42.2.3.2.20 IPU Shadow Registers Memory Status Register (IPU_SRM_STAT)

The register contains status bits of SRM updates. There is a bit for each module. the bit is set when the SRM is currently updating the module's registers. When the SRM completes updating the registers of the

module the bit is cleared. SW should not update the module's registers while it is being updated by the SRM.

The register is shown in Figure 42-80, and the register fields are described in Table 42-77.

Address 0xBASE+0xE00024C (IPU_SRM_STAT) Access: User read-only

Figure 42-97. IDMAC Configuration Register (IDMAC_CONF)

Table 42-94. Register Field Descriptions

Field	Description
31–17	Reserved, should be cleared.
16 P_ENDIAN	Pixel Endianness. The pixel Endianness must not be changed while any of the IDMAC channels is enabled. 0 - little endian 1 - Big endian
15–6	Reserved, should be cleared.
5 RDI	Read Data Interleaving. This bit must match the slave read data interleaving support. If the AXI slave connected to the IPUv3EX supports read data interleaving then this bit must be set. If the AXI slave does not support read data interleaving then the IDMAC can utilize this and issue more address phases on read. In that case it is recommended to have this bit cleared. 0 - The AXI slave does not support read data interleaving 1 - The AXI slave supports read data interleaving
4–3 WIDPT	Write Interleaving Depth These 2 bits define the Write Interleaving Depth of the AXI port. This bits should be configured by the user according to the AXI slave's Write Interleaving Depth. WIDPT defines the maximal number of active bursts (yet to be responded) with different IDs. IDMAC will block data phase if the next data's ID is new (no such ID active) and the number of active IDs is equal to WIDPT. 00 Write Interleaving Depth of 1 01 Write Interleaving Depth of 2 10 Write Interleaving Depth of 3 11 Write Interleaving Depth of 4
2–0 MAX_REQ_READ	Maximum Read Requests. This fields sets the maximum pending requests allowed in the AXI Read requests queue.

Field	Description
31–27 DP_CYP_ASYNC0	CYP - Cursor Y Position Represents the cursors vertical starting position Y in pixel count (from 0 to CYH).Live View Resolution Mode.
26–16 DP_CYH_ASYNC0	CYH - Cursor Height Specifies the height of the hardware cursor in pixels.
15–11 DP_CXP_ASYNC0	CXP - Cursor X Position Represents the cursors horizontal starting position X in pixel count (from 0 to CXW).
10–0 DP_CXW_ASYNC0	CXW - Cursor Width. Specifies the width of the hardware cursor in pixels.

42.2.3.4.16 DP Color Cursor Mapping async0 Flow Register (DP_CUR_MAP_ASYNC0)

The LCD Color Cursor Mapping Register defines the color of the cursor in passive or TFT color modes.

Address 0xBASE+0xF040070 (DP_CUR_MAP_ASYNC0) Access: User read/write

Table 42-148. DP_DEBUG Field Descriptions

Field	Description
29 CYP_EN_OLD_1	The async flow has been broken in the middle of a cursor (This filed is relevant for debug unit #1)
28 COMBYP_EN_OLD_1	the async1 flow has been broken in the middle of combining (This filed is relevant for debug unit #1)
27 FG_ACTIVE_1	Displaying the partial frame has been started (This filed is relevant for debug unit #1)
26-16 V_CNT_OLD_1	The exact row where the async flow has been broken (This filed is relevant for debug unit #0)
13 CYP_EN_OLD_0	The async flow has been broken in the middle of a cursor (This filed is relevant for debug unit #0)
12 COMBYP_EN_OLD_0	the async flow has been broken in the middle of combining (This filed is relevant for debug unit #0)
11 FG_ACTIVE_0	Displaying the partial frame has been started for async flow (This filed is relevant for debug unit #0)
10-0 V_CNT_OLD_0	The exact row where the async flow has been broken (This filed is relevant for debug unit #0)

42.2.3.5 IC Registers

42.2.3.5.1 IC Configuration Register (IC_CONF)

This register contains control parameter for IC 3 tasks (pre-processing for encoding, pre-processing for view-finder and post processing).

Address 0xBASE+0xE020000 (IC_CONF) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 42-149. IC Configuration Register (IC_CONF)

Table 42-149. IC_CONF Field Descriptions

Field	Description
31 CSI_MEM_WR_EN	CSI direct memory write enable. This bit enables writing data from sensor directly to memory even when a raw sensor is not attached. 0 CSI direct writing to memory is disabled. 1 CSI direct writing to memory is enabled.
30 RWS_EN	Raw sensor enable. This bit indicate if a raw sensor is attached (Bayer format). 0 Raw sensor is not attached. 1 Raw sensor is attached. This bit is used together with the CSI_MEM_WR_EN bit as follows: CSI_MEM_WR_EN=0, RWS_EN=0 - data is fed from the CSI to the IC for processing; CSI_MEM_WR_EN=1, RWS_EN=0 - data is fed from the CSI to the IC for processing and also for writing to the system memory; CSI_MEM_WR_EN=0, RWS_EN=1 - data is fed from the CSI to the system memory (via the IC) and from the system memory to the IC for processing; CSI_MEM_WR_EN=1, RWS_EN=1 - non-valid configuration.
29 IC_KEY_COLOR_EN	Key color enable. This bit enables the key color feature. 0 Key color is disabled. 1 Key color is enabled.
28 IC_GLB_LOC_A	Global alpha. This bit select the source of alpha parameter. 0 Alpha parameter is local. 1 Alpha parameter is global.
27–21	Reserved
20 PP_ROT_EN	Post-processing rotation task enable. This bit enable post-processing rotation task. 0 Rotation is disabled. 1 Rotation is enabled.
19 PP_CMB	Post-processing task combining enable. This bit enables combining. 0 Combining is disabled. 1 Combining is enabled.
18 PP_CSC2	
17 PP_CSC1	Post-processing task color conversion YUV-->RGB enable. This bit enables YUV-->RGB. 0 YUV-->RGB is disabled. 1 YUV-->RGB is enabled.
16 PP_EN	Post-processing task enable. This bit enables the post-processing task. 0 Task is disabled. 1 Task is enabled.
15–13	Reserved

Table 42-149. IC_CONF Field Descriptions (continued)

Field	Description
12 PRPVF_ROT_EN	Preprocessing rotation task for viewfinder enable. This bit enable preprocessing rotation task for viewfinder. 0 Rotation is disabled. 1 Rotation is enabled.
11 PRPVF_CMB	Preprocessing task for view-finder combining enable. This bit enables combining. 0 Combining is disabled. 1 Combining is enabled.
10 PRPVF_CSC2	Pre-processing task for view-finder second color conversion enable. This bit enables second color conversion. 0 Second color conversion is disabled. 1 Second color conversion is enabled.
9 PRPVF_CSC1	Pre-processing task for view-finder first color conversion enable. This bit enables first color conversion. 0 First color conversion is disabled. 1 First color conversion is enabled.
8 PRPVF_EN	Preprocessing task for view-finder enable. This bit enables the view-finder task. 0 Task is disabled. 1 Task is enabled.
7–3	Reserved
2 PRPENC_ROT_EN	Preprocessing rotation task for encoding enable. This bit enable preprocessing rotation task for encoding. 0 Rotation is disabled. 1 Rotation is enabled.
1 PRPENC_CSC1	Preprocessing task for encoding color conversion enable. This bit enables color conversion. 0 Color conversion is disabled. 1 Color conversion is enabled.
0 PRPENC_EN	Preprocessing task for encoding enable. This bit enables the encoding task. 0 Task is disabled. 1 Task is enabled.

42.2.3.5.2 IC Preprocessing Encoder Resizing Coefficients Register (IC_PRP_ENC_RSC)

This register contains the resizing and downsizing parameters for preprocessing task for encoding.

Address 0xBASE+0xE020004 (IC_PRP_ENC_RSC) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 42-150. IC_PRP_ENC_RSC Field Descriptions

Field	Description
31–30 PRPENC_DS_R_V	Preprocessing task for encoding downsizing vertical ratio. This field contains the downsizing vertical coefficient of preprocessing for encoding.
29–16 PRPENC_RS_R_V	Preprocessing task for encoding resizing vertical ratio. This field contains the resizing vertical coefficient of preprocessing for encoding. Resizing ratio is equal to PRPENC_RS_R_V: M Where M = 2^13; SI - input size; SO - output size PRPENC_RS_R_V = floor(M*(SI-1)/(SO-1));
15–14 PRPENC_DS_R_H	Preprocessing task for encoding downsizing horizontal ratio. This field contains the downsizing horizontal coefficient of preprocessing for encoding. Values: 00 1 01 2 10 4 11 RSV
13–0 PRPENC_RS_R_H	Preprocessing task for encoding resizing horizontal ratio. This field contains the resizing horizontal coefficient of preprocessing for encoding. Resizing ratio is equal to PRPENC_RS_R_H: M Where M = 2^13; SI - input size; SO - output size PRPENC_RS_R_H = floor(M*(SI-1)/(SO-1));

42.2.3.5.3 IC Preprocessing View-Finder Resizing Coefficients Register (IC_PRP_VF_RSC)

This register contains the resizing and downsizing parameters for preprocessing task for display.

Address 0xBASE+0xE020008 (IC_PRP_VF_RSC) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 42-155. IC IDMAC Parameters 1 Register (IC_IDMAC_1)

Table 42-155. IC_IDMAC_1 Field Descriptions

Field	Description
31–26	Reserved
25 ALT_CB7_BURST_16	This bit defines the number of pixels within a burst (burst size) coming from the IDMAC for IC's CB7 when used in alternate mode. For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 - Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 - Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
24 ALT_CB6_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB6 when used in alternate mode. For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 - Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 - Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
23	Reserved
22 T3_FLIP_RS	LEFT/RIGHT flip for Post Processing (PP) task; his bit affect the flipping done on the resizing unit. The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 - horizontal flip enabled 0 - no flip
21 T2_FLIP_RS	LEFT/RIGHT flip for View Finder (VF) task; this bit affect the flipping done on the resizing unit. The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 - horizontal flip enabled 0 - no flip
20 T1_FLIP_RS	LEFT/RIGHT flip for Encoding (ENC) task; this bit affect the flipping done on the resizing unit. The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 - horizontal flip enabled 0 - no flip
19 T3_FLIP_UD	UP/DOWN flip for Post Processing (PP) task The value of this field must be identical to the corresponding channel's VF parameters in the IDMAC's CPMEM 1 - Vertical flip enable 0 - no flip
18 T3_FLIP_LR	LEFT/RIGHT flip for Post Processing (PP) task; this bit affect the flipping done on the rotation unit The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 - horizontal flip enabled 0 - no flip

Table 42-155. IC_IDMAC_1 Field Descriptions (continued)

Field	Description
17 T3_ROT	Rotation for Post Processing (PP) task The value of this field must be identical to the corresponding channel's ROT parameters in the IDMAC's CPMEM 1 - 90 degree rotation clockwise 0 - no rotation
16 T2_FLIP_UD	UP/DOWN flip for View Finder (VF) task The value of this field must be identical to the corresponding channel's VF parameters in the IDMAC's CPMEM 1 - Vertical flip enable 0 - no flip
15 T2_FLIP_LR	LEFT/RIGHT flip for View Finder (VF) task; this bit affect the flipping done on the rotation unit The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 - horizontal flip enabled 0 - no flip
14 T2_ROT	Rotation for View Finder (VF) task The value of this field must be identical to the corresponding channel's ROT parameters in the IDMAC's CPMEM 1 - 90 degree rotation clockwise 0 - no rotation
13 T1_FLIP_UD	UP/DOWN flip for Encoding (ENC) task The value of this field must be identical to the corresponding channel's VF parameters in the IDMAC's CPMEM 1 - Vertical flip enable 0 - no flip
12 T1_FLIP_LR	LEFT/RIGHT flip for Encoding (ENC) task; this bit affect the flipping done on the rotation unit The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 - horizontal flip enabled 0 - no flip
11 T1_ROT	Rotation for Encoding (ENC) task The value of this field must be identical to the corresponding channel's ROT parameters in the IDMAC's CPMEM 1 - 90 degree rotation clockwise 0 - no rotation
10–8	Reserved
7 CB7_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB7 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 - Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 - Burst size is 16 pixels; The Matching NPB[6:2] should be 01111

Table 42-155. IC_IDMAC_1 Field Descriptions (continued)

Field	Description
6 CB6_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB6 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 - Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 - Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
5 CB5_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB5 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 - Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 - Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
4 CB4_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB4 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 - Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 - Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
3 CB3_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB3 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 - Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 - Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
2 CB2_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB2 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 - Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 - Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
1 CB1_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB1 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 - Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 - Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
0 CB0_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB0 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 - Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 - Burst size is 16 pixels; The Matching NPB[6:2] should be 01111

7-4 mpm_dmfc_brdg_max_rq	MPM memory Bridge Max Requests for the IC DMFC interface 0000 Feature is disabled 0001 Max request is 1 .... 1111 Max request are15
3-0 mpm_rw_brdg_max_rq	MPM memory Bridge Max Requests between MPM's read and writes 0000 Feature is disabled 0001 Max request is 1 .... 1111 Max request are15

42.2.3.6 IRT Registers

42.2.3.7 CSI0 registers

42.2.3.7.1 CSI0 Sensor Configuration Register (CSI0_SENS_CONF)

Address 0xBASE+0xE030000 (CSI0_SENS_CONF) Access: User read-write

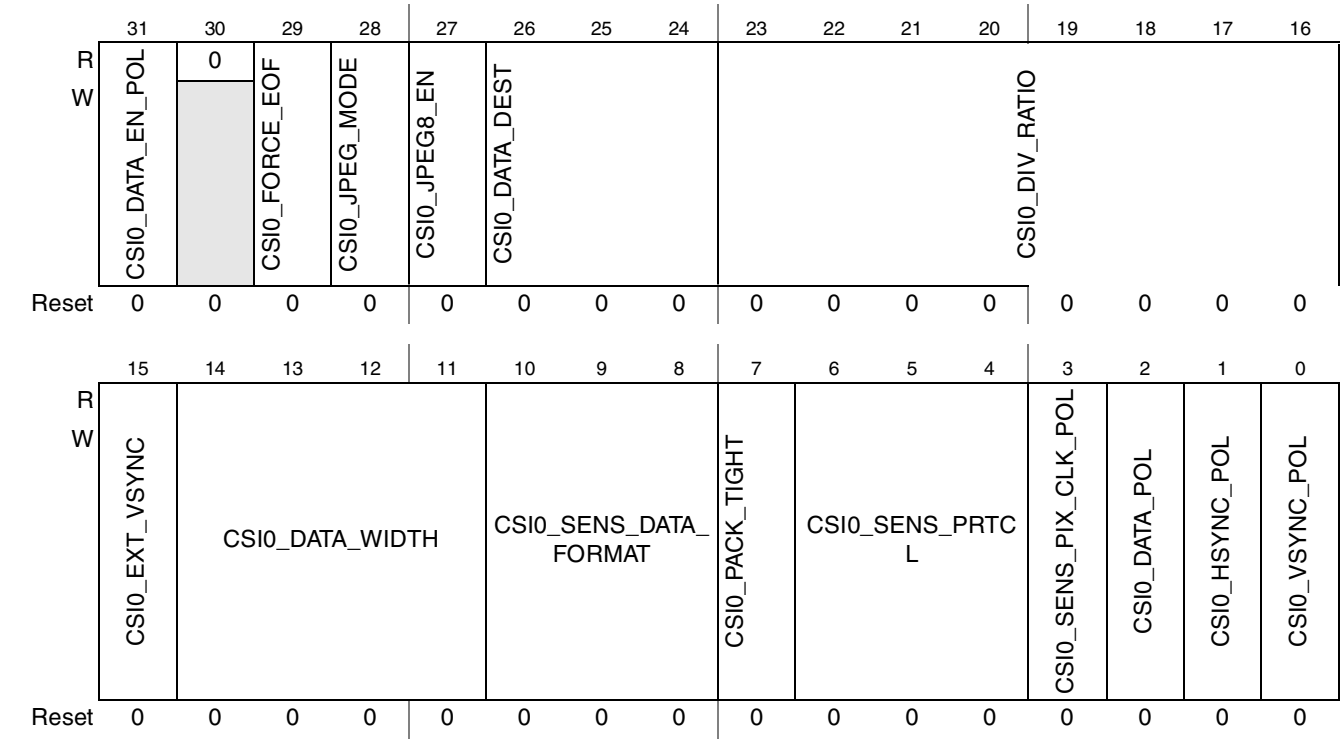

Figure 42-159. CSI0 Sensor Configuration Register (CSI0_SENS_CONF)

Table 42-159. Register Field Descriptions

31 CSI0_DATA_EN_POL	Invert IPP_IND_SENSB_DATA_EN input. This bit selects the polarity of IPP_IND_SENSB_DATA_EN signal. 0 IPP_IND_SENSB_DATA_EN is directly applied to internal circuitry. 1 IPP_IND_SENSB_DATA_EN is inverted before applied to internal circuitry.
30	Reserved, should be cleared.
29 CSI0_FORCE_EOF	Force End of frame This is a self clear bit allowing the user to force an End-of-frame event; This bit can be used in cases where the frame sent by the sensor was not completed. 1 - force end of frame 0 - no action
28 CSI0_JPEG_MODE	JPEG Mode - this bit defines the mode of the control signals when working in JPEG mode 1 - The data is valid as long as HSYNC and VSYNC signals are active; HSYNC is valid for single frame 0 - The frame starts withe the assertion of VSYNC. The frame ends on the next VSYNC or by setting the CSI0_FORCE_EOF bit

Table 42-159. Register Field Descriptions (continued)

27 CSI0_JPEG8_EN	JPEG8 enable bit 1 - JPEG8 detection is enabled 0 - JPEG8 is disabled
26–24 CSI0_DATA_DEST	These bits enable the destination of the data coming from the CSI. CSI0_DATA_DEST[0] - CSI0_DATA_DEST[1] - destination is IC CSI0_DATA_DEST[2] - destination is IDMAC via SMFC
23–16 CSI0_DIV_RATIO	DIV Ratio Clock division ratio minus 1. This field defines the division ratio of HSP_CLK into SENSB_MCLK: SENSB_MCLK rate = HSP_CLK rate /(DIV_RATIO+1)
15 CSI0_EXT_VSYNC	External VSYNC enable. This bits select between external and internal VSYNC. 0 Internal VSYNC mode. 1 External VSYNC mode.
14–11 CSI0_DATA_WIDTH	Data width. This field defines the number of bits per color. Values: 0000 - 4 bits per color 0001 - 8 bits per color 0010 - 9 bits per color 0011 - 10 bits per color 0100 - 11 bits per color 0101 - 12 bits per color 0110 - 13 bits per color 0111 - 14 bits per color 1000 - 15 bits per color 1001 - 16 bits per color
10–8 CSI0_SENS_DATA_FORMAT	Data format from the sensor. This field defines the data format for the input of the CSI sensor. Values: 000 - full RGB or YUV444 001 - YUV422 (YUYV...) 010 - YUV422 (UYVY...) 011 - Bayer or Generic data 100 - RGB565 101 - RGB555 110 - RGB444 111 - JPEG
7 CSI0_PACK_TIGHT	CSI0 Pack Tight When the data format is YUV or RGB and the component's width is 9-16 bits, it can be sent to the memory in 2 different ways 1 - Three 10 bits components are packed into a 32 bit word. Color extension/reduction is performed 0 - Each component is written as a 16 bit word where the MSB is written to bit #15, color extension is done for the remaining least significant bits.

Table 42-159. Register Field Descriptions (continued)

6–4 CSI0_SENS_PRTCL	Sensor protocol. This bit defines the sensor timing/data mode protocol. Values: 000 Gated clock mode 001 Non-gated clock mode 010 CCIR progressive mode (BT.656) 011 CCIR interlaced mode (BT.656) 100 CCIR progressive (BT.1120 DDR mode: data arrives on every edge of the clock) 101 CCIR progressive (BT.1120 SDR mode: data arrives only on the positive edge of the clock) 110 CCIR interlaced mode (BT.1120 DDR mode: data arrives on every edge of the clock) 111 CCIR interlaced mode (BT.1120 SDR mode: data arrives only on the positive edge of the clock)
3 CSI0_SENS_PIX_CLK_POL	Invert pixel clock input. This bit selects the polarity of pixel clock. 0 pixel clock is directly applied to internal circuitry. 1 pixel clock is inverted before applied to internal circuitry.
2 CSI0_DATA_POL	Invert data input. This bit selects the polarity of data input. 0 data lines are directly applied to internal circuitry. 1 data lines are inverted before applied to internal circuitry.
1 CSI0_HSYNC_POL	Invert IPP_IND_SENSB_HSYNC input. This bit selects the polarity of IPP_IND_SENSB_HSYNC signal. 0 IPP_IND_SENSB_HSYNC is directly applied to internal circuitry. 1 IPP_IND_SENSB_HSYNC is inverted before applied to internal circuitry.
0 CSI0_VSYNC_POL	Invert IPP_IND_SENSB_VSYNC input. This bit selects the polarity of IPP_IND_SENSB_VSYNC signal. 0 IPP_IND_SENSB_VSYNC is not inverted before applied to internal circuitry. 1 IPP_IND_SENSB_VSYNC is inverted before applied to internal circuitry.

42.2.3.7.2 CSI0 Sense Frame Size Register (CSI0_SENS_FRM_SIZE)

Figure 42-168. CSI0 SKIP Register (CSI0_SKIP)

Table 42-168. CSI0_SKIP Field Descriptions

Field	Description
31-24	Reserved
23–19 CSI0_SKIP_ISP	
18–16 CSI0_MAX_RATIO_SKIP_ISP	
15-10	Reserved
9-8 CSI0_ID_2_SKIP	Reserved

Table 42-168. CSI0_SKIP Field Descriptions (continued)

Field	Description
7–3 CSI0_SKIP_SMFC	CSI0 SKIP SMFC These 5 bits define the skipping pattern of the frames send to the SMFC. Skipping is done for a set of frames. The number of frames in a set is defined at CSI0_MAX_RATIO_SKIP_SMFC. when CSI0_MAX_RATIO_SKIP_SMFC = 1 => CSI0_SKIP_SMFC[0] is used; other bits are ignored when CSI0_MAX_RATIO_SKIP_SMFC = 2 => CSI0_SKIP_SMFC[1:0] are used; other bits are ignored when CSI0_MAX_RATIO_SKIP_SMFC = 3 => CSI0_SKIP_SMFC[2:0] are used; other bits are ignored when CSI0_MAX_RATIO_SKIP_SMFC = 4 => CSI0_SKIP_SMFC[3:0] are used; other bits are ignored when CSI0_MAX_RATIO_SKIP_SMFC = 5 => CSI0_SKIP_SMFC[4:0] are used; Setting bit #n of CSI0_SKIP_SMFC means that the #n frame in the set is skipped. For example: if CSI0_MAX_RATIO_SKIP_SMFC = 4 and CSI0_SKIP_SMFC = 11010 Frames #0 & Frame #2 will not be skipped as bit0 and bit2 are cleared Frames #1 & Frame #3 will be skipped as bit1 and bit3 are set bit #4 is ignored as CSI0_MAX_RATIO_SKIP_SMFC is set to 4
2–0 CSI0_MAX_RATIO_SKIP_SMFC	CSI0 Maximum Ratio Skip for SMFC These bits define the number of frames in a skipping set. The skipping number is equal to CSI0_MAX_RATIO_SKIP_SMFC+1; The maximum value of this bits is 5. When set to 0 the skipping is disabled.

42.2.3.7.11 CSI0 Compander Control Register (CSI0_CPD_CTRL)

Address 0xBASE+0xE030028 (CSI0_CPD_CTRL) Access: User read-write

Figure 42-178. CSI0 Compander Offset Register 1 (CSI0_CPD_OFFSET1)

Table 42-178. CSI0_CPD_OFFSET1 Field Descriptions

Field	Description
31-30	Reserved
29-20 CSI0_CPD_B_OFFSET	CSI0 Blue component offset The value is between -512 to 511. The value is added to the blue component before companding. Clipping: If the result of the blue components value + the offset is smaller than 0, the result is zero If the result of the blue components value + the offset is greater than 1023, the result is 1023
19-10 CSI0_GB_OFFSET	CSI0 Green Blue component offset The value is between -512 to 511. The value is added to the blue component before companding. Clipping: If the result of the green-blue components value + the offset is smaller than 0, the result is zero If the result of the green-blue components value + the offset is greater than 1023, the result is 1023 If the input format is RGB/YUV then CSI1_GB_OFFSET must be equal to CSI1_GR_OFFSET
9-0 CSI0_GR_OFFSET	CSI0 Green Red component offset The value is between -512 to 511. The value is added to the green-red component before companding. Clipping: If the result of the green-red components value + the offset is smaller than 0, the result is zero If the result of the green-red components value + the offset is greater than 1023, the result is 1023

42.2.3.7.21 CSI0 Compander Offset Register 2 (CSI0_CPD_OFFSET2)

This register contain Offset parameters used for companding.

Figure 42-180. CSI1 Sensor Configuration Register (CSI1_SENS_CONF)

Table 42-180. Register Field Descriptions

Field	Description
31 CSI0_DATA_EN_POL	Invert IPP_IND_SENSB_DATA_EN input. This bit selects the polarity of IPP_IND_SENSB_DATA_EN signal. 0 IPP_IND_SENSB_DATA_EN is directly applied to internal circuitry. 1 IPP_IND_SENSB_DATA_EN is inverted before applied to internal circuitry.
30	Reserved, should be cleared.
29 CSI1_FORCE_EOF	Force End of frame This is a self clear bit allowing the user to force an End-of-frame event; This bit can be used in cases where the frame sent by the sensor was not completed. 1 - force end of frame 0 - no action
28 CSI1_JPEG_MODE	JPEG Mode - this bit defines the mode of the control signals when working in JPEG mode 1 - The data is valid as long as HSYNC and VSYNC signals are active; HSYNC is valid for single frame 0 - The frame starts withe the assertion of VSYNC. The frame ends on the next VSYNC or by setting the CSI0_FORCE_EOF bit
27 CSI1_JPEG8_EN	JPEG8 enable bit 1 - JPEG8 detection is enabled 0 - JPEG8 is disabled
26–24 CSI1_DATA_DEST	These bits enable the destination of the data coming from the CSI. CSI1_DATA_DEST[0] - CSI1_DATA_DEST[1] - destination is IC CSI1_DATA_DEST[2] - destination is IDMAC via SMFC
23–16 CSI1_DIV_RATIO	DIV Ratio Clock division ratio minus 1. This field defines the division ratio of HSP_CLK into SENSB_MCLK: SENSB_MCLK rate = HSP_CLK rate /(DIV_RATIO+1)
15 CSI1_EXT_VSYNC	External VSYNC enable. This bits select between external and internal VSYNC. 0 Internal VSYNC mode. 1 External VSYNC mode.
14–11 CSI1_DATA_WIDTH	Data width. This fields defines the number of bits per color. Values: 0000 - 4 bits per color 0001 - 8 bits per color 0010 - 9 bits per color 0011 - 10 bits per color 0100 - 11 bits per color 0101 - 12 bits per color 0110 - 13 bits per color 0111 - 14 bits per color 1000 - 15 bits per color 1001 - 16 bits per color

Table 42-180. Register Field Descriptions (continued)

Field	Description
10–8 CSI1_SENS_DATA_FORMAT	Data format from the sensor. This field defines the data format for the input of the CSI sensor. Values: 000 - full RGB or YUV444 001 - YUV422 (YUYV...) 010 - YUV422 (UYVY...) 011 - Bayer or Generic data 100 - RGB565 101 - RGB555 110 - RGB444 111 - JPEG
7 CSI1_PACK_TIGHT	CSI1 Pack Tight When the data format is YUV or RGB and the component's width is 9-16 bits, it can be sent to the memory in 2 different ways 1 - Three 10 bits components are packed into a 32 bit word. Color extension/reduction is performed 0 - Each component is written as a 16 bit word where the MSB is written to bit #15, color extension is done for the remaining least significant bits.
6–4 CSI1_SENS_PRTCL	Sensor protocol. This bit defines the sensor timing/data mode protocol. Values: 000 Gated clock mode 001 Non-gated clock mode 010 CCIR progressive mode (BT.656) 011 CCIR interlaced mode (BT.656) 100 CCIR progressive (BT.1120 DDR mode: data arrives on every edge of the clock) 101 CCIR progressive (BT.1120 SDR mode: data arrives only on the positive edge of the clock) 110 CCIR interlaced mode (BT.1120 DDR mode: data arrives on every edge of the clock) 111 CCIR interlaced mode (BT.1120 SDR mode: data arrives only on the positive edge of the clock)
3 CSI1_SENS_PIX_CLK_POL	Invert pixel clock input. This bit selects the polarity of pixel clock. 0 pixel clock is directly applied to internal circuitry. 1 pixel clock is inverted before applied to internal circuitry.
2 CSI1_DATA_POL	Invert data input. This bit selects the polarity of data input. 0 data lines are directly applied to internal circuitry. 1 data lines are inverted before applied to internal circuitry.
1 CSI1_HSYNC_POL	Invert IPP_IND_SENSB_HSYNC input. This bit selects the polarity of IPP_IND_SENSB_HSYNC signal. 0 IPP_IND_SENSB_HSYNC is directly applied to internal circuitry. 1 IPP_IND_SENSB_HSYNC is inverted before applied to internal circuitry.
0 CSI1_VSYNC_POL	Invert IPP_IND_SENSB_VSYNC input. This bit selects the polarity of IPP_IND_SENSB_VSYNC signal. 0 IPP_IND_SENSB_VSYNC is not inverted before applied to internal circuitry. 1 IPP_IND_SENSB_VSYNC is inverted before applied to internal circuitry.

Figure 42-189. CSI1 SKIP Register (CSI1_SKIP)

Table 42-189. CSI1_SKIP Field Descriptions

Field	Description
31-24	Reserved
23–19 CSI1_SKIP_ISP	
18–16 CSI1_MAX_RATIO_SKIP_ISP	
17-10	Reserved
9-8 CSI1_ID_2_SKIP	Reserved

Table 42-189. CSI1_SKIP Field Descriptions (continued)

Field	Description
7–3 CSI1_SKIP_SMFC	CSI1 SKIP SMFC These 5 bits define the skipping pattern of the frames send to the SMFC. Skipping is done for a set of frames. The number of frames in a set is defined at CSI1_MAX_RATIO_SKIP_SMFC. when CSI1_MAX_RATIO_SKIP_SMFC = 1 => CSI1_SKIP_SMFC[0] is used; other bits are ignored when CSI1_MAX_RATIO_SKIP_SMFC = 2 => CSI1_SKIP_SMFC[1:0] are used; other bits are ignored when CSI1_MAX_RATIO_SKIP_SMFC = 3 => CSI1_SKIP_SMFC[2:0] are used; other bits are ignored when CSI1_MAX_RATIO_SKIP_SMFC = 4 => CSI1_SKIP_SMFC[3:0] are used; other bits are ignored when CSI1_MAX_RATIO_SKIP_SMFC = 5 => CSI1_SKIP_SMFC[4:0] are used; Setting bit #n of CSI1_SKIP_SMFC means that the #n frame in the set is skipped. For example: if CSI1_MAX_RATIO_SKIP_SMFC = 4 and CSI1_SKIP_SMFC = 11010 Frames #0 & Frame #2 will not be skipped as bit0 and bit2 are cleared Frames #1 & Frame #3 will be skipped as bit1 and bit3 are set bit #4 is ignored as CSI1_MAX_RATIO_SKIP_SMFC is set to 4
2–0 CSI1_MAX_RATIO_SKIP_SMFC	CSI1 Maximum Ratio Skip for SMFC These bits define the number of frames in a skipping set. These bits define the number of frames in a skipping set. The skipping number is equal to CSI1_MAX_RATIO_SKIP_SMFC+1; The maximum value of this bits is 5. When set to 0 the skipping is disabled.

42.2.3.8.11 CSI1 Compander Control Register (CSI1_CPD_CTRL)

Address 0xBASE+0xE038028 (CSI1_CPD_CTRL) Access: User read-write

31-30	Reserved
29-20 CSI1_CPD_B_OFFSET	CSI1 Blue component offset The value is between -512 to 511. The value is added to the blue component before companding. Clipping: If the result of the blue components value + the offset is smaller than 0, the result is zero If the result of the blue components value + the offset is greater than 1023, the result is 1023
19-10 CSI1_CPD_GB_OFFSET	CSI1 Green Blue component offset The value is between -512 to 511. The value is added to the blue component before companding. Clipping: If the result of the green-blue components value + the offset is smaller than 0, the result is zero If the result of the green-blue components value + the offset is greater than 1023, the result is 1023 If the input format is RGB/YUV then CSI1_GB_OFFSET must be equal to CSI1_GR_OFFSET
9-0 CSI1_CPD_GR_OFFSET	CSI1 Green Red component offset The value is between -512 to 511. The value is added to the green-red component before companding. Clipping: If the result of the green-red components value + the offset is smaller than 0, the result is zero If the result of the green-red components value + the offset is greater than 1023, the result is 1023

42.2.3.8.21 CSI1 Compander Offset Register 2 (CSI1_CPD_OFFSET2)

These registers contain Offset parameters used for companding.

Figure 42-201. DI0 General Register (DI0_GENERAL)

Table 42-201. DI0_GENERAL Field Descriptions

Field	Description
31 di0_pin8_pin15_sel	This bit routes PIN8 over PIN15 1 - PIN8 is routed to PIN15, PIN8 is also routed to PIN8 0 - PIN15 is routed to PIN15, PIN8 is routed to PIN8
30–28 di0_disp_y_sel	DI0 Display Vertical coordinate (Y) select. This field defines which one of the 8 counters will be used as a display's line counter. 000 counter #1 is selected ... 111 counter #8 is selected
27–24 DI0_CLOCK_STOP_MODE	DI clock stop mode When performing a clock change. The DI stops the clock to the display. These field defines when the clock will be stopped 0000 - stop at the next edge of the display clock 0001-1001 stop at the next event of one of the counters (counter #1 to counter #9) 1100 - stop at EOL (end of a line), but if stop request is during blanking interval, stop now 1101 - stop at EOF (end of a frame), but if stop request is during blanking interval, stop now 1110 - stop at EOL (end of a line), but if stop request is during blanking interval, stop at the end of the next line 1111 - stop at EOF (end of a frame), but if stop request is during blanking interval, stop at the end of the next frame Stopping at EOL/EOF is supported for the case where the data is coming from the IDMAC (DMA access). In case that only direct accesses is performed, the user should set this field to 0000

Table 42-201. DI0_GENERAL Field Descriptions (continued)

Field	Description
23 DI0_DISP_CLOCK_INIT	Display clock's initial mode For synchronization error conditions the display clock can be stopped on the next VSYNC 1 - The display's clock is running after the next VSYNC (indicating new frame) 0 - The display's clock is stopped after the next VSYNC (indicating new frame)
22 di0_mask_sel	DI0 Mask select. IPP_PIN_2 output of the DI that functions as MASK signal can come from 2 sources: counter #2 or extracted from the MASK data coming from the memory. 1 IPP_PIN_2 is coming from extracted MASK data coming from the memory 0 IPP_PIN_2 is coming from counter #2
21 di0_vsync_ext	DI0 External VSYNC. This bit selects the source of the VSYNC signal 1 External to the IPUv3EX 0 Internally generated by the IPUv3EX
20 di0_clk_ext	DI0 External Clock. This bit selects the source of the DI0's clock 1 The source of the clock is external to the IPUv3EX 0 The clock is internally generated by the IPUv3EX
19-18 DI0_WATCHDOG_MODE	DI0 watchdog mode In case of a display error where the DI clock is stopped (defined at di0_err_treatment). An internal watchdog counts DI clocks. If this timer reached its pre defined value the DI will skip the current frame and restart on the frame. This 2 bits define the number of DI clock cycles that the timer counts. 00 The timer counts 4 DI cycles 01 The timer counts 16 DI cycles 10 The timer counts 64 DI cycles 11 The timer counts 128 DI cycles
17 di0_polarity_disp_clk	DI0 Output Clock's polarity This bits define the polarity of the DI0's clock. 1 The output clock is active high 0 The output clock is active low
16	Reserved
15–12 di0_sync_count_sel	For synchronous flow error: selects synchronous flow synchronization counter in DI:
11 di0_err_treatment	In case of synchronous flow error there are 2 ways to handle the display 1 to wait (i.e. stop clock) 0 Drive the last component
10 di0_erm_vsync_sel	DI0 error recovery module's VSYNC source select The error recovery module detect a case where the DI's VSYNC is asserted before the EOF. This bit selects the source of the VSYNC signal monitored by this mechanism. 1- vsync_post - an internal VSYNC signal asserted 2 lines after the DI's VSYNC 0 - vsync_pre - an internal VSYNC signal asserted 2 lines before the DI's VSYNC

Table 42-201. DI0_GENERAL Field Descriptions (continued)

Field	Description
9 di0_polarity_cs1	DI0 Chip Select's 1 polarity This bits define the polarity of the DI's CS1. 1 The CS1 is active high 0 The CS1 is active low
8 di0_polarity_cs0	DI0 Chip Select's 0 polarity This bits define the polarity of the DI's CS0. 1 The CS0 is active high 0 The CS0 is active low
7-0 di0_polarity_<i+1>	DI0 output pin's polarity This bits define the polarity of each of the DI's outputs. 1 The output pin is active high 0 The output pin is active low

Table 42-202. DI0_BS_CLKGEN0 Field Descriptions

Field	Description
31–25	Reserved.
24–16 di0_disp_clk_offset	DI0 Display Clock Offset The DI has the ability to delay the display's clock This field defines the amount of IPUv3EX's clock cycles added as delay on this clock.
15–12	Reserved.
11–0 di0_disp_clk_period	DI0 Display Clock Period This field defines the Display interface clock period for display write access. This parameter contains an integer part (bits 11:4) and a fractional part (bits 3:0). It defines a fractional division ratio of the HSP_CLK clock for generation of the display's interface clock.

42.2.3.9.3 DI0 Base Sync Clock Gen 1 Register (DI0_BS_CLKGEN1)

Address 0xBASE+0xE040008 (DI0_BS_CLKGEN1) Access: User read/write

Table 42-203. DI0_BS_CLKGEN1 Field Descriptions

Field	Description
31–25	Reserved.
24–16 di0_disp_clk_down	DI0 display clock falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is a time interval between display's access start point and display 's interface clock falling edge.
15–9	Reserved.
8–0 di0_disp_clk_up	DI0 display clock rising edge position This parameter contains an integer part (bits 8:1) and a fractional part (bit 0). The position value is a time interval between display's access start point and display 's interface clock rising edge.

42.2.3.9.4 DI0 Sync Wave Gen 1 Register 0 (DI0_SW_GEN0_1)

Address 0xBASE+0xE04000C (DI0_SW_GEN0_1) Access: User read/write

Figure 42-210. DI0 Sync Wave Gen 7 Register 0 (DI0_SW_GEN0_7)

Table 42-210. DI0_SW_GEN0_7 Field Descriptions

Field	Description
31	Reserved.
30–19 di0_run_value_m1_7	DI0 counter #7 pre defined value This fields defines the counter #7 pre defines value. When the counter is auto reload mode (di0_cnt_auto_reload_7 bit is set), the counter automatically restarts. otherwise the counter restarts for the amount of time defined on the corresponding di0_step_repeat field.
18–16 di0_run_resolution_7	DI0 counter #1 Run Resolution This field defines the trigger causing the counter to increment. 000 - Counter is disabled 001 - The counter is triggered by the same trigger that triggers the displays clock. 010 - The Counter is triggered by counter #1 011 - The Counter is triggered by counter #2 100 - The Counter is triggered by counter #3 101 - The Counter is triggered by counter #4 110 - The Counter is triggered by counter #5 111 Counter is always on.
14–3 di0_offset_value_7	DI0 counter #7 offset value The counter can start counting after a pre defined delay This field defines the amount of cycles that the counter will be delayed by
2–0 di0_offset_resolution_1	DI0 counter #7 offset Resolution This field defines the trigger causing the offset counter to increment 000 - Counter is disabled 001 - The counter is triggered by the same trigger that triggers the displays clock. 010 - The Counter is triggered by counter #1 011 - The Counter is triggered by counter #2 100 - The Counter is triggered by counter #3 101 - The Counter is triggered by counter #4 110 - The Counter is triggered by counter #5 111 Counter is always on.

Figure 42-213. DI0 Sync Wave 1 Gen Register 1 (DI0_SW_GEN1_1)

Table 42-213. DI0_SW_GEN1_1 Field Descriptions

Field	Description
31	Reserved.
30–29 di0_cnt_polarity_gen_en_1	DI0 Counter polarity generator enable The counter's output polarity can be changed on the fly. 00 Dynamic polarity change is disabled 01 The counters UP and DOWN value are calculated according to the trigger selected by cnt_polarity_trigger_sel field. When selecting this mode the UP and DOWN values has to be a multiple of 2. 10 Dynamic polarity change is enabled 11 Outputs polarity is dynamically changed every time the counter reaches its pre defined value
28 di0_cnt_auto_reload_1	Counter auto reload mode 1 - The counter will automatically be reloaded forever, ignoring the value of the di0_step_repeat_<i> field 0 - The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the di0_step_repeat_1 field
27–25 di0_cnt_clr_sel_1	Counter Clear select This field defines the source of the signals that clears the counter. 000 - Counter is disabled 001 - The counter is triggered by the same trigger that triggers the displays clock. 010 - Reserved 011 - Reserved 100 - Reserved 101 - CSI VSYNC. The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. 110 - External VSYNC 111 Counter is always on.
24–16 di0_cnt_down_1	Counter falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's falling edge.

Table 42-213. DI0_SW_GEN1_1 Field Descriptions (continued)

Field	Description
15	Reserved
14–12 di0_cnt_polarity_trigger_sel_1	DI0 Counter's toggling trigger select This field selects the counter's trigger causing the output to toggle 000 - Counter is disabled 001 - The counter is triggered by the same trigger that triggers the displays clock. 010 - Reserved 011 - Reserved 100 - Reserved 101 - CSI VSYNC. The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. 110 - External VSYNC 111 Counter is always on.
11–9 di0_cnt_polarity_clr_sel_1	DI0 counter's polarity Clear select This field selects the input to the counter telling the counter wether to invert the output 000 - Output is always inverted 001 - Output is kept the same (no inversion) 010 - Reserved 011 - Reserved 100 - Reserved 101 - Reserved 110 - Reserved 111 - Reserved
8–0 di0_cnt_up_1	Counter rising edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's rising edge.

Figure 42-218. DI0 Sync Wave 1 Gen Register 1 (DI0_SW_GEN1_1)

Table 42-218. DI0_SW_GEN1_6 Field Descriptions

Field	Description
31	Reserved.
30–29 di0_cnt_polarity_gen_en_6	DI0 Counter polarity generator enable The counter's output polarity can be changed on the fly. 00 Dynamic polarity change is disabled 01 The counters UP and DOWN value are calculated according to the trigger selected by cnt_polarity_trigger_sel field. When selecting this mode the UP and DOWN values has to be a multiple of 2. 10 Dynamic polarity change is enabled 11 Outputs polarity is dynamically changed every time the counter reaches its pre defined value
28 di0_cnt_auto_reload_6	Counter auto reload mode 1 - The counter will automatically be reloaded forever, ignoring the value of the di0_step_repeat_<i> field 0 - The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the di0_step_repeat_<i> field

Table 42-218. DI0_SW_GEN1_6 Field Descriptions (continued)

Field	Description
27–25 di0_cnt_clr_sel_6	Counter Clear select This field defines the source of the signals that clears the counter. 000 - Counter is disabled 001 - The counter is triggered by the same trigger that triggers the displays clock. 010 - The Counter is triggered by counter #1 011 - The Counter is triggered by counter #2 100 - The Counter is triggered by counter #3 101 - The Counter is triggered by counter #4 110 - The Counter is triggered by counter #5 111 Counter is always on.
24–16 di0_cnt_down_6	Counter falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's falling edge.
15	Reserved
14–12 di0_cnt_polarity_trigger_sel_6	DI0 Counter's toggling trigger select This field selects the counter's trigger causing the output to toggle 000 - Counter is disabled 001 - The counter is triggered by the same trigger that triggers the displays clock. 010 - The Counter is triggered by counter #1 011 - The Counter is triggered by counter #2 100 - The Counter is triggered by counter #3 101 - The Counter is triggered by counter #4 110 - The Counter is triggered by counter #5 111 Counter is always on.
11–9 di0_cnt_polarity_clr_sel_6	DI0 counter's polarity Clear select This field selects the input to the counter telling the counter wether to invert the output 000 - Output is always inverted 001 - Output is kept the same (no inversion) 010 - Output is inverted if the output of counter #1 is set 011 - Output is inverted if the output of counter #2 is set 100 - Output is inverted if the output of counter #3 is set 101 - Output is inverted if the output of counter #4 is set 110 - Output is inverted if the output of counter #5 is set 111 - Reserved
8–0 di0_cnt_up_6	Counter rising edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's rising edge.

42.2.3.9.19 DI0 Sync Wave 7 Gen Register 1 (DI0_SW_GEN1_7)

Table 42-221. DI0_SW_GEN1_9 Field Descriptions

Field	Description
31-29 di0_gentime_sel_9	Counter #9 main waveform select This field defines the counter that counter #9's auxiliary waveform will be attached too. 000 - Counter #9's waveform is attached to counter #1's waveform 001 - Counter #9's waveform is attached to counter #2's waveform 010 - Counter #9's waveform is attached to counter #3's waveform 011 - Counter #9's waveform is attached to counter #4's waveform 100 - Counter #9's waveform is attached to counter #5's waveform 101 - Counter #9's waveform is attached to counter #6's waveform 110 - Counter #9's waveform is attached to counter #7's waveform 111 - Counter #9's waveform is attached to counter #8's waveform
30–29 di0_cnt_polarity_gen_en_9	DI0 Counter polarity generator enable The counter's output polarity can be changed on the fly. 00 Dynamic polarity change is disabled 01 The counters UP and DOWN value are calculated according to the trigger selected by cnt_polarity_trigger_sel field. When selecting this mode the UP and DOWN values has to be a multiple of 2. 10 Dynamic polarity change is enabled 11 Outputs polarity is dynamically changed every time the counter reaches its pre defined value
28 di0_cnt_auto_reload_9	Counter auto reload mode 1 - The counter will automatically be reloaded forever, ignoring the value of the di0_step_repeat_<i> field 0 - The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the di0_step_repeat_<i> field
27–25 di0_cnt_clr_sel_9	Counter Clear select This field defines the source of the signals that clears the counter. 000 - Counter is disabled 001 - The counter is triggered by the same trigger that triggers the displays clock. 010 - The Counter is triggered by counter #1 011 - The Counter is triggered by counter #2 100 - The Counter is triggered by counter #3 101 - The Counter is triggered by counter #4 110 - The Counter is triggered by counter #5 111 Counter is always on.
24–16 di0_cnt_down_9	Counter falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's falling edge.
15 di0_tag_sel_9	Counter #9 can send a synchronous tag when counter #9 reach its predefined value or when it's triggering counter reaches its pre defined value. 1 - tag source is counter #9 0 - Tag's source is the triggering counter.
14-9	Reserved
8–0 di0_cnt_up_9	Counter rising edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's rising edge.

Table 42-222. DI0_SYNC_AS_GEN Field Descriptions

Field	Description
31–29	Reserve
28 di0_sync_start_en	Reserve
27–16	Reserve
15–13 di0_vsync_sel	VSYNC select This field defines which of the counters functions as VSYNC signal 000 - VSYNC is coming from counter #1 001 - VSYNC is coming from counter #2 ... 111 - VSYNC is coming from counter #8
12	Reserved.
11–0 di0_sync_start	DI0 Sync start This field defines the number of low (including blanking rows) on the which the DI0 starts preparing the data for the next frame.

42.2.3.9.23 DI0 Data Wave Gen <i> Registers (DI0_DW_GEN_<i>)

The DI0_DW_GEN_<i> register holds pointers for the waveform generators.

These registers have different bit arrangements for parallel and serial display. When using a parallel display Table 42-223 is applicable. When using a serial interface Table 42-224 is applicable

Address 0xBASE+0xE040058 (DI0_DW_GEN_<i>) Access: User read/write
offset 4
range 0 .. 11

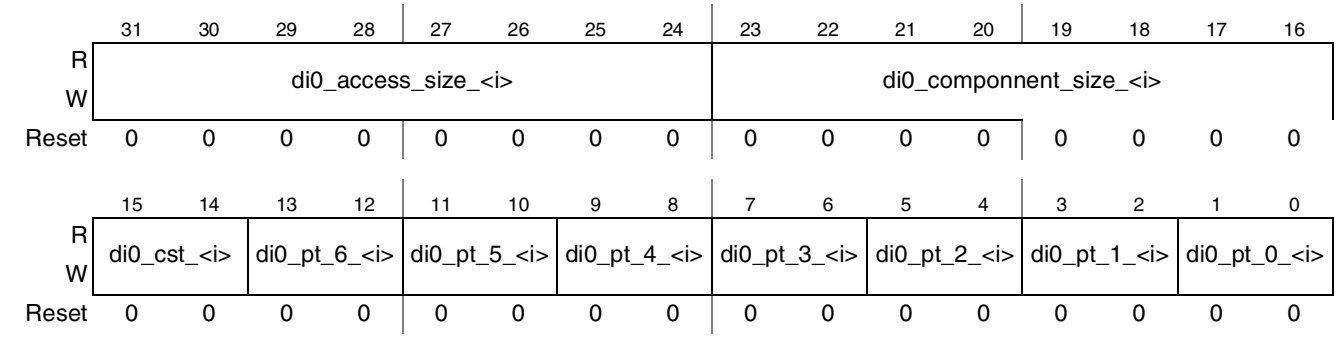

Figure 42-223. DI0 Data Wave Gen <i> Registers (DI0_DW_GEN_<i>)

Table 42-223. DI0_DW_GEN <i> Field Descriptions for parallel display

Field	Description
31–24 di0_access_size_<i>	DI0 Access Size <i> This field defines the amount of IPUv3EX cycles between any 2 accesses (an access may be a pixel or generic data that may have more one component)
23–16 di0_componnent_size_<i>	DI0 component Size This field defines the amount of IPUv3EX cycles between any 2 components
15-14 di0_cst_<i>	DI0 Chip Select pointer for waveform <i> This field points to a register that defines the waveform of the CS pin. The CS is automatically mapped to a specific display 00 - The waveform is defined according to the settings on DI0_DW_SET0_<i> 01- The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI0_DW_SET3_<i>
13-12 di0_pt_6_<i>	DI0 PIN_17 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_17 pin. 00 - The waveform is defined according to the settings on DI0_DW_SET0_<i> 01- The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI0_DW_SET3_<i>
11-10 di0_pt_5_<i>	DI0 PIN_16 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_16 pin. 00 - The waveform is defined according to the settings on DI0_DW_SET0_<i> 01- The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI0_DW_SET3_<i>

Table 42-223. DI0_DW_GEN <i> Field Descriptions for parallel display

Field	Description
9-8 di0_pt_4 _<i>	DI0 PIN_15 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_15 pin. 00 - The waveform is defined according to the settings on DI0_DW_SET0_<i> 01- The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI0_DW_SET3_<i>
7-6 di0_pt_3 _<i>	DI0 PIN_14 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_14 pin. 00 - The waveform is defined according to the settings on DI0_DW_SET0_<i> 01- The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI0_DW_SET3_<i>
5-4 di0_pt_2 _<i>	DI0 PIN_13 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_13 pin. 00 - The waveform is defined according to the settings on DI0_DW_SET0_<i> 01- The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI0_DW_SET3_<i>
3-2 di0_pt_1 _<i>	DI0 PIN_12 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_12 pin. 00 - The waveform is defined according to the settings on DI0_DW_SET0_<i> 01- The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI0_DW_SET3_<i>
1-0 di0_pt_0 _<i>	DI0 PIN_11 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_11 pin. 00 - The waveform is defined according to the settings on DI0_DW_SET0_<i> 01- The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI0_DW_SET3_<i>

Table 42-224. DI0_DW_GEN <i> Field Descriptions for serial display

Field	Description
31–24 di0_seria l_period_ <i>	DI0 Serial Period <i> This field defines the period of the time base serial display clock. The units are the internal DI clock
23–16 di0_start _period_ <i>	DI0 start period This field defines the amount of cycles between the point where the access is ready to be launched to the actual point where the time base serial display clock restarts. The units are the internal DI clock

Table 42-224. DI0_DW_GEN <i> Field Descriptions for serial display

Field	Description
15-14 di0_cst_<i>	DI0 Chip Select pointer for waveform <i> This field points to a register that defines the waveform of the CS pin. For serial displays the down value as defined on DI0_DW_SET*_<i> is measured from the assertion of the last serial display time base clock. 00 - The waveform is defined according to the settings on DI0_DW_SET0_<i> 01- The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI0_DW_SET3_<i>
13-9	Reserved
8-4 di0_serial_valid_bits<i>	DI0 Serial valid bits. This field defines the amount of valid bits to be transmitted within the 32 bits internal word aligned to bit[0]. The actual amount of valid bits is di0_serial_valid_bits_<i> + 1
3-2 di0_serial_rs_<i>	DI0 Serial RS This field points to a register that defines the waveform of the RS pin. For serial displays the down value as defined on DI0_DW_SET*_<i> is measured from the assertion of the last serial display time base clock. 00 - The waveform is defined according to the settings on DI0_DW_SET0_<i> 01- The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI0_DW_SET3_<i>
1-0 di0_serial_clk_<i>	DI0 serial clock<i> This field points to a register that defines the waveform of the Serial clock pin. 00 - The waveform is defined according to the settings on DI0_DW_SET0_<i> 01- The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI0_DW_SET3_<i>

Table 42-232. DI0_SSC Field Descriptions

Field	Description
31–24	Reserved.
23 DI0_PIN17_ERM	DI0 PIN17 error recovery mode. This bit defines the error recovery mode of the PIN17 pin. 1 - The PIN17 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN17 pin following a display error detection
22 DI0_PIN16_ERM	DI0 PIN16 error recovery mode. This bit defines the error recovery mode of the PIN16 pin. 1 - The PIN16 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN16 pin following a display error detection
21 DI0_PIN15_ERM	DI0 PIN15 error recovery mode. This bit defines the error recovery mode of the PIN15 pin. 1 - The PIN15 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN15 pin following a display error detection
20 DI0_PIN14_ERM	DI0 PIN14 error recovery mode. This bit defines the error recovery mode of the PIN14 pin. 1 - The PIN14 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN14 pin following a display error detection
19 DI0_PIN13_ERM	DI0 PIN13 error recovery mode. This bit defines the error recovery mode of the PIN13 pin. 1 - The PIN13 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN13 pin following a display error detection

Table 42-232. DI0_SSC Field Descriptions (continued)

Field	Description
18 DI0_PIN12_ERM	DI0 PIN12 error recovery mode. This bit defines the error recovery mode of the PIN12 pin. 1 - The PIN12 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN12 pin following a display error detection
17 DI0_PIN11_ERM	DI0 PIN11 error recovery mode. This bit defines the error recovery mode of the PIN11 pin. 1 - The PIN11 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN11 pin following a display error detection
16 DI0_CS_ERM	DI0 GLUELOGIC error recovery mode. This bit defines the error recovery mode of the GLUELOGIC (see Table 42-425). 1 - The GLUELOGIC is release in case of a synchronous display error. The release will be done on the next VSYNC 0 - Nothing is done to the GLUELOGIC following a display error detection
15–6	Reserved.
5 DI0_WAIT_ON	Wait On This field defines the DC's response to WAIT signal 1 - The DC holds the flow as long as WAIT is asserted 0 - The DC continues the flow regardless the WAIT signal
4	Reserved
3 DI0_BYTE_EN_RD_IN	Byte Enable Read In This bit selects the source of the byte enable pins 1 The write byte enable signals are routed via bits [17:16] of the display's data, The read byte enable signals are routed via bits [19:18 of the display's data 0 The byte enable signals are routed via bits [17:16] of the display's data for both read and write
2-0 DI0_BYTE_EN_PNTR	Byte Enable Pointer This pointer selects the pin asserted along with the byte enables signals 000 wave form of byte enable as pin_11 001 wave form of byte enable as pin_12 ... 111 wave form of byte enable as suitable CS pin

42.2.3.9.32 DI0 Polarity Register (DI0_POL)

Address 0xBASE+0xE040164 (DI0_POL) Access: User read/write

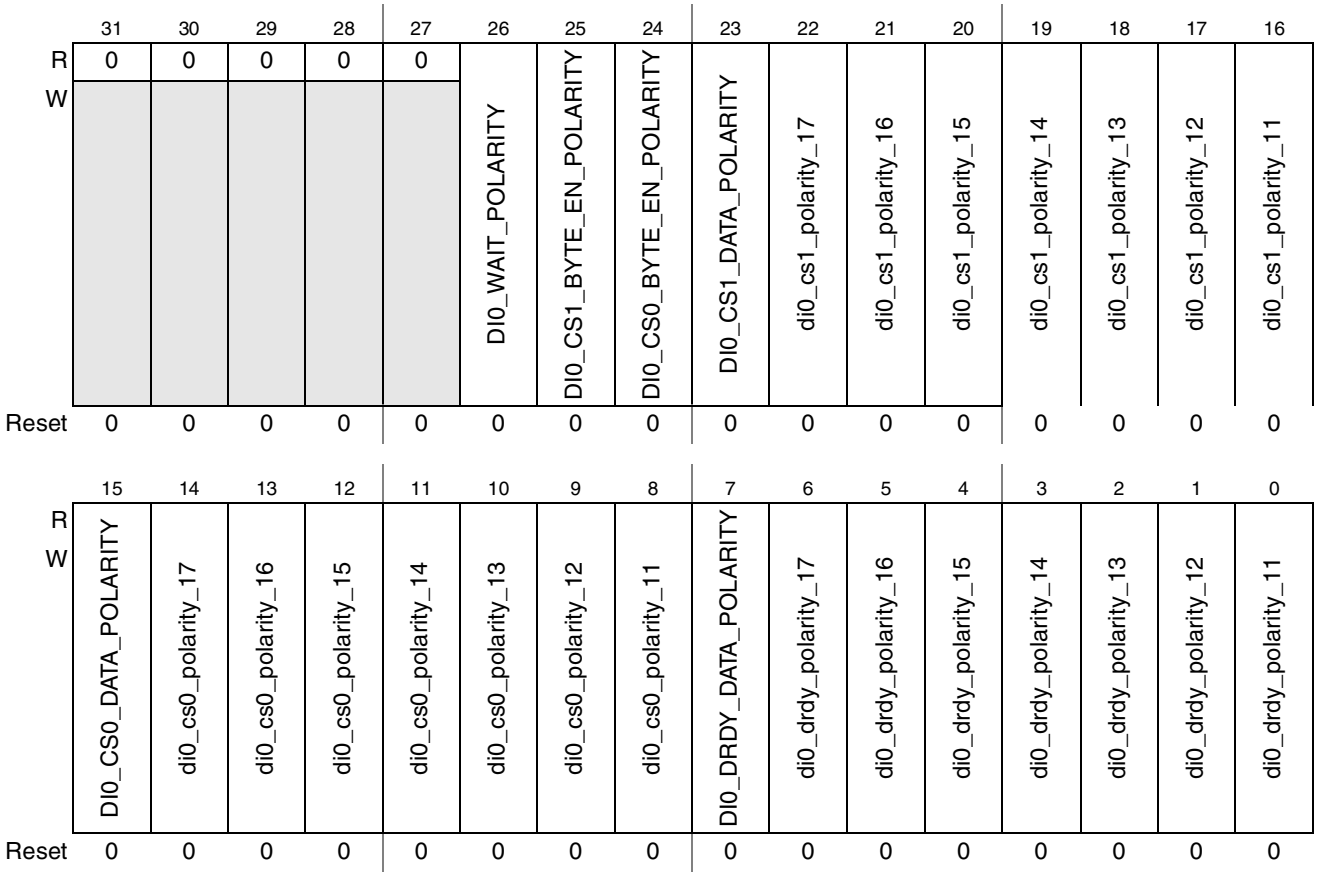

Figure 42-232. DI0 Polarity Register (DI0_POL)

Table 42-233. DI0_POL Field Descriptions

Field	Description
31-27	Reserved.
26 DI0_WAIT_POLARITY	WAIT polarity This bit defines the polarity of the wait signal input coming from the displa1 1 - active high 0 active low
25 DI0_CS1_BYTE_EN_POLARITY	Byte Enable associated with CS1 polarity This bit defines the polarity of the byte enable signals to the display 1 - active high 0 active low
24 DI0_CS0_BYTE_EN_POLARITY	Byte Enable associated with CS0 polarity This bit defines the polarity of the byte enable signals to the display 1 - active high 0 active low

Table 42-233. DI0_POL Field Descriptions (continued)

Field	Description
23 DI0_CS1_DATA_POLARITY	Data Polarity associated with CS1
22-16 di0_cs1_polarity_[17:11]	DI0 output pin's polarity for CS1 This bits define the polarity of each of the DI's outputs when CS1 is asserted 1 The output pin is active high 0 The output pin is active low
15 DI0_CS0_DATA_POLARITY	Data Polarity associated with CS0
14-8 di0_cs0_polarity_[17:11]	DI0 output pin's polarity for CS1 This bits define the polarity of each of the DI's outputs when CS1 is asserted 1 The output pin is active high 0 The output pin is active low
7 DI0_DRDY_DATA_POLARITY	Data Polarity associated with DRDY
6-0 di0_drdy_polarity_[17:11]	DI0 output dynamic pin's polarity for synchronous access This bits define the polarity of each of the DI's outputs when synchronous display access is asserted 1 The output pin is active high 0 The output pin is active low The pins' default polarity is the same as defined in the di0_drdy_polarity_[17:11] bits

42.2.3.9.33 DI0 Active Window 0 Register (DI0_AW0)

Address 0xBASE+0xE040168 (DI0_AW0) Access: User read/write

Figure 42-237. DI1 General Register (DI1_GENERAL)

Table 42-238. DI1_GENERAL Field Descriptions

Field	Description
31 di1_pin8_pin15_sel	This bit routes PIN8 over PIN15 1 - PIN8 is routed to PIN15, PIN8 is also routed to PIN8 0 - PIN15 is routed to PIN15, PIN8 is routed to PIN8\
30–28 di1_disp_y_sel	DI1 Display Vertical coordinate (Y) select. This field defines which one of the 8 counters will be used as a display's line counter. 000 counter #1 is selected ... 111 counter #8 is selected

Table 42-238. DI1_GENERAL Field Descriptions (continued)

Field	Description
27–24 DI1_CLOCK_STOP_MODE	DI clock stop mode When performing a clock change. The DI stops the clock to the display. These field defines when the clock will be stopped 0000 - stop at the next edge of the display clock 0001-1001 stop at the next event of one of the counters (counter #1 to counter #9) 1100 - stop at EOL (end of a line), but if stop request is during blanking interval, stop now 1101 - stop at EOF (end of a frame), but if stop request is during blanking interval, stop now 1110 - stop at EOL (end of a line), but if stop request is during blanking interval, stop at the end of the next line 1111 - stop at EOF (end of a frame), but if stop request is during blanking interval, stop at the end of the next frame Stopping at EOL/EOF is supported for the case where the data is coming from the IDMAC (DMA access). In case that only direct accesses is performed, the user should set this field to 0000
23 DI1_DISP_CLOCK_INIT	Display clock's initial mode For synchronization error conditions the display clock can be stopped on the next VSYNC 1 - The display's clock is running after the next VSYNC (indicating new frame) 0 - The display's clock is stopped after the next VSYNC (indicating new frame)
22 di1_mask_sel	DI1 Mask select. IPP_PIN_2 output of the DI that functions as MASK signal can come from 2 sources: counter #2 or extracted from the MASK data coming from the memory. 1 IPP_PIN_2 is coming from extracted MASK data coming from the memory 0 IPP_PIN_2 is coming from counter #2
21 di1_vsync_ext	DI1 External VSYNC. This bit selects the source of the VSYNC signal 1 External to the IPUv3EX 0 Internally generated by the IPUv3EX
20 di1_clk_ext	DI1 External Clock. This bit selects the source of the DI's clock 1 The source of the clock is external to the IPUv3EX 0 The clock is internally generated by the IPUv3EX
19-18 DI1_WATCHDOG_MODE	DI1 watchdog mode In case of a display error where the DI clock is stopped (defined at di0_err_treatment). An internal watchdog counts DI clocks. If this timer reached its pre defined value the DI will skip the current frame and restart on the frame. This 2 bits define the number of DI clock cycles that the timer counts. 00 The timer counts 4 DI cycles 01 The timer counts 16 DI cycles 10 The timer counts 64 DI cycles 11 The timer counts 128 DI cycles
17 di1_polarity_disp_clk	DI1 Output Clock's polarity This bits define the polarity of the DI's clock. 1 The output clock is active high 0 The output clock is active low
16	Reserved
15–12 di1_sync_count_sel	For synchronous flow error: selects synchronous flow synchronization counter in DI:

Table 42-238. DI1_GENERAL Field Descriptions (continued)

Field	Description
11 di1_err_treatment	In case of synchronous flow error there are 2 ways to handle the display 1 to wait (i.e. stop clock) 0 Drive the last component
10 di1_erm_vsync_sel	DI1 error recovery module's VSYNC source select The error recovery module detect a case where the DI's VSYNC is asserted before the EOF. This bit selects the source of the VSYNC signal monitored by this mechanism. 1- vsync_post - an internal VSYNC signal asserted 2 lines after the DI's VSYNC 0 - vsync_pre - an internal VSYNC signal asserted 2 lines before the DI's VSYNC
9 di1_polarity_cs1	DI1 Chip Select's 1 polarity This bits define the polarity of the DI's CS1. 1 The CS1 is active high 0 The CS1 is active low
8 di1_polarity_cs0	DI1 Chip Select's 0 polarity This bits define the polarity of the DI's CS0. 1 The CS0 is active high 0 The CS0 is active low
7-0 di1_polarity_<i+1>	DI1 output pin's polarity This bits define the polarity of each of the DI's outputs. 1 The output pin is active high 0 The output pin is active low

Table 42-239. DI1_BS_CLKGEN0 Field Descriptions

Field	Description
31–25	Reserved.
24–16 di1_disp_clk_offset	DI1 Display Clock Offset The DI has the ability to delay the display's clock This field defines the amount of IPUv3EX's clock cycles added as delay on this clock.

Table 42-239. DI1_BS_CLKGEN0 Field Descriptions (continued)

Field	Description
15–12	Reserved.
11–0 di1_disp_clk_period	DI1 Display Clock Period This field defines the Display interface clock period for display write access. This parameter contains an integer part (bits 11:4) and a fractional part (bits 3:0). It defines a fractional division ratio of the HSP_CLK clock for generation of the display's interface clock.

42.2.3.10.3 DI1 Base Sync Clock Gen 1 Register (DI1_BS_CLKGEN1)

Address 0xBASE+0xE048008 (DI1_BS_CLKGEN1) Access: User read/write

Table 42-240. DI1_BS_CLKGEN1 Field Descriptions

Field	Description
31–25	Reserved.
24–16 di1_disp_clk_down	DI1 display clock falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is a time interval between display's access start point and display 's interface clock falling edge.
15–9	Reserved.
8–0 di1_disp_clk_up	DI1 display clock rising edge position This parameter contains an integer part (bits 8:1) and a fractional part (bit 0). The position value is a time interval between display's access start point and display 's interface clock rising edge.

Field	Description
14–3 di1_offset_value_9	DI1 counter #9 offset value The counter can start counting after a pre defined delay This field defines the amount of cycles that the counter will be delayed by
2–0 di1_offset_resolution_9	DI1 counter #9 offset Resolution This field defines the trigger causing the offset counter to increment 000 - Counter is disabled 001 - The counter is triggered by the same trigger that triggers the displays clock. 010 - The Counter is triggered by counter #1 011 - The Counter is triggered by counter #2 100 - The Counter is triggered by counter #3 101 - The Counter is triggered by counter #4 110 - The Counter is triggered by counter #5 111 Counter is always on.

Figure 42-249. DI0 Sync Wave 1 Gen Register 1 (DI0_SW_GEN1_1)

Table 42-250. DI1_SW_GEN1_1 Field Descriptions

Field	Description
31	Reserved.
30–29 di1_cnt_polarity_gen_en_1	DI1 Counter polarity generator enable The counter's output polarity can be changed on the fly. 00 Dynamic polarity change is disabled 01 The counters UP and DOWN value are calculated according to the trigger selected by cnt_polarity_trigger_sel field. When selecting this mode the UP and DOWN values has to be a multiple of 2. 10 Dynamic polarity change is enabled 11 Outputs polarity is dynamically changed every time the counter reaches its pre defined value
28 di1_cnt_auto_reload_1	Counter auto reload mode 1 - The counter will automatically be reloaded forever, ignoring the value of the di1_step_repeat_<i> field 0 - The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the di1_step_repeat_1 field
27–25 di1_cnt_clr_sel_1	Counter Clear select This field defines the source of the signals that clears the counter. 000 - Counter is disabled 001 - The counter is triggered by the same trigger that triggers the displays clock. 010 - Reserved 011 - Reserved 100 - Reserved 101 - CSI VSYNC. The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. 110 - External VSYNC 111 Counter is always on.
24–16 di1_cnt_down_1	Counter falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's falling edge.
15	Reserved
14–12 di1_cnt_polarity_trigger_sel_1	DI1 Counter's toggling trigger select This field selects the counter's trigger causing the output to toggle 000 - Counter is disabled 001 - The counter is triggered by the same trigger that triggers the displays clock. 010 - Reserved 011 - Reserved 100 - Reserved 101 - CSI VSYNC. The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. 110 - External VSYNC 111 Counter is always on.

Table 42-250. DI1_SW_GEN1_1 Field Descriptions (continued)

Field	Description
11–9 di1_cnt_polarity_clr_sel_1	DI1 counter's polarity Clear select This field selects the input to the counter telling the counter wether to invert the output 000 - Output is always inverted 001 - Output is kept the same (no inversion) 010 - Reserved 011 - Reserved 100 - Reserved 101 - Reserved 110 - Reserved 111 - Reserved
8–0 di1_cnt_up_1	Counter rising edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's rising edge.

Table 42-260. DI1_DW_GEN <i> Field Descriptions

Field	Description
31–24 di1_access_size_<i>	DI1 Access Size <i> This field defines the amount of IPUv3EX cycles between any 2 accesses (an access may be a pixel or generic data that may have more one component)
23–16 di1_component_size_<i>	DI1 component Size This field defines the amount of IPUv3EX cycles between any 2 components
15-14 di1_cst_<i>	DI1 Chip Select pointer for waveform <i> This field points to a register that defines the waveform of the CS pin. The CS is automatically mapped to a specific display 00 - The waveform is defined according to the settings on DI1_DW_SET0_<i> 01- The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI1_DW_SET3_<i>
13-12 di1_pt_6_<i>	DI1 PIN_17 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_17 pin. 00 - The waveform is defined according to the settings on DI1_DW_SET0_<i> 01- The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI1_DW_SET3_<i>
11-10 di1_pt_5_<i>	DI1 PIN_16 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_16 pin. 00 - The waveform is defined according to the settings on DI1_DW_SET0_<i> 01- The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI1_DW_SET3_<i>
9-8 di1_pt_4_<i>	DI1 PIN_15 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_15 pin. 00 - The waveform is defined according to the settings on DI1_DW_SET0_<i> 01- The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI1_DW_SET3_<i>
7-6 di1_pt_3_<i>	DI1 PIN_14 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_14 pin. 00 - The waveform is defined according to the settings on DI1_DW_SET0_<i> 01- The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI1_DW_SET3_<i>
5-4 di1_pt_2_<i>	DI1 PIN_13 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_13 pin. 00 - The waveform is defined according to the settings on DI1_DW_SET0_<i> 01- The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI1_DW_SET3_<i>

Table 42-260. DI1_DW_GEN <i> Field Descriptions (continued)

Field	Description
3-2 di1_pt_1_<i>	DI1 PIN_12 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_12 pin. 00 - The waveform is defined according to the settings on DI1_DW_SET0_<i> 01- The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI1_DW_SET3_<i>
1-0 di1_pt_0_<i>	DI1 PIN_11 pointer for waveform <i> This field points to a register that defines the waveform of the PIN_11 pin. 00 - The waveform is defined according to the settings on DI1_DW_SET0_<i> 01- The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI1_DW_SET3_<i>

Table 42-261. DI1_DW_GEN <i> Field Descriptions for serial display

Field	Description
31–24 di1_serial_period_<i>	DI1 Serial Period <i> This field defines the period of the time base serial display clock. The units are the internal DI clock
23–16 di1_start_period_<i>	DI1 start period This field defines the amount of cycles between the point where the access is ready to be launched to the actual point where the time base serial display clock restarts. The units are the internal DI clock
15-14 di1_cst_<i>	DI1 Chip Select pointer for waveform <i> This field points to a register that defines the waveform of the CS pin. For serial displays the down value as defined on DI1_DW_SET*_<i> is measured from the assertion of the last serial display time base clock. 00 - The waveform is defined according to the settings on DI1_DW_SET0_<i> 01- The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI1_DW_SET3_<i>
13-9	Reserved
8-4 di1_serial_valid_bits_<i>	DI1 Serial valid bits. This field defines the amount of valid bits to be transmitted within the 32 bits internal word aligned to bit[0]. The actual amount of valid bits is di1_serial_valid_bits_<i> + 1

Table 42-261. DI1_DW_GEN <i> Field Descriptions for serial display

Field	Description
3-2 di1_serial_rs_<i>	DI1 Serial RS This field points to a register that defines the waveform of the RS pin. For serial displays the down value as defined on DI1_DW_SET*_<i> is measured from the assertion of the last serial display time base clock. 00 - The waveform is defined according to the settings on DI1_DW_SET0_<i> 01- The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI1_DW_SET3_<i>
1-0 di1_serial_clk_<i>	DI1 serial clock<i> This field points to a register that defines the waveform of the Serial clock pin. 00 - The waveform is defined according to the settings on DI1_DW_SET0_<i> 01- The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 - The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 - The waveform is defined according to the settings on DI1_DW_SET3_<i>

Table 42-268. DI1_SER_CONF Field Descriptions

Field	Description
31–28 DI1_SERIAL_LLA_PNTR_RS_R_1	RS 3 waveform pointer for read low level access This pointer defines which waveform set will be chosen when the read low level access is targeted to RS group 1. 0000 Waveform set #1 0001Waveform set #2 ... 1011 Waveform set #12 1100 Reserved 1101 Reserved .... 1100 Reserved
27–24 DI1_SERIAL_LLA_PNTR_RS_R_0	RS 2 waveform pointer for low level access This pointer defines which waveform set will be chosen when the read low level access is targeted to RS group 0. 0000 Waveform set #1 0001Waveform set #2 ... 1011 Waveform set #12 1100 Reserved 1101 Reserved .... 1100 Reserved

Table 42-268. DI1_SER_CONF Field Descriptions (continued)

Field	Description
23–20 DI1_SERIAL_LLA_PNTR_RS_W_1	RS 1 waveform pointer for write low level access This pointer defines which waveform set will be chosen when the write low level access is targeted to RS group 1. 0000 Waveform set #1 0001Waveform set #2 ... 1011 Waveform set #12 1100 Reserved 1101 Reserved .... 1100 Reserved
19–16 DI1_SERIAL_LLA_PNTR_RS_W_0	RS 0 waveform pointer for write low level access This pointer defines which waveform set will be chosen when the write low level access is targeted to RS group 0. 0000 Waveform set #1 0001Waveform set #2 ... 1011 Waveform set #12 1100 Reserved 1101 Reserved .... 1100 Reserved
15–8 DI1_SERIAL_LATCH	DI1 Serial Latch This field defines how many cycles to insert between serial read accesses start to data sampling in the IPUv3EX.
7–6	Reserved
5 DI1_LLA_SER_ACCESS	Direct Low Level Access to Serial display 1MCU access is performed via a direct path to the serial display in LLA mode, in this mode only the MCU in LLA mode can access the serial port 0 MCU access to the serial display port is not done directly, hence other source are allowed to access the serial port. The arbitration is done automatically
4 DI1_SER_CLK_POLARITY	Serial Clock Polarity The output polarity of the SER_CLK pin 1 - The clock is inverted 0 - The clock is not inverted
3 DI1_SERIAL_DATA_POLARITY	Serial Data Polarity The output polarity of the SER_DATA pin 1 - The data is inverted 0 - The data is not inverted
2 DI1_SERIAL_RS_POLARITY	Serial RS Polarity The output polarity of the SER_RS pin 1 - The RS is inverted 0 - The RS is not inverted

Table 42-268. DI1_SER_CONF Field Descriptions (continued)

Field	Description
1 DI1_SERIAL_CS_POLARITY	Serial Chip Select Polarity The output polarity of the SER_CS pin 1 - The CS is inverted 0 - The CS is not inverted
0 DI1_WAIT4SERIAL	Wait for Serial When the parallel display share pins with the serial port. Accessing the parallel port is not allowed till the serial port completes its access. 1 The parallel port should wait to the serial port as the pins are shared 0 The parallel port should not wait to the serial port as the pins are not shared

Table 42-269. DI1_SSC Field Descriptions

Field	Description
31–24	Reserved.
23 DI1_PIN17_ERM	DI1 PIN17 error recovery mode. This bit defines the error recovery mode of the PIN17 pin. 1 - The PIN17 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN17 pin following a display error detection

Table 42-269. DI1_SSC Field Descriptions (continued)

Field	Description
22 DI1_PIN16_ERM	DI1 PIN16 error recovery mode. This bit defines the error recovery mode of the PIN16 pin. 1 - The PIN16 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN16 pin following a display error detection
21 DI1_PIN15_ERM	DI1 PIN15 error recovery mode. This bit defines the error recovery mode of the PIN15 pin. 1 - The PIN15 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN15 pin following a display error detection
20 DI1_PIN14_ERM	DI1 PIN14 error recovery mode. This bit defines the error recovery mode of the PIN14 pin. 1 - The PIN14 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN14 pin following a display error detection
19 DI1_PIN13_ERM	DI1 PIN13 error recovery mode. This bit defines the error recovery mode of the PIN13 pin. 1 - The PIN13 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN13 pin following a display error detection
18 DI1_PIN12_ERM	DI1 PIN12 error recovery mode. This bit defines the error recovery mode of the PIN12 pin. 1 - The PIN12 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN12 pin following a display error detection
17 DI1_PIN11_ERM	DI1 PIN11 error recovery mode. This bit defines the error recovery mode of the PIN11 pin. 1 - The PIN11 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 - Nothing is done to the PIN11 pin following a display error detection
16 DI1_CS_ERM	DI1 GLUELOGIC error recovery mode. This bit defines the error recovery mode of the GLUELOGIC (see Table 42-425). 1 - The GLUELOGIC is release in case of a synchronous display error. The release will be done on the next VSYNC 0 - Nothing is done to the GLUELOGIC following a display error detection
15–6	Reserved.
5 DI1_WAIT_ON	Wait On This field defines the DC's response to WAIT signal 1 - The DC holds the flow as long as WAIT is asserted 0 - The DC continues the flow regardless the WAIT signal
4 DI1_BYTE_EN_POLARITY	Byte Enable polarity This bit defines the polarity of the byte enable signals to the display 1 - active high 0 active low

Table 42-269. DI1_SSC Field Descriptions (continued)

Field	Description
3 DI1_BYTE_EN_RD_IN	Byte Enable Read In This bit selects the source of the byte enable pins 1 The write byte enable signals are routed via bits [17:16] of the display's data, The read byte enable signals are routed via bits [19:18 of the display's data 0 The byte enable signals are routed via bits [17:16] of the display's data for both read and write
2-0 DI1_BYTE_EN_PNTR	Byte Enable Pointer This pointer selects the pin asserted along with the byte enables signals 000 wave form of byte enable as pin_11 001 wave form of byte enable as pin_12 ... 111 wave form of byte enable as suitable CS pin

15-12	Reserved.
11-9 WM1_CLR	Watermark “clear” level of DMASMFC channel 1. 000 clear watermark level when FIFO is full on 1/8 of their size. 001 clear watermark level when FIFO is full on 2/8 of their size. ... 110clear watermark level when FIFO is full on 7/8 of their size. 111clear watermark level when FIFO is full.
8-6 WM1_SET	Watermark “set” level of DMASMFC channel 1. 000 set watermark level when FIFO is full on 1/8 of their size. 001 set watermark level when FIFO is full on 2/8 of their size. ... 110set watermark level when FIFO is full on 7/8 of their size. 111set watermark level when FIFO is full.

Table 42-276. SMFC_MAP Field Descriptions (continued)

Field	Description
5-3 WM0_CLR	Watermark “clear” level of DMASMFC channel 0. 000 clear watermark level when FIFO is full on 1/8 of their size. 001 clear watermark level when FIFO is full on 2/8 of their size. ... 110clear watermark level when FIFO is full on 7/8 of their size. 111clear watermark level when FIFO is full.
2-0 WM0_SET	Watermark “set” level of DMASMFC channel 0. 000 set watermark level when FIFO is full on 1/8 of their size. 001 set watermark level when FIFO is full on 2/8 of their size. ... 110set watermark level when FIFO is full on 7/8 of their size. 111set watermark level when FIFO is full.

42.2.3.11.3 SMFC Burst Size Register (SMFC_BS)

This register holds the burst size value for each DMASMFC channel. The burst size is the number of IDMAC’s active accesses that will done for each IDMAC’s burst. This number is a function of PFS, BPP & NPB parameters in the IDMAC’s CPMEM. These are the parameters corresponding to the IDMAC’s channel used. The table below describes what should be the burst size according to PFS, BPP & NPB settings

Table 42-277. SMFC Burst Size

BPP	PFS	BURST_SIZE
8	6	NPB[6:4]
16	6	NPB[6:4]
All other	All other	NPB[6:2]

Figure 42-276. DC Read Channel Configuration Register (DC_READ_CH_CONF)

Table 42-279. DC_READ_CH_CONF Field Descriptions

Field	Description
31–16 TIME_OUT_VALUE	Time out value. In case of a error during read accesses to the display, where no response from the display was received. A time-out counter will terminate the current access and perform the next commend defined in the microcode. This field defines the amount of the hsp_clk cycles counted before the time-out event is issued. This event is tied to the interrupt controller and can generate an error interrupt.
11 CS_ID_3	This bit maps an asynchronous display to a chip select 1 - display #3 is connected to CS1 0 - display #3 is connected to CS0
10 CS_ID_2	This bit maps an asynchronous display to a chip select 1 - display #2 is connected to CS1 0 - display #2 is connected to CS0
9 CS_ID_1	This bit maps an asynchronous display to a chip select 1 - display #1 is connected to CS1 0 - display #1 is connected to CS0
8 CS_ID_0	This bit maps an asynchronous display to a chip select 1 - display #0 is connected to CS1 0 - display #0 is connected to CS0
7	Reserved
6 CHAN_MASK_DEFAULT_0	Event mask bit for the read channel When more then one event is used during a flow (EOF, EOL, NL, NF, EOFIELD, etc.) masks all the event besides the event that is defined as the highest priority event 1 - All the events are used - no mask 0 - Only the highest priority event is used, the rest are masked
5–4 W_SIZE_0	Word Size The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 - 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 - 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 - 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 - 32 bits are used
3–2 PROG_DISP_ID_0	The field defines which one of the 4 displays can be read. 00 - display #0 01 - display #1 10 - display #2 11 - display #3
1 PROG_DI_ID_0	This bit select the DI which a read transaction can be performed through 1 - DI #1 0 - DI #0
0 RD_CHANNEL_EN	This bit enables the read channel. 1 - The Read channel is enabled 0 - The Read channel is disabled

Figure 42-290. DC Write Channel 2 Configuration Register (DC_WR_CH_CONF_2)

Table 42-293. DC_WR_CH_CONF_2 Field Descriptions

Field	Description
31–27	Reserved.
26–16 PROG_ START_ TIME_2	This field defines the delay between display ‘s vertical synchronization pulse and the start time point of DC’s channel 2 window. The delay is defined in pairs of rows. It is used for tearing elimination
15–9	Reserved.
8 CHAN_ MASK_D EFAULT _2	Event mask bit for channel #2 When more then one event is used during a flow (EOF, EOL, NL, NF, EOFIELD, etc.) masks all the event besides the event that is defined as the highest priority event 1 - All the events are used - no mask 0 - Only the highest priority event is used, the rest are masked
7–5 PROG_ CHAN_T YP_2	This field define the mode of operation of channel #2 000 - Disable 001 - Reserved 010 - Reserved 100 - Normal mode without anti-tearing. For sync display this is the only mode allowed 101 - Normal mode with anti-tearing 110 - Reserved 111 - Additional command channel is added to the flow handled by DC channel #2
4–3 PROG_ DISP_ID _2	The field defines which one of the 4 displays is associated with channel #2. 00 - display #0 01 - display #1 10 - display #2 11 - display #3
2 PROG_ DI_ID_2	This bit select the DI which a transaction associated with channel #2 can be performed to 1 - DI #1 0 - DI #0
1-0 W_SIZE _2	Word Size The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 - 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 - 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 - 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 - 32 bits are used

Figure 42-298. DC Command Channel 4 Configuration Register (DC_CMD_CH_CONF_4)

Table 42-301. DC_CMD_CH_4 Field Descriptions

Field	Description
31–24 COD_CMND_START_CHAN_RS1_4	This field is a pointer to the address within the microcode memory where the routine that handles the command start event resides (associated with channel #4); This field is relevant when RS is equal to 1
23–16	Reserved.

Table 42-301. DC_CMD_CH_4 Field Descriptions (continued)

Field	Description
15–8 COD_CMND_START_CHAN_RS0_4	This field is a pointer to the address within the microcode memory where the routine that handles the command start event resides (associated with channel #4); This field is relevant when RS is equal to 0
7–2	Reserved.
1–0 W_SIZE_4	Word Size associated with channel #4 The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 - 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 - 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 - 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 - 32 bits are used

42.2.3.12.24 DC Write Channel 5 Configuration Register (DC_WR_CH_CONF_5)

Address 0xBASE+0xE05805C (DC_WR_CH_CONF_5) Access: User read/write

Figure 42-299. DC Write Channel 5 Configuration Register (DC_WR_CH_CONF_5)

Table 42-302. DC_WR_CH_CONF_5 Field Descriptions

Field	Description
31–27	Reserved.
26–16 PROG_START_TIME_5	This field defines the delay between display ‘s vertical synchronization pulse and the start time point of DC’s channel 5 window. The delay is defined in pairs of rows. It is used for tearing elimination
15–9	Reserved.

Table 42-302. DC_WR_CH_CONF_5 Field Descriptions (continued)

Field	Description
9 FIELD_ MODE_5	Field mode bit for channel #5 This bit defines if the channel works in field mode or frame mode; This bit is relevant if the flow is sync flow 1 - Field mode 0 - Frame mode
8 CHAN_ MASK_D EFAULT _5	Event mask bit for channel #5 When more then one event is used during a flow (EOF, EOL, NL, NF, EOFIELD, etc.) masks all the event besides the event that is defined as the highest priority event 1 - All the events are used - no mask 0 - Only the highest priority event is used, the rest are masked
7–5 PROG_ CHAN_T YP_5	This field define the mode of operation of channel #5 000 - Disable 001 - Reserved 010 - Reserved 100 - Normal mode without anti-tearing. For sync display this is the only mode allowed 101 - Normal mode with anti-tearing 110 - Reserved 111 - Additional command channel is added to the flow handled by DC channel #5
4–3 PROG_ DISP_ID _5	The field defines which one of the 4 displays is associated with channel #5. 00 - display #0 01 - display #1 10 - display #2 11 - display #3
2 PROG_ DI_ID_5	This bit select the DI which a transaction associated with channel #5 can be performed to. When channel 28 is connected to DI0, channel 23 must be connected to DI1 even if ch23 is not used. This is done by writing 1 to this bit. 1 - DI #1 0 - DI #0
1-0 W_SIZE _5	Word Size associated with channel #5 The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 - 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 - 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 - 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 - 32 bits are used

Figure 42-329. DC General Register (DC_GEN)

Table 42-332. DC_GEN Field Descriptions

Field	Description
31–25	Reserved.
24 DC_BK_EN	Cursor blinking enable 1- blinking is enabled 0 - blinking is disabled
23–16 DC_BKDIV	Blinking Rate This field defines the blinking rate. The blinking occurs every N-th frame While N is defined by DC_BKDIV
15–9	Reserved.
8 DC_CH5_TYPE	Channel 5 is used for synchronous flow. When this channel is used for accessing asynchronous display that is activated in a synchronous way 1 - Enable the asynchronous interface via channel 5 0 - normal mode, synchronous flow via channel 5
7 SYNC_PRIORITY_1	When 2 sync flows are running, this bit sets the priority of channel #1. This bit should be 1 - high Priority 0 - low Priority both SYNC_PRIORITY_5 and SYNC_PRIORITY_1 should not have the value of 0
6 SYNC_PRIORITY_5	When 2 sync flows are running, this bit sets the priority of channel #5. This bit should be 1 - high priority 0 - low Priority both SYNC_PRIORITY_5 and SYNC_PRIORITY_1 should not have the value of 0
5 MASK4CHAN_5	Sync flow can be associated with a mask channel. Only one sync flow can have a mask. 1 - mask channel is associated to the sync flow via DP 0 - mask channel is associated to the sync flow via DC (without DP) This bit is ignored if MASK_EN is clear

Table 42-332. DC_GEN Field Descriptions (continued)

Field	Description
4 MASK_EN	Enable of the mask channel 1 - mask channel is enabled 0 - mask channel is disabled
3	Reserved
2–1 SYNC_1_6	This field 00 - Channel 1 of the DC handles async flow 01 - Illegal 10 - Channel 1 of the DC handles sync flow 11 - illegal
0	Reserved

Figure 42-391. DMFC Read Channel Register (DMFC_RD_CHAN)

Table 42-394. DMFC_RD_CHAN Field Descriptions

Field	Description
31–26	Reserved.
25–24 dmfc_ppw_c	Pixel Per Word coded. This field defines the size of the read data from the display. 00 8 bit per pixel 01 16 bit per pixel 10 24 (rgb) bit per pixel or 32 bit per pixel 11 - Reserved
23-21 dmfc_wm_clr_0	Watermark Clear This field defines the watermark's level of the DMFC read FIFO. Crossing this level will clear the watermark signal to the IDMAC. The WM level is the amount of free bursts at the FIFO (dmfc_wm_clr_0 > dmfc_wm_set_0)
20-18 dmfc_wm_set_0	Watermark Set This field defines the watermark's level of the DMFC read FIFO. Crossing this level will send the watermark signal to the IDMAC. The WM level is the amount of free bursts at the FIFO (dmfc_wm_clr_0 > dmfc_wm_set_0)
17 dmfc_wm_en_0	Watermark enable. This bit enables the watermark feature of the FIFO 1 - WM feature is enabled 0 - WM feature is disabled
16–8	Reserved.
7-6 dmfc_burst_size_0	Read burst Size This field defines the burst size of the DMFC's read accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 - 32 words of 128 bit (4 pixels of 32 bit each, going to the IDMAC) 01 - 16 words of 128 bit 10 - 8 words of 128 bit 11 - 4 words of 128 bit
5–0	Reserved.

Figure 42-392. DMFC Write Channel Register (DMFC_WR_CHAN)

Table 42-395. DMFC_WR_CHAN Field Descriptions

Field	Description
31–30 dmfc_burst_size_2c	Burst size of IDMAC's channel 43 This field defines the burst size of the IDMAC's channel 43 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 - 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 - 16 words of 128 bit 10 - 8 words of 128 bit 11 - 4 words of 128 bit
29-27 dmfc_fifo_size_2c	DMFC FIFO size for IDMAC's channel 43 This field defines the FIFO partition for the DMFC channel connected to IDMAC's channel 43 000 - All (512X128 words) the DMFC's FIFO is allocated to this channel 001 - 256X128 words are allocated to this channel 010 - 128X128 words are allocated to this channel 011 - 64X128 words are allocated to this channel 100 - 32X128 words are allocated to this channel 101- 16X128 words are allocated to this channel 110 - 8X128 words are allocated to this channel 111 - 4X128 words are allocated to this channel
26–24 dmfc_st_addr_2c	DMFC Start Address for IDMAC's channel 43 This field defines the base address at the DMFC's FIFO of the partition allocated to the channel connected to IDMAC's channel 43. The FIFO is partitioned to 8 equal segments. Each segment is 64X128 words The value of this field is the number of the segment 000 - Segment 0 001 - Segment 1 ... 111 - Segment 7
23–22 dmfc_burst_size_1c	Burst size of IDMAC's channel 42 This field defines the burst size of the IDMAC's channel 42 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 - 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 - 16 words of 128 bit 10 - 8 words of 128 bit 11 - 4 words of 128 bit
21-19 dmfc_fifo_size_1c	DMFC FIFO size for IDMAC's channel 42 This field defines the FIFO partition for the DMFC channel connected to IDMAC's channel 42 000 - All (512X128 words) the DMFC's FIFO is allocated to this channel 001 - 256X128 words are allocated to this channel 010 - 128X128 words are allocated to this channel 011 - 64X128 words are allocated to this channel 100 - 32X128 words are allocated to this channel 101- 16X128 words are allocated to this channel 110 - 8X128 words are allocated to this channel 111 - 4X128 words are allocated to this channel

Table 42-395. DMFC_WR_CHAN Field Descriptions (continued)

Field	Description
18–16 dmfc_st_addr_1c	DMFC Start Address for IDMAC's channel 42 This field defines the base address at the DMFC's FIFO of the partition allocated to the channel connected to IDMAC's channel 42. The FIFO is partitioned to 8 equal segments. Each segment is 64X128 words The value of this field is the number of the segment 000 - Segment 0 001 - Segment 1 ... 111 - Segment 7
15–14 dmfc_burst_size_2	Burst size of IDMAC's channel 41 This field defines the burst size of the IDMAC's channel 41 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 - 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 - 16 words of 128 bit 10 - 8 words of 128 bit 11 - 4 words of 128 bit
13-11 dmfc_fifo_size_2	DMFC FIFO size for IDMAC's channel 41 This field defines the FIFO partition for the DMFC channel connected to IDMAC's channel 41 000 - All (512X128 words) the DMFC's FIFO is allocated to this channel 001 - 256X128 words are allocated to this channel 010 - 128X128 words are allocated to this channel 011 - 64X128 words are allocated to this channel 100 - 32X128 words are allocated to this channel 101- 16X128 words are allocated to this channel 110 - 8X128 words are allocated to this channel 111 - 4X128 words are allocated to this channel
10–8 dmfc_st_addr_2	DMFC Start Address for IDMAC's channel 41 This field defines the base address at the DMFC's FIFO of the partition allocated to the channel connected to IDMAC's channel 41. The FIFO is partitioned to 8 equal segments. Each segment is 64X128 words The value of this field is the number of the segment 000 - Segment 0 001 - Segment 1 ... 111 - Segment 7
7–6 dmfc_burst_size_1	Burst size of IDMAC's channel 28 This field defines the burst size of the IDMAC's channel 28 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 - 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 - 16 words of 128 bit 10 - 8 words of 128 bit 11 - 4 words of 128 bit

Table 42-395. DMFC_WR_CHAN Field Descriptions (continued)

Field	Description
5-3 dmfc_fifo_size_1	DMFC FIFO size for IDMAC's channel 28 This field defines the FIFO partition for the DMFC channel connected to IDMAC's channel 28 000 - All (512X128 words) the DMFC's FIFO is allocated to this channel 001 - 256X128 words are allocated to this channel 010 - 128X128 words are allocated to this channel 011 - 64X128 words are allocated to this channel 100 - 32X128 words are allocated to this channel 101- 16X128 words are allocated to this channel 110 - 8X128 words are allocated to this channel 111 - 4X128 words are allocated to this channel
2–0 dmfc_st_addr_1	DMFC Start Address for IDMAC's channel 28 This field defines the base address at the DMFC's FIFO of the partition allocated to the channel connected to IDMAC's channel 28. The FIFO is partitioned to 8 equal segments. Each segment is 64X128 words The value of this field is the number of the segment 000 - Segment 0 001 - Segment 1 ... 111 - Segment 7

Figure 42-396. DMFC General 1 Register (DMFC_GENERAL1)

Table 42-399. DMFC_GENERAL1 Field Descriptions

Field	Description
31–27	Reserved.
23 WAIT4EOT_9	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 - FIFO #9 is in wait4eot mode 0 - FIFO #9 is in normal mode
23 WAIT4EOT_6F	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 - FIFO #6F is in wait4eot mode 0 - FIFO #6F is in normal mode
22 WAIT4EOT_6B	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 - FIFO #6B is in wait4eot mode 0 - FIFO #6B is in normal mode
21 WAIT4EOT_5F	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 - FIFO #5F is in wait4eot mode 0 - FIFO #5F is in normal mode
20 WAIT4EOT_5B	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 - FIFO #5B is in wait4eot mode 0 - FIFO #5B is in normal mode
19 WAIT4EOT_4	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 - FIFO #4 is in wait4eot mode 0 - FIFO #4 is in normal mode
18 WAIT4EOT_3	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 - FIFO #3 is in wait4eot mode 0 - FIFO #3 is in normal mode
17 WAIT4EOT_2	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 - FIFO #2 is in wait4eot mode 0 - FIFO #2 is in normal mode
16 WAIT4EOT_1	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 - FIFO #1 is in wait4eot mode 0 - FIFO #1 is in normal mode

Table 42-399. DMFC_GENERAL1 Field Descriptions (continued)

Field	Description
15-13 dmfc_wm_clr_9	Watermark Clear This field defines the watermark's level of the DMFC's write FIFO. Crossing this level will clear the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set)
12-10 dmfc_wm_set_9	Watermark Set This field defines the watermark's level of the DMFC write FIFO. Crossing this level will send the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set
9 dmfc_wm_en_9	Watermark enable. This bit enables the watermark feature of the FIFO 1 - WM feature is enabled 0 - WM feature is disabled
8	Reserved
6-5 dmfc_burst_size_9	Burst size of IDMAC's channel 44 This field defines the burst size of the IDMAC's channel 44 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. This channel is targeted for MASK - the FIFO size is always 32X128; The base address is always the upper half of the 8th segment 00 - 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 - 16 words of 128 bit 10 - 8 words of 128 bit 11 - 4 words of 128 bit
4-2	Reserved.
1–0 dmfc_dcdp_sync_pr	DMFC's memory access priority settings for simultaneous synchronous flows from DC & DP 00 - Forbidden - should not be used. 01 - DC has higher priority over DP 10 - DP has higher priority over DC 11 - Round Robin

Field	Description
31-16	Reserved
15-13 dmfc_wm_clr_2_alt	Watermark Clear (for alternate flow) This field defines the watermark's level of the DMFC's write FIFO. Crossing this level will clear the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set)
12-10 dmfc_wm_set_2_alt	Watermark Set (for alternate flow) This field defines the watermark's level of the DMFC write FIFO. Crossing this level will send the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set
9 dmfc_wm_en_2_alt	Watermark enable. (for alternate flow) This bit enables the watermark feature of the FIFO 1 - WM feature is enabled 0 - WM feature is disabled
7-0	Reserved

Table 42-404. DMFC_DP_CHAN_ALT Field Descriptions

Field	Description
31–16	Reserved.
31–30 dmfc_burst_size_6f_alt	Burst size of IDMAC's channel 29 (for alternate flow) This field defines the burst size of the IDMAC's channel 29 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 - 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 - 16 words of 128 bit 10 - 8 words of 128 bit 11 - 4 words of 128 bit

Table 42-404. DMFC_DP_CHAN_ALT Field Descriptions (continued)

Field	Description
29-27 dmfc_fifo_size_6f_alt	DMFC FIFO size for IDMAC's channel 29 (for alternate flow) This field defines the FIFO partition for the DMFC channel connected to IDMAC's channel 29 000 - All (512X128 words) the DMFC's FIFO is allocated to this channel 001 - 256X128 words are allocated to this channel 010 - 128X128 words are allocated to this channel 011 - 64X128 words are allocated to this channel 100 - 32X128 words are allocated to this channel 101- 16X128 words are allocated to this channel 110 - 8X128 words are allocated to this channel 111 - 4X128 words are allocated to this channel
26–24 dmfc_st_addr_6f_alt	DMFC Start Address for IDMAC's channel 29 (for alternate flow) This field defines the base address at the DMFC's FIFO of the partition allocated to the channel connected to IDMAC's channel 29. The FIFO is partitioned to 8 equal segments. Each segment is 64X128 words The value of this field is the number of the segment 000 - Segment 0 001 - Segment 1 ... 111 - Segment 7
23–22 dmfc_burst_size_6b_alt	Burst size of IDMAC's channel 24 (for alternate flow) This field defines the burst size of the IDMAC's channel 24 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 - 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 - 16 words of 128 bit 10 - 8 words of 128 bit 11 - 4 words of 128 bit
21-19 dmfc_fifo_size_6b_alt	DMFC FIFO size for IDMAC's channel 24 (for alternate flow) This field defines the FIFO partition for the DMFC channel connected to IDMAC's channel 24 000 - All (512X128 words) the DMFC's FIFO is allocated to this channel 001 - 256X128 words are allocated to this channel 010 - 128X128 words are allocated to this channel 011 - 64X128 words are allocated to this channel 100 - 32X128 words are allocated to this channel 101- 16X128 words are allocated to this channel 110 - 8X128 words are allocated to this channel 111 - 4X128 words are allocated to this channel
18–16 dmfc_st_addr_6b_alt	DMFC Start Address for IDMAC's channel 24 (for alternate flow) This field defines the base address at the DMFC's FIFO of the partition allocated to the channel connected to IDMAC's channel 24. The FIFO is partitioned to 8 equal segments. Each segment is 64X128 words The value of this field is the number of the segment 000 - Segment 0 001 - Segment 1 ... 111 - Segment 7
15–8	Reserved

Table 42-404. DMFC_DP_CHAN_ALT Field Descriptions (continued)

Field	Description
7–6 dmfc_burst_size_5b_alt	Burst size of IDMAC's channel 23 (for alternate flow) This field defines the burst size of the IDMAC's channel 23 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 - 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 - 16 words of 128 bit 10 - 8 words of 128 bit 11 - 4 words of 128 bit
5-3 dmfc_fifo_size_5b_alt	DMFC FIFO size for IDMAC's channel 23 (for alternate flow) This field defines the FIFO partition for the DMFC channel connected to IDMAC's channel 23 000 - All (512X128 words) the DMFC's FIFO is allocated to this channel 001 - 256X128 words are allocated to this channel 010 - 128X128 words are allocated to this channel 011 - 64X128 words are allocated to this channel 100 - 32X128 words are allocated to this channel 101- 16X128 words are allocated to this channel 110 - 8X128 words are allocated to this channel 111 - 4X128 words are allocated to this channel
2–0 dmfc_st_addr_5b_alt	DMFC Start Address for IDMAC's channel 23 (for alternate flow) This field defines the base address at the DMFC's FIFO of the partition allocated to the channel connected to IDMAC's channel 23. The FIFO is partitioned to 8 equal segments. Each segment is 64X128 words The value of this field is the number of the segment 000 - Segment 0 001 - Segment 1 ... 111 - Segment 7

Figure 42-405. VDI Field Size Register (VDI_FSIZE)

Table 42-408. VDI_FSIZE Register Description

Field	Description
31–26	Reserved
25–16 VDI_FHEIGHT	Frame height The value to be written to this register is the frame's height minus 1. The frame height should not be smaller than 16. When VDI_CMB_EN bit is clear: • The frame height should not be greater than 1080. • The frame's height must be even (which means that both fields have the same height) • The frame's height in 4:2:0 format, must be multiple of 4 (which means that both chroma fields have the same height) When VDI_CMB_EN bit is set: • The frame height should not be greater than 1200.
15–10	Reserved
9–0 VDI_FWIDTH	Frame width. The value to be written to this register is the frame's width minus 1. The Frame width should not be smaller than 16. The width must be even. When VDI_CMB_EN bit is clear • The Frame width should not be greater than 720. When VDI_CMB_EN bit is set: • The Frame width should not be greater than .

42.2.3.14.2 VDI Control Register (VDI_C)

The register used to control modes of operations of VDI module.

Address 0xBASE+0xE068004 (VDI_C) Access: User read-write

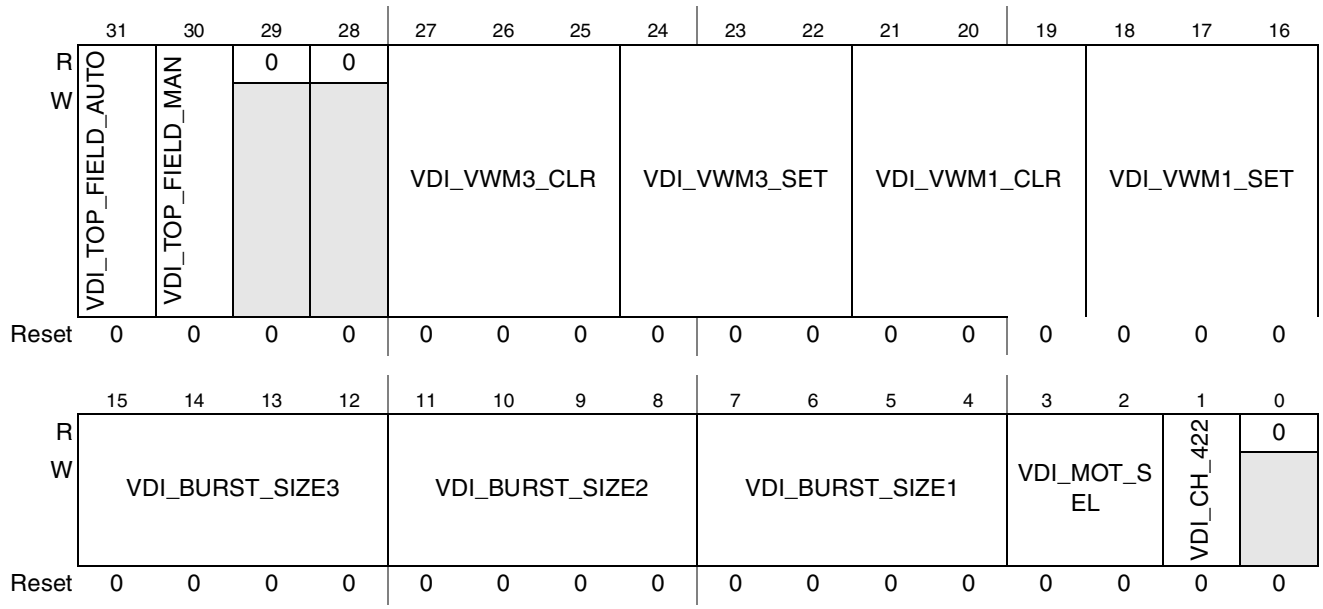

Figure 42-406. VDI Control Register (VDI_C)

Table 42-409. VDI_C Register Description

Field	Description
31	VDI top filed (automatic) This defines what would be the top field to be processed when the data is coming from the CSI 0 - top field is field 0 1- top field is field 1
30	VDI top filed (manual) This defines what would be the next top field to be processed when the data is coming from the memory 0 - top field is field 0 1- top field is field 1
29–28	Reserved
27-25 VDI_VWM3_CLR	VDI WaterMark “clear” level for channel 3. 0 clear watermark level when FIFO3 is full on 1/8 of their size. 1 clear watermark level when FIFO3 is full on 2/8 of their size. ... ... 7 clear watermark level when FIFO3 is full.
24-22 VDI_VWM3_SET	VDI WaterMark “set” level for channel 3. 0 set watermark level when FIFO3 is full on 1/8 of their size. 1 set watermark level when FIFO3 is full on 2/8 of their size. ... ... 7 set watermark level when FIFO3 is full.

Table 42-409. VDI_C Register Description (continued)

Field	Description
21-19 VDI_VWM1_CLR	VDI WaterMark “clear” level for channel 1 or channel 4 (channels 1 and 4 are not working simultaneously). 0 clear watermark level when FIFO1 is full on 1/8 of their size. 1 clear watermark level when FIFO1 is full on 2/8 of their size. ... ... 7 clear watermark level when FIFO1 is full.
18-16 VDI_VWM1_SET	VDI WaterMark “set” level for channel 1 or channel 2 (channels 1 and 4 are not working simultaneously). 0 set watermark level when FIFO1 is full on 1/8 of their size. 1 set watermark level when FIFO1 is full on 2/8 of their size. ... ... 7 set watermark level when FIFO1 is full.
15-12 VDI_BURST_SIZE3	Burst Size for channel 3. 0 Burst size is 1 access. 1 Burst size is 2 accesses. ... ... 15 Burst size is 16 accesses. The VDI’s burst size is restrict by the IDMAC’s restriction - This value must match the IDMAC settings and follow the IDMAC’s restrictions
11-8 VDI_BURST_SIZE2	Burst Size for channel 2. 0 Burst size is 1 access. 1 Burst size is 2 accesses. ... ... 15 Burst size is 16 accesses. The VDI’s burst size is restrict by the IDMAC’s restriction - This value must match the IDMAC settings and follow the IDMAC’s restrictions
7-4 VDI_BURST_SIZE1	Burst Size for channels 1 or 4 (channels 1 and 4 are not working simultaneously). 0 Burst size is 1 access. 1 Burst size is 2 accesses. ... ... 15 Burst size is 16 accesses. The VDI’s burst size is restrict by the IDMAC’s restriction - This value must match the IDMAC settings and follow the IDMAC’s restrictions
3-2 VDI_MOT_SEL	Motion select. 0 Motion determined by ROM “1” (shared toward medium/high motion). 1 Motion determined by ROM “2” (This option will not work well for high motion). 2 Full motion, only vertical filter is used 3 Forbidden.
1 VDI_CH_422	Chroma format at input and output of VDI. 0 Chroma format is 420. 1 Chroma format is 422.
0	Reserved

42.3.2.2 IBIW & IBIR - Internal Bus Interface for Write and Read

The Internal Bus Interface handles the internal IPUv3EX protocol communicating between the IDMAC and the IPUv3EX's sub modules. The IBIR handles channels that perform read from external memory. The IBIW handles channels that perform write accesses to external memory.

42.3.2.3 FCW & FCR - Format Converter Write and Read

The Format Converter performs packing ("write direction") / unpacking ("read" direction) of pixels with programmable position and width of color components, decoding 4- or 8-bits coded pixels according to a loaded look-up table, panning of an image read from the system memory according to a panning offset (start pixel address). The Format Converter supports formats with a pixel width of 4, 8, 12, 16, 18, 24 or 32 bits. The format converter unit handles two pixels simultaneously.

The IPUv3EX sub modules can handle only the formats, presented below. Each component is 8 bit:

Figure 42-409. IPUv3EX **internal pixel formats**

The pixel can be stored in the memory in the formats presented below. (R/G/B means that this could component can be R or G or B; A is the location of the alpha component).

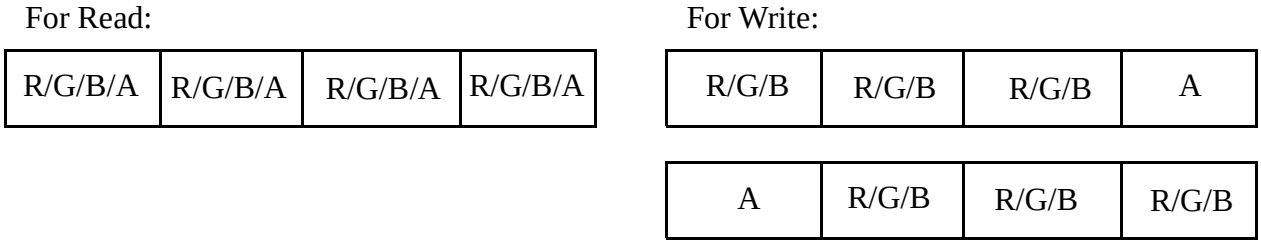

Figure 42-410. IPUv3EX **external pixel formats**

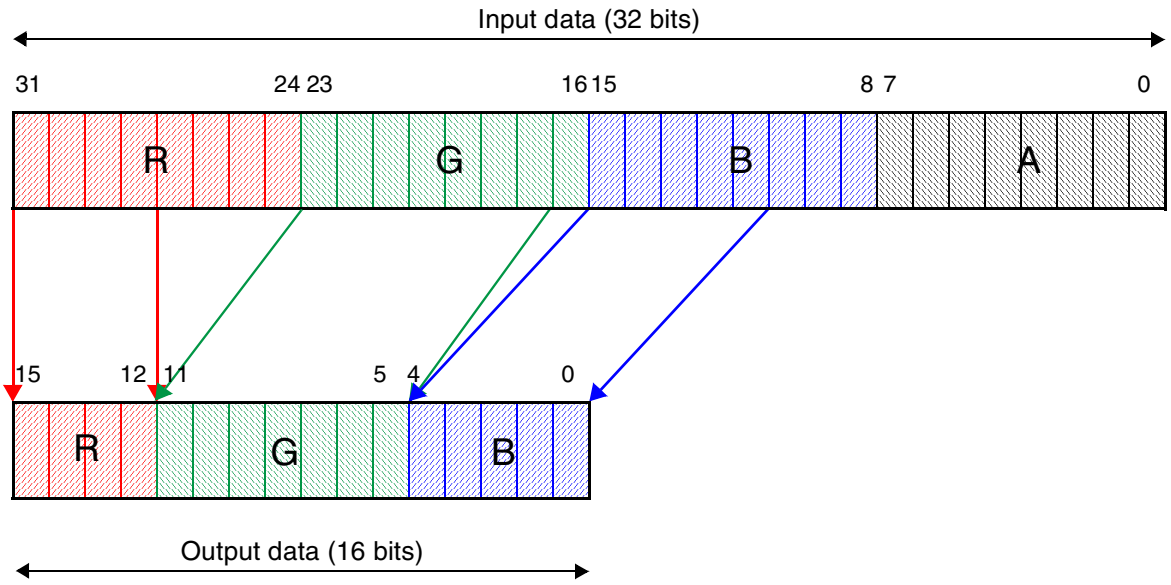
Formatting parameters are written in the Channel Parameter Memory (See: 42.3.2.10 CPMEM - Channel Parameter Memory). The following parameters are used:

- Offset OFS0 between MSB position of the color component 0 and MSB position of packed pixel. The color component 0 occupies the most significant bits of the unpacked pixel (mostly this is the R component). The OFS0 range is from 0 to 31.
- Color component 0 width WID0 minus 1.
- Offset OFS1 between MSB position of the color component 1 and MSB position of packed pixel. The color component 1 occupies the middle left bits of the unpacked pixel (mostly this is the G component). The OFS1 range is from 0 to 31.
- Color component 1 width WID1 minus 1.
- Offset OFS2 between MSB position of the color component 2 and MSB position of packed pixel. The color component 2 occupies the middle right bits of the unpacked pixel (mostly this is the B component). The OFS2 range is from 0 to 31.
- Color component 2 width WID2 minus 1.
- Offset OFS3 between MSB position of the color component 3 and MSB position of packed pixel. The color component 3 occupies the least significant bits of the unpacked pixel (mostly this is the A component). The OFS3 range is from 0 to 31. For write specified DMA channels, the OFS3 value is set to 24 or 0 bits.
- In cases of read with separate alpha (alpha is located in a separate buffer in the system’s memory than the pixel data), the alpha component size is defined according to WID3.

Figure 42-411 and Figure 42-412 show examples of data packing and unpacking.



Byte 0 (red) **OFS0 = 0** **WID0 = 3**
Byte 1 (green) **OFS1 = 4** **WID1 = 6**
Byte 2 (blue) **OFS2 = 11** **WID2 = 4**

Figure 42-411. Data Packing Example

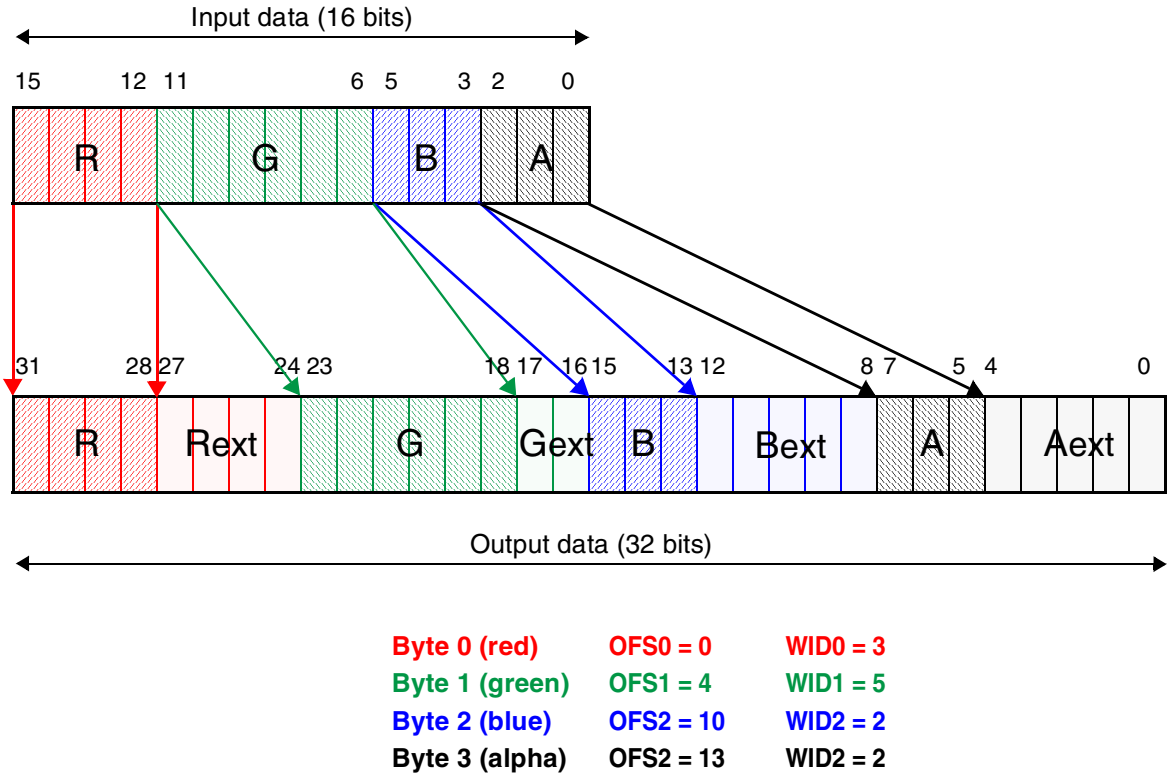


Figure 42-412. Data Unpacking Example

If read data has the coded format, it is decoded via the look-up table. The Look-Up Table Memory (See: 42.3.2.9 LUT- Look Up Table) must be loaded at the IDMAC initialization step. The LUT output format must match the IPUv3EX internal format RGBA 8888 where R is placed in MSB and A is placed in LSB. The A field is used only for graphics data.

42.3.2.4 Buffering units

The buffering units (BUFW, BUFR) are used to store the data consist of different coded color components

- On write transactions (BUFW), before writing to memory & after the format has been coded.
- On read transactions (BUFR), after reading from memory & before the format has been decoded.

Each buffering unit includes 4 X 64 bytes buffers. Each buffer, for each direction, can handle any kind of color component (interleaved - Y / partial interleaved - Y, UV / non interleaved - Y, U, V).

The Write buffers are controlled by the buffer controller for write (BCW) and AXIW units.

The Read buffers are controlled by the buffer controller for read (BCR) and AXIR units.

42.3.2.4.1 Handling real time channels

The memory controller connected to the AXI bus of the IPUv3M can use the AXI ID associated with each burst in order to distinguish between real time and non real time channels. In order to do that the user has to set the channel's ID according to the settings in the memory controller and set the priority of the channel according to its nature. The buffer controller (BCW/BCR) holds all the pending requests that won the arbitration. However, as the memory controller can distinguish between the real time channels and non real time channels within the IPU, there could be a situation where the real time requests are blocked as the IPU's queue is filled with non real time requests. In order to avoid that the user can limit the number of non-real time requests in the queue.

The queue for read requests can handle up to 8 requests. The queue for write requests can handle up to 6 requests. The user can limit the number of non real time requests by setting the USED_BUFS_MAX_W for write requests and USED_BUFS_MAX_R for read requests. The feature that limits the number of requests is enabled by setting the USED_BUFS_EN_R bit for the read requests and USED_BUFS_EN_W for the write requests.

42.3.2.5 AXIW - AXI Write and AXIR - AXI Read

The AXI Master Interfaces are responsible for data transfer from/to the system memory. The Interface supports only 64-bits burst accesses of 1-8 words, with nonalignment of a byte resolution.

2 separate & independent AXI masters are used for "read" (AXIR) & "write" (AXIW), each can be programmed (via CPMEM) with 4 different ID's to support out-of-order accesses within bursts.

42.3.2.6 CC_W & CC_R - Channel Control Write and Read

The Channel Control units is the main control unit of the IDMAC.

- It arbitrates the channels according to the priority.
- Control the address arithmetic unit.
- Function as a memory interface to the CPMEM. It reads the parameters from the CPMEM, prepare the controls accordingly and write back updated parameters to the CPMEM.
- The read unit provides the parameters to the IBIR unit
- The write unit provides the parameters to the AXIW unit

The CC calculates all the parameters related to the access except the address and BS (burst size) which are calculated at the AAU.

The priority is set according to:

- The channel's corresponding bit in the IDMAC_CH_PRI_1 & IDMAC_CH_PRI_2 registers.
- The watermark signal generated from the sub module. The watermark signal is ignored unless the channel's corresponding IDMAC_WM_EN bit is set.
- Special priority for alpha channels

A priority value is calculated for each of the enabled channels according to the above conditions. Then the CC units selects between the channels with the same priority value in a round-robin fashion.

Table 42-412. Calculated priority value

alpha channel	Channel's priority bit	watermark signal	Priority Value
0	0	0	0
0	0	1	1
0	1	0	2
0	1	1	3
1	0	0	1
1	0	1	2
1	1	0	3
1	1	1	4

42.3.2.7 AAU_W & AAU_R- Address Arithmetic Unit for Write and Read

The AAU_R & AAU_W units calculate the address in the system memory to be accessed by the IPUv3EX. These units also calculate the burst size (BS). The address calculation is done according to parameters stored in the CPMEM.

The following main addressing parameters are used:

- XB—Horizontal pixel position in frame
- YB—Vertical pixel position in frame
- SL—Stride line minus 1 (gap in bytes between two pixels in the same column in two consecutive rows).
- SX—Horizontal pixel scrolling offset
- SY—Vertical pixel scrolling offset
- EBA—Frame buffer base address in bytes (there are two such parameters to support double buffering)
- BPP—Bits per pixel
- FW—Frame width minus 1
- FH—Frame height minus 1

Relations between the addressing parameters and image frame are shown in Figure 42-413.

The system memory address in bytes is calculated as:

$$ADDR = EBA + (XB + SX) \cdot BPP + (YB + SY) \cdot (SL + 1)$$

- with 0 < XB =< FW and 0 < YB =< FH.
- For non-interleaved formats the 4 LSB bits of SX are defined according to the IOX parameter.

When double buffering is used, the EBA0 is the base address of the buffer 0 and the EBA1 is the base address of the buffer 1. The IPU_CHA_CUR_BUF Register is a status register. It contains 1-bit pointers to the current working buffers for all IPUv3EX DMA channels. The IPUv3EX automatically toggles a pointer after completion of the current buffer processing. If the MCU is a data source for specific double-buffered channel, it should check this status bit in order to know what is the IPUv3EX current buffer. The MCU is allowed to write to the buffer only when a working DMA channel does not use it. After the MCU has been fill the buffer, it has to set the corresponding bit in the IPU_CHA_BUF0_RDY and IPU_CHA_BUF1_RDY Registers. If needed, the MCU can only clear the pointer by writing 1 but not set it.

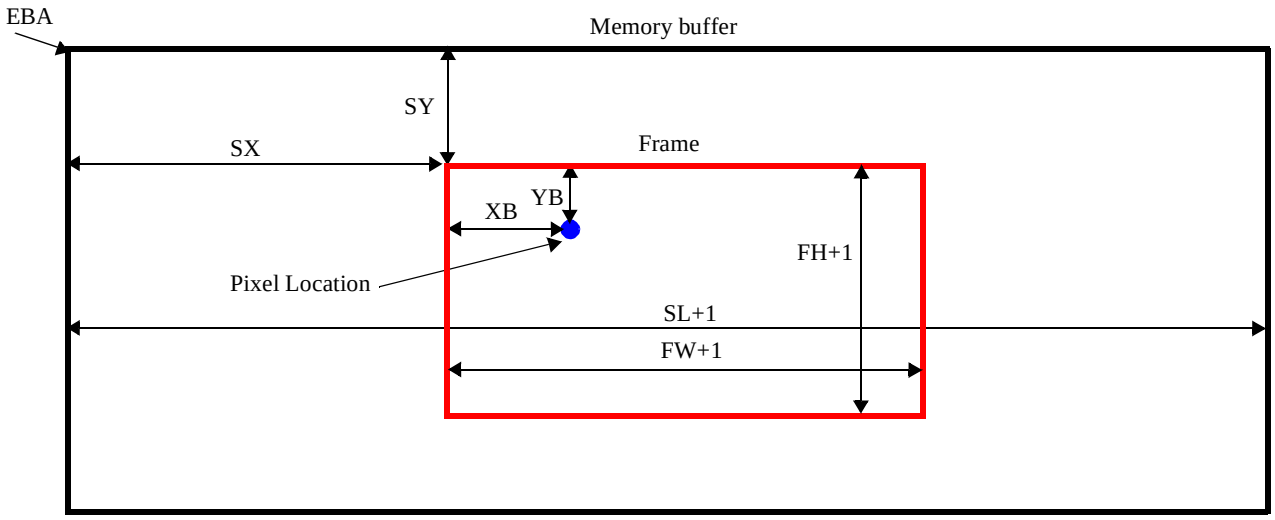

Figure 42-413. Addressing Parameters and Image Frame

The XB and YB coordinates are calculated according to addressing mode. There are two addressing modes:

- 2D mode
- Block mode

In 2D mode the pixel data is transferred to the memory row-by-row. There are two ways to use 2D mode: start from YB = 0 and finish at YB =< FH (YB is incremented) or start from YB = FH and finish at YB =< 0 (YB is decremented). The second option provides vertical flip of the image.

In block mode the frame is divided into blocks. This is needed for rotation or post-filtering, where the order used for data transfers is block-by-block. The order of the block transfer is according to the VF,HF and ROT bits in the IDMAC Channel Parameter Memory. The order within the block is row-by-row where the block size is limited by the block width (BW) and block height (BH) parameters. The BW and BH parameters are set by IC rotation section and cannot be configured through the Channel Parameter Memory.

The Channel Control is responsible for the address calculation flow. It takes channel parameters from the Channel Parameter Memory, updates them and controls the Address Arithmetic Unit.

42.3.2.7.1 Scrolling support

Automatic display of a changing image (animation) or moving image (scrolling) is implemented by reading frames (from a background buffer) with incremental offset. Enabling the scrolling feature is done by setting the channel's corresponding SCE bit. The scrolling step is controlled by channel's corresponding SDX and SDY parameters. The scrolling direction is defined by the channel's corresponding SDRX and SDRY parameters. The maximum number of scrolled frames to be read is defined by the channel's corresponding SM parameter.

When the last programmed frame is reached (IDMAC's internal counter reached SM), IDMAC can perform one of the following (controlled by the SCC bit):

- Return to the first frame, without any SW intervention. The return point is defined by SX0 and SY0 parameters.
- Interrupt the MCU, to generate the next content.

42.3.2.8 ATC - Alpha Transparency Controller

The Alpha transparency controller (ATC) handles the alpha buffers on the external memory for cases where the pixel data and the alpha data are located on separate buffers (separate alpha mode). In that case the IDMAC reads the alpha data and the pixel data, merge them together and provides a pixel that includes the alpha information to the relevant sub module. The ATC's main functions are:

- Generates requests for alpha channels, following a request to pixel data from the module.
- Maintain an internal alpha memory buffer for each channel.
- When there isn't enough alphas in the memory the ATC blocks the corresponding pixel channels.
- When there is a request of pixel channel the ATC load and accumulate its alphas in a register.
- ATC memory controller can manage 8 channels of alphas.
- ATC supports synchronous new frame before end of frame errors.

In order to configure the channel to use separate alpha the channel's corresponding IDMAC_SEP_AL bit should be set in addition to the ALU bit in the CPMEM of the corresponding channel.

Figure 42-414 is the ATC's block diagram.

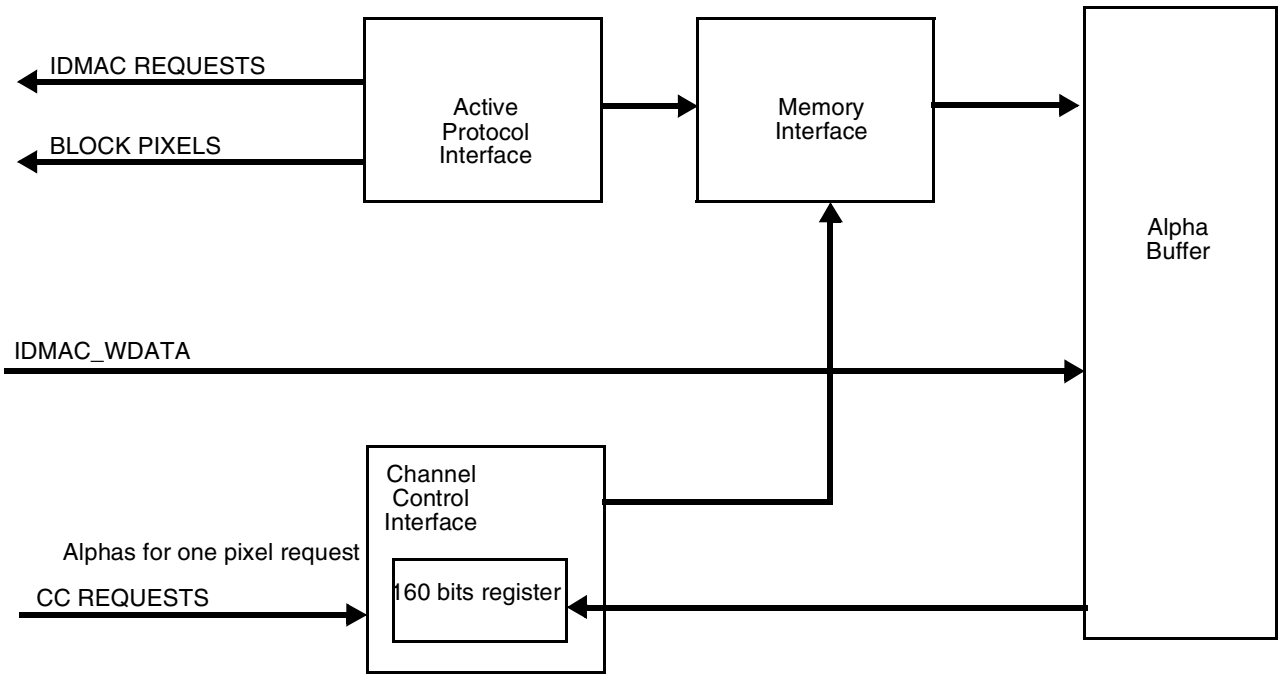

Figure 42-414. ATC block diagram

The ATC alpha buffer memory can hold up to 8 buffers of alphas. A pointer to a buffer in the ATC memory is defined according to the ALBM parameter in the CPMEM. Table 42-413 describes the relations between a data channel, an alpha channel and the pointer in the alpha buffer mmeory.

Table 42-413. Alpha channels mapping

data channel number	associated alpha channel number	Alpha buffer memory (ALBM)
14	17	0
15	18	1
27	31	2
29	33	3
23	51	4
24	52	5

42.3.2.8.1 Conditional read

The alpha data can be used to reduce reads from the memory of pixels that are going to be transparent (alpha = 0). The conditional read feature is enabled by the CRE bit in the CPMEM. If all the corresponding alpha values for a single burst of pixels are all equal to zero, the IDMAC will block the access to the external memory and provide a data of all zeros to the corresponding channel. This way some of the accesses to the memory can be prevented thus reducing the load on the memory.

42.3.2.9 LUT- Look Up Table

When working in coded pixel format, the data read from the memory is the decoded value of pixel according to address given. In case of 8 bit code, the data read from the memory is the decoded value of the pixel according to the address given.

In case of 4 bit code configuration, The address of the 4 bit decoded values is set according to DEC_SEL parameter in the CPMEM

00 = addresses 0 to 15

01 = addresses 64 to 79

10 = addresses 128 to 143

11 = addresses 192 to 207

Table 42-414. Look-Up Table Memory Structure

Address	Word	DEC_SEL	Description
0	Word0	4 BPP = 00 8 BPP = don't care	Decoded Pixels [15:0] for both 8 and 4 bit coded configuration
...	...		
15	Word15		
16	Word16	don't care	Decoded Pixels [63:16] for 8 bit coded configuration only
...	...		
63	Word63

255	Word255		

42.3.2.10 CPMEM - Channel Parameter Memory

The CPMEM holds the configuration parameters for each IDMAC channel. The CPMEM can holds the settings of 80 channels. Each channel's settings are defined by a two mega-words. Each mega-word is 160 bits wide. The following diagram illustrates the CPMEM's structure.

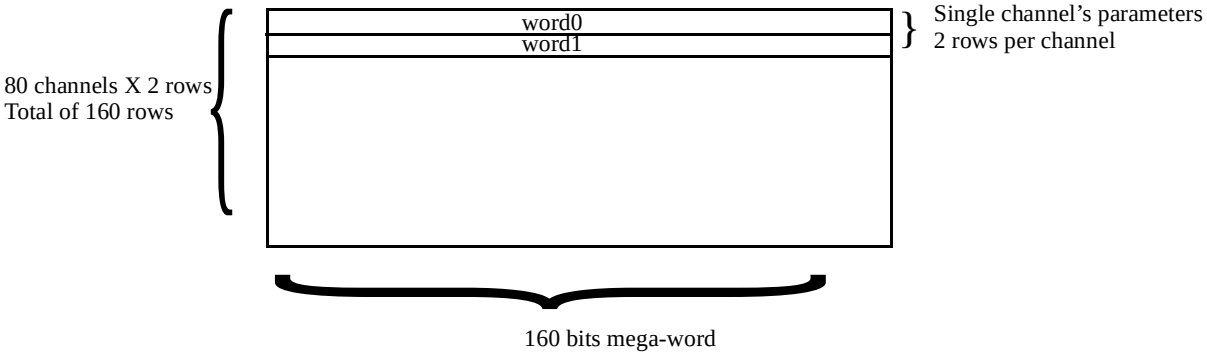

Figure 42-415. CPMEM structure

Each IDMAC channel can be configured to work in one of two different modes:

- Non Interleaved mode where the Y:U:V data is organized in 3 separate buffers in the system's memory
- Interleaved mode where the Y:U:V data is organized in a single buffer in the system's memory

The parameters and the way they are organized are different for each mode (interleaved or non-interleaved).

The following tables describe the IDMAC parameters and their organization in each mode.

42.3.2.10.1 CPMEM's words' structure for non interleaved mode

The table below describes the CPMEM's words' structure for non interleaved mode. Each CPMEM word consist of 160 bits. The bits that are not listed in the table below are reserved bits

.

Name	Mnemonic	Size	Location	Description
Word 0				
XV Virtual Coordinate	XV	10 bits	W0[9:0]	Variable coordinates for determining next block address. {X1,Y1} and {X2,Y2} coordinates will be determined according to {XV,YV} upon restart of channel. These coordinates are used for Y:U:V (Y pointer) and RGB formats.
YV Virtual Coordinate	YV	9 bits	W0[18:10]	
XB inner Block Coordinate	XB	13 bits	W0[31:19]	Variable coordinates for determining address within the block. These coordinates are used for Y:U:V (Y pointer) and RGB formats. Need 24 bits for 2D transfer support.
YB inner Block Coordinate	YB	12 bits	W0[43:32]	
New Sub Block	NSB_B	1 bit	W0[44]	This bit determines if the next value for {XB,YB} should be taken from {XB,YB} saved in channel parameter memory or from new {x1,y1}/{x2,y2}.
Current Field	CF	1 bit	W0[45]	CF = 0 Current field is even CF = 1 Current field is odd
Mem U Buffer Offset	UBO	22 bits	W0[67:46]	Double buffer destination address offset for Y:U:V (U pointer) formats.The actual physical address value is divided by 8 (i.e. this parameter includes bits [24:3] of the actual address)
Mem V Buffer Offset	VBO	22 bits	W0[89:68]	Double buffer destination address offset for Y:U:V (V pointer) format. The actual physical address value is divided by 8 (i.e. this parameter includes bits [24:3] of the actual address)
Initial Offset X	IOX	4 bits	W0[93:90]	The IOX parameter, is the offset in pixels for a frame that starts at a non aligned address. for 42x formats must be even.
Reduce Double Read or Writes	RDRW	1 bits	W0[94:94]	This bit is relevant for YUV4:2:0 formats. For read channels: U and V components are not read from odd rows. (read - supported only for the VDI) For write channels: U and V components are not written to odd rows. (write - supported for all write channels)
Scan Order	SO	1 bit	W0[113]	SO = 0 Scan order is progressive SO = 1 Scan order is interlaced

Band Mode	BNDM	3 bits	W0[116:114]	BNDM = 000 bands disable. BNDM = 001 bands enable. Band height = 4 lines. BNDM = 010 bands enable. Band height = 8 lines. BNDM = 011 bands enable. Band height = 16 lines. BNDM = 100 bands enable. Band height = 32 lines. BNDM = 101 bands enable. Band height = 64 lines. BNDM = 110 bands enable. Band height = 128 lines. BNDM = 111 bands enable. Band height = 256 When working in band mode, the channel's corresponding IDMAC_BNDM_EN bit has to be set.
Block Mode	BM	2 bits	W0[118:117]	BM = 00 block mode disable. BW = FW, BH = FH BM = 01 block mode enable. BW = 8, BH = 8 BM = 10 block mode enable. BW = 16, BH = 16 (this mode is reserved for future use) BM = 11 not used
Rotation	ROT	1 bit	W0[119]	ROT = 0 -> No rotation ROT = 1 -> 90 degree rotation clockwise
Horizontal Flip	HF	1 bit	W0[120]	HF = 0 -> No flip HF = 1 -> Horizontal flip enable
Vertical Flip	VF	1 bit	W0[121]	VF = 0 -> No flip VF = 1 -> Vertical flip enable
Threshold Enable	THE	1 bit	W0[122]	THE = 0 -> Threshold disable THE = 1 -> Threshold enable
Conditional Access Polarity	CAP	1 bit	W0[123]	CAP = 0 -> If conditional bit in CM register is low skip the access CAP = 1 -> If conditional bit in CM register is high skip the access. This mode is reserved for future use.
Conditional Access Enable	CAE	1 bit	W0[124]	CAE = 0 -> Conditional access disable CAE = 1 -> Conditional access enable This mode is reserved for future use.
Frame Width	FW	13 bits	W0[137:125]	Number of pixels in one row, of the channel frame. FW 000000000000 = 0001 pixels 000000000001 = 0002 pixels ..... 111111111111 = 8192 pixels

Frame Height	FH	12 bits	W0[149:138]	Number of pixels in one column, of the channel frame. FH 000000000000 = 0001 line 000000000001 = 0002 lines ..... 111111111111 = 4096 lines For progressive YUV 4:2:0 (non interleaved and partial interleaved formats) the FH value should be a multiple of 2. For interlaced YUV 4:2:0 (non interleaved and partial interleaved formats) the FH value should be a multiple of 4.
Word 1				
Ext Mem Buffer 0 Address	EBA0	29 bits	W1[28:0]	1st double buffer destination address for RGB and Y:U:V (Y pointer) formats. This parameter must not be changed if the corresponding channel is enabled. The actual physical address value is divided by 8 (i.e. this parameter includes bits [31:3] of the actual address)
Ext Mem Buffer 1 Address	EBA1	29 bits	W1[57:29]	2nd double buffer destination address for RGB and Y:U:V (Y pointer) formats. This parameter must not be changed if the corresponding channel is enabled. The actual physical address value is divided by 8 (i.e. this parameter includes bits [31:3] of the actual address)
Interlace Offset	ILO	20 bits	W1[77:58]	2nd double buffer destination address for RGB and Y:U:V (Y pointer) formats. An interlaced data stored in the memory can be read as a consecutive progressive only if FW*BPP is a multiplication of 8. The actual physical address value is divided by 8 (i.e. this parameter includes bits [22:3] of the actual address). For YUV420 formats, the ILO is relevant only to the Y component as the U and V components do not exist for the even lines. This value is signed

Number of Pixels in Whole Burst Access	NPB	7 bits	W1[84:78]	Number of pixels per burst access. The following are valid numbers of pixels in a memory burst access according to the BPP parameter: NPB 0000000 = 01 pixels in each burst 0000001 = 02 pixels in each burst ..... 1111111 = 128 pixels in each burst Range: 32BPP => 1 -> 16 pixels 24BPP => 1 -> 20 pixels 16BPP => 1 -> 32 pixels 12BPP => 1 -> 40 pixels 08BPP => 1 -> 64 pixels 04BPP => 1 -> 128 pixels
Pixel Format Select	PFS	4 bits	W1[88:85]	4'h0 = non-interleaved 4:4:4 4'h1 = non-interleaved 4:2:2 4'h2 = non-interleaved 4:2:0 4'h3 = partial interleaved 4:2:2 4'h4 = partial interleaved 4:2:0 4'h5 to 4'hF = NA
Alpha Used	ALU	1 bit	W1[89]	1 = the alpha associated with the data of this channel resides on another channel (separate buffer) 0 = the alpha associated with the data of this channel resides along with the pixel data (same buffer) The corresponding alpha channel must be enabled to assure correct behavior.
Alpha Channel Mapping	ALBM	2 bits	W1[92:90]	Alpha channel mapping – This parameter is a pointer to a buffer in the ATC memory. This parameter is relevant only to data channels that are associated with a separate alpha buffer (like graphic plane channels). The parameter should be programmed on the data channels' ALBM. Setting this parameter to any other channel has no meaning. See Table 42-413 for exact ALBM mapping.
AXI Id	ID	2 bits	W1[94:93]	AXI protocol id
Threshold	TH	7 bits	W1[101:95]	0000000 = 32 lines 0000001 = 64 lines ..... 1111111 = 4096 lines

Stride Line	SLY	14 bits	W1[115:102]	Address vertical scaling factor in bytes for memory access. Also number of maximum bytes in the “Y” component row according to memory limitations. SLY 00000000000000 = 00001 bytes 00000000000001 = 00002 bytes ..... 11111111111111 = 16384 bytes
Width3	WID3	3 bits	W1[127:125]	Fourth color component size of the input-unpacking/ output-packing pixel. WID3 000 = 1 bits 001 = 2 bits ..... 111 = 8 bits As this is a non-interleaved format, this field is relevant only to the alpha associated with this pixel channel.
Stride Line	SLUV	14 bits	W1[141:128]	Address vertical scaling factor in bytes for memory access. Also number of maximum bytes in the “U” or “V” component row according to memory limitations. SLUV 00000000000000 = 00001 bytes 00000000000001 = 00002 bytes ..... 11111111111111 = 16384 bytes
Conditional Read Enable	CRE	1 bit	W1[149:149]	This bit enables the conditional read feature.

Table 42-415. Channel Parameters Memory for non-interleaved

42.3.2.10.2 CPMEM’s words’ structure for interleaved mode

The table below describes the CPMEM’s words’ structure for interleaved mode. Each CPMEM word consist of 160 bits. The bits that are not listed in the table below are reserved bits

Name	Mnemonic	Size	Location	Description
Word 0				
XV Virtual Coordinate	XV	10 bits	W0[9:0]	Variable coordinates for determining next block address. {X1,Y1} and {X2,Y2} coordinates will be determined according to {XV,YV} upon restart of channel. These coordinates are used for Y:U:V (Y pointer) and RGB formats.
YV Virtual Coordinate	YV	9 bits	W0[18:10]	
YB inner Block Coordinate	XB	13 bits	W0[31:19]	Variable coordinates for determining address within the block. These coordinates are used for Y:U:V (Y pointer) and RGB formats. Need 24 bits for 2D transfer support.
XB inner Block Coordinate	YB	12 bits	W0[43:32]	

New Sub Block	NSB_B	1 bit	W0[44]	This bit determines if the next value for {XB,YB} should be taken from {XB,YB} saved in channel parameter memory or from new {x1,y1}/{x2,y2}.
Current Field	CF	1 bit	W0[45]	CF = 0 Current field is even CF = 1 Current field is odd
Scroll X counter	SX	12 bits	W0[57:46]	Holds the temporary count for the Scroll X in between frame For interleaved YUV4:2:2 formats the SX should be a multiple of 2.
Scroll Y counter	SY	11 bits	W0[68:58]	Holds the temporary count for the Scroll Y in between frame
Number of Scroll	NS	10 bits	W0[78:69]	This variable holds the total number of Scrolls
Scroll Delta X	SDX	7 bits	W0[85:79]	Frame start row offset, compared to last frame. SDX 0000000 = 00 pixels 0000001 = 01 pixels 0000010 = 02 pixels ..... 1111110 = 30 pixels 1111111 = 127 pixels For interleaved YUV4:2:2 formats the SDX should be a multiple of 2.
Scroll Max	SM	10 bits	W0[95:86]	Frame maximum row and column increment offset in frame. SM 0000000000 = 0001 0000000001 = 0002 ..... 1111111111 = 1024
Scrolling Configuration	SCC	1 bit	W0[96]	Determines if scrolling will continue from zero when NS counter has reached SM or stop at the current value for SX and SY for the next frames to come. SCC 0 => Scrolling will stop at NS = SM 1 => Scrolling will start from “0” at NS = SM
Scrolling Enable	SCE	1 bit	W0[97]	SCE = 0 Scrolling disable SCE = 1 Scrolling enable
Scroll Delta Y	SDY	7 bits	W0[104:98]	Frame start column offset, compared to last frame. SDY 0000000 = 00 pixels 0000001 = 01 pixels 0000010 = 02 pixels ..... 1111110 = 30 pixels 1111111 = 127 pixels

Scroll Horizontal Direction	SDRX	1 bit	W0[105]	Determines if the next frame will move right or left compared to the current frame. SDRX 0 => Next frame will be right of current 1 => Next frame will be left of current
Scroll Vertical Direction	SDRY	1 bit	W0[106]	Determines if the next frame will move down or up compared to the current frame. SDRY 0 => Next frame will be down of current 1 => Next frame will be up of current
Bits Per Pixel	BPP	3 bits	W0[109:107]	3'h0 = 32 Bits per pixel 3'h1 = 24 Bits per pixel 3'h2 = 18 Bits per pixel 3'h3 = 16 Bits per pixel 3'h4 = 12 Bits per pixel 3'h5 = 08 Bits per pixel 3'h6 = 04 Bits per pixel
Decode Address Select	DEC_SEL	2 bits	W0[111:110]	Upon 4BPP, selects between two look-up tables DEC_SEL 00 = addresses 0 to 15 01 = addresses 64 to 79 10 = addresses 128 to 143 11 = addresses 192 to 207
Access Dimension	DIM	1 bit	W0[112]	DIM = 0 Access Dimension is 2d DIM = 1 Access Dimension is 1d
Scan Order	SO	1 bit	W0[113]	SO = 0 Scan order is progressive SO = 1 Scan order is interlaced
Band Mode	BNDM	3 bits	W0[116:114]	BNDM = 000 bands disable. BNDM = 001 bands enable. Band height = 4 lines. BNDM = 010 bands enable. Band height = 8 lines. BNDM = 011 bands enable. Band height = 16 lines. BNDM = 100 bands enable. Band height = 32 lines. BNDM = 101 bands enable. Band height = 64 lines. BNDM = 110 bands enable. Band height = 128 lines. BNDM = 111 bands enable. Band height = 256 When working in band mode, the channel's corresponding IDMAC_BNDM_EN bit has to be set.

Block Mode	BM	2 bits	W0[118:117]	BM = 00 block mode disable. BW = FW, BH = FH BM = 01 block mode enable. BW = 8, BH = 8 BM = 10 block mode enable. BW = 16, BH = 16 (this mode is reserved for future use) BM = 11 not used
Rotation	ROT	1 bit	W0[119]	ROT = 0 -> No rotation ROT = 1 -> 90 degree rotation clockwise
Horizontal Flip	HF	1 bit	W0[120]	HF = 0 -> No flip HF = 1 -> Horizontal flip enable
Vertical Flip	VF	1 bit	W0[121]	VF = 0 -> No flip VF = 1 -> Vertical flip enable
Threshold Enable	THE	1 bit	W0[122]	THE = 0 -> Threshold disable THE = 1 -> Threshold flip enable
Conditional Access Polarity	CAP	1 bit	W0[123]	CAP = 0 -> If conditional bit in CM register is low skip the access CAP = 1 -> If conditional bit in CM register is high skip the access
Conditional Access Enable	CAE	1 bit	W0[124]	CAE = 0 -> Conditional access disable CAE = 1 -> Conditional access enable
Frame Width	FW	13 bits	W0[137:125]	Number of pixels in one row, of the channel frame. FW 000000000000 = 0001 pixels 000000000001 = 0002 pixels ..... 111111111111 = 8192 pixels For interleaved YUV4:2:2 formats the FW should be a multiple of 2.
Frame Height	FH	12 bits	W0[149:138]	Number of pixels in one column, of the channel frame. FH 000000000000 = 0001 line 000000000001 = 0002 lines ..... 111111111111 = 4096 lines
Word 1				
Ext Mem Buffer 0 Address	EBA0	29 bits	W1[28:0]	1st double buffer destination address for RGB and Y:U:V (Y pointer) formats. This parameter must not be changed if the corresponding channel is enabled.The actual physical address value is divided by 8 (i.e. this parameter includes bits [31:3] of the actual address)

Ext Mem Buffer 1 Address	EBA1	29 bits	W1[57:29]	2nd double buffer destination address for RGB and Y:U:V (Y pointer) formats. This parameter must not be changed if the corresponding channel is enabled.The actual physical address value is divided by 8 (i.e. this parameter includes bits [31:3] of the actual address)
Interlace Offset	ILO	20 bits	W1[77:58]	2nd double buffer destination address for RGB and Y:U:V (Y pointer) formats. An interlaced data stored in the memory can be read as a consecutive progressive only if FW*BPP is a multiplication of 8.The actual physical address value is divided by 8 (i.e. this parameter includes bits [22:3] of the actual address). This value is signed
Number of Pixels in Whole Burst Access	NPB	7 bits	W1[84:78]	Number of pixels per burst access. The following are valid numbers of pixels in a memory burst access according to the BPP parameter: NPB 0000000 = 01 pixels in each burst 0000001 = 02 pixels in each burst ..... 1111111 = 128 pixels in each burst Range: 32BPP => 1 -> 16 pixels 24BPP => 1 -> 20 pixels 16BPP => 1 -> 32 pixels 12BPP => 1 -> 40 pixels 08BPP => 1 -> 64 pixels 04BPP => 1 -> 128 pixels
Pixel Format Select	PFS	4 bits	W1[88:85]	4'h0 to 4'h4 = NA 4'h5 = Code (LUT) 4'h6 = Generic data 4'h7 = RGB (& also YUV interleaved 4:4:4) 4'h8 = interleaved 4:2:2 Y1U1Y2V1[1] 4'h9 = interleaved 4:2:2 Y2U1Y1V1[2] 4'hA = interleaved 4:2:2 U1Y1V1Y2[3] 4'hB = interleaved 4:2:2 U1Y2V1Y1[4] 4'hC to 4'hF = NA
Alpha Used	ALU	1 bit	W1[89]	1 = the alpha associated with the data of this channel resides on another channel (separate buffer) 0 = the alpha associated with the data of this channel resides along with the pixel data (same buffer) The corresponding alpha channel must be enabled to assure correct behavior.

Alpha Channel Mapping	ALBM	3 bits	W1[92:90]	Alpha channel mapping – This parameter is a pointer to a buffer in the ATC memory. This parameter is relevant only to data channels that are associated with a separate alpha buffer (like graphic plane channels). The parameter should be programmed on the data channels' ALBM. Setting this parameter to any other channel has no meaning. See Table 42-413 for exact ALBM mapping.
AXI Id	ID	2 bits	W1[94:93]	AXI protocol id; IPUv3EX is targeted to an AXI slave that can handle up to 2 requests with 2 different IDs + one request with a third ID. In case that IPUv3EX is going to be used on a system that can handle more than 2 requests with different IDs, the number of different IDs programmed in the CPMEM for different channels is limited for 2. This limitation is relevant for read channels only. For write channels there's no such limitation
Threshold	TH	7 bits	W1[101:95]	0000000 = 32 lines 0000001 = 64 lines ..... 1111111 = 4096 lines
Stride Line	SL	14 bits	W1[115:102]	Address vertical scaling factor in bytes for memory access. Also number of maximum bytes in row according to memory limitations. SL 00000000000000 = 00001 bytes 00000000000001 = 00002 bytes ..... 11111111111111 = 16384 bytes
Width0	WID0	3 bits	W1[118:116]	First color component size of the input-unpacking/ output-packing pixel. WID0 000 = 1 bits 001 = 2 bits ..... 111 = 8 bits This field is relevant only for interleaved RGB format (PFS = 4'h7)
Width1	WID1	3 bits	W1[121:119]	Second color component size of the input-unpacking/ output-packing pixel. WID1 000 = 1 bits 001 = 2 bits ..... 111 = 8 bits This field is relevant only for interleaved RGB format (PFS = 4'h7)

Width2	WID2	3 bits	W1[124:122]	Third color component size of the input-unpacking/ output-packing pixel. WID2 000 = 1 bits 001 = 2 bits ..... 111 = 8 bits This field is relevant only for interleaved RGB format (PFS = 4'h7)
Width3	WID3	3 bits	W1[127:125]	Fourth color component size of the input-unpacking/ output-packing pixel. WID3 000 = 1 bits 001 = 2 bits ..... 111 = 8 bits This field is relevant only for interleaved RGB format (PFS = 4'h7)
Offset0	OFS0	5 bits	W1[132:128]	Number of bits between MSB of pixel and MSB of color component, on input. 1 states that the color component will be the first color component aligned to MSB of output pixel. OFS0 00000 = No offset 00001 = u => 1 bit sleft, p => 1 bit sright ..... 11111 = u => 31 bit sleft, p => 31 bit sright * u = unpacking * p = packing * sleft = shift left * sright = shift right This field is relevant only for interleaved RGB format (PFS = 4'h7)
Offset1	OFS1	5 bits	W1[137:133]	Number of bits between MSB of pixel and MSB of color component on input. 2 states that the color component will be the second color component aligned to MSB output pixel. OFS1 00000 = No offset 00001 = u => 1 bit sleft, p => 1 bit sright ..... 11111 = u => 31 bit sleft, p => 31 bit sright * u = unpacking * p = packing * sleft = shift left * sright = shift right This field is relevant only for interleaved RGB format (PFS = 4'h7)

Offset2	OFS2	5 bits	W1[142:138]	Number of bits between MSB of pixel and MSB of color component on input. 3 states that the color component will be the third color component aligned to MSB output pixel. OFS2 00000 = No offset 00001 = u => 1 bit sleft, p => 1 bit sright ..... 11111 = u => 31 bit sleft, p => 31 bit sright * u = unpacking * p = packing * sleft = shift left * sright = shift right This field is relevant only for interleaved RGB format (PFS = 4'h7)
Offset3	OFS3	5 bits	W1[147:143]	Number of bits between MSB of pixel and MSB of color component on input. 4 states that the color component will be the fourth color component aligned to MSB output pixel. OFS3 00000 = No offset 00001 = u => 1 bit sleft, p => 1 bit sright ..... 11111 = u => 31 bit sleft, p => 31 bit sright * u = unpacking * p = packing * sleft = shift left * sright = shift right This field is relevant only for interleaved RGB format (PFS = 4'h7)
Select SX SY Set	SXYS	1 bit	W1[148:148]	This bit selects between the settings on: SC_CORD and SC_CORD1
Conditional Read Enable	CRE	1 bit	W1[149:149]	This bit enables the conditional read feature.
Decode Address Select bit[2]	DEC_SEL2	1 bit	W1[150:150]	This field is reserved

[1] Y1U1Y2V1 means byte0 = bits [7:0] =Y1; byte1 = bits [15:8] =U1; byte2 = bits [23:16] =Y2; byte3 = bits [31:24] = V1

[2] Y2U1Y1V1 means byte0 =Y2; byte1 =U1; byte2 =Y1; byte3 = V1

[3] U1Y1V1Y2 means byte0 =U1; byte1 =Y1; byte2 =V1; byte3 = Y2

[4] U1Y2V1Y1 means byte0 =U1; byte1 =Y2; byte2 =V1;byte3 = Y1

Table 42-416. Channel Parameters Memory for interleaved

42.3.2.10.3 Accessing the CPMEM for programming

Each IDMAC's channel's parameters are located on 2 CPMEM entries. Each Entry is 160 bit. The CPMEM is memory mapped and accessible via the AHB bus. The AHB bus is accesses are 32bit wide. A CPMEM entry is composed of 5x32bit words. The next CPMEM entry starts at the next 8x32bit words (0x0, 0x20,0x40, etc.).

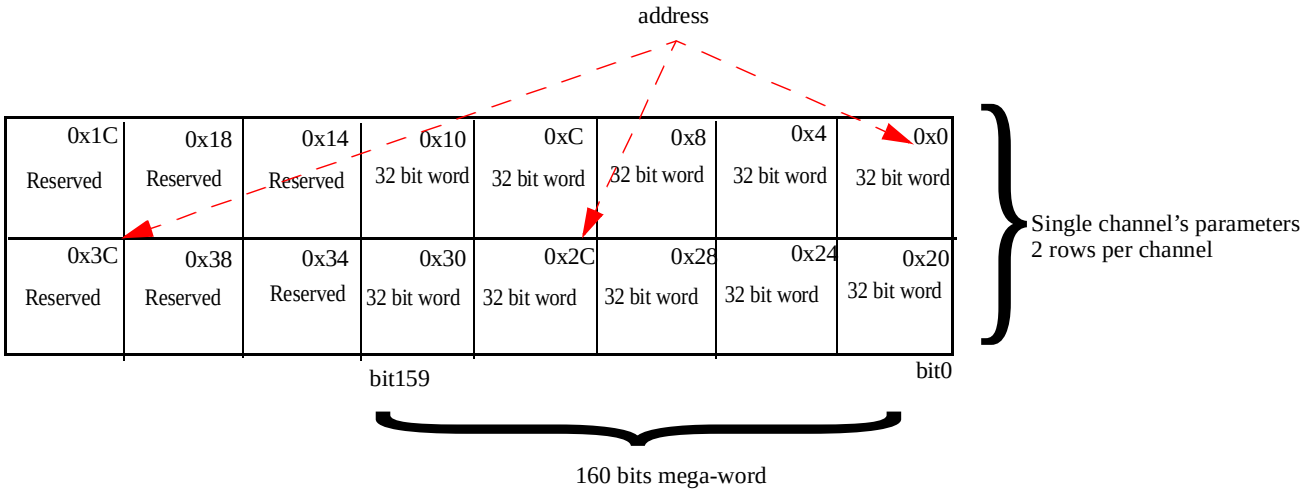

Figure 42-416. CPMEM's word structure

42.3.2.10.4 Alternate IDMAC settings

Some of the IDMAC channels support alternate flow. This means that a physical IDMAC channel can use alternate set of parameters. Switching between the flows is controlled by the CM. For the primary flow the IDMAC's settings are read from the channel's corresponding entry in the CPMEM. The alternate settings can be stored in anther entry on the CPMEM. The pointer to the alternate entry on the CPMEM is stored on the physical channel's corresponding IDMAC_SUB_ADDR parameters.

42.3.2.11 IDMAC's modes of operation

42.3.2.11.1 Rotation modes

Rotation is performed by the IDMAC and the Rotation unit inside the IC. The frame is partitioned into 8X8 pixels blocks. The IC reorders the pixels within a block. The IDMAC reorders the block. The reordering is done according to the ROT, VF & HF parameters in the CPMEM. The IC uses blocks of 8X8 pixels. As a result the AXI burst size is short. Knowing that it is more efficient to use longer bursts, the IDMAC provide the lock feature. This feature manipulates the arbitration mechanism such that a sequence of short bursts will be performed. The sequence is stopped once 8 accesses had been performed. Enabling the lock feature is done by setting the channel's corresponding IDMAC_LOCK_EN bit.

The following diagram illustrate various options for reordering of blocks.

- ROTATE means that the ROT bit is set

- HORIZONTAL means that the HF bit is set
- VERTICAL means that the VF bit is set

.

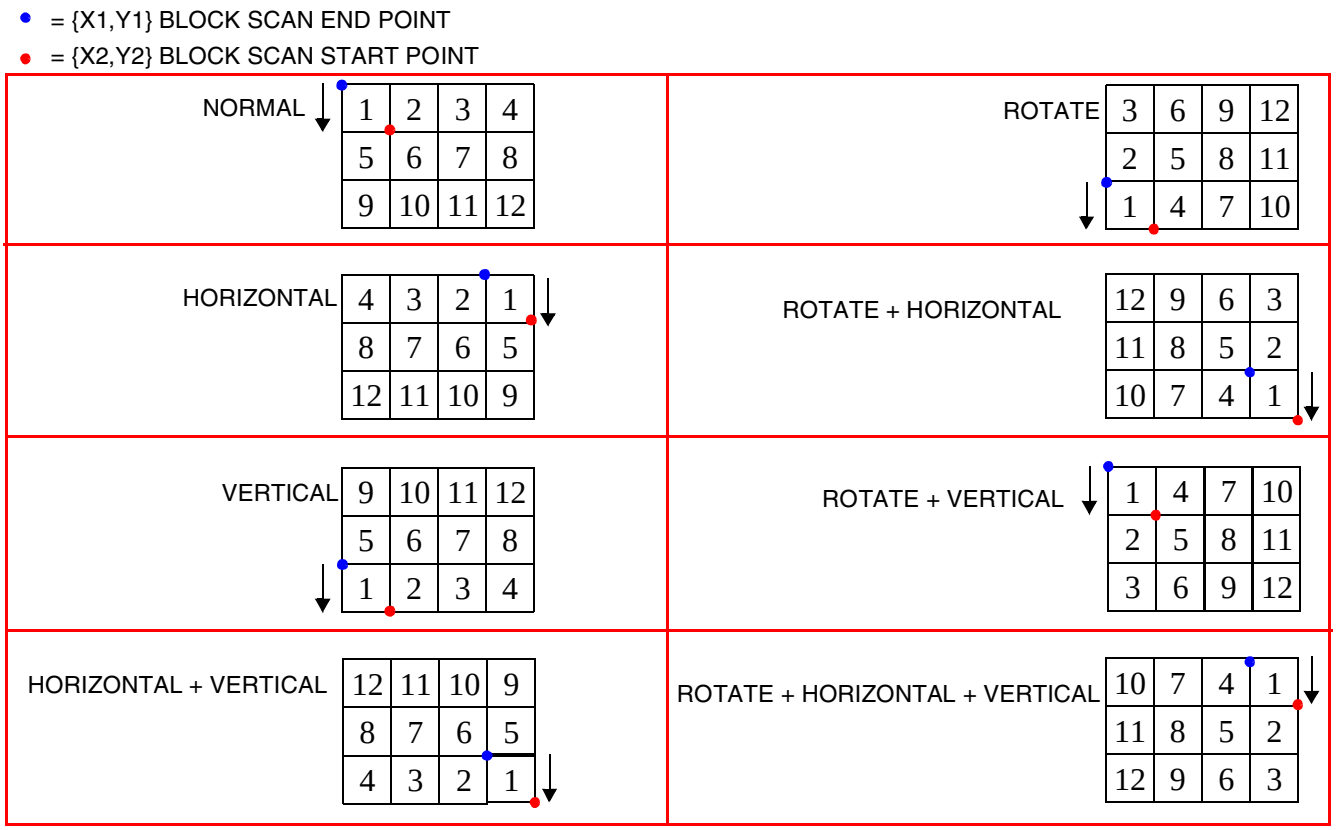

Figure 42-417. Rotation options

42.3.2.11.2 Frame size

The IPUv3EX supports various non-interleaved modes; the Frame Height (FH) and Frame Width (FW).

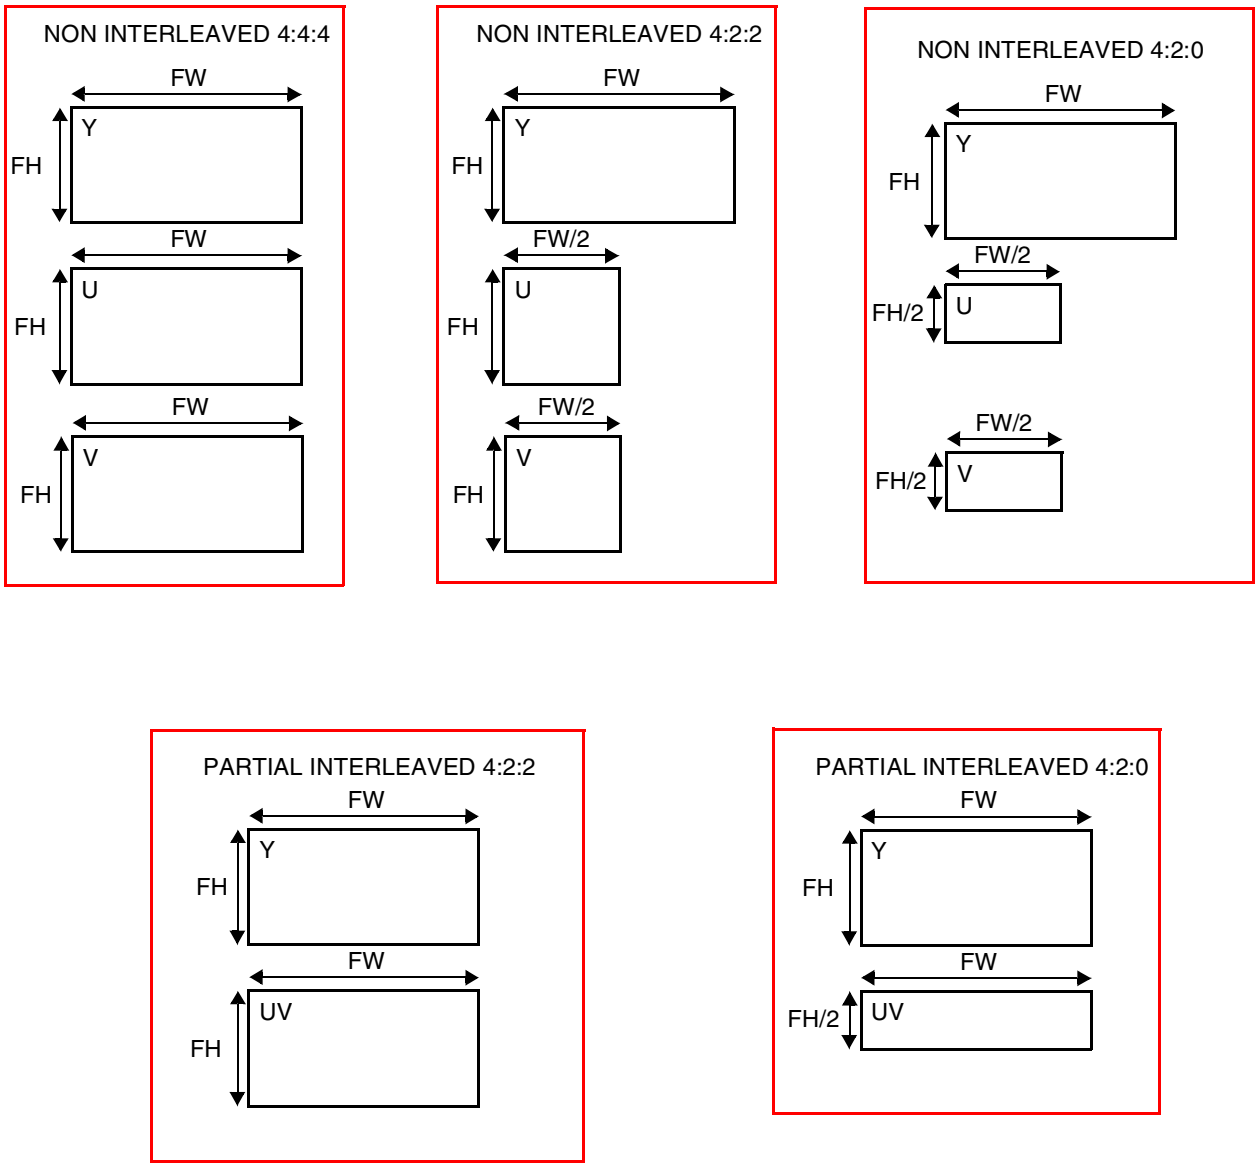

Figure 42-418. Frame size in various modes

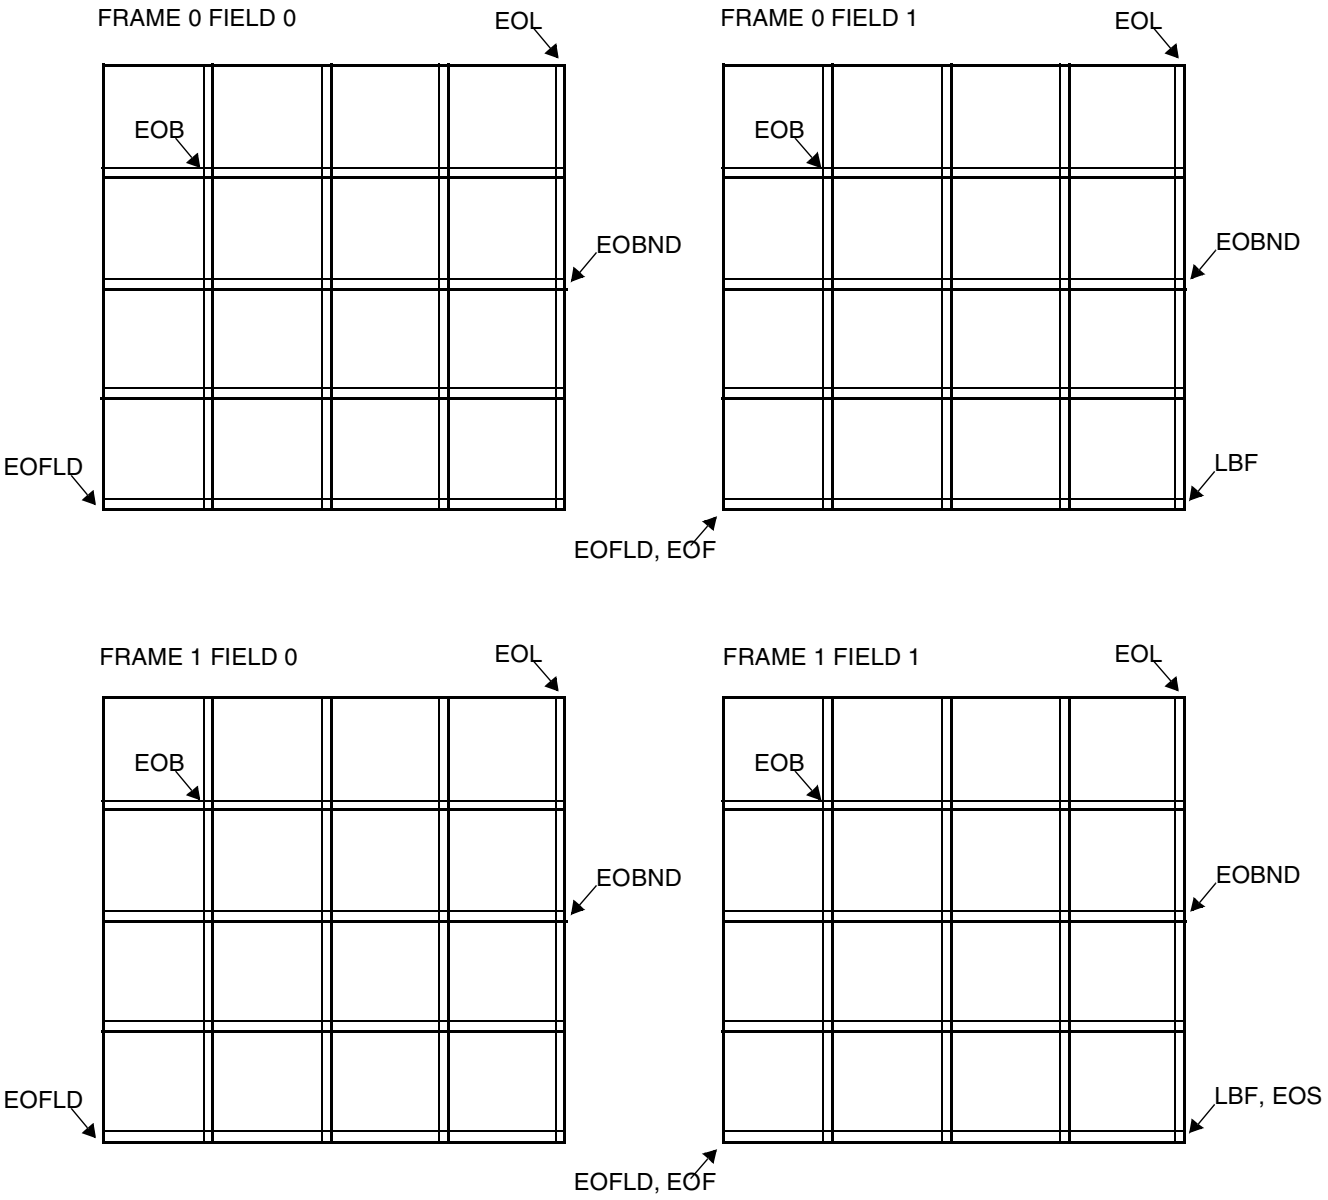

Figure 42-419. Frame's controls

42.3.2.12 IDMAC's restriction

The data must be received from the system's memory through the AXIR interface ("read" direction) "in-order" within a single burst. The entire burst can occur "out-of-order."

42.3.2.13 IDMAC's Endianness support

Byte Endianness - only LE (little endian) is supported

Pixel Endianness - both LE & BE are supported, only for read direction (only 4 BPP case is meaningful, supported only for the “read“ direction)

42.3.2.14 IDMAC’s internal events

Some of the IDMAC’s internal signals can be used for monitor the progress of flows. These bits can be polled by software. Some of these bits can be used to trigger an interrupt or an SDMA event. Table 42-417 describes the available events and their meaning

Table 42-417. IDMAC’s internal events

IDMAC event’s type	Monitored on	Event’s meaning
end of frame	IDMAC_EOF	This is the channel’s end of frame indication. This indication is asserted once the entire frame was read/written via the IDMAC. This indication is normally used as an interrupt or SDMA event
new frame acknowledge	IDMAC_NFACK	This indication means that the IDMAC acknowledge the new frame’s request from the module. It can be used to track the starting point of a flow or a frame.
new frame before end of fram error	IDMAC_NFB4EOF_ERR	This error indication may indicate on data lost. This indication is asserted when a new frame starts before the completion of the previous frame. For example if a real time input (from camera) was not written properly to the memory due to FIFO full condition.
end of scroll	IDMAC_EOS	end of scroll; This indication is asserted when the scroll counter finished counting its pre defined value
end of band	IDMAC_EOBND	This is the end of band indication. Any time IDMAC complete reading/writing a band it will assert this indication. This is useful to manually control a flow via channels working in band mode.
treshold	IDMAC_TH	Threshold crossing indication. The treshold is defined according to the TH parameter in the IDMAC.
channel busy	IDMAC_CH_BUSY	This signal is asserted when a channel is between NFACK event to EOF event. Negation of these indications is one of the conditions for low power modes handshake.

42.3.3 Camera Sensor Interface (CSI)

IPUv3EX has 2 identical camera sensor interfaces (CSI). The CSI description below refers to a single CSI.

42.3.3.1 CSI Block Diagram

The CSI Block Diagram is shown in Figure 42-420.

Figure 42-420. CSI Block Diagram

The CSI consists of synchronizer, interface logic, Data packing unit and Sensor Interface Control. The CSI is controlled via the peripheral bus registers. All programming parameters for the CSI are double buffered with synchronous change at the frame start.

The CSI gets data from the sensor, synchronizes the data and the control signals to the IPUv3EX clock (HSP_CLK), and transfer it according to configuration of DATA_DEST register to one or more of the following: IC, SMFC.

42.3.3.2 CSI Interface

CSI supports two types of interfaces. The interface is determined via the DATA_SOURCE register.

42.3.3.2.1 Parallel interface

In parallel interface a single value arrives in each clock, except when working in BT.1120 mode, in which two values arrive in each cycle. Each value can be 8-16 bit wide according to configuration of DATA_WIDTH. If DATA_WIDTH is configured to N, then 20-N LSB bits are ignored.

CSI can work with several data formats according to SENS_DATA_FORMAT configuration. In case the data format is YUV, the output of the CSI is always YUV444 (even if the data arrives in YUV422 format).

The polarity of the inputs can be configured using the registers SENS_PIX_CLK_POL, DATA_POL, HSYNC_POL and VSYNC_POL.

42.3.3.3 TEST MODE

When TEST_GEN_MODE register is configured to 1, the TEST MODE which is a debugging mode, is operated. The CSI generates the frame by itself and sends it to one of the destination units. The sent frame is a chess board composed of black and configured color squares. The configured color is set with the registers PG_B_VALUE, PG_G_VALUE and PG_R_VALUE. The data can be sent in different frequencies according to the configuration of DIV_RATIO register.

42.3.3.4 Sensor Image Frame Relations

Figure 42-421 illustrates the generalized relations between image frames produced by a sensor and accepted by the CSI. Generally, four frame definitions exist. The virtual frame A starts with the VSYNC signal. After vertical blanking starts frame B. The HSYNC signal indicates boundaries of the frame B. The frame B includes both the active sensor frame C and horizontal blanking intervals. A size of the blanking intervals depends on sensor type and programming. The size of the frame sent by the sensor (the actual pixels) has to be configured in the registers SENS_FRM_WIDTH and SENS_FRM_HEIGHT. The CSI selects a window (the frame D) inside the frame C by skipping rows and columns according to parameters

defined in registers HSC, VSC, ACT_FRM_HEIGHT and ACT_FRM_WIDTH. frame D is sent to the rest of the IPUv3EX.

Note: the following limitation must exist:

SENS_FRM_HEIGHT >= VSC + ACT_FRM_HEIGHT

SENS_FRM_WIDTH >= HSC + ACT_FRM_WIDTH

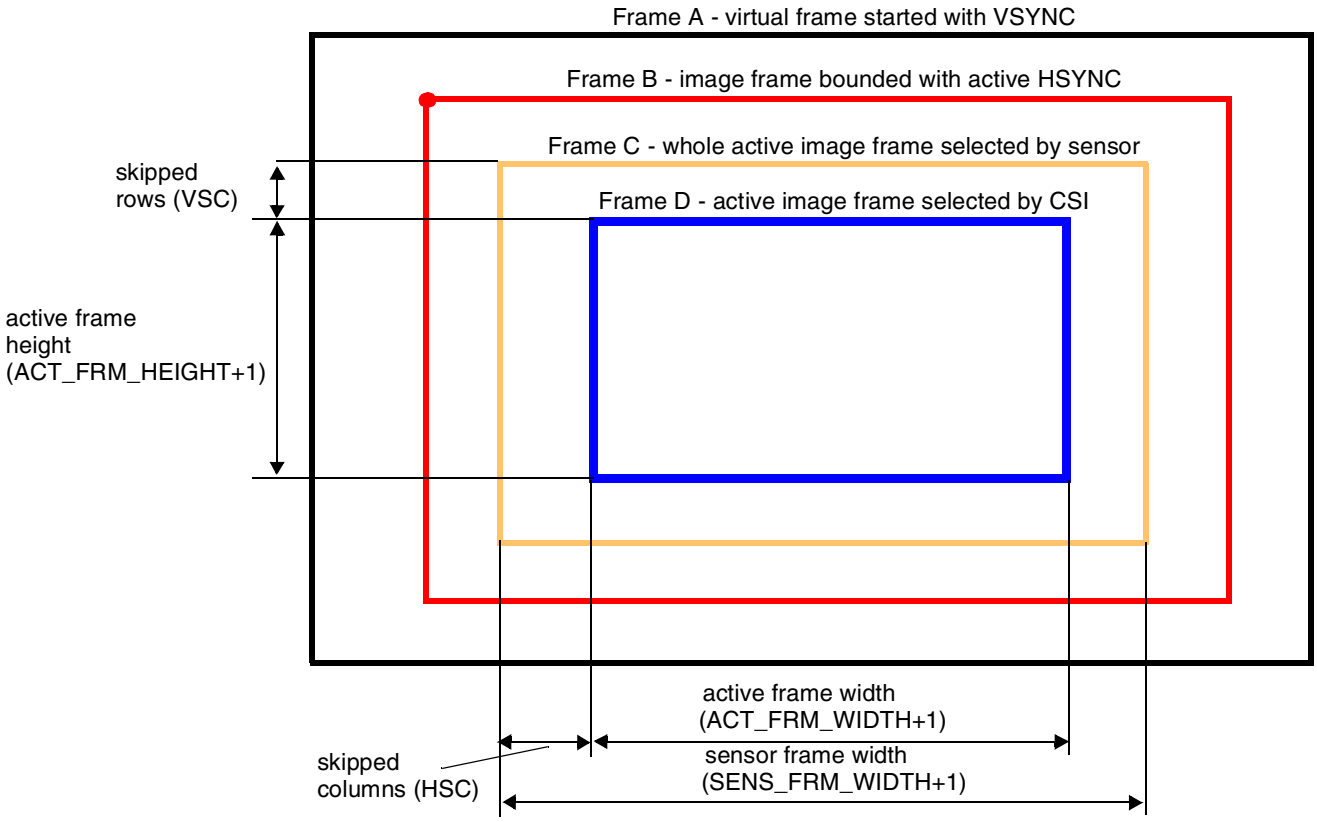

Figure 42-421. Sensor Image Frames

42.3.3.5 Companding

Companding is performed as follows:

input: 10-bit unsigned number.In case that component's size is bigger than 10 bit, 10 MSB bits are taken. In case that component's size is less than 10 bit, color extraction is performed.

First step: shift:

$$x \rightarrow clip(x + offset, 0, 1023) \qquad \textit{Eqn. 42-2}$$

where the offset is a 10 bit signed number that is configured in CPD_OFFSET1 and CPD_OFFSET2 registers.

second step - piecewise-linear map:

$$y = Min[255, (y1[k]+(((x-x1[k])*slope[k])>>6 + 1))>>1] \quad \textit{Eqn. 42-3}$$

where:

- the input range 0..1023 is partitioned to 16 equal segments: x1[k] .. x1[k+1] - 1 where x1[k] = 0, 64, 128, 192, 256, .. . 960.

- The linear map, in each segment, is characterized by y1[k] (9-bit unsigned number) and slope[k] (8-bit unsigned number).

Each destination unit can get the data after being companded depending on the configuration of CPD register. If this register is configured to 3'h0, the compander units are disable in order to save power. Parameters of the companding are equal for all destinations and can be set in the CPD registers.

2 companding units are located in the CSI. This is because when working in BT.1120 modes 2 components arrive in each cycle and the companding for each 2 components has to be in parallel. When CSI works in other mode, only one compander is needed, so the other one is disabled to save power.

42.3.3.6 Timing/Data mode protocols

CSI can work in several timing/data mode protocols according to SENS_PRTCL configuration:

42.3.3.6.1 gated mode

In this mode VSYNC is used to indicate beginning of a frame, HSYNC is used to indicate beginning of a raw. Sensor clock is ticking all the time.

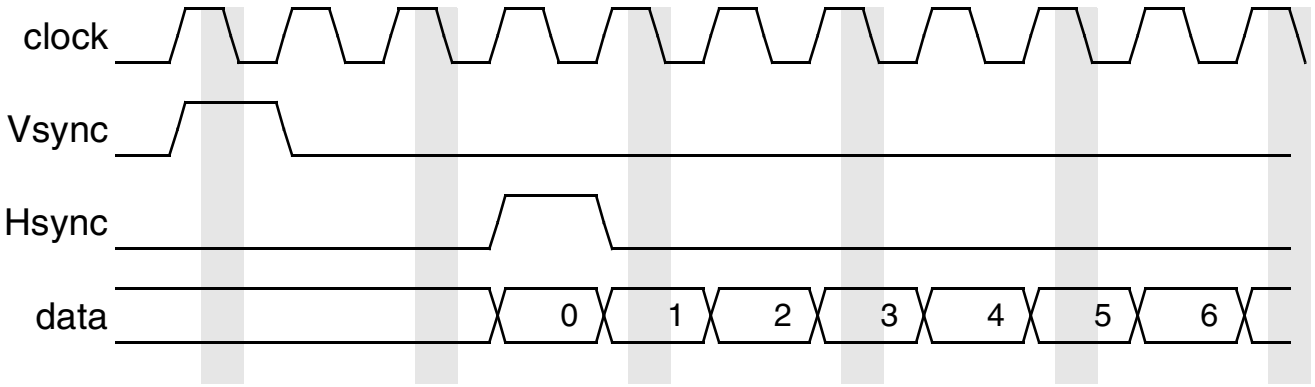

Figure 42-422. gated mode

42.3.3.6.2 non-gated mode

In this mode VSYNC is used to indicate beginning of a frame. Sensor clock is ticking only when data is valid. HSYNC is not used.

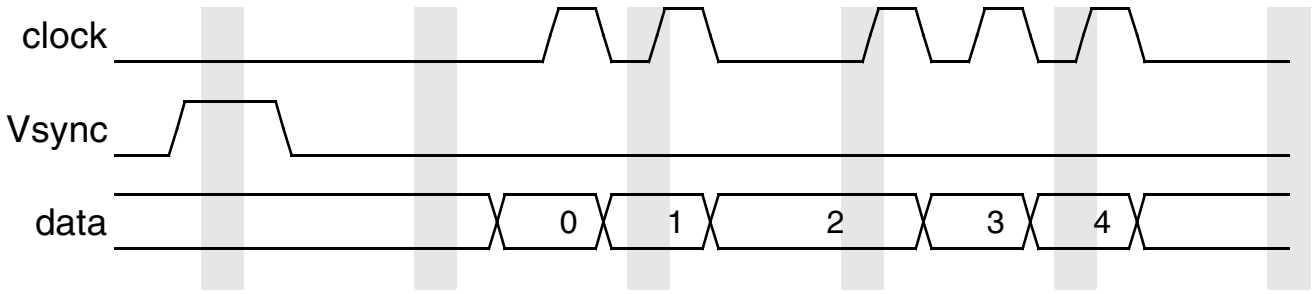

Figure 42-423. non-gated mode

42.3.3.6.3 BT.656 mode

In this mode the CSI works in compliance with recommendation ITU-R BT.656. The timing reference signals (frame start, frame end, line start, line end) are embedded in the data bus input. Each timing reference signal consists of a four word sequence. The first three words are fixed and configured in the CCIR_PRECOM register. The fourth word contains information defining field, the state of field blanking and the state of line blanking. these states are configured in registers CCIR_CODE_1 (for field 0) and CCIR_CODE_2 (for field 1).

In this mode in each cycle one value of data arrives

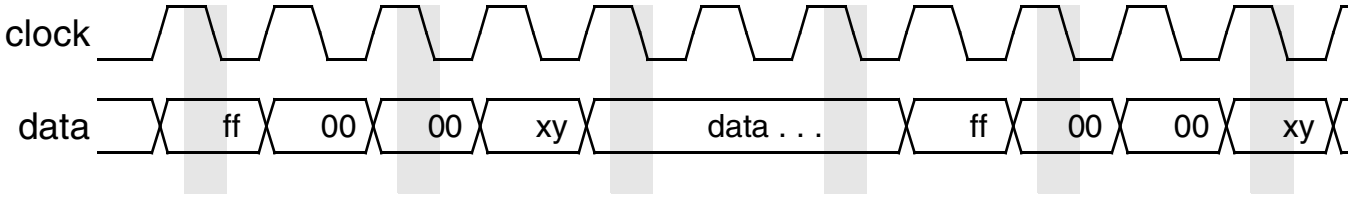

Figure 42-424. BT.656 mode

In this diagram the first three words are 0xff, 0x00, 0x00. The fourth word is XY and it includes the timing reference.

42.3.3.6.4 BT.1120 mode

In this mode the CSI works in compliance with recommendation ITU-R BT.1120. The timing reference signals (frame start, frame end, line start, line end) are embedded in the data bus input. Each timing reference signal consists of a four word sequence. The first three words are fixed and configured in the CCIR_PRECOM register. The fourth word contains information defining field, the state of field blanking and the state of line blanking. these states are configured in registers CCIR_CODE_1 (for field 0) and CCIR_CODE_2 (for field 1).

In this mode, the CSI can also work in DDR mode - data arrives on every edge of the clock. In addition, in each cycle two value of data arrive.

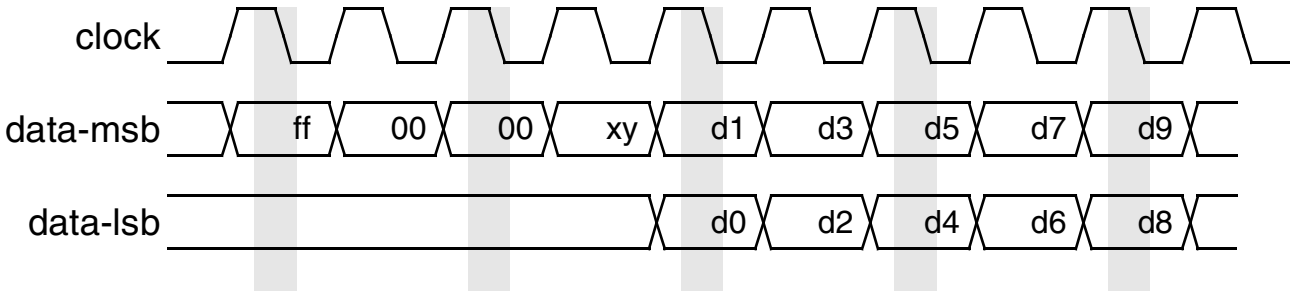

Figure 42-425. BT.1120 mode - SDR mode

In the above diagram each data arrives with the posedge of the clock.

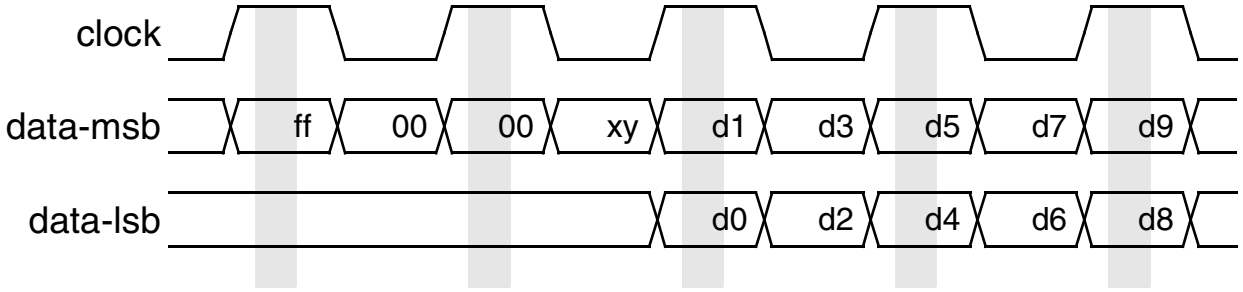

Figure 42-426. BT.1120 mode - DDR mode

In the above diagram data arrives in the posedge and the negedge of the clock.

42.3.3.7 packing to memory

the data bus output to the SMFC is 128-bit. The following table shows the how the CSI performs the packing before sending the data to the SMFC.

Table 42-418. Packing Unit

data format	component size	companded	regular packing	tight packing
Bayer, Generic data, JPEG	8	{8DC[1],8DC,8DC,...,8DC}	{8D,8D,8D,...,8D[2]}	NA
	9-16	{8DC,8DC,8DC,...,8DC}	{16DE[3],16DE,...,16DE}	NA
RGB, YUV	8	{8DC,8DC,8DC,8R}	{8D,8D,8D,8R}	NA
	9-10	{8DC,8DC,8DC,8R}	{16DE,16DE,16DE,16R[4]}	{10DE,10DE,10DE,2R}
	11-16	{8DC,8DC,8DC,8R}	{16DE,16DE,16DE,16R}	{10DT[5],10DT,10DT,2R}

[1] DC - data after being companded

[2] D - data arrived from sensor.

[3] DE - data after being extended.

[4] R- reserved bits

[5] DT - data after being truncated.

The tight packing functionality is enabled when PACK_TIGHT register is set. It is only used when data format is RGB or YUV and the data width is bigger than 8.

42.3.3.8 Skipping frames

Some of the frames that are sent to the SMFC can be skipped. skipped frames are ignore by the CSI and are not sent to the corresponding unit. . Using SKIP_SMFC and MAX_RATIO_SKIP_SMFC registers the user can define the frames for the SMFC that will be skipped.

42.3.3.9 CSI Restrictions

The frequency of the sensor clock must not be greater than the IPUv3EX clock (HSP_CLK)

SENS_FRM_HEIGHT >= VSC + ACT_FRM_HEIGHT

SENS_FRM_WIDTH >= HSC + ACT_FRM_WIDTH

42.3.4 Sensor Multi FIFO Controller (SMFC)

The Sensor Multifile Controller used as buffer between CSI and IDMAC. Two masters (CSIs) can be connected to SMFC. Both masters can be active simultaneously. Each master can send up to 4 frames, distinguished by csi_id bus. The frame can be mapped to one of four IDMAC channels via SMFC mapping registers. Each DMA channel have dedicated FIFO.

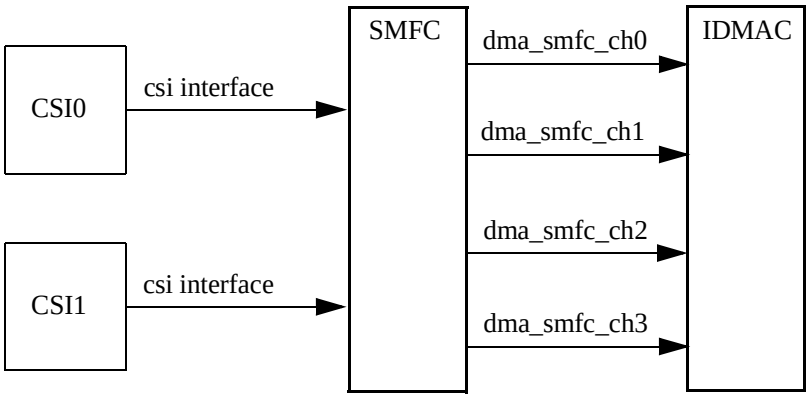

Figure 42-427. SMFC data flow

42.3.4.1 SMFC's Features

- Support two CSI masters and four DMA channels
- Automatic FIFO size calculation

42.3.4.2 SMFC's Functional description

SMFC support up two four DMA channels. Each channel have dedicated FIFO controller, as shown in Figure 42-428 Sampled data and frame ID are kept in the buffers till the buffer is selected by Round Robin Priority Mechanism. Then content of ID buffer are compared to CH#_MAP bits and corresponding FIFO controller is activated. As result a content of the buffer are copied to the RAM. The wptr and the "base" are used to calculate the location in the RAM. The rptr are following after wptr during dma_active signal, initiated by DMA.

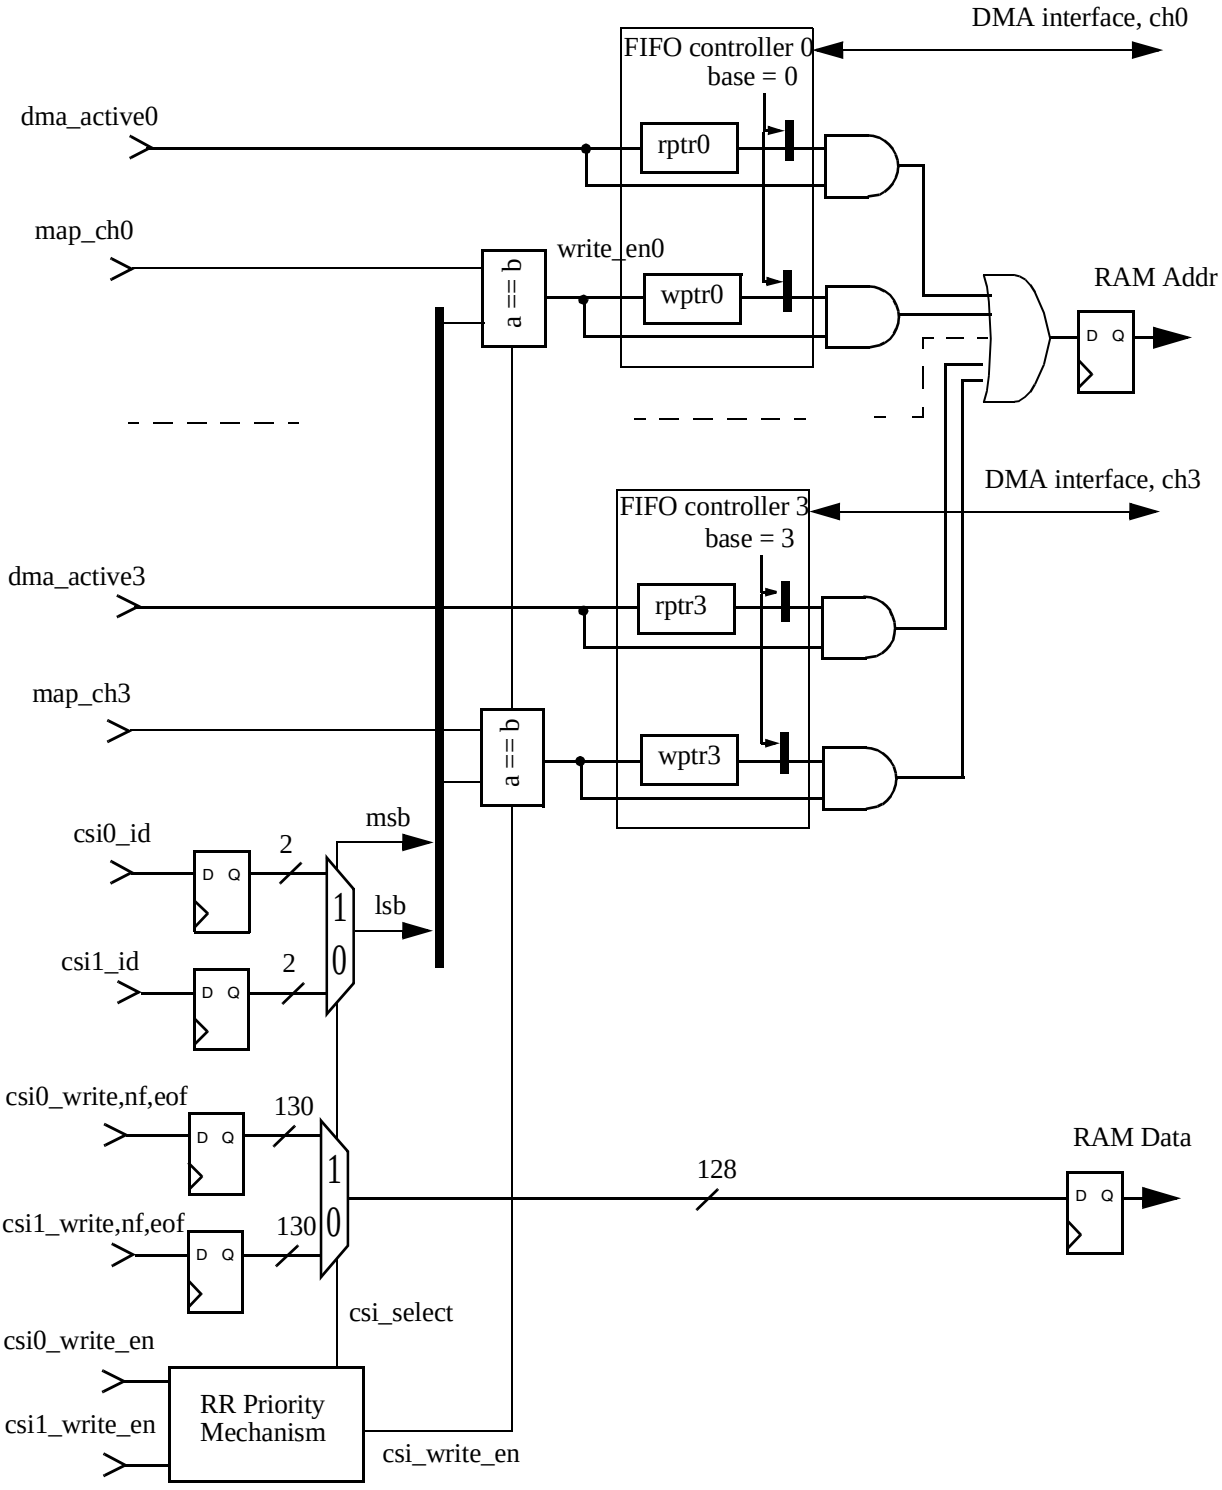

Figure 42-428. Sensor Multi FIFO Controller

Four FIFOs are implemented with single RAM due to the fact that the channels can't be active simultaneously. The memory space of SMFC divided to four equal sectors. Each FIFO have fixed base address - "base". The "base" used as MSB for corresponding pointer in order to calculate absolute address of the RAM. FIFO size of channels 1 and 3 are fixed and is equal to size of one sector. FIFO size of channels 0 and 2 depend from other channels as shown in Table 42-419. Other configuration are not allowed.

Table 42-419.

Number of DMA channels required	enable/disable of channels 3,2,1,0	FIFO size (sectors), per channels 3,2,1,0
1	0 0 0 1	0 0 0 4
2	0 1 0 1	0 2 0 2
3	1 1 0 1	1 1 0 2
4	1 1 1 1	1 1 1 1

NOTE: channels should not be enabled after activation of channel 0 or/and channel 2. This can cause to overlapping of FIFO areas and other malfunctions.

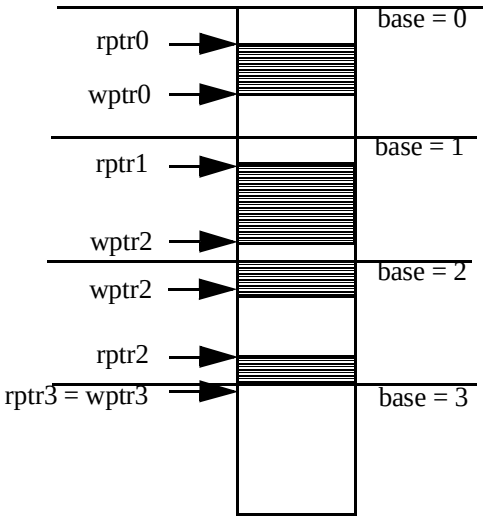

Figure 42-429. SMFC memory map when DMA channels 3,2,1,0 are enabled

42.3.4.2.1 SMFC Master interface.

SMFC Master interface shown in Figure 42-430

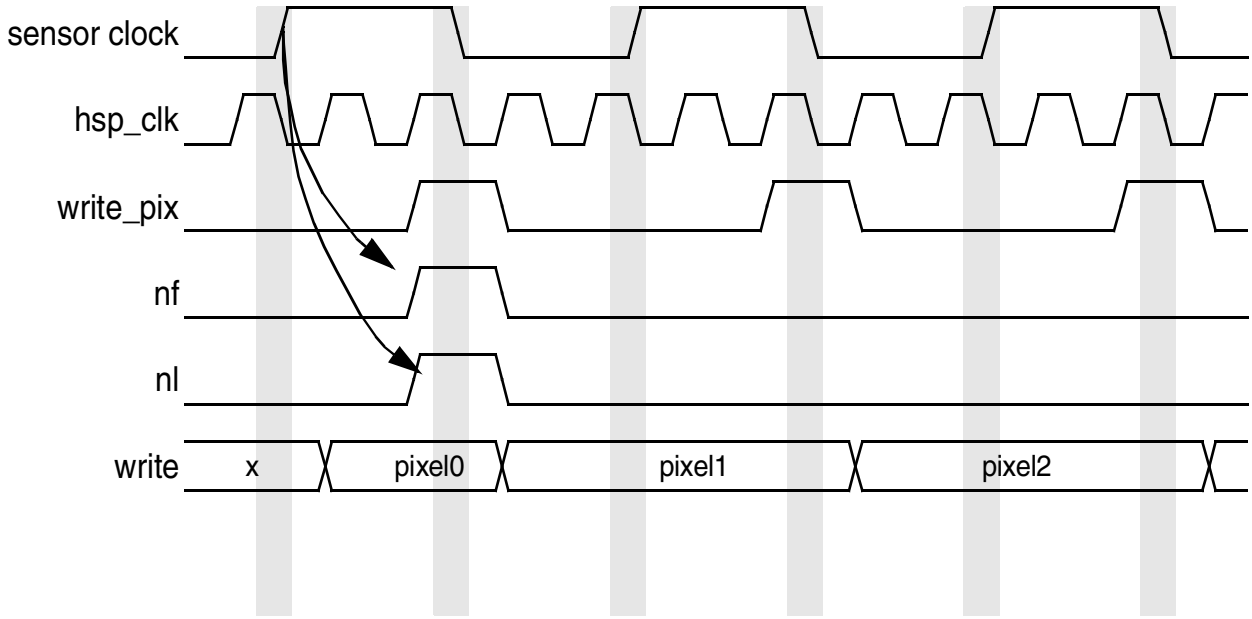

Figure 42-430. Timing diagram of SMFC slave interface

Sensor clock can be asynchronous to IPUv3EX clock (hsp_clk). The CSI synchronize data arrived from the sensor to hsp_clk. The csi_write signal indicate when data on csi_pix bus can be sampled by hsp_clk clock.

42.3.4.2.2 Restrictions

1. DMA channels should not be enabled after activation of channel 0 or/and channel 2. This can cause to overlapping of FIFO area and other malfunctions.
2. Watermark set value should be greater than watermark clear value.
3. One frame should not be mapped to few DMA channel.

42.3.5 Image Converter (IC)

42.3.5.1 IC Block Diagram

The IC Block Diagram is shown in Figure 42-431.

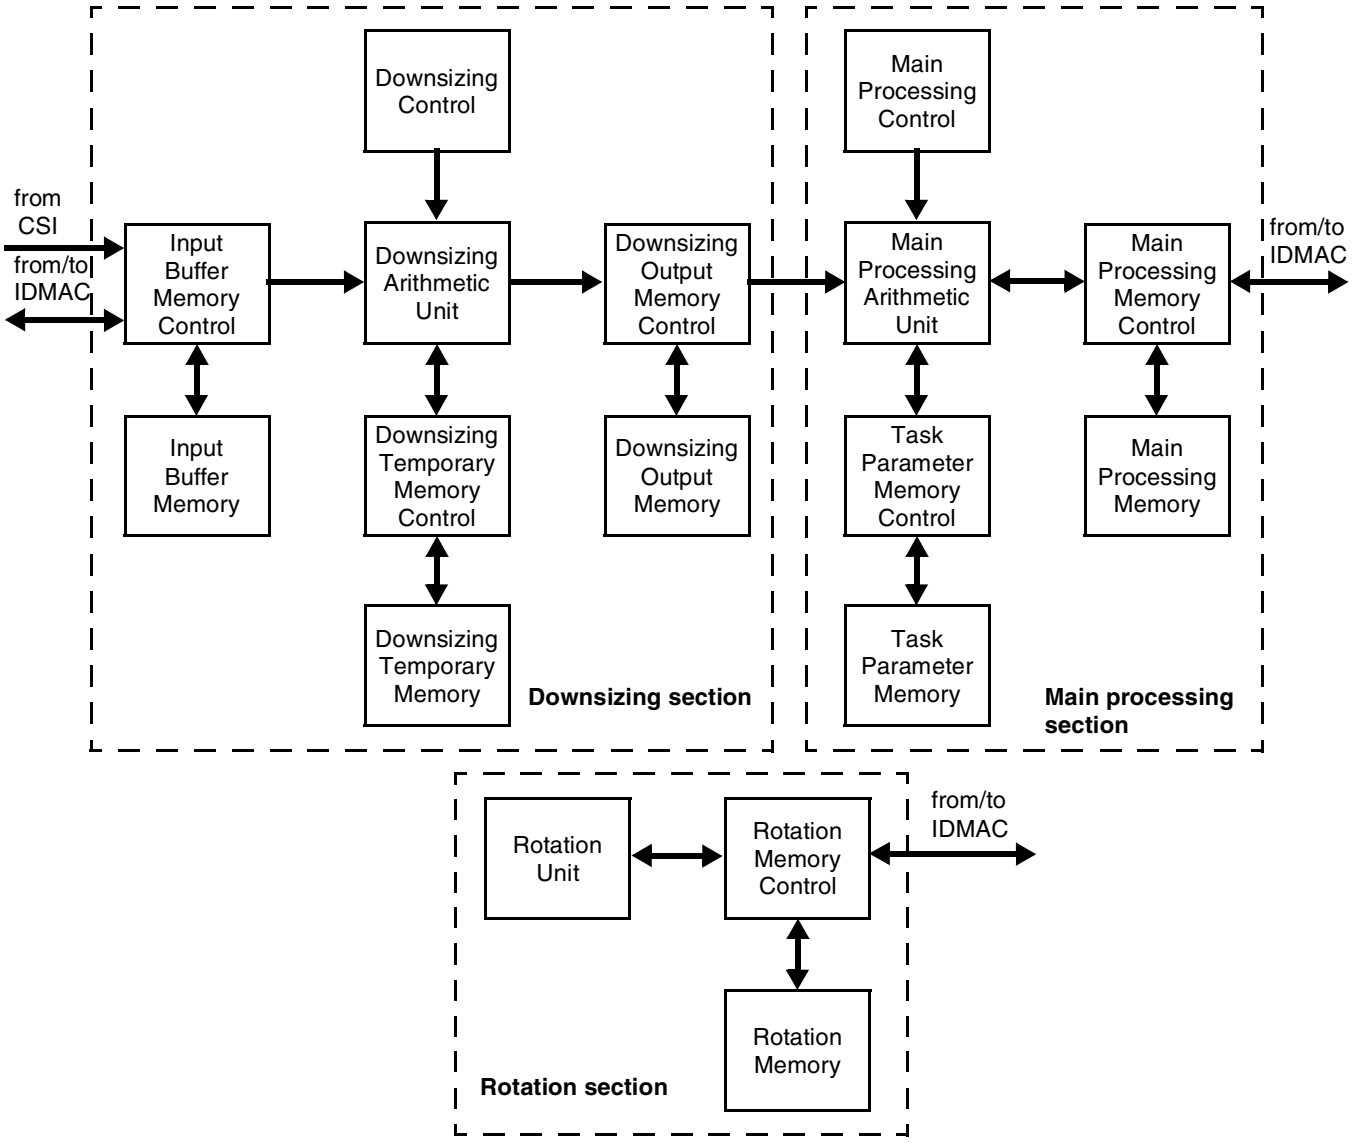

Figure 42-431. IC Block Diagram

The IC contains three processing sections: downsizing, main processing and rotation. The module is controlled via the peripheral bus registers. Some processing parameters should be written by the MCU to the Task Parameter Memory. Writing to the memory is performed via the AHB bus.

42.3.5.2 Processing tasks

Each of three processing section performs up to three processing tasks with time sharing:

1. Preprocessing task for encoding.
2. Preprocessing task for displaying image from sensor (viewfinder).
3. Postprocessing task.

The tasks are performed by single hardware. The MCU configures each task before enabling it. Tasks switching is transparent for the MCU. The time unit for task switching in the downsizing section corresponds to a processing time of one burst of eight pixels, in the main processing section - to a processing time of one image line, in the rotation section - to a processing time of one image frame.

All three tasks includes similar operations controlled by commands. Task configuring consists in definition of commands for each task as described in Table 42-420.

Table 42-420. Task Commands

Command code	Command	Processing unit	Command parameters	Description
EN	Task Enable	DSU, MPU		Task will enabled from next frame. Task 1 is preprocessing for encoding. Task 2 is preprocessing for viewfinder. Task 3 is postprocessing.
	Downsizing	DSU	Downsizing ratio (GCR)	Downsizing ratio 1:1, 2:1, 4:1
	Resizing	MPU	Resizing ratio (GCR)	Resizing ratio from 2:1 to 1:M Resizing ratio = N:M; M =2^13; N = floor(M*(SI-1)/(SO-1)); SI - input size; SO - output size
CSC1	Color space conversion 1	MPU	Color conversion coefficients and offsets (TPM)	Color conversion matrix 1
CSC2	Color space conversion 2	MPU	Color conversion coefficients and offsets (TPM)	Color conversion matrix 2 Used only for Task 2 and Task 3 It is not performed if the first color space conversion or combining are disabled
GLOB_A	Global alpha	MPU		Used only for Task 2 and Task 3
CMB	Combining	MPU		Combining video with graphics. Used only for Task2 and Task3.

The MCU writes the commands to the IC_CONF Register. Because there is no double buffering for all the IC parameters, the MCU must disable a task before changing its parameters. After being disabled, the task is still allowed to complete its current frame execution. At frame finish, the IPUv3EX sends an interrupt to the MCU indicating that the MCU can change task parameters. The MCU enables the task again and task execution is resumed from start of the next frame.

42.3.5.3 Downsizing Section

The sensor data from the CSI is written into a FIFO located in the Input Buffer Memory. Depending on programmed processing flow, the FIFO data can be sent to the system memory via the IDMAC or straight forward to the Downsizing Unit. In the first case, the data is processed by the MCU and returned by the IDMAC to another FIFO located in the Input Buffer Memory.

For postprocessing, the IDMAC transfers a data from the system memory to the third FIFO. The data is read by the Downsizing Unit when the postprocessing is performed.

Each or three FIFOs has 128 pages. Each page can store one burst of 2 or 4 words which corresponds to 8 or 16 pixels. The size of the burst is defined according to the channel's corresponding CB#_BURST_SIZE bit. The memory word width is 128 bits. Each memory word contains color components of four adjacent pixels or 16 bytes of generic data (e.g. Bayer). Access to the FIFOs is controlled by the Input Buffer Memory Control.

The Downsizing Unit performs averaging and decimation of image pixels both in horizontal and vertical directions according to the following equations:

$$HP_{R,c} = \frac{1}{DS\_R\_H} \sum_{k=0}^{DS\_R\_H-1} IP_{r+k,c}$$

$$VP_{R,C} = \frac{1}{DS\_R\_V} \sum_{l=0}^{DS\_R\_V-1} HP_{R,c+l}$$

where $IP_{r,c}$ - the input pixel, $HP_{R,c}$ - the pixel after horizontal downsizing, $VP_{R,C}$ - the pixel after vertical downsizing, DS_R_H and DS_R_V - the horizontal and vertical downsizing ratios according to the IC_PRP_ENC_RSC, IC_PRP_VF_RSC and IC_PP_RSC Registers. The final calculation result is rounded to 8 bits.

Each of three downsizing tasks processes the data by bursts of 8 pixels. Normally, the current task runs until emptying the corresponding input FIFO. After finishing burst processing, the Downsizing Unit may switch between the current task and another task with higher priority, if the Input Buffer Memory has received a burst for this new task.

Averaging is performed firstly in the horizontal direction. All color components of a pixel are processed in parallel. After horizontal averaging has finished for a single output pixel, the new pixel value is added to the corresponding pixel value of a temporary row derived from previous averaging steps. This provides vertical averaging of the pixels. The temporary row is stored in the Downsizing Temporary Memory. The memory word width matches one accumulated pixel width (36 bits). There are three temporary rows stored in this memory - one per downsizing task.

After vertical averaging has been finished, the output row is written to the Downsizing Output Memory. The memory word of 48 bits includes two output pixels. For each task, the memory has a double buffer of one row. When the Downsizing Unit fills the foreground part of the double buffer, the Main Processing

Unit takes pair or pixels from the background part. After the new downsized row has been ready, the foreground and background memory pointers are swapped.

42.3.5.4 Main Processing Section

The Main Processing Unit reads pairs of pixels from the Downsizing Output Memory background part. It processes the complete pixel row for the current task and after that switches to another task if the input data for this new task is ready. For each task, the Main Processing Unit is able to perform the following sequence of operations:

1. Horizontal flipping the image (optional) performed with reading from the Downsizing Output Memory. Flipping is enabled via the VF, HF & ROT parameters of the corresponding DMA channels (See: Table 42-415. Channel Parameters Memory for non-interleaved and See: Table 42-416. Channel Parameters Memory for interleaved) responsible for output of the task results. The preprocessing task for encoding uses the VF, HF & ROT parameters from IDMAC channel #20, the preprocessing task for viewfinder - from the IDMAC channel #21, the postprocessing task - from the IDMAC channel #22.
2. Horizontal resizing by bilinear interpolation between two adjacent pixels received from the Downsizing Output Memory according to the equation:

$$HP_{R,c} = IP_{r,c} + RS\_C\_H \cdot (IP_{r+1,c} - IP_{r,c})$$

where RS_C_H - the current horizontal resizing coefficient. The calculation result is rounded to 8 bits. The resizing coefficient is calculated as

$$RS\_C\_H = \left(\sum_{k=0}^{R-1} RS\_R\_H \right) \bmod (8196)$$

where RS_R_H - the horizontal resizing ratio from the IC_PRP_ENC_RSC, IC_PRP_VF_RSC and IC_PP_RSC Registers. The RS_R_H parameter is equal to a numerator N of the resizing ratio N:M with M =2^13.

The resulting row of the horizontal resizing is stored in the Task Parameter Memory.

3. Vertical resizing by bilinear interpolation between the current and previous results of horizontal resizing. Both current and previous results of horizontal resizing is stored in the Task Parameter Memory. Resizing is accomplished according to the equation:

$$VP_{R,C} = HP_{R,c} + RS\_C\_V \cdot (HP_{R,c+1} - HP_{R,c})$$

where RS_C_V - the current vertical resizing coefficient. The calculation result is rounded to 8 bits. The

resizing coefficient is calculated as

$$RS\_C\_V = \left(\sum_{k=0}^{C-1} RS\_R\_V \right) \bmod (8196)$$

where RS_R_V - the horizontal resizing ratio from the IC_PRP_ENC_RSC, IC_PRP_VF_RSC and IC_PP_RSC Registers. The RS_R_V parameter is equal to a numerator N of the resizing ratio N:M with M =2^13.

At completion of vertical resizing, this row is updated - the current result of horizontal resizing replaces the previous one.

4. First color space conversion YUV to RGB or RGB to YUV with the conversion matrix CSC1. The conversion matrix coefficients are programmable. They are stored in the Task Parameter Memory. The conversion equations are:

$$\begin{aligned} Z_0 &= 2^{SCALE-1} \cdot (X_0 \cdot C_{00} + X_1 \cdot C_{01} + X_2 \cdot C_{02} + A_0) \\ Z_1 &= 2^{SCALE-1} \cdot (X_0 \cdot C_{10} + X_1 \cdot C_{11} + X_2 \cdot C_{12} + A_1) \\ Z_2 &= 2^{SCALE-1} \cdot (X_0 \cdot C_{20} + X_1 \cdot C_{21} + X_2 \cdot C_{22} + A_2) \end{aligned}$$

where for YUV to RGB: X_0=Y, X_1=U, X_2=V, Z_0=R, Z_1=G, Z_2=B,
for RGB to YUV: X_0=R, X_1=G, X_2=B, Z_0=Y, Z_1=U, Z_2=V.

All the parameters of the conversion matrix are written by the MCU to the Task Parameter Memory (See: 42.3.5.6 IC Task Parameter Memory). The final calculation result is limited according to the SAT_MODE parameter and rounded to 8 bits.

5. Combining video with graphics. There are the following combining options:
   - local alpha blending,
   - global alpha blending,
   - use of key color.

   If both alpha blending and color keying are enabled, color keying has higher priority (graphic pixels of the key color are fully transparent independently on the alpha value).
   Combining mode is selected via the IC_CONF Register. The combining equation is:

$$OP = IGP \cdot \alpha + IVP \cdot (1 - \alpha)$$

where IGP - an input graphics pixel, IVP - an input video pixel, α=(A+floor(A/128))/256 - an alpha value, A - a global or local transparency parameter. The global A is written in the IC_CMBP_1 Register, the local A arrives together with the graphics pixel.

A graphics pixel becomes transparent when color keying is enabled and a pixel color matches a key color (independently on an alpha parameter).

The graphics data is read from a FIFO located in the Main Processing Memory. The FIFO contains 32 pages of size of 8 pixels. The size of the burst is defined according to the channel's corresponding CB#_BURST_SIZE bit. The graphics pixel format in the FIFO is RGB or RGBA or YUV 4:4:4 or YUVA. The graphics data is loaded by the IDMAC to the FIFO from the system memory.

6. Second color space conversion YUV to RGB or RGB to YUV with the conversion matrix CSC2. Typically this is color space conversion RGB to YUV. It is not performed if the first color space conversion or combining are disabled. This operation is designed for TV output. The conversion matrix coefficients are programmable with the same parameters and equation as the first color conversion.

All the operation are executed by an unified processing unit sequentially. Steps 1 and 2 cannot be interrupted by another task. All other steps can be interrupted by a task with higher priority if an input row is ready for this task. Preprocessing tasks priority is higher than postprocessing task priority.

The processing unit consists of three identical parts for each color component. All three color components are processed in parallel. Each of the processing operations can be enabled or disabled by an appropriate command according to.

The processing results are written to an output FIFO located in the Main Processing Output Memory row-by-row. The FIFO contains 32 pages, each page can include one burst of 8 or 16 pixels. The size of the burst is defined according to the channel's corresponding CB#_BURST_SIZE bit. The IDMAC transfers the output bursts to the system memory or to the display via DMFC (Channel 21only). The Main Processing Memory contains three buffers for each tasks: the temporary row buffer, the graphics FIFO and the output FIFO. Each memory word (128 bits) stores 4 adjacent pixels in formats RGB or RGBA or YUV 4:4:4.

42.3.5.5 Rotation Section

The rotation section includes the Rotation Memory which stores an input rectangular block of 8x8 pixels and an output FIFO containing four pages of 8 pixels each one. The Rotation Memory word width corresponds to four adjacent pixels - 96 bits. The input block is loaded to the memory by the IDMAC like to a FIFO.

The Rotation Unit rewrites pixels from the input block to the output FIFO with corresponding relocation of a pixel inside the block. Rotation and/or left/right flipping and/or up/down flipping are enabled separately for each of three tasks. Configuring the rotation and flipping options is performed via the VF, HF & ROT parameters of the corresponding DMA channels (See: Table 42-415. Channel Parameters Memory for non-interleaved and See: Table 42-416. Channel Parameters Memory for interleaved) responsible for task data input. The preprocessing task for encoding uses the VF, HF & ROT parameters from the IDMAC channel #45, the preprocessing task for viewfinder - from the IDMAC channel #46, the postprocessing task - from the IDMAC channel #47.

Rotation and flip options are shown in Table 42-421.

Table 42-421. Rotation and Flip Options

ROT	FLR	FUD	Image
0	0	0	
0	0	1	
0	1	0	
0	1	1	
1	0	0	1	0	1	
1	1	0	
1	1	1	

After finishing the rotation task, the IDMAC returns the output FIFO content to the system memory. When writing to the system memory, the IDMAC changes a location of the block relative to an input block location in order to provide proper rotation of the whole frame. Rotation tasks switching is performed after completion of rotation of the whole frame.

42.3.5.6 IC Task Parameter Memory

Table 42-422 presents IC task parameter memory details.

1 The address documented in this table is the relative address within the TPM. This is the address that should be accessed when writing or reading from this memory via the AHB bus.

2 Each word is aligned to 64 bit accessible via the AHB bus in 2 separate 32bit accesses.

3 s - sign position, x - binary digit position

42.3.5.7 IC's DMA channels

The table below mas the IDMAC channels of the IC and the IRT to the corresponding tasks. The IC's channel name is the name of the channel at IC level. The IC channel name is referred on the IC's programming model.

Table 42-423. IC's DMA Channels

IDMAC's channel number	IC's channel name	Read/Write	Source	Destination	Processing Flow Purpose
20	CB0	Write	IC ENC	Memory	Preprocessing data from IC (encoding task) to memory
21	CB1	Write	IC VF	Memory/DMFC	Preprocessing data from IC (viewfinder task) to memory; This channel can be configured to send the data directly to the DMFC. This is done by programming the ic_dmfc_sel bit.
22	CB2	Write	IC PP	Memory	Postprocessing data from IC to memory
14	CB3	Read	Memory	IC VF	Graphics data for combining (viewfinder task)
15	CB4	Read	Memory	IC PP	Graphics data for combining (post-processing task)
11	CB5	Read	Memory	IC PP	Postprocessing data from memory
12	CB6	Read	Memory	IC VF	Preprocessing data from sensor stored in memory (for example Bayer)
5	CB7	Write	IC	Memory	Direct data from IC (sensor data) to memory
48	CB8	Write	ENC ROT	Memory	Preprocessing data after rotation (encoding task)
49	CB9	Write	VF ROT	Memory	Preprocessing data after rotation (viewfinder task)
45	CB10	Read	Memory	ENC ROT	Preprocessing data for rotation (encoding task)
46	CB11	Read	Memory	VF ROT	Preprocessing data for rotation (viewfinder task)
50	CB12	Write	PP ROT	Memory	Postprocessing data after rotation
47	CB13	Read	Memory	PP ROT	Postprocessing data for rotation

42.3.5.8 IC restrictions

- The input's frame width to the IC must be a multiplication of 8 pixels
- When performing resizing the frame width must be multiple of burst size - 8 or 16 pixels as defined by CB#_BURST_16 parameter.

42.3.5.9 IC bridge

The IC module utilize a single memory to serve read and write channels. These memories are the IBM, RM and MPM. The IDMAC has separate mechanism to handle read and write channels. As a result a contention between read and write channels may occur on each one of the memories. In order to resolve the contention an IC bridge module is connected between the channels associated with this memory. The bridge prioritize a read channel over a write channel. In order to avoid starvation of the write channels, the

user can limit the maximum consecutive requests of the same channel that will be served. The limitation is done by programming the memory's corresponding <>_brdg_max_rq field.

42.3.6 Display Port

The display port handles all the IPUv3EX features targeted for controlling and sending data to the display. The display port consists of 4 modules.

DC - a display controller,

DP - a display processor,

DMFC - a display multi-FIFO controller

DI - a display interface. The DI is instantiated twice to provide two symmetrical display interfaces.

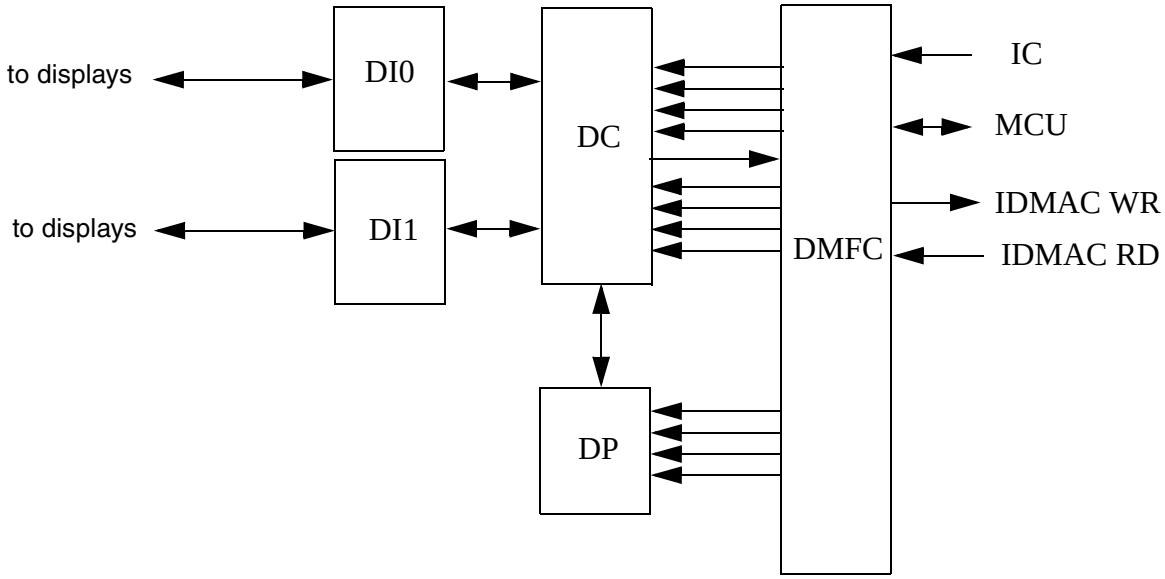

Figure 42-432. The display port

42.3.6.1 Display ports channels

The display port send data to the display over several channels. The data source may be the system's memory (via the IDMAC) the IC module and the MCU. The display port can read data from the display and send it to the MCU or IDMAC.

The data is routed over channels. The table below maps the IDMAC channels to DMFC, DC, DP channels and describes each channel.

Table 42-424. Display port channels

IDMAC's channel number	Display port's destination	DMFC channel number	DC channel number	Corresponding alpha channel	channel usage
21	DC	Programmable using dmfc_ic_in_port	Programmable using dmfc_ic_in_port	NA	This channel is coming from the IC module. When data is coming from the IC, the IC channel replaces one of the IDMAC's channels connected to the DMFC. When the IC_DMFC_SEL bit is set the output of the IC is routed to the DMFC. This channel can be routed to the DC channels 1,2,5B,5F,6B,6F. Routing this channel to the DC channel is done with the dmfc_ic_in_port bits. The DC's channel allocated to the IC channel can't be used for data coming from other source.
23	DP	5B	5	51	This channel is for the DP's primary flow. When a single plane is used, the data should be sent over this channel. When 2 planes are combined in this flow, the second plane should come on channel 27.
24	DP	6B	6	52	This channel is for the DP's secondary flow. When a single plane is used, the data should be sent over this channel. When 2 planes are combined in this flow, the second plane should come on channel 29.
27	DP	5F	5	31	This channel is for the DP's main flow. When a single plane is used, the data should be sent over channel 23 and this channel should not be used. When 2 planes are combined in this flow, one plane should come on channel 23 and the other plane on this channel.
28	DC	1	1	NA	This channel can serve sync and async flows. When channel 28 is connected to DI0, channel 23 must be connected to DI1 even if ch23 is not used. This is done by programming the PROG_DISP_ID_5 field
29	DP	6F	6	33	This channel is for the DP's secondary flow. When a single plane is used, the data should be sent over channel 24 and this channel should not be used. When 2 planes are combined in this flow, one plane should come on channel 24 and the other plane on this channel.
40	DC	0	0	NA	This is a read channel

Table 42-424. Display port channels

IDMAC's channel number	Display port's destination	DMFC channel number	DC channel number	Corresponding alpha channel	channel usage
41	DC	2	2	NA	This channel can serve only async flow
42	DC	1C		NA	Command stream. See 42.3.6.6, "Display port's restrictions
43	DC	2C		NA	Command stream. See 42.3.6.6, "Display port's restrictions
44	DC	3		NA	Mask channel. This mask channel can be associated with channel 23 or channel 28

42.3.6.2 Supported display interfaces

- The display port has 2 DI interfaces. Each interface can handle up to 3 displays.
- The total number of supported displays is 4.
- Each DI can handle up to 2 async interface - only one of them can be serial interface.
- Each DI can handle one synchronous interface. Asynchronous displays that are accessed in synchronous mode are considered synchronous interface.

42.3.6.2.1 Synchronous Interfaces

The DI supports the following synchronous display interfaces.

1. Synchronous generic interfaces to TFT dumb displays or RGB interfaces of smart displays.
2. Synchronous interfaces to Sharp displays.
3. Synchronous interfaces to TV encoders:
   a) PAL
   b) NTSC

   TV interfaces can operate in progressive or interlaced modes.
4. Synchronous interface to a graphic accelerator
5. BT.656
6. BT.1120

BT.1120 and BT.655 support

BT.1120 and BT.656 are supported. Only video data is supported, sending data during blanking intervals is not supported. The component size is always 8 bit.

42.3.6.2.2 Asynchronous Parallel Interfaces

The DI has a flexible asynchronous interface. The interface include 2 chip selects (CS) and 7 general purpose control signals. The user can decide which of the 7 signals will be associated to each one of the

asynchronous displays (up to 2 displays per DI). The using can configured some of the control signals to be shared by more than one display.

42.3.6.2.3 Asynchronous Serial Interfaces

See Section 42.3.10.5, “Serial display interface”

42.3.6.3 Display port’s bandwidth

When the IPUv3EX clock (HSP_CLK) is equal to 133Mhz, the peak bandwidth supported by the display port is as follows

- 110 Mega-Accesses/Sec if the DI clock is derived from an external to IPUv3EX source (like another PLL)
- 120 Mega-Accesses/Sec if the DI clock is derived from the IPUv3EX clock (HSP_CLK)

An access can be a pixel, component or generic data.

42.3.6.4 Display Dual Mode

This mode is useful for smart display with synchronous interface. The data is sent to the display only when the data has changed or when the display processor’s settings are changed. The physical interface to this display has synchronous interface’s characteristics.

42.3.6.5 Display Errors

There are few types of errors that may impact the image sent to the display. The IPUv3EX provides some automatic mechanisms allowing the system to overcome these errors.

42.3.6.5.1 Data starvation errors

These type of errors may happen for synchronous displays if the data is ready at the DI to be sent to the display at the time point it is required. This anomaly may happen if the system is very loaded and the IDMAC was not able to read data from the external memory and provide it to the DMFC.

Frame boundary errors

In case that a new frame should be sent to the display but the data of the previous frame was not sent completely, the IPUv3EX will reset the display modules and flush the internal buffers. As the IPUv3EX expects that the new frame indication will be triggered at least 2 lines (blanking interval) before the actual data is to be sent. The should recover and be ready with the data of the new frame within the blanking interval period.

Error within a frame

In case that a pixel was missed within a frame i.e. the pixel did not arrived to the DI on time. The IPUv3EX has 2 ways to handle the situation. The mode is selected by configuring the DI#_ERR_TREATMENT bit.

Redo the last access. The IPUv3EX will keep sending the last access to the display. The IPUv3EX will drop any pixel that arrive till the end of the line. If the data of the next line arrives correctly the IPUv3EX will continue working normally as overcame the problem. In case that the data of the next line is also incorrect the IPUv3EX will perform the same procedure as described on frame boundary errors.

Freeze the clock. In this mode the IPUv3EX freezes the clock sent to the display till the correct data arrives. In order to avoid a case where the clock is frozen forever and the system is stuck: when the clock is frozen, a watchdog timer starts counting. When the timer completed counting the IPUv3EX will perform the same procedure as described on frame boundary errors. The number of cycles to be counted by the watchdog timer is defined according to the DI#_WATCHDOG_MODE bits.

42.3.6.5.2 Anti tearing errors

In case of anti tearing errors, the IPUv3EX indicates about the error by asserting the corresponding DC_TEARING_ERR_# bit. See also Section 42.3.7.1.2, “Antitearing control”

42.3.6.6 Display port’s restrictions

- In case where 2 synchronous flows are used and additional asynchronous flow via DP is used. The asynchronous flow via DP can be targeted to the same DI that the synchronous flow via DP is targeted.
- There are only 2 command channels (42 and 42). Command channels are associated with data channels (24,28,41).
  - When channel 28 is associated with a command, the command stream will come from channel 42
  - When channel 41 is associated with a command, the command stream will come from channel 43
  - Channel 24 can be associated with a command stream only if channel 28 or channel 41 do not use a command stream. If channel 28 is not associated with a command stream then channel 24 can be associated with channel 42. If channel 41 is not associated with a command stream and channel 28 is associated with a command stream then channel 24 can be associated with channel 43.
- A channel that uses an alternate flow, cannot be associated with a command stream (ch. 24 or ch. 41)
- In case of a synchronous display using external clock, The DI where the synchronous display is connected to can be connected to another async display. But, it can support only the write direction. Read via the asynchronous interface cannot be performed if this DI uses external clock

42.3.7 DC - Display Controller

IPUv3EX handles few display flows supporting few displays. The IPUv3EX’s flows’ data sources can be the MCU, the system’s memory, a camera or an external device connected on the display’s port such as an external graphic accelerator. The data’s destination can be any device connected on one of the DI ports.

The DC controls the flows coming to and from the DI port. The DC manages the flows, decides which flows are currently active and when each flow is activated. The arbitrates between the active flows, gets the data from the predefined source and distribute it to the correct DI.

The DC's core is the microcode. The microcode contains a set of routine. A routine is built of a set of commands stored in the template's (microcode) memory. For each event (like new frame, end of frame etc.) a specific routine is executed. The user writes the routines and map them to a specific events. The routine contains instructions to the DC about the way of handling the data/address/commands associated with the display. The routine may contain information about the data's mapping, about waveform's characteristics, and more.

Figure 42-433 shows the micro architecture diagram for the DC block

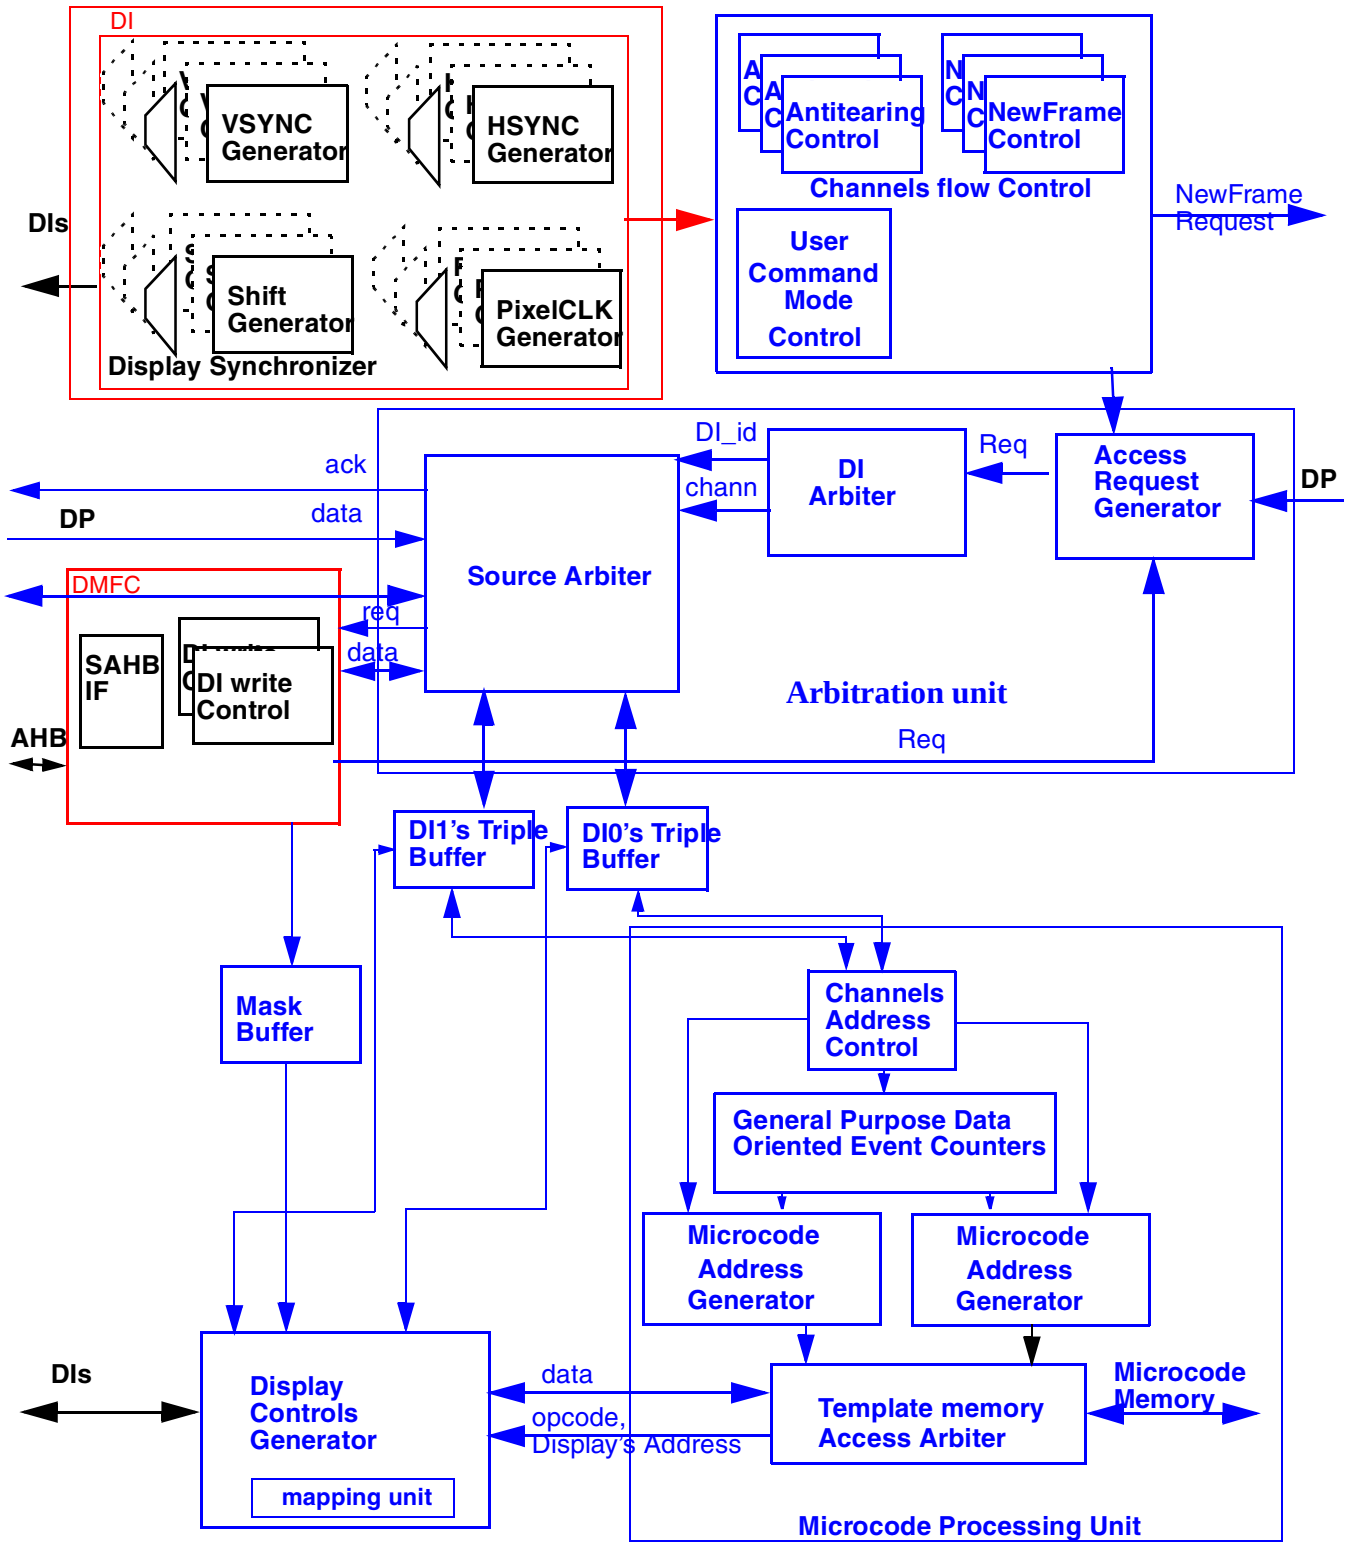

Figure 42-433. DC - Display Controller Block Diagram

42.3.7.1 Channels flow control

42.3.7.1.1 New Frame control

The channels flow control schedules the flows handled by the DC

For asynchronous flows the scheduling is done according to a request coming from the Frame Synchronization Unit (FSU) on the control module (CM).

For Synchronous flows the scheduling is done according to a trigger that is generated by a timer located on the one of the display's interface modules (DI)

42.3.7.1.2 Antitearing control

Anti tearing mechanism uses a signal indicating on a display's refresh of a frame. The supported tearing elimination triggers can be:

- An internally generated VSYNC signal
- A VSYNC signal generated by the display. The data source is the memory.
- A VSYNC signal coming from the CSI

The DC has the capability to avoid image tearing. For asynchronous flows where the source of the data is the system's memory or postprocessing, the DC monitors the position of a display's refresh pointer. Writing to the display is started only after crossing the window start point by the display refresh pointer. After that, writing to the display is allowed only when a write pointer does not advance beyond the refresh pointer. To provide anti-tearing mode, a window start time (in rows) must be defined in the PROG_START_TIME_1, PROG_START_TIME_2, PROG_START_TIME_5, PROG_START_TIME_6 registers for the corresponding channels.

The antitearing mechanism is limited to a case where only asynchronous flows are handle via the target DI.

In the case when tearing cannot be avoided (when the refresh rate is too high and the refresh pointer overtakes the write pointer after full refresh cycle), an error interrupt is generated. Tearing elimination mode can be disabled via the PROG_CHAN_TYP field for the corresponding channel.

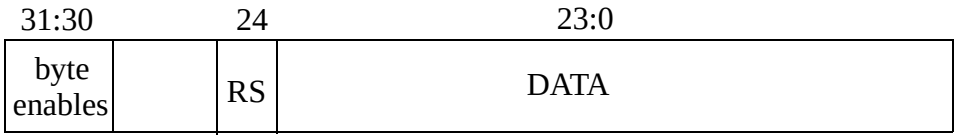
When the data arrives directly from the camera via IC, tearing can be avoided only for the 2:1 ratio between a sensor scan rate and a display refresh rate. The additional conditions for tearing elimination in this case are to synchronize the sensor and display VSYNCs (by programming the VSYNC's settings on the DI) and full-screen image from the camera via IC channel.

42.3.7.1.3 User command mode control

A user may prepare in the system's memory a buffer that holds commends to be sent to the external device. The command buffer includes the same amount of lines as the data buffer. The line of commands are sent to the display line by line. A line of data is sent following each line of commands. This mode is activated by programming the PROG_CHAN_TYP of the corresponding channel.

The structure of the command is as follows:

Figure 42-434. Structure of a command word



42.3.7.2 Arbitration Unit

This unit arbitrates the requests coming from the DMFC and from the DP and sends them to corresponding DI.

42.3.7.2.1 Access request generator

The requests coming from the DMFC or DP are sorted according to the target DI and then served according to a hard coded priority. The priority order is Sync flow, MCU access, IDMAC's Async flows.

42.3.7.2.2 DI arbiter

This units arbitrates between the DIs. The priority is hard coded. The priority order is Sync flow, MCU access, IDMAC's Async flows. In case of 2 simultaneous requests to different DIs with the same priority the requests are served in a Round-Robin fashion. In case of 2 simultaneous Sync flow requests to different DI, the user can bypass the Round Robin mechanism and prioritize one DI on the other according to the SYNC_PRIORITY_1 & SYNC_PRIORITY_5 bits. Setting low priority to both of these channels is forbidden.

42.3.7.2.3 Source arbiter

Once the source of the request to be served was selected and the target DI was chosen, this unit routes the request and all the signals, associated with it, to the correct triple buffer and to the correct source of the data.

42.3.7.3 Microcode processing unit

The main control unit of the DC is the Microcode processing unit (MPU). The data coming to the DC may be associated with some additional information like new frame, new line, new address etc. The information is processed in the MPU. The MPU executes the associated routine. The routine includes a set of instructions of the actions to be performed by the DC and DI.

42.3.7.3.1 Channels address control

This unit controls the display's address for each channel. This unit is responsible of defining the next address to be accessed (by incrementing or jumping). Stores special events flags(like EOF, EOL etc.). Based on the display's address and the special events the type of the routines to be executed is defined.

42.3.7.3.2 General purpose Data oriented events counters

A user may define up to 4 general purpose events. The events are triggered by a standard event (NF, NL). The standard event restarts a counter, when the counter completes counting the user's general purpose event is asserted. This event activates a routine like any other events.

42.3.7.3.3 Microcode address generator

This unit calculates the physical address of the template memory where the event associated routine resides. In addition these unit arbitrates between simultaneous events and select the event to be served. The arbitration is done according to a user defined priority. The priority of each event is set according to the #_CHAN_PRIORITY_CHAN_# bits of each channel. There are 2 modes of arbitration

- Serving all the pending events according to the priority
- Serving only the highest priority event while ignoring all the other events

The arbitration mode is defined according to the CHAN_MASK_DEFAULT bit of each channel.

42.3.7.3.4 Template's Memory Access Arbiter

This unit gets memory access requests from the 2 microcode address generator units and arbitrates between them in a Round Robin fashion. In case that only one of the requests belongs to a synchronous flow, this request is selected.

42.3.7.4 DC's Template structure

The template memory contains 256 template words. Each template word is a 42 bits words. Accessing a template word require 2 accesses (32bit each).

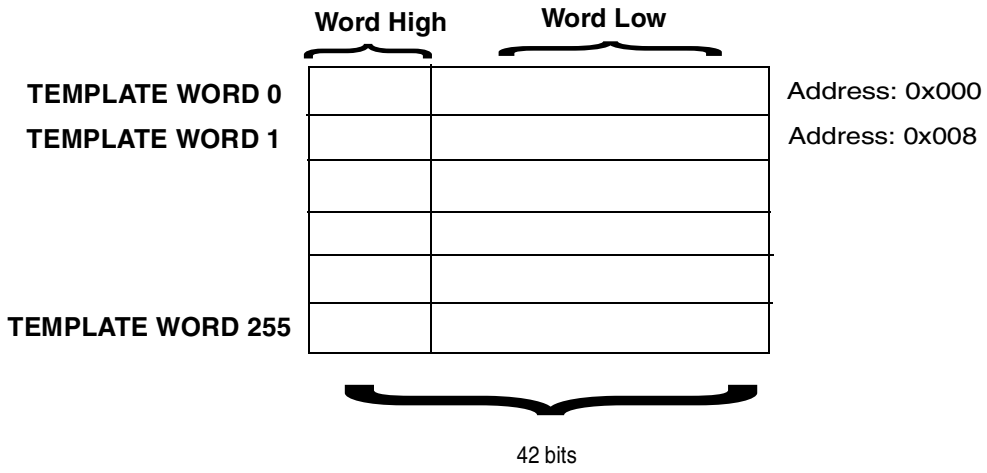


Figure 42-435. Template's structure

Figure 42-436. DC template's memory map

DC template's fields description

Table 42-425. DC template's fields description

Field	Description
STOP	Stop bit - This bit should be set in order to indicate that the current command is the last command of the routine
OPCODE	The command's code
OPERAND	The command's operand - for some of the commands this field can hold a parameter associated with the command
MAPPING	The MAPPING field holds a pointer to a register holding 3 fields: MAPPING_PNTR_BYTE0_X, MAPPING_PNTR_BYTE1_X, MAPPING_PNTR_BYTE2_X. This pointers point to sets of OFFSET and MASK parameters that define the mapping scheme. MAPPING = 0 means that mapping is disabled. The value in this field should be incremented by 1 to get the correct X pointer value In order to point to MAPPING_PNTR_BYTE2_0, MAPPING_PNTR_BYTE1_0, MAPPING_PNTR_BYTE0_0 the user should write 1 to the MAPPING field

Table 42-425. DC template's fields description

Field	Description
WAVEFORM	For data oriented output pins. The IPUv3EX has 4 waveform generator units. The IPUv3EX holds 12 sets of waveforms' configuration registers called DI0_DW_GEN_<i> and DI1_DW_GEN_<i> The WAVEFORM field defines which one of the 12 waveforms' configuration registers is used. The DI1_DW_GEN_X register holds a pointer to one of the 4 waveform generators units for each of the data oriented pins. 0 - The waveform of the data oriented output pins is not affected 1 -Points to DI0_DW_GEN_0 or DI1_DW_GEN_0 2 - Points to DI0_DW_GEN_1 or DI1_DW_GEN_1 ... 12 - Points to DI0_DW_GEN_11 or DI1_DW_GEN_11

Table 42-425. DC template's fields description

Field	Description
GLUELOGIC	For signals generated by waveform generator #3; This field provides extra flexibility on the signals waveform
	GLUELOGIC[6] - This bit defines if we are in clock mode (1) or CS mode(0). 1- clock mode When the command is related to the display clock's pin then only if we are in clock mode, GLUELOGIC[5:4] are valid. 0- CS mode When the command is related to the CS pin then only if we are in CS mode, GLUELOGIC[3:0] are valid.
	GLUELOGIC[5:4] - clock mode settings 00 - Freeze the display clock following the execution of the current command 01 - Freeze the display clock before the execution of the next command to be executed 10 - Enable (unfreeze) the display clock following the execution of the current command 11 - Enable (unfreeze) the display clock before the execution of the next command to be executed
	GLUELOGIC[3] - CS mode settings 1 - Once the signal is asserted then it remains asserted (high or low according to the polarity) 0 - No impact on the waveform
	GLUELOGIC[2] - CS mode settings 1 - Once the signal is negated then it remains negated (high or low according to the polarity) 0 - No impact on the waveform
	GLUELOGIC[1] - CS mode settings 1- The current waveform can be attached to the previous waveform. If the previous waveform was asserted and the current waveform start asserted the two waveforms will be attached so the signals' waveforms will be consecutive. This impact the behavior of the previous waveform. This can be done only if GLUELOGIC[0] of the previous waveform is set to 1 0 - No impact on the waveform
	GLUELOGIC[0] - CS mode settings 1 - this bit allows the next waveform to be attached to the current waveform.
SYNC	The data associated with this command should be synchronized to the DI's one of gen_time_sync generators' output. 0000 - No sync. The data is sent without any synchronization to any event 0001 - Sync with unit #1 0010 - Sync with unit #2 ... 1010 - Sync with unit #10 1011 - 1111 Reserved

DC template's command description

The diagram below illustrates the command processing flow. The command is being fetched from the microcode memory. The Opcode is decoded. According to the decoding several controls are sent to the

processing unit. In addition the processing unit gets the pixel's data and the display's address. The processed data/ address is stored in an internal register. There are 2 types of commands

HOLD - In this type of commands the data/address is stored in the register and not sent to the DI. The data/address is held in the register for further processing in the following commands.

WRITE - In this type of commands the data/address is stored in the register and also sent to the DI.

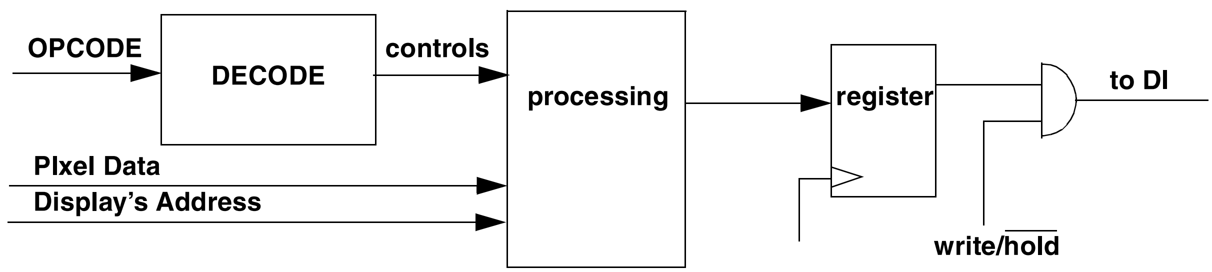

Figure 42-437. Opcode processing

The table below describes the DC's Commands.

BMA	S	0	0	1	1	LF	AF	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	N		0	0	SYNC	
	BRANCH_MICROCODE_ADDRESS jump to Microcode address which is stored at an internal Microcode address register. The branch will be done to the ADDRESS stored with the HMA/HMA1 command. The BMA command manages the repeat cycles by one of the auto decrement counters (internal counters), the counter's id is defined by LF-bit (0/1) The N operand defines the N-number of routine's repetitions. In case of N=0. The BMA command functions as a JUMP command. As long as the internal counter didn't reached its predefined value, the microcode will branch to the pre defined address stored by the HMA/HMA1 commands. Selecting between HMA and HMA1 is done by the AF bit (it is calculated according to the "1 - AF" value). - That's the subroutine's microcode start address When the counter reached its predefined value, the microcode will branch to the pre defined address stored by the HMA/HMA1 commands. Selecting between HMA and HMA1 is done by the AF bit (it is calculated according to the "AF" value). - That's the subroutine's microcode return address BMA synchronization (SYNC field): The BMA command can be used for context switching between 2-channels. When switching between flows the user can run a routine for a new channel, which actually affects the previous flow. This feature is useful when a new flow breaks the current flow (post command for example): SYNC is used for display_id selection // 0 0 0 - current display // 0 0 1 - previous display // 1 0 0 - display 0 // 1 0 1 - display 1 // 1 1 0 - display 2 // 1 1 1 - display 3																																

42.3.7.5 Display controls' generator

This unit generates the control signals associated with the data that are sent to the DI module.

42.3.7.5.1 Bus Mapping Unit

The Bus Mapping Unit is responsible for programmable mapping of the input data and commands to the display interface format and vice versa. Address mapping is done by this unit as well (programmable via micro code). The internal DI format for data and commands is a 24-bits word divided into three byte components (eight zeroes are added to MSB for 16-bits words from the DC). This word can be output or input in one, two, three or four cycles of the display clock.

The word coming from the memory is a 32bit word. The mapping operation is done on 24 bits only. The 24 bit are selected from the received 32 bit according to the W_SIZE_# field. The 24 bit input word is partitioned to a 3 bytes (3X8bits). Each byte can be mapped to any position at the 24bit output word. The exact position is set according to the MD_MASK & MD_OFFSET fields.

The MAPPING_PNTR_BYTE0_X, MAPPING_PNTR_BYTE1_X, MAPPING_PNTR_BYTE2_X fields holds the pointers for the MD_MASK & MD_OFFSET for each byte.

The MAPPING field holds a pointer to a register holding 3 fields: MAPPING_PNTR_BYTE0_X, MAPPING_PNTR_BYTE1_X, MAPPING_PNTR_BYTE2_X.

0 - no mapping i.e. 32 bits are sent as is.

1 - points to MAPPING_PNTR_BYTE0_0, MAPPING_PNTR_BYTE1_0, MAPPING_PNTR_BYTE2_0

2 - points to MAPPING_PNTR_BYTE0_1, MAPPING_PNTR_BYTE1_1, MAPPING_PNTR_BYTE2_1

...

30 - points to MAPPING_PNTR_BYTE0_29, MAPPING_PNTR_BYTE1_29, MAPPING_PNTR_BYTE2_29

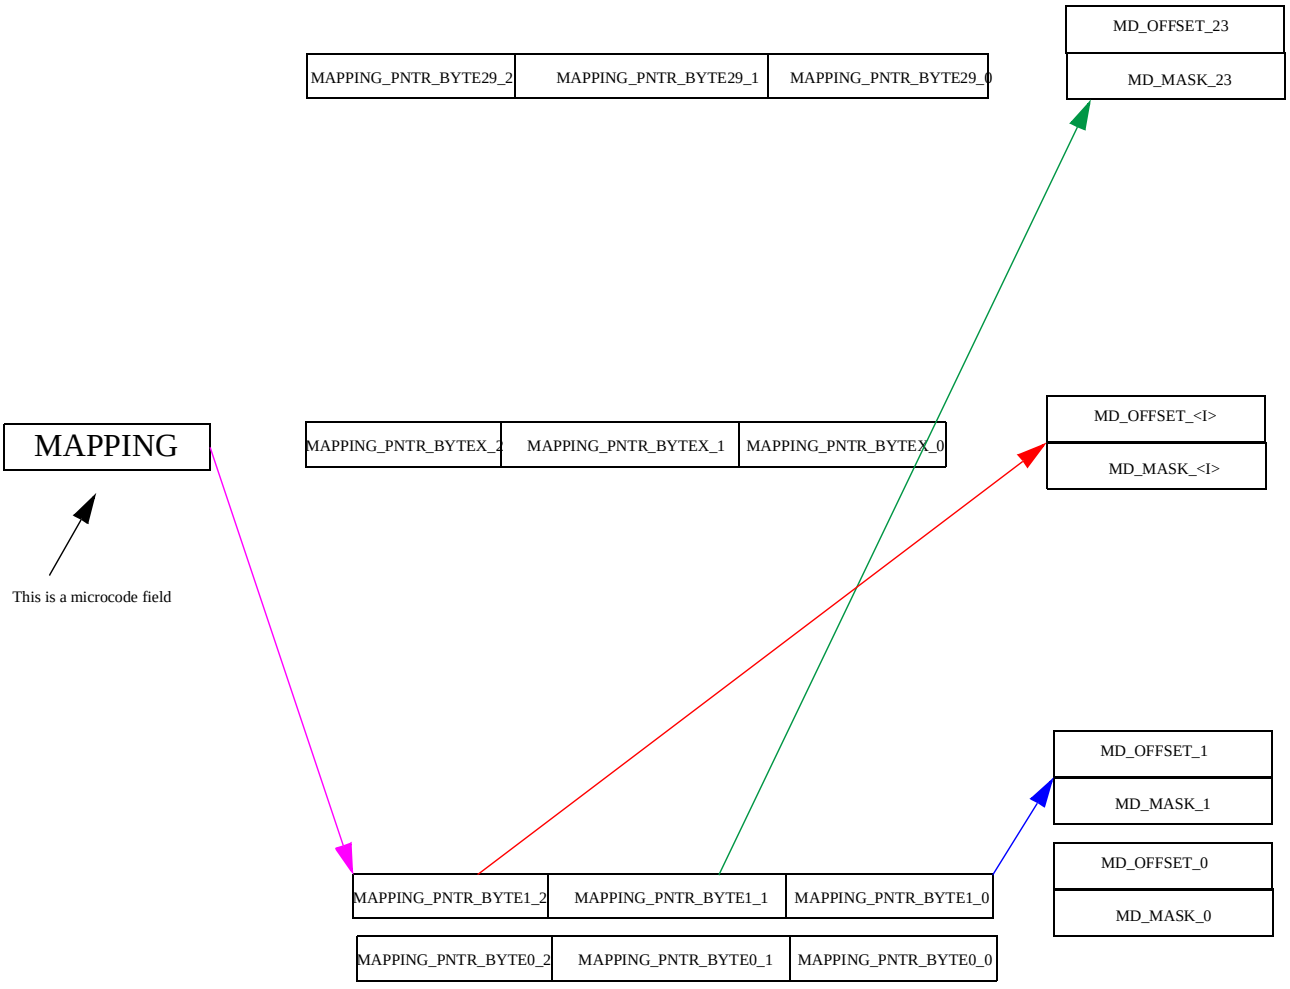

Figure 42-438. Mapping scheme

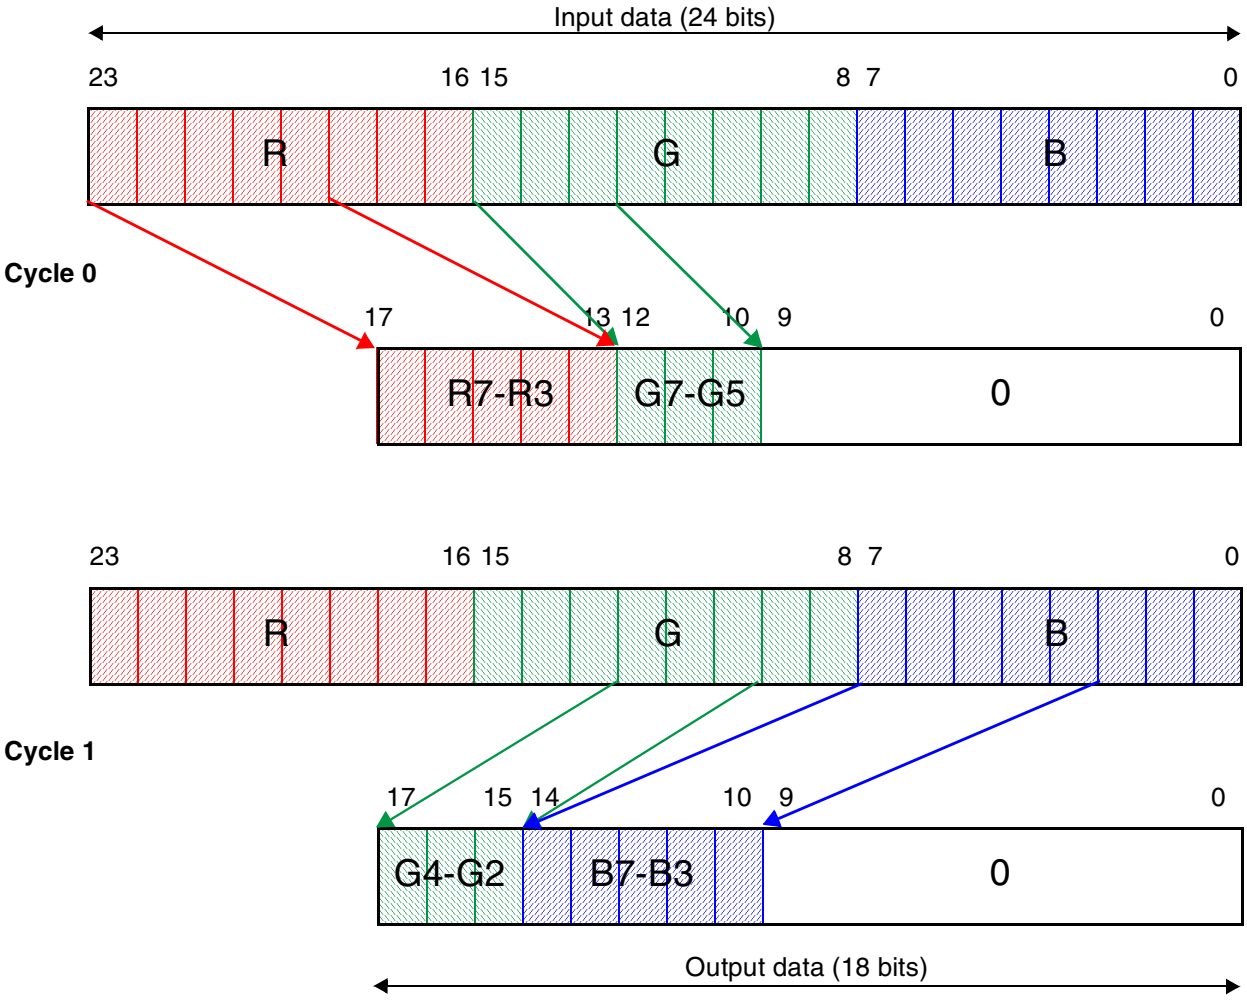
The mapping rule written in each of the Registers defines two types of parameters for the specific byte component and display:

1. Offsets of the byte component MSB relative to the output word LSB. Because the offsets can change dynamically, they are defined separately for the display clock cycles zero, one and two.
2. Numbers of the display clock cycles at which every bit of the byte component should be valid on the display bus. There are eight such 2-bit numbers in the Register.

Figure 42-439 presents an example of programming data packing for one of displays. Cycle 0 and Cycle1 in the diagram represent two separate atomic operations performed by the microcode template.



Cycle 0

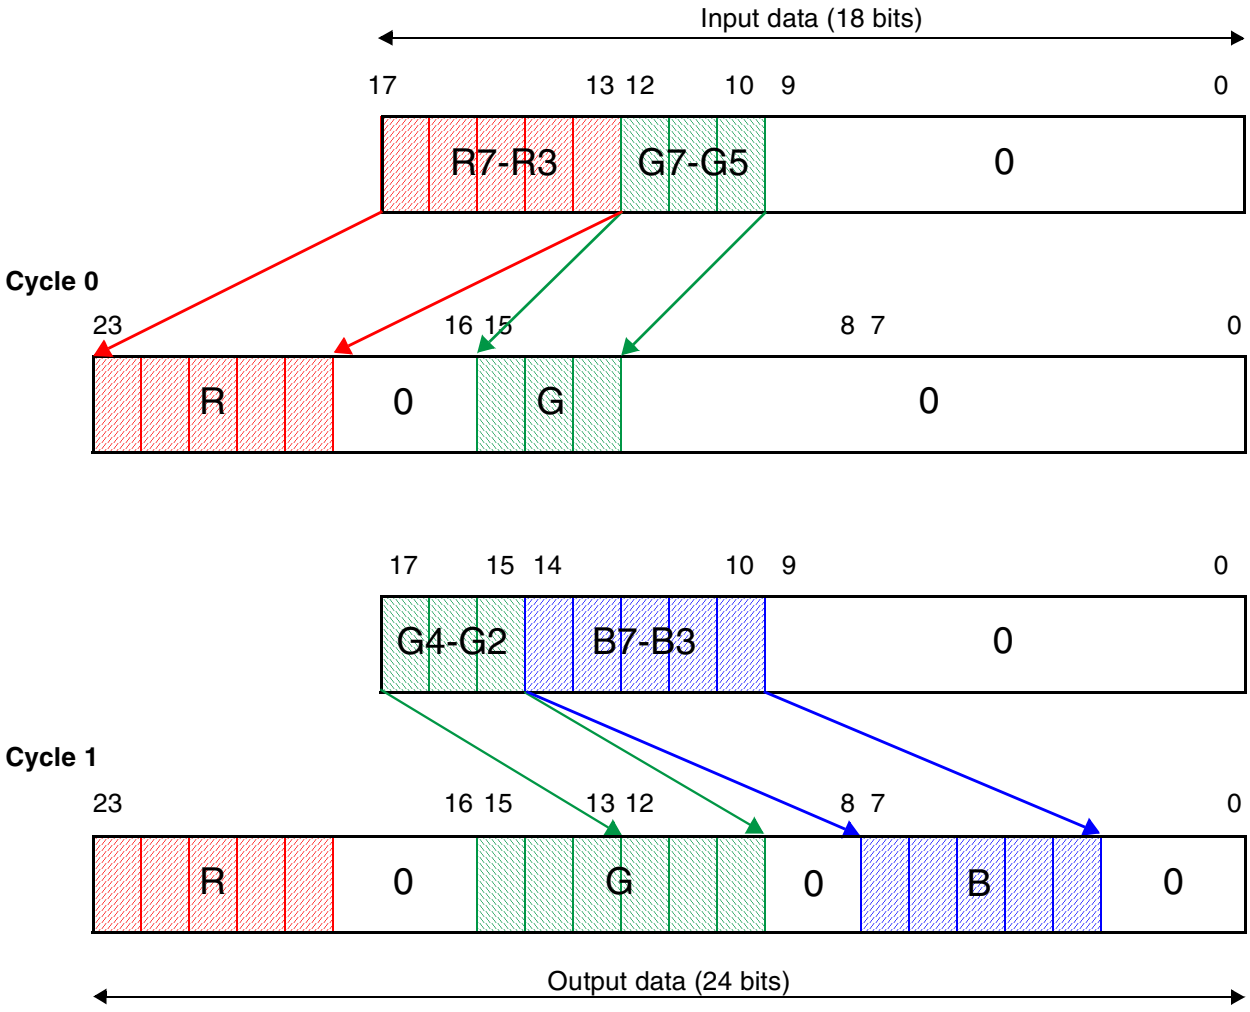
MD_OFFSET_[R] = 0x11 ; MD_MASK_[R] = 0xF8
MD_OFFSET_[G] = 0xC ; MD_MASK_[G] = 0xE0
MD_OFFSET_[B] = 0x0 ; MD_MASK_[B] = 0x0

Cycle 1

MD_OFFSET_[R] = 0x0; MD_MASK_[R] = 0x0
MD_OFFSET_[G] = 0x14 ; MD_MASK_[G] = 0x1C
MD_OFFSET_[B] = 0xE ; MD_MASK_[B] = 0xF8

Figure 42-439. Example of Data Packing for Writing Data to the Display

Figure 42-440 presents an example of programming data packing for one of displays. Cycle 0 and Cycle1 in the diagram represent two separate atomic operations performed by the microcode template.



Cycle 0

MD_OFFSET_[R] = 0x11 ; MD_MASK_[R] = 0xF8
MD_OFFSET_[G] = 0xC ; MD_MASK_[G] = 0xE0
MD_OFFSET_[B] = 0x0 ; MD_MASK_[B] = 0x0

Cycle 1

MD_OFFSET_[R] = 0x0; MD_MASK_[R] = 0x0
MD_OFFSET_[G] = 0x14 ; MD_MASK_[G] = 0x1C
MD_OFFSET_[B] = 0xE ; MD_MASK_[B] = 0xF8

Figure 42-440. Example of Data Unpacking for Reading Data from the Display

The same packing/unpacking registers are used for parallel and serial interface.

42.3.8 DMFC - Display Multi FIFO Controller

Figure 441 shows the block diagram for the DMFC block

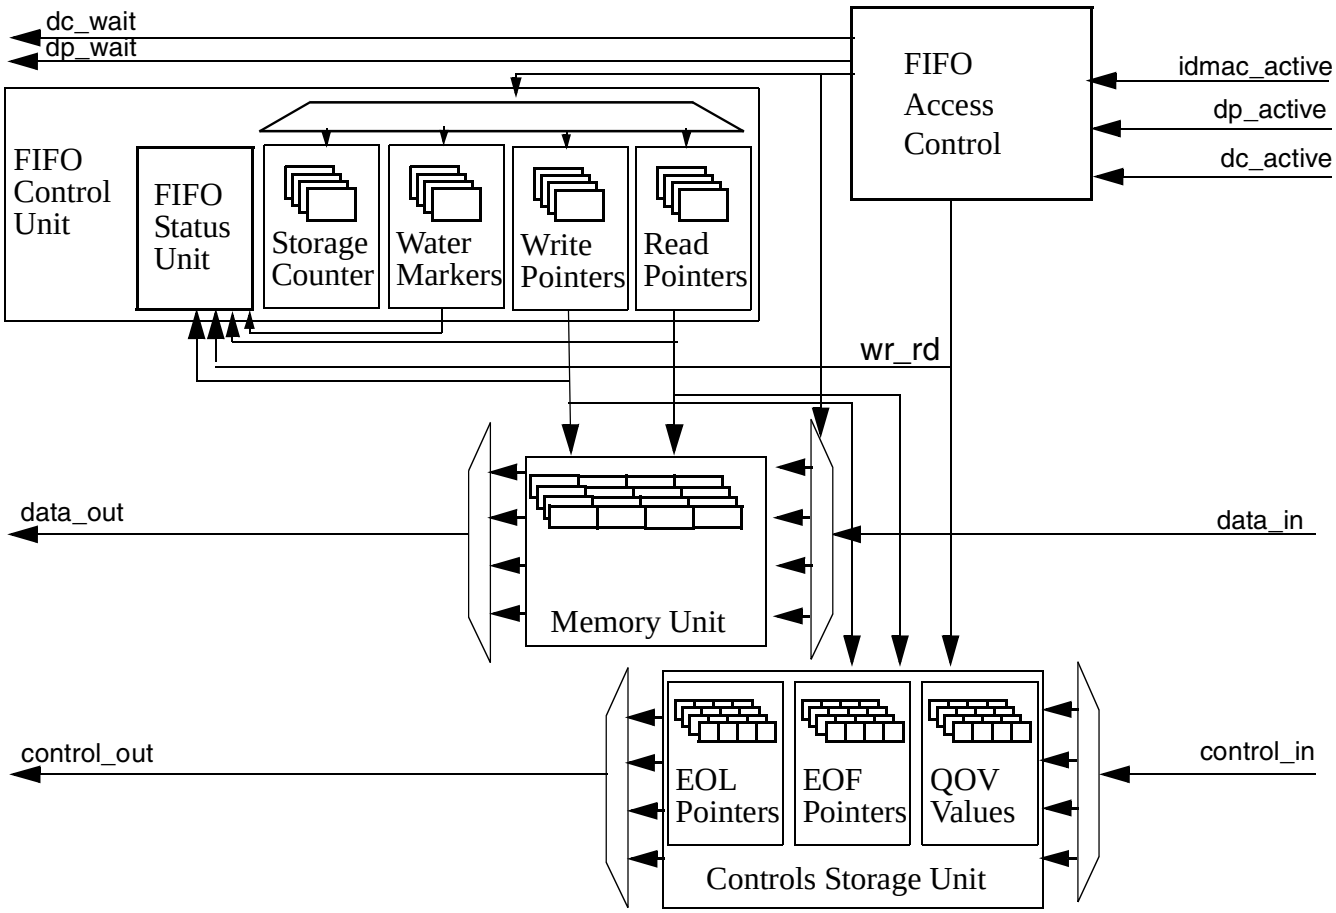


Figure 441. Display Multi Fifo Controller Block Diagram

The Display Multi Fifo Control manages Multi channels FIFOs. The DMFC serves the following clients

- IDMAC - both read and write
- DP - read only
- DC - both read and write
- IC - write only
- AHB - both read and write

The DP and the DC read channels are physically attached to an IDMAC or an IC channel. As the IC has only one output channel connected to the DMFC. When the input is coming from the IC it replaces a channel that was physically attached to the IDMAC. The DMFC uses a single physical memory that serves the DP and DC read channels. The AHB accesses to the DC and the DC's write channel (read from display) use a separate physical memory.

42.3.8.1 DP and DC read channels

Each one of the DP and the DC read (read from memory) channels is physically attached to an IDMAC read channel. A portion of the physical memory is allocated for each channel. The DMFC arbitrates between channels according to a predefined priority.

The DMFC controls each of the FIFOs

- Assert a request any time there's available place on the FIFO.
- Make sure that there's available place on the FIFO to accept the coming data.
- Optionally assert a watermark indication to avoid starvation

42.3.8.1.1 FIFO allocation to channels

The physical memory is partitioned to 8 segments. For each channel the user has to define the start address at a segment's boundary using the DMFC_ST_ADDR parameter. The size of the FIFO allocated to a channel is defined by the DMFC_FIFO_SIZE parameter. The user must allocate the FIFO and avoid overlapping between FIFOs.

The DMFC hold few special indications like EOF, EOL, EOFILD. The most important one is end of line (EOL). If the size of the FIFO is shorter than or equal to the IDMAC line's length (FW) than no special restrictions on the DMFC usage.

If the size of the FIFO is greater than the IDMAC line's length (FW) than the user has to be aware to the following restriction for each channel.

The DMFC has two operation modes which are distinguished by the wait4eot bit. For each channel the DMFC can store a maximum number of EOL indication. The maximum number of EOL indications of EOL is given on Table 42-427.

Table 42-427. DMFC's number of EOL indications

IDMAC's Channel	Maximum lines on the FIFO
23	Up to 3 lines
27	Up to 2 lines
28	Up to 2 lines
Other	Up to 1 line

If the use case is that the number of EOL indications cannot exceed the maximum number of EOL indications than the user should have the wait4eot cleared.

If the use case is that the number of EOL indication can exceed the maximum number of EOL indications than the user should have the wait4eot set.

Having the wait4eot bit set has performance impact as the DMFC analyzes the data prior to sending it to the destination. In addition the DMFC cannot utilize the entire FIFO allocated to this channel.

The user need to specify the burst size of the IDMAC by setting the DMFC_BURST_SIZE field. This field must match the IDMAC settings. In case that the IDMAC's burst size is not a power-of-2 number, the value of this field should be rounded up to the nearest power-of-2 number. The burst size must not be greater than the FIFO's size.

42.3.8.1.2 Arbitration between channels

The arbitration between channels is fully hardware controlled. IDMAC has the highest priority. Then the synchronous channels. Then the asynchronous channels.

42.3.8.1.3 Watermark

The DMFC can generate a water mark signal for each channel. The watermark signal is sent to the IDMAC and dynamically increases the channels priority on the IDMAC's arbitration.

The watermark feature is enabled by the DMFC_WM_EN bit. The FIFO is partitioned to bursts. The user can set the watermark level at a burst boundary.

The watermark signal is set when the number of bursts on the FIFO + the number of already requested burst is smaller than the value specified on DMFC_WM_SET bit.

The watermark signal is cleared when the number of bursts on the FIFO + the number of already requested burst is greater than the value specified on DMFC_WM_CLR bit.

DMFC_WM_SET must be smaller than DMFC_WM_CLR.

42.3.8.2 IC interface

One of the IDMAC channels can be replaced by a flow coming from the IC using the DMFC_IC_IN_PORT. The user has to provide the IC's setting to the DMFC by programming the DMFC_IC_FRAME_WIDTH_RD, DMFC_IC_FRAME_HEIGHT_RD and DMFC_IC_FRAME_PPW_C fields. The burst size of the channel coming from the IC should always be programmed to 4 words.

42.3.8.3 DC write channel and AHB accesses

The second physical memory of the DMFC serves the

- IDMAC write channel (read from display)
- 2 AHB channels that can be read or write

The IDMAC write channel is programmed using the DMFC_RD_CHAN register in a similar way to the DC and DP read channels described above. The user has to provide the frame width and height for this channel and the pixel per word parameter.

The AHB channels are used from accesses via the AHB port to the display. The accesses are distributed between channels according to the MCU_T parameter.

42.3.9 DP - Display Processor

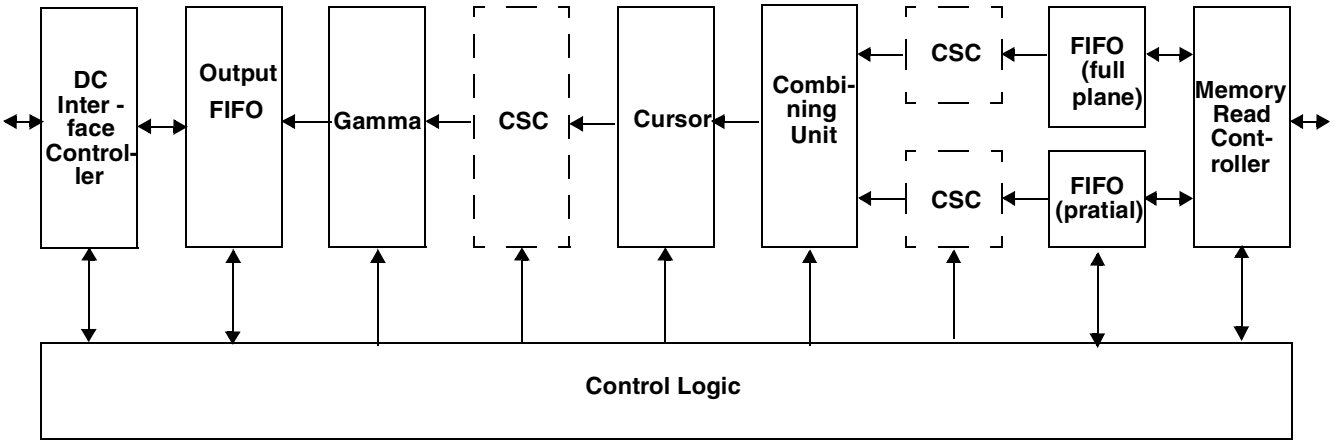

Figure 42-442. DP Micro architecture diagram

The display processor processes the image prior to sending it to the display. The main task performed by the DP is combining between 2 planes. The DP has 2 input FIFOs holding the data of full plane and the partial plane. In addition the DP performs some image enhancement functions like gamma correction, Color space conversion including Gamut mapping.

42.3.9.1 The DP programming model

The DP supports 3 flows. One sync flow and 2 Async flows. The DP holds 3 sets of registers. one set for each flow. Hence when referring to a register in this section the information is applicable to all the 3 sets. for example when referring to DP_COM_CONF, the information is applicable to DP_COM_CONF_SYNC, DP_COM_CONF_ASYNC0 and DP_COM_CONF_ASYNC1.

42.3.9.2 Displayed Planes

Figure 42-443 shows the planes displayed on a display. There are full and partial planes. The partial plane's position is defined relatively to the upper left corner of the full plane (BGXP and BGYP). The size of the partial and full planes is defined on the corresponding IDMAC's channels' FW and FH parameters. The cursor position and parameters are set in the DP_CUR_POS register.

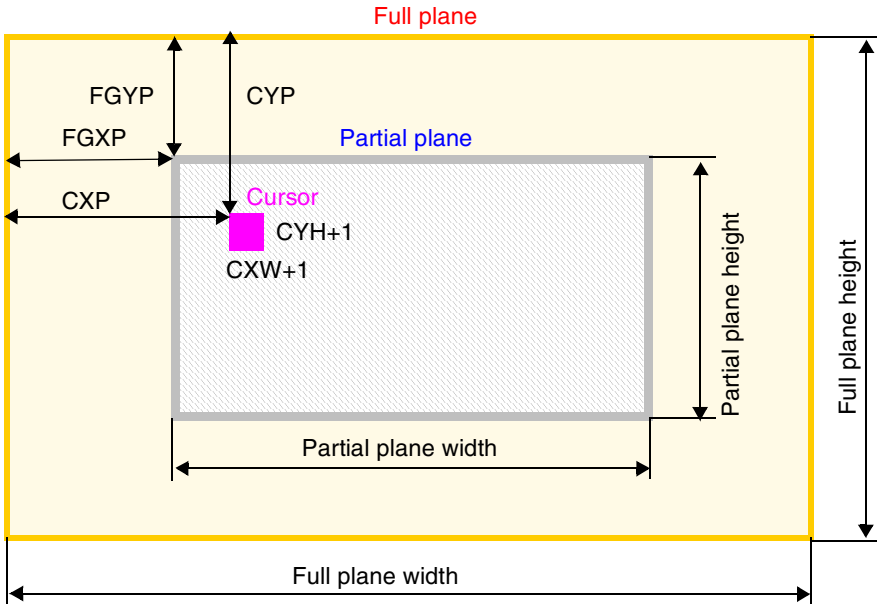

Figure 42-443. Displayed Planes

42.3.9.3 Combining Unit

The Combining Unit performs combining between the full and the partial planes. Each one of the planes may be graphics or video plane.

There are the following combining options:

- local alpha blending,
- global alpha blending,
- use of key color.
- order of the planes (full is presented over the partial plane and vice versa)

Combining mode is selected via the DP_COM_CONF Register. The combining equation is:

$$OP = BG*(1 - a) + FG*a \qquad \textit{Eqn. 42-4}$$

Where BG and FG are 2 input pixels; The DP_GWSEL bit defines if the BG is the pixel coming from the full plane or the partial plane.

a= (A+floor(A/128))/256 - an alpha value

A - a global or local transparency parameter.

The global A is written in the DP_GWAV field, the local A arrives together with the pixel.

A pixel becomes transparent when color keying is enabled and a pixel color matches a key color (independently on an alpha parameter). The color keying is defined on:DP_GWCKR, DP_GWCKG, DP_GWCKB

Combining takes 1 cycle per pixel. The Combining Unit outputs 24-bit words in the RGB/YUV format.

42.3.9.4 Cursor Generator

The Combining Unit output is passes through the Cursor Generator. The cursor's size and position are set via the DP_CUR_POS Register, a cursor color - via the DP_CUR_MAP Register. Different logic functions of combining the cursor with the image are supported as defined by the DP_COC field. The cursor can be blinking. The blinking mechanism resides on the display controller module. The blinking parameters are defined on the DC_BK_EN and DC_BKDVIV fields.

42.3.9.5 Color Space Conversion unit - CSC

The DP can get 2 input pixels from 2 different color spaces (YUV or RGB) and convert one of them to a common color space (YUV or RGB). In addition the 2 inputs can be of the same color space where the result is converted to another color space (YUV or RGB). The DP has a single CSC unit that can be placed on one of 3 locations:

- At the output of one of the 2 input FIFOs
- At the output of the cursor generator.

Placing is done according to the DP_CSC_DEF field.

The color conversion implements a 3x3 matrix multiplication between the full RGB pixels and the color conversion constants, in order to obtain a YCC format image.

The conversion formula is:

$$x \rightarrow Clip(Round(S * 2^{E})),\ S = Ax + B \qquad \textit{Eqn. 42-5}$$

where

A is a 3x3-dimensional matrix of weights, each a 10-bit signed number with 8 fractional digits

$$A = \begin{bmatrix} CSC\_A0 & CSC\_A1 & CSC\_A2 \\ CSC\_A3 & CSC\_A4 & CSC\_A5 \\ CSC\_A6 & CSC\_A7 & CSC\_A8 \end{bmatrix}$$

B is a 3-dimensional vector of offsets, each a 14-bit signed number with 2 fractional digits

$$B = \begin{bmatrix} CSC\_B0 & CSC\_B1 & CSC\_B2 \end{bmatrix}$$

S is a 3 dimensional vector of sums, each a 16-bit signed number with 4 fractional digits

$$S=Ax+B \quad \textit{Eqn. 42-6}$$

E is an exponent, assuming one of the following values: -1,0,1,2 (allowing weights up to 8). The CSC_S parameters are encoded by 2 bits, please refer to the CSC_S parameter description.

$$E = [CSC\_S0\ CSC\_S1\ CSC\_S2]$$

A more explicit formula:

$$S[i] = (sum(A[i][j]*In[j]) >> 4) + (B[i] << 2) + (1 << (3-E[i])) \quad \textit{Eqn. 42-7}$$

$$Out[i] = Clip(S[i] >> 4-E[i]) \quad \textit{Eqn. 42-8}$$

Where Clip() performs clipping to the range 0..255 (either per-component clipping or more sophisticated clipping that preserves the hue of the pixel)

42.3.9.5.1 Gamut mapping

When the color transformation produces colors outside the allowed range, they must be mapped back. This is called gamut mapping. The DP supports 2 clipping algorithms. (controlled by GAMUT_SAT_EN bit)

Hue preserving clipping algorithm is suitable only for RGB components. For YUV components, the per-component clipping algorithm is used.

Per component Clipping

This mapping is performed by clipping each of the components independently to its allowed range of values (the final value being uint8):

- Y: to 0..255 or 16..235 according to the SAT_MODE bit
- U/V: to 0.255 or 16..240 according to the SAT_MODE bit

Hue Preserving Clipping

Hue Preserving clipping is done in the following way

- First stage - eliminating negative values

```
N = min(R,G,B)
if (N<0) X-> X-N, where X=R,G,B
```

- At this stage, all components are non-negative and the MSB's beyond d=11 bits are ignored (assumed 0).
- Second stage - eliminating large values

```
M = max(R,G,B) (d-bit integer)
if (M>255)
M’ = M >> (m-7), where m=8..d-1 is the index of the most-significant non-zero
bit in M
D’ = Ceil(256*255/M’) = 256..510 (since M’ = 128..255)
Ceil(x) = the smallest integer which is not smaller than x
Implemented by a hard-wired 128x9-bit LUT
X -> min(255, (X*D’)>>(m+1)), where X=R,G,B (8x9 multiplier)
else
X -> X
```

42.3.9.6 Gamma correction

The DP includes a gamma correction function.

It is approximated bt the piece-wise polynomial:

$$\text{gammar} = (\text{GAMMA\_C<i>} + (\text{R[4:0]} * \text{GAMMA\_S<i>}) >> 7 \qquad \textit{Eqn. 42-9}$$

Where R is the input red componnent, that’s a 9 bit input composed pixel_in*2+pixel_in[7].

pixel_in is the 8 bit input pixel.

i is equal to MSB of R.

In order to calculate GAMMA_S<i> a following equation is used:

$$\text{GAMMA\_S[i]} = (\text{GAMMA\_C<i+1>} - \text{GAMMA\_C<i>})/16 \qquad \textit{Eqn. 42-10}$$

Single approximation slope is used for Gamma Correction of red, green and blue color components. However the Gamma Correction module instantiated three times since processing for color components should be done in parallel. The gamma transform is also available for changing the contrast of the luminance component only.

42.3.9.7 DC interface

The DC interface unit perform 2 tasks

- Starts the flow via the DP by getting a request from the DC and once the DP is ready send the new frame request to the IDMAC.
- Control the DP’s output FIFO and send the data to the DC using an handshake mechanism.

42.3.9.8 DP’s flows management

The DP can manage up to 3 flows: one synchronous flow and 2 asynchronous flows. However the DP can handle only one flow simultaneously. The DP has an automatic mechanism to control and switch between flows. The DP’s highest priority flow is the sync flow. An async flow can be executed during the blanking interval of the sync flow. An async flow can be stopped in order to serve the sync flow. The sync flow cannot be broken.The DP holds 3 sets of registers, one set for each flow. The registers are located in the

SRM memory. According to the flow that needs to be executed the correct set of registers is loaded to the DP.

Figure 42-444 illustrates the flow management done by the DP.

A flow starts when a request from the DC arrives and the internal pipe is empty. For sync flows the full frame NF (new frame) indication is immediately. In case that a partial frame is also used the NF indication will be sent one row before the row that the partial plane is actually positioned.

In case of ASYNC flow the DP first check if the previous async flow was broken. If yes, the DP restores the last settings of the previous flow. If this is a new async flow the DP will first reload the flow's parameters from the SRM. In case that a partial frame is also used the NF indication will be sent one row before the row that the partial plane is actually positioned.

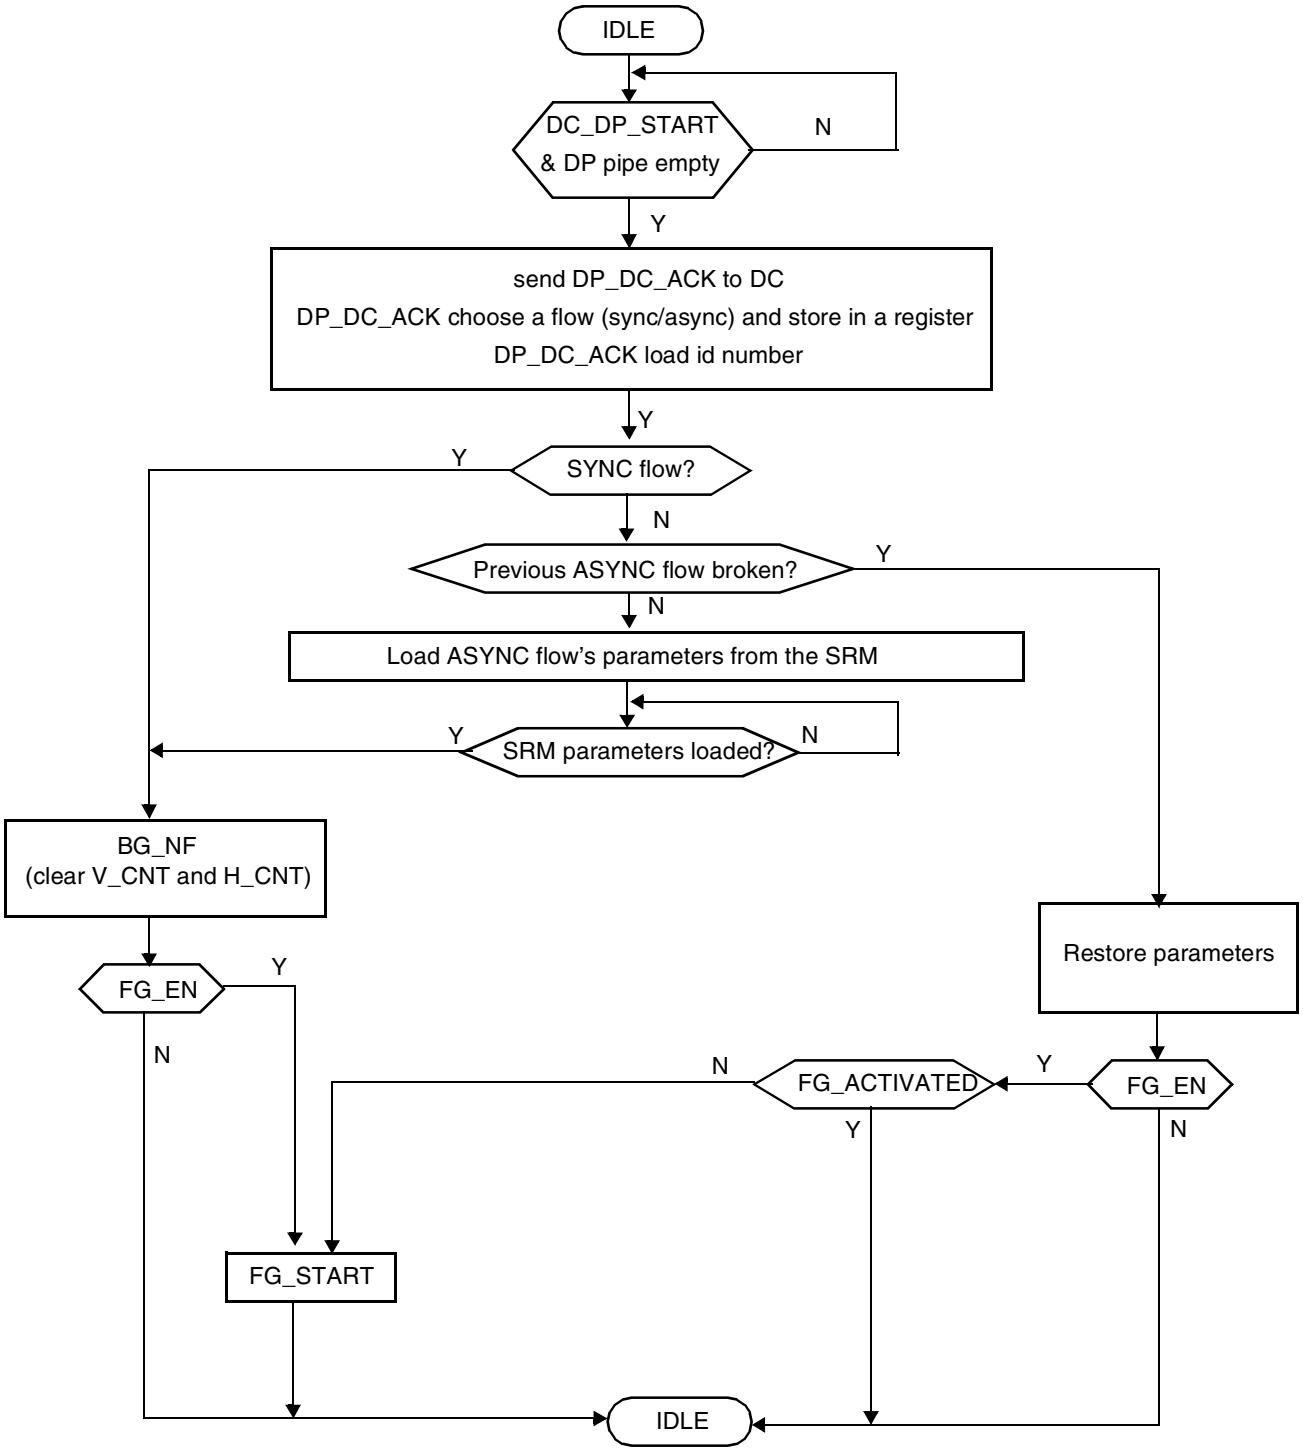

Figure 42-444. DP flow management chart

42.3.9.9 DP debug unit

The DP supports synchronous and asynchronous flows using the same hardware. The asynchronous flow can be broken by the synchronous flow. The DP's debug unit provides the ability to know on which row exactly the async flow has been broken. This is done by providing an interrupt (with DP_DEBUG_CNT register) and providing row status flags (on DP_DEBUG_STAT register).

As the async flow can broken multiple times within a specific frame The user can control the breaking point the issues the debug event by programming BRAKE_CNT field

42.3.9.10 Restriction

When both full and partial planes are processed, the full plane's minimal frame width is 13 pixels.

The Minimum frame height supported by the DP is 2 lines.

42.3.10 Display Interface (DI)

The DI provides arbitrates access to up to three displays with time multiplexing. It converts a data from the DC or the MCU (low level access for serial interface only) to a format suitable for the specific display interface. The DI generates display clocks and other display control signals with programmable timings. The DI outputs data to or inputs from parallel and/or serial interfaces.

This module generates all the control signals sent to the display. The DC sends to the DI; the data for the display and a set of control signals. The controls coming from the DC are used in order to generate the control signals sent to the display. One exception is serial low level access (LLA) where the DC is bypassed and the data is directly coming from the MCU. Figure 42-445 is the DI's block diagram.

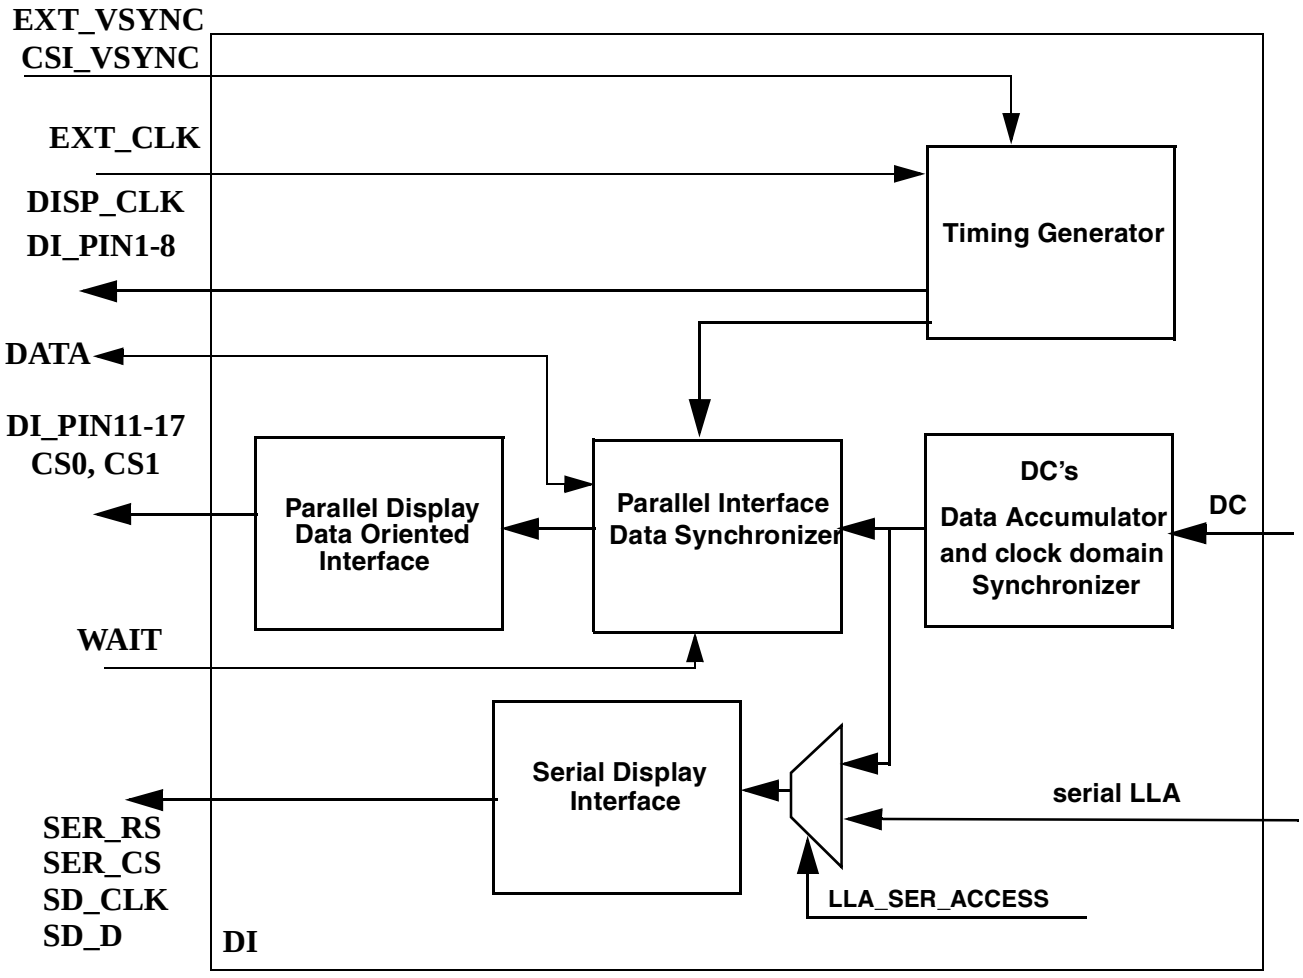

Figure 42-445. DI's block diagram

The display interface includes 2 groups of control signal:

- Time oriented signals - these type of signals are generated according to the DI's internal timers. These are free running signals that change their state according to a pre defined waveform. For example VSYNC, HSYNC, display's clock (pixel clock) etc.
- Data oriented signals - The DC may add markers to data sent to the DI. This markers are used to indicates about a specific attribute of the data (for example: end-of-line, end-of-frame, chip-select etc.). The marker coming from the DC triggers a specific waveform of one or more signals on the display's interface. The specific waveform will be seen on the bus along with the associated data. The markers may be synced to a time oriented signal. For example: attach the end-of-frame signal to the next VSYNC.

42.3.10.1 DC interface, data accumulator and clock domain synchronizer

The data accumulator is the DI's input buffer. It receives the data from the DC along with a set of control signals. The data accumulator receives the data from the DC's clock domain and synchronize it to the DI's clock domain.

42.3.10.2 Parallel interface data synchronizer and data oriented interface

The data accumulated in the DI's input buffer will be sent to the display according to the DI's internal events. Each event is generated by a counter. A tag is attached to each data by the DC's microcode using the SYNC field in the DC's microcode. The tag selects the event that the data will be synced to. Once the corresponding event is generated the data will be sent to the display. A data can be a pixel or a component (part of a pixel).The data synchronization occurs separately for each component. For asynchronous displays the tag will be equal to 0 i.e. the data is not synchronized to any event. The data will be sent out of the buffer immediately.

42.3.10.3 Timing generator

The timing generator is used for generating the waveforms' of each pin of the display's interface.

The timing generator is built of 10 counters. One counter functions as a time base This timer is called the BASE TIMER (BS). The other 9 counters are used in order to generate the control signals' waveforms. The last counter (counter #9) is special see Section 42.3.10.3.3, "Counter #9"

The DI clock can be derived from IPUv3EX's clock (HSP_CLK) or from an external source (via the ipp_di_#_ext_clk pin). The clock's source is statically selected by configuring the DI#_CLK_EXT bit.

Figure 42-447 illustrates the main parameters of a waveform. A waveform's segment is built of 5 parameters. Each segment can be has 2 phase "ACTIVE PHASE" and "OFFSET PHASE".

- TIMEBASE - this is the base timer (fundamental timebase); all the other parameters are derived from this timer. The timebase is generated by counting DI clock cycles. The amount of cycles is defined according to DI#_DISP_CLK_PERIOD. This field defines the Display interface clock period, This parameter contains an integer part (bits 11:4) and a fractional part (bits 3:0). It defines a fractional division ratio of the Di's source clock for generation of the display's interface clock. The timebase is generated from edge aligned pulses of the DI clock.
  The user can delay the timebase starting point by defining an offset to the timebase. This is done by configuring the DI#_DISP_CLK_OFFSET field. The offset is calculated from the point where the DI is enabled to the point where the timebase starts ticking. The display clock waveform is generated between 2 edges of the timebase. The waveform is defined according to the DI#_DISP_CLK_UP and DI#_DISP_CLK_DOWN. Each pin has a specific timebase that is derived from the fundamental timebase
  Figure 42-446 illustrates the relations between the TIMEBASE and the DI's clock

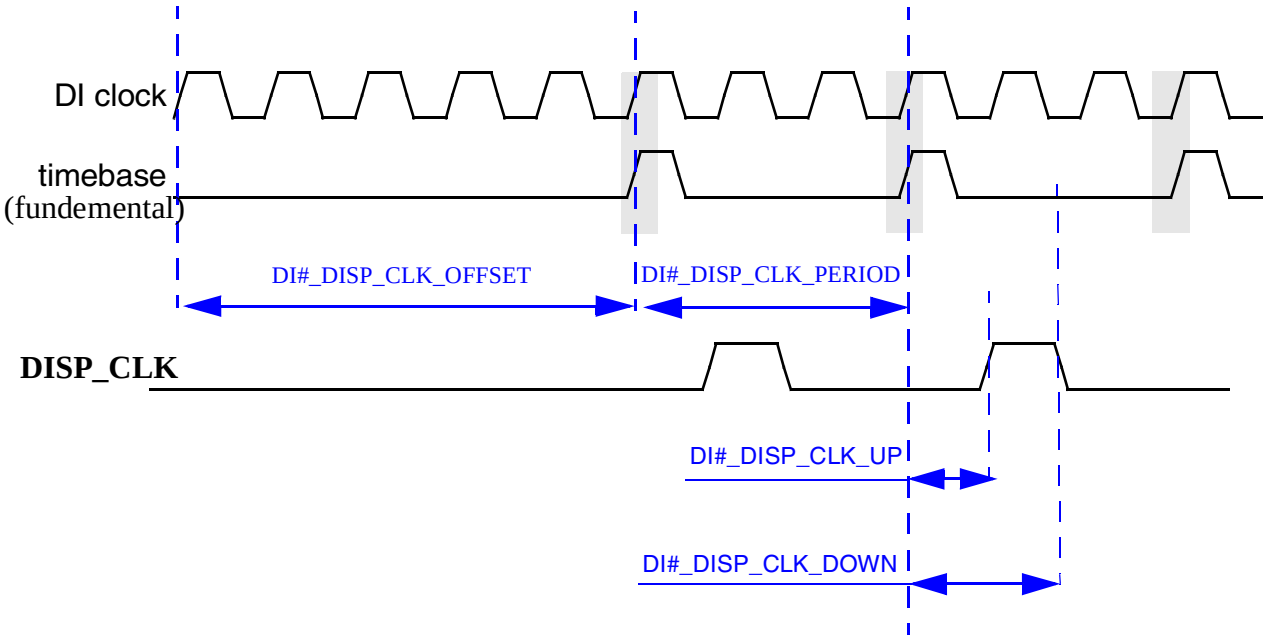

Figure 42-446. Timebase, DI's clock and display's clock relations

- OFFSET - this parameter defines when the length of the "OFFSET PHASE" it is defined by di#_offset_value_<N> field, where N is the counter's index.
- STEP - This parameter defines the length of the "ACTIVE PHASE"; it is defined by the di#_step_repeat_<N> field, where N is the counter's index. If the counter is in auto reload mode (di#_cnt_auto_reload_<N> bit is set) then the counter will be automatically reloaded forever. The value of di#_step_repeat_<N> is ignored in that case.
- RUN - The "ACTIVE PHASE" is partitioned to several "RUN sections"; this parameter defines the length of the "RUN section"; it is defined by the di#_run_value_m1_<N> field, where N is the counter's index.
- UP - Each "RUN section" contains the waveform of a single pulse. This parameter defines the offset from the beginning of the "RUN section" to the assertion of the signal; it is defined by the di#_cnt_up_<N> field, where N is the counter's index.
- DOWN - This parameter defines the offset from the beginning of the "RUN section" to the negation of the signal; it is defined by the di#_cnt_down_<N> field, where N is the counter's index. In case where DOWN < UP the waveform will have a 50% duty cycle.

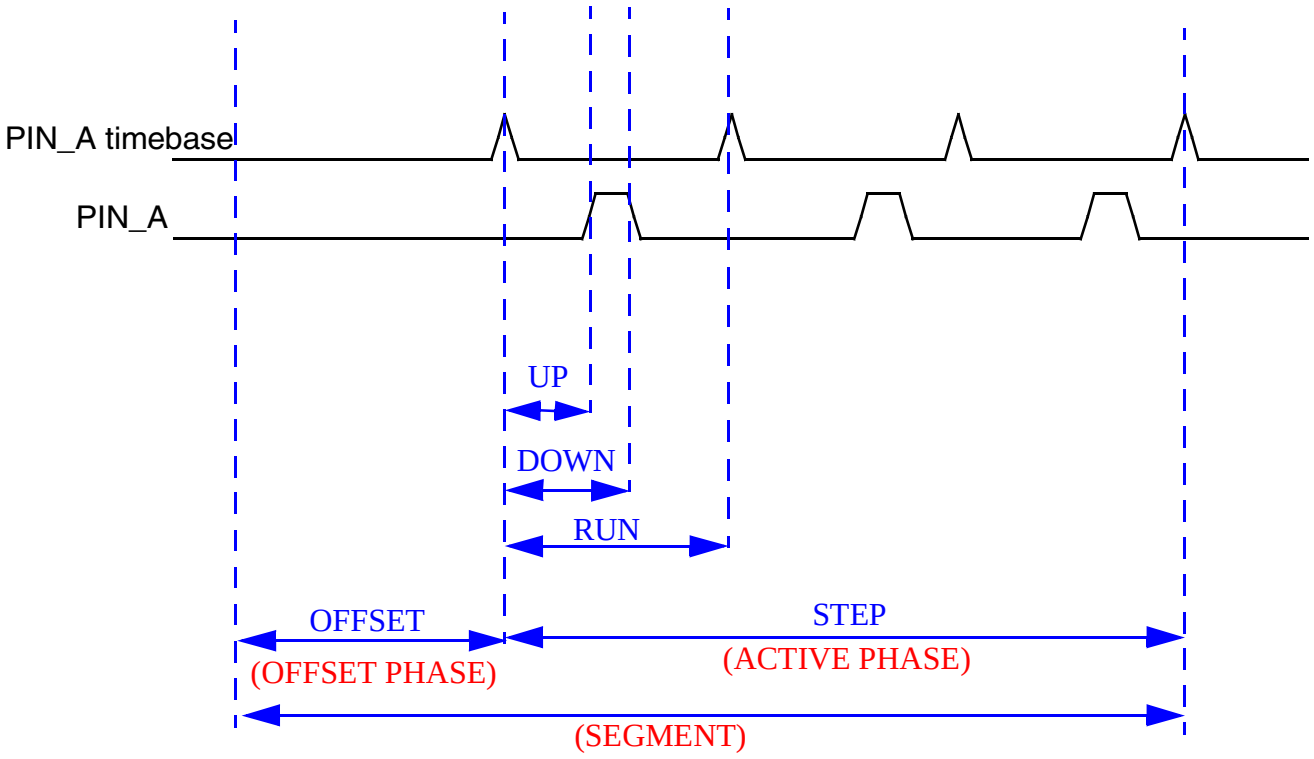

Figure 42-447. DI waveform's main parameters

42.3.10.3.1 Waveform's concatenation

The DI provides the ability to derive the waveform from the fundamental timebase or from another PIN. In that case one pin's waveform is used as another pin's timebase. Figure 42-448 is an example. PIN_A and PIN_C are derived from the fundamental timebase however PIN_B is derived from PIN_A's wavefore.The trigger is selected by DI#_RUN_RESOLUTION_<N>, where <N> is the index of the counter. A counter can be triggered by counter with lowered index. For example: counter #5 can be triggered by counter #3 but can't be triggered by counter #7.

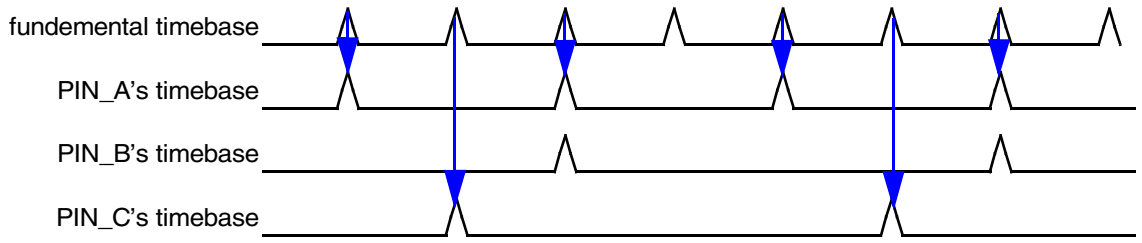

Figure 42-448. DI pins - Waveform's time bases concatenation

42.3.10.3.2 The basic counter

The DI has 9 counters. Figure 42-449 illustrates the counter's structure. A counter is built of 3 units: timebase generator, waveform generator and polarity generator.

The timebase generator

The timebase generator gets 3 triggers. Clear, offset and run trigger. The Clear is the trigger that resets the counter. It is selected by programming the DI#_CNT_CLR_SEL_<N>.

The Offset trigger is the trigger used for counting the OFFSET_PHASE. The user can select the source of the trigger by programming the DI#_OFFSET_RESOLUTION_<N>. The offset's value is defined by programming the DI#_OFFSET_VALUE_<N>

The RUN trigger is the trigger used for counting the RUN period. The user can select the source of the trigger by programming the DI#_RUN_RESOLUTION_<N>. The RUN's value is defined by programming the DI#_RUN_VALUE_<N>

The timebase generator counts according to the DI_CLK or according to another counter's output. In order to use a source different than DI_CLK, the user should set the POLARITY_GEN_EN bits to 01.

Waveform generator

This unit generates the waveform. It gets the values of RUN, UP, DOWN and STEP and build the waveform accordingly. The waveform is counted according to the signal generated by the timebase generator.

Polarity generator

The waveform's polarity is controlled by 2 units. The static polarity is changed according to the POLARITY_<#> bit of each pin. This bit defines if the waveform of the pin is active high or active low.

The other unit controlling the polarity is the polarity generator. This unit is enabled by setting the POLARITY_GEN_EN[1] to 1. The polarity generator has 2 modes: “toggle mode” and “normal polarity mode”. The mode is defined according to POLARITY_GEN_EN[0].

- Normal polarity mode - In this mode the polarity is changed according to 2 other counters. The counter selected by POLARITY_TRIGGER_SEL define the sampling point. The counter selected by POLARITY_CLR_SEL defines the polarity value. At the sampling point the polarity value is defined. The current polarity value defines the current polarity of the waveform.
- Toggle mode - In this mode, the output of the timebase generator’s output causes the polarity to toggle. Any tick of the timebase generator inverts the polarity. When this mode is enabled the ticks generated by the counter selected by POLARITY_TRIGGER_SEL initialize the polarity generator and the timebase generator causes the polarity to toggle.

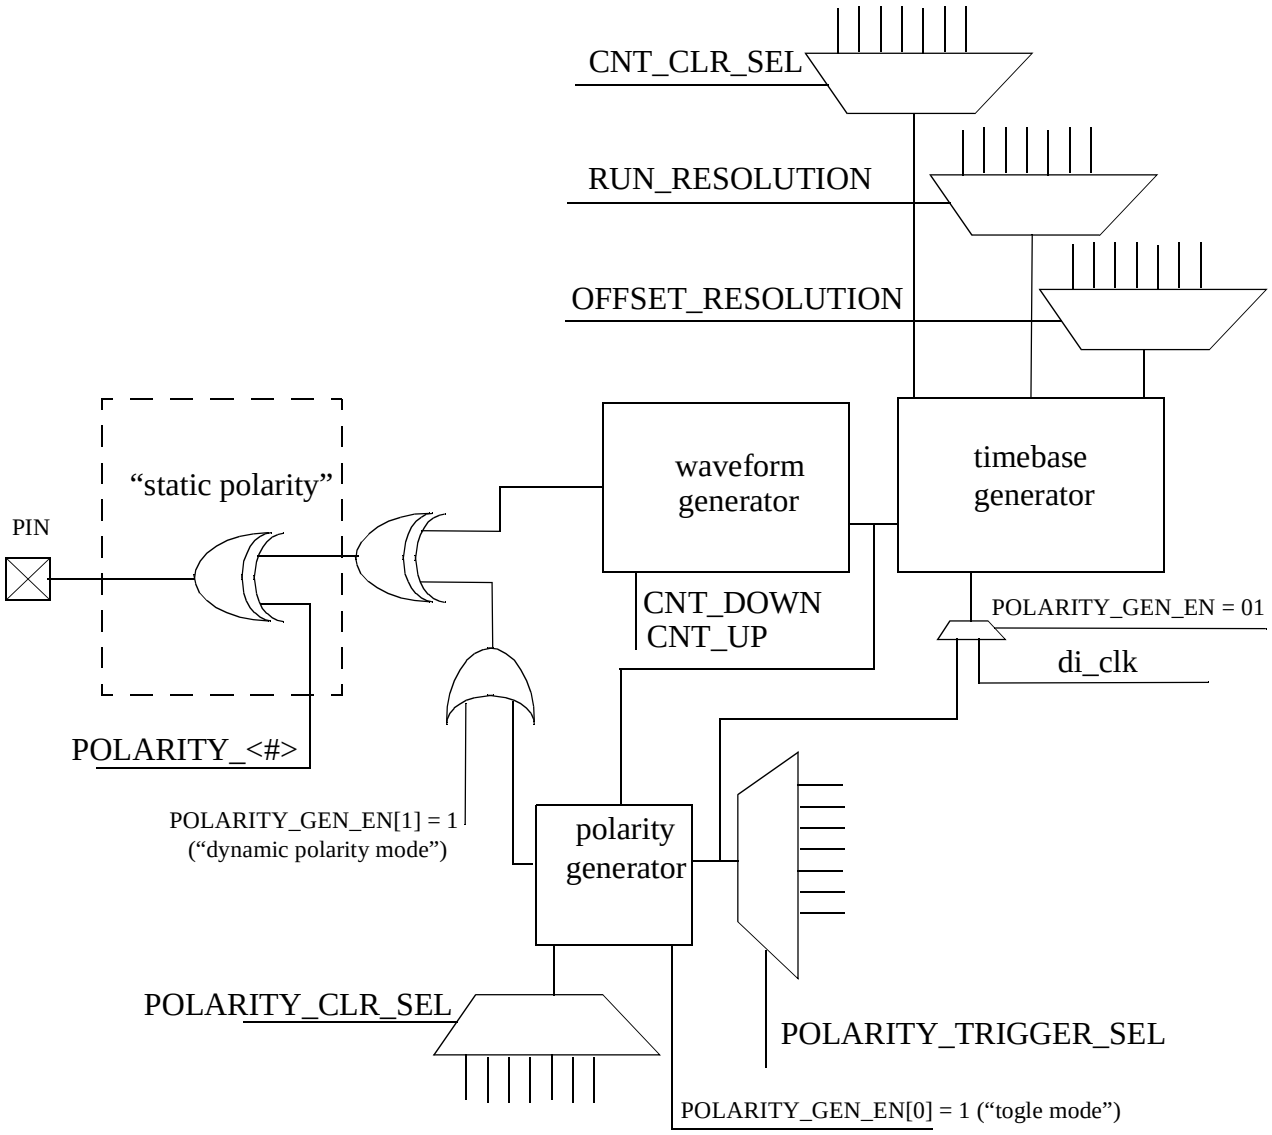

Figure 42-449. DI's counter's structure

Figure 42-450 provides an example for waveform generation using different trigger sources. The waveform is generated for PIN_D. PIN_D counter is cleared by the PIN_C's timebase. The offset period is calculated by counting cycles of PIN_B's timebase. The RUN period is calculated by counting cycles of PIN_A's timebase. The UP and DOWN periods of the waveform are calculated by counting cycles of PIN_D's timebase.

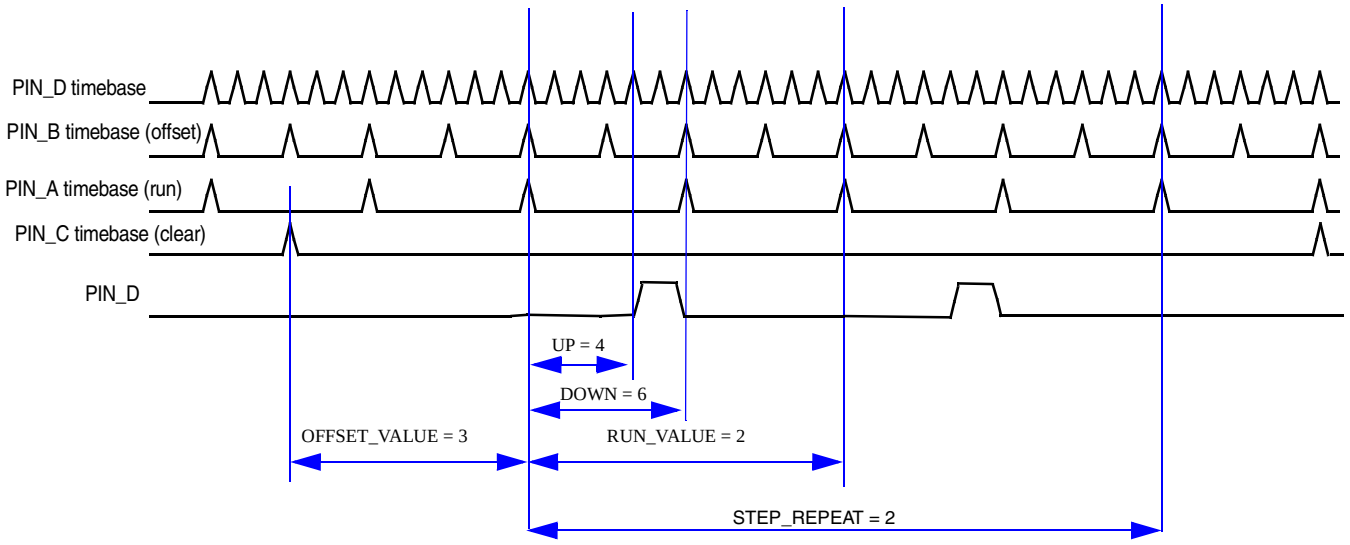

Figure 42-450. Clear, offset and run triggers and values - Example

42.3.10.3.3 Counter #9

The last counter (counter #9) is an auxiliary counter and it is not used for generating a waveform for a specific pin. It can be used in order to attach another waveform to an existing one. The user define the waveform for a specific pin (main pin). The user defines the auxiliary waveform using counter #9. The 2 waveforms are logically ORed. The combined waveform will be routed to the main pin. The main waveform that this counter is attached to is defined according to DI#_GENTIME_SEL_9.

The tag of counter #9 can be generated from counter #9 or from the main waveform. This is selected according to the DI#_TAG_SEL_9.

42.3.10.3.4 DI's active window

The DI provides an alternative way to define the synchronous display setting by using an active window and thus need to program less counters. The synchronous display's active window is a rectangle on the display where IPUv3EX sends data. The active window is set by programming the parameters defined on DI#_AW0 and DI#_AW1 registers. Figure 42-451 illustrates the different parameters defining the active window. The display's vertical and horizontal position are defined according to counters. The DI#_AW_HCOUNT_SEL selects the counter which the horizontal position is calculated according to. DI#_AW_VCOUNT_SEL selects the counter which the vertical position is calculated according to. The Active data is sent according to a trigger. DI#_AW_TRIG_SEL selects the counter which calculates this trigger. This trigger usually functions as a data enable signal.

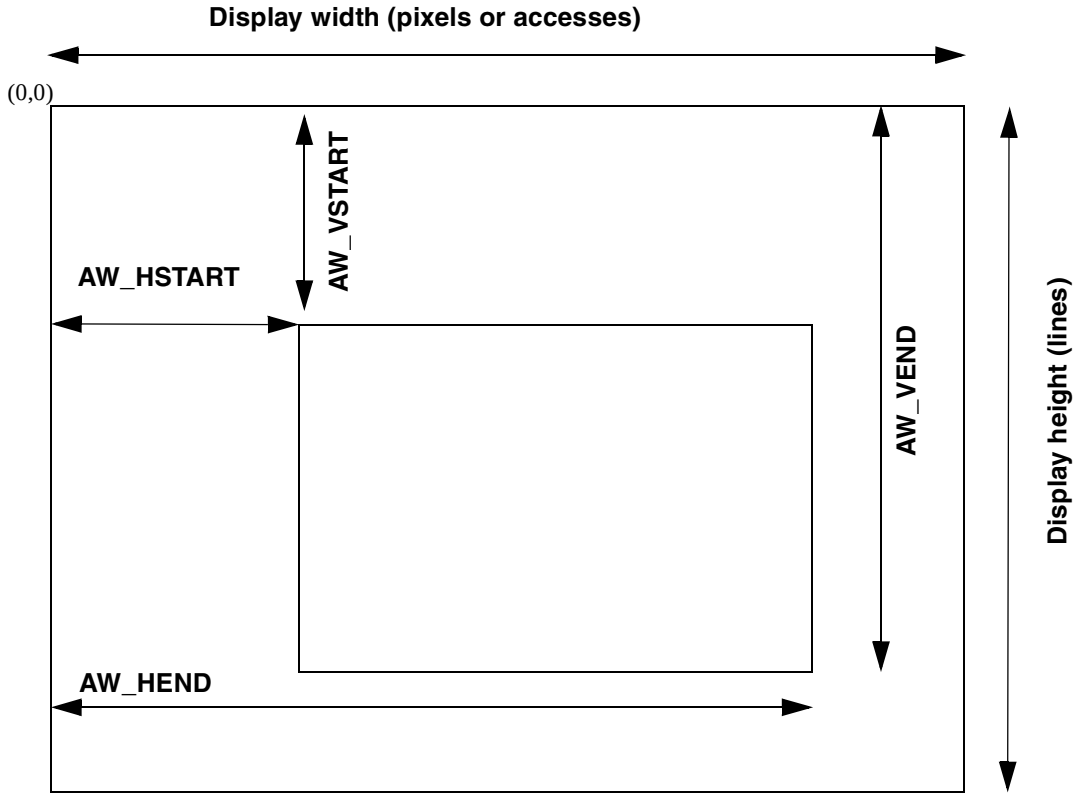

Figure 42-451. DI's Active Window

42.3.10.4 Waveform settings for asynchronous interface pins

The DI provides 8 signals that are used for asynchronous interface. These signals are PIN11 through PIN17 (ipp_di_#_pin_11 through ipp_di_0_pin_17) and the CS (ipp_di_0_do_dispb_d0_cs). The DI holds 12 wave set quartets. Each quartet includes 4 registers (DI#_DW_SET<j>_<i>). Each DW_SET register holds the UP and DOWN values of the waveform. The DW_SET register is selected in the following way. The WAVEFORM field in the DC template is a pointer that points to one of the 12 quartets. In addition the WAVEFORM field points to one of 12 DI#_DW_GEN_<i> registers. The DI#_DW_GEN_<i> holds 9 pointers. The pointers are 2 bits field that points to one of the registers from the DI#_DW_SET<j>_<i> quartet. Each one of the 8 pointers in the DI#_DW_GEN_<i> registers is related to a specific pin of the DI's asynchronous interface. Figure 42-452 illustrates the relations between the registers controlling the asynchronous interface's signals

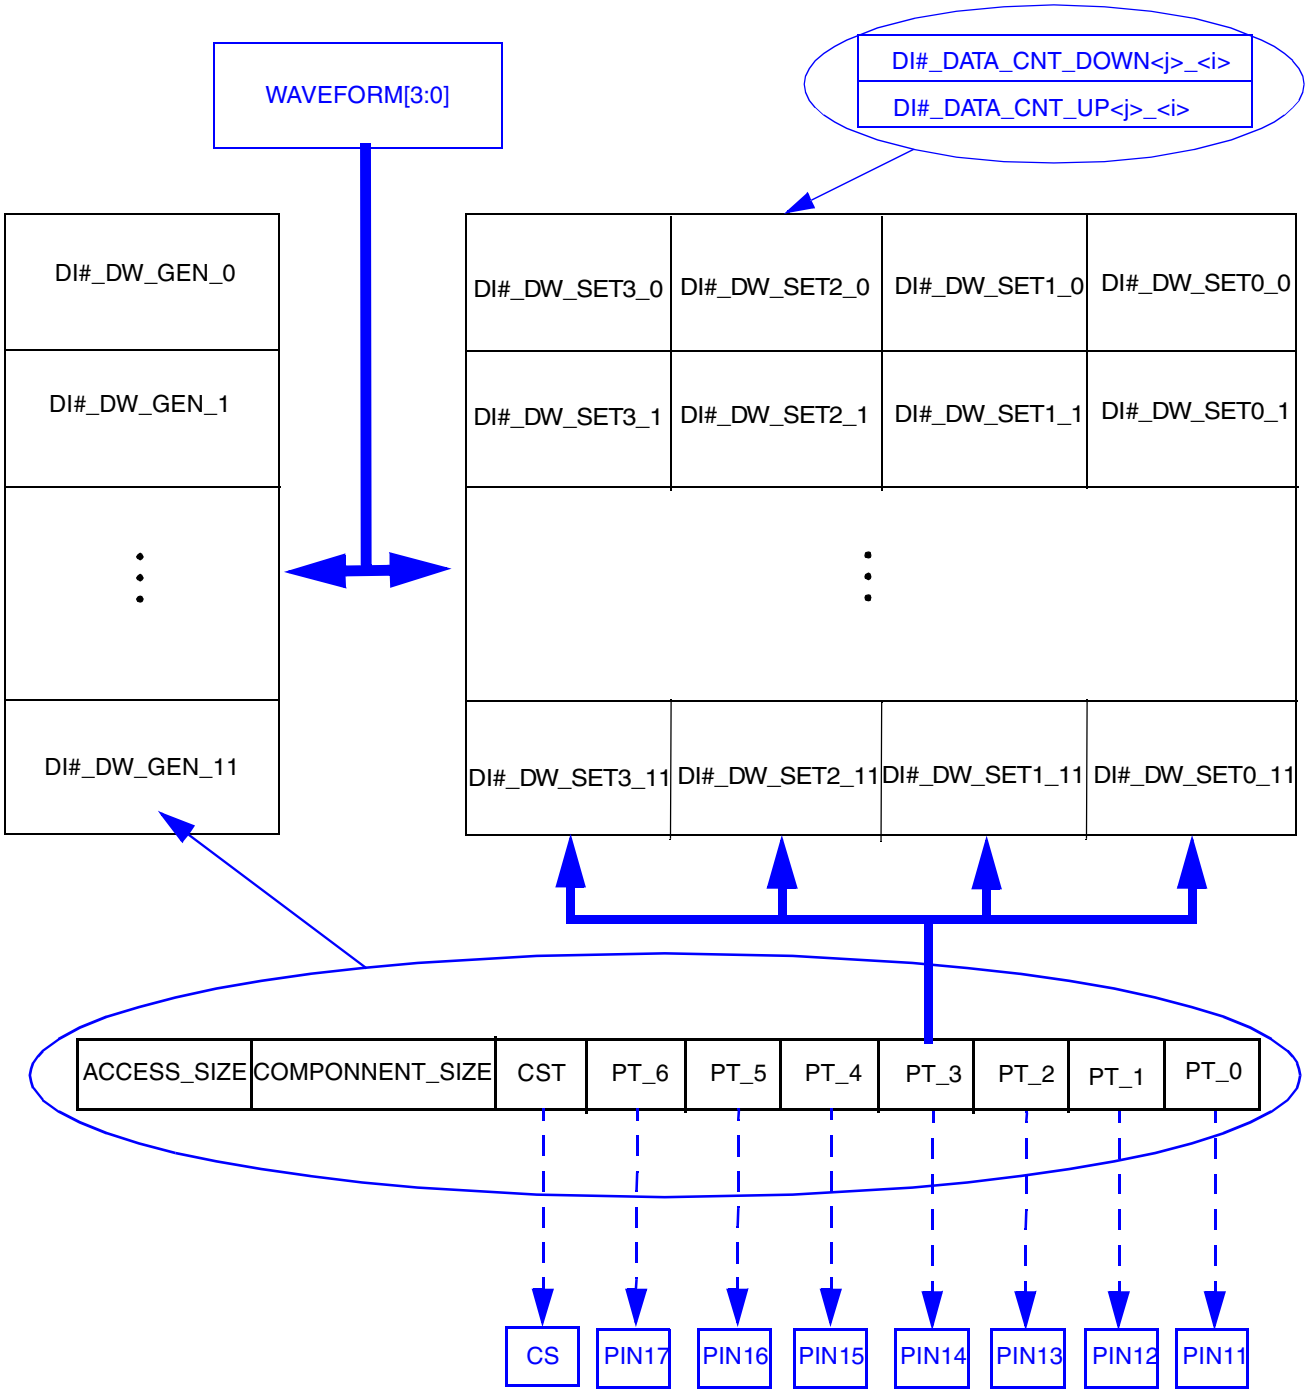

Figure 42-452. Waveform settings for asynchronous interface pins - parallel interface

The DI#_DW_GEN_<i> register includes the data's waveform settings as well. ACCESS_SIZE defines the amount of DI clock cycles that a pixel is valid on the bus. When generic data is sent, this field defines

the amount of cycles that the generic data is valid on the bus. A pixel may be broken into few components. The COMPONNENT_SIZE field defines the amount of cycles that each component is valid on the bus.

The COMPONNENT_SIZE is always smaller or equal to ACCESS_SIZE. For synchronous interface COMPONNENT_SIZE is always equal to ACCESS_SIZE. In case that there's a need for some gap between one type of accesses to another having the COMPONNENT_SIZE smaller than ACCESS_SIZE can be useful (for example read after write accesses that require some gap between them).

42.3.10.5 Serial display interface

The DI supports the following asynchronous serial interfaces:

1. 3-wire (with bidirectional data line).
2. 4-wire (with separate data input and output lines).
3. 5-wire type 1 (with sampling RS by the serial clock).
4. 5-wire type 2 (with sampling RS by the chip select signal).

- For serial interfaces, accessed in LLA mode, data and preamble lengths and other parameters are controlled via the DI0_SER_CONF and DI1_SER_CONF Registers.

The serial display interface includes generators for the CS,RS and CLK signals of the display interface and a bidirectional datashifter. Figure 42-453 provides a block diagram of the serial display interface.

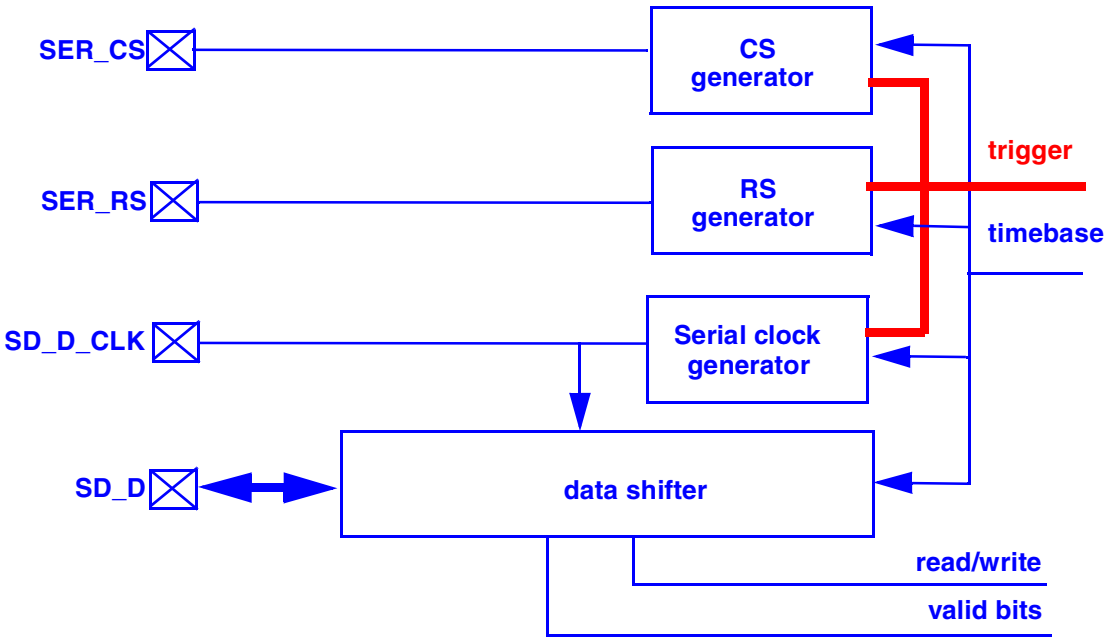

Figure 42-453. Serial display interface

42.3.10.5.1 Waveform settings for serial interface pins

When serial interface is used the fields in the DI#_DW_GEN_<i> register have different meaning than the parallel interface. The registers includes pointers to DW_SET for the CS, RS and CLK pins of the serial interface. Figure 42-454 illustrates the relations between the registers controlling the serial interface's signals

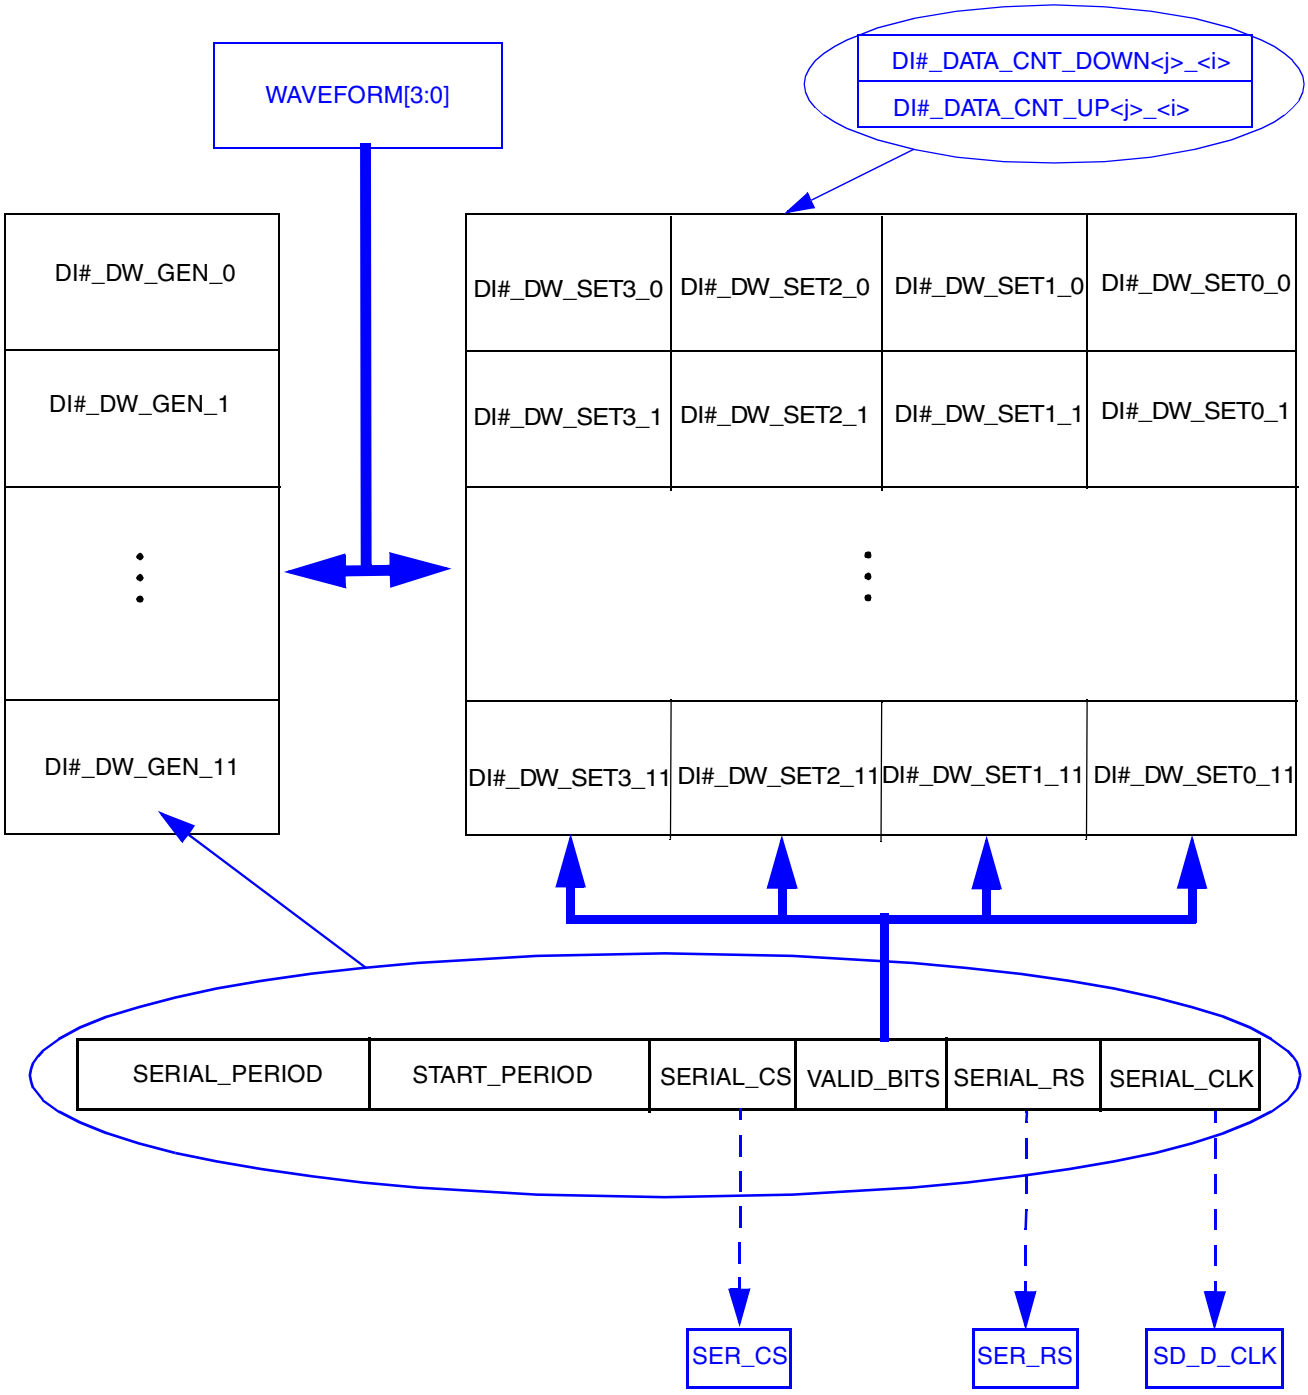

Figure 42-454. Waveform settings for asynchronous interface pins - serial interface

Figure 42-455 provides an example of the waveform's settings for the serial interface. A waveform generation starts following a trigger indicating that the serial interface has won the DI's arbitration. Therefore the next access will be via the serial interface. The waveform is based on timebase ticks. All the

waveform's settings are defined by counting DI_CLK cycles. The timebase starts ticking after counting DI_CLK cycles defined on the START_PERIOD parameters. The number of timebase ticks is defined according to the VALID_BITS field. The VALID_BITS field defines how many bits will from the 32 bit word sent to the DI are valid and should be sent via the serial interface. The valid bits are the least significant bits of the word coming from the DC. The amount of DI_CLK cycles between each timebase tick is defined according to the SERIAL_PERIOD parameter. Each one of the serial interfaces control signals may have a different waveform defined according to its corresponding UP and DOWN values.

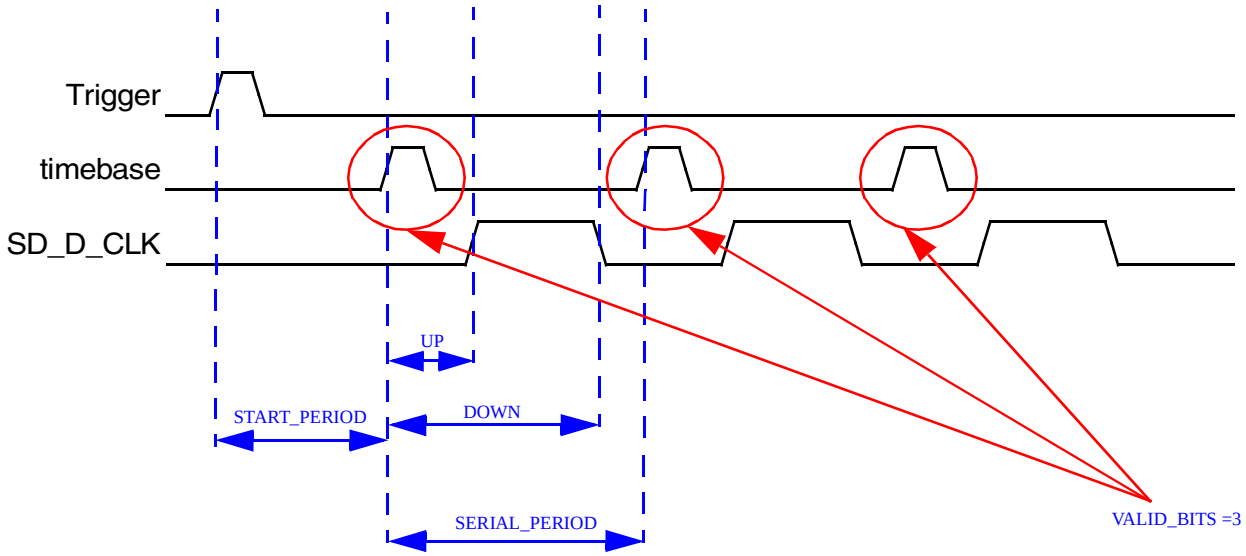

Figure 42-455. Serial interface waveform example

The CS and RS signals can have a single change (one rising and one falling edges) between 2 consecutive triggers.The UP value for RS and CS is measured from the first timebase tick. The DOWN value is measured from the last timebase tick. Figure 42-456 provides an example of the RS behavior, CS behaves in a similar way.

The data is sent according to the timebase ticks. The MSB bit of the data is transmitted first. When receiving serial data, the data is sampled every timebase tick. The user can program an offset from the timebase tick by programming the DI#_SERIAL_LATCH field. This value will move the serial data sampling point. The value is measured by counting DI_CLK cycles.

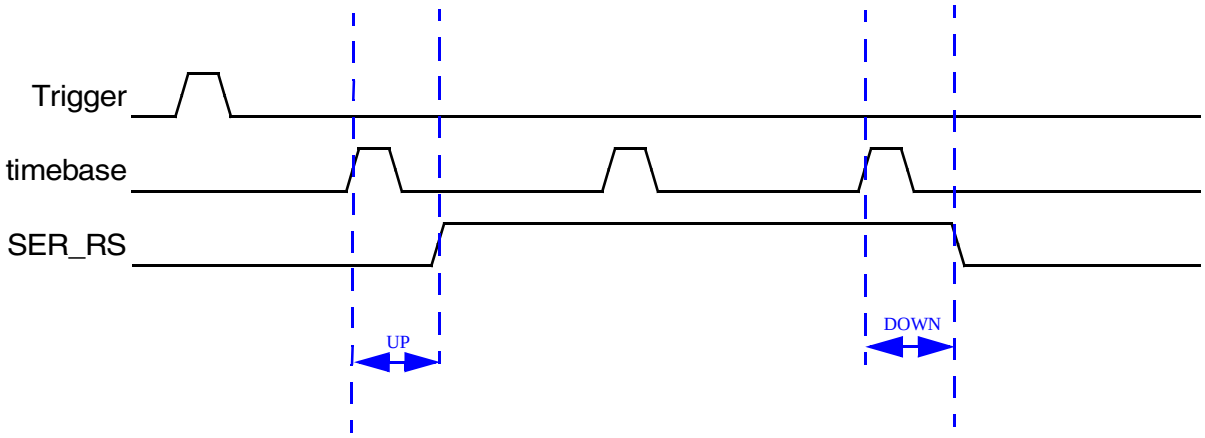

Figure 42-456. Serial interface waveform example of RS

42.3.10.6 Low Level Access - LLA

LLA is a MCU direct access to the display. For parallel displays the DI's behavior for LLA is the same as any other access to a parallel display. For serial displays the DI allows a DI arbitration bypass. This is done if the DI#_LLA_SER_ACCESS bit is set. IN that case there is a direct access from the DMFC to the DI which bypasses the DC allowing simultaneous access to both serial and parallel interfaces. When DI#_LLA_SER_ACCESS bit is set, the user must not do any other kind of accesses to the serial interface except LLA. When DI#_LLA_SER_ACCESS bit is set the corresponding DI#_WAIT4SERIAL must be clear.

42.3.10.7 Using a mask channel

The IPUv3EX is able to provide the windowing function on displays that have data enable control. This is achieved by masking of some screen regions according to a 1-bit/pixel mask read from the memory via IDMAC through channel #44. When the mask value is zero, the pixel is not displayed. This feature can be used for dual-port smart displays.

42.3.11 Video De Interlacing Module (VDI)

The Video De-interlace block (VDI) deinterlaces standard interlaced video to produce progressive video, that is used for upsizing to HD formats or for display on progressive displays. For VDI operation three fields are necessary F(n-1),F(n),F(n+1). The F(n-1) field arrived through CSI interface in real time mode or through channel 1 and then stored in FIFO1. The F(n) arrived through channel 2. At least three lines of F(n) are stored in Line Store memory. The F(n+1) arrived through channel 3 and stored in FIFO3. FIFO controllers read data from FIFOs and then data aligned in pixels buffers. From the buffers the data arrived to Line Padding Controller (LPC). The LPC padding missing line at the beginning and end of the frame.

The DeInterlacing module (DI) perform the processing. Then data send to IC module for processing or for transferring to external memory.

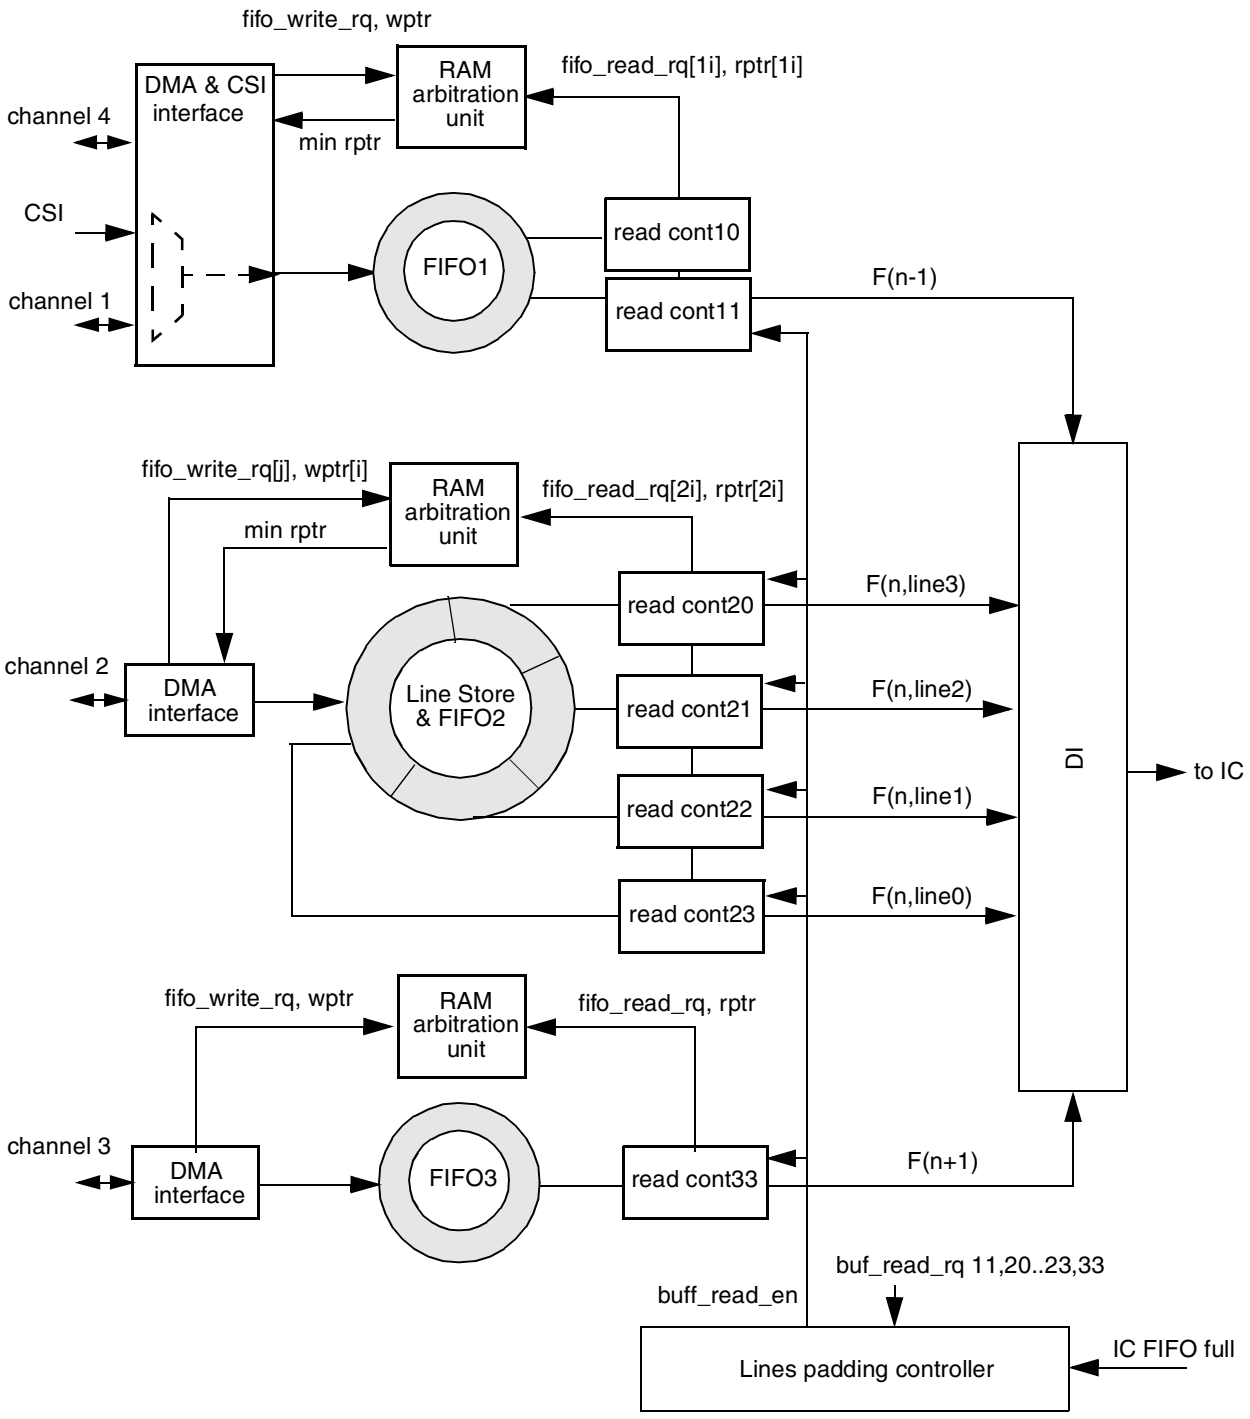

Figure 42-457. VDI Block Diagram

42.3.11.1 VDI Features

Key features of the VDI module include:

- Deintarlacing
  - maximum horizontal resolution 720 pixels
  - maximum pixel rate 60MP
  - Support YUV422 and YUV420 formats
- CSI FIFO mode

42.3.11.2 De interlacer (DI) module

The block diagram of the DI block is shown in **Figure 42-458.** Pipelining is inserted at all stages, so that the design may run at a fast clock speed, if needed.

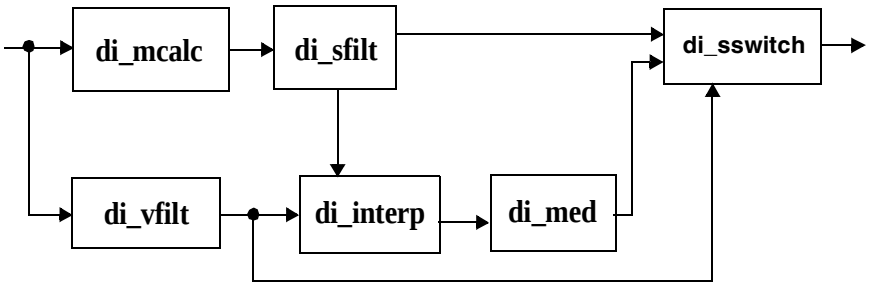

Figure 42-458. DI block diagram

42.3.11.2.1 Vertical Filter Block (di_vfilt)

The di_vfilt block performs spatial vertical filtering of pixels. It is a four tap vertical filter:

$$vfilt\_out = (-3.0*pix1 + 19.0*pix2 + 19.0*pix3 - 3.0*pix4)/32.0 \qquad \textit{Eqn. 42-11}$$

Where pix1, pix2, pix3, pix4 are four pixels in same horizontal location on four consecutive lines of a field. vfilt_out is pixel being predicted (between pix2 and pix3)

42.3.11.2.2 Motion Calculator Block (di_mcalc)

The mcalc block estimates the amount of motion for any given pixel by looking at pixel values in current, previous and next fields. The generic formula used to calculate the estimated motion is:

$$m = SAT(Ks*(|e-w|/(|e-w|+|n-s|+SPA\_DETAIL))) \quad \textit{Eqn. 42-12}$$

- Where, n is the pixel above the pixel being predicted
- s is the pixel below the pixel being predicted
- e is the pixel in previous field at same spatial location as the pixel being predicted
- w is the pixel in next field at same spatial location as the pixel being predicted
- m is motion estimation for the pixel being predicted (range from 0 to 1)
- Ks is slope control and decides how quickly the algorithm switches from no motion (m=0) to full motion (m=1)
- SPA_DETAIL is a constant (50) that is added to |n-s|.
- SAT() is saturate at 1 function

The motion calculator block is simplified in a certain respect, by removing the need for a divider, while providing a degree of flexibility. The main motivators for this are the following observations:

1. the above equation defines a set of curves based on the value of |n-s|, but the curves are fairly closely spaced, so that using a granularity of 8 in |n-s| to define specific curves to use gives pretty much the same quality of picture as using all of the curves; and once |n-s| reaches about 120, the effect of an increased |n-s| value is hard to observe
2. once |e-w| gets to about 15, the motion is usually saturated to a value of 1

Based on the above observations, the motion calculator is now implemented with the use of two “ROM”s, using the 4 LSBs of |e-w| and bits 6:3 of |n-s|.

The motion calculator has 3 modes of operation. These modes are defined by the VDI_MOT_SEL field. In case that the user has an information about the motion (For example SW analyzing motion vectors provided by a video decoder) he can select one of the modes listed below. Changing the value of the VDI_MOT_SEL has an affect only on the next frame.

- When VDI_MOT_SEL==2'b01, m_calc is 0 (no motion – use weave)
- When VDI_MOT_SEL==2'b10, We assume high motion and use min(15,delta_t).
- When VDI_MOT_SEL==2'b00, We assume low motion and use sat([0,15],delta_t-8) (delta_t-8 is signed operation).

42.3.11.2.3 Spatial Motion Filter (di_sfilt)

The di_sfilt block spreads motion signal over five pixels:

$$M_{spread} = MAX(m3, (0.5*m1 + m2 + m3 + m4 + 0.5*m5)/4.0) \quad \textit{Eqn. 42-13}$$

- Where, m3 is motion estimate for current pixel
- m2 is motion estimate for previous pixel
- m4 is motion estimate for next pixel
- m1 is motion estimate for pixel before previous pixel
- m5 is motion estimate for pixel after next pixel

42.3.11.2.4 Interpolated Pixel Calculator Block (di_interp)

The di_interp block uses the motion estimated by the di_sfilt block and computes an interpolated pixel that is weighted sum of the surrounding four pixels (n, s, e, w). The block performs the following calculations:

```
        if (M_spread <= 0.5) {
i = (1-2*M_spread)*(e+w)/2 + 2*M_spread*vfilt_out
} else {
        i = vfilt_out
}
```

Where,i is the interpolated pixel

n, s, e, w are surrounding pixels as explained earlier

42.3.11.2.5 Median Filter Block (di_med)

The di_med block performs a 5-point median of n, s, e, w and i pixels. It should be noted that the median required here is not a true 5-point, but can be implemented more efficiently as a 3-point median:

$$\text{med} = \text{MEDIAN}(\min(\max(n,s),\max(e,w)), \max(\min(n,s),\min(e,w)), i) \quad \textit{Eqn. 42-14}$$

42.3.11.2.6 Soft Switch Block (di_sswitch)

The final output of the deinterlacer is a blend of the median value and the vertical filter, assuming that the pixel data n,s are uncorrelated with the pixel data e,w. By uncorrelated, we mean (max(n,s) < min(e,w)) or (min(n,s) > max(e,w)).

```
        if (M_spread <= 0.5 || not(uncorrelated)) {
pix_out = med
} else { /* M_spread > 0.5 */
pix_out = (1-2*(M_spread-0.5))*med + 2*(M_spread-0.5)*vfilt_out
}
```

42.3.11.3 DMA only Mode

In DMA only mode the data is coming from IDMAC only.

42.3.11.4 Real Time Mode

In Real Time Mode the F(n-1) are coming from CSI. The CSI write to FIFO1. The DI module read F(n-1) from processing. In addition IDMAC read the field from FIFO1 and store in external memory. Then stored frames are used as F(n) and F(n+1).

42.3.11.5 CSI only Mode

In CSI only mode VDI do not perform any processing and used as FIFO only. The data arrived from CSI written to FIFO1. The IDMAC read data from the FIFO1. The FIFO3 and Line store memory are not used. The ID module are turned OFF. The CSI only mode can be used as alternative to SMFC, when appropriate.

42.3.11.6 VDI Restrictions

- Maximum output pixel rate is 60MP.
- The output pixel format (YUV422 or YUV420) are equal to input format.

42.3.12 Control Module (CM)

42.3.12.1 Block Diagram

The CM Block Diagram is shown in Figure 42-459.

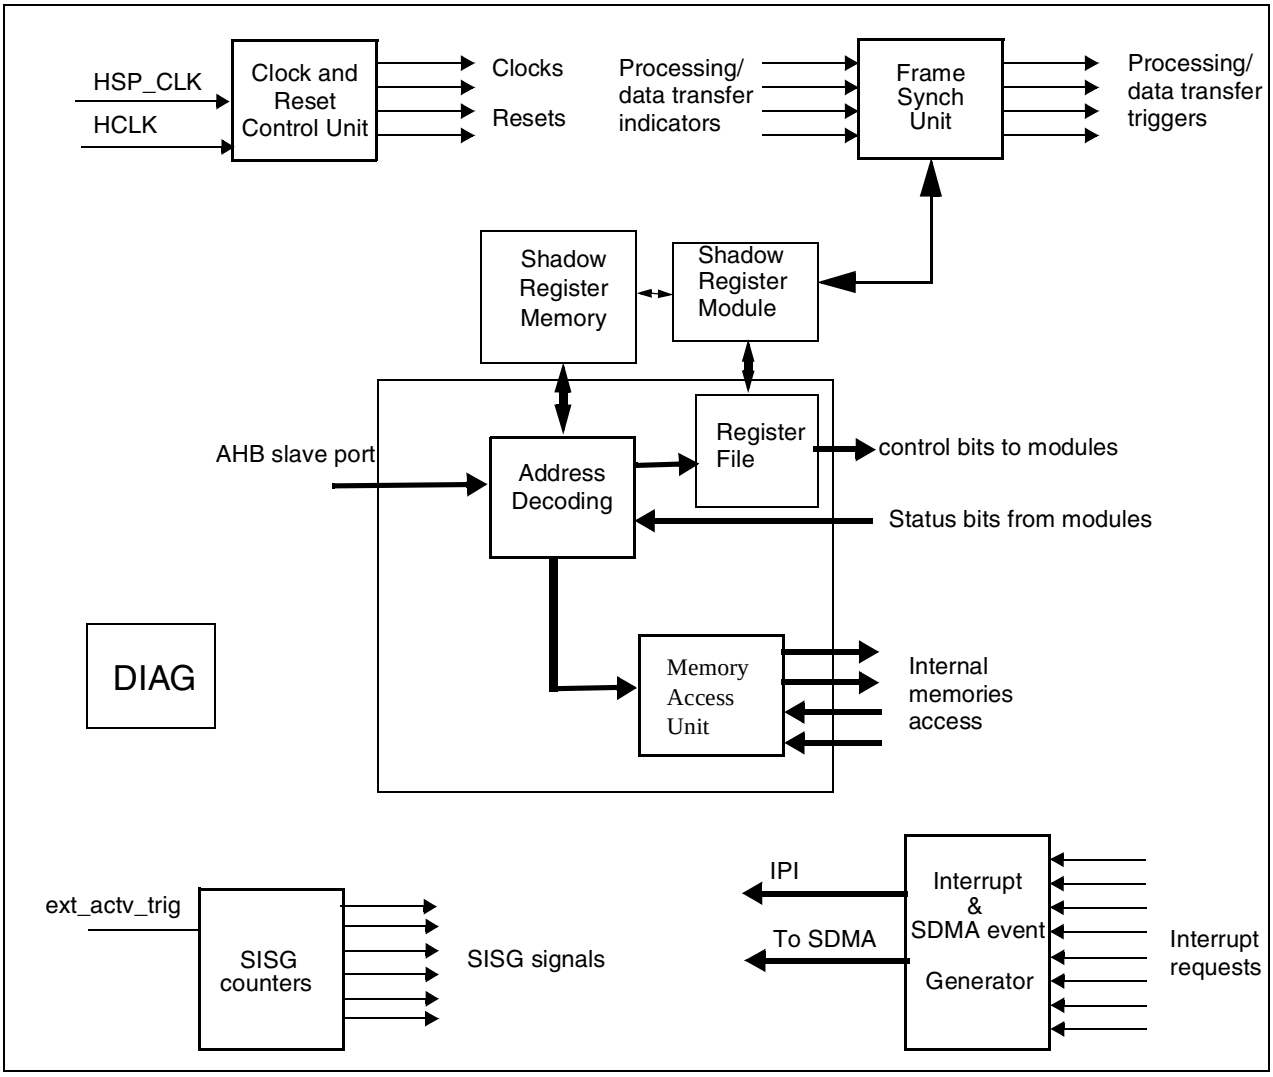

Figure 42-459. CM Block Diagram

The CM consists of the Frame Synchronization Unit (FSU), the Interrupt Generator (IG), the General Configuration Registers (GCR), the Clock and Reset Control Unit (CRCU) and the Shadow Registers Module (SRM).

42.3.12.2 Frame Synchronization Unit

42.3.12.2.1 General Description

The FSU provides synchronization of tasks performed by different IPUv3EX sub modules and MCU tasks. This allows to build complex processing flows which are performed automatically (without MCU involvement in synchronization of the IPUv3EX's tasks). The FSU supports double buffering of image frames stored in the external memory and allows chaining IPUv3EX processing flows in automatic mode. Table 42-430 describes the most important use cases of chaining the IPUv3EX tasks.

42.3.12.2.2 Frame Synchronization Flow

1. Initialization

   The MCU initializes all the parameters for a task by writing to the GCR and to the parameters memories of each IPUv3EX sub-modules. The initialization must occur before the MCU enables the task.

2. Enabling

   After the initialization step has been completed, the MCU enables the task by setting its enable bit in an appropriate register.

3. Triggering

   After the task is enabled, the FSU waits for triggering signal. The triggering signals is a combination of the enable bit and the buffer ready signal which can be driven by the MCU (DMA_CH_BUF<0/1>_RDY_<#>) and/or by the preceding task (IDMAC_EOF_# or Frame Complete signal from the DC).

   The trigger causes the FSU to invoke the relevant unit to start by assertion of the NEW_FRM_RDY signal. In some cases triggering occurs at the enabling step (when the enable bit is the trigger for the task).

4. Operating

   The triggering step cause the task to move to active mode, this is the operating step. In this step, the FSU monitors the synchronization signals from MCU, IDMAC and the corresponding processing units, and controls the units operation. The FSU also controls the IDMAC buffer toggling when double buffer page flipping is used.

   The FSU checks at end of each frame if the next frame can be served. If the answer is yes, the FSU stays in active mode with re-sending the <TASK>_NEW_FRM_RDY signal and updating the relevant flags (e.g. DMA<BL>_<#>_CUR_BUF and DMA<BL>_<#>_BUF_RDY). If the answer is no, the FSU moves to pause mode and pauses the task waiting until the next frame can be served.

5. Disabling

   When the task is disabled by the MCU (by negating the enable bit), it moves back to non-active mode.

42.3.12.2.3 FSU's fundamentals

Trigger source select

A flow is triggered by a trigger. The trigger may be asserted manually by the MCU or may be a result of the completion of the preceding task. Trigger's source select choose the source of the trigger. The trigger means that the data is ready to be processed by the sub module. The trigger source select is defined by the corresponding SRC_SEL bits of the module or task.

Trigger destination select

A module or task that process data needs to know that the following task in the chain is ready to receive the processed data. The user needs to specify what is the destination of the processed data. This is done by setting the corresponding DEST_SEL bits of the module or task.

Double buffering

The IPUv3EX supports double buffering in the system's memory. When a flow is processed frame by frame the first frame will be read from one location (BUF0) in the memory, the next frame will be read from another location in the memory (BUF1). The location in the memory of the buffers is defined by the EBA0 and EBA1 parameters of the corresponding channel in the CPMEM. The IDMAC use the correct buffer according to the DMA_CH_CUR_BUF_# signal. The FSU automatically toggles the DMA_CH_CUR_BUF_# to point on the correct buffer to be used by the channel. In order to work in double buffer mode the corresponding DMA_CH_DB_MODE_SEL_# needs to be set.

Alternative flow

Some of the IPUv3EX sub modules can handle 2 flows via them one is the main flow and the other is the alt flow. In order to support an alternate flow via the same module an alternative configuration should be used by the module. This includes

- Alternate registers including an alternative module's setup - this is handled by the SRM
- Alternate IDMAC settings: parameters in the CPMEM, separate alpha
- Alternate SRC_SEL as the source of the trigger may come from a different function.
- Alternate FSU settings (CUR_BUF, BUF_RDY, DB_MODE_SEL)
- Some of the display modules alternate settings are handled by programming an alternative set of registers.

The FSU handles the switch to the alternate flow, it controls the update of the alternate configuration and send the appropriate signals to other modules in the IPUv3EX indicating about a need to switch to the alternate configuration.

Once a frame is completed there is a chance that there are 2 buffers ready. One is the next buffer of the current flow and the other is the a buffer in an alternate flow. The FSU will automatically select between the next buffer to handle in a round-robin fashion.

IPU task chaining - Single flow

The diagram below illustrates task chaining in the IPUv3EX. In this example a single flow is handled

The Frames are coming from the same camera module. The frames are handled frame by Frame. The first frame arriving Frame0 is stored in BUF0 of the "INPUT BUFFER". Once the Frame0 is ready in BUF0, the processing module is triggered and data is read from BUF0 to the processing module. In the meantime, Frame1 coming from the camera is written to BUF1 of the "INPUT BUFFER". The processing module processes the data and stores the first frame on BUF0 of the "OUTPUT BUFFER". Once the processing is done and the frame is ready, the display module is triggered to pick the data and send it to the display.

The processing module will start working on the next frame once the data is ready in the “INPUT_BUFFER” and there’s a free buffer in the “OUTPUT_BUFFER”.

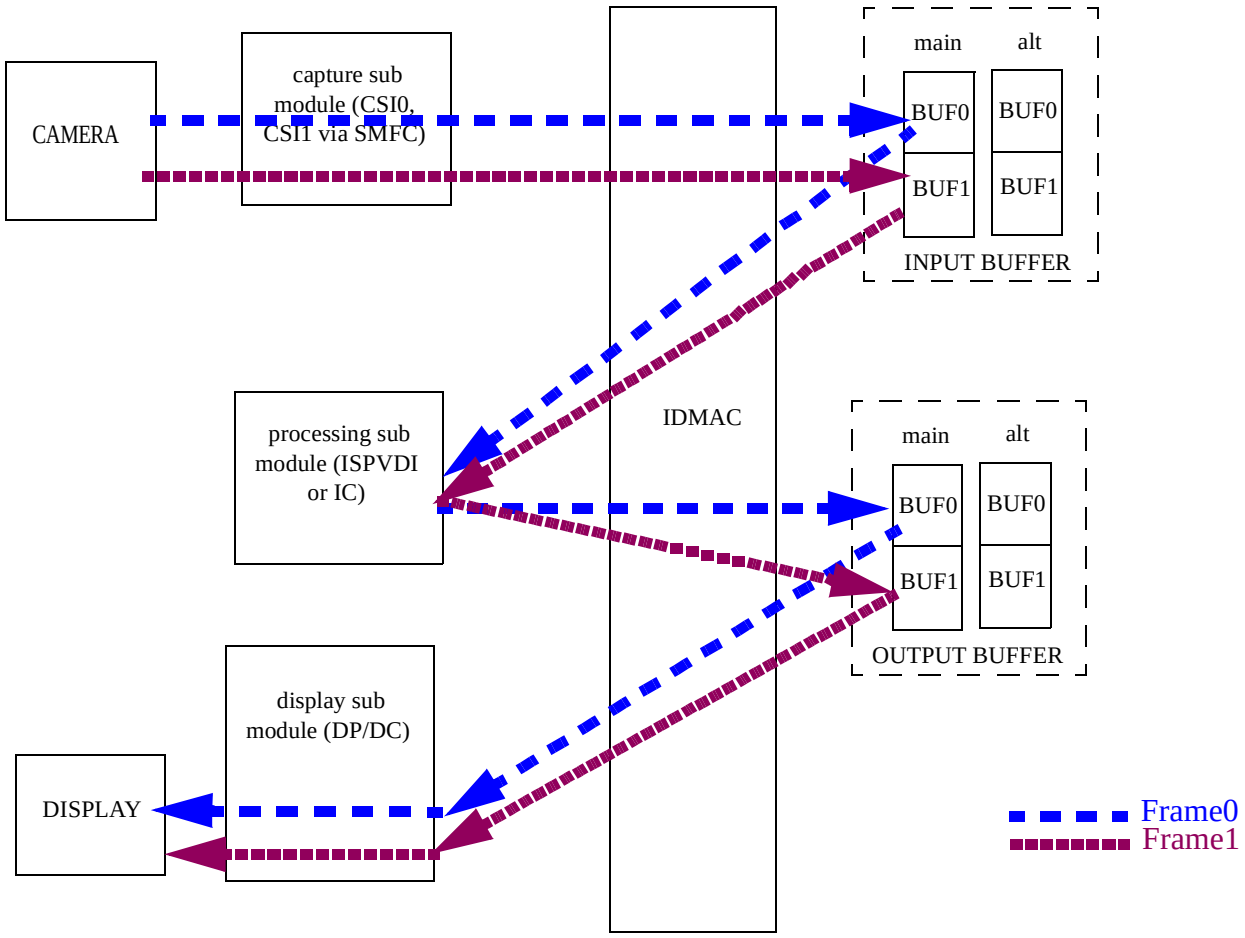

Figure 42-460. IPUv3EX **tasks’ chaining illustration - single flow**

IPUv3EX **task chaining - double flow**

The diagram below illustrates task chaining in the IPUv3EX. In this example double flow is handled. In addition to the flow described on the previous example, another flow is handled via the display modules. In that case the DC will handle 2 flows. Once sending Frame0 to the display is complete, the FSU will decide in whether to handle Frame1 or Frame0_ALT. The decision is made according the readiness of the other buffers in the memory, in case of 2 ready buffers (main flow and alternate) the FSU will switch between them in a round robin fashion.

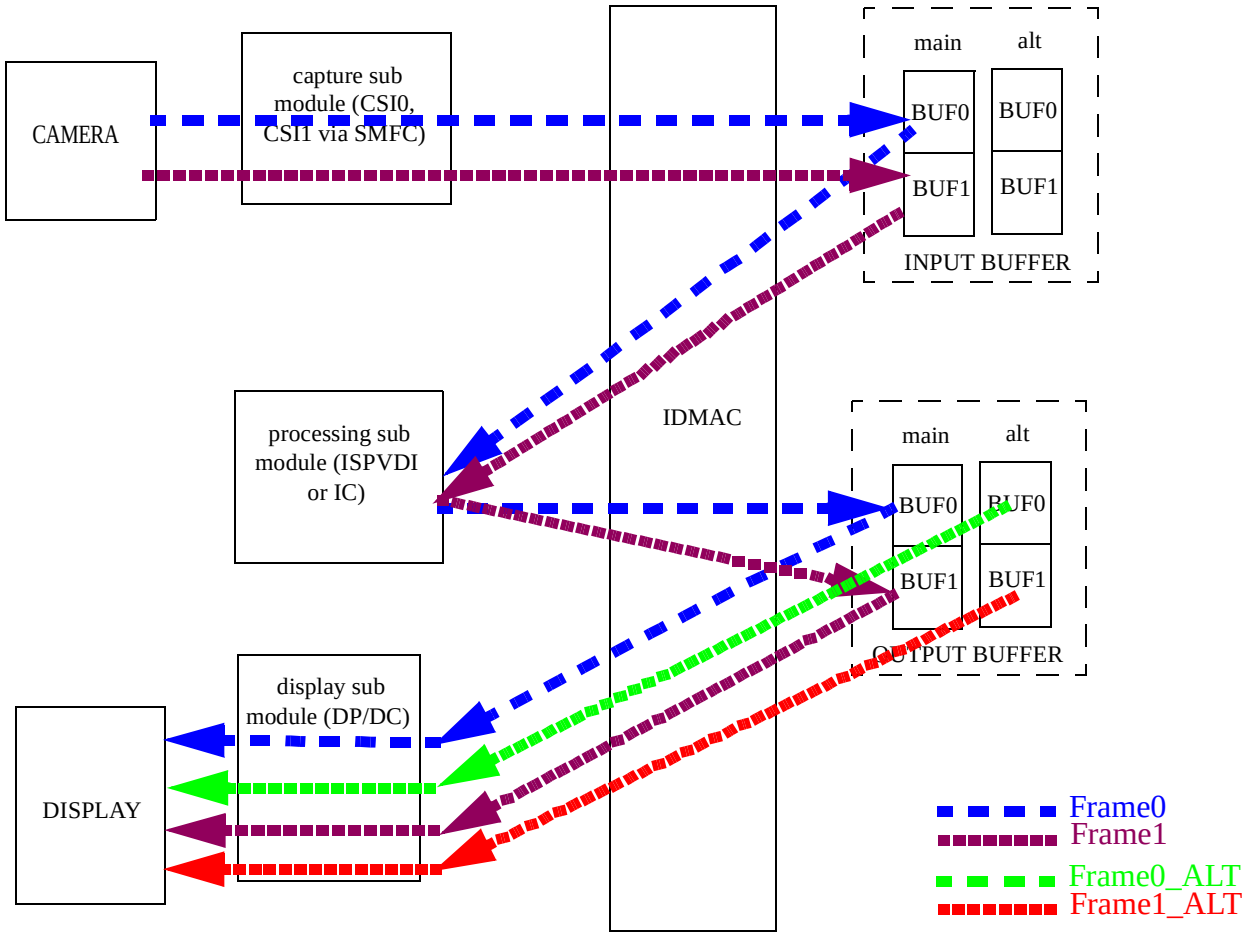

Figure 42-461. IPUv3EX **tasks' chaining illustration - double flow**

42.3.12.2.4 IPUv3EX **main flows**

IPUv3EX's flows can be partitioned into 5 groups

- CF - capture flows
- PF - processing flows
- SF - synchronous display flows
- AF - Asynchronous display flows
- DF - Direct flow from IC to the display

Tasks from different groups can be chained as illustrated below.

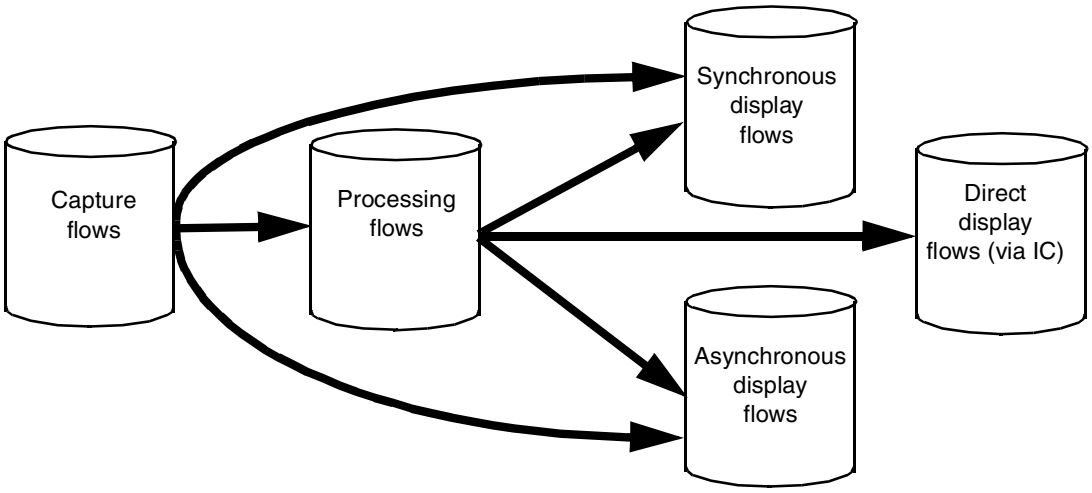

Figure 42-462. IPUv3EX **task flows chaining**

The tables below describe the most important use cases of chaining the IPUv3EX tasks. The tables show the main task for each group.

The physical DMA channel is the DMA channel that is used for the main flow - this is the IDMAC channel that is physically connected to the module - the CPMEM parameters should be configured according to the physical channel number. In case of an alternate flow then an alternate entry in the CPMEM should be configured as well

Table 42-428 describes capturing flows where data is captured from the sensor and sent to the memory without processing. This flows can be chained to the processing and display flows described on: Table 42-429, Table 42-430, Table 42-431 and on Table 42-432.

Table 42-428. IPUv3EX**'s capture flows**

	Flow	Tasks chain	Physical DMA Channels		
			Video Input	Other Input	Output
1.	Capturing image from sensor and storing it in the memory (via SMFC) without processing	CSI0 or CSI1 --> SMFC --> MEM	---	---	IDMAC_CH_0 IDMAC_CH_1 IDMAC_CH_2 IDMAC_CH_3

Table 42-428. IPUv3EX's capture flows (continued)

	Flow	Tasks chain	Physical DMA Channels		
			Video Input	Other Input	Output
2.	Capturing image from sensor and storing it in the memory (via IC) without processing	CSI0 or CSI1 --> MEM	---	---	IDMAC_CH_5
3.	Capturing interlaced input and storing it in the memory (via VDI) while performing video de-interlacing in the VDI.	CSI0 or CSI1 -> VDI --> MEM		IDMAC_CH_9 IDMAC_CH_10	IDMAC_CH_5 IDMAC_CH_13
		Interlaced input coming from one of the CSIs is sent to the memory without processing via channel #13. In addition 2 more inputs are read from the memory via channels 9 and 10. The processed image is written to the memory via ch 5 in progressive scan mode.			

Table 42-429 describe processing flows via the IC . This flows can start from the memory, can be chained to a capturing flow described on Table 42-428. The target of this flow can be chained to the display flows described on Table 42-430 and on Table 42-431.

Table 42-429. IPUv3EX's Processing flows

	Flow	Tasks chain	Physical DMA Channels		
			Video Input	Other Input	Output
4.	Preprocessing image from sensor for encoding	CSI0 or CSI1 --> SMFC --> MEM	---	---	IDMAC_CH_0 IDMAC_CH_1 IDMAC_CH_2 IDMAC_CH_3

	Flow	Tasks chain	Physical DMA Channels		
			Video Input	Other Input	Output
4.	Asynchronous display refresh via DC	MEM --> DC	IDMAC_CH_28	---	---
5.	Asynchronous display refresh via DC	MEM --> DC	IDMAC_CH_41	---	---
6.	Asynchronous display refresh via DC	MEM --> DC	IDMAC_CH_28	IDMAC_CH_42 (command)	---
		Comment: IDMAC_CH_42 can be optionally used as command channel associated with IDMAC_CH_28			
7.	Asynchronous display refresh via DC	MEM --> DC	IDMAC_CH_41	IDMAC_CH_43 (command)	---
		Comment: IDMAC_CH_43 can be optionally used as command channel associated with IDMAC_CH_41			
8.	Asynchronous display refresh via DP	MEM --> DP ASYNC	IDMAC_CH_24	IDMAC_CH_42 (command)	---
		Comment: IDMAC_CH_42 can be optionally used as command channel associated with IDMAC_CH_24			
9.	Asynchronous display refresh via DP	MEM --> DC	IDMAC_CH_24	IDMAC_CH_43 (command)	---
		Comment: IDMAC_CH_43 can be optionally used as command channel associated with IDMAC_CH_24			
10.	Reading data from asynchronous display	DC --> MEM	---	---	IDMAC_CH_50

Table 42-432 describes direct flows via the IC. These are processing flows via the IC where the output is sent directly to the DMFC. From that point the any of the display flows described on Table 42-430 and on Table 42-431 can be chained.

Table 42-432. IIPUv3EX direct flows to the display via the IC

	Flow	Tasks chain	Physical DMA Channels		
			Video Input	Other Input	Output
1.	Rotation and preprocessing of image from sensor for viewfinder and displaying it on synchronous display via DP	CSI0 or CSI1 --> SMFC --> MEM	---	---	IDMAC_CH_0 IDMAC_CH_1 IDMAC_CH_2 IDMAC_CH_3
		MEM --> IC (ROT VF) --> MEM	IDMAC_CH_46	---	IDMAC_CH_49
		MEM --> IC (PRP VF) --> DMFC	IDMAC_CH_12	IDMAC_CH_14	Direct to the DMFC
		MEM --> DP SYNC (BG/FG)	IDMAC_CH_23 /IDMAC_CH_27	IDMAC_CH_44 (mask)	---
2.	Rotation and preprocessing of image from sensor for viewfinder and displaying it on asynchronous display via DP	CSI0 or CSI1 --> SMFC --> MEM	---	---	IDMAC_CH_0 IDMAC_CH_1 IDMAC_CH_2 IDMAC_CH_3
		MEM --> IC (ROT VF) --> MEM	IDMAC_CH_46	---	IDMAC_CH_49
		MEM --> IC (PRP VF) --> DMFC	IDMAC_CH_12	IDMAC_CH_14	Direct to the DMFC
		MEM --> DP SYNC (BG/FG)	IDMAC_CH_24 /IDMAC_CH_29	command channel	---
3.	Preprocessing image from sensor for viewfinder and direct displaying it on asynchronous display	CSI0 or CSI1 --> SMFC --> MEM	---	---	IDMAC_CH_0 IDMAC_CH_1 IDMAC_CH_2 IDMAC_CH_3
		MEM --> IC (PRP VF) --> DC	IDMAC_CH_12	IDMAC_CH_14	---
4.	Preprocessing image from sensor for viewfinder and direct displaying it on asynchronous display	CSI0 or CSI1 --> IC (PRP VF) --> DC	---	IDMAC_CH_14	IDMAC_CH_21
5.	Preprocessing image from sensor for viewfinder and direct displaying it on asynchronous display via DP	CSI0 or CSI1 --> IC (PRP VF) --> DP ASYNC	---	IDMAC_CH_14	IDMAC_CH_21

Table 42-432. IIPUv3EX direct flows to the display via the IC (continued)

	Flow	Tasks chain	Physical DMA Channels		
			Video Input	Other Input	Output
6.	Capturing interlaced input via CSI, then perform video de-interlacing in the VDI. Then processing in the IC and direct displaying it on asynchronous display via DP	CSI0 or CSI1 -> VDI --> IC (PRP VF) --> DP ASYNC	--	IDMAC_CH_9 IDMAC_CH_10 IDMAC_CH_14	IDMAC_CH_13 IDMAC_CH_21
		Interlaced input coming from one of the CSIs is sent to the memory without processing via channel #13. In addition 2 more inputs are read from the memory via channels 9 and 10. The processed image is sent to the IC for further processing then it is sent to the display			
7.	Capturing interlaced input via CSI, then perform video de-interlacing in the VDI. Then processing in the IC and direct displaying it on asynchronous display	CSI0 or CSI1 -> VDI --> IC (PRP VF) --> DC	--	IDMAC_CH_9 IDMAC_CH_10 IDMAC_CH_14	IDMAC_CH_13 IDMAC_CH_21
		Interlaced input coming from one of the CSIs is sent to the memory without processing via channel #13. In addition 2 more inputs are read from the memory via channels 9 and 10. The processed image is sent to the IC for further processing then it is sent to the display			

42.3.12.2.5 Snooping

This function allows to reduce the rate of write accesses from the system memory to a smart display. When snooping is enabled, writing to the display is performed only if the corresponding system memory buffers has been changed. Any change of data in the system memory buffers is registered by the External Memory Controller of the chip. When writing to the system memory is performed, the External Memory Controller asserts the emi_snooping1 or emi_snooping2 pins of the IPUv3EX. After receiving these signals, the CM initiates transfer of the corresponding buffer to a display buffer, either in system's memory or in a smart display. Selecting the snooping mechanism as the trigger for the flow is done by setting the <>_SRC_SEL bits of the corresponding flow to snoop1 or snoop2 mode.

The emi_snooping1 and emi_snooping2 signals are synchronized to the IPUv3EX's clock. The synchronize on the emi_snooping2 signal can be bypassed by setting the bit SNOOP2_SYNC_BYP bit.

42.3.12.2.6 Automatic Window Refresh

By programming the <>_SRC_SEL bits of the corresponding flow to autoref mode, automatic refresh of a window on the smart display is enabled. This means that the flow is triggered any time the refresh counter completes its counting. The refresh period is defined via the AUTOREF_PER field (the time unit is 2^{17} periods of the HSP_CLK clock). The actual value of refresh period is equal to

$$T_{HSP}*2\text{^}17\ *(AUTO\_REF\_PER+1). \qquad \textit{Eqn. 42-15}$$

42.3.12.2.7 Autorefresh and snooping

Auto-refresh can be conditional. In this case, it is accomplished emi_snooping1 or emi_snooping2 pins of the IPUv3EX are asserted. This is defined by setting the <>_SRC_SEL bits to autoref+snoop1 or autoref_snoop2 mode.

42.3.12.2.8 Synchronization with A Video/Graphics source

The IPUv3EX supports direct synchronization with a video/graphics source (e.g. an integrated graphics accelerator, rendering graphics frames). Up to three frame buffers are supported for this synchronization. It is performed using the following signals

- The source instructs the IPUv3EX which frame should be transferred to the display by providing a 3 bit one-hot vector.
- The IPU notifies the source which frame is currently transferred to the display by providing a 3 bit one-hot vector.
- The IPU provides to the source an end-of-frame trigger (after which it switches to the frame indicated by the source).

This mechanism is provided for the main plane of the primary flow to the DP (ch 23). The SRC_SEL of this channel has to be defined as external source.

Triple buffer mode is enabled by setting the channel's corresponding bit on IPU_CH_TRB_MODE_SEL register. Setting this bit overrides the channel's corresponding settings on the IPU_CH_DB_MODE_SEL register. The CPMEM's settings of the corresponding channel can hold 2 pointers for 2 buffers (EBA0 and EBA1). The third pointer resides on an alternate entry in the CPMEM. The pointer to the alternate entry is defined by the channel's corresponding IDMAC_SUB_ADDR field. EBA0 of the alternate entry in the CPMEM is used as a third pointer. All the other settings of alternate entry in the CPMEM must be the same as the channel's standard entry in the CPMPM.

Once the channel reached end-of-frame event, the FSU automatically switch between pointers according to the signals coming from the source and notifies the source that the IPUv3EX reached the end-of-frame.

IPUv3EX has 2 identical bridges allowing direct synchronization with 2 sources. The 2 bridges support exactly the same protocol.

42.3.12.3 Interrupt Generator

The IG produces two interrupts to the MCU - the functional interrupt and the error interrupt. All the interrupts are maskable.

Table 42-433 describes the functional interrupts.

Table 42-433. Functional Interrupts Summary

Table 42-434 describes the error interrupts. The panic column indicates if this signal is part of the logic generating the ipu_panic signal. The ipu_panic signal can be used for indicating about errors that are result of data rate problems. Such problems may be a result of the IPUv3EX running in slower clock then required by the use case. This signal can be used in order to indicate the system that the IPUv3EX can't handle the desired data rate. In that case the system may need to increase the clock to the IPUv3EX or simplify the use case.

Table 42-434. Error Interrupts Summary

42.3.12.4 SDMA event generator

The IPUv3EX provides an SDMA event signal that can be used as trigger to the SoC's SDMA. IPUv3EX routes an internal event to the SDMA event signal. The internal event causing the assertion of the SDMA signal is enabled by setting the corresponding bit on the IPU_SDMA_EVENT_# registers. The user is allowed to enable multiple events. When one of these events occurs the ipu_sdma_event signal will be asserted. Similar to interrupts, the ipu_sdma_event signal is cleared by writing one to the corresponding bit in the IPU_INT_STAT_# registers.

It is not recommended to use the same internal event for a simultaneous generation of an interrupt signal and an SDMA event. This will require special software care when clearing the corresponding bit in the IPU_INT_STAT_# registers.

42.3.12.5 General Configuration Registers

The GCR contains a set of control/status/data registers. It provides IPUv3EX interface to the AHB slave bus. The HCLK rate is equal to the HSP_CLK rate. The detail description of the registers is found in Section 42.2.1, "Memory Map"."

42.3.12.6 Shadow Registers Module (SRM)

IPUv3EX supports frame by frame task switching. This means that a sub module can handle a frame with one configuration and handle the following frame with different configuration. Changing the configuration is done by updating the module's parameters. In order to allow automatic flow without a need of the SW to update all the parameters at the frame boundaries.A Register of a module that has the shadowing capabilities has a shadow register file that resides in the Shadow Register Memory.

The modules supporting this function may use it in one of the following ways:

42.3.12.6.1 Switching between 2 flows

Upon request from the FSU the SRM switches between the registers and the content in the Shadow Register Memory. When a module use one of the configuration SW is allowed to update the parameters in the memory. This is normally used when 2 flows are supported via one module.

- The current flow's configuration is stored in the module's registers
- The alternate flow configuration is stored in the SRM.
- When switching between flows the current flow's configuration is stored in the SRM. The alternate flow's configuration is written to the module's registers. When the alternate flow ends the configurations are swapped again.

This process is fully controlled by the FSU

42.3.12.6.2 Updating parameters between frames

This mode is used when the user needs to update the parameters of the current task being processed by the module. The updates can't affect the frame that is currently being processed. The update is effective only on the next frame. The SRM performs the parameters update only when there's a specific request by the user.

- The current frame's configuration is stored in the module's registers
- The next frame's configuration is stored in the SRM.
- On frame's boundary the SRM reads the new configuration from the SRM and writes it to the module's registers. The old configuration is lost.

42.3.12.6.3 Updating the memory

In order to avoid data coherency problems, the user should set a flag indicating that he is currently updating the memory region of a specific module. When the flag is set the SRM will not attempt to replace the parameters relevant to the specific module currently being updated by the user.

The user should clear this flag when he completes the update, and the parameters are ready to be used.

The flag is the corresponding SRM_MODE field for each module. This field controls the SRM logic that handles the modules registers

- 00 - MCU is allowed to access the module's region in the RAM; The automatic swapping mechanism is disabled.
- 01 - The SRM logic is controlled by the FSU. The update will be done of the next frame.
- 10 - The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame
- 11 - Update now. The SRM is controlled by the MCU. The Register will be update now

Each module uses the SRM mechanism according to the modules behavior, the table below summarizes the SRM support for each module

Table 42-435. SRM support per module

Module	Switching between 2 flows support	Updating parameters between frames	comment
CSI1, CSI0	NO	YES	SRM_MODE can be 00 or 01. The update will happen only once. When set to 01: after the update the state machine is automatically moved to 00 mode. It is recommended to make sure that the first frame has started by polling the corresponding NFACK bit before setting the SRM_MODE
DI1, DI0	NO	YES	DI0, DI1 parameters are needed when clock change is performed (See: 42.3.12.9 Clock Change procedure). SRM_MODE can be 00 or 01. The update will happen only once. When set to 01: after the update the state machine is automatically moved to 00 mode

Table 42-435. SRM support per module

Module	Switching between 2 flows support	Updating parameters between frames	comment
DC	YES	NO	SRM_MODE can be 00 or 10.
DP	YES	NO	SRM_MODE can be 00, 10 or 11. When set to 11: after the update the state machine is automatically moved to 10 mode 10 is not supported for SYNC flows

In order to update parameters the user should monitor the SRM_BUSY bit of the corresponding module. When the SRM is not busy the user should set the SRM_MODE to 00. The user will now update the register file in the memory. When done the user should switch the SRM_MODE field to the desired mode.

42.3.12.6.4 SRM priority

The SRM updates the registers according to a pre defined priority. The priority is set according to the SRM_PRI bits of each module. The user must set a unique value for each module.

42.3.12.6.5 SRM entries mapping

The table below maps any IPUv3EX register to an address in the SRM. The registers marked as NONE do not have an SRM entry

PG column indicates if this register is saved during power gating mode

LPSR column indicates if this register is swapped during low power screen refresh mode (LPSR)

.

Table 42-436. IPUv3EX SRM entries mapping

42.3.12.7 Memory Access Unit

The Memory Access Unit (MA) supports MCU access to the IPUv3EX internal memories. Some of the IPUv3EX

internal memories are memory mapped. This unit handles accessing these memories. The table below describe the accessible memories and their limitations.

Table 42-437. Internal Memories Access Support and Limitations

Memory	Function	Support and Limitations
lut	IDMAC's look up table	Accessible only when All the IDMAC channels that use the LUT are disabled
cpmem	IDMAC's Channel parameter Memory	This memory can be accessed while tasks are enabled. Must be configured before enabling processing tasks. IDMAC channel parameters must not be changed in the CPM when the corresponding DMA channel is enabled excluding the base addresses (EBA0 and EBA1). One of these parameters can be changed during channel operation if it relates to the non-active double buffer.
tpm	IC's task parameter memory	Must be configured before enabling processing tasks. This memory can be accessed while tasks are enabled. IC task parameters must not be changed in the TPM when the corresponding task is active.
dc_template	DC's template memory	Can be configured before enabling tasks. Must not be accessed while operation. Both read and write access to the DC's template memory are forbidden when there is any enabled channel which can use the template

42.3.12.8 SISG - Still Image Synchronization Generator

The IPUv3EX incudes a "Still Image Synchronization Generator" (SISG), providing time-sensitive control signals synchronizing the image sensor with camera peripherals, such as a flash lamp and a mechanical shutter.

The SISG is implemented using a single time base counter, and six Time Compare Units - as described in Figure 42-463.

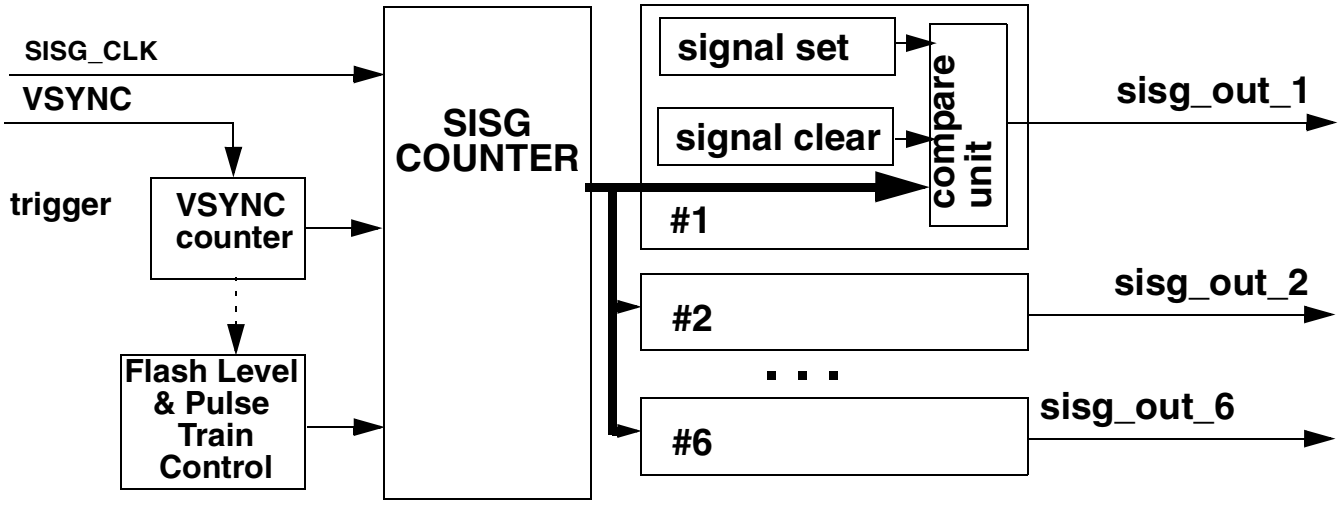

Figure 42-463. Still Image Signal Generator

The SISG inputs are

- Activation trigger
- VSYNC: the frame-boundary signal from the sensor.

The SISG is activated by one of the following triggers

- The MCU by setting the MCU_ACTV_TRIG bit
- An external signal (GPIO pin).

Upon activation, the counter is reset and then there are the following two possibilities

- Counting starts immediately
- Counting start is delayed until one of the next 7 VSYNC signals (programmable via the NO_OF_VSYNC bits).

During the counting period, the SISG can generate up to 6 output strobes.

- Each strobe can be individually enabled or disabled and has a programmable polarity
- The edges of the strobes are generated at specified counter values - to achieve pixel-level resolution - as specified by programmable SISG_SET& SISG_CLR time tag registers.
- The clock has 25 bits, to allow strobe generation during a time period of up to two 12M pixel frames

The SISG can repeat the above sequence for up to 32 cycles (this is provided to generate a train of flash pulses, for anti-red-eye or for measurements in low-light conditions). The repetition is implemented by resetting the counter and this can be triggered by one of the following events:

- A VSYNC signal
- A pre-defined value reached by the counter.

After the last sequence, when the counter reaches its maximal value, it stops counting and the SISG remains in idle mode until the next activation.

42.3.12.9 Clock Change procedure

The IPUv3EX supports dynamic clock rate changes.

Types of change:

- DVFS transitions: frequent, initiated by the SoC's power modes controller (GPC) and the SoC's clock controller module (CCM)
- Other: infrequent, initiated by SW.

IPUv3EX may have on-going activities at this stage.

The display interface clocks may either change or remain unchanged. During screen refresh, the display clock would typically not change. During asynchronous access, it may be appropriate to change also the display interface clock. The choice between these options would be made in advance by the user

If the IPUv3EX display interface uses the external clock (ipp_di_0_ext_clk or ipp_di_1_ext_clk) source, it remains unchanged. A change in the rate of this clock is performed fully by SW, without the special HW support described below. In particular, the SW may have to stop explicitly any interaction with the display (e.g. screen refresh) before performing the change.

The user is responsible to make sure that the lowest planned clock (in DVFS transitions) is still high enough to support the expected activities (e.g. data rate through the display bus)

The procedure below describes the IPUv3EX handshaking with the CCM.

1. The user prepares 2 sets of clock modes CLOCK_MODE_0 is the default clock mode, CLOCK_MODE_1 is the alternate clock mode. The IPUv3EX toggles between these two settings following the next assertion of ipg_clk_change_rq. If the user sets the SRM_CLOCK_CHANGE_MODE bit then he should also prepare the registers in the SRM for each of the DIs. These registers include all the DI settings adjusted to the new clock.
2. CCM asserts the ipg_clk_change_rq signal when a clock change is needed
3. The CM calculates the new clock frequency and send it to the DI (signals are di0_clk_freq, and di1_clk_freq). These signals should be sent to the DI only after getting the di_clk_change_ack signal from the DIs. The values of this field could be.
    - 00 - 1/4 of full frequency
    - 01 - 1/2 of full frequency
    - 10 - full frequency
    - 11 - illegal
4. The CM sends a cm_clk_change_rq signal to the DIs.
5. The DI stops the clock to the display (freeze mode) according to DI0_CLOCK_STOP_MODE & DI1_CLOCK_STOP_MODE bits. If the DI is disable, the ACK from the DI is not needed and the CM will assume that the DI sent an ACK.

6. Once the clock to the display is stopped, the DI sends a signal to the CM called di_clk_change_ack
7. The CM wait for the clock change signals from both of the DIs
8. If the SRM_CLOCK_CHANGE_MODE bit is set the CM should read the new DI settings from the SRM and override the previous DI settings. Then the CM clears the SRM_CLOCK_CHANGE_MODE bit
9. Once the above is complete the CM asserts the ipg_clk_change_ack signal to the CCM
10. The CM sends the signals di0_clk_freq, and di1_clk_freq to the DIs.
11. The CCM will negate the cm_clk_change_rq
12. The CCM will now change the clocks
13. When the new clock arrives the ipu_clk_changed signal will be asserted.
14. The state machine on each DI will now move out of freeze mode and continue working with the new clock.

42.3.12.10 Low Power Modes - Stop, PG and LPSR modes

IPUv3EX supports 3 low power modes

- STOP: on this mode the clock to the IPUv3EX is stopped
- PG: power gating, where the clock to the IPUv3EX is stopped and the power is for the IPUv3EX is turned off. Some of the memories are kept powered, so the wake up from this mode will be faster.
- LPSR: low power screen refresh.The clock to the IPUv3EX is changed to a slower frequency, the IPUv3EX performs only screen refresh.

The user should not request both LPSR and PG. at the same time. This case is not supported and the results are not predictable.

The CCM may assert one of the 2 signals: stop_clk_at_stop_req OR stop_clk_at_wait_req

The IPUv3EX OR them internally as there's no difference between them with regards to IPUv3EX's behavior.

In all these modes the clock to the IPUv3EX is going to be stopped (assertion of stop_clk_at_stop_req).

IPUv3EX should complete all his tasks:

- CSIs complete transferring the last frame. Wait for csi_busy = 0
- IDMAC completes all the flows (all CH_BUSY = 0)
- All the flows in the FSU are complete. New ones do not start.
- CM sends stop request to the DIs
- Once the DI sent all the data to the display, it asserts an ACK signal

Only when all the above occurs, the CM can assert an internal signal called "IPU_IDLE"

IPU_IDLE is the starting point for any of the low power modes.

42.3.12.10.1 STOP Mode

In this mode the IPUv3EX sends the ipu_stby_ack after getting to IPU_IDLE state. The CCM will gate off the clock to the IPUv3EX.

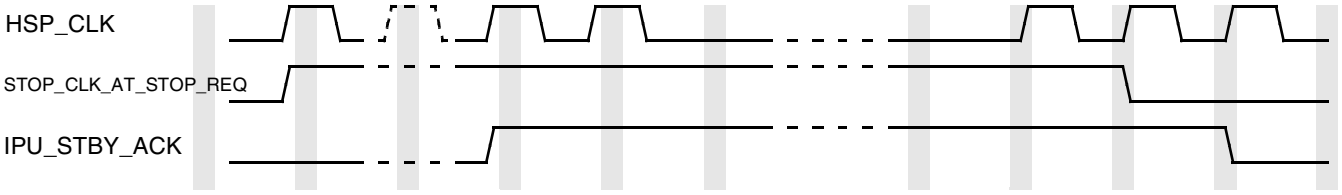

Figure 42-464. Entering and Exiting STOP Mode

Wake up from STOP mode

When the SoC decides to wake up from STOP mode it should

- Resume the clock to the IPUv3EX
- Negate the stop_clk_at_stop_req or stop_clk_at_wait_req signal.
- The IPUv3EX will then negate the ipu_stby_ack signal
- The IPUv3EX will resume screen refresh.

42.3.12.10.2 Power Gating

On power gating mode the clock to the IPUv3EX is stopped and part of the IPUv3EX is powered down. Only the memories that are essential for a quick and smooth wake up are kept powered.

The procedure for entering PG mode is the similar to the procedure for entering STOP mode.

1. If the stop request is asserted and the "gpc_pg_ipu" signal is asserted then we are entering PG mode.
2. The IPUv3EX follows the same process as on STOP mode till getting into IPU_IDLE state.
3. The IPUv3EX saves in the SRM the content of the registers of the modules participating in screen refresh. The modules are:
   - DI0 & DI1
   - DC
   - DP
   - DMFC
   - IDMAC
   - IC
   - CM
4. After saving the registers the IPUv3EX will send the ipu_stby_ack signal to the CCM.

5. The CCM will gate off the clock to the IPUv3EX.
6. The GPC will gate off the power to the IPUv3EX. The memories listed below are needed for quick and smooth wake up, therefore the memories listed below are kept powered.

Table 42-438. Memories that are Powered at PG mode

Sub Module	Instance name	Description
IDMAC	ipu_memories_lut0 ipu_memories_lut1	Look UP table memory
IDMAC	ipu_memories_cpmem	Channel parameter memory
CM shadow	ipu_memories_srm	Shadow registers memory
IC + IRT	ipu_memories_tpm	IC's task's parameters memory
DC	ipu_memories_dc_template	DC's template

Wake up from PG mode

1. The GPC resumes power to the IPUv3EX
2. The GPC drives the signal gpc_ipu_pwgtd indicating that the IPUv3EX wakes up from PG mode.
3. The SoC's reset controller resets the IPUv3EX by asserting the ipg_hard_async_reset_b signal.
4. The CCM resumes the clock to the IPUv3EX.
5. The IPUv3EX reads the registers from the SRM and write the content to the module's registers.
6. The IPUv3EX sends the ipu_wakeup_ack to the CCM indicating that the wake up procedure is complete. This signal is negated when gpc_ipu_pwgtd is negated.
7. The IPUv3EX resumes screen refresh.

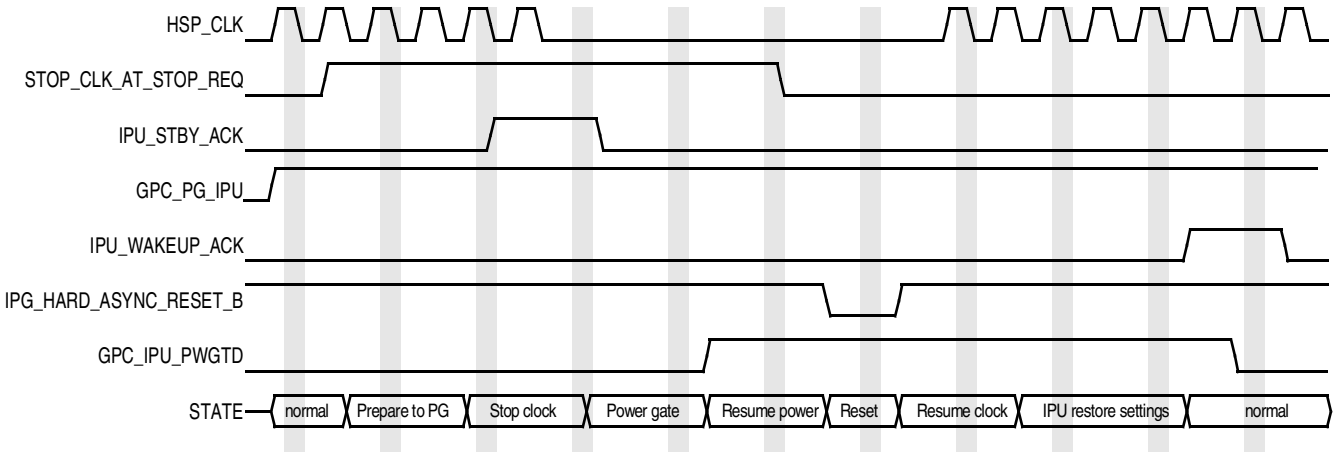

Figure 42-465. Entering and Exiting PG mode

42.3.12.10.3 Low Power Screen Refresh mode - LPSR

On Low Power Screen Refresh mode, the clock to the IPUv3EX is changed to a slower frequency, the IPUv3EX performs only screen refresh to a single display via the DP (channels 23 & 27).

Preparations

1. The user sets the LPSR_MODE bit indicating that the next assertion of stop_clk_at_stop_req OR stop_clk_at_wait_req activates the LPSR procedure.
2. The user moves the IPUv3EX to screen refresh flow. This means that if other tasks are active (flows via CSI, SMFC, or multiple flows to multiple displays) - this tasks needs to be complete and disabled. This is step is fully done by the user (SW). The only flow that remains active is screen refresh to a single display done via the DP (channels 23 & 27)
3. The user stores in the SRM the planned configuration for the modules involved in the LPSR flow. These configuration will e switched with the active registers' settings on later stage. The relevant modules are:
   - DI0 & DI1
   - DC
   - DP
   - DMFC
   - IDMAC
   - CM

Entering LPSR

The flow for entering LPSR is the same as stop mode.

1. The IPUv3EX follows the same procedure as on STOP mode till getting into IPU_IDLE state.
2. IPUv3EX swaps the registers of the relevant modules with the pre stored content from the SRM. The content of the registers of the current flow is stored in the SRM. The IPUv3EX will switch back to this configuration after exiting from LPSR.
3. The IPUv3EX sends the ipu_stby_ack
4. The CCM will gate off the clock to the IPUv3EX.
5. The CCM will switch to the new clock
6. After changing the clock, the CCM asserts ccm_lpsr_ipu, this signal is synched inside the IPUv3EX to the hsp_clk
7. The IPUv3EX will resume screen refresh with the new settings.

Exit from LPSR

1. The CCM negates ccm_lpsr_ipu.
2. The CM sends standby request to the DI
3. The DI should complete processing the current frame and stop the clock to the display and send an acknowledge signal to the CM.

4. The SRM swaps the registers' configuration. current configuration (LPSR) is saved in the SRM, the previous (original) configuration is stored in the modules' registers.
5. IPUv3EX asserts the ipu_wakeup_ack signal indicating that it is now safe to leave LPSR mode.
6. CCM stops the clocks to IPUv3EX
7. CCM resumes the clock to the IPUv3EX - This clock is the same clock used prior to entering the LPSR mode.
8. CCM negates the stop_clk_at_stop_req (or stop_clk_at_wait_req)
9. IPUv3EX negates the ipu_stby_ack and the ipu_wakeup_ack signals
10. The IPUv3EX resumes screen refresh with the original settings.

The diagram below illustrates the procedure for entering and leaving LPSR mode

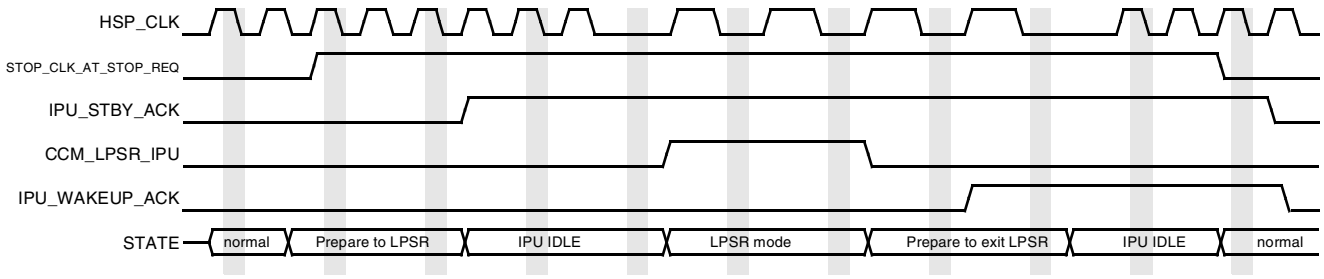

Figure 42-466. Entering and Exiting LPSR mode

42.3.13 IPUv3EX Diagnostics Unit

The IPUv3EX has a 16 bit diagnostic bus called ipu_diagbus. This bus can be connected at SoC level so these 16 outputs of the IPUv3EX can be routed to the SoC's pins and used for signals monitoring during debug.

The internal signals that can be monitored are internal status signals. There are 18 groups of signals. In order to route the selected group the user need to set the IPU_DIAGBUS_MODE and select the correct group. The modules are arranged in groups as described on the tables below.

Table 42-439. IPUv3EX diag bus groups 0-3

Chapter 43
Keypad Port (KPP)

43.1 Introduction

The Keypad Port (KPP) is a 16-bit peripheral that can be used as a keypad matrix interface or as general purpose input/output (I/O). Figure 43-1 shows the KPP block diagram.

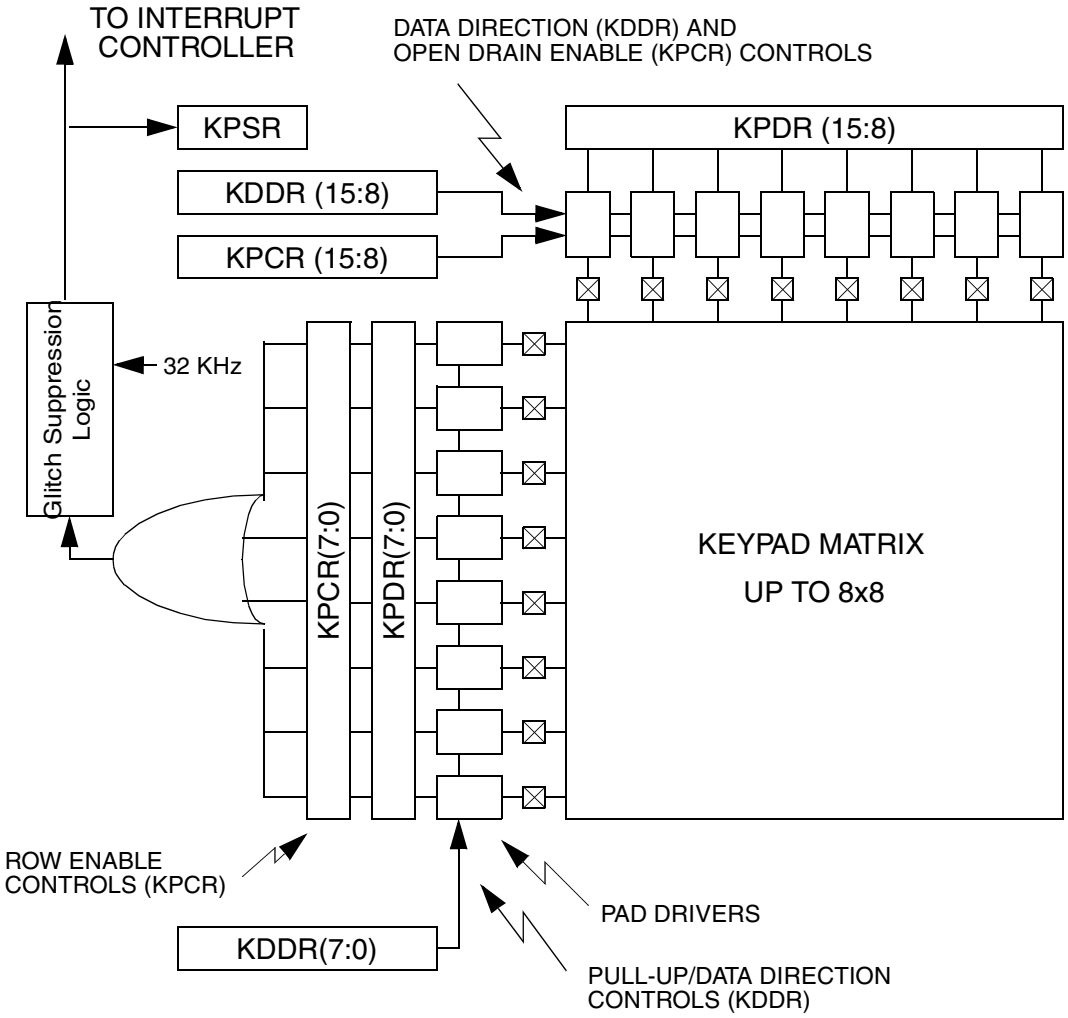

Figure 43-1. KPP Peripheral Block Diagram

43.2 Overview

The KPP is designed to interface with the keypad matrix with 2-point contact or 3-point contact keys. The KPP is designed to simplify the software task of scanning a keypad matrix. With appropriate software support, the KPP is capable of detecting, debouncing, and decoding one or multiple keys pressed simultaneously on the keypad.

43.2.1 Features

The KPP includes these distinctive features:

- Supports up to an 8×8 external key pad matrix
- Port pins can be used as general purpose I/O
- Open drain design
- Glitch suppression circuit design
- Multiple-key detection
- Long key-press detection
- Standby key-press detection
- Synchronizer chain clear
- Supports a 2-point and 3-point contact key matrix

43.2.2 Modes of Operation

This module supports the following modes of operation:

- Run Mode—This is the normal functional mode in which the KPP can detect any key press event.
- Low Power Modes—The keypad can detect any key press even in low power modes (when there is no MCU clock).

43.3 External Signal Description

There are 16 pins dedicated to the KPP. Keypads of any configuration up to eight rows and eight columns are supported through the software configuration of the peripheral pins. Any pins not used for the keypad are available as general purpose I/O. The registers are configured such that the pins can be treated as an I/O port up to 16 bits wide.

See Table 43-1 for the list of external signals.

Table 43-1. Signal Properties

Name	Port	Function	Reset State	Pull up
ipp_ind_col[7:0]	—	Column input pin, from chip	0	Active[1]
ipp_ind_row[7:0]	—	Row input pin, from chip	1	Active[1]
ipp_do_col[7:0]	—	Column output pin going to chip	0	—
ipp_obe_col[7:0]	—	Enables the corresponding column outputs	0	—

Table 43-1. Signal Properties (continued)

Name	Port	Function	Reset State	Pull up
ipp_ode_col[7:0]	—	Used to set the column outputs	0	—
ipp_do_row[7:0]	—	Row output pin going to chip	0	—
ipp_obe_row[7:0]	—	Enables the corresponding row output	0	—

[1] The corresponding pads are required to be pull-up enabled.

43.3.1 Input Pins

Any of the 16 pins associated with the KPP can be configured as inputs by writing a “0” to the appropriate bits in the KDDR. Additionally, the least significant 8 bits (ROW inputs) corresponding to KDDR7:0 have internal pull-ups, which are enabled when the pin is used as an input.

43.3.2 Output Pins

Any of the 16 pins associated with the KPP can be configured as outputs by writing the appropriate bits in the KDDR to a “1”. Additionally, the 8 most significant bits (15–8) can be designated as open drain outputs by writing a “1” to the appropriate bits in the KPCR. The lower 8 bits (7–0) are always in “totem pole” style, driven when configured as outputs. See Table 43-2.

Table 43-2. Keypad Port Column Modes

KDDR (15:8)	KPCR (15:8)	Pin Function
0	x	Input
1	0	Totem-Pole Output
1	1	Open-Drain Output

NOTE

Totem pole capability should be provided for column pins. Totem pole configuration helps for a faster discharge of keypad capacitance when all columns need to be quickly brought to a “1” during the scan routine. With this configuration, a time delay between the scanning of two subsequent columns is reduced.

43.4 Memory Map and Register Definition

The KPP module contains four registers. Section 43.4.3, Register Descriptions” provides detailed descriptions of the KPP registers.

43.4.1 KPP Memory Map

Table 43-3 shows the KPP memory map.

Table 43-3. KPP Memory Map

Address	Use	Access	Reset Value	Section/Page
0xBASE+0x000 (KPCR)	Keypad Control Register	R/W	0x0000	43.4.3.1/43-5
0xBASE+0x002 (KPSR)	Keypad Status Register	R/W	0x0000	43.4.3.2/43-6
0xBASE+0x004 (KDDR)	Keypad Data Direction Register	R/W	0x0000	43.4.3.3/43-7
0xBASE+0x006 (KPDR)	Keypad Data Register	R/W	0xXXXX	43.4.3.4/43-8

43.4.2 Register Summary

Figure 43-2 shows the key to the register fields and Table 43-4 shows the register figure conventions.

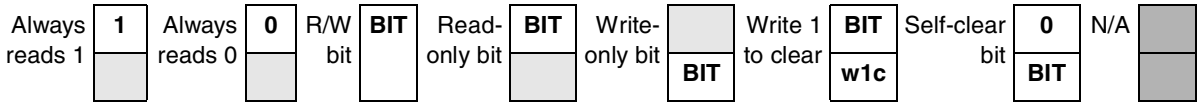

Figure 43-2. Key to Register Fields

Table 43-4. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 43-5 shows the KPP register summary.

43.4.3 Register Descriptions

This section consists of register descriptions. Each register is listed in the order of its address.

43.4.3.1 Keypad Control Register (KPCR)

The Keypad Control Register determines which of the eight possible column strobes are to be open drain when configured as outputs, and which of the eight row sense lines are considered in generating an interrupt to the core.

It is up to the programmer to ensure that pins being used for functions other than the keypad are properly disabled. The KPCR register is byte- or half-word–addressable.

Figure 43-3 shows the valid bits in the KPCR register, and Table 43-6 provides its field descriptions.

0xBASE+0x000 (KPCR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	KCO7	KCO6	KCO5	KCO4	KCO3	KCO2	KCO1	KCO0	KRE7	KRE6	KRE5	KRE4	KRE3	KRE2	KRE1	KRE0
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 43-3. KPCR Register

Table 43-6. Keypad Control Register Field Descriptions

Field	Description
15–8 KCO	Keypad Column Strobe Open-Drain Enable. Setting a column open-drain enable bit (KCO7–KCO0) disables the pull-up driver on that pin. Clearing the bit allows the pin to drive to the high state. This bit has no effect when the pin is configured as an input. 0 Column strobe output is totem pole drive. 1 Column strobe output is open drain. **Note:** Configuration of external port control logic (for example, GPIO) should be done properly so that the KPP module controls an open-drain enable of the pin.
7–0 KRE	Keypad Row Enable. Setting a row enable control bit in this register enables the corresponding row line to participate in interrupt generation. Likewise, clearing a bit disables that row from being used to generate an interrupt. This register is cleared by a reset, disabling all rows. The row-enable logic is independent of the programmed direction of the pin. Writing a “0” to the data register of the pins configured as outputs will cause a keypad interrupt to be generated if the row enable associated with that bit is set. 0 Row is not included in the keypad key press detect. 1 Row is included in the keypad key press detect.

43.4.3.2 Keypad Status Register (KPSR)

The Keypad Status Register reflects the state of the key press detect circuit. The KPSR register is byte- or half-word addressable.

Figure shows the KPSR register, and Table 43-7 provides its field descriptions.

0xBASE+0x002 (KPSR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 43-4. KPSR Register Diagram

Table 43-7. Keypad Status Register Field Descriptions

Field	Description
15–10	Reserved
9 KRIE	Keypad Release Interrupt Enable. The software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0 No interrupt request is generated when KPKR is set. 1 An interrupt request is generated when KPKR is set.

Table 43-7. Keypad Status Register Field Descriptions (continued)

Field	Description
8 KDIE	Keypad Key Depress Interrupt Enable. Software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice-versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0 No interrupt request is generated when KPKD is set. 1 An interrupt request is generated when KPKD is set.
7–4	Reserved, should be cleared
3 KRSS	Key Release Synchronizer Set. Self-clear bit. The Key release synchronizer is set by writing a logic one into this bit. Reads return a value of “0”. 0 No effect 1 Set bits which sets keypad release synchronizer chain
2 KDSC	Key Depress Synchronizer Clear. Self-clear bit. The Key depress synchronizer is cleared by writing a logic “1” into this bit. Reads return a value of “0”. 0 No effect 1 Set bits that clear the keypad depress synchronizer chain
1 KPKR	Keypad Key Release. The keypad key release (KPKR) status bit is set when all enabled rows are detected high after synchronization (the KPKR status bit will be set when cleared by a reset). The KPKR bit may be used to generate a maskable key release interrupt. The key release synchronizer may be set high by software after scanning the keypad to ensure a known state. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by software prior to the system exiting the state it represents. 0 No key release detected 1 All keys have been released Reset value of register is “0” as long as reset is asserted. However when reset is de-asserted, the value of the register depends upon the external row pins and can become “1”.
0 KPKD	Keypad Key Depress. The keypad key depress (KPKD) status bit is set when one or more enabled rows are detected low after synchronization. The KPKD status bit remains set until cleared by the software. The KPKD bit may be used to generate a maskable key depress interrupt. If desired, the software may clear the key press synchronizer chain to allow a repeated interrupt to be generated while a key remains pressed. In this case, a new interrupt will be generated after the synchronizer delay (4 cycles of the 32 KHz clock) elapses if a key remains pressed. This functionality can be used to detect a long key press. This allows detection of additional key presses of the same key or other keys. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by the software prior to the system exiting the state it represents. 0 No key presses detected 1 A key has been depressed

43.4.3.3 Keypad Data Direction Register (KDDR)

The bits in the KDDR control the direction of the keypad port pins. The upper eight bits in the register affect the pins designated as column strobes, while the lower eight bits affect the row sense pins. Setting any bit in this register configures the corresponding pin as an output. Clearing any bit in this register configures the corresponding port pin as an input. For the Keypad Row DDR, an internal pull-up is enabled

if the corresponding bit is clear. This register is cleared by a reset, configuring all pins as inputs. The KDDR register is byte- or half-word addressable.

NOTE

When a pin is used as row pin for keypad purposes, all corresponding pull-ups should be enabled at the upper level (for example, IOMUX) when the bit in row DDR is cleared.

Figure 43-5 shows the valid bits in the KDDR register, and Table 43-8 provides its field descriptions.

Field	Description
15–8 KCDD	Keypad Column Data Direction Register. Setting any bit configures the corresponding pin as an output. 0 COLn pin is configured as an input. 1 COLn[1] pin is configured as an output.
7–0 KRDD	Keypad Row Data Direction. Setting any bit configures the corresponding pin as an output. 0 ROWn pin configured as an input. 1 ROWn[2] pin configured as an output.

[1] n=7-0
[2] n=7-0

43.4.3.4 Keypad Data Register (KPDR)

This 16-bit register is used to access the column and row data. Data written to this register is stored in an internal latch, and for each pin configured as an output, the stored data is driven onto the pin. A read of this register returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register.

The KPDR register is byte- or half-word–addressable. This register is not initialized by a reset. Valid data should be written to this register before any bits are configured as outputs.

Figure 43-6 shows the KPDR register, and Table 43-9 provides its field descriptions.

43.5 Functional Description

The Keypad Port (KPP) is designed to simplify the software task of scanning a keypad matrix. With appropriate software support and matrix organization, the KPP is capable of detecting, debouncing, and decoding one or more keys pressed simultaneously on the keypad.

Logic in the KPP is capable of detecting a key press even while the processor is in one of the low power standby modes providing that a 32 KHz clock is on. The KPP may generate a CPU interrupt any time a key press or key release is detected. This interrupt is capable of forcing the processor out of a low power mode.

43.5.1 Keypad Matrix Construction

The KPP is designed to interface to a keypad matrix, which shorts the intersecting row and column lines together whenever a key is depressed. The interface is not optimized for any other switch configuration.

43.5.2 Keypad Port Configuration

The software must initialize the KPP for the size of the keypad matrix. Pins connected to the keypad columns should be configured as open-drain outputs. Pins connected to the keypad rows should be configured as inputs. On-chip, pull-up resistors should be implemented for active keypad rows.

In addition to enabled row inputs in the Keypad Control register, corresponding interrupt (depress or/and release) must also be enabled to generate an interrupt.

Discrete switches that are not part of the matrix may be connected to any unused row inputs. The second terminal of the discrete switch is connected to ground. The hardware detects closures of these switches without the need for software polling.

43.5.3 Keypad Matrix Scanning

Keypad scanning is performed by a software loop that walks a zero across each of the keypad columns, reading the value on the rows at each step. The process is repeated several times in succession, with the results of each pass optionally compared to those from the previous pass. When several (3 or 4) consecutive scans yield the same key closures, a valid key press has been detected. Software then can decode exactly which switch was depressed and pass the value up to the next higher software layer.

The basic debouncing period, which must be defined in the software routine, may be controlled with an internal timer. The basic period is the period between the scan of two consecutive columns, so the debouncing time between two consecutive scans of the whole matrix shall be the number of columns multiplied by the basic period.

43.5.4 Keypad Standby

There is no need for the CPU to continually scan the keypad. Between key presses, the keypad can be left in a state that requires no software intervention until the next key press is detected. To place the keypad in a standby state, software should write all column outputs low. Row inputs are left enabled. At this point, the CPU can attend to other tasks or revert to a low power standby mode. The KPP will interrupt the CPU if any key is pressed.

Upon receiving a keypad interrupt, the CPU should set all the column strobes high, and begin a normal keypad scanning routine to determine which key was pressed. It is important that open-drain drivers be used when scanning to prevent a possible DC path between power and ground through two or more switches.

43.5.5 Glitch Suppression on Keypad Inputs

A glitch suppression circuit qualifies the keypad inputs to prevent noise from inadvertently interrupting the CPU. The circuit is a 4-state synchronizer clocked from a 32 KHz clock source. This clock must continue to run in any low power mode where the keypad is a wake-up source, as the CPU interrupt is generated from the synchronized input. An interrupt is not generated until all four synchronizer stages have latched a valid key assertion. This guarantees the filtering out of any noise less than three clock periods (for 32 KHz clock: 93.75 µs) in duration. Noise filtering of the duration between three to four clock periods (for the 32 KHz clock: between 93.75 µs and 125 µs) cannot be guaranteed. The interrupt output is latched in an S-R latch and remains asserted until cleared by the software. The Set input of the latch is rising-edge clocked. See Figure 43-7.

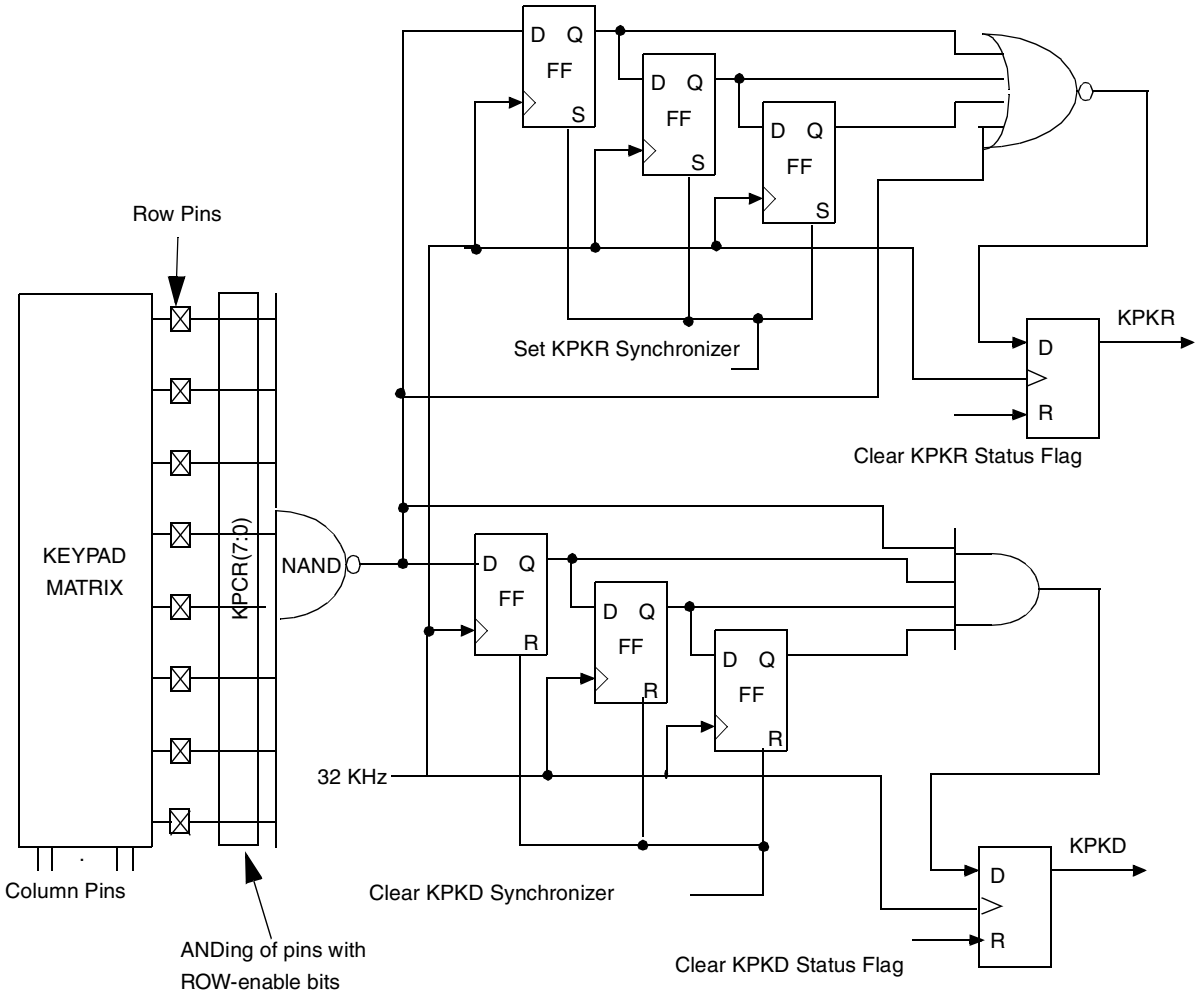

Figure 43-7. Keypad Synchronizer Functional Diagram

43.5.6 Multiple Key Closures

Using the key press and Key release interrupts, the software can detect multiple keys or achieve n key rollover. The key scanning routine can be programmed accordingly. Refer to Section 43.6, Initialization/Application Information," for more information.

See Figure 43-6 and Figure 43-9 for illustrations of the interfacing of a 2-contact keypad matrix with the KPP controller. With proper enabling of row lines and the performing scan-routine, multiple key presses can be detected. When keys present on the same row are pressed, corresponding row lines (multiple lines) become low when the column is driven low during a scan-routine. By reading the data-register, pressed

keys can be detected. Similarly, when keys present on same row line are pressed, the corresponding row line (only one line) becomes low when logic “0” is driven on the column line during a scan-routine.

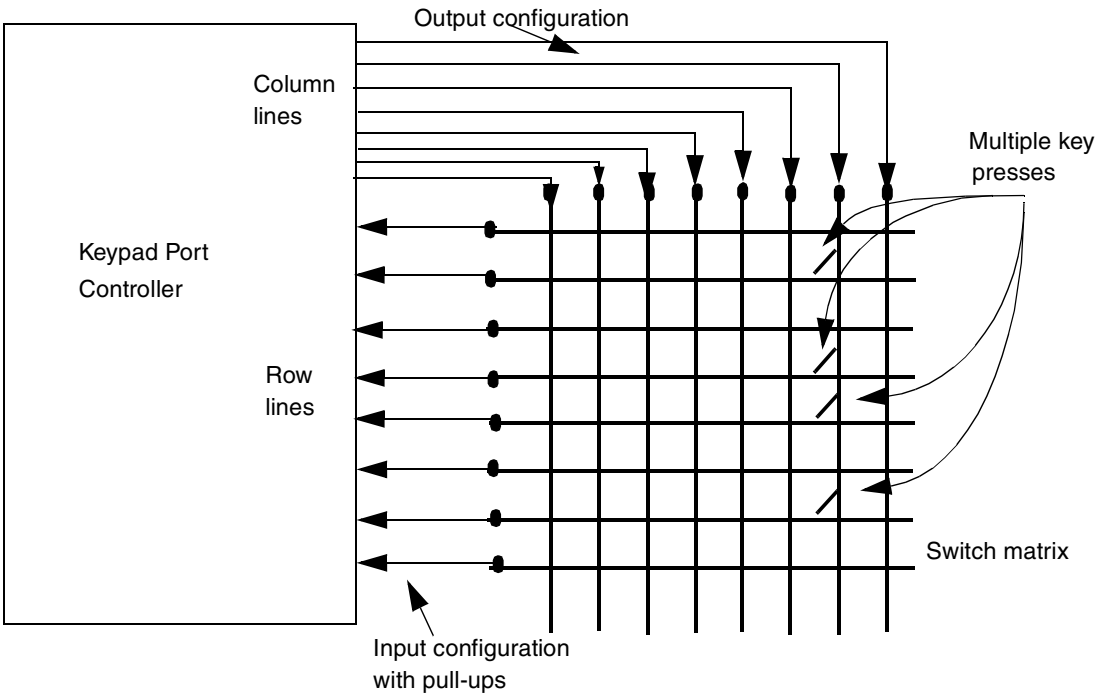

Figure 43-8. Multiple Key Presses on Same Column Line (Simplified View)

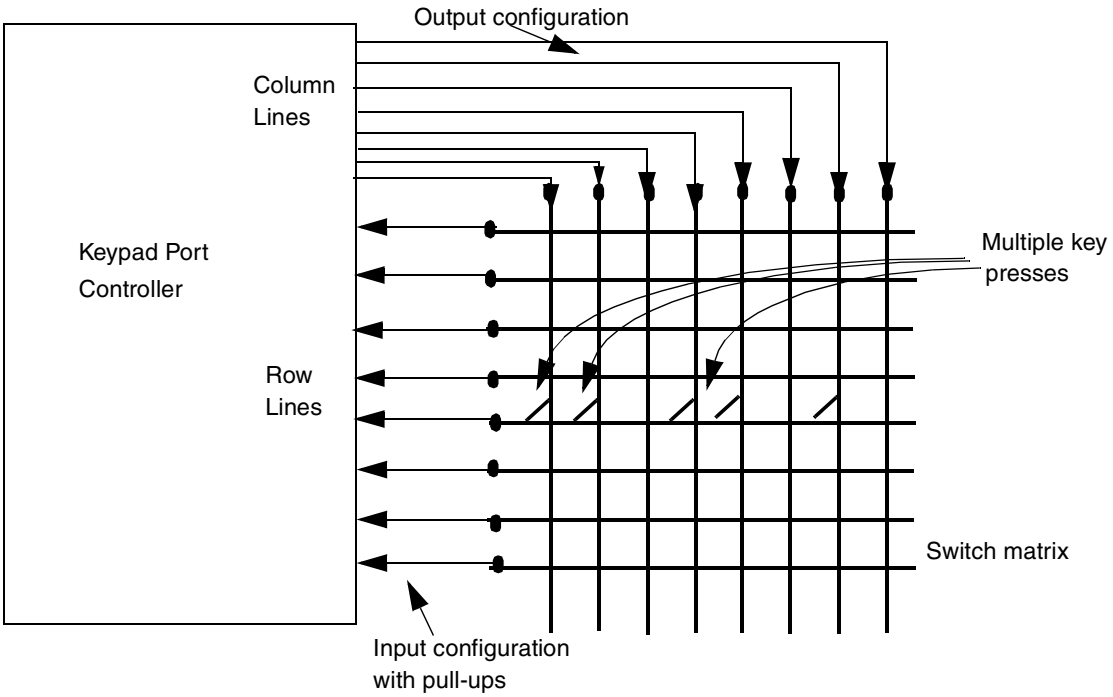

Figure 43-9. Multiple Key Presses on Same Row Line (Simplified View)

NOTE

An n key rollover is a technique with which the system can recognize the order in which keys are pressed.

43.5.6.1 Ghost Key Problem and Correction

The KPP module detects if one or multiple keys are pressed or released. In the case where a simple keypad matrix with two-contact switches is used, there is a chance of “ghost” key detection when three or more keys are pressed. This is a limitation imposed by such a keypad matrix. As can be seen in Figure 43-10, three keys pressed simultaneously can cause a short between the column currently “scanned” by the software and another column. Depending on the location of the third key pressed, a “ghost” key press may be detected.

However, this can be corrected by using a keypad matrix that provides “ghost” key protection. Such a matrix implements a one-way “diode” at all keypad points between rows and columns. This way, the multiple pressing of three keys will not cause a short at a fourth key (see Figure 43-11).

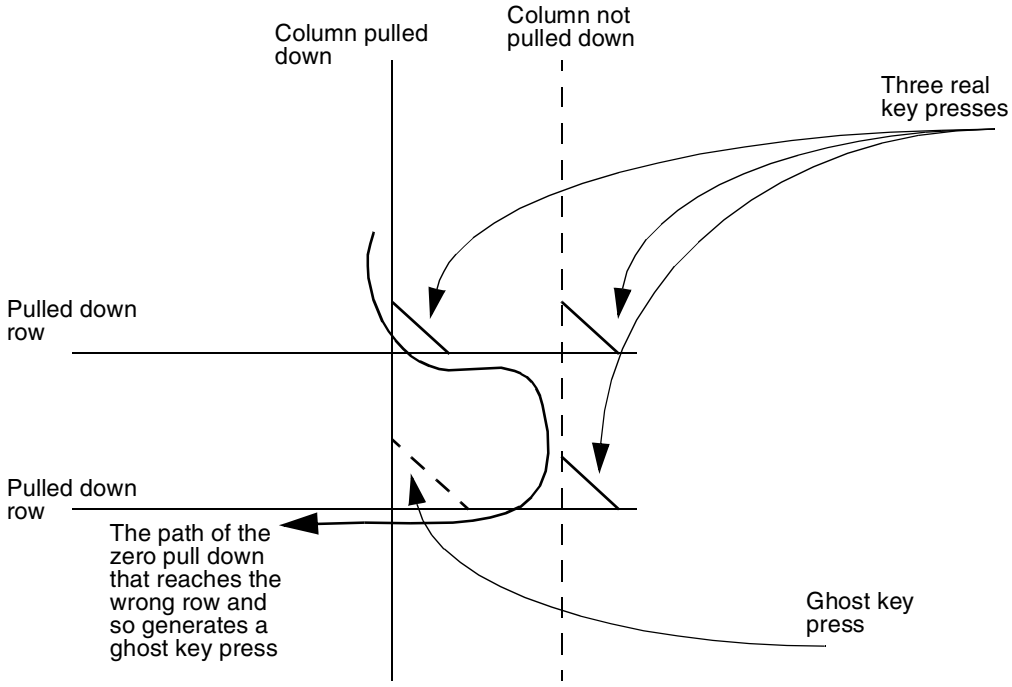

Figure 43-10. Decoding Wrong Three- Key-Presses

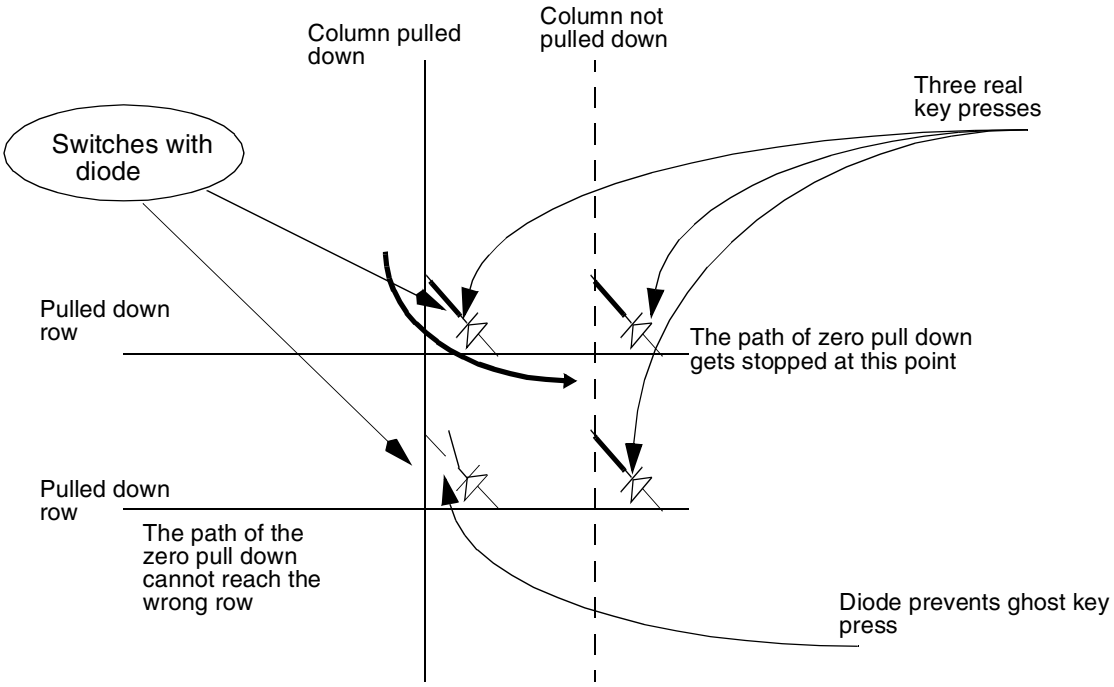

Figure 43-11. Matrix with "Ghost" Key Protections

43.5.7 3-Point Contact Keys Support

The KPP module supports interfacing to a matrix consisting of 3-point contact keys. As shown in Figure 43-12, two points of such a key are connected to keypad lines, while a third point is connected to ground (low logic). The keypad lines should be configured as input and a pull-up should to be present on these lines. When such a key is pressed, corresponding keypad lines go low and an interrupt is generated. There is no need to perform a scanning routine for identification of pressed key as it can be done by reading

the keypad data-register. A limitation with such a matrix is that for every key at least one keypad row line should be used.

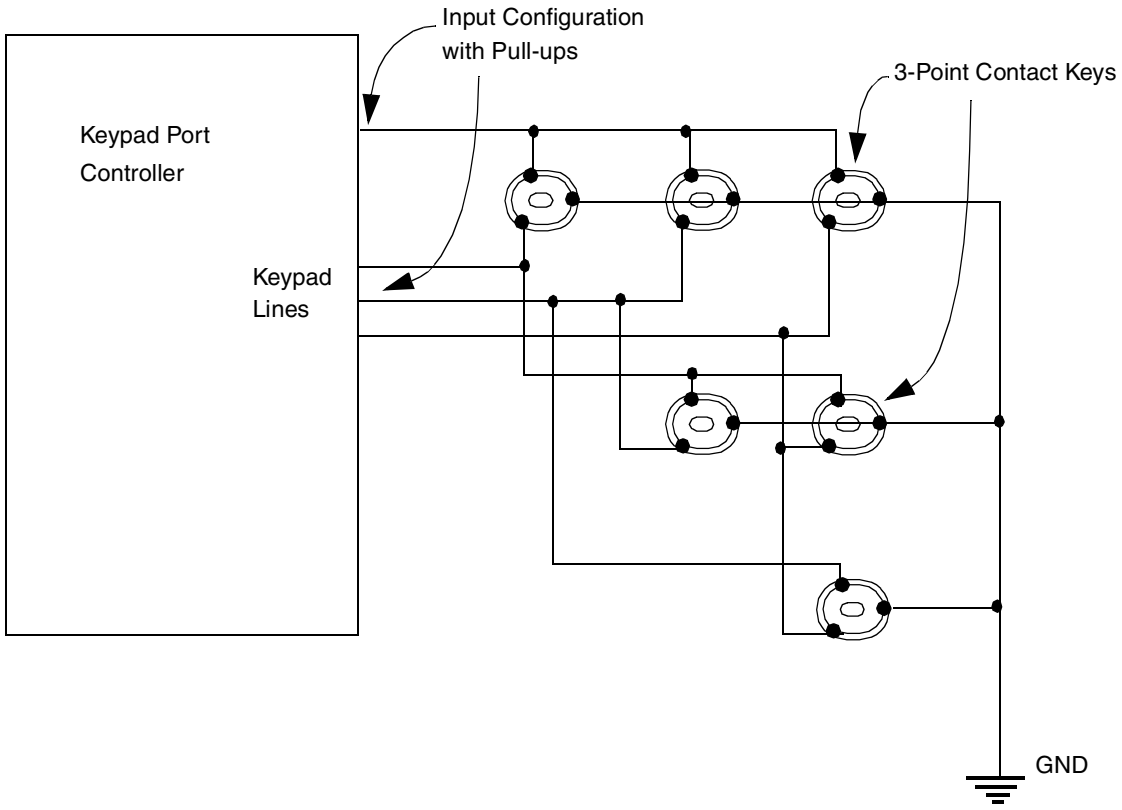

Figure 43-12. KPP Interface with 3-point Contact Key Matrix (Simplified View)

43.6 Initialization/Application Information

This section provides the sequences for typical keypad configuration and scanning and key press interrupt scanning.

43.6.1 Typical Keypad Configuration and Scanning Sequence

Perform the following steps to configure the keypad:

1. Enable the number of rows in the keypad (KPCR[7–0]).
2. Write 0s to KPDR[15–8].
3. Configure the keypad columns as open-drain (KPCR[15–8]).
4. Configure columns as output and rows as input (KDDR[15–0]).
5. Clear the KPKD Status Flag and Synchronizer chain.
6. Set the KDIE control bit, and clear the KRIE control bit (avoid false release events).
7. The system is now in standby mode, awaiting a key press.

43.6.2 Key Press Interrupt Scanning Sequence

Perform the following steps to perform a keypad scanning routine:

1. Disable both (depress and release) keypad interrupts.
2. Write 1s to KPDR[15:8], setting column data to 1s.
3. Configure columns as totem pole outputs (for quick discharging of keypad capacitance).
4. Configure columns as open-drain.
5. Write a single column to 0, and other columns to 1.
6. Sample row inputs and save data. Multiple key presses can be detected on a single column.
7. Repeat Steps 2–6 for remaining columns.
8. Return all columns to 0 in preparation for standby mode.
9. Clear KPKD and KPKR status bit(s) by writing to a “1”; set the KPKR synchronizer chain by writing a “1” to the KRSS register; and clear the KPKD synchronizer chain by writing a “1” to the KDSC register.
10. Re-enable the appropriate keypad interrupt(s) so that the KDIE detects a key hold condition, or the KRIE detects a key-release event.

43.6.3 Additional Comments

The order of key press detection can be done in software only. Therefore, the software may need to run the scan routines at very short intervals of time per the application’s demands. The reason that such functionality cannot be put in the KPP module is that the module is limited by the number of external pins.

For the keys that require a very precise order (such as game keys), individual GPIO pins may be more useful.

Chapter 44
Multi Master Multi Memory Interface (i.MX51)

44.1 Introduction

The Multi-Master Multi Memory Interface (M4IF) controls memory accesses (read/write/erase/program) from one or more masters through different port interfaces to different external memory controllers ESDCTLv2, NFCv2, and WEIMv2, and to some internal memories in the system as well. i.MX51 block diagram is shown in Figure 44.1.2.

44.1.1 Overview

M4IF module is the EMIv2 module interconnect between system masters and external or internal memory controllers. M4IF module is responsible for major functions in EMIv2 module. It contains the heart of arbitration logic for the different memory interfaces. It contains the write and read buffers to support best performance data flow with minimum latency. It contains an AXI port gasket modules for each master. It manages the AXI access type and transfers it to the arbitration logic. From the arbitration it moves on to dedicated memory controller.

M4IF module is capable of handling several AXI accesses of a different type. Any EMIv2 handshake protocol between EMIv2 and system level like Low Power Mode entry and DVFS would be handled by M4IF module. M4IF would interface between the system request and the internal logic needs including memory controllers limitations.

The following sections describe the M4IF modules.

44.1.1.1 AXI Port Gasket

This is the EMIv2 interface module to AXI masters. M4IF contains 8 AXI port gaskets. This module samples the access signals, address and controls into FIFO and sorts the access to the proper destination - Fast External Memory, Slow External Memory, Internal1 Memory or Internal2 Memory channels. The module controls the AXI interface and complies to AXI bus protocol.

44.1.1.2 Dedicated Write Buffers Module

Each AXI port gasket (Master) has a Dedicated Write buffer Module. Write data from a master is sampled in the Write Buffers Module and transferred to the Memory controller upon request. The Write Buffer size is different from master to master and is calculated as follows:

buffer_size (Bytes) = buffer depth (num of slots) * 8 (max num of data per burst) * 9 Bytes (64bit-data, 8bit-strobe).

44.1.1.3 Read Shared Buffers Module

The Read Shared buffer Module serves all 8 AXI ports. M4IF contains 4 read buffers, one read buffer per channel - Slow External, Fast External, Internal1, and Internal2 Memory channels. The data from the

memory controller is written to the read buffer. The gasket provides the data back to the master when necessary.

Refer to Section 44.3.21, Buffers Size Table.

44.1.1.4 Fast Arbitration Module

The Fast Arbitration Module arbitrates master's accesses to the ESDCTL (DDR controller) by using most comprehensive information to optimize accesses to the ESDCTL, such as Page hit/miss read/write access and so on. If needed this additional information influence can be disabled and the arbitration will function in fixed priority mode, based on the user defined priority. More details on the dynamic priority arbitration can be found in the functional description section. See Section 44.3.5, Fast Arbitration Module Functional Description - 1st Degree.

44.1.1.5 Slow Arbitration Module

The Slow Arbitration Module arbitrates between the masters using a pre-defined bus division. It then sends the accesses to the WEIM memory controller and Nand-Flash controller (NFC). The division is configurable with high resolution. Further details will be provided in Section 44.3.9, Arbitration Scheme when Masters are in Same Priority (Bus Division).

44.1.1.6 Internal 1 Memory Arbitration Module

The Internal 1 Arbitration Module arbitrates between the masters using a pre-defined bus division. It then sends the accesses to the internal RAM1 memory controller. The division is configurable with high resolution. Further details will be provided in Section 44.3.9, Arbitration Scheme when Masters are in Same Priority (Bus Division).

44.1.1.7 Internal 2 Memory Arbitration Module

The Internal 2 Arbitration Module arbitrates between the masters using a pre-defined bus division. It then sends the accesses to the internal RAM2 memory controller. The division is configurable with high resolution. Further details will be provided in Section 44.3.9, Arbitration Scheme when Masters are in Same Priority (Bus Division).

44.1.1.8 Debug Unit

The Debug Unit gives the ability to monitor several internal important EMIv2 signals to have better debug capability of the system. It is recommended that these signals would be routed out of the chip based on SoC debug definition. In addition, the debug unit would give the option to do a profiling of the arbitration unit of each channel. In that case the user would be able to trace its master bus performance and to be able to fine tune the arbitration's parameters. The debug unit contains several registers as well, so that the info can be read from the registers, observed on the pads, or analyzed by the profiling unit data. The debug unit will be described in detail in the functional section.

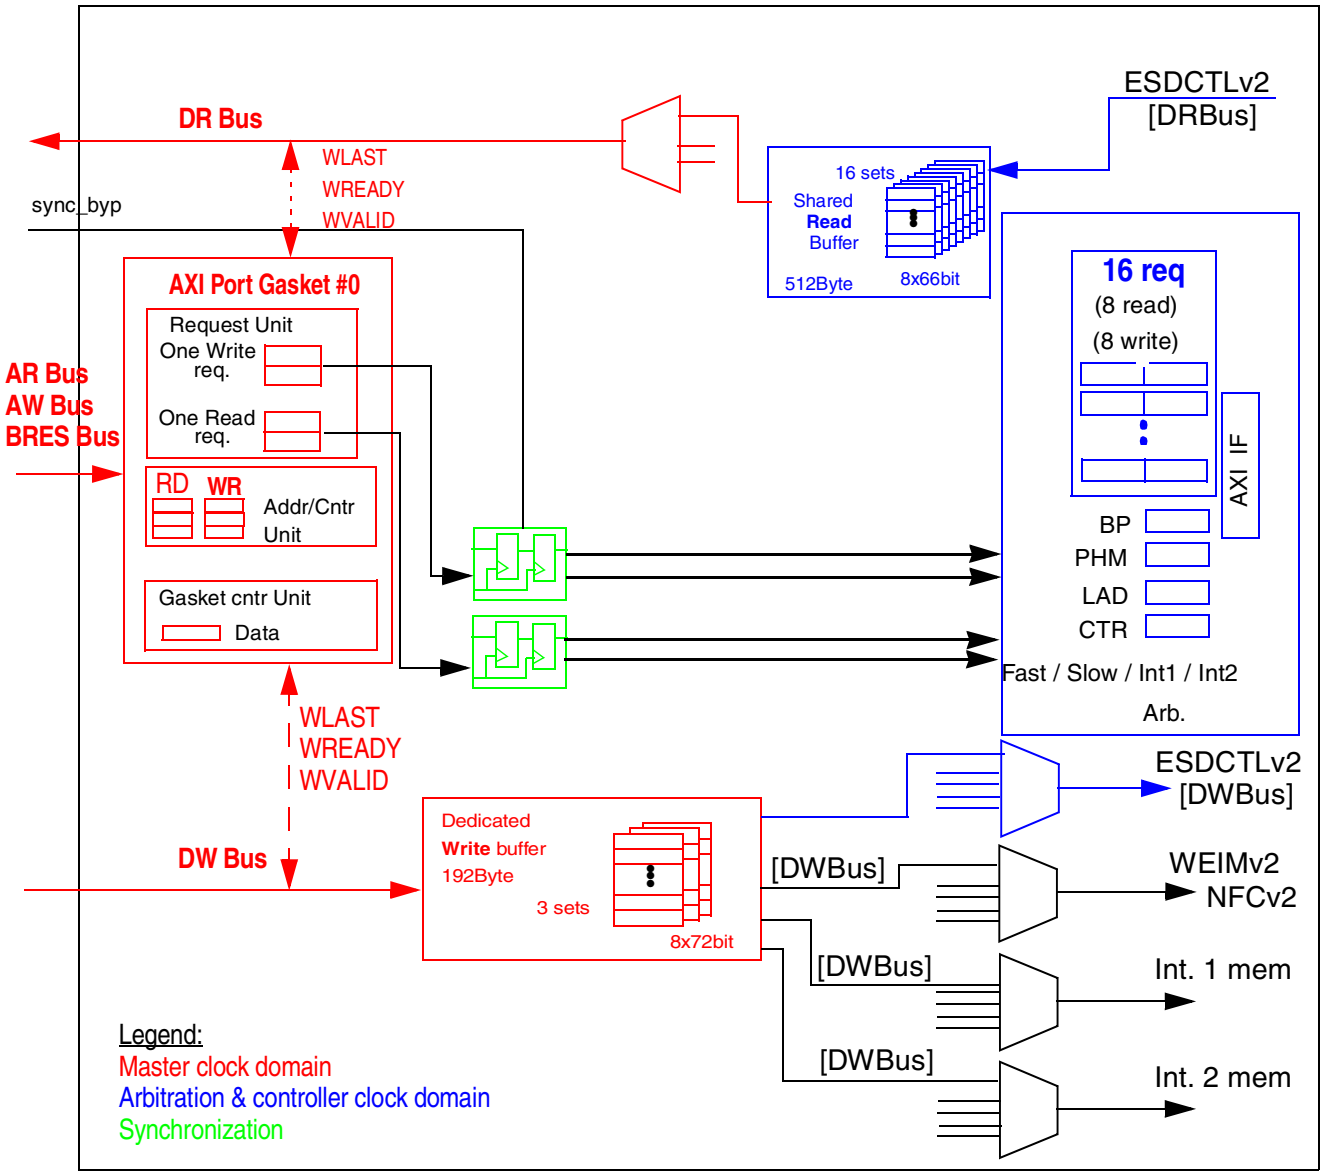

Figure 44-1. M4IF Detailed Block Diagram

44.1.2 Features

The M4IF module includes the following features:

- Supports multiple requests from up to 8 masters through different input ports interfaces. Each port can support either of the following two data width options:
  - — x32 AXI port.
  - — x64 AXI port.
- Arbitrates any master access to 5 main memory controllers, ESDCTLv2, WEIMv2, NFCv2, internal 1 salve 0 / slave 1 memory controller and internal 2 memory controller at system level.

- Supports different asynchronous master clock domain for each AXI port, using synchronization system with bypass configuration option in case clocks are aligned and balanced.
- Supports memory snooping up to two regions, for ESDCTLv2 memory region only. An example of which would be monitoring a region in external memory for write accesses:
  - The region's location is specified by a base address (from 2 KB up to 16 MB), which is divided into 64 equal segments.
  - Each segment has an access status and enable bit in the M4IF register definition.
  - M4IF generates a DMA_ACCESS for each snooping detection, total of two.
- Supports memory watermark protection for up to 8 different chip selects (2 of ESDCTL and 6 of WEIM) for preselected masters.
  - Two configurable WM configurations, for two separate masters/domains.
  - Configurable protected memory region (base address with 4 KB resolution) for each one of the watermark memory regions.
  - One status bit for each memory region that indicates security violation.
  - Maskable watermark interrupt generation capability in case of security violation for the two WM configurations.
- Separate read and write data buffer for better performance and minimum latency.
- Separate arbitration logic for fast memory interfaces - ESDCTLv2, slow memory interfaces - WEIMv2 & NFCv2, internal 1 slave 0 / slave 1 memory interfaces and for internal 2 memory interfaces like internal ROM and RAM.
- Separate clocks for each arbitration module.
- Enhanced arbitration scheme for fast channel, considering page hit/miss, last access details (read/write), fixed priority configuration,MIF4 mechanism and MIF4 prediction.
- Support AXI exclusive and lock access per arbitration path, so that locked access of one of the masters to WEIMv2 doesn't lock all EMIv2 and access to ESDCTLv2 for example can still be served.
- Bus Division arbitration scheme with programable resolution for the slow, internal memory and internal 2 memory arbitration logics.
- Support low power mode techniques so that user can put into low power entire M4IF or just part of it like slow arbitration only and so on.
- Support auto power saving features for minimum power consumption in idle mode.
- Support warm reset to allow dynamic reset configuration with minimum system impact.
- Support several debug capabilities.

44.1.3 Modes of Operation

The following sections describe the operation modes supported in M4IF module.

44.1.3.1 Normal Operating Modes

At the normal operation mode M4IF can serve each master access read or write in parallel. All clocks are enabled and READY signal of the AXI protocol are at high condition. Any access from any master can be served. For more details about normal operation mode please refer to Section 44.3, Functional Description.

44.1.3.2 Low Power Modes

Low Power mode operation is supported in M4IF. A low power mode request (lpmd) coming from the SoC would start low power mode routine. In this mode new accesses cannot pass through M4IF between a master and a memory controller, external or internal. Entering into this mode would lead the whole EMIv2 to be in Low power mode, meaning SDRAM external devices will be in self refresh mode and new accesses will not be served. All arbitration modules would finish to serve all pending requests and clean their buffers. Pending accesses on the memory controller bus will be completed.

In parallel to this routine, M4IF passes the lpmd request to the memory controllers to initialize their low power mode sequence. At the end of this process each memory controller sends back to M4IF lpmd acknowledge (lpack). M4IF, in turn, sends the Low Power Mode Acknowledge signal to the system based on its own process acknowledge and on the memory controllers‘acknowledge. This allows the system’s clock controller module to disable EMIv2 clocks without any risk.

Getting out of low power mode is done by first enabling all EMIv2 clocks and then by changing low power mode request signal to LOW state. After enabling the internal sub modules, gaskets and arbitrations, M4IF will enable new access entry to EMIv2.

In addition to the description above M4IF supports getting into low power mode by SW definition. Please refer to M4IF control register for more details.

M4IF supports partial low power mode as well. The system can enter each memory arbitration path into low power mode separately, so that one path can be in idle mode while the other is in low power mode. For example, if DDR SDRAM is currently working and no accesses to WEIM or NFC are needed, the system can set lpmd_slow signal to high so that slow path will be entered into low power mode. Other option will be to rely on auto power saving mode to allow M4IF to enter this path into low power mode automatically.

For more details on power saving mode please refer to Section 44.1.3.5, Power Saving Mode.

NOTE

In partial low power mode, it is the system’s responsibility to stop accesses to the shut-down path.

44.1.3.3 Debug Mode

44.1.3.3.1 Step By Step Mode

This mode allows the user to freeze a specific arbitration after every new transaction that is sent outside the M4IF. The user could then monitor several internal signals of M4IF (while the specific arbitration is on hold) and later write to a register that will release the current transaction and freeze the next one.

Currently, there is no option to enter this mode in the middle of a working system. Entering this mode must be done when there are no transactions in the system. Preferably immediately after reset, before any AXI accesses has been issued to M4IF/EMI.

Another way to ensure a quiet system is using the LPMD/LPACK mechanism, either by HW or SW (see Section 44.2.3.30, M4IF Control Register #0). By using the LPMD mechanism the M4IF guarantees that all pending accesses have been served.

Once the “step by step” mode has been enabled all accesses are halted. The properties of the access at the top of the PA fifo can be read via IP registers. (see Section 44.2.3.28, Step By Step Address)

In order to release the access at the top of the fifo, the appropriate bit in the MDCR should be set. Either one of the 4 bits: FSBS,SSBS,ISBS or I2SBS depending on which arbitration is being halted.

This process will repeat itself until the SBS_EN bit in the MDCR is cleared.

44.1.3.3.2 Debug Unit Functional description

For details about functionality of the Debug Unit in M4IF please refer to Section 44.3, Functional Description.

44.1.3.3.3 Debug Signals

The signal list that can be reflected outside is shown in Table 44-1:

Table 44-1. M4IF Debug Signals

Signal Name	Number of Bits	Description
master_fast	[2:0]	EMI Master number of the **selected** access at fast arbitration bus.
master_slow	[2:0]	EMI Master number of the **selected** access at slow arbitration bus.
master_int1	[2:0]	EMI Master number of the **selected** access at internal 1 memory arbitration bus.
master_int2	[2:0]	EMI Master number of the **selected** access at internal 2 memory arbitration bus.
master_id_fast	[3:0]	Master ID of the **selected** access at fast arbitration bus.
master_id_slow	[3:0]	Master ID of the **selected** access at slow arbitration bus.
master_id_int1	[3:0]	Master ID of the **selected** access at internal 1 memory arbitration bus.
master_id_int2	[3:0]	Master ID of the **selected** access at internal 2 memory arbitration bus.
id_fast	[3:0]	AXI transaction ID of the **selected** access at the fast memory arbitration bus.
id_slow	[3:0]	AXI transaction ID of the **selected** access at the slow memory arbitration bus.
id_int1	[3:0]	AXI transaction ID of the **selected** access at the internal 1 memory arbitration bus.
id_int2	[3:0]	AXI transaction ID of the **selected** access at the internal 2 memory arbitration bus.
dyn_pr_fast	[5:0]	Fast Dynamic priority of a **certain** request. (configured by MDCR[20:16])
dyn_pr_slow	[5:0]	**Equal 0**, there is no Dynamic Priority mechanism in slow arbitration
dyn_pr_int1	[5:0]	**Equal 0**, there is no Dynamic Priority mechanism in internal 1 arbitration

Table 44-1. M4IF Debug Signals (continued)

Signal Name	Number of Bits	Description
dyn_pr_int2	[5:0]	**Equal 0**, there is no Dynamic Priority mechanism in internal 2 arbitration
acc_type_fast	—	access type of the **selected** access at fast arbitration bus.
acc_type_slow	—	access type of the **selected** access at slow arbitration bus.
acc_type_int1	—	access type of the **selected** access at internal 1 memory arbitration bus.
acc_type_int2	—	access type of the **selected** access at internal 2 memory arbitration bus.
addr_fast	[31:0]	AXI ADDRESS of the **selected** access at fast arbitration bus.
addr_slow	[31:0]	AXI ADDRESS of the **selected** access at slow arbitration bus.
addr_int1	[31:0]	AXI ADDRESS of the **selected** access at internal 1 memory arbitration bus.
addr_int2	[31:0]	AXI ADDRESS of the **selected** access at internal 2 memory arbitration bus.

The selected arbitration's signals are routed outside via a bus called: **ipp_do_emi_debug**. Only one arbitration can be viewed on the debug bus.

They are ordered on this bus in the following way:

ipp_do_emi_debug[50:0] = {valid_strobe,master,master_id,id,dyn_pr,access_type,addr}

where,

- valid_strobe — a signal to indicate that a valid request is selected, this signal will be 3 clocks wide. The clock depends on the arbitration which is selected.
- master — EMIv2 master port (0:7), 3 bits wide.(Selected between: master_fast, master_slow, master_int1, master_int2)
- master_id — system MASTER ID, 4 bits wide.
- id — AXI transaction ID, 4 bits wide.
- dyn_pr — the updated dynamic priority of a request, 6 bits wide.
- access_type — write (0) or read (1), 1 bit.
- addr — the address that is accessed (base address), 32 bits wide.

44.1.3.4 DVFS

DVFS is supported in M4IF. When DVFS request is high, M4IF sends DVFS request to the memory controllers while it keeps working normally. Reacting to DVFS request, the memory controllers would change their READY signals state to low and start DVFS routine while M4IF will keep working as in normal mode. Since READY signals of the memory controllers is low, no new access will pass from M4IF to the memory controller but only piped access in the memory controller will be cleaned. At the end, the memory controller pipeline will be cleaned and a DVFS ack signals will be sent back to M4IF. M4IF will then send a DVFS ack signal to the system to allow changing frequency.

In addition to the description above M4IF supports DVFS request to be enabled by register configuration. Please refer to DVFS register for more details.

44.1.3.5 Power Saving Mode

44.1.3.5.1 Arbitration Power Saving

In order to support power saving mode to reduce power consumption of the system, M4IF would be able to detect whether there is a request pending on any of the arbitration modules or not. The power saving register defines the time period that should pass from the last served request in a certain arbitration. If during the specified time period no request was observed on the arbitration the arbitration module would send low power mode request to its memory controller and would enter itself to low power mode as well. The power saving mode is defined and functioned separately for each arbitration. In that case fast arbitration can be in normal mode while the slow arbitration can be in powder saving mode. Getting out of this mode would be started automatically when a new request to the specific arbitration is issued by one of the masters. It is important to mention that it would take few cycles to serve the request since getting out of power saving mode routine is takes few cycles at M4IF as well as in the memory controller.

44.1.3.5.2 Gasket Power Saving

Power saving feature is also supported for each gasket individually. The gasket will detect a number of cycles that it were idle. Upon reaching this configurable number of cycles, the gasket will de-assert its clock gating enable, and almost all the FFs inside will stop. There will be a few FFs still running on a free running clock, in order to be able to wake from this mode. In this mode the 3 ready signals: AWREADY, ARREADY and WREADY will be de-asserted until an access is issued to this gasket. When detecting a new access (AWVALID, ARVALID or WVALID asserted), the gasket will assert its clock enable signal (in the next cycle). There is a minimum number of cycles that the READY signals has to be de-asserted after the clock enable is re-asserted. Please note these cycles are of the **master clock**. For each master the clock period is different. The number of cycles is configurable via a register. The number of idle cycles that will initiate this process is also a configurable number. Refer to Section 44.2.3.1, Power Saving Masters 0 for further details.

Figure 44-2 illustrates the behaviour of the clock enable and of the ready signals upon exiting from power saving. In this diagram the “ready off cycles” (ROC) is at its default value 3.

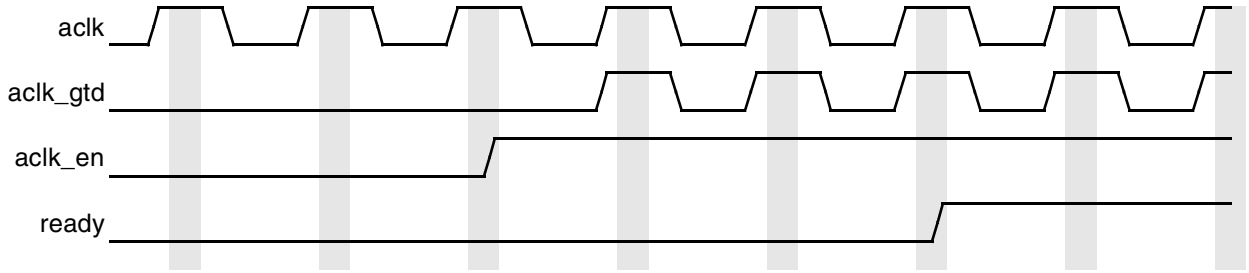

Figure 44-2. Behaviour of Clock Enable and Ready Signals

44.2 Memory Map and Register Definition

The sections below describe the register definition of M4IF module. It contains all information on registers definition like watermark and control registers. It contains all user programable master priority register per arbitration path as well as priority specific definition for fast arbitration.

44.2.1 Memory Map

M4IF memory area is in the IP memory region dedicated for its registers. M4IF registers are located at 0xBASE+0x0000 - 0xBASE+0x0FFF.

44.2.2 Register Summary

The conventions in Figure 44-3 and Table 44-2 serve as a key for the register summary and individual register diagrams.

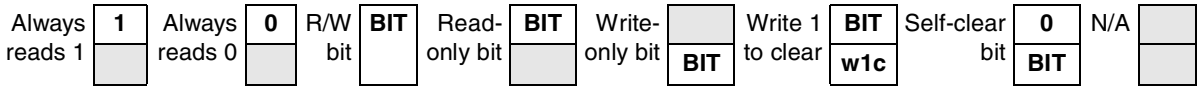

Figure 44-3. Key to M4IF Register Fields

Table 44-2 provides a key for register figures and tables and the register summary.

Table 44-2. M4IF Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
w1s	Write one to set. A status bit that can be read, and is set by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 44-3 shows the M4IF register summary.

44.2.3 Register Descriptions

This section consists of M4IF register descriptions in address order. Please refer to next sections for detailed description of each register.

44.2.3.1 Power Saving Masters 0

The PSM0 determines the power saving features for masters #0 and #1.

Address 0xBASE+0x000 (PSM0) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 44-4. Power Saving Masters 0 Register

Detailed description of Power Saving Masters 0 register is shown in Table 44-4.

Table 44-4. Power Saving Masters 0 Register Field Descriptions

Field	Description
31-24 M1_PST	master #1 Power Saving Timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 - timer is configured to 100 clock cycles. ... ... 00001010 Default value- 1000 clock cycles. ... ... 11111111 - timer clock is defined to 25500 clock cycles.
23	Reserved.
22 M1_WIS	Master #1 Write Idle Status.This read only bit indicates whether master #1 write request buffer is idle (empty) or not. 0 - idle 1 - not idle
21 M1_RIS	Master #1 Read Idle Status.This read only bit indicates whether master #1 read request buffer is idle (empty) or not. 0 - idle 1 - not idle
20 M1_PSS	Master #1 Power Saving Status. This read only bit indicates whether master #1 gasket is in power saving mode. 0 - not in power saving 1 - power saving
19-17 M1_ROC	master #1 Ready Off Cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. 3'b001 - 3'b111 (3'b000 is a forbidden value)
16 M1_PSD	master #1 Power Saving Disable. 0 - power saving enabled 1 - power saving disabled (default)
15-8 M0_PST	master #0 power saving timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 - timer is configured to 100 clock cycles. ... ... 00001010 Default value- 1000 clock cycles. ... ... 11111111 - timer clock is defined to 25500 clock cycles.
7	Reserved.
6 M0_WIS	Master #0 Write Idle Status.This read only bit indicates whether master #0 write request buffer is idle (empty) or not. 0 - idle 1 - not idle

Table 44-4. Power Saving Masters 0 Register Field Descriptions (continued)

Field	Description
5 M0_RIS	Master #0 Read Idle Status.This read only bit indicates whether master #0 read request buffer is idle (empty) or not. 0 - idle 1 - not idle
4 M0_PSS	Master #0 Power Saving Status. This read only bit indicates whether master #0 gasket is in power saving mode. 0 - not in power saving 1 - power saving
3-1 M0_ROC	master #0 Ready Off Cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. Default value is 3 cycles. 3'b001 - 3'b111 (3'b000 is a forbidden value)
0 M0_PSD	master #0 Power Saving Disable. 0 - power saving enabled 1 - power saving disabled (default)

44.2.3.2 Power Saving Masters 1

The PSM1 determines the power saving features for masters #2 and #3.

Address 0xBASE+0x004 (PSM1) Access: User read-write

Figure 44-5. Power Saving Masters 1 Register

Detailed description of Power Saving Masters 1 register is shown in Table 44-4.

Table 44-5. Power Saving Masters 1 Register Field Descriptions

Field	Description
31-24 M3_PST	master #3 Power Saving Timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 - timer is configured to 100 clock cycles. ... ... 00001010 Default value- 1000 clock cycles. ... ... 11111111 - timer clock is defined to 25500 clock cycles.
23	Reserved.
22 M3_WIS	Master #3 Write Idle Status.This read only bit indicates whether master #3 write request buffer is idle (empty) or not. 0 - idle 1 - not idle
21 M3_RIS	Master #3 Read Idle Status.This read only bit indicates whether master #3 read request buffer is idle (empty) or not. 0 - idle 1 - not idle
20 M3_PSS	Master #3 Power Saving Status. This read only bit indicates whether master #3 gasket is in power saving mode. 0 - not in power saving 1 - power saving
19-17 M3_ROC	master #3 Clock Off Cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. 3'b001 - 3'b111 (3'b000 is a forbidden value)
16 M3_PSD	master #3 Power Saving Disable. 0 - power saving enabled 1 - power saving disabled (default)
15-8 M2_PST	master #2 Power Saving Timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 - timer is configured to 100 clock cycles. ... ... 00001010 Default value- 1000 clock cycles. ... ... 11111111 - timer clock is defined to 25500 clock cycles.
7	Reserved.
6 M2_WIS	Master #2 Write Idle Status.This read only bit indicates whether master #2 write request buffer is idle (empty) or not. 0 - idle 1 - not idle

Table 44-5. Power Saving Masters 1 Register Field Descriptions (continued)

Field	Description
5 M2_RIS	Master #2 Read Idle Status.This read only bit indicates whether master #2 read request buffer is idle (empty) or not. 0 - idle 1 - not idle
4 M2_PSS	Master #2 Power Saving Status. This read only bit indicates whether master #2 gasket is in power saving mode. 0 - not in power saving 1 - power saving
3-1 M2_ROC	master #2 Ready Off Cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. Default value is 3 cycles. 3'b001 - 3'b111 (3'b000 is a forbidden value)
0 M2_PSD	master #2 Power Saving Disable. 0 - power saving enabled 1 - power saving disabled (default)

44.2.3.3 M4IF Debug Status Register #6

The MDSR6 reflects the total number of accesses made by a specific requesting the desired arbitration. The arbitration can be fast, slow,intr1 or intr2. Please refer to Section 44.2.3.32, M4IF Debug Control Register.

Address 0xBASE+0x018 (MDSR6) Access: User read only

Detailed description of M4IF Debug Status Register #7 register is shown in Table 44-8.

Table 44-8. M4IF Debug Status Register #7 Register Field Descriptions

Field	Description
31-0 STR	Sum Time Request. These bits reflect the sum of time (in arbitration clock cycles) all the requests of a specific kind were pending at a specfic arbitation. (The arbitration is configured in the MDCR register)

44.2.3.5 M4IF Debug Status Register #8

The MDSR8 reflects the the sum of time all the requests of a specific master were pending in the desired arbitration. The arbitration can be fast, slow,intr1 or intr2 and is configured in the MDCR register. Please refer to Section 44.2.3.32, M4IF Debug Control Register

Address 0xBASE+0x020 (MDSR8) Access: User read only

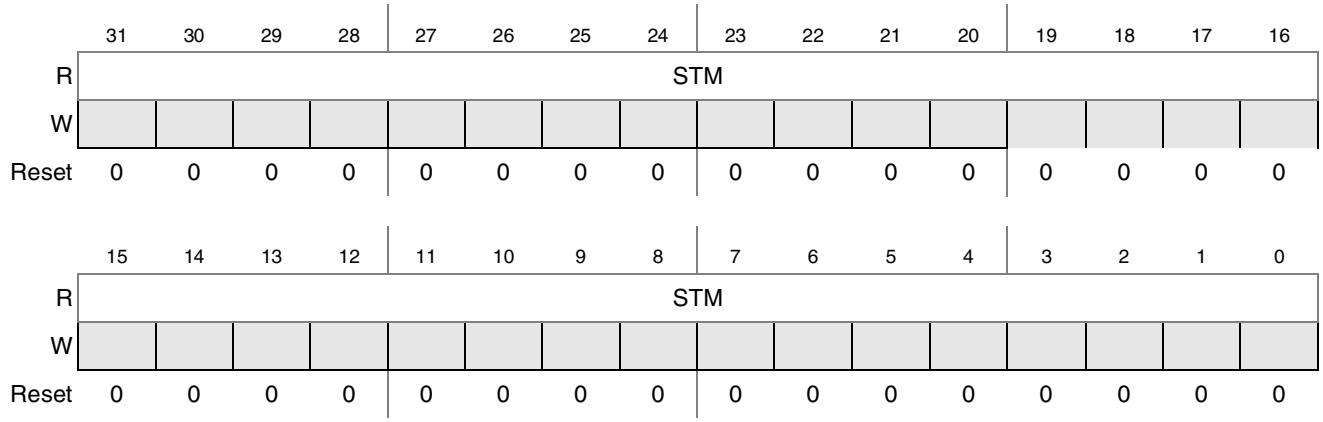

Figure 44-8. M4IF Debug Status Register #8 Register

Detailed description of M4IF Debug Status Register #8 register is shown in Table 44-9.

Table 44-9. M4IF Debug Status Register #8 Register Field Descriptions

Field	Description
31-0 STM	Sum Time Master. These bits reflect the sum of time (in arbitration clock cycles) all the requests of a specific master were pending at a specific arbitration. (The arbitration is configured in the MDCR register)

44.2.3.6 M4IF Debug Status Register #0

The MDSR0 reflects the maximum values of the chosen dynamic priority and the “time for bus” of a master. The desired dynamic priority is configured in the MDCR. Please refer to Section 44.2.3.32, M4IF Debug Control Register

Address 0xBASE+0x024 (MDSR0) Access: User read only

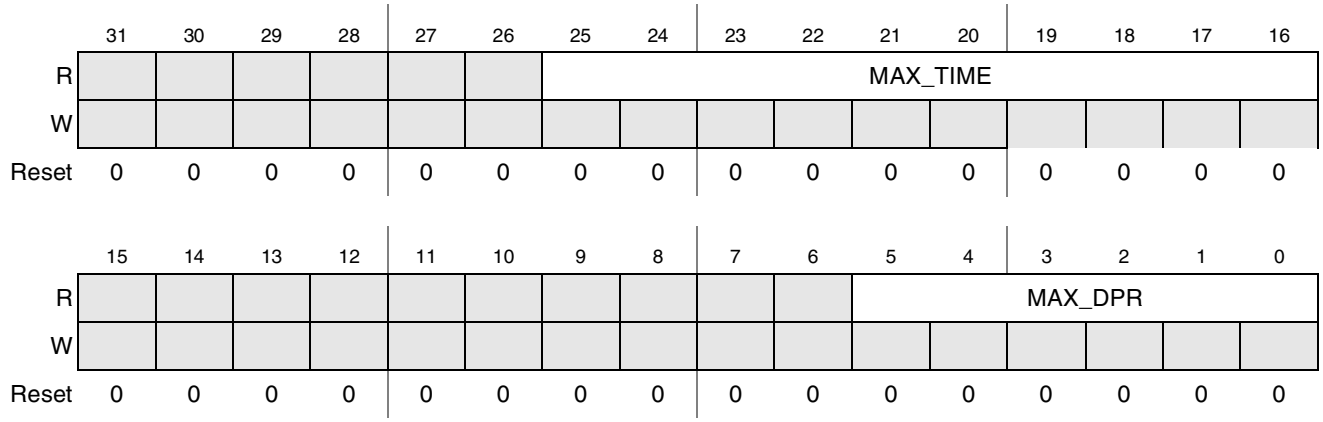

Figure 44-9. M4IF Debug Status Register #0 Register

Detailed description of M4IF Debug Status Register #0 register is shown in Table 44-10.

Table 44-10. M4IF Debug Status Register #0 Register Field Descriptions

Field	Description
31-26	Reserved.
25-16 MAX_TIME	Maximum Time for Bus. This field represents the maximum number of cycles the selected master (see DDPM field in MDCR) was pending on the bus.
15-6	Reserved.
5-0 MAX_DPR	Maximum Dynamic Priority. These bits reflect the maximum value of the dynamic priority which was selected by the MDCR.

44.2.3.7 M4IF Debug Status Register #1

The MDSR1 reflects the total number of accesses that were made through the desired arbitration. The arbitration can be fast, slow or intr, and is configured in the MDCR register. Please refer to Section 44.2.3.32, M4IF Debug Control Register

Address 0xBASE+0x028 (MDSR1) Access: User read only

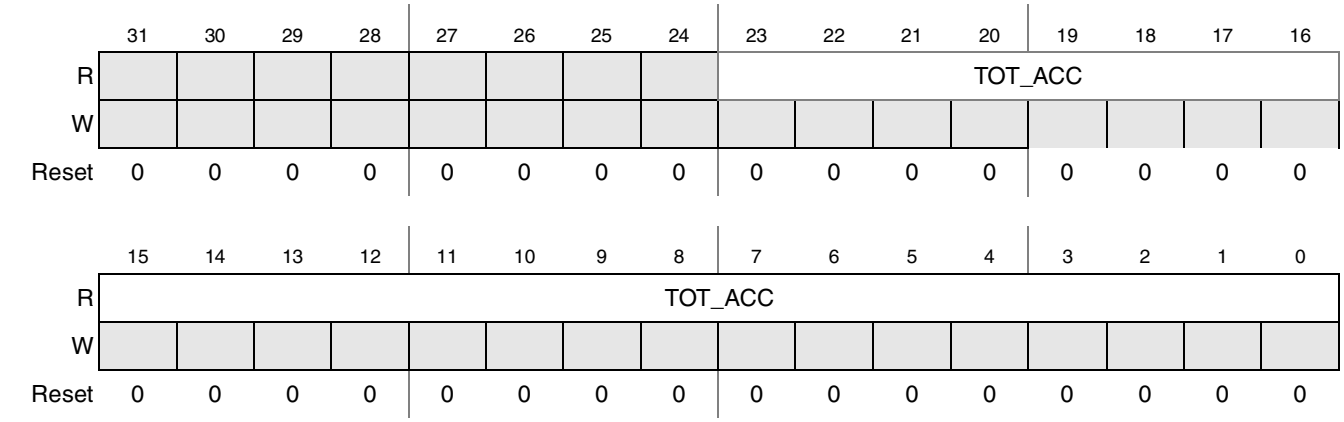

Figure 44-10. M4IF Debug Status Register #1 Register

Detailed description of M4IF Debug Status Register #1 register is shown in Table 44-11

Table 44-11. M4IF Debug Status Register #1 Register Field Descriptions

Field	Description
31-24	Reserved.
23-0 TOT_ACC	Total Accesses. These bits reflect the total number of accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.

44.2.3.8 M4IF Debug Status Register #2

The MDSR2 reflects the number of groups of 32 accesses (resolution is of 32 accesses) that master0 and master1 made through the desired arbitration. The arbitration can be fast, slow,int1 or int2 and i configured in the MDCR register. Please refer to Section 44.2.3.32, M4IF Debug Control Register

Address 0xBASE+0x02C (MDSR2) Access: User read only

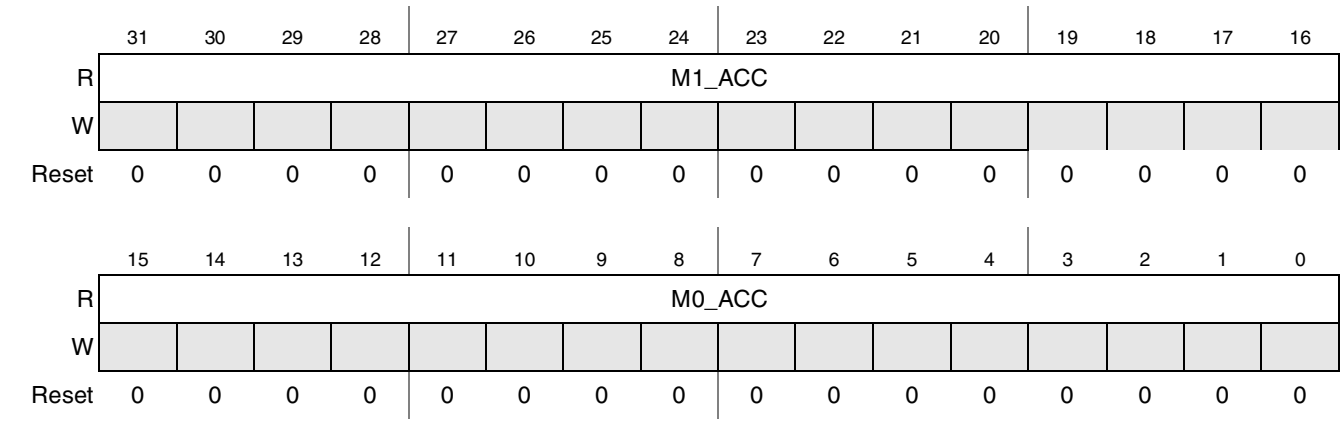

Figure 44-11. M4IF Debug Status Register #2 Register

Detailed description of M4IF Debug Status Register #2 register is shown in Table 44-12

Table 44-12. M4IF Debug Status Register #2 Register Field Descriptions

Field	Description
31-16 M1_ACC	Master1 Accesses. These bits reflect the total number of master1 accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.
15-0 M0_ACC	Master0 Accesses. These bits reflect the total number of master0 accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.

44.2.3.9 M4IF Debug Status Register #3

The MDSR3 register reflects the number of groups of 32 accesses (resolution is of 32 accesses) that master2 and master3 made through the desired arbitration. The arbitration can be fast, slow or internal and is configured in the MDCR register. Please refer to Section 44.2.3.32, M4IF Debug Control Register

Address 0xBASE+0x030 (MDSR3) Access: User read only

Table 44-15. M4IF Debug Status Register #5 Register Field Description

Field	Description
31-16 M7_ACC	Master7 Accesses. These bits reflect the total number of master7 accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.
15-0 M6_ACC	Master6 Accesses. These bits reflect the total number of master6 accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.

44.2.3.12 F_Basic Priority Reg #0

FBPM0 register contains the basic priority value for masters 0,1,2,3 for the fast arbitration logic only. Different register are used for slow arbitration and internal memory arbitration logic.

Address 0xBASE+0x040 (FBPM0) Access: User read-write

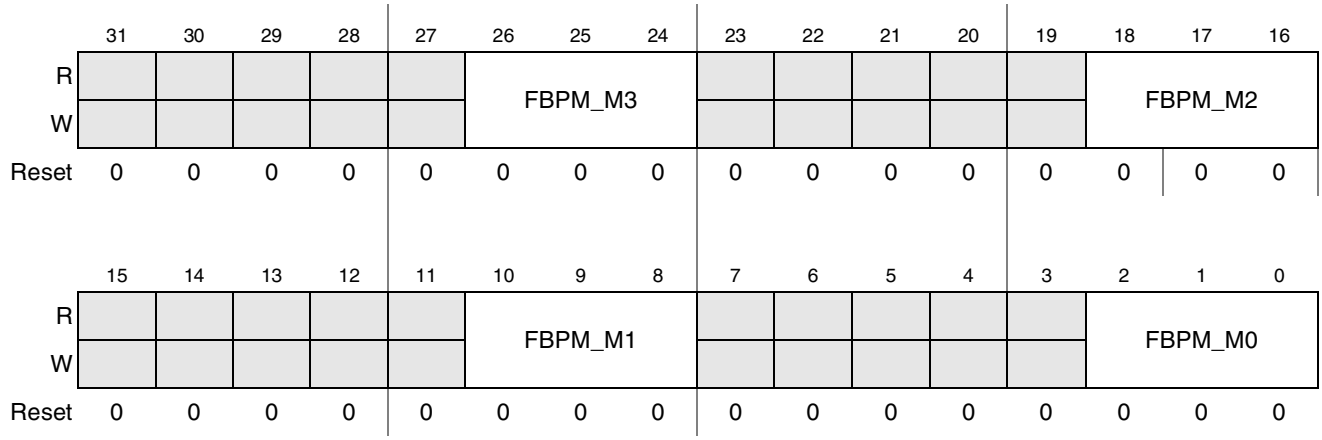

Figure 44-15. F_Basic Priority Reg #0 Register

Detailed description of F_Basic Priority Reg #0 register is shown in Table 44-16.

Table 44-16. F_Basic Priority Reg #0 Register Field Descriptions

Field	Description
31-27	Reserved.
26-24 FBPM_M3	User defined value. These bits represent the basic priority value as configured by the user to master 3 000 encoding 0 001 encoding 1 ... ... 111 encoding 7
23-19	Reserved
18-16 FBPM_M2	User defined value. These bits represent the basic priority value as configured by the user to master 2. 000 encoding 0 001 encoding 1 ... ... 111 encoding 7
15-11	Reserved
10-8 FBPM_M1	User defined value. These bits represent the basic priority value as configured by the user to master 1. 000 encoding 0 001 encoding 1 ... ... 111 encoding 7

Table 44-16. F_Basic Priority Reg #0 Register Field Descriptions (continued)

Field	Description
7-3	Reserved
2-0 FBPM_M0	User defined value. These bits represent the basic priority value as configured by the user to master 0. 000 encoding 0 001 encoding 1 ... ... 111 encoding 7

44.2.3.13 F_Basic Priority Reg #1

FBPM1 register contains the basic priority value for masters 4,5,6,7 for the fast arbitration logic only. Different register are used for slow arbitration and internal memory arbitration logic.

Address 0xBASE+0x044 (FBPM1) Access: User read-write

W																
Reset	0	0	0	0	0	0	0	1	1	0	0	0	0	1	0	1

Figure 44-17. MIF4 Scoring Register Register

Detailed description of MIF4 Scoring Register register is shown in Table 44-18.

Table 44-18. MIF4 Scoring Register Register Field Descriptions

Field	Description
31-20	Reserved
21-19 MIF4_PAG_HIT	MIF4 Page Hit Rate. This value will be added by the mif4 arbitration logic to any pending request that is considered as page hit. Default value of MIF4_PAG_HIT is 0x00100 - encoding 4.
18-16 MIF4_ACC_HIT	MIF4 Access Hit Rate. Any pending access that is considered as page hit is checked to be a consecutive access type or not. If it is a consecutive access than the weighting value of this request will increase by MIF4_ACC_HIT value. Default value of is MIF4_ACC_HIT 0x0010 - encoding 2.
11-8 MIF4_DYN_JMP	MIF4 Dynamic Jump. Each time a request is being popped outside the MIF4 arbitration, the other pending requests will increase there dynamic score value by MIF4_DYN_JMP value. Default MIF4_DYN_JMP value is 0x0001 - encoding 1
7-4 MIF4_DYN_MAX	MIF4 Dynamic Maximum. MIF4_DYN_MAX is the maximum dynamic score value that each request inside the MIF4 mechanism can get. Default MIF4_DYN_MAX value is 0x1000 - encoding 8
3-0 MIF4_GUARD	MIF4 Guard. After a request reached the maximum dynamic score value, it will wait another MIF4_GUARD cycles and then force the request to pop outside the MIF4 arbitration. If MIF4_GUARD equals 0, this guarding mechanism is disabled. Default MIF4_GUARD value is 0x0101 - encoding 5

44.2.3.15 Snooping Base Address Register #0

The SBAR0 register contains the snooping window base address for region 0, the size of snooping window and the snooping control bit fields which are used by the fast arbitration logic to monitor the write access to CSD0 and CSD1.

Address 0xBASE+0x04C (SBAR0) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 44-18. Snooping Base Address Register #0

Details on the register fields are shown below in Table 44-19

Table 44-19. Snooping Base Address Register #0 Field Descriptions

Field	Description
31–11 SWBA0	Snooping Window Base Address. This field defines the snooping window base address (upper 21 bits of address) to be monitored by the M3IF. M3IF monitors write accesses to the memory region above the base address window. See description in Table 44-20
10–8	Reserved
7-5 SSW0	Snooping Strobe Width - Determines the width (in fast clock cycles) of the strobe that is outputted to IPU. Reset value is 100 - encoding 4
4–1 SWSZ0	Snooping Window Size. This field define the snooping window size as described in Table 44-20
0 SE0	Snooping Enable. This bit enables snooping detection. The M3IF monitors and detects write accesses to the snooping window. 0 Snooping feature is disabled. 1 Snooping feature is enabled.

Table 44-20. SBAR0 Field Descriptions

SWSZ0	Snooping Window Size	Window Base Address Bits	Window Address Bits in Use
0000	2 KByte	[31:11]	[10:0]
0001	4 KByte	[31:12]	[11:0]

Figure 44-19. Snooping Enable Register Low #0

Details on the register fields are shown below in Table 44-21.

Table 44-21. Snooping Enable Register Low #0 Field Descriptions

Field	Description
31–0 SSEL0	Snooping Segment Enable Low 0. This register contains the enable bits for the lower 32 segments [31:0] in the snooping window (defined by the SBAR0 register). If snooping is enabled for segment #x (respective SSEL0 bit is high), than any write access detected to that segment will set the DMA_ACCESS0 for one cycle and the respective snooping status bit will be set. If the SSEL0 bit is low, and a write access to the respective segment is detected by the M3IF, only the relevant status bit in the snooping status register will be set but the DMA_ACCESS0 will not be generated. 0 Snooping segment #x is disabled. 1 Snooping segment #x is enabled.

44.2.3.17 Snooping Enable Register High #0

The SERH0 register contains the enable bits for the upper 32 segments [63:32] in SBAR0 register.

Address 0xBASE+0x054 (SERH0) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 44-20. Snooping Enable Register High #0

Details on the register fields are shown below in Table 44-22.

Table 44-22. Snooping Enable Register High #0 Field Descriptions

Field	Description
31–0 SSEH0	Snooping Segment Enable High 0. This register contains the enable bits for the higher 32 segments [63:32] in the snooping window (defined by the SBAR0 register). If snooping is enabled for segment #x (respective SSEH0 bit is high), than any write access detected to that segment will set the DMA_ACCESS0 for one cycle and the respective snooping status bit will be set. If the SSEH0 bit is low, and a write access to the respective segment is detected by the M3IF, only the relevant status bit in the snooping status register will be set but the DMA_ACCESS0 will not be generated. 0 Snooping segment #x is disabled. 1 Snooping segment #x is enabled.

44.2.3.18 Snooping Status Register Low #0

The SSRL0 register contains the snooping status bits for the lower 32 segments.

Figure 44-23. Snooping Base Address Register #1

Details on the register fields are shown below in Table 44-25.

Table 44-25. Snooping Base Address Register #1 Field Descriptions

Field	Description
31–11 SWBA1	Snooping Window Base Address. This field defines the snooping window base address (upper 21 bits of address) to be monitored by the M3IF. M3IF monitors write accesses to the memory region above the base address window. See description in Table 44-26
10–8	Reserved
7-5 SSW1	Snooping Strobe Width - Determines the width (in fast clock cycles) of the strobe that is outputted to IPU. Reset value is 100 - encoding 4
4–1 SWSZ1	Snooping Window Size. This field define the snooping window size as described in Table 44-26
0 SE1	Snooping Enable. This bit enables snooping detection. The M3IF monitors and detects write accesses to the snooping window. 0 Snooping feature is disabled. 1 Snooping feature is enabled.

Table 44-26. SBAR1 Field Descriptions

SWSZ1	Snooping Window Size	Window Base Address Bits	Window Address Bits in Use

Details on the register fields are shown below in Table 44-30.

Table 44-30. Snooping Status Register High #1 Field Descriptions

Field	Description
31–0 SSSH1	Snooping Segment Status High 1. This register contains the snooping status bits for the higher 32 segments [63:32] in the snooping window (defined by the SBAR1 register). A bit in the SSRH1 register is asserted if snooping to the respective segment occurred. **Note:** If snooping occurred the status bit will be updated regardless of the respective snooping segment enable bit SSEH1[x]. The DMA_ACCESS1 will be asserted only if the respective snooping segment enable bit SSEH1[x] is enabled. 0 Snooping for segment #x did not occur. 1 Snooping for segment #x occurred.

44.2.3.25 I2_Unit_Level_Arbitration_ Register

The I2ULA register configure the unit level arbitration configuration bits of each logic unit in levels 3,4 and 5. Please refer to Section 44.3.9, Arbitration Scheme when Masters are in Same Priority (Bus Division)" for more details on the arbitration logic units.

Address 0xBASE+0x074 (I2ULA) Access: User read-write

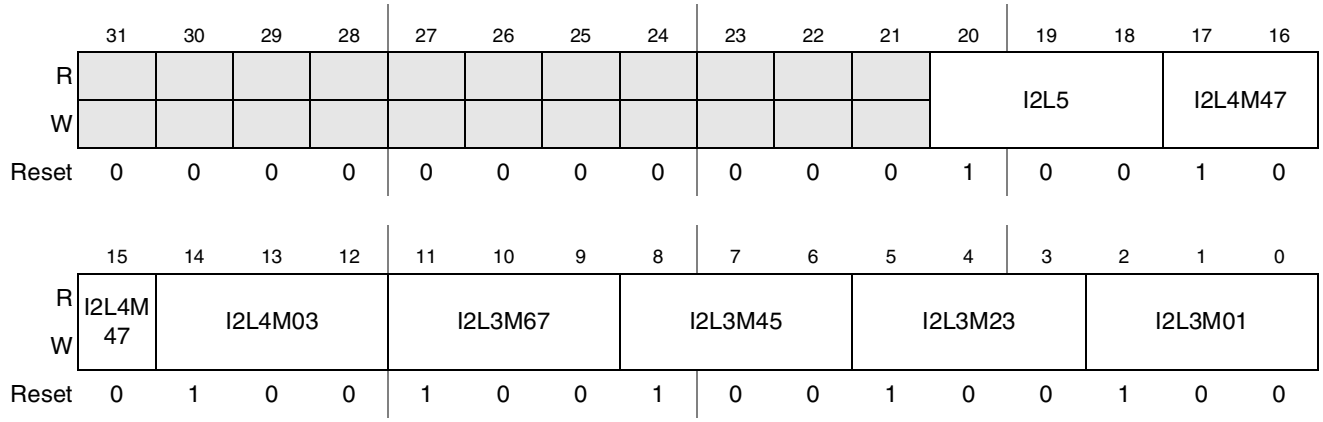

Figure 44-28. I2_Unit_Level_Arbitration_ Register

Table 44-31. Register Field Descriptions

Field	Description
31-21	Reserved.
20-18 I2L5	Int 2 Level 5 - These bits configure the arbitration mode of level 5 arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL5 is 0x100 - encoding 4.
17-15 I2L4M47	Int 2 Level 4 (m47) - These bits configure the arbitration mode of level 4(m47) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL4M47 is 0x100 - encoding 4.
14-12 I2L4M03	Int 2 Level 4 (m03) - These bits configure the arbitration mode of level 4(m03) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL4M03 is 0x100 - encoding 4.
11-9 I2L3M67	Int 2 Level 3 (m67) - These bits configure the arbitration mode of level 3(m67) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL3M67 is 0x100 - encoding 4.
8-6 I2L3M45	Int 2 Level 3 (m45) - These bits configure the arbitration mode of level 3(m45) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL3M45 is 0x100 - encoding 4.
5-3 I2L3M23	Int 2 Level 3 (m23) - These bits configure the arbitration mode of level 3(m23) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL3M23 is 0x100 - encoding 4.
2-0 I2L3M01	Int 2 Level 3 (m01) - These bits configure the arbitration mode of level 3(m01) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL3M01 is 0x100 - encoding 4.

44.2.3.26 Int. 2 Memory Arbitration Control Register

The I2ACR holds control bits for the int2. memory channel arbitration.

Address 0xBASE+0x078 (I2ACR) Access: User read-write

Figure 44-30. M4IF Internal 2 Control Register

Details on the register fields are shown below in Table 44-33.

Table 44-33. M4IF Internal 2 Control Register Field Descriptions

Field	Description
31-14	Reserved
13 I2DVACK	Intr 2 DVFS acknowledge. This read only bit indicates whether a dvfs acknowledge on the internal 2 memory channel was asserted.
12 I2LPACK	Intr 2 low-power acknowledge. This read only bit indicates whether a low-power acknowledge on the internal 2 memory channel was asserted.
11 I2PSS	Intr 2 Power Saving Status. This read only bit indicates whether internal 2 mem. channel is in power saving mode. 0 - not in power saving 1 - power saving
10-3 I2PST	Internal 2memory arbitration Power Saving Timer - these bits defines the timer value of the power saving mode of the internal 2 memory arbitration. The value in this field represent clock cycles of the internal 2 memory arbitration clock multiplied by 8. Default value is set to 80 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 - timer is configured to 8 clock cycles. ... ... 00001010 Default value- 80 clock cycles. ... ... 11111111 - timer clock is defined to 2040 clock cycles.
2 I2DVFS	Internal mem. 2 DVFS request. SW request for DVFS of internal 2 mem. channel. 0 - no dvfs request 1 - dvfs request

Table 44-33. M4IF Internal 2 Control Register Field Descriptions (continued)

Field	Description
1 I2LPMD	Internal mem. 2 LPMD request. SW request for LPMD of internal 2 mem. channel. 0 - no lpmd request 1 - lpmd request
0 DI2PS	Disable Internal 2 memory Power Saving mode - this bit when configured can disable auto power saving mode of the internal 2 memory interface. 0 - power saving is enabled 1- power saving is disabled (default mode)

Details on the register fields are shown below in Table 44-35

Table 44-35. Register Field Descriptions

Field	Description
31-30 Reserved	Reserved bits.
29 SBS_VLD	Step By Step Valid. This bit reflects whether there is a pending request in the arbitration that is configured in bits [1:0] of the MDCR register. 0 - not valid 1 - valid
28 SBS_TYPE	Step By Step Request Type. These bits reflect the pending request type (read/write) as configured in bits [1:0] of the MDCR register. 0 - write 1 - read
27-25 SBS_LEN	Step By Step Length. These bits reflect the AXI “LEN” field of the pending request as configured in bits [1:0] of the MDCR register. 3’b000 - burst of length 1 3’b001 - burst of length 2 . . 3’b111 - burst of length 8
24-23 SBS_SIZE	Step By Step Size. These bits reflect the AXI “SIZE” field of the pending request as configured in bits [1:0] of the MDCR register. 2’b00 - 8 bits 2’b01 - 16 bits 2’b10 - 32 bits 2]b11 - 64 bits

Table 44-35. Register Field Descriptions (continued)

Field	Description
22-21 SBS_BURST	Step By Step Burst. These bits reflect the AXI “BURST” field of the pending request as configured in bits [1:0] of the MDCR register. 2’b00 - reserved 2’b01 - INCR burst 2’b10 - WRAP burst 2’b11 - reserved
20-18 SBS_PROT	Step By Step Protection. These bits reflect the AXI “PROT” field of the pending request as configured in bits [1:0] of the MDCR register.
17-16 SBS_LOCK	Step By Step Lock. These bits reflect the AXI “LOCK” field of the pending request as configured in bits [1:0] of the MDCR register.
15-12 SBS_CACHE	Step By Step Cache. These bits reflect the AXI “CACHE” field of the pending request as configured in bits [1:0] of the MDCR register.
11-8 SBS_AXI_ID	Step By Step AXI ID. These bits reflect the AXI “ID” field of the pending request as configured in bits [1:0] of the MDCR register.
7-4 SBS_MASTER_ID	Step By Step Master ID. These bits reflect the Master ID of the pending request as configured in bits [1:0] of the MDCR register.
3-1 SBS_MASTER	Step By Step Master. These bits reflect the EMI Master port of the pending request as configured in bits [1:0] of the MDCR register.
0 SBS_END	Step By Step Endianness. This bit reflects the endianness of the pending request as configured in bits [1:0] of the MDCR register.

Table 44-36. M4IF Control Register #0 Field Descriptions

Field	Description
31 SW_RST	Software reset. This bit resets all the configuration registers (except for the bit itself). 0 - reset 1 - no reset
30-28	Reserved.
27 FDVACK	Fast DVFS acknowledge. This read only bit indicates whether a dvfs acknowledge on the fast channel was asserted.
26 SDVACK	Slow DVFS acknowledge. This read only bit indicates whether a dvfs acknowledge on the slow channel was asserted.
25 IDVACK	Intr DVFS acknowledge. This read only bit indicates whether a dvfs acknowledge on the internal memory channel was asserted.
24 DVACK	General DVFS acknowledge. This read only bit indicates whether a dvfs acknowledge on the whole EMI was asserted.
23 FLPACK	Fast low-power acknowledge. This read only bit indicates whether a low-power acknowledge on the fast channel was asserted.
22 SLPACK	Slow low-power acknowledge. This read only bit indicates whether a low-power acknowledge on the slow channel was asserted.
21 ILPACK	Intr low-power acknowledge. This read only bit indicates whether a low-power acknowledge on the internal memory channel was asserted.
20 LPACK	General low-power acknowledge. This read only bit indicates whether a low-power acknowledge on the whole EMI was asserted.
19	Reserved.
18 FPSS	Fast Power Saving Status. This read only bit indicates whether fast channel is in power saving mode. 0 - not in power saving 1 - power saving
17 SPSS	Slow Power Saving Status. This read only bit indicates whether slow channel is in power saving mode. 0 - not in power saving 1 - power saving
16 IPSS	Intr Power Saving Status. This read only bit indicates whether internal mem. channel is in power saving mode. 0 - not in power saving 1 - power saving
15 EAS3	Enable Stop Arbitration M3 - Stop all read accesses to M3 that are not from to the same slave as the ones already inside the gasket. 0 - disabled (not stopping) 1- enabled (stopping) - default
14 EAS2	Enable Stop Arbitration M2 - Stop all read accesses to M2 that are not from to the same slave as the ones already inside the gasket. 0 - disabled (not stopping) - default 1- enabled (stopping)
13 EAS1	Enable Stop Arbitration M1 - Stop all read accesses to M1 that are not from to the same slave as the ones already inside the gasket. 0 - disabled (not stopping) - default 1- enabled (stopping)

Table 44-36. M4IF Control Register #0 Field Descriptions (continued)

Field	Description
12 EAS0	Enable Stop Arbitration M0 - Stop all read accesses to M0 that are not from to the same slave as the ones already inside the gasket. 0 - disabled (not stopping) 1- enabled (stopping) - default
11 FDVFS	Fast DVFS request. SW request for DVFS of fast channel. 0 - no dvfs request 1 - dvfs request
10 SDVFS	Slow DVFS request. SW request for DVFS of slow channel. 0 - no dvfs request 1 - dvfs request
9 IDVFS	Internal mem. DVFS request. SW request for DVFS of internal mem. channel. 0 - no dvfs request 1 - dvfs request
8 DVFS	General DVFS request. SW request for DVFS of whole EMI. 0 - no dvfs request 1 - dvfs request
7 FLPMD	Fast LPMD request. SW request for LPMD of fast channel. 0 - no lpmd request 1 - lpmd request
6 SLPMD	Slow LPMD request. SW request for LPMD of slow channel. 0 - no lpmd request 1 - lpmd request
5 ILPMD	Internal mem. LPMD request. SW request for LPMD of internal mem. channel. 0 - no lpmd request 1 - lpmd request
4 LPMD	General LPMD request. SW request for LPMD of whole EMI. 0 - no lpmd request 1 - lpmd request
3	Reserved.
2 DFPS	Disable Fast arb. Power Saving mode - this bit when configured can disable auto power saving mode of the fast arbitration and its memory controller. 0 - power saving is enabled 1- power saving is disabled (default mode)
1 DSPS	Disable Slow arb. Power Saving mode - this bit when configured can disable auto power saving mode of the slow arbitration and its memory controllers. 0 - power saving is enabled 1- power saving is disabled (default mode)
0 DIPS	Disable Internal memory Power Saving mode - this bit when configured can disable auto power saving mode of the internal memory interface. 0 - power saving is enabled 1- power saving is disabled (default mode)

44.2.3.31 M4IF Control Register #1

MCR1 register defines the timer values of each arbitration to be used for auto power saving mode.

Address 0xBASE+0x090 (MCR1) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	EAS7	EAS6	EAS5	EAS4			IPST									SPST

Reset	0	0	0	1	0	1	0	0	0	0	0	0	1	0	1	0

Figure 44-34. M4IF Control Register #1

Table 44-37 describes the details of each field in the MCR1 register.

Table 44-37. M4IF Control Register #1 Field Descriptions

Field	Description
31 EAS7	Enable Stop Arbtration M7 - Stop all read accesses to M7 that are not from to the same slave as the ones already inside the gasket. 0 - disabled (not stopping) 1- enabled (stopping) - default
30 EAS6	Enable Stop Arbitration M6 - Stop all read accesses to M6 that are not from to the same slave as the ones already inside the gasket. 0 - disabled (not stopping) - default 1- enabled (stopping)
29 EAS5	Enable Stop Arbitration M5 - Stop all read accesses to M5 that are not from to the same slave as the ones already inside the gasket. 0 - disabled (not stopping) - default 1- enabled (stopping)
28 EAS4	Enable Stop Arbitration M4 - Stop all read accesses to M4 that are not from to the same slave as the ones already inside the gasket. 0 - disabled (not stopping) - default 1- enabled (stopping)
27-26	Reserved

Table 44-37. M4IF Control Register #1 Field Descriptions (continued)

Field	Description
25-18 IPST	Internal 1 memory arbitration Power Saving Timer - these bits defines the timer value of the power saving mode of the internal 1 memory arbitration. The value in this field represent clock cycles of the internal 1 memory arbitration clock multiplied by 8. Default value is set to 80 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 - timer is configured to 8 clock cycles. ... ... 00001010 Default value- 80 clock cycles. ... ... 11111111 - timer clock is defined to 2040 clock cycles.
17	Reserved
16-9 SPST	Slow arbitration Power Saving Timer - these bits defines the timer value of the power saving mode of the slow arbitration. The value in this field represent clock cycles of the slow memory arbitration clock multiplied by 8. Default value is set to 80 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 - timer is configured to 8 clock cycles. ... ... 00001010 Default value- 80 clock cycles. ... ... 11111111 - timer clock is defined to 2040 clock cycles.
8	Reserved
7-0 FPST	Fast arbitration Power Saving Timer - these bits defines the timer value of the power saving mode of the fast arbitration. The value in this field represent clock cycles of the fast memory arbitration clock multiplied by 8. Default value is set to 80 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 - timer is configured to 8 clock cycles. ... ... 00001010 Default value- 80 clock cycles. ... ... 11111111 - timer clock is defined to 2040 clock cycles.

44.2.3.32 M4IF Debug Control Register

The MDCR controls several functions in the debug unit.

Address 0xBASE+0x094 (MDCR) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 44-35. M4IF Debug Control Register

Details on the register fields are shown below in Table 44-38.

Table 44-38. M4IF Debug Control Register Field Descriptions

Field	Description
31 DBG_EN	Debug Enable. Enable debug units counters and summing. 0 - disable 1 - enable default is “disable”
30-28	Reserved.
27 DBG_RST	Debug Reset. Reset all debug unit’s counters and summing. 0 - no reset 1 - reset
26-24	Reserved.
23 I2SBS_EN	Step By Step Enable int2. Enable step by step mode for int2 channel. 0 - disable 1 - enable default is “disable”
22	Reserved.
21 I1SBS_EN	Step By Step Enable slow. Enable step by step mode for slow channel. 0 - disable 1 - enable default is “disable”

Table 44-38. M4IF Debug Control Register Field Descriptions (continued)

Field	Description
20 DDPT	Debug Dynamic Priority Type. Read or Write request reflect on the debug unit registers. 0 - write 1 - read
19-17 DDPM	Debug Dynamic Priority Master. Which master to reflect on the debug unit registers.
16	Reserved.
15 FSBS_EN	Step By Step Enable fast. Enable step by step mode for fast channel. 0 - disable 1 - enable default is “disable”
14 FSBS	Fast Step By Step. This bit trigger the fast arbitration in step by step mode. Write ‘1’ to this register in order to initiate a new transaction inside the fast arbitration. This bit goes down to ‘0’ when the new transaction is pending on AXI bus and then waiting for another write ‘1’ in order to initiate the next transaction. 1 Fast arbitration is waiting to a new transaction to go out on the AXI bus. 0 There is a pending transaction on the AXI bus.
13 SSBS	Slow Step By Step. This bit trigger the slow arbitration in step by step mode. Write ‘1’ to this register in order to initiate a new transaction inside the slow arbitration. This bit goes down to ‘0’ when the new transaction is pending on AXI bus and then waiting for another write ‘1’ in order to initiate the next transaction. 1 Slow arbitration is waiting to a new transaction to go out on the AXI bus. 0 There is a pending transaction on the AXI bus.
12 I1SBS	Int1 Step By Step. This bit trigger the int1 arbitration in step by step mode. Write ‘1’ to this register in order to initiate a new transaction inside the int1 arbitration. This bit goes down to ‘0’ when the new transaction is pending on AXI bus and then waiting for another write ‘1’ in order to initiate the next transaction. 1 Int1 arbitration is waiting to a new transaction to go out on the AXI bus. 0 There is a pending transaction on the AXI bus.
11 I2SBS	Int2 Step By Step. This bit trigger the int2 arbitration in step by step mode. Write ‘1’ to this register in order to initiate a new transaction inside the int2 arbitration. This bit goes down to ‘0’ when the new transaction is pending on AXI bus and then waiting for another write ‘1’ in order to initiate the next transaction. 1 Int2 arbitration is waiting to a new transaction to go out on the AXI bus. 0 There is a pending transaction on the AXI bus.
10	Reserved.
9-8 RARB	Read Arbitration. These 2 bits decide which arbitration will be reflected on the debug status registers when reading them. 00 - fast arbitration 01 - slow arbitration 10 - internal 1 mem. arbitration 11 - internal 2 mem. arbitration
7-2	Reserved
1-0 VARB	Visibility Arbitration. These 2 bits decide which arbitration to reflect on the EMI debug output pins and on the step by step registers. 00 - fast arbitration 01 - slow arbitration 10 - internal 1 mem. arbitration 11 - internal 2 mem. arbitration

44.2.3.33 Fast Arbitration Control Register

The FACR register is the control register of the fast arbitration logic. It contains several configuration field in order to let the user optimize the arbitration.

Address 0xBASE+0x098 (FACR) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R																
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R								FRDT	FDPUR							FDPE
W																
Reset	0	0	0	0	0	0	0	1	1	0	1	0	0	0	0	1

Figure 44-36. Fast Arbitration Control Register

Table 44-39 describes the details of each field in the FACR register.

Table 44-39. Fast Arbitration Control Register Field Descriptions

Field	Description
31-9	Reserved
8 FRDT	Read Through bit - this bit indicates the read mode from fast channel 0 - store and forward 1- read through (default)
7-4 FDPUR	Dynamic Priority Update Resolution - This field defines the minimum time resolution (in number of arbitration selections) that each priority master would be update by the dynamic priority logic.The minimum value is 2 selections. The value can be changed by the user in order to achieve lower resolution to reduce dynamic priority influence on the arbitration logic. It is recommended not to use higher value than average access time of the memory controller. 0000 reserved 0001 encoding 2 ... ... 1010 Default value- encoding 11. ... ... 1111 Dynamic priority calculation updates will be done once per 15 selections minimum.
3-1	Reserved
0 FDPE	Dynamic Priority Enable. This bit defines whether arbitration logic would use dynamic priority logic or not. 0 Dynamic Priority is not used, disabled. 1 Dynamic Priority is used, enabled.

44.2.3.34 F_Priority Weighting Configuration Register

The FPWC register configure the weighting values of each field in the arbitration. Each weighting field has a default value based on model simulation. It is highly recommended to use these default values and not to change it, any change to these values should be done within an extreme care.

IMPORTANT - At any configuration of these values, the user must make sure that the following restriction is kept:

FPHR+FAHR+FDPM+[highest basic priority of fast channel] < 16

Address 0xBASE+0x09C (FPWC) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R										FAHR			FPHR			
W																
Reset	0	0	0	0	0	0	0	0	0	0	1	0	0	1	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	1	0	0	1	0	1	0	0	0

Figure 44-37. F_Priority Weighting Configuration Register

Table 44-40 describes in details FPWC register fields.

/

Table 44-40. F_Priority Weighting Configuration Register Field Descriptions

Field	Description
31-23	Reserved.
22-20 FAHR	Access Hit Rate. Any pending access that is considered as page hit is checked to be a consecutive access type or not. If it is a consecutive access than the weighting value of this request will increase by FAHR value. Default value of FAHR is 0x010 - encoding 2.
19-16 FPHR	Page Hit Rate. This value will be added by the dynamic arbitration logic to any pending request that is considered as page hit. Default value of FPHR is 0x0100 - encoding 4.
15-11	Reserved.
10-8 FPCR	Pending Cycles Rate. Each timing resolution the dynamic arbitration updates a pending request, it will increase its weighting value by FPCR value. Default FPCR value is 0x001 - encoding 1.

Table 44-40. F_Priority Weighting Configuration Register Field Descriptions (continued)

Field	Description
10	Reserved.
6-5 FAPR	Access Penalty Rate. This value is decreased from any data in a served request. For example, for served access of burst2 type, the weighting value will be decreased by 2xFAPR. Default FAPR value is 0x01 - encoding 1.
4	Reserved.
3–0 FDPM	Dynamic Priority Maximum. This field defines the maximum value of the dynamic priority. This value can be changed in order to get larger window for the dynamic arbitration. Default value of FDPM is 0x1000 - encoding 8.

44.2.3.35 Slow Arbitration Control Register

The SACR register is the control register of the slow arbitration logic. It contains several configuration fields in order to let the user optimize the arbitration.

Address 0xBASE+0x0A0 (SACR) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 44-39. Power saving masters 2 Register

Detailed description of Power saving masters 2 register is shown in Table 44-4.

Table 44-42. Power saving masters 2 Register Field Descriptions

Field	Description
31-24 M5_PST	master #5 power saving timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 - timer is configured to 100 clock cycles. ... ... 00001010 Default value- 1000 clock cycles. ... ... 11111111 - timer clock is defined to 25500 clock cycles.
23	Reserved.
22 M5_WIS	Master #5 Write Idle Status.This read only bit indicates whether master #5 write request buffer is idle (empty) or not. 0 - idle 1 - not idle
21 M5_RIS	Master #5 Read Idle Status.This read only bit indicates whether master #5 read request buffer is idle (empty) or not. 0 - idle 1 - not idle

Table 44-42. Power saving masters 2 Register Field Descriptions (continued)

Field	Description
20 M5_PSS	Master #5 Power Saving Status. This read only bit indicates whether master #5 gasket is in power saving mode. 0 - not in power saving 1 - power saving
19-17 M5_ROC	master #5 ready off cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. 3'b001 - 3'b111 (3'b000 is a forbidden value)
16 M5_PSD	master #5 power saving disable. 0 - power saving enabled 1 - power saving disabled (default)
15-8 M4_PST	master #4 power saving timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 - timer is configured to 100 clock cycles. ... ... 00001010 Default value- 1000 clock cycles. ... ... 11111111 - timer clock is defined to 25500 clock cycles.
7	Reserved.
6 M4_WIS	Master #4 Write Idle Status.This read only bit indicates whether master #4 write request buffer is idle (empty) or not. 0 - idle 1 - not idle
5 M4_RIS	Master #4 Read Idle Status.This read only bit indicates whether master #4 read request buffer is idle (empty) or not. 0 - idle 1 - not idle
4 M4_PSS	Master #4 Power Saving Status. This read only bit indicates whether master #4 gasket is in power saving mode. 0 - not in power saving 1 - power saving
3-1 M4_ROC	master #4 ready off cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. Default value is 3 cycles. 3'b001 - 3'b111 (3'b000 is a forbidden value)
4 M0_PSD	master #4 power saving disable. 0 - power saving enabled 1 - power saving disabled (default)

44.2.3.37 Int. Memory Arbitration Control Register

The IACR register is the control register of the internal memory arbitration logic. It contains several configuration field in order to let the user optimize the arbitration.

Address 0xBASE+0x0A8 (IACR) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 44-41. Power saving masters 3 Register

Detailed description of Power saving masters 3 register is shown in Table 44-4.

Table 44-44. Power saving masters 3 Register Field Descriptions

Field	Description
31-24 M7_PST	master #7 power saving timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 - timer is configured to 100 clock cycles. ... ... 00001010 Default value- 1000 clock cycles. ... ... 11111111 - timer clock is defined to 25500 clock cycles.
23	Reserved.
22 M7_WIS	Master #7 Write Idle Status.This read only bit indicates whether master #7 write request buffer is idle (empty) or not. 0 - idle 1 - not idle
21 M7_RIS	Master #7 Read Idle Status.This read only bit indicates whether master #7 read request buffer is idle (empty) or not. 0 - idle 1 - not idle

Table 44-44. Power saving masters 3 Register Field Descriptions (continued)

Field	Description
20 M7_PSS	Master #7 Power Saving Status. This read only bit indicates whether master #7 gasket is in power saving mode. 0 - not in power saving 1 - power saving
19-17 M7_ROC	master #7 ready off cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. 3'b001 - 3'b111 (3'b000 is a forbidden value)
16 M7_PSD	master #7 power saving disable. 0 - power saving enabled 1 - power saving disabled (default)
15-8 M6_PST	master #6 power saving timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 - timer is configured to 100 clock cycles. ... ... 00001010 Default value- 1000 clock cycles. ... ... 11111111 - timer clock is defined to 25500 clock cycles.
7	Reserved.
6 M6_WIS	Master #6 Write Idle Status.This read only bit indicates whether master #6 write request buffer is idle (empty) or not. 0 - idle 1 - not idle
5 M6_RIS	Master #6 Read Idle Status.This read only bit indicates whether master #6 read request buffer is idle (empty) or not. 0 - idle 1 - not idle
4 M6_PSS	Master #6 Power Saving Status. This read only bit indicates whether master #6 gasket is in power saving mode. 0 - not in power saving 1 - power saving
3-1 M6_ROC	master #6 ready off cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. Default value is 3 cycles. 3'b001 - 3'b111 (3'b000 is a forbidden value)
6 M0_PSD	master #6 power saving disable. 0 - power saving enabled 1 - power saving disabled (default)

44.2.3.39 F_Unit_Level_Arbitration_ Register

The FULA register configure the unit level arbitration configuration bits of each logic unit in levels 3,4 and 5. Please refer to Section 44.3.9, Arbitration Scheme when Masters are in Same Priority (Bus Division)" for more details on the arbitration logic units.

Address 0xBASE+0x0B0 (FULA) Access: User read-write

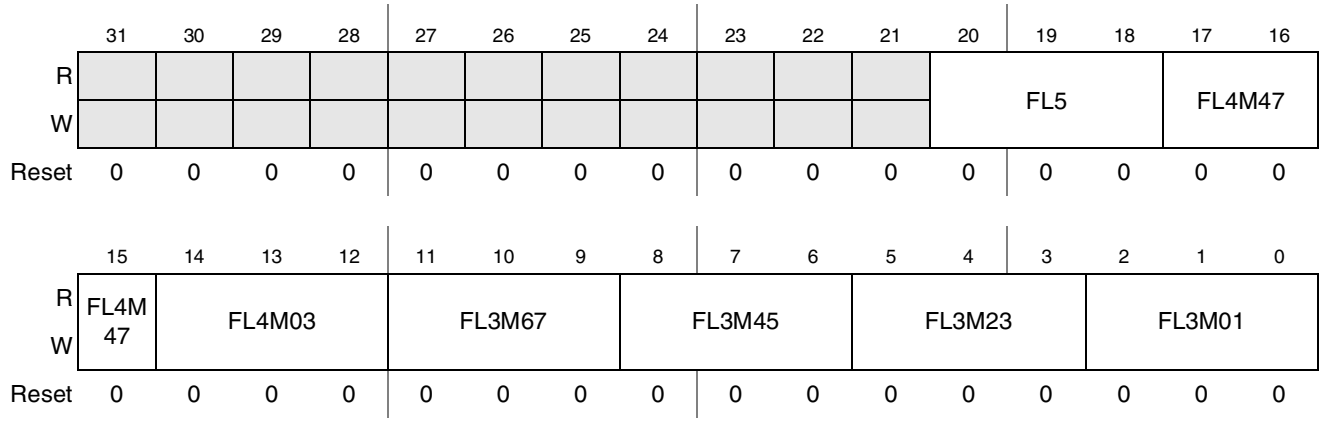

Figure 44-42. F_Unit_Level_Arbitration_ Register

Table 44-45 describes in details FULA register fields.

Table 44-45. F_Unit_Level_Arbitration_ Register Field Descriptions

Field	Description
31-21	Reserved.
20-18 FL5	Fast Level 5 - These bits configure the arbitration mode of level 5 arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL5 is 0x000 - encoding 0.
17-15 FL4M47	Fast Level 4 (m47) - These bits configure the arbitration mode of level 4(m47) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL4M47 is 0x000 - encoding 0.
14-12 FL4M03	Fast Level 4 (m03) - These bits configure the arbitration mode of level 4(m03) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL4M03 is 0x000 - encoding 0.
11-9 FL3M67	Fast Level 3 (m67) - These bits configure the arbitration mode of level 3(m67) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL3M67 is 0x000 - encoding 0.
8-6 FL3M45	Fast Level 3 (m45) - These bits configure the arbitration mode of level 3(m45) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL3M45 is 0x000 - encoding 0.
5-3 FL3M23	Fast Level 3 (m23) - These bits configure the arbitration mode of level 3(m23) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL3M23 is 0x000 - encoding 0.
2-0 FL3M01	Fast Level 3 (m01) - These bits configure the arbitration mode of level 3(m01) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 44-62. Default value of FL3M01 is 0x000 - encoding 0.

44.2.3.40 S_Unit_Level_Arbitration_ Register

The SULA register configure the unit level arbitration configuration bits of each logic unit in levels 3,4 and 5. Please refer to Section 44.3.9, Arbitration Scheme when Masters are in Same Priority (Bus Division)" for more details on the arbitration logic units.

Address 0xBASE+0x0B4 (SULA) Access: User read-write

Figure 44-46. Fast_Dynamic_Priority_Control Register

Table 44-49 describes in details FDPC register fields.

Table 44-49. Fast_Dynamic_Priority_Control Register Field Descriptions

Field	Description
31-25	Reserved.
FD4_MAS 24-22	Fast Dynamic 4 master - These bits indicate which master is to be reflected in the FDPS register, for dynamic priority 4.
FD4_RW 21	Fast Dynamic 4 read/write - This bit indicates whether a read or a write request is to be reflected in the FDPS register, for dynamic priority 4. 0 - write 1- read
20	Reserved.
FD3_MAS 19-17	Fast Dynamic 3 master - These bits indicate which master is to be reflected in the FDPS register, for dynamic priority 3.
FD3_RW 16	Fast Dynamic 3 read/write - This bit indicates whether a read or a write request is to be reflected in the FDPS register, for dynamic priority 3. 0 - write 1- read
15	Reserved.
FD2_MAS 14-12	Fast Dynamic 2 master - These bits indicate which master is to be reflected in the FDPS register, for dynamic priority 2.
FD2_RW 11	Fast Dynamic 2 read/write - This bit indicates whether a read or a write request is to be reflected in the FDPS register, for dynamic priority 2. 0 - write 1- read
10	Reserved.
FD1_MAS 9-7	Fast Dynamic 1 master - These bits indicate which master is to be reflected in the FDPS register, for dynamic priority 1.
FD1_RW 6	Fast Dynamic 1 read/write - This bit indicates whether a read or a write request is to be reflected in the FDPS register, for dynamic priority 1. 0 - write 1- read
5	Reserved.
FD0_MAS 4-2	Fast Dynamic 0 master - These bits indicate which master is to be reflected in the FDPS register, for dynamic priority 0.
FD0_RW 1	Fast Dynamic 0 read/write - This bit indicates whether a read or a write request is to be reflected in the FDPS register, for dynamic priority 0. 0 - write 1- read
0	Reserved.

44.2.3.44 Master Len Interrupt

This is a status register that indicates whether a “LEN>8” interrupt had occurred.

Address 0xBASE+0x0C4 (MLEN) Access: User read only

Figure 44-47. Master Len Interrupt

The description of the “Master LEN Interrupt” register can be found in Table 44-50

Table 44-50. Master Len Interrupt Field Descriptions

Field	Description
31-16	Reserved
15 fb816	A burst of 16 bit or 8 bit was handled in the fast arbitration. This bit can be cleared by writing 1 to it. 0 - no burst occurred 1 - burst occurred
14 fb816	A burst of 16 bit or 8 bit was handled in the slow arbitration. This bit can be cleared by writing 1 to it. 0 - no burst occurred 1 - burst occurred
13 fb816	A burst of 16 bit or 8 bit was handled in the int1 arbitration. This bit can be cleared by writing 1 to it. 0 - no burst occurred 1 - burst occurred
12 fb816	A burst of 16 bit or 8 bit was handled in the int2 arbitration. This bit can be cleared by writing 1 to it. 0 - no burst occurred 1 - burst occurred
11-8	Reserved
m7len	Master 7 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.
m6len	Master 6 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.

Table 44-50. Master Len Interrupt Field Descriptions (continued)

Field	Description
m5len	Master 5 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.
m4len	Master 4 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.
m3len	Master 3 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.
m2len	Master 2 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.
m1len	Master 1 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.
m0len	Master 0 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.

44.2.3.45 Watermark start ADDR_0 register

The WMSA0 register defines the watermark start address of space area #0. Watermark space #0 corresponds in general to AP privilege master which is defined by SoC AP via at the EMIv2 boundary. AP privilege master is the only master that can configure/read this register.

Address 0xBASE+0x0D4 (WMSA0_0) Access: User read-write

Figure 44-64. Watermark Interrupt and Status #0 Register

Table 44-53 describes in details WMIS0 register fields.

Table 44-53. Watermark Interrupt and Status #0 Register Field Descriptions

Field	Description
31 WIE0	WaterMark Enable. This bit enables the WaterMark mechanism of space #0 including the interrupt generation. For example, if WME is set and a WaterMark violation is detected a WaterMark interrupt is generated. 0 WaterMark is disabled. 1 WaterMark is enabled.
30	Reserved.

Table 44-53. Watermark Interrupt and Status #0 Register Field Descriptions (continued)

Field	Description
29-19 FVMID0	Fast Violation Master ID - these bits contain the Master [29:27] Master ID [26:23] and AXI ID [22:19] of the master which tried to access a watermark area in the fast channel with WM[0] in low state.
18-8 SVMID0	Slow Violation Master ID - these bits contain the Master [18:16] Master ID [15:12] and AXI ID [11:8] of the master which tried to access a watermark area in the slow channel with WM[0] in low state.
7 WS0_7	WaterMark Status0_7. This bit indicates if WaterMark violation had occurred in the WaterMark space #0 memory region of SDRAM/MDDR CS1 as defined in WMSA0_7 and WMEA0_7. WS0_7 is cleared by writing a one to the bit. 0 SDRAM/MDDR CSD1 WaterMark violation did not occur. 1 SDRAM/MDDR CSD1 WaterMark violation had occurred.
6 WS0_6	WaterMark Status0_6. This bit indicates if WaterMark violation had occurred in the WaterMark space #0 memory region of SDRAM/MDDR CS0 as defined in WMSA0_6 and WMEA0_6. WS0_6 is cleared by writing a one to the bit. 0 SDRAM/MDDR CSD0 WaterMark violation did not occur. 1 SDRAM/MDDR CSD0 WaterMark violation had occurred.
5 WS0_5	WaterMark Status0_5. This bit indicates if WaterMark violation had occurred in the WaterMark space #0 memory region of WEIMv2 CS0 as defined in WMSA0_5 and WMEA0_5. WS0_5 is cleared by writing a one to the bit. 0 WEIMv2 CS5 WaterMark violation did not occur. 1 WEIMv2 CS5 WaterMark violation had occurred.
4 WS0_4	WaterMark Status0_4. This bit indicates if WaterMark violation had occurred in the WaterMark space #0 memory region of WEIMv2 CS0 as defined in WMSA0_4 and WMEA0_4. WS0_4 is cleared by writing a one to the bit. 0 WEIMv2 CS4 WaterMark violation did not occur. 1 WEIMv2 CS4 WaterMark violation had occurred.
3 WS0_3	WaterMark Status0_5. This bit indicates if WaterMark violation had occurred in the WaterMark space #0 memory region of WEIMv2 CS3 as defined in WMSA0_3 and WMEA0_3. WS0_3 is cleared by writing a one to the bit. 0 WEIMv2 CS3 WaterMark violation did not occur. 1 WEIMv2 CS3 WaterMark violation had occurred.
2 WS0_2	WaterMark Status0_5. This bit indicates if WaterMark violation had occurred in the WaterMark space #0 memory region of WEIMv2 CS0 as defined in WMSA0_2 and WMEA0_2. WS0_2 is cleared by writing a one to the bit. 0 WEIMv2 CS2 WaterMark violation did not occur. 1 WEIMv2 CS2 WaterMark violation had occurred.
1 WS0_1	WaterMark Status0_1. This bit indicates if WaterMark violation had occurred in the WaterMark space #0 memory region of WEIMv2 CS0 as defined in WMSA0_1 and WMEA0_1. WS0_1 is cleared by writing a one to the bit. 0 WEIMv2 CS1 WaterMark violation did not occur. 1 WEIMv2 CS1 WaterMark violation had occurred.
0 WS0_0	WaterMark Status0_0. This bit indicates if WaterMark violation had occurred in the WaterMark space #0 memory region of WEIMv2 CS0 as defined in WMSA0_0 and WMEA0_0. WS0_0is cleared by writing a one to the bit. 0 WEIMv2 CS0 WaterMark violation did not occur. 1 WEIMv2 CS0 WaterMark violation had occurred.

44.2.3.48 Fast Watermark Violation Address #0 register

The FWMVA0 register contains the address of the access that violated the watermark space #0 for fast channel (SDR/DDR) corresponding to watermark interrupt and status #0 register. AP privilege master is the only master that can read this register.

Address 0xBASE+0x118 (FWMVA0) Access: User read only

44.3 Functional Description

This section and the sub section below provide a functional description on the internal logic of M4IF. This section describes in high level the way an access paths between system level through M4IF till the memory controller. The sub sections below describes in more details each part of M4IF sub modules and its functionality.

44.3.1 Write Access Description

An AXI access is detected on one or more AXI port gaskets and latched into the addr/ctrl internal buffer. If the buffer is not full, the access can be served and data starts to enter to the write buffer. As was shown in Figure 44.1.2 the data is latched in the master clock domain. When WLAST signal is detected on the bus, an internal logic inside the gasket generates a request to the right arbitration module based on the address decoding that was done when the addr first arrived to the gasket. Since the request is generated in the master clock domain it is needed to sync it to the arbitration clock domain. This way it is guaranteed by design that all the data is stored in the buffer when the request is high at the arbitration.

The arbitration module starts to calculate priority to this new valid request and chooses it according to the arbitration's criterion. At the moment the access was chosen by the arbitration, it passes to the memory controller. The memory controller gets the data from the write buffer based on the **one_hot_wr_sel** control

of the buffer that is increment in the memory controller's clock domain. When the last data is pulled out of the buffer to the memory controller, the arbitration generates the WLAST signal as required in AXI bus protocol. The spot in the write buffer (and in the gasket's addr/ctrl buffer) will be cleared when a valid write response is issued from the gasket to the master.

In terms of write response, the gasket sends a **bufferable** response on the AXI response channel the moment the last data has reached the specific memory controller. In case of a **non-bufferable** access the response would be sent only after the write access is finished in the memory controller, and the memory controller itself sent a response.

44.3.2 Read Access Description

In a similar way when the access is a read access, the AXI addr and control signals are latched in a read control buffer inside the gasket. They are then transferred to the right arbitration module according to the address decoding in the gasket. Based on the arbitration scheme the request is served. The addr and control signals are sent to the memory controller. Data that comes out of the controller is written directly to the read buffer. The read buffer is dedicated to the specific memory controller, and is shared between all 8 AXI masters. The master can pull the data out of the buffer at the moment it gets RVALID signal from the memory controller.

A detailed description of M4IF sub module's functionality is described in the following sub sections.

44.3.3 AXI Port Gasket Functional Description

The AXI port gasket is an AXI interface to any master in the system. The gasket is a x64 AXI bus interface and can be fitted to a x32 AXI interface as well. In order to connect a x32 master to the gasket, the wdata and wstrb bus should be duplicated. The rdata bus should connect to the lower 32 bits out of the 64 that come out of the read buffer.

The gasket works with Data Interleaving Depth (DID) of 1. This is a big difference from previous versions of M4IF, where the gasket worked with DID of 2. It can hold as many accesses as its buffer depth (which is parametric) regardless of the AXI ID. This is another noticeable change from the previous M4IF, which was limited to 2 pending IDs.

Each gasket can generate up to two parallel requests to the arbitration logic, one for write and one for read. All requests can be valid in parallel to the same or to different arbitration modules.

The read addr fifo and read requests logic is similar to the write logic. The same fifo exist also for other AXI control signal so it can give the whole information to the arbitration whenever a request is valid at the arbitration module.

The write data is coming on the bus from the master directly into the write buffer. Since the write buffer is dedicated to each master that data is latched in the same clock domain of the master and no synchronization is needed.

44.3.4 Read/Write Buffer Functional Description

M4IF module includes up to 12 data buffers. Up to 8 write data buffers, and 4 read data buffers. The write buffers are dedicated for each master in the system. If a master is removed from the system, its gasket and its write buffer are removed, thus saving a lot of area. The read data buffers are dedicated for each arbitration. In the read buffer data is written by the specific controller and pulled out by any of the 8 masters, while in the write buffer, the dedicated master writes the data into the buffer and each of the 4 arbitration modules can pull out the data.

Therefore, in the write buffer the data is written in the master clock domain while in the read buffer the data is written in the specific arbitration clock domain.

Both the read and write buffer types, divided into fixed data slots in which data can be written. The slots are of depth 8 (the maximal burst length) and of 64bits size. In addition to the data, the buffers store the write strobe (8 bit) for write, and the read response (rresp, 2bit) for read. Each slot has a pointer_in and a pointer_out to mange the two way data, the way in which it is written into the slot and the way it pulled out of the slot. It is important to mention that data of a certain access can not be stored in two different slots.

There are two configuration options to pull the data out of the read buffers, “read through” and “store & forward”. In “store and forward” operation mode, the data can be pulled out by the slave only when all the datum of the burst is stored in the buffer, that is,. after RVALID, RREADY and RLAST signals are high on the bus. In “read trough” operation mode, the data can be pulled out of the buffer by the slave a few cycles after the first data was written to buffer, due to synchronization reasons.
For fast memory controllers it is recommended to use the “read through” and therefore to achieve a minimum latency between the controller and the master. However, for slow memory controller when there is an option that it would take time for the memory controller to write the data into the buffer, it is recommended to use the “store & forward” operation mode and to ensure the master bus won’t be busy for a long period of time.

On the write data buffer it is simpler, there is only one operation mode, the “store & forward” mode. In order to achieve best performance the arbitration guarantees that when a request is served and moves to the memory controller, all the data is already latched in the write buffer and can be pulled out by the memory controller without any busy or abort cycles in between each data word of the access. This happens since the access request is asserted at the arbitration only after the last data was written to the buffer.

The write buffer gets data from its master. Data can be pulled out of the write buffers by the 4 memory controllers in parallel. In the read buffer, only one memory controller can write to the buffer but several masters can pull the data at the same time, depending on the number of slots in the buffer.

44.3.5 Fast Arbitration Module Functional Description - 1st Degree

The fast arbitration module is responsible for all the accesses that go to ESDCTLv2 memory controller, LPDDR/DDR2 SDRAM memory devices. As was described in the sections before, the addr decoding is done at the AXI port gasket, any access that is pointed to the ESDCTL memory controller would be sent to the fast arbitration module. The fast arbitration arbitrates between all masters request, read and write. The overall number of request is 16, 8 request for read and 8 for write. Each request can be valid on the arbitration logic at any time, it is guaranteed by EMIv2 design, that whenever a write request is valid on the arbitration logic all the data is already stored in the write buffer. It means that data is ready on the bus

between the buffer and the specific memory controller whenever a specific request was chosen by the arbitration module. The fast arbitration uses a dynamic priority engine to perform a high performance low latency data path arbitration. The dynamic arbitration uses the following parameters in its engine and calculate the priority of each request accordingly.

44.3.5.1 Page Hit / Miss

LPDDR SDRAM memory device is divided into several banks depending on the specific memory configuration detailed by the memory manufacturer. Before any READ or WRITE commands can be issued to a bank in the LPDDR SDRAM, a row in that bank must be opened. This is accomplished by the ACTIVE command, by which both the Bank and the Row are selected. More than one bank can be active at any time. Once a row is open, a READ or WRITE command could be issued to that row. A subsequent ACTIVE command to another row in the same bank can only be issued after the previous row has been closed. The minimum time interval between two successive ACTIVE commands on the same bank is defined by t_{RC} timing parameter of the LPDRRDR SDRAM device. A Subsequent ACTIVE command to another bank can be issued while the first bank is being accessed, which results in a reduction of total row-access overhead. The minimum time interval between two successive ACTIVE commands on the different banks is defined by t_{RRD} timing parameter of the LPDRRDR SDRAM device.

Therefore, selecting access to the same Bank and the same Row one after the other would be issued in a minimum time at the controller. The arbitration would give high score to a page hit access (same Bank and same Row) than any other access in order to get the highest performance from the controller. (the score level can be configured by the user)

The decoding of the address to bank, row and cs is done in the gasket per each access that arrives from the master. It is later passed on to the “scoring” mechanism in the fast arbitration, in order to be able to calculate the appropriate score for each request. The order of elements on the address is: {cs,bank,row,column}. There is an option to work in “bank interleaving” or “address interleaving” mode. In this mode the order would be: {cs,row,bank,column}. For further details, please refer to the ESDCTLv2 spec.

NOTE

The page hit/mis feature will be functional at clock ratios of up to 1:2 (master:arbitration). At ratios greater than that, the low-frequency master’s page hit/miss score will not be valid, and the master will be selected not according to its page hit/miss score.

44.3.5.2 Last Access Details

In order to perform high density on the LPDDR SDRAM external bus it is needed to consider last access type when choosing the next request (access) on the arbitration to be served. In addition to Page Hit / Miss parameter in the arbitration, a consecutive READ command (READ after READ) would be issued faster than a WRITE after READ. The same is true for a consecutive WRITE command, (WRITE after WRITE).

The dynamic arbitration logic would prefer a consecutive command access in order to get the highest performance from the controller.

44.3.5.3 Basic Priority Configuration

In continue to FBP register description, each master in EMIv2 will have a basic priority configuration based on the user configuration. This basic priority value will be the base value for each master. The dynamic arbitration as described below start its calculation from the basic priority value per each master.

For Elvis project (i.MX51) the recommended configuration of the basic priorities for register FBPM0 (Section 44.2.3.12, F_Basic Priority Reg #0) should be 0x00000203.

44.3.5.4 Priority Calculation

The Fast arbitration module is designed to arbitrate read and write AXI accesses from a maximum number of 8 masters towards the ESDCTL memory controller.

This arbitration takes into account several parameters in order to decide which access to the controller is the most efficient one, out of all the pending requests as was described before.

The arbitration handles a dynamic priority mechanism to allow for a better decision making between the masters. Each master gets a basic priority, which is configurable via an IP register. A dynamic priority' as well as page/hit miss score, are added to this basic priority. Thus a total score is formed and according to this score the request is evaluated by the "decision mechanism" of the arbitration.

The dynamic priority is calculated per each request. Each master has 2 possible requests (1 read and 1 write) and therefore a total of 16 dynamic priorities is evaluated per arbitration. If a request is pending on the "decision mechanism" and other requests are chosen at that time, then after a defined amount of selections (configurable by register), the dynamic priority of this request will increase by a defined number of "points" (also configurable via a register). If, however, a request is chosen, then at that cycle, the dynamic priority of this request will be decreased by the same number of "points" times the number of data words in the burst. (the number of cycles it was taken to served the access)

There is a maximum limit for the dynamic priority. The limit is the same for all masters, and can be configured via a register.

Whenever a master's priority reaches either its limit, it cannot surpass that limit. If theoretically, there is a situation in which the limit needs to be exceeded, the priority will remain at its limit value.

Figure 44-86 illustrates the dynamic priority mechanism for a limit offset of 50 "points":

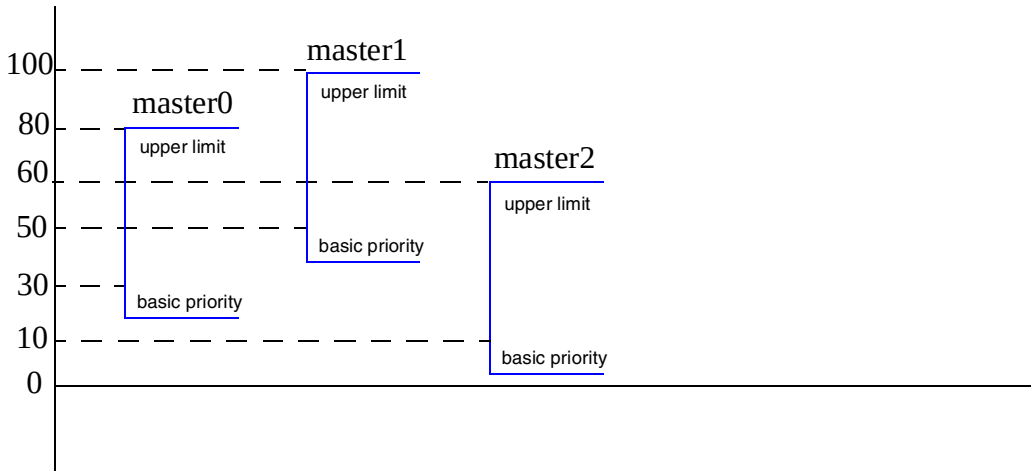

Figure 44-86. Master's Dynamic Priority Scheme

From the above illustration, it is noticeable that one master can "take control" over the arbitration if its basic priority is too high in comparison to the other masters.

There is an option to set a **static priority** to a master. By setting a master's basic priority to "1", the user makes sure that the total score of all of this master's requests will remain fixed on "1". This ensures that the specific master will get access on the bus only when all the other masters are not pending on the "decision mechanism". For that reason, a regular basic priority must have a value of "2" and above.

Therefore, the system configuration needs to be such that the odds of such a situation would be as low as possible. The default settings of the fast arbitration, and the entire M4IF system, were set based on an intensive modeling simulations, changes to these values must be done with extreme care.

In case all the masters have the same score, a simple arbitration logic is used to chose the next request to be served as described in section 1.5.8.

For Elvis project (i.MX51) the recommended configuration of the FPWC register (Section 44.2.3.34, F_Priority Weighting Configuration Register) should be 0x00120125

44.3.5.5 2nd Degree Arbitration (MIF4)

After choosing the best suited request out of the possible 16, it is latched inside a buffer of size 8 (parametric) and there goes through a second degree arbitration. The requests which are stored in this buffer are arbitrated in a similar way to the first degree. Here there's a simpler dynamic priority mechanism. Each request gets a single point for each time another request was chosen over it. When a request is chosen its dynamic counter is reset. The page hit and access hit get smaller amount of points. Not 10 and 5 (default values) like in the first degree, but 4 and 2. (This points are configurable using the MIF4 Scoring register)

The order of accesses from the same master with the same AXI ID is kept. Even if an access has a high score due to page and access hit, it won't be able to bypass an access from the same master with the same AXI ID that arrived before it.

From the second degree arbitration, the selected request is stored in a fifo of depth 4 (parametric). This fifo provides the AXI accesses between the M4IF and the ESDCTLv2.

The 2nd degree arbitration also have 2 more features in its engine:

44.3.5.5.1 Guarding Mechanism

The second degree arbitration is guarded from starvation by using a counter that prevent from a specific request to be stuck inside the 2nd degree buffer for more then a predefined number of clock cycles. For more information about this mechanism please refer to the MIF4 Scoring register.

44.3.5.5.2 Prediction

The second degree arbitration has the ability to predict the {cs,bank,row} that are going to be used by the ESDCTLv2 before the transaction is actually being sent on the AXI bus. By that, we are able to prepare the memory device for future transactions and improve our overall performance. for more information regarding this feature please refer to the ESDCTLv2 spec.

44.3.5.5.3 Recommended configuration

For Elvis project (i.MX51) the recommended configuration of the MIF4 scoring register (Section 44.2.3.14, MIF4 Scoring Register) should be 0x001901A3

44.3.6 Slow Arbitration Module Functional Description

The slow arbitration module is responsible to all access that goes to WEIMv2 memory controller and NFCv2 memory controller, Nor / PSRAM memory devices or Nand devices. As was described in the sections before, the addr decoding is done at the AXI port gasket, any access that is pointed to one of these memory controllers would be sent to the slow arbitration module. The slow arbitration module arbitrates between all masters request, read and write. The overall number of request is 16, 8 request for read and 8 for write. Each request can be valid on the arbitration logic in any time, it is guarantee by EMIv2 design, that whenever a request is valid on the arbitration logic all the data is already stored in the write shared buffer. It means that data is ready on the bus whenever a specific request was chosen by the arbitration module. The slow arbitration uses the "bus divison" mechanism, as described in Section 44.3.9, Arbitration Scheme when Masters are in Same Priority (Bus Division)

44.3.7 Internal 1 Memory Arbitration Module Functional Description

The Internal 1 memory arbitration module is responsible to all access that goes to system internal 1 memory controller, like ROM and RAM devices. As was described in the sections before, the addr decoding is done at the AXI port gasket, any access that is pointed to internal 1 memory space would be sent to the internal 1 memory arbitration module. The internal 1 memory arbitration module arbitrates between all masters request, read and write. The overall number of request is 16, 8 request for read and 8 for write. Each request can be valid on the arbitration logic in any time, it is guarantee by EMIv2 design,

that whenever a request is valid on the arbitration logic all the data is already stored in the write shared buffer. It means that data is ready on the bus whenever a specific request was chosen by the arbitration module. The internal 1 memory arbitration uses the “bus divison” mechanism, as described in Section 44.3.9, Arbitration Scheme when Masters are in Same Priority (Bus Division)

44.3.8 Internal 2 Memory Arbitration Module Functional Description

The Internal 2 memory arbitration module is responsible to all access that goes to system internal 2 memory controller, like ROM and RAM devices. As was described in the sections before, the addr decoding is done at the AXI port gasket, any access that is pointed to internal 2 memory space would be sent to the internal 2 memory arbitration module. The internal 2 memory arbitration module arbitrates between all masters request, read and write. The overall number of request is 16, 8 request for read and 8 for write. Each request can be valid on the arbitration logic in any time, it is guarantee by EMIv2 design, that whenever a request is valid on the arbitration logic all the data is already stored in the write shared buffer. It means that data is ready on the bus whenever a specific request was chosen by the arbitration module. The internal 2 memory arbitration uses the “bus divison” mechanism, as described in Section 44.3.9, Arbitration Scheme when Masters are in Same Priority (Bus Division)”

44.3.9 Arbitration Scheme when Masters are in Same Priority (Bus Division)

The following section describes the arbitration mechanism when ever the priority of two or more master requests are with the same value. It is most likely that this scheme will be dominant in the slow and internal memory arbitration where the special priority parameters are disables or even when the dynamic priority is disabled.

The low level arbitration scheme exist in all arbitration modules. It is built of several levels of the same logic unit which are connected in a tree built. Figure 44-87 describes the general built of the low level arbitration structure.

Each level of arbitrations (4 levels total) is built of the same logic unit. Each logic unit can be configured to a different arbitration scheme up on 3 input signals that can be partially configured by the user. It is important to mention that the logic unit follows its configured arbitration scheme only when both inputs (masters or requests) are with the same priority level.

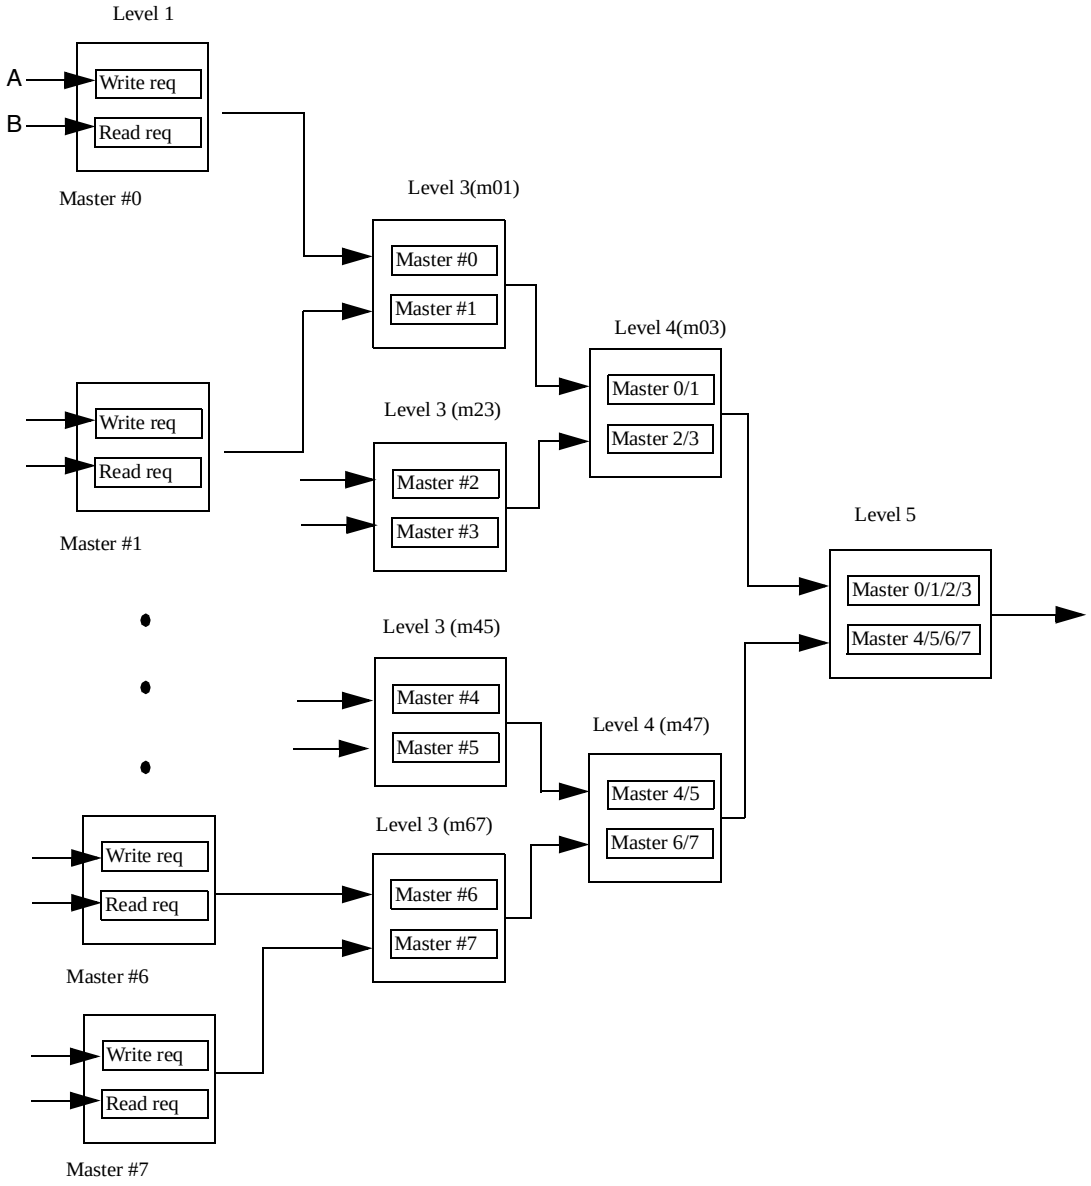

Figure 44-87. Low level arbitration structure

The 3 configuration bits of fast arbitration unit are defined as shown in Table 44-62 below:

Table 44-62. Logic Unit Fast Arbitration Configuration

#	bit 2	bit 1	bit0	arbitration scheme
0	0	0	0	100% priority to B.
1	0	0	1	25% priority to A
2	0	1	0	single 50%
3	0	1	1	double 50%
4	1	0	0	75% priority to A
5	1	0	1	100% priority to A
6	1	1	0	Reserved
7	1	1	1	Reserved

As was mentioned above the user can configure only part of the logic unit levels. Level 1 have a fixed priority scheme configuration and can not be changed while level 3, 4, and 5 can be configured for one of the above arbitration configurations as shown in Table 44-62.

Figure 44-88 describes schematically the arbitration scheme of each condition

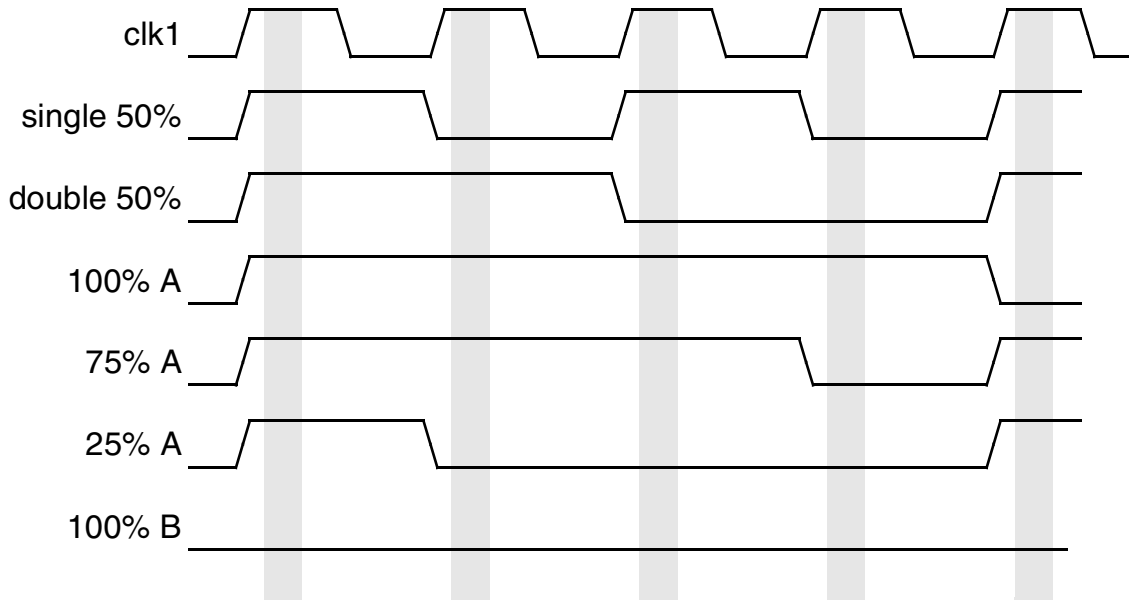

Figure 44-88. Logic units arbitration scheme.

The configuration of the logic units in level 2,3 and 4can be done via the F_Unit_Level_Arbitration_ Register. However, configuration of logic units in level 1 is fixed. Unit level 1 in hard wired configured to ‘double 50%’ state.

For ‘slow’ and ‘intr’ arbitrations, the scheme has changed from previous versions of M4IF. Now there are more configurations that were added, as described in the Table 44-63.Table 44-58

Table 44-63. Slow and Intr Arbitration Bus Division Configuration

#	bit 2	bit 1	bit0	arbitration scheme
0	0	0	0	100% priority to B.
1	0	0	1	12.5% to A.
2	0	1	0	25% to A.
3	0	1	1	37.5% to A.
4	1	0	0	50% - 50%
5	1	0	1	62.5% A.
6	1	1	0	75% to A.
7	1	1	1	100% to A.

44.3.10 WEIM-NFC Downsizer

The slow channel of EMIv2 ultimately splits to 2 memory controllers, WEIM and NFC. These 2 controllers’ AXI data bus width is 32 bits. The slow arbitration has an AXI data bus width of 64. Therefore, a 64bit_to_32bit downsizer is required. Such a downsizer is placed inside the M4IF between the slow arbitration and the AXI interfaces to WEIM and NFC. The downsizer handles bursts of length up to 8 (awlen/areln <= 7) for 64 (awsize/arsize=3) and 32 (awsize/arsize=2) bits. As for 8 and 16 bit accesses, the downsizer only supports single accesses (awlen/arlen=0). The downsizer is also a splitter and can determine the destination of an accesses, whether WEIM or NFC, based on the address of that access.

Note: Single length bursts will always have an output burst type (**awburst_weim** or **awburst_nfc**) INCR (2’b01). The awsize field, in case of 64bit accesses, will change from 64bit (2’b11) to 32bit (2’b10)

Note: Whenever sending burst of size 32 bit through the downsizer, wstrb[7:4] has to be tied to wstrb[3:0]

44.3.10.1 Endianness in Downsizing

The downsizer takes into consideration the endianness of each accesses. If the endianness as LE (0) then the data for addresses with 3 LSbits decoded to: 0,1,2 or 3, will be taken from the lower 32bits out of 64. The data for addresses with 3 LSbits decoded to:4,5,6 or 7 will be taken from the upper 32bits. If the endianness is BE (1) then for addresses with 3 LSbits decoded to: 0,1,2 or 3 data will be taken from the **upper** 32bits, and data corresponding to addresses with 3 LSbits decoded to:4,5,6 or 7 will be taken from the **lower** 32bits.

Note: The information about the destination of an AXI access is not taken into account in the arbitration module. The slow arbitration does not select accesses based on the memory controller’s condition (busy/idle and so on.).

44.3.11 Internal 1 Downsizer

The internal 1 memory channel of EMIv2 ultimately splits to 2 memory controllers, INT1_S0 and INT1_S1. These 2 controllers' AXI data bus width is 32 bits. The internal 1 memory arbitration has an AXI data bus width of 64. Therefore, a 64bit_to_32bit downsizer is required. Such a downsizer is placed inside the M4IF between the internal 1 memory arbitration and the AXI interfaces to INT1_S0 and INT1_S1. The downsizer handles bursts of length up to 8 (awlen/areln <= 7) for 64 (awsize/arsize=3) and 32 (awsize/arsize=2) bits. As for 8 and 16 bit accesses, the downsizer only supports single accesses (awlen/arlen=0). The downsizer is also a splitter and can determine the destination of an accesses, whether INT1_S0 or INT1_S1, based on the address of that access.

Note: Single length bursts will always have an output burst type (**awburst_int1_s0** or **awburst_int1_s1**) INCR (2'b01). The awsize field, in case of 64bit accesses, will change from 64bit (2'b11) to 32bit (2'b10)

Note: Whenever sending burst of size 32 bit through the downsizer, wstrb[7:4] has to be tied to wstrb[3:0]

44.3.11.1 Endianness in Downsizing

The downsizer takes into consideration the endianness of each accesses. If the endianness as LE (0) then the data for addresses with 3 LSbits decoded to: 0,1,2 or 3, will be taken from the lower 32bits out of 64. The data for addresses with 3 LSbits decoded to:4,5,6 or 7 will be taken from the upper 32bits. If the endianness is BE (1) then for addresses with 3 LSbits decoded to: 0,1,2 or 3 data will be taken from the **upper** 32bits, and data corresponding to addresses with 3 LSbits decoded to:4,5,6 or 7 will be taken from the **lower** 32bits.

Note: The information about the destination of an AXI access is not taken into account in the arbitration module. The internal 1 memory arbitration does not select accesses based on the memory controller's condition (busy/idle and so on.)

44.3.12 Clocks

M4IF module contains the following clocks:

- ESDCTLv2 main clock **(up to 200MHz)**
- Slow arbitration clock. **(up to 133MHz)**
- Internal 1 memory arbitration clock. **(up to 166MHz)**
- Internal 2 memory arbitration clock. (**up to 166MHz**)
- 8 x masters clocks, can be asynchronous to EMIv2 arbitration clocks. **(up to 166MHz)**
- Sky Blue interface clock. **(up to 66MHz)**

M4IF assumes all of its 3 main clocks: aclk_fast, aclk_slow, and aclk_intr, are on by default (after reset). If the system wishes to turn one of the clocks off, it must do so by going through the specific lpmd sequence. For example, if the system wishes to turn "aclk_fast" off, it should wake up with this clock on, send an "lpmd_fast" request, wait for "lpack_fast" acknowledge, and only then turn "aclk_fast" off. "lpmd_fast" will have to be asserted for the whole duration of "aclk_fast" being off.

Due to synchronization issues, the general "LPMD"/"DVFS" sequences will only be available when "aclk_fast" is on. **If "aclk_fast" is turned off, these sequences will not work**.

44.3.12.1 Clock Ratios

The “sky blue interface” clock’s (ipg_clk_s) frequency should be shorter (at least 1/2) than that of aclk_fast, aclk_slow, aclk_int1, aclk_int2 and all the master clocks at all times.

44.3.13 Reset

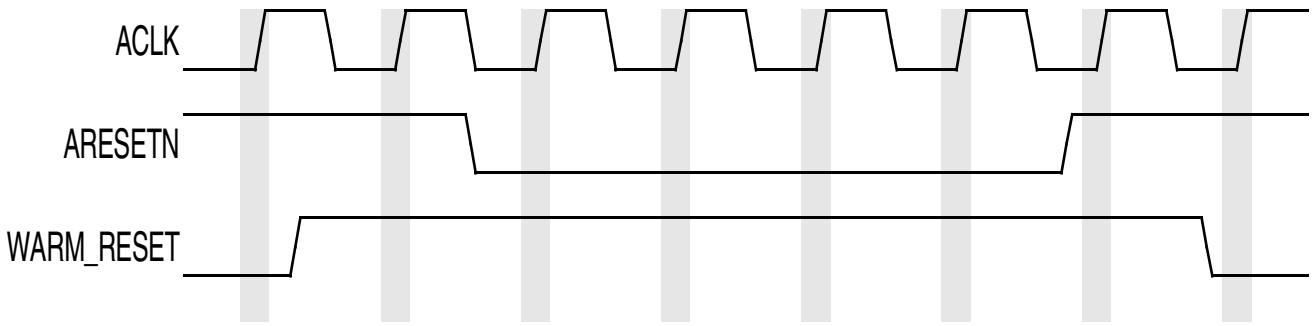
M4IF module as well as the entire EMIv2 module support 3 main reset signals, hard_reset, warm_reset and sw_reset. The reset tree at M4IF module as well as in EMIv2 is built in a way it provides the maximum flexibility to SoC so it can control the reset scheme according to its needs.

44.3.13.1 Software Reset

The software reset is a reset given only to the IP configuration registers. This is done via IP write to bit 31 (SW_RST) in the MCR0 register.

44.3.13.2 Warm Reset

Warm reset is a reset given to the whole system but the configuration register. The warm reset is issued by asserting the regular reset (aresetn) and by asserting the “warm_reset” signal along with it. The “warm_reset” signal must be asserted before the assertion of the “arestn” signal, and must be deasserted after the deassertion of the “aresetn” signal. As illustrated below:



44.3.13.3 EMI Programing Sequence after Warm Reset

This section describes the flow of getting into self-refresh mode before and during warm reset, as well as configuration that is needed to be made to ESDCTL when getting out of warm reset

Please note that after issuing a precharge all via special command register in the exit warm reset, it is recommended by devices to issue a manual auto refresh command, but not necessary.

Figure 44-89. Getting into self refresh before warm_reset assertion

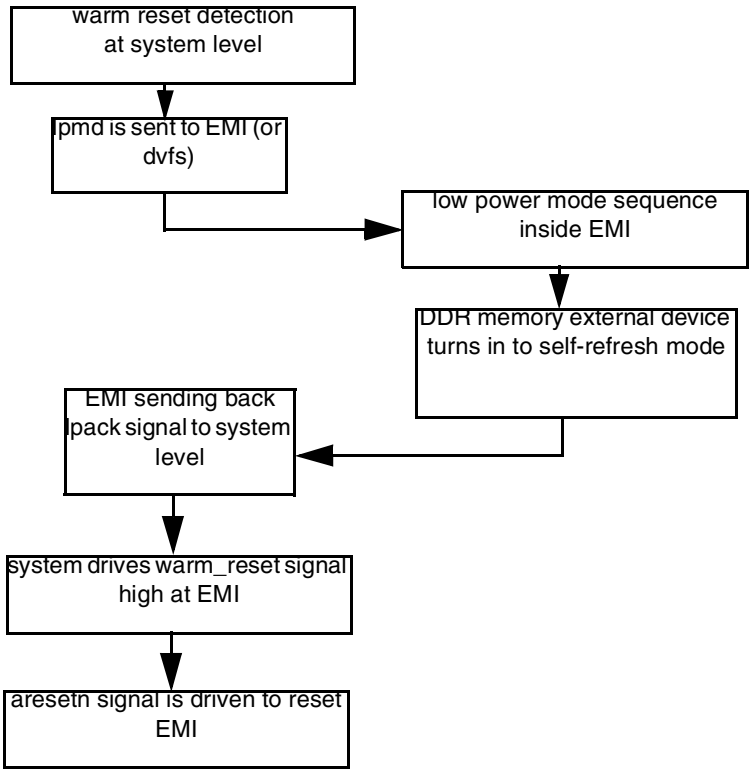


Figure 44-90. Sequence of getting out of self refresh after warm reset

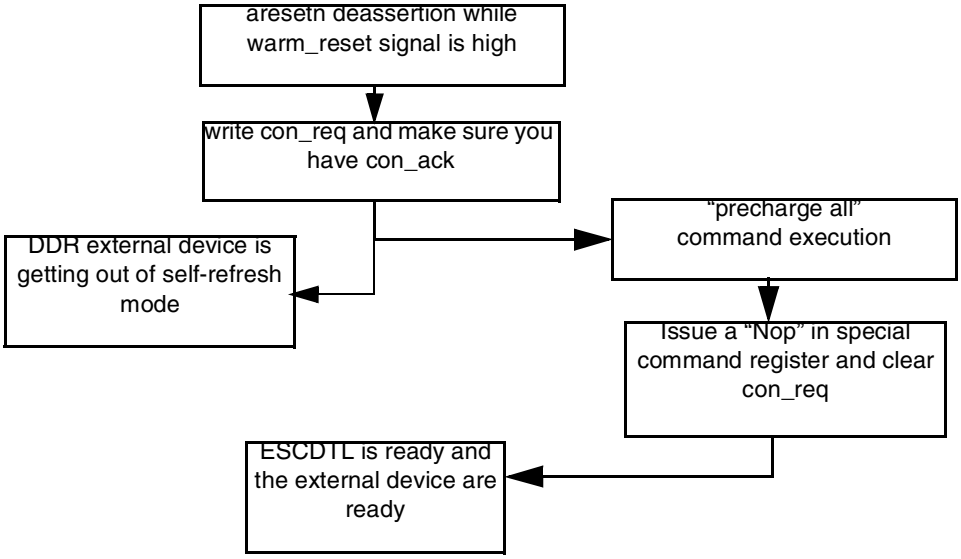

44.3.14 Interrupts

The following interrupts are supported in M4IF module.

- Watermark violation interrupt AP domain.
- Watermark violation interrupt BP domain.
- Master burst length bigger then 8 violation interrupt.

44.3.15 Endianness

M4IF supports both Endianness modes, Little and Big. The memory controllers would take care of the right storage location in the memory, based on Endianness mode and memory data bus size.

The endianness input ports, **endianess_m0** through **endianess_m7**, must not change if the master has outstanding requests inside the M4IF. The master must wait for all read datum and write responses to complete.

44.3.16 AXI Interface Restrictions

This section describes the built-in limitation in current M4IF design that lead to some restriction on the EMIv2 AXI IF support.

> ***Note***: Not complying to these restrictions, will cause an error at best, and an unknown state (possibly dead lock) at worst

44.3.16.1 General Interface Limitations

11. M4IF supports write data interleaved depth of 1 (no interleaving of data is allowed)
12. awcache/arcache - Non-bufferable accesses are supported. In write access there will be a single bit to support bufferable and non-bufferable access types. According to AXI protocol, AWCACHE[0] would reflect the type of the access, AWCACHE[0]=1'b0 means a non-bufferable access and AWCACHE[0]=1'b1 means a bufferable access. The rest of the "cache" signals are not used inside the M4IF. The 'awcache' and 'arcache' output signals (inputs to the memory controller) are set according to the corresponding 'awcache' and 'arcache' inputs from the master.
13. A master that needs to ensure that the written data has reached the destination memory, has to apply non-bufferable access and wait for the response channel.
14. If large block write transfers should be done, it is recommend that the master would drive at least one non-bufferable write access for each ID at the end of the write block transfer to ensure transfer complete at the memory device.
15. In order to keep data access coherency between write and read access of the same master, the response signal will be sent as follow:
    - bufferable write access - BRESP will be sent when last data of the access has entered the memory controller.
    - non-bufferable write access - BRESP will be sent when the data was physically written into the external memory device, and valid response was issued by the controller.
16. The AXI ID bus contains 4 bits total, to reflect the AXI transaction ID as configured by the master. Note: inside M4IF additional 3 bits will be added for internal use only to reflect master number between 0 to 7.

17. Master ID is supported in EMIv2 in a similar way it was used in former versions. Master ID is supported only for address buses and should be considered as ADDR timing. AWMASTER is used for Master ID in write address and ARMASTER for master ID in read address.Each field includes 4 bits max. Note, the master ID is not an AXI requirement and it is supported for AHB masters option mainly.
18. Burst length up to 8 double-words (64 bits), is supported. Access types incr and wrap are supported, fixed access type is not supported. AWSIZE/ARSIZE are 2 bits wide. AWLEN/ARLEN are 3 bits wide.
19. The maximum data bus size is 64 bits.
20. ~~Burst size of 32bits and 64bits are supported, burst size less than 32bits are not supported~~. Burst accesses are supported for all data sizes (8/16/32/64 bits).
21. Single access type is supported in all size range from 8bits up to 64bits.

44.3.16.2 Atomic Accesses

M4IF module support AXI atomic accesses. The atomic access logic is separated to each arbitration module, so that one CS can be locked or under exclusive monitor while other master can continue access another CS on a different arbitration. For example, if one of the master issued a locked access to CSD0 the atomic logic will block any access to the fast channel from any other master (CSD0 & CSD1). At the same time if a master issues other access to WEMv2 CS0 this access would be served as usual.

44.3.16.2.1 AXI Locked Accesses

The M4IF allows a master to perform a lock on a slave region. The lock means that only this master, when using the specific AXI ID of the lock access, can access the locked region.
The master is determined based on EMI master port (0:7) not based on the MASTER_ID field.
All other requests from other masters will be masked till the lock access is done. The lock access request would be active only when the request is served by the arbitration. In case there are other pending accesses of the same master that were issues before the lock access, it would be served first by the arbitration before the lock access take place. The lock is removed upon selecting request from this master, with the lock ID, and ARLOCK/AWLOCK signals indicates an unlocked access (can be either regular or exclusive access).

44.3.16.2.2 Exclusive Accesses

The M4IF deals with exclusive access for each arbitration path separately, each arbitration has its own exclusive access monitor and it is not affected by other exclusive accesses to other arbitrations. Thus, once an exclusive read from a certain master with a specific AXI ID has been selected by the arbitration module, the specific monitor would be active following this access. If another exclusive access occurs to the same arbitration, the monitor would be updated by the new exclusive access and the old access will be dropped from the monitor. In case a write exclusive access related to the first exclusive read access arrives, it would be treated as a regular access and not as an exclusive one. The data of this write exclusive access would not be written and the response will be sent as a regular access.
M4IF supports an exclusive accesses of a single burst type only, that is, the exclusive monitor will monitor a single address only. In case an exclusive access of burst length higher than 1 is done, the exclusive monitor will not be activated.

44.3.16.3 Write Data Interleaving

M4IF has data interleaving depth of 1 as opposed to previous version where the depth was 2. This means that data interleaving is not supported in M4IF.

44.3.17 IPS Interface

All M4IF registers are IPS memory mapped. The registers will be configurable read/write via IPS bus interface only.

The IPS interface unit inside EMIv2 would combined all IPS interfaces from EMIv2 sub modules and M4IF as one of them. The IPS IF unit would route the access to the right sub module based on ips_module_en signal and address decoding.

M4IF registers uses an accessibility policy as described in the EMIv2 spec Chapter.

All M4IF registers are 32bit width. Only IP accesses of 32bit data width are supported.

M4IF IP accesses should be used in one of the following 2 manners:

1. Check all the status bit are idle. Only if all of them idle, an IP access could be made.

Status bit list: FPSS, SPPS, IPSS, I2PSS, M#_PSS (#= Master number)

2. Send a LPMD request to a specific arbitration before configuring it’s registers.

44.3.18 WaterMark Functionality Overview

The WaterMark security feature is used to protect a configurable memory regions (WaterMark space) for up to 8 predefined different CS, 2 CS of ESDCTL and up to 6 of WEIM, no watermark capabilities exist for NFC CS and the internal memory interface. The access (read or write) to the WaterMark space is permitted only if the appropriate control bit of this particular access is high. For read - **m#_wtrmrk_ap(bp)_rd**, for write - **m#_wtrmrk_ap(bp)_wr**. The watermark regions are configurable via the watermark registers where watermark space #0 is for AP masters use and watermark space #1 is for BP masters use. AP masters and BP masters can configure each its own registers only. An AP master cannot configure BP master registers and vice versa. AP and BP masters are being identified by the predefined via at the EMIv2 boundary signals. SoC integration should configure these vias with the right values according to the master ID’s in the system. Only a predefined privilege master (Ap or BP) can configure the watermark registers. Access to the WaterMark space when watermark bits are low is considered as a WaterMark violation. A WaterMark interrupt will be generated in such a violation. In addition the master who cause the violation would not get access, and will receive an error response (DECERR). In case an access was made to watermark space #0 when **wtrmrk_ap** is in low, an AP watermark interrupt will be generated. The same goes for BP watermarked regions. In both cases the address and the master ID of the first master which made a violated access would be kept in the watermark status register till the interrupt is cleared.

Up to two WaterMark spaces can be defined for each predefined CS mapped by the M3IF. The WaterMark space is configurable through a set of configuration registers that contains the WaterMark space start and end address for each chip select. The watermark address has a resolution of 4KByte, means:

- The start address can be set at the end of the first 4KByte at address 0xFFF.
- The start and end address can be set in steps of 4 KByte.

Figure 44-1 illustrates a WaterMark space in SDRAM CSD0 memory region. The red shaded area in the figure is the WaterMark #0 space defined in SDRAM CSD0 memory region while the purple shaded area is the watermark #1 space. These memory regions are accessible only by those masters that their **wtrmrk_ap(bp)** bits are high during the access. Accesses to this region by other masters when wtrmrk_ap(bp) are low generates an interrupt (if enabled through the WaterMark control and status register) and sets the respective WaterMark space (clear by one) status bit. The blue shaded area is the non protected SDRAM CSD0 memory region, means that it is accessible by all masters connected to the M3IF.

NOTE

In case that WEIM operates in collapse mode (CS0 and CS1 are combined as one space) the watermark region definition works as if CS0 and CS1 where separate spaces, start and end address keeps configuration as it was in the non-collapse mode.

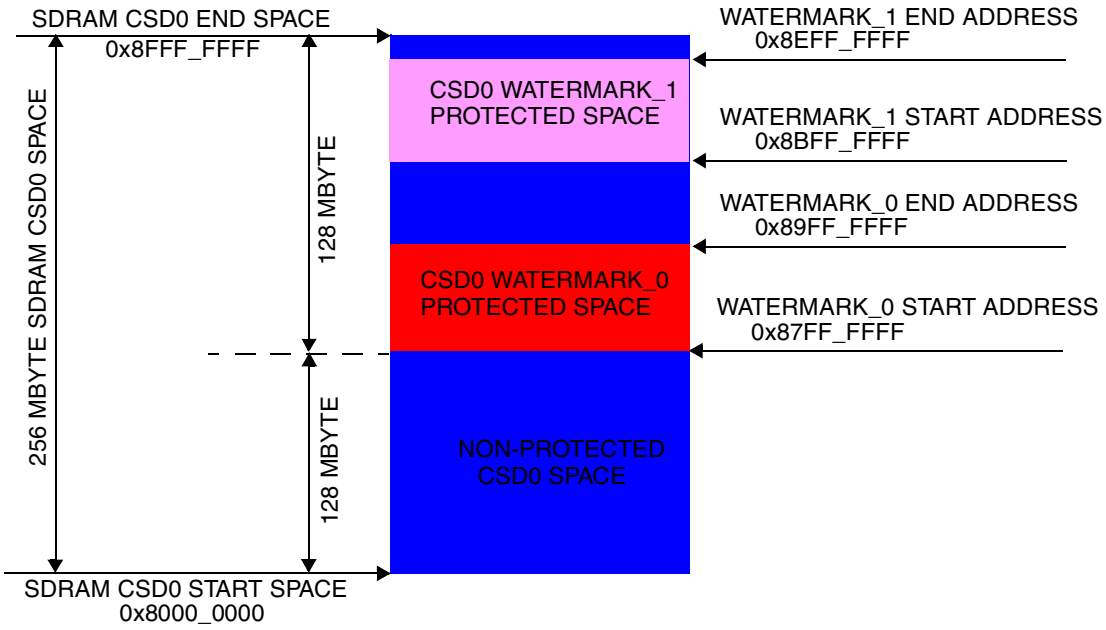

Figure 44-1 SDRAM CS0 WaterMark Space Diagram

44.3.19 Snooping Functionality Overview

The M3IF snooping feature (used by the Image Processor Unit, IPU), monitors and detects write accesses to a configurable window (snooping window) in two of the memory regions mapped by the M3IF. Both memory regions must be in the fast channel (ESDCTLv2). The snooping window base address, memory region, and window size are configurable parameters via the different snooping configuration registers. The snooping window is further divided into 64 equally sized segments.

A detected write access to the snooping window results in:

- The respective segment status bit in SSRL0/SSRL1 and/or SSRH1/SSRH1 registers is set.
- **dma_acceess0** and/or **dma_access1** strobes will assert for a fixed number of fast clock cycles, provided that the snooping segment enable bit is set for the snooped segment. The number of cycles is configurable as well (see register) and is set to 4 by default. The snooping segment enable bit is configured via 2 snooping configuration registers, SERL0/SERL1 and SERH0/SERH1.

It is the software's responsibility to clear the snooped segment status bits (by writing 1 to clear them). The snooped segment status bit will be set for each snooping detection regardless of its value.

44.3.20 Debug Unit

The M4IF has a debug unit in order to allow for better debug capabilities.

The debug unit is consisted of 2 main parts, visibility unit and profiling units.

44.3.20.1 Visibility Unit

This unit muxes and reflects several crucial signals from within M4IF, outside. These signals are described in detail in Section 44.1.3.3.3, Debug Signals". The muxing is done between the 4 channels: fast, slow, internal 1 memory and internal 2 memory. **The user cannot reflect mixed (from different channels) signals using the debug unit as they are from different clock domains**. The desired channel is configured via the MDCR register.

The visibility unit is disabled by default. In order to enable it the user must write to the MDCR register's "DBG_EN" bit. Please refer to Section 44.2.3.32, M4IF Debug Control Register for details.

Note that this unit monitors the signals from within the M4IF, even in a case of fail write exclusive attempt.

44.3.20.2 Profiling Units

There are 4 profiling units inside the debug unit. Each unit is responsible for profiling a single channel (fast, slow, internal memory, and internal 2 memory).

A single profiling unit contains counters which record the number of accesses through the specific channel for each master. The counters are read via IP bus. The information in the IP register does not contain the lower 5 bits of the counter. Meaning, the numbers which are read in the MDSR2-5 registers indicate the number of **groups of 32 accesses**. For example, if master5 performed a total of 274 accesses, the number which will be read in the upper 16 bits of MDSR4 will be: **trunc(274/32)=8**. In order to get the approximate real number of accesses, the user will have to multiply the number in the register by 32. In the above example the outcome will be: **8x32=256**. The error will be **(274-256)/274=7%**. The profiling unit is designed to handle massive use-cases, in which there will be thousands of accesses. In these cases the error will become negligible.

The profiling unit also calculates the maximal dynamic priority of a specific request. The request is selected via the MDCR configuration register. It also calculates the maximal time the master of that request was pending on the bus without getting it. These are read via MDSR0 register.

In order to calculate the average time it took a master to get bus, the profiling unit sums the time (in memory-controller's clock cycles) it took each access to get the bus. This sum can later be read via the MDSR8 register. The average can be calculated by reading the counter for the number of accesses that this master performed (via the MDSR2-5 registers), and dividing the 2 numbers.

Additional 2 registers which contain information about the profiling unit are MDSR6 and MDSR7. MDSR6 contains the total number of accesses a specific request (configured in the MDCR) has accessed the bus. MDSR7 contains the sum of "time for bus" for this specific request. An average of "time for bus" for this request can be calculated by dividing the 2 numbers. There is an option to use these 2 registers not only for a specific request, but for a type of access (read or write). Each master has 2 requests for read and 2 for write. The MDSR6-7 registers can be used to accumulate the statistics for a single request or for both. This is configured by the "SPC_REQ" bit of MDCR.

There is an option to reset all counter of the profiling unit by setting to "1" the "DBG_RST" bit in the MDCR. As long as this bit is asserted all counters will remain 0.

The debug unit's profiling is disabled by default. In order to enable it the user must write to the MDCR register's "DBG_EN" bit. Please refer to Section 44.2.3.32, M4IF Debug Control Register for details.

44.3.21 Buffers Size Table

Table 44-64. Master Buffers

Master #	Master Port Name	Master Port Write Buffers	Master Port Write Command Buffers	Master Port Read Command Buffers
0	IPU	72bx8x4	65bx4	65bx4
1	VPU	72bx8x8	65bx8	65bx16
2	MAX	72bx8x1	65bx1	65bx1
3	ARM	72bx8x6	65bx6	65bx6
4	SDMA	72bx8x1	65bx1	65bx1
5	GPU	72bx8x8	65bx8	65bx12
6	GPU2D	72bx8x4	65bx4	65bx6
7	USB	72bx8x4	65bx4	65bx5

Table 44-65. Slave Buffers

Slave#	Slave Port Name	Slave Port Read Buffers	Slave Pending Address Buffer	Slave Last Address Read buffer	Slave Last address Write buffer
0	FAST	66bx16x8	85bx1	13bx16	13bx3
1	SLOW	66bx4x8	67bx2	13bx4	13bx3
2	INT1	66bx2x8	67bx2	13bx2	13bx3
3	INT2	66bx2x8	67bx3	13bx2	13bx4

44.3.22 Synchronization

There are 12 AXI clock domain involved in the M4IF module. 8 master clocks and 4memory-controller clocks. Clock domain crossings are possible only from master clock to arbitration clock and vice versa. There cannot be a clock domain crossing between master clocks.

44.3.22.1 Synchronization Table

The following table shows the clock-domain relations between all 8 domains of the gaskets/masters, and 4 domains of the arbitrations/slaves.

S - always synchronizer on this path

[] - no synchronizer (domains are synchronized)

NC - No hardware connection at all

Table 44-66. Sync Table

Master #	Master Port Name	FAST	SLOW	INT1	INT2
0	IPU	S	S	S	S
1	VPU	S	S	S	S
2	MAX	S	S	[]	S
3	ARM	S	S	S	S
4	SDMA	S	S	[]	S
5	GPU	S	S	S	NC
6	GPU2D	S	S	S	S
7	USB	S	S	[]	S

44.3.23 Supporting 8/16 Bit Bursts

In previous versions of M4IF (For Marley, Elvis-S, Elvis TO2) bursts of data size 8bit or 16bit were not supported. The only allowed transfers for this data size were singles (bursts with a single data).

This has changed in the latest version of M4IF (Elvis TO3).

It now supports bursts of data size 8/16 bit, and of length up to 8 beat. INCR and WRAP type bursts are supported (according to the AXI protocol spec restrictions).

4 status bits allow indication whether this kind of burst (8/16 bit) occurred. Please refer to: 44.2.3.44, “Master Len Interrupt” for further details.

44.3.24 Dead-Lock Prevention in Read Accesses

M4IF allows flexibility to work in a “parallel routes” scheme. Since it has 4 separate arbitration modules, it can allow parallel work of EMIv2 against all 4 slaves. For example, master #0 can send two requests to

two different memory controllers (say DDR and NFC) and both controllers can handle these requests at the same time without interrupting each other.

This parallel scheme provides enhanced latency hiding when several masters work in parallel against several slaves, or even when a single master works versus multiple slaves.

However, there is a rare theoretical case in which this parallel scheme can cause a dead-lock for read requests. This rare case can only occur if there are 2 masters (or more) that work against the 2 slaves (or more) in a manner of interleaving the read accesses between the slaves. Meaning, a master issues read requests back and forth between two slaves. One request to the first slave and the other to the second slave repeating this over and over. A second master does exactly the same (working with the same slaves).

In order to prevent this case from happening with a 100% certainty, a protection mechanism has been added to the M4IF called “Arbit Stop”.

This mechanism limits a master from sending interleaved read requests. If there is an unfinished access in the master’s read address buffer, M4IF will accept read accesses that are directed to the same slave as the access that is already inside the buffer. If an access to a different location is issued, it will not be inserted to the buffer. The access will wait on the bus until all accesses in the buffer are served and only then will be accepted.

The limitation is only on the read path. It does affect the write path.

Each master can be configured independently to have this limitation or not. Please refer to Section 44.2.3.30, M4IF Control Register #0 for specific details.

Chapter 45
NAND Flash Controller (NFC)

45.1 Introduction

The Nand Flash Controller (NFC) is composed of various control logic units, a 4.5-Kbyte internal RAM and an internal ECC engine. The NFC can interface standard NAND Flash memory devices. Figure 45-1 shows the block diagram of the NAND Flash controller.

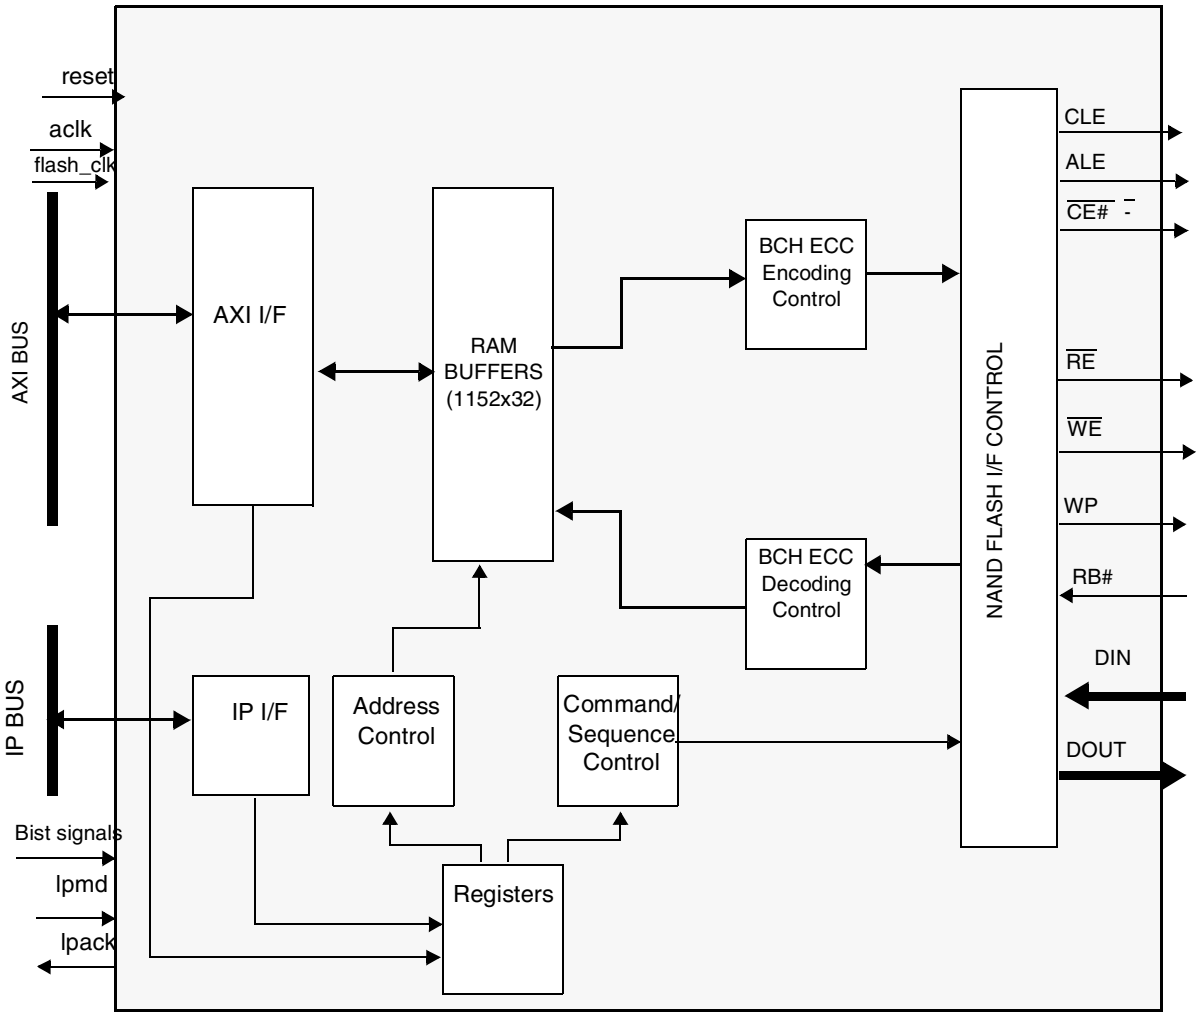

Figure 45-1. NAND Flash Controller Block Diagram

45.2 Overview

The NAND Flash Controller (NFC) can communicate with standard asynchronous NAND Flash devices. It provides a glueless interface to both 8-bits and 16-bits NAND Flash devices with page size of 512B, 2KB, or 4KB.
The NFC is configured by the host through x16/x32 AXI bus and IP bus and according to the configuration it initiates an operation (automatic or atomic) towards the NAND flash device. When the operation is finished the NFC issues an interrupt to the host.
The NFC works in two clock domains. aclk (fast clock) for communication with the AXI and ECC calculations and flash_clk(slow clock) for communication with the NAND flash device.

45.3 Features

The NFC includes the following features:

- x8 / x16 NAND Flash bus.
- Page size of 512B, 2KB and 4KB.
- Internal memory mapped RAM of 4KB + spare of 512B.
- AXI Host interface that can access the internal RAM buffers and several registers. It supports:
  - Read / Write Burst
  - 16-bits / 32-bits bus transfers
- Support atomic (manual) and automatic modes of operation with up to 6 address phases.
- Supports interleaved accesses to up to 4 NAND devices while hiding the busy period of each device
- Supports ECC-BCH(8192) error correction code of 4/8 error bits in 528/538 bytes (512B main data +16B/26B spare).
- Communicates with the system DMA
  - DMA read request after a full page read.
  - DMA write request at the beginning of a full-page programming.
- Multiple Reset
  - AXI reset/Cold Reset/ Warm Reset
- IO pins sharing support
  - Allows sharing of the IO pins with other memory controllers through special arbitration logic.
- Power down handshake mechanism for power saving.

45.4 Restrictions

- In case of working with NAND device of x16bits bus then the ratio between aclk and flash clock must be at least 1:4 (i.e the aclk is at least 4 times faster than the flash_clk).
- In AUTO_COPY_BACK operation with ADD_OP=01 the NFC can copy data only to the following page.
- The address that the NFC drives to the NAND flash device must be aligned to address 0. i.e the columns address must be “0”.
- It is not allowed to configure NUM_OF_ITERATION greater than NUM_OF_DEVICE

45.5 External Signal Description

This section describes the NFC external signals.

45.5.1 Overview

The following signals shown in Table 45-2 are used to configure and control the NFC and its attached Flash device. Signals ending with _b are active-low signals.

Table 45-2. NFC Signal Properties

Name	Function	I/O	Reset
ipp_nfc_ale_out	Flash Address Latch Enable	O	0
ipp_nfc_ce0_out	Flash #0 Chip Enable	O	1
ipp_nfc_ce1_out	Flash #1 Chip Enable	O	1
ipp_nfc_ce2_out	Flash #2 Chip Enable	O	1
ipp_nfc_ce3_out	Flash #3 Chip Enable	O	1
ipp_nfc_cle_out	Flash Command Latch Enable	O	0
ipp_nfc_rb0_in	Flash #0 Ready/Busy	I	1
ipp_nfc_rb1_in	Flash #1 Ready/Busy	I	1
ipp_nfc_rb2_in	Flash #2 Ready/Busy	I	1
ipp_nfc_rb3_in	Flash #3 Ready/Busy	I	1
ipp_nfc_re_out	Flash Read Enable	O	1
ipp_nfc_read_data_in [15:0]	NFC data input from the NAND Flash	I	
ipp_nfc_we_out	Flash Write Enable	O	1
ipp_nfc_wp_out	Flash Write Protect	O	1
ipp_nfc_write_data_out [15:0]	NFC data output towards the NAND Flash	O	0000

45.5.2 Detailed Signal Descriptions

Table 45-3 gives a detailed description of the NFC signals.

Table 45-3. NFC Detailed Signal Descriptions

Signal	I/O	Description
ipp_nfc_ce0_out	O	Flash #0 Chip Enable. This signal indicates the NAND Flash selection. When the NAND Flash device is accessed, this signal is low. This pin also is called CE0#.
ipp_nfc_ce1_out	O	Flash #1 Chip Enable. TThis signal indicates the NAND Flash selection. When the NAND Flash device is accessed, this signal is low. This pin is also called CE1#.
ipp_nfc_ce2_out	O	Flash #2 Chip Enable. This signal indicates the NAND Flash selection. When the NAND Flash device is accessed, this signal is low. This pin is also called CE2#.
ipp_nfc_ce3_out	O	Flash #3 Chip Enable. This signal indicates the NAND Flash selection. When the NAND Flash device is accessed, this signal is low. This pin is also called CE3#.
ipp_nfc_re_out	O	Flash Read Enable. This signal controls the read data from the NAND device. The read data is latched on the rising edge of the signal. This pin is also called RE#.
ipp_nfc_we_out	O	Flash Write Enable.This signal controls the write of commands, address and data to the NAND device. The write is latched on the rising edge of the signal. This pin is also called WE#.
ipp_nfc_cle_out	O	Flash Command Latch Enable. The signal controls the command that is being sent to the command register of NAND device. When active high, commands are latched into the command register of NAND device on the rising edge of the WE# signal. This pin is also called CLE#.
ipp_nfc_ale_out	O	Flash Address Latch Enable. The signal controls address that is being sent to the address register of NAND Flash. When active high, addresses are latched into the NAND device address register of NAND device on the rising edge of the WE# signal. This pin is also called ALE#.
ipp_nfc_wp_out	O	Flash Write Protect. This signal provides inadvertent program/erase protection. This signal is active (held low) during power-up. This pin is is also called WP#.
ipp_nfc_rb0_in	I	Flash #0 Ready/Busy. This signal indicates the status of the NAND Flash operation. When low, it indicates that a program, erase, or read operation of NAND Flash is in process. Upon completion of the process, this signal returns to high state. This pin is also called RB. **Note:** This signal is connected to an open drain output, via a 100 KOhm pull-up resister (outside the external NAND Flash memory device).
ipp_nfc_rb1_in	I	Flash #1 Ready/Busy. This signal indicates the status of the NAND Flash operation. When low, it indicates that a program, erase, or read operation of NAND Flash is in process. Upon completion of the process, this signal returns to high state. This pin is also called RB. **Note:** This signal is connected to an open drain output, via a 100 KOhm pull-up resister (outside the external NAND Flash memory device).

Table 45-3. NFC Detailed Signal Descriptions

Signal	I/O	Description
ipp_nfc_rb2_in	I	Flash #2 Ready/Busy. This signal indicates the status of the NAND Flash operation. When low, it indicates that a program, erase, or read operation of NAND Flash is in process. Upon completion of the process, this signal returns to high state. This pin is also called RB. **Note:** This signal is connected to an open drain output, via a 100 KOhm pull-up resister (outside the external NAND Flash memory device).
ipp_nfc_rb3_in	I	Flash #3 Ready/Busy. This signal indicates the status of the NAND Flash operation. When low, it indicates that a program, erase, or read operation of NAND Flash is in process. Upon completion of the process, this signal returns to high state. This pin is also called RB. **Note:** This signal is connected to an open drain output, via a 100 KOhm pull-up resister (outside the external NAND Flash memory device).
ipp_nfc_write_data_out[15:0]	O	Flash data output. The NFC uses this bus to drive command/address/data to the NAND device.
ipp_nfc_read_data_in[15:0]	I	Flash data input. The NFC uses this bus to latch data from the NAND device during read operation.

45.6 NFC Memory Map and Registers Definition

45.6.1 Memory Map

Table 45-4 shows the whole memory map of the NFC. Table 45-5 shows the NFC-AXI memory map and shows the NFC-IP memory map.

Table 45-4. Memory map

Address	Use	Access
0xAXI_BASE+0x0000–0xAXI_BASE+0x11FF	Internal RAM	R/W
0xAXI_BASE+0x1200–0xAXI_BASE+0x1BFF	AXI Reserved	-
0xAXI_BASE+0x1E00–0xAXI_BASE+0x1E43	AXI Registers	R/W

Section 45.7, “Register Descriptions” provides the detailed descriptions for all of the NFC registers.

45.6.2 Internal RAM Address Space and Organization

The internal RAM is divided into 4KB of main area and 1/2KB of spare area. The main area is used to hold the data of the NAND device page in read/program operations and is divided into 8 data buffers (also called data sections) of 512B each. The spare area is used to hold user-reserved data as well as the ECC encoding and is divided into 8 buffers of 64B each. Each main area buffer is associated with spare area buffer. For example spare area buffer 0 is associated with main area buffer 0.

Table 45-7 shows the organization of the main and spare area buffers inside the internal RAM. The host can use all of the spare area except for the ECC code areas. For further information of the internal RAM refer to 45.8.4/45-61

The NFC automatically generates ECC code for both main and spare area during data programming to NAND Flash. When programming/reading a page, the main and spare area buffer number must be selected using the RAM buffer address (RBA) field at NFC_CONFIGURATION1 Spare Area Buffers

Table 45-7. Internal RAM

Address	Use	Access
0xAXI_BASE+0x0000–0xAXI_BASE+0x01FF	Main area Buffer 0	R/W
0xAXI_BASE+0x0200–0xAXI_BASE+0x03FF	Main area Buffer 1	R/W
0xAXI_BASE+0x0400–0xAXI_BASE+0x05FF	Main area Buffer 2	R/W
0xAXI_BASE+0x0600–0xAXI_BASE+0x07FF	Main area Buffer 3	R/W
0xAXI_BASE+0x0800–0xAXI_BASE+0x09FF	Main area Buffer 4	R/W
0xAXI_BASE+0x0A00–0xAXI_BASE+0x0BFF	Main area Buffer 5	R/W
0xAXI_BASE+0x0C00–0xAXI_BASE+0x0DFF	Main area Buffer 6	R/W
0xAXI_BASE+0x0E00–0xAXI_BASE+0x0FFF	Main area Buffer 7	R/W
0xAXI_BASE+0x1000–0xAXI_BASE+0x103F	Spare area Buffer 0 (SB0)	R/W
0xAXI_BASE+0x1040–0xAXI_BASE+0x107F	Spare area Buffer 1 (SB1)	R/W
0xAXI_BASE+0x1080–0xAXI_BASE+0x10BF	Spare area Buffer 2 (SB2)	R/W
0xAXI_BASE+0x10C0–0xAXI_BASE+0x10FF	Spare area Buffer 3 (SB3)	R/W
0xAXI_BASE+0x1100–0xAXI_BASE+0x113F	Spare area Buffer 4 (SB4)	R/W
0xAXI_BASE+0x1140–0xAXI_BASE+0x117F	Spare area Buffer 5 (SB5)	R/W
0xAXI_BASE+0x1180–0xAXI_BASE+0x11BF	Spare area Buffer 6 (SB6)	R/W
0xAXI_BASE+0x11C0–0xAXI_BASE+0x11FF	Spare area Buffer 7 (SB7)	R/W

In case working with a NAND device with spare area of 16B per section of 512B (i.e 512B+spare of 16B, 2KB+ spare of 64B or 4KB + spare of 128B) then only the first 16B of each spare buffer will be used for both user-reserved and ECC code. The number of spare buffers that will be used corresponds the number of main area buffers which are derived from the page size. For example in page size of 4K+ spare of 128B there are 8 main buffers of 512B each and 8 spare buffers of 16B each.

In case working with a NAND device of 4KB + spare of 218B then the size of the first 7 spare buffers (i.e SB0-SB6) will be 26B and the size of the last spare buffer (i.e SB7) will be 36B.

Note:

- In case working with a NAND device with page size of 4K+ spare of 218B with ECC_MODE of 8bits then the last 10B of the last spare buffer (i.e AXI_BASE+0x11DA-AXI_BASE+0x11E3) are not ECC protected. Moreover, in case of 4bits ECC_MODE then the SPAS should be configured to 0x40 (i.e spare of 128B) and the NFC will use only the first 16B (8B for user-reserved and 8B for ECC) for every section of 512B. That means that the NFC will use only 128B of spare out of the 218B available.

Table 45-8 shows the sub-organization of the spare area buffers in case of working with NAND device of 4K+218B. Note that the sub-organization of the first 7 buffers (SB0-SB6) are different from the last buffer (SB7).

Table 45-9 shows the sub-organization of the spare area buffers in case of working with NAND devices of 512B+16B, 2K+64B or 4K+128B (i.e 16B per spare buffer)Register Summary

Table 45-8. Spare Area Buffer for 4K+218B NAND

	Reserved for user / Not in Use [3]								Reserved for user / Not in Use [3]							
	Reserved for user / Not in Use [3]								Reserved for user / Not in Use [3]							
0xAXI_BASE+0x11E4-0xAXI_BASE+0x11FF	Reserved for user															

[1] When working in 4 bits ECC_MODE, this Byte is an ECC Byte. When working in 8bits ECC_MODE, this Byte is user-reserved

[2] When working in 8 bits ECC_MODE, this Byte is an ECC Byte. When working in 4 bits ECC_MODE, this Byte is not in use.

[3] When working in 8 bits ECC_MODE, this Byte is an unprotected ECC user-reserved. When working in 4 bits ECC_MODE this byte is not used

In case of working with NAND devices of 512B+16B, 2K+64B or 4K+128B (i.e 16B of spare buffer) then only ECC_MODE of 4bits is allowed and then the first 8B of the relevant spare buffers are reserved for user and the rest 8B are reserved for ECC. For example in NAND device of 2K+64B only the first 4 spare buffers are in use.

45.6.3 Register Summary

Figure 45-2 shows the key to the register fields and Table 45-10 shows the register figure conventions.

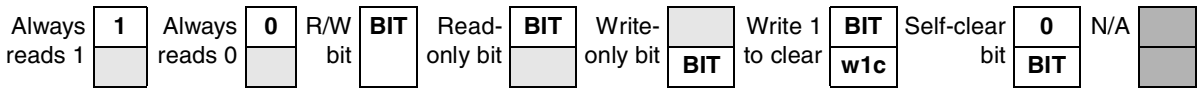

Figure 45-2. Key to Register Fields

Table 45-10. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Reset Values	
0	Resets to zero.
1	Resets to one.

45.7 Register Descriptions

45.7.1 Nand Flash Command (NAND_CMD)

This register contains the commands to be written during a command phase. The bit assignments for the register are shown in Figure 45-3 and the field descriptions are shown in Table 45-13.

0xAXI_BASE+0x1E00 (NAND_CMD) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	NAND CMD3								NAND CMD2							
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	NAND CMD1								NAND CMD0							
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 45-3. NAND Command Register

Table 45-13. NAND Command Field Descriptions

Field	Description
31–24 NAND_CMD3	NAND Flash Command3. second NAND Flash command which will be written to the NAND Flash device during an automatic copy-back operations at the write phase.
23–16 NAND_CMD2	NAND Flash Command2. First NAND Flash command which will be written to the NAND Flash device during an automatic copy-back operations at the write phase.
15–8 NAND_CMD1	NAND Flash Command1. Second NAND Flash command (command confirmation) which will be written to the NAND Flash device during an automatic erase/read/program/copy-back operations. In copy-back operation this command is the second command at the read phase.
7–0 NAND_CMD0	NAND Flash Command0. First NAND Flash command which will be written to the NAND Flash device during an automatic and atomic erase/read/program/copy-back operations. In copy-back operation this command is the second command at the read phase. In atomic(manual) operation only this command will hold the command that will be written to the NAND device.

45.7.2 NAND Flash Address0 (NAND_ADD0)

This register contains the 32 lowest address bits to be written during an address phase to address group0. The bit assignments for the register are shown in Figure 45-4 and the field descriptions are shown in Table 45-14.

Note:

- The NFC is always aligned to column 0 therefore the address bits of the column suppose to be zero.
- In case of Erase operation the lsb of the page address should be written to NAND_ADD0[0], In other operations the lsb of the column address should be written to NAND_ADD0[0].
  - For example: Assume 4 devices are connected to the NFC, erasing block 0 of device #0 requires writing 48'h0 to NFC_ADDx register. Erasing block 0 requires writing 48'h1 to NFC_ADDx register. Assuming 2KB devices: Programming page 0 requires writing 48'h10000 to NFC_ADDx register (16 lower bits are column address). For furhter examples refer to ADD_OP at 45.7.28/45-49

0xAXI_BASE+0x1E04 (NAND_ADD0) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 45-4. NAND Address0 Register

Table 45-14. NAND Address0 Command Field Descriptions

Field	Description
31–0 NAND_ADD0	NAND Flash address group 0. This defines the lower 32 bits of address group 0. This will be used as the address of the page/block in an automatic and atomic operations.

45.7.3 NAND Flash Address1 (NAND_ADD1)

This register contains the 32 lowest address bits to be written during an address phase to address group1. The bit assignments for the register are shown in Figure 45-5 and the field descriptions are shown in Table 45-15.

Note:

- The NFC is always aligned to column 0 therefore the address bits of the column suppose to be zero.
- In case of Erase operation the lsb of the page address should be written to NAND_ADD1[0], In other operations the lsb of the column address should be written to NAND_ADD1[0].

0xAXI_BASE+0x1E08 (NAND_ADD1) Access: User read-write

Figure 45-5. NAND Flash Address1 (NAND_ADD1) Register

Table 45-15. NAND Address1 Field Descriptions

Field	Description
31–0 NAND_ADD1	NAND Flash address group 1. This defines the lower 32 bits of address group 1. This will be used as the address of the page/block in automatic operations depending on ADD_OP.

45.7.4 NAND Flash Address2 (NAND_ADD2)

This register contains the 32 lowest address bits to be written during an address phase to address group2. The bit assignments for the register are shown in Figure 45-6 and the field descriptions are shown in Table 45-16.

Note:

- The NFC is always aligned to column 0 therefore the address bits of the column suppose to be zero.
- In case of Erase operation the lsb of the page address should be written to NAND_ADD2[0], In other operations the lsb of the column address should be written to NAND_ADD2[0].

Figure 45-16. NFC_configuration1 Register

Table 45-26. NFC_CONFIGURATION1 Field Descriptions

Field	Description
31-24 Reserved	Reserved
23-16 NF_STATUS	NAND Flash Status. This field holds the last NAND device status that was read by the NFC. This register is updated every time that a read status command is executed (AUTO_STAT, atomic read status).
15 Reserved	Reserved
14-12 ACTIVE_CS	Active CS. This field indicates the NAND device ID to which the NFC will target its operations. This field is being used only during atomic operations (i.e if one of FCMD, FADD, FDI or FDO is set). During an automatic operation the NAND ID is defined based on the ADD_OP register. 000 - access NAND device connected to CS0 001 - access NAND device connected to CS1 010 - access NAND device connected to CS2 011 - access NAND device connected to CS3 100 - access NAND device connected to CS4 101 - access NAND device connected to CS5 110 - access NAND device connected to CS6 111 - access NAND device connected to CS7

Table 45-26. NFC_CONFIGURATION1 Field Descriptions

Field	Description
11–8 NUM_OF_ITERATIONS	Num Of Iterations. Defines how many times NFC will execute AUTO_READ/AUTO_PROG/AUTO_ERASE/AUTO_COPY_BACK without setting an interrupt. When automatic operation bit is set, NFC executes the automatic operation NUM_OF_ITERATIONS+1 times. For example: If NUM_OF_ITERATION is set to 4'h4,and then an AUTO_READ operation is set, then NFC will read 5 pages from the NAND devices. It is the system's responsibility to read the pages content from the NFC's RAM. When NUM_OF_ITERATIONS is greater than 0 and NUM_OF_DEVICES is greater than 0 then an interleaved accesses will be executed and in that case SDMA will be used. For example if NUM_OF_ITERATIONS=1 (i.e 2iterations) and NUM_OF_DEVICES=1(i.e 2 devices) then the NFC will access 1st device then 2nd device and only then issue an interrupt. For furhter examples refer to ADD_OP at 45.7.28/45-49 Note: It is not allowed to configured NUM_OF_ITERATION greater than NUM_OF_DEVICES 4'h0 execute automatic operation 1 time. 4'h1 execute automatic operation 2 times. ... 4'hf execute automatic operation 16 times.
7-6 Reserved	Reserved
6-4 RBA	Ram Buffer Address. Specifies which 1/2K of the internal ram to use when accessing the NAND device. In either Atomic or Automatic operations when NO_SDMA bit is set the value of RBA indicates from which part of the internal RAM to fetch the data in a program operation or to which part of the internal RAM to store the data in a read operation. For example if RBA is set to "100" and the page size is 1/2K (i.e PS is set to "00") and a program operation is configured then the NFC will program the NAND device with the data that is located at the 5th 1/2KB of the internal RAM. In that case it is the user responsiblity to store the requested data at the 5th 1/2KB before starting the program operation. Note that in case the page size is 2KB or 4KB then the NFC will fetch/store the data from/to continous RBA. For example if RBA is set to "000" and page size is 2KB and a program operation is configured then the NFC will program the NAND device with the data that is stored at 1st, 2nd, 3rd, 4th 1/2KB. Note: • In case the page size is 2KB then only RBA of "000" and "100" are allowed and in case the page size is 4KB then only RBA of "000" is allowed. • In case of working with SDMA (i.e NO_SDMA is set to "0") then the NFC will set RBA to "000" in either read or program operations. 000 Use 1st 1/2K of the internal ram. 001 Use 2nd 1/2K of the internal ram 010 Use 3rd 1/2K of the internal ram 011 Use 4th 1/2K of the internal ram 100 Use 5th1/2K of the internal ram 101 Use 6th 1/2K of the internal ram 110 Use 7th 1/2K of the internal ram 111 Use 8th 1/2K of the internal ram
3 Reserved	Reserved

Table 45-26. NFC_CONFIGURATION1 Field Descriptions

Field	Description
2 NFC_RST	NFC Reset. This bit resets the NFC state machines. This bit should be used when issuing a reset command to the NAND Flash device during an operation. When a NAND device received a reset command (0xff) during an operation it aborts its operation and returns to idle. In order to do the same to the NFC, this bit must be set before the reset command is sent. This bit is self cleared. 0 Do not reset the NFC state machine 1 Reset the NFC state machine
1 NF_CE	NAND Flash Force CE. Setting this bit forces the CE# signal that is driven to the NAND Flash device to 0. There are some NAND devices that require that the CE# will be kept low during the busy period. Therefore when working with such a NAND device with RBB_MODE=0 (in that mode the NFC toggles the CE# while perforing a read status during the busy period) NF_CE should set to “1” and then the CE will be forced to “0”. This bit is not self cleared. 0 CE# signal operates normally 1 CE# signal is asserted as long as this bit is set to 1.
0 SP_EN	NAND Flash Spare Enable. This bit determines whether the host will program/read the spare area only or main and spare area together to/from the NAND device. This features is supported only in NAND devices of 1/2KB page size. When this bit is enabled then the NFC will program/read 16B of spare area. **Note:** There is no ECC when SP_EN=1 0 Program/read main and spare area. 1 Program/read spare area only.

45.7.15 ECC Status and Result of Flash Operation (ECC_STATUS_RESULT)

This register shows the number of bits that were detected/corrected for every page section of 528/538 bytes in the main and spare area as a result of the BCH ECC check. The bit assignments for the register are shown in Figure 45-17 and the field descriptions are shown in Table Table 45-27.

This field shows the number of bit errors in 512 bytes main plus 16/26 bytes spare (totally 528/538 bytes) as a result of the BCH ECC check upon read. 0000 No error 0001>1-bit Error (Correctable Error) 0010> 2-bit Error (Correctable Error) 0011> 3-bit Error (Correctable Error) 0100> 4-bit Error (Correctable Error) 0101> 5-bit Error (Correctable Error for 8bit ecc-mode) 0110> 6-bit Error (Correctable Error for 8bit ecc-mode) 0111> 7-bit Error (Correctable Error for 8bit ecc-mode) 1000> 8-bit Error (Correctable Error for 8bit ecc-mode) 1111 > Uncorrectable error. others > Reserved
3-0 NOBER1	Number Of bit Errors for first 528/538 bytes section. This field shows the number of bit errors in 512 bytes main plus 16/26 bytes spare (totally 528/538 bytes) as a result of the BCH ECC check upon read. 0000 No error 0001>1-bit Error (Correctable Error) 0010> 2-bit Error (Correctable Error) 0011> 3-bit Error (Correctable Error) 0100> 4-bit Error (Correctable Error) 0101> 5-bit Error (Correctable Error for 8bit ecc-mode) 0110> 6-bit Error (Correctable Error for 8bit ecc-mode) 0111> 7-bit Error (Correctable Error for 8bit ecc-mode) 1000> 8-bit Error (Correctable Error for 8bit ecc-mode) 1111 > Uncorrectable error. others > Reserved

45.7.16 Status Summary (STATUS_SUM)

This register shows a summary status of the Nand device as well as a summary result of the ECC check after a page read. The bit assignments for the register are shown in Figure 45-18 and the field descriptions are shown in Table Table 45-28.

0xAXI_BASE+0x1E3C (STATUS_SUM) Access: User read-only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 45-18. Status_Sum

Table 45-28. STATUS_SUM Register Field Description

Field	Description
31-16 Reserved	Reserved
15-8 ECC_SUM	Ecc Summary report. reports correctable/non-correctable ECC result after a page read for each Nand device. Every Nand device has a bit in this field that states if the last page read from this device had any uncorrectable ECC sections. (bit 0 to Nand0, bit 1 to Nand1, etc). During a page read, NFC checks for error-bits in each section of the page (refer to ECC chapter for more information). If any of the sections had a non-correctable ECC result, then the corresponding bit will be set. If all sectors of the page had correctable ECC errors or no error at all, then the corresponding bit will not be set. If NFC reports an uncorrectable ECC status, the user must clear this field manually.
7-0 NAND_STATUS_SUM	NAND Status Summary. Reports the status of all NAND devices. After NFC executes a status-read operation, as part of the automatic operations (Not status-read of atomic operation (FDO)) to any NAND device, it stores the pass/fail indication of the status register in this field. Each NAND device has 1 bit that stores its status. (bit 0 to Nand0, bit 1 to Nand1, etc). This field is being cleared at any write to LAUNCH_NFC register, thus if an automatic operation was carried more than once to a specific CS, then this field will indicate if any of the operations resulted in an error by the NAND device.

45.7.17 Initiate a Nand Transaction (LAUNCH NFC)

Address of block memory in the NAND Flash that is unlocked in Write Protection mode. The bit assignments for the register are shown in Figure 45-19 and the field descriptions are shown in Table 45-29.

	0xAXI_BASE+0x1E40 (LAUNCH NFC)														Access: User read-write

Figure 45-19. Launch NFC Register

Table 45-29. Launch NFC register Field Description

Field	Description
31–13	Reserved
12 AUTO_STAT	Automatic Status Read operation. When this bit is set, NFC will automatically perform a status read operation: send status read command that is defined in ST_CMD in NFC_CONFIGURATION2, and then issues 1 pulse of RE_B. The status result will be stored in NF_STATUS field. The summary of the status will be recorded in NAND_STATUS_SUM field. The status-read operation will be executed only once, and it will be not affected from NUM_OF_ITERATION field. 0 Don't execute a status read operation 1 Execute a status read operation.
11 AUTO_COPY_BACK1	Auto copy back sequence to multiple NAND devices. When this bit is set and interleaved mode is configured (i.e NUM_OF_ITERATION and NUM_OF_DEVICES are greater than 0) , NFC will execute a page copy back sequence in interleaved mode as following: <command phase> < address phases> <command phase> <command phase> < address phases> <command phase>. For further information refer to 45.9.1.4/45-65 The commands will be issued from NAND_CMD0, NAND_CMD1, NAND_CMD2 and NAND_CMD3. The source address will be taken from the address group0 and the target address will be taken from address group1. 0 Don't execute a page copy back. 1 Execute a page copy back
10 AUTO_COPY_BACK0	Auto copy back sequence. When this bit is set, NFC will execute a page copy back sequence: <command phase> < address phases> <command phase> <command phase> < address phases> <command phase>. The first command phase will be taken from NAND_CMD0, the second command phase will be taken from NAND_CMD1 the third command phase will be taken from NAND_CMD2 and the last command phase will be taken from NAND_CMD3. In case of ADD_OP other than 01 then the source address will be taken from the address group0 and the target address will be taken from address group1. In case ADD_OP is set to "01" then the NFC will use only address group0 and copy the page to address group0+1 no matter what is address group1. If the user wish to use a device other than device #0 for this operation, then ADD_OP to 2'b01 or 2'b11 must be configured together with the appropriate address. For further information refer to 45.9.1.4/45-65 0 Don't execute a page copy back. 1 Execute a page copy back
9 AUTO_ERASE	Auto erase sequence. When this bit is set, NFC will execute a full block erase sequence: <command phase> < address phases> <command phase> The commands will be issued from NAND_CMD0 and NAND_CMD1. The address will be taken from the active address group. For further information refer to 45.9.1.3/45-65 0 Don't execute a full block erase. 1 Execute a full block erase
8 Reserved	Reserved

Table 45-29. Launch NFC register Field Description

Field	Description
7 AUTO_READ	Auto read sequence. When this bit is set, NFC will execute a full page-read sequence: <command phase> < address phases> <command phase> <busy polling> <data transfer><read status>. The commands will be issued from NAND_CMD0 and NAND_CMD1. The address will be taken from the active address group. If NUM_OF_ITERATIONS is greater than 0, then NFC will continue reading the next page until NUM_OF_ITERATIONS is reached. NFC will monitor the AXI address in order to decide when next page read should start. For further information refer to FMP and to 45.9.1.2/45-65 0 Don't execute a full page read. 1 Execute a full page read
6 AUTO_PROG	Auto program sequence. When this bit is set, NFC will execute a full page-program sequence: <command phase> < address phases> <data transfer> <command phase>. The commands will be issued from NAND_CMD0 and NAND_CMD1. The address will be taken from the active address group. If NUM_OF_ITERATIONS is greater than 0, then NFC will start programming the next page until NUM_OF_ITERATIONS is reached. NFC will monitor the AXI address in order to decide when next page program should start. For further information refer to FPM and to 45.9.1.1/45-64 0 Don't execute a full page program. 1 Execute a full page program
5–3 FDO	NAND atomic Flash Data Output. This bit enables NAND Flash Data Output. 001 One page data out[1]. For further information refer to 45.9.2.5/45-71 010 NAND Flash ID data out. Toggles 6 times the read enable signal (re) and store the returned data at the main buffer according to RBA. For further information refer to 45.9.2.6/45-72 100 NAND Flash Status Register data out. This operation toggle once the read enable signal (re) and store the status in NF_STATUS. For further information refer to 45.9.2.7/45-74 Other options are reserved.
2 FDI	NAND Flash atomic Data Input. This field enables NAND Flash Data Input. For further information refer to 45.9.2.4/45-70 0 No NAND Flash data input operation 1 Enable NAND Flash data input operation
1 FADD	NAND Flash atomic Address Input. This field enables NAND Flash Address Input. For further information refer to 45.9.2.3/45-69 0 No NAND Flash Address input operation 1 Enable NAND Flash Address input operation
0 FCMD	NAND Flash atomic Command Input. This field enables the NAND Flash Command Input. The atomic command will be taken from NAND_CMD0. For further information refer to 45.9.2.2/45-68 0 No NAND Flash Command input operation 1 Allow NAND Flash Command input operation

[1] Page size is determined by SP_EN register bit (main + spare or spare only). It is 528 bytes (main+spare) or 16 bytes (spare) regardless of the nfc_fms setting.

NOTE

When the basic operation is completed, this register is self cleared. Only one of the bit fields can be set at any one given time.

45.7.18 NAND Flash Write Protection (NF_WR_PROT)

This register specifies the Protection command which the controller will perform: Lock, Unlock, or Lock Tight. It also indicates the NAND Flash Write Protection Status. Lock, Unlock or Lock Tight status.

The bit assignments for the register are shown in Figure 45-20 and the field descriptions are shown in Table 45-30.

Table 45-30. NAND Flash Write Protection Register Field Descriptions

Field	Description
31 US7	Unlocked Status for CS7. This bit indicates whether there are any unlocked blocks in the NAND Flash. This bit gets updated according to WPC. 0 There are no unlocked blocks in NAND Flash 1 there are unlocked block(s) in NAND Flash
30 LS7	Locked Status for CS7. When “1” This bit indicate whether all NAND Flash blocks are in locked status or in lock-Unlock status. This bit gets updated according to WPC. 0 not all NAND Flash blocks are in locked status 1 there are unlocked block(s) in NAND Flash
29 LTS7	Lock-tight Status for CS7. Indicates if any of the locked block(s) is (are) have a lock-tight status. This bit gets updated according to WPC. 0 Locked block(s) is (are) not lock-tight 1 Locked block(s) is (are) lock-tight
28 US6	Unlocked Status for CS6. This bit indicates whether there are any unlocked blocks in the NAND Flash. This bit gets updated according to WPC. 0 There are no unlocked blocks in NAND Flash 1 there are unlocked block(s) in NAND Flash

Table 45-30. NAND Flash Write Protection Register Field Descriptions (continued)

Field	Description
27 LS6	Locked Status for CS6. When “1” This bit indicate whether all NAND Flash blocks are in locked status or in lock-Unlock status. This bit gets updated according to WPC. 0 not all NAND Flash blocks are in locked status 1 there are unlocked block(s) in NAND Flash
26 LTS6	Lock-tight Status for CS.: Indicates if any of the locked block(s) is (are) have a lock-tight status. This bit gets updated according to WPC. 0 Locked block(s) is (are) not lock-tight 1 Locked block(s) is (are) lock-tight
25 US5	Unlocked Status for CS5. This bit indicates whether there are any unlocked blocks in the NAND Flash. This bit gets updated according to WPC. 0 There are no unlocked blocks in NAND Flash 1 there are unlocked block(s) in NAND Flash
24 LS5	Locked Status for CS5. When “1” This bit indicate whether all NAND Flash blocks are in locked status or in lock-Unlock status. This bit gets updated according to WPC. 0 not all NAND Flash blocks are in locked status 1 there are unlocked block(s) in NAND Flash
23 LTS5	Lock-tight Status for CS5. Indicates if any of the locked block(s) is (are) have a lock-tight status. This bit gets updated according to WPC. 0 Locked block(s) is (are) not lock-tight 1 Locked block(s) is (are) lock-tight
22 US4	Unlocked Status for CS4. This bit indicates whether there are any unlocked blocks in the NAND Flash. This bit gets updated according to WPC. 0 There are no unlocked blocks in NAND Flash 1 there are unlocked block(s) in NAND Flash
21 LS4	Locked Status for CS4. When “1” This bit indicate whether all NAND Flash blocks are in locked status or in lock-Unlock status. This bit gets updated according to WPC. 0 not all NAND Flash blocks are in locked status 1 there are unlocked block(s) in NAND Flash
20 LTS4	Lock-tight Status for CS4, Indicates if any of the locked block(s) is (are) have a lock-tight status. This bit gets updated according to WPC. 0 Locked block(s) is (are) not lock-tight 1 Locked block(s) is (are) lock-tight
19 US3	Unlocked Status for CS3. This bit indicates whether there are any unlocked blocks in the NAND Flash. This bit gets updated according to WPC. 0 There are no unlocked blocks in NAND Flash 1 there are unlocked block(s) in NAND Flash

Table 45-30. NAND Flash Write Protection Register Field Descriptions (continued)

Field	Description
18 LS3	Locked Status for CS3.When “1” This bit indicate whether all NAND Flash blocks are in locked status or in lock-Unlock status. This bit gets updated according to WPC. 0 not all NAND Flash blocks are in locked status 1 there are unlocked block(s) in NAND Flash
17 LTS3	Lock-tight Status for CS3: Indicates if any of the locked block(s) is (are) have a lock-tight status. This bit gets updated according to WPC. 0 Locked block(s) is (are) not lock-tight 1 Locked block(s) is (are) lock-tight
16 US2	Unlocked Status for CS2. This bit indicates whether there are any unlocked blocks in the NAND Flash. This bit gets updated according to WPC. 0 There are no unlocked blocks in NAND Flash 1 there are unlocked block(s) in NAND Flash
15 LS2	Locked Status for CS2.When “1” This bit indicate whether all NAND Flash blocks are in locked status or in lock-Unlock status. This bit gets updated according to WPC. 0 not all NAND Flash blocks are in locked status 1 there are unlocked block(s) in NAND Flash
14 LTS2	Lock-tight Status for CS2: Indicates if any of the locked block(s) is (are) have a lock-tight status. This bit gets updated according to WPC. 0 Locked block(s) is (are) not lock-tight 1 Locked block(s) is (are) lock-tight
13 US1	Unlocked Status for CS1. This bit indicates whether there are any unlocked blocks in the NAND Flash. This bit gets updated according to WPC. 0 There are no unlocked blocks in NAND Flash 1 there are unlocked block(s) in NAND Flash
12 LS1	Locked Status for CS1.When “1” This bit indicate whether all NAND Flash blocks are in locked status or in lock-Unlock status. This bit gets updated according to WPC. 0 not all NAND Flash blocks are in locked status 1 there are unlocked block(s) in NAND Flash
11 LTS1	Lock-tight Status for CS1: Indicates if any of the locked block(s) is (are) have a lock-tight status. This bit gets updated according to WPC. 0 Locked block(s) is (are) not lock-tight 1 Locked block(s) is (are) lock-tight
10 US0	Unlocked Status for CS1. This bit indicates whether there are any unlocked blocks in the NAND Flash. This bit gets updated according to WPC. 0 There are no unlocked blocks in NAND Flash 1 there are unlocked block(s) in NAND Flash

Table 45-30. NAND Flash Write Protection Register Field Descriptions (continued)

Field	Description
9 LS0	Locked Status for CS0.When “1” This bit indicate whether all NAND Flash blocks are in locked status or in lock-Unlock status. This bit gets updated according to WPC. 0 not all NAND Flash blocks are in locked status 1 there are unlocked block(s) in NAND Flash
8 LTS0	Lock-tight Status for CS0: Indicates if any of the locked block(s) is (are) have a lock-tight status. This bit gets updated according to WPC. 0 Locked block(s) is (are) not lock-tight 1 Locked block(s) is (are) lock-tight
7–6 BLS	Buffer Lock Set. This field specifies the buffer lock status of first 2KB in the internal buffer (first 2KByte of main data together with 256Bytes of spare data). The other 2KB are always Unlocked. The lock refers only to Nand Accesses. AXI can access all the internal RAM regardless of this field. Any Nand read command, to the first 2KB of the internal RAM, would take place, but, would not be written to the internal RAM (Ecc result on such a read is not valid).(for more details see section 11.10.4/11-46) 00 Locked (default) 01 Locked 10 Unlocked 11 Locked
5–3 CS2L	Chip Select to Lock. When modifying lock status using WPC field, only 1 of the 4 CS supported will be affected. CS2L determines which of the 4 CS will be affected: 000 - CS0 lock status. 001 - CS1 lock status. 010 - CS2 lock status. 011 - CS3 lock status. 100 - CS4 lock status. 101 - CS5 lock status. 110 - CS6 lock status. 111 - CS7 lock status.
2-0 WPC	Write Protection Command. The Command field specifies the operation which the controller will perform. Since, the design might work in a slower clock then IP clock, then, the user must check that his WPC command was updated (by reading relevant LSX/USX/LTSX bits), before any new write to WPC. 100 Unlock NAND Flash block(s) according to given block address range 010 Lock NAND Flash block(s) 001 Lock-tight locked blocks(s) (see also 45.9.6/45-82)

Table 45-31. Write Protect Modes

State	Status bits - US -LS -LTS
Lock - all blocks are locked	010
Unlock-lock - there are unlocked blocks	110

State	Status bits - US -LS -LTS
Unlock-Lockt - there are unlocked blocks: cant change to other state	101
Lockt - all block are locked: cant change to other state	001

45.7.19 Address to Unlock in Write Protection Mode (UNLOCK_BLK_ADD0)

Address of block memory in the NAND Flash that is unlocked in Write Protection mode. This register is relevant only when using chip select 0. The bit assignments for the register are shown in Figure 45-21 and the field descriptions are shown in Table 45-32.

	0xBASE+0x3004 (UNLOCK_BLK_ADD0)												Access: User read-write

45.7.27 NAND Flash Operation Configuration2 (NFC_CONFIGURATION2)

This register is a configuration register for the NAND Flash device to control the ECC-Enable or Disable, Mask Interrupt, endianess, etc

The bit assignments for the register are shown in Figure 45-29 and the field descriptions are shown in Table 45-40

	0xBASE+0x3024 (NFC CONFIGURATION2)												Access: User read-write			
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ST_CMD								SPAS

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	INT_MSK	auto_prog_done_msk	Num_Adr_phase1		EDC			PPB		ECC_mode	Num_Adr_phases 0	Num_cmd_phases	ECC_EN	SYM	PS	
RESET	0	0	1	0	0	0	0	1	0	0	1	1	1	0	0	1

Figure 45-29. NFC_CONFIGURATION2 Register

Table 45-40. NFC_CONFIGURATION2 Register Field Descriptions

Field	Description
31-24 ST_CMD	Status Command. This is the command NFC will use when executing automatic status-read operations. For most NAND devices this value should be 8'h70
23-16 SPAS	Spare Area Size. This field specifies the size of gthe spare area of the NAND device.This size is in halfwords and refers to a full page. For example when working with a NAND device with page of 2KB + 64B then spare area is 64B so the SPAS should be set to 8'h20.
15 INT_MSK	Mask interrupt Bit. This bit enables the interrupt by masking or not masking the interrupt bit. 0 Mask interrupt is disabled (interrupt enabled) 1 Mask interrupt is enabled (interrupt disabled)
14 AUTO_PROG_DONE_MSK	Auto Program Done Mask. This bit enables the auto_prog_done by masking or not masking the AUTO_PROG_DONE bit. 0 Mask AUTO_PROG_DONE is disabled (auto_prog_done enabled) 1 Mask AUTO_PROG_DONE is enabled (auto_prog_done disabled)
13-12 NUM_ADR_PHASES1	Number Of Address Phases1. he number of address phases need to be executed to the Nand Devices during read/program oeprations. 2'b00 - 3 phases 2'b01 - 4 phases 2'b10 - 5 phases 2'b11 - 6 phases
11–9 EDC	Extra dead cycles. This field specifies number of dead cycles after a read operation, before nfc will allow any other slave to use the shared IO. NFC will delay its ack_en signal according to this field. This will occur any time the NFC stops reading, whether its during a read (because of WEIM request), at the end of a read, or at the end of any read operation. The purpose of this field is to prevent contention on the shared IO when using memories with slow data-to-high-z response (large tRHZ field).
8–7 PPB	Pages Per Block. Indicates how many pages are in 1 Block of the Nand Flash. PPB is used to: - Calculate the next block to erase in AUTO_ERASE. - Calculate in ADD_OP=1/3 where to start the address of the block after extracting the lsb for CS. 00 - 32 pages per block 01 - 64 pages per block 10 - 128 pages per block (default value) 11 - 256 pages per block

Table 45-40. NFC_CONFIGURATION2 Register Field Descriptions (continued)

Field	Description
6 ECC_MODE	ECC_MODE. This bit selects the error correction capabilities, either 4bit correction or 8bit correction. in 4bit ECC_MODE the NFC uses 16Bytes of spare area for for every 512B section of the Nand device. (8B for user specific applications and 8B for ECC). In 8bit ECC_MODE the NFC uses 26B of spare area for every 512B section of the Nand device (12Bytes for user specific application, 14Bytes for ECC). Note that in order to use 8bit ECC_MODE, you must have a NAND device that has at least 26Bytes of spare area for every 512B main section. Note:. -In case working with a NAND device with page size of 4K+ spare of 218B with ECC_MODE of 8bits then the last 10B of the last spare buffer are not ECC protected. Moreover, in case of 4bits ECC_MODE then the SPAS should be configured to 0x40 (i.e spare of 128B) and the NFC will use only the first 16B (8B for user-reserved and 8B for ECC) for every section of 512B. That means that the NFC will use only 128B of spare out of the 218B available. For further information of the ECC algorithm refer to 45.9.4/45-78. 0 - 4bit error correction (default value). 1 - 8bit error correction.
5 NUM_ADR_PHASES0	Number Of Address Phases0. The number of address phases need to be executed to the NAND Device during an AUTO_ERASE operation 0 1 phase less then NUM_ADR_PHASES1 1 2 phases less then NUM_ADR_PHASES1
4 NUM_CMD_PHASES	Number Of Command Phases. he number of command phases need to execute to the NAND Device during AUTO_READ operation(i.e, is read-confirm command is needed or not) 0 1 command phase for reading a page 1 2 command phases for reading a page (read command & read-confirm command)
3 ECC_EN	ECC operation Enable. This bit determines whether ECC operation is executed or bypassed The default is ECC enable. 0 ECC operation is bypassed 1 ECC operation is executed
2 SYM	Symmetric mode. This bit controls the speed of access as well as RE# waveform during read. 0 Two flash clock cycles per access of RE# or WE#, (asymmetric RE waveform). For further information refer to 45.9.5/45-80. 1 One flash clock cycle per access of RE# or WE#, (symmetric RE waveform).
1-0 PS	Page Size. Determines the Nand device page size. 00 - 1/2KB page 01 - 2KB page 10- 4KB page 11 - 4KB page

45.7.28 NAND Flash Operation Configuration3 (NFC_CONFIGURATION3)

This register is a configuration register for the NAND Flash device to control the ECC-Enable or Disable, Mask Interrupt, endianess, etc

The bit assignments for the register are shown in Figure 45-30 and the field descriptions are shown in Table 45-41

	0xBASE+0x3028 (NFC CONFIGURATION3)												Access: User read-write

Figure 45-30. NAND_FLASH_CONFIG Register

Table 45-41. NFC_CONFIGURATION3 Register Field Descriptions

Field	Description
31–21 Reserved	Reserved
20 NO_SDMA	NO_SDMA. When this bit is set, then the system is transferring data to/from the RAM by a different master then the SDMA. Furthermore, it means that dma_wr_req and dma_rd_req signals, are not being used. When SDMA is being used to transfer data to/from the RAM, then it starts each transfer upon assertion of dma_wr_req or dma_rd_req. This activates FMP protection mechanism, and prevents RBA from automatically incrementing. When not using SDMA, then the system must first copy data to the RAM (for program), and only then set the AUTO_PROG bit of the NFC. NFC will automatically increment RBA to point to the next section in the RAM, so if the system wants to program more than 1 page (using NUM_OF_ITERATIONS field) it can do it up to a full use of the RAM. During read, NFC will write the page to the RAM, and again will automatically increment RBA, so if NUM_OF_ITERATIONS is not 4'h0, NFC will automatically start another read sequence and will write it to the next slot in the RAM. NFC will not stop after the RAM was fully used. It is the system responsibility to configure NUM_OF_ITERATIONS field to prevent RAM overflow/underflow. NOTE: Setting this bit disables FMP protection mechanism, so the system must fill the RAM with data before setting AUTO_PROG bit. 0 SDMA is responsible for data transfer to/from NFC RAM. 1 SDMA is not in being used for NFC operations.

Table 45-41. NFC_CONFIGURATION3 Register Field Descriptions (continued)

Field	Description
19-16 FMP	Fifo Mode Protect. During an automatic operation, the system can access NFC's RAM. This means that the system can copy a part of a page to the RAM, then set an automatic program, and only then continue copying the data into the RAM (The system will write into the RAM, and the NFC will read the RAM and send the data to the NAND simultaneously). A similar process can be activated during read, while NFC will start reading the next page before the system finishes to read all the previous page. In order to prevent overwrite of the RAM, the NFC uses a protection mechanism in which the NFC monitors the AXI address, and maintains a safety buffer in which the AXI must be ahead of the NAND operation. This is the system responsibility to make sure that only 1 master is accessing the NFC during such operations otherwise other masters might "confuse" this protection mechanism. This protection mechanism is protecting only the main area of the RAM, so any system operations must access the spare area prior to the main area. (During program, the system should first copy the spare area data into the RAM and only then copy the main data. During read, the system should first read the spare area, and only then read the main data) The buffer size is defined using FMP field: 000 Disable protection buffer. 001 64B 010 128B (default) 011 256B 100 512B 101 1KB (Not to be used with 1/2KB devices) 110 2KB (Not to be used with 1/2KB devices) 111 4KB (To be used only with 4KB devices) **Note:** FMP will be disabled if NO_SDMA bit is set.
15 RBB_MODE	Ready-Busy mode. This bit determines how the NFC monitors the ready-busy signals of the NAND devices only during an automatic operation. During an Atomic operation NFC always monitors the relevant ipp_nfc_rbbx signal. If this bit is cleared, NFC will perform status-read operations to determine the NAND device status. When RBB_MODE is 0 and atomic operation is executed then the user must connect the all ipp_nfc_rbbx signals to "1" (ready). 0 NFC monitors ready-busy status by doing a status-read command (default) 1 NFC monitors ready-busy status by checking ipp_nfc_rbbX signals
14–12 NUM_OF_DEVICES	Num Of Devices. Defines how many NAND devices are connected to the NFC. 000 1 NAND device 001 2 NAND devices 010 3 NAND devices 011 4 NAND devices 100 5 NAND devices 101 6 NAND devices 110 7 NAND devices 111 8 NAND devices

Table 45-41. NFC_CONFIGURATION3 Register Field Descriptions (continued)

Field	Description
11 DMA_MODE	Dma Mode. This bit determines the functionality of the dma_req signals (dma_rd_req and dma_wr_req). If this bit is set, then NFC will output only 1 dma request signal on dma_rd_req which is a logical OR of dma_rd_req & dma_wr_req. The system can determine the request type by reading DMA_STATUS register. If this bit is used, then the system must clear DMA_STATUS field after reading it. 0 NFC outputs 2 dma request signals 1 NFC outputs 1 dma signal which is the logical OR of the 2 dma requests.
10-8 SBB	Status Busy Bit. Indicates which bit in the NAND status register is the Ready/Busy indication. For example: In Samsung's K9K8GU0M bit 6 of the status register is the Ready/Busy indication.
7 Reserved	Reserved
6-4 Sb2R	Status bit to Record. Indicates which bit in the NAND status register is the Pass/Fail indication. For example: In Samsung's K9K8GU0M bit 0 of the status register is the Pass/Fail indication.
3 FW	Flash Width. Determines the Nand Flash IO width (x8/x16). 0 - x16 1 - x8
2 TOO	Two On One. When this bit is set, then NFC assumes there are 2 x8 NAND devices connected to every CS line (One device on the lower byte of ipp_nfc_read_data_in/ipp_nfc_write_data_out, and one device on the upper byte). When using 2 devices on one CS line, then NFC should be configured as if an x16 device is connected to it in order to use all data lines. If 2 devices of 1/2KB page are connected in this manner, then each automatic page-program will transfer 1KB of data from the NFC's RAM to the NAND devices, so RBA field must be 1KB aligned (3'h0, 3'h2, 3'h4 or 3'h6). In atomic operations, NFC transfers only 1/2KB data each time REG_FDI is set, so its the user's responsibility to update RBA field and to set FDI again. If 2 devices of 2KB page are connected in this manner, then each automatic page-program will transfer 4KB of data from the NFC's RAM to the NAND devices, so RBA field must be 4KB aligned (3'h0). In atomic operations, NFC transfers only 2KB data each time FDI is set, so its the user's responsibility to update RBA field and to set FDI again. If 2 devices of 4KB page are connected in this manner, then the user must not use automatic operations since the RAM can not hold 8KB data. Only atomic operations are permitted in this mode. 0 Only 1 device is connected to all CS lines. 1 2 NAND devices are connected to each active CS line.

Table 45-41. NFC_CONFIGURATION3 Register Field Descriptions (continued)

Field	Description
1–0 ADD_OP	Addressing Options. This field defines how NFC handles the addressing of the pages/blocks during an automatic operations. 00 - NFC will use only address group 0 (i.e NAND_ADD0, NAND_ADD8 for all the relevant devices). So in interleaved mode (i.e NUM_OF_ITERATIONS and NUM_OF_DEVICES are greater than 0) then the NFC will act as following: First operation will be sent to CS0 and NFC will drive the address from address group 0 Second operation will be sent to CS1 and NFC will drive the address from address group 0 Third operation will be sent to CS2 and NFC will drive the address from address group 0 and so on untill NUM_OF_ITERATIONS is reached. 01 - NFC will use only address group 0 (i.e NAND_ADD0, NAND_ADD8) and will only use one NAND device as following: The NFC will use the lowest bits of the NAND_ADD0 as the CS for the operations according to NUM_OF_DEVICES . In case of 1 or 2 devices then the lsb (of the page) is used for the CS. In case of 4 devices the 2 lsb (of the page) are used for the CS and in case of 8 devices then the 3 lsb (of the page) are used for CS. Those lowest bits will be removed from the address that will be driven to the NAND device. Moreover for CS calculations, NFC ignores the column address and leaves it as it is. For example: Assume 4 devices are connected to the NFC, erasing block 0 of device #0 requires writing 48'h0 to address group 0 register. Erasing block 0 of device #1 requires writing 48'h1 to NFC_ADD0 register. Assume 2KB page devices: Programming page 0 of device #1 requires writing 48'h10000 to NFC_ADD register (16 lower bits are column address and don't take place in CS-Address extraction) If NUM_OF_ITERATIONS is greater than "0" then the NFC will increment the address group 0 every iteration (For page operations NFC will use the same block address, and will increment the page address. for block operations(erase), NFC will increment the block address) and access the same device (according to the extracted CS) untill NUM_OF_ITERATIONS is reached. For example in Erase: if 4 devices are connected to NFC and PPB is 10 (128 pages per block) and we wish to make two erase iterations (i.e NUM_OF_ITERATIONS=1) of 4th.5th blocks (block number 3,4) of device3 (CS3) then address group 0 supposes to be 48'h603 (2 lsb are used for the CS, 7 bits are used for the page and the rest are used for the block). In the 2nd iteration the address will be incremented to 48'h803 (increment block by 1). For example in Program/Read: if 4 devices are connected to NFC and PPB is 10 (128 pages per block) and we wish to make 3 program/read iterations (i.e NUM_OF_ITERATIONS=2) to/from 2nd,3rd,4th page (page number 1,2,3) of the 2nd block(block number 1) of device3 (CS3) then address group 0 supposes to be 48'h2070000 (16 lsb are used for the column, 2 bits are used for CS, 7 bits are used for the page and the rest are used for the block). In the 2nd iteration the address will be incremented to 48'h20B0000 (increment page by 1) and In the 3rd iteration the address will be incremented to 48'h20F0000 (increment page by 1). Note: - This option can be used only when using 1,2,4 or 8 NAND device. - Only single device will be accessed (No interleaving) even if both NUM_OF_ITERATIONS and NUM_OF_DEVICES are greater than "0" 10 - NFC will use all the address groups. Each device with the associated address group (device0 with address group 0, device1 with address group 1 and so on). So in interleaved mode (i.e NUM_OF_ITERATIONS and NUM_OF_DEVICES are greater than 0) then the NFC will act as following: First operation will be sent to CS0 and NFC will drive the address from address group 0. Second operation will be sent to CS1 and NFC will drive the address from address group 1. Third operation will be sent to CS2 and NFC will drive the address from NAND_ADD3, and so on.

Table 45-41. NFC_CONFIGURATION3 Register Field Descriptions (continued)

Field	Description
	11 - NFC will use all the address groups and also will use the lowest bits of the NAND_ADDx as the CS for the operations. So in interleaved mode (i.e NUM_OF_ITERATIONS and NUM_OF_DEVICES are greater than 0) then the NFC will act as following: First operation will be sent to CSX based on address group 0 (i.e NAND_ADD0, NAND_ADD8). Second operation will be sent to CSY based on address group 1 (i.e NAND_ADD1, NAND_ADD8). Third operation will be sent to CSZ based on address group 2 (i.e NAND_ADD2, NAND_ADD9), and so on. In case of 1 or 2 devices then the lsb (of the page) is used for the CS. In case of 4 devices the 2 lsb (of the page) are used for the CS and in case of 8 devices then the 3 lsb (of the page) are used for CS. Those lowest bits will be removed from the address that will be driven to the NAND device. Moreover for CS calculations, NFC ignores the column address and leaves it as it is. For example in Erase: if 4 devices are connected to NFC and PPB is 10 (128 pages per block) and we wish to make 3 erase iterations (i.e NUM_OF_ITERATIONS=2) the first iteration to the 4th block (block number 3) of device3 (CS3), the second iteration to 2nd block (block number 1) of device1(CS1) and the 3rd to the 1st block (block number 0) of device0 (CS0). Then the address for the 1st iteration will be driven from address group 0 that supposes to be 48'h603 (2 lsb will be used for the CS then 7 bits will be used for the page and the rest are used for the block(which is 3)). The address for the second iteration will be driven from address group 1 that suppposes to be 48'h201 and the address for the 3rd iteration will be driven from address group 2 that supposes to be 48'h0 Note: -This option can be used only when using 1,2,4 or 8 NAND device. In this mode, every address group involved must specify a different CS - It is not allowed to configure NUM_OF_ITERATIONS greater than NUM_OF_DEVICES

45.7.29 NAND Flash IP control (NFC_IPC)

This register holds the IP write handshake registers as well as the interrupt register.

The bit assignments for the register are shown in Figure 45-31 and the field descriptions are shown in Table 45-42

	0xBASE+0x302C (NFC IPC)													Access: User read-write		
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 45-31. NFC_IPC Register

Table 45-42. NFC_IPC Register Field Descriptions

Field	Description
31 INT	Interrupt.The output port ipi_int_nfc is a logic AND between this bit and INT_MSK bit. This bit will rise after NFC finishes an atomic operation (setting any bit in LAUNCH_NFC[5:0]) or in automatic operation (AUTO_READ/AUTO_PROG/AUTO_ERASE/AUTO_COPY_BACK0/1) it will issue the interrupt only after NUM_OF_ITERATIONS is reached. When interrupt is being set after an automatic operation it means that all status registers from all relevant NAND devices have been read and the status is stored in STATUS_SUM register. This bit is not self cleared, so it must be cleared by the user (by writing “0”). 0 NFC didn’t finish its operation. 1 NFC finished its operation and is ready to accept next operation.
30 AUTO_PROG_ DONE	Automatic Program Done. Indicates that SDMA finished transferring all NUM_OF_ITERATIONS pages to the NFC. This allows the software to prepare SDMA with the data of next group of pages to be transferred to the NAND devices. This bit is not self cleared, so it must be cleared by the user (by writing “0”). 0 SDMA didn’t finish transferring NUM_OF_ITERATIONS pages to NFC. 1 SDMA finished transferring num_of_iterations pages to NFC.
29 LPS	Low Power Status. This read-only bit reflects the low power mode of the nfc. 0 - nfc is not in a low power mode 1 - nfc is in a low power mode
28 RB_B	RB_B Status. This read-only bit reflects the RB_B signal of the Nand device. 0 - Nand device is busy. 1 - Nand device is idle.
27–26 DMA_STATUS	Dma Status. This field indicates which dma request signal is asserted. This field is not self cleared, so it must be cleared by the user. 00 All dma request signals are deasserted. 01 dma_wr_req was asserted 10 dma_rd_req was asserted 11 Both dma_rd_req & dma_wr_req were asserted.
25-2 Reserved	Reserved
1 CACK	IP configuration acknowledge. Whenever this bit is set, IP is permitted to configure NFC’s IP registers. 0 - Configuration of NFC’s registers is forbidden. 1 - Configuration of NFC’s registers is permitted.
0 CREQ	IP request to configure NFC. Whenever IP wants to configure NFC it must set this bit to one, and poll on CACK until it is high. Only then configuration is permitted. After configuration is done, the user must deassert this bit. This feature prevents configuring the NFC during an operation and causing an unexpected behaviour. 0 - No request to configure NFC. 1 - A request to configure NFC is vallid.

45.7.30 AXI Error Address (AXI_ERR_ADD)

Address of the first erronous AXI access. The bit assignments for the register are shown in Figure 45-32 and the field descriptions are shown in Table 45-43.

	0xBASE+0x3030 (AXI_ERR_ADD)													Access: User read-write		
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R																
W

R				AXI_ERR_ADD												
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 45-32. AXI_ERR_ADD Register

Table 45-43. AXI_ERR_ADD Register Field Description

Field	Description
31–13 Reserved	Reserved
12–0 AXI_ERR_ADD	AXI Error Address. Whenever NFC returns an error response on the AXI interface, it will sample the address in which the error occured, and store it in this register for debug purposes. NOTE: Only the first error-address will be stored. If second AXI error response will occur, the second error-address will be lost. Reading from this register, will unlock this register, so, second error-address will be sampled.

45.7.31 Delay-Line (NFC_DELAY_LINE)

The NFC includes 4 delay line units where each unit can adjust the timepoint in which the NFC latches the read data by 1/2 fast clock cycle (aclk) and therefore the 4 delay lines can adjust that timepoint by up to 2 fast clock cycles (aclk)
NFC_DELAY_LINE register represents single delay line unit. By default the NFC latches the data after a fixed 1 flash_clk cycle + 1 fast clock cycle (aclk).
Writing to NFC_DELAY_LINE register will adjust the fast clock cycle delay.
The bit assignments for the register are shown in Figure 45-33 and the field descriptions are shown in Table 45-44.

	0xBASE+0x3034 (NFC_DELAY_LINE)												Access: User read-write			
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																
R W	NFC_OFF_DEL								NFC_ABS_DEL							
RESET	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

Figure 45-33. NFC_DELAY_LINE Register

Table 45-44. NFC_DELAY_LINE Register Field Description

Field	Description
31–16 Reserved	Reserved
15–8 NFC_OFF_DEL	NFC Delay-line Offset delay. The field represents positive and negative numbers using twos compliment representation. This allows positive and negative offsets from the quarter cycle measured value. For example, to add 3 delay units to the measured delay, this field should be 00000011, to subtract 3 delay units, it will be set to 11111101.
7–0 NFC_ABS_DEL	NFC Delay-line Absolute delay. This field decides the specific delay line absolute delay in fractions of a cycle terms. The fraction is process and frequency independent. The delay for the delay line would be (NFC_ABS_DEL / 512) * tCK. So for the default value of 128 we get a quarter cycle delay.

45.8 Functional Description

This section provides the functional description for the NAND Flash Controller.

45.8.1 Reset

There are several options to reset the NFC:
axi_reset - asserting axi_reset_b will reset all axi related functionality, such as axi state machines and axi registers. axi_reset_b resets ip registers as well.
cold reset - asserting of ipp_reset_b will reset all the functionality that is responsible to communicate with the NAND include the ECC engine.

warm_reset - this signal is checked during assertion of axi_reset_b, and if it is high, then all configuration registers will not be reset. This will enable a quick return-to-action reset operation.

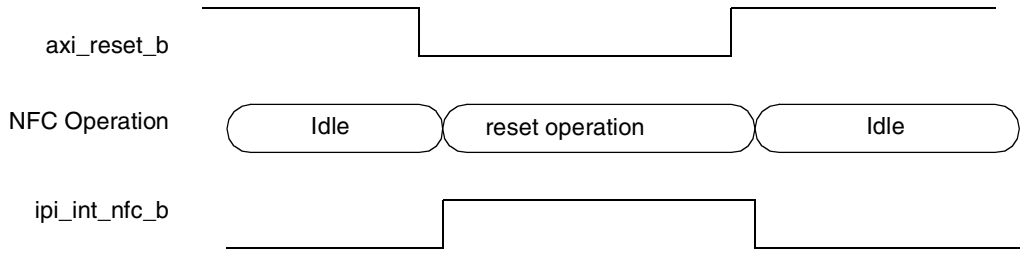

Figure 45-34. Interrupt functionality during reset

45.8.2 NAND Flash I/F Control

The NAND Flash I/F Control generates all the following control signals:

CE# (Flash Chip Enable), RE# (Read Enable for read operations), WE# (Flash Write Enable),
CLE# (Flash Command Latch Enable), ALE (Flash Address Latch Enable).
It monitors the RB_B (Flash Ready/Busy indication) to check if the NAND Flash is in the middle of operation.
Ratio of ipp_flash_clk and aclk should be an integer value and a minimum of 2 (aclk is at least double the frequency of ipp_flash_clk) as long as the clocks are synchronous.
The following will specify the operation of the NFC during program or read:
1/2KB page:
There is a need to configure the address and command sequence before every page of 512B.
Every page is transferred to 1/2KB in the nfc internal RAM buffer so it is important to change RBA register to choose which 1/2KB section of the RAM will be written or read from.
2KB page:
The commands and address cycles occur at the beginning of the program or read sequence. After the command and address sequence, there are four sections of data program/read of 512B each. Every section of 1/2KB is transferred to/from a different 1/2KB in the nfc internal RAM buffer. After command &

address cycles are done, upon kicking off a 2K page (writing 16’h4 or 16’h8 to LAUNCH_NFC register), the NFC will transfer the 2K page from/to its internal RAM to/from the NAND device.
Every page is written to 2KB in the nfc internal RAM buffer so it is important to change RBA register to choose which 2KB section of the RAM will be written or read from. Legal values for RBA field are RBA=0 & RBA=4.
4KB page:
The commands and address cycles occur at the beginning of the program or read sequence. After the command and address sequence, there are eight sections of data program/read of 512B each. Every one of the 1/2KB is transferred to/from different 1/2KB in the nfc internal RAM buffer. After command & address cycles are done, upon kicking off a 4KB (writing 16’h4 or 16’h8 to LAUNCH_NFC register), the NFC will transfer the 4KB page from/to its internal RAM from/to the NAND device.
In 4KB page , it is only legal to write 3’b000 to RBA register.
ECC is always calculated for data section of 1/2KB even if the page size is 2KB/4KB.
Figure 45-35, Figure 45-36, and Figure 45-37 show the NAND Flash read, program, and erase timing diagrams.

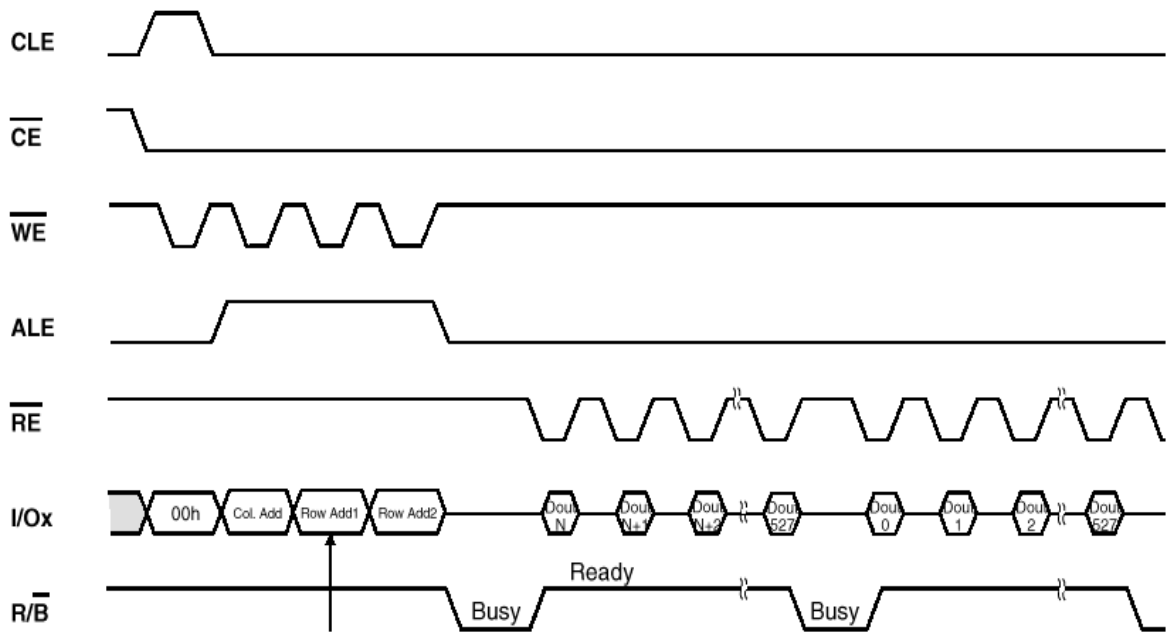

Figure 45-35. Read Operation

1 ALE can be asserted & deasserted separately for each address phase.
2 Number of ALE phases is determined by the user.

PAGE PROGRAM OPERATION

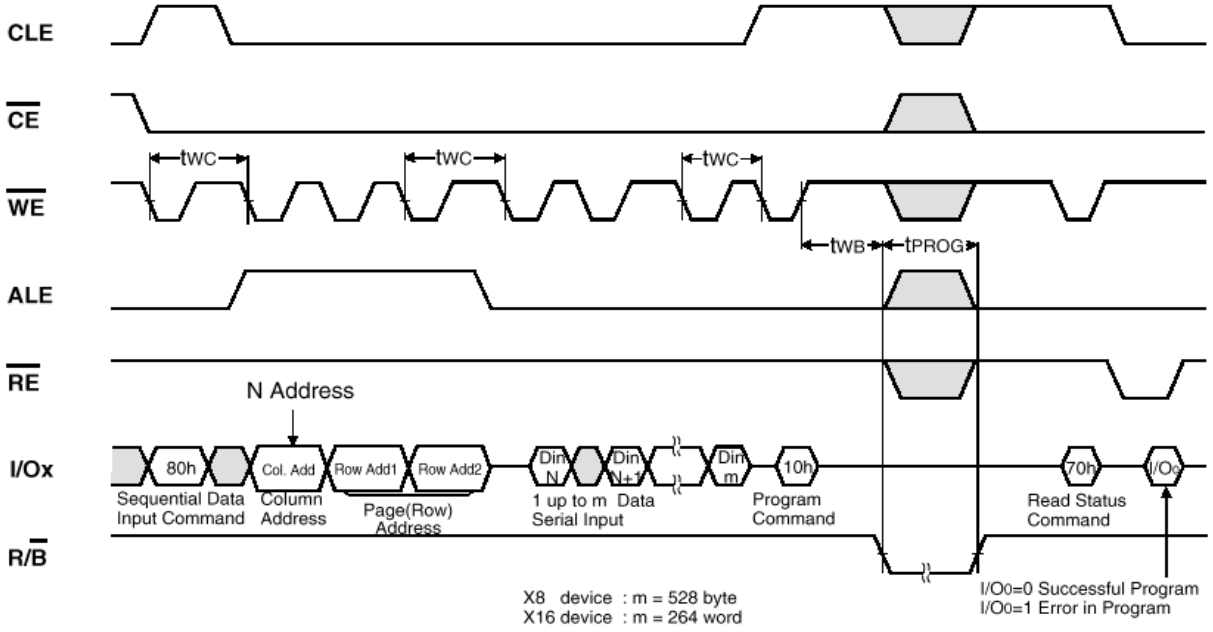

Figure 45-36. Program Operation

BLOCK ERASE OPERATION (ERASE ONE BLOCK)

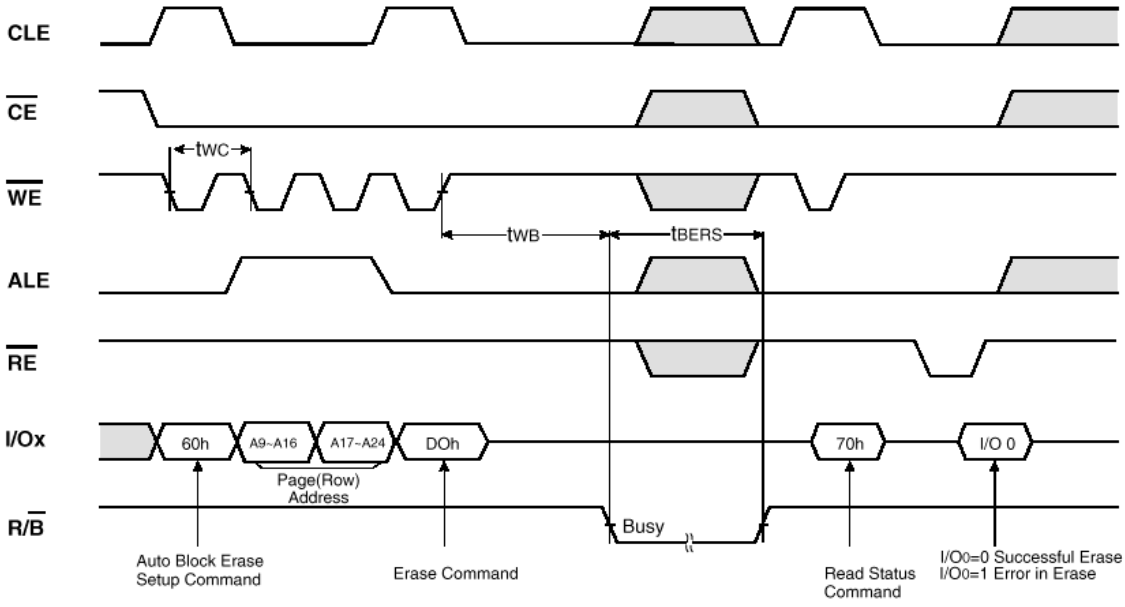

Figure 45-37. Erase Operation

45.8.3 DMA Request Operation

There are two DMA request signals:

- dma_rd_request—triggers after NFC finished reading a page.
- dma_wr_request—triggers either on write to AUTO_PROG bit, or after NFC finished transferring data from NFC's RAM to the NAND device during an automatic program operation, but only if there are more pages to program based on NUM_OF_ITERATIONS field.

The configuration bit DMA_MODE selects between a mode of 2 independent dma-request signals, and a combined signal which asserts both on dma_rd_request triggering & on dma_wr_request triggering. This joined dma-request signal is functional on dma_rd_req pin, whereas dma_wr_req pin will be unused in such a mode.

45.8.4 Internal RAM

The internal RAM Buffer is a 4608 Byte single Port RAM buffer. This memory has 1152 words of 32-bits each, where1024 words are used for the main are buffers (data sections) and the remaining 128 words are allotted to spare area buffers, which are used for ECC (Error Correction) and other user-reserved.
Although the RAM is a single port RAM, the NFC holds a mechanism that allows accessing the RAM from two sources at the same time. For example: When NFC reads data from the RAM in order to program it into the NAND device, the host can write to another location in the RAM and prepare the data for the second page program. This mechanism can be achieved since the Flash side is relatively slow, so, there are idle cycles in which the NFC can service the host. Example of a good use for this feature is that the host instead of writing a full page to the NFC, writes only part of the page, and then launches the program operation. Now the host can continue writing the page to the RAM while NFC is reading it out and sends it to the NAND device. Such a use can almost hide the page transfer time from the host to the NFC.
NOTE: There is a limitation for using the dual-port ability of the RAM. The User must not perform AXI read transactions during NFC-program operation, and the user must not perform AXI write transactions during NFC-read operation (If NFC is reading from the RAM - during program, then the user must not read from the RAM also, and while NFC is writing to the RAM, the user must not write to the RAM either.)
When FMP (Fifo Mode Protect field in NFC_CONFIGURATION3 register) is set, the NFC assumes that the host is acting as the example above. NFC will monitor the RAM and makes sure that there is always enough data in the RAM for the NFC to write. i.e if the host is becoming slow when writing the page into the RAM, then the NFC will pause the program operation and waits until the host continues to write the page. Same monitoring is applied in read operations, when the host reads only a part of a read page, and NFC starts reading another page. The NFC may overwrite the previous page before the host can read it - so the NFC monitors the progress of the host and pauses the read operation before an overwrite can occur. To ensure that this protection mechanism would work properly, the system must make sure that only 1 master is accessing the NFC during the entire operation (for example: SDMA, ARM, etc).
The NFC logically divides the RAM into 8 sections. Each section contains 512B of main data and 64B of spare area. When reading (or programming) from the NAND device, the NFC writes the main data from the NAND device into the main area, and the spare data from the device is written into the spare section. If the NAND device spare data is less than 64B per 512B main data, then the NFC's spare section in the internal RAM will not be fully used. For example in NAND device that has 2KB main data and 64B spare data, then this device has 16B spare data for every 512B main data, then the spare data in the RAM will be located as following: first 16B of spare data in spare buffer 0 ,next 16B in spare buffer 1, and so on.

When using a NAND device in which the spare area size is not fully divided by 512B sections, then the remainder will be located at the last spare section. For example in a NAND device with 4KB main data + 218B spare data, then the division will be 27.25B of spare for each 512B of main data. Then the NFC rounds this number down to the nearest even number, which 26B, and that would be the number of Bytes located in each spare buffer. The remaining Bytes will be added to the last section, meaning that the last spare section will contain 26+10=36B.

45.8.5 AXI Bus Interface

The AXI bus interface is an adapter between ABMA AXI bus and the internal bus.
On the AXI bus side it supports a 16-bit and 32-bit transactions, burst and non burst operations. On the internal bus side it supports 32-bit bus width.
AXI interface supports only INCR accesses (no WRAP nor FIXED), with length of 1-16 data transfers (defined by arlen/awlen of 4 bit).
AXI domain is divided to 2 regions: internal RAM & AXI registers. Any access to AXI registers, must be 32bit wide, with length of 1 data transfer (single access).

45.8.5.1 LPMD/ DVFS

DVFS is supported using a handshake with the system. The system asserts lpmd signal to request a power down. NFC will respond with assertion of lpack, as soon as it becomes idle from its current operation. lpack assertion signals to the HOST that the NFC is ready for power down.
lpack will be asserted if there is no active axi transaction and there is no active flash accesses.
The NFC holds a register in IP domain (LPS) that indicates the status of the lpack signal.

45.8.5.2 Burst Access Support

Not all AXI burst transactions are supported. Table 45-45 lists NFC supported access burst types.

Table 45-45. NAND Flash Burst Access Support

HBURST	BURST TYPE	SUPPORTED	Description
00	FIXED	No	Fixed address burst
01	INCR	Yes	Incrementing-address burst
10	WRAP	No	Incrementing-address burst that wraps at wrap boundary
11	Reserved	Yes	-

Note:

NFC supports bursts of 16/32-bit words only. Bursts of byte words (8-bits) are not supported.

45.8.6 IP interface

The IP interface is an adapter between IP protocol and internal control registers.
NFC's registers are divided between AXI domain & IP domain to enable better security and data protection.
Write sequence to IP must follow a write handshake protocol:
Whenever the host wants to write to one of the IP registers, he must first assert CREQ field. Whenever the NFC will be ready to accept the write, he will assert CACK. Now the write sequence can go on. Upon completion of all write sequences, the host must clear the CREQ field.

The purpose of the handshake mechanism, is to prevent a situation where control registers are being changed during an operation and by that causing an unexpected behavior.

45.8.7 I/O Pins Sharing

The NAND Flash Controller has logic that allows it to share I/O pins with pins of another memory controller.

The arbitration between the NFC and the other memory has hard priority favouring the other memory. Since NFC's accesses are long, when the other memory requests the bus, the NFC will always halt its operation as soon as possible based on its internal state and the other memory will be granted. The only operations that will not halt in the middle are relatively short ones, such as command phase, address phase or spare area read. The host must take into account, that spare area read is the longest operation of the above and can take up to 32 Flash-clock cycles (for 8bit memory in non-symmetric mode).

This hard decision arbitration contains a dead-lock counter in favour of the NFC. The counter counts fast clocks cycles (aclk) in which the NFC requests the bus, but not being granted. If the counter reaches a certain value, it will cause the arbitration to favour the NFC over the other memory. Meaning, that if the other memory will deassert its request it won't get it again until the NFC will be granted at least once. After that grant, arbitration returns to normal mode, meaning, that if the other memory requests the bus, the NFC will pause as soon as possible based on the previous description.

This priority based arbitration mechanism must be taken into account when sharing the I/O bus with another memory.

45.9 NFC Operation

This section describes the operation of the NFC. It is divided to the following sub-sections:

- Automatic operations (45.9.1/45-64).
- Atomic operations (45.9.2/45-67).
- Atomic operations sequence (45.9.3/45-75).
- ECC operation (45.9.4/45-78).
- Symmetric/Asymmetric operation (45.9.5/45-80).
- Delay line operation(45.9.6/45-82).
- Write Protection peraion (45.9.7/45-83).

45.9.1 Automatic Operations

The NFC offers the user a simplification in accessing the NAND device, by automatically performing common NAND sequences. All automatic operations require some kind of preparations from the host, before the automatic operation is performed. NFC informs the host about the completion of the operation.

45.9.1.1 Automatic program operation

Setting AUTO_PROG bit in LAUNCH_NFC register, results in NFC executing a full page program including a status read at the end (The status-read operation will be executed only in case that RBB_MODE=0). NFC will repeat this operation several times as defined in NUM_OF_ITERATIONS field in NFC_CONFIGURATION1 register.
Upon setting AUTO_PROG bit, NFC will immediately set dma_wr_req (For systems that are using SDMA for filling the NFC's RAM). After setting dma_wr_req NFC will start executing the program operation by sending a command defined in NAND_CMD0 register, followed by sending the address from the relevant address group (The address will be divided into several address phases as defined in NUM_OF_ADDRESS_PHASES register). After the address phases finished the NFC will start copying the data from the NFC's RAM to the NAND device (If the RAM contains enough data as defined by FMP), and then NFC will issue a program-confirm command defined in NAND_CMD1 register. NFC will monitor the Ready/Busy status of the NAND device, and will read the status of the device as soon as the device returns to ready state.
When NUM_OF_ITERATIONS is greater than 0 and NUM_OF_DEVICES is greater than 0 (meaning interleaved mode. More than 1 page should be programmed to several devices), then NFC will operate a little different:
- NFC will set the next dma_wr_req after the data-transfer phase finished (meaning the RAM can be overwritten)
- NFC will start issuing the next page before the previous device returns to idle (Thus hiding the busy time of the device).
The address that will be sent depends on ADD_OP.
NFC will not set dma_wr_req after the data transfer of the last page (As defined in NUM_OF_ITERATIONS).
Automatic program operation generates 2 types of interrupts:
- INT will be set when all NAND devices that were involved in the operation returned to idle (And their status is recorded inside the NFC).

- AUTO_PROG_DONE will be set when NFC detects that all pages have been copied to its internal RAM (Meaning that the SDMA can be configured with parameters for next set of pages to be programmed).

45.9.1.2 Automatic Read Operation

Setting AUTO_READ bit in LAUNCH_NFC register, results in NFC executing a full page read. NFC will repeat this operation several times as defined in NUM_OF_ITERATIONS field in NFC_CONFIGURATION1 register.
Upon setting AUTO_READ bit, NFC will start executing a page read operation from the NAND device: read-command followed by address phases and a read-confirm-command if needed. Then NFC will monitor the read/busy status of the device, and will start reading the data as soon as the device returns to ready state. NFC will read the status of the operation afterwords.
NFC will set dma_rd_req when it finishes reading a full page from the NAND device (After fixing ECC errors if there are any).
If NUM_OF_ITERATIONS is greater than 0, then NFC pauses after reading a page, and waits for the system to read out the data from NFC's RAM. NFC will continue to read the next page as soon as the system reads enough data as defined in FMP register.
INT will be set after NFC has read the status register of all NAND devices that were involved in the operation.

45.9.1.3 Automatic erase operation

Setting AUTO_ERASE bit in LAUNCH_NFC register, results in NFC executing a full block erase. NFC will repeat this operation several times as defined in NUM_OF_ITERATIONS field in NFC_CONFIGURATION1 register.
Upon setting AUTO_ERASE bit, NFC will start executing a block erase operation from the NAND device: Erase-command, followed by erase-address, followed by erase-confirm-command. Then NFC will monitor the read/busy status of the device, and will read the status of the device as soon as the device returns to ready.
INT will be set when all NAND devices that were involved in the operation returned to idle (And their status is recorded inside the NFC).

45.9.1.4 Automatic copy-back operation

Setting AUTO_COPY_BACK0 bit in LAUNCH_NFC register, results in NFC executing a full copy-back operation.
NFC will send a command (defined in NAND_CMD0 register), then address phases (defined in the relevant address group), then another command phase (defined in NAND_CMD1 register), then NFC will monitor the ready/busy status of the NAND device, then another command phase (defined in NAND_CMD2 register), then address phases (defined in relevant address group), then last command phase (defined in NAND_CMD3 register), then again NFC will monitor the ready/busy status of the NAND device. Finally NFC will check the status of the operation.
INT will be set when the status of the NAND device is ready.
Setting AUTO_COPY_BACK1 will result in NFC executing AUTO_COPY_BACK0 operation to all NAND devices connected to it (with the same addresses to all the devices).

NFC will perform AUTO_COPY_BACK1 in an interleaved mode (meaning, that if a NAND device is getting busy, NFC will continue to the next device, and will get back to the first device as soon as it becomes ready). So, if the system wants to perform a copy-back operation with the same addresses to all the NAND devices, it is much more efficient to use AUTO_COPY_BACK1 then using AUTO_COPY_BACK0 several times.

45.9.1.5 Automatic status-read operation

Setting AUTO_STAT bit in LAUNCH_NFC register, results in NFC executing a full status read operation to the NAND device.
NFC will send status read command (defined in ST_CMD in NFC_CONFIGURATION2 register), then it will read the status of the device and store it in NF_STATUS field in NFC_CONFIGURATION1 register.

45.9.3.2 Atomic Program Sequence Operation

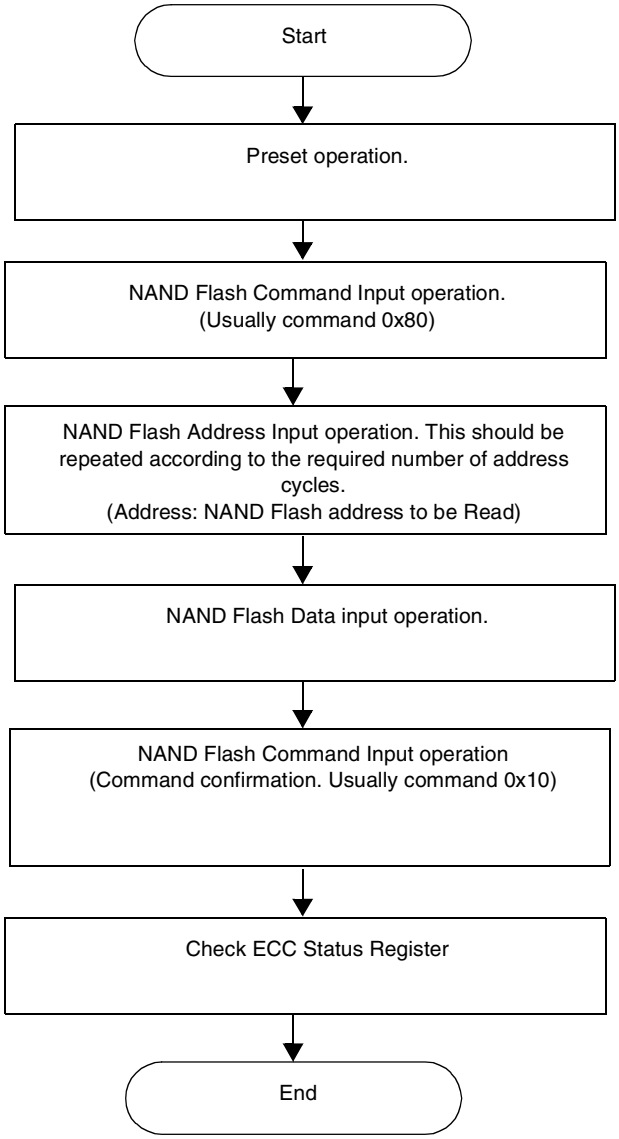

Figure 45-48. Flow Chart of Program NAND Flash Data Operation

45.9.3.3 Atomic Erase Sequence Operation

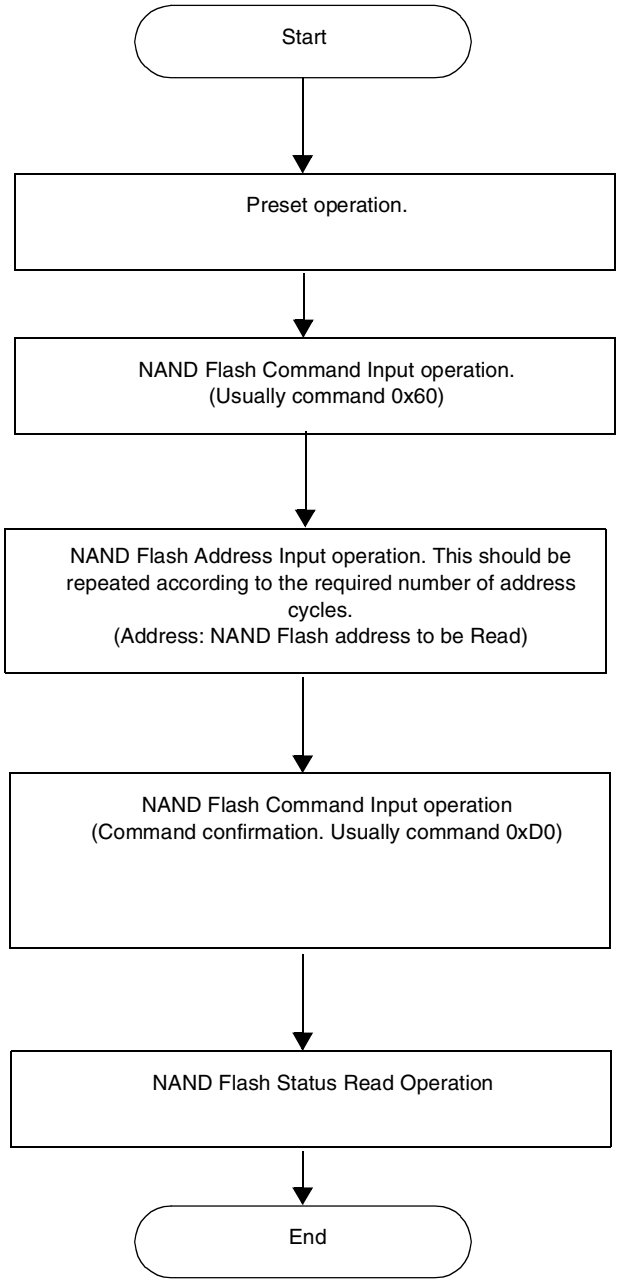

Figure 45-49. Flow Chart of Erase NAND Flash Operation

45.9.4 ECC Operation

45.9.4.1 ECC Normal Operation

The BCH ECC engine is responsible for detection and correction of up to 4/8 bits in each 528/538 byte section.
NFC divides the page into data sections of 1/2KB + spare area buffer. The ECC algorithm protects each data section and the associated spare area buffer.
When the NFC accesses the NAND Flash device for Program operation, it generates ECC code (8/14 bytes for each 528/538 bytes). These 8/14 bytes of ECC code are calculated based on the generator polynomial g(x) = x^13 + x^4 + x^3 + x + 1
When the NFC accesses the NAND Flash device for a Read operation, it performs a BCH decoding algorithm, and indicates how many bit errors were detected and corrected.
After a Read operation, the host can determine how many bit errors were found per 528/538 bytes by reading the status register (ECC_STATUS_RESULT). If the indication is uncorrectable error then it means that the number of bit errors that were detected (N) exceed the number of bit errors that can be corrected (T) according to ECC_MODE. Due to an algorithm weakness there might be a decoding error with a very low probability that the NFC will indicate that T number of bits error were detected and corrected instead of uncorrectable errors
Table 45-46 shows the ECC code assignment of the NAND Flash spare area.
Upon program, the BCH ECC bytes are written directly to the NAND Flash device (and are not written back to the internal RAM). This means that if a user wants to read the ECC that was generated, he must read it from the NAND Flash device spare area.

45.9.4.2 ECC Bypass Operation

In ECC bypass operation, the spare area is copied from NFC internal Ram Buffer to the nandflash device during program operation. During read operation the ECC detect-fix mechanism will not work as well as status register will not be updated.

Table 45-46. ECC Code/Result Readability

operation	Read operation		Program operation		
	ECC Code from spare area buffer	ECC status register	ECC Code from spare area buffer	ECC status register	ECC content in Nand Flash device
ECC operation	ECC code copied from nandflash device spare area	Valid	Invalid (old data [1])	-	ECC code genrated by the NFC
ECC bypass	ECC code copied from nandflash device spare area	Valid	Invalid (old data)	-	Data from spare area of NFC internal Ram

[1]Old data: ECC code is not updated to spare buffer, so ECC code placement of spare buffer remains old data.

45.9.4.3 How to Operate the ECC

In order to generate ECC and carry out the correction by the NFC,

— Program with ECC operation / Read with ECC operation

In order to generate ECC by the NFC and carry out the correction by the host,

— Program with ECC operation / Read without ECC operation

45.9.5 Symmetric/Asymmetric Mode Operation

In the default state of the NFC 1 flash clock cycle is used for toggeling RE#/WE#.
In order not to work with lower frequency of flash clock, the SYM bit in NFC_CONFIGURATION2 register should be set to “0” and that will change the WE# and RE# period during read or program to be 2 flash clock cycles instead of 1.
Setting SYM bit also changes the duty cycle of RE# to be ~50% during read operation.
Latching the data during a read operation is done 1 flash_clk cycle + 1 aclk cycle after negedge of RE#.
The user can adjust the c‘apturing timepoint by setting values to NFC_DEL_LINE register.

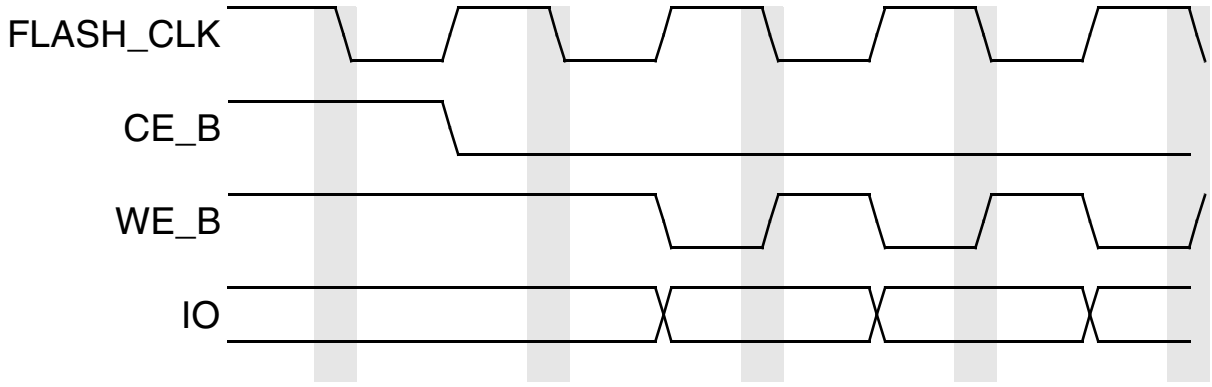

Figure 45-50. One Flash Clock Cycle Per Data Input (SYM bit =1)

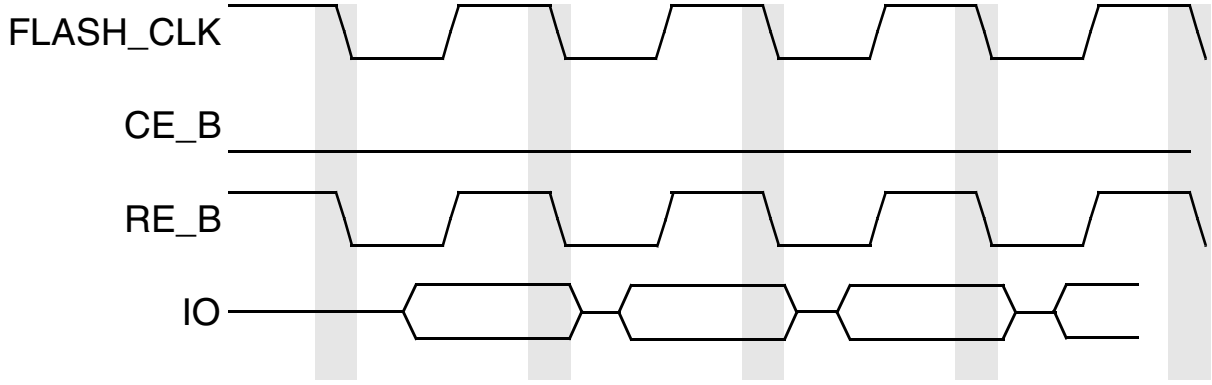

Figure 45-51. One Flash Clock Cycle Per Data Output (SYM bit =1)

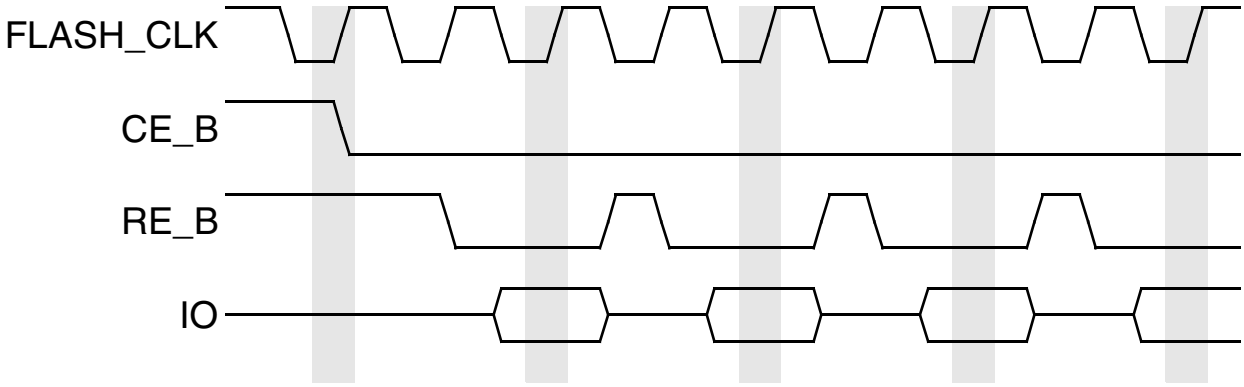

Figure 45-52. Two Flash Clock Cycles Per Data Output (SYM bit =0)

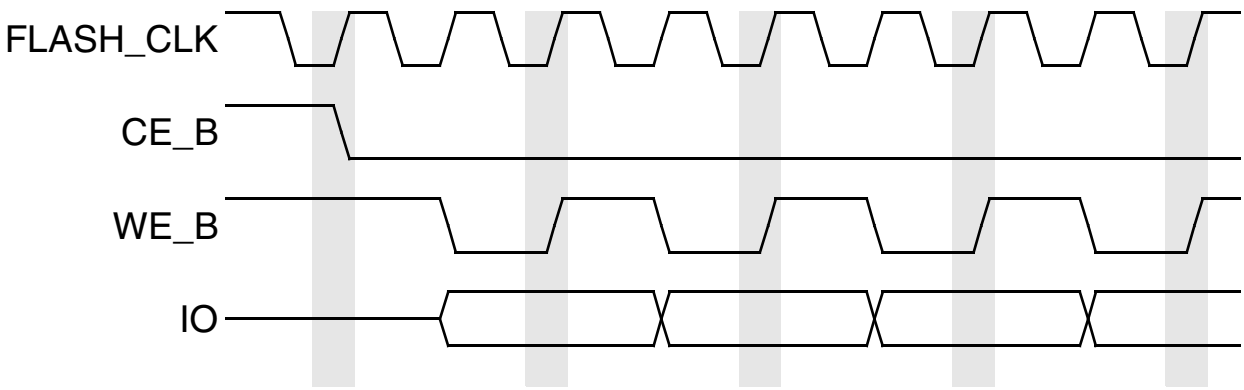

Figure 45-53. Two Flash Clock Cycles Per Data Input (SYM bit =0)

45.9.6 Delay Line Operation

NAND data-read path is a very long path. It Starts with RE_B negedge, then goes to the I/O PADs, through the board to the NAND device, which outputs the DATA after tREA [ns], then back through the I/O PADs until being latched by the NFC.

NFC offers a way of adjusting the data-latching timepoint, so that long read-data path will not require a degredation in frequency (And in performance).

The NFC generates an internal RE_B signal which is 1 flash_clk delayed from the RE_B that goes to the NAND device. This delayed RE_B is then passes through a delay-line (composed of 4 delay line units) which delays it by a configurable time measured by aclk fractions and up to 1/4 aclk cycle per delay-line unit. The delay-line output is used to latch the data.

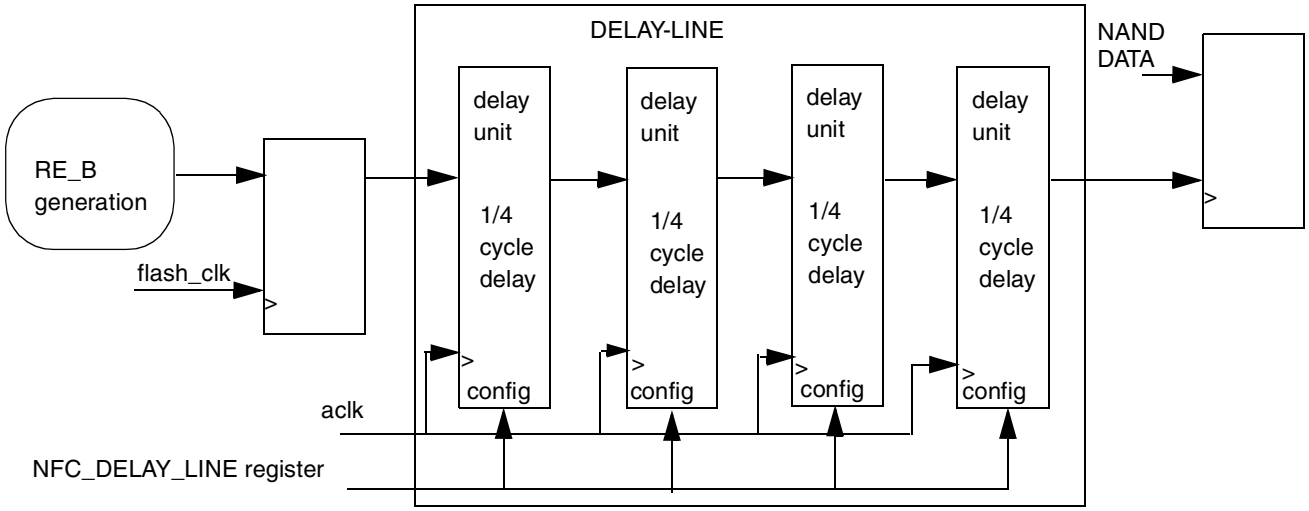

Figure 45-54. Delay Line Operation

45.9.7 Write Protection Operation

The NFC offers a software write protection feature, and a hardware write protection feature. Both are described in this section.

45.9.7.1 Write Protection for RAM Buffer (LSB 2KB)

The NFC offers a software write protection feature for the first 4 sections (main + spare area data) of the RAM buffer, which protects RAM buffer data. This write protection is carried out by setting the WPC bit of the NF_WR_Prot register.

The default state is locked state, and the first 4 sections go to this state after a cold or warm reset.

Write protection availability for main/spare memory regions in the RAM buffer are described on Table 45-7. A state diagram of RAM buffer write protection is shown in Figure 45-55

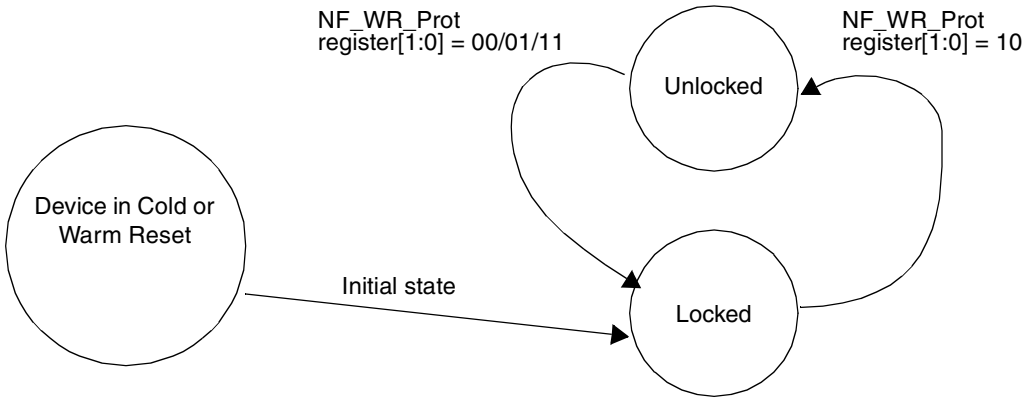

Figure 45-55. State Diagram of RAM Buffer Write Protection

45.9.7.2 Write Protection Modes

NFC offers both hardware and software Write Protection options for the NAND Flash device. The software Write Protection feature is used by executing the LOCK BLOCK command or LOCK-TIGHT BLOCK command, and the hardware Write Protection feature is used by executing a cold or warm reset. The WP signal is asserted only upon POR.

45.9.7.3 Write Protection Commands

There are two write protection states: **Locked**, and **Lock-Tight**.

- **Locked** state means that memory block in question is write protected (it cannot be written to), but the UNLOCK command can “un”-lock it. Useful for frequently changed memory blocks.
- **Lock-Tight** state is a higher level of protection, and means that the memory block in question is write protected, but the UNLOCK command cannot unlock it. Useful for memory blocks whose contents are rarely changed.
- If a user tries to modify a locked or locked-tight block, then the operation would not be carried to the Nand device and the user will not be notified about it.

The followings summarizes the locking functionality.

- — - All blocks power-up in a locked state. The UNLOCK command can unlock these blocks.
- — - The LOCK-TIGHT BLOCK command locks blocks and prevents it (them) from being unlocked.
  - – *Lock-Tight state can be reverted to locked state only when Cold/Warm reset is executed.*
- — - Writing to the unlock start/end address registers (Unlock_Start_Blk_Add and Unlock_End_Blk_Add) while the NFC is in the **Lock-Tight** state does not affect the unlock address.

45.9.7.4 Write Protection Status

The current Write Protection status of the NFC can be read in NAND Flash Write Protection status register (NAND_Flash_WR_Pr_St). There are three bits: US,LS, and LTS, which are not cleared by hot reset. These Write Protection status bits are updated as soon as the Write Protection command is entered.

Figure 45-56 shows a state diagram for the write protection of the NFC.

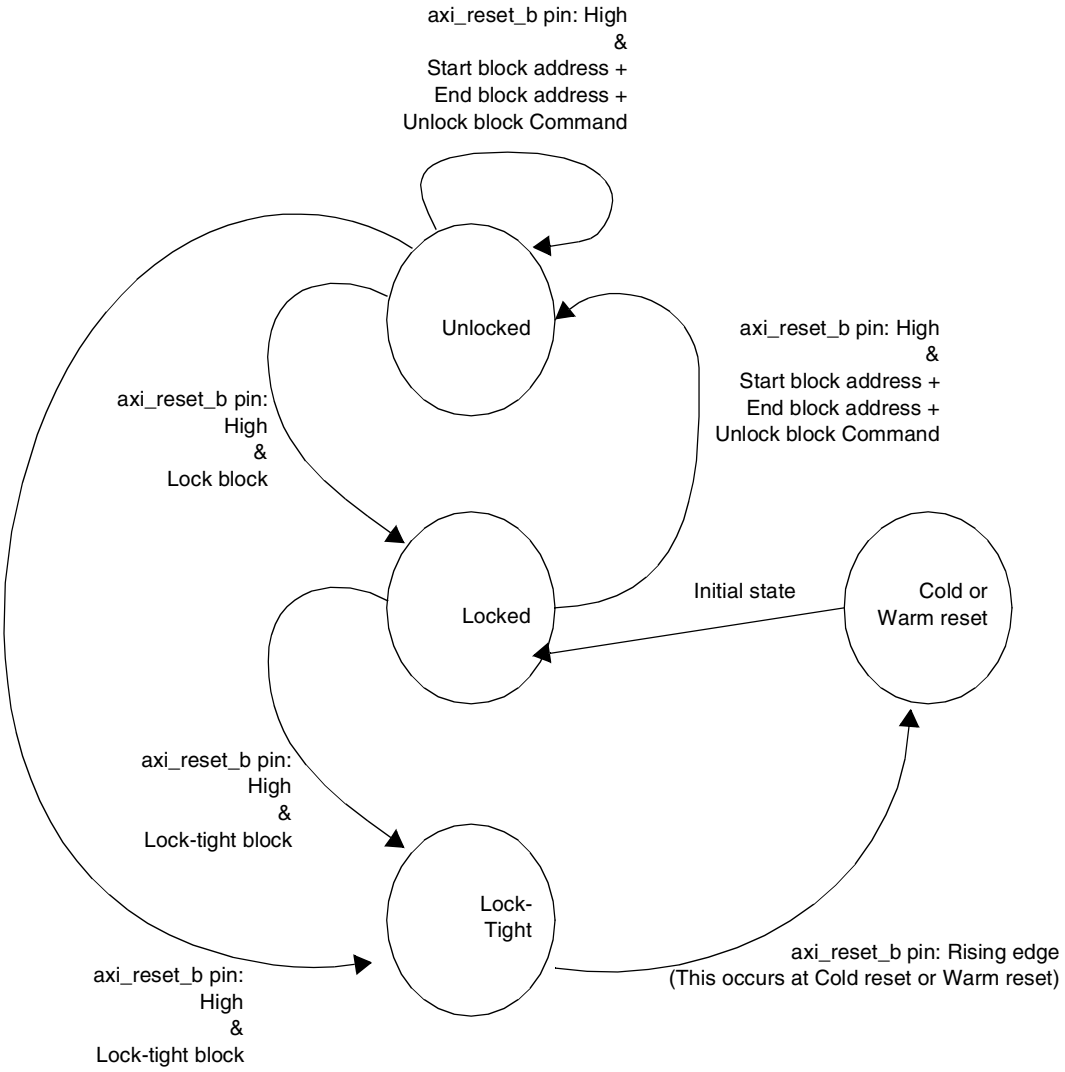

Figure 45-56. State diagram of NAND Flash Write Protection

45.9.7.4.1 Lock Sequence

The following describes the “lock” sequence:

1. Command Sequence: LOCK BLOCK Command (02h)
2. All blocks default to locked after initial Cold reset or Warm reset
3. Locking some of the blocks is not available; all memory blocks are locked upon reset
4. Unlocked memory blocks can be locked by using the LOCK BLOCK command. The status of a locked memory block can be changed to “unlocked” or “lock-tight” using the appropriate software commands.

45.9.7.4.2 Unlock Sequence

The following describes the “unlock” sequence:

1. Command Sequence: Start block address + End block address + UNLOCK BLOCK Command(04h)
2. Unlocked blocks can be programmed or erased
3. The status of an unlocked block can be changed to *locked* or *lock-tight* using the appropriate software commands
4. Only one sequential area can be released to unlocked state from locked state; Unlocking multi areas is not available

45.9.7.4.3 Lock-tight Sequence

The following describes the “lock-tight” sequence:

1. Only locked blocks can be “locked-tight” by the LOCK-TIGHT BLOCK command.
2. Command Sequence: LOCK-TIGHT BLOCK Command (01h)
3. Unlocking multi area is not available
4. Lock-tight blocks revert to the locked state at Cold/Warm reset.

45.9.8 Delay Line Operation

45.9.8.1 Delay line background

When a read access is issued towards the NAND flash device then it takes a relatively long time from the assertion of the RE_B till the read data is latched by the NFC. The read data path starts with the deassertion of the RE_B (read enable) signal through the propogation in the I/O pads and till the RE_B port of the NAND flash device on the board. When the NAND flash device detects the assertion of the RE_B signal it drives the associated read data back after Trea[ns] through the I/O pads and till being latched by the NFC. The NAND flash device is committed to keep driving the data for Trhoh [ns] after the posedge of RE_B. The delay line is used to compensate the long delay of the read data path and to adjust the sampling edge of the read data without any performance or frequency degradation.

The NFC generates an internal RE_B signal which is delayed by 1 flash clock cycle from the RE_B that is driven to the NAND device. The delayed RE_B passes through a delay line and the output of the delay line is used to latch the read data.

The delay line is composed from 4 delay line units. Each unit can delay the RE_B signal by a configurable time measured by axi slow clock (fast clock of the NFC) fractions and up to 1/2 axi slow clock cycle. So the delay line can shift the RE_B signal by total of 2 axi slow clock cycles. Each fraction is 1/256 part of axi slow clock cycle and is configured in NFC_DELAY_LINE[NFC_ABS_DEL] register. This register is associated with a single delay line unit. By default the NFC latches the data after a fixed delay of 1 flash clock cycle + 1 axi slow clock cycle.

Figure 45-57 shows the read data path and Figure 45-58 shows the associated timing diagram.

45.9.8.2 Delay line and flash clock settings

The following will show how to set the flash clock cycle (2*Trp) and configure the desired value of the delay line. The calculations are based on parameters which depends on the NAND flash device, Freescale controller and the operating conditions.

- Assume the internal delay of the RE_B + the internal delay of the read data is D1[ns]
- Assume the board delay of the RE_B + board delay of the read data is D2[ns]
- Assume the delay of the RE_B caused by the delay line is Ddel[ns]. Note that the delay line has a minimal delay even if configured to zero delay
- Assume Trea[ns] is RE_B access time
- Assume Trp[ns] is RE_B pulse width
- Assume Trhoh[ns] is read data hold time from RE_B high

Note: The parameter D1 can be obtained from the AC characteristics of the Freescale device.

In order to sample the read data on time it is required that:

- 2Trp +Ddel > Trea + D1 + D2
- Trp + Ddel < Trhoh + D1 + D2
- Trp > Trp min defined by the NAND flash AC characteristics.

For example if:

- D1 = 10ns
- D2 = 2ns
- Delay line is configured to zero delay and its minimal delay is Ddel=3ns
- Trea = 20ns
- Trhoh = 15ns
- Trp min defined by the device is 12ns
- axi slow clock cycle is 7.5ns

In that case the pulse width of flash clock should be 14.5ns < Trp < 24ns or in other words the cycle of flash clock should be 29ns < Trc < 48ns (i.e flash clock frequency is 20.8Mhz < F< 34.4Mhz)

In case it required to work with Trp which is 12ns (i.e the minimal allowed by the NAND device) then it is possible by using the delay line as following. Setting a delay of 14.5 - 12 = 2.5ns means that we should delay the RE_B signal by 2.5/7.5 = 1/3 cycle of slow axi clock, which is approximately 85 parts of 256, So it is needed to configure NFC_DELAY_LINE[NFC_ABS_DEL] = 8'd85

Note:
For the above example the allowed ratio between axi slow clock cycle and flash clock cycle are 1:4 ,1:5 or1:6. If the cycle of the flash clock is set to 37.5ns (i.e ratio 1:4) and the total delay of the delay line is configured to 1 axi slow clock cycle(as the default value) then the latching edge of the read data will be delayed by 1 axi slow clock cycle, which is 7.5ns and it isn't guaranteed that the read data will be latched correctly.

Chapter 46
Parallel Advanced Technology Attachment (P-ATA)

The ATA block is an AT attachment host interface. Its main use is to interface with hard disc drives and optical disc drives. It interfaces with the ATA device over a number of ATA signals. See Figure 46-1 for the block diagram of the ATA interface.

It is possible to connect a bus buffer between the host side and the device side. In this case, the ata_buffer_en signal should be used to control the direction the buffer is driving to. If ata_buffer_en is high, it drives outward to the device. If ata_buffer_en is low, it drives inward to the host.

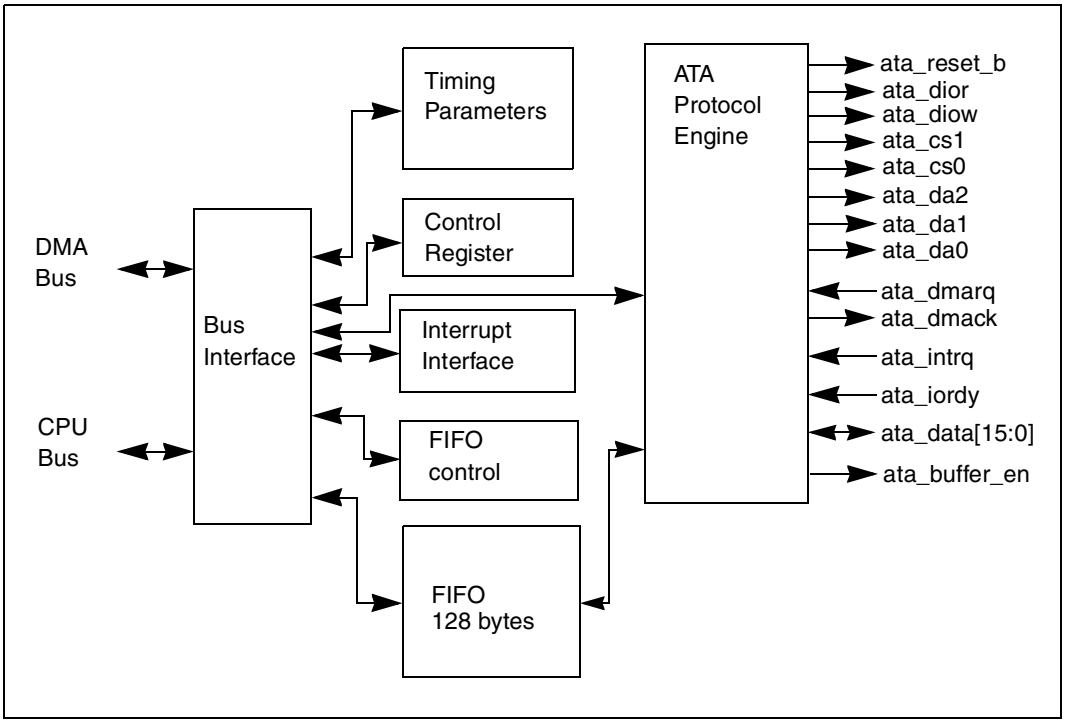

Figure 46-1. ATA interface Block Diagram.

46.1 Overview

The ATA block is a AT attachment host interface. Its main use is to interface with IDE hard disc drives and ATAPI optical disc drives. It interfaces with the ATA device over a number of ATA signals.

The ATA interface is compliant to the ATA-6 standard and supports the following protocols:

- PIO mode 0, 1, 2, 3, and 4
- Multiword DMA mode 0, 1 and 2
- Ultra DMA modes 0, 1, 2, 3 and 4 with bus clock of 50 MHz or higher
- Ultra DMA mode 5 with bus clock of 80 MHz or higher.

The ATA interface has 2 busses connected:

- One CPU bus for communication with the host processor
- One DMA bus for communication with the host DMA unit

All internal registers are visible from both busses, allowing smart DMA access to program the interface.

Before accessing the ATA bus, the host must program the timing parameters to be used on the ATA bus. The timing parameters control the timing on the ATA bus. Most timing parameters are programmable as a number of clock cycles (1 to 255). Some are implied.

After programming the timing parameters, there are two protocols that can be active at the same time on the ATA bus:

- First protocol. This protocol is a PIO mode access that can be performed at any time by the host CPU or the host smart DMA to the ATA bus. During PIO mode access, the incoming IP bus cycle is translated to an ATA bus cycle by the ATA protocol engine. The IP bus cycle is stalled until completion of the ATA bus cycle on read, or until putting the write data on the ATA bus on write. The PIO mode is a slow protocol, mainly intended to program the ATA disc drive, but also possible to use to transfer data to/from the disc drive. During PIO mode, the FIFO is not active.
- Second protocol. This protocol is the DMA mode access. DMA mode is started by the ATA interface after receiving a DMA request from the drive, and only if the ATA interface has been programmed to accept the DMA request. In DMA mode, either multiword DMA or ultra DMA protocol is used on the ATA bus. Once started, data transfer is organized between the ATA bus and the FIFO. Data transfer will pause to prevent FIFO overflow / FIFO underflow. Data transfer will resume when there is again space in the FIFO, or when the FIFO has been refilled. During DMA transfer, there is no direct interface between the ATA bus and the host IP or host DMA IP bus. Instead, the transfer takes place between the ATA bus and the FIFO; the FIFO informs the host DMA unit when it needs to be refilled or emptied. In this case, it sends an ALARM flag to the host DMA. When the host DMA receives the fifo_tx_alarm, it should write some data to the FIFO. (typically 32 bytes). When the host DMA receives the fifo_rcv_alarm, it should read some data from the FIFO (typically 32 bytes). The FIFO filling level at which the alarms are produced, is programmable. For completeness, there is a third alarm associated with the host DMA operation fifo_txfer_end_alarm. This alarm signals the end of the transfer, and requests the smart DMA to take steps to complete the transfer: transfer the bytes remaining in the FIFO to the host memory, and inform the host CPU the transfer is completed.

All transfers between FIFO and host IP or DMA IP bus are zero wait states transfer, so high-speed transfer between FIFO and DMA/host bus is possible.

When a PIO access is performed during a running DMA transfer, the DMA transfer will be paused, the PIO access done, and the DMA transfer will resume again.

46.1.1 Features

The ATA interface includes the following features:

- Programmable timing on the ATA bus. Works with wide range of bus frequencies.
- Compliant with ATA-6 specification
  - Supports PIO modes 0, 1, 2, 3 and 4
  - Supports multiword DMA modes 0, 1 and 2
  - Supports ultra DMA modes 0, 1, 2, 3 and 4 with bus clock of at least 50 MHz
  - Supports ultra DMA mode 5 with bus clock of at least 80 MHz
- Can be used with off-chip bus transceiver if pads are not compliant with ATA voltage levels
- 128-byte FIFO part of interface
- FIFO receive alarm, FIFO transmit alarm, and FIFO end of transmission alarm to DMA unit
- Zero-wait cycles transfer between DMA bus and FIFO allows fast FIFO reading/writing

46.1.2 Modes of Operation

The interface offers two operation modes that can be used together:

- PIO Mode

  An access to the ATA bus in PIO mode occurs whenever a ATA pio register is read or written by the host CPU or the host (smart) DMA unit. During a PIO transfer the incoming IP bus cycle is translated to an ATA PIO bus cycle by the ATA protocol engine. No buffering of data occurs, so the host CPU or host DMA cycle is stalled until the ATA bus read data is available on read, or is stalled until the IP bus data can we put on the ATA bus during write.

  PIO accesses can be done to the bus at any time, even during a running ATA DMA transfer. In this case, the DMA transfer is paused, the pio cycle is completed, and the DMA transfer is resumed.
- DMA Mode

  In DMA mode, data is transferred between the ATA bus and the FIFO. Two different DMA protocols are supported on the ATA bus: ultra DMA mode and multiword DMA mode. Selection is made using a control register bit.

  A DMA transfer will be started when DMA mode transfer has been enabled by writing some control bit, and when the drive connected to the ATA bus pulls its DMARQ line high.

  During an ATA bus DMA transfer, data is transferred between the ATA bus and the FIFO. The transfer will pause to avoid FIFO overflow and FIFO underflow.

  It is the task of the host CPU or the host smart DMA unit to read data or write data to the FIFO to keep the transfer going. Normal set-up is that the host (smart) DMA unit takes on this task. For this purpose, the fifo_rcv_alarm and fifo_tx_alarm signals are sent to the host DMA unit. fifo_rcv_alarm informs the host DMA unit that there is at least 1 packet of data waiting in the FIFO to be read by the host DMA. Whenever this signal is high, the host DMA should transfer one packet of data from the FIFO to the main memory. Typical packet size is 32 bytes (8 long words), but other packet sizes can be handled too. fifo_tx_alarm informs the host DMA unit that there is space for at

least 1 packet to be written by the host DMA. Whenever this signal is high, the host DMA should transfer one packet of data from main memory to the FIFO. Typical packet size is 32 bytes (8 long words), but other packet sizes can be handled too.

46.2 External Signal Description

See Table 46-1 for the list of signals entering and existing this module to peripherals within the chip.

Table 46-1. Signal Properties

Name	Port	Function	Reset State	Type
ata_reset_b	—	ATA bus reset signal. Active low. If active, ata device is reset[1]	0	out
ata_dior	—	ATA bus read strobe	1	out
ata_diow	—	ATA bus write strobe	1	out
ata_cs1	—	ATA bus chip select 1	1	out
ata_cs0	—	ATA bus chip select 0	1	out
ata_da2	—	ATA bus address line 2	0	out
ata_da1	—	ATA bus address line 1	0	out
ata_da0	—	ATA bus address line 0	0	out
ata_dmarq	—	ATA bus DMA request	—	in
ata_dmack	—	ATA bus DMA acknowledge	1	out
ata_intrq	—	ATA bus interrupt request	—	in
ata_iordy	—	ATA bus iordy	—	out
ata_data[15:0]	—	ATA data bus (little-endian)	Hi-z	tri-state in-out
ata_buffer_en	—	Buffer enable for external bus transceiver[2]	0	out

[1]This signal is a standard ATA bus signal. It conforms with the ATA specification.
[2]It is optional to put a 74xxx245 bus transceiver between the host side of the data bus and the device side of the data bus. If the transceiver is used, its enable should be tied low (always enable), and its direction pin should be tied to ata_buffer_en, in such a way that it drives from host to device when ata_buffer_en is high, and drives from device to host when ata_buffer_en is low.

46.2.1 Detailed Signal Descriptions

For a detailed description of the ATA bus signal, refer to the ATA-6 specification.

46.2.1.1 ata_reset_b (out)

This signal is the ATA reset signal. When low, the ATA bus is in reset state. When high, no reset. The ATA bus is in reset whenever the appropriate bit in the control register is cleared. After system reset, the ATA bus is in reset.

46.2.1.2 ata_dior (out)

This signal correspond to ATA signal DIOR. During PIO and multiword DMA transfer, function is read strobe. During ultra DMA in burst, function is HDMARDY. During ultra DMA out burst, function is host strobe.

46.2.1.3 ata_diow (out)

This signal corresponds to ATA signal DIOW. During PIO and multiword DMA transfer, function is write strobe. During ultra DMA burst, function is STOP, signalling whenever host wants to terminate running ultra DMA transfer.

46.2.1.4 ata_cs0, ata_cs1, ata_da2, ata_da1, ata_da0 (out)

These signals are the address group of the ATA bus. ata_cs0, ata_cs1 are the chip selects; ata_da2, ata_da1 and ata_da0 are the 3 address lines. All these five lines follow the same timing.

46.2.1.5 ata_dmarq (in)

This signal is the ATA bus device DMA request. Its pulled high by the device if it wants to transfer data using multiword DMA or ultra DMA mode

46.2.1.6 ata_dmack (out)

This signal is the ATA bus host DMA acknowledge. Its pulled low by the host when it grants the DMA request.

46.2.1.7 ata_intrq (in)

This signal is the ATA bus interrupt request. Its pulled high by the device whenever it wants to interrupt the host CPU.

46.2.1.8 ata_iordy (in)

This signal is the ATA bus IORDY line. It has the following functions:

- IORDY—active low wait during PIO cycles
- DDMARDY—active low device ready during ultra DMA out transfers
- DSTROBE—device strobe during ultra DMA in transfers

46.2.1.9 ata_data[15:0] (in/out–tristate)

This is the ATA data bus.

46.2.1.10 ata_buffer_en

This is a buffer direction control signal.

46.2.2 Electrical Spec on the ATA Bus, Bus Buffers

To meet electrical spec on the ATA bus, several requirements must be met. For a detailed description, refer to the ATA specification.

This electrical spec must be met for the pads used on the ATA I/Os if no bus buffers and bus transceivers are used.

Alternative is to use bus buffers. This is the only way to operate the ATA interface if 3.3 V or 5.0 V compatibility on the ATA bus is wanted, and no 3.3 V or 5.0 V tolerant pads on the device are available.

The use of bus buffers introduces delay on the bus and introduces skew between signal lines. These factors will make it difficult to operate the bus at the highest speed (UDMA-5) when bus buffers are used. If fast UDMA mode operation is needed, this may not be compatible with bus buffers.

Another area of attention is the slew rate limit imposed by the ATA specification on the ATA bus. According to this limit, any signal driven on the bus should have a slew rate between 0.4 and 1.2 V/ns with a 40 pF load. Not many vendors of bus buffers specify slew rate of the outgoing signals.

When bus buffers are used, the ata_data bus buffer is special. This is a bidirectional bus buffer, so a direction control signal is needed. This direction control signal is ata_buffer_en. When its high, the bus should drive from host to device. When its low, the bus should drive from device to host. Steering of the signal is such that contention on the host and device tristate busses is always avoided.

46.2.3 Timing on ATA bus

Timing on the ATA bus is explained in this section. It is also explained how to make sure the ATA interface meets timing. Timing is explained with timing figures and also equations are provided that need to be fulfilled for the host to meet timing.

46.2.3.1 Timing Parameters

In the timing equations, some timing parameters are used. These parameters depend on the implementation of the ATA interface on silicon, the bus buffer used, the cable delay and cable skew. Refer to Table 46-2 for the list of parameters used to specify the ATA timing.

Table 46-2. Timing Parameters

Name	Meaning	Controlled by
T	Bus clock period	clock generator
ti_ds	Set-up time ata_data to ata_iordy edge (UDMA-in only)	top level design
ti_dh	hold time ata_iordy edge to ata_data (UDMA-in only)	top level design
tco	propagation delay bus clock L-to-H to ata_cs0, ata_cs1, ata_da2, ata_da1, ata_da0, ata_dior, ata_diow, ata_dmack, ata_data, ata_buffer_en	top level design
tsu	set-up time ata_data to bus clock L-to-H	top level design
tsui	set-up time ata_iordy to bus clock H-to-L	top level design

Table 46-2. Timing Parameters (continued)

Name	Meaning	Controlled by
thi	hold time ata_iordy to bus clock H to L	top level design
tskew1	Max difference in propagation delay bus clock L-to-H to any of following signals ata_cs0, ata_cs1, ata_da2, ata_da1, ata_da0, ata_dior, ata_diow, ata_dmack, ata_data (write), ata_buffer_en	top level design
tskew2	Max difference in buffer propagation delay for any of following signals ata_cs0, ata_cs1, ata_da2, ata_da1, ata_da0, ata_dior, ata_diow, ata_dmack, ata_data (write), ata_buffer_en	transceiver
tskew3	Max difference in buffer propagation delay for any of following signals ata_iordy, ata_data (read)	transceiver
tbuf	Max buffer propagation delay	transceiver
tcable1	cable propagation delay for ata_data	cable
tcable2	cable propagation delay for control signals ata_dior, ata_diow, ata_iordy, ata_dmack	cable
tskew4	Max difference in cable propagation delay between ata_iordy and ata_data (read)	cable
tskew5	Max difference in cable propagation delay between (ata_dior, ata_diow, ata_dmack) and ata_cs0, ata_cs1, ata_da2, ata_da1, ata_da0, ata_data(write)	cable
tskew6	Max difference in cable propagation delay without accounting for ground bounce	cable

46.2.3.2 PIO Mode Timing

A timing diagram for PIO read mode is given in Figure 46-2.

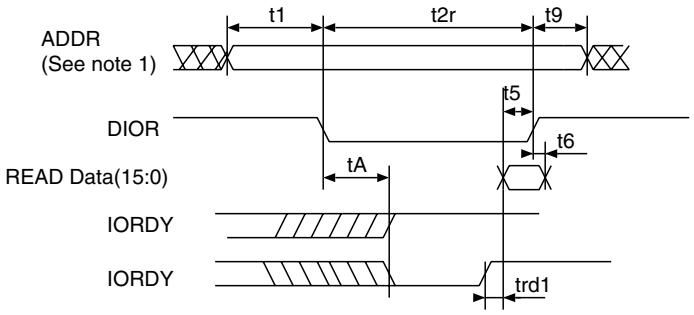

Figure 46-2. PIO Read Mode Timing

To fulfill read mode timing, the different timing parameters given in Table 46-3 must be observed.

Table 46-3. Timing Parameters PIO Read

ATA Parameter	PIO Read Mode Timing Parameter[1]	Value	How to meet?
t1	t1	t1(min) = time_1 × T - (tskew1 + tskew2 + tskew5)	time_1
t2	t2r	t2(min) = time_2r × T - (tskew1 + tskew2 + tskew5)	time_2r
t9	t9	t9(min) = time_9 × T - (tskew1 + tskew2 + tskew6)	time_9

Table 46-3. Timing Parameters PIO Read (continued)

ATA Parameter	PIO Read Mode Timing Parameter[1]	Value	How to meet?
t5	t5	t5(min) = tco + tsu + tbuf + tbuf + tcable1 + tcable2	if not met, increase time_2
t6	t6	0	
tA	tA	tA(min) = (1.5 + time_ax) × T - (tco + tsui + tcable2 + tcable2 + 2 × tbuf)	time_ax
trd	trd1	trd1(max) = (–trd) + (tskew3 + tskew4) trd1(min) = (time_pio_rdx - 0.5) × T – (tsu + thi) (time_pio_rdx - 0.5) × T > tsu + thi + tskew3 + tskew4	time_pio_rdx
t0	—	t0(min) = (time_1 + time_2 + time_9) × T	time_1, time_2r, time_9

1 See Figure 46-2.

In PIO write mode, timing waveforms are somewhat different. A timing diagram is given in Figure 46-3.

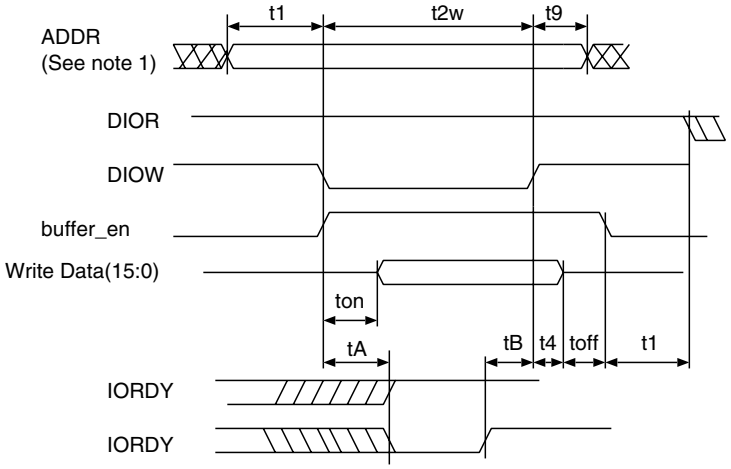

Figure 46-3. PIO Write Mode Timing

To fulfill this timing, several parameters need to be observed. See Table 46-4 for details on PIO write mode timing.

Table 46-4. Timing Parameters PIO Write

ATA Parameter	PIO Write Mode Timing Parameter[1]	Value	How to Meet?
t1	t1	t1(min) = time_1 × T – (tskew1 + tskew2 + tskew5)	time_1
t2	t2w	t2(min) = time_2w × T – (tskew1 + tskew2 + tskew5)	time_2w
t9	t9	t9(min) = time_9 × T – (tskew1 + tskew2 + tskew6)	time_9

Table 46-4. Timing Parameters PIO Write (continued)

ATA Parameter	PIO Write Mode Timing Parameter[1]	Value	How to Meet?
t3	—	t3(min) = (time_2w – time_on) × T – (tskew1 + tskew2 + tskew5)	if not met, increase time_2w
t4	t4	t4(min) = time_4 × T – tskew1	time_4
tA	tA	tA = (1.5 + time_ax) × T – (tco + tsui + tcable2 + tcable2 + 2 × tbuf)	time_ax
t0	—	t0(min) = (time_1 + time_2 + time_9) × T	time_1, time_2r, time_9
—	—	Avoid bus contention when switching buffer on by making ton long enough	—
—	—	Avoid bus contention when switching buffer off by making toff long enough	—

1 See Figure 46-3.

46.2.3.3 Timing in Multiword DMA Mode

In multi-word DMA mode, see Figure 46-4 for read timing diagram and Figure 46-5 for write timing diagram.

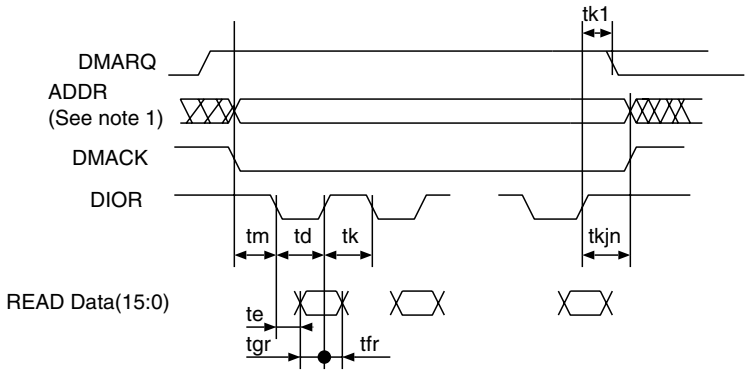

Figure 46-4. MDMA Read Timing

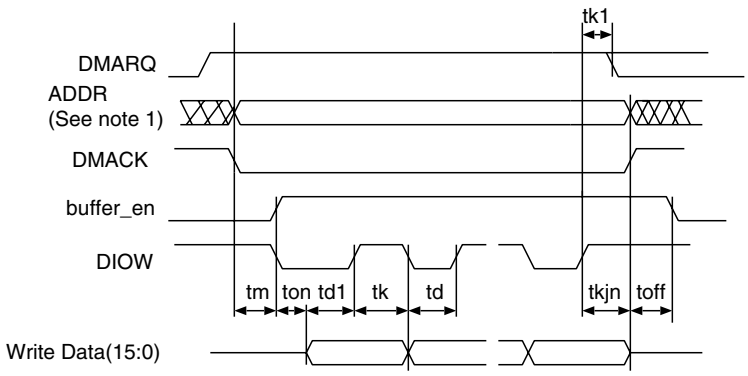

Figure 46-5. MDMA Write Timing

To meet the timing requirement, a number of timing parameters must be controlled. See Table 46-5 for details on timing parameters for MDMA read and write.

Table 46-5. Timing Parameters MDMA Read and Write

ATA Parameter	MDMA Read TIming[1] and MDMA Write TIming[2]	Value	How to Meet?
tm, ti	tm	tm(min) = ti(min) = time_m × T – (tskew1 + tskew2 + tskew5)	time_m
td	td, td1	td1(min) = td(min) = time_d × T – (tskew1 + tskew2 + tskew6)	time_d
tk	tk	tk(min) = time_k × T – (tskew1 + tskew2 + tskew6)	time_k
t0	-	t0(min) = (time_d + time_k) × T	time_d, time_k
tg(read)	tgr	tgr(min–read) = tco + tsu + tbuf + tbuf + tcable1 + tcable2 tgr(min–drive) = td – te(drive)	time_d
tf(read)	tfr	tfr(min–drive) = 0k	—
tg(write)	—	tg(min–write) = time_d × T –(tskew1 + tskew2 + tskew5)	time_d
tf(write)	—	tf(min–write) = time_k × T – (tskew1 + tskew2 + tskew6)	time_k
tL	—	tL(max) = (time_d + time_k–2)×T – (tsu + tco + 2×tbuf + 2×tcable2)	time_d, time_k[3]
tn, tj	tkjn	tn= tj= tkjn = (max(time_k,. time_jn) × T – (tskew1 + tskew2 + tskew6)	time_jn
—	ton toff	ton = time_on × T – tskew1 toff = time_off × T – tskew1	—

1 See Figure 46-4.

2 See Figure 46-5.

3 tk1 in the UDMA figures equals (tk -2*T)

46.2.3.4 UDMA In Timing Diagrams

UDMA mode timing is more complicated than PIO mode or MDMA mode. In this section, timing diagrams for UDMA in are provided.

Figure 46-6 shows timing for UDMA in transfer start.

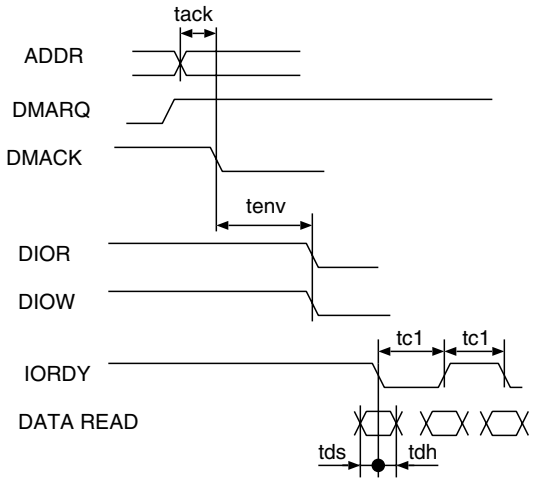

Figure 46-6. UDMA in Transfer Start Timing Diagram

Figure 46-7 shows timing for host terminating UDMA in transfer.

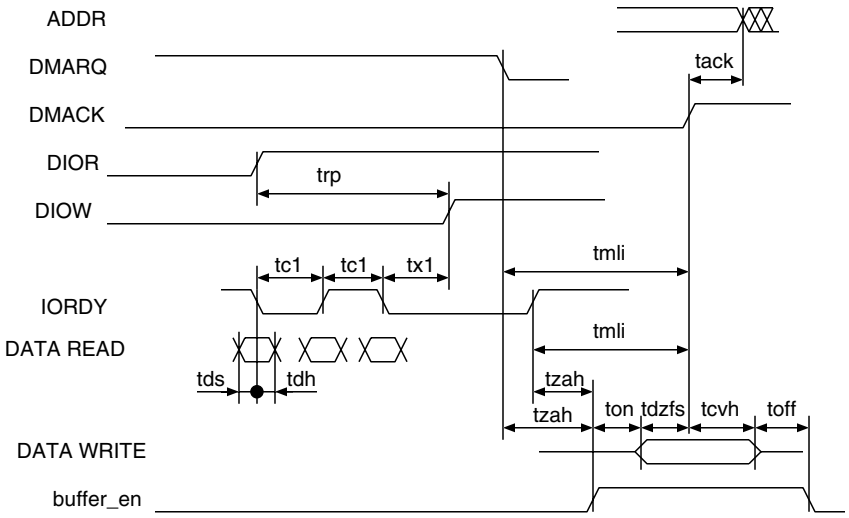

Figure 46-7. UDMA in Host Terminates Transfer

Figure 46-8 shows timing for device terminating UDMA in transfer.

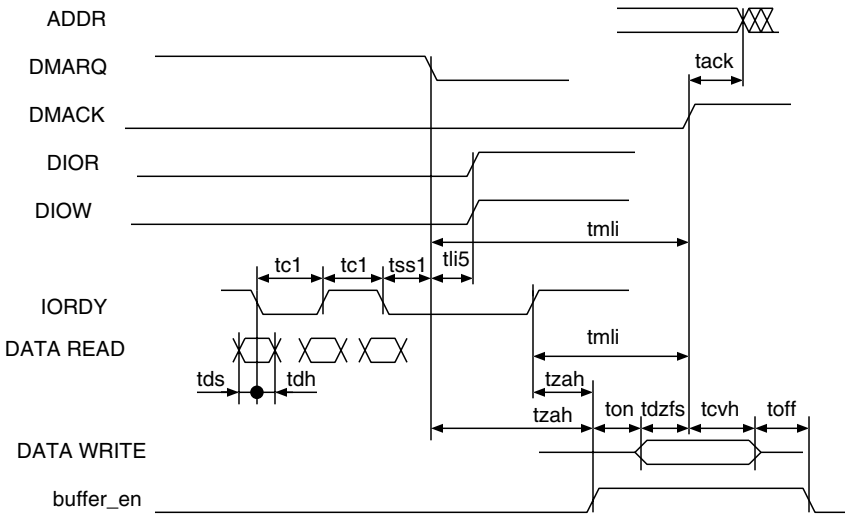

Figure 46-8. UDMA in Device Terminates Transfer

Timing parameters for UDMA in burst are listed in Table 46-6.

Table 46-6. Timing Parameters for UDMA in Burst

ATA Parameter	Spec Parameter	Value	Required Conditions
tack	tack	tack(min) = (time_ack × T) – (tskew1 + tskew2)	time_ack
tenv	tenv	tenv(min) = (time_env × T) – (tskew1 + tskew2) tenv(max) = (time_env × T) + (tskew1 + tskew2)	time_env
tds	tds1	tds – (tskew3) – ti_ds > 0	tskew3, ti_ds, ti_dh should be low enough
tdh	tdh1	tdh – (tskew3) –ti_dh > 0	
tcyc	tc1	(tcyc – tskew + **TBD**) > T	T big enough
trp	trp	trp(min) = time_rp × T – (tskew1 + tskew2 + tskew6)	time_rp
	tx1[1]	(time_rp × T) – (tco + tsu + 3T + 2 ×tbuf + 2×tcable2) > trfs (drive)	time_rp
tmli	tmli1	tmli1(min) = (time_mlix + 0.4) × T	time_mlix
tzah	tzah	tzah(min) = (time_zah + 0.4) × T	time_zah
tdzfs	tdzfs	tdzfs = (time_dzfs × T) – (tskew1 + tskew2)	time_dzfs
tcvh	tcvh	tcvh = (time_cvh ×T) – (tskew1 + tskew2)	time_cvh
—	ton toff	ton = time_on × T – tskew1 toff = time_off × T – tskew1	—

1 There is a special timing requirement in the ATA host that requires the internal DIOW to go only high three clocks after the last active edge on the DSTROBE signal. The equation given on this line tries to capture this constraint.

2. Make ton and toff big enough to avoid bus contention.

46.2.3.5 UDMA Out Timing Diagrams

UDMA mode timing is more complicated than PIO mode or MDMA mode. This section provides timing diagrams for UDMA out.

Figure 46-9 shows timing for UDMA out transfer start.

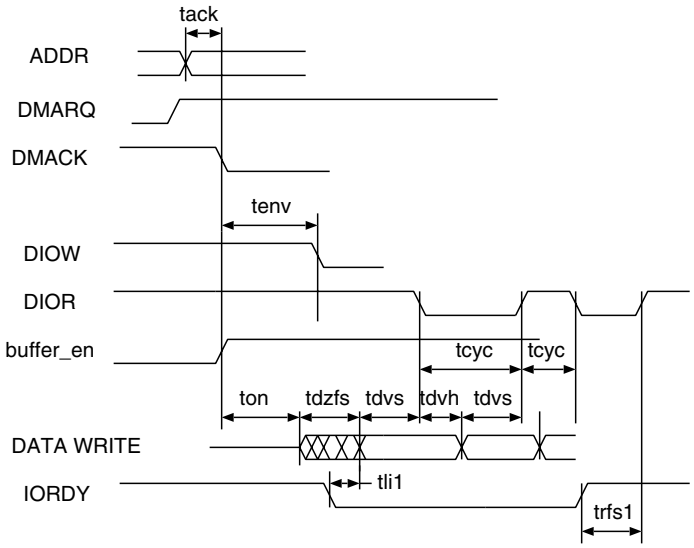

Figure 46-9. UDMA Out Transfer Start Timing Diagram

Figure 46-10 shows timing for host terminating UDMA out transfer.

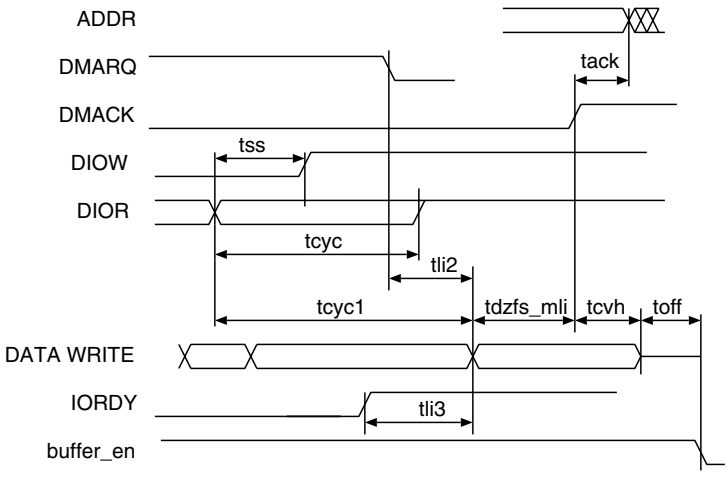

Figure 46-10. UDMA Out Host Terminates Transfer

Figure 46-11 shows the timing for device terminating UDMA out transfer.

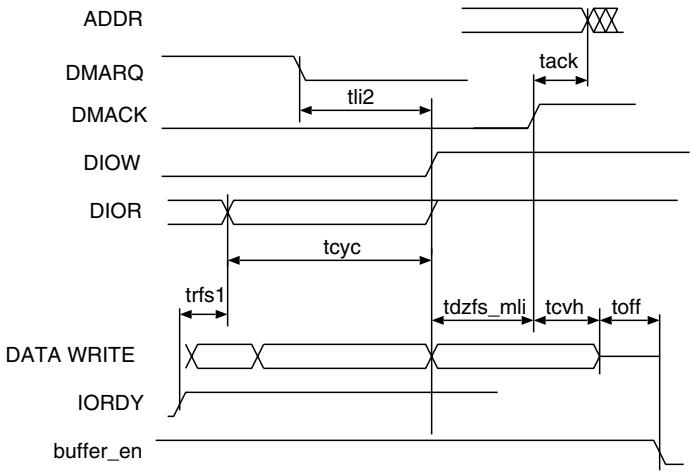

Figure 46-11. UDMA Out Device Terminates Transfer

Timing parameters for UDMA out burst are listed in Table 46-7.

Table 46-7. Timing Parameters UDMA Out Burst

ATA Parameter	Spec Parameter	Value	How to meet ?
tack	tack	tack(min) = (time_ack × T) – (tskew1 + tskew2)	time_ack
tenv	tenv	tenv(min) = (time_env × T) – (tskew1 + tskew2) tenv(max) = (time_env × T) + (tskew1 + tskew2)	time_env
tdvs	tdvs	tdvs = (time_dvs × T) – (tskew1 + tskew2)	time_dvs
tdvh	tdvh	tdvs = (time_dvh × T) – (tskew1 + tskew2)	time_dvh
tcyc	tcyc	tcyc = time_cyc × T – (tskew1 + tskew2)	time_cyc
t2cyc		t2cyc = time_cyc × 2 × T	time_cyc
trfs1	trfs	trfs = 1.6 × T + tsui + tco + tbuf + tbuf	—
—	tdzfs	tdzfs = time_dzfs × T – (tskew1)	time_dzfs
tss	tss	tss = time_ss × T – (tskew1 + tskew2)	time_ss
tmli	tdzfs_mli	tdzfs_mli =max(time_dzfs, time_mli) × T – (tskew1 + tskew2)	—
tli	tli1	tli1 > 0	—
tli	tli2	tli2 > 0	—
tli	tli3	tli3 > 0	—
tcvh	tcvh	tcvh = (time_cvh ×T) – (tskew1 + tskew2)	time_cvh
—	ton toff	ton = time_on × T – tskew1 toff = time_off × T – tskew1	—

46.3 Memory Map and Register Definition

Section 46.3.3, Register Descriptions," provides the detailed descriptions for all ATA registers.

46.3.1 Memory Map

Table 46-8 shows the ATA memory map.

Table 46-8. ATA Memory Map

Address	Register	Description	Access	Reset Value	Section/Page
0xBASE+0x000 (TIME_OFF)	TIME_OFF	transceiver timing parameter. Controls toff	R/W	0x01	46.3.3.2.1/46-21
0xBASE+0x001 (TIME_ON)	TIME_ON	transceiver timing parameter. Controls ton	R/W	0x01	46.3.3.2.2/46-21
0xBASE+0x002 (TIME_1)	TIME_1	PIO timing parameter. Controls t1	R/W	0x01	46.3.3.2.3/46-22
0xBASE+0x003 (TIME_2W)	TIME_2W	PIO timing parameter. Controls t2 during write cycles	R/W	0x01	46.3.3.2.4/46-22
0xBASE+0x004 (TIME_2R)	TIME_2R	PIO timing parameter. Controls t2 during read cycles	R/W	0x01	46.3.3.2.5/46-22
0xBASE+0x005 (TIME_AX)	TIME_AX	PIO timing parameter. Controls tA	R/W	0x01	46.3.3.2.6/46-23
0xBASE+0x00F (TIME_PIO_RDX)	TIME_PIO_RDX	PIO timing parameter. Controls trd	R/W	0x01	46.3.3.2.7/46-23
0xBASE+0x007 (TIME_4)	TIME_4	PIO timing parameter. Controls t4	R/W	0x01	46.3.3.2.8/46-23

46.3.2 Register Summary

Figure 46-12 shows the key to the register fields and Table 46-9 shows the register figure conventions.

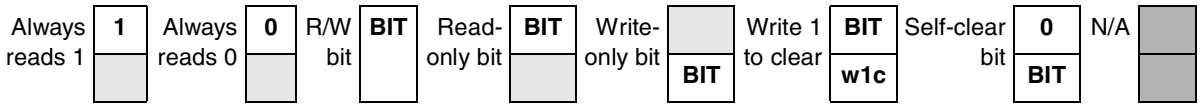

Figure 46-12. Key to Register Fields

Table 46-9. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

46.3.3 Register Descriptions

This section contains the detailed register descriptions for the ATA registers.

46.3.3.1 Endianness

The ATA interface works both in little-endian or big-endian mode. The addresses of all registers remain the same regardless of endianess mode. The few 16-bit and 32-bit registers represent strings of 2 or 4 bytes. The byte order in the 16-bit or 32-bit register is dependent on endianess selection.

- Little endian, 16-bit or 32-bit register:
  - bits [7:0]: byte 0
  - bits [15:8]: byte 1
  - bits [23:8]: byte 2
  - bits [31:24]: byte 3
- Big endian, 32-bit register
  - bits [31:24]: byte 0
  - bits [23:16]: byte 1
  - bits [15:8]: byte 2
  - bits [7:0]: byte 3
- Big endian, 16-bit register
  - bits [15:8]: byte 0
  - bits [7:0]: byte 1

46.3.3.2 Timing Registers

Registers (ata_base +$0) until (ata_base + $17) contain timing parameters. These timing parameters control the timing on the ATA bus as shown in details in the following illustrations:

- Section 46.2.3.2, PIO Mode Timing”
- Section 46.2.3.3, Timing in Multiword DMA Mode”
- Section 46.2.3.4, UDMA In Timing Diagrams”
- Section 46.2.3.5, UDMA Out Timing Diagrams”

Every timing parameter is 8-bit wide and can assume valid values between 1 and 255. Reset value is always 1.

All figures in this section show timing registers.

46.3.3.2.1 TIME_OFF Register

See Figure 46-13 for illustration of valid bits in the TIME_OFF Register and Table 46-8 for description of the bit fields.

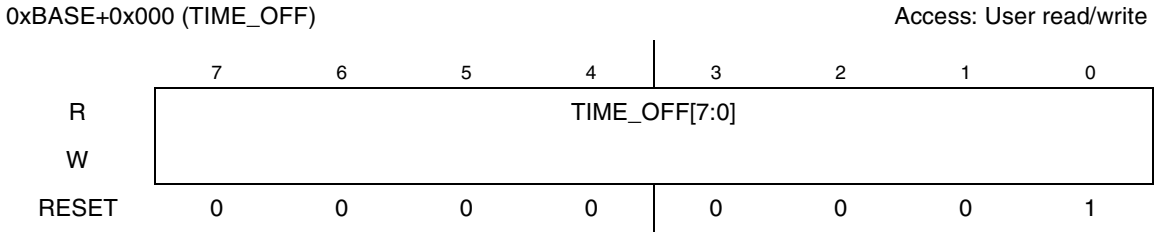

Figure 46-13. TIME_OFF Register

46.3.3.2.2 TIME_ON Register

See Figure 46-14 for illustration of valid bits in the TIME_ON Register and Table 46-8 for description of the bit fields.

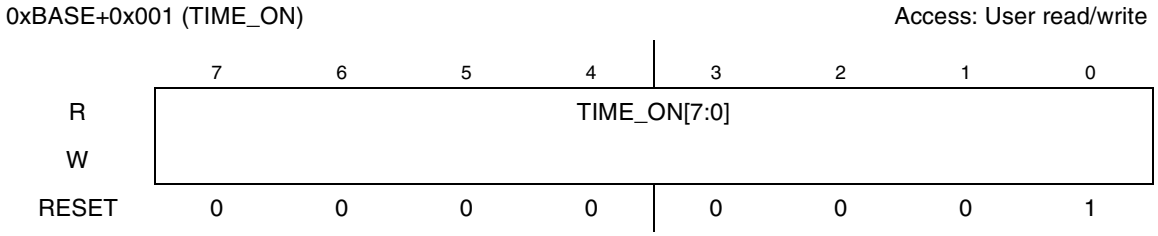

Figure 46-14. TIME_ON Register

46.3.3.2.3 TIME_1 Register

See Figure for illustration of valid bits in the TIME_1 Register and Table 46-8 for description of the bit fields.

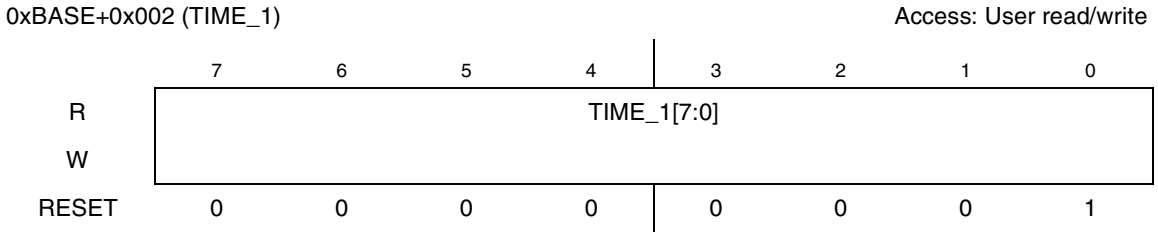

Figure 46-15. TIME_1 Register

46.3.3.2.4 TIME_2W Register

See Figure 46-16 for illustration of valid bits in the TIME_2W Register and Table 46-8 for description of the bit fields.

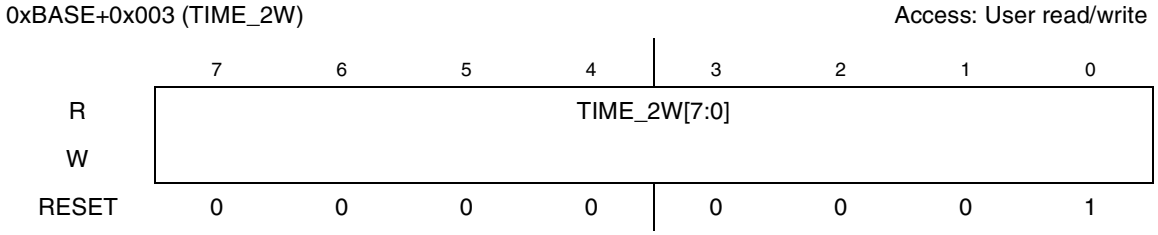

Figure 46-16. TIME_2W Register

46.3.3.2.5 TIME_2R Register

See Figure 46-17 for illustration of valid bits in the TIME_2R Register and Table 46-8 for description of the bit fields.

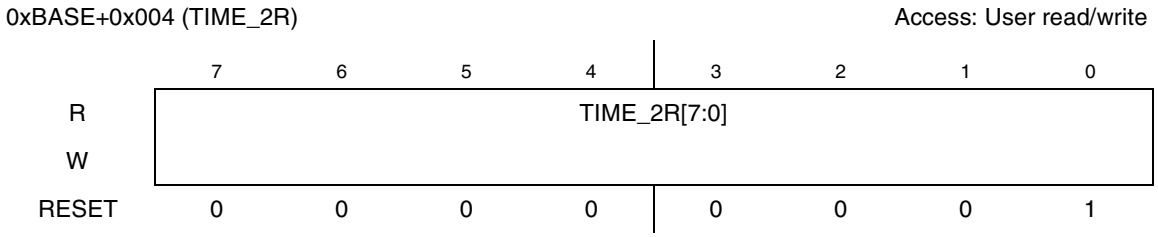

Figure 46-17. TIME_2R Register

46.3.3.2.6 TIME_AX Register

See Figure 46-18 for illustration of valid bits in the TIME_AX Register and Table 46-8 for description of the bit fields.

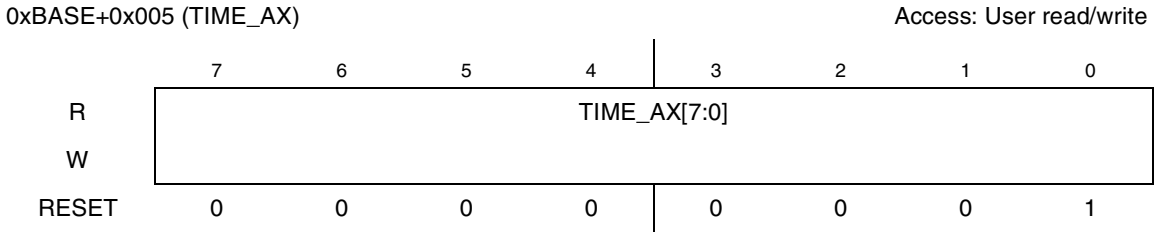

Figure 46-18. TIME_AX Register

46.3.3.2.7 TIME_PIO_RDX Register

See Figure 46-19 for illustration of valid bits in the TIME_PIO_RDX Register and Table 46-8 for description of the bit fields.

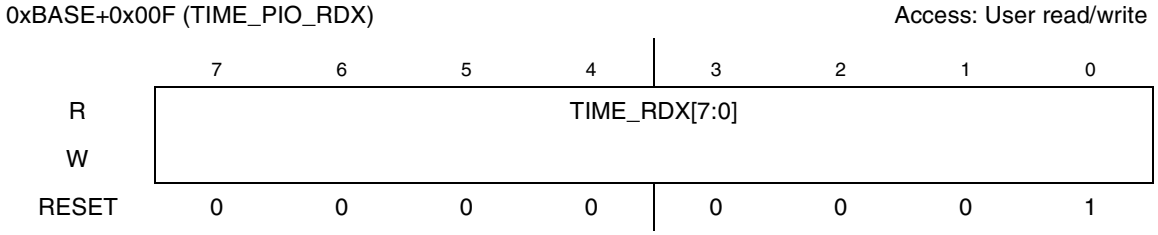

Figure 46-19. TIME_PIO_RDX Register

46.3.3.2.8 TIME_4 Register

See Figure 46-20 for illustration of valid bits in the TIME_4 Register and Table 46-8 for description of the bit fields.

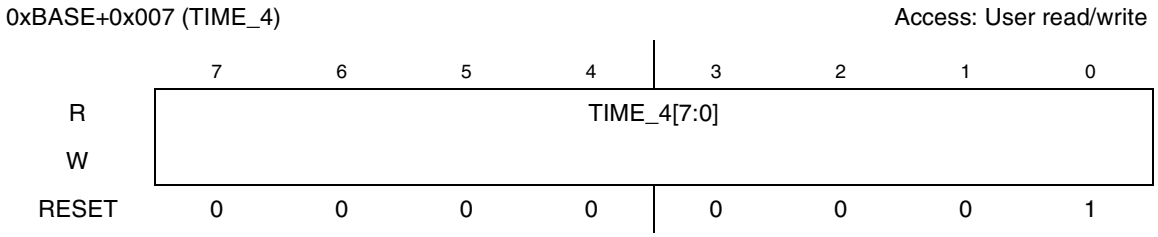

Figure 46-20. TIME_4 Register

46.3.3.2.9 TIME_9 Register

See Figure 46-21 for illustration of valid bits in the TIME_9 Register and Table 46-8 for description of the bit fields.

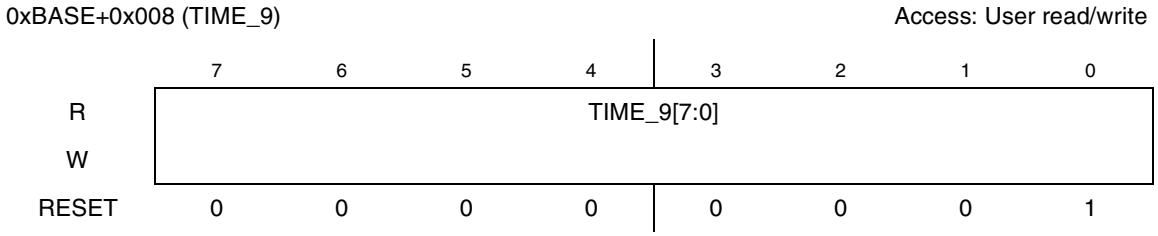

Figure 46-21. TIME_9 Register

46.3.3.2.10 TIME_M Register

See Figure 46-22 for illustration of valid bits in the TIME_M Register and Table 46-8 for description of the bit fields.

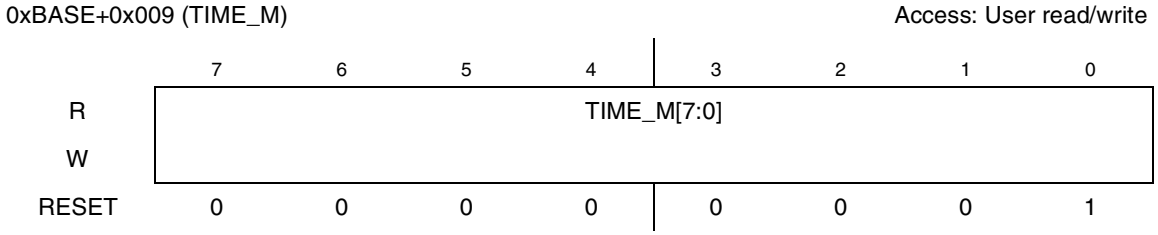

Figure 46-22. TIME_M

46.3.3.2.11 TIME_JN Register

See Figure 46-23 for illustration of valid bits in the TIME_JN Register and Table 46-8 for description of the bit fields.

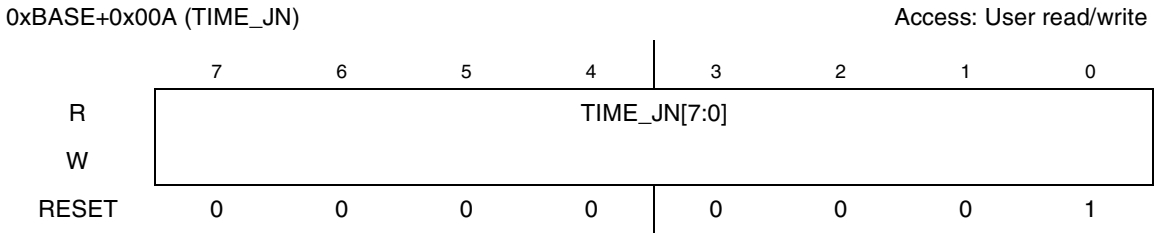

Figure 46-23. TIME_JN Register

46.3.3.2.12 TIME_D Register

46.3.3.2.15 TIME_ENV Register

See Figure 46-27 for illustration of valid bits in the TIME_ENV Register and Table 46-8 for description of the bit fields.

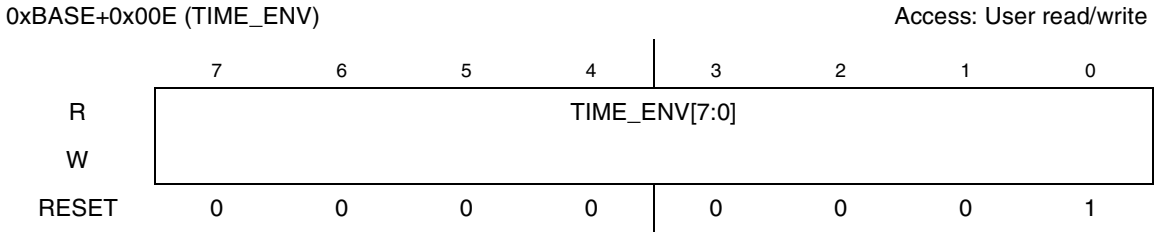

Figure 46-27. TIME_ENV Register

46.3.3.2.16 TIME_RPX Register

See Figure 46-28 for illustration of valid bits in the TIME_RPX Register and Table 46-8 for description of the bit fields.

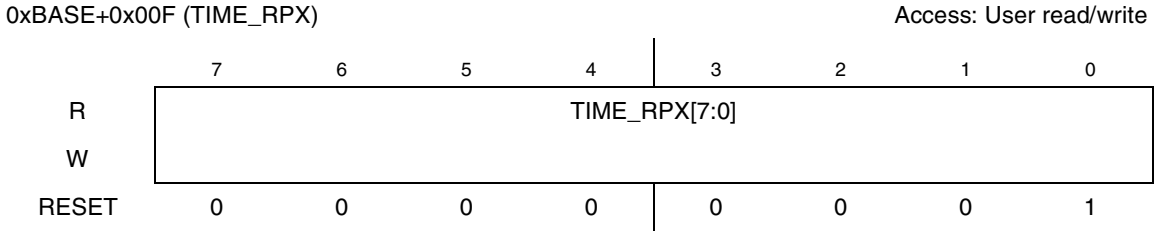

Figure 46-28. TIME_RPX Register

46.3.3.2.17 TIME_ZAH Register

See Figure 46-29 for illustration of valid bits in the TIME_ZAH Register and Table 46-8 for description of the bit fields.

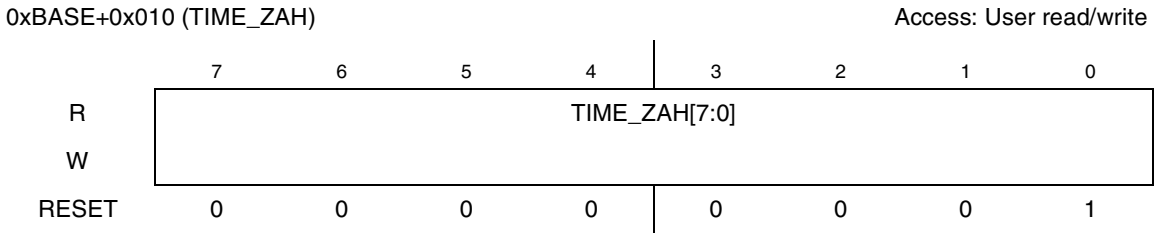

Figure 46-29. TIME_ZAH Register

46.3.3.2.18 TIME_MLIX Register

See Figure 46-30 for illustration of valid bits in the TIME_MLIX Register and Table 46-8 for description of the bit fields.

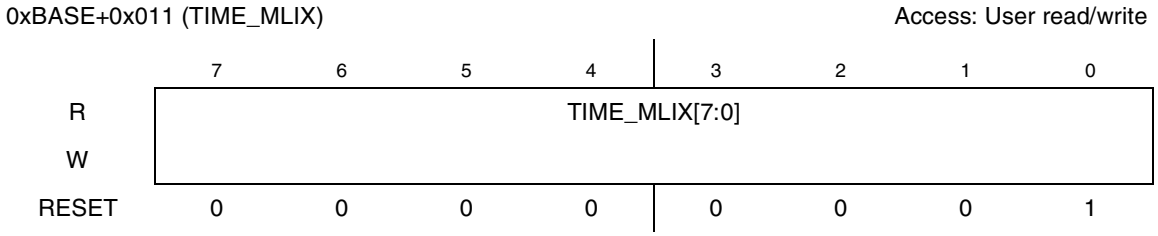

Figure 46-30. TIME_MLIX

46.3.3.2.19 TIME_DVH Register

See Figure 46-31 for illustration of valid bits in the TIME_DVH Register and Table 46-8 for description of the bit fields.

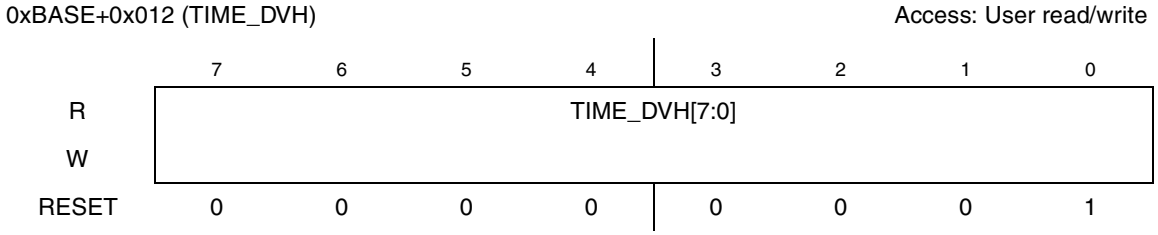

Figure 46-31. TIME_DVH Register

46.3.3.2.20 TIME_DZFS Register

See Figure 46-32 for illustration of valid bits in the TIME_DZFS Register and Table 46-8 for description of the bit fields.

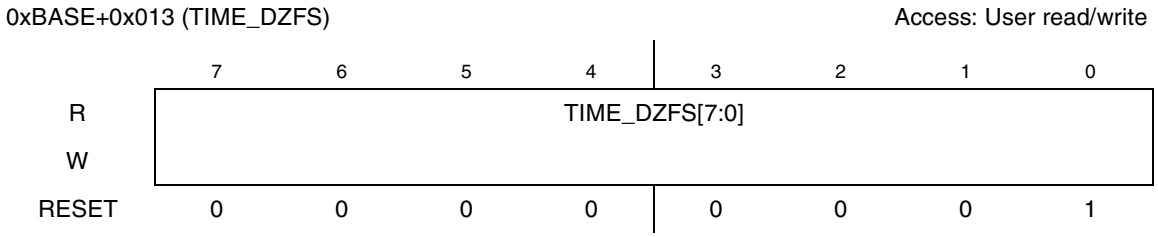

Figure 46-32. TIME_DZFS Register

46.3.3.2.21 TIME_DVS Register

See Figure 46-33 for illustration of valid bits in the TIME_DVS Register and Table 46-8 for description of the bit fields.

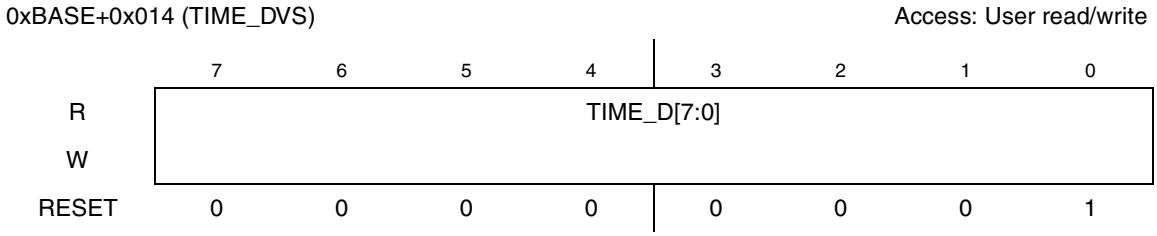

Figure 46-33. TIME_DVS

46.3.3.2.22 Time_CVH Register

See Figure 46-34 for illustration of valid bits in the TIME_CVH Register and Table 46-8 for description of the bit fields.

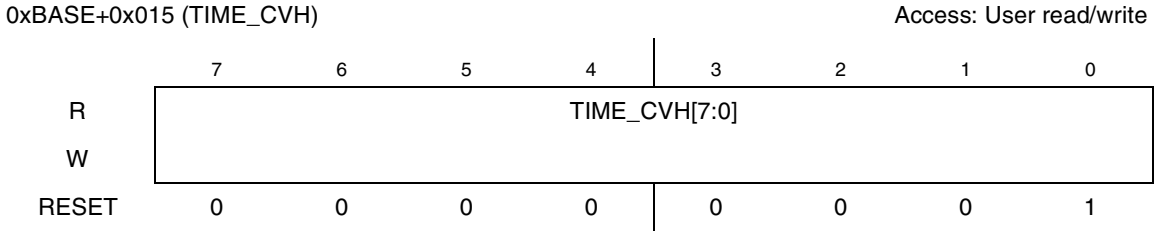

Figure 46-34. TIME_CVH Register

46.3.3.2.23 TIME_SS Register

See Figure 46-35 for illustration of valid bits in the TIME_SS Register and Table 46-8 for description of the bit fields.

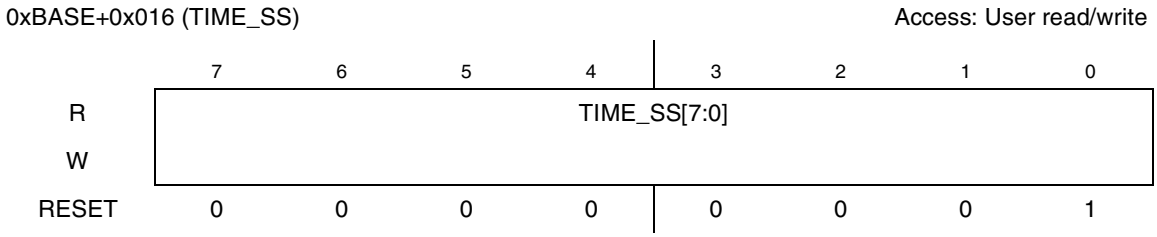

Figure 46-35. TIME_SS Register

46.3.3.2.24 TIME_CYC Register

See Figure 46-36 for illustration of valid bits in the TIME_CYC Register and Table 46-8 for description of the bit fields.

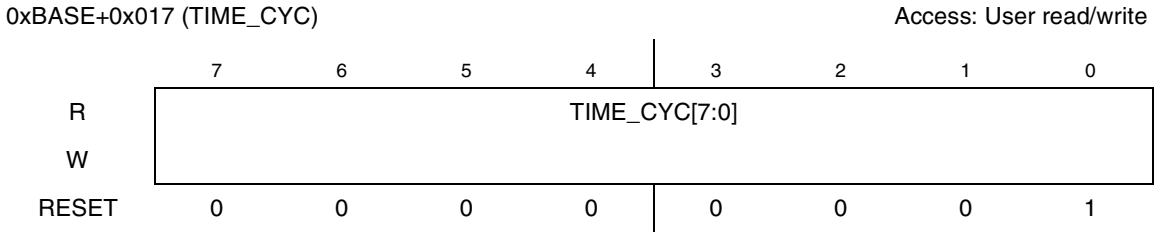

Figure 46-36. TIME_CYC

46.3.3.3 FIFO Data Registers

The following subsections provide figures for the FIFO Data register in 16- and 32-bit mode.

46.3.3.3.1 FIFO_Data Register in 16-bit Mode

See Figure 46-37 for illustration of valid bits in the FIFO_Data Register in 16-bit mode and Table 46-8 for description of the bit fields.

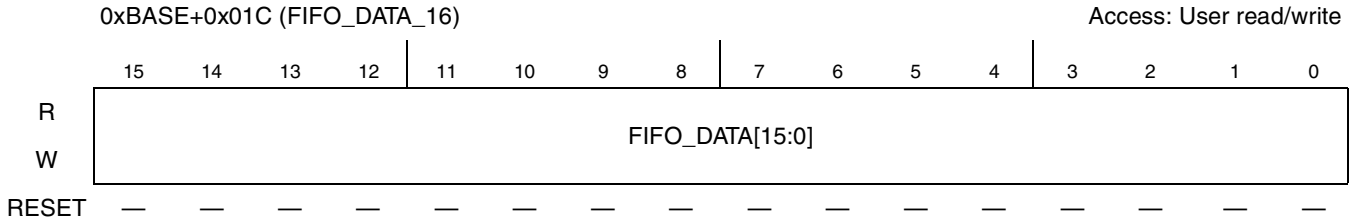

Figure 46-37. FIFO_Data Register In 16-bit Mode

46.3.3.3.2 FIFO_Data Register in 32-bit Mode

See Figure 46-38 for illustration of valid bits in the FIFO_Data Register in 32-bit mode and Table 46-8 for description of the bit fields.

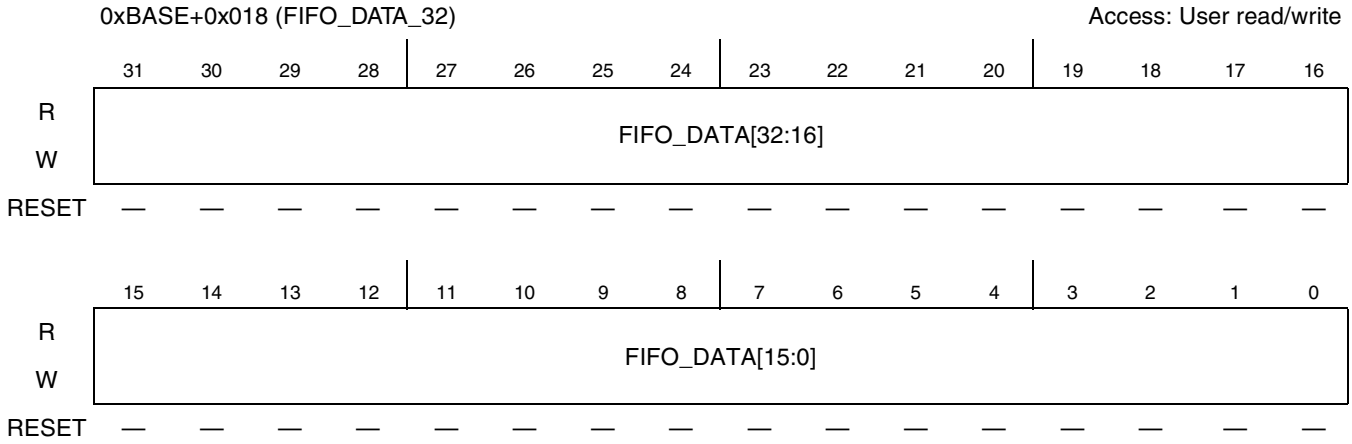

Figure 46-38. FIFO_Data Register in 32-bit Mode

The FiFO_DATA register is used to read or write data to the internal FIFO. It can be accessed as a 16-bit register or as a 32-bit register. Any long write to the register will put the four bytes written into the FIFO. Any word write will put the two bytes written into the FIFO. Any long read will read four bytes from the FIFO. Any word read will read two bytes from the FIFO.

46.3.3.3.3 FIFO_FILL Register

See Figure 46-39 for illustration of valid bits in the FIFO_FILL register and Table 46-8 for description of the bit fields.

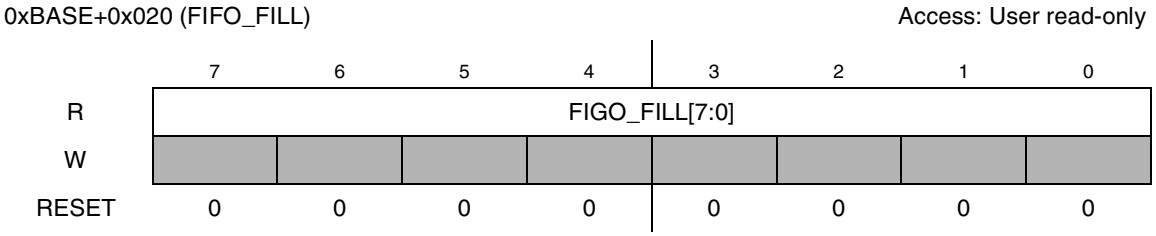

Figure 46-39. FIFO_FILL Register

FIFO_FILL is a read-only register. Any read to it returns the current number of halfwords present in the fifo.

46.3.3.4 ATA_CONTROL Register

See Figure 46-40 for illustration of valid bits in the ATA Control Register and Table 46-11 for description of the bit fields.

0xBASE+0x024 (ATA_CONTROL) Access: User read/write

	7	6	5	4	3	2	1	0
R W	fifo_rst_b	ata_rst_b	fifo_tx_en	fifo_rcv_en	dma_pending	dma_ultra_selected	dma_write	iordy_en
RESET	0	0	0	0	0	0	0	0

Figure 46-40. ATA Control Register

Table 46-11. ATA Control Register Field Descriptions

Field	Description
7 fifo_rst_b	This field controls if the internal FIFO is in reset or enabled 0 FIFO reset 1 FIFO normal operation
6 ata_rst_b	This bit controls the level on the ata_reset_b pin, and controls the reset of the internal ata protocol engine. 0 ata_reset_b = 0, ata drive is reset, and internal protocol engine reset. 1 ata_reset_b = 1, ata drive is not reset and internal protocol engine normal operation.
5 fifo_tx_en	FIFO transmit enable. This bit controls if the FIFO will make transmit data requests to the DMA. If enabled, the FIFO will request the DMA to refill it whenever FIFO filling drops below the alarm level. 0 FIFO refill by DMA disabled 1 FIFO refill by DMA enabled
4 fifo_rcv_en	FIFO receive enable. This bit controls if the FIFO will make receive data requests to the DMA. If enabled, the FIFO will request the DMA to empty it whenever FIFO filling becomes greater or equal to the alarm level. 0 FIFO empty by DMA disabled 1 FIFO empty by DMA enabled
3 dma_pending	DMA pending bit. This bit controls if the ATA interface will respond to a DMA request originating in the drive. If this bit is asserted, the ATA interface will start a multiword DMA or ultra DMA burst whenever the drive asserts ata_dmarq. 0 ATA interface will not start DMA burst 1 ATA interface will start multiword DMA or ultra DMA burst whenever drive asserts dmarq
2 dma_ultra_selected	This bit indicates if a DMA burst started, the UDMA or MDMA protocol will be used 0 Multiword DMA protocol will be used 1 Ultra DMA protocol will be used
1 dma_write	This bit indicates the data direction on any DMA burst started 0 DMA in burst, ATA interface reads from drive 1 DMA out burst, ATA interface writes to drive
0 iordy_en	This bit indicates if the ata_iordy handshake will be used during PIO mode 0 IORDY will be disregarded 1 IORDY handshake will be used

46.3.3.5 Interrupt Registers

A group of three registers control the interrupt interface from the ATA module and going to the CPU and DMA. There are two interrupts controlled by these registers:

- ipbus_int. This interrupt is controlled by bits 3,4, 5 and 6 of the interrupt registers. It will be asserted if one of the 4 bits is set in the interrupt_pending register, while the same bit is set in the interrupt_enable register. This interrupt goes to the CPU.
- fifo_txfer_end_alarm. This interrupt is controlled by bit 7 of the interrupt registers. If ata_intrq1 is set in both the interrupt enable and interrupt pending register, fifo_txfer_end_alarm will be asserted. The goal of this interrupt is to inform the DMA that the running data transfer has ended. This interrupt goes to the smart DMA.

These three registers have mostly the same bits. If a bit is set in the interrupt pending register, its interrupt is pending, and will produce an interrupt if the same bit is set in the interrupt enable register. Some bits in the interrupt pending register are sticky bits. Writing a ‘1’ to the corresponding bit in the interrupt clear bit, will reset them.

46.3.3.5.1 Interrupt_Pending Register

See Figure 46-41 for illustration of valid bits in the Interrupt_Pending Register and Table 46-12 for description of the bit fields.

Figure 46-41. Interrupt_Pending Register

[1] Interrupts ata_intrq1 and ata_intrq2 only reset to 0 if during reset the interrupt input is low.

Table 46-12. Interrupt Pending Register Field Description

Field	Description
7 ata_intrq1	ATA interrupt request 1 This bit reflects the value of the ata_intrq interrupt input. It is set in the interrupt pending register when the drive interrupt is pending, cleared otherwise. When the bit is set in the interrupt pending register, and the same bit is set in the interrupt enable register, fifo_txfer_end_alarm will be asserted, signalling the DMA the end of the transfer. The interrupt clear register has no influence on this bit.
6 fifo_underflow	FIFO underfow This bit reports FIFO underflow. Sticky bit. It is set in the interrupt pending register when there is a FIFO underflow condition. It is cleared by writing a ‘1’ to this bit in the interrupt clear register. When the bit is set in the interrupt pending register, and the same bit is set in the interrupt enable register, ipbus_int will be active, signalling interrupt to the cpu.

Table 46-12. Interrupt Pending Register Field Description (continued)

Field	Description
5 fifo_overflow	FIFO overflow This bit reports FIFO overflow. Sticky bit. It is set in the interrupt pending register when there is a FIFO overflow condition. It is cleared by writing a '1' to this bit in the interrupt clear register. When the bit is set in the interrupt pending register, and the same bit is set in the interrupt enable register, ipbus_int will be active, signalling interrupt to the cpu.
4 controller_idle	Controller Idle This bit reports controller idle. It is set when the ATA protocol engine is idle, there is no activity on the ATA bus. It is cleared when there is activity on the ATA bus. When the bit is set in the interrupt pending register, and the same bit is set in the interrupt enable register, ipbus_int will be active, signalling interrupt to the cpu. The interrupt clear register has no influence on this bit.
3 ata_intrq2	ATA interrupt request 2 This bit reflects the value of the ata_intrq interrupt input. It is set in the interrupt pending register when the drive interrupt is pending, cleared otherwise. It has exactly same functioning as ata_intrq1, but this bit affects ipbus_int, while the other affects interrupt to the DMA. When the bit is set in the interrupt pending register, and the same bit is set in the interrupt enable register, ipbus_int will be asserted, signalling the CPU the drive is requesting attention. The interrupt clear register has no influence on this bit.

46.3.3.6 FIFO Alarm Register

See Figure 46-44 for illustration of valid bits in the FIFO_Alarm Register.

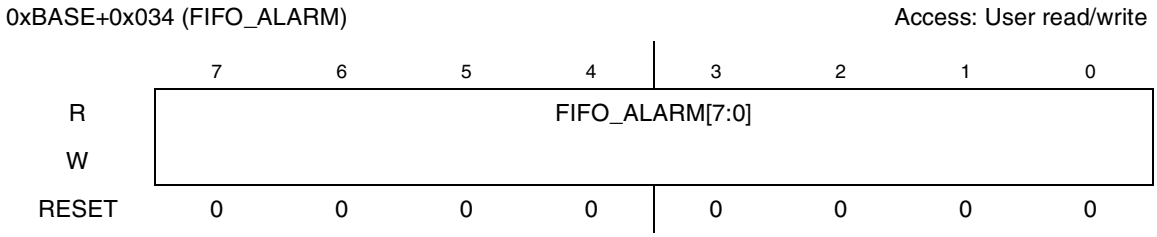

Figure 46-44. FIFO_Alarm Register

This register contains the threshold to generate fifo_rcv_alarm and fifo_tx_alarm to the DMA interface.

- If (`fifo_tx_enable == 1 && fifo_fill < fifo_alarm`): fifo_tx_alarm is set 1, request is made to DMA to refill fifo.
- If (`fifo_rcv_alarm == 1 && fifo_fill >= fifo_alarm`): fifo_rcv_alarm is set 1, request is made to DMA to empty fifo.

46.3.3.7 Drive Registers connected to ATA Bus

Some registers are addressable, but are not present in the ATA interface module. A list is given in Table 46-15. If a read or write access is made to one of these registers, the read or write is mapped to a PIO read or write cycle on the ATA bus, and the corresponding register in the device attached to the ATA bus is accessed.

If the drive_data register is accessed while the ATA interface operates in big-endian mode, the bytes to/from the ATA bus are swapped. No swaps occur in little-endian mode, nor for any other register.

Table 46-15. Drive Registers Connected to ATA Bus

Address	Name	Description	Access
0xBASE+0x0A0 (DRIVE_DATA)	drive_data	Drive data register	R/W
0xBASE+0x0A4 (DRIVE_FEATURES)	drive_features	Drive features register	R/W

0xBASE+0x0C8 (DRIVE_CONTROL)	drive_control	Drive control register	Write-only

46.4 Functional Description

The ATA interface provides two ways to communicate with the ATA peripherals connected to the ATA bus

- PIO mode read/write operation to the ATA bus.
- DMA transfers with the ATA bus

The operation of the peripheral is described in detail in the following sections.

46.4.1 Resetting ATA Bus

The ATA bus reset ata_reset_b is asserted whenever bit 6 ata_rst_b of register ata_control is cleared to 0. At the same time, the ATA protocol engine is reset. When this bit is set to 1, the reset is released.

46.4.2 Programming ATA Bus Timing and iordy_en

The timing the ATA interface will operate with on the ATA bus is programmable. The 24 timing registers at 0xBASE+0x0 to 0xBASE+0x17 are used for this. How these registers affect the timing parameters on the ATA bus is detailed in Section 46.2, External Signal Description.” It is allowed to reprogram these registers at any time when the ATA bus is idle, so before reprogramming make sure that:

- bit dma_pending in ata_control register is cleared.
- bit controller_idle in interrupt_pending register is set.

These two conditions can be accomplished by first writing dma_pending to 0, then waiting until controller_idle is set, then reprogram the timing parameters. If dma_pending was 1 before the

reprogramming started, it should be set again after new timing is in effect to allow the drive to finish the current DMA transfer.

It makes only sense to reprogram the bus timing in the middle of an ongoing DMA transfer when this is necessary because the operating system wants to change the bus clock period. (Dynamic voltage frequency scaling).

It is necessary to wait for controller_idle because a PIO read or write to the ATA bus terminates after the bus cycle with the CPU has been terminated. If the wait for controller_idle does not occur, the new timing values may affect a bus cycle that is still running, and cause error.

The bit iordy_en in register ata_control influences whether the ATA interface will response to the iordy signal coming from the drive. To reprogram it, same rules as for the timing registers apply: Only allowed when dma_pending is cleared, while controller_idle is set.

46.4.3 Access to ATA Bus in PIO Mode

Access to the ATA bus in PIO mode is possible after the following conditions have been met:

- ata_rst_b bit in register ata_control is set.
- Timing parameters have been programmed.

To access the drive in PIO mode, simply read or write to the correct drive register. The bus cycle will be translated to an ATA cycle, and the drive is accessed.

When drive registers are accessed while the ATA bus is in reset, the read or write is discarded, not done.

46.4.4 Using DMA Mode to Receive Data from ATA bus

Apart from PIO mode, the ATA interface supports also MDMA and UDMA mode to transfer data. DMA mode can be used to receive data from the drive (DMA in transfer). In DMA receive mode, the protocol engine will transfer data from the drive to the FIFO using multiword DMA or ultra DMA protocol. The transfer will pause when one of following occurs:

- The FIFO is full.
- The drive deasserts its dma request signal ata_dmarq.
- The bit dma_pending in the ata_contol register is cleared.

When the cause of the transfer pausing is removed, the transfer restarts. The end of the transfer is signalled by the drive to the host by asserting the ata_intrq signal. Alternatively, the host can read the device status register. In this register, the drive will also indicate if the transfer has ended.

The transfer of data from the FIFO into the memory is handled by the host system DMA. Whenever the FIFO filling is above the alarm threshold, the DMA should read one packet of data from the FIFO, and store this in main memory. In doing so, the DMA prevents the FIFO from getting full, and keeps the transfer from drive to FIFO running.

The steps for setting up a DMA data transfer from device to host are:

1. Make sure the ATA bus is not in reset and all timing registers are programmed.
2. Make sure the FIFO is empty by reading it until empty or by resetting it.
3. Initialize the DMA channel connected to fifo_rcv_alarm. Every time fifo_rcv_alarm is high, the DMA should read <packetsize> long ints from the FIFO, and store them to main memory. (typical packetsize is 8 longs)
4. Write 2 × <packetsize> to fifo_alarm register. In this way, FIFO requests attention to DMA when there is at least one packet ready for transfer.
5. To make the ATA ready for a DMA transfer from device to host, take the following steps:
   a) Make sure the FIFO is out of reset by setting bit fifo_rst_b to 1 in the ata control register.
   b) Program fifo_rcv_en=1 in decontrol register. This enables the FIFO to by emptied by the DMA.
   c) Program dma_pending =1, dma_write=0, ultra_mode_selected=0/1 in ata_control register. ultra_mode_selected should be 1 if you want to transfer data using UDMA mode, it should be 0 if you want to transfer data using MDMA mode.
6. Now the host side of the DMA is ready. Send commands to the drive in PIO mode that cause it to request DMA transfer on the ATA bus. The nature of these commands is beyond the scope of this document. Consult the ATA specification to know how to communicate with the drive.
7. When the drive now requests DMA transfer by pulling ata_dmarq high, the ATA interface acknowledges with ata_dmack, and the transfer starts. Data is transferred automatically to the FIFO, and from there on to the host memory.
8. During the transfer, the host can monitor for end of transfer by reading some device ATA registers. These reads will cause the running DMA to pause; after the read is completed, the DMA resumes. The host can also wait unit the drive asserts ata_intrq. This also indicates end of transfer.
9. On end of transfer, the host or host DMA should wait until controller_idle is set, and next read the remaining halfwords from the FIFO, and transfer these to memory.

NOTE

There may be less than <packetsize> remaining bytes, so transfer will not be automatic by the DMA.

46.4.5 Using DMA Mode to Transmit Data to ATA bus

Apart from PIO mode, the ATA interface supports also MDMA and UDMA mode to transfer data. DMA mode can be used to transmit data to the drive (DMA out transfer). In DMA transmit mode, the protocol engine will transfer data from the FIFO to the drive using metalwork DMA or ultra DMA protocol. The transfer will pause when one of following occurs:

- The FIFO is empty.
- The drive deasserts its dma request signal ata_dmarq.
- The bit dma_pending in the ata_contol register is cleared.

When the cause of the transfer pausing is removed, the transfer restarts. The end of the transfer is signalled by the drive to the host by asserting the ata_intrq signal. Alternatively, the host can read the device status register. In this register, the drive will also indicate if the transfer has ended.

The transfer of data from the memory to the FIFO is handled by the host system DMA. Whenever the FIFO filling is below the alarm threshold, the DMA should read one packet of data from the main memory, and store this in the FIFO. In doing so, the DMA prevents the FIFO from getting empty, and keeps the transfer from FIFO to drive running.

The steps for setting up a DMA data transfer from device to host are:

1. Make sure the ATA bus is not in reset and all timing registers are programmed.
2. Make sure the FIFO is empty by reading it until empty, or by resetting it.
3. Initialize the DMA channel connected to fifo_tx_alarm. Every time fifo_tx_alarm is high, the DMA should read <packetsize> long ints from the main memory, and write them to the FIFO. (typical packetsize is 8 longs). Program the DMA such that it will not transfer more than <sectorsize> longwords in total.
4. Write FIFO_SIZE – 2 × <packetsize> to fifo_alarm register. In this way, FIFO will request attention to DMA when there is room for at least one extra packet. FIFO_SIZE should be given in halfwords. (typical 64 halfwords)
5. To make the ATA ready for a DMA transfer from host to device, perform the following steps:
   a) Make sure the FIFO is out of reset by setting bit fifo_rst_b to 1 in the ata control register.
   b) Program fifo_tx_en = 1 in ata_control register. This enables the FIFO to be filled by DMA.
   c) Program dma_pending = 1, dma_write = 1, ultra_mode_selected = 0/1 in ata_control register. ultra_mode_selected should be 1 if you want to transfer data using UDMA mode, it should be 0 if users want to transfer data using MDMA mode.
6. Now, the host side of the DMA is ready. Send commands to the drive in PIO mode that cause it to request DMA transfer on the ATA bus. The nature of these commands is beyond the scope of this document. You should consult the ATA specification to know how to communicate with the drive.
7. When the drive now requests DMA transfer by pulling ata_dmarq high, the ATA interface acknowledges with ata_dmack, and the transfer starts. Data is transferred automatically from the FIFO, and also from host memory to FIFO.
8. During the transfer, the host can monitor for end of transfer by reading some device ATA registers. These reads will cause the running DMA to pause; after the read is completed, the DMA resumes. The host can also wait unit the drive asserts ata_intrq. This also indicates end of transfer.

On end of transfer, no extra FIFO manipulations are needed.

Chapter 47
Pulse-Width Modulator (PWM)

The pulse-width modulator (PWM) has a 16-bit counter and is optimized to generate sound from stored sample audio images. It can also generate tones. It uses 16-bit resolution and a 4 × 16 data FIFO to generate sound.

This section presents an overview of the PWM. Figure 47-1 illustrates the PWM block diagram.

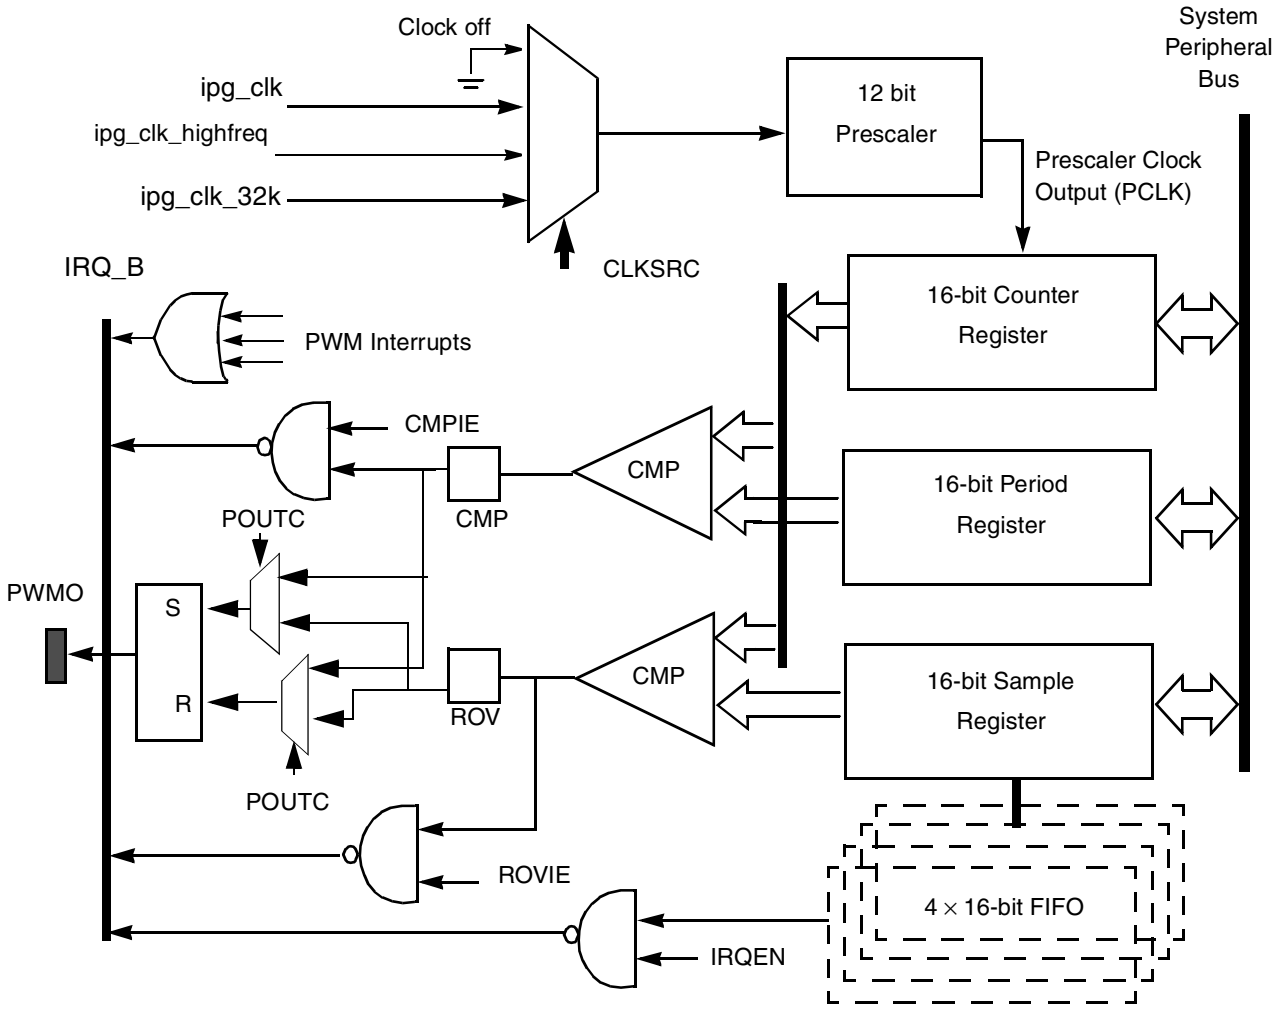

Figure 47-1. Pulse-Width Modulator Block Diagram

The following features characterize the PWM:

- 16-bit up-counter with clock source selection
- 4 × 16 FIFO to minimize interrupt overhead
- 12-bit prescaler for division of clock
- Sound and melody generation
- Active high or active low configured output
- Can be programmed to be active in low power and debug modes
- Interrupts at compare and rollover

47.1 Signal Description

The PWM follows IP Bus protocol for interfacing with the processor core. It does not have any interface signals with any other module inside the chip except for clock and reset inputs from the Clock module and interrupt signals to the processor interrupt handler. There is a single output signal going outside the chip boundary.

47.1.1 External Signals

PWM has a single output signal to the chip boundary named ipp_do_pwmo.

Table 47-1 outlines the external signals.

Table 47-1. External Signals

Name	Direction	Function	Reset State	Pull up
ipp_do_pwmo	Output	This is the functional output of the PWM. The modulated signal of the module is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the PWM. The smallest period can be two ipg_clk clock periods with duty cycle of 50%	0	—

47.2 Memory Map and Register Definition

The PWM module includes six user-accessible 32-bit registers. Section 47.2.2, Register Descriptions," provides the detailed descriptions for all of the PWM registers.

Table 47-2. PWM Memory Map

Offset	Register	Access	Reset Value	Section/Page
0xBASE+0x00 (PWMCR)	PWM Control Register (PWMCR)	R/W	0x0000_0000	47.2.2.1/47-5

47.2.1 Register Summary

Figure 47-2 shows the key to the register fields and Table 47-3 shows the register figure conventions.

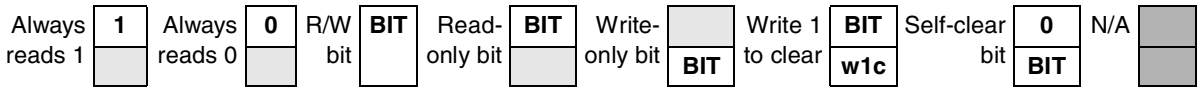

Figure 47-2. Key to Register Fields

Table 47-3. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 47-4 shows the PWM register summary.

Figure 47-3. PWM Control Register (PWMCR)

Table 47-5 shows the PWMCR field descriptions.

Table 47-5. PWMCR Field Descriptions

Field	Description
31–28 Reserved	Reserved. These reserved bits are always read as zero.
27–26	FIFO Water Mark These bits are used to set the data level at which the FIFO empty flag will be set and the corresponding interrupt generated. 00 FIFO empty flag is set when there are more than or equal to 1 empty slots in FIFO 01 FIFO empty flag is set when there are more than or equal to 2 empty slots in FIFO 10 FIFO empty flag is set when there are more than or equal to 3 empty slots in FIFO 11 FIFO empty flag is set when there are more than or equal to 4 empty slots in FIFO
25 STOPEN	Stop Mode Enable This bit keeps the PWM functional while in stop mode. When this bit is cleared, the input clock is gated off in stop mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in stop mode 1 Active in stop mode
24 DOZEN	Doze Mode Enable This bit keeps the PWM functional in doze mode. When this bit is cleared, the input clock is gated off in doze mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in doze mode 1 Active in doze mode

Table 47-5. PWMCR Field Descriptions (continued)

Field	Description
23 WAITEN	Wait Mode Enable This bit keeps the PWM functional in wait mode. When this bit is cleared, the input clock is gated off in wait mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in wait mode 1 Active in wait mode
22 DBGEN	Debug Mode Enable This bit keeps the PWM functional in debug mode. When this bit is cleared, the input clock is gated off in debug mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in debug mode 1 Active in debug mode
21 BCTR	Byte Data Swap Control This bit determines the byte ordering of the 16-bit data when it goes into the FIFO from the sample register. 0 byte ordering remains the same 1 byte ordering is reversed
20 HCTR	Half-word Data Swap Control This bit determines which half word data from the 32 bit IP-Bus interface is written into the lower 16 bits of the sample register. 0 Half word swapping does not take place 1 Half words from write data bus are swapped
19–18 POUTC	PWM Output Configuration This bit field determines the mode of PWM output on the output pin. 00 Output pin is set at rollover and cleared at comparison 01 Output pin is cleared at rollover and set at comparison 10 PWM output is disconnected 11 PWM output is disconnected
17–16 CLKSRC	Select Clock Source These bits determine which clock input will be selected for running the counter. After reset the system functional clock is selected. The input clock can also be turned off if these bits are set to 00. This field value should only be changed when the PWM is disabled 00 Clock is off 01 ipg_clk 10 ipg_clk_highfreq 11 ipg_clk_32k
15 –4 PRESCALER	Counter Clock Prescaler Value This bit field determines the value by which the clock will be divided before it goes to the counter. 0x000 Divide by 1 0x001 Divide by 2 ... 0xfff Divide by 4096
3 SWR	Software Reset PWM is reset when this bit is set to 1. It is a self clearing bit. A write 1 to this bit is a single wait state write cycle. When the module is in reset state this bit is set and is cleared when the reset procedure is over. Setting this bit resets all the registers to their reset values except for the STOPEN, DOZEN, WAITEN, and DBGEN bits in this control register. 0 PWM is out of reset 1 PWM is undergoing reset

Table 47-5. PWMCR Field Descriptions (continued)

Field	Description
2–1 REPEAT	Sample Repeat This bit field determines the number of times each sample from the FIFO is to be used. 00 Use each sample once 01 Use each sample twice 10 Use each sample four times 11 Use each sample eight times
0 EN	PWM Enable This bit enables the PWM. If this bit is not enabled, the clock prescaler and the counter is reset. When the PWM is enabled, it begins a new period, the output pin is set to start a new period while the prescaler and counter are released and counting begins. 0 PWM disabled 1 PWM enabled

47.2.2.2 PWM Status Register (PWMSR)

The PWM status register (PWMSR), shown in Figure 47-4, contains seven bits which display the state of the FIFO and the occurrence of rollover and compare events. The FIFOAV bit is read-only but the other four bits can be cleared by writing 1 to them. FE, ROV, and CMP bits are associated to Fifo-Empty, Roll-over, and Compare interrupts, respectively.

Field	Description
31–7 Reserved	Reserved. These reserved bits are always read as zero.
6 FWE	FIFO Write Error Status. This bit shows that an attempt has been made to write FIFO when it is full. 0 FIFO write error not occurred 1 FIFO write error occurred

Table 47-6. PWMSR Field Descriptions (continued)

Field	Description
5 CMP	Compare Status. This bit shows that a compare event has occurred. 0 Compare event not occurred 1 Compare event occurred
4 ROV	Roll-over Status. This bit shows that a roll-over event has occurred. 0 Roll-over event not occurred 1 Roll-over event occurred
3 FE	FIFO Empty Status Bit. This bit indicates the FIFO data level in comparison to the water level set by FWM field in the control register. 0 Data level is above water mark 1 When the data level falls below the mark set by FWM field
2–0 FIFOAV	FIFO Available. These read-only bits indicate the data level remaining in the FIFO. An attempted write to these bits will not affect their value and no transfer error is generated. 000 No data available 001 1 word of data in FIFO 010 2 words of data in FIFO 011 3 words of data in FIFO 100 4 words of data in FIFO 101 Unused 110 Unused 111 Unused

47.2.2.3 PWM Interrupt Register (PWMIR)

The PWM Interrupt register (PWMIR), shown in Figure 47-5, contains three bits which control the generation of the compare, rollover and FIFO empty interrupts.

0xBASE+0x08 (PWMIR) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 47-7. PWMIR Field Descriptions

Field	Description
31–3 Reserved	Reserved. These reserved bits are always read as zero.
2 CIE	Compare Interrupt Enable. This bit controls the generation of the Compare interrupt. 0 Compare Interrupt not enabled 1 Compare Interrupt enabled
1 RIE	Roll-over Interrupt Enable. This bit controls the generation of the Rollover interrupt. 0 Roll-over interrupt not enabled 1 Roll-over Interrupt enabled
0 FIE	FIFO Empty Interrupt Enable. This bit controls the generation of the FIFO Empty interrupt. 0 FIFO Empty interrupt disabled 1 FIFO Empty interrupt enabled

47.2.2.4 PWM Sample Register (PWMSAR)

The PWM sample register (PWMSAR), shown in Figure 47-6, is the input to the FIFO. 16-bit words are loaded into the FIFO. The FIFO can be written and read when the PWM is disabled. The PWM will run at the last set duty-cycle setting if all the values of the FIFO has been utilized, until the FIFO is reloaded or the PWM is disabled. When a new value is written, the duty cycle changes after the current period is over.

A value of zero in the sample register results in the ipp_pwm_pwmo output signal being always low/high (POUTC = 00 is low and POUTC = 01 is high), and hence no output waveform will be produced. If the value in this register is higher than the PERIOD + 1, the output will never be reset/set depending on POUTC value.

0xBASE+0x0C (PWMSAR) Access: User read-write

Table 47-8. PWMSAR Field Descriptions

Field	Description
31–16 Reserved	These are reserved bits and writing a value will not affect the functionality of PWM and are always read as zero.
15–0 SAMPLE	Sample Value. This is the input to the 4x16 FIFO. The value in this register denotes the value of the sample being currently used.

47.2.2.5 PWM Period Register (PWMPR)

The PWM period register (PWMPR), shown in Figure 47-7, determines the period of the PWM output signal. After the counter value matches PERIOD + 1, the counter is reset to start another period.

PWMO (Hz) = PCLK(Hz) ÷ (period + 2)

A value of zero in the PWMPR will result in a period of two clock cycles for the output signal. Writing 0xFFFF to this register will achieve the same result as writing 0xFFFE.

A change in the period value due to a write in PWMPR results in the counter being reset to zero and the start of a new count period.

0xBASE+0x10 (PWMPR) Access: User read-write

Field	Description
31–16 Reserved	These are reserved bits and writing a value will not affect the functionality of PWM and are always read as zero.
15–0 COUNT	Counter Value. These bits are the counter register value and denotes the current count state the counter register is in.

47.3 Functional Description

The following sections detail the PWM operation and function.

47.3.1 Operation

The output of the PWM is a toggling signal whose frequency and duty cycle can be modulated by programming the appropriate registers. It has a 16-bit up counter which counts from 0x0000 until the counter value equals the [Value in Period register] + 1. After this match occurs the counter is reset to 0x0000.

At the beginning of a count period cycle, the PWMO pin is set to one (default) and the counter begins counting up from 0x0000. The sample value in the sample FIFO is compared on each count of prescaler clock. When the sample and count values match, the PWMO signal is cleared to zero (default). The counter continues counting until the period match occurs and subsequently another period cycle begins.

When the PWM is enabled the counter starts running and generates an output with the reset values in the period and sample registers. It is recommended that the programming of these registers be done before PWM is enabled.

A hardware reset results in all the PWM count and sample registers begin cleared and the FIFO being flushed. The control register shows that FIFO is empty and it can be written into, and the PWM is disabled. A software reset has the same results, however the state of the STOPEN, DOZEN, WAITEN, and DBGEN bits in the control register are not affected. Software reset can be asserted even when the PWM is in disabled state.

47.3.1.1 Clocks

The clock that feeds the prescaler can be selected from:

- **High frequency Clock** (ipg_clk_highfreq) pat_ref or ckih

  This is a high frequency clock provided by the Clock Module (CM). This clock is supposed to be on in the low power mode when the ipg_clk is turned off. Thus the PWM can be run on this clock in the low power mode. The CRM is expected to provide this clock after synchronizing it to ahb_clk in the normal functional mode and switch to the unsynchronized version in the low power mode.
- **Low Reference Clock** (ipg_clk_32k) ckil

  This is the 32 KHz low reference clock which is provided by the CM. This clock is supposed to be on in the low power mode when ipg_clk is turned off. Thus PWM can be run on this clock in the low power mode. The CRM is expected to provide this clock after synchronizing it to ahb_clk in the normal functional mode and switch to the unsynchronized version in the low power mode.
- **Global Functional Clock** (ipg_clk)

  This clock is supposed to be on in normal operations. In low power modes it can be switched off.

The clock input source is determined by the CLKSRC field of the PWM control register. **The CLKSRC value should only be changed when the PWM is disabled.**

A change in the value of the PRESCALER field of the control register is immediately reflected on its output clock frequency.

47.3.1.2 FIFO

Digital sample values can be loaded into the pulse-width modulator as 16-bit words. The endianess can be changed using the BCTR and HCTR bits of the control register. A 4-word (16-bit) FIFO minimizes interrupt overhead. A maskable interrupt is generated when the number of data words fall below the water level set by the FWM field in the control register.

A write in the sample register results in the value being stored into the FIFO if it is not full. A write when the FIFO is full sets FWE (FIFO write error) bit in the status register and the FIFO contents remain unchanged. The FIFO can be written into when the PWM is disabled. The FIFOAV field shows how many data words are currently contained in the FIFO and if it can be written into.

A read on the sample register yields the current FIFO value being used or will be used by the PWM for generation on the output signal. Therefore a write and a subsequent read on the sample register may result in different values being obtained.

47.3.1.3 Rollover and Compare Event

The counter is reset to 0x0000 after its value equals the PERIOD + 1 and resumes counting thereafter. This event is referred to as a rollover. When PERIOD = 0x0000, the counter is reset after count reaches 0x0001. Therefore PERIOD = 0xFFFF or 0xFFFE results in the counter value being reset after count until 0xFFFF. During a rollover event the output is either set (default), reset or has no effect according to the programming of the POUTC field in the control register. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

When the counter value reaches the sample value, the output of the PWM is reset (default), set, or has no effect according to the programming of the POUTC field of control register. This event is referred to as a compare event. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

If the rollover event sets the PWM output signal the compare event will reset it and vice versa for a particular programming configuration of POUTC field.

47.3.1.4 Low Power Mode Behavior

In low power modes if the clock from the selected clock source is available, the PWM counter continues to run and an output is produced depending on whether the control bit for that mode is set. In the absence of the clock itself or if the corresponding low power bit in the control register is 0, the counter is reset and resumes counting when it exits the low power mode.

47.3.1.5 Debug Mode Behavior

In debug mode, PWM has the option of continuing to run or be halted. If the DBGEN bit is not set in the PWMCR, the PWM is halted. If the DBGEN bit is set, then the PWM will continue to run in the debug mode.

Chapter 48
Run-Time Integrity Checker (RTIC)

The Run-Time Integrity Checker (RTIC) function is to ensure the integrity of the peripheral memory contents and assist with boot authentication. The RTIC can verify memory contents during system boot and during runtime execution. If the memory contents at runtime fail to match the hash signature, an error in the security monitor is triggered.

Figure 48-1 is a block diagram of the RTIC.

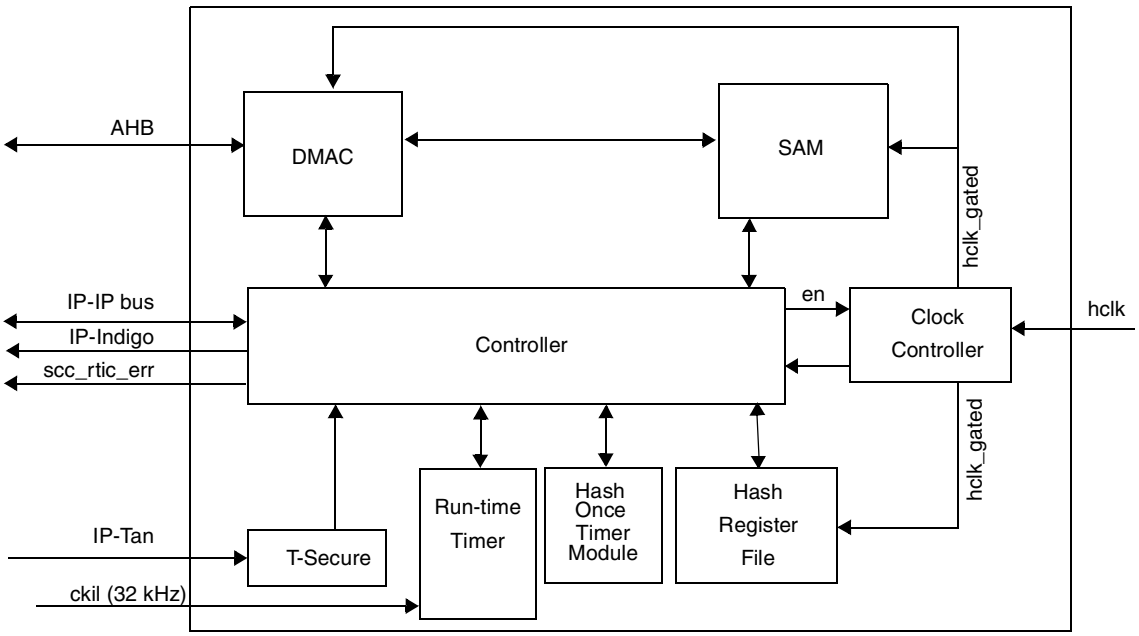

Figure 48-1. RTIC Block Diagram

48.1 Features

The RTIC offers the following features:

- SHA-1 message authentication
- Input DMA interface
- Segmented data gathering to support non-contiguous data blocks in memory (up to two segments per block)
- Works with high assurance boot process
- Support for up to four independent memory blocks
- Programmable DMA bus duty cycle timer and watchdog timer

- Power-saving clock gating logic
- Hardware configurable big/little-endian data format
- Full word memory reads (word-aligned addresses, multiple of 32-bit lengths)

48.1.1 Modes of Operation

The RTIC operates in two primary modes:

- One-time hash mode
  - Is used during high assurance boot for code authentication or one time integrity checking
  - Stores hash result internally and signals interrupt to host
- Continuous hash mode
  - Is used at run-time to continuously to verify integrity of memory contents
  - Checks re-generated hash against internally stored values and interrupts host only if error occurs

48.2 Initialization/Application Information

The RTIC serves as a single-use hash accelerator to assist with code authentication and other services at boot time as well as an autonomous/passive memory integrity checker during runtime. It is programmed through the IP-slave interface and scans the peripheral memory contents over the AHB interface using direct memory access.

Figure 48-2 shows a typical system configuration using the RTIC.

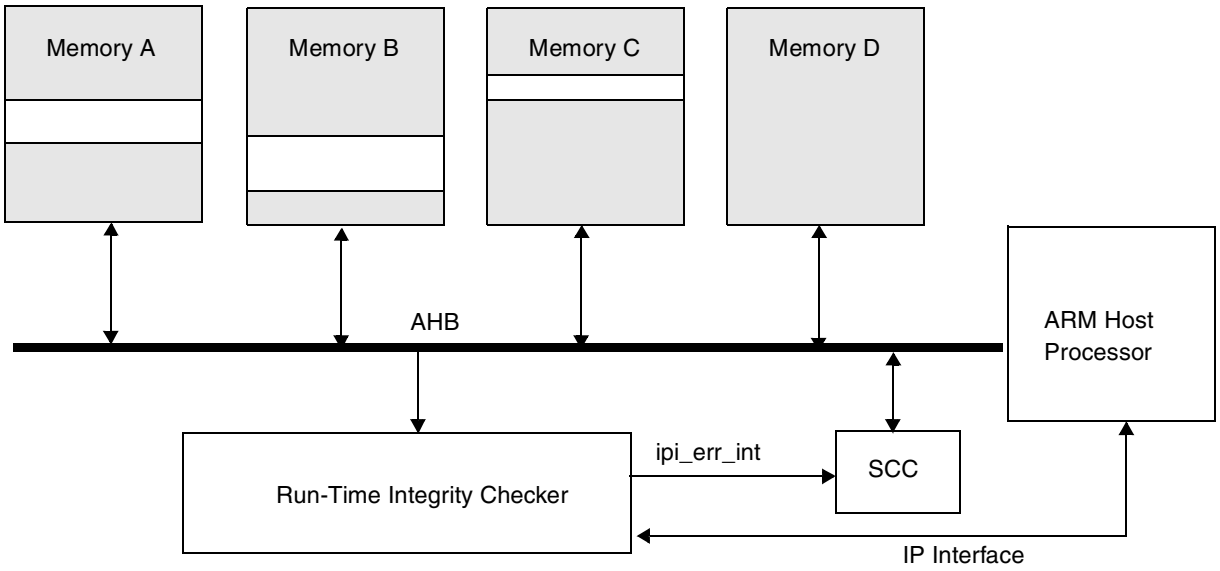

Figure 48-2. System Diagram

In this example, there are four independent memory blocks that can be checked by the RTIC. Memories A,B, and C have their contents partitioned over non-contiguous spaces. Memory D does not contain any physical partitioning. The host program sthe RTIC with the starting address and length of each partition

inside memory A, B, and C. For memory D, only one starting address and length is specified, with the second start address/length fields for memory D being set to 0.

After setting the A/B/C/D hash once memory enable bits in the RTIC control register and hash once bit in the RTIC command register, the RTIC hashes each memory and stores the result in its hash register file to be read by the host. If the RTIC is used to verify that the memories are not corrupted during runtime, the A/B/C/D run-time memory enable bits in the control register must be set, followed by the runtime check bit in the RTIC command register. The RTIC rehashes each enabled memory in a continuous loop until either an error occurs or the RTIC is reset.

NOTE

Detailed information about the RTIC is provided in the i.MX51 Security Manual. Contact your Freescale representative for information about obtaining this document.

Chapter 49
Symmetric/Asymmetric Hashing and Random Accelerator (SAHARA)

The symmetric/asymmetric hashing and random accelerator (SAHARA) is a security coprocessor that can be used on cell phone baseband processors or wireless PDAs. It implements block encryption algorithms, (AES, DES, and 3DES), hashing algorithms (MD5, SHA-1, SHA-224, and SHA-256), a stream cipher algorithm (ARC4), and a hardware random number generator. It has a slave IP bus interface that the host can use to write configuration and command information and to read status information. It also has a DMA controller with an AHB bus interface that reduces the burden on the host to move the required data to and from memory.

See Figure 49-1 for the block diagram of SAHARA.

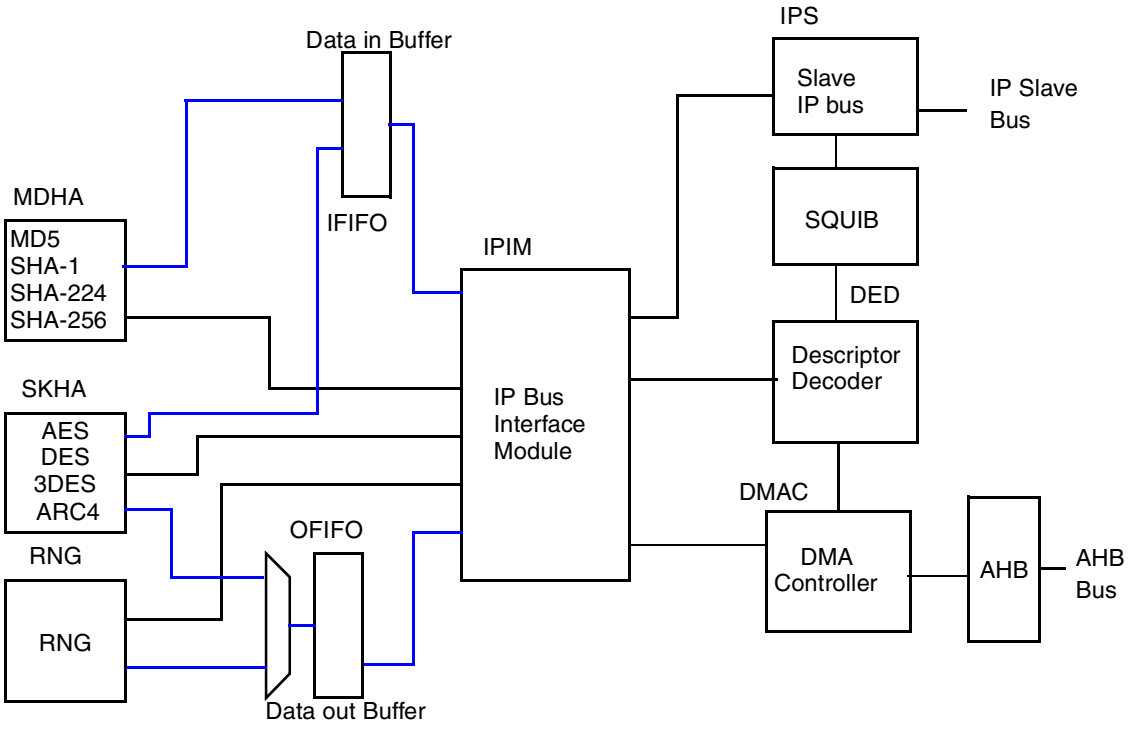

Figure 49-1. Block Diagram of SAHARA

49.1 Features

SAHARA accelerates the following security functions:

- AES encryption/decryption
  - — ECB, CBC, CTR, and CCM modes
  - — 128-bit key
- DES/3DES
  - — ECB, CBC, and CTR modes
  - — 56-bit key with or without parity (DES)
  - — 112-bit or 168-bit key with parity (3DES)
- ARC4 (RC4-compatible cipher)
  - – 5-16 byte key
  - – Host accessible S-box
- MD5, SHA-1, SHA-224 and SHA-256 hashing algorithms.
  - — Messages lengths that are multiples of bytes (with auto padding).
  - — Auto padding supported.
  - — HMAC (support for IPAD and OPAD via Descriptors).
  - — Up to 2^{32} byte message length (with auto padding).
- Pseudorandom number generator
  - — Entropy is generated via independent free running ring oscillators

SAHARA also provides the following features:

- Descriptor based processing to reduce communication between host processor and SAHARA
- Multiple Master Interface (SQUIB), allows two masters to share SAHARA transparently.
- ARM TrustZone support via additional AHB and IPBus signalling
- Low power design
  - — Automatic power down of individual blocks when not in use
  - — Clock gating on registers
  - — RNG sleep mode
- Restricted access to potentially sensitive information
  - — Internal registers are cleared after a Descriptor chain has completed processing in BATCH mode.
  - — Security Monitor can cause data to be cleared.
  - — Scan reset and scan exit signals prevent data being scanned out.
- Mixed endianness support.
- Optimization for maximum of 8-word AHB burst

49.1.1 Modes of Operation

SAHARA can be used in three modes: batch, dedicated, and debug. The mode bits can be changed only when SAHARA is idle (that is, when the status register busy bit is 0). Otherwise, the mode bits are not written and no other indication is given. Debug mode can be entered only when the secure state bit in the status register is 0, which reflects the SCC secure state input (typically from the SCC module).

49.1.1.1 Batch Mode

Batch mode is the default operating mode. After a chain of descriptors has been processed, the internal functional blocks are initialized and an interrupt is generated. Initializing SAHARA prevents a task from being able to access the left over data from a descriptor chain of a different task.

49.1.1.2 DedicateD Mode

Dedicated mode is used when SAHARA is dedicated to a single task. In dedicated mode, SAHARA does not reset internal state information at the end of a descriptor chain. This allows a task to improve performance by not having to save and restore its context information between each set of descriptor chains. This is useful when a task does not have access to all data at one time, and must therefore present its descriptors at different times.

49.1.1.3 Debug Mode

In direct access debug mode, the host writes directly to the address space of the internal hardware blocks. SAHARA single-steps descriptors only when in debug mode. This is intended only for interactive debugging and is disabled when the Security Monitor is in the secure state (that is, the scc_secure_state input is asserted).

In debug mode, the host processor can read and write the internal encryption engine's registers. It is up to the host processor to set up the internal flow control by writing the appropriate value in the internal flow control register. If this is not set up properly, then when attempting to get a module to read data from the input buffer, the module will probably generate an error and require resetting. No interrupts are generated while SAHARA is in debug mode.

The processing of a descriptor can be traced in debug mode by writing to the Single_Step bit in the command register. This causes the descriptor decoder to perform a single operation of descriptor processing, and then allows the host to monitor the internal registers to see the result of that operation. Writing to the Single_Step bit in the command register multiple times causes the descriptor processing to proceed until it completes. If two single-step commands arrive too quickly, the second is simply ignored. During the single step processing, the status register state bits indicate busy. When the processing completes, the state reverts back to idle.

When single stepping, the internal flow control register is modified by the descriptor decoder. The host should not change it or an error may result.

NOTE

Detailed information about the SAHARA is provided in the i.MX51 Security Manual. Contact your Freescale representitive for information about obtaining this document.

Chapter 50
Security Controller (SCC)

The Security Controller (SCC) is composed of two sub-blocks, secure RAM, and a security monitor (see Figure 50-1).

The primary functionality of the SCC is to establish the following:

- A centralized security state controller and hardware security state with a hardware-configured, unalterable security policy
- An uninterruptible hardware mechanism that detects and responds to threat detection signals (specifically, platform test access signals)
- A device-unique data protection/encryption resource that enables off-chip storage of security-sensitive data
- An internal storage resource that automatically and irrevocably destroys plain text security sensitive data upon threat detection

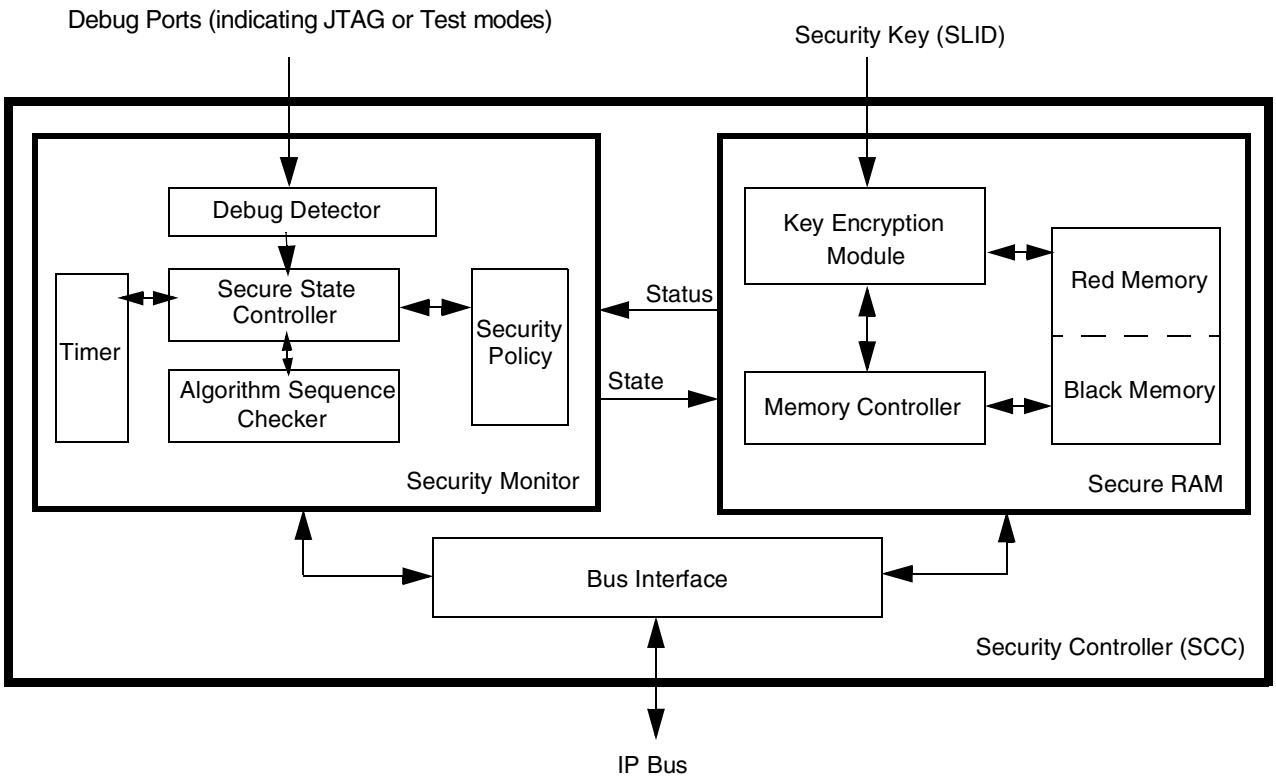

Figure 50-1. Security Controller Block Diagram

50.1 Overview

Security and security services, in an embedded or data processing platform, refer to the platform's ability to provide mandatory and optional information protection services. Information in this context refers to all embedded data, both program store and data load. Therefore, a secure platform is intended to protect information/data from unauthorized access in the form of inspection (read), modification (write), or execution (use).

NOTE

Detailed information about the SCC is provided in the i.MX51 Security Manual. Contact your Freescale representitive for information about obtaining this document.

Chapter 51
Subscriber Identification Module (SIM)

The subscriber identification module (SIM) is designed to facilitate communication to SIM cards or Eurochip pre-paid phone cards. The SIM module has two ports that can be used to interface with the various cards. See the SIM block diagram in Figure 51-1.

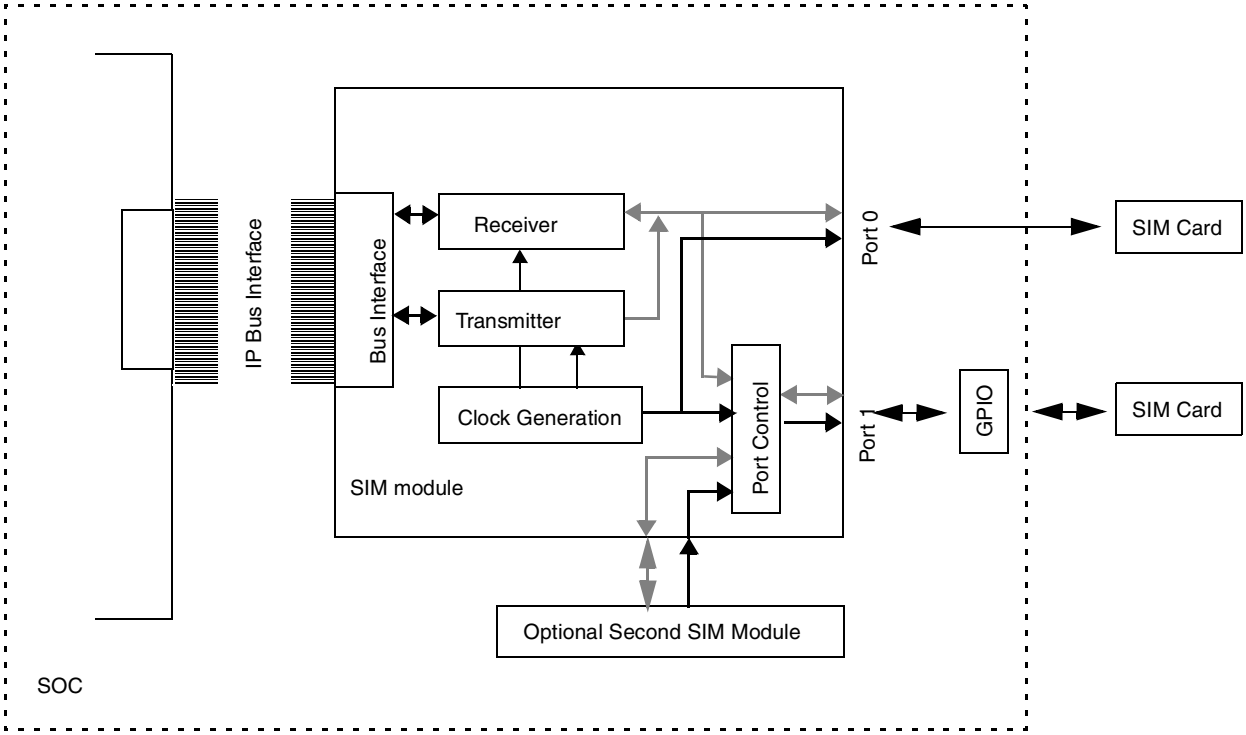

Figure 51-1. SIM Block Diagram

51.1 Overview

The SIM design is summarized in the following sections.

- Section 51.1.1, “Modes of Operation”
- Section 51.1.2, “SIM Bus Interface Overview”
- Section 51.1.3, “SIM Clock Generator Overview”
- Section 51.1.4, “SIM Transmitter Overview”
- Section 51.1.5, “SIM Receiver Overview”
- Section 51.1.6, “SIM Port Control Overview”
- Section 51.1.7, “SIM General Purpose Counter Overview”
- Section 51.1.8, “SIM LRC Block Overview”
- Section 51.1.9, “SIM CRC Block Overview”

51.1.1 Modes of Operation

The SIM module I/O interface can be operated in one of three modes of operation, as summarized below.

- Two wire interface

  In this mode both the IC pin RX and TX are used to interface to the SmartCard. This is activated by resetting the 3VOLTx bit in the port control register to a “0”.

- External one wire interface

  In this mode the IC pins RX and TX are tied together external to the IC and routed to the SmartCard. The 3VOLT bit in the port control register is reset to a “0” and the OD_Px bit in the OD_CONFIG register is set to a “1”. For this interface to work properly the IC pin (RX-TX) must be pulled high by a resistor. The value should be selected small enough to give a fast enough rise time.

- Internal one wire interface

  In this mode the IC pin TX is routed to the SmartCard. The receive pin RX is connected to the TX pin internal to the IC. The 3VOLTx bit in the port control register is reset to a “1” and the OD_Px bit in the OD_CONFIG register is set to a “1”. For this interface to work properly the IC pin TX must be pulled high by a resistor. The value should be selected small enough to give a fast enough rise time.

CAUTION

For the internal one wire interface to work, the bond pad must be capable of simultaneous input and output. The input path should not be disabled when the output is enabled.

51.1.2 SIM Bus Interface Overview

The SIM module is designed with a separate block that encompasses the interface to the IP Bus. The bus interface is built in such a way as to be easily modified to other bus definitions. The SIM module is to be considered a 32-bit peripheral. To avoid endian issues with register access, all read/writes should be done as word access(32 bit). The bus interface has the following features:

- Peripheral Address/chip select decoding
- Illegal Address generation
- Dynamic wait state generation (tied inactive)
- Register organization
- Register bit implementations

See Table 51-1 for summary of SIM top level interrupts.

Table 51-1. SIM Top Level Interrupt Summary

Flag	Interrupt Sources	Interrupt Masks	Description
SIMIRQ_N	XTE, OEF, SDI0, SDI1, TFO, GPCNT, BWT, BGT, CWT, RTE	XTM, OIM, SDIM0, SDIM1, TFOM, GPCNTM, BWTM, BGTM, CWTM, RTM	SIM General Interrupt
SIMDAT_N	TC, ETC, TFE, RDRF, TDTF, RFE	TCIM, ETCIM, TFEIM, RIM, TDTFM,RFEM	SIM Data Interrupt

51.1.3 SIM Clock Generator Overview

The SIM module contains a block designed specifically for generating the clocks used internal to the SIM module, and the clocks provided to the SIM cards. The clock generator has the following features:

- Programmable Divisor (CLK_PRESCALER[7:0]) for SIM card clock generation (***45%~55% duty cycle except for divider by 3, 5, 7, 9***)
- Receive clock generation (/1, /2, /4, /8, /16, /32, /31) from first stage
- Transmit clock generation (/12, /8) from second stage
- Programmable Divisor for Receive clock generation
- There are no interrupt sources generated by the SIM clock generator block

51.1.4 SIM Transmitter Overview

The SIM transmitter block contains the transmit state machine, transmit shift register, and transmit FIFO. The transmitter has the following features.

- 16 bytes deep transmit FIFO
- Automatic NACK generation on parity and overrun errors
- Hardware data format support (inverse convention or direct convention)
- Retransmission of data upon SIM card NACK request with programmable maximum threshold of retransmissions
- Programmable guard time between transmitted bytes
- Six interrupt sources (see Table 51-2)

Table 51-2. SIM Transmitter Interrupt Summary

Flag	Flag Register	Mask	Mask Register	Description
TC	XMT_STATUS	TCIM	INT_MASK	Transmit Complete
ETC	XMT_STATUS	ETCIM	INT_MASK	Early Transmit Complete
TFE	XMT_STATUS	TFEIM	INT_MASK	Transmit FIFO Empty
XTE	XMT_STATUS	XTM	INT_MASK	Transmit Threshold Error
TFO	XMT_STATUS	TFOM	INT_MASK	Transmit FIFO Overfill Error
TDTF	XMT_STATUS	TDTFM	INT_MASK	Transmit Data Threshold Flag

51.1.5 SIM Receiver Overview

The SIM Receiver block contains the receive state machine, receive FIFO, and control logic. The receiver has the following features.

- 288 bytes deep receive FIFO
- Decoding of initial character mode for setting data format
- Hardware data format support (inverse convention or direct convention)
- NACK detection

- 11 ETU character support
- Character Wait Time Counter
- Six interrupt sources (see Table 51-3)

Table 51-3. SIM Receiver Interrupt Summary

Flag	Flag register	Mask	Mask register	Description
BGT	RCV_STATUS	BGTM	INT_MASK	Block Guard Time flag
BWT	RCV_STATUS	BWTM	INT_MASK	Block Wait Time flag
RTE	RCV_STATUS	RTM	INT_MASK	Receive Nack threshold
CWT	RCV_STATUS	CWTM	INT_MASK	Character Wait Time flag
OEF	RCV_STATUS	OIM	INT_MASK	Overrun Error Flag
RDRF	RCV_STATUS	RIM	INT_MASK	Receive Data Register Full
RFE	RCV_STATUS	RFEM	INT_MASK	Receive Fifo Empty

51.1.6 SIM Port Control Overview

The SIM module supports numerous port control functions necessary for SIM card interaction. Each of the two SIM card ports has the following I/O: CLK, $\overline{\text{RST}}$, DATA_RCV, DATA_XMT, SIMPD (SIM Presence Detect), and SVEN (SIM Vcc enable). The following list gives a number of the important features of the port logic.

- Open-drain or push pull DATA_XMT pin
- Port 1, port 0, or alternate port selection
- SIM card presence detect with interrupt capability
- Deep sleep wake-up via SIM card presence detect interrupt
- Manual control of all SIM card interface signals
- Automatic power down of port logic on SIM card presence detect
- Two interrupt sources (see Table 51-4)

Table 51-4. SIM Card Detect Interrupts

Flag	Flag register	Mask	Mask Register	Description
SDI1	PORT1_DETECT	SDIM1	PORT1_DETECT	SIM Detect Interrupt for port 1
SDI0	PORT0_DETECT	SDIM0	PORT0_DETECT	SIM Detect Interrupt for port 0

51.1.7 SIM General Purpose Counter Overview

The SIM module provides a 16-bit counter that can be configured to count using clock sources from the card clock, receive clock, or transmitter clock (ETU Clock). A programmable 16-bit register is provided to compare with the counter for interrupt generation:

- Selectable clock source
- 16-bit counter and comparator

- One Interrupt source (see Table 51-5)

Table 51-5. SIM General Purpose Counter Interrupts

Flag	Flag Register	Mask	Mask Register	Description
GPCNT	XMT_STATUS	GPCNTM	INT_MASK	GPCNT Comparator Interrupt

51.1.8 SIM LRC Block Overview

The SIM module contains a block designed to generate linear redundancy checking (LRC) information for both received and transmitted characters. The LRC block has the following features:

- 8-bit LRC value
- Valid LRC Detector
- There are no interrupt sources generated by the SIM LRC block

51.1.9 SIM CRC Block Overview

The SIM module contains a block designed to generate cyclic redundancy checking (CRC) information for both received and transmitted characters. The CRC block has the following features:

- 16-bit CRC value
- 16-bit CRC Polynomial Generator
- Valid CRC Detector
- There are no interrupt sources generated by the SIM CRC block

51.2 External Signal Description

51.2.1 Overview

See Table 51-6 for summary of the SIM module signals.

Table 51-6. Signal Properties

Name	Port	Function	Reset State	Pull-up
External Signals (Pads)				
sim_pin_sclk0	out	Clock for the smartcard on port0	0	Active
sim_pin_srst0	out	Reset signal for port0	0	Active
sim_pin_sven0	out	Vcc enable signal for port0	0	Active
sim_pin_data0_tx_out	out	Transmit data signal for port0	0	Active/Passive
pin_sim_rcvd0_in	in	Receive data signal for port0	—	—
pin_sim_simpd0	in	Card insertion detect signal for port0	—	—
sim_pin_sclk1	out	Clock for the smartcard on port1	0	Active

Table 51-6. Signal Properties (continued)

Name	Port	Function	Reset State	Pull-up
sim_pin_srst1	out	Reset signal for port1	0	Active
sim_pin_sven1	out	Vcc enable signal for port1	0	Active
sim_pin_data1_tx_out	out	Transmit data signal for port1	0	Active/Passive
pin_sim_rcvd1_in	in	Receive data signal for port1	—	—
pin_sim_simpd1	in	Card insertion detect signal for port1	—	—
Module Interrupts				
ipi_int_sim_ipb_int	out	Active high SIM Interrupt. Composed of OEF, XTE, SDI1 and SDI0.	0	—
ipi_int_sim_data_irq	out	Active high SIM Data Interrupt. Composed of TC, ETC, TFE, and RDRF.	0	—
Module DMA Requests				
ipd_sim_tx_dmareq_b	out	Active low. Transmitter DMA request	1	—
ipd_sim_rx_dmareq_b	out	Active low. Receiver DMA request	1	—
Alternate SIM Signals				
sim_arcvd_in	out	Alternate Receive data line. Output to secondary SIM module	1	—
sim_asimpd	out	Alternate SIM presence detect line. Output to secondary SIM module	0	—
sim_aclk	in	Alternate SIM clock. Input from secondary SIM module	—	—
sim_arst	in	Alternate SIM reset line. Input from secondary SIM module	—	—
sim_adata_tx_out	in	Alternate transmit data line. Input from secondary SIM module	—	—
sim_adata_tx_gz	in	Alternate transmit tri-state control signal. Input from secondary SIM module	—	—
sim_aven	in	Alternate SIM vcc enable line. Input from secondary SIM module	—	—
sim_arcvd_io	out	I/O Alternate Receive data line. Output to secondary SIM module	1	—

51.2.2 Detailed Signal Descriptions

The following subsections discuss the signals.

51.2.2.1 sim_pin_sclk0

The sim_pin_sclk0 is an output from the chip to the SmartCard. This signal is the clock that the SIM module provides for the SmartCard. Typical frequencies are 1 MHz to 5 MHz. This clock is 372 times the data rate that is on pin sim_pin_data0_tx_out. There is no required timing relationship between this clock signal and any of the other data signals. This is because of the asynchronous nature of the protocol.

51.2.2.2 sim_pin_srst0

The sim_pin_srst0 is the reset signal from the SIM to the SmartCard.

51.2.2.3 sim_pin_sven0

The sim_pin_sven0 is the SmartCard power supply enable control signal.

51.2.2.4 sim_pin_data0_tx_out

The sim_pin_data0_tx_out is the data transmitted from the SIM module to the SmartCard. In a 1-wire mode of operating, this output port must be bidirectional with a pull-up resister off chip.

51.2.2.5 pin_sim_rcvd0_in

The pin_sim_rcvd0_in is the receive data coming from the SmartCard to the SIM module.

51.2.2.6 pin_sim_simpd0

The pin_sim_simpd0 is the SmartCard insertion detect.

51.2.2.7 sim_pin_sclk1

The sim_pin_sclk1 is an output from the chip to the smartcard. This signal is the clock that the SIM module provides for the smartcard. Typical frequencies are 1 MHz to 5 MHz. This clock is 372 times the data rate that is on pin sim_pin_data1_tx_out. There is no required timing relationship between this clock signal and any of the other data signals. This is because of the asynchronous nature of the protocol.

51.2.2.8 sim_pin_srst1

The sim_pin_srst1 is the reset signal from the SIM to the SmartCard.

51.2.2.9 sim_pin_sven1

The sim_pin_sven1 is the SmartCard power supply enable control signal.

51.2.2.10 sim_pin_data1_tx_out

The sim_pin_data1_tx_out is the data transmitted from the SIM module to the SmartCard. In a one wire mode of operating, this output port must be bidirectional with a pull-up resister off chip.

51.2.2.11 pin_sim_rcvd1_in

The pin_sim_rcvd1_in is the receive data coming from the SmartCard to the SIM module.

51.2.2.12 pin_sim_simpd1

The pin_sim_simpd1 is the SmartCard insertion detect.

51.2.2.13 ipg_enable_clk

The ipg_enable_clk is to control external ipg_clk gating when needed. SIM module has no dedicated signal to gating the ipg_perclk, but the Clock Controller module can synchronize ipg_enable_clk to ipg_perclk domain to gating ipg_perclk.

51.3 Memory Map and Register Definition

Section 51.3.3, “Register Descriptions” on page 51-XIII provides the detailed descriptions for all of the SIM registers.

51.3.1 Memory Map

Table 51-7 shows the SIM memory map.

Table 51-7. SIM Memory Map

Address	Register	Access	Reset Value	Section/Page
0x5001_8000 (PORT1_CNTL)	SIM Port1 Control register	R/W	0x0000_0000	51.3.3.1/51-XIII
0x5001_8004 (SETUP)	SIM Setup register	R/W	0x0000_0000	51.3.3.2/51-XV
0x5001_8008 (PORT1_DETECT)	SIM Port 1 Detect register	R/W	0x0000_— — — —	51.3.3.3/51-XVI
0x5001_800C (XMT_BUF)	SIM Transmit Buffer register	R/W	0x0000_0000	51.3.3.4/51-XVII
0x5001_8010 (RCV_BUF)	SIM Receive Buffer register	R	0x0000_0000	51.3.3.5/51-XVII
0x5001_8014 (PORT0_CNTL)	SIM Port0 Control register	R/W	0x0000_0000	51.3.3.6/51-XIX
0x5001_8018 (CNTL)	SIM Control register	R/W	0x0000_0006	51.3.3.7/51-XX
0x5001_801C (CLK_PRESCALER)	SIM Clock Prescaler register	R/W	0x0000_0002	51.3.3.8/51-XXII
0x5001_8020(RCV_THRESHOLD)	SIM Receive Threshold register	R/W	0x0000_0001	51.3.3.9/51-XXIII
0x5001_8024 (ENABLE)	SIM Enable register	R/W	0x0000_0000	51.3.3.10/51-XXIV

Table 51-7. SIM Memory Map (continued)

Address	Register	Access	Reset Value	Section/Page
0x5001_8028 (XMT_STATUS)	SIM Transmit Status register	R/W	0x0000_00B8	51.3.3.11/51-XXV
0x5001_802C (RCV_STATUS)	SIM Receive Status register	R/W	0x0000_0040	51.3.3.12/51-XXVII
0x5001_8030 (INT_MASK)	SIM Interrupt Mask register	R/W	0x0000_1FFF	51.3.3.13/51-XXIX
0x5001_803C (PORT0_DETECT)	SIM Port0 Detect register	R/W	0x0000_— — — —	51.3.3.14/51-XXXI
0x5001_8040 (DATA_FORMAT)	SIM Data Format register	R/W	0x0000_0000	51.3.3.15/51-XXXII
0x5001_8044(XMT_THRESHOLD)	SIM Transmit Threshold register	R/W	0x0000_0000	51.3.3.16/51-XXXIII
0x5001_8048 (GUARD_CNTL)	SIM Transmit Guard Control register	R/W	0x0000_0000	51.3.3.17/51-XXXIV
0x5001_804C (OD_CONFIG)	SIM Open Drain Configuration Control register	R/W	0x0000_0000	51.3.3.18/51-XXXV
0x5001_8050 (RESET_CNTL)	SIM Reset Control register	R/W	0x0000_0000	51.3.3.19/51-XXXVI
0x5001_8054 (CHAR_WAIT)	SIM Character Wait Time register	R/W	0x0000_FFFF	51.3.3.20/51-XXXVII
0x5001_8058 (GPCNT)	SIM General Purpose Counter register	R/W	0x0000_FFFF	51.3.3.21/51-XXXVIII
0x5001_805C (DIVISOR)	SIM Divisor register	R/W	0x0000_00FF	51.3.3.22/51-XXXIX
0x5001_8060 (BWT)	SIM Block Wait Time register	R/W	0x0000_FFFF	51.3.3.23/51-XXXIX
0x5001_8064 (BGT)	SIM Block Guard Time register	R/W	0x0000_0000	51.3.3.24/51-XL
0x5001_8068 (BWT_H)	SIM Block Wait Time register HIGH	R/W	0x0000_FFFF	51.3.3.25/51-XLI
0x5001_806C (XMT_FIFO_STAT)	SIM Transmit FIFO Status register	R	0x0000_0000	51.3.3.26/51-XLII
0x5001_8070 (RCV_FIFO_CNT)	SIM Receive FIFO Counter register	R	0x0000_0000	51.3.3.27/51-XLIII
0x5001_8074 (RCV_FIFO_WPTR)	SIM Receive FIFO Write Pointer register	R	0x0000_0000	51.3.3.28/51-XLIV
0x5001_8078 (RCV_FIFO_RPTR)	SIM Receive FIFO Read Pointer register	R	0x0000_0000	51.3.3.29/51-XLV

51.3.2 Register Summary

Figure 51-2 shows the key to the register fields and Table 51-8 shows the register figure conventions.

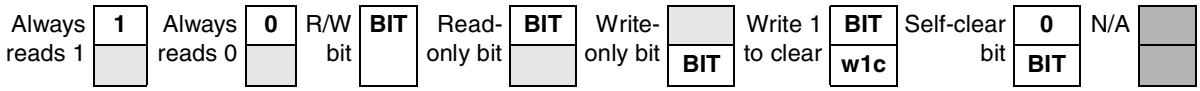

Figure 51-2. Key to Register Fields

Table 51-8. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 51-9 shows SIM register summary.

51.3.3 Register Descriptions

This section contains the detailed descriptions for the SIM registers.

51.3.3.1 SIM Port1 Control Register (PORT1_CNTL)

See Figure 51-3 for illustration of valid bits in the SIM Port1 Control Register and Table 51-10 for description of the bit fields.

0x5001_8000 (PORT1_CNTL) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 51-3. SIM Port1 Control Register

Table 51-10. SIM Port1 Control Register Field Descriptions

Field	Description
31–8	Reserved
7 SFPD1	Auto Power Down port1. Writing a “1” to this location will start the auto power down sequence for port 1. This bit will autoclear. A read of this bit will give a “0”. 0 No effect 1 Start Auto Power down
6 3VOLT1	External one wire interface for SIM Card port1. Used to configure the Port 1 transmit pin as bi-directional. This allows the Port 1 Receive pin to be re-used as General Purpose I/O. This operation is restricted to bi-directional data SIM cards only. This bit should not be changed while the receiver or transmitter is enabled! 0 Port1 uses both RCV and XMT pins 1 Port1 XMT pin bidirectional. Port1 RCV PIN unused
5 SCSP1	SIM Card Clock Stop Polarity Port1. Used to control the polarity of the idle SIM clock when the clock is disabled by SCEN1. It will be forced low by hardware during the auto power down sequence. This forces the clock be a logic 0 when stopped by auto power down as required by ISO 7816 spec. 0 Clock is logic 0 when stopped by SCEN1 1 Clock is logic 1 when stopped by SCEN1
4 SCEN1	SIM card Clock Enable Port 1. Used to enable/disable the clock to the SIM card. It can be forced low by hardware during the auto power down sequence. 0 SIM Card Clock Enabled Port1 1 SIM Card Clock Disabled Port1
3 SRST1	SIM card Reset. Used to control state of reset line to the SIM card. It can be forced low by hardware during the auto power down sequence. SIM card reset signals are active low. 0 SIM Card reset Port1 inactive (default) 1 SIM Card reset Port1 active
2 STEN1	SIM card Transmit Enable Port 1. Used to enable/disable the XMT data to the SIM card. It can be forced low by hardware during the auto power down sequence. 0 Port1 Transmit Data is forced to zero (default) 1 Port 1 Transmit Data controlled by SIM module

Table 51-10. SIM Port1 Control Register Field Descriptions (continued)

Field	Description
1 SVEN1	SIM card Vcc Enable Port 1. Used to control the state of the SVEN1 pin on SIM card port 1. The SVEN1 pin controls the SIM card Vcc enable in the power management chip. It can be forced low by hardware during the auto power down sequence. 0 SIM card Voltage Port 1 disabled (default) 1 SIM card Voltage Port 1 enabled
0 SAPD1	SIM card Auto Power Down Port 1. Used to enable/disable the auto power down function for port 1. It will be forced low at the end of the auto power down sequence. 0 Auto power down Port 1 disabled (default) 1 Auto power down Port 1 enabled

51.3.3.2 SIM Setup Register (SETUP)

See Figure 51-4 for illustration of valid bits in the SIM Setup Register and Table 51-11 for description of the bit fields.

Figure 51-4. SIM Setup Register

Table 51-11. SIM Setup Register Field Descriptions

Field	Description
31–2	Reserved
1 SPS	SIM card Port Select. Controls which port the SIM interface uses. **Note:** The AMODE bit must be zero when the SPS bit is set to 1. 0 Port 0 Enabled (default) 1 Port 1 Enabled
0 AMODE	Alternate SIM Card Mode enable. Enables an alternate SIM module to control SIM card Port 1. **Note:** The SPS bit must be 0 to give the alternate SIM module control. 0 Alternate Port Disabled (default) 1 Alternate Port Enabled

51.3.3.3 SIM Port1 Detect Register (PORT1_DETECT)

See Figure 51-5 for illustration of valid bits in the SIM Port1 Detect Register and Table 51-12 for a detailed description of the bit fields. A summary is as follows:

SPDS1 determines which edge transition of the SIMPD1 pin is used for SIM card presence detection. Presence detection can be used to determine if the card has been inserted or removed. The occurrence of the SIMPD1 edge specified by SPDS1 causes the following:

- SDI1 is set.
- If the SDIM1 mask is clear, an interrupt on SIMIRQ_N
- If SAPD1 in the PORT1_CNTL register is set, an auto power down sequence begins.

If SIM card insertion is expected, SAPD1 can be set low to avoid the auto-power-down sequence. There is no auto-power-up sequence. The bit SPDP1 can be used to determine the current state of the SIMPD1 pin.

0x5001_8008 (PORT1_DETECT) Access: User read/write

Table 51-12. SIM Port 1 Detect Register Field Descriptions

Field	Description
31–4	Reserved
3 SPDS1	SIM Presence Detect Select Port 1. Controls which edge of the SIMPD1 pin is used to detect the presence of the SIM card. 0 Falling edge of SIMPD1 Input (default) 1 Rising edge of SIMPD1 Input
2 SPDP1	SIMPD1 input pin status. This bit reflects the state of the SIMPD1 pin. It is not a latched register bit, but instead a synchronized version of the state of the SIMPD1 pin itself. 0 SIMPD1 pin is logic low 1 SIMPD1 pin is logic high

Table 51-12. SIM Port 1 Detect Register Field Descriptions (continued)

Field	Description
1 SDI1	SIM Detect Interrupt Flag Port 1. Status flag to indicate the insertion or removal of a SIM card has been detected on port 1. Can create an interrupt to the MCU if SDIM1 is low. Write a “1” to this bit to clear. 0 No insertion or removal of SIM card detected on Port 1(default) 1 Insertion or removal of SIM card detected on Port 1
0 SDIM1	SIM Detect Interrupt Mask Port 1. Interrupt mask for the SDI1 interrupt flag. 0 SDI1 enabled 1 SDI1 masked (default)

51.3.3.4 SIM Transmit Buffer Register (XMT_BUF)

See Figure 51-6 for illustration of valid bits in the SIM Transmit Buffer Register and Table 51-13 for description of the bit fields.

0x5001_800C (XMT_BUF) Access: User read/write

Figure 51-7. SIM Port 1 Receive Buffer Register

Table 51-14. SIM Port 1 Receive Buffer Register Field Descriptions

Field	Description
31–11	Reserved
10 CWT	CWT flag. The CWT indicates that this byte was late. It is not necessary to clear the byte since it is overwritten by the next byte received into that location of the FIFO. 0 Byte was on time 1 Byte was late
9 FE	Frame Error flag. The FE flag indicates whether a frame error was detected during the reception of the corresponding byte read in the RCV field. The FE flag cannot create an interrupt. It need not be cleared since it will be overwritten by the next byte received into that location of the FIFO. 0 Byte contains no framing error (default) 1 Byte contains a framing error
8 PE	Parity Error flag. The FE flag indicates whether a parity error was detected during the reception of the corresponding byte read in the RCV field. The PE flag cannot create an interrupt. It need not be cleared since it will be overwritten by the next byte received into that location of the FIFO. A parity error can create a NACK pulse. 0 Byte contains no parity error (default) 1 Byte contains a parity error
7–0 RCV	Receive buffer. Read from the next location in the receive buffer. Reads from this register return zero when the SPS bit is zero.

51.3.3.6 SIM Port0 Control Register (PORT0_CNTL)

Figure 51-8. SIM Port0 Control Register

Table 51-15. SIM Port0 Control Register Field Descriptions

Field	Description
31–8	Reserved
7 SFPD0	Auto Power Down port0. Writing a “1” to this location will start the auto power down sequence for port 0. This bit will autoclear.A read of this bit will give a “0”. 0 No effect 1 Start Auto Power down
6 3VOLT0	External one wire interface for SIM Card port0. Used to configure the Port 0 transmit pin as bi-directional. This allows the Port 0 Receive pin to be re-used as General Purpose I/O. This operation is restricted to bi-directional data SIM cards only. This bit should not be changed while the receiver or transmitter is enabled! 0 Port0 uses both RCV and XMT pins 1 Port0 XMT pin bidirectional. Port0 RCV pin unused
5 SCSP0	SIM Card Clock Stop Polarity port0. Used to control the polarity of the idle SIM clock when the clock is disabled by SCEN0. It will be forced low by hardware during the auto power down sequence. This forces the clock to be a logic 0 when stopped by auto power down as required by ISO 7816 spec. 0 Clock is logic 0 when stopped by SCEN0 1 Clock is logic 1 when stopped by SCEN0
4 SCEN0	SIM card Clock Enable Port 0. Used to enable/disable the clock to the SIM card. It can be forced low by hardware during the auto power down sequence. 0 SIM Card Clock Disabled Port 0 1 SIM Card Clock Enabled Port 0
3 SRST0	SIM card Reset. Used to control state of reset line to the SIM card. It can be forced low by hardware during the auto power down sequence. SIM card reset signals are active low. 0 SIM Card reset Port0 inactive (default) 1 SIM Card reset Port0 active

Table 51-15. SIM Port0 Control Register Field Descriptions (continued)

Field	Description
2 STEN0	SIM card Transmit Enable Port 0. Used to enable/disable the XMT data to the SIM card. It can be forced low by hardware during the auto power down sequence. 0 Port0 Transmit Data is forced to zero (default) 1 Port 0 Transmit Data controlled by SIM module
1 SVEN0	SIM card Vcc Enable Port 0. Used to control the state of the SVEN0 pin on SIM card port 0. The SVEN0 pin controls the SIM card Vcc enable in the power management chip. It can be forced low by hardware during the auto power down sequence. 0 SIM card Voltage Port 0 disabled (default) 1 SIM card Voltage Port 0 enabled
0 SAPD0	SIM card Auto Power Down Port 0. Used to enable/disable the auto power down function for port 0. It will be forced low at the end of the auto power down sequence. 0 Auto power down Port 0 disabled (default) 1 Auto power down Port 0 enabled

51.3.3.7 SIM Control Register (CNTL)

See Figure 51-9 for illustration of valid bits in the SIM Control Register and Table 51-16 for description of the bit fields.

Figure 51-9. SIM Control Register

Table 51-16. SIM Control Register Field Descriptions

Field	Description
31–16	Reserved
15 BWTEN	Block wait time enable. Writing a “1” to this bit will enable the BWT and BGT functions. The BWT and BGT functions can then be individually selected using the interrupt mask. 0 Disable BWT, BGT 1 Enable BWT, BGT

Table 51-16. SIM Control Register Field Descriptions (continued)

Field	Description
14 XMT_CRC_LRC	Transmit CRC or LRC. This bit specifies whether or not to transmit the redundancy checking data at the end of a transmission (that is, when the FIFO becomes empty). 0 No Redundancy check info transmitted (default) 1 Transmit LRC or CRC info when FIFO empties (whichever is enabled)
13 CRCEN	CRC Enable. This bit enables the calculation of the 16-bit CRC value for both receiver and transmitter. The result of the calculation is continuously compared to the expected remainder and reflected in the CRCOK bit in the RCV_STAT register. Clearing this bit resets the current CRC residual value in the SIM hardware. 0 16-bit Cyclic Redundancy Checking disabled (default) 1 16-bit Cyclic Redundancy Checking enabled
12 LRCEN	LRC Enable. This bit enables the calculation of the 8-bit LRC value for both receiver and transmitter. The result of the calculation is continuously compared to zero and reflected in the LRCOK bit in the RCV_STAT register. Clearing this bit resets the current LRC value in the SIM hardware. 0 8-bit Linear Redundancy Checking disabled (default) 1 8-bit Linear Redundancy Checking enabled
11 CWTEN	Character Wait Time Counter Enable. Enables the character wait time counter. Clearing this bit resets the counter to zero. 0 Character Wait time Counter off (default) 1 Character Wait time counter on
10–9 GPCNT_CLK_SEL[1:0]	General Purpose Counter Clock Select. Selects which clock source is used by SIM Module general purpose counter. The only way to reset the counter is to set these bits to zero. The counter will begin counting as soon as the clock input is selected and the clocks are enabled. These input clocks are enabled through other register bits of the SIM module (KILL_CLOCK, RCV_EN, and XMT_EN respectively). 00 Disabled / Reset 01 Card Clock 10 Receive Clock 11 ETU Clock (transmit clock)
8–6 BAUD_SEL[2:0]	SIM Baud Rate Select. Selects the asynchronous baud rate divisor of the clock When set to “111”, the divisor is set to the value programmed in the DIVISOR register. This allows for more flexible baud rate determination. 000 31 (372/1 Fi/Di) 001 32 (512/2 Fi/Di) 010 16 (512/4 Fi/Di) 011 8 (512/8 Fi/Di) 100 4 (512/16 Fi/Di) 101 2 (512/32 Fi/Di) 110 1 (512/64 Fi/Di) 111 DIVISOR Reg
5	Reserved
4 SAMPLE12	Sample12. Set the third stage divider. This sets the corresponding sample rate which is the number of times a bit being received is sampled. 0 divide by 8(default) 1 divide by 12
3 ONACK	Overrun NACK Enable. Enables overrun NACK generation. 0 NACK generation on overrun is disabled (default) 1 NACK generation on overrun is enabled

Table 51-16. SIM Control Register Field Descriptions (continued)

Field	Description
2 ANACK	Automatic NACK Enable. Enables nack generation for parity errors or invalid initial characters when in ICM mode. 0 NACK generation on errors disabled 1 NACK generation on errors enabled (default)
1 ICM	Initial Character Mode. Enables initial character mode. Will be automatically cleared by hardware once a valid initial character is received. 0 Initial Character Mode disabled 1 Initial Character Mode enabled (default)
0	Reserved

51.3.3.8 SIM Clock Prescaler Register (CLK_PRESCALER)

See Figure 51-10 for illustration of valid bits in the SIM Clock Prescaler Register and Table 51-17 for description of the bit fields.

Figure 51-10. SIM Clock Prescaler Register

Table 51-17. SIM Clock Prescaler Register Field Descriptions

Field	Description
31–8	Reserved
7–0 CLK_PRESCALER	Clock prescaler divisor register. The value written to this register will determine the first stage divider setting. If the ipg_perclk is 66Mhz, a typical setting would be 0x0e. This would set the SIM card clock to 66Mhz/14 = 4.7Mhz. The duty cycle of divided clock will be between 45% and 55% according to ISO7816 requirement. For the odd divider factor (2K+1), the duty cycle will be K/(2K+1) and (K+1)/(2k+1). So for 0x03, the duty cycle is 33%-66%. For 0x05, the duty cycle is 40%-60%. For 0x07, the duty cycle is 43%-57%, and for 0x09, the duty cycle is 44%-56%. For all other values, the clock duty cycle can meet the ISO7816 requirement. 0x00~0x02 ipg_perclk/ 2 0x03 ipg_perclk / 3 0x04 ipg_perclk / 4 0x05 ipg_perclk / 5 0x06 ipg_perclk / 6 ... 0xFD ipg_perclk / 253 0xFE ipg_perclk / 254 0xFF ipg_perclk / 255

51.3.3.9 SIM Receive Threshold Register (RCV_THRESHOLD)

See Figure 51-11 for illustration of valid bits in the SIM Receive Threshold Register and Table 51-18 for description of the bit fields.

Figure 51-11. SIM Receive Threshold Register

Table 51-18. SIM Receive Threshold Register Field Descriptions

Field	Description
31–13	Reserved

Table 51-18. SIM Receive Threshold Register Field Descriptions (continued)

Field	Description
12–9 RTH[3:0]	Receive Nack Threshold. Used to specify the number of consecutive NACK's transmitted by the SIM module, for a given character, before the receive threshold error (RTE) flag is triggered. A value of 0 indicates that RTE is never set. When a valid character is received by the SIM, the internal counter keeping track of the NACK count resets to zero for the subsequent byte being received. If the ANACK bit is clear in the CNTL register, RTH has no effect.
8–0 RDT[8:0]	Receive Data Threshold. Determines the number of unread bytes that must exist in the FIFO to trigger the receive data register full (RDRF) interrupt flag. If the number of unread bytes in the receive FIFO is greater than or equal to the value in RDT, the RDRF flag in the RCV_STATUS register will be set. A value of zero indicates that there must be 288 unread bytes in the FIFO to trigger RDRF. The RDT value can be altered at any time, and the RDRF flag will be updated accordingly. If a value of more than 288 is entered in this register, the register value will remain 288.

51.3.3.10 SIM Enable Register (ENABLE)

See Figure 51-12 for illustration of valid bits in the SIM Enable Register and Table 51-19 for description of the bit fields.

Figure 51-12. SIM Enable Register

Table 51-19. SIM Enable Register Field Descriptions

Field	Description
31–2	Reserved
3 TXDMA_EN	Transmitter DMA Enable. This bit allows SIM to request for DMA transfers. When enabled, DMA requests are generated when the number of bytes in the transmit FIFO is less than or equal to the value programmed in the TDT[3:0] bits in the XMT_THRESHOLD register and XMT_EN is set. 0 SIM Transmitter DMA requests disabled. 1 SIM Transmitter DMA requests enabled.
2 RXDMA_EN	Receiver DMA Enable. This bit allows SIM to request for DMA transfers. When enabled, DMA requests are generated when the number of bytes in the receive FIFO is more than or equal to the value programed in the RDT[8:0] in the RCV_THRESHOLD register and RCV_EN is set 0 SIM Receiver DMA request disabled. 1 SIM Receiver DMA request enabled.

Table 51-19. SIM Enable Register Field Descriptions (continued)

Field	Description
1 XMT_EN	SIM Transmit Enable. Used to enable/disable the SIM transmit state machine. When the SIM is being used to receive data, XMT_EN should be deasserted. This bit also enables the xmt_clk and rcv_clk inputs to the General Purpose Counter. **Note:** Setting this bit (transition from 0 to 1) will reset the CRC and LRC values. 0 SIM Transmitter disabled (default) 1 SIM Transmitter enabled
0 RCV_EN	SIM Receiver Enable. Used to enable/disable the SIM receive state machine. The RCV_EN bit should be left high whenever the SIM module is in use. The SIM module has an automatic receive mode operation that disables the reception of characters when the transmitter is operational. Once the transmitter has completed sending the last character, the receiver is automatically enabled. This bit also enables the RCV_CLK input to the General Purpose Counter. 0 SIM Receiver disabled (default) 1 SIM Receiver enabled

51.3.3.11 SIM Transmit Status Register (XMT_STATUS)

See Figure 51-13 for illustration of valid bits in the SIM Transmit Status Register and Table 51-20 for description of the bit fields.

0x5001_8028 (XMT_STATUS) Access: User read/write

Figure 51-13. SIM Transmit Status Register

Table 51-20. SIM Transmit Status Register Field Descriptions

Field	Description
31–9	Reserved
8 GPCNT	General purpose Counter Flag. Used to indicate when the General purpose counter has reached the value in the GPCNT register. 0 GPCNT time not reached, or bit has been cleared. (default). 1 General Purpose counter has reached the GPCNT value.

Table 51-20. SIM Transmit Status Register Field Descriptions (continued)

Field	Description
7 TDTF	Transmit Data Threshold Flag. Used to indicate when the number of bytes in the transmit FIFO is less than or equal to the value programmed in the TDT[3:0] bits in the XMT_THRESHOLD register. 0 Number of bytes in FIFO is greater than TDT[3:0], or bit has been cleared. 1 Number of bytes in FIFO is less than or equal to TDT[3:0] (default)
6 TFO	Transmit FIFO Overfill Error. Used to indicate when the Transmit FIFO has been written with more than 16 bytes. The TFO bit can only be cleared by setting the FLUSH_XMT or SOFT_RESET bit in the RESET_CNTL register. 0 No transmit FIFO overfill error has occurred (default). 1 A Transmit FIFO overfill error has occurred.
5 TC	Transmit Complete. Used to indicate whether the SIM transmitter is ready for a new transmission. The TC flag becomes set after the guard time has expired for the last byte in the transmit FIFO. The TC flag will create an interrupt if TCIM in the INT_MASK register is low. The TC bit is a write-one-to-clear bit. 0 Transmit pending or in progress 1 Transmit complete (default)
4 ETC	Early Transmit Complete. Used to indicate that the SIM transmitter has finished sending the current byte and the transmit FIFO is empty. This bit differs from the TC bit in that it is set before the guard time of the last byte has elapsed. The ETC flag will create an interrupt if ETCIM in the INT_MASK register is low. The ETC bit is a write-one-to-clear bit. 0 Transmit pending or in progress 1 Transmit complete (default)
3 TFE	Transmit FIFO Empty. Used to indicate that the SIM transmit FIFO has emptied. This bit will be set when the last byte in the transmit FIFO has been transferred to the SIM transmitter shift register. The TFE flag will create an interrupt if TFEIM in the INT_MASK register is low. The TFE bit is a write-one-to-clear bit. 0 Transmit FIFO is not empty 1 Transmit FIFO is empty (default)
2–1	Reserved
0 XTE	Transmit NACK Threshold Error. Used to indicate the transmit NACK threshold has been reached. When XTE is high, no further transmissions will be done until the XTE flag is cleared. Any data transmissions still pending in the transmit FIFO will be aborted, and the TC, ETC, and TFE flags will be set. The XTE flag will create an interrupt if XTM in the IMT_MASK register is low. The XTE bit is a write-one-to-clear bit. 0 Transmit NACK threshold has not been reached (default) 1 Transmit NACK threshold reached; transmitter frozen

51.3.3.12 SIM Receive Status Register (RCV_STATUS)

Figure 51-14. SIM Receive Status Register

Table 51-21. SIM Receive Status Register Field Descriptions

Field	Description
31–12	Reserved
11 BGT	Block guard time error flag. Used to indicate if the block guard time was too small. The threshold is set by the block guard time register. 0 Block guard time was sufficient. 1 Block guard time was too small.
10 BWT	Block wait time error flag. Used to indicate if the block wait time has been exceeded. The threshold is set by the block wait time registers. 0 Block wait time not exceeded. 1 Block wait time was exceeded.
9 RTE	Receive NACK threshold error flag. Used to indicate whether the number of consecutive NACK's generated by the SIM module in response to receive parity errors, for the byte being received, equals the value programmed in the RTH[3:0] in the RCV_THRESHOLD register. This bit would never be set unless the ANACK bit is set in the CNTL register. The SAPDx bit in the PORTx_CNTL resister must be set to enable the threshold error to trigger the auto power down sequence. RTE is a write once to clear bit. Clearing this bit also resets the internal counter for consecutive NACK's being transmitted for a given byte. 0 Number of NACKs generated by the receiver is less than the value programmed in RTH[3:0] 1 Number of NACKs generated by the receiver is equal to the value programmed in RTH[3:0]
8 CWT	Character Wait Time Counter Flag. Used to indicate when the time between received characters is equal to or greater than the value programmed in the CHAR_WAIT register. 0 No CWT violation has occurred (default). 1 Time between two consecutive characters exceeded the value in CHAR_WAIT.

Table 51-21. SIM Receive Status Register Field Descriptions (continued)

Field	Description
7 CRCOK	Cyclic Redundancy Check Okay flag. Used to indicate when the calculated 16-bit CRC value matches the expected value for the current input data stream. The value is calculated across all received characters from the point the CRCEN bit is set in the CNTL register. The current CRC residual can be reset by three mechanisms: • Clear CRCEN bit in CNTL register • Set XMT_EN bit in ENABLE register • Automatically by hardware when ETC flag is set at the end of a transmission. 0 Current CRC value does not match remainder. 1 Current calculated CRC value matches the expected result.
6 LRCOK	Linear Redundancy Check Okay flag. Used to indicate when the calculated 8-bit LRC value is zero value for the current input data stream. The value is calculated across all received characters from the point the LRCEN bit is set in the CNTL register. The current LRC residual can be reset by three mechanisms: • Clear LRCEN bit in CNTL register • Set XMT_EN bit in ENABLE register • Automatically by hardware when ETC flag is set at the end of a transmission. 0 Current LRC value does not match remainder. 1 Current calculated LRC value matches the expected result (that is, zero).
5 RDRF	Receive Data Register Full. Used to indicate when the number of bytes in the receive FIFO is more than or equal to the value programed in the RDT[8:0] in the RCV_THRESHOLD register. 0 Number of unread bytes in receive buffer < value set by RDT[8:0] (default), or bit has been cleared. 1 Number of unread bytes in receive buffer >= value set by RDT[8:0].
4 RFD	Receive FIFO has unread Data. Used to indicate that there is at least one unread byte in the receive data FIFO. Can only be cleared by reading all bytes out of the receive FIFO. The RFD bit cannot be used to create an interrupt. Normally, the SIM triggers the interrupt with RDRF and software uses RFD to read all of the bytes out of the receive FIFO. 0 There are no unread bytes in the receive FIFO (default). 1 There is at least one unread byte in the receiver FIFO.
3–2	Reserved
1 RFE	Receive FIFO Empty. Used to indicate that the SIM receive FIFO has emptied. This bit will be set when the last byte in the receive FIFO has been transferred to the IPS bus. The RFE flag will create an interrupt if RFEIM in the INT_MASK register is low. The RFE bit is a write-one-to-clear bit. 0 Receive FIFO is not empty 1 Receive FIFO is empty (default)
0 OEF	Overrun Error Flag. Used to indicate that the SIM was unable to store received data due to already having 288 unread bytes in the FIFO. It does not necessarily indicate that data has been lost. If the ONACK control bit in the CNTL register is set, there will be a NACK pulse generated on bytes that would otherwise cause a loss of data due to a full FIFO. These bytes should be retransmitted by the SIM card which implies that no data has actually been lost. In this case, the OEF flag is just an indicator that this situation has occurred which may be helpful in system debug. For the case where ONACK is not set, a set OEF flag does indicate a loss of data since all bytes received with the OEF flag set will indeed be lost (including the byte that caused the bit to be set). The OEF flag will cause an interrupt if the OIM bit in the INT_MASK register. The OEF flag is a write-one-to-clear bit. 0 No overrun error has occurred (default). 1 A byte was received when the received FIFO was already full.

51.3.3.13 SIM Interrupt Mask Register (INT_MASK)

Field	Description
31–4	Reserved
3 SPDS0	SIM Presence Detect Select Port 0. Controls which edge of the SIMPD0 pin is used to detect the presence of the SIM card. 0 Falling edge of SIMPD0 Input (default) 1 Rising edge of SIMPD0 Input
2 SPDP0	SIMPD0 input pin status. This bit reflects the state of the SIMPD0 pin. It is not a latched register bit, but instead a synchronized version of the state of the SIMPD0 pin itself. 0 SIMPD0 pin is logic low 1 SIMPD0 pin is logic high
1 SDI0	SIM Detect Interrupt flag Port 0. Status flag to indicate the insertion or removal of a SIM card has been detected on port 0. Can create an interrupt to the MCU if SDIM0 is low. Write a “1” to this bit to clear. 0 No insertion or removal of SIM card detected on Port 0 (default) 1 Insertion or removal of SIM card detected on Port 0
0 SDIM0	SIM Detect Interrupt Mask Port 0. Interrupt mask for the SDI0 interrupt flag. 0 SDI0 enabled 1 SDI0 masked (default)

51.3.3.15 SIM Data Format Register (DATA_FORMAT)

See Figure 51-17 for illustration of valid bits in the SIM Data Format Register and Table 51-24 for description of the bit fields.

Figure 51-18. SIM Transmit Threshold Register

Table 51-25. SIM Transmit Threshold Register Field Descriptions

Field	Description
31–8	Reserved
7–4 XTH[3:0]	Transmit NACK Threshold. Used to set the NACK threshold for the transmitter. Once the threshold number set by XTH has been reached for the current byte being transmitted, the error flag XTE in the XMT_STATUS register will be set. Setting of XTE causes the remaining transmissions queued in the transmit FIFO to be aborted and no more transmissions to occur until software clears XTE. To trigger XTE, a given byte being transmitted must reach the XTH threshold itself. Transmit NACKs accumulated on one byte are not carried over to the next. 0x0XTE will never be set; retransmission after NACK reception is disabled. 0x1XTE will be set after 1 nack is received; 0 retransmissions occurs. 0x2XTE will be set after 2 nacks are received; at most 1 retransmission occurs. 0x3XTE will be set after 3 nacks are received; at most 2 retransmissions occurs. ... ... 0xXXTE will be set after X nacks are received; at most (X - 1) retransmissions occurs. ... ... 0xFXTE will be set after 15 nacks are received; at most 14 retransmissions occurs.
3–0 TDT	Transmit Data Threshold. Used to set the threshold value for the Transmit FIFO at which the TDTF bit in the XMT_STATUS register will be set. When the number of bytes in the Transmit FIFO is less than or equal to TDT[3:0], TDTF will be set.

51.3.3.17 SIM Transmit Guard Control Register (GUARD_CNTL)

See Figure 51-19 for illustration of valid bits in the SIM Transmit Guard Control Register and Table 51-26 for description of the bit fields.

0x5001_8048 (GUARD_CNTL) Access: User read/write

Figure 51-19. SIM Transmit Guard Control Register

Table 51-26. SIM Transmit Guard Control Register Field Descriptions

Field	Description
31–9	Reserved
8 RCVR11	Receiver use 11 ETUs. Used to configure the SIM module receiver for 11 ETU operation (that is, 1 Stop bit). This bit is provided for support of T=1 cards. 0 Receiver configured for 12 ETU operation (default) 1 Receiver configured for 11 ETU operation
7–0 GETU	Transmit Guard ETUs. Used to control the number of additional Elementary Time Units (ETUs) inserted between bytes transmitted by the SIM transmitter. An ETU is equivalent to one bit time at the given baud rate (for example, the length of a START bit). The guard time has no effect on the SIM receiver. A value of 0x00 inserts no additional ETUs, while a value of 0xFE inserts 254 additional ETUs. A value of 0xFF subtracts one ETU by reducing the number of STOP bits from two to one.

51.3.3.18 SIM Open Drain Configuration Control Register (OD_CONFIG)

See Figure 51-20 for illustration of valid bits in the SIM Open Drain Configuration Control Register and Table 51-27 for description of the bit fields.

Figure 51-21. SIM Reset Control Register

Table 51-28. SIM Reset Control Register Field Descriptions

Field	Description
31–7	Reserved
6 DBUG	DEBUG. Used to configure the operation of the SIM module when a debug event occurs. When set, a debug event (generated by such causes as OnCE module and external control) will make the receive FIFO read pointer to be frozen. 0 Debug event has no affect on SIM module (default). 1 Debug event prohibits read pointer changes for receive FIFO.
5 STOP	STOP. Used to configure the operation of the SIM module when a processor STOP instruction is executed. This bit is added to provide support for SIM cards that do not allow the SIM Card clock to be stopped while power is applied. See Figure 51-37. 0 STOP instruction shuts down all SIM clocks (default). 1 STOP instruction shuts down all clocks except for the BAUD_CLK (clock provided to SIM Card).
4 DOZE	DOZE. Used to configure the operation of the SIM module when a processor DOZE instruction is executed. See Figure 51-37. 0 DOZE instruction has no effect on SIM module (default). 1 DOZE instruction will cause SIM module to gate SIM clocks when the transmit FIFO is empty.
3 KILL_CLOCK	Kill SIM Clock. Used to enable/disable the SIM clock input to the SIM module. This bit will gate all SIM clocks including the SIM card clock regardless of the state of the STOP bit described above. 0 SIM input clock enabled (default). 1 SIM input clock disabled.
2 SOFT_RST	Software Reset. Used to reset the entire SIM module. This acts the same as a hardware reset for the SIM module. This bit is self-clearing. **Note:** Software should allow a minimum of 4 reference clock cycles (CKIH) before attempting to access the SIM module after a software reset. 0 SIM Normal operation (default). 1 SIM held in Reset.

Table 51-28. SIM Reset Control Register Field Descriptions (continued)

Field	Description
1 FLUSH_XMT	Flush Transmitter. This bit operates as a SIM transmitter reset. The receive portion of the SIM module is not affected. The software must clear this bit before the SIM transmitter can operate. 0 SIM Transmitter normal operation (default). 1 SIM Transmitter held in Reset.
0 FLUSH_RCV	Flush Receiver. This bit operates as a SIM receiver reset. The transmit portion of the SIM module is not affected. The software must clear this bit before the SIM receiver can operate. 0 SIM Receiver normal operation (default). 1 SIM Receiver held in Reset.

51.3.3.20 SIM Character Wait Time Register (CHAR_WAIT)

Field	Description
31–16	Reserved
15–0 GPCNT	General Purpose Counter. The value written to this register will be used to compare to the general purpose counter in the SIM module. Once the General purpose counter reaches this value, the GPCNT flag in the XMT_STATUS register will be set. This counter is intended to be used for any events that must be monitored for duration based on the card clock, receiver sample rate, or ETU rate (transmit clock). Example: ATR arrival time and ATR duration. Default is 0xFFFF

51.3.3.22 SIM Divisor Register (DIVISOR)

See Figure 51-24 for illustration of valid bits in the SIM Divisor Register and Table 51-31 for description of the bit fields.

51.4 Functional Description

To best describe the organization of the SIM module from a user's point of view, it is instructive to view the SIM at a number of different levels of hierarchy. See Figure 51-32 for illustration of the organization of SIM and connection of the signals to the two available serial ports.

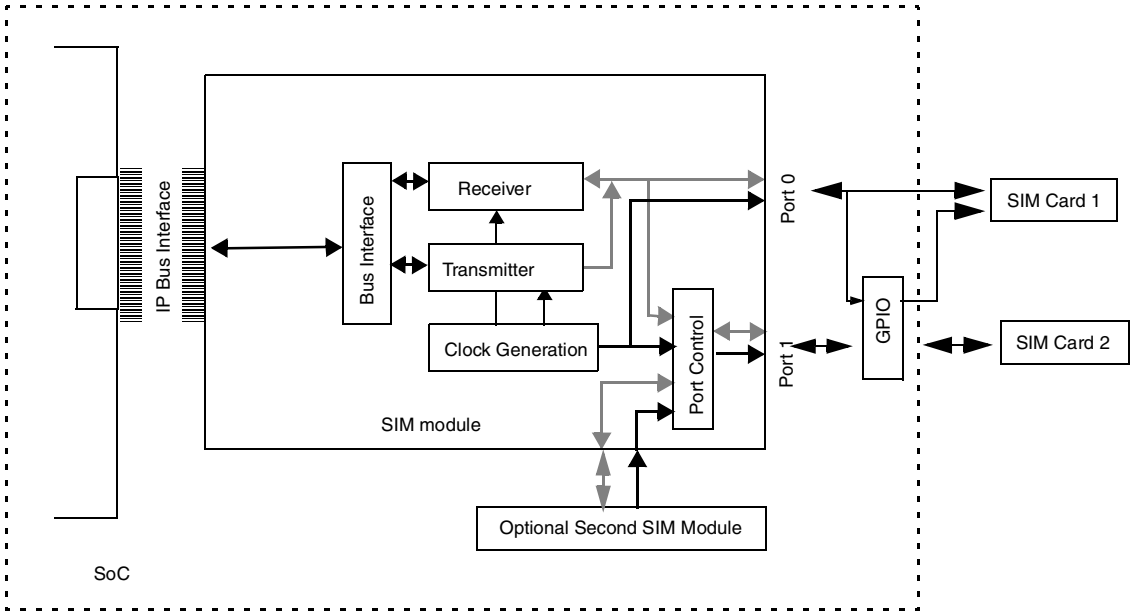

Figure 51-32. Block Diagram for SIM Module

The SIM module is essentially a standard UART with some special provisions made for SIM card communication. The SIM consists of nine main parts:

- IP Bus Interface
- Bus interface
- Clock generator
- Transmitter
- Receiver
- Port controller
- General purpose counter
- LRC blocks
- CRC blocks

See Figure 51-33 for illustration of the block diagram in detail, specifically the nine main parts.

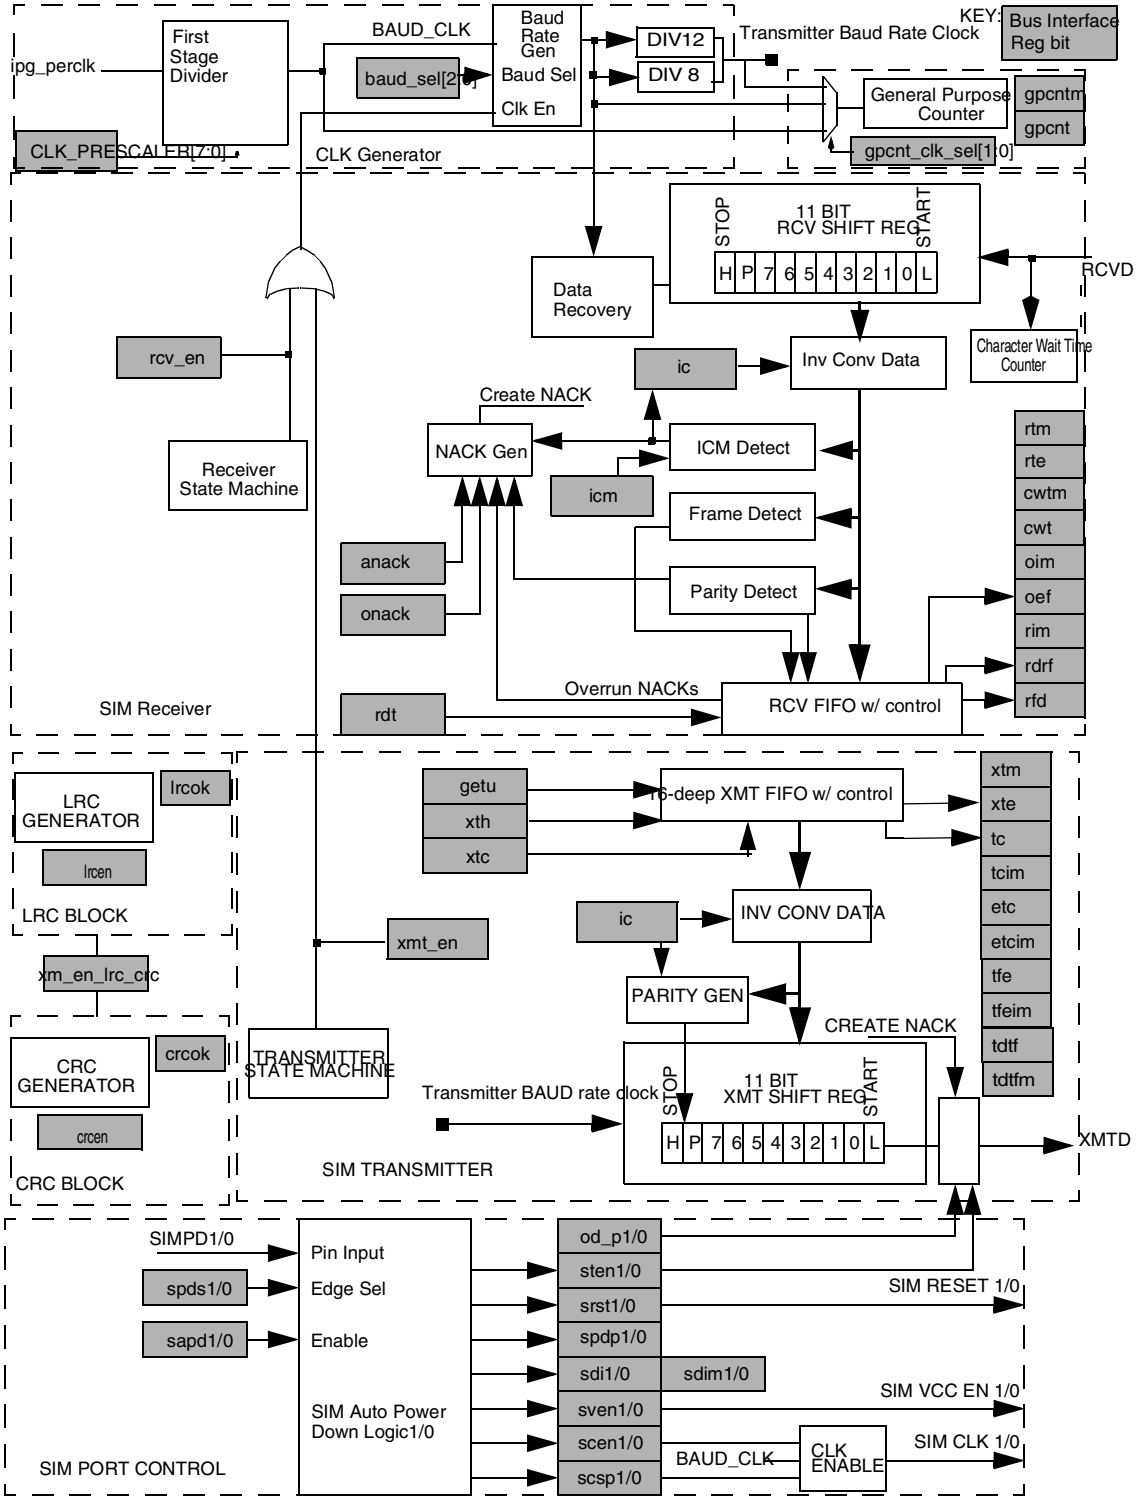

Figure 51-33. SIM Detailed Block Diagram

51.4.1 SIM Bus Interface

The SIM Bus interface block has been designed to enable the SIM module to be easily ported to other MCU cores. The bus interface block contains all of the logic that uses the bus interface signals. See Figure 51-34.

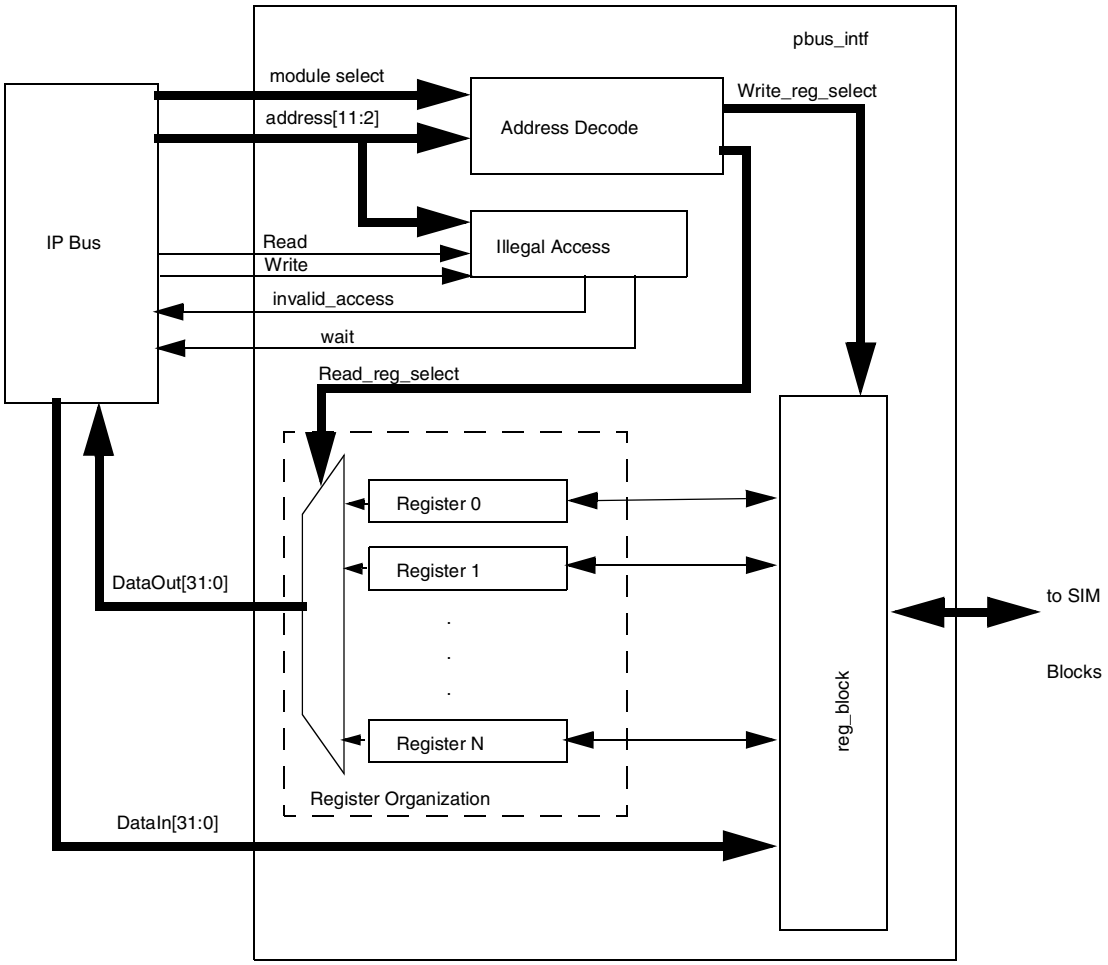

Figure 51-34. SIM Bus Interface

The bus interface block is responsible for peripheral bus address decoding, illegal access detection, dynamic wait-state requests, register organization, and register bit implementations. The address decoding uses the module address bus input along with the module select output of the IP bus to decode if the SIM module is being addressed. This decoding of these signals is done asynchronously. The output of the address decode is used with the read/write signals from the IP bus to determine the action requested by the bus master. If the read signal is active, the data_out bus will be driven with the register selected by the address decoding. If the write signal is active, the data_in bus will be latched into the register selected by the address decoder at the rising edge of the data_strobe signal.

The illegal access detection is implemented similarly to the address decoding. If the module_select signal becomes active while the address inputs are pointing to an unimplemented address, the invalid signal is

asserted asynchronously to the bus master. The invalid signal can also be generated under certain register access conditions such as writing to a full transmit FIFO, or writing to a read-only register. See Figure 51-35.

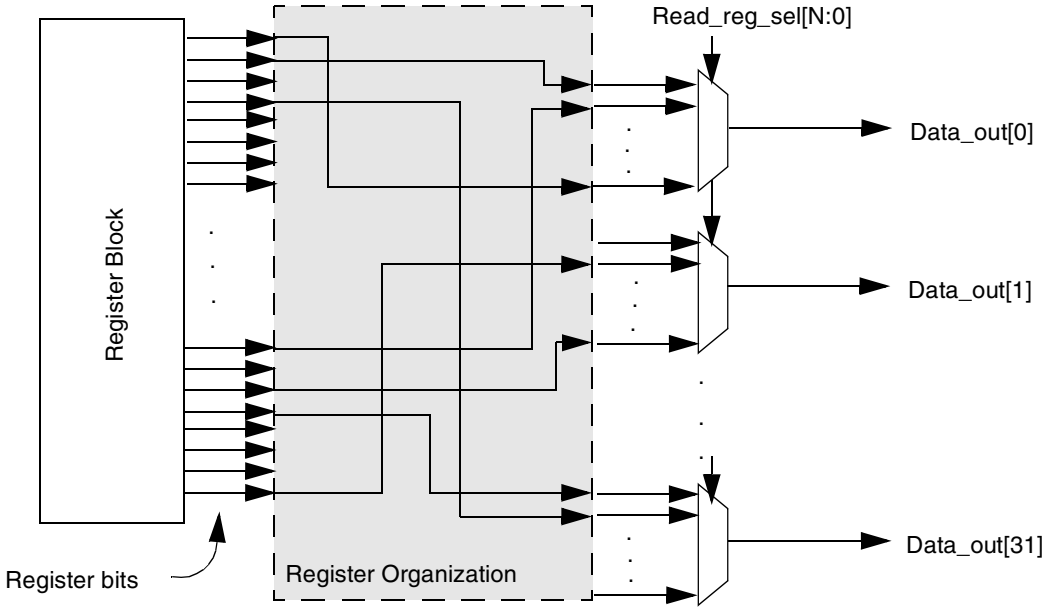

Figure 51-35. SIM Read Registers

The register bit implementations are done inside the reg_block sub-module. This block accepts the decoded read and write signals for the register bits generated in the address decoder. The data_strobe output is used as the clock input to the register bits in order to clock in the new data during a write access. The write_reg_sel signals are used to gate the write action with the address decoding. The clearing mechanisms for status bits are implemented as write-one-to-clear. See Figure 51-36.

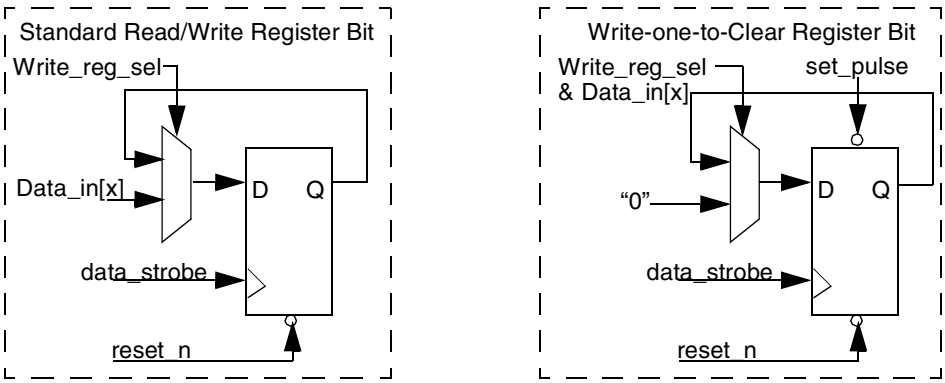

Figure 51-36. Register Bit Diagram

In the "write-one-to-clear" register bit example, "set_pulse" represents a pulsed signal generated in the data_strobe clock domain to set the register output.

51.4.2 SIM Clock Generator

The clock generator is responsible for implementing clock tree synthesis constructs, scan clock muxing, baud rate clock (BAUD_CLK) generation, and providing clocks to the transmitter, receiver, and port controller sections of the SIM module. See Figure 51-37 for the schematic of the SIM clock generator. The dividers outlined in bold, generate a pulsed (gated) clock of the desired frequency. The pulse is equal in duration to one half the ipg_perclk period. This clock is used internal to the SIM module to drive the transmit and receive sections of the module.

The dividers outline in normal, generate a clock of 45%~55% duty cycle to drive the clock pin of the SmartCard. This clock is not used internal to the SIM module.

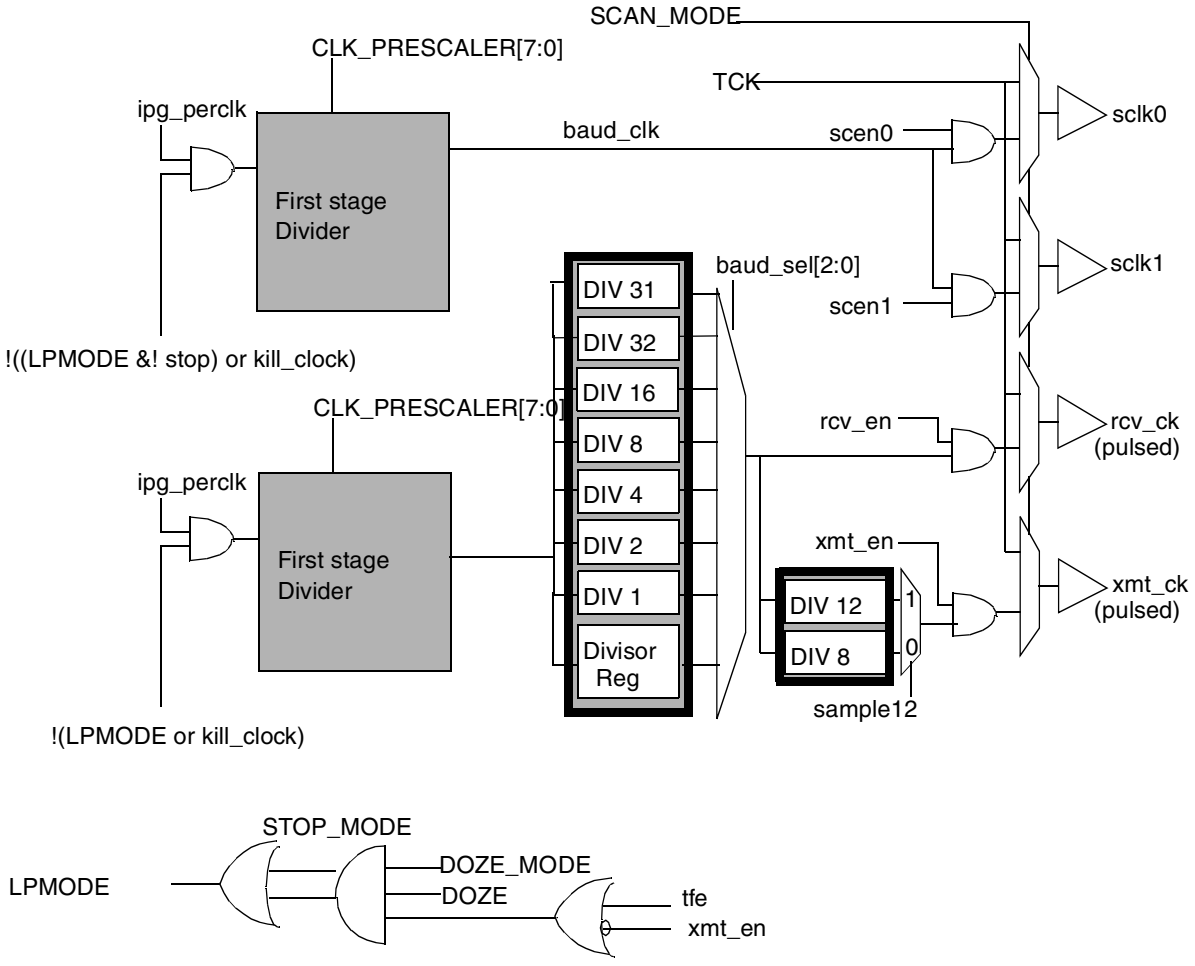

Figure 51-37. SIM Clock Generator

51.4.2.1 Clock Tree Synthesis

The clock tree synthesis constructs used in the current implementation follow the current clock methodology(srs3.1 clock methodology). This can be seen in the RTL of the sim_clocks.v module. There

is an instance of the special cell (clk_driver_pos.v) to drive each clock. This cell can then be used to control the clock skew during the layout process.

51.4.2.2 Scan Test

The scan clock muxing is implemented according to the design for testability rules.

51.4.2.3 Baud Clock Generation

The baud rate clock generation performed by the clock generator results in different frequencies. The default frequency is a divide by two of the ipg_perclk input. The baud rate can be programmed to be ipg_perclk divided by the even value using the CLK_PRESCALER[7:0] bits as shown in the CLK_PRESCALER register. The baud rate clock is generated in two forms in the design. The BAUD_CLK that is used by the SIM cards (SCLK0, SCLK1) is generated so that it must be 45%~55% duty at the divide values. This is necessary to meet the requirements of the ISO 7816 specification. The BAUD_CLK that is used internal to the SIM module is generated as a gated version of the ipg_perclk clock. The resultant clock will be a pulse of one-half ipg_perclk period in width with the expected frequency. The gated baud clock complies with the clock methodology initiative. The 50% duty cycle clock does not comply with the clock methodology initiative but this clock is not used as a clock internal to the SIM module. It is only used as a data path.

51.4.2.4 Transmitter Clock Generation

The transmitter clock (xmt_clk) is generated by the clock generator based on the values passed to it for the baud rate select (baud_sel[2:0]) and sample12. The transmit clock is gated by the transmit enable (XMT_EN) register bit. When the transmitter is enabled, the clock generator counts the appropriate number of receive clock (rcv_clk) positive edges to determine when to toggle the transmitter clock output. The transmitter clock is always based upon the receive clock.

51.4.2.5 Receiver Clock Generation

The receiver clock (rcv_clk) is generated by the clock generator based on the value passed to it for the baud rate select (baud_sel[2:0]). The receiver clock is gated by the receiver enable (RCV_EN) register bit. When the receiver is enabled, the clock generator counts the appropriate number of BAUD_CLK positive edges to determine when to toggle the receiver clock output. The number of BAUD_CLK positive edges is determined by the value of the baud rate select input (baud_sel[2:0]) and is programmable to these divisors: 31 (slowest because used with the 372/1 Fi/Di rate), 32, 16, 8, 4, 2, 1, and divisor[7:0]. The programmable divisor (divisor[7:0]) is programmable via the DIVISOR_REG register.

51.4.2.6 Port Control Clock Generation

The port controller clocks are provided by the clock generator for use on the SIM card ports. These clocks are equivalent in frequency to the BAUD_CLK and are gated by the SIM clock enable (scen0 and scen1) signals. The level at which the card clocks (SCLK0, SCLK1) are stopped when disabled is determined by the SIM clock select polarity (SCSP0, SCSP1) inputs to the clock generator. Synchronizers are

implemented to ensure glitch free operation of the card clocks when enabling/disabling, or changing the clock stopped polarity.

51.4.2.7 Low Power Mode Clock Control

The clock generator block is responsible for gating the clocks to the SIM module appropriately whenever a low power mode instruction is decoded. The IP interface provides two signals that encode the two available low-power states of the processor. These states are: STOP and DOZE. The response to the DOZE instruction is controlled through the use of the DOZE bit in the RESET_CNTL register. See the RESET_CNTL register description. The response to the STOP instruction is controlled through the use of the STOP bit in the RESET_CNTL register. See the RESET_CNTL description

51.4.3 SIM Transmitter

The SIM Transmitter block has been designed to localize all transmit related circuitry into one section of hierarchy. The Transmitter block comprises the following sections of logic: transmit state machine, transmit shift register, transmit FIFO, guard time generator, transmit NACK control, and transmit data convention.

51.4.3.1 Transmit State Machine

The Transmit state machine is the heart of the transmitter block. The state machine is responsible for sequencing through a transmit operation while reacting to inputs from the receiver, the transmit FIFO, and the guard time circuit. See Figure 51-38 for flow diagram of the transmit state machine.

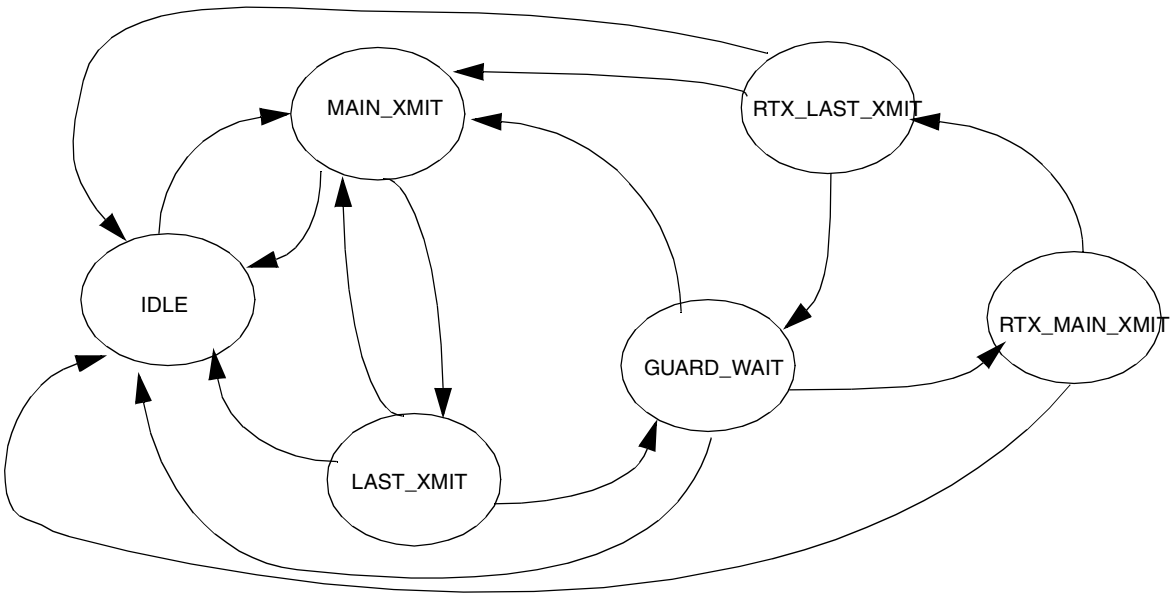

Figure 51-38. Transmit State Machine

The functions performed by each state are as follows:

- IDLE
  - This is the initial state. The state machine waits here until it detects XMT_EN is set and a write to the transmit FIFO has occurred. The data pointed to by the transmit read pointer is loaded into the shift register, and the state machine transitions to the MAIN_XMIT state. Any time XMT_EN is cleared, the state machine returns to this state.
- MAIN_XMIT
  - The transmitter is operating normally in this state. The data in the shift register is shifting once every transmit clock cycle. When the second to last bit of the current transmission is about to be sent, the state machine transitions to the LAST_XMIT state.
- LAST_XMIT
  - This state transmits the last bit of the current transmission and determines the next operation. One of the following will occur.
    - If GETU[7:0] is non-zero, jump to the GUARD_WAIT state.
    - If a transmit NACK error occurred, with a zero in GETU[7:0], jump to MAIN_XMIT state to retransmit the current byte.
    - If no transmit NACK, and GETU[7:0] is zero, load the shift register, jump to MAIN_XMIT to transmit the next byte
    - If no transmit NACK, GETU[7:0] is zero, and the FIFO is empty, jump to IDLE state; set the transmit complete (TC) flag.
- GUARD_WAIT
  - The state machine remains in this state until the Guard time counter has expired.
    - If a transmit NACK error occurred on last transmission, jump to RTX_MAIN_XMIT and re-transmit
    - If no transmit NACK and the FIFO is not empty, load the shift register, jump to MAIN_XMIT to transmit the next byte.
    - If no transmit NACK and the FIFO is empty, return to the IDLE state.
    - If transmit NACK threshold is detected, stop transmitter, set XTE flag, and jump to the IDLE state.
- RTX_MAIN_XMIT
  - The transmitter is operating normally in this state. The data in the shift register is shifting once every transmit clock cycle. When the second to last bit of the current transmission is about to be sent, the state machine transitions to the RTX_LAST_XMIT state. This state is identical to the MAIN_XMIT state except that it retransmits the previously NACKed byte.
- RTX_LAST_XMIT
  - This state transmits the last bit of the current re-transmission and determines the next operation. One of the following will occur.
    - If GETU[7:0] is non-zero, jump to the GUARD_WAIT state.
    - If a transmit NACK error occurred, with a zero in GETU[7:0], jump to GUARD_WAIT state to check Transmit NACK threshold.

- If no transmit NACK, GETU[7:0] is zero, and the FIFO is not empty, load the shift register, jump to MAIN_XMIT to transmit the next byte
- If no transmit NACK, GETU[7:0] is zero, and the FIFO is empty, jump to IDLE state; set the transmit complete (TC) flag.

51.4.3.2 Transmit Shift Register

The transmit shift register is 11 bits wide and controlled by the transmit state machine described previously. The shift register shifts out data at the transmit clock frequency (xmt_ck).

51.4.3.3 Transmit FIFO

The transmit FIFO is implemented inside the transmitter block. The FIFO depth is 16 bytes. The FIFO block is shared by both SIM module ports. The transmit FIFO cannot be accessed by the alternate SIM module through the alternate port. Each write to the transmit FIFO increases the transmit FIFO write pointer. Each time the transmit shift register is loaded from the transmit FIFO, the transmit FIFO read pointer is increased. When the read and write pointers are equal, the transmit FIFO empty flag (TFE) is set. Software has no visibility of the transmit FIFO pointers, but a transmit FIFO threshold value can be set to alert the software when the number of bytes in the FIFO has reached a specified level. A read of the transmit FIFO register (XMT_BUF) will return the last byte written to the FIFO. Writes to the transmit FIFO can occur at any time.

The transmit FIFO can be flushed by setting the XMT_FLUSH bit in the RESET_CNTL register. A transmit NACK threshold error (XTE) will halt the transmitter, and flush the transmit FIFO. The flush operation resets the transmit read and write pointers to equal values. Everything in the transmitter block is reset by the transmit flush operation. This does not include the control registers associated with the transmitter. The Transmit data threshold flag (TDTF) does not get cleared by the XMT_FLUSH operation.

51.4.3.4 Transmit Guard Time Generator

The guard time generator is simply a counter that is clocked by the transmit clock in order to delay the beginning of the next transmission and the setting of the transmit complete interrupt flag (TC) by a programmable amount of transmit bit widths (ETU’s). The duration of the count is controlled by the

GUARD_CNTL register (GETU[7:0]). See Figure 51-39 for depiction of three transmit operations in order to show the effect of the guard time generator logic

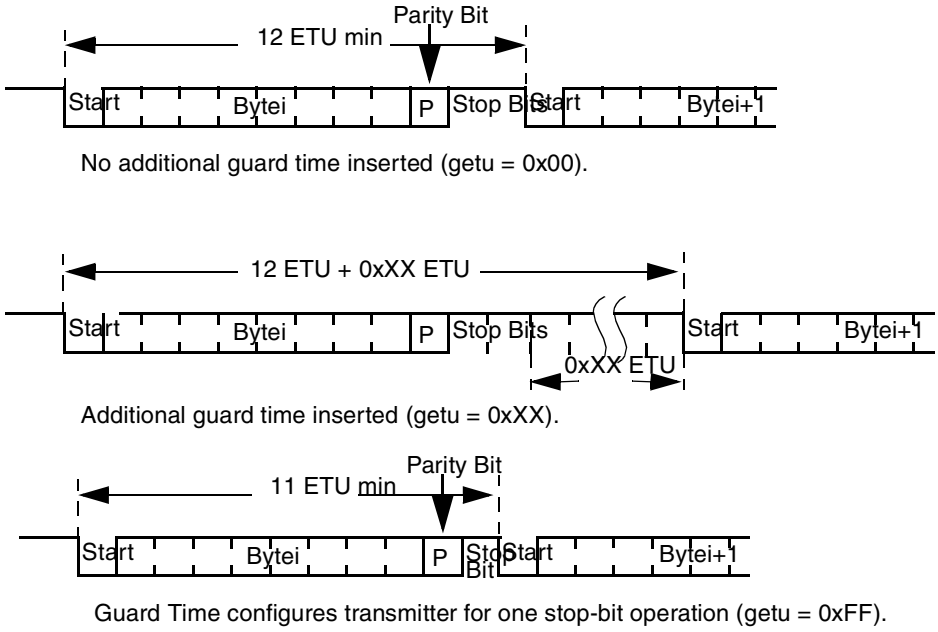

Figure 51-39. Transmit Guard Time

51.4.3.5 Transmit NACK Generator

The transmit NACK generator is responsible for driving the transmitter output low during the STOP bit time to signify an error was detected in the received data from the SIM card. This logic responds to a NACK request generated by the receiver block. See Figure 51-40 shows a typical SIM transaction with the NACK pulse inserted.

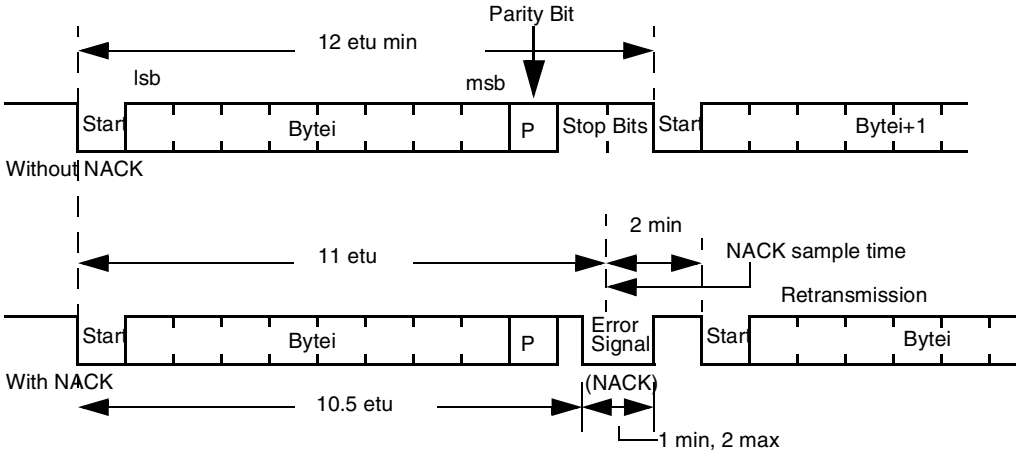

Figure 51-40. Transmit NACK Generator

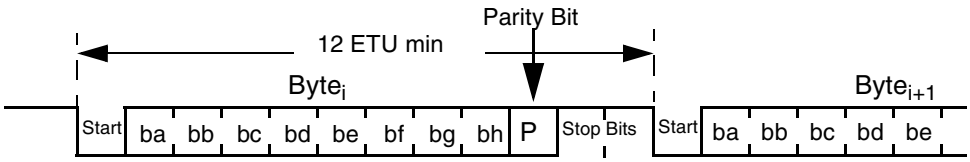
The transmit NACK generator is also responsible for keeping track of the number of NACKs received during a transmit operation. The SIM receive state machine detects NACKs generated by the SIM card,

and reports them to the transmit NACK logic. Once the number of detected NACKs has reached the programmed threshold (XTH[3:0]), an interrupt flag is generated, the transmit FIFO is flushed, and the transmitter is disabled.

51.4.3.6 Transmit Data Convention Logic

The transmit data convention logic provides the support for the two different data conventions available in SIM cards. See Figure 51-41 for illustration of SIM data conventions.



Parity Bit: if configured for even parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be even
if configured for odd parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be odd
When configured for inverse convention, the parity bit is inverted by SIM before being transmitted.

Direct Convention: *ba* is lsb of data byte to be sent. *bh* is msb.
Neither the data bits nor parity bit is logically inverted.

Inverse Convention: *ba* is msb of data byte to be sent. *bh* is lsb.
Both the data bits and parity bit are logically inverted by hardware.

Figure 51-41. SIM Data Conventions

The direct data convention is the default. If the inverse convention bit (IC) in the DATA_FORMAT register is set, the transmit data convention logic converts the output of the transmit FIFO to the inverse convention before sending it to the transmit shift register.

51.4.4 SIM Receiver

The SIM Receiver block has been designed to localize all receive related circuitry into one section of hierarchy. The receiver block is comprised of the following functions: receive state machine and the receive FIFO.

51.4.4.1 Receive State Machine

The receive state machine is responsible for sampling the receive data pin and capturing the bit value into the receive shift register. Additionally, the receive state machine can detect the START bit, parity errors, framing errors, and initial character when operating in initial character mode.

Once enabled by the RCV_EN bit in the ENABLE register, the receive state machine sequences through the states as shown in Figure 51-42.

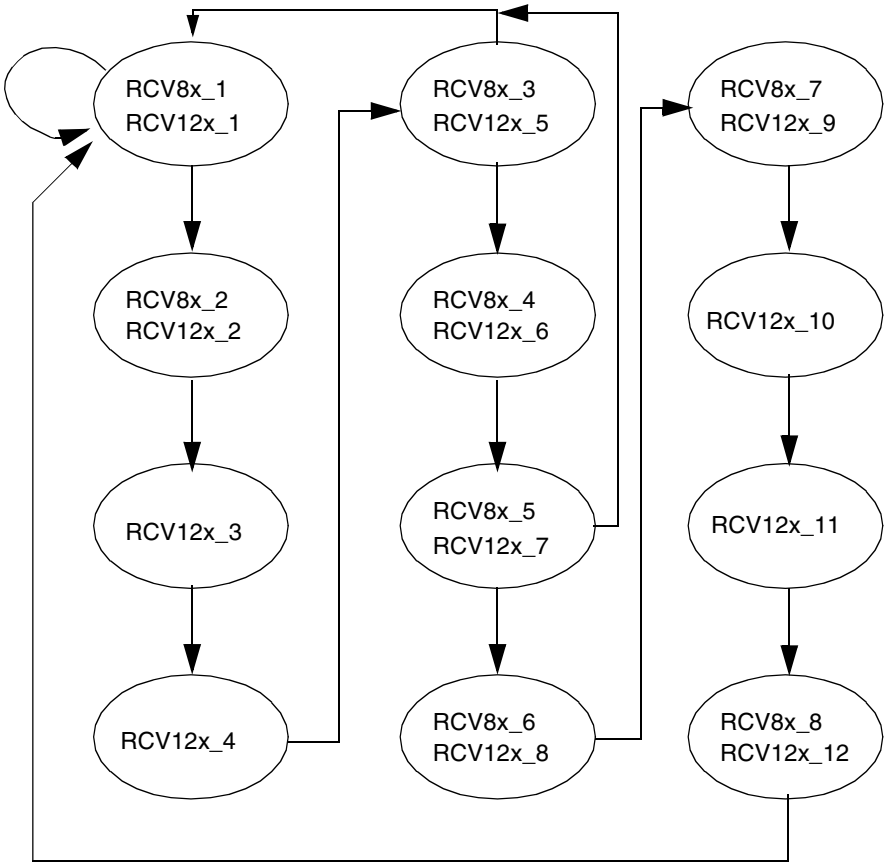


Figure 51-42. Receive State Machine

The states identified with a “8x” are used when operating in a 8x oversampling mode. The states identified with a “12x” are used when operating in a 12x oversampling mode. This mode is only used when sample12 is set to “1”. The number following the oversampling mode identifier represents the state number in the current mode. There are 12 states in “12x” mode, and 8 states in “8x” mode. Some states simply implement a one RCV_CK delay. States that perform additional functions are:

- RCV8x_1, RCV12x_1
  - This is the initial state of the receive state machine. If the first bit has not been received, the state machine remains in this state until a valid START bit is detected. For every subsequent bit, this state is simply a one RCV_CK cycle delay.
- RCV8x_2, RCV12x_2
  - This state captures the first sample of the current receive data input.
- RCV12x_3
  - This state captures the second sample of the current receive data input.

- RCV12x_4
  - This state captures the third sample of the current receive data input.
- RCV8x_3, RCV12x_5
  - This state checks if we are receiving a correct START Bit. If not, Then we return to state 1.
- RCV8x_4, RCV12x_6
  - If we are in the 11th Bit, We check for Parity or Initial Character errors and send NACK if needed.
- RCV8x_5, RCV12x_7
  - Store current Bit value in Shift Register. If this is the first bit and the value is not 0, restart the State Machine.
- RCV8x_6, RCV12x_8
  - If the current bit is the last bit of the transfer, Set flag to transfer Shift Register to Receive Buffer.
- RCV8x_7, RCV12x_9
  - Clear flag for transferring Shift Register to Receive Buffer.
- RCV12x_10
  - If the current bit is the last bit of the transfer (first stop bit), this state takes the sample of the NACK window.
- RCV12x_11
  - If the current bit is the last bit of the transfer (first stop bit), this state takes the sample of the NACK window.
- RCV8x_8, RCV12x_12
  - This state represents the end of the current receive input bit. Several operations occur during this state, including:
    - Increment bit counter
    - Perform a majority vote on the NACK samples and notify the transmitter if a NACK pulse was detected.

51.4.4.2 Data Sampling/Voting

The receive state machine runs at the receive clock rate (RCV_CK). This clock is used to oversample the received data at either a 8X or 12X sample rate. For each input bit, the receive state machine captures three samples. A majority voting algorithm is then applied to determine the value of the bit received. The value common to two or more of the samples is determined to be the bit value in the receive shift register.

51.4.4.3 Start Bit Detection

The SIM receive input is defined to be high when not active. The data transmission is defined to begin with a low pulse for a bit duration. This is called the start bit. The receive state machine is responsible for detecting and validating the start bit. The receive state machine samples the start bit three times using a

majority voting scheme to determine if the start bit is valid. This effectively filters out any low receive inputs shorter than one RCV_CK period.

See Figure 51-43 for illustration of a typical SIM data transaction with the START bit identified.

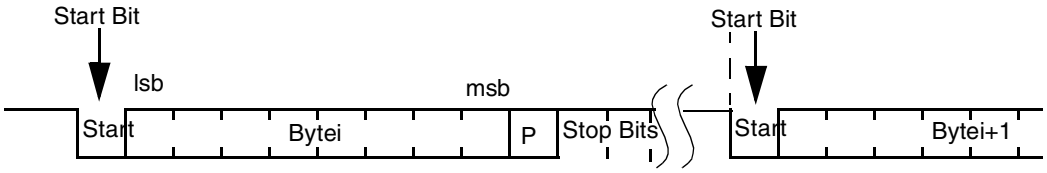

Figure 51-43. Start Bit Diagram

51.4.4.4 Parity Error Detection

The receive state machine is responsible for detecting parity errors in the received data. Data is always transmitted with even parity, except when in inverse convention mode. In inverse convention mode, all data bits and the parity bit are complemented making the data appear to be odd parity. The parity bit is defined as the tenth bit of the received data. The parity of the second through the tenth received bit is calculated by the receiver parity logic. This logic determines if the parity of the nine received bits is correct.

See Figure 51-44 for illustration of a typical SIM data transaction with the parity bit identified.

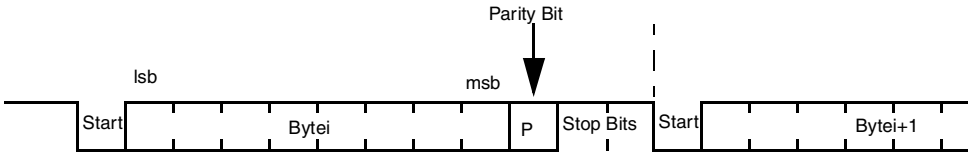

Figure 51-44. Parity Bit Diagram

When a parity error is detected on a given byte, the RCV_PF bit for that byte is set in the receive FIFO. A parity error cannot cause an interrupt, but it can signal the SIM transmitter to create a NACK pulse to the SIM card asking for a retransmission of the corrupted data. NACK generation upon a parity error is enabled by setting the ANACK bit in the CNTL register.

51.4.4.5 Framing Error Detection

The receive state machine is responsible for detecting framing errors in the received data. A SIM data transaction is defined as 11 or 12 bits long consisting of the start bit, 8 data bits, 1 parity bit and 1 or 2 stop bits. A framing error occurs when the stop bit is not detected during the 11th bit time of a data transaction. The stop bit is generally defined as two bit times (ETU's) of a high pulse following the parity bit. When the GUARD_CNTL register is programmed to 0xFF, the stop bit is defined as one bit time. A framing error can only occur when the parity bit of the current byte is low, and the stop bit arrives late.

See Figure 51-45 for illustration of a typical SIM data transaction with the stop bits identified. Also, shown is a SIM data transaction with a late arriving stop bit indicating a framing error.

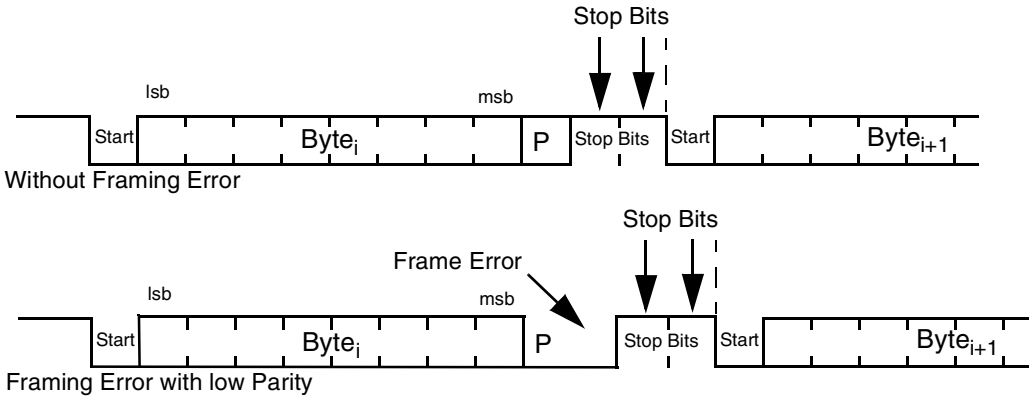

Figure 51-45. Framing Error Diagram

When a framing error is detected on a given byte, the RCV_FE bit for that byte is set in the receive FIFO. A framing error cannot cause an interrupt, nor can it create a NACK pulse to the SIM card asking for a retransmission of the corrupted data.

51.4.4.6 NACK Detection

The existence of the NACK pulse is sampled by the receive state machine at 11 Elementary Time Units (ETUs) after the falling edge of the START bit. An ETU is equivalent in time to 1 transmit clock period. Once the receiver detects a NACK, it signals the transmitter that an error occurred. The transmitter will not initiate retransmission for at least another two ETU times as required by the ISO 7816 specification.

51.4.4.7 Initial Character Detection

The SIM receive state machine supports the detection of special characters that allow it to determine what data format is being used by the connected SIM card. When placed in initial character mode, the SIM expects to receive one of two potential characters that it will use to set the data format control bit, IC, in the DATA_FORMAT register.

The two possible data formats are inverse convention and direct convention. Figure 51-46 and Figure 51-47 illustrate the differences between the two formats. Essentially, inverse convention differs from direct convention in that the order of the data is flipped msb for lsb and the data bits and parity bit

are logically inverted. When receiving inverse convention data, the transformation of the data back to direct convention format is done in hardware, including the inversion of the data and parity bits.

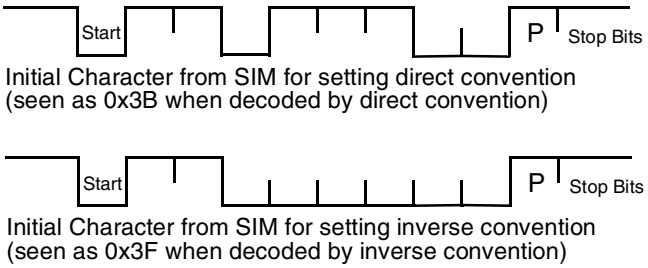

Figure 51-46. Valid Initial Characters

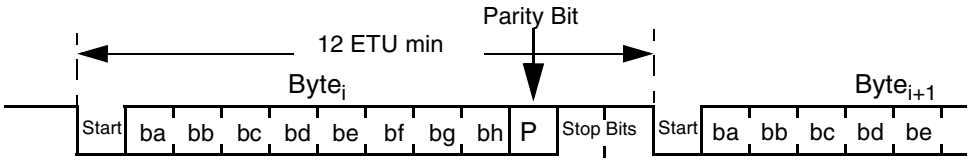

Parity Bit: if configured for even parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be even
if configured for odd parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be odd
When configured for inverse convention, the parity bit is inverted by SIM card before being transmitted.

Direct Convention: *ba* is lsb of data byte to be sent. *bh* is msb.
Neither the data bits nor parity bit is logically inverted.

Inverse Convention: *ba* is msb of data byte to be sent. *bh* is lsb.
Both the data bits and parity bit are logically inverted by SIM card.

Figure 51-47. Inverse Convention versus Direct Convention

51.4.4.8 Receive FIFO

The receive FIFO is implemented inside a sub-block of the receiver block. The FIFO depth is 288 bytes. The FIFO block is shared by both SIM module ports. The receive FIFO cannot be accessed by another SIM module through the alternate port. Only the port1 IO pins can be accessed through the alternate port. The secondary SIM would then uses its own internal FIFO while using the primary SIM IO ports. This is only done if it is required to control two SIM cards at the same time. It the two SIM card access only occurs one at a time, then a single SIM module can control both SIM cards (one on port0 and one on port1). The receive FIFO is accessed through the RCV_BUF register.

The receive FIFO is loaded from the receive shift register after the final bit of the current SIM card transmission has been received. The FIFO contains 10 bits per transmission. The lower eight bits contain the received data byte. Bits 8 and 9 contain the parity and framing status for the received byte.

Each read from the receive FIFO increases the receive FIFO read pointer. Each time the receive shift register is transferred to the receive FIFO, the receive FIFO write pointer is increased. When the difference between the read and write pointers equals the programmed threshold value (RDT), the receive data register full flag (RDRF) will be set. An interrupt can be generated by the RDRF flag if the RIM bit in the INT_MASK register is cleared. Software has no visibility of the receive FIFO pointers. A write to the receive FIFO register (RCV_BUF) will generate an invalid access exception to the processor.

The receive FIFO can be flushed by setting the RCV_FLUSH bit in the RESET_CNTL register. The flush operation resets the receive read and write pointers to equal values. All logic associated with the receiver will be reset by the flush operation except for receiver control registers.

51.4.4.9 Overrun Detection

The receive FIFO logic is responsible for detecting an overrun condition. When a received byte is transferred from the receive shift register to a receive FIFO that contains 288 unread bytes, the SIM receiver will flag an overrun condition. This condition will always set the overrun error flag, OEF in the RCV_STATUS register. The received byte will be discarded leaving the 288 unread bytes in the FIFO unaltered. The SIM module will generate a NACK to the SIM card on an overrun condition if the ONACK bit in the CNTL register is set. The SIM module will continually NACK SIM card transmissions until a read of the receive FIFO occurs.

51.4.4.10 Character Wait Time Counter

The SIM receiver block includes a 16-bit counter that counts the number of bit times (ETUs) between received characters. When enabled, the Character Wait Time Counter (CWT) will not start counting until after the START bit(s) of a valid character has been received. The counter is synchronized to the receive character bit positions so that an accurate count of the number of ETUs between characters can be made. The Character Wait Time Counter has a 16-bit programmable comparator. Software can write the expected number of ETUs between characters to the comparator. If the time between characters exceeds this value, an interrupt flag will be set and an interrupt generated if the mask is clear.

51.4.5 SIM Port Control

The SIM Port Control block has been designed to localize all port related circuitry into one section of hierarchy. The port control block comprises the following functions: SIM card interface, SIM Card presence detect, and SIM card auto-power down.

51.4.5.1 SIM Card Interface

The SIM module allows for direct control of two separate SIM cards. The SIM module does not support simultaneous communication with two SIM cards. To achieve simultaneous communication with two SIM cards, a second SIM module must be used. The SIM module can relinquish control of the inactive port to a secondary SIM module by setting the AMODE bit in the SETUP register. When alternate SIM Card Mode enable, output signals in port1 is directly from the secondary SIM module and input signals in port1 will pass through to the secondary SIM module.

The SIM card clock is generated in the SIM clock generator. The SIM card reset and SIM card voltage enable are controlled by software through the PORTx_CNTL registers.

See Figure 51-48 for illustration of a example SIM module hookup to two SIM cards. The power management chip shown is used to provide Vcc for the SIM card, and level translators for the remaining signals when interfacing to a SIM card operating at a different voltage than SIM module. The SIM module can directly access a SIM card if it is operating at the same voltage. In this case, the 3VOLTx bit in the PORTx_CNTL registers can be configured so the SIM Port transmit output as bi-directional. This frees up

the SIM port receive pin to be used as general purpose I/O. If the SIM module and the SIM card are operating at different voltages, then the power management level translators must be used. In this case, the 3VOLTx bit must be cleared and then both the RX and TX pins will be used.

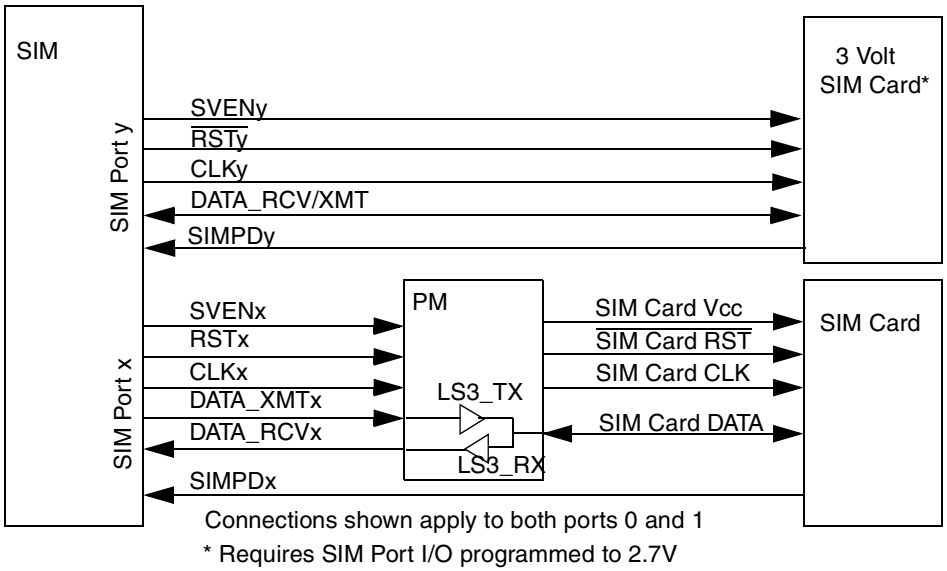

Figure 51-48. SIM Card Hookup

51.4.5.2 SIM Card Presence Detect

The SIMPDx input allows for detection of the insertion or removal of a SIM card. The SPDSx control bit in the PORTx_DETECT register allows the software to configure which edge of the SIMPDx pin will cause a presence detect event. A maskable interrupt can be generated when a SIMPDx event occurs.

An internal pull-down device is present on the SIMPDx pins. This will provide for a high to low transition on the SIMPDx pin when a SIM card is removed.

51.4.5.3 SIM Card Automatic Power Down

When interfacing to the SIM cards, it is necessary to follow a particular sequence when powering them up and down. The SIM port control block contains hardware that provides the correct sequence to power down a SIM card (see Figure 51-49). The power up sequence must be done manually by the software using the pin control bits supplied in the PORTx_CNTL registers.

The power down sequence is specified in ISO 7816 as follows:

1. RST transitions from high to low.
2. CLK is turned off to a low.
3. I/O transitions from high impedance to low.
4. SIM Vcc is turned off.

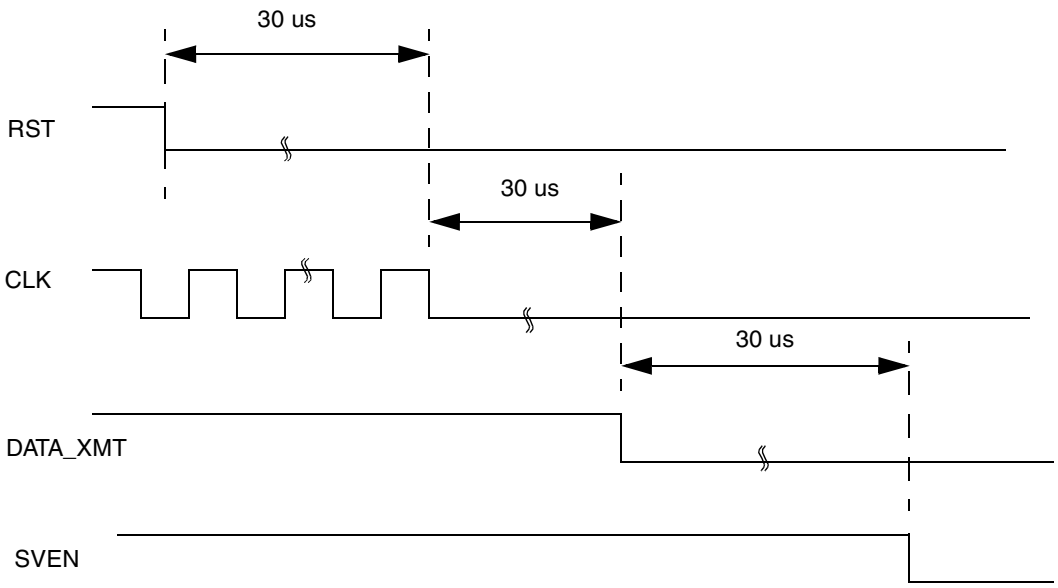

Figure 51-49. Auto Power Down Sequence

51.4.6 SIM General Purpose Counter

The SIM module provides a 16-bit counter for use when timing events during SIM card communication. The clock source for the counter is selectable between three sources: BAUD_CLK, RCV_CLK, or XMT_CK (ETU clock). The GPCNT_CLKSEL[1:0] bits in the CNTL register are used to select the clock input. The counter is enabled as soon as the input clock is selected. The starting of the counter is immediate once the input clock is running. Software can control the three input clock sources by using the KILL_CLOCK, RCV_EN and XMT_EN bits provided in the RESET_CNTL and ENABLE registers.

To run the counter from the card clock source the following conditions must be met:

1. ‘KILL_CLOCK = 0’ in the RESET_CNTL register.
2. ‘GPCNT_CLKSET[1:0] = 01’ in the CNTL register.

The counter will begin to count at the card clock rate as soon as these conditions are met.

To run the counter from the receive clock source the following conditions must be met:

1. ‘KILL_CLOCK = 0’ in the RESET_CNTL register.
2. ‘RCV_EN = 1’ or XMT_EN = 1 in the ENABLE register.
3. ‘GPCNT_CLKSET[1:0] = 10’ in the CNTL register.

The counter will begin to count at the receive clock rate as soon as these conditions are met.

To run the counter from the ETU (transmit) clock source the following conditions must be met:

1. ‘KILL_CLOCK = 0’ in the RESET_CNTL register.
2. Either one of the following:
   “RCV_EN = 1’ in the ENABLE register and ‘CWT_EN = 1’ in the CNTL register
   ‘XMT_EN = 1’ in the ENABLE register

3. ‘GPCNT_CLKSET[1:0] = 11’ in the CNTL register.

The counter will begin to count at the ETU clock rate as soon as these conditions are met.

The counter can be reset by setting GPCNT_CLKSEL[1–0] to 00. A 16-bit comparator value is provided that allows the software to select a count value at which an interrupt flag can be set and an interrupt generated if the mask is clear.

51.4.7 SIM LRC Block

The SIM module provides an 8-bit Linear Redundancy Check (LRC) generator/checker. The block is provided for use with T = 1 SIM cards that support LRC. This block can be enabled through the LRCEN bit in the CNTL register. This block performs an 8-bit exclusive-OR on all received or transmitted characters. At the end of the reception of a block of characters, the result is expected to be 00. If so, the LRCOK bit is set in the RCV_STAT register. During transmission, the LRC block Exclusive-ORs each character that is transmitted with the current value of the LRC. If the XMT_CRC_LRC bit in the CNTL register is set, the LRC value will automatically be sent by the SIM transmitter as the final character when the transmit FIFO empties.

The LRC value can be reset in multiple ways. Clearing the LCREN bit in the CNTL register will reset the LRC value. At the end of a transmission (either after the LRC byte is transmitted, or after the last character in the transmit FIFO is sent when XMT_CRC_LRC is clear), the LRC value is automatically reset by the SIM hardware. Finally, when setting the XMT_EN bit, the SIM hardware resets the LRC value.

51.4.8 SIM CRC Block

The SIM module provides an 16-bit Cyclic Redundancy Check (CRC) generator/checker. The block is provided for use with T=1 SIM cards that support CRC. This block can be enabled through the CRCEN bit in the CNTL register. This block performs a polynomial based check on all received or transmitted characters. The polynomial description is shown in Figure 51-50. The polynomial used is the standard CRC-CCITT where g(x) = x^16 + x^12 + x^5 + 1. The CRC register is initialized to all “1” before the data is shifted in. Before transmission the resulting CRC is inverted. For example, transmitting a 0xFA results in the following:

- Data = 0x5F (bit reversal of 0xFA)
- crc = 0x4AEA
- invert the crc = 0xB515 (bit reversal of 0xADA8
- data transmitted = 0xFA, 0xAD, 0xA8

See Figure 51-50 for illustration of the SIM CRC block.

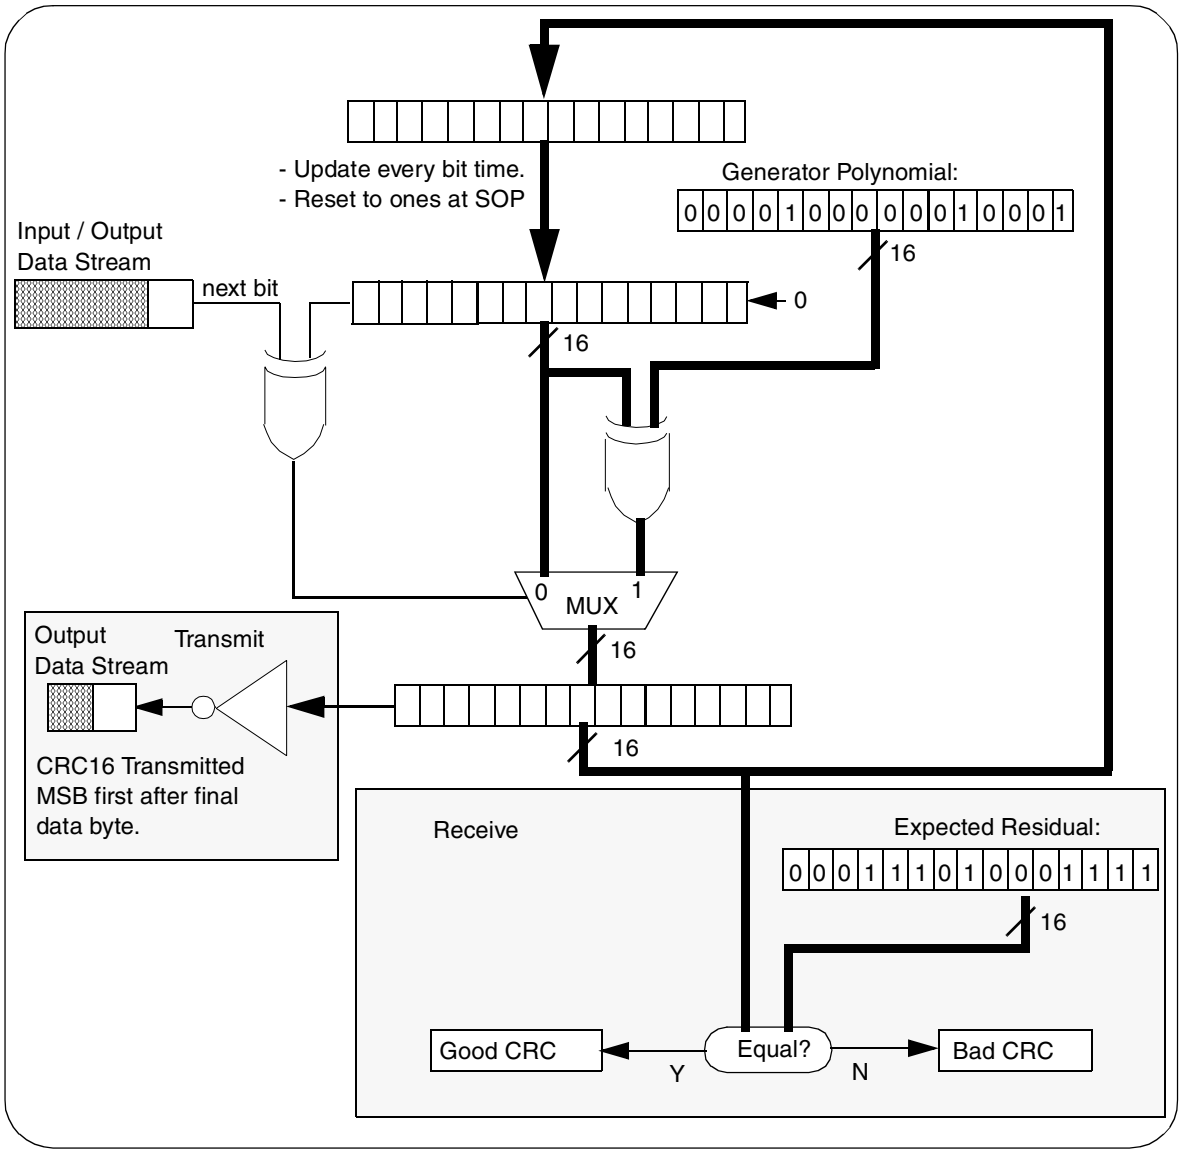

Figure 51-50. CRC Block Diagram

At the end of the reception of a block of characters, the residual from the CRC calculation is compared to 0x1D0F. If so, the CRCOK bit is set in the RCV_STAT register. During transmission, the CRC block updates the current value of the CRC residual using each character. If the XMT_CRC_LRC bit in the CNTL register is set, the CRC value will automatically be inverted and sent by the SIM transmitter as the final two characters when the transmit FIFO empties.

The CRC value can be reset in multiple ways. Clearing the CRCEN bit in the CNTL register will reset the CRC value. At the end of a transmission (either after the CRC characters are transmitted, or after the last character in the transmit FIFO is sent when XMT_CRC_LRC is clear), the CRC value is automatically reset by the SIM hardware. Finally, when setting the XMT_EN bit, the SIM hardware resets the CRC value.

51.4.9 Module Interrupts

See Table 51-39 for the list of all possible interrupt sources and their corresponding mask bits. All SIM interrupts are logically ORed to create the active low irq_n and data_irq_n signals that go to the ITC module. All mask bits are such that a logic 1 implies that the corresponding interrupt is disabled (masked), whereas a 0 implies that the interrupt enabled (unmasked). All of these mask bits are logic 1 out of reset (all interrupts are masked).

Table 51-39. SIM Module Interrupts

Flag	Flag Register	Mask	Mask Register	Description
TC	XMT_STATUS	TCIM	INT_MASK	Transmit Complete
ETC	XMT_STATUS	ETCIM	INT_MASK	Early Transmit Complete
TFE	XMT_STATUS)	TFEIM	INT_MASK	Transmit FIFO Empty
XTE	XMT_STATUS	XTM	INT_MASK	Transmit Threshold Error
TFO	XMT_STATUS	TFOM	INT_MASK	Transmit FIFO Overfill error
TDTF	XMT_STATUS	TDTFM	INT_MASK	Transmit Data Threshold Flag
GPCNT	XMT_STATUS	GPCNTM	INT_MASK	General Purpose Counter Comparator Flag
RDRF	RCV_STATUS	RIM	INT_MASK	Receive data register full (FIFO threshold level reached)
OEF	RCV_STATUS	OIM	INT_MASK	Overrun Error Flag
CWT	RCV_STATUS	CWTM	INT_MASK	Character Wait Time Counter Comparator Flag
BWT	RCV_STATUS	BWTM	INT_MASK	Block Wait Time Counter Comparator Flag
BGT	RCV_STATUS	BGTM	INT_MASK	Block Guard Time Counter Comparator Flag
RTE	RCV_STATUS	RTM	INT_MASK	Receive NACK Threshold Error
SDI1	PORT1_DETECT	SDIM1	PORT1_DETECT	SIM Detect Interrupt for port 1
SDI0	PORT0_DETECT	SDIM0	PORT0_DETECT)	SIM Detect Interrupt for port 0

51.5 Initialization/Application Information

This section describes the intended programming model for using the SIM module. The section describes how to begin a typical mode of operation using the registers.

51.5.1 Configuring SIM for Operation

The following is a list of items that need to be performed to configure the SIM module for operation:

1. To select the port in the SETUP register, do the following steps:
   a) Select which SIM module port is active by writing the SPS bit.

b) Select whether the second SIM module port is active at the same time under the control of an alternate SIM module by writing the AMODE bit.

2. Enable the selected port (for port 1, see PORT1_CNTL register; for port 0, see PORT0_CNTL) following the SIM power up procedure specified in ISO 7816.
   a) Enable power to the SIM card using the SVEN1 or SVEN0 bit.
   b) Enable SIM module transmit data output using the STEN1 or STEN0 bit. This is required to allow the SIM receiver to create NACK pulses.
   c) Enable SIM card clock using the SCEN1 or SCEN0 bit.
   d) Release the SIM card reset using the SRST1 or SRST0 bit (assert SRSTx high).
3. Select XMT port driver type (open-drain or push-pull) in the OD_CONFIG register.
   a) Configure the selected port to be open drain or push-pull by using the OD_P1 or OD_P0 bit.
4. Choose the port Baud rate in the CNTL register.
   a) Select the SIM card clock rate by using the CLK_PRESCALER[7:0] register
   b) Select the SIM card baud rate by using the BAUD_SEL[2:0] bits and SAMPLE12

NOTE

Follow the ISO 7816 spec with regards to card clock frequencies to ensure the maximum frequency specification is not violated.

5. Select Data format type, or place SIM receiver in initial character mode.
   a) Select inverse convention or direct convention by using the IC bit in the DATA_FORMAT register, or
   b) Enable initial character mode by using the ICM bit in the CNTL register

51.5.1.1 Configuring SIM Receive

The following is a list of items that need to be performed to configure the SIM receiver for operation:

1. Enable NACK capability in CNTL register.
   a) Select NACK generation on parity errors, or invalid initial character by using the ANACK bit.
   b) Select NACK generation on overrun conditions by using the ONACK bit.
2. Select the desired Receive NACK threshold and receive FIFO threshold in RCV_THRESHOLD register.
   a) Program the threshold at which the RDRF flag will be set by using the RDT bits.
   b) Program the threshold at which the RTE flag will be set by writing to the RTH[3:0] bits. If an auto power down after RTE flag is set, is desired, then enable the SIM card auto power down by setting the SAPD0,1 bits in the port0,1_cntl register.
3. Configure the Character Wait Time Counter, the Block Wait Timer Counter and the Block Guard Time Counter.
4. Enable interrupts in the INT_MASK register.
   a) Enable the receive data register full interrupt by using the RIM bit
   b) Enable the receive threshold error interrupt by using the RTM bit.

c) Enable the overrun condition interrupt by using the OIM bit
d) Enable the Character Wait Time interrupt by using the CWTM bit

51.5.1.2 Configuring SIM Transmitter

The following is a list of items that need to be performed to configure the SIM transmitter for operation:

1. Select desired re-transmission threshold for NACKed characters in XMT_THRESHOLD register.
   a) Program the threshold at which the XTE flag will be set by using the XTH[3:0] bits
2. Select the guard time between transmissions in the GUARD_CNTL register.
   a. Program the desired guard time between characters transmitted by the SIM module by using the GETU[7:0] bits
3. Select the desired Transmit FIFO threshold level in the XMT_THRESHOLD register.
   a) Program the desired threshold using the TDT[3:0] bits
4. Enable interrupts in the INT_MASK register.
   a) Enable the transmit complete interrupt by using the TCIM BIT
   b) Enable the early transmit complete interrupt by using the ETCIM bit
   c) Enable the transmit FIFO empty interrupt by using the TFEIM bit
   d) Enable the transmit threshold error interrupt by using the XTM bit
   e) Enable the transmit FIFO threshold interrupt by using the TDTFM bit
   f) Enable the transmit FIFO overfill interrupt by using the TFOM bit

51.5.1.3 Configuring SIM General Purpose Counter

The following is a list of items that need to be performed in order to configure the SIM General Purpose Counter for operation:

1. Select desired clock source for the General Purpose Counter using the CNTL register.
   a) Use the GPCNT_CLKSEL[1:0] bits to select the desired clock source for the counter
2. Program counter comparator using the GPCNT register.
   a) Use the GPCNT[15:0] bits to select the desired count value at which the GPCNT interrupt flag will be set.
3. Enable the selected clock source for the General Purpose Counter using either the RESET_CNTL or ENABLE registers.
   a) If the GP Counter is configured for the card clock, enable the clock by clearing the KILL_CLOCK bit in the RESET_CNTL register.
   b) If the GP Counter is configured for the receive oversample clock, enable this clock by setting the RCV_EN bit or XMT_EN bit in the ENABLE register.
   c) If the GP Counter is configured for the transmit oversample clock, enable this clock by setting the XMT_EN bit in the ENABLE register.
4. Enable interrupts in the INT_MASK register.
   a) Enable the general purpose counter interrupt by using the GPCNTM BIT

51.5.1.4 Configuring SIM to Measure WWT (Work Wait Time) for Type = 0 Smartcards

The following is a list of items that need to be performed in order to configure the SIM to measure work wait time. This is intended for type = 0 SmartCards. Work wait time is a combination of BWT and CWT. The CWT timer is to measure the time between the start bits of two consecutive characters in the block received from the SmartCard. If this time is larger that the value programmed in the cwt[15:0] register, then a flag will be set and an interrupt generated. This timer can be used for both type = 0 and type = 1 SmartCards. The BWT and BGT timer are used to measure the delay between the leading edge of the last character of the block received by the card and the leading edge of the first character of the next block sent by the card. If you want the SIM to enforce a WWT of 100 bits. Then, activate both the CWT and BWT and program both of them for a value of 100 bits. When measuring WWT, the BGT timer will not be used so it will be masked (inactive) by the BGTM bit. Below is the sequence to program the SIM to send and receive data while checking WWT.

1. Program both the CWT and the BWT (low and high) registers to the WWT (work wait time) value that needs to be enforced. Set BGT register to 0 (this is the default value).
2. Activate both the CWT and BWT functions by setting the CWTEN and BWTEN bit in the CNTL register.
3. Enable the CWT and BWT interrupts by clearing the CWTM and BWTM bits in the INT_MASK register.
4. Program the data to send to the SmartCard by writing data to XMT_BUFFER
5. Activate the SIM transmit and receive by setting bits XMT_EN and RCV_EN in the ENABLE register.
6. If the software has more data to send, then as the FIFO starts to get near empty, it should write more data to the XMT_BUFFER. If the software does not have any more data to send then proceed to the next step.
7. When SmartCard has completed its transmission to the SIM module, disable the BWT by clearing the bit BWTEN in the CNTL register. This will prepare SIM to measure the next block wait time.
8. Disable the SIM transmitter by clearing the XMT_EN bit in the ENABLE register.
9. Program the next data to send by writing data to the XMT_BUFFER.
10. Enable the BWT function by setting the BWTEN bit in the CNTL register.
11. Enable the SIM transmitter by setting the XMT_EN bit in the ENABLE register.
12. Steps 6 to 10 can be repeated for each transmission to the SmartCard.
13. If a CWT or a BWT interrupt occurs, then the software should consider that a WWT violation. The software should clear the CWT or BWT interrupt by writing a “1” to the BWT or CWT bit in the RCV_STATUS register.

51.5.1.5 Configuring SIM to measure CWT, BWT, BGT for type=1 SmartCards

The following is a list of items that need to be performed in order to configure the SIM to measure CWT, BWT, BGT. This is intended for type = 1 SmartCards. The CWT timer is to measure the time between start bits in the consecutive characters received from the SmartCard. If this time is larger that the value programmed in the CWT[15:0] register, then a flag will be set and an interrupt generated. This timer can

be used for both type = 0 and type = 1 SmartCards. The BWT, BGT timer is used to measure the delay between the leading edge of the last character of the block received by the card and the leading edge of the first character of the next block sent by the card. If this time is larger than the value in the both BWT registers (BWT and BWT_H), then the BWT flag will be set and an interrupt generated. If the time is less than the value in the BGT register, then the BGT flag will be set and an interrupt generated.

1. Program the CWT, BWT, BWT_H and BGT registers to the value that needs to be enforced.
2. Activate both the CWT and BWT functions by setting the CWTEN and BWTEN bit in the CNTL register.
3. Enable the CWT, BWT, BGT interrupts by clearing the CWTM, BWTM, BGTM bits in the INT_MASK register.
4. Program the data to send to the SmartCard by writing data to XMT_BUFFER
5. Activate the SIM transmit and receive by setting bits XMT_EN and RCV_EN in the ENABLE register.
6. If the software has more data to send, then as the FIFO starts to get near empty, it should write more data to the XMT_BUFFER. If the software does not have any more data to send then proceed to the next step.
7. When SmartCard has completed its transmission to the SIM module, disable the BWT by clearing the bit BWTEN in the CNTL register. This will prepare SIM to measure the next block wait time.
8. Disable the SIM transmitter by clearing the XMT_EN bit in the ENABLE register.
9. Program the next data to send by writing data to the XMT_BUFFER.
10. Enable the BWT function by setting the BWTEN bit in the CNTL register.
11. Enable the SIM transmitter by setting the XMT_EN bit in the ENABLE register.
12. Steps 6 to 10 can be repeated for each transmission to the SmartCard.
13. If a CWT or a BWT interrupt occurs, then the software should read the RCV_STATUS register to determine if the error was caused by a CWT, BWT, or a BGT violation. The software should clear the CWT, BWT, BGT interrupt by writing a “1” to the CWT, BWT, BGT bit in the RCV_STATUS register.

51.5.1.6 Configuring SIM Linear Redundancy Check (LRC) Block

The following is a list of items that need to be performed in order to configure the SIM Linear Redundancy Check Block for operation:

1. Enable the LRC block by using the CNTL register
   a) Use the LRCEN bit to enable the LRC block
   b) Use the XMT_CRC_LRC bit to enable the transmission of the LRC Character after the last character in the Transmit FIFO is sent. Refer to the T=1 programming model for more details.

51.5.1.7 Configuring SIM Cyclic Redundancy Check (CRC) Block

The following is a list of items that must be performed to configure the SIM Cyclic Redundancy Check Block for operation:

1. Enable the CRC block by using the CNTL register.
   a) Use the CRCEN bit to enable the CRC block
   b) Use the XMT_CRC_LRC bit to enable the transmission of the CRC Characters after the last character in the Transmit FIFO is sent. Refer to the T=1 Programming model for more details.

51.5.2 Using the SIM Receiver

Once the SIM has been properly configured (such as correct baud rate and correct data format), SIM receptions can be enabled by setting the receive enable bit, RCV_EN, in the ENABLE register. As bytes are received, they will be placed in the 288 byte deep receive data FIFO. Unread bytes can be accessed from this FIFO at any time. There is no need to disable the receiver to access the FIFO. The FIFO should only be read when the receive FIFO data flag, RFD, in the RCV_STATUS register is set. The RFD flag, which cannot create an interrupt, is high any time there is at least one unread byte in the receive FIFO. If the receive FIFO is read when RFD is low, it will simply produce the last byte read.

The receive data register full flag, RDRF, in the RCV_STATUS register can be used to determine when the receive FIFO has reached a given threshold value. This flag will create an interrupt if the RIM bit in the INT_MASK register is clear. To control at which point RDRF is set, program the receive data threshold, RDT, in the RCV_THRESHOLD register. If the number of unread bytes in the receive FIFO is equal to or greater than the value set by RDT, RDRF will be set.

NOTE

A value of 0x0 in RDT implies that there must be 288 unread bytes in the receive FIFO to trigger RDRF.

The value in RDT can be changed at any time to alter this threshold level. The comparison between the number of unread bytes in the FIFO and the value set by RDT is continuously updated so that any change in either will be immediately reflected in the state of RDRF. For instance, if RDT is set to 5, and there are 3 unread bytes in the FIFO, changing RDT to 2 will immediately cause RDRF to be set. Likewise, setting RDT back to 5 will cause RDRF to clear. Similarly, if there are 5 unread bytes in the receive FIFO and RDT is set to 3, RDRF will remain high until 3 reads are complete, assuming RDT is left as a constant and no new data is received.

The standard flow for receiving bytes from the SIM card is to set RDT to the appropriate value, wait for RDRF to cause an interrupt (RIM clear), and then read bytes out of the receive FIFO as long as RFD is high. In addition to checking RFD between every byte, it is also recommended that software check for the existence of a set OEF flag as well.

51.5.2.1 Receive Parity Errors and Parity NACK Generation

The SIM receiver checks every byte received for proper parity. The IC control bit in the DATA_FORMAT register controls whether it checks for odd parity or even parity. When checking for odd parity, the number of logic ones contained in the 9 received bits (8 data bits and 1 parity bit) should be odd. Likewise, when

checking for even parity, the number of logic ones contained in the 9 received bits (8 data bits and 1 parity bit) should be even.

When a parity error is detected on a given byte, the PORTx_PE bit for that byte is set in the FIFO. The PORTx_PE flag for each byte is read out of the FIFO when the data itself is read. There is no need to attempt to clear the parity error flag in the FIFO. It is simply overwritten the next time a byte is received into that position of the FIFO. A parity error cannot cause an interrupt.

It is possible for the SIM to automatically request that the SIM card re-send a byte found to have a parity error by generating a NACK pulse on the SIM XMT pin. The SIM will generate a NACK pulse on a byte received with a parity error if the control bit ANACK in the CNTL register is set. Bytes with parity errors that cause a NACK pulse are still placed into the FIFO just as bytes that do not cause a NACK pulse. It is up to the software to discard data bytes with parity errors.

To control NACK generation by the SIM receiver use the RTH[3:0], Receive NACK threshold, in the RCV_THRESHOLD register. This set of bits specify the number of consecutive NACK's generated by the SIM module on a received byte, before generating an RTE (receive threshold interrupt flag) in the RCV_STATUS register. The RTE flag would also force the SIM port to power down the card if the SAPD0,1 bit is set in the PORT0,1_CNTL register.

NOTE

The ANACK bit must be set in the CNTL register to enable this feature. The control bit ANACK is also used in initial character mode to enable the retransmission of initial characters in the event that an invalid initial character is received.

When a valid character has been received by the SIM, the internal counter keeping track of the number of NACK's transmitted on the current byte resets to zero. Clearing the receive threshold error (RTE) bit would also clear that counter.

When generating a NACK pulse, the SIM will generate the low pulse starting at 10.5 ETUs and lasting for 1 ETU.

51.5.2.2 Receive Frame Errors

The SIM receiver checks every byte received for a proper stop bit. A stop bit should exist during at least the first half of the 11th ETU time after the start of the character. If this is not true, a frame error is flagged. When a frame error is detected on a given byte, the PORTx_FE bit for that byte is set in the FIFO. The PORTx_FE flag for each byte is read out of the FIFO when the data itself is read. There is no need to clear the frame error flag in the FIFO. It is simply overwritten the next time a byte is received into that position of the FIFO. A frame error cannot cause an interrupt, nor can it create a NACK pulse to the receiver asking for a retransmission of the corrupted data.

51.5.2.3 Receive Overrun Errors and Overrun NACK Generation

When there already exists 288 unread bytes in the FIFO, a received character will cause the SIM receiver to flag an overrun condition. This condition will always set the overrun error flag, OEF in the

RCV_STATUS register. The received byte will be discarded leaving the 288 unread bytes in the FIFO unaltered.

It is possible for the SIM to automatically request that the SIM card resend the byte that caused the overrun condition by generating a NACK pulse on the SIM XMT pin. The SIM will generate a NACK pulse for the byte that caused the overrun condition if the control bit ONACK in the CNTL register is set. In this case, the existence of an OEF flag does not indicate the loss of data, but rather a NACK (that is, retransmission request) due to a full receive FIFO. As opposed to transmit NACK generation, there is no limit to the number of times an overrun condition will cause a NACK other than to disable ONACK itself. When generating a NACK pulse, the SIM will generate the low pulse starting at 10.5 ETUs and lasting for 1 ETU.

If the control bit ONACK is clear, the existence of a high OEF flag indicates the loss of data. The OEF flag can create an interrupt if the OIM bit in the INT_MASK register is clear.

To clear the OEF flag, software must simply write a “one” to the OEF bit position in the RCV_STATUS register. A high OEF flag has no effect on the operation of the SIM receiver other than to create an interrupt if OIM is clear.

51.5.2.4 Using Initial Character Mode and Resulting Receive Data Formats

The SIM receiver supports the detection of special characters that allow it to determine what data format is being used by the connected SIM card. When placed in initial character mode, the SIM expects to receive one of two potential values that it will use to set the data format control bit, IC, in the DATA_FORMAT register.

The two possible data formats are inverse convention and direct convention. Essentially, inverse convention differs from direct convention in that the order of the data is flipped msb for lsb, and the data bits and parity bit are logically inverted. When receiving inverse convention data, the transformation of the data back to direct convention format is done in hardware, including the inversion of the data and parity bits.

To place the SIM into initial character mode, set the ICM bit in the CNTL register. Once a valid initial character is received, the IC bit in the DATA_FORMAT register will be set accordingly by the hardware, and the ICM bit will be cleared. Software can read the state of the IC bit to determine which mode the SIM is currently using.

The 0x3B (as decoded by direct convention) with parity bit high will cause direct convention to be used (IC set to logic 0), whereas a 0x3F (as decoded by inverse convention) with parity bit high will cause inverse convention to be used (IC set to logic 1).

When the receiver is in initial character mode, all received bytes will continue to be placed into the receive FIFO whether they be valid initial characters or not. If a valid initial character is received that causes the data format being used to change, all subsequent bytes will be decoded with that format before being placed into the FIFO, including the initial character byte itself. That is, if the IC bit is low, and the correct initial character for setting inverse convention is received, that character and all subsequently received characters will be stored in the FIFO after having been decoded using inverse convention (for example, the initial character will be stored as 0x3F).

If the receiver is in initial character mode (ICM is high), and an invalid initial character is received, the SIM can be configured to automatically request that the initial character be retransmitted by setting the ANACK control bit in the CNTL register. When generating a NACK pulse, the SIM will generate the low pulse starting at 10.5 ETUs and lasting for 1 ETUs. The invalid initial character will be placed into the receive FIFO and marked with a parity error to signify that this is an invalid initial character.

51.5.2.5 Initial Character Mode Programming Notes

The usage of the initial character mode requires close attention to the programming model. There is a condition where a parity error in the initial byte for direct convention (0x3B) could be decoded as what appears to be a valid initial character for inverse convention (that is, 0x3F). The SIM module will not recognize this as a valid initial character for inverse convention and will mark the character by setting the parity error flag. The software must look for the existence of a parity error before recognizing a character as a valid initial character.

51.5.2.6 Automatic Receiver Mode

The SIM module has an automatic receive mode that inhibits the data being transmitted by the SIM module from entering the SIM receive buffer through the feedback path of the SIM data pin. The SIM module receiver should normally be enabled while the transmitter is operational. Automatic receive mode saves the software from having to actively manage the transition from transmitter to receiver. The auto receive mode is always active whenever the receiver is enabled.

51.5.2.7 Using the SIM Receiver with “T=1” SIM Cards

The SIM module provides hardware support for “T=1” type SIM cards. These type of cards present several requirements above and beyond the standard “T=0” cards. The features provided to meet the requirements that pertain to the SIM receiver are as follows:

- 11 ETU Characters
  - “T=1” cards can transmit with character lengths of 11 ETUs (that is, one STOP bit). The SIM module provides the RCVR11 bit in the GUARD_CNTL register in order to configure the receiver state machine to accept 11 ETU characters.
- Character Wait Time Counter
  - The character waiting time (CWT) is defined as the time between the start bits of two consecutive characters received from the SmartCard. The value of CWT can range from 12 ETU to 32779 ETU. The SIM module provides a 16-bit counter with programmable comparator clocked at the ETU bit rate to identify when the CWT has been exceeded by the SIM card.
- Block Waiting Time
  - The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The block wait time must not exceed a value that is programmable. The SIM module provides a 32-bit Block Wait Timer that can be used to identify when the BWT has been violated (divided in two registers).

- Block Guard Time
  - The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The block guard must be greater than a value that is programmable. The SIM module provides a 16-bit Block Guard Timer that can be used to identify when the BGT has been violated.
- Error Detection Code
  - "T=1" cards can specify LRC or CRC error detection codes to be used. The SIM module provides hardware support for both the LRC and CRC operations.

51.5.3 Using SIM Transmitter

Once the SIM has been properly configured (such as data XMT enabled, correct baud rate, and correct data format), the transmitter can be enabled by setting the XMT_EN bit in the ENABLE register. If data had been previously written to the transmit FIFO, the transmitter will begin to send the first character. If no data is written to the transmit FIFO before enabling the transmitter, then the transmitter will wait until the first character is written before beginning transmission. Clearing the XMT_EN bit while the transmitter is in operation, will halt any transmission in progress, flush the transmit FIFO, and reset the transmit state machine.

Data can be written to the transmit FIFO at any time.

The transmit data threshold flag, TDTF, in the XMT_STATUS register can be used to determine when the transmit FIFO has reached a given threshold value. This flag will create an interrupt if the TDTFM bit in the INT_MASK register is clear. To control at which point TDTF is set, program the transmit data threshold, TDT[3:0], in the XMT_THRESHOLD register. If the number of bytes remaining in the transmit FIFO is equal to or less than the value set by TDT[4:0], TDTF will be set.

NOTE

A value of 0x0 in TDT[3:0] implies that the transmit FIFO must be empty to trigger TDTF.

The value in TDT[3:0] can be changed at any time to alter this threshold level. The comparison between the number of remaining bytes in the transmit FIFO and the value set by TDT[3:0] is continuously updated so that any change in either will be immediately reflected in the state of TDTF. Unlike the RDRF flag for the receive FIFO, TDTF is latched and remains set until the software writes a 1 to the TDTF bit location in the XMT_STATUS register. For instance, if TDT[3:0] is set to 5, and there are 6 bytes remaining in the FIFO, changing TDT[3:0] to 6 will immediately cause TDTF to be set. However, setting TDT[3:0] back to 5 will not cause TDTF to clear.

The standard flow for transmitting bytes from the SIM card is to set TDT[3:0] to the appropriate value, write up to 16 bytes to the transmit FIFO, enable the transmitter, wait for TDTF to cause an interrupt (TDTFM clear), and then write additional bytes to the transmit FIFO.

NOTE

For the SIM module to transmit successfully, the transmit pin must be connected to the receive pin of the same port. This connection is necessary for the SIM to decode transmit NACKs sent to it by the SIM card. Without this connection, all transmissions will appear to have a NACK thereby causing the first byte to be transmitted continuously. When operating in external one wire interface mode (3VOLT0 or 3VOLT1), this connection is made internal to the SoC.

51.5.3.1 Transmit Data Formats

There are two possible data formats that the SIM module uses when transferring data to the SIM: card — inverse convention or direct convention. The format used depends on the state of inverse convention bit (IC in the DATA_FORMAT register). Software can set the IC bit, or it can be set automatically by hardware when using the initial character mode.

51.5.3.2 Transmit NACK

The SIM transmitter can respond to NACKs created by the SIM card. A NACK will be decoded if the SIM card creates a logic low level on the SIM receive pin during the STOP bit time at the end of a transmitted byte. To prevent a situation where the SIM interface is stalled by an infinite number of NACK pulses on a given byte, the SIM module can be configured to limit the number of times it will respond to NACKs. The XTH[3:0] control field in the XMT_THRESHOLD register allows software to set a threshold on the number of times a given byte will be retransmitted. If the threshold is reached, a transmit threshold error, XTE in the XMT_STATUS register, is asserted.

When XTE is set, the SIM transmitter is halted, and all pending transfers are aborted, and the TC, ETC, AND TFE flags are set. All bytes remaining in the transmit FIFO are lost. There is no way to restart the transmission on the next byte in the FIFO. The transmitter remains frozen until XTE is cleared by software. The only way to clear XTE is to write a 1 to the XTE bit in the XMT_THRESHOLD register. The XTE flag can create an interrupt if the XTM mask in the XMT_THRESHOLD register is clear.

It is possible to disable the detection of NACKs from the SIM card by setting XTH[3:0] to 0x0. By setting XTH[3:0] to 0x1, it is possible to disable all retransmissions while still setting XTE on the first NACK received. In general, XTE is set on the NACK that causes the threshold set by XTH[3:0] to be reached. This final NACK does not cause a retransmission whereas all previous NACKs will cause a retransmission.

51.5.3.3 Transmit Guard Time

The time between data bytes sent from the SIM transmitter can be altered using the transmit guard time control. By default, the minimum time between start bits of successive transmitted bytes is 12 ETUs (Elementary Time Units). An ETU is equivalent in time to 1 bit time. Therefore, the amount of time an

ETU consumes is determined by the baud rate chosen. The 12 ETUs that form the default character transmission time consist of a start bit, 8 data bits, a parity bit and two stop bits. The number of stop bits (idle bits) can be extended by an integer number of ETUs. The number of additional ETUs can be programmed directly into the GETU[7:0] bits of the GUARD_CNTL register. Programming the GETU[7:0] bits to 0xFF will configure the SIM transmitter to use only one stop bit for each character transmission.

51.5.3.4 Using SIM Transmit with “T=1” SIM Cards

The SIM module provides hardware support for “T=1” type SIM cards. These type of cards present several requirements above and beyond the standard “T=0” cards. The features provided to meet the requirements that pertain to the SIM transmitter are as follows:

- 11 ETU Characters
  - The SIM module transmitter has a programmable guard time register that allows the programmer to specify the number of ETUs between character transmissions. Programming a value of 255 (0xFF) in the GETU[7:0] bits in the GUARD_CNTL register will set the number of ETUs per character transmitted to 11.
- Character Waiting Time
  - The character waiting time (CWT) is defined as the time between the start bits of two consecutive characters. The value of CWT can range from 12 ETU to 32779 ETU. The time between transmitted characters is controlled by the programmable guard time in the GUARD_CNTL register. However, the time between the last byte in the transmit FIFO, and the next transmitted byte can be largely affected by software response time to the transmit interrupts. The SIM transmitter provides a Transmit FIFO threshold (TDTF) interrupt to signal the system when the expected number of characters have been transmitted from the transmit FIFO. The minimum CWT is achieved only if the software can respond to the TDTF interrupt and write new data to the transmit FIFO before the last character in the Transmit FIFO has been sent.
- Block Waiting Time
  - The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BWT is always greater than 1800 ETU. The SIM transmitter provides a General Purpose Counter that can be used to track the BWT. The BWT is purely determined by software response time to the transmit interrupts.
- Block Guard Time
  - The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BGT is 22 ETU. The SIM module supports the BGT by providing the ability to generate an interrupt when the last byte is received, and transmitting within two ETU after the XMT_EN bit is set. The BGT will be determined by the speed at which the software can react to an interrupt and enable the transmitter.

- Error Detection Code
  - “T=1” cards can specify LRC or CRC error detection codes to be used. The SIM module provides hardware support for both the LRC and CRC operation.

51.5.4 Suggested “T=1” Compliant Programming Model

This section describes the suggested programming model for supporting “T=1”, “T=0”, and known “special” cards using the SIM module on the SoC. This should be used as a rough guide for how to configure the SIM module for use with SIM cards specified by ISO 7816-3 and EMV. Some details are not addressed. Other uses for some of the SIM features are not included (for example, GP Counter uses for some ISO timing requirements).

51.5.4.1 Answer To Reset (ATR) Detection

The first step to communicating with a SIM card is to provide power and a clock signal to the card. Once the card is detected as present (using the presence detect features, or some other method), the SIM card should be powered up according to the power up sequence specified in the ISO 7816-3 specification.

1. Apply voltage to the SIM card by setting the SVEN0 or SVEN1 bit in the PORTx_CNTL register
2. Select the appropriate clock frequency for the SIM card by programming the CLK_PRESCALER[7:0] register.
3. Enable the clock to the SIM card by setting the SCEN0 or SCEN1 bit in the PORTx_CNTL register
4. Remove the card from reset by setting the SRST0 or SRST1 bit in the PORTx_CNTL register

The first communication between the SIM card and the SIM module will be a block of data sent from the SIM card to the SIM module after the card is powered and the card reset is removed. This block is called the Answer To Reset (ATR). To receive the ATR, the SIM module should be configured for 12 ETU character reception. According to the ISO 7816-3 spec, both “T=0” and “T=1” cards will communicate initially using 12 ETU character durations.

NOTE

We are aware of some card manufacturers that communicate at 11.5 ETU character durations (Geldkarte). This will complicate the initial card detection sequence shown below.

5. Clear RCVR11 bit in the GUARD_CNTL register

The next item to configure for ATR reception is the NACK capability of the SIM module. The ISO 7816-3 spec allows the SIM module to NACK any communication errors that occur during the initial communication at 12 ETU.

NOTE

The Europay Mastercard and VISA (EMV) cards are similar to “T=1”, but do not allow the SIM module to NACK during the initial communication. This will again complicate the initial card detection sequence shown below.

6. Set ANACK bit in the CNTL register to enable NACK generation

In order for the SIM module to notify when characters are received, the receive interrupt(s) can be enabled. A threshold can be set for the number of characters to receive before generating an interrupt.

7. Enable RDRF and OEF interrupts by setting RIM and OIM bits in INT_MASK register
8. Set desired threshold for received characters by writing RDT in RCV_THRESHOLD register

The SIM should be setup to perform in initial character mode. This will cause the hardware to identify the first valid character sent during the ATR as an initial character. This character will automatically configure the hardware for the data convention used by the SIM card.

9. Set Initial Character Mode by setting the ICM bit in the CNTL register

The ISO 7816-3 spec requires that SIM cards meet certain timing restrictions. One of these is the time from the deassertion of the card reset to the beginning of the ATR sequence. The SIM module General Purpose Counter can be used to verify that the SIM card begins its ATR within the 400 to 40,000 clock cycle range.

1. Set General Purpose Counter Comparator to 0x9C40 using GPCNT register.
2. Enable General Purpose Counter Interrupt by clearing GPCNTM in INT_MASK register.
3. Enable General Purpose Counter by programming the GPCNT_CLKSEL[1:0] bits to 01 so the card clock is used for counting.

The ISO7816-3 spec states that the maximum allowed time between two characters during the ATR is 9600 ETUs (Initial Waiting Time). The Character Wait Time Counter should be setup to detect any errors for this condition.

1. Set Character Wait Time Counter Comparator to 9600 using the CHAR_WAIT register
2. Enable the Character Wait Time Counter Interrupt by clearing CWTM in INT_MASK register
3. Enable the Character Wait Time Counter by setting the CWTEN bit in the CNTL register

The last step in preparing for ATR reception is to enable the receiver.

4. Set RCV_EN bit in ENABLE register

The SIM module will generate interrupts once a threshold number of characters is received. The software should react to these interrupts and read the characters from the receive FIFO (RCV_BUF) until the complete ATR has been received. If a General Purpose Counter interrupt occurs before the final ATR character is received, then the card should be deactivated according to the ISO 7816-3 spec. Otherwise, once a valid ATR is received, the software will know from the ATR information the specific characteristics for this card (refer to the ISO 7816-3 spec for details).

51.5.4.2 Programming Considerations for Geldkarte Cards

There is at least one manufacturer of SIM cards (Geldkarte) that we know of that does not send the ATR in 12 ETU mode or support NACKs. This creates an issue with detecting a valid ATR from a SIM card. Since any kind of card can be attached to the SIM module, the software and hardware do not know how to begin communication. Basically, if the card fails to send a valid ATR on the first try, disable NACKs, configure the SIM module for 11 ETU and try again. The software should toggle between 12 and 11 ETU modes with and without NACKs enabled until a valid ATR is received, or the number of attempts to communicate passes a predetermined error threshold.

Figure 51-51 shows the flow chart for the suggested Geldkarte Compliant SIM Initialization.

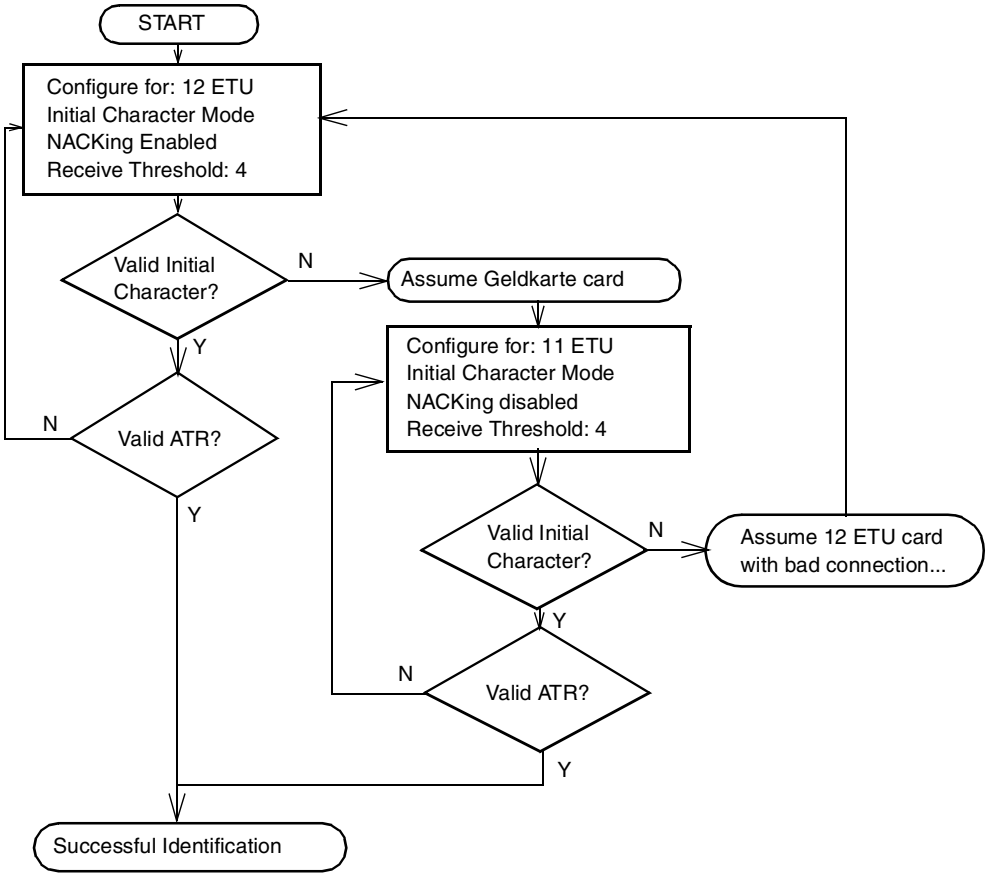

Figure 51-51. Suggested "T=1", EMV, Geldkarte Compliant SIM Initialization

51.5.4.3 Programming Considerations for T=0 SIM Cards

If the card is of type T=0, the software should adjust the following parameters according to the information in the ATR:

1. Adjust the baud rate by changing the values of BAUD_SEL[2:0] and SAMPLE12 in the CNTL register
2. Adjust the guard time between characters by changing the value of GETU[7:0] in the GUARD_CNTL register
3. Adjust NACK capability by modifying the values of the ONACK and ANACK bits in the CNTL register
4. Adjust the stop clock polarity by modifying the values of the SCSP0 or SCSP1 bits in the PORTx_CNTL register
5. Adjust the level of transmit NACK re-transmissions allowed by modifying the value of the XTH[3:0] bits in the XMT_THRESHOLD register
6. Adjust the level for the Receive NACK threshold by modifying the RTH[3:0] bits in the RCV_THRESHOLD register.

If a negotiation with the SIM card is desired, the software sends a PPS response to the SIM card. To send the response, the following steps should be performed:

1. Set the desired transmit FIFO threshold level by writing the TDT[3:0] bits in the XMT_THRESHOLD register
2. Write the characters to be sent as response (max 16) to the transmit FIFO using the XMT_BUF register
3. Clear all transmit interrupt flags in the XMT_STAT register by writing a one to them
4. Enable the transmit interrupts desired by clearing the mask bits in the INT_MASK register. If more than 16 character are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the SIM card.
5. Enable the transmitter by setting the XMT_EN bit in the ENABLE register

At this point, the SIM module will transmit the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt will be set when the threshold number of characters are remaining in the FIFO. The software can then write an additional number of characters to be sent without interrupting transmission to the SIM card.

Once the transmission is complete, the SIM module should be completely configured for standard operation with the T=0 SIM card. The software can continue to service RDRF interrupts for received characters, and TDTF interrupts for transmitted characters.

51.5.4.4 Programming Considerations for T=1 SIM Cards

If the card is of type T=1, the software should adjust the following parameters according to the information in the ATR:

1. Adjust the baud rate by changing the values of BAUD_SEL[2:0] and SAMPLE12 in the CNTL register
2. Adjust the guard time between characters by changing the value of GETU[7:0] in the GUARD_CNTL register. Setting GETU[7:0] to 0xFF configures the SIM transmitter for 11 ETU transmissions
3. Disable NACK capability by clearing the ONACK and ANACK bits in the CNTL register. T=1 cards do not allow NACKs.
4. Adjust the stop clock polarity by modifying the values of the SCSP0 or SCSP1 bits in the PORTx_CNTL register
5. Set Character Wait Time Counter Comparator to value specified in the ATR by using the CHAR_WAIT register
6. Enable the Character Wait Time Counter Interrupt by clearing CWTM in INT_MASK register
7. Enable the Character Wait Time Counter by setting the CWTEN bit in the CNTL register
8. Enable CRC or LRC error checking according to the ATR information by setting either the CRCEN or LRCEN bit in the CNTL register. These bits will never be set at the same time!

For T=1 cards, the ATR is sent using a T=0 type of structure (12 ETU, no LRC or CRC). If a negotiation with the SIM card is desired, the software will send a PPS response to the SIM card. Otherwise, the

protocol is initiated with a block transfer from the SIM module. In order to send the response or the first block, the following steps should be performed:

9. Set the desired transmit FIFO threshold level by writing the TDT[3:0] bits in the XMT_THRESHOLD register
10. Write the characters to be sent as response (max 16) to the transmit FIFO using the XMT_BUF register
11. Clear all transmit interrupt flags in the XMT_STAT register by writing a 1 to them
12. Enable the transmit interrupts desired by clearing the mask bits in the INT_MASK register. If more than 16 character are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the SIM card.
13. Enable the transmission of the error checking characters (LRC or CRC) by setting the XMT_CRC_LRC bit in the CNTL register.

NOTE

If the card supports PPS, the software may not be allowed to send the LRC/CRC information until the PPS exchange is completed. If so, do not set the XMT_CRC_LRC bit during the PPS exchange.

14. Enable the transmitter by setting the XMT_EN bit in the ENABLE register

At this point, the SIM module will transmit the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt will be set when the threshold number of characters are remaining in the FIFO. The software can then write an additional number of characters to be sent without interrupting transmission to the SIM card.

Once the transmission is complete, the SIM module should be completely configured for standard operation with the T=1 SIM card. The software can continue to service RDRF interrupts for received characters, and TDTF interrupts for transmitted characters.

Chapter 52
Smart Direct Memory Access (SDMA) Controller

52.1 Introduction

The Smart Direct Memory Access (SDMA) controller offers highly-competitive DMA features combined with software-based virtual-DMA flexibility. It enables data transfers between peripheral I/O devices and internal/external memories.

The SDMA controller helps maximize system performance by off-loading the CPU in dynamic data routing.

52.1.1 Overview

Figure 52-1 shows a block diagram of the SDMA controller. It includes the custom RISC core along with its RAM, ROM, DMA units, and the scheduler.

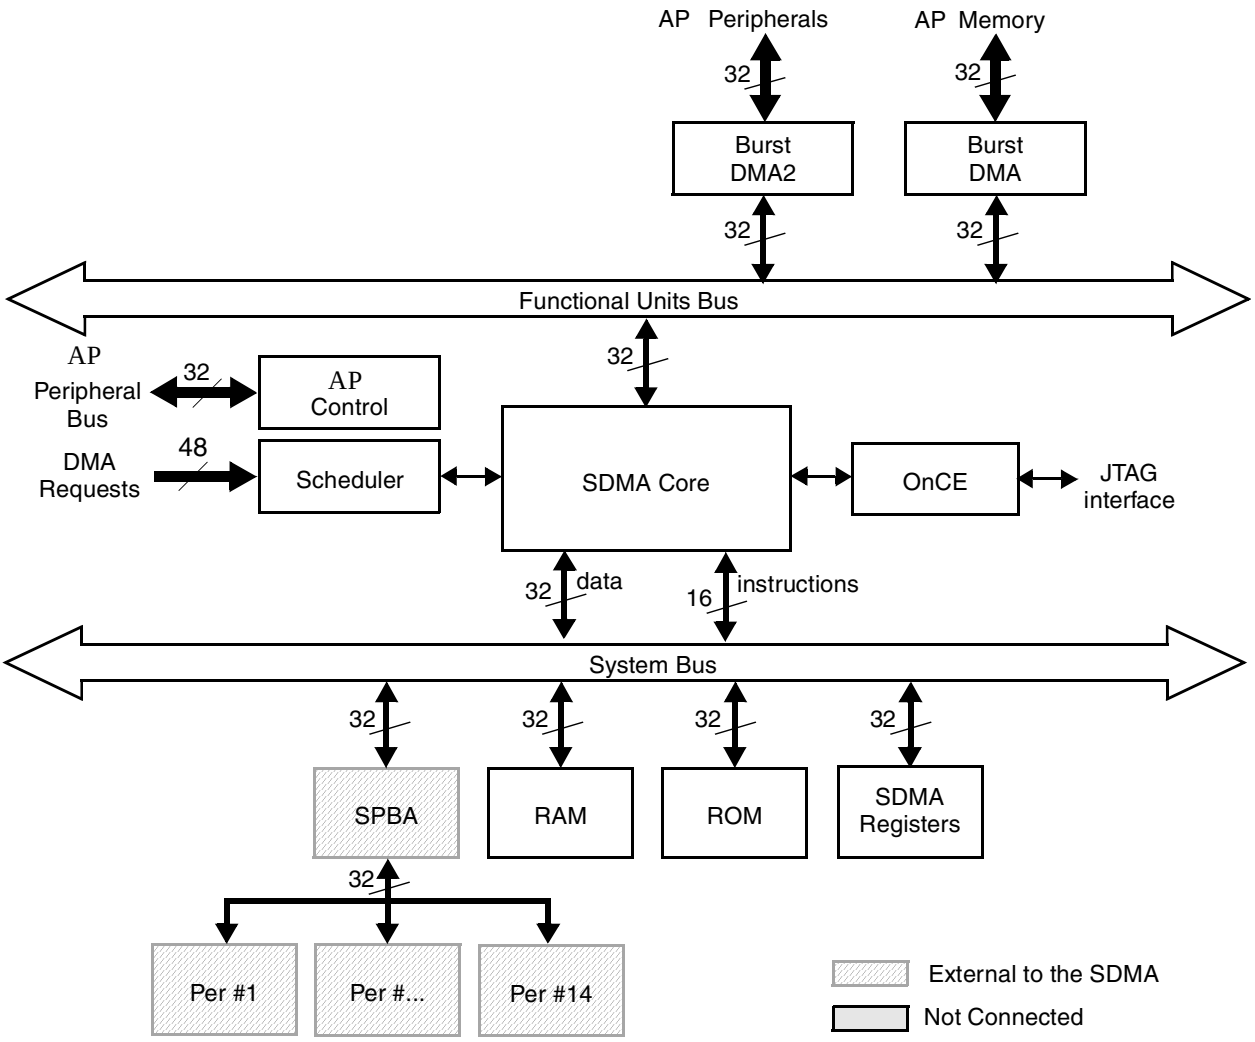

Figure 52-1. SDMA Block Diagram

The SDMA core executes short routines that perform DMA transfers; these routines are called *scripts*. The SDMA core interfaces to its own memory via the SDMA system bus. The SDMA system bus supports a 32-bit data path and a 16-bit address bus. The system bus datapath is used for both 16-bit instruction (program) memory access and 32-bit data access. DMA units interface to the core via the Functional Unit Bus and use dedicated registers to perform DMA transfers.

The SDMA memory contains a ROM and a RAM. The ROM contains startup scripts (for example, boot code) and other common utilities, which are referenced by the scripts that reside in the RAM. The internal RAM is divided into a context area and a script area (more details about this mapping are available in Section 52.13.5.1, Instruction Memory Map" and Section 52.13.5.2, Data Memory Map").

Every transfer channel requires one context area to keep the contents of all the core and unit registers while inactive. Channel scripts are downloaded into the internal RAM by the SDMA using a dedicated channel that is started during the boot sequence. Downloads are invoked using commands and pointers provided by the AP. Every channel contains a corresponding channel script located in RAM and/or ROM that can

be reconfigured independently as-needed. Channel scripts can be stored in an external memory and downloaded when needed. The SDMA can be configured with any mixture of scripts to enable an endless combination of supported services.

The scheduler monitors and detects DMA requests, mapping them to channels, and mapping individual channels to a pre-configured priority. At any given point, the scheduler presents the highest priority channel that requires service to the SDMA core. A special SDMA core instruction is used to “conditionally yield” the current channel being executed to an eligible channel that requires service. If (and only if) there is an eligible channel pending, will the current channel execution be preempted.

There are two `yield` instructions that differently determine the eligible channels: In the first version, eligible channels are pending channels with a strictly higher priority than the current channel priority. In the second version (`yieldge`), eligible channels are pending channels with a priority that is greater or equal to the current channel priority. The scheduler detects devices that need service through its 48 DMA request inputs. After a request is detected, the scheduler determines the channel(s) that is (are) triggered by this request and marks it (them) as pending in the “Channel Pending (EP)” register. The priorities of all the pending channels are continuously evaluated in order to update the highest pending priority. The channel pending flag is cleared by the channel script when the transfer has completed.

The AP Control module contains the control registers used to configure the 32 individual channels. There are 48 Channel Enable registers, and every register maps one DMA request to any desired combination of channels. The 32 Priority registers are used to assign a programmable 1-of-7 level priority to every possible channel. This module also contains all other control registers that the AP can access.

The 48 DMA requests that are connected to the scheduler come from a variety of sources. The “receive register full” and “transmit register empty” signals found in the UART and USB ports are typical examples of DMA requests that can be connected to the SDMA. These requests can be used to trigger a specific SDMA channel, or several channels.

There is an OnCE compatible debug port for product development. The OnCE includes support for setting breakpoints, single-step and trace, and register dump capability. In addition, all memory locations are accessible from the debug port.

52.1.2 Features

The following are the SDMA features:

- Multi-channel DMA supporting up to 32 time-division multiplexed DMA channels
- Hardware or software driven triggers for each channel
- 48 hardware driven triggers that can be mapped to any channel.
- Memory accesses including linear addressing, FIFO addressing and 2D addressing
- Fast context-switching with two-level, priority-based preemptive multi-tasking
- 16-bit instruction-set micro-RISC engine (the SDMA core)
- Two DMA units with some or all the following features:
  - Auto-flush and prefetch capability
  - Flexible address management (increment, decrement, and no address changes on source and destination address)

- Misaligned data-transfer support
- Uni-directional and bi-directional flows (copy mode)
- Up to eight-word buffers for configurable burst transfers

- Support of byte-swapping
- An available API and library of scripts
- Little-Endian and Big-Endian modes
- Hardware handshakes for low-power entry sequence
- Security support to lock contents of the SDMA script RAM.
- 4-KB ROM containing startup scripts (for example, boot code) and other common utilities that can be referenced by RAM-located scripts
- 8-KB RAM area is divided into a processor context area and a code space area used to store channel scripts that are downloaded from the system memory
- Debug support, including a OnCE port, real-time monitors, and embedded cross-trigger events
- Supported clock frequencies in process:
  - Configurable clock options for the SDMA core and the AP DMA units
    - 1:2 ratio with maximum of SDMA core running at AP Peripheral Bus speed and DMA running at max DMA frequency.
    - 1:1 ratio when both SDMA core and AP DMA clocks are set to the AP Peripheral Bus speed.
- Peripheral bus interface for configuration register programming by the AP
- The SDMA RISC engine (arithmetic and logic operations), which is referred to as the “SDMA core.”
- An internal peripheral bus connected to the Shared Peripherals Bus Interface (SPBA) that enables access to up to 14 shared peripherals. SDMA supports 32-bit accesses to word peripherals and 16-bit accesses to half-word peripherals.
- The burst DMA unit is able to perform burst accesses to the external memory
- The Burst DMA2 unit is connected to the AP Cross bar switch to Service AP Peripherals.
- All the DMA units are 32-bit AHB masters. They are connected to different buses, thus allowing concurrent accesses.

52.2 Functional Description

Figure 52-2 shows the SDMA topology, and is composed of the following components:

- SDMA Core (Section 52.3, SDMA Core.”)
- SDMA Scheduler (Section 52.4, Scheduler.”)
- Functional Units:
  - Burst DMA (Section 52.6.1, Burst DMA Unit.”)
  - Burst DMA2 Unit (Section 52.6.2, Burst DMA2 Unit.”)
- AP Control for AP control register access.
- Internal RAM and ROM Memory (Section 52.13, SDMA Programming Model)

- OnCE debug Port (Section 52.19, The OnCE Controller.")

The functional unit bus provides access by the SDMA core to the DMA units. The system bus provides access to SDMA internal memory and also supports up to 14 peripherals.

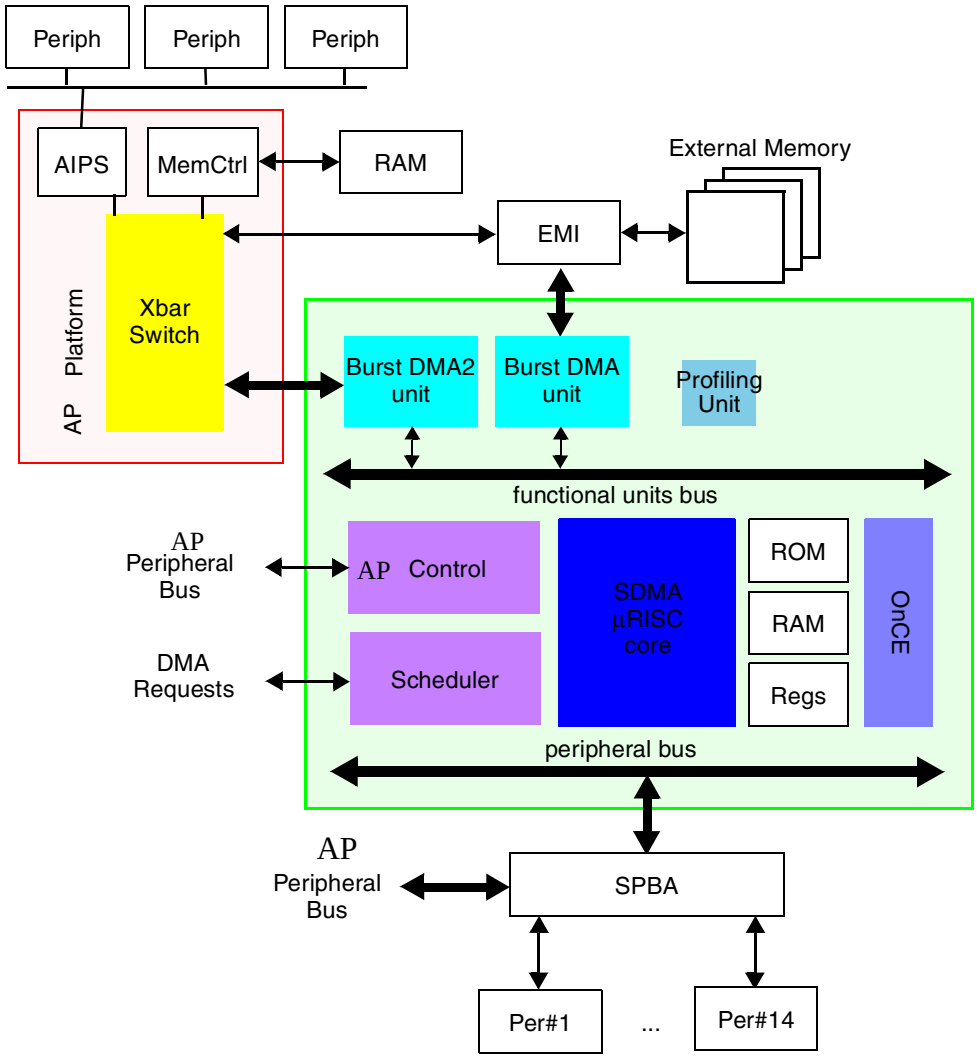

Figure 52-2. SDMA Connections

52.3 SDMA Core

The SDMA core is a customized RISC-like processor that is specifically developed to control DMA units and perform L1 tasks like byte-stuffing or framing. The SDMA core incorporates on-chip debug capability using the OnCE.

The SDMA core is based on a 32-bit register architecture with 16-bit instructions. There are eight general purpose 32-bit registers, four flags (T, LM, SF, and DF), and four PCU registers (PC, RPC, SPC, and EPC) that can address 16,384 16-bit instructions.

52.3.1 SDMA Core Structure

Figure 52-3 shows the structure of the SDMA core. It also shows the different registers, calculation resources, and possible data movements.

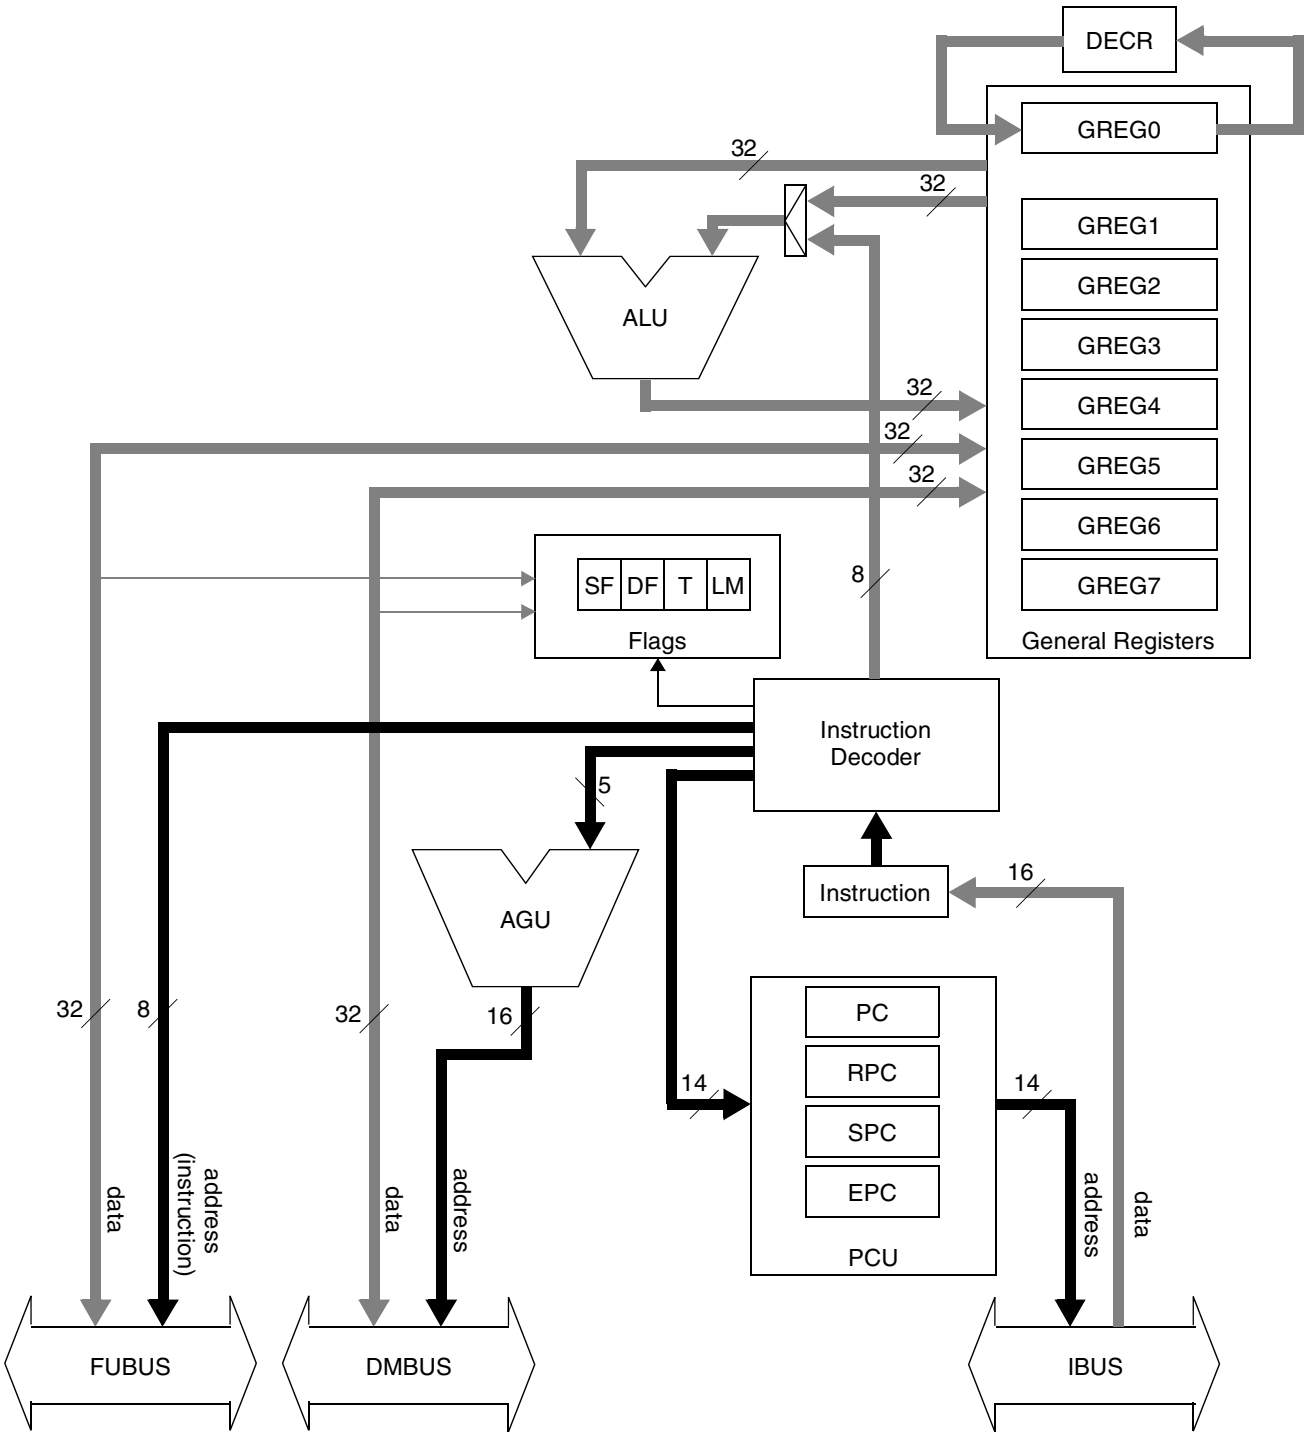

Figure 52-3. SDMA Core

- The Program Control Unit (PCU) is described in Section 52.3.2, Program Control Unit (PCU).” It handles the state of the core and generates the instruction fetch addresses. Instructions are retrieved from the Instruction Bus (IBUS) and stored in the SDMA core instruction register prior to their decoding. The PCU contains the following registers:
  - The Program Counter (PC) contains the address of the current instruction.
  - The Return Program Counter (RPC) contains the address of the instruction that follows a jump to the subroutine.
  - The Start Program Counter (SPC) contains the address of the first instruction of the current hardware loop.
  - End Program Counter (EPC) contains the address of the last instruction of the current hardware loop.
- The other core registers are the general purpose registers (GREGn) and the flags.
  - The general purpose registers can be used to hold data and addresses. They can be loaded with immediate values (for example, 8-bit data that are encoded in the instruction), results of calculations that were performed with the ALU, 32-bit data that comes from the memory or peripherals via the Data Memory Bus (DMBUS), 32-bit data that comes from the DMAs via the Functional Units Bus (FUBUS) or another general purpose register. Their content can be the operands of the ALU, the data to send on either bus (DMBUS or FUBUS), or a pointer to memory (DMBUS address).
  - The general register 0 (GREG0) is also the hardware loop counter. In hardware loops, it cannot be used for any other purpose. This register uses a dedicated decrement unit (DECR) shown in Figure 52-3.
  - The flags reflect the status of operations:
    - SF and DF are set when the last load or store on either bus (FUBUS or DMBUS) received an error response.
    - LM is set when the core is executing instructions inside a hardware loop.
    - T is set when the ALU operation result was 0 or the loop counter reaches 0 (the latter is preponderant when an ALU operation is the last instruction of a hardware loop).
- The ALU has two operands: any general register and either a second general register or an immediate value. The result is always stored into the first general register. A NOP function can be utilized by moving a register’s contents into itself (For example, the instruction: `mov R0,R0`).
- The 16-bit instructions are fetched via the instruction bus (IBUS) whose address is driven by the PC. The SDMA RAM and ROM are visible to the core as 16-bit devices through this interface.
- The memory (RAM and ROM), memory mapped registers, and external peripherals are accessed via the DMBUS. The address is always taken from a general register whose content is added to a 5-bit immediate value. This is the only available addressing mode. The DMBUS is a 32-bit data bus. Except for the peripherals that are external to the SDMA, the address accuracy is the 32-bit word (for example, adding 1 to an address points to the next word, not the next byte).
- The functional units are accessed via the FUBUS connection. The data is exchanged with any general register, but the address (which in fact is the instruction and the selector of the functional unit) comes from an 8-bit field of the corresponding load or store.

52.3.2 Program Control Unit (PCU)

This part of the SDMA core is dedicated to the control of the RISC engine as implied by the instructions that are executed. Its behavior is determined by the instruction type and the inputs of the SDMA. It contains the PC, RPC, SPC, and EPC registers that are described in Section 52.3.1, SDMA Core Structure."

52.3.2.1 Instruction Types

The state sequence and the delay of execution vary according to the type of the instruction. There are six possible categories of instructions, as follows:

1. `standard`—Most of the instructions belong to this category, and always last 1 cycle.
2. `ldf`/`stf`—These are respectively the load and store instructions that access the functional units. They last 1+n cycles where n is the number of wait-states of the targeted functional unit.
3. `ld`/`st`—These are the load and store instructions that access the memory and peripherals. They last 1+n cycles where n is the number of wait-states of the targeted device (1 for the ROM, RAM, and memory mapped registers, 1 + the external peripheral wait-states). These instructions always last at least two cycles, but the core is able to handle them in one cycle. The first wait-state is inserted outside the core.
4. `branch`—These are all the instructions that cause the Program Counter to point to another instruction other than the following one (for example, one that breaks the sequential flow). There are the absolute jumps, the conditional branches, the jump to the sub-routines, and the return from the sub-routine.
5. `loop`-modified load or store—The hardware `loop` instruction modifies the potential behavior of any load or store inside the `loop` (for example, when the LM flag is set). A jump may be implied after any such load or store if it received an error. The error causes an early exit of the loop, which means a jump to the instruction that follows the one that is pointed to by EPC. An additional cycle is required by the PCU to perform the jump (+1 to the `ld`/`st`/`ldf`/`stf` original execution delay). Although there is usually an implicit jump after the last instruction of the loop when the PC goes back to SPC, this is performed at no cycle cost.
6. `done`—The `done`, `yield`, or `yieldge` instructions are used to control channel switching. When no channel switching is performed, these instructions last a single cycle. When there is a change of channel or context switch, the delay is variable and depends on many factors (as detailed in Section 52.4.4, Context Switching").

52.3.2.2 PCU States

The PCU state is visible through outputs of the SDMA (see Section 52.20.8.4, Real-Time Debug Outputs") or the OnCE status register (see Section 52.19.4.9, OnCE Status Register (OSTAT)").

The PCU state is a four-bit field that can take the values shown in Table 52-1. Figure 52-4 shows the possible state transitions and the corresponding conditions.

Table 52-1. PCU States

Value	State	Description
0	Program	The is the usual instruction cycle.
1	Data	This state is inserted when there are wait-states during a load or a store on the data bus (ld/st type).
2	Change of Flow	This is the second cycle of any instruction that breaks the sequence of instructions (branch and done types). This state lasts only a single cycle; it is always followed by the Program state.
3	Error in Loop	This state is used when an error causes a hardware loop exit (loop-modified load or store type). This state only lasts a single cycle; it is always followed by the Program state.
4	Debug	he SDMA is stopped in debug mode.
5	Functional Unit	This state is inserted when there are wait-states during a load or a store on the functional units bus (ldf/stf type).
6	Sleep	No script is running: The core is idle after saving the last channel context.
7	Save	The context switch FSM is saving the current channel.
8	Program in Sleep	Same as Program except there is no associated channel, this state is used when instructions are executed after entering debug mode, whereas the core was in either Sleep mode.
9	Data in Sleep	This is the same as Data except there is no associated channel.
10	Change of Flow in Sleep	This is the same as Change of Flow except there is no associated channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
11	Error in Loop in Sleep	This is the same as Error in Loop except there is no associated. channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
12	Debug in Sleep	This is the same as Debug except the core was put in debug mode when no channel was active.
13	Functional Unit in Sleep	This is the same as Functional Unit except there is no associated channel.
14	Sleep after Reset	This shows that no script is running, and the core is idle after a reset. When a channel becomes active, no context is restored but the core starts its boot program located at address 0 (or the address available in register in Section 52.12.3.22, Channel 0 Boot Address (CHN0ADDR)”).
15	Restore	The context switch FSM is restoring the next channel context.

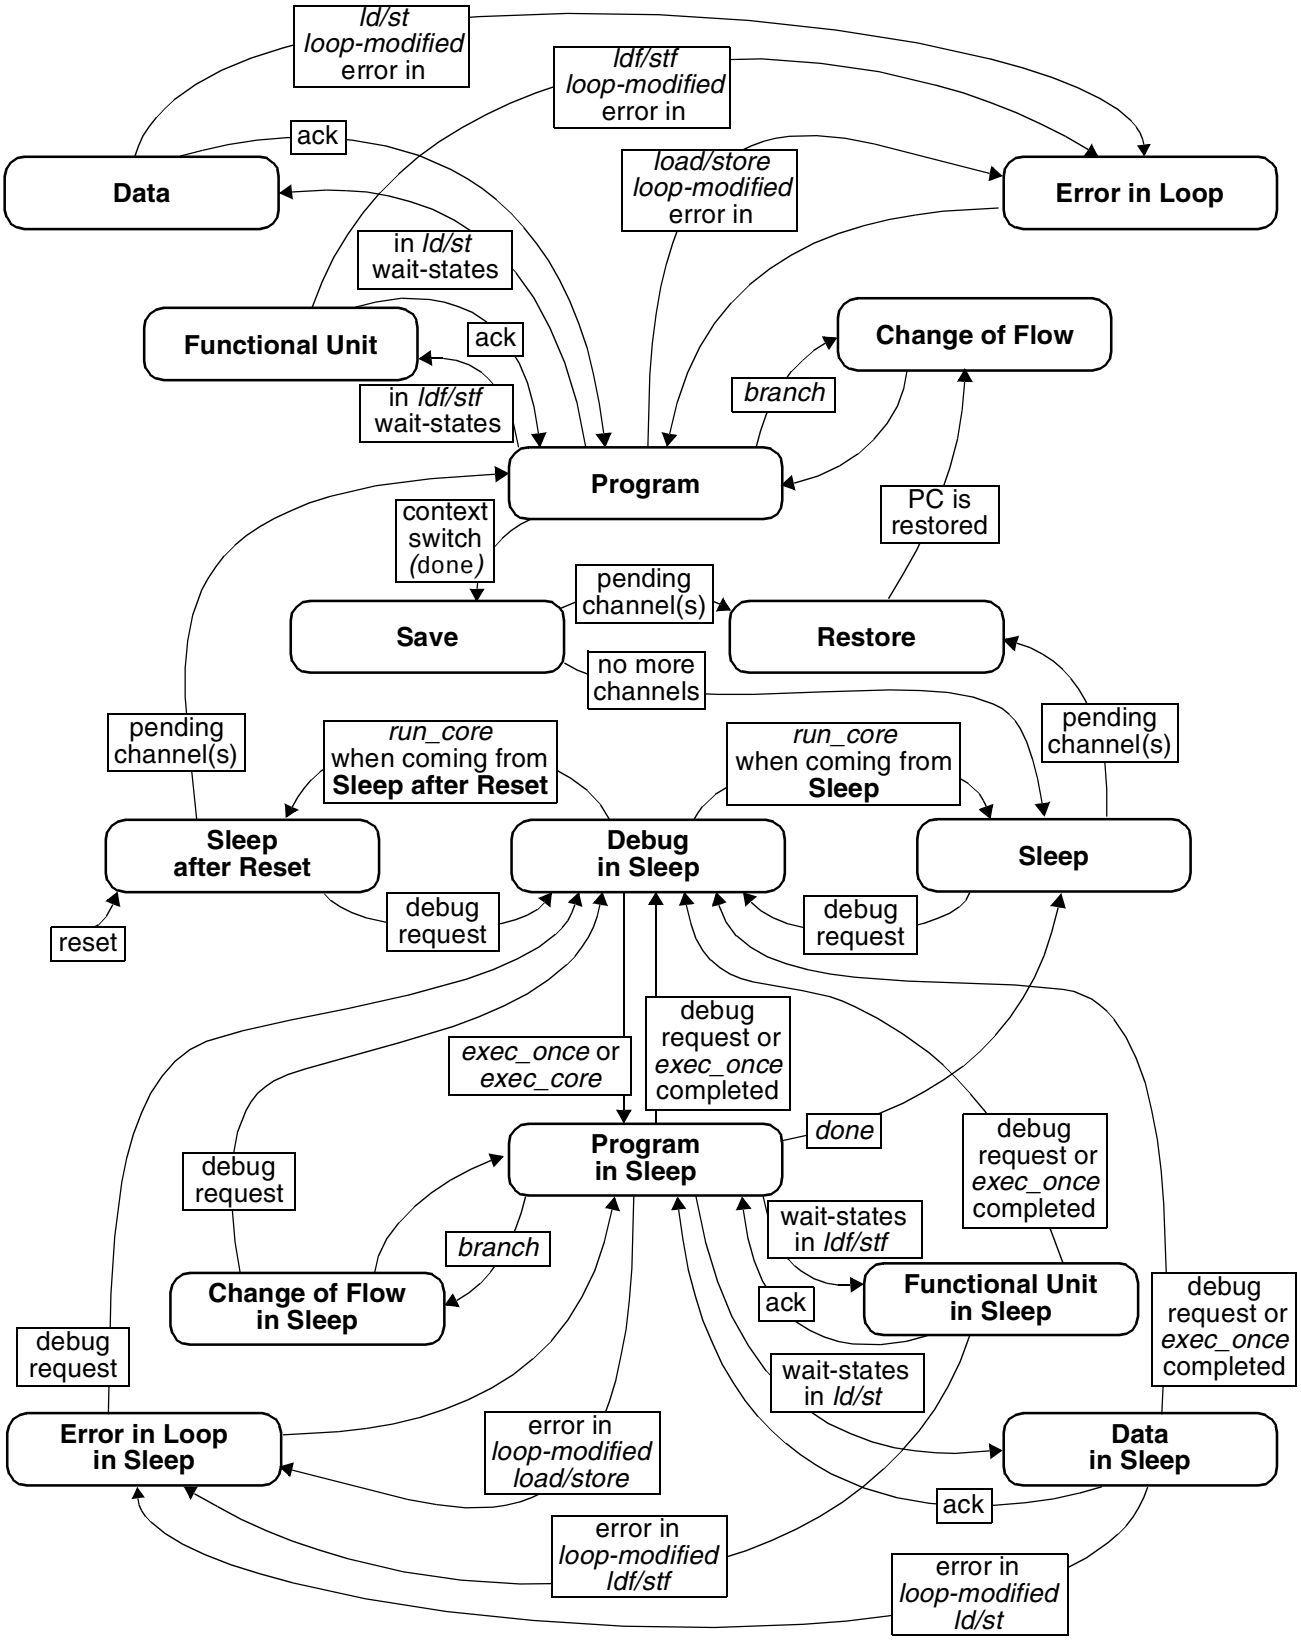

Figure 52-4. PCU State Diagram

52.3.3 SDMA Core Memory

The SDMA has two memory spaces: one for the instructions and one for the data. As both spaces share the same resources (ROM and RAM devices), the system bus manages possible conflicts when the core accesses the same resource for both an instruction read and a data read or write. Program and data memory is further described in Section 52.13.5, Address Space."

Instructions of 16-bit width are stored in 32-bit wide devices and can be accessed as data. The mapping is Big Endian: an even instruction address (terminated by 0) accesses the most significant part of the 32-bit data (bits [31:16]), and an odd instruction address (terminated by 1) accesses the least significant part of the 32-bit data (bits [15:0]). Instructions can be fetched out of internal ROM or RAM.

Data can be read from ROM, RAM, memory mapped registers, and external peripherals, and written to the same devices (except the ROM).

The ROM contains bootload scripts, channel scripts, and common subroutines which may be referenced by channel scripts elsewhere in the ROM or RAM.

The RAM is divided into a context area and a code space area which may be used to store channel scripts. The RAM contains undefined values after a hardware reset. Channel scripts and initial context values are downloaded into RAM using channel 0 which is reserved for bootload functions.

52.4 Scheduler

All channel scheduling hardware is included in the Scheduler.

52.4.1 Primary Functions

The scheduler is a hardware-based design used to coordinate the timely execution of 32 virtual DMA channels by the SDMA core on the basis of channel status and priority. The scheduler performs the following functions:

- Monitors, detects, and registers the occurrence of any one of the 48 DMA requests
- Links a specific request to a channel or group of channels (channel mapping)
- Ignores requests that are not mapped to a previously configured channel
- Maintains a list of all the channels that are requesting service
- Assigns a pre-programmed priority level (1 of 7) to every channel requesting service
- Detects and flags overrun/underrun conditions

52.4.2 Channels and DMA Requests

52.4.2.1 Channels

A Virtual Channel (hereafter simply called a channel) manages a flow of data through the SDMA. Flows are typically unidirectional. The SDMA can have up to 32 simultaneously operating channels, numbered from 0 to 31. Channel 0 is usually dedicated to control the SDMA script downloading. All the channels can be assigned by the AP software.

52.4.2.2 DMA Requests

A DMA request is caused by externally (for example, external to the SDMA) controlled conditions (for example, UART receive FIFO reaches a threshold). The SDMA currently supports up to 48 DMA requests.

52.4.2.3 Mapping from DMA Requests to Channels and Priorities

A channel can stall waiting on a single DMA request. A single DMA request can awake more than one channel (in fact, any request can awake any combination of channels). The mapping between DMA requests and channels is program-controlled. There is a storage element assigned for each of the 48 requests that contains a bitmap table of the channels that are awakened by the event. Every channel also has a three-bit register that indicates its priority.

52.4.3 Scheduler Functional Description

Section 52.4.3.1, Scheduler Overview" describes the behavior of the SDMA scheduler—from the channel enabling conditions to the highest priority pending channel selection.

52.4.3.1 Scheduler Overview

The scheduler algorithm is built in hardware. It is provided with possibilities for the AP to control its behavior. The scheduler processes incoming DMA requests, maps detected requests to 0, one, or several channels, maintains a list of channels that are requesting service (pending channels), identifies the top

priority and its associated channel, and selects the next active channel when the current channel yields. Figure 52-5 shows a functional overview.

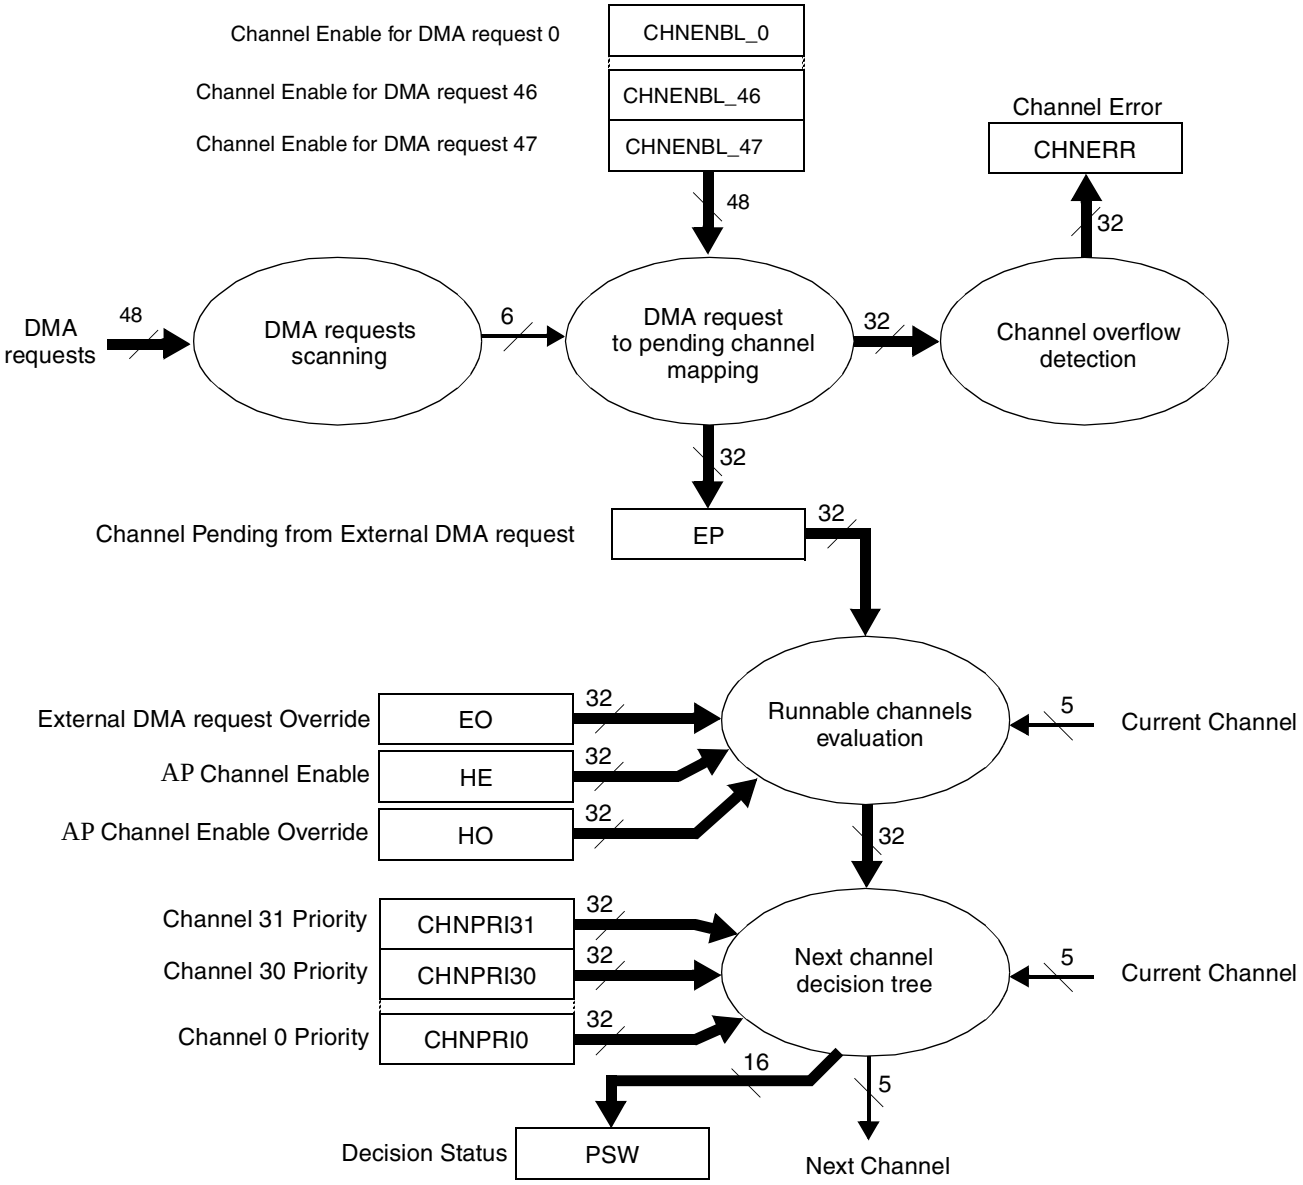

Figure 52-5. SDMA Hardware Scheduler

52.4.3.2 DMA Requests Scanning

The scheduler contains a 48-bit edge detection device that detects the rising edge of every DMA request and transmits the request number to the next stage. The DMA requests are assumed to be generated on the same reference clock as the SDMA core clock; they are detected as soon as the signal goes from a 1-to-n-cycles low state to a 1-to-m-cycles high state.

This system is able to detect single-cycle pulses as well as level-based DMA requests such as a FIFO threshold crossing. In this case, the SDMA provides a memory mapped register that can be used by the channel script to monitor the DMA requests lines, and thus determines whether the data transfer is done or not done, and then continues with the transfer or closes the channel.

When several DMA requests are detected at the same time, they are forwarded to the next scheduler stage at the rate of one request per cycle. No request is lost.

Figure 52-6 shows examples of valid DMA requests.

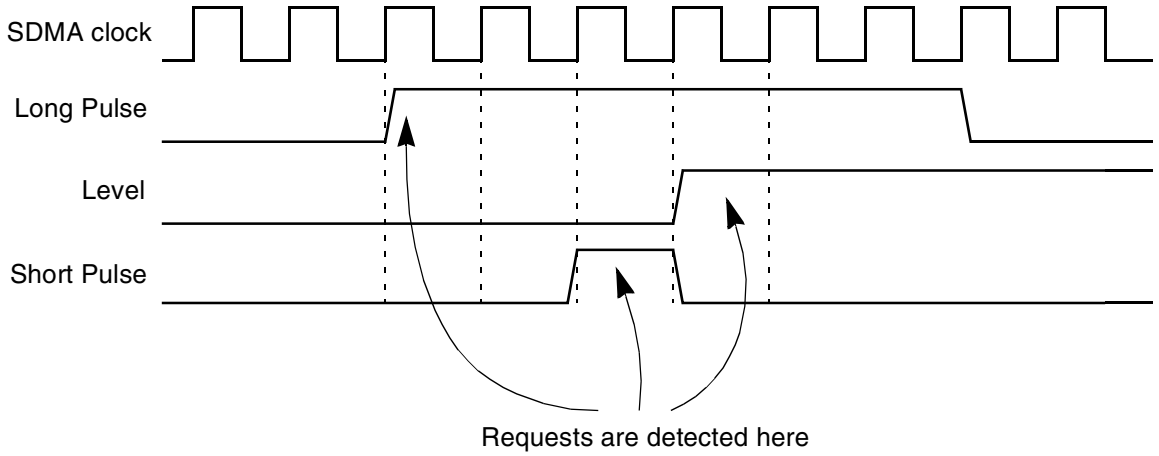

Figure 52-6. Examples of Valid DMA Requests

The DMA request inputs are connected to various sources that depend on the SoC. The exact list of DMA request inputs and their associated number is available in each respective project-specific chapter.

52.4.3.3 Mapping DMA Requests to Pending Channels

Whenever a DMA request is detected by the first stage, its number is used in the second stage to determine the channels that have to be activated. This is performed with an array of 48 registers that are 32 bits wide: There are 48 Channel Enable Registers (CHNENBLn), one register per DMA request. The DMA request number selects the Channel Enable Registers, and every bit of this 32-bit register indicates that the corresponding channel must be activated when it is a 1.

This information is passed on the EP register. For every bit of the Channel Enable Register that is set, the corresponding bit of the EP register is also set, and the remaining bits of EP are left unchanged. The transformation of EP is summarized by Equation 52-1:

$$\text{EP} = \text{EP or CHNENBLn} \qquad \textit{Eqn. 52-1}$$

The EP register is used to know which channels require service because they received a DMA request.

Typical contents of the CHNENBLn registers are all 0s, except for a single bit set. For example, a DMA request triggers one channel, but all 0s or several 1s are possible. One DMA request could activate several channels, and the channel execution sequence can be controlled by the channel priorities and numbers, as explained in the next sections. Table 52-2 illustrates an example configuration.

NOTE

From the table, the DMA request 0 is programmed to simultaneously trigger channels 0, 1, and 31. Also, DMA requests 30-47 are not used in this example. The remaining channels 2 to 30, are configured to be triggered by DMA requests 29 to 1, respectively.

Table 52-2. Channel Enable RAM Programming Example

52.4.3.4 Channel Overflow

A channel overflow occurs when a DMA request requires service from channel *n* by setting bit *n* of the register EP, but this bit is already set, meaning channel *n* is already pending. This can come from an overrun/underrun condition. This detection is possible only when the DMA requests are pulses, because a level-based DMA request stays high until it is serviced, even though an underrun or overrun condition occurs, thus preventing another edge detection of the DMA request.

The channel overflow information is saved in the 32-bit CHNERR register (1 bit per channel). You can configure the SDMA to trigger an interrupt to the AP when there are 1s in CHNERR. Every bit of CHNERR is masked with the corresponding bit of INTRMASK and if it gives a 1, the corresponding bit of INTR is set, triggering the interrupt.

52.4.3.5 Runnable Channels Evaluation

The EP register is used in conjunction with several other 32-bit registers to determine the channels that are runnable. Registers EO, DO, HO and HE, are controlled by the AP. EP is controlled by the DMA requests and their mapping to channels.

Several channels may be runnable at any given time. The i^{th} channel is runnable if (and only if) the condition below is true:

(HE[i] or HO[i]) and (DO[i]) and (EP[i] or EO[i]) ***Eqn. 52-2***

After reset, the HE[i], HO[i], EP[i], and EO[i] bits are all cleared whereas the DO[i] bits are all set. The functions associated with DO are not available for this device. When DO[i] is set, the scheduler condition becomes:

(HE[i] or HO[i]) and (EP[i] or EO[i]) ***Eqn. 52-3***

The registers in these equations are controlled as follows:

- AP (host) channel enable flag HE[i] may be set or cleared by the AP with the HSTART and STOP_STAT registers. It can also be cleared by the i^{th} channel script.

  Typical usage is for the AP to set this flag to activate the channel. The flag is cleared by the SDMA core when the transfer is done.
- Externally triggered channel pending flag EP[i] is set by the scheduler when the channel was activated by a DMA request. It can be cleared by the i^{th} channel script.
- The AP channel override flag HO[i] may be set or cleared by the AP. When set, it enables the i^{th} channel to run without the involvement of the AP.

  Typical usage is for the AP to set this flag for channels that do not need AP supervision such as channels that are controlled by DMA request events (EP).
- DO should always be set to 1 so that the runnable channel evaluation considers only HO, HE, EP, and EO.
- Externally triggered channel override flag EO[i] may be set or cleared by the AP. When set, it prevents the i^{th} channel from stopping and stalling on incoming peripheral DMA requests. This is the case when the channel is not handling data transfers with peripherals (for example, a memory to memory transfer).

The SDMA can clear the HE[i], and EP[i] bits by means of a `done` or `notify` instruction. The `done` instruction causes a reschedule; thus, enabling another channel to preempt the current one, while the `notify` instruction does not. The `done` and `notify` instructions can clear either HE[i] or EP[i] (never more than one at a time).

Table 52-3. Runnable Channel Selection Control

Register	Set by	Cleared By
HO	Write to HOSTOVR register	Write to HOSTOVR register
HE	Write to HSTART register	Write to STOP_STAT register or by the channel script with the `done` or `notify` instructions.

Table 52-3. Runnable Channel Selection Control (continued)

Register	Set by	Cleared By
DO	Write to DSPOVR register	Write to DSPOVR register
EO	Write to EVTOVER register	Write to EVTOVER register
EP	Set by external DMA request event input.	By the channel script with the `done` or `notify` instructions

52.4.3.6 Next Channel Decision Tree

The next channel number is computed from the runnable channels list, the current channel number, and their respective priorities. It is re-evaluated every cycle, but is only used when the current channel yields or terminates by executing a `yield`, `yieldge`, or `done` instruction.

The decision tree is based on the selection of the runnable channel that has the highest priority. The highest priority channel is selected according to the following rules:

- Runnable channels are sorted by priority.
- If one of the channels with the highest priority had been preempted by a channel with a higher priority, but did not want to yield to a channel of the same priority (for example, it executed a `yield`, not a `yieldge`), it is elected as the next channel.
- The channels that belong to the highest priority group are sorted by their number and the channel that has the highest number in this group becomes the next channel. For example, if priorities are the same, channel 31 will be selected before channel 30.

When the current channel requires a reschedule with a `yield`(`ge`) or a `done` instruction, the context switch decision is based on the instruction parameter, the current channel number and priority, and the next channel number and priority. The possible cases are all listed in the Table 52-4. The grayed cells in Table 52-4 correspond to unusual cases that should not occur with a typical usage of the SDMA.

Table 52-4. Channel Switching Decision with a yield, yield(ge), or done

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
`yield` (`done 0`)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Current
			Current < Next	Next[1]
	Not runnable	Not runnable	none	none[2] (occurs when the channel was disabled by the AP)
	Not runnable	Runnable	none	Next[1] (occurs when the channel was disabled by the AP)

Table 52-4. Channel Switching Decision with a yield, yield(ge), or done (continued)

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
yieldge (done 1)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Next[1]
			Current < Next	Next[1]
	Not runnable	Not runnable	none	none[2] (occurs when the channel was disabled by the AP)
	Not runnable	Runnable	none	Next[1] (occurs when the channel was disabled by the AP)
done (done >1)	Not runnable	Not runnable	none	none[2]
	Runnable	Not runnable	none	Current[3] (occurs when the done instruction does not disable the channel runnable condition)
	Not runnable	Runnable	none	Next[1]
	Runnable	Runnable	none	Current[3] (occurs when the done instruction does not disable the channel runnable condition)

1 Current channel script execution is stopped, its context is saved; the next channel context is restored and its script execution resumes

2 Current channel context is saved and SDMA enters IDLE mode

3 Current channel context is saved, then restored, and the current channel script resumes execution

Finally, when the SDMA is in IDLE mode and a runnable channel is elected as the next channel, its context is immediately restored and the script execution resumes.

The *combinatorial-decision* tree supports dynamic modifications of the EP, EO, HE, HO, and DO flags as well as dynamic modifications of the channel priorities. The propagation times are detailed in Section 52.4.3.8, Scheduler Pipeline Timing Diagram."

The decision tree status is available in the PSW register, which is continuously updated. It contains the next channel priority, the next channel number, the current channel priority, and the current channel number. When a priority is read as 0, it means the channel is not runnable.

A few examples of decisions are presented below:

- Channel 31 is running with priority 5, channels 13 and 24 are pending with the same priority 5; channel 24 is eligible as the next channel since 24 > 13.
- Channel 31 is running with priority 7, channels 13 and 24 are pending with priority 5; channel 31 is the next channel because its priority is greater than the other pending channels.
- Channels 7, 23, and 29 are pending with the same priority. Channel 7 is active and runs a yieldge; it is preempted by channel 29. After a period of time, channel 29 runs a yieldge, it is then

preempted by channel 23 that is the selected channel since channel 29 is the current channel. Later, channel 23 runs a `yieldge` and is preempted by channel 29. Channels 23 and 29 will go on switching after every `yieldge` until one of them terminates. It is only at that point that channel 7 becomes eligible again.

- Channel 11 is running with priority 3, and channel 15 is pending with priority 4. When the channel 31 script executes a `yield` instruction, it gets preempted by channel 15; then channels 6 and 18 with priority 3 become pending. Because channel 11 was preempted after executing a `yield` and there is no pending channel with a strictly greater priority, it is eligible as the next channel (although its number 11 < 18).

52.4.3.7 Scheduler State Diagram

The Figure 52-7 summarizes the behavior of the SDMA scheduler with details about the exact mechanism of the priority decision tree. It is important to understand the scheduler is a hardwired pipeline, which means all the stages are performed simultaneously every cycle, but a change on any given stage is reflected on the next stage after the delays presented in Section 52.4.3.8, Scheduler Pipeline Timing Diagram."

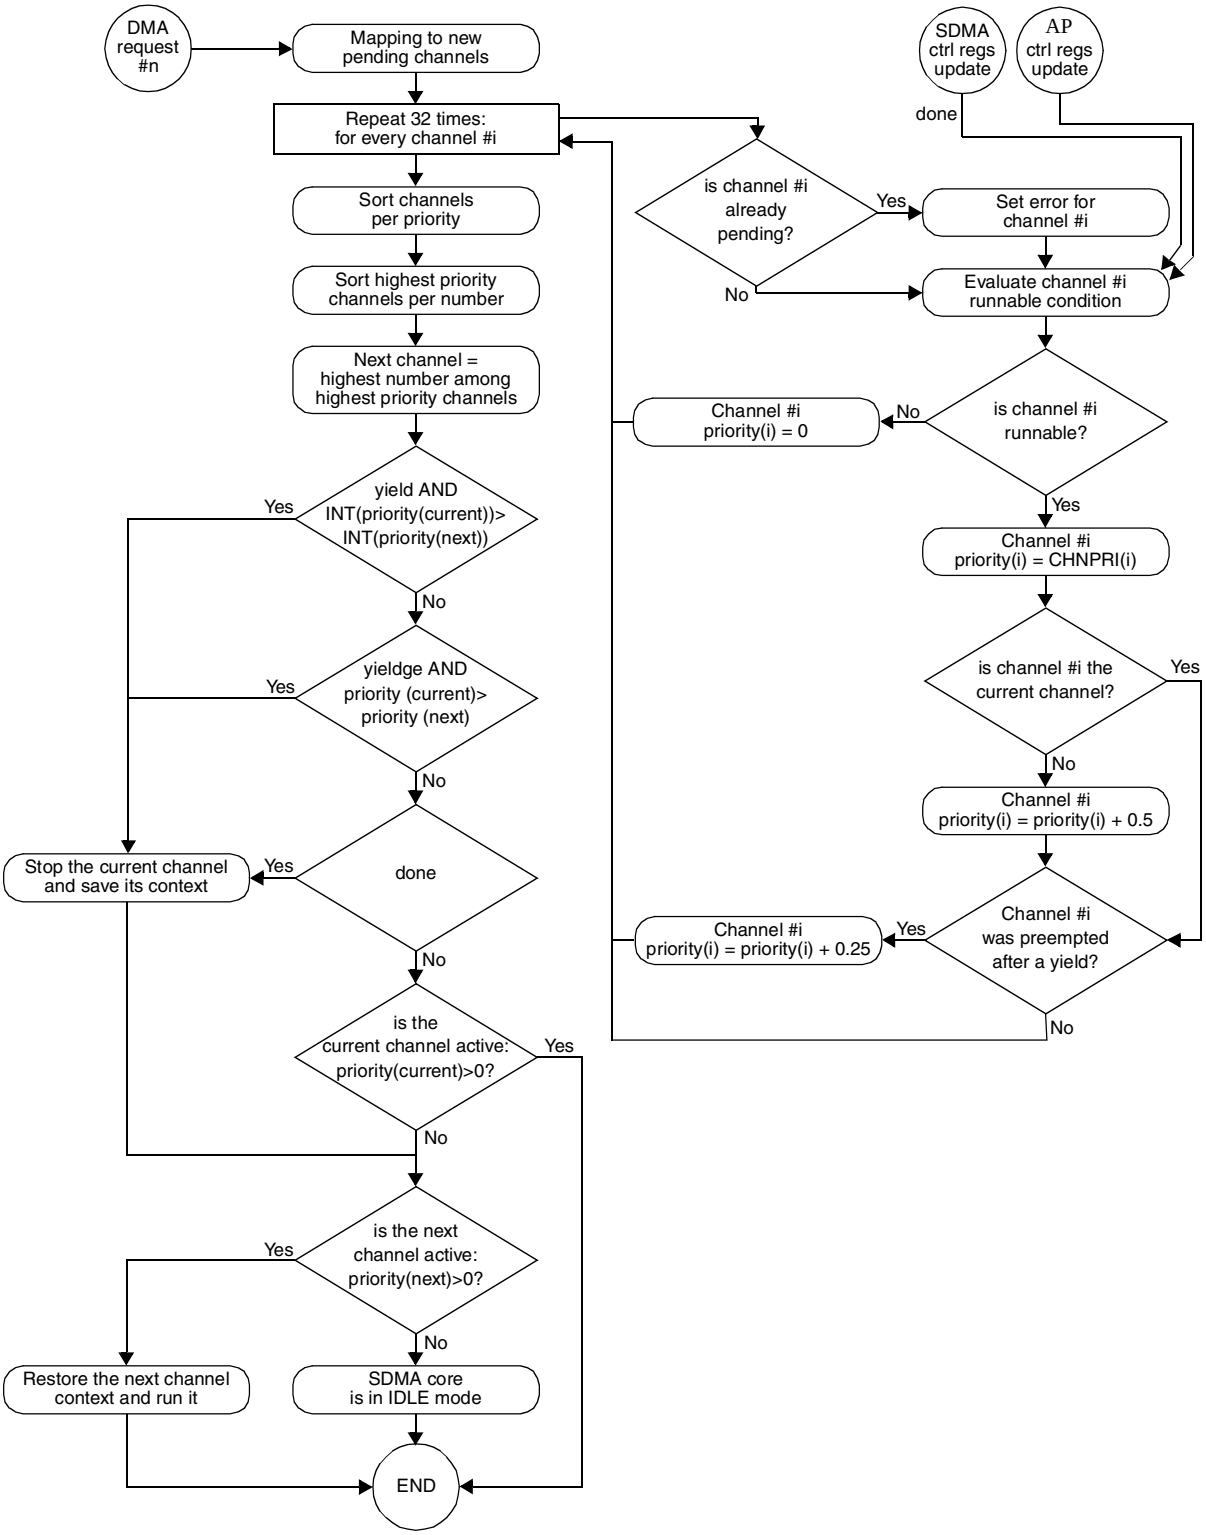

Figure 52-7. Scheduler State Diagram

52.4.3.8 Scheduler Pipeline Timing Diagram

The SDMA scheduler process of DMA-request and control-register modifications is not immediate. Figure 52-8 shows the exact delays of all the tasks. The reference clock is the SDMA core clock.

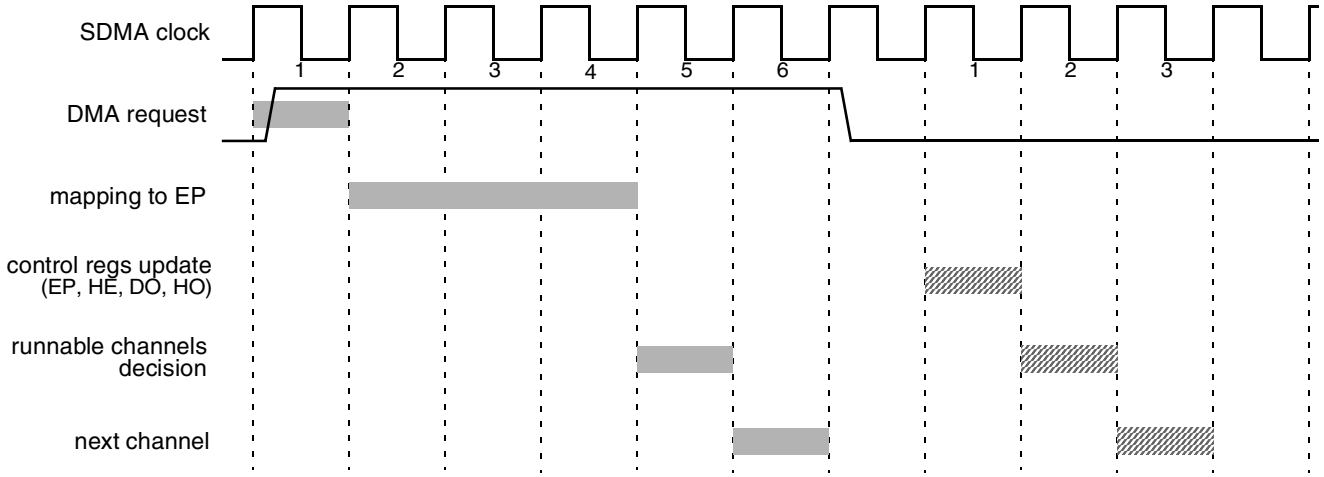

Figure 52-8. Scheduler Timing Diagram

Two numbers can be inferred from this timing diagram. First, it takes six SDMA core clock cycles to update the next channel from a DMA request. Second, it takes three SDMA core clock cycles to update the next channel from a direct modification of the condition registers (EP, DO, HE, or HO) by any processor. The processors that can modify these bits include SDMA with a `done` instruction or the AP with a write access through the corresponding control port on their respective peripheral bus).

52.4.3.9 Channel-DMA Request Mapping

The 48 DMA request inputs to the SDMA scheduler are listed in project-specific chapters. Refer to the respective chapters for this information.

52.4.3.10 Examples: How to Start a Channel

A channel can be started when Equation 52-2 is true for channel *i*:

(HE[i] or HO[i]) and (DO[i]) and (EP[i] or EO[i])

Once this equation is true, the scheduler can start this channel according to the priority of all pending channels. Several examples of configuration are listed below:

1. To start a channel triggered by AP software:
   - Initially, configure HO[i]=0, DO[i]=1, and EO[i]=1 using registers indicated in Table 52-3.
   - AP software triggers the channel by writing to the HSTART register to set HE[i]=1, thereby setting Equation 52-2 true.
2. To start a channel triggered by DMA request event.
   - Initially, configure HO[i]=1, DO[i]=1, and EO[i]=0 using registers indicated in Table 52-3.

— The DMA request is asserted to trigger the channel by setting EP[i]=1, which makes Equation 52-2 true.

52.4.4 Context Switching

On execution of a `done` or `yield(ge)` instruction, the current channel may be changed either because it has finished (which necessarily happens when the `done` instruction is executed), or it was preempted by a higher priority channel (which is possible but not systematic when the `yield(ge)` is executed).

Upon a channel change the SDMA goes through a context switch procedure. When the current channel yields or ends, the context for that channel is saved into the context RAM locations for that channel. When the next channel starts running, its context is first restored from RAM.

Since context RAM is not yet initialized by reset, there will be no context restore at the beginning of the first channel (bootload channel) run after reset. It is expected that the bootload channel will be used to initialize the context for all other channels. When the bootload channel finishes running or yields, SDMA will enter its SAVE state and save that channel's context into RAM. Then, if the bootload channel is called again later, the context will be restored from RAM when the channel starts again.

The context structure for each channel is defined in Section 52.13.4, Context Switching." and Table 52-43. There will be one context area reserved for each channel. When a channel ends or yields, the SDMA core registers are automatically saved into the context RAM and later restored from the context RAM when the channel is next run. The total RAM space reserved for 32-channel contexts is either 3K or 4K depending on whether the SMSZ bit is set in the CHN0ADDR register, which enables an additional 8 words of scratch RAM for each context.

52.4.4.1 Context Switch Modes

The exact procedure to save the context of the old channel, and to restore the context of the new channel depends on the context switch mode selected by the AP in the CONFIG control register. The following are the context switch modes:

- By default, the "dynamic" context switch is set. This mode provides the most efficient context switch for an average of eight cycles to stop the current channel, save its context, restore the next channel context, and resume its execution. It consists of saving modified registers of the current channel in the background (for example, during the channel execution)—which leaves very few registers to save when the switch is decided—resuming execution of the next channel as soon as possible (for example, when the minimal set of registers is restored), and continuing the restore phase during this execution.
- In "dynamic with no loop" mode, the same principle is followed except the modified registers are only saved in the background when the loop flag is not set. This mode offers almost the same effectiveness as the previous one, but it prevents the system from accessing the RAM during loops to save power. This is the recommended mode for an efficient context-switch when the loop bodies are short.
- In "dynamic power" mode, no background saving is performed, which reduces power consumption to the minimum. The modified registers are only saved when the context switch starts. The restore

phase is the same as before. This is the mode that achieves the optimal power consumption at the cost of a slower context-switch.

- In a “static” context switch, all the registers are saved when a context switch is decided, and all the registers are restored before starting the execution of the new channel. This mode enables a predictable behavior of the context switch since all the registers are restored prior to the channel start and all registers are saved after the channel termination.

NOTE

Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized during the context SAVE phase when the channel is done or yields. Subsequent calls to the same channel or different channels may use any of the dynamic context modes. This will ensure that all context locations for the bootload channel are initialized, and prevent undefined values in context RAM from being loaded during the context restore if the channel is re-started later.

52.4.4.2 Context Switch Procedure

The Program Control Unit goes into the *save* state, the current context is spilled into memory, and the next channel context is restored according to the context-switch mode that was selected by the AP.

The context switch procedure is as follows:

1. Load the current context’s spill base address.
2. Spill the modified registers of the current channel to memory according to the selected context switch mode while the channel is running.

   On a `done` or `yield(ge)` that causes the channel preemption, the PCU goes into the *save* state. In *static* mode, all the registers are saved; whereas, in either *dynamic* mode, the registers that were modified but not yet saved are then saved, and the PCU registers and flags are finally saved.
3. Put the SDMA core into *sleep* and wait for new channels to be serviced. This step is skipped if there are pending channels when the current channel is saved.

   As soon as there is at least one pending channel, the PCU goes into its *restore* state to restore the context of the channel that was elected by the scheduler.

   Once a channel is elected, it remains the current channel until its script requests a rescheduling operation with a `done` or `yield(ge)` instruction. That means the current channel cannot be modified by the AP, even if it is no more runnable or if its priority is modified.

   The AP can however force a reschedule by writing the corresponding bit in the CONFIG register, which has the same effect as if the script had executed a `done` instruction. That feature should only be used to stop the SDMA in emergency cases.
4. Load the context base-address of the new channel.

   In “static” mode, all the registers are restored. In either “dynamic” modes, only the PCU registers are restored.

   The new channel is running. In “static” mode, no more activity regarding context restoring or saving is performed. In either “dynamic” modes, the registers are restored in the background every time an access to the context RAM is possible, and priority is given to restoring the registers that

are required by the next instruction to be executed. When a register has not been restored and the next instruction needs it, this instruction gets stalled until the register was restored.

In “dynamic” and “dynamic with no loop” modes, background saving of dirty registers is performed every time an access to the context RAM is possible and allowed by the context switch mode.

NOTE

The contents of a channel context space in the context RAM depends on the selected context switch mode. In “dynamic” and “dynamic with no loop” modes, the contents of the context RAM tend to match the contents of the SDMA registers (except for the PCU registers and flags that are never saved in the background). In “dynamic power” and “static” modes, the contents of the context RAM remain unchanged until the channel terminates with a done or gets preempted.

52.4.4.3 Context Map in Memory

Refer to Section 52.13.4, Context Switching.”

52.5 Profiling Unit

Profiling Unit in SDMA is used for measuring certain performance related numbers which can be used to do performance analysis of SDMA. This will be useful for doing S/W based profiling of SDMA. This Unit contains 5 separate counters. All the counters are running at SDMA Core Clock. All these counters can be programmed individually to measure one of the following values:

- Number of cycles when SDMA is in Sleep State.
- Number of cycles when one of the DMA is in Sleep State.
- Number of cycles for which a particular channel is active.
- Number of cycles for which a particular channel is runnable but it is pending due to some higher priority channels.
- Number of cycles for which SDMA core is in FUBUS state. For understanding FUBUS state refer PCU States.
- Number of cycles for which one of the DMA request is asserted but it is pending to be serviced.
- Number of cycles for which a particular DMA is in sleep state while running a particular channel

One additional counter (6th) is there which has an extra feature in addition to the above mentioned ones. It can be used as a free running counter which can be enabled both by SDMA core as well as AP core. All the counters are 32 bit registers whose 9 bits (31:23) are used to program the counter, 23rd bit is the over flow bit and the remaining 22 bits (21:0) are used as counter. For details of the programming refer to Profile Counter Registers (PRF_CNT_x)

Another register is Profile Status/Config register. This register contains “Profile Enable” (PRF_CFG[0]) bit and “Interrupt enable” (PRF_CGF[6:1]) bits for all the counters. For details refer to Profile Config/Status Register (PRF_CGF)

52.5.1 Profiling Sequence

The profiling sequence is as follows:

1. Program the 9 bit of the Registers (PRF_CNT_x[31:23]) corresponding to the counters that need to be enabled.
2. To enable the Interrupt to be sent to AP core, program the Interrupt Enable bits for the corresponding counters.
3. Run the software that needs to be profiled and enable the Profile Enable bit when the profiling has to be started. All the counters, OFL, and ISR bits of Profile Config/Status Register (PRF_CGF) will be reset as soon as the Profile Enable bit is set (rising edge).
4. The interrupt will be sent to AP core if any of the counter overflows and its Interrupt Enable bit is set in the Profile Config/Status Register (PRF_CGF).
5. Interrupt service Routine in the AP core has to disable the Profile Enable bit in order to stop all the counters. Counters keep on running even after sending the interrupt to AP core.
6. Interrupt Service Routine in AP core has to clear the ISR bit of Profile Config/Status Register (PRF_CGF). This bit is W1C bit.
7. After completing steps 5 and 6, the AP core can read any of the 6 registers to record the profiling values for the software.

NOTEs

While running the sixth Register in Free Running Counter mode, SDMA core can set/reset the EN bit of Profile Config/Status Register (PRF_CGF). This EN bit should be set/reset after the Profile Enable bit is set (in step 3). Setting/Resetting this bit will start/stop the counter respectively.

Disabling of all the counters can be done at any point of time while the profile software is running. When the profile enable bit is cleared, all counters stop and its value freezes. All the counters rerun from the same value again if the Profile Enable bit is set.

52.6 Functional Units

The functional units are small systems that are used by the SDMA core to handle data transfers between the core and a bus domain external to the SDMA.

The SDMA core is able to control and exchange data with these systems by sending instructions and reading or writing data from/to the functional units' registers via the FUBUS. This is done with the `ldf` and `stf` instructions.

The following sections provide introductions to the available functional units. Section 52.18, Functional Units Programming Model" provides descriptions the functional units' behaviors.

52.6.1 Burst DMA Unit

The burst DMA unit enables the SDMA core to perform data transfers to and from the AP memory. It is optimized for accessing SDRAM-like devices. It does not provide control to assign a privilege level to the DMA access. The burst DMA unit provides the SDMA with means to do the following:

- Perform up to 8-beat read and write bursts to the AP memory, which optimizes throughput when accessing SDRAM-type devices because of an internal, 36-byte FIFO
- Access the AP memory at once or twice the SDMA core frequency
- Copy data from one AP memory location to another AP memory location at the AP bus speed, which provides a very high throughput
- Control the method for addressing the AP memory (automatic increment of addresses or frozen addresses—the former aimed at accessing RAM-like memory and the latter aimed at accessing single-address FIFOs)
- Enable or disable automatic prefetch when reading data from the AP memory. When the prefetch mode is selected, the burst DMA automatically triggers external bursts to fill its FIFO without waiting for the SDMA core to request the corresponding data, greatly improving throughput.
- Rely on the DMA to automatically flush its FIFO content when there is enough data to generate an 8-beat burst to the AP memory. Or, it forces a flush when a data transfer must terminate.

  In the former case, the SDMA core may only be stalled when it tries writing data and there is not enough room left in the FIFO. In the latter case, the core is stalled until the data is effectively written to the AP memory.

  In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the AP memory. This error status is retrieved by a later access to the burst DMA. Terminating a write data transfer with a forced flush command guarantees that any bus error to the AP memory is caught.
- Handle address alignment issues between the AP memory map and the SDMA core data. This enables the core to read or write 32-bit data from the burst DMA, whereas the corresponding AP address is not 32-bit aligned. This drastically improves the SDMA scripts' efficiency since the same loop that transfers 32 bits at a time can be used regardless of the start and end addresses in the AP memory space.

This unit structure and registers are described in Section 52.6.1.1, Burst DMA Structure" and Section 52.6.1.2, Burst DMA Registers."

52.6.1.1 Burst DMA Structure

The burst DMA is depicted in Figure 52-9. It is essentially made up of a 36-byte FIFO, address registers, and a controlling state-machine. The 36-byte FIFO enables eight-word buffering with address alignment, and the state-machine manages clock adaptation when required.

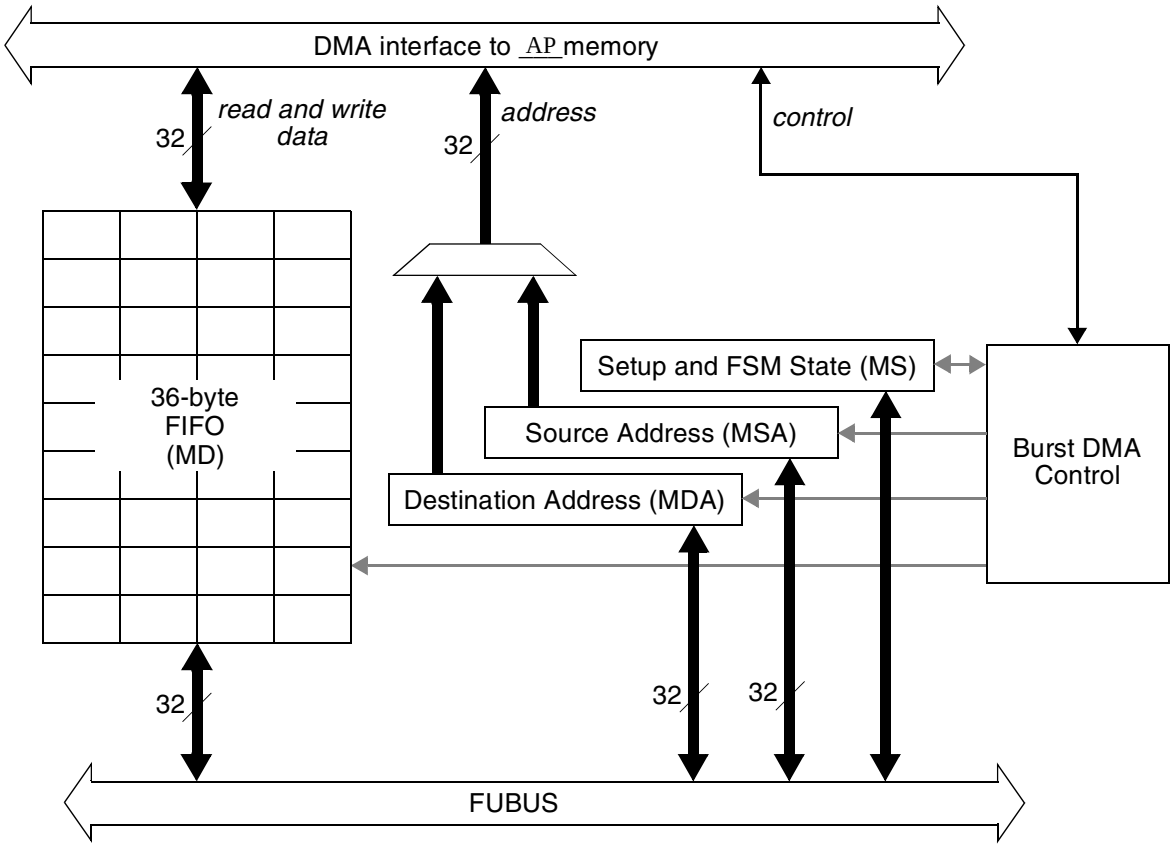

Figure 52-9. Burst DMA Structure

52.6.1.2 Burst DMA Registers

There are four registers, as follows, that may be accessed from the SDMA core:

- MSA (Memory Source Address) — Holds the source byte address in the AP memory map for reading data from this location. This register is automatically modified every time the core reads new data from the FIFO.
- MDA (Memory Destination Address) — Holds the destination byte address in the AP memory map for writing data to this location. This register is automatically modified every time the core writes new data into the FIFO.
- MD (Memory Data) — Labels the 36-byte FIFO access point: Reading a byte, halfword, or word from MD respectively retrieves the first 1, 2, or 4 bytes of the FIFO (for example, the bytes that were stored first by the DMA state-machine when transferring data from the AP memory).

  When the FIFO does not hold as many bytes as required by the SDMA core, the core is stalled until the missing bytes are read from the AP memory. In the case of prefetch mode, the DMA controller decides when it should start a burst to AP memory in order to reduce the risk to not have the required data for the future accesses of the core. When there is no prefetching, a burst is triggered when the required data is not available in the FIFO.

  Writing a byte, halfword, or word to MD stores 1, 2, or 4 bytes, respectively, at the end of the FIFO (for example, these bytes are transmitted to the AP memory after all the other bytes that were

previously stored in the FIFO). When the FIFO does not have enough room left to hold the written data, the SDMA core is stalled until a sufficient amount of FIFO contents are flushed out to the AP memory. Flushing is decided by the DMA controller when there are enough bytes in the FIFO to perform the largest allowed burst to AP memory (the exact size depends on the burst start address and the AHB 1 Kbyte boundary rule). However, the SDMA core has the ability to force the flushing operation at any time, for example, when at the end of the data transfer, prior to channel closure.

- MS (Memory Setup) — Contains the state of the burst DMA control, the two flags that define whether each address register is incremented after every access to the external memory, and another flag that is set when a bus error occurred.

52.6.1.3 Data Transfers

Three typical usages have been identified that involve the burst DMA: the data transfer startpoint, the endpoint, or both. Every case requires a different procedure, as listed in the following sections:

52.6.1.3.1 Data Retrieval from the AP Memory

The following steps retrieve data from AP memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the source address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the source address register itself (MSA).
- Read data from the FIFO using the *ldf MD* instruction as many times as needed. If an error occurred during the fetch from AP memory, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from the FIFO.

52.6.1.3.2 Storing Data Into the AP Memory

The following steps store data from AP memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the destination address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the destination address register itself (MDA).
- Store data into the FIFO using the *stf MD* instruction as many times as needed.
- When the transfer is finished and if the DMA worked in automatic flush mode, force the flush of the FIFO. This instruction is stalled until all the FIFO data is effectively sent to the AP memory and the error status of the transfer is available in the DF flag.

52.6.1.3.3 Transferring Data Between Two AP Memory Locations

The following steps copy data between two AP memory locations using the burst DMA unit:

- Set up the MS flags to reflect the modes for the source and destination addresses (all the combinations are possible), then initialize the source address register (MSA) and the destination address register (MDA). Both addresses must be word-aligned.
- Use as many *stf MD* instructions with the *COPY* flag as needed. Every instruction triggers a burst read of a given number of words from the source address (this number is provided to the burst

DMA via the SDMA core general purpose register, which is referenced in the *stf* instruction). Once all the data is loaded into the FIFO, the DMA empties it with a write burst of the same count to the destination address. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.

- Once the transfer is done, there should be a final access to the burst DMA to check the error status.

52.6.2 Burst DMA2 Unit

The second burst DMA2 unit is the replica of the first Burst DMA unit. This DMA is used to connect BP side memory. It is optimized for accessing SDRAM-like devices. It does not provide control to assign a privilege level to the DMA access. The burst DMA2 unit provides the SDMA with means to do the following:

- Perform up to 8-beat read and write bursts to the BP memory, which optimizes throughput when accessing SDRAM-type devices because of an internal, 36-byte FIFO
- Access the memory at once or twice the SDMA core frequency
- Copy data from one BP memory location to another BP memory location at the BP bus speed, which provides a very high throughput
- Control the method for addressing the BP memory (automatic increment of addresses or frozen addresses—the former aimed at accessing RAM-like memory and the latter aimed at accessing single-address FIFOs)
- Enable or disable automatic prefetch when reading data from the BP memory. When the prefetch mode is selected, the burst DMA2 automatically triggers external bursts to fill its FIFO without waiting for the SDMA core to request the corresponding data, greatly improving throughput.
- Rely on the DMA to automatically flush its FIFO content when there is enough data to generate an 8-beat burst to the BP memory. Or, it forces a flush when a data transfer must terminate.

  In the former case, the SDMA core may only be stalled when it tries writing data and there is not enough room left in the FIFO. In the latter case, the core is stalled until the data is effectively written to the memory.

  In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the memory. This error status is retrieved by a later access to the burst DMA2. Terminating a write data transfer with a forced flush command guarantees that any bus error to the memory is caught.
- Handle address alignment issues between the memory map and the SDMA core data. This enables the core to read or write 32-bit data from the burst DMA2, whereas the corresponding BP address is not 32-bit aligned. This drastically improves the SDMA scripts' efficiency since the same loop that transfers 32 bits at a time can be used regardless of the start and end addresses in the BP memory space.

This unit structure and registers are described in Section 52.6.2.1, Burst DMA2 Structure" and Section 52.6.2.2, Burst DMA2 Registers."

52.6.2.1 Burst DMA2 Structure

The burst DMA2 is depicted in Figure 52-10. It is essentially made up of a 36-byte FIFO, address registers, and a controlling state-machine. The 36-byte FIFO enables eight-word buffering with address alignment, and the state-machine manages clock adaptation when required.

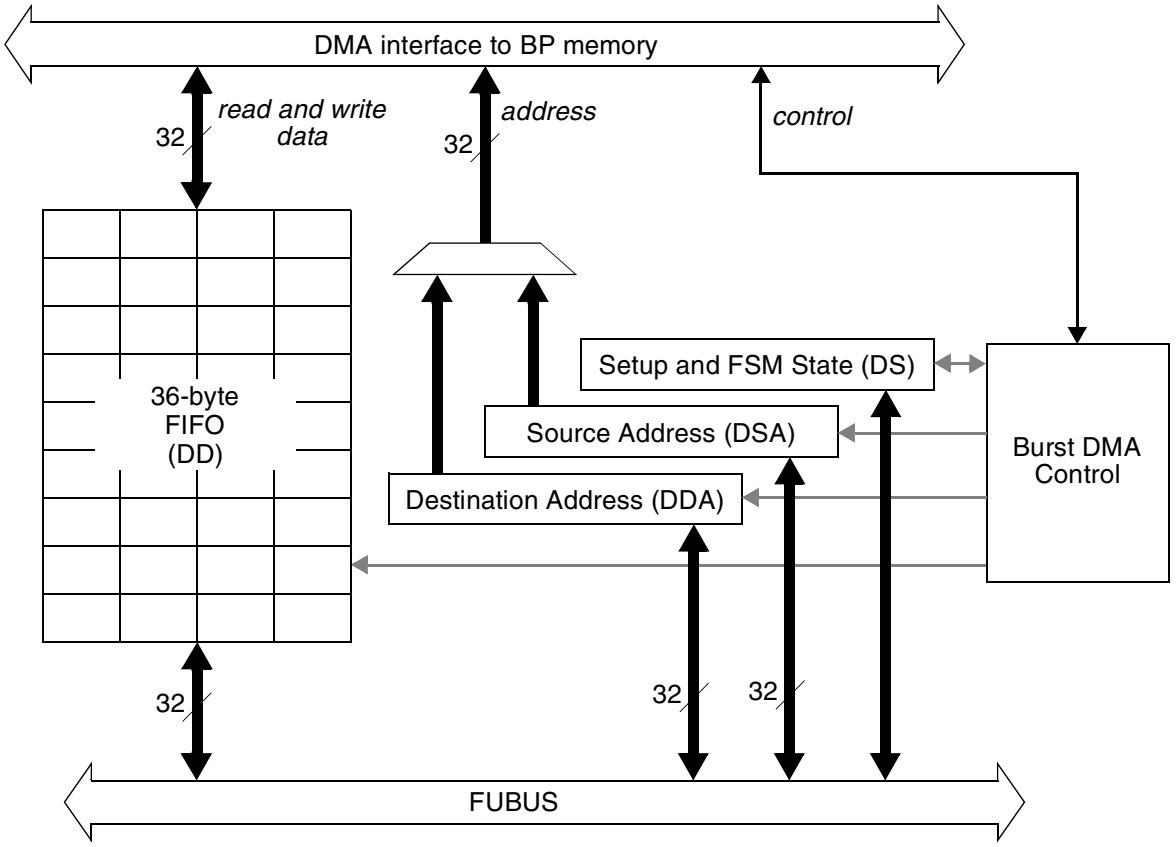

Figure 52-10. Burst DMA2 Structure

52.6.2.2 Burst DMA2 Registers

There are four registers, as follows, that may be accessed from the SDMA core:

- DSA (Memory Source Address) — Holds the source byte address in the memory map for reading data from this location. This register is automatically modified every time the core reads new data from the FIFO.
- DDA (Memory Destination Address) — Holds the destination byte address in the memory map for writing data to this location. This register is automatically modified every time the core writes new data into the FIFO.
- DD (Memory Data) — Labels the 36-byte FIFO access point: Reading a byte, halfword, or word from DD respectively retrieves the first 1, 2, or 4 bytes of the FIFO (for example, the bytes that were stored first by the DMA state-machine when transferring data from the memory).

  When the FIFO does not hold as many bytes as required by the SDMA core, the core is stalled until the missing bytes are read from the BP memory. In the case of prefetch mode, the DMA controller

decides when it should start a burst to BP memory in order to reduce the risk to not have the required data for the future accesses of the core. When there is no prefetching, a burst is triggered when the required data is not available in the FIFO.

Writing a byte, halfword, or word to DD stores 1, 2, or 4 bytes, respectively, at the end of the FIFO (for example, these bytes are transmitted to the BP memory after all the other bytes that were previously stored in the FIFO). When the FIFO does not have enough room left to hold the written data, the SDMA core is stalled until a sufficient amount of FIFO contents are flushed out to the memory. Flushing is decided by the DMA controller when there are enough bytes in the FIFO to perform the largest allowed burst to memory (the exact size depends on the burst start address and the AHB 1 Kbyte boundary rule). However, the SDMA core has the ability to force the flushing operation at any time, for example, when at the end of the data transfer, prior to channel closure.

- DS (Memory Setup) — Contains the state of the burst DMA2 control, the two flags that define whether each address register is incremented after every access to the external memory, and another flag that is set when a bus error occurred.

52.6.2.3 Data Transfers

Three typical usages have been identified that involve the burst DMA2: the data transfer startpoint, the endpoint, or both. Every case requires a different procedure, as listed in the following sections:

52.6.2.3.1 Data Retrieval from the BP Memory

The following steps retrieve data from BP memory using the burst DMA2 unit:

- Set up the DS flags to reflect the mode for the source address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the source address register itself (DSA).
- Read data from the FIFO using the *ldf DD* instruction as many times as needed. If an error occurred during the fetch from BP memory, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from the FIFO.

52.6.2.3.2 Storing Data Into the BP Memory

The following steps store data from BP memory using the burst DMA2 unit:

- Set up the DS flags to reflect the mode for the destination address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the destination address register itself (DDA).
- Store data into the FIFO using the *stf DD* instruction as many times as needed.
- When the transfer is finished and if the DMA worked in automatic flush mode, force the flush of the FIFO. This instruction is stalled until all the FIFO data is effectively sent to the BP memory and the error status of the transfer is available in the DF flag.

52.6.2.3.3 Transferring Data Between Two BP Memory Locations

The following steps copy data between two BP memory locations using the burst DMA2 unit:

- Set up the DS flags to reflect the modes for the source and destination addresses (all the combinations are possible), then initialize the source address register (DSA) and the destination address register (DDA). Both addresses must be word-aligned.
- Use as many *stf DD* instructions with the *COPY* flag as needed. Every instruction triggers a burst read of a given number of words from the source address (this number is provided to the burst DMA2 via the SDMA core general purpose register, which is referenced in the *stf* instruction). Once all the data is loaded into the FIFO, the DMA empties it with a write burst of the same count to the destination address. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.

Once the transfer is done, there should be a final access to the burst DMA2 to check the error status

52.7 SDMA Security Support

The SDMA provides support to SDMA software to block unauthorized updates to the scripts in RAM.

SDMA supports the following Security modes:

- Open Mode: has full control to load scripts and context into SDMA RAM. This is the default mode.
- Locked Mode: The AP loads scripts and channel contexts at startup when it is still executing known safe software. When finished, it locks the SDMA to prevent further updates to RAM and selected registers. More details described in Section 52.7.1, Locked Mode."

52.7.1 Locked Mode

The LOCK bit in the SDMA_LOCK register provides support for SDMA scripts to freeze RAM contents after the initial bootload routine to prevent future unauthorized updates to SDMA RAM. After initial RAM contents are uploaded, AP software can set the LOCK bit to secure the RAM contents to prevent future updates by an unauthorized. After the LOCK bit is written with a '1', the SDMA is "locked" until reset.

The LOCK bit can be read in the SDMA's internal memory map in the LOCK register (see Section 52.14.3.20/52-106). SDMA scripts which load information into RAM can check the value of the LOCK bit to determine if an upload to RAM is allowed. If not allowed, the script can refuse to allow the request to copy data into the RAM to continue. The exact use of the LOCK bit in SDMA scripts for security control will be described in SDMA software documentation (see Section 52.25, References").

While SDMA is locked, attempts to write to the SDMA_LOCK, CHN0ADR, ILLINSTADDR, and ONCE_ENB registers will be ignored. All registers remain readable. Writes to other registers are still allowed.

Once the SDMA is locked, the LOCK bit can only be cleared by a reset. A hardware reset will always clear the LOCK bit. A software reset initiated by writing to the RESET register will only clear the LOCK bit if the SRESET_LOCK_CLR bit in the SDMA_LOCK register is set. Since SDMA_LOCK register cannot be updated if SDMA is locked, the SRESET_LOCK_CLR bit must be configured before setting the LOCK bit. The SREST_LOCK_CLR bit will also be cleared by resets that clear the LOCK bit.

The SDMA RISC core uses the ILLINST and CHN0ADDR registers as pointers to determine where to jump to after an illegal instruction or upon boot after a reset. The LOCK bit prevents updates to these registers to protect against unauthorized changes to these pointers.

While SDMA is locked, the ONCE_ENB register cannot be written to prevent the OnCE under AP control from being used to gain access to SDMA internal memory. If AP control of the OnCE is enabled before setting the LOCK bit, the AP can use the ONCE for debug purpose after LOCK is set.

52.8 OnCE and PCU Debug States

The SDMA has two different debug modes in which the OnCE performs debug instructions. Refer to Figure 52-4 for an example of the PCU states in debug. The following are the two debug states:

- When a channel is running (that is, when CCR and CCPRI are different from 0, which can be read in the PSW register), SDMA can execute a `SoftBkpt` instruction from the channel script or receive a debug request. When either happens, the SDMA enters its "Classical" *Debug* state, which is described in Section 52.18.3, OnCE and Real-Time Debug."
- When a channel is not running, the SDMA can be in *Sleep* state or in *Sleep after Reset* state. If a debug request is sent to the core, it enters its *Debug in Sleep* state. This debug mode works similarly to the "Classical" *Debug* state, except it returns to the original state (*Sleep* or *Sleep after Reset*) when the debug mode is left via the `exec_core` instruction of the OnCE. From this *Debug in Sleep* state, the SDMA can execute a program whereas no channel is running. If a new debug request is sent to the core or if a `SoftBkpt` is executed, it comes back to this *Debug in Sleep* state.

The OnCE is provided with several instructions that can be executed when the core is in either debug state. Table 52-5 summarizes the behavior of these OnCE debug instructions. There exists other secondary OnCE instructions that are described in Section 52.18.3, OnCE and Real-Time Debug."

Table 52-5. SDMA in Debug Mode

Instruction	Debug	Debug in Sleep
`exec_once`	`exec_once` <instruction> SDMA executes the <instruction> and returns to the *Debug* state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.	`exec_once` <instruction> SDMA executes the <instruction> and returns to the *Debug in Sleep* state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.
`run_core`	`run_core` <instruction> SDMA executes the <instruction>, leaves the *Debug* state and continues executing the channel script from the position where it stopped. This command must not be used with an instruction that modifies the PC value.	`run_core` <instruction> SDMA executes the <instruction> and returns to its *Sleep* or *Sleep after Reset* initial state. This command must not be used with an instruction that modifies the PC value.
`exec_core`	`exec_core` <instruction> It is similar to `run_core` except it requires an instruction that changes the PC value (jump, branch...): the SDMA jumps to the new PC value, leaves the *Debug* state and starts executing instructions from this new PC value.	`exec_core` <instruction> If the previous state was *Sleep after Reset*, the SDMA returns to this state, and Chn0Addr value overrides the PC value. Otherwise, the SDMA jumps to the new PC value and starts executing instructions from this new PC.

NOTE

The feature `exec_core` in *Debug in Sleep* after *Sleep after Reset* was added for the Channel boot (channel 0) to allow the debugger to return to *Sleep after Reset* state with a new PC value. The SDMA will be ready to boot at the Chn0Addr address.

52.9 SDMA Clocks and Low Power Modes

The SDMA receives several root clocks from the SoC clock controller module and performs adaptive clock gating to optimize its power consumption. From a user standpoint, clock gating and power mode selection are fully automatized inside the SDMA. Root clock control is available from the SoC clock controller module.

There are numerous clock sources that are used in the SDMA. They belong to one of two possible clock domains listed in Table 52-6, and have frequency constraints within each domain. Clocks are considered asynchronous between domains.

Within the AP/SDMA clock domain, all clocks must come from the same PLL. The AP DMA interfaces (burst DMA) receive their clock from the AP DMA clock source whose frequency can be once or twice the frequency of the SDMA core clock. The DMA interfaces are designed to work at the AP DMA frequency, but the SDMA core is physically limited to a maximum 104 MHz frequency. Since this is lower than the maximum AP DMA frequency, the SDMA core clock is tied to the AP peripheral clock frequency.

The AP Peripheral Bus Clock source must be an exact sub-frequency of the SDMA Core clock source (any integer value greater or equal to 1).

Table 52-6. Clocking Scheme

Clock Domain	Source Clock	Comments
AP	SDMA core (SDMA main core)	Source clock for the core and all its operations; this clock is thus used by most of the SDMA sub-modules.
	AP DMA	DMA interface for the burst DMA. It is balanced with the main clock source, and its frequency is either once or twice the main clock frequency.
	AP peripheral	Connection to the AP peripheral bus. It is a sub-frequency of the main clock frequency.
Burst DMA2	AP DMA	DMA interface for the Burst DMA2. It is balanced with the main clock source, and its frequency is either once or twice the main clock frequency.
	BP peripheral	Connection to the BP peripheral bus; no constraint regarding its frequency but it is usually a sub-frequency of the BP DMA clock frequency.
JTAG	TCK	Clock for JTAG access, limited to maximum of 1/8 of the SDMA core clock frequency.

The JTAG clock is sampled by the SDMA main clock to determine its rising edge. This simplifies design and clock management, but it also adds a ratio constraint between those two clocks. It is guaranteed the

JTAG interface works properly when the frequency of TCK is lower than 1/8th of the frequency of the SDMA main clock (which is about 8 MHz when the SDMA core clock frequency is 66 MHz).

52.9.1 Clock Gating and Low Power Modes

The SDMA automatically performs power saving without requiring user involvement. It implements two levels of automatic clock gating.

52.9.1.1 Coarse Clock Gating

Every sub-module clock comes from one of the five available sources, and is gated with the sub-module specific enabling condition. Table 52-7 displays the sub-module clocks and their source. It also indicates the relationships that may exist between different sub-modules clock enables.

Table 52-7. Sub-Modules Clocks

Sub-Module	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
Core	SDMA Main Core	The core sub-module clock is running when the core is not in one of its sleep states (Sleep or Sleep after Reset) or there is a pending channel. Typically, the core sub-module clock is stopped once all the channels are processed and the core enters its sleep state. A new pending channel awakes the core sub-module clock.	None
Memories	SDMA Main Core	The clock activation only occurs during a core access.	Disabled when Core sub-module clock is disabled or no memory access in progress
Scheduler	SDMA Main Core	Its clock only runs when scheduling is needed: for example, when there are pending channels, upon reception of a DMA request, and anytime the AP modifies the channel running conditions.	None
AP Control	SDMA Main Core & AP peripheral	The AP peripheral clock is solely used to determine the frequency ratio with the SDMA main clock. The control registers' clock is based on SDMA main clock; it is active when the AP or the SDMA modifies the contents of one of these registers.	None
Burst DMA	SDMA Main Core & AP DMA	The burst DMA has two clocks: The first clock is derived from the SDMA main core clock and drives registers that are connected to the FUBUS. The second clock is derived from the AP DMA clock and drives registers that are connected to the AP DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the burst DMA is not used by the running channel script).	Disabled when Core sub-module clock is disabled

Table 52-7. Sub-Modules Clocks (continued)

Sub-Module	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
Burst DMA2	SDMA Main Core & AP DMA	The burst DMA2 has two clocks: The first clock is derived from the SDMA main core clock and drives registers that are connected to the FUBUS. The second clock is derived from the AP DMA clock and drives registers that are connected to the AP DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the burst DMA2 is not used by the running channel script).	Disabled when Core clock is disabled
OnCE	SDMA Main Core	The OnCE clock is derived from main source clock. It is disabled by default. In order to use the OnCE, its clock must be explicitly turned on, either by enabling the OnCE access from the AP peripheral bus (register ONCE_ENB), or by driving the clk_gating_off input pin high. This is a SDMA input whose driver depends on the SoC implementation (typically a JTAG controller). The OnCE also receives the TCK input, which is the JTAG clock. It does not use it as a functional clock; the TCK input is sampled instead. Refer to Section 52.19.5.2, Synchronization Implementation."	When enabled, all other clocks are systematically on (clock gating is off)

52.9.1.2 Refined Clock Gating

The SDMA implements a second level of clock gating on a register-per-register basis. Unlike the first level that covers all the SDMA flip-flops, except the synchronizers (only five flip-flops are always running), the second level is only available for eligible registers, which amounts to about 90% of the SDMA flip-flops.

These gated registers are only clocked when the hardware logic detects a new data loading. This additional gating further reduces dynamic power consumption.

52.9.1.3 Low Power Modes and User Control

Power savings are automatically managed by the SDMA hardware without any user involvement; however, one can distinguish three different power modes: SLEEP, RUN, and DEBUG. The following Table describes these modes, and shows how to switch from one mode to another.

Table 52-8. Power Modes

Power Mode	Sub-modules							Comments
	Core	Memories	Scheduler	AP Control	Burst DMA	Burst DMA2	OnCE	
SLEEP	off[1]	off	wait[2]	wait	off	off	off	Set when the PCU state is either *Sleep* or *Sleep after Reset* and the SDMA is not in DEBUG mode. This is the default mode after reset.
RUN	on[3]	wait	wait	wait	wait	wait	off	Set for the other PCU states that are reachable out of debug: *Program*, *Data*, *Change of Flow*, *Error in Loop*, *Debug*, *Functional Unit*, *Save,* or *Restore*.
DEBUG	on	on	on	on	on	on	on	Set regardless of the PCU state when clock gating is turned off to use the OnCE features (either *clk_gating_off* pin high or ONCE_ENB[0] set).

1 *off*: no clock

2 *wait*: only clocked when accessed or stimulated

3 *on*: clock is always running

It is possible to control the SDMA power mode. The procedures to force the SDMA into either mode are described in Section 52.9.1.3.1, SLEEP Mode."

52.9.1.3.1 SLEEP Mode

This is the default mode after reset; therefore, resetting the SDMA forces this mode. However, the common procedure is as follows:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Disable all channels (via the STOP_STAT control register, and the HO, DO, EO if necessary).
- Wait for the active channels to complete or force a reschedule via the reschedule bit in the RESET register.
- The SDMA is in SLEEP mode making it possible to completely shut off its clock from the chip level clock controller using the procedure described in Section 52.9.1.4, Stop Mode Response."

52.9.1.3.2 RUN Mode

This is the default mode when a channel is running:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Activate at least one channel (via the HSTART control registers, a DMA request, and/or the HO, DO, EO register bits).

52.9.1.3.3 DEBUG Mode

The DEBUG mode must be set when one needs to use the debugging facilities of the SDMA:

- Ensure the SDMA clocks are running from the CCM.
- Set the *clk_gating_off* pin high or use the SDMA to set ONCE_ENB[0].

52.9.1.4 Stop Mode Response

The SDMA receives a stop request from the chip level clock controller. This request may be asserted when the chip enters the stop low power mode. If the SDMA is running when the request is received, then the SDMA will complete all pending channels before returning to the SLEEP state. The SDMA sends an acknowledgement to the clock controller when the SLEEP state is entered indicating that the SDMAs clocks can be turned off.

52.9.2 Reset

After reset (either received from the reset module or a software reset required by the AP), the SDMA is in IDLE mode. It will start its boot code located at address 0 once a channel is activated. Activating a channel can be done by the AP after programming a positive priority and setting the channel bit in the EVTPEND register.

There will not be a context RESTORE for the first channel (bootload channel) called after a reset because the context data in RAM has not been initialized. Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized. Subsequent calls to the same channel or different channels may use any of the dynamic context modes

52.10 Software Interface

A separate document exists that fully describes the SDMA Application Programming Interface (API): Refer to the latest revision of document *i.MX51 SDMA Scripts User Manual.*

52.11 Initialization Information

This section discusses the following:

- Section 52.11.1, Hardware Reset”
- Section 52.11.2, Channel Script Execution”
- Section 52.11.3, Initialization and Script Execution Setup Sequence”

52.11.1 Hardware Reset

After reset, the program RAM, context RAM, data RAM, and RAM containing the channel enable registers (CHNENBLn) have unpredictable contents. The active register set is assigned to channel 0 and the PC is initialized to all zeros. However, since the channel enable register is all zeros, there are no active channels and the SDMA is halted waiting for the boot channel to start.

The AP will have to setup the SDMA in order to boot it. The CONFIG register must be initialized to determine the DMA/core clock ratio (1 or 2). and whether the Burst DMA2 unit is used. Channel Enable Registers must also be initialized.

To start up the SDMA, the AP first creates some channel control blocks (CCB) and buffer descriptors (BD) in AP memory for the boot channel (channel 0) and then initializes the channel 0 pointer register (MC0PTR) to the address of the first control block. Section 52.23.1, Data Structures for Boot Code and Channel Scripts” provides an overview of the data structure for the CCB and BD’s. The HSTART,

HOSTOVR and EVTOVR registers are then configured according to Equation 52-2 on page 52-17 to allow channel 0 to run.

Upon being enabled, the SDMA begins executing the script located at the address indicated by the Channel 0 Boot Address register (CHN0ADDR) in the program memory. The reset value of CHN0ADDR points to the default bootload script in ROM. This ROM script will read the channel 0 pointer register (MC0PTR) to determine the location of the Channel Control Block (CCB) in AP memory. The script will then begin fetching by DMA the first channel control block which contains a pointer to the location channel 0 Buffer Descriptor chain which is also fetched via DMA. If the buffer descriptor contains a valid command, the script interprets the command in each buffer descriptor and proceeds to implement the command and move on to the next buffer descriptor control block. The buffer descriptor commands for channel zero are typically set up to load SDMA's program RAM, Data RAM, and initial values for the channel contexts. Some channel scripts expect particular parameters to be passed

There are two ways to make the SDMA boot on a user-defined script. The OnCE (either via its JTAG interface or its AP Control interface) can be used to download any code in the SDMA RAM and force the SDMA to boot on that code. Also, the CHN0ADDR register in the AP programming model can be modified to point to user code in RAM which would need to either have been loaded via the ONCE or default bootload routine (ex before a S/W reset).

52.11.2 Channel Script Execution

The execution of an SDMA script depends on both the instructions that make up the script, the data context upon which it operates, and commands or parameters passed in the buffer descriptor or. All these items must be initialized before the script is allowed to execute. Each of the 32 channels has a separate context, but may share scripts and locations in data RAM.

Channels are initialized by the AP by using channel 0 to download any required scripts and data values and the channels initial context. The context contains all the initial values of the SDMA core registers. This includes the Program Counter (PC) which is set to the start of the desired script in SDMA program memory.

The AP selects which trigger conditions that must occur for the channel to start by configuring the CHNENBL, HOSTOVR and EVTOVR registers. The trigger events include AP setting HE (HSTART) or a hardware DMA request asserts an event input to SDMA. The channel can becomes active according to its priority compared with other runnable channels when the selected trigger(s) cause Equation 52-2 on page 52-17 to evaluate as true.

The specific parameters to be passed to each script in the buffer descriptor or context are documented in the software documentation for each script. Please refer to Section 52.25, References" for complete script documentation. Section 52.23.1.1, Buffer Descriptor Format" provides an overview of the buffer descriptor format.

52.11.3 Initialization and Script Execution Setup Sequence

To summarize, the following steps are minimally required to setup SDMA and run channel scripts.

- Perform Hardware Reset. The program RAM, context RAM, data RAM and CHNENBLn registers have unpredictable contents after this reset.
- Initialize CHNENBLn registers to map DMA request events to desired channels.
- Configure CHNPRIn registers to select priority for runnable channels, A non-zero priority is required for the channel to run.
- Configure the CONFIG register to select DMA to SDMA core clock ratio.
- Set up channel control blocks and buffer descriptors in AP to specify the loading of SDMA program RAM and channel contexts for each SDMA channel to be used. Reference Section 52.23.1, Data Structures for Boot Code and Channel Scripts."
- Configure MC0PTR register with base address of AP Channel Control Block base address.
- Initialize CHNENBLn registers to map DMA request events to associated channel. Reference Section 52.4.3.3, Mapping DMA Requests to Pending Channels."
- Configure CHNPRIn registers to set priority for each channel to be run.
- For each channel to be run, configure HOSTOVR (HO) and EVTOVR (EO) registers to select which events (hardware and/or software trigger events) must occur for the channel to be runnable. Reference Section 52.4.3.5, Runnable Channels Evaluation."
- Set bit 0 of the HSTART register to set HE[0] and allow Channel 0 to run (assumes EO[0] andDO[0] were both set in previous step). This will cause SDMA to load the program RAM and channel contexts configured previously.
- Wait for Channel 0 to finish running. This is indicated by HI[0]=1 in the SDMA_INTR register, or by optional interrupt to the AP.
- Set the LOCK bit in the SDMA_LOCK register to prevent un-authorized uploads of data to SDMA RAM.
- Additional channel scrips can now be run by enabling the selected software or hardware trigger event according to Equation 52-2.

52.12 AP Memory Map and Control Register Definitions

The AP controls the SDMA by means of several interface registers. Those registers are described in the current section.

52.12.1 AP Memory Map

The following table provides the memory map for the AP control SDMA registers.

Table 52-9. AP Memory Map

Address	Register	Access	Reset Value	Section/Page
General Registers				
0x83FD_4000 (MC0PTR)	AP (MCU) Channel 0 Pointer	R/W	0x0000_0000	52.12.3.2/52-49
0x83FD_4004 (INTR)	Channel Interrupts	R/W	0x0000_0000	52.12.3.2/52-49
0x83FD_4008 (STOP_STAT)	Channel Stop/Channel Status	R	0x0000_0000	52.12.3.3/52-50

Table 52-9. AP Memory Map (continued)

Address	Register	Access	Reset Value	Section/Page
0x83FD_400C (HSTART)	Channel Start	R/W	0x0000_0000	52.12.3.4/52-50
0x83FD_4010 (EVTOVR)	Channel Event Override	R/W	0x0000_0000	52.12.3.5/52-51
0x83FD_4014 (DSPOVR)	Channel BP Override	R/W	0xFFFF_FFFF	52.12.3.6/52-52
0x83FD_4018 (HOSTOVR)	Channel AP Override	R/W	0x0000_0000	52.12.3.7/52-53
0x83FD_401C (EVTPEND)	Channel Event Pending	R	0x0000_0000	52.12.3.8/52-53
0x83FD_4024 (RESET)	Reset Register	R	0x0000_0000	52.12.3.9/52-54
0x83FD_4028 (EVTERR)	DMA Request Error Register	R	0x0000_0000	52.12.3.10/52-55
0x83FD_402C (INTRMASK)	Channel AP Interrupt Mask	R/W	0x0000_0000	52.12.3.11/52-56
0x83FD_4030 (PSW)	Schedule Status	R	0x0000_0000	52.12.3.12/52-57
0x83FD_4034 (EVTERRDBG)	DMA Request Error Register	R	0x0000_0000	52.12.3.13/52-58

52.12.2 Register Summary

The following definitions serve as a key for the AP control SDMA register summary.

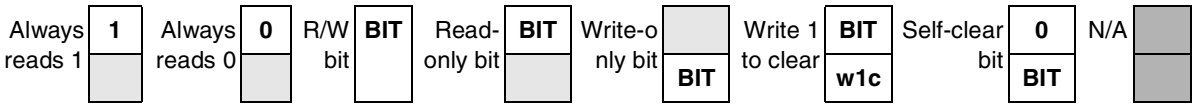

Figure 52-11. Key to Register Fields

Table 52-10 provides a key for register figures.

Table 52-10. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

All registers are clocked with the SDMA clock (which means the AP must ensure that the SDMA clock is running when it wants to access any register).

52.12.3 Register Descriptions

The following sections provide figures and detailed field descriptions of the SDMA registers.

52.12.3.1 AP Channel 0 Pointer (MC0PTR)

The following table presents the register; Table 52-12 provides its field descriptions.

0x83FD_4000 (MC0PTR) Access: User Read/Write
Wait State: 0

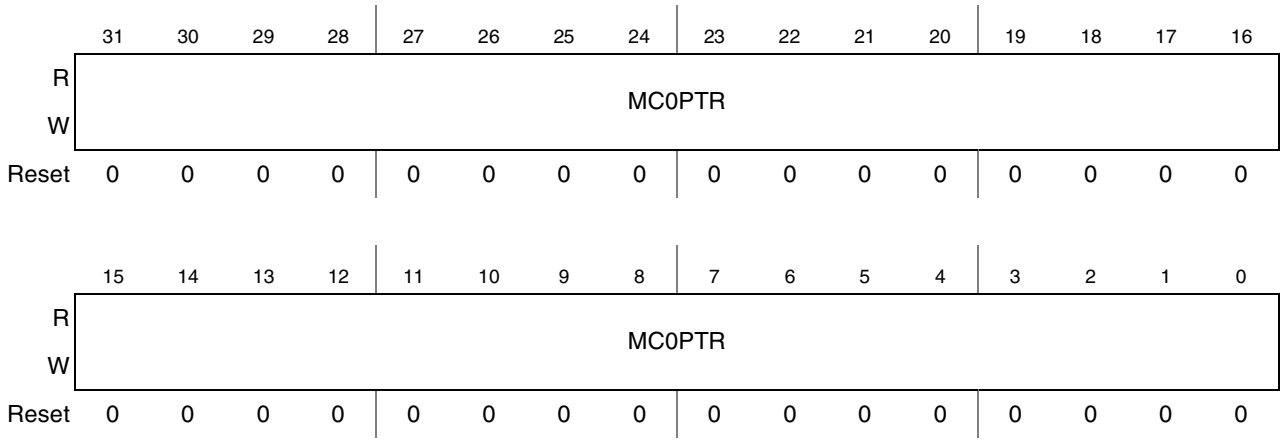

Figure 52-12. AP Channel 0 Pointer (MC0PTR)

Table 52-12. MC0PTR Field Descriptions

Field	Description
31–0 MC0PTR	**Channel 0 Pointer** contains the 32-bit address, in AP memory, of channel 0 control block (the boot channel). Refer to the document *i.MX51 SDMA Scripts User Manual* for the use of this register. The AP has a read/write access and the SDMA has a read-only access.

52.12.3.2 Channel Interrupts (INTR)

Figure 52-13 presents the register; Table 52-13 provides its field descriptions.

0x83FD_4004 (INTR) Access: User Read/Write
Wait State: 0

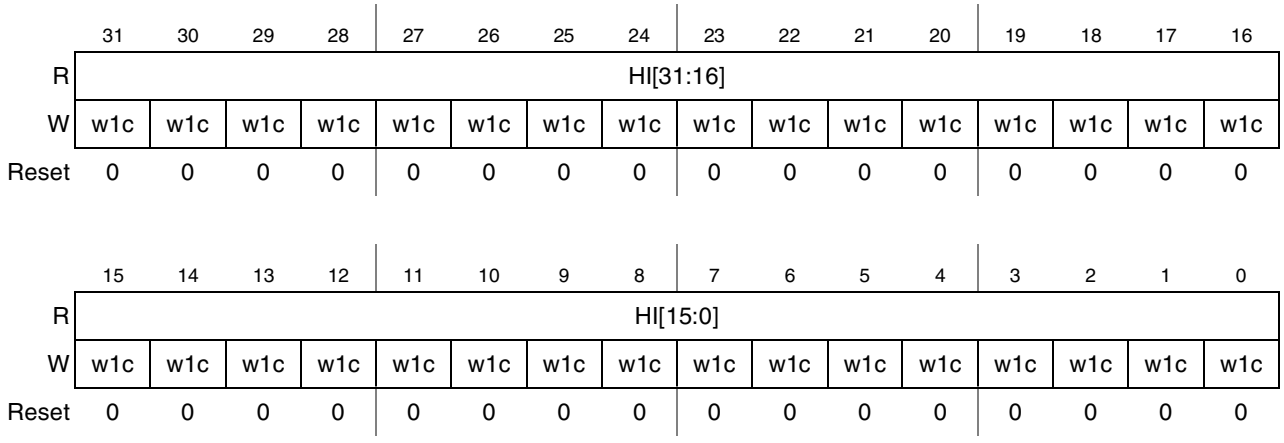

Figure 52-13. Channel Interrupts (INTR) Register

Table 52-13. INTR Field Descriptions

Field	Description
31–0 HI[31:0]	The AP Interrupts register contains the 32 HI[i] bits. If any bit is set, it will cause an interrupt to the AP. This register is a “write-ones” register to the AP. When the AP sets a bit in this register the corresponding HI[i] bit is cleared. The interrupt service routine should clear individual channel bits when their interrupts are serviced, failure to do so will cause continuous interrupts. The SDMA is responsible for setting the HI[i] bit corresponding to the current channel when the corresponding done instruction is executed.

52.12.3.3 Channel Stop/Channel Status (STOP_STAT)

Figure 52-14 presents the register; Table 52-14 provides its field descriptions.

0x83FD_4008 (STOP_STAT) Access: User Read/Write
Wait State: 0

Figure 52-14. Channel Stop/Channel Status (STOP_STAT) Register

Table 52-14. STOP_STAT Field Descriptions

Field	Description
31–0 HE	This 32-bit register gives access to the AP Enable bits. There is one bit for every channel. This register is a “write-ones” register to the AP. When the AP writes 1 in bit i of this register, it clears the HE[i] and HSTART[i] bits. Reading this register yields the current state of the HE[i] bits.

52.12.3.4 Channel Start (HSTART)

Figure 52-15 presents the register; Table 52-15 provides its field descriptions.

0x83FD_400C (HSTART) Access: User Read-Only
Wait State: 0

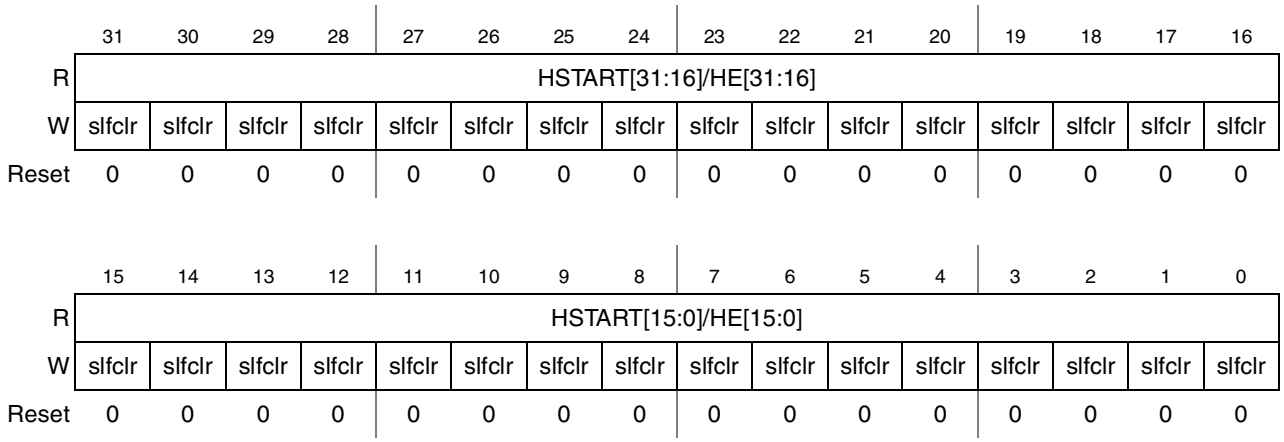

Figure 52-15. Channel Start (HSTART) Register

Table 52-15. HSTART Field Descriptions

Field	Description
31–0 HSTART/HE	The HSTART/HE registers are 32 bits wide with one bit for every channel. When a bit is written to 1, it enables the corresponding channel. Two physical registers are accessed with that address (HSTART and HE), which enables the AP to trigger a channel a second time before the first trigger is processed. • This register is a “write-ones” register to the AP. Neither HSTART[i] bit can be set while the corresponding HE[i] bit is cleared. • When the AP tries to set the HSTART[i] bit by writing a one (if the corresponding HE[i] bit is clear), the bit in the HSTART[i] register will remain cleared and the HE[i] bit will be set. • If the corresponding HE[i] bit was already set, the HSTART[i] bit will be set. The next time the SDMA channel *i* attempts to clear the HE[i] bit by means of a done instruction, the bit in the HSTART[i] register will be cleared and the HE[i] bit will take the old value of the HSTART[i] bit. • Reading this register yields the current state of the HSTART[i] bits. This mechanism enables the AP to pipeline two HSTART commands per channel.

52.12.3.5 Channel Event Override (EVTOVR)

Figure 52-16 presents the register; Table 52-16 provides its field descriptions.

0x83FD_4010 (EVTOVR) Access: User Read/Write
Wait State: 0

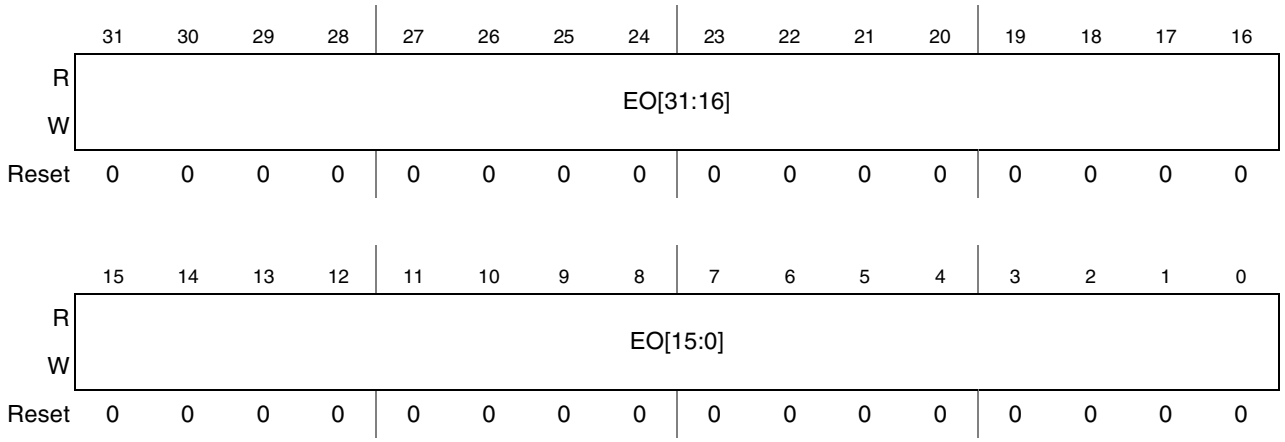

Figure 52-16. Channel Event Override (EVTOVR) Register

Table 52-16. EVTOVR Field Descriptions

Field	Description
31–0 EO	The Channel Event Override register contains the 32 EO[i] bits. A bit set in this register causes the SDMA to ignore DMA requests when scheduling the corresponding channel.

52.12.3.6 Channel BP Override (DSPOVR)

Figure 52-17 presents the register; Table 52-17 provides its field descriptions.

0x83FD_4014 (DSPOVR) Access: User Read/Write
Wait State: 0

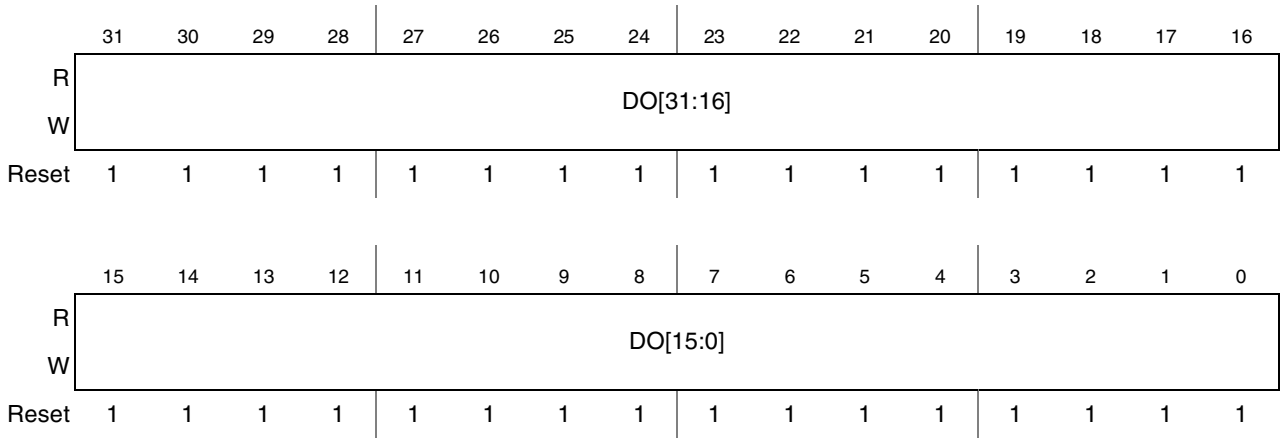

Figure 52-17. Channel DSP Override (DSPOVR) Register

Table 52-17. DSPOVR Field Descriptions

Field	Description
31–0 DO	This register is reserved. **All DO bits should be set to the reset value of 1.** A setting of 0 will prevent SDMA channels from starting according to Equation 52-2 on page 52-17. 0 - Reserved 1 - Reset value.

52.12.3.7 Channel AP Override (HOSTOVR)

Figure 52-18 presents the register; Table 52-18 provides its field descriptions.

0x83FD_4018 (HOSTOVR) Access: User Read/Write
Wait State: 0

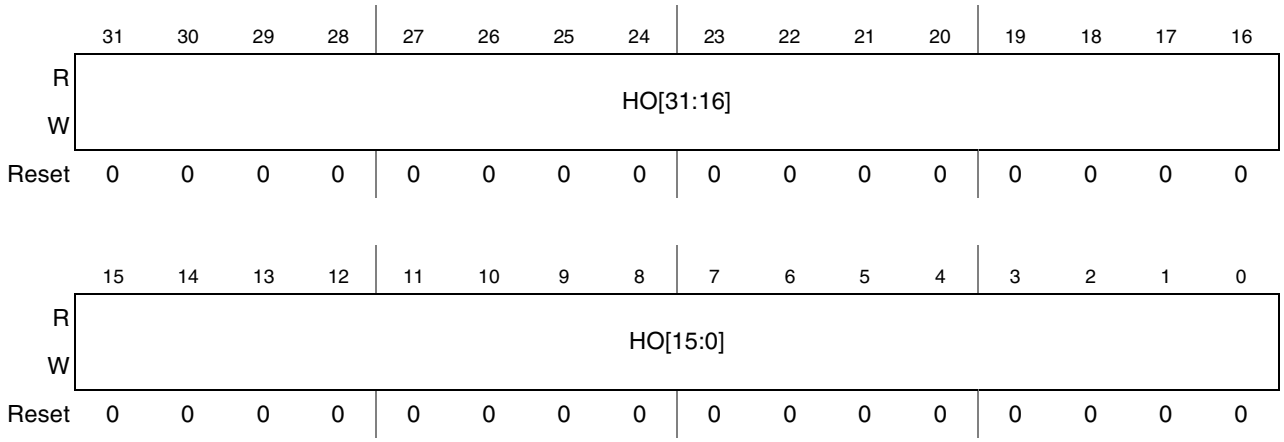

Figure 52-18. Channel AP Override (HOSTOVR) Register

Table 52-18. HOSTOVR Field Descriptions

Field	Description
31–0 HO	The Channel AP Override register contains the 32 HO[i] bits. A bit set in this register causes the SDMA to ignore the AP enable bit (HE) when scheduling the corresponding channel.

52.12.3.8 Channel Event Pending (EVTPEND)

Figure 52-19 presents the register; Table 52-19 provides its field descriptions.

0x83FD_401C (EVTPEND) Access: User Read-Only

Figure 52-19. Channel Event Pending (EVTPEND) Register

Table 52-19. EVTPEND Field Descriptions

Field	Description
31–0 EP	The Channel Event Pending register contains the 32 EP[i] bits. Reading this register enables the AP to determine what channels are pending after the reception of a DMA request. • Setting a bit in this register causes the SDMA to reevaluate scheduling as if a DMA request mapped on this channel had occurred. This is useful for starting up channels, so that initialization is done before awaiting the first request. The scheduler can also set bits in the EVTPEND register according to the received DMA requests. • The EP[i] bit may be cleared by the done instruction when running the channel *i* script. This a “write-ones” mechanism: Writing a ‘0’ does not clear the corresponding bit.

52.12.3.9 Reset Register (RESET)

Figure 52-20 presents the register; Table 52-20 provides its field descriptions.

0x83FD_4024 (RESET) Access: User Read-Only
Wait State: 0

W															slfclr	slfclr
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 52-20. Reset Register

Table 52-20. RESET Field Descriptions

Field	Description
31–2	Reserved
1 RESCHED	When set, this bit forces the SDMA to reschedule as if a script had executed a done instruction. This enables the AP to recover from a runaway script on a channel by clearing its HE[i] bit via the STOP register, and then forcing a reschedule via the RESCHED bit. The RESCHED bit is cleared when the context switch starts.
0 RESET	When set, this bit causes the SDMA to be held in a software reset. The internal reset signal is held low 16 cycles; the RESET bit is automatically cleared when the internal reset signal rises.

52.12.3.10 DMA Request Error Register (EVTERR)

Figure 52-21 presents the register; Table 52-21 provides its field descriptions.

0x83FD_4028 (EVTERR) Access: User Read-Only
Wait State: 0

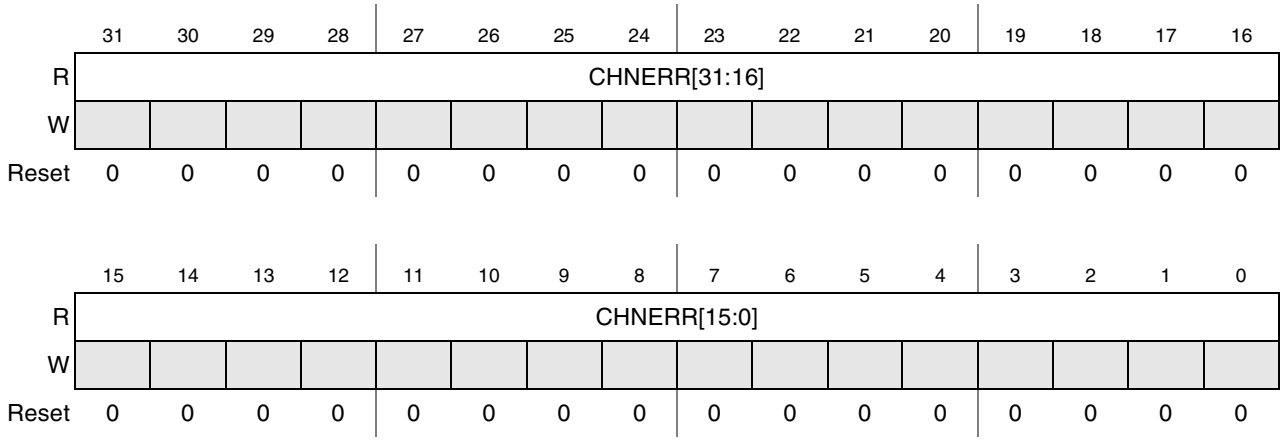

Figure 52-21. DMA Request Error (EVTERR) Register

Table 52-21. EVTERR Field Descriptions

Field	Description
31–0 CHNERR	This register is used by the SDMA to warn the AP when an incoming DMA request was detected and it triggers a channel that is already pending or being serviced. This probably means there is an overflow of data for that channel. • An interrupt is sent to the AP if the corresponding channel bit is set in the INTRMASK register. • This is a “write-ones” register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the AP or during SDMA reset. • The CHNERR[i] bit is set when a DMA request that triggers channel *i* is received through the corresponding input pins and the EP[i] bit is already set; the EVTERR[i] bit is unaffected if the AP tries to set the EP[i] bit, whereas, that EP[i] bit is already set.

52.12.3.11 Channel AP Interrupt Mask Flags (INTRMASK)

Figure 52-22 presents the register; Table 52-22 provides its field descriptions.

0x83FD_402C (INTRMASK) Access: User Read/Write
Wait State: 0

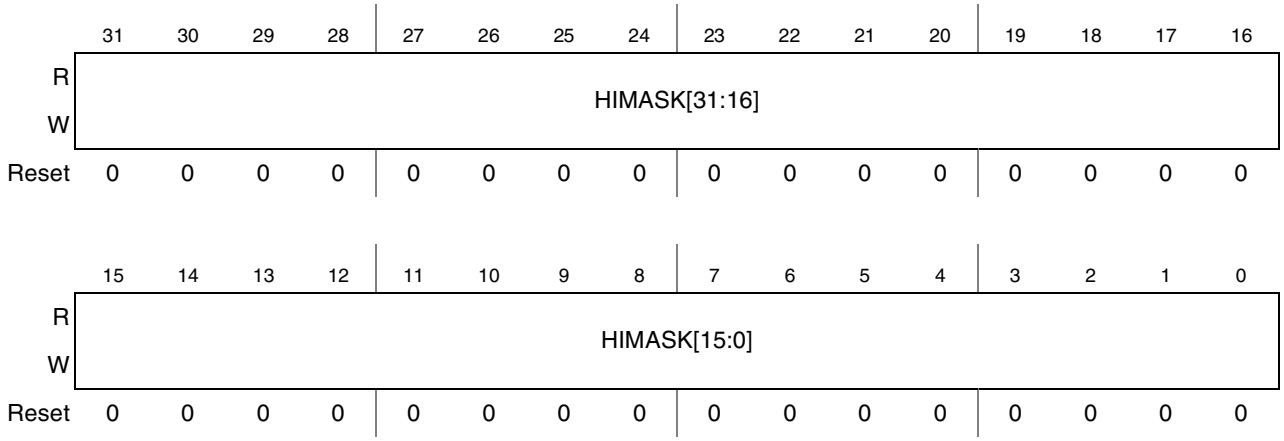

Figure 52-22. Channel AP Interrupt Mask Flags (INTRMASK) Register

Table 52-22. INTRMASK Field Description

Field	Description
31–0 HIMASK	The Interrupt Mask Register contains 32 interrupt generation mask bits. If bit HIMASK[i] is set, the HI[i] bit is set and an interrupt is sent to the AP when a DMA request error is detected on channel *i* (for example, EVTERR[i] is set).

52.12.3.12 Schedule Status (PSW)

Figure 52-23 presents the register; Table 52-23 provides its field descriptions.

0x83FD_4030 (PSW) Access: User Read-Only
Wait State: 0

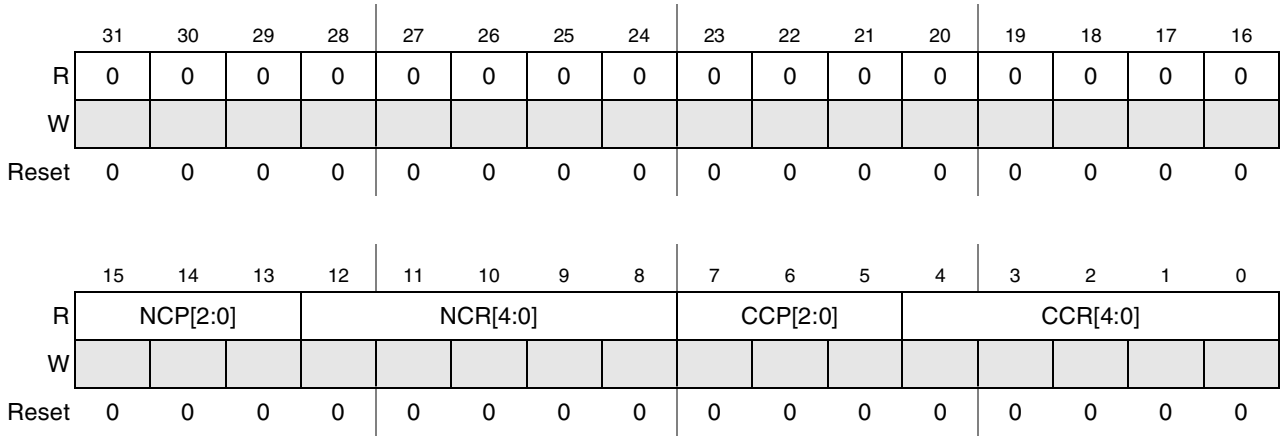

Figure 52-23. Schedule Status (PSW) Register

Table 52-23. PSW Field Descriptions

Field	Description
31–16	Reserved
15–13 NCP[2:0]	The Next Channel Priority gives the next pending channel priority. When the priority is 0, it means there is no pending channel and the NCR value has no meaning. 0 No running channel 1–7 Active channel priority
12–8 NCR[4:0]	The Next Channel Register indicates the number of the next scheduled pending channel with the highest priority.
7–4 CCP[2:0]	The Current Channel Priority indicates the priority of the current active channel. When the priority is 0, no channel is running: The SDMA is idle and the CCR value has no meaning. In the case that the SDMA has finished running the channel and has entered sleep state, CCP will indicate the priority of previous running channel. 0 No running channel 1–7 Active channel priority
3–0 CCR[4:0]	The Current Channel Register indicates the number of the channel that is being executed by the SDMA.In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel.

52.12.3.13 DMA Request Error Register for Debug (EVTERRDBG)

Figure 52-24 presents the register; Table 52-24 provides its field descriptions.

Figure 52-25. Configuration Register (CONFIG)

Table 52-25. CONFIG Register Field Descriptions

Field	Description
31–13	Reserved
12 DSPCtrl	This bit **should be configured as 1.** This implies SDMA is controlled by single core. 0- Dual core to control SDMA 1- Single core to control SDMA
11 RTDOBS	Indicates if Real-Time Debug pins are used: They do not toggle by default in order to reduce power consumption. 0 RTD pins disabled 1 RTD pins enabled
10–6	Reserved
4 ACR	AP DMA / SDMA Core Clock Ratio. Selects the clock ratio between AP DMA interfaces (burst DMA and burst DMA2) and the internal SDMA core clock. The frequency selection is determined separately by the chip clock controller. This bit has to match the configuration of the chip clock controller that generates the clocks used in the SDMA. 0 AP DMA interface frequency equals twice core frequency 1 AP DMA interface frequency equals core frequency

Table 52-25. CONFIG Register Field Descriptions (continued)

Field	Description
3–2	Reserved
1–0 CSM	Selects the Context Switch Mode. The AP has a read/write access. The SDMA cannot modify that register. The value at reset is 3, which selects the dynamic context switch by default. That register can be modified at anytime but the new context switch configuration will only be taken into account at the start of the next restore phase. NOTE: The first call to SDMA's channel 0 Bootload script after reset should use static context switch mode to ensure the context RAM for channel 0 is initialized in the channel SAVE Phase. After Channel 0 is run once, then any of the dynamic context modes can be used. 0 static 1 dynamic low power 2 dynamic with no loop 3 dynamic

52.12.3.15 SDMA Lock Register (SDMA_LOCK)

Figure 52-26 presents the register; Table 52-26 provides its field descriptions.

Figure 52-26. SDMA LOCK(SDMA_LOCK) Register

Table 52-26. ONCE_ENB Field Descriptions

Field	Description
31–2	Reserved
1 SRESET_LOCK_CLR	The SRESET_LOCK_CLR bit determine if the LOCK bit is cleared on a software reset triggered by writing to the RESET register. This bit cannot be changed if LOCK=1. SREST_LOCK_CLR is cleared by conditions that clear the LOCK bit. 0 Software Reset does not clear the LOCK bit. 1 Software Reset clears the LOCK bit.
0 LOCK	The LOCK bit is used to restrict access to update SDMA script memory through ROM channel zero scripts and through the OnCE interface under MCU control. The LOCK bit is set: • The SDMA_LOCK, ONCE_ENB,CH0ADDR, and ILLINSTADDR registers cannot be written. These registers can be read, but writes are ignored. • SDMA software executing out of ROM or RAM may check the LOCK bit in the LOCK register on page 52-106 to determine if certain operations are allowed, such as up-loading new scripts. Once the LOCK bit is set to 1, only a reset can clear it. The LOCK bit is cleared by a hardware reset. LOCK is cleared by a software reset only if SRESET_LOCK_CLR is set. 0 LOCK disengaged. 1 LOCK enabled.

52.12.3.16 OnCE Enable (ONCE_ENB)

Figure 52-27 presents the register; Table 52-27 provides its field descriptions.

0x83FD_4040 (ONCE_ENB) Access: User Read/Write
Wait State: 0

Figure 52-30. OnCE Status Register (ONCE_STAT)

Table 52-30. ONCE_STAT Field Descriptions

Field	Description
31–16	Reserved
15–12 PST[3:0]	The Processor Status bits reflect the state of the SDMA RISC engine. Its states are as follows: • The “Program” state is the usual instruction execution cycle. • The “Data” state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The “Change of Flow” state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The “Change of Flow in Loop” state is used when an error causes a hardware loop exit. • The “Debug” state means the SDMA is in debug mode. • The “Functional Unit” state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In “Sleep” modes, no script is running (this is the RISC engine idle state). The “after Reset” is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). • The “in Sleep” states are the same as above except they do not have any corresponding channel: They are used when entering debug mode after reset. The reason is that it is necessary to return to the “Sleep after Reset” state when leaving debug mode. 0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Restore
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an `rbuffer` command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	This flag is raised when the OnCE is controlled from the AP peripheral interface. 0 The JTAG interface controls the OnCE. 1 The AP peripheral interface controls the OnCE.

Table 52-30. ONCE_STAT Field Descriptions (continued)

Field	Description
6–3	Reserved
2–0 ECDR	Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one of the EDR bits is set (the meaning of the encoding is given below). The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addra_cond, addrb_cond, and data_cond conditions. The value of those fields is given by the EDR bits. EDR[0] 1 matched addra_cond EDR[1] 1 matched addrb_cond EDR[2] 1 matched data_cond

52.12.3.20 OnCE Command Register (ONCE_CMD)

Figure 52-31 presents the register; Table 52-31 provides its field descriptions.

Figure 52-33. Channel 0 Boot Address (CHN0ADDR) Register

Table 52-33. CHN0ADDR Register Field Descriptions

Field	Description
31–15	Reserved
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context, which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism. 0 24 words per context 1 32 words per context The value of SMSZ cannot be changed if the LOCK bit in the SDMA_LOCK register is set.
13–0 CHN0ADDR	This 14-bit register is used by the boot code of the SDMA. After reset, it points to the standard boot routine in ROM (channel 0 routine). By changing this address, you can perform a boot sequence with your own routine. The very first instructions of the boot code fetch the contents of this register (it is also mapped in the SDMA memory space) and jump to the given address. The reset value is 0x0050 (decimal 80). The value of CHN0ADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.

52.12.3.23 DMA Requests (EVT_MIRROR)

Figure 52-34 presents the register; Table 52-34 provides its field descriptions.

Wait State: 1

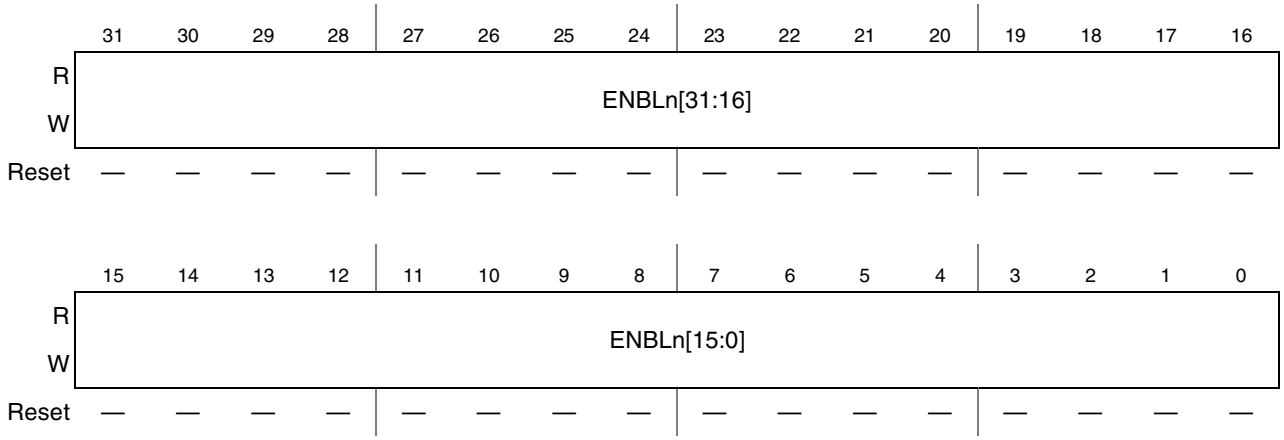

Figure 52-42. Channel Enable RAM (CHNENBLn) Register

[1] for n = 0 to 47

Table 52-42. CHNENBLn Field Descriptions

Field	Description
31–0 ENBLn	This 32-bit value selects the channels that are triggered by the DMA request number *n*. If ENBLn[i] is set to 1, bit EP[i] will be set when the DMA request *n* is received. These 48 32-bit registers are physically located in a RAM, with no known reset value. It is thus essential for the AP to program them before any DMA request is triggered to the SDMA, otherwise an unpredictable combination of channels may be started.

52.13 SDMA Programming Model

The following section describes the programming model for the SDMA RISC engine, including its processor, memory, and internal control registers.

All addresses are related to the internal SDMA memory map, which is completely different from the AP memory maps. The AP processor has no access to any hardware resource described, except when those resources are described in Section 52.12, AP Memory Map and Control Register Definitions."

52.13.1 State and Registers Per Channel

The SDMA can be seen as a set of 32 identical devices that are able to perform one data transfer channel each. Only one channel can work at a time, but every channel state is available at any time. This chapter lists the components of every channel state.

52.13.2 General Purpose Registers

Each channel has eight general purpose registers of 32 bits for use by scripts. General register 0 has a dedicated function for the `loop` instruction, but otherwise can be used for any purpose.

52.13.3 Functional Unit State

Each channel context has some state that is part of the functional units. The specific allocation of this state is part of the functional unit definition that is described in Section 52.18.1, Burst DMA Unit," Section 52.18.2, Burst DMA2 Unit." This state must be saved/restored on context switches.

52.13.3.1 Program Counter Register (PC)

The PC is 14 bits. Since instructions are 16 bits in width and all memory in the SDMA is 32 bits in width, the low order bit of the PC selects which half of the 32-bit word contains the current instruction. A low order bit of zero selects the most significant half of the word.[1]

52.13.3.2 Flags

Each channel has the following four flags:

- The T bit reflects the status of some arithmetic and test instructions. It is set when the result of an addition or a subtraction is zero and cleared otherwise. It is also the copy of the tested bits. Finally, it can also be set when the loop counter (GReg0) reaches zero. When the last instruction of the hardware loop is an operation that can modify the T flag, its effect on T is discarded and replaced by the GReg0 status.
- Two additional bits, SF and DF, are used to indicate error conditions resulting from loading data sources and storing to destinations, respectively. Access errors set these bits, and successful transactions clear them. They can also be cleared by specific instructions (`CLRF` and `loop`). The source fault (SF) is updated by the loads LD and LDF; the destination fault (DF) is updated by the stores ST and STF.

  Access errors are caused by several conditions including writing to the ROM, writing to a read-only memory mapped register, accessing an unmapped address, or any transfer error received by a peripheral when it is accessed.

  The SF and DF flags have a major impact on the behavior of the hardware loop: If SF or DF is set when starting a hardware loop and it is not masked by the `loop` instruction, the loop body will not be executed. Inside the loop body, if a load or store sets the corresponding SF or DF flag, the loop exits immediately. Testing the status of the T flag at the end of the loop (as well as testing both SF and DF) tells if the loop exited abnormally as any anticipated exit prevents GReg0 from reaching the zero value and thus setting the T flag. This is also valid if the fault occurs at the last instruction of the last loop.
- The last flag is the loop mode flag, LM, which is composed of two bits. The most significant bit indicates when the processor is currently operating in loop mode. It is set by the `loop` instruction and is cleared after execution of the last instruction of the last loop. The least significant bit is set

1. For example, big-Endian.

when the program counter points to the last instruction of a loop on the last path. It is used for a channel that is restored with this configuration to know that the next program counter is EPC. As with the dynamic context switch Greg0, which indicates when the program must get out of the loop, it can be restored only on the last instruction of the loop. This, however, is too late to fetch the next instruction after the loop.

52.13.3.3 Return Program Counter (RPC)

The RPC is 14 bits. It is set by the jump to the subroutine instructions and used by the return from the subroutine instructions. Instructions are available to transfer its contents to and from a general register.

52.13.3.4 Loop Mode Start Program Counter (SPC)

The SPC is 14 bits. It is set by the `loop` instruction to the location immediately following it.

52.13.3.5 Loop Mode End Program Counter (EPC)

The EPC is 14 bits. It is set by the `loop` instruction to the location of the next instruction after the loop.

52.13.4 Context Switching

Each channel has a separate context consisting of the eight general purpose registers and additional registers representing the state of the functional units. The active registers and functional units contain the context of the active channel. The context of inactive channels is stored in SDMA RAM, which is part of the SDMA address space.

In a function of the selected context switching mode (Section 52.4.4, Context Switching”), modified registers by the program can be saved in the channel RAM space while the program is going on. In every cycle, a write access to the RAM is possible.

On a `done` or `yield(ge)` instruction, SDMA goes into “real” context switching. In one of the dynamic modes, modified registers not previously saved, as well as the PC-Loop registers, are stored into the context area of the channel that will be closed. The new PC-Loop registers are loaded from the context area of the new channel. All other registers are restored while the program is executed, giving priority to registers used by the decoded instruction. Therefore, in the best case, only the PC and Loop registers should be saved and restored during this context-switching phase, which only requires five SDMA cycles.

In static mode, the context switch stores all registers in the old channel RAM space, and restores all registers from the new channel RAM space. It requires 26 SDMA cycles.

The address of the context memory for channel *i* is *CONTEXT_BASE* + 24**i* or *CONTEXT_BASE* + *32***i* where CONTEXT_BASE equals 0x0800. Table 52-43 presents the layout of a channel context in memory:

52.13.5 Address Space

The SDMA has four internal buses, as follows:

- The Instruction bus reads instructions from the memory. Its address map is described in Section 52.13.5.1, Instruction Memory Map."
- The Data bus (DMBUS) accesses the same memories as those visible on the Instruction bus, some memory-mapped registers (scheduler status and OnCE registers), and up to 14 peripherals. Its address map is described in Section 52.13.5.2, Data Memory Map."
- The Functional Units bus (FUBUS) accesses the Burst DMA2, burst DMA. The addressing mechanism is further detailed in Section 52.18, Functional Units Programming Model."
- The Context Switch bus reads/writes registers into context-switch RAM space. It is a 64-bit bus dedicated for accessing this RAM space for updating the context of the running channel. While the program is going on, this bus has the lowest priority compared to the Instruction and Data buses, except for restoring a register needed for the decoded instruction to be executed. On the save part of a context switch (when the PCU is in its slave state), this is the only one used. On the restore part, the Instruction bus has the priority to read the next instruction at the restored PC and otherwise the Context Switch bus is used. It is not possible to control the actual data transfers that occur on this bus.

52.13.5.1 Instruction Memory Map

The instruction memory map is based on a 14-bit address bus and a 16-bit data (instruction) bus. Each address corresponds to a 16-bit data location. Instructions are fetched from either program ROM or program RAM. An SDMA script is able to change the contents of the program RAM, which is also visible from the data bus.

The first two instruction locations (at 0 and 1) are special. Location 0 is where the PC is set on reset. Location 1 is where the PC is set upon the execution of an illegal instruction. It is expected that both of these locations will contain a `jmp` to handle routines.

Table 52-44. SDMA Instruction Memory Space

Device	SDMA Address (Hex)	Base Address Label	Module Name	WS	Description
ROM	0x0000 ↓ 0x07FF	SDMA_IBUS_ROM_ADDR	—	0	4 KB internal ROM with boot code and standard routines.
RAM	0x1000 ↓ 0x1FFF	SDMA_IBUS_RAM_ADDR	—	0	8 KB internal RAM with channels context and user data/routines.

52.13.5.2 Data Memory Map

All of the data accessible to SDMA scripts make up the data memory space of the SDMA. This address space has several components:

- ROM (also visible on the Instruction bus)

- RAM (also visible on the Instruction bus)
- Shared Peripherals Registers
- SDMA Internal Registers (scheduler, OnCE, and registers that are also accessible by the AP)

SDMA scripts can read and write to the context RAM, data RAM, shared peripheral registers, and internal registers.

The address range is 16 bits and the data width is 32 bits. Each address corresponds to a 32-bit data word. When accessing peripheral registers (USB and so on), the data width may be different. The exact address map for the peripherals depends on the project (as presented in each respective chapter).

The SDMA can perform only 32-bit access to shared peripheral registers. For this device, shared peripherals registers are aliased as if byte addressed. This is a consequence of connections through the SPBA shared peripheral bus outside of the SDMA. The result is that although address space 4 Kwords (16KB) is allocated for each peripheral, only the first 4 KB of the peripheral's register space can accessed. For example, the shared peripheral register at address 0x3000 is mapped also to addresses 0x3001, 0x3002, 0x3003. A read or write access to any of any of these 4 addresses will respond as if the access was to address 0x3000.

Data access is performed with *ld* and *st* instructions that take the address from a general purpose register in the core (GReg*n*). The mapping between the general purpose register contents and the address bus is given in Table 52-45:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sz	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
address															

Table 52-45. GReg*n* to DMBUS Address Mapping

Grayed bits are simply discarded but they must be cleared to ensure forward-script compatibility.

- sz (bit 31) indicates the peripheral data width: 0 is used for a 32-bit peripheral and 1 is used for a 16-bit peripheral.
- address (bits 15 down to 0) is the address of the accessed resource (internal memory, internal register, or shared peripheral).

Table 52-46. SDMA Data Memory Space

Device	SDMA Address (Hex)	Size	Description
ROM	0x0000 → 0x03FF	4 KB	4 KB internal ROM with boot code and standard routines

52.14.2 Register Summary

The following definitions serve as a key for the SDMA internal register summary.

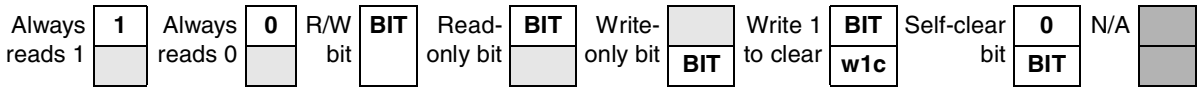

Figure 52-43. Key to Register Fields

Table 52-48 provides a key for register figures.

Table 52-48. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.

Table 52-48. Register Figure Conventions (continued)

Convention	Description
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Note: for n = 0 to 31

Table 52-49 presents a summary of the SDMA internal (core) registers.

52.14.3 SDMA Core Register Descriptions

The SDMA core has access to several memory mapped registers through its internal data bus. They are described in the following sections.

52.14.3.1 AP (MCU) Channel 0 Pointer (MC0PTR)

The following table shows the register; Table 52-50 provides its field descriptions.

0x7000 (MC0PTR) Access: User Read-Only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	MC0PTR[15:0]															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 52-44. AP (MCU) Channel 0 Pointer (MC0PTR) Register

Table 52-50. MC0PTR Field Descriptions

Field	Description
31–0 MC0PTR	Contains the address—in the AP memory space—of the initial SDMA context and scripts that are loaded by the SDMA boot script running on channel 0.

52.14.3.2 Current Channel Pointer (CCPTR)

Figure 52-45 shows the register; Table 52-51 provides its field descriptions.

0x7002 (CCPTR) Access: User Read-Only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	CCPTR[15:0]															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 52-45. Current Channel Pointer (CCPTR) Register

Table 52-51. CCPTR Field Descriptions

Field	Description
31–16	Reserved
15–0 CCPTR	Contains the start address of the context data for the current channel: Its value is *CONTEXT_BASE* + 24**CCR* or *CONTEXT_BASE* + 32**CCR* where CONTEXT_BASE = 0x0800. The value 24 or 32 is selected according to the programmed channel scratch RAM size in the register shown in Section 52.12.3.22, Channel 0 Boot Address (CHN0ADDR)."

52.14.3.3 Current Channel Register (CCR)

Figure 52-46 shows the register; Table 52-52 provides its field descriptions.

0x7003 (CCR) Access: User Read-Only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	CCR[4:0]				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 52-46. Current Channel Register (CCR)

Table 52-52. CCR Field Descriptions

Field	Description
31–5	Reserved
4–0 CCR	Contains the number of the current running channel whose context is installed. In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel. The PST bits in the OSTAT register indicate when the SDMA is in sleep state.

52.14.3.4 Highest Pending Channel Register (NCR)

Figure 52-47 shows the register; Table 52-53 provides its field descriptions.

0x7004 (NCR) Access: User Read-Only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	NCR[4:0]				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 52-47. Highest Pending Channel Register (NCR)

Table 52-53. NCR Field Descriptions

Field	Description
31–5	Reserved
4–0 NCR	Contains the number of the pending channel that the scheduler has selected to run next.

52.14.3.5 External DMA Requests Mirror (EVENTS)

Figure 52-48 shows the register; Table 52-54 provides its field descriptions.

0x7005 (EVENTS) Access: User Read-Only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	EVENTS[15:0]															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 52-48. External DMA Requests Mirror (EVENTS)

Table 52-54. EVENTS Field Descriptions

Field	Description
31–0 EVENTS	Reflects the status of the SDMA's external DMA requests. It is meant to allow any channel to monitor the states of these SDMA inputs. This register displays EVENTS 0-31. The EVENTS2 register displays events 32-47.

NOTE

This register is very useful in the case of DMA requests that are active when a peripheral FIFO level is above the programmed watermark. The activation of the DMA request (rising edge) is detected by the SDMA logic and it can enable one or several channels. One of the channels accesses the peripheral and reads or writes a number of data that matches the watermark level (for example, if the watermark is four words, the channel reads or writes four words).

If the channel is effectively executed long after the DMA request was received, reading or writing the watermark number of data may not be sufficient to reset the DMA request (for example, if the FIFO watermark is four and at the channel execution it already contains nine pieces of data). This means no new rising edge may be detected by the SDMA, although there still remains transfers to perform. Therefore, if the channel were terminated at that time, it would not be restarted, causing potential overrun or underrun of the peripheral.

The proposed mechanism is for the channel to check this register after it has performed the "watermark" number of accesses to the peripheral. If the bit for the DMA request that triggers this channel is set, it means there is still another watermark number of data to transfer. This goes on until the bit is cleared. The same script can be used for multiple channels that require this behavior. The script can determine its channel number from the CCR register and infer the corresponding DMA request bit to check. It needs a reference table that is coherent with the request-channel matrix that the AP programmed.

52.14.3.6 Current Channel Priority (CCPRI)

Figure 52-49 shows the register; Table 52-55 provides its field descriptions.

0x7006 (CCPRI) Access: User Read-Only

Figure 52-52. OnCE Event Cell Control Register (ECTL)

Table 52-58. ECTL Field Descriptions

Field	Description
31–14	Reserved
13 EN	Event Cell Enable. If the EN bit is set, the event cell is allowed to generate debug requests (the cell is awakened). If it is cleared, the event detection unit is disabled and no hardware breakpoint is generated, but matching conditions are still reflected on the emulation pin. 0 Cell is disabled. 1 Cell is enabled.
12 CNT	Event Counter Enable. The event counter enable bit determines if the cell counter is used during the event detection. In order to use the event counter during an event detection process, the event cell counter register should be loaded with a value equal to the number of times minus one that an event occurs before a debug request is sent. After every event detection, the counter is decreased. When the counter reaches the value 0, the event detection cell sends a debug request to the core. The event counter register should be written and the EN bit should be set before each new event detection process uses the event counter. 0 Counter is disabled. 1 Counter is enabled.
11–10 ECTC[1:0]	The event cell trigger condition bits select the combination of address and data matching conditions that generate the final address/data condition. During program execution, if this event cell trigger condition goes to 1, a debug request is sent to the SDMA. The EN bit must be set to enable the debug request generation. 00 address ONLY 01 data ONLY 10 address AND data 11 address OR data

Table 52-58. ECTL Field Descriptions (continued)

Field	Description
9–8 DTC[1:0]	The data trigger condition bits define when data is considered matching after comparison with the data register of the event detection unit. The operations are performed on unsigned values. 00 equal 01 not equal 10 greater than 11 less than
7–6 ATC[1:0]	The address trigger condition bits select how the two address conditions (addressA and addressB) are combined to define the global address matching condition. The supported combinations are described, as follows. 00 addressA ONLY 01 addrA AND addrB 10 addrA OR addrB 11 reserved
5–4 ABTC[1:0]	The Address B Trigger Condition (ABTC) controls the operations performed by address comparator B. All operations are performed on unsigned values. This comparator B outputs the addressB condition. 00 equal 01 not equal 10 greater than 11 less than
3–2 AATC[1:0]	The Address A Trigger Condition (AATC) controls the operations performed by address comparator A. All operations are performed on unsigned values. This comparator A outputs the addressA condition. 00 equal 01 not equal 10 greater than 11 less than
1–0 ATS[1:0]	The access type select bits define the memory access type required on the SDMA memory bus. 00 read ONLY 01 write ONLY 10 read or write 11 —

Table 52-66. OSTAT Field Descriptions

Field	Description
31–16	Reserved
15–12 PST[3:0]	The Processor Status bits reflect the state of the SDMA RISC engine. • The “Program” state is the usual instruction execution cycle. • The “Data” state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The “Change of Flow” state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel-switching instructions). • The “Change of Flow in Loop” state is used when an error causes a hardware loop exit. • The “Debug” state means the SDMA is in debug mode. • The “Functional Unit” state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In “Sleep” modes, no script is running (this is the RISC engine idle state). The “after Reset” is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). • The “in Sleep” states are the same as above except they do not have any corresponding channel. They are used when entering debug mode after reset; the reason is that it is necessary to return to the “Sleep after Reset” state when leaving debug mode. 0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow Loop Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Restore
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an `rbuffer` command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.

Table 52-66. OSTAT Field Descriptions (continued)

Field	Description
7 MST	This flag is raised when the OnCE is controlled from the AP peripheral interface. 0 JTAG interface controls the OnCE. 1 AP peripheral interface controls the OnCE.
2–0 ECDR[2:0]	Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one EDR bit is set; the meaning of the encoding is as follows: EDR[0] 1 matched addressA condition EDR[1] 1 matched addressB condition EDR[2] 1 matched data condition The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addressA, addressB, and data conditions; the value of those fields is given by the EDR bits.

52.14.3.18 Channel 0 Boot Address (MCHN0ADDR)

Table 52-67. MCHN0ADDR Field Descriptions

Field	Description
31–15	Reserved

Table 52-67. MCHN0ADDR Field Descriptions (continued)

Field	Description
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context, which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism. 0 24 words per context 1 32 words per context
13–0 CHN0ADDR[13:0]	Contains the address of the channel 0 routine programmed by the AP; it is loaded into a general register at the very start of the boot and the SDMA jumps to the address it contains. By default, it points to the standard boot routine in ROM.

52.14.3.19 Mode Status Register (MODE)

Figure 52-62 shows the register; Table 52-68 provides its field descriptions.

0x701D (MODE) Access: User Read-Only

Figure 52-67. Profile Free Running Counter (PRF_CNT) Register

Table 52-73. PRF_CNT Field Descriptions

Field	Description
31–30 SEL	SEL bit shows if the profile counter is configured properly as free running counter. These can be configured by AP side by programming 31-30 bit of 0x83FD_40x090 (PRF_CNT_6). Also the profile counters should be enabled by using the 0 bit of 0x83FD_40x094 (PRF_CFG). 11: Counter is selected as free running counter. 10: Counter would not work as free running counter. 0x: Counter would not work as free running counter.:
29 EN	When the bit is set, the free running counter will start counting, provided the SEL bit shows 11 and also the profile counters should be enabled by using the 0 bit of 0x83FD_40x094 (PRF_CFG). 1: Start the free running counter. 0: free running counter is disabled.
28-23 RES	Reserved.
22 OFL	Profile free running counter has overflowed is represented by this bit. 1: Profile free running counter has overflowed. 2: Profile free running counter has not overflowed.
21-0 COUNTER	This shows the count value of the profile free running counter,

52.15 SDMA Peripheral Registers

Refer to the respective peripherals' chapters more information.

52.16 SDMA Initialization

The document *i.MX51 SDMA Scripts User Manual* describes the setup of the SDMA. This section provides a quick description of several initialization procedures.

NOTE

There may be differences with the actual implementation in the API.

52.16.1 Hardware Reset

After reset, the RAM that holds contexts, data, scripts, and the DMA request-channels matrix has unpredictable content. The core registers are all reset to 0, including the PC; the PCU state is *Sleep after Reset*. No channel can be activated because all of the priorities are also reset to 0.

52.16.2 Standard Boot Sequence

The following is the standard boot sequence:

1. Initialize the CONFIG register—detailed in Section 52.12.3.14, Configuration Register (CONFIG)”—to determine the AP DMA/core clock ratio (1 or 2)
2. Initialize the DMA request-channels matrix (see Section 52.12.3.30, Channel Enable RAM (CHNENBLn)”).
3. Program the channel control registers—Channel Event Override (EVTOVR), Channel BP Override (DSPOVR), Channel BP Override (HOSTOVR), and Channel Event Pending (EVTPEND)—according to the channel allocation.
4. Perform any necessary setup as required by the standard boot script in ROM (this is described in i.MX51 SDMA Scripts User Manual).
5. Trigger channel 0 with the Channel Start (HSTART) register, which starts the execution of the ROM script starting at address 0. This boot downloads channel scripts and contexts in RAM.

52.16.3 User-Defined Boot Sequence

The following is a user-defined boot sequence:

1. Initialize the Configuration Register (CONFIG), Channel Enable RAM (CHNENBLn), Channel Event Override (EVTOVR), Channel BP Override (DSPOVR), Channel AP Override (HOSTOVR), and Channel Event Pending (EVTPEND).
2. Use the OnCE (either via its JTAG interface or its AP control registers) to download any code in the SDMA RAM. Section 52.20.5.4, Accessing the Memory” describes how to write data to the RAM via the OnCE.
3. Use the OnCE instructions to make the PC default value point to the new boot script start address, or rely on the ROM startup script, which first jumps to the address in Channel 0 Boot Address (CHN0ADDR). (This register default address points to the standard boot script.)

52.16.4 Script Loading and Context Initialization

The execution of an SDMA script depends on both the instructions that make up the script and the data context upon which it operates. Both must be initialized before the script is allowed to execute. Each of the 32 channels has a separate data context, but may share scripts and locations in the data RAM.

The AP manages the space in program RAM and data RAM. It also manages the assignment of SDMA channels to the device drivers that need them. Channels are initialized by the AP via the channel 0 boot script. The boot channel downloads any required scripts with their data and the channels' initial contexts. Every context contains all the initial values of the registers, including the PC. Then the AP can enable any channel that becomes active and begins fetching and executing instructions from its script.

52.17 Instruction Description

The following sections introduce the instruction of the SDMA. Instruction set details are available in Section 52.21, Instruction Set."

52.17.1 Scheduling Instructions

The following are scheduling instructions:

- `done`—The instruction causes certain scheduling or interrupt bits to be set or cleared, which may cause a change in the schedule-ability of the running channel. Then the instruction causes the SDMA to evaluate the current scheduling priorities and to choose the highest priority ready channel. If this channel is not the current channel, a context switch will take place. If there are no runnable channels, the SDMA will enter the stopped mode. The `done` 5 has a special usage reserved for debug, as explained in Section 52.17.17, Debug Instructions."
- `yield`—These instructions are special cases of the `done` instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater than the current channel priority.
- `yieldge`—These instructions are special cases of the `done` instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater or equal to the current channel priority.
- `notify`—The `notify` instruction affects the scheduling bits, but does not cause rescheduling.

52.17.2 Conditional Branch Instructions

The conditional branch instructions of an 8-bit displacement, which is sign-extended and added to the current PC (which points to the next instruction) if the condition is satisfied. Otherwise, control passes to the next sequential instruction.

- `BF`—Branch if False. The branch is taken if the T bit in the processor status is zero (false).
- `BT`—Branch if True. The branch is taken if the T bit in the processor status is one (true).
- `BSF`—Branch if Source Fault. The branch is taken if the SF bit in the processor status is one.
- `BDF`—Branch if Destination Fault. The branch is taken if the DF bit in the processor status is one.

52.17.3 Unconditional Jump Instructions

There are two varieties of unconditional control transfers: an absolute transfer and a through-register transfer. Absolute transfers have a 14-bit address field that replaces the current PC.

- JMP—Jump. Causes the processor to jump to an absolute address encoded in the instruction itself.
- JSR—Jump to Subroutine. Causes the processor to jump to a subroutine, the address of which is encoded in the instruction itself.
- JMPR—Jump through Register. Causes the processor to jump to an absolute address contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.
- JSRR—Jump to Subroutine through Register. Causes the processor to jump to a subroutine, the address of which is contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.

52.17.4 Subroutine Return Instructions

The following are subroutine return instructions:

- RET—Return from Subroutine. The RET restores the contents of RPC to PC.
- LDRPC—Load from RPC to Register. THe LDRPC instruction is meant to be used when more than one level of subroutines are required. It stores the contents of RPC in any General register.

52.17.5 Loop Instruction

The following is a `loop` instruction:

LOOP—Enters Loop Mode. Before entering loop mode, the `loop` instruction can optionally clear the fault flags (SF and/or DF) based on a 2-bit field in the instruction. This feature is linked to the fact that setting SF or DF in loop mode will cause an immediate exit of the loop.

52.17.6 Miscellaneous Instructions

The following are miscellaneous instructions:

- CLRF—Clear Fault Flags. This instruction clears any combination of SF and DF.
- MOV r,s—This moves data from `GReg[s]` to `GReg[r]`.
- LDI r,immediate—This loads `GReg[r]` with a zero-extended immediate value.

52.17.7 Logic Instructions

The following are logic instructions:

- XOR r,s—This performs an `exclusive or` between `GReg[r]` and `GReg[s]`, and stores the result in `GReg[r]`.
- XORI r,immediate—This performs an `exclusive or` between `GReg[r]` and a zero-extended immediate value, and stores the result in `GReg[r]`.

- OR r,s—This performs an or between GReg[r] and GReg[s], and stores the result in GReg[r].
- ORI r,immediate—This performs an or between GReg[r] and a zero-extended immediate value and, stores the result in GReg[r].
- ANDN r,s—This performs an and between GReg[r] and the negated GReg[s], and stores the result in GReg[r].
- ANDNI r,immediate—This performs an and between GReg[r] and the negated zero-extended immediate value, and stores the result in GReg[r].
- AND r,s—This performs an and between GReg[r] and GReg[s], and stores the result in GReg[r].
- ANDI r,immediate—This performs an and between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].

52.17.8 Arithmetic Instructions

Arithmetic instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the result is zero, otherwise it is cleared.

- ADD r,s—This performs the addition of GReg[r] and GReg[s], and stores the result in GReg[r].
- ADDI r,immediate—This performs the addition of GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- SUB r,s—This performs the subtraction of GReg[s] from GReg[r], and stores the result in GReg[r].
- SUBI r,immediate—This performs the subtraction of a zero-extended immediate value from GReg[r], and stores the result in GReg[r].

52.17.9 Compare Instructions

Compare instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the comparison is true, otherwise it is cleared.

NOTE

Only one version of the immediate form is implemented. Non-equality comparisons to immediate values will require two instructions.

- CMPEQ r,s—This sets T when registers GReg[r] and GReg[s] are equal.
- CMPEQI r,immediate—This sets T when register GReg[r] and the zero-extended immediate value are equal.
- CMPLT r,s—This sets T when register GReg[r] is less than and not equal to GReg[s]. The comparison is signed.
- CMPHS r,s—This sets T when register GReg[r] is greater than or equal to GReg[s]. The comparison is signed.

52.17.10 Test Instructions

Test instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if any bit in the result is one, otherwise it is cleared.

- `TST r,s`—This performs an `and` between `GReg[r]` and `GReg[s]`, and sets T if the result is not zero.
- `TSTI r,immediate`—This performs an `and` between `GReg[r]` and a zero-extended immediate value, and sets `T` if the result is not zero.

52.17.11 Byte Permutation Instructions

These instructions shuffle the bytes in a register. For the purpose of describing these instructions, have the bytes in a register be numbered from the most significant as b_3, b_2, b_1, b_0.

- `RORB r`—The rotate right byte. The result is b_0, b_3, b_2, b_1.
- `REVB r`—The reverse bytes in word. The result is b_0, b_1, b_2, b_3.
- `REVBLO r`—The reverse, two low-order bytes. The result is b_3, b_2, b_0, b_1.

52.17.12 Bit Shift Instructions

The following are bit shift instructions:

- `ROR1 r`—The rotate right 1 bit. This instruction does a circular right shift of 1 bit.
- `LSR1 r`—The logical shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by a 0.
- `ASR1 r`—The arithmetic shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by itself.
- `LSL1 r`—The logical shift left 1 bit. This instruction shifts all bits to the left by 1. The low order bit is replaced by zero.

52.17.13 Bit Manipulation Instructions

- `BCLRI r,n`—The bit clear is immediate; clears bit number *i* in register *r*.
- `BSETI r,n`—The bit set is immediate; sets bit number *i* in register *r*.
- `BTSTI r,n`—The bit test is immediate; tests bit number *i* in register *r* (T becomes equal to the selected register bit).

52.17.14 SDMA Memory Access Instructions

All memory accesses are 32 bits. Any memory location that is implemented with less than 32 bits (for example, peripheral registers) causes unimplemented bits to be read as 0s. All memory accesses will cause either the SF or DF flags in the processor status to be set if they cause a fault. What constitutes a fault, especially when accessing peripheral registers, is a property of the memory location.

- `LD r,(b,d)`—The load instruction creates an address by adding the displacement field (d) to the contents of the base register (b). The SDMA location at the resulting address is read and placed in the destination register (r).
- `ST r,(b,d)`—The store instruction creates an address in the same manner as the load instruction. The register (r) is stored in the SDMA location at the resulting address.

52.17.15 Functional Unit Instructions

The functional unit instructions have an 8-bit field that is placed on the functional unit bus. Some of these bits are used to select which functional unit should be involved in the transfer. The remaining bits are decoded by the selected functional unit so their specific use depends on the functional unit. See Section 52.18, Functional Units Programming Model.”

There are two functional unit instructions, as follows:

- `LDF r,fub`—The 8-bit field is placed on the functional unit bus and a read is issued to the selected functional unit. As a result of this instruction, the SF may be set in the processor status.
- `STF r,fub`—The 8-bit field is placed on the functional unit bus and a write is issued to the selected functional unit. As a result of this instruction, the DF may be set in the processor status.

52.17.16 Illegal Instructions

All instruction encodings that are illegal cause the following actions:

- The current PC (which points to one beyond the offending instruction) is put in the EPC register.
- The loop mode bit is cleared.
- The PC is set to the value stored in the Illegal Instruction Trap Address (ILLINSTADDR) register (the default value is 0x0001).

ILLEGAL—Although any instruction other than those indicated in the SDMA specification will trigger the illegal instruction mechanism, the ILLEGAL instruction code is preferred as it will always be kept as *illegal* in the possible future versions of the SDMA core.

52.17.17 Debug Instructions

The following are debug instructions:

- `SOFTBKPT`—The software breakpoint instruction causes the core to stop and enter debug mode. The core can then be accessed and started by the OnCE debug module only.
- `done 5`—This instruction is used for debugging, as it copies the contents of the PCU registers and flags to the context memory. Information on this instruction is described in Section 52.20.5.2, Saving the Context.”
- `CpShReg`—This instruction copies the context memory into the PCU registers and flags. Modifying the corresponding memory location before executing this instruction enables you to have the channel continue from a new instruction address. This instruction is described in Section 52.20.5.3, Restoring the Context.”

52.18 Functional Units Programming Model

The functional unit instructions cause an 8-bit code, found in the low eight bits of the instruction, to be asserted on the functional unit control bus. Some of these bits are used to select one of several functional units. Functional units which can be selected include SDMA registers such as MSA and MSD which are not mapped in the SDMA memory map, and are accessible only through the functional unit bus. These Functional Unit Registers are listed in Table 52-74. In order to establish a programming convention, assume the selection bits are some number of the most significant bits of the 8-bit code. Furthermore, some number of the least significant bits is decoded by a given functional unit to establish the type of operation to perform.

Table 52-74. Functional Unit Registers

Functional Unit	Register	Register Name	Section/Page
Burst DMA Unit	MSA	Memory Source Address Register	52.18.1.1/52-116
	MDA	Memory Source Address Register	52.18.1.2/52-117
	MD	Memory Data Buffer Register	52.18.1.3/52-117 (Write) 52.18.1.5/52-119 (Read) 52.18.1.6/52-122
	MS	Memory State Register	52.18.1.4/52-118
Burst DMA2 Unit	DSA	BP Source Address Register	52.18.2.1/52-130
	DDA	BP Source Address Register	52.18.2.2/52-130
	DD	BP Data Buffer Register	52.18.2.3/52-131 (Write) 52.18.2.5/52-132 (Read) 52.18.2.6/52-135
	DS	BP State Register	52.18.2.4/52-131

More information regarding the functional units can be found in Section 52.6.2, Burst DMA2 Unit," and Section 52.6.1, Burst DMA Unit".

52.18.1 Burst DMA Unit

The DMA instructions control the DMA state machine and may cause a DMA cycle on the associated memory bus. There are four registers associated with the burst DMA unit, a Memory Source Address register (MSA), a Memory Destination Address register (MDA), a Memory Data buffer (MD), and a state register (MS).
The burst DMA has two different uses:

- A data transfer between External Memory Interface and SDMA general register
- A data transfer in copy mode where blocks of data are transferred from the source address to the destination address

52.18.1.1 Memory Source Address Register (MSA)

The source address register contains the pointer into EMI memory associated with the next read data transfer. It has byte granularity.

Reading the register with the `ldf` instruction has no side effects, and gives the address value in the EMI memory of the next data that is read by the SDMA during an `ldf MD` instruction.

Writing the source address register has two side effects: If the prefetch bit is set, a DMA read cycle (8-word read access) is issued with the new address. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MSA to guarantee all the data is effectively written to memory.

The MSA register has two modes of programming:

- Frozen—In frozen mode, the MSA register is not modified after DMA accesses.
- Incremented (default mode)—In incremental mode, MSA is incremented by the number of bytes transferred during read cycles.

52.18.1.2 Memory Destination Address Register (MDA)

The destination address register contains the pointer into EMI memory associated with the next write data transfer. It has byte granularity.

Reading the MDA register with the `ldf` instruction has no side effects. It gives the address value in the EMI memory where the next SDMA data (`stf r,MD` instruction) is stored when MD FIFO is flushed.

Writing the destination address register has one side effect. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MDA to guarantee all the data is effectively written to memory.

The MDA register has two modes of programming:

- Frozen—In frozen mode, the MDA register is not modified after DMA accesses.
- Incremented (default mode)—The MDA register is incremented by the number of bytes transferred during write cycles.

52.18.1.3 Memory Data Buffer Register (MD)

The data buffer register consists of a bank of 36 bytes that behave like FIFO. This FIFO stores the eight words received when a read burst is triggered by the DMA (DMA is in read mode). The MD register is in write mode after a writing in MDA or after an `stf MD` instruction. In that case, a burst write access is automatically triggered when there are more than eight words in MD. For bandwidth optimization, any transfers between DMA and the EMI controller are based on burst accesses.

An `ldf r,MD|SIZE` instruction that reads the data buffer may cause a DMA cycle, as follows:

- If there are less bytes in the FIFO than the size parameter of the instruction. For instance, if only two bytes are available in MD and a 4-byte read is requested, a burst read access is executed to complete the two bytes.
- If the prefetch bit is set, and after reading there is enough space in the FIFO to store a full burst, a burst read access is triggered.

An `stf r,MD|SIZE` instruction that writes to the data buffer may cause a DMA cycle if the number of written bytes in MD is higher than 32 (eight words) or if the flush bit is set.

When DMA is used for data transfer between SDMA and EMI (reading or writing), no immediate error is possible because the module manages a data misalignment issue; therefore, it is allowed to read/write a word to/from a half-word address. However, the addresses (source or destination) must belong to the EMI memory mapping. The only potential error, in this mode, would be the error sent back by the EMI controller when an access to a super-user page is detected. The whole transfer on the DMA associated bus will be considered successful when there are no errors seen on the bus during the transfer. In copy mode, an immediate error could be returned to SDMA as described in Section 52.18.1.10, Error Management."

52.18.1.4 State Register (MS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer. MS is also accessed to set-up the conditional yielding feature.

The initialization value of this register is 0 and it consists of the following:

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	spriv	stype	0	0	dpriv	dtype
W																
R	0	0	0	0	y	d	e		0	0	n					
W																

Figure 52-68. MS Structure

Table 52-75. MS Field Descriptions

Field	Description
31–22	Reserved
21 spriv	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
20 stype	Source Mode. Indicates if MSA has to be incremented (or not) during accesses. 0 Frozen—MSA is not modified. 1 Incremented—MSA is incremented by the number of transferred bytes during read access.
19–18	Reserved
17 dpriv	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved
16 dtype	Destination Mode. Indicates if MDA has to be incremented (or not) during accesses. 0 Frozen—MDA is not modified. 1 Incremented—MDA is incremented by the number of transferred bytes during write access.
15–12	Reserved

Table 52-75. MS Field Descriptions (continued)

Field	Description
11 y	Conditional Yielding selector. When selected, the `yield`/`yieldge` instructions will not switch channels if the Burst DMA is in Write Mode, and it has less than four bytes in its FIFO. This is aimed at reducing the number of inefficient FIFO flushes due to context switches. 0 Always yields 1 Yields conditionally (when there are less than four bytes in the FIFO in write mode)
10 d	Access Direction or DMA Mode. DMA is in write mode when data was written into MD by `stf MD` instructions, or if a previous DMA cycle on the external bus was a write access. Writing MDA or MSA changes the DMA mode to the respective value. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by SDMA with an `ldf MD` instruction. Reading MDA or MSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9–8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 *reserved* 10 Error mode 11 error read burst
7–6	Reserved
5–0 n	Number of bytes in the MD FIFO.

52.18.1.5 Burst DMA Write (stf)

When received from a `stf` instruction, the function code bits are interpreted as follows, depending on the addressed register:

Register	7	6	5	4	3	2	1	0
MSA	s		p	freeze	r			spriv
MDA								dpriv
MD			f	cpy			sz	
MS								

Figure 52-69. STF Code Bits

Table 52-76. STF Code Bit Field Descriptions

Field	Description
7–6 s	Functional Unit selector 00 for Burst DMA
5 p (MSA)	Prefetch Flag 0 No prefetch 1 Prefetch required from new MSA

Table 52-76. STF Code Bit Field Descriptions (continued)

Field	Description
5 f (MD)	Forced Flush Flag 0 Automatic flush 1 FIFO contents are flushed (including the new written data).
4 freeze (MSA/MDA)	Address Freeze Mode 0 Address is normally incremented. 1 Address is frozen.
4 cpy (MD)	Copy Mode selection 0 Write Mode 1 Copy Mode
3–2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1–0 sz (MD/MS)	Transfer Size 00 size 0 (no data stored in the FIFO) 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
0 spriv (MSA)	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
0 dpriv (MDA)	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved

The possible write instructions are listed in Table 52-77 (unused bits should always be cleared).

Table 52-77. Burst DMA STF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	stf r,MSA	Writes content of the SDMA general register (r) to the source address register. MSA is in incremented mode.
00_0_1_00_00	stf r,MSA|FR	Writes content of the SDMA general register (r) to the source address register. MSA is in frozen mode.
00_1_0_00_00	stf r,MSA|PF	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access. MSA is in incremented mode.
00_1_1_00_00	stf r,MSA|PF|FR	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access.
00_0_0_01_00	stf r,MDA	Writes content of the SDMA general register (r) to the destination address register. MDA is in incremented mode.
00_0_1_01_00	stf r,MDA|FR	Writes content of the SDMA general register (r) to the destination address register. MDA is in frozen mode.

Table 52-77. Burst DMA STF Instruction List (continued)

Binary	Assembly	Comments
00_1_0_10_00	stf r,MD|SZ0|FL	No data transfers between the SDMA and MD, but all valid written data of the MD is flushed to the memory. An acknowledge or error is sent back to the SDMA core on transfer completion.
00_0_0_10_01	stf r,MD|SZ8	8-bit (byte) transfer to write buffer MD
00_1_0_10_01	stf r,MD|SZ8|FL	8-bit (byte) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_10	stf r,MD|SZ16	16-bit (half-word) transfer to write buffer MD
00_1_0_10_10	stf r,MD|SZ16|FL	16-bit (half-word) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_11	stf r,MD|SZ32	32-bit (word) transfer to write buffer MD
00_1_0_10_11	stf r,MD|SZ32|FL	32-bit (word) transfer to write buffer MD and flush after transfer. All valid written data of MD is flushed to memory.
00_0_1_10_00	stf r,MD|CPY	No data transfer between SDMA and MD but starts a copy transfer whose length is given by the 4 LSB of *r* register. (Maximum burst length is eight words.)
00_0_0_11_11	stf r,MS	32-bit (word) transfer to status register MS
00_0_0_11_00	stf r,MS|SZ0	Clears the error flag (if set). Other MS bits are unchanged; this instruction is also known as `clref` MS.

NOTE

When a flush bit is set, the SDMA flushes the FIFO including the newly written data. An acknowledge is sent to the core before the flush completes (except if size 0 is used). The goal of this flush bit is to force a flush, but it is recommended to use it only when needed (for example, when finishing a row of pixels during 2D data transfers). Indeed, if this bit is omitted and if there are more than 32 bytes in the FIFO, a burst write access is automatically triggered.

Since all the `stf r,MD` instructions (including the copy mode) acknowledge the SDMA core before the store is effective (except if size 0 is used), it is recommended to perform an `ldf` from MS before terminating a channel in order to check the final error status. (The `ldf` from MS will stall the core until all the data was flushed out and the transfer status is known.)

After every `stf MD` instruction, the MDA is incremented by the number of bytes that are written in MD, except when it is programmed in frozen mode.

52.18.1.6 Burst DMA Read (ldf)

When received from an `ldf` instruction, the function code bits are interpreted as follows, depending on the addressed register:

Register	7	6	5	4	3	2	1	0
MSA	s				r			
MDA								
MD			p				sz	
MS								

Figure 52-70. LDF Code Bits

Table 52-78. LDF Code Bit Field Descriptions

Field	Description
7–6 s	Functional Unit selector 00 for Burst DMA
5 p (MD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
3–2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1–0 sz (MD)	Transfer Size 00 reserved 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

Table 52-79 lists the possible write instructions (unused bits should always be cleared).

Table 52-79. Burst DMA LDF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	ldf r,MSA	Copies the source address register value into an SDMA general register. It gives the memory address of the next data that will be read with an `ldf` MD instruction.
00_0_0_01_00	ldf r,MDA	Copies the destination address register value into an SDMA general register. It gives the memory address where the next incoming data will be flushed.
00_0_0_10_01	ldf r,MD|SZ8	8-bit (byte) read
00_1_0_10_01	ldf r,MD|SZ8|PF	8-bit (byte) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_10	ldf r,MD|SZ16	16-bit (half-word) read

Table 52-79. Burst DMA LDF Instruction List (continued)

Binary	Assembly	Comments
00_1_0_10_10	ldf r,MD|SZ16|PF	16-bit (half-word) read. If after this reading, and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_11	ldf r,MD|SZ32	32-bit (word) read
00_1_0_10_11	ldf r,MD|SZ32|PF	32-bit (word) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_11_00	ldf r,MS	Copy the status register value into an SDMA general register.

NOTE

Read data is 0-extended before writing in the SDMA general registers. When reading the MD register, the DMA takes data from the FIFO if it is available. If part or whole data is not in the FIFO, an external burst read access is performed to provide the missing data. The SDMA is stalled as long as the required read data is not complete.

After every reading, MSA is incremented by the number of read bytes from MD FIFO, except when MSA is programmed in frozen mode.

52.18.1.7 Prefetch/Flush and Auto-Flush Management

The prefetch and auto-flush management enables the SDMA RISC machine to go on while a DMA access is performed. When the RISC core requires a prefetch (p = 1) to the Burst DMA, it will receive an immediate transfer acknowledge before the DMA has finished the external access. This enables the RISC core to do other things like accessing another DMA machine.

The basic principle in prefetch mode is for the DMA to anticipate data reads from the SDMA RISC engine by fetching external bursts of data as soon as there is enough space in the DMA FIFO to store it. If ever the RISC engine required data that is not available in the FIFO, the read acknowledge is delayed until the data is available, but it does not have to wait until the burst completes.

The auto-flush basic principle is similar: An automatic flush is triggered every time there are eight words to be written in the FIFO. If the FIFO is full and the RISC engine requires another write, it is stalled until the burst has started and enough space was freed in the FIFO to store that new data. This means the SDMA RISC engine does not have to wait for the completion of a burst to receive its acknowledge and continue its processing.

In particular, an auto-flush is executed when DMA is in write mode and if the following is true:

- If the FIFO is empty and the first write is to a word-aligned address of any size (ex: the 2 LSB of MDA[1:0]= 0x0), the auto-flush is triggered immediately after the write of the 32’nd byte.
- If the FIFO is empty, and if MDA is an odd byte address (1, 3, 5, 7,...) and an `stf MD|SZ8` is executed, the byte is flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.

- If the FIFO is empty, and if MDA is a half-word address (2, 6, 0xA,...) and an `stf MD|SZ16` is executed, the two bytes of the incoming data are flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is not a word-aligned address (ex 1, 2, 3, 5, 6, 7, 9,...), and an `stf MD|SZ32` is executed, the first 1 to 3 bytes will be flushed up to the next word aligned address. Afterwards, an auto-flush will be triggered each time the FIFO receives 32-bytes.

  Therefore, if an `stf MD|SZ32` is executed with MDA equal to 0x1 and with an empty MD FIFO, the bytes located at addresses 1, 2, and 3 are flushed, and the byte located at address 4 remains in MD FIFO. This solves the misalignment issue. Additionally, the next write instructions (`stf`) complete the FIFO until it contains eight words; then a burst write is executed by the DMA to empty the FIFO. Protocol on the external bus does not support bursts of different data types (byte, half-word, or word).

For example, consider the case where data is written using a byte access, `stf MD|SZ8`. The value of MDA during the very first byte write determines when the auto-flush will occur as follows:

- If MDA=0x0, the flush occurs following the write of byte 32
- If MDA=0x1, the flush occurs following the write of byte 1, byte 3 and byte 35.
- If MDA=0x2, the flush occurs following the write of byte 2 and byte 34.
- If MDA=0x3, the flush occurs following the write of byte 1 and byte 33.
- If MDA=0x4, the flush occurs following the write of byte 32

The flush command forces the DMA to flush all MD valid bytes to the EMI controller. An acknowledge is sent immediately to the SDMA, and any potential error is reported on a future access. It is thus essential to conclude a transfer with a last read from MS, which will stall the core until all data was flushed out and returned to the transfer status (acknowledge or error).

NOTE

During this kind of auto-flush—which occurs only at the beginning of a misaligned write transfer—no acknowledge is sent back to the SDMA, which is stalled until a flush is completed.

52.18.1.8 Data Alignment and Endianness

52.18.1.8.1 Burst DMA in Read Mode

For every read access to MD, the data returned to the SDMA core and the new FIFO state depends on the MSA status and the access size. The FIFO is considered as a stack of 36 bytes: Data is fetched externally on a 32-bit bus, but the valid bytes only are stored in the FIFO and left-aligned (for a transfer of consecutive words, it is only the first word that may be truncated). Table 52-80 shows the FIFO byte alignment strategy and the corresponding MSA, the returned data, and the new FIFO state for any access size of an internal read from MD.

Table 52-80. FIFO Read Configuration

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
00	x0 x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 and so on...	sz8	00 00 00 x0	01	x1 x2 x3 y0 y1 y2 y3 z0
		sz16	00 00 x0 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz32	x0 x1 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3

52.18.1.8.2 Burst DMA in Write Mode

For every write access to the MD, the new FIFO state depends on the MDA status and the access size. The FIFO is considered as a stack of 36 bytes: Data is stored in the FIFO according to the internal access size and the former MDA value. Table 52-81 shows the FIFO byte alignment strategy corresponding to MDA, as well as the new FIFO state for any access size of an internal write to MD.

Table 52-81. FIFO Write Configuration

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
00	tt uu vv ww ?? ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	01	tt uu vv ww x0 ?? ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	10	tt uu vv ww x0 x1 ?? ?? ?? ?? ?? ??
		sz32	x0 x1 x2 x3	00	tt uu vv ww x0 x1 x2 x3 ?? ?? ?? ??
01	tt uu vv ww xx ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	10	tt uu vv ww xx x0 ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	11	tt uu vv ww xx x0 x1 ?? ?? ?? ?? ??

		sz16	?? ?? x0 x1	00	tt uu vv ww xx yy x0 x1 ?? ?? ?? ??
		sz32	x0 x1 x2 x3	10	tt uu vv ww xx yy x0 x1 x2 x3 ?? ??
11	tt uu vv ww xx yy zz ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	00	tt uu vv ww xx yy zz x0 ?? ?? ?? ??
		sz16	?? ?? x0 x1	01	tt uu vv ww xx yy zz x0 x1 ?? ?? ??
		sz32	x0 x1 x2 x3	11	tt uu vv ww xx yy zz x0 x1 x2 x3 ??

NOTE

If the FIFO mode changes from a write to a read mode, all remaining written bytes in MD are lost but no error is returned. Typically, this happens if an `ldf` MD is executed after `stf` MD instructions. Before a mode change, it is recommended to force the flush of a potential remaining byte by a `stf MD|SZ0|FL` instruction. In the same way, if a FIFO mode changes from a read to a write mode, all prefetched data present in the FIFO is lost and no error is returned.

52.18.1.8.3 Endianness

Big and Little Endian are supported by the Burst DMA, but data is always stored in MD in Big Endian. Byte manipulation is performed when data is exchanged with an Burst controller (for example, during read or write burst accesses).

52.18.1.9 Copy Mode

A mechanism is available to perform fast AP-to-AP transfers. Data does not flow through the SDMA core: It is kept in the DMA FIFO. This mechanism is selected when writing MD with a special option in the instruction code (copy flag). It is possible to transfer up to eight words in one SDMA instruction (this does not mean in one cycle). In this mode, every time an `stf MD|CPY` is executed, a read burst is executed and directly followed by a write burst transfer. Burst transfers are limited to eight words. The size of the transfer (in words)—given by the SDMA general register (4 LSB)—is also limited to eight. The following SDMA code shows how 100 bytes could be copied from the MSA address to the MDA address. This is sample code only.

Example 52-1. Burst DMA copy mode example

```
        ldi r0,@src
        stf r0,MSA                  // Source address setup
        ldi r1,@dst
        stf r1,MSA                  // Destination address setup
        ldi r0,0x64                 // data transfer counter
        ldi r1,0x8
MAIN_XFER:
        cmphs r0,r1                 // Is r0 >= 0x8
        bf LAST_XFER                // If not, jump to last transfer label
        stf r1,MD|CPY               // Copy 8 words from MSA to MDA address.
        subi r0,0x8                 // Decrement counter
        jmp MAIN_XFER               // return to main transfer loop
LAST_XFER:
        stf r0,MD|CPY
```

The main transfer loop is executed 12 times; then `r0` equals 4 and the last transfer loop is run.

In this mode, an acknowledge is transmitted to the core as soon as the read burst can start; thus, a first copy instruction returns an immediate acknowledge and subsequent copy instructions will be acknowledged as soon as the previous copy has finished.

52.18.1.10 Error Management

Another point to consider is the management of errors. Because the DMA immediately sends an acknowledge to the RISC core (except for the `stf MS|SZ0|FLS` instruction), it assumes no error will occur. If an error occurs, it is flagged (transfer error acknowledge) for the following DMA access. This should not be a problem if the DMA is used properly. The MD accesses are meant to stall the SDMA as little as possible to optimize throughput and hide calculation time. Therefore, final access to MS should be performed before closing a channel. This access waits until any pending operation is finished in the burst DMA and gather any remaining error.

In copy mode, an error could be immediately returned to the SDMA on execution of the `ldf` copy or `stf` copy instruction. It happens when MSA or MDA are not word addresses (for example, 0[4]). This is because copy mode must only be used for transferring a large packet of aligned data.

When an error is received during a *read* transfer to the external bus, which may occur during the burst accesses, the MD FIFO contains the valid beats of the burst, and the error flag of MS is set to 2'b11 (error read burst). It is possible to read MS ("n" field) to know how much valid data remains in MD and when MD is empty (after `ldf` instructions). The next read MD instruction sets the MS error flag to 2'b10 (error mode), and an error is sent back to the SDMA core. In error mode, it is possible to read MSA, which gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, gives rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

In "error read burst" mode, writing MDA, MSA, or MD, or starting a copy transfer by a `stf MD|COPY` instruction will cancel the error mode. Table 52-82 shows when an immediate error is sent back according to the executed instruction.

Table 52-82. Possibilities in ERROR READ BURST Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA (|U |PF) stf rn, MDA stf rn,MD|COPY	NO	Error mode is reset. MSA, MDA, or MD are updated and a DMA cycle may start. For the `stf MD|COPY`, a copy loop is executed.
stf rn, MS	NO	MS is updated.

ldf rn, MS
ldf rn, MSA
ldf rn, MDA
	NO	MS, MSA, and MDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).

ldf rn, MD	YES/NO	Immediate error if there is no more data available for read in the FIFO.

When an error is received during a *write* transfer, the error is reported to the next DMA access. In this case, an error is sent to the SDMA core and the DMA goes to its error mode. Reading MS gives the number of bytes that remain in MD; reading MDA gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, give rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

Table 52-83. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA stf rn, MDA	Yes	Any attempt to modify MD, MSA, MDA will raise an immediate error and burst DMA remains in error mode. When address registers are write-accessed, an error is returned.
stf rn, MS	No	This is the only way to exit error mode. MS[9:8] must be reset by an `stf MS|SZ0` instruction.

ldf rn, MS
ldf rn, MSA
ldf rn, MDA
	No	MS, MSA, and MDA could be read in error mode without any side effects (for example, no DMA cycle is triggered).

ldf rn, MD	Yes	Whatever the DMA direction (read or write), an `ldf rn` triggers an immediate error.

52.18.1.11 Conditional Yielding

The standard SDMA transfer is based upon a hardware loop that has the following structure:

Example 52-2. Hardware Loop

```
loop
load Rn,source  // can be ldf or ld
<computation>   // can be done through functional units
store Rn,dest   // can be st or stf
done 0          // yield
```

This structure needs to be kept independent of the functional units' particularities regarding the context switch. However, there can be variations in the context switch's efficiency, which can depend on the number of data received up to that point, and on the data itself.

The DMA, with its 8-word burst capability, has a preferable context switch period when its address register is 8-word aligned: It is the only moment that occurs once every eight loops when the succession of bursts is not broken by the context switch. When this is not the case, a context switch requires the storing (or loading) of less than eight words, which requires separate accesses and is far less efficient. The rest of the 8-word packet is stored (or loaded) after the context restore, and this is done as separate accesses.

The proposed solution is a conditional yielding, which occurs only when the DMA is in an optimum state. It does not require any modification to the scripts. The condition is decided at the DMA level.

The DMA can be programmed in two modes—conditional or always-true—for every channel, which provides complete flexibility. By default, the DMA is not in conditional mode.

The DMA condition is computed from the FIFO fill level and the various modes, as follows:

- When copy mode is selected, regardless of the transfer direction ('read' or 'write'), the condition is always true.
- In read mode, the condition is always true.

- In write mode, the condition is true when there are four bytes or less in the FIFO; it is false when there are more than four bytes. The 4-byte limit comes from the possibility of saving those bytes as MD with absolutely no impact on the bus accesses.

The aim at conditional yielding is to avoid splitting bus accesses (especially bursts).

52.18.2 Burst DMA2 Unit

The DMA instructions control the DMA state machine and may cause a DMA cycle on the associated memory bus. There are four registers associated with the Burst DMA2 unit, a Memory Source Address register (DSA), a Memory Destination Address register (DDA), a Memory Data buffer (DD), and a state register (DS).
The burst DMA2 has two different uses:

- A data transfer between External Memory Interface and SDMA general register
- A data transfer in copy mode where blocks of data are transferred from the source address to the destination address

52.18.2.1 Memory Source Address Register (DSA)

The source address register contains the pointer into EMI memory associated with the next read data transfer. It has byte granularity.

Reading the register with the `ldf` instruction has no side effects, and gives the address value in the EMI memory of the next data that is read by the SDMA during an `ldf DD` instruction.

Writing the source address register has two side effects: If the prefetch bit is set, a DMA read cycle (8-word read access) is issued with the new address. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying DSA to guarantee all the data is effectively written to memory.

The DSA register has two modes of programming:

- Frozen—In frozen mode, the DSA register is not modified after DMA accesses.
- Incremented (default mode)—In incremental mode, DSA is incremented by the number of bytes transferred during read cycles.

52.18.2.2 Memory Destination Address Register (DDA)

The destination address register contains the pointer into EMI memory associated with the next write data transfer. It has byte granularity.

Reading the DDA register with the `ldf` instruction has no side effects. It gives the address value in the EMI memory where the next SDMA data (`stf r,DD` instruction) is stored when DD FIFO is flushed.

Writing the destination address register has one side effect. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying DDA to guarantee all the data is effectively written to memory.

The DDA register has two modes of programming:

- Frozen—In frozen mode, the DDA register is not modified after DMA accesses.
- Incremented (default mode)—The DDA register is incremented by the number of bytes transferred during write cycles.

52.18.2.3 Memory Data Buffer Register (DD)

The data buffer register consists of a bank of 36 bytes that behave like FIFO. This FIFO stores the eight words received when a read burst is triggered by the DMA (DMA is in read mode). The DD register is in write mode after a writing in DDA or after an `stf DD` instruction. In that case, a burst write access is automatically triggered when there are more than eight words in DD. For bandwidth optimization, any transfers between DMA and the EMI controller are based on burst accesses.

An `ldf r,DD|SIZE` instruction that reads the data buffer may cause a DMA cycle, as follows:

- If there are less bytes in the FIFO than the size parameter of the instruction. For instance, if only two bytes are available in DD and a 4-byte read is requested, a burst read access is executed to complete the two bytes.
- If the prefetch bit is set, and after reading there is enough space in the FIFO to store a full burst, a burst read access is triggered.

An `stf r,DD|SIZE` instruction that writes to the data buffer may cause a DMA cycle if the number of written bytes in DD is higher than 32 (eight words) or if the flush bit is set.

When DMA is used for data transfer between SDMA and EMI (reading or writing), no immediate error is possible because the module manages a data misalignment issue; therefore, it is allowed to read/write a word to/from a half-word address. However, the addresses (source or destination) must belong to the EMI memory mapping. The only potential error, in this mode, would be the error sent back by the EMI controller when an access to a super-user page is detected. The whole transfer on the DMA associated bus will be considered successful when there are no errors seen on the bus during the transfer. In copy mode, an immediate error could be returned to SDMA as described in Section 52.18.1.10, Error Management."

52.18.2.4 State Register (DS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer. DS is also accessed to set-up the conditional yielding feature.

The initialization value of this register is 0 and it consists of the following:

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	stype	0	0	0	dtype
W																
R	0	0	0	0	y	d	e		0	0	n					
W																

Figure 52-71. DS Structure

Table 52-84. MS Field Descriptions

Field	Description
31-21	Reserved
20 stype	Source Mode. Indicates if DSA has to be incremented (or not) during accesses. 0 Frozen—DSA is not modified. 1 Incremented—DSA is incremented by the number of transferred bytes during read access.
19-17	Reserved
16 dtype	Destination Mode. Indicates if DDA has to be incremented (or not) during accesses. 0 Frozen—DDA is not modified. 1 Incremented—DDA is incremented by the number of transferred bytes during write access.
15–12	Reserved
11 y	Conditional Yielding selector. When selected, the `yield`/`yieldge` instructions will not switch channels if the Burst DMA2 is in Write Mode, and it has less than four bytes in its FIFO. This is aimed at reducing the number of inefficient FIFO flushes due to context switches. 0 Always yields 1 Yields conditionally (when there are less than four bytes in the FIFO in write mode)
10 d	Access Direction or DMA Mode. DMA is in write mode when data was written into DD by `stf DD` instructions, or if a previous DMA cycle on the external bus was a write access. Writing DDA or DSA changes the DMA mode to the respective value. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by SDMA with an `ldf DD` instruction. Reading DDA or DSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9–8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 *reserved* 10 Error mode 11 error read burst
7–6	Reserved
5–0 n	Number of bytes in the DD FIFO.

52.18.2.5 Burst DMA2 Write (stf)

When received from a `stf` instruction, the function code bits are interpreted as follows, depending on the addressed register:

Register	7	6	5	4	3	2	1	0
DSA	s		p	freeze	r			
DDA								
DD			f	cpy			sz	
DS								

Figure 52-72. STF Code Bits

Table 52-85. STF Code Bit Field Descriptions

Field	Description
7–6 s	Functional Unit selector 00 for Burst DMA2
5 p (DSA)	Prefetch Flag 0 No prefetch 1 Prefetch required from new DSA
5 f (DD)	Forced Flush Flag 0 Automatic flush 1 FIFO contents are flushed (including the new written data).
4 freeze (DSA/DDA)	Address Freeze Mode 0 Address is normally incremented. 1 Address is frozen.
4 cpy (DD)	Copy Mode selection 0 Write Mode 1 Copy Mode
3–2 r	Register selection 00 DSA 01 DDA 10 DD 11 DS
1–0 sz (DD/DS)	Transfer Size 00 size 0 (no data stored in the FIFO) 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

The possible write instructions are listed in Table 52-77 (unused bits should always be cleared).

Table 52-86. Burst DMA2 STF Instruction List

Binary	Assembly	Comments
01_0_0_00_00	stf r,DSA	Writes content of the SDMA general register (r) to the source address register. DSA is in incremented mode.
01_0_1_00_00	stf r,DSA|FR	Writes content of the SDMA general register (r) to the source address register. DSA is in frozen mode.
01_1_0_00_00	stf r,DSA|PF	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access. DSA is in incremented mode.

Table 52-86. Burst DMA2 STF Instruction List (continued)

Binary	Assembly	Comments
01_1_1_00_00	stf r,DSA|PF|FR	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access.
01_0_0_01_00	stf r,DDA	Writes content of the SDMA general register (r) to the destination address register. DDA is in incremented mode.
01_0_1_01_00	stf r,DDA|FR	Writes content of the SDMA general register (r) to the destination address register. DDA is in frozen mode.
01_1_0_10_00	stf r,DD|SZ0|FL	No data transfers between the SDMA and DD, but all valid written data of the DD is flushed to the memory. An acknowledge or error is sent back to the SDMA core on transfer completion.
01_0_0_10_01	stf r,DD|SZ8	8-bit (byte) transfer to write buffer DD
01_1_0_10_01	stf r,DD|SZ8|FL	8-bit (byte) transfer to write buffer DD and flush after transfer. All valid written data of the DD is flushed to memory.
01_0_0_10_10	stf r,DD|SZ16	16-bit (half-word) transfer to write buffer DD
01_1_0_10_10	stf r,DD|SZ16|FL	16-bit (half-word) transfer to write buffer DD and flush after transfer. All valid written data of the DD is flushed to memory.
01_0_0_10_11	stf r,DD|SZ32	32-bit (word) transfer to write buffer DD
01_1_0_10_11	stf r,DD|SZ32|FL	32-bit (word) transfer to write buffer DD and flush after transfer. All valid written data of DD is flushed to memory.
01_0_1_10_00	stf r,DD|CPY	No data transfer between SDMA and DD but starts a copy transfer whose length is given by the 4 LSB of *r* register. (Maximum burst length is eight words.)
01_0_0_11_11	stf r,DS	32-bit (word) transfer to status register DS
01_0_0_11_00	stf r,DS|SZ0	Clears the error flag (if set). Other DS bits are unchanged; this instruction is also known as `clref` DS.

NOTE

When a flush bit is set, the SDMA flushes the FIFO including the newly written data. An acknowledge is sent to the core before the flush completes (except if size 0 is used). The goal of this flush bit is to force a flush, but it is recommended to use it only when needed (for example, when finishing a row of pixels during 2D data transfers). Indeed, if this bit is omitted and if there are more than 32 bytes in the FIFO, a burst write access is automatically triggered.

Since all the `stf r,DD` instructions (including the copy mode) acknowledge the SDMA core before the store is effective (except if size 0 is used), it is recommended to perform an `ldf` from DS before terminating a channel in order to check the final error status. (The `ldf` from DS will stall the core until all the data was flushed out and the transfer status is known.)

After every `stf DD` instruction, the DDA is incremented by the number of bytes that are written in DD, except when it is programmed in frozen mode.

52.18.2.6 Burst DMA2 Read (ldf)

When received from an `ldf` instruction, the function code bits are interpreted as follows, depending on the addressed register:

Register	7	6	5	4	3	2	1	0
DSA	s				r			
DDA								
DD			p				sz	
DS								

Figure 52-73. LDF Code Bits

Table 52-87. LDF Code Bit Field Descriptions

Field	Description
7–6 s	Functional Unit selector 00 for Burst DMA2
5 p (DD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
3–2 r	Register selection 00 DSA 01 DDA 10 DD 11 DS
1–0 sz (DD)	Transfer Size 00 reserved 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

Table 52-79 lists the possible write instructions (unused bits should always be cleared).

Table 52-88. Burst DMA2 LD2F Instruction List

Binary	Assembly	Comments
01_0_0_00_00	ldf r,DSA	Copies the source address register value into an SDMA general register. It gives the memory address of the next data that will be read with an `ldf` DD instruction.
01_0_0_01_00	ldf r,DDA	Copies the destination address register value into an SDMA general register. It gives the memory address where the next incoming data will be flushed.
01_0_0_10_01	ldf r,DD|SZ8	8-bit (byte) read
01_1_0_10_01	ldf r,DD|SZ8|PF	8-bit (byte) read. If after this reading and the DD FIFO is empty, a burst read access at the DSA address is triggered.
01_0_0_10_10	ldf r,DD|SZ16	16-bit (half-word) read

Table 52-88. Burst DMA2 LD2F Instruction List (continued)

Binary	Assembly	Comments
01_1_0_10_10	ldf r,DD|SZ16|PF	16-bit (half-word) read. If after this reading, and the DD FIFO is empty, a burst read access at the DSA address is triggered.
01_0_0_10_11	ldf r,DD|SZ32	32-bit (word) read
01_1_0_10_11	ldf r,DD|SZ32|PF	32-bit (word) read. If after this reading and the DD FIFO is empty, a burst read access at the DSA address is triggered.
01_0_0_11_00	ldf r,DS	Copy the status register value into an SDMA general register.

NOTE

Read data is 0-extended before writing in the SDMA general registers. When reading the DD register, the DMA takes data from the FIFO if it is available. If part or whole data is not in the FIFO, an external burst read access is performed to provide the missing data. The SDMA is stalled as long as the required read data is not complete.

After every reading, DSA is incremented by the number of read bytes from DD FIFO, except when DSA is programmed in frozen mode.

52.18.2.7 Prefetch/Flush and Auto-Flush Management

The prefetch and auto-flush management enables the SDMA RISC machine to go on while a DMA access is performed. When the RISC core requires a prefetch (p = 1) to the Burst DMA2, it will receive an immediate transfer acknowledge before the DMA has finished the external access. This enables the RISC core to do other things like accessing another DMA machine.

The basic principle in prefetch mode is for the DMA to anticipate data reads from the SDMA RISC engine by fetching external bursts of data as soon as there is enough space in the DMA FIFO to store it. If ever the RISC engine required data that is not available in the FIFO, the read acknowledge is delayed until the data is available, but it does not have to wait until the burst completes.

The auto-flush basic principle is similar: An automatic flush is triggered every time there are eight words to be written in the FIFO. If the FIFO is full and the RISC engine requires another write, it is stalled until the burst has started and enough space was freed in the FIFO to store that new data. This means the SDMA RISC engine does not have to wait for the completion of a burst to receive its acknowledge and continue its processing.

In particular, an auto-flush is executed when DMA is in write mode and if the following is true:

- If the FIFO is empty and the first write is to a word-aligned address of any size (ex: the 2 LSB of DDA[1:0]= 0x0), the auto-flush is triggered immediately after the write of the 32’nd byte.
- If the FIFO is empty, and if DDA is an odd byte address (1, 3, 5, 7, . . .) and an `stf DD|SZ8` is executed, the byte is flushed to memory. Once DDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.

- If the FIFO is empty, and if DDA is a half-word address (2, 6, 0xA, . . .) and an `stf DD|SZ16` is executed, the two bytes of the incoming data are flushed to memory. Once DDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if DDA is not a word-aligned address (ex 1, 2, 3, 5, 6, 7, 9, . . .), and an `stf DD|SZ32` is executed, the first 1 to 3 bytes will be flushed up to the next word aligned address. Afterwards, an auto-flush will be triggered each time the FIFO receives 32-bytes.

  Therefore, if an `stf DD|SZ32` is executed with DDA equal to 0x1 and with an empty DD FIFO, the bytes located at addresses 1, 2, and 3 are flushed, and the byte located at address 4 remains in DD FIFO. This solves the misalignment issue. Additionally, the next write instructions (`stf`) complete the FIFO until it contains eight words; then a burst write is executed by the DMA to empty the FIFO. Protocol on the external bus does not support bursts of different data types (byte, half-word, or word).

For example, consider the case where data is written using a byte access, `stf DD|SZ8`. The value of DDA during the very first byte write determines when the auto-flush will occur as follows:

- If DDA=0x0, the flush occurs following the write of byte 32
- If DDA=0x1, the flush occurs following the write of byte 1, byte 3 and byte 35.
- If DDA=0x2, the flush occurs following the write of byte 2 and byte 34.
- If DDA=0x3, the flush occurs following the write of byte 1 and byte 33.
- If DDA=0x4, the flush occurs following the write of byte 32

The flush command forces the DMA to flush all DD valid bytes to the EMI controller. An acknowledge is sent immediately to the SDMA, and any potential error is reported on a future access. It is thus essential to conclude a transfer with a last read from DS, which will stall the core until all data was flushed out and returned to the transfer status (acknowledge or error).

NOTE

During this kind of auto-flush—which occurs only at the beginning of a misaligned write transfer—no acknowledge is sent back to the SDMA, which is stalled until a flush is completed.

52.18.2.8 Data Alignment and Endianness

52.18.2.8.1 Burst DMA2 in Read Mode

For every read access to DD, the data returned to the SDMA core and the new FIFO state depends on the DSA status and the access size. The FIFO is considered as a stack of 36 bytes: Data is fetched externally on a 32-bit bus, but the valid bytes only are stored in the FIFO and left-aligned (for a transfer of consecutive words, it is only the first word that may be truncated). Table 52-80 shows the FIFO byte alignment strategy and the corresponding DSA, the returned data, and the new FIFO state for any access size of an internal read from DD.

Table 52-89. FIFO Read Configuration

Before read		Internal read access size	Read data	After read	
DSA[1:0]	FIFO state			DSA[1:0]	FIFO state
00	x0 x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 and so on...	sz8	00 00 00 x0	01	x1 x2 x3 y0 y1 y2 y3 z0
		sz16	00 00 x0 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz32	x0 x1 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
01	x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 and so on...	sz8	00 00 00 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz16	00 00 x1 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz32	x1 x2 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
10	x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 and so on...	sz8	00 00 00 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz16	00 00 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz32	x2 x3 y0 y1	10	y2 y3 z0 z1 z2 z3 t0 t1
11	x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 t2 and so on...	sz8	00 00 00 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz16	00 00 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
		sz32	x3 y0 y1 y2	11	y3 z0 z1 z2 z3 t0 t1 t2

52.18.2.8.2 Burst DMA2 in Write Mode

For every write access to the DD, the new FIFO state depends on the DDA status and the access size. The FIFO is considered as a stack of 36 bytes: Data is stored in the FIFO according to the internal access size

and the former DDA value. Table 52-81 shows the FIFO byte alignment strategy corresponding to DDA, as well as the new FIFO state for any access size of an internal write to DD.

Table 52-90. FIFO Write Configuration

Before write		Internal write access size	Written data	After write	
DDA[1:0]	FIFO state			DDA[1:0]	FIFO state
00	tt uu vv ww ?? ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	01	tt uu vv ww x0 ?? ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	10	tt uu vv ww x0 x1 ?? ?? ?? ?? ?? ??
		sz32	x0 x1 x2 x3	00	tt uu vv ww x0 x1 x2 x3 ?? ?? ?? ??
01	tt uu vv ww xx ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	10	tt uu vv ww xx x0 ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	11	tt uu vv ww xx x0 x1 ?? ?? ?? ?? ??
		sz32	x0 x1 x2 x3	01	tt uu vv ww xx x0 x1 x2 x3 ?? ?? ??
10	tt uu vv ww xx yy ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	11	tt uu vv ww xx yy x0 ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	00	tt uu vv ww xx yy x0 x1 ?? ?? ?? ??
		sz32	x0 x1 x2 x3	10	tt uu vv ww xx yy x0 x1 x2 x3 ?? ??
11	tt uu vv ww xx yy zz ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	00	tt uu vv ww xx yy zz x0 ?? ?? ?? ??
		sz16	?? ?? x0 x1	01	tt uu vv ww xx yy zz x0 x1 ?? ?? ??
		sz32	x0 x1 x2 x3	11	tt uu vv ww xx yy zz x0 x1 x2 x3 ??

NOTE

If the FIFO mode changes from a write to a read mode, all remaining written bytes in DD are lost but no error is returned. Typically, this happens if an `ldf` DD is executed after `stf` DD instructions. Before a mode change, it is recommended to force the flush of a potential remaining byte by a `stf DD|SZ0|FL` instruction. In the same way, if a FIFO mode changes from a read to a write mode, all prefetched data present in the FIFO is lost and no error is returned.

52.18.2.8.3 Endianness

Big and Little Endian are supported by the Burst DMA2, but data is always stored in DD in Big Endian. Byte manipulation is performed when data is exchanged with an Burst controller (for example, during read or write burst accesses).

52.18.2.9 Copy Mode

A mechanism is available to perform fast AP-to-AP transfers. Data does not flow through the SDMA core: It is kept in the DMA FIFO. This mechanism is selected when writing DD with a special option in the instruction code (copy flag). It is possible to transfer up to eight words in one SDMA instruction (this does not mean in one cycle). In this mode, every time an `stf DD|CPY` is executed, a read burst is executed and directly followed by a write burst transfer. Burst transfers are limited to eight words. The size of the transfer (in words)—given by the SDMA general register (4 LSB)—is also limited to eight. The following SDMA code shows how 100 bytes could be copied from the DSA address to the DDA address. This is sample code only.

Example 52-3. Burst DMA2 copy mode example

```
        ldi r0,@src
        stf r0,DSA                  // Source address setup
        ldi r1,@dst
        stf r1,DSA                  // Destination address setup
        ldi r0,0x64                 // data transfer counter
        ldi r1,0x8
MAIN_XFER:
        cmphs r0,r1                 // Is r0 >= 0x8
        bf LAST_XFER                // If not, jump to last transfer label
        stf r1,DD|CPY               // Copy 8 words from DSA to DDA address.
        subi r0,0x8                 // Decrement counter
        jmp MAIN_XFER               // return to main transfer loop
LAST_XFER:
        stf r0,DD|CPY
```

The main transfer loop is executed 12 times; then `r0` equals 4 and the last transfer loop is run.

In this mode, an acknowledge is transmitted to the core as soon as the read burst can start; thus, a first copy instruction returns an immediate acknowledge and subsequent copy instructions will be acknowledged as soon as the previous copy has finished.

52.18.2.10 Error Management

Another point to consider is the management of errors. Because the DMA immediately sends an acknowledge to the RISC core (except for the `stf DS|SZ0|FLS` instruction), it assumes no error will occur. If an error occurs, it is flagged (transfer error acknowledge) for the following DMA access. This should not be a problem if the DMA is used properly. The DD accesses are meant to stall the SDMA as little as possible to optimize throughput and hide calculation time. Therefore, final access to DS should be performed before closing a channel. This access waits until any pending operation is finished in the Burst DMA2 and gather any remaining error.

In copy mode, an error could be immediately returned to the SDMA on execution of the `ldf` copy or `stf` copy instruction. It happens when DSA or DDA are not word addresses (for example, 0[4]). This is because copy mode must only be used for transferring a large packet of aligned data.

When an error is received during a *read* transfer to the external bus, which may occur during the burst accesses, the DD FIFO contains the valid beats of the burst, and the error flag of DS is set to 2'b11 (error read burst). It is possible to read DS ("n" field) to know how much valid data remains in DD and when DD is empty (after `ldf` instructions). The next read DD instruction sets the DS error flag to 2'b10 (error mode), and an error is sent back to the SDMA core. In error mode, it is possible to read DSA, which gives the address of the error data. Any attempt to read or write DD, or to modify DDA or DSA in error mode, gives rise to an error; therefore, an error flag must be reset by clearing DS at the end of the SDMA code section responsible for error management.

In "error read burst" mode, writing DDA, DSA, or DD, or starting a copy transfer by a `stf DD|COPY` instruction will cancel the error mode. Table 52-82 shows when an immediate error is sent back according to the executed instruction.

Table 52-91. Possibilities in ERROR READ BURST Mode

DMA Instruction	Immediate Error	Comments
stf rn, DD stf rn, DSA (IU IPF) stf rn, DDA stf rn,DD|COPY	NO	Error mode is reset. DSA, DDA, or DD are updated and a DMA cycle may start. For the `stf DD|COPY`, a copy loop is executed.
stf rn, DS	NO	DS is updated.

ldf rn, DS
ldf rn, DSA
ldf rn, DDA
	NO	DS, DSA, and DDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).

ldf rn, DD	YES/NO	Immediate error if there is no more data available for read in the FIFO.

When an error is received during a *write* transfer, the error is reported to the next DMA access. In this case, an error is sent to the SDMA core and the DMA goes to its error mode. Reading DS gives the number of bytes that remain in DD; reading DDA gives the address of the error data. Any attempt to read or write DD, or to modify DDA or DSA in error mode, give rise to an error; therefore, an error flag must be reset by clearing DS at the end of the SDMA code section responsible for error management.

Table 52-92. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, DD stf rn, DSA stf rn, DDA	Yes	Any attempt to modify DD, DSA, DDA will raise an immediate error and Burst DMA2 remains in error mode. When address registers are write-accessed, an error is returned.
stf rn, DS	No	This is the only way to exit error mode. DS[9:8] must be reset by an `stf DS|SZ0` instruction.

ldf rn, DS
ldf rn, DSA
ldf rn, DDA
	No	DS, DSA, and DDA could be read in error mode without any side effects (for example, no DMA cycle is triggered).

ldf rn, DD	Yes	Whatever the DMA direction (read or write), an `ldf rn` triggers an immediate error.

52.18.2.11 Conditional Yielding

The standard SDMA transfer is based upon a hardware loop that has the following structure:

Example 52-4. Hardware Loop

```
loop
load Rn,source  // can be ldf or ld
<computation>   // can be done through functional units
store Rn,dest   // can be st or stf
done 0          // yield
```

This structure needs to be kept independent of the functional units' particularities regarding the context switch. However, there can be variations in the context switch's efficiency, which can depend on the number of data received up to that point, and on the data itself.

The DMA, with its 8-word burst capability, has a preferable context switch period when its address register is 8-word aligned: It is the only moment that occurs once every eight loops when the succession of bursts is not broken by the context switch. When this is not the case, a context switch requires the storing (or loading) of less than eight words, which requires separate accesses and is far less efficient. The rest of the 8-word packet is stored (or loaded) after the context restore, and this is done as separate accesses.

The proposed solution is a conditional yielding, which occurs only when the DMA is in an optimum state. It does not require any modification to the scripts. The condition is decided at the DMA level.

The DMA can be programmed in two modes—conditional or always-true—for every channel, which provides complete flexibility. By default, the DMA is not in conditional mode.

The DMA condition is computed from the FIFO fill level and the various modes, as follows:

- When copy mode is selected, regardless of the transfer direction ('read' or 'write'), the condition is always true.
- In read mode, the condition is always true.

- In write mode, the condition is true when there are four bytes or less in the FIFO; it is false when there are more than four bytes. The 4-byte limit comes from the possibility of saving those bytes as DD with absolutely no impact on the bus accesses.

The aim at conditional yielding is to avoid splitting bus accesses (especially bursts).

52.18.3 OnCE and Real-Time Debug

The On-Chip Emulation module (OnCE) is the debug interface to the SDMA. It supports the access to all core internal devices (registers, memory, and so on), and provides a set of mechanisms that control the core. The OnCE is accessed by JTAG ports at the chip's board level, or by the host via its peripheral bus.

To reduce the size of the hardware material involved, all tasks supported by the OnCE are performed on the SDMA core. The architecture of the SDMA OnCE is relatively simple and very flexible.

The commands supported by the SDMA OnCE are listed in the following sections.

52.18.3.1 Memory and Register Access

A set of mechanisms is provided to access SDMA memory and register locations. Both reading and writing are allowed. The access is supported if the processor is in debug mode.

Those registers can also be accessed through the AP Control interface when the OnCE is controlled by the AP, as described in Section "Using the BP."

52.18.3.2 Hardware Breakpoints

An event detection unit is implemented to support memory breakpoints. The unit watches the data exchanged between the SDMA memory bus and the core. A debug request is sent to the core when matching conditions occur. The unit supports mixed conditions based on address range, access type, and data value. Event detection unit configuration registers are memory mapped in the SDMA space (see Section 52.14.3, SDMA Core Register Descriptions"): You can modify them through a regular memory access or the AP control interface.

52.18.3.3 Watchpoints

One output pin is provided to monitor matching trigger conditions that are defined in the event detection unit.

52.18.3.4 Software Breakpoints

The SDMA instruction set contains a software breakpoint. Upon executing a software breakpoint instruction, the core suspends normal execution and enters debug mode. No hardware step execution mode is implemented in the OnCE module, but this feature may be implemented at the software level with this instruction.

52.18.3.5 Core Control

Commands are provided to monitor and control processor activity. You can halt the core, rerun the core from another address location, and get processor status. Any hardware breakpoint on the instruction bus is not supported, but this feature may be implemented by inserting a software breakpoints program.

52.19 The OnCE Controller

The OnCE controller receives commands from the AP or from the JTAG controller. Each command is interpreted before being sent to the core.

52.19.1 OnCE Commands

A small set of commands supports the communication between the OnCE module and the external world. This command set enables you to perform any of the following tasks: control processor activity, save core context, and execute an SDMA instruction from the OnCE module. Combined together, these tasks perform more complex commands.

A full OnCE command contains a 4-bit instruction (the OnCE command opcode) and a variable length data field (the OnCE data). During command execution, the OnCE data is transferred in a OnCE internal register before being exchanged with the SDMA. Some data values are also exported. This mechanism creates a link between the processor and the external world. Nine commands are defined: Table 52-93 presents their formats.

Table 52-93. OnCE Command Opcode Values

Instruction Opcode	Name	Action	Register	Data Field Size	Mode
0000	rstatus	Reads the OnCE status register	STATUS	16-bit	normal/debug
0001	dmov	Updates general register GReg1	GREG1	32-bit	debug
0010	exec_once	Runs the instruction from the SDMA instruction register	INSTRUCTION	16-bit	debug
0011	run_core	Returns to normal execution	BYPASS	1-bit	debug
0100	exec_core	Returns to normal execution via a jump instruction that specifies the new address	INSTRUCTION	16-bit	debug
0101	debug_rqst	Stops the core after execution of current instruction	BYPASS	1-bit	normal
0110	rbuffer	Reads the real time buffer	RTB	32-bit	normal/debug
0111-1110	reserved	Reserved	BYPASS	1-bit	normal/debug
1111	bypass	Bypasses TAP controller	BYPASS	1-bit	normal/debug

Each instruction corresponds to a specific action performed on the OnCE module. The nature of the associated data field is clearly identified. The `dmov` command is followed by a 32-bit data value (which is a data value for the SDMA); the `exec_once` and the `exec_core` commands are followed by a 16-bit data value (which is an instruction for the SDMA); the `rstatus` command is followed by a 16-bit control value (which is the content of the OnCE status register); the `rbuffer` command is followed by a 32-bit data value.

The debug_rqst and the run_core commands are followed by a single bit data field (this is a bypass value). Finally, the bypass instruction enables the SDMA JTAG TAP controller to be daisy-chained with another JTAG TAP controller. This is a JTAG-only feature. The set of commands is simple, but enables you to perform any possible task on the SDMA during a debug process.

52.19.2 Sending Commands to the OnCE Controller

The JTAG access is the standard access to the OnCE, but sometimes the JTAG is not available to fix some bugs (if the chip is in production for instance), an additional access is then required. Therefore, one AP access to the OnCE is provided.

52.19.2.1 Using the JTAG Interface

A serial access is performed through the five JTAG pins TCK, TRST, TMS, TDI, and TDO. A Test Access Port controller is provided to decode the TMS control signal. It produces shift-enable signals (shift_ir and shift_dr), and updates enable signals (update_ir and update_dr). It is fully compliant with the IEEE 1149.1 testability (JTAG) standard.

During the shift_ir state, the command opcode is shifted into the OnCE controller (for example, the signal from the TDI pin is shifted into the command register and the TDO pin receives the signal shifted out). After transferring the four bits of the command, an update_ir signal is asserted and the command is decoded. The target data register is now clearly identified and the corresponding control signal is produced, as follows: bypass enable signal (bp_en), instruction enable signal (inst_en), data enable (data_en), and status enable signal (stat_en).

During the shift_dr state, the TDI signal is shifted into one of the following target registers: bypass register (1 bit), SDMA instruction register (16 bits), SDMA data register (32 bits), or OnCE status register (16 bits). The TDO pin is connected to the output of the selected register to receive the signals shifted out.

The JTAG access is disabled when the AP access is enabled.

52.19.2.2 Using the AP

The AP access to the OnCE is not the standard access, but it is required if the JTAG is not available. For example, if the SDMA ROM is out of use on a chip in production, and the AP needs to download new code and restart the SDMA, the OnCE can easily perform this operation. This type of debug operation justifies the use of an AP access to the OnCE.

To drive the OnCE, the AP uses some registers contained in the AP Control module of the SDMA. These registers are accessed through the AP peripheral bus. Most of these registers are connected to another register in the OnCE controller. Thus, accessing one of these registers is equivalent to accessing the associated register in the OnCE controller.

The set of registers in the AP Control module is listed below:

- ONCE_ENB register (1 bit, read/write)—This 1-bit register enables the AP access to the OnCE. When this bit is set, the signals from the JTAG are ignored. When it is cleared, all writing operations to the following registers through the Host Control interface are ignored. This register is reset on a JTAG reset.

- ONCE_CMD register (4 bits, read/write)—This 4-bit register receives the command opcode. It is connected to the command register in the controller. A write access to this register causes the associated command to be executed on the OnCE. For example, after writing “0001” in this register, a `dmov` command is executed.

NOTE

On the AP side, the `rstatus` and `bypass` commands are not supported. This register is reset on a JTAG reset.

- ONCE_DATA register (32 bits, read/write)—This 32-bit register is connected to the SDMA data register. This register is used when executing a `dmov` or `rbuffer` command.

NOTE

Before requesting a `dmov` command, the 32-bit data to transfer must be written in the ONCE_DATA register. At the end of the execution, the register is updated with GReg1 former value. This register is reset on a JTAG reset.

- ONCE_INSTR register (16 bits, read/write)—This 16-bit register is connected to the SDMA instruction register. This register is used when executing an `exec_core` or an `exec_once` command.

NOTE

Before requesting an `exec_core` or an `exec_once` command, the appropriate instruction must be written in the ONCE_INSTR register. This register is reset on a JTAG reset.

- ONCE_STAT register (16 bits, read only)—A read access to the ONCE_STAT register returns the content of the OnCE status register (OSTAT). This register is read only.
- The bypass register is not useful when the AP controls the OnCE, therefore no register is defined in the AP Control module to access the bypass register.

52.19.2.3 Conflicts Between the JTAG and the AP Accesses

When AP access to the SDMA OnCE is enabled (that is, when the bit in the ONCE_ENB register is set), the JTAG access is disabled. This guarantees that the module is not accessed at the same time on both sides.

It is possible to check whether the JTAG access to the SDMA OnCE is enabled from the JTAG port. When the JTAG access is disabled, the SDMA TDO always returns 1. The check requires the following steps:

- Execute a `dmov` command from debug mode (with neither 0xffffffff nor 0x0 as `dmov` value: 0x5a5a5a5a is good).
- Execute another `dmov` command (the value here is not important).

  The returned value from the latter `dmov` command should be the original one if the JTAG access is enabled; if it is 0xffffffff instead of the original input value, this means the JTAG access is disabled.

52.19.3 Executing a Command from the OnCE

All the commands defined in Section 52.19.1, OnCE Commands" can be accessed through the JTAG. The AP can access all these commands except the `rstatus` command. On the AP side, the OnCE status is directly accessed by reading the ONCE_STAT register.

52.19.3.1 Nature of the Commands

Two types of commands may be distinguished. First, there are two commands that do not interact with the core: `rstatus` and `rbuffer`. Those commands may be requested at any time: They do not depend on the core status.

NOTE

Each of these commands exports a data value or a status value from the SDMA.

There are also commands that interact with the core: `dmov`, `run_core`, `exec_core`, `exec_once`, and `debug_rqst`. These commands are core status dependent, as follows:

- During user mode only the `debug_rqst` is taken into account.
- During debug mode, all these commands are taken into account except the `debug_rqst`. For example, an `exec_once` command requested while not in debug mode has no effect.

52.19.3.2 Execution Request

The SDMA starts executing a task in debug mode when requested by the OnCE controller. The execution starting time depends on the type of access used to communicate with the OnCE.

If the JTAG is used, the request is send after decoding the `update_dr` state in the TAP controller. Therefore, always cross this state when sending a command through the JTAG. If the OnCE is driven from the AP side, the request is sent after detecting a write access to the ONCE_CMD register. All the registers involved in this operation must be loaded first.

The following is an example of an `exec_core` command execution from the AP side: After writing '010' in the ONCE_CMD register, the OnCE controller asks the SDMA to execute the instruction contained in the ONCE_INSTR register. The instruction involved should be available in the ONCE_INSTR register before the beginning of the execution.

52.19.3.3 Command Execution

The following list shows the commands and details how each command is executed:

- `rstatus` command execution—The `rstatus` command exports the content of the OnCE status register (OSR). If the JTAG is used, the status information is captured in the OnCE status register during the capture_dr state, and shifted out after 16 TCK clock cycles in the shift_dr state. The `rstatus` command is not supported on the AP side, but a status register is provided instead. The `rstatus` may be performed in both debug and user modes.

- `dmov` command execution—The `dmov` command accesses SDMA internal registers. Executing a `dmov` instruction exchanges the 32-bit data values between the SDMA data register and the general register GReg[1].

  If the JTAG is used, the content of GReg1 is captured in the SDMA data register during the capture_dr state, then it is shifted out after 32 TCK clock cycles in the shift_dr state. During the update_dr state, GReg1 is updated with the new, shifted-in 32-bit data value. If the OnCE is driven from the AP side, the data values contained in GReg1 and the SDMA data register are exchanged after detecting a write access to the ONCE_CMD register. The ONCE_DATA register must therefore be loaded first.

- `exec_once` command execution—The `exec_once` command executes the instruction loaded in the SDMA instruction register. The command may only be requested from debug mode. The SDMA returns to debug mode at the end of the execution.

  Change of flow instructions as well as instructions that may cause a context switch are not supported: The comprehensive list comprises `done/yield/yiedge` (except `done` 5), BF, BT, BSF, BDF, JMP, JSR, JMPR, JSRR, RET, and LOOP, as well as all the illegal instructions.

  No other command should be requested before the SDMA returns to debug mode. The SDMA status (for example, whether it is in debug mode or not) can be detected by polling with the `rstatus` OnCE command, monitoring the debug_mode pin, or checking the Section 52.12.3.19, OnCE Status Register (ONCE_STAT)" register via the AP control interface.

  NOTE

  Most of the instructions are single-cycle, which omits the step of polling the status. Loads and stores to DMA units are typical instructions that might require this polling.

  If the JTAG is used, the 16-bit instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift_dr state. A request is sent to the core when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the AP side, the request is sent to the SDMA when detecting a write access to the ONCE_CMD register. The ONCE_INSTR register must be therefore be loaded first.

- `run_core` command execution—The `run_core` command leaves debug mode and resume normal program execution. The next instruction executed is the last instruction decoded before entering debug mode. Be sure to restore core context before re-running the core. This procedure is detailed in Section 52.20.5.3, Restoring the Context."

  If the JTAG is used, a 1-bit bypass value is shifted in the bypass register in the shift_dr state. The SDMA is rerun when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the AP side, the core is rerun when detecting a write access to the ONCE_CMD register.

- `exec_core` command execution—The `exec_core` command resumes program execution from any address. The 16-bit instruction provided with the `exec_core` overwrites the last instruction decoded before entering debug mode. This command is designed to support change of flow instructions, so that a program execution can be restarted from any address. After executing an `exec_core` command, the SDMA leaves debug mode. The `exec_core` command is usually used with a `jmp` instruction.

If the JTAG is used, the 16-bit branch instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift_dr state. The SDMA is rerun when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the AP side, the SDMA reruns when detecting a write access to the ONCE_CMD register. The ONCE_INSTR register must therefore be loaded first. For example, to restart the SDMA from the program address 0x100, the instruction loaded should be a `jump to address 0x100` instruction.

- `debug_rqst` command execution—The `debug_rqst` command puts the SDMA in debug mode. If the JTAG is used, a 1-bit bypass value is shifted in the bypass register during the shift_dr state. A debug request is sent to the SDMA when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the AP side, the debug request is sent when detecting a write access to the ONCE_CMD register. When the SDMA is already in debug mode, this command is simply ignored.
- `rbuffer` command execution—The `rbuffer` command exports the content of the real time buffer (RTB). If the JTAG is used, the content of the real time buffer (RTB) is captured in the SDMA data register during the capture_dr state. The register is completely shifted out after maintaining the shift_dr state during 32 TCK clock cycles. If the OnCE is driven from the AP side, the content of the RTB is captured in the ONCE_DATA register after detecting a write access to the ONCE_CMD register.
- `bypass` command execution—This command is only available from the JTAG interface. It enables daisy-chaining of the SDMA JTAG TAP controller with other JTAG TAP controllers. This command does not change the SDMA state and can be executed in any mode (run, debug, or sleep). It selects the bypass register of the TAP controller.

52.19.4 Registers Descriptions

See Section 52.14.3, SDMA Core Register Descriptions," and Section 52.12, AP Memory Map and Control Register Definitions," for detailed information on each register.

52.19.4.1 Event Cell Counter Register (ECOUNT)

The event cell counter register is a 16-bit register that contains the number of times minus one that an event detection occurs before generating a debug request. This register should be written before attempting to use the event detection counter during an event detection process. The event cell counter register is cleared on a JTAG reset.

52.19.4.2 Event Cell Address Registers (EAA or EAB)

The event cell contains two address registers—the event cell address register (a), called EAA, and the event cell address register (b), called EAB. Every address register is a 16-bit register that stores a user-defined address value. This value computes one of the following address conditions: addra_cond or addrb_cond. Every address register is cleared on a JTAG reset.

52.19.4.3 Event Cell Address Mask Register (EAM)

The event cell address mask register is a 16-bit register that contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before comparing addresses.

NOTE

There is a common address mask value for the two address comparators. If bit *i* of this register is set, then bit *i* of the address value latched from the memory bus does not influence the result of the address comparison. The event cell address mask register is cleared on a JTAG reset.

52.19.4.4 Event Cell Data Register (ED)

The event cell data register is a 32-bit register that contains a user-defined data value. This data value is an input for the data comparator, which generates the data_cond condition. The event cell data register is cleared on a JTAG reset.

52.19.4.5 Event Cell Data Mask Register (EDM)

The event cell data mask register is a 32-bit register that contains a user-defined data mask value. This mask is applied to the data value latched from the memory bus before comparing data. Setting bit *i* of the event cell data mask register means that bit *i* of the data value latched from the address bus does not influence the result of the data comparison. The event cell data mask register is cleared on a JTAG reset.

52.19.4.6 Real Time Buffer Register (RTB)

The real Time Buffer register is a 32-bit register that stores and retrieves run-time information without putting the SDMA in debug mode. Refer to Section 52.20.8.2, Real Time Buffer" for more details.

52.19.4.7 Event Control Register (ECTL)

The event cell control register is a 16-bit register that defines cell event occurrence conditions. The event cell control register is cleared on a JTAG reset. See also Section 52.20.6, OnCE Event Detection Unit" for more details.

52.19.4.8 Trace Buffer (TB)

The Trace Buffer register retrieves the information in the Trace Buffer. See Section 52.20.8.1, Trace Buffer" for more details.

52.19.4.9 OnCE Status Register (OSTAT)

The OnCE status register is a 16-bit register that contains processor and event detection unit status. The OSTAT is a read-only register. Refer to Section 52.12.3.19, OnCE Status Register (ONCE_STAT)" for detailed description of the individual fields in the OSTAT register.

Figure 52-74 shows the OSTAT structure.

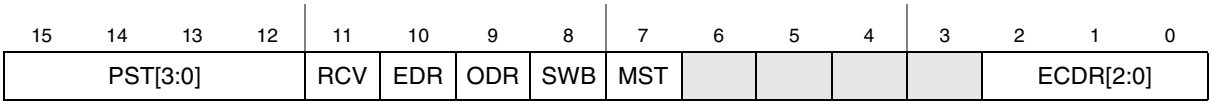

Figure 52-74. OnCE Status Register (OnCE)

Where PST[3:0] is the SDMA core state, RCV is set when the real-time buffer (RTB) is modified. EDR, ODR, and SWB are set, respectively, when the SDMA has entered debug mode because of an external debug request, a OnCE debug_rqst command, or a software breakpoint. MST is set when the OnCE is controlled from the AP control interface, and when ECDR is a three-flag set that shows the event cell condition(s) that put the core in debug mode. The OSTAT never provides more than one reason for entering debug mode.

There are two ways of accessing OSTAT content, as follows:

1. Send an `rstatus` command to the OnCE controller through the JTAG, or read the ONCE_STAT register through the AP access. Executing the `rstatus` command through the JTAG can be performed in both user and debug modes.
2. Perform an SDMA read access to the location in the SDMA core memory map (OSTAT register) debug mode using the `exec_once` command. With this method of access, the SDMA state reflected by the PST (processor status bit) is always DATA.

The register may also be accessed by a running application.

52.19.5 JTAG Interface Requirements

Because the signals received from the JTAG (running on TCK) are transferred to the OnCE controller (running on the SDMA clock), a synchronization mechanism is required.

52.19.5.1 TCK Speed Limitation

In the JTAG top-level layer, the TDO signal is always captured on a TCK falling edge. To guarantee a stable TDO signal from the SDMA during this operation, a falling edge detection is performed on TCK.

Before being latched in the *I* flip-flop (see Figure 52-75) on TCK falling edge, the TDO signal must be stable at the input of the flip-flop. This condition is verified if the TCK period is superior to the following delay:

worst-case edge detection delay + negative-edge signal propagation delay + JTAG top-level logic propagation delay

The frequency relationship, TCK < CLK/8, limitation guarantees that all operations are performed as expected.

52.19.5.2 Synchronization Implementation

Figure 52-75 shows the synchronization mechanism. Flip-flops tck0, tck1, and tck2 perform falling- and rising-edge detections on TCK. They generate the posedge_detected and negedge_detected nets that are used to sample the TDI and TMS inputs into the respective tdi and tms flip-flops, and update the tdo flip-flop to `yield` the TDO output. In the design, the only signal that might go metastable is the output of

the tck0 flip-flop. This signal is captured in the tck1 flip-flop and no logical operation is performed on it to minimize a metastability propagation risk.

The TDI and TMS flip-flops also cannot go metastable: The propagation time of the rising-edge detection signal through tck0, tck1, and tck2 guarantees that the TDI and TMS inputs are stable when captured in the TDI and TMS flip-flops.

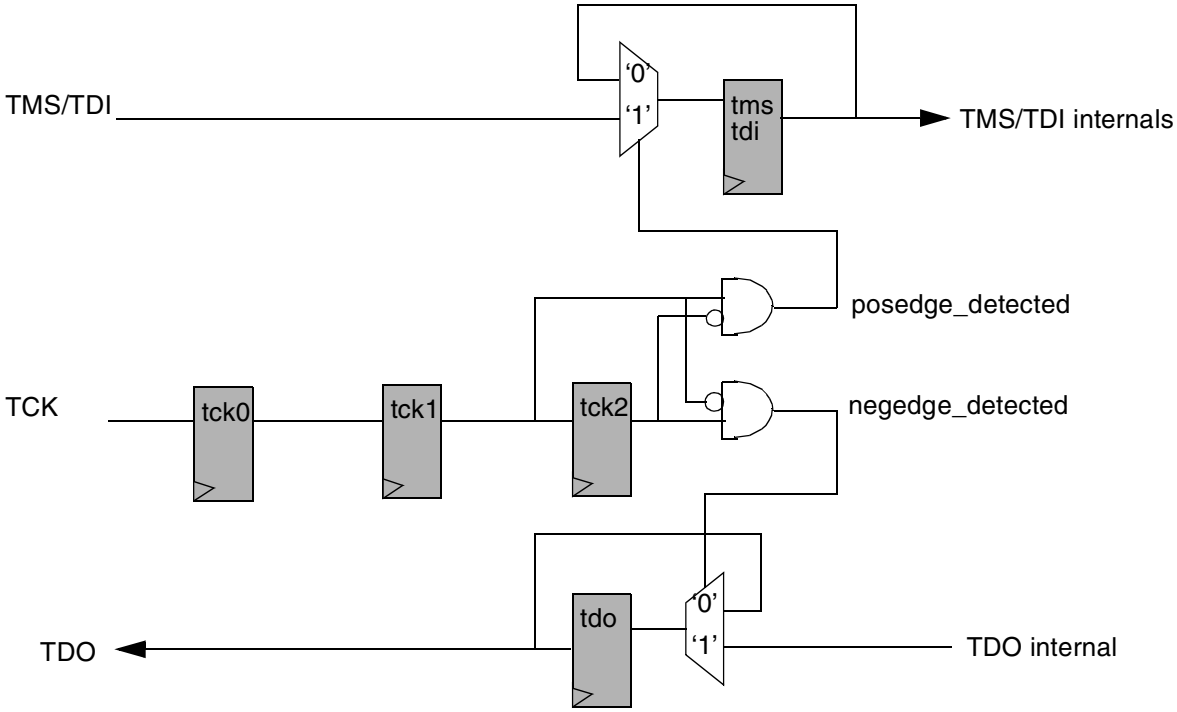

Figure 52-75. OnCE Synchronization Layer

Figure 52-76 shows synchronization timings. It takes three CLK clock cycles to synchronize TDI on the SDMA clock.

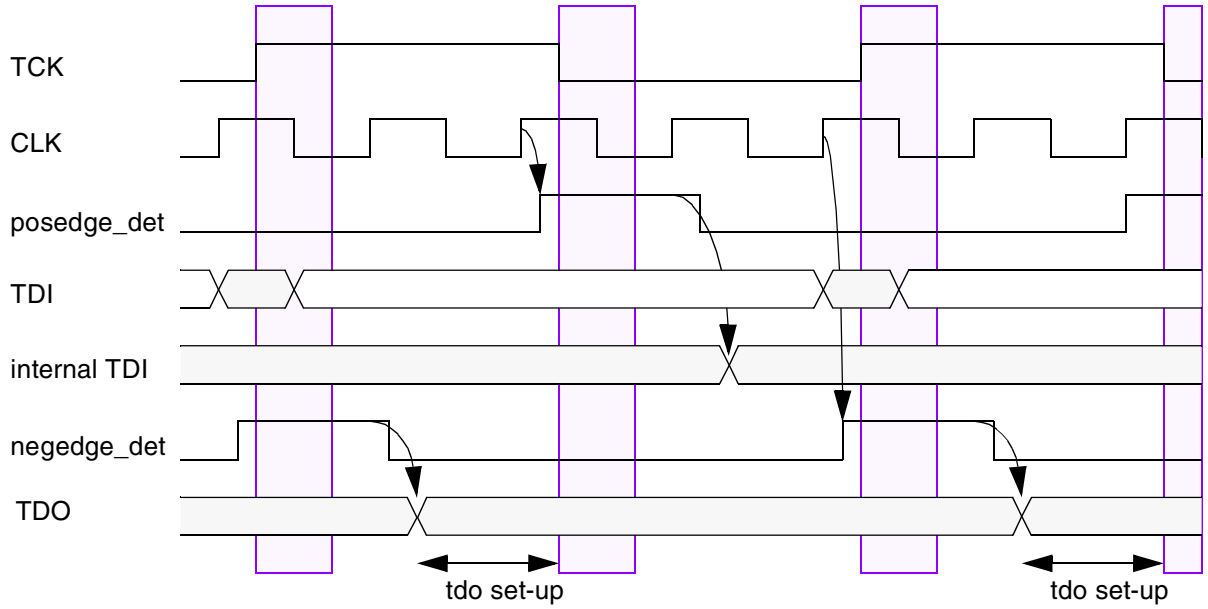

Figure 52-76. Synchronization Timings

52.19.5.3 JTAG Controller Start-Up Recommended Procedure

To ensure correct TAP controller initialization, it is recommended to use the following procedure:

1. Assert JTAG reset TRSTB (for example, set low).
2. Set TMS low.
3. Wait for 1 TCK clock.
4. Release JTAG reset TRSTB (for example, set high).
5. Wait for a minimum of five TCK cycles.

52.20 Using the OnCE

This section provides the elements necessary to run the OnCE module during a debug process. In addition to the basic set of commands described in Section 52.19.1, OnCE Commands," more complex commands can be built to meet users' requirements.

52.20.1 Activating Clocks in Debug Mode

For power consumption issues, some clocks in the SDMA are disabled when not needed. This is the case for instance when the SDMA is in sleep mode. Clock gating management depends on the interface used to control the OnCE.

- For the JTAG access, the SDMA clock gating must be turned off via the clk_gating_off input.
- For the AP access, the SDMA clock gating is automatically turned off when the AP access is enabled (see Section 52.12.3.16, OnCE Enable (ONCE_ENB)").

52.20.2 Getting the Current Status

Most of the commands the OnCE supports have an impact on the status of the SDMA. It is not permissible to request the execution of an instruction on the SDMA from the OnCE while the SDMA is not in debug mode. Such a violation may cause unpredictable behavior, and it might be necessary to reset the SDMA. Therefore, the value of the PST bits provided in the OnCE status register should always be checked before sending any request to the SDMA.

52.20.3 Methods of Entering Debug Mode

A debug request may be asserted at any time, but it is not always taken into account immediately. Debug mode cannot be entered in the middle of an instruction, or during the save or restore states of a context switch. The request is ignored when the core is already in debug mode. Refer to Figure 52-4, which shows all possible transitions to the debug state, as there are several ways to enter debug mode.

52.20.3.1 External Debug Request During Reset

To enter debug mode after exiting reset, the external debug line has to be maintained high. This line is handled by the JTAG top-level block.

NOTE

The SDMA detects the debug requests only if the SDMA clock is running (see Section 52.20.1, Activating Clocks in Debug Mode"). The debug request line should be not be maintained high when the SDMA is in debug mode.

The `debug_rqst` command (from the OnCE command set) is not supported during system reset.

52.20.3.2 Debug Request During Normal Activity

During normal activity, the SDMA enters debug mode when the following is true:

1. If the debug request line from the JTAG top-level is asserted, or
2. If the OnCE controller receives a debug_rqst command.

   The `debug_rqst` command can be sent by the JTAG access or by an access on the AP side (if the AP access is enabled).

52.20.3.3 Software Breakpoint Instruction

The SDMA enters debug mode at the end of the execution of a software breakpoint instruction. This instruction must be inserted in program flow executed by the core.

52.20.3.4 Event Detection Unit Matching Condition

If the event detection is enabled, a debug request is sent to the core after detecting a matching condition on the SDMA memory bus. See Section 52.20.6, OnCE Event Detection Unit" for more details.

52.20.4 Executing Instructions in Debug Mode

The OnCE supports a mechanism to execute instructions in debug mode. If the SDMA is in debug mode, then the `exec_once` command can be used to execute an SDMA instruction from the OnCE controller. The SDMA returns to debug mode at the end of each execution. Some instructions are not supported by the `exec_once` command: `done/yield/yiedge` (except `done` 5), BF, BT, BSF, BDF, JMP, JSR, JMPR, JSRR, RET, and LOOP, as well as all the illegal instructions are not supported.

NOTE

While instructions are executed in debug mode from the OnCE, the program counter of the SDMA is not incremented.

52.20.5 Command Sequences Examples

This section provides examples of command sequences that run the SDMA in debug mode. These sequences are available for both the AP and JTAG accesses.

The following presents the syntax used in this section. The data field provided with each command is put in parenthesis with the command name. A '-' is used if the data field provided is a *don't care* value.

```
my_command(data_field);    // executing my_command with a data field
my_command(-);             // executing my_command with a don't care data field
```

The value returned by the command (if there is one) is referred by an assignment. In case the value returned by the command is not used, the assignment is omitted. For an AP access, the value returned (it is always a data value) is obtained by reading back into the SDMA data register.

```
data_out = my_command(data_in);// returning a data value
```

To clarify the syntax, the instructions' opcodes are referred to by their names. In practice, use the corresponding 16-bit encoding.

52.20.5.1 Getting the SDMA Status

NOTE

Before executing any command that affects the SDMA (like `dmov` or `exec_once`), check that the SDMA is in debug mode.

Use the following snippet:

```
rstatus(); // read SDMA status until the SDMA is in debug mode
...
rstatus();
```

If the SDMA is not in debug mode, then a debug request must be generated. In this case, the SDMA enters debug mode at the end of the execution of the current instruction. Use this snippet:

```
debug_rqst(-); // debug request
```

In the following sections, it is assumed that the SDMA was successfully put into debug mode.

52.20.5.2 Saving the Context

The first debug task is to save the SDMA context, which is the content of the eight general-purpose registers, the loop and PC-related registers, and the flags. Use the general register GReg[1] as an intermediate register to export the entire context of the SDMA.

Example 52-5 shows how to save GReg[0], GReg[1], GReg[2] and GReg[3]. The sequence of commands used to export additional general registers is very similar to this.

Example 52-5. Save GReg[0], GReg[1], GReg[2], and GReg[3]

```
GReg1_data = dmov(-);                // the value exported is the content of GReg[1]
exec_once(“mov GReg1,GReg0”);        // puts the content of GReg[0] into GReg[1]
GReg0_data = dmov(-);                // the value exported is the content of GReg[0]
exec_once(“mov GReg1, GReg2”);       // puts the content of GReg[2] into GReg[1]
GReg2_data = dmov(-);                // the value exported is the content of GReg[2]
exec_once(“mov GReg1, GReg3”);       // puts the content of GReg[3] into GReg[1]
GReg3_data = dmov(-);                // the value exported is the content of GReg[3]
```

Get the value of the internal flags (SF, DF, T, and LM), of the loop related registers (EPC and SPC), and of the PC-related registers (PC and RPC). Use a `done` 5, which is the formatting instruction dedicated to the debug. This instruction formats the flags and the values contained in the registers. It also writes the resulting values into the channel context memory. It should not be used when entering debug from the IDLE state (for example, with no active channel script running on the SDMA), because it will update a channel context that may belong to any channel.

```
exec_once(“done 5”);       // formatting the value of flags and registers
```

At this point, the channel context should be up-to-date in memory, and debug operations should now be possible. However, the context can be exported with the following instructions:

Example 52-6. Exporting the Context

```
dmov(ctx_base_addr);                 // loading GReg[1] with the channel context base address
exec_once(“ld GReg0,(GReg1,0)”);     // get RPC-PC into GReg0
exec_once(“ld GReg1, (GReg1,1)”);    // get SPC-EPC into GReg1
Loop_data = dmov(-);                 // read back the value of Loop registers
exec_once(“mov GReg1, GReg0”);       // puts the PC info into GReg1
PC_data = dmov(-);                   // reads back the content of the PC registers
```

After this sequence of operations, the entire SDMA context is exported via the OnCE.

52.20.5.3 Restoring the Context

At this point in the operation, restore the context of the SDMA. It can be different from the original context located in memory, and the content previously saved into the debugging application via the OnCE. Example 52-7 shows how it is possible to modify the current channel context:

Example 52-7. Modifying the Current Channel Context

```
dmov(Loop_data);                    // put Loop former value into GReg[1]
exec_once(“mov GReg0, GReg1”);      // copy to GReg[0]
dmov(PC_data);                      // put PC former value into GReg[1]
exec_once(“mov GReg2, GReg1”);      // copy to GReg[2]
dmov(ctx_base_addr);                // put channel context base address into GReg[1]
exec_once(“st GReg0, (GReg1,1)”);   // restore Loop context
exec_once(“st GReg2, (GReg1,0)”);   // restore PC context
```

Once the context in memory is the desired context (with or without applying the previous instruction sequence), it can be restored to the *real* PC and loop registers in the SDMA core:

```
exec_once(“cpShReg”);      // restore flags and PC & loop related registers
```

After this command, the SDMA core PC, RPC, SPC, EPC registers, as well as the flags contain the same data as what is stored in the context RAM for the current channel.

Example 52-8 shows how to restore the context of general registers GReg[0], GReg[1], GReg[2] and GReg[3].

Example 52-8. Restoring the General Register Context

```
dmov(GReg3_data);          // put GReg[3] restore value in GReg[1]
exec_once(“mov GReg3, GReg1”);// restore GReg[3]
dmov(GReg2_data);          // put GReg[2] restore value in GReg[1]
exec_once(“mov GReg2, GReg1”);// restore GReg[2]
dmov(GReg0_data);          // put GReg[0] restore value in GReg[1]
exec_once(“mov GReg0, GReg1”);// restore GReg[0]
dmov(GReg1_data);          // restore GReg[1]
```

At this point, it is possible to restart the normal program execution.

NOTE

Every SDMA core general register value can be modified by a `mov` instruction, which makes modification of these registers easy during debug. Unfortunately, there is no such instruction as a `mov` to directly modify the contents of either PCU register or flag (PC, RPC, SPC, EPC, T, LM, SF, or DF). The `cpShReg` instruction is meant to provide a means for changing these register contents via the context memory.

52.20.5.4 Accessing the Memory

In the following example, it is assumed that the SDMA context is entirely saved. If true, it is permissible to modify the general purpose registers during debugging activity.

To perform a memory read access, the target address is stored via the OnCE in GReg[1], then the load instruction is executed on the SDMA (the data loaded from the memory overwrites the address contained in GReg[1]), and then the result value is read back via the OnCE.

```
macro READ:       dmov(target_addr);                 // put the target address in GReg[1]
                  exec_once(“ld GReg1,(GReg1,0)”);   // execute the load instruction
                  res_data = dmov(-);                // exports the result data value
```

For a memory write access, the target address is written in GReg[0], and the value to store is written in GReg[1]. Then the store instruction is executed on the SDMA.

```
macro WRITE:      dmov(target_addr);                 // puts the target address in GReg[1]
                  exec_once(“mov GReg0,GReg1”);      // puts the target address in GReg[0]
                  dmov(target_data);                 // puts the target data in GReg[1]
                  exec_once(“st GReg1,(GReg0,0)”);   // performs the store operation
```

This sequence is shown as an example; however, many other sequences are possible.

NOTE

This sequence of commands can also be applied to memory-mapped registers.

52.20.5.5 Resuming Program Execution

Before resuming program execution, it is assumed that the SDMA context is properly restored. There are two ways to restart the SDMA. Start by executing the last instruction fetched before entering debug mode, as follows.

```
run_core(-);              // resume execution from where we stopped before
```

If necessary, restart the execution from a different address. In this case, use the `exec_core` command. The data field provided with this command must be the encoding of a `jump` instruction.

```
exec_core(“jmp start_addr”);// rerun the SDMA from another address
```

In these two examples, the SDMA exits debug mode and keeps executing the code fetched from the memory.

52.20.5.6 Single Stepping in RAM

To execute a program step-by-step from the RAM, insert software breakpoints in the program flow at appropriate places so that the SDMA only executes one instruction before returning to debug mode.

First, read the next instruction to execute in the RAM. Then, depending on the value of this instruction, compute the address where a software breakpoint instruction should be inserted. The instruction at the corresponding address must be saved, and, the software breakpoint instruction is inserted. After restarting the SDMA, there is only one instruction executed before meeting the software breakpoint.

Example 52-9 shows the macro functions READ and WRITE, which correspond to the sequence of commands (described above) used to access the memory.

NOTE

The data read from the memory are 32-bit values, while the instructions are 16-bit values only. This is why it is best to only use addresses divided by two when accessing the memory.

Example 52-9. READ and WRITE Macro Functions

```
next_instr = READ(run_addr/2);      // read the next instruction to execute
// the tool now has to compute the address where the breakpoint
// instruction should be inserted, this address is the “bkpt_addr”
instr_save = READ(bkpt_addr/2);     // save the instruction before overwriting
STORE(“bkpt instruction”,bkpt_addr/2);// store the bkpt instruction in memory
exec_core(“jmp run_addr”);          // rerun the SDMA
rstatus(-);                         // wait for the SDMA to enter debug mode
...
rstatus(-);
STORE(instr_save,bpkt_addr/2);      // restore the instruction overwritten
```

In case of branched conditional instructions, a breakpoint instruction should be written at the two possible target addresses.

52.20.5.7 Single Stepping in ROM

No single-step mechanism is supported in ROM. The program code can be loaded in the RAM, where the single-step mechanism can be executed.

52.20.6 OnCE Event Detection Unit

The event detection unit watches signals from the data memory bus (DMBUS), which the SDMA core uses to access its RAM, ROM, and memory mapped registers. A debug request is sent to the OnCE controller when user-defined conditions on address and/or data values are true. See Figure 52-77.

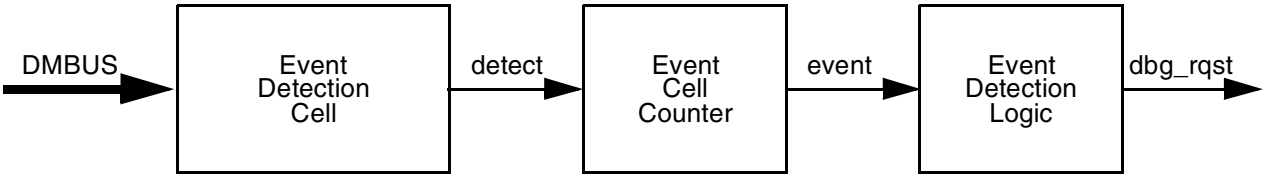

Figure 52-77. Event Detection Unit

A counter, provided with the detection cell, is decreased after an event detection. A debug request is sent to the core only when the counter reaches the value of 0. It is possible to disable the use of the counter if a debug request has to be generated after each event detection.

The event cell is the basic module that supports hardware breakpoints on an address value and/or data values coming from the SDMA memory bus. The trigger condition that generates the debug request is a mixed condition based on those values.

Figure 52-78 shows the event cell architecture. The event cell contains the address (stored in the memory address register) and the data (stored in the memory data register) used during the last memory access. There are some user-defined reference values located in memory mapped registers—the event cell addresses, the event cell address mask, the event cell data, and the event cell data mask. These registers are accessed by standard load/store instructions just like regular memory locations.

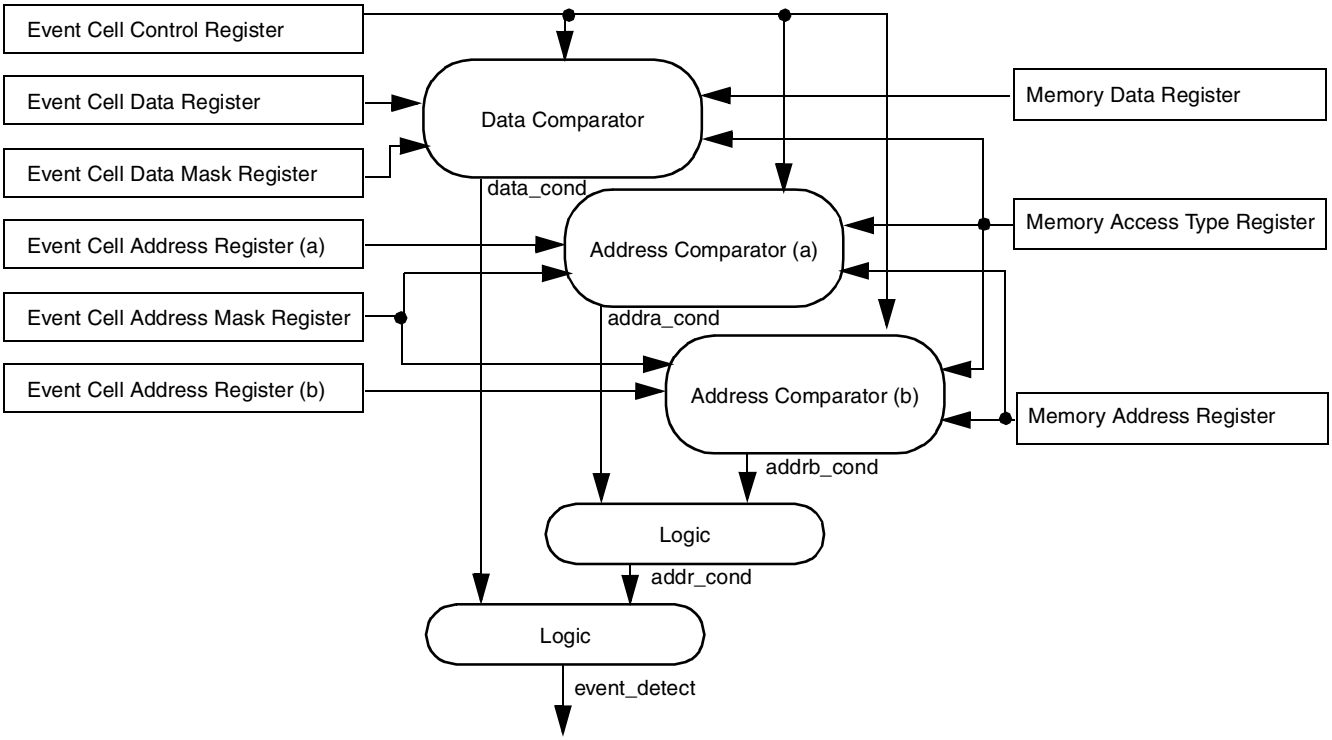

Figure 52-78. Event Cell Architecture

To define a memory breakpoint, three conditions are taken into account: The first two conditions are comparisons of the current memory address with user-defined reference addresses (these conditions are called addressA and addressB). The third condition consists of a comparison between the data received on the DMBUS and a user-defined reference data (this condition is called data). An intermediate address condition is set to express a dependency between addressA and addressB conditions.

52.20.7 Clock Gating and Reset

This section details how to use the clocks and handle the reset signals.

52.20.7.1 Clocks

Because the SDMA uses clock gating to save power, it is necessary to disable the clock gating and force the clocks to be enabled when using the OnCE. When the OnCE is accessed through its JTAG interface, clock gating must be disabled outside the SDMA via a dedicated SDMA input port clk_gating_off. The reason why detection is not performed automatically by the SDMA internal hardware is that it would cost power to monitor activity on the JTAG interface.

This clk_gating_off input is controlled by a control bit in the System JTAG Controller. Refer to the System JTAG Controller chapter for more information.

When the OnCE is accessed through the AP Control interface, clock gating is automatically turned off. This is done when bit 0 of the ONCE_ENB register (see Section 52.12.3.16, OnCE Enable (ONCE_ENB)") is set. A write access to this register is possible even when the OnCE clock is not running. If the AP access is used, the bit in the ONCE_ENB register must be set before any attempt to access any other OnCE register.

52.20.7.2 Resets

The OnCE reset is different from the SDMA main reset. The OnCE reset is connected to the TRST_B pin.

Normally, activating the SDMA reset while keeping the OnCE reset inactive (when possible) enables you to reset the core without having to reprogram the OnCE.

52.20.8 Real Time Features

To rebuild the skeleton of a program execution, it is necessary to store the addresses of the program instructions where jumps are taken: A trace buffer is therefore provided. A real time buffer has also been added to receive data values written during a program execution. The content of this register may be exported through JTAG ports without stopping the core.

52.20.8.1 Trace Buffer

The Trace Buffer is a 32-stage buffer that contains appropriate information to identify the 32 last changes of flow detected during a program execution. Figure 52-79 shows an overview of the Trace Buffer.

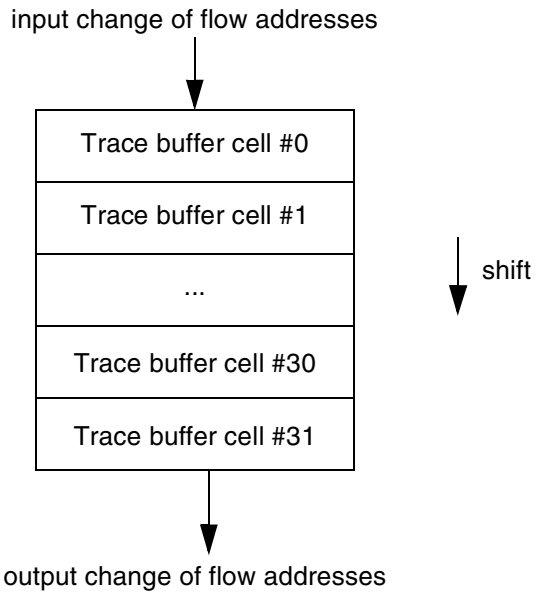

Figure 52-79. Trace Buffer

Each cell of the trace buffer contains two reference addresses and a flag. The flag is set when the addresses stored in the cell correspond to a valid change of flow; otherwise, the flag is cleared. The three most significant bits are unused.

After every change of flow detection, the address of current instruction and the address of the target instruction are stored at the top of the Trace Buffer (cell #0). The flag in the cell is set to indicate that a valid change of flow was detected. Former cell values are shifted one level down. The Trace Buffer contains the 32 last changes of flow. All the flags are reset on a software or a hardware reset, and after each transition from debug mode to user mode.

A memory mapped register of SDMA core, the Trace Buffer register (TB), is provided to read the content of the Trace Buffer. This operation should be done in debug mode. Performing a read access to the Trace Buffer register returns the content of the bottom of the Trace Buffer (cell #31). After every read access, the trace buffer is shifted one level down, and the flag at the top of the trace buffer is cleared.

A typical OnCE command sequence that retrieves the oldest change-of-flow information is a follows:

```
exec_once(“mov r1, TB”);          // stores the oldest change-of-flow in GReg1
dmov(-);                          // retrieves GReg1 contents
```

This sequence requires the SDMA to be put in debug mode.

This Register is also visible from AP side. Refer to section Section 52.12.3.26, OnCE Trace Buffer Register (OTB). The only difference is, while reading from AP side it can be done even when it is not in debug mode. But the ONCE ENB bit of Register OnCE Enable (ONCE_ENB) should be set.

52.20.8.2 Real Time Buffer

The Real Time Buffer register (RTB) is a memory mapped register that can be accessed as a regular memory location by the SDMA core during program execution. This register is located in the OnCE. Executing ar `rbuffer` command (see Section 52.19, The OnCE Controller” for further details) exports the content of this register through JTAG ports.

When a write access is performed at the memory location corresponding to the RTB, the receive flag (for example, the RCV bit) is set in the OnCE Status Register (OSR). This flag is cleared at the end of the execution of a `rbuffer` command.

NOTE

Every write access to the RTB memory location updates the RTB register even if the RCV flag is set. The RTB is cleared on a JTAG reset.

52.20.8.3 Emulation Pin

The debug_matched_event emulation pin reflects the matching condition status detected by the Event Detection Unit. Since it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

52.20.8.4 Real-Time Debug Outputs

Table 52-94 shows the debug signals that are available at the SDMA boundaries. Their availability at chip boundaries depends on the project.

Table 52-94. Real-Time Debug Output Pins

Pin	Description
debug_core_state[3:0]	The core_state bits reflect the state of the SDMA core. • The “Program” state is the usual instruction execution cycle. • The “Data” state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The “Change of Flow” state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The “Change of Flow in Loop” state is used when an error causes a hardware loop exit. • The “Debug” state means the SDMA is in debug mode. • The “Functional Unit” state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In “Sleep” modes, no script is running (this is the core idle state); the “after Reset” is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 is executed (boot operation). • The “in Sleep” states are the same as above except they do not have any corresponding channel: they are used when entering debug mode after reset; the reason is that it is necessary to return to the “Sleep after Reset” state when leaving debug mode. 0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Context Switch Saving Channel 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change of Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Context Switch Restoring Channel
debug_yield	Pulse that is active when a `yield` (`done` 0) or a `yieldge` (`done` 1) instruction is executed. 0 - 1 `yield`/`yieldge` executed
debug_core_run	Active when the SDMA core is executing instructions. 0 Debug or sleep mode 1 Run mode
debug_event_channel_sel	Indicates if debug_event_channel displays current channel or last received event 0- debug_event_channel[5:0] gives the number of the current channel 1- debug_event_channel[5:0] gives the number of the last received event

Table 52-94. Real-Time Debug Output Pins (continued)

Pin	Description
debug_event_channel[5:0]	Gives the number of any DMA request as soon as it is received or the number of the current channel. The value of debug_event_channel_sel indicates if debug_event_channel displays the current channel or last received event. The signal debug_event_channel_sel must be observed to determine what information is provided on debug_event_chanel at any given time.
debug_pc[13:0]	Program Counter value; it has a meaning when the core is in run mode.
debug_mode	Set when the core is in debug. 0 - 1 Core is in debug
debug_bus_error	Set when an error was received during a load or a store (`ld`, `st`, `ldf`, or `stf` instruction) and registered in SF or DF flag. 0 No error during last load/store 1 Error during last load/store
debug_bus_device[4:0]	Indicates the device or functional unit that is accessed by the current instruction. The debug_bus_device output is always valid when in sleep mode, debug mode, or executing any instruction that does not access the functional units or the memory mapped devices, “no access” is output. 0 No access 1 MSA 2 MDA 3 MD 4 MS 5 Reserved 6 Reserved 7 Reserved 8 Reserved 9 DSA 10 DDA 11 DD 12 DS 13 CA 14 CS 15 Reserved 16 Memory (RAM or ROM) 17 Memory mapped register 18 Peripheral #1 19 Peripheral #2 20 Peripheral #3 21 Peripheral #4 22 Peripheral #5 23 Peripheral #6 24 Peripheral #7 25 Peripheral #8 26 Peripheral #9 27 Peripheral #10 28 Peripheral #11 29 Peripheral #12 30 Peripheral #13 31 Peripheral #14

Table 52-94. Real-Time Debug Output Pins (continued)

Pin	Description
debug_bus_rwb	Indicates the direction of the access given by debug_bus_device 0 Write access (st or stf) 1 Read access (ld or ldf)
debug_matched_dmbus	Pulse indicating the OnCE event detection unit has detected a match on the data bus during an access to memory (RAM or ROM), a memory mapped register or a peripheral that is hooked to the SDMA. 0 - 1 data bus match detected
debug_rtbuffer_write	Pulse indicating when the real-time buffer is written by the core. 0 - 1 RTB was modified
debug_evt_chn_lines[7:0]	Eight lines that generate short pulses when DMA requests are received or channels are (re)started. Every line is controlled through two parameters defined in registers Cross-Trigger Events Configuration Register (1) and (2) (XTRIG_CONF1 and XTRIG_CONF2) (as described in Section 52.12, AP Memory Map and Control Register Definitions,"). The following two parameters are available for every line: • CNF—Indicates what is monitored on the line: 0 for a channel start, 1 for a DMA request reception • NUM[5:0]—Gives the number of the DMA request or channel to monitor

The matched_event emulation pin reflects the matching condition status detected by the Event Detection Unit. Because it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

All real-time debug outputs are disabled by default (for example, they are stuck to 0) to avoid power consumption when they are not used. They are enabled when bit 11 (RTDOBS) of the Configuration Register (CONFIG) is set. Signals provided to the system JTAG controller for SDMA debug mode status will also be enabled when the *clk_gating_off* input is asserted.

52.21 Instruction Set

52.21.1 Instruction Encoding

This section presents a short summary of the instruction codes. All context switch instructions are listed for information only; they cannot function properly out of the context switch routine.

```
x...x           - don't care
rrr             - destination/source general register
sss             - additional source general register
bbb             - general register used as address base register
ddddd           - address displacement
nnnnn           - bit number
uuuuuuuu        - function unit command bits
pppppppp        - branch displacement (signed)
iiiiiiii        - 8-bit immediate
jjj             - control bit to clear
ff              - flag to clear
```

52.21.2 SDMA Instruction Set

This section describes all the useful instructions from the SDMA set. Table 52-95 summarizes the instructions.

Table 52-95. SDMA Instruction List

Instruction	Description	Page
ADD	Addition	on page 52-170
ADDI	Add with Immediate Value	on page 52-171
AND	Logical AND	on page 52-172
ANDI	Logical AND with Immediate Value	on page 52-173
ANDN	Logical AND NOT	on page 52-174
ANDNI	Logical AND with Negated Immediate Value	on page 52-175
ASR1	Arithmetic Shift Right by 1 Bit	on page 52-176
BCLRI	Bit Clear Immediate	on page 52-177
BDF	Conditional Branch if Destination Fault	on page 52-178
BF	Conditional Branch if False	on page 52-179

Table 52-95. SDMA Instruction List (continued)

Instruction	Description	Page
BSETI	Bit Set Immediate	on page 52-180
BSF	Conditional Branch if Source Fault	on page 52-181
BT	Conditional Branch if True	on page 52-182
BTSTI	Bit Test immediate	on page 52-183
CLRF	Clear CPU flags	on page 52-184
CMPEQ	Compare for Equal	on page 52-185
CMPEQI	Compare with Immediate for Equal	on page 52-186
CMPHS	Compare for Higher or Same	on page 52-187
CMPLT	Compare for Less Than	on page 52-188
cpShReg	Update Context of PCU Registers and Flags	on page 52-189
DONE	DONE, Yield	on page 52-190
ILLEGAL	ILLEGAL Instruction	on page 52-192
JMP	Unconditional Jump Immediate	on page 52-193
JMPR	Unconditional Jump	on page 52-194
JSR	Unconditional Jump to Subroutine Immediate	on page 52-195
JSRR	Unconditional Jump to Subroutine	on page 52-196
LD	Load Register	on page 52-197
LDF	Load Register from Functional Unit	on page 52-199
LDI	Load Register with Immediate Value	on page 52-201
LDRPC	Load from RPC to Register	on page 52-202
LOOP	Hardware Loop	on page 52-203
LSL1	Logical Shift Left by 1 Bit	on page 52-206
LSR1	Logical Shift Right by 1 Bit	on page 52-207
MOV	Logical Move	on page 52-208
NOTIFY	Notify to MCU	on page 52-209
OR	Logical OR	on page 52-210
ORI	Logical OR with Immediate Value	on page 52-211
RET	Return from Subroutine	on page 52-212
REVB	Reverse Byte Order	on page 52-213
REVBLO	Reverse Low Order Bytes	on page 52-214
ROR1	Rotate Right by 1 Bit	on page 52-215
RORB	Rotate Right by 1 Byte	on page 52-216
SOFTBKPT	Software Breakpoint	on page 52-217

Table 52-95. SDMA Instruction List (continued)

Instruction	Description	Page
ST	Store Register	on page 52-218
STF	Store Register in Functional Unit	on page 52-219
SUB	Subtract	on page 52-222
SUBI	Subtract with Immediate	on page 52-223
TST	Test with Zero	on page 52-224
TSTI	Test Immediate	on page 52-225
XOR	Logical Exclusive OR	on page 52-226
XORI	Exclusive OR with Immediate	on page 52-227

ADD

Addition

Operation:

```
GReg[r] ← GReg[s] + GReg[r]
T ← (GReg[r] == 0)
```

Assembler:

Syntax: `add r,s`

Example: `add 0,3`
to ADD GReg[3] and GReg[0] and store the result in GReg[0]

CPU Flags: T

Cycles: 1

Description: Performs the ADDition of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*. The T flag is set if the result of the operation is 0. It is cleared if the result is not 0.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	1	s	s	s

Instruction Fields:

`rrr` - destination register field:

```
000 - GReg[0]
001 - GReg[1]
010 - GReg[2]
011 - GReg[3]
100 - GReg[4]
101 - GReg[5]
110 - GReg[6]
111 - GReg[7]
```

`sss` - source register field:

```
000 - GReg[0]
001 - GReg[1]
010 - GReg[2]
011 - GReg[3]
100 - GReg[4]
101 - GReg[5]
110 - GReg[6]
111 - GReg[7]
```

ADDI

Add with Immediate Value

Operation:

```
GReg[r] ← GReg[r] + immediate
T ← (GReg[r] == 0)
```

Assembler:

Syntax: `addi r,immediate`

Example: `addi 6,112`
to ADD GReg[6] and decimal value 112 and store the result in GReg[6]

CPU Flags: T

Cycles: 1

Description: Add a 0-extended immediate value to a general register; stores the result in the general register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`iiiiiiii` - immediate value:
`00000000` - 0
`00000001` - 1
...
`11111110` - 254
`11111111` - 255

AND

Logical AND

Operation:

GReg[r] ← GReg[s] & GReg[r]

Assembler:

Syntax: `and r,s`

Example: `and 1,2`
to AND GReg[1] and GReg[2] and store the result in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	1	s	s	s

Instruction Fields:

`rrr` - destination register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

`sss` - source register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

ANDI

Logical AND with Immediate Value

Operation:

GReg[r] ← GReg[r] & immediate

Assembler:

Syntax: `andi r,immediate`

Example: `andi 7,45`
to AND GReg[7] and decimal value 45 and store the result in GReg[7]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between a 0-extended immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

`rrr` - register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

`iiiiiiii` - immediate value:
`00000000` - 0
`00000001` - 1
...
`11111110` - 254
`11111111` - 255

ANDN

Logical AND NOT

Operation:

GReg[r] ← ~GReg[s] & GReg[r]

Assembler:

Syntax: `andn r,s`

Example: `andn 3,4`
to AND GReg[3] and NOT GReg[4] (bit inverted) and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the negation of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	0	s	s	s

Instruction Fields:

`rrr` - destination register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

`sss` - source register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

ANDNI Logical AND with Negated Immediate Value

Operation:

GReg[r] ← GReg[r] & ~immediate

Assembler:

Syntax: andni r,immediate

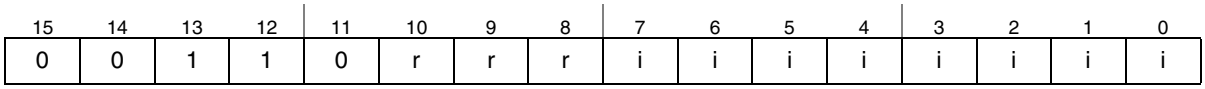
Example: andni 0,2
to AND GReg[0] and decimal value -3 (inverted 32-bit value 2) and store the result in GReg[0]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between the negation of a 0-extended 8-bit immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format:



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:
000 - GReg[0]
001 - GReg[1]
010 - GReg[2]
011 - GReg[3]
100 - GReg[4]
101 - GReg[5]
110 - GReg[6]
111 - GReg[7]

iiiiiiii - immediate value:
00000000 - 0
00000001 - 1
...
11111110 - 254
11111111 - 255

ASR1 Arithmetic Shift Right by 1 Bit

Operation:

`GReg[r]:{b31,b30,...,b1,b0} ← GReg[r]:{b31,b31,b30,...,b1}`

Assembler:

`Syntax: asr1 r`

Example: asr1 3
to divide by 2 the signed value of GReg[3] and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any general register to the right and keep the same sign: The left bit (bit 31) is kept untouched.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	0

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

BCLRI

Bit Clear Immediate

Operation:

```
GReg[r]:{b31,...,b(i+1),0,b(i-1),...,b0} ←
GReg[r]:{b31,...,b(i+1),b(i),b(i-1),...,b0}
```

Assembler:

Syntax: `bclri r,i`

Example: `bclri 1,12`
to clear bit 12 in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Clear the bit of register r specified by the 5-bit immediate field

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	1	i	i	i	i	i

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`iiiii` - bit number field:
`00000` - bit 0
`00001` - bit 1
...
`11110` - bit 30
`11111` - bit 31

BDF

Conditional Branch if Destination Fault

Operation:

`if (DF == 1) PC ← PC + 1 + displacement else PC ← PC + 1`

Assembler:

Syntax: `bdf label`

Example: bdf LLL
To jump to LLL if DF is set, or go to the next instruction if DF is cleared; the displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag DF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag DF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	1	p	p	p	p	p	p	p	p

Instruction Fields:

`pppppppp` - signed displacement field:
`00000000` - 0
`00000001` - 1
...
`01111110` - 126
`01111111` - 127
`10000000` - -128
`10000001` - -127
...
`11111110` - -2
`11111111` - -1

BF

Conditional Branch if False

Operation:

```
if (T == 0) PC ← PC + 1 + displacement
else PC ← PC + 1
```

Assembler:

Syntax: `bf label`

Example: `bf LLL`
To jump to LLL if T is cleared, or go to the next instruction if T is set. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is cleared, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is set, no jump is performed: The next instruction is located at the next PC address.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	0	p	p	p	p	p	p	p	p

Instruction Fields:

`pppppppp` - signed displacement field:
`00000000` - 0
`00000001` - 1
...
`01111110` - 126
`01111111` - 127
`10000000` - -128
`10000001` - -127
...
`11111110` - -2
`11111111` - -1

BSETI

Bit Set Immediate

Operation:

```
GReg[r]:{b31,...,b(i+1),1,b(i-1),...,b0} ←
GReg[r]:{b31,...,b(i+1),b(i),b(i-1),...,b0}
```

Assembler:

Syntax: `bseti r,i`

Example: bseti 6,5
to set bit 5 in GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Sets bit number i in the selected General Register.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	0	i	i	i	i	i

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`iiiii` - bit number field:
`00000` - bit 0
`00001` - bit 1
...
`11110` - bit 30
`11111` - bit 31

BSF

Conditional Branch if Source Fault

Operation:

```
if (SF == 1) PC ← PC + 1 + displacement
else PC ← PC + 1
```

Assembler:

Syntax: `bsf label`

Example: `bsf LLL`
To jump to LLL if SF is set, or go to the next instruction if SF is cleared. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag SF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag SF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	0	p	p	p	p	p	p	p	p

Instruction Fields:

`pppppppp` - signed displacement field:
`00000000` - 0
`00000001` - 1
...
`01111110` - 126
`01111111` - 127
`10000000` - -128
`10000001` - -127
...
`11111110` - -2
`11111111` - -1

BT

Conditional Branch if True

Operation:

```
if (T == 1) PC ← PC + 1 + displacement
else PC ← PC + 1
```

Assembler:

Syntax: `bt label`

Example: bt LLL
To jump to LLL if T is set, or go to the next instruction if T is cleared. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	1	p	p	p	p	p	p	p	p

Instruction Fields:

`pppppppp` - signed displacement field:
`00000000` - 0
`00000001` - 1
...
`01111110` - 126
`01111111` - 127
`10000000` - -128
`10000001` - -127
...
`11111110` - -2
`11111111` - -1

BTSTI

Bit Test immediate

Operation:

`T ← GReg[r]:b(i)`

Assembler:

Syntax: `btsti r,i`

Example: `btsti 2,29`
to test bit 29 in GReg[2] and copy its value in flag T

CPU Flags: T

Cycles: 1

Description: T is loaded with the value of bit number i from the selected general register.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	1	i	i	i	i	i

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`iii` - bit number field:
`00000` - bit 0
`00001` - bit 1
...
`11110` - bit 30
`11111` - bit 31

CLRF

Clear CPU flags

Operation:

```
if (ff%2 == 0) SF ← 0
if (ff/2 == 0) DF ← 0
```

Assembler:

Syntax: `clrf ff`

Example: clrf 2
to clear flag SF and keep flag DF unchanged

CPU Flags: SF, DF

Cycles: 1

Description: Clears a selection of the CPU fault flags: SF, DF, both SF and DF or none can be cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	f	f	0	0	0	0	0	1	1	1

Instruction Fields:

`ff` - flags field:
`00` - clear `SF` and clear `DF`
`01` - clear `DF`
`10` - clear `SF`
`11` - no clear

CMPEQ

Compare for Equal

Operation:

```
T ← (GReg[s] == GReg[r])
```

Assembler:

Syntax: `cmpeq r,s`

Example: `cmpeq 7,5`
to compare GReg[7] and GReg[5] and set flag T if they are equal

CPU Flags: T

Cycles: 1

Description: Subtracts the destination general register *r* from the source general register *s*, and sets T if the result is 0, clears T if the result is not 0.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	1	s	s	s

Instruction Fields:

`rrr` - destination register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`sss` - source register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

CMPEQI Compare with Immediate for Equal

Operation:

```
T ← (GReg[r] == immediate)
```

Assembler:

Syntax: `cmpeqi r,immediate`

Example: `cmpeqi 2,13`
To compare GReg[2] and decimal value 13 and set flag T if they are equal

CPU Flags: T

Cycles: 1

Description: Subtracts the 0-extended 8-bit immediate value from the general register, and sets T if the result is 0, clears T if the result is not 0. The immediate value is the low-order byte of the instruction.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`iiiiiiii` - immediate value:
`00000000` - 0
`00000001` - 1
...
`11111110` - 254
`11111111` - 255

CMPHS

Compare for Higher or Same

Operation:

T ← (GReg[r] ≥ GReg[s])

Assembler:

Syntax: `cmphs r,s`

Example: `cmphs 0,1`
To compare GReg[0] and GReg[1] and set flag T if GReg[0] is higher than or equal to GReg[1]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is higher than or equal to the source general register *s*, clears T otherwise. The comparison is unsigned.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	1	s	s	s

Instruction Fields:

`rrr` - destination register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`sss` - source register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

CMPLT

Compare for Less Than

Operation:

T ← (GReg[r] < GReg[s])

Assembler:

Syntax: `cmplt r,s`

Example: `cmplt 7,4`
To compare GReg[7] and GReg[4] and set flag T if GReg[7] is lower than GReg[4]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is lower than the source general register *s*, clears T otherwise. The comparison is signed.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	0	s	s	s

Instruction Fields:

`rrr` - destination register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

`sss` - source register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

cpShReg Update Context of PCU Registers and Flags

Assembler:

Syntax: cpShReg

CPU Flags: none

Cycles: 1

Description: SF, RPC, T, PC,LM, EPC, DF, and SPC registers are updated according to the value of their corresponding bits in the context memory. This instruction must only be used in debug mode via the OnCE. It reverses the done 5 operation.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	0	1	1	1	0	0	0	1	0

Instruction Fields:

DONE

DONE, Yield

Operation:

```
if (jjj&6 == 2) HE[CCR] ← 0
if (jjj == 3) HI[CCR] ← 1
if (jjj == 4) EP[CCR] ← 0
if ((jjj == 0) && (NCP > CCP)) CCR ← NCR
else if ((jjj == 1) && (NCP >= CCP)) CCR ← NCR
else CCR ← NCR
```

(CCR stands for Current Channel Register; NCR stands for Next Channel Register)

Assembler:

Syntax: `done jjj`

Example: `done 3`
To clear HE bit for the current channel, send an interrupt to the AP for the current channel and reschedule.

CPU Flags: Unaffected

Cycles: Variable if a context switch is done, 1 otherwise

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required. Sends an interrupt to the corresponding CPU (AP) by setting the appropriate flag, if required (HI for the corresponding channel number). Reschedules according to the mode and the NCP (Next Channel Priority) and CCP (Current Channel Priority) values. According to the scheduling decision, the NCR (Next Channel Register) is copied to the CCR (Current Channel Register) and channel contexts are switched.
If several channels with the same highest priority are pending, they are ordered by their number from 31 down to 0. The higher number is selected (for example, channel 26 is selected if channels 3, 12, 14, and 26 with the same highest priority are pending).
If no flag is modified, the reschedule can allow the replacement of the current channel by another channel with a priority strictly greater than the current channel priority (`yield`). Or, it can allow the replacement of the current channel by another channel with a priority greater than or equal to the current channel priority (`yieldge`). In the latter case, the selected channel will always be the first one with the same priority, starting from channel number 31 down to channel 0 (the current channel does not belong to the set of selectable channels).

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	0

Instruction Fields:

jjj - Channel Flags field:
000 - No channel flags affected: Reschedule only if the next channel priority is greater than current channel priority (yield)
001 - No channel flags affected: Reschedule only if the next channel priority is greater than or equal to the current channel priority (yieldge)
010 - Clear HE for the current channel and reschedule
011 - Clear HE, set HI for the current channel and reschedule
100 - Clear EP for the current channel and reschedule
101 - Reserved for debug to copy relevant registers into context memory
110 - RESERVED
111 - RESERVED

For the scheduling rules, refer to Section 52.4.3, Scheduler Functional Description." Every possible done instruction is further described as follows:

- done 0/yield is executed by a channel script when it accepts preemption by a higher priority channel;
- done 1/yieldge is executed by a channel script when it accepts preemption by a higher priority channel and it also accepts a roll-up with other channels that have the same priority;
- done 2 is executed by a channel script that was triggered by a AP start via the Channel Start (HSTART) register, when its task is completed and it requires termination;
- done 3 is executed by a channel script that was triggered by a AP start via the Channel Start (HSTART) register, when its task is completed, it requires termination and it needs to trigger an interrupt to the AP upon closure;
- done 4 is executed by a channel script that was triggered by a DMA request, when its task is completed and it requires termination;
- done 5 is used in debug mode only; it copies the PCU registers and flags to the context memory of the current channel;

ILLEGAL

ILLEGAL Instruction

Operation:

PC ← 0001

Assembler:

Syntax: illegal

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the Illegal instruction routine located at address 0001. All unauthorized instructions result in an Illegal instruction behavior; however, the ILLEGAL instruction must be used to guarantee software compatibility with future versions of the SDMA.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1

Instruction Fields:

JMP

Unconditional Jump Immediate

Operation:

PC ← absolute_address

Assembler:

Syntax: `jmp label`

Example: `jmp LLL`
the assembler translates the label to the exact address

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	a	a	a	a	a	a	a	a	a	a	a	a	a	a

Instruction Fields:

`aaaaaaaaaaaaaa` - address field:
`00000000000000` - 0
`00000000000001` - 1
...
`11111111111110` - 16382
`11111111111111` - 16383

JMPR

Unconditional Jump

Operation:

PC ← GReg[r]

Assembler:

Syntax: `jmpr r`

Example: `jmpr 0`
To jump to address stored in GReg[0]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the absolute address contained in a General Register.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	0

Instruction Fields:

`rrr` - register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

JSR Unconditional Jump to Subroutine Immediate

Operation:

RPC ← PC + 1
PC ← absolute_address

Assembler:

Syntax: `jsr r`

Example: `jsr LLL`
Jumps to subroutine starting at LLL; the assembler translates the label to exact address

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine located at the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	a	a	a	a	a	a	a	a	a	a	a	a	a	a

Instruction Fields:

`aaaaaaaaaaaaaa` - address field:
`00000000000000` - 0
`00000000000001` - 1
...
`11111111111110` - 16382
`11111111111111` - 16383

JSRR

Unconditional Jump to Subroutine

Operation:

```
RPC ← PC + 1
PC ← GReg[r]
```

Assembler:

Syntax: `jsrr r`

Example: `jsrr 5`
Jumps to subroutine located at address stored in GReg[5]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine at address contained in a General Register

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	1

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

LD

Load Register

Operation:

```
GReg[r] ← [GReg[b] + displacement]
if (transfer_error) SF ← 1
else SF ← 0
```

Assembler:

Syntax: `ld r,(b,displacement)`

Example: `ld 1,(2,23)`
Loads data into GReg[1]; the data is located at address obtained by adding decimal value 23 to GReg[2]

CPU Flags: SF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to fetch on the DM bus. The data received from the bus is stored in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	0	r	r	r	d	d	d	d	d	b	b	b

Instruction Fields:

`rrr` - destination register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
...
`111` - `GReg[7]`

`bbb` - base address register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
...
`111` - `GReg[7]`

`ddddd` - displacement value:
`00000` - 0
`00001` - 1

...
11111 - 31

LDF

Load Register from Functional Unit

Operation:

```
GReg[r] ← [fu_address]
if (transfer_error) SF ← 1
else SF ← 0
```

fu_address is an 8-bit field and depends on addressed functional unit

Assembler:

Syntax: `ldf r,fu_address`

Example: `ldf 0,13`
Loads data coming from the Burst DMA register MD into GReg[0]; it is a 32-bit access with no prefetch

CPU Flags: SF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and stores the data received from the bus in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	0	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the LDF instruction usage with each functional unit:

- Section 52.18.1.6, Burst DMA Read (ldf)" for Burst DMA
- Section 52.18.2.6, Burst DMA2 Read (ldf) for BP DMA

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`ffffffff` - functional unit source register and action (unspecified values are reserved):
`00000000` - MSA

00000100 - MDA
00001001 - MD byte
00001010 - MD halfword
00001011 - MD word
00001100 - MS
00101001 - MD byte - prefetch
00101010 - MD halfword - prefetch
00101011 - MD word - prefetch
01000000 - DSA
01000100 - DDA
01001001 - DD byte
01001010 - DD halfword
01001011 - DD word
01001100 - DS
01101001 - DD byte - prefetch
01101010 - DD halfword - prefetch
01101011 - DD word - prefetch
11000000 - PSA
11001000 - PD
11010000 - PDA
11011000 - PD in copy mode (rrr contents are lost)
11101000 - PD - prefetch next data
11111111 - PS

LDI

Load Register with Immediate Value

Operation:

GReg[r] ← immediate

Assembler:

Syntax: `ldi r,immediate`

Example: `ldi 6,1`
loads decimal value 1 into GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Stores a 0-extended immediate value in a General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

`rrr` - register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

`iiiiiiii` - immediate value:
`00000000` - 0
`00000001` - 1
...
`11111110` - 254
`11111111` - 255

LDRPC

Load from RPC to Register

Operation:

GReg[r] ← RPC

Assembler:

Syntax: `ldrpc r`

Example: `ldrpc 3`
copies RPC to GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Stores the contents of the RPC in a General Register. That instruction may be used to have more than one level of subroutines.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	1	0

Instruction Fields:

`rrr` - register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

LOOP

Hardware Loop

Operation:

```
if (ff%2 == 0) SF ← 0
if (ff/2 == 0) DF ← 0
if ((GReg[0] == 0) || (SF == 1) || (DF == 1))
            PC ← PC + loop_size + 1
else
        {
            SPC ← PC + 1
            EPC ← PC + loop_size + 1
            LM ← 1
            PC ← PC + 1
        }
```

during every instruction execution in the loop:

```
if ((SF == 1) || (DF == 1))
        {
            LM ← 0
            PC ← EPC
        }
else if ((PC + 1) == EPC)
        {
            GReg[0] ← GReg[0] - 1
            if (GReg[0] == 0)
            {
                LM ← 0
                PC ← EPC
            }
            else PC ← SPC
        }
else PC ← nextPC(instruction)
```

after the execution of the last instruction of the loop body:

```
if (GReg[0] == 0)
            T ← 1
else
            T ← 0
```

Assembler:

Syntax: `loop n{,ff}`

Example: `loop 3,1`

Executes GReg[0] times the instructions comprised between PC+1 and PC+3 (included); ff=1 clears the DF flag before starting the loop. When omitted, the `ff` field is set to 0 (clearing both SF and DF).

CPU Flags: LM[1:0], T

Cycles: 2 when the loop count (GReg[0]) is 0 or SF or DF is set at loop start, 1+1 when the loop starts but exits abnormally (SF or DF set inside the loop which adds 1 cycle to the offending load or store to jump to EPC), 1 when the loop is executed normally

Description: The `loop` instruction executes a sequence of instructions several times. The number of times is given by the contents of GReg[0], the loop counter. SDMA will jump to the first instruction after the end of the loop if the value in GReg[0] is 0. Otherwise the SDMA enters loop mode. It sets the most significant bit of the LM flag that will only be reset once the last instruction of the last loop is executed. The instructions in the loop are executed GReg[0] times.
The management of fault flags (SF and DF) is as follows. When entering the hardware loop, SF and DF can be cleared according to the ff field of the instruction. After that operation, if any flag is still set the loop will not be executed. The SDMA will jump to the first instruction after the end of the loop without entering loop mode. During the execution of the loop, if any fault flag is set by a LD, LDF, ST, or STF instruction, the SDMA will immediately exit loop mode and jump to the first instruction after the end of the loop. In that case, GReg0 is not decremented for that last piece of the loop body execution (even if the SF or DF flag is set at the last instruction of the loop body).
The T flag reflects the state of GReg[0] after the end of the loop, which is an indicator of the complete execution of the loop. If the loop exited because of an error (SF or DF set), GReg[0] will not be 0 at the end of the loop, hence T will be cleared. If the loop executes without fault, GReg[0] will be 0 at the end of the loop, hence T will be set. The boundary case when a source or destination fault occurs at the last instruction of the last loop is considered as an anticipated exit of the loop, which causes the T flag to be cleared. If the last instruction executed before leaving the hardware loop also tries to modify the T flag, the flag is updated according to the value of GReg[0], NOT according to the result of the last executed instruction.

Limitations: 1. Jump instructions (JMP, JMPR, JSR, JSRR, BF, BT, BSF, BDF) are not allowed inside the hardware loop.
2. GReg[0] cannot be written to inside the hardware loop (it can be read).
3. The empty loop (0 instruction in the body) is forbidden.
4. If GReg[0] == 0 at the start of the loop, which causes a jump to EPC, the T flag is not updated.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	0	f	f	n	n	n	n	n	n	n	n

Instruction Fields:

`ff` - flags field:
`00` - clear `SF` and clear `DF`
`01` - clear `DF`
`10` - clear `SF`
`11` - no clear

nnnnnnnn - loop size
00000000 - empty loop: forbidden value
00000001 - 1 instruction in the loop
00000010 - 2 instructions in the loop
...
11111111 - 255 instructions in the loop

LSL1 Logical Shift Left by 1 Bit

Operation:

GReg[r]:{b30,...,b1,b0,0} ← GReg[r]:{b31,b30,...,b1,b0}

Assembler:

Syntax: `lsl1 r`

Example: `lsl1 2`
multiplies by 2 the value in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the left. The right bit (bit 0) is set to 0. No overflow is detected by the hardware.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	1

Instruction Fields:

`rrr` - register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

LSR1

Logical Shift Right by 1 Bit

Operation:

`GReg[r]:{0,b31,b30,...,b1}` ← `GReg[r]:{b31,b30,...,b1,b0}`

Syntax: `lsr1 r`

Example: `lsr1 4`
divides by 2 the unsigned value contained in GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the right. The left bit (bit 31) is set to 0.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	1

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

MOV

Logical Move

Operation:

GReg[r] ← GReg[s]

Assembler:

Syntax: `mov r,s`

Example: `mov 4,0`
copies GReg[0] to GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Move the contents of the source General Register s to the destination General Register r.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	0	1	s	s	s

Instruction Fields:

`rrr` - destination register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

`sss` - source register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

NOTIFY

Notify to MCU

Operation:

```
if (jjj&4 == 0) {
            if (jjj&2 == 2) HE[CCR] ← 0
            if (jjj&1 == 1) HI[CCR] ← 1
}
else if (jjj == 4) EP[CCR] ← 0
```

(CCR stands for Current Channel Register)

Assembler:

Syntax: `notify jjj`

Example: `notify 3`
clears the HE bit for the current channel and sends an interrupt to the Host for the current channel

CPU Flags: Unaffected

Cycles: 1

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required, sends an interrupt to the corresponding CPU by setting the appropriate flag if required (HI for the corresponding channel number).

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	1

Instruction Fields:

`jjj` - Channel Flags field:
`000` - unused
`001` - set HI for the current channel
`010` - clear HE for the current channel
`011` - clear HE, set HI for the current channel
`100` - clear EP for the current channel
`101` - RESERVED
`110` - RESERVED
`111` - RESERVED

OR

Logical OR

Operation:

GReg[r] ← GReg[s] | GReg[r]

Assembler:

Syntax: `or r,s`

Example: `or 3,6`
ORs GReg[3] and GReg[6] and stores the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the OR of the source General Register s and the destination General Register r, and stores the result in the destination General Register r.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	1	s	s	s

Instruction Fields:

`rrr` - destination register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

`sss` - source register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

ORI

Logical OR with Immediate Value

Operation:

GReg[r] ← GReg[r] | immediate

Assembler:

Syntax: ori r,immediate

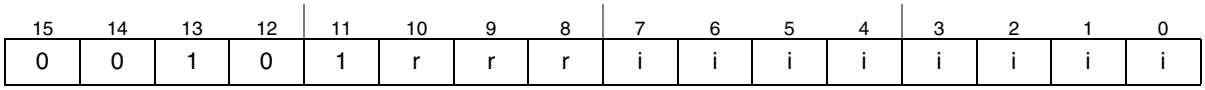
Example: ori 1,56
ORs GReg[1] and the decimal value 56 and stores the result in GReg[1]

CPU Flags: unaffected

Cycles: 1

Description: Performs an OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format:



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:
000 - GReg[0]
001 - GReg[1]
010 - GReg[2]
011 - GReg[3]
100 - GReg[4]
101 - GReg[5]
110 - GReg[6]
111 - GReg[7]

iiiiiiii - immediate value:
00000000 - 0
00000001 - 1
...
11111110 - 254
11111111 - 255

RET

Return from Subroutine

Operation:

PC ← RPC

Assembler:

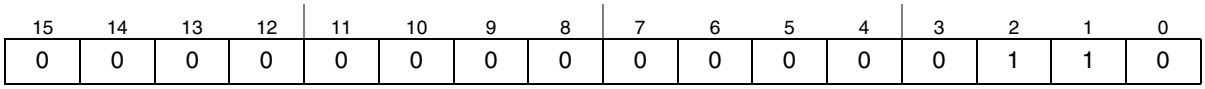
Syntax: `ret`

CPU Flags: Unaffected

Cycles: 2

Description: Return from subroutine.

Instruction Format:



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

Instruction Fields: None

REVB

Reverse Byte Order

Operation:

`GReg[r]:{B3,B2,B1,B0} ← GReg[r]:{B0,B1,B2,B3}`

Assembler:

`Syntax:  revb r`

Example: `revb 5`
reverses bytes order in GReg[5]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse the byte order of any General Register.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	0

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

REVBLO

Reverse Low Order Bytes

Operation:

GReg[r]:{B3,B2,B0,B1} ← GReg[r]:{B3,B2,B1,B0}

Assembler:

Syntax: `revblo r`

Example: `revblo 0`
reverses low order bytes in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse both low order bytes of any General Register.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	1

Instruction Fields:

`rrr` - register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

ROR1

Rotate Right by 1 Bit

Operation:

`GReg[r]:{b0,b31,b30,...,b1}` ← `GReg[r]:{b31,b30,...,b1,b0}`

Assembler:

Syntax: `ror1 r`

Example: `ror1 3`
rotates bits to the right in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Rotate the bits of any General Register to the right.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	0

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

RORB

Rotate Right by 1 Byte

Operation:

`GReg[r]:{B0,B3,B2,B1} ← GReg[r]:{B3,B2,B1,B0}`

Assembler:

Syntax: `rorb r`

Example: `rorb 2`
rotates bytes to the right in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Rotate the bytes of any General Register to the right.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	1	0

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

SOFTBKPT Software Breakpoint

Operation:

Stops the current script and enters debug mode

Assembler:

Syntax: softbkpt

CPU Flags: Unaffected

Cycles:

Description: When the core executes this instruction, it has the same effect as receiving a debug request from the OnCE or via the external debug request input: the script execution halts, the PCU enters its debug state and waits for the OnCE commands that are described in Section 52.18.3, OnCE and Real-Time Debug."

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Instruction Fields: None

ST

Store Register

Operation:

```
[GReg[b] + displacement] ← GReg[r]
if (transfer_error) DF ← 1
else DF ← 0
```

Assembler:

Syntax: `st r,(b,displacement)`

Example: `st 7,(0,9)`
stores the value from GReg[7] into memory at address obtained by adding decimal value 9 to GReg[0]

CPU Flags: DF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to store on the DM bus. The data sent on the bus comes from the source General Register r. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	r	r	r	d	d	d	d	d	b	b	b

Instruction Fields:

`rrr` - source register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
...
`111` - `GReg[7]`

`bbb` - base address register field:
`000` - `GReg[0]`
...
`110` - `GReg[6]`
`111` - `GReg[7]`

`ddddd` - displacement value:
`00000` - 0
`00001` - 1
...
`11111` - 31

STF

Store Register in Functional Unit

Operation:

```
[fu_address] ← GReg[r]
if (transfer_error) DF ← 1
else DF ← 0
```

fu_address is an 8-bit field

Assembler:

Syntax: `stf r,fu_address`

Example: `stf 3,0x2B`
stores the 32-bit contents of GReg[3] to the Burst DMA register MD; waits until the flush to external memory is completed

CPU Flags: DF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and sends the contents of the source General Register r on the bus. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	1	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the STF instruction usage with each functional unit:

- Section 52.18.1.5, Burst DMA Write (stf)" for Burst DMA
- Section 52.18.2.5, Burst DMA2 Write (stf) for Burst DMA2

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`ffffffff` - functional unit destination register and action (unspecified values are reserved):
`00000000` - MSA in incremented mode

00000100 - MDA in incremented mode
00001001 - MD byte
00001010 - MD halfword
00001011 - MD word
00001100 - clear MS error flag
00001111 - MS
00010000 - MSA in frozen mode
00010100 - MDA in frozen mode
00011000 - MD in copy mode - number of words in rrr
00100000 - MSA in incremented mode - start prefetch
00101000 - MD no data - flush
00101001 - MD byte - flush
00101010 - MD halfword - flush
00101011 - MD word - flush
00110000 - MSA in frozen mode - start prefetch
01000000 - DSA in incremented mode
01000100 - DDA in incremented mode
01001001 - DD byte
01001010 - DD halfword
01001011 - DD word
01001100 - clear DS error flag
01001111 - DS
01010001 - DSA in frozen mode - 8-bit data width
01010010 - DSA in frozen mode - 16-bit data width
01010011 - DSA in frozen mode - 32-bit data width
01010101 - DDA in frozen mode - 8-bit data width
01010110 - DDA in frozen mode - 16-bit data width
01010111 - DDA in frozen mode - 32-bit data width
01011000 - DD in copy mode - number of data in rrr
01100000 - DSA in incremented mode - prefetch data
01101000 - DD no data - flush
01101001 - DD byte - flush
01101010 - DD halfword - flush
01101011 - DD word - flush
01110001 - DSA in frozen mode - 8-bit data width - prefetch data
01110010 - DSA in frozen mode - 16-bit data width - prefetch data
01110011 - DSA in frozen mode - 32-bit data width - prefetch data
11000001 - PSA in frozen mode - 8-bit data width
11000010 - PSA in frozen mode - 16-bit data width
11000011 - PSA in frozen mode - 32-bit data width
11000101 - PSA in incremented mode - 8-bit data width
11000110 - PSA in incremented mode - 16-bit data width
11000111 - PSA in incremented mode - 32-bit data width
11001000 - PD
11001001 - PSA in decremented mode - 8-bit data width

11001010 - PSA in decremented mode - 16-bit data width
11001011 - PSA in decremented mode - 32-bit data width
11001100 - clear PS error flag
11001101 - PSA data width becomes 8-bit
11001110 - PSA data width becomes 16-bit
11001111 - PSA data width becomes 32-bit
11010001 - PDA in frozen mode - 8-bit data width
11010010 - PDA in frozen mode - 16-bit data width
11010011 - PDA in frozen mode - 32-bit data width
11010101 - PDA in incremented mode - 8-bit data width
11010110 - PDA in incremented mode - 16-bit data width
11010111 - PDA in incremented mode - 32-bit data width
11011001 - PDA in decremented mode - 8-bit data width
11011010 - PDA in decremented mode - 16-bit data width
11011011 - PDA in decremented mode - 32-bit data width
11011101 - PDA data width becomes 8-bit
11011110 - PDA data width becomes 16-bit
11011111 - PDA data width becomes 32-bit
11100001 - PSA in frozen mode - 8-bit data width - prefetch data
11100010 - PSA in frozen mode - 16-bit data width - prefetch data

11111111 - PS

SUB

Subtract

Operation:

```
GReg[r] ← GReg[r] - GReg[s]
T ← (GReg[r] == 0)
```

Assembler:

Syntax: `sub r,s`

Example: `sub 4,7`
SUBtracts GReg[7] from GReg[4] and stores the result in GReg[4]

CPU Flags: T

Cycles: 1

Description: Subtracts the source General Register s from the destination General Register r, and stores the result in the destination General Register r. The T flag is set if the result of the operation is 0; it is cleared if the result is not 0.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	0	s	s	s

Instruction Fields:

`rrr` - destination register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`sss` - source register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

SUBI

Subtract with Immediate

Operation:

`GReg[r] ← GReg[r] - immediate T ← (GReg[r] == 0)`

Assembler:

Syntax: `sub r,immediate`

Example: `sub 1,255`
SUBtracts decimal value 255 from GReg[1] and stores the result in GReg[1]

CPU Flags: T

Cycles: 1

Description: Subtracts a 0-extended 8-bit immediate value from a General Register; stores the result in the General Register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`iiiiiiii` - immediate value:
`00000000` - 0
`00000001` - 1
...
`11111110` - 254
`11111111` - 255

TST

Test with Zero

Operation:

```
T ← ((GReg[s] & GReg[r]) != 0)
```

Assembler:

Syntax: `tst r,s`

Example: `tst 2,3`
ANDs GReg[2] and GReg[3] and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of the source General Register s and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	0	s	s	s

Instruction Fields:

`rrr` - destination register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`sss` - source register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

TSTI

Test Immediate

Operation:

```
T ← ((GReg[r] & immediate) != 0)
```

Assembler:

Syntax: `tsti r,immediate`

Example: `tsti 5,13`
ANDs GReg[5] and decimal value 13 and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of a 0-extended 8-bit immediate value and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`iiiiiiii` - immediate value:
`00000000` - 0
`00000001` - 1
...
`11111110` - 254
`11111111` - 255

XOR

Logical Exclusive OR

Operation:

GReg[r] ← GReg[s] ^ GReg[r]

Assembler:

Syntax: `xor r,s`

Example: `xor 0,3`
XORs GReg[0] and GReg[3] and stores the result in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the eXclusive OR of the source General Register s and the destination General Register r, and stores the result in the destination General Register r.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	0	s	s	s

Instruction Fields:

`rrr` - destination register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

`sss` - source register field:
`000` - GReg[0]
`001` - GReg[1]
`010` - GReg[2]
`011` - GReg[3]
`100` - GReg[4]
`101` - GReg[5]
`110` - GReg[6]
`111` - GReg[7]

XORI

Exclusive OR with Immediate

Operation:

`GReg[r] ← GReg[r] ^ immediate`

Assembler:

`Syntax:` `xori r,immediate`

Example: `xor 7,5`
XORs GReg[5] and decimal value 5 and stores the result in GReg[7]

CPU Flags: Unaffected

Cycles: 1

Description: Performs an eXclusive OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

`rrr` - register field:
`000` - `GReg[0]`
`001` - `GReg[1]`
`010` - `GReg[2]`
`011` - `GReg[3]`
`100` - `GReg[4]`
`101` - `GReg[5]`
`110` - `GReg[6]`
`111` - `GReg[7]`

`iiiiiiii` - immediate value:
`00000000` - 0
`00000001` - 1
...
`11111110` - 254
`11111111` - 255

YIELD, YIELDGE DONE, Yield

Limitations: By default, unsupported assembler syntax. Can be aliased to the corresponding `done` instructions (`yield` = `done` 0; `yieldge` = `done` 1). Refer to the `done` instruction description on page 52-190.

52.22 Software Restrictions

52.22.1 Unsupported Burst DMA Access Sequence

The SDMA does not support triggering a pre-fetch followed by a flush of the Burst DMA without reading or writing any data. If the flush occurs while the background pre-fetch DMA operation is still in progress, it could result in un-defined behavior. An example of the sequence which could result in undefined results is in **Example 52-10**.

Example 52-10. Instruction sequence not supported

```
stf r1, MSA|PF    ; Update source address, triggers data pre-fetch in the background
mov R0,R0         ; Execute multiple assembly instructions, none of which read
mov R0,R0         ; or write data to/from MD
stf MD|SZ0|FL     ; Flush FIFO without writing data. If the pre-fetch is still in
                  ; progress when this instruction is executed, there could be
                  ; undefined operation.
```

A work-around to avoid any undesirable results is to first read MD to ensure the pre-fetch is complete before the flush is attempted.

Example 52-11. Work-Around to Example 52-10

```
stf r1, MSA|PF    ; Update source address, triggers data pre-fetch
mov R0,R0         ; Execute multiple assembly instructions, none of which read
mov R0,R0         ; or write data to/from MD
ldf r2, MD        ; dummy read of MD to ensure pre-fetch is complete before the
                  ; next instruction
stf MD|SZ0|FL     ; Flush FIFO without writing data.
```

52.23 Application Notes

52.23.1 Data Structures for Boot Code and Channel Scripts

SDMA boot code downloads the different channel contexts and the scripts that will be executed on SDMA channels during the application. The boot code is run after reset when channel 0 is started by the AP. The boot code is also known as channel 0 script.

The boot code is based on the Channel Control Block (CCB) and Buffer Descriptor (BD) mechanisms that are data structures located into the AP memory space. With these data structures, it is possible to instruct SDMA to download scripts and contexts but also to dump a context or a script to a destination data buffer. Channel scripts also use the CCB and BD data structures to pass instructions and/or pointers to data to be copied.

The format, processing, and field definition of the CCB and BD are defined and performed entirely by the software script rather than the SDMA hardware. An overview of the format and structure is provided here, but for complete details refer to the SDMA software documentation of Section 52.25, References."

The CCB and BD data structures are accessed by SDMA using DMA and processed by the SDMA scripts. The ROM contains common sub-routines for processing these data structures which may be called by the bootload and channel scripts.

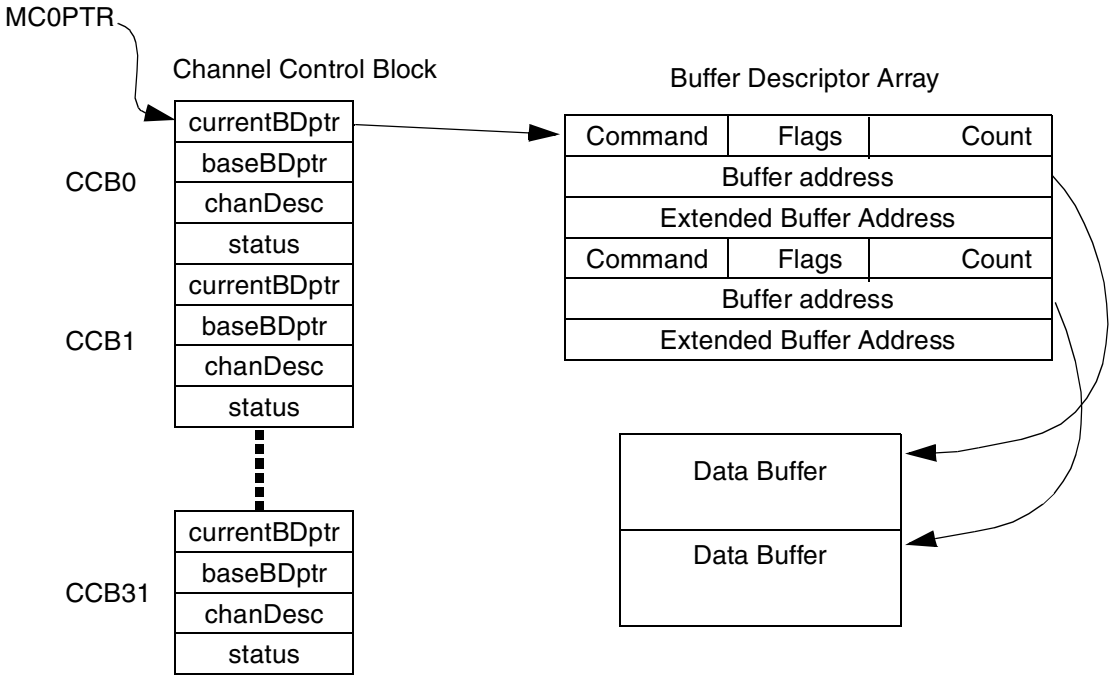

Figure 52-80. Data Structures Layout

Figure 52-80 shows an example how these data structures are linked to pass command and pointers to data buffers. The SDMA's MC0PTR register holds the base address of the Channel 0 Control Block (CCB0). The Channel 0 control block holds a pointer to the array of buffer descriptors. The buffer descriptors are used to tell the channel 0 (boot channel) what to do as described Section 52.23.1.1, Buffer Descriptor Format."

52.23.1.1 Buffer Descriptor Format

Buffer descriptors are three longs (32-bit words) in size as shown in Figure 52-81. A buffer descriptor describes the properties of the data buffer it points to. The buffer descriptors can be used for linear or circular data buffers in the AP processor memory. The CCB contains a pointer to the base BD as well as the current BD.

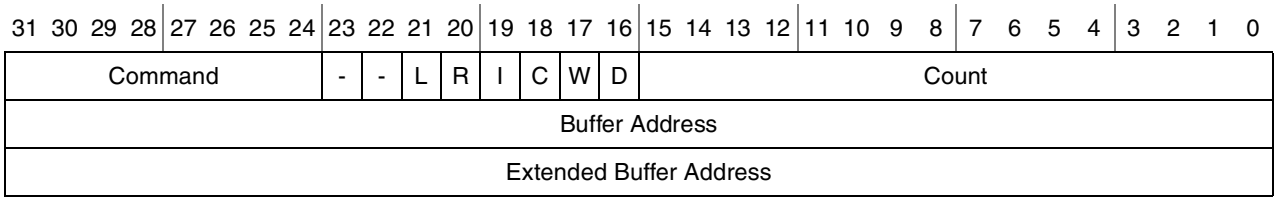

Figure 52-81. Buffer Descriptor

Table 52-96 summarizes the definitions of fields in the buffer descriptor.

Table 52-96. Buffer Descriptor Field Descriptions

Field	Description
31–24 Command	Command. The command field is used to differentiate operations performed within a script when the script accesses this particular buffer descriptor. The use of this field can be defined by the script. The command values defined for the bootload script are defined in Section 52.23.1.2, Buffer Descriptor Commands for Bootload scripts." Refer to the individual script definition in script library documents in Section 52.25, References" for command field definitions for other scripts.
23–22	Reserved
21 L	Last Buffer Descriptor: This bit is set in SDMA IPC scripts to indicate to the receiving Core that the transfer has ended. Whenever the source finishes transferring the count it wanted to transfer, it sets LAST_BIT in the destination BD, to let the destination know that transfer is over .This bit also tells the destination software that when it processes the destination BDs, they need not process any BD after the BD with the LAST_BIT set.For example, when the DSP prepares a single buffer descriptor with count equals to 25 and MCU prepares a single buffer descriptor with count equals 100. When 25 bytes have been transferred from DSP to MCU, the DSP buffer descriptor is normally closed while the MCU buffer descriptor will have the L bit set and the byte count updated to 25.
20 R	erroR. Indicates an error occurred on the channel's buffer descriptor requested command. Some scripts may overwrite the command field with an error code indicating the source of the error. 0 No Error 1 Error
19 I	Interrupt. When SDMA has finished to process data transfer attached to this buffer descriptor, send an interrupt to the AP. 0 No Interrupt 1 Interrupt the processor when BD is complete
18 C	CONTinuous. This buffer is allowed to receive multiple transmit buffers or is allowed to transmit to multiple receive buffers.The Continuos bit is decoded at the end of the processing of a BD to determine if the SDMA script must open a new BD to potentially continue the data transfer. 0 No further buffer descriptors 1 SDMA should move to the next Buffer descriptor after this one
17 W	Wrap. Indicates if this buffer descriptor is the last one for the channel control block. When encountering this bit set, the SDMA scripts updates the CurrentBD pointer to point to the first Buffer Descriptor of the array. This bit is set if the AP wants to organize the array of BD in a circular way (like a ring). When all BD have been processed and if Wrap bit and CONtinuous bit are set in the last BD, the SDMA script will wrap around and it will try to re-open the first BD. 0 No Error 1 Wrap to first buffer descriptor after this one is processed.
16 D	D - "Done": bit 16: indicates the "ownership" of the buffer descriptor. When D=0 the host owns the buffer descriptor; when D=1 SDMA owns the buffer descriptor. In the case of the channel 0, D=1 indicates the SDMA has not yet processed this buffer, D=0 indicates the SDMA has processed this buffer. 0 AP owns the buffer. 1 SDMA owns the buffer

Table 52-96. Buffer Descriptor Field Descriptions

Field	Description
15–0 Count	Count. the count field (bit 15-0) indicates the size of the data to be transmitted, the size of the data buffer pointed to by the buffer descriptor. The SDMA memory structure is different for program memory (16-bits shorts/half-words) and data memory (32-bits long). For channel 0 buffer descriptors, Count is expressed in 16-bit half-words when PM is addressed and in 32-bit words when DM is addressed. Count is typically expressed in bytes for other channel scripts, but the unit is dependant on the script.
31–0	Buffer address. Address pointer to the data buffer.
31–0	Extended buffer address. Additional pointer or other information required by some scripts.

The buffer descriptors form an array of programmable size. If the last buffer descriptor is marked by the Wrap flag-bit W=1, the array of buffer descriptor is treated as a ring with some logically continuous portion owned by the AP with D=0, and the remainder owned by the SDMA with D=1. The count field of the buffer descriptor indicates how much data has been transmitted.

If AP has prepared 3 buffers to be filled by the SDMA script, it has also prepared 3 BD, one for each buffer. The *Cont* and *Wrap* bits are used to organize the buffers in a circular way. For example, *CONT*inous bit is set to 1 in the 2 first BDs and *Wrap* is set in the 3rd BD. The SDMA script opens and processes BD#1. Since *CONT*inous bit is set for this BD, the SDMA will open the second BD and it will process it. Each time a BD is processed, its *Done* bit is reset by the SDMA. After the 3rd BD, if *CONT*inous is not set but if *Wrap* is set, the SDMA script stops here and the next time the channel will be triggered, the script will open the BD pointed by the currentBDptr pointer of the CCB and it will correspond to the first buffer descriptor.

If the *CONT*inous bit and *Wrap* bits are both set in the 3rd BD, the script will close it and it will try to open the first BD. An error may occur at this point if the BD#1 has already been processed and its *Done* bit is 0. The SDMA script cannot process a BD with a *Done* bit to 0. It means the BD is not ready to be processed. To avoid this situation, the *CONT*inous bit should not be set for the last BD if *Wrap* is set, and the Interrupt flag must set for the last BD. It will warn the owner of the BD that all the BDs have been processed and it has to re-set to 1 the *Done* bit of all the BD's if it desires the SDMA to fill them again. Basically, if the AP expects the SDMA to fill up the buffers in a circular fashion, then it's the responsibility of the AP to set the *Done* bit of a buffer descriptor at an appropriate time.

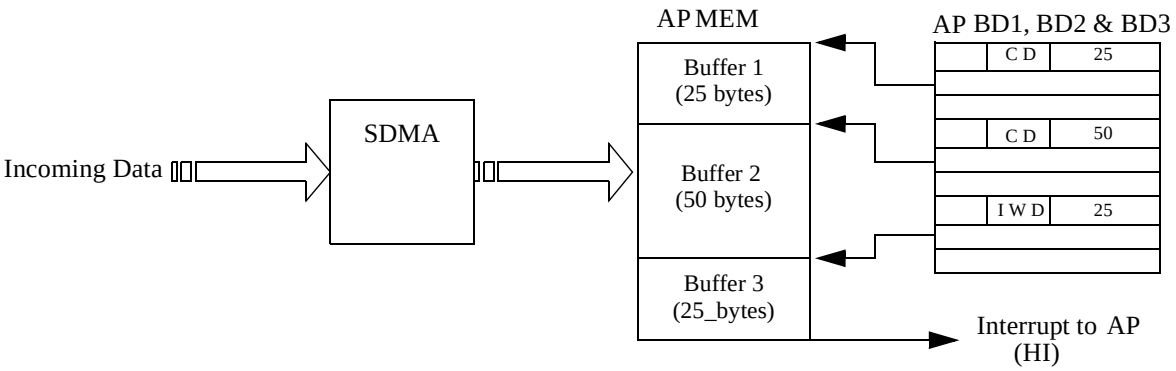

Figure 52-82. Buffer Descriptor Flow

Figure 52-82 shows an example buffer descriptor flow. When the incoming data is stored and fills the first buffer of 25 bytes, the SDMA script opens the second BD because the *CONT*inuous bit was set. Then next incoming data is put in the second buffer. After receiving 50 bytes, the second buffer descriptor is also closed. The *Done* bit is reset and the third BD is opened. After receiving another 25 bytes, the third buffer is full and an interrupt is sent to the AP because the Interrupt flag is set in the 3rd BD. The *CONT*inuous flag is not present the transfer is over. The next time the script will be triggered, the BD to be opened will be the first buffer descriptor since the *Wrap* flag was set in the 3rd BD. It is the AP responsibility to set the *Done* bit of all the BD if it wants to use the same buffers.

52.23.1.2 Buffer Descriptor Commands for Bootload scripts

The command field of the buffer descriptor is defined separately for each script. Table 52-97 lists the buffer descriptor commands defined for the channel 0 bootload script.

Table 52-97. Channel Zero Buffer Descriptor Commands

Command Field (binary)	Command	Description	Buffer Address	Extended Buffer Address
0000_0001 (0x01)	C0_SET_DM	Load SDMA data memory (RAM) from AP memory buffer	AP memory source address	SDMA memory destination address
0000_0010 (0x02)	C0_GET_DM	Copy SDMA data memory (RAM) to AP memory buffer	AP memory destination address	SDMA memory source address
0000_0100 (0x04)	C0_SET_PM	Load SDMA program memory (RAM) from AP memory buffer	AP memory source address	SDMA memory destination address
0000_0110 (0x06)	C0_GET_PM	Copy SDMA program memory (RAM) to AP memory buffer	AP memory destination address	SDMA memory source address
cccc_c111 (0x07 | CHN)	C0_SETCTX	Load Context for channel ccccc into SDMA RAM from AP memory buffer	AP memory source address	—
cccc_c011 (0x03 | CHN)	C0_GETCTXT	Copy Context for channel ccccc from SDMA RAM to AP memory buffer	AP memory destination address	—

The Channel 0 bootload commands are summarized as follows:

- C0_SET_[PM-DM]: load the buffer descriptor data in the SDMA local memory at the address pointed to by the “extended buffer address” field. The SDMA RAM can be seen as a Program Memory (PM, 16-bit address) or Data Memory (DM 32-bit address). When C0_SET_PM is used, the count field is expressed in “shorts” (16-bit half words), this command can be used to download scripts. When C0_SET_DM is used, the count field is expressed in “long” (32-bit words), this command can be used to download channel contexts to the context channel area in RAM.
- C0_GET_[PM-DM]: write to the buffer descriptor’s data buffer the content of the SDMA local memory from the address pointed to by the “extended buffer address” field for the length defined by the count in the buffer descriptor. C0_GET_PM is used to dump some part of the Program Memory (may be used to dump context of a channel), therefore count is expressed in “shorts”; while C0_GET_DM is used to dump to the buffer descriptor’s data buffer, so the count field is in “longs.”

- C0_SETCTX: load a context into the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using the channel number the script computes the offset of the context data pointer for the channel relative to the context page base to use as the destination address in SDMA memory. Then the C0_SET_DM command explained above is invoked to load SDMA RAM from memory. The counter indicates the size in words of the context structure.

  Command value: (in binary) cccc c111, where ccccc is the channel number (5 bits). For instance, 0x0F means set context for channel 1, 0xFF means set context for channel 31.
- C0_GETCTX: write to the buffer descriptor's data buffer the content of the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using this channel number, the script computes the offset of the context data pointer for the channel relative to the context page base to use as the source address for the copy. Then the C0_GET_DM command explained above is invoked to copy the context to memory. The counter indicates the size in words of the context structure.

  Command value: (in binary): cccc c011, where ccccc is the channel number (5 bits). For instance, 0x03 means get context of channel 1, 0xFB means get context of channel 31.

NOTE

To download channel context, C0_SETDM and C0_SETCTXT command can be used but the second one is easier because the channel number is embedded into the command field, whereas with the C0_SETDM, the pointer to the channel context area must be written into the extended buffer address field of the buffer descriptor.

52.23.1.3 Example of Buffer Descriptors for Channel 0.

Figure 52-84 illustrates the buffer descriptors that must be set in AP memory space, before execution of boot code, to download contexts and scripts of channels 1, 4, and 10. After boot code execution, SDMA memory will be populated with the different contexts and scripts as presented in Figure 52-83.

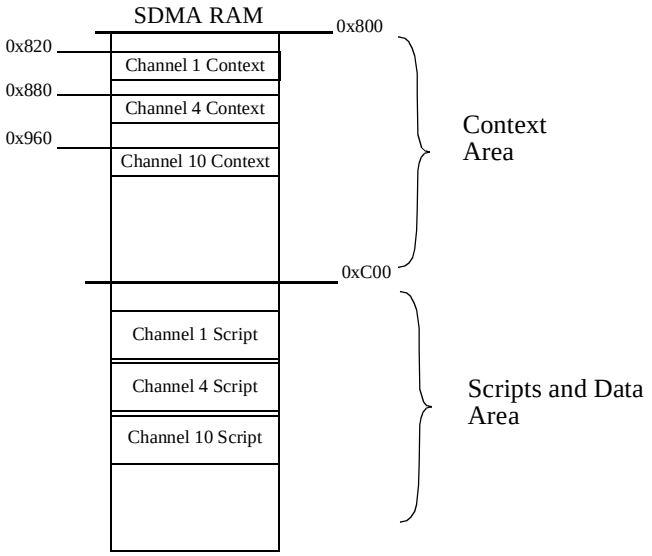

Figure 52-83. Example of SDMA RAM After Boot Session

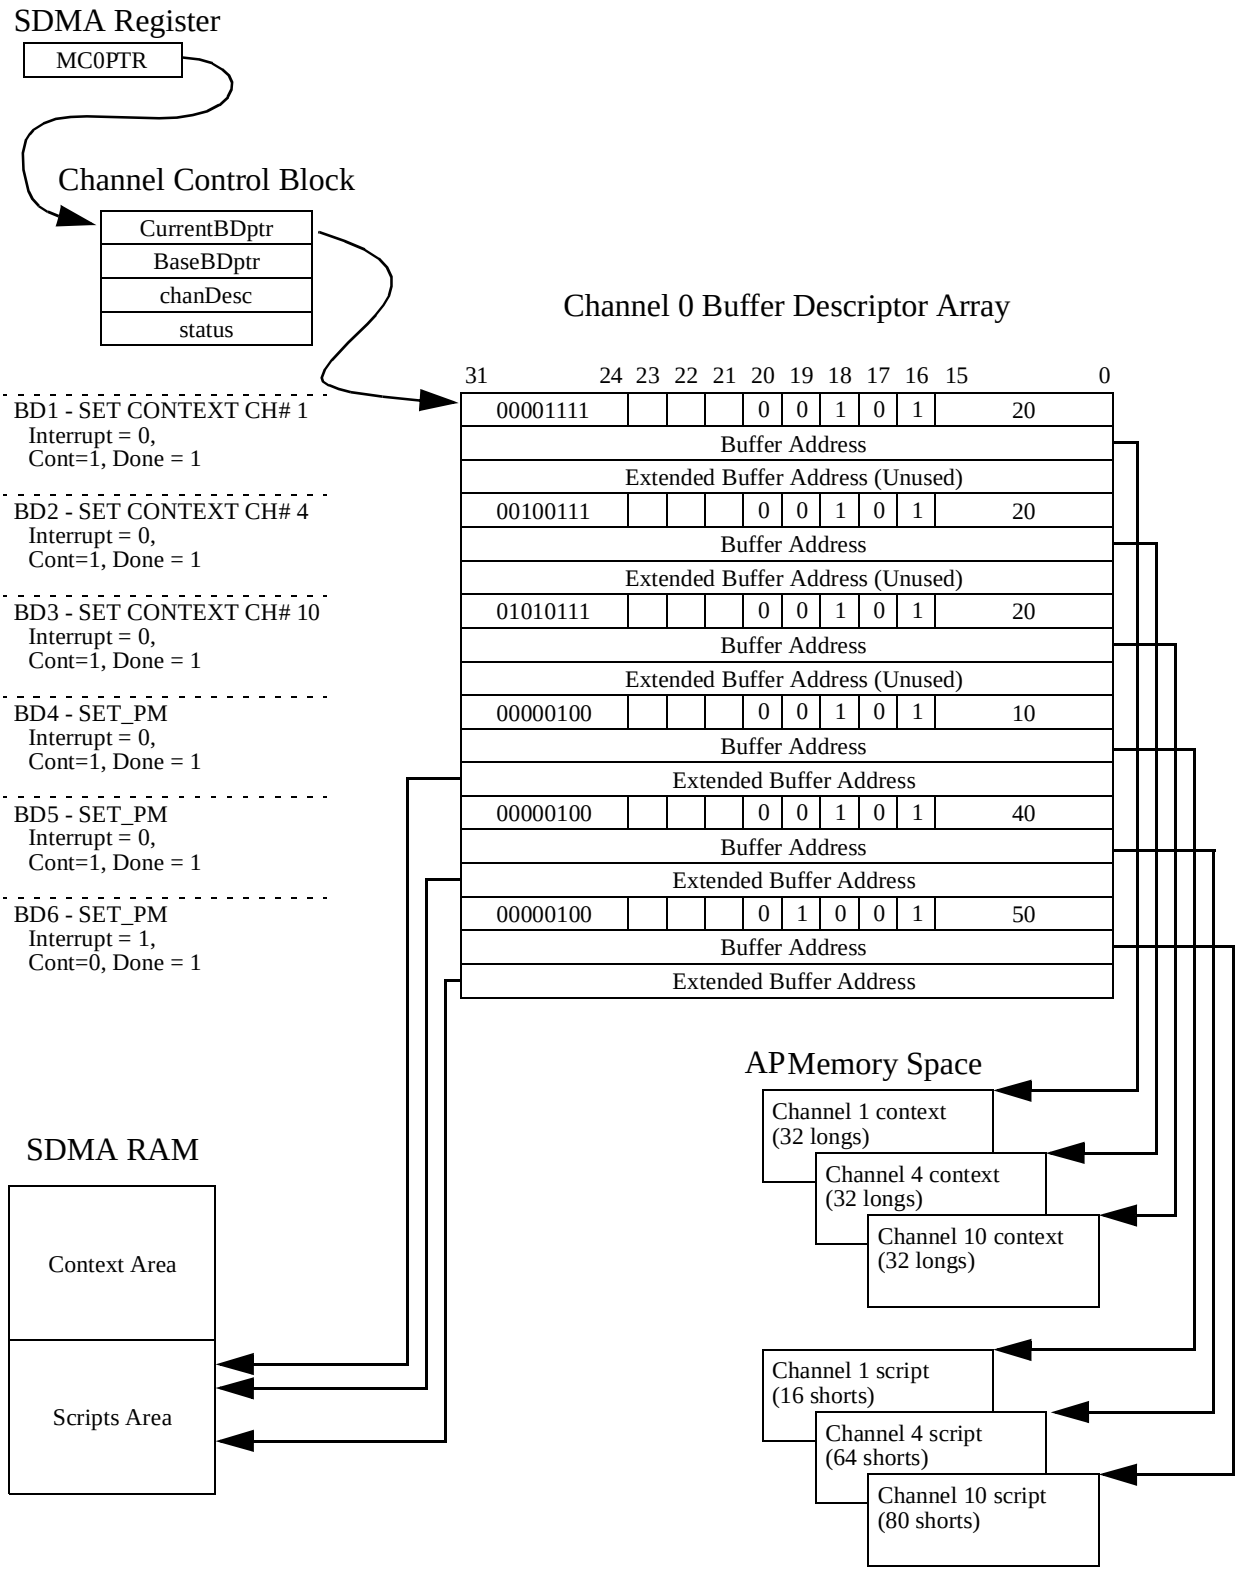

Figure 52-84. Example of Buffer Descriptors for 3 Scripts and 3 Contexts

52.23.1.4 Channel Context

There are 32 channel context memory structures pointed to by the local save area pointer. These channel context memory structures are fixed. The script in the SDMA computes the memory offset for a given channel based on the structure length and channel number. Figure 52-85 shows the structure of the channel context as it is saved in the SDMA local memory (RAM).

A channel context consists in 24 words, one per register. A total of 32 words are reserved for every channel. The additional 8 words are called scratch ram and they are dedicated to each channel. This memory area is commonly used for stack management.

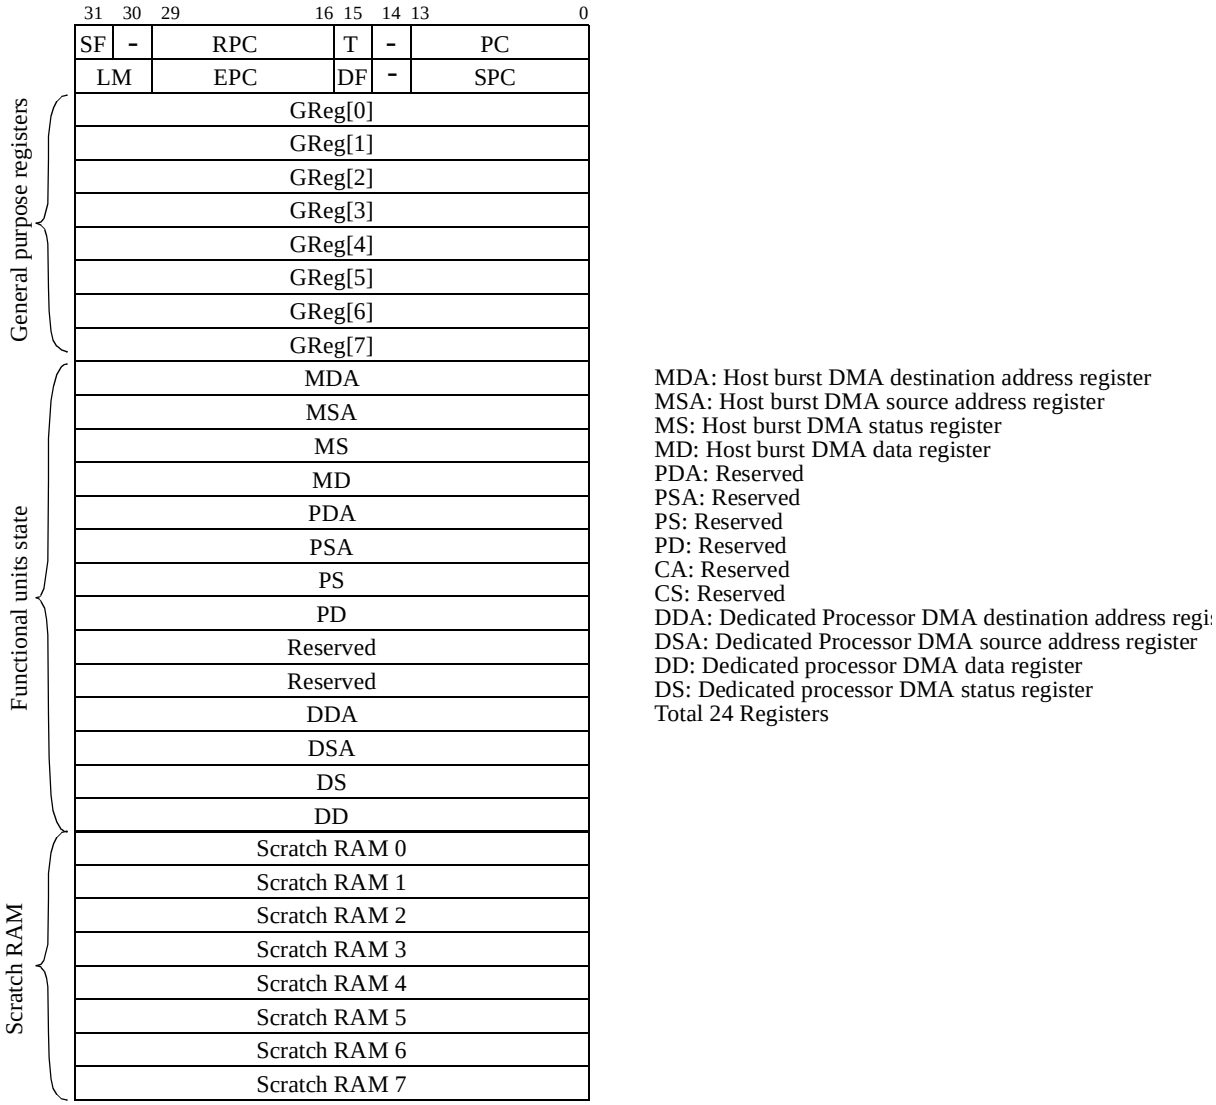

Figure 52-85. Channel Context Memory Structure

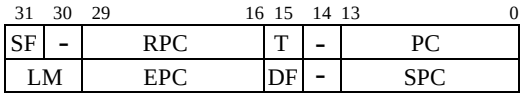
The structure is divided in 4 areas:

- Channel status registers
- General purpose registers

- Functional units state registers reflecting the state of the AP DMAs (Burst and Burst DMA2).
- Scratch RAM

The details of the channel context status registers are described in Figure 52-86.

The PC field of the first long register must point to the SDMA RAM address where the script that will be executed on the channel is located and this value equals the one stored in the extended buffer address of the buffer descriptor with C0_SETPM command.



SF: Source fault while loading data
RPC: Return program counter
T: Test bit: status of arithmetic and test instructions
PC: Program counter
LM: Loop mode
EPC: Loop end program counter
DF: Destination fault while storing data
SPC: Loop Start program counter

Figure 52-86. SDMA State Registers (ShPC, ShLoop)

52.24 Definitions, Acronyms, Abbreviations

channel	Refers to a defined path for flow of data between a source and sink. A channel is uni-directional. Example source and sink nodes are AP Processor or Peripherals. Up to 32 channels can be defined and operating at any one time.
context switch	Saving micro RISC (for example, SDMA core) registers by copying their contents into internal SRAM space followed by a load of the registers from a different channel. Essentially, a context switch means that the current state of the SDMA micro-RISC engine is saved, and the new state of the core is determined by loading the core registers with the state of a different channel.
script	An assembly language program executed by the SDMA core. Scripts reside in the ROM or may be pre-loaded into the SDMA SRAM.
Virtual DMA	DMA function executed as observed from the outside. However, the function is actually executed by a script in the micro-RISC core.

Chapter 53
Sony/Philips Digital Interface Transmitter (SPDIF Tx)

53.1 Introduction

The Sony/Philips Digital Interface Transmitter (SPDIF Tx) audio module is a stereo transmitter that allows the processor to transmit digital audio over it. Figure 53-1 shows a block diagram of the SPDIF transmitter data paths and its interface.

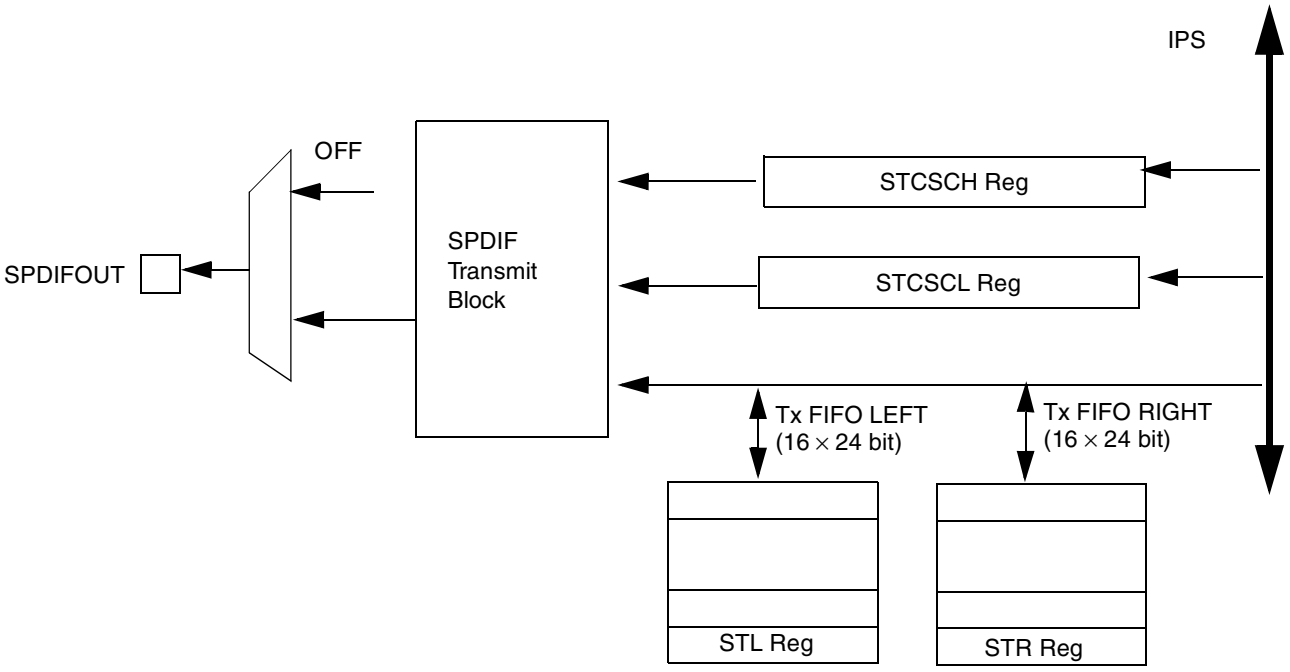

Figure 53-1. SPDIF Transmitter Data Interface Block Diagram

53.1.1 Overview

For the SPDIF transmitter, the audio data is provided by the processor via the STL and STR registers. The channel status is also provided via the corresponding registers. Zero is always inserted in the user data. The SPDIF transmitter generates a SPDIF output bitstream in the biphase mark format (IEC958), which consists of audio data, channel status, and user data.

In the SPDIF transmitter, the IEC958 biphase bit stream is generated on both edges of the SPDIF transmit clock. The SPDIF transmit clock is generated by the SPDIF internal clock generate module and the sources are from outside of the SPDIF block.

Figure 53-2 shows the clock structure of the SPDIF transmitter.

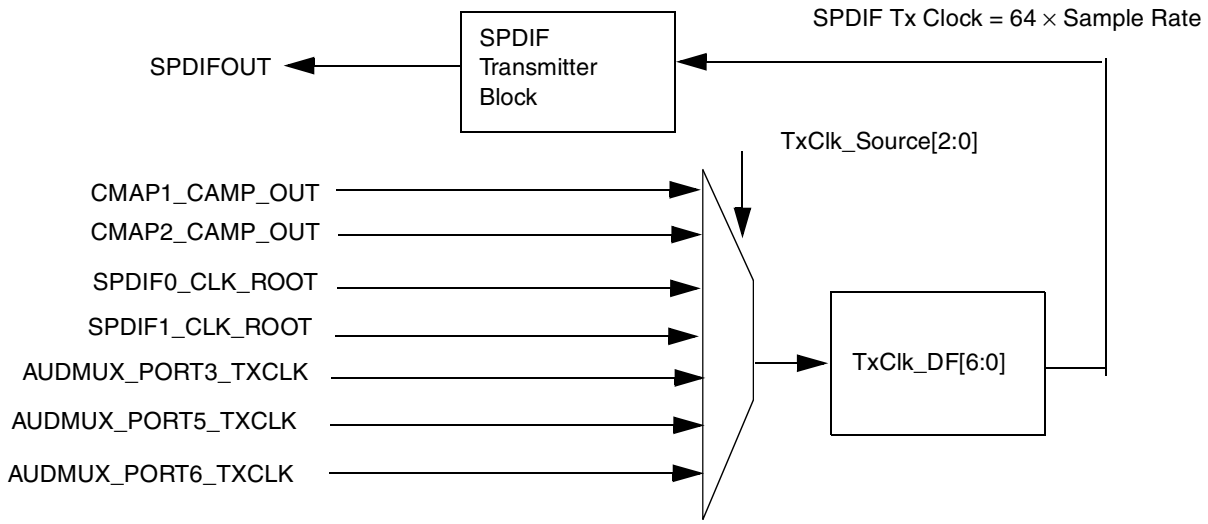

Figure 53-2. SPDIF Transmitter Clock Diagram

53.1.2 Features

The features are as follows:

- SPDIF Transmitter
  - IEC 60958 format SPDIF output
  - 7 transmit clock source
  - Consumer channel status support
- Support for interrupt and DMA

53.2 External Signal Description

Table 53-1 shows the signal properties.

Table 53-1. Signal Properties

Signal Name	Signal Type	Description
SPDIFOUT	Output	SPDIF Output Line IEC958 data in biphase mark format. (Consumer channel status).

53.3 Memory Map and Register Definition

This section contains a register map, key to register fields, register figure conventions, and a register summary.

53.3.1 Memory Map

Table 53-3 shows the SPDIF register map.

Table 53-2. SPDIF Register Map

Address	Register	Access	Reset Value
0xBASE_00(SCR)	SPDIF Configuration Register	R/W	32‘h0000_0400
0xBASE_0C(SIE)	SPDIF Interrupt Enable register	R/W	32’h0000_0000

0xBASE_2C(STL)	SPDIF Tx Left channel data register	W	32’h0000_0000
0xBASE_30(STR)	SPDIF Tx Right channel data register	W	32’h0000_0000
0xBASE_34(STCSCH)	SPDIF Tx Consumer channel status High register	W	32’h0000_0000
0xBASE_38(STCSCL)	SPDIF Tx Consumer channel status low register	W	32’h0000_0000
0xBASE_50(STC)	SPDIF Tx Clk config register	R/W	32’h0002_0f00

53.3.2 Register Summary

Figure 53-3 shows the key to the register fields and Table 53-3 shows the register figure conventions.

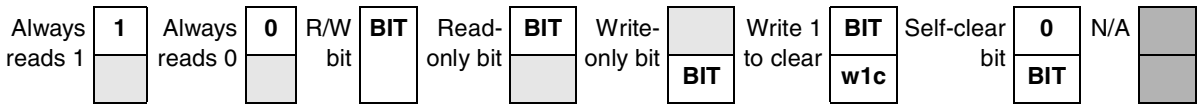

Figure 53-3. Key to Register Fields

Table 53-3. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit’s value (other than a hardware reset).

Table 53-3. Register Figure Conventions (continued)

Convention	Description
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 53-4 shows the SPDIF register summary.

Table 53-4. SPDIF Register Summary

53.3.3 Register Descriptions

This section provides the detailed register descriptions in address order.

53.3.3.1 SPDIF Configuration Register (SCR)

See Figure 53-4 for illustration of valid bits in the SPDIF Configuration Register and Table 53-5 for description of the bit fields in the register.

0x43FA_0000 (SCR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	TxAutoSync	TxFIFOEmpty_Sel[1]
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TxFIFOEmpty_Sel[0]	0	Low_Power	SW_Reset	TxFifo_Ctrl[1:0]		0	PDIR_Tx	0	0	ValCtrl	TxSel[2:0]			0	0
W																
RESET	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0

Figure 53-4. SPDIF Config Register

Table 53-5. SPDIF Config Register (SCR) Field Descriptions

Field	Description
3–8	Reserved
17 TxAutoSync	0 Tx FIFO auto sync off 1 Tx FIFO auto sync on
16–15 TxFIFOEmpty_Sel[1:0]	00 Empty interrupt if 0 sample in Tx left and right FIFOs 01 Empty interrupt if at most 4 sample in Tx left and right FIFOs 10 Empty interrupt if at most 8 sample in Tx left and right FIFOs 11 Empty interrupt if at most 12 sample in Tx left and right FIFOs
14	Reserved
13 Low_Power	When 1 is written to this bit, SPDIF enters low-power mode. Read return 1 when SPDIF is in low-power mode.
12 SW_reset	When 1 is written to this bit, SPDIF software resets. Need to read the register 5 times to make it come out of the reset status. When in the reset process, it returns 1 when read. Otherwise, it returns 0 when read.

Table 53-5. SPDIF Config Register (SCR) Field Descriptions

Field	Description
11–10 TxFifo_Ctrl	00 Send out digital zero on SPDIF Tx 01 Normal operation 10 Reset to 1 sample remaining 11 Reserved
9	Reserved
8 PDIR_TX	DMA Transmit Request enable. DMA transfer starts when the PDIR_Tx bit is set, and the TxFIFO is empty compared to the Tx watermark.
7–6	Reserved
5 ValCtrl	0 Outingoing Validity always set 1 Outingoing Validity always clear
4–2 TxSel	000 Off and output 0 101 Normal operation
1–0	Reserved

53.3.3.2 SPDIF Interrupt Enable Register (SIE)

See Figure 53-5 for illustration of valid bits in the SPDIF Interrupt Enable Register and Table 53-6 for description of the bit fields in the register.

0x43FA_000C (SIE) Access: User read/write

Figure 53-6. SPDIF Interrupt Status/Clear Register (SIS/SIC)

Table 53-7. SPDIF Interrupt Status/Clear Register (SIS/SIC) Field Descriptions

Field	Description
31–20	Reserved
19 TxUnOv	SPDIF transmit FIFO under/overrun Interrupt bit. When SPDIF transmit FIFO under/overrun interrupt happens, read 1 from the bit, else read 0. Write 1 to the bit to clear SPDIF transmit FIFO under/overrun interrupt.

Field	Description
18 TxResyn	SPDIF transmit FIFO resync Interrupt bit. When SPDIF transmit FIFO resync interrupt happens, read 1 from the bit, else read 0. write 1 to the bit to clear the SPDIF transmit FIFO resync interrupt.
17–2	Reserved.
1 TxEm	SPDIF transmit FIFO empty interrupt bit. When SPDIF transmit FIFO empty interrupt happens, read 1 from the bit, else read 0. Can't be cleared with writing 1 to the bit. To clear it, write data to Tx FIFO.
0	Reserved.

53.3.3.4 SPDIF Tx Left Channel Data Register (STL)

See Figure 53-7 for illustration of valid bits in the SPDIF Tx Left Channel Data Register and Table 53-8 for description of the bit fields in the register.

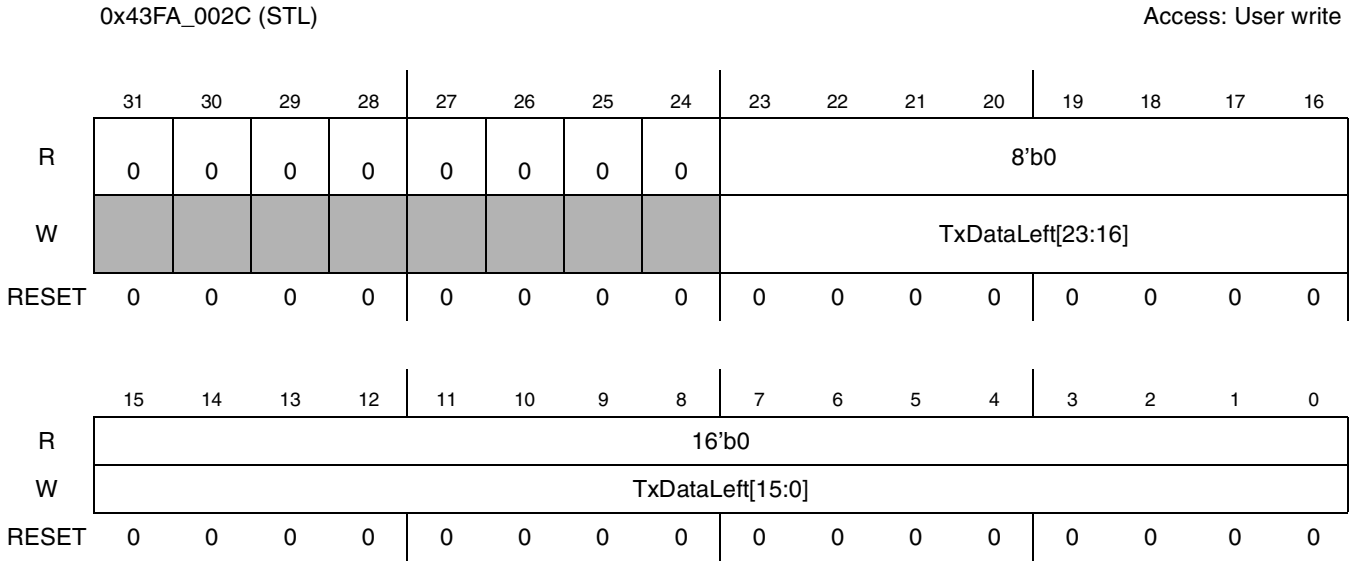

Figure 53-7. SPDIF Tx Left Channel Data Register

Table 53-8. SPDIF Tx Left Channel Data Register (STL) Field Descriptions

Field	Description
32–24	Reserved.
23–0 TxDataLeft[24:0]	SPDIF transmit left channel data. It is write-only, and always returns zeros when read

53.3.3.5 SPDIF Tx Right Channel Data Register (STR)

See Figure 53-8 for illustration of valid bits in the SPDIF Tx Right Channel Data Register and Table 53-9 for description of the bit fields in the register.

7	Reserved
6–0 TxClk_DF [6:0]	Divider factor(1–128) 4'd0: divider factor is 1 4'd1: divider factor is 2 .... 4'd127: divider factor is 128

53.4 Functional Description

Audio data for the SPDIF transmitter is provided via the STL and STR registers. Clocking for SPDIF transmitter is from the AUDMUX_Port3_TXCLK signal, AUDMUX_Port5_TXCLK signal, AUDMUX_Port6_TXCLK signal, the on-chip quartz oscillator and the external clock input. A

multiplexer is used to choose the clock source. The SPDIF transmitter clock source can be divided down as needed using TxClk_DF bits in STC register. The SPDIF transmitter output can be chosen from either the SPDIF transmitter block, or disabled.

Zero is always inserted in the user data.

53.4.0.1

Chapter 54
System Reset Controller (SRC)

54.1 Introduction

The SRC generates the different reset signals for all of the modules in the i.MX51. Figure 54-1 is a block diagram of the the SRC.

54.1.1 Overview

The reset control is responsible for the generation of all resets signals and boot decoding. The reset control determines the source and the type of reset, such as POR, WARM, COLD, and performs the necessary reset qualification and stretching sequences. Based on the type of reset, the reset logic generates the reset sequence for the entire IC. Whenever the chip is powered on, the reset is isseud threw ipp_reset_b signal and the entire chip is reset.

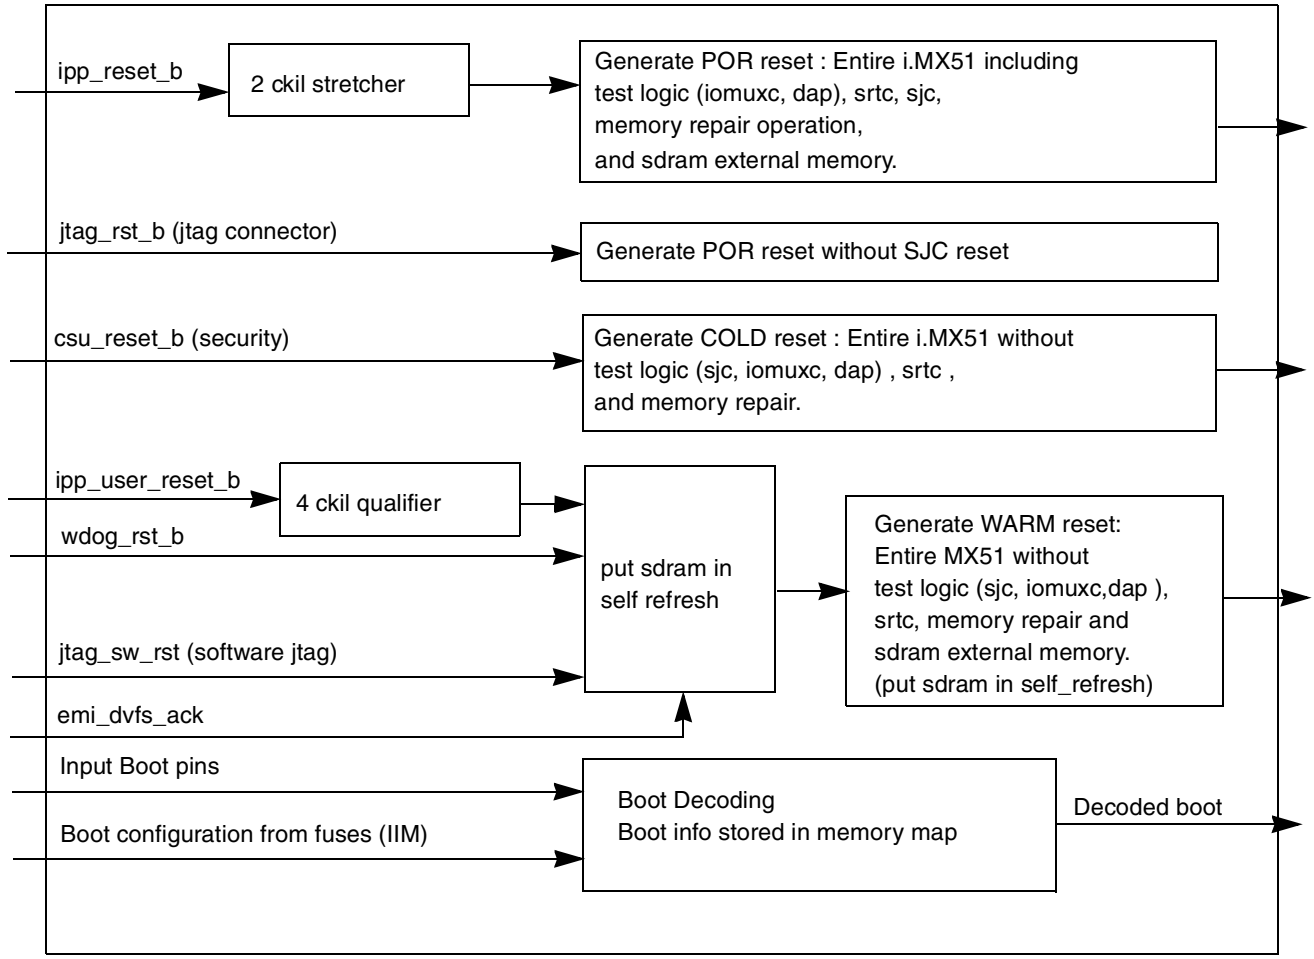

Figure 54-1. SRC High-Level Diagram

54.1.2 Features

The SRC includes the following features.

- Receives and handles the resets from all the reset sources
- Reset the appropriate domains based upon the resets sources and the nature of the reset.
- Latches the BMOD pins and common configuration signals from the internal fuse
- The SRC has 32-bit IP bus interface

54.2 Register Definition

This section contains a register summary and key to register conventions.

54.2.1 Register Summary

The conventions in Figure 54-2 and Table 54-1 serve as a key for the register summary and individual register diagrams.

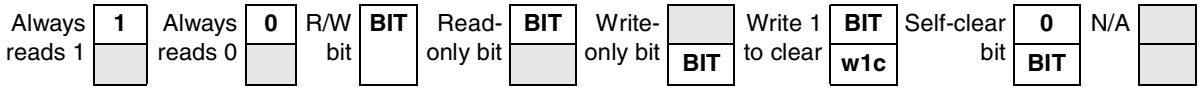

Figure 54-2. Key to Register Fields

Table 54-1 provides a key for register figures and tables and the register summary.

Table 54-1. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

54.2.2 Register Descriptions

This section consists of register descriptions in address order. All registers are reseted on POR sequence.

54.2.2.1 SRC Control Register (SCR)

Figure 54-3 presents the Reset control register (SCR), which contains bits that control operation of the reset controller. Table 54-3 provides its field descriptions.

0xBase_000 (SCR) Access: Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	mask_wdog_rst				warm_rst_bypass_count		sw_open_vg_rst	sw_ipu_rst	sw_vpu_rst	sw_gpu_rst	warm_reset_enable
W																
Reset	0	0	0	0	0	1	0	1	0	0	1	0	0	0	0	1

Figure 54-3. SRC Control Register (SCR)

Table 54-3. SCR Field Descriptions

Field	Description
31–8	Reserved
10-7 mask_wdog_rst	Mask wdog_rst_b source. If these 4 bits are coded from A to 5 then, wdog_rst_b input to SRC will be masked and wdog_rst_b will not create reset to the IC. 0101 wdog_rst_b is masked 1010 wdog_rst_b is not masked (default) any other code will be coded to 1010 i.e. wdog_rst_b is not masked Note: During the time the WDOG event is masked using SRC logic, it is likely that WDOG Reset Status Register (WRSR) bit 1 (which indicates WDOG timeout event) will get asserted. SW / OS developer must prepare for this case. Re-enable WDOG is possible, by un-mask it in SRC, though it must be preceded by servicing the WDOG. However, for the case that the event has been asserted, the status bit (WRSR bit-1) will remain asserted, regardless of servicing the WDOG module. (HW reset is the only mean to cause de-assertion of that bit).
5-6 warm_rst_bypass_count	Defines the ckil cycles to count before bypassing the emi acknowledge for warm reset. If the emi acknowledge will not be asserted before this counter has elapsed, then a cold reset will be initiated. 00 Counter not to be used - system will wait until emi acknowledge until it is asserted. 01 Wait 16 ckil cycles before changing warm reset to a cold reset. 10 Wait 32 ckil cycles before changing warm reset to a cold reset. 11 Wait 64 ckil cycles before changing warm reset to a cold reset

Table 54-3. SCR Field Descriptions (continued)

Field	Description
4 sw_open_vg_rst	Software reset for open_vg 0 do not assert open_vg reset 1 assert open_vg reset Note: this is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrutp once the software has finished. Please referto SISR register for details. N ote: the reset process will involve 8 open_vg cycles before negating the open_vg reset, to allow reset assertion to propagate into open_vg.
3 sw_ipu_rst	Software reset for ipu 0 do not assert ipu reset 1 assert ipu reset Note: this is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrutp once the software has finished. Please referto SISR register for details.
2 sw_vpu_rst	Software reset for vpu 0 do not assert vpu reset 1 assert vpu reset Note: this is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrutp once the software has finished. Please referto SISR register for details. N ote: the reset process will involve 8 vpu cycles before negating the vpu reset, to allow reset assertion to propagate into vpu.
1 sw_gpu_rst	Software reset for gpu 0 do not assert gpu reset 1 assert gpu reset Note: this is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrutp once the software has finished. Please referto SISR register for details. N ote: the reset process will involve 8 gpu cycles before negating the gpu reset, to allow reset assertion to propagate into gpu.
0 warm_reset_enable	Warm reset enable bit. Warm reset will be enabled only if warm_reset_enable bit is set. Otherwise all warm reset sources will generate cold reset. 0 Warm reset disabled 1 Warm reset enabled

54.2.2.2 SRC Boot Mode Register (SBMR)

Figure 54-4 presents the Boot Mode register (SBMR), which contains bits that reflect the status of Boot Mode Pins of the chip. The default values for those bits depends on the values of pins/fuses during reset sequence, hence the question mark on their default value. Table 54-4 provides its field descriptions.

0xBase_004 (SBMR) Access: User read-only

54.2.2.3 SRC Reset Status Register (SRSR)

Figure 54-5 presents the SRC Reset Status register of the chip. The SRSR is a write to one clear register which records the source of the reset events for the chip. The SRC reset status register will capture all the reset sources that have occurred. Table 54-5 provides its field descriptions.

0xBase_008 (SRSR) Access: Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 54-5. SRC Reset Status Register (SRSR)

This register is reset on $\overline{\text{ipp\_reset\_b}}$. This is a read-write register,

For bit[6-0] - writing zero does not have any effect. Writing one will clear the corresponding bit. The individual bits can be cleared by writing one to that bit. When the system comes out of reset, this register will have bits set corresponding to all the reset sources that occurred during system reset. Software has to take care to clear this register by writing one after every reset that occurs so that the register will contain the information of recently occurred reset.

Table 54-5. SRSR Field Descriptions

Field	Description
31–17	Reserved
16 warm_boot	Warm boot indication gives software capability to notify that warm boot was initiated by software. This indicates to the software that it saved the needed info in the memory before initiating the warm reset. In this case , software will set this bit to '1', before initiating the warm reset. The warm_boot bit should be used as indication only after a warm_reset sequence. Software should clear this bit after warm_reset to indicate that next warm_reset is not done with warm_boot. Please refer to Section 54.3.1.2.2, Reset Sequence and De-Assertion for details on warm_reset. 0 warm boot process not initiated by software. 1 warm boot initiated by software.
15–7	Reserved

Table 54-5. SRSR Field Descriptions (continued)

Field	Description
6 jtag_sw_rst	JTAG SW reset. Indicates whether the reset was the result of software reset from JTAG. 0 Reset is not a result of software reset from JTAG. 1 Reset is a result of software reset from JTAG. Connections at chip-level: jtag_sw_rst -> sjc_gpccr_reg_2_b
5 jtag_rst_b	HIGH - Z JTAG reset. Indicates whether the reset was the result of HIGH-Z reset reset from JTAG. 0 Reset is not a result of HIGH-Z reset from JTAG. 1 Reset is a result of HIGH-Z reset from JTAG. Connections at chip-level: jtag_rst_b -> sjc_ieee_reset_b
4 wdog_rst_b	IC Watchdog Time-out reset. Indicates whether the reset was the result of the watchdog time-out event. 0 Reset is not a result of the watchdog time-out event. 1 Reset is a result of the watchdog time-out event.
3 ipp_user_reset_b	Indicates whether the reset was the result of the ipp_user_reset_b qulified reset. 0 Reset is not a result of the ipp_user_reset_b qulified as COLD event. 1 Reset is a result of the ipp_user_reset_b qulified as COLD event.
2 csu_reset_b	Indicates whether the reset was the result of the csu_reset_b input. 0 Reset is not a result of the csu_reset_b event. 1 Reset is a result of the csu_reset_b event. Note: If case the csu_reset_b occured during a warm reset process, during the phase that ipg_clk is not available yet, then the occurance of csu reset will not be reflected in this bit.
1	Reserved.
0 ipp_reset_b	Indicates whether reset was the result of ipp_reset_b pin (Power-up sequence) 0 Reset is not a result of ipp_reset_b pin. 1 Reset is a result of ipp_reset_b pin.

54.2.2.4 SRC Interrupt Status Register(SISR)

Figure 54-8 presents the SRC Interrupt Status Register (SISR). Table 54-8 provides its field descriptions.

0xBase_014 (SISR) Access: User write one to clear

54.3 Functional Description

54.3.1 Reset Control

This section details the reset control of this device.

54.3.1.1 Reset Inputs and Outputs

The Reset control logic receives reset requests from all the potential reset sources. All the immediate sources of reset are directly passed to the reset stretching block whereas the resets which require qualification are passed on to the reset qualification logic before they are sent to the reset stretching block.

All reset inputs and outputs are described in Figure 54-10:

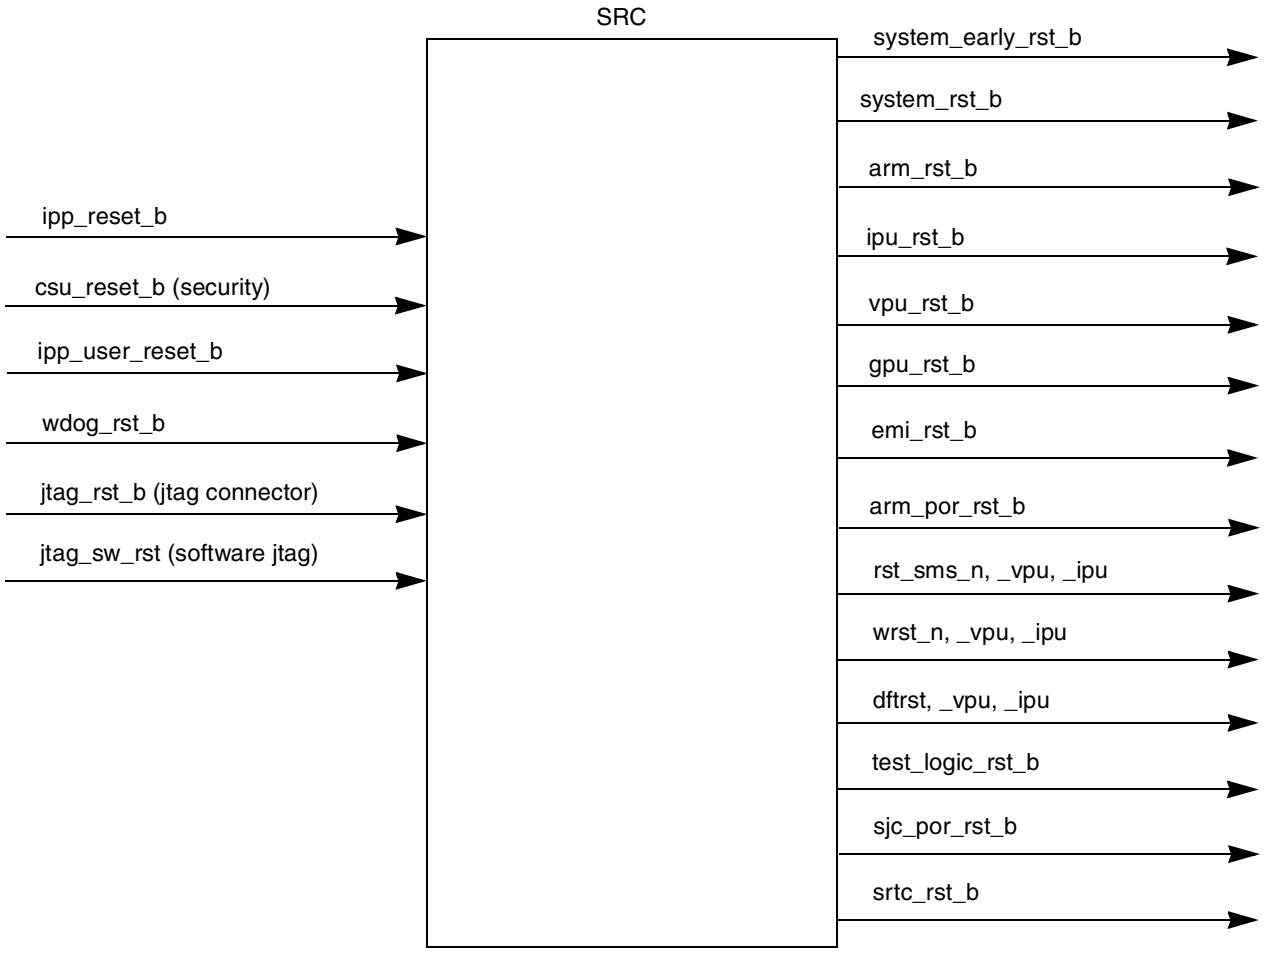

Figure 54-10. SRC Inputs and Outputs

The reset sources, type and behavior are shown in the Table 54-10. As there is no chip POR the $\overline{\text{ipp\_reset\_b}}$ is used to reset the entire chip including test logic and JTAG modules.

NOTE

All resets are expected to be active low except jtag_sw_rst.

Table 54-10. Reset Priorities, Sources, Types, and Behavior

Priority	Sources	Type	Behavior
1	ipp_reset_b	POR	Reset IC = system_early_rst_b + system_rst_b + arm_por_rst+ arm_soc_rst_b + arm_dbg_rst_b + ipu_rst_b + vpu_rst_b + gpu_rst_b + open_vg_rst_b + emi_rst_b + rst_sms_n + wrst + dftrst + test_logic_rst_b + srtc_rst_b + sjc_por_rst_b
2	csu_reset_b	Cold	Reset IC - rst_sms_n - wrst - dftrst - test_logic_rst_b - srtc_rst_b - sjc_por_rst_b - arm_por_rst - arm_dbg_rst_b = system_early_rst_b + system_rst_b + arm_soc_rst_b + ipu_rst_b + vpu_rst_b + gpu_rst_b + open_vg_rst_b + emi_rst_b
3	ipp_user_reset_b (qualified 4 ckil's)	Warm	Reset IC - rst_sms_n - wrst - dftrst - test_logic_rst_b - srtc_rst_b- arm_por_rst - arm_dbg_rst_b - sjc_por_rst_b + warm_reset_signal = system_early_rst_b + system_rst_b + arm_soc_rst_b + ipu_rst_b + vpu_rst_b + gpu_rst_b + open_vg_rst_b + emi_rst_b + warm_reset_signal
4	wdog_rst_b This reset will not be generated if mask_wdog_rst bits are coded to 5.	Warm	Reset IC - rst_sms_n - wrst - dftrst - test_logic_rst_b - srtc_rst_b - arm_por_rst - arm_dbg_rst_b - sjc_por_rst_b + warm_reset_signal = system_early_rst_b + system_rst_b + arm_soc_rst_b + ipu_rst_b + vpu_rst_b + gpu_rst_b + open_vg_rst_b + emi_rst_b + warm_reset_signal
5	jtag_rst_b (jtag connector)	POR - sjc_por_rst_b	Reset IC - sjc_por_rst_b = system_early_rst_b + system_rst_b + arm_por_rst+ arm_soc_rst_b + arm_dbg_rst_b + ipu_rst_b + vpu_rst_b + gpu_rst_b + open_vg_rst_b + emi_rst_b + rst_sms_n + wrst + dftrst + test_logic_rst_b + srtc_rst_b
6	jtag_sw_rst (software jtag)	Warm	Reset IC - rst_sms_n - wrst - dftrst - test_logic_rst_b - srtc_rst_b - arm_por_rst - arm_dbg_rst_b + warm_reset_signal - sjc_por_rst_b = system_early_rst_b + system_rst_b + arm_rst_b + ipu_rst_b + vpu_rst_b + gpu_rst_b+ open_vg_rst_b + emi_rst_b + warm_reset_signal

The reset priorities are POR (strongest), COLD and WARM (weakest). If a stronger reset is asserted during the sequence of a wicker reset, then the wicker sequence will be interfered and the stronger reset sequence will commence. There is no priority inside a reset type group. If a reset is asserted during reset sequence of reset from the same type group , then the reset sequence will be interfered and a new reset sequence (from the same type) will commence.

The following lists the functionality of each of these reset outputs:

- system_early_rst_b — Resets the system modules that need to start first as ccm, pll_ip's, iim, fuseboxes, emi etc.
- system_rst_b — Resets functional modules.
- arm_rst_b — Resets ARM module (on regular system reset)
- ipu_rst_b — Resets IPU module (on regular system reset and on power gating of ipu)
- vpu_rst_b — Resets VPU module (on regular system reset and on power gating of vpu)
- gpu_rst_b — Resets GPU module (on regular system reset and on power gating of gpu)
- open_vg_rst_b — Resets Open_VG module (on regular system reset and on power gating of open_vg)

- emi_rst_b — Resets SDRAM controller.
- arm_por_rst — Resets ARM por input.
- arm_soc_rst_b - Reset for arm SOC.
- arm_dbg_rst_b - Reset debug logic of ARM.
- test_logic_rst_b - Reset test logic. (iomuxc, dap)
- sjc_por_rst_b - reset to SJC.
- srtc_rst_b - Resets SRTC.

The following are related to SMS(STAR memory system):

- rst_sms_n - Resets SMS
- dftrst - Resets SMS DFT
- wrst - Resets JPC wrapper.

SRC will also generate rst_sms_n dftrst and wrst_n for specific accelerators. Since those modules are not involved in the memory repair process, then they will be similar to the functional resets of those modules. Note that dftrst is active high, hence its inverted version equalls the functional reset.

- dftrst_ipu = wrst_n_ipu = rst_sms_n_ipu = ipu_rst_b
- dftrst_vpu = wrst_n_vpu = rst_sms_n_vpu = vpu_rst_b

Note: It is assumed that each reset source will deassert after its assertion, either due to reset generated to the system from SRC, or either by negation of the reset source (in case it came from an external source to the IC). In the later case, the reset source is assumed to be held for atleast 2 ckil cycles so that SRC can sample it.

54.3.1.2 Reset Handling

54.3.1.2.1 Reset Qualification

The reset qualification logic qualifies the reset source before sending it out to the chip as a valid reset. Warm resets are in this category. All remaining reset sources are immediate resets and are acknowledged by the reset circuitry the moment they are asserted.

Warm resets are not immediate resets. Warm resets do reset the CCM, the source of SDRAMC clock. So, if a Warm reset were to immediately reset the CCM, then the SDRAMC clock would be shut off and this may cause the SDRAM data to be lost. During normal mode of operation of the chip, the protocol that is followed before shutting off the SDRAMC clock is that an emi_dvfs_req signal is sent to SDRAMC and only after the SDRAMC sends an acknowledge signal, emi_dvfs_ack, are the clock to the SDRAMC gated off.

However, the implication here is that a valid warm reset source condition will not be able to cause a chip reset until the SDRAMC sends the acknowledge signal (emi_dvfs_ack). For example, a JTAG reset event has occurred but the JTAG reset will not be serviced until the emi_dvfs_ack signal is received. So, essentially all Warm reset sources depend on the SDRAMC providing the emi_dvfs_ack acknowledge signal before the reset is performed. When the SDRAM controller is not used, emi_dvfs_ack is defaulted high.

The occurrence of warm reset results in the assertion of warm_reset signal before the system resets are asserted to indicate EMI that the reset occurred is a warm reset.

A reset source is updated in the Reset status register when it becomes valid, provided it is asserted for the minimum amount of time after asserting. So, all immediate resets would be immediately updated in the Status register. Warm resets would be updated when the emi_dvfs_ack signal is received from the SDRAMC.

Once the reset is qualified, depending on the source of the reset, internal resets would be asserted appropriately.

54.3.1.2.2 Reset Sequence and De-Assertion

The system_early_rst_b and the system_rst_b will assert immediately after any reset source is recognized (except for the case of warm reset when emi needs to answer emi_dvfs_ack first). After all reset sources are released, the SRC initiates the following set of events depending on the type of reset that occurred.

$\overline{\text{IPP\_RESET\_B}}$(POR)

This is a external signal from the pads and whenever the chip is powered up the reset signal is passed through this pin indicating power-up sequence and the SRC resets the entire chip including test logic and JTAG module. All SRC registers will be reset on the POR sequence, as follows.

1. As soon as $\overline{\text{IPP\_RESET\_B}}$ occurs all resets are asserted and the entire chip is reset by SRC Module. The $\overline{\text{IPP\_RESET\_B}}$ is stretched for 2 CKIL cycles and the stretching sequence takes place after 2 CKIL clocks of $\overline{\text{IPP\_RESET\_B}}$ pin de-assertion.
2. test_logic_rst_b, sjc_por_rst_b and srtc_rst_b signals are de-asserted together with IPP_RESET_B signal. Those outputs are also deasserted after the stretching of IPP_RESET_B has deasserted.
3. After the above resets de-asserts, system_early_rst_b reset is de-asserted after 2 CKIL clock. The system_early_rst_b is used for the CCM and PLL-IP's to start generating pll clock ouputs and the system root clocks.
4. Once system root clocks are ready, CCM will assert system_clk_ready signal. This signal is generated during the ignition sequence in CCM and it involves the preparation of FPM/CKIH/PLL's to generate clock roots for functional operation. Please refer to Ignition Sequence in CCM chapter.
5. Once this signal arives to SRC , it will initiate smart sfp operation. This operation will be finished once the SRC receives the assertion on signal "sfp_ready".
6. After SFP operation finish, SRC will enable IIM and fusebox clocks, so that fuses can be loaded to IIM. IIM will notify with iim_ready_flag on the finish of the fusebox loading.
7. SRC will prepare the boot information and then de assert emi_rst_b.
8. SRC will wait 8 ipg clock cycles, and then SRC will enable EMI clocks.
9. SRC will wait 8 CKIL clocks to allow EMI to generate fixed external clock to external memory SDRAM.
10. SRC will enable VPU and GPU clocks so that reset will penetrate this module.
11. After 8 ipg cycles, src will dissable vpu, open_vg and gpu clocks.

12. After 8 ipg cycles, resets to all modules will be de-asserted (system_rst_b, vpu_rst_b, gpu_rst_b, open_vg_rst_b, ipu_rst_b).
13. If en_tester_control signal is asserted, SRC will wait for assertion of tester_ack signal to continue. This signal allows tester to receive determinism on the reset sequence.
14. After 8 ipg cycles, system clocks will be enabled (en_system_clk).

NOTE

The memory repair operation is bypassed when the smart_bypass signal is asserted.

COLD RESET

The sequence is similar to $\overline{\text{IPP\_RESET\_B}}$ except the memory repair operation is not performed and test_logic_reset is not fired.

1. Once the reset source de-asserts, system_early_rst_b reset is de-asserted after at least 2 CKIL clock. The system_early_rst_b is used for the CCM and PLL-IP's to start generating pll clock ouputs and the system root clocks.
2. Once system root clocks are ready, CCM will assert system_clk_ready signal. This signal is generated during the ignition sequence in CCM and it involves the preparation of FPM/CKIH/PLL's to generate clock roots for functional operation. Please refer to Ignition Sequence in CCM chapter.
3. Once this signal arives to SRC ,SRC will enable IIM and fusebox clocks, so that fuses can be loaded to IIM. IIM will notify with iim_ready_flag on the finish of the fusebox loading.
4. SRC will prepare the boot information and then de assert emi_rst_b.
5. SRC will wait 8 ipg clock cycles, and then SRC will enable EMI clocks.
6. SRC will wait 8 CKIL clocks to allow EMI to generate fixed external clock to external memory SDRAM.
7. SRC will enable VPU and GPU clocks so that reset will penetrate this module.
8. After 8 ipg cycles, src will dissable vpu, open_vg and gpu clocks.
9. After 8 ipg cycles resets to all modules will be de-asserted (system_rst_b, vpu_rst_b, gpu_rst_b, open_vg_rst_b, ipu_rst_b).
10. If en_tester_control signal is asserted, SRC will wait for assertion of tester_ack signal to continue. This signal allows tester to receive determinism on the reset sequence.
11. After 8 ipg cycles, system clocks will be enabled (en_system_clk).

WARM RESET

WARM reset will be enabled only if warm_reset_enable bit is programed. Otherwise all warm reset sources will generate cold reset. This bit will be reset only by por reset.

A WARM reset is similar to a cold reset except that before the reset is fired a signal to emi is asserted emi_dvfs_req (generates dvfs assertion to emi) to request to prepare emi to a WARM reset, i.e. to finish the transactions and to put the sdram in selfrefresh. Another signal will be asserted to emi (warm_reset) that will wrap the warm reset sequence and will notify emi that a warm reset is in process.

One of the sources of the WARM reset is ipp_user_reset_b. If this is the case, it is qualified for 4 CKIL edges. The WARM reset is initiated immediately after 4 CKIL edges. The system does not come out of reset until the the ipp_user_reset_b is released.

During WARM reset, request to put SDRAM in self refresh is sent to SDRAMC. The request is sent through generation of dvfs signal to EMI. The request is passed through CCM to be combined with CCM's capability to request dvfs. Only after the EMI sends an acknowledge signal, emi_dvfs_ack is warm reset generated. The implication here is that a valid WARM reset source condition will not be able to cause a chip reset until the EMI sends the acknowledge signal (emi_dvfs_ack). For example, a WDOG reset event has occurred but the WDOG reset will not be serviced until the emi_dvfs_ack signal is received. So, essentially all WARM reset sources depend on the EMI providing the emi_dvfs_ack acknowledge signal before the reset is performed. When the EMI is not used, emi_dvfs_ack is defaulted high.

After the acknowledge signal, emi_dvfs_ack , is received the warm reset is generated. The warm_reset input to SDRAMC reflects the value of the warm_reset_enable bit. This signal indicates to SDRAMC that the upcoming reset is WARM.

In case the handshake mechanism with SDRAMC is stuck meaning no emi_dvfs_ack is recieved, cold reset will be generated after a number of CKIL clocks. The number of ckil clocks is defined in register SCR bit warm_rst_bypass_count. the default of this bit is 16 ckil count.

The following is a basic description of the warm reset sequence:

1. ARM sets warm_reset_enable bit to enable the WARM Reset functionality. If this bit is not set, all WARM reset sources will result in Cold Reset.
2. Assertion of one of the WARM reset sources.
3. The reset source is qualified in the SRC.
4. If emi_dvfs_ack signal is low, then SRC triggers the SDRAM Ctrl. to switch to self refresh mode using emi_dvfs_req signal. This is done threw CCM to combine with the dvfs sent from CCM in case of frequency change of EMI.
5. Wait for emi_dvfs_ack signal from the EMI. If no ack is recieved during warm_rst_bypass_count number of CKIL clocks, cold reset will be generated.
6. Assert warm_reset signal to EMI.
7. SRC asserts system resets
8. The de-assertion sequence is exactly the same as in the Cold Reset except waiting for 8 CKIL's for EMI to generate fixed external clock to external memory SDRAM. This stage is not needed in WARM reset since SDRAM is held in selfrefresh in WARM reset and there is no need to reconfigure it when going out of WARM reset.

WARM BOOT

Software can save any needed information in the memory before initiating a warm reset. In this case, software will set warm_boot bit before initiating warm reset. After the system returns to run mode, the warm_boot bit will still be set, indicating the software that data was saved in memory and can be reused.

Figure 54-11, Figure 54-12, Figure 54-13, Figure 54-14 shows the behavior of different resets for POR, Cold, and Warm reset cases respectively.

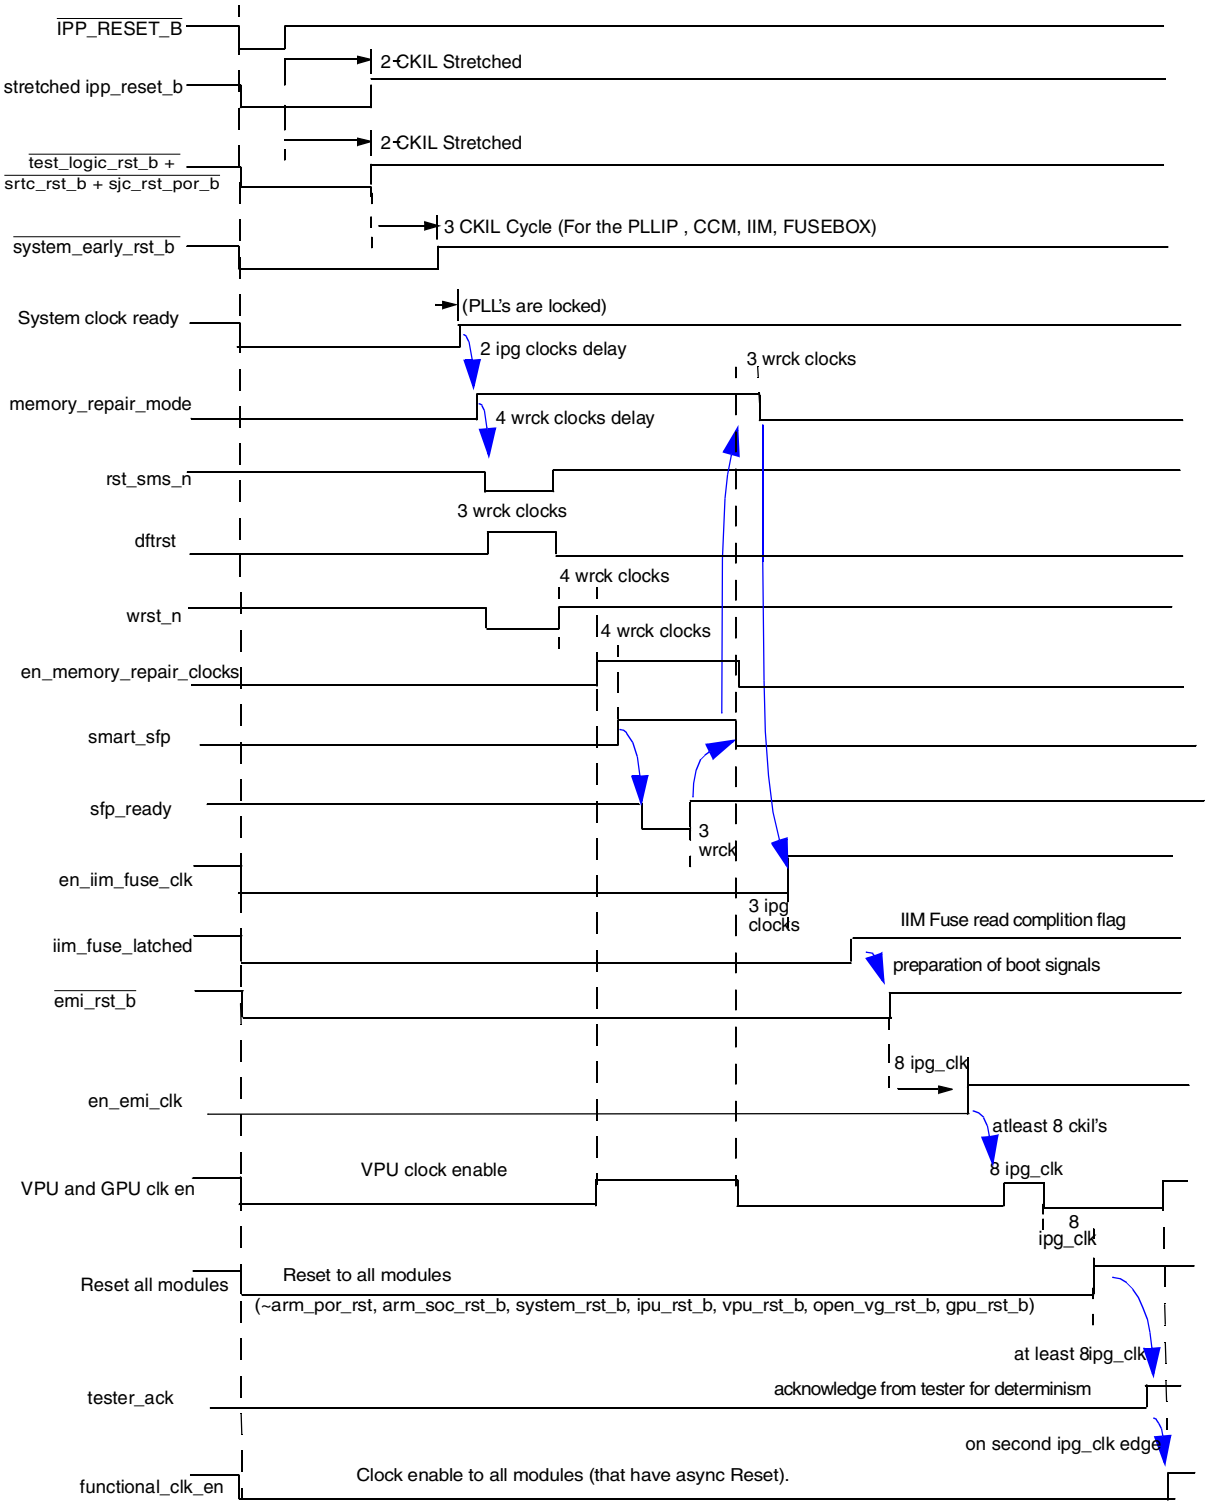

Figure 54-11. Behavior of IPP_RESET_B(POR)

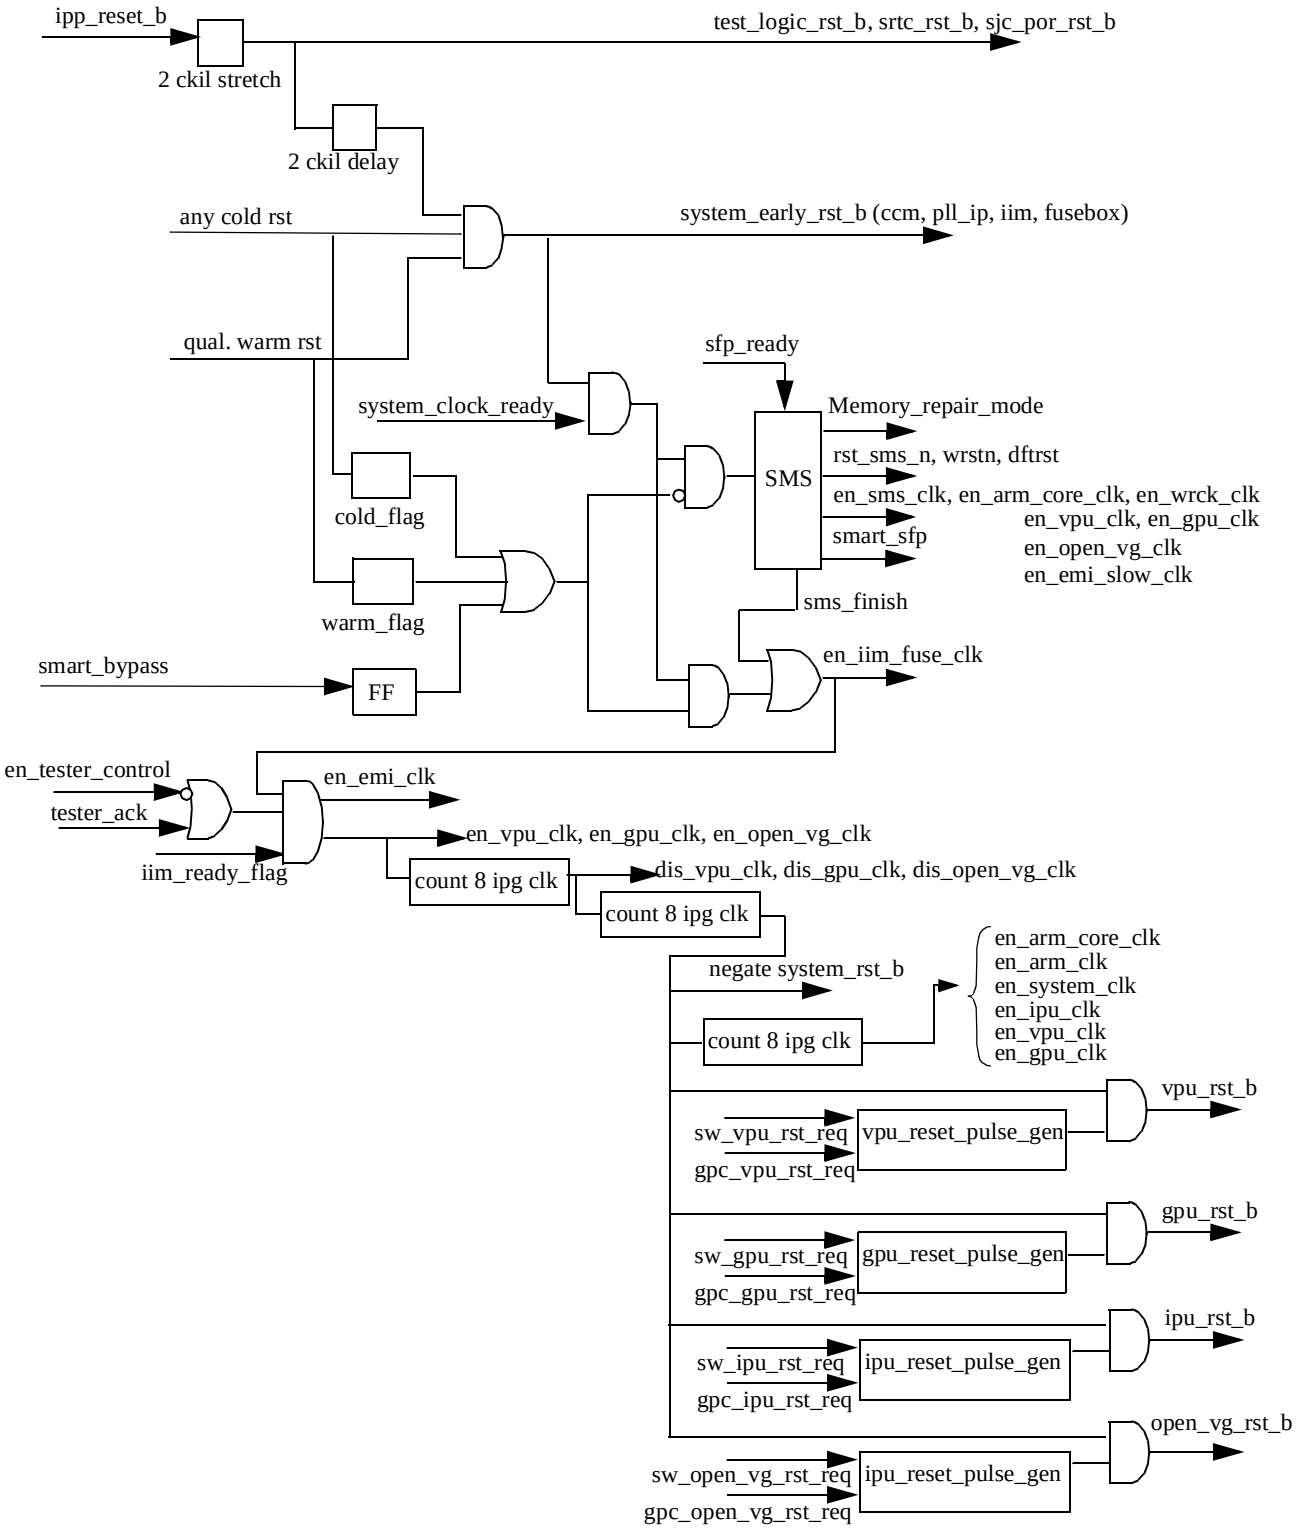

Figure 54-12. Reset Diagram

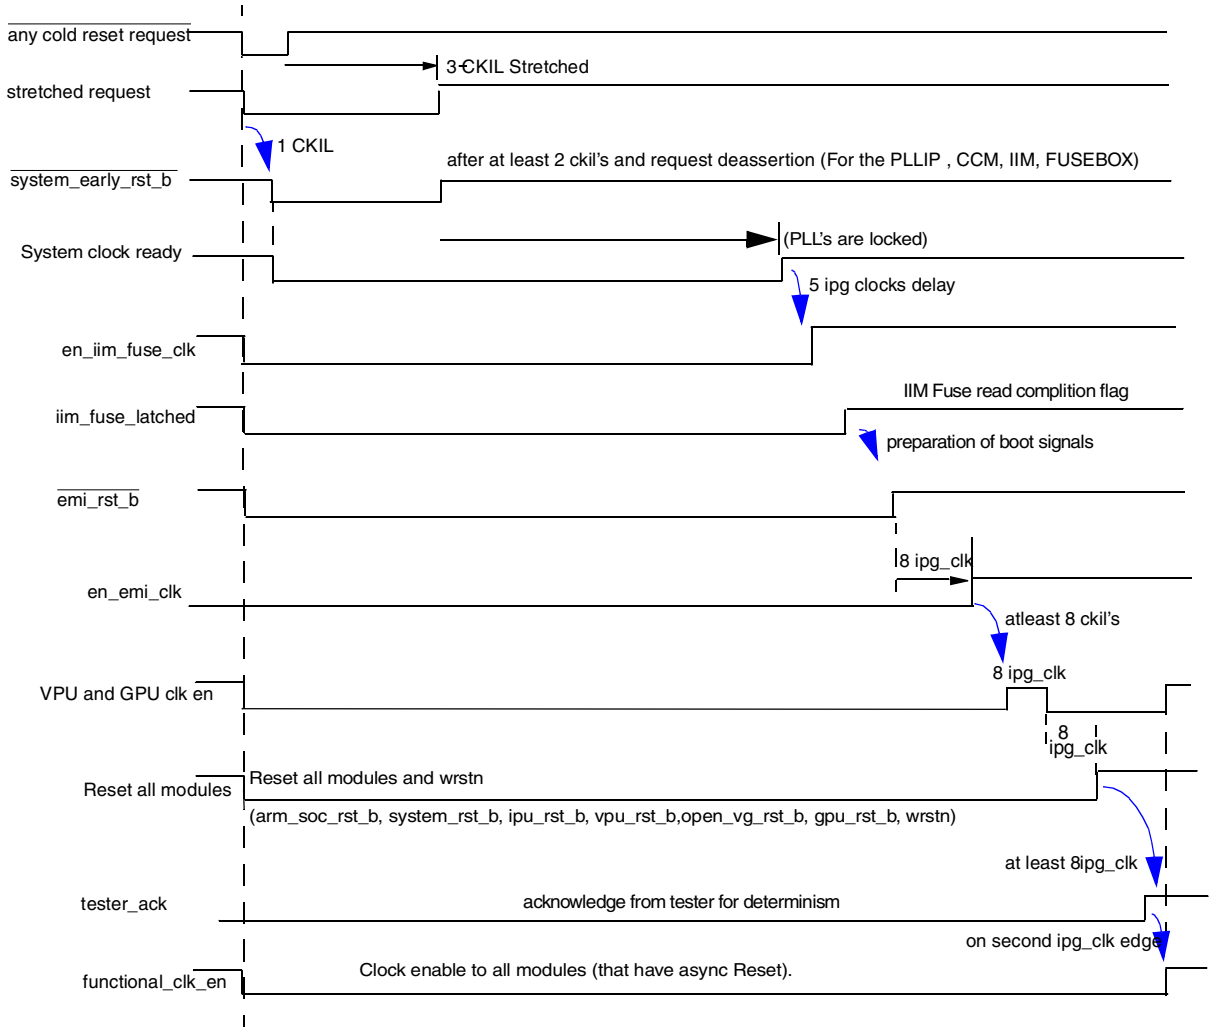

Figure 54-13. Cold Reset Sequence

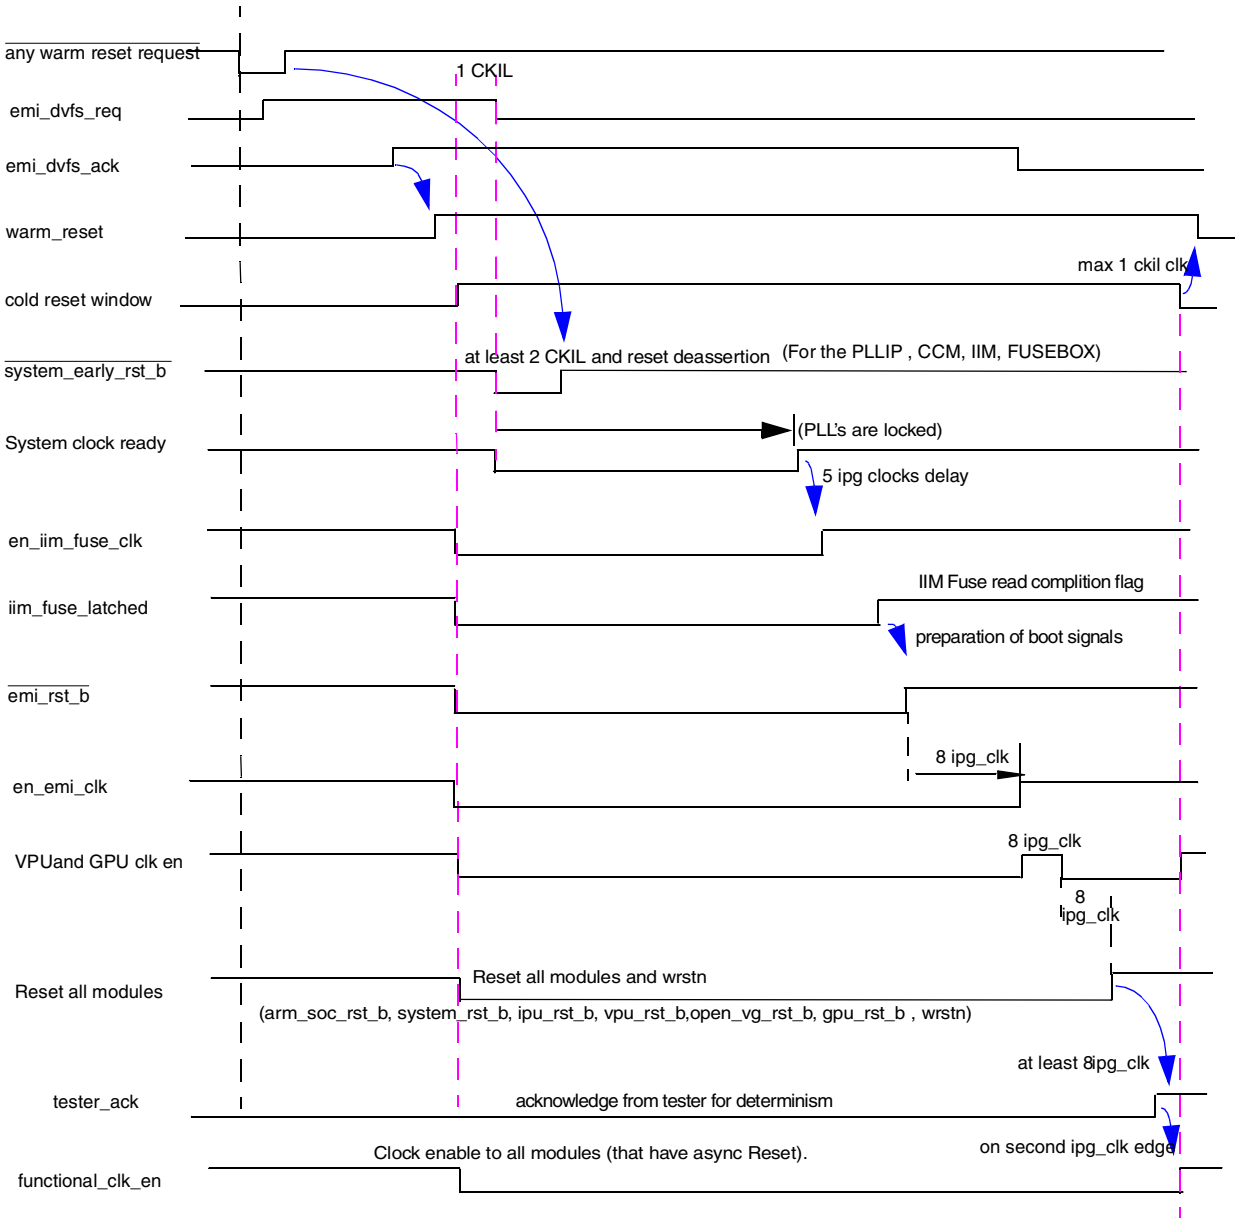

Figure 54-14. Warm Reset Sequence

54.3.1.2.3 SMS Submodule

The sms submodule manages the memory repair signals during por. The sms sub module will start its operation after system_clock_ready notification from CCM and only if the reset sequence is due to por sequence (ipp_reset_b). The SMS submodule operation can be bypassed by smart_bypass assertion signal from the pad. If the smart_bypass is asserted, only the assertion part of sms reset signals will take place, but smart_sfp - sfp_ready sequence will not be perofrmed.

The SMS sequence is as follows:

1. Upon assertion of system_clock_ready signal, count 2 ipg clocks and assert the memory_repair_mode signal.
2. Wait 4 wrck clocks.
3. Assert sms reset signals on wrck clock edge:
   - rst_sms_n = 0
   - wrst_n = 0
   - dftrst = 1
4. Wait 3 wrck clocks
5. . De assert the reset signals on wrck clock edge:

- rst_sms_n = 1
- wrst_n = 1
- dftrst = 0

6. Wait 4 wrck clocks
7. Enable memory repair clocks, i.e. en_arm_core_clk=1, en_emi_slow_clk=1, en_vpu_clk=1, en_gpu_clk=1, en_open_vg_clk=1, en_sms_clk=1 and en_wrck_clk=1 on wrck edge.
8. Wait 4 wrck clocks
9. Assert smart_sfp signal on wrck edge.
10. Monitor de assertion and assertion of sfp_ready signal.
11. Once assertion of sfp_ready signal, de assert smart_sfp, de assert clock enables en_arm_core_clk=0 , en_emi_slow_clk=0, en_vpu_clk=0, en_gpu_clk=0, en_open_vg_clk=0, en_sms_clk=0 and en_wrck_clk=0 on wrck edge, de assert memory_repair_mode signal. (all on wrck edges).
12. Wait 4 wrck clocks
13. Assert sms_finish to notify that SRC can continue with enable IIM clocks .

Figure 54-15 describes the SMS flow.

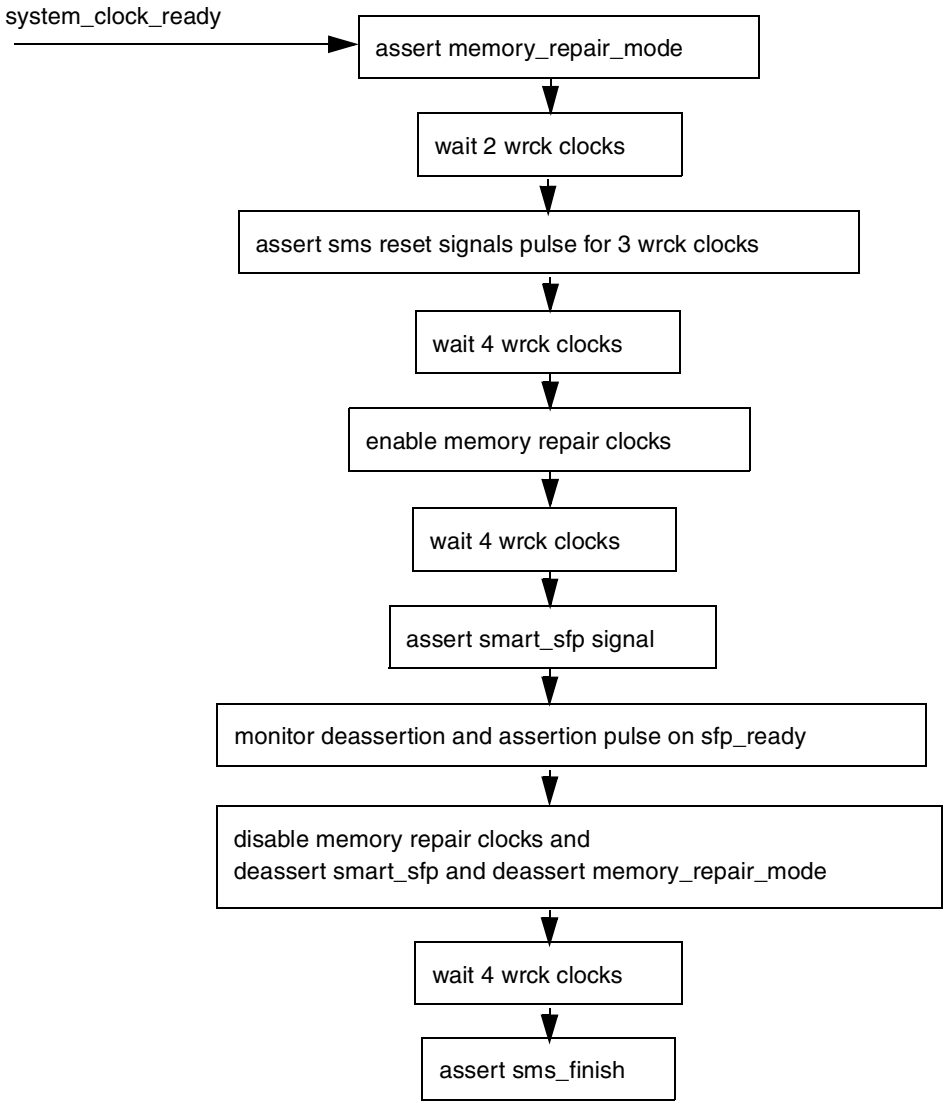

Figure 54-15. SMS flow diagram

54.3.1.2.4 Reset Pulse Generators

Except from POR, cold, and warm sequence resets, a reset pulse can be generated for VPU, Open VG, GPU and IPU. Those reset pulses can be generated upon sw reset bit assertion, or by signal from GPC requesting the reset pulse. Once the sw bit or the gpc signal are asserted, the respective reset will be asserted.

If the reset source is GPC request , then once the GPC signal is deasserted, the respective reset will be deaseerted.

If the reset source is sw bit, then once the reset asertion sequence will be finished, the reset will be deasserted, and after reset deassertion sequence , the sw bit will be cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrupt once the software reset has finished. Please refer to SISR register for details.

Below is explanation how each of those reset pulse generators are functioning:

IPU reset pulse generator:

Upon assertion of sw_ipu_rst bit (sw_ipu_rst = ‘1’) or assertion of gpc_reset_ipu_req (gpc_reset_ipu_req=’0’) then SRC should do the following:

1. If the request came from gpc, i.e. gpc_reset_ipu_req=’0’ then negate ipu_reset_done internally to SRC. This will cause negation of power_gating_reset_done signal to CCM.
2. Close ipu clocks (en_ipu_clk=’0’)
3. Assert ipu reset (ipu_rst_b=’0’)

SRC will continue with the reset deassertion step described below in the following cases:

- If the reset source was the software bit, then SRC will continue to the deassertion steps imediately.
- If the reset source was GPC request, then upon de assertion of gpc_reset_ipu_req (gpc_reset_ipu_req=’1’) SRC will continue to the deassertion steps:
  a) Deassert ipu reset (ipu_rst_b=’1’)
  b) Count at least 8 ipg_clk to allow reset to penetrate reset tree
  c) Open ipu clocks (en_ipu_clk=’1’)
  d) If the request came from gpc, i.e. gpc_reset_ipu_req caused the reset request then assert ipu_reset_done internally to SRC. If the request came from sw_ipu_rst bit assertion then generate interrupt (if its not masked) to notify that reset ipu passed reset and is ready to be used, and clear the sw_ipu_rst bit.

Figure 54-16 describes the flow of ipu reset pulse generator.

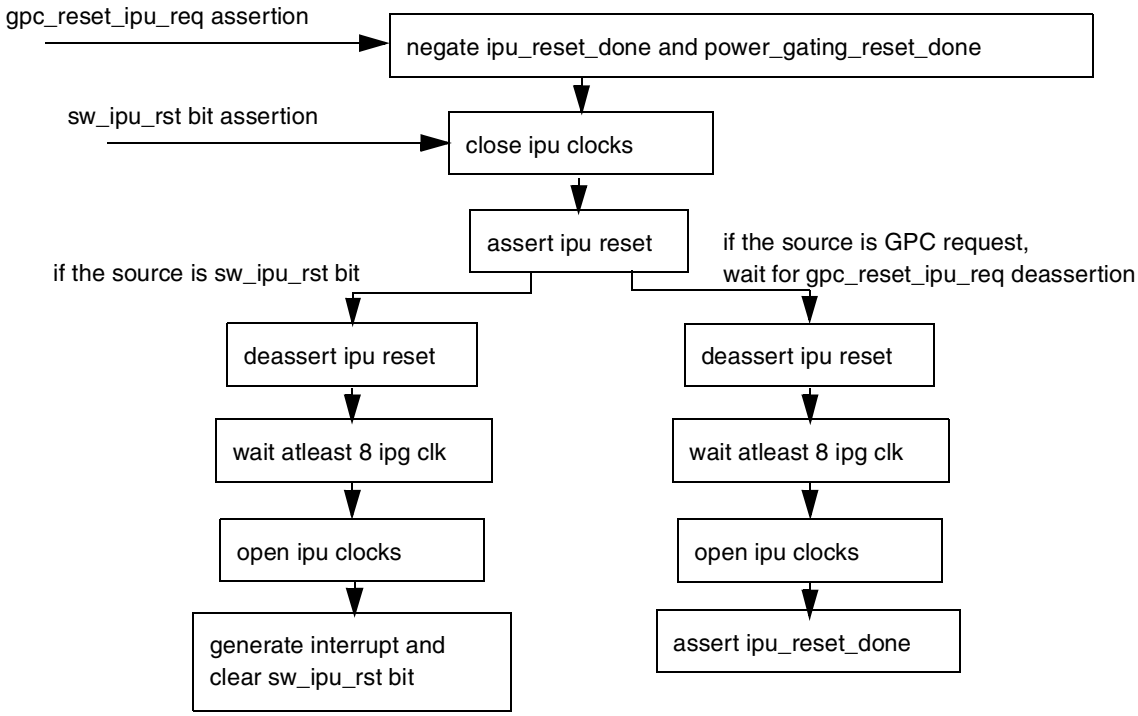

Figure 54-16. ipu Reset Pulse Generator

VPU reset pulse generator:

VPU reset pulse can be generated from sw_vpu_rst bit or gpc_reset_vpu_req.

If the request came from gpc, i.e. gpc_reset_vpu_req='0' then negate vpu_reset_done internally to SRC. This will cause negation of power_gating_reset_done signal to CCM. On this stage also deassert vpu_reset_penetrated.

1. Close vpu clocks (en_vpu_clk='0') (just to make sure they are closed)
2. Assert vpu reset (vpu_rst_b='0').
3. If the source was GPC request, wait for change from 1 to 0 on gpc_vpu_switch_b signal to notify that power is back.
4. Count atleast 8 ipg_clk clocks so that reset will propagate the reset tree
5. Open vpu clocks.
6. Count at least 16 ipg_clk clocks so that reset will propagate in vpu (this stage will happen only after pll relock and clocks are ready prior to exiting from stop)
7. Close vpu clocks (en_vpu_clk='0')
8. Wait at least 8 ipg_clk cycles so that clocks to vpu will be closed, and then assert vpu_reset_penetrated so that GPC will be notified that reset assertion is performed and GPC can continue with release of ISO signal.

Upon deassertion of gpc_reset_vpu_req (gpc_reset_vpu_req=’1’) and the completion of the above procedure then perform the following steps:

1. Deassert vpu reset (vpu_rst_b=’1’)
2. Count atleast 8 ipg_clk clocks so that reset will propagate the reset tree
3. Open vpu clocks (en_vpu_clk=’1’).
4. Count atleast 16 ipg_clk clocks so that reset will propagate in vpu
5. Assert vpu_reset_done internally to SRC.

If the request came from software bit, i.e. sw_vpu_rst = ‘1’ then perform the following steps:

1. Close vpu clocks (en_vpu_clk=’0’)
2. Assert vpu reset (vpu_rst_b=’0’)
3. Count at least 8 ipg_clk clocks so that reset will propagate the reset tree
4. Open vpu clocks (en_vpu_clk=’1’)
5. Count at least 16 ipg_clk clocks so that reset will propagate in vpu
6. Close vpu clocks (en_vpu_clk=’0’)
7. Wait at least 8 ipg_clk cycles so that clocks to vpu will be closed.

SRC will continue to the deassertion steps immediately.

1. Deassert vpu reset (vpu_rst_b=’1’)
2. Count at least 8 ipg_clk clocks so that reset will propagate the reset tree
3. Open vpu clocks (en_vpu_clk=’1’).
4. Count at least 16 ipg_clk clocks so that reset will propagate in vpu
5. Generate interrupt (if its not masked) to notify that reset vpu passed reset and is ready to be used and clear sw_vpu_rst.

Figure 54-17 describes the flow of vpu reset pulse generator.

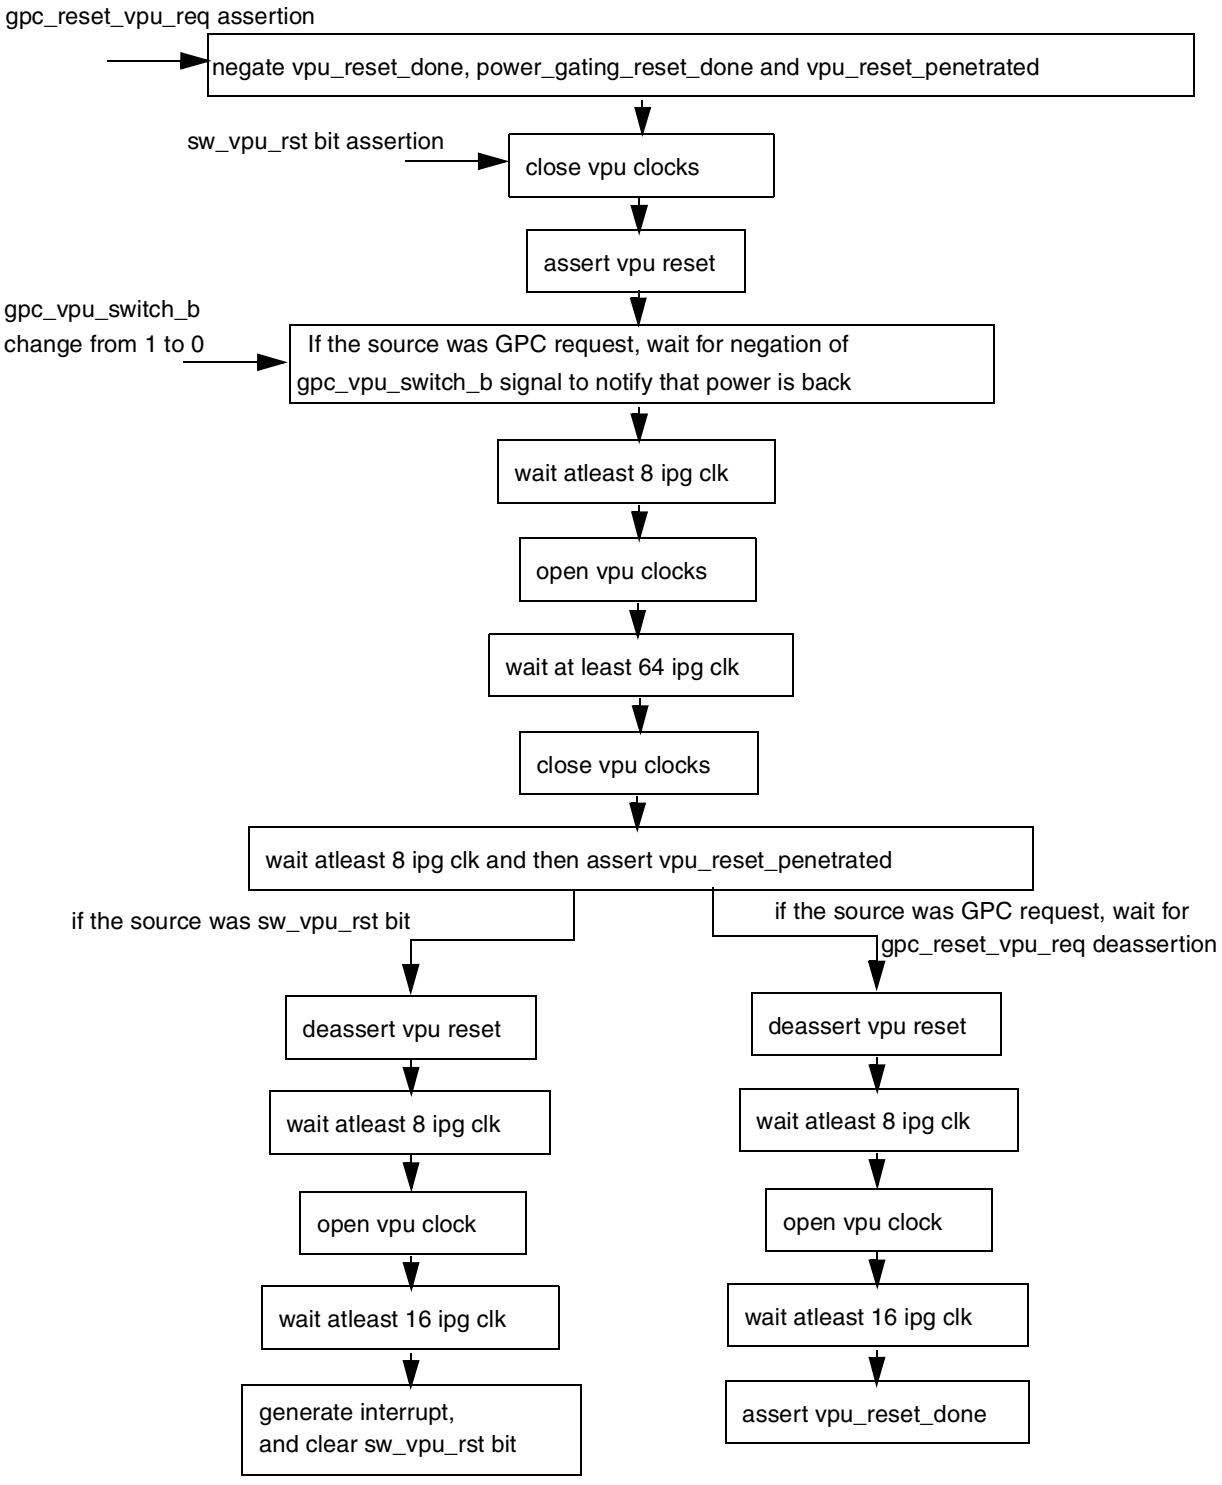

Figure 54-17. vpu Reset Pulse Generator

GPU reset pulse generator:

GPU reset pulse can be generated from sw_gpu_rst bit or gpc_reset_gpu_req.

If the request came from gpc, i.e. gpc_reset_gpu_req=’0’ then negate gpu_reset_done internally to SRC. This will cause negation of power_gating_reset_done signal to CCM. On this stage also deassert gpu_reset_penetrated.

1. Close gpu clocks (en_gpu_clk=’0’) (just to make sure they are closed)
2. Assert gpu reset (gpu_rst_b=’0’).
3. If the source was GPC request, wait for change from 1 to 0 on gpc_gpu_switch_b signal to notify that power is back.
4. Count at least 8 ipg_clk clocks so that reset will propagate the reset tree
5. Open gpu clocks.
6. Count at least 16 ipg_clk clocks so that reset will propagate in gpu (this stage will happen only after pll relock and clocks are ready prior to exiting from stop)
7. Close gpu clocks (en_gpu_clk=’0’)
8. Wait at least 8 ipg_clk cycles so that clocks to gpu will be closed, and then assert gpu_reset_penetrated so that GPC will be notified that reset assertion is performed and GPC can continue with release of ISO signal.

Upon de assertion of gpc_reset_gpu_req (gpc_reset_gpu_req=’1’) and finish of the above procedure then:

1. Deassert gpu reset (gpu_rst_b=’1’)
2. Count at least 8 ipg_clk clocks so that reset will propagate the reset tree
3. Open gpu clocks (en_gpu_clk=’1’).
4. Count at least 16 ipg_clk clocks so that reset will propagate in gpu
5. Assert gpu_reset_done internally to SRC.

If the request came from software bit, i.e. sw_gpu_rst = ‘1’ then perform the following steps:

1. Close gpu clocks (en_gpu_clk=’0’)
2. Assert gpu reset (gpu_rst_b=’0’)
3. Count at least 8 ipg_clk clocks so that reset will propagate the reset tree
4. Open gpu clocks (en_gpu_clk=’1’)
5. Count at least 16 ipg_clk clocks so that reset will propagate in gpu
6. Close gpu clocks (en_gpu_clk=’0’)
7. Wait a tleast 8 ipg_clk cycles so that clocks to gpu will be closed.

SRC will continue to the deassertion steps imediately.

1. Deassert gpu reset (gpu_rst_b=’1’)
2. Count atleast 8 ipg_clk clocks so that reset will propagate the reset tree
3. Open gpu clocks (en_gpu_clk=’1’).
4. Count atleast 16 ipg_clk clocks so that reset will propagate in gpu

5. Generate interrupt (if its not masked) to notify that reset gpu passed reset and is ready to be used and clear sw_gpu_rst.

Figure 54-18d escribes the flow of gpu reset pulse generator:

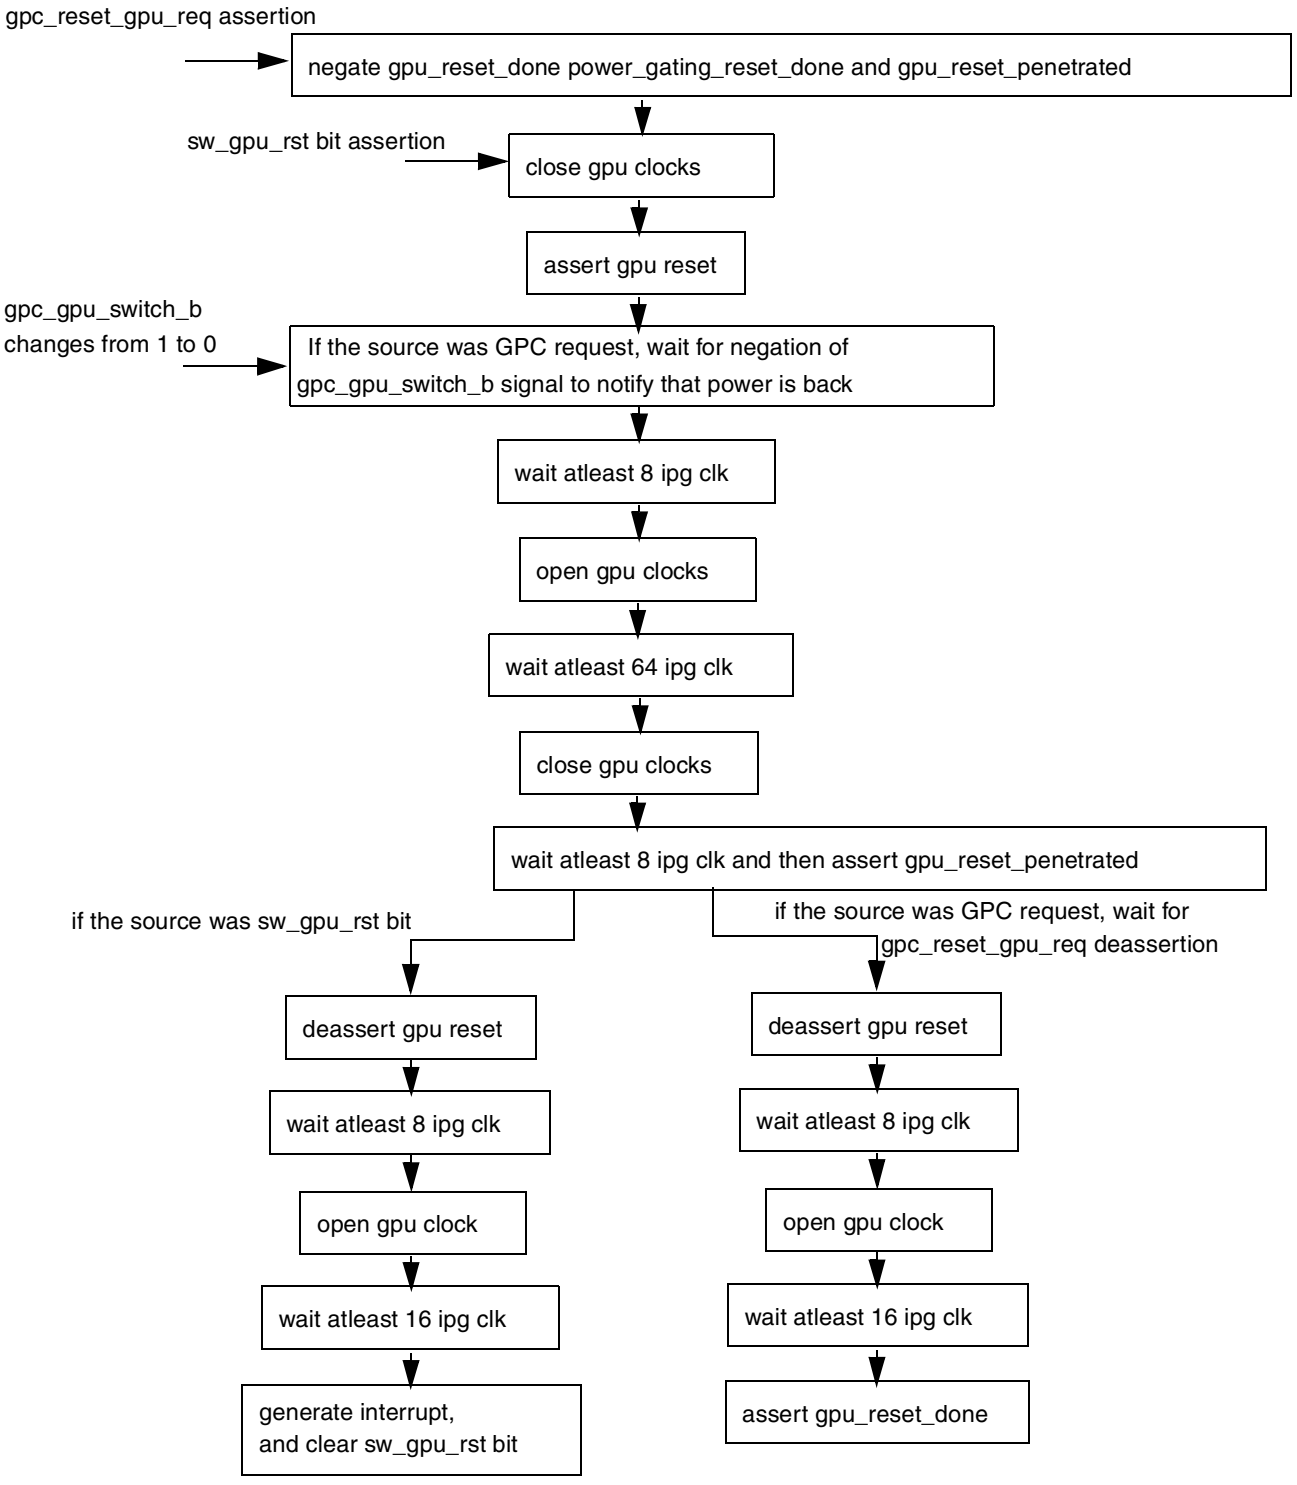

Figure 54-18. gpu Reset Pulse Generator Flow

Open_VG reset pulse generator:

Open_VG reset pulse can be generated from sw_open_vg_rst bit or gpc_reset_open_vg_req.

If the request came from gpc, i.e. gpc_reset_open_vg_req=’0’ then negate open_vg_reset_done internally to SRC. This will cause negation of power_gating_reset_done signal to CCM. On this stage also deassert open_vg_reset_penetrated.

1. Close open_vg clocks (en_open_vg_clk=’0’) (just to make sure they are closed)
2. Assert open_vg reset (open_vg_rst_b=’0’).
3. If the source was GPC request, wait for change from 1 to 0 on gpc_open_vg_switch_b signal to notify that power is back.
4. Count atleast 8 ipg_clk clocks so that reset will propagate the reset tree
5. Open open_vg clocks.
6. Count at least 16 ipg_clk clocks so that reset will propagate in open_vg (this stage will happen only after pll relock and clocks are ready prior to exiting from stop)
7. Close open_vg clocks (en_open_vg_clk=’0’)
8. Wait at least 8 ipg_clk cycles so that clocks to open_vg will be closed, and then assert open_vg_reset_penetrated so that GPC will be notified that reset assertion is performed and GPC can continue with release of ISO signal.

Upon de assertion of gpc_reset_open_vg_req (gpc_reset_open_vg_req=’1’) and finish of the above procedure then:

1. Deassert open_vg reset (open_vg_rst_b=’1’)
2. Count at least 8 ipg_clk clocks so that reset will propagate the reset tree
3. Open open_vg clocks (en_open_vg_clk=’1’).
4. Count at least 16 ipg_clk clocks so that reset will propagate in open_vg.
5. Assert open_vg_reset_done internally to SRC.

If the request came from software bit, i.e. sw_open_vg_rst = ‘1’ then:

1. Close open_vg clocks (en_open_vg_clk=’0’)
2. Assert open_vg reset (open_vg_rst_b=’0’)
3. Count at least 8 ipg_clk clocks so that reset will propagate the reset tree
4. Open open_vg clocks (en_open_vg_clk=’1’)
5. Count at least 16 ipg_clk clocks so that reset will propagate in open_vg
6. Close open_vg clocks (en_open_vg_clk=’0’)
7. Wait at least 8 ipg_clk cycles so that clocks to open_vg will be closed.

SRC will continue to the deassertion steps imediately.

1. Deassert open_vg reset (open_vg_rst_b=’1’)
2. Count at least 8 ipg_clk clocks so that reset will propagate the reset tree
3. Open open_vg clocks (en_open_vg_clk=’1’).

4. Count at least 16 ipg_clk clocks so that reset will propagate in open_vg.
5. Generate interrupt (if its not masked) to notify that reset open_vg passed reset and is ready to be used and clear sw_open_vg_rst.

Figure 54-19 describes the flow of open_vg reset pulse generator:

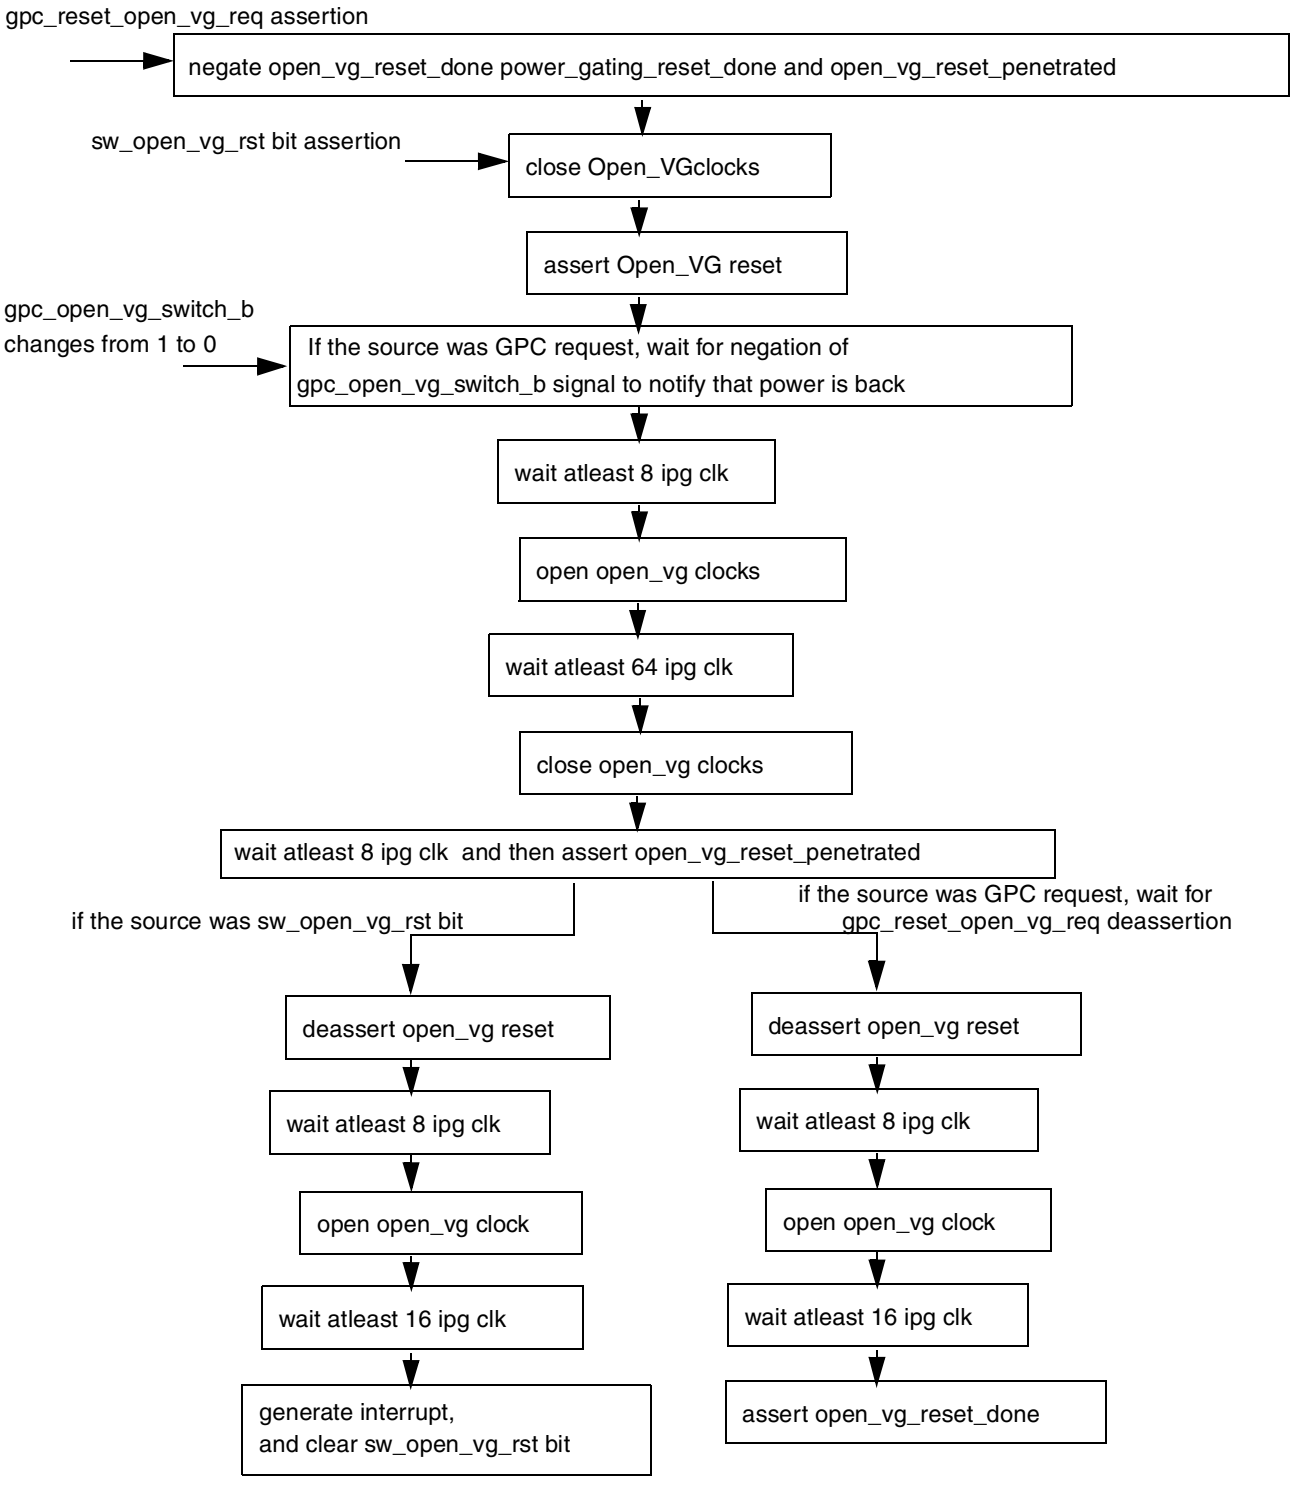

Figure 54-19. open_vg Reset Pulse Generator Flow

Upon assertion of ipu_reset_done, vpu_reset_done, open_vg_reset_done and gpu_reset_done, SRC will generate assertion of power_gating_reset_done to notify ccm that all needed resets has finished and ccm can continue with waking the system from stop mode, i.e enabling arm and system's clocks.

54.3.1.2.5 SRTC_RST_B generation

SRTC_RST_B will be generated during POR sequence together with test_logic_rst_b.

On the srtc_rst_b path there will be a mux that enables a generation of reset on srtc_rst_b pad from TCU , in case of test_mode. The enable of this mux is test_mode input. When the test_mode input equals '0' , the generated srtc_rst_b will be the functional srtc reset (generated during POR scenario). When the test_mode input equals '1', the generated srtc_rst_b will be connected to the tcu_reset input. In this case, tcu will have complete controlability of srtc_rst_b , and will be able to generate a reset for srtc.

Figure 54-20 describes this mux.

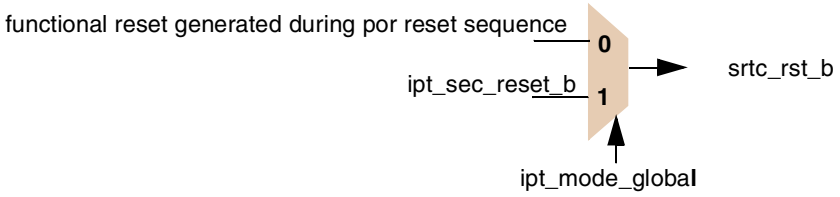

Figure 54-20. srtc_rst_b Generation

54.3.2 SJC_POR_RST_B Generation

SJC will be reseted by sjc_por_rst_b output of SRC. This output will be toggled only on POR sequence together with test_logic_rst_b. It will not be toggled on IEEE reset (jtag_rst_b).

54.3.3 SRC_MEGAMIX_ISO Generation

In normal functional mode (after system came out of reset), the GPC is controling the ISO signal for the isolation cells that wrap the Megamix. During reset sequence, SRC will drive the ISO signal for those isolation cells. SRC will drive those isolation cells by generation of src_megamix_iso output signal. This signal will equal to '0' during reset sequence, until deassertion of "reset_all_modules" (untill reset_all_modules='1'). After the deassertion of "reset_all_modules", the value of the ISO signal generated from GPC (gpc_megamix_iso) will be assigned to the output src_megamix_iso, and delivered to the isolation cells wraping the megamix.

54.3.4 Parallel Reset Requests

This chapter describes the behavior when paralel reset requests are received. In the parallel reset requests case SRC follows the following rules:

- The order of strength of resets is POR = strongest, cold = medium, and warm = weakest.
- If a stronger reset is asserted during a weaker reset's sequence, the stronger reset takes over and begins its reset process. The following cases fall into this category:
  - POR reset request in the middle of cold or warm reset process—the cold or warm reset process will be stopped and the POR sequence will start.
  - COLD reset request in the middle of warm reset process—the warm reset process will be stoped and the cold sequence will start.
- If a weaker reset is asserted during stronger reset sequence, the stronger reset sequence continues without interference. If at the end of the stronger reset process, the weaker request is still asserted then the weaker sequence will commence. The following cases fall into this category:
  - COLD or WARM reset requests in the middle of POR reset process—the POR process continues without interference.
  - WARM reset request in the middle of COLD reset process—the COLD process continues without interference.
- If a similar reset request is asserted during the process of reset handling, then the process of reset handling will start over (with the same process). The following cases fall into this category:
  - POR reset request in the middle of POR reset process—the POR process starts over.
  - COLD reset request in the middle of COLD reset process—the COLD process starts over.

There is one exception to this category: a WARM reset request in the middle of WARM reset process. In this case, the new WARM reset process cannot restart because EMI is reset. There cannot be the required handshake with EMI when EMI is reset. For this case, the first WARM reset will continue. Only if the second WARM reset is still asserted after the first one has finished, does the WARM sequence begin again.

54.3.5 DFT Mux on Reset Outputs

All functional reset output described above are muxed before exiting SRC. The mux is controlled by ipt_mode_global signal. The mux chooses between the functional reset and the DFT reset, as shown in Figure 54-21.

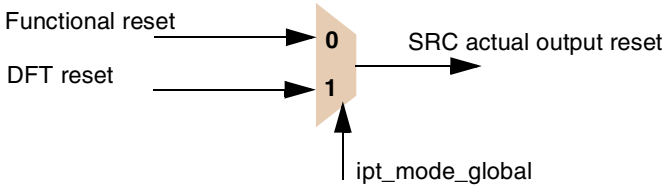

Figure 54-21. MUX Between Functional Reset and DFT Reset

Table 54-11 describes the DFT reset assigned to each of the reset outputs.

Table 54-11. DFT Reset Assigment

SRC Reset Output	DFT Reset Generation
arm_por_rst	~(ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b)
arm_soc_rst_b	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
dftrst	~(ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b)
dftrst_vpu	~(ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b)
dftrst_ipu	~(ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b)
emi_rst_b	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
ipu_rst_b	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
rst_sms_n	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
rst_sms_n_vpu	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
rst_sms_n_ipu	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
system_early_rst_b	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
system_rst_b	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
test_logic_rst_b	ipp_reset_b
vpu_rst_b	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
wrst_n	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
wrst_n_vpu	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
wrst_n_open_vg	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
wrst_n_gpu	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
wrst_n_ipu	ipp_reset_b & ipp_user_reset_b & ipt_sec_reset_b
srtc_rst_b	ipt_sec_reset_b
src_por_b	ipp_reset_b

Note: src_por_b is an internal reset generated for SRC module only. This reset is asserted on por only (ipp_reset_b). It is equal to the functional test_logic_reset_b.

54.3.6 Boot Mode Control

54.3.6.1 BMOD Pin Latching

The exact boot sequence for the i.MX51 is controlled by the values of the BMOD pins on this device.

All the boot pins will be sampled at deassertion of system_early_rst_b.

The value of the BMOD pins will be latched after the IIM asserts the fuse read completion flag. After latching, the values of the BMOD pins are used to determine the booting options of the core as given in the SBMR register.

The information for DIR_BT_DIS is programed in the fuse box.

The Boot mode information for MEM_TYPE, PG_SIZE, BUS_WIDTH, MEM_CTL can be provided to the SRC from either e-fuses or GPIO signals. The gpio_bt_sel e-fuse defines the source to be used to derive the boot information. When gpio_bt_sel is set, e-fuses are used. When cleared, GPIO signals are used.

When FSL test mode is chosen (01 for BMOD[1:0]) then the Fuses signals are used.

When Internal Boot From Fuses mode is chosen (10 for BMOD[1:0]) then e-fuses signals are used, without consideration on the gpio_bt_sel e-fuse value.

The boot information is provided in the SBMR register. Figure shows the selection of Boot mode information.

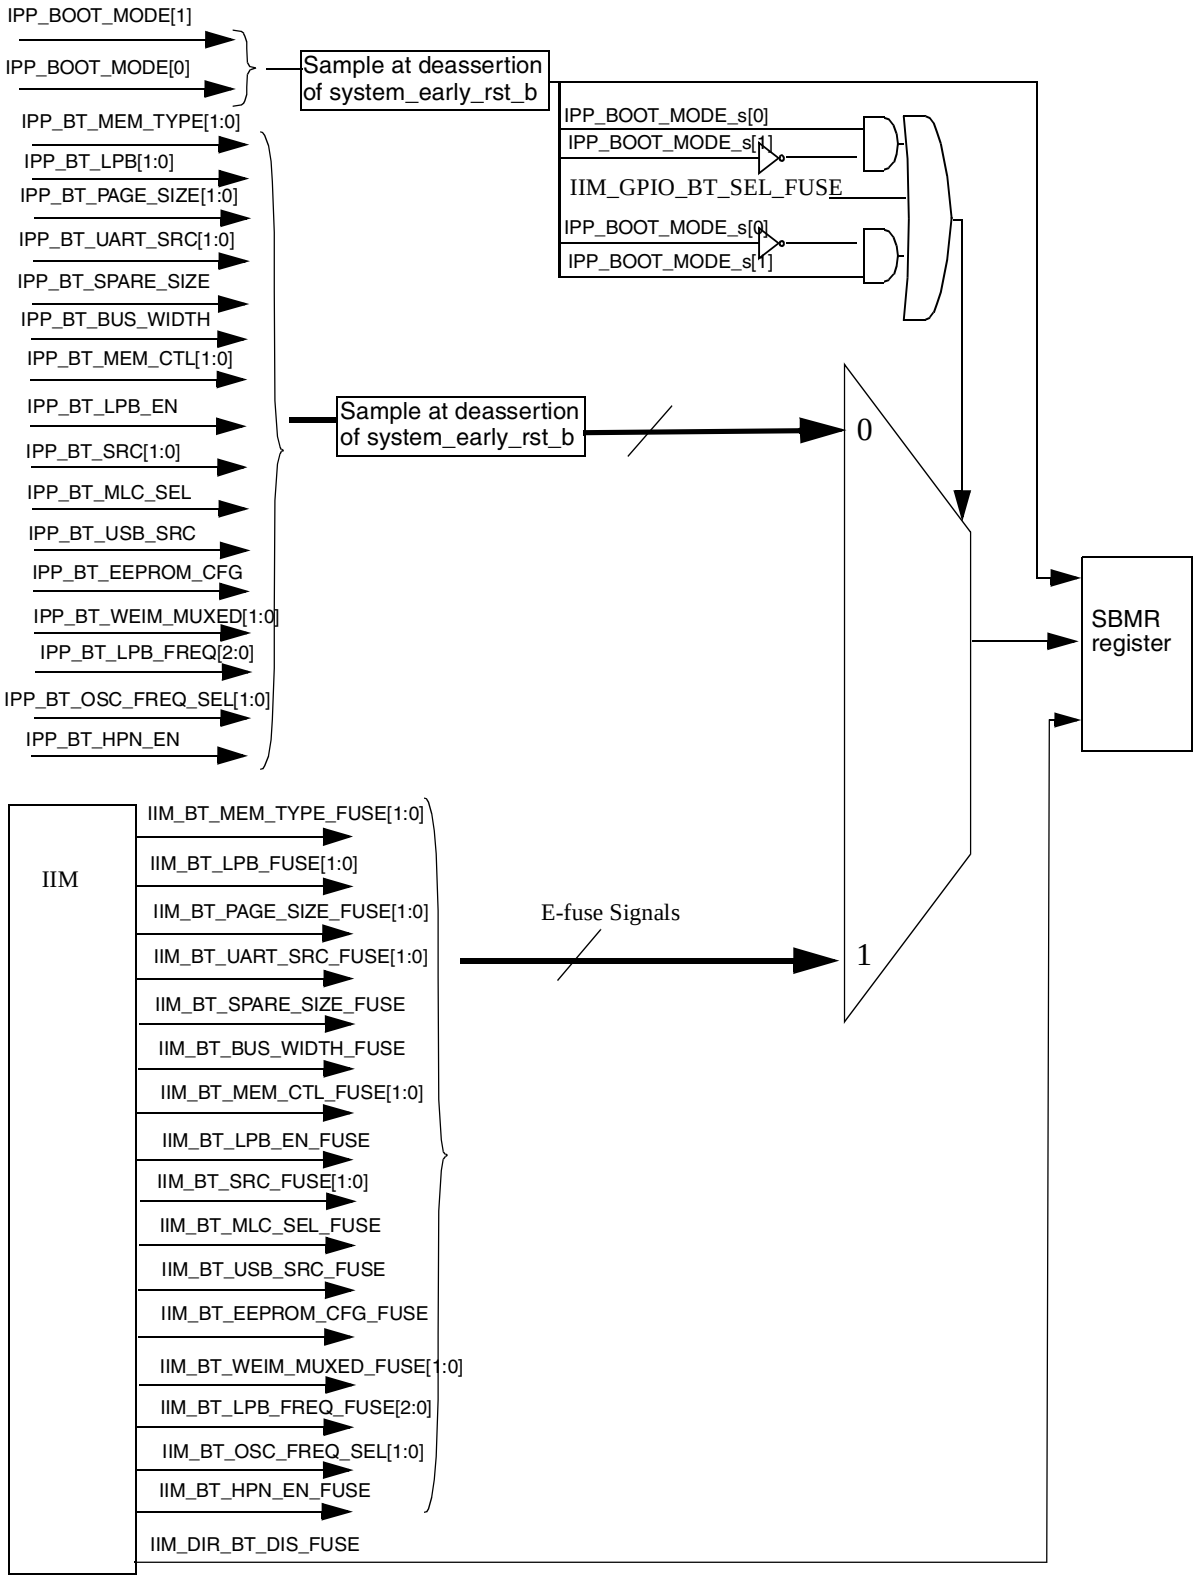

Figure 54-22. Boot Mode Information

Note: IPP signals that need to be latched by SRC will be set to the corresponding mode based on system_rst_b signal. When system_rst_b signal equals ‘0’, the IOMUX will shift to the needed mode for transfering boot values on the IO pins. When system_rst_b signal equals ‘1’, the IOMUX will shift to the default mode.

54.3.6.2 Output Boot Signals

The output boot signals are as follows:

- src_int_boot—internal boot indicator: Boot mode = External + WEIM mem type, are counted as external mode for ARM.
  - assign src_int_boot = iim_dir_bt_dis_fuse || ~(ipp_boot_mode[1:0]=01 && test_mode[2:0]=3’b111 && (BT_MEM_CTL[1:0]==2'b00))
- src_weim_boot_cfg[2] - Multiplexed address mode: To be driven based on SBMR bit [16] value. (0-not muxed, 1-Multiplexed mode). Connect to EMI pin src_weim_boot_cfg[2].
  - src_weim_boot_cfg[1]= SBMR[16]&SBMR[17] | ~SBMR[16]&~SBMR[17] ;
  - src_weim_boot_cfg[0]= SBMR[16] | SBMR[17] ;
- src_boot_add[31:0] - boot address - output to ARM Platform
  - IF src_int_boot=0 then src_boot_add[31:0]=32’h B000_0000
  - Otherwise src_boot_add[31:0]=32’h 0000_0000
- ipp_do_boot_mode_inv[1:0] - inversion of IPP_BOOT_MODE[1:0]. Once the boot signals (ipp_boot_mode[1:0]) are sampled in SRC, SRC will generate the inversion of ipp_boot_mode[1:0] on those pins. The IO ring will use system_rst_b to generate the ipp_do_boot_mode_inv[1:0] on the boot pads:

When system_rst_b=0, the boot pads will be configured as inputs, allowing boot info to propagate to SRC’s inputs ipp_boot_mode[1:0].

When system_rst_b=1 , the boot pads will be configured as output, allowing ipp_do_boot_mode_inv[1:0] to be generated to the pads, i.e. it will be noticed on the pads that the value has flipped.

The board will catch this flip and in this way will be notified that the system sequence has changed, and it is allowed to use the boot pads for a different purpose.

Chapter 55
Secure Real Time Clock (SRTC)

55.1 Overview

The SRTC helps to comply with issues arising out of different application requiring secure and certifiable time for example Digital Rights Management (DRM) schemes.

DRM are used to offer access to digital content, by a consumer, while still offering protection to the owner. The consumer can only use the digital content in authorized ways. There are typically rights rules associated with the content defining how it can be used, or for how long. One of the right rules associated with the content is a time based usage. For example, a sample of music could be allowed to be played for only one week. If the consumer were able to modify the time source to act as if it were last week, then the DRM hardware would allow the content to be used for an extra week.

In order to enforce those rules, trusted hardware is required. Otherwise, the rights rules might be bypassed, and the content used in ways not desired by the owner. To be able to enforce a time restriction on the use of the content, trusted time source is required. This trusted time source must provides features that allow the system software designer to ensure that the time kept by the device is certifiable. SRTC provides a certifiable time to user and can raise alarm if tampering with counters is detected.

The SRTC is comprised of two separated submodules:

- Lower power domain SRTC (SRTC LP)
- High power domain SRTC (SRTC HP)

SRTC LP block is in always powered up domain and is isolated from the rest of the logic by means of isolation cell. Isolations cells are library instantiated cells, which insure that the powered up logic does not get corrupted when the power goes down in the rest of the SoC. It is powered by the Coin Cell battery

SRTC HP is in the normal supply domain. It is powered by the main digital supply powering the SoC

55.1.1 Low Power SRTC (SRTC LP) Description

The SRTC LP is a real time clock with enhanced security capabilities. Its purpose is to provide an accurate time read at all time, regardless of the main system power state and without the need to use external on-board time source such as external RTC. The SRTC LP can wake up the system when preset time alarm is asserted.It is divided into following units:

- Counters and registers
  - — Non-rollover 47-bit time counter
  - — 32-bit alarm register

  - General purpose registers
  - Secured monotonic counter
- SRTC Monitor
  - SRTC state machine
  - SRTC power and clock detectors

See Figure 55-1 for the SRTC module partitioning.

55.1.2 High Power SRTC (SRTC HP) Description

The SRTC HP contains all the interfaces to the core (IPBus interface). It contains counter, alarm and has the capability of generating a number of user defined periodic interrupt. Access to SRTC LP registers can only be done through the SRTC HP and when SRTC HP is powered up.

SRTC HP is partitioned into following units.

- Address Decode
- Counters and registers
  - Non-secure 47-bit time counter
  - Programmable non-secure 47-bit alarm with interrupt
  - Periodic alarm with interrupt

See Figure 55-1 for the SRTC module partitioning.

The non secure time counter can be synchronized with the secured time counter by writing to a SRTC HP bit (time_sync-Time Synchronization). When written, the content of the secure counter is automatically copied to the non-secure counter

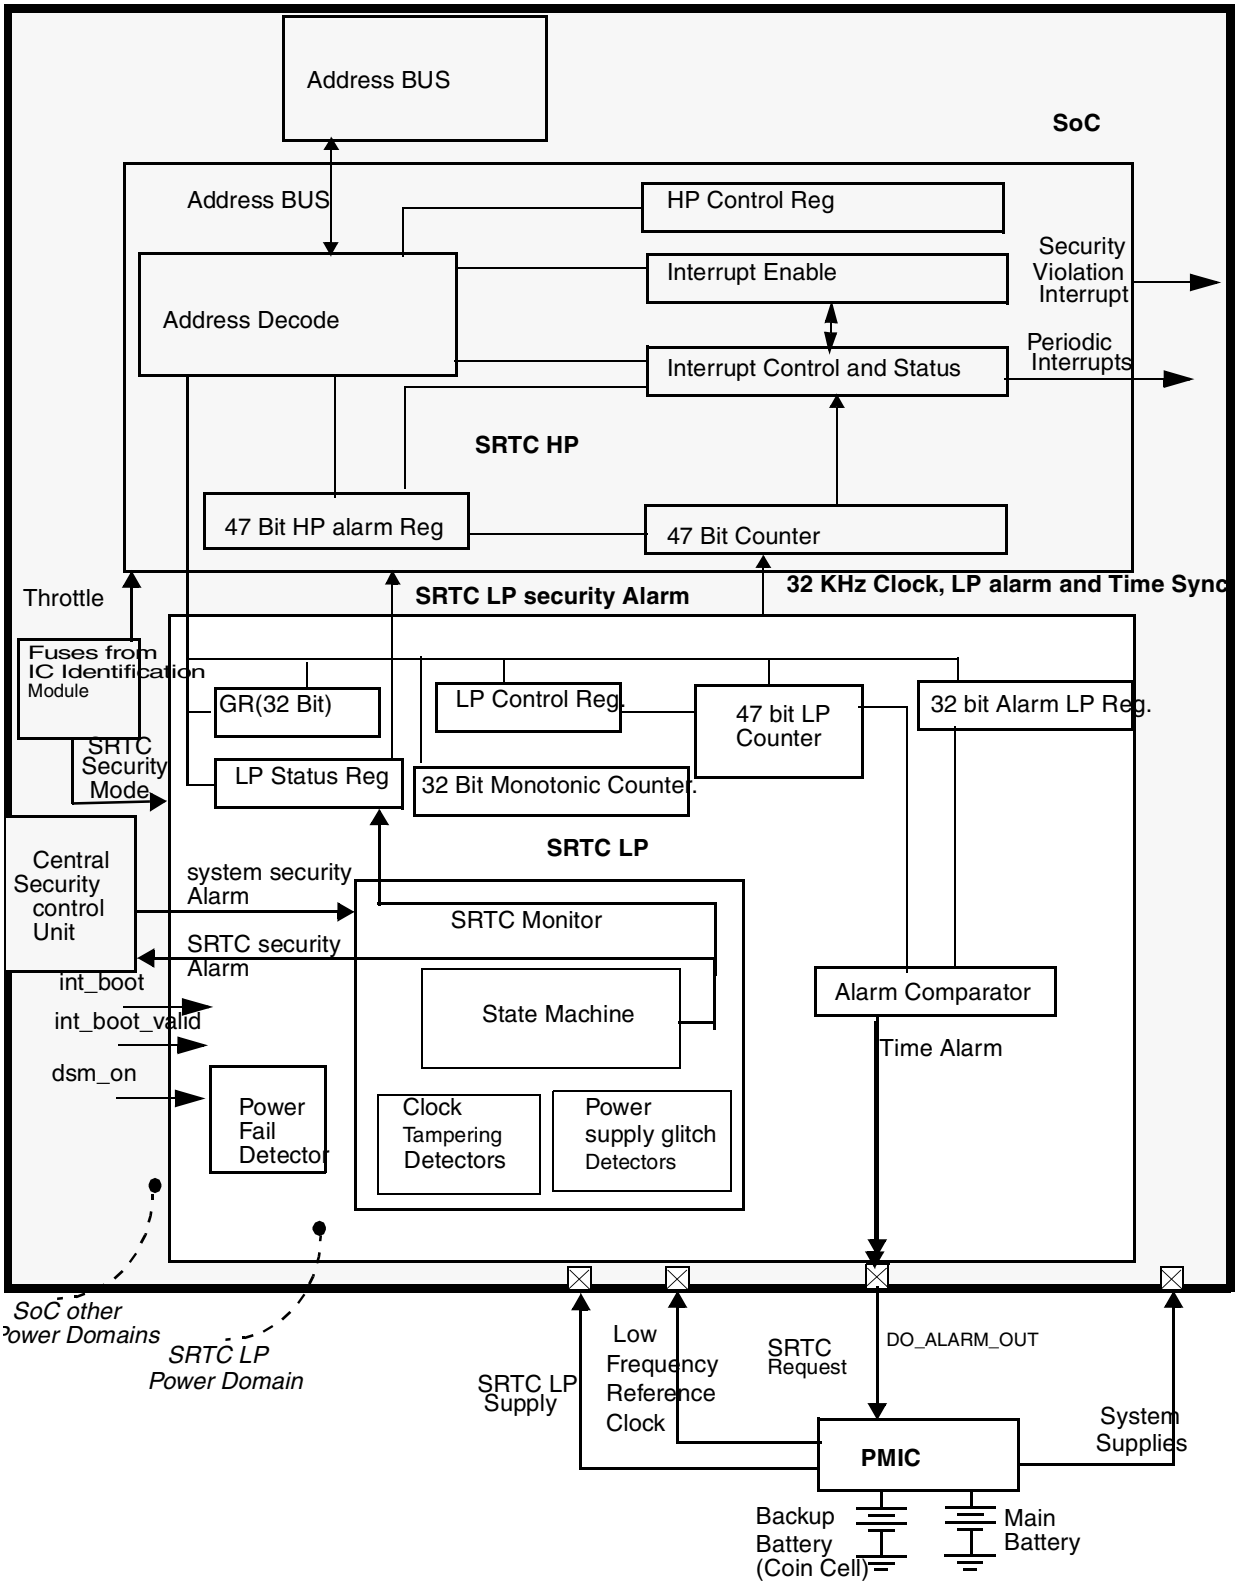

Figure 55-1. Block Diagram

55.1.3 Features

The SRTC modules includes the following features:

- Secure 47-bit time counter running on 32.768KHz clock
- Non-secure 47-bit time counter running on 32.768KHz clock
- User mode protection and/or ARM's TrustZone mode protection-
  SRTC secured registers cannot be configured by non-secured SW . A dedicated control bit can allow non-secured SW to update the secured registers. This bit can be set only by secured SW
  In any case, SRTC secured registers cannot be configured when SRTC is locked.
- Re-programming protection:
  - SRTC time cannot be altered after SRTC is locked (when SRTC set to the appropriate security mode)
  - SRTC cannot be disabled after SRTC is locked (when SRTC set to the appropriate security mode)
- Power loss protection:
  - Separated power supply
  - Accurate continuous time is kept during power down system states and main power source losses
  - In the event of a total power loss (main power source and backup power source), SRTC time read is invalidated
  - In the event of unstable voltage power source, SRTC time read is invalidated
  - In the event of low voltage power source that disrupts normal time counting, SRTC time read is invalidated
- Clock source protection:
  - Directly connects to a low frequency crystal (32.768 kHz) or to a PMIC 32.768 kHz clock source
  - In the event that SRTC frequency drops, SRTC time read is invalidated
- SRTC time can be invalidated by a system security alarm
- SRTC can assert a system security alarm and fast interrupt request to alert the processor that time read was invalidated
- Programmable secure 32-bit alarm with interrupt (alarm of the secure- LP section). In case of system power up mode, this alarm generates interrupt to alert the processor. In case of system power down mode, this alarm alert the power management IC (PMIC) via an external pin to instruct the PMIC to power up the system. Note that this feature does not require any PMIC special support. This signal can be connected to an on-board power on button circuit.
- Programmable non-secure 47-bit alarm with interrupt (alarm of the non-secure, HP, section)
- Periodic non-secure alarm with interrupt
- Secured monotonic counter
- General purpose "always powered" registers

- Ultra low power consumption. SRTC LP power consumption during system power down state is less than 3 µA.(TYP)
- Separate calibration logic for 47 bit HP and LP counters

55.1.4 Modes of Operations

The SRTC has three functional modes, defined by IC Identification Module dedicated fuses, and can be found in one of four states.

The SRTC modes are as follows.

- Mode #1—High Security
- Mode #2—Medium Security
- Mode #3—Low Security

SRTC states are defined as follows.

- “Initialization”—SRTC is powered up for the first time or after system POR.
- “Non valid”—SRTC time is not set, time read is not authenticated
- “Valid”—Valid time was set, time read is authentic

NOTE

For detailed information about the SRTC, contact your Freescale representive.

Chapter 56
Synchronous Serial Interface (SSI)

This chapter describes the Synchronous Serial Interface (SSI). It discusses the architecture, the programming model, the operating modes, and initialization of SSI.

56.1 Overview

The SSI is a full-duplex, serial port that allows the chip to communicate with a variety of serial devices. These serial devices can be standard CODer-DECoder (CODECs), Digital Signal Processors (DSPs), microprocessors, peripherals, and popular industry audio CODECs that implement the inter-IC sound bus standard (I^2S) and Intel AC97 standard.

SSI is typically used to transfer samples in a periodic manner. The SSI consists of independent transmitter and receiver sections with independent clock generation and frame synchronization.

See Figure 56-1 for illustration of the block diagram for the SSI. It consists of control registers to set up the port, status register, separate transmit and receive circuits with FIFO registers, and separate serial clock and frame sync generation for the transmit and receive sections. The second set of Tx and Rx FIFOs, replicates the logic used for the first set of FIFOs.

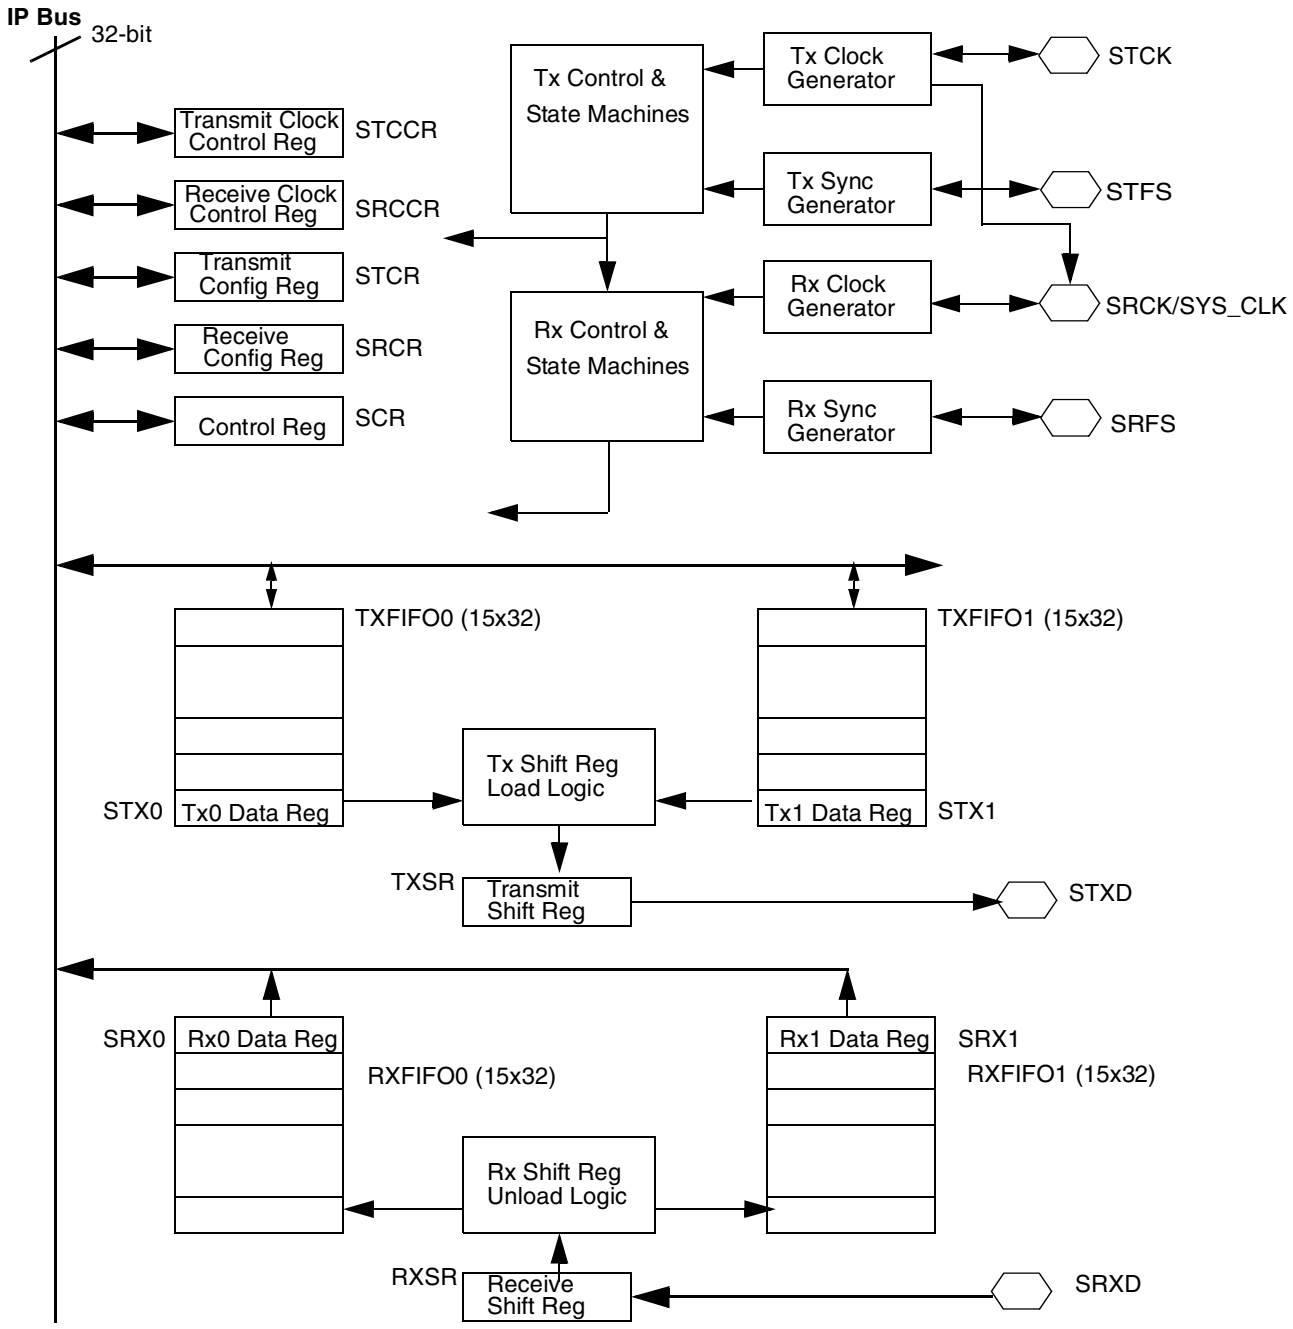

Figure 56-1. SSI Block Diagram

56.1.1 Features

The SSI includes the following features:

- Independent (asynchronous) or shared (synchronous) transmit and receive sections with separate or shared internal/external clocks and frame syncs, operating in Master or Slave mode.
- Normal mode operation using frame sync

- Network mode operation allowing multiple devices to share the port with as many as thirty-two time slots
- Gated Clock mode operation requiring no frame sync
- Two sets of Transmit and Receive FIFOs. Each of the four FIFOs is 15 × 32 bits. The two sets of Tx/Rx FIFOs can be used in Network mode to provide two independent channels for transmission and reception
- Programmable data interface modes such like I2S, LSB, MSB aligned
- Programmable word length (8, 10, 12, 16, 18, 20, 22 or 24 bits)
- Program options for frame sync and clock generation
- Programmable I2S modes (Master, Slave or Normal). Oversampling clock, ccm_ssi_clk available as output from SRCK in I2S Master mode
- AC97 support
- Completely separate clock and frame sync selections for the receive and transmit sections. In AC97 standard, the clock is taken from an external source and frame sync is generated internally.
- External ccm_ssi_clk input for use in I2S Master mode. Programmable oversampling clock (ccm_ssi_clk) of the sampling frequency available as output in master mode at SRCK, when operated in sync mode.
- Programmable internal clock divider
- Time Slot Mask Registers for reduced CPU overhead (for Tx and Rx both)
- SSI power-down feature
- Programmable wait states for CPU accesses
- IP Interface for register accesses, compliant to SRS 3.0.2 standard

56.1.2 Modes of Operation

SSI has the following basic operating modes.

- Normal mode
  - — Asynchronous protocol
  - — Synchronous protocol
- Network mode
  - — Asynchronous protocol
  - — Synchronous protocol
- Gated Clock mode
  - — Synchronous protocol only

These modes can be programmed by several bits in the SSI control registers. See Table 56-1 for the list of SSI operating modes and some of the typical applications in which they can be used:

Table 56-1. SSI Operating Modes

TX, RX Sections	Serial Clock	Mode	Typical Application
Asynchronous	Continuous	Normal	Multiple synchronous CODECs
Asynchronous	Continuous	Network	TDM CODEC or DSP networks
Synchronous	Continuous	Normal	Multiple synchronous CODECs
Synchronous	Continuous	Network	TDM CODEC or DSP network
Synchronous	Gated	Normal	SPI-type devices; DSP to MCU

The transmit and receive sections of the SSI can be synchronous or asynchronous. In Synchronous mode, the transmitter and the receiver use a common clock and frame synchronization signal. Masking of slots for Transmit and Receive section can differ in synchronous mode. Also the shifting of data in independent and for receive section depends on RXBIT0 and RSHFD bits in SRCR register. In Asynchronous mode, the transmitter and receiver each has its own clock and frame synchronization signals.

Normal or Network mode can be selected. In Normal mode, the SSI functions with one data word of I/O per frame. In Network mode, any number from two to thirty-two data words of I/O per frame can be used. Network mode is typically used in star time division multiplex networks with other processors or CODECs, allowing interface to time division multiplexed networks without additional logic. Gated clock mode option can be selected in Normal synchronous mode only. During Gated-mode the clock is not-continuous and runs only during data-transmission. These distinctions result in the basic operating modes that allow the SSI to communicate with a wide variety of devices.

The SSI supports both Normal and Network modes, and these can be selected independently of whether the transmitter and receiver are synchronous or asynchronous. Typically these protocols are used in a periodic manner, where data is transferred at regular intervals, such as at the sampling rate of an external CODEC. Both modes use the concept of a frame. The beginning of the frame is marked with a frame sync when programmed with continuous clock. The frame sync occurs at a periodic interval. The length of the frame is determined by the DC[4:0] bits in either the SRCCR or STCCR register, depending on whether data is being transmitted or received. The number of words transferred per frame depends on the mode of the SSI.

In Normal mode, one data word is transferred per frame. In Network mode, the frame is divided into anywhere between two and thirty-two time slots, where in each time slot one data word can optionally be transferred.

Apart from the above basic modes of operation, SSI supports the following modes which require some specific programming.

- I2S mode
- AC97 mode
  - AC97 Fixed mode
  - AC97 Variable mode

In (non-I2S) slave modes (external frame sync), the programmed word length setting of the SSI should be equal to the word length setting of the master. In I2S slave mode, the programmed word length setting of the SSI can be lesser than or equal to the word length setting of the I2S master (external CODEC).

In slave modes, the programmed frame length setting (DC bits) of the SSI can be lesser than or equal to the frame length setting of the master (external CODEC).

The following sections provide detailed descriptions of the above modes.

56.1.2.1 Normal Mode

Normal mode is the simplest mode of the SSI. It is used to transfer data in one time slot per frame. A time slot is a unit of data and the WL[3:0] bits define the number of bits in a time slot. In Continuous Clock mode, a frame sync occurs at the beginning of each frame. The length of the frame is determined by the following factors:

- The period of the Serial Bit Clock (DIV2, PSR, PM[7:0] bits for internal clock or the frequency of the external clock on the STCK port)
- The number of bits per time slot (WL[3:0] bits)
- The number of time slots per frame (DC[4:0] bits)

If Normal mode is configured with more than one time slot per frame, data is transferred only in the first time slot. No data is transferred in subsequent time slots. In Normal mode, DC[4:0] values corresponding to more than a single time slot in a frame, only results in lengthening of the frame.

56.1.2.1.1 Normal Mode Transmit

The conditions for data transmission from the SSI in Normal mode are:

- SSI Enabled (SSIEN = 1)
- Write data to Transmit Data Register (STX)
- Transmitter Enabled (TE = 1)
- Frame sync active (for continuous clock case)
- Bit clock begins

When the above conditions occur in Normal mode, the next data word is transferred into the Transmit Shift Register (TXSR) from the Transmit Data Register 0 (STX0), or from the Transmit FIFO 0 Register, if transmit FIFO 0 is enabled. The new data word is transmitted on arrival of frame-sync preceded by clocks in continuous clock mode. In gated external mode, data word in transmitted on arrival of frame-sync. In gated-internal mode, data word is transmitted whenever data is available in Tx-FIFO.

If Transmit FIFO 0 is not enabled and the transmit data register empty enable (TDE0_EN) and transmit interrupt enable (TIE) bits are set, transmit interrupt occurs when the word in SSI_STX0 is shifted to Transmit Shift (TXSR) register for shifting.

If Transmit FIFO 0 is enabled and the transmit fifo full enable (TFF0_EN) and transmit interrupt enable (TIE) bits are set, transmit interrupt occurs when the number of empty slots in Transmit Fifo 0 exceed or are equal to the selected threshold value i.e. Transmit Fifo 0 Watermark (TFWM0) value. If transmit FIFO

0 is enabled and filled with data, 15 data words can be transferred before the core must write new data to the STX0 register.

The STXD port is disabled except during the data transmission period. For a continuous clock, the optional frame sync output and clock outputs are not disabled, even if both receiver and transmitter are disabled.

56.1.2.1.2 Normal Mode Receive

The conditions for data reception from the SSI are:

- SSI enabled (SSIEN = 1)
- Receiver enabled (RE = 1)
- Frame sync active (for continuous clock case)
- Bit clock begins

With the above conditions in Normal mode with a continuous clock, each time the frame sync signal is generated (or detected) a data word is clocked in. With the above conditions and a gated clock, each time the clock begins, a data word is clocked in.

If Receive FIFO 0 is not enabled and Receive Interrupt enable (RIE) and Received Data 0 Ready enable (RDR0_EN) bits are set, receive interrupt occurs when received data word is transferred from the Receive Shift Register (RXSR) to the Receive Data Register 0 (SRX0) thus setting the Receive Data Ready 0 (RDR0) flag.

If Receive FIFO 0 is enabled, and Receive Interrupt enable (RIE) and Received Fifo 0 full enable (RDR0_EN) bits are set, receive interrupt occurs when the received data word is transferred to the Receive FIFO 0 and Receive FIFO 0 reaches the selected threshold and results in Receive FIFO Full 0 (RFF0) flag to get set.

The core program has to read the data from the Receive Data Register 0 (SRX0) (in case Receive FIFO0 is disabled) before a new data word is transferred from the Receive Shift Register (RXSR), otherwise the Receive Overrun Error 0 (ROE0) bit is set. If receive FIFO 0 is enabled, the Receive Overrun Error 0 (ROE0) bit is set when the Receive FIFO 0 data level reaches the selected threshold and a new data word is ready to be transferred to the Receive FIFO 0.

See Figure 56-2 for illustration of transmitter and receiver timing for an 8-bit word in the first time slot in Normal mode, continuous clock with a late word length frame sync. The Tx Data register is loaded with the data to be transmitted. On arrival of the clock, this data is transferred to the Transmit Shift Register which gets transmitted on arrival of the frame-sync on the STXD output. Simultaneously, the Receive Shift

Register shifts in the received data available on the SRXD input and at the end of the time slot, this data is transferred to the Rx Data Register.

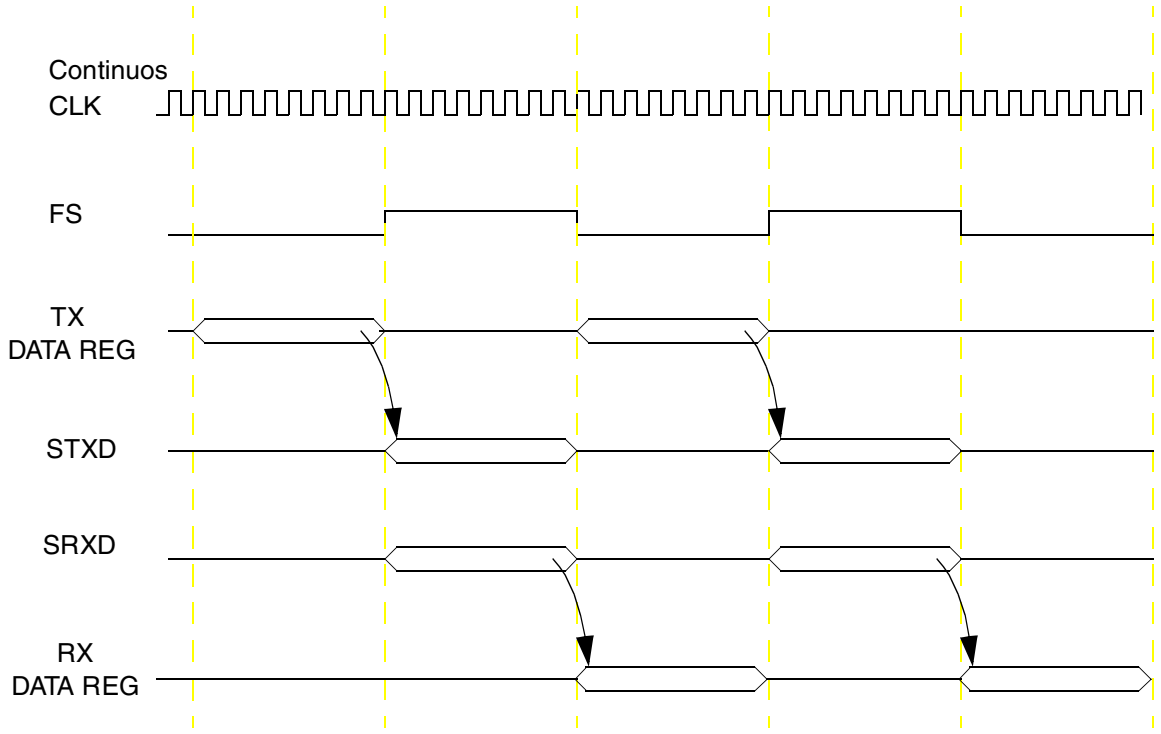

Figure 56-2. Normal Mode Timing - Continuous Clock

Figure 56-3 shows a similar case for internal (SSI generates clock) gated clock mode, and Figure 56-4 shows a case for external (SSI receives clock) gated clock mode.

NOTE

A pull-down resistor is required in the gated clock case because the clock port is disabled between transmissions.

The Tx Data register is loaded with the data to be transmitted. On arrival of the clock, this data is transferred to the transmit shift register which gets transmitted on arrival of the frame-sync on the STXD output. Simultaneously, the receive shift register shifts in the received data available on the SRXD input and at the end of the time slot, this data is transferred to the Rx Data Register. In case of Internal Gated clock mode, the Tx Data line and clock output port are put in the high-impedance state at the end of transmission of the last bit (at the completion of the complete clock cycle), whereas in External Gated clock mode, the Tx Data line is tri-stated at the last inactive edge of the incoming bit clock (during the last bit in a data word).

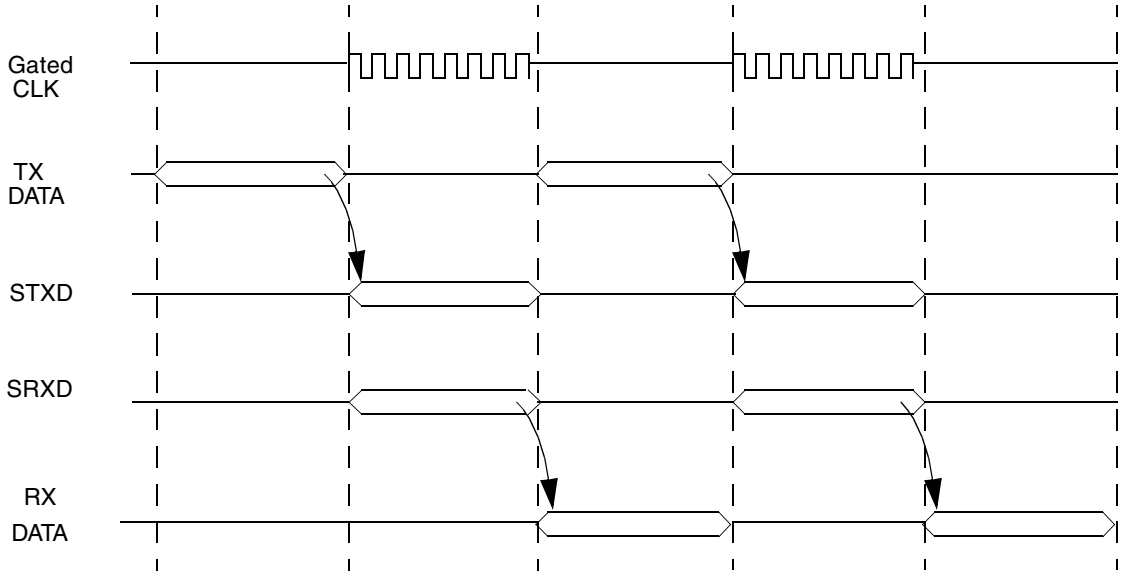

Figure 56-3. Normal Mode Timing—Internal Gated Clock

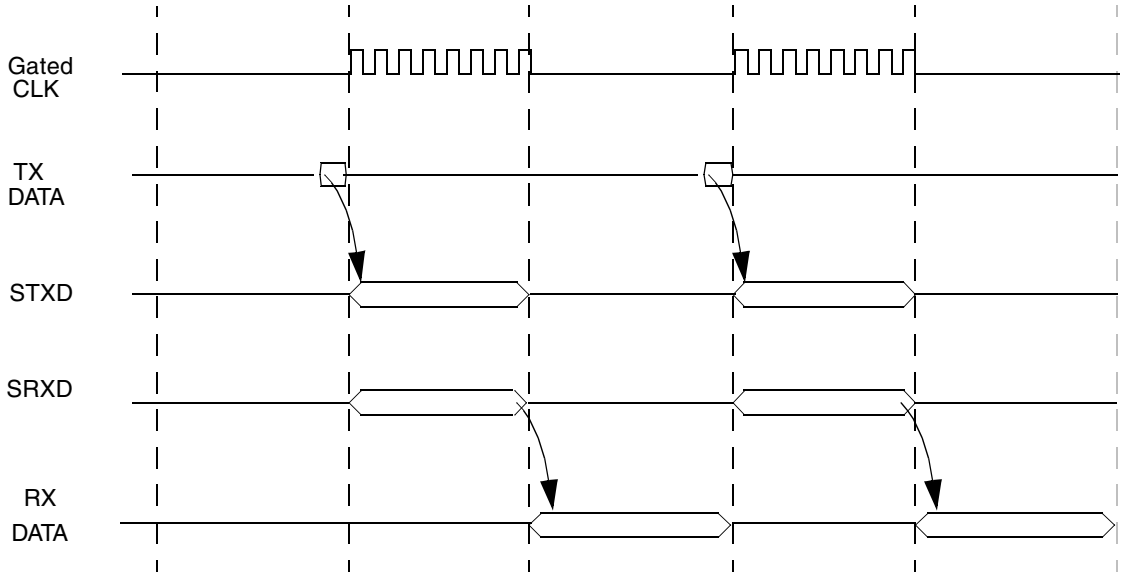

Figure 56-4. Normal Mode Timing—External Gated Clock

56.1.2.2 Network Mode

Network mode is used for creating a Time Division Multiplexed (TDM) network, such as a TDM CODEC network or a network of DSPs. In Continuous Clock mode, a frame sync occurs at the beginning of each frame. In this mode, the frame is divided into more than one time slot. During each time slot, one data word can be transferred. Each time slot is then assigned to an appropriate CODEC or DSP on the network. The DSP can be a master device that controls its own private network, or a slave device that is connected to an existing TDM network and occupies a few time slots.

The frame sync signal indicates the beginning of a new data frame. Each data frame is divided into time slots and transmission and/or reception of one data word can occur in each time slot (rather than in just the frame sync time slot as in Normal mode). The frame rate dividers, controlled by the DC[4:0] bits, select two to thirty-two time slots per frame. The length of the frame is determined by the following factors:

- The period of the serial bit clock (PSR, PM[7:0] bits for internal clock, or the frequency of the external clock on the STCK port)
- The number of bits per sample (WL[3:0] bits)
- The number of time slots per frame (DC[4:0] bits)

In Network mode, data can be transmitted in any time slot. The distinction of the Network mode is that each time slot is identified with respect to the frame sync (data word time). This time slot identification allows the option of transmitting data during the time slot by writing to the STX registers or ignoring the time slot as determined by STMSK register bits. The receiver is treated in the same manner and received data is only transferred to the receive data register/fifo if the corresponding time slot is enabled (through SRMSK).

By utilizing the STMSK and SRMSK registers, software only has to service the SSI during valid time slots. This eliminates any overhead associated with unused time slots. Refer to Section 56.3.3.20, SSI Transmit Time Slot Mask Register (STMSK)" and Section 56.3.3.21, SSI Receive Time Slot Mask Register (SRMSK)" for more information on STMSK and SRMSK.

In the Two-Channel mode of operation, the second set of Transmit and Receive FIFOs and Data Registers are used to create two separate channels. These channels are completely independent, with a their own set of Core interrupts and DMA requests, which are identical to the ones available for the default channel. In this mode, data is transmitted/received in enabled time slots alternately from/to FIFO 0 and FIFO 1, starting from FIFO 0. The first data word is taken from FIFO 0 and transmitted in the first enabled time slot and subsequently, data is loaded from FIFO 1 and FIFO 0 alternately and transmitted. Similarly, the first received data is sent to FIFO 0 and subsequent data is sent to FIFO 1 and FIFO 0 alternately. Time slots can be selected through the Transmit and Receive Time Slot Mask registers (STMSK and SRMSK). For using this mode of operation, the TCH_EN bit (SCR[8]) needs to be set.

56.1.2.2.1 Network Mode Transmit

The transmit portion of SSI is enabled when the SSIEN and the TE bits in the SCR are both set. However, for continuous clock, when the TE bit is set, the transmitter is enabled only after detection of a new frame sync (transmission starts from the next frame boundary).

Normal start-up sequence for transmission is to perform the following:

1. Enable Network Mode.
2. Enable SSI
3. Write the data to be transmitted to the STX register. This clears the TDE flag
4. Set the TE bit to enable the transmitter on the next frame boundary (for continuous clock case).
5. Enable transmit interrupts.

(Alternatively, the programmer may decide not to transmit in a time slot by configuring the STMSK.) TDE flag is cleared as data is shifted from STX register to TXSR, but the STXD port remains disabled during

the time slots. When the next frame sync is detected or generated (continuous clock), the data word in TXSR and is shifted out (transmitted). When the STX register is empty, the TDE bit is set, which causes a transmitter interrupt (in case the FIFO is disabled) to be sent if the TIE bit is set. Software can poll the TDE bit or use interrupts to reload the STX register with new data for the next time slot. Failing to reload the STX register before the TXSR is finished shifting (empty) causes a transmitter underrun and the TUE error bit is set. In case the FIFO is enabled, the TFE flag is set in accordance with the watermark setting and this flag causes the transmitter interrupt to occur.

The operation of clearing the TE bit disables the transmitter after completion of transmission of the current frame. Setting the TE bit enables transmission from the next frame. During that time the STXD port is disabled. The TE bit should be cleared after the TDE bit is set to ensure that all pending data is transmitted.

To summarize, the Network mode transmitter generates interrupts every enabled time slot (when FIFO is disabled) and requires the core program to respond to each enabled time slot in one of the following ways:

- Write data in data register to enable transmission in the next time slot.
- Configure the time slot register to disable transmission in the next time slot (unless time slot is already masked by STMSK register bit).
- Do nothing—transmit underrun occurs at the beginning of the next time slot and the previous data is re-transmitted.

In the Two-Channel mode of operation, both the channels (Data Registers, FIFOs, Interrupts and DMA requests) operate in the same manner, as described above. The only difference in case of the second channel is that the Interrupts related to this channel are generated only in case this mode of operation is selected (TDE1 is low by default).

56.1.2.2.2 Network Mode Receive

The receiver portion of the SSI is enabled when both the SSIEN and the RE bits in the SCR are set. However, the receive enable only takes place during that time slot if RE is enabled before the second to last bit of the word. If the RE bit is cleared, the receiver is disabled at the end of the current frame. SSI is capable of finding the start of the next frame automatically. When the word is completely received, it is transferred to the SRX register, which sets the RDR bit (Receive Data Ready). Setting the RDR bit causes a receive interrupt to occur if the receiver interrupt is enabled (the RIE bit is set) and (Receive data ready enable) RDR_EN bit is set. The second data word (second time slot in the frame) begins shifting in immediately after the transfer of the first data word to the SRX register. The core program has to read the data from the Receive Data Register (which clears RDR) before the second data word is completely received (ready to transfer to RX data register) or a receive overrun error occurs (the ROE bit is set).

An interrupt can occur after the reception of each enabled data word or the programmer can poll the RDR flag. The core program response can be one of the following:

- Read RX and use the data.
- Read RX and ignore the data.
- Do nothing—the receiver overrun exception occurs at the end of the current time slot.

NOTE

For a continuous clock, the optional frame sync output and clock output signals are not affected, even if the transmitter or receiver is disabled. TE and RE do not disable the bit clock or the frame sync generation. To disable the bit clock and the frame sync generation, the SSIEN bit in the SCR can be cleared or TFR_CLK_DIS/RFR_CLK_DIS bits can be set or the port control logic external to the SSI (for example, in the IOMUX) can be reconfigured.

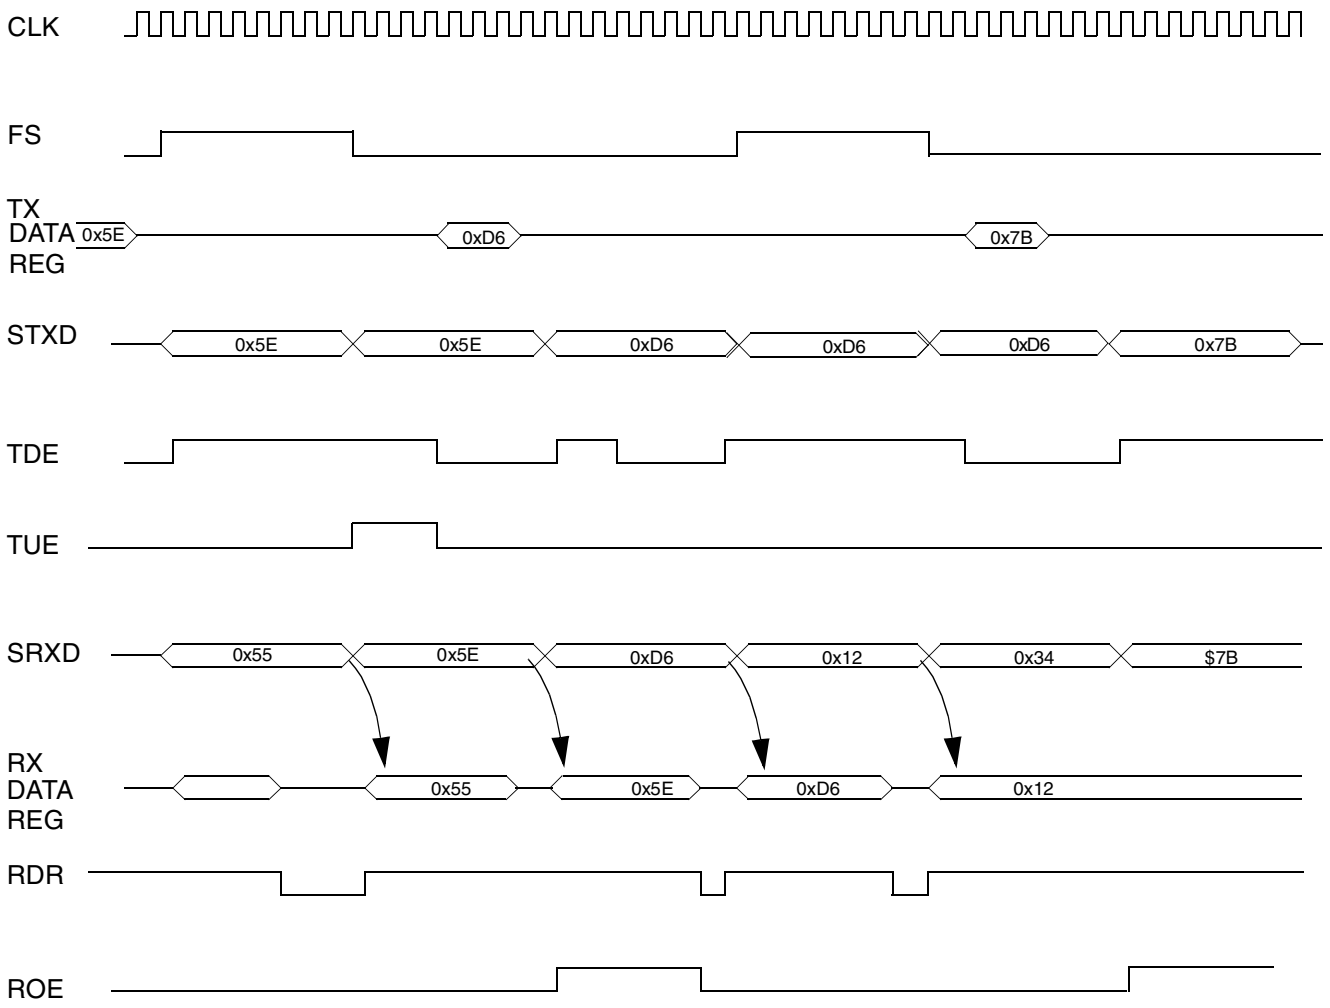
In the Two-Channel mode of operation, both the channels (Data Registers, FIFOs, Interrupts and DMA requests) operate in the same manner, as described above. The only difference in case of the second channel is that the Interrupts related to this channel are generated only in case this mode of operation is selected.

The transmitter and receiver timing for an 8-bit word with continuous clock, FIFO disabled, three words per frame sync in Network mode is shown in Figure 56-5 (“Network Mode Timing - Continuous Clock”).

NOTE

The transmitter repeats the value 0x5E because of an underrun condition

For the receive section, data received on the SRXD pin gets transferred to the Rx Data register at the end of each time slot. If the FIFO is disabled, the RDR flag gets set and causes a receiver interrupt if RE, RIE and RDR_EN bits are set. If the FIFO is enabled, then the RFF flag is used for interrupt generation (this flag is set in accordance with the watermark settings). Here all time slots are enabled. The receive data ready flag is set after reception of the first data (0x55). Since the flag is not cleared (Rx Data Register is not read by core), the Receive Overrun Error (ROE) flag is set on reception of the next data (0x5E). ROE flag is cleared on writing ‘1’ to the corresponding interrupt status bit in SSI Status Register.



Note: Processor must write '1' to the corresponding TUE/ROE Interrupt status bit in SISR to clear TUE/ROE Interrupt.

Figure 56-5. Network Mode Timing—Continuous Clock

56.1.2.3 Gated Clock Mode

Gated Clock mode is often used to hook up to SPI-type interfaces on Microcontroller Units (MCUs) or external peripheral chips. In Gated Clock mode, the presence of the clock indicates that valid data is on the STXD or SRXD ports. For this reason, no frame sync is needed in this mode. Once transmission of data has completed, the clock is pulled to the inactive state. Gated clocks are allowed for both the transmit and receive sections with either internal or external clock in Normal mode. Gated clocks are not allowed in Network mode. See Table 56-5 ("Clock Pin Configurations") for SSI configuration for gated-mode operation.

The clock runs when the TE bit and/or the RE bit are appropriately enabled. For the case of internally generated clock, all internal bit clocks, word clocks, and frame clocks continue to operate. When a valid

time slot occurs (such as the first time slot in Normal mode), the internal bit clock is enabled onto the appropriate clock port. This allows data to be transferred out in periodic intervals in Gated Clock mode. With an external clock, the SSI waits for a clock signal to be received. Once the clock begins, valid data is shifted in. Care should be taken to clear all DC bits (0x00000) when SSI is used in Gated mode. In gated mode of operation the TFS, RFS, TLS, RLS, TFRC, and RFRC bits of AISR register are not generated.

For Gated clock operated in external clock mode, a proper clock signalling must be applied to the SSI STCK in order for it to function properly. When TSCKP is 0, CLK_IST value should be 1. When TSCKP is 1, CLK_IST value should be 0. If the SSI uses rising edge transition to clock data (TSCKP=0) and the falling edge transition to latch data (RSCKP=0), the clock must be in an active low state when idle. If the SSI uses falling edge transition to clock data (TSCKP=1) and the rising edge transition to latch data (RSCKP=1), the clock must be in a active high state when idle. Figure 56-6 through Figure 56-9 illustrate the different edge clocking/latching.

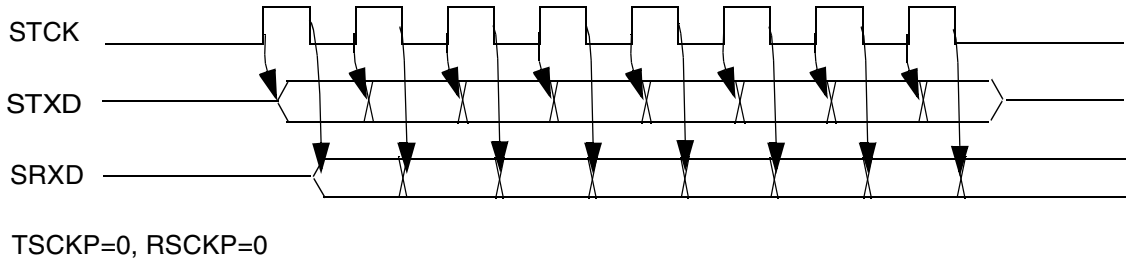


Figure 56-6. Internal Gated Mode Timing—Rising Edge Clocking/Falling Edge Latching

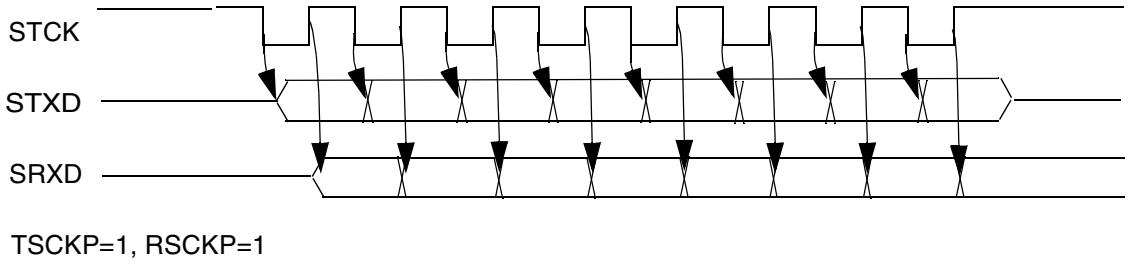

Figure 56-7. Internal Gated Mode Timing—Falling Edge Clocking/Rising Edge Latching

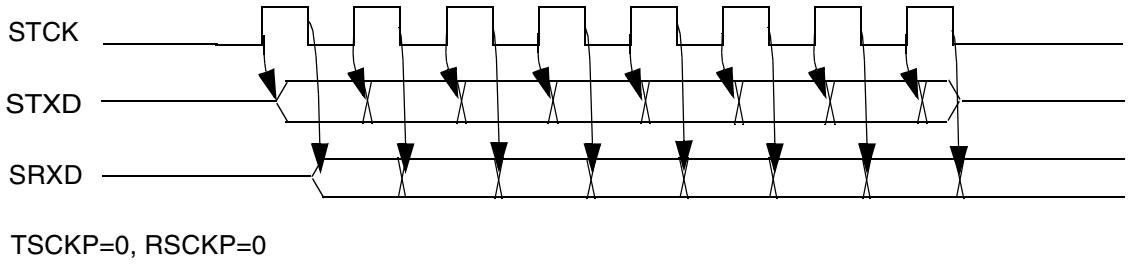

Figure 56-8. External Gated Mode Timing—Rising Edge Clocking/Falling Edge Latching

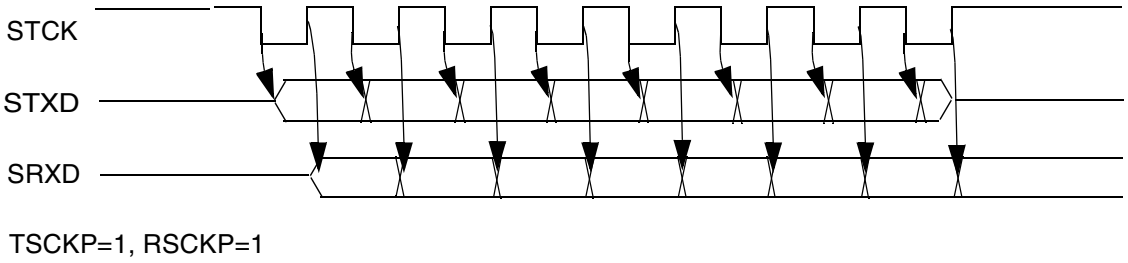

Figure 56-9. External Gated Mode Timing—Falling Edge Clocking/Rising Edge Latching

NOTE

- The bit clock ports must be kept free of timing glitches. If a single glitch occurs, all ensuing transfers will be out of synchronization.
- In case of External Gated Mode, even though the Tx Data line is put in the high-impedance state at the last non-active edge of the bit clock, the round trip delay should be sufficient to take care of hold time requirements at the external receiver.

56.1.2.4 I2S Mode

The SSI is compliant to I^2S bus specification from Philips Semiconductors (February 1986, Revised June 5, 1996). See Figure 56-10 for an illustration of the basic I2S protocol timing.

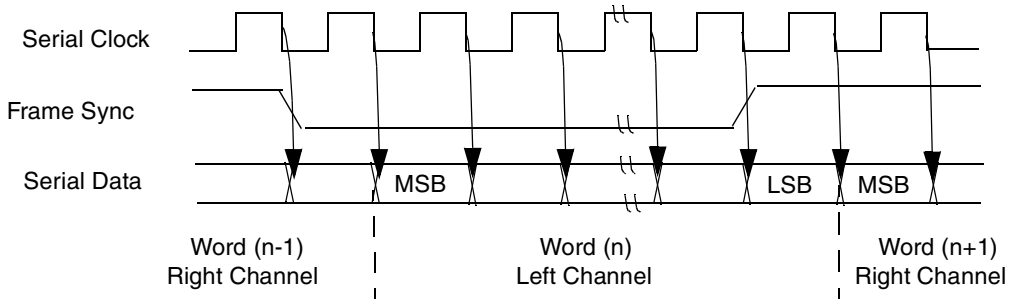

Figure 56-10. I^2S Mode Timing—Serial Clock, Frame Sync and Serial Data

Select I^2S mode using the options listed in Table 56-2.

Table 56-2. I^2S Mode Selection

I^2S_MODE[1]	I2S_MODE[0]	Mode Type
0	0	Normal mode
0	1	I2S master mode
1	0	I2S slave mode
1	1	Normal mode

In normal mode operation, no register bits are forced to any particular state internally and the user can program the SSI to work in any operating condition.

When I2S modes are entered (I2S master (01) or I2S slave (10)), the following settings are recommended:

- Sync mode (SCR[4] =1)
- Tx shift direction: MSB transmitted first (STCR[4]=0)
- Rx shift direction: MSB received first (SRCR[4]=0)
- Tx data clocked at falling edge of the clock (STCR[3]=1)
- Rx data latched at rising edge of the clock (SRCR[3]=1)
- Tx frame sync active low (STCR[2]=1)
- Rx frame sync active low (SRCR[2]=1)
- Tx frame sync initiated one bit before data is transmitted (STCR[0]=1)
- Rx frame sync initiated one bit before data is received (SRCR[0]=1)
- TX Frame Rate should be 2 i.e. (STCCR[12:8] = 1)
- RX Frame Rate should be 2 i.e. (SRCCR[12:8] = 1)

In I^2S master mode(SCR[6:5]=01), the following additional settings are recommended:

- TXDIR bit (STCR[5]) set to 1 to select internal generated bit clock
- TFDIR bit (STCR[6]) set to 1 to select internal generated frame sync

In I^2S master mode(SCR[6:5]=01), the following settings are internally overridden by the hardware:

- Network mode is selected (SCR[3]=1)
- Tx frame sync length set to one-word-long-frame (STCR[1]=0)
- Rx frame sync length set to one-word-long-frame (SRCR[1]=0)
- Tx shifting with regard to bit 0 of TXSR (STCR[9]=1)
- Rx shifting with regard to bit 0 of RXSR (SRCR[9]=1)

The user needs to set the following control bits to configure the bit clock and frame sync:

- PM (STCCR[7:0])
- PSR (STCCR[17])
- DIV2 (STCCR[18]
- WL (STCCR[16:13]
- DC (STCCR[12:8])

The word length is fixed to 32 in I^2S Master mode and the WL bits determine the number of bits that will contain valid data (out of the 32 transmitted/received bits in each channel). The fixing of word duration as 32 simplifies the relation between oversampling clock (ccm_ssi_clk) and Frame Sync (ccm_ssi_clk becomes an integer multiple of Frame Sync).

In I^2S slave mode (SCR[6:5]=10), the following additional settings are recommended:

- TXDIR bit (STCR[5]) set to 0 to select external generated bit clock
- TFDIR bit (STCR[6]) set to 0 to select external generated frame sync

In I^2S slave mode (SCR[6:5]=10), the following settings are internally overridden by the hardware:

- Normal mode is selected (SCR[3]=0)
- Tx frame sync length set to one-bit-long-frame (STCR[1]=1)
- Rx frame sync length set to one-bit-long-frame (SRCR[1]=1)
- Tx shifting with regard to bit 0 of TXSR (STCR[9]=1)
- Rx shifting with regard to bit 0 of RXSR (SRCR[9]=1)

The user needs to set the following control bits to configure the data transmission:

- WL (STCCR[16:13])
- DC (STCCR[12:8])

The word length is variable in I^2S slave mode and the WL bits determine the number of bits that will contain valid data. The actual word length is determined by the external CODEC. The external I^2S Master still sends frame sync according to the I^2S protocol (early, word wide and active low), the SSI internally operates so that each frame sync transition is the start of a new frame (the WL bits determine the number of bits to be transmitted/received). After one data word has been transferred, the SSI waits for the next frame sync transition to start operation in the next time slot. Transmit (STMSK) and receive (SRMSK) mask bits should not be used in I^2S Slave mode of operation.

56.1.2.5 AC97 Mode

In AC97 mode of operation, the SSI transmits a 16-bit Tag Slot at the start of a frame and the rest of the slots (in that frame) are all 20-bits wide. The same sequence is followed while receiving data. Refer to the AC97 specification for details regarding transmit and receive sequences and data formats.

Note that the SSI only has one RxDATA pin so the SSI can only support one codec. Secondary codecs are not supported.

When AC97 mode is enabled, the following settings are internally overridden by the hardware. The programmed register values are not changed by entering AC97 mode but they no longer apply to the module's operation. Writing to the programmed register fields will update their values; these updates can be seen by reading back the register fields. However, these settings will not take effect until AC97 mode is turned off.

The register bits within the bracket are the equivalent settings:

- Sync mode is entered (SCR[4] =1)
- Network mode is selected (SCR[3]=1)
- Tx shift direction is MSB transmitted first (STCR[4]=0)
- Rx shift direction is MSB received first (SRCR[4]=0)
- Tx data is clocked at rising edge of the clock (STCR[3]=0)
- Rx data is latched at falling edge of the clock (SRCR[3]=0)
- Tx frame sync is active high (STCR[2]=0)
- Rx frame sync is active high (SRCR[2]=0)
- Tx frame sync length is one-word-long-frame (STCR[1]=0)

- Rx frame sync length is one-word-long-frame (SRCR[1]=0)
- Tx frame sync initiated one bit before data is transmitted (STCR[0]=1)
- Rx frame sync initiated one bit before data is received (SRCR[0]=1)
- Tx shifting w.r.t. bit 0 of TXSR (STCR[9]=1)
- Rx shifting w.r.t. bit 0 of RXSR (SRCR[9]=1)
- Tx FIFO is enabled (STCR[7]=1)
- Rx FIFO is enabled (SRCR[7]=1)
- TFDIR bit (STCR[6]) is forced to 1 internally to select internal generated frame sync
- TXDIR bit (STCR[5]) is forced to 0 internally to select external generated bit clock

Any alteration of these bits individually will not affect the operational conditions of the SSI unless AC97 mode is deselected.

Hence, the only control bits needed to be set by the user to configure the data transmission/reception are the WL (STCCR[16:13]) and DC (STCCR[12:8]) bits. In AC97 mode, the WL bits can only legally take the values corresponding to 16-bit (truncated data) or 20-bit time slots. In case WL bits are set to select 16-bit time slots, the SSI pads the transmit data (four least significant bits) with zeros and while receiving, stores only the most significant 16 bits in the Rx FIFO.

Follow this sequence to program the SSI to work in AC97 mode:

1. Program the WL bits to a value corresponding to either 16 or 20 bits. The WL bit setting is only for the data portion of the AC97 frame (Slots #3 through #12). The Tag slot (Slot #0) is always 16 bits wide and the Command Address and Command Data slots (Slots #1 and #2) are always 20 bits wide.
2. Select the number of time slots by programming the DC bits. For AC97 operation, DC bits should be set to a value of 0xC, resulting in 13 time slots per frame.
3. Write data to be transmitted, in Tx FIFO 0 (through Tx Data Register 0)
4. Program the FV, TIF, RD, WR, and FRDIV bits in SACNT register
5. Update the contents of SACADD, SACDAT, and SATAG (for Fixed mode only) registers
6. Enable the AC97 mode of operation (AC97EN bit in SACNT register)

Once the SSI starts transmitting and receiving data (after being configured in AC97 mode), the programmer needs to service the interrupts, as and when they are raised (updates to command address/data or tag registers, reading of received data and writing more data for transmission). Further details regarding fixed and variable mode implementation are provided in the following sections.

While using AC97 in Two-Channel Mode (TCH_EN=1), it is recommended that the received tag is not stored in the Rx FIFO (TIF=0). In case the programmer needs to update the SATAG register and also issue a RD/WR command (in a single frame), it is recommended that the SATAG register be updated prior to issuing a RD/WR command.

56.1.2.5.1 AC97 Fixed Mode (SACNT[1]=0)

In fixed mode of operation, SSI transmits in accordance with the Frame Rate Divider bits which decides the number of frames for which the SSI should be idle, after operating for one frame.

In a valid frame, TAG Value (written by Core) will be transmitted in Slot #0, Command Address will be transmitted in Slot #1 in case of RD/WR Command, and Command Data will be transmitted in Slot #2 in case of a WR Command. The data from TX-FIFO is transmitted in Slot #3–Slot #12 depending on the valid slots indicated by the TAG value.

While receiving, bit 15 of the TAG Value (Slot #0) is checked to see if the CODEC is ready. If this bit is set, the frame is received. The received TAG provides the information about Slots containing valid data. The the corresponding TAG bit is valid, the Command Address (Slot #1) and Command Data (Slot #2) values are stored in the corresponding registers. The received data (Slot #3–Slot #12) is then stored in the Rx-FIFO (for valid slots).

56.1.2.5.2 AC97 Variable Mode (SACNT[1]=1)

In Variable Mode, the transmit slots which should contain data in the current frame are determined by SLOTREQ bits received in the previous frame. While receiving, if the CODEC is ready, the frame is received and the SLOTREQ bits (contained in Slot #1) are stored for scheduling transmission in the next frame.

The SACCST, SACCEN, and SACCDIS registers helps in determining which transmit slots are active. This information is used to ensure that SSI does not transmit data for powered-down/inactive channels.

56.1.2.6 External Frame and Clock Operation

When applying external frame sync and clock signals to SSI, there should be at least 4-bit clock cycles between the enabling of the transmit or receive section and the rising edge of the corresponding frame sync signal. The transition of STFS or SRFS should be synchronized with the rising edge of external clock signal, STCK or SRCK.

56.1.2.7 Data Alignment Formats Supported

The SSI supports three data formats in order to provide flexibility with handling data. These formats dictate how data is written to (and read from) the data registers. Therefore, data can appear in different places in STX0/1 and SRX0/1 based on the data format and the number of bits per word. Independent data formats are supported for both the transmitter and receiver (that is, the transmitter and receiver can use different data formats).

The supported data formats are:

- MSB alignment
- LSB alignment
  - — Zero-extended (receive data only)
  - — Sign-extended (receive data only)

With MSB alignment, the most significant byte is bits 31 through 24 of the data register if the word length is larger than or equal to 16 bits. If the word length is less than 16 bits and MSB alignment is chosen, the most significant byte is bits 15 through 8. With LSB alignment, the least significant byte is bits 7 through

0. Data alignment is controlled by the TXBIT0 bit in the STCR and the RXBIT0 bit in the SRCR. See Table 56-3 for the bit assignment for all the data formats supported by the SSI.

Table 56-3. Data Alignment

Format	Bit Number																													
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
8-bit LSB Aligned																									7	6	5	4	3	2	1	0
8-bit MSB Aligned																	7	6	5	4	3	2	1	0								
10-bit LSB Aligned																							9	8	7	6	5	4	3	2	1	0
10-bit MSB Aligned																	9	8	7	6	5	4	3	2	1	0						
12-bit LSB Aligned																					11	10	9	8	7	6	5	4	3	2	1	0
12-bit MSB Aligned																	11	10	9	8	7	6	5	4	3	2	1	0				
16-bit LSB Aligned																	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
16-bit MSB Aligned	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																
18-bit LSB Aligned															17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
18-bit MSB Aligned	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0														
20-bit LSB Aligned													19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
20-bit MSB Aligned	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0												
22-bit LSB Aligned											21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
22-bit MSB Aligned	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0										
24-bit LSB Aligned									23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
24-bit MSB Aligned	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								

In addition, receive data can either be zero-extended or sign-extended if LSB alignment is selected. With zero-extension, all bits above the most significant bit are 0s. This format is useful when data is stored in a pure integer format. With sign-extension, all bits above the most significant bit are equal to the most significant bit. This format is useful when data is stored in a fixed-point integer format (which implies fractional values). Receive data extension is controlled by the RXEXT bit in the SRCR. Transmit data used

with LSB alignment has no concept of sign/zero-extension. Unused bits above the most significant bit are simply ignored.

When configured in I2S or AC97 mode, the SSI forces the selection of LSB alignment. However, RXEXT still permits a choice between zero-extension and sign-extension.

Refer to Section 56.3.3.10, SSI Transmit Configuration Register (STCR)" and Section 56.3.3.11, SSI Receive Configuration Register (SRCR)" for more details on the relevant bits in the STCR and SRCR registers.

56.2 External Signal Description

The Synchronous Serial Interface (SSI) is connected to chip pads through the Digital Audio Mux (AUDMUX) module or directly as well. Refer to the AUDMUX chapter for programming details of various multiplexing options. Table 56-4 shows the signal properties.

Table 56-4. Signal Properties

Name	Port	I/O	Function	Reset State	Pull up
SRCK	—	I/O	Serial Receive Clock	0	Passive
SRFS	—	I/O	Serial Receive Frame Sync	0	Passive
SRXD	—	I	Serial Receive Data	—	—
STCK	—	I/O	Serial Transmit Clock	0	Passive
STFS	—	I/O	Serial Transmit Frame Sync	0	Passive
STXD	—	O	Serial Transmit Data	0	Passive

56.2.1 Detailed Signal Descriptions

This section provides detailed signal descriptions.

56.2.1.1 SRCK—Serial Receive Clock

The SRCK port can be used as either an input or an output. This clock signal is used by the receiver in asynchronous mode and is always continuos. During synchronous mode, the STCK port is used instead for clocking in data. In SSI synchronous modes, this port can be used as an output port for the oversampling clock, (ccm_ssi_clk). In I^2S master mode, this port can be used to output ccm_ssi_clk to external CODEC.

56.2.1.2 SRFS—Serial Receive Frame Sync

The SRFS port can be used as either an input or an output. The frame sync is used by the receiver to synchronize the transfer of data. The frame sync signal can be one bit or one word in length and can occur one bit before the transfer of data or right at the transfer of data. If SRFS is configured as input, the external device should drive SRFS during rising edge of STCK or SRCK.

56.2.1.3 SRXD—Serial Receive Data

The SRXD port is an input and is used to bring serial data into the Receive Data Shift Register.

56.2.1.4 STCK—Serial Transmit Clock

The STCK port can be used as either an input or an output. This clock signal is used by the transmitter and can be either continuous or gated. During Gated Clock mode, data on the STCK port is valid only during the transmission of data, otherwise it is pulled to the inactive state. In Synchronous mode, this port is used by both the transmit and receive sections.

56.2.1.5 STFS—Serial Transmit Frame Sync

The STFS port can be used as either an input or an output. The frame sync is used by the transmitter to synchronize the transfer of data. The frame sync signal can be one bit or one word in length and can occur one bit before the transfer of data or right at the transfer of data. In Synchronous mode, this port is used by both the transmit and receive sections. In Gated Clock mode, frame sync signals are not used. If STFS is configured as input, the external device should drive STFS during rising edge of STCK if TSCKP is +ve edge triggered. The external device should drive STFS during falling edge of STCK if TSCKP is –ve edge triggered.

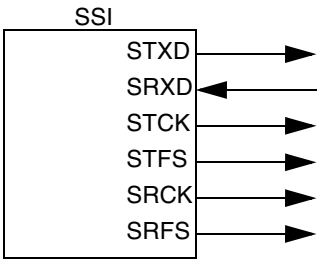
56.2.1.6 STXD—Serial Transmit Data

The STXD port is an output and transmits data from the Serial Transmit Shift Register. The STXD port is an output port when data is being transmitted and is disabled between data word transmissions and on the trailing edge of the bit clock after the last bit of a word is transmitted.

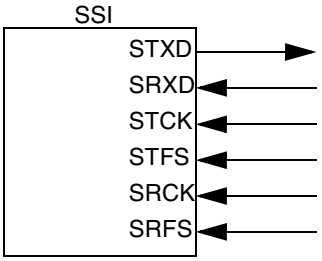
Figure 56-11 (“Asynchronous (SYN=0) SSI Configurations—Continuous Clock”) and Figure 56-12 (“Synchronous SSI Configurations—Continuous and Gated Clock”) show the main SSI configurations. These ports support all transmit and receive functions with continuous or gated clock as shown.

NOTE

Gated clock implementations do not require the use of the frame sync ports (STFS and SRFS).



SSI Internal Continuous Clock for TX/RX (RXDIR=1,TXDIR=1,RFDIR=1,TFDIR=1,SYN=0)



SSI External Continuous Clock for TX/RX (RXDIR=0,TXDIR=0,RFDIR=0,TFDIR=0,SYN=0)

0x43FA+0x0054 (SACCEN)	SSI AC97 Channel Enable Register	W	0x0000_0000	56.3.3.23/56-68
0x43FA+0x0058 (SACCDIS)	SSI AC97 Channel Disable Register	W	0x0000_0000	56.3.3.24/56-69

[1]SSI Test Register is intended for debugging purposes only and is not visible to the end user.
[2]SSI Option Register intended for internal use only and is not visible to the end user.

56.3.2 Register Summary

Figure 56-14 shows the key to the register fields and Table 56-8 shows the register figure conventions.

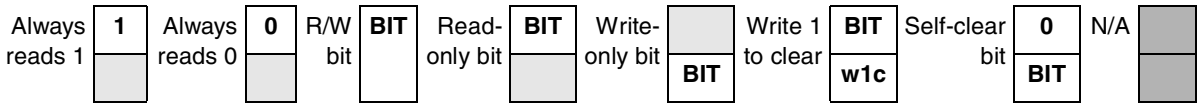

Figure 56-14. Key to Register Fields

Table 56-8. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 56-9 shows the SSI register summary.

Figure 56-16. SSI1 Transmit Data Register

Table 56-10. SSI Transmit Data Register Field Descriptions

Field	Description
31–0 STX0 STX1	SSI Transmit Data. These bits store the data to be transmitted by the SSI. These are implemented as the first word of their respective Tx FIFOs. Data written to these registers is transferred to the Transmit Shift Register (TXSR), when shifting of the previous data is complete. If both FIFOs are in use, data is alternately transferred from STX0 and STX1, to TXSR. Multiple writes to the STX registers will not result in the previous data being over-written by the subsequent data. STX1 can only be used in Two-Channel mode of operation. Protection from over-writing is present irrespective of whether the transmitter is enabled or not. Example 1: If Tx FIFO0 is in use and user writes Data1...Data16 to STX0, Data16 will not over-write Data1. Data1...Data15 are stored in the FIFO while Data16 is discarded. Example 2: If Tx FIFO0 is not in use and user writes Data1, Data2 to STX0, then Data2 will not over-write Data1 and will be discarded.

NOTE

Enable SSI (SSIEN=1) before writing to SSI Transmit Data Registers.

56.3.3.2 SSI Transmit FIFO 0 and 1 Registers

The SSI Transmit FIFO registers are 15 × 32-bit registers. These registers are not directly accessible by the end user. Transmit Shift Register (TXSR) receives its values from these FIFO registers. Transmitted data is first-in-first-out. When the Transmit Interrupt Enable (TIE) bit in the SIER and either of the Transmit FIFO Empty Enable (TFE0 or 1) bits in the SIER are set, the core is interrupted whenever the number of empty slots exceed or are equal to the selected threshold value of corresponding Tx-FIFO.

56.3.3.3 SSI Transmit Shift Register (TXSR)

The SSI Transmit Shift Register (TXSR) is a 24-bit shift register that contains the data being transmitted. This register is not directly accessible by the end user. When a continuous clock is used, data is shifted out to the Serial Transmit Data (STXD) port by the selected (internal/external) bit clock when the associated (internal/external) frame sync is asserted. When a gated clock is used, data is shifted out to the STXD port by the selected (internal/external) gated clock. The Word Length control bits (WL[3:0]) in the STCCR (described in SSI Transmit and Receive Clock Control Registers) determine the number of bits to be shifted out of the TXSR before it is considered empty and can be written to again. This word length can be 8, 10, 12, 16, 18, 20, 22 or 24 bits. The data to be transmitted occupies the most significant portion of the shift register if TXBIT0 is ‘0’, otherwise it occupies the least significant portion. The unused portion of the register is ignored. Data is always shifted out of this register with the Most Significant Bit (MSB) first when the SHFD bit of the STCR is cleared. If this bit is set, the Least Significant Bit (LSB) is shifted out first.

Figure 56-17 through Figure 56-20 show the transmitter loading and shifting operation. The figures show the working for some WL values, the same can be extended for other values.

Figure 56-22. SSI1 Receive Data Register

Table 56-11. SSI_1 Receive Data Register Field Descriptions

Field	Description
31–0 SRX0 SRX1	SSI Receive Data. These bits store the data received by the SSI. These are implemented as the first word of their respective Rx FIFOs. These bits receive data from the RXSR depending on the mode of operation. In case both FIFOs are in use, data is transferred to each data register alternately. SRX1 can only be used in Two-Channel mode of operation.

56.3.3.5 SSI Receive FIFO 0 and 1 Registers

The SSI Receive FIFO Registers are 15 × 32-bit registers. These registers are not directly accessible by the end user (except in SSI test mode). They always accepts data from the Receive Shift Register (RXSR). The core is interrupted when the data level in either of the SSI Receive FIFOs reaches the selected threshold, if the associated interrupt is enabled.

56.3.3.6 SSI Receive Shift Register (RXSR)

The SSI Receive Shift Register (RXSR) is a 24-bit, shift register that receives incoming data from the serial receive data SRXD port. This register is not directly accessible by the end user. When a continuous clock is used, data is shifted in by the selected (internal/external) bit clock when the associated (internal/external) frame sync is asserted. When a gated clock is used, data is shifted in by the selected (internal/external) gated clock. Data is assumed to be received MSB first if the SHFD bit of the SRCR is cleared. If this bit is set, the data is received LSB first. Data is transferred to the appropriate SSI Receive Data Register (SRX0/1) or Receive FIFOs (if the receive FIFO is enabled and the corresponding SRX is full) after 8, 10, 12, 16, 18, 20, 22 or 24 bits have been shifted in depending on the WL[3:0] control bits. For receiving less than 24 bits of data, LSB bits are appended with zero. The following figures show the receiver loading and shifting operation.

Figure 56-23–Figure 56-26 show the working for some WL values; the same can be extended for other values.

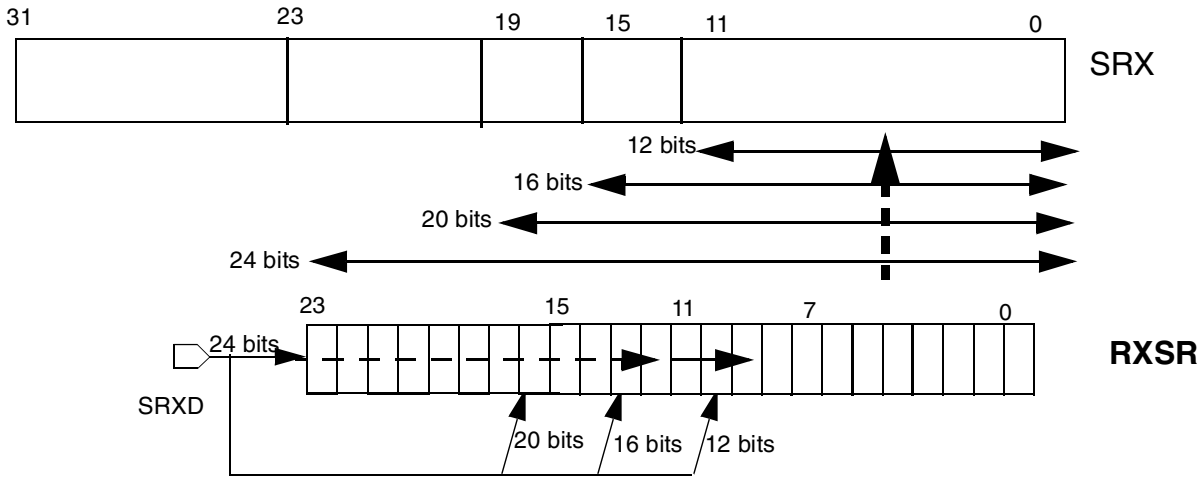

Figure 56-26. Receive Data Path (RXBIT0=1, RSHFD=1) (LSB Alignment)

56.3.3.7 SSI Control Register (SCR)

The SSI Control Register (SCR) is a 10-bit register used to set up the SSI. SSI reset is controlled by bit 0 in the SCR. SSI operating modes are also selected in this register (except AC97 mode which is selected in SACNT register).

See Figure 56-27 for illustration of valid bits in SSI Control Register and Table 56-12 for description of the bit fields in the register.

Figure 56-27. SSI Control Register

Table 56-12. SSI Control Register Field Descriptions

Field	Description
31–12	Reserved
11 RFR_CLK_DIS	Receive Frame Clock Disable. This bit provide option to keep the Frame-sync and Clock enabled or disabled after current receive frame, in which receiver is disabled by clearing RE bit. Writing to this bit has effect only when RE is disabled. 0 Continue Frame-sync/Clock generation after current frame during which RE is cleared. This may be required when Frame-sync and Clocks are required from SSI, even when no data is to be received. 1 Stop Frame-sync/Clock generation at next frame boundary. This will be effective also in case where receiver is already disabled in current or previous frames.
10 TFR_CLK_DIS	Transmit Frame Clock Disable. This bit provide option to keep the Frame-sync and Clock enabled or disabled after current transmit frame, in which transmitter is disabled by clearing TE bit. Writing to this bit has effect only when SSI is enabled TE is disabled. 0 Continue Frame-sync/Clock generation after current frame during which TE is cleared. This may be required when Frame-sync and Clocks are required from SSI, even when no data is to be received. 1 Stop Frame-sync/Clock generation at next frame boundary. This will be effective also in case where transmitter is already disabled in current or previous frames.
9 CLK_IST	Clock Idle State. This bit controls the idle state of the transmit clock port during SSI internal gated mode. Note: When Clock idle state is ‘1’ the clock polarity should always be negative edge triggered and when Clock idle = ‘0’ the clock polarity should always be positive edge triggered. 0 Clock idle state is ‘0’. 1 Clock idle state is ‘1’.

Table 56-12. SSI Control Register Field Descriptions (continued)

Field	Description
8 TCH_EN	Two-Channel Operation Enable. This bit allows SSI to operate in the two-channel mode. In this mode while receiving, the RXSR transfers data to SRX0 and SRX1 alternately and while transmitting, data is alternately transferred from STX0 and STX1 to TXSR. For an even number of slots, Two-Channel Operation can be enabled to optimize usage of both FIFOs or disabled as in the case of odd number of active slots. This feature is especially useful in I2S mode, where data for Left Speaker can be placed in Tx-FIFO0 and for Right speaker in Tx-FIFO1. 0 Two-channel mode disabled. 1 Two-channel mode enabled.
7 SYS_CLK_EN	System Clock (Oversampling Clock) Enable. When set, this bit allows the SSI to output the (ccm_ssi_clk) at the SRCK port, provided that synchronous mode, and transmit internal clock mode are set. The relationship between bit clock and ccm_ssi_clk is determined by DIV2, PSR, and PM bits. This feature is especially useful in I2S Master mode to output oversampling clock on SRCK port. 0 ccm_ssi_clk not output on SRCK port. 1 ccm_ssi_clk output on SRCK port.
6–5 I2S MODE[1:0]	I2S Mode Select. These bits allow the SSI to operate in Normal, I2S Master or I2S Slave mode. Refer to Section 56.1.2.4 for a detailed description of I2S Mode of operation. Refer to Table 56-2 (“Mode Selection”) for details regarding settings.
4 SYN	Synchronous Mode. This bit controls whether SSI is in synchronous mode or not. In synchronous mode, the transmit and receive sections of SSI share a common clock port (STCK) and frame sync port (STFS). 0 Asynchronous mode selected. 1 Synchronous mode selected.
3 NET	Network Mode. This bit controls whether SSI is in network mode or not. 0 Network mode not selected. 1 Network mode selected.
2 RE	Receive Enable. This control bit enables the receive section of the SSI. When this bit is enabled, data reception starts with the arrival of the next frame sync. If data is being received when this bit is cleared, data reception continues until the end of the current frame and then stops. If this bit is set again before the second to last bit of the last time slot in the current frame, then reception continues without interruption. 0 Receive section disabled. 1 Receive section enabled.

Table 56-12. SSI Control Register Field Descriptions (continued)

Field	Description
1 TE	Transmit Enable. This control bit enables the transmit section of the SSI. It enables the transfer of the contents of the STX registers to the TXSR and also enables the internal transmit clock. The transmit section is enabled when this bit is set and a frame boundary is detected. When this bit is cleared, the transmitter continues to send data until the end of the current frame and then stops. Data can be written to the STX registers with the TE bit cleared (the corresponding TDE bit will be cleared). If the TE bit is cleared and then set again before the second to last bit of the last time slot in the current frame, data transmission continues without interruption. The normal transmit enable sequence is to write data to the STX register(s) and then set the TE bit. The normal disable sequence is to clear the TE and TIE bits after the TDE bit is set. In gated clock mode, clearing the TE bit results in the clock stopping after the data currently in TXSR has shifted out. When the TE bit is set, the clock starts immediately (for internal gated clock mode). After enabling/disabling transmission, SSI expects 4 setup clock cycles before arrival of frame-sync for frame-sync to be accepted by SSI. In case of fewer clock cycles, there is high probability of the frame-sync to get missed. 0 Transmit section disabled. 1 Transmit section enabled.
0 SSIEN	SSIEN — SSI Enable This bit is used to enable/disable the SSI. When disabled, all SSI status bits are preset to the same state produced by the power-on reset, all control bits are unaffected, the contents of Tx and Rx FIFOs are cleared. When SSI is disabled, all internal clocks are disabled (except register access clock). 0 SSI is disabled. 1 SSI is enabled.

56.3.3.8 SSI Interrupt Status Register (SISR)

The SSI Interrupt Status Register (SISR) is used to monitor the SSI. This register is used by the core to interrogate the status of the SSI. In gated mode of operation the TFS, RFS, TLS, RLS, TFRC and RFRC bits of AISR register are not generated. The status bits are described in the following table.

NOTE

- SSI Status flags are valid when SSI is enabled.
- Refer to Section 56.4.3 and Section 56.4.4 for interrupt source mapping.
- All the flags in the SISR are updated after the first bit of the next SSI word has completed transmission or reception. Certain status bits (ROE0/1 and TUE0/1) are cleared by writing 1 to the corresponding interrupt status bit in SISR.

See Figure 56-28 for illustration of valid bits in SSI Interrupt Register and Table 56-13 for description of the bit fields in the register.

Figure 56-28. SSI Interrupt Status Register

Table 56-13. SSI Interrupt Status Register Field Descriptions

Field	Description
31–19	Reserved
24 RFRC	Receive Frame Complete. This flag is set at the end of the frame during which Receiver is disabled. If Receive Frame & Clock are not disabled in the same frame, this flag is also set at the end of the frame in which Receive Frame & Clock are disabled. See description of RFR_CLK_DIS (add cross reference) bit for more details on how to disable Receiver Frame & Clock or keep them enabled after receiver is disabled. 0 End of Frame not reached 1 End of frame reached after disabling RE or disabling RFR_CLK_DIS, when receiver is already disabled.
23 TFRC	Transmit Frame Complete. This flag is set at the end of the frame during which Transmitter is disabled. If Transmit Frame & Clock are not disabled in the same frame, this flag is also set at the end of the frame in which Transmit Frame & Clock are disabled. See description of TFR_CLK_DIS (add cross reference) bit for more details on how to disable Receiver Frame & Clock or keep them enabled after receiver is disabled. 0 End of Frame not reached 1 End of frame reached after disabling TE or disabling TFR_CLK_DIS, when transmitter is already disabled.
18 CMDAU	Command Address Register Updated. This bit causes the Command Address Updated interrupt (when CMDAU_EN bit is set). This status bit is set each time there is a difference in the previous and current value of the received Command Address. This bit is cleared on reading the SACADD register. 0 No change in SACADD register. 1 SACADD register updated with different value.
17 CMDDU	Command Data Register Updated. This bit causes the Command Data Updated interrupt (when CMDDU_EN bit is set). This status bit is set each time there is a difference in the previous and current value of the received Command Data. This bit is cleared on reading the SACDAT register. 0 No change in SACDAT register. 1 SACDAT register updated with different value.

Table 56-13. SSI Interrupt Status Register Field Descriptions (continued)

Field	Description
16 RXT	Receive Tag Updated. This status bit is set each time there is a difference in the previous and current value of the received tag. It causes the Receive Tag Interrupt (if RXT_EN bit is set). This bit is cleared on reading the SATAG register. 0 No change in SATAG register. 1 SATAG register updated with different value.
15 RDR1	Receive Data Ready 1. This flag bit is set when SRX1 or Rx FIFO 1 is loaded with a new value and Two-Channel mode is selected. RDR1 is cleared when the Core reads the SRX1 register. If Rx FIFO 1 is enabled, RDR1 is cleared when the FIFO is empty. If RIE and RDR1_EN are set, a Receive Data 1 interrupt request is issued on setting of RDR1 bit in case Rx FIFO1 is disabled, if the FIFO is enabled, the interrupt is issued on RFF1 assertion. The RDR1 bit is cleared by POR and SSI reset. 0 No new data for Core to read. 1 New data for Core to read.
14 RDR0	Receive Data Ready 0. This flag bit is set when SRX0 or Rx FIFO 0 is loaded with a new value. RDR0 is cleared when the Core reads the SRX0 register. If Rx FIFO 0 is enabled, RDR0 is cleared when the FIFO is empty. If RIE and RDR0_EN are set, a Receive Data 0 interrupt request is issued on setting of RDR0 bit in case Rx FIFO0 is disabled, if the FIFO is enabled, the interrupt is issued on RFF0 assertion. The RDR0 bit is cleared by POR and SSI reset. 0 No new data for Core to read. 1 New data for Core to read.
13 TDE1	Transmit Data Register Empty 1. This flag is set whenever data is transferred to TXSR from STX1 register and Two-Channel mode is selected. If Tx FIFO1 is enabled, this occurs when there is at least one empty slot in STX1 or Tx FIFO1. If Tx FIFO1 is not enabled, this occurs when the contents of STX1 are transferred to TXSR. The TDE1 bit is cleared when the Core writes to STX1. If TIE and TDE1_EN are set, an SSI Transmit Data 1 interrupt request is issued on setting of TDE1 bit. The TDE1 bit is cleared by POR and SSI reset. 0 Data available for transmission. 1 Data needs to be written by the Core for transmission.
12 TDE0	Transmit Data Register Empty 0. This flag is set whenever data is transferred to TXSR from STX0 register. If Tx FIFO 0 is enabled, this occurs when there is at least one empty slot in STX0 or Tx FIFO 0. If Tx FIFO 0 is not enabled, this occurs when the contents of STX0 are transferred to TXSR. The TDE0 bit is cleared when the Core writes to STX0. If TIE and TDE0_EN are set, an SSI Transmit Data 0 interrupt request is issued on setting of TDE0 bit. The TDE0 bit is cleared by POR and SSI reset. 0 Data available for transmission. 1 Data needs to be written by the Core for transmission.
11 ROE1	Receiver Overrun Error 1. This flag is set when the RXSR is filled and ready to transfer to SRX1 register or to Rx FIFO 1 (when enabled) and these are already full and Two-Channel mode is selected. If Rx FIFO 1 is enabled, this is indicated by RFF1 flag, else this is indicated by the RDR1 flag. The RXSR is not transferred in this case. The ROE1 flag causes an interrupt if RIE and ROE1_EN are set. The ROE1 bit is cleared by POR and SSI reset. It is also cleared by writing ‘1’ to this bit. Clearing the RE bit does not affect the ROE1 bit. 0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.

Table 56-13. SSI Interrupt Status Register Field Descriptions (continued)

Field	Description
10 ROE0	Receiver Overrun Error 0. This flag is set when the RXSR is filled and ready to transfer to SRX0 register or to Rx FIFO 0 (when enabled) and these are already full. If Rx FIFO 0 is enabled, this is indicated by RFF0 flag, else this is indicated by the RDR0 flag. The RXSR is not transferred in this case. The ROE0 flag causes an interrupt if RIE and ROE0_EN are set. The ROE0 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit. Clearing the RE bit does not affect the ROE0 bit. 0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.
