemented in hardware. The video codec hardware is designed to reduce logic gate count by sharing parts of sub-modules for multi-standard video decoding. It mainly includes the following hardware components.

61.4.1.2.1 Inter-Predictor

The Inter-Predictor module uses a reconstructed motion vector that represents the displacement between the block currently being decoded and the corresponding location in the reference frame, to calculate interpolated pixel data for motion compensation.

61.4.1.2.2 AC/DC and Intra-Predictor

There are two intra-prediction modules in the video decoding hardware. One is for the MPEG-4/H.263 P3/VC-1 AC/DC prediction and another for the H.264 intra-prediction. In case of VC-1 decoding, the hardware prediction mode decision is used. It brings high performance and low power consumption. The coefficient data of decoding is re-ordered automatically based on the detected prediction mode. For H.264 intra-prediction mode in decoding, hardware mode decision or software based made decision is used.

61.4.1.2.3 Inverse Transform/inverse Quantization

VPU has only one transform/quantization module. It operates in several types of inverse transform/quantization for MPEG-2, VC-1 and H.264. Each inverse transform/quantization for decoding uses different coefficients and different data processes, but it uses same control and data flow in many cases.

61.4.1.2.4 De-blocking/Overlap-Smoothing Filter

Deblocking filter removes blocking artifacts resulting from quantization and different motion vectors. The filter processing supports H.264 and VC-1, and operates within coding loop. Filtered frames are used as reference frames for motion compensation of subsequent coded frames. Overlap-smoothing filter supports VC-1 overlap-smoothing feature, and processed before deblocking filter. For H.264, H263 and VC-1, the de-blocking filter operates within decoding loop. Filtered frames are used as reference frames for motion compensation of subsequent coded frames.

61.4.1.2.5 Coefficient buffer interface

Coefficient buffer interface provides a channel for the BIT processor to send variable-length-decoded coefficients to video decoding hardware for decoding process. The coefficient buffer interface also performs reordering of coefficients based on the scan type.

61.4.1.2.6 Macroblock controller

VPU video decoding processing has a complex and large number of pipelines for high-performance. It’s not suitable to manage it wholly by the BIT processor. The macroblock controller is to control all sub modules of the video decoding hardware based on the configuration of pipelining by the BIT processor. The pipeline structure may change for different firmware running on the BIT processor. This scheme reduces the load on the BIT processor and guarantees the programmability of the IP.

Before decoding a macroblock, the BIT processor configures how the pipeline of the decoding is structured. If all processes are completed for decoding a macroblock, the macroblock controller indicates its completion. In summarization, the BIT processor configures which sub-modules are enabled for current macroblock processing, and the macroblock controller manages corresponding sub-modules based on the pipelining configuration.

Figure 61-12 shows the connectivity of macroblock controller.

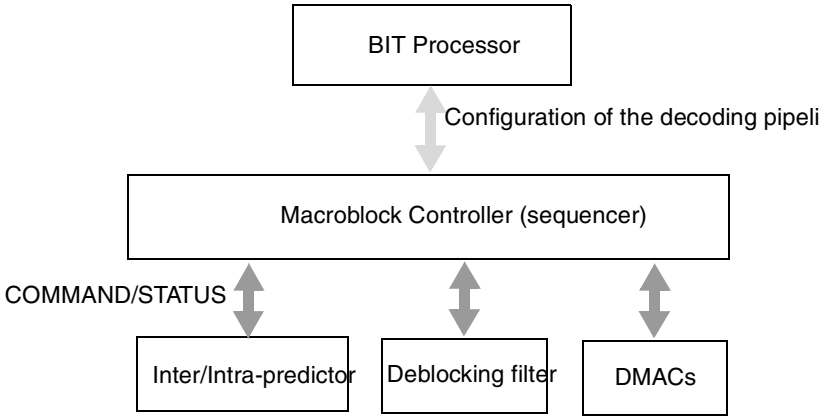

Figure 61-12. Connectivity of Macroblock Controller

61.4.1.2.7 Rotation/Mirroring

VPU supports rotation together with mirroring function for decoding output image to display. It is done by rotator/mirror module. The rotation/mirroring process in decoding process requires additional bandwidth because VPU has to re-use the un-rotated image for decoding the next image. So the rotated image is written to other memory space. In this scheme, the display I/F has not to change memory space for displaying the decoded image because subsequent rotated image is written to the same space. The rotator modules support 8-types mode of 90 × n degree(n = 0, 1, 2, 3) rotating and mirroring.

Figure 61-13 gives architecture diagram of post rotation/mirroring module.

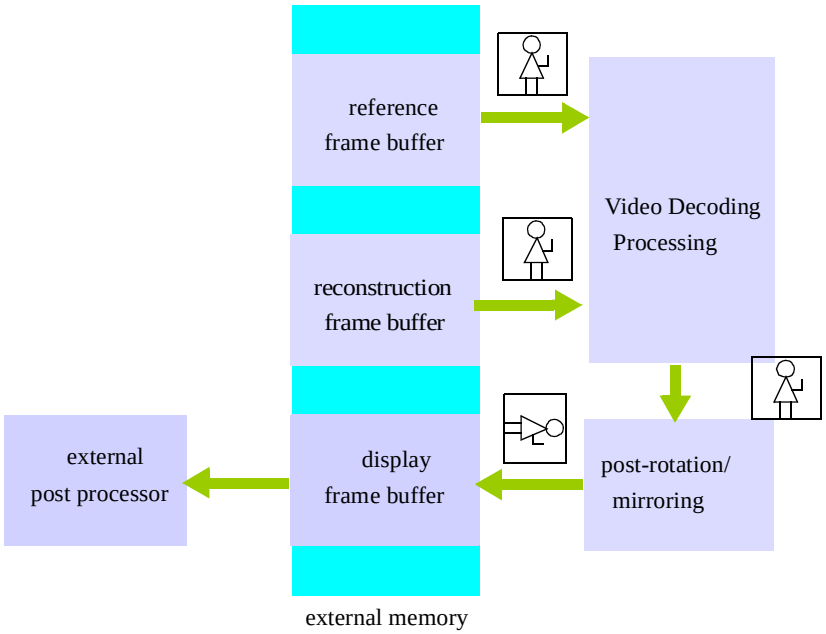

Figure 61-13. Post Rotation/Mirroring

61.4.2 Clocks

There are four clock domains in VPU, as follows.

- AXI bus clock domain (aclk)
  - Controls all AXI bus related functions
  - Maximum frequency is 166 MHz
  - Derives from the same clock as other modules performing AXI bus access in the i.MX51
  - Frequency determined by the whole system performance requirement.
- Decoding core clock domain (cclk)
  - VPU functional clock
  - Controls all VPU decoding functionality, with a maximum frequency of 166 MHz
  - Actual value of the core clock dependent upon maximum use case
  - Clock frequency scaling done through the VPU API
- IP bus clock domain (ipg_clk_s)
  - Controls VPU registers read/write function, with a maximum frequency of 66.5 MHz
  - Gated clock of IP green-line clock (ipg_clk) with ips_module_en
  - Turned off for power saving when there are no registers read/write
- Reference clock domain (rclk)—Used as reference clock for vpu_idle related logic.

VPU has all four clock domains because it involves in AXI signal generation, functional calculation, IP bus configuration, vpu_idle control logic. Only positive edge clocks are used in VPU design. Each clock is fully asynchronous with other clocks and separated from other clocks.

All clocks can be gated off when VPU is in the idle state to reduce power consumption. Aclk and cclk can be chosen by external system environment ad there is no restriction about the value of aclk and cclk. The actual frequency of aclk and cclk affects bus bandwidth and video decoding processing capability.

61.4.3 Reset

There are four reset signals going into VPU module, corresponding to four clock domains, active low.

- areset_n: used in AXI bus interface. Corresponding clock is aclk.
- creset_n: used in BIT processor and video decoder. Corresponding clock is cclk.
- ipg_hard_pos_async_reset_b: used in IP bus interface. Corresponding clock is ipg_clk_s.
- rreset_n: used in reference counter for vpu_idle or vpu_underrun. Corresponding clock is rclk.

The number of cycles for each reset signal must be at least 8 cycles.

VPU embeds an internal reset controller for feature of the software reset from the BIT processor. If any of the VPU blocks, with the exception of the BIT processor is needed to reset (software reset), the host processor can enable this software reset by setting the software reset register through VPU API. Besides, the BIT processor cannot be reset by this software reset scheme, because the reset signal of the BIT processor is connected directly to external reset signal.

If reset fires when VPU is processing a transaction through the AXI bus, there is no guarantee that the AHB will complete the transaction normally, since VPU will be reset. If there are any corrupted data in memory, it can be discarded by software. Basically, if the host processor needs to issue a reset, it must check that there is no transaction on AHB bus between the VPU and external AHB bus interface. In general, the AHB bus is free of VPU transactions when one frame decoding is completed. The start of next frame processing need software configuration.

61.4.4 Interrupts

There is one interrupt signal output from VPU. Basically, this interrupt is used to indicate completion of decoding one frame. It is generated when VPU interrupt is enabled and as well as the interrupt condition is met. The interrupt signal is active high and retains until the host processor clears it by writing “1” to the interrupt clear register. This signal is synchronized to the positive edge of aclk.

When getting frame completion interrupt, the software need to set the parameters for next frame processing and start the BIT processor again. The parameters are mainly the source/destination frame buffer base address. It can be different from the previous frame buffer since the previous completed frame of data may be needed for other image block like display block or IPU in the system.

Basically, the following operation responding to interrupt is dependent upon the application. For example, the software can send the decoded frame to the Image Processing Unit for post-processing and display, at the same time the software should prepare the next stream to be processed to the external memory before starting a new processing. This can be done through VPU driver.

61.4.5 Endianness

VPU supports both little- and big-endian memory systems. User should specify the endianness of the bitstream buffer and frame buffer corresponding to the application scenario. The endianness configuration can be done through VPU API.

61.5 Initialization Information

VPU embedded BIT processor is highly optimized to handle bitstream data. In addition to processing bitstreams, the BIT processor also controls the communication between VPU and host processor.

The BIT processor firmware to drive video decoding is divided into 2 parts.

One is boot code, which is downloaded by host processor through the IP bus to BIT processor internal memory, it’s loaded only once at the VPU initialization stage. The size of the boot code is 1 KB . This boot code has also to be written to a region of external memory, and the base address of the firmware region is written through VPU API.

The other is a package of firmware for driving decoding processing. Before starting decoding, firmware has to be written to the continuous region of external memory following the boot code. At run-time, the BIT processor will self download firmware into internal memory corresponding to the activated decoding standard, it’s loaded through the AXI bus.

The VPU initialization process is shown in Figure 61-14.

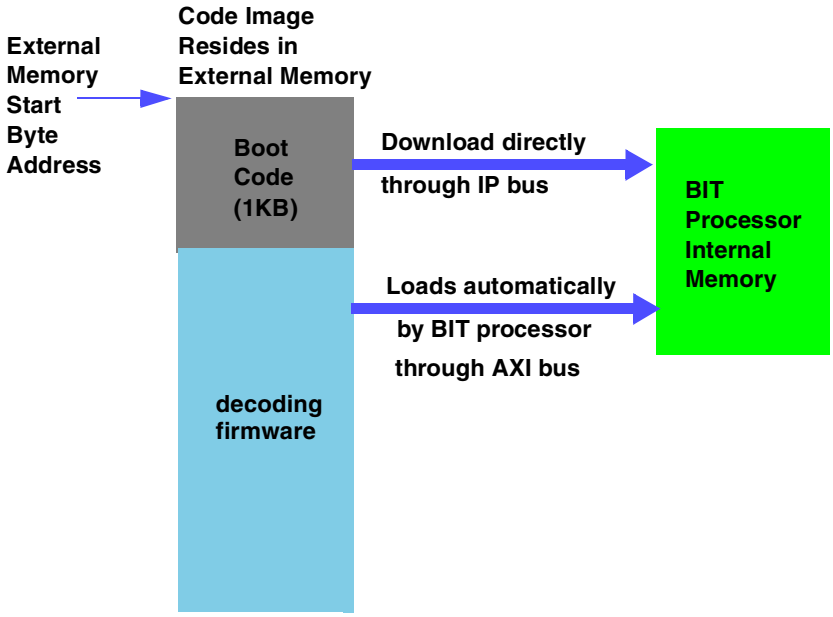

Figure 61-14. VPU Initialization Process

61.6 Application Information

Figure 61-15 shows roles of the BIT processor and VPU video processing core module and how to interface with application software. Basically, at the frame level, host processor communicates with VPU through the provided API's. To give the video decoding more flexibility and debugging capability, all processes related to the bitstream are assigned to the BIT processor.

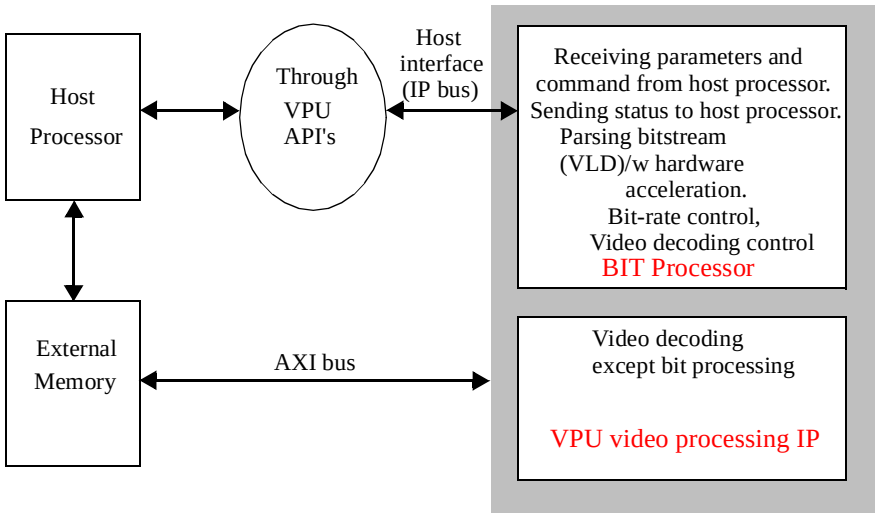

Figure 61-15. VPU interface with Application Software Diagram

61.6.1 Video Decoding Processing Control

This section describes how BIT processor controls the video decoding and communicates with the host.

61.6.1.1 Video Decoding Process Flow

VPU can handle a maximum of 4 processes simultaneously. Each process can have a different format - MPEG-4, MPEG-2, H.264 or VC-1. Figure 61-16 shows a simplified state diagram for running decoding process.

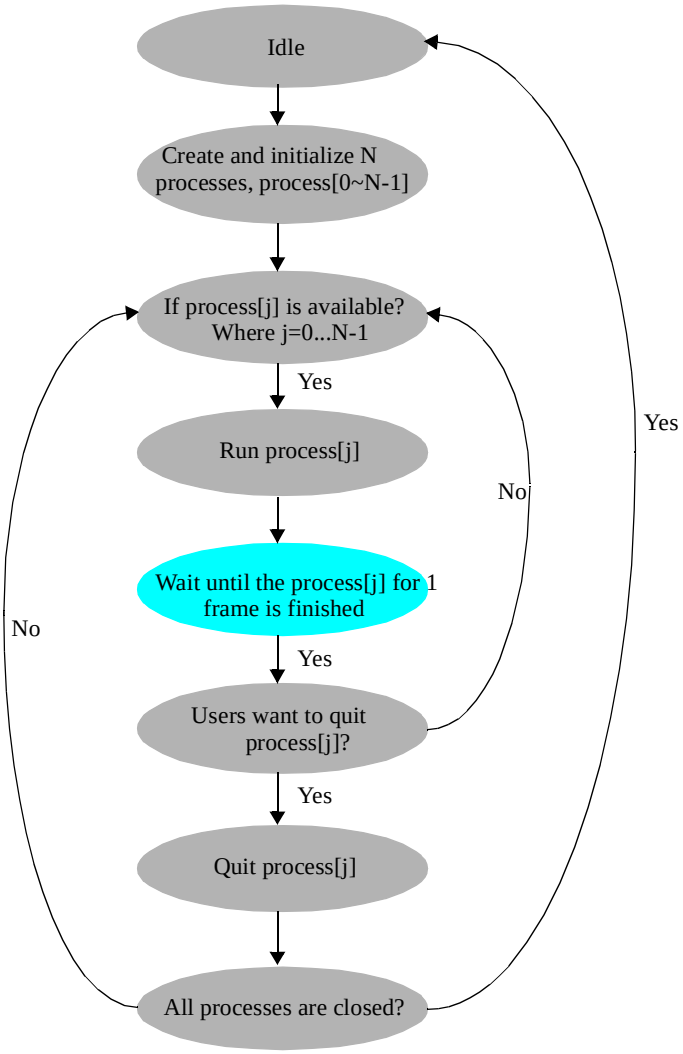

Figure 61-16. Decoding Process State Diagram

Each decoding process consists of the following three categories:

- Create processes—Software creates and configures processes.
- Running processes—At a proper time instance, software will begin a specific process. The proper time instance means when the decoding is in idle state and bitstream to be decoded is ready in the external memory.
- Quit Processes—Software can quit a specific process.

If more than one process is ready to run, each process must be assigned to different process ID - RunIndex, which is range from 0 to 3. Basically, the ID is assigned based on the order of creation. For example, when 1 MPEG-4 Decoding + 1 H.264 Decoding + 1 MPEG-2 Decoding + 1 VC1 Decoding are running simultaneously, MPEG-4 Decoding is assigned to process index “0”, H.264 Decoding is assigned to process index “1”, MPEG-2 Decoding is assigned to index “2”, and VC1 decoding is assigned to process index “3”.

There is no priority rules for executing processes, after creating all processes at the initialization step, the host enables the BIT processor to execute process specified with the RunIndex. All processes are executed in time-division like mechanism, after one process finishes decoding a frame, another process then can be executed.

In conjunction with the process ID, the RunCodStd needs to be set, to define which coding standard is used with the created process and whether the created process will decode a bitstream. Table 61-13 shows the dedicated RunCodStd value for each decoding standard. All this can be done through VPU API.

Table 61-13. RunCodStd Register Value For Coding Standard

Coding standard	RunCodStd
H264 decoding	0
VC-1 decoding	1
MPEG-2 decoding	2

61.6.1.2 Video Decoding Process Command

The following seven execution commands initialize, run, quit, set frame, and set parameter processes. A command is sent by writing the command value to the RunCommand register through VPU API.

- SEQ_INIT: This command is to initiate a decoding process. API should set following configuration parameters before sending this command to VPU.
  - Bitstream buffer base address and size
  - Frame buffers base addresses and stride lines
- SEQ_END: This command is to terminate a decoding process.
  - After this command, no more PICTURE_RUN commands will be accepted for this process.
- PICTURE_RUN: This command is to decode one picture.
  - In decoding case, frame destination address should be set before executing.
- SET_FRAME_BUF: This command informs frame buffer addresses, which are to be used as a decoding, to the BIT processor. Total 63 frame buffers may be used for decoding.

- The decoding image must be reserved for motion compensation reference until it is not used for reference. So the decoded frame buffer is re-used carefully. The BIT processor receives the whole frame buffer address by this command before picture decoding is started. Then the BIT processor manages the frame buffer allocation for next storage area for decoding.
- The frame buffer addresses are stored to external memory address. The luminance and two chrominance buffer addresses for each frame index must be stored.

- DEC_PARA_SET: This command adds a sequence parameter set or a picture parameter set to the decoder.
  - The sequence parameter set or the picture parameter set may be conveyed via “out-of-band”. In that case, the host must transfer the sequence parameter set or picture parameter set to decoder by this command.
  - The sequence parameter set or picture parameter set must be written to the Parameter buffer of the BIT processor in RBSP format prior to executing this command. The BIT processor decodes the transferred sequence/the picture parameter and stores decoded contents. The decoded sequence/picture parameter set will be activated at decoding slice header with the matched sequence/picture parameter set id.
  - Multiple sequence/picture parameter sets may be delivered to decoder. They are distinguished by different sequence/picture parameter set id. BIT processor can process 32 sequence parameter sets and 256 picture parameter sets.
  - The type (sequence or picture) and size (byte count) of conveyed sequence/picture parameter set must be delivered to BIT processor by command argument register.
- DEC BUF FLUSH: Flush data in bitstream buffer.
  - After this command finished, bitstream buffer read pointer will be 0. So host must set bitstream buffer write pointer as 0.
- GET F/W VERSION: Get firmware version.

There is a busy status register in the VPU to show whether the BIT processor is executing a command. The busy status keeps “1” until the command is finished, then the BIT processor can accept a new command.

61.6.1.3 Video Decoding Process Finish Detection

VPU raises the interrupt signal or busy state is asserted when a process finishes decoding a frame. So there are three ways of detecting whether the process is finished:

- Polling VPU interrupt status register. When interrupt is generated, the interrupt status register can indicate that.
- Polling VPU busy status register. When a PICTURE_RUN command is issued to BIT processor and the process is under operation, the busy status keeps “1”, as soon as the busy status becomes “0”, the decoding process is finished.
- Capture the interrupt signal from system level, respond to interrupt request within system interrupt service routine.

There is a single busy status register for all processes, user knows which process is finished by the specified running process ID—RunIndex. Interrupt status can be cleared by writing 1 to interrupt clear register. Busy state can be self-cleared after read out.

61.6.1.4 Video Decoding Process Flow Example

Figure 61-17 shows a process flow example for decoding an H.264 bitstream and decoding an MPEG4 bitstream simultaneously. At first both decoding process are created and initialized, then each process is executed with PICTURE_RUN command alternately. More details are described as below.

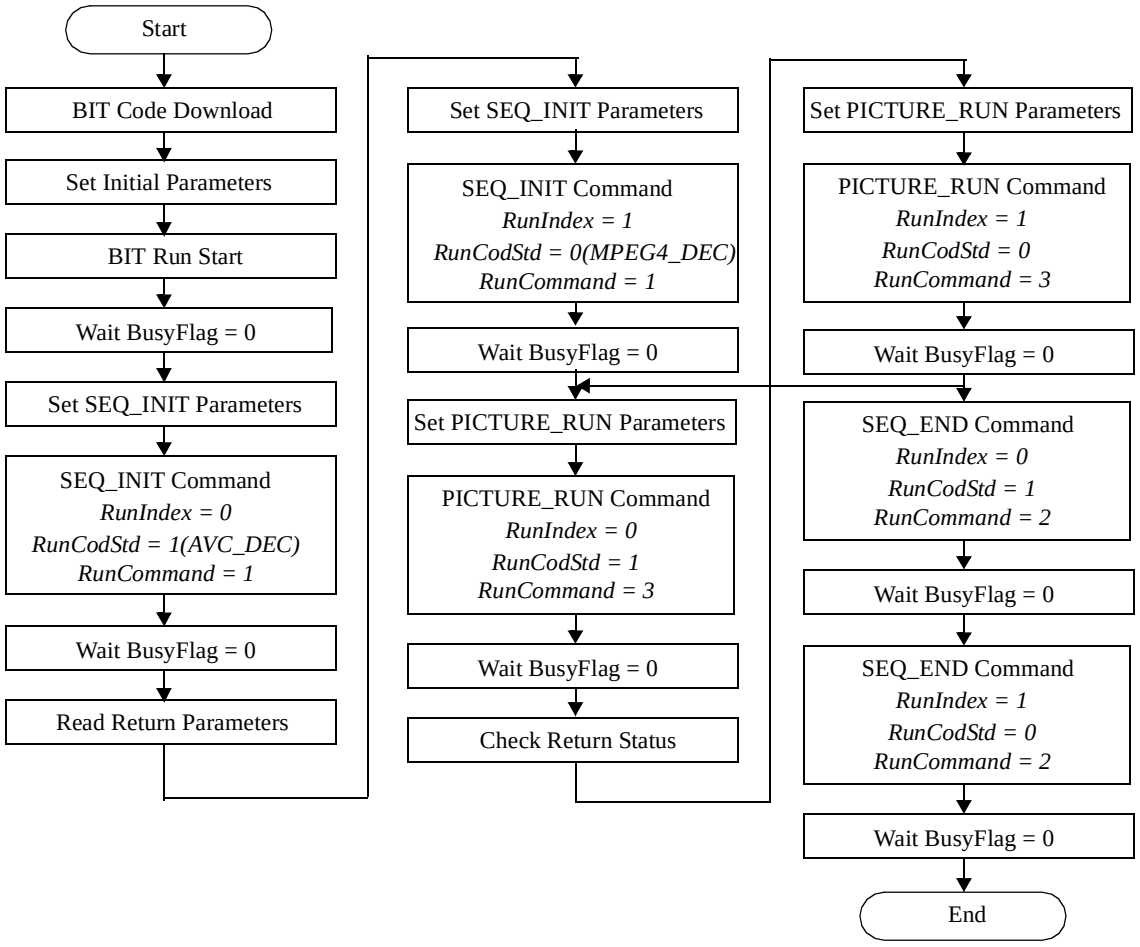

Figure 61-17. H.264 decoding and MPEG4 decoding process flow

*RunCommand = 1 (SEQ_INIT); RunCommand = 2 (SEQ_END);
RunCommand = 3 (PICTURE_RUN)

1. Initialize VPU
   - — BIT Code Download: Load BIT Processor firmware to memory.
   - — Set Initial Parameters: General configuration for BIT processor, setting working buffer base address, BIT Code memory address, bitstream buffer control and so on.
   - — BIT Run Start: Run BIT processor to initialize VPU.
2. Create and initialize an H.264 decoding process
   - — Set SEQ_INIT parameters: Configure base address and size of bitstream buffer, base address of frame buffers and so on.

- Run SEQ_INIT command: Initiate an H.264 decoding process.
- Wait BusyFlag=0: Wait BIT processor completes SEQ_INIT command execution.
- Read Return Parameters: Read the features of decoded bitstream, such as the picture resolution and number of reference frames, this can be done by reading the RetSrcFormat and Ret264Info register through VPU API. In this way, the host can prepare the required frame buffers.

3. Create and initialize an MPEG4 decoding process
   - The flow is similar to the H.264 decoding process except the run standard setting.
4. Run the H.264 decoding process
   - Set PICTURE_RUN Parameters: Configure the frame destination address.
   - Run PICTURE_RUN command: Start the H.264 decoding process.
   - Wait BusyFlag=0: Wait the BIT processor completes PICTURE_RUN command execution. It also means one frame process is finished. (The finish detection can be implemented in other way described in Section 61.6.1.3, Video Decoding Process Finish Detection) The decoded frame can be sent to the Image Processing Unit for post-processing and display. The actual operation is dependant on the application.
5. Run the MPEG4 decoding process
   - The flow is similar to the H.264 decoding process. The decoding process should configure frame source address in addition to destination address.
6. Execute step 4 and step 5 alternately.
   - Before running decoding process, the host should load new bitstream to the bitstream buffer if it is empty, and update the frame destination address according to the application.
7. Stop the decoding processes
   - Run SEQ_END command to each process to terminate it.

Basically, the process flow for decoding is similar, though it may have minor change for different firmware version. The detailed implementation is done in the VPU driver.

61.6.2 Video Encoding Processing Control

This section describes how BIT processor controls the video decoding and communicates with the host.

61.6.2.1 The Pipeline for Encoding

Figure 61-18 shows the six pipeline stages for H.264 encoding. In the encoding path, there are two separated data paths. The upper four stages are for the encoding path and the lower four stages are for reconstruction.

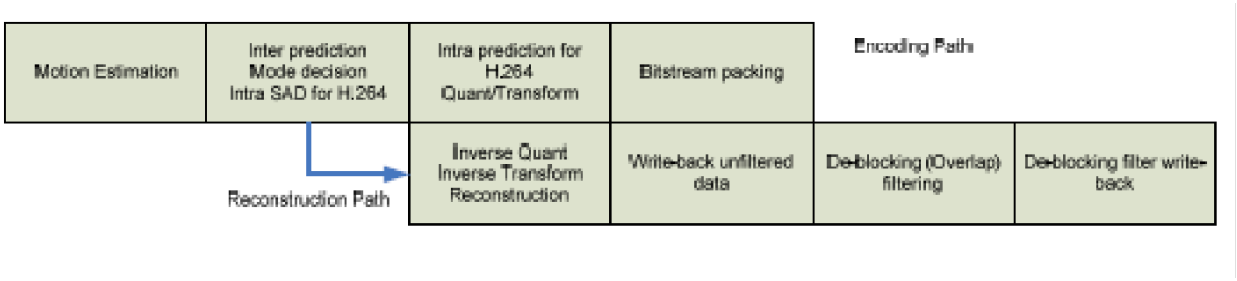

Figure 61-18. Encoding Pipeline Stage for H.264

The sub block in each stage is controlled by the BIT processor and the main controller (macroblock sequencer). The steps in the H.264 encoding pipeline stages are as follows.

- Pipeline stage 1
  a) The motion estimation (ME) block searches the motion vectors.
  b) The BIT processor reads the motion vectors from ME.
  c) The used data (reference luminance and current macroblock luminance data) is moved to the MC block for reuse.
- Pipeline stage 2
  a) The MC block writes the predicted data from ME motion vector.
  b) Intra predictor calculates the Intra SAD and cost for mode decision.
  c) Inter/intra prediction block writes the predicted data to predicted local memory for subtraction in the next pipeline stage.
- Pipeline stage 3
  a) Execute intra prediction and transfer the results to quantizer/transform.
  b) Quantized and transformed data is written to residual buffers for bitstream packing.
  c) Quantized and transformed data is transferred to inverse quantizer/inverse transform.
  d) Inverse quantized and inverse transformed data is added (reconstructed) with prediction block data to make reconstructed frame.
- Pipeline stage 4
  a) The BIT processor reads the residual buffer and makes the bitstream.
  b) Write back the unfiltered pixel data.
- Pipeline stage 5
  a) The deblocking filter reads the reconstructed data from its local memory and runs deblocking filtering for H.264/VC-1 or overlap smoothing for VC-1 intra block.

b) The filtered pixel data, that is the final reconstructed picture, is stored in the local memory ofb the deblocking filter block for write back.

- Pipeline stage 6
  a) The write-back DMA writes the decoded picture into external frame buffer.
  b) The decoded picture is now the reference picture for next picture decoding.

Figure 61-19 shows the five pipeline stages for MPEG-4/H.263 encoding when the deblocking filter is disabled and Figure 61-20 shows the six pipeline stages for H.263 when the deblocking filter is enabled. The encoding data path in MPEG-4/H.263 is similar to the H.264 encoding data path, with the exception of the inserting AC/DC prediction.

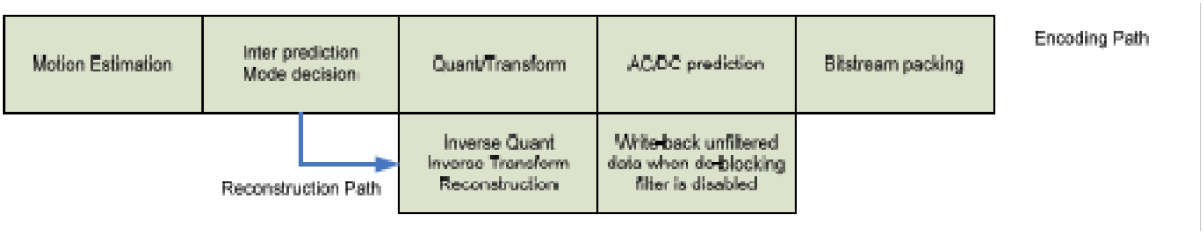

Figure 61-19. MPEG-4/H.263 Encoding Pipeline Stage when Deblocking Filter is Disabled

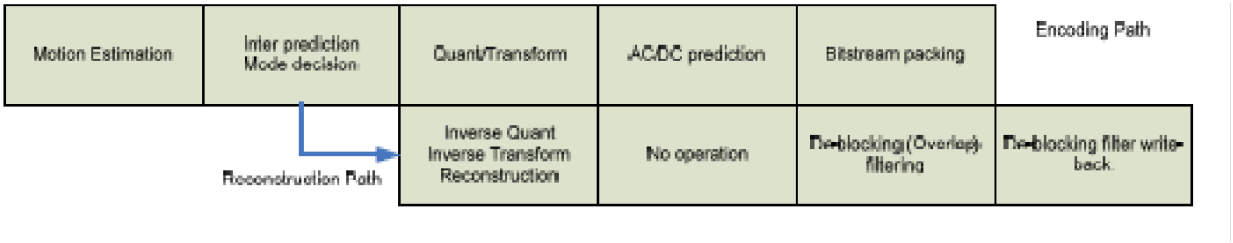

Figure 61-20. H.263 Encoding Pipeline Stage when Deblocking Filter is Enabled

61.6.3 Video Codec Processing Buffer Requirement

VPU has full access to the whole external memory. It uses external memory to load or store image frame, bitstream, program, and data for the BIT processor. AC/DC predication and deblocking filtering also use external memory. The buffer size requirement is dependent on the standard and target application. For example, the H.264 decoding uses multiple reference frames up to 16. MPEG-4 and H.263 decoding uses only one reference frame. Also each standard requires different temporary memory size when it processes deblocking or overlap-smoothing filtering.

VPU uses fthe ive kinds of buffer as follows:

- Frame Buffer—for storing image frame.
- BIT processor program memory—for boot code and firmware.
- Working Buffer—for intermediate data from the BIT processor and the video decoding hardware.
- Bitstream Buffer—for loading bitstream.

- Parameter Buffer—for BIT processor command execution argument and return data.
- Search RAM—for the use of ME module to reduce SDRAM bus loading.

Different buffers can be noncontiguous in external memory, although each buffer needs to be contiguous.

61.6.3.1 Frame Buffer

This section describes the memory map of the frame buffer and the size requirement.

As shown in Figure 61-21, a frame buffer is specified with the base address and the stride line. A complete image consists of Y, U, and V components. Therefore, an image needs three frame buffers for Y, U, and V components, these buffers can be noncontiguous in memory. The stride line means the width of the luminance component buffer in pixel unit must be a multiple of 8. The stride line for U and V frame buffers is a half of the Y frame buffer and is extracted automatically based on the stride line of the Y frame buffer. VPU supports 11-bits for stride line size.

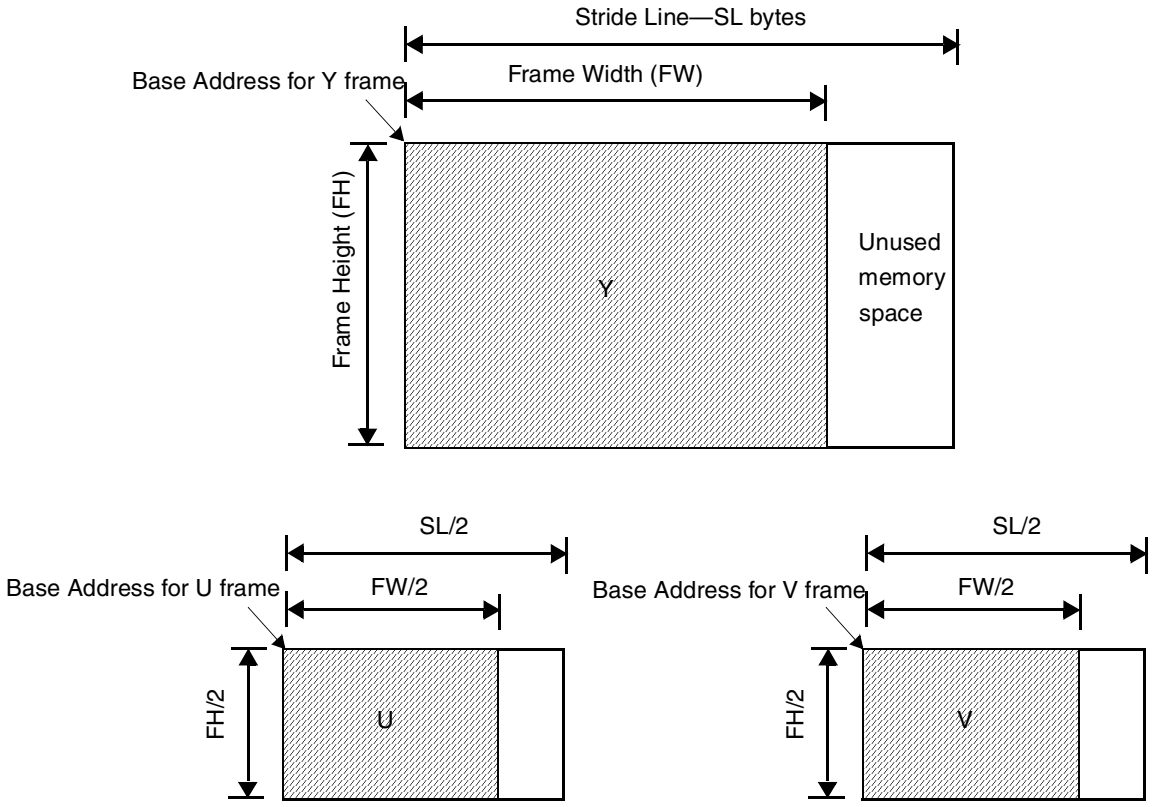

Figure 61-21. Frame Buffer configuration

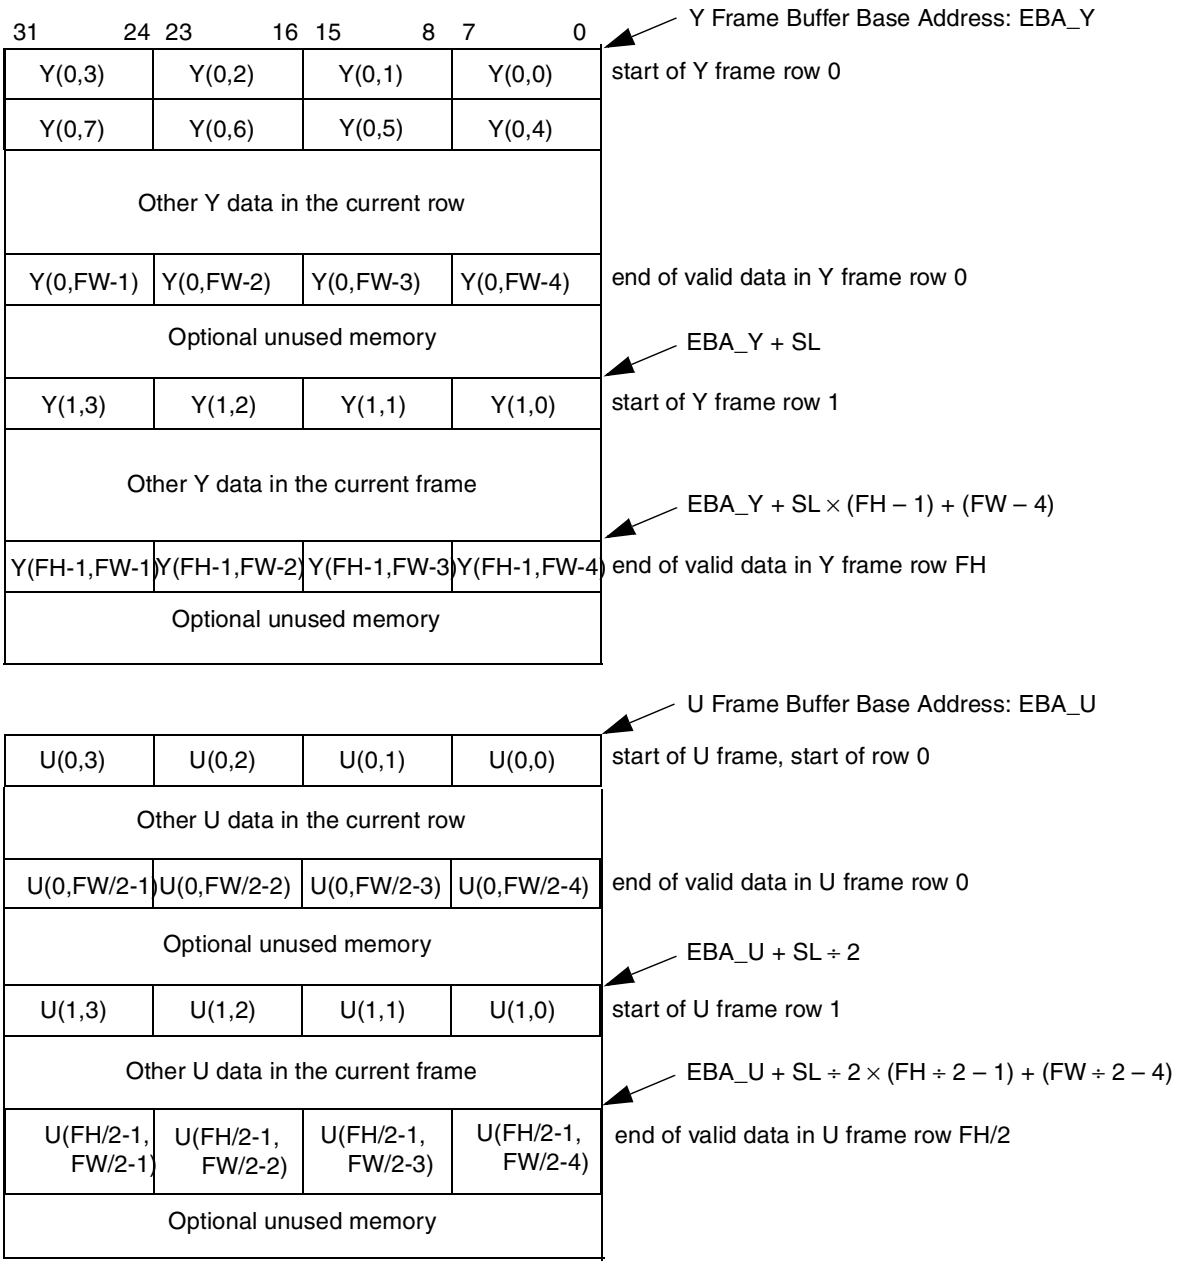
Figure 61-22 shows the memory map of the frame buffer. For V frame buffer, the memory map is the same as the U frame buffer except the base address.

VPU supports both little and big endian system. It means Y(0,0) could be located in the bit[31:24]. User can specify the endianness through VPU API.



FH: Frame Height
SL: Stride Line
FW: Frame Width

Figure 61-22. Frame Buffer Address Map in Little Endian

Table 61-14 shows the frame buffer requirement for MPEG-4, H.264, and VC-1. The H.264 decoder requires multiple reference frames up to 16. In the case of VC-1 main profile, the decoder needs two reference frames to decode a B picture. Also, VC-1 requires two more frames that it stores for range reduction or multiresolution.

Table 61-14 also shows the memory requirement in case of QCIF/CIF/VGA resolution image. In the case of H.264 decoding, the required size for the reference frame is dependent on the level being supported. The VPU supports up to H264 decoding level 3.0, which the maximum decoded picture buffer size is defined as 3037.5 Kbytes in the standard. To support H.264 CIF at level 3.0, 2524 Kbytes is needed if 16 reference frames are used.

Table 61-14. Frame Buffer Requirement

		MEPG-4 Decoder	H.264 Decoder	VC-1 Decoder
QCIF	Reference Frames	2	16	2
	Instant Frames	1	1	2
	Display Frames	1	1	2
	Total Frames	4	18	6
	Picture Size[1]	37 Kbyte	37 Kbyte	37 Kbyte
	Total Frame Size	148 Kbyte	668 Kbyte	222 Kbyte
CIF	Reference Frames	2	16	2
	Instant Frames	1	1	2
	Display Frames	1	1	2
	Total Frames	4	18	6
	Picture Size	148 Kbyte	148 Kbyte	148 Kbyte
	Total Frame Size	592 Kbyte	2672 Kbyte	891 Kbyte
VGA	Reference Frames	2	5	2
	Instant Frames	1	1	2
	Display Frames	1	1	2
	Total Frames	4	7	6
	Picture Size	450 Kbyte	450 Kbyte	450 Kbyte
	Total Frame Size	1800 Kbyte	3150 Kbyte	2700 Kbyte

1 The picture size is the minimum size of one frame buffer with the assumption that the picture is YUV 4:2:0 format and the stride line is equal to frame width.

61.6.3.2 BIT Processor Program Buffer

At the initialization stage of VPU, the host processor must download boot code to the BIT processor. After initialization, the BIT processor loads a program corresponding to the activated standard. The program size of the boot code is 1 Kbyte. The current version of BIT firmware has a total 48 Kbyte size to support multistandards decoding.

61.6.3.3 Working Buffer

Besides buffers for frames and firmware, additional working buffer for intermediate data from the BIT processor and decoding is needed. The buffers are such as the reconstructed pixel row buffer for MPEG-4 AC/DC prediction or H.264 intra prediction, context saving buffer for running multiple processes and various temporal storage buffer for decoding process.

The required working buffer size varies according to decode size, decoding standard, decoding capability. For example, AC/DC prediction buffer size is determined by picture width and the maximum bitstream re-ordering buffer for data partition is determined by the maximum bitstream size of one picture. The working buffer size may change for different firmware version. The current version of firmware requires a maximum 256 Kbyte for working. Its size can be set through the VPU API. The detailed working buffer is organized as Table 61-15.

Table 61-15. Working Buffer Organization

Working Buffer Type	Name	Description	Size
Static buffer	STATIC_PRC_DMEM	BIT processor data memory of each process for context switching.	5 Kbytes for each process
	STATIC_PRC_SEQ	Static data storage of each sequence.	8 Kbytes for each process
Temp avc decoding buffer	AVC_DEC_PRED	Neighboring prediction buffer for bit stream parsing	204 Kbytes
	AVC_DEC_IP	Intra prediction buffer of Y/Cb/Cr	
	AVC_DEC_DBK	Deblocking filter buffer	
	AVC_DEC_SLICE	Slice data RBSP buffer. All slice data RBSP of one picture is stored.	

61.6.3.4 Bitstream Buffer

The host processor has to assign buffers for bitstreams on a per instance basis. If VPU handles N-bitstreams simultaneously in an application, the host should assign N bitstream buffers and specify the base address and size. The External bitstream buffer is “ring buffer” type. The start address of ring buffer and buffer size must be written by host to BIT processor. The current read or write address of ring buffer is automatically wrapped-around by firmware.

In decoding case, the host writes the bitstream to be decoded then BIT processor reads bitstream. In this case, the bitstream overwriting or underflow may occur and if it occurs, decoding will fail. To prevent overwriting or underflow, current bitstream read/write pointer must be exchanged between the host and the BIT processor.

The BIT processor writes current read pointer of ring buffer to internal register, and the host must write current write pointer of ring buffer to internal register. The BIT processor checks the bit buffer empty (underflow) status by comparing current read pointer and write pointer. If no more bitstream data is available to be decoded (buffer empty status), the BIT processor stops bitstream decoding to prevent misreading the bitstream and waits until the host writes more bitstream data and updates write pointer. The

host must check the current read pointer and write pointer before writing more bitstream data to ring buffer to prevent overwriting bitstream data.

61.6.3.5 Parameter Buffer

Host processor must reserve parameter buffer in external memory for BIT processor command execution argument and return data.

61.6.3.6 Search RAM

The CodaHx14's motion estimation module uses a search RAM to reduce the bandwidth on the external SDRAM. Generally, motion estimation reads a reference pixel data several times. To avoid this bandwidth overhead, the motion estimation module loads the reference pixel data form the external SDRAM one time and stores them to the search RAM through AXI bus. The stored reference pixel data is loaded several times to search the motion vector, but these operations are conducted through AMBA AXI bus. Therefore the bandwidth of loading reference pixel data is reduced by using search RAM in AXI bus.

The size of search RAM is as follows:

(# of horizontal pixel × 36 + 8 macroblocks) bytes.

For example ,in CIF encoding, the search RAM size is 352 × 36 + 2048 = 14720 bytes = 14.375 Kbyte.

61.6.3.7 Buffer Requirement Summary

Table 61-16 shows a summary of buffer requirement for each decoding instance, where bitstream buffer size is not considered because the size is not limited. The total size may change for different firmware version. Except the BIT processor program memory, other kinds of buffer has to be assigned on a per instance basis. The overall buffer size for a multiparty call application is nearly the sum of each instanced decoding.

Table 61-16. Summary of Buffer Requirement

		MEPG-4 Decoder	H.264 Decoder	VC-1 Decoder
QCIF	Frames buffer	148 Kbytes	668 Kbytes	222 Kbytes
	BIT processor program buffer	128 Kbytes		
	Parameter buffer	8 Kbytes		
	Bitstream buffer	1000 Kbytes		
	Working Buffer	13 Kbytes	256 Kbytes	13 Kbytes
	Total	1297 Kbytes	2060 Kbytes	1371 Kbytes

Table 61-16. Summary of Buffer Requirement (continued)

		MEPG-4 Decoder	H.264 Decoder	VC-1 Decoder
CIF	Frames Size	592 Kbytes	2672 Kbytes	891 Kbytes
	BIT processor program buffer	128 Kbytes		
	Parameter buffer	8 Kbytes		
	Bitstream buffer	1000 Kbytes		
	Working Buffer	13 Kbytes	256 Kbytes	13 Kbytes
	Total	1741 Kbytes	4064 Kbytes	2040 Kbytes
VGA	Frame Size	1800 Kbytes	3150 Kbytes	2700 Kbytes
	BIT processor program buffer	128 Kbytes		
	Parameter buffer	8 Kbytes		
	Bitstream buffer	1000 Kbytes		
	Working Buffer	13 Kbytes	256 Kbytes	13 Kbytes
	Total	2949 Kbytes	4542 Kbytes	3849 Kbytes

Chapter 62
Watchdog Timer (WDOG)

The watchdog (WDOG) timer module protects against system failures by providing a method of escaping from unexpected events or programming errors.

62.1 Overview

Once the WDOG module is activated, it must be serviced by the software on a periodic basis. If servicing does not take place, the timer times out. There is also an option for programmable interrupt generation before the counter actually times out. The time at which the interrupt needs to be generated prior to counter timeout can be programmed through watchdog interrupt control register (WICR).

Upon a time-out, the WDOG timer module asserts the internal system reset signal, wdog_rst, which will be going to CCMs. This signal can also be asserted via a software write to the watchdog control register (WCR). There is a power-down counter that is enabled out of any reset (POR, warm/cold). This counter has a fixed time-out period of 16 seconds after which it asserts the ipp_wdog signal. The ipp_wdog is also asserted by time-out counter expiration if WDT bit in WCR (WDOG control register) is set. Flow diagrams for the time-out counter power down counter and interrupt operations are shown in Figure 62-10, Figure 62-11, and Figure 62-12.

The input clock ipg_async_ckil_clk is the asynchronous 32 kHz clock. The power down counter works on this clock.

NOTE

ipg_clk_32k is the synchronized version of the Async. CKIL on the IP global functional clock. Because the synchronized version is not available (the IP global functional clock is off) in low-power mode, it will receive the raw CKIL clock from the CCM. These synchronizers will be bypassed while going into low power modes in CCM.The WDOG module can continue or suspend the timer operation in the low power modes.

Figure 62-1 shows the WDOG block diagram.

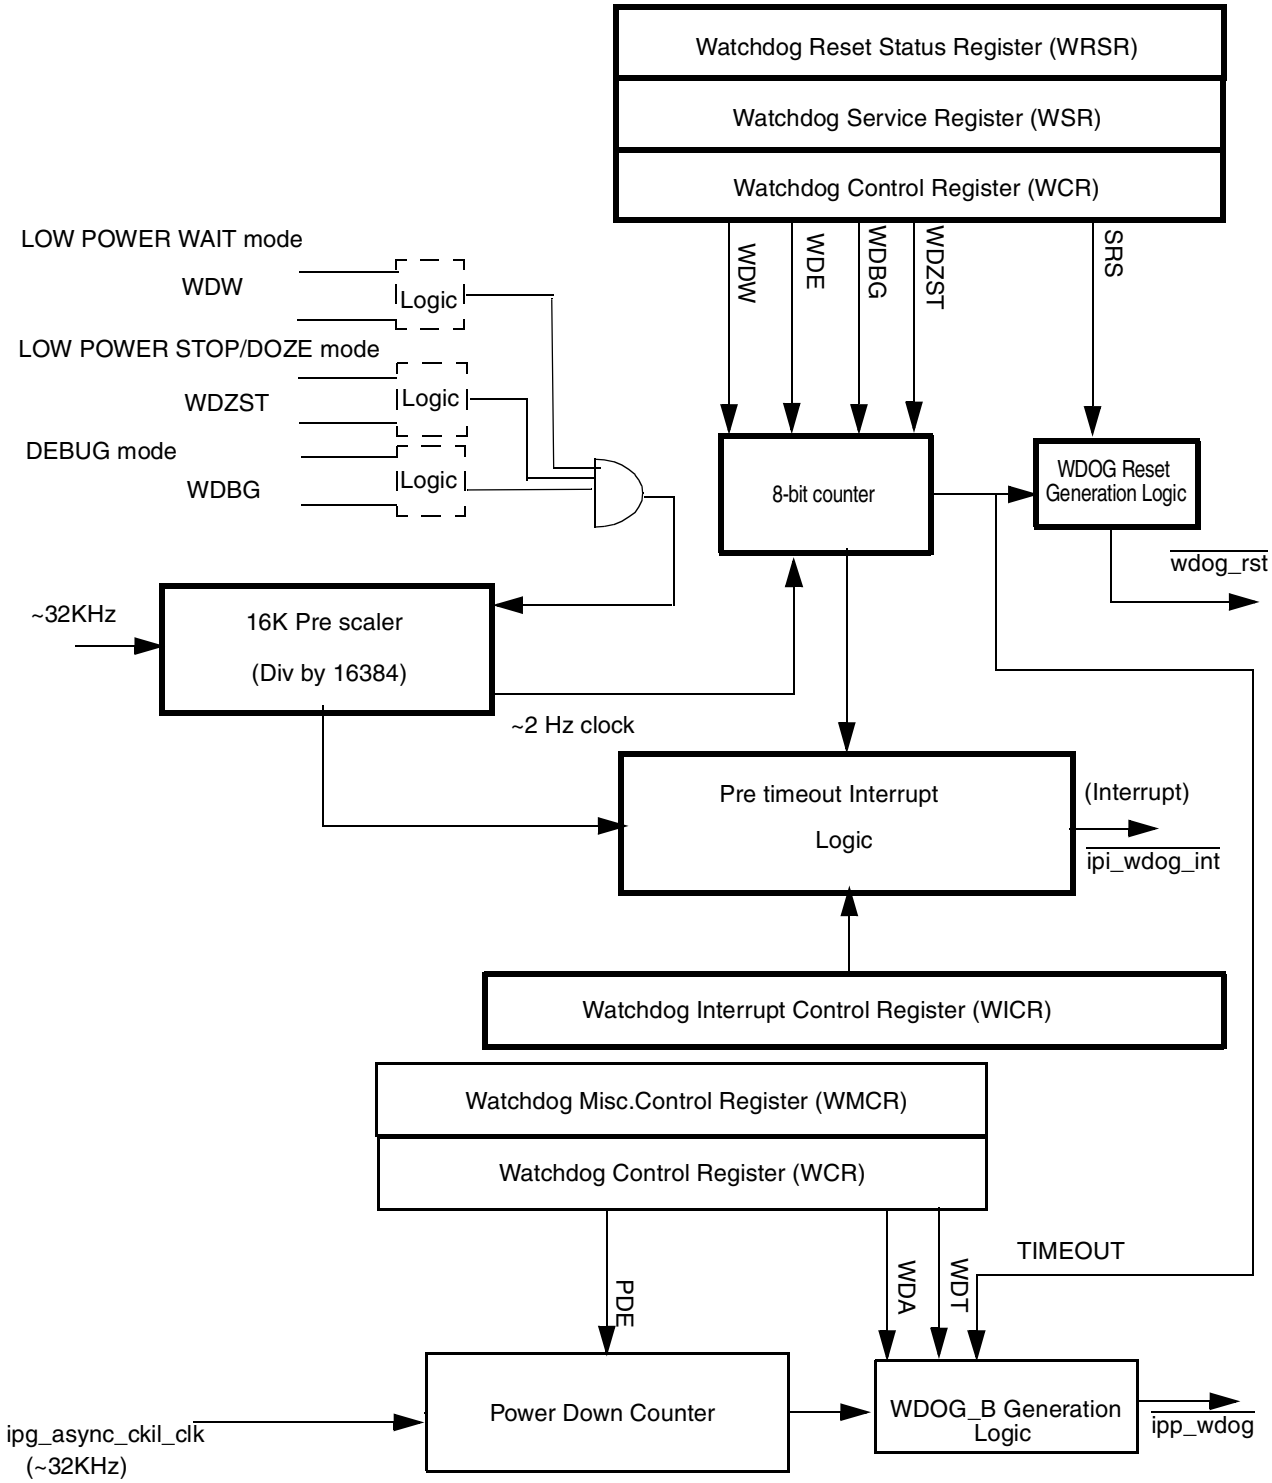


Figure 62-1. WDOG Block Diagram

62.2 Features

The WDOG features are as follows:

- A time-out counter with time-out periods from 0.5 seconds up to 128 seconds
- Time resolution of 0.5 seconds
- Configurable time-out counter that can be programmed to run or stop during low-power modes
- Configurable time-out counter that can be programmed to run or stop during DEBUG mode
- Programmable interrupt generation prior to time-out.
- Programmable time duration between interrupt and timeout events, from 0 to 128 seconds in steps of 0.5 seconds.
- A power down counter with fixed time-out period of 16 seconds, which if not disabled after reset deassertion asserts $\overline{\text{ipp\_wdog}}$ signal low
- Power down counter enabled out of any reset (POR, warm/cold reset) by default

62.3 External Signal Description

The WDOG module port signals going to pins are listed in Table 62-1.

Table 62-1. Signal Properties

Name	Port	Function	Reset State	Pull up
$\overline{\text{ipp\_wdog}}$	—	Asserted by software, power down counter timeout and timeout condition.	1	—

The $\overline{\text{ipp\_wdog}}$ signal can be routed to external pin of the IC. It is asserted by a software request (setting the WCR bits), by power down counter timeout, and timeout counter expiration.

62.4 Memory Map and Register Definitions

The WDOG module has user-accessible, 16-bit registers used to configure, operate, and monitor the state of the Watchdog Timer. Section 62.5, Register Descriptions," provides the detailed descriptions for all of the WDOG registers.

62.4.1 Watchdog Timer Memory Map

Table 62-2 shows the WDOG memory map. Watchdog uses 16-bit registers. All registers are byte writable except WRSR, which is a read only register.

Table 62-2. WDOG Memory Map

Address	Register	Access	Reset Value	Section/Page
General Registers				
0xBASE+0x000 (WCR)	Watchdog Control Register	R/W	0x0030	62.5.1/62-5

Table 62-2. WDOG Memory Map (continued)

Address	Register	Access	Reset Value	Section/Page
0xBASE+0x002 (WSR)	Watchdog Service Register	R/W	0x0000	62.5.2/62-7
0xBASE+0x004 (WRSR)	Watchdog Reset Status Register	R	0x00XX	62.6.5/62-12
0xBASE+0x006 (WICR)	Watchdog Interrupt Control Register	R/W	0x0004	62.5.4/62-8
0xBASE+0x008 (WMCR)	Watchdog Miscellaneous Control Register	R/W	0x0001	62.5.4/62-8

62.4.2 Register Summary

Figure 62-2 shows the key to the register fields and Table 62-3 shows the register figure conventions.

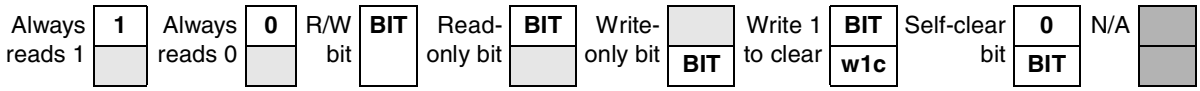

Figure 62-2. Key to Register Fields

Table 62-3. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 62-4 shows the WDOG register summary.

62.5 Register Descriptions

This section provides detailed descriptions of the watchdog registers.

62.5.1 Watchdog Control Register (WCR)

The Watchdog Control Register (WCR) is a 16-bit read/write register. It controls the WDOG operation. Figure 62-3 shows the register; Table 62-5 provides its field descriptions.

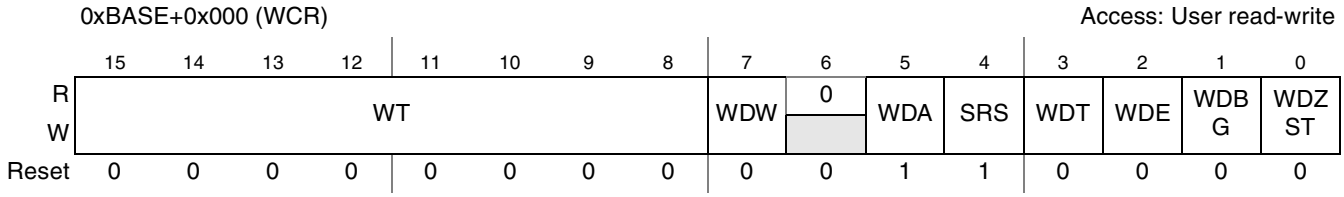

Figure 62-3. Watchdog Control Register

NOTE

WDZST, WDBG and WDW bits are write-once only bits. Once the software does a write access to the WCR Register, these bits are locked and cannot be reprogrammed. WDE and WDT are write one once only bits. Once software sets them, they cannot be reset.

WDT bit gets reset only on POR(Power on Reset).

Table 62-5. WCR Register Descriptions

Field	Description
15–8 WT	Watchdog Timeout Field. This 8-bit field contains the time-out value that is loaded into the Watchdog counter after the service routine has been performed or after the Watchdog is enabled. After reset, WT[7:0] must have a value written to it before enabling the Watchdog otherwise count value of zero which is 0.5 seconds is loaded into the counter and the new timeout value takes effect after it has been serviced. 0x00 - 0.5 Seconds(Default). 0x01 - 1.0 Seconds. 0x02 - 2.0 Seconds. 0x03 - 2.5 Seconds. ..... 0xff - 128 Seconds. **NOTE:** The new timeout value is reloaded to the counter after the WDOG is enabled or after the service routine to WSR(WDOG service register) has been performed.
7 WDW	Watchdog Disable for Wait.This bit determines the operation of WDOG during Low Power WAIT mode. This is a write once only bit. 0 Continue WDOG timer operation(Default). 1 Suspend WDOG timer operation.
6	Reserved
5 WDA	$\overline{\text{ipp\_wdog}}$ assertion. Controls the software assertion of the $\overline{\text{ipp\_wdog}}$ signal. 0 Assert $\overline{\text{ipp\_wdog}}$ output. 1 No effect on system(Default).
4 SRS	Software Reset Signal. Controls the software assertion of the WDOG-generated reset signal. This bit automatically resets to “1” after it has been asserted to “0”. 0 Assert system reset signal. 1 No effect on the system(Default).
3 WDT	$\overline{\text{ipp\_wdog}}$ Timeout assertion. Determines if the $\overline{\text{ipp\_wdog}}$ gets asserted upon a Watchdog Timeout Event. 0 No effect on ipp_wdog(Default). 1 Assert $\overline{\text{ipp\_wdog}}$ upon a Watchdog Timeout event. **Note:** There is no effect on $\overline{\text{wdog\_rst}}$ upon writing on this bit. $\overline{\text{ipp\_wdog}}$ gets asserted along with $\overline{\text{wdog\_rst}}$ if this bit is set.
2 WDE	Watchdog Enable. Enables or disables the WDOG module. Software can only write “1” in this bit. It is not possible to reset this bit by a software write, once the bit is set. **Note:** This bit can be set/reset in debug mode (exception). 0 Disable the Watchdog. 1 Enable the Watchdog.
1 WDBG	Watchdog DEBUG Enable. Determines the operation of the WDOG module during DEBUG mode. This bit is write once-only. 0 Continue WDOG timer operation(Default). 1 Suspend the watchdog timer.
0 WDZST	Watchdog Low Power. Determines the operation of the WDOG module during low-power modes. This bit is write once-only. **Note:** The WDOG module can continue/suspend the timer operation in the low-power modes (STOP mode). 0 Continue timer operation(Default). 1 Suspend the watchdog timer.

62.5.2 Watchdog Service Register (WSR)

When enabled, the WDOG requires that a service sequence be written to the Watchdog Service Register (WSR). Figure 62-4 shows the register; Table 62-6 provides its field descriptions.

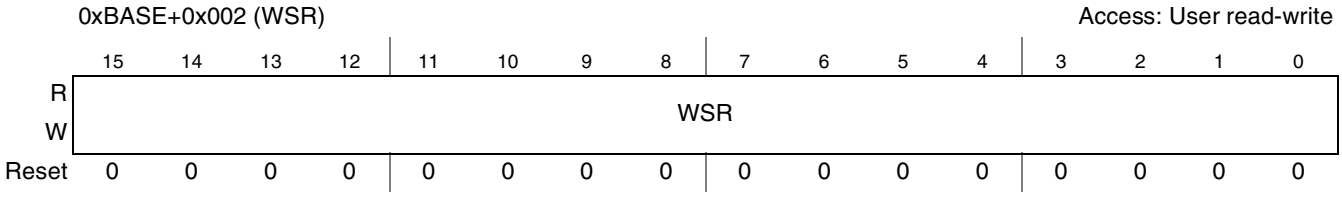

Figure 62-4. Watchdog Service Register (WSR)

Table 62-6. Watchdog Service Register Description

Field	Description
15–0 WSR	Watchdog Service Register. This 16-bit field contains the Watchdog service sequence. Both writes must occur in the order listed prior to the time-out, but any number of instructions can be executed between the two writes. The service sequence must be performed as follows: Write 0x 5555 to the Watchdog Service Register (WSR) Write 0x AAAA to the Watchdog Service Register (WSR)

NOTE

Executing the service sequence will reload the WDOG time out counter irrespective of whether interrupt has been generated or not.

62.5.3 Watchdog Reset Status Register (WRSR)

The WRSR is a read-only register that records the source of the output reset assertion. It is not cleared by a hard reset. It records the source of the output reset assertion. Therefore, only one bit in the WRSR will always be asserted high. The register will always indicate the source of the last reset generated due to WDOG. Any write performed on this register will generate an ips_xfr_err.

A reset can be generated by the following sources, as listed in priority from highest to lowest:

- Watchdog Timeout
- Software Reset

:

Figure 62-5 shows the register; Table 62-7 provides its field descriptions.

0xBASE+0x004 (WRSR) Access: User read-only

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	TOUT	SFTW
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	—	—

Figure 62-5. Watchdog Reset Status Register (WRSR)

Table 62-7. Watchdog Reset Status Register Description

Field	Description
15–2	Reserved
1 TOUT	Time-out. Indicates whether the reset is the result of a WDOG time-out. 0 Reset is not the result of a WDOG time-out. 1 Reset is the result of a WDOG time-out.
0 SFTW	Software Reset. Indicates whether the reset is the result of a WDOG software reset by asserting SRS bit 0 Reset is not the result of a software reset. 1 Reset is the result of a software reset.

62.5.4 Watchdog Interrupt Control Register (WICR)

The WICR is a 16-bit read/write register. It controls the WDOG interrupt generation. The reset value for WIE bit in WICR is 0 and that of WICT field is 0x04. WTIS bit will reflect the status whether the interrupt has occurred or not.

Figure 62-6 shows the register. Table 62-8 provides its field descriptions.

0xBASE+0x006 (WICR) Access: User read-write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	WIE	WTIS	0	0	0	0	0	0	WICT[7:0]							
W		w1c														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

Figure 62-6. Watchdog Interrupt Control Register (WICR)

Table 62-8. Watchdog Interrupt Control Register Description

Field	Description
15 WIE	Watchdog Timer Interrupt enable bit. Reset value is 0. This bit is write once only 0 Disable Interrupt(Default). 1 Enable Interrupt.
14 WTIS	Watchdog TImer Interrupt Status bit will reflect the timer interrupt status, whether interrupt has occurred or not.Once the interrupt has been triggered software must clear this bit by writing 1 to it. 0 No interrupt has occurred(Default). 1 Interrupt has occurred

Field	Description
13–8	Reserved
7–0 WICT	Watchdog Interrupt Count Timeout (WICT) field determines, how long before the counter timeout must the interrupt occur. The reset value is 0x04 implies interrupt will occur 2 seconds before timeout. The maximum value that can be programmed to WICT field is 127.5 seconds with a resolution of 0.5 seconds.This field is write-once only. WICT[7:0] = 0x00 Time duration between interrupt and timeout is 0 seconds. WICT[7:0] = 0x01 Time duration between interrupt and timeout is 0.5 seconds. ... WICT[7:0] = 0x04 Time duration between interrupt and timeout is 2 seconds(Default). ... WICT[7:0] = 0xff Time duration between interrupt and timeout is 127.5 seconds.

62.5.5 Watchdog Miscellaneous Control Register (WMCR)

Figure 62-7 shows the Register. Table 62-9 shows the description.

	0xBASE+0x008 (WMCR)												Access: User read-write			
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 62-7. Watchdog Miscellaneous Control Register (WMCR)

Table 62-9. Watchdog Miscellaneous Control Register Description

Field	Description
15–1	Reserved
0 PDE	Power Down Enable bit. Reset value of this bit is 1 means the power down counter inside WDOG is enabled. The software must write 0 to this bit to disable the counter within 16 seconds of reset deassertion. Once disabled this counter cannot be enabled again. 0 Power Down Counter of WDOG is disabled. 1 Power Down Counter of WDOG is enabled.(Default)

62.6 Functional Description

This section describes the timing information for the WDOG module.

62.6.1 Timing Specifications

62.6.1.1 Time-out Event

The WDOG provides time-out periods from 0.5 seconds up to 128 seconds with a time resolution of 0.5 seconds. It uses the ipg_clk_32k clock (32.768 kHz frequency clock) as an input to prescalers. The prescalers divide the clock by a fixed value of 16384 (div by 16K) to achieve the resolution of 0.5 seconds

and a frequency of 2 Hz. The output of the prescaler circuitry is connected to the input of a 8-bit counter to obtain a range of 0.5 to 128 seconds. The user can determine the time-out period by writing to the WDOG Time-out field (WT[7:0]) in the WDOG Control Register (WCR). The WDOG has to be enabled for the timeout counter to start running. After the timeout, the WDOG outputs a system reset signal and asserts ipp_wdog if WDT bit in WCR(WDOG Control register) is set. Detailed description of timeout condition and its prevention can be found in the Section 62.6.3, Watchdog After Reset."

62.6.1.2 Interrupt Event

Prior to time-out the WDOG can generate an interrupt which can be considered as a warning signal to indicate that the time-out will occur shortly. The interrupt will be generated only if the WIE bit in WICR Register is set. The interrupt will be deasserted only if software clears the WTIS bit in WICR Register. The time duration between interrupt event and time-out event can be controlled by writing to the WICT field of WICR Register. It can vary between 0 and 128 seconds. If the WDOG is serviced (Section 62.6.3.3, Servicing the WDOG to Reload the Counter") before the interrupt generation then the counter will be reloaded with the timeout value WT[7:0] of WCR and interrupt won't be triggered.

62.6.1.3 Power-down Counter Event

Soon after reset, the power down counter in WDOG starts running and expires after 16 seconds thereby asserting ipp_wdog. To prevent this, the software must disable this counter by clearing the PDE bit of WMCR register within 16 seconds of reset deassertion. Once disabled this counter cannot be enabled again until the next system reset occurs. This feature is provided to prevent hanging up of cores after reset.

62.6.2 Watchdog During Reset

A system reset (cold/warm) resets all registers (except the WRSR and WDT bit in WCR) to their initial default values, and places the time-out counter in the idle state until the WDOG is enabled. The Watchdog Reset Status Register (WRSR) contains the source of the reset events which are triggered from WDOG The WDT bit in WCR gets reset only on POR (Power on Reset) and not by a system reset.

62.6.3 Watchdog After Reset

The following subsections define the WDOG Time-out Counter state after reset.

62.6.3.1 Initial Load

The initial load into the timeout counter is done by setting the Watchdog Enable (WDE) bit in the WCR. The WT[7:0] field of Watchdog Control Register (WCR) must have a time-out value written to it before the watchdog is enabled. Otherwise the count value of zero timeout value, which is 0.5 seconds, is loaded into the counter, and the new timeout value takes effect after it has been serviced.

Another way of loading the time-out value into the counter is the service sequence being written to the Watchdog Service Register (WSR). The service sequence is described in the Section 62.6.3.3, Servicing the WDOG to Reload the Counter. The counter flow diagram is shown in Figure 62-10.

62.6.3.2 Timer Countdown

After the WDOG is enabled, the counter is activated and begins to count down from its initial programmed value. The timer will time-out when the counter reaches zero. The WDOG outputs a system reset signal and asserts ipp_wdog (WDT bit should be set in WCR register) after the counter reaches zero.

However the Timeout condition can be prevented by reloading the counter with the new timeout value(WT[7:0] of WCR) if a service routine (See Section 62.6.3.3, Servicing the WDOG to Reload the Counter) is performed before the counter reaches zero. If any system errors occur that prevent the software from servicing the Watchdog Service Register (WSR), then the timeout condition occurs.

By performing the service routine, the WDOG reloads its counter to the time-out value indicated by bits WT[7:0] of the WCR, and it re-starts the countdown. A system reset will reset the counter and place it in the idle state at any time during the countdown. The counter flow diagram is shown in Figure 62-10.

62.6.3.3 Servicing the WDOG to Reload the Counter

The proper service sequence to reload a time-out value to the counter begins by writing 0x5555 followed by 0xAAAA to the WSR. To reload the counter, the IP writes must take place within the time-out value indicated by bits WT[7:0] of the WCR. Any number of instructions can be executed between the two writes. This service sequence is also used to activate the counter during the initial load. See Section 62.6.3.1, Initial Load.” The time-out value can be changed at any point of the time and the counter reloads the new timeout value whenever the core services the Watchdog.

If the WSR is not loaded with 0x5555 prior to writing 0xAAAA to the WSR, the counter is not reloaded. If any value other than 0xAAAA is written to the WSR after 0x5555, the counter is not reloaded. If WDOG is serviced before the interrupt generation event, then both time out and interrupt are prevented from triggering. This service sequence reloads the counter with the timeout value WT[7:0] of WCR at any point of time.

62.6.3.4 Interrupt

WDOG generates an interrupt before timing out if the WIE bit is set in WICR. The exact time at which the interrupt should occur prior to timeout depends on the value of WICT field of WICR register. For example, if the WICT field has a value 0x04, the interrupt will be generated 2 seconds prior to time-out. If the WDOG is serviced before the interrupt generation, the counter will be reloaded with the timeout value WT[7:0] of WCR, and an interrupt will not be triggered. Once the interrupt is triggered, the WTIS bit in WICR Register will be set. The software needs to clear this bit so as to service the interrupt.

62.6.3.5 Power-down Counter after Reset

The power-down counter inside WDOG is enabled out of reset. This counter has a fixed time out value of 16 seconds, after which it drives the ipp_wdog signal low. To prevent this PDE bit in WMCR must be cleared by the software.

62.6.4 Low-Power and DEBUG Modes

The WDOG module can either continue or suspend the timer operation during low-power modes (WAIT and STOP) and DEBUG mode.

62.6.4.1 Low-Power Mode (WAIT, STOP)

The WDOG timer can be configured for continual operation or suspended in low-power WAIT/STOP mode.

62.6.4.1.1 STOP Mode

If the WDOG Timer Disable bit for low power STOP mode (WDZST) bit in the WCR is 0, the WDOG Timer continues to operate using the ipg_clk_32k clock (32.768 kHz frequency clock). If the low-power STOP Enable (WDZST) bit is set to 1, the WDOG operation is suspended. Upon exiting low-power STOP mode, the WDOG operation returns to what it was prior to entering the STOP mode.

62.6.4.1.2 WAIT Mode

If the WDOG Timer Disable bit for the low-power WAIT mode (WDW) bit in the WCR is 0, the WDOG Timer continues to operate using the ipg_clk_32k clock (32.768 kHz frequency clock). If the low-power WAIT Enable (WDW) bit is set to 1, the WDOG operation is suspended. Upon exiting low-power WAIT mode, the WDOG operation returns to what it was prior to entering the WAIT mode.

62.6.4.2 DEBUG Mode

The WDOG Timer can be configured for continual operation, or the operation can be suspended during debug mode. If the WDOG debug enable (WDBG) bit is set to 1 in the Watchdog Control Register (WCR), the WDOG module operation is suspended in debug mode. After 2 CKIL clocks of ipg_debug signal assertion, the counter is stopped, but register read and write accesses continue to function normally. Also, while in DEBUG mode, the WDE bit can be enabled-disabled directly.

NOTE

If the WDE bit is cleared while in DEBUG mode, it remains cleared even after exiting DEBUG mode. If the WDE bit is not cleared while in DEBUG mode, the WDOG count continues from its value before DEBUG mode was entered.

62.6.5 Watchdog Reset Control

The WDOG generated reset signal $\overline{\text{wdog\_rst}}$ can be asserted by the following:

- A software write to the Software Reset Signal (SRS) bit of the WCR.
- WDOG time-out. See Section 62.6.1.1, Time-out Event.

The $\overline{\text{wdog\_rst}}$ is generated for 1 clock cycle of ipg_clk_32k for a time-out. In case of a software reset, the $\overline{\text{wdog\_rst}}$ is asserted for 1 clock cycle of ipg_clk_32k (IP global functional clock). It remains asserted for for 1 clock cycle of ipg_clk_32k even if a system reset is asserted in between.

The watchdog-generated reset signal wdog_rst is an output to the for system reset generation.

NOTE

The of the IC generates the system reset signal on assertion of wdog_rst.

62.6.6 ipp_wdog Operation

The WDOG module asserts ipp_wdog a under the following scenarios.

- Software write to WDA bit of WCR.
- WDOG timeout condition, WDT bit in WCR(WDOG Control register) must be set for this scenario. Description of timeout condition can be found in the Section 62.6.1.1, Time-out Event."
- WDOG Power down Counter time-out, PDE bit of WMCR should not be cleared for this scenario. Description of this counter can be found in the Section 62.6.1.3, Power-down Counter Event."

If asserted by a software write to the WDA bit, it remains asserted as long as the WDA bit is "0". The power down counter timeout asserts it low until next system reset. Whenever a ipp_wdog is asserted due to a time-out condition, it remains asserted until a POR (Power-on reset) occurs. It is cleared after the POR occurs and not due to any other system reset.

Figure 62-8 shows the scenarios under which ipp_wdog is asserted

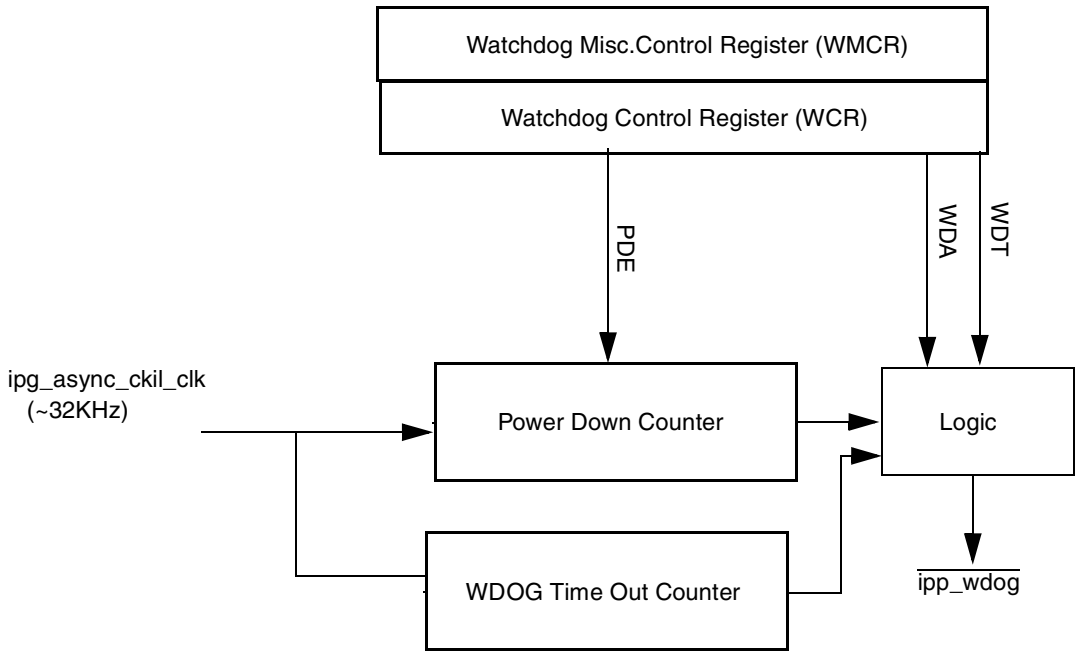

Figure 62-8. IPP_WDOG Operation

62.7 Initialization/Application Information

This section discusses the software restrictions and provides flow diagrams.

62.7.1 Software Restrictions

There are two software restrictions, as follows:

- The Power Down Counter, which is enabled out of any reset (Cold or Warm), time outs after 16 seconds. The ipp_wdog signal will be asserted low, and the WDI pin of the Power Management IC will be driven low. Therefore, once the system is out of reset, the software must ensure that it clears the PDE bit in WMCR within 16 seconds of reset (cold or warm) deassertion.
- The WDOG timer is not able to detect events that happen for periods of less than 1 ipg_clk_32k cycle. For example in repeated WAIT entry/exit, if the RUN mode time is less than 1 ipg_clk_32k cycle and if WDW bit is set, WDOG may not see any ipg_clk_32k edge during its wake time. Therefore, the WDOG timer may never time out although the system is in RUN mode for a finite duration. The time duration for events such as debug entry/exit should be more than 2 ipg_clk_32k cycles.

62.7.2 Flow Diagrams

Figure 62-9, Figure 62-10, and Figure 62-11 show the flow diagrams for the watchdog operation.

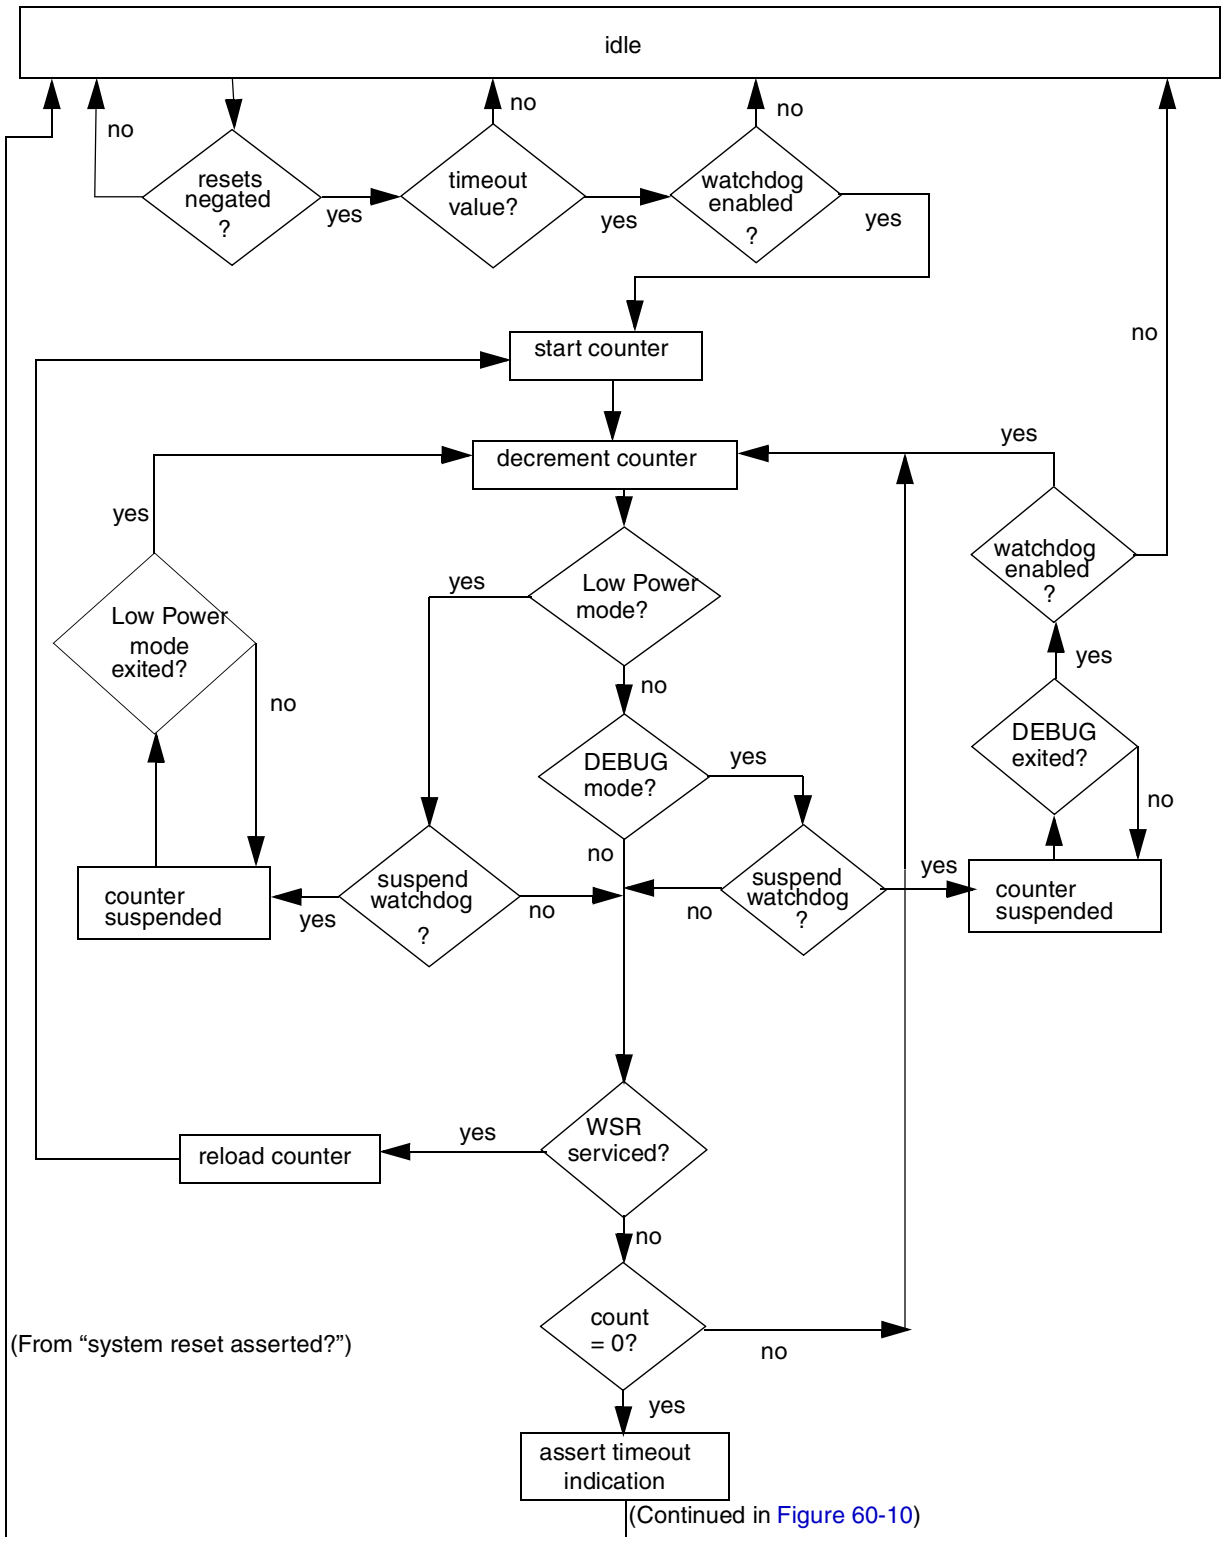

Figure 62-9. Time-out Counter Flow Diagram, 1of 2

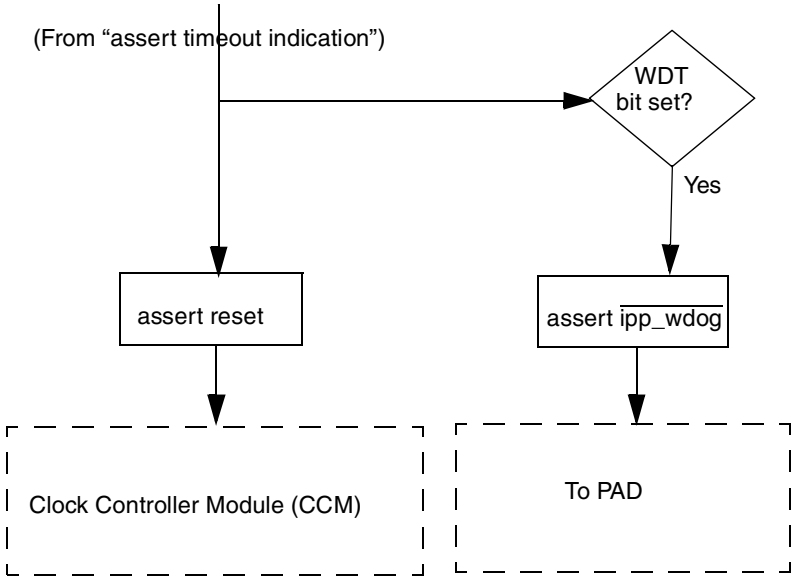

NOTE: A system reset will force the state machine to “idle” at any time during countdown.

Figure 62-10. Time-out Counter Flow Diagram, 2 of 2

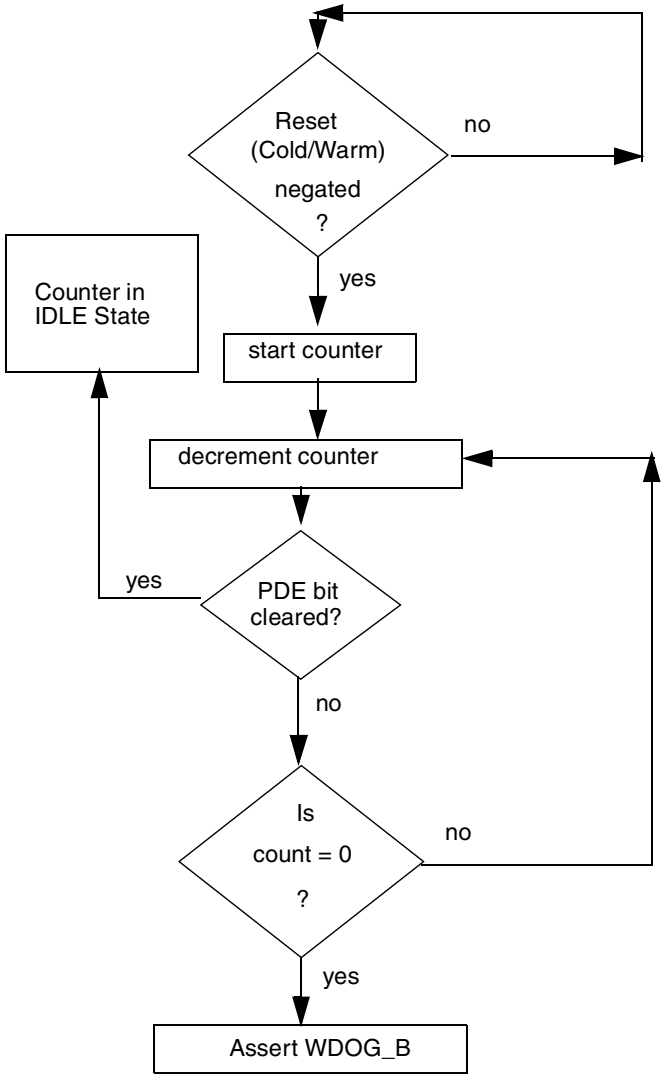

Figure 62-11. Power-Down Counter Flow Diagram

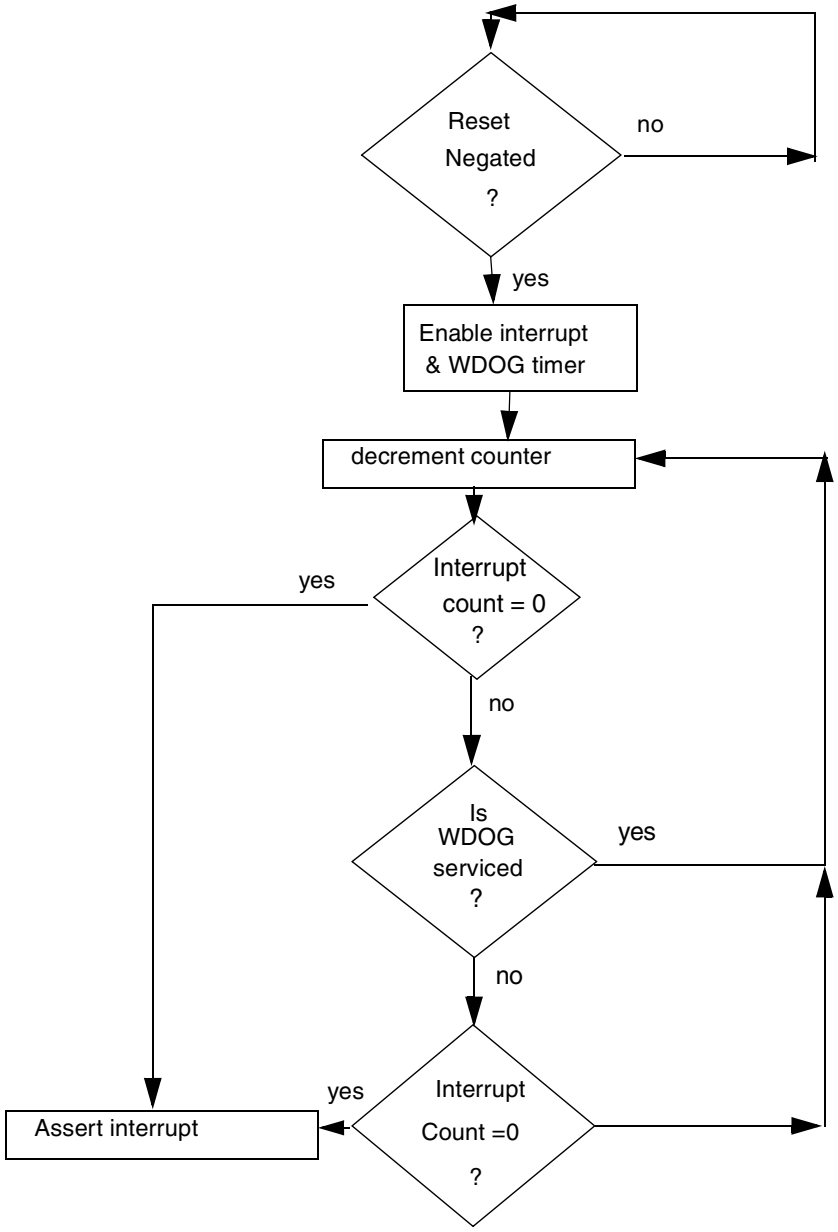

Figure 62-12. Interrupt Generation Flow Diagram

Chapter 63
Wireless External Interface Module (WEIM)

The Wireless External Interface Module (WEIM) handles the interface to devices external to the chip, including generation of chip selects, clock and control for external peripherals and memory. It provides asynchronous access to devices with SRAM-like interface and synchronous access to devices with NOR-Flash like or PSRAM like interface. Figure 63-1 illustrates a high level block diagram of the WEIM.

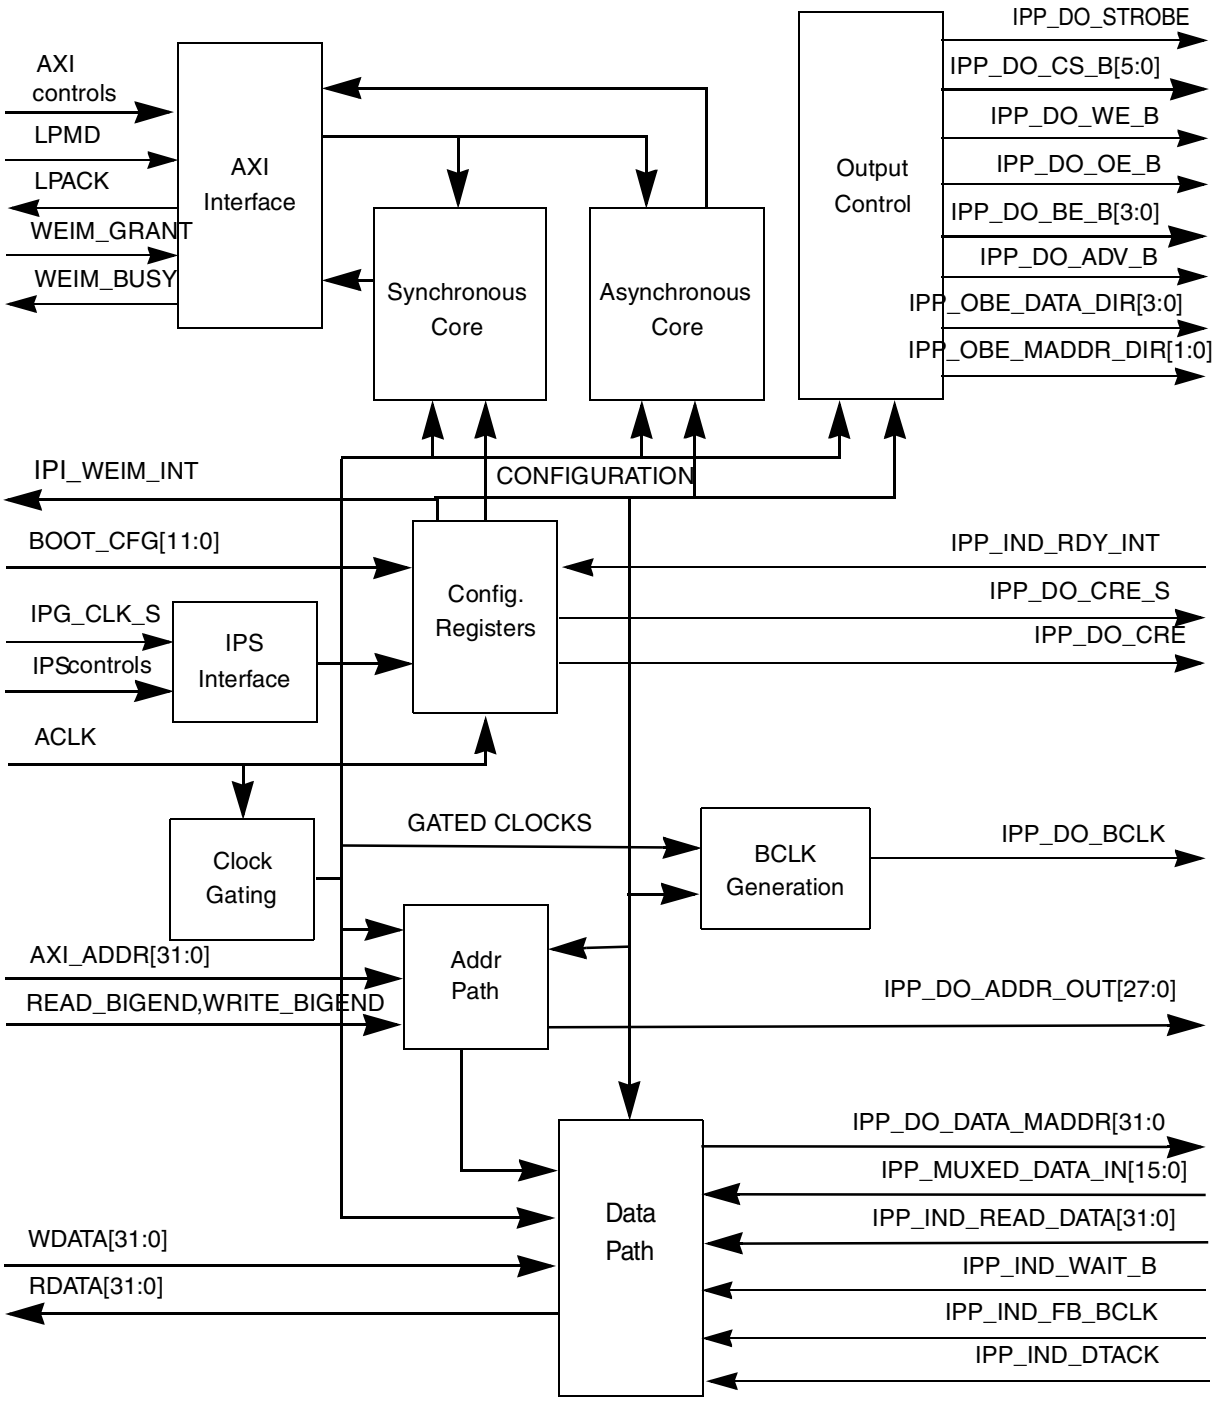

Figure 63-1. WEIM Block Diagram

63.1 Features

The following list describes the key features:

- Up to six chip selects for external devices:
  - Flexible address decoding. Each chip select memory space determine separately, according to VIA port configuration (see Section 63.4.1.1, Chip Select Memory Map"). Configurable Chip Select 0 base address (by VIA).
  - Individual select signal for each one of the memory space defined. Up to 6 memory spaces may be defined and program individually.
  - 28 bit external address bus, max memory size can be 256 Mbyte (2 Gigabit).
- Selectable Write Protection for each Chip Select
- Support for multiplexed address/data bus operation ×16 and ×32 port size
- Programmable Data Port Size for each Chip Select (×8, ×16, and ×32).
- Programmable Wait-State generator for each Chip Select, for write and read accesses separately.
- Asynchronous accesses with programmable setup and hold times for control signals
- Support for Asynchronous page mode accesses (×16 and ×32 port size).
- Independent synchronous Memory Burst Read Mode support for Nor-Flash and PSRAM memories (×16 and ×32 port size)
- Independent synchronous Memory Burst Write Mode support for PSRAM and Nor-Flash like memories (CellularRAM™ from Micron, Infineon, and Cypress, OneNand™ and utRAM™ from Samsung, and COSMORAM™ from Toshiba)
- Support of NAND Flash devices with a NOR Flash-like interface—MDOC™ (M-Systems), OneNand (Samsung)
- Independent programmable variable/fix Latency support for read and write synchronous (burst) mode.
- Support for Big Endian and Little Endian operation modes per access
- ARM AXI slave interface. One ID at a time support
- External Interrupt support, RDY_INT signal function as external interrupt
- Boot from external device support according to boot signals, using RDY_INT signal.
  - RDY signal support assertion after reset for MDOC (M-Systems) device
  - INT signal support assertion after reset for OneNand (Samsung) device

63.2 Modes of Operation

The WEIM has the following modes of operation:

- Asynchronous Mode
- Asynchronous Page Mode
- Multiplexed Address/Data mode
- Burst Clock Mode

- Low Power Modes
- Boot Mode

See details in Section 63.5.3, WEIM Operational Modes."

63.2.1 Asynchronous Mode

Asynchronous mode is a non-burst mode that is used for SRAM access. In this mode, a single data is read/written with each access (asserted address). All control timings are controlled by preset values in chip select configuration registers.

63.2.2 Asynchronous Page Read Mode

Setting the APR bit causes the WEIM to perform memory bursted accesses by emulating page mode operation. the external address asserts for each piece of data. The initial access timing is according to RWSC field, and the next address assertions timing is according to PAT field. When APR bit is set, RCSN OEN, RADVN, and RBEN fields are ignored for burst access to the external device.

The page size can be set via the BL field to 2,4, 8, 16, or 32 words (the word size is determined by the DSZ field).

63.2.3 Multiplexed Address/Data Mode

In this mode multiplexing addresses and data bits on the same pins is supported for synchronous/asynchronous accesses to ×8/×16/×32 data width memory devices. Table 63-1 shows the pins that drives data/address in 8/16/32 non-muxed mode and 16/32 muxed mode.

Table 63-1. Data and Address Bus

	Non Multiplexed Address/Data Mode						
	8 Bit (DSZ=100)	**8 Bit (DSZ=101)**	**8 Bit (DSZ=110)**	**8 Bit (DSZ=111)**	**16 Bit (DSZ=001)**	**16 Bit (DSZ=010)**	**32 bit (DSZ = 011)**
Address	ipp_do_addr_out	ipp_do_addr_out	ipp_do_addr_out	ipp_do_addr_out	ipp_do_addr_out	ipp_do_addr_out	ipp_do_addr_out
Data In	ipp_ind_ read_data [7:0]	ipp_ind_ read_data [15:8]	ipp_ind_ read_data [23:16]	ipp_ind_ read_data [31:24]	ipp_ind_ read_data [15:0]	ipp_ind_ read_data [31:16]	ipp_ind_ read_data

	Multiplexed Address/Data mode						
Address					ipp_do_addr_out		ipp_do_addr_out
Data In					ipp_muxed_data _in		ipp_ind_read_da ta
Data Out					ipp_do_addr_out [15:0]		ipp_do_data_ma ddr

63.2.4 Burst Clock Mode

The controller has the ability to support a burst synchronous operations in a various frequencies, depending on the frequency of the input clock supplied by the system (WEIM clock). The WEIM clock can be divided by one, Two, Three or four and it frequency can be change according to the requirements. Variable and fix latency are supported for this mode, according to the external device requirements.

- Synchronous read mode. This is a burst mode, it is used for reading from Flash/PSRAM memory devices. In this mode after address assertion a burst of sequential data can be read. Data exchange is carried out according to BCLK been generated by WEIM. An access is delayed according to external WAIT_B signal assertion (signal from the memory device).
- Synchronous write mode. A burst mode, it is used for accessing an external devices which support synchronous write type of access (PSRAM protocol). In this mode after address assertion a burst of sequential data can be written to the external device. Access may be delayed according to WAIT_B signal assertion (signal from the memory device) before first piece of data arrived to the external device.

NOTE

Maximum frequency of the WEIM main clock is 133 MHz. It may be reduced by the system for special cases of external devices, which demand a different frequency then integer division of the 133-MHz clock.

63.2.5 Low-Power Modes

The Input Clock is gated by ACT_CS bits, when all the ACT_CS are negated (all CS disable) the internal clock is turned off. Awready/wready and arready signal are de-asserted and the master cannot access the WEIM.

63.2.6 Boot Mode

It is possible to perform a boot operation from the external device located on CS0. The relevant bits are configured by boot mode signals according to the external device parameters (port size, protocol assertion, and so on). Table 63-2 shows the boot configuration settings.

Table 63-2. Boot Configuration Settings

BOOT_CFG Bits	Configured Bits	Place
11	DSZ[2]	CS0GCR1

1:0	DSZ[1:0]	CS0GCR1

63.3 External Signal Description

This section provides an overview and detailed description of the signal properties.

63.3.1 Overview

Table 63-3 lists external signal properties.

Table 63-3. Signal Properties

Name	Port	Function	I/O	Reset	Pull Up
ACLK		AXI clock	I	Low	
ACLK_SLOW		AXI all time clock	I	Low	
IPG_CLK_S		IPG clock	I	Low	
RST_B		Reset	I		
WEIM_WARM_RESET		Warm Reset	I		
BOOT_CFG[11:0]		Boot Configuration	I	—	
WEIM_NFC_BASE[3:0]	VIA	WEIM CS0 base address	I	—	
ACT_CS[5:0]	VIA	Active chip selects configuration	I	—	
ADDRS0[1:0]	VIA	Address Space of CS0	I	—	
ADDRS1[1:0]	VIA	Address Space of CS1	I	—	
ADDRS2[1:0]	VIA	Address Space of CS2	I	—	
ADDRS3[1:0]	VIA	Address Space of CS3	I	—	
ADDRS4[1:0]	VIA	Address Space of CS4	I	—	
ADDRS5[1:0]	VIA	Address Space of CS5	I	—	
BIT_24_CRE_VIA	VIA	CRE is driven on bit 24	I		
BIT_25_CRE_VIA	VIA	CRE is driven on bit 25	I		
BIT_26_CRE_VIA	VIA	CRE is driven on bit 26	I		
BIT_27_CRE_VIA	VIA	CRE is driven on bit 27	I		
AWADDR[31:0]	AXI WAC	Axi Write Address	I	—	
AWSIZE[2:0]	AXI WAC	Axi write access size	I	—	
AWBURST[1:0]	AXI WAC	Axi write access burst type	I	—	

Table 63-3. Signal Properties (continued)

Name	Port	Function	I/O	Reset	Pull Up
AWLEN[3:0]	AXI WAC	Axi write access length	I	—	
AWPORT0	AXI WAC	Axi write access protection type	I	—	
AWVALID	AXI WAC	Axi write address valid	I	—	
AWID[3:0]	AXI WAC	Axi write address ID	I	—	
WRITE_BIGEND	AXI WAC	Axi write address endian mode	I	—	
AWREADY	AXI WAC	WEIM ready for write address	O	—	
WDATA[31:0]	AXI WDC	Axi Write Data	I	—	
WSTRB[3:0]	AXI WDC	Axi write byte strobe	I	—	
WID[1:0]	AXI WDC	Axi write data ID	I	—	
WALID	AXI WDC	Axi write data valid	I	—	
WLAST	AXI WDC	Axi last write data	I	—	
WREADY	AXI WDC	WEIM ready for write data	O	—	
BRESP	AXI WRC	Axi write response	O	—	
BVALID	AXI WRC	Axi write response valid	O	—	
BID	AXI WRC	Axi write response ID	O	—	
BREADY	AXI WRC	AXI ready for write response	I	—	
ARADDR[31:0]	AXI RAC	Axi read Address	I	—	
ARSIZE[2:0]	AXI RAC	Axi read access size	I	—	
ARBURST[1:0]	AXI RAC	Axi read access burst type	I	—	
ARLEN[3:0]	AXI RAC	Axi read access length	I	—	
ARPORT0	AXI RAC	Axi read access protection type	I	—	
ARVALID	AXI RAC	Axi read address valid	I	—	
ARID[3:0]	AXI RAC	Axi read address ID	I	—	
READ_BIGEND	AXI RAC	Axi read address endian mode	I	—	
ARREADY	AXI RAC	WEIM ready for read address	O	—	
RDATA[31:0]	AXI RDC	Axi read Data	O	—	
RID[1:0]	AXI RDC	Axi read data ID	O	—	
RVALID	AXI RDC	Axi read data valid	O	—	
RRESP	AXI RDC	Axi read error response	O	—	
RLAST	AXI RDC	Axi last read data	O	—	
RREADY	AXI RDC	AXI ready for read data	I	—	
IPS_ADDR	IPS	IPS address	I	—	
IPS_MODULE_EN	IPS	IPS module enable	I	—	

Table 63-3. Signal Properties (continued)

Name	Port	Function	I/O	Reset	Pull Up
IPS_RWB	IPS	IPS write enable	I	—	
IPS_WDATA[31:0]	IPS	IPS write data	I	—	
IPS_RDATA[31:0]	IPS	IPS read data	O	—	
IPS_XFR_ERR	IPS	IPS error response	O	—	
IPS_XFR_WAIT	IPS	IPS wait response	O	—	
IPI_WEIM_INT	IPS	Interrupt toward the master	O	—	
LPMD		Low power request	I		
LPACK		Low power acknowledge	O		
WEIM_GRANT		Handshake signal from other slaves or arbiter	I		
WEIM_BUSY		Handshake signal to other slaves or arbiter	O		
IPP_IND_BCLK	IPP	Burst Clock (BCLK)	O	0	
IPP_IND_RDY_INT	IPP	External interrupt/ready after reset for NandFlash Based memories with NorFlash interface	I	—	
IPP_IND_FB_BCLK	IPP	Feedback Burst Clock	I	0	
IPP_IND_READ_DATA[31:0]	IPP	Input Data Bus	I	—	
IPP_MUXED_DATA_IN[15:0]	IPP	Input Data Bus in muxed mode	I	—	
IPP_IND_WAIT_B	IPP	Memory Ready/Busy/Wait (WAIT)	I	—	pull up
IPP_DO_CS_B[5:0]	IPP	Chip Selects (CS)	O	High	
IPP_DO_OE_B	IPP	Memory Output Enable (OE)	O	1	
IPP_DO_WE_B	IPP	Memory Write Enable (WE)	O	1	
IPP_DO_BE_B[3:0]	IPP	Bytes Enable (BE)	O	High	
IPP_DO_ADV_B	IPP	Address Valid (ADV)	O	1	
IPP_DO_CRE	IPP	Memory Register Set	O	Low	
IPP_DO_CRE_SEL	IPP	CRE signal select	O	Low	
IPP_DO_STROBE	IPP	Logic analyzer signal	O	Low	
IPP_DO_ADDR_OUT[27:0]	IPP	Address Bus	O	Low	
IPP_DO_DATA_MADDR_OUT[31:0]	IPP	Output Data bus/Address and DATA Bus in Multiplexed mode	O	Low	
IPP_DO_DATA_DIR[3:0]	IPP	DATA IO Direction	O	Low	
IPP_DO_MADDR_DIR[1:0]	IPP	Muxed address IO Direction	O	Low	

63.3.2 Detailed Signal Descriptions

The following is a detailed description of the WEIM signals mentioned in Table 63-4.

Table 63-4. Detailed Signal Descriptions

Signal	I/O		Description
ACLK	I		AXI clock, maximal frequency 133 Mhz
ACLK_SLOW	I		AXI all time clock
IPG_CLK_S	I		IPG clock.
RST_B	I		Active low HW reset.
WEIM_WARM_RESET	I		Warm Reset. If this signal is asserted the rst_b will reset only the internal FF and state machine while SW registers will keep their current state.This signal is active high signal.
BOOT_CFG[11:0]	I		Boot Configuration. These input pins determine the state after reset of DSZ[2],AUS, CSREC[2:1],DSZ[1:0], MUM, OEA[1], RAL,RWSC[4:2] of CSRCR0 and ERRST bit of WCR., see Table 63-2 for detailed description.
WEIM_NFC_BASE[3:0]	I		WEIM CS0 base address. Those via connection are holding the 4 MSB of the WEIM base address. **Note:** In case those inputs are driven by fuses/external register and not by VIA the value of those signals can be changed only during reset. WEIM_NFC_BASE shouldn't be configured to F in order to avoid memory address wrap around.
ACT_CS[5:0]	I		Active chip selects. Each bit in the ACT_CS[5:0] bus represent one of the six chip selects of the WEIM. When ACT_CS[x]=1'b1, the corresponding chip select is active and has a valid address space according to it address space configuration determine from ADDRSx[1:0] bus input. The configuration is fixed and is set by VIA connection, please refer to the SOC chapter for the specific WEIM chip select configuration. **Note:** In case those inputs are driven by fuses/external register and not by VIA the value of those signals can be changed only during reset.
ADDRS0[1:0] ADDRS1[1:0] ADDRS2[1:0] ADDRS3[1:0] ADDRS4[1:0] ADDRS5[1:0]	I		Address Space. ADDRSx[1:0] is setting the space for each chip selects which is active (see ACT_CS[5:0] input description). The address space of the first active chip selects must be the biggest one, the following active chip selects address space may be equal or lower. Total address space size is 512 Mbyte. The configuration is fixed and is set by VIA connection, please refer to the SOC chapter for the specific WEIM chip select configuration. Please see Table for values supported and examples of configurations. **Note:** In case those inputs are driven by fuses/external register and not by VIA the value of those signals can be changed only during reset.
BIT_24_CRE_VIA			CRE is driven on bit 24
BIT_25_CRE_VIA			CRE is driven on bit 25
BIT_26_CRE_VIA			CRE is driven on bit 26
BIT_27_CRE_VIA			CRE is driven on bit 27
AWADDR[31:0]	I		Axi Write Address
AWSIZE[2:0]	I		Axi write access size
AWBURST[1:0]	I		Axi write access burst type.
AWLEN[3:0]	I		Axi write access length

Table 63-4. Detailed Signal Descriptions (continued)

Signal	I/O		Description
AWPORT0	I		Axi write access protection type. Only privileged/Normal mode are supported. 0 Normal Mode. 1 Privileged Mode.
AWVALID	I		Axi write address valid
AWID[3:0]	I		Axi write address ID
WRITE_BIGEND	I		Axi write address endian mode. 0 Access is in little endian. 1 Access is in big endian.
AWREADY	O		WEIM ready for write address
WDATA[31:0]	I		Axi Write Data
WSTRB[3:0]	I		Axi write byte strobe
WID[1:0]	I		Axi write data ID
WALID	I		Axi write data valid
WLAST	I		Axi last write data
WREADY	O		WEIM ready for write data
BRESP	O		Axi write response
BVALID	O		Axi write response valid
BID	O		Axi write response ID
BREADY	I		AXI ready for write response
ARADDR[31:0]	I		Axi read Address
ARSIZE[2:0]	I		Axi read access size
ARBURST[1:0]	I		Axi read access burst type
ARLEN[3:0]	I		Axi read access length
ARPORT0	I		Axi read access protection type
ARVALID	I		Axi read address valid
ARID[3:0]	I		Axi read address ID
READ_BIGEND	I		Axi read address endian mode
ARREADY	O		WEIM ready for read address
RDATA[31:0]	O		Axi read Data
RID[1:0]	O		Axi read data ID
RVALID	O		Axi read data valid
RRESP	O		Axi read error response
RLAST	O		Axi last read data
RREADY	I		AXI ready for read data

Table 63-4. Detailed Signal Descriptions (continued)

Signal	I/O	Description	
IPS_ADDR[11:2]	I		IPS address
IPS_MODULE_EN	I		IPS module enable
IPS_RWB	I		IPS write enable. Active low signal. 0 - write 1- read
IPS_WDATA[31:0]	I		IPS write data
IPS_RDATA[31:0]	O		IPS read data
IPS_XFR_ERR	O		IPS error. Ips error will be generated whenever ips_module_en is asserted and ips_addr points to illegal address. (ips_addr[11:2] > 26'h)
IPS_XFR_WAIT	O		IPS wait. Ips wait will be asserted in case the access to register need more than 1 cycle. (see WEIM IP access register and Error address register).
IPI_WEIM_INT	O		Interrupt toward the master
LPMD	I		Low power request. Upon getting a low power request the WEIM completes the current AXI access, asserts the lpack signal and de-assert the wready/awready and arready signals. De-assertion of the lpmd will de-assert the lpack signal and assert the wready/awready and arready signals.
LPACK	O		Low power acknowledge. Lpack will be asserted if lpmd is high and there is no active/pending axi access.
WEIM_GRANT	I		Handshake signal from NFC. 0 - NFC is using the shared memory bus. Therefore, WEIM can't start axi access (if new access reaches WEIM it will be pending until WEIM_GRANT will be deasserted). 1- NFC isn't using the shared memory bus. Therefore, WEIM can access the bus immediately. **Note**: In 16 bit Muxed WEIM does not use the data bus therefore, there is no sharing of data bus with NFC and WEIM does not wait for grant from NFC.
WEIM_BUSY	O		Handshake signal to NFC. 0 WEIM does not have active or pending access or the current access is 16 Muxed mode. 1 WEIM has active or pending access and the current access is not 16 muxed mode.
IPP_DO_BCLK	O		Burst Clock (BCLK). This active-high output signal is used to clock external, burst-capable devices to synchronize the loading and incrementing of addresses and delivery of burst read and write data to/from the WEIM. Its behavior is affected by the BCM bit in the WEIM Configuration Register and the SWR, SRD, BCD and BCS bit fields in the Chip Select Configuration Registers.
IPP_IND_DTACK	I		Data Ack. for async. access. This input is used as a data ack. signal for single async. accesses.
IPP_IND_RDY_INT	I		External interrupt for NandFlash Based memories with NorFlash interface. ready after reset - Some External devices may use this signal for initial period after reset to indicate of a ready/wait state before boot sequence. This feature can be set by ERRST bit in the WCR.
IPP_IND_FB_BCLK	I		Burst Clock Feedback. This input is used to provide input data sampling clock in high data speed. It is a feedback from the IO PAD of the BCLK output pin that intend to align the clock used by the memory, and the one that is used to sample the read data.
IPP_MUXED_DATA_IN[15:0]	I		Input Data Bus. This bus is the 16 LSB input data from external devices in 32 bit muxed mode.

Table 63-4. Detailed Signal Descriptions (continued)

Signal	I/O	Description	
IPP_IND_READ_DATA[31:0]	I		Input Data Bus. This bus is the 32 bit input data from external devices (in 32 bit muxed mode only 16 LSB are used).
IPP_IND_WAIT_B	I		Ready/Busy/Wait signal. This active-low input signal is asserted by external burst capable devices which support fix or variable latency of data. It is serviced in synchronous mode only (SWR=1/SRD=1). WAIT will have a pull up resistor in IO. The signal indicates whether the External device is ready for data transaction or not. Busy cycles (or wait cycles) of the external device can occur at the start of a Burst access or at page boundary crossover. **Note:** For burst devices WAIT output should be configured to change one cycle before data is ready (before delay). Some External devices may not use this input signal for ready state indication (fix latency without WAIT signal monitoring), in this case WEIM should be configured accordingly (see RFL/WFL/PSZ bits description).
IPP_DO_CS_B[5:0]	O		Chip Selects. This signals are chip selects active-low output pins. Its behavior is affected by the RCSA/WCSA and RCSN/WCSN bit fields in the Chip Select Configuration Registers.
IPP_DO_OE_B	O		Output Enable. This active-low output signal indicates the bus access is a read and enables external devices to drive the data bus with read data. Its behavior is affected by the OEA and OEN bit fields in the Chip Select Configuration Registers.
IPP_DO_WE_B	O		Memory Write Enable. This active-low output signal indicates the bus access is a write and enables external devices to sample the data bus. Its behavior is affected by the WEA and WEN bit fields in the Chip Select Configuration Registers.
IPP_DO_BE_B[3:0]	O		Byte Enable. Those active-low output signals indicate active data bytes for the current access. They may be configured to assert for write cycles only. BE[0] corresponds to DATA_OUT[7:0], BE[1] corresponds to DATA_OUT[15:8], BE[2] corresponds to DATA_OUT[23:16], BE[3] corresponds to DATA_OUT[31:24]. n write accesses its behavior is affected by the BEA and BEN bit fields for Asynchronous mode only. In read access (synchronous or asynchronous) it always assert at start of access and negate at end of the access.
IPP_DO_ADV_B	O		Address Valid. This active-low output signal is asserted during burst mode accesses to cause the external burst capable device to load a new starting burst address. Assertion of ADV indicates that a valid address is present on the address bus. Its behavior is affected by the SWR, SRD, BCD, BCS, RADVA, WADVA, WAVDN, and RADVN bit fields in the Chip Select Configuration Registers. In asynchronous mode, ADV length is affected by the RADVA, WADVA, WADVN, and RADVN bit fields. Minimum length of ADV signal in all modes is one WEIM clock cycle.
IPP_DO_CRE	O		CRE is used as CRE/PS for CellularRam type of memory. It used for Mode Register Set command. It can be configured ad active low or active high signal. See CRE and CREP bits description in the CSGCRx registers.
IPP_DO_CRE_SEL	O		CRE select used for top level muxing of CRE signal with other signal
IPP_DO_STROBE	O		Strobe. This signal allows capture current access controls, address and data on logic analyzer. Sync. and async. accesses are supported. Note: Strobe signal for read data is active (RL + 1) cycles after data on external bus is valid.

Table 63-4. Detailed Signal Descriptions (continued)

Signal	I/O		Description
IPP_DO_ADDR_OUT[27:0]	O		Address Bus. These pins are used as address bits [27:0]. In 32 bit data multiplexed mode the 16 LSB of the data out and the 16 LSB of the address are muxed on the 16 LSB address bits.These pins represent [27:2] AXI address bits for word-width memory, [26:1] bits for half-word width memory and [25:0] bits for byte-width memory. **Note:** CRE bit is driven on one bit of ADDR_OUT[27:24] according to BIT_2x_CRE_VIA. In 32 bit muxed mode BE [3:2] are driven of ADDR_OUT[23:22]
IPP_DO_DATA_MADDR_OUT[31:0]	O		Output Data Bus. Those signals are output data bus used to transfer data to an external devices. Bidirectional data bus are made in IO PAD from DATA_IN[31:0] and DATA_OUT[31:0]. In 32 bit multiplexed mode the 16 MSB of data out and the 12 MSB of the address are muxed on the 16 LSB of the data. In 16 bit multiplexed mode this bus is not used. **Note**: In 32 bit muxed mode CRE bit is driven on DATA_MADDR_OUT[15] during address phase.
IPP_DO_DATA_DIR[3:0]	O		Input/Output directions for the DATA bus pads. 1 value indicates OUT direction, Zero value indicates Input direction (default). When working in multiplexed mode this bus influenced from ADH bit field in the chip select configuration registers.
IPP_DO_MADDR_DIR[1:0]	O		Input/Output directions for the address bus pads. 1 value indicates OUT direction, Zero value indicates Input direction (default). When working in multiplexed mode this bus influenced from ADH bit field in the chip select configuration registers. In non-muxed mode this directions will be always output.

63.4 Memory Map and Register Definition

The WEIM module includes 33 user-accessible 32-bit registers. The common register called the WEIM Configuration Register (WCR) which contains control bits that configure the WEIM for certain operation modes. Other 30 registers named Chip Select 0–5 General 1, General 2, Read and Write Configuration register correspondingly (CS0GCR1, CS0GCR2, CS0RCR1, CS0RCR2, CS0WCR,...,CS5GCR1, CS5GCR2, CS5RCR1, CS5RCR2, CS5WCR) and compose six groups of Chip Select Configuration Registers 0–5 (CS0CR–CS5CR) for each chip select. Configuration Registers layout is slightly different for the register group of CS0–CS0CR, because CS0CR reset state depends on boot signals input. These registers are accessible with IPS control signals only with word size (32-bit) reads and writes accesses. Additional registers are the WEIM IP access register (for ips sync. access and CS0 boot config. sync.) and Error address register (holds AXI error address).

63.4.1 Memory Map

Table 63-5 shows the WEIM memory map.

Table 63-5. WEIM Registers Memory Map

Address	Register	Access	Reset Value	Section/Page
General Registers				
0xBASE+0x2020 (CS0GCR1)	Chip Select 0 General Configuration Register 1	R/W[1]	0x00XY008W X-BOOT_CFG[10:8],0 Y-BOOT_CFG[11], BOOT_CFG[1:0],0 0, W-BOOT_CFG[2],0,0, 1	63.4.3.1/63-20

63.4.2 Register Summary

The conventions in Figure 63-2 and Table 63-7 serve as a key for the register summary and individual register diagrams.

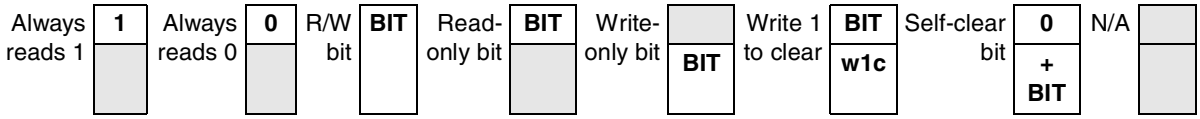

Figure 63-2. Key to Register Fields

Table 63-7 provides a key for register figures and tables and the register summary.

Table 63-7. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 63-8 shows the register summary. Note that only the first entry reflects an actual register in this file. The other entries in the table diverge from the registers they summarize in order to display additional register summary examples.

63.4.3 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number.

The 160 bits used to control Individual Chip Select are divided into five registers: Chip Select x General Configuration Register 1 (CSxGCR1), Chip Select x General Configuration Register 2 (CSxGCR2), Chip Select x Read Configuration register1 (CSxRCR1), Chip Select x Read Configuration register2 (CSxRCR2) and Chip Select x Write Configuration Register (CSxWCR). In addition there are three general registers WCR, WIAR, and EAR.

NOTE

All WEIM registers are sampled by IPG_CLK_S. Therefore IPG_CLK_S must be active when accessing through IP bus.

Read access from all registers (except WIAR and EAR) will generate 1 IPG_XFR_WAIT cycle.

Read access from WIAR and EAR will generates 6 IPG_XFR_WAIT cycles.

Write access to all registers (except EAR) will generates 3 IPG_XFR_WAIT cycles.

Write access to EAR will generates 6 IPG_XFR_WAIT cycles.

63.4.3.1 Chip Select x General Configuration Register 1

Figure 63-3 shows the chip select x general configuration register 1. Table 63-9 describes its fields.

Address 0xBASE+0x2020 (CS0GCR1)
0xBASE+0x2018 (CS1GCR1)
0xBASE+0x2030 (CS2GCR1)
0xBASE+0x2048 (CS3GCR1)
0xBASE+0x2060 (CS4GCR1)
0xBASE+0x2078 (CS5GCR1)

Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 63-3. Chip Select x General Configuration Register 1

Table 63-9. Chip Select x General Configuration Register 1 Field Descriptions

Field	Description
31–28 PSZ	Page Size. This bit field indicates memory page size in words (word is defined by the DSZ field). PSZ is used when fix latency mode is applied, WFL=1 for sync. write accesses, RFL=1 for sync. Read accesses. When working in fix latency mode WAIT signal from the external device is not being monitored, PSZ is used to determine if page boundary is reached and renewal of access is preformed. This bit field is ignored when sync. Mode is disabled or fix latency mode is not being used for write or read access separately. It can be valid for both access type, read or write, or only for one type, according to configuration. PSZ is cleared by a hardware reset. 0000 8 words page size 0001 16 words page size 0010 32 words page size 0011 64 words page size 0100 128 words page size 0101 256 words page size 0110 512 words page size 0111 1024 (1k) words page size 1000 2048 (2k) words page size 1001–1111 Reserved
27 WP	Write Protect. This bit prevents writes to the address range defined by the corresponding chip select. WP is cleared by a hardware reset. 0 Writes are allowed in the memory range defined by chip. 1 Writes are prohibited. All attempts to write to an address mapped by this chip select result in a error response and no assertion of the chip select output.

Table 63-9. Chip Select x General Configuration Register 1 Field Descriptions (continued)

Field	Description
26–24 GBC	Gap Between Chip Selects. This bit field, according to the settings shown below, determines the minimum time between end of access to the current chip select and start of access to different chip select. GBC is cleared by a hardware reset. 000 minimum of 0 WEIM clock cycles before next access from different chip select (async. mode only) 001 minimum of 1 WEIM clock cycles before next access from different chip select 001 minimum of 2 WEIM clock cycles before next access from different chip select ... 111 minimum of 7 WEIM clock cycles before next access from different chip select
23 AUS	Address UnShifted. This bit indicates an unshifted mode for address assertion for the relevant chip select accesses. AUS bit is cleared by hardware reset. 0 Address shifted according to port size (DSZ config.) 1 Address unshifted **Note**: Reset value for CS0GCR1 for is BOOT_CFG[10]. For CS1GCR1-CS5GCR1 reset value is 0.
22–20 CSREC	CS Recovery. This bit field, according to the settings shown below, determines the minimum pulse width of CS, OE, and WE control signals before executing a new back to back access to the same chip select. CSREC is cleared by a hardware reset. 000 0 WEIM clock cycles minimum width of CS, OE and WE signals (read async. mode only) 001 1 WEIM clock cycles minimum width of CS, OE and WE signals 010 2 WEIM clock cycles minimum width of CS, OE and WE signals ... 111 7 WEIM clock cycles minimum width of CS, OE and WE signals **Note:** Reset value for CS0GCR1 for CSREC[2:1] is BOOT_CFG[9:8], for CSREC[0] is 0. For CS1GCR1-CS5GCR1 reset value is 000.
19 SP	Supervisor Protect. This bit prevents accesses to the address range defined by the corresponding chip select when the access is attempted in the User mode. SP is cleared by a hardware reset. 0 User mode accesses are allowed in the memory range defined by chip select. 1 User mode accesses are prohibited. All attempts to access an address mapped by this chip select in User mode results in an error response and no assertion of the chip select output.
18–16 DSZ	Data Port Size. This bit field defines the width of an external device's data port as shown below. 000 Reserved. 001 16 bit port resides on DATA[15:0] 010 16 bit port resides on DATA[31:16] 011 32 bit port resides on DATA[31:0] 100 8 bit port resides on DATA[7:0] 101 8 bit port resides on DATA[15:8] 110 8 bit port resides on DATA[23:16] 111 8 bit port resides on DATA[31:24] **Note:** Only async. access supported for 8 bit port. Reset value for CS0GCR1 for DSZ is BOOT_CFG[11],BOOT_CFG[1:0].For CS1GCR1-CS5GCR1 reset value is 001.

Table 63-9. Chip Select x General Configuration Register 1 Field Descriptions (continued)

Field	Description
15–14 BCS	Burst Clock Start. When SRD=1 or SWR=1,this bit field determines the number of WEIM clock cycles delay from start of access before the first rising edge of BCLK is generated. When BCD=0 value of BCS=0 results in a half clock delay after the start of access. For other values of BCD a one clock delay after the start of access is applied, not an immediate assertion. BCS is cleared by a hardware reset. 00 0 WEIM clock cycle additional delay 01 1 WEIM clock cycle additional delay 10 2 WEIM clock cycle additional delay 11 3 WEIM clock cycle additional delay
13–12 BCD	Burst Clock Divisor. This bit field contains the value used to program the burst clock divisor for BCLK generation. It is used to divide the internal WEIMbus frequency. BCD is cleared by a hardware reset. **Note:** For other then the mentioned below frequency such as 104 MHz, WEIM clock (input clock) should be adjust accordingly. 00 Divide WEIM clock by 1 01 Divide WEIM clock by 2 10 Divide WEIM clock by 3 11 Divide WEIM clock by 4
11 WC	Write Continuous. The WI bit indicates that write access to the memory are always continuous accesses regardless of the BL field value. WI is cleared by hardware reset. 0 Write access burst length occurs according to BL value. 1 Write access burst length is continuous.
10–8 BL	Burst Length. The BL bit field indicates memory burst length in words (word is defined by the DSZ field) and should be properly initialized for mixed wrap/increment accesses support. Continuous BL value corresponds to continuous burst length setting of the external memory device. For fix memory burst size, type is always wrap. In case not matching wrap boundaries in both the memory (BL field) and Master access on the current address, WEIM update address on the external device address bus and regenerates the access. BL is cleared by a hardware reset. When APR=1, Page Read Mode is applied, BL determine the number of words within the read page burst. BL is cleared by a hardware reset for CS0GCR1 – CS5GCR1. 000 4 words Memory wrap burst length (read page burst size when APR = 1) 001 8 words Memory wrap burst length (read page burst size when APR = 1) 010 16 words Memory wrap burst length (read page burst size when APR = 1) 011 32 words Memory wrap burst length (read page burst size when APR = 1) 100 Continuous burst length (2 words read page burst size when APR = 1) 101 Reserved 110 Reserved 111 Reserved
7 CREP	Configuration Register Enable Polarity. This bit indicates CRE memory pin assertion state, active-low or active-high, while executing a memory register set command to the external device (PSRAM memory type). CREP is set by a hardware reset. **Note:** Whenever PSRAM is connected the CREP value must be correct also for accesses where CRE is disabled. For Non-PSRAM memory CREP value should be 1. 0 CRE signal is active low. 1 CRE signal is active high.
6 CRE	Configuration Register Enable. This bit indicates CRE memory pin state while executing a memory register set command to PSRAM external device. CRE is cleared by a hardware reset. 0 CRE signal use is disable. 1 CRE signal use is enable.

Table 63-9. Chip Select x General Configuration Register 1 Field Descriptions (continued)

Field	Description
5 RFL	Read Fix Latency. This bit field determine if the controller is monitoring the WAIT signal from the External device connected to the chip select (handshake mode - fix or variable data latency) or if it start sampling data according to RWSC field, it only valid in synchronous mode. RFL is cleared by a hardware reset. When RFL=1 Burst access is terminated on page boundary and resume on the following page according to BL bit field configuration, because WAIT signal is not monitored from the external device. 0 the External device WAIT signal is being monitored, and it reflect the external data bus state 1 the state of the External devices is determined internally (Fix latency mode only)
4 WFL	Write Fix Latency. This bit field determine if the controller is monitoring the WAIT signal from the External device connected to the chip select (handshake mode - fix or variable data latency) or if it start data transfer according to WWSC field, it only valid in synchronous mode. WFL is cleared by a hardware reset. When WFL=1 Burst access is terminated on page boundary and resume on the following page according to BL bit field configuration, because WAIT signal is not monitored from the external device 0 the External device WAIT signal is being monitored, and it reflect the external data bus state 1 the state of the External devices is determined internally (Fix latency mode only)
3 MUM	Multiplexed Mode. This bit determines the address/data multiplexed mode for asynchronous and synchronous accesses for 8 bit, 16 bit or 32 bit devices (DSZ config. dependent). 0 Multiplexed Mode disable 1 Multiplexed Mode enable **Note:** Reset value for CS0GCR1 for MUM is BOOT_CFG[2].For CS1GCR1-CS5GCR1 reset value is 0.
2 SRD	Synchronous Read Data. This bit field determine the read accesses mode to the External device of the chip select. The External device should be configured to the same mode as this bit implicates. SRD is cleared by a hardware reset. 0 Read accesses are in Asynchronous mode 1 Read accesses are in Synchronous mode **Note**: Sync. accesses supported only for 16/32 bit port.
1 SWR	Synchronous Write Data. This bit field determine the write accesses mode to the External device of the chip select. The External device should be configured to the same mode as this bit implicates. SWR is cleared by a hardware reset. 0 Write accesses are in Asynchronous mode 1 Write accesses are in Synchronous mode **Note**: Sync. accesses supported only for 16/32 bit port.
0 CSEN	CS Enable. This bit controls the operation of the chip select pin. CSEN is set by a hardware reset for CSGCR0 to allow external boot operation. CSEN is cleared by a hardware reset to CSGCR1–CSGCR5. 0 Chip select function is disabled; attempts to access an address mapped by this chip select results in an error respond and no assertion of the chip select output 1 Chip select is enabled, and is asserted when presented with a valid access. **Note**: Reset value for CS0GCR1 for CSEN is 1. For CS1GCR1-CS1GCR5 reset value is 0.

63.4.3.2 Chip Select x General Configuration Register 2

Figure 63-4 shows the register; Table 63-10 shows its field descriptions.

Address 0xBASE+0x2024 (CS0GCR2)
0xBASE+0x201C (CS1GCR2)
0xBASE+0x2034 (CS2GCR2)
0xBASE+0x204C (CS3GCR2)
0xBASE+0x2064 (CS4GCR2)
0xBASE+0x207C (CS5GCR2)

Access: User read-write

Figure 63-4. Chip Select x General Configuration Register 2

Table 63-10. Chip Select x General Configuration Register 2 Field Descriptions

Field	Description
31–10	Reserved
9 DAP	Data Acknowledge Polarity. This bit indicates DTACK memory pin assertion state, active-low or active-high, while executing an async access using DTACK signal from the external device. DAP is cleared by a hardware reset. 0 DTACK signal is active high 1 DTACK signal is active low
8 DAE	Data Acknowledge Enable. This bit indicates external device is using DTACK pin as strobe/terminator of an async. access. DTACK signal may be used only in asynchronous single read (APR=0) or write accesses. DTACK poling start point is set by DAPS bit field. polarity of DTACK is set by DAP bit field. DAE is cleared by a hardware reset. 0 DTACK signal use is disable 1 DTACK signal use is enable
7–4 DAPS	Data Acknowledge Poling Start. This bit field determine the starting point of DTACK input signal polling. DAPS is used only in asynchronous single read or write accesses. **Note:** Since DTACK is an async. signal the start point of DTACK signal polling is at least 3 cycles after the start of access. DAPS is cleared by a hardware reset. 0000 3 WEIM clk cycle between start of access and first DTACK check 0001 4 WEIM clk cycles between start of access and first DTACK check 0010 5 WEIM clk cycles between start of access and first DTACK check ... 0111 10 WEIM clk cycles between start of access and first DTACK check .... 1011 14 WEIM clk cycles between start of access and first DTACK check ... 1111 18 WEIM clk cycles between start of access and first DTACK check

Table 63-10. Chip Select x General Configuration Register 2 Field Descriptions (continued)

Field	Description
3–2	Reserved
1–0 ADH	Address hold time - This bit field determine the address hold time after ADV negation when mum = 1 (muxed mode). When mum = 0 this bit has no effect. For read accesses the field determines when the pads direction will be switched. 00 0 cycle after ADV negation 01 1 cycle after ADV negation 10 2 cycle after ADV negation 11 Reserved **Note:** Reset value for CS0GCR2 for ADH is 10. For CS1GCR2-CS5GCR2 reset value is 00.

63.4.3.3 Chip Select x Read Configuration Register 1

Figure 63-5 shows the register; Table 63-11 shows its field descriptions.

Address 0xBASE+0x2008 (CS0RCR1)

Figure 63-5. Chip Select x Read Configuration Register 1

Table 63-11. Chip Select x Read Configuration Register 1 Field Descriptions

Field	Description
31–30	Reserved
29–24 RWSC	Read Wait State Control. This bit field programs the number of wait-states, according to the settings shown below, for synchronous or asynchronous read access to the external device connected to the chip select. When SRD=1 and RFL=0, RWSC indicates the number of burst clock (BCLK) cycles from the start of an access, before the controller can start sample data.Since WAIT signal can be asserted one cycle before the first data can be sampled, the controller starts evaluating the WAIT signal state one cycle before, this is referred as handshake mode or variable latency mode. When SRD=1 and RFL=1, RWSC indicates the number of burst clock (BCLK) cycles from the start of an access, until the external device is ready for data transfer, this is referred as fix latency mode. When SRD=0, RFL bit is ignored, RWSC indicates the asynchronous access length and the number of WEIM clock cycles from the start of access until the external device is ready for data transfer. RWSC is cleared by a hardware reset. 000000 Reserved 000001 RWSC value is 1 000010 RWSC value is 2 ... 000111 RWSC value is 7 001000 RWSC value is 8 001000 RWSC value is 9 ... 100000 RWSC value is 32 100001 RWSC value is 33 100010 RWSC value is 34 ... 111101 RWSC value is 61 111110 RWSC value is 62 111111 RWSC value is 63 **Note:** Reset value for CS0RCR1 for RWSC[4:2] is BOOT_CFG [7:5] for RWSC[5] and RWSC[1:0] is 0. For CG1RCR1-CS1RCR5 reset value is 000000.
23	Reserved
22–20 RADVA	ADV Assertion. This bit field determines when ADV signal is asserted for synchronous or asynchronous read modes according to the settings shown below. RADVA is cleared by a hardware reset. 000 0 WEIM clock cycles between beginning of access and ADV assertion 001 1 WEIM clock cycles between beginning of access and ADV assertion 010 2 WEIM clock cycles between beginning of access and ADV assertion ... 111 7 WEIM clock cycles between beginning of access and ADV assertion
19 RAL	Read ADV Low. This bit field determine ADV signal negation time. When RAL=1, RADVN bit field is ignored and ADV signal will stay asserted until end of access. When RAL=0 negation of ADV signal is according to RADVN bit field configuration. RAL is configured at reset time with the BOOT_CFG[3] pin for CS0RCR1. RAL is cleared by a hardware reset for CS1RCR1 – CS5RCR1.

Table 63-11. Chip Select x Read Configuration Register 1 Field Descriptions (continued)

Field	Description
18–16 RADVN	ADV Negation. This bit field determines when ADV signal to memory is negated during read accesses. When SRD=1 (synchronous read mode), ADV negation occurs according to the following formula: (RADVN + RADVA + BCD + BCS + 1) WEIM clock cycles from start of access. When asynchronous read mode is applied (SRD=0) and RAL=0 ADV negation occurs according to the following formula: (RADVN + RADVA + 1) WEIM clock cycles from start of access. RADVN is cleared by a hardware reset. **Note**: Reset value for CS0RCR1 for RADVN is 2. For CS1RCR1 - CS5RCR1 reset value is 000. **Note**: This field should be configured so ADV negation will occur before the end of access. For ADV negation at the same time with the end of access user should RAL bit.
15	Reserved
14–12 OEA	OE Assertion. This bit field determines when OE signal are asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. OEA is cleared by a hardware reset. In muxed mode OE assertion occurs (OEA + RADVN + RADVA + ADH +1) WEIM clock cycles from start of access. 000 0 WEIM clock cycles between beginning of access and OE assertion 001 1 WEIM clock cycles between beginning of access and OE assertion 010 2 WEIM clock cycles between beginning of access and OE assertion ... 111 7 WEIM clock cycles between beginning of access and OE assertion **Note**: Reset value for CS0RCR1 is 000 if BOOT_CFG[2] is 0. If BOOT_CFG[2] is 1 the reset value for CS0RCR1 is 010. Reset value CS1RCR1 - CS5RCR1 is 000.
11	Reserved
10–8 OEN	OE Negation. This bit field determines when OE signal is negated during read cycles in asynchronous single mode only (SRD=0 and APR = 0), according to the settings shown below. This bit field is ignored when SRD=1. OEN is cleared by a hardware reset. 000 0 WEIM clock cycles between end of access and OE negation 001 1 WEIM clock cycles between end of access and OE negation 010 2 WEIM clock cycles between end of access and OE negation ... 111 7 WEIM clock cycles between end of access and OE negation
7	Reserved
6–4 RCSA	Read CS Assertion. This bit field determines when CS signal is asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. RCSA is cleared by a hardware reset. 000 0 WEIM clock cycles between beginning of read access and CS assertion 001 1 WEIM clock cycles between beginning of read access and CS assertion 010 2 WEIM clock cycles between beginning of read access and CS assertion ... 111 7 WEIM clock cycles between beginning of read access and CS assertion

Table 63-11. Chip Select x Read Configuration Register 1 Field Descriptions (continued)

Field	Description
3	Reserved
2–0 RCSN	Read CS Negation. This bit field determines when CS signal is negated during read cycles in asynchronous single mode only (SRD=0 and APR = 0), according to the settings shown below. This bit field is ignored when SRD=1. RCSN is cleared by a hardware reset. 000 0 WEIM clock cycles between end of read access and CS negation 001 1 WEIM clock cycles between end of read access and CS negation 010 2 WEIM clock cycles between end of read access and CS negation ... 111 7 WEIM clock cycles between end of read access and CS negation

Table 63-12. Chip Select x Read Configuration Register 2 Field Descriptions

Field	Description
31–16	Reserved
15 APR	Asynchronous Page Read. This bit field determine the asynchronous read mode to the external device. When APR=0, the async. read access is done as single word (where word is defined by the DSZ field). when APR=1, the async. read access executed as page read. page size is according to BL field config., RCSN,RBEN,OEN and RADVN are being ignored. APR is cleared by a hardware reset for CS1GCR1 – CS5GCR1. **Note:** SRD=0 and MUM=0 must apply when APR=1

Table 63-12. Chip Select x Read Configuration Register 2 Field Descriptions (continued)

Field	Description
14–12 PAT	Page Access Time. This bit field is used in Asynchronous Page Read mode only (APR=1). the initial access is set by RWSC as in regular asynchronous mode. the consecutive address assertions width determine by PAT field according to the settings shown below. when APR=0 this field is ignored. PAT is cleared by a hardware reset for CS1GCR1 – CS5GCR1. 000 Address width is 2 WEIM clock cycles 001 Address width is 3 WEIM clock cycles 010 Address width is 4 WEIM clock cycles 011 Address width is 5 WEIM clock cycles 100 Address width is 6 WEIM clock cycles 101 Address width is 7 WEIM clock cycles 110 Address width is 8 WEIM clock cycles 111 Address width is 9 WEIM clock cycles
11–10	Reserved
9–8 RL	Read Latency. This bit field indicates cycle latency when executing a synchronous read operation. The fields holds the feedback clock loop delay in aclk cycle units. This field is cleared by a hardware reset. 00 Feedback clock loop delay is up to 1 cycle for BCD = 0 or 1.5 cycles for BCD != 0 01 Feedback clock loop delay is up to 2 cycle for BCD = 0 or 2.5 cycles for BCD != 0 10 Feedback clock loop delay is up to 3 cycle for BCD = 0 or 3.5 cycles for BCD != 0 11 Feedback clock loop delay is up to 4cycle for BCD = 0 or 4.5 cycles for BCD != 0
7	Reserved
6–4 RBEA	Read BE Assertion. This bit field determines when BE signal is asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. RBEA is cleared by a hardware reset. 000 0 WEIM clock cycles between beginning of read access and BE assertion 001 1 WEIM clock cycles between beginning of read access and BE assertion 010 2 WEIM clock cycles between beginning of read access and BE assertion ... 111 7 WEIM clock cycles between beginning of read access and BE assertion
3 RBE	Read BE enable. This bit field determines if BE will be asserted during read access. 0 BE are disabled during read access. 1 BE are enable during read access according to value of RBEA and RBEN bit fields.
2–0 RBEN	Read BE Negation. This bit field determines when BE signal is negated during read cycles in asynchronous single mode only (SRD=0 and APR=0), according to the settings shown below. This bit field is ignored when SRD=1. RBEN is cleared by a hardware reset. 000 0 WEIM clock cycles between end of read access and BE negation 001 1 WEIM clock cycles between end of read access and BE negation 010 2 WEIM clock cycles between end of read access and BE negation ... 111 7 WEIM clock cycles between end of read access and BE negation

Table 63-13. Chip Select x Write Configuration Register 1 Field Descriptions

Field	Description
31 WAL	Write ADV Low. This bit field determine ADV signal negation time in write accesses. When WAL=1, WADVN bit field is ignored and ADV signal will stay asserted until end of access. When WAL=0 negation of ADV signal is according to WADVN bit field configuration. WAL is configured at reset time with the BOOT_CFG[3] pin for CSWCR0. WAL is cleared by a hardware reset for CSWCR1 – CSWCR5.
30 WBED	Write Byte Enable Disable. When asserted this bit prevent from IPP_DO_BE_B[x] to be asserted during write accesses. This bit is cleared by hardware reset.

Table 63-13. Chip Select x Write Configuration Register 1 Field Descriptions (continued)

Field	Description
29–24 WWSC	Write Wait State Control. This bit field programs the number of wait-states, according to the settings shown below, for synchronous or asynchronous write access to the external device connected to the chip select. When SWR=1 and WFL=0, WWSC indicates the number of burst clock (BCLK) cycles from the start of an access, before the memory can sample the first data.Since WAIT signal can be asserted one cycle before the first data can be sampled, the controller starts evaluating the WAIT signal state one cycle before, this is referred as handshake mode or variable latency mode. When SWR=1 and WFL=1, WWSC indicates the number of burst clock (BCLK) cycles from the start of an access, until the external device is ready for data transfer, this is referred as fix latency mode. When SWR=0, WFL bit is ignored, WWSC indicates the asynchronous access length and the number of WEIM clock cycles from the start of access until the external device is ready for data transfer. WWSC is cleared by a hardware reset. 000000 Reserved 000001 WWSC value is 1 000010 WWSC value is 2 000011 WWSC value is 3 ... 111111 WWSC value is 63 **Note**: Reset value for CS0WCR for WWSC[4:2] is BOOT_CFG [7:5], for WWSC[5] and WWSC[1:0] is 0. For CS1WCR - CS5WCR5 reset value is 000000.
23–21 WADVA	ADV Assertion. This bit field determines when ADV signal is asserted for synchronous or asynchronous write modes according to the settings shown below. WADVA is cleared by a hardware reset. 000 0 WEIM clock cycles between beginning of access and ADV assertion 001 1 WEIM clock cycles between beginning of access and ADV assertion 010 2 WEIM clock cycles between beginning of access and ADV assertion ... 111 7 WEIM clock cycles between beginning of access and ADV assertion
20–18 WADVN	ADV Negation. This bit field determines when ADV signal to memory is negated during write accesses. When SWR=1 (synchronous write mode), ADV negation occurs according to the following formula: (WADVN + WADVA + BCD + BCS + 1) WEIM clock cycles. When asynchronous read mode is applied (SWR=0) ADV negation occurs according to the following formula: (WADVN + WADVA + 1) WEIM clock cycles. **Note**: Test value for CS0WCR for WADVN is 2. For CS1WCR–CS5WCR reset value is 000. This field should be configured so ADV negation will occur before the end of access. For ADV negation at the same time with the end of access user should WAL bit.
17–15 WBEA	BE Assertion. This bit field determines when BE signal is asserted during write cycles in async. mode only (SWR=0), according to the settings shown below. BEA is cleared by a hardware reset. 000 0 WEIM clock cycles between beginning of access and BE assertion 001 1 WEIM clock cycles between beginning of access and BE assertion 010 2 WEIM clock cycles between beginning of access and BE assertion ... 111 7 WEIM clock cycles between beginning of access and BE assertion **Note**: Reset value for CS0WCR for WBEA is 2. For CS1WCR - CS5WCR reset value is 000.
14–12 WBEN	BE[3:0] Negation. This bit field determines when BE[3:0] bus signal is negated during write cycles in async. mode only (SWR=0), according to the settings shown below. This bit field is ignored when SWR=1. BEN is cleared by a hardware reset. 000 0 WEIM clock cycles between end of access and WE negation 001 1 WEIM clock cycles between end of access and WE negation 010 2 WEIM clock cycles between end of access and WE negation ... 111 7 WEIM clock cycles between end of access and WE negation **Note**: Reset value for CS0WCR for WBEN is 2. For CS1WCR - CS5WCR reset value is 000.

Table 63-13. Chip Select x Write Configuration Register 1 Field Descriptions (continued)

Field	Description
11–9 WEA	WE Assertion. This bit field determines when WE signal is asserted during write cycles (synchronous or asynchronous mode), according to the settings shown below. This bit field is ignored when executing a read access to the external device. WEA is cleared by a hardware reset. 000 0 WEIM clock cycles between beginning of access and WE assertion 001 1 WEIM clock cycles between beginning of access and WE assertion 010 2 WEIM clock cycles between beginning of access and WE assertion ... 111 7 WEIMclock cycles between beginning of access and WE assertion **Note**: Reset value for CS0WCR for WEA is 2. For CS1WCR - CS5WCR reset value is 000.
8–6 WEN	WE Negation. This bit field determines when WE signal is negated during write cycles in asynchronous mode only (SWR=0), according to the settings shown below. This bit field is ignored when SWR=1. WEN is cleared by a hardware reset. 000 0 WEIM clock cycles between beginning of access and WE assertion 001 1 WEIM clock cycles between beginning of access and WE assertion 010 2 WEIM clock cycles between beginning of access and WE assertion ... 111 7 WEIM clock cycles between beginning of access and WE assertion **Note**: Reset value for CS0WCR for WEN is 2. For CS1WCR - CS5WCR reset value is 000.
5–3 WCSA	Write CS Assertion. This bit field determines when CS signal is asserted during write cycles (synchronous or asynchronous mode), according to the settings shown below.this bit field is ignored when executing a read access to the external device. WCSA is cleared by a hardware reset. 000 0 WEIM clock cycles between beginning of write access and CS assertion 001 1 WEIM clock cycles between beginning of write access and CS assertion 010 2 WEIM clock cycles between beginning of write access and CS assertion ... 111 7 WEIMclock cycles between beginning of write access and CS assertion
2–0 WCSN	Write CS Negation. This bit field determines when CS signal is negated during write cycles in asynchronous mode only (SWR=0), according to the settings shown below. This bit field is ignored when SWR=1. WCSN is cleared by a hardware reset. 000 0 WEIM clock cycles between end of read access and CS negation 001 1 WEIM clock cycles between end of read access and CS negation 010 2 WEIM clock cycles between end of read access and CS negation ... 111 7 WEIM clock cycles between end of read access and CS negation

Figure 63-9. WEIM Configuration Register

Table 63-15. WEIM Configuration Register Field Descriptions

Field	Description
31–11	Reserved
10–9 WDOG_LIMIT	Memory Watch Dog (WDog) cycle limit. This bit field determines the number of BCLK cycles (ACLK cycles in dtack mode) before the WDOG counter terminates the access and send an error response to the master. 00 128 BCLK cycles 01 256 BCLK cycles 10 512 BCLK cycles 11 1024 BCLK cycles
8 WDOG_EN	Memory WDog enable. This bit controls the operation of the WDOG counter that terminates the WEIM access. 0 Memory WDOG is Disabled 1 Memory WDog is Enabled
7–6	Reserved
5 INTPOL	Interrupt Polarity. This bit field determines the polarity of the external device interrupt. 0 External interrupt polarity is active low 1 External interrupt polarity is active high
4 INTEN	Interrupt Enable. When this bit is set the External signal RDY_INT as active interrupt. When interrupt occurs, INT bit at the WCR will be set and the WEIM_EXT_INT signal will be asserted correspondingly. This bit is cleared by a hardware reset. 0 External interrupt Disable 1 External interrupt Enable
3	Reserved

Table 63-15. WEIM Configuration Register Field Descriptions (continued)

Field	Description
GBCD 1–2	General Burst Clock Divisor. When BCM bit is set, this bit field contains the value used to program the burst clock divisor for Continuos BCLK generation. The other BCD bit fields for each chip select are ignored. It is used to divide the internal AXI bus frequency. When BCM=0 GBCD bit field has no influence. GBCD is cleared by a hardware reset. 00 Divide WEIM clock by 1 01 Divide WEIM clock by 2 10 Divide WEIM clock by 3 11 Divide WEIM clock by 4
0 BCM	Burst Clock Mode. This bit selects the burst clock mode of operation. It is used for system debug mode. BCM is cleared by a hardware reset. **Note:** The BCLK frequency in this mode is according to GBCD bit field. The BCLK phase is opposite to the WEIM clock in this mode if GBCD is 0. This bit should be used only in async. accesses. No sync access can be executed if this bit is set. 0 The burst clock runs only when accessing a chip select range with the SWR/SRD bits set. When the burst clock is not running it remains in a logic 0 state. When the burst clock is running it is configured by the BCD and BCS bit fields in the chip select Configuration Register. 1 The burst clock runs whenever ACLK is active (independent of chip select configuration)

63.4.3.8 WEIM IP Access Register

Figure 63-10 shows the register; Table 63-16 shows its field descriptions.

Address 0xBASE+0x2094 (WIAR) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 63-10. WEIM IP Access Register

Table 63-16. WEIM IP Access Register Field Descriptions

Field	Description
31–5	Reserved
4 ACLK_EN	ACLK enable. This bit gates the ACLK for the WEIM except from FFs that get ipg_aclk_s. After reset ACLK is enabled. 0 ACLK is disabled 1 ACLK is enabled

Table 63-16. WEIM IP Access Register Field Descriptions (continued)

Field	Description
3 ERRST	Enable READY After Reset. This bit indicates RDY_INT signal is used by an External Device on CS0. It used as a ready/busy status after reset of the device. ERRST is configured at reset time with the BOOT_CFG[4] pin. It is sticky bit, self cleared once RDY_INT signal assertion is detected. BOOT_CFG[4] pin will be ignored until hardware reset will be applied. When ERRST=1 the first fetch access from WEIM to the external device located on CS0 will be pending until RDY_INT signal indicate external device is ready, then WEIM will execute the access. 0 RDY_INT After Reset Disable 1 RDY_INT After Reset Enable **Note:** Reset value for ERRST is BOOT_CFG[4].
2 INT	Interrupt. This bit indicates interrupt assertion by an external device according to RDY_INT signal. When polling this bit, INT=0 indicates interrupt not occurred and INT=1 indicates assertion of the external device interrupt. This bit is cleared by a hardware reset.
1 IPS_ACK	IPS ACK. The WEIM is ready for ips access. There is no active AXI access and no new AXI access is accepted until this bit is cleared. This bit is cleared by the master after it completes the ips accesses. 0 Master can't access ips. 1 Master can access ips.
0 IPS_REQ	IPS request. The Master requests to access one of the IPS registers.Dutring such access the WEIM should not preform any AXI/memory accesses. The WEIM finishes the AXI accesses that already starts and asserts the IPS_ACK bit. 0 No Master requests ips access 1 Master requests ips access

63.4.3.9 Error Address Register

Figure 63-11 shows the register; Table 63-17 shows its field descriptions.

Address 0xBASE+0x2098 (EAR) Access: User read-write

Figure 63-11. Error Address Register

Table 63-17. Error Address Register Field Descriptions

Field	Description
31–0	Error Address. This bit field holds the AXI address of the last access that caused error. This register is read only register.

63.5 Functional Description

This section provides the functional description for the WEIM module.

63.5.1 Clocks

The WEIM has the following four input clocks:

- ACLK—WEIM clock (main clock, AXI clock), with a Max frequency of 133 MHz. This clock can be gated externally when there is no active AXI access.
- ACLK_SLOW—WEIM all time running ACLK. Used for FF that must be active even when WEIM is in low power down mode to provide clock for lpack/lpmd registers, IP registers, IP to AXI sync. registers.
- IPG_CLK_S—IPG clock for IP accesses.

NOTE

IP registers are activated by ACLK_SLOW clock.

BCLK is a clock which created from WEIM clock for External device usage. Integer division by 1, 2, 3, and 4 of the clock can be use with BCD bit field configuration, according to external devices demands.WEIM clock frequency may be reduce for lower frequency support which can’t be achieved via BCD bit field.

- FB_CLK is BCLK after pads delays.

63.5.2 Bus Sizing Configuration

The WEIM supports byte, half word, and word operands allowing access to ×8, ×16, ×32 ports. It can be address/data multiplexed in ×16, ×32 ports. The port size is programmable via the DSZ bit field in the corresponding Chip Select Configuration Register. A 8-bit port can reside in each one of the bytes of the data bus.A 16-bit port can reside on the lower 16 bits of the data bus, DATA_IN/OUT[15:0] or on the higher 16 bits of the data bus, DATA_IN/OUT[31:16] (see Table 63-1).

In the case of a multi-cycle transfer, the lower two address bits (ADDR[1:0]) are incremented appropriately. The WEIM address bus is configured according to DSZ bit field and AUS bits. There is either one bit (for ×16 port size) or two bits (for ×32 port size) right shift of the address bits (only when AUS=0) and no bit shift when AUS = 1 or DSZ[2] = 1.

The WEIM has a data multiplexer which takes the four bytes of the AXI data bus and routes them to their required positions to properly interface to memory.

NOTE

A word access to or from a ×16 port requires two external bus cycles to complete the transfer.

A word access to or from a ×8 port requires four external bus cycles to complete the transfer.

63.5.2.1 8-Bit Port Support

WEIM has limited support for mot68000 and Intel 386 protocols.

63.5.2.1.1 MOTOROLA 68000

WEIM has limited support for the mot6800 protocol; it only supports basic read or write asynchronous operation.

WEIM does not support the following for the mot6800 protocol:

- Read modify write operations
- Synchronous access operations
- All special accesses (CPU space, bus arbitration, bus control, bus error, and reset operations)
- FC outputs

63.5.2.1.2 Intel 386

WEIM has limited support for Intel 386 protocol; it only supports basic read or write asynchronous non-pipelined operations.

WEIM does not support the following for the Intel 386 protocol:

- Other bus cycle operations (interrupt, halt, and refresh)
- Bus Lock operation
- M/IO, DC, LBA, NA, REFRESH, and BS8 signals

63.5.3 WEIM Operational Modes

WEIM has the following main operational modes, which are selected by control bit fields settings. For details see the corresponding bit field descriptions of SWR/SRD/MUM. All modes are supported with 8-bit, 16-bit, or 32-bit port configuration, according to the DSZ bit field.

Table 63-18. WEIM Operation Modes Field Settings

Control Bit Fields			Brief Mode Description
MUM	SRD	SWR	
0	0	0	Asynchronous write/Asynchronous read for APR=0/ Asynchronous page read for APR=1, none multiplexed
		1	Synchronous write/ Asynchronous read or APR=0/ Asynchronous page read for APR=1,none multiplexed
	1	0	Asynchronous write/Synchronous read none multiplexed
		1	Synchronous write/read none multiplexed

Table 63-18. WEIM Operation Modes Field Settings (continued)

Control Bit Fields			Brief Mode Description
MUM	SRD	SWR	
1	0	0	Asynchronous write/read multiplexed
		1	Synchronous write/ Asynchronous read multiplexed
	1	0	Asynchronous write/Synchronous read multiplexed
		1	Synchronous write/read multiplexed

63.5.4 Burst Mode (Synchronous) Memory Operation

This mode is enabled for read or write access individually. Bit SWR set the burst mode for write operations at the corresponding chip select and bit SRD set it for read operation.

When this mode is set, the controller attempts to translate the Master burst accesses to memory burst accesses, being limited by the memory burst length, predefined by BL value, or memory and Master WRAP/INCR boundary crossing non-matching. Only the first address accessed is displayed by the controller on the external address bus, in a memory burst sequence.

WEIM may translate from some Master sequential accesses to one or few memory bursts, but not from two Master individual accesses to one memory burst.

For the first access in a memory burst sequence, the WEIM assert $\overline{\text{ADV}}$, causing the external burst device to latch the starting burst address and then toggle the burst clock (BCLK) a predefined number of cycles in order to latch the first unit of data. Subsequent accessed data units can then be burst in fewer clock cycles, realizing an overall increase in bus bandwidth.

NOTE

The BCLK signal toggles only when burst access is executed toward the external device (BCM=1’b0 for normal mode use), it runs with a 50% duty cycle until the end of access is reached. When access is terminated BCLK stop toggling.

Memory burst accesses are terminated by the WEIM whenever it detects the following:

- The specific burst length has executed completely—end of access
- Write access—missing data in write buffer (master is delaying the data transfer toward the WEIM
- Next sequential access crosses boundary with unequal condition (wrap/increment, burst length) on the Master and memory.
- Current memory burst length reached.

63.5.5 Burst Clock Divisor (BCD)

In some cases it may be necessary to slow the external bus in relation to the internal bus to allow accesses to burst devices that have a maximum operating frequency which is less than the operating frequency of

the internal bus. The internal bus frequency can be divided by one, two, three, or four for presentation on the external bus in burst mode operation.

To achieve frequency of BCLK other then an integer division, the cycle time of the WEIM clock entering the controller need to be changed accordingly.

By programming the BCD bit field to various values, two signals on the external bus are affected; $\overline{\text{ADV}}$ and BCLK. The $\overline{\text{ADV}}$ signal is asserted according to RADVA or WADVA bit fields programming and it negated according to the formula mentioned in RADVN and WADVN bit fields description. The BCLK signal runs with a 50% duty cycle until the end of access is reached.

If BCM = 1, the BCLK runs at frequency according to GBCD bit field settings on every async. Memory access (regardless of the SWR and SRD bits configuration). Caution should be exercised when using BCM bit, the GBCD bit field should be updated once and not change when BCLK is toggling. The BCM bit is used mainly for system debug mode. It has no functional use of the WEIM in normal mode.

63.5.6 Burst Clock Start (BCS)

In an effort to allow greater flexibility in achieving the minimum number of wait states on burst accesses, the user can determine when they want the BCLK to start toggling after the start of access. This allows the BCLK to be skewed from point of data capture on the WEIM clock by any number of WEIM clock cycles. Care must be exercised when setting BCS bit field in conjunction with the BCD, and RWSC/WWSC bit fields. See the external timing diagrams from Section 63.8.7, Burst Read Memory Accesses Timing Diagram - BCD=0," and Section 63.8.8, Burst Read Memory Accesses Timing Diagram - BCD=1," for some examples of when to use the BCS, BCD, and RWSC/WWSC bit fields together.

63.5.7 Multiplexed Address/Data Mode

A control bit MUM allows support memory with multiplexed address/data bus both in asynchronous and in synchronous modes. Caution should be exercised for using OEA/WEA and ADH bit fields. They should be configured according to the external device requirements, as it determines the time point of end of address phase and start of data phase.

63.5.8 Mixed Master/Memory Burst Modes Support

To provide mixed sequential/wrap accesses with different length WEIM interprets burst signal and generate additional $\overline{\text{ADV}}$ signals whenever there appear unequal address or burst boundary crossing condition. BL bit field is used to notify WEIM about current memory burst and wrap condition for properly external address generation. In case of non matching boundaries in both the memory and Master access, WEIM starts a new memory burst access by updating address from Master on address bus and generating $\overline{\text{ADV}}$ signal.

63.5.9 AXI (Master) Bus Cycles Support

The WEIM use an ARM AXI slave interface. It has a 32-bit bus and supports one access (one ID) at a time, no out of order or parallel accesses are supported.

The following AXI protocol signals are not supported: AWLOCK, AWCACHE, ARLOCK, and ARCACHE.

Bus sampling and signal use is as follows:

- ARID bus is sampled when new read access is valid on the read address channel and is reflected on the RID bus output toward the master.
- AWID bus is sampled when new write access is valid on the write address channel and is reflected on the WID/BID bus output toward the master.
- ARPROT and AWPROT signal are partially used. ARPROT[0] and AWPROT[0] bits are used for normal/privileged access detection. ARPROT[2:1] and AWPROT[2:1] are not used.
- When sampling a valid access on both of the address channels, the read access will be performed first while write access is pending. After last data transfer completed, the pending write will be executed.

A new access may be executed one cycle after sampling a valid access on the read or write address channels. For write access data should be present at write buffer for fast execution. This will apply assuming there is no current access (back to back) which can cause a recovery or end of access penalty cycles, according to configuration.

NOTE

Only 32-bit word size accesses are supported for burst mode accesses.

Only 8-bit (1 byte), 16-bit (2 byte) and 32-bit (4 byte) word size supported for single access.

Maximum number of burst length is 16.

According to AXI protocol burst access should not cross 4 KB blocks. In case WEIM gets an access that crosses the 4 Kbyte, memory address calculation is invalid.

AXI transfers are also supported as shown in Table 63-19. These AXI cycles will be translated into the necessary cycles on the memory side. For example for optimal operation in case ARM cache is configured to 8 beat burst with wrap, a synchronous flash and cellular RAM memory should be configured in 16 word wrap burst mode when using a 16-bit data port, and in 8 word wrap burst mode when using a 32-bit data port. WEIM uses BL bit field for support different memory configurations. The controller splits the transaction when needed in some cases as shown in Table 63-19.

Table 63-19. AXI Burst Cycles Supported

Burst Length—Number of Data Transfers	Burst Size—Bytes in Transfer	Burst Type	Description
1	1	INCR	Single transfer
1	2	INCR	Single transfer
1	4	INCR	Single transfer
2	4	WRAP	2-beat wrapping burst
4	4	WRAP	4-beat wrapping burst

Table 63-19. AXI Burst Cycles Supported (continued)

Burst Length—Number of Data Transfers	Burst Size—Bytes in Transfer	Burst Type	Description
8	4	WRAP	8-beat wrapping burst
16	4	WRAP	16-beat wrapping burst
2	4	INCR	2-beat incrementing burst
3	4	INCR	3-beat incrementing burst
4	4	INCR	4-beat incrementing burst
5	4	INCR	5-beat incrementing burst
6	4	INCR	6-beat incrementing burst
7	4	INCR	7-beat incrementing burst
8	4	INCR	8-beat incrementing burst
9	4	INCR	9-beat incrementing burst
10	4	INCR	10-beat incrementing burst
11	4	INCR	11-beat incrementing burst
12	4	INCR	12-beat incrementing burst
13	4	INCR	13-beat incrementing burst
14	4	INCR	14-beat incrementing burst
15	4	INCR	15-beat incrementing burst
16	4	INCR	16-beat incrementing burst

Table 63-20. AXI To Memory Burst Splits Number

AXI Burst Type	Memory Burst Type Config.	# of Accesses to X8 Memory Port size	# of Accesses to X16 Memory Port size	# of Accesses to X32 Memory Port size
INC16 Aligned Addr.	WRAP4	16	8	4
	Cont.	1	1	1

	Cont.	1	1	1
WRAP8 Unaligned Addr.	WRAP16	2 or 3	1	2
	Cont.	2	2	2

63.5.10 WAIT_B Signal, RWSC, and WWSC Bit Fields Usage

Most of the external devices supporting burst mode for write or read accesses provide a signal that indicates data is valid on the memory bus. For this mode, called handshake mode, the RFL and WFL bits are cleared and the RWSC/WWSC bit fields indicate when the controller should start sampling this signal from the external device, in other words, how many BCLK cycles should be masked.

For devices that are not using this signal or have a fixed latency ability, the RFL and WFL bits may be set for internal calculation regarding BCLK cycles penalty until data is valid (memory initial access time). For this mode, RWSC/WWSC indicates when the data is ready for sampling by the controller (read access) or the external device (write access). There is a separation between the read and write accesses wait-state control. For read access, the RWSC bit field is valid and the WWSC bit field is ignored whereas for write access, WWSC is valid and RWSC is ignored.

63.5.11 IPS Register Interface

Access to the registers of the WEIM, read or write, is made with IPS protocol signals. The system should avoid changing the registers while master/memory transaction is valid, as this can cause an unknown behavior of the controller.

The register access size is 32 bit as the register size definition. Other access sizes (byte or half word) are not supported.

63.5.12 MRS Set for PSRAM

Memory registers of PSRAM devices can be configured according to external signal, which indicates whether the access is to a memory array or memory register domain. When the CRE bit is set, the following transactions to the external device will assert the CRE signal. The polarity of this signal is determined by the CREP bit for active low or active high assertion of the signal.

63.5.13 WEIM Access Termination

WEIM is monitoring the corresponding CSx control signal every time variable latency access or dtack access is performed toward the external device.

In variable latency accesses the watch dog timer (counter) counts BCLK cycle if it reaches the wdog_limit (according the WDOG_LIMIT bit field in the WCR) before the device signals in can drive/sample new data the controller will terminate the access and generate an error response transfer toward the master.

In dtack access the watch dog counts ACLK cycles instead of BCLK and it reaches the wdog_limit before the device asserts the dtack signal the controller will terminate the access and generate an error response transfer toward the master.

This WDOG can by disabled by WDOG_EN bit in the WCR.

63.5.14 Error Conditions

The following conditions cause an error (AXI error or IPS error) response signal:

- AXI errors
  - Access to a disabled chip select - access to a mapped chip select address space where the CSEN bit in the corresponding chip select Configuration Register is clear
  - Access to a non mapped address - access to an address that is not mapped to any CS.
  - User access to a supervisor-protected chip select address space (the SP bit in the corresponding chip select Configuration Register is set)
  - User access in fixed mode access
  - User preform write access to write protected chip select
  - First write data ID and write address ID do not match. (No data is written to the memory).
  - First Write Data ID and write address ID match but one or more of the other Write data IDs does not match the First Write data ID (data is written to memory according)
  - Access duration to external device from CSx signal assertion is 128/256/512/1024 cycles (access is terminated by the controller) - This error can be disabled be software.
- IPS errors
  - User read or write access to a reserved/non-valid address in the WEIM Configuration Register

63.5.15 DTACK Mode

In DTACK mode the WEIM uses DTACK signal as an indication when to end the access.

DTACK is an asynchronous edge/level sensitive signal. DTACK polarity is configurable by DAP bit in CsxGCR2 (default value is 0).

In this case WEIM begins the access and after few cycles (according DAPS field) and waits until DTACK (after synchronization) becomes asserted then sample the data in read access and completes the current data access. (see Figure 63-25, Figure 63-26, and Figure 63-27).

If more than one data is needed CS will be negated between access (CSREC field is not zero) the AXI burst access will be split in to single accesses (see Figure 63-28).

63.5.16 RDY_INT Signal as Interrupt

The WEIM has an external interrupt support. When INTEN bit in the WCR is set, signal RDY_INT is used as interrupt, its status is being reflected by INT bit and output signal. It cleared by writing one to the INT bit. When INTEN is cleared, the interrupt is disable. This interrupt is a level interrupt and its polarity can be configured by INTPOL bit in the WCR.

63.5.17 RDY_INT Signal as Ready After Reset Indication

This feature is used for boot propose from external devices based on NandFlash array memory with NorFlash interface.

When ERRST bit is set. RDY_INT signal is monitored to determine ready after reset of the external device located on CS0.

The monitoring is taking place when CS0 is accessed for the first time. The access will be pending until assertion of the signal is detected. When detection occurs, the ERRST bit is self-cleared and pending access is executed to the external device on CS0.

63.5.18 WEIM_GRANT/WEIM_BUSY Handshake Description

Prior to executing command to one of the external device (chip select),WEIM assert WEIM_BUSY signal (1’b1) and check the WEIM_GRANT signal status. If WEIM_GRANT signal is high, it indicates external data bus is not used by other slaves (Nand Flash Controller) and WEIM may start to execute the access. If WEIM_GRANT is low, WEIM waits until it is set (1’b1) before executing the access.

WEIM keeps WEIM_BUSY signal set until it completes the access toward the external device.

Once WEIM_GRANT signal is set, it cannot be reset until WEIM_BUSY signal is cleared by the WEIM.

NOTE

The 16-bit Muxed WEIM does not use the data bus, therefore, there is no sharing of the data bus with NFC. WEIM does not wait for a WEIM_GRANT signal from NFC and does not assert the WEIM_BUSY signal.

63.5.19 LPMD/LPACK Handshake Description

These signals used for frequency and/or voltage change and entering low power mode during normal operation of the WEIM. Before any change is taking place, the controller and all the relevant external devices should be in idle state which means no access or data transfer is in process.

LPMD input signal is asserted, once WEIM detect the assertion of LPMD, all ready signals of the AXI channels are negated and WEIM is not sampling new accesses. It finish all the on going accesses and

already pending ones. When WEIM is in idle state LPACK output signal is asserted. WEIM will stay in idle state and LPACK signal will stay assert until LPMD signal is negated.

63.5.20 Endianness

Big- and little-endianness are supported by the controller according to the Table 63-21.

Table 63-21. WEIM Out/in Data in Case AXI Out/in Data is 0xB3B2B1B0

Endian mode	AXI access	AXI address [1:0]	Port Size and Used Bits								
			Word Port				Half Word Port			Byte Port	
			[31:24]	[23:16]	[15:8]	[7:0]	External address [0]	[31:24] ([15:8])	[23:16] ([7:0])	External address [1:0]	[31:24] ([23:16]) ([15:8]) ([7:0])
Big	Word	0	**0xB3**	**0xB2**	**0xB1**	**0xB0**	0	**0xB3**	**0xB2**	0	**0xB3**

										1	**0xB1**
		2	**0xB3**	**0xB2**			1	**0xB3**	**0xB2**	2	**0xB2**
										3	**0xB3**
	Byte	0				**0xB0**	0		**0xB0**	0	**0xB0**
		1			**0xB1**			**0xB1**		1	**0xB1**
		2		**0xB2**			1		**0xB2**	2	**0xB2**
		3	**0xB3**					**0xB3**		3	**0xB3**

63.5.21 Strobe Signal Use

The strobe signal is toggling according to address/data valid condition on the external bus for read and write accesses and for both synchronous and asynchronous modes.

At any time point when address/data is valid on the external bus, the strobe signal will generate a positive edge which can be used to sample the external data and control signal.

NOTE

Strobe signal for read data is active (RL + 1) cycles after data on external bus is valid.

63.6 Initialization Information

This section provides intialization information.

63.6.1 Active Chip Selects and Address Space Configuration

Each chip select activation is set using VIA port configuration. Refer to the SOC chapter for the specific WEIM chip select configuration. Chip select is determine when the corresponding bit of the ACT_CS[5:0] input is set to one, else it is in none active state. Each one of the six chip selects' address space can be

determined by ADDRS0[1:0]...ADDRS5[1:0] WEIM inputs. The minimum address space size per chip select is 32 Mbyte, maximum size is 256 Mbyte. Overall address space for all chip select is 512 Mbyte. Base address is {WEIM_NFC_BASE,28'h0}, topmost base address is CS0 base address + 0x1FFF_FFFF.

Address space order is determine from the largest space on CS0 to the smallest one on CS5. Not all the chip select must be used (determine by the active bit per CS inputs). Equal size for several chip select may apply. It is the user responsibility to ensure the total space size configured is within the 512 Mbyte dedicated to the WEIM.

NOTE

If the total address space is smaller then 512 Mbyte, it is referred as reserved space and can not be used.

Table 63-22. Examples of Address Space Configuration

Chip Select #	Example1	Example2	Example3	Example4
CS0	256 Mbyte	128 Mbyte	128 Mbyte	256 Mbyte
CS1	128 Mbyte	128 Mbyte	64 Mbyte	64 Mbyte
CS2	64 Mbyte	128 Mbyte	64 Mbyte	64 Mbyte
CS3	64 Mbyte	64 Mbyte	32 Mbyte	32 Mbyte
CS4	—	32 Mbyte	32 Mbyte	32 Mbyte
CS5	—	32 Mbyte	32 Mbyte	32 Mbyte

The address space is set with the matching ADDRSx[1:0] input bus according to Table 63-23.

Table 63-23. Address Space Configuration

ADDRSx[1:0]	Size
2'b00	32 Mbyte
2'b01	64 Mbyte
2'b10	128 Mbyte
2'b11	256 Mbyte

63.6.2 Booting from WEIM

WEIM is ready to work with CS0 after hardware reset, but it has been configured for very slowly access (for boot purpose) with additional setup and hold time. Other CS are disabled by hardware reset. Therefore, any CS has to be properly initialized before using it by writing values to the corresponding chip select configuration registers.

APR,PAT,BL,AUS, CSREC[2:1], DSZ, MUM, RWSC[4:2], RAL, WWSC[4:2], WAL and ERRST bit fields can be determined for reset values according to BOOT_CFG[11:0] pin settings.

63.7 Application Note

Application note uses next functions to illustrate WEIM and memory accesses, as follows:

- WR16(address, data) is a 16 bit write access
- WR32(address, data) is a 32 bit write access
- RD16(address, data) is a 16 bit read access
- RD32(address, data) is a 32 bit read access,
- WR_I(address, data, delta, counter) is a write data sequence, there data(i+1) = data(i)+ delta, COMMAND_SEQUENCE, CHECK_STATUS

All addresses are byte address. ‘CS0 is a Chip Select 0 base address. ‘WEIM_ is a prefix of WEIM’s registers. ‘h is a prefix of hexadecimal constant. // is a comment beginning. csba[cs] is a dimension of CS base addresses. “addr” means an address offset in current CS address space. Examples use CS0 address space, but it may be any except boot mode functionality. Configuration examples were checked with some below defined memory models and may require some adjustment for other family members.

63.7.1 Access to AMD Flash

The configurations in this section are for am29pdl128g_70.

63.7.1.1 Boot

To boot from AMD flash next boot, use the following configuration:

- `BOOT_CFG= ‘h263` for 32 bit memory
- `BOOT_CFG= ‘h261` for 16 bit memory

63.7.1.2 AMD Asynchronous Mode Configuration

The next WEIM register configuration used for AMD flash asynchronous access is as follows:

```
        WR32(‘WEIM_CS0RCR1,’h0a018000);
        WR32(‘WEIM_CS0WCR1,’h0704a240);
        WR32(‘WEIM_CS0GCR1,’h00430081); // for 32 bit memory
    or
        WR32(‘WEIM_CS0GCR1,’h00410081); // for 16 bit memory
```

63.7.1.3 AMD Synchronous Mode Configuration

63.7.1.4 Utility

Use the following configuration for utility:

```
    // Single data word programming to addr, 32-bit memory
        port_size = 32;
        WR32(‘CS0+(’h0555<<2),’h00aa); // command sequence
        WR32(‘CS0+(’h02aa<<2),’h0055);
        WR32(‘CS0+(’h0555<<2),’ha0); // command code
        WR32(‘CS0+addr, data); // addr & data
// Polling end of programming
```

```
    edata = data; // expected data
    data = ~edata;
    errst = 0;
while(!(data == edata) &&!errst)
       begin: BR_EN
       RD16(‘CS0+addr, data);          // Read status
       if(data[7]!== edata[7])
          begin
          if(data[5] == 1)
              begin
              RD16(‘CS0+addr, data3);
              RD16(‘CS0+addr, data);
              if(data[6] !== data3[6])
                  begin
                  $display("CHECK_STATUS: Error timout on single data program");
                  errst = 1;
                  disable BR_EN;
                  end
              end
         end
       else
          begin
          RD16(‘CS0+addr, data3);
          if(port_size == 32)
              RD32(‘CS0+addr, data);
          else
              begin
              RD16(‘CS0+addr, data);
              edata[31:16] = 16’h0;
              end
          if(data !== edata)
              begin
              $display("CHECK_STATUS: Error in data write on single data program");
                errst =2;
              disable BR_EN;
              end
          end
       end
// Single data word programming to addr, 16-bit memory
    port_size = 16;
    WR32(‘CS0+(’h0555<<1),’h00aa); // command sequence
    WR32(‘CS0+(’h02aa<<1),’h0055);
    WR32(‘CS0+(’h0555<<1),’ha0); // commund code
    WR32(‘CS0+addr, data); // addr & data
// Polling end of programming - the same as for 32 bit
```

63.7.2 Access to Intel Sibley Flash

The configurations in this section are for the Sibley family muxed and non-muxed devices.

63.7.2.1 Boot

To boot from Intel Sibley flash next boot use the following configuration:

- `BOOT_CFG= ‘h281` for 16 bit non-muxed memory,
- `BOOT_CFG= ‘h285` for 16 bit muxed memory.

63.7.2.2 Intel Sibley Flash Asynchronous Mode Configuration

Use the following configuration for Intel Sibley Flash asynchronous mode configuration.

```
WR32('WEIM_CS0GCR1,'h00210081);
WR32('WEIM_CS0RCR1,'h0e020000);
WR32('WEIM_CS0RCR2,'h00000000);
WR32('WEIM_CS0WCR1,'h0704a040);
```

63.7.2.3 Intel Sibley Flash Synchronous Mode Configuration

Use the following configuration for 133 MHz synchronous access to flash:

```
      // Set memory to synchronous read mode
           WR16('CS0+('h5903<<1),'h0060);
           WR16('CS0+('h5903<<1),'h0003);
           WR16('CS0+('h0000<<1),'h00ff);
      // Set WEIM configuration to synchronous timing
           WR32('WEIM_CS0GCR1,'h50214225);                    // 133 MHz
           WR32('WEIM_CS0RCR1,'h0c000000);                    // 12 cycles on memory
Next configuration used for 66 MHz synchronous access to muxed flash:
      // Set memory to synchronous read mode
           WR16('CS0+('h3103<<1),'h0060);
           WR16('CS0+('h3103<<1),'h0003);
           WR16('CS0+('h0000<<1),'h00ff);
      //-------------------------------------------------------------------------
      // Set WEIM configuration to synchronous timing
           WR32('WEIM_CS0GCR1,'h5021122d);                    // 66 MHz
           WR32('WEIM_CS0RCR1,'h07000000);                    // 7cycles on memory
```

63.7.2.4 Utility

The Intel Sibley device uses the following utility algorithms:

```
      // Single data word programming to addr
           WR16('CS0+addr,'h0060);                // Unlock
           WR16('CS0+addr,'h00d0);
           WR16('CS0+addr, 'h0041);
           WR16('CS0+addr, data);
           WR16('CS0+caddr, 'h0070);                // Read Status command
           while('CS0+data[7] == 0)                          // Wait / Polling
               RD16('CS0+addr, data);             // Read status
           RD16('CS0+addr, data);                 // Read status
           WR16('CS0+'h0000,'h00ff);
      // Write buffer programming
           WR16('CS0+addr,'h0060);                // Unlock
           WR16('CS0+addr,'h00d0);
           data    = 0;
           WR16('CS0+addr, 'h0070);               // Read Status command
           while(data[7] == 0)                           // Wait
               RD16('CS0+addr, data);             // Read status
WR16('CS0+'h0000,'h00ff);
           WR16('CS0+addr,'h00e9);          // Write Buffer command
           WR16('CS0+addr,255);             // Word counter (<256)
           for(i=0; i<'h200; i = i + 'h40)
              WR_I('CS0+addr+i, data+((i>2)*'h0010_0001), 'h0010_0001, 16); // Data
           WR16('CS0+addr,'h00d0);          // Write Confirm command
           data  = 0;
```

```
while(data[7] == 0)                    // Wait
   RD16(‘CS0+addr, data);          // Read status
RD16(‘CS0+addr, data);             // Read status
WR16(‘CS0+’h0000,’h00ff);
```

63.7.3 Access to MDOC Device

The configurations in this section are for the MDOC H3 device.

63.7.3.1 Boot

To boot from MDOC device, the ERRST bit should be configured to 1, so WEIM will hold the first reaccess to CS0 until the MDOC asserts the RDY signal.

- `BOOT_CFG= ‘h271` may be used for boot from non-muxed MDOC device
- `BOOT_CFG= ‘h275` may be used for boot from muxed MDOC device

63.7.3.2 MDOC Asynchronous Mode Configuration

Use the following for MDOC asynchronous mode configuration.

```
// Non-muxed mode
WR32(‘WEIM_CS0GCR1,’h00410081);
WR32(‘WEIM_CS0RCR1,’h0e121010);
WR32(‘WEIM_CS0RCR2,’h00000000);
WR32(‘WEIM_CS0WCR1,’h12092492);
// Muxed mode
WR32(‘WEIM_CS0GCR1,’h00410081);
WR32(‘WEIM_CS0RCR1,’h0e121010);
WR32(‘WEIM_CS0RCR2,’h00000000);
WR32(‘WEIM_CS0WCR1,’h12092492);
```

63.7.3.3 MDOC Synchronous Mode Configuration

TBD

63.7.3.4 Utility

The MDOC H3 device uses the following utility algorithms:

```
// Read Manufacturer ID and Device ID
    RE16(‘CS0+’h9400,’h4833);
    RE16(‘CS0+’h9422,’hb7cc);
```

63.7.4 Access to Micron PSRAM

The configurations in this section are for mt45w4mw16bfb_706.

63.7.4.1 Micron PSRAM Asynchronous Mode Configuration

Use the following for Micron PSRAM asynchronous mode configuration.

```
// 16 bit memory
           WR32('WEIM_CS0GCR1,'h403104b1);
           WR32('WEIM_CS0RCR1,'h0b010000);
           WR32('WEIM_CS0RCR2,'h00000008);
           WR32('WEIM_CS0WCR1,'h0b040040);
       // 32 bit memory
           WR32('WEIM_CS0GCR1,'h403304b1);
           WR32('WEIM_CS0RCR1,'h0f010000);
           WR32('WEIM_CS0RCR2,'h00000008);
           WR32('WEIM_CS0WCR1,'h0f040040);
```

63.7.4.2 Micron PSRAM Synchronous Mode Configuration

Use the following for Micron PSRAM synchronous mode configuration.

```
// 16 bit memory
           WR32('WEIM_CS0GCR1,'h403104b1);
           WR32('WEIM_CS0WCR1,'h0b040000);
           WR16('CS0+('h85947<<1),'h0040); // memory configuration
           WR32('WEIM_CS0GCR1,'h4021_5487);// fixed latency memory wrap 4
           WR32('WEIM_CS0RCR1,'h04000000);
           WR32('WEIM_CS0RCR2,'h00000008);
           WR32('WEIM_CS0WCR1,'h04000000);
       // 32 bit memory
           WR32('WEIM_CS0GCR1,'h6003_04f1);
           WR32('WEIM_CS0WCR1,'h0b04_0000);
           WR32('CS0+('h85947<<2),'h0040); // memory configuration
           WR32('WEIM_CS0GCR1,'h4003_1487); // var latency memory inc. page size 128
           WR32('WEIM_CS0RCR1,'h04000000);
           WR32('WEIM_CS0RCR2,'h00000008);
           WR32('WEIM_CS0WCR1,'h04000000);
```

63.7.5 Access to Samsung OneNAND

The configurations in this section are for kfg1g16q2a and kfm1g16q2a83.

63.7.5.1 Boot

There are two ways to boot from Samsung OneNand. In the first way, the ERRST bit set to 0 and user has to poll the interrupt status in the OneNand interrupt register (or set interrupt handler there). In the second way, the ERRST bit set to 1 and the user should enable the device interrupt output before the first read from CS0 access issued.

- `BOOT_CFG= 'h261` may be used for boot from non-muxed Samsung OneNand.
- `BOOT_CFG= 'h265` may be used for boot from muxed Samsung OneNand.

Load sectors 2,3 to DataRAM, page 0 as shown below:

```
WR16(‘CS0+(’hF241<<1),’h0);        // Clear interrupt status
WR16(‘CS0+(’hF100<<1),’h0);        // block[8:0] address
WR16(‘CS0+(’hF107<<1),’h2);        // sector[1:0] and page[7:2] addresses
WR16(‘CS0+(’hF200<<1),’h802);      // buffer[11:8] address and counter[1:0]
WR16(‘CS0+(’hF101<<1),’h0);        // DDP choose
WR16(‘CS0+(’hF220<<1),’h0);        // Set command
```

63.7.5.2 Samsung OneNand Asynchronous Mode Configuration

Use the following for Samsung OneNand asynchronous mode configuration.

```
// Non-muxed memory
    WR32(‘WEIM_CS0GCR1,’h00410081);
    WR32(‘WEIM_CS0RCR1,’h0b010000);
    WR32(‘WEIM_CS0RCR2,’h00000000);
    WR32(‘WEIM_CS0WCR1,’h0c092480);
// Muxed memory
    WR32(‘WEIM_CS0GCR1,’h00410089);
    WR32(‘WEIM_CS0RCR1,’h0b010000);
    WR32(‘WEIM_CS0RCR2,’h00000000);
    WR32(‘WEIM_CS0WCR1,’h0c092480);
```

63.7.5.3 Samsung OneNand Synchronous Mode Configuration

Set memory and WEIM to synchronous read mode as shown:

```
WR16(‘CS0+(’hF221<<1),’hc0e0); // Synchronous read, 4 clk latency
WR32(‘WEIM_CS0GCR1,’h50412405); // 44 MHz (non-muxed)
WR32(‘WEIM_CS0RCR1,’h05010000);
```

The muxed Samsung OneNand supports synchronous write as shown:

```
// Set memory & WEIM to synchronous read and write mode
    WR16(‘CS0+(’hF221<<1),’hc0f2); // Sync. read and write, 4 clk latency
    WR32(‘WEIM_CS0GCR1,’h5041240f); // 44 MHz
    WR32(‘WEIM_CS0RCR1,’h05010000);
    WR32(‘WEIM_CS0WCR1,’h05040000);
```

63.7.5.4 Utility

The Samsung OneNand uses the following utility algorithms:

```
// Unlock Block command
    WR16(‘CS0+(’hF100<<1),’h0);        // DFS
    WR16(‘CS0+(’hF100<<1),’h0);        // DBS
    WR16(‘CS0+(’hF24c<<1),’h2);        // SBA - block number (2)
    WR16(‘CS0+(’hF241<<1),’h0);        // Clear interrupt status
    WR16(‘CS0+(’hF220<<1),’h23);       // Unlock command
    data =’h0;
    while(!(data &’h0004))             // Polling
       RD32(‘WIAR, data); // Read status
// Erase block command
    WR16(‘CS0+(’hF100<<1),’h2);        // DFS and block ([8:0]) address
    WR16(‘CS0+(’hF101<<1),’h0);        // DBS
    WR16(‘CS0+(’hF241<<1),’h0);        // Clear interrupt status
           WR16(‘CS0+(’hF220<<1),’h94);            // Erase command
```

```
        data ='h0;
        while(!(data &'h0004))                  // Wait
            RD32('WIAR, data); // Read status
    // Program page command
        WR16('CS0+('hF100<<1),'h2);             // DFS and block[8:0] address
        WR16('CS0+('hF107<<1),'h0);             // sector[1:0] and page[7:2] addresses
             WR16('CS0+('hF200<<1),'h800);          // buffer[11:8] address and counter[1:0]
        WR16('CS0+('hF241<<1),'h0);             // Clear interrupt status
        WR16('CS0+('hF220<<1),'h80);            // Program command
        data ='h0;
        while(!(data &'h0004))                  // Wait
            RD32('WIAR, data); // Read status
```

63.7.6 Access to Samsung UtRAM

The configurations in this section are intended for k1b5616b2m.

63.7.6.1 Samsung UtRAM Asynchronous Mode Configuration

Use the following for Samsung UtRAM asynchronous mode configuration.

```
        WR32('WEIM_CS0GCR1,'h400104b1);
        WR32('WEIM_CS0RCR1,'h0a010000);
        WR32('WEIM_CS0RCR2,'h00000008);
        WR32('WEIM_CS0WCR1,'h0b040040);
```

63.7.6.2 Samsung UtRAM Synchronous Mode Configuration

Use the following for Samsung UtRAM synchronous mode configuration.

```
RD16('CS0+('hff_ffff<<1),data);             // command sequence
        RD16('CS0+('hff_ffff<<1),data);
        RD16('CS0+('hff_ffff<<1),data);
        RD16('CS0+('hff_feff<<1),data);
        RD16('CS0+('h00_82a0<<1),data);             // memory sync. configuration
        WR32('WEIM_CS0GCR1,'h4021_53b7);            // fixed latency memory wrap 32
        WR32('WEIM_CS0RCR1,'h0500_0000);
        WR32('WEIM_CS0WCR1,'h0300_0000);
```

63.7.7 Access to Spansion Flash

The configurations in this section are for s29ws256n0s.

63.7.7.1 Boot

To boot from Spansion flash, use `BOOT_CFG= 'h261`.

63.7.7.2 Spansion Asynchronous Mode Configuration

Use the following for Spansion asynchronous mode configuration.

```
WR32('WEIM_CS0GCR1,'h00410081);
        WR32('WEIM_CS0RCR1,'h0a018000);
        WR32('WEIM_CS0RCR2,'h00000000);
```

```
          WR32('WEIM_CS0WCR1,'h0704a240);
WR16('CS0+('hF220<<1),'h94);            // Erase command
          data ='h0;
          while(!(data &'h0004))                  // Wait
              RD32('WIAR, data); // Read status
      // Program page command
          WR16('CS0+('hF100<<1),'h2);             // DFS and block[8:0] address
          WR16('CS0+('hF107<<1),'h0);             // sector[1:0] and page[7:2] addresses
          WR16('CS0+('hF200<<1),'h800);           // buffer[11:8] address and counter[1:0]
          WR16('CS0+('hF241<<1),'h0);             // Clear interrupt status
          WR16('CS0+('hF220<<1),'h80);            // Program command
          data ='h0;
          while(!(data &'h0004))                  // Wait
              RD32('WIAR, data); // Read status
```

63.7.7.3 Spansion Synchronous Mode Configuration

Use the following for Spansion synchronous mode configuration.

```
WR16('CS0+('h0555<<1),'h00aa);   // command sequence
          WR16('CS0+('h02aa<<1),'h0055);
          WR16('CS0+('h0555<<1),'hd0);
          WR16('CS0+('h0000<<1),'h1ec4);   // memory sync. configuration
          WR32('WEIM_CS0GCR1,'h50411325); // 66 MHz
          WR32('WEIM_CS0RCR1,'h05000000); // 5 cycles on memory
```

63.7.7.4 Utility

The Spansion Flash device uses the following utility algorithms:

```
      // Single word programming
          COMMAND_SEQUENCE(cs,16,'ha0);           // single word programming
          WR16('CS0+addr, data);
          CHECK_STATUS('CS0+addr,data,16,1,errst);
      // Write buffer programming
          COMMAND_SEQUENCE(0,16,'h25);              // write buffer programming
          WR16('CS0+addr,'h001f);                     // counter-1
          WR_I('CS0+addr, data, 'h0010_0001, 16); // data
          WR16('CS0+addr,'h0029);                     // write buffer to flash
          CHECK_STATUS('CS0+addr+'h3e,data[31:16]+'h00f0,16,1,errst);
There COMMAND_SEQUENCE and CHECK_STATUS are next functions:
      task COMMAND_SEQUENCE;
          input[2:0]    cs;
          input[7:0]    port_size;
          input[31:0]   code;
      begin
          if(port_size == 16)
             begin
             WR16(csba[cs]+('h0555<<1),'h00aa);
             WR16(csba[cs]+('h02aa<<1),'h0055);
             WR16(csba[cs]+('h0555<<1),code);
             end
          else
             begin
             WR32(csba[cs]+('h0555<<2),'h00aa);
             WR32(csba[cs]+('h02aa<<2),'h0055);
             WR32(csba[cs]+('h0555<<2),code);
```

```
            end
        end
        endtask
        task     CHECK_STATUS;
            input[31:0] addr;
            input[31:0] edata;
            input[7:0]   port_size;
            input[7:0]   opcode;
            output[7:0] errst;
            reg[31:0]    data;
            reg[31:0]    data3;
        begin
            errst = 0;
            data  = 0;
            data3 = 0;
while(!(data == edata) && !errst) // Wait operation
          begin: BR_EN
          RD16(addr, data);             // Read status
          if(data[7] !== edata[7])
              begin
              if(data[5] == 1)
                   begin
                   RD16(addr, data3);
                   RD16(addr, data);
                   if(data[6] !== data3[6])
                        begin
                        $display("CHECK_STATUS: Error timout on single data program");
                        errst = 1;
                        disable BR_EN;
                        end
                   end
              else
                   begin
                   if(opcode == 2)
                        if(data[1] == 1)
                            begin
                            RD16(addr, data3);
                            if(port_size == 32)
                               RD32(addr, data);
                            else
                               RD16(addr, data);
                            if(data[1] == 1 && data !== edata)
                               begin
                               $display("CHECK_STATUS: Error on write buffer");
                               errst =3;
                               disable BR_EN;
                               end
                            end
                   end
              end
          else
              begin
              RD16(addr, data3);
              if(port_size == 32)
                   RD32(addr, data);
              else
                   begin
```

```
                RD16(addr, data);
                edata[31:16] = 16'h0;
                end
            if(data !== edata)
                begin
                $display("CHECK_STATUS: Error in data write on single data program");
                errst =2;
                disable BR_EN;
                end
            end
        end
end
endtask
```

63.7.8 8-Bit Support

For intel mode, use the connections as shown in Table 63-24.

Table 63-24. Intel Mode Pin Connections

Appendix A
IOMUX Controller (IOMUXC)

A.1 Introduction

A.1.1 Overview

The IOMUX controller (IOMUXC), together with the IOMUX, enables the i.MX51 to share one BGA contact with several functional blocks. The sharing is done by multiplexing the BGA contact input/output signals. For each BGA contact there are up to 8 muxing options (called ALT modes). Because different modules require different BGA contact settings (like pull up, keeper, etc), the IOMUXC also controls the BGA contact settings parameters.

The IOMUX consist of only combinatorial logic combined from several basic iomux cells, each basic iomux cell handles only one BGA contact signals muxing.

Figure A-1 illustrates the IOMUX/IOMUXC connectivity in the system.

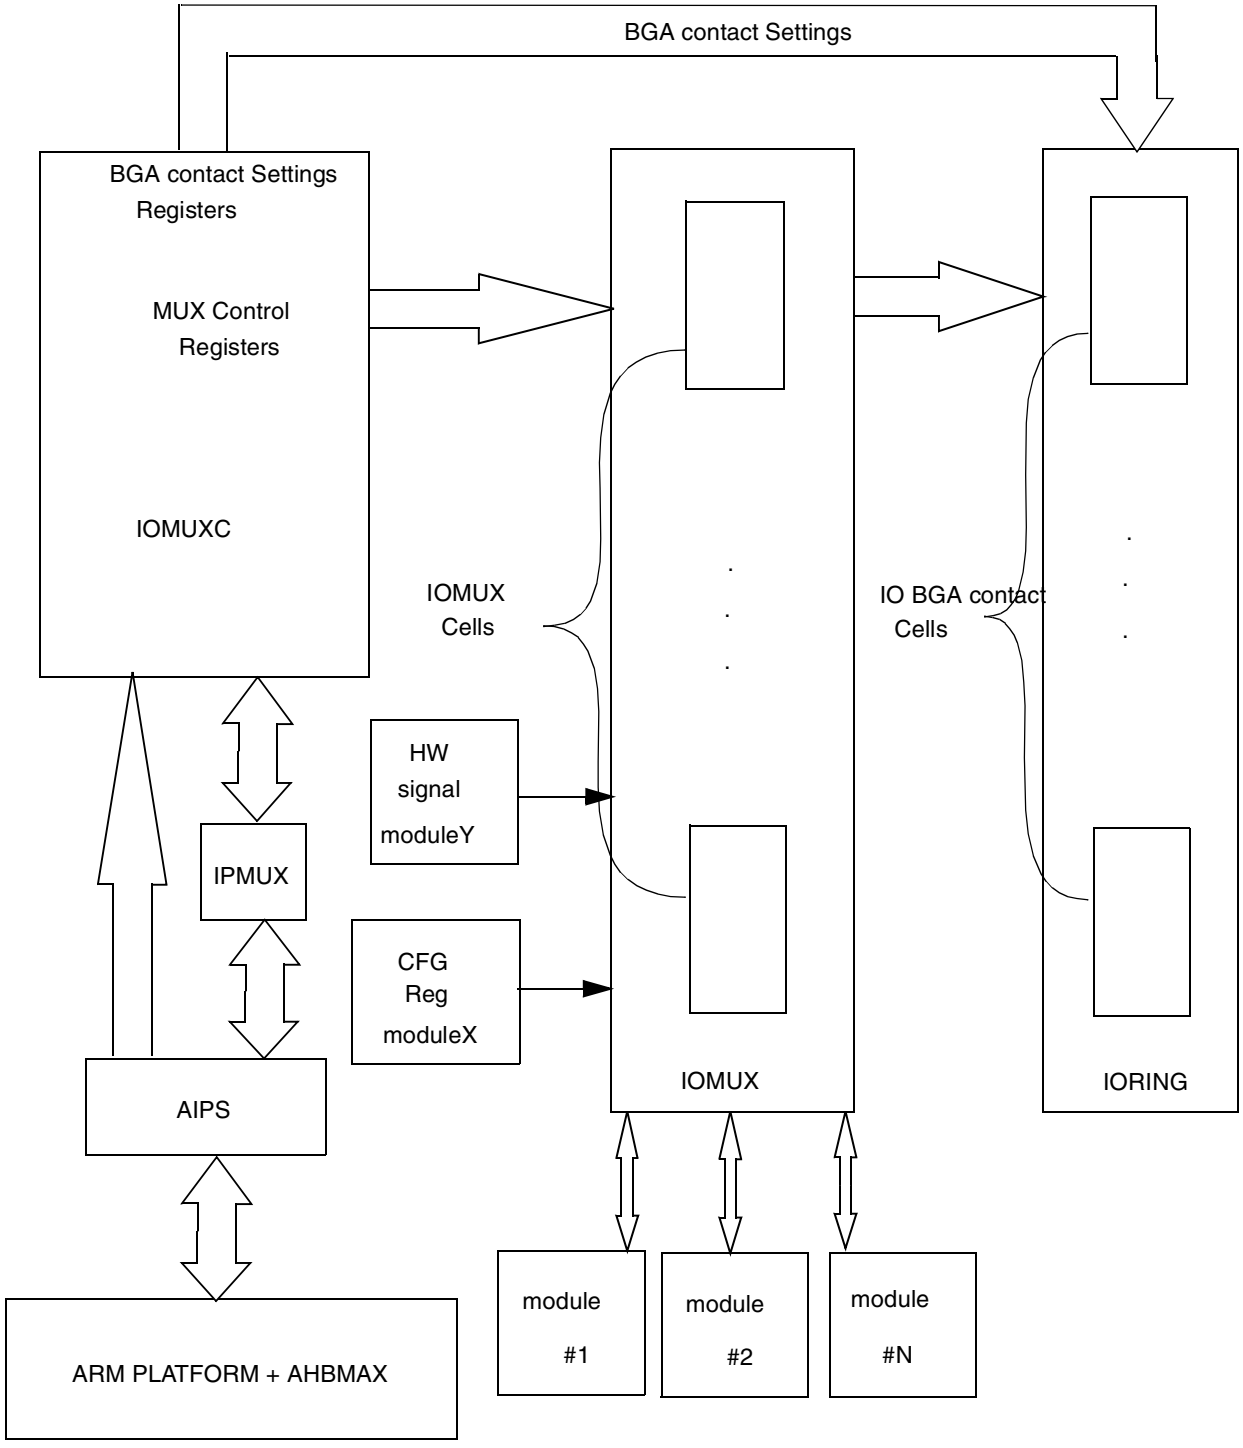

Figure A-1. IOMUX SoC Level Block Diagram

A.1.2 Features

The IOMUXC features are as follows:

- 32 bits SW Mux control registers (IOMUXC_SW_MUX_CTL_PAD_<BGA contact NAME> or IOMUXC_SW_MUX_CTL_GRP_<GROUP NAME>) to configure a specific mux mode of each BGA contact or a predefined group of pads and to enable forcing the input path of the BGA contact/s (SION bit).
- 32 bits SW BGA contact control registers (IOMUXC_SW_PAD_CTL_PAD_<PAD_NAME> or IOMUXC_SW_PAD_CTL_GRP_<GROUP NAME>) to configure specific BGA contact settings of each contact or a predefined group of pads.
- 32 bits General Purpose Registers—Two 32 bits registers according to SOC requirements for any usage.
- 32 bits “Daisy Chain” Control registers—register to control the input path to a module when more than one contact may drive this module input.
- IPS Interface—Peripheral bus to allow registers configuration and readiness (all registers are read/write registers).

A.1.2.1 SW Mux and BGA contact Control

For the SW_PAD_CTL_PAD and SW_PAD_CTL_GRP registers, each I/O configuration parameter uses two different indicators as follows:

- Associated bits shown below the white bit-location boxes are the default values for that parameter. These values are configurable by software.
- Associated bits shown below the gray bit-location boxes (read-only) are always zero and are simply the values read from that particular register location and they do not reflect the actual configuration default. These values are not configurable by software. For default configuration parameter values, refer to Chapter 4, “External Signals and Pin Multiplexing.”

A.1.3 Modes of Operation

There is only one mode of operation: normal mode.

A.2 External Signal Description

There are no signals in the IOMUX that connect off chip (they all control the PADS functionality).

A.3 Functional Description

The IOMUXC Detailed Block Diagram is illustrated in Figure A-2.

The IOMUXC is consist of 2 sub blocks:

- IOMUXC_REGISTERS: includes all the IOMUXC registers (6 main types are illustrated).
- IOMUXC_LOGIC: includes all the IOMUXC combinatorial logic (IP interface controls, address decoder, observability muxes).

The IOMUXC external signals and the IOMUXC sub blocks connections internal signals are also detailed in this diagram. The following are the naming conventions used along with some explanation:

- <BGA contact> - any BGA contact logic name.
- <GRP> - any BGA contact group logic name.
- <FUNC> - one of the following BGA contact control functions:
  - SRE (1 bit slew rate control).
  - DSE (2 bits drive strength control).
  - ODE (1 bit open drain control).
  - HYS (1 bit hysteresis control).
  - PULL_KEEP_CTL (4 bits pull up/down and keeper controls)
  - PUS (2 bits pull up/down configuration value)
  - PUE (1 bit pull/keep select)
  - PKE (1 bit enable/disable pull up, pull down or keeper capability)
  - DDR_MODE_SEL (1 bit ddr_mode control)
  - DDR_INPUT (1 bit ddr_input control)
- ips_addr[X:2] - since the IOMUXC registers are all 32 bits width address lines 0,1 are not used. X will be calculated automatically by the tool according to the final register number: X is smallest integer value which satisfy the constraint: 2^(X-1) >= (Total number of IOMUXC registers).

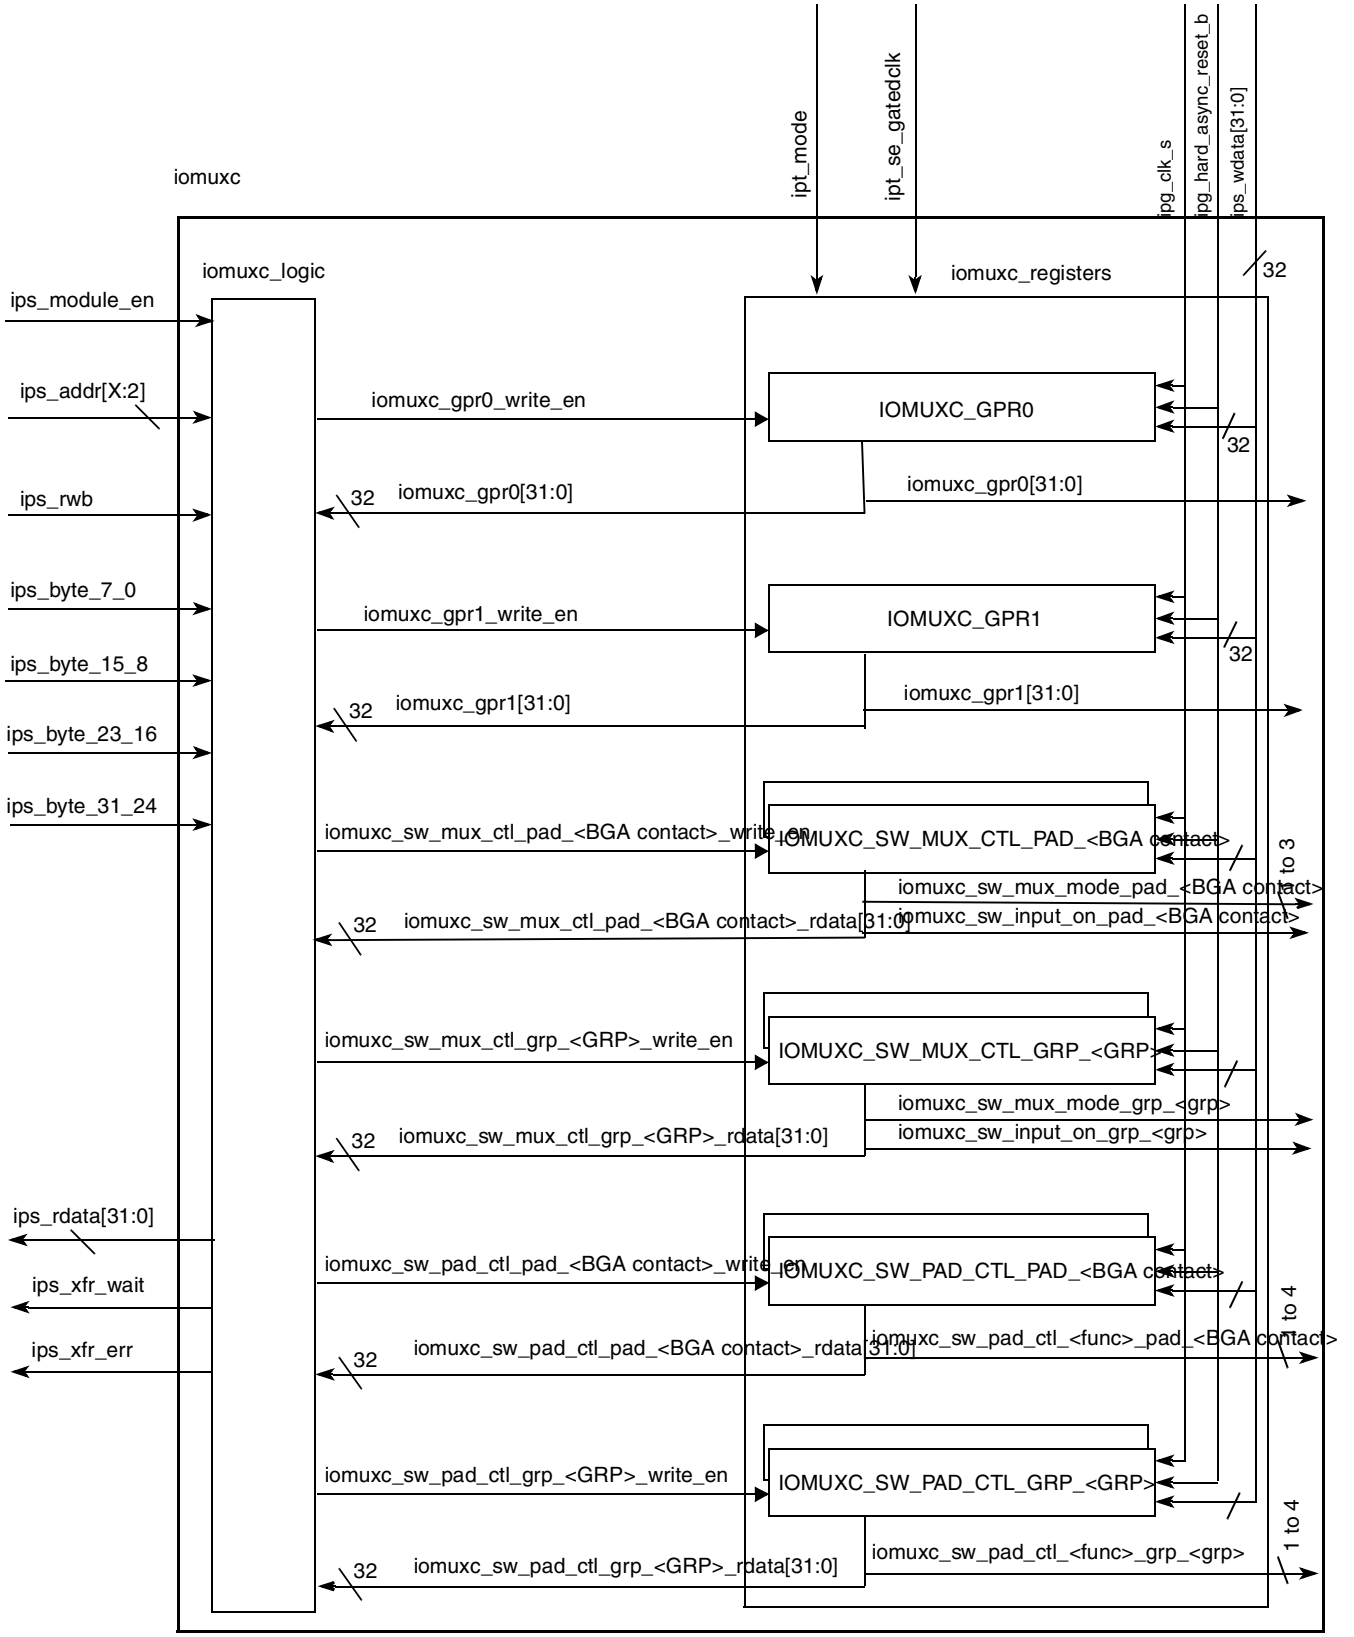

Figure A-2. IOMUXC Block Diagram

The IOMUX consist of a number (about the number of pads in the SoC) of basic iomux_cell units. If only one functional mode is required for a specific BGA contact then there is no need for IOMUXing and the signals can be connected directly from the module to the IORING. IOMUX cell is required whenever 2 or more functional modes are required for a specific BGA contact or when one functional mode and the one test mode are required.

The basic iomux_cell design, which allows 2 levels of HW signal control (in ALT6 and ALT7 modes - ALT7 gets highest priority) is shown in Figure A-3.

A.3.1 ALT6 and ALT7 Extended Muxing Modes

The ALT7 and ALT6 Extended Muxing Modes allows any signal in the system (Fuse, BGA contact input, JTAG, SW register, etc) to override any SW configuration and to force the ALT6/ALT7 Muxing Mode. It also allows an IOMUX SW register to control a group of pads.

A.3.2 SW Loopback through SION Bit

A limited but satisfying option exist to override the regular BGA contact functionality and force the input path to be active (ipp_ibe==1'b1) regardless of the value driven by the corresponding module. This can be done by setting the SION (SW Input On) bit in the IOMUXC_SW_MUX_CTL register (when available) to "1" and can be used for:

- LoopBack - Module X drives the contact and also receive contact value as an input.
- GPIO Capture - Module X drives the BGA contact and the value is captured by GPIO.

NOTE

Software loopback is not affecting EMI PADS.

A.3.3 Daisy Chain—Multi Pads Ddriving Same Module Input Pin

In some cases, more than one BGA contact may drive a single module input pin.

Such cases require adding one more level of IOMUXing: all these input signals are muxed and a dedicated SW controlled register controls the mux in order to select the required input path. This means that a BGA contact involved in such "Daisy Chain" situation may require 2 SW configuration commands: one for selecting the mode for this contact and one for defining it as the input path.

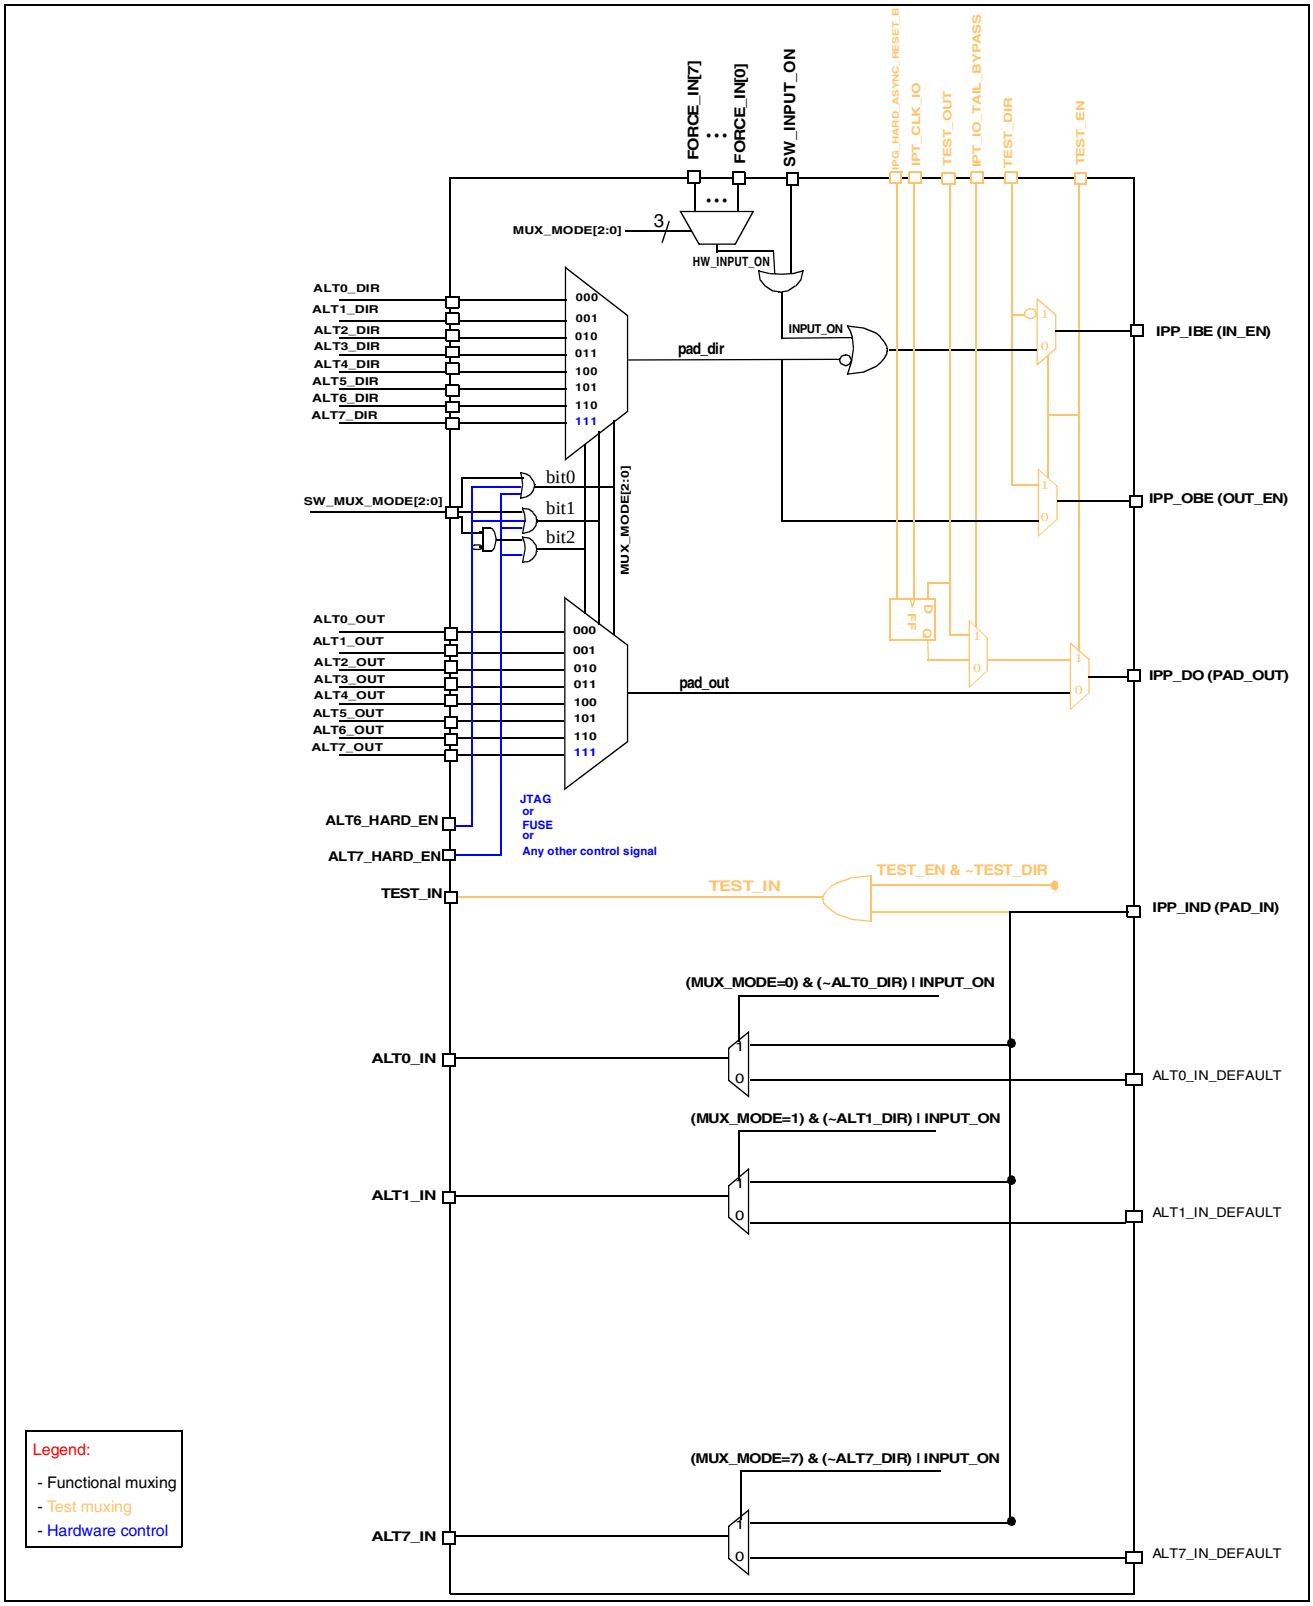

Figure A-3. IOMUX Cell Block Diagram

A.3.4 Interrupts

There are no interrupts that are generated by the IOMUX controller.

A.4 Memory Map and Register Definition

A.4.1 Registers Definition

A.4.1.1 General Purpose Registers

Table A-702. Register IOMUXC_SW_PAD_CTL_PAD_NANDF_D0 Bits Description

Field	Description
31-14	Reserved
13 HVE	High / Low Output Voltage Range. This bit selects the output voltage mode for NANDF_D0. 0 High output voltage mode 1 Low output voltage mode **Note:** This bit also serves as “HVE” setting for pads NANDF_CS0 and NANDF_CS1, which have no dedicated bits for that purpose in their corresponding IOMUXC_SW_PAD_CTL registers
12-9	Reserved
8 HYS	Hyst. Enable Field Select one out of next values for BGA contact: NANDF_D0. 0: Hysteresis Disabled 1: Hysteresis Enabled
7 PKE	Pull / Keep Enable Field Select one out of next values for BGA contact: NANDF_D0. 0: Pull/Keeper Disabled 1: Pull/Keeper Enabled
6 PUE	Pull / Keep Select Field Select one out of next values for BGA contact: NANDF_D0. 0: Keeper 1: Pull

Table A-702. Register IOMUXC_SW_PAD_CTL_PAD_NANDF_D0 Bits Description

Field	Description
