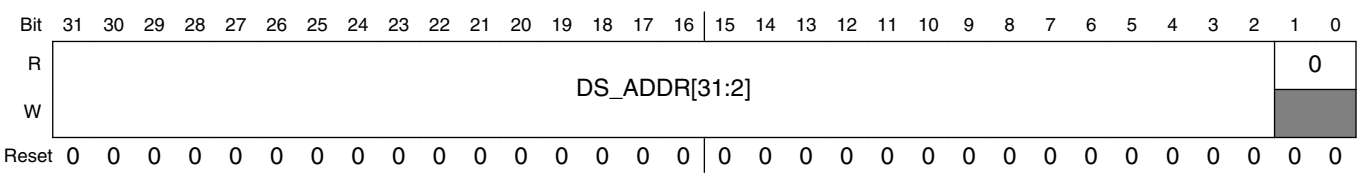
30.7.1 DMA System Address (ESDHCV3x_DSADDR)

This register contains the physical system memory address used for DMA transfers.

Addresses: ESDHCV3-3_DSADDR is 5002_0000h base + 0h offset = 5002_0000h



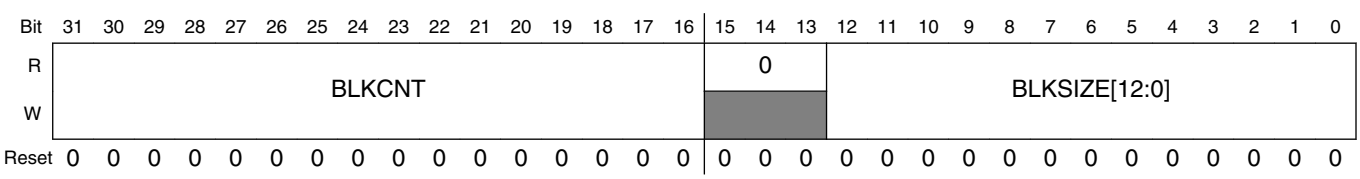
ESDHCV3x_DSADDR field descriptions

Field	Description
31–2 DS_ADDR[31:2]	DMA System Address: This register contains the 32-bit system memory address for a DMA transfer. As the address must be word (4 bytes) align, the least 2 bits are reserved, always 0. When the ESDHC stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The Host Driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The Host driver shall wait, until ESDHCV3_PRSSTAT[DLA] bit is cleared, before writing to this register. The ESDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, ESDHC will automatically change SEQ burst type to NSEQ. As this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions.
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

30.7.2 Block Attributes (ESDHCV3x_BLKATTR)

This register is used to configure the number of data blocks and the number of bytes in each block.

Addresses: ESDHCV3-3_BLKATTR is 5002_0000h base + 4h offset = 5002_0004h



ESDHCV3x_BLKATTR field descriptions

Field	Description
31–16 BLKCNT	Blocks Count For Current Transfer: This register is enabled when ESDHCV3_XFERTYP[BCEN] bit is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The Host Driver shall set this register to a value between 1 and the maximum block count. The ESDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. This register should be accessed only when no transaction is executing (that is, after transactions have stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored. When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend.

Table continues on the next page...

ESDHCV3x_BLKATTR field descriptions (continued)

Field	Description
	This is because when Suspend command is sent out, ESDHC will regard the current transfer is aborted and change BLKCNT register back to its original value instead of keeping the dynamical indicator of remained block count. When restoring transfer content prior to issuing a Resume command, the Host Driver shall restore the previously saved block count. 0xFFFF 65535 blocks 0x0002 2 blocks 0x0001 1 blocks 0x0000 Stop Count
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12–0 BLKSIZE[12:0]	Transfer Block Size: This register specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations will be ignored. 0x1000 4096 Bytes 0x800 2048 Bytes 0x200 512 Bytes 0x1FF 511 Bytes 0x004 4 Bytes 0x003 3 Bytes 0x002 2 Bytes 0x001 1 Bytes 0x000 No data transfer

30.7.3 Command Argument (ESDHCV3x_CMDARG)

This register contains the SD/MMC Command Argument.

Addresses: ESDHCV3-3_CMDARG is 5002_0000h base + 8h offset = 5002_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CMDARG[31:0]																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESDHCV3x_CMDARG field descriptions

Field	Description
31–0 CMDARG[31:0]	Command Argument: The SD/MMC Command Argument is specified as bits 39-8 of the Command Format in the SD or MMC Specification.This register is write protected when the Command Inhibit (CMD) bit in the Present State register is set.

30.7.4 Command Transfer Type (ESDHCV3x_XFERTYP)

This register is used to control the operation of data transfers. The Host Driver sets this register before issuing a command followed by a data transfer, or before issuing a Resume command. To prevent data loss, the ESDHC prevents writing to the bits, that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.

The Host Driver shall check the Command Inhibit DAT bit (CDIHB) and the Command Inhibit CMD bit (CIHB) in the Present State register before writing to this register. When the CDIHB bit in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Besides, block count must also be non-zero, or indicated as single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise ESDHC will ignore the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is '1), otherwise ESDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, that is, response time-out, ESDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver should issue the command again to re-try the transfer. It is also possible that for some reason the card responds the command but ESDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The CMDTYP field of this register is used to initiate three special commands; these are:

- Suspend: ESDHC does not monitor the content of the Suspend command response and therefore assumes that the commnand succeeds when issued. It then operates assuming the card bus has been released and that it is permissible to issue the next command using the DAT line. It is the responsibility of S/W to check the status of the Suspend command and send another command marked as Suspend to inform the ESDHC that a Suspend command was successfully issued. Refer to Suspend Resume for more details. After the end bit of command is sent, ESDHC de-asserts Read Wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the ESDHC will maintain its

current state and the Host Driver shall restart the transfer by setting the Continue Request bit in the Protocol Control register.

- Resume: S/W re-starts the data transfer by restoring the registers saved before sending the Suspend Command and then sends the Resume Command. The ESDHC will check for a pending busy state before starting write transfers.
- Abort: If this command is set when executing a read transfer, ESDHC will stop reads to the buffer. If this command is set when executing a write transfer, ESDHC will stop driving the DAT line. After issuing the Abort command, the Host Driver should issue a software reset (Abort Transaction).

The following table shows the summary of how register settings determine the type of data transfer.

Table 30-49. Transfer Type Register Setting for Various Transfer Types

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

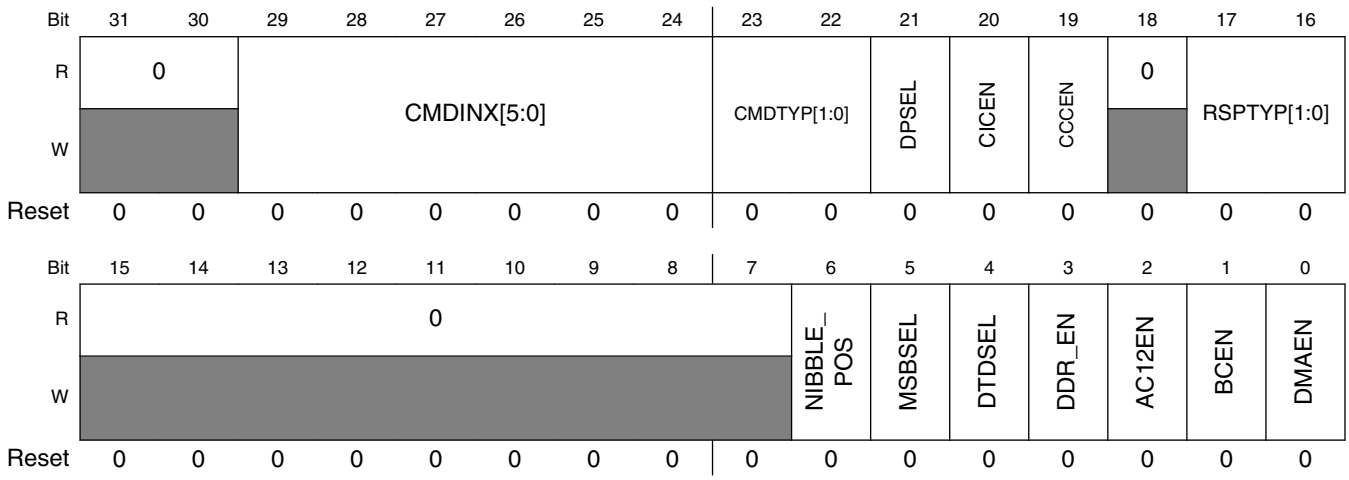
The following table shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, in regards to the Response Type bits and the name of the response type.

Table 30-50. Relationship Between Parameters and the Name of the Response Type

Response Type	Index Check Enable	CRC Check Enable	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3,R4
10	1	1	R1,R5,R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to indicate that ESDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command will be used with R5b.
- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

Addresses: ESDHCV3-3_XFERTYP is 5002_0000h base + Ch offset = 5002_000Ch



ESDHCV3x_XFERTYP field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved
29–24 CMDINX[5:0]	Command Index: These bits shall be set to the command number that is specified in bits 45-40 of the Command-Format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23–22 CMDTYP[1:0]	Command Type: 11 Abort CMD12, CMD52 for writing I/O Abort in CCCR 10 Resume CMD52 for writing Function Select in CCCR 01 Suspend CMD52 for writing Bus Suspend in CCCR 00 Normal mode. Used for all other commands
21 DPSEL	Data Present Select: This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52). • Commands with no data transfer, but using the busy signal on DAT[0] line (R1b or R5b such as, CMD38) **NOTE:** In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. When the Write Protect switch is on, (that is, the WPSPL bit is active as '0'), any command with a write operation will be ignored. That is to say, when this bit is set, while the DTDSEL bit is 0, writes to the register Transfer Type are ignored. 1 Data Present 0 No Data Present
20 CICEN	Command Index Check Enable: If this bit is set to 1, the ESDHC will check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked.

Table continues on the next page...

ESDHCV3x_XFERTYP field descriptions (continued)

Field	Description
	1 Enable 0 Disable
19 CCCEN	Command CRC Check Enable: If this bit is set to 1, the ESDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. (Refer to RSPTYP[1:0] and table "Relationship Between Parameters and the Name of the Response Type ".) 1 Enable 0 Disable
18 Reserved	This read-only field is reserved and always has the value zero. Reserved
17–16 RSPTYP[1:0]	Response Type Select: 00 No Response 01 Response Length 136 10 Response Length 48 11 Response Length 48, check Busy after response
15–7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6 NIBBLE_POS	In DDR 4 bit mode nibble position indication. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single Block Select: This bit enables multiple block DAT line data transfers. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (See table above.) 1 Multiple Blocks 0 Single Block
4 DTDSEL	Data Transfer Direction Select: This bit defines the direction of DAT line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the ESDHC and is set to 0 for all other commands. 1 Read (Card to Host) 0 Write (Host to Card)
3 DDR_EN	Dual Data Rate mode selection
2 AC12EN	Auto CMD12 Enable: Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the ESDHC will issue a CMD12 automatically when the last block transfer has completed. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the ESDHC will ignore this bit no matter if it is set or not. 1 Enable 0 Disable

Table continues on the next page...

ESDHCV3x_XFERTYP field descriptions (continued)

Field	Description
1 BCEN	Block Count Enable: This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 1 Enable 0 Disable
0 DMAEN	DMA Enable: This bit enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the Host Driver sets the DPSEL bit of this register. Whether the Simple DMA, or the Advanced DMA, is active depends on the DMA Select field of the Protocol Control register. 1 Enable 0 Disable

30.7.5 Command Response n (ESDHCV3x_CMDRSP*n*)

This register is used to store part n of the response bits from the card.

The table below describes the mapping of command responses from the SD Bus to Command Response registers for each response type. In the table, R[] refers to a bit range within the response data as transmitted on the SD Bus.

Table 30-52. Response Bit Definition for Each Response Type

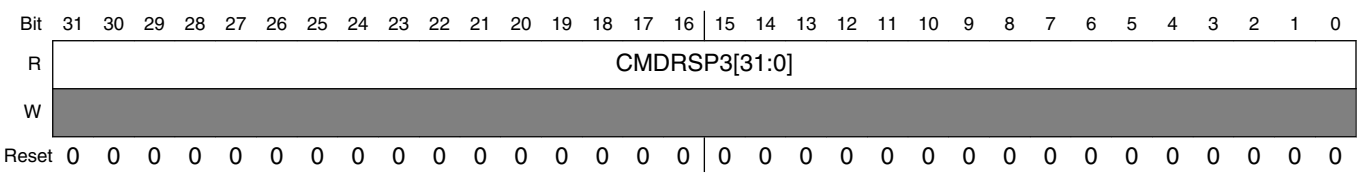
Response Type	Meaning of Response	Response Field	Response Register
R1,R1b (normal response)	Card Status	R[39:8]	ESDHCV3_CMDRSP0
R1b (Auto CMD12 response)	Card Status for Auto CMD12	R[39:8]	ESDHCV3_CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{ESDHCV3_CMDRSP3[23:0] , ESDHCV3_CMDRSP2, ESDHCV3_CMDRSP1, ESDHCV3_CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	ESDHCV3_CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	ESDHCV3_CMDRSP0
R5, R5b	SDIO response	R[39:8]	ESDHCV3_CMDRSP0
R6 (Publish RCA)	New Published RCA[31:16] and card status[15:0]	R[39:9]	ESDHCV3_CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the ESDHCV3_CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the ESDHCV3_CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the ESDHCV3_CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the ESDHC only stores part of the response data in the Command Response registers. This enables the Host Driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by the ESDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the ESDHC will check R[47:1], and if the response length is 136 the ESDHC will check R[119:1].

As ESDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, the ESDHC stores the Auto CMD12 response in the ESDHCV3_CMDRSP3 register. The CMD_wo_DAT response is stored in ESDHCV3_CMDRSP0. This allows the ESDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When the ESDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

Addresses: ESDHCV3-3_CMDRSP0 is 5002_0000h base + 10h offset = 5002_0010h
ESDHCV3-3_CMDRSP1 is 5002_0000h base + 14h offset = 5002_0014h
ESDHCV3-3_CMDRSP2 is 5002_0000h base + 18h offset = 5002_0018h
ESDHCV3-3_CMDRSP3 is 5002_0000h base + 1Ch offset = 5002_001Ch



ESDHCV3x_CMDRSP*n* field descriptions

Field	Description
31–0 CMDRSP3[31:0]	Command Response n: Refer to the table "Response Bit Definition for Each Response Type" above for the mapping of command responses from the SD Bus to this register for each response type.

30.7.6 Data Buffer Access Port (ESDHCV3x_DATPORT)

This is a 32-bit data port register used to access the internal buffer.

Addresses: ESDHCV3-3_DATPORT is 5002_0000h base + 20h offset = 5002_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ESDHCV3x_DATPORT field descriptions

Field	Description
31–0 DATCONT[31:0]	Data Content: The Buffer Data Port register is for 32-bit data access by the ARM platform or the external DMA. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s.

30.7.7 Present State (ESDHCV3x_PRSTAT)

The Host Driver can get status of the ESDHC from this 32-bit read only register.

NOTE

The reset value of Present State Register depend on testbench connectivity.

- The Host Driver issues CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DAT lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands will be issued when Command Inhibit (DAT) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

Addresses: ESDHCV3-3_PRSSTAT is 5002_0000h base + 24h offset = 5002_0024h

ESDHCV3x_PRSSTAT field descriptions

Field	Description
31–24 DLSL[7:0]	DAT[7:0] Line Signal Level: This status is used to check the DAT line level to recover from errors, and for debugging.This is especially useful in detecting the busy signal level from DAT[0]. The reset value is effected by the external pull-up/pull-down resistors. By default, the read value of this bit field after reset is 8'b11110111, when DAT[3] is pulled down and the other lines are pulled up. DAT[7]: Data 7 line signal level DAT[6]: Data 6 line signal level DAT[5]: Data 5 line signal level DAT[4]: Data 4 line signal level DAT[3]: Data 3 line signal level DAT[2]: Data 2 line signal level DAT[1]: Data 1 line signal level DAT[0]: Data 0 line signal level
23 CLSL	CMD Line Signal Level: This status is used to check the CMD line level to recover from errors, and for debugging. The reset value is effected by the external pull-up/pull-down resistor, by default, the read value of this bit after reset is 1'b1, when the command line is pulled up.
22–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19 WPSPL	Write Protect Switch Pin Level:

Table continues on the next page...

ESDHCV3x_PRSSTAT field descriptions (continued)

Field	Description
	The Write Protect Switch is supported for memory and combo cards.This bit reflects the inverted value of the SD_WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the SD_WP pin is not used, it should be tied low, so that the reset value of this bit is high and write is enabled. 1 Write enabled (SD_WP=0) 0 Write protected (SD_WP=1)
18 CDPL	Card Detect Pin Level: This bit reflects the inverse value of the SD_CD# pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing As it must be debounced by software. A software reset does not effect this bit. A write to the Force Event Register does not effect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the SD_CD# pin (that is, when a card is inserted in the socket, it is 0 on the SD_CD# input, and consequently the CDPL reads 1.) 1 Card present (SD_CD#=0) 0 No card present (SD_CD#=1)
17 Reserved	This read-only field is reserved and always has the value zero. Reserved
16 CINS	Card Inserted: This bit indicates whether a card has been inserted. The ESDHC debounces this signal so that the Host Driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not effect this bit. The Software Reset For All in the System Control register does not effect this bit.A software reset does not effect this bit. 1 Card Inserted 0 Power on Reset or No Card
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11 BREN	Buffer Read Enable: This status bit is used for non-DMA read transfers. The ESDHC may implement multiple buffers to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is high, valid data greater than the watermark level exist in the buffer. A change of this bit from 1 to 0 occurs when any read from the buffer is made. A change of this bit from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 1 Read enable 0 Read disable
10 BWEN	Buffer Write Enable: This status bit is used for non-DMA write transfers. The ESDHC can implement multiple buffers to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, valid data greater than the watermark level can be written to the buffer. A change of this bit from 1 to 0 occurs when any write to the buffer is made. A change of this bit from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled.

Table continues on the next page...

ESDHCV3x_PRSSTAT field descriptions (continued)

Field	Description
	1 Write enable 0 Write disable
9 RTA	Read Transfer Active: This status bit is used for detecting completion of a read transfer. This bit is set for either of the following conditions: • After the end bit of the read command. • When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. A Transfer Complete interrupt is generated when this bit changes to 0. This bit is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from ESDHC internal buffer. • When all valid data blocks have been transferred from ESDHC internal buffer to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1. 1 Transferring data 0 No valid data
8 WTA	Write Transfer Active: This status bit indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the ESDHC. This bit is set in either of the following cases: • After the end bit of the write command. • When writing 1 to the Continue Request bit in the Protocol Control register to restart a write transfer. This bit is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple). • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request. During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining when to issue commands during Write Busy state. 1 Transferring data 0 No valid data
7 SDOFF	SD Clock Gated Off Internally: This status bit indicates that the SD Clock is internally gated off, because of buffer over/under-run or read pause without read wait assertion, or the driver has cleared SDCLKEN bit to stop the SD clock. This bit is for the Host Driver to debug data transaction on the SD bus. 1 SD Clock is gated off 0 SD Clock is active
6 PEROFF	ipg_perclk Gated Off Internally:

Table continues on the next page...

ESDHCV3x_PRSSTAT field descriptions (continued)

Field	Description
	This status bit indicates that the ipg_perclk is internally gated off. This bit is for the Host Driver to debug transaction on the SD bus. When INITA bit is set, ESDHC sending 80 clock cycles to the card, the SDCLKEN bit must be '1' to enable the output card clock, otherwise the ipg_perclk will never be gate off, so ipg_perclk and ipg_clk will be always active. 1 ipg_perclk is gated off 0 ipg_perclk is active
5 HCKOFF	hclk Gated Off Internally: This status bit indicates that the hclk is internally gated off. This bit is for the Host Driver to debug during a data transfer. 1 hclk is gated off 0 hclk is active
4 IPGOFF	ipg_clk Gated Off Internally: This status bit indicates that the ipg_clk is internally gated off. This bit is for the Host Driver to debug. 1 ipg_clk is gated off 0 ipg_clk is active
3 SDSTB	SD Clock Stable This status bit indicates that the internal card clock is stable. This bit is for the Host Driver to poll clock status when changing the clock frequency. It is recommended to clear SDCLKEN bit in System Control register to remove glitch on the card clock when the frequency is changing. 1 clock is stable 0 clock is changing frequency and not stable
2 DLA	Data Line Active This status bit indicates whether one of the DAT lines on the SD Bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD Bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This bit will be set in either of the following cases: • After the end bit of the read command. • When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. This bit will be cleared in either of the following cases: (1) When the end bit of the last data block is sent from the SD Bus to the ESDHC. (2) When the Read Wait state is stopped by a Suspend command and the DAT2 line is released. The ESDHC will wait at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), the ESDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait in order to use the suspend / resume function. This bit will remain 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD Bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This bit will be set in either of the following cases:

Table continues on the next page...

ESDHCV3x_PRSSTAT field descriptions (continued)

Field	Description
	• After the end bit of the write command. • When writing to 1 to the Continue Request bit in the Protocol Control register to continue a write transfer. This bit will be cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, the ESDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the ESDHC will assume the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and as a result of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DAT0 line is released. 1 DAT Line Active 0 DAT Line Inactive
1 CDIHB	Command Inhibit (DAT): This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates that the ESDHC can issue the next SD/MMC Command. Commands with a busy signal belong to Command Inhibit (DAT) (for example, R1b, R5b type). Except in the case when the command busy is finished, changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE:** The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0. 1 Cannot issue command which uses the DAT line 0 Can issue command which uses the DAT line
0 CIHB	Command Inhibit (CMD): If this status bit is 0, it indicates that the CMD line is not in use and the ESDHC can issue a SD/MMC Command using the CMD line. This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the Command Inhibit (DAT) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If the ESDHC cannot issue the command because of a command conflict error (Refer to Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this bit will remain 1 and the Command Complete is not set. The Status of issuing an Auto CMD12 does not show on this bit. 1 Cannot issue command 0 Can issue command using only CMD line

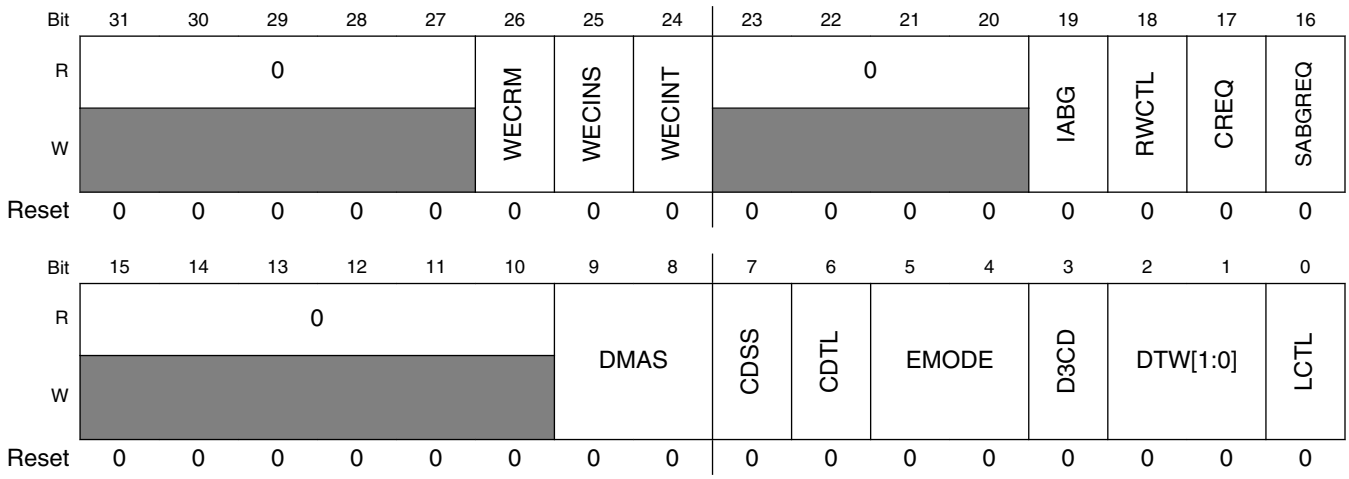
30.7.8 Protocol Control (ESDHCV3x_PROCTL)

There are three cases to restart the transfer after stop at the block gap. The appropriate case depends on whether ESDHC issues a Suspend command or the SD card accepts the Suspend command.

1. If the Host Driver does not issue a Suspend command, the Continue Request will be used to restart the transfer.
2. If the Host Driver issues a Suspend command and the SD card accepts it, a Resume command will be used to restart the transfer.
3. If the Host Driver issues a Suspend command and the SD card does not accept it, the Continue Request will be used to restart the transfer.

Any time Stop At Block Gap Request stops the data transfer, the Host Driver will wait for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the Host Driver will clear the Stop At Block Gap Request before or simultaneously.

Addresses: ESDHCV3-3_PROCTL is 5002_0000h base + 28h offset = 5002_0028h



ESDHCV3x_PROCTL field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26 WECRM	Wakeup Event Enable On SD Card Removal: This bit enables a wakeup event, through a Card Removal, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Removal Status and the ESDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the Card Removal Status and the ESDHC interrupt. 1 Enable 0 Disable
25 WECINS	Wakeup Event Enable On SD Card Insertion: This bit enables a wakeup event, through a Card Insertion, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Insertion Status and the ESDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the Card Insertion Status and the ESDHC interrupt.

Table continues on the next page...

ESDHCV3x_PROCTL field descriptions (continued)

Field	Description
	1 Enable 0 Disable
24 WECINT	Wakeup Event Enable On Card Interrupt: This bit enables a wakeup event, through a Card Interrupt, in the Interrupt Status register. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the Card Interrupt Status and the ESDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the Card Interrupt Status and the ESDHC interrupt. 1 Enable 0 Disable
23–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19 IABG	Interrupt At Block Gap: This bit is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0 to avoid an inadvertent interrupt. When the Host Driver detects an SDIO card insertion, it sets this bit according to the CCCR of the card. 1 Enabled 0 Disabled
18 RWCTL	Read Wait Control: The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise the ESDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SDIO card insertion, it sets this bit according to the CCCR of the card. If the card does not support read wait, this bit will never be set to 1, otherwise DAT line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the ESDHC will stop the SD Clock to pause reading operation. 1 Enable Read Wait Control, and assert Read Wait without stopping SD Clock at block gap when SABGREQ bit is set 0 Disable Read Wait Control, and stop SD Clock at block gap when SABGREQ bit is set
17 CREQ	Continue Request: This bit is used to restart a transaction which was stopped using the Stop At Block Gap Request. When a Suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit to 1 to restart the transfer. The ESDHC automatically clears this bit, therefore it is not necessary for the Host Driver to set this bit to 0. If both Stop At Block Gap Request and this bit are 1, the continue request is ignored. 1 Restart 0 No effect
16 SABGREQ	Stop At Block Gap Request: This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the Transfer Complete is set to 1, indicating a transfer completion, the Host Driver will leave this bit set to 1. Clearing both the Stop At Block Gap Request and Continue Request does not

Table continues on the next page...

ESDHCV3x_PROCTL field descriptions (continued)

Field	Description
	cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The ESDHC will honor the Stop At Block Gap Request for write transfers, but for read transfers it requires that the SDIO card support Read Wait. Therefore, the Host Driver will not set this bit during read transfers unless the SDIO card supports Read Wait and has set the Read Wait Control to 1, otherwise the ESDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the Host Driver writes data to the Data Port register, the Host Driver will set this bit after all block data is written. If this bit is set to 1, the Host Driver will not write data to the Data Port register after a block is sent. Once this bit is set, the Host Driver will not clear this bit before the Transfer Complete bit in Interrupt Status Register is set, otherwise the ESDHCs behavior is undefined. This bit effects Read Transfer Active, Write Transfer Active, DAT Line Active and Command Inhibit (DAT) in the Present State register. 1 Stop 0 Transfer
15–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–8 DMAS	DMA Select: This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00 No DMA or Simple DMA is selected 01 ADMA1 is selected 10 ADMA2 is selected 11 reserved
7 CDSS	Card Detect Signal Selection: This bit selects the source for the card detection. 1 Card Detection Test Level is selected (for test purpose) 0 Card Detection Level is selected (for normal purpose)
6 CDTL	Card Detect Test Level: This is bit is enabled while the Card Detection Signal Selection is set to 1 and it indicates card insertion. 1 Card Detect Test Level is 1, card inserted 0 Card Detect Test Level is 0, no card inserted
5–4 EMODE	Endian Mode: The ESDHC supports all four endian modes in data transfer. Refer to Data Buffer for more details. 00 Big Endian Mode 01 Half Word Big Endian Mode 10 Little Endian Mode 11 Reserved
3 D3CD	DAT3 as Card Detection Pin: If this bit is set, DAT3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DAT3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 may set the card into the SPI mode, which the ESDHC does not support. In case of SDIO application, if SD_CD signal is not multiplexed to ESDHC block, S/W should set D3CD bit.

Table continues on the next page...

ESDHCV3x_PROCTL field descriptions (continued)

Field	Description
	1 DAT3 as Card Detection Pin 0 DAT3 does not monitor Card Insertion
2–1 DTW[1:0]	Data Transfer Width: This bit selects the data width of the SD bus for a data transfer. The Host Driver sets it to match the data width of the card. Possible Data transfer Width is 1-bit, 4-bits or 8-bits. 10 8-bit mode 01 4-bit mode 00 1-bit mode 11 Reserved
0 LCTL	LED Control: This bit, fully controlled by the Host Driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this bit can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the bit once before the first command is sufficient; it is not necessary to reset the bit between commands. 1 LED on 0 LED off

30.7.9 System Control (ESDHCV3x_SYSCTL)

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

ESDHCV3x_SYSCTL field descriptions (continued)

Field	Description
27 INITA	Initialization Active: When this bit is set, 80 SD-Clocks are sent to the card. After the 80 clocks are sent, this bit is self cleared. This bit is very useful during the card power-up period when 74 SD-Clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the CIHB and CDIHB bits in the Present State Register are set, writing 1 to this bit is ignored (that is, when command line or data lines are active, write to this bit is not allowed). On the other hand, when this bit is set, that is, during initialization active period, it is allowed to issue commands, and the command bit stream will appear on the CMD pad after all 80 clock cycles are completer. When this command ends, the driver can make sure that the 80 clock cycles are sent out, which is very useful when the driver needs to send 80 cycles to the card and does not want to wait until this bit is self cleared.
26 RSTD	Software Reset For DAT Line: Only part of the data circuit is reset. DMA circuit is also reset. The following registers and bits are cleared by this bit: • Data Port register • Buffer is cleared and initialized.Present State register • Buffer Read Enable • Buffer Write Enable • Read Transfer Active • Write Transfer Active • DAT Line Active • Command Inhibit (DAT) Protocol Control register • Continue Request • Stop At Block Gap Request Interrupt Status register • Buffer Read Ready • Buffer Write Ready • DMA Interrupt • Block Gap Event • Transfer Complete 1 Reset 0 No Reset
25 RSTC	Software Reset For CMD Line: Only part of the command circuit is reset. The following registers and bits are cleared by this bit: • Present State register Command Inhibit (CMD) • Interrupt Status register Command Complete 1 Reset 0 No Reset
24 RSTA	Software Reset For ALL: This reset effects the entire Host Controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During its initialization, the Host Driver will set this bit to 1 to reset the ESDHC. The ESDHC will reset this bit to 0 when the capabilities registers are valid and the Host Driver can read them. Additional use of Software Reset For All does not affect the value of the Capabilities registers. After this bit is set, it is recommended that the Host Driver reset the external card and re-initialize it.

Table continues on the next page...

ESDHCV3x_SYSCTL field descriptions (continued)

Field	Description
	b Reset 0 No Reset
23 IPP_RST_N	If the card supports it, this Register value will be output directly to the CARD through the pad for hardware reset.
22–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19–16 DTOCV	Data Timeout Counter Value: This value determines the interval by which DAT line timeouts are detected. Refer to the Data Timeout Error bit in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the base clock SDCLK value by this value. The Host Driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events. 1111 Reserved 1110 SDCLK x 2^{27} 0001 SDCLK x 2^{14} 0000 SDCLK x 2^{13} 1111 Reserved (in DDR mode) 1110 SDCLK x 2^{26} (in DDR mode) 0001 SDCLK x 2^{13} (in DDR mode) 0000 SDCLK x 2^{12} (in DDR mode)
15–8 SDCLKFS	SDCLK Frequency Select: This register is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this register holds the prescaler (this register) and divisor (next register) of the Base Clock Frequency register. Setting 00h bypasses the frequency prescaler of the SD Clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. **NOTE:** In ESDHC this register field can not be set to 00h(that is, bypass). The smallest value is 01h, that is divided by 2. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this bit field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD Clock after reset is 375 kHz. According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD Clock frequency is 50 MHz and will never exceed this limit. Only the following settings are allowed: 0x80 Base clock divided by 256 0x40 Base clock divided by 128 0x20 Base clock divided by 64

Table continues on the next page...

ESDHCV3x_SYSCTL field descriptions (continued)

Field	Description
	0x10 Base clock divided by 32 0x08 Base clock divided by 16 0x04 Base clock divided by 8 0x02 Base clock divided by 4 0x01 Base clock divided by 2
7–4 DVS[3:0]	Divisor: This register is used to provide a more exact divisor to generate the desired SD clock frequency. **NOTE:** The divider can even support odd divisor without deterioration of duty cycle. The setting are as following: 0x0 Divisor by 1 0x1 Divisor by 2 0xe Divisor by 15 0xf Divisor by 16
3 SDCLKEN	SD Clock Enable The Host Controller will stop SDCLK when writing this bit to 0. SDCLK Frequency can be changed when this bit is 0. Then, the Host Controller will maintain the same clock frequency until SDCLK is stopped (Stop at SDCLK=0). If the Card Inserted in the Present State register is cleared, this bit should be cleared by the Host Driver to save power.
2 PEREN	Peripheral Clock Enable: If this bit is set, ipg_perclk will always be active and no automatic gating is applied. Thus the SDCLK is active except when auto gating-off during buffer danger (buffer about to over-run or under-run). When this bit is cleared, the ipg_perclk will be automatically off when there is no transaction on the SD bus. As this bit is only a feature enabling bit, clearing this bit does not stop SDCLK immediately. The ipg_perclk will be internally gated off, if none of the following factors are met: • The cmd part is reset, or • Data part is reset, or • A soft reset, or • The cmd is about to send, or • Clock divisor is just updated, or • Continue request is just set, or • This bit is set, or • Card insertion is detected, or • Card removal is detected, or • Card external interrupt is detected, or • 80 clocks for initialization phase is ongoing 1 ipg_perclk will not be automatically gated off 0 ipg_perclk will be internally gated off
1 HCKEN	HCLK Enable: If this bit is set, hclk will always be active and no automatic gating is applied. When this bit is cleared, hclk will be automatically off when no data transfer is on the SD bus. 1 hclk will not be automatically gated off 0 hclk will be internally gated off

Table continues on the next page...

ESDHCV3x_SYSCTL field descriptions (continued)

Field	Description
0 IPGEN	IPG Clock Enable: If this bit is set, ipg_clk will always be active and no automatic gating is applied. The ipg_clk will be internally gated off, if none of the following factors are met: • The cmd part is reset, or • Data part is reset, or • Soft reset, or • The cmd is about to send, or • Clock divisor is just updated, or • Continue request is just set, or • This bit is set, or • Card insertion is detected, or • Card removal is detected, or • Card external interrupt is detected, or • The ipg_perclk is not gated off **NOTE:** The ipg_clk will not be auto gated off if the ipg_perclk is not gated off. Clearing only this bit has no effect unless the PEREN bit is also cleared. 1 ipg_clk will not be automatically gated off 0 ipg_clk will be internally gated off

30.7.10 Interrupt Status (ESDHCV3x_IRQSTAT)

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. Before clearing the Card Interrupt, make sure that the card stops asserting the interrupt, that is, the Card Driver stops servicing the interrupt condition. Otherwise, the CINT bit will be asserted again.

The table below shows the relationship between the Command Timeout Error and the Command Complete.

Table 30-66. ESDHC Status for Command Timeout Error/Command Complete Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the Transfer Complete and the Data Timeout Error.

Table 30-67. ESDHC Status for Data Timeout Error/Transfer Complete Bit Combinations

Transfer Complete	Data Timeout Error	Meaning of the Status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data Transfer Complete

The table below shows the relationship between the Command CRC Error and Command Timeout Error.

Table 30-68. ESDHC Status for Command CRC Error/Command Timeout Error Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	No error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

ESDHCV3x_IRQSTAT field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28 DMAE	DMA Error:

Table continues on the next page...

ESDHCV3x_IRQSTAT field descriptions (continued)

Field	Description
	Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. This error can be caused by either Simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. As any error corrupts the whole data block, the Host Driver will re-start the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 1 Error 0 No Error
27–25 Reserved	This read-only field is reserved and always has the value zero. Reserved
24 AC12E	Auto CMD12 Error: Occurs when detecting that one of the bits in the Auto CMD12 Error Status register has changed from 0 to 1. This bit is set to 1, not only when the errors in Auto CMD12 occur, but also when the Auto CMD12 is not executed due to the previous command error. 1 Error 0 No Error
23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22 DEBE	Data End Bit Error: Occurs either when detecting 0 at the end bit position of read data, which uses the DAT line, or at the end bit position of the CRC. 1 Error 0 No Error
21 DCE	Data CRC Error: Occurs when detecting a CRC error when transferring read data, which uses the DAT line, or when detecting the Write CRC status having a value other than 010. 1 Error 0 No Error
20 DTOE	Data Timeout Error: Occurs when detecting one of following time-out conditions. • Busy time-out for R1b,R5b type • Busy time-out after Write CRC status • Read Data time-out. 1 Time out 0 No Error
19 CIE	Command Index Error: Occurs if a Command Index error occurs in the command response. 1 Error 0 No Error
18 CEBE	Command End Bit Error: Occurs when detecting that the end bit of a command response is 0.

Table continues on the next page...

ESDHCV3x_IRQSTAT field descriptions (continued)

Field	Description
	1 End Bit Error Generated 0 No Error
17 CCE	Command CRC Error: Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this bit is set when detecting a CRC error in the command response. • The ESDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the ESDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then the ESDHC will abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error will also be set to 1 to distinguish CMD line conflict. 1 CRC Error Generated. 0 No Error
16 CTOE	Command Timeout Error: Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the ESDHC detects a CMD line conflict, in which case a Command CRC Error will also be set (as shown in the table above), this bit will be set without waiting for 64 SDCLK cycles. Because the command will be aborted by the ESDHC. 1 Time out 0 No Error
15–9 Reserved	This read-only field is reserved and always has the value zero. Reserved
8 CINT	Card Interrupt: This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the ESDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the Host System. Writing 1 to this bit will clear it, but as the interrupt factor from the SDIO card is not clear, this bit is set again. In order to clear this bit, reset the interrupt factor from the external card and then clear this bit. When this status bit is set, and the Host Driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be cleared to deactivate the interrupt signal to the Host System. After completion of the card interrupt service, (it should reset the interrupt factors in the SDIO card and the interrupt signal should not be asserted), write 1 to clear this bit, enable the Card Interrupt Signal Enable and start sampling the interrupt signal again. 1 Generate Card Interrupt 0 No Card Interrupt
7 CRM	Card Removal: This status bit is set if the Card Inserted bit (PRSSTNT[CINS]) changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of CINS should be confirmed, because the card state may possibly change when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. In order to leave it cleared, clear the Card Removal Status Enable bit IRQSTATEN[CRMSEN]in Interrupt Status Enable register. 1 Card removed 0 Card state unstable or inserted

Table continues on the next page...

ESDHCV3x_IRQSTAT field descriptions (continued)

Field	Description
6 CINS	Card Insertion: This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if a card is inserted. In order to leave it cleared, clear the Card Inserted Status Enable bit in Interrupt Status Enable register. 1 Card inserted 0 Card state unstable or removed
5 BRR	Buffer Read Ready: This status bit is set if the Buffer Read Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Read Enable bit in the Present State register for additional information. 1 Ready to read buffer 0 Not ready to read buffer
4 BWR	Buffer Write Ready: This status bit is set if the Buffer Write Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Write Enable bit in the Present State register for additional information. 1 Ready to write buffer: 0 Not ready to write buffer
3 DINT	DMA Interrupt: Occurs only when the internal DMA finishes the data transfer successfully. When errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set. Either Simple DMA or ADMA finishes data transferring, this bit will be set. 1 DMA Interrupt is generated 0 No DMA Interrupt
2 BGE	Block Gap Event: If the Stop At Block Gap Request bit in the Protocol Control register is set, this bit is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this bit is not set to 1. In the case of a Read Transaction: This bit is set at the falling edge of the DAT Line Active Status (When the transaction is stopped at SD Bus timing). The Read Wait must be supported in order to use this function. In the case of Write Transaction: This bit is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 1 Transaction stopped at block gap 0 No block gap event
1 TC	Transfer Complete: This bit is set when a read or write transfer is completed.

Table continues on the next page...

ESDHCV3x_IRQSTAT field descriptions (continued)

Field	Description
	In the case of a Read Transaction: This bit is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request bit in the Protocol Control register (after valid data has been read to the Host System). In the case of a Write Transaction: This bit is set at the falling edge of the DAT Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request bit in the Protocol Control register, and the data transfers are completed. (After valid data is written to the SD card and the busy signal released.) 1 Transfer complete 0 Transfer not complete
0 CC	Command Complete: This bit is set when you receive the end bit of the command response (except Auto CMD12). Refer to the Command Inhibit (CMD) in the Present State register. 1 Command complete 0 Command not complete

30.7.11 Interrupt Status Enable (ESDHCV3x_IRQSTATEN)

Setting the bits in this register to 1 enables the corresponding Interrupt Status to be set by the specified event. If any bit is cleared, the corresponding Interrupt Status bit is also cleared (that is, when the bit in this register is cleared, the corresponding bit in Interrupt Status Register is always 0).

- Depending on IABG bit setting, ESDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the Card Interrupt, asserted from the card, to the time the Host System is informed.
- To detect a CMD line conflict, the Host Driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

Addresses: ESDHCV3-3_IRQSTATEN is 5002_0000h base + 34h offset = 5002_0034h

30.7.12 Interrupt Signal Enable (ESDHCV3x_IRQSIGEN)

This register is used to select which interrupt status is indicated to the Host System as the interrupt. These status bits all share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

Addresses: ESDHCV3-3_IRQSIGEN is 5002_0000h base + 38h offset = 5002_0038h

30.7.13 Auto CMD12 Status (ESDHCV3x_AUTOC12ERR)

When the Auto CMD12 Error Status bit in the Status register is set, the Host Driver will check this register to identify what kind of error the Auto CMD12 indicated. This register is valid only when the Auto CMD12 Error status bit is set.

The table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 30-72. Relationship Between Command CRC Error and Command Timeout Error for Auto CMD12

Auto CMD12 CRC Error	Auto CMD12 Timeout Error	Type of Error
0	0	No Error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the ESDHC is going to issue an Auto CMD12.
   - Set bit 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
   - Set bit 0 to 0 if the Auto CMD12 is issued
2. At the end bit of an Auto CMD12 response.
   - Check errors correspond to bits 1-4.
   - Set bits 1-4 corresponding to detected errors.
   - Clear bits 1-4 corresponding to detected errors
3. Before reading the Auto CMD12 Error Status bit 7.
   - Set bit 7 to 1 if there is a command that cannot be issued
   - Clear bit 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, bit 7 will be sampled when the driver is not writing to the Command register. It is suggested to read this register only when the AC12E bit in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error bits (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Addresses: ESDHCV3-3_AUTOC12ERR is 5002_0000h base + 3Ch offset = 5002_003Ch

23 SRS	Suspend / Resume Support:

Table continues on the next page...

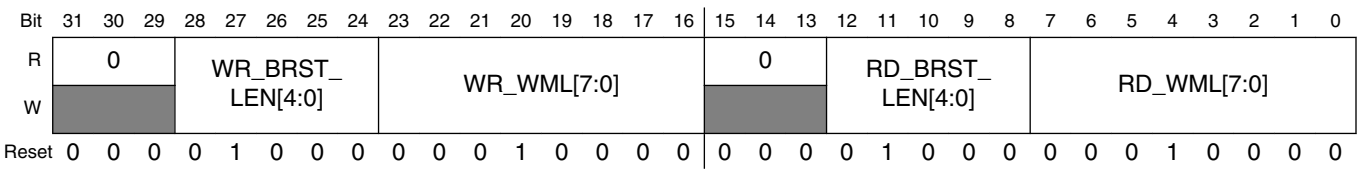
ESDHCV3x_HOSTCAPBLT field descriptions (continued)

Field	Description
	This bit indicates whether the ESDHC supports Suspend / Resume functionality. If this bit is 0, the Suspend and Resume mechanism, as well as the Read Wait, are not supported, and the Host Driver will not issue either Suspend or Resume commands. 1 Supported 0 Not supported
22 DMAS	DMA Support: This bit indicates whether the ESDHC is capable of using the internal DMA to transfer data between system memory and the data buffer directly. 1 DMA Supported 0 DMA not supported
21 HSS	High Speed Support: This bit indicates whether the ESDHC supports High Speed mode and the Host System can supply a SD Clock frequency from 25 MHz to 50 MHz. 1 High Speed Supported 0 High Speed Not Supported
20 ADMAS	ADMA Support: This bit indicates whether the ESDHC supports the ADMA feature. 1 Advanced DMA Supported 0 Advanced DMA Not supported
19 -	Reserved
18–16 MBL[2:0]	Max Block Length: This value indicates the maximum block size that the Host Driver can read and write to the buffer in the ESDHC. The buffer will transfer block size without wait cycles. 000 512 bytes 001 1024 bytes 010 2048 bytes 011 4096 bytes
15–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

30.7.15 Watermark Level (ESDHCV3x_WML)

Both write and read watermark levels (FIFO threshold) are configurable. There value can range from 1 to 128 words. Both write and read burst lengths are also configurable. There value can range from 1 to 31 words.

Addresses: ESDHCV3-3_WML is 5002_0000h base + 44h offset = 5002_0044h



ESDHCV3x_WML field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28–24 WR_BRST_ LEN[4:0]	Write Burst Length: The number of words the ESDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (that is, it is not able to clear this field). **NOTE:** Due to a system restriction, the actual burst length may not exceed 16.
23–16 WR_WML[7:0]	Write Watermark Level: The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12–8 RD_BRST_ LEN[4:0]	Read Burst Length: The number of words the ESDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (that is, it is not able to clear this field. **NOTE:** Due to a system restriction, the actual burst length may not exceed 16.
7–0 RD_WML[7:0]	Read Watermark Level: The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.

30.7.16 Force Event (ESDHCV3x_FEVT)

The Force Event Register is not a physically implemented register. Rather, it is an address at which the Interrupt Status Register can be written if the corresponding bit of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register sets the corresponding bit of Interrupt Status Register. A read from this register always results in 0's. In order to change the corresponding status bits in the Interrupt Status Register, set IPGEN bit in System Control Register so that ipg_clk is always active.

Forcing a card interrupt will generate a short pulse on the DAT[1] line, and the driver will treat this interrupt as a normal interrupt. The interrupt service routine will skip polling the card interrupt factor as the interrupt is self cleared.

Addresses: ESDHCV3-3_FEVT is 5002_0000h base + 50h offset = 5002_0050h

30.7.17 ADMA Error Status Register (ESDHCV3x_ADMAES)

When an ADMA Error Interrupt occurrs, the ADMA Error States field (ADMAES) in this register holds the ADMA state and the ADMA System Address register (ADSADDR) holds the address of the error descriptor.

To recover from this error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address
- ST_CADR: This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address

In case of a write operation, the Host Driver should use ACMD22 command (see below table) to get the number of the written block, because unwritten data may exist in the Host Controller.

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The Host Driver can distinguish this error by reading the Valid bit of the error descriptor.

Table 30-77. ADMA Error State Coding

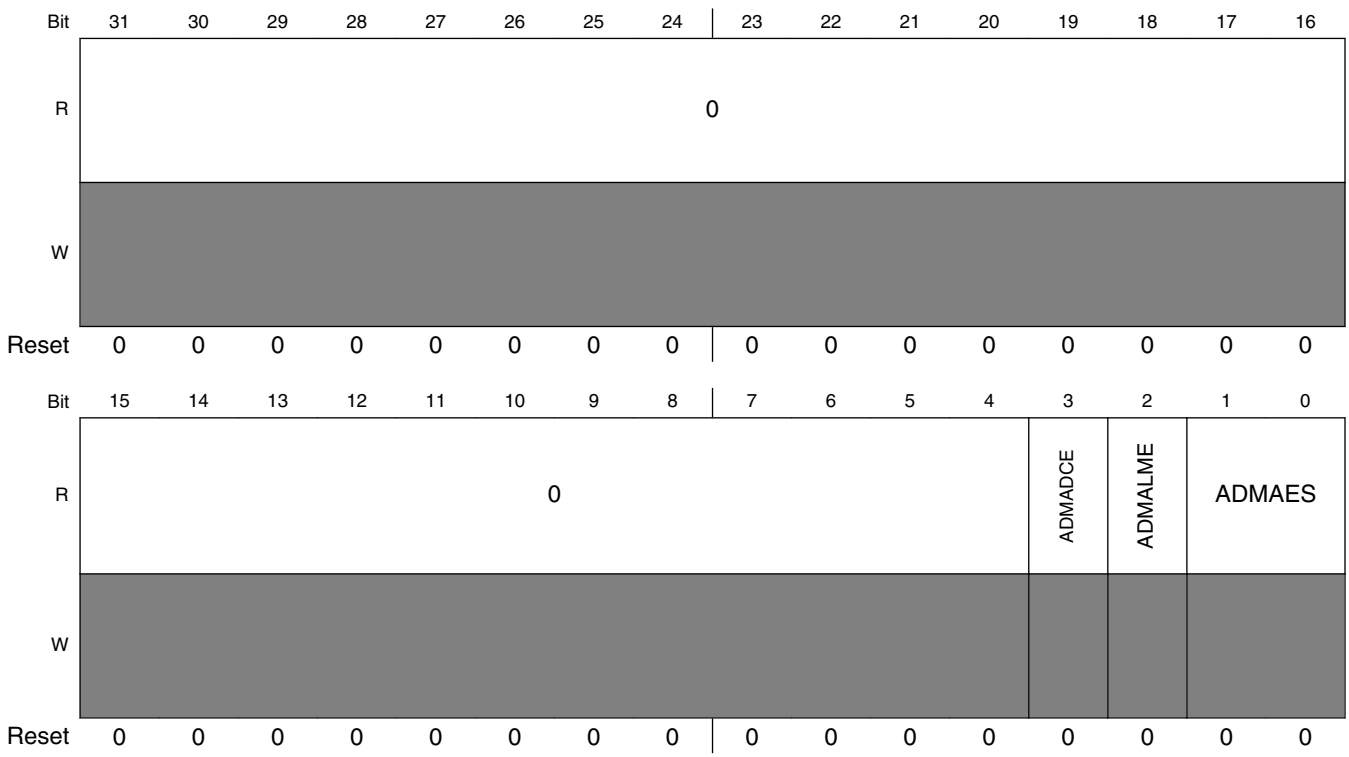
D01-D00	ADMA Error State (when error has occurred)	Contents of ADMA System Address Register
00	ST_STOP (Stop DMA)	Holds the address of the next executable Descriptor command
01	ST_FDS (Fetch Descriptor)	Holds the valid Descriptor address

Table continues on the next page...

Table 30-77. ADMA Error State Coding (continued)

D01-D00	ADMA Error State (when error has occurred)	Contents of ADMA System Address Register
10	ST_CADR (Change Address)	No ADMA Error is generated
11	ST_TFR (Transfer Data)	Holds the address of the next executable Descriptor command

Addresses: ESDHCV3-3_ADMAES is 5002_0000h base + 54h offset = 5002_0054h



ESDHCV3x_ADMAES field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3 ADMADCE	ADMA Descritor Error: This error occurs when invalid descriptor fetched by ADMA: 1 Error 0 No Error
2 ADMALME	ADMA Length Mismatch Error: This error occurs in the following 2 cases: • While the Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length • Total data length can not be divided by the block length

Table continues on the next page...

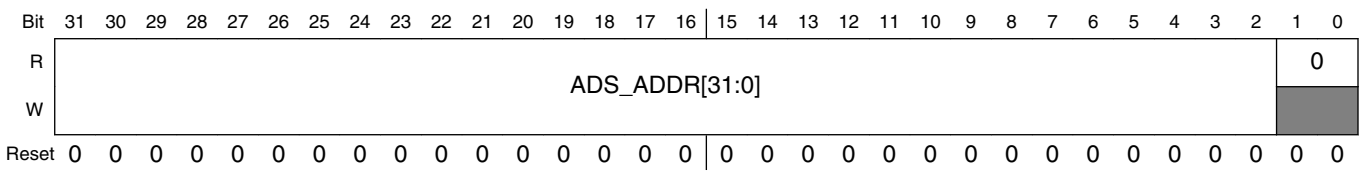
ESDHCV3x_ADMAES field descriptions (continued)

Field	Description
	1 Error 0 No Error
1–0 ADMAES	ADMA Error State (when ADMA Error is occurred.): This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. Refer to ADMA Error Status Register (ESDHCV3_ADMAES) for more details.

30.7.18 ADMA System Address (ESDHCV3x_ADSADDR)

This register contains the physical system memory address used for ADMA transfers.

Addresses: ESDHCV3-3_ADSADDR is 5002_0000h base + 58h offset = 5002_0058h



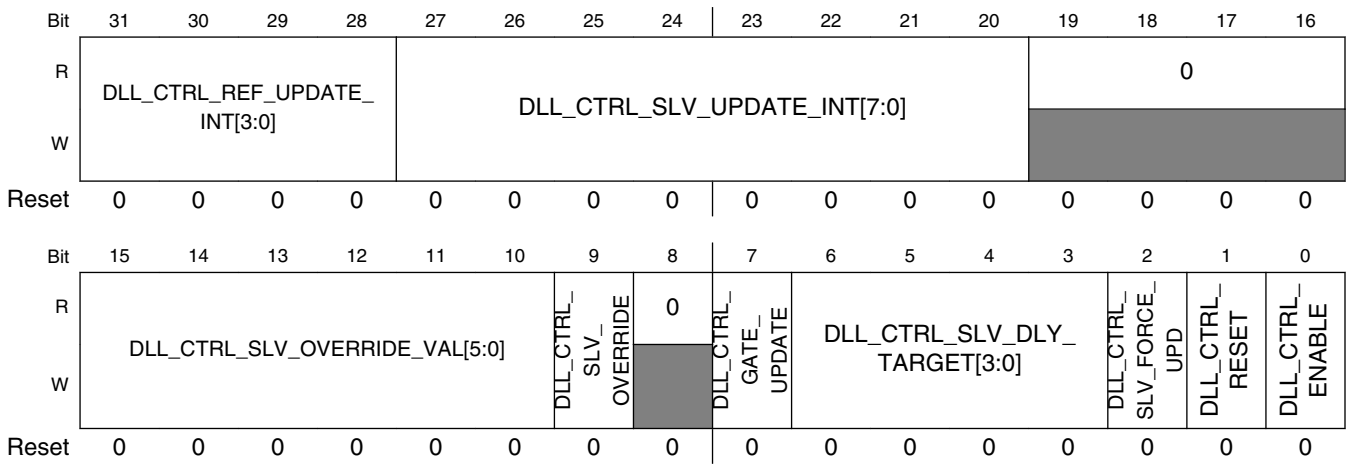
ESDHCV3x_ADSADDR field descriptions

Field	Description
31–2 ADS_ ADDR[31:0]	ADMA System Address: This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the Host Driver will set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register will hold the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned. As this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so this register value cannot be changed when the TC bit is set. Such restriction is also listed in on page 30-142.
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

30.7.19 DLL (Delay Line) Control (ESDHCV3x_DLLCTRL)

This register contains control bits for DLL.

Addresses: ESDHCV3-3_DLLCTRL is 5002_0000h base + 60h offset = 5002_0060h



ESDHCV3x_DLLCTRL field descriptions

Field	Description
31–28 DLL_CTRL_REF_UPDATE_INT[3:0]	DLL control loop update interval. The interval cycle is (2 + REF_UPDATE_INT) * ref_clock. By default, the DLL control loop will update every two ref_clock cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 DLL_CTRL_SLV_UPDATE_INT[7:0]	Slave delay line update interval. If default 0 is used, it means 256 cycles of ref_clock. A value of 0x0f results in 15 cycles and so on. **NOTE:** The software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. **NOTE:** The slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–10 DLL_CTRL_SLV_OVERRIDE_VAL[5:0]	When SLV_OVERRIDE=1 This field is used to select 1 of 64 physical taps manually. A value of 0 selects tap 1, and a value of 0x3f selects tap 64.
9 DLL_CTRL_SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to tbe enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE=0
8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 DLL_CTRL_GATE_UPDATE	Set this bit to 1 to force DLL to not update from now on. Beacue, when clock_in exists, glitches might appear during update. This bit is used by software if we met such kind of condition. Set it to 0 to allow DLL to update automatically

Table continues on the next page...

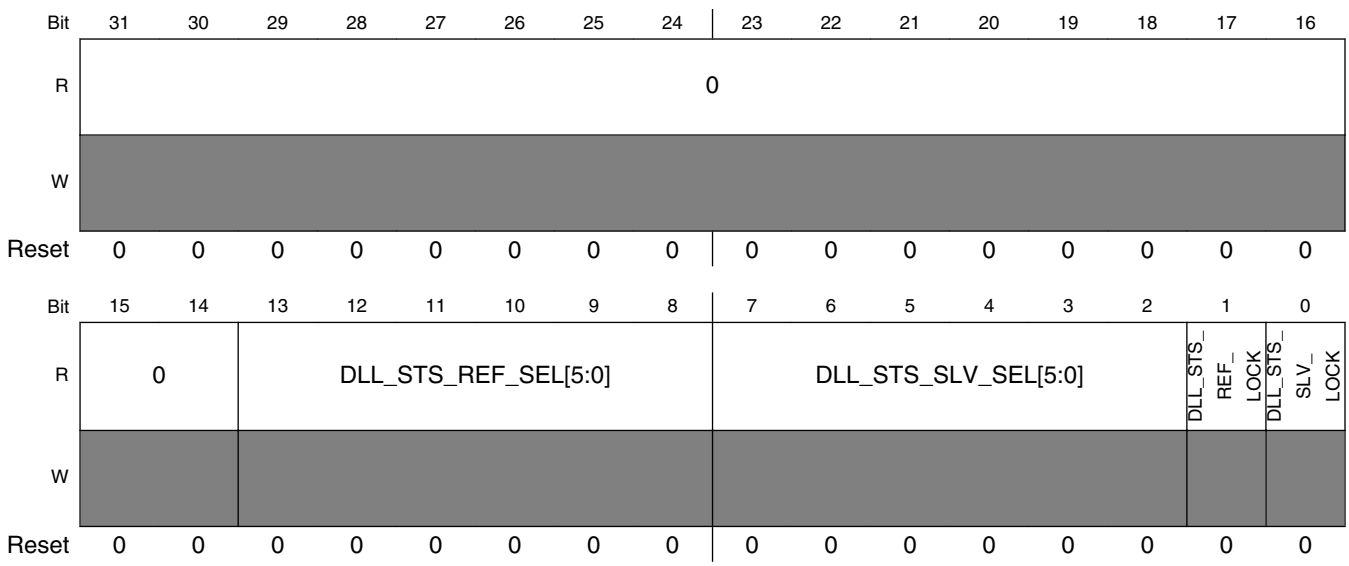
ESDHCV3x_DLLCTRL field descriptions (continued)

Field	Description
6–3 DLL_CTRL_ SLV_DLY_ TARGET[3:0]	The delay target for the ESDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. So the input read-clock can be delayed relative input data from (ref_clock/2)/16 to ref_clock/2
2 DLL_CTRL_ SLV_FORCE_ UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line will update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when ESDHC is idle. This function may not work when ESDHC is working on data/cmd/response.
1 DLL_CTRL_ RESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an ref_clock half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again
0 DLL_CTRL_ ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. **NOTE:** Using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled

30.7.20 DLL Status (ESDHCV3x_DLLSTS)

This register contains the DLL status information. All bits are read only and will read the same as the power-reset value.

Addresses: ESDHCV3-3_DLLSTS is 5002_0000h base + 64h offset = 5002_0064h



ESDHCV3x_DLLSTS field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

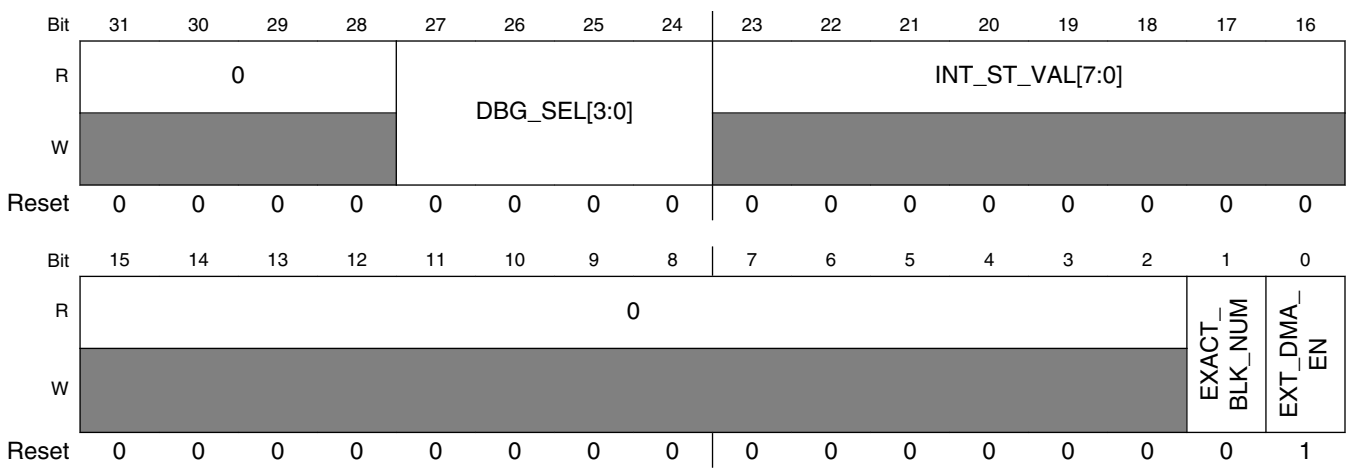
ESDHCV3x_DLLSTS field descriptions (continued)

Field	Description
13–8 DLL_STS_REF_SEL[5:0]	Reference delay line select taps. **NOTE:** this is encoded by 6 bits for 64 taps.
7–2 DLL_STS_SLV_SEL[5:0]	Slave delay line select status. This is the instant value generated from the reference chain. Because only when ref_lock is detected can the reference chain get updated, this value should be the right value to be updated next to the slave line when reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

30.7.21 Vendor Specific Register (ESDHCV3x_VENDOR)

This register contains the vendor specific control/status register.

Addresses: ESDHCV3-3_VENDOR is 5002_0000h base + C0h offset = 5002_00C0h



ESDHCV3x_VENDOR field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved
27–24 DBG_SEL[3:0]	Debug Select Select the internal sub-block to show its internal state value.
23–16 INT_ST_VAL[7:0]	Internal State Value Internal state value, reflecting the corresponding state value selected by Debug Select field. This field is read-only and write to this field does not have effect.

Table continues on the next page...

ESDHCV3x_VENDOR field descriptions (continued)

Field	Description
15–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 EXACT_BLK_NUM	Exact block number block read enable for SDIO CMD53 This bit should be set before S/W issues CMD53 multi-block read with exact block number. This bit should not be set if the CMD53 multi-block read is not exact block number. 0 none exact block read 1 exact block read for SDIO CMD53
0 EXT_DMA_EN	External DMA Request Enable Enable the request to external DMA. When the internal DMA (either Simple DMA or Advanced DMA) is not in use, and this bit is set, ESDHC will send out DMA request when the internal buffer is ready. This bit is particularly useful when transferring data by ARM platform polling mode, and it is not allowed to send out the external DMA request. By default, this bit is set. 0 In any scenario, ESDHC does not send out external DMA request 1 When internal DMA is not active, the external DMA request will be sent out

30.7.22 MMC Boot Register (ESDHCV3x_MMCBOOT)

This register contains the MMC Fast Boot control register.

Addresses: ESDHCV3-3_MMCBOOT is 5002_0000h base + C4h offset = 5002_00C4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BOOT_BLK_CNT[15:0]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								AUTO_SABG_EN	BOOT_EN	MMC_BOOT_MODE	BOOT_ACK	DTOCV_ACK[3:0]			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESDHCV3x_MMCBOOT field descriptions

Field	Description
31–16 BOOT_BLK_CNT[15:0]	The value defines the Stop At Block Gap value of automatic mode. When received card block cnt is equal to BOOT_BLK_CNT and AUTO_SABG_EN is 1, then Stop At Block Gap.
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

ESDHCV3x_MMCBOOT field descriptions (continued)

Field	Description
7 AUTO_SABG_EN	When boot, enable auto stop at block gap function. This function will be triggered, and host will stop at block gap when received card block cnt is equal to BOOT_BLK_CNT.
6 BOOT_EN	Boot mode enable 0: fast boot disable 1: fast boot enable
5 MMC_BOOT_MODE	Boot mode select 0: normal boot 1: alternative boot
4 BOOT_ACK	Boot ack mode select 0: no ack 1: ack
3–0 DTOCV_ACK[3:0]	Boot ACK time out counter value. 0000 SDCLK x 2^8 0001 SDCLK x 2^9 0010 SDCLK x 2^10 0011 SDCLK x 2^11 0100 SDCLK x 2^12 0101 SDCLK x 2^13 0110 SDCLK x 2^14 0111 SDCLK x 2^15 1110 SDCLK x 2^22 1111 Reserved 0000 SDCLK x 2^7 (when in DDR mode) 0001 SDCLK x 2^8 (when in DDR mode) 0010 SDCLK x 2^9 (when in DDR mode) 0011 SDCLK x 2^10 (when in DDR mode) 0100 SDCLK x 2^11 (when in DDR mode) 0101 SDCLK x 2^12 (when in DDR mode) 0110 SDCLK x 2^13 (when in DDR mode) 0111 SDCLK x 2^14 (when in DDR mode) 1110 SDCLK x 2^21 (when in DDR mode) 1111 Reserved (when in DDR mode)

30.7.23 Host Controller Version (ESDHCV3x_HOSTVER)

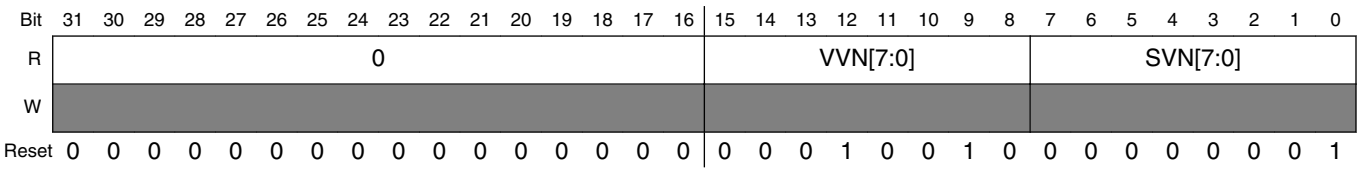
This register contains the vendor Host Controller version information. All bits are read only and will read the same as the power-reset value.

NOTE

The VVN field is 0x12 for both ESDHCV2 and ESDHCV3. Todetermine whether the controller is ESDHCV2 or ESDHCV3 do the following:

Set DLLCTRL [10]. This bit only exists in ESDHCV3. If it is set to 1 successfully, then the controller is ESDHCV3, otherwise it is ESDHCV2.

Addresses: ESDHCV3-3_HOSTVER is 5002_0000h base + FCh offset = 5002_00FCh



ESDHCV3x_HOSTVER field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–8 VVN[7:0]	Vendor Version Number: These status bits are reserved for the vendor version number. The Host Driver will not use this status. Settings not shown are reserved. 0x00 Freescale ESDHC Version 1.0 0x10 Freescale ESDHC Version 2.0 0x11 Freescale ESDHC Version 2.1 0x12 Freescale ESDHC Version 2.2
7–0 SVN[7:0]	Specification Version Number: These status bits indicate the Host Controller Specification Version. Settings not shown are reserved. — 0x01 SD Host Specification Version 2.0, supports Test Event Register and ADMA.

Chapter 31
External Memory Controller (EXTMC)

31.1 General Introduction

The EXTMC is a memory controller of all memory devices in the system, both internal and external. It provides a capability to the system to control the external memory device, by performing several type of access like read, write, program and erase as well as internal memories of the system. All access from the system to a memory device is arbitrated inside EXTMC by the Multi Master Multi Memory Interface (M4IF) sub-block to the right memory controller to perform the access.

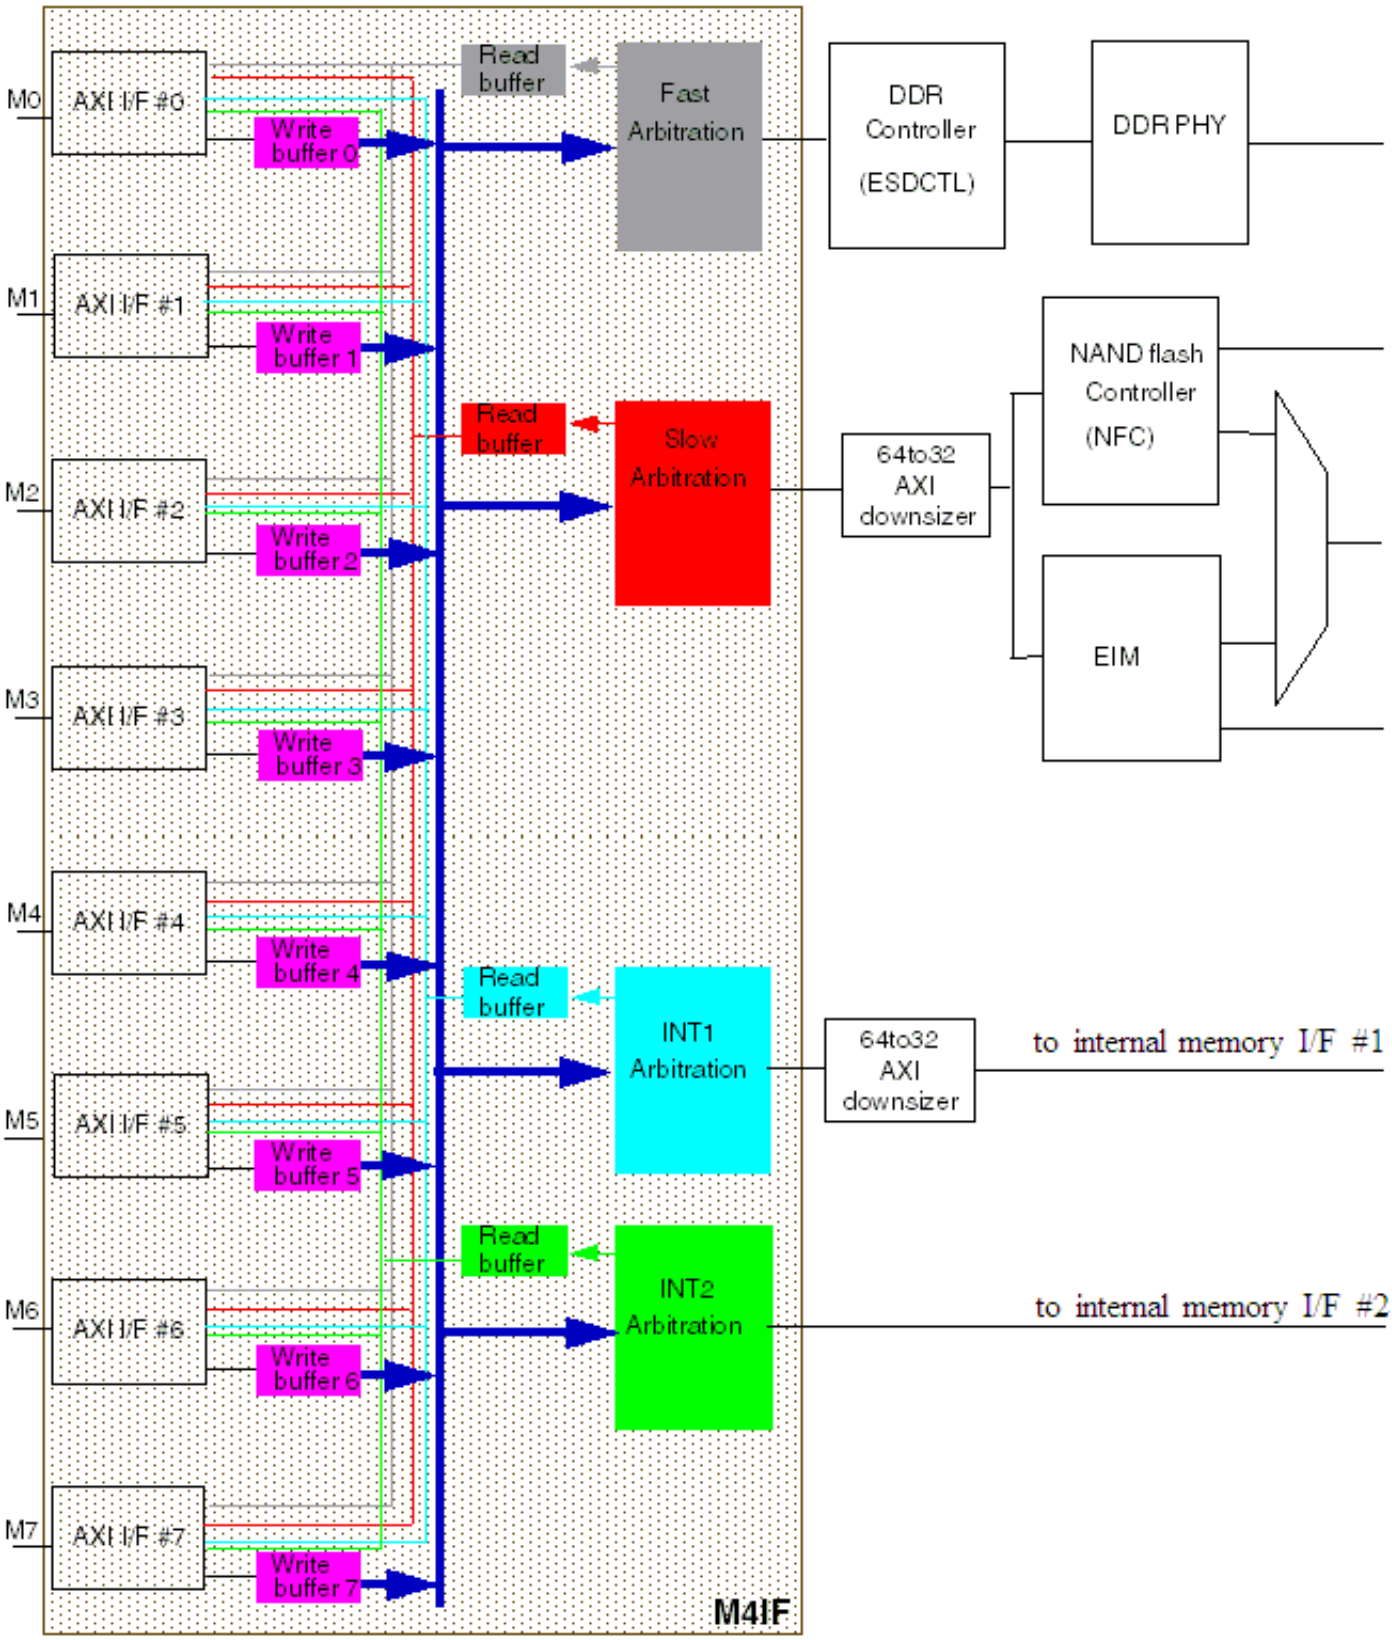


Figure 31-1. EXTMC high level block diagram

31.1.1 Overview

The EXTMC is an External Memory Controller with arbitration logic between multi AXI masters to multi memory controllers, divided into four major channels: fast memories channel (DDR2/DDR3), slow memories channel (NOR-FLASH/PSRAM/NAND-FLASH etc.) and two Internal Memory channels. The internal channels can be used for any AXI compliant slave. They are mostly used for accessing the internal memories of the chip (RAM and ROM).

In order to increase performance, the EXTMC separates the buffering and arbitration between accesses to fast channel slow channel and Internal Memory channels. Therefore, parallel accesses can occur. By separating these four channels, slow accesses do not interfere with fast accesses. EXTMC is being designed such that accesses by a slow master with a narrow bus does not block the access by a fast master with a wide bus.

The EXTMC contains the following sub-blocks:

31.1.1.1 AXI Port Gasket

This is the EXTMC interface to AXI masters and includes 8 AXI port gaskets. This domain sample the data into the buffers, samples the access (address and controls) into FIFO and sort the access to the right channel - fast, slow or Internal Memory channels (Intr1 or Intr2).

31.1.1.2 Dedicated Write Buffers Module

Each AXI port gasket (Master) has a Dedicated Write buffer Module. Write data from masters is sampled in the Write Buffers Module with master clock domain and being transferred to the Memory controller upon request in memory controller clock domain. The Write Buffers' size varies from master to master. Please refer to the M4IF spec chapter.

31.1.1.3 Read Shared Buffers Module

The Read Shared buffer Module serves all 8 AXI ports, one read buffer per each arbitration, slow, fast and internal memory channels, a total of four read buffers. Read data from memory controllers is sampled in the Read buffers with memory controller clock domain, and being transferred to the AXI port gasket upon request. The data from

the memory controller is written to the read buffer in one clock domain, while the gasket provides the data back to the master with master clock domain. See the M4IF chapter for more information.

31.1.1.4 Fast Arbitration Module

The Fast Arbitration Module arbitrates accesses to the Enhanced SDRAM Controller (ESDCTL), using most comprehensive information to optimize accesses to the ESDCTL, such as Page hit/miss read/write access etc. If needed this additional information can be disabled and the arbitration will function in fixed priority mode, based on the user defined priority, more details on the dynamic priority arbitration can be found in M4IF Chapter.

31.1.1.5 Slow and Intr Arbitration Modules

The Slow Arbitration Module uses a reduced model of the fast arbitration which arbitrates accesses to Slow Memories such as External Interface Module (EIM) and NAND Flash Controller (NFC). The slow arbitration block is based on the fast arbitration block design. The algorithm of the slow channel is much simpler than the fast channel, and its latency is smaller in comparison. For a detailed description please refer to M4IF spec.

31.1.1.6 Memory Controller Modules

These blocks includes all memory controllers, ESDCTL, and NFC. The memory controllers receives the access request from the arbitration block and transfer the access to the relevant memory. It is important to mention that although EXTMC arbitrates the internal memory access in the system, it does not contain any internal memory controller like RAM/ROM controller.

31.1.1.7 IPS Interface unit

IPS Interface unit is the EXTMC interface to IP Bus. EXTMC registers would all be IP Bus based, this unit would route block access to the relevant sub-block above based on addr and ips_module_en signal. In EXTMC the following sub-blocks include block registers: M4IF, ESDCTL, EIM, NFC.

31.1.1.8 Debug Unit

Debug unit privides the ability to monitor several important internal EXTMC signals, improving the debug capability of the system.

In addition, the debug unit gives the ability to profile a master connected to EXTMC and get the bus performance of the arbitration.

Please refer to M4IF spec for a detailed description of its registers and functionality.

31.1.2 Features

The EXTMC includes the following features:

- Multi Master Multi Memory Interface (M4IF)
  - Supports multiple accesses from 8 masters through different input ports interfaces. Each port can support either of the following two data width options:
    - x32 AXI port.
    - x64 AXI port.
  - Support different clock domain for each AXI port master.
  - Configureable memory watermark protection per CS.
  - Enhanced arbitration scheme for fast channel, consider page hit/miss, last access details (read/write) and fixed priority configuration.
- Enhanced SDRAM Controller (ESDRAMC)
  - Up to 2 chip selects support up to 1GByte each.
  - Support x16/x32 DDR2 memories up to 400MHz (800MHz data rate).
  - Support x16/x32 DDR3 memories up to 400MHz (800MHz data rate).
  - Support x16/x32 LPDDR2 1ch memories up to 400MHz (800MHz data rate).
  - Support latency hiding logic.
- NandFlash Controller - (NFC)
  - x8/x16 NAND interface.
  - 4.5K RAM Internal Buffer.
  - MLC and SLC memory support.
  - Configureable operation mode - symmetric and asymmetric.
  - Configureable page mode, 1/2K,2K or 4K.
  - Pages per blocks supported are 32, 64, 128, 256.
  - Up to 6 address cycles.
  - ECC support up to 16bit.
  - Support for up to 8 mutually exclusive, yet interleaved nand devices.
  - Automatic Common Nand Operations.
- External Interface Memory Controller - (EIM)
  - Up to 6 chip selects.

- Support x32/x16 PSRAM (up to 133 MHz).
- support x32/x16 muxed mode PSRAM / NOR (up to 133 MHz).
- Support x32/x16 NOR (up to 133 MHz).

- Support Dynamic Voltage and Frequency Scaling Core (DVFSC).
- Support watermark configuration.
- Support of automatic shut-down (power saving features).
- Enhanced debug capabilities (trace mode).

31.1.3 Modes of Operation

The following sub sections describes several operation modes of EXTMC. In order to have a better knowledge on operation modes of each sub-block in EXTMC, please refer to each sub-block Chapter for "Modes of Operation" section.

31.1.3.1 Low Power Modes

SoC system control provides an LPM request signal to EXTMC in order to let EXTMC enter into low power mode. At the end of low power mode sequence, EXTMC sends back an acknowledge signal to inform the system it entered into low power mode.

In this mode, all internal clocks in EXTMC and its sub-blocks would be disabled by the system clock controller. Low power mode definition is described in more details in each sub-block separately.

31.1.3.2 Debug Mode

Several internal signals would be routed out by EXTMC debug unit allowing tracking the internal logic mainly for the arbitration mechanism and memory served accesses.

The debug unit is described in detail in M4IF Chapter.

31.1.3.3 Dynamic Voltage and Frequency Scaling (DVFS) support

EXTMC provides real-time support of voltage and/or frequency change to its memory controllers. There is an handshake mechanism between EXTMC and the system so that EXTMC is informed of any frequency change that is going to be made in the system. When this handshake signal is sent to EXTMC suspends all access to the external/internal

memories controllers and finishes any in-process access in the memory controller. Accesses coming from the masters will be accepted but not forwarded to the memory controllers.

After that the frequency change logic inside EXTMC would be active so that at the end of the routine an acknowledge would be sent to inform a change clock frequency is allowed. At the moment the frequency was changed, the system should lower the handshake signal (request) to EXTMC which means the frequency change is done. EXTMC would force a new measure in the delay line and move back to idle after the measure unit is updated with the new value (ready signals of the memory controllers will return to HIGH).

EXTMC does not allow accesses to the memory during a measure.

More details of DVFS support, Delay Line and measurement unit can be found in ESDCTL Chapter.

31.1.3.4 Power Saving Mode

EXTMC supports few power saving modes other than LPMD. M4IF provides information on whether there are pending requests to a certain arbitration, when was the last request in this arbitration etc. Based on that info, both the specific arbitration and its corresponding memory controller, would be able to enter power saving modes like Self refresh and Auto Self refresh in ESDCTL memory controller. In this mode, each arbitration path is considered as a separate domain so that in a certain time internal memory path can be in power saving mode while DDR memory path will continue to work. It is important to mention that each power saving mode would leave an active logic to be able to get out of this mode whenever a new access arrives. In this case it would take few more cycles to serve the request since getting out of power saving mode routine is taking place first.

A quiet similar mechanism exists in each of M4IF gaskets. M4IF can automatically shut off the clock of a specific gasket based on internal timer that counts a certain number of idle cycle.

Please refer to M4IF Chapter for more details on Power Saving mode.

31.2 Sharing of I/O Pins

EXTMC does not contain any I/O pins sharing or muxing between different arbitration paths. The only I/O sharing done inside EXTMC is EIM and NFC I/O pin sharing.

31.2.1 EIM and NFC IO pin sharing

EXTMC controls the I/O pin sharing between NFC and EIM.

The EIM in i.MX53 supports the following muxing modes:

Table 31-1. EIM multiplexing

Setup	Non Multiplexed Address/Data Mode						Multiplexed Address/ Data mode	
	8 Bit			16 Bit		32 Bit	16 Bit	32 Bit
	MUM = 0, DSZ = 100	MUM = 0, DSZ = 101	MUM = 0, DSZ = 111	MUM = 0, DSZ = 001	MUM = 0, DSZ = 010	MUM = 0, DSZ = 011	MUM = 1, DSZ = 001	MUM = 1, DSZ = 011
A[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]
A[25:16]	EIM_A[25:16]	EIM_A[25:16]	EIM_A[25:16]	EIM_A[25:16]	EIM_A[25:16]	EIM_A[24:16][1]	EIM_A[25:16]	NANDF_D[8:0]
D[7:0], EIM_EB0	NANDF_D[7:0]	-	-	NANDF_D[7:0][2]	-	NANDF_D[7:0]	EIM_DA[7:0]	EIM_DA[7:0]
D[15:8], EIM_EB1	-	NANDF_D[15:8]	-	NANDF_D[15:8][3]	-	NANDF_D[15:8]	EIM_DA[15:8]	EIM_DA[15:8]
D[23:16], EIM_EB2	-	-	-	-	EIM_D[23:16]	EIM_D[23:16]	-	NANDF_D[7:0]
D[31:24], EIM_EB3	-	-	EIM_D[31:24]	-	EIM_D[31:24]	EIM_D[31:24]	-	NANDF_D[15:8]

1. For 32-bit mode, the address range is A[24:0], due to address space allocation in memory map.
2. NANDF_D[7:0] multiplexed on ALT3 mode of PATA_DATA[7:0]
3. NANDF_D[15:8] multiplexed on ALT3 mode of PATA_DATA[15:8]

Muxing between data pads of EIM and NFC exist on the output path only, based on which memory controller own the bus for the specific transaction.

The sharing control logic is based on the fix priority arbitrating between EIM and NFC. EIM has the priority on the external bus whenever there is a conflict between EIM and NFC. However, when NFC is using the bus and EIM access is issued in parallel, NFC will free up the bus after number of clock cycles that depends on the specific command/ access type which is currently served in NFC. No specific time period is guaranteed for the NFC to free up the bus for EIM pending access.

31.3 Memory Map and Register Definition

Table 31-2. External/Internal EXTMC Memory Map

Address	Ext memory CS	Access	Reset Value
0x{int_mem_base[3:0],000_0000} - 0x{int_mem_end[3:0],FFF_FFFF}[1]	Internal Memory region (2GB)	R/W[2]	Defined by SoC via
0x{esdctl_base[3:0],000_0000} - 0x{esdctl_base[3:0],FFF_FFFF}	CSD0 SDRAM/DDR memory region (256 MB)	R/W	Defined by SoC via
0x{(esdctl_base[3:0]+1),000_0000} - 0x{(esdctl_base[3:0]+1),FFF_FFFF}	CSD1 SDRAM/DDR memory region (256 MB)	R/W	Defined by SoC via
0x{weim_nfc_base[3:0][3] ,000_0000} - 0x{(weim_nfc_base[3:0]+1),FFE_FFFF}	EIM CS memory region (configure-able, up to 512MB total) EXTMC	R/W	Defined by SoC via
0x{(weim_nfc_base[3:0]+1),FFF_0000} - 0x{(weim_nfc_base[3:0]+1),FFF_FFFF}	NFC memory region (4K, NandFlash) - support up to 4 CS	R/W	Defined by SoC via

1. Internal memory space is configured by SoC vias at system level. Please refer to int_mem_base[3:0] and int_mem_end[3:0] signal description for more details and for SoC configuration Chapter for specific chip configuration.
2. Note that Internal memory space may contain some read-only memory region.
3. EIM and NFC base address must not be equal to 0xF, since wrap around addressing is not supported in EIM.

31.3.1 IP Bus Memory Map

EXTMC registers are mapped to IP bus memory area and contains 16Kbyte space for all EXTMC registers. For more details on the block registers, please refer to each EXTMC sub-block's spec.

Table 31-3. EXTMC Block memory map

Start ADDR	End ADDR	Block name
0x63FD_8000	0x63FD_8FFF	M4IF
0x63FD_9000	0x63FD_9FFF	ESDCTL
0x63FD_A000	0x63FD_AFFF	EIM
0x63FD_B000	0x63FD_BEFF	NFC
0x63FD_BF00	0x63FD_BFFF	EXTMC

31.4 Functional Description

EXTMC is the external memory arbitration and controller, and the internal memory arbitration of the system. Each master access to the internal or external memory region would be routed out through EXTMC. The EXTMC is based on AXI pipeline separate read and write buses and therefore it can reorder the access of the masters inside the arbitration to provide the highest throughput on the external memory bus.

EXTMC has separate arbitration control blocks for fast and slow external/internal interfaces. An access to the slow interface can be served in parallel to an access of the fast interface without any interference between them.

In addition, EXTMC interface supports asynchronous master interface. Therefore, a slow master would be able to read/write data in parallel to other fast master accesses. The arbitration logic would optimize the access between the masters to the memory controller to provide maximum throughput on the external memory bus and in the same time a minimum latency for pending access in the arbitration.

Special care is taken in order to reduce power in idle and low power mode. Power saving modes exist to provide automatic capability of reducing the power consumption without any special user configuration.

DVFS is supported for both frequency and voltage changes based on handshake mechanism between EXTMC and the system.

A detailed functional description on the sub-block functionality can be found in each block chapter.

31.4.1 Clocks

EXTMC contains the following clock domains:

- ESDCTL main clock (up to 400MHz)
- Slow arbitration clock. (up to 133MHz)
- Internal memory arbitration 1 & 2 clocks. (up to 200MHz)
- 8 x masters clocks, can be asynchronous to EXTMC arbitration clocks (up to 200MHz).
- NFC main clock - should be integer divided from slow arbitration clock.
- SDCLK - DRAM clock.
- BCLK - NOR Flash/PSRAM clock EIM in synchronous mode.
- EXTMC IP Bus clock.

- This clock should be at least 2X slower than the fast, slow, and internal arbitration clocks.
- This clock should be at least 2X slower than any master's clock

The EXTMC arbitrator (M4IF) assumes all of its 4 main clocks: ESDCTL main clock (aclk_fast), Slow arbitration clock (aclk_slow) and Internal memory arbitrations clock (aclk_int1,aclk_int2), are on by default (after reset). If the system wishes to turn one of the clocks off, it must do so by going through the specific lpmd sequence. For example, if the system wishes to turn off "aclk_fast", it will have to wake up with this clock on, send an "lpmd_fast" request, wait for "lpack_fast" acknowledge, and only then turn off "aclk_fast". "lpmd_fast" will have to be asserted for the whole duration of "aclk_fast" being off.

31.4.2 Reset

EXTMC supports cold reset and warm reset.

31.4.2.1 Cold Reset

Cold Reset is the general ARESET signal that enters EXTMC and generates an HW reset to all sub-blocks of EXTMC. All logic is being reset when cold reset is asserted besides the POR reset logic.

31.4.2.2 Warm Reset

Warm reset is supported for ESDCTL only. In this mode the data outside in the external device will be kept during warm reset and will be ready to be used at the moment the device is getting out of warm reset. See the ESDCTL Chapter for more details.

31.4.3 Interrupts

The following interrupt are supported in EXTMC.

- Watermark violation ARM platform interrupt.
- Watermark violation BP interrupt.
- NFC interrupt.
- EIM int for OneNand and MDOC support.
- Configure-able AP_ORed interrupt of all EXTMC interrupts.

- Configure-able BP_ORed interrupt of all EXTMC interrupts.
- LEN interrupt from M4IF

31.4.4 Endianness

EXTMC supports Little endian only. Detailed description on EXTMC endianess may be found on EXTMC Endianness .

31.4.5 IP Bus Interface

All EXTMC registers are IP Bus memory mapped. The registers will be configureable read/write via IP Bus interface only.

The IP Bus interface unit inside EXTMC combines all IP Bus interfaces from EXTMC sub-blocks as appears in Table 31-3. The IP Bus IF unit routes the access to the right sub-block based on ips_module_en signal and address decoding.

EXTMC registers use an accessibility policy as described below.

EXTMC decodes ips_master_id of each block access. The privilege master has the capability to lock or unlock any register from being configured by any other master but the BP Watermark registers. Therefore, the system can ensure that when there is a lock on the registers, no register will be changed by a master other than the privilege master. In a similar way, the BP master is the only master that can lock and configure BP Watermark registers so that even the privilege master can not changed its values. In a case of a non-privilege master that tries to access a lock register, EXTMC does not respond in error; no error signal is sent back on the bus.

See the Register Definition section in this document for more details on the lock mechanism.

All EXTMC registers are 32-bit width. Only block accesses of 32-bit data width are supported.

NOTE

There is no special mechanism inside EXTMC to prevent block register configuration while other operations on AXI are taking place. Therefore, system should control block configuration and prevent a conflict in that case.

When the access is done to a valid address location but no register is mapped to that location, an ips_xfr_err will be generated as long as the XFR_ERR_EN bit in the IPLCK register is high. If XFR_ERR_EN bit is low the ips_xfr_err signal is disabled and remains low.

31.5 Application Information

31.5.1 Buffers Size

See the M4IF chapter for exact buffer sizes for each master and slave

31.5.2 Master to Slave Paths - Restrictions

EXTMC can send any access from any master to any slave. However there are few restrictions.

- Some paths must be synchronized
- Some paths are disconnected

Please refer to the M4IF chapter for exact details.

31.5.3 EXTMC Endianness

31.5.3.1 Introduction to Endianness

EXTMC supports Little Endian mode only. The chapter describes the data arrangement on the data bus in all stages inside EXTMC starting at the AXI interface at M4IF toward the external memory bus at the various memory controllers.

31.5.3.2 AXI Endianness Support

EXTMC support AXI masters with bus width of x64 and x32. Therefore, the sections below are related to these bus width only.

31.5.3.3 AXI master x64

This section shows the data location on AXI bus as it entered into EXTMC on M4IF AXI gaskets. In the next section we will show the data byte locations inside EXTMC toward the external bus and the storage at external memory devices.

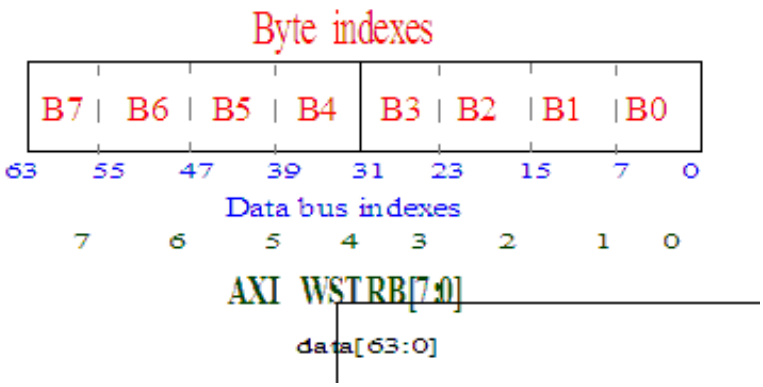

Figure 31-2. Little Endian Bytes Placement on AXI x64

It can be seen from this illustration that the data byte with index 0 uses byte lane 0 (data[7:0]) and data byte with index 7 uses byte lane 7 (data[63:56]).

31.5.3.4 AXI master x32

This section shows the data location on AXI bus as it entered into EXTMC on M4IF AXI gaskets. The following section demonstrates the data byte locations inside EXTMC toward the external bus, and the storage at external memory devices.

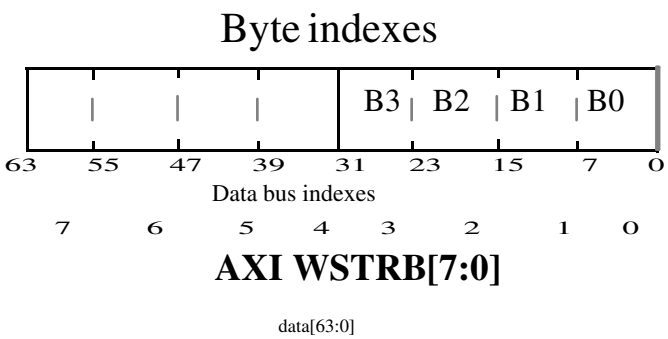

Figure 31-3. Little Endian Bytes Placement on AXI x32

As shown in this illustration, the data byte with index 0 uses byte lane 0 (data[7:0]) and data byte with index 3 uses byte lane 3 (data[31:24]).

31.5.3.5 EXTMC Endianness support

The following sections will describe the Endianness support in each of EXTMC sub-blocks. In general, EXTMC support LE only.

31.5.3.6 M4IF Endianess support

The following figures shows the way M4IF handle little Endian mode. In general M4IF has two different operation modes regardless to Endian mode, it would change its operation logic based on fast, slow, and internal. Since fast and internal arbitration path are x64 while slow arbitration is x32, the way M4IF should provide the data to the memory controller is different.

31.5.3.6.1 M4IF behavior for x64 arbitration

In this case M4IF would provide the data on the bus the way it was provided to it from the masters in the system without any change.

31.5.3.6.2 M4IF behavior for x32 arbitration

In this case M4IF would provide the data on the x32 bus according to the byte lanes. If the access is between B0 to B3, it provides lower 32 word (byte0-3), while when the access is between B4 to B7 it provides higher 32 word (byte4-7).

The following figures shows some examples in LE mode for x32 arbitration:

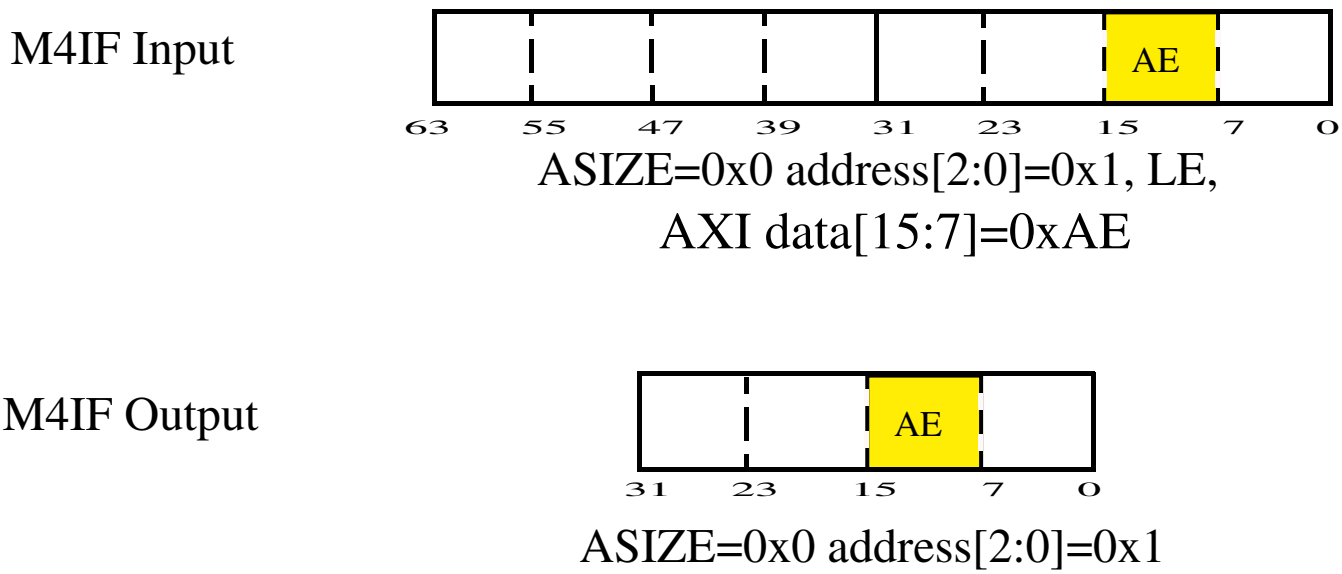

Figure 31-4. Byte access for AXI x64 master and x32 Arbitration slave

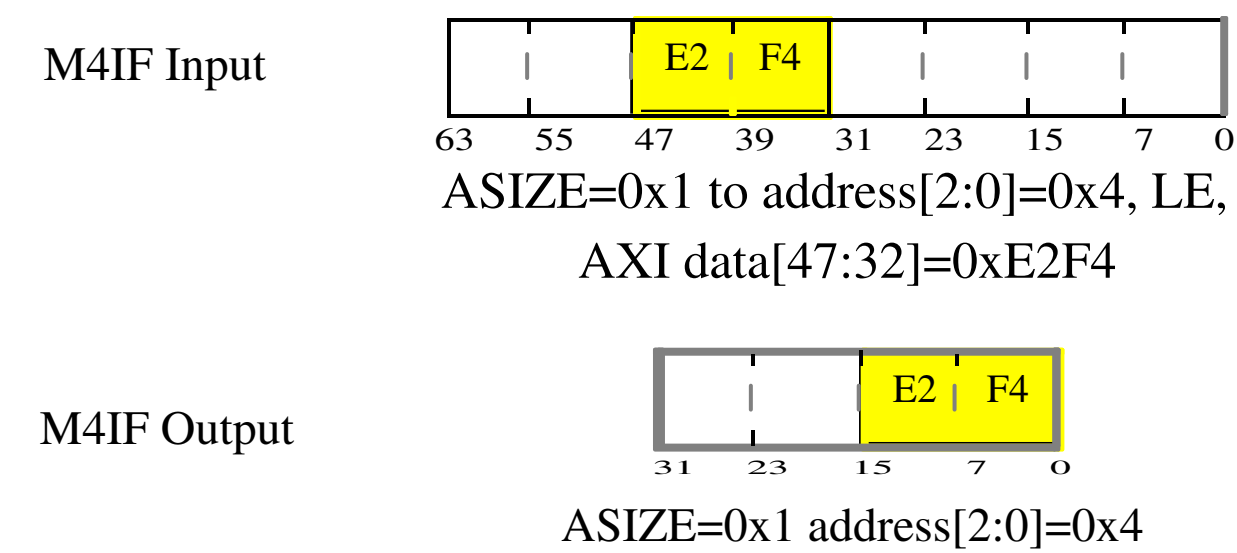

Figure 31-5. Half-Word access for AXI x64 master and x32 Arbitration slave

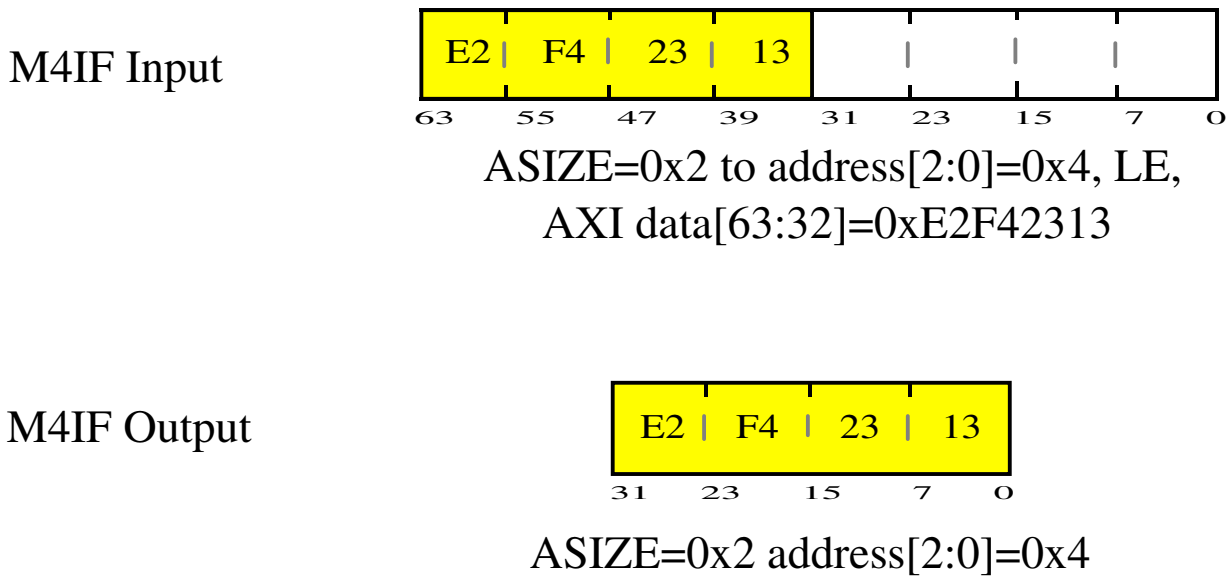

Figure 31-6. Word access for AXI x64 master and x32 Arbitration slave

31.5.4 Data Storage Arrangement

This Section describes the way various memory controllers in EXTMC arrange the data in the external memory device. The section describes only x32 and x16 external memory devices, because x8 devices are not supported in EXTMC.

The following figures describe the data storage location in the external memory devices.

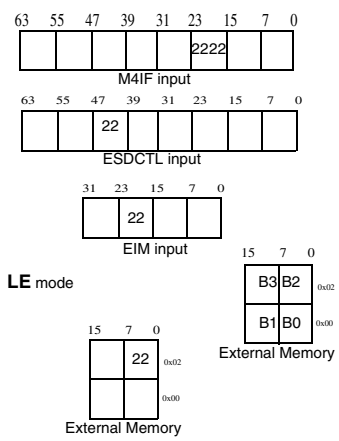

Figure 31-7. Byte access, ASIZE=0x0, ext. memory x16

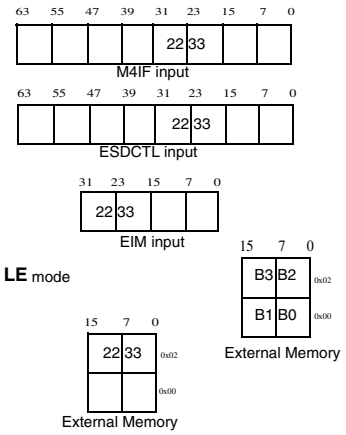

Figure 31-8. Half-word access, ASIZE=0x1, ext. memory x16

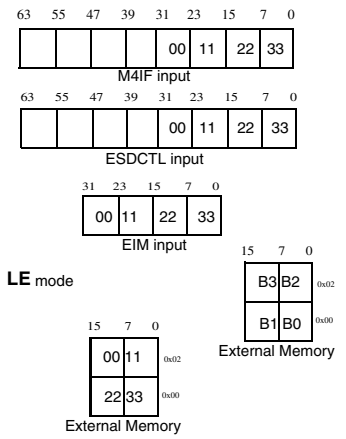

Figure 31-9. Word access, ASIZE=0x2, ext. memory x16

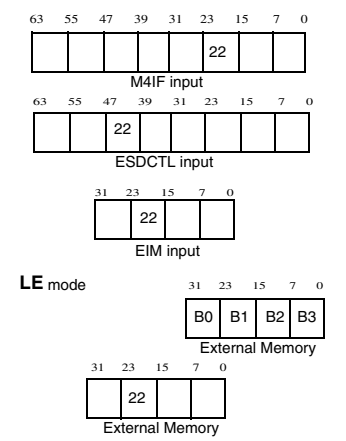

Figure 31-10. Byte access, ASIZE=0x0, ext. memory x32

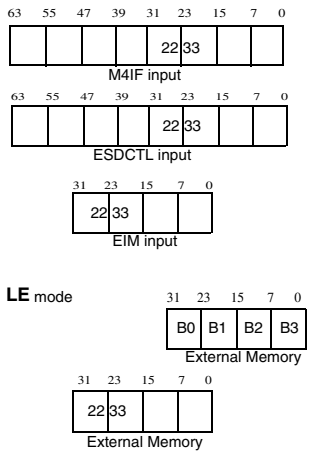

Figure 31-11. Half-word access, ASIZE=0x1, ext. memory x32

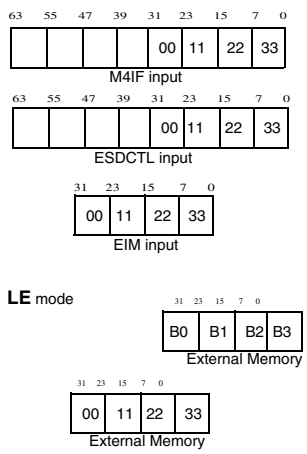

Figure 31-12. Word access, ASIZE=0x2, ext. memory x32

31.6 Programmable Registers

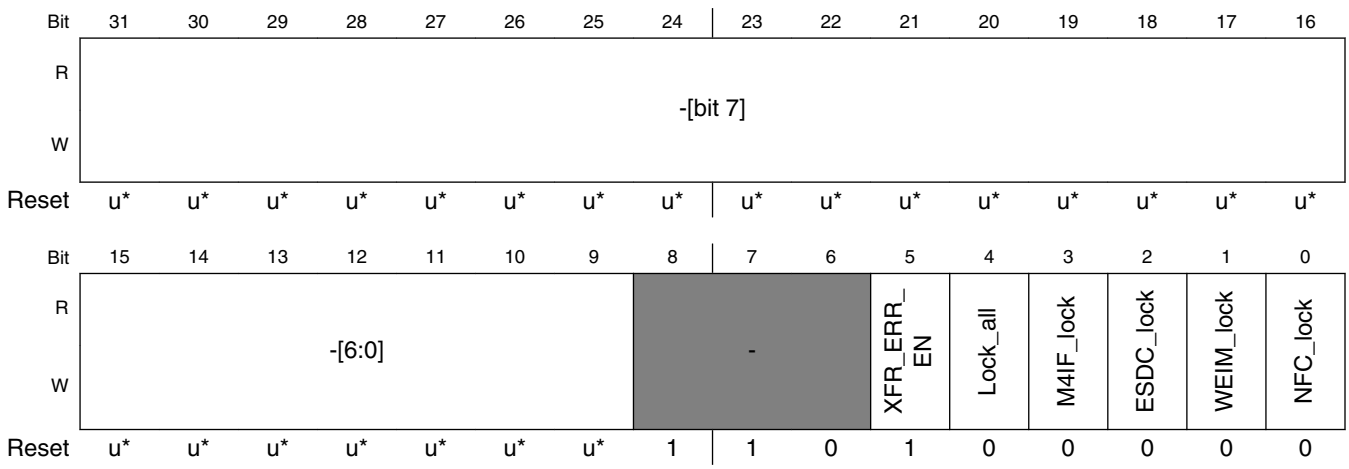
EXTMC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FD_BF00	IP Lock register (EXTMC_EXTMC_IPLCK)	32	R/W	See section	31.6.1/ 1556
63FD_BF04	Interrupt control and Status register (EXTMC_EXTMC_EICS)	32	R/W	See section	31.6.2/ 1557

31.6.1 IP Lock register (EXTMC_EXTMC_IPLCK)

EXTMC_IPLCK register contains the locking configuration bits of each block registers region in EXTMC sub-blocks. This register is accessible by the ARM platform privilege master only as defined at SoC level. Other non privilege masters can only read the content of this register.

Address: EXTMC_EXTMC_IPLCK is 63FD_BF00h base + 0h offset = 63FD_BF00h



* Notes:
- u = Unaffected by reset.

EXTMC_EXTMC_IPLCK field descriptions

Field	Description
31–9 -	N/A.
8–6 -	Reserved.
5 XFR_ERR_EN	EXTMC's ips_xfr_err enable bit. 0 ips_xfr_err is disabled (always equal to 0). 1 ips_xfr_err is enabled.
4 Lock_all	Lock all EXTMC registers from being configured by non privilege masters. 0 register is unlocked. 1 register is locked.
3 M4IF_lock	Lock M4IF registers from being configured by non privilege masters (except BP privilege registers). 0 register is unlocked. 1 register is locked.
2 ESDC_lock	Lock ESDCTL registers from being configured by non privilege masters.

Table continues on the next page...

EXTMC_EXTMC_IPLCK field descriptions (continued)

Field	Description
	0 register is unlocked. 1 register is locked.
1 WEIM_lock	Lock EIM registers from being configured by non privilege masters. 0 register is unlocked. 1 register is locked.
0 NFC_lock	Lock NFC register from being configured by non privilege masters. 0 register is unlocked. 1 register is locked.

31.6.2 Interrupt control and Status register (EXTMC_EXTMC_EICS)

EXTMC_EICS register configured the ORed interrupt scheme. It contains a masking bit for the ORed interrupt as well. EXTMC_EICS is a general type register, when Lock_all bit in IPLCK register is high, only ARM platform master can to write to EXTMC_EICS register, when Lock_all bit is low, all other masters as well as ARM platform can write to it.

Address: EXTMC_EXTMC_EICS is 63FD_BF00h base + 4h offset = 63FD_BF04h

EXTMC_EXTMC_EICS field descriptions

Field	Description
31 EAOIE	EXTMC AP_ORed Interrupt Enable. This bit enables the AP_ORed interrupt generation of EXTMC. For example, if EAOIE bit is set and one of EXTMC sub-block interrupt is generated, AP_ORed interrupt based on its configuration is generated as well. 0 EXTMCv2.1 AP_ORed interrupt is disabled.

Table continues on the next page...

EXTMC_EXTMC_EICS field descriptions (continued)

Field	Description
	1 EXTMCv2.1 AP_ORed interrupt is enabled. (default)
30 EBOIE	EXTMC BP_ORed Interrupt Enable. This bit enables the BP_ORed interrupt generation of EXTMC. For example, if EBOIE bit is set and one of EXTMC sub-block interrupt is generated, BP_ORed interrupt based on its configuration is generated as well. 0 EXTMC BP_ORed interrupt is disabled. 1 EXTMC BP_ORed interrupt is enabled. (default)
29–16 -	Reserved.
15 AUTO_PROG_ DONE_BP_int	BP AUTO_PROG_DONE_int - this bit defines whether AUTO_PROG_DONE BP interrupt is included in the EXTMC BP_ORed interrupt or not. 0 interrupt is not included in BP_ORed.(default) 1 interrupt is included in BP_ORed.
14 AUTO_PROG_ DONE_BP_int	ARM platform AUTO_PROG_DONE_int - this bit defines whether AUTO_PROG_DONE ARM platform interrupt is included in the EXTMC AP_ORed interrupt or not. 0 interrupt is not included in AP_ORed. 1 interrupt is included in AP_ORed. (default)
13 BLEN_int	BP LEN_int - this bit defines whether LEN BP interrupt is included in the EXTMC BP_ORed interrupt or not. 0 interrupt is not included in BP_ORed.(default) 1 interrupt is included in BP_ORed.
12 ALEN_int	ARM platform LEN_int - this bit defines whether LEN ARM platform interrupt is included in the EXTMC AP_ORed interrupt or not. 0 interrupt is not included in AP_ORed. 1 interrupt is included in AP_ORed. (default)
11 BM4IF_AP_int	BP M4IF_AP_int - this bit defines whether M4IF ARM platform interrupt is included in the EXTMC BP_ORed interrupt or not. 0 interrupt is not included in BP_ORed.(default) 1 interrupt is included in BP_ORed.
10 BM4IF_BP_int	BP M4IF_BP_int - this bit defines whether M4IF BP interrupt is included in the EXTMC BP_ORed interrupt or not. 0 interrupt is not included in BP_ORed. 1 interrupt is included in BP_ORed. (default)
9 BWEIM_int	BP WEIM_int - this bit defines whether EIM interrupt is included in the EXTMC BP_ORed interrupt or not. 0 interrupt is not included in BP_ORed. 1 interrupt is included in BP_ORed. (default)
8 BNFC_int	BP NFC_int - this bit defines whether NFC interrupt is included in the EXTMC BP_ORed interrupt or not. 0 interrupt is not included in BP_ORed. 1 interrupt is included in BP_ORed. (default)

Table continues on the next page...

EXTMC_EXTMC_EICS field descriptions (continued)

Field	Description
7 MAIS	M4IF ARM platform interrupt status. This bit indicates if M4IF ARM platform interrupt had occurred. MAIS is updated in the first positive edge of ipg_clk_s in a block read access to EICS. 0 M4IF ARM platform interrupt did not occur. 1 M4IF ARM platform interrupt had occurred.
6 MBIS	M4IF BP interrupt status. This bit indicates if M4IF BP interrupt had occurred. MBIS is updated in the first positive edge of ipg_clk_s in a block read access to EICS. 0 M4IF BP interrupt did not occur. 1 M4IF BP interrupt had occurred.
5 WIS	EIM interrupt status. This bit indicates if EIM interrupt had occurred. WIS is updated in the first positive edge of ipg_clk_s in a block read access to EICS. 0 EIM interrupt did not occur. 1 EIM interrupt had occurred.
4 NIS	NFC interrupt status. This bit indicates if NFC interrupt had occurred. NIS is updated in the first positive edge of ipg_clk_s in a block read access to EICS. 0 NFC interrupt did not occur. 1 NFC interrupt had occurred.
3 AM4IF_AP_int	ARM platform M4IF_AP_int - this bit defines whether M4IF ARM platform interrupt is included in the EXTMC AP_ORed interrupt or not. 0 interrupt is not included in AP_ORed. 1 interrupt is included in AP_ORed. (default)
2 AM4IF_BP_int	ARM platform M4IF_BP_int - this bit defines whether M4IF BP interrupt is included in the EXTMC AP_ORed interrupt or not. 0 interrupt is not included in AP_ORed.(default) 1 interrupt is included in AP_ORed.
1 AWEIM_int	ARM platform WEIM_int - this bit defines whether EIM interrupt is included in the EXTMC AP_ORed interrupt or not. 0 interrupt is not included in AP_ORed. 1 interrupt is included in AP_ORed. (default)
0 ANFC_int	ARM platform NFC_int - this bit defines whether NFC interrupt is included in the EXTMC AP_ORed interrupt or not. 0 interrupt is not included in AP_ORed. 1 interrupt is included in AP_ORed. (default)

Chapter 32
Fast Ethernet Controller (FEC)

32.1 Overview

This chapter provides a feature-set overview, a functional block diagram, and transceiver connection information for the 10- and 100-Mbps media independent interfaces (MII), 10- and 100-Mbps reduced media independent interfaces (RMII), and the 7-wire serial interface. Detailed functional descriptions and application/initialization information are included.

The Fast Ethernet controller (FEC) is designed to support both 10- and 100-Mbps Ethernet/IEEE 802.3 networks. An external transceiver interface and transceiver function are required to complete the interface to the media. The FEC supports three different standard physical interfaces (MAC-PHY) for connection to an external Ethernet transceiver.

The FEC is implemented with a combination of hardware and microcode. The following figure is a block diagram of the FEC.

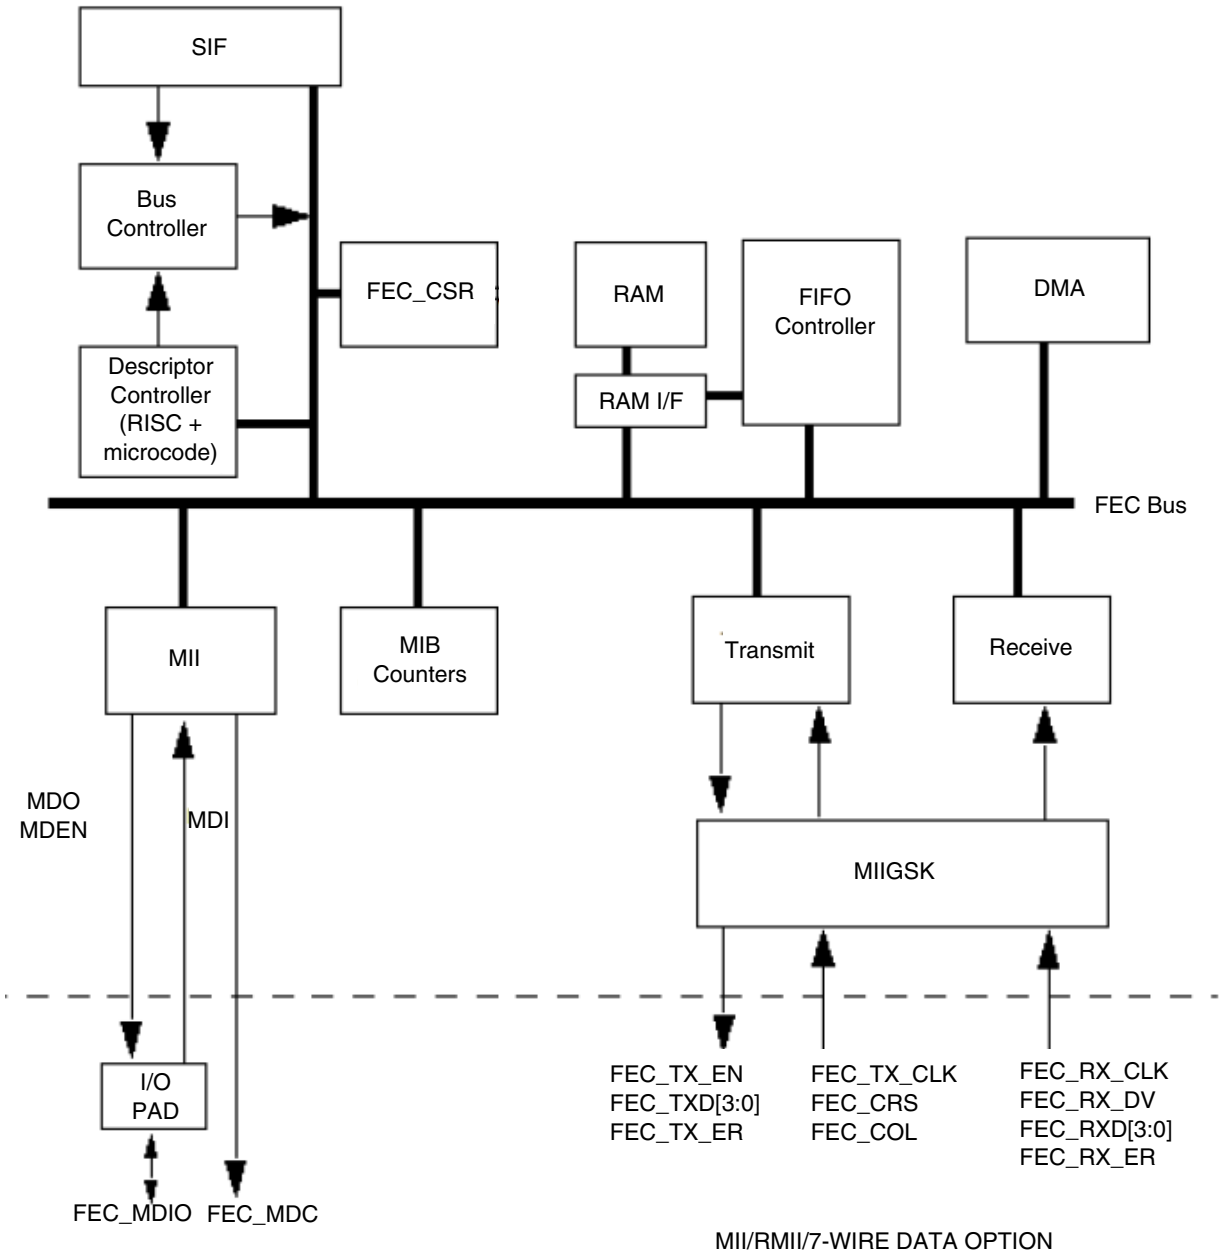

Figure 32-1. FEC Block Diagram

The following section provides information regarding the FEC submodules.

- The descriptor controller is a RISC-based controller that provides the following functions in the FEC:
  - Initialization (those internal registers not initialized by the user or hardware)
  - High-level control of the DMA channels (initiating DMA transfers)
  - Interpreting buffer descriptors
  - Address recognition for receive frames
  - Random number generation for transmit collision backoff timer

NOTE

This DMA engine is for the transfer of FEC data only and is not related to the system DMA controller.

- The RAM is the focal point of all data flow in the FEC and is divided into transmit and receive FIFOs. The FIFO boundaries are programmable using the FEC_FRSR register. User data flows to and from the DMA block, from and to the receive/transmit FIFOs. Transmit data flows from the transmit FIFO to the transmit block, and receive data flows from the receive block to the receive FIFO.
- The user controls the FEC by writing, through the slave interface (SIF) submodule, to control registers located in each block. The control and status register (FEC_CSR) provides global control (for example, Ethernet reset and enable) and interrupt handling registers.
- The MII provides a serial channel for control/status communication with the external physical layer device (transceiver). This serial channel consists of the management data clock and management data input/output lines of the MII interface (FEC_MDC and FEC_MDIO, respectively).
- The DMA provides multiple channels allowing transmit data, transmit descriptor, receive data and receive descriptor accesses to run independently.
- The transmit and receive blocks provide the Ethernet MAC functionality (with some assistance from microcode).
- The message information block (MIB) maintains counters for a variety of network events and statistics. It is not necessary for operation of the FEC but provides valuable counters for network management. The counters supported are the RMON (RFC 1757) Ethernet statistics group and some of the IEEE 802.3 counters. See Message Information Block (MIB) Counters Memory Map, for more information.
- The MII gasket block (MIIGSK) provides an interface between the MII (Media Independent Interface specified by IEEE 802.3 standard) I/F and RMII (low pin count Reduced Media Independent Interface as specified by the RMII Consortium™ standard) I/F.

32.1.1 Features

The FEC incorporates the following features:

- Support for three different Ethernet physical interfaces:
  - 10-Mbps and 100-Mbps IEEE Std. 802.3™ MII
  - 10-Mbps and 100-Mbps RMII
  - 10-Mbps 7-wire interface (industry standard)
- IEEE 802.3 full-duplex flow control
- Programmable max frame length supports IEEE 802.1 VLAN tags and priority

- Support for full-duplex operation (200Mbps throughput) with a minimum system clock rate of 50 MHz
- Support for half-duplex operation (100Mbps throughput) with a minimum system clock rate of 25 MHz
- Retransmission from transmit FIFO following a collision (no processor bus utilization)
- Automatic internal flushing of the receive FIFO for runts (collision fragments) and address recognition rejects (no processor bus utilization)
- Address recognition
  - Frames with broadcast address can be always accepted or always rejected
  - Exact match for single 48-bit individual (unicast) address
  - Hash (64-bit hash) check of individual (unicast) addresses
  - Hash (64-bit hash) check of group (multicast) addresses
  - Promiscuous mode

32.2 Modes of Operation

The primary operational modes are described in this section.

32.2.1 Full- and Half-Duplex Operation

Full-duplex mode is intended for use on point to point links between switches or end node to switch. Half-duplex mode is used in connections between an end node and a repeater or between repeaters. Selection of the duplex mode is controlled by the FEC_TCR[FDEN] bit. When configured for full-duplex mode, flow control can be enabled, which is effected by the FEC_TCR[RFC_PAUSE], FEC_TCR[TFC_PAUSE], and FEC_RCR[FCE] bits. See Full-Duplex Flow Control, for more details.

32.2.2 Interface Options

The following interface options are supported. A detailed discussion of the interface configurations is provided in Network Interface Options.

32.2.2.1 10-Mbps and 100-Mbps Media Independent Interface (MII)

The MII is defined by the IEEE 802.3 standard for 10/100-Mbps operation. The MAC-PHY interface can be configured to operate in MII mode by asserting FEC_RCR[MII_MODE].

The speed of operation is determined by the FEC_TX_CLK and FEC_RX_CLK signals which are driven by the external transceiver. The transceiver either autonegotiates the speed or control by software via the serial management interface (FEC_MDC/FEC_MDIO) signals to the transceiver. See the descriptions in MII management frame register (FEC_MMFR) and MII speed control register (FEC_MSCR) respectively, as well as MII documentation for a description of how to read and write registers in the transceiver through this interface.

32.2.2.2 10 Mbps and 100 Mbps RMII Interface

RMII is a reduced MII interface specified by the RMII Consortium™ standard. The purpose of this interface is to provide a low cost alternative to the MII, with 8 pin interface instead of 16 (Not including MDC, MDIO pins).

The FEC uses a gasket (MIIGSK) to support RMII. It will operate in RMII mode by setting FEC_MIIGSK_CFGR[I/F_MODE] = 01, while setting FEC_MIIGSK_CFGR[I/F_MODE] = 00 will disable RMII mode. The speed selection in RMII Mode is supported by configuring the FEC_MIIGSK_CFGR[FRCONT]. The serial management interface is still available in RMII mode.

32.2.2.3 10-Mbps 7-Wire Interface Operation

The FEC supports a 7-wire interface as used by many 10 Mbps ethernet transceivers. The FEC_RCR[MII_MODE] bit controls this functionality. If this bit is cleared, the MII mode is disabled and the 10 Mbps, 7-wire mode is enabled.

32.2.3 Address Recognition Options

The address options supported are promiscuous, broadcast reject, individual address (hash or exact match), and multicast hash match. Address recognition options are discussed in detail in Ethernet Address Recognition.

32.2.4 Internal Loopback

Two levels of internal loopback modes are supported. The first level, which will loop data back before they enter MIIGSK, is selected by FEC_RCR[LOOP]. The second level, which will loop data back inside MIIGSK RMII domain, is selected by setting FEC_MIIGSK_CFGR[LBMODE] and FEC_MIIGSK_CFGR[I/F_MODE] = 01. Loopback mode is discussed in detail in Internal and External Loopback.

32.3 Functional Description

This section provides a detailed description of the functions of the FEC including:

- Network interface options
- Frame transmission and reception
- Full-duplex flow control
- Internal and external loopback

32.3.1 Network Interface Options

The FEC supports an MII interface, an RMII interface for 10/100 Mbps Ethernet and a 7-wire serial interface for 10 Mbps Ethernet.

The interface mode is selected by FEC_MIIGSK_CFGR[I/F_MODE] together with the FEC_RCR[MII_MODE] bit as shown in the table below.

Table 32-1. Interface Mode Selection

FEC_MIIGSK_CFGR[I/F_MODE]	FEC_RCR[MII_MODE]	Interface Mode Selected
00	0	7-Wire
00	1	MII
01	1	RMII

In MII mode, there are 18 signals defined by the IEEE 802.3 standard and supported by the FEC_ These signals are shown in the table below.

Table 32-2. MII Mode Signal Configuration

Signal Description	FEC Signal Name	Direction
Transmit clock	FEC_TX_CLK	In
Transmit enable	FEC_TX_EN	Out
Transmit data	FEC_TXD[3:0]	Out

Table continues on the next page...

Table 32-2. MII Mode Signal Configuration (continued)

Signal Description	FEC Signal Name	Direction
Transmit error	FEC_TX_ER	Out
Collision	FEC_COL	In
Carrier sense	FEC_CRS	In
Receive clock	FEC_RX_CLK	In
Receive data valid	FEC_RX_DV	In
Receive data	FEC_RXD[3:0]	In
Receive error	FEC_RX_ER	In
Management data clock	FEC_MDC	Out
Management data input/output	FEC_MDIO	I/O

In RMII mode, a reduced set of 10 signals are used. These signals are shown in Table 32-3.

Table 32-3. RMII Mode Signal Configuration

Signal Description	FEC Signal Name	Direction
Synchronous clock reference (REF_CLK)	FEC_TX_CLK	In
Transmit Enable	FEC_TX_EN	Out
Transmit Data	FEC_TXD[1:0]	Out
Carrier Sense/Receive Data Valid (CRS_DV)	FEC_RX_DV	In
Receive Data	FEC_RXD[1:0]	In
Receive Error	FEC_RX_ER	In
Management Data Clock	FEC_MDC	Out
Management Data Input/Output	FEC_MDIO	I/O

The 7-wire serial interface operates in what is generally referred to as AMD mode. 7-wire mode connections to the external transceiver are shown in Table 32-4.

Table 32-4. 7-Wire Mode Signal Configuration

Signal Description	FEC Signal Name	Direction
Transmit clock	FEC_TX_CLK	In
Transmit enable	FEC_TX_EN	Out
Transmit data	FEC_TXD[0]	Out
Collision	FEC_COL	In
Receive clock	FEC_RX_CLK	In
Receive data valid	FEC_RX_DV	In
Receive data	FEC_RXD[0]	In

32.3.2 FEC Frame Transmission

The Ethernet transmitter is designed to work with almost no intervention from software. After FEC_ECR[ETHER_EN] is set to 1 and data appears in the transmit FIFO, the FEC is able to transmit on to the network.

When the transmit FIFO fills to the watermark (defined by the FEC_TFWR register), the FEC transmit logic asserts FEC_TX_EN and starts transmitting the preamble (PA) sequence, the start frame delimiter (SFD), and then the frame information from the FIFO. However, the controller postpones transmission if the network is busy (that is, the carrier sense signal FEC_CRS is asserted). Before transmitting, the controller waits for carrier sense to become inactive, then determines if carrier sense remains inactive for 60 bit periods. If so, the transmission begins after waiting an additional 36 bit periods (96 bit periods after carrier sense originally became inactive). See Transmission Error Handling for more details.

If a collision occurs during transmission of a frame in half-duplex mode, the Ethernet controller follows the specified backoff procedures (see Collision Handling) and attempts to retransmit the frame until the retry limit is reached. The transmit FIFO stores at least the first 64 bytes of the transmit frame, so that they do not have to be retrieved from system memory in case of a collision. This improves bus utilization and latency in case immediate retransmission is necessary.

When all the frame data has been transmitted, if the TC bit is set in the transmit frame control word then a 32-bit cyclic redundancy check (CRC) known as the frame check sequence (FCS) is appended. If the ABC bit is set in the transmit frame control word, a bad CRC is appended to the frame data regardless of the TC bit value. Following the transmission of the CRC, the Ethernet controller writes the frame status information to the MIB block. Short frames are automatically padded by the transmit logic (if the TC bit in the transmit buffer descriptor for the end of frame buffer is set to 1).

Both buffer (TXB) and frame (TXF) interrupts can be generated as determined by the settings in the FEC_EIMR.

The transmit error interrupts are HBERR, BABT, LATE_COL, COL_RETRY_LIM, and XFIFO_UN. If the transmit frame length exceeds MAX_FL bytes the BABT interrupt is asserted: however, the entire frame is transmitted (no truncation).

Transmission is paused by setting the graceful transmit stop (GTS) bit in the FEC_TCR register. When the FEC_TCR[GTS] is set to 1, the FEC transmitter stops immediately if transmission is not in progress; otherwise, it continues transmission until the current

frame either finishes or terminates with a collision. After the transmitter has stopped the GRA (graceful stop complete) interrupt is asserted. If FEC_TCR[GTS] is cleared, the FEC resumes transmission with the next frame.

The Ethernet controller transmits bytes LSB first.

32.3.2.1 Transmit Inter-Packet Gap (IPG) Time

The minimum inter-packet gap (IPG) time for back-to-back transmission is 96 bit periods. After completing a transmission or after the backoff algorithm completes, the transmitter waits for carrier sense to be negated before starting its 96-bit-period IPG counter. Frame transmission begins 96 bit periods after carrier sense is negated if it stays negated for at least 60 bit periods. If carrier sense is asserted during the last 36 bit periods, it is ignored and a collision occurs.

32.3.2.2 Collision Handling

If a collision occurs during frame transmission, the Ethernet controller continues the transmission for at least 32 bit periods, transmitting a jam pattern consisting of 32 ones. If the collision occurs during the preamble sequence, the jam pattern is sent after the end of the preamble sequence.

If a collision occurs within 512 bit periods, the retry process is initiated. The transmitter waits a random number of slot periods, where one slot period is 512 bit periods. If a collision occurs after 512 bit periods, then no retransmission is performed and the end of frame buffer is closed with a late collision (LC) error indication.

32.3.2.3 Transmission Error Handling

The Ethernet controller reports frame transmission error conditions using the FEC RxBDs, the FEC_EIR register, and the MIB block counters.

There are four types of transmission errors:

- Transmitter underrun
- Retransmission attempts limit expired
- Late collision
- Heartbeat

The FEC's procedures for handling these errors are described in the following subsections.

32.3.2.3.1 Transmitter Underrun

If this error occurs, the FEC sends 32 bits that ensure a CRC error, then stops transmitting. All remaining buffers for that frame are then flushed and closed. The UN bit is set in the FEC_EIR and the UN interrupt is asserted (if enabled in the FEC_EIMR register). The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame.

32.3.2.3.2 Retransmission Attempts Limit Expired

When this error occurs, the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and the RL bit is set in the FEC_EIR. The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame.

The "RL" interrupt is asserted if enabled in the FEC_EIMR register.

32.3.2.3.3 Late Collision

When a collision occurs after the slot time (512 bits starting at the preamble), the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and the LC bit is set in the FEC_EIR register. The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame.

The LC interrupt is asserted if enabled in the FEC_EIMR register.

32.3.2.3.4 Heartbeat

Some transceivers have a self-test feature called "heartbeat" or "signal quality error." To signify a good self-test, the transceiver indicates a collision to the FEC within 4 microseconds after completion of a frame transmitted by the Ethernet controller. This indication of a collision does not imply a real collision error on the network, but is rather an indication that the transceiver still seems to be functioning properly. This is called the heartbeat condition.

If the HBC bit is set in the FEC_TCR register and the heartbeat condition is not detected by the **FEC** after a frame transmission, then a heartbeat error occurs. When this error occurs, the FEC closes the buffer, sets the HB bit in the FEC_EIR register, and generates the HBERR interrupt if it is enabled.

32.3.3 FEC Frame Reception

The FEC receiver is designed to work with almost no intervention from the host and can perform address recognition, CRC checking, short frame checking, and maximum frame length checking.

When the driver enables the FEC receiver by setting FEC_ECR[ETHER_EN] to 1, it immediately starts processing receive frames. When FEC_RX_DV asserts, the receiver first checks for a valid PA/SFD header. If the PA/SFD is valid, it is stripped and the frame is processed by the receiver. If a valid PA/SFD is not found, the frame is ignored.

In serial mode, the first 16 bit periods of RX_D0 following assertion of FEC_RX_DV are ignored. Following the first 16 bit periods the data sequence is checked for alternating 1/0s. If a 0b11 or 0b00 data sequence is detected during bit periods 17 to 21, the remainder of the frame is ignored. After bit period 21, the data sequence is monitored for a valid SFD (11). If a 0b00 is detected, the frame is rejected. When a 0b11 is detected, the PA/SFD sequence is complete.

In MII mode, the receiver checks for at least one byte matching the SFD. Zero or more PA bytes can occur, but if a 0b00 bit sequence is detected prior to the SFD byte, the frame is ignored.

After the first 6 bytes of the frame have been received, the FEC performs address recognition on the frame.

After a collision window (64 bytes) of data has been received, and if address recognition has not rejected the frame, the receive FIFO is signaled that the frame is accepted and can be passed on to the DMA. If the frame is a runt (due to collision) or is rejected by address recognition, the receive FIFO is notified to reject the frame. Thus no collision fragments are presented to the user except late collisions, which indicate serious LAN problems.

During reception, the Ethernet controller checks for various error conditions and after the entire frame is written into the FIFO, a 32-bit frame status word is written into the FIFO. This status word contains the M, BC, MC, LG, NO, CR, OV and TR status bits, and the frame length. See Reception Error Handling for more details.

Receive Buffer (RXB) and Frame Interrupts (RXF) can be generated if enabled by the FEC_EIMR register. The only receive error interrupt is babbling receiver error (BABR). Receive frames are not truncated if they exceed the max frame length (MAX_FL); however, the BABR interrupt occurs and the LG bit in the receive buffer descriptor (RxBD) is set. See Ethernet Receive Buffer Descriptor (RxBD) for more details.

When the receive frame is complete, the FEC sets the L bit in the RxBD, writes the other frame status bits into the RxBD, and clears the E bit. The Ethernet controller next generates a maskable interrupt (RXF bit in FEC_EIR, maskable by RXF bit in FEC_EIMR), indicating that a frame has been received and is in memory. The Ethernet controller then waits for a new frame.

The Ethernet controller receives serial data LSB first.

32.3.3.1 Receive Inter-Packet Gap (IPG) Time

The receiver receives back-to-back frames with a minimum spacing of 28-bit periods. If an inter-packet gap between receive frames is less than 28 bit periods, the second frame may be discarded by the receiver.

32.3.3.2 Ethernet Address Recognition

Address recognition is accomplished through the use of the receive block and microcode running on the microcontroller. The flowchart shown in Figure 32-2 illustrates the address recognition decisions made by the receive block, while Figure 32-3 illustrates the decisions made by the microcontroller.

The FEC filters the received frames based on destination address (DA) type - individual (unicast), group (multicast), or broadcast (all-ones group address). The difference between an individual address and a group address is determined by the I/G bit in the DA field.

If the DA is a broadcast address, and broadcast reject (FEC_RCR[BC_REJ]) is cleared, then the frame is accepted unconditionally, as shown in Figure 32-2. Otherwise, if the DA is not a broadcast address, then the microcontroller runs the address recognition subroutine, as shown in Figure 32-3.

If the DA is a group (multicast) address and flow control is disabled, then the microcontroller performs a group hash table lookup using the 64-entry hash table programmed in FEC_GAUR and FEC_GALR. If a hash match occurs, the receiver accepts the frame. The hash algorithm is described in Hash Algorithm.

If flow control is enabled, the microcontroller does an exact address match check between the DA and the designated PAUSE DA (01:80:C2:00:00:01). If the receive block determines that the received frame is a valid pause frame, then the frame is rejected.

NOTE

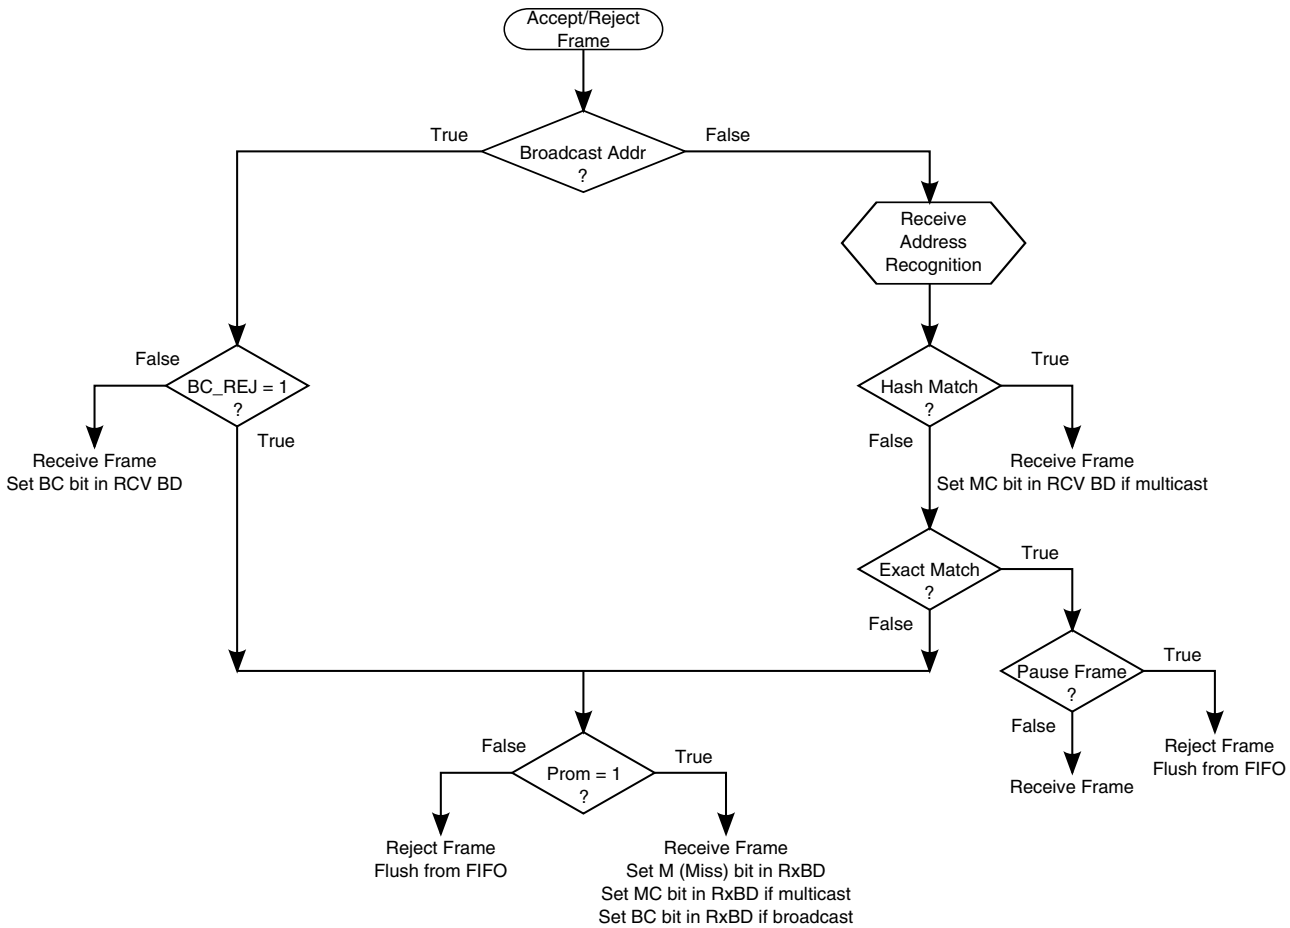
The receiver detects a pause frame with the DA field set to either the designated PAUSE DA or the unicast physical address.

If the DA is the individual (unicast) address, the microcontroller performs an individual exact match comparison between the DA and 48-bit physical address that the user programs in the FEC_PALR and FEC_PAUR registers. If an exact match occurs, the frame is accepted; otherwise, the microcontroller does an individual hash table lookup using the 64-entry hash table programmed in registers, FEC_IAUR and FEC_IALR (the hash algorithm is described in Hash Algorithm). In the case of an individual hash match, the frame is accepted. Again, the receiver accepts or rejects the frame based on pause frame detection, shown in Figure 32-2.

If neither a hash match (group or individual), nor an exact match occur, then if promiscuous mode is enabled (FEC_RCR[PROM] = 1), the frame is accepted and the MISS bit in the receive buffer descriptor is set. Otherwise, the frame is rejected.

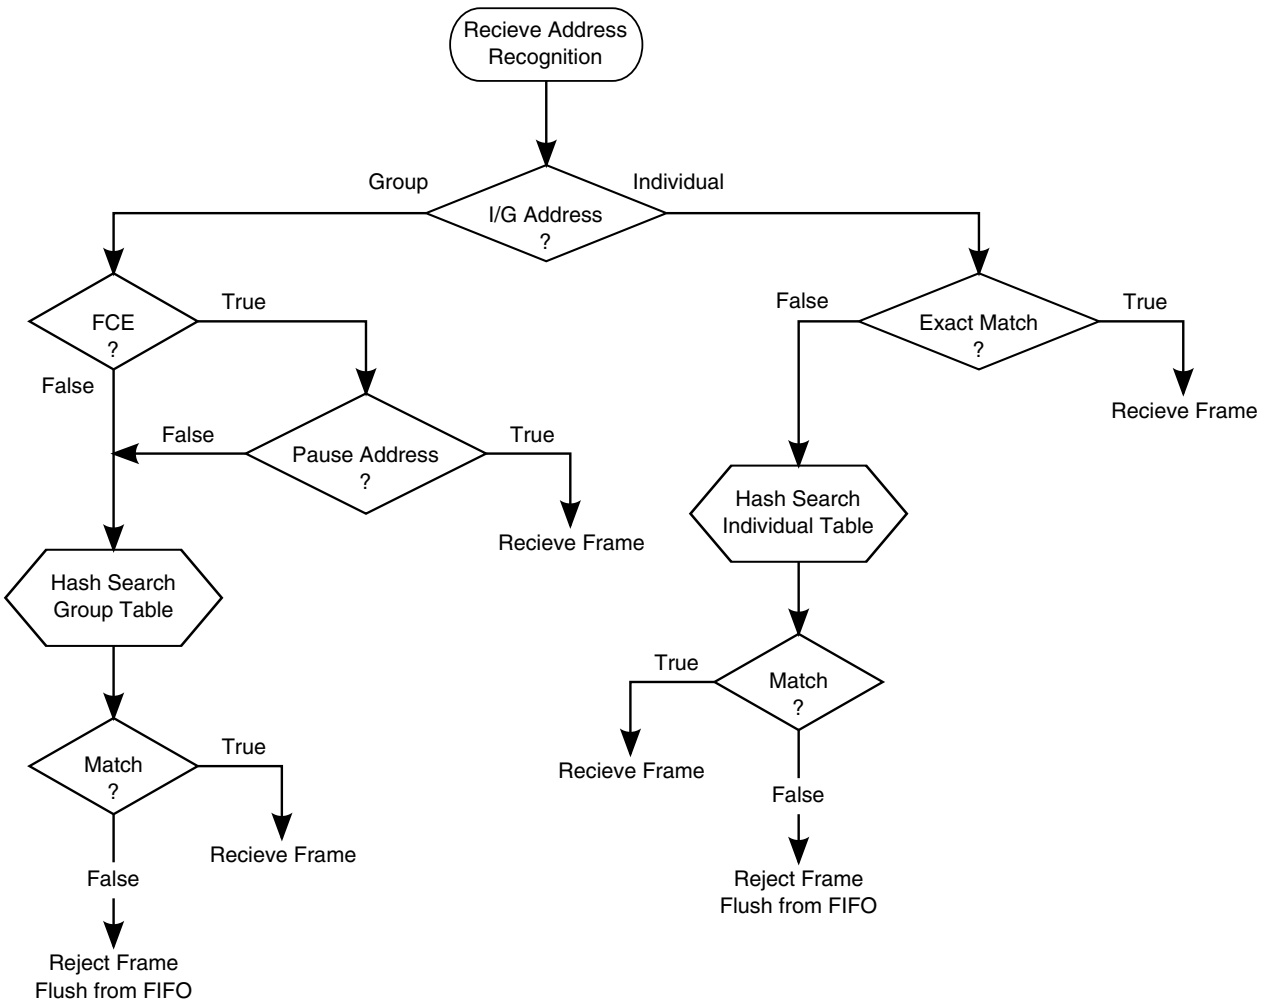
Similarly, if the DA is a broadcast address, broadcast reject (FEC_RCR[BC_REJ]) is asserted, and promiscuous mode is enabled, then the frame is accepted and the MISS bit in the receive buffer descriptor is set. Otherwise, the frame is rejected.

In general, when a frame is rejected, it is flushed from the FIFO.



NOTES:
BC_REJ - Field in RCR register (BroadCast REJect)
PROM-Field in RCR register (PROMiscuous mode)
Pause Frame - Valid PAUSE frame received

Figure 32-2. Ethernet Address Recognition-Receive Block Decisions



NOTES:

I/G - Individual/Group bit in Destination Address (least signifigant bit in first byte recieved in MAC frame)

Figure 32-3. Ethernet Address Recognition-Microcode Decisions

32.3.3.2.1 Hash Algorithm

The hash table algorithm used in the group and individual hash filtering operates as follows. The 48-bit destination address is mapped into one of 64 bits, which are represented by 64 bits stored in FEC_GAUR, FEC_GALR (group address hash match) or FEC_IAUR, FEC_IALR (individual address hash match). This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63. The MSB of the CRC result selects FEC_GAUR (MSB = 1) or FEC_GALR (MSB = 0). The least significant five bits of the hash result select the bit within the selected register. If the CRC generator selects a bit that is set in the hash table, the frame is accepted; otherwise, it is rejected. For example, if eight group addresses are stored in the hash table

and random group addresses are received, the hash table prevents roughly 56/64 (87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The hash table registers must be initialized by the user. The CRC32 polynomial to use in computing the hash is shown in the following equation:

$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^{8} + X^{7} + X^{5} + X^{4} + X^{2} + X + 1$$

Table 32-5 shows example destination addresses and corresponding hash values is included below for reference.

32.3.3.3 Reception Error Handling

The Ethernet controller reports frame reception error conditions using the FEC RxBDs, the FEC_EIR register, and the MIB counters.

There are five types of reception errors:

- Overrun
- Non-octet (dribbling bits)
- CRC
- Frame-length violation
- Truncation

These are described in the following subsections.

32.3.3.3.1 Overrun

If the receive block has data to put into the receive FIFO and the receive FIFO is full, the FEC sets the OV bit in the RxBD. All subsequent data in the frame is discarded, and subsequent frames can also be discarded until the receive FIFO is serviced by the DMA and space is made available. At this point the receive frame/status word is written into the FIFO with the OV bit set. This frame must be discarded by the driver.

32.3.3.3.2 Non-Octet (Dribbling Bits)

The Ethernet controller handles up to seven dribbling bits when the receive frame terminates past an non-octet aligned boundary. Dribbling bits are not used in the CRC calculation. If there is a CRC error, then the frame non-octet aligned (NO) error is reported in the RxBD. If there is no CRC error, then no error is reported.

32.3.3.3.3 CRC

When a CRC error occurs with no dribble bits, the FEC closes the buffer and sets the CR bit in the RxBD. CRC checking cannot be disabled, but the CRC error can be ignored if checking is not required.

32.3.3.3.4 Frame Length Violation

When the receive frame length exceeds MAX_FL bytes the BABR interrupt is generated, and the LG bit in the end of frame RxBD is set. The frame is not truncated unless the frame length exceeds 2047 bytes).

32.3.3.3.5 Truncation

When the receive frame length exceeds 2047 bytes, the frame is truncated and the TR bit is set in the RxBD.

32.3.4 Full-Duplex Flow Control

Full-duplex flow control allows the user to transmit pause frames and to detect received pause frames. Upon detection of a pause frame, FEC data frame transmission stops for a given pause duration.

To enable pause frame detection, the FEC must operate in full-duplex mode (FEC_TCR[FDEN] asserted) and flow control enable (FEC_RCR[FCE]) must be asserted. The FEC detects a pause frame when the fields of the incoming frame match the pause frame specifications, as shown in Table 32-6. In addition, the receive status associated with the frame indicates that the frame is valid.

Table 32-6. Pause Frame Field Specification

48-bit destination address	0x0180_C200_0001 or physical address
48-bit source address	Any
16-bit type	0x8808
16-bit opcode	0x0001

Table continues on the next page...

Table 32-6. Pause Frame Field Specification (continued)

48-bit destination address	0x0180_C200_0001 or physical address
16-bit pause duration	0x0000-0xFFFF

Pause frame detection is performed by the receiver and microcontroller modules. The microcontroller runs an address recognition subroutine to detect the specified pause frame destination address, while the receiver detects the type and opcode pause frame fields. On detection of a pause frame, FEC_TCR[GTS] is asserted by the FEC internally. When transmission has paused, the FEC_EIR[GRA] interrupt is asserted and the pause timer begins to increment.

NOTE

The pause timer makes use of the transmit backoff timer hardware, which is used for tracking the appropriate collision backoff time in half-duplex mode. The pause timer increments after every slot time, until FEC_OPD[PAUSE_DUR] slot times have expired.

On FEC_OPD[PAUSE_DUR] expiration, FEC_TCR[GTS] is cleared allowing FEC data frame transmission to resume.

NOTE

The receive flow control pause (FEC_TCR[RFC_PAUSE]) status bit is asserted while the transmitter is paused due to reception of a pause frame.

To transmit a pause frame, the FEC must operate in full-duplex mode and the user must assert flow control pause (FEC_TCR[TFC_PAUSE]). On assertion of transmit flow control pause (FEC_TCR[TFC_PAUSE]), the transmitter asserts FEC_TCR[GTS] internally. When the transmission of data frames stops, the FEC_EIR[GRA] (graceful stop complete) interrupt asserts. Following FEC_EIR[GRA] assertion, the pause frame is transmitted. On completion of pause frame transmission, flow control pause (FEC_TCR[TFC_PAUSE]) and FEC_TCR[GTS] are cleared internally.

The user must specify the desired pause duration in the FEC_OPD register.

NOTE

When the transmitter is paused due to receiver/microcontroller pause frame detection, transmit flow control pause (FEC_TCR[TFC_PAUSE]) still can be asserted and causes the transmission of a single pause frame. In this case, the FEC_EIR[GRA] interrupt is not asserted.

32.3.5 Internal and External Loopback

Both internal and external loopback are supported by the Ethernet controller. In loopback mode, both of the FIFOs are used and the FEC actually operates in a full-duplex fashion. Both internal and external loopback are configured using combinations of the LOOP and DRT bits in the FEC_RCR register, the FDEN bit in the FEC_TCR register and the LBMODE bit in FEC_MIIGSK_CFGR register. Furthermore internal loopback has two levels which loops data back in MII domain and RMII domain respectively.

For both internal and external loopback set FDEN = 1 and FEC_RCR[DRT] = 0.

For the MII domain internal loopback set FEC_RCR[LOOP] = 1 and FEC_MIIGSK_CFGR[LBMODE] = 0. FEC_TX_EN and FEC_TX_ER will not assert during internal loopback. During the MII domain internal loopback, the transmit/receive data rate is higher than in normal operation because the internal system clock is used by the transmit and receive blocks instead of the clocks from the external transceiver. This will cause an increase in the required system bus bandwidth for transmit and receive data being DMA'd to/from external memory. It may be necessary to pace the frames on the transmit side and/or limit the size of the frames to prevent transmit FIFO underrun and receive FIFO overflow.

For the RMII domain internal loopback, set FEC_RCR[LOOP] = 0 and FEC_MIIGSK_CFGR[LBMODE] = 1. The data is sent from the MII domain into MIIGSK, converted to RMII format by a RMII transmitter inside the MIIGSK, then looped back through a RMII receiver of the MIIGSK, finally gets back to the MII domain.

For external loopback set FEC_RCR[LOOP] = 0, FEC_MIIGSK_CFGR[LBMODE] = 0, and configure the external transceiver for loopback.

32.4 Initialization/Application Information

32.4.1 Initialization Sequence

This section describes which registers are reset due to hardware reset, which are reset by the FEC RISC, and what locations the user must initialize prior to enabling the FEC.

32.4.1.1 Hardware Controlled Initialization

In the FEC, registers and control logic that generate interrupts are reset by hardware. A hardware reset negates output signals and resets general configuration bits.

Other registers are reset when the FEC_ECR[ETHER_EN] bit is cleared, as indicated in Table 32-7. FEC_ECR[ETHER_EN] is cleared by a hard reset or can be cleared by software to halt operation. By clearing FEC_ECR[ETHER_EN], the configuration control registers such as the FEC_TCR and FEC_RCR do not reset, but the entire data path resets.

Table 32-7. Effect on FEC of Clearing FEC_ECR[ETHER_EN]

Register/Machine	Reset Value
XMIT block	Transmission is aborted (bad CRC appended)
RECV block	Receive activity is aborted
DMA block	All DMA activity is terminated
FEC_RDAR	Cleared
FEC_TDAR	Cleared
Descriptor Controller block	Halt operation
MIIGSK	Interface to transceiver is disabled

32.4.1.2 User Initialization (Prior to Asserting FEC_ECR[ETHER_EN])

The user must initialize portions of the FEC prior to setting the FEC_ECR[ETHER_EN] bit. The exact values depend on the particular application. The order of initializations is not important except those that are explicitly mentioned.

The FEC and FEC FIFO/DMA registers which require initialization are defined in Table 32-8.

Table 32-8. Registers Requiring Initialization before Setting FEC_ECR[ETHER_EN]

Register	Location (FEC or FIFO/DMA)	Comments
FEC_EIMR	FEC	Requires initialization
FEC_EIR	FEC	Must be cleared by writing 0xFFFF_FFFF
FEC_TFWR	FEC	Optional
FEC_IALR / FEC_IAUR	FEC	-
FEC_GAUR / FEC_GALR	FEC	-

Table continues on the next page...

Table 32-8. Registers Requiring Initialization before Setting FEC_ECR[ETHER_EN] (continued)

Register	Location (FEC or FIFO/ DMA)	Comments
FEC_PALR / FEC_PAUR	FEC	-
FEC_OPD	FEC	Only needed for full-duplex flow control
FEC_RCR	FEC	-
FEC_TCR	FEC	-
FEC_MSCR	FEC	Optional
FEC_MIIGSK_CFGR	FEC	Must be configured before setting FEC_MIIGSK_ENR[EN]
FEC_MIIGSK_ENR	FEC	EN bit must be set
MIB counters	FEC	Must be cleared
FEC_FRSR	FIFO/DMA	Initialization is optional
FEC_EMRBR	FIFO/DMA	-
FEC_ERDSR	FIFO/DMA	-
FEC_ETDSR	FIFO/DMA	-
Transmit Descriptor ring	FIFO/DMA	Must be emptied
Receive Descriptor ring	FIFO/DMA	Must be emptied

32.4.1.3 Microcontroller Initialization

In the FEC, the descriptor control RISC initializes some registers after FEC_ECR[ETHER_EN] is asserted. After the microcontroller initialization sequence is complete, the hardware is ready for operation.

The microcontroller initialization sequence follows:

1. Initialize BackOff Random Number Seed
2. Activate Receiver
3. Activate Transmitter
4. Clear Transmit FIFO
5. Clear Receive FIFO
6. Initialize Transmit Ring Pointer
7. Initialize Receive Ring Pointer
8. Initialize FIFO Count Register

32.4.1.4 User Initialization (after asserting FEC_ECR[ETHER_EN])

After asserting FEC_ECR[ETHER_EN], the user can set up the buffer/frame descriptors and write to the FEC_TDAR and FEC_RDAR. See Buffer Descriptors for more details.

32.4.2 Buffer Descriptors

This section provides a description of the operation of the driver/DMA through the buffer descriptors (BD). It is followed by a detailed description of the receive and transmit descriptor fields.

32.4.2.1 Driver/DMA Operation with Buffer Descriptors

The data for the FEC frames must reside in memory external to the FEC. The data for a frame is placed in one or more buffers. Associated with each buffer is a buffer descriptor (BD) which contains a starting address (pointer), data length, and status/control information (which contains the current state for the buffer). To permit maximum user flexibility, the BDs are also located in external memory and are read in by the FEC DMA engine.

Software "produces" buffers by allocating/initializing memory and initializing buffer descriptors. Setting the RxBD[E] or TxBD[R] bit "produces" the buffer. Software writing to either the FEC_TDAR or FEC_RDAR tells the FEC that a buffer has been placed in external memory for the transmit or receive data traffic, respectively. The hardware reads the BDs and "consumes" the buffers after they have been produced. After the data DMA is complete and the buffer descriptor status bits have been written by the DMA engine, the RxBD[E] or TxBD[R] bit is cleared by hardware to signal the buffer has been "consumed." Software can poll the BDs to detect when the buffers have been consumed or can rely on the buffer/frame interrupts. These buffers can then be processed by the driver and returned to the free list.

The FEC_ECR[ETHER_EN] signal operates as a reset to the BD/DMA logic. When FEC_ECR[ETHER_EN] is cleared the DMA engine BD pointers are reset to point to the starting transmit and receive BDs. The buffer descriptors are not initialized by hardware during reset. At least one transmit and receive buffer descriptor must be initialized by software before the FEC_ECR[ETHER_EN] bit is set.

The buffer descriptors operate as two separate rings. FEC_ERDSR defines the starting address for receive BDs and FEC_ETDSR defines the starting address for transmit BDs. The last buffer descriptor in each ring is defined by the Wrap (W) bit. When set, W indicates that the next descriptor in the ring is at the location pointed to by FEC_ERDSR and FEC_ETDSR for the receive and transmit rings, respectively.

NOTE

Buffer descriptor rings must start on a 128-bit boundary.

32.4.2.2 Ethernet Transmit Buffer Descriptor (TxBD)

Table 32-9 shows the transmit buffer descriptor format. Table 32-10 describes the TxBD fields.

Status bits for the buffer/frame are not included in the transmit buffer descriptors. Transmit frame status is indicated by individual interrupt bits (error conditions) and in statistic counters in the MIB block. See Message Information Block (MIB) Counters Memory Map, for more details.

Table 32-9. Transmit Buffer Descriptor (TxBD)

Offset	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0x0000	R	TO1	W	TO2	L	TC	ABC	PTP								
	Data Length															
0x0004	Tx Data Buffer Pointer A[31:16]															
	Tx Data Buffer Pointer A[15:0]															

Table 32-10. Transmit Buffer Descriptor Field Definitions

Offset	Field	Description
0x0000	31 R	Ready. Written by the FEC and the user. 0 The data buffer associated with this BD is not ready for transmission. The user is free to manipulate this BD or its associated data buffer. The FEC clears this bit after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, which has been prepared for transmission by the user, has not been transmitted or is currently being transmitted. No fields of this BD can be written by the user after this bit is set.
0x0000	30 TO1	Transmit software ownership. This field is reserved for software use. This read/write bit is not modified by hardware, nor does its value affect hardware.
0x0000	29 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in FEC_ETDSR.
0x0000	28 TO2	Transmit software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
0x0000	27 L	Last in frame. Written by user. 0 The buffer is not the last in the transmit frame. 1 The buffer is the last in the transmit frame.

Table continues on the next page...

Table 32-10. Transmit Buffer Descriptor Field Definitions (continued)

Offset	Field	Description
0x0000	26 TC	Tx CRC. Written by user (only valid if L = 1). 0 End transmission immediately after the last data byte. 1 Transmit the CRC sequence after the last data byte.
0x0000	25 ABC	Append bad CRC. Written by user (only valid if L = 1). 0 No effect 1 Transmit the CRC sequence inverted after the last data byte (regardless of TC value).
0x0000	24 PTP	PTP. Written by user (only valid if L = 1). 0 No effect 1 The frame is an IEEE1588 PTP frame. FEC will inform IPTP Assist modue to capture the timestamp for this frame in case of successful transmission. If unmasked, an interrupt will be issued by the IPTP Assist block after the timestamp is available.
0x0000	23-16	Reserved.
0x0000	15-0 Data Length	Data Length, written by user. Data length is the number of octets the FEC transmits from this BD's data buffer. It is never modified by the FEC. Bits [10:0] are used by the DMA engine, bits[15:11] are ignored.
0x0004	31-0 A	Tx data buffer pointer[1]

1. The transmit buffer pointer, which contains the address of the associated data buffer, must always be divisible by 16. The buffer must reside in memory external to the FEC. This value is never modified by the Ethernet controller.

32.4.2.2.1 Driver/DMA Operation with Transmit Buffer Descriptors

Data is presented to the FEC for transmission by arranging it in buffers referenced by the channel's TxBDs. After the software driver has set up the buffers for a frame, it sets up the corresponding BDs. In the TxBD the user initializes the R, W, L, and TC bits and the length (in bytes) in the first longword, and the buffer pointer in the second longword.The last step in setting up the BDs for a transmit frame is to set the R bit in the first BD for the frame. The driver follows that with a write to FEC_TDAR which triggers the FEC to poll the next BD in the ring.

The Ethernet controller confirms transmission by clearing the ready bit (R bit) when DMA of the buffer is complete.

32.4.2.2.1.1 Transmit Frame in Multiple Buffers

Typically a transmit frame is divided between multiple buffers. For example, it is possible to have an application payload in one buffer, TCP header in a 2nd buffer, IP header in a 3rd buffer, and Ethernet/IEEE 802.3 header in a 4th buffer. The FEC does not prepend the Ethernet header (Destination Address, Source Address, Length/Type

field(s)), so this must be provided by the driver in one of the transmit buffers. The FEC or the driver can append the Ethernet CRC to the frame. The driver must set the TC bit in the transmit BD to determine whether the CRC is appended by the FEC or by the driver.

The driver (TxBD software producer) sets up Tx BDs in such a way that a complete transmit frame is given to the hardware at once. If a transmit frame consists of three buffers, first the BD's are initialized with pointer, length and control (W, L, TC, ABC) and then the TxBD[R] bits are set to 1 in *reverse order* (3rd, 2nd, 1st BD) to insure that the complete frame is ready in memory before the DMA begins. If the TxBDs are set up in order, the DMA controller could DMA the first BD before the 2nd was made available, potentially causing a transmit FIFO underrun.

In the FEC, the DMA is notified by the driver that new transmit frame(s) are available by writing to the FEC_TDAR register. When this register is written to (data value is not significant) the FEC RISC tells the DMA to read the next transmit BD in the ring. After started, the RISC + DMA continues to read and interpret transmit BDs in order and DMA the associated buffers, until a transmit BD is encountered with the R bit = 0. At this point the FEC polls this BD one more time. If the R bit = 0 the second time, then the RISC stops the transmit descriptor read process until software sets up another transmit frame and writes to FEC_TDAR.

When the DMA of each transmit buffer is complete, the DMA writes back to the BD to clear the R bit, indicating that the hardware consumer is finished with the buffer.

32.4.2.3 Ethernet Receive Buffer Descriptor (RxBD)

Table 32-11. Receive Buffer Descriptor (RxBD)

Offset	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x0000	E	RO1	W	RO2	L	PTP		M	B	MC	LG	NO		CR	OV	TR
	Data Length															
0x0004	Rx Data Buffer Pointer A[31:16]															
	Rx Data Buffer Pointer A[15:0]															

Table 32-12. Receive Buffer Descriptor Field Definitions

Offset	Field	Description
0x0000	31 E	Empty. Written by the FEC (=0) and user (=1). 0 The data buffer associated with this BD has been filled with received data, or data reception has been aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.

Table continues on the next page...

Table 32-12. Receive Buffer Descriptor Field Definitions (continued)

Offset	Field	Description
0x0000	30 RO1	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
0x0000	29 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in FEC_ERDSR.
0x0000	28 RO2	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
0x0000	27 L	Last in frame. Written by the FEC. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
0x0000	26 PTP	PTP frame received. Written by the FEC. This bit is valid only if the L-bit is set. 0 Received frame is not an IEEE1588 PTP frame. 1 Received frame is an IEEE1588 PTP frame. FEC has informed IPTP Assist block to capture the timestamp for this frame. If unmasked, an interrupt will be issued by the IPTP Assist block after the timestamp is available.
0x0000	25	Reserved.
0x0000	24 M	Miss. Written by the FEC. This bit is set by the FEC for frames that were accepted in promiscuous mode, but were flagged as a "miss" by the internal address recognition. Thus, while in promiscuous mode, the user can use the M-bit to quickly determine whether the frame was destined to this station. This bit is valid only if the L-bit is set and the PROM bit is set. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode.
0x0000	23 BC	Set if the DA is broadcast (FF:FF:FF:FF:FF:FF).
0x0000	22 MC	Set if the DA is multicast and not BC.
0x0000	21 LG	Rx frame length violation. Written by the FEC. A frame length greater than FEC_RCR[MAX_FL] was recognized. This bit is valid only if the L-bit is set. The receive data is not altered in any way unless the length exceeds 2047 bytes.
0x0000	20 NO	Receive non-octet aligned frame. Written by the FEC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error. This bit is valid only if the L-bit is set. If this bit is set the CR bit is not set.
0x0000	19	Reserved
0x0000	18 CR	Receive CRC error. Written by the FEC. This frame contains a CRC error and is an integral number of octets in length. This bit is valid only if the L-bit is set.

Table continues on the next page...

Table 32-12. Receive Buffer Descriptor Field Definitions (continued)

Offset	Field	Description
0x0000	17 OV	Overrun. Written by the FEC. A receive FIFO overrun occurred during frame reception. If this bit is set, the other status bits, M, LG, NO, CR, and CL lose their normal meaning and is zero. This bit is valid only if the L-bit is set.
0x0000	16 TR	Set if the receive frame is truncated (frame length > 2047 bytes). If the TR bit is set the frame is discarded and the other error bits ignored as they can be incorrect.
0x0000	15-0 Data Length	Data length. Written by the FEC. Data length is the number of octets written by the FEC into this BD's data buffer if L = 0 (the value is equal to FEC_EMRBR), or the length of the frame including CRC if L = 1. It is written by the FEC once as the BD is closed.
0x0004	31-0	RX data buffer pointer[1]

1. The receive buffer pointer, which contains the address of the associated data buffer, must always be divisible by 16. The buffer must reside in memory external to the FEC. This value is never modified by the Ethernet controller.

32.4.2.3.1 Driver/DMA Operation with Receive Buffer Descriptors

Unlike the transmit case, the length of the receive frame is unknown by the driver ahead of time. Therefore the driver must set a variable to define the length of all receive buffers. In the FEC, this variable is written to the FEC_EMRBR register.

The driver (RxBD software producer) sets up some number of "empty" buffers for the Ethernet by initializing the address field and the E and W bits of the associated receive BDs. The hardware (receive DMA) consumes these buffers by filling them with data as frames are received, and clearing the E bit and writing to the L bit (1 indicates last buffer in frame), the frame status bits (if L = 1) and the length field.

If a receive frame spans multiple receive buffers, the L bit is only set for the last buffer in the frame. For non-last buffers, the length field in the receive BD is written by the DMA (at the same time the E bit is cleared) with the default receive buffer length value. For end of frame buffers, the L=1 bit is set in the receive BD, and information written to the status bits (M, BC, MC, LG, NO, CR, OV, TR). Some of the status bits are error indicators which, if set, indicate the receive frame is discarded and not given to higher layers. The frame status/length information is written into the receive FIFO following the end of the frame (as a single 32-bit word) by the receive logic. The length field for the end of frame buffer is written with the length of the entire frame, not just the length of the last buffer.

For simplicity the driver can assign the default receive buffer length to be large enough to contain an entire frame, keeping in mind that a malfunction on the network or out-of-specification implementation could result in giant frames. Frames of 2 Kbytes (2048 bytes) or larger are truncated by the FEC at 2047 bytes, so software never sees a receive frame larger than 2047 bytes.

As in the transmit case, the FEC polls the receive descriptor ring after the driver sets up receive BDs and writes to the FEC_RDAR register. As frames are received the FEC fills receive buffers and update the associated BDs, then reads the next BD in the receive descriptor ring. If the FEC reads a receive BD and finds the E bit is cleared, it polls this BD once more. If E is still cleared, then the FEC stops reading receive BDs until the driver writes to FEC_RDAR.

NOTE

Whenever the software driver sets an E bit in one or more receive descriptors, the driver follows that with a write to FEC_RDAR.

32.5 Programmable Registers

32.5.1 Top Level Block Memory Map

The FEC implementation requires a 1 Kbyte memory space. This space is divided into 2 sections of 512 bytes each. The first is used for control/status registers, and the second contains event/statistics counters held in the MIB block.

Table 32-13 defines the top level memory map. For the base address of a particular block instantiation, see the system memory map.

Table 32-13. Block Memory Map

Base Address Offset	Function
0x0000-01FF	Control/Status Registers
0x0200-02FF	MIB Block Counters
0x0300-03FF	Extension Registers (MIIGSK)

32.5.2 Message Information Block (MIB) Counters Memory Map

Table 32-14 shows the MIB counters memory map, which defines the locations in the MIB RAM space where hardware maintained counters reside. It is the responsibility of software to poll the counters often enough to ensure that rollover is detected. For example, on a 100 Mbps channel an octets counter could roll over every 5.7 minutes.

These counters fall in the 0x0200-0x03FF address offset range, and are divided into RMON counters and IEEE counters, as follows:

- RMON counters are included which cover the Ethernet statistics counters defined in RFC 1757. In addition to the counters defined in the Ethernet statistics group, a counter is included to count truncated frames as the FEC only supports frame lengths up to 2047 bytes. The RMON counters are implemented independently for transmit and receive to insure accurate network statistics when operating in full-duplex mode.
- IEEE counters are included which support the mandatory and recommended counter packages defined in section 5 of ANSI/IEEE Std. 802.3 (1998 edition). The IEEE basic package objects are supported by the FEC but do not require counters in the MIB block. In addition, some of the recommended package objects which are supported do not require MIB counters. Counters for transmit and receive full-duplex flow control frames are included as well.

Table 32-14. MIB Counters Memory Map

Base Address Offset	Mnemonic	Description
0x0200	RMON_T_DROP	Count of frames not counted correctly
0x0204	RMON_T_PACKETS	RMON Tx packet count
0x0208	RMON_T_BC_PKT	RMON Tx broadcast packets
0x020C	RMON_T_MC_PKT	RMON Tx multicast packets
0x0210	RMON_T_CRC_ALIGN	RMON Tx packets w CRC/Align error
0x0214	RMON_T_UNDERSIZE	RMON Tx packets < 64 bytes, good crc
0x0218	RMON_T_OVERSIZE	RMON Tx packets > MAX_FL bytes, good crc
0x021C	RMON_T_FRAG	RMON Tx packets < 64 bytes, bad crc
0x0220	RMON_T_JAB	RMON Tx packets > MAX_FL bytes, bad crc
0x0224	RMON_T_COL	RMON Tx collision count
0x0228	RMON_T_P64	RMON Tx 64 byte packets
0x022C	RMON_T_P65TO127	RMON Tx 65 to 127 byte packets
0x0230	RMON_T_P128TO255	RMON Tx 128 to 255 byte packets
0x0234	RMON_T_P256TO511	RMON Tx 256 to 511 byte packets
0x0238	RMON_T_P512TO1023	RMON Tx 512 to 1023 byte packets
0x023C	RMON_T_P1024TO2047	RMON Tx 1024 to 2047 byte packets
0x0240	RMON_T_P_GTE2048	RMON Tx packets w > 2048 bytes
0x0244	RMON_T_OCTETS	RMON Tx octets
0x0248	IEEE_T_DROP	Count of frames not counted correctly
0x024C	IEEE_T_FRAME_OK	Frames transmitted OK
0x0250	IEEE_T_1COL	Frames transmitted with single collision
0x0254	IEEE_T_MCOL	Frames transmitted with multiple collisions
0x0258	IEEE_T_DEF	Frames transmitted after deferral delay
0x025C	IEEE_T_LCOL	Frames transmitted with late collision

Table continues on the next page...

Table 32-14. MIB Counters Memory Map (continued)

Base Address Offset	Mnemonic	Description
0x0260	IEEE_T_EXCOL	Frames transmitted with excessive collisions
0x0264	IEEE_T_MACERR	Frames transmitted with Tx FIFO underrun
0x0268	IEEE_T_CSERR	Frames transmitted with carrier sense error
0x026C	IEEE_T_SQE	Frames transmitted with SQE error
0x0270	IEEE_T_FDXFC	Flow control pause frames transmitted
0x0274	IEEE_T_OCTETS_OK	Octet count for frames transmitted w/o error
0x0284	RMON_R_PACKETS	RMON Rx packet count
0x0288	RMON_R_BC_PKT	RMON Rx broadcast packets
0x028C	RMON_R_MC_PKT	RMON Rx multicast packets
0x0290	RMON_R_CRC_ALIGN	RMON Rx packets w CRC/Align error

0x0298	RMON_R_OVERSIZE	RMON Rx packets > MAX_FL bytes, good crc
0x029C	RMON_R_FRAG	RMON Rx packets < 64 bytes, bad crc
0x02A0	RMON_R_JAB	RMON Rx packets > MAX_FL bytes, bad crc
0x02A4	RMON_R_RESVD_0	-
0x02A8	RMON_R_P64	RMON Rx 64 byte packets
0x02AC	RMON_R_P65TO127	RMON Rx 65 to 127 byte packets
0x02B0	RMON_R_P128TO255	RMON Rx 128 to 255 byte packets
0x02B4	RMON_R_P256TO511	RMON Rx 256 to 511 byte packets
0x02B8	RMON_R_P512TO1023	RMON Rx 512 to 1023 byte packets
0x02BC	RMON_R_P1024TO2047	RMON Rx 1024 to 2047 byte packets
0x02C0	RMON_R_P_GTE2048	RMON Rx packets w > 2048 bytes
0x02C4	RMON_R_OCTETS	RMON Rx octets
0x02C8	IEEE_R_DROP	Count of frames not counted correctly
0x02CC	IEEE_R_FRAME_OK	Frames received OK
0x02D0	IEEE_R_CRC	Frames received with CRC error
0x02D4	IEEE_R_ALIGN	Frames received with alignment error
0x02D8	IEEE_R_MACERR	Receive FIFO overflow count
0x02DC	IEEE_R_FDXFC	Flow control pause frames received
0x02E0	IEEE_R_OCTETS_OK	Octet count for frames received w/o error

32.5.3 MIIGSK Registers Memory Map

Table 32-15. MIIGSK Registers Memory Map

Offset	Mnemonic	Description
0x0300	FEC_MIIGSK_CFGR	MIIGSK Configuration Register
0x0308	FEC_MIIGSK_ENR	MIIGSK Enable Register

This section includes the FEC memory map and detailed descriptions of all the registers, followed by a description of the buffers.

The FEC is programmed by a combination of control and status registers (FEC_CSRs) and buffer descriptors. The FEC_CSRs are used for mode control and to extract global status information. The descriptors are used to pass data buffers and related buffer information between the hardware and software.

The FEC implementation requires a 1 Kbyte memory space. This space is divided into 2 sections of 512 bytes each. The first is used for control/status registers, and the second contains event/statistics counters held in the MIB block.

Table defines the top level memory map. For the base address of a particular block instantiation, see the system memory map.

Table 32-17. Block Memory Map

Base Address Offset	Function
0x0000-01FF	Control/Status Registers
0x0200-02FF	MIB Block Counters
0x0300-03FF	Extension Registers (MIIGSK)

The following table shows the FEC register memory map. For the base address of a particular block instantiation, see the system memory map.

FEC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FE_C004	Ethernet interrupt event register (FEC_EIR)	32	R/W	0000_0000h	32.5.4/ 1595

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FE_C188	Maximum receive buffer size register (FEC_EMRBR)	32	R/W	0000_0000h	32.5.26/ 1616

32.5.4 Ethernet interrupt event register (FEC_EIR)

The FEC_EIR bit assignments are shown below. When an event occurs that sets a bit in the FEC_EIR, an interrupt is generated if the corresponding bit in the interrupt mask register (FEC_EIMR) is also set. The bit in the FEC_EIR is cleared if a one is written to that bit position; writing zero has no effect. This register is cleared upon hardware reset.

Interrupts can be divided into three classes as follows:

- Interrupts that occur in normal operation: these include GRA, TXF, TXB, RXF, RXB, and MII.
- Interrupts that result from errors or problems detected in the network or transceiver: these include HBERR, BABR, BABT, LC, and RL.
- Interrupts that result from internal errors are EBERR and UN.

Some of the error interrupts are independently counted in the MIB block counters. The correspondence between interrupts and counters is shown in the following table. Software can choose to mask off the interrupts because these errors are visible to network management through the MIB counters.

Table 32-19. Error Interrupts and Block Counters

Interrupt	Counter(s)
HBERR	IEEE_T_SQE
BABR	RMON_R_OVERSIZE (good CRC), RMON_R_JAB (bad CRC)
BABT	RMON_T_OVERSIZE (good CRC), RMON_T_JAB (bad CRC)
LATE_COL	IEEE_T_LCOL
COL_RETRY_LIM	IEEE_T_EXCOL
XFIFO_UN	IEEE_T_MACERR

Address: FEC_EIR is 63FE_C000h base + 4h offset = 63FE_C004h

FEC_EIR field descriptions

Field	Description
31 HBERR	Heartbeat error. This interrupt indicates that HBC is set in the FEC_TCR register and that the COL input was not asserted within the Heartbeat window following a transmission.
30 BABR	Babbling receive error. This bit indicates a frame was received with length in excess of FEC_RCR[MAX_FL] bytes.
29 BABT	Babbling transmit error. This bit indicates that the transmitted frame length has exceeded FEC_RCR[MAX_FL] bytes. This condition is usually caused by a frame that is too long being placed into the transmit data buffer(s). Truncation does not occur.
28 GRA	Graceful stop complete. This interrupt is asserted for one of three reasons. Graceful stop means that the transmitter is put into a pause state after completion of the frame currently being transmitted. 1) A graceful stop, which was initiated by the setting of the FEC_TCR[GTS] bit is now complete. 2) A graceful stop, which was initiated by the setting of the FEC_TCR[TFC_PAUSE] bit is now complete. 3) A graceful stop, which was initiated by the reception of a valid full-duplex flow control "pause" frame is now complete. See the "Full-Duplex Flow Control" section of the Functional Description chapter.
27 TXF	Transmit frame interrupt. This bit indicates that a frame has been transmitted and that the last corresponding buffer descriptor has been updated.
26 TXB	Transmit buffer interrupt. This bit indicates that a transmit buffer descriptor has been updated.
25 RXF	Receive frame interrupt. This bit indicates that a frame has been received and that the last corresponding buffer descriptor has been updated.
24 RXB	Receive buffer interrupt. This bit indicates that a receive buffer descriptor has been updated that was not the last in the frame.
23 MII	MII interrupt. This bit indicates that the MII has completed the data transfer requested.
22 EBERR	Ethernet bus error. This bit indicates that a system bus error occurred when a DMA transaction was underway. When the EBERR bit is set, FEC_ECR[ETHER_EN] is cleared, halting frame processing by the FEC_ When this occurs software needs to insure that the FIFO controller and DMA are also soft reset.
21 LC	Late collision. This bit indicates that a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame is truncated with a bad CRC and the remainder of the frame is discarded.
20 RL	Collision retry limit. This bit indicates that a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. Can only occur in half-duplex mode.
19 UN	Transmit FIFO underrun. This bit indicates that the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.
18–0 -	Reserved, read as 0

32.5.5 Ethernet interrupt mask register (FEC_EIMR)

The FEC_EIMR controls which of the interrupt events flagged in the FEC_EIR are allowed to generate actual interrupts. If the corresponding bits in both the FEC_EIR and FEC_EIMR are set, the interrupt is signaled to the ARM platform. The interrupt signal remains asserted until a 1 is written to the FEC_EIR bit (write 1 to clear) or a 0 is written to the FEC_EIMR bit. This register is cleared upon a hardware reset.

The FEC_EIMR bit assignments are the same as for the FEC_EIR.

Address: FEC_EIMR is 63FE_C000h base + 8h offset = 63FE_C008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FEC_EIMR field descriptions

Field	Description
31 HBERR	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
30 BABR	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
29 BABT	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
28 GRA	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared.

Table continues on the next page...

FEC_EIMR field descriptions (continued)

Field	Description
	0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
27 TXF	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
26 TXB	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
25 RXF	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
24 RXB	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
23 MII	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
22 EBERR	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.

Table continues on the next page...

FEC_EIMR field descriptions (continued)

Field	Description
21 LC	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
20 RL	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
19 UN	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
18–0 Reserved	This read-only field is reserved and always has the value zero. Reserved, read as 0

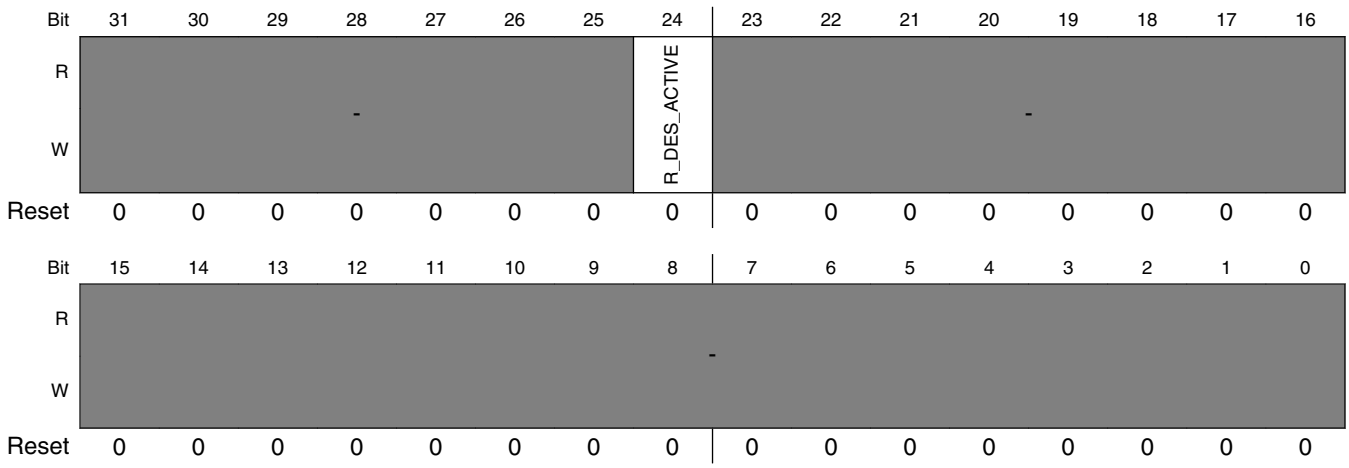
32.5.6 Receive descriptor active register (FEC_RDAR)

FEC_RDAR is a user-writeable command register which indicates that the receive descriptor ring has been updated, and that empty receive buffers have been produced by the driver with the empty bit set.

The FEC_RDAR[R_DES_ACTIVE] bit is set whenever the register is written, independent of the data actually written by the user. When set, the FEC polls the receive descriptor ring and processes receive frames (provided FEC_ECR[ETHER_EN] is also set to 1). After the FEC polls a receive descriptor whose empty bit is not set, then the FEC clears the FEC_RDAR[R_DES_ACTIVE] bit and ceases receive descriptor ring polling until the user sets the bit again, signifying that additional descriptors have been placed into the receive descriptor ring.

The FEC_RDAR is cleared at reset, and when FEC_ECR[ETHER_EN] is cleared.

Address: FEC_RDAR is 63FE_C000h base + 10h offset = 63FE_C010h



FEC_RDAR field descriptions

Field	Description
31–25 -	Reserved, read as 0
24 R_DES_ACTIVE	Set to one when this register is written, regardless of the value written. Cleared by the FEC device when the FEC polls a receive descriptor whose empty bit is not set. Also cleared when FEC_ECR[ETHER_EN] is cleared.
23–0 -	Reserved, read as 0

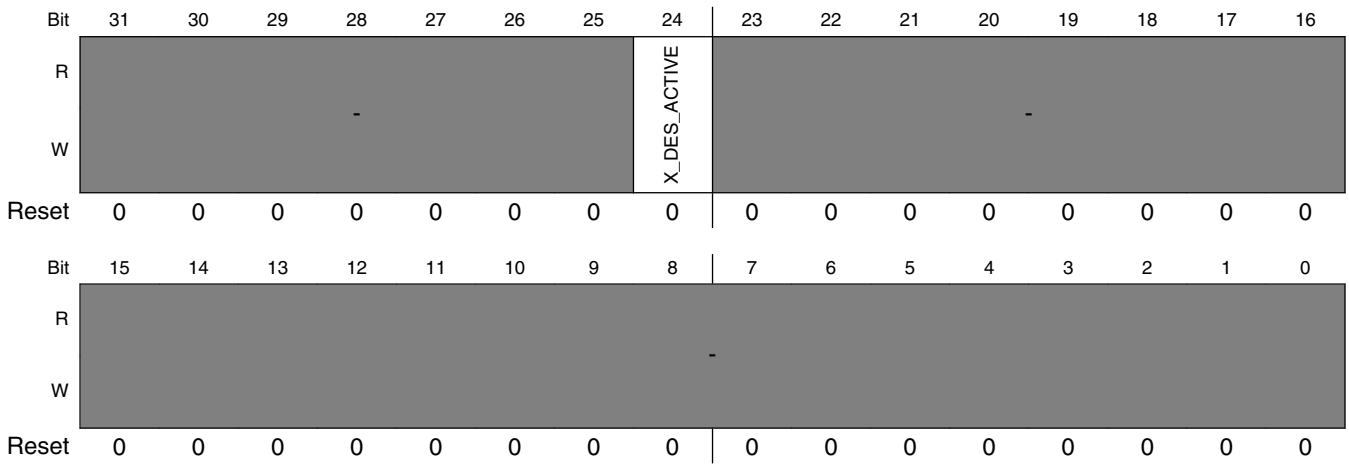
32.5.7 Transmit descriptor active register (FEC_TDAR)

The FEC_TDAR is a command register, written to by the user, to indicate that the transmit descriptor ring has been updated (transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor).

Whenever the register is written the FEC_TDAR[X_DES_ACTIVE] bit is set to 1, independent of the data actually written by the user. When set, the FEC polls the transmit descriptor ring and process transmit frames (provided FEC_ECR[ETHER_EN] is also set to 1). After the FEC polls a transmit descriptor whose ready bit is not set, then the FEC clears the FEC_TDAR[X_DES_ACTIVE] bit and ceases transmit descriptor ring polling until the user sets the bit again, signifying additional descriptors have been placed into the transmit descriptor ring.

The FEC_TDAR is cleared at reset, when FEC_ECR[ETHER_EN] is cleared, or when FEC_ECR[RESET] is set to 1.

Address: FEC_TDAR is 63FE_C000h base + 14h offset = 63FE_C014h



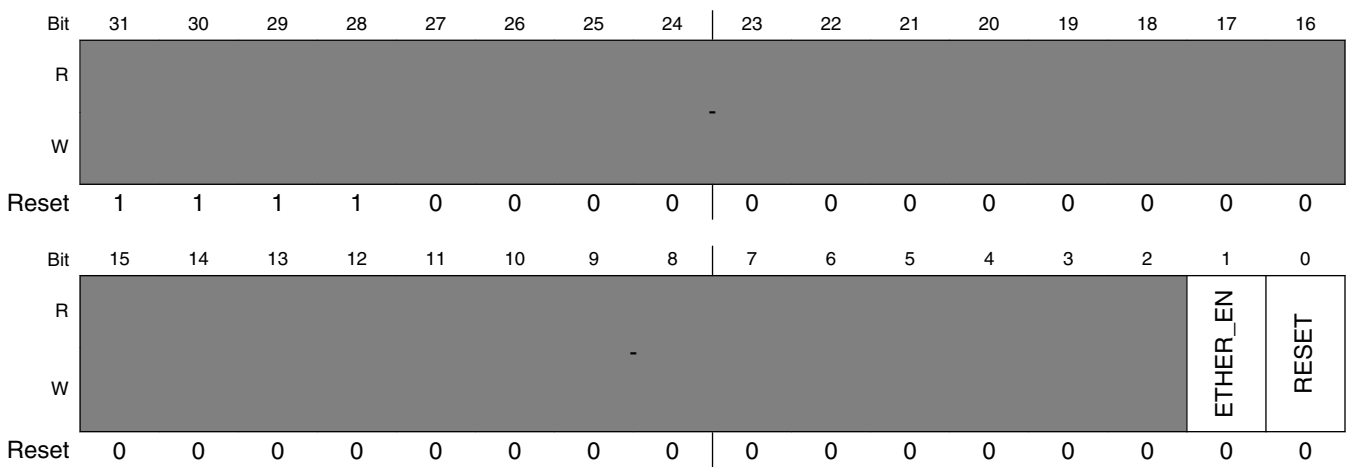
FEC_TDAR field descriptions

Field	Description
31–25 -	Reserved, read as 0
24 X_DES_ACTIVE	Set to one when this register is written, regardless of the value written. Cleared by the FEC device when the FEC polls a transmit descriptor whose ready bit is not set. Also cleared when FEC_ECR[ETHER_EN] is cleared.
23–0 -	Reserved, read as 0

32.5.8 Ethernet control register (FEC_ECR)

The ECR is used to enable/disable the FEC_ ECR is a read/write user register, though both fields in this register can also be altered by hardware.

Address: FEC_ECR is 63FE_C000h base + 24h offset = 63FE_C024h



FEC_ECR field descriptions

Field	Description
31–2 -	Reserved.
1 ETHER_EN	When this bit is set, the FEC is enabled, and reception and transmission are possible. When this bit is cleared, reception is immediately stopped and transmission is stopped after a bad CRC is appended to any currently transmitted frame. The buffer descriptor(s) for an aborted transmit frame are not updated after clearing this bit. When ETHER_EN is cleared, the DMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. The ETHER_EN bit is altered by hardware under the following conditions: FEC_ECR[RESET] is set by software, in which case ETHER_EN is cleared an error condition causes the FEC_EIR[EBERR] bit to set, in which case ETHER_EN is cleared
0 RESET	When this bit is set, the equivalent of a hardware reset is performed but it is local to the FEC_ETHER_EN is cleared and all other FEC registers take their reset values. Also, any transmission/reception currently in progress is abruptly aborted. This bit is automatically cleared by hardware during the reset sequence. The reset sequence takes approximately 8 system clock cycles after RESET is written with a 1.

32.5.9 MII management frame register (FEC_MMFR)

The FEC_MMFR is used to communicate with the attached MII compatible PHY device(s), providing read/write access to their MII registers. Performing a write to FEC_MMFR causes a management frame to be generated unless the MII-SPEED field of the FEC_MSCR has been set to 0, in which case FEC_MSCR is set to a non-zero value and an MII frame is generated with the data previously written to FEC_MMFR. This allows FEC_MMFR and FEC_MSCR to be programmed in either order if the MII-SPEED field of FEC_MSCR is zero (for further details see MII speed control register (FEC_MSCR)).

The FEC_MMFR does not reset to a definite value.

To perform a read or write operation on the MII Management Interface, the FEC_MMFR must be written to by the user. To generate a valid read or write management frame, the ST field must be written with a 01 pattern, and the TA field must be written with a 10. If other patterns are written to these fields, a frame is generated but does not comply with the IEEE 802.3 MII definition.

To generate an IEEE 802.3-compliant MII management interface write frame (write to a PHY register), the user must write {01 01 PHYAD REGAD 10 DATA} to the bit fields of the FEC_MMFR, as shown in MII management frame register (FEC_MMFR). Writing this pattern causes the control logic to shift out the data in the FEC_MMFR following a preamble generated by the control state machine. During this time the contents of the FEC_MMFR is altered as the contents are serially shifted and is unpredictable if read by

the user. After the write management frame operation has completed, the MII interrupt is generated. At this time the contents of the FEC_MMFR matches the original value written.

To generate an MII management interface read frame (read a PHY register) the user must write {01 10 PHYAD REGAD 10 XXXX} to the bit fields of the FEC_MMFR shown in MII management frame register (FEC_MMFR) (the contents of the 4-bit DATA field are arbitrary). Writing this pattern causes the control logic to shift out the data in the FEC_MMFR following a preamble generated by the control state machine. During this time the contents of the FEC_MMFR is altered as the contents are serially shifted, and is unpredictable if read by the user. After the read management frame operation has completed, the MII interrupt is generated. At this time the contents of the FEC_MMFR matches the original value written except for the DATA field whose contents have been replaced by the value read from the PHY register.

If the FEC_MMFR is written to while frame generation is in progress, the frame contents is altered. Software uses the MII interrupt to avoid writing to the FEC_MMFR while frame generation is in progress.

Address: FEC_MMFR is 63FE_C000h base + 40h offset = 63FE_C040h

* Notes:
- u = Unaffected by reset.

FEC_MMFR field descriptions

Field	Description
31–30 ST	Start of frame delimiter. These bits must be programmed to 01 for a valid MII management frame.
29–28 OP	Operation code. This field must be programmed to 10 (read) or 01 (write) to generate a valid MII management frame. A value of 11 produces "read" frame operation while a value of 00 produces "write" frame operation, but these frames is not MII compliant.
27–23 PA	PHY address. This field specifies one of up to 32 attached PHY devices.
22–18 RA	Register address. This field specifies one of up to 32 registers within the specified PHY device.
17–16 TA	Turn around. This field must be programmed to 10 to generate a valid MII management frame.
15–0 DATA	Management frame data. This is the field for data to be written to or read from the PHY register.

32.5.10 MII speed control register (FEC_MSCR)

The FEC_MSCR provides control of the frequency of the MII clock (FEC_MDC signal), and allows a preamble drop on the MII management frame.

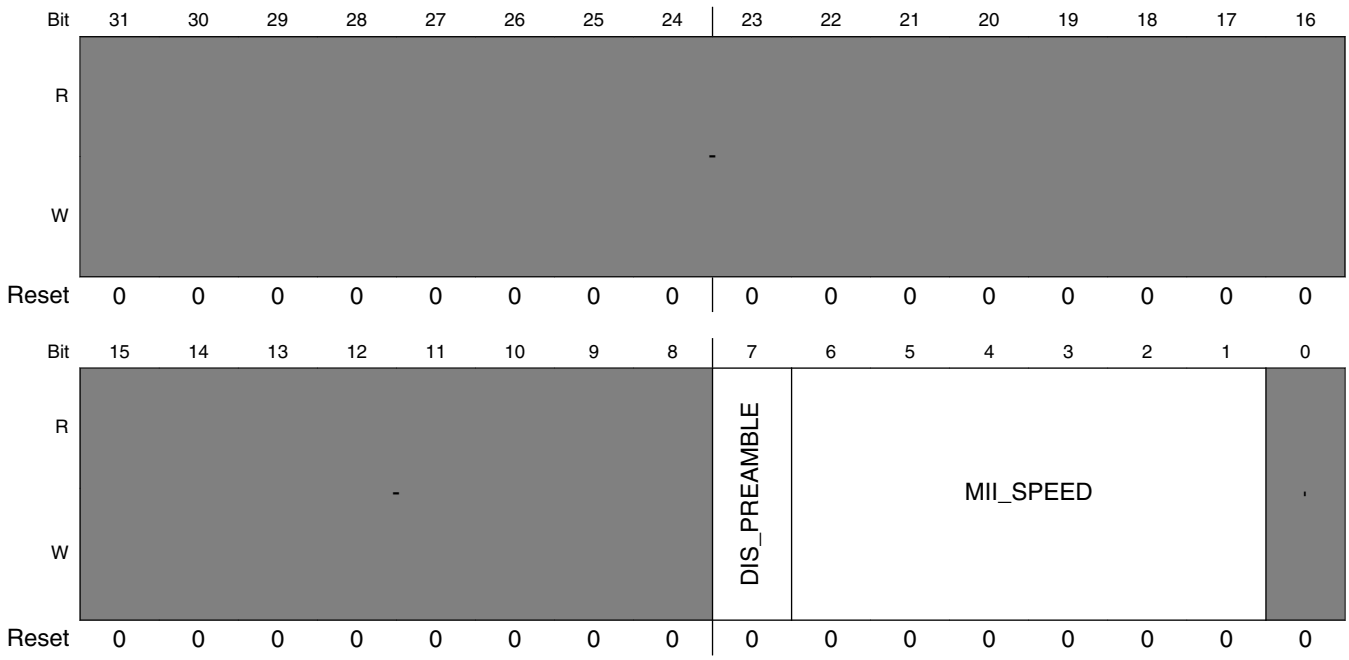
The MII_SPEED field must be programmed with a value to provide an FEC_MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value in order to generate a read or write management frame. After the management frame is complete the FEC_MSCR can optionally be set to zero to turn off the FEC_MDC. The FEC_MDC generated has a 50% duty cycle except when MII_SPEED is changed during operation (change takes effect following either a rising or falling edge of FEC_MDC).

The FEC_MDC frequency depends on both the system clock frequency and the MII_SPEED register. If the system clock is 25 MHz, programming the MII_SPEED register to 0x0000_0005 results in an FEC_MDC frequency of 25 MHz * 1/10 = 2.5 MHz. A table showing optimum values for MII_SPEED for different system clock frequencies is provided below.

Table 32-26. Programming Examples for FEC_MSCR

System Clock Frequency	MII_SPEED (field in reg)	FEC_MDC frequency
25 MHz	0x5	2.5 MHz
33 MHz	0x7	2.36 MHz
40 MHz	0x8	2.5 MHz
50 MHz	0xA	2.5 MHz
66 MHz	0xD	2.54 MHz

Address: FEC_MSCR is 63FE_C000h base + 44h offset = 63FE_C044h



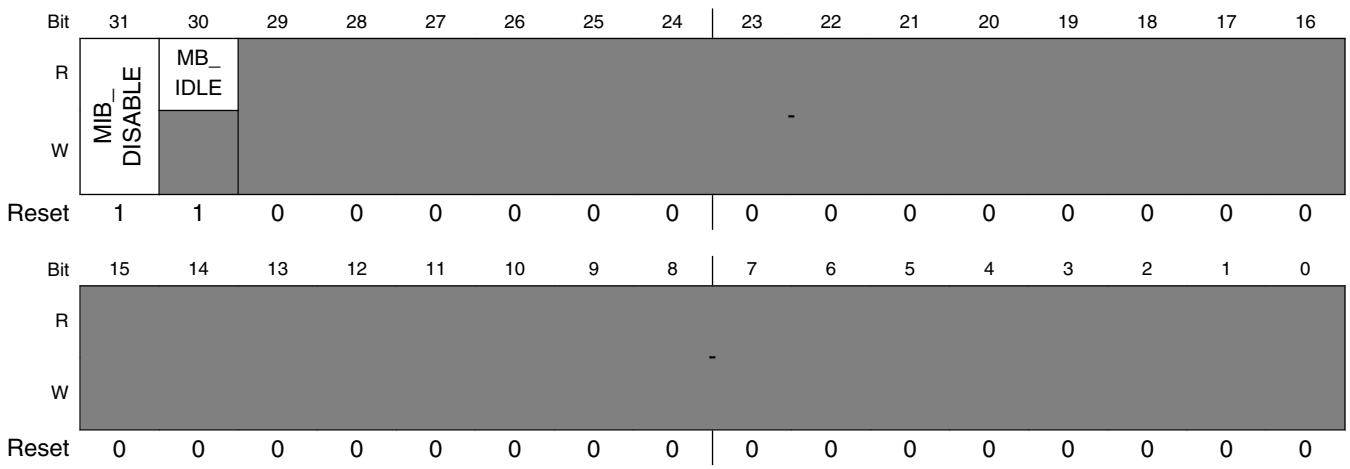
FEC_MSCR field descriptions

Field	Description
31–8 -	Reserved, read as 0
7 DIS_PREAMBLE	Asserting this bit causes preamble (0xFFFF_FFFF) not to be prepended to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY device(s) does not require it.
6–1 MII_SPEED	MII_SPEED controls the frequency of the MII management interface clock (FEC_MDC) relative to the system clock. A value of 0 in this field "turns off" the FEC_MDC and leave it in low voltage state. Any non-zero value results in the FEC_MDC frequency of 1/(MII_SPEED*2) of the system clock frequency.
0 -	Reserved, read as 0

32.5.11 MIB control register (FEC_MIBC)

The MIB control register is a read/write register used to provide control of and to observe the state of the Message Information Block (MIB). This register is accessed by user software if there is a need to disable the MIB operation. For example, in order to clear all MIB counters in RAM the user disables the MIB, then clears all the MIB RAM locations, then enables the MIB. The MIB_DISABLE bit is reset to 1. See MIB Counters Memory Map for the locations of the MIB counters.

Address: FEC_MIBC is 63FE_C000h base + 64h offset = 63FE_C064h



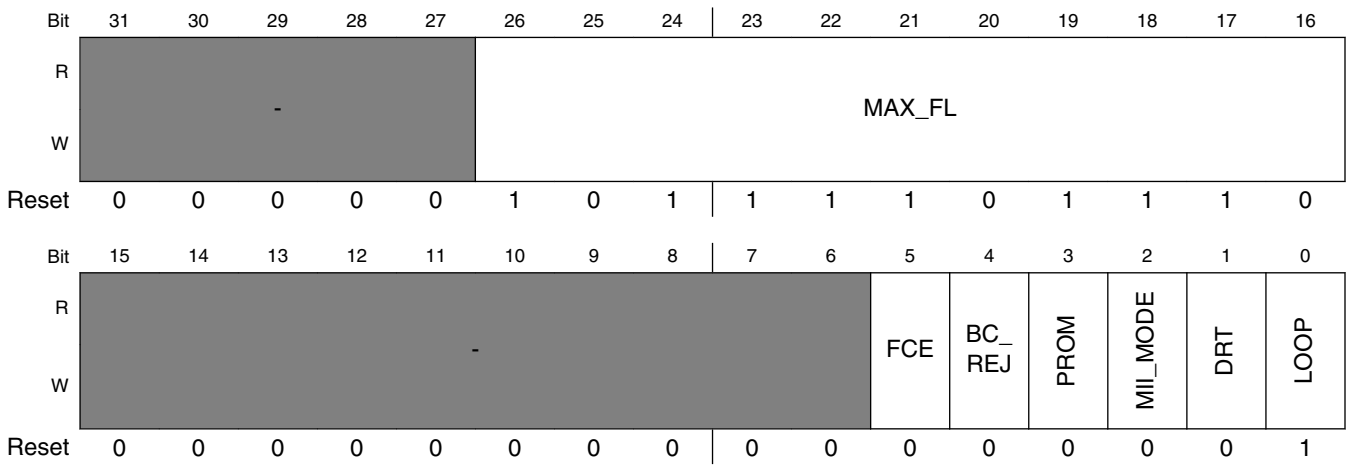
FEC_MIBC field descriptions

Field	Description
31 MIB_DISABLE	A read/write control bit. If set, the MIB logic halts and not update any MIB counters.
30 MB_IDLE	A read-only status bit. If set the MIB block is not currently updating any MIB counters.
29–0 -	Reserved.

32.5.12 Receive control register (FEC_RCR)

The FEC_RCR is programmed by the user, and controls the operational mode of the receive block. It can only be written to when FEC_ECR[ETHER_EN] = 0 (that is, during initialization).

Address: FEC_RCR is 63FE_C000h base + 84h offset = 63FE_C084h



FEC_RCR field descriptions

Field	Description
31–27 -	Reserved, read as 0
26–16 MAX_FL	Maximum frame length. Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL causes the BABT interrupt to occur. Receive Frames longer than MAX_FL causes the BABR interrupt to occur and sets the LG bit in the end of frame receive buffer descriptor. The recommended default value to be programmed by the user is 1518 or 1522 (if VLAN Tags are supported).
15–6 -	Reserved, read as 0
5 FCE	Flow control enable. When FCE is set to 1, the receiver detects pause frames. Upon pause frame detection, the transmitter stops transmitting data frames for a given duration.
4 BC_REJ	Broadcast frame reject. When BC_REJ is set to 1, frames with DA (destination address) = 0xFF_FF_FF_FF_FF_FF are rejected unless the PROM bit is set to 1. If both BC_REJ and PROM are set to 1, then frames with broadcast DA is accepted and the M (MISS) bit is set in the receive buffer descriptor.
3 PROM	Promiscuous mode. All frames are accepted regardless of address matching.
2 MII_MODE	Media independent interface mode. Selects external interface mode. Setting this bit to one selects MII mode, setting this bit equal to zero selects 7-wire mode (used only for serial 10 Mbps). This bit controls the interface mode for both transmit and receive blocks.
1 DRT	Disable receive on transmit.

Table continues on the next page...

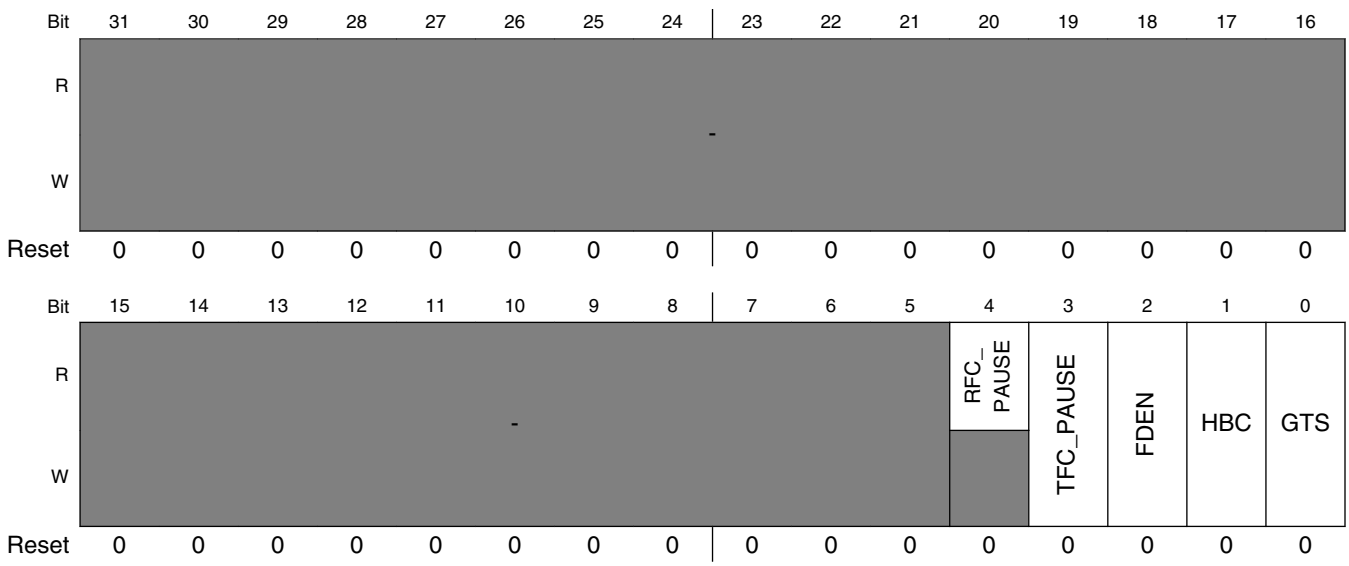
FEC_RCR field descriptions (continued)

Field	Description
	0 Receive path operates independently of transmit (use for full-duplex or to monitor transmit activity in half-duplex mode). 1 Disable reception of frames while transmitting (normally used for half-duplex mode).
0 LOOP	Internal loopback.When LOOP is set to 1, transmitted frames are looped back internal to the device and the transmit output signals are not asserted. The system clock is substituted for the FEC_TX_CLK when LOOP is set to 1. DRT must be set to zero when setting LOOP to 1.

32.5.13 Transmit control register (FEC_TCR)

This register is read/write, and is written by the user to configure the transmit block. Bits [2:1] must only be modified when FEC_ECR[ETHER_EN] = 0 (that is, during initialization). This register is cleared at system reset.

Address: FEC_TCR is 63FE_C000h base + C4h offset = 63FE_C0C4h



FEC_TCR field descriptions

Field	Description
31–5 -	Reserved read as 0
4 RFC_PAUSE	Receive frame control pause. This read-only status bit is set to 1 when a full-duplex flow control pause frame has been received and the transmitter is paused for the duration defined in this pause frame. This bit automatically clears when the pause duration is complete. 0 Transmitter is not paused 1 Transmitter is paused after reception of full-duplex flow control pause frame
3 TFC_PAUSE	Transmit frame control pause. When this bit is set to 1, a pause frame is transmitted according to the following steps:

Table continues on the next page...

FEC_TCR field descriptions (continued)

Field	Description
	1. FEC stops transmission of data frames after the current transmission is complete. 2. The GRA interrupt in the FEC_EIR register is asserted. 3. With transmission of data frames stopped, the FEC transmits a MAC control pause frame. 4. The FEC clears the TFC_PAUSE bit and resume transmitting data frames. The FEC can still transmit a MAC control pause frame when the transmitter is paused due to user assertion of GTS or reception of a pause frame. 0 No pause frame is transmitted 1 Pause frame is transmitted
2 FDEN	Full duplex enable. When FDEN is set to 1, frames are transmitted independent of carrier sense and collision inputs. This bit must only be modified when ETHER_EN is cleared. 0 Full duplex is not enabled 1 Full duplex is enabled
1 HBC	Heartbeat control. When HBC is set to 1, the heartbeat check is performed after end of transmission and the HB bit in the status register is set if the collision input does not assert within the heartbeat window. This bit must only be modified when ETHER_EN is cleared. 0 Heartbeat check is not performed after end of transmission 1 Heartbeat check is performed after end of transmission
0 GTS	Graceful transmit stop. When GTS is set to 1, the FEC stops transmission after any frame that is currently being transmitted is complete and the GRA interrupt in the FEC_EIR register is asserted. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission has completed, a "restart" can be accomplished by clearing the GTS bit. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS = 1, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There can be old frames in the transmit FIFO that is transmitted when GTS is reasserted. To avoid this, clear FEC_ECR[ETHER_EN] following the GRA interrupt. 0 Graceful transmit stop is not enabled 1 Graceful transmit stop is enabled.

32.5.14 Physical address low register (FEC_PALR)

The FEC_PALR is written by the user, and contains the lower 32 bits (bytes 0,1,2,3) of the 48-bit address used in the address recognition process to check for possible match between the DA field of receive frames and an individual DA. This register is also used for bytes 0 through 3 of the 6-byte source address field when transmitting pause frames. This register is unaffected by reset and must be initialized by the user.

Address: FEC_PALR is 63FE_C000h base + E4h offset = 63FE_C0E4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FEC_PALR field descriptions

Field	Description
31–0 PADDR1	Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8) and 3 (bits 7:0) of the 6-byte individual address to be used for exact match, and the source address field in pause frames.

32.5.15 Physical address upper register (FEC_PAUR)

The FEC_PAUR is written by the user, and contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to check for possible match between the DA field of receive frames and an individual DA. In addition, this register is used in bytes 4 and 5 of the 6-byte source address field when transmitting pause frames. Bits 15:0 of FEC_PAUR contain a constant type field (0x8808) used for transmission of pause frames. This register is unaffected by reset, and bits 31:16 must be initialized by the user.

Address: FEC_PAUR is 63FE_C000h base + E8h offset = 63FE_C0E8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

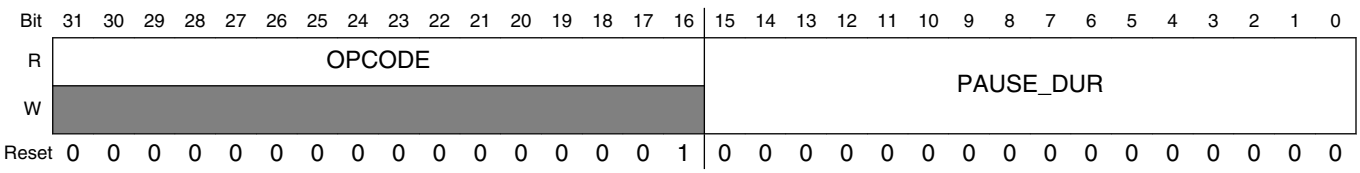
FEC_PAUR field descriptions

Field	Description
31–16 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address to be used for exact match, and the source address field in pause frames.
15–0 TYPE	Type field in pause frames. This field has a constant value of 0x8808.

32.5.16 Opcode and pause duration register (FEC_OPDR)

FEC_OPDR contains the 16-bit Opcode, and 16-bit pause duration fields used in transmission of a pause frame. The Opcode field is a constant value, 0x0001. When another node detects a pause frame, that node pauses transmission for the duration specified in the pause duration field. This register is not reset and must be initialized by the user.

Address: FEC_OPDR is 63FE_C000h base + ECh offset = 63FE_C0ECh



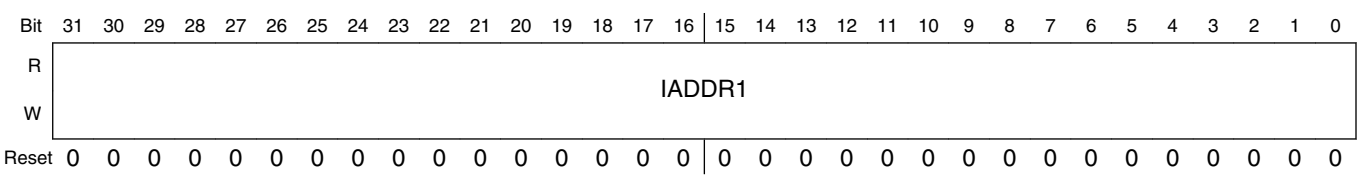
FEC_OPDR field descriptions

Field	Description
31–16 OPCODE	Opcode field used in pause frames. These bits are a constant, 0x0001.
15–0 PAUSE_DUR	Pause duration field used in pause frames.

32.5.17 Descriptor individual address upper register (FEC_IAUR)

The FEC_IAUR is written by the user, and contains the upper 32 bits of the 64-bit individual address hash table used in the address recognition process to check for possible match between the DA field of receive frames and an individual DA. This register is unaffected by reset, and must be initialized by the user.

Address: FEC_IAUR is 63FE_C000h base + 118h offset = 63FE_C118h



FEC_IAUR field descriptions

Field	Description
31–0 IADDR1	The upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR1 contains hash index bit 63. Bit 0 of IADDR1 contains hash index bit 32.

32.5.18 Descriptor individual address lower register (FEC_IALR)

The FEC_IALR is written by the user, and contains the lower 32 bits of the 64-bit individual address hash table used in the address recognition process to check for possible match with the DA field of receive frames with an individual DA. This register is unaffected by reset, and must be initialized by the user.

Address: FEC_IALR is 63FE_C000h base + 11Ch offset = 63FE_C11Ch

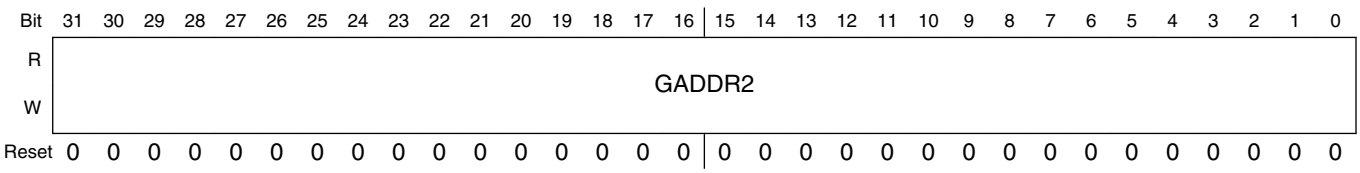
FEC_GAUR field descriptions

Field	Description
31–0 GADDR1	The GADDR1 register contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR1 contains hash index bit 63. Bit 0 of GADDR1 contains hash index bit 32.

32.5.20 Descriptor group address lower register (FEC_GALR)

The FEC_GALR is written by the user, and contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. This register must be initialized by the user.

Address: FEC_GALR is 63FE_C000h base + 124h offset = 63FE_C124h



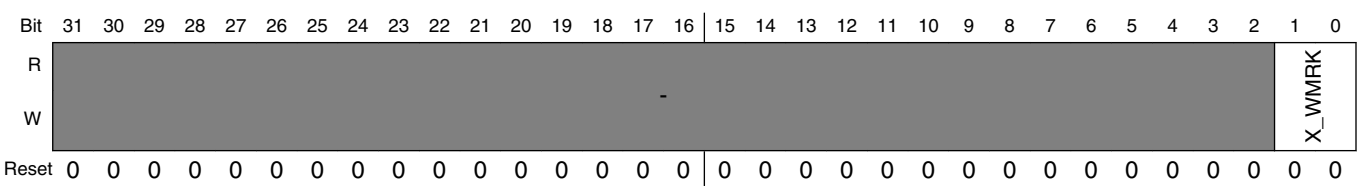
FEC_GALR field descriptions

Field	Description
31–0 GADDR2	The GADDR2 register contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

32.5.21 Transmit FIFO watermark register (FEC_TFWR)

The FEC_TFWR is programmed by the user to control the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows the user to minimize transmit latency (FEC_TFWR[1:0] = 0n) or allow for larger bus access latency (FEC_TFWR[1:0] = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. In some use cases the byte counts associated with the FEC_TFWR field need to be modified to match system requirements, such as the worst-case bus access latency by the transmit data DMA channel.

Address: FEC_TFWR is 63FE_C000h base + 144h offset = 63FE_C144h



FEC_TFWR field descriptions

Field	Description
31–2 -	Reserved, read as 0

Table continues on the next page...

FEC_TFWR field descriptions (continued)

Field	Description
1–0 X_WMRK	Number of bytes written to transmit FIFO before transmission of a frame begins 0x 64 bytes written 10 128 bytes written 11 192 bytes written

32.5.22 FIFO receive bound register (FEC_FRBR)

The FEC_FRBR register can be read to determine the upper address bound of the FIFO RAM. Drivers can use this value, along with the FEC_FRSR to appropriately divide the available FIFO RAM between the transmit and receive data paths.

Address: FEC_FRBR is 63FE_C000h base + 14Ch offset = 63FE_C14Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0

FEC_FRBR field descriptions

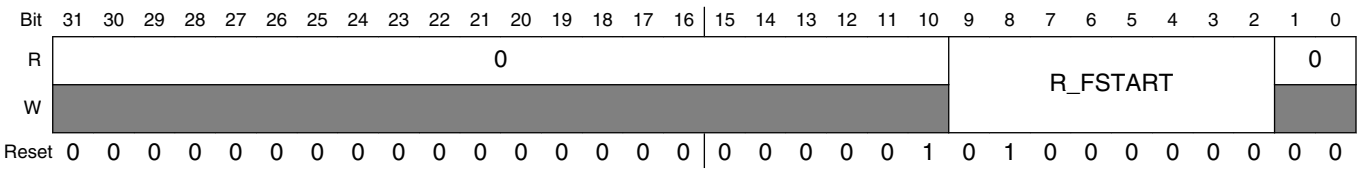
Field	Description
31–10 Reserved	This read-only field is reserved and always has the value zero. Reserved, read as 0 (except bit 10, which is read as 1).
9–2 R_BOUND	Read-only. Highest valid FIFO RAM address.
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved, read as 0.

32.5.23 FIFO receive FIFO start registers (FEC_FRSR)

FEC_FRSR is an 8-bit register programmed by the user to indicate the starting address of the receive FIFO. FEC_FRSR marks the boundary between the transmit and receive FIFOs. The transmit FIFO uses addresses from the start of the FIFO to the location four bytes before the address programmed into the FEC_FRSR. The receive FIFO uses the addresses from FEC_FRSR to FEC_FRBR inclusive.

The default value of the receive FIFO starting address is 0x40. This is the value assigned by hardware at reset.

Address: FEC_FRSR is 63FE_C000h base + 150h offset = 63FE_C150h



FEC_FRSR field descriptions

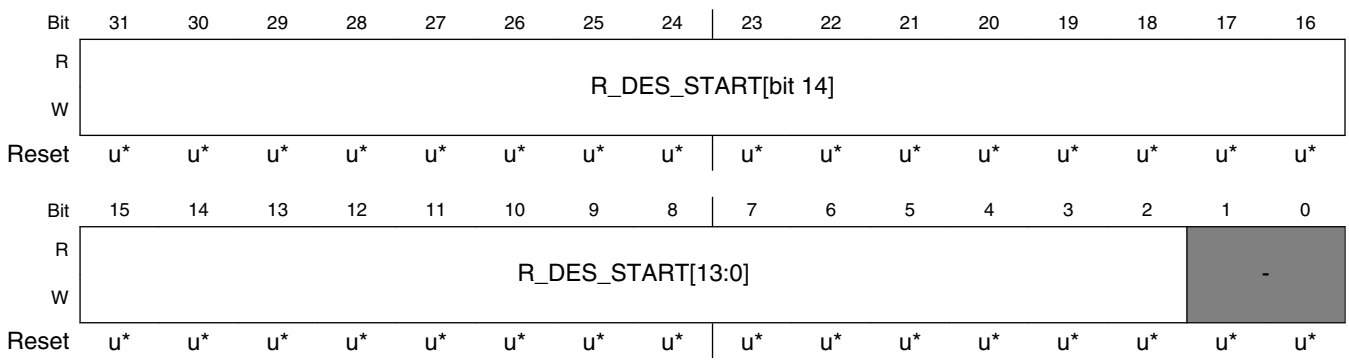
Field	Description
31–10 Reserved	This read-only field is reserved and always has the value zero. Reserved, read as 0 (except bit 10, which is read as 1).
9–2 R_FSTART	Address of first receive FIFO location. Acts as delimiter between receive and transmit FIFOs.
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved, read as 0.

32.5.24 Receive buffer descriptor ring start register (FEC_ERDSR)

The register is written by the user, and provides a pointer to the start of the circular receive buffer descriptor queue in external memory. This pointer must be 128-bit aligned (that is, evenly divisible by 16).

This register is unaffected by reset and must be initialized by the user prior to operation.

Address: FEC_ERDSR is 63FE_C000h base + 180h offset = 63FE_C180h



* Notes:
- u = Unaffected by reset.

FEC_ERDSR field descriptions

Field	Description
31–2 R_DES_START	Pointer to start of receive buffer descriptor queue.
1–0 -	Reserved, read as 0

32.5.25 Transmit buffer descriptor ring start register (FEC_ETDSR)

The register is written by the user, and provides a pointer to the start of the circular transmit buffer descriptor queue in external memory. This pointer must be 128-bit aligned (that is, evenly divisible by 16).

This register is unaffected by reset and must be initialized by the user prior to operation.

Address: FEC_ETDSR is 63FE_C000h base + 184h offset = 63FE_C184h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	X_DES_START[bit 14]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	X_DES_START[13:0]														-	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FEC_ETDSR field descriptions

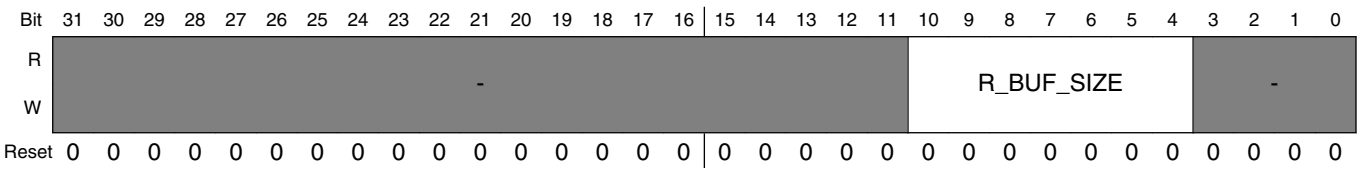
Field	Description
31–2 X_DES_START	Pointer to start of transmit buffer descriptor queue.
1–0 -	Reserved, read as 0

32.5.26 Maximum receive buffer size register (FEC_EMRBR)

The FEC_EMRBR is a user-programmable register which dictates the maximum size of all receive buffers. Note that because receive frames is truncated at 2k-1(2047) bytes, bits 31-11 are not used. The programmed value accounts for the fact that the receive CRC is always written into the last receive buffer. To allow one maximum size frame per buffer, FEC_EMRBR must be set to FEC_RCR[MAX_FL] or larger. The FEC_EMRBR must be evenly divisible by 16. To ensure this, bits 3-0 are forced low, and hence only bits 10-4 are actually used. To minimize bus utilization (descriptor fetches) it is recommended that FEC_EMRBR be greater than or equal to 256 bytes.

The FEC_EMRBR is unaffected by reset, and must be initialized by the user.

Address: FEC_EMRBR is 63FE_C000h base + 188h offset = 63FE_C188h



FEC_EMRBR field descriptions

Field	Description
31–11 -	Reserved, is written to 0 by the host processor.
10–4 R_BUF_SIZE	Receive buffer size.
3–0 -	Reserved, is written to 0 by the host processor.

Chapter 33
Fast Infrared Interface (FIRI)

33.1 Overview

The Fast Infrared Interface block (FIRI) is capable of establishing any of the following links:

- 0.576 Mbit/s
- 1.152 Mbit/s
- 4 Mbit/s half duplex (using a LED and IR detector)

The FIRI supports these links:

- 0.576 Mbit/s
- 1.152 Mbit/s Medium Infrared (MIR) physical layer protocol
- 4 Mbit/s Fast Infrared (FIR) physical layer protocol (defined by IrDA, version 1.4)

FIRI interface signals are multiplexed with UART counterpart signals using a GPIO configuration for a complete infrared interface that supports SIR, MIR, and FIR modes, as illustrated in Figure 33-1. In addition, the Serial Infrared (SIR) protocol, which supports data rate 115.2 kbps or lower, is implemented in the UART block.

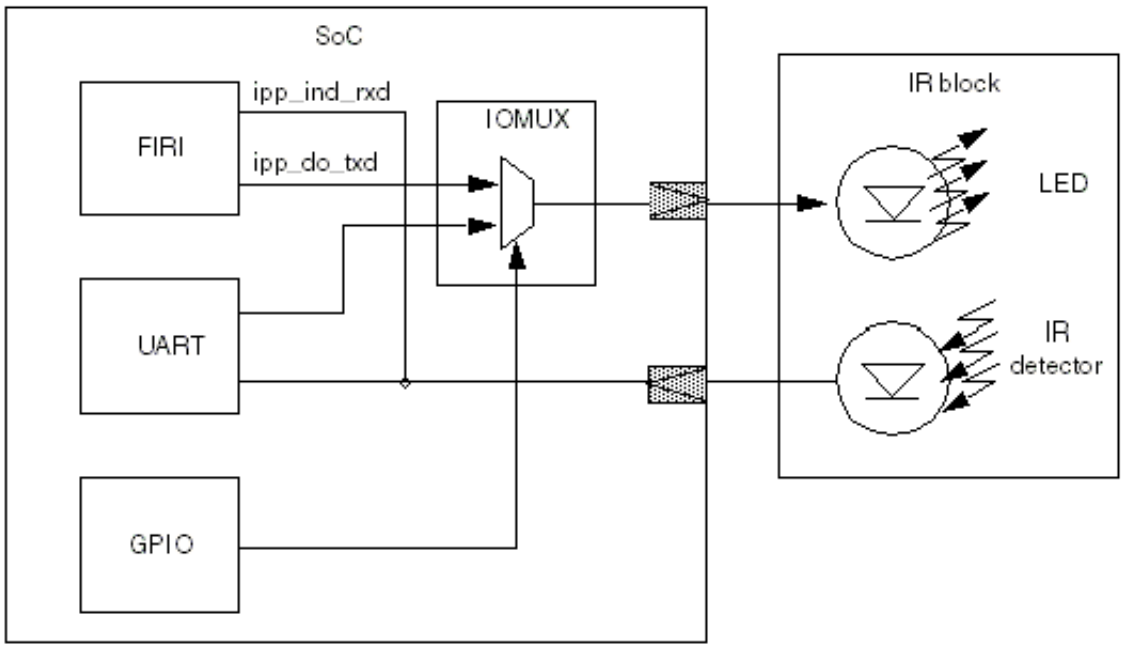


Figure 33-1. FIRI Integration Diagram

See Figure 33-2 for an illustration of the hardware components that comprise the FIRI controller.

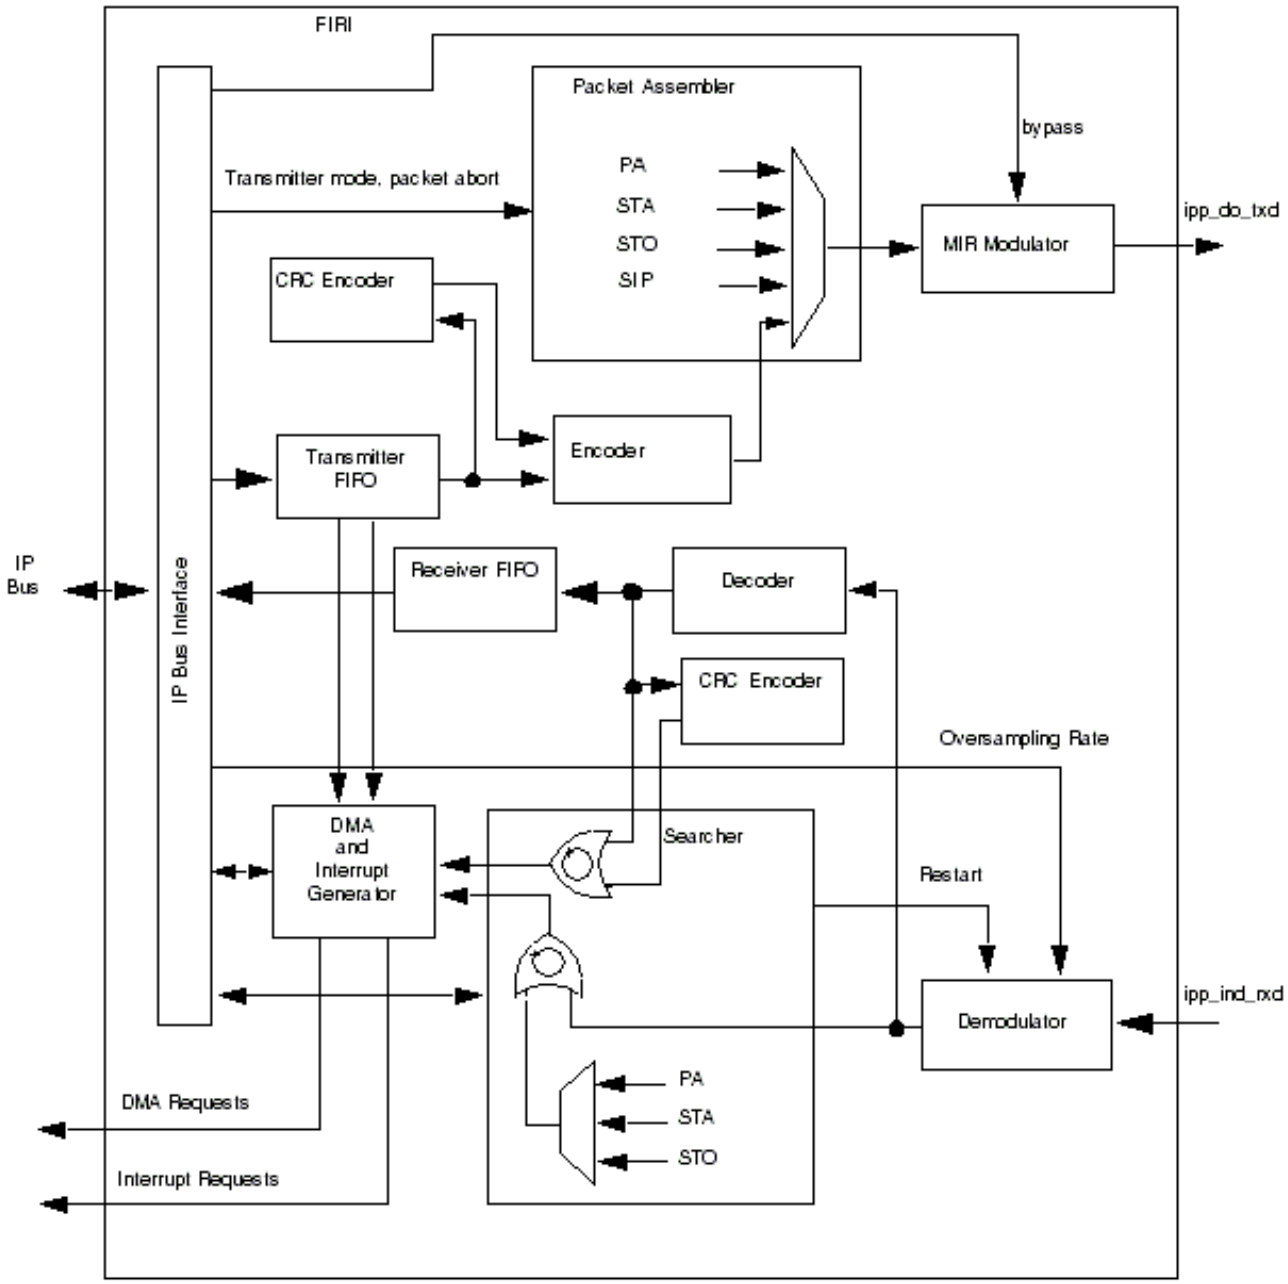

Figure 33-2. FIRI Block Diagram

The FIRI is divided into these four major functional components:

- Transmitter
- Receiver
- FIFO
- IP Bus interface

Each of the four components that make up the FIRI is further made up of individual blocks. The transmitter consists of these sub-blocks:

- Packet Assembler
- CRC Encoder
- MIR Modulator

The receiver consists of these sub-blocks:

- Searcher
- CRC Encoder
- Decoder
- Demodulator

33.1.1 Overview of IrDA Medium Infrared and Fast Infrared Standards

The FIRI supports:

- MIR (0.576 Mbit/s, 1.152 Mbit/s)
- FIR (4 Mbit/s) physical layer protocols

This sub-section provides a brief overview of the MIR and FIR standards.

33.1.1.1 MIR Packet Structure

The MIR packet format follows the standard High-Level Data Link Control (HDLC) format, except that it requires two beginning flags.

The MIR packet consists of:

- Two beginning flags (STA)
- An address
- Control fields
- Data fields
- A frame check sequence (CRC) field
- A minimum of one ending flag (STO)

See the table below for an illustration of the MIR packet structure, where STA (start flag) and STO (stop flag) are equal, predefined sequences (the left symbol is transmitted/ received first).

Table 33-1. MIR Packet Structure

STA	STA	Address	Control & Data	CRC	STO

The fields in the table above are defined as follows:

- STA, STO

  The MIR links use the same physical layer flag, b'0111,1110, for both STA and STO.

- 8-bit Address Field
- 8-bit Control Field plus up to 2045 bytes in the information field
- CRC field

  The MIR links use a 16-bit CRC-CCITT to check received frames for errors. The CRC is computed from the ADDR and Data fields.

The address, control, data, and CRC fields are not transmitted in original form: They are first converted according to the MIR standards described in the next sections.

33.1.1.2 FIR Packet Structure

See the table below for an illustration of the 4 Mbit/s FIR data packet format. The chip patterns and symbols for PA, STA, CRC field, and STO are listed in the following table, where PA (preamble), STA, and STO are a predefined sequence (left symbol transmitted/ received first).

Table 33-2. FIR Packet Structure

PA	STA	Address & Control & Data	CRC32	STO

The fields in the table above are defined as follows:

- PA-The preamble field is used by the receiver to establish phase lock. The preamble field consists of exactly sixteen repeated transmissions of the following stream of symbols:

  b'1000,0000,1010,1000

- STA-The STA consists of exactly one transmission of the following stream of symbols:

  b'0000,1100,0000,1100,0110,0000,0110,0000

- STO-The STO consists of exactly one transmission of a stream of symbols:

  b'0000,1100,0000,1100,0000,0110,0000,0110

- ACD-The payload data is encoded as described in the 4 PPM encoding in the preceding table. The encoded symbols reside in the ACD field and can be up to 2048 bytes long.
- CRC32-The CRC field consists of the 4 PPM encoded data, resulting from the IEEE 802 CRC32 algorithm for cyclic redundancy check as applied to the payload data contained in the packet.

33.1.1.3 MIR CRC

The CRC field is 16 bits long and generated according to the CRC-CCITT algorithm. The CRC polynomial is defined as follows:

$$CRC(x) = x^{16} + x^{12} + x^5 + 1$$

The CRC(x) value is inverted prior to transmission.

33.1.1.4 FIR CRC

The CRC32 field is 32 bits long and generated according to IEEE 802 CRC32 algorithm. The CRC32 polynomial is defined as follows:

$$CRC32(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The CRC(x) value is inverted prior to transmission.

33.1.1.5 MIR Modulation

For MIR data rates, the NZR modulation scheme is used. A "0" is represented by a light pulse. The optical pulse duration is nominally 1/4 of a bit duration. The LED is off when a "1" is transmitted.

Table 33-3. MIR Modulation

Data Bit	Data Symbol (Address, Control, and Data)
0	1000
1	0000

NOTE

Tolerance of bit rate according to the standard must not exceed +0.1%.

33.1.1.6 FIR Modulation

For 4.0 Mbit/s, the modulation scheme is 4 PPM. In the modulation scheme, a pair of bits is taken together and called a data symbol. A data symbol is divided into four chips, only one of which contains an optical pulse. The nominal pulse duration is 125 ns. A "1" is represented by a light pulse.

Table 33-4. 4 PPM Mapping

Data Bit Pair	4 PPM Data Symbol
00	1000
01	0100
10	0010
11	0001

Verify that the tolerance of chip rate according to the standard does not exceed +0.01%. Pulse width tolerance of an electrical signal driven by an IR detector (photodiode) can be greater than the tolerance of the optical signal defined by IrDA, and can depend on the LED and IR devices used with the FIRI.

33.1.2 Features

The FIRI includes the following distinctive features:

- 0.576 Mbit/s, MIR protocol
- 1.152 Mbit/s, MIR protocol
- 4 Mbit/s, 4 PPM, FIR protocol
- Device Destination Detection Hardware Support
- Interrupt generation
- DMA capability
- SIP generation for collision avoidance

33.1.3 Modes of Operation

The FIRI supports the following modes:

- Hardware packet assembly:
  - FIR mode
  - 0.576 Mbps MIR mode
  - 1.152 Mbps MIR mode
  - Serial Infrared Interaction Pulse (SIP) generation
- Hardware packet search:
  - FIR mode
  - 0.576 Mbps MIR mode
  - 1.152 Mbps MIR mode
- Software packet assembling
- Software packet search

33.2 External Signal Description

See the following table for the list of signals used to control the FIRI.

Table 33-5. Signal Properties

Name	Direction	Port	Function	Reset State	Pull up
Signals Connecting To IC IO					
LED and IR Detector Interface					
IPP_DO_TXD	Output	ipp_do_txd	Data transmit signal. Active high.	1	-
IPP_IND_RXD	Input	ipp_ind_rxd	Data receive signal. Active high.	NA	at top level IO ring, if necessary

33.2.1 Detailed Signal Descriptions

33.2.1.1 IPP_DO_TXD

The Data Transmit Signal is the output signal from the Packet Assembler sub-block. It must be connected to an LED through the IOMUX, as shown in Figure 33-1. Add a DC-level translator off-chip, if necessary.

33.2.1.2 IPP_IND_RXD

The Data Receive Signal is driven by IR detector. Add a DC-level translator off-chip, if necessary. The signal is input to the Demodulator sub-block.

33.3 Programmable Registers

The FIRI includes six 32-bit registers, a transmit FIFO, and a receive FIFO. For information about the FIFOs, see Transmitter FIFO and Receiver FIFO.

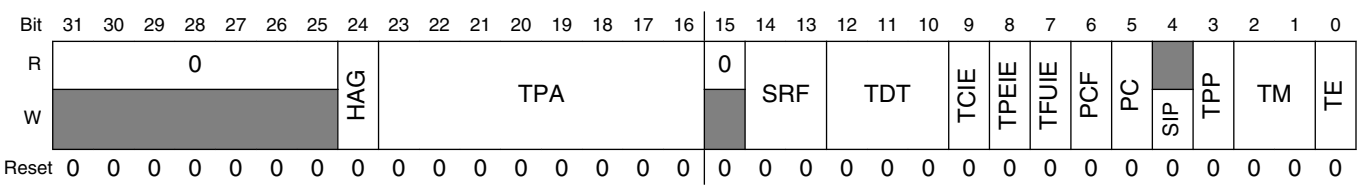
FIRI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FA_8000	FIRI Transmit Control Register (FIRI_TCR)	32	R/W	0000_0000h	33.3.1/ 1627
63FA_8004	FIRI Transmit Count Register (FIRI_TCTR)	32	R/W	0000_0000h	33.3.2/ 1629
63FA_8008	FIRI Receive Control Register (FIRI_RCR)	32	R/W	0000_0000h	33.3.3/ 1630
63FA_800C	FIRI Transmit Status Register (FIRI_TSR)	32	w1c	0000_0000h	33.3.4/ 1632
63FA_8010	FIRI Receive Status Register (FIRI_RSR)	32	w1c	0000_0000h	33.3.5/ 1633
63FA_801C	FIRI Control Register (FIRI_CR)	32	R/W	0000_0000h	33.3.6/ 1634

33.3.1 FIRI Transmit Control Register (FIRI_TCR)

The Transmitter Control Register is a 32-bit, read-write register that controls transmitter operation. The table below shows the register; The figure below shows its field descriptions.

Address: FIRI_TCR is 63FA_8000h base + 0h offset = 63FA_8000h



FIRI_TCR field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value zero. Reserved
24 HAG	Hardware Address Generator. When this bit is set, the content of the TPA bits is transmitted as a packet address. When the bit is cleared, the packet address is read from TX FIFO. 0 Read packet address from TX FIFO 1 Use TPA bits as packet address
23–16 TPA	Transmit Packet Address. This field contains the 8-bit Transmit Packet Address. If the HAG bit is cleared, the TPA bits have no effect.
15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14–13 SRF	Start Field Repeat Factor. This field contains the number of PA or STA fields transmitted in the beginning of the packet for FIR and MIR mode, respectively. In FIR mode, only the 00 value should be used. 00 16 PA or 2 STA fields is transmitted. 01 32 PA or 4 STA fields is transmitted. 10 64 PA or 8 STA fields is transmitted. 11 128 PA or 16 STA fields is transmitted.
12–10 TDT	This field controls the TX FIFO depth that triggers a DMA request. Refer to Transmitter FIFO, for details. **NOTE:** To avoid TX FIFO overflow, verify that the sum of TDT level and burst length (set by BL bits in the FIR_ICR register) does not exceed TX FIFO size, which is 128 bytes. 0 DMA request generated when TX FIFO is empty 1 DMA request generated when TX FIFO contain 16 bytes of data 2 DMA request generated when TX FIFO contain 32 bytes of data 3 DMA request generated when TX FIFO contain 48 bytes of data - ... - ... 7 DMA request generated when TX FIFO contains 112 bytes of data
9 TCIE	Transmit Complete Interrupt Enable. This bit enables the TC status bits of the FIRI_TSR register to generate a Transmit Complete Interrupt. 0 Transmit Complete Interrupt is not triggered by TC bit. 1 Transmit Complete Interrupt is triggered by TC bit.
8 TPEIE	Transmitter Packet End Interrupt Enable. This bit enables the TPE and SIPE status bits of the FIRI_TSR register to generate a Packet End Interrupt. 0 PEI interrupt is not triggered by TPE or SIPE bits. 1 PEI interrupt is triggered by TPE or SIPE bits.
7 TFUIE	Transmitter FIFO Underrun Interrupt Enable. This bit enables the TFU status bit of the FIRI_TSR register to generate a TFU interrupt. 0 TFU interrupt disabled 1 TFU interrupt enabled
6 PCF	Packet Complete by FIFO. This bit determines how a packet is completed if a TX FIFO underrun event occurs. Do not write software intentionally to cause underrun events. However, if due to erroneous

Table continues on the next page...

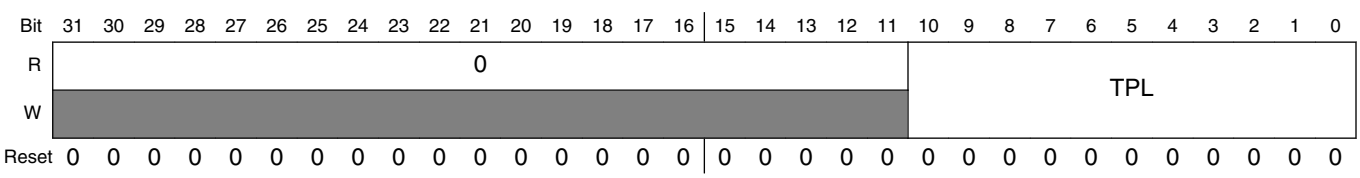
FIRI_TCR field descriptions (continued)

Field	Description
	conditions, the value of this bit selects between two recovery modes. Set the PCF based on system and upper layer IrDA protocol requirements. 0 Send CRC and STO fields 1 Send packet abort symbol
5 PC	Packet Complete. This bit determines how a packet is completed when the TE bit is cleared or when the SIP bit is set in the middle of the transfer. Do not write software intentionally to clear the TE bit, or to set the SIP bit in the middle of the transfer. However, if it is done due to erroneous conditions, the value of this PC bit selects between two recovery modes. Set PC based on system and upper layer IrDA protocols requirements. 0 Send CRC and STO fields 1 Send packet abort symbol
4 SIP	Transmit Enable of SIP. Writing "1" to this bit produces a "Serial Infrared Interaction Pulse" transmission. Writing a "0" to this bit is ignored. This bit is always read as "0". If this bit is set while in the middle of the transfer, the packet will be completed according to the setting of the PC bit.
3 TPP	Transmitter Pulse Polarity bit. 0 Transmitted pulse is not inverted. 1 Transmitted pulse is inverted.
2–1 TM	Transmitter Mode. This bits controls the transmission mode. 00 4 Mbps FIR Mode 01 0.576 Mbps MIR Mode 10 1.152 Mbps MIR Mode 11 Software Packet Assembling
0 TE	Transmitter Enable. This bit controls the FIRI transmitter. If this bit is cleared in the middle of the transfer, the packet will be completed according to the setting of the PC bit. When the packet is completed, the transmitter clocks are then gated OFF. 0 Transmitter Disabled 1 Transmitter Enabled

33.3.2 FIRI Transmit Count Register (FIRI_TCTR)

The Transmitter Count Register is 32-bit, read-write register that controls the packet size. The figure below shows the register; The table below shows its field descriptions.

Address: FIRI_TCTR is 63FA_8000h base + 4h offset = 63FA_8004h



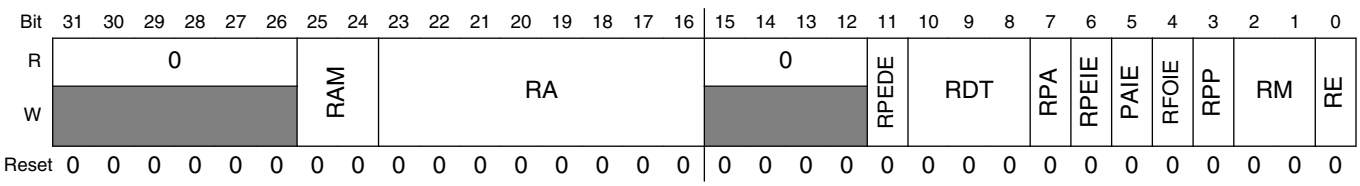
FIRI_TCTR field descriptions

Field	Description
31–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10–0 TPL	Transmit Packet Length bits. The length of the address, control, and data fields (see Table 33-1 and FIR Packet Structure). 0 Send 1 byte 1 Send 2 bytes - ... - ... 2047 Send 2048 bytes

33.3.3 FIRI Receive Control Register (FIRI_RCR)

The Receiver Control Register is 32-bit, read-write register that controls receiver operation. The figure below shows the register; The table below shows its field descriptions.

Address: FIRI_RCR is 63FA_8000h base + 8h offset = 63FA_8008h



FIRI_RCR field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value zero. Reserved
25–24 RAM	Address Match bit. The value of this bit can be changed when the RE bit is cleared. 00 Does not match address 01 Match packet address to RA bits 10 Match packet address to Broadcast address 11 Match packet address to RA bits and to broadcast address
23–16 RA	Receiver Address. Determines Receiver Packet Address. If the RAM bit value is 00 or 10, the RA bit has no effect. The value of this bit can be changed when the RE bit is cleared.
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11 RPEDE	Receiver Packet End DMA Request Enable bit; Enable DMA request generation at the end of the packet. If this bit is set, verify that the BL value in the FIRICR register is not greater than the sum of the address, control, data, and CRC field length.

Table continues on the next page...

FIRI_RCR field descriptions (continued)

Field	Description
	0 DMA request is not affected by the end of packet. 1 DMA request is generated at the end of packet.
10–8 RDT	Receiver DMA Request Trigger level. Sets minimum RX FIFO depth, which triggers a DMA request. For more details, refer to Receiver FIFO. **NOTE:** To avoid RX FIFO underflow, set the RDT level to less than or equal value of the burst length (set by the BL bit in the FIRI_CR register). 0 Reserved 1 DMA request generated when RX FIFO contains 16 bytes of data 2 DMA request generated when RX FIFO contains 32 bytes of data 3 DMA request generated when RX FIFO contains 48 bytes of data - ... - ... 7 DMA request generated when RX FIFO contains 112 bytes of data
7 RPA	Receiver Packet Abort bit. Determines behavior of the RX FIFO upon detection of an illegal symbol. When an illegal symbol is detected, the DDE or CRCE bit in the FIRI_RSR register is set. If the RPA bit is set, the RX FIFO pointers are cleared and the receiver starts to search for the PA or STA fields for FIR and MIR mode, respectively. If RPA is cleared, the receiver continues to write to the RX FIFO. 0 Does not clear the RX FIFO upon detection of an illegal symbol 1 Clears the RX FIFO upon detection of illegal symbol
6 RPEIE	Receiver Packet End Interrupt Enable bit. Enables the RPE status bit in the FIRI_RSR register to assert the Packet End Interrupt. 0 PEI interrupt is not triggered by RPE bit. 1 PEI interrupt is triggered by RPE bit.
5 PAIE	Packet Abort Interrupt Enable bit. Enables the DDE, CRCE status bits in the FIRI_RSR register to cause a PAI interrupt. 0 PAI interrupt is disabled. 1 PAI interrupt is enabled.
4 RFOIE	Receiver FIFO Overrun Interrupt Enable bit. Enables the RFO status bit in the FIRI_RSR register to cause a RFOI interrupt. 0 RFOI interrupt is disabled. 1 RFOI interrupt is enabled.
3 RPP	Receiver Pulse Polarity bit. 0 Receiver signal is not inverted. 1 Received signal is inverted.
2–1 RM	Receiver Mode bits. 00 FIR Mode 01 0.576 Mbps MIR Mode 10 1.152 Mbps MIR Mode 11 Software Packet Assembling
0 RE	Receiver enable bit. When this bit is cleared, the receiver clocks are gated OFF.

Table continues on the next page...

FIRI_RCR field descriptions (continued)

Field	Description
	0 Receiver is disabled. 1 Receiver is enabled.

33.3.4 FIRI Transmit Status Register (FIRI_TSR)

The Transmit Status Register is 32-bit register that reflects the status of the transmitter and the TX FIFO. The FIRI_TSR contains read-only and write-one-to-clear bits. The figure below shows the register; The table below shows its field descriptions.

Address: FIRI_TSR is 63FA_8000h base + Ch offset = 63FA_800Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TFP								0				TC	SIPE	TPE	TXU
W													w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FIRI_TSR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–8 TFP	Transmitter FIFO Pointer bits. The value of the TFP bits represent the number of available bytes in TX FIFO (read-only bits).
7–4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3 TC	Transmit Complete bit. Indicates that the transmission is completed (including the CRC and STO fields), and the transmitter FIFO is empty. This bit is cleared by writing a "1". 0 Transmitting is not completed. 1 Transmitting is completed.
2 SIPE	SIP End bit. Indicates that "Serial Infrared Interaction Pulse" has been transmitted. This bit is cleared by writing a "1". 0 SIP transmission is not completed. 1 SIP had been transmitted.
1 TPE	Transmitter Packet End bit. Indicates that the TPS bytes of data (address, control, and data fields) have been transmitted. This bit is cleared by writing a "1".

Table continues on the next page...

FIRI_TSR field descriptions (continued)

Field	Description
	0 Transmissions of address, control, and data fields are not completed. 1 Address, control, and data fields had been transmitted.
0 TXU	Transmitter FIFO Underrun bit. Indicates the occurrence of a TX FIFO underrun. A TX FIFO underrun occurred if the transmitter attempted to read from the TX FIFO when the TX FIFO is empty. This bit is cleared by writing a "1". 0 No transmitter FIFO underrun 1 Transmitter FIFO is underrun

33.3.5 FIRI Receive Status Register (FIRI_RSR)

The Receive Status Register is 32-bit register that reflects the status of the receiver and the FIFO. It contains read-only and write-one-to-clear bits. The figure below shows the register; The table below shows its field descriptions.

Address: FIRI_RSR is 63FA_8000h base + 10h offset = 63FA_8010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

FIRI_RSR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–8 RFP	Receiver FIFO Pointer bits. The value of the RFP bits represent the number of available bytes in the RX FIFO (read-only bits).
7–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 PAS	Preamble Search bit. Indicates that the receiver is searching for PA+STA, or STA fields for FIR and MIR modes, respectively (read-only bit). 0 Receiver does not search for the PA or STA field. 1 Receiver searches for the PA or STA field.
4 RPE	Receiver Packet End bit. Indicates that the STO field or packet abort symbol (b'0000,000 and b'0000,0000 for MIR and FIR, respectively) is detected. This bit is cleared by writing a "1".

Table continues on the next page...

FIRI_RSR field descriptions (continued)

Field	Description
	0 STO was not detected. 1 STO field is detected.
3 RFO	Receiver FIFO Overrun bit. Indicates that the receiver attempted to write to the RX FIFO when the RX FIFO is full. This bit is cleared by writing a "1". 0 Receiver FIFO is not overrun. 1 Receiver FIFO is overrun.
2 BAM	Broadcast Address Match bit. Indicates that the address field of the packet matches the Broadcast Address 0xFF. This bit is cleared by writing a "1". 0 No Broadcast 1 Broadcast packet
1 CRCE	CRC Error bit. Indicates that the CRC check failed. This bit is cleared by writing a "1". 0 No CRC check failure 1 CRC check failure
0 DDE	Address, Control, or Data Field Error bit. Indicates that an illegal symbol has been detected in the address, control, data, or CRC32/CRC fields. This bit is cleared by writing a "1". 0 No illegal symbols in address, control, data, or CRC field 1 Illegal symbol in address, control, data, or CRC field

33.3.6 FIRI Control Register (FIRI_CR)

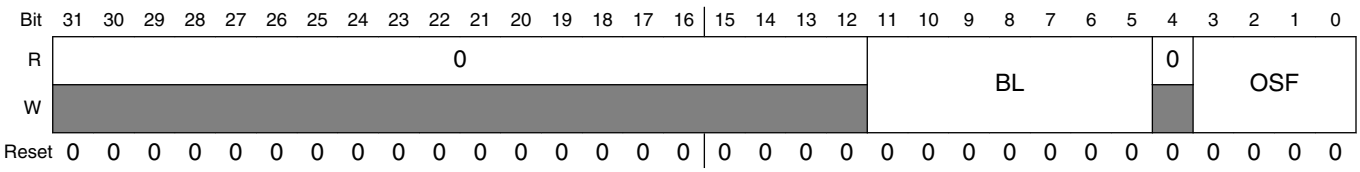
The Control Register is a 32-bit, read-write register that is shared by receiver and transmitter. The figure below shows the register; The table below shows its field descriptions.

To enable proper receive operations, the period of the divided clock must be four or more times shorter than the pulse width of the IPP_IND_RXD signal, and one or more times shorter than the gap between two consecutive pulses.

NOTE

The pulse width of the IPP_IND_RXD signal is dependent upon the characteristics of the LED and the Photo Diode used with the FIRI, and is different from the pulse width defined by IrDA for the optical signal. The value of the OSF bits must be adjusted accordingly. A greater OSF value leads to a better SNR on the expense of an increase in the power consumption.

Address: FIRI_CR is 63FA_8000h base + 1Ch offset = 63FA_801Ch



FIRI_CR field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11–5 BL	Burst Length. Used to prevent an overrun of the TX FIFO and an underrun of the RX FIFO. The DMA request of the transmitter deasserts when the number of vacant bytes in the TX FIFO is less than the burst length settings specified by the BL bits. The DMA request of the receiver deasserts when the number of available bytes in the RX FIFO is less than the burst length settings specified by the BL bits. 1 1 byte 2 2 bytes 3 3 bytes - ... 127 127 bytes 0 128 bytes
4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3–0 OSF	Over Sampling Factor. This field controls the oversampling factor of the "chip" on the IPP_IND_RXD signal if the RE bit in the FIRI_RCR register is set, or the prescaling factor of the IPG_CLK_FIRI_BAUD signal if the TE bit in the FIRI_TCR register is set. **NOTE:** The "chip" rate is 4 and 2 times greater than the bit rate for MIR and FIR, respectively. 0 Does not oversample 1 Oversamples by 2 2 Oversamples by 3 - ... - ... 15 Oversamples by 16

33.4 Functional Description

This section details the FIRI functional description.

33.4.1 Transmitter Overview

The transmitter has three modes of operation:

- MIR

- FIR
- Software Packet Assembly

33.4.1.1 MIR Mode-Transmitter

In MIR mode, the following sequence occurs:

1. The Packet Assembler block sends the STA sequences (two or more times) to the MIR Modulator sub-block.
2. The Encoder block accesses the TX FIFO, aligns the data, and sends the ACD (Address, Control, and Data) fields to the Packet Assembler sub-block.
3. The CRC field calculated by CRC block follows the ACD field; after which, the STO bits are sent to the Modulator.

33.4.1.2 FIR Mode-Transmitter

In FIR mode, the following sequence occurs:

1. The Packet Assembler block sends the predefined PA (16 or more times) and STA sequences to the LED.
2. The Encoder block accesses the TX FIFO, encodes the data (4 PPM), and sends the ACD (Address, Control and Data) to the Packet Assembler sub-block.
3. The CRC32 field calculated by CRC block follows the ACD field; after which, the STO bits are sent to the Modulator.

NOTE

The MIR Modulator block is not operable in FIR mode.

If the DMA request is not served during MIR or FIR modes, and there is no valid data to transmit, the Assembler sub-block terminates the packet using the packet-abort symbol (with CRC/CRC32 and STO fields [see the PCF bit description]), and a TFUI interrupt is generated. The packet can also be aborted by the packet length counter or by the software (see PC bit description).

33.4.1.3 Serial Infrared Interaction Pulse

The transmitter must send the "Serial Infrared Interaction Pulse" (SIP) at 500 ms to guarantee that low speed IR devices will not interfere with its pulses. The pulse must be 8.7 µs wide; and positive phase must be 1.6 µs wide.

33.4.1.4 Software Packet Assembly Mode

In Software Packet Assembly mode, the entire packet is read from the TX FIFO, including the PA, STA, and STO bits. The MIR modulator and Encoder sub-blocks are disabled. This mode is used for debug purposes and can be used for testing compatibility with future IrDA protocols, if appropriate.

33.4.2 Transmitter FIFO

The transmitter FIFO is a 128-byte FIFO used for holding transmit data. The TX FIFO gets filled by the accesses to the Transmitter FIFO address (by core or DMA) and is emptied by the transmitter. When the DMA is used, a pre-programmed FIFO trigger level controls the triggering of the DMA request. When the TX FIFO is emptied below the trigger-level, a DMA request signal is asserted. The DMA request gets deasserted when the number of vacant bytes in the TX FIFO is less than the burst length settings specified by the BL bits in the FIRI_CR register. If the DMA request was not serviced and, as a result, there are no more data in the TX FIFO, the TFU bit in the FIRI_TSR register sets, and the $\overline{\text{IPI\_INT\_FIFO}}$ interrupt signal asserts depending on TFOIE bit in the FIRI_TCR register. During the transmit operation, the TFP bit value in the FIRI_TSR register reflects the amount of available bytes in the TX FIFO.

33.4.3 Receiver Overview

The receiver has three modes of operation:

- MIR
- FIR
- Software Packet Disassembly Modes

In MIR and FIR modes, each incoming pulse is oversampled by the programmable factor in the Demodulator sub-block. Next, the Demodulator detects the edges of the pulses and synchronizes to the phase of the transmitted pulse. Phase correction is performed until the end of the packet because the bit rate tolerance accumulates to very large values for long packets.

33.4.3.1 MIR Mode-Receiver

In MIR mode, the Searcher sub-block searches for the STA field. If the sequence is matched, the data stream following the STA field is sent to the Decoder block. The Decoder block searches for five consecutive "1"s and skips next the "zero" bit inserted by the transceiver for phase synchronization. The data is then written to the RX FIFO. In parallel, the Searcher sub-block searches for the STO field. When the STO field is detected, a PEI interrupt is generated together with a DMA request, and the corresponding flag is set in the status register. The Searcher sub-block continuously searches for illegal symbols (seven or more consecutive "1"s). If an illegal symbol is detected, the PAI interrupt is generated and the corresponding flag is set in the status register.

33.4.3.2 FIR Mode-Receiver

In FIR mode, the Searcher sub-block searches for the PA field and then for the STA field. If found, the "chip" stream is converted to a data stream by the Decoder sub-block and then it is written to the RX FIFO. In a parallel operation, the Searcher sub-block searches for the STO field. When the STO field is detected, a PEI interrupt can be generated together with a DMA request. While receiving, the Searcher sub-block continuously searches the PA, STA, ACD, CRC32, and STO fields for illegal symbols. In addition, the Searcher sub-block looks for a packet abort symbol. On detection of an illegal symbol, a PAI interrupt is generated and the corresponding flag is set in the status register.

In MIR and FIR modes, the "Address" bits can be compared to a predefined value or/and to the broadcast value 0xFF (see the description of RAM bits). If the CRC field value does not match an expected value calculated by the CRC Encoder sub-block, a PAI interrupt is generated. The CRC field sends the RX FIFO, irrespective of a comparison result.

33.4.3.3 Software Packet Disassembly Mode

In Software Packet Disassembly mode, the entire packet is sent to the RX FIFO, even if illegal symbols have been detected.

33.4.4 Receiver FIFO

The receiver FIFO is a 128-byte FIFO, used for holding received data. RX FIFO gets filled by incoming data and emptied by excess RX FIFO (by the core or DMA). When DMA is used, a pre-programmed FIFO trigger level controls the triggering of the DMA

request. When RX FIFO is filled beyond the trigger level, a DMA request signal is asserted. The DMA request gets deasserted when the number of available bytes in RX FIFO is less than the burst length settings specified by the BL bits in the FIRI_CR register. If the DMA request was not serviced and, as a result, there are no vacant bytes in the RX FIFO for receive data, the RFO bit in the FIRI_RSR register is set and the IPI_INT_FIFO interrupt signal is asserted depending on RFOIE bit in the FIRI_RCR register. During a receive operation, the RFP bits' value in the FIRI_RSR register reflects the amount of available bytes in the RX FIFO.

33.5 Initialization/Application Information

33.5.1 Examples of FIRI Programming

33.5.1.1 Transmitter Programming Scenario

The purpose of this scenario is to transmit 1024 bytes in FIR mode using an infrared link. Verify that the packet length is 512 bytes.

- Configure Clock Controller. For this example, the frequency of the IPG_CLK_FIRI_BAUD clock is 48 MHz.
- Configure the DMA for DMA-service FIRI transactions. A DMA transaction will be requested by the negative edge of DMA_REQ[1]. The DMA access size is 4 bytes. For this example, the burst length is 4 accesses.
- Configure the FIRI to work with a 32-byte burst (FIRICR.BL bits).

NOTE

Observe the burst length of the DMA, and the burst length selected by FIRI_CR. The BL bits are not necessarily equal.

- Set the FIRI Oversampling Factor (FIRI_CR.OSF bits) to 6 to achieve a 4-Mbit rate with the IPG_CLK_FIRI_BAUD clock.
- Configure the FIRI to transmit 512-byte long packets (FIRI_TCTR.TPL bits).
- Set the DMA trigger level to 16 (FIRI_TCR.TDT bits). A DMA request will be generated when there are only 16 bytes remaining in the TX FIFO. Select FIR mode (FIRI_TCR.TM bits).
- Finally, enable the transmitter (FIRI_TCT.TE bit). The FIRI immediately asserts a DMA request because the TX FIFO is empty. The DMA controller delivers a first burst to the FIRI. The FIRI starts the transmission.

33.5.1.2 Receiver Programming Scenario

Fort the receiver programming scenario, the data is transmitted in FIR mode. An interrupt should be generated at the end of each packet.

- Configure Clock Controller. For this example, the frequency of the IPG_CLK_FIRI_BAUD clock is 48 MHz.
- Configure the DMA for the FIRI to DMA transactions. The DMA transaction will be requested by the negative edge of $\overline{\text{DMA\_REQ}}$[0]. DMA access size is 4 bytes. For this example, burst length is 4 accesses.
- Configure the FIRI to work with 32-byte burst (FIRI_CR.BL bits). Set the FIRI Oversampling Factor (FIRI_CR.OSF bits) to 6 to achieve a 4-Mbit rate with the IPG_CLK_FIRI_BAUD clock.
- Set the DMA trigger level to 16 (FIRI_RCR.RDT bits). A DMA request is generated when there are 16 bytes in RX FIFO. Select FIR mode (FIRI_RCR.RM bits). Enable Packet End Interrupt.
- Finally, enable the receiver (FIRI_RCR.RE bit). The receiver searches for the PA and STA fields. When a PEI interrupt is generated, verify that the software clears the FIRI_RSR.RPE bit

Chapter 34
Flexible Controller Area Network (FLEXCAN)

34.1 Introduction

The Flexible Controller Area Network (FLEXCAN) block is a communication controller implementing the CAN protocol according to the CAN 2.0B protocol specification [Ref. 1]. A general block diagram is shown in Figure 34-1, and describes the main sub-blocks implemented in the FLEXCAN block, including two embedded memories, one for storing Message Buffers and another one for storing Rx Individual Mask Registers. Support for 64 Message Buffers is provided. The functions of the sub-blocks are described in subsequent sections.

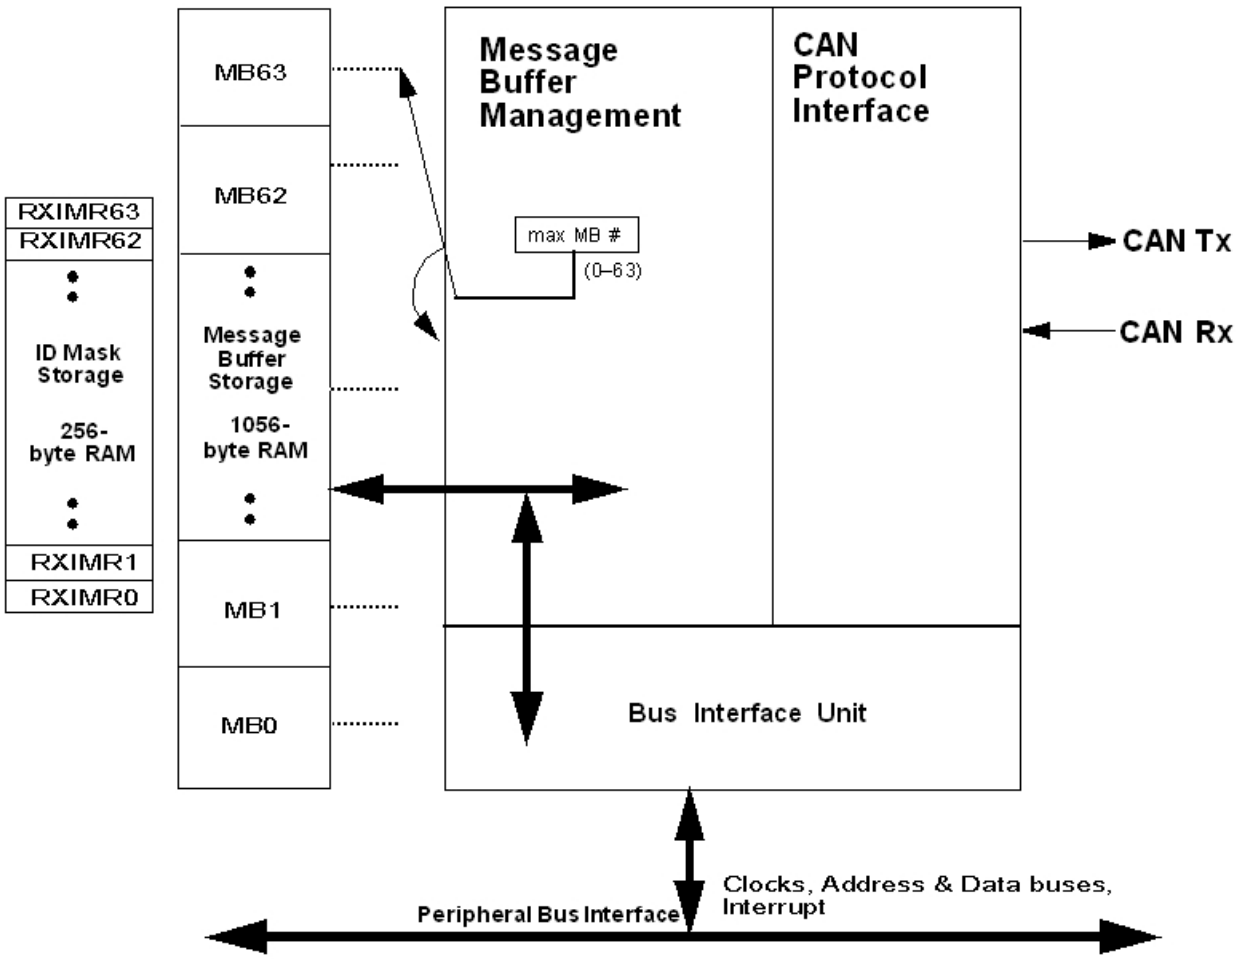


Figure 34-1. FLEXCAN Block Diagram

34.1.1 General Overview

The CAN protocol was designed primarily to be used as a vehicle serial data bus, meeting the specific requirements of this field: real-time processing, reliable operation in the EMI environment of a vehicle, cost-effectiveness and required bandwidth. The FLEXCAN block is a full implementation of the CAN protocol specification, which supports both standard and extended message frames. Sixty-four Message Buffers are supported. The Message Buffers are stored in an embedded RAM dedicated to the FLEXCAN.

The CAN Protocol Interface (CPI) sub-block manages the serial communication on the CAN bus, requesting RAM access for receiving and transmitting message frames, validating received messages and performing error handling. The Message Buffer Management (MBM) sub-block handles Message Buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms. The Bus Interface

Unit (BIU) sub-block controls the access to and from the internal interface bus, in order to establish connection to the ARM and to other blocks. Clocks, address and data buses, interrupt outputs and test signals are accessed through the Bus Interface Unit

34.1.2 FLEXCAN Block Features

The FLEXCAN includes these distinctive features:

- Full Implementation of the CAN protocol specification
  - Standard data and remote frames
  - Extended data and remote frames
  - Zero to eight bytes data length
  - Programmable bit rate up to 1 Mb/sec
  - Content-related addressing
- Flexible Message Buffers of zero to eight bytes data length
- Each Message Buffer configurable as Rx or Tx, all supporting standard and extended messages
- Individual Rx Mask Registers per Message Buffer
- Includes 1056 bytes (64 Mbytes) of RAM used for Message Buffer storage
- Includes 256 bytes (64 Mbytes) of RAM used for individual Rx Mask Registers
- Full featured Rx FIFO with storage capacity for 6 frames and internal pointer handling
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 8 extended, 16 standard or 32 partial (8 bits) IDs, with individual masking capability
- Selectable backwards compatibility with previous CAN version
- Programmable clock source to the CAN Protocol Interface, either bus clock or crystal oscillator
- Unused message buffer and Rx Mask Register space can be used as general purpose RAM space
- Listen only mode capability
- Programmable loop-back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number or highest priority
- Time Stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independent of the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes, with programmable wake up on bus activity
- Configurable Glitch filter width to filter the noise on CAN bus when waking up

34.1.3 Modes of Operation

The FLEXCAN has four functional modes: Normal Mode (User and Supervisor), Freeze Mode, Listen-Only Mode and Loop-Back Mode. There are also two low power modes: Disable Mode and Stop Mode.

- Normal Mode (User or Supervisor):

In Normal Mode, the block operates receiving and/or transmitting message frames, errors are handled normally and all the CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze Mode:

It is enabled when the FRZ bit in the MCR Register is asserted. If enabled, Freeze Mode is entered when the HALT bit in MCR is set or when Debug Mode is requested at ARM platform level . In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See Freeze Mode.

- Listen-Only Mode:

The block enters this mode when the LOM bit in the Control Register is asserted. In this mode, transmission is disabled, all error counters are frozen and the block operates in a CAN Error Passive mode [Ref. 1]. Only messages acknowledged by another CAN station will be received. If FLEXCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- Loop-Back Mode:

The block enters this mode when the LPB bit in the Control Register is asserted. In this mode, FLEXCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FLEXCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FLEXCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- Block Disable Mode:

This low power mode is entered when the MDIS bit in the MCR Register is asserted. When disabled, the block shuts down the clocks to the CAN Protocol Interface and Message Buffer Management sub-blocks. Exit from this mode is done by negating the MDIS bit in the MCR Register. See Block Disable Mode.

- Stop Mode:

This low power mode is entered when Stop Mode is requested at the ARM platform level . When in Stop Mode, the block puts itself in an inactive state and then informs the ARM that the clocks can be shut down globally. Exit from this mode happens when the Stop Mode request is removed or when activity is detected on the CAN bus and the Self Wake Up mechanism is enabled. See Stop Mode.

34.2 External Signal Description

34.2.1 Signals Overview

The FLEXCAN has two I/O signals, both of which are summarized in Table 34-1 and described in more detail in the following sub-sections.

Table 34-1. FLEXCAN Signals

Signal Name	Direction	Description
CAN Rx	Input	CAN Receive Pin
CAN Tx	Output	CAN Transmit Pin

34.2.2 Signal Descriptions

34.2.2.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level. Recessive state is represented by logic level.

34.2.2.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level. Recessive state is represented by logic level.

34.3 Buffers

34.3.1 Standard/Extended Message Buffer (MB0) Memory Map

The FLEXCAN stores CAN messages for transmission and reception using a Message Buffer structure. Each individual Message Buffer is formed by 16 bytes mapped on memory as described in Table 34-2.

Table 34-2 shows a Standard/Extended Message Buffer (MB0) memory map, using 16 bytes total (0x80,0x8F space).

Table 34-2. Message Buffer MB0 Memory Mapping

Address Offset	Message Buffer Field
0x80	Control and Status (C/S)
0x84	Identifier Field
0x88,0x8F	Data Field 0, Data Field 7 (1 byte each)

34.3.2 Message Buffer Structure

The Message Buffer structure used by the FLEXCAN is represented below. Both the Extended and Standard Frames (29-bit Identifier and 11-bit Identifier, respectively) used in the CAN specification are represented.

Table 34-3. Message Buffer Structure

	31			28	27			24		22	21	20	19			16	15														0
	0			3	4			7		9	10	11	12			15	16														31
0x0	U / R				CODE				U / R	SR	ID	RT	LENGTH				TIME STAMP															
0x4		ID (Standard/Extended)												ID (Extended)																		
0x8	Data Byte 0								Data Byte 1								Data Byte 2														Data Byte 3	
0xC	Data Byte 4								Data Byte 5								Data Byte 6														Data Byte 7	
	U / R = Unimplemented or Reserved																															

CODE Message Buffer Code

This 4-bit field can be accessed (read or write) by the ARM core and by the FLEXCAN itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 34-4 and Table 34-5.

Table 34-4. Message Buffer Code for Rx buffers

Rx Code BEFORE Rx New Frame	Description	Rx Code AFTER Rx New Frame	Comment
0000	INACTIVE: Message Buffer is not active.		Message buffer does not participate in the matching process.
0100	EMPTY: Message buffer is active and empty.	0010	Message buffer participates in the matching process. When a frame is received successfully, the code is automatically updated to FULL.
0010	FULL: Message buffer is full.	0010	The act of reading the C/S word followed by unlocking the Message buffer does not make the code return to EMPTY. It remains FULL. If a new frame is written to the message buffer after the C/S word was read and the message buffer was unlocked, the code still remains FULL.
		0110	If the message buffer is FULL and a new frame is overwritten to this message buffer before the ARM had time to read it, the code is automatically updated to OVERRUN. Refer to for details about overrun behavior.
0110	OVERRUN: a frame was overwritten into a full buffer.	0010	If the code indicates OVERRUN but the ARM reads the C/S word and then unlocks the message buffer, when a new frame is written to the message buffer the code returns to FULL.
		0110	If the code already indicates OVERRUN, and yet another new frame must be written, the message buffer will be overwritten again, and the code will remain OVERRUN. Refer to for details about overrun behavior.
0XY1[1, 1]	BUSY: FLEXCAN is updating the contents of the message buffer. The ARM must not access the Message Buffer.	0010	An EMPTY buffer was written with a new frame (XY was 01).
		0110	A FULL/OVERRUN buffer was overwritten (XY was 11).

1. Note that for Tx message buffers (see Table 34-5), the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register.

Table 34-5. Message Buffer Code for Tx buffers

RTR	Initial Tx code	Code after successful transmission	Description
X	1000		INACTIVE: Message Buffer does not participate in the arbitration process.

Table continues on the next page...

Table 34-5. Message Buffer Code for Tx buffers (continued)

RTR	Initial Tx code	Code after successful transmission	Description
X	1001	-	ABORT: Message Buffer was configured as Tx and ARM core aborted the transmission. This code is only valid when AEN bit in MCR is asserted. Message Buffer does not participate in the arbitration process.
0	1100	1000	Transmit data frame unconditionally once. After transmission, the message buffer automatically returns to the INACTIVE state.
1	1100	0100	Transmit remote frame unconditionally once. After transmission, the message buffer automatically becomes an Rx message buffer with the same ID.
0	1010	1010	Transmit a data frame whenever a remote request frame with the same ID is received. This message buffer participates simultaneously in both the matching and arbitration processes. The matching process compares the ID of the incoming remote request frame with the ID of the message buffer. If a match occurs this message buffer is allowed to participate in the current arbitration process and the Code field is automatically updated to '1110' to allow the message buffer to participate in future arbitration runs. When the frame is eventually transmitted successfully, the Code automatically returns to '1010' to restart the process again.
0	1110	1010	This is an intermediate code that is automatically written to the message buffer by the MBM as a result of match to a remote request frame. The data frame will be transmitted unconditionally once and then the code will automatically return to 1010. The ARM can also write this code with the same effect.

SRR Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to '1' by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FLEXCAN receives this bit as dominant, then it is interpreted as arbitration loss.

1 = Recessive value is compulsory for transmission in Extended Format frames

0 = Dominant is not a valid value for transmission in Extended Format frames

IDE ID Extended Bit

This bit identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

RTR Remote Transmission Request

This bit is used for requesting transmissions of a data frame. If FLEXCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FLEXCAN treats it as bit error. If the value received matches the value transmitted, it is considered as a successful bit transmission.

1 = Indicates the current message buffer has a Remote Frame to be transmitted

0 = Indicates the current message buffer has a Data Frame to be transmitted

LENGTH Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the message buffer space (see Table 34-3). In reception, this field is written by the FLEXCAN, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the ARM and corresponds to the DLC field value of the frame to be transmitted. When RTR=1, the Frame to be transmitted is a Remote Frame and does not include the data field, regardless of the Length field.

TIME STAMP Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

PRIO Local priority

This 3-bit field is only used when LPRIO_EN bit is set in MCR and it only makes sense for Tx buffers. These bits are not transmitted. They are appended to the regular ID to define the transmission priority.

ID Frame Identifier

In Standard Frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In Extended Frame format, all bits are used for frame identification in both receive and transmit cases.

DATA Data Field

Up to eight bytes can be used for a data frame. For Rx frames, the data is stored as it is received from the CAN bus. For Tx frames, the ARM core prepares the data field to be transmitted within the frame.

34.3.3 Rx FIFO Structure

When the FEN bit is set in the MCR, the memory area from 0x80 to 0xFF (which is normally occupied by MB0 to MB7) is used by the reception FIFO engine. Table 34-6 shows the Rx FIFO data structure. The region 0x80-0x8F contains an message buffer structure which is the port through which the ARM core reads data from the FIFO (the oldest frame received and not read yet). The region 0x90-0xDF is reserved for internal use of the FIFO engine. The region 0xE0-0xFF contains an 8-entry ID table that specifies filtering criteria for accepting frames into the FIFO. Table 34-7 shows the three different formats that the elements of the ID table can assume, depending on the IDAM field of the MCR. Note that all elements of the table must have the same format.

Table 34-6. Rx FIFO Structure

			= Unimplemented or Reserved			

REM Remote Frame

This bit specifies if Remote Frames are accepted into the FIFO if they match the target ID.

1 = Remote Frames can be accepted and data frames are rejected

0 = Remote Frames are rejected and data frames can be accepted

EXT Extended Frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

RXIDA Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits are used for frame identification. In the extended frame format, all bits are used.

RXIDB_0, RXIDB_1 Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3 Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

34.4 Functional Description

34.4.1 Overview

The FLEXCAN is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed by a set of 64 Message Buffers that store configuration and control data, time stamp, message ID and data. The memory corresponding to the first 8 message buffers can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 8 extended IDs or 16 standard IDs or 32 8-bit ID slices), each one with its own individual mask register. Simultaneous reception through FIFO and mailbox is supported. For mailbox reception, a matching algorithm makes it possible to store received frames only into message buffers that have the same ID programmed on its ID field. A masking scheme makes it possible to match the ID programmed on the message buffer with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of message buffers to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the message buffer ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be 'active' at a given time if it can participate in the matching and arbitration algorithms that are happening at that time. An Rx message buffer with a '0000' code is inactive (refer to Table 34-4). Similarly, a Tx message buffer with a '1000' or '1001' code is also inactive (refer to Table 34-5). An message buffer not programmed with '0000','1000' or '1001' will be temporarily deactivated (will not participate in the current arbitration or matching run) when the ARM writes to the C/S field of that message buffer.

The FLEXCAN also provide a glitch filter which can filter the noises on CAN bus when the FLEXCAN is in the STOP mode. The glitch filter width is configurable by the register.

34.4.2 Transmit Process

In order to transmit a CAN frame, the ARM must prepare a Message Buffer for transmission by executing the following procedure:

- If the message buffer is active (transmission pending), write an ABORT code ('1001') to the Code field of the Control and Status word to request an abortion of the

transmission, then read back the Code field and the IFLAG register to check if the transmission was aborted. If backwards compatibility is desired (AEN in MCR negated), just write ,'1000', to the Code field to inactivate the message buffer but then the pending frame may be transmitted without notification (see Table 34-5).
- Write the ID word.
- Write the data bytes.
- Write the Length, Control and Code fields of the Control and Status word to activate the message buffer.

Once the message buffer is activated in the fourth step, it will participate into the arbitration process and eventually be transmitted according to its priority. At the end of the successful transmission, the value of the Free Running Timer is written into the Time Stamp field, the Code field in the Control and Status word is updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new Code field after transmission depends on the code that was used to activate the message buffer in step four (see Table 34-4 and Table 34-5). When the Abort feature is enabled (AEN in MCR is asserted), after the Interrupt Flag is asserted for a message buffer configured as transmit buffer, the message buffer is blocked, therefore the ARM is not able to update it until the Interrupt Flag is negated by ARM. It means that the ARM must clear the corresponding IFLAG before starting to prepare this message buffer for a new transmission or reception.

34.4.3 Arbitration process

The arbitration process is an algorithm executed by the MBM that scans the whole message buffer memory looking for the highest priority message to be transmitted. All message buffers programmed as transmit buffers will be scanned to find the lowest ID[1] or the lowest message buffer number or the highest priority, depending on the LBUF and LPRIO_EN bits on the Control Register. The arbitration process is triggered in the following events:

- During the CRC field of the CAN frame
- During the error delimiter field of the CAN frame
- During Intermission, if the winner message buffer defined in a previous arbitration was deactivated, or if there was no message buffer to transmit, but the ARM wrote to the C/S word of any message buffer after the previous arbitration finished
- When MBM is in Idle or Bus Off state and the ARM writes to the C/S word of any message buffer
- Upon leaving Freeze Mode

1. Actually, if LBUF is negated, the arbitration considers not only the ID, but also the RTR and IDE bits placed inside the ID at the same positions they are transmitted in the CAN frame.

When LBUF is asserted, the LPRIO_EN bit has no effect and the lowest number buffer is transmitted first. When LBUF and LPRIO_EN are both negated, the message buffer with the lowest ID is transmitted first but. If LBUF is negated and LPRIO_EN is asserted, the PRIO bits augment the ID used during the arbitration process. With this extended ID concept, arbitration is done based on the full 32-bit ID and the PRIO bits define which message buffer should be transmitted first, therefore message buffers with PRIO = 000 have higher priority. If two or more message buffers have the same priority, the regular ID will determine the priority of transmission. If two or more message buffers have the same priority (3 extra bits) and the same regular ID, the lowest message buffer will be transmitted first.

Once the highest priority message buffer is selected, it is transferred to a temporary storage space called Serial Message Buffer (SMB), which has the same structure as a normal message buffer but is not user accessible. This operation is called 'move-out' and after it is done, write access to the corresponding message buffer is blocked (if the AEN bit in MCR is asserted). The write access is released in the following events:

- After the message buffer is transmitted
- FLEXCAN enters in HALT or BUS OFF
- FLEXCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the SMB is transmitted according to the CAN protocol rules. FLEXCAN transmits up to eight data bytes, even if the DLC (Data Length Code) value is bigger.

34.4.4 Receive Process

To be able to receive CAN frames into the mailbox message buffers, the ARM must prepare one or more Message Buffers for reception by executing the following steps:

- If the message buffer has a pending transmission, write an ABORT code ('1001') to the Code field of the Control and Status word to request an abortion of the transmission, then read back the Code field and the IFLAG register to check if the transmission was aborted. If backwards compatibility is desired (AEN in MCR negated), just write '1000' to the Code field to inactivate the message buffer, but then the pending frame may be transmitted without notification. If the message buffer already programmed as a receiver, just write '0000' to the Code field of the Control and Status word to keep the message buffer inactive. (See Table 34-3)
- Write the ID word
- Write '0100' to the Code field of the Control and Status word to activate the message buffer

Once the message buffer is activated in the third step, it will be able to receive frames that match the programmed ID. At the end of a successful reception, the message buffer is updated by the MBM as follows:

- The value of the Free Running Timer is written into the Time Stamp field
- The received ID, Data (8 bytes at most) and Length fields are stored
- The Code field in the Control and Status word is updated (see Table 34-4 and Table 34-5)
- A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit

Upon receiving the message buffer interrupt, the ARM should service the received frame using the following procedure:

- Read the Control and Status word (mandatory - activates an internal lock for this buffer)
- Read the ID field (optional - needed only if a mask was used)
- Read the Data field
- Read the Free Running Timer (optional - releases the internal lock)

Upon reading the Control and Status word, if the BUSY bit is set in the Code field, then the ARM should defer the access to the message buffer until this bit is negated. Reading the Free Running Timer is not mandatory. If not executed the message buffer remains locked, unless the ARM reads the C/S word of another message buffer. Note that only a single message buffer is locked at a time. The only mandatory ARM read operation is the one on the Control and Status word to assure data coherency (see Table 34-4).

The ARM should synchronize to frame reception by the status flag bit for the specific message buffer in one of the IFLAG Registers and not by the Code field of that message buffer. Polling the Code field does not work because once a frame was received and the ARM services the message buffer (by reading the C/S word followed by unlocking the message buffer), the Code field will not return to EMPTY. It will remain FULL, as explained in Table 34-2 . If the ARM tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the message buffer, the message buffer is actually deactivated from any currently ongoing matching process. As a result, a newly received frame matching the ID of that message buffer may be lost. In summary: never do polling by reading directly the C/S word of the message buffers. Instead, read the IFLAG registers.

Note that the received ID field is always stored in the matching message buffer, thus the contents of the ID field in an message buffer may change if the match was due to masking. Note also that FLEXCAN does receive frames transmitted by itself if there exists an Rx matching message buffer, provided the SRX_DIS bit in the MCR is not

asserted. If SRX_DIS is asserted, FLEXCAN will not store frames transmitted by itself in any message buffer, even if it contains a matching message buffer, and no interrupt flag or interrupt signal will be generated due to the frame reception.

To be able to receive CAN frames through the FIFO, the ARM must enable and configure the FIFO during Freeze Mode (see Freeze Mode). Upon receiving the frames available interrupt from FIFO, the ARM should service the received frame using the following procedure:

- Read the Control and Status word (optional - needed only if a mask was used for IDE and RTR bits)
- Read the ID field (optional - needed only if a mask was used)
- Read the Data field
- Clear the frames available interrupt (mandatory - release the buffer and allow the ARM to read the next FIFO entry)

34.4.5 Matching Process

The matching process is an algorithm executed by the MBM that scans the message buffer memory looking for Rx message buffers programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the 8-entry ID table from FIFO is scanned first and then, if a match is not found within the FIFO table, the other message buffers are scanned. In the event that the FIFO is full, the matching algorithm will always look for a matching message buffer outside the FIFO region.

When the frame is received, it is temporarily stored in a hidden auxiliary message buffer called Serial Message Buffer (SMB). The matching process takes place during the CRC field of the received frame. If a matching ID is found in the FIFO table or in one of the regular message buffers, the contents of the SMB will be transferred to the FIFO or to the matched message buffer during the 6th bit of the End-Of-Frame field of the CAN protocol. This operation is called "move-in". If any protocol error (CRC, ACK, etc.) is detected, than the move-in operation does not happen.

For the regular mailbox message buffers, an message buffer is said to be "free to receive" a new frame if the following conditions are satisfied:

- The message buffer is not locked
- The Code field is either EMPTY or else it is FULL or OVERRUN but the ARM has already serviced the message buffer (read the C/S word and then unlocked the message buffer)

If the first message buffer with a matching ID is not "free to receive" the new frame, then the matching algorithm keeps looking for another free message buffer until it finds one. If it can not find one that is free, then it will overwrite the last matching message buffer (unless it is locked) and set the Code field to OVERRUN (refer to Table 34-4and Table 34-5). If the last matching message buffer is locked, then the new message remains in the SMB, waiting for the message buffer to be unlocked.

Suppose, for example, that the FIFO is disabled and there are two message buffers with the same ID, and FLEXCAN starts receiving messages with that ID. Let us say that these message buffers are the second and the fifth in the array. When the first message arrives, the matching algorithm will find the first match in message buffer number 2. The code of this message buffer is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm will find message buffer number 2 again, but it is not "free to receive" so it will keep looking and find message buffer number 5 and store the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching message buffers that are "free to receive" so it decides to overwrite the last matched message buffer, which is number 5. In doing so, it sets the Code field of the message buffer to indicate OVERRUN.

The ability to match the same ID in more than one message buffer can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the ARM to service the message buffers. By programming more than one message buffer with the same ID, received messages will be queued into the message buffers. The ARM can examine the Time Stamp field of the message buffers to determine the order in which the messages arrived.

The matching algorithm described above can be changed to be the same one used in previous versions of the FLEXCAN. When the BCC bit in MCR is negated, the matching algorithm stops at the first message buffer with a matching ID that it finds, whether this message buffer is free or not. As a result, the message queueing feature does not work if the BCC bit is negated.

Matching to a range of IDs is possible by using ID Acceptance Masks. FLEXCAN supports individual masking per message buffer. During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is "don't care". Please note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed if the BCC bit is asserted and while the block is in Freeze Mode.

FLEXCAN also supports an alternate masking scheme with only three mask registers (RGXMASK, RX14MASK and RX15MASK) for backwards compatibility. This alternate masking scheme is enabled when the BCC bit in the MCR Register is negated.

34.4.6 Data Coherence

In order to maintain data coherency and proper FLEXCAN operation, the ARM software must obey the rules described in Transmit Process and Receive Process when accessing a message buffer structure within the block. Violating these rules may cause FLEXCAN to behave in an unpredictable way.

34.4.6.1 Transmission Abort Mechanism

The abort mechanism provides a safe way to request an abort of a pending transmission. A feedback mechanism is provided to inform the ARM if the transmission was aborted or if the frame could not be aborted and was transmitted instead. In order to maintain backwards compatibility, the abort mechanism must be explicitly enabled by asserting the AEN bit in the MCR.

In order to abort a transmission, the ARM must write a specific abort code (1001) to the Code field of the Control and Status word. When the abort mechanism is enabled, the active message buffers configured as transmission must be aborted first and then they may be updated. If the abort code is written to an message buffer that is currently being transmitted, or to an message buffer that was already loaded into the SMB for transmission, the write operation is blocked and the message buffer is not deactivated, but the abort request is captured and kept pending until one of the following conditions are satisfied:

- The block loses the bus arbitration
- There is an error during the transmission
- The block is put into Freeze Mode

If none of conditions above are reached, the message buffer is transmitted correctly, the interrupt flag is set in the IFLAG register and an interrupt to the ARM is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, if one of the above conditions is reached, the frame is not transmitted, therefore the abort code is written into the Code field, the interrupt flag is set in the IFLAG and an interrupt is (optionally) generated to the ARM.

If the ARM writes the abort code before the transmission begins internally, then the write operation is not blocked, therefore the message buffer is updated and no interrupt flag is set. In this way the ARM just needs to read the abort code to make sure the active message buffer was deactivated. Although the AEN bit is asserted and the ARM wrote

the abort code, in this case the message buffer is deactivated and not aborted, because the transmission did not start yet. One message buffer is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- ARM writes 1001 into the code field of the C/S word
- ARM reads the Code field and compares it to the value that was written
- If the Code field that was read is different from the value that was written, the ARM must read the corresponding IFLAG to check if the frame was transmitted or it is being currently transmitted. If the corresponding IFLAG is set, the frame was transmitted. If the corresponding IFLAG is reset, the ARM must wait for it to be set, and then the ARM must read the Code field to check if the message buffer was aborted (CODE=1001) or it was transmitted (CODE=1000).

34.4.6.2 Message Buffer Deactivation

Deactivation is a mechanism provided to maintain data coherence when the ARM writes to the Control and Status word of active message buffers out of Freeze Mode. Any ARM write access to the Control and Status word of an message buffer causes that message buffer to be excluded from the transmit or receive processes during the current matching or arbitration round. The deactivation is temporary, affecting only for the current match/arbitration round.

The purpose of deactivation is data coherency. The match/arbitration process scans the message buffers to decide which message buffer to transmit or receive. If the ARM updates the message buffer in the middle of a match or arbitration process, the data of that message buffer may no longer be coherent, therefore deactivation of that message buffer is done.

Even with the coherence mechanism described above, writing to the Control and Status word of active message buffers when not in Freeze Mode may produce undesirable results. Examples are:

- Matching and arbitration are one-pass processes. If message buffers are deactivated after they are scanned, no re-evaluation is done to determine a new match/winner. If an Rx message buffer with a matching ID is deactivated during the matching process after it was scanned, then this message buffer is marked as invalid to receive the frame, and FLEXCAN will keep looking for another matching message buffer within the ones it has not scanned yet. If it can not find one, then the message will be lost. Suppose, for example, that two message buffers have a matching ID to a received frame, and the user deactivated the first matching message buffer after FLEXCAN

has scanned the second. The received frame will be lost even if the second matching message buffer was "free to receive".

- If a Tx message buffer containing the lowest ID is deactivated after FLEXCAN has scanned it, then FLEXCAN will look for another winner within the message buffers that it has not scanned yet. Therefore, it may transmit an message buffer with ID that may not be the lowest at the time because a lower ID might be present in one of the message buffers that it had already scanned before the deactivation.
- There is a point in time until which the deactivation of a Tx message buffer causes it not to be transmitted (end of move-out). After this point, it is transmitted but no interrupt is issued and the Code field is not updated. In order to avoid this situation, the abort procedures described in should be used.

34.4.6.3 Message Buffer Lock Mechanism

Besides message buffer deactivation, FLEXCAN has another data coherence mechanism for the receive process. When the ARM reads the Control and Status word of an "active not empty" Rx message buffer, FLEXCAN assumes that the ARM wants to read the whole message buffer in an atomic operation, and thus it sets an internal lock flag for that message buffer. The lock is released when the ARM reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another message buffer. The message buffer locking is done to prevent a new frame to be written into the message buffer while the ARM is reading it.

NOTE

The locking mechanism only applies to Rx message buffers which have a code different than INACTIVE (0000) or EMPTY[2] (0100). Also, Tx message buffers can not be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth message buffers of the array are programmed with the same ID, and FLEXCAN has already received and stored messages into these two message buffers. Suppose now that the ARM decides to read message buffer number 5 and at the same time another message with the same ID is arriving. When the ARM reads the Control and Status word of message buffer number 5, this message buffer is locked. The new message arrives and the matching algorithm finds out that there are no "free to receive" message buffers, so it decides to override message buffer number 5. However, this message buffer is locked, so the new message can not be written there. It will remain in the SMB waiting for the message buffer to be unlocked, and only then will be written to the message buffer. If the message buffer is not unlocked in time and yet another new message with the same ID arrives,

2. In previous FLEXCAN versions, reading the C/S word locked the message buffer even if it was EMPTY. This behavior will be honoured when the BCC bit is ne

then the new message overwrites the one on the SMB and there will be no indication of lost messages either in the Code field of the message buffer or in the Error and Status Register.

While the message is being moved-in from the SMB to the message buffer, the BUSY bit on the Code field is asserted. If the ARM reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the message buffer until the BUSY bit is negated.

NOTE

If the BUSY bit is asserted or if the message buffer is empty, then reading the Control and Status word does not lock the message buffer.

Deactivation takes precedence over locking. If the ARM deactivates a locked Rx message buffer, then its lock status is negated and the message buffer is marked as invalid for the current matching round. Any pending message on the SMB will not be transferred anymore to the message buffer.

34.4.7 Rx FIFO

The receive-only FIFO is enabled by asserting the FEN bit in the MCR. The reset value of this bit is zero to maintain software backwards compatibility with previous versions of the block that did not have the FIFO feature. When the FIFO is enabled, the memory region normally occupied by the first 8 Message Buffers (0x80-0xFF) is now reserved for use of the FIFO engine. Management of read and write pointers is done internally by the FIFO engine. The ARM can read the received frames sequentially, in the order they were received, by repeatedly accessing a Message Buffer structure at the beginning of the memory.

The FIFO can store up to 6 frames pending service by the ARM. An interrupt is sent to the ARM when new frames are available in the FIFO. Upon receiving the interrupt, the ARM must read the frame (accessing an message buffer in the 0x80 address) and then clear the interrupt. The act of clearing the interrupt triggers the FIFO engine to replace the message buffer in 0x80 with the next frame in the queue, and then issue another interrupt to the ARM. If the FIFO is full and more frames continue to be received, an OVERFLOW interrupt is issued to the ARM and subsequent frames are not accepted until the ARM creates space in the FIFO by reading one or more frames. A warning interrupt is also generated when 4frames are accumulated in the FIFO.

A powerful filtering scheme is provided to accept only frames intended for the target application, thus reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of 8 32-bit registers that can be configured to one of the following formats:

- Format A: 8 extended or standard IDs (including IDE and RTR)
- Format B: 16 standard IDs or 16 extended 14-bit ID slices (including IDE and RTR)
- Format C: 32 standard or extended 8-bit ID slices

NOTE

A chosen format is applied to all 8 registers of the filter table. It is not possible to mix formats within the table.

The eight elements of the filter table are individually affected by the first eight Individual Mask Registers (RXIMR0 - RXIMR7), allowing very powerful filtering criteria to be defined. The rest of the RXIMR, starting from RXIM8, continue to affect the regular message buffers, starting from MB8. If the BCC bit is negated, then the FIFO filter table is affected by the legacy mask registers as follows: element 6 is affected by RX14MASK, element 7 is affected by RX15MASK and the other elements (0 to 5) are affected by RXGMASK.

34.4.8 CAN Protocol Related Features

34.4.8.1 Overload Frames

FLEXCAN does transmit overload frames due to detection of the following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

34.4.8.2 Time Stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

Note that the Free Running Timer can be reset upon a specific frame reception, enabling network time synchronization. Refer to TSYN description in Control Register (FLEXCAN_CTRL).

34.4.8.3 Protocol Timing

The FLEXCAN supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control Register has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW. See Control Register (FLEXCAN_CTRL) .

The PRESDIV field controls a prescaler that generates the Serial Clock (Sclock), whose period defines the "time quantum" used to compose the CAN waveform. A time quantum is the atomic unit of time handled by the CAN engine.

$$f_{Tq} = \frac{f_{CANCLK}}{(Prescaler\ \ value)}$$

A bit time is subdivided into three segments[3]

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section
- Time Segment 1: This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CTRL Register so that their sum (plus 2) is in the range of 4 to 16 time quanta
- Time Segment 2: This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CTRL Register (plus 1) to be 2 to 8 time quanta long

$$Bit\ \ Rate = \frac{f_{Tq}}{(number\ \ of\ \ Time\ \ Quanta)}$$

3. For further explanation of the underlying concepts please refer to ISO/DIS 11519-1, Section 10.3. Reference also the Bosch CAN 2.0A/B protocol specification dated September 1991 for bit timing.

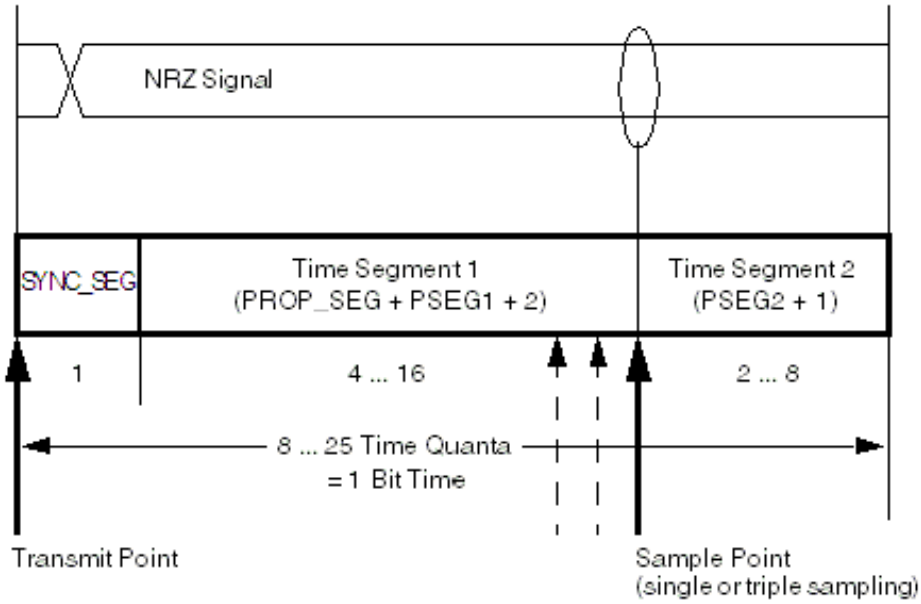

Figure 34-2. Segments within the Bit Time

Table 34-8. Time Segment Syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

Table 34-9 gives an overview of the CAN compliant segment settings and the related parameter values.

Table 34-9. CAN Standard Compliant Bit Time Segment Settings

Time Segment 1	Time Segment 2	Re-synchronization Jump Width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

NOTE

It is the user's responsibility to ensure the bit time settings are in compliance with the CAN standard. For bit time calculations,

use an IPT (Information Processing Time) of 2, which is the value implemented in the FLEXCAN block.

34.4.8.4 Arbitration and Matching Timing

During normal transmission or reception of frames, the arbitration, matching, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in Figure 34-3.

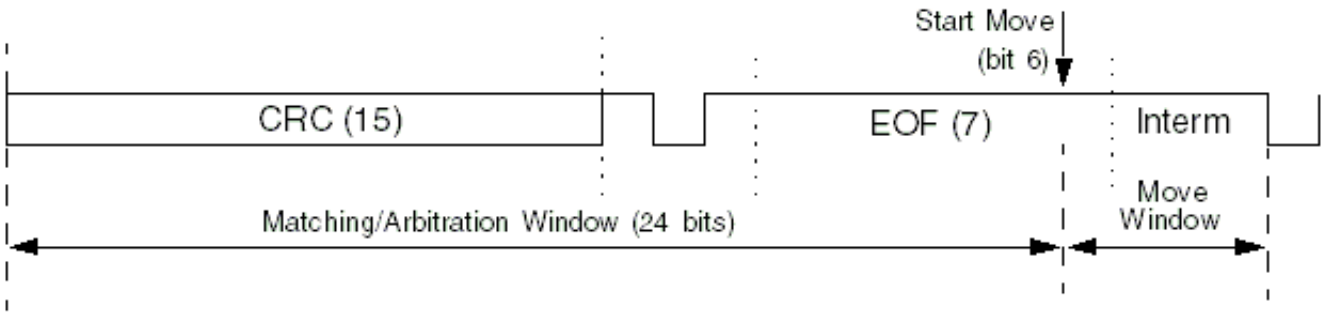

Figure 34-3. Arbitration, Match and Move Time Windows

When doing matching and arbitration, FLEXCAN needs to scan the whole Message Buffer memory during the available time slot. In order to have sufficient time to do that, the following requirements must be observed:

- A valid CAN bit timing must be programmed, as indicated in Table 34-9
- The peripheral clock frequency can not be smaller than the oscillator clock frequency, that is, the PLL can not be programmed to divide down the oscillator clock
- There must be a minimum ratio between the peripheral clock frequency and the CAN bit rate, as specified in Table 34-10.

Table 34-10. Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate

Number of Message Buffers	Minimum Ratio
16	8
32	8
64	16

A direct consequence of the first requirement is that the minimum number of time quanta per CAN bit must be 8, so the oscillator clock frequency should be at least 8 times the CAN bit rate. The minimum frequency ratio specified in Table 34-10. can be achieved by choosing a high enough peripheral clock frequency when compared to the oscillator clock

frequency, or by adjusting one or more of the bit timing parameters (PRESDIV, PROPSEG, PSEG1, PSEG2). As an example, taking the case of 64 Mbytes, if the oscillator and peripheral clock frequencies are equal and the CAN bit timing is programmed to have 8 time quanta per bit, then the prescaler factor (PRESDIV + 1) should be at least 2. For prescaler factor equal to one and CAN bit timing with 8 time quanta per bit, the ratio between peripheral and oscillator clock frequencies should be at least 2.

34.4.9 Modes of Operation Details

34.4.9.1 Freeze Mode

This mode is entered by asserting the HALT bit in the MCR Register or when the ARM platform is put into Debug Mode. In both cases it is also necessary that the FRZ bit is asserted in the MCR Register and the block is not in any of the low power modes (Disable, Stop). When Freeze Mode is requested during transmission or reception, FLEXCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off or Idle state
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish
- Ignores the Rx input pin and drives the Tx pin as recessive
- Stops the prescaler, thus halting all CAN protocol activities
- Grants write access to the Error Counters Register, which is read-only in other modes
- Sets the NOT_RDY and FRZ_ACK bits in MCR

After requesting Freeze Mode, the user must wait for the FRZ_ACK bit to be asserted in MCR before executing any other action, otherwise FLEXCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible.

Exiting Freeze Mode is done in one of the following ways:

- ARM negates the FRZ bit in the MCR Register
- The ARM platform is removed from Debug Mode and/or the HALT bit is negated

Once out of Freeze Mode, FLEXCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

34.4.9.2 Block Disable Mode

This low power mode is entered when the MDIS bit in the MCR Register is asserted. If the block is disabled during Freeze Mode, it shuts down the clocks to the CPI and MBM sub-blocks, sets the LPM_ACK bit and negates the FRZ_ACK bit. If the block is disabled during transmission or reception, FLEXCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish
- Ignores its Rx input pin and drives its Tx pin as recessive
- Shuts down the clocks to the CPI and MBM sub-blocks
- Sets the NOT_RDY and LPM_ACK bits in MCR

The Bus Interface Unit continues to operate, enabling the ARM to access memory mapped registers, except the Free Running Timer, the Error Counter Register and the Message Buffers, which cannot be accessed when the block is in Disable Mode. Exiting from this mode is done by negating the MDIS bit, which will resume the clocks and negate the LPM_ACK bit.

34.4.9.3 Stop Mode

This is a system low power mode in which all ARM platform clocks are stopped for maximum power savings. If FLEXCAN receives the global Stop Mode request during Freeze Mode, it sets the LPM_ACK bit, negates the FRZ_ACK bit and then sends a Stop Acknowledge signal to the ARM, in order to shut down the clocks globally. If Stop Mode is requested during transmission or reception, FLEXCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish
- Ignores its Rx input pin and drives its Tx pin as recessive
- Sets the NOT_RDY and LPM_ACK bits in MCR
- Sends a Stop Acknowledge signal to the ARM, so that it can shut down the clocks globally

Exiting Stop Mode is done in one of the following ways:

- ARM resuming the clocks and removing the Stop Mode request
- ARM resuming the clocks and Stop Mode request as a result of the Self Wake mechanism

In the Self Wake mechanism, if the SLF_WAK bit in MCR Register was set at the time FLEXCAN entered Stop Mode, then upon detection of a recessive to dominant transition on the CAN bus, FLEXCAN sets the WAK_INT bit in the ESR Register and, if enabled by the WAK_MSK bit in MCR, generates a Wake Up interrupt to the ARM. Upon receiving the interrupt, the ARM should resume the clocks and remove the Stop Mode request. FLEXCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up. Table 34-11 details the effect of SLF_WAK and WAK_MSK upon wake-up from Stop Mode. Note that wake-up from Stop Mode only works when both bits are asserted.

Table 34-11. Wake-up from Stop Mode

SLF_WAK	WAK_MSK	ARM Platform Clocks Enabled	Wake-up Interrupt Generated
0	0	No	No
0	1	No	No
1	0	No	No
1	1	Yes	Yes

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the Rx CAN input line while in Stop Mode. See the WAK_SRC bit in. This feature can be used to protect FLEXCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

34.4.10 Interrupts

The block can generate 70 interrupt sources (64 interrupts due to message buffers and 6 interrupts due to ORed interrupts from message buffers, Bus Off, Error, Tx Warning, Rx Warning and Wake Up).

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has assigned a flag bit in the IFLAG Registers. The bit is set when the corresponding buffer completes a successful transmission/reception and is cleared when the ARM writes it to '1' (unless another interrupt is generated at the same time).

NOTE

It must be guaranteed that the ARM only clears the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags.

These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (bit FEN on MCR set), the interrupts corresponding to message buffers 0 to 7 have a different behavior. Bit 7 of the IFLAG1 becomes the "FIFO Overflow" flag; bit 6 becomes the FIFO Warning flag, bit 5 becomes the "Frames Available in FIFO flag" and bits 4-0 are unused. See Control Register (FLEXCAN_CTRL).

A combined interrupt for all message buffers is generated by an Or of all the interrupt sources from message buffers. This interrupt gets generated when any of the message buffers generates an interrupt. In this case the ARM must read the IFLAG Registers to determine which message buffer caused the interrupt.

The other 5 interrupt sources (Bus Off, Error, Tx Warning, Rx Warning and Wake Up) generate interrupts like the message buffer ones, and can be read from the Error and Status Register. The Bus Off, Error, Tx Warning and Rx Warning interrupt mask bits are located in the Control Register, and the Wake-Up interrupt mask bit is located in the MCR.

34.5 Initialization/Application Information

This section provides instructions for initializing the FLEXCAN.

34.5.1 FLEXCAN Initialization Sequence

The FLEXCAN may be reset in two ways:

- ARM platform level hard reset which resets all memory mapped registers asynchronously
- SOFT_RST bit in MCR, which resets some of the memory mapped registers synchronously (refer to the Memory Map table to see what registers are affected by soft reset)

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The SOFT_RST bit remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in any of the low power modes. The low power mode should be exited and the clocks resumed before applying soft reset.

The clock source (CLK_SRC bit) should be selected while the block is in Disable Mode. After the clock source is selected and the block is enabled (MDIS bit negated), FLEXCAN automatically goes to Freeze Mode. In Freeze Mode, FLEXCAN is un-synchronized to the CAN bus, the HALT and FRZ bits in MCR Register are set, the internal state machines are disabled and the FRZ_ACK and NOT_RDY bits in the MCR Register are set. The Tx pin is in recessive state and FLEXCAN does not initiate any transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FLEXCAN is put into Freeze Mode (see). The following is a generic initialization sequence applicable to the FLEXCAN:

- Initialize the Module Configuration Register
  - Enable the individual filtering per message buffer and reception queue features by setting the BCC bit
  - Enable the warning interrupts by setting the WRN_EN bit
  - If required, disable frame self reception by setting the SRX_DIS bit
  - Enable the FIFO by setting the FEN bit
  - Enable the abort mechanism by setting the AEN bit
  - Enable the local priority feature by setting the LPRIO_EN bit
- Initialize the Control Register
  - Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW
  - Determine the bit rate by programming the PRESDIV field
  - Determine the internal arbitration mode (LBUF bit)
- Initialize the Message Buffers
  - The Control and Status word of all Message Buffers must be initialized
  - If FIFO was enabled, the 8-entry ID table must be initialized
  - Other entries in each Message Buffer should be initialized as required
- Initialize the Rx Individual Mask Registers
- Set required interrupt mask bits in the IMASK Registers (for all message buffer interrupts), in CTRL Register (for Bus Off and Error interrupts) and in MCR Register for Wake-Up interrupt
- Negate the HALT bit in MCR

Starting with the last event, FLEXCAN attempts to synchronize to the CAN bus.

34.6 Programmable Registers

This section describes the registers and data structures in the FLEXCAN. The base address of the FLEXCAN-1 is 0x53FE_8000, the base of the FLEXCAN-2 is 0x53FE_C000. The addresses presented here are relative to the base address.

The address space occupied by FLEXCAN has 96 bytes for registers starting at the block base address, followed by message buffer storage space in embedded RAM starting at address 0x080, and an extra ID Mask storage space in a separate embedded RAM starting at address 0x880.

The complete memory map for a FLEXCAN with 64 Mbytes capability is shown below. Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming the SUPV bit in the MCR Register. These registers are identified as S/U in the Access column shown below.

The Rx Global Mask (RXGMASK), Rx Buffer 14 Mask (RX14MASK) and the Rx Buffer 15 Mask (RX15MASK) registers are provided for backwards compatibility, and are not used when the BCC bit in MCR is asserted.

The address ranges 0x080, 0x47F and 0x880, 0x97F are occupied by two separate embedded memories. These two ranges are completely occupied by RAM (1056 and 256 bytes, respectively).

34.6.1 Module Configuration Register (FLEXCANx_MCR)

This register defines global system configurations, such as the block operation mode (low power, for example) and maximum message buffer configuration. Most of the fields in this register can be accessed at any time, except the MAXMB field, which should only be changed while the block is in Freeze Mode.

Addresses: FLEXCAN-1_MCR is 53FC_8000h base + 0h offset = 53FC_8000h

FLEXCAN-2_MCR is 53FC_C000h base + 0h offset = 53FC_C000h

FLEXCANx_MCR field descriptions

Field	Description
31 MDIS	This bit controls whether FLEXCAN is enabled or not. When disabled, FLEXCAN shuts down the clocks to the CAN Protocol Interface and Message Buffer Management sub-blocks. This is the only bit in MCR not affected by soft reset. 1 Disable the FLEXCAN block 0 Enable the FLEXCAN block
30 FRZ	The FRZ bit specifies the FLEXCAN behavior when the HALT bit in the MCR Register is set or when Debug Mode is requested at ARM platform level. When FRZ is asserted, FLEXCAN is enabled to enter Freeze Mode. Negation of this bit field causes FLEXCAN to exit from Freeze Mode. 1 Enabled to enter Freeze Mode 0 Not enabled to enter Freeze Mode

Table continues on the next page...

FLEXCANx_MCR field descriptions (continued)

Field	Description
29 FEN	This bit controls whether the FIFO feature is enabled or not. When FEN is set, message buffers 0 to 7 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xFF) is used by the FIFO engine. 1 FIFO enabled 0 FIFO not enabled
28 HALT	Assertion of this bit puts the FLEXCAN block into Freeze Mode. The ARM should clear it after initializing the Message Buffers and Control Register. No reception or transmission is performed by FLEXCAN before this bit is cleared. While in Freeze Mode, the ARM has write access to the Error Counter Register, that is otherwise read-only. Freeze Mode can not be entered while FLEXCAN is in any of the low power modes. 1 Enters Freeze Mode if the FRZ bit is asserted. 0 No Freeze Mode request.
27 NOT_RDY	This read-only bit indicates that FLEXCAN is either in Disable Mode, Stop Mode or Freeze Mode. It is negated once FLEXCAN has exited these modes. 1 FLEXCAN block is either in Disable Mode, Stop Mode or Freeze Mode 0 FLEXCAN block is either in Normal Mode, Listen-Only Mode or Loop-Back Mode
26 WAK_MSK	This bit enables the Wake Up Interrupt generation. 1 Wake Up Interrupt is enabled 0 Wake Up Interrupt is disabled
25 SOFT_RST	When this bit is asserted, FLEXCAN resets its internal state machines and some of the memory mapped registers. The following registers are reset: MCR (except the MDIS bit), TIMER, ECR, ESR, IMASK1, IMASK2, IFLAG1, IFLAG2. Configuration registers that control the interface to the CAN bus are not affected by soft reset. The following registers are unaffected: CTRL RXIMR0,RXIMR63 RXGMASK, RX14MASK, RX15MASK all Message Buffers The SOFT_RST bit can be asserted directly by the ARM when it writes to the MCR Register. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFT_RST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. Soft reset cannot be applied while clocks are shut down in any of the low power modes. The block should be first removed from low power mode, and then soft reset can be applied. 1 Resets the registers marked as affected by soft reset shown in the memory map 0 No reset request
24 FRZ_ACK	This read-only bit indicates that FLEXCAN is in Freeze Mode and its prescaler is stopped. The Freeze Mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZ_ACK bit to know when FLEXCAN has actually entered Freeze Mode. If Freeze Mode request is negated, then this bit is negated once the FLEXCAN prescaler is running again. If Freeze Mode is requested while FLEXCAN is in any of the low power modes, then the FRZ_ACK bit will only be set when the low power mode is exited.

Table continues on the next page...

FLEXCANx_MCR field descriptions (continued)

Field	Description
	1 FLEXCAN in Freeze Mode, prescaler stopped 0 FLEXCAN not in Freeze Mode, prescaler running
23 SUPV	This bit configures some of the FLEXCAN registers to be either in Supervisor or Unrestricted memory space. The registers affected by this bit are marked as S/U in the Access Type column of the Memory Map. Reset value of this bit is 1, so the affected registers start with Supervisor access restrictions. 1 Affected registers are in Supervisor memory space. Any access without supervisor permission behaves as though the access was done to an unimplemented register location 0 Affected registers are in Unrestricted memory space
22 SLF_WAK	This bit enables the Self Wake Up feature when FLEXCAN is in Stop Mode. If this bit had been asserted by the time FLEXCAN entered Stop Mode, then FLEXCAN will look for a recessive to dominant transition on the bus during these modes. If a transition from recessive to dominant is detected during Stop Mode, then FLEXCAN generates, if enabled to do so, a Wake Up interrupt to the ARM so that it can resume the clocks globally. This bit can not be written while the block is in Stop Mode. 1 FLEXCAN Self Wake Up feature is enabled 0 FLEXCAN Self Wake Up feature is disabled
21 WRN_EN	When asserted, this bit enables the generation of the TWRN_INT and RWRN_INT flags in the Error and Status Register. If WRN_EN is negated, the TWRN_INT and RWRN_INT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. 1 TWRN_INT and RWRN_INT bits are set when the respective error counter transition from <96 to ℜ≥ 96. 0 TWRN_INT and RWRN_INT bits are zero, independent of the values in the error counters.
20 LPM_ACK	This read-only bit indicates that FLEXCAN is either in Disable Mode and Stop Mode. Either of these low power modes can not be entered until all current transmission or reception processes have finished, so the ARM can poll the LPM_ACK bit to know when FLEXCAN has actually entered low power mode. 1 FLEXCAN is either in Disable Mode, or Stop mode 0 FLEXCAN not in any of the low power modes
19 WAK_SRC	This bit defines whether the integrated low-pass filter is applied to protect the Rx CAN input. 1 FLEXCAN us
18 DOZE	This bit defines whether FLEXCAN is allowed to enter low power mode when Doze Mode is requested at ARM platform level. This bit is automatically reset when FLEXCAN wakes up from Doze Mode upon detecting activity on the CAN bus (self wake-up enabled). Doze Mode is not supported in i.MX53 1 FLEXCAN is enabled to enter low power mode when Doze Mode is requested 0 FLEXCAN is not enabled to enter low power mode when Doze Mode is requested
17 SRX_DIS	This bit defines whether FLEXCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the block will not be stored in any message buffers, regardless if the message buffers is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. 1 Self reception disabled 0 Self reception enabled
16 BCC	This bit is provided to support Backwards Compatibility with previous FLEXCAN versions. When this bit is negated, the following configuration is applied:

Table continues on the next page...

FLEXCANx_MCR field descriptions (continued)

Field	Description
	For ARM platforms supporting individual Rx ID masking, this feature is disabled. Instead of individual ID masking per message buffer, FLEXCAN uses its previous masking scheme with RXGMASK, RX14MASK and RX15MASK. The reception queue feature is disabled. Upon receiving a message, if the first message buffer with a matching ID that is found is still occupied by a previous unread message, FLEXCAN will not look for another matching message buffer. It will override this message buffer with the new message and set the CODE field to 0110 (overrun). Upon reset this bit is negated, allowing legacy software to work without modification. 1 Individual Rx masking and queue feature are enabled. 0 Individual Rx masking and queue feature are disabled.
15–14 -	Reserved
13 LPRIO_EN	This bit is provided for backwards compatibility reasons. It controls whether the local priority feature is enabled or not. It is used to extend the ID used during the arbitration process. With this extended ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. 1 Local Priority enabled 0 Local Priority disabled
12 AEN	This bit is supplied for backwards compatibility reasons. When asserted, it enables the Tx abort feature. This feature guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. 1 Abort enabled 0 Abort disabled
11–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–8 IDAM	This 2-bit field identifies the format of the elements of the Rx FIFO filter table, as shown below. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Rx FIFO Structure. 00 Format A One full ID (standard or extended) per filter element. 01 Format B Two full standard IDs or two partial 14-bit extended IDs per filter element 10 Format C Four partial 8-bit IDs (standard or extended) per filter element. 11 Format D All frames rejected.
7–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5–0 MAXMB	This 6-bit field defines the maximum number of message buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to 16 Mbyte configuration. This field should be changed only while the block is in Freeze Mode. Maximum message buffers in use = MAXMB + 1. MAXMB has to be programmed with a value smaller or equal to the number of available Message Buffers, otherwise FLEXCAN will not transmit or receive frames.

34.6.2 Control Register (FLEXCANx_CTRL)

This register is defined for specific FLEXCAN control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, Loop Back Mode, Listen Only Mode, Bus Off recovery behavior and interrupt enabling (Bus-Off, Error, Warning). It also determines the Division Factor for the clock prescaler. Most of the fields in this register should only be changed while the block is in Disable Mode or in Freeze Mode. Exceptions are the BOFF_MSK, ERR_MSK, TWRN_MSK, RWRN_MSK and BOFF_REC bits, that can be accessed at any time.

Addresses: FLEXCAN-1_CTRL is 53FC_8000h base + 4h offset = 53FC_8004h

FLEXCAN-2_CTRL is 53FC_C000h base + 4h offset = 53FC_C004h

FLEXCANx_CTRL field descriptions

Field	Description
31–24 PRESDIV	This 8-bit field defines the ratio between the CPI clock frequency and the Serial Clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the CPI clock frequency. The Maximum value of this register is 0xFF, that gives a minimum Sclock frequency equal to the CPI clock frequency divided by 256. For more information refer to Protocol Timing. Sclock frequency = CPI clock frequency / (PRESDIV + 1)
23–22 RJW	This 2-bit field defines the maximum number of time quanta[1] that a bit time can be changed by one re-synchronization. The valid programmable values are 0,3. Resync Jump Width = RJW + 1.
21–19 PSEG1	This 3-bit field defines the length of Phase Buffer Segment 1 in the bit time. The valid programmable values are 0,7. Phase Buffer Segment 1 = (PSEG1 + 1) x Time-Quanta.
18–16 PSEG2	This 3-bit field defines the length of Phase Buffer Segment 2 in the bit time. The valid programmable values are 1,7. Phase Buffer Segment 2 = (PSEG2 + 1) x Time-Quanta.

Table continues on the next page...

FLEXCANx_CTRL field descriptions (continued)

Field	Description
15 BOFF_MSK	This bit provides a mask for the Bus Off Interrupt. 1 Bus Off interrupt enabled 0 Bus Off interrupt disabled
14 ERR_MSK	This bit provides a mask for the Error Interrupt. 1 Error interrupt enabled 0 Error interrupt disabled
13 -	Reserved 1 The CAN engine clock source is the bus clock, 66.5MHz 0 The CAN engine clock source is the oscillator clock, 24.576MHz
12 LPB	This bit configures FLEXCAN to operate in Loop-Back Mode. In this mode, FLEXCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FLEXCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FLEXCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. 1 Loop Back enabled 0 Loop Back disabled
11 TWRN_MSK	This bit provides a mask for the Tx Warning Interrupt associated with the TWRN_INT flag in the Error and Status Register. This bit has no effect if the WRN_EN bit in MCR is negated and it is read as zero when WRN_EN is negated. 1 Tx Warning Interrupt enabled 0 Tx Warning Interrupt disabled
10 RWRN_MSK	This bit provides a mask for the Rx Warning Interrupt associated with the RWRN_INT flag in the Error and Status Register. This bit has no effect if the WRN_EN bit in MCR is negated and it is read as zero when WRN_EN is negated. 1 Rx Warning Interrupt enabled 0 Rx Warning Interrupt disabled
9–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 SMP	This bit defines the sampling mode of CAN bits at the Rx input. 1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples, a majority rule is used 0 Just one sample is used to determine the bit value
6 BOFF_REC	This bit defines how FLEXCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the block remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFF_REC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FLEXCAN will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFF_REC bit can be re-asserted again during Bus Off, but it will only be effective the next time the block enters Bus Off. If BOFF_REC was

FLEXCANx_CTRL field descriptions (continued)

Field	Description
	negated when the block entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery. 1 Automatic recovering from Bus Off state disabled 0 Automatic recovering from Bus Off state enabled, according to CAN Spec 2.0 part B
5 TSYN	This bit enables a mechanism that resets the free-running timer each time a message is received in Message Buffer 0. This feature provides a means to synchronize multiple FLEXCAN stations with a special SYNC message (for example, global network time). If the FEN bit in MCR is set (FIFO enabled), MB8 is used for timer synchronization instead of MB0. 1 Timer Sync feature enabled 0 Timer Sync feature disabled
4 LBUF	This bit defines the ordering mechanism for Message Buffer transmission. When asserted, the LPRIO_EN bit does not affect the priority arbitration. 1 Lowest number buffer is transmitted first 0 Buffer with highest priority is transmitted first
3 LOM	This bit configures FLEXCAN to operate in Listen Only Mode. In this mode, transmission is disabled, all error counters are frozen and the block operates in a CAN Error Passive mode [Ref. 1]. Only messages acknowledged by another CAN station will be received. If FLEXCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message. 1 FLEXCAN block operates in Listen Only Mode 0 Listen Only Mode is deactivated
2–0 PROP_SEG	This 3-bit field defines the length of the Propagation Segment in the bit time. The valid programmable values are 0,7. Propagation Segment Time = (PROPSEG + 1) * Time-Quanta. Time-Quantum = one Sclock period.

1. One time quantum is equal to the Sclock period.

34.6.3 Free Running Timer (FLEXCANx_TIMER)

This register represents a 16-bit free running counter that can be read and written by the ARM. The timer starts from 0x0000 after Reset, counts linearly to 0xFFFF, and wraps around.

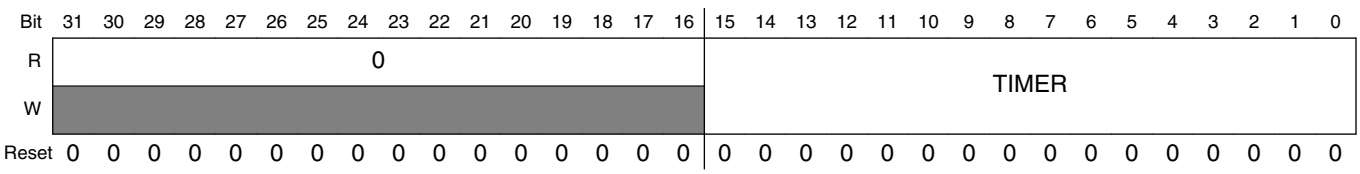
The timer is clocked by the FLEXCAN bit-clock (which defines the baud rate on the CAN bus). During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. During Freeze Mode, the timer is not incremented.

The timer value is captured at the beginning of the identifier field of any frame on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

Writing to the timer is an indirect operation. The data is first written to an auxiliary register and then an internal request/acknowledge procedure across clock domains is executed. All this is transparent to the user, except for the fact that the data will take some time to be actually written to the register. If desired, software can poll the register to discover when the data was actually written.

Addresses: FLEXCAN-1_TIMER is 53FC_8000h base + 8h offset = 53FC_8008h

FLEXCAN-2_TIMER is 53FC_C000h base + 8h offset = 53FC_C008h



FLEXCANx_TIMER field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. This read-only bitfield is reserved and always has the value zero.
15–0 TIMER	Timer value Contains the free-running counter value.

34.6.4 Rx Global Mask (FLEXCANx_RXGMASK)

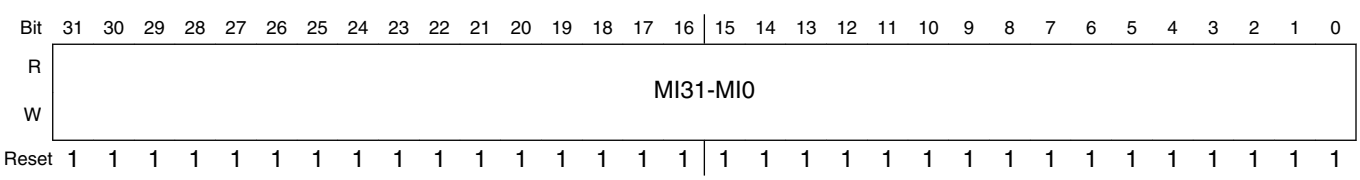
Supports individual masks per message buffer, setting the BCC bit in MCR causes the RXGMASK Register to have no effect on the block operation.

RXGMASK is used as acceptance mask for all Rx message buffers, excluding message buffers 14, 15, which have individual mask registers. When the FEN bit in MCR is set (FIFO enabled), the RXGMASK also applies to all elements of the ID filter table, except elements 6-7, which have individual masks.

The contents of this register must be programmed while the block is in Freeze Mode, and must not be modified when the block is transmitting or receiving frames.

Addresses: FLEXCAN-1_RXGMASK is 53FC_8000h base + 10h offset = 53FC_8010h

FLEXCAN-2_RXGMASK is 53FC_C000h base + 10h offset = 53FC_C010h



FLEXCANx_RXGMASK field descriptions

Field	Description
31–0 MI31-MI0	For normal Rx message buffers, the mask bits affect the ID filter programmed on the message buffer. For the Rx FIFO, the mask bits affect all bits programmed in the filter table (ID, IDE, RTR). 1 The corresponding bit in the filter is checked against the one received 0 the corresponding bit in the filter is dont care

34.6.5 Rx 14 Mask (FLEXCANx_RX14MASK)

Setting the BCC bit in MCR causes the RX14MASK Register to have no effect on the block operation.

RX14MASK is used as acceptance mask for the Identifier in Message Buffer 14. When the FEN bit in MCR is set (FIFO enabled), the RXG14MASK also applies to element 6 of the ID filter table. This register has the same structure as the Rx Global Mask Register. It must be programmed while the block is in Freeze Mode, and must not be modified when the block is transmitting or receiving frames.

- Address Offset: 0x14
- Reset Value: 0xFFFF_FFFF

Addresses: FLEXCAN-1_RX14MASK is 53FC_8000h base + 14h offset = 53FC_8014h
FLEXCAN-2_RX14MASK is 53FC_C000h base + 14h offset = 53FC_C014h

Field	Description
31–0 MI31-MI0	Acceptance mask for the Identifier in Message Buffer 14

34.6.6 Rx 15 Mask (FLEXCANx_RX15MASK)

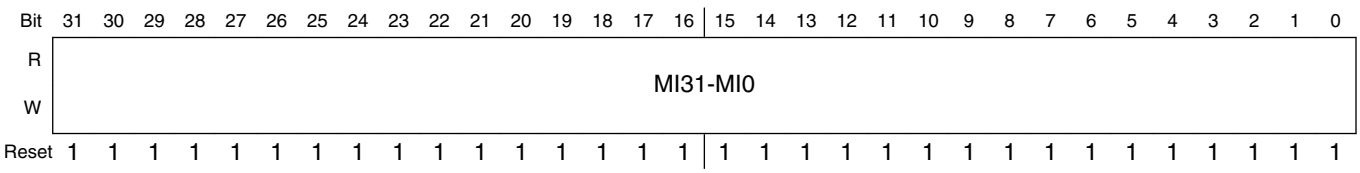
Setting the BCC bit in MCR causes the RX15MASK Register to have no effect on the block operation.

When the BCC bit is negated, RX15MASK is used as acceptance mask for the Identifier in Message Buffer 15. When the FEN bit in MCR is set (FIFO enabled), the RXG14MASK also applies to element 7 of the ID filter table. This reg

structure as the Rx Global Mask Register. It must be programmed while the block is in Freeze Mode, and must not be modified when the block is transmitting or receiving frames.

- Address Offset: 0x18
- Reset Value: 0xFFFF_FFFF

Addresses: FLEXCAN-1_RX15MASK is 53FC_8000h base + 18h offset = 53FC_8018h
FLEXCAN-2_RX15MASK is 53FC_C000h base + 18h offset = 53FC_C018h



FLEXCANx_RX15MASK field descriptions

Field	Description
31–0 MI31-MI0	Acceptance mask for the Identifier in Message Buffer 15

34.6.7 Error Counter Register (FLEXCANx_ECR)

This register has 2 8-bit fields reflecting the value of two FLEXCAN error counters: Transmit Error Counter (Tx_Err_Counter field) and Receive Error Counter (Rx_Err_Counter field). The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FLEXCAN block. Both counters are read only except in Freeze Mode, where they can be written by the ARM.

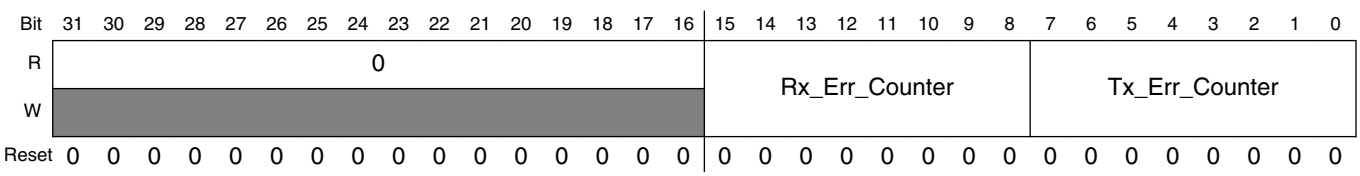
Writing to the Error Counter Register while in Freeze Mode is an indirect operation. The data is first written to an auxiliary register and then an internal request/acknowledge procedure across clock domains is executed. All this is transparent to the user, except for the fact that the data will take some time to be actually written to the register. If desired, software can poll the register to discover when the data was actually written.

FLEXCAN responds to any bus state as described in the protocolthat is transmit Error Active or Error Passive flag, delay its transmission start time (Error Passive) and avoid any influence on the bus when in , Bus Off state. The following are the basic rules for FLEXCAN bus state transitions.

- If the value of Tx_Err_Counter or Rx_Err_Counter increases to be greater than or equal to 128, the FLT_CONF field in the Error and Status Register is updated to reflect Error Passive state.

- If the FLEXCAN state is Error Passive and either Tx_Err_Counter or Rx_Err_Counter decrements to a value less than or equal to 127. While the other already satisfies this condition, the FLT_CONF field in the Error and Status Register is updated to reflect ErrorError Active state.
- If the value of Tx_Err_Counter increases to be greater than 255, the FLT_CONF field in the Error and Status Register is updated to reflect Bus Off state and an interrupt may be issued. The value of Tx_Err_Counter is then reset to zero.
- If FLEXCAN is in Bus Off state then Tx_Err_Counter is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, Tx_Err_Counter is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the Tx_Err_Counter. When Tx_Err_Counter reaches the value of 128, the FLT_CONF field in the Error and Status Register is updated to be Error Active and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the Tx_Err_Counter value.
- If during system start-up only one node is operating, then its Tx_Err_Counter increases in each message it is trying to transmit as a result of acknowledge errors (indicated by the ACK_ERR bit in the Error and Status Register). After the transition to Error Passive state, the Tx_Err_Counter does not increment anymore by acknowledge errors. Therefore the device never goes to the Bus Off state.
- If the Rx_Err_Counter increases to a value greater than 127, it is not incremented further even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to Error Active state.

Addresses: FLEXCAN-1_ECR is 53FC_8000h base + 1Ch offset = 53FC_801Ch
FLEXCAN-2_ECR is 53FC_C000h base + 1Ch offset = 53FC_C01Ch



FLEXCANx_ECR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. This read-only bitfield is reserved and always has the value zero
15–8 Rx_Err_Counter	Receive Error Counter
7–0 Tx_Err_Counter	Transmit Error Counter

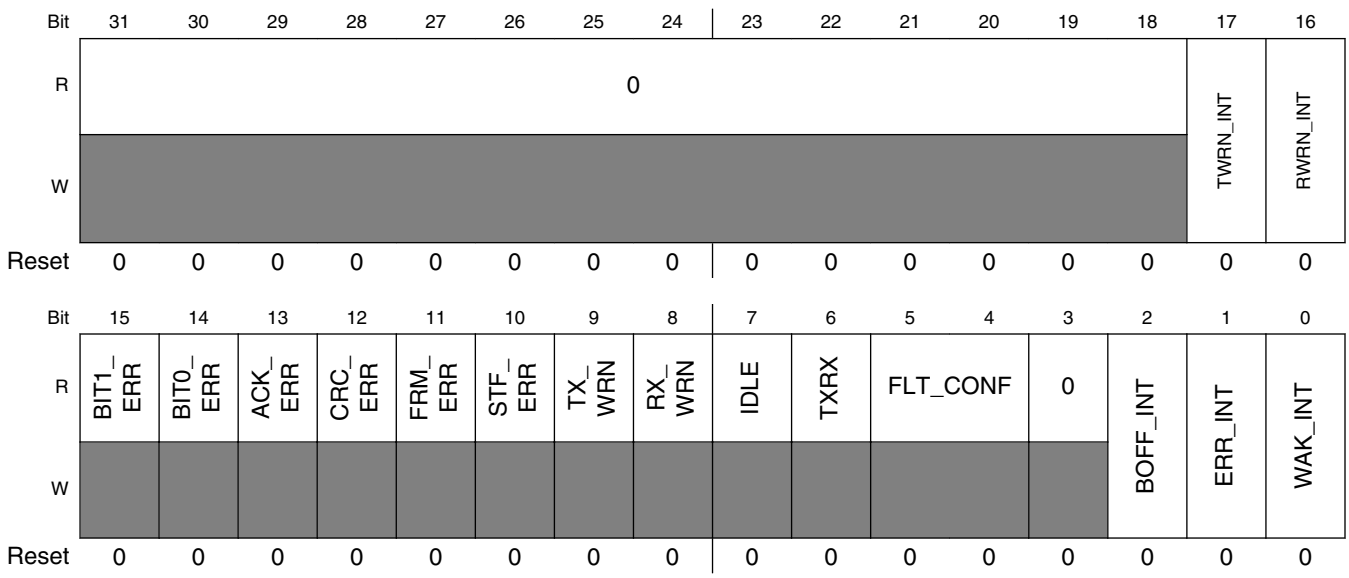
34.6.8 Error and Status Register (FLEXCANx_ESR)

This register reflects various error conditions. Four of these error conditions may be programed to signal an interrupt to the ARM. The reported error conditions (bits 15, 10) are those that occurred since the last time the ARM read this register. The ARM read action clears (bits 15,10)(bits. (Bits 9, 4) (bits are status bits.

Most bits in this register are read only, except TWRN_INT, RWRN_INT, BOFF_INT, WAK_INT and ERR_INT, that are interrupt flags that can be cleared by writing 1 to them (writing 0 has no effect).

Addresses: FLEXCAN-1_ESR is 53FC_8000h base + 20h offset = 53FC_8020h

FLEXCAN-2_ESR is 53FC_C000h base + 20h offset = 53FC_C020h



FLEXCANx_ESR field descriptions

Field	Description
31–18 Reserved	This read-only field is reserved and always has the value zero. Reserved
17 TWRN_INT	If the WRN_EN bit in MCR is asserted, the TWRN_INT bit is set when the TX_WRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control Register (TWRN_MSK) is set, an interrupt is generated to the ARM. This bit is cleared by writing it to 1. Writing 0 has no effect. 1 The Tx error counter transition from < 96 to ℜ≥ 96 0 No such occurrence
16 RWRN_INT	If the WRN_EN bit in MCR is asserted, the RWRN_INT bit is set when the RX_WRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control Register (RWRN_MSK) is set, an interrupt is generated to the ARM. This bit is cleared by writing it to 1. Writing 0 has no effect.

Table continues on the next page...

FLEXCANx_ESR field descriptions (continued)

Field	Description
	1 The Rx error counter transition from < 96 to ℜ≥ 96 0 No such occurrence
15 BIT1_ERR	This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message. This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits. 1 At least one bit sent as recessive is received as dominant 0 No such occurrence
14 BIT0_ERR	This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message. 1 At least one bit sent as dominant is received as recessive 0 No such occurrence
13 ACK_ERR	This bit indicates that an Acknowledge Error has been detected by the transmitter node, that is, a dominant bit has not been detected during the ACK SLOT. 1 An ACK error occurred since last read of this register 0 No such occurrence
12 CRC_ERR	This bit indicates that a CRC Error has been detected by the receiver node, that is, the calculated CRC is different from the received. 1 A CRC error occurred since last read of this register. 0 No such occurrence
11 FRM_ERR	This bit indicates that a Form Error has been detected by the receiver node, that is, a fixed-form bit field contains at least one illegal bit. 1 A Form Error occurred since last read of this register 0 No such occurrence
10 STF_ERR	This bit indicates that a Stuffing Error has been detected. 1 A Stuffing Error occurred since last read of this register. 0 No such occurrence.
9 TX_WRN	This bit indicates when repetitive errors are occurring during message transmission. 1 TX_Err_Counter ℜ≥ 96 0 No such occurrence
8 RX_WRN	This bit indicates when repetitive errors are occurring during message reception. 1 Rx_Err_Counter ℜ≥ 96 0 No such occurrence
7 IDLE	This bit indicates when CAN bus is in IDLE state. 1 CAN bus is now IDLE 0 No such occurrence
6 TXRX	This bit indicates if FLEXCAN is transmitting or receiving a message when the CAN bus is not in IDLE state. This bit has no meaning when IDLE is asserted.

Table continues on the next page...

FLEXCANx_ESR field descriptions (continued)

Field	Description
	1 FLEXCAN is transmitting a message (IDLE=0) 0 FLEXCAN is receiving a message (IDLE=0)
5–4 FLT_CONF	This 2-bit field indicates the Confinement State of the FLEXCAN block, as shown in below: If the LOM bit in the Control Register is asserted, the FLT_CONF field will indicate Error Passive. Because the Control Register is not affected by soft reset, the FLT_CONF field will not be affected by soft reset if the LOM bit is asserted 01 Error Passive 1x Bus off
3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2 BOFF_INT	This bit is set when FLEXCAN enters Bus Off state. If the corresponding mask bit in the Control Register (BOFF_MSK) is set, an interrupt is generated to the ARM. This bit is cleared by writing it to 1. Writing 0 has no effect. 1 FLEXCAN block entered Bus Off state 0 No such occurrence
1 ERR_INT	This bit indicates that at least one of the Error Bits (bits 15-10) is set. If the corresponding mask bit in the Control Register (ERR_MSK) is set, an interrupt is generated to the ARM. This bit is cleared by writing it to 1. Writing 0 has no effect. 1 Indicates setting of any Error Bit in the Error and Status Register 0 No such occurrence
0 WAK_INT	When FLEXCAN is Stop Mode and a recessive to dominant transition is detected on the CAN bus and if the WAK_MSK bit in the MCR Register is set, an interrupt is generated to the ARM. This bit is cleared by writing it to 1. Writing 0 has no effect. 1 Indicates a recessive to dominant transition received on the CAN bus when the FLEXCAN is in Stop Mode 0 No such occurrence

34.6.9 Interrupt Masks 2 Register (FLEXCANx_IMASK2)

This register allows any number of a range of 32 Message Buffer Interrupts to be enabled or disabled. It contains one interrupt mask bit per buffer enabling the ARM to determine which buffer generates an interrupt after a successful transmission or reception (that is, when the corresponding IFLAG2 bit is set).

NOTE

Setting or clearing a bit in the IMASK2 Register can assert or negate an interrupt request if the corresponding IFLAG2 bit is set.

Addresses: FLEXCAN-1_IMASK2 is 53FC_8000h base + 24h offset = 53FC_8024h
FLEXCAN-2_IMASK2 is 53FC_C000h base + 24h offset = 53FC_C024h

FLEXCANx_IMASK2 field descriptions

Field	Description
31–0 BUF63M,BUF32M	Each bit enables or disables the respective FLEXCAN Message Buffer (MB32 to MB63) Interrupt. 1 The corresponding buffer Interrupt is enabled 0 The corresponding buffer Interrupt is disabled

34.6.10 Interrupt Masks 1 Register (FLEXCANx_IMASK1)

This register allows the enabling or disabling of any number of a range of 32 Message Buffer Interrupts. It contains one interrupt mask bit per buffer enabling the ARM to determine which buffer generates an interrupt after a successful transmission or reception (that is, when the corresponding IFLAG1 bit is set).

NOTE

Setting or clearing a bit in the IMASK1 Register can assert or negate an interrupt request if the corresponding IFLAG1 bit is set.

Addresses: FLEXCAN-1_IMASK1 is 53FC_8000h base + 28h offset = 53FC_8028h
FLEXCAN-2_IMASK1 is 53FC_C000h base + 28h offset = 53FC_C028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FLEXCANx_IMASK1 field descriptions

Field	Description
31–0 BUF31M-BUF0M	Each bit enables or disables the respective FLEXCAN Message Buffer (MB0 to MB31) Interrupt. 1 The corresponding buffer Interrupt is enabled 0 The corresponding buffer Interrupt is disabled

34.6.11 Interrupt Flags 2 Register (FLEXCANx_IFLAG2)

This register defines the flags for 32 Message Buffer interrupts. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing it to 1. Writing 0 has no effect.

When the AEN bit in the MCR is set (Abort enabled), while the IFLAG2 bit is set for a message buffer configured as Tx, the writing access done by ARM into the corresponding message buffer will be blocked.

Addresses: FLEXCAN-1_IFLAG2 is 53FC_8000h base + 2Ch offset = 53FC_802Ch
FLEXCAN-2_IFLAG2 is 53FC_C000h base + 2Ch offset = 53FC_C02Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BUF63I-BUF32I																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FLEXCANx_IFLAG2 field descriptions

Field	Description
31–0 BUF63I-BUF32I	Each bit flags the respective FLEXCAN Message Buffer (MB32 to MB63) interrupt. 1 The corresponding buffer has successfully completed transmission or reception 0 No such occurrence

34.6.12 Interrupt Flags 1 Register (FLEXCANx_IFLAG1)

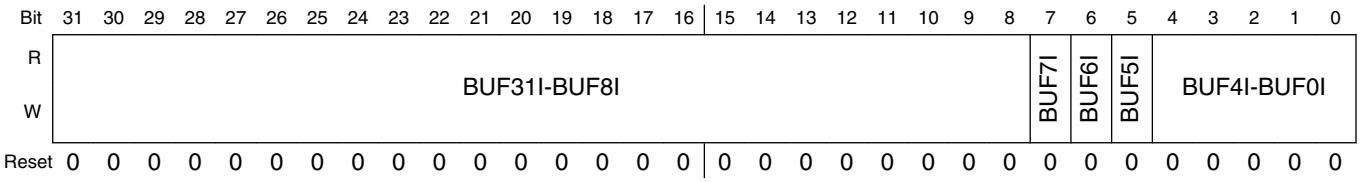
This register defines the flags for 32 Message Buffer interrupts and FIFO interrupts. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit . If the corresponding IMASK1 bit is set, an interrupt will be generated. The Interrupt flag must be cleared by writing it to 1. Writing 0 has no effect.

When the AEN bit in the MCR is set (Abort enabled), while the IFLAG1 bit is set for a message buffer configured as Tx, the writing access done by ARM into the corresponding message buffer will be blocked.

When the FEN bit in the MCR is set (FIFO enabled), the function of the 8 least significant interrupt flags (BUF7I - BUF0I) is changed to support the FIFO operation. BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO, while BUF4I to BUF0I are not used.

Addresses: FLEXCAN-1_IFLAG1 is 53FC_8000h base + 30h offset = 53FC_8030h

FLEXCAN-2_IFLAG1 is 53FC_C000h base + 30h offset = 53FC_C030h



FLEXCANx_IFLAG1 field descriptions

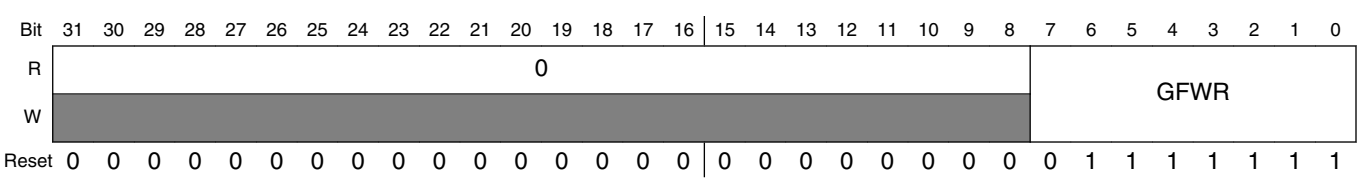
Field	Description
31–8 BUF31I-BUF8I	Each bit flags the respective FLEXCAN Message Buffer (MB8 to MB31) interrupt. 1 The corresponding message buffer has successfully completed transmission or reception 0 No such occurrence
7 BUF7I	If the FIFO is not enabled, this bit flags the interrupt for MB7. If the FIFO is enabled, this flag indicates an overflow condition in the FIFO (frame lost because FIFO is full). 1 MB7 completed transmission/reception or FIFO overflow 0 No such occurrence
6 BUF6I	If the FIFO is not enabled, this bit flags the interrupt for MB6. If the FIFO is enabled, this flag indicates that 4 out of 6 buffers of the FIFO are already occupied (FIFO almost full). 1 MB6 completed transmission/reception or FIFO almost full 0 No such occurrence
5 BUF5I	If the FIFO is not enabled, this bit flags the interrupt for MB5. If the FIFO is enabled, this flag indicates that at least one frame is available to be read from the FIFO. 1 MB5 completed transmission/reception or frames available in the FIFO 0 No such occurrence
4–0 BUF4I-BUF0I	If the FIFO is not enabled, these bits flag the interrupts for MB0 to MB4. If the FIFO is enabled, these flags are not used and must be considered as reserved locations. 1 Corresponding message buffer completed transmission/reception 0 No such occurrence

34.6.13 Glitch Filter Width Register (FLEXCANx_GFWR)

The Glitch Filter just takes effects when FLEXCAN enters the STOP mode.

Addresses: FLEXCAN-1_GFWR is 53FC_8000h base + 34h offset = 53FC_8034h

FLEXCAN-2_GFWR is 53FC_C000h base + 34h offset = 53FC_C034h



FLEXCANx_GFWR field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–0 GFWR	It determines the Glitch Filter Width. The width will be divided from Oscillator clock by GFWR values. By default, it is 5.33us when the oscillator is 24MHz.

34.6.14 Rx Individual Mask Registers (FLEXCANx_RXIMR)

These registers are used as acceptance masks for ID filtering in Rx message buffers and the FIFO. If the FIFO is not enabled, one mask register is provided for each available Message Buffer, providing ID masking capability on a per Message Buffer basis. When the FIFO is enabled (FEN bit in MCR is set), the first 8 Mask Registers apply to the 8 elements of the FIFO filter table (on a one-to-one correspondence) while the rest of the registers apply to the regular message buffers starting from MB8.

The Individual Rx Mask Registers are implemented in RAM so they are not affected by reset and must be explicitly initialized prior to any reception. Furthermore, they can only be accessed by the ARM while the block is in Freeze Mode. Out of Freeze Mode, write accesses are blocked and read accesses will return all zeros. Furthermore, if the BCC bit in the MCR Register is negated, any read or write operation to these registers results in access error.

Addresses: FLEXCAN-1_RX0IMR is 53FC_8000h base + 880h offset = 53FC_8880h
FLEXCAN-1_RX63IMR is 53FC_8000h base + 97Ch offset = 53FC_897Ch
FLEXCAN-2_RX0IMR is 53FC_C000h base + 880h offset = 53FC_C880h
FLEXCAN-2_RX63IMR is 53FC_C000h base + 97Ch offset = 53FC_C97Ch

Field	Description
31–0 MI31-MI0	For normal Rx message buffers, the mask bits affect the ID filter programmed on the message buffer. For the Rx FIFO, the mask bits affect all bits programmed in the filter table (ID, IDE, RTR). 1 The corresponding bit in the filter is checked against the one received 0 the corresponding bit in the filter is dont care

Chapter 35
Electrical Fuse Array (FUSEBOX)

35.1 Introduction

The FUSEBOX consists of electrically programmable poly fuses (FUSEBOX analog) and a digital control block (FUSEBOX digital) that has a Functional Interface (FI) that can interface with the IC Identification Module (IIM) or other dedicated fusebox control modules. A FUSEBOX Interface (FI) connects directly to the FUSEBOX FI inside FUSEBOX.

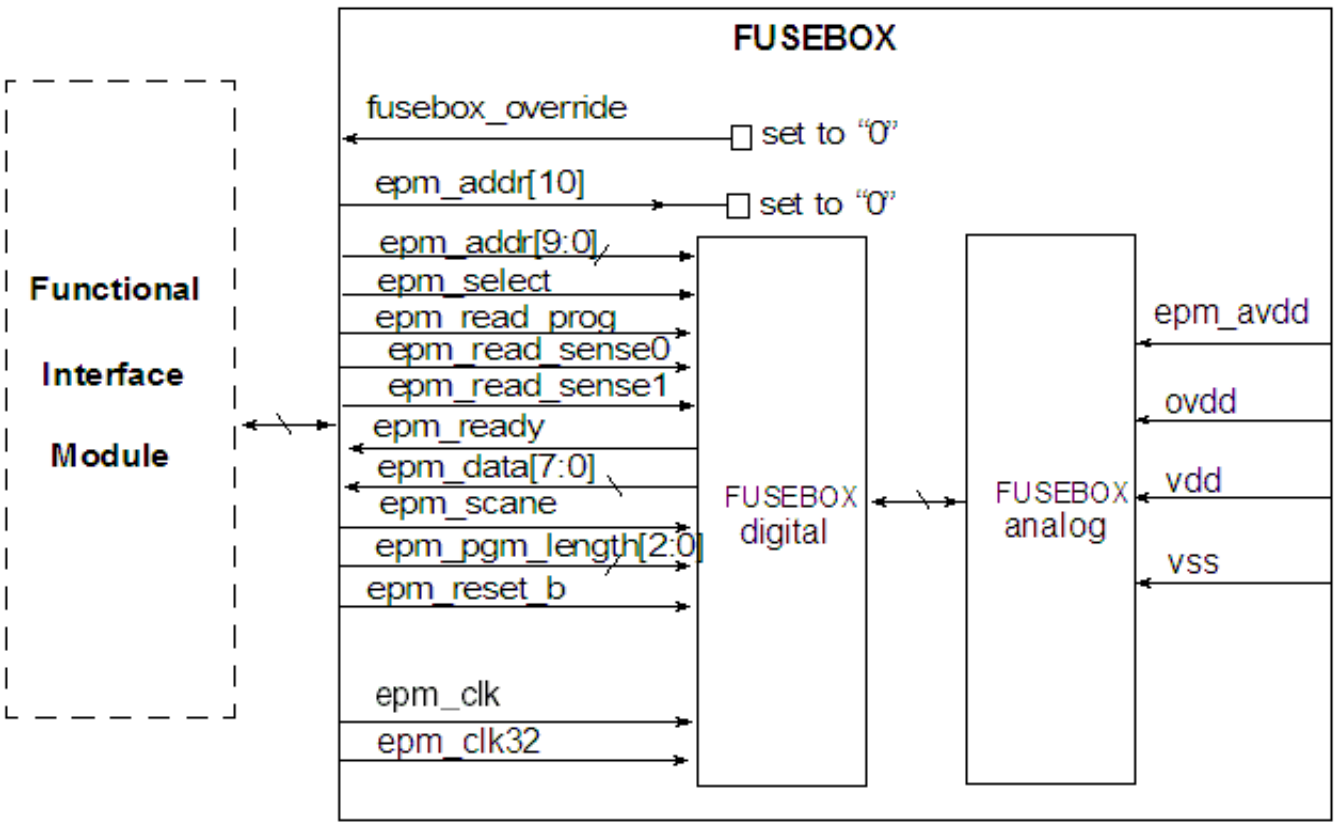

Figure 35-1. FUSEBOX Block Diagram

35.1.1 Overview

There are two major building blocks inside the FUSEBOX, an analog block and a digital block. In addition, fusebox_override signal that is connected to Functional Interface can be used to bypass the FUSEBOX. fusebox_override is set to ground by default, and it can be set to core vdd, if it is necessary, by a metal 6 layer change inside FUSEBOX.

The FUSEBOX digital block decodes the 11 bit address signal and generates control signals to the analog block. The FUSEBOX is able to support up to 1024 bit fuses. One 1024 bit FUSEBOX is used regardless of the size of the fuseboxes to keep a uniform Functional Interface.

There are two sizes of the analog block, 128 and 256 fuses. The interface between the 128 bit analog and the digital block is illustrated in Figure 35-2. The interface between the 256 bit analog and the digital block is illustrated in Figure 35-3. The interface signals

in the two cases are the same except that the 128 bit analog block has 16 additional unconnected decoded address signals. When fusebox_overrid is set to core vdd, all the outputs from the FUSEBOX to the Functional Interface will be grounded.

The 128 bit analog block contains a 16 row x 8 column fuse array (total 2*128 poly fuses due to redundancy), eight sense amplifiers, and other supporting circuitry. Likewise the 256 bit analog block contains a 32 row x 8 column fuse array, eight sense amplifiers, and supporting circuitry.

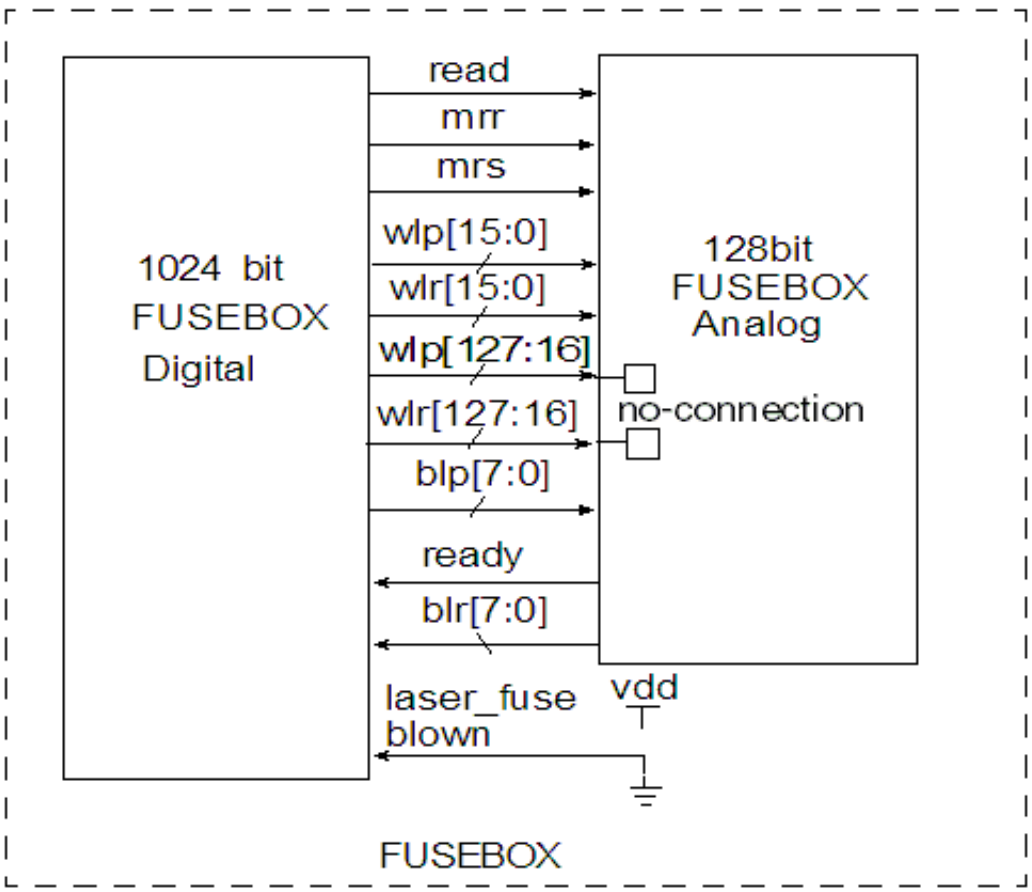

Figure 35-2. Interface Between 128 FUSEBOX Analog and FUSEBOX Digital Block

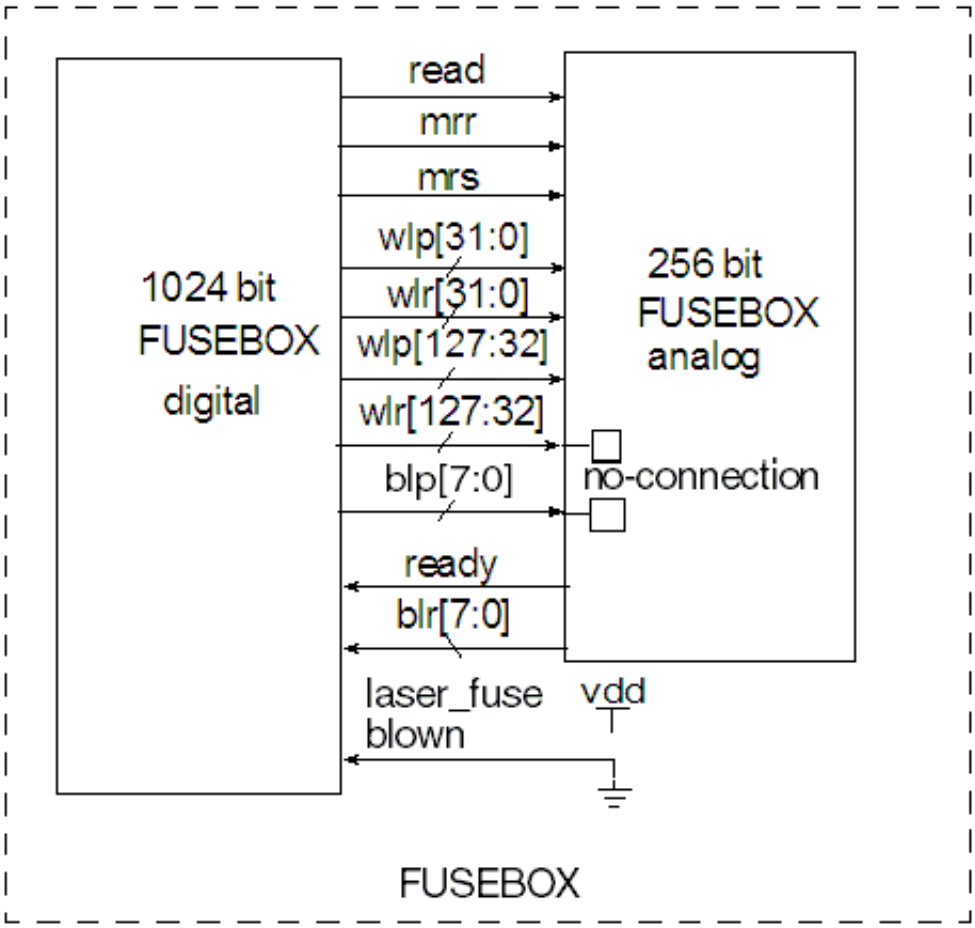

Figure 35-3. Interface Between 256 FUSEBOX Analog and FUSEBOX Digital Block

35.1.2 Modes of Operation

All FUSEBOX operations are self-timed and begin relative to the rising edge on the epm_select line. Most interface signals are shared by all Fuseboxes. Only the FUSEBOX selects (epm_select), read data (epm_data) and ready status (epm_ready) signals are unique to each FUSEBOX. The 32KHz clock is not used within the IIM, but may be used with other FIs. It is passed through to the FUSEBOX to time program operations. The 32KHz clock distributed to the Fuseboxes should be on during FUSEBOX program operations and should be gated off during read operation. The epm_clk is used to sample the epm_select, epm_ready and epm_data signals in order to synchronize these signals with the Functional Interface inside a FUSEBOX. This epm_clk is a gated clock used by the local FIs.

35.1.2.1 Normal Operating Modes

35.1.2.1.1 Word Read

Read operations are done on a word (8-bit) basis. The target word is specified by the address lines epm_addr[9:3]. The bottom three address lines (bit-select lines) are ignored in a read operation. The timing for fuse word read cycles is shown in Figure 1-4. This timing diagram shows one read cycle followed by the start of a second read, demonstrating how quickly one read can follow another. Each read command is registered on the rising edge of epm_select. The address (epm_addr[9:3]) and read command (epm_read_prog) must be stable tsels before the rising edge of epm_select and must remain stable at least tselh hold time beyond the rising edge. epm_ready is negated immediately after the command is registered, indicating that the FUSEBOX is busy. After a tdv delay from the active edge of epm_select, the data is made available on blr by the analog FUSEBOX. The epm_ready acknowledge signal is asserted tready after the initial assertion of epm_select and the data is available on the epm_data. The FUSEBOX synchronizes epm_ready and the data to the epm_clk clock and drives the synchronized data onto the IP Bus. The time between the valid epm_data and epm_ready is signified by tsync in Figure 1-4 and is one-half of one epm_clk cycle. Once the read data has been latched, epm_select is negated by the Functional Interface. epm_select must remain negated a minimum cycle to cycle delay of tccd before the next cycle (read or program) may begin. epm_data remains at a steady state until replaced by data from a subsequent read cycle.

In the read mode operation, the internal signal wlp[127:0] and blp[7:0] remain low ("0") irrespective of epm_addr[2:0].

Table 35-1. FUSEBOX Timing Parameters

Description	Designator	Timing Value
Setup time to epm_select active edge	t_{sels}	2 nS
Hold time after epm_select active edge	t_{selh}	2 nS
Delay from epm_select to epm_ready negation (read). Delay from the rise edge of 32Khz clock to epm_ready (program).	t_{nrdy}	200 pS - 1000 pS
Assert time from epm_select active edge to negation of read from digital	t_{rdd}	1nS - 4 nS
Data valid after epm_select active edge	t_{dv}	30 nS - 100 nS
Epm_ready signal asserted after epm_select active edge (read only)	t_{rdy}	<= (t_{dv} + 1.5 epm_clk)
Epm_ready signal asserted after epm_select active edge (program only)	t_{ready}	(epm_pgm_length) * $period_{32KHz}$

Table continues on the next page...

Table 35-1. FUSEBOX Timing Parameters (continued)

Description	Designator	Timing Value
Data driven out to bus after analog ready signal asserts (read only)	t_{datrdy}	0 - 1 epm_clk
epm_data to epm_ready synchronization delay (read). epm_ready to negation of epm_select (program)	t_{sync}	one-half of 1 epm_clk cycle (rising edge to falling edge) > 3nS if epm_clk duty cycle is not 50%
rising-edge of epm_ready to negative-edge of epm_select (read only)	t_{rdysel}	> 2nS typically one-half of 1 epm_clk cycle (falling edge to rising edge)
Minimum cycle to cycle delay (Consecutive Read)	t_{ccdr}	5 nS
Minimum cycle to cycle delay (Consecutive program)	t_{ccdp}	0.5 uS

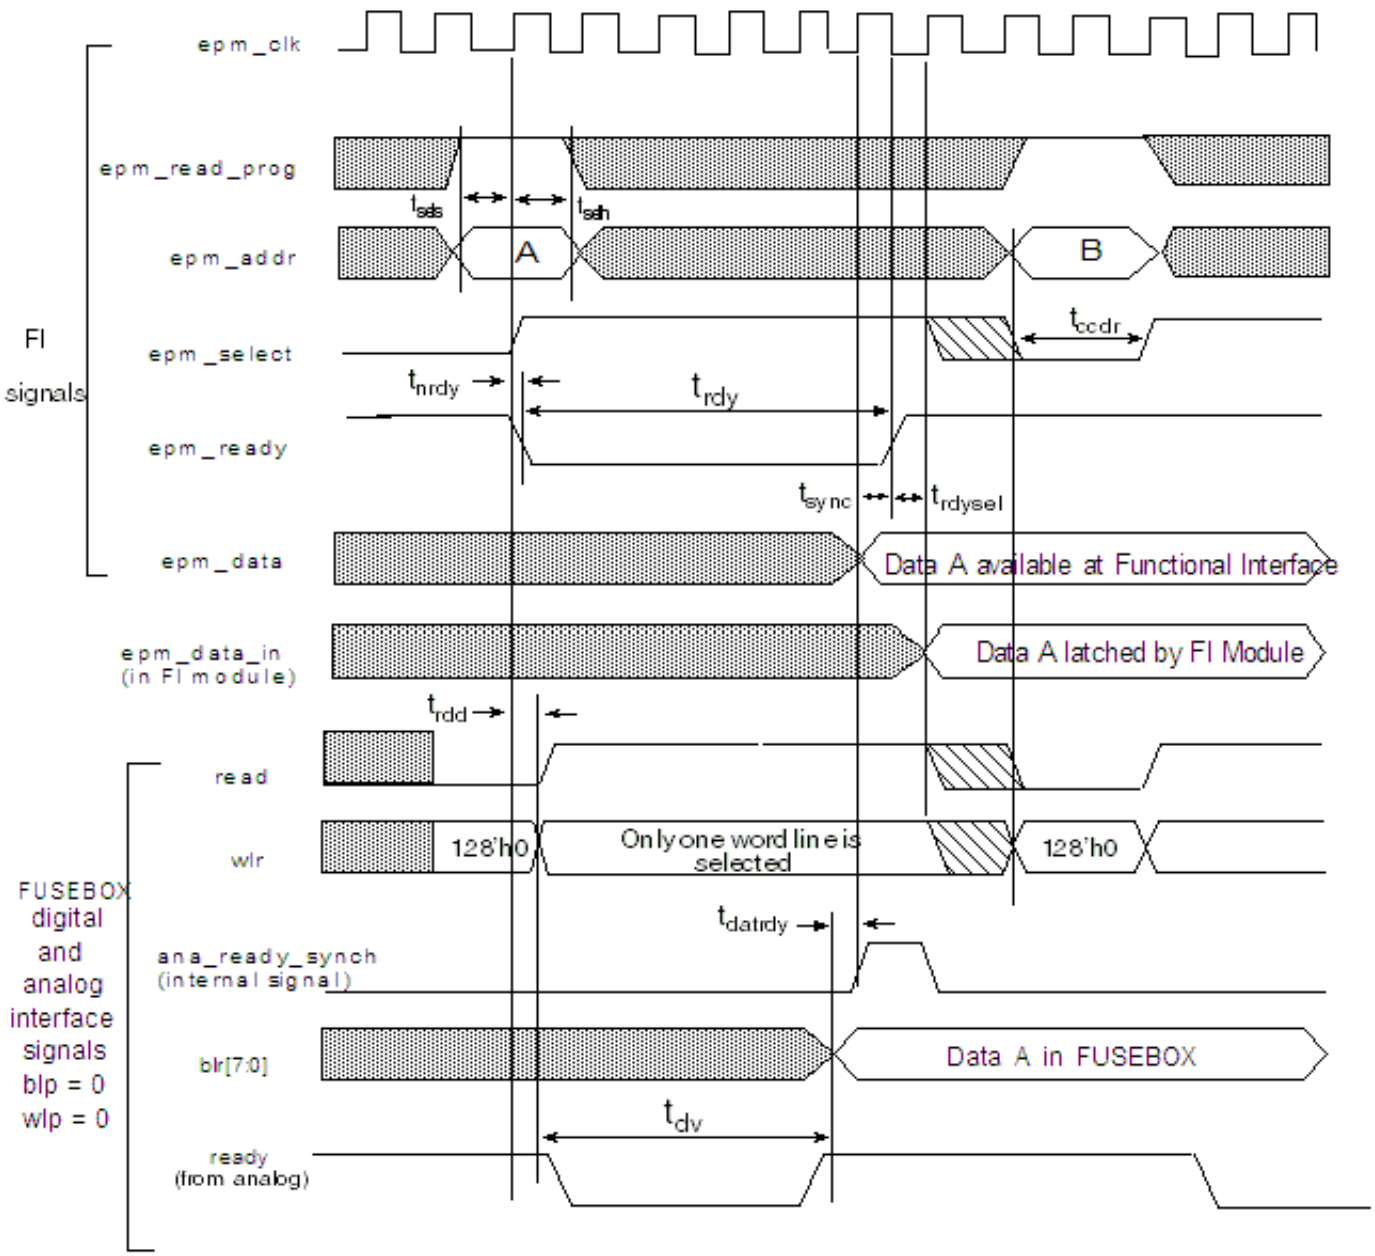

Figure 35-4. FUSEBOX Read Cycle Timing

35.1.2.1.2 Bit Program

Program operations are done on a bit-basis. The target bit is specified by the full address bus (epm_addr[10:0]). Program operations can only blow fuses (change them from logic 0 to logic 1), so there is no program data bus associated with the FUSEBOX. The timing for a program operation is shown in Figure 1-5. As in the read cycle, the address and program command are latched on the rising edge of epm_select. The address must be setup tsels ahead of the rising edge and remain held tselh past the edge of epm_select.

Once the program command is registered, on the next rising edge of the 32KHz clock, the FUSEBOX will initiate the program operation. An internal counter will start to count the number of 32K clock cycles, and the epm_ready signal is de-asserted. After the specified number of 32 KHz clocks (determined by epm_pgm_length[2:0]), the FUSEBOX will complete the program operation and assert the epm_ready signal. epm_pgm_length[2:0] needs to be set tsels ahead of the rising edge of epm_select and to be held until the completion of the internal counter. Consult Table 35-1 for specific timing values. The Functional Interface module synchronizes the epm_ready response to the epm_clk during the period tsync. After recognizing that the program operation has completed, the Functional Interface module negates the epm_select line. To avoid accidental selection of more than one bit line at a time, the 8 bit de-coded bit-line-program (blp) needs to be checked before generate blp[7:0].

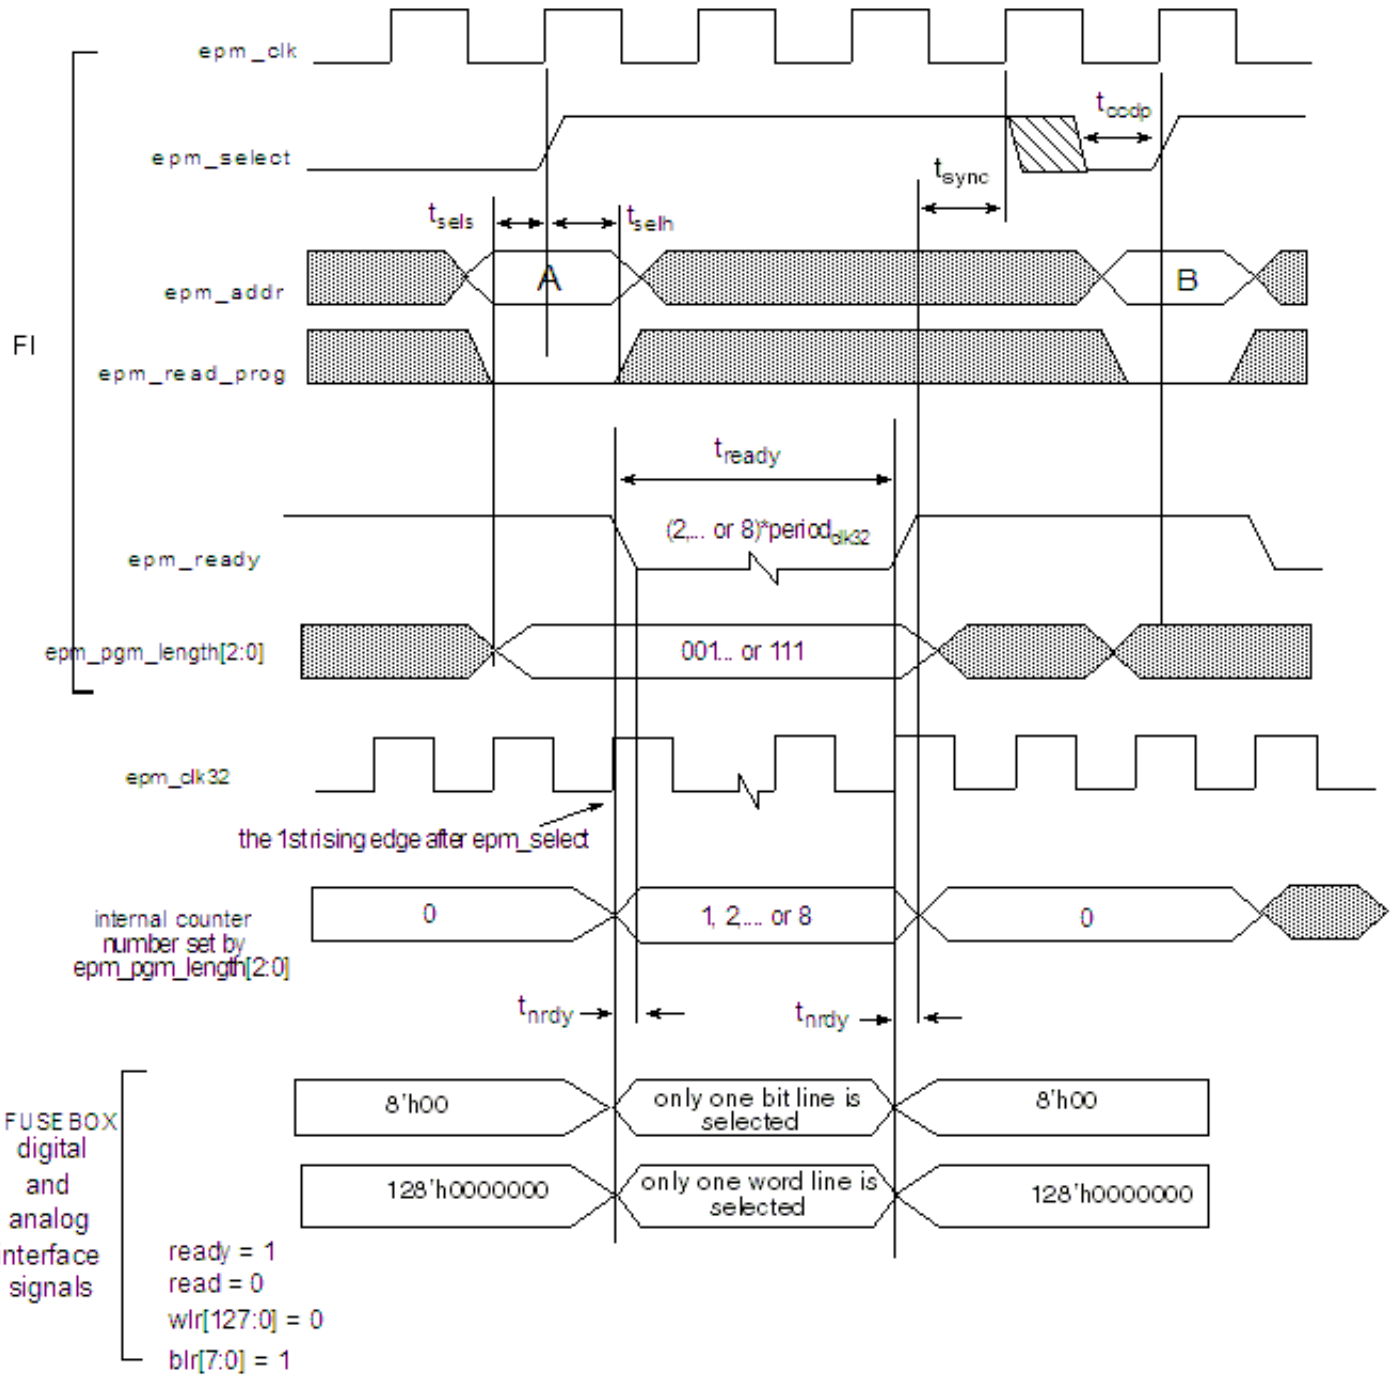

Figure 35-5. Fuse Program Cycle Timing

The fuse stress time is controlled by epm_pgm_length[2:0] and 32Khz clock. The number of 32Khz cycles is counted by an internal counter which is control by epm_pgm_length[2:0]. The counter starts counting at the first rising edge of the 32K clock after both epm_select and epm_pgm_length[2:0] are asserted. Table 35-2 shows the relationship between epm_pgm_length[2:0] and the number of 32K clock cycles.

In program mode operation, the internal signal ready and blr[7:0] remains high ("1"), and wlr[127:0] and read/mrr/mrs remains low ("0") in the program mode operation.

Table 35-2. Fuse Program Length Table

epm_pgm_length[2:0]	32KHz clock cycles	Program Length
000	0	fuses are not stressed
001	2	62.5 uS
010	3	93.75 uS
011	4	125 uS
100	5	156.25 uS
101	6	187.5 uS
110	7	218.75 uS
111	8	250 uS

NOTE

The Functional Interface module controller must determine that the target fuse bank is indeed an e-Fuse bank (not a laser fuse bank) before allowing the program cycle to proceed. This is determined by examining the appropriate fuse_type signal, which is fixed at SoC integration time.

35.1.2.2 Bypass FUSEBOX

A hard wired metal option exists in the analog block of the FUSEBOX to bypass the FUSEBOX outputs. By default, the metal is connected to core vss. When this wire is re-connected to core vdd via metal 6 change, the digital FUSEBOX block asserts the epm_data going to the Functional Interface module to 0 and epm_ready to the Functional Interface module to 1. It also asserts the fusebox_override signal to the Functional Interface module to 1.

35.1.2.3 Low Power Modes

The FUSEBOX is turned off as soon as epm_select is set to "0" state in both program and read operations.

35.2 External Signal Description

External signals are the power supplies shown in Table 35-3. During chip power on, digital core vdd needs to be powered up before epm_avdd. If epm_avdd is connected to ovdd at the chip level, digital core vdd needs to be powered up before the ovdd.

Table 35-3. Signal Properties

Signal	I/O	Function	Routing Constrain
EPM_AVDD	I	Power supply for programming fuses. Can present only in program operation.	The metal resistance needs to be less than 1 Ω from I/O pad to the block input.
OVDD	I	Power supply that needs to be available in both program and read operation. This power supply is usually the I/O pad supply in the segment.	The metal resistance needs to be less than 1.5 Ω from I/O pad to the block input.
VDD	I	Digital core vdd.	N/A.
VSS	I	Power ground. Core vss, ovss, or a dedicated FUSEBOX ground can be used.	The metal resistance needs to be less than 1 Ω from I/O pad to the block input.

35.2.1 Detailed Signal Descriptions

Table 35-4. FUSEBOX Detailed Signal Descriptions

Signal	I/O	Description
EPM_AVDD	I	Power supply for programming fuses. At least a 2.775V voltage source that is able to supply 60mA current in program operation. 3.3V voltage source is preferred.
OVDD	I	Power supply that needs to be available in both program and read operation. Usually, it is the I/O pad supply in the segment. This supply needs to provide 8mA with 1.95V ovdd or 20mA with 2.775V ovdd in read mode operation. Max. 1.95V is preferred to avoid stressing fuses.
VDD	I	Digital core vdd, 1.2V typical. Needs to be powered up before epm_avdd.
VSS	I	Power ground that is able to sustain 60mA current in program operation. Core vss, ovss, or dedicated FUSEBOX ground can be used.

35.3 Functional Description

The FUSEBOX module receives 11 bit address signal and other control signals from a FUSEBOX Interface module, see Figure 35-1. The mode of operation and the location of bit cells of the FUSEBOX are controlled by the FUSEBOX Interface module. See Overview for detail descriptions.

The FUSEBOX generates two outputs, epm_ready and epm_data[7:0]. Both signals are connected to the FUSEBOX Interface module. Epm_ready indicates the completion of the program or read operation. The FUSEBOX Interface module can start the next operation cycle after detecting the rise edge of epm_ready from the FUSEBOX. In read operation, The FUSEBOX Interface module also stores the epm_data[7:0] when the rise edge of epm_ready is detected.

35.3.1 Clocks

EPM_CLK32 is a 32.768Khz clock that needs to be present during FUSEBOX program operation.

EPM_CLK is the same clock that a FUSEBOX Interface module uses to generate FUSEBOX interface signals. The maximum frequency of EPM_CLK is 166 Mhz. The worst duty cycle of EPM_CLK is 40% - 60%.

35.3.2 Reset

EPM_RESET_B needs to be connected to an early system reset signal so that the FUSEBOX can be reset during chip power up.

35.3.3 Interrupts

No interrupt signal is generated by FUSEBOX.

35.4 Initialization Information

The FUSEBOX is initialized and controlled by the IIM. Please refer to the IIM chapter for more details.

Chapter 36
General Power Controller (GPC)

36.1 Introduction

GPC is a General Power Control module.

36.1.1 Overview

GPC block includes the following sub-blocks of Advanced Power Saving techniques:

- Two DVFS sub-blocks (ARM platform and peripherals clock/power domains)
- SRPG sub-block for SRPG-ed module: ARM platform

Each of the sub-blocks has its own IP registers. The GPC also includes an arbitration block of DVFS voltage/frequency updates.

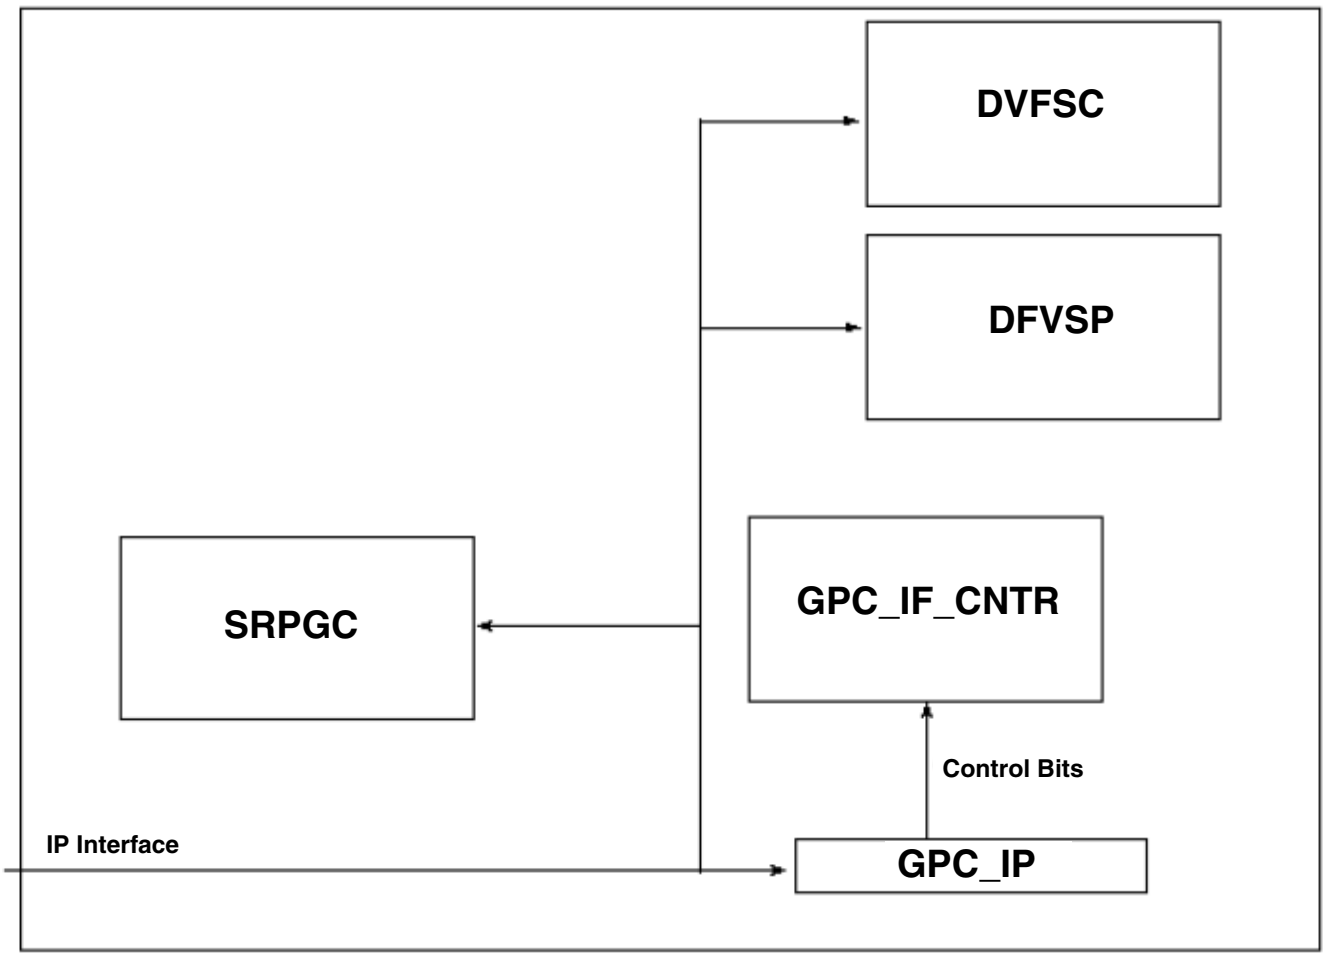

Figure 36-1. GPC Block Diagram

36.1.2 Features

- Simultaneous usage of DVFS of each domain.

- Internal counter for bypass of voltage_ready signal

- Possibility of switching between Configurable SPI (CSPI) usage and I2C Interface (I2C) .

36.2 Functional Description

GPC block includes the following sub-blocks of Advanced Power Saving techniques:

- 2 DVFS sub-blocks (ARM platform and peripherals clock/power domains)
- SRPG sub-block for SRPG-ed module: ARM platform

Each of sub-blocks has its own IP registers. As well, GPC includes an arbitration block of DVFS voltage/frequency updates.

In the following sections the global operation of the sub-blocks is described. For further details of DVFS and SRPG refer appropriate sub-block Block Guide document.

36.2.1 DVFS - Dynamic Voltage & Frequency Scaling

Dynamic Voltage & Frequency Scaling is a well-known technique to reduce power consumption in mobile devices.

In order to improve power saving efficiency, DVFS is applied both on ARM platform domain (DVFSC) and peripherals domain (DVFSP). DVFSC uses mainly ARM's IDLE signal for load monitoring, but also uses s/w writable info as secondary inputs. DVFSP uses hardware accelerators activity signals, bus activity signals and memory activity indicators for load monitoring. Both DVFS load tracking controllers are h/w implemented, providing: high resolution of load tracking (for higher efficiency), no MIPS requirements from ARM platform for continuous operation (more power saving, no additional ARM platform load).

Voltage update requests (to PMIC, via CSPI) may be served in one of the following ways:

- Hardware triggering of CSPI, by GPC
- ARM interrupts serving CSPI

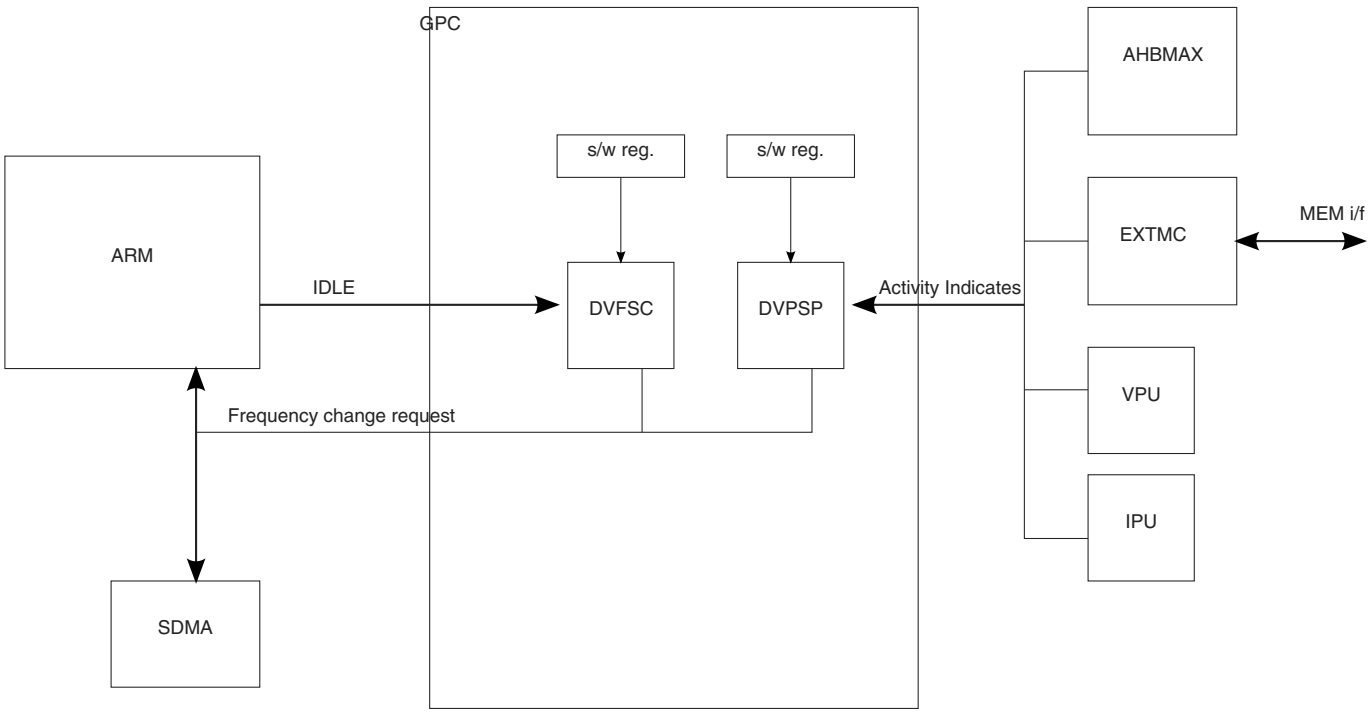

Figure 36-2. DVFS System High Level Diagram

36.2.2 DVFS Change Request Sequence Diagrams

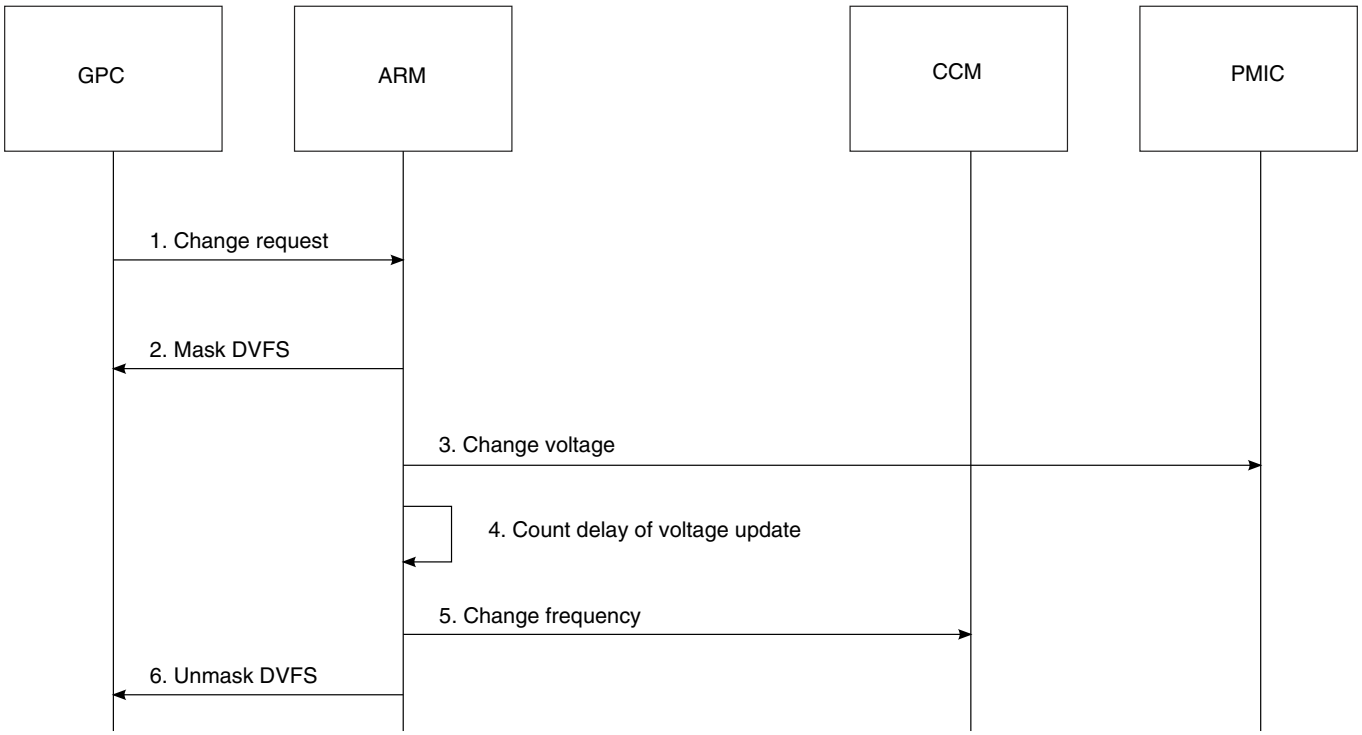

Figure 36-3. DVFS - frequency increase

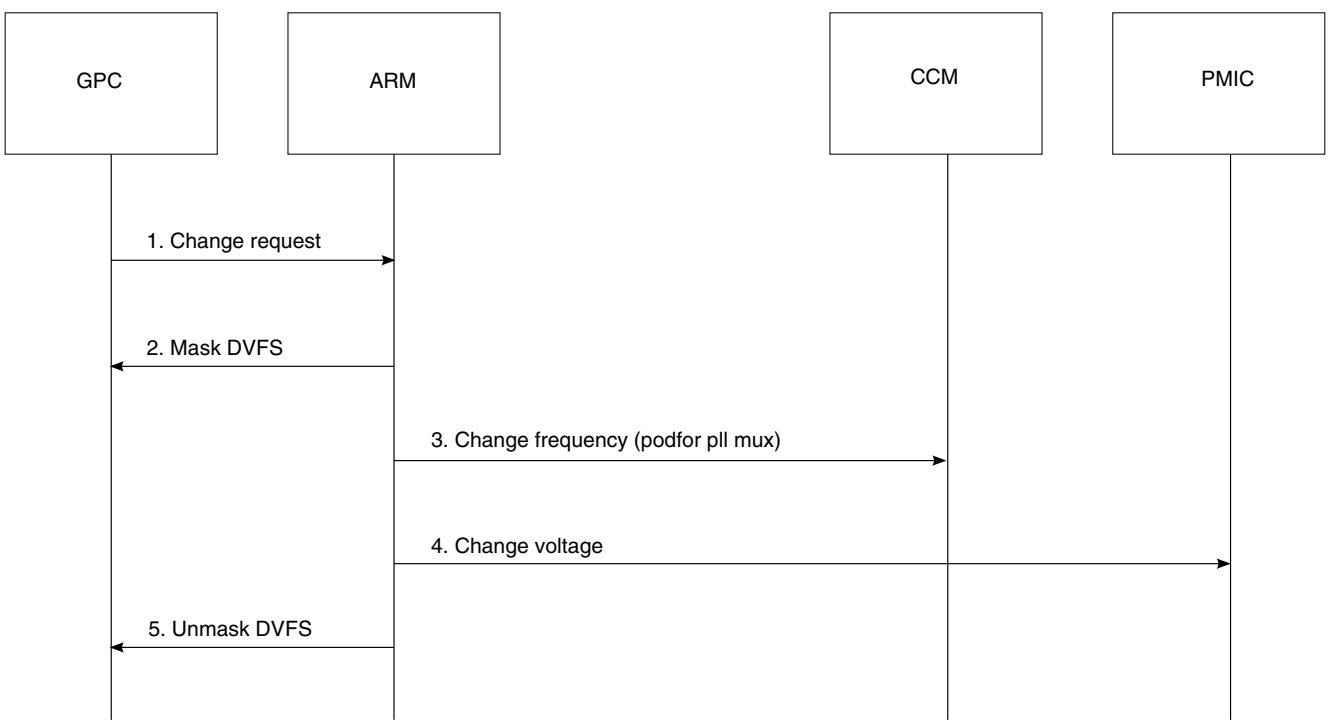

Figure 36-4. DVFS - frequency decrease

DVFSC and DVFSP will have one common interrupt line to ARM and DMA request to SDMA. SDMA (or ARM) will choose only one domain to serve.

DVFSP frequency change will be performed with post-dividers values update only.

DVFSC frequency change can be performed in 2 ways:

- PLL and post-dividers values update
- post-dividers values only update

When PLL update is required, Controller will switch ARM platform clock to another PLL, will wait until the previous PLL is locked on the required frequency, and then will switch the ARM platform clock back to the first PLL.

36.2.3 Frequency / Voltage Change Controller Description

Controller is responsible of correct frequency and voltage update flow.

36.2.3.1 GPC Controller Description

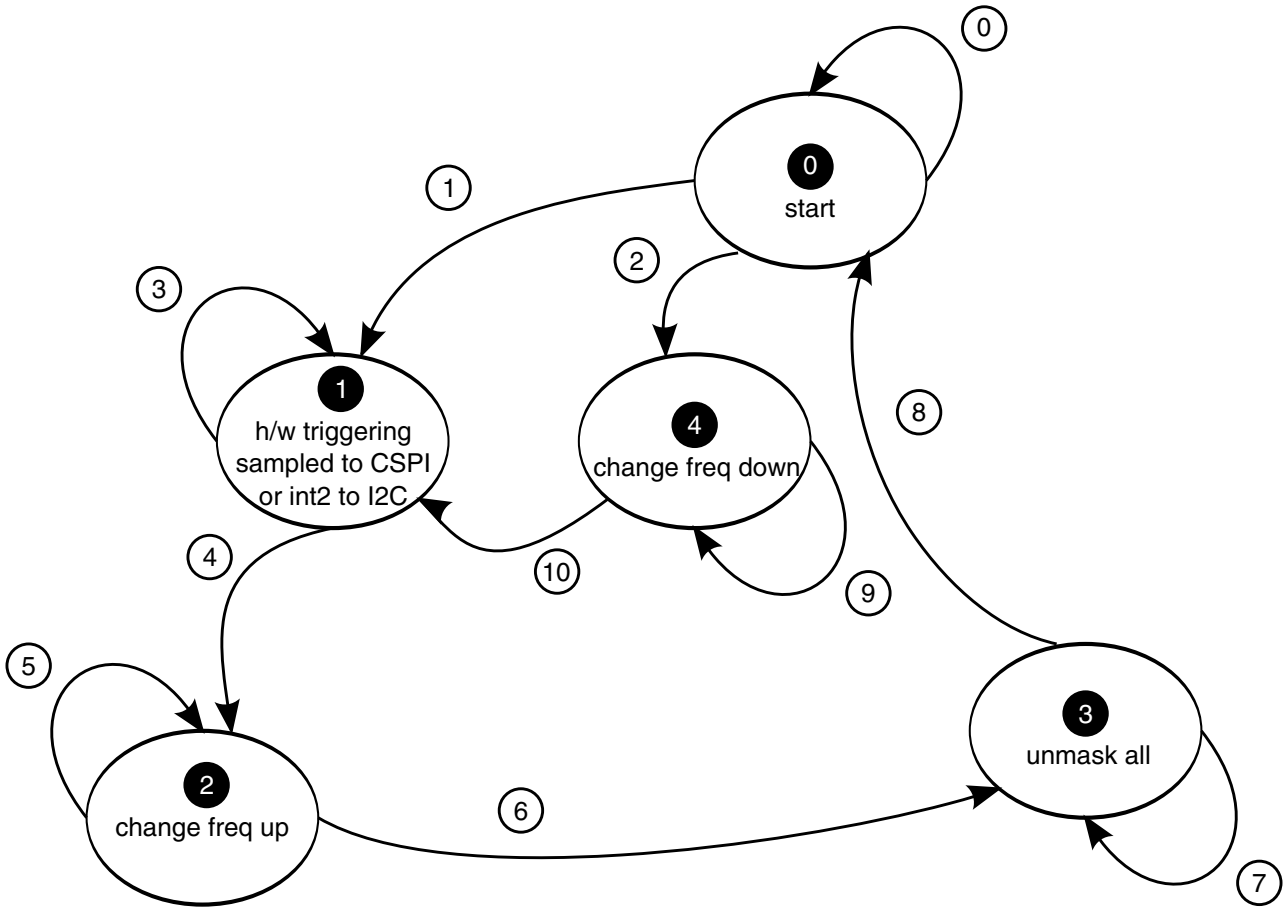

Figure 36-5. GPC DVFS State machine

Table 36-1. GPC Controller Description

Transition	Transition condition	Output
0	not (1)	-
1	STRT bit asserted, and ((freq/voltage increase needed) | (!freq/volt_inc & ! freq_update))	-
2	STRT bit set, and freq/voltage decrease needed and freq_update	-
3	not (4)	Sample h/w triggering selected reg index to CSPI or sending int2 to I2C for PMIC Start counter if VCNTU==1 (pmic ack not needed)
4	(voltage_ready & pmic ack needed) | (counter finished & !pmic ack needed)	-

Table continues on the next page...

Table 36-1. GPC Controller Description (continued)

Transition	Transition condition	Output
5	not (6)	If (dvfs update up), trigger freq. change Reset counter
6	(dvfs update up & clk change ack) | !(dvfs update up)	-
7	1 clk	unmask all, enable all toggle dvfs_cnt_res_arm or dvfs_cnt_res_per
8	not (8)	-
9	not (10)	If (dvfs update dw), trigger freq. change IRQ masked: IRQM=1
10	(dvfs update dw& clk change ack) | !(dvfs update dw) | !freq_update	-

36.2.3.2 Clock Control Module Frequency Update Controller Description

Additional State Machine is required in CCM to take care about frequency update sequence, as defined below:

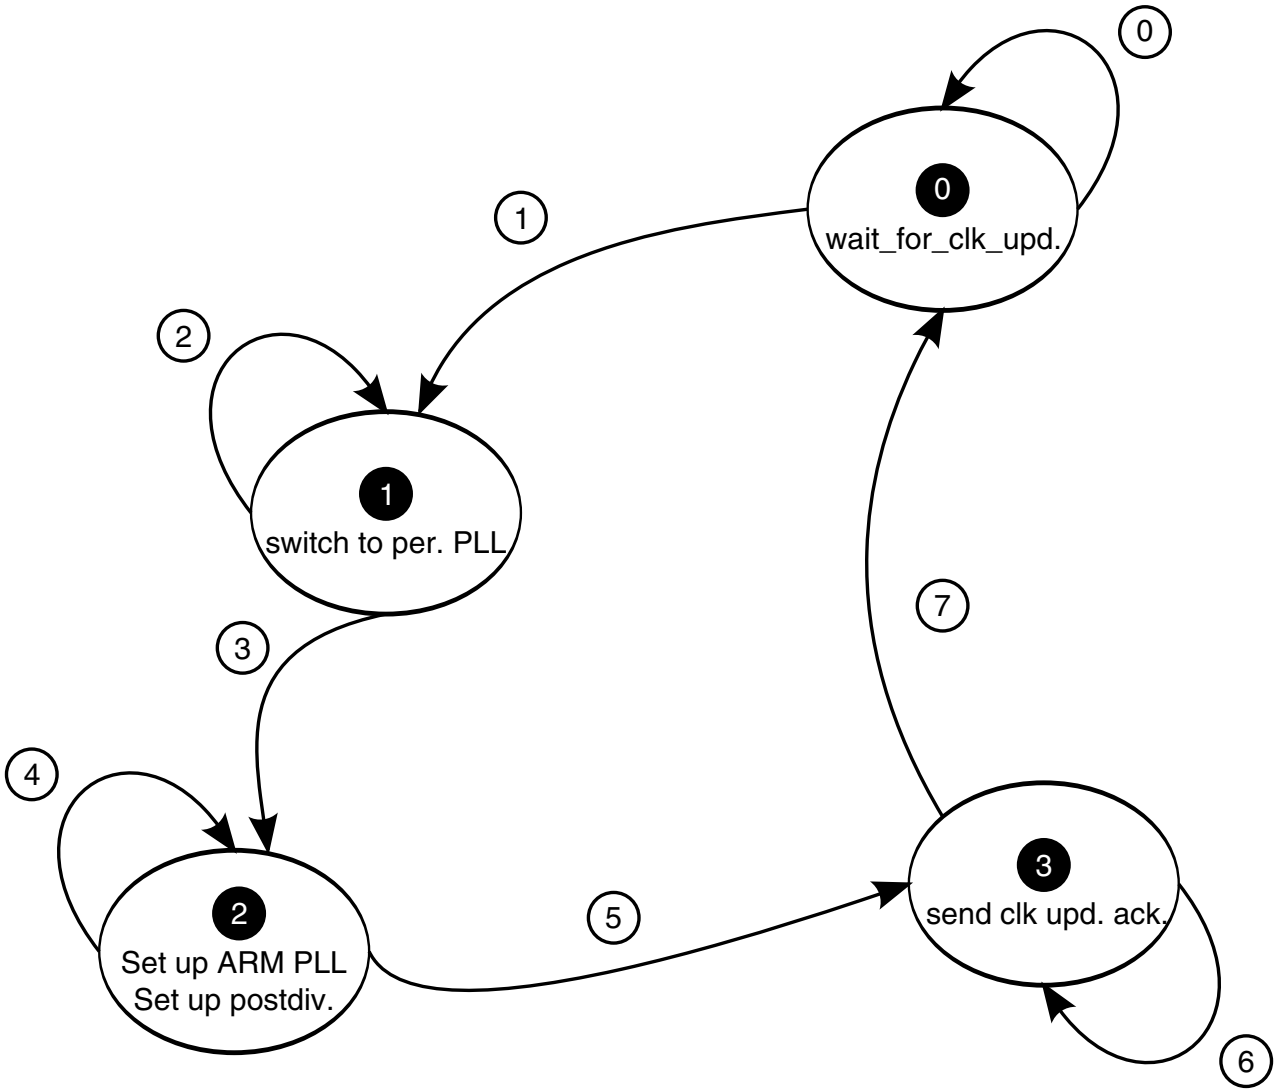

Figure 36-6. CCM Frequency Update Controller

Table 36-2. CCM Frequency Update Controller Description

Transition	Transition condition	Output
0	not (1)	clk upd ack negated
1	clk update request	-
2	not (3)	switch ARM clk to per. PLL
3	clk switched to per. PLL	-
4	not (5)	apply new PLL settings, if needed apply new postdiv settings if needed
5	ARM PLL & postdiv upd ack.	-
6	1 clk	clk update ack to GPC asserted.

Table continues on the next page...

Table 36-2. CCM Frequency Update Controller Description (continued)

Transition	Transition condition	Output
7	not (6)	-

36.2.4 State Retention Power Gating (SRPG)

State Retention Power Gating (SRPG) is an advanced power saving technique - the values of FFs are saved, while the supply for the combinational logic is gated. Such special power gating allows significant power saving during low-power (stand-by) states, when no logical operation is needed. Relatively the simple Power Gating techniques, SRPG allows to restore the state very quickly and continue the processing from the state, sampled before stand-by period.

SRPG Controller manages all the related signals for entering and exiting SRPG state of relevant modules. Not all the modules have SRPG design.

SRPG power down sequence:

CCM sends power down request when the chip enters stop or wait mode. The user should define which modules will be powered down (PGCR registers of corresponding SRPG, bit 0).

SRPG power up sequence:

The modules receive power up request in following order:

NEON and CTA8.

36.2.5 PMIC Interface Requirements for APM Support

PMIC APM interface is done through SPI protocol by enhanced CSPI module with HW triggering. Below is the description of modules requirements for APM support.

- CSPI
  - Will have 16 HW trigger registers.
  - Each register will be 32 bits:
    - 1 bits read/write (always write)
    - 6 bits address
    - 1 bit not used
    - 24 bits data
  - Each register will have an associated signal that starts the transaction to Atlas

- GPC
  - will have a 4-bit select register to select one of 16 HW trigger signals, if CSPI is used.
  - will trigger the signals during DVFS state machine according to select register value.
- PMIC
  - Only one 24-bit register should be updated for voltage change. One CSPI HW trigger will be able to make the change, or I2C will get int2.

Ability to use SDMA for h/w controllers inputs analysis and/or CSPI programming will provide high level of s/w flexibility and will be kept for backup.

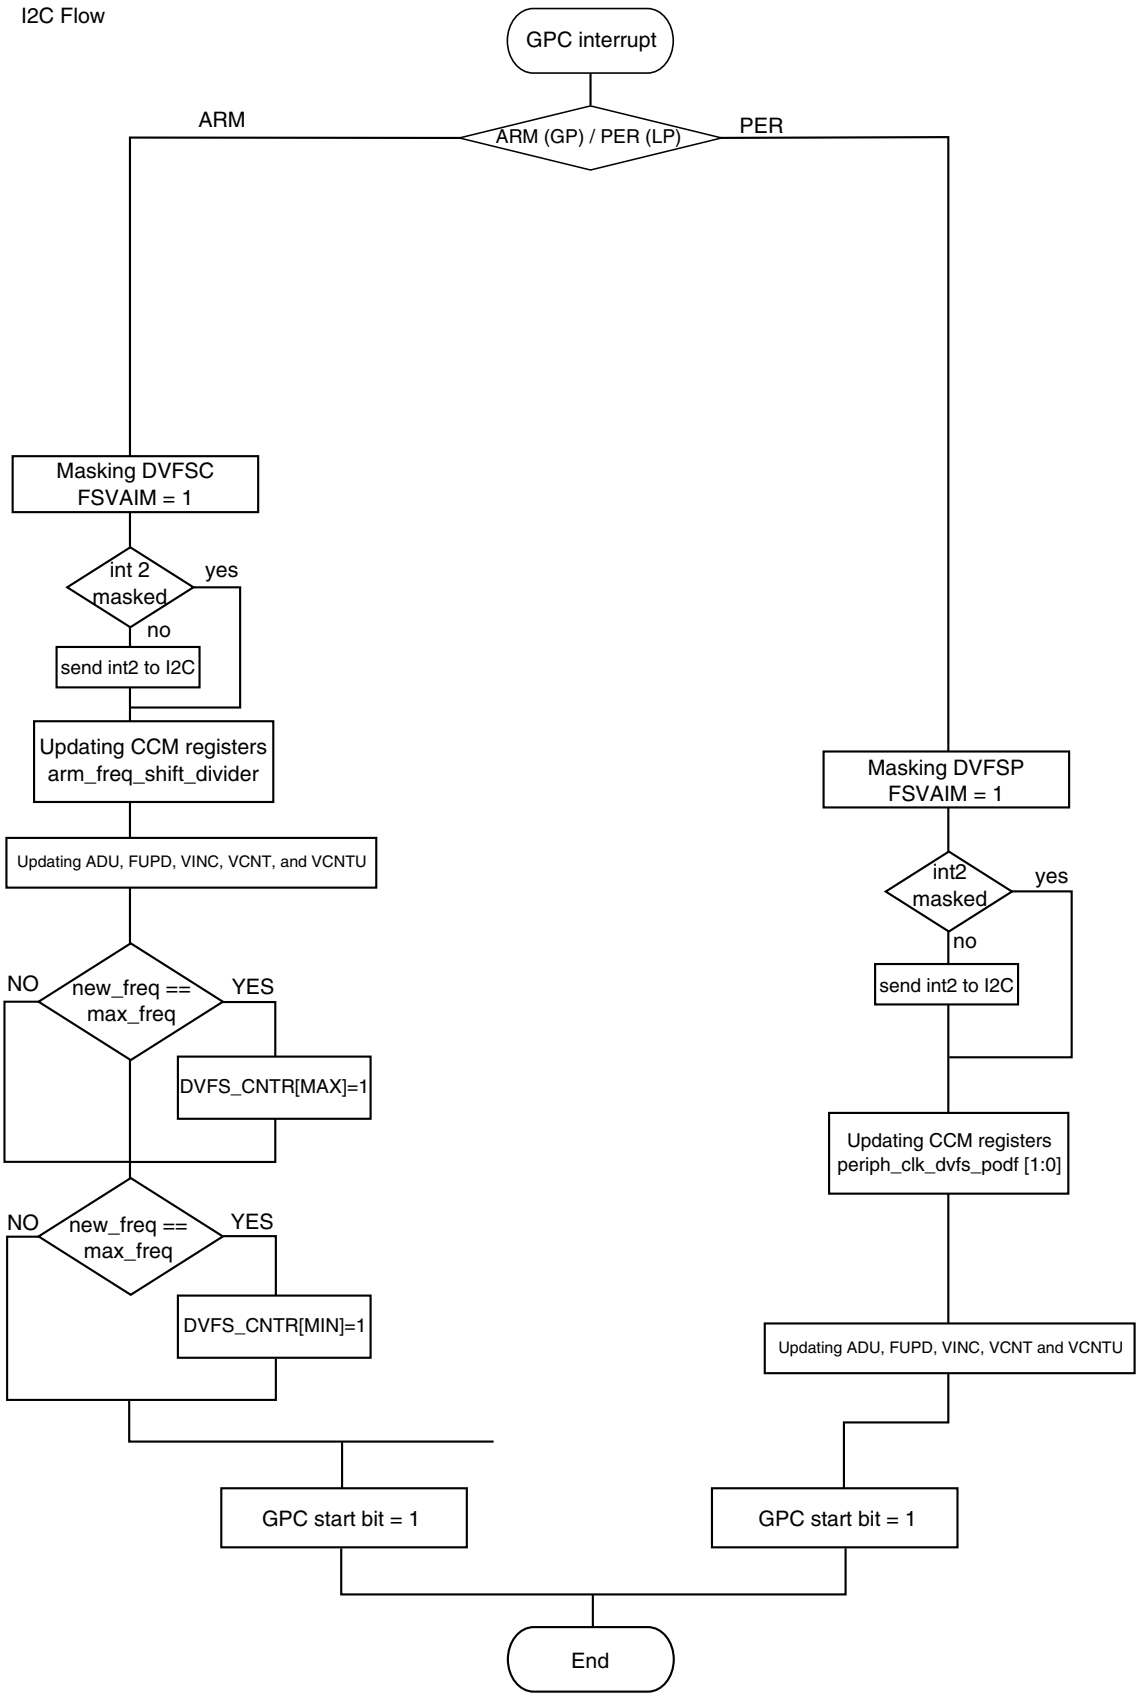

Figure 36-7. PMIC Interface Requirements IPC Flow

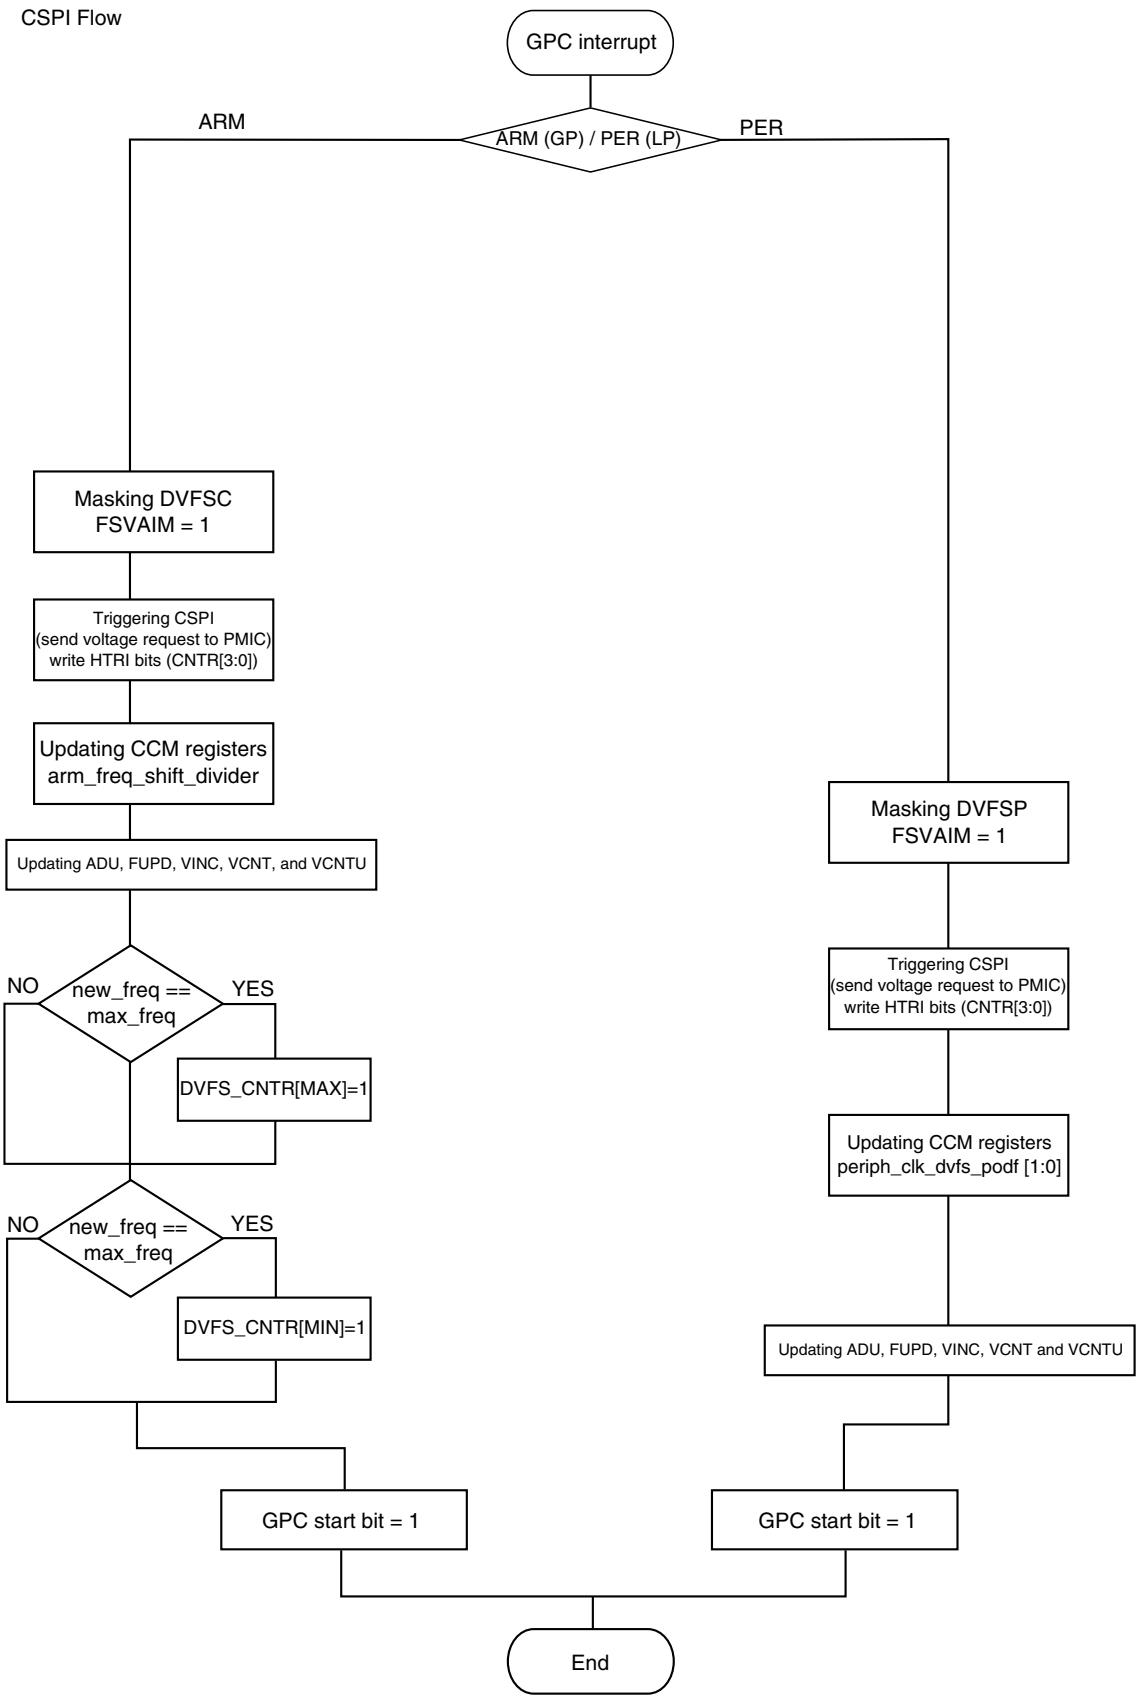

Figure 36-8. PMIC Interface Requirements CSPI Flo

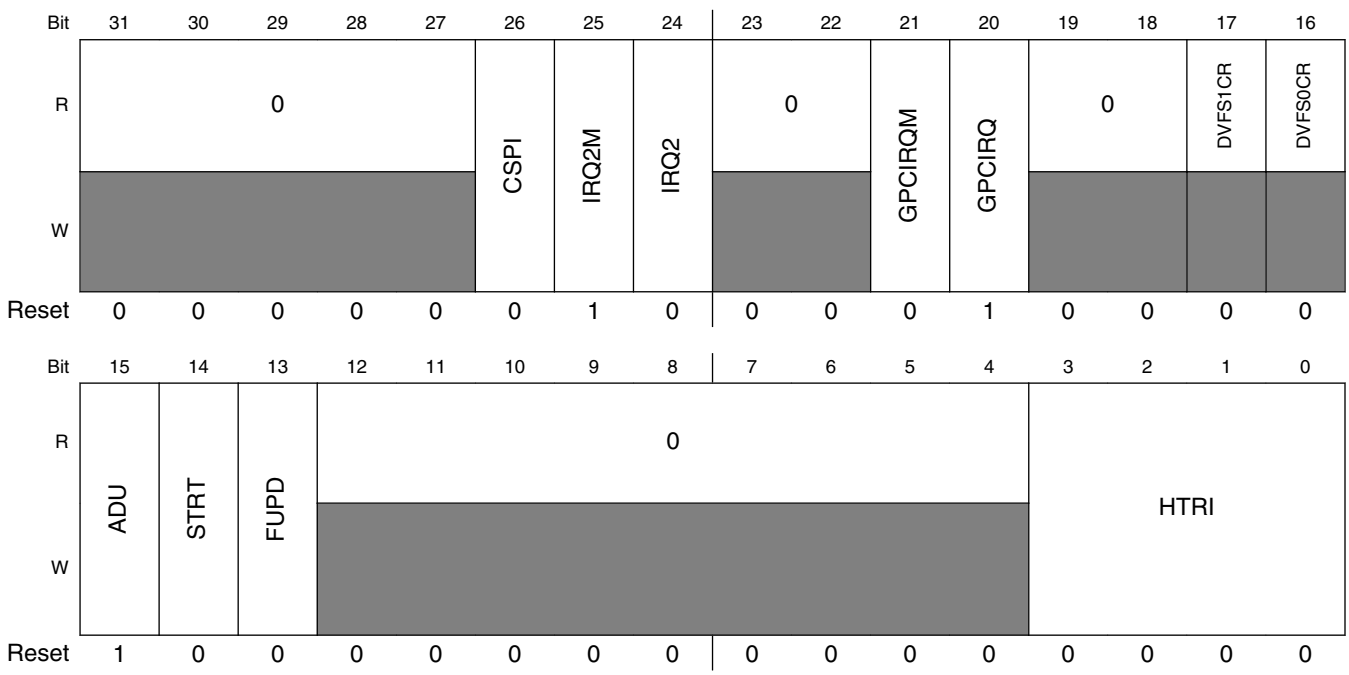
36.3 Programmable Registers

GPC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53FD_8000	Interface Control Register (GPC_CNTR)	32	R/W	0210_8000h	36.3.1/ 1716
53FD_8008	Voltage Counter Register (GPC_VCR)	32	R/W	0000_0001h	36.3.2/ 1718
53FD_8010	NEON register (GPC_NEON)	32	R/W	0000_0030h	36.3.3/ 1719

36.3.1 Interface Control Register (GPC_CNTR)

Address: GPC_CNTR is 53FD_8000h base + 0h offset = 53FD_8000h



GPC_CNTR field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

GPC_CNTR field descriptions (continued)

Field	Description
26 CSPI	CSPI or I2C is used (hw trigger will be generated or irq2 will be sent for PMIC) 0 default - I2C is in use 1 CSPI is in use
25 IRQ2M	int2 (for I2C) masking 0 int2 will be sent by GPC FSM if CSPI is '0' (I2C is in use) 1 default - int2 is masked, but GPC FSM will wait for INT2 bit to be negated by writing '1', if CSPI is '0'.
24 IRQ2	Status bit, write 1 to clear.
23–22 Reserved	This read-only field is reserved and always has the value zero. Reserved
21 GPCIRQM	GPC interrupt/event masking 1 interrupt/event is masked 0 not masked
20 GPCIRQ	GPC will generate ARM IRQ or Smart Direct Memory Access (SDMA) event, as a result of DVFS change requests 1 GPC will generate ARM IRQ 0 GPC will generate SDMA event
19–18 Reserved	This read-only field is reserved and always has the value zero. Reserved
17 DVFS1CR	DVFSP Change request (bit is read-only) 1 DVFS1 is requesting for frequency/voltage update 0 DVFS1 has no request
16 DVFS0CR	DVFSC Change request (bit is read-only) 1 DVFS0 is requesting for frequency/voltage update 0 DVFS0 has no request
15 ADU	ARM domain freq/voltage update needed 1 ARM domain frequency and/or voltage update needed 0 PER domain frequency and/or voltage update needed
14 STRT	Controller start Controller operation will be started when bit set to "1". Bit will be set automatically to "0" when frequency / voltage change finished. There is still a possibility to write "0" by s/w. 1 Controller operation in progress. No IRQ is allowed during voltage update procedure (IRQ will be masked) 0 Controller operation finished. New freq/voltage change request is available
13 FUPD	Frequency update needed 1 frequency update needed 0 frequency updated is not needed

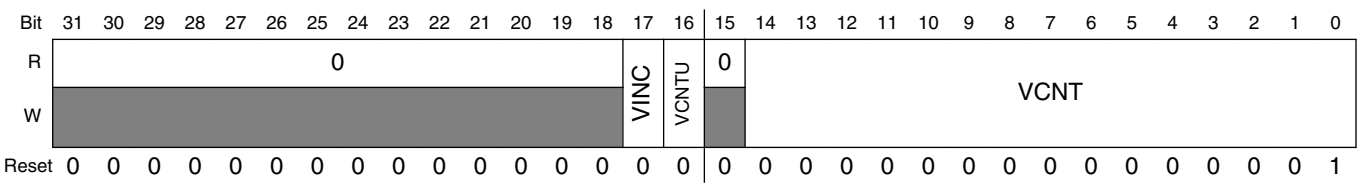
Field	Description
12–4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3–0 HTRI	Hardware Triggering Register Index Indicates which one of the CSPI h/t register will be written to the PMIC. 0000 register #0 will be triggered, 0001 register #1 will be triggered, 0010 register #3 will be triggered...

36.3.2 Voltage Counter Register (GPC_VCR)

VCR Register - Voltage Counter Register

Address: GPC_VCR is 53FD_8000h base + 8h offset = 53FD_8008h



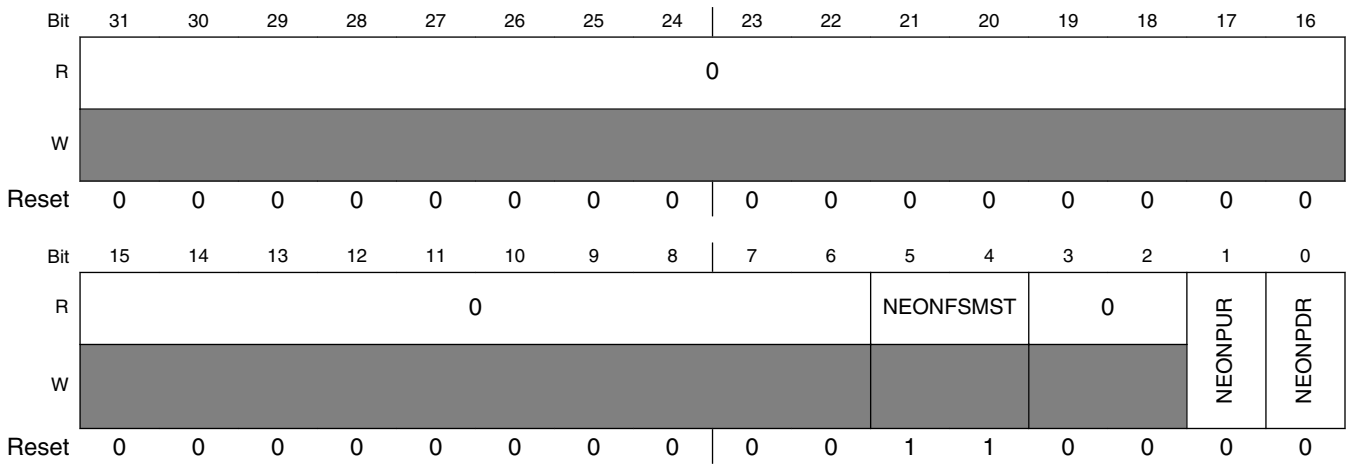
GPC_VCR field descriptions

Field	Description
31–18 Reserved	This read-only field is reserved and always has the value zero. Reserved
17 VINC	Voltage increase 1 Voltage will be increased 0 Voltage will be decreased
16 VCNTU	Voltage Count Used 1 VCNT is used 0 VCNT is not used, "voltage ready" signal of PMIC will be used.
15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14–0 VCNT	Voltage update Count Counting delay of the voltage update, if PMIC's "voltage ready" signal is not used Counter is using SYS_CLK (CKIH) clock

36.3.3 NEON register (GPC_NEON)

NEON Register - Register Control Power for NEON

Address: GPC_NEON is 53FD_8000h base + 10h offset = 53FD_8010h



GPC_NEON field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5–4 NEONFSMST	Neon FSM status bits - state of Neon State Machine: 11 Power up acknowledge / Normal state 01 Power down request 00 Power down acknowledge 10 Power up request
3–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 NEONPUR	NEON Power Up Request. Assertion causes Neon PowerDown state machine to change state from PowerDown to PowerUp request. Will clear itself after a single clock.
0 NEONPDR	NEON Power Down Request. Assertion starts Neon PowerDown state machine. Will clear itself after a single clock.

Chapter 37
General Purpose Input/Output (GPIO)

37.1 Introduction

The GPIO generates up to 32 signals for general-purpose.

A block diagram of the GPIO is shown in .

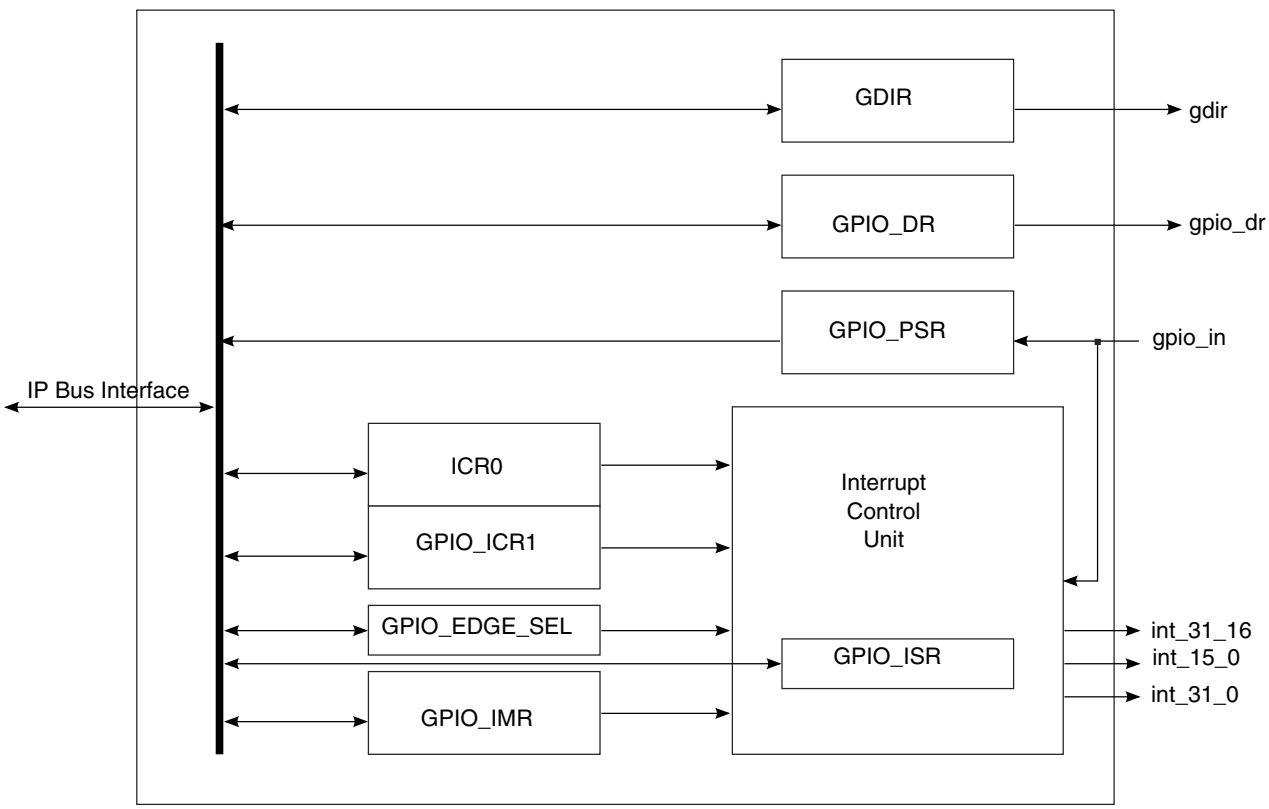


Figure 37-1. GPIO Block Diagram

37.2 General Overview

The GPIO general-purpose input/output peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs.

When configured as an output, it is possible to write to an internal register to control the state driven on the output pin. When configured as an input, it is possible to detect the state of the input by reading the state of an internal register.

In addition, the GPIO peripheral can produce CORE interrupts.

The GPIO is one of the blocks controlling the IOMUX of the Chip.

shows the Chip multiplexing scheme.

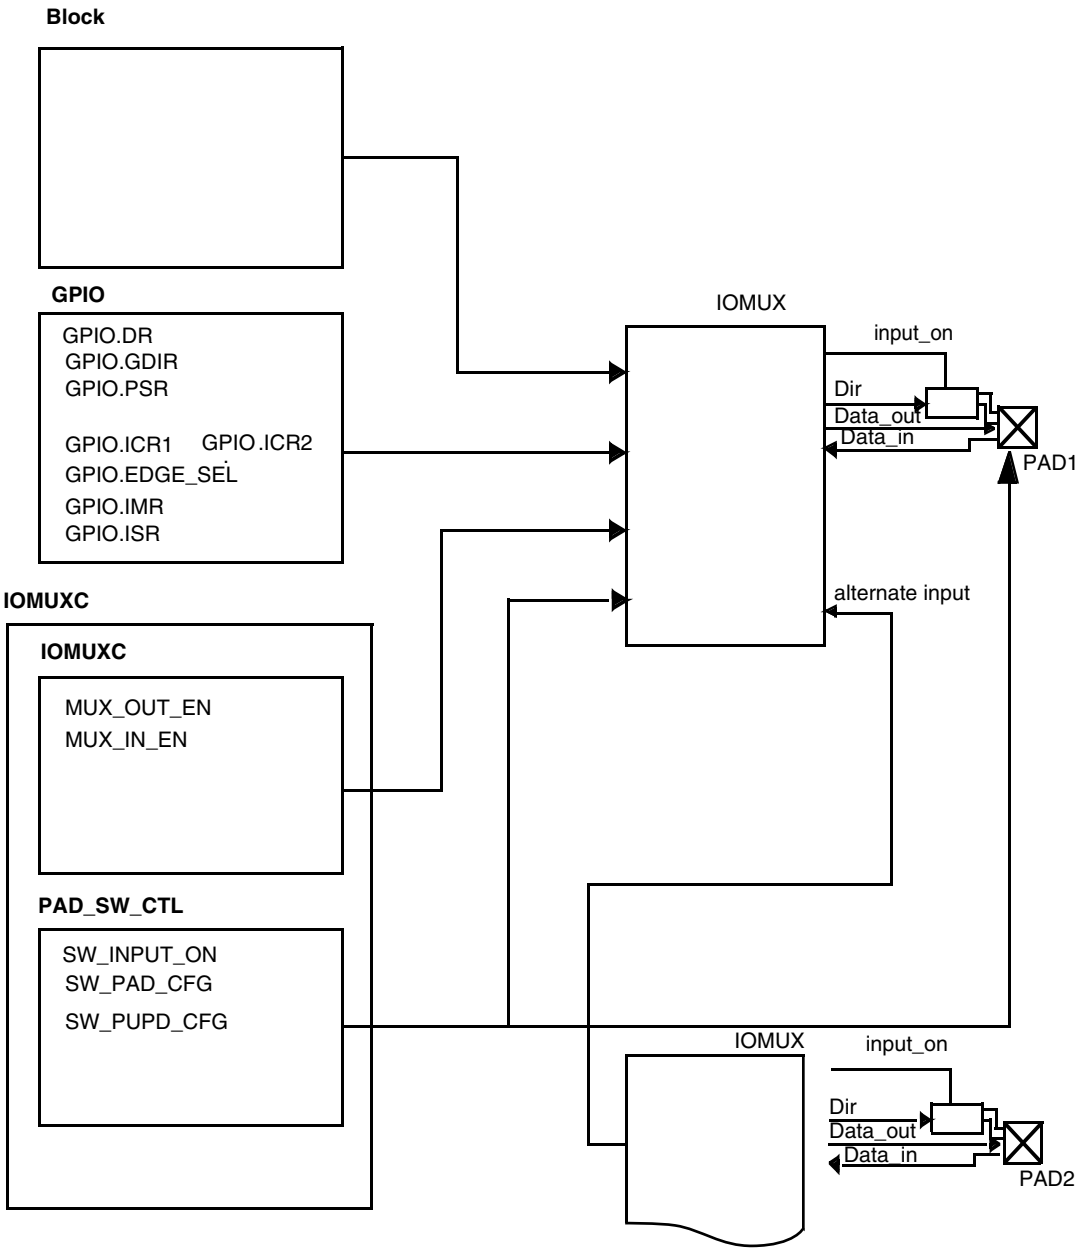

Figure 37-2. Chip IOMUX Scheme

The GPIO functionality is provided through eight registers, an edge-detect circuit, and interrupt generation logic.

The eight registers are:

- Data register (GPIO_DR)
- GPIO direction register (GPIO_GDIR)
- Pad sample register (GPIO_PSR)
- Interrupt control registers (GPIO_ICR1, GPIO_ICR2)

- Edge select register (GPIO_EDGE_SEL)
- Interrupt mask register (GPIO_IMR)
- Interrupt status register (GPIO_ISR)

Each GPIO input has a dedicated edge-detect circuit which can be configured through software to detect rising edges, falling edges, logic low-levels or logic high-levels on the input signals. The outputs of the edge detect circuits are optionally masked by setting the corresponding bit in the interrupt mask register (GPIO_IMR). These qualified outputs are OR'ed together to generate three one-bit interrupt lines:

- interrupt_or_31_16: One-bit interrupt OR of 16 high interrupts.
- interrupt_or_15_0: One-bit interrupt OR of 16 low interrupts.
- ipi_gpio_int: One-bit interrupt OR of 32 interrupts.

In addition, the 32-bit signal ipi_gpio_int32 gives the user access to all 32 individual interrupts.

37.2.1 Features

The GPIO includes the following features:

- General purpose input/output logic capabilities:
  - Drives specific data to output using the data register (GPIO_DR)
  - Controls the direction of the signal using the GPIO direction register (GPIO_GDR)
  - Enables the core to sample the status of the corresponding inputs by reading the pad sample register (GPIO_PSR).
- GPIO interrupt capabilities:
  - Supports up to 32 interrupts
  - Identifies interrupt edges
  - Generates three active-high interrupts to the SoC interrupt controller

37.3 GPIO Functional Description

37.3.1 GPIO Function

A GPIO signal can operate as a general-purpose input/output when the IOMUX is set to GPIO mode. Each GPIO signal may be independently configured as either an input or an output using the GPIO direction register (GPIO_GDIR).

When configured as an output (GPIO_GDIR bit = 1), the value in the data bit in the GPIO data register (GPIO_DR) is driven on the corresponding GPIO line. When a signal is configured as an input (GPIO_GDIR bit = 0), the state of the input can be read from the corresponding PSR bit.

37.3.2 GPIO Programming

37.3.2.1 GPIO Read Mode

The programming sequence for reading input signals should be as follows:

1. Configure IOMUX to select GPIO mode (Via IOMUX Controller (IOMUXC)).
2. Configure GPIO direction register (GPIO_GDR) to input.
3. Read value from data reg*ister*/pad status register.

A pseudocode description to read [input3:input0] values is as follows:

```
write sw_mux_ctl_<input0>_<input1>_<input2>_<input3> , 32'h00000000  // SET INPUTS TO
GPIO MODE.
write GDIR[31:4,input3_bit, input2_bit, input1_bit, input0_bit,] 32'hxxxxxxx0   // SET GDIR
TO
INPUT.
read DR             // READ INPUT VALUE FROM DR.
read PSR            // READ INPUT VALUE FROM PSR.
```

NOTE

While the GPIO direction is set to input (GPIO_GDIR = 0), a read access to GPIO_DR does not return GPIO_DR data. Instead, it returns the PSR data, which is the corresponding input signal value.

37.3.2.2 GPIO Write Mode

The programming sequence for driving output signals should be as follows:

1. Configure IOMUX to select GPIO mode (Via IOMUXC).
2. Configure GPIO direction register (GPIO_GDR) to output.
3. Write value to data register (GPIO_DR).

A pseudocode description to drive 4'b0101 on [output3:output0] is as follows:

```
write sw_mux_ctl_<output0>_<output1>_<output2>_<output3> , 32'h00000000  // SET OUTPUTS
TO GPIO MODE.
write GDIR[31:4,output3_bit,output2_bit, output1_bit, output0_bit,] 32'hxxxxxxxF    // SET
GDIR
TO OUTPUT.
```

```
write DR, 32'hxxxxxxx5          // WRITE OUTPUT VALUE TO DR.
read_cmp PSR, 32'hxxxxxxx5          // READ OUTPUT VALUE FROM PSR ONLY.
```

NOTE

While GPIO direction is set to output, the real internal value can only be verified through the GPIO_PSR, and not through the GPIO_DR.

37.3.3 Interrupt Control Unit

In addition to the general-purpose input/output function, the edge-detect logic in the GPIO peripheral reflects whether a transition has occurred on a given GPIO signal that is configured as an input (GDIR bit = 0). The interrupt control registers (GPIO_ICR1 and GPIO_ICR2) may be used to independently configure the interrupt condition of each input signal (low-to-high transition, high-to-low transition, low, or high).

The interrupt control unit is built of 32 interrupt control subunits, where each subunit handles a single interrupt line.

37.4 Programmable Registers

There are eight 32-bit GPIO registers. All registers are accessible from the IP interface. Only 32-bit access is supported.

The GPIO memory map is shown in the following table.

GPIO memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53F8_4000	GPIO data register (GPIO-1_DR)	32	R/W	0000_0000h	37.4.1/ 1729
53F8_4004	GPIO direction register (GPIO-1_GDIR)	32	R/W	0000_0000h	37.4.2/ 1731
53F8_4008	GPIO pad status register (GPIO-1_PSR)	32	R	0000_0000h	37.4.3/ 1732
53F8_400C	GPIO interrupt configuration register1 (GPIO-1_ICR1)	32	R/W	0000_0000h	37.4.4/ 1733
53F8_4010	GPIO interrupt configuration register2 (GPIO-1_ICR2)	32	R/W	0000_0000h	37.4.5/ 1737

Table continues on the next page...

GPIO memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

37.4.1 GPIO data register (GPIOx_DR)

The 32-bit GPIO_DR register stores data that is ready to be driven to the output lines. If the IOMUXC is in GPIO mode and a given GPIO direction bit is set, then the corresponding DR bit is driven to the output. If a given GPIO direction bit is cleared, then a read of GPIO_DR reflects the value of the corresponding signal.Two wait states are required in read access for synchronization.

The results of a read of a DR bit depends on the IOMUXC input mode settings and the corresponding GDIR bit as follows:

- If GDIR[*n*] is set and IOMUXC input mode is GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and IOMUXC input mode is GPIO, then reading DR[*n*] returns the corresponding input signal's value.

- If GDIR[*n*] is set and IOMUXC input mode is not GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and IOMUXC input mode is not GPIO, then reading DR[*n*] always returns zero.

Addresses: GPIO-1_DR is 53F8_4000h base + 0h offset = 53F8_4000h
GPIO-2_DR is 53F8_8000h base + 0h offset = 53F8_8000h
GPIO-3_DR is 53F8_C000h base + 0h offset = 53F8_C000h
GPIO-4_DR is 53F9_0000h base + 0h offset = 53F9_0000h
GPIO-5_DR is 53FD_C000h base + 0h offset = 53FD_C000h
GPIO-6_DR is 53FE_0000h base + 0h offset = 53FE_0000h
GPIO-7_DR is 53FE_4000h base + 0h offset = 53FE_4000h

GPIOx_DR field descriptions

Field	Description
31–0 DR	Data bits. This register defines the value of the GPIO output when the signal is configured as an output (GDIR[n]=1). Writes to this register are stored in a register. Reading GPIO_DR returns the value stored in the register if the signal is configured as an output (GDIR[n]=1), or the input signal's value if configured as an input (GDIR[n]=0). **NOTE:** The I/O multiplexer must be configured to GPIO mode for the GPIO_DR value to connect with the signal. Reading the data register with the input path disabled always returns a zero value.

37.4.2 GPIO direction register (GPIOx_GDIR)

GPIO_GDIR functions as direction control when the IOMUXC is in GPIO mode. Each bit specifies the direction of a one-bit signal. The mapping of each DIR bit to a corresponding SoC signal is determined by the SoC's pin assignment and the IOMUX table-for more details consult the IOMUXC chapter.

Addresses: GPIO-1_GDIR is 53F8_4000h base + 4h offset = 53F8_4004h
GPIO-2_GDIR is 53F8_8000h base + 4h offset = 53F8_8004h
GPIO-3_GDIR is 53F8_C000h base + 4h offset = 53F8_C004h
GPIO-4_GDIR is 53F9_0000h base + 4h offset = 53F9_0004h
GPIO-5_GDIR is 53FD_C000h base + 4h offset = 53FD_C004h
GPIO-6_GDIR is 53FE_0000h base + 4h offset = 53FE_0004h
GPIO-7_GDIR is 53FE_4000h base + 4h offset = 53FE_4004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

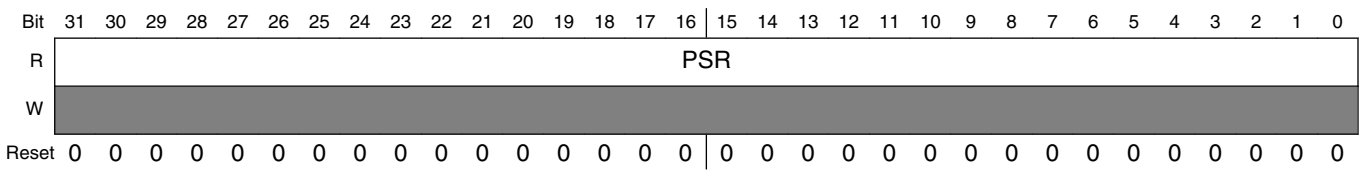
GPIOx_GDIR field descriptions

Field	Description
31–0 GDIR	GPIO direction bits. Bit n of this register defines the direction of the GPIO[n] signal. **NOTE:** GPIO_GDIR affects only the direction of the I/O signal when the corresponding bit in the I/O MUX is configured for GPIO. 0 GPIO is configured as input. 1 GPIO is configured as output.

37.4.3 GPIO pad status register (GPIOx_PSR)

GPIO_PSR is a read-only register. Each bit stores the value of the corresponding input signal (as configured in the IOMUX). This register is clocked with the ipg_clk_s clock, meaning that the input signal is sampled only when accessing this location. Two wait states are required any time this register is accessed for synchronization.

Addresses: GPIO-1_PSR is 53F8_4000h base + 8h offset = 53F8_4008h
GPIO-2_PSR is 53F8_8000h base + 8h offset = 53F8_8008h
GPIO-3_PSR is 53F8_C000h base + 8h offset = 53F8_C008h
GPIO-4_PSR is 53F9_0000h base + 8h offset = 53F9_0008h
GPIO-5_PSR is 53FD_C000h base + 8h offset = 53FD_C008h
GPIO-6_PSR is 53FE_0000h base + 8h offset = 53FE_0008h
GPIO-7_PSR is 53FE_4000h base + 8h offset = 53FE_4008h



GPIOx_PSR field descriptions

Field	Description
31–0 PSR	GPIO pad status bits (status bits). Reading GPIO_PSR returns the state of the corresponding input signal. Settings: **NOTE:** The I/O multiplexer must be configured to GPIO mode for GPIO_PSR to reflect the state of the corresponding signal.

37.4.4 GPIO interrupt configuration register1 (GPIOx_ICR1)

GPIO_ICR1 contains 16 two-bit fields, where each field specifies the interrupt configuration for a different input signal.

Addresses: GPIO-1_ICR1 is 53F8_4000h base + Ch offset = 53F8_400Ch
GPIO-2_ICR1 is 53F8_8000h base + Ch offset = 53F8_800Ch
GPIO-3_ICR1 is 53F8_C000h base + Ch offset = 53F8_C00Ch
GPIO-4_ICR1 is 53F9_0000h base + Ch offset = 53F9_000Ch
GPIO-5_ICR1 is 53FD_C000h base + Ch offset = 53FD_C00Ch
GPIO-6_ICR1 is 53FE_0000h base + Ch offset = 53FE_000Ch
GPIO-7_ICR1 is 53FE_4000h base + Ch offset = 53FE_400Ch

GPIOx_ICR1 field descriptions

Field	Description
31–30 ICR15	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
29–28 ICR14	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
27–26 ICR13	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive.

Table continues on the next page...

GPIOx_ICR1 field descriptions (continued)

Field	Description
	10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
25–24 ICR12	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
23–22 ICR11	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
21–20 ICR10	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
19–18 ICR9	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
17–16 ICR8	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive.

Table continues on the next page...

GPIOx_ICR1 field descriptions (continued)

Field	Description
	10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
15–14 ICR7	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
13–12 ICR6	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
11–10 ICR5	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
9–8 ICR4	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
7–6 ICR3	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive.

Table continues on the next page...

GPIOx_ICR1 field descriptions (continued)

Field	Description
	10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
5–4 ICR2	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
3–2 ICR1	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.
1–0 ICR0	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.

37.4.5 GPIO interrupt configuration register2 (GPIOx_ICR2)

GPIO_ICR2 contains 16 two-bit fields, where each field specifies the interrupt configuration for a different input signal.

Addresses: GPIO-1_ICR2 is 53F8_4000h base + 10h offset = 53F8_4010h
GPIO-2_ICR2 is 53F8_8000h base + 10h offset = 53F8_8010h
GPIO-3_ICR2 is 53F8_C000h base + 10h offset = 53F8_C010h
GPIO-4_ICR2 is 53F9_0000h base + 10h offset = 53F9_0010h
GPIO-5_ICR2 is 53FD_C000h base + 10h offset = 53FD_C010h
GPIO-6_ICR2 is 53FE_0000h base + 10h offset = 53FE_0010h
GPIO-7_ICR2 is 53FE_4000h base + 10h offset = 53FE_4010h

37.4.6 GPIO interrupt mask register (GPIOx_IMR)

GPIO_IMR contains masking bits for each interrupt line.

Addresses: GPIO-1_IMR is 53F8_4000h base + 14h offset = 53F8_4014h
GPIO-2_IMR is 53F8_8000h base + 14h offset = 53F8_8014h
GPIO-3_IMR is 53F8_C000h base + 14h offset = 53F8_C014h
GPIO-4_IMR is 53F9_0000h base + 14h offset = 53F9_0014h
GPIO-5_IMR is 53FD_C000h base + 14h offset = 53FD_C014h
GPIO-6_IMR is 53FE_0000h base + 14h offset = 53FE_0014h
GPIO-7_IMR is 53FE_4000h base + 14h offset = 53FE_4014h

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

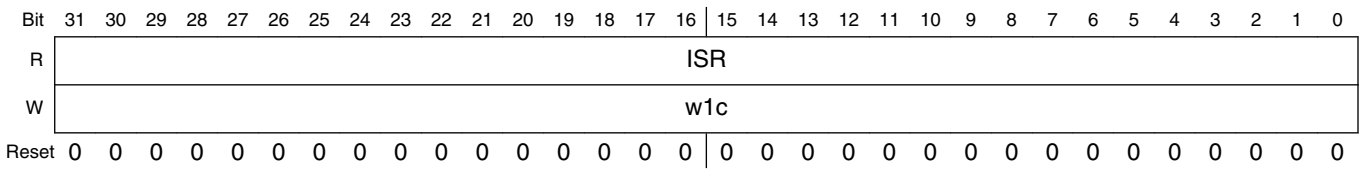
GPIOx_IMR field descriptions

Field	Description
31–0 IMR	Interrupt Mask bits. This register is used to enable or disable the interrupt function on each of the 32 GPIO signals. Settings: Bit IMR[n] (n=0...31) controls interrupt n as follows: 0 Interrupt n is disabled. 1 Interrupt n is enabled.

37.4.7 GPIO interrupt status register (GPIOx_ISR)

The GPIO_ISR functions as an interrupt status indicator. Each bit indicates whether an interrupt condition has been met for the corresponding input signal. When an interrupt condition is met (as determined by the corresponding interrupt condition register field), the corresponding bit in this register is set. Two wait states are required in read access for synchronization. One wait state is required for reset.

Addresses: GPIO-1_ISR is 53F8_4000h base + 18h offset = 53F8_4018h
GPIO-2_ISR is 53F8_8000h base + 18h offset = 53F8_8018h
GPIO-3_ISR is 53F8_C000h base + 18h offset = 53F8_C018h
GPIO-4_ISR is 53F9_0000h base + 18h offset = 53F9_0018h
GPIO-5_ISR is 53FD_C000h base + 18h offset = 53FD_C018h
GPIO-6_ISR is 53FE_0000h base + 18h offset = 53FE_0018h
GPIO-7_ISR is 53FE_4000h base + 18h offset = 53FE_4018h



GPIOx_ISR field descriptions

Field	Description
31–0 ISR	Interrupt status bits - Bit n of this register is asserted (active high) when the active condition (as determined by the corresponding ICR bit) is detected on the GPIO input and is waiting for service. The value of this register is independent of the value in GPIO_IMR. When the active condition has been detected, the corresponding bit remains set until cleared by software. Status flags are cleared by writing a 1 to the corresponding bit position.

37.4.8 GPIO edge select register (GPIOx_EDGE_SEL)

GPIO_EDGE_SEL may be used to override the ICR registers' configuration. If the GPIO_EDGE_SEL bit is set, then a rising edge or falling edge in the corresponding signal generates an interrupt. This register provides backward compatibility. On reset all bits are cleared (ICR is not overridden).

Addresses: GPIO-1_EDGE_SEL is 53F8_4000h base + 1Ch offset = 53F8_401Ch
GPIO-2_EDGE_SEL is 53F8_8000h base + 1Ch offset = 53F8_801Ch
GPIO-3_EDGE_SEL is 53F8_C000h base + 1Ch offset = 53F8_C01Ch
GPIO-4_EDGE_SEL is 53F9_0000h base + 1Ch offset = 53F9_001Ch
GPIO-5_EDGE_SEL is 53FD_C000h base + 1Ch offset = 53FD_C01Ch
GPIO-6_EDGE_SEL is 53FE_0000h base + 1Ch offset = 53FE_001Ch
GPIO-7_EDGE_SEL is 53FE_4000h base + 1Ch offset = 53FE_401Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPIOx_EDGE_SEL field descriptions

Field	Description
31–0 GPIO_EDGE_SEL	Edge select. When GPIO_EDGE_SEL[*n*] is set, the GPIO disregards the ICR[*n*] setting, and detects any edge on the corresponding input signal.

Chapter 38
General Purpose Timer (GPT)

38.1 Overview

This chapter describes the General Purpose Timer (GPT) module interface. It is also a reference for software driver programming. The GPT has a 32-bit up-counter. The timer counter value can be captured in a register using an event on an external pin. The capture trigger can be programmed to be a rising or/and falling edge. The GPT can also generate an event on the DO_CMPOUT*n* pins and an interrupt when the timer reaches a programmed value. The GPT has a 12-bit prescaler, which provides a programmable clock frequency derived from multiple clock sources.

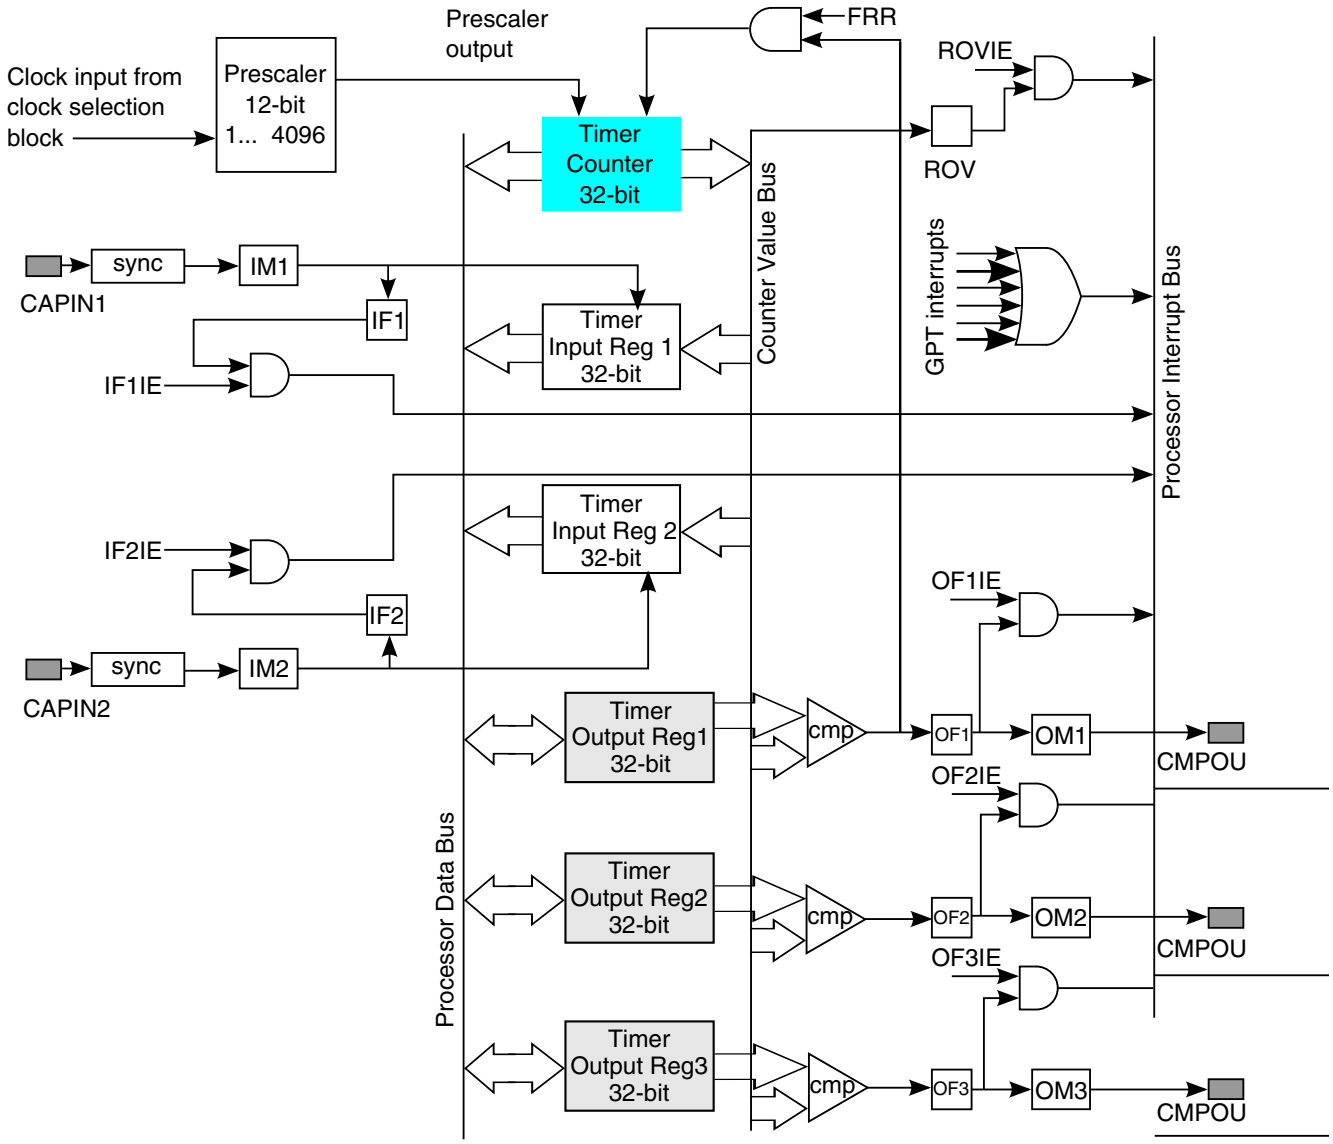

Figure 38-1. GPT Block Diagram

The following figure shows the GPT functional clocking scheme.

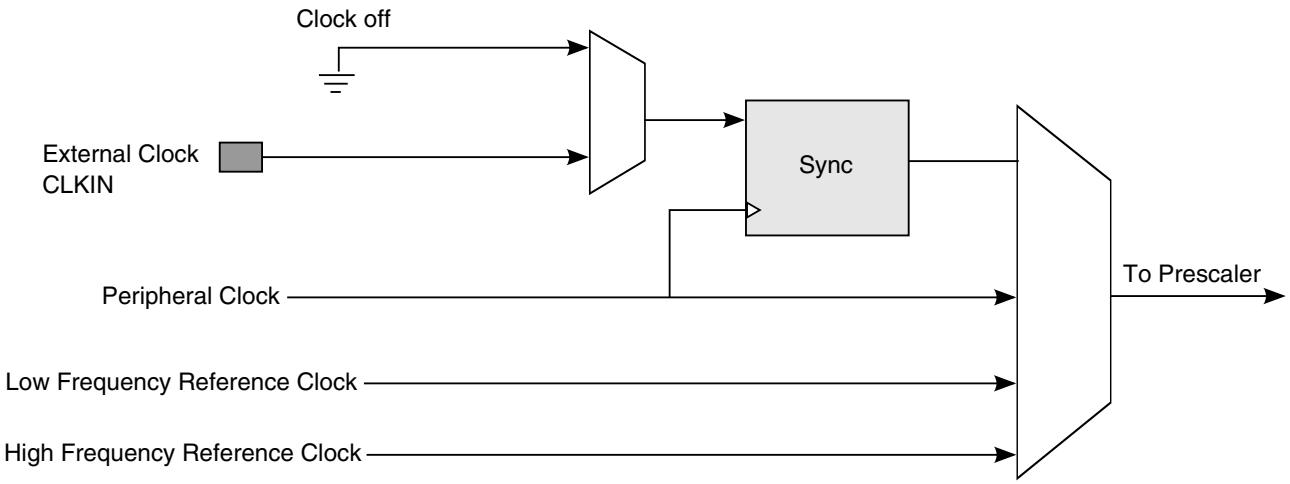

Figure 38-2. GPT Counter Clocks Diagram

38.1.1 Features

- One 32-bit up-counter with clock source selection, including external clock.
- Two input capture channels with a programmable trigger edge.
- Three output compare channels with a programmable output mode. A "forced compare" feature is also available.
- Can be programmed to be *active* in low power and debug modes.
- Interrupt generation at capture, compare, and rollover events.
- Restart or free-run modes for counter operations.

38.1.2 Modes and Operation

The GPT supports the modes described in the indicated sections:

- Operating Modes
  - Restart Mode
  - Free-Run Mode

38.2 External Signals

The GPT follows the IP Bus protocol for interfacing with the processor core. The GPT does not have *any interface signals with any other module inside the chip,* except for the clock and reset inputs (from the clock and reset controller module) and for the interrupt signals *to* the processor interrupt handler. There are functional and clock inputs, and functional output signals going outside the chip boundary.

The following table describes all block signals that connect off-chip.

Table 38-1. Off-Chip Module Signals

Name	Direction	Function	Reset State	Pull-Up
IND_CLKIN	I	Input pin for an external clock that the counter can be operated at.	-	Passive Hysteresis
IND_CAPIN1	I	Input pin for a capture event for Input Capture Channel 1.	-	Passive
IND_CAPIN2	I	Input pin for a capture event for Input Capture Channel 2.	-	Passive
DO_CMPOUT1	O	Output pin that indicates a "compare event" occurrence in Output Compare Channel 1.	0	Passive
DO_CMPOUT2	O	Output pin that indicates a "compare event" occurrence in Output Compare Channel 2.	0	Passive
DO_CMPOUT3	O	Output pin that indicates a "compare event" occurrence in Output Compare Channel 3.	0	Passive

There are six signals (three input, three output) in the GPT module that *can be* connected to the chip pads.

38.2.1 External Clock Input: IND_CLKIN

The GPT counter can be operated using an external clock from outside the device, and this is the input pin used for that purpose. This clock is treated as asynchronous to the peripheral clock. To ensure proper operations of GPT, the external clock input frequency should be less than 1/4 of frequency of the peripheral clock. Hysteresis characteristics on this pad will be required because this is a clock input.

38.2.2 Input Capture Trigger Signals: IND_CAPIN1, IND_CAPIN2

The GPT counter value can be stored in a register, triggered by an event from *outside the device*. A positive or/and negative edge on these signals can trigger this capture event. These signals are treated as asynchronous to the peripheral clock. Only those transitions which occur *at least a single clock cycle* (the clock selected to run the counter) *after the previous recorded transition* are guaranteed to trigger a capture event.

38.2.3 Output Compare Signals: DO_CMPOUT1, DO_CMPOUT2, DO_CMPOUT3

The output compare signals indicate that output compare events have gone through a specified transition.

38.3 Functional Description

This section provides a complete functional description of the GPT.

38.3.1 Operating Modes

The GPT counter can be programmed to work in either of two modes: Restart mode or Free-Run mode.

38.3.1.1 Restart Mode

In Restart mode (selectable through the GPT Control Register GPT_CR), when the counter reaches the compared value, the counter resets and starts again from 0x00000000. The Restart feature is associated only with Compare Channel 1.

Any write access to the Compare register of Channel 1 will reset the GPT counter. This is done to avoid possibly missing a compare event when compare value is changed from a higher value to lower value while counting is proceeding.

For the other two compare channels, when the compare event occurs the counter is *not reset*.

38.3.1.2 Free-Run Mode

In Free-Run mode, when compare events occur for all 3 channels, the counter is *not reset*; instead the counter continues to count until 0xffffffff, and then rolls over (to 0x00000000).

38.3.2 Operation

The General Purpose Timer (GPT) has a single counter (GPT_CNT) that is a 32-bit free-running *up-counter,* which starts counting *after it is enabled by software* (EN=1).

The counter's clock source is the output of the prescaler labelled "Prescaler output" in Figure 38-1.

- If the GPT timer is disabled (EN=0), then the Main Counter *and* Prescaler Counter freeze their current count values. The ENMOD bit determines the value of the GPT counter when the EN bit is set and the Counter is enabled again.
  - If the ENMOD bit is set (=1), then the Main Counter and Prescaler Counter values are reset to 0, when GPT is enabled (EN=1).
  - If ENMOD bit is programmed to 0, then the Main Counter and Prescaler Counter restart counting from their frozen values, when GPT is enabled again (EN=1).
- If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then the Main Counter and Prescaler Counter freeze at their current count values *when* GPT enters low power mode. When GPT exits a low power mode, the Main Counter and Prescaler Counter start counting from their frozen values *regardless* of the ENMOD bit value. Note that the GPT_CNT can be read *at any time* by the processor, and that *both* Input Capture Channels use the *same* counter (GPT_CNT).
- A hardware reset resets all the GPT registers to their respective reset values. All registers except the Output Compare Registers (OCR1, OCR2, OCR3) obtain a value of 0x0. The Compare registers are reset to 0xffffffff.
- The software reset (SWR bit in the GPT_CR control register) resets *all* of the register bits *except* the EN, ENMOD, STOPEN, WAITEN, and DBGEN bits. The state of these bits is not affected by a software reset. Note that a software reset can be given *while the GPT is disabled.*

38.3.2.1 Clocks

The clock that is input to the prescaler can be selected from 4 clock sources:

- High Frequency Clock

Provided by the Clock Controller Module (CCM), the High Frequency Clock is intended to be ON in Normal Power mode when the Peripheral Clock is turned OFF, thereby enabling the GPT to be operated using the High Frequency Clock *in Normal Power mode*. The CCM is expected to provide this clock *after* synchronizing it to the System Bus Clock in Normal functional mode; the CCM is also expected to switch to the *unsynchronized* version of the High Frequency Clock in a Low Power mode.

- Low Reference Clock

  This 32 kHz Low Reference Clock (provided by the CCM) is intended to be ON in Low Power mode when the Peripheral Clock is turned OFF, thereby enabling the GPT to be operated using the Low Reference Clock in Low Power mode. The CCM is expected to provide the Low Reference Clock *after* synchronizing it to the System Bus Clock in Normal functional mode; the CCM is also expected to switch to the *unsynchronized* version of the Low Reference Clock in a Low Power mode.

- External Clock

  The External Clock comes from *outside the device* and can be selected to run the GPT counter. The External Clock is treated as *asynchronous to the Peripheral Clock,* and is synchronized to the Peripheral Clock, *inside* the module. Therefore, the External Clock frequency is limited to < 1/4 frequency of the Peripheral Clock, for proper GPT operations. Note that in Low Power modes, *if* the Peripheral Clock is not available, then the External Clock *cannot be used* to run the counter.

- Peripheral Clock

  If the Peripheral Clock or the External Clock is selected(CLKSRC=001 or 011) as Clock Source, then the Peripheral Clock will be ON in normal GPT operations. In Low Power modes, if the GPT is programmed to be disabled (STOPEN or WAITEN or DOZEN=0), then the Peripheral Clock can be switched OFF.

- Crystal Oscillator Clock

  This 24MHz Crystal Oscillator Clock (provided by the CCM) is intended to be used against frequency change of Peripheral Clock changes to provide a more accruate timer clock for operation system. The CCM is expected to provide the 24M Crystal Oscillator Clock *without* synchronizing it to the System Bus Clock in Normal functional mode. Synchronization is done in GPT module. Before synchronization, the 24M Crystal Oscillator Clock is divided by a 24M clock prescaler, to make sure the clock frequency less than half of System Bus Clock .

The clock input source is configured using the clock source field (CLKSRC, in the GPT_CR control register). The clock input to the prescaler can be disabled by programming the CLKSRC bits (of the GPT_CR control register) to 000. **The CLKSRC field value should be changed** *only after disabling the GPT* (by setting the EN bit in the GPT_CR to 0).

The PRESCALER field selects the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by a value (from 1 to 4096) and can be changed *at any time*. A change in the value of the PRESCALER field *immediately affects* the output clock frequency.

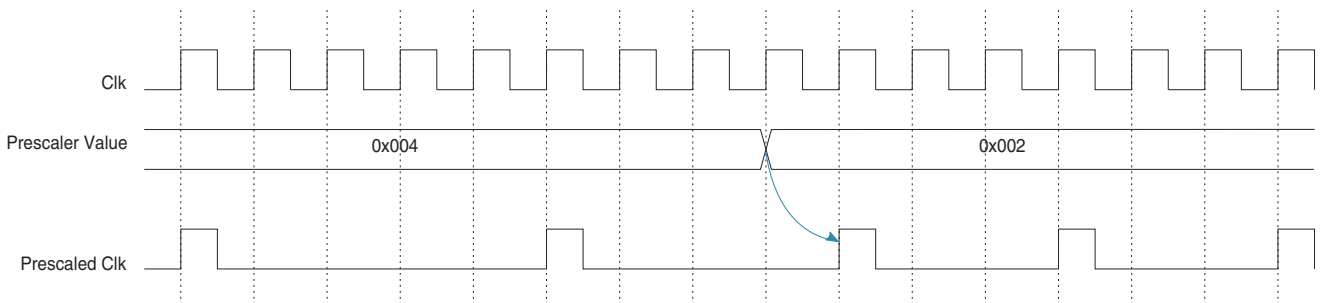

Figure 38-3. Prescaler Value Change Timing Diagram

38.3.2.2 Input Capture

There are two Input Capture Channels, and each Input Capture Channel has a dedicated capture pin, capture register and input edge detection/selection logic. Each input capture function has an associated status flag, and can cause the processor to make an interrupt service request.

When a selected edge transition occurs on an Input Capture pin, the contents of the GPT_CNT is captured on the corresponding capture register and the appropriate interrupt status flag is set. An interrupt request can be generated when the transition is detected *if* its corresponding enable bit is set (in the Interrupt Register). The capture can be programmed to occur on the input pin's rising edge, falling edge, on both rising and falling edges, or the capture can be disabled. The events are synchronized with the clock that was selected to run the counter. Only those transitions that occur at least one clock cycle (clock selected to run the counter) *after* the previous recorded transition will be guaranteed to trigger a capture event. There can be up to one clock cycle of uncertainty in the latching of the input transition. The Input Capture registers can be read *at any time* without affecting their values.

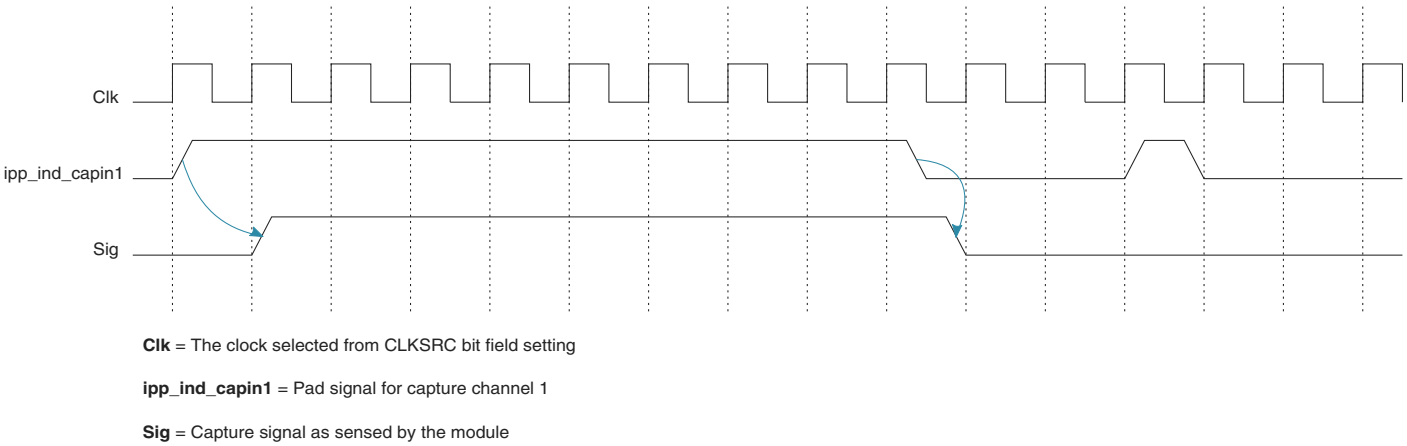

Figure 38-4. Input Capture Event Timing

38.3.2.3 Output Compare

The three Output Compare Channels *use the same counter* (GPT_CNT) as the Input Capture Channels. When the programmed content of an Output Compare register matches the value in GPT_CNT, an output compare status flag is set and an interrupt is generated (if the corresponding bit is set in the interrupt register). Consequently, the Output Compare timer pin will be set, cleared, toggled, not affected at all or provide an active-low pulse for one input clock period (subject to the restriction on the maximum frequency allowed on the pad) according to the mode bits (that were programmed).

There is also a "forced-compare" feature that allows the software to generate a compare event when required, *without the condition of the counter value that is equal to the compare value*. The action taken as a result of a forced compare is the same as when an output compare match occurs, *except that the status flags are not set and no interrupt can be generated*. Forced channels take programmed action immediately after the write to the force-compare bits. These bits are self-negating and always read as zeros.

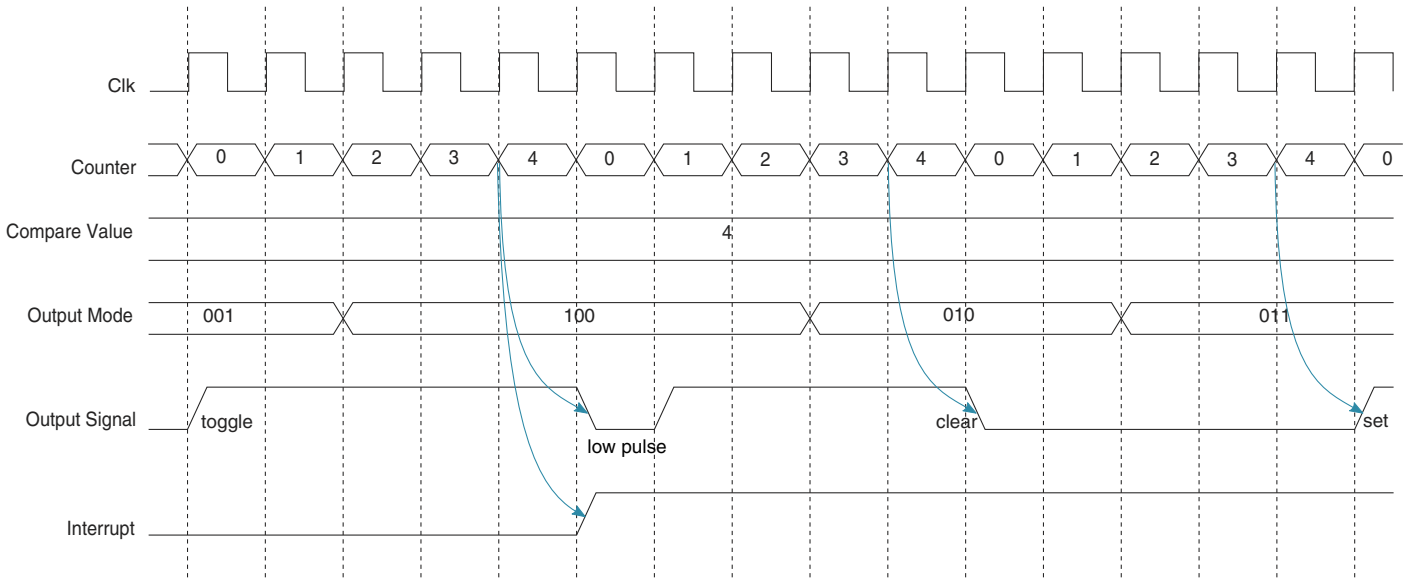

Figure 38-5. Output Compare and Interrupt Timing

38.3.2.4 Interrupts

There are 6 different interrupts that are generated by the GPT. If the selected clock for running the counter is available, then *all interrupts can be generated in Low Power and Debug modes*.

- Rollover Interrupt

  The Rollover Interrupt is generated when the GPT counter reaches 0xffffffff, then resets to 0x00000000 and continues counting. The Rollover Interrupt is enabled by the ROVIE bit in the GPT_IR register; the associated status bit is the ROV bit in the GPT_SR register.

- Input Capture Interrupt 1, 2

  After a capture event occurs, the associated Input Capture Channel generates an interrupt. The "capture event" interrupts are enabled by the IF2IE and IF1IE bits (in the GPT_IR register); the associated status bits are IF2 and IF1 (in the GPT_SR register). The capture of the counter value because of a capture event is *not affected by a pending capture interrupt*. The Capture register is updated with a new counter value when a capture event occurs, regardless of whether that Capture Channels' interrupt has been serviced or not.

- Output Compare Interrupt 1, 2, 3

After a compare event occurs, the associated Output Compare Channel generates an interrupt. The "compare event" interrupts are enabled by the OF3IE, OF2IE, and OF1IE bits (in the GPT_IR register); the associated status bits are OF3, OF2, and OF1 (in the GPT_SR register). A "forced compare" does not generate an interrupt.

A *cumulative* interrupt line is also present, which is asserted whenever any of the above interrupts are posted. The cumulative interrupt line has *no* associated enables or status bits.

38.3.2.5 Low Power Mode Behavior

In Low Power modes, if the clock from the selected clock source is available (except for the External Clock, which can be used *only if* the Peripheral Clock is available), the counter will continue to run depending on whether the control bit for that mode is set. If the clock is not present or if the corresponding low power bit in the GPT_CR control register is 0, the Main Counter and the Prescaler Counter freeze at their current values and resume counting (from their frozen values) when the Low Power mode is exited.

38.3.2.6 Debug Mode Behavior

In Debug mode, the modules in the device have the option of continuing to run or be halted.

- If the DBGEN bit is set, then the GPT timer will continue to run in Debug mode.
- If the DBGEN bit is not set (in the GPT_CR control register), then the GPT timer is halted.

38.4 Programmable Registers

The GPT has 10 user-accessible 32-bit registers, which are used to configure, operate, and monitor the state of the GPT.

An IP bus write access to the GPT Control Register (GPT_CR) and the GPT Output Compare Register1 (GPT_OCR1) results in *one cycle of wait state*, while other valid IP bus accesses incur 0 wait states.

Irrespective of the Response Select signal value, a Write access to the GPT Status Registers (Read-only registers GPT_ICR1, GPT_ICR2, GPT_CNT) will generate a bus exception.

- If the Response Select signal is driven Low, then the Read/Write access to the *unimplemented* address space of GPT (*ips_addr* is greater than or equal to $BASE + $028) will generate a bus exception.
- If the Response Select is driven High, then the Read/Write access to the unimplemented address space of GPT will *not* generate any error response (like a bus exception).

GPT memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53FA_0000	GPT Control Register (GPT_CR)	32	R/W	0000_0000h	38.4.1/ 1757

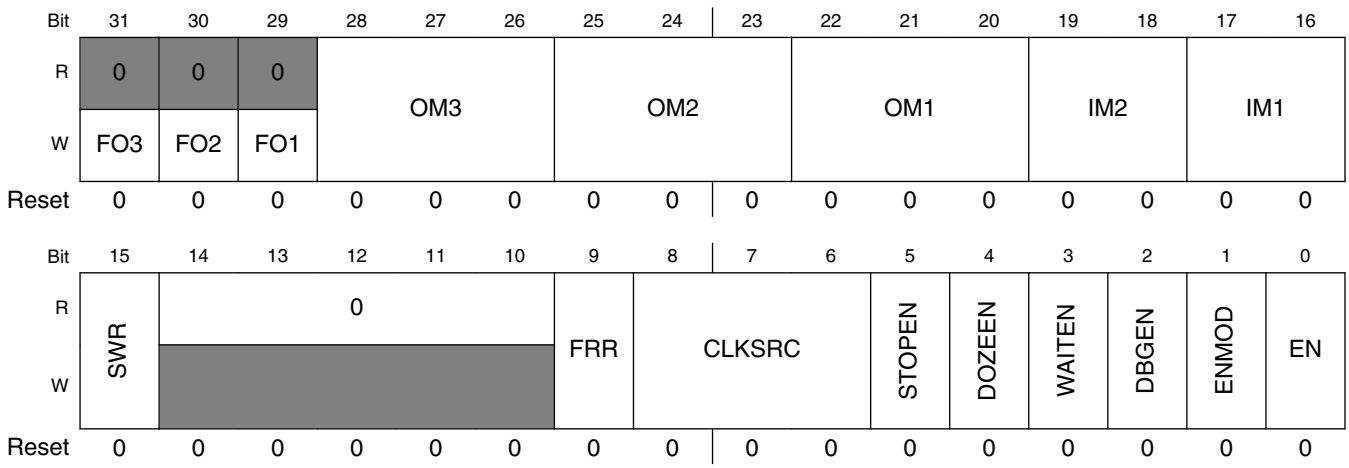
38.4.1 GPT Control Register (GPT_CR)

The GPT Control Register (GPT_CR) is used to program and configure GPT operations. An IP Bus Write to the GPT Control Register occurs after one cycle of wait state, while an IP Bus Read occurs after 0 wait states.

Address: GPT_CR is 53FA_0000h base + 0h offset = 53FA_0000h



GPT_CR field descriptions

Field	Description
31 FO3	FO3 Force Output Compare Channel 3 FO2 Force Output Compare Channel 2 FO1 Force Output Compare Channel 1 The FO*n* bit causes the pin action *programmed* for the timer Output Compare *n* pin (according to the OM*n* bits in this register). • The OF*n* flag (OF3, OF2, OF1) in the status register is **not affected**. • This bit is self-negating and always read as zero. 0 Writing a 0 has no effect. 1 Causes the programmed pin action on the timer Output Compare *n* pin; the OF*n* flag is not set.
30 FO2	See F03
29 FO1	See F03
28–26 OM3	OM3 (bits 28-26) controls the Output Compare Channel 3 operating mode. OM2 (bits 25-23) controls the Output Compare Channel 2 operating mode. OM1 (bits 22-20) controls the Output Compare Channel 1 operating mode. The OM*n* bits specify the response that a compare event will generate on the output pin of Output Compare Channel *n*.

Table continues on the next page...

GPT_CR field descriptions (continued)

Field	Description
	• The toggle, clear, and set options cause a change on the output pin *only* if a compare event occurs. • When OM*n* is programmed as 1xx (active low pulse), the output pin is set to one immediately on the next input clock; a low pulse (that is an input clock in width) occurs when there is a compare event. Note that here, "input clock" refers to the clock selected by the CLKSRC bits of the GPT Control Register. 000 Output disconnected. No response on pin. 001 Toggle output pin 010 Clear output pin 011 Set output pin 1xx Generate an active low pulse (that is one input clock wide) on the output pin.
25–23 OM2	See OM3
22–20 OM1	See OM3
19–18 IM2	IM2 (bits 19-18, Input Capture Channel 2 operating mode) IM1 (bits 17-16, Input Capture Channel 1 operating mode) The IM*n* bit field determines the transition on the input pin (for Input capture channel *n*), which will trigger a capture event. 00 capture disabled 01 capture on rising edge only 10 capture on falling edge only 11 capture on both edges
17–16 IM1	See IM2
15 SWR	Software reset. This is the software reset of the GPT module. It is a self-clearing bit. • The SWR bit is set when the module is in reset state. • The SWR bit is cleared when the reset procedure finishes. • Setting the SWR bit resets **all of the registers** to their default reset values, except for the CLKSRC, EN, ENMOD, STOPEN, WAITEN, and DBGEN bits in the GPT Control Register (this control register). 0 GPT is not in reset state 1 GPT is in reset state
14–10 Reserved	This read-only field is reserved and always has the value zero. Reserved bits. • Writing a value to these reserved bits will not affect GPT operations. • These reserved bits are always read as zero. • It is recommended that all writes to these reserved bits be 0 (for forward compatibility).
9 FRR	Free-Run or Restart mode. The FFR bit determines the behavior of the GPT when a compare event in channel 1 occurs. • In Restart mode, after a compare event, the counter resets to 0x00000000 and resumes counting (after the occurrence of a compare event). • In Free-Run mode, after a compare event, the counter continues counting until 0xFFFFFFFF and then rolls over to 0.

Table continues on the next page...

GPT_CR field descriptions (continued)

Field	Description
	0 Restart mode 1 Free-Run mode
8–6 CLKSRC	Clock Source select. The CLKSRC bits select which clock will go to the prescaler (and subsequently be used to run the GPT counter). • The CLKSRC bit field value should only be changed after disabling the GPT by clearing the EN bit in this register (GPT_CR). • A software reset does not affect the CLKSRC bit. 000 No clock 001 Peripheral Clock 010 High Frequency Reference Clock 011 External Clock (IND_CLKIN) 100 Low Frequency Reference Clock 101 Crystal oscillator as Reference Clock others Reserved
5 STOPEN	GPT Stop Mode enable. The STOPEN read/write control bit enables GPT operation *during Stop mode*. • A hardware reset resets the STOPEN bit. • A software reset *does not affect* the STOPEN bit. 0 GPT is disabled in Stop mode. 1 GPT is enabled in Stop mode.
4 DOZEEN	GPT Doze Mode Enable. • A hardware reset resets the DOZEEN bit. • A software reset *does not affect* the DOZEEN bit. 0 GPT is disabled in doze mode. 1 GPT is enabled in doze mode.
3 WAITEN	GPT Wait Mode enable. The WAITEN read/write control bit enables GPT operation *during Wait mode*. • A hardware reset resets the WAITEN bit. • A software reset *does not affect* the WAITEN bit. 0 GPT is disabled in wait mode. 1 GPT is enabled in wait mode.
2 DBGEN	GPT debug mode enable. The DBGEN read/write control bit enables GPT operation *during Debug mode*. • A hardware reset resets the DBGEN bit. • A software reset *does not affect* the DBGEN bit. 0 GPT is disabled in debug mode. 1 GPT is enabled in debug mode.
1 ENMOD	GPT Enable mode.

Table continues on the next page...

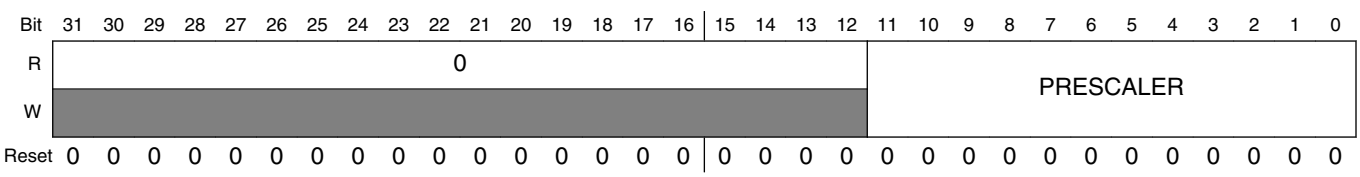
GPT_CR field descriptions (continued)

Field	Description
	When the GPT is disabled (EN=0), then both the Main Counter and Prescaler Counter *freeze their current count values*. The ENMOD bit determines the value of the GPT counter when Counter is enabled again (if the EN bit is set). • If the ENMOD bit is 1, then the Main Counter and Prescaler Counter values are reset to 0 after GPT is enabled (EN=1). • If the ENMOD bit is 0, then the Main Counter and Prescaler Counter restart counting *from their frozen values* after GPT is enabled (EN=1). • If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then the Main Counter and Prescaler Counter *freeze at their current count values* when the GPT enters low power mode. • When GPT exits low power mode, the Main Counter and Prescaler Counter start counting from their frozen values, regardless of the ENMOD bit value. • Setting the SWR bit will clear the Main Counter and Prescaler Counter values, regardless of the value of EN or ENMOD bits. • A hardware reset resets the ENMOD bit. • A software reset *does not affect* the ENMOD bit. 0 GPT counter will retain its value when it is disabled. 1 GPT counter value is reset to 0 when it is disabled.
0 EN	GPT Enable. The EN bit is the GPT module enable bit. **Before setting the EN bit**, we recommend that *all registers be properly programmed*. • A hardware reset resets the EN bit. • A software reset *does not affect* the EN bit. 0 GPT is disabled. 1 GPT is enabled.

38.4.2 GPT Prescaler Register (GPT_PR)

The GPT Prescaler Register (GPT_PR) contains bits that determine the divide value of the clock that runs the counter.

Address: GPT_PR is 53FA_0000h base + 4h offset = 53FA_0004h



GPT_PR field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value zero. Reserved bits.

Table continues on the next page...

GPT_PR field descriptions (continued)

Field	Description
	• Writing a value to these reserved bits will not affect GPT operations. • These reserved bits are always read as zero.
11–0 PRESCALER	Prescaler bits. The clock selected by the CLKSRC field is divided by [PRESCALER + 1], and then used to run the counter. • A change in the value of the PRESCALER bits cause the Prescaler counter to reset and a new count period to start immediately. • See Figure 38-3 for the timing diagram. 0x000 Divide by 1 0x001 Divide by 2 ... ... 0xFFF Divide by 4096

38.4.3 GPT Status Register (GPT_SR)

The GPT Status Register (GPT_SR) contains bits that indicate that a counter has rolled over, and if any event has occurred on the Input Capture and Output Compare channels. The bits are cleared by writing a 1 to them.

Address: GPT_SR is 53FA_0000h base + 8h offset = 53FA_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

GPT_SR field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value zero. Reserved bits. • Writing a value to these reserved bits will not affect GPT operations. • These reserved bits are always read as zero.
5 ROV	Rollover Flag. The ROV bit indicates that the counter has reached its *maximum possible value* and *rolled over* to 0 (from which the counter continues counting). The ROV bit is only set if the counter has reached 0xFFFFFFFF in both Restart and Free-Run modes.

Table continues on the next page...

GPT_SR field descriptions (continued)

Field	Description
	0 Rollover has not occurred. 1 Rollover has occurred.
4 IF2	IF2 Input capture 2 Flag IF1 Input capture 1 Flag The IF*n* bit indicates that a capture event has occurred on Input Capture channel *n*. 0 Capture event has not occurred. 1 Capture event has occurred.
3 IF1	See IF2
2 OF3	OF3 Output Compare 3 Flag OF2 Output Compare 2 Flag OF1 Output Compare 1 Flag The OF*n* bit indicates that a compare event has occurred on Output Compare channel *n*. 0 Compare event has not occurred. 1 Compare event has occurred.
1 OF2	See OF3
0 OF1	See OF3

38.4.4 GPT Interrupt Register (GPT_IR)

The GPT Interrupt Register (GPT_IR) contains bits that control whether interrupts are generated after rollover, input capture and output compare events.

Address: GPT_IR is 53FA_0000h base + Ch offset = 53FA_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

2 OF3IE	OF3IE Output Compare 3 Interrupt Enable OF2IE Output Compare 2 Interrupt Enable OF1IE Output Compare 1 Interrupt Enable The OF*n*IE bit controls the Output Compare Channel *n* interrupt. 0 Output Compare Channel *n* interrupt is disabled. 1 Output Compare Channel *n* interrupt is enabled.
1 OF2IE	See OF3IE
0 OF1IE	See OF3IE

38.4.5 GPT Output Compare Register 1 (GPT_OCR1)

The GPT Compare Register 1 (GPT_OCR1) holds the value that determines when a compare event will be generated on Output Compare Channel 1. Any write access to the Compare register of Channel 1 while in Restart mode (FRR=0) will reset the GPT counter.

An IP Bus Write access to the GPT Output Compare Register1 (GPT_OCR1) occurs *after* one cycle of wait state; an IP Bus Read access occurs *immediately* (0 wait states).

Address: GPT_OCR1 is 53FA_0000h base + 10h offset = 53FA_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

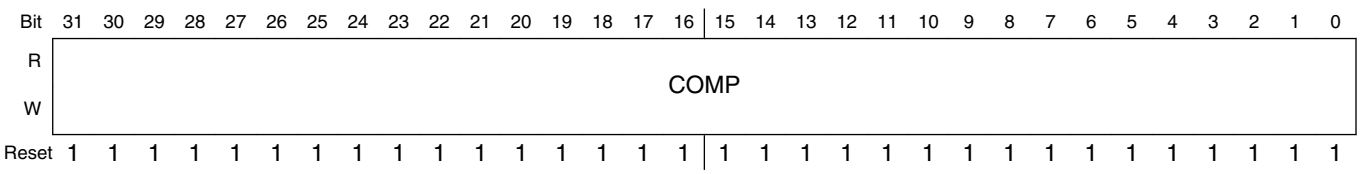
GPT_OCR1 field descriptions

Field	Description
31–0 COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 1.

38.4.6 GPT Output Compare Register 2 (GPT_OCR2)

The GPT Compare Register 2 (GPT_OCR2) holds the value that determines when a compare event will be generated on Output Compare Channel 2.

Address: GPT_OCR2 is 53FA_0000h base + 14h offset = 53FA_0014h



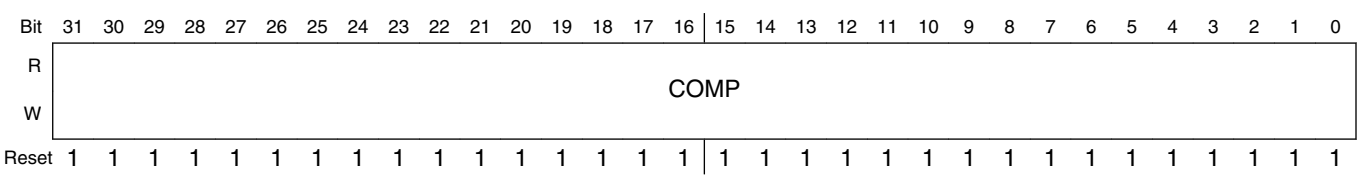
GPT_OCR2 field descriptions

Field	Description
31–0 COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 2.

38.4.7 GPT Output Compare Register 3 (GPT_OCR3)

The GPT Compare Register 3 (GPT_OCR3) holds the value that determines when a compare event will be generated on Output Compare Channel 3.

Address: GPT_OCR3 is 53FA_0000h base + 18h offset = 53FA_0018h



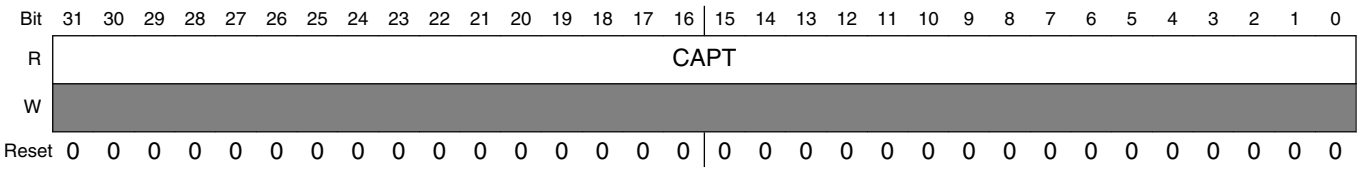
GPT_OCR3 field descriptions

Field	Description
31–0 COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 3.

38.4.8 GPT Input Capture Register 1 (GPT_ICR1)

The GPT Input Capture Register 1 (GPT_ICR1) is a read-only register that holds the value that was in the counter during the last capture event on Input Capture Channel 1.

Address: GPT_ICR1 is 53FA_0000h base + 1Ch offset = 53FA_001Ch



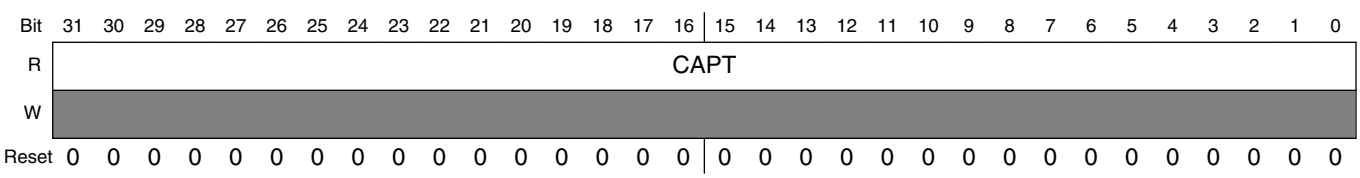
GPT_ICR1 field descriptions

Field	Description
31–0 CAPT	Capture Value. After a capture event on Input Capture Channel 1 occurs, the current value of the counter is loaded into GPT Input Capture Register 1.

38.4.9 GPT Input Capture Register 2 (GPT_ICR2)

The GPT Input capture Register 2 (GPT_ICR2) is a read-only register which holds the value that was in the counter during the last capture event on input capture channel 2.

Address: GPT_ICR2 is 53FA_0000h base + 20h offset = 53FA_0020h



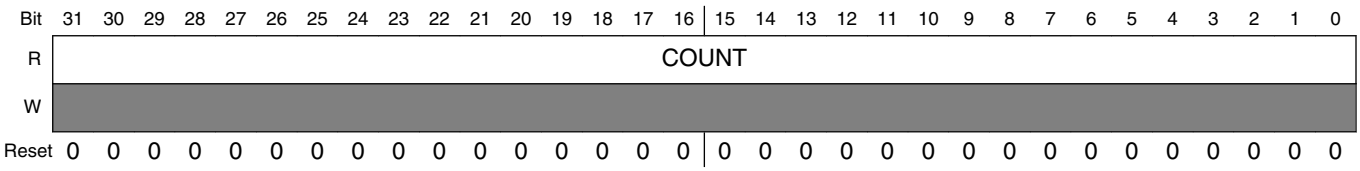
GPT_ICR2 field descriptions

Field	Description
31–0 CAPT	Capture Value. After a capture event on Input Capture Channel 2 occurs, the current value of the counter is loaded into GPT Input Capture Register 2.

38.4.10 GPT Counter Register (GPT_CNT)

The GPT Counter Register (GPT_CNT) is the main counter's register. GPT_CNT is a read-only register and can be read without affecting the counting process of the GPT.

Address: GPT_CNT is 53FA_0000h base + 24h offset = 53FA_0024h



GPT_CNT field descriptions

Field	Description
31–0 COUNT	Counter Value. The COUNT bits show the current count value of the GPT counter.

Chapter 39
2D Graphics Processing Unit (GPU2D)

39.1 Overview

This block guide describes key architectural features of the G12 OpenVG core as well as details of the G12 OpenVG IP customizing and integration in the i.MX53.

The ATI™ Z160(G12) IP is an embedded, 2D and vector graphics accelerator targeting the OpenVG 1.0.1 graphics API and feature set.

It accelerates 2D bitmap graphics operations, such as BitBlt, fill and raster operations using a separate 2D graphics acceleration unit.

Vector graphics rendering is accelerated by a separate anti-aliasing polygon rasterizer, which is connected to the 2D graphics acceleration unit.

The core has a rich, but well-chosen set of features, with emphasis being on very high image quality and low memory bandwidth consumption.

The GPU top level block diagram is presented at GPU2D Block Diagram.

39.2 GPU2D Feature List

The following chapters describe the functional features of the graphics processor.

39.2.1 Frame Buffer

- Frame buffer sizes supported up-to 2048x2048
- ARGB4444, RGB565, ARGB1555, ARGB5551, ARGB8888 frame buffer modes
- Configurable ARGB order in frame buffer: ARGB, BGRA, ABGR, RGBA
- Linear and block-based (4x4 pixels) frame buffer modes
- Fast buffer clears
- Support for OpenVG render to Image

39.2.2 2D Bitmap Graphics (Separate 2D Unit)

- Parallel operation with the 3D pipeline, independent command input
- BitBlt (surface-to-surface copy)
  - Format conversion from monochrome/ARGB/YUV to ARGB during BitBlt
- Block fill
- Internal 32-bit color precision
- Source bitmap format:
  - 1/4/8-bit monochrome
  - ARGB4444, RGB565, ARGB1555, ARGB5551, ARGB8888
  - Configurable ARGB order: ARGB, BGRA, ABGR, RGBA
  - Packed YUV 4:2:2 formats (FOURCC codes YUY2, UYVY, YVYU), two pixels per 32 bits of data.
  - 1-bit bitmap maps to foreground and background colors.
  - 4-bit bitmap is optionally gamma corrected to 8-bit alpha values and can be combined with foreground color to draw anti-aliased fonts.
- Destination bitmap format:
  - ARGB4444, RGB565, ARGB1555, ARGB5551, ARGB8888, B8, A8, AB88
  - Configurable ARGB order: ARGB, BGRA, ABGR, RGBA
- Supports three source bitmaps for separate mask/pattern/alpha bitmap support plus reading destination for ROP, blend and color key operations
- Supports masking source coordinates for wrapping patterns
- Supports ROP4 (ROP3 with separate ROPs for masked and unmasked pixels) logical operations
- Supports inverting mask and alpha values from source
- Supports destination rotation by 0/90/180/270 degrees Supports programmable blending with optional alpha un-premultiply
- Supports per pixel and constant alpha with optional modulation by source color alpha for OpenVG alpha masking Supports color keying by source and destination colors, with optional ignoring of alpha channel
- Supports one scissor rectangle for destination coordinates
- Dithering (ordered)
- Color component masking
- RGB reads and writes
- Non-power of two source and destination bitmap sizes supported (stride must be a multiple of 32-bits)
- BitBlt with scaling implemented with the 3D rendering pipeline, bilinear filtering with texture lookups, programmable filter kernels possible with the programmable Pixel processor

39.2.3 Vector Graphics

- Parallel operation with the 3D pipeline, independent command input
- Rasterization of convex and concave polygons with anti-aliasing
- Efficient native polygon rendering (no tessellation to triangles)
- Non-zero and odd-even fill rules
- Primitives supported:
  - Polygons
  - OpenVG path primitives (except Elliptical Arcs): Horizontal/vertical lines, generic lines, curves, smooth curves, moveto, path closing
  - Curve types supported: cubic and quadratic BÈzier
  - Strokes with thickness, joints and end caps, unlimited stroke thickness
  - Special case handling of singularities for thick strokes
  - Supports paths with a maximum of 256 crossings along a horizontal or a vertical line
- Input coordinates:
  - Absolute and relative coordinate input in floating point
  - Fixed-point (byte, short, int) and floating-point coordinate input - 0.8, 0.16, 16.16 formats
  - Little- and Big-endian support separately selectable for command stream and data.
- Geometry
  - User to surface transform for vertices and stroke shape
  - Hardware curve tessellation
  - Adjustable accuracy for curve and round cap splitting
  - OpenVG/SVG join types: Miter (with miter limit), round, bevel
  - OpenVG/SVG cap types: Butt, round, square
- Pixel processing:
  - Programmable gradient and texturing processor
  - Linear and radial gradients (with focal point)
  - Perspective texture mapping with filtering
  - Two textures supported
  - sRGB and pre-multiply support for textures
  - 16-sample anti-aliasing
  - 4x RGSS AA (Rotated Grid Super Sample)
  - Per-pixel alpha-masking
  - Maximum texture size: 1024x1024 pixels
- Vector graphics rendering system ARM platform load:
  - Display list generation during path creation ñ commands and vertices are stored to an internal format/buffer, no format conversion is performed

- Filling or stroking a path only requires a few register writes to start the operation in hardware
- Display lists are transferred to the vector graphics rasterizer using DMA without ARM platform interaction

39.3 GPU2D Block Diagram

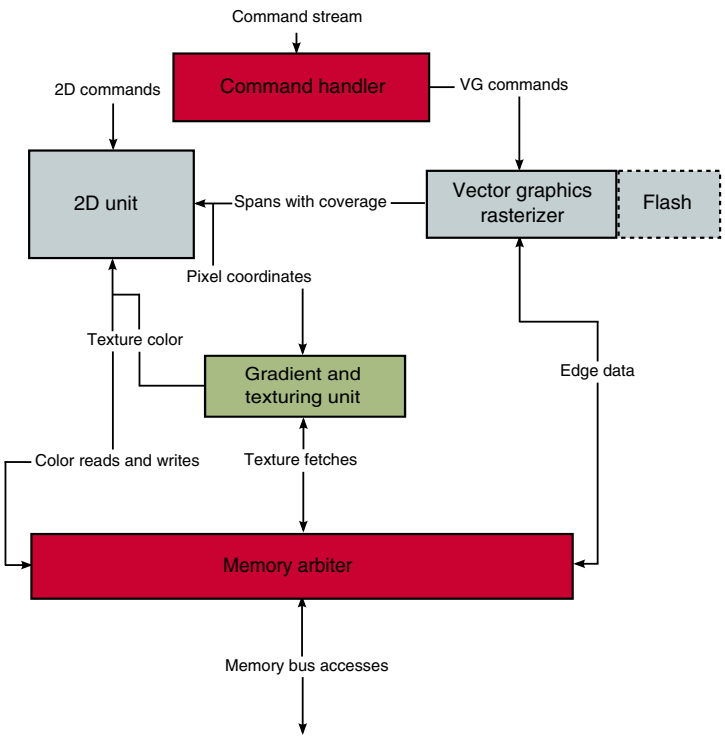


Figure 39-1. GPU2D Block Diagram

39.4 GPU SoC Interface

39.4.1 GPU2D Top Level Diagram

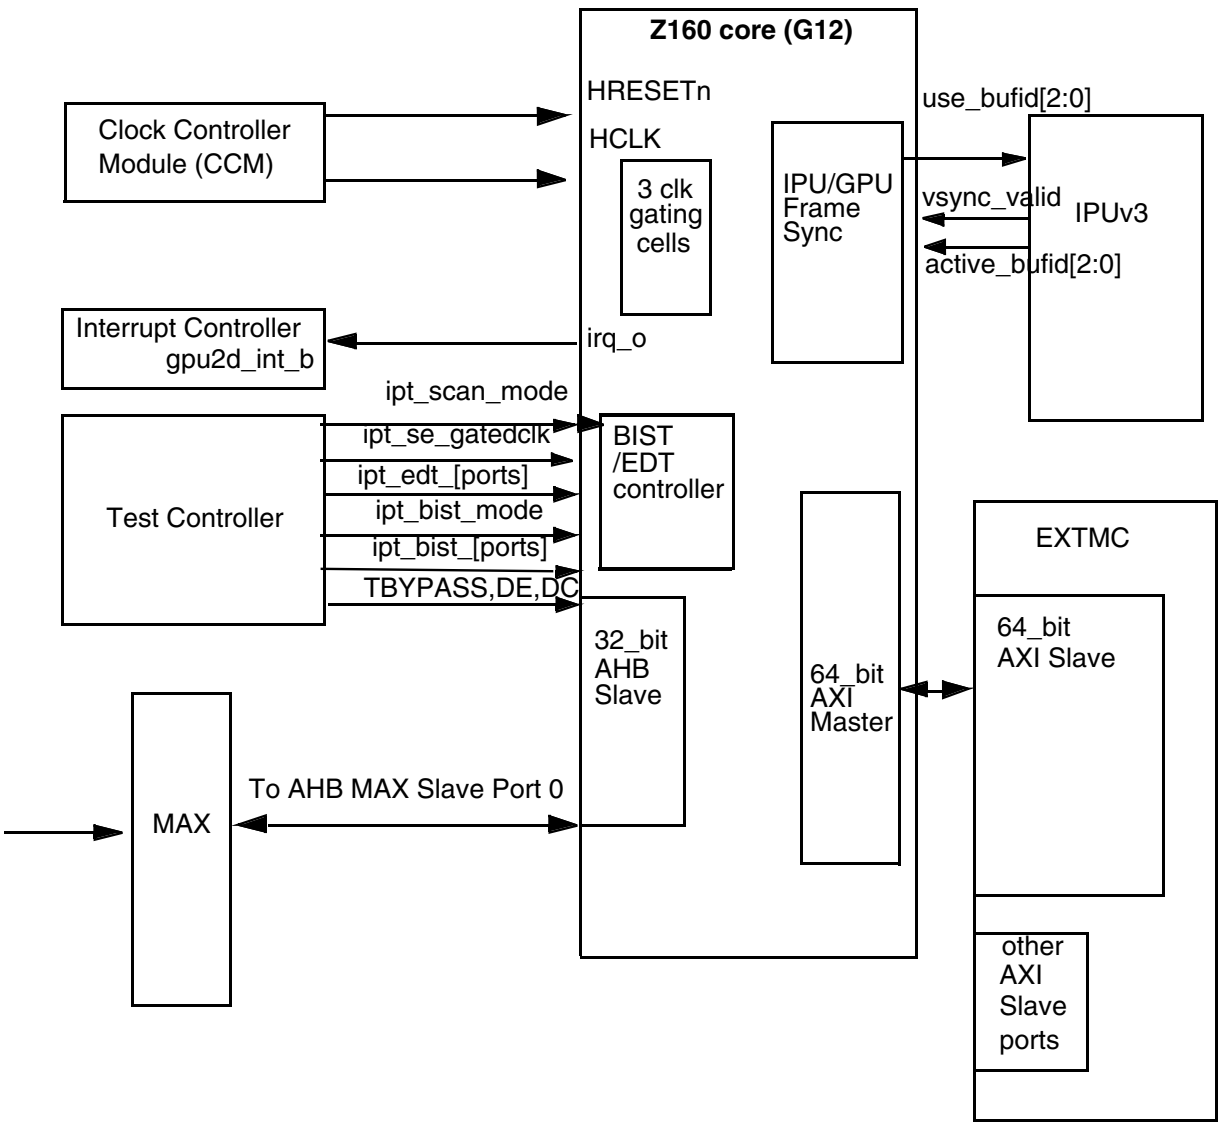

Figure 39-2. GPU2D System Connectivity

39.4.2 SoC Bus Connection

The GPU2D has the following two bus interfaces in SoC:

- 32_bit AHB slave bus.

This port is connected to ARM through MAX slave port 0, it allows access to the control registers and is the command stream input to Z160 core. The AHB interface is a fully compliant ARM AMBA AHB bus interface. It has been designed to comply with Rev 2.0 of the AMBA specification and it implements the Retry capable Slave part of the specification

- 64_bit AXI master bus

The external memory master bus is a standard 64_bit AMBA AXI master bus.

39.5 Other Signals Connection

Table 39-1. Z160(G12) miscellaneous signals

Name	Type	Source/ destination	Description
gpu2d_int_b	Output	Interrupt controller	Interrupt output from the Z160 (G12) OpenVG Graphics Core. Active LOW.
gpu2d_use_bufid[2:0]	Output	Image Processing Unit (IPU) frame sync	Tell IPU which buffer can be displayed
ipu_vsync_valid	Input	IPU frame sync	Tell GPU2D one frame is finished
ipu_active_bufid[2:0]	Input	IPU frame sync	Tell GPU2D which frame is free to be overwritten

39.6 Clocking Architecture

There is one clock input to the GPU2D, namely HCLK. In fact Z160(G12) core needs 5 clock inputs, named bus_clk, clk_0,clk_1,clk_2,clk_3, which are divided from HCLK but balanced and therefore, count as only one clock domain.

39.7 Power Management

Table 39-2. GPU2D miscellaneous signals

Clock name	Enable signal	Clocked sub-blocks	Related area
bus_clk(hclk)		Busif	4%
clk_0(hclk)	Input	Arbiter, Input	1%
clk_1	clock1_ena	Bcache	20%

Table continues on the next page...

Table 39-2. GPU2D miscellaneous signals (continued)

Clock name	Enable signal	Clocked sub-blocks	Related area
clk_2	clock2_ena	2D, V3	45%
clk_3	clock3_ena	V1, V2	30%

The different use cases and the associated clock settings are presented at the following table. For the use-cases where the core is not used at all, also bus_clk and clk_0 should be gated off to maximize the power savings. This cannot be controlled by the core itself.

Use case	bus clk	clk 0	clk 1	clk 2	clk 3
Idle	on	on	off	off	off
Bitmap case - standalone	on	on	on	on	off
Vector graphics	on	on	on	on	on

Figure 39-3. Graphics Core Operating Mode

If the whole chip go into low power mode, all clk source will be shut down by CCM.

39.8 Modes of Operation

The GPU2D supports

- 2D bitmap acceleration mode
- Vector Graphic acceleration mode
- low power mode

39.9 Reset

The GPU2D has only 1 reset port named HRESETn. The internal Z160 core (G12) contains asynchronous reset signals for each corresponding clock domain - namely rst_n for the clk clocks and bus_rst_n for the busclk clock, which are directly connected to HRESETn.

Resets are active low. The reset signals asynchronously reset all of the DFFs in the design.

39.10 Interrupts

The Z160 Core (G12) generates individual interrupts internally. Each interrupt can be enabled or disabled by changing its own enable bit. Setting the enable bit HIGH enables the corresponding interrupt.

The interrupts from all sources in the Z160 Core (G12) are combined (ORed) and output as the active LOW **gpu2d_int_b** interrupt.

39.11 DMA

GPU2D is a DMA master in fact, it read command and write data to system memory through EXTMC.

GPU2D also can be feed by DMA through MAX slave port 0.

39.12 Memory Map

The Z160 Graphics Core (G12) memory map is described in the following sections:

- AHB slave interface
- AXI master memory interface (EXTMC port).

39.12.1 AHB Slave Interface

This is based on the GPU2D occupying slave port 0 of the crossbar., whose base address is 0x20000000. GPU2D has 2 kinds of registers, one is "Interface" registers which can be read/write accessible, the others are "Internal" registers which only can be written through Z160's slave ports.

GPU2D Memory Map

Description	Memory Address Base	Memory Address End
Registers	0x2000 0000	0x200007FC

Description of all user-accessible registers in the design can be found from regs.html

Interface registers can only be accessed by status read / write channel directly through the slave port, which is mapped to 0x400 - 0x7fc address range. These registers are used to read and clear interrupts by the ARM platform, for example.

Internal 2D / VG registers are write only. They can only be accessed by two writing commands through the slave port (GPU2D's base address). The first command is a register address write, followed by a data write command.

In practice, this means that the command stream, which is prepared by the software driver is written through the 0x000-0x3ff address range either directly, or through the DMA operation by the core. These registers are not accessible directly by slave ports channel, like interface registers are not accessible through this channel.

39.12.2 AXI Master Memory Interface (EXTMC Port)

The Z160 Graphics Core (G12 or GPU2D) can access memory with or without a *Memory Management Unit* (MMU):

Translation is performed using a table with 8KB entries, one for each 4KB page in a 32MB linear address space.

Chapter 40
3D Graphics Processing Unit (GPU3D)

40.1 Overview

The 3D Graphics Processing Unit (GPU3D) is an embedded engine capable of DirectX9 Shader Model 3.0+ program execution. The GPU3D is focused on accelerating user level graphics APIs such as OpenGL ES 2.0 & 1.1, OpenVG 1.0, and Direct3D Mobile 1.2.

40.2 GPU3D Features Overview

The GPU3D IP core has the following high-level features:

- Built to accelerate OpenGL ES 2.0 and Direct3D Mobile 1.2
- Unified Shader Architecture
  - Uses dynamically shared shader ALU/memory resources between vertex and pixel shaders.
- General purpose exports to system memory from Vertex & Pixel Shaders
  - Can be used in vertex shader for tessellation of HOS, sub-division surfaces etc.
  - Can be used in pixel shader for generating vertices etc.
- Supports 2- and 4- sample MSAA
- Command Processor:
  - As a DMA master, support advanced packet based command stream manager allowing for efficient and flexible transfer of graphics commands and host data from the host system to the graphics processor core
- Graphics Memory Controller and Graphics Memory (GMEM)
  - Customer configurable on-chip memory used to accelerate 3D rendering using a binning architecture significantly reducing external system bandwidth requirements. i.MX53 adopts a 256KB internal GMEM.
- Integrated Power Management

Block-level clock gating managed automatically in the IP.

40.3 Capabilities and Performance

- 32 bit FP Internal Shader Precision
- Compressed Texture Support: ETC, DXTC, and ATI_TC
- Supports general purpose exports to system memory from Vertex and Pixel shaders.
- Uses indexed vertex data fetches from the Vertex Shader as a high-bandwidth vertex data path.
- Latency hiding through FIFOs and multi-threading
- Sophisticated Shader support
  - 512 4-Component constants
  - 1024 Shader Instructions
  - 16 Textures
  - 16 4-Component Interpolants
  - 64 General Purpose Registers
- Rich texture format and types
  - Compressed
  - 16 bit Floating point
  - Cube map
  - Volume textures
  - Non power-of-2
  - Anisotropic
- 1 Primitive (Triangle/Line/Point) every 6 clocks
- 2 Vector (4 component) and 1 Scalar (single component) ALU instruction per clock
- 1 Control Flow Instructions (Jumps, loops) per clock
- 1 Export per clock
- 14 component Pixel Shader input interpolant per clock
- Early-Z testing at up to 4 pixels per clock
- 1 pixel (at 4 sample MSAA) per clock with alpha blending and depth test

40.4 GPU3D Block Diagram

The GPU3D contains three primary blocks:

- Graphics Core (GC)
  - Programmable graphics engine that performs all of the data processing and memory transactions
- Graphics Arbiter (GARB)
  - Controls the GMEM and arbitrates between requests from the GC and the system
- Graphics Memory (GMEM)

- Local SRAM buffers (4x64KB buffers) that are used for the tile / bin of pixels when the GC is working on

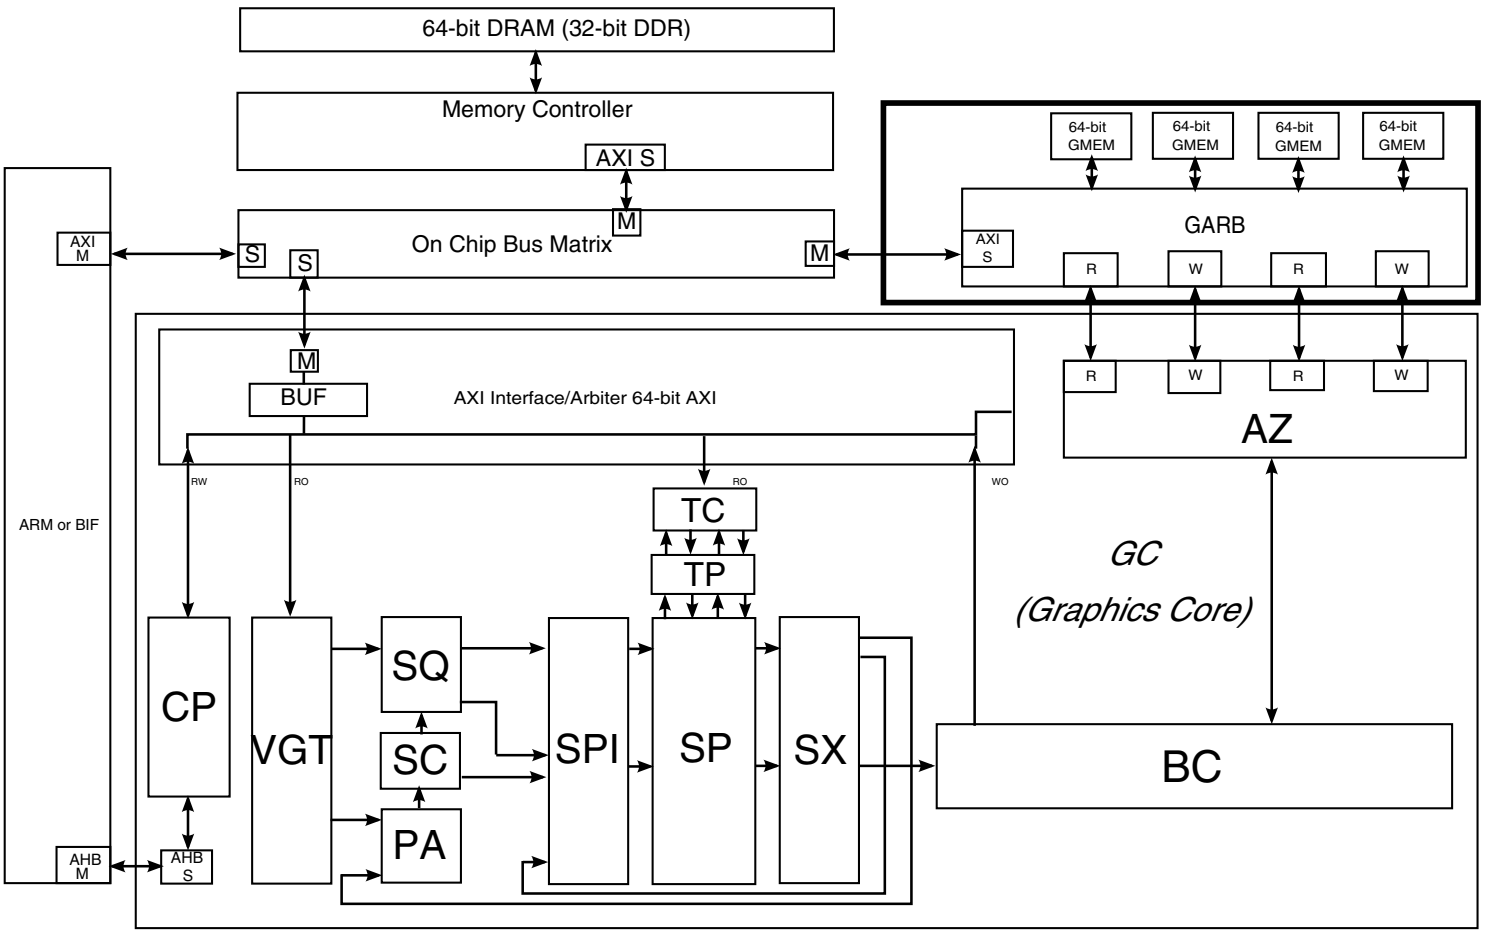

Figure 40-1. GPU3D Top Level Block Diagram

40.5 GPU3D Interface

40.5.1 GPU3D Top Level Diagram

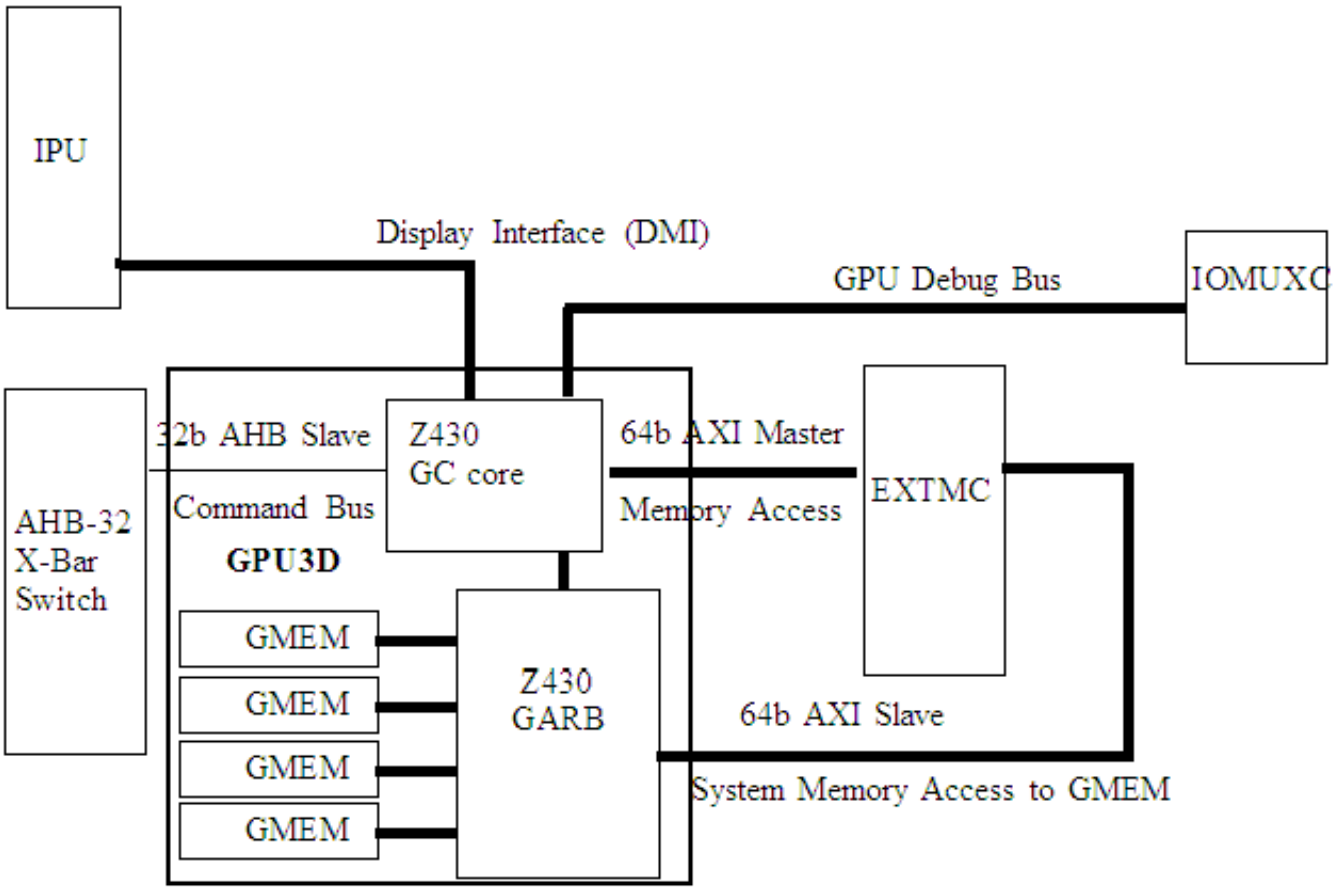

Figure 40-2. GPU3D System Connectivity

40.5.2 SoC Interface Summary

- Slave Interface to ARM platform or controller interface
  - Peripheral AMBA 2.0 AHB-Lite Host Interface
  - Provides host access to graphics core from the system processor.
  - 32b wide, synchronous with core.
  - Support for clock gating for phase removal on AHB clock.
- AXI Master Interface into memory system (AXI V1.0)
  - 64b wide, synchronous
  - Provides access to system memory from the graphics core.
  - Programmable number of read and write requests to the memory system
  - Number of outstanding request limited by system resources.
- AXI slave interface for system access to graphics memory (though GARB to GMEM)

    - 64b wide, synchronous interface
    - 1 outstanding read and write request
- Display Module Interface (DMI)
    - For synchronization with the display processor. (IPU)
    - Provides indication to display processor from graphics core that a newly rendered frame is ready and that the display must perform a buffer flip at the next vertical blank.
    - Provides indication to graphics core from the display processor that the buffer identified by buffer ID has been displayed at least once..
- Control Interface Block (CIB on AHB slave bus)
    - Holding block for clock gating, reset etc.
    - Interrupt Interface (INT)
    - Error and status interrupts to the controller.
- Design For Test Interface (DFT)
    - Memory test collar access.
    - Scan/BIST access.
- Debug bus
    - GPIO register as control functions
    - Set of signals OR chained between internal masters for debug purposes
    - 32b bus muxed to 16b output to pad

40.5.3 Memory Interface Detail

40.5.3.1 Access Type

The GPU3D core generates 128 and 256 bit bursts to external memory from its internal masters, which are arbitrated by a Memory Hub (MH). The MH supports up to 64 outstanding transactions, 8 AXI IDs, and contains a MMU.

Typical graphics use cases (usually games) will utilize approximately 400 to 500 MB/s and require a memory latency of less that 90ns (70ns is preferred).

The Memory Hub selects between the following clients in the graphics core:

- CP - (Command Processor) Read/Write
- VGT - (Vertex Grouper and Tesselator) Read Only
- TC - (Texture Cache) Read only
- RB - (Render Block) Write Only

Sub-Client	Sub-Client Designation	AXI ID	Operation	Transaction Size (Bytes)	Sub-Client Outstanding Transaction Limit
Ring Buffer	CPr0	0	Read	32	Programmable (Note 1)
Indirect Buffer #1	CPr1	1	Read	32	Programmable (Note 1)
Indirect Buffer #2	CPr2	2	Read	32	Programmable (Note 1)

All transactions are incrementing address bursts. The starting address is always aligned to the burst size, that is, all 16 Byte bursts start at a 16-Byte aligned address; all 32 Byte bursts start at a 32-Byte aligned address.

Command stream and vertex data is read in bursts of 256 bits.

The Burst cache combines color accesses from several smaller objects to 4x4 pixel (16-bit), or 4x2 pixel (32-bit), which are transferred to memory in bursts of 256 bits.

Color writes use byte enables when incomplete pixel blocks are written to the memory

40.5.3.2 Memory Management

The GPU3D GC core include a Memory Management Unit (MMU) capable of remapping a programmably sized region of the 32 bit GC memory space. This unit will use a single level mapping table, with each 32 bit table entry mapping a 4K byte region. Hence to map a 1 M byte region will require 256 table entries or a table 1K in size.

To make the remapping more efficient the GC will include a Translation Lookaside Buffer (TLB) which acts as a 'cache' of translations. This cache will hold a total of 128 translations organized as 16 'lines' of 8 translations each. Each of the 16 'lines' is fully associative, allowing translations for sections of up to 16 different surfaces to be simultaneously stored in the TLB.

Each client within the GC can be selected whether or not to use the MMU remapping function.

Any accesses that do not use the MMU may be limited to a programmable range of physical address space, with accesses outside of thatregion resulting in a page fault fatal error.

When the driver requests memory from the OS, the virtual to physical translation is stored in the GPU3D's Page Table. The page table is a contiguous physical chunk of memory whose starting address is defined as the page table base (PTB) and whose extent depends on the amount of virtual memory required by the driver. For example, if supporting 4KB pages and each page table entry is 32b, a virtual address range of 64MB available to the driver would require 16K entries or 64KB of page table storage.

Note that the page table used by the graphics is not the same as the page table used by the ARM processor. Specifically, the GPU page table is a single level page table, and not all access control mechanisms are implemented.

In its simplest form, using a 4KB page, bits [11:0] of the virtual address can be the same as the physical address[11:0] and can be used as an index into the page. Bits [31:12] of the virtual address, in conjunction with the Virtual Address Base register, can be used as an index into the page table to find the address of the relevant page table entry (PTE).

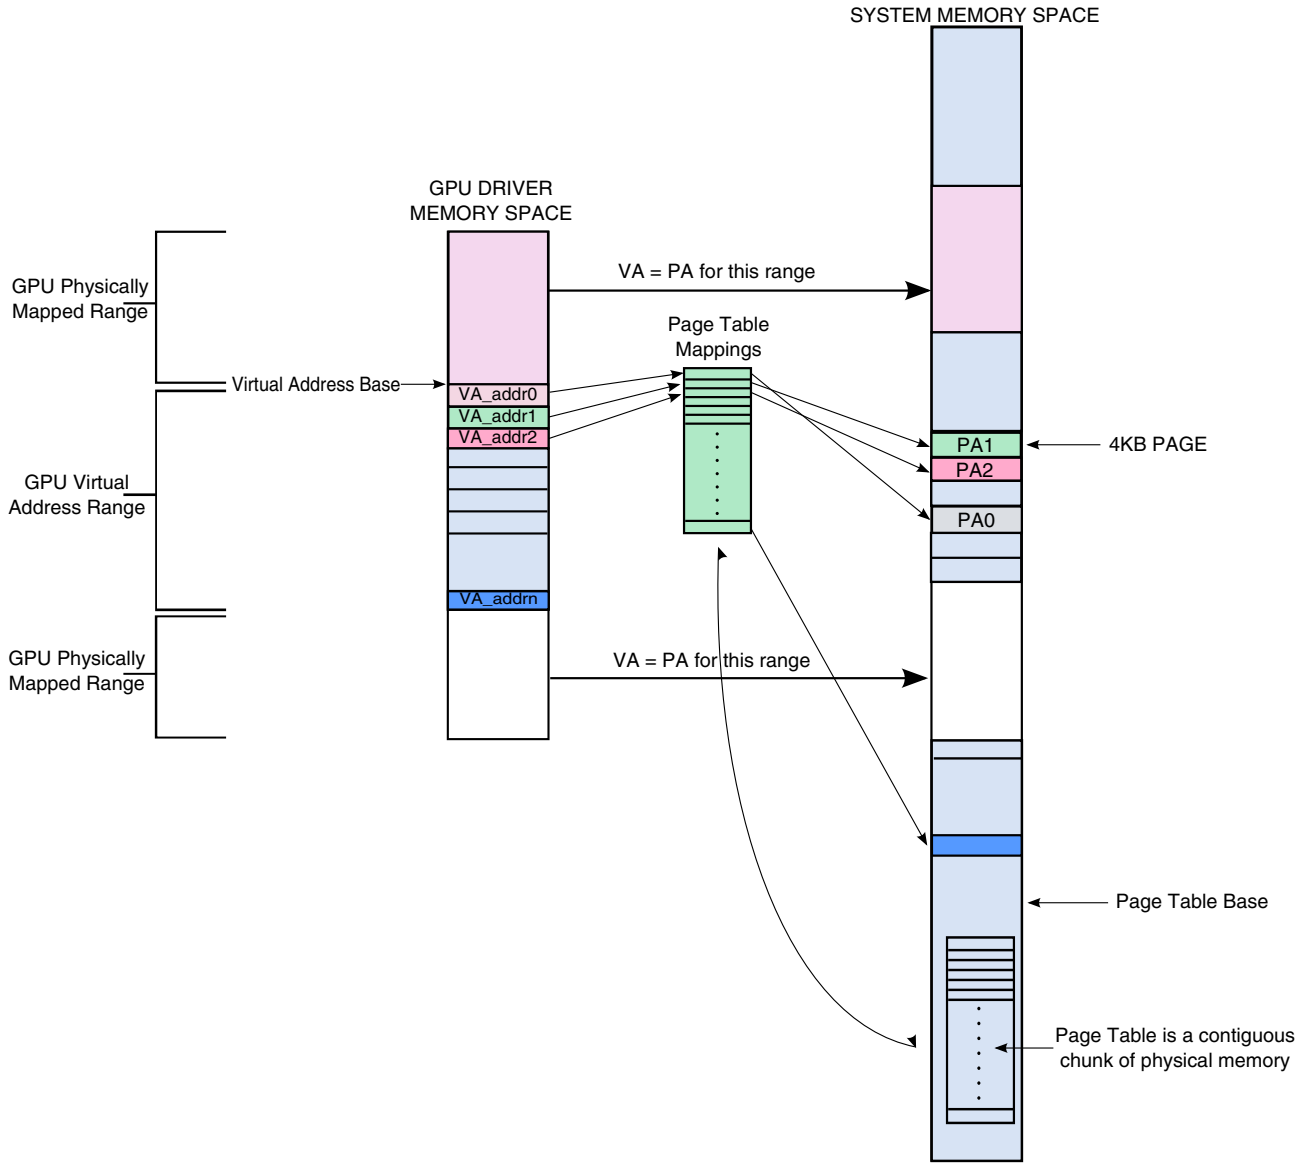

Figure 40-3. GPU3D Memory Mapping Concept

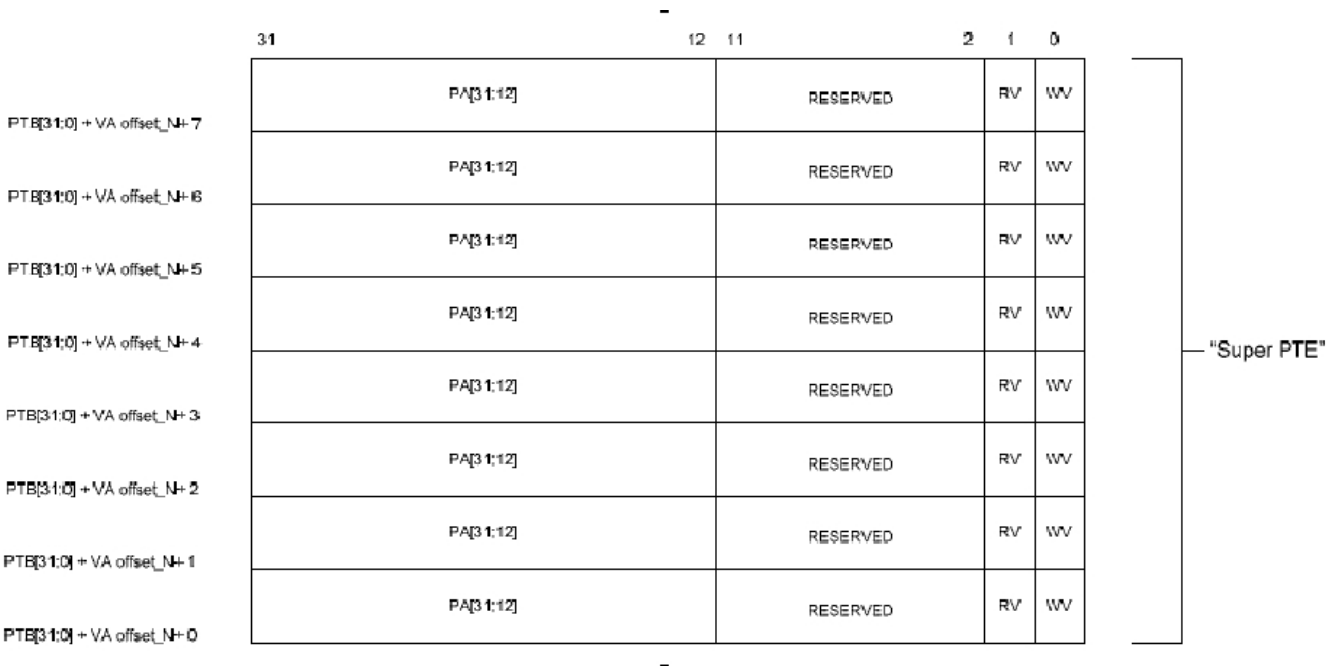

Figure 40-4. Page Table Entry Format in External Memory

40.5.4 DMI Interface Detail

GPU3D DMI ports

Name	Type	Source	Description
gpu_use_bufid[2:0]	Output	GPU3D	Tell IPU which buffer can be displayed, one-hot coded
ipu_vsync_valid	Input	IPU	Tell GPU3D one frame is finished, high in vertical blank period
ipu_active_bufid[2:0]	Input	IPU	Tell GPU3D which frame is free to be overwritten, one-hot coded

The vertical sync (VSYNC) from the display controller occurs after each frame is displayed, during the vertical blanking period.

One-hot encoded USE_BUFID signals are updated by GPU3D whenever there is a new rendered buffer available (and the previous value of USE_BUFID has already been sampled by the IPU / display controller), so it can change anywhere in the frame. It is re-synchronized and sampled a few cycles before the start of the vertical blanking period (rising edge of VSYNC) in display controller, while the currently finished buffer (ACTIVE_BUFID signals) is updated by display controller at the rising edge of VSYNC, ACTIVE_BUFID are then re-synchronized and sampled by GPU3D after synchronizing to VSYNC rising edge.

40.5.5 Debug Bus and GPIO

40.5.5.1 Debug Bus

The GPU3D has a 32b debug bus output that is controlled by a 18b 'GPIO' bus. The 32b debug bus should be mapped to system GPIO. In i.MX53, this 32b bus is MUXed to 16b to reduce the number of external pins required. The MUXing of these pins is controlled by 2 bits in the GPIO register.

40.5.5.2 GPIO Register

The GPU3D supports 16 general purpose input pins that can be configured as soft reset, debug mux select bits etc. The bus is implemented as a system register (whose offset is 0x2FFFC from GPU3D base address) along with 2_bit debug bus control information. The registered inputs are semi-static and have no timing constraints associated with them. The following table shows GPIO register implementation.

GPIO register-R/W 18 bit- (0x2FFFC)

field name	bits	default	Description
debug bus control	17:16	0x0	00 - output lower 16 bits 01 - output upper 16 bits 10 - toggle between outputing lower and upper 16 bits per 83MHz clock 11 - unused
GPIO bus	15:0	0x0000	debug bus control

Table 40-1. GPIO bus functions

GPIO BIT	Debug Function	Reset/Misc Function
15	1'b0	Ignore SQ RTR for AHB
14	1'b0	Ignore VGT RTR for AHB
13	1'b0	Ignore CP RTR for AHB
12	1'b0	Ignore RTR for AHB
11	Sub-Block Select[3]	Ignore RTR
10	Sub-Block Select[2]	VGT Soft Reset
9	Sub-Block Select[1]	SC Soft Reset
8	Sub-Block Select[0]	CIB Soft Reset
7	1'b0	1'b0
6	1'b0	1'b1
5	Sub-Block Addr[5]	SX Soft Reset

Table continues on the next page...

Table 40-1. GPIO bus functions (continued)

GPIO BIT	Debug Function	Reset/Misc Function
4	Sub-Block Addr[4]	SQ Soft Reset
3	Sub-Block Addr[3]	RB Soft Reset
2	Sub-Block Addr[2]	MH Soft Reset
1	Sub-Block Addr[1]	PA Soft Reset
0	Sub-Block Addr[0]	CP Soft Reset

The functionality in the Reset/Misc Function is the same as the functionality in the RBBM_SOFT_RESET register and the RBBM_DEBUG register. The bits are logically OR'd together.

There is latency built into the debug bus due to the registered daisy chain nature of the debug bus. From the time GPIO gets registered (count this as clock 1), it can take up to 10 clock cycles before valid Debug Bus data is resident in the Debug Bus register. This latency applies any time the state of GPIO is changed.

40.6 Clocking Architecture

40.6.1 Clock Input

The GPU3D design has 2 clocks at top level: aclk_gpu for the Graphics Core (GC) and aclk_garb for the Graphice Memory Arbiter (GARB).These 2 clocks are synchronous, they're actually in a single domain. There is no multicycle paths, latches or negative edge flops are used in the design. (The CKGATER uses a negative latch, but that is a special cell).

Both clocks (aclk_gpu and aclk_garb) are synchronous and in phase with core clock. Actually they come from one source in CCM but has separate gating cell so that clock (aclk_gpu) to the Graphics core (GC) can be removed independently of the GARB (aclk_garb), which make GMEM still accessible when Graphics Core (GC) is shut down.

Both clocks (aclk_gpu and aclk_garb) should be implemented with programmable dividers to run at full speed, synchronous bus speed, and half bus speed to meet system power use cases.

40.6.2 Clock Gating

GPU3D graphics core (GC) supports three levels of clock gating, which is done by internal block CIB (Control Interface Block):

- Explicit removal of clocks to the GC core by the system under software control
- Designer controlled removal of clocks to logic blocks (controlled by internal CIB block)
- Instantiated clock gating by synthesis tool.

Explicit clock gating is invoked under system control and as such is transparent to the GPU3D. All clocks (aclk_gpu and aclk_garb) are removed. Prior to clock removal, the system should ensure that the GPU3D is idle (no outstanding bus traffic, no outstanding command activity in command buffer). Removing the clocks to the GPU3D does not impact internal state (unless power is also removed).

Designers can chose to remove clocks to blocks or sections of blocks based on those functions becoming idle. Power Management Override bits are supported which selectively disable designer instantiated clock gating. The GC powers up with the clock gating disabled with the exception of the AHB busclock and the GMEM clocks which power up with clock gating enabled. It is the responsibility of the driver to enable the clock gating functionality by disabling (clearing) the power management override bits. The GARB instantiate default enabled clock gaters for GMEM clock for power saving, which can be overridden (disabled) by pm_override[3:0] from the GC to the GARB.

In particular, the output 'idle' signal (gpu_idle, active high) signal from the CIB should be used to clock gate the core clock signals (aclk_garb) to reduce power consumption.

40.7 Reset

GPU3D has only an asynchronous reset port named hresetn at top level, which is active low and will reset GC, GARB & GMEM.

Please note that **the internal Graphics Core (GC) uses synchronous reset which is propagated through the design as a standard synchronous signal. So clocks (ack_gc and aclk_garb) must be turned on when hard reset (hresetn) asserted.** The supplied reset (hresetn) is passed through a reset conditioning circuit in the CIB. This conditioning circuit extends reset assertion long enough to guarantee that all internal circuits are reset correctly. This circuit counts 20 bus cycles after the de-assertion of reset so GPU3D need 20 bus cycles to complete a reset.

In addition to the top level hard reset (hresetn) there are soft resets for each internal blocks that can be controlled by Software.

40.8 Interrupts

The graphics core provides a single interrupt pin to the system (gpu_int_b). Once asserted the interrupt pin remains asserted (active low) until the ARM platform clears the IRQ bit in the RBBM_IRQ register.

In general interrupts are used to signal error conditions or to support frame buffer swap.

40.9 Memory Map

The GPU3D has 2 memory map spaces in i.MX53:

- AHB slave interface (GC space)
- AXI slave memory interface (GMEM space).

Memory Map

Description	Memory Address Base	Memory Address End
GC space (register, instruction)	0x3000 0000	0x3002 FFFF
GMEM space (256KB)	0xF802 0000	0xF805 FFFF

Chapter 41
I2C Controller (I2C)

41.1 Overview

This chapter describes block-level operation and programming of I2C. The chapter is intended for a block driver software developer. To understand how the block is integrated at the SoC level, a system software developer can refer to discussions of the block in the appropriate SoC-level chapter(s).

References: This document assumes an understanding of the following reference:

1. The I2C Bus Specification, Version 2.1

The Inter IC (I2C) provides functionality of a standard I2C slave and master. The I2C is designed to be compatible with the standard Philips I2C bus protocol.

I2C is a two-wire, bidirectional serial bus that provides a simple, efficient method of data exchange, minimizing the interconnection between devices. This bus is suitable for applications requiring occasional communications over a short distance between many devices. The flexible I2C standard allows additional devices to be connected to the bus for expansion and system development. See the connection diagram in the figure below.

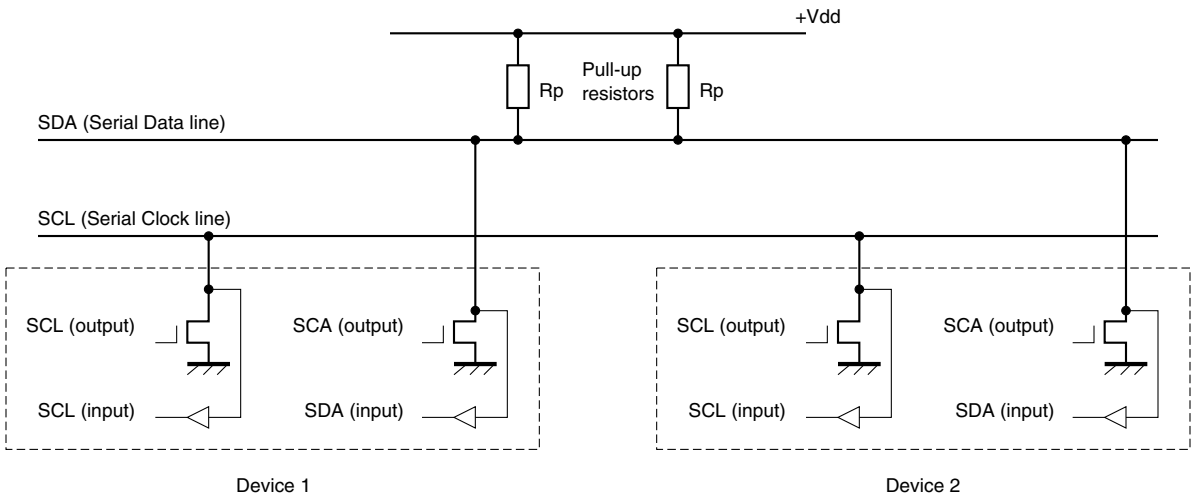

Figure 41-1. Connection of Devices to I2C Bus

The I2C interface operates up to 400 kbps, but it depends on the pin loading and timing characteristics. For pin requirement details, refer to Philips I2C Bus Specification, Version 2.1. The I2C system is a true multiple-master bus including arbitration and collision detection that prevents data corruption if multiple devices attempt to control the bus simultaneously. This feature supports complex applications with multiprocessor control and can be used for rapid testing and alignment of end products through external connections to an assembly-line computer. The figure below shows the block diagram of I2C.

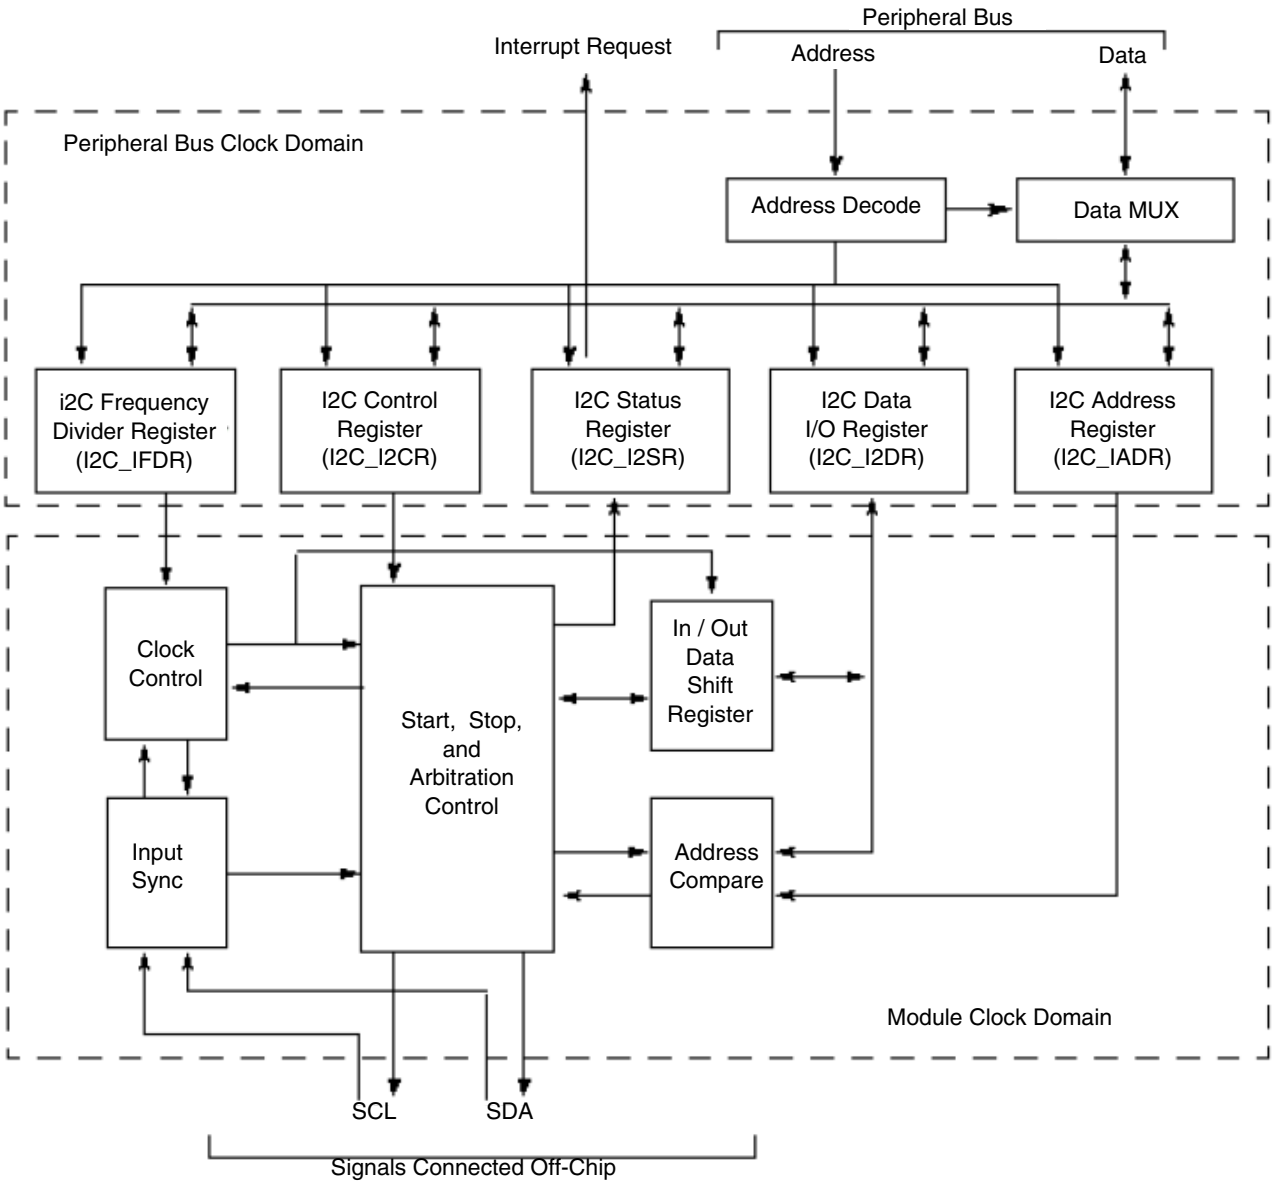

Figure 41-2. I2C Block Diagram

41.1.1 Features

The I2C has the following key features:

- Compatibility with I2C bus standard
- Multiple-master operation
- Software-programmable for one of 64 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven, byte-by-byte data transfer
- Arbitration-lost interrupt with automatic mode switching from master to slave

- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated START signal generation
- Acknowledge bit generation/detection
- Bus-busy detection

41.1.2 Modes and Operations

The I2C primarily operates in two different functional modes.

41.1.2.1 Standard Mode

In Standard mode, I2C supports the data transfer rates up to 100 Kbits/s.

41.1.2.2 Fast Mode

In Fast Mode, data transfer rates up to 400 Kbits/s can be achieved.

As per block operation, there is no special configuration required for Fast and Standard mode. It is the data transfer rate which distinguishes Standard and Fast mode.

41.2 External Signals

The table below describes all I2C signals that connect off-chip.

For I2C compliance, all devices connected to the SCL and SDA signals must have open-drain or open-collector outputs. The logic AND function is exercised on both lines with external pull-up resistors.

Input of SCL and SDA also need to be manually opened by set SION bit in IOMUX after corresponding PADs were selected as I2C function.

Table 41-1. Off-Chip Block Signals

Signal	I/O	Description	Reset State[1]	Pull-Up/Down[1]
SCL	I/O	Serial Clock	1	Active
SDA	I/O	Serial Data	1	Active

1. The reset state values and pull-up/down requirements provided in this table are from the block-level perspective. To understand how the block is integrated at the SoC level, the system software developer must see discussions of the block in the appropriate SoC-level chapter(s). For example, a block signal that requires a pull-up coul

up option built into the SoC. In this case, the system software developer must ensure the proper programming at the SoC level.

41.3 Functional Description

41.3.1 I2C System Configuration

Out of a reset, the I2C defaults to slave receive operations. Thus, when not operating as a master or responding to a slave transmit address, the I2C will default to the slave receiver state.

For exceptions, see Initialization Sequence.

NOTE

The I2C is designed to be compatible with the Philips™ I2C bus protocol. For information on system configuration, protocol, and restrictions, refer to the I2C Bus Specification, Version 2.1. The I2C supports Standard and Fast modes only.

41.3.2 I2C Protocol

The I2C communication protocol consists of six components, as follows:

- START
- Data Source/Recipient
- Data Direction
- Slave Acknowledge
- Data Acknowledge
- STOP

See the figure below for the I2C standard communication protocol, as defined in the following sections.

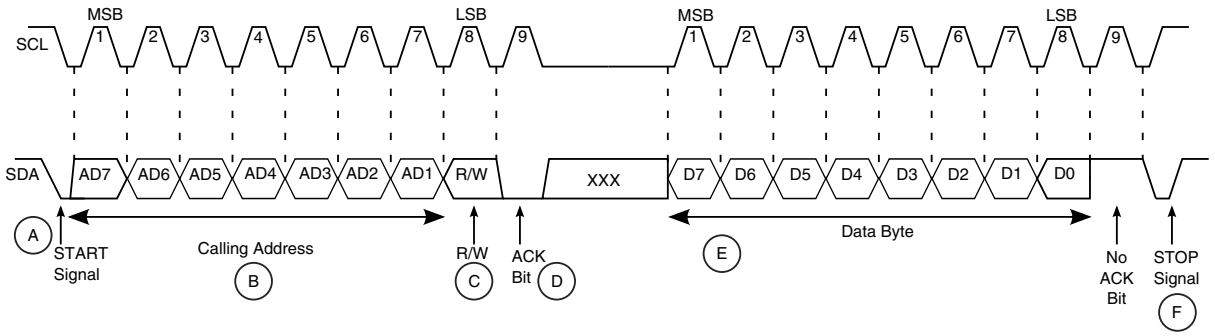

Figure 41-3. I2C Standard Communication Protocol

41.3.2.1 START Signal

When no other device is a bus master (both SCL and SDA lines are at logic high), a device can initiate communication by sending a START signal (see A in Figure 41-3).

A START signal is defined as a high-to-low transition of SDA while SCL is high. This signal denotes the beginning of a data transfer (each data transfer can be several bytes long) and awakens all slaves.

41.3.2.2 Slave Address Transmission

The master sends the slave address in the first byte after the START signal (B). After the seven-bit calling address, it sends the R/W bit (C), which tells the slave data transfer direction.

Each slave must have a unique address. An I2C master must not transmit an address that is the same as its slave address; it cannot be master and slave at the same time.

The slave whose address matches that sent by the master pulls SDA low at the ninth clock (D) to return an acknowledge bit.

41.3.2.3 Data Transfer

When successful slave addressing is achieved, the data transfer can proceed (E) on a byte-by-byte basis in the direction specified by the R/W bit sent by the calling master.

Data can be changed only while SCL is low and must be held stable while SCL is high, as shown in Figure 41-3. SCL is pulsed once for each data bit, most-significant bit first. The receiving device must acknowledge each byte by pulling SDA low at the ninth clock; therefore, a data byte transfer takes nine clock pulses.

If it does not acknowledge the master, the slave receiver must leave SDA high. The master can then generate a STOP signal to abort the data transfer or generate a START signal (a repeated start, as shown in Figure 41-4) to start a new calling sequence.

If the master receiver does not acknowledge the slave transmitter after a byte transmission, it means end-of-data to the slave. The slave releases SDA for the master to generate a STOP or START signal.

NOTE

Writing to the data register triggers transmit operation.

Transmit data should always be written after MTX bit is programmed. Transmit data is not latched inside until the transfer is initiated on the interface bus.

After the transmit data write in I2C, software can either wait for a transfer-done interrupt or it can poll for ICF bit for zero, if new data has to be written during the previous data transfer. The IIF bit may not be polled if the IIEN bit is set because the I2C will generate an interrupt when IIF is set.

41.3.2.4 STOP Signal

The master can terminate communication by generating a STOP signal to free the bus. A STOP signal is defined as a low-to-high transition of SDA while SCL is at logical high (F).

NOTE

A master can generate a STOP even if the slave has made an acknowledgment, at which point the slave must release the bus.

41.3.2.5 Repeat Start

Instead of signalling a STOP, the master can repeat the START signal, followed by a calling command

(see A in the figure below). A repeated START occurs when a START signal is generated without first generating a STOP signal to end the communication. The master uses a repeated START to communicate with another slave or with the same slave in a different mode (transmit/receive mode) without releasing the bus.

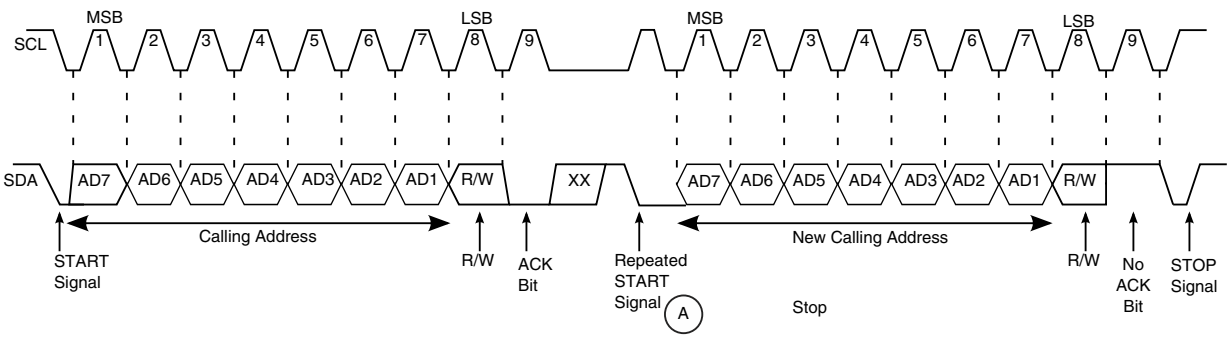

Figure 41-4. Repeated START

41.3.3 Arbitration Procedure

If multiple devices simultaneously request the bus, the bus clock is determined by a synchronization procedure in which the low period equals the longest clock-low period among the devices, and the high period equals the shortest. A data arbitration procedure determines the relative priority of competing devices.

A device loses arbitration if it sends logic high while another sends logic low; it immediately switches to slave-receive mode and stops driving SDA. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, hardware sets the arbitration lost bit in the I2C Status register (I2C_I2SR[IAL] to indicate loss of arbitration).

41.3.4 Clock Synchronization

Because wire-AND logic is used, a high-to-low transition on SCL affects devices connected to the bus. Devices start counting their low period when the master drives SCL low. When a device clock goes low, it holds SCL low until the clock high state is reached. However, the low-to-high change in this device clock may not change the state of SCL if another device clock is still in its low period. Therefore, the device with the longest low period holds the synchronized clock SCL low.

Devices with shorter low periods enter a high wait state during this time (see the figure below). When all devices involved have counted off their low period, the synchronized clock SCL is released and pulled high. There is then no difference between device clocks and the state of SCL, so all of the devices start counting their high periods. The first device to complete its high period pulls SCL low again.

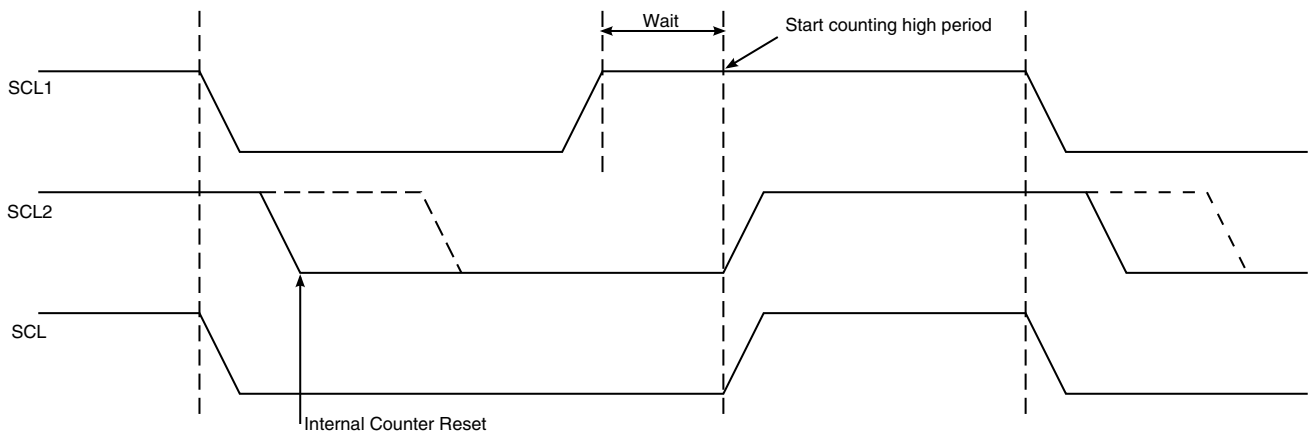

Figure 41-5. Synchronized Clock SCL

41.3.5 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. Slave devices can hold SCL low after completing one byte transfer (9 bits). In such a case, the clock mechanism halts the bus clock and forces the master clock into a wait state until the slave releases SCL.

41.3.6 Clock Stretching

Slaves can use the clock synchronization mechanism to slow down the transfer bit rate. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is longer than the master SCL low period, the resulting SCL bus signal low period is stretched.

41.3.7 Peripheral Bus Accesses

I2C is a 16-bit block. Only half-word accesses should be performed to the block.

41.3.8 Generation of Transfer Error on IP Bus

If an address is received on the Peripheral slave bus interface that is not implemented, an access error is generated.

41.3.9 Clocks

There are two input clocks for I2C.

1. Peripheral Clock:The clock is used for Peripheral bus register read/writes.
2. Module Clock:This is the functional clock of the I2C. The serial bit clock frequency is derived from the module clock. The module clock and peripheral clocks are synchronous to each other. The minimum frequency of module clock should be 12.8 MHz for Fast Mode to achieve 400 Kbps operation.

41.3.10 Reset

The I2C can be reset in two ways.

1. Global reset: A hard asynchronous reset of the whole I2C.
2. Software reset: An internal reset for whole I2C, except I2C_IADR and I2C_IFDR registers, is initiated by deasserting the I2C_I2CR[IEN] bit.

41.3.11 Interrupts

There is only one interrupt from the block. The interrupt is enabled by setting the I2C_I2CR[IIEN] bit.

The interrupt is generated in any one of the following conditions.

- One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock).
- An address is received that matches its own specific address in slave-receive mode.
- Arbitration is lost.

41.3.12 Byte Order

The block only supports the little endian mode.

41.4 Initialization

41.4.1 Initialization Sequence

Before the interface can transfer serial data, registers must be initialized, as follows:

1. Set the data sampling rate (I2C_IFDR[IC] to obtain SCL frequency from the system bus clock.
2. Update the address in the (I2C_IADR) to define its slave address (address can range from 0 to 0x7f).
3. Set the I2C enable bit (I2C_I2CR[IEN]) to enable the I2C bus interface system.
4. Modify the bits in the I2C_I2CR to select master/slave mode, transmit/receive mode, and interrupt-enable or not.

41.4.2 Generation of START

After completion of the initialization procedure, serial data can be transmitted by selecting the master transmitter mode. On a multiple-master bus system, the busy bus (I2C_I2SR[IBB]) must be tested to determine whether the serial bus is free. If the bus is free (IBB = 0), the START signal and the first byte (the slave address) can be sent. The data written to the data register comprises the address of the desired slave and the LSB indicates the transfer direction.

The free time between a STOP and the next START condition is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I2C is busy after writing the calling address to the data register (I2C_I2DR) before proceeding to load data into the data register (I2C_I2DR).

41.4.3 Post-Transfer Software Response

Sending or receiving a byte sets the data transferring bit (I2C_I2SR[ICF]), which indicates one byte communication is finished. Upon completion, the interrupt status (I2C_I2SR[IIF]) is also set. An external interrupt is generated if the interrupt enable (I2C_I2CR[IIEN]) is set. The software must first clear the interrupt status (I2C_I2SR[IIF]) in the interrupt routine.

(See the flow chart in Figure 41-7.) The data transferring bit (I2C_I2SR[ICF]) is cleared either by reading from I2C_I2DR in receive mode or by writing to this register in transmit mode.

The software can service the I2C I/O in the main program by monitoring the interrupt status (I2C_I2SR[IIF]) if the interrupt enable is deasserted. In this case, the interrupt status should be polled of the data transferring bit (I2C_I2SR[ICF]) because the operation is different when arbitration is lost.

When an interrupt occurs at the end of the address cycle, the master is always in transmit mode; that is, the address is sent. If master receive mode is required, then I2C_I2CR[MTX] should be toggled and dummy read of I2C_I2DR register has to be done for triggering receive data.

During slave-mode address cycles (I2C_I2SR[IAAS] = 1), the slave read/write bit I2C_I2SR[SRW] is read to determine the direction of the next transfer. The transmit/receive bit (I2C_I2CR[MTX]) should also be programmed accordingly. For slave-mode data cycles (IAAS = 0), SRW is invalid. MTX should be read to determine the current transfer direction.

41.4.4 Generation of STOP

A data transfer ends when the master signals a STOP, which can occur after all data is sent.

For a master receiver to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last data byte. This is done by setting the transmit acknowledge bit (I2C_I2CR[TXAK]) before reading the next-to-last byte. Before the last byte is read, a STOP signal must be generated.

41.4.5 Generation of Repeated START

After the data transfer, if the master still wants the bus, it can signal another START followed by another slave address without signalling a STOP.

41.4.6 Slave Mode

In the slave interrupt service routine (see Figure 41-7), the block addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (I2C_I2CR[MTX]) according to the I2C_I2SR[SRW]. Writing to the I2C_I2CR clears the IAAS automatically. The only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred; interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer can now be initiated by writing information to I2C_I2DR for slave transmits, or read from I2C_I2DR in slave-receive mode. A dummy read of I2C_I2DR in slave/receive mode releases SCL, allowing the master to send data.

In the slave transmitter routine, the receive acknowledge bit (I2C_I2SR[RXAK]) must be tested before sending the next byte of data. Setting RXAK means an end-of-data signal from the master receiver, after which the software must switch it from transmitter to receiver mode. Reading the data register (I2C_I2DR) then releases SCL so that the master can generate a STOP signal.

41.4.7 Arbitration Lost

If several devices try to engage the bus at the same time, one becomes master. Hardware immediately switches devices that lose arbitration to slave receive mode. Data output to SDA stops, but SCL is still generated until the end of the byte during which arbitration is lost. An interrupt occurs at the falling edge of the ninth clock of this transfer if the arbitration is lost (I2C_I2SR[IAL] = 1), and the slave mode is selected (I2C_I2CR[MSTA] = 0).

See the flow chart in Figure 41-7.

If a device that is not a master tries to transmit or do a START, hardware inhibits the transmission, clears MSTA without signalling a STOP, generates an interrupt to the ARM platform, and sets I2C_I2SR[IAL] to indicate a failed attempt to engage the bus. When considering these cases, the slave service routine should first test I2C_I2SR[IAL], and the software should clear it if it is set.

For Multi-master mode, when an I2C is enabled when the bus is busy and asserts START, the I2C_I2SR[IAL] bit gets set only for SDA=0, SCL=0/1, SDA=1, and SCL=0, but not for SDA=1 and SCA=1, which is the same as bus idle state.

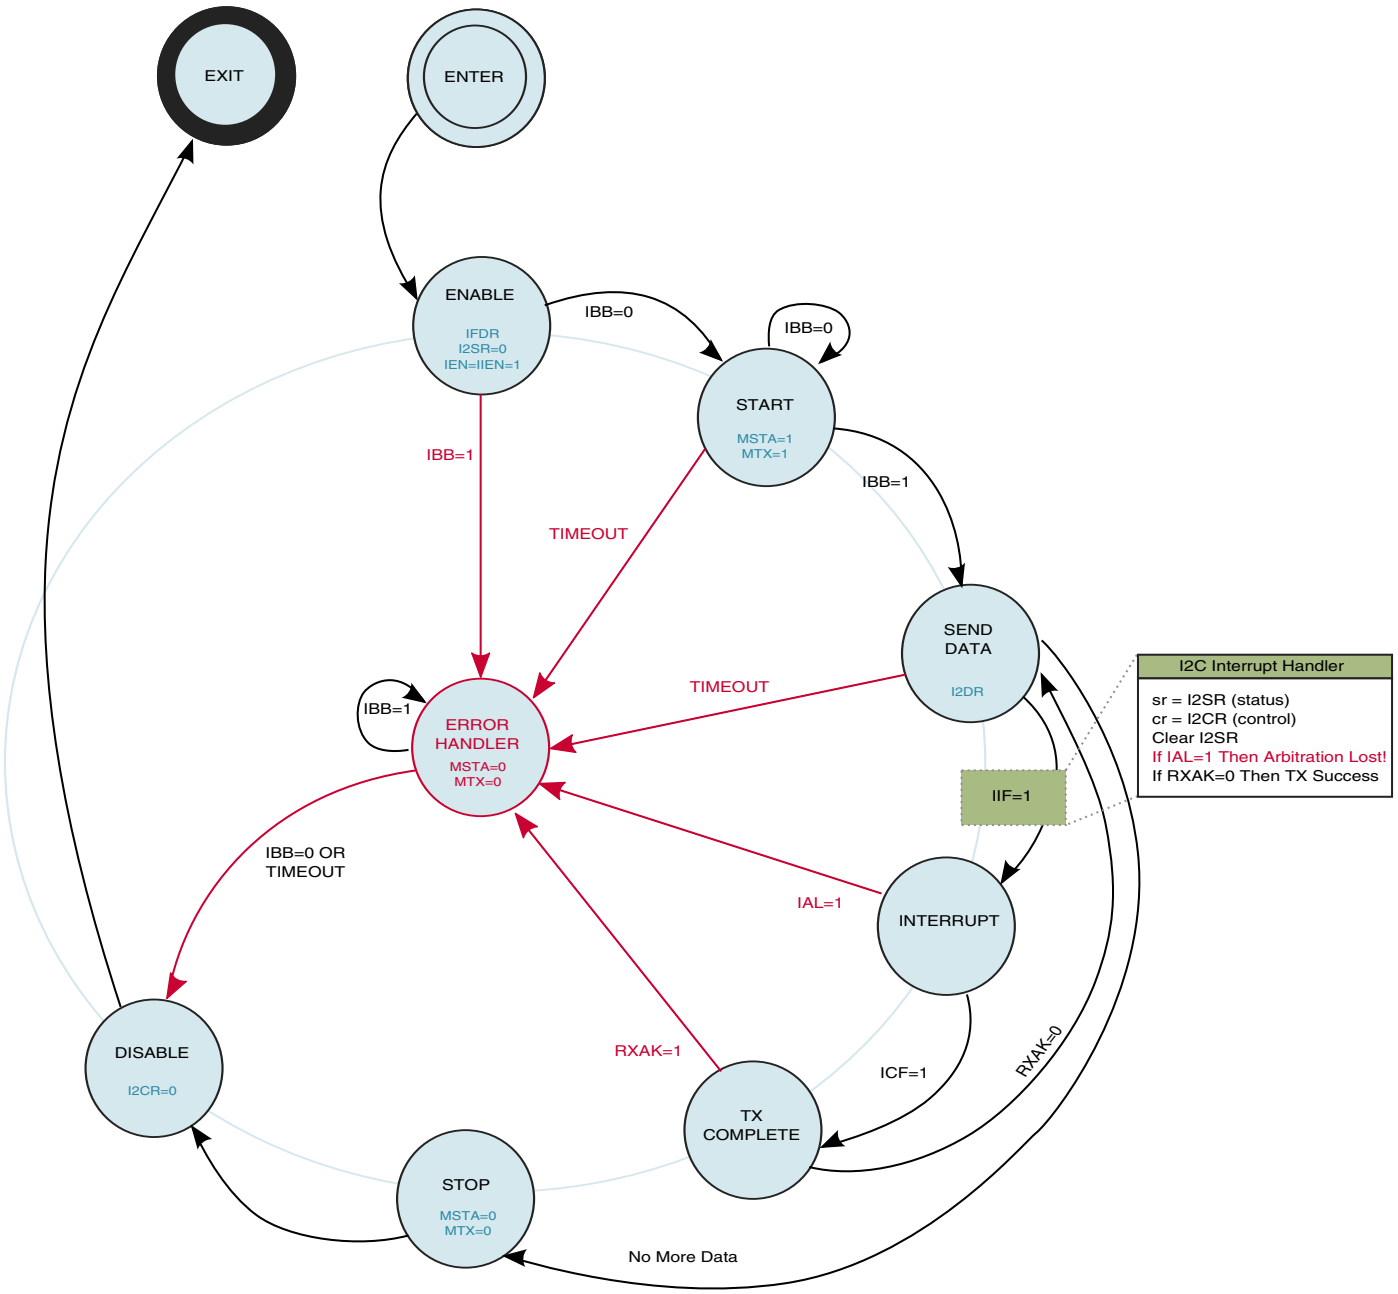

Figure 41-6. I2C Programming State Diagram

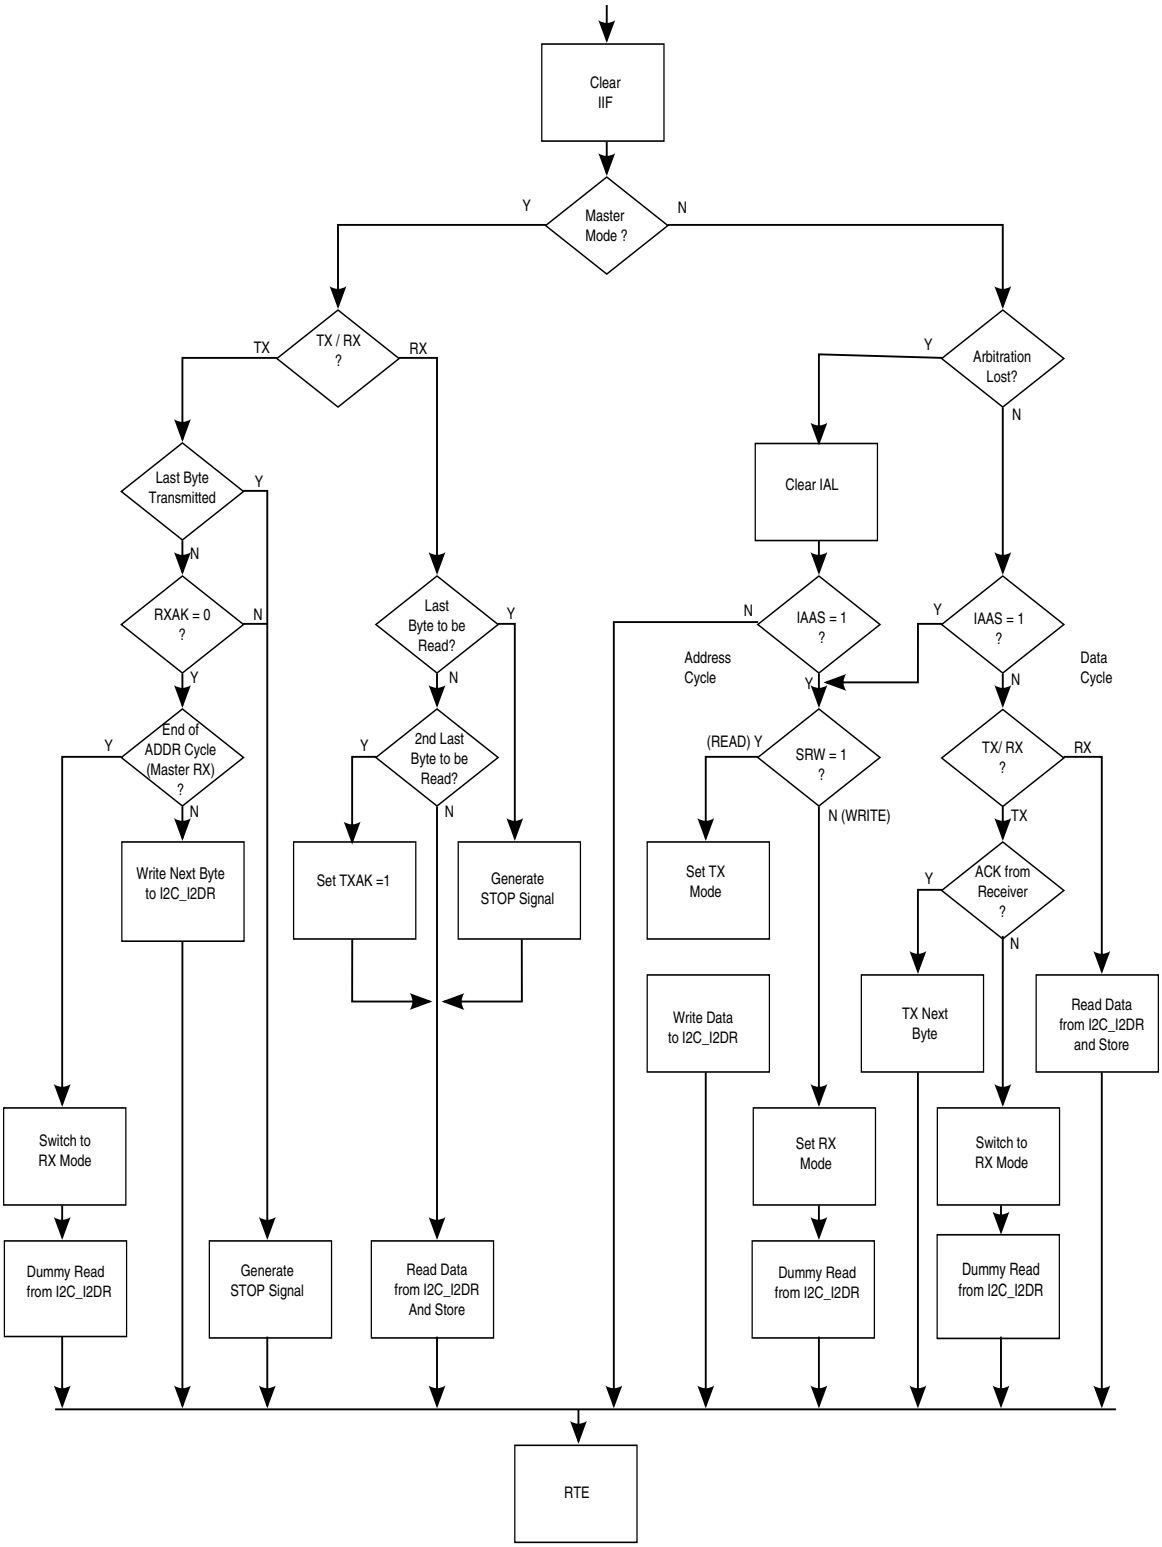

Figure 41-7. Flow-Chart of Typical I2C Interrupt Routine

NOTE

For a repeated start-only, the stop generation stage will not occur in master mode. A loop will repeat itself without stopping for the next start.

For Master Rx mode, I2C is programmed as master transmit during address mode and after slave address transfer, MTX bit should be cleared and Dummy read on I2C_I2DR register should be performed so that I2C can read the next receive data.

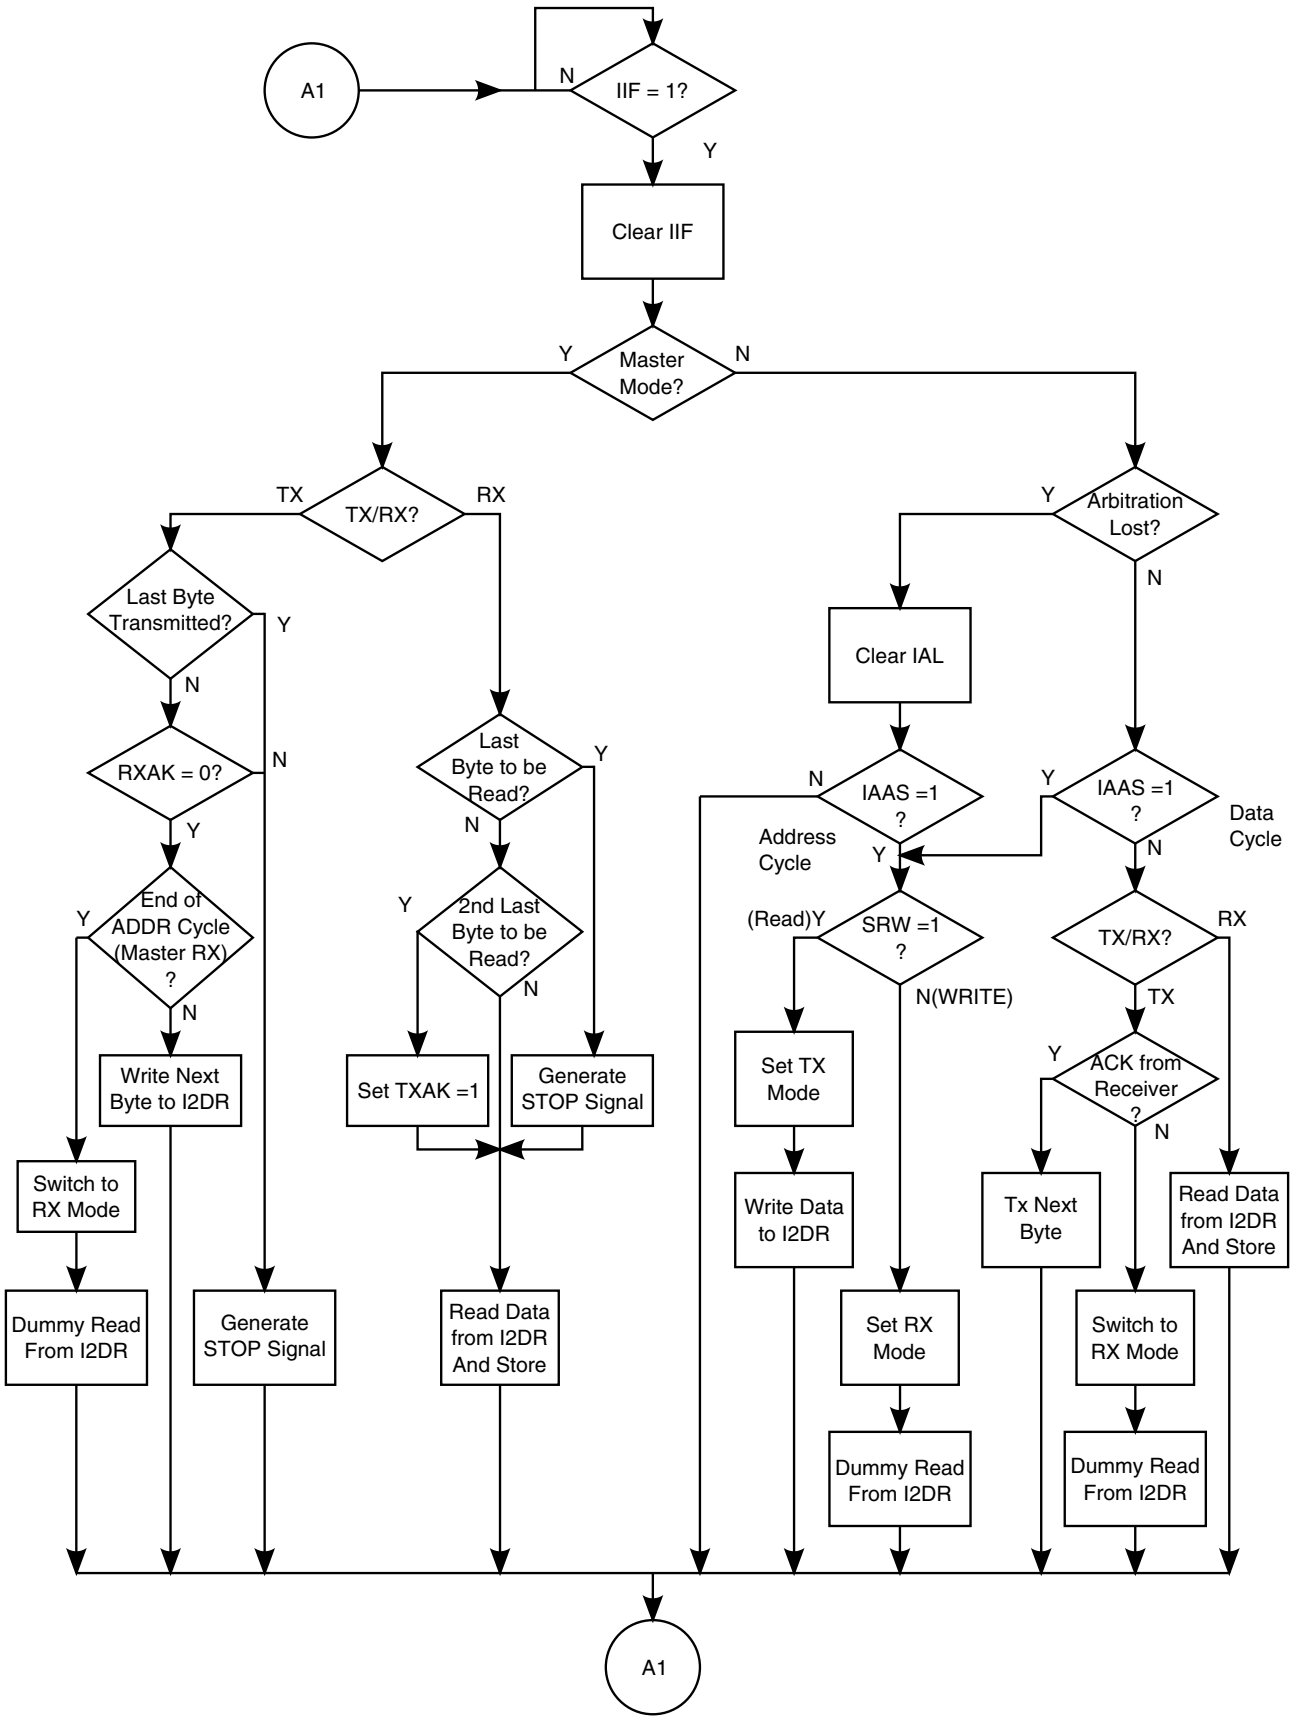

Figure 41-8. Flow Chart for Typical I2C Polling Routi

NOTE

The time-out value will depend on the bus frequency at which I2C is operating. The Min. Time-out for polling IIF bit at I2C Max bus frequency of 400KHz is, T_{min} = 25 μs (= 2.5*10 μs). This value can be interpolated for any bus frequency.

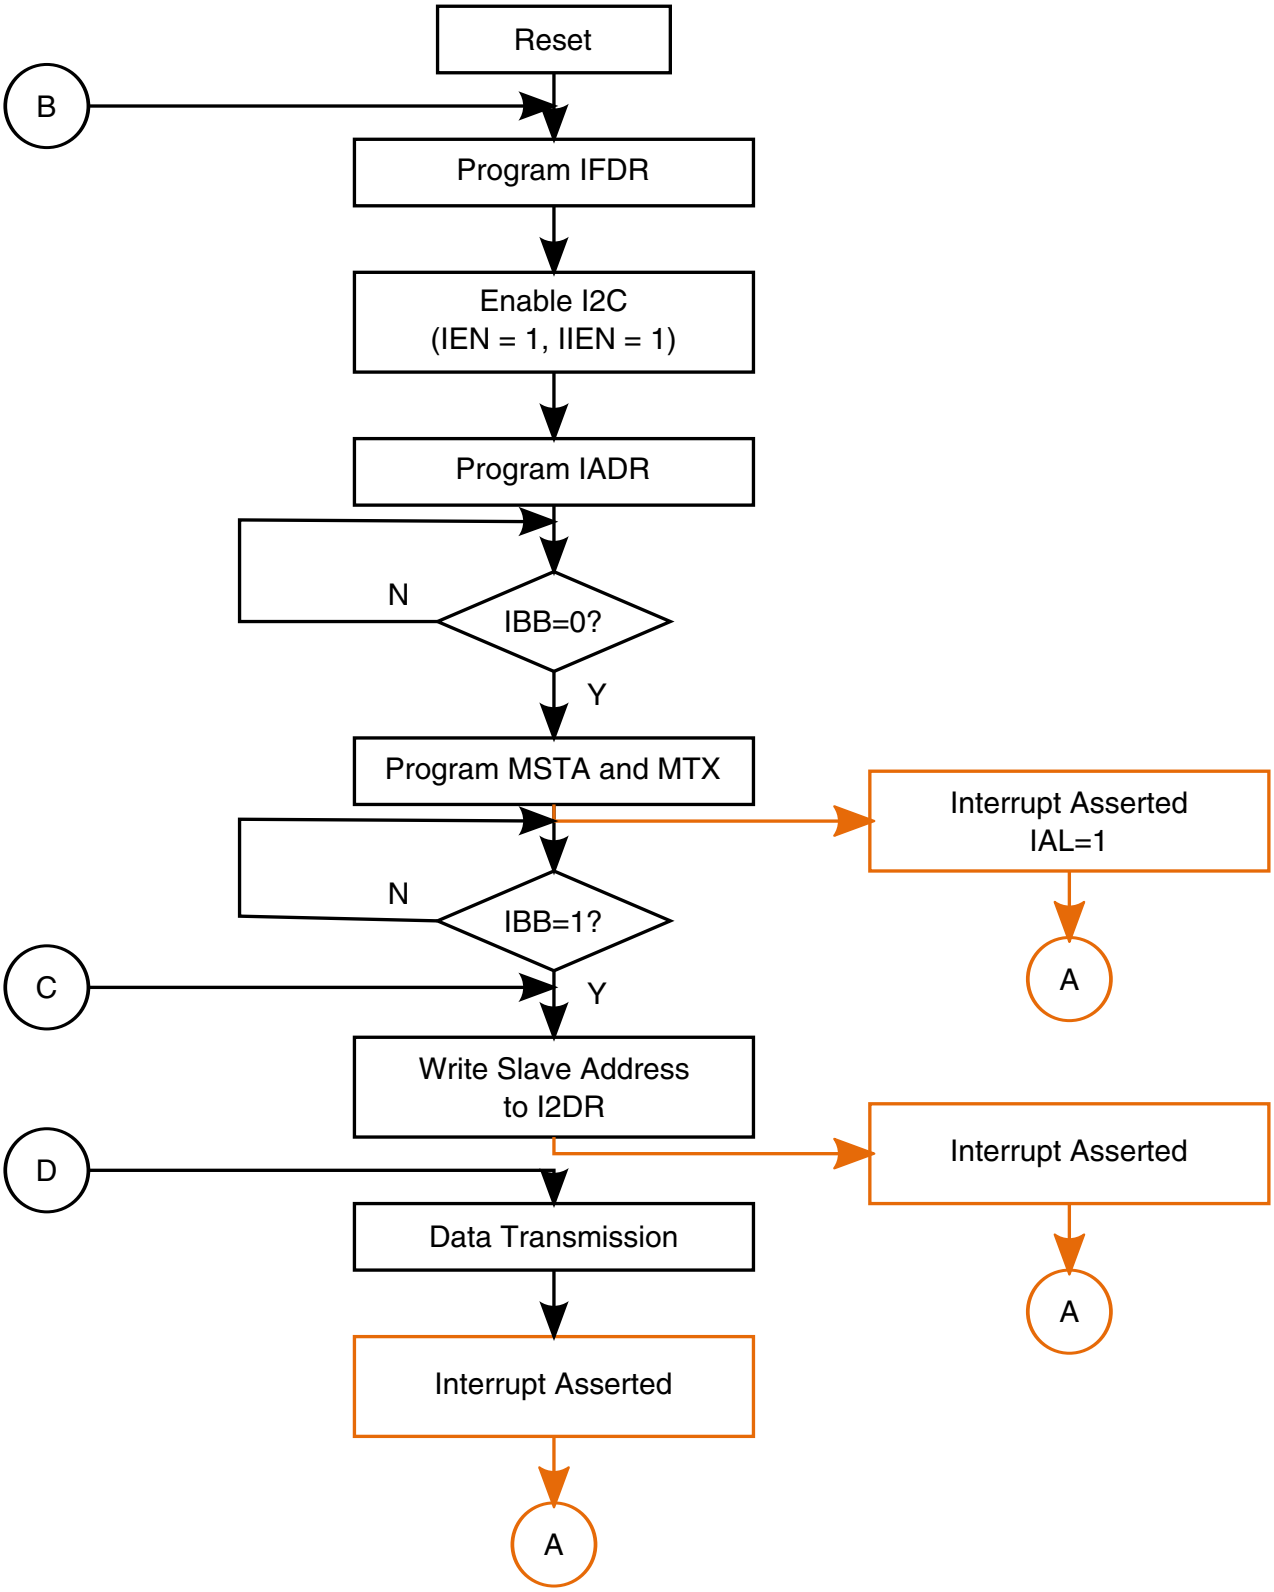

Figure 41-9. Detailed Flow Chart of a Typical I2C Master Tx Mode, Part 1

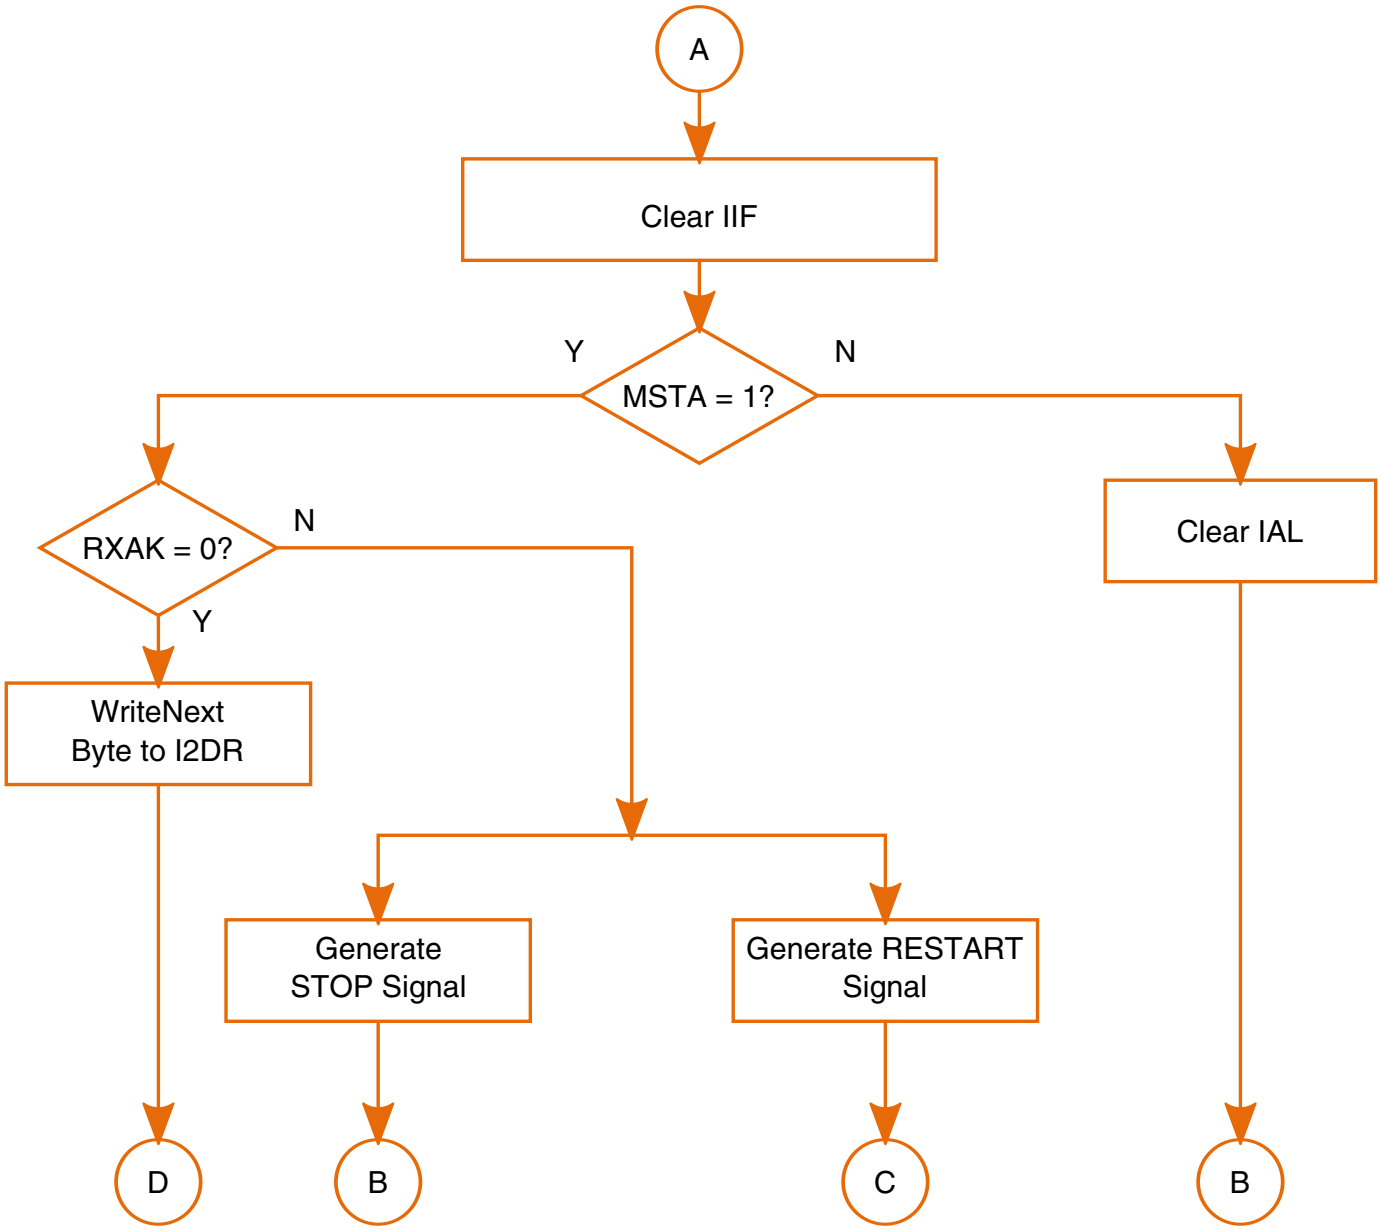

Figure 41-10. Detailed Flow Chart of a Typical I2C Master Tx Mode, Part 2

Figure 41-9 and Figure 41-10 show the Master Transmit mode operation with interrupt sub-routine. In case interrupt is generated and the MSTA bit is 0, then bus arbitration is lost and IAL is set. Software can clear IAL bit and re-program I2C. If MSTA bit is 1, then it will be a transfer done interrupt and software can check RXAK bit for data receive acknowledgement by slave and accordingly decide to either generate STOP, REPEAT START by writing in I2C_I2CR register or next data transfer by writing into I2C_I2DR register.

NOTE

The IBB bit is asserted by START condition on the bus, and it is deasserted by STOP condition on bus. Therefore, if arbitration is lost due to an unexpected STOP condition during transfer, then IBB is cleared. If arbitration is lost due to data mismatch, then it will not be cleared. Software should always clear the IEN bit and then set it if arbitration is lost.

41.5 Software Restriction

Software should take care that there is a delay of at least two Module Clock cycles after it sets the I2C_I2CR[RSTA] bit before writing to the I2C_I2DR register. Maximum possible clock period of Module Clock is 78 ns.

41.6 Programmable Registers

41.6.1 I2C Memory Map/Register Definition

The I2C contains five 16-bit registers.

NOTE

Registers at offsets 0x0002, 0x0006, 0x000A, and 0x000E are reserved for future additions.

I2C memory map

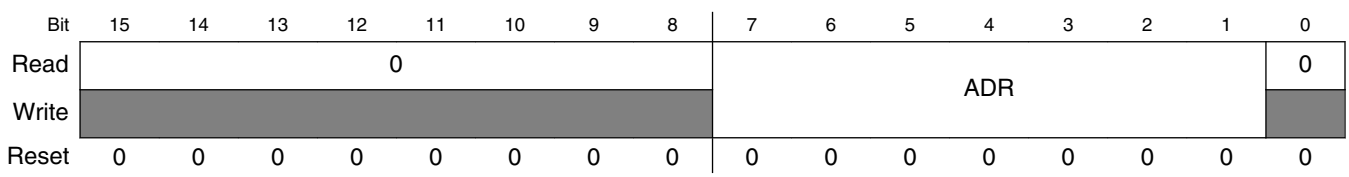
Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53FE_C000	I2C Address Register (I2C-3_IADR)	16	R/W	0000h	41.61.1/ 1813
53FE_C004	I2C Frequency Divider Register (I2C-3_IFDR)	16	R/W	0000h	41.61.2/ 1814
53FE_C008	I2C Control Register (I2C-3_I2CR)	16	R/W	0000h	41.61.3/ 1815
53FE_C00C	I2C Status Register (I2C-3_I2SR)	16	R/W	0081h	41.61.4/ 1817
53FE_C010	I2C Data I/O Register (I2C-3_I2DR)	16	R/W	0000h	41.61.5/ 1818

I2C memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FC_4000	I2C Address Register (I2C-2_IADR)	16	R/W	0000h	41.61.1/ 1813
63FC_4004	I2C Frequency Divider Register (I2C-2_IFDR)	16	R/W	0000h	41.61.2/ 1814
63FC_4008	I2C Control Register (I2C-2_I2CR)	16	R/W	0000h	41.61.3/ 1815
63FC_400C	I2C Status Register (I2C-2_I2SR)	16	R/W	0081h	41.61.4/ 1817
63FC_4010	I2C Data I/O Register (I2C-2_I2DR)	16	R/W	0000h	41.61.5/ 1818
63FC_8000	I2C Address Register (I2C-1_IADR)	16	R/W	0000h	41.61.1/ 1813
63FC_8004	I2C Frequency Divider Register (I2C-1_IFDR)	16	R/W	0000h	41.61.2/ 1814
63FC_8008	I2C Control Register (I2C-1_I2CR)	16	R/W	0000h	41.61.3/ 1815
63FC_800C	I2C Status Register (I2C-1_I2SR)	16	R/W	0081h	41.61.4/ 1817
63FC_8010	I2C Data I/O Register (I2C-1_I2DR)	16	R/W	0000h	41.61.5/ 1818

41.61.1 I2C Address Register (I2Cx_IADR)

Addresses: I2C-3_IADR is 53FE_C000h base + 0h offset = 53FE_C000h
I2C-2_IADR is 63FC_4000h base + 0h offset = 63FC_4000h
I2C-1_IADR is 63FC_8000h base + 0h offset = 63FC_8000h



I2Cx_IADR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–1 ADR	Slave address. Contains the specific slave address to be used by the I2C. Slave mode is the default I2C mode for an address match on the bus.

Table continues on the next page...

I2Cx_IADR field descriptions (continued)

Field	Description
	NOTE: The I2C_IADR holds the address the I2C responds to when addressed as a slave. The slave address is not the address sent on the bus during the address transfer. The register is not reset by a software reset.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved

41.61.2 I2C Frequency Divider Register (I2Cx_IFDR)

The I2C_IFDR provides a programmable prescaler to configure the clock for bit-rate selection. The register does not get reset by software reset. The following table describes the Divider values for register field "IC". Table below describes the register values for field "IC".

Table 41-12. I2C_IFDR Register Field Values

IC	Divider		IC	Divider		IC	Divider		IC	Divider
0x00	30		0x10	288		0x20	22		0x30	160
0x01	32		0x11	320		0x21	24		0x31	192
0x02	36		0x12	384		0x22	26		0x32	224
0x03	42		0x13	480		0x23	28		0x33	256
0x04	48		0x14	576		0x24	32		0x34	320
0x05	52		0x15	640		0x25	36		0x35	384
0x06	60		0x16	768		0x26	40		0x36	448
0x07	72		0x17	960		0x27	44		0x37	512

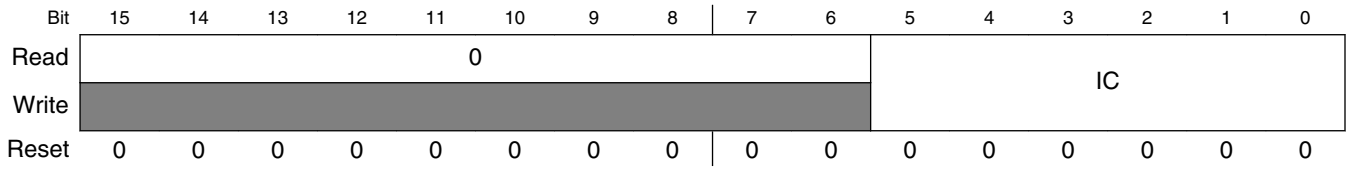
Addresses: I2C-3_IFDR is 53FE_C000h base + 4h offset = 53FE_C004h
I2C-2_IFDR is 63FC_4000h base + 4h offset = 63FC_4004h
I2C-1_IFDR is 63FC_8000h base + 4h offset = 63FC_8004h



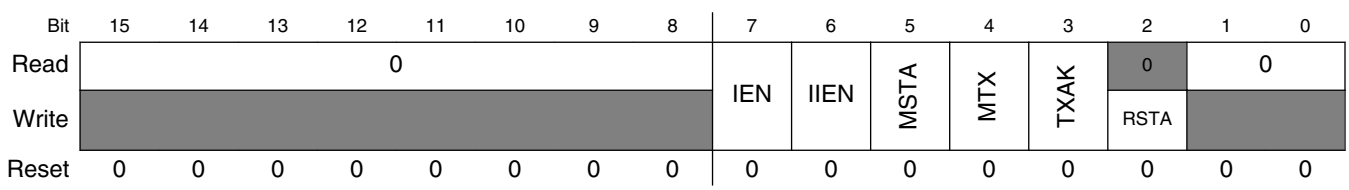
I2Cx_IFDR field descriptions

Field	Description
15–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5–0 IC	I2C clock rate. Pre scales the clock for bit-rate selection. Due to potentially slow SCL and SDA rise and fall times, bus signals are sampled at the prescaler frequency. The serial bit clock frequency is equal to IPG_CLK_ROOT divided by the divider shown in I2C Data I/O Register I2C Frequency Divider Register. **NOTE:** The IC value should not be changed during the data transfer, however, it can be changed before REPEAT START or START programming sequence in I2C. The I2C protocol supports bit rates up to 400 kbps. The IC bits need to be programmed in accordance with this constraint.

41.61.3 I2C Control Register (I2Cx_I2CR)

The I2C_I2CR is used to enable the I2C and the I2C interrupt. It also contains bits that govern operation as a slave or a master.

Addresses: I2C-3_I2CR is 53FE_C000h base + 8h offset = 53FE_C008h
I2C-2_I2CR is 63FC_4000h base + 8h offset = 63FC_4008h
I2C-1_I2CR is 63FC_8000h base + 8h offset = 63FC_8008h



I2Cx_I2CR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 IEN	I2C enable. Also controls the software reset of the entire I2C. Resetting the bit generates an internal reset to the block. If the block is enabled in the middle of a byte transfer, slave mode ignores the current bus transfer and starts operating when the next start condition is detected. Master mode is not aware that the bus is busy so initiating a start cycle may corrupt the current bus cycle, ultimately causing either the current master or the I2C to lose arbitration. After which, bus operation returns to normal.

Table continues on the next page...

I2Cx_I2CR field descriptions (continued)

Field	Description
	0 The block is disabled, but registers can still be accessed. 1 The I2C is enabled. This bit must be set before any other I2C_I2CR bits have any effect.
6 IIEN	I2C interrupt enable. **NOTE:** If data is written during the START condition, that is, just after setting the I2C_I2CR[MSTA] and I2C_I2CR[MTX] bits, then the ICF bit is cleared at the falling edge of SCLK after START. If data is written after the START condition and falling edge of SCLK, then ICF bit is cleared as soon as data is written. 0 I2C interrupts are disabled, but the status flag I2C_I2SR[IIF] continues to be set when an interrupt condition occurs. 1 I2C interrupts are enabled. An I2C interrupt occurs if I2C_I2SR[IIF] is also set.
5 MSTA	Master/slave mode select bit. If the master loses arbitration, MSTA is cleared without generating a STOP signal. **NOTE:** Module clock should be on for writing to the MSTA bit. **NOTE:** The MSTA bit is cleared by software to generate a STOP condition; it can also be cleared by hardware when the I2C loses the bus arbitration. 0 Slave mode. Changing MSTA from 1 to 0 generates a STOP and selects slave mode. 1 Master mode. Changing MSTA from 0 to 1 signals a START on the bus and selects master mode.
4 MTX	Transmit/receive mode select bit. Selects the direction of master and slave transfers. 0 Receive. When a slave is addressed, the software should set MTX according to the slave read/write bit in the I2C status register (I2C_I2SR[SRW]). 1 Transmit. In master mode, MTX should be set according to the type of transfer required. Therefore, for address cycles, MTX is always 1.
3 TXAK	Transmit acknowledge enable. Specifies the value driven onto SDA during acknowledge cycles for both master and slave receivers. **NOTE:** Writing TXAK applies only when the I2C bus is a receiver. 0 An acknowledge signal is sent to the bus at the ninth clock bit after receiving one byte of data. 1 No acknowledge signal response is sent (that is, the acknowledge bit = 1).
2 RSTA	Repeat start. Always reads as 0. Attempting a repeat start without bus mastership causes loss of arbitration. 0 No repeat start 1 Generates a repeated START condition
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

41.61.4 I2C Status Register (I2Cx_I2SR)

The I2C_I2SR contains bits that indicate transaction direction and status.

Addresses: I2C-3_I2SR is 53FE_C000h base + Ch offset = 53FE_C00Ch
I2C-2_I2SR is 63FC_4000h base + Ch offset = 63FC_400Ch
I2C-1_I2SR is 63FC_8000h base + Ch offset = 63FC_800Ch

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								ICF	IAAS	IBB	IAL	0	SRW	IIF	RXAK
Write																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	1

I2Cx_I2SR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 ICF	Data transferring bit. While one byte of data is transferred, ICF is cleared. 0 Transfer is in progress. 1 Transfer is complete. This bit is set by the falling edge of the ninth clock of the last byte transfer.
6 IAAS	I2C addressed as a slave bit. The ARM platform is interrupted if the interrupt enable (I2C_I2CR[IIEN]) is set. The ARM platform must check the slave read/write bit (SRW) and set its TX/RX mode accordingly. Writing to I2C_I2CR clears this bit. 0 Not addressed 1 Addressed as a slave. Set when its own address (I2C_IADR) matches the calling address.
5 IBB	I2C bus busy bit. Indicates the status of the bus. **NOTE:** When I2C is enabled (I2C_I2CR[IEN] = 1), it continuously polls the bus data (SDAK) and clock (SCLK) signals to determine a START or STOP condition. 0 Bus is idle. If a STOP signal is detected, IBB is cleared. 1 Bus is busy. When START is detected, IBB is set.
4 IAL	Arbitration lost. Set by hardware in the following circumstances (IAL must be cleared by software by writing a "0" to it at the start of the interrupt service routine): • SDA input sampled low when the master drives high during an address or data-transmit cycle. • SDA input sampled low when the master drives high during the acknowledge bit of a data-receive cycle. For the above two cases, the bit is set at the falling edge of 9th SCL clock during the ACK cycle. • A start cycle is attempted when the bus is busy. • A repeated start cycle is requested in slave mode. • A stop condition is detected when the master did not request it. **NOTE:** Software cannot set the bit. 0 No arbitration lost. 1 Arbitration is lost.

Table continues on the next page...

I2Cx_I2SR field descriptions (continued)

Field	Description
3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2 SRW	Slave read/write. When the I2C is addressed as a slave, IAAS is set, and the slave read/write bit (SRW) indicates the value of the R/W command bit of the calling address sent from the master. SRW is valid only when a complete transfer has occurred, no other transfers have been initiated, and the I2C is a slave and has an address match. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave
1 IIF	I2C interrupt. Must be cleared by the software by writing a "0" to it in the interrupt routine. **NOTE:** The software cannot set the bit. 0 No I2C interrupt pending. 1 An interrupt is pending. This causes a processor interrupt request (if the interrupt enable is asserted [IIEN = 1]). The interrupt is set when one of the following occurs: • One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock). • An address is received that matches its own specific address in slave-receive mode. • Arbitration is lost.
0 RXAK	Received acknowledge. This is the value received of the SDA input for the acknowledge bit during a bus cycle. 0 An "acknowledge" signal was received after the completion of an 8-bit data transmission on the bus. 1 A "No acknowledge" signal was detected at the ninth clock.

41.61.5 I2C Data I/O Register (I2Cx_I2DR)

In master-receive mode, reading the data register allows a read to occur and initiates the next byte to be received. In slave mode, the same function is available after it is addressed.

Addresses: I2C-3_I2DR is 53FE_C000h base + 10h offset = 53FE_C010h
I2C-2_I2DR is 63FC_4000h base + 10h offset = 63FC_4010h
I2C-1_I2DR is 63FC_8000h base + 10h offset = 63FC_8010h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								DATA							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Cx_I2DR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–0 DATA	Data Byte. Holds the last data byte received or the next data byte to be transferred. Software writes the next data byte to be transmitted or reads the data byte received. **NOTE:** The core-written value in I2C_I2DR cannot be read back by the core. Only data written by the I2C bus side can be read.

Chapter 42
IC Identification Module (IIM)

42.1 Overview

The IC Identification Module (IIM) provides an interface for reading, and in some cases programming and/or overriding, identification and control information stored in on-chip fuse elements. The block supports electrically-programmable poly fuses (e-Fuses).

The IIM also provides a set of volatile software-accessible signals which can be used for software control of hardware elements, not requiring non-volatility.

The IIM provides the primary user-visible mechanism for interfacing with on-chip fuse elements. Among the uses for the fuses are unique chip identifiers, mask revision numbers, cryptographic keys, and various control signals requiring permanent non-volatility. The IIM also provides up to 28 volatile control signals

42.1.1 Modes of Operation

The IIM is in its functional mode (all specified functionality available) any time it is out of reset and supplied with the proper clocks.

42.2 Functional Description

The IIM is an 8-bit IP Bus peripheral which implements interfaces for laser fuses and/or e-Fuses, as well as the hardware revision codes, cryptographic keys, and miscellaneous SoC-level feature enabling circuitry. Up to eight banks, each with up to 2048 fuses, are supported. Laser fuse banks and e-Fuse banks may be mixed.

42.2.1 Signal Groups

Listed below are the intended uses for the five fuse banks. Each fuse bank may contain up to 2048 fuses, and the unspecified fuses in each bank below mScay be used for implementation-specific purposes. However, access protection is specified on a per-bank basis; this may limit the use of the unspecified fuses.

The IIM implements non-volatile "Hardware-Visible" control signals. These are all capable of driving SoC-level nets to allow them to permanently enable or disable features in the system.

42.2.1.1 System JTAG Control

Among the hardware control signals implemented in Fuse Bank 0 are the Secure JTAG mode control bits. These fuses are used to allow or disallow JTAG access to secured resources.

Three JTAG security levels are envisioned, as shown in the table below.

Table 42-1. JTAG Security Level Control Bits

Security Mode	JTAG_SMODE	JTAG_SCC_DIS	Description
No Debug	2'b11	x	The highest security level.
Secure JTAG	2'b01	x	Limit the JTAG access by using key based authentication mechanism.
JTAG Enable	2'b00	1'b1	Low Security, all JTAG features are enabled.
SCC JTAG	2'b00	1'b0	No security.

JTAG debug access may be semi-permanently enabled by blowing the jtag_bp bit (JTAG Bypass Security). This, however, can be overridden by blowing the jtag_re bit (JTAG Security Re-enable). Blowing the jtag_bp bit effectively changes the security level from 'Secure JTAG' to 'JTAG Enable', without actually modifying the JTAG_SMODE fuses.

NOTE

The IIM must only allow the jtag_bp fuse to be blown if the JTAG debug security level is "Secure JTAG" (JTAG_SMODE = 2'b01) and ipt_response_in = 1, ipt_secur_block = 0. This indicates that the SJC has processed a valid response in its challenge/response protocol, and the JTAG security bypass functionality should be allowed. JTAG security is re-instated to the "Secure JTAG" level by blowing the jtag_re bit.

In addition to the three JTAG security levels, the JTAG debug notification normally passed to the Security Controller (SCC), which causes it to transition out of the secure state when debugging has become active, can be gated off using the jtag_scc fuse in JAC. If jtag_scc is left unblown, the debug active signals are masked, and do not propagate to the SCC. If jtag_scc is blown, the debug active signals propagate to the SCC as normal.

NOTE

Leaving the jtag_scc fuse unblown represents a very significant security risk, and should only be done in as few parts as possible to debug secure operation of the SCC. Once SCC debugging is complete, the jtag_scc fuse should immediately be blown. The reason for including this functionality in a fuse is to avoid the need to modify parts using FIB for SCC debugging, but the convenience afforded by the fuse must not be allowed to foster an unguarded attitude toward the dangers such insecure parts would pose.

42.2.1.2 Fuse Bank 0

Fuse Bank 0 contains manufacturing information such as Unique ID (UID), consists of fab ID, lot and wafer number, and die coordinates. These bits are usable by OSs such Microsoft PocketPC, which require a unique device ID. It also contains JTAG and debug features controls, IMEI information, and 24 bits for user purpose.

42.2.1.3 Fuse Bank 1

Fuse Bank 1 contains response reference value for the system JTAG controller, memories information and 40 bits for user purposes.

42.2.1.4 Fuse Bank 2

Fuse Bank 2 contains the 256-bit SCC key.

42.2.1.4.1 SCC Key Format

The-256 bit keys derived from Fuse Bank 2 are used as the secret keys for the Secure RAM controller in the SCC(s). Each key actually consists of three 56-bit keys. Each of the three 56-bit keys corresponds to a 64-bit DES key with the parity bits removed, and processed through the key permutation.

The value in Fuse Bank 1includes 159 random bits and 9 Hamming Code bits. The Hamming Code will detect all 1, 2, and 3 bit errors in the codeword. It will also detect most (though not all) multiple bit errors. Numbering the bits in the key from 0 to 167, the code bits are bits 0, 1, 2, 4, 8, 16, 32, 64, and 128. All of the remaining bits are data bits. Each of the code bits is the modulo 2 sum (i.e XOR or parity) of a subset of the bits in the entire word, as described below.

To determine which bits are used to form each code bit, first look at the binary representation of the bit position of each code bit (ignoring bit 0 for the time being) as shown in the table below.

Table 42-2. Binary Representation of Bit Position

Code Bit	Binary Representation
0	0b00000000
1	0b00000001
2	0b00000010
4	0b00000100
8	0b00001000
16	0b00010000
32	0b00100000
64	0b01000000
128	0b10000000

For code bit number 1, there is a single '1' bit in its binary representation. This code bit is the modulo 2 sum (XOR) of all bit positions which also have a '1' in this same point in their binary representation (that is, all odd bit positions). Alternatively, if we bitwise AND code bit 1's bit number with a data bit's bit number, and the result is not zero, then that bit gets XOR'ed into code bit 1. The same is true for the other code bits, excepting code bit 0. For example, code bit 2 is the XOR of bits 3, 6, 7, 10, 11, 14, 15...254,255. Code bit 128 is the XOR of all bits from 129 through 255 inclusive. After all of the other code bits have been calculated, code bit 0 is simply the XOR of all of the other bits, including the other code bits.

Another way to look at this is to ask which code bits a data bit affects. If we look at the binary representation of the bit position of a data bit, the 1's represent the code bits that this data bit affects. For example, data bit 99 (0b01100011) is XOR'ed into code bits 1, 2, 32, and 64.

42.2.1.4.2 SCC Key Checking

The SCC checks the key using the Hamming Code. If there are any errors in the key, the SCC refuses to use it. In addition, the SCC checks the key against several known weak keys, which it will also refuse to use. The following figure shows a list of hexadecimal key patterns that are checked (x means don't care); no key matching any of these patterns should be programmed into Fuse Bank 1.

```

Figure 42-1. Known Weak SCC Key Patterns

42.2.1.5 Fuse Bank 3

Fuse Bank 3 is intended to hold data relevant to the Super-Root Key (SRK) of DSP domain. It may hold an entire SRK (that is, an up to 1024-bit RSA public key), a hash of an SRK (that is, a 160-bit SHA-1 hash), or an SRK one-of-many selector. The boot code for a specific product must know where to find and validate the SRK.

42.2.1.6 Fuse Bank 4

Fuse Bank 4 is a 16-word (128 fuses) bank added to i.MX53 for general purpose use.

42.2.1.7 Software-Controllable Volatile Signals

The IIM implements up to 28 software-controllable, HW-Visible, volatile control signals. These are implemented in four 8-bit registers, each with a lock bit to inhibit modification of the associated register until the IIM is reset. These 28 signals may all drive SoC-level

nets. They are always software-readable, but can only be modified by software if the Lock bit (bit 7) is not set in the register. The sequence for modifying these bits is shown in the figure below.

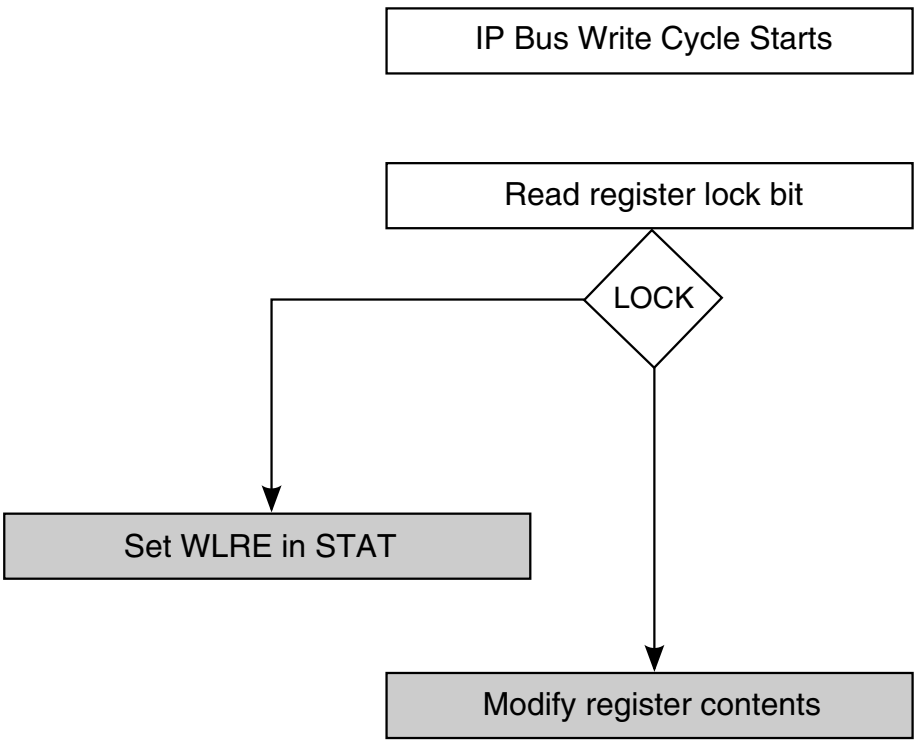

Figure 42-2. IIM_SCS Register Write Sequence

42.2.2 FUSEBOX Signals

The figure below shows the FUSEBOX interface.

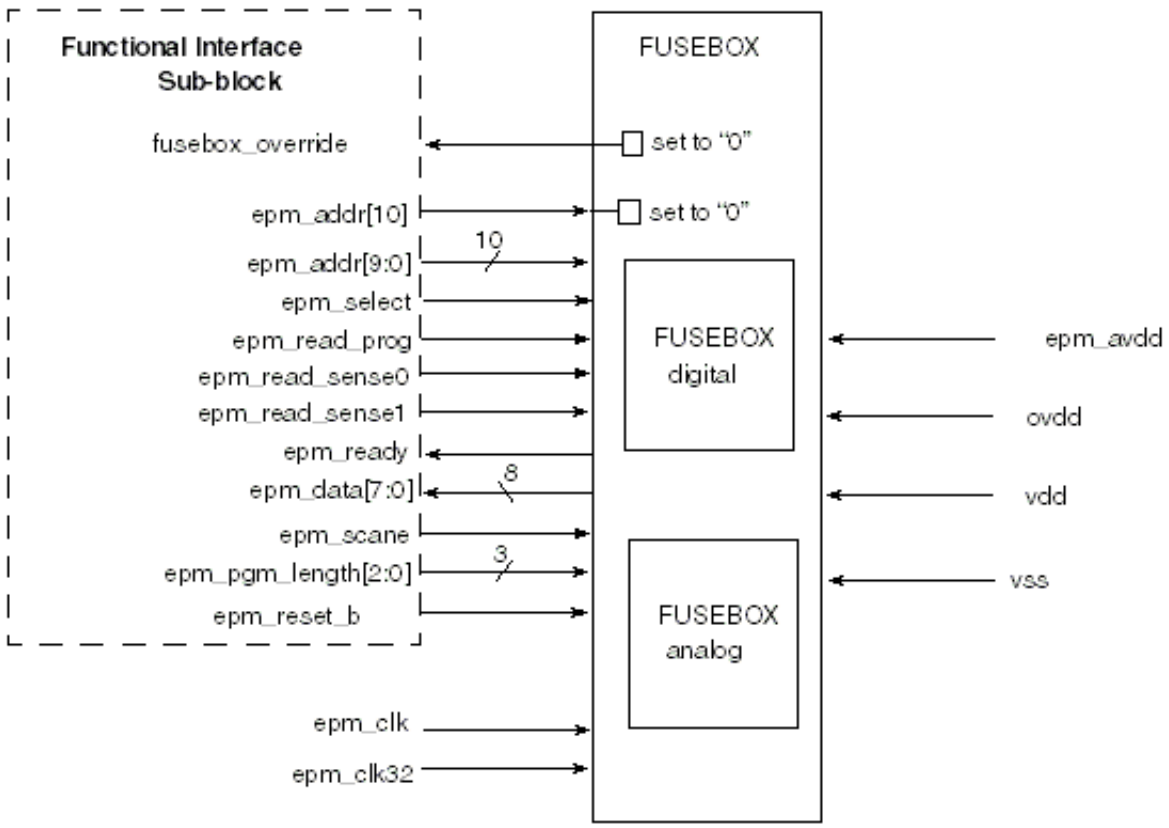

Figure 42-3. FUSEBOX Interface

The signals are summarized from the fuse box's perspective in the following table.

Table 42-3. FUSEBOX Signal Overview

Signal Name	Signal Type	Signal Description
EPM_ADDR[10:0]	I	This bus provides the address for a read or program operation. Read operations are done on a word (8-bit) basis, so the word address is carried on address[10:3]. Program operations are done on a bit-basis, so the bit address is carried on address[10:0]. Address bits l2:0] carry the bit location in a byte, epm_addr[10] is set to "0" for 1024 bit digital block.
		State Meaning
		Timing Needs to be held to desired value at least 2 nS before and after asserting epm_select in both program and read operation.
$\overline{\text{EPM\_CLK}}$	I	Local clock used for synchronization of signals between FI and FUSEBOX. It is the clock used by a FUSEBOX Interface sub-block for creating FUSEBOX interface signals. The max. read clock is 166Mhz with worst 40%-60% duty cycle.
$\overline{\text{EPM\_CLK32}}$	I	The 32.768 KHz clock used in the FUSEBOX to time the program operation in read operation. This clock does not need to be utilized in the FI sub-block.

Table continues on the next page...

Table 42-3. FUSEBOX Signal Overview (continued)

Signal Name	Signal Type	Signal Description
EPM_DATA[7:0]	O	This bus carries the read data from the FUSEBOX during a read cycle.
		State Meaning
		Timing
EPM_PGM_LENGTH [2:0]	I	These signals define the length of the program pulse.
		State Meaning
		Timing
EPM_READY	I	This signal indicates the progress of the current read/program cycle. New commands should only be issued by the FI sub-block while epm_ready is asserted.
		State Meaning Asserted -- The fuse is blown. Negated -- The fuse is not blown.
		Timing Latched at the rise edge of epm_clk half clock cycle ahead of epm_ready
EPM_READ_PROG	I	This signal selects whether the current operation is a read or program cycle. This signal is latched into the FUSEBOX on the rising edge of epm_select.
		State Meaning Assertion- FUSEBOX is in read operation. Negation- FUSEBOX is in program operation.
		Timing Needs to be held to desired value at least 2nS before and after asserting epm_select in both program and read operation.
EPM_READ_SENSE0	I	This signal allows sensing of the 0 (unblown) state to be stressed. This can be useful in detecting marginally blown fuses.
		State Meaning Assertion-When asserted (high), the sense circuitry is configured to stress the sensing of the 0 (unblown) state. Negation- No stress is added.
		Timing This signal is latched by the FUSEBOX on the rising edge of epm_select. It needs to be set to desired value at least 2nS before epm_select is asserted an to be held until epm_select is negated.
EPM_READ_SENSE1	I	This signal allows sensing of the 1 (blown) state to be stressed. This can be useful in detecting marginally blown fuses.
		State Meaning Assertion-When asserted (high), the sense circuitry is configured to stress the sensing of the 1 (blown) state. Negation- No stress is added.
		Timing This signal is latched by the FUSEBOX on the rising edge of epm_select. It needs to be set to desired value at least 2nS before epm_select is asserted and to be held until epm_select is negated.

Table continues on the next page...

Table 42-3. FUSEBOX Signal Overview (continued)

Signal Name	Signal Type	Signal Description
EPM_RESET_B	I	Reset FUSEBOX digital signals during power up. This signal needs to be connected to a early system reset. The signal is active low.
EPM_SCANE	I	This signal indicates whether the FUSEBOX is scannable via JTAG. It shall be always de-asserted because the JTAG function is disabled inside FUSEBOX in cmos065 design.
EPM_SELECT	I	This signal starts a read/program operation and epm_select rising edge needs to be synchronized with the rising edge of epm_clk. There is no restriction for epm_select falling edge to be synchronized with epm_clk. The FUSEBOX senses the rising edge of this signal to start the operation. On the rising edge of epm_select, the address, operation to perform and program data are latched. There is one select signal for each fuse bank.
		State Meaning Assertion- In Read/program operation. Negation- Not in read/program operation.
		Timing This signal must remain asserted throughout the read/program operation.
FUSEBOX_OVERRIDE	O	FUSEBOX override signal to the Functional Interface sub-block. It is connected to VSS by default. It can be re-connected to core VDD via Metal 6 layer change.
		State Meaning Assertion- The FUSEBOX is bypassed. All outputs are set to 0. Negation- The FUSEBOX outputs are sent to FI sub-blocks.
		Timing

42.2.2.1 FUSEBOX Operations

All FUSEBOX operations are self-timed and begin relative to the rising edge on the epm_select line. Most interface signals are shared by all Fuseboxes. Only the FUSEBOX selects (epm_select), read data (epm_data) and ready status (epm_ready) signals are unique to each FUSEBOX. The 32 KHz clock is not used within the IIM, but may be used with other FI sub-blocks. It is passed through to the FUSEBOX to time program operations. The 32 KHz clock distributed to the Fuseboxes should be on during FUSEBOX program operations and should be gated off during read operation. The epm_clk is used to sample the epm_select, epm_ready and epm_data signals in order to synchronize these signals with the Functional Interface inside a FUSEBOX. This epm_clk is a gated clock used by the local FI sub-blocks.

42.2.2.1.1 Word Read

Read operations are done on a word (8-bit) basis. The target word is specified by the address lines epm_addr[9:3]. The bottom three address lines (bit-select lines) are ignored in a read operation.

The timing for fuse word read cycles is shown in the figure below. This timing diagram shows one read cycle followed by the start of a second read, demonstrating how quickly one read can follow another. Each read command is registered on the rising edge of epm_select. The address (epm_addr[9:3]) and read command (epm_read_prog) must be stable tsels before the rising edge of epm_select and must remain stable at least tselh hold time beyond the rising edge. epm_ready is negated immediately after the command is registered, indicating that the FUSEBOX is busy. After a tdv delay from the active edge of epm_select, the data is made available on blr by the analog FUSEBOX. The epm_ready acknowledge signal is asserted tready after the initial assertion of epm_select and the data is available on the epm_data. The FUSEBOX synchronizes epm_ready and the data to the epm_clk clock and drives the synchronized data onto the IP Bus. The time between the valid epm_data and epm_ready is signified by tsync in the figure below and is one-half of one epm_clk cycle. Once the read data has been latched, epm_select is negated by the Functional Interface sub-block. epm_select must remain negated a minimum cycle to cycle delay of tccd before the next cycle (read or program) may begin. epm_data remains at a steady state until replaced by data from a subsequent read cycle.

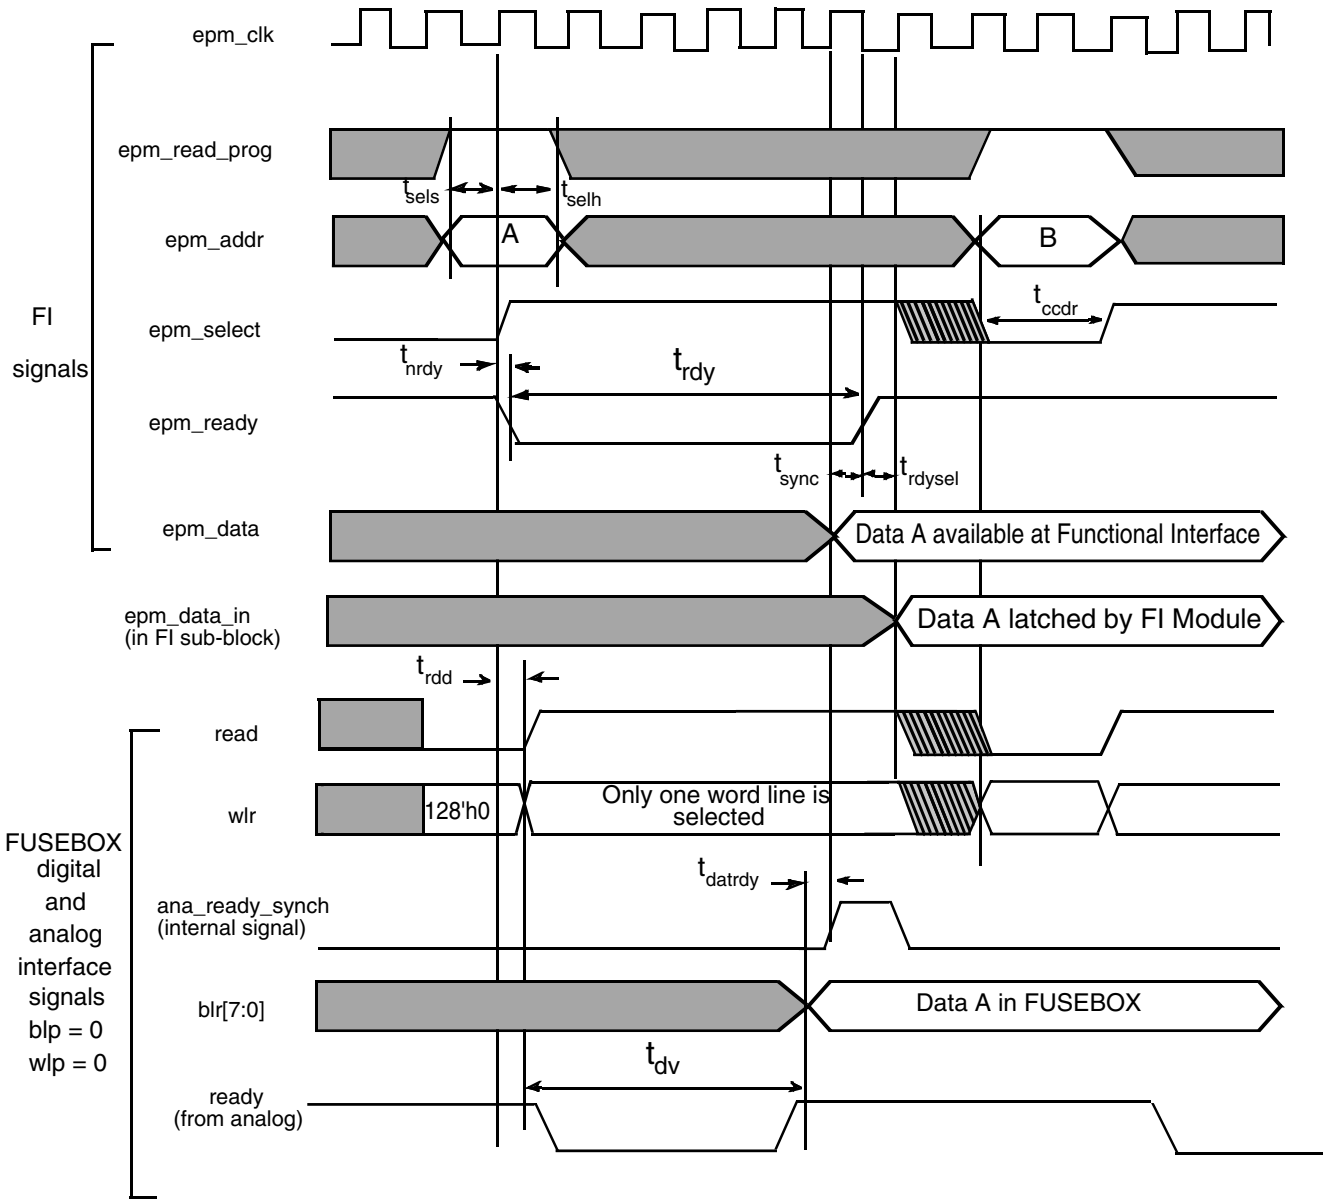

Figure 42-4. FUSEBOX Read Cycle Timing

42.2.2.1.2 Bit Program

Program operations are done on a bit-basis. The target bit is specified by the full address bus (epm_addr[10:0]). Program operations can only blow fuses (change them from logic 0 to logic 1), so there is no program data bus associated with the FUSEBOX. The timing for a program operation is shown in Figure 42-5.

As in the read cycle, the address and program command are latched on the rising edge of epm_select. The address must be setup tsels ahead of the rising edge and remain held tselh past the edge of epm_select. Once the program command is registered, on the next rising edge of the 32 KHz clock, the FUSEBOX initiates the program operation. An internal counter starts to count the number of 32K clock cycles, and the epm_ready signal is de-asserted.

After the specified number of 32 KHz clocks (determined by epm_pgm_length[2:0]), the FUSEBOX completes the program operation and asserts the epm_ready signal. epm_pgm_length[2:0] needs to be set tsels ahead of the rising edge of epm_select and needs to be held until the completion of the internal counter. Consult Table 42-4 for specific timing values. The Functional Interface sub-block synchronizes the epm_ready response to the epm_clk during the period tsync. After recognizing that the program operation has completed, the Functional Interface sub-block negates the epm_select line. To avoid accidental selection of more than one bit line at a time, the 8 bit de-coded bit-line-program (BLP) needs to be checked before generate blp[7:0].

Table 42-4. Timing Values

Designator	Timing Value	Description
t_{sels}	2 nS	Setup time to epm_select active edge
t_{selh}	2 nS	Hold time after epm_select active edge
t_{nrdy}	200 pS -1000 pS	Delay from epm_select to epm_ready negation (read). Delay from the rise edge of 32 Khz clock to epm_ready (program).
t_{rdd}	1 nS-4 nS	Assert time from epm_select active edge to negation of read from digital
t_{dv}	30 nS-100 nS	Data valid after epm_select active edge
t_{rdy}	< (t_{dv} + 1.5 epm_clk)	Epm_ready signal asserted after epm_select active edge (read only)
t_{ready}	(epm_pgm_length) * $period_{32KHz}$	Epm_ready signal asserted after epm_select active edge (program only)
t_{datrdy}	0-1 epm_clk	Data driven out to bus after analog ready signal asserts (read only)
t_{sync}	one-half of 1 epm_clk cycle (rising edge to falling edge) > 3nS if epm_clk duty cycle is not 50%	epm_data to epm_ready synchronization delay (read). epm_ready to negation of epm_select (program)
t_{rdysel}	> 2nS typically one-half of 1 epm_clk cycle (falling edge to rising edge)	rising-edge of epm_ready to negative-edge of epm_select (read only)
t_{ccdr}	5 nS	Minimum cycle to cycle delay (Consecutive Read)
t_{ccdp}	0.5 uS	Minimum cycle to cycle delay (Consecutive program)

Table continues on the next page...

Table 42-4. Timing Values (continued)

Designator	Timing Value	Description
t_{sels}	2 nS	Setup time to epm_select active edge
t_{selh}	2 nS	Hold time after epm_select active edge
t_{nrdy}	200 pS -1000 pS	Delay from epm_select to epm_ready negation (read). Delay from the rise edge of 32 Khz clock to epm_ready (program).

See the timing diagram of the fuse program in the figure below.

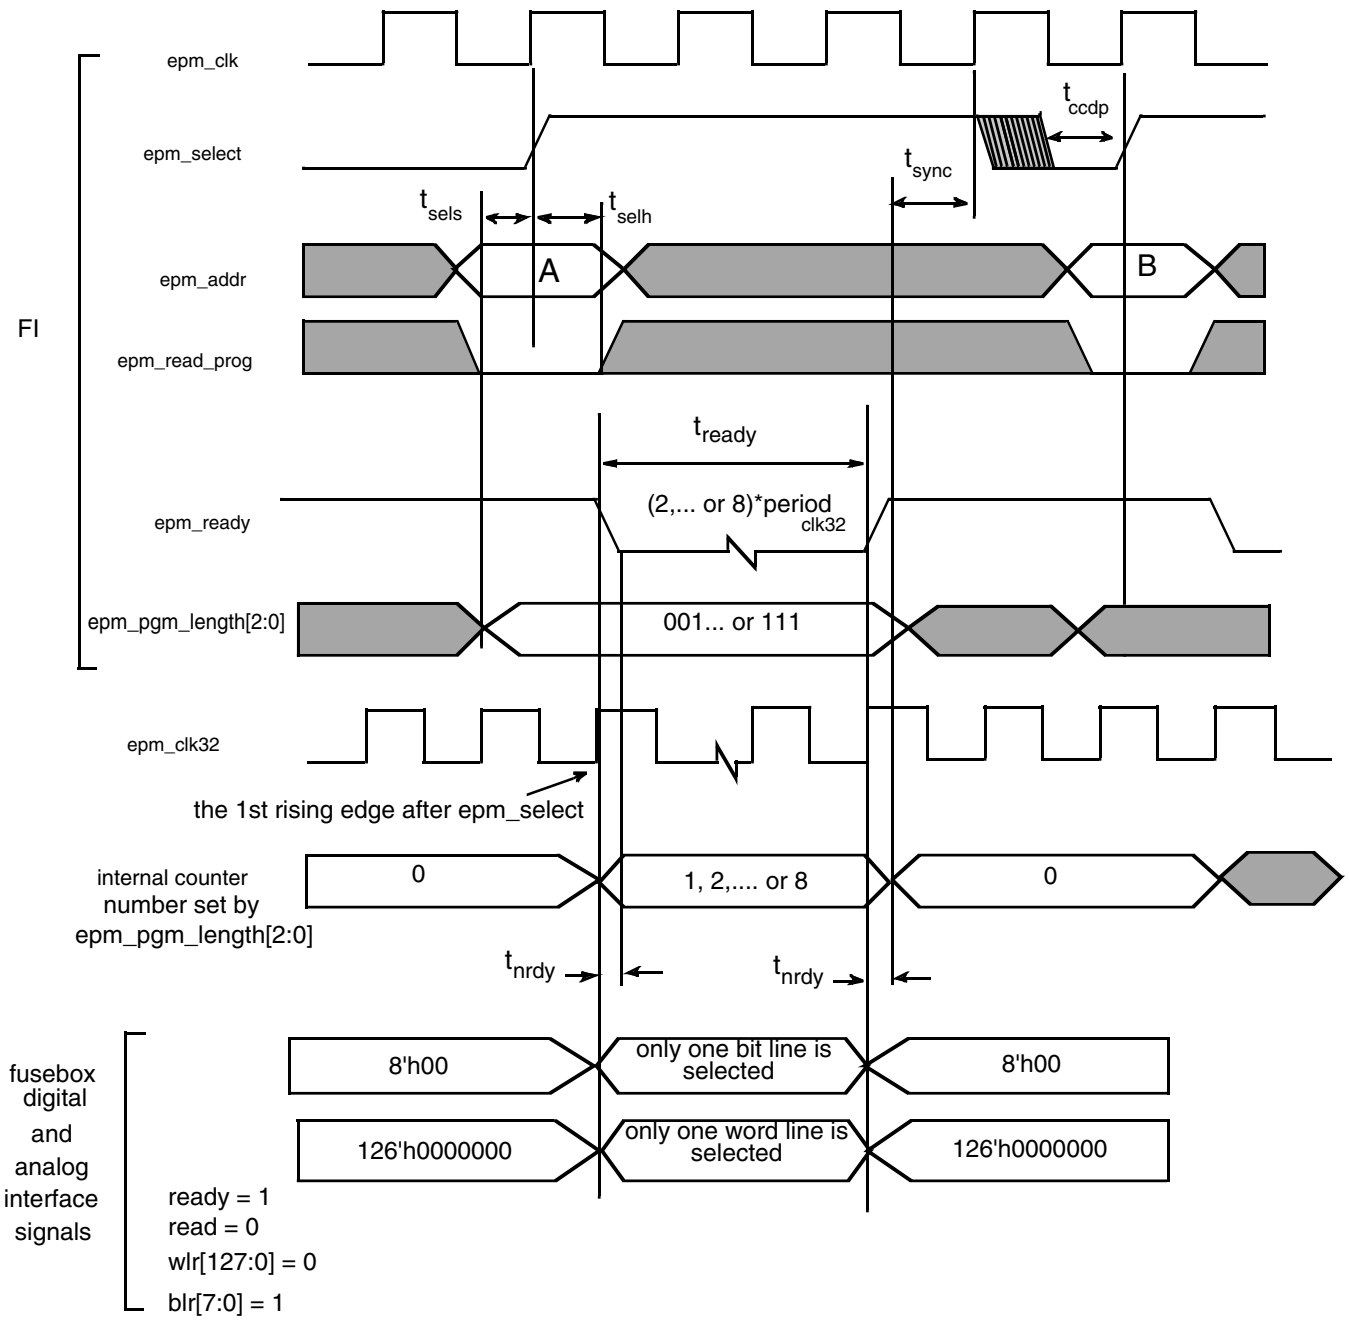

Figure 42-5. Fuse Program Cycle Timing

NOTE

The IIM controller must determine that the target fuse bank is indeed an e-Fuse bank (not a laser fuse bank) before allowing the program cycle to proceed. This is determined by examining the appropriate fuse_type signal, which is fixed at SoC integration time.

42.2.3 Fuse Value Storage

The values of fuses may be read from one of the following three places:

- Software fuse value shadow cache
- Hardware-visible fuse value shadow cache, driving SOC nets
- Fuse elements themselves

The reasons for caching the fuse values are to reduce the risk of accidental programming of e-Fuses due to repeated reads and to reduce power consumption associated with sense cycles.

42.2.3.1 Software Fuse Value Shadow Cache

Each word in the cache RAM includes a valid bit and a parity bit, as shown in the following figure. The valid bit is set if the data bits and parity bit have been set according to the sensed state of the corresponding fuses, Odd parity is used across the data bits only (that is, the valid bit is not included in the parity calculation).

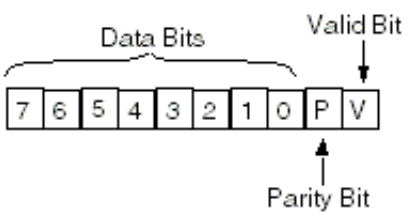

Figure 42-6. Software Cache Word Format

All bits are set to 0 when IIM comes out of reset. When a fuse word is read, the IIM will first attempt to read it from the cache (except for the hardware-visible fuses; see Hardware-Visible Fuse Shadow Cache). A sense cycle will only be run to the fuses if the cached word is invalid or the parity is incorrect. The overall cached fuse word read sequence is shown in Read Sequence. The cache words and fuse words is one to one mapped.

42.2.3.2 Hardware-Visible Fuse Shadow Cache

The hardware-visible fuse include fuses in bank0 and bank1, and FBAC words of each bank.The IIM must sense these fuses and write their values to the appropriate registers when it comes out of reset, and must ensure than any change to the fuses is also immediately reflected in the registers. The overall hardware-visible word read sequence is shown in Read Sequence. Each word has a parity bit as shown below.

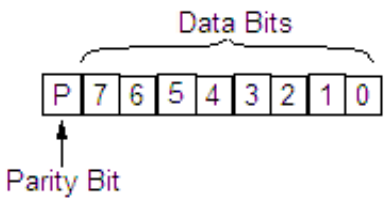

Figure 42-7. Hardware Cache Word Format

If parity error detected on shadow cache, IIM will set error bit PARITYE, and re initialize cache from fuses.

42.2.4 Fuse Protection

The following subsections describe fuses used as protection bits.

42.2.4.1 FUSEBOX Bank Protection Fuse

FBWP of each bank control whether this bank can be programed. FBOP of each bank control whether this bank can be overridden. FBRP of each bank control whether this bank can be read. FBSP control whether this bank can be scanned. FBESP control whether this bank can be explicitly sensed.

42.2.4.2 Scan Out Protection

To prevent the secret keys scanned out by hacker, specific logic is added (shown in the figure below). It resets all flip-flops in IIM before entering scan mode.

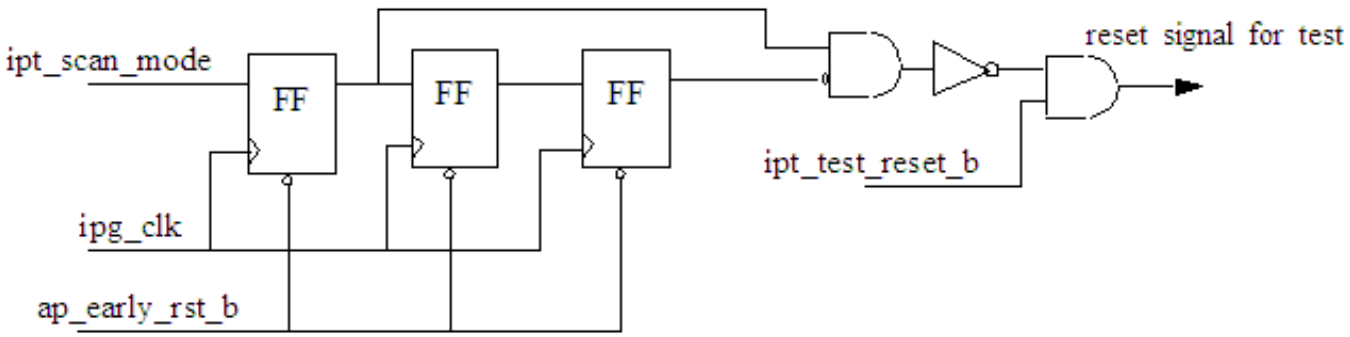

Figure 42-8. Scan Out Protection Circuit

42.2.5 Fuse Bank Operations

This section discusses the following sequences:

- Read Sequence
- Explicit Sense Sequence
- Programming Sequence
- Override Sequence

42.2.5.1 Read Sequence

Fuses may be read using the IP Bus interface from any bank which is not read-inhibited (that is, FBACx[FBRP] is unblown). The read sequence from a hardware-visible signals word is shown below.

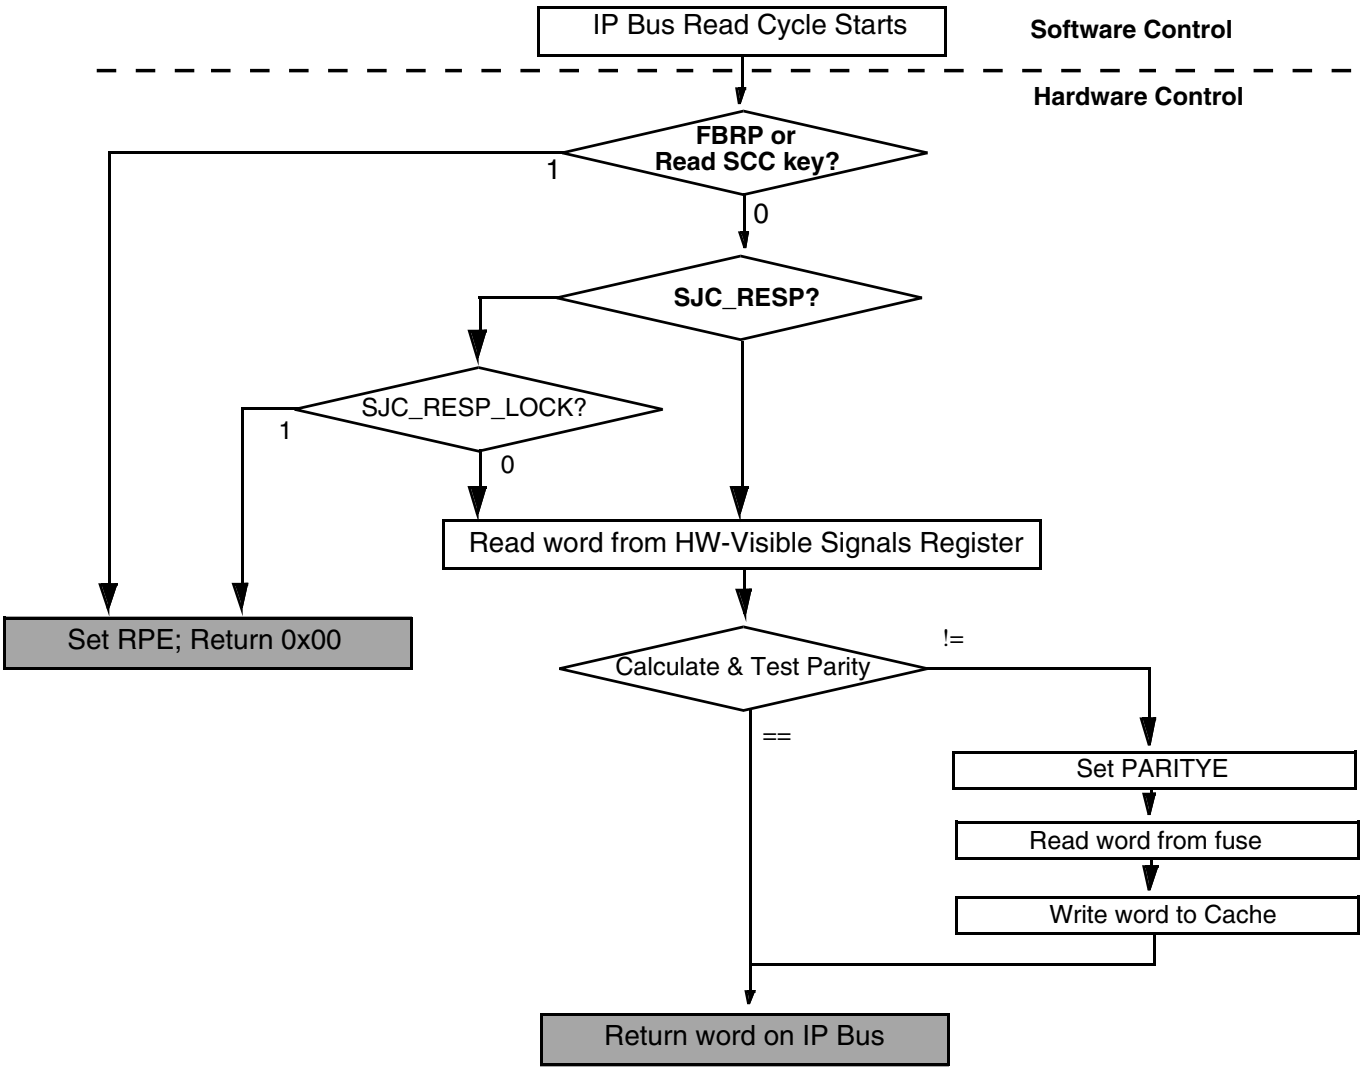

Figure 42-9. Hardware Visible Fuse Read

The read sequence to a cacheable fuse word is shown in the figure below.

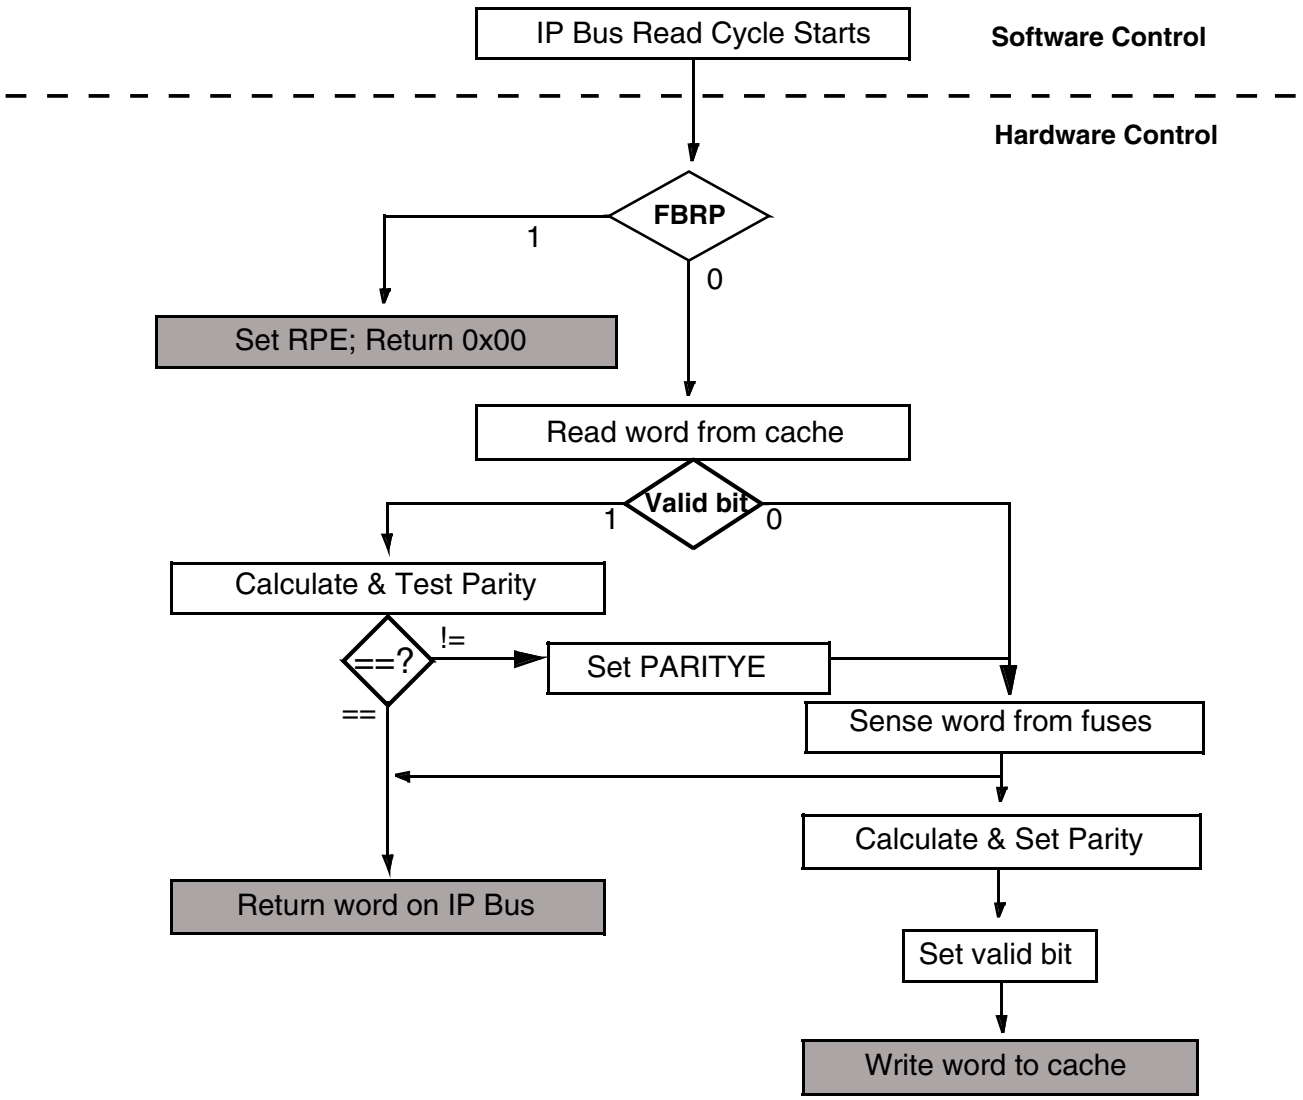

Figure 42-10. Software Fuse Read

42.2.5.2 Explicit Sense Sequence

The explicit sense sequence using IP Bus is depicted in the figure below.

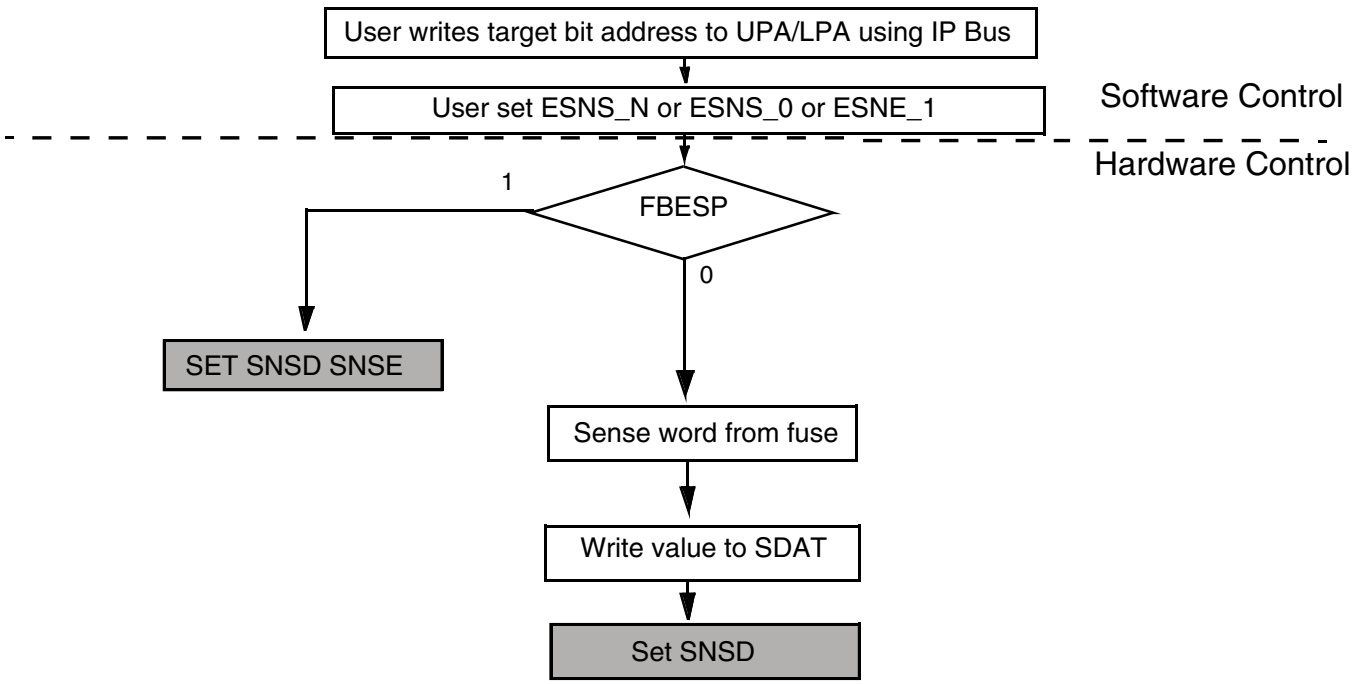

Figure 42-11. Explicit Sense Sequence

42.2.5.3 Programming Sequence

The software-controlled e-Fuse programming sequence using the IP Bus is depicted in the figure below.

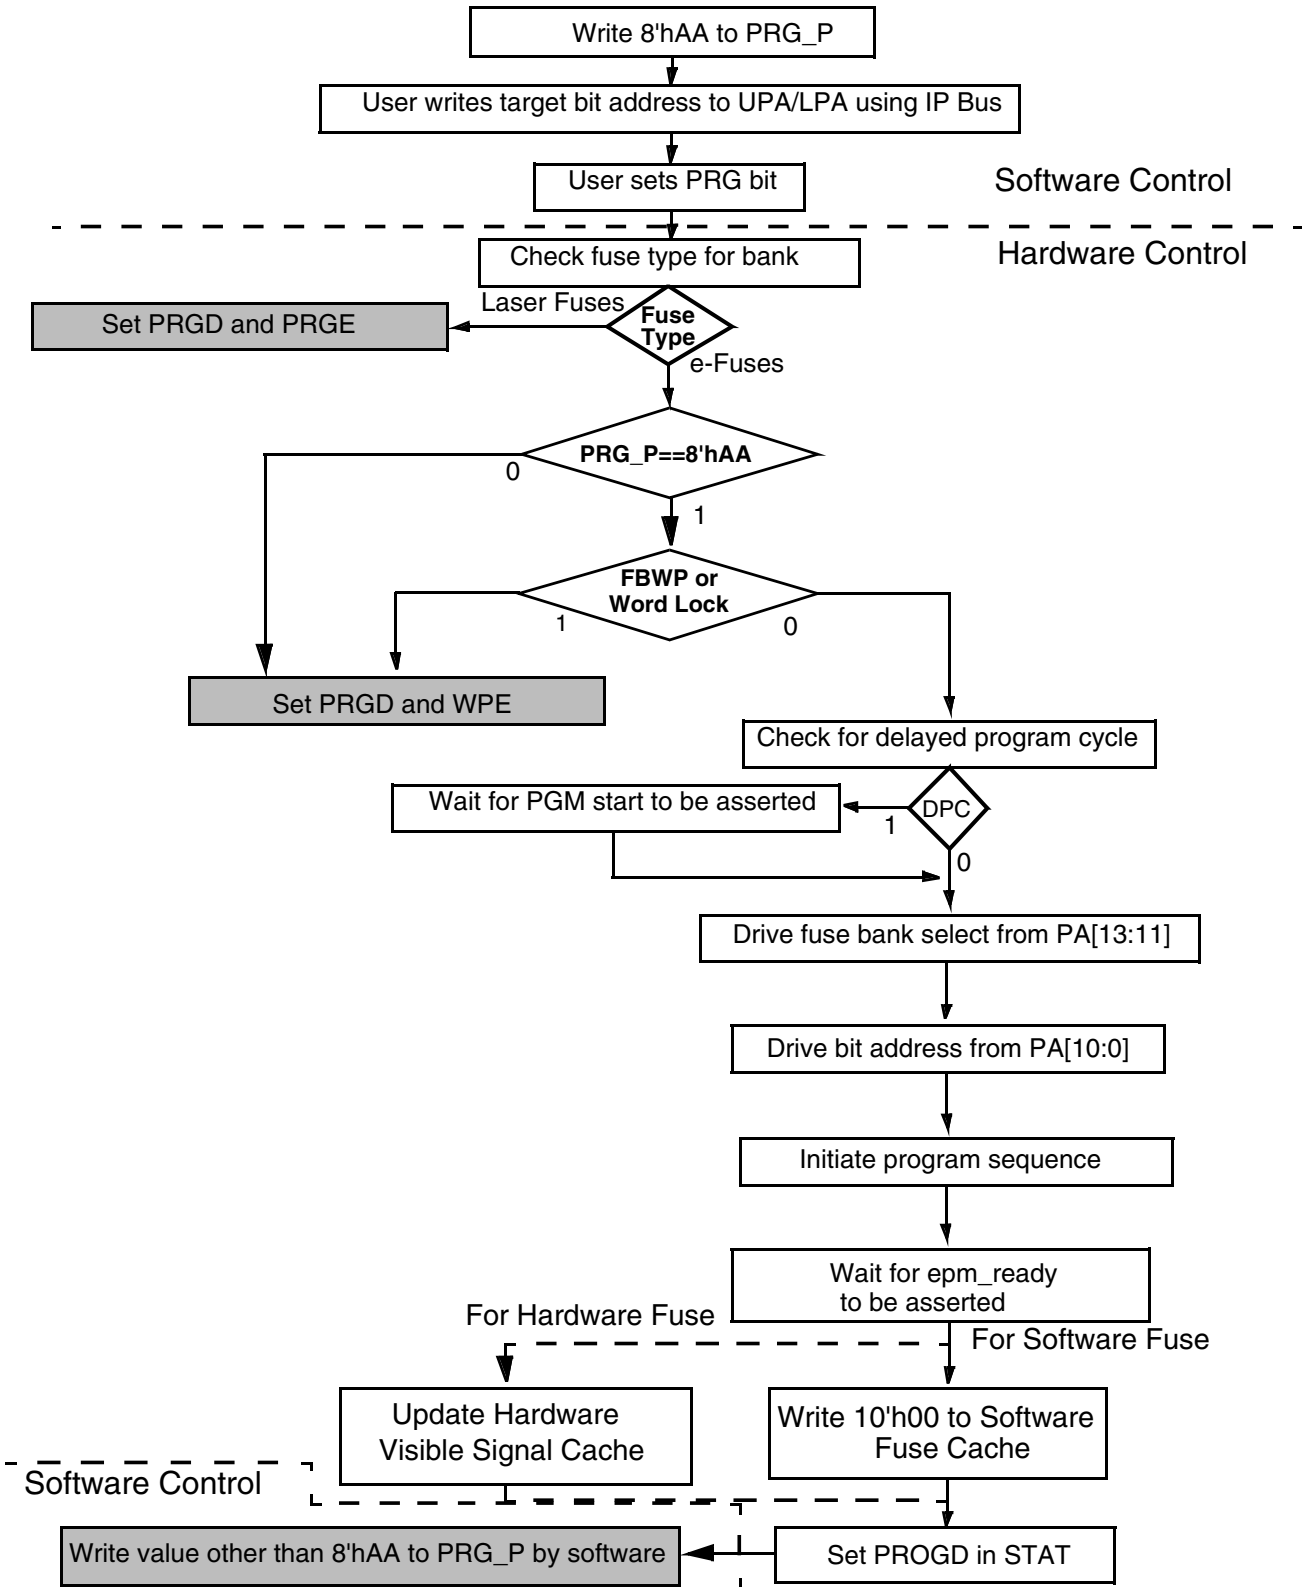

Figure 42-12. e-Fuse Program Sequence

Fuses may also be programmed directly using the JTAG interface, so long as the IIM asserts the appropriate epm_scane signal. The IIM is not involved in this programming sequence aside from allowing or disallowing it using the epm_scane signal.

Note that minimum program voltage is 2.775 V, maximum program voltage is 3.3 V. This must be taken into account when designing the architecture of an IC which includes e-Fuses. For complete parametric specifications, refer to the FUSEBOX specification.

42.2.5.4 Override Sequence

The override sequence is depicted in the following figure. .

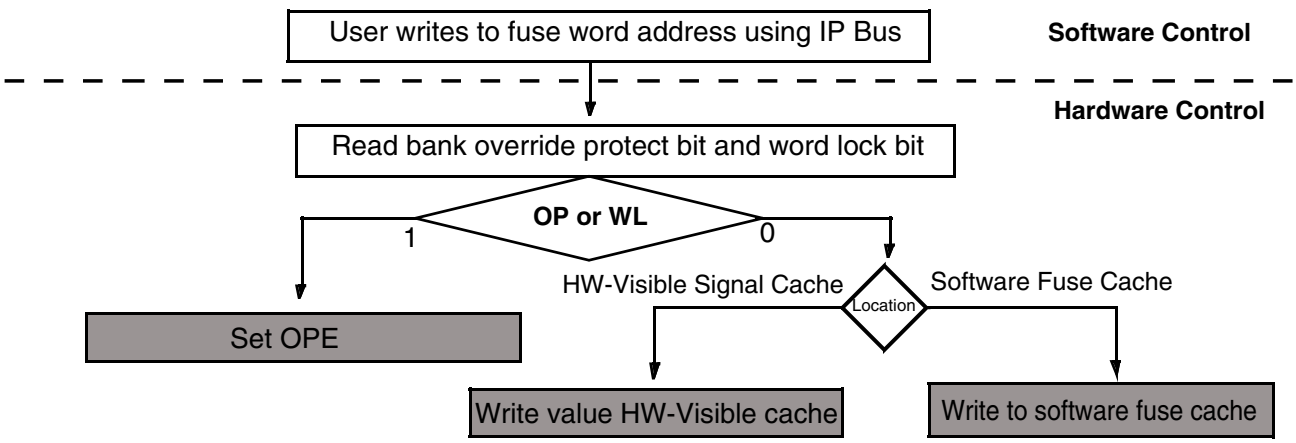

Figure 42-13. Fuse Value Override Sequence

42.3 Initialization/Application Information

42.3.1 Initialization

When the IIM come out of reset, IIM automatically senses the hardware-visible fuses and writes their values into the appropriate registers. IIM also senses the fuse access control word from each of the fuse banks, and set epm_scane according to the values of fbsp bits. Software fuses are not sensed until software has made a read request for them. Software cache will be set to 0 on reset.

After the IIM come out of reset, all the hardware visible fuses must be read out to hardware visible cache within 200us, to ensure the hardware visible fuses are loaded before the second reset at the SoC-level. IIM reads HWV2 first. The initialization time depends on the number of hardware visible fuses.

Initialization time = (number of hardware visible fuse word) x (100 ns + 4 ipg_clk cycles)

After the initialization is complete, fuse_latched will be asserted, as shown in the following figure.

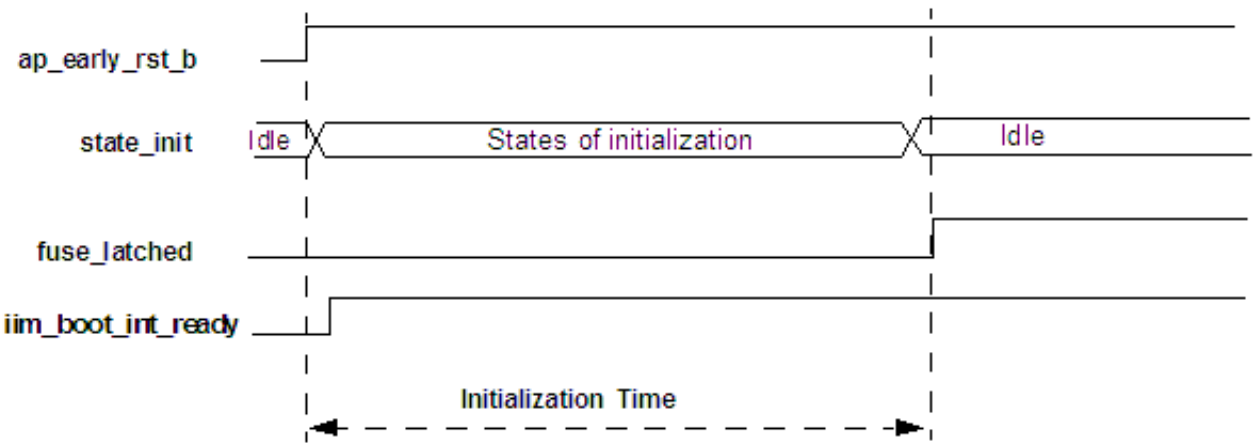

Figure 42-14. Timing Diagram of Initialization

42.3.2 Program

After JATG programming, reset must be applied to synchronize the fuse value to hardware visible signal cache.

A wait period is required between program and read operation.

42.4 Programmable Registers

All IIM registers are 8-bits wide, but addressable on 32-bit boundaries. Only the bottom 8 bits (the usable bits) of each register are shown in the following diagrams. The top 24 bits always read as 0 and writes to them are ignored..

All IIM registers can be accessed in user mode except FCTL, which controls programming functions and can be accessed in supervisor mode only.

IIM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63F9_8000	Status register (IIM_STAT)	8	w1c	00h	42.4.1/ 1844
63F9_8004	Status IRQ Mask register (IIM_STATM)	8	R/W	00h	42.4.2/ 1845
63F9_8008	Module Errors register (IIM_ERR)	8	R/W	See section	42.4.3/ 1846
63F9_800C	Error IRQ Mask register (IIM_EMASK)	8	R/W	See section	42.4.4/ 1847
63F9_8010	Fuse Control register (IIM_FCTL)	8	R/W	30h	42.4.5/ 1848
63F9_8014	Upper Address register (IIM_UA)	8	R/W	00h	42.4.6/ 1849
63F9_8018	Lower Address register (IIM_LA)	8	R/W	00h	42.4.7/ 1850
63F9_801C	Explicit Sense Data register (IIM_SDAT)	8	R	00h	42.4.8/ 1850
63F9_8020	Product Revision register (IIM_PREV)	8	R	Unaffected	42.4.9/ 1851
63F9_8024	Silicon Revision register (IIM_SREV)	8	R	00h	42.4.10/ 1851
63F9_8028	Program Protection register (IIM_PREG_P)	8	R/W	00h	42.4.11/ 1852
63F9_802C	Software-Controllable Signals register 0 (IIM_SCS0)	8	R/W	00h	42.4.12/ 1852
63F9_8034	Software-Controllable Signals register 2 (IIM_SCS2)	8	R/W	00h	42.4.13/ 1853
63F9_8038	Software-Controllable Signals register 3 (IIM_SCS3)	8	R/W	00h	42.4.14/ 1854

42.4.1 Status register (IIM_STAT)

All block status information is read using the STAT register.

Address: IIM_STAT is 63F9_8000h base + 0h offset = 63F9_8000h

Bit	7	6	5	4	3	2	1	0
Read	BUSY	-					PRGD	SNSD
Write							w1c	w1c
Reset	0	0	0	0	0	0	0	0

IIM_STAT field descriptions

Field	Description
7 BUSY	Indicates whether the IIM is busy with a program or sense cycle. Any attempt to access the IIM registers other than STAT while it is busy with a program or sense cycle (BUSY asserted) results in a bus error. 0 The IIM is not busy with a program or sense cycle 1 The IIM is busy with a program or sense cycle
6–2 -	Reserved
1 PRGD	Program Done. Indicates an e-Fuse program operation is done. Assertion causes an interrupt request (irq_b signal asserted) if PRGD_M is set in the Status IRQ Mask Register. This bit is automatically set by hardware upon completion of an e-Fuse program cycle; software must clear the bit by writing 1 to it. 0 Program operation has not finished (read); no meaning (write) 1 Program operation has finished (read); clear bit (write)
0 SNSD	Explicit Sense Cycle Done. Indicates that an explicit fuse sense cycle is done, and the data is available in SDAT. Assertion causes an interrupt request if SNSD_M is set in the Status IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 No explicit sense cycle has finished (read); no meaning (write) 1 An explicit sense cycle has finished (read); clear bit (write)

42.4.2 Status IRQ Mask register (IIM_STATM)

Address: IIM_STATM is 63F9_8000h base + 4h offset = 63F9_8004h

Bit	7	6	5	4	3	2	1	0
Read Write	-						PRGD_M	SNSD_M
Reset	0	0	0	0	0	0	0	0

IIM_STATM field descriptions

Field	Description
7–2 -	Reserved
1 PRGD_M	Program Mask. Masks or unmasks IRQ generation due to PRGD events. 0 PRGD events do not cause an IRQ 1 PRGD events cause an IRQ
0 SNSD_M	Explicitly Sense Cycle Done Mask. Masks or unmasks IRQ generation due to SNSD events. 0 SNSD events do not cause an IRQ 1 SNSD events cause an IRQ

42.4.3 Module Errors register (IIM_ERR)

Address: IIM_ERR is 63F9_8000h base + 8h offset = 63F9_8008h

Bit	7	6	5	4	3	2	1	0
Read Write	PRGE	WPE	OPE	RPE	WLRE	SNSE	PARITYE	-
Reset	0	0	0	0	0	0	0	u*

* Notes:
- u = Unaffected by reset.

IIM_ERR field descriptions

Field	Description
7 PRGE	Program Error. Indicates an e-Fuse program operation ended in failure. Assertion causes an interrupt request if PRGE_M is set in the Errors IRQ Mask Register. A program failure occurs when an attempt is made to program laser fuses. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 Program operation has not finished with error (read); no meaning (write) 1 Program operation has finished with an error (read); clear bit (write)
6 WPE	Write Protect Error. Indicates an e-Fuse program operation was attempted to a write-protected fuse bank, or a locked words, or when the value of PRG_P is not 8'hAA. Assertion causes an interrupt request if WPE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no write-protect error (read); no meaning (write) 1 There was a write-protect error (read); clear bit (write)
5 OPE	Override Protect Error. Indicates an attempt was made to override the values in an override-protected fuse bank, or a locked words. Assertion causes an interrupt request if OPE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no override-protect error (read); no meaning (write) 1 There was an override-protect error (read); clear bit (write)
4 RPE	Read Protect Error. Indicates an attempt was made to read values from a read-protected fuse bank or SCC. Assertion causes an interrupt request if RPE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no read-protect error (read); no meaning (write) 1 There was a read-protect error (read); clear bit (write)
3 WLRE	Write to Locked Register Error. Indicates an attempt was made to write to a locked SCS register. Assertion causes an interrupt request if WLRE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no write-to-locked-register error (read); no meaning (write) 1 There was a write-to-locked-register error (read); clear bit (write)
2 SNSE	Explicit Sense Cycle Error. Indicates that an explicit fuse sense was refused, because FBESP is set to 1, or more than two bits of SNS_N, SNS_1, SNS_0, PRG are asserted at the same moment. Assertion

Table continues on the next page...

IIM_ERR field descriptions (continued)

Field	Description
	causes an interrupt request if SNSE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no explicit sense error (read); no meaning (write) 1 There was an explicit sense error (read); clear bit (write)
1 PARITYE	Parity Error of Cache. Indicate that an parity error was detected in hardware fuse cache or software fuse cache. Assertion causes an interrupt request if PARITYE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no explicit sense error (read); no meaning (write) 1 There was an explicit sense error (read); clear bit (write)
0 -	Reserved

42.4.4 Error IRQ Mask register (IIM_EMASK)

Address: IIM_EMASK is 63F9_8000h base + Ch offset = 63F9_800Ch

Bit	7	6	5	4	3	2	1	0
Read Write	PRGE_M	WPE_M	OPE_M	RPE_M	WLRE_M	SNSE_M	PARITYE_M	-
Reset	0	0	0	0	0	0	0	u*

* Notes:
- u = Unaffected by reset.

IIM_EMASK field descriptions

Field	Description
7 PRGE_M	Program Error Mask. Masks or unmasks IRQ generation due to PRGE events. 0 PRGE events do not cause an IRQ 1 PRGE events cause an IRQ
6 WPE_M	Write Protect Error Mask. Masks or unmasks IRQ generation due to WPE events. 0 WPE events do not cause an IRQ 1 WPE events cause an IRQ
5 OPE_M	Override Protect Error Mask. Masks or unmasks IRQ generation due to OPE events. 0 OPE events do not cause an IRQ 1 OPE events cause an IRQ
4 RPE_M	Read Protect Error Mask. Masks or unmasks IRQ generation due to RPE events. 0 RPE events do not cause an IRQ 1 RPE events cause an IRQ

Table continues on the next page...

IIM_EMASK field descriptions (continued)

Field	Description
3 WLRE_M	Write to Locked Register Error Mask. Masks or unmasks IRQ generation due to WLRE events. 0 WLRE events do not cause an IRQ 1 WLRE events cause an IRQ
2 SNSE_M	Explicit Sense Cycle Error Mask. Masks or unmasks IRQ generation due to SNSE events. 0 SNSE events do not cause an IRQ 1 SNSE events cause an IRQ
1 PARITYE_M	Parity Error of Cache Mask. Masks or unmasks IRQ generation due to PARITYE events. 0 PARITYE events do not cause an IRQ 1 PARITYE events cause an IRQ
0 -	Reserved

42.4.5 Fuse Control register (IIM_FCTL)

Address: IIM_FCTL is 63F9_8000h base + 10h offset = 63F9_8010h

Bit	7	6	5	4	3	2	1	0
Read Write	DPC	PRG_LENGTH[2:0]			ESNS_N	ESNS_0	ESNS_1	PRG
Reset	0	0	1	1	0	0	0	0

IIM_FCTL field descriptions

Field	Description
7 DPC	Delayed Program Cycle. This bit is a control bit, selecting immediate or delayed program. When this bit is cleared, program cycles start immediately upon setting of PRG bit. When this bit is asserted, program cycles is delayed until input signal delayed_pgm_start is asserted. 0 Program cycles begin immediately upon setting of the PRG bit 1 Program cycles are delayed; they do not begin until delayed_pgm_start signal is asserted
6–4 PRG_ LENGTH[2:0]	Program Length. This 3 bits define the length of program pulse PRG_LENGTH* (period of 32k clock) Setting is unknown.
3 ESNS_N	Explicit Sense - Normal. Writing 1 to this bit initiate an unstressed (normal) explicit sense cycle. Read of this bit always returns zero. FSM generate a "done" signal when the operation complete. This bit is cleared automatically by hardware when sense operation completed. Only one of ESNS_N, ESNS_0, ESNS_1, PRG can be asserted, otherwise ESNS_E will be asserted to indicate this error. 0 Return 0 for all read (read); No meaning (write) 1 Initiate an unstressed explicit sense cycle (write)

Table continues on the next page...

IIM_FCTL field descriptions (continued)

Field	Description
2 ESNS_0	Explicit Sense - 0-stressed. Writing 1 to this bit initiate a 0-stressed explicit sense cycle. Read of this bit always returns zero.FSM generate a "done" signal when the operation complete. This bit is cleared automatically by hardware when sense operation completed. During 0-stressed explicit sense cycles, the **epm_readsense0** signal is asserted to the fuse banks. Only one of ESNS_N, ESNS_0, ESNS_1, PRG can be asserted, otherwise ESNS_E will be asserted to indicate this error. 0 Return 0 for all read (read); No meaning (write) 1 Initiate a 0-stressed explicit sense cycle (write)
1 ESNS_1	Explicit Sense - 1-stressed. Writing 1 to this bit initiate a 1-stressed explicit sense cycle. Read of this bit always returns zero. FSM generate a "done" signal when the operation complete. This bit is cleared automatically by hardware when sense operation completed. During 1-stressed explicit sense cycles, the **epm_readsense1** signal is asserted to the fuse banks. Only one of ESNS_N, ESNS_0, ESNS_1, PRG can be asserted, otherwise ESNS_E will be asserted to indicate this error. Only one of ESNS_N, ESNS_0, ESNS_1, PRG can be asserted, otherwise ESNS_E will be asserted to indicate this error. 0 Return 0 for all read (read); No meaning (write) 1 Initiate a 1-stressed explicit sense cycle (write)
0 PRG	Program. Writing 1 to this bit initiate a fuse program cycle. Read of this bit always returns zero. FSM generate a "done" signal when the operation complete. This bit is cleared automatically by hardware when program operation completed. Only one of ESNS_N, ESNS_0, ESNS_1, PRG can be asserted, otherwise ESNS_E will be asserted to indicate this error. 0 Return 0 for all read (read); No meaning (write) 1 Initiate a program cycle (write)

42.4.6 Upper Address register (IIM_UA)

The top part of the address of the e-Fuse bit to be programmed or the word to be sensed in an explicit sense cycle. Note that programming is done by bit, so the program address is a full-bit address. Sensing is done on 8-bit words, so the bottom three bits of the address are ignored.

Address: IIM_UA is 63F9_8000h base + 14h offset = 63F9_8014h

Bit	7	6	5	4	3	2	1	0
Read Write	-				A[13-8]			
Reset	0	0	0	0	0	0	0	0

IIM_UA field descriptions

Field	Description
7–6 -	Reserved

Table continues on the next page...

IIM_UA field descriptions (continued)

Field	Description
5–0 A[13-8]	The top six bits of the address of the e-Fuse bit to be programmed or the word to be sensed explicitly. The address must be written prior to setting the PRG or ESNS_x bit in FCTL to initiate the program/sense operation. A[13-11] select the Fuse bank. A[10-8] provide the most significant portion of the row address within the bank.

42.4.7 Lower Address register (IIM_LA)

The bottom 8 bits of the address of the e-Fuse bit to be programmed or word to be explicitly sensed.

Address: IIM_LA is 63F9_8000h base + 18h offset = 63F9_8018h

Bit	7	6	5	4	3	2	1	0
Read Write	A							
Reset	0	0	0	0	0	0	0	0

IIM_LA field descriptions

Field	Description
7–0 A	The bottom eight bits of the address of the e-Fuse bit to be programmed or word to be sensed explicitly. The address must be written prior to setting the PRG or ESNS_x bit in FCTL to initiate a program or sense operation. A[7:3] provides the least significant portion of the row address. A[2:0] select the bit position within the selected row.

42.4.8 Explicit Sense Data register (IIM_SDAT)

On an explicit sense cycle, the data sensed from the fuses is placed in this register at the conclusion of the sense cycle. Software can recognize the conclusion of the sense cycle by the assertion of SNSD in STAT.

Address: IIM_SDAT is 63F9_8000h base + 1Ch offset = 63F9_801Ch

Bit	7	6	5	4	3	2	1	0
Read	D							
Write								
Reset	0	0	0	0	0	0	0	0

IIM_SDAT field descriptions

Field	Description
7–0 D	The data sensed from the fuses. Setting is unknown.

42.4.9 Product Revision register (IIM_PREV)

The product revision. This corresponds to the top eight bits of the deprecated HW_REV register.

Address: IIM_PREV is 63F9_8000h base + 20h offset = 63F9_8020h

Bit	7	6	5	4	3	2	1	0
Read	PROD_REV					PROD_VT		
Write								
Reset	u*	u*	u*	u*	u*	u*	u*	u*

* Notes:
- u = Unaffected by reset.

IIM_PREV field descriptions

Field	Description
7–3 PROD_REV	Product Revision. The product revision (specific to the product or product family). Setting according to product revision.
2–0 PROD_VT	Product vendor or technology. The product vendor and/or technology (specific to the product or product family). Setting according to product vendor/technology.

42.4.10 Silicon Revision register (IIM_SREV)

The silicon revision (that is, mask revision). This corresponds to the bottom 8 bits of the deprecated HW_REV register.

Address: IIM_SREV is 63F9_8000h base + 24h offset = 63F9_8024h

Bit	7	6	5	4	3	2	1	0
Read	SILICON_REV							
Write								
Reset	0	0	0	0	0	0	0	0

IIM_SREV field descriptions

Field	Description
7–0 SILICON_REV	Mask Set Revision. The mask set revision used in fabrication of the part. The value changes with each change to the mask set. Setting according to mask set revision.

42.4.11 Program Protection register (IIM_PREG_P)

This register is used to against accidental fuse programming. The fuses can be blown only when the value of this register is 8'hAA. Software should only program this register to 8'hAA while actively blowing fuses. After the program operation is complete, this register should be immediately reprogrammed to a different value.

Address: IIM_PREG_P is 63F9_8000h base + 28h offset = 63F9_8028h

Bit	7	6	5	4	3	2	1	0
Read Write	PROTECTION_REG							
Reset	0	0	0	0	0	0	0	0

IIM_PREG_P field descriptions

Field	Description
7–0 PROTECTION_REG	The fuses can be blown only when the value of this register is 8'hAA. Any attempt to program the fuse while the value is other than 8'hAA will be terminated with error. WPE bit will be asserted. Setting is undefined.

42.4.12 Software-Controllable Signals register 0 (IIM_SCS0)

This register is physically located in the hardware-visible signals sub-block. It implements software-controlled, volatile signals which can drive SoC-level nets for feature enabling.

Address: IIM_SCS0 is 63F9_8000h base + 2Ch offset = 63F9_802Ch

Bit	7	6	5	4	3	2	1	0
Read	LOCK	HAB_JDE	SCS[26:21]					
Write								
Reset	0	0	0	0	0	0	0	0

IIM_SCS0 field descriptions

Field	Description
7 LOCK	Lock this register. This bit is used to lock the contents of this register until the next reset. The intended usage is to have trusted software program the register as desired and lock it before allowing distrusted software to run. This bit is write only, read of this bit return 0. 0 The register is not locked, it may be modified 1 The register is locked, all attempts to modify it are ignored
6 HAB_JDE	HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properly signed command to do so is found and validated by the HAB. The HAB musts lock the register before passing control to the OS whether or not JTAG debugging has been enabled. Once JTAG is enabled by HAB_JDE bit, it can not be disabled unless the system is reset by POR. 0 JTAG debugging is not enabled by the HAB (it may still be enabled by other mechanisms) 1 JTAG debugging is enabled by the HAB (though this signal may be gated off)
5–0 SCS[26:21]	These bits may be used in an implementation-defined way.

42.4.13 Software-Controllable Signals register 2 (IIM_SCS2)

SCS2 and SCS3 registers are physically located in the hardware-visible signals sub-block. They implement software-controlled, volatile signals that can drive SoC-level nets for feature enabling.

Each IIM fuse bank include a read protection bit to inhibit software fuses read and sense and to support secure computing environments. When a fuse bank's read protection bit is set (i.e.'1'), the bank's fuses cannot be read or sensed by software. The read protection bit cannot be changed if the sticky lock bit was asserted.

This is the fuse bank read lock register. This corresponds to five i.MX53 fuse banks.

Address: IIM_SCS2 is 63F9_8000h base + 34h offset = 63F9_8034h

Bit	7	6	5	4	3	2	1	0
Read	LOCK	-		FBRL4	FBRL3	FBRL2	FBRL1	FBRL0
Write								
Reset	0	0	0	0	0	0	0	0

IIM_SCS2 field descriptions

Field	Description
7 LOCK	Lock this register. 0 The register is not locked, it may be modified 1 The register is locked, all attempts to modify it are ignored

Table continues on the next page...

IIM_SCS2 field descriptions (continued)

Field	Description
6–5 -	Reserved
4 FBRL4	Read lock for fuse bank #4
3 FBRL3	Read lock for fuse bank #3
2 FBRL2	Read lock for fuse bank #2
1 FBRL1	Read lock for fuse bank #1
0 FBRL0	Read lock for fuse bank #0

42.4.14 Software-Controllable Signals register 3 (IIM_SCS3)

SCS2 and SCS3 registers are physically located in the hardware-visible signals sub-block. They implement software-controlled, volatile signals that can drive SoC-level nets for feature enabling.

Each IIM fuse bank include a read protection bit to inhibit software fuses read and sense and to support secure computing environments. When a fuse bank's read protection bit is set (i.e.'1'), the bank's fuses cannot be read or sensed by software. The read protection bit cannot be changed if the sticky lock bit was asserted.

This is the fuse bank write lock register. This corresponds to the five i.MX53 fuse banks.

Address: IIM_SCS3 is 63F9_8000h base + 38h offset = 63F9_8038h

Bit	7	6	5	4	3	2	1	0
Read Write	LOCK	-		FBWL4	FBWL3	FBWL2	FBWL1	FBWL0
Reset	0	0	0	0	0	0	0	0

IIM_SCS3 field descriptions

Field	Description
7 LOCK	Lock this register. 0 The register is not locked, it may be modified 1 The register is locked, all attempts to modify it are ignored
6–5 -	Reserved

Table continues on the next page...

IIM_SCS3 field descriptions (continued)

Field	Description
4 FBWL4	Write lock for fuse bank #4
3 FBWL3	Write lock for fuse bank #3
2 FBWL2	Write lock for fuse bank #2
1 FBWL1	Write lock for fuse bank #1
0 FBWL0	Write lock for fuse bank #0

Chapter 43
IOMUX Controller (IOMUXC)

43.1 Introduction

43.1.1 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the SoC to share one pad with several functional blocks. This is done by multiplexing the pad input/output signals. For each pad there are up to 8 muxing options (called ALT modes). Since different blocks require different pad settings (like pull up, keeper, etc.), the IOMUXC also controls the pad setting parameters.

The IOMUXC consists of only combinatorial logic combined from several basic IOMUXC cells. Each basic IOMUXC cell handles the muxing of only one pad, and each pad connects to one package I/O, called a pin.

Figure below illustrates the IOMUX/IOMUXC connectivity in the system.

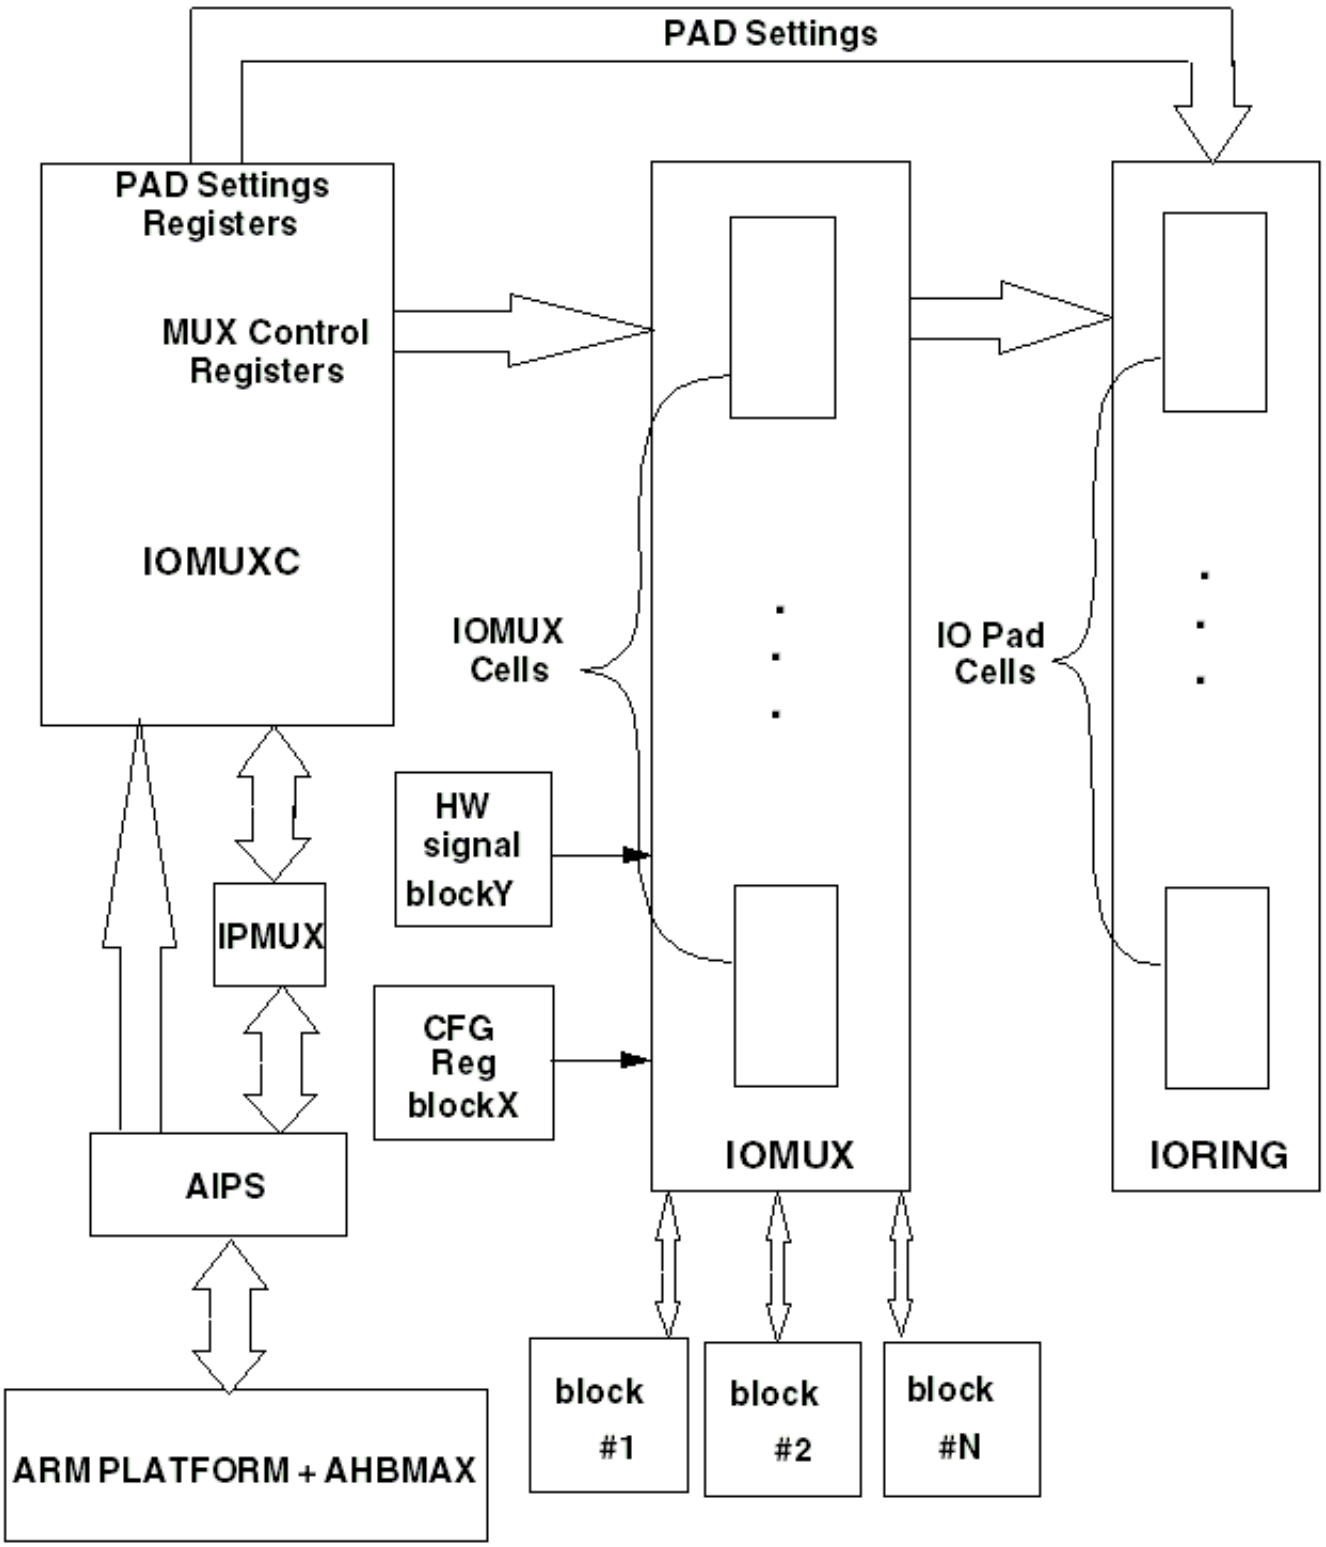

Figure 43-1. IOMUX SoC-Level Block Diagram

43.1.2 Features

The IOMUXC features are:

- 32-bit General Purpose Registers - Two 32 bits registers according to SoC requirements for any usage
- 32-bit SW Mux control registers (IOMUXC_SW_MUX_CTL_PAD_<PAD NAME> or IOMUXC_SW_MUX_CTL_GRP_<GROUP NAME>) to configure a specific mux mode for each pad or a predefined group of pads and to enable forcing the input path of the pad/s (SION bit).
- 32-bit SW Pad control registers (IOMUXC_SW_PAD_CTL_PAD_<PAD_NAME> or IOMUXC_SW_PAD_CTL_GRP_<GROUP NAME>) to configure specific pad settings for each pad or a predefined group of pads.
- 5 32-bit OBSERVE_MUX registers (IOMUXC_OBSERVE_MUX_0-4)
- 32-bit Daisy Chain Control registers - register to control the input path to a block when more than one pad may drive this block input.
- IP Bus Interface - IP peripheral bus to allow registers configuration and readiness (all registers are read/write registers).

Each SW MUX/PAD CTL IOMUXC register handles only one pad or one group of pads.

Only the minimum number of registers required by SW will be implemented by HW. For example, if only ALT0 and ALT1 modes are used on Pad X, then only one bit register will be generated as the MUX_MODE control field in the SW Mux control register of Pad X.

The SW Mux control registers may allow forcing the pads to become input (input path enabled), regardless of the functional direction driven. This may be useful for loopback and GPIO data capture.

43.1.3 Modes of Operation

There is only one mode of operation - normal mode.

43.2 External Signal Description

There are no signals in the IOMUXC that connect off chip (they all control the pads functionality).

43.3 Programmable Registers

There are four main groups of registers;

1. The General Purpose Registers (GPR) - used to select operating modes for general features in the SoC, usually not related to the IOMUXC itself.

2. The Observability Registers - can be used for debugging in order to reflect internal signals values.

3. The Software MUX Control Registers - used to configure the IOMUXC multiplexing, and "connect" the pad to a given port in a block.

4. The pad settings Registers - Used to control the pad settings configuration. For some pads (in order to save chip route) the pad settings are grouped in one register, i.e., changing the group register will affect the settings for all pads in the group.

NOTE

The pad settings for SDCLK_0_B and SDCLK_1_B are identical with the SDCLK_0 and SDCLK_1 respectively.

Table 43-2. DDR Output Driver Average Impedance

Parameter	Symbol	Test Conditions	Drive strength (DSE)								Unit
			000	001	010	011	100	101	110	111	
Output Driver Impedance[1]	Rdrv2[2]	LPDDR1/DDR2 mode NVCC_DRAM = 1.8 V DDR_SEL = 00 Calibration resistance = 300 Ω[3]	Hi-Z[4]	300	150	100	75	60	50	43	Ω
		DDR2 mode NVCC_DRAM = 1.8 V DDR_SEL = 01 Calibration resistance = 180 Ω[3]	Hi-Z[4]	180	90	60	45	36	30	26	
		DDR2 mode NVCC_DRAM = 1.8 V DDR_SEL = 10 Calibration resistance = 200 Ω[3]	Hi-Z[4]	200	100	66	50	40	33	28	
		DDR2 mode NVCC_DRAM= 1.8 V DDR_SEL = 11 Calibration resistance = 140 Ω[3]	Hi-Z[4]	140	70	46	35	28	23	20	
		LPDDR2 mode NVCC_DRAM= 1.2 V DDR_SEL = 01[5] Calibration resistance = 160 Ω[3]	Hi-Z[4]	160	80	53	40	32	27	23	
		LPDDR2 mode NVCC_DRAM = 1.2 V DDR_SEL = 10 Calibration resistance = 240 Ω[3]	Hi-Z[4]	240	120	80	60	48	40	34	
		LPDDR2 mode NVCC_DRAM = 1.2 V DDR_SEL = 11 Calibration resistance = 160 Ω[3]	Hi-Z[4]	160	80	53	40	32	27	23	
		DDR3 mode NVCC_DRAM = 1.5 V DDR_SEL = 00 Calibration resistance = 200 Ω[3]	Hi-Z[4]	240	120	80	60	48	48	34	

1. Output driver impedance is controlled across PVTs (process, voltages, and temperatures) using calibration procedure and pu_*cal, pd_*cal input pins.
2. Output driver impedance deviation (calibration accuracy) is ±5% (max/min impedance) across PVTs.
3. Calibration is done against external reference resistor. Value of the resistor should be varied depending on DDR mode and DDR_SEL setting.
4. Disabled.

5. If DDR_SEL = 01 or DDR_SEL = 11 are selected with NVCC_DRAM = 1.2 V for LPDDR2 operation, the external reference resistor value must be 160 Ω for a correct ZQ calibration. In any case, reference resistors attached to the DDR memory devices should be kept to 240 Ω per the JEDEC standard.

IOMUXC_GPR0 field descriptions (continued)

Field	Description
11 MLBCLK_IN_ INV	MLBCLK_IN to MLB block is inverted (comparing to MLB device on board) for the following MLB outputs, DATAOUT and SIGOUT. (in addition also the pads output enable are driven by the inverted clock DATA_OE and SIG_OE). This bit should be used for high speed (1024fs) in case of timing issues. 0 MLBCLK_IN is not inverted.[default] 1 MLBCLK_IN is inverted.
10 DMAREQ_ MUX_SEL10	Selects between two possible sources for SDMA_EVENT[13]: 0 uart2.ipd_uart_tx_dmareq_b 1 firi.dma_req_b[1]
9 DMAREQ_ MUX_SEL9	Selects between two possible sources for SDMA_EVENT[12]: 0 uart2.ipd_uart_rx_dmareq_b 1 firi.dma_req_b[0]
8 DMAREQ_ MUX_SEL8	Selects between two possible sources for SDMA_EVENT[3]: 0 uart4.ipd_uart_tx_dmareq_b 1 pata.ata_tx_fifo_alarm
7 DMAREQ_ MUX_SEL7	Selects between two possible sources for SDMA_EVENT[2]: 0 uart4.ipd_uart_rx_dmareq_b 1 pata.ata_rcv_fifo_alarm
6 DMAREQ_ MUX_SEL6	Selects between two possible sources for SDMA_EVENT[39]: 0 cspi.ipd_req_cspi_tdma_b 1 iomux.sdma_events[15] - External DMA Request from pad DISP0_DAT16 or GPIO_17
5 DMAREQ_ MUX_SEL5	Selects between two possible sources for SDMA_EVENT[38]: 0 cspi.ipd_req_cspi_rdma_b 1 epit2.ipi_int_epit_oc
4 DMAREQ_ MUX_SEL4	Selects between two possible sources for SDMA_EVENT[14]: 0 spdif.drq0_spdif_b 1 iomux.sdma_events[14] - External DMA Request from pad DISP0_DAT17 or GPIO_18
3 DMAREQ_ MUX_SEL3	Selects between two possible sources for SDMA_EVENT[11]: 0 esdhc4.ipd_esdhcv2_dreq_b 1 cti2.CTITRIGOUT[0]
2 DMAREQ_ MUX_SEL2	Selects between two possible sources for SDMA_EVENT[10]: 0 i2c3.ipi_int_b 1 esdhc3.ipd_esdhcv3_dreq_b
1 DMAREQ_ MUX_SEL1	Selects between two possible sources for SDMA_EVENT[21]: 0 i2c2.ipi_int_b 1 esdhc2.ipd_esdhcv2_dreq_b

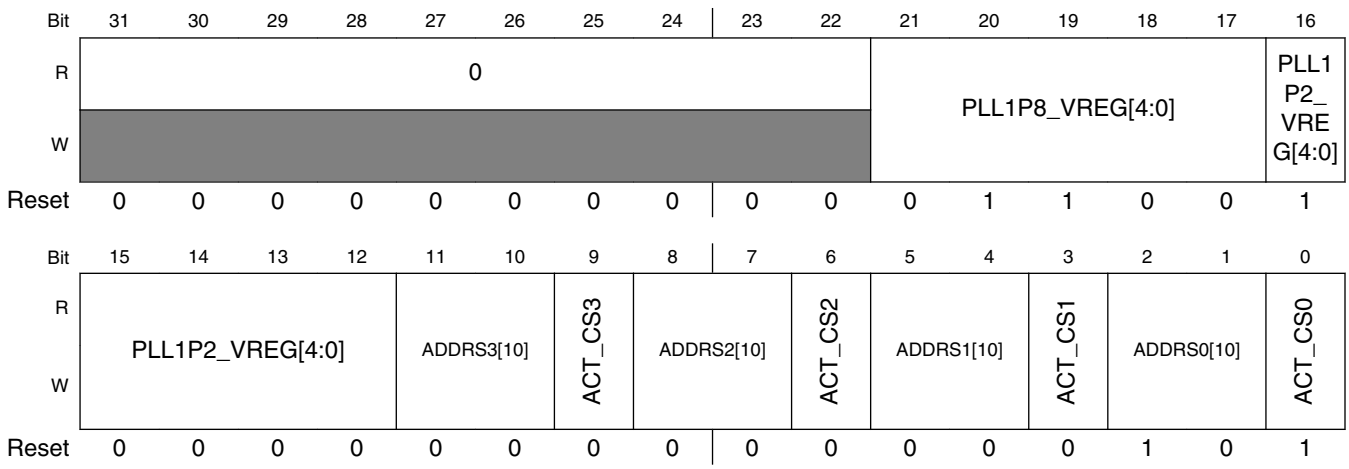
Table continues on the next page...

IOMUXC_GPR0 field descriptions (continued)

Field	Description
0 DMAREQ_ MUX_SEL0	Selects between two possible sources for SDMA_EVENT[20]: 0 i2c1.ipi_int_b 1 esdhc1.ipd_esdhcv2_dreq_b

43.3.2 General Purpose Register 1 (IOMUXC_GPR1)

Address: IOMUXC_GPR1 is 53FA_8000h base + 4h offset = 53FA_8004h



IOMUXC_GPR1 field descriptions

Field	Description
31–22 Reserved	This read-only field is reserved and always has the value zero. Reserved
21–17 PLL1P8_ VREG[4:0]	Defines the output for voltage regulators. For the 1.8V regulator: 0x00 = 1.5V and 0x1F = 2.275V in 25mV steps. This puts the reset value for 1.8V at 0x0C
16–12 PLL1P2_ VREG[4:0]	Defines the output for voltage regulators. For the 1.2V regulator: 0x00 = 0.8V and 0x1F = 1.575 in 25mV steps. This puts the reset value for 1.2V at 0x10.
11–10 ADDRS3[10]	Active Chip Select and Address Space. Each of the ACT_CSx represents one of the four chip selects of the WEIM. When ACT_CSx=1'b1, the corresponding chip select is active and has a valid address space according to its address space configuration determined by ADDRSx[10] bits ADDRSx[10] is setting the space for each chip select which is active. The address space of the first active chip select must be the biggest one, the following active chip select address spaces may be equal or lower. Total address space size is 128 MByte. Address Space Configuration options (ADDRSx[10]):

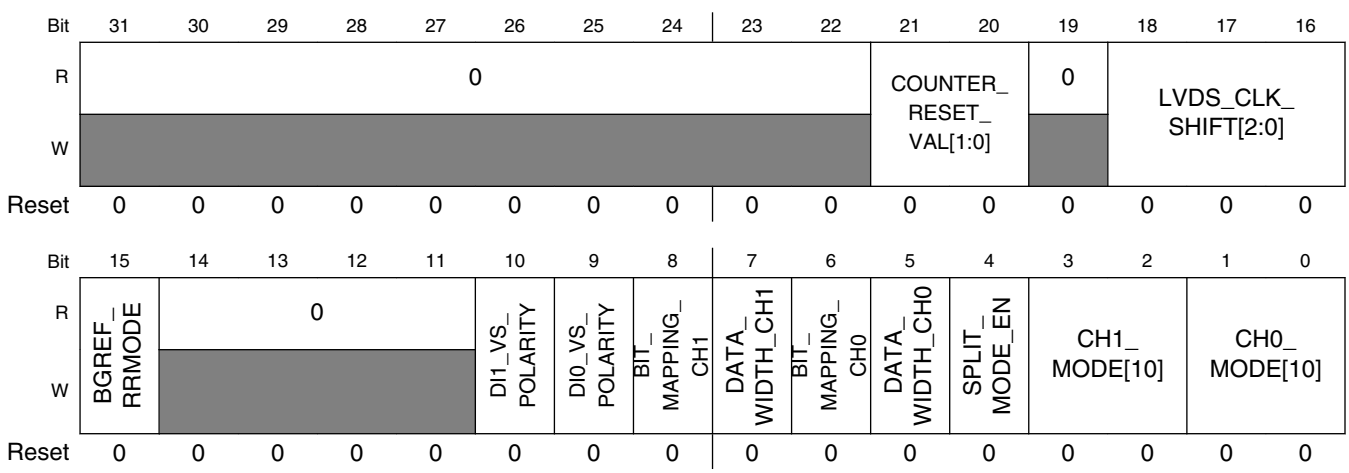
43.3.3 General Purpose Register 2 (IOMUXC_GPR2)

Address: IOMUXC_GPR2 is 53FA_8000h base + 8h offset = 53FA_8008h



IOMUXC_GPR2 field descriptions

Field	Description
31–22 Reserved	This read-only field is reserved and always has the value zero. Reserved
21–20 COUNTER_ RESET_ VAL[1:0]	Reset value for the LDB counter which determines when the shift registers are loaded with data. Note: Used for debug purposes only. In normal functional operation must be '00' 00 Reset value is 5 01 Reset value is 3 10 Reset value is 4 11 Reset value is 6
19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18–16 LVDS_CLK_ SHIFT[2:0]	Shifts the LVDS output clock in relation to the data. Note: Used for debug purposes only. In normal functional operation must be '000' 000 Output clock is '1100011' (normal operation) 001 Output clock is '1110001' 010 Output clock is '1111000' 011 Output clock is '1000111' 100 Output clock is '0001111' 101 Output clock is '0011111' 110 Output clock is '0111100' 111 Output clock is '1100011'
15 BGREF_ RRMODE	Select reference resistor for bandgap 0 External resistor of 28 kOhms is selected 1 Internal resistor is selected
14–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10 DI1_VS_ POLARITY	Vsync polarity for IPU's DI1 interface. 0 ipu_di1_vsync is active high. 1 ipu_di1_vsync is active low.
9 DI0_VS_ POLARITY	Vsync polarity for IPU's DI0 interface. 0 ipu_di0_vsync is active high. 1 ipu_di0_vsync is active low.
8 BIT_MAPPING_ CH1	Data mapping for LVDS channel 1. 0 Use SPWG standard. 1 Use JEIDA standard.
7 DATA_WIDTH_ CH1	Data width for LVDS channel 1. Note: This bit must be set when using JEIDA standard (bit_mapping_ch1 is set) 0 Data width is 18 bits wide (lvds1_tx3 is not used) 1 Data width is 24 bits wide.

Table continues on the next page...

IOMUXC_GPR2 field descriptions (continued)

Field	Description
6 BIT_MAPPING_CH0	Data mapping for LVDS channel 0. 0 Use SPWG standard. 1 Use JEIDA standard.
5 DATA_WIDTH_CH0	Data width for LVDS channel 0. Note: This bit must be set when using JEIDA standard (bit_mapping_ch0 is set) 0 Data width is 18 bits wide (lvds0_tx3 is not used) 1 Data width is 24 bits wide.
4 SPLIT_MODE_EN	Enable split mode. 0 Split mode is disabled. 1 Split mode is enabled. In this mode both channels should be enabled and working with the same DI (ch0_mode and ch1_mode should both be either '01' or '11')
3–2 CH1_MODE[10]	LVDS channel 1 operation mode 00 Channel disabled. 01 Channel enabled, routed to DI0 10 Channel disabled. 11 Channel enabled, routed to DI1.
1–0 CH0_MODE[10]	LVDS channel 0 operation mode 00 Channel disabled. 01 Channel enabled, routed to DI0 10 Channel disabled. 11 Channel enabled, routed to DI1.

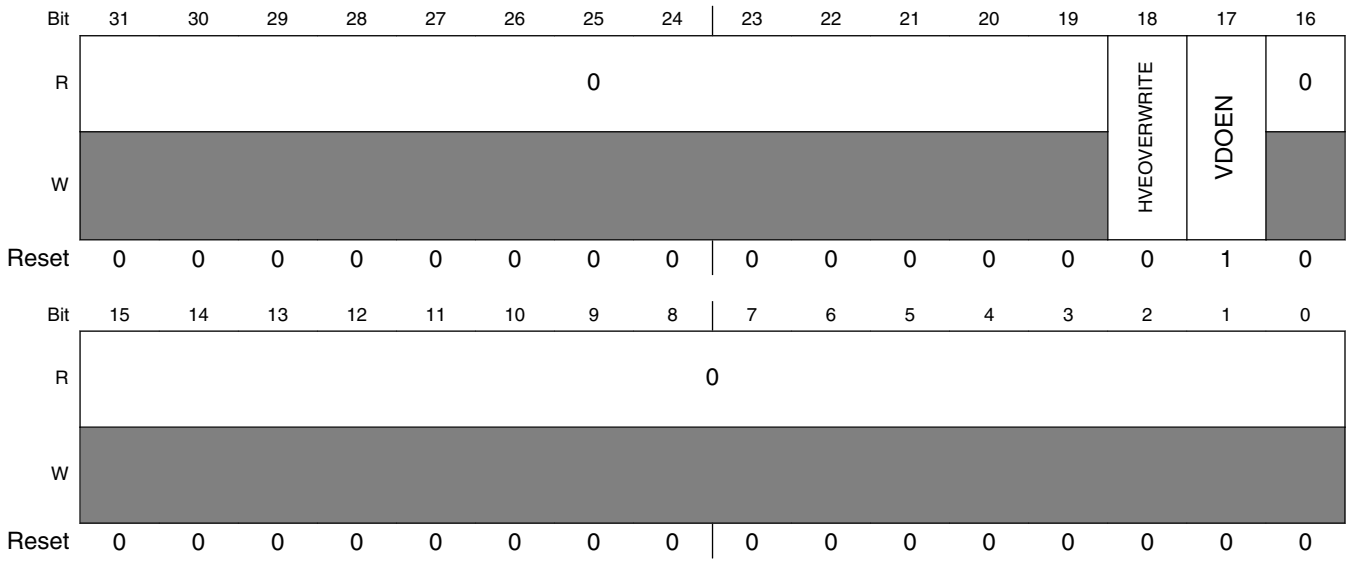
43.3.272 IOMUXC_SW_PAD_CTL_PAD_NVCC_CSI__0 (IOMUXC_SW_PAD_CTL_PAD_NVCC_CSI__0)

Address: IOMUXC_SW_PAD_CTL_PAD_NVCC_CSI__0 is 53FA_8000h base + 43Ch offset = 53FA_843Ch



IOMUXC_SW_PAD_CTL_PAD_NVCC_CSI__0 field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18 HVEOVERWRITE	HVEOVERWRITE (ipp_owr) Select one out of next values for pad: NVCC_CSI__0. This field affects the voltage levels for the following PADS: CSI0_DAT19, CSI0_DAT18, CSI0_DAT17, CSI0_DAT16, CSI0_DAT15, CSI0_DAT14, CSI0_DAT13, CSI0_DAT12, CSI0_DAT11, CSI0_DAT10, CSI0_DAT9, CSI0_DAT8, CSI0_DAT7, CSI0_DAT6, CSI0_DAT5, CSI0_DAT4, CSI0_VSYNC, CSI0_DATA_EN, CSI0_MCLK, CSI0_PIXCLK 0 PAD support high voltage (3.0V-3.6V). Out of reset value is 0. The HVEOVERWRITE field should be updated before automatic voltage detector is disabled. 1 PAD support low voltage (1.65V-3.1V)
17 VDOEN	VDOEN (ipp_oen) Select one out of next values for pad: NVCC_CSI__0. 0 Voltage detector output disable and HVEOVERWRITE field will be used. It is recommended to disable the automatic voltage detector after boot and update the HVEOVERWRITE field with the actual I/O supply value. 1 Voltage detector output enable. (default 1) **NOTE:**
16–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18 HVEOVERWRITE	HVEOVERWRITE (ipp_owr) Select one out of next values for pad: NVCC_EIM__1. This field affects the voltage levels for the following PADS: EIM_D31, EIM_D30, EIM_D29, EIM_D28, EIM_D27, EIM_D26, EIM_D25, EIM_D24, EIM_D23, EIM_D22, EIM_D21, EIM_D20, EIM_D19, EIM_D18, EIM_D17, EIM_D16 0 PAD support high voltage (3.0V-3.6V). Out of reset value is 0. The HVEOVERWRITE field should be updated before automatic voltage detector is disabled. 1 PAD support low voltage (1.65V-3.1V)
17 VDOEN	VDOEN (ipp_oen) Select one out of next values for pad: NVCC_EIM__1. 0 Voltage detector output disable and HVEOVERWRITE field will be used. It is recommended to disable the automatic voltage detector after boot and update the HVEOVERWRITE field with the actual I/O supply value. 1 Voltage detector output enable. (default 1)
16–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

IOMUXC_SW_PAD_CTL_PAD_NVCC_EIM__4 field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18 HVEOVERWRITE	HVEOVERWRITE (ipp_owr) Select one out of next values for pad: NVCC_EIM__4. This field affects the voltage levels for the following PADS: EIM_A25, EIM_EB2, EIM_EB3, EIM_A24, EIM_A23, EIM_A22, EIM_A21, EIM_A20, EIM_A19, EIM_A18, EIM_A17, EIM_A16, EIM_CS0, EIM_CS1, EIM_OE 0 PAD support high voltage (3.0V-3.6V). Out of reset value is 0. The HVEOVERWRITE field should be updated before automatic voltage detector is disabled. 1 PAD support low voltage (1.65V-3.1V)
17 VDOEN	VDOEN (ipp_oen) Select one out of next values for pad: NVCC_EIM__4. 0 Voltage detector output disable and HVEOVERWRITE field will be used. It is recommended to disable the automatic voltage detector after boot and update the HVEOVERWRITE field with the actual I/O supply value. 1 Voltage detector output enable. (default 1)
16–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

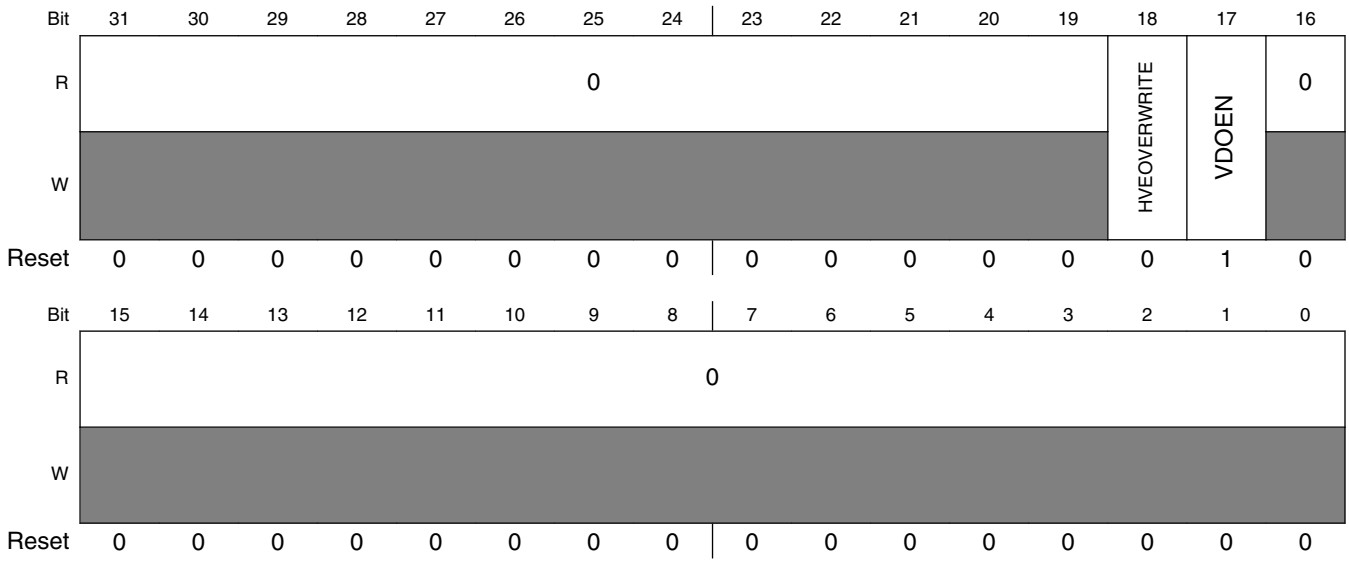
43.3.336 IOMUXC_SW_PAD_CTL_PAD_NVCC_EIM__7 (IOMUXC_SW_PAD_CTL_PAD_NVCC_EIM__7)

Address: IOMUXC_SW_PAD_CTL_PAD_NVCC_EIM__7 is 53FA_8000h base + 53Ch offset = 53FA_853Ch



IOMUXC_SW_PAD_CTL_PAD_NVCC_EIM__7 field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18 HVEOVERWRITE	HVEOVERWRITE (ipp_owr) Select one out of next values for pad: NVCC_EIM__7. This field affects the voltage levels for the following PADS: EIM_RW, EIM_LBA, EIM_EB0, EIM_EB1, EIM_DA0, EIM_DA1 EIM_DA2, EIM_DA3, EIM_DA4, EIM_DA5, EIM_DA6, EIM_DA7, EIM_DA8, EIM_DA9, EIM_DA10, EIM_DA11, EIM_DA12, EIM_DA13, EIM_DA14, EIM_DA15, NANDF_WE_B, NANDF_RE_B, EIM_WAIT, EIM_BCLK 0 PAD support high voltage (3.0V-3.6V). Out of reset value is 0. The HVEOVERWRITE field should be updated before automatic voltage detector is disabled. 1 PAD support low voltage (1.65V-3.1V)
17 VDOEN	VDOEN (ipp_oen) Select one out of next values for pad: NVCC_EIM__7. 0 Voltage detector output disable and HVEOVERWRITE field will be used. It is recommended to disable the automatic voltage detector after boot and update the HVEOVERWRITE field with the actual I/O supply value. 1 Voltage detector output enable. (default 1)
16–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

IOMUXC_SW_PAD_CTL_PAD_NVCC_FEC field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18 HVEOVERWRITE	HVEOVERWRITE (ipp_owr) Select one out of next values for pad: NVCC_FEC. This field affects the voltage levels for the following PADS: FEC_MDC, FEC_TXD0, FEC_TXD1, FEC_TX_EN, FEC_RXD0, FEC_RXD1, FEC_CRS_DV, FEC_RX_ER, FEC_REF_CLK, FEC_MDIO 0 PAD support high voltage (3.0V-3.6V). Out of reset value is 0. The HVEOVERWRITE field should be updated before automatic voltage detector is disabled. 1 PAD support low voltage (1.65V-3.1V)
17 VDOEN	VDOEN (ipp_oen) Select one out of next values for pad: NVCC_FEC. 0 Voltage detector output disable and HVEOVERWRITE field will be used. It is recommended to disable the automatic voltage detector after boot and update the HVEOVERWRITE field with the actual I/O supply value. 1 Voltage detector output enable. (default 1)
16–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

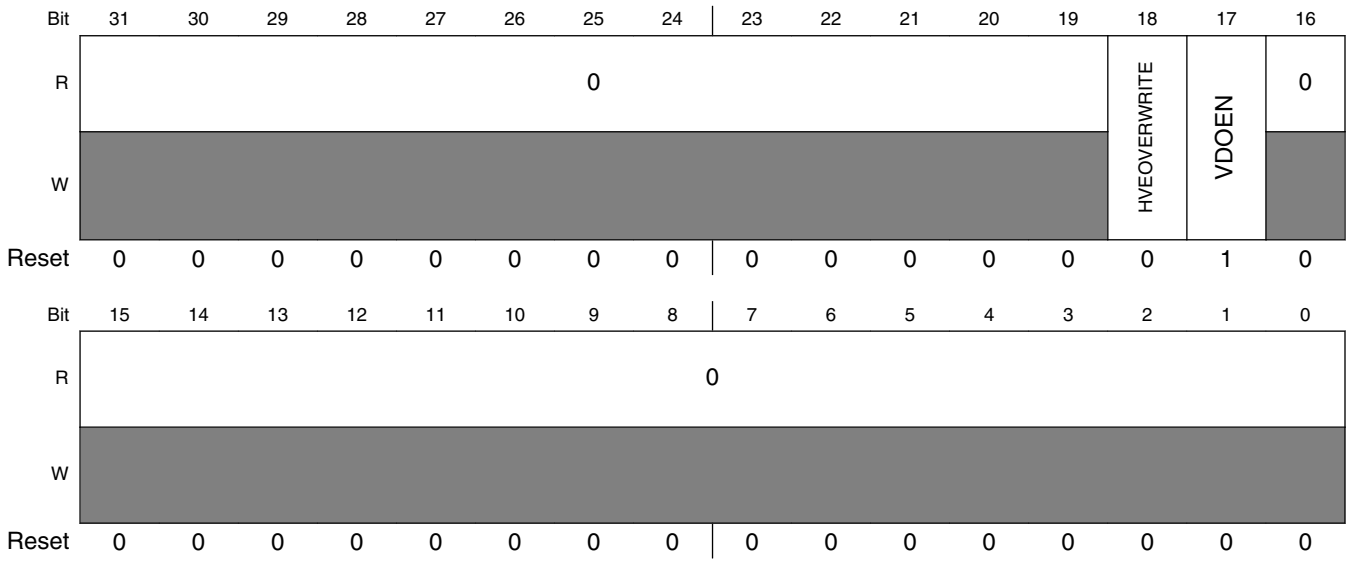
Address: IOMUXC_SW_PAD_CTL_PAD_NVCC_PATA__2 is 53FA_8000h base + 624h offset = 53FA_8624h



IOMUXC_SW_PAD_CTL_PAD_NVCC_PATA__2 field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18 HVEOVERWRITE	HVEOVERWRITE (ipp_owr) Select one out of next values for pad: NVCC_PATA__2. This field affects the voltage levels for the following PADS: PATA_CS_1, PATA_CS_0, PATA_DA_2, PATA_DA_1, PATA_DA_0, PATA_IORDY, PATA_RESET_B, PATA_DIOR, PATA_INTRQ, PATA_BUFFER_EN, PATA_DMARQ, PATA_DMACK, PATA_DIOW 0 PAD support high voltage (3.0V-3.6V). Out of reset value is 0. The HVEOVERWRITE field should be updated before automatic voltage detector is disabled. 1 PAD support low voltage (1.65V-3.1V)
17 VDOEN	VDOEN (ipp_oen) Select one out of next values for pad: NVCC_PATA__2. 0 Voltage detector output disable and HVEOVERWRITE field will be used. It is recommended to disable the automatic voltage detector after boot and update the HVEOVERWRITE field with the actual I/O supply value. 1 Voltage detector output enable. (default 1)
16–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

43.3.395 IOMUXC_SW_PAD_CTL_PAD_PATA_DATA0 (IOMUXC_SW_PAD_CTL_PAD_PATA_DATA0)

IOMUXC_SW_PAD_CTL_PAD_NVCC_SD2 field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18 HVEOVERWRITE	HVEOVERWRITE (ipp_owr) Select one out of next values for pad: NVCC_SD2. This field affects the voltage levels for the following PADS: SD2_DATA0,SD2_DATA1, SD2_DATA2, SD2_DATA3, SD2_CMD, SD2_CLK 0 PAD support high voltage (3.0V-3.6V). Out of reset value is 0. The HVEOVERWRITE field should be updated before automatic voltage detector is disabled. 1 PAD support low voltage (1.65V-3.1V)
17 VDOEN	VDOEN (ipp_oen) Select one out of next values for pad: NVCC_SD2. 0 Voltage detector output disable and HVEOVERWRITE field will be used. It is recommended to disable the automatic voltage detector after boot and update the HVEOVERWRITE field with the actual I/O supply value. 1 Voltage detector output enable. (default 1)
16–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

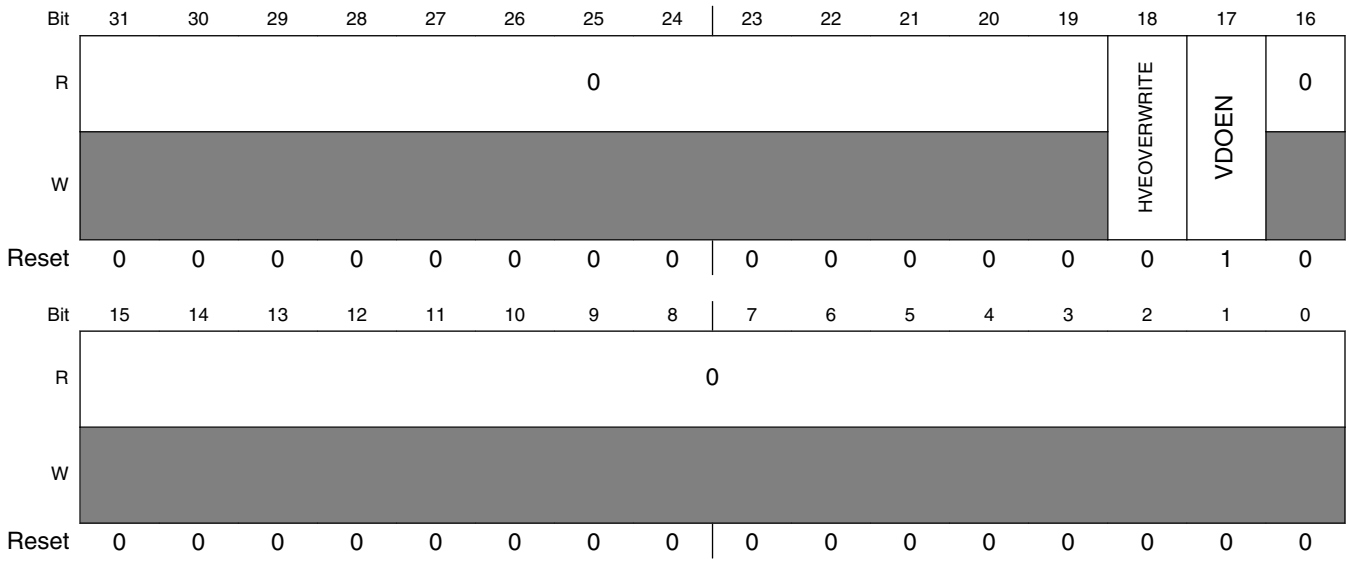
43.3.439 IOMUXC_SW_PAD_CTL_PAD_NVCC_GPIO (IOMUXC_SW_PAD_CTL_PAD_NVCC_GPIO)

Address: IOMUXC_SW_PAD_CTL_PAD_NVCC_GPIO is 53FA_8000h base + 6D8h offset = 53FA_86D8h



IOMUXC_SW_PAD_CTL_PAD_NVCC_GPIO field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18 HVEOVERWRITE	HVEOVERWRITE (ipp_owr) Select one out of next values for pad: NVCC_GPIO. This field affects the voltage levels for the following PADS: GPIO_18, GPIO_17, GPIO_16, GPIO_8, GPIO_7, GPIO_5, GPIO_4, GPIO_2, GPIO_6, GPIO_3, GPIO_9, GPIO_1, GPIO_0 0 PAD support high voltage (3.0V-3.6V). Out of reset value is 0. The HVEOVERWRITE field should be updated before automatic voltage detector is disabled. 1 PAD support low voltage (1.65V-3.1V)
17 VDOEN	VDOEN (ipp_oen) Select one out of next values for pad: NVCC_GPIO. 0 Voltage detector output disable and HVEOVERWRITE field will be used. It is recommended to disable the automatic voltage detector after boot and update the HVEOVERWRITE field with the actual I/O supply value. 1 Voltage detector output enable. (default 1)
16–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

43.3.440 IOMUXC_SW_PAD_CTL_PAD_POR_B (IOMUXC_SW_PAD_CTL_PAD_POR_B)

43.4 Functional Description

The IOMUXC Detailed Block Diagram is illustrated in Figure 43-552.

The IOMUXC is consist of 2 sub blocks:

- IOMUXC_REGISTERS: includes all the IOMUXC registers (6 main types are illustrated).
- IOMUXC_LOGIC: includes all the IOMUXC combinatorial logic (IP interface controls, address decoder, observability muxes).

The IOMUXC external signals and the IOMUXC sub-blocks connections internal signals are also detailed in this diagram. The following are the naming conventions used along with some explanation:

- <PAD> - any pad logic name.
- <GRP> - any pad group logic name.
- <FUNC> - one of the following pad control functions:
  - SRE (1 bit slew rate control).
  - DSE (2 bits drive strength control).
  - ODE (1 bit open drain control).
  - HYS (1 bit hysteresis control).
  - PULL_KEEP_CTL (4 bits pull up/down and keeper controls)
  - PUS (2 bits pull up/down configuration value)
  - PUE (1 bit pull/keep select)
  - PKE (1 bit enable/disable pull up, pull down or keeper capability)
  - DDR_MODE_SEL (1 bit ddr_mode control)
  - DDR_INPUT (1 bit ddr_input control)
- ips_addr[X:2] - since the IOMUXC registers are all 32 bits width address lines 0,1 are not used. X will be calculated automatically by the tool according to the final register number: X is smallest integer value which satisfy the constraint: 2^(X-1) >= (Total number of IOMUXC registers).

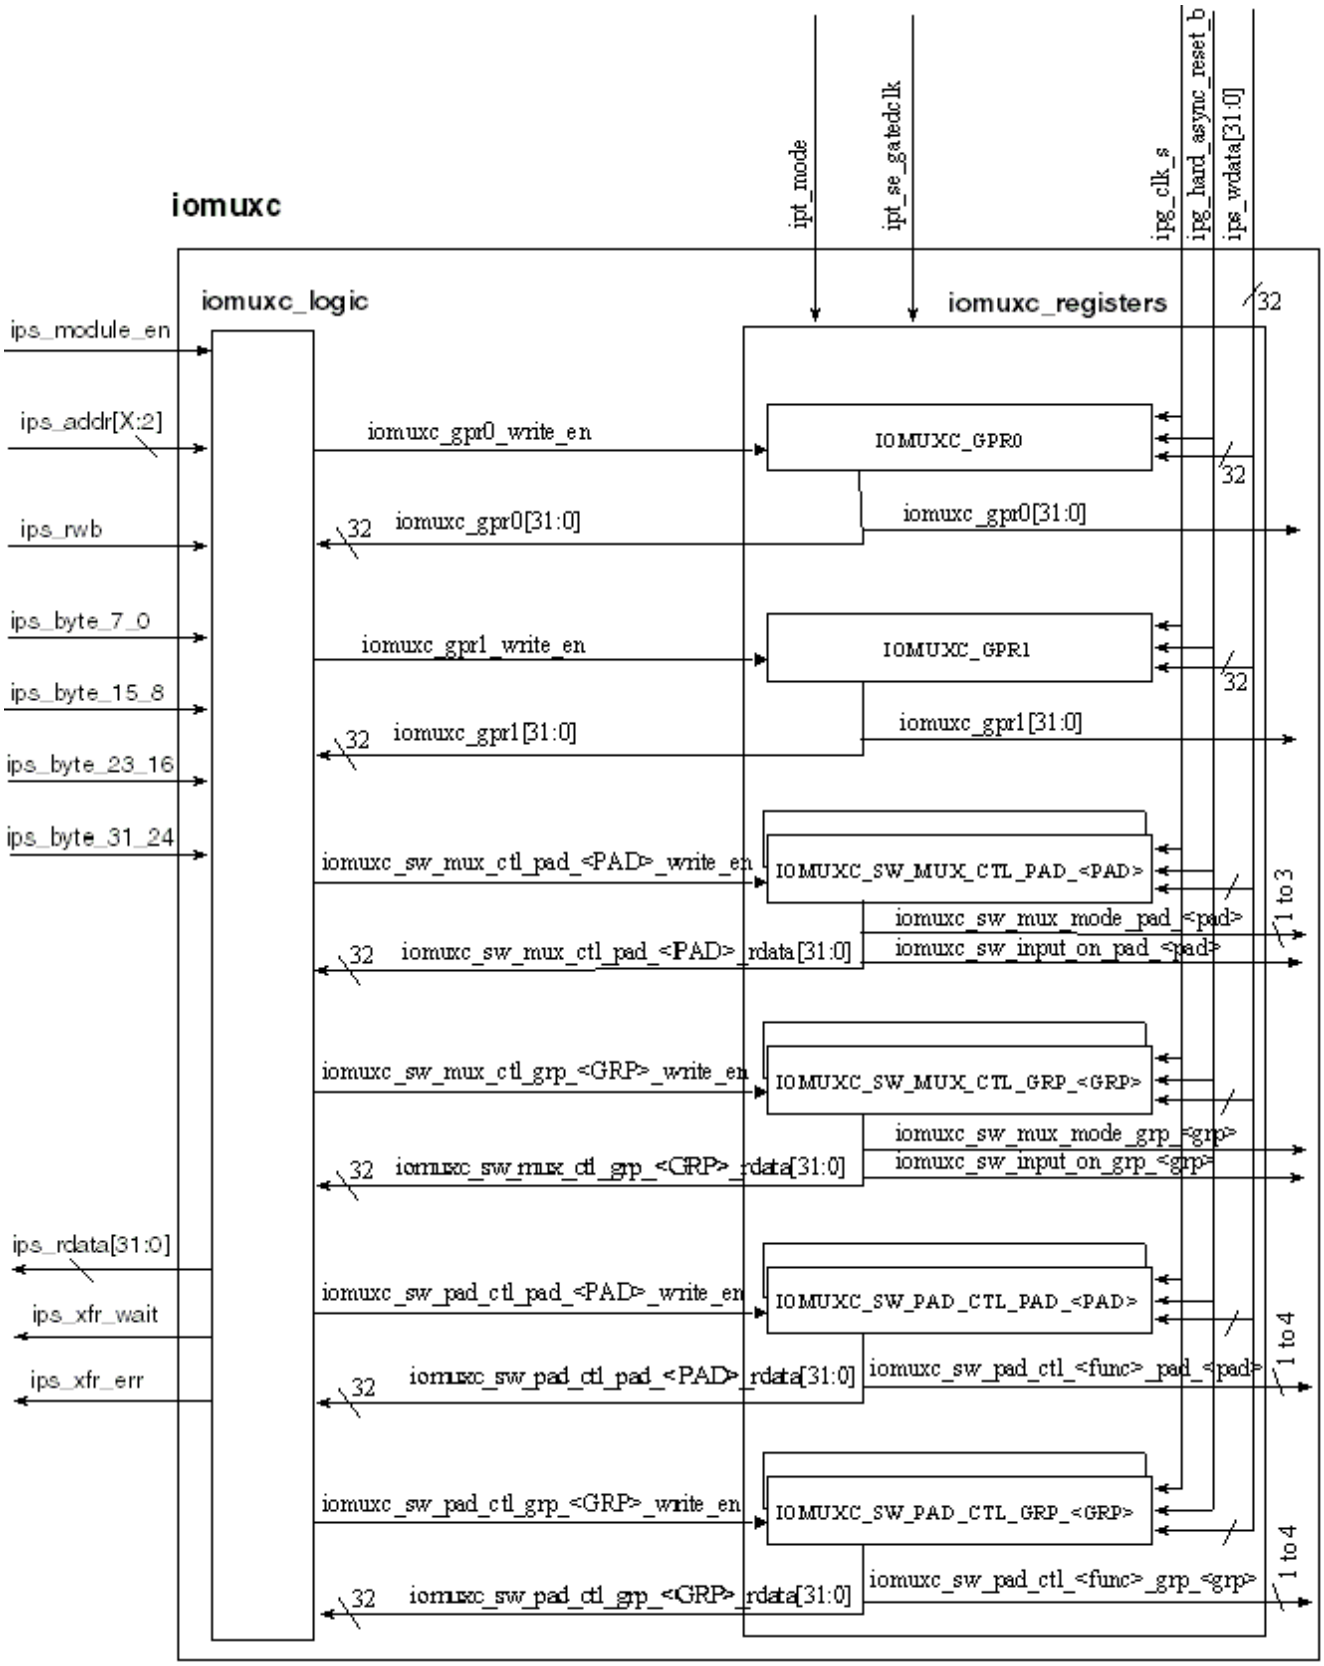

Figure 43-552. IOMUXC Block Diagram

The IOMUXC consists of a certain number of basic iomux_cell units, roughly equal to the number of pads in the SoC. If only one functional mode is required for a specific pad, then there is no need for IO Multiplexing and the signals can be connected directly from the block to the IO ring. An IOMUXC cell is required whenever 2 or more functional modes are needed for a specific pad, or when one functional mode and one test mode are required.

The basic iomux_cell design, which allows 2 levels of HW signal control (in ALT6 and ALT7 modes - ALT7 gets highest priority), is shown in Figure 43-553.

43.4.1 ALT6 and ALT7 Extended Muxing Modes

The ALT7 and ALT6 Extended Muxing Modes allow any signal in the system (Fuse, Pad input, JTAG, SW register, etc) to override any SW configuration and to force the ALT6/ ALT7 Muxing Mode.They also allow an IOMUXC SW register to control a group of pads.

43.4.2 SW Loopback through SION Bit

One option exists to override the regular pad functionality and force the input path to be active (ipp_ibe==1'b1), regardless of the value driven by the corresponding block. This can be done by setting the SION (SW Input On) bit in the IOMUXC_SW_MUX_CTL register (when available) to "1". It can be used for:

- LoopBack - Block X drives the pad and also receive pad value as an input.
- GPIO Capture - Block X drives the pad and the value is captured by GPIO.

NOTE

Software loopback is not affecting EMI pads.

43.4.3 Daisy Chain - Multi Pads Driving same Block Input Pin

In some cases, more than one pad may drive a single block input pin.

Such cases require adding one more level of I/O Multiplexing: all these input signals are muxed and a dedicated SW controlled register controls the mux in order to select the required input path. This means that a pad involved in such "Daisy Chain" situation may require 2 SW configuration commands: one for selecting the mode for this pad and one for defining it as the input path.

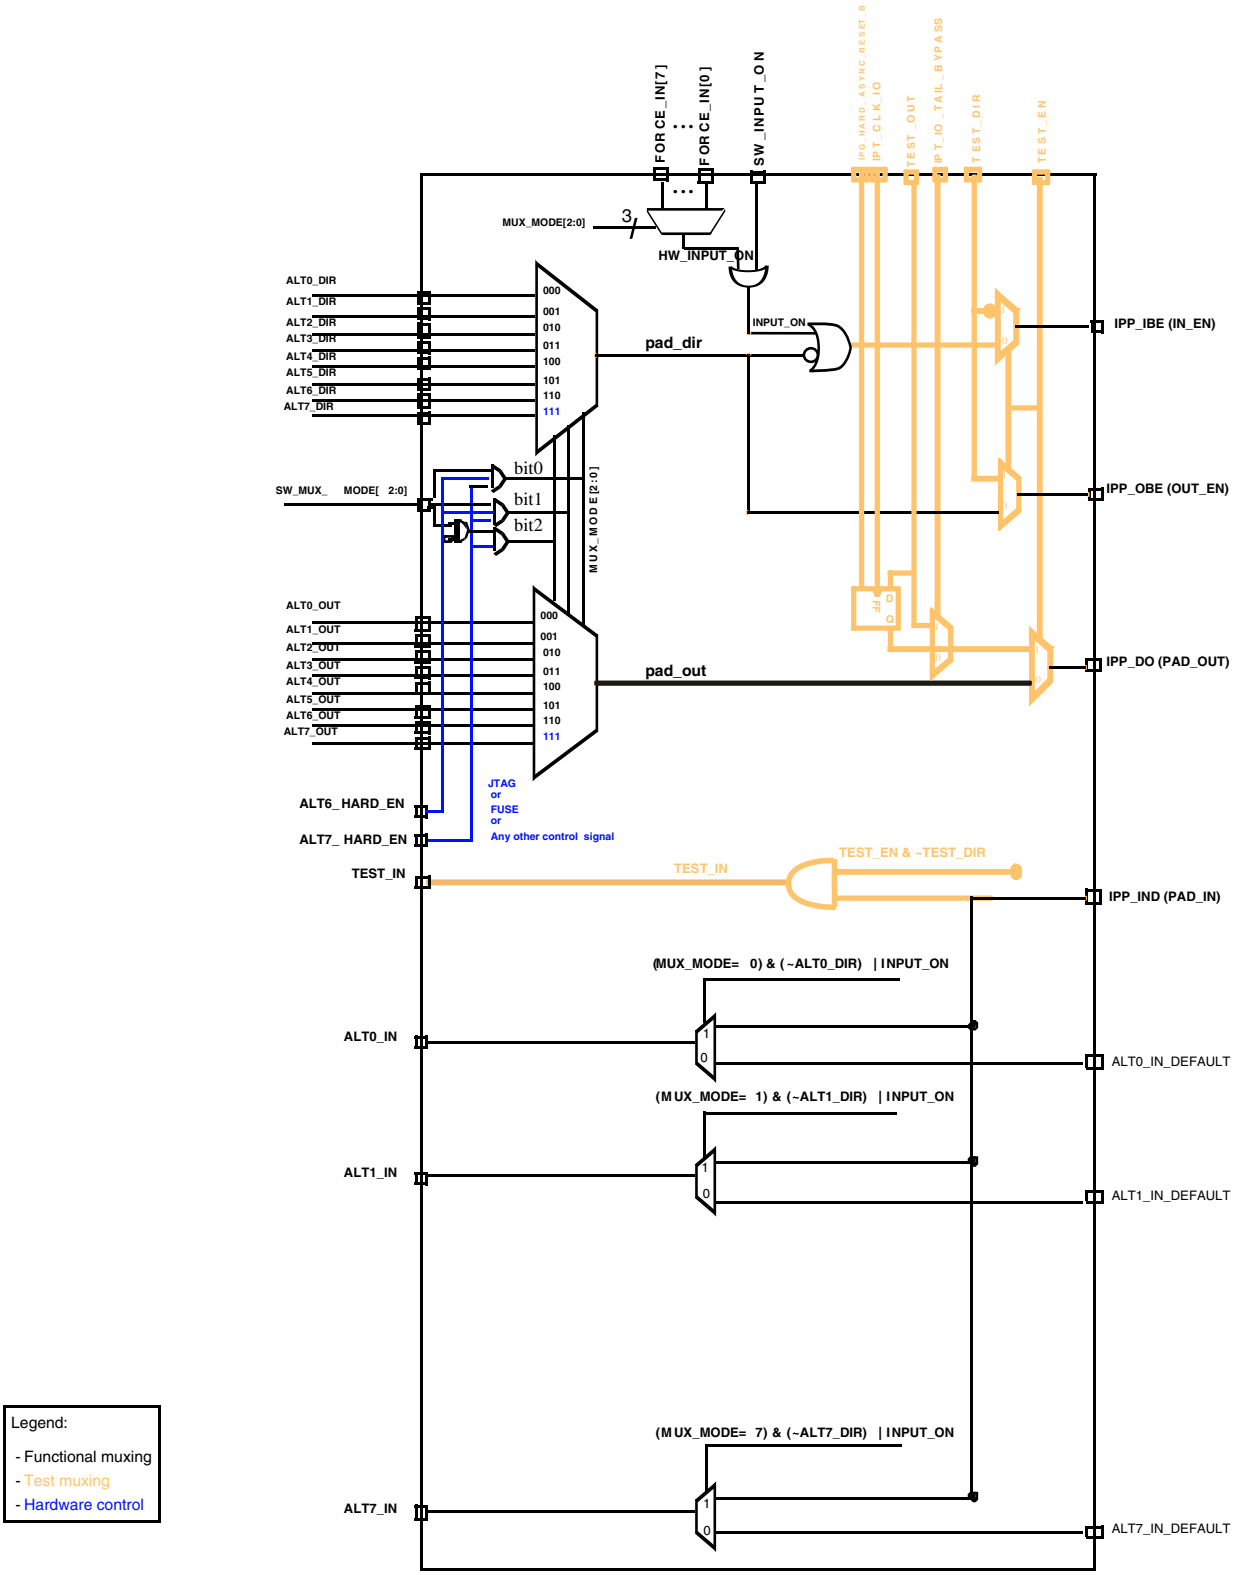

Figure 43-553. IOMUXC Cell Block Diagram

43.4.4 Interrupts

There are no interrupts that are generated by the IOMUX Controller (IOMUXC).

Chapter 44
IEEE 1588 Precision Time Protocol Assist (IPTP)

44.1 Introduction

The objective of the IEEE1588 standard is to specify a protocol to synchronize independent clocks running on separate nodes of a distributed measurement and control system to a high degree of accuracy and precision. The clocks communicate with each other over a communication network. The protocol generates a master-slave relationship among the clocks in the system. Within a given subnet of a network, there will be a single master clock. All clocks ultimately derive their time from a clock known as the grandmaster clock.

The protocol will enable synchronization between heterogeneous systems that include clocks of various inherent precision, resolution, and stability. The protocol will support system wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

Measurement and control applications use distributed system technologies such as network communication, local computing, and distributed objects . Many of these applications will be enhanced by having an accurate system wide sense of time achieved by having local clocks in each sensor, actuator, or other system devices. Existing protocols for clock synchronization are not optimal for these applications. For example, Network Time Protocol (NTP) targets large distributed computing systems with millisecond synchronization requirements.

Although IPTP (IEEE1588 Precision Time Protocol Assist) allows software-only implementations, hardware-assisted implementations deliver more precise clock synchronization.

The simplest IPTP implementations include ordinary applications at the top of the network protocol stack and generate time stamps at the application level. Typically, this implementation incurs the largest protocol stack delay fluctuation, thus yielding the least accuracy as the largest amount of error is introduced into the time stamp.

Hardware-assisted methods achieve the greatest accuracy due to the fact that they generate time stamps at the physical layer (as close to the wire as possible). Network-protocol-delay fluctuations, for these implementations, typically range from sub-microseconds to nanoseconds.

In this sub-block, the IPTP implementation is a hardware-assisted method. The hardware assist includes a time stamp unit to recognize PTP frames and transfer relevant time stamps, and a real-time clock with high resolution that is accurate to the sub-nanosecond.

44.2 IPTP Block Diagram

Figure 44-1 shows the Time Stamp Unit (TSU) and the IPTP Real Time Clock (RTC) sub-blocks integrated with the ARM platform.

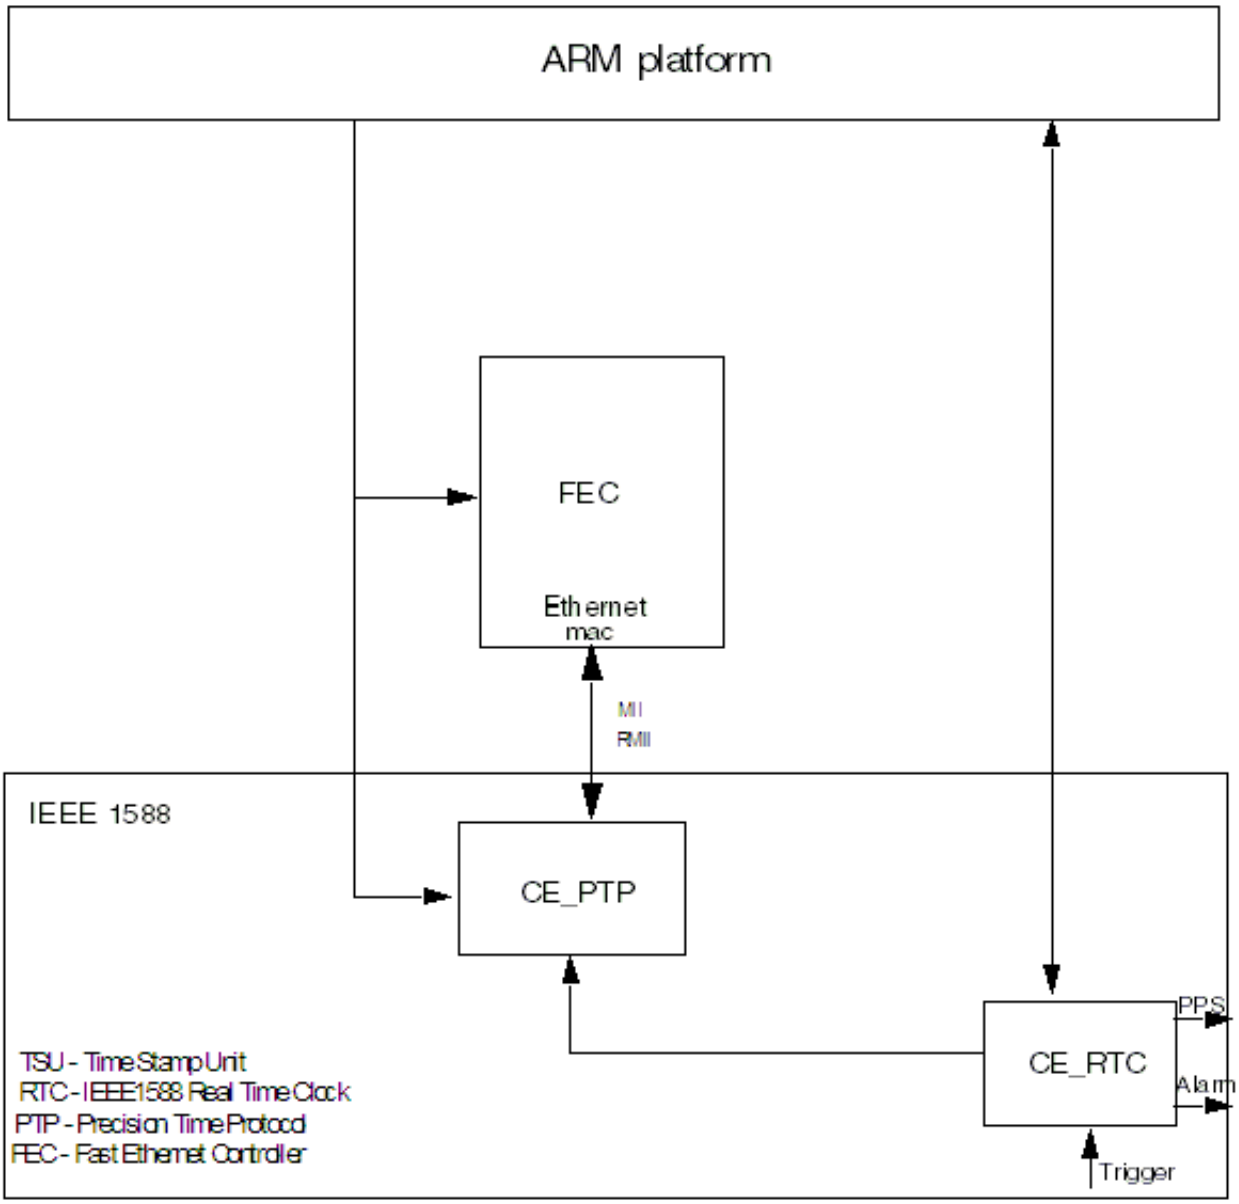

Figure 44-1. IPTP block diagram

44.3 Time Stamp Unit (TSU) Key Features

- Support IPTP V2
- Supports Ethernet systems
- Support IPTP time stamping
- Recognition of PTP frames on receive side
  - Sync type
  - Delay_Req type
  - Delay_Resp type
  - Follow_Up type

    - Management type
    - Pdelay_Req
    - Pdealy_Resp
    - Announce
    - Pdelay_Resp_Follow_Up
    - Signaling
- Support PTP frame with VLAN tag (single VLAN)
- Support the detection of a new Ethernet type (IPTP V2)
- Supports MII/RMII Physical I/F
- Support Ethernet frame monitoring on full and half duplex modes
- Supports slave and master mode
- Support single- or multi- IPTP masters
- Support out-of-band mode of operation
    - Out-of-band (time stamp is read through host I/F)
- Time stamp captured close to the physical line
- Support the ability to timestamp Tx and Rx packets based on signals that are generated by the PHY upon detection of Start-Of-Frame appearing on the line
- Supports configured values for the PTP header fields
- Supports configured values for fields offset
- Supports interrupt notification due to following:
    - Rx PTP frame detection (for all the event messages)
    - Tx PTP frame transmission which was marked by the software as a PTP frame
    - Rx and Tx time stamp overrun error

44.4 IPTP Real Time Clock (RTC) Key Features

- Support single IPTP RTC.
- Support timer frequency compensation.
- Support timer offset update.
- Support configured source of clock.
- Time stamp capture on two general purpose external triggers through new GPIO connection.
    - Maskable interrupts on GPIO time stamp trigger
    - Programmable polarity for both output trigger signals
- Two 64-bit alarm (future time) registers that hold the value of the future time.
    - Maskable interrupts on alarm
    - Programmable polarity for both alarm (future time) output signals
- One 64-bit fixed period interval (FIPER) start register. Used to define the starting time of PPS signals generation
- Three programmable timer output pulse period phase aligned with IPTP timer clock

  - Pulse Per Second (PPS) signals are aligned to frequency and phase
  - Maskable interrupts associated with each pulse
- Separate maskable timer interrupt event register
- Phase aligned adjustable (divide by N) clock output

44.5 IPTP Implementation Assumptions

The IPTP V2 standard makes several assumptions about the environment in which it operates. The following assumptions must be met to ensure correct operation of this implementation:

- The network must support multicast and unicast communication
- It must be possible to prevent multicast messages from propagating beyond a subnet
- Each clock implementing the protocol must meet the physical performance requirements, including oscillator frequency and time adjustment range.
- A clock's stated properties, including its stratum and identifier, must accurately describe the clock.

The following assumptions must be met to achieve optimal clock synchronization performance:

- A clock may contain asymmetric delays in its time stamp mechanism or protocol path. If these asymmetries are not negligible, they must be correctly accounted for.
- Network delay between master and slave on a subnet must be constant
- Boundary clocks must be used to synchronize across subnets
- The time stamps used in PTP are generated as close to the physical layer as practical for a given clock implementation. In cases where the most accurate time stamps can be generated only after a message has actually been transmitted, the actual value is communicated in the Follow_Up message from the master clock.
- The computing power of clocks implementing the protocol must be great enough, and the number of clocks per subnet must be small enough, to meet the standard constraints.
- The inherent stability of a clock's oscillator must be adequate. (The oscillator serving as the time base for a PTP clock has an accuracy and stability such that a second measured in the time base of the PTP clock is within +/- 0.01% of the SI second over the rated temperature range of the PTP clock.)

44.6 Modes of Operation

- Out-of-band - This mode is determined in the TSMR register. All the time stamps are transferred through the host interface, using dedicated registers. T

transmitter's time stamps after last indication in the buffer descriptor, and the receiver's time stamps when a PTP bit is set in the RxBD. The software is responsible for setting the PTP bit in the TxBD. In both receiver and transmitter the hardware can set an interrupt before accessing the time stamps.

- PTP frame parsing options - All of the relevant parsing values and fields can be configured using TSPDR register, retaining high flexibility.
- Pulse per second - The FIPER registers (IPTP_TMR_FIPER) can be configured by software in order to generate the pulse per second outputs.
- Alarm mode - The IPTP_TMR_ALARM register can be configured by software as an alarm (future time) value. When the IPTP RTC reaches this value, an interrupt is generated to the core, and a dedicated output trigger signal will be asserted.
- Input trigger - The IPTP_TMR_ETTS register configures a synchronous trigger to the IPTP RTC in order to capture a time stamp.
- Source clock select - This mode is configured in the Timer Control Register (IPTP_TMR_CTRL). There are two options for the source clock that can be connected to the IPTP RTC.
- Time Stamp Point - The IPTP_PTP_TSMR register can be configured to sample the IPTP RTC according to SFD detection or according to an external time stamp lock trigger.

44.7 Time Stamp Unit (TSU)

The TSU logic implementation supports out-of-band mode of operation. As mentioned in the preceding sections, the hardware assumption is that the IPTP is running on an Ethernet system.

In out-of-band method, the reporting is done using dedicated registers per interface. The software will read the transmitter's time stamps after the "last" indication of the TxBD, and the receiver's time stamps when a PTP bit is set in the RxBD. If there is sufficient time to guarantee that the software will be able to read the time stamp register between PTP frames, then the out-of-band method is sufficient.

The TSU logic supports MII/RMII Physical I/F.

In order to snapshot a precise time stamp, the hardware either observes the ports on the interfaces between the Media Access Controller (MAC) devices and the physical layer devices (PHY) to detect an SFD, or receives an external lock trigger and captures the timestamp on the transmit and receive sides.

Figure 44-2 shows the time stamp point of a PTP frame with SFD detection.

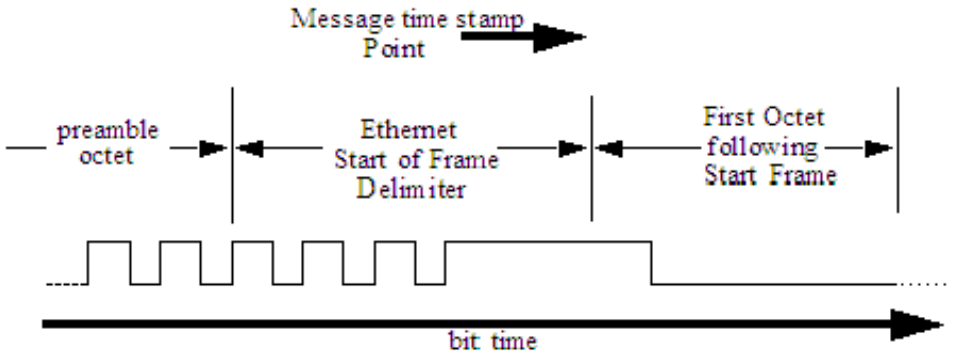

Figure 44-2. Message time stamp point with SFD detection

In addition, the TSU detects a Precise Time Protocol (PTP) frame of a specific type and generates an indication to the ARM platform and to the MAC.

In the IEEE1588 V2 specification, there are 10 types of PTP frames:

- Sync message
- Follow_Up message
- Delay_Req message
- Delay_Resp message
- Management message
- Pdelay_Req message
- Pdelay_Resp message
- Announce message
- Pdelay_Resp_Follow_Up message
- Signaling message

Those 10 messages are divided into two groups:

- PTP event
- PTP general

The PTP event group consists of Sync, Delay_Req, Pdelay_Req, and Pdealy_Resp messages. These messages should be time stamped and can cause an interrupt generation. The PTP general group consists of the rest of the frames; these frames transfer time stamps and determine general system parameters.

In order to detect a PTP frame see Table 44-32 and Table 44-34 for the parsing fields and values.

44.7.1 PTP Event Interrupts

In the case of out-of-band mode, the software can use the TSU interrupts as a trigger to read the time stamps registers. The software should clear the event register and read the time stamp before the next PTP frame detection. If a new PTP frame arrives and the relevant bit in the event register is still set, an overrun indication will be asserted.

44.8 IPTP Real Time Clock (RTC)

In a distributed control system containing multiple clocks, individual clocks tend to drift apart due to instabilities inherent in source oscillators and environmental conditions such as temperature, air circulation, mechanical stresses, vibration, aging, etc. Hence, some kind of correction is necessary to synchronize individual clocks to maintain the notion of global time, which is accurate to some requisite clock resolution.

In order to achieve this goal, the IPTP RTC supports the following:

- The nominal increment is chosen according to the nominal oscillator frequency
- The drift is compensated by slightly increasing or decreasing the increment

Figure 44-3 illustrates the block diagram of the IPTP RTC.

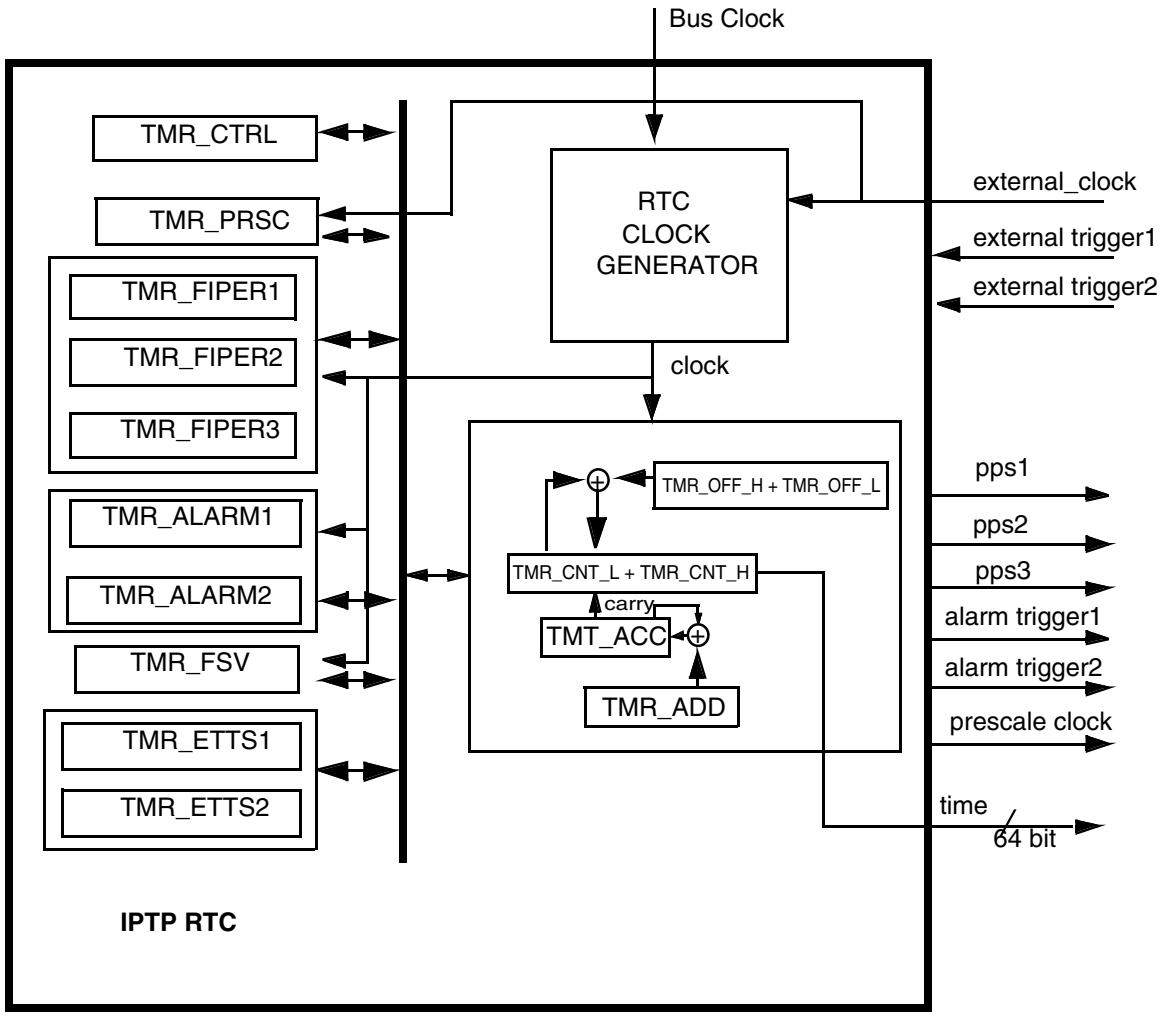

Figure 44-3. IPTP RTC block diagram

All of the constituents of the frequency compensated clock operate at the frequency of the external clock source. The frequency compensation value contained in the addend register is added to the accumulator once every external clock. The clock counter is incremented whenever the accumulator asserts an overflow pulse signal. Therefore, the nominal frequency at which the clock counter is incremented is the frequency that the software determined by updating the addend with a frequency compensation value.

The update of the frequency compensation value can be done every cycle of clock synchronization by Sync and delay messages.

Table 44-1 shows examples of possible IPTP RTC parameters. The results have been calculated according to the this equation:

frequency_compensation_value = 2^32/frequency_ratio.

Table 44-1. Values Example

Frequency of the Clock	Frequency of the Counter	Frequency Ratio	Frequency Compensation Value
200MHz	150MHz	1.33	0xc07b301
200MHz	190MHz	1.05	0xf3cf3cf
200MHz	70MHz	2.86	0x5982af7

In addition to the frequency compensation, the RTC enables updating the offset of the timer counter. The offset value is derived from the time stamps transferred on PTP frames.

The software uses the offset register in order to add the correction value. The timer counter adds the value of the offset register if a write transaction to the relevant address is detected. The values in the offset register and in the addend register are represented in 2's complement.

The standard demands sub-microseconds resolution. The IPTP RTC contains a 64-bit timer register and a 32-bit addend register. If the clock reaches 200MHz, by configuring the addend to 0xFFFF_FFFF, the counter will tick every 5ns.

IPTP RTC supports the following features:

- Two alarm output triggers, asserted if the timer value reaches the alarm (future time) register value
- Three pulse per second output signals, generated by configuring the FIPER registers. The signals are aligned in phase and frequency to the timer, and edge aligned to the IPTP timer reference output clock (prescale clock). The PPSs signal width is according to the period of the selected timer clock or according to the width of the IPTP timer reference output clock
- Two input triggers in order to capture time stamps in a dedicated register
- IPTP timer reference output clock which is a divided output clock, by configuring the prescale register
- Input of a time stamp lock trigger to sample the IPTP RTC according to an external trigger

44.8.1 RTC Clock Sources

The IPTP RTC enables three sources of input clock: an external oscillator, DPLL-3, DPLL-4, or the FEC_PHY clock.

All the clocks should meet the performances and requirements of the s

44.8.2 Prescale Output Clock and Pulse per Second Edge Alignment

In order to generate pulse per second signals that are edge aligned to the output prescale clock, as shown in Figure 44-4, the software configuration should be according to the following:

1. The ratio between the prescale clock divider value and the FIPER value should be devisable by the clock period, see Timer Fixed Interval Period 1 Regtister (IPTP_TMR_FIPER1).
2. Configure the TMR_FSV register to a value which is less by 3 clock periods than the required FIPER enabling time.
3. Note that each time when writing a new value to TMR_FSV, also write to the FIPERx register with the required PPS interval value.

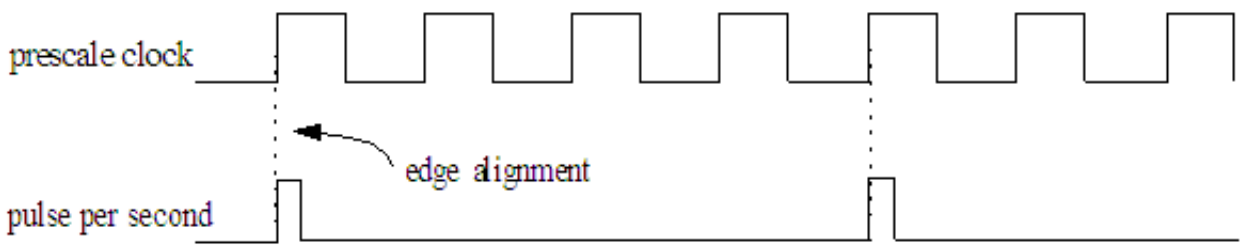

Figure 44-4. PPS and Prescale Clock Edge Alignment

44.9 PTP Frame Reception

The following describes the main actions performed for each operation mode when a PTP frame is received.

44.9.1 Out-of-Band Mode

In order to work in out-of-band mode the FEC should be configured as follows:

- FEC in Ethernet Mode
- Set IPTP mode in UPSMR[PTPE]

The Rx TSU is monitoring the received Ethernet frame on the physical line. When SFD is detected or external time stamp lock trigger is received, the IPTP Rx TSU locks the real time value of the IPTP clock.

If the Rx TSU parse unit has detected a PTP frame, it will notify the Ethernet MAC that a PTP frame has been detected, and the Ethernet controller will set RxBD[RPTP]. In addition, the Rx TSU will set the corresponding bit in the event register and generate an interrupt to the ARM platform.

When the software detects that a PTP frame has arrived, either by getting an interrupt or by polling the RxBD[RPTP], it will read the dedicated time stamp register (IPTP_TMR_UCx_RXTS_H/L) through the host interface.

In case the PTP frame is marked with CRC, Overrun, or Non-octet receive errors, the interrupt in the TMR_PEVENT will not be set and the software should drop this frame regardless of the indication in the RxBD[RPTP].

44.10 PTP Frame Transmission

The following describes the main actions performed for each operation mode when a PTP frame is transmitted.

44.11 Cycle Delay from Time Stamp Location

The following table describes the delay on the Ethernet line, in clock cycles, for each of the interfaces between the Media Access Controller (MAC) devices and the physical layer devices (PHY) in Tx and Rx.

Table 44-2 describes the delay on the Ethernet line.

Table 44-2. Delay on Ethernet Line

MII		RMII10		RMII100	
Tx	Rx	Tx	Rx	Tx	Rx
0	1	1	3-4	0.5	4

44.12 Initialization Sequence

44.12.1 RTC Mode Registers

1. Initialize the TMR_ALARMn registers to 0xFFFF_FFFF
2. Initialize the TMR_FSV register to 0xFFFF_FFFF
3. Program the IPTP timer clock period in IPTP_TMR_CTRL[tclk_period]
4. Select the timer clock source in the IPTP_TMR_CTRL[clksel]
5. Program the IPTP_TMR_TEMASK register
6. Write 0xFFFF_FFFF to IPTP_TMR_TEVENT to clear the RTC Event register
7. Program the TMR_ADD according to the needed drift compensation needed value

44.12.1.1 Enable Sequence

1. Enable the RTC by setting IPTP_TMR_CTRL[TE]
2. Enable the PTP by setting IPTP_PTP_TSMR[EN]
3. Enable the FEC.

44.13 Programmable Registers

All IPTP registers are 32-bits wide, located on 32-bit address boundaries, and should only be accessed as 32-bit quantities.

All addresses used in this chapter are offsets from RTC Base and PTP Base. (See "Memory Map" chapter.)

44.13.1 Timer Control Register (IPTP_TMR_CTRL)

The IPTP_TMR_CTRL defines control fields relevant to the IPTP timer. IPTP_TMR_CTRL is a writable register in order to reset, configure, and initialize the IPTP timer clock. Only one of these registers is active for the entire Engine.

Address: IPTP_TMR_CTRL is 63FD_4000h base + 0h offset = 63FD_4000h

44.13.2 Timer Events Register (IPTP_TMR_TEVENT)

The IPTP timer implementation requires several interrupt event signals. It needs to add a new interrupt output line for the timer, independent of the existing Tx, Rx and Error interrupts. The IPTP timer interrupt does not require any interrupt coalescing. Software may poll this register at any time to check for pending interrupts. If an event occurs and its corresponding enable bit is set in the event mask register (EMASK), the event also causes a hardware interrupt at the Programmable Interrupt Controller (PIC). A bit in the timer event register is cleared by writing a 1 to that bit position.

Address: IPTP_TMR_TEVENT is 63FD_4000h base + 4h offset = 63FD_4004h

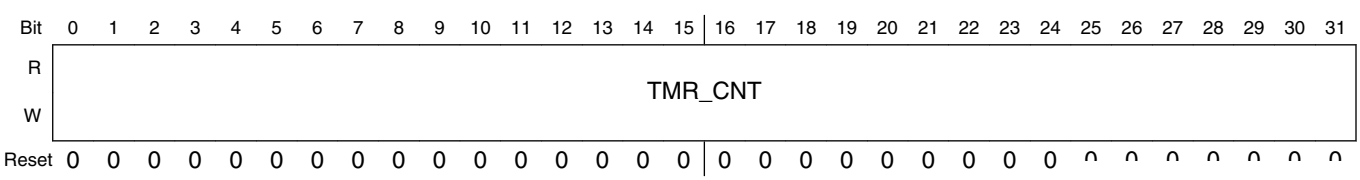
44.13.4 Timer Counter Low Register (IPTP_TMR_CNT_L)

The timer counter register (IPTP_TMR_CNT_L) represents accurate time in terms of clock ticks or in nano-seconds. This is a read/write register. Writing to these registers will override the previous time.

Address: IPTP_TMR_CNT_L is 63FD_4000h base + Ch offset = 63FD_400Ch



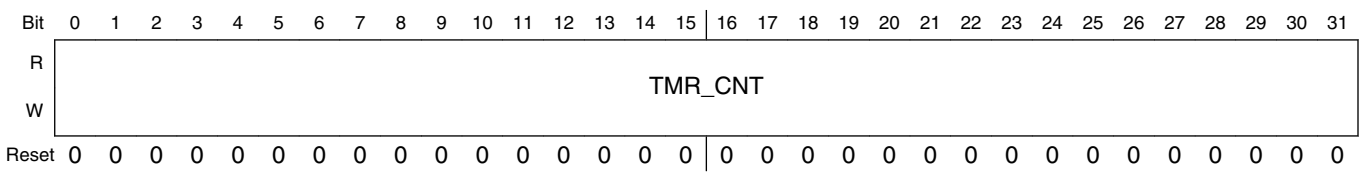
IPTP_TMR_CNT_L field descriptions

Field	Description
0–31 TMR_CNT	H/L value of the current time counter. Current time is calculated by adding TMROFF_H/L with the TMR_CNT_H/L counter. This register can be written through the register writes. Writes to the TMR_CNT_L register copies the written value into the shadow TMR_CNT_L register. Writes to the TMR_CNT_H register copies the values written into the shadow TMR_CNT_H register. Contents of the shadow registers are copied into the TMR_CNT_L and TMR_CNT_H registers following a write into the TMR_CNT_H register. Writes to these registers have precedence over the timer increment. The TMR_CNT_L register must be written first. Reads from the TMR_CNT_L register copies the entire 64-bit clock time of the read enable into the TMR_CNT_H/L shadow registers. Read instruction from the TMR_CNT_H register reads the value stored in the TMR_CNT_H shadow register. In order to get the correct 64-bit TMR_CNT_H/L counter values, the TMR_CNT_L register must be read first.

44.13.5 Timer Counter High Register (IPTP_TMR_CNT_H)

The timer counter register (PTP_TMR_CNT_H) represents accurate time in terms of clock ticks or in nano-seconds. This is a read/write register. Writing to these registers will override the previous time.

Address: IPTP_TMR_CNT_H is 63FD_4000h base + 10h offset = 63FD_4010h



IPTP_TMR_CNT_H field descriptions

Field	Description
0–31 TMR_CNT	H/L value of the current time counter. Current time is calculated by adding TMROFF_H/L with the TMR_CNT_H/L counter. This register can be written through the register writes. Writes to the TMR_CNT_L register copies the written value into the shadow TMR_CNT_L register. Writes to the TMR_CNT_H register copies the values written into the shadow TMR_CNT_H register. Contents of the shadow registers are copied into the TMR_CNT_L and TMR_CNT_H registers following a write into the TMR_CNT_H register. Writes to these registers have precedence over the timer increment. The TMR_CNT_L register must be written first. Reads from the TMR_CNT_L register copies the entire 64-bit clock time of the read enable into the TMR_CNT_H/L shadow registers. Read instruction from the TMR_CNT_H register reads the value stored in the TMR_CNT_H shadow register. In order to get the correct 64-bit TMR_CNT_H/L counter values, the TMR_CNT_L register must be read first.

44.13.6 Timer Addend Register (IPTP_TMR_ADD)

The Timer Drift Compensation Addend Register (IPTP_TMR_ADD) is used to hold the timer frequency compensation value (FreqCompensationValue). The nominal frequency of the clock counter is determined by the frequency division ratio (FreqDivRatio) and the clock frequency (FreqClock). This register is programmed with 232/FreqDivRatio. Frequency division ratio (FreqDivRatio) is the ratio between the frequency of the oscillator (TimerOsc) and the desired clock frequency (NominalFreq). FreqDivRatio is a design constant chosen to be greater than 1.0001. The ADDEND value is added to the 32-bit accumulator register at every rising edge of the oscillator clock (TimerOsc). The clock counter is incremented at every carry pulse of the accumulator.

Address: IPTP_TMR_ADD is 63FD_4000h base + 14h offset = 63FD_4014h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ADDEND																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

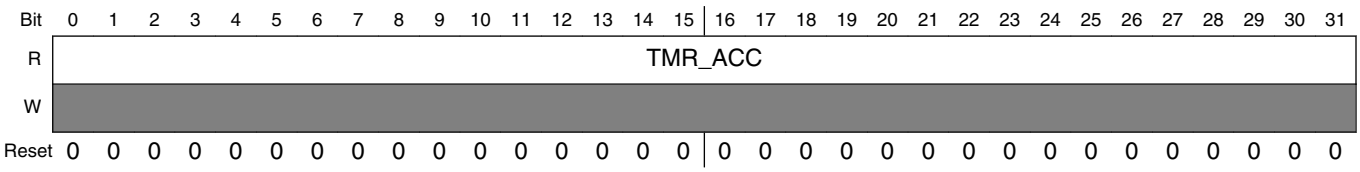
IPTP_TMR_ADD field descriptions

Field	Description
0–31 ADDEND	Timer drift compensation addend register value. It is programmed with a value of 2^32/FreqDivRatio. For example: FreqOsc = 50 MHz FreqClock = 40 MHz FreqDivRatio = 1.25 RTCAD = ceil(2^32/1.25) = 0xCCCC_CCCD default value is 32'h0

44.13.7 Timer Accumulator Register (IPTP_TMR_ACC)

The Timer Accumulator Register accumulates the value of the addend register into it. An overflow pulse of the accumulator is used to increment the timer clock (IPTP_TMR_CNT) by IPTP_TMR_CTRL[TCLK_PERIOD]. This register is read only. This register is writable only in debug mode (IPTP_TMR_CTRL[DBG]).

Address: IPTP_TMR_ACC is 63FD_4000h base + 18h offset = 63FD_4018h



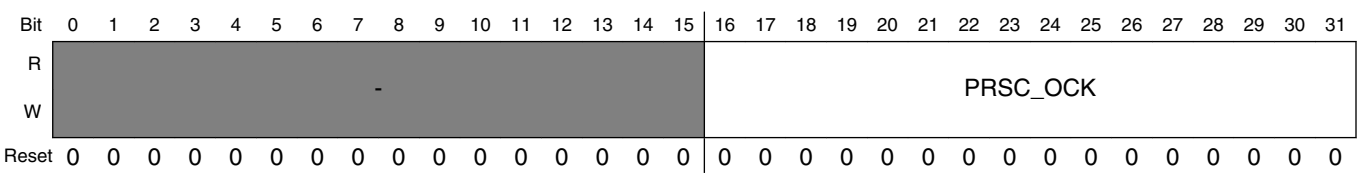
IPTP_TMR_ACC field descriptions

Field	Description
0–31 TMR_ACC	32bit timer accumulator value

44.13.8 Timer Prescale Register (IPTP_TMR_PRSC)

The Timer Prescale Register is used to adjust output clock frequency. 1588_ACC_PTP_Mask Register Timer Prescale Register shows the IPTP_TMR_PRSC register.

Address: IPTP_TMR_PRSC is 63FD_4000h base + 1Ch offset = 63FD_401Ch



IPTP_TMR_PRSC field descriptions

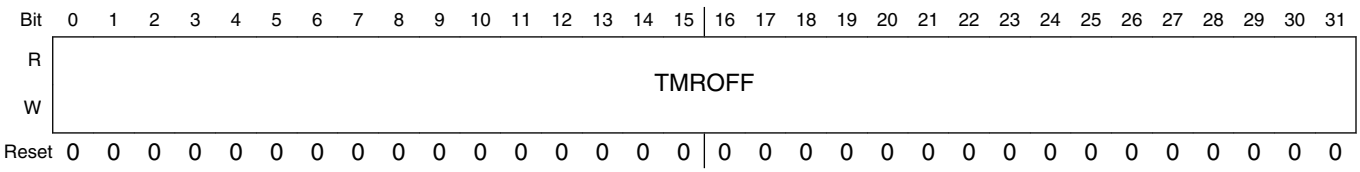
Field	Description
0–15 -	RESERVED
16–31 PRSC_OCK	Output clock division/prescale factor. Output clock is generated by dividing the timer clock by this number. Setting the prescaler value to 16'h1 will generate an output clock in the same frequency as the selected timer clock. default value is 16'h0

44.13.9 Timer Offset Low Register (IPTP_TMR_OFF_L)

The timer offset register is used to update the timer to the current time by adding its value to the clock counter

.

Address: IPTP_TMR_OFF_L is 63FD_4000h base + 20h offset = 63FD_4020h



IPTP_TMR_OFF_L field descriptions

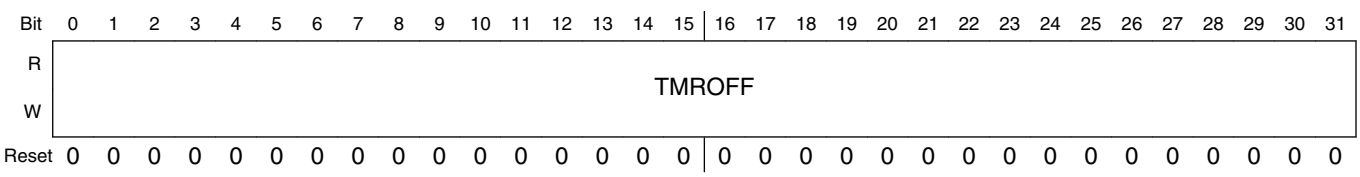
Field	Description
0–31 TMROFF	The TMROFF value, which is determined by the software calculations, updates the timer clock counter (TMR_CNT) with its value. The update is executed when the hardware detects write transaction to the offset high register. default value is 32'h0

44.13.10 Timer Offset High Register (IPTP_TMR_OFF_H)

The timer offset register is used to update the timer to the current time by adding its value to the clock counter

.

Address: IPTP_TMR_OFF_H is 63FD_4000h base + 24h offset = 63FD_4024h



IPTP_TMR_OFF_H field descriptions

Field	Description
0–31 TMROFF	The TMROFF value, which is determined by the software calculations, updates the timer clock counter (TMR_CNT) with its value. The update is executed when the hardware detects write transaction to the offset high register. default value is 32'h0

44.13.11 Alarm 1 Time Low Register (IPTP_TMR_ALARM1_L)

The Alarm (future time) Comparator Register (IPTP_TMR_ALARM1_L) holds alarm time for comparison with the current timer clock counter (IPTP_TMR_CNT)

Address: IPTP_TMR_ALARM1_L is 63FD_4000h base + 28h offset = 63FD_4028h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

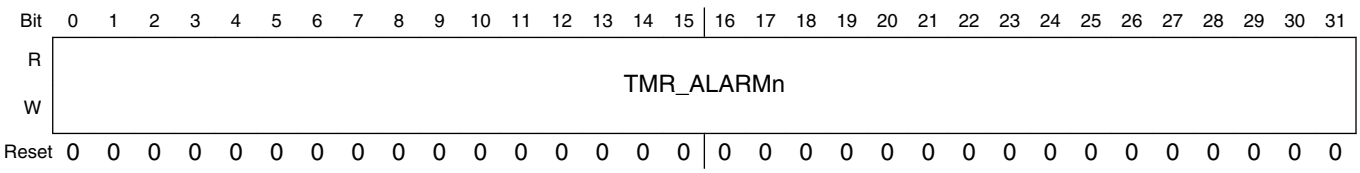
IPTP_TMR_ALARM1_H field descriptions

Field	Description
0–31 TMR_ALARMn	The IPTP RTC interrupt is generated when the value of the RTC counter (TMR_CNT_L/TMR_CNT_H) is greater than or equal to TMR_ALARMn[TMR_ALARM]. This value should be configured before enabling the timer. default value is 32'h0

44.13.13 Alarm 2 Time Low Register (IPTP_TMR_ALARM2_L)

The Alarm (future time) Comparator Register (IPTP_TMR_ALARM_H/ IPTP_TMR_ALARM_L) holds alarm time for comparison with the current timer clock counter (IPTP_TMR_CNT)

Address: IPTP_TMR_ALARM2_L is 63FD_4000h base + 30h offset = 63FD_4030h



IPTP_TMR_ALARM2_L field descriptions

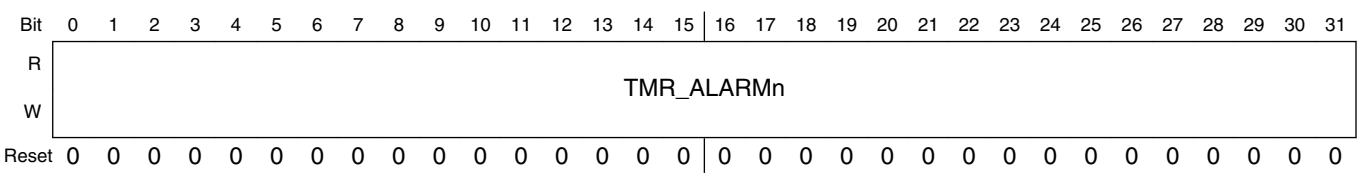
Field	Description
0–31 TMR_ALARMn	The IPTP RTC interrupt is generated when the value of the RTC counter (TMR_CNT_L/TMR_CNT_H) is greater than or equal to TMR_ALARMn[TMR_ALARM]. This value should be configured before enabling the timer. default value is 32'h0

44.13.14 Alarm 2 Time High Register (IPTP_TMR_ALARM2_H)

The Alarm (future time) Comparator Register (IPTP_TMR_ALARM_H/ IPTP_TMR_ALARM_L) holds alarm time for comparison with the current timer clock counter (IPTP_TMR_CNT)

.

Address: IPTP_TMR_ALARM2_H is 63FD_4000h base + 34h offset = 63FD_4034h



IPTP_TMR_ALARM2_H field descriptions

Field	Description
0–31 TMR_ALARMn	The IPTP RTC interrupt is generated when the value of the RTC counter (TMR_CNT_L/TMR_CNT_H) is greater than or equal to TMR_ALARMn[TMR_ALARM]. This value should be configured before enabling the timer. default value is 32'h0

44.13.15 Timer Fixed Interval Period 1 Regtister (IPTP_TMR_FIPER1)

The Timer Fixed Interval Period Pulse Generator Register is used to generate periodic pulses. This register is reset with 0xFFFF_FFFF to prevent any false pulse upon initialization. The down count register loads the value programmed in the Fixed Period Interval Register (FIPER). The FIPER must be programmed before the timer is enabled and before the FIPER start value (FSV), which triggers the start of the down counting, is configured. At every tick of the FreqOsc, the counter decrements by the value of IPTP_TMR_CTRL[TCLK_PERIOD]. It generates a pulse when the down counter value reaches zero regardless of the timer value. It reloads the down counter in the cycle following a pulse. The software is responsible for loading these registers with desired period intervals. There are three FIPER registers.

Address: IPTP_TMR_FIPER1 is 63FD_4000h base + 38h offset = 63FD_4038h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	FIPER

IPTP_PTP_TSPDR2 field descriptions

Field	Description
0–15 DPNGE	Destination port field value, represents PTP general For PTP over UDP/IPv4 or PTP over UDP/IPv6 the recommended value according to IEEE1588 standard (1588_ACC_PTP_Mask Register Time Stamp Unit Parsing Offset Values) is 0x0140. default value is 0x0140
16–31 DPNEV	Destination port field value, represents PTP event For PTP over UDP/IPv4 or PTP over UDP/IPv6 the recommended value according to IEEE1588 standard (1588_ACC_PTP_Mask Register Time Stamp Unit Parsing Offset Values) is 0x013F default value is 0x013F

44.13.26 Time Stamp Unit Parsing Definitons Register 3 (IPTP_PTP_TSPDR3)

In order to detect a PTP frame, the TSU parses several fields in the Ethernet frame.

The IPTP_PTP_TSPDR3 register is used to determine the values of the PTP control field.

The values for the parsing can be modified and are used only when IPTP_PTP_TSMR[PTPV] = 0. When IPTP_PTP_TSMR[PTPV] = 1, this register is ignored.

Address: IPTP_PTP_TSPDR3 is 63FD_4000h base + 28008h offset = 63FF_C008h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

IPTP_PTP_TSPDR3 field descriptions

Field	Description
0–7 SYCTL	Control field value represents Sync message. The recommended value according to IEEE1588 standard (1588_ACC_PTP_Mask Register Time Stamp Unit Parsing Offset Values) is 0x00. default value is 0x00
8–15 DRCTL	Control field value represents Delay_Req message. The recommended value according to IEEE1588 standard (1588_ACC_PTP_Mask Register Time Stamp Unit Parsing Offset Values) is 0x01. default value is 0x01
16–23 DRPCTL	Control field value represents Delay_Resp message. The recommended value according to IEEE1588 standard (1588_ACC_PTP_Mask Register Time Stamp Unit Parsing Offset Values) is 0x03.

Table continues on the next page...

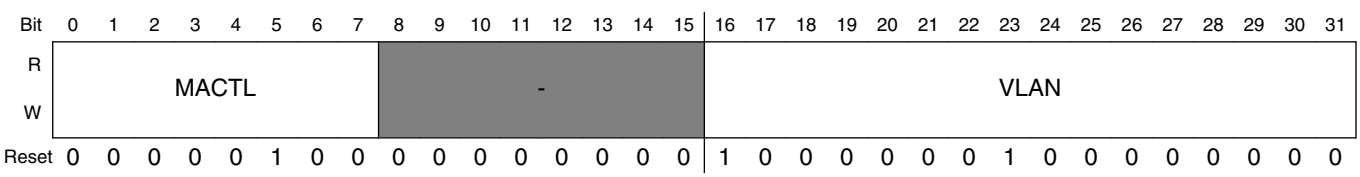
IPTP_PTP_TSPDR3 field descriptions (continued)

Field	Description
	default value is 0x03
24–31 FUCTL	Control field value represents Follow_Up message. The recommended value according to IEEE1588 standard (1588_ACC_PTP_Mask Register Time Stamp Unit Parsing Offset Values) is 0x02. default value is 0x02

44.13.27 Time Stamp Unit Parsing Definitons Register 4 (IPTP_PTP_TSPDR4)

The IPTP_PTP_TSPDR4[MACTL] field is used to determine the values of the PTP control field and is in continuance to the IPTP_PTP_TSPDR3 register. The values for the parsing can be modified and are used only when IPTP_PTP_TSMR[PTPV] = 0. When IPTP_PTP_TSMR[PTPV] = 1, this field is ignored. In addition, IPTP_PTP_TSPDR4 register provides a configured value to detect a VLAN field. This value can be detected during bytes 12-13 and cause a shifting of 4 bytes for all other parsing offsets. In case of a VLAN frame, the offsets should be configured exactly as for non VLAN frame. This field is relevant for both IPTP_PTP_TSMR[PTPV] = 0 and IPTP_PTP_TSMR[PTPV] = 1.

Address: IPTP_PTP_TSPDR4 is 63FD_4000h base + 2800Ch offset = 63FF_C00Ch



IPTP_PTP_TSPDR4 field descriptions

Field	Description
0–7 MACTL	Control field value represents Management message. The recommended value according to IEEE1588 standard (1588_ACC_PTP_Mask Register Time Stamp Unit Parsing Offset Values) is 0x04. default value is 0x04
8–15 -	RESERVED
16–31 VLAN	VLAN tag value (0x8100) default value is ox8100

44.13.28 Time Stamp Unit Parsing Offset Values (IPTP_PTP_TSPOV)

In order to detect a PTP frame, the TSU parses several fields in the Ethernet frame. TSU offset values register (IPTP_PTP_TSPOV) is used to determine the offset of each field in the Ethernet frame. In case the structure of the frame has been changed or manipulated, the field's offsets can be configured.

The parser allows to detect a PTP header as defined in IEEE1588 V1 and V2. In order to retain high flexibility, all of the parsing values and their offsets can be configured

.

1588_ACC_PTP_Mask Register Time Stamp Unit Parsing Offset Values describes the structure of the PTP frame according to IEEE1588 V1 (IPTP_PTP_TSMR[PTPV]=0)

Table 44-32. PTP Frame Structure according to IEEE1588 V1

Layer Name	Octet Number	Field Name	Field Value
IP	12-13	Ethernet Type Field	0x0800
UDP	23	IP Type Field.	0x11
PTP Event	36-37	UDP port	0x013F
PTP General	36-37	UDP port	0x0140
Sync	74	Control	0x00
Delay_Req	74	Control	0x01
Follow_Up	74	Control	0x02
Delay_Resp	74	Control	0x03
Management	74	Control	0x04

1588_ACC_PTP_Mask Register Time Stamp Unit Parsing Offset Values describes the structure of the PTP frame according to IEEE1588 V2 (IPTP_PTP_TSMR[PTPV]=1) when working with PTP over UDP/IPv4 or PTP over UDP/IPv6.

NOTE

Note: X signifies the PTP common message header offset.

Table 44-33. PTP Frame Structure according to IEEE1588 V2 PTP over UDP/IPv4 or PTP over UDP/IPv6

Layer Name	Octet Number	Field Name	Field Value according to standard
IP	12-13	Ethernet Type Field	0x0800

44.13.30 Timer PTP Event Register (IPTP_PTP_TMR_PEVENT)

The IPTP_PTP_TMR_PEVENT is used as the TSU event register. The IPTP_PTP_TMR_PEVENT reports events recognized on the Ethernet channel and generates interrupts. After event recognition, the TSU sets the corresponding IPTP_PTP_TMR_PEVENT bit. The IPTP_PTP_TMR_PEVENT bits are cleared by writing ones; writing zeros does not affect bit values. All unmasked bits must be cleared before the ARM Platform clears the internal interrupt request.

Interrupts generated by the TSU event register (IPTP_PTP_TMR_PEVENT) can be masked in the TSU mask register (IPTP_PTP_TMR_PEMASK), which has the same bit format as IPTP_PTP_TMR_PEVENT. If a IPTP_PTP_TMR_PEMASK bit = 1, the corresponding interrupt in the event register is enabled. If the bit is 0, the interrupt is masked.

Address: IPTP_PTP_TMR_PEVENT is 63FD_4000h base + 28018h offset = 63FF_C018h

44.13.32 Timer Stamp Unit Receiver TIme High (IPTP_TMR_UC_RXTS_H)

TheTime Stamp Unit Receiver Time High (IPTP_TMR_UC_TXTS_H) register is shown in 1588_ACC_PTP_Mask Register Timer Stamp Unit Receiver TIme High.

The IPTP_TMR_UC_TXTS_L/TMR_UC_TXTS_H registers are used to capture the time stamp of a recognized PTP frame on the transmitter lines. The TSU samples the IPTP RTC 64-bit counter immediately after detecting the message time stamp point (See MTSP bit in IPTP_TSMR_CTRL). The sampled value becomes valid only after one of the frame events. In this case, the ARM platform reads the value in order to calculate the synchronization's commands.

IPTP_TMR_UC_RXTS_L/IPTP_TMR_UC_RXTS_H have the same purpose on the receiver lines

Address: IPTP_TMR_UC_RXTS_H is 63FD_4000h base + 28020h offset = 63FF_C020h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

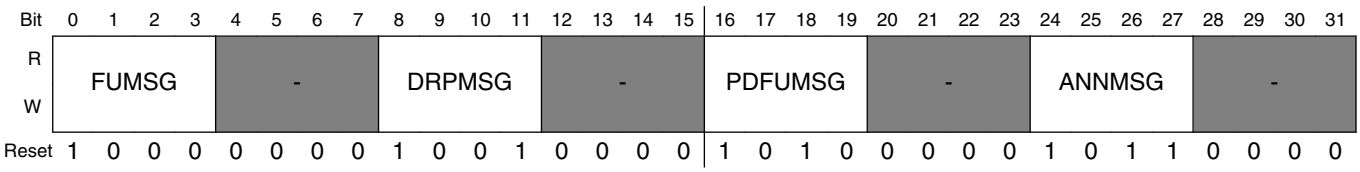
12–15 -	RESERVED set to 0x0
16–19 PDRMSG	Message Type field value represents Pdelay_Req message. The recommended value according to IEEE1588 standard (Table 44-34) 0x2. default value is 0x2
20–23 -	RESERVED set to 0x0
24–27 PDRPMSG	Message Type field value represents Pdelay_Resp message. The recommended value according to IEEE1588 standard (Table 44-34) 0x3. default value is 0x3
28–31 -	RESERVED set to 0x0

44.13.37 Time Stamp Unit Parsing Definitons Register 6 (IPTP_PTP_TSPDR6)

The IPTP_PTP_TSPDR6 register is used to determine the values of the PTP MessageType field and is in continuance with the IPTP_PTP_TSPDR5 register.

The values for the parsing can be modified and are used only when IPTP_PTP_TSMR[PTPV] = 1. When IPTP_PTP_TSMR[PTPV] = 0, this register is ignored.

Address: IPTP_PTP_TSPDR6 is 63FD_4000h base + 28064h offset = 63FF_C064h



IPTP_PTP_TSPDR6 field descriptions

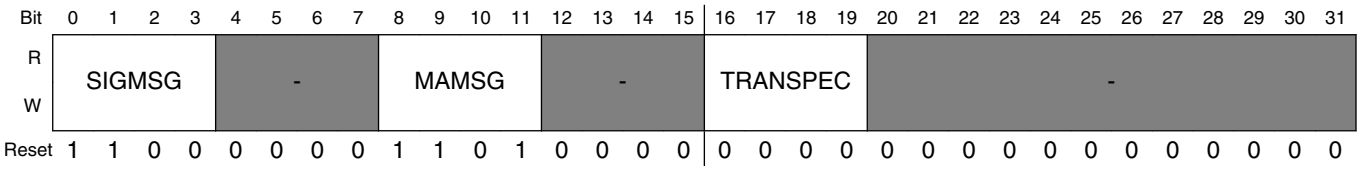
Field	Description
0–3 FUMSG	Message Type field value represents Follow_Up message. The recommended value according to IEEE1588 standard (Table 44-34) is 0x8. default value is 0x8
4–7 -	RESERVED set to 0x0
8–11 DRPMSG	Message Type field value represents Delay_Resp message. The recommended value according to IEEE1588 standard (Table 44-34) is 0x9. default value is 0x9
12–15 -	RESERVED set to 0x0
16–19 PDFUMSG	Message Type field value represents Pdelay_Resp_Follow_Up message. The recommended value according to IEEE1588 standard (Table 44-34) is 0xA. default value is 0xA
20–23 -	RESERVED set to 0x0
24–27 ANNMSG	Message Type field value represents Announce message. The recommended value according to IEEE1588 standard (Table 44-34) is 0xB. default value is 0xB
28–31 -	RESERVED set to 0x0

44.13.38 Time Stamp Unit Parsing Definitons Register 7 (IPTP_PTP_TSPDR7)

The IPTP_PTP_TSPDR7 register is used to determine the values of the PTP MessageType field and is in continuance with the IPTP_PTP_TSPDR6 register.

The values for the parsing can be modified and are used only when IPTP_PTP_TSMR[PTPV] = 1. When IPTP_PTP_TSMR[PTPV] = 0, this register is ignored.

Address: IPTP_PTP_TSPDR7 is 63FD_4000h base + 28068h offset = 63FF_C068h



IPTP_PTP_TSPDR7 field descriptions

Field	Description
0–3 SIGMSG	Message Type field value represents Signaling message. The recommended value according to IEEE1588 standard (Table 44-34) is 0xC. default value is 0xC
4–7 -	RESERVED set to 0x0
8–11 MAMSG	Message Type field value represents Management message. The recommended value according to IEEE1588 standard (Table 44-34) is 0xD. default value is 0xD
12–15 -	RESERVED set to 0x0
16–19 TRANSPEC	transportSpecific field value represents a subtype of the Ethertype. **NOTE:** This field is parsed only when PTP_TSMR[ENTRN]=1, PTP_TSMR[PTPV] = 1, and PTP_TSMR[ENUDP] = 0. default value is 0x0
20–31 -	RESERVED set to 0x0

44.13.39 1588_ACC_PTP_Event Register (IPTP_1588_ACC_PTP_Event)

The IPTP_1588_ACC_PTP_EVENT register reports events recognized on the Ethernet channel and generates interrupts. After event recognition, the TSU sets the corresponding event bit. The event bits are cleared by writing ones. Writing zeros does not affect bit values. All unmasked bits must be cleared before the ARM platform clears the internal interrupt request.

Interrupts generated by the event register can be masked in the mask register (IPTP_1588_ACC_PTP_MASK), which has the same bit format as the event register. If a mask bit = 1, the corresponding interrupt in the event register is enabled. If the bit is 0, the interrupt is masked.

Address: IPTP_1588_ACC_PTP_Event is 63FD_4000h base + 28160h offset = 63FF_C160h

44.13.40 1588_ACC_PTP_Mask Register (IPTP_1588_ACC_PTP_Mask)

The IPTP_1588_ACC_PTP_EVENT register reports events recognized on the Ethernet channel and generates interrupts. After event recognition, the TSU sets the corresponding event bit. The event bits are cleared by writing ones. Writing zeros does not affect bit values. All unmasked bits must be cleared before the ARM platform clears the internal interrupt request.

Interrupts generated by the event register can be masked in the mask register (IPTP_1588_ACC_PTP_MASK), which has the same bit format as the event register. If a mask bit = 1, the corresponding interrupt in the event register is enabled. If the bit is 0, the interrupt is masked.

Address: IPTP_1588_ACC_PTP_Mask is 63FD_4000h base + 28164h offset = 63FF_C164h

Chapter 45
Image Processing Unit (IPU)

45.1 Overview

The IPU v3M is planned to be a part of the video and graphics subsystem in an application processor. This is an enhanced version of the IPUv1.

The goal of the IPU is to provide comprehensive support for the flow of data from an image sensor and/or to a display device. This support covers all aspects of these activities:

- Connectivity to relevant devices - cameras, displays, graphics accelerators, TV encoders and decoders.
- Related image processing and manipulation: sensor image signal processing, display processing, image conversions, etc.
- Synchronization and control capabilities (to avoid tearing artifacts).

This integrative approach leads to several significant advantages:

- Automation: The involvement of the ARM platform in image management is minimized. In particular, display refresh/update and a camera preview (displaying the input from an image sensor) can be performed completely autonomously. The resulting benefits are reducing the overhead due to SW-HW synchronization, freeing the ARM platform to perform other tasks and reduced power consumption (when the ARM core is idle and can be powered down).
- Optimal data path: Access to system memory is minimized. In particular, significant processing can be performed on-the-fly while receiving data from an image sensor and/or sending data to a display. System memory is used essentially only when a change in pixel order or frame rate is needed. The resulting benefits are reduced load on the system bus and further reduction of power consumption.
- Resource sharing: Maximal HW reuse for different applications, resulting with the support of a wide range of requirements with minimal HW.

The HW reuse mentioned above is enabled by a sophisticated configurability of each HW block. This configurability also allows the support of a wide range of external devices, data formats and operation modes. The resulting flexibility is important also because the support requirements are evolving significantly, so expected future changes need to be anticipated and accounted for.

The following further principles guided the choice of support provided by the IPU:

- For key applications that DESERVE and NEED HW support (for acceleration or low power), provide the best support (leading to an optimal implementation).
- For additional applications that can benefit from the HW, consider cost vs. benefit of making minor modifications/extensions to support them.
- For all other relevant applications (to be supported by SW), verify that their support is not degraded.
- Whenever possible, let the operating system (and its windowing system) act as it would without the IPU.

45.2 Architecture

A simplified block diagram of the IPU is shown. The role of each block is described in IPU.

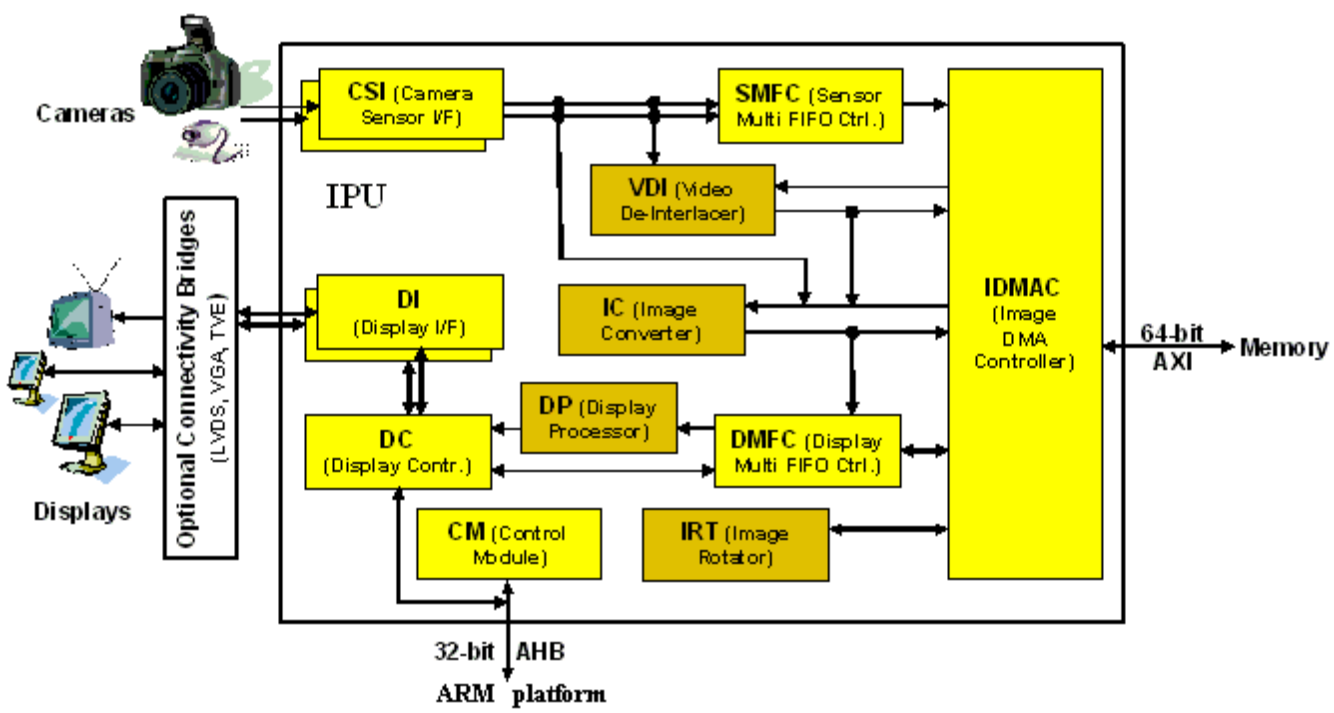

Figure 45-1. IPU Block Diagram

Table 45-1. IPU - Block Description

Block	Description
CSI - Camera Sensor Interface	Controls a camera port; provides interface to an image sensor or a related device. IPU includes 2 such blocks.
DI - Display Interface	Provides interface to displays, display controllers and related devices. IPU includes 2 such blocks.
DC - Display Controller	Controls the display ports.
DP - Display Processor	Performs the processing required for data sent to display.
IC - Image Converter	Performs resizing, color conversion/correction, combining with graphics, and horizontal inversion.
VDIC - Video De Interlacer	Performs video de interlacing (Interlaced -> progressive) or combining.
IRT - Image Rotator	Performs rotation (90 or 180 degrees) and inversion (vertical/horizontal).
IDMAC - Image DMA Controller	Controls the memory port; transfers data to/from system memory.
DMFC - Display Multi FIFO Controller	Controls FIFOs for IDMAC channels related to the display system.
CM - Control Module	Provides control and synchronization.

45.3 Features And Functionality

45.3.1 External Ports

IPU has the following ports:

- Two camera ports - each controlled by a CSI sub-block, providing a connection to image sensors and related devices.
- Two display ports - each controlled by a DI sub-block, providing a connection to displays and related devices.
- Memory port - AXI (AHB V3.0) master, controlled by the IDMAC - providing connection to the system memory.
- AHB-lite slave port, providing connection to the ARM Platform (and to any other master connected to the ARM's cross-bar switch).
- Additional ports for control and debug.

45.3.1.1 Camera Ports

The role of these ports is to receive input from image sensors (or TV decoders) and to provide support for time-sensitive control signals to the camera. (Non-time-sensitive controls; configuration, reset are performed by the ARM platform through I2C I/F or GPIO signals).

Each of the camera ports includes the following features:

- Direct connectivity to most relevant image sensors and to TV decoders.
- Interface types
  - Parallel interface
    - Up to 20-bit input data bus.
    - A single value in each cycle, except for special cases listed in the table below (comments column).
    - Programmable polarity.
- The data formats
  - Interleaved color components, up to 16 bits per value (component).
  - The supported formats are listed in the table below.

Table 45-2. Data Formats Supported By The Camera Port

Format	Resolution	On-The-Fly Processing	Direct path to memory	Comments
Bayer RGB	8 bits/value	No	8- or 16-bit values	
	10 bits/value	No	Written to the MSB of a 16-bit word	
	16 bits/value	Yes		
Full RGB or YUV 4:4:4	444/555 mode	Yes, starting with color extension to 8 bits/ sample	Yes	In parallel I/F: through an 8-bit or 16-bit bus
	565 mode			In parallel I/F: through an 8-bit or 16-bit bus
	8 bits/value (888 mode)	Yes	Yes	
	8-16 bits/value	No	8- or 16-bit components are written to the MSB of a 16-bit word 10 bits/ value can also be packed in a 32-bit word	
YUV 4:2:2 Component order: UY1VY2... or Y1UY2V...	8 bits/value	Yes	Yes	In parallel I/F: through an 8-bit bus (such as BT.656) or 16-bit bus (such as BT.1120)
	9-10 bits/value	No	Written to the MSB of a 16-bit word	In parallel I/F: through a 10-bit bus (such as BT.656) or 20-bit bus (such as BT.1120)
	16 bits/value	No	Written to the MSB of a 16-bit word	
Gray scale	8 bits/value	Yes	Yes	
	16 bits/value	No	Written to the MSB of a 16-bit word	

Table continues on the next page...

Table 45-2. Data Formats Supported By The Camera Port (continued)

Format	Resolution	On-The-Fly Processing	Direct path to memory	Comments
Generic data		No	Yes In a parallel I/F, if wider than 8 bits, each bus word is written to the MSB of a 16-bit word	May be used for any other formant, such as JPEG/MPEG4

- Scan order: progressive or interlaced data (expected only for YUV 4:2:2) is sent directly to system memory, where it can be read back for further processing.
- Frame size: up to 8192 x 4096 pixels
- Synchronization: video mode
  - The sensor is the master of the pixel clock (PIXCLK) & synchronization signals
  - Synchronization signals are received using either of the following methods:
    - Dedicated control signals -VSYNC, HSYNC - with programmable pulse width & polarity
    - Controls embedded in the data stream, following loosely the BT.656 protocol, with flexibility in code values and location.
- Synchronization : still image capture
  - The image capture is triggered by the ARM platform or by an external signal (such as a mechanical shutter).
  - Synchronized strobes are generated for up to 6 outputs - the sensor and camera peripherals (such as flash, mechanical shutter).
- Additional features
  - Frame rate reduction, by the periodic skipping of frames
    - The supported reduction ratios are: m:n, where m,n<=5
    - This is supported independently for the different destinations - IC, SMFC.
  - Window-of-interest selection
  - Pre-flash - for red-eye reduction and for measurements (such as focus) in low-light conditions

Several sensors can be connected to each of the CSIs. Simultaneous functionality (sending data) is supported as follows:

- Two sensors can send data independently, each through a different port.
- Only one of the (non-generic) streams can be transferred to theVDIC or IC for on-the-fly processing, while the others are sent directly to system memory.

The input rate supported by the camera port is as follows:

- Parallel interface:

  - Average: up to 135M values/sec Bayer - 90 M pixels/sec (e.g., 9M pixels @ 15 fps) YUV 4:2:2 - 45 M pixels/sec (e.g., 3M pixels @ 15 fps) YUV 4:4:4 or RGB - 30 M pixels/sec (e.g., 3M pixels @ 10 fps)
  - Peak: up to 180 values/sec (to account for up to 35% blanking intervals)
- When two or more sensors are used simultaneously, the total rate supported is as above.
- On-the-fly processing (as listed in the table above) may be restricted to a lower input rate. See Processing for further details.
- I/O pads may also be restricted to a lower input rate.

45.3.1.2 Display Ports

The role of these ports is to communicate with display devices, either directly or through a controller (such as a graphics accelerator) or a bridge (such as a TV encoder or an LVDS interface bridge).

45.3.1.2.1 Access Modes

Two access modes are supported.

Synchronous access

In this mode, the IPU transfers a two-dimensional block of pixels to the display device, in synchronization with the screen refresh cycle.

This mode has a dual role:

- For a RAM-less display or a TV screen, this mode is used to perform the screen refresh process from a display buffer in system memory.
- For a "smart" display, this mode is used to transfer a rectangular block of pixels to the display's screen and, in some cases, also to the display buffer
  - The transferred block may be only part of the screen (the rest of the screen being refreshed by the integrated controller, from the internal buffer). Moreover, a mask can be used to transfer to the display only parts of the block, such as a window partly hidden by other windows.
  - If the block is transferred only to the screen, the transfer rate must be equal to the refresh rate. If, however, the transfer is also to the display's memory, the rate can be reduced to the rate at which the input buffer is updated.

In all cases (including the last one), the IPU sends to the display all the synchronization signals controlling the screen refresh and the block transfer is synchronized with these signals. This synchronization means that tearing effects are avoided when using this mode.

Asynchronous Access:

This is the main mode used for communicating with an external display controller (possibly in a smart display or a graphics accelerator). In this mode, the IPU performs random access - read/write - to the memory and registers of the controller.

Two types of addressing methods are supported

- Generic linear addressing of pixels and generic data
- 2-dimensional (X/Y) addressing of pixels

The following access types are provided:

- Data transfer to the external device, after on-the-fly processing in the
- Data transfer (DMA) - read/write - between the host's system memory and the external device, through the IPU's memory port (controlled by the IDMAC), such as the transfer of a rectangular block of pixels (possibly full screen).
- Host access - read/write - to an external device, through the AHB-slave port
  - Access types
    - Direct access - emulating a directly-addressed access (see below) This includes burst access (incremental; up to 8 words/burst)
    - Low-level access - leaving to the host the explicit generation of the access protocol
  - The possible accessing modules include the ARM platform and the system DMA controller (as well as any other AHB master connected to the ARM's cross-bar switch).

Transfer of video/graphics data stream to controller's display buffer is performed using one of the first two modes above. Unlike in the synchronous mode, this process is not tightly-synchronized with the screen refresh cycle. However, a loose synchronization - to avoid tearing - is still possible: the appropriate timing for the transfer can be derived from the VSYNC signal of the screen refresh - either generated by the IPU's display controller or received from the external controller.

The asynchronous access requires the specification of an address. The display interface uses "indirect addressing", namely, there is no address bus, and the address, as well as control and configuration commands, are embedded in the data stream. The access procedure - including writing addresses and commands - is managed autonomously by the interface, in one of two ways:

- Automatic emulation of transparent access, following microcode ("access template") generated by the ARM Platform. This mechanism is very flexible, supporting a wide variety of devices.
- Streaming commands/addresses from a buffer stored (by the ARM Platform) in system memory.

Note that direct access requires the use of the first method - automatic emulation.

The Interface

The display interface is very flexible and supports a wide variety of devices from major manufacturers. The following interface types are provided (in each of the two display ports)

- Parallel video interface (for synchronous access) - up to 24-bit data bus.
  - Control protocol - follows Sharp HR and generic TFT definitions
  - Supports BT.656 (8-bit) and BT.1120 (16-bit) protocols
  - Supports HDTV standards SMPTE274 (1080i/p) and SMPTE296 (720p)
- A parallel bidirectional bus interface (for asynchronous access) - up to 32-bit data bus.
  - Compatible with MIPI-DBI standard.
  - Control protocol - either system-80 or system-68K The timing and polarity of the signals are programmable.
  - Byte-enable - optional, for a 16-bit interface
  - Burst access For direct access, the burst is determined by the corresponding signal in the AHB interface.
- A serial interface - 3-wire, 4-wire and 5-wire (two flavors) (for asynchronous access)

The supported formats for pixel data are

- RGB - color depth fully configurable; up to 8 bits/value (color component)
- YUV 4:2:2, 8 bits/value (for TV encoder)

In the parallel interfaces, the data bus has up to 32 bits. Non-trivial mapping of pixels to the bus is restricted to the 24 LSB's. This mapping is fully configurable and very flexible. In the serial interfaces, the data is mapped in the same way as in the parallel interfaces and then serialized.

The interface also supports "generic data". Such data is transferred - byte-by-byte, without modification - between the system memory and the display device (through a serial interface or 8/16-bit parallel interface). Non-conventional pixel formats can be supported by considering them as "generic data".

For the interface clock, there are the following options (independently for each port)

- Derived from the IPU internal clock (master mode)
- Provided by an external source (slave mode)

The transfer rate supported:

- For single port (for on-chip interfaces):

- 170 Mega-Accesses/Sec if the DI clock is derived from an external to IPU source (like another PLL)
- 180 Mega-Accesses/Sec if the DI clock is derived from the IPU clock (HSP_CLK)
- When off-chip interfaces are involved the rate may be limited by IO capabilities. Please refer to the device's data-sheet for exact numbers.

For synchronous access with one cycle/pixel, this enables, e.g (including 35% blanking intervals)

- 1080p (1920x1080) @ 60 fps
- WSXGA+ (1680x1050) @ 60 fps
- The combined rate for the two ports is up to 180 MP/sec

The interface includes the following additional features:

- Screen size: up to 4096 x 2048 pixels, programmable by software.
- Scan Order: progressive or interlaced
- Synchronization
  - Programmable horizontal and vertical synchronization output signals (for synchronous access)
  - Data enabling output signal
- Software contrast control using 8-bit programmable pulse-width modulation (PWM) Two dedicated PWM outputs are provided

Connecting To Display Devices

IPU allows the connectivity to multiple display devices. In particular, it supports the following setup:

- Primary LCD display; can be smart, dumb (RAM-less) or dual-port; may use the parallel interface or (through an integrated bridge) LVDS interface.
- Second LCD display; can be smart or dumb (RAM-less); may use parallel or serial interface or (through an integrated bridge) LVDS interface.
- TV Output: either digital parallel output, or (through an integrated TV encoder bridge) analog output.

Each of the above connections has independent settings - interface timing, access template, chip-select, etc.

Simultaneous functionality of the above devices is possible in each of the following ways:

- Two devices can be accessed (synchronously or asynchronously) independently, each through a different port: each using any of the available interfaces.

- Two devices can time-share asynchronous accesses through the legacy serial & parallel interfaces, using the CS signals.
- An asynchronous access can be performed during vertical blanking intervals of a synchronous access (screen refresh; to the same or other device).

The possibilities for simultaneous functionality by time-sharing the legacy interfaces in a single port are summarized in the following table.

Table 45-3. Simultaneous Functionality of Display Port By Time-Sharing Legacy Interfaces

	Second/Third Display Type		
Primary Display Type	**Smart Display Serial Interface**	**Smart Display Parallel Interface Asynchronous access**	**RAM-less display or TV screen**
Smart Display Parallel Interface Asynchronous access	Yes	Yes	Yes; access to the smart display is restricted to blanking intervals
Dual Port Smart Display Synchronous access	Yes	Yes, access to the secondary display is restricted to blanking intervals	Not Available
TFT RAM-less Display Or TV screen	Yes	Yes, access to the smart display is restricted to blanking intervals	Not Available
Graphics Accelerator	Yes	Yes, if the accelerator supports a chip select functionality	Not Available

45.3.1.3 Memory Port

The memory port is an AXI (AHB V3.0) master port, used to read/write data - typically two-dimensional blocks from/to system memory.

The interface supports the following features

- Clock rate up to 200 MHz (equal to the internal clock)
- 64-bit data bus
- The supported data formats are listed in the table below.

Table 45-4. Data Formats Supported By The Memory Interface

Format	Resolution	Input/Output	Comments
Non-interleaved YUV (in three separate buffers)	8 bits/value	both	4:4:4, 4:2:2, 4:2:0 formats
Partially-interleaved YUV (in two separate buffers)	8 bits/value	both	4:2:2, 4:2:0 formats Y buffer and UV buffer
Interleaved YUV (all color components in a single buffer)	8 bits/value	both	4:4:4 format (YUV...) 4:2:2 format (UY1VY2... or UY2VY1... or Y1UY2V...or Y2UY1V...)
Interleaved true color	8, 12,16, 18, 24, 32 bits/ pixel 0 - 8 bits per R/G/B/A value	both	Flexible component location A: translucency value (only in input)
Coded color (using a palette)	4,8 bits/pixel	input only	
Gray scale	8 bits/pixel	both	
	4 bits/pixel	input only	Transferred to display port
Generic data (Transparent M)	8 bits/unit	both	E.g.: From CSI; to DI; Compressed data to/from DP Translucency for combining

- The pixel formats are translated to/from a uniform internal format: RGBA/YUVA 8:8:8:8
- The supported ordering of bytes and pixels is little endian. For 4 bits/pixel, big endian is also supported.
- Addressing modes include:
  - Sequential access (to a contiguous memory buffer) - for generic data.
  - Raster-scan within a two-dimensional window of a video/display buffer - for both pixel and generic data.
  - Raster-scan of two-dimensional blocks within a two-dimensional window (for rotation of pixel data)
- Additional features
  - Scan order: progressive or interlaced Interlaced access is supported for fields which are stored either in separate memory buffers or with rows interleaved in a single buffer.
  - Reordered scan, implementing inversion and rotation.
    - Rotation and horizontal inversion - only when transferring two-dimensional blocks (to/from the IRT)
    - Vertical inversion - also in row-by-row raster-scan

- Scrolling
  - Applications Panning within a frame Frame scrolling
  - Not supported for non-interleaved and partially-interleaved formats
  - Resolution Vertical: single pixel Horizontal: 18 BPP - 4 pixels; 12, 4 BPP or YUV 422 - 2 pixels; other formats - one pixel
- Conditional read (for combining): fully-transparent or hidden pixels are not read.
  - This is supported, for graphics. by reading the transparency (alpha) from a separate buffer
- Input/output FIFOs (in the SMFC, DMFC and in the processing sub-blocks) - size adjusted to provide resilience for latency of up to 1500 cycles.

45.3.1.4 Processing

The IPU processes rectangular blocks of pixels. The processing is performed in these sub-blocks - VDIC, DP, IC and IRT.

(see the IPU block diagram and Table 45-1).

45.3.1.4.1 Processing flows

Several time-shared data flows are supported, as described in the following table.

Table 45-5. Time-Shared Data Flows through the IPU

Name	Number	Type	Flow	Target	Restrictions
Display Refresh/ Update	5 flows (at most two of them of type DS1)	DS1	Fmem -> DP -> Display	Synchronous Access (e.g. display refresh; controlled by the DI)	
		DS2	Fmem -> DP -> Display	Asynchronous Access (e.g. display update)	
		DS3	Fmem <-> Display	Generic Data Transfer	
	1 flow	DS4	ARM Platform<-> Display	Direct Access	
Video Playback	flows	PL1	Bmem -> VDIC -> IC -> Bmem -> IRT -> Fmem + DSx	Main option	
		PL2	Fmem -> IRT -> Bmem -> IC -> DP	Low power (branching to DSx, as a video plane)	Large enough window No other video flows
		PL3	Fmem -> VDIC -> IC -> DP	Low power (branching to DSx, as a video plane)	Interlaced source Large enough window No other video flows

Table continues on the next page...

Table 45-5. Time-Shared Data Flows through the IPU (continued)

Name	Number	Type	Flow	Target	Restrictions
Camera Pre-view	1 flow (VF2 may be used also as a playback flow)	VF1	Sensor -> IC -> Bmem -> IRT -> Fmem+DSx	main option	Single progressive input
		VF2	Sensor -> Fmem -> VDIC -> IC -> Bmem -> IRT -> Fmem+ DSx	two inputs and/or interlaced input	When the VDIC is used, one of the three input fields can go directly from the sensor to the VDIC. In that case the sensor output goes to the memory via the VDIC and not the SMFC
		VF3	Sensor -> IC -> DP	Low power Smart Display Tearing-less (branching to DS2, as a video plane)	Single progressive input Refresh rate = 2x sensor frame rate Large enough window No other video flows
		VF4	Sensor -> IC -> Fmem + DS1	Low power RAM-less Display Single Display Buffer (in internal memory) Tearing-less	Single progressive input Refresh rate = 2x sensor frame rate Large enough window No other video flows
Video Record	1 flow	RCx	IC -> Bmem -> IRT -> Fmem	(branching from VFx)	
Graphic Overlays	2 flows	GF1	Fmem -> IC	(combining with the main flow	
	2 flow	GF2	Fmem -> DP		

Comments

- System memory usage - legend
  - Fmem: frame double-buffer (page-flip) in system memory (typically external)
  - Bmem: two possibilities
    - A frame double buffer, as above
    - A band (4-256 rows) double-buffer (page-flip) in system memory (could be internal)
  - Direct arrow between two processing stages represents an internal pipeline
- Time-sharing
  - IC can time-share tightly three flows: one VFx, one RCx and one PLx (with independent processing parameters)
  - DP can time-share one DS1 flow and a one DS2 flow (each with different destinations and independent processing parameters)

    - Direct access to display (DS4) time-shares tightly the display port with other active DSx flows.
    - Other time-sharing (between PLx; between DS2&DS3; in IRT) is frame-by-frame
- Any of the processing stages in the above flows can be skipped.
- Triggering and synchronization
    - Flow segments starting from a sensor are triggered and synchronized by input from the sensor
    - Flow segments ending with display refresh are triggered and synchronized by the refresh control mechanism in the DI.
    - Flow segments starting and ending in system memory, are triggered either by the double buffering mechanism or by explicit configuration and are processed continuously without delay, at a rate determined by the available resources. These flow segments have a lower priority than the sensor/display-driven flows.

The functionality of each of the processing blocks is described below.

45.3.1.4.2 Display Processor (DP)

The Display Processor performs all the processing required for data sent to a display.

- Input: from the IC and/or from system memory
    - Order: rows, progressive or interlaced
    - Format: YUVA/RGBA, non-decimated, 8 bits/value
- Processing chain
    - Combining 2 video/graphics planes
    - Overlaying a simple HW cursor 32 x 32 pixels, uniform color; may be combined logically with the full plane.
    - Color conversion/correction - linear (multiplicative & additive) Programmable; including:
        - YUV <-> RGB, YUV<->YUV conversions where YUV stands for any one of the color formats defined in the MPEG-4 standard
        - Adjustments: brightness, contrast, color saturation, etc.
        - Special effects: gray-scale, color inversion, sephia, blue-tone, etc.
        - Color-preserving clipping, for gamut mapping
        - Hue-preserving gamut mapping - for minimal color distortion
        - Applied to the output of combining or to one of the inputs
    - Gamma correction and contrast stretching - programmable piecewise-linear map
- Output: to display (through the DC)
    - Rate: up to 180M pixels/sec (e.g., WSXGA (1680x10508) @ 75 fps + 35% blanking intervals)
    - Format: YUV/RGB, non-decimated, 8 bits/value

The DP processes a single data flow at any given time, but supports up to three data flows by time sharing.

- A Primary flow:
  - The input is loaded periodically using a timer (e.g. for a synchronous access)
  - Optionally, frames are skipped if the content has not changed (as appropriate for a smart display)
- Two secondary flows:
  - Asynchronous; processed when the DP is not needed for the primary flow (during blanking intervals or when a primary frame is skipped).
  - The two secondary flows are switched frame-by-frame.

45.3.1.5 Video De-Interlacer or Combiner (VDIC)Video De-Interlacer (VDI)

The Video De-Interlacer and Combiner has two operation modes

- De-interlacing: converts an interlaced video stream to progressive order.
- Combining: combines two video/graphics planes and a background color

45.3.1.5.1 De interlacing in the VDIC

The Video De-Interlacer converts an interlaced video stream to progressive order, using a high-quality 3-field motion-adaptive filter.

- Video source - SDTV: 480i30 (720x480 @ 30 fps) or 576i25 (720x576 @ 25 fps) and HDTV: 1080i30 (1920x1080 @ 30 fps)
- Input: - three consecutive fields
  - Source
    - The most recent field may come from the CSI or from system memory
    - The other two fields are read from memory
  - Field size: up to 968x1024 pixels (may be a vertical stripe of a wider field; e.g. 1920 pixels)
  - Pixel format: YUV 4:2:2/4:2:0, 8 bits/value
- Output: progressive frame
  - Destination: to system memory or to the Image Converter.
  - Frame size: up to 968X2048 pixels
  - Rate: up to 180 MP/sec (e.g., 1920x1080 @ 85 fps)
  - Format: same as input format

The de-interlacing is performed using a high-quality 3-field filter which is motion adaptive:

- For slow motion - retains the full resolution (of both top and bottom fields)
- For fast motion - prevents motion artifacts

The VDIC supports a single video stream at any given time.

45.3.1.5.2 Combining in the VDIC

- Input for combining: two progressive video/graphics planes
  - Source: system memory
  - Plane size: up to 1920x1200 pixels.
  - Pixel format: RGB/YUV 4:2:2, 8 bits/value

In this mode:

- The two input planes are read from system memory, using the previous field and next field input FIFOs.
- Their relative height, up/down is configurable
- Each of them may cover only part of the output frame. For the remaining part of the frame, i.MX 6Dual/6Quad uses the following values:
  - Down plane: a 24-bit background color, stored in an internal register
  - Up plane: a transparent pixel
- The combining method is identical to the one in the DP, IC.

45.3.1.5.3 Image Converter (IC)

The Image Converter performs various operations on a video stream.

- Input: from sensor or from system memory
  - Frame size: up to 4096x4096 pixels
  - Rate: up to150M pixels/sec (e.g.,4 MP @ 30 fps + 35% blanking intervals)
  - Order: rows, progressive. If resizing is not used, interlaced order is also acceptable.
  - Pixel format: YUV/RGB, 8 bits/value
- Processing chain:
  - Resizing
    - Fully flexible resizing ratio Maximal downsizing ratio: 16:1 Subject to this limitation, any N->M resizing can be performed
    - Independent horizontal and vertical resizing ratios.
  - Color conversion/correction - linear (multiplicative & additive) Programmable; including:
    - YUV <-> RGB, YUV<->YUV conversions where YUV stands for any one of the color formats defined in the MPEG-4 standard
    - Adjustments: brightness, contrast, color saturation...
    - Special effects: gray-scale, color inversion, sephia, blue-t[illegible]

    - Combining with a graphics plane (e.g. application-specific overlay)
    - Horizontal inversion
- Output: to system memory or (for a single active flow) to a display device (through the DP).
    - Frame size: up to 1024x1024 pixels
    - Rate: up to75Mpixels/sec (e.g.,1920x1080 @ 30 fps)
    - Order: rows, progressive. If resizing is not used, interlaced order is also acceptable.
    - Format: YUV/RGB, 8 bits/value

The IC supports three time-shared data flows: record, camera preview and playback (the first two share a common input).

45.3.1.5.4 Image Rotator (IRT)

- Input/output: from/to system memory
    - Rate: up to 75M pixels/sec
    - Order: raster scan of 8x8-pixel blocks
    - Format: YUV/RGB, non-decimated, 8 bits/value
- Transformation: combination of the following
    - 90-degree rotation
    - Horizontal inversion
    - Vertical inversion

45.3.1.6 Automatic Procedures

The IPU is equipped with powerful control and synchronization capabilities to perform its tasks with minimal involvement of the ARM Core and minimal use of memory.

In particular, it includes:

- An integrated DMA controller with an AXI master port, allowing autonomous access to the system memory.
- An integrated display controller, performing screen refresh of a RAM-less display.
- A page-flip double buffering mechanism, synchronizing read and write access to system memory, to prevent tearing effects.
- A double/triple buffer synchronization mechanism with a video/graphics source.
- Internal synchronization, e.g., between input from sensor and output to display

As a result, in most cases, the ARM platform is involved only when it also performs part of the processing (e.g. video coding). In particular, the following procedures are performed by the IPU completely autonomously:

- Screen refresh for RAM-less displays
- Update of the ("partial plane") display buffer used for screen refresh (located either in system memory or in an external display controller, e.g. of a smart display or graphics accelerator), when the content is generated in a different ("full plane") buffer.

Typically, there are extended periods of times in which there is no other activity in the system. The ARM platform, being idle, can be put to a low-power mode, reducing the power consumption and extending significantly the battery life.

The IPU supports several techniques to reduce further the power consumption of the display system:

- Dynamically optimized screen refresh rate (see Screen Refresh below)
- Optimized update of the display buffer (see Update Of The Display Buffer below)
- Dynamic backlight control, with low-light compensation by image enhancement

Further features and capabilities of the automatic procedures are outlined below

45.3.1.6.1 Screen Refresh

- The refresh rate may vary within a predefined range. Within this range, the rate is dynamically adjusted to the content update rate.
- An indication about the availability of new content is obtained as follows:
  - If the page-flip double buffering is used, the mechanism provides this indication
  - If only a single buffer is used (and incrementally updated), the IPU can receive an indication of a modification, either through a dedicated external "snooping" signal (e.g. from the EXTMC), or from the ARM platform (by setting an internal flag).
- The IPU counts the refresh cycles: the total and those with new content. The ARM platform can use these counters to optimize display management (e.g. switching display buffer compression on/off). The counters are reset by the ARM platform.
- The transferred data may be processed on the way, using the IC and DP.

45.3.1.6.2 Update Of The Display Buffer

- Conditional update The IPU can receive an external "snooping" signal indicating a modification of the full plane buffer (as during screen refresh above). It monitors the signal and, upon detection, it performs one of the following:
  - Performs an update, without any SW intervention
  - Interrupts the ARM core, that can initiate some more involved procedure (e.g. selective update)
- Automatic display of a changing image (animation) or moving image (scrolling) This is implemented by reading frames (from a full plane buffer) with incremental offset.

When the IPU reaches the last programmed frame, it can perform one of the following:
    - Return to the first frame, without any SW intervention
    - Interrupt the ARM platform, to generate the next content.
- The timing of the update can be adjusted to avoid tearing.
- The transferred data may be processed on the way, using the IC and DP

45.3.1.6.3 Camera Preview

- Tearing artifacts can be prevented by (automatic) page-flip double buffering in system memory
- Alternatively, the video stream from an image sensor can be sent directly to the display buffer used for screen refresh. The significance of this option is that only a single frame buffer is needed (and not two). This buffer may be located either in system memory or in an external display controller.
    - This option is useful, e.g., in a low frame rate, when tearing is not visible.
    - When tearing must be prevented, the refresh cycle in the display can be synchronized with the timing signals from the sensor (two refresh cycles for each input frame): the IPU receives a VSYNC signal from the sensor and generates from it synchronization signals for the display.

45.4 Functional Description

45.4.1 IPU detailed block diagram

The following figure is the IPU top level block diagram.

45.4.2.2 IBIW & IBIR - Internal bus interface for write and read

The Internal Bus Interface handles the internal IPU protocol communicating between the IDMAC and the IPU's sub modules. The IBIR handles channels that perform read from external memory. The IBIW handles channels that perform write accesses to external memory.

45.4.2.3 FCW & FCR - Format converter write and read

The format converter performs packing ("write direction") / unpacking ("read" direction) of pixels with programmable position and width of color components, decoding 4- or 8-bits coded pixels according to a loaded look-up table, panning of an image read from the system memory according to a panning offset (start pixel address).

The format converter supports formats with a pixel width of 4, 8, 12, 16, 18, 24 or 32 bits. The format converter unit handles two pixels simultaneously.

The IPU sub modules can handle only the formats, presented below. Each component is 8 bit:

Figure 45-4. IPU internal pixel formats

The pixel can be stored in the memory in the formats presented below. (R/G/B means that this could component can be R or G or B; A is the location of the alpha component).

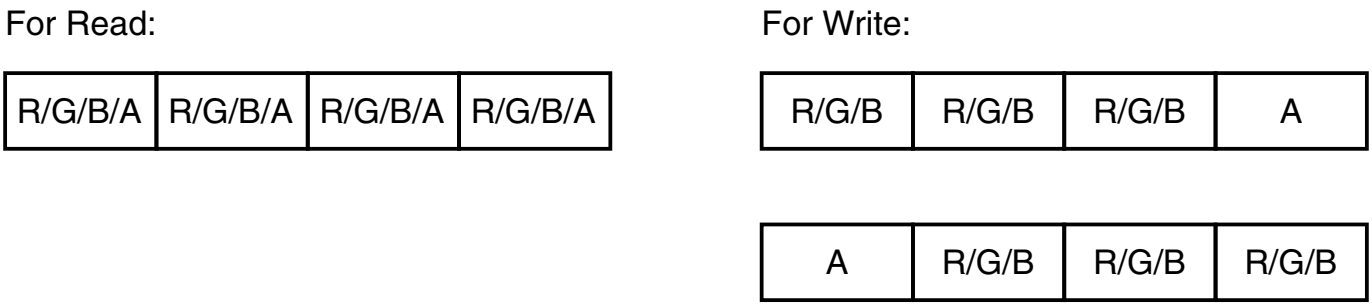

Figure 45-5. IPU external pixel formats

Formatting parameters are written in the channel parameter memory (CPMEM - Channel Parameter Memory). The following parameters are used:

- Offset OFS0 between MSB position of the color component 0 and MSB position of packed pixel. The color component 0 occupies the most significant bits of the unpacked pixel (mostly this is the R component). The OFS0 range is from 0 to 31.
- Color component 0 width WID0 minus 1.
- Offset OFS1 between MSB position of the color component 1 and MSB position of packed pixel. The color component 1 occupies the middle left bits of the unpacked pixel (mostly this is the G component). The OFS1 range is from 0 to 31.
- Color component 1 width WID1 minus 1.
- Offset OFS2 between MSB position of the color component 2 and MSB position of packed pixel. The color component 2 occupies the middle right bits of the unpacked pixel (mostly this is the B component). The OFS2 range is from 0 to 31.
- Color component 2 width WID2 minus 1.
- Offset OFS3 between MSB position of the color component 3 and MSB position of packed pixel. The color component 3 occupies the least significant bits of the

unpacked pixel (mostly this is the A component). The OFS3 range is from 0 to 31. For write specified DMA channels, the OFS3 value is set to 24 or 0 bits.

- In cases of read with separate alpha (alpha is located in a separate buffer in the system's memory than the pixel data), the alpha component size is defined according to WID3.

The figures below show examples of data packing and unpacking.

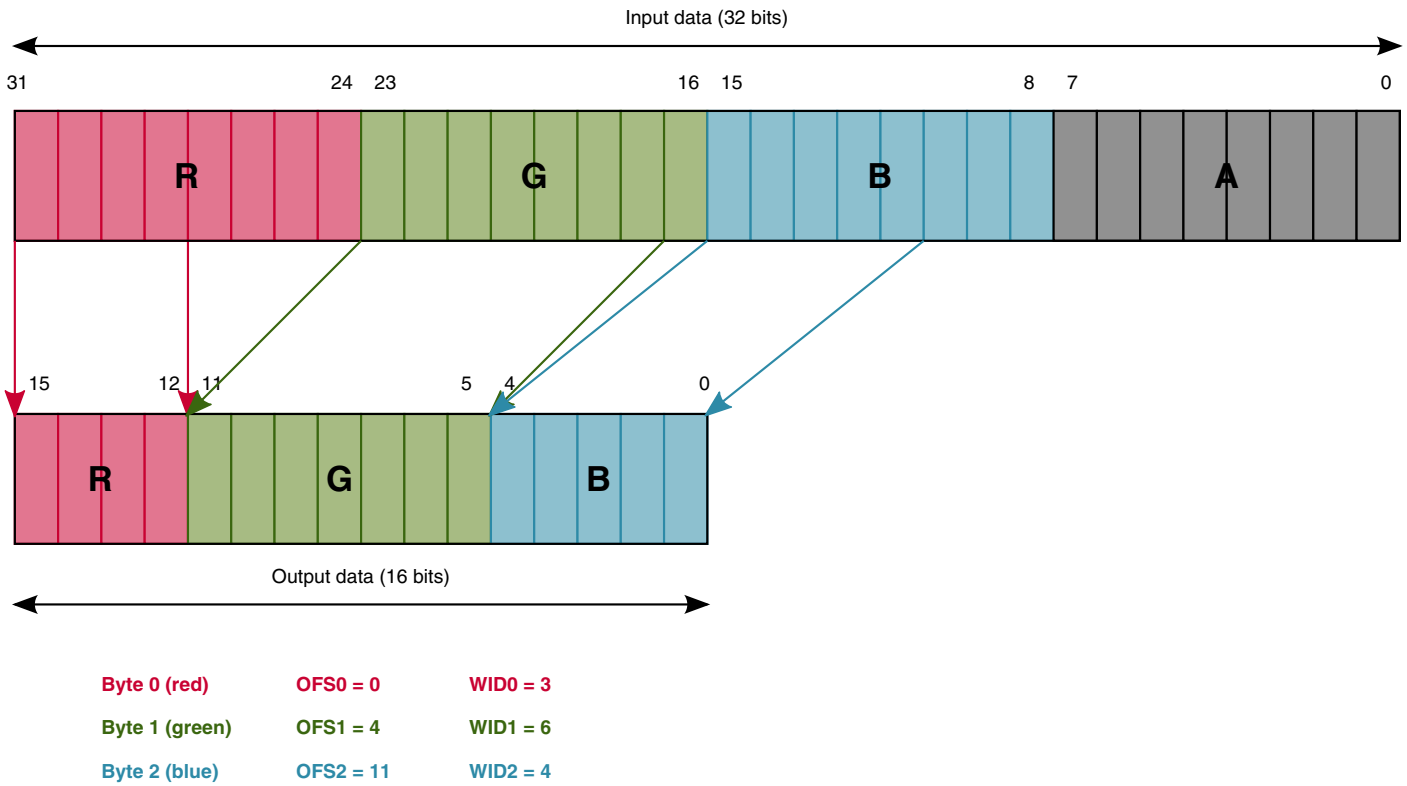

Figure 45-6. Data Packing Example

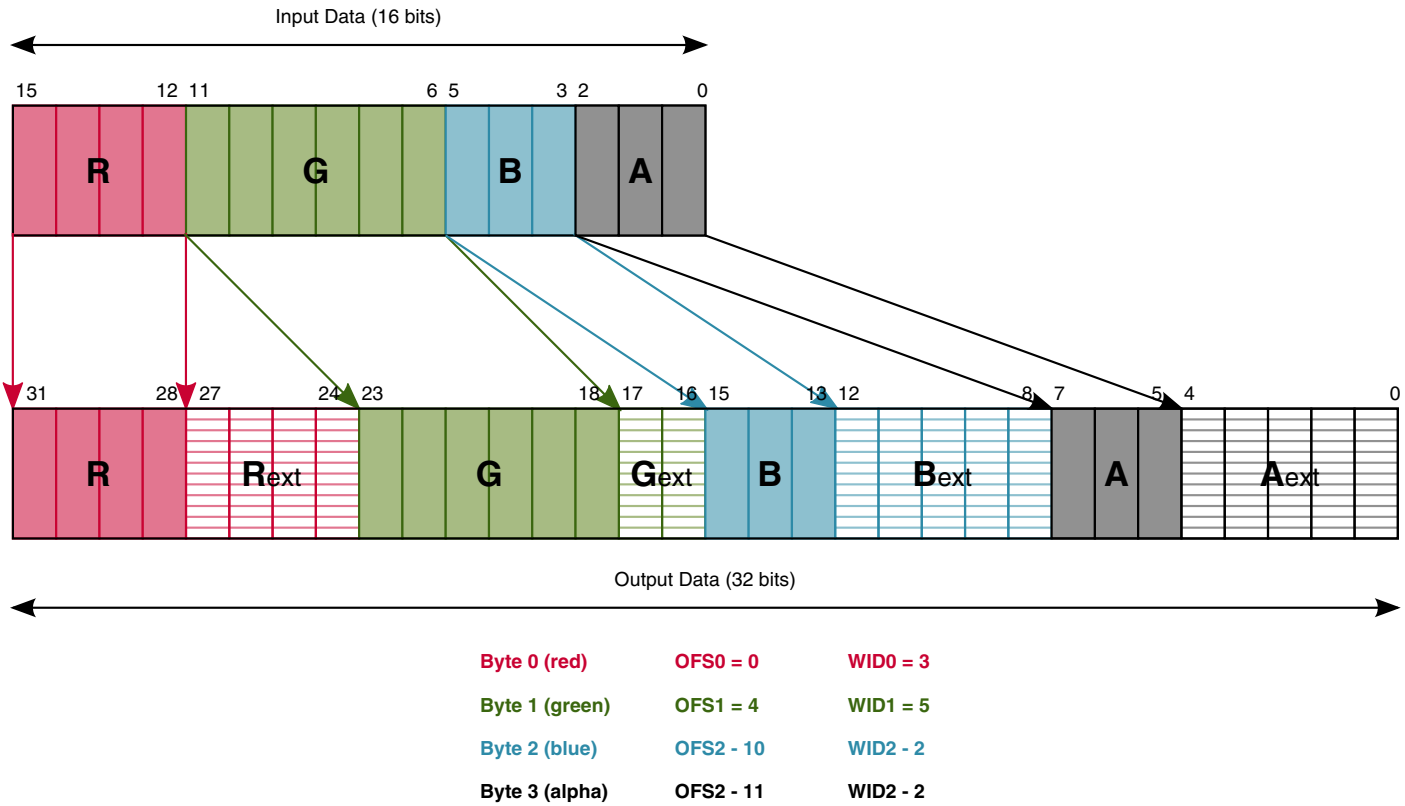

Figure 45-7. Data Unpacking Example

If read data has the coded format, it is decoded via the look-up table. The Look-Up Table Memory (LUT- Look Up Table) must be loaded at the IDMAC initialization step. The LUT output format must match the IPU internal format RGBA 8888 where R is placed in MSB and A is placed in LSB. The A field is used only for graphics data.

45.4.2.4 Buffering units

The buffering units (BUFW, BUFR) are used to store the data consisting of different coded color components.

- On write transactions (BUFW), before writing to memory & after the format has been coded.
- On read transactions (BUFR), after reading from memory & before the format has been decoded.

Each buffering unit includes 4 X 64 bytes buffers. Each buffer, for each direction, can handle any kind of color component (interleaved - Y / partial interleaved - Y, UV / non interleaved - Y, U, V).

The Write buffers are controlled by the buffer controller for write (BCW) and AXIW units.

The Read buffers are controlled by the buffer controller for read (BCR) and AXIR units.

45.4.2.4.1 Handling real time channels

The memory controller connected to the AXI bus of the IPU can use the AXI ID associated with each burst in order to distinguish between real time and non real time channels.

In order to do that, the user has to set the channel's ID according to the settings in the memory controller and set the priority of the channel according to its nature. The buffer controller (BCW/BCR) holds all the pending requests that won the arbitration. However, as the memory controller can distinguish between the real time channels and non real time channels within the IPU, there could be a situation where the real time requests are blocked as the IPU's queue is filled with non real time requests. To avoid that, the user can limit the number of non-real time requests in the queue.

The queue for read requests can handle up to 8 requests. The queue for write requests can handle up to 6 requests. The user can limit the number of non real time requests by setting the USED_BUFS_MAX_W for write requests and USED_BUFS_MAX_R for read requests. The feature that limits the number of requests is enabled by setting the USED_BUFS_EN_R bit for the read requests and USED_BUFS_EN_W for the write requests.

45.4.2.5 AXIW - AXI Write and AXIR - AXI Read

The AXI Master Interfaces are responsible for data transfer from/to the system memory. The Interface supports only 64-bits burst accesses of 1-8 words, with nonalignment of a byte resolution.

2 separate & independent AXI masters are used for "read" (AXIR) & "write" (AXIW), each can be programmed (via CPMEM) with 4 different IDs to support out-of-order accesses within bursts.

45.4.2.6 CC_W & CC_R - Channel Control Write and Read

The Channel Control unit is the main control unit of the IDMAC.

- It arbitrates the channels according to the priority.
- Controls the address arithmetic unit.

- Functions as a memory interface to the CPMEM. It reads the parameters from the CPMEM, prepares the controls accordingly and writes back updated parameters to the CPMEM.
- The read unit provides the parameters to the IBIR unit
- The write unit provides the parameters to the AXIW unit

The CC calculates all the parameters related to the access except the address and BS (burst size), which are calculated at the AAU.

The priority is set according to:

- The channel's corresponding bit in the IDMAC_CH_PRI_1 & IDMAC_CH_PRI_2 registers.
- The watermark signal generated from the sub module. The watermark signal is ignored unless the channel's corresponding IDMAC_WM_EN bit is set.
- Special priority for alpha channels

A priority value is calculated for each of the enabled channels according to the above conditions. Then, the CC unit selects between the channels with the same priority value in a round-robin fashion.

Table 45-8. Calculated priority value

alpha channel	Channel's priority bit	watermark signal	Priority Value
0	0	0	0
0	0	1	1
0	1	0	2
0	1	1	3
1	0	0	1
1	0	1	2
1	1	0	3
1	1	1	4

45.4.2.6.1 Locking the arbitration and reordering the AXI bursts

The performance of the overall system can be improved by sending AXI bursts of consecutive addresses. This can be done by reordering the AXI bursts in a way that accesses that belong to the same channel will be sent one after the other. This can be done by controlling the IDMAC_LOCK_# bits of the corresponding channel.

An IDMAC request that won the arbitration will be served for the next bursts according to the settings of the IDMAC_LOCK_# bits. The block that issued the request (DMFC on IPU) will assert the request only if it has enough room in its FIFO to accept the number

of bursts defined by the IDMAC_LOCK_# bits. IPU provides this capability to channels that serve real time screen refresh to synchronous display (23,27,28). In addition, it provides this capability to channels that may generate very short AXI bursts (IC and IRT)

45.4.2.7 AAU_W & AAU_R- Address Arithmetic Unit for Write and Read

The AAU_R & AAU_W units calculate the address in the system memory to be accessed by the These units also calculate the burst size (BS). The address calculation is done according to parameters stored in the CPMEM.

The following main addressing parameters are used:

- XB-Horizontal pixel position in frame
- YB-Vertical pixel position in frame
- SL-Stride line minus 1 (gap in bytes between two pixels in the same column in two consecutive rows).
- SX-Horizontal pixel scrolling offset
- SY-Vertical pixel scrolling offset
- EBA-Frame buffer base address in bytes (there are two such parameters to support double buffering)
- BPP-Bits per pixel
- FW-Frame width minus 1
- FH-Frame height minus 1

Relations between the addressing parameters and image frame are shown in the table below.

The system memory address in bytes is calculated as:

$$ADDR = EBA + (XB + SX) \cdot BPP + (YB + SY) \cdot (SL + 1)$$

with $0 < XB =< FW$ and $0 < YB =< FH$.

For non-interleaved formats the 4 LSB bits of SX are defined according to the IOX parameter.

When double buffering is used, the EBA0 is the base address of the buffer 0 and the EBA1 is the base address of the buffer 1. The IPU_CHA_CUR_BUF Register is a status register. It contains 1-bit pointers to the current working buffers for all IPU DMA channels. The IPU automatically toggles a pointer after completion of the current buffer processing. If the ARM platform is a data source for specific double-buffered channel, it should check this status bit in order to know what is the IPU current buffer. The ARM platform is allowed to write to the buffer only when a working DMA channel does not

use it. After the ARM platform has been fill the buffer, it has to set the corresponding bit in the IPU_CHA_BUF0_RDY and IPU_CHA_BUF1_RDY Registers. If needed, the ARM platform can only clear the pointer by writing 1 but not set it.

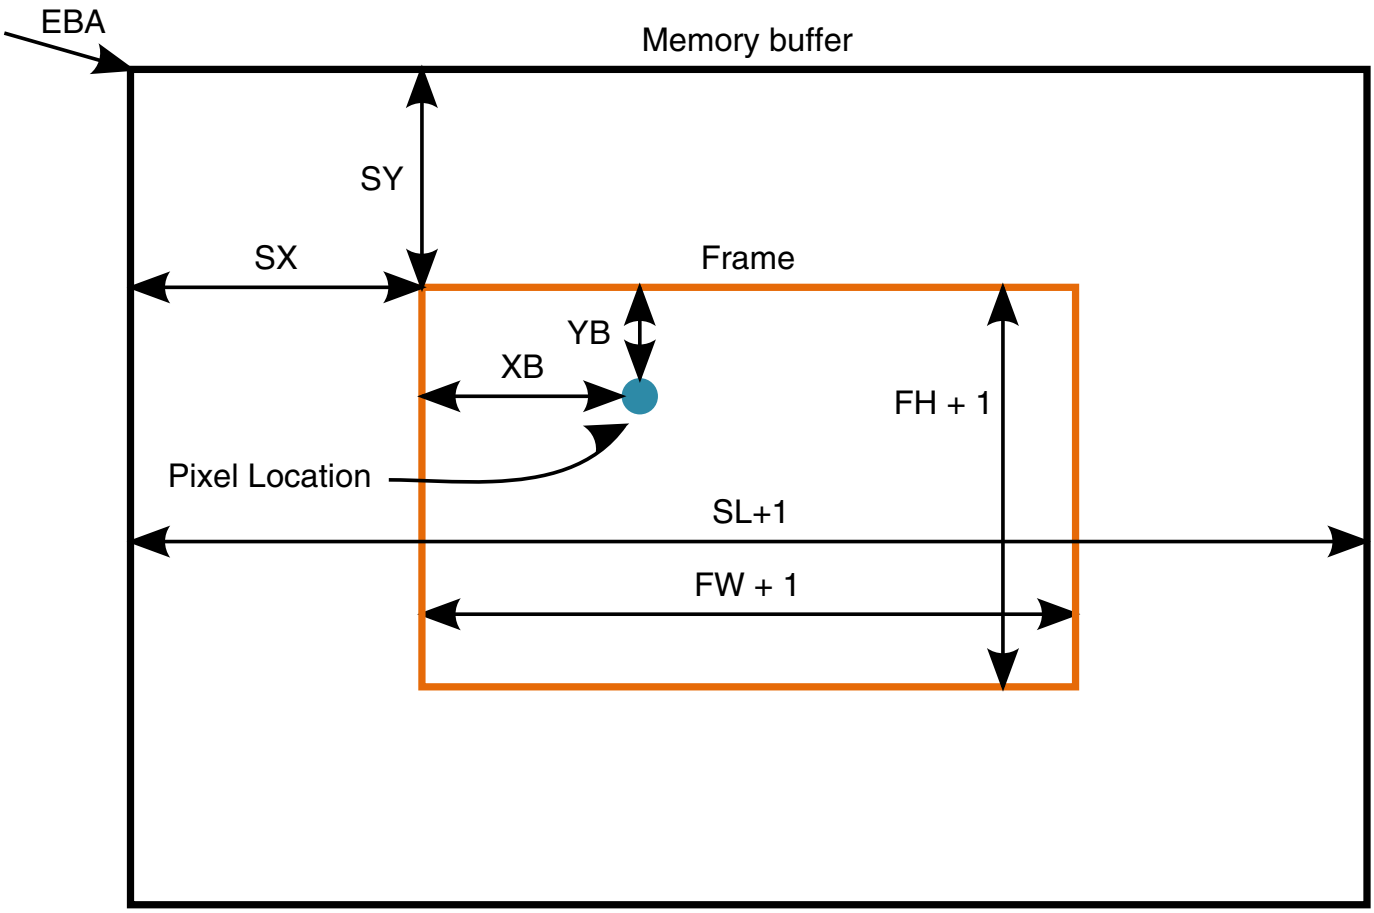

Figure 45-8. Addressing Parameters and Image Frame

The XB and YB coordinates are calculated according to addressing mode. There are two addressing modes:

- 2D mode
- Block mode

In 2D mode the pixel data is transferred to the memory row-by-row. There are two ways to use 2D mode: start from YB = 0 and finish at YB =< FH (YB is incremented) or start from YB = FH and finish at YB =< 0 (YB is decremented). The second option provides vertical flip of the image.

In block mode the frame is divided into blocks. This is needed for rotation or post-filtering, where the order used for data transfers is block-by-block. The order of the block transfer is according to the VF,HF and ROT bits in the IDMAC Channel Parameter

Memory. The order within the block is row-by-row where the block size is limited by the block width (BW) and block height (BH) parameters. The BW and BH parameters are set by IC rotation section and cannot be configured through the Channel Parameter Memory.

The Channel Control is responsible for the address calculation flow. It takes channel parameters from the Channel Parameter Memory, updates them and controls the Address Arithmetic Unit.

45.4.2.7.1 Scrolling support

Automatic display of a changing image (animation) or moving image (scrolling) is implemented by reading frames (from a background buffer) with incremental offset. Enabling the scrolling feature is done by setting the channel's corresponding SCE bit.

The scrolling step is controlled by channel's corresponding SDX and SDY parameters, and the scrolling direction is defined by the channel's corresponding SDRX and SDRY parameters. The maximum number of scrolled frames to be read is defined by the channel's corresponding SM parameter.

When the last programmed frame is reached (IDMAC's internal counter reached SM), IDMAC can perform one of the following (controlled by the SCC bit):

- Return to the first frame, without any SW intervention. The return point is defined by SX0 and SY0 parameters.
- Interrupt the ARM platform, to generate the next content.

45.4.2.8 ATC - Alpha Transparency Controller

The Alpha transparency controller (ATC) handles the alpha buffers on the external memory for cases where the pixel data and the alpha data are located on separate buffers (separate alpha mode). In that case the IDMAC reads the alpha data and the pixel data, merge them together and provides a pixel that includes the alpha information to the relevant sub module.

The ATC's main functions are:

- Generates requests for alpha channels, following a request to pixel data from the module.
- Maintain an internal alpha memory buffer for each channel.
- When there isn't enough alphas in the memory the ATC blocks the corresponding pixel channels.
- When there is a request of pixel channel the ATC load and accumulate its alphas in a register.

- ATC memory controller can manage 8 channels of alphas.
- ATC supports synchronous new frame before end of frame errors.

In order to configure the channel to use separate alpha the channel's corresponding IDMAC_SEP_AL bit should be set in addition to the ALU bit in the CPMEM of the corresponding channel.

The following figure is the ATC's block diagram.

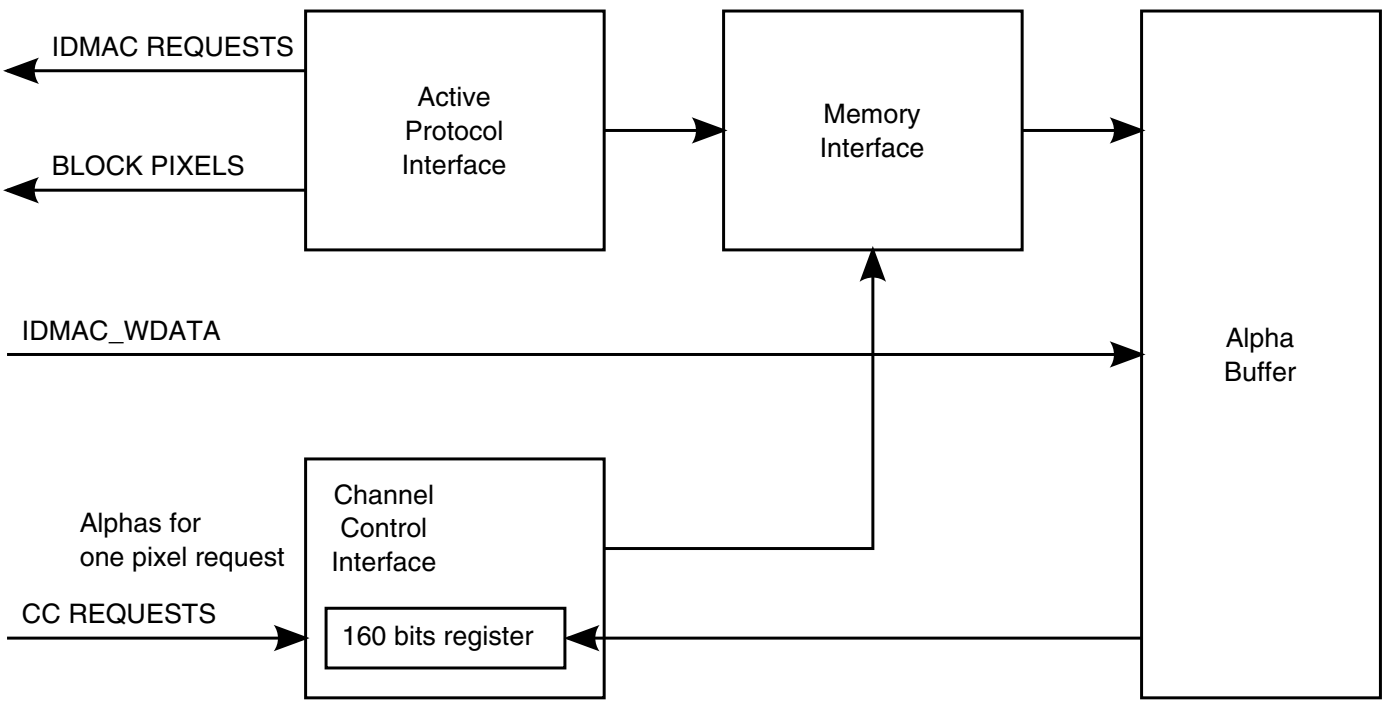

Figure 45-9. ATC block diagram

The ATC alpha buffer memory can hold up to 8 buffers of alphas. A pointer to a buffer in the ATC memory is defined according to the ALBM parameter in the CPMEM. The table below describes the relations between a data channel, an alpha channel and the pointer in the alpha buffer memory.

Table 45-9. Alpha channels mapping

data channel number	associated alpha channel number	Alpha buffer memory (ALBM)
14	17	0
15	18	1
27	31	2
29	33	3
23	51	4
24	52	5

Table continues on the next page...

Table 45-9. Alpha channels mapping (continued)

data channel number	associated alpha channel number	Alpha buffer memory (ALBM)
25	19	6

45.4.2.8.1 Conditional read

The alpha data can be used to reduce reads from the memory of pixels that are going to be transparent (alpha = 0). The conditional read feature is enabled by the CRE bit in the CPMEM.

If all of the corresponding alpha values for a single burst of pixels are equal to zero, the IDMAC will block the access to the external memory and provide a data of all zeros to the corresponding channel. This way some of the accesses to the memory can be prevented, thus reducing the load on the memory.

45.4.2.9 LUT- Look Up Table

When working in coded pixel format, the data read from the memory is the decoded value of pixel according to address given. In case of 8 bit code, the data read from the memory is the decoded value of the pixel according to the address given.

In case of 4 bit code configuration, The address of the 4 bit decoded values is set according to DEC_SEL parameter in the CPMEM

00 = addresses 0 to 15

01 = addresses 64 to 79

10 = addresses 128 to 143

11 = addresses 192 to 207

Table 45-10. Look-Up Table Memory Structure

Address	Word	DEC_SEL	Description

45.4.2.10 CPMEM - Channel Parameter Memory

The CPMEM holds the configuration parameters for each IDMAC channel. The CPMEM can holds the settings of 80 channels. Each channel's settings are defined by a two mega-words. Each mega-word is 160 bits wide.

The following diagram illustrates the CPMEM's structure.

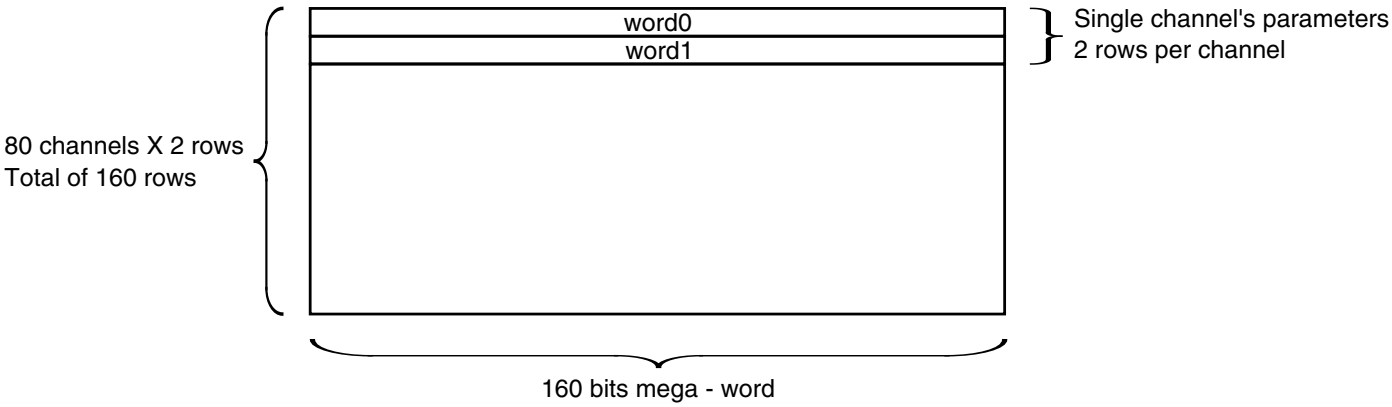

Figure 45-10. CPMEM structure

Each IDMAC channel can be configured to work in one of two different modes:

- Non Interleaved mode where the Y:U:V data is organized in 3 separate buffers in the system's memory
- Interleaved mode where the Y:U:V data is organized in a single buffer in the system's memory

The parameters and the way they are organized are different for each mode. The Pixel Format Select (PFS) value of the CPMEM words are used by the IPU to determine if the words should be interpreted as interleaved or non-interleaved format.

The following tables describe the IDMAC parameters and their organization in each mode.

45.4.2.10.1 CPMEM's words' structure for non interleaved mode

The table below describes the CPMEM's words' structure for non interleaved mode. Each CPMEM word consist of 160 bits. The bits that are not listed in the table below are reserved bits.

Table 45-11. Channel Parameters Memory for non-interleaved

Name	Mnemonic	Size	Location	Description
Word 0				
XV Virtual Coordinate	XV	10 bits	W0[9:0]	Variable coordinates for determining next block address. {X1,Y1} and {X2,Y2} coordinates will be determined according to {XV,YV} upon restart of channel. These coordinates are used for Y:U:V (Y pointer) and RGB formats.
YV Virtual Coordinate	YV	9 bits	W0[18:10]	

Table continues on the next page...

Table 45-11. Channel Parameters Memory for non-interleaved (continued)

XB inner Block Coordinate	XB	13 bits	W0[31:19]	Variable coordinates for determining address within the block. These coordinates are used for Y:U:V (Y pointer) and RGB formats. Need 24 bits for 2D transfer support.
YB inner Block Coordinate	YB	12 bits	W0[43:32]	
New Sub Block	NSB_B	1 bit	W0[44]	This bit determines if the next value for {XB,YB} should be taken from {XB,YB} saved in channel parameter memory or from new {x1,y1}/{x2,y2}.
Current Field	CF	1 bit	W0[45]	CF = 0 Current field is even CF = 1 Current field is odd
Mem U Buffer Offset	UBO	22 bits	W0[67:46]	Double buffer destination address offset for Y:U:V (U pointer) formats.The actual physical address value is divided by 8 (i.e. this parameter includes bits [24:3] of the actual address)
Mem V Buffer Offset	VBO	22 bits	W0[89:68]	Double buffer destination address offset for Y:U:V (V pointer) format. The actual physical address value is divided by 8 (i.e. this parameter includes bits [24:3] of the actual address)
Initial Offset X	IOX	4 bits	W0[93:90]	The IOX parameter, is the offset in pixels for a frame that starts at a non aligned address. for 42x formats must be even.
Reduce Double Read or Writes	RDRW	1 bits	W0[94:94]	This bit is relevant for YUV4:2:0 formats. For read channels: U and V components are not read from odd rows. (read - supported only for the VDIC) For write channels: U and V components are not written to odd rows. (write - supported for all write channels)
Scan Order	SO	1 bit	W0[113]	SO = 0 Scan order is progressive SO = 1 Scan order is interlaced

Table continues on the next page...

Table 45-11. Channel Parameters Memory for non-interleaved (continued)

Band Mode	BNDM	3 bits	W0[116:114]	BNDM = 000 bands disable. BNDM = 001 bands enable. Band height = 4 lines. BNDM = 010 bands enable. Band height = 8 lines. BNDM = 011 bands enable. Band height = 16 lines. BNDM = 100 bands enable. Band height = 32 lines. BNDM = 101 bands enable. Band height = 64 lines. BNDM = 110 bands enable. Band height = 128 lines. BNDM = 111 bands enable. Band height = 256 When working in band mode, the channel's corresponding IDMAC_BNDM_EN bit has to be set.
Block Mode	BM	2 bits	W0[118:117]	BM = 00 block mode disable. BW = FW, BH = FH BM = 01 block mode enable. BW = 8, BH = 8 BM = 10 block mode enable. BW = 16, BH = 16 (this mode is reserved for future use) BM = 11 not used
Rotation	ROT	1 bit	W0[119]	ROT = 0 -> No rotation ROT = 1 -> 90 degree rotation clockwise
Horizontal Flip	HF	1 bit	W0[120]	HF = 0 -> No flip HF = 1 -> Horizontal flip enable
Vertical Flip	VF	1 bit	W0[121]	VF = 0 -> No flip VF = 1 -> Vertical flip enable
Threshold Enable	THE	1 bit	W0[122]	THE = 0 -> Threshold disable THE = 1 -> Threshold enable
Conditional Access Polarity	CAP	1 bit	W0[123]	CAP = 0 -> If conditional bit in CM register is low skip the access CAP = 1 -> If conditional bit in CM register is high skip the access. This mode is reserved for future use.
Conditional Access Enable	CAE	1 bit	W0[124]	CAE = 0 -> Conditional access disable CAE = 1 -> Conditional access enable This mode is reserved for future use.

Table continues on the next page...

Table 45-11. Channel Parameters Memory for non-interleaved (continued)

Frame Width	FW	13 bits	W0[137:125]	Number of pixels in one row, of the channel frame. FW 000000000000 = 0001 pixels 000000000001 = 0002 pixels ..... 111111111111 = 8192 pixels
Frame Height	FH	12 bits	W0[149:138]	Number of pixels in one column, of the channel frame. FH 000000000000 = 0001 line 000000000001 = 0002 lines ..... 111111111111 = 4096 lines For progressive YUV 4:2:0 (non interleaved and partial interleaved formats) the FH value should be a multiple of 2. For interlaced YUV 4:2:0 (non interleaved and partial interleaved formats) the FH value should be a multiple of 4.
Word 1				
Ext Mem Buffer 0 Address	EBA0	29 bits	W1[28:0]	1st double buffer destination address for RGB and Y:U:V (Y pointer) formats. This parameter must not be changed if the corresponding channel is enabled. The actual physical address value is divided by 8 (i.e. this parameter includes bits [31:3] of the actual address)
Ext Mem Buffer 1 Address	EBA1	29 bits	W1[57:29]	2nd double buffer destination address for RGB and Y:U:V (Y pointer) formats. This parameter must not be changed if the corresponding channel is enabled. The actual physical address value is divided by 8 (i.e. this parameter includes bits [31:3] of the actual address)
Interlace Offset	ILO	20 bits	W1[77:58]	2nd double buffer destination address for RGB and Y:U:V (Y pointer) formats. An interlaced data stored in the memory can be read as a consecutive progressive only if FW*BPP is a multiplication of 8. The actual physical address value is divided by 8 (i.e. this parameter includes bits [22:3] of the actual address). For YUV420 formats, the ILO is relevant only to the Y component as the U and V components do not exist for the even lines. This value is signed

Table continues on the next page...

Table 45-11. Channel Parameters Memory for non-interleaved (continued)

Number of Pixels in Whole Burst Access	NPB	7 bits	W1[84:78]	Number of pixels per burst access. The following are valid numbers of pixels in a memory burst access according to the BPP parameter: NPB 0000111 = 08 pixels in each burst 0001111 = 16 pixels in each burst ..... 0111111 = 64 pixels in each burst Range: 16BPP => 1 -> 32 pixels (for YUV444 NI) 08BPP => 1 -> 64 pixels (For YUV420 NI/PI and YUV422 NI/PI) In NI/PI formats the NPB has to be a multiplication of 8
Pixel Format Select	PFS	4 bits	W1[88:85]	4'h0 = non-interleaved 4:4:4 4'h1 = non-interleaved 4:2:2 4'h2 = non-interleaved 4:2:0 4'h3 = partial interleaved 4:2:2 4'h4 = partial interleaved 4:2:0 4'h5 to 4'hF = NA
Alpha Used	ALU	1 bit	W1[89]	1 = the alpha associated with the data of this channel resides on another channel (separate buffer) 0 = the alpha associated with the data of this channel resides along with the pixel data (same buffer) The corresponding alpha channel must be enabled to assure correct behavior.
Alpha Channel Mapping	ALBM	2 bits	W1[92:90]	Alpha channel mapping - This parameter is a pointer to a buffer in the ATC memory. This parameter is relevant only to data channels that are associated with a separate alpha buffer (like graphic plane channels). The parameter should be programmed on the data channels' ALBM. Setting this parameter to any other channel has no meaning. See Table 45-9 for exact ALBM mapping.
AXI Id	ID	2 bits	W1[94:93]	AXI protocol id
Threshold	TH	7 bits	W1[101:95]	0000000 = 32 lines 0000001 = 64 lines ..... 1111111 = 4096 lines

Table continues on the next page...

Table 45-11. Channel Parameters Memory for non-interleaved (continued)

Stride Line	SLY	14 bits	W1[115:102]	Address vertical scaling factor in bytes for memory access. Also number of maximum bytes in the "Y" component row according to memory limitations. SLY 00000000000000 = 00001 bytes 00000000000001 = 00002 bytes ..... 11111111111111 = 16384 bytes
Width3	WID3	3 bits	W1[127:125]	Fourth color component size of the input-unpacking/ output-packing pixel. WID3 000 = 1 bits 001 = 2 bits ..... 111 = 8 bits As this is a non-interleaved format, this field is relevant only to the alpha associated with this pixel channel.
Stride Line	SLUV	14 bits	W1[141:128]	Address vertical scaling factor in bytes for memory access. Also number of maximum bytes in the "U" or "V" component row according to memory limitations. SLUV 00000000000000 = 00001 bytes 00000000000001 = 00002 bytes ..... 11111111111111 = 16384 bytes
Conditional Read Enable	CRE	1 bit	W1[149:149]	This bit enables the conditional read feature.

45.4.2.10.2 CPMEM's words' structure for interleaved mode

The table below describes the CPMEM's words' structure for interleaved mode. Each CPMEM word consist of 160 bits. The bits that are not listed in the table below are reserved bits

Table 45-12. Channel Parameters Memory for interleaved

45.4.2.10.3 Accessing the CPMEM for programming

Each IDMAC's channel's parameters are located on 2 CPMEM entries. Each Entry is 160 bit. The CPMEM is memory mapped and is accessible via the AHB bus. The AHB bus's accesses are 32bit wide. A CPMEM entry is composed of 5x32bit words. The next CPMEM entry starts at the next 8x32bit words (0x0, 0x20,0x40, etc.).

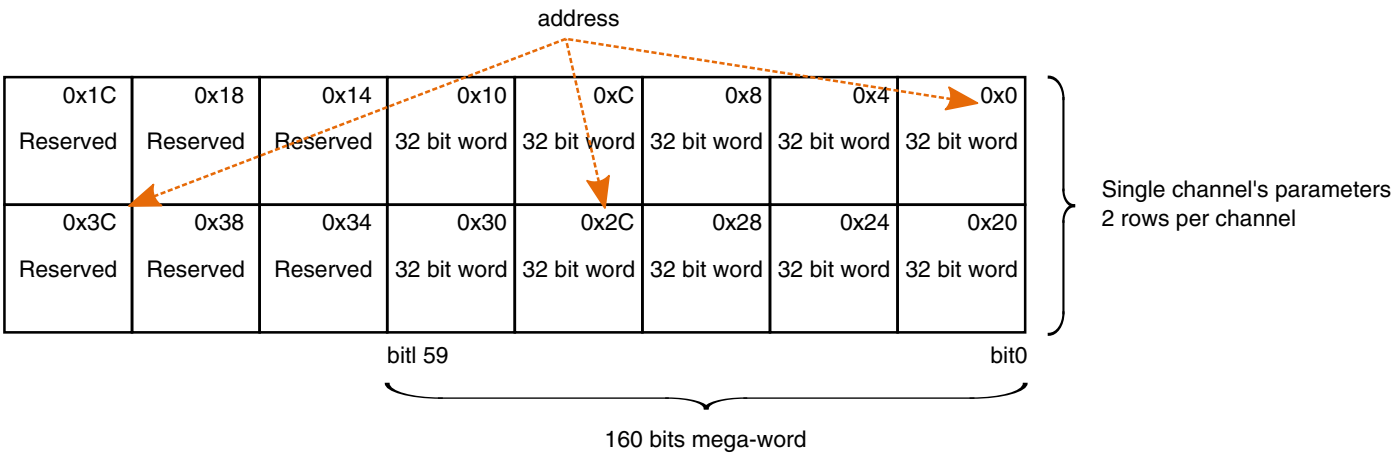

Figure 45-11. CPMEM's word structure

45.4.2.10.4 Alternate IDMAC settings

Some of the IDMAC channels support alternate flow. This means that a physical IDMAC channel can use alternate set of parameters. Switching between the flows is controlled by the CM.

The primary flow the IDMAC's settings are read from the channel's corresponding entry in the CPMEM. The alternate settings can be stored in another entry on the CPMEM. The pointer to the alternate entry on the CPMEM is stored on the physical channel's corresponding IDMAC_SUB_ADDR parameters.

45.4.2.11 IDMAC's modes of operation

45.4.2.11.1 Rotation modes

Rotation is performed by the IDMAC and the Rotation unit inside the IC.

The frame is partitioned into 8X8 pixels blocks. The IC reorders the pixels within a block. The IDMAC reorders the block. The reordering is done according to the ROT, VF & HF parameters in the CPMEM.

The following diagram illustrate various options for reordering of blocks

- ROTATE means that the ROT bit is set
- HORIZONTAL means that the HF bit is set
- VERTICAL means that the VF bit is set

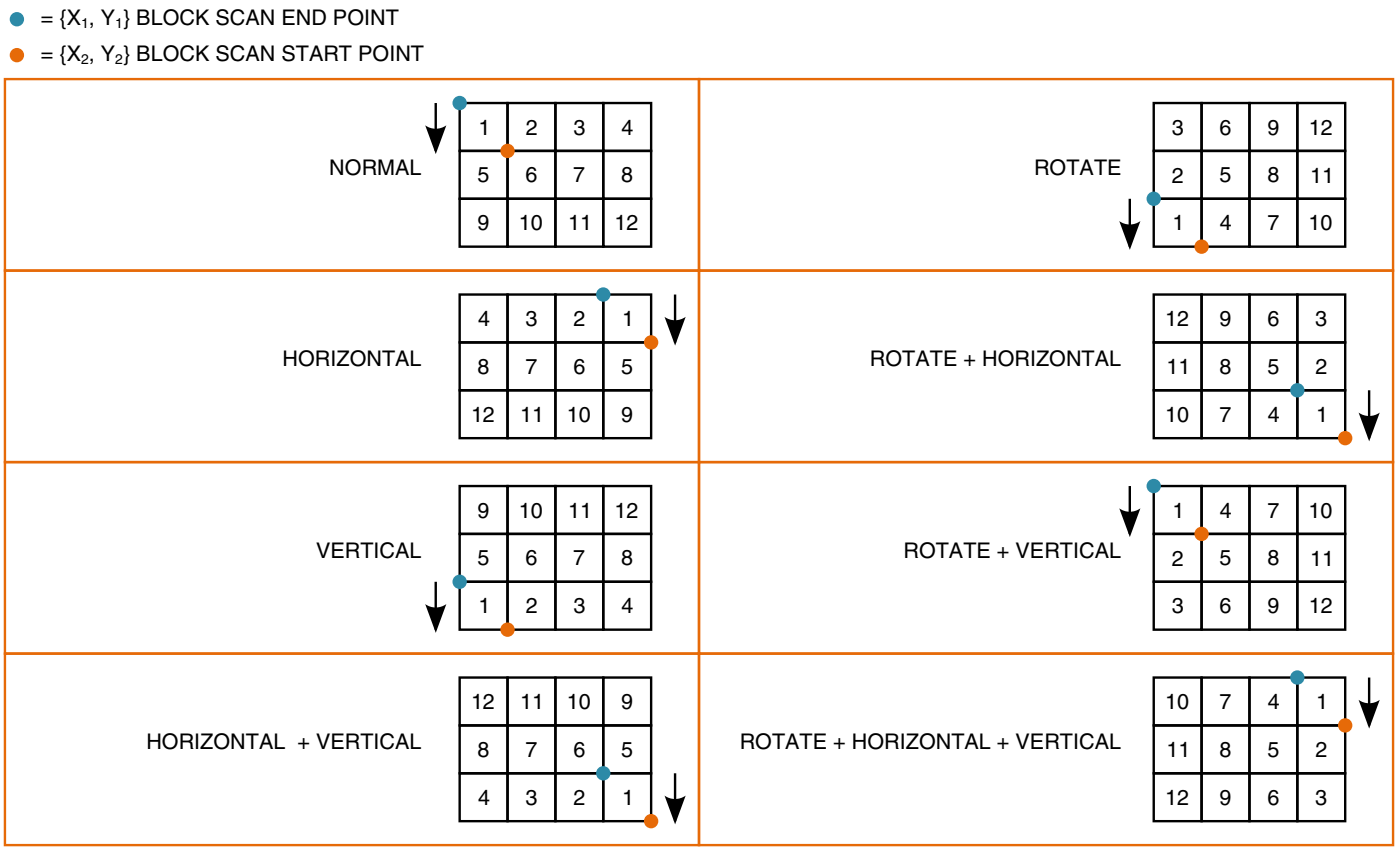

Figure 45-12. Rotation options

45.4.2.11.2 Frame size

The IPU supports various non-interleaved modes; the Frame Height (FH) and Frame Width (FW).

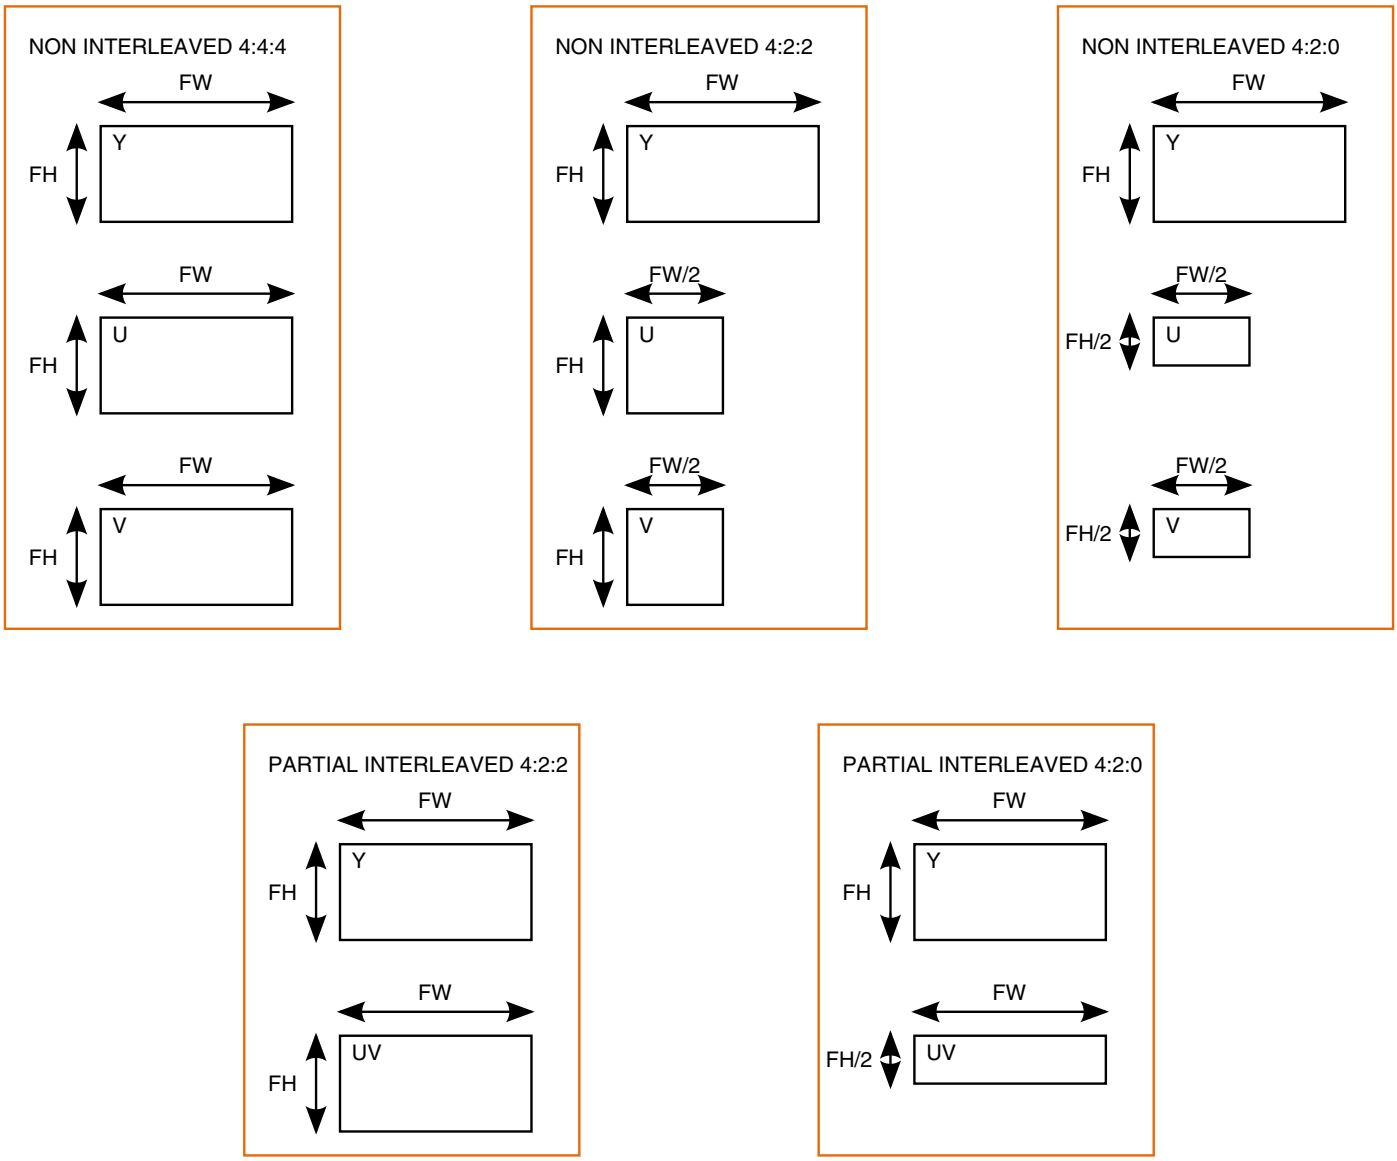

Figure 45-13. Frame size in various modes

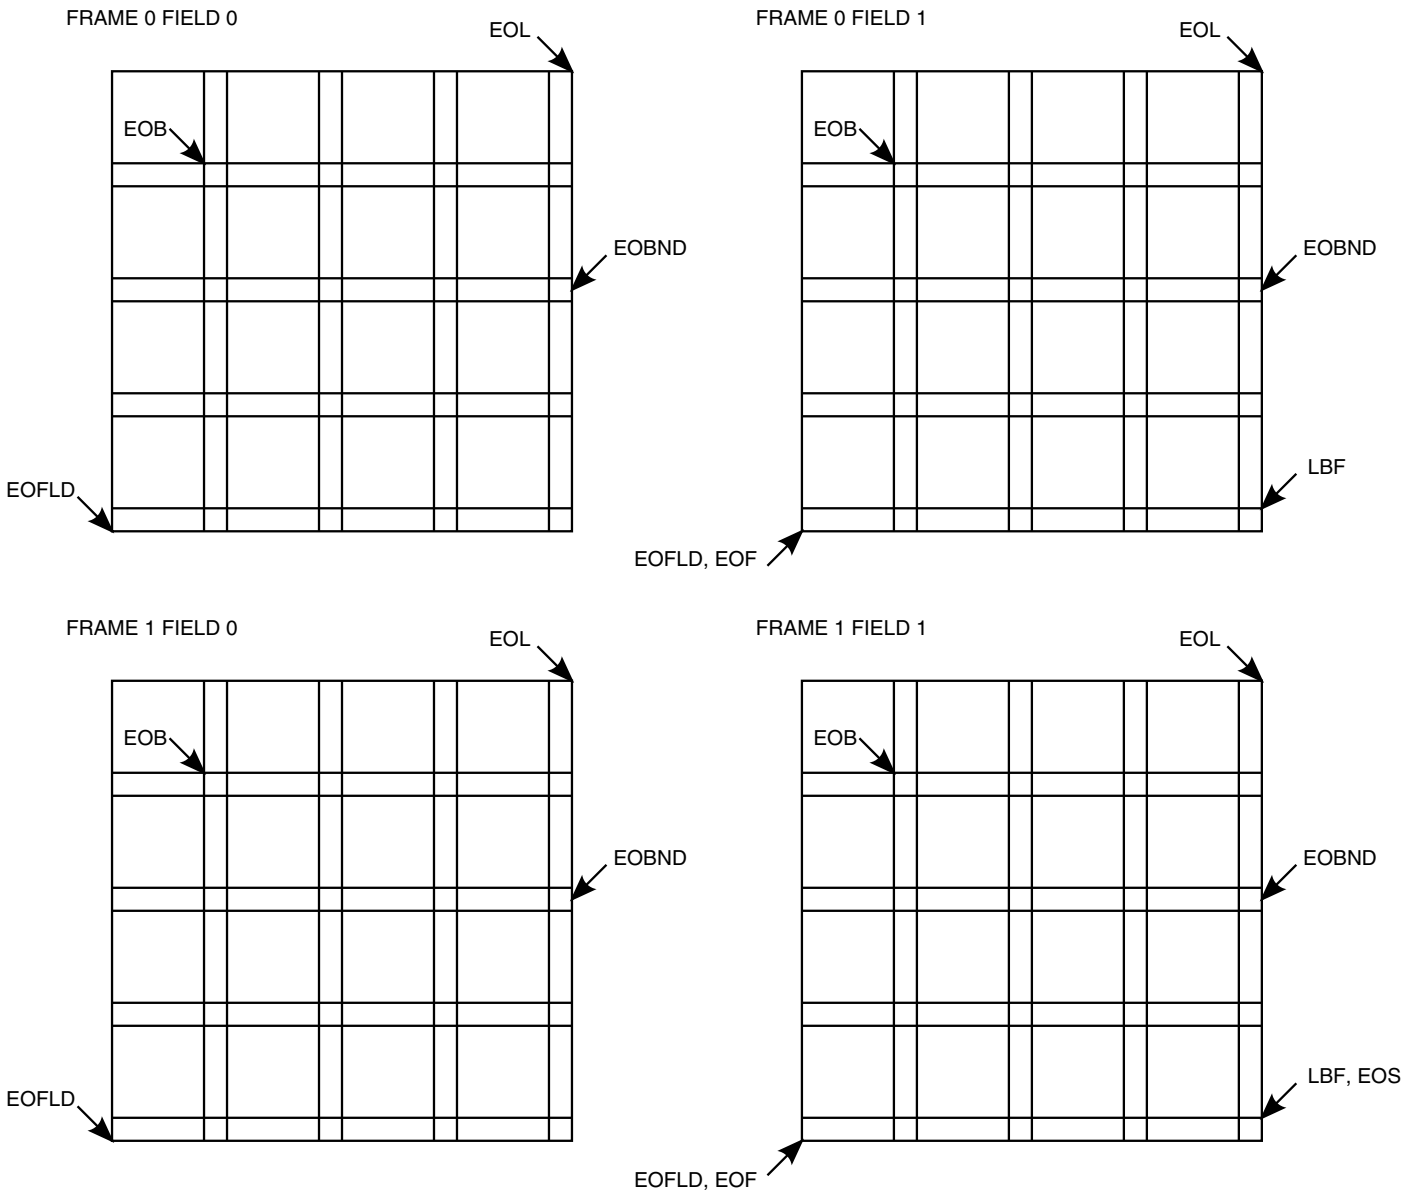

Figure 45-14. Frame's controls

45.4.2.12 IDMAC's restriction

The data must be received from the system's memory through the AXIR interface ("read" direction) "in-order" within a single burst. The entire burst can occur "out-of-order."

45.4.2.13 IDMAC's Endianness support

Byte Endianness - only LE (little endian) is supported

Pixel Endianness - both LE & BE are supported, only for read direction (only 4 BPP case is meaningful, supported only for the "read" direction)

45.4.2.14 IDMAC's internal events

Some of the IDMAC's internal signals can be used for monitor the progress of flows. These bits can be polled by software. Some of these bits can be used to trigger an interrupt or an SDMA event.

The following table describes the available events and their meaning

Table 45-13. IDMAC's internal events

IDMAC event's type	Monitored on	Event's meaning
end of frame	IDMAC_EOF	This is the channel's end of frame indication. This indication is asserted once the entire frame was read/written via the IDMAC. This indication is normally used as an interrupt or SDMA event
new frame acknowledge	IDMAC_NFACK	This indication means that the IDMAC acknowledge the new frame's request from the module. It can be used to track the starting point of a flow or a frame.
new frame before end of frame error	IDMAC_NFB4EOF_ERR	This error indication may indicate on data lost. This indication is asserted when a new frame starts before the completion of the previous frame. For example if a real time input (from camera) was not written properly to the memory due to FIFO full condition.
end of scroll	IDMAC_EOS	end of scroll; This indication is asserted when the scroll counter finished counting its pre defined value
end of band	IDMAC_EOBND	This is the end of band indication. Any time IDMAC complete reading/writing a band it will assert this indication. This is useful to manually control a flow via channels working in band mode.
treshold	IDMAC_TH	Threshold crossing indication. The treshold is defined according to the TH parameter in the IDMAC.
channel busy	IDMAC_CH_BUSY	This signal is asserted when a channel is between NFACK event to EOF event. Negation of these indications is one of the conditions for low power modes handshake.

45.4.3 Camera Sensor Interface (CSI)

The IPU has 2 identical camera sensor interfaces (CSI). The CSI description below refers to a single CSI.

45.4.3.1 CSI Block Diagram

This figure shows the CSI Block Diagram.

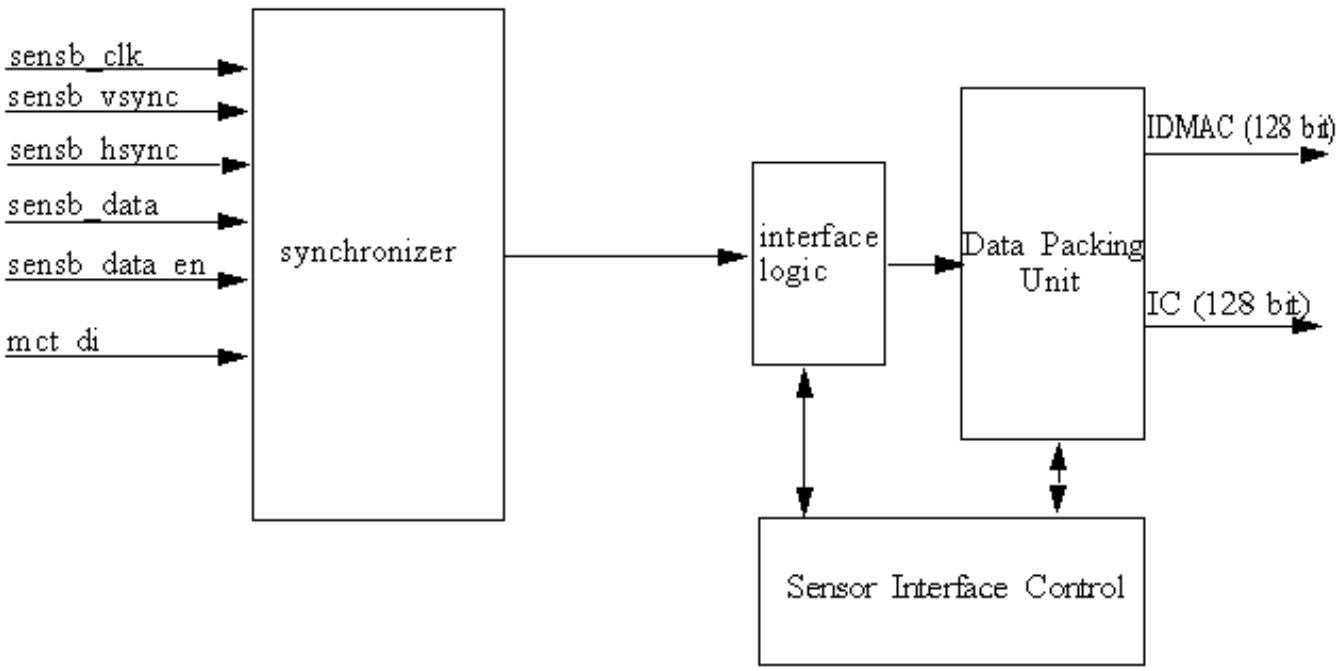

Figure 45-15. CSI Block Diagram

The CSI consists of synchronizer, interface logic, Data packing unit and Sensor Interface Control. The CSI is controlled via the peripheral bus registers. All programming parameters for the CSI are double buffered with synchronous change at the frame start.

The CSI gets data from the sensor, synchronizes the data and the control signals to the IPU clock (HSP_CLK), and transfer it according to configuration of DATA_DEST register to one or more of the following: IC, SMFC.

45.4.3.2 CSI Interface

CSI supports two types of interfaces. The interface is determined via the DATA_SOURCE register.

45.4.3.2.1 Parallel interface

In parallel interface a single value arrives in each clock, except when working in BT.1120 mode, in which two values arrive in each cycle. Each value can be 8-16 bit wide according to configuration of DATA_WIDTH. If DATA_WIDTH is configured to N, then 20-N LSB bits are ignored.

CSI can work with several data formats according to SENS_DATA_FORMAT configuration. In case the data format is YUV, the output of the CSI is always YUV444 (even if the data arrives in YUV422 format).

The polarity of the inputs can be configured using the registers SENS_PIX_CLK_POL, DATA_POL, HSYNC_POL and VSYNC_POL.

45.4.3.3 TEST MODE

When TEST_GEN_MODE register is configured to 1, the TEST MODE which is a debugging mode, is operated.

The CSI generates the frame by itself and sends it to one of the destination units. The sent frame is a chess board composed of black and configured color squares. The configured color is set with the registers PG_B_VALUE, PG_G_VALUE and PG_R_VALUE. The data can be sent in different frequencies according to the configuration of DIV_RATIO register.

CSI Test Mode requires the following CSIx_SENS_CONF settings:

CSIx_EXT_VSYNC = 0x1 (External VSYNC mode)

CSIx_DATA_WIDTH = 0x1 (8 bits per color)

CSIx_SENS_DATA_FORMAT = 0x0 (Full RGB or YUV444)

CSIx_PACK_TIGHT = 0x0 (Each component is written as a 16 bit word where the MSB is written to bit #15, color extension is done for the remaining leat significant bits.)

CSIx_SENS_PRTCL = 0x1 (Non-gated clock sensor timing/data mode)

CSIx_SENS_PIX_CLK_POL = 0x1 Pixel clock is inverted before applied to internal circuitry

CSIx_DATA_POL = 0x0 (Data lines are directly applied to internal circuitry.)

CSIx_HSYNC_POL = 0x0 (HSYNC is directly applied to internal circuitry)

CSIx_VSYNC_POL = 0x0 (VSYNC is directly applied to internal circuitry)

45.4.3.4 Sensor Image Frame Relations

The figure below illustrates the generalized relations between image frames produced by a sensor and accepted by the CSI. Generally, four frame definitions exist. The virtual frame A starts with the VSYNC signal. After vertical blanking starts frame B. The HSYNC signal indicates boundaries of the frame B. The frame B includes both the active sensor frame C and horizontal blanking intervals. A size of the blanking intervals depends on sensor type and programming. The size of the frame sent by the sensor (the actual pixels) has to be configured in the registers SENS_FRM_WIDTH and SENS_FRM_HEIGHT. The CSI selects a window (the frame D) inside the frame C by skipping rows and columns according to parameters defined in registers HSC, VSC, ACT_FRM_HEIGHT and ACT_FRM_WIDTH. frame D is sent to the rest of the IPU.

NOTE

The following limitation must exist:

SENS_FRM_HEIGHT >= VSC + ACT_FRM_HEIGHT

SENS_FRM_WIDTH >= HSC + ACT_FRM_WIDTH

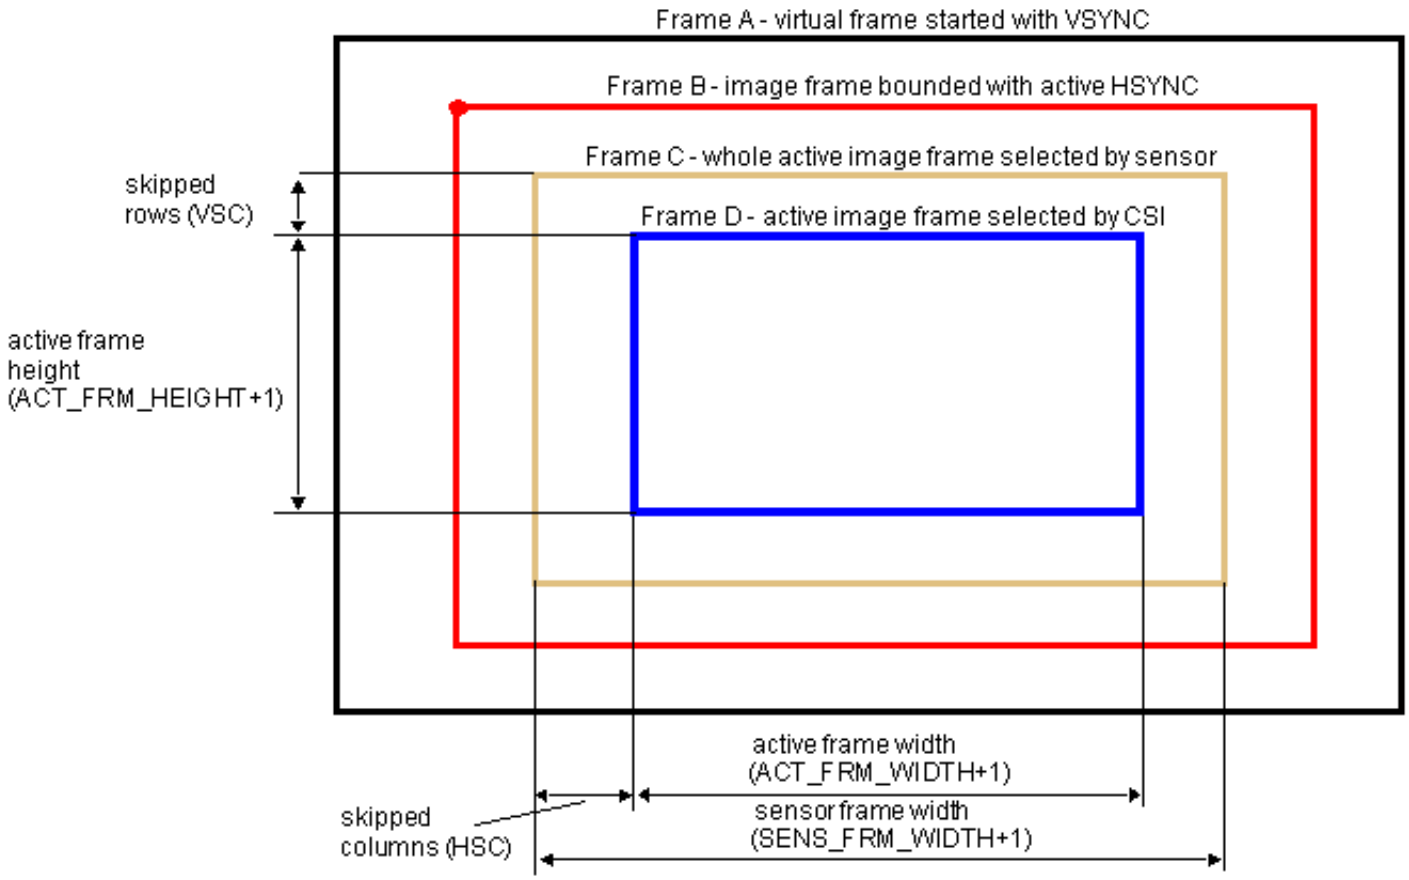

Figure 45-16. Sensor Image Frames

45.4.3.5 Timing/Data mode protocols

CSI can work in several timing/data mode protocols, according to SENS_PRTCL configuration.

45.4.3.5.1 gated mode

In this mode VSYNC is used to indicate beginning of a frame, HSYNC is used to indicate beginning of a raw. Sensor clock is ticking all the time.

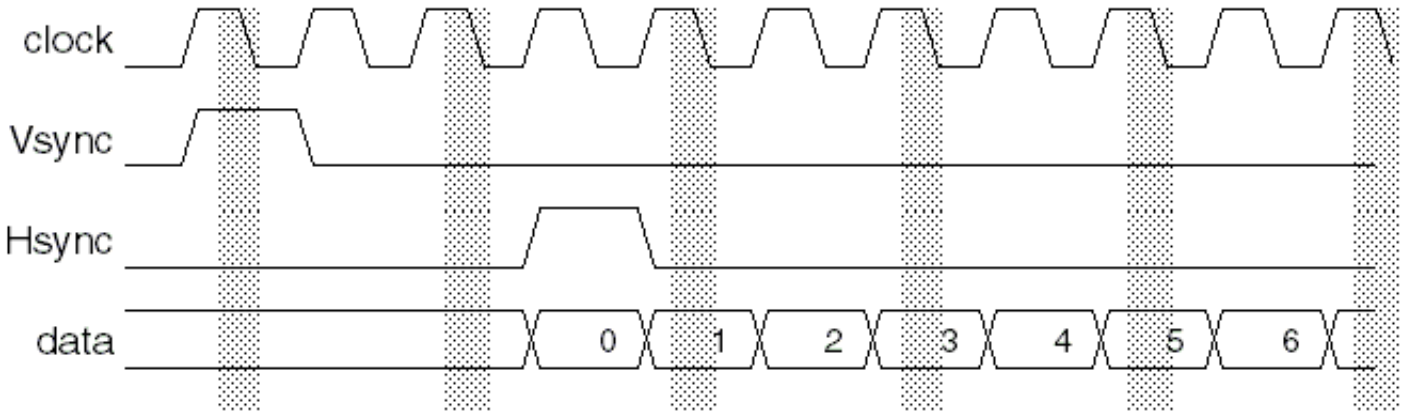

Figure 45-17. gated mode

45.4.3.5.2 non-gated mode

In this mode VSYNC is used to indicate beginning of a frame. Sensor clock is ticking only when data is valid. HSYNC is not used.

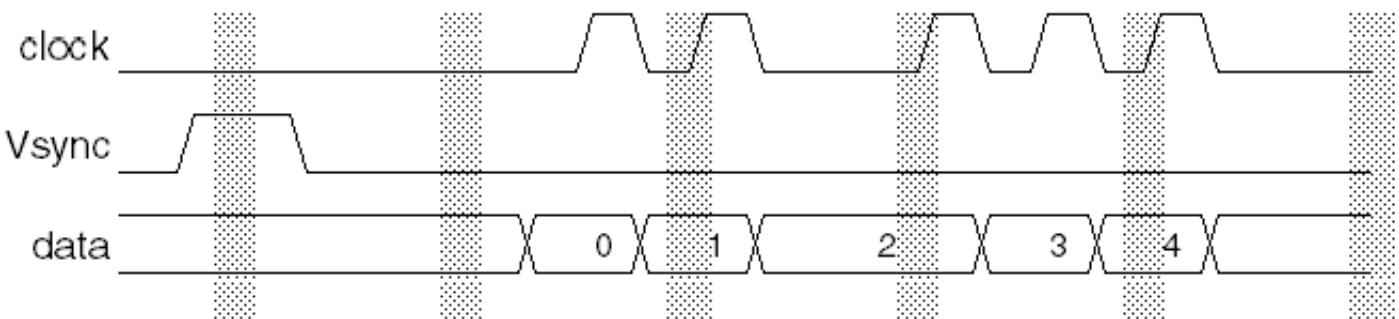

Figure 45-18. non-gated mode

45.4.3.5.3 BT.656 mode

In this mode the CSI works in compliance with recommendation ITU-R BT.656. The timing reference signals (frame start, frame end, line start, line end) are embedded in the data bus input. Each timing reference signal consists of a four word se

three words are fixed and configured in the CCIR_PRECOM register. The fourth word contains information defining field, the state of field blanking and the state of line blanking. these states are configured in registers CCIR_CODE_1 (for field 0) and CCIR_CODE_2 (for field 1).

In this mode in each cycle one value of data arrives

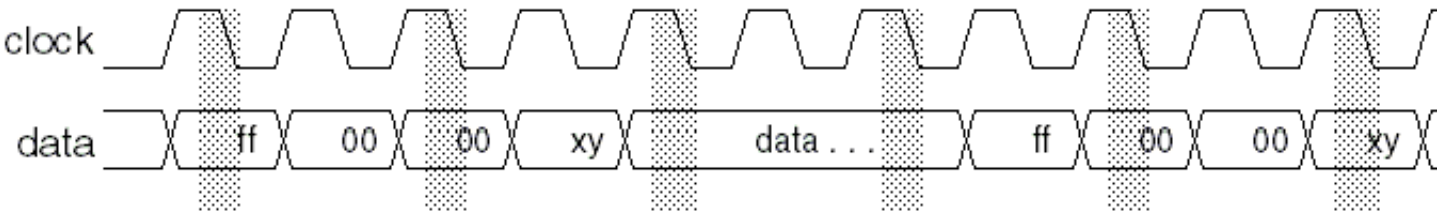

Figure 45-19. BT.656 mode

In this diagram the first three words are 0xff, 0x00, 0x00. The fourth word is XY and it includes the timing reference.

45.4.3.5.4 BT.1120 mode

In this mode the CSI works in compliance with recommendation ITU-R BT.1120. The timing reference signals (frame start, frame end, line start, line end) are embedded in the data bus input. Each timing reference signal consists of a four word sequence. The first three words are fixed and configured in the CCIR_PRECOM register. The fourth word contains information defining field, the state of field blanking and the state of line blanking. these states are configured in registers CCIR_CODE_1 (for field 0) and CCIR_CODE_2 (for field 1).

In this mode, the CSI can also work in DDR mode - data arrives on every edge of the clock. In addition, in each cycle two value of data arrive.

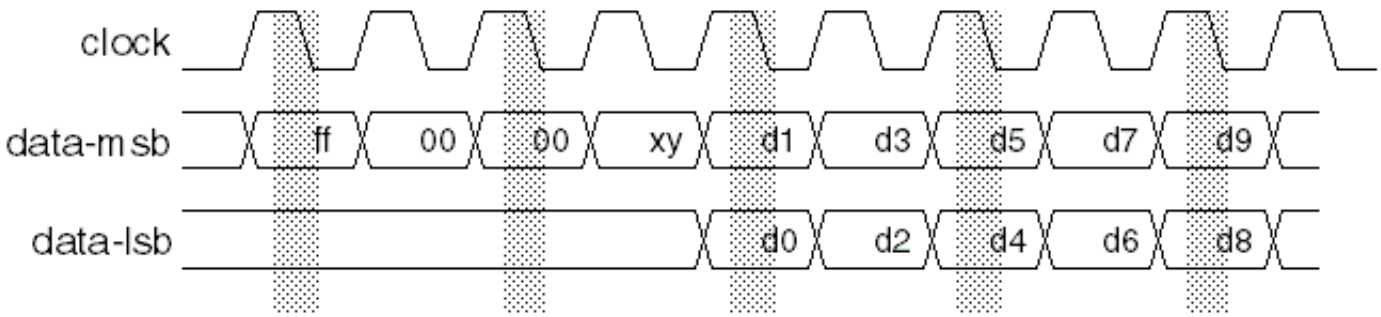

Figure 45-20. BT.1120 mode - SDR mode

In the above diagram each data arrives with the positive edge of the clock.

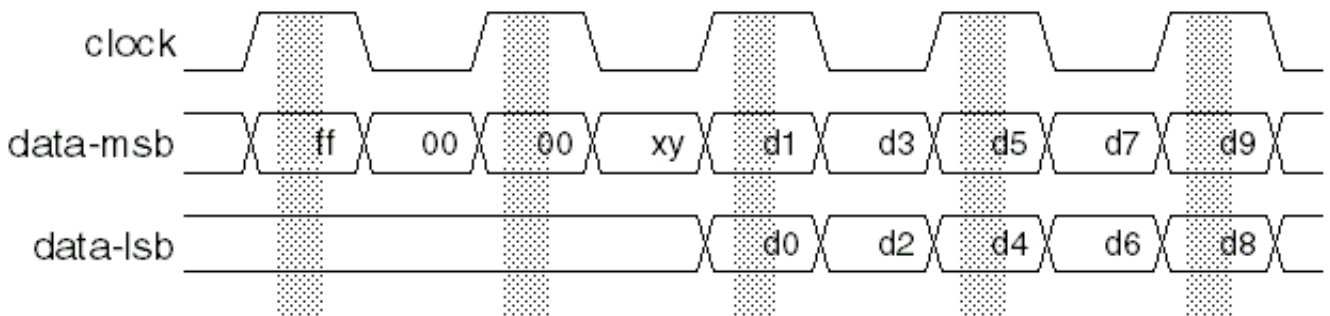

Figure 45-21. BT.1120 mode - DDR mode

In the above diagram, data arrives in the positive edge and the negative edge of the clock.

45.4.3.6 Packing to memory

The data bus output to the SMFC is 128-bit.

The following table shows the how the CSI performs the packing before sending the data to the SMFC.

The data bus output to the SMFC is 128-bit. The following table shows the how the CSI performs the packing before sending the data to the SMFC.

Table 45-14. Packing Unit

data format	component size	companded	regular packing	tight packing
Bayer, Generic data, JPEG	8	{8DC[1] ,8DC,8DC,...,8DC}	{8D,8D,8D,...,8D[2] }	NA
	9-16	{8DC,8DC,8DC,...,8DC}	{16DE[3] ,16DE,...,16DE}	NA
RGB, YUV	8	{8DC,8DC,8DC,8R}	{8D,8D,8D,8R}	NA
	9-10	{8DC,8DC,8DC,8R}	{16DE,16DE,16DE,16R[4] }	{10DE,10DE,10DE,2R}
	11-16	{8DC,8DC,8DC,8R}	{16DE,16DE,16DE,16R}	{10DT[5] ,10DT,10DT,2R}

1. DC - data after being companded
2. D - data arrived from sensor.
3. DE - data after being extended.
4. R- reserved bits
5. DT - data after being truncated.

The tight packing functionality is enabled when PACK_TIGHT register is set. It is only used when data format is RGB or YUV and the data width is bigger than 8.

45.4.3.7 Skipping frames

Some of the frames that are sent to the SMFC can be skipped. skipped frames are ignore by the CSI and are not sent to the corresponding unit. Using SKIP_SMFC and MAX_RATIO_SKIP_SMFC registers the user can define the frames for the SMFC that will be skipped.

45.4.3.8 16 bit camera support

Devices that support 16 bit data bus can be connected to the CSI. This can be done in one of the following ways.

16 bit YUV422

In this mode the CSI receives 2 components per cycle. The CSI is programmed to accept the data as 16 bit generic data. The captured data will be stored in the memory through the SMFC. The IDMAC needs to be programmed to store 16bit generic data. When the data is read back from the memory for further processing in the IPU it will be read as YUV422 data.

16 bit RGB as generic data

In this mode the CSI receives 3 components per cycle. If the external device is 24bit - the user can get connect a 16 bit sample of it (such as RGB565) The CSI is programmed to accept the data as 16 bit generic data. The captured data will be stored in the memory through the SMFC. The IDMAC needs to be programmed to store 16bit generic data. When the data is read back from the memory for further processing in the IPU it will be read as 16 bit RGB data. The IDMAC's mapping unit will be used

to remap the 16 bit data to the internal 24bpp RGB format In this mode on the fly processing is can't be performed. The data has to be sent to the memory first and then further processed by the IPU.

16 bit RGB565

This is the only mode that allows on the fly processing of 16 bit data. In this mode the CSI is programmed to receive 16 bit generic data. In this mode the interface is restricted to be in "non-gated mode" and the CSI#_DATA_SOURCE bit has to be set If the external device is 24bit - the user can connect a 16 bit sample of it (RGB565 format). The IPU has to be configured in the same way as the case of CSI#_SENS_DATA_FORMAT=RGB565

45.4.3.9 CSI Restrictions

The frequency of the sensor clock must not be greater than the IPU clock (HSP_CLK)

SENS_FRM_HEIGHT >= VSC + ACT_FRM_HEIGHT

SENS_FRM_WIDTH >= HSC + ACT_FRM_WIDTH

45.4.4 Sensor Multi FIFO Controller (SMFC)

The Sensor Multifile Controller used as buffer between CSI and IDMAC. Two masters (CSIs) can be connected to SMFC. Both masters can be active simultaneously.

Each master can send up to 4 frames, distinguished by csi_id bus. The frame can be mapped to one of four IDMAC channels via SMFC mapping registers. Each DMA channel have dedicated FIFO.

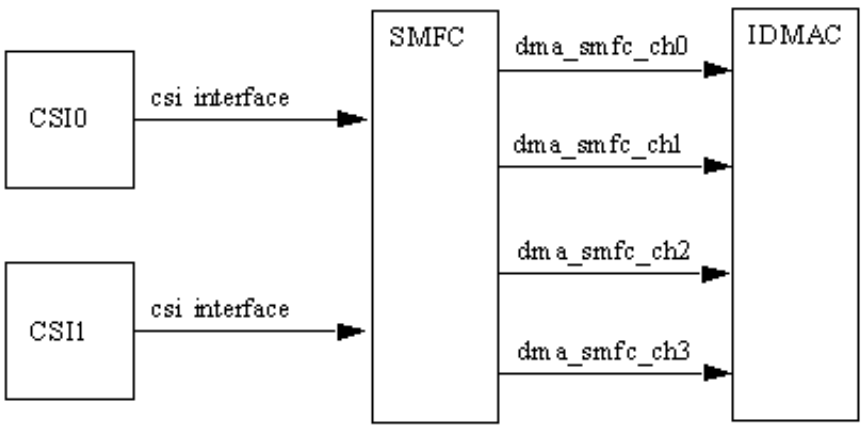

Figure 45-22. SMFC data flow

45.4.4.1 SMFC's Features

- Support two CSI masters and four DMA channels
- Automatic FIFO size calculation

45.4.4.2 SMFC's Functional description

SMFC supports up to four DMA channels. Each channel has a dedicated FIFO controller, as shown in the following figure. Sampled data and frame ID are kept in the buffers until the buffer is selected by Round Robin Priority Mechanism. Then, the content of ID buffer is compared to CH#_MAP bits and the corresponding FIFO controller is activated. As a result, the content of the buffer is copied to the RAM. The wptr and the "base" are used to calculate the location in the RAM. The rptr are following after wptr during dma_active signal, initiated by DMA.

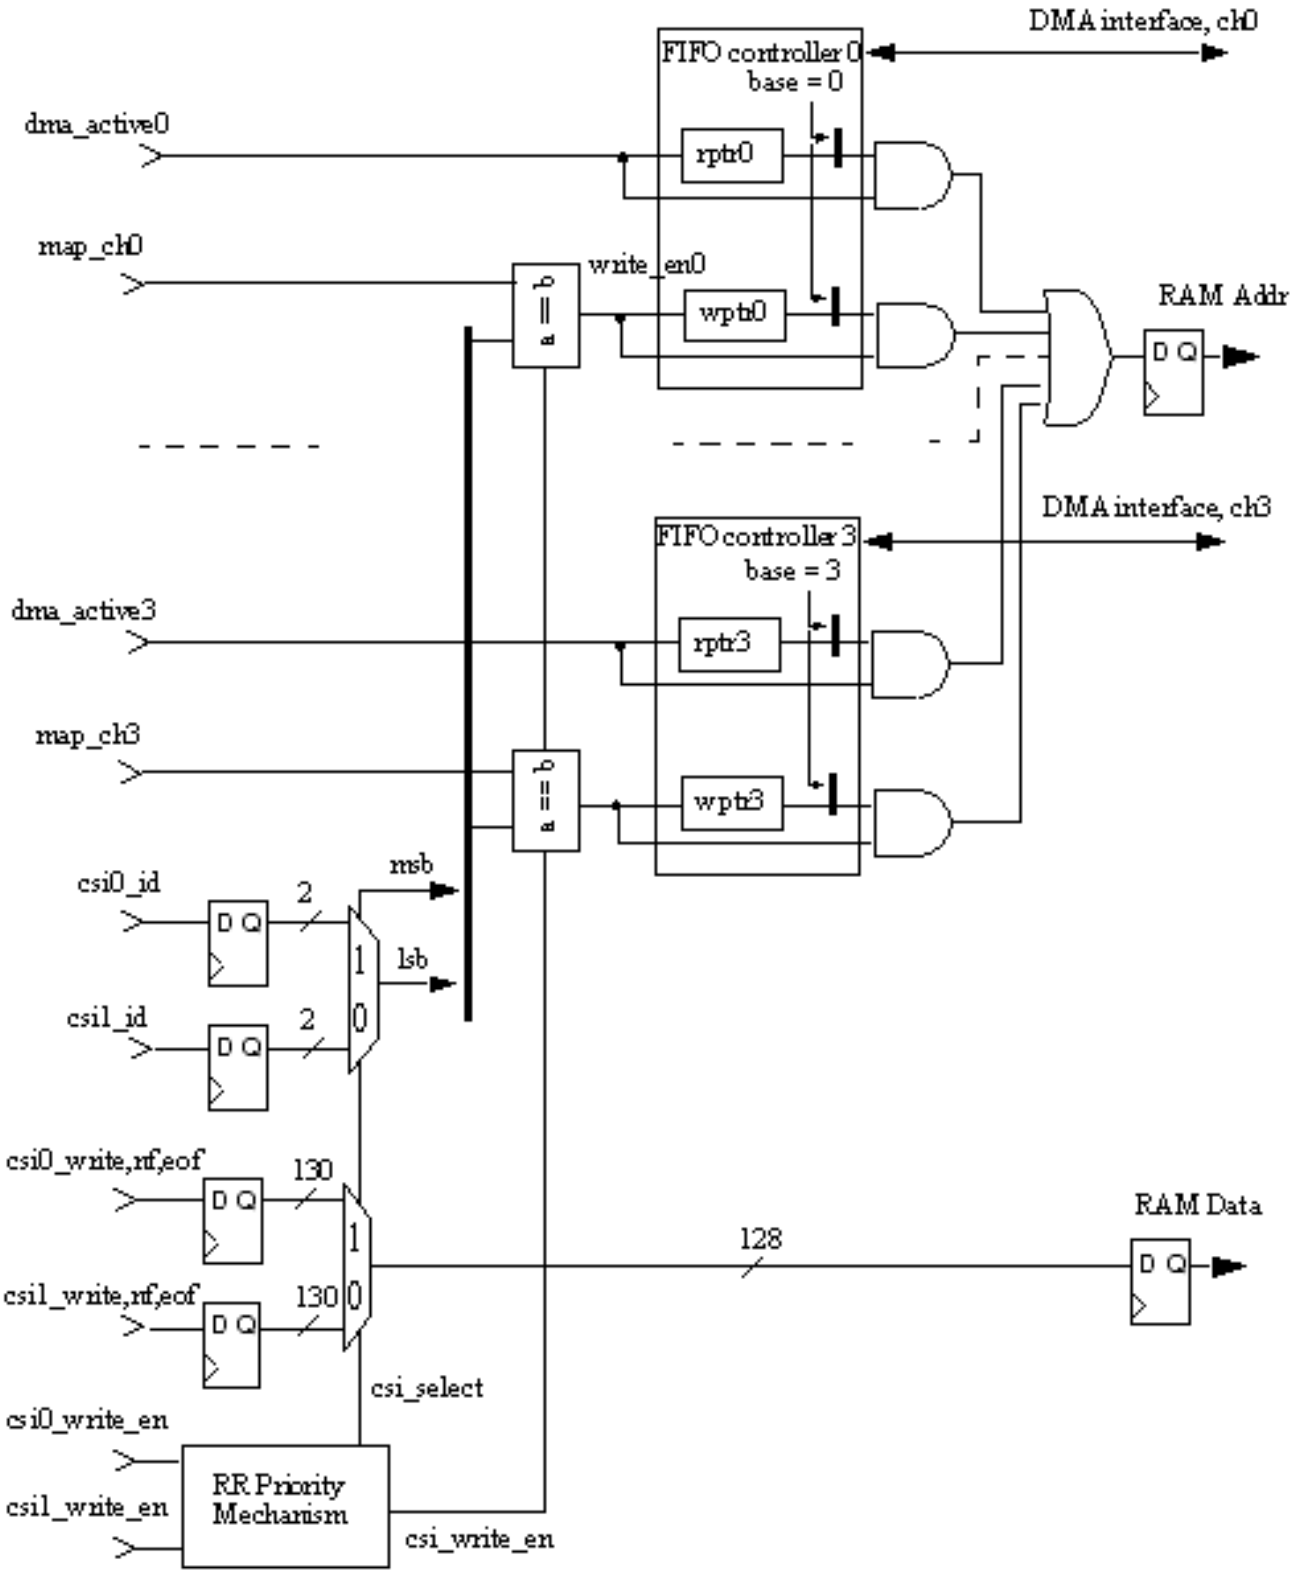

Figure 45-23. Sensor Multi FIFO Controller

Four FIFOs are implemented with single RAM due to the fact that the channels can't be active simultaneously. The memory space of SMFC is divided into four equal sectors. Each FIFO has a fixed base address - "base". The "base" used as MSB for corresponding pointer in order to calculate absolute address of the RAM. FIFO size of channels 1 and 3 are fixed and is equal to size of one sector. FIFO size of channels 0 and 2 depend from other channels as shown in the table below. Other configuration are not allowed.

Number of DMA channels required	enable/disable of channels 3,2,1,0	FIFO size (sectors) per channels 3,2,1,0
1	0 0 0 1	0 0 0 4
2	0 1 0 1	0 2 0 2
3	1 1 0 1	1 1 0 2
4	1 1 1 1	1 1 1 1

NOTE

Channels should not be enabled after activation of channel 0 or/ and channel This can cause to overlapping of FIFO areas and other malfunctions.

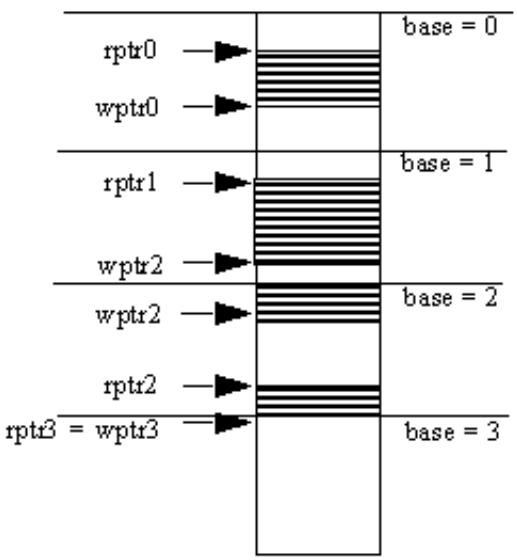

Figure 45-24. SMFC memory map when DMA channels 3,2,1,0 are enabled

45.4.4.2.1 SMFC Master interface.

SMFC Master interface is shown in the following figure.

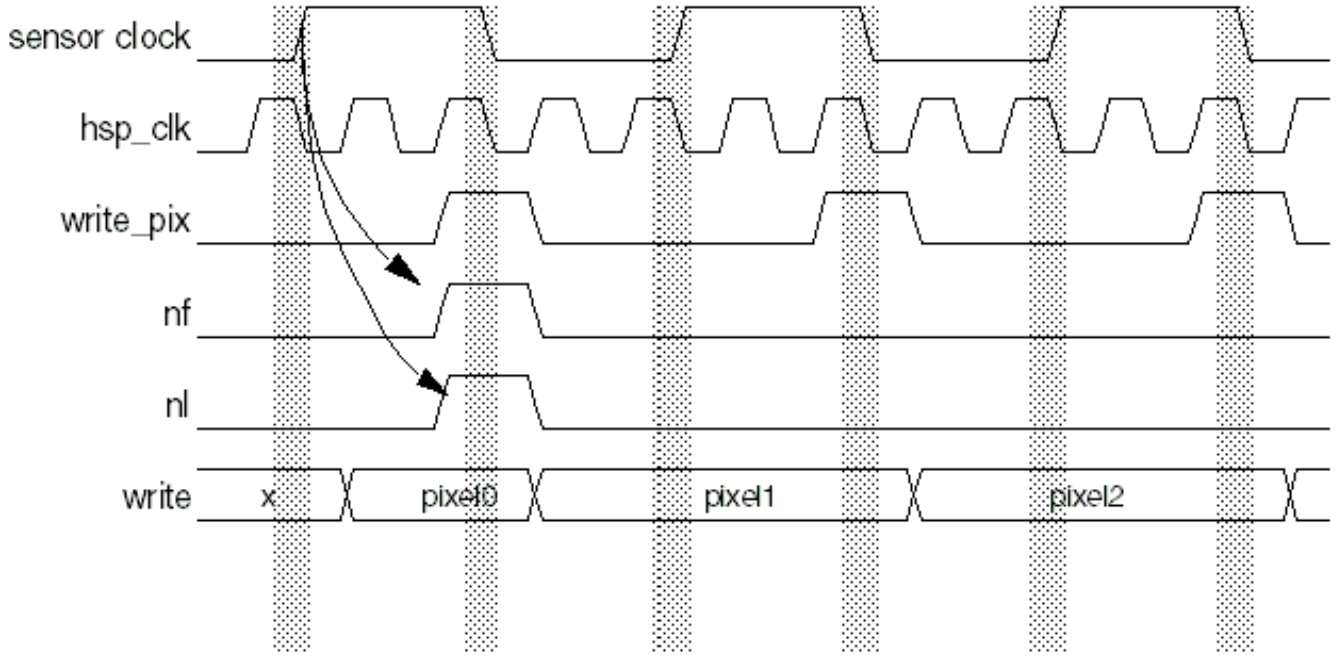

Figure 45-25. Timing diagram of SMFC slave interface

Sensor clock can be asynchronous to IPU clock (hsp_clk). The CSI synchronize data arrived from the sensor to hsp_clk. The csi_write signal indicates when data on csi_pix bus can be sampled by hsp_clk clock.

45.4.4.2.2 Restrictions

1. DMA channels should not be enabled after activation of channel 0 or/and channel 2. This can cause to overlapping of FIFO area and other malfunctions.
2. Watermark set value should be greater than watermark clear value.
3. One frame should not be mapped to few DMA channel.

45.4.5 Image Converter

45.4.5.1 IC Block Diagram

The IC Block Diagram is shown in the following figure.

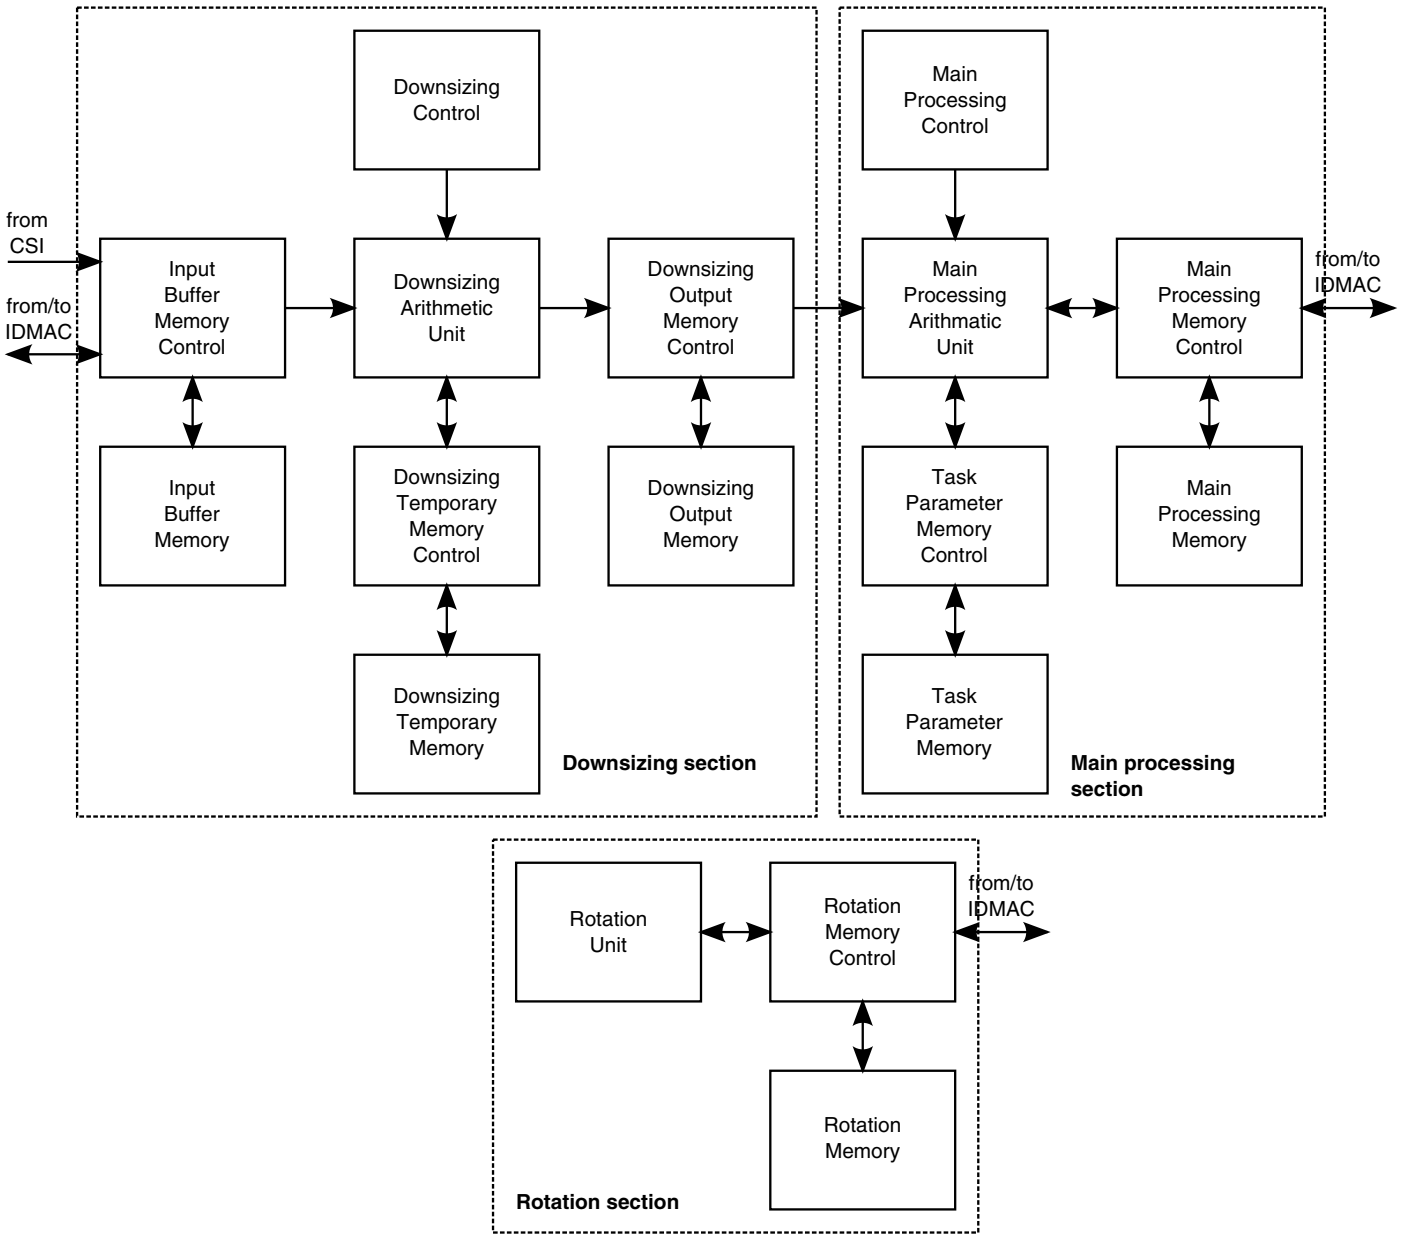

Figure 45-26. IC Block Diagram

The IC contains three processing sections: downsizing, main processing and rotation. The block is controlled via the peripheral bus registers. Some processing parameters should be written by the ARM core to the Task Parameter Memory. Writing to the memory is performed via the AHB bus.

45.4.5.2 Processing tasks

Each of the three processing sections performs up to three processing tasks with time sharing:

1. Preprocessing task for encoding.
2. Preprocessing task for displaying image from sensor (viewfinder).
3. Postprocessing task.

The tasks are performed by single hardware. The ARM platform configures each task before enabling it.

Tasks switching is transparent for the ARM platform. The time unit for task switching in the downsizing section corresponds to a processing time of one burst of eight pixels, in the main processing section - to a processing time of one image line, in the rotation section - to a processing time of one image frame.

All three tasks include similar operations controlled by commands. Task configuring consists in definition of commands for each task, as described in the following table.

Table 45-16. Task Commands

Command code	Command	Processing unit	Command parameters	Description
EN	Task Enable	DSU, MPU		Task will enabled from next frame. Task 1 is preprocessing for encoding. Task 2 is preprocessing for viewfinder. Task 3 is postprocessing.
	Downsizing	DSU	Downsizing ratio (GCR)	Downsizing ratio 1:1, 2:1, 4:1
	Resizing	MPU	Resizing ratio (GCR)	Resizing ratio from 2:1 to 1:M Resizing ratio = N:M; M =2^13; N = floor(M*(SI-1)/(SO-1)); SI - input size; SO - output size
CSC1	Color space conversion 1	MPU	Color conversion coefficients and offsets (TPM)	Color conversion matrix 1
GLOB_A	Global alpha	MPU		Used only for Task 2 and Task 3
CMB	Combining	MPU		Combining video with graphics. Used only for Task2 and Task3.

The ARM platform writes the commands to the IC_CONF Register. Because there is no double buffering for all the IC parameters, the ARM platform must disable a task before changing its parameters. After being disabled, the task is still allowed to complete its

current frame execution. At frame finish, the IPU sends an interrupt to the ARM platform indicating that the ARM platform can change task parameters. The ARM platform enables the task again and task execution is resumed from start of the next frame.

45.4.5.3 Downsizing Section

The sensor data from the CSI is written into a FIFO located in the Input Buffer Memory. Depending on programmed processing flow, the FIFO data can be sent to the system memory via the IDMAC or straight forward to the Downsizing Unit.

In the first case, the data is processed by the ARM platform and returned by the IDMAC to another FIFO located in the Input Buffer Memory.

For postprocessing, the IDMAC transfers a data from the system memory to the third FIFO. The data is read by the Downsizing Unit when the postprocessing is performed.

Each or three FIFOs has 128 pages. Each page can store one burst of 2 or 4 words which corresponds to 8 or 16 pixels. The size of the burst is defined according to the channel's corresponding CB#_BURST_SIZE bit. The memory word width is 128 bits. Each memory word contains color components of four adjacent pixels or 16 bytes of generic data (e.g. Bayer). Access to the FIFOs is controlled by the Input Buffer Memory Control.

The Downsizing Unit performs averaging and decimation of image pixels both in horizontal and vertical directions according to the following equations:

$$HP_{R,c} = \frac{1}{DS\_R\_H} \sum_{k=0}^{DS\_R\_H-1} IP_{r+k,c}$$

$$VP_{R,C} = \frac{1}{DS\_R\_V} \sum_{l=0}^{DS\_R\_V-1} HP_{R,c+l}$$

where IPr,c - the input pixel, HPR,c - the pixel after horizontal downsizing, VPR,C - the pixel after vertical downsizing, DS_R_H and DS_R_V - the horizontal and vertical downsizing ratios according to the IC_PRP_ENC_RSC, IC_PRP_VF_RSC and IC_PP_RSC Registers. The final calculation result is rounded to 8 bits.

Each of three downsizing tasks processes the data by bursts of 8 pixels. Normally, the current task runs until emptying the corresponding input FIFO. After finishing burst processing, the Downsizing Unit may switch between the current task and another task with higher priority, if the Input Buffer Memory has received a burst for this new task.

Averaging is performed firstly in the horizontal direction. All color components of a pixel are processed in parallel. After horizontal averaging has finished for a single output pixel, the new pixel value is added to the corresponding pixel value of a temporary row derived from previous averaging steps. This provides vertical averaging of the pixels. The temporary row is stored in the Downsizing Temporary Memory. The memory word width matches one accumulated pixel width (36 bits). There are three temporary rows stored in this memory - one per downsizing task.

After vertical averaging has been finished, the output row is written to the Downsizing Output Memory. The memory word of 48 bits includes two output pixels. For each task, the memory has a double buffer of one row. When the Downsizing Unit fills the foreground part of the double buffer, the Main Processing Unit takes pair or pixels from the background part. After the new downsized row has been ready, the foreground and background memory pointers are swapped.

45.4.5.4 Main Processing Section

The Main Processing Unit reads pairs of pixels from the Downsizing Output Memory background part. It processes the complete pixel row for the current task and after that switches to another task if the input data for this new task is ready.

For each task, the Main Processing Unit is able to perform the following sequence of operations:

1. Horizontal flipping the image (optional) performed with reading from the Downsizing Output Memory. Flipping is enabled via the VF, HF & ROT parameters of the corresponding DMA channels (Table 45-11 and Table 45-12) responsible for output of the task results. The preprocessing task for encoding uses the VF, HF & ROT parameters from IDMAC channel #20, the preprocessing task for viewfinder - from the IDMAC channel #21, the postprocessing task - from the IDMAC channel #22.
2. Horizontal resizing by bilinear interpolation between two adjacent pixels received from the Downsizing Output Memory according to the equation:

$$HP_{R,c} = IP_{r,c} + RS\_C\_H \cdot (IP_{r+1,c} - IP_{r,c})$$

where RS_C_H - the current horizontal resizing coefficient. The calculation result is rounded to 8 bits. The resizing coefficient is calculated as

$$RS\_C\_H = \left(\sum_{k=0}^{R-1} RS\_R\_H \right) \bmod(8196)$$

where RS_R_H - the horizontal resizing ratio from the IC_PRP_ENC_RSC, IC_PRP_VF_RSC and IC_PP_RSC Registers. The RS_R_H parameter is equal to a numerator N of the resizing ratio N:M with M =2^13.

The resulting row of the horizontal resizing is stored in the Task Parameter Memory.

3. Vertical resizing by bilinear interpolation between the current and previous results of horizontal resizing. Both current and previous results of horizontal resizing is stored in the Task Parameter Memory. Resizing is accomplished according to the equation:

$$VP_{R,C} = HP_{R,c} + RS\_C\_V \cdot (HP_{R,c+1} - HP_{R,c})$$

where RS_C_V - the current vertical resizing coefficient. The calculation result is rounded to 8 bits. The resizing coefficient is calculated as

$$RS\_C\_V = \left(\sum_{k=0}^{C-1} RS\_R\_V \right) \bmod(8196)$$

where RS_R_V - the horizontal resizing ratio from the IC_PRP_ENC_RSC, IC_PRP_VF_RSC and IC_PP_RSC Registers. The RS_R_V parameter is equal to a numerator N of the resizing ratio N:M with M =2^13.

At completion of vertical resizing, this row is updated - the current result of horizontal resizing replaces the previous one.

4. First color space conversion YUV to RGB or RGB to YUV with the conversion matrix CSC1. The conversion matrix coefficients are programmable. They are stored in the Task Parameter Memory. The conversion equations are:

$$Z_0 = 2^{SCALE-1} \cdot (X_0 \cdot C_{00} + X_1 \cdot C_{01} + X_2 \cdot C_{02} + A_0)$$
$$Z_1 = 2^{SCALE-1} \cdot (X_0 \cdot C_{10} + X_1 \cdot C_{11} + X_2 \cdot C_{12} + A_1)$$
$$Z_2 = 2^{SCALE-1} \cdot (X_0 \cdot C_{20} + X_1 \cdot C_{21} + X_2 \cdot C_{22} + A_2)$$

   where for YUV to RGB: X_0=Y, X_1=U, X_2=V, Z_0=R, Z_1=G, Z_2=B, for RGB to YUV: X_0=R, X_1=G, X_2=B, Z_0=Y, Z_1=U, Z_2=V.

   All the parameters of the conversion matrix are written by the ARM platform to the Task Parameter Memory (IC Task Parameter Memory). The final calculation result is limited according to the SAT_MODE parameter and rounded to 8 bits.

5. Combining video with graphics. There are the following combining options:
   - local alpha blending,
   - global alpha blending,
   - use of key color.

   If both alpha blending and color keying are enabled, color keying has higher priority (graphic pixels of the key color are fully transparent independently on the alpha value).

   Combining mode is selected via the IC_CONF Register. The combining equation is:

$$OP = IGP \cdot \alpha + IVP \cdot (1 - \alpha)$$

   where IGP - an input graphics pixel, IVP - an input video pixel, α=(A+floor(A/128))/256 - an alpha value, A - a global or local transparency parameter. The global A is written in the IC_CMBP_1 Register, the local A arrives together with the graphics pixel.

   A graphics pixel becomes transparent when color keying is enabled and a pixel color matches a key color (independently on an alpha parameter).

The graphics data is read from a FIFO located in the Main Processing Memory. The FIFO contains 32 pages of size of 8 pixels. The size of the burst is defined according to the channel's corresponding CB#_BURST_SIZE bit. The graphics pixel format in the FIFO is RGB or RGBA or YUV 4:4:4 or YUVA. The graphics data is loaded by the IDMAC to the FIFO from the system memory.

All the operation are executed by an unified processing unit sequentially. Steps 1 and 2 cannot be interrupted by another task. All other steps can be interrupted by a task with higher priority if an input row is ready for this task. Preprocessing tasks priority is higher than postprocessing task priority.

The processing unit consists of three identical parts for each color component. All three color components are processed in parallel. Each of the processing operations can be enabled or disabled by an appropriate command according to.

The processing results are written to an output FIFO located in the Main Processing Output Memory row-by-row. The FIFO contains 32 pages, each page can include one burst of 8 or 16 pixels. The size of the burst is defined according to the channel's corresponding CB#_BURST_SIZE bit. The IDMAC transfers the output bursts to the system memory or to the display via DMFC (Channel 21only). The Main Processing Memory contains three buffers for each tasks: the temporary row buffer, the graphics FIFO and the output FIFO. Each memory word (128 bits) stores 4 adjacent pixels in formats RGB or RGBA or YUV 4:4:4.

45.4.5.5 Rotation Section

The rotation section includes the Rotation Memory, which stores an input rectangular block of 8x8 pixels and an output FIFO containing four pages of 8 pixels each one. The Rotation Memory word width corresponds to four adjacent pixels - 96 bits. The input block is loaded to the memory by the IDMAC like to a FIFO.

The Rotation Unit rewrites pixels from the input block to the output FIFO with corresponding relocation of a pixel inside the block. Rotation and/or left/right flipping and/or up/down flipping are enabled separately for each of three tasks. Configuring the rotation and flipping options is performed via the VF, HF & ROT parameters of the corresponding DMA channels (Table 45-11 and Table 45-12) responsible for task data input. The preprocessing task for encoding uses the VF, HF & ROT parameters from the IDMAC channel #45, the preprocessing task for viewfinder - from the IDMAC channel #46, the postprocessing task - from the IDMAC channel #47.

Rotation and flip options are shown in the following table.

Table 45-17. Rotation and Flip Options

ROT	FLR	FUD	Image
0	0	0	
0	0	1	
0	1	0

ROT	FLR	FUD	Image
1	0	1	
1	1	0	
1	1	1	

After finishing the rotation task, the IDMAC returns the output FIFO content to the system memory. When writing to the system memory, the IDMAC changes a location of the block relative to an input block location in order to provide proper rotation of the whole frame. Rotation tasks switching is performed after completion of rotation of the whole frame.

45.4.5.6 IC Task Parameter Memory

The following table presents IC task parameter memory details.

Table 45-18. IC Parameters

Address[1]	Word[2]	Parameter	Field	Description
x2008	Encoding CSC1 word0 and word1	C22	8:0	Coefficients of color conversion matrix1 for encoding task: Z0 = X0*C00 + X1*C01 +X2*C02+A0; Z1 = X0*C10 + X1*C11 +X2*C12+A1; Z2 = X0*C20 + X1*C21 +X2*C22+A2; Coefficients format is s.xxxxxxxx[3];
		C11	17:9	
		C00	26:18	
		A0	39:27	Offset of color conversion matrix1 for encoding task: Offset format is sxx.xxxxxxxxx
		SCALE	41:40	Scale of coefficients for color conversion matrix1 for encoding task: 0 --> coefficients *2 1 --> coefficients*1 2 --> coefficients*0.5 3 --> coefficients*0.25
		SAT_MODE	42:42	Saturation mode for color conversion matrix1 for encoding task: 0 --> (min, max) = (0, 255) 1 --> (min, max) = (16, 240) for Z1,Z2 1 --> (min, max) = (16, 235) for Z0
x2010	Encoding CSC1 word2 and word3	C20	8:0	Coefficients of color conversion matrix1 for encoding task: Z0 = X0*C00 + X1*C01 +X2*C02+A0; Z1 = X0*C10 + X1*C11 +X2*C12+A1; Z2 = X0*C20 + X1*C21 +X2*C22+A2; Coefficients format is s.xxxxxxxx;
		C10	17:9

1. The address documented in this table is the relative address within the TPM. This is the address that should be accessed when writing or reading from this memory via the AHB bus.
2. Each word is aligned to 64 bit accessible via the AHB bus in 2 separate 32bit accesses.
3. s - sign position, x - binary digit position

45.4.5.7 IC's DMA channels

The table below mas the IDMAC channels of the IC and the IRT to the corresponding tasks.

The IC's channel name is the name of the channel at IC level. The IC channel name is referred on the IC's programming model.

Table 45-19. IC's DMA Channels

IDMAC's channel number	IC's channel name	Read/ Write	Source	Destination	Processing Flow Purpose
20	CB0	Write	IC ENC	Memory	Preprocessing data from IC (encoding task) to memory
21	CB1	Write	IC VF	Memory/DMFC	Preprocessing data from IC (viewfinder task) to memory; This channel can be configured to send the data directly to the DMFC. This is done by programming the ic_dmfc_sel bit.
22	CB2	Write	IC PP	Memory	Postprocessing data from IC to memory
14	CB3	Read	Memory	IC VF	Graphics data for combining (viewfinder task)
15	CB4	Read	Memory	IC PP	Graphics data for combining (post-processing task)
11	CB5	Read	Memory	IC PP	Postprocessing data from memory
12	CB6	Read	Memory	IC VF	Preprocessing data from sensor stored in memory (for example Bayer)
5	CB7	Write	IC	Memory	Direct data from IC (sensor data) to memory
48	CB8	Write	ENC ROT	Memory	Preprocessing data after rotation (encoding task)
49	CB9	Write	VF ROT	Memory	Preprocessing data after rotation (viewfinder task)
45	CB10	Read	Memory	ENC ROT	Preprocessing data for rotation (encoding task)
46	CB11	Read	Memory	VF ROT	Preprocessing data for rotation (viewfinder task)
50	CB12	Write	PP ROT	Memory	Postprocessing data after rotation
47	CB13	Read	Memory	PP ROT	Postprocessing data for rotation

45.4.5.8 IC restrictions

- The input's frame width to the IC must be a multiplication of 8 pixels
- When performing resizing the frame width must be multiple of burst size - 8 or 16 pixels as defined by CB#_BURST_16 parameter.

45.4.5.9 IC bridge

The IC sub-block utilizes a single memory to serve read and write channels. These memories are the IBM, RM and MPM. The IDMAC has separate mechanism to handle read and write channels. As a result, a contention between read and write channels may occur on each one of the memories. In order to resolve the contention, an IC bridge sub-block is connected between the channels associated with this memory.

The bridge prioritizes a read channel over a write channel. In order to avoid starvation of the write channels, the user can limit the maximum consecutive requests of the same channel that will be served. The limitation is done by programming the memory's corresponding <>_brdg_max_rq field.

45.4.6 Display port

The display port handles all the IPU features targeted for controlling and sending data to the display. The display port consists of 4 modules.

DC - a display controller,

DP - a display processor,

DMFC - a display multi-FIFO controller

DI - a display interface. The DI is instantiated twice to provide two symmetrical display interfaces.

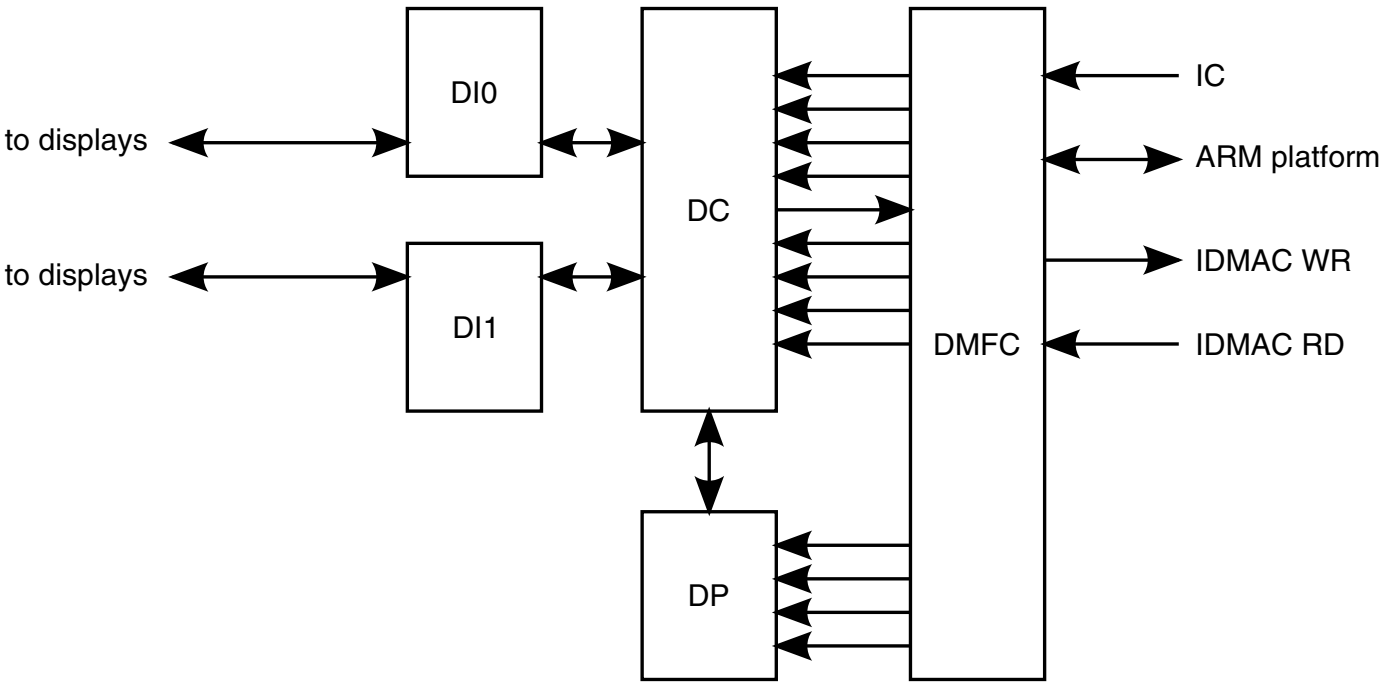

Figure 45-27. The display port

45.4.6.1 Display ports channels

The display port send data to the display over several channels. The data source may be the system's memory (via the IDMAC) the IC block and the ARM platform. The display port can read data from the display and send it to the ARM platform or IDMAC.

The data is routed over channels. The table below maps the IDMAC channels to DMFC, DC, DP channels and describes each channel.

Table 45-20. Display port channels

IDMAC's channel number	Display port's destination	DMFC channel number	DC channel number	Corresponding alpha channel	channel usage
21	DC	Programmable using dmfc_ic_in_port	Programmable using dmfc_ic_in_port	NA	This channel is coming from the IC module. When data is coming from the IC, the IC channel replaces one of the IDMAC's channels connected to the DMFC. When the IC_DMFC_SEL bit is set the output of the IC is routed to the DMFC. This channel can be routed to the DC channels 1,2,5B,5F,6B,6F. Routing this channel to the DC channel is done with the dmfc_ic_in_port bits. The DC's channel allocated to the IC channel can't be used for data coming from other source.

Table continues on the next page...

Table 45-20. Display port channels (continued)

IDMAC's channel number	Display port's destination	DMFC channel number	DC channel number	Corresponding alpha channel	channel usage
23	DP	5B	5	51	This channel is for the DP's primary flow. When a single plane is used, the data should be sent over this channel. When 2 planes are combined in this flow, the second plane should come on channel 27.
24	DP	6B	6	52	This channel is for the DP's secondary flow. When a single plane is used, the data should be sent over this channel. When 2 planes are combined in this flow, the second plane should come on channel 29.
27	DP	5F	5	31	This channel is for the DP's main flow. When a single plane is used, the data should be sent over channel 23 and this channel should not be used. When 2 planes are combined in this flow, one plane should come on channel 23 and the other plane on this channel.
28	DC	1	1	NA	This channel can serve sync and async flows. When channel 28 is connected to DI0, channel 23 must be connected to DI1 even if ch23 is not used. This is done by programming the PROG_DISP_ID_5 field
29	DP	6F	6	33	This channel is for the DP's secondary flow. When a single plane is used, the data should be sent over channel 24 and this channel should not be used. When 2 planes are combined in this flow, one plane should come on channel 24 and the other plane on this channel.
40	DC	0	0	NA	This is a read channel
41	DC	2	2	NA	This channel can serve only async flow
42	DC	1C		NA	Command stream. See Display port's restrictions
43	DC	2C		NA	Command stream. See Display port's restrictions
44	DC	3		NA	Mask channel. This mask channel can be associated with channel 23 or channel 28

45.4.6.2 Supported display interfaces

- The display port has 2 DI interfaces. Each interface can handle up to 3 displays.
- The total number of supported displays is 4.
- Each DI can handle up to 2 async interface - only one of them can be serial interface.
- Each DI can handle one synchronous interface. Asynchronous displays that are accessed in synchronous mode are considered synchronous interface.

45.4.6.2.1 Synchronous Interfaces

The DI supports the following synchronous display interfaces.

1. Synchronous generic interfaces to TFT dumb displays or RGB interfaces of smart displays.
2. Synchronous interfaces to Sharp displays.
3. Synchronous interfaces to TV encoders:
   - PAL
   - NTSC

   TV interfaces can operate in progressive or interlaced modes.
4. Synchronous interface to a graphic accelerator
5. BT.656
6. BT.1120

   BT.1120 and BT.655 support

   BT.1120 and BT.656 are supported. Only video data is supported, sending data during blanking intervals is not supported. The component size is always 8 bit.

45.4.6.2.2 Asynchronous Parallel Interfaces

The DI has a flexible asynchronous interface. The interface include 2 chip selects (CS) and 7 general purpose control signals.

The user can decide which of the 7 signals will be associated to each one of the asynchronous displays (up to 2 displays per DI). The using can configured some of the control signals to be shared by more than one display.

45.4.6.2.3 Asynchronous Serial Interfaces

See Serial display interface

45.4.6.3 Display port's bandwidth

When the IPU clock (HSP_CLK) is equal to 200 Mhz, the peak bandwidth supported by the display port is as follows

For on chip devices

- 170 Mega-Accesses/Sec if the DI clock is derived from an external to IPU source (like another PLL)
- 180 Mega-Accesses/Sec if the DI clock is derived from the IPU clock (HSP_CLK)

For off chip devices (Like an external LCD)

- 170 Mega-Accesses/Sec if the DI clock is derived from an external to IPU source (like another PLL)
- 180 Mega-Accesses/Sec if the DI clock is derived from the IPU clock (HSP_CLK)

An access can be a pixel, component or generic data.

45.4.6.4 Display Dual Mode

This mode is useful for smart display with synchronous interface. The data is sent to the display only when the data has changed or when the display processor's settings are changed. The physical interface to this display has synchronous interface's characteristics.

45.4.6.5 Display Errors

There are a few types of errors that may impact the image sent to the display. The IPU provides some automatic mechanisms, which allow the system to overcome these errors.

45.4.6.5.1 Data starvation errors

These types of errors may happen for synchronous displays if the data is ready at the DI to be sent to the display at the time point it is required. This anomaly may happen if the system is very loaded and the IDMAC was not able to read data from the external memory and provide it to the DMFC.

Frame boundary errors

In case that a new frame should be sent to the display but the data of the previous frame was not sent completely, the IPU will reset the display modules and flush the internal buffers, as the IPU expects that the new frame indication will be triggered at least 2 lines (blanking interval) before the actual data is to be sent. The should recover and be ready with the data of the new frame within the blanking interval period.

Error within a frame

In case that a pixel was missed within a frame i.e. the pixel did not arrived to the DI on time. The IPU has 2 ways to handle the situation. The mode is selected by configuring the DI#_ERR_TREATMENT bit.

Redo the last access. The IPU will keep sending the last access to the display. The IPU will drop any pixel that arrive till the end of the line. If the data of the next line arrives correctly the IPU will continue working normally as overcame the problem. In case that the data of the next line is also incorrect the IPU will perform the same procedure as described on frame boundary errors.

Freeze the clock. In this mode, the IPU freezes the clock sent to the display till the correct data arrives. In order to avoid a case where the clock is frozen forever and the system is stuck: when the clock is frozen, a watchdog timer starts counting. When the timer completed counting the IPU will perform the same procedure as described on frame boundary errors. The number of cycles to be counted by the watchdog timer is defined according to the DI#_WATCHDOG_MODE bits.

45.4.6.5.2 Anti tearing errors

In case of anti tearing errors, the IPU indicates about the error by asserting the corresponding DC_TEARING_ERR_# bit.

See also Antitearing control.

45.4.6.6 Display port's restrictions

- In case where 2 synchronous flows are used and additional asynchronous flow via DP is used. The asynchronous flow via DP can be targeted to the same DI that the synchronous flow via DP is targeted.
- There are only 2 command channels (42 and 42). Command channels are associated with data channels (24,28,41).
  - When channel 28 is associated with a command, the command stream will come from channel 42
  - When channel 41 is associated with a command, the command stream will come from channel 43
  - Channel 24 can be associated with a command stream only if channel 28 or channel 41 do not use a command stream. If channel 28 is not associated with a command stream then channel 24 can be associated with channel 42. If channel 41 is not associated with a command stream and channel 28 is associated with a command stream then channel 24 can be associated with channel 43.

- A channel that uses an alternate flow, cannot be associated with a command stream (ch. 24 or ch. 41)
- In case of a synchronous display using external clock, The DI where the synchronous display is connected to can be connected to another async display. But, it can support only the write direction. Read via the asynchronous interface cannot be performed if this DI uses external clock

45.4.7 DC - Display Controller

IPU handles few display flows supporting few displays. The IPU's flows' data sources can be the ARM platform, the system's memory, a camera or an external device connected on the display's port such as an external graphic accelerator. The data's destination can be any device connected on one of the DI ports.

The DC controls the flows coming to and from the DI port. The DC manages the flows, decides which flows are currently active and when each flow is activated. The arbitrates between the active flows, gets the data from the predefined source and distribute it to the correct DI.

The DC's core is the microcode. The microcode contains a set of routine. A routine is built of a set of commands stored in the template's (microcode) memory. For each event (like new frame, end of frame etc.) a specific routine is executed. The user writes the routines and map them to a specific events. The routine contains instructions to the DC about the way of handling the data/address/commands associated with the display. The routine may contain information about the data's mapping, about waveform's characteristics, and more.

The figure below shows the micro architecture diagram for the DC block

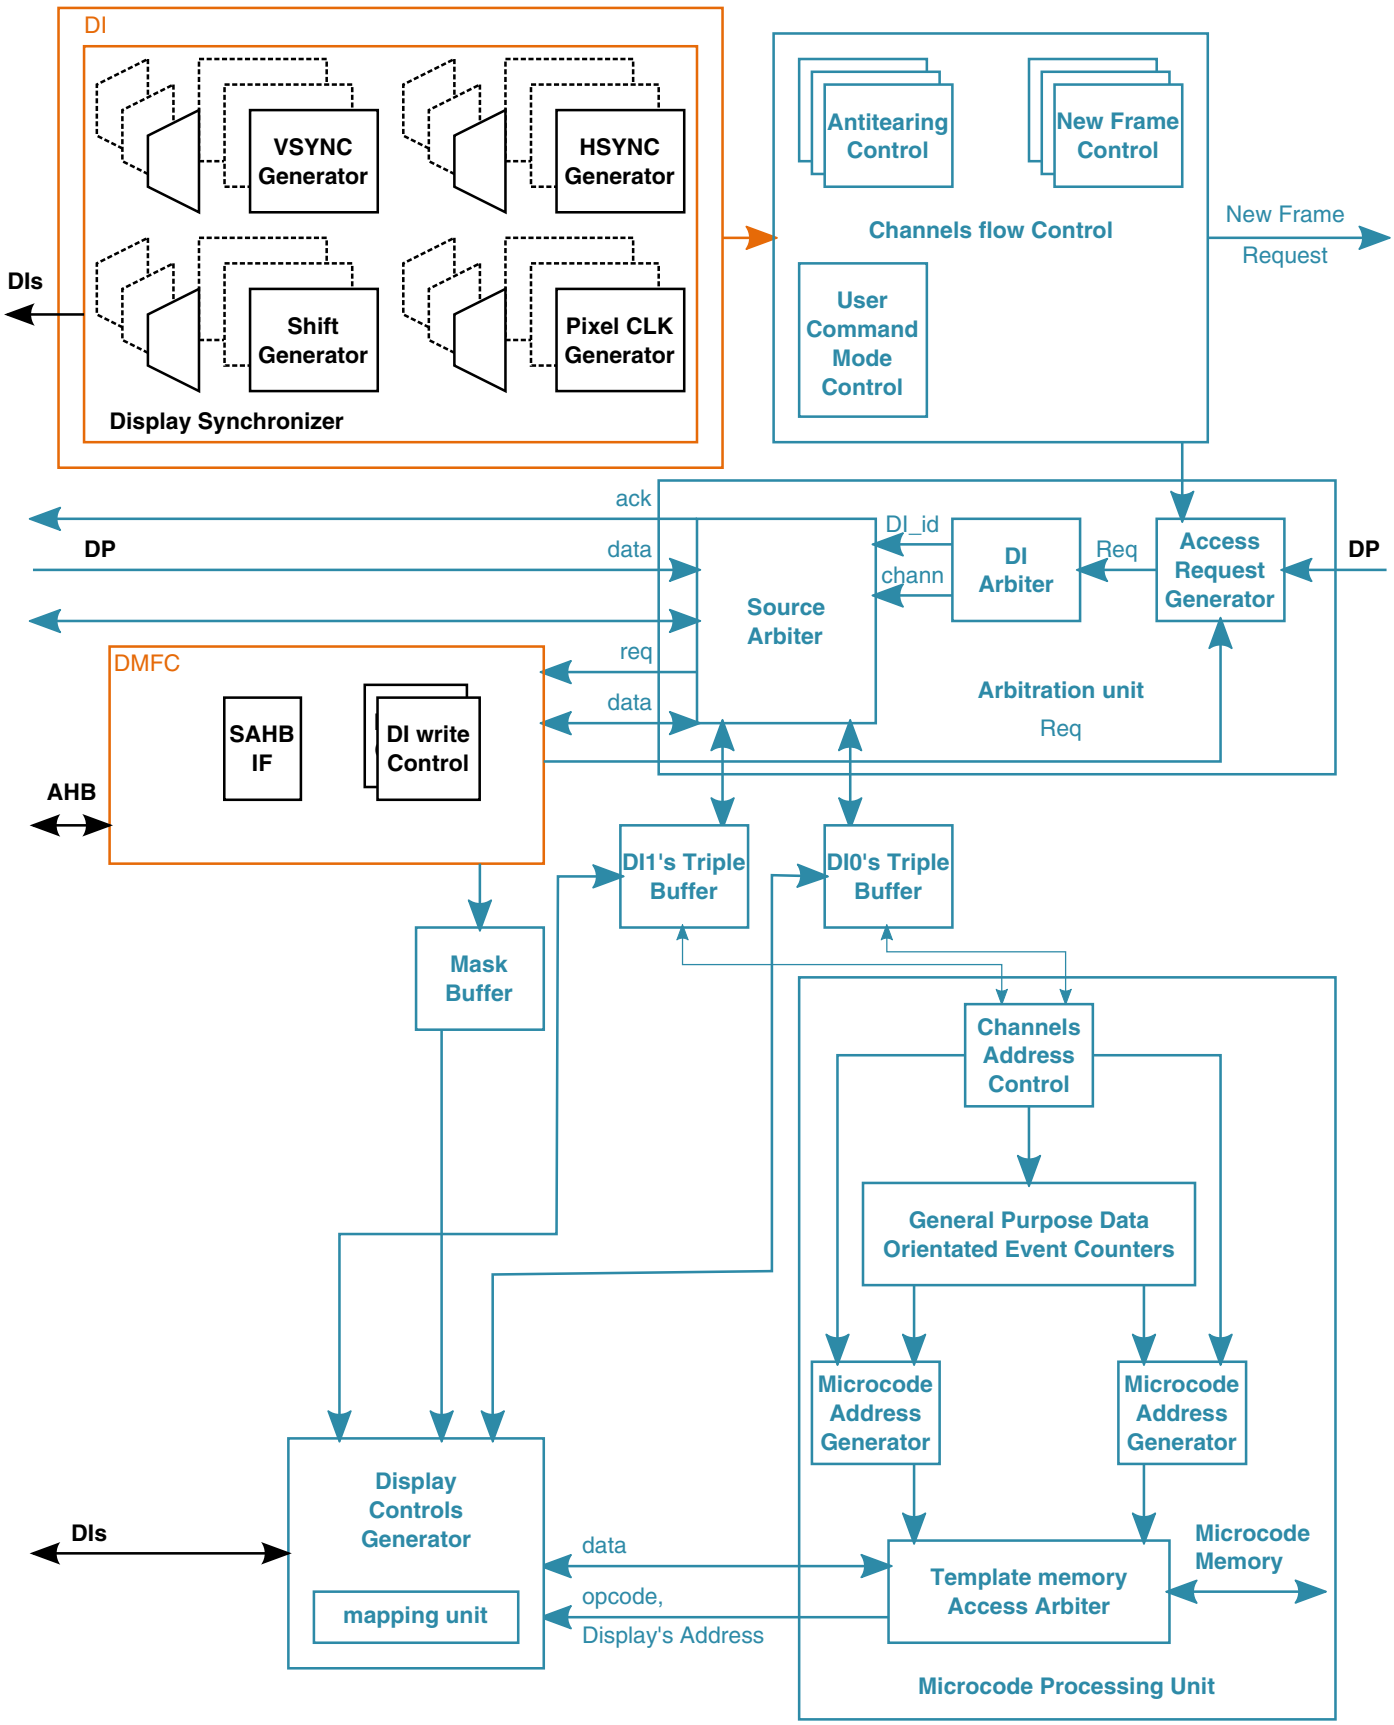

Figure 45-28. DC - Display Controller Block Diagrar

45.4.7.1 Channels flow control

45.4.7.1.1 New Frame control

The channels flow control schedules the flows handled by the DC

For asynchronous flows the scheduling is done according to a request coming from the Frame Synchronization Unit (FSU) on the control sub-block (CM).

For Synchronous flows the scheduling is done according to a trigger that is generated by a timer located on the one of the display's interface blocks (DI)

45.4.7.1.2 Antitearing control

Anti tearing mechanism uses a signal indicating on a display's refresh of a frame.

The supported tearing elimination triggers can be:

- An internally generated VSYNC signal
- A VSYNC signal generated by the display. The data source is the memory.
- A VSYNC signal coming from the CSI

The DC has the capability to avoid image tearing. For asynchronous flows where the source of the data is the system's memory or postprocessing, the DC monitors the position of a display's refresh pointer. Writing to the display is started only after crossing the window start point by the display refresh pointer. After that, writing to the display is allowed only when a write pointer does not advance beyond the refresh pointer. To provide anti-tearing mode, a window start time (in rows) must be defined in the PROG_START_TIME_1, PROG_START_TIME_2, PROG_START_TIME_5, PROG_START_TIME_6 registers for the corresponding channels.

The antitearing mechanism is limited to a case where only asynchronous flows are handle via the target DI.

In the case when tearing cannot be avoided (when the refresh rate is too high and the refresh pointer overtakes the write pointer after full refresh cycle), an error interrupt is generated. Tearing elimination mode can be disabled via the PROG_CHAN_TYP field for the corresponding channel.

When the data arrives directly from the camera via IC, tearing can be avoided only for the 2:1 ratio between a sensor scan rate and a display refresh rate. The additional conditions for tearing elimination in this case are to synchronize the sensor and display VSYNCs (by programming the VSYNC's settings on the DI) and full-screen image from the camera via IC channel.

45.4.7.1.3 User command mode control

A user may prepare in the system's memory a buffer that holds commends to be sent to the external device. The command buffer includes the same amount of lines as the data buffer. The line of commands are sent to the display line by line. A line of data is sent following each line of commands. This mode is activated by programming the PROG_CHAN_TYP of the corresponding channel.

The structure of the command is as follows:

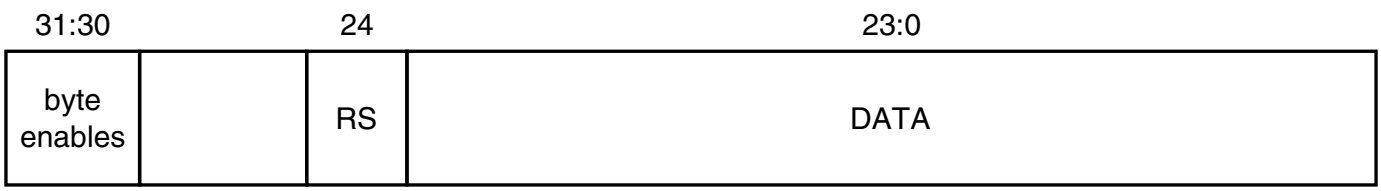

Figure 45-29. Structure of a command word

45.4.7.2 Arbitration Unit

This unit arbitrates the requests coming from the DMFC and from the DP and sends them to corresponding DI.

45.4.7.2.1 Access request generator

The requests coming from the DMFC or DP are sorted according to the target DI and then served according to a hard coded priority. The priority order is Sync flow, ARM platform access, IDMAC's Async flows.

45.4.7.2.2 DI arbiter

This units arbitrates between the DIs. The priority is hard coded. The priority order is Sync flow, ARM platform access, IDMAC's Async flows.

In case of 2 simultaneous requests to different DIs with the same priority the requests are served in a Round-Robin fashion. In case of 2 simultaneous Sync flow requests to different DI, the user can bypass the Round Robin mechanism and prioritize one DI on the other according to the SYNC_PRIORITY_1 & SYNC_PRIORITY_5 bits. Setting low priority to both of these channels is forbidden.

45.4.7.2.3 Source arbiter

Once the source of the request to be served was selected and the target DI was chosen, this unit routes the request and all the signals, associated with it, to the correct triple buffer and to the correct source of the data.

45.4.7.3 Microcode processing unit

The main control unit of the DC is the Microcode processing unit (MPU). The data coming to the DC may be associated with some additional information like new frame, new line, new address etc. The information is processed in the MPU. The MPU executes the associated routine. The routine includes a set of instructions of the actions to be performed by the DC and DI.

45.4.7.3.1 Channels address control

This unit controls the display's address for each channel. This unit is responsible for defining the next address to be accessed (by incrementing or jumping). Stores special events flags (like EOF, EOL etc.). Based on the display's address and the special events, the type of the routines to be executed is defined.

45.4.7.3.2 General purpose Data oriented events counters

A user may define up to 4 general purpose events. The events are triggered by a standard event (NF, NL). The standard event restarts a counter, when the counter completes counting the user's general purpose event is asserted. This event activates a routine like any other events

45.4.7.3.3 Microcode address generator

This unit calculates the physical address of the template memory where the event associated routine resides. In addition, these unit arbitrates between simultaneous events and select the event to be served.

The arbitration is done according to a user defined priority. The priority of each event is set according to the #_CHAN_PRIORITY_CHAN_# bits of each channel. There are 2 modes of arbitration:

- Serving all the pending events according to the priority
- Serving only the highest priority event while ignoring all the other events

The arbitration mode is defined according to the CHAN_MASK_DEFAULT bit of each channel.

45.4.7.3.4 Template's Memory Access Arbiter

This unit gets memory access requests from the 2 microcode address generator units and arbitrates between them in a Round Robin fashion. In case that only one of the requests belongs to a synchronous flow, this request is selected.

45.4.7.4 DC's Template structure

The template memory contains 256 template words. Each template word is a 42 bits words. Accessing a template word require 2 accesses (32bit each).

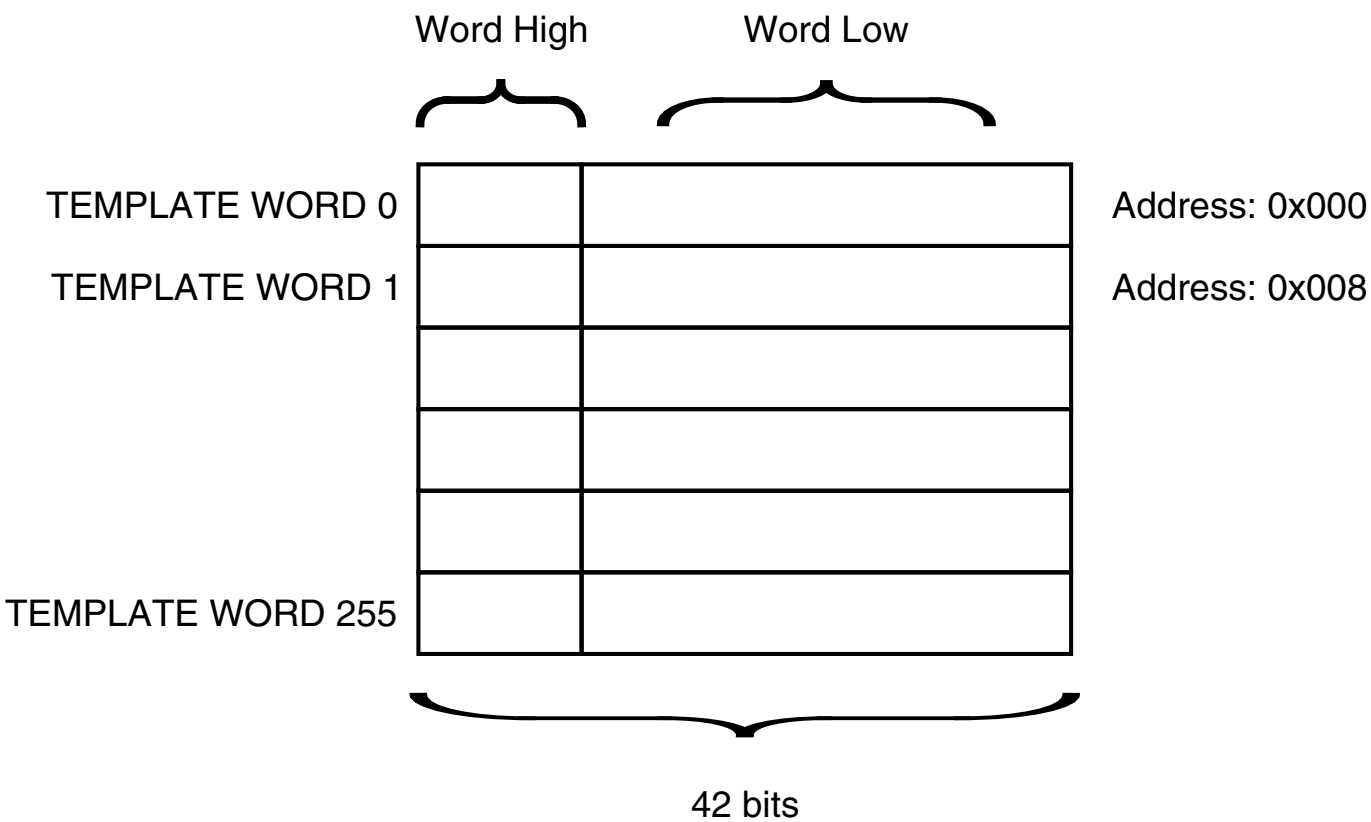

Figure 45-30. Template's structure

45.4.7.4.1 DC template's memory map

DC template's fields description

Table 45-23. DC template's fields description

Field	Description
STOP	Stop bit - This bit should be set in order to indicate that the current command is the last command of the routine
OPCODE	The command's code
OPERAND	The command's operand - for some of the commands this field can hold a parameter associated with the command
MAPPING	The MAPPING field holds a pointer to a register holding 3 fields: MAPPING_PNTR_BYTE0_X, MAPPING_PNTR_BYTE1_X, MAPPING_PNTR_BYTE2_X. This pointers point to sets of OFFSET and MASK parameters that define the mapping scheme. MAPPING = 0 means that mapping is disabled. The value in this field should be incremented by 1 to get the correct X pointer value In order to point to MAPPING_PNTR_BYTE2_0, MAPPING_PNTR_BYTE1_0, MAPPING_PNTR_BYTE0_0 the user should write 1 to the MAPPING field
WAVEFORM	For data oriented output pins. The IPU has 4 waveform generator units. The IPU holds 12 sets of waveforms' configuration registers called DI0_DW_GEN_<i> and DI1_DW_GEN_<i> The WAVEFORM field defines which one of the 12 waveforms' configuration registers is used. The DI1_DW_GEN_X register holds a pointer to one of the 4 waveform generators units for each of the data oriented pins. 0 - The waveform of the data oriented output pins is not affected 1 -Points to DI0_DW_GEN_0 or DI1_DW_GEN_0 2 - Points to DI0_DW_GEN_1 or DI1_DW_GEN_1 ... 12 - Points to DI0_DW_GEN_11 or DI1_DW_GEN_11

Table continues on the next page...

Table 45-23. DC template's fields description (continued)

Field	Description
GLUELOGIC	For signals generated by waveform generator #3; This field provides extra flexibility on the signals waveform
	GLUELOGIC[6] - This bit defines if we are in clock mode (1) or CS mode(0). 1- clock mode When the command is related to the display clock's pin then only if we are in clock mode, GLUELOGIC[5:4] are valid. 0- CS mode When the command is related to the CS pin then only if we are in CS mode, GLUELOGIC[3:0] are valid.
	GLUELOGIC[5:4] - clock mode settings 00 - Freeze the display clock following the execution of the current command 01 - Freeze the display clock before the execution of the next command to be executed 10 - Enable (unfreeze) the display clock following the execution of the current command 11 - Enable (unfreeze) the display clock before the execution of the next command to be executed
	GLUELOGIC[3] - CS mode settings 1 - Once the signal is asserted then it remains asserted (high or low according to the polarity) 0 - No impact on the waveform
	GLUELOGIC[2] - CS mode settings 1 - Once the signal is negated then it remains negated (high or low according to the polarity) 0 - No impact on the waveform
	GLUELOGIC[1] - CS mode settings 1- The current waveform can be attached to the previous waveform. If the previous waveform was asserted and the current waveform start asserted the two waveforms will be attached so the signals' waveforms will be consecutive. This impact the behavior of the previous waveform. This can be done only if GLUELOGIC[0] of the previous waveform is set to 1 0 - No impact on the waveform
	GLUELOGIC[0] - CS mode settings 1 - this bit allows the next waveform to be attached to the current waveform.
SYNC	The data associated with this command should be synchronized to the DI's one of gen_time_sync generators' output. 0000 - No sync. The data is sent without any synchronization to any event 0001 - Sync with unit #1 0010 - Sync with unit #2 ... 1010 - Sync with unit #10 1011 - 1111 Reserved

DC template's command description

The diagram below illustrates the command processing flow. The command is being fetched from the microcode memory. The Opcode is decoded. According to the decoding several controls are sent to the processing unit. In addition the processing unit gets the pixel's data and the display's address. The processed data/ address is stored in an internal register. There are 2 types of commands

HOLD - In this type of commands the data/address is stored in the register and not sent to the DI. The data/address is held in the register for further processing in the following commands.

WRITE - In this type of commands the data/address is stored in the register and also sent to the DI.

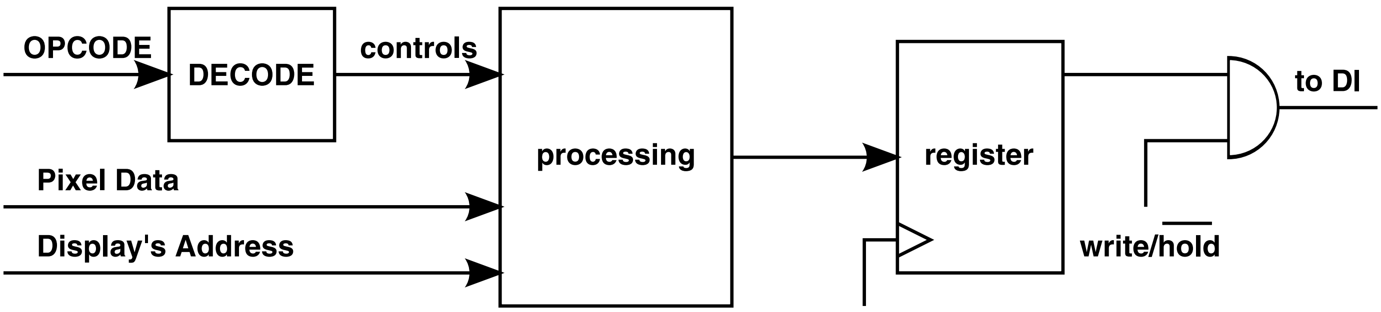

Figure 45-31. Opcode processing

The table below describes the DC's Commands.

Table 45-24. DC template's commands description (continued)

Command	COMMAND[41:0]
BMA	S 0 0 1 1 LF AF 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 N 0 0 SYNC
	BRANCH_MICROCODE_ADDRESS jump to Microcode address which is stored at an internal Microcode address register. The branch will be done to the ADDRESS stored with the HMA/HMA1 command. The BMA command manages the repeat cycles by one of the auto decrement counters (internal counters), the counter's id is defined by LF-bit (0/1) The N operand defines the N-number of routine's repetitions. In case of N=0. The BMA command functions as a JUMP command. As long as the internal counter didn't reached its predefined value, the microcode will branch to the pre defined address stored by the HMA/HMA1 commands. Selecting between HMA and HMA1 is done by the AF bit (it is calculated according to the "1 - AF" value). - That's the subroutine's microcode start address When the counter reached its predefined value, the microcode will branch to the pre defined address stored by the HMA/HMA1 commands. Selecting between HMA and HMA1 is done by the AF bit (it is calculated according to the "AF" value). - That's the subroutine's microcode return address BMA synchronization (SYNC field): The BMA command can be used for context switching between 2-channels. When switching between flows the user can run a routine for a new channel, which actually affects the previous flow. This feature is useful when a new flow breaks the current flow (post command for example): SYNC is used for display_id selection // 0 0 0 - current display // 0 0 1 - previous display // 1 0 0 - display 0 // 1 0 1 - display 1 // 1 1 0 - display 2 // 1 1 1 - display 3

45.4.7.5 Display controls' generator

This unit generates the control signals associated with the data that are sent to the DI block.

45.4.7.5.1 Bus Mapping Unit

The Bus Mapping Unit is responsible for programmable mapping of the input data and commands to the display interface format and vice versa. Address mapping is done by this unit as well (programmable via micro code).

The internal DI format for data and commands is a 24-bits word divided into three byte components (eight zeroes are added to MSB for 16-bits words from the DC). This word can be output or input in one, two, three or four cycles of the display clock.

The word coming from the memory is a 32bit word. The mapping operation is done on 24 bits only. The 24 bit are selected from the received 32 bit according to the W_SIZE_# field. The 24 bit input word is partitioned to a 3 bytes (3X8bits). Each byte can be mapped to any position at the 24bit output word. The exact position is set according to the MD_MASK & MD_OFFSET fields.

The MAPPING_PNTR_BYTE0_X, MAPPING_PNTR_BYTE1_X, MAPPING_PNTR_BYTE2_X fields holds the pointers for the MD_MASK & MD_OFFSET for each byte.

The MAPPING field holds a pointer to a register holding 3 fields: MAPPING_PNTR_BYTE0_X, MAPPING_PNTR_BYTE1_X, MAPPING_PNTR_BYTE2_X.

0 - no mapping i.e. 32 bits are sent as is.

1 - points to MAPPING_PNTR_BYTE0_0, MAPPING_PNTR_BYTE1_0, MAPPING_PNTR_BYTE2_0

2 - points to MAPPING_PNTR_BYTE0_1, MAPPING_PNTR_BYTE1_1, MAPPING_PNTR_BYTE2_1

...

30 - points to MAPPING_PNTR_BYTE0_29, MAPPING_PNTR_BYTE1_29, MAPPING_PNTR_BYTE2_29

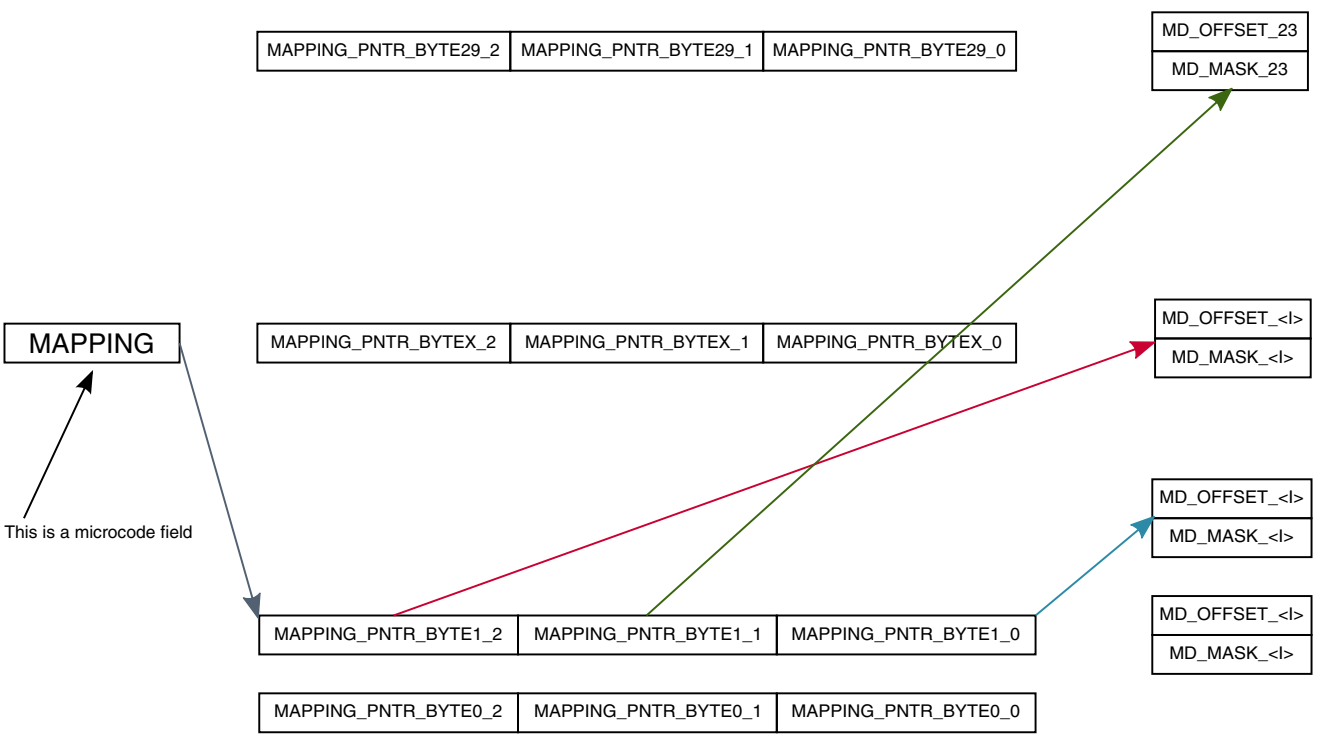

Figure 45-32. Mapping scheme

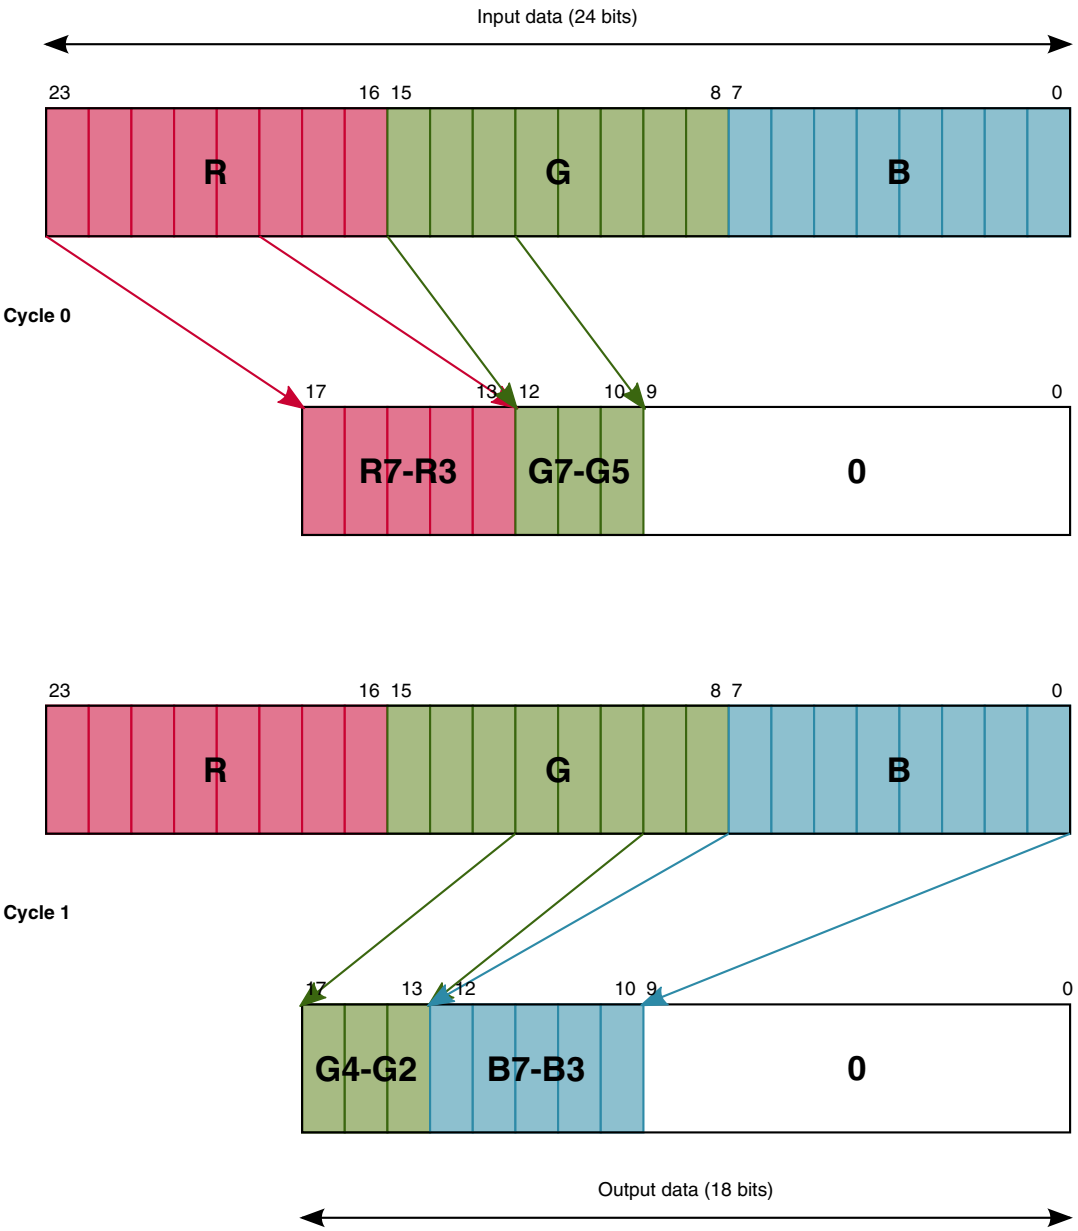
The mapping rule written in each of the Registers defines two types of parameters for the specific byte component and display:

1. Offsets of the byte component MSB relative to the output word LSB. Because the offsets can change dynamically, they are defined separately for the display clock cycles zero, one and two.
2. Numbers of the display clock cycles at which every bit of the byte component should be valid on the display bus. There are eight such 2-bit numbers in the Register.

Figure 45-33 presents an example of programming data packing for one of displays. Cycle 0 and Cycle1 in the diagram represent two separate atomic operations performed by the microcode template.



Cycle 0

MD_OFFSET_[R] - 0x11; MD_MASK_[R] - 0xF8

MD_OFFSET_[G] - 0xC; MD_MASK_[G] - 0xE0

MD_OFFSET[B] = 0x0; MD_MASK_[B] = 0x0

Cycle 1

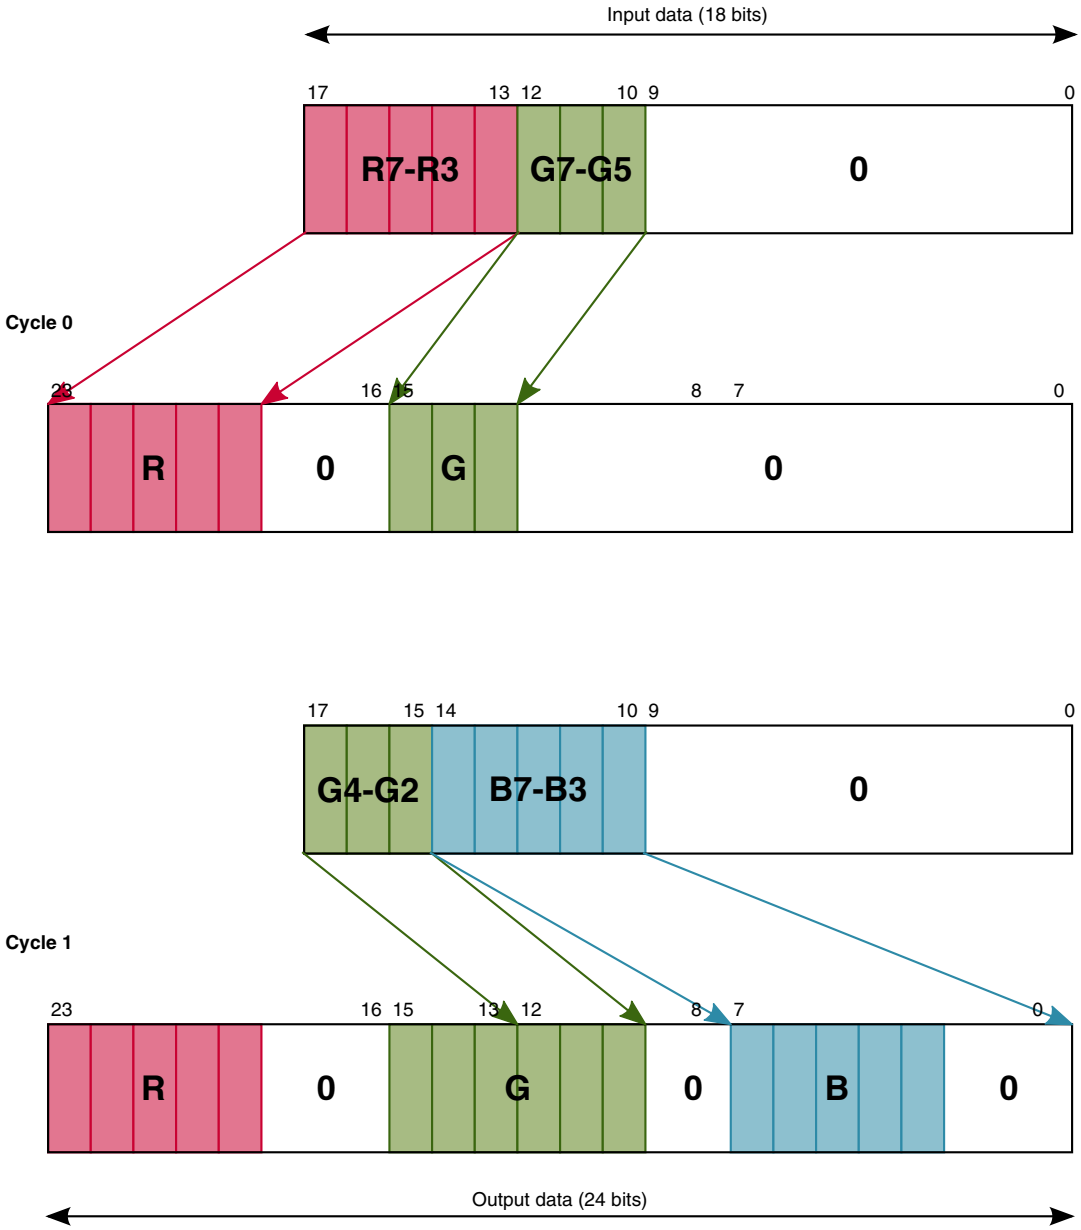
MD_OFFSET_[R] = 0x0; MD_MASK_[R] = 0x0

MD_OFFSET_[G] = 0x14; MD_MASK_[G] = 0x1C

MD_OFFSET_[B] = 0XE; MD_MASK_[B] = 0xF8

Figure 45-33. Example of Data Packing for Writing Data to th

The following figure presents an example of programming data packing for one of displays. Cycle 0 and Cycle1 in the diagram represent two separate atomic operations performed by the microcode template.



Cycle 0

MD_OFFSET_[R] - 0x11; MD_MASK_[R] - 0xF8

MD_OFFSET_[G] - 0xC; MD_MASK_[G] - 0xE0

MD_OFFSET[B] = 0x0; MD_MASK_[B] = 0x0

Cycle 1

MD_OFFSET_[R] = 0x0; MD_MASK_[R] = 0x0

MD_OFFSET_[G] = 0x14; MD_MASK_[G] = 0x1C

MD_OFFSET_[B] = 0XE; MD_MASK_[B] = 0xF8

Figure 45-34. Example of Data Unpacking for Reading Data from the Display

The same packing/unpacking registers are used for parallel and serial interface.

45.4.8 DMFC - Display Multi FIFO Controller

The following figure shows the block diagram for the DMFC block.

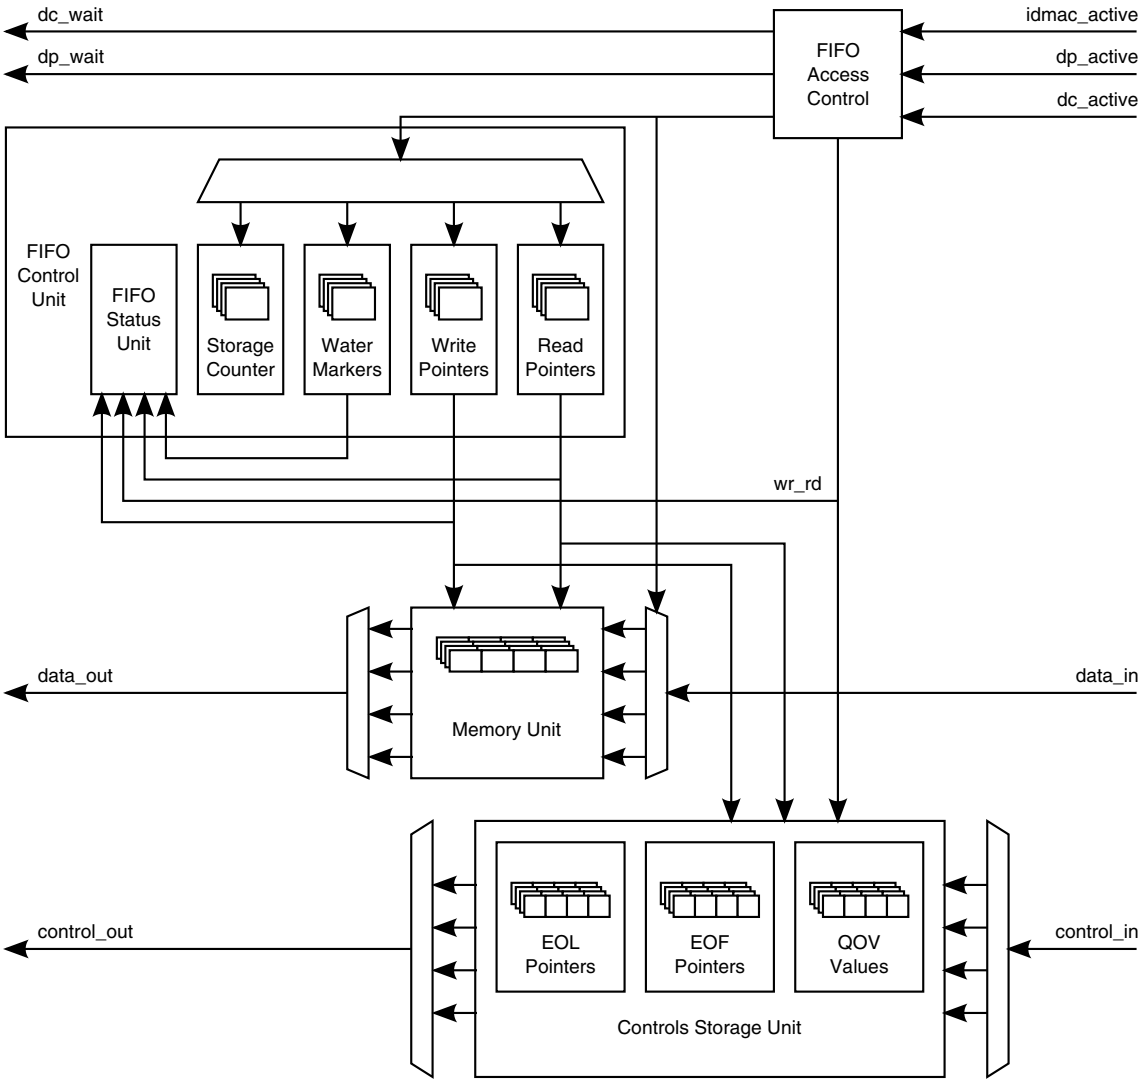


Figure 45-35. Display Multi Fifo Controller Block Diagram

The Display Multi Fifo Control manages Multi channels FIFOs. The DMFC serves the following clients:

- IDMAC - both read and write
- DP - read only
- DC - both read and write

- IC - write only
- AHB - both read and write

The DP and the DC read channels are physically attached to an IDMAC or an IC channel. As the IC has only one output channel connected to the DMFC. When the input is coming from the IC it replaces a channel that was physically attached to the IDMAC. The DMFC uses a single physical memory that serves the DP and DC read channels. The AHB accesses to the DC and the DC's write channel (read from display) use a separate physical memory.

45.4.8.1 DP and DC read channels

Each one of the DP and the DC read (read from memory) channels is physically attached to an IDMAC read channel. A portion of the physical memory is allocated for each channel. The DMFC arbitrates between channels according to a predefined priority.

The DMFC controls each of the FIFOs

- Assert a request any time there's available place on the FIFO.
- Make sure that there's available place on the FIFO to accept the coming data.
- Optionally assert a watermark indication to avoid starvation

45.4.8.1.1 FIFO allocation to channels

The physical memory is partitioned to 8 segments. For each channel the user has to define the start address at a segment's boundary using the DMFC_ST_ADDR parameter.

The size of the FIFO allocated to a channel is defined by the DMFC_FIFO_SIZE parameter. The user must allocate the FIFO and avoid overlapping between FIFOs.

The DMFC hold few special indications like EOF, EOL, EOFILD. The most important one is end of line (EOL). If the size of the FIFO is shorter than or equal to the IDMAC line's length (FW) than no special restrictions on the DMFC usage.

If the size of the FIFO is greater than the IDMAC line's length (FW) than the user has to be aware to the following restriction for each channel.

The DMFC has two operation modes which are distinguished by the wait4eot bit. For each channel the DMFC can store a maximum number of EOL indication. The maximum number of EOL indications of EOL is given in the table below.

Table 45-25. DMFC's number of EOL indications

IDMAC's Channel	Maximum lines on the FIFO
23	Up to 3 lines
27	Up to 2 lines
28	Up to 2 lines
Other	Up to 1 line

If the use case is that the number of EOL indications cannot exceed the maximum number of EOL indications than the user should have the wait4eot cleared.

If the use case is that the number of EOL indication can exceed the maximum number of EOL indications than the user should have the wait4eot set.

Having the wait4eot bit set has performance impact as the DMFC analyzes the data prior to sending it to the destination. In addition the DMFC cannot utilize the entire FIFO allocated to this channel.

The user need to specify the burst size of the IDMAC by setting the DMFC_BURST_SIZE field. This field must match the IDMAC settings. In case that the IDMAC's burst size is not a power-of-2 number, the value of this field should be rounded up to the nearest power-of-2 number. The burst size must not be greater than the FIFO's size.

45.4.8.1.2 Arbitration between channels

The arbitration between channels is fully hardware controlled. IDMAC has the highest priority. Then the synchronous channels. Then the asynchronous channels.

45.4.8.1.3 Watermark

The DMFC can generate a water mark signal for each channel. The watermark signal is sent to the IDMAC and dynamically increases the channels priority on the IDMAC's arbitration.

The watermark feature is enabled by the DMFC_WM_EN bit. The FIFO is partitioned to bursts. The user can set the watermark level at a burst boundary.

The watermark signal is set when the number of bursts on the FIFO + the number of already requested burst is smaller than the value specified on DMFC_WM_SET bit.

The watermark signal is cleared when the number of bursts on the FIFO + the number of already requested burst is greater than the value specified on DMFC_WM_CLR bit.

DMFC_WM_SET must be smaller than DMFC_WM_CLR.

45.4.8.2 IC interface

One of the IDMAC channels can be replaced by a flow coming from the IC using the DMFC_IC_IN_PORT. The user has to provide the IC's setting to the DMFC by programming the DMFC_IC_FRAME_WIDTH_RD, DMFC_IC_FRAME_HEIGHT_RD and DMFC_IC_FRAME_PPW_C fields. The burst size of the channel coming from the IC should always be programmed to 4 words.

45.4.8.3 DC write channel and AHB accesses

The second physical memory of the DMFC serves the

- IDMAC write channel (read from display)
- 2 AHB channels that can be read or write

The IDMAC write channel is programmed using the DMFC_RD_CHAN register in a similar way to the DC and DP read channels described above. The user has to provide the frame width and height for this channel and the pixel per word parameter.

The AHB channels are used from accesses via the AHB port to the display. The accesses are distributed between channels according to the MCU_T parameter.

45.4.9 DP - Display Processor

The display processor processes the image prior to sending it to the display. The main task performed by the DP is combining between 2 planes. The DP has 2 input FIFOs holding the data of full plane and the partial plane. In addition the DP performs some image enhancement functions like gamma correction, Color space conversion including Gamut mapping.

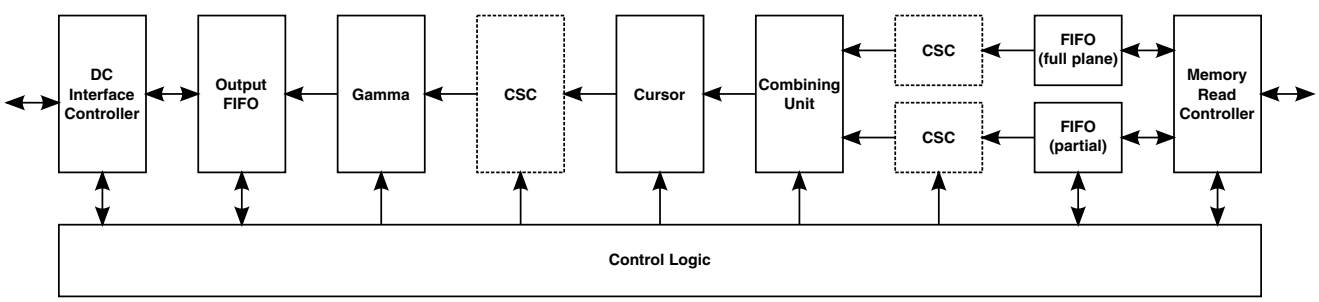

Figure 45-36. DP Micro architecture diagram

45.4.9.1 The DP programming model

The DP supports 3 flows. One sync flow and 2 Async flows. The DP holds 3 sets of registers. one set for each flow. Hence when referring to a register in this section the information is applicable to all the 3 sets. for example when referring to DP_COM_CONF, the information is applicable to DP_COM_CONF_SYNC, DP_COM_CONF_ASYNC0 and DP_COM_CONF_ASYNC1.

45.4.9.2 Displayed Planes

The following figure shows the planes displayed on a display.

There are full and partial planes. The partial plane's position is defined relatively to the upper left corner of the full plane (BGXP and BGYP). The size of the partial and full planes is defined on the corresponding IDMAC's channels' FW and FH parameters. The cursor position and parameters are set in the DP_CUR_POS register.

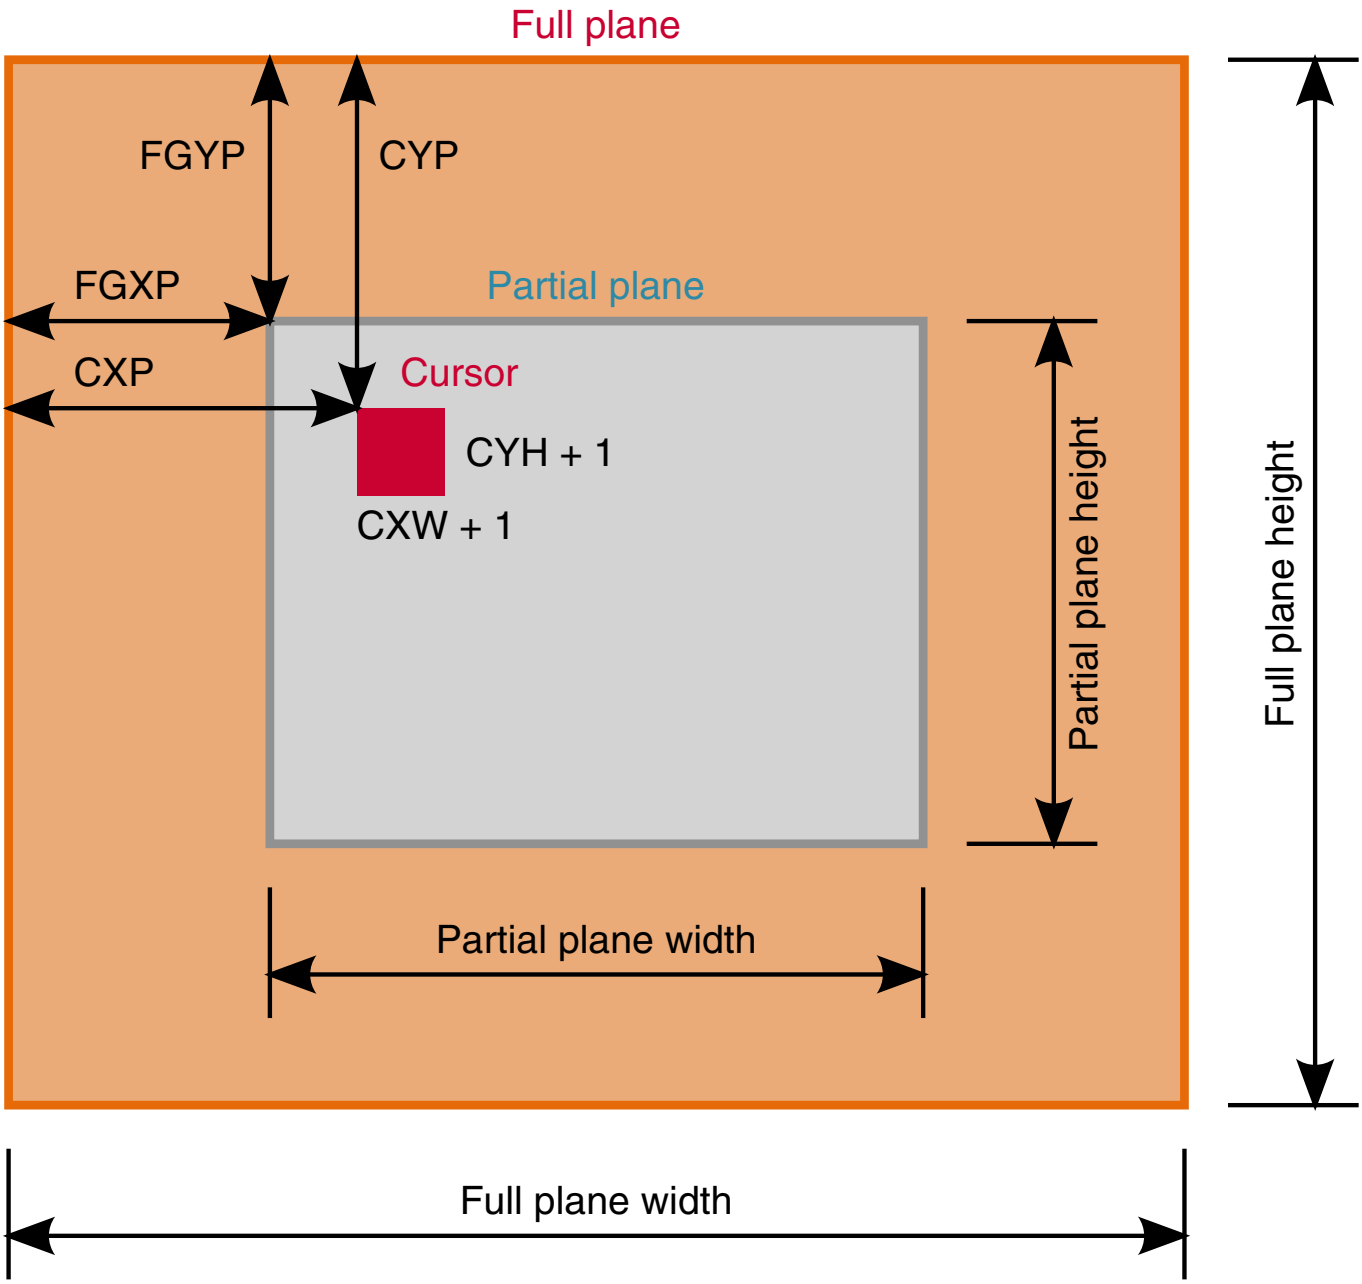

Figure 45-37. Displayed Planes

45.4.9.3 Combining Unit

The Combining Unit performs combining between the full and the partial planes. Each one of the planes may be graphics or video plane.

There are the following combining options:

- local alpha blending,
- global alpha blending,
- use of key color.
- order of the planes (full is presented over the partial plane and vice versa)

Combining mode is selected via the DP_COM_CONF Register. The combining equation is:

OP = BG*(1 - a) + FG*a

Where BG and FG are 2 input pixels; The DP_GWSEL bit defines if the BG is the pixel coming from the full plane or the partial plane.

a= (A+floor(A/128))/256 - an alpha value

A - a global or local transparency parameter.

The global A is written in the DP_GWAV field, the local A arrives together with the pixel.

A pixel becomes transparent when color keying is enabled and a pixel color matches a key color (independently on an alpha parameter). The color keying is defined on:DP_GWCKR, DP_GWCKG, DP_GWCKB

Combining takes 1 cycle per pixel. The Combining Unit outputs 24-bit words in the RGB/YUV format.

45.4.9.4 Cursor Generator

The Combining Unit output is passes through the Cursor Generator. The cursor's size and position are set via the DP_CUR_POS Register, a cursor color - via the DP_CUR_MAP Register. Different logic functions of combining the cursor with the image are supported as defined by the DP_COC field.

The cursor can be blinking. The blinking mechanism resides on the display controller sub-block. The blinking parameters are defined on the DC_BK_EN and DC_BKDVIV fields.

45.4.9.5 Color Space Conversion unit - CSC

The DP can get 2 input pixels from 2 different color spaces (YUV or RGB) and convert one of them to a common color space (YUV or RGB). In addition the 2 inputs can be of the same color space where the result is converted to another color space (YUV or RGB).

The DP has a single CSC unit that can be placed on one of 3 locations:

- At the output of one of the 2 input FIFOs
- At the output of the cursor generator.

Placing is done according to the DP_CSC_DEF field.

The color conversion implements a 3x3 matrix multiplication between the full RGB pixels and the color conversion constants, in order to obtain a YCC format image.

The conversion formula is:

x -> Clip(Round(S* 2^E)), S=Ax+B

where

A is a 3x3-dimensional matrix of weights, each a 10-bit signed number with 8 fractional digits

$$A = \begin{bmatrix} CSC\_A0 & CSC\_A1 & CSC\_A2 \\ CSC\_A3 & CSC\_A4 & CSC\_A5 \\ CSC\_A6 & CSC\_A7 & CSC\_A8 \end{bmatrix}$$

B is a 3-dimensional vector of offsets, each a 14-bit signed number with 2 fractional digits

$$B = \begin{bmatrix} CSC\_B0 & CSC\_B1 & CSC\_B2 \end{bmatrix}$$

S is a 3 dimensional vector of sums, each a 16-bit signed number with 4 fractional digits

S=Ax+B

E is an exponent, assuming one of the following values: -1,0,1,2 (allowing weights up to 8). The CSC_S parameters are encoded by 2 bits, please refer to the CSC_S parameter description.

$$E = [CSC\_S0\ CSC\_S1\ CSC\_S2]$$

A more explicit formula:

S[i] = (sum(A[i][j]*In[j]) >> 4) + (B[i] << 2) + (1 << (3-E[i]))

Out[i] = Clip(S[i] >> 4-E[i])

Where Clip() performs clipping to the range 0..255 (either per-component clipping or more sophisticated clipping that preserves the hue of the pixel)

45.4.9.5.1 Gamut mapping

When the color transformation produces colors outside the allowed range, they must be mapped back. This is called gamut mapping. The DP supports 2 clipping algorithms. (controlled by GAMUT_SAT_EN bit)

Hue preserving clipping algorithm is suitable only for RGB components. For YUV components, the per-component clipping algorithm is used.

Per component Clipping

This mapping is performed by clipping each of the components independently to its allowed range of values (the final value being uint8):

•Y: to 0..255 or 16..235 according to the SAT_MODE bit

•U/V: to 0.255 or 16..240 according to the SAT_MODE bit

Hue Preserving Clipping

Hue Preserving clipping is done in the following way

•First stage - eliminating negative values

```
N = min(R,G,B)
if (N<0) X-> X-N, where X=R,G,B
```

•At this stage, all components are non-negative and the MSB's beyond d=11 bits are ignored (assumed 0).

•Second stage - eliminating large values

```
M = max(R,G,B) (d-bit integer)
if (M>255)
```

```
M' = M >> (m-7), where m=8..d-1 is the index of the most-significant non-zero
bit in M
D' = Ceil(256*255/M') = 256..510 (since M' = 128..255)
Ceil(x) = the smallest integer which is not smaller than x
Implemented by a hard-wired 128x9-bit LUT
X -> min(255, (X*D')>>(m+1)), where X=R,G,B (8x9 multiplier)
else
X -> X
```

45.4.9.6 Gamma correction

The DP includes a gamma correction function. It is approximated by the piece-wise polynomial:

gammar = GAMMA_C<i> + ((R[4:0] * GAMMA_S<i>) >> 4 + 1)>>1

Where R is the input red component, that's a 9 bit input composed pixel_in*2+pixel_in[7].

Single approximation slope is used for Gamma Correction of red, green and blue color components. However the Gamma Correction block instantiated three times since processing for color components should be done in parallel. The gamma transform is also available for changing the contrast of the luminance component only.

The required Gamma correction slope for a specific display should by provided by the display manufacture. This information can be provided in various forms, as graph or formula. The gamma correction input pixel level (Gin) should be normalized to a maximum of 383. The gamma correction output pixel level (Gout) should be normalized to a maximum of 255. Then a following data should be collected:

Table 45-26. Gamma correction values

Gin	Gout
0	Gout0
2	Gout1
4	Gout2
8	Gout3
16	Gout4
32	Gout5
64	Gout6
96	Gout7
128	Gout8
160	Gout9
192	Gout10

Table continues on the next page...

Table 45-26. Gamma correction values (continued)

Gin	Gout
224	Gout11
256	Gout12
288	Gout13
320	Gout14
352	Gout15

Based on the table above the values of DP_GAMMA_S_SYNC<i> and DP_GAMMA_C_SYNC<i> fields for gamma correction control registers are calculated as following:

Table 45-27. Gamma correction values

i	DP_GAMMA_C_SYNC<i>	DP_GAMMA_S_SYNC<i>
0	Gout0	16*(Gout1-Gout0)
1	2*Gout1-Gout2	16*(Gout2-Gout1)
2	2*Gout2-Gout3	8*(Gout3-Gout2)
3	2*Gout3-Gout4	4*(Gout4-Gout3)
4	2*Gout4-Gout5	2*(Gout5-Gout4)
5	Gout5	Gout6-Gout5

12	Gout12	Gout13-Gout12
13	Gout13	Gout14-Gout13
14	Gout14	Gout15-Gout14
15	Gout15	255-Gout15

45.4.9.7 DC interface

The DC interface unit performs 2 tasks.

- Starts the flow via the DP by getting a request from the DC and once the DP is ready send the new frame request to the IDMAC.
- Control the DP's output FIFO and send the data to the DC using an handshake mechanism.

45.4.9.8 DP's flows management

The DP can manage up to 3 flows: one synchronous flow and 2 asynchronous flows. However the DP can handle only one flow simultaneously. The DP has an automatic mechanism to control and switch between flows.

The DP's highest priority flow is the sync flow. An async flow can be executed during the blanking interval of the sync flow. An async flow can be stopped in order to serve the sync flow. The sync flow cannot be broken. The DP holds 3 sets of registers, one set for each flow. The registers are located in the SRM memory. According to the flow that needs to be executed the correct set of registers is loaded to the DP.

The figure below illustrates the flow management done by the DP.

A flow starts when a request from the DC arrives and the internal pipe is empty. For sync flows the full frame NF (new frame) indication is immediately. In case that a partial frame is also used the NF indication will be sent one row before the row that the partial plane is actually positioned.

In case of ASYNC flow the DP first check if the previous async flow was broken. If yes, the DP restores the last settings of the previous flow. If this is a new async flow the DP will first reload the flow's parameters from the SRM. In case that a partial frame is also used the NF indication will be sent one row before the row that the partial plane is actually positioned.

45.4.9.9 DP debug unit

The DP supports synchronous and asynchronous flows using the same hardware. The asynchronous flow can be broken by the synchronous flow. The DP's debug unit provides the ability to know on which row exactly the async flow has been broken. This is done by providing an interrupt (with DP_DEBUG_CNT register) and providing row status flags (on DP_DEBUG_STAT register).

As the async flow can broken multiple times within a specific frame The user can control the breaking point the issues the debug event by programming BRAKE_CNT field.

45.4.9.10 Restriction

When both full and partial planes are processed, the full plane's minimal frame width is 13 pixels.

The Minimum frame height supported by the DP is 2 lines.

45.4.10 Display Interface (DI)

The DI provides arbitrates access to up to three displays with time multiplexing. It converts a data from the DC or the ARM platform (low level access for serial interface only) to a format suitable for the specific display interface.

The DI generates display clocks and other display control signals with programmable timings. The DI outputs data to or inputs from parallel and/or serial interfaces.

This block generates all the control signals sent to the display. The DC sends to the DI; the data for the display and a set of control signals. The controls coming from the DC are used in order to generate the control signals sent to the display. One exception is serial low level access (LLA), where the DC is bypassed and the data is coming directly from the ARM platform. The figure below is the DI's block diagram.

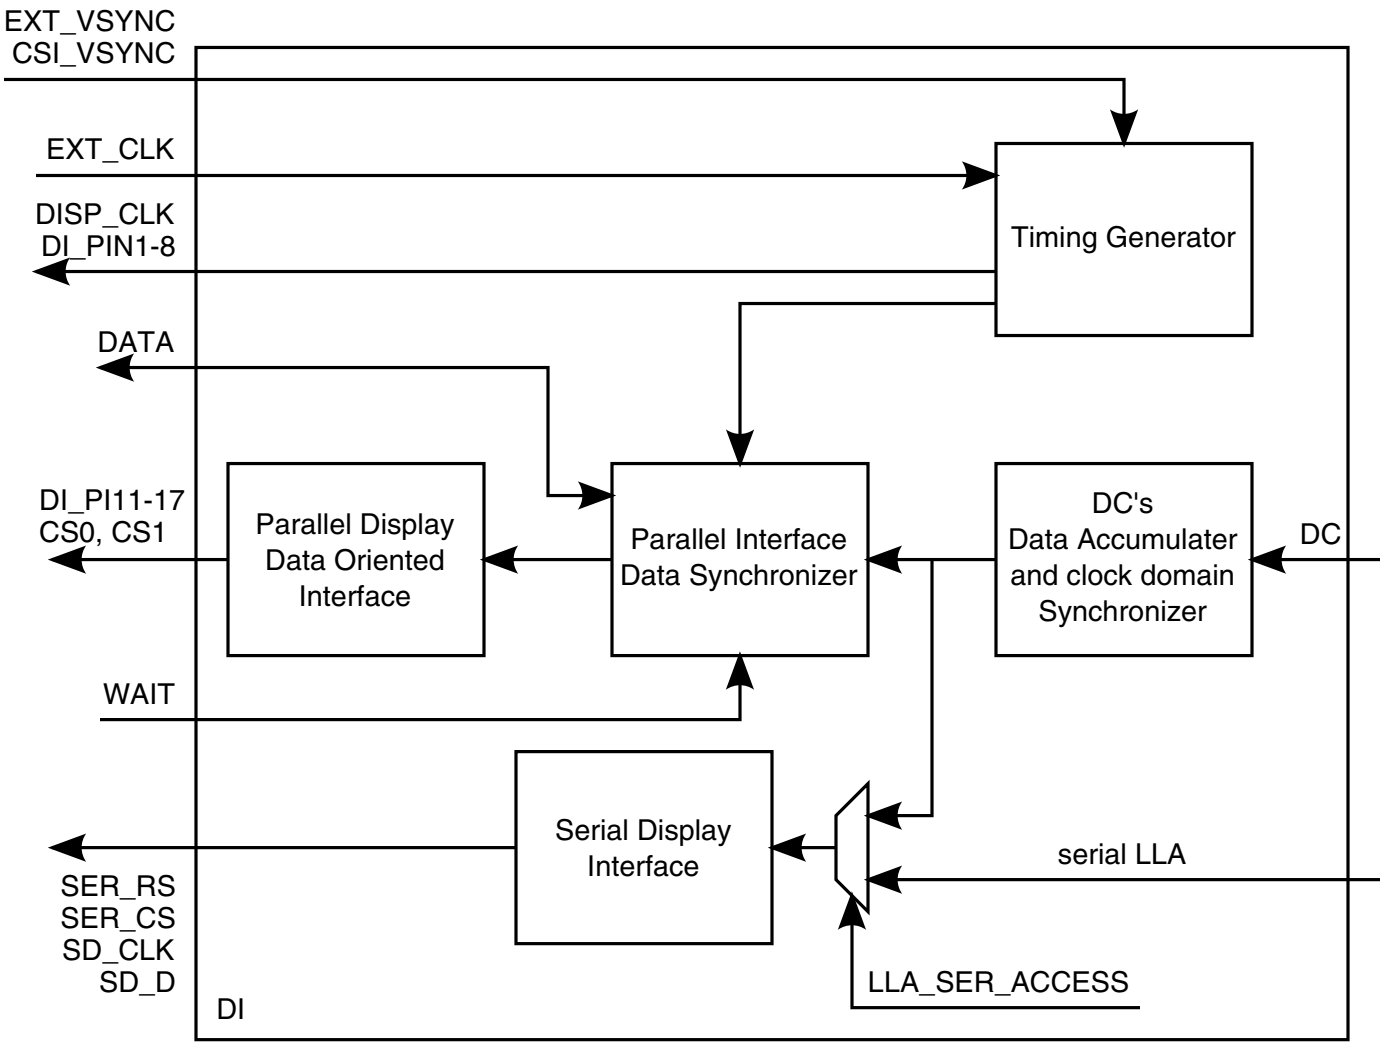

Figure 45-39. DI's block diagram

The display interface includes 2 groups of control signals:

- Time oriented signals - These type of signals are generated according to the DI's internal timers. These are free running signals that change their state according to a pre-defined waveform. For example VSYNC, HSYNC, display's clock (pixel clock) etc.
- Data oriented signals - The DC may add markers to data sent to the DI. These markers are used to indicate a specific attribute of the data (for example: end-of-line, end-of-frame, chip-select etc.). The marker coming from the DC triggers a specific waveform of one or more signals on the display's interface. The specific waveform will be seen on the bus along with the associated data. The markers may be synced to a time oriented signal. For example: attach the end-of-frame signal to the next VSYNC.

45.4.10.1 DC interface, data accumulator and clock domain synchronizer

The data accumulator is the DI's input buffer. It receives the data from the DC along with a set of control signals. The data accumulator receives the data from the DC's clock domain and synchronize it to the DI's clock domain.

45.4.10.2 Parallel interface data synchronizer and data oriented interface

The data accumulated in the DI's input buffer will be sent to the display according to the DI's internal events. Each event is generated by a counter. A tag is attached to each data by the DC's microcode using the SYNC field in the DC's microcode. The tag selects the event that the data will be synced to.

Once the corresponding event is generated, the data will be sent to the display. A data can be a pixel or a component (part of a pixel).The data synchronization occurs separately for each component. For asynchronous displays the tag will be equal to 0 i.e. the data is not synchronized to any event. The data will be sent out of the buffer immediately.

45.4.10.3 Timing generator

The timing generator is used for generating the waveforms' of each pin of the display's interface.

The timing generator is built of 10 counters. One counter functions as a time base This timer is called the BASE TIMER (BS). The other 9 counters are used in order to generate the control signals' waveforms. The last counter (counter #9) is special see Counter number 9.

The DI clock can be derived from IPU's clock (HSP_CLK) or from an external source (via the ipp_di_#_ext_clk pin). The clock's source is statically selected by configuring the DI#_CLK_EXT bit.

Figure 45-41 illustrates the main parameters of a waveform. A waveform's segment is built of 5 parameters. Each segment can be has 2 phase "ACTIVE PHASE" and "OFFSET PHASE".

- TIMEBASE - this is the base timer (fundamental timebase); all the other parameters are derived from this timer. The timebase is generated by counting DI clock cycles. The amount of cycles is defined according to DI#_DISP_CLK_PERIOD. This field

defines the Display interface clock period, This parameter contains an integer part (bits 11:4) and a fractional part (bits 3:0). It defines a fractional division ratio of the Di's source clock for generation of the display's interface clock. The timebase is generated from edge aligned pulses of the DI clock. The user can delay the timebase starting point by defining an offset to the timebase. This is done by configuring the DI#_DISP_CLK_OFFSET field. The offset is calculated from the point where the DI is enabled to the point where the timebase starts ticking. The display clock waveform is generated between 2 edges of the timebase. The waveform is defined according to the DI#_DISP_CLK_UP and DI#_DISP_CLK_DOWN. Each pin has a specific timebase that is derived from the fundamental timebase. The following figure illustrates the relations between the TIMEBASE and the DI's clock

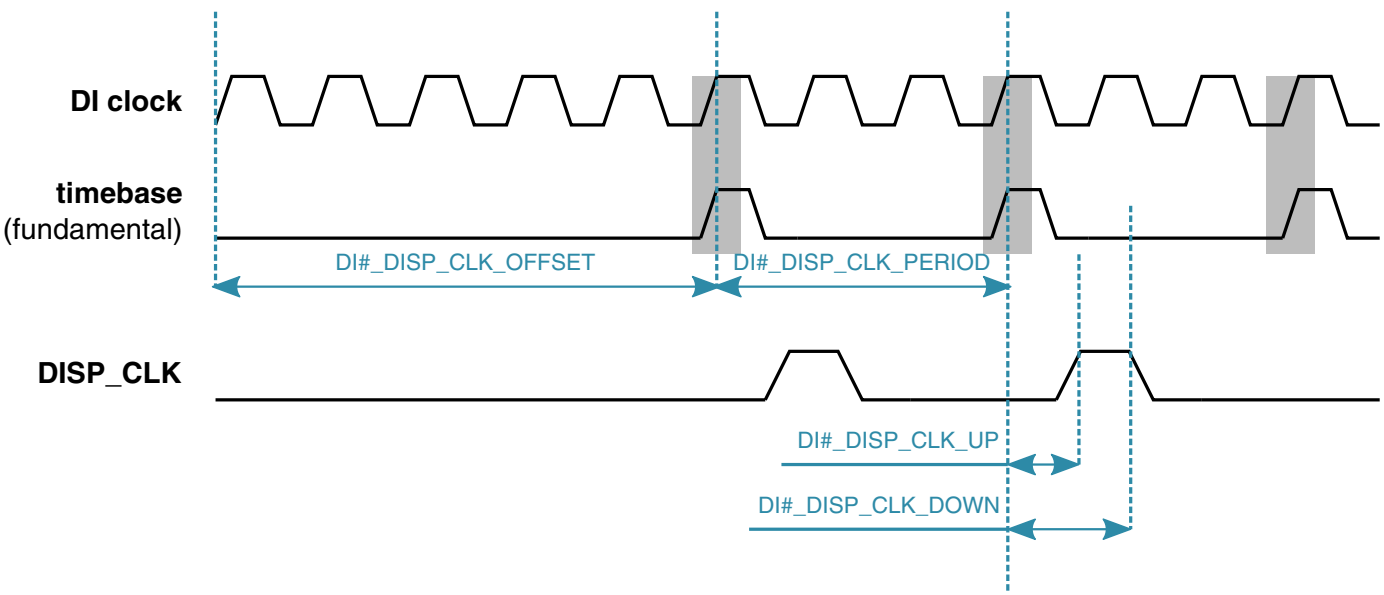

Figure 45-40. Timebase, DI's clock and display's clock relations

- OFFSET - this parameter defines when the length of the "OFFSET PHASE" it is defined by di#_offset_value_<N> field, where N is the counter's index.
- STEP - This parameter defines the length of the "ACTIVE PHASE"; it is defined by the di#_step_repeat_<N> field, where N is the counter's index. If the counter is in auto reload mode (di#_cnt_auto_reload_<N> bit is set) then the counter will be automatically reloaded forever. The value of di#_step_repeat_<N> is ignored in that case.
- RUN - The "ACTIVE PHASE" is partitioned to several "RUN sections"; this parameter defines the length of the "RUN section"; it is defined by the di#_run_value_m1_<N> field, where N is the counter's index.

- UP - Each "RUN section" contains the waveform of a single pulse. This parameter defines the offset from the beginning of the "RUN section" to the assertion of the signal; it is defined by the di#_cnt_up_<N> field, where N is the counter's index.
- DOWN - This parameter defines the offset from the beginning of the "RUN section" to the negation of the signal; it is defined by the di#_cnt_down_<N> field, where N is the counter's index. In case where DOWN < UP the waveform will have a 50% duty cycle.

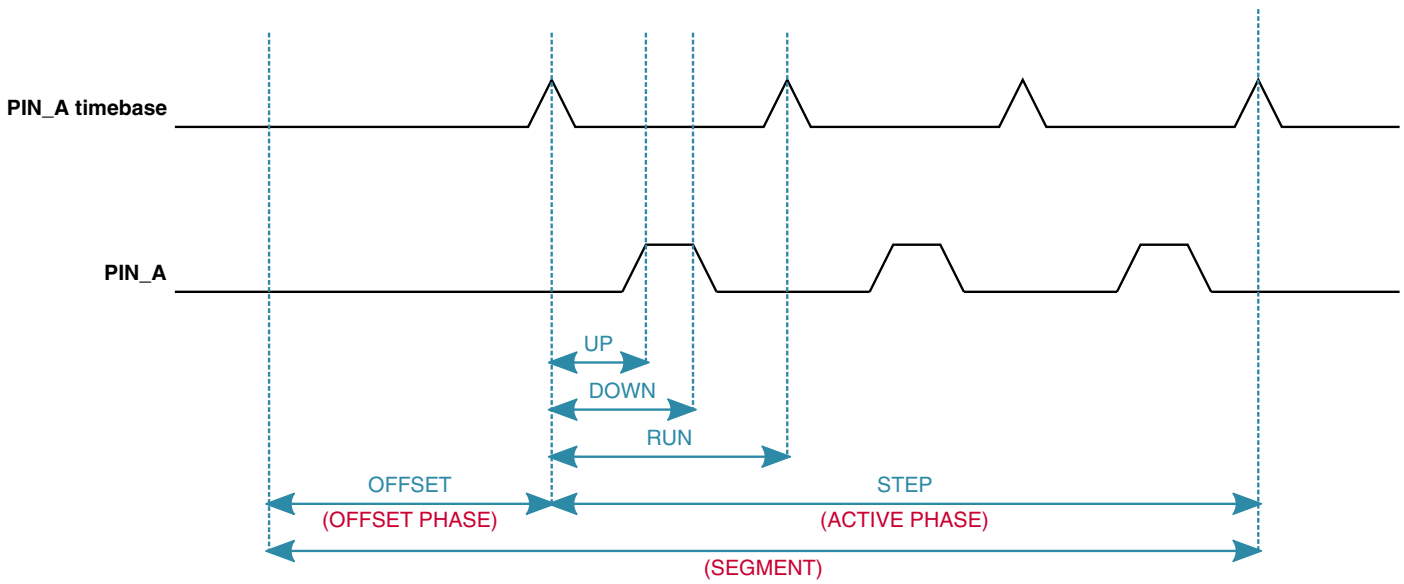

Figure 45-41. DI waveform's main parameters

45.4.10.3.1 Waveform concatenation

The DI provides the ability to derive the waveform from the fundamental timebase or from another PIN. In that case, one pin's waveform is used as another pin's timebase.

The following figure provides an example. PIN_A and PIN_C are derived from the fundamental timebase. However, PIN_B is derived from PIN_A's wavefore. The trigger is selected by DI#_RUN_RESOLUTION_<N>, where <N> is the index of the counter. A counter can be triggered by a counter with lowered index. For example: counter #5 can be triggered by counter #3 but can't be triggered by counter #7.

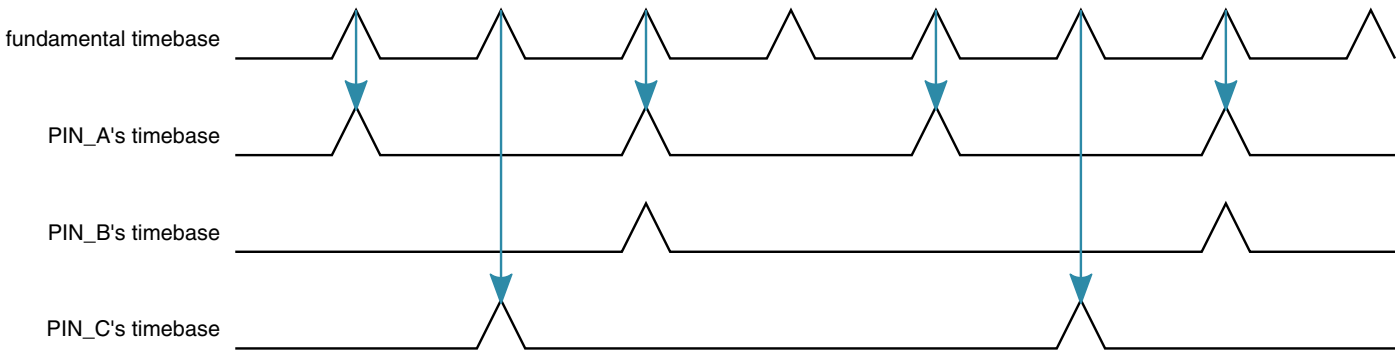

Figure 45-42. DI pins - Waveform's time bases concatenation

45.4.10.3.2 The basic counter

The DI has 9 counters. A counter is built of 3 units: timebase generator, waveform generator and polarity generator.

Figure 45-43 illustrates the counter's structure.

The timebase generator

The timebase generator gets 3 triggers. Clear, offset and run trigger. The Clear is the trigger that resets the counter. It is selected by programming the DI#_CNT_CLR_SEL_<N>.

The Offset trigger is the trigger used for counting the OFFSET_PHASE. The user can select the source of the trigger by programming the DI#_OFFSET_RESOLUTION_<N>. The offset's value is defined by programming the DI#_OFFSET_VALUE_<N>

The RUN trigger is the trigger used for counting the RUN period. The user can select the source of the trigger by programming the DI#_RUN_RESOLUTION_<N>. The RUN's value is defined by programming the DI#_RUN_VALUE_<N>

The timebase generator counts according to the DI_CLK or according to another counter's output. In order to use a source different than DI_CLK, the user should set the POLARITY_GEN_EN bits to 01.

Waveform generator

This unit generates the waveform. It gets the values of RUN, UP, DOWN and STEP and build the waveform accordingly. The waveform is counted according to the signal generated by the timebase generator.

Polarity generator

The waveform's polarity is controlled by 2 units. The static polarity is changed according to the POLARITY_<#> bit of each pin. This bit defines if the waveform of the pin is active high or active low.

The other unit controlling the polarity is the polarity generator. This unit is enabled by setting the POLARITY_GEN_EN[1] to 1. The polarity generator has 2 modes: "toggle mode" and "normal polarity mode". The mode is defined according to POLARITY_GEN_EN[0].

- Normal polarity mode - In this mode the polarity is changed according to 2 other counters. The counter selected by POLARITY_TRIGGER_SEL define the sampling point. The counter selected by POLARITY_CLR_SEL defines the polarity value. At the sampling point the polarity value is defined. The current polarity value defines the current polarity of the waveform.
- Toggle mode - In this mode, the output of the timebase generator's output causes the polarity to toggle. Any tick of the timebase generator inverts the polarity. When this mode is enabled the ticks generated by the counter selected by POLARITY_TRIGGER_SEL initialize the polarity generator and the timebase generator causes the polarity to toggle.

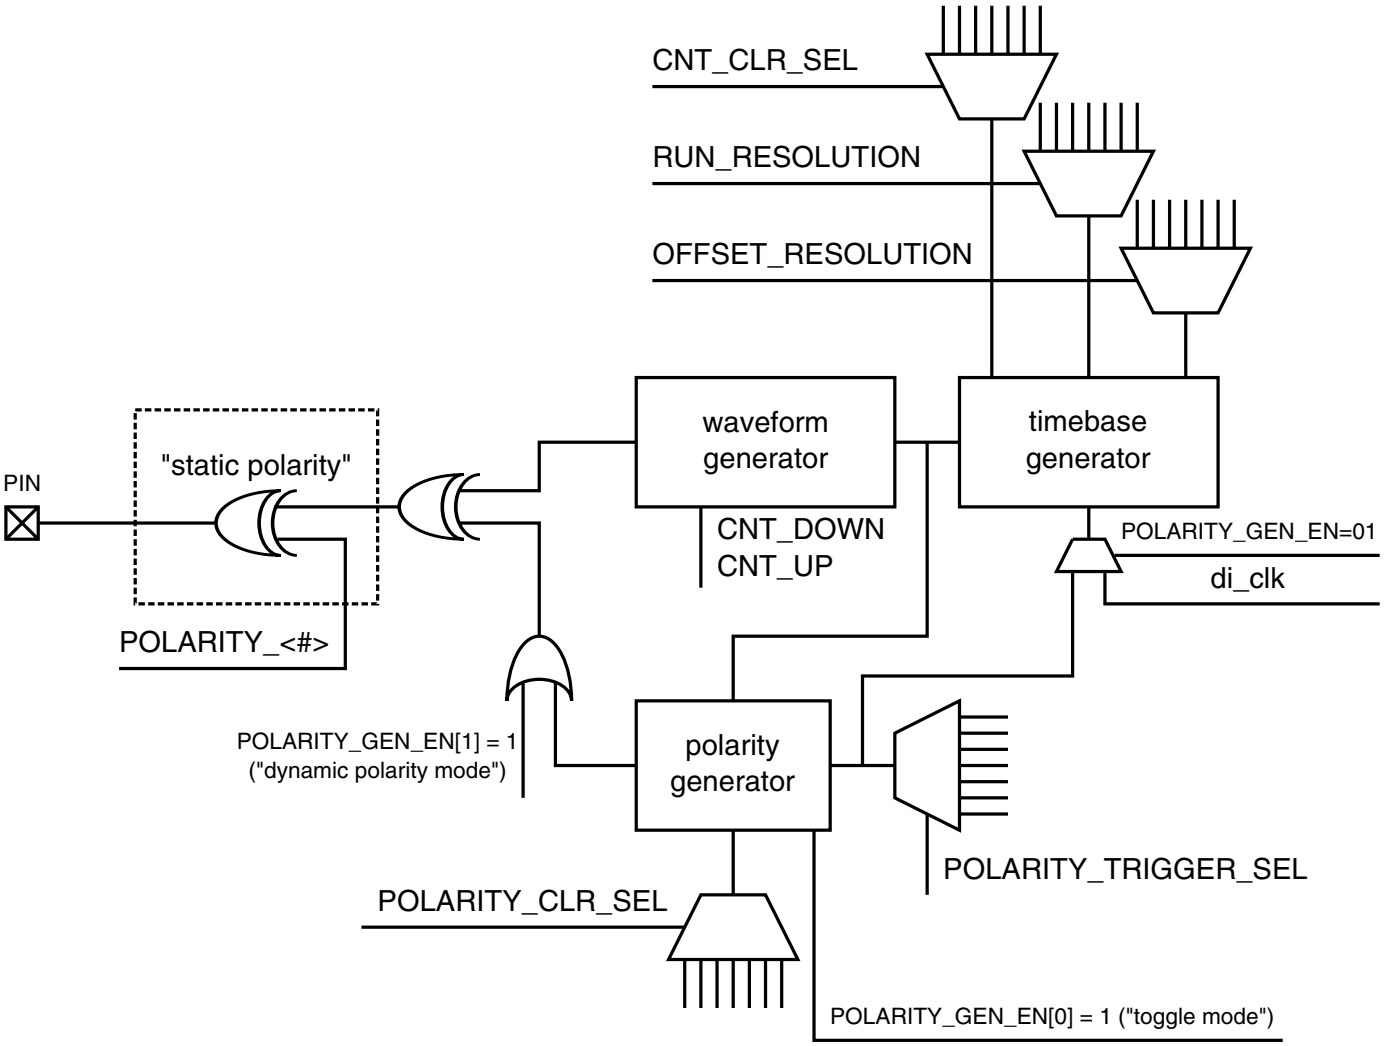

Figure 45-43. DI's counter's structure

The following figure provides an example for waveform generation using different trigger sources. The waveform is generated for PIN_D. PIN_D counter is cleared by the PIN_C's timebase. The offset period is calculated by counting cycles of PIN_B's timebase. The RUN period is calculated by counting cycles of PIN_A's timebase. The UP and DOWN periods of the waveform are calculated by counting cycles of PIN_D's timebase.

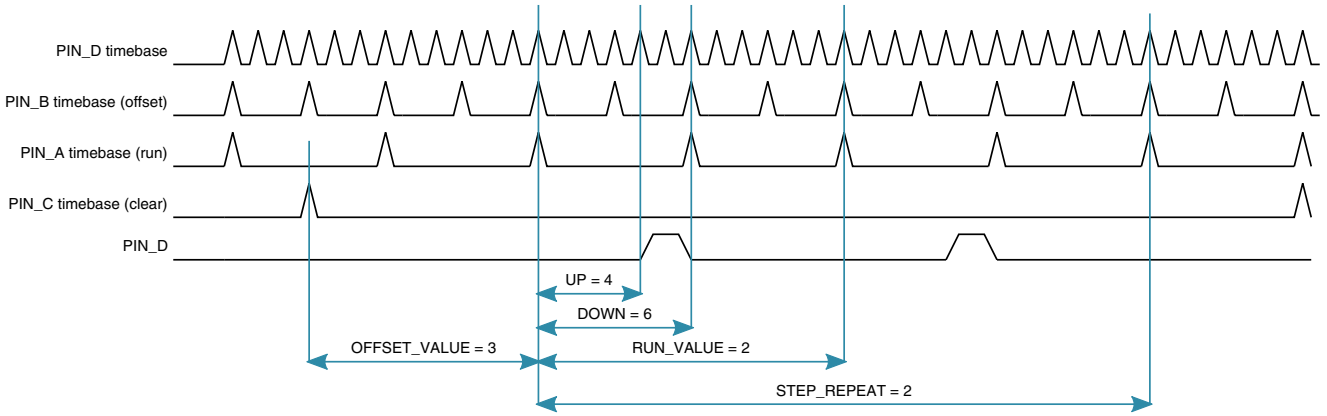

Figure 45-44. Clear, offset and run triggers and values - Example

45.4.10.3.3 Counter number 9

The last counter (counter #9) is an auxiliary counter and it is not used for generating a waveform for a specific pin. It can be used in order to attach another waveform to an existing one.

The user define the waveform for a specific pin (main pin). The user defines the auxiliary waveform using counter #9. The 2 waveforms are logically ORed. The combined waveform will be routed to the main pin. The main waveform that this counter is attached to is defined according to DI#_GENTIME_SEL_9.

The tag of counter #9 can be generated from counter #9 or from the main waveform. This is selected according to the DI#_TAG_SEL_9.

45.4.10.3.4 DI's active window

The DI provides an alternative way to define the synchronous display setting by using an active window and thus, needs to program less counters. The synchronous display's active window is a rectangle on the display where IPU sends data. It is set by programming the parameters defined on DI#_AW0 and DI#_AW1 registers.

The following figure illustrates the different parameters defining the active window. The display's vertical and horizontal position are defined according to counters. The DI#_AW_HCOUNT_SEL selects the counter which the horizontal position is calculated according to. DI#_AW_VCOUNT_SEL selects the counter which the vertical position is calculated according to. The Active data is sent according to a trigger. DI#_AW_TRIG_SEL selects the counter which calculates this trigger. This trigger usually functions as a data enable signal.

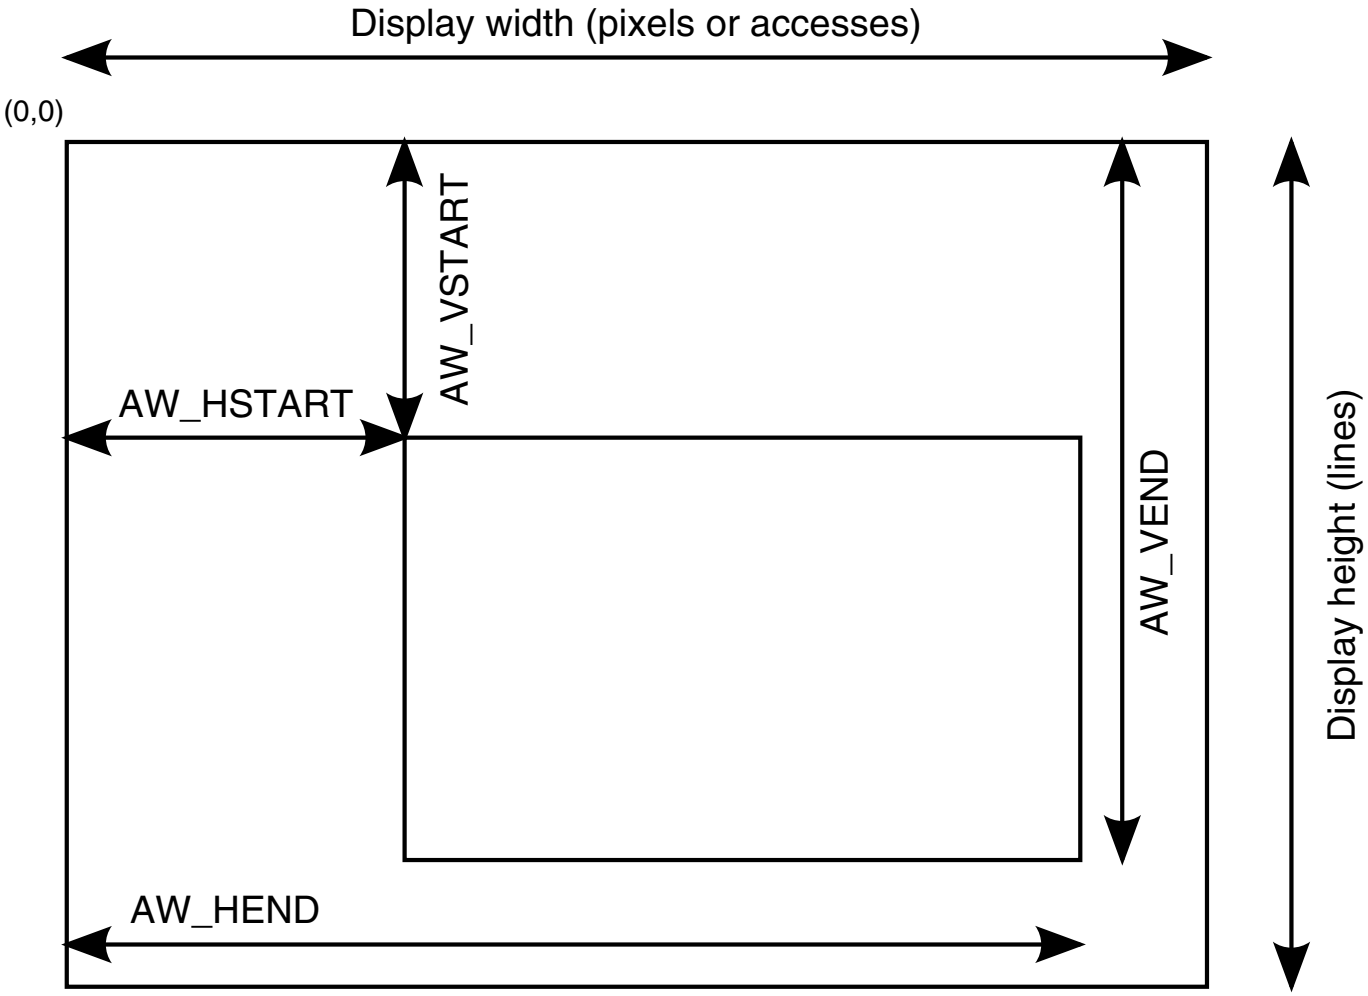

Figure 45-45. DI's Active Window

45.4.10.4 Waveform settings for asynchronous interface pins

The DI provides 8 signals that are used for asynchronous interface. These signals are PIN11 through PIN17 (ipp_di_#_pin_11 through ipp_di_0_pin_17) and the CS (ipp_di_0_do_dispb_d0_cs).

The DI holds 12 wave set quartets. Each quartet includes 4 registers (DI#_DW_SET<j>_<i>). Each DW_SET register holds the UP and DOWN values of the waveform. The DW_SET register is selected in the following way. The WAVEFORM field in the DC template is a pointer that points to one of the 12 quartets. In addition the WAVEFORM field points to one of 12 DI#_DW_GEN_<i> registers. The DI#_DW_GEN_<i> holds 9 pointers. The pointers are 2 bits field that points to one of the registers from the DI#_DW_SET<j>_<i> quartet. Each one of the 8 pointers in the

DI#_DW_GEN_<i> registers is related to a specific pin of the DI's asynchronous interface. The following figure illustrates the relations between the registers controlling the asynchronous interface's signals.

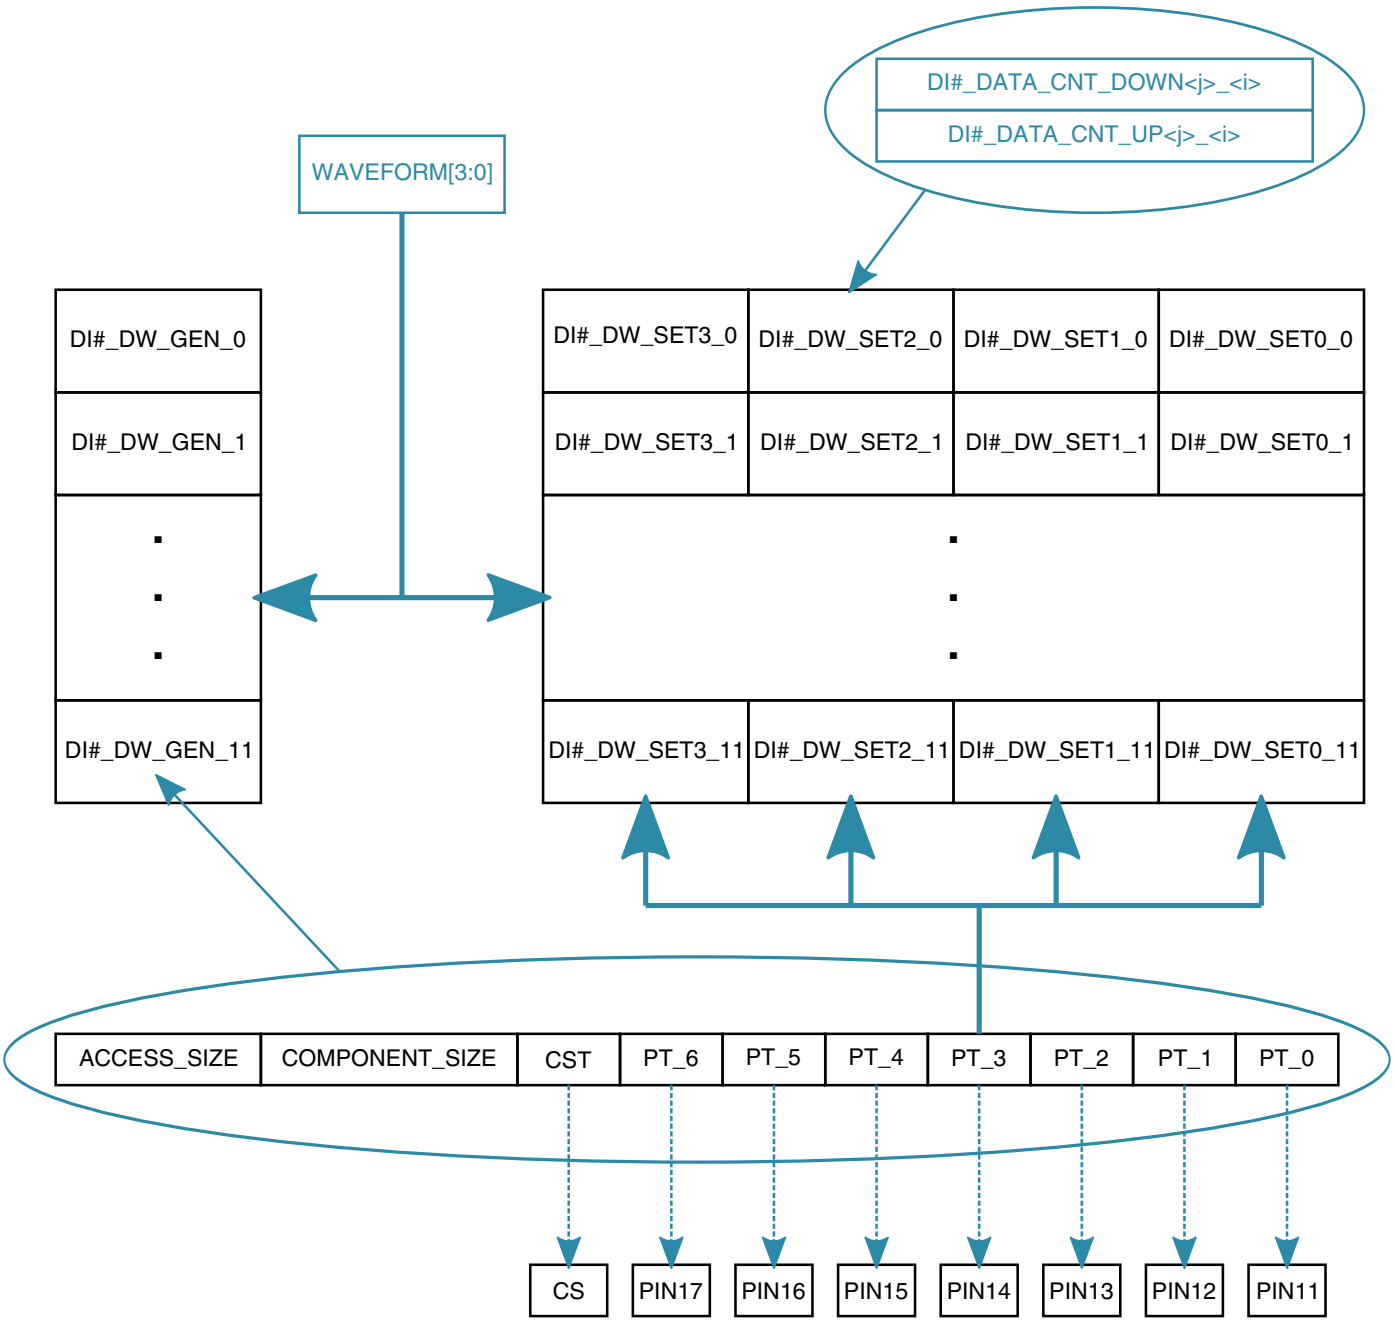

Figure 45-46. Waveform settings for asynchronous interface pins - parallel interface

The DI#_DW_GEN_<i> register includes the data's waveform settings as well. ACCESS_SIZE defines the amount of DI clock cycles that a pixel is valid on the bus. When generic data is sent, this field defines the amount of cycles that the generic data is

valid on the bus. A pixel may be broken into few components. The COMPONNENT_SIZE field defines the amount of cycles that each component is valid on the bus.

The COMPONNENT_SIZE is always smaller or equal to ACCESS_SIZE. For synchronous interface COMPONNENT_SIZE is always equal to ACCESS_SIZE. In case that there's a need for some gap between one type of accesses to another having the COMPONNENT_SIZE smaller than ACCESS_SIZE can be useful (for example read after write accesses that require some gap between them).

45.4.10.5 Serial display interface

The DI supports the following asynchronous serial interfaces:

1. 3-wire (with bidirectional data line).
2. 4-wire (with separate data input and output lines).
3. 5-wire type 1 (with sampling RS by the serial clock).
4. 5-wire type 2 (with sampling RS by the chip select signal).
    - For serial interfaces accessed in LLA mode, data and preamble lengths and other parameters are controlled via the DI0_SER_CONF and DI1_SER_CONF Registers.

The serial display interface includes generators for the CS, RS and CLK signals of the display interface and a bidirectional datashifter. The figure below provides a block diagram of the serial display interface.

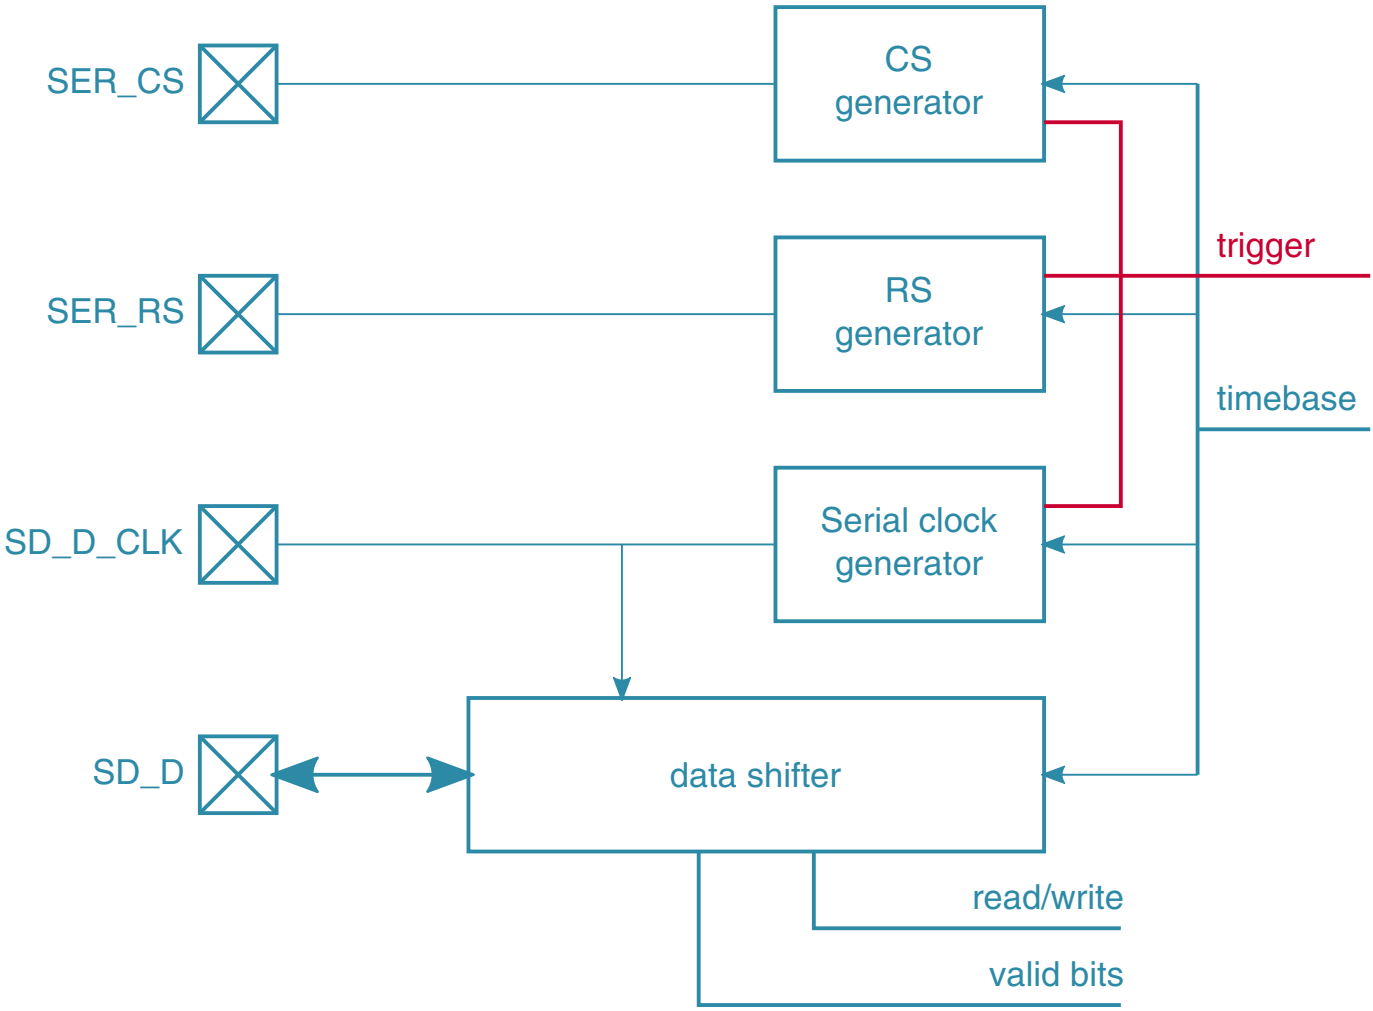

Figure 45-47. Serial display interface

45.4.10.5.1 Waveform settings for serial interface pins

When serial interface is used the fields in the DI#_DW_GEN_<i> register have different meaning than the parallel interface. The registers includes pointers to DW_SET for the CS, RS and CLK pins of the serial interface.

The following figure illustrates the relations between the registers controlling the serial interface's signals.

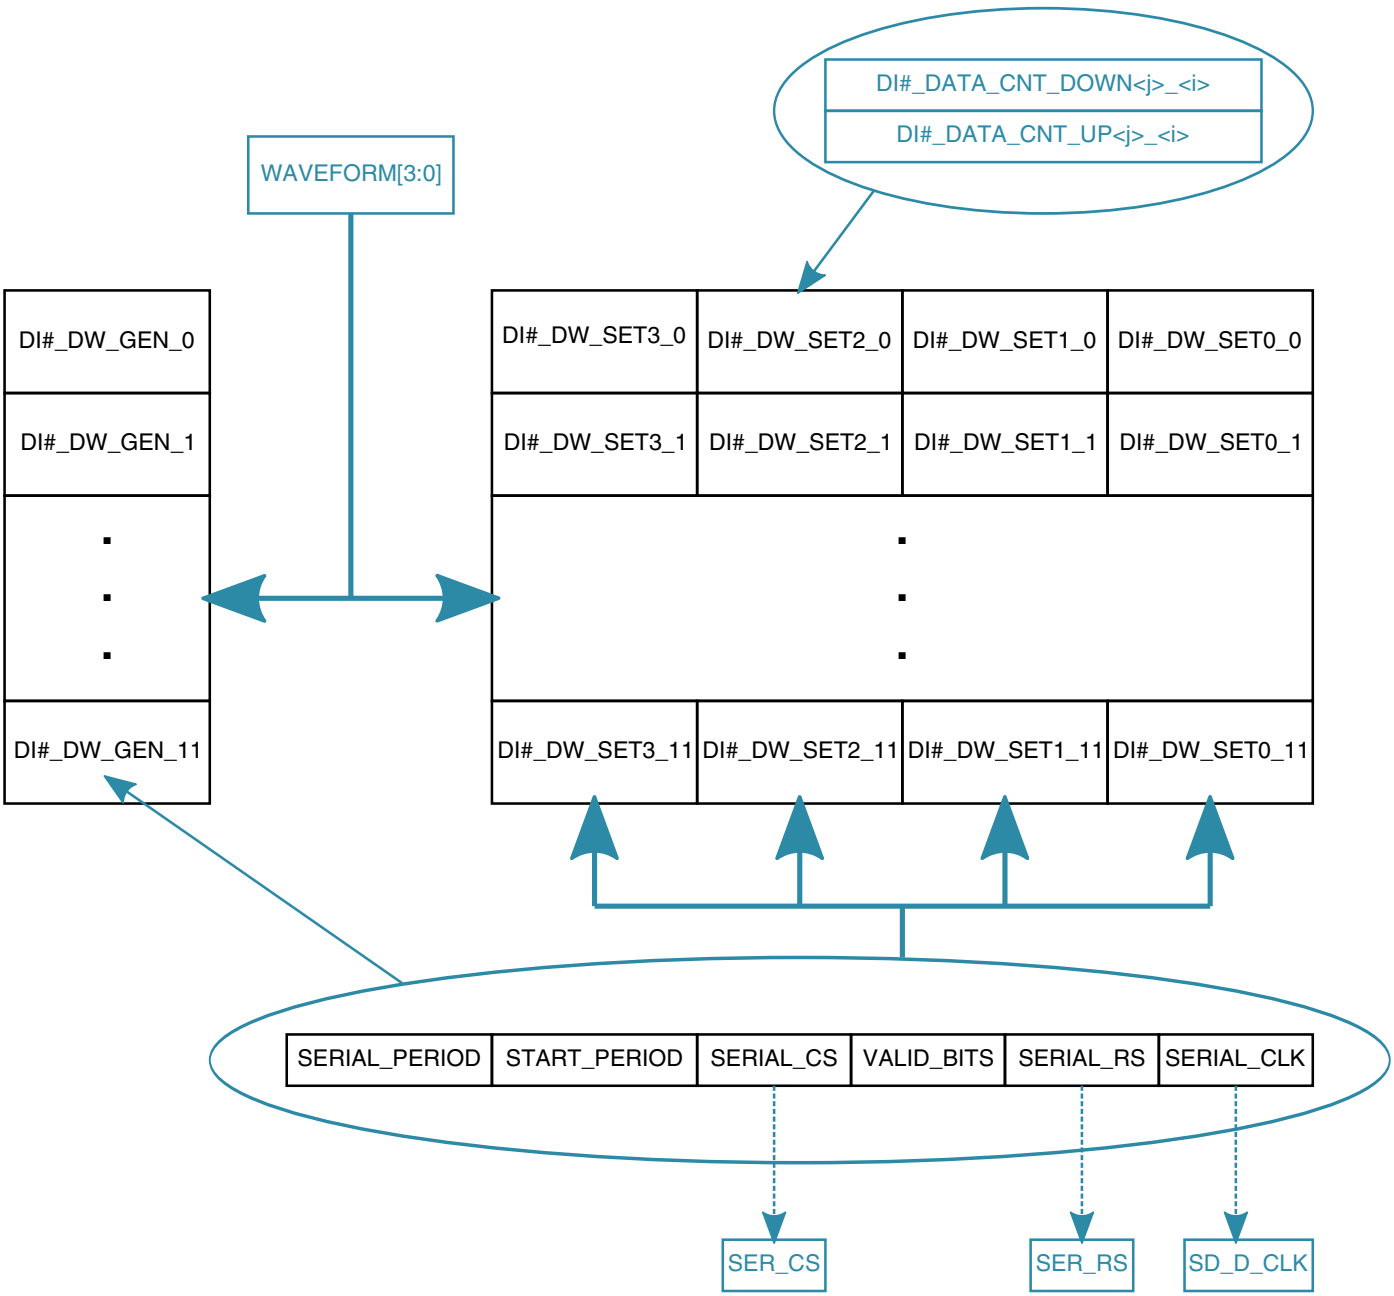

Figure 45-48. Waveform settings for asynchronous interface pins - serial interface

The following figure provides an example of the waveform's settings for the serial interface. A waveform generation starts following a trigger indicating that the serial interface has won the DI's arbitration. Therefore the next access will be via the serial interface. The waveform is based on timebase ticks. All the waveform's settings are defined by counting DI_CLK cycles. The timebase starts ticking after counting DI_CLK cycles defined on the START_PERIOD parameters. The number of timebase ticks is defined according to the VALID_BITS field. The VALID_BITS field defines how many bits will from the 32 bit word sent to the DI are valid and should be sent via the serial

interface. The valid bits are the least significant bits of the word coming from the DC. The amount of DI_CLK cycles between each timebase tick is defined according to the SERIAL_PERIOD parameter. Each one of the serial interfaces control signals may have a different waveform defined according to its corresponding UP and DOWN values.

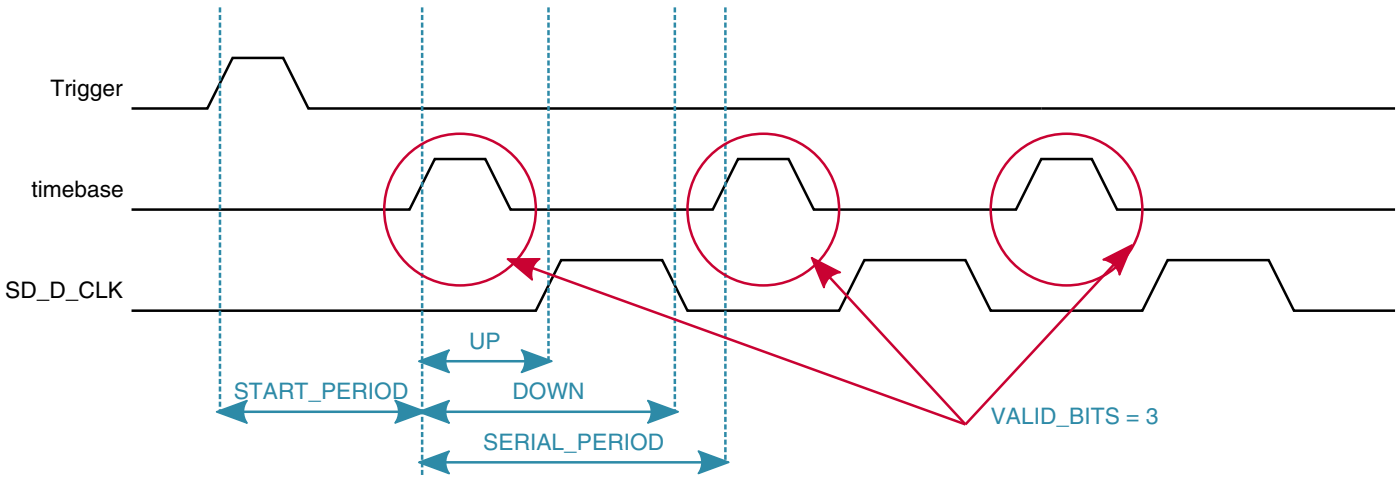

Figure 45-49. Serial interface waveform example

The CS and RS signals can have a single change (one rising and one falling edges) between 2 consecutive triggers.The UP value for RS and CS is measured from the first timebase tick. The DOWN value is measured from the last timebase tick. The figure below provides an example of the RS behavior, CS behaves in a similar way.

The data is sent according to the timebase ticks. The MSB bit of the data is transmitted first. When receiving serial data, the data is sampled every timebase tick. The user can program an offset from the timebase tick by programming the DI#_SERIAL_LATCH field. This value will move the serial data sampling point. The value is measured by counting DI_CLK cycles.

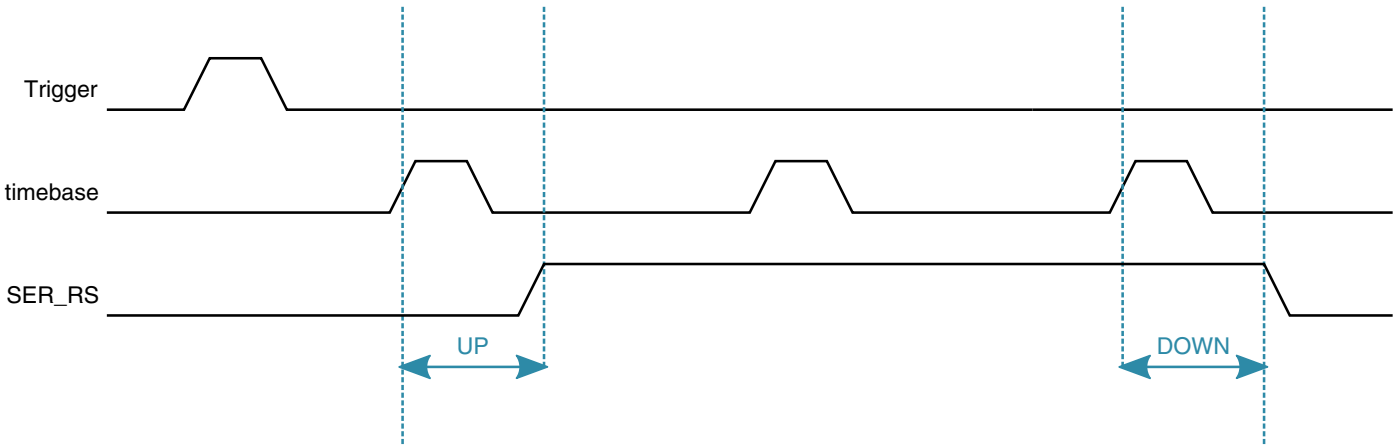

Figure 45-50. Serial interface waveform example of RS

45.4.10.6 Low Level Access - LLA

LLA is a ARM platform direct access to the display. For parallel displays the DI's behavior for LLA is the same as any other access to a parallel display. For serial displays the DI allows a DI arbitration bypass. This is done if the DI#_LLA_SER_ACCESS bit is set.

In that case there is a direct access from the DMFC to the DI which bypasses the DC allowing simultaneous access to both serial and parallel interfaces. When DI#_LLA_SER_ACCESS bit is set, the user must not do any other kind of accesses to the serial interface except LLA. When DI#_LLA_SER_ACCESS bit is set the corresponding DI#_WAIT4SERIAL must be clear.

45.4.10.7 Using a mask channel

The IPU is able to provide the windowing function on displays that have data enable control. This is achieved by masking of some screen regions according to a 1-bit/pixel mask read from the memory via IDMAC through channel #44.

When the mask value is zero, the pixel is not displayed. This feature can be used for dual-port smart displays.

45.4.11 Video De Interlacing or Combining Block (VDIC)

The Video De-Interlacer and Combiner has two operation modes:

- De-interlacing: converts an interlaced video stream to progressive order.
- Combining: combines two video/graphics planes and a background color.

The Video De-interlace block (VDIC) deinterlaces standard interlaced video to produce progressive video, that is used for upsizing to HD formats or for display on progressive displays. For VDIC operation three fields are necessary F(n-1),F(n),F(n+1). The F(n-1) field arrived through CSI interface in real time mode or through channel 1 and then stored in FIFO1. The F(n) arrived through channel 2. At least three lines of F(n) are stored in Line Store memory. The F(n+1) arrived through channel 3 and stored in FIFO3. FIFO controllers read data from FIFOs and then data aligned in pixels buffers. From the buffers the data arrived to Line Padding Controller (LPC). The LPC padding missing line at the beginning and end of the frame. The DeInterlacing sub-block (DI) perform the processing. Then data send to IC sub-block for processing or for transferring to external memory.

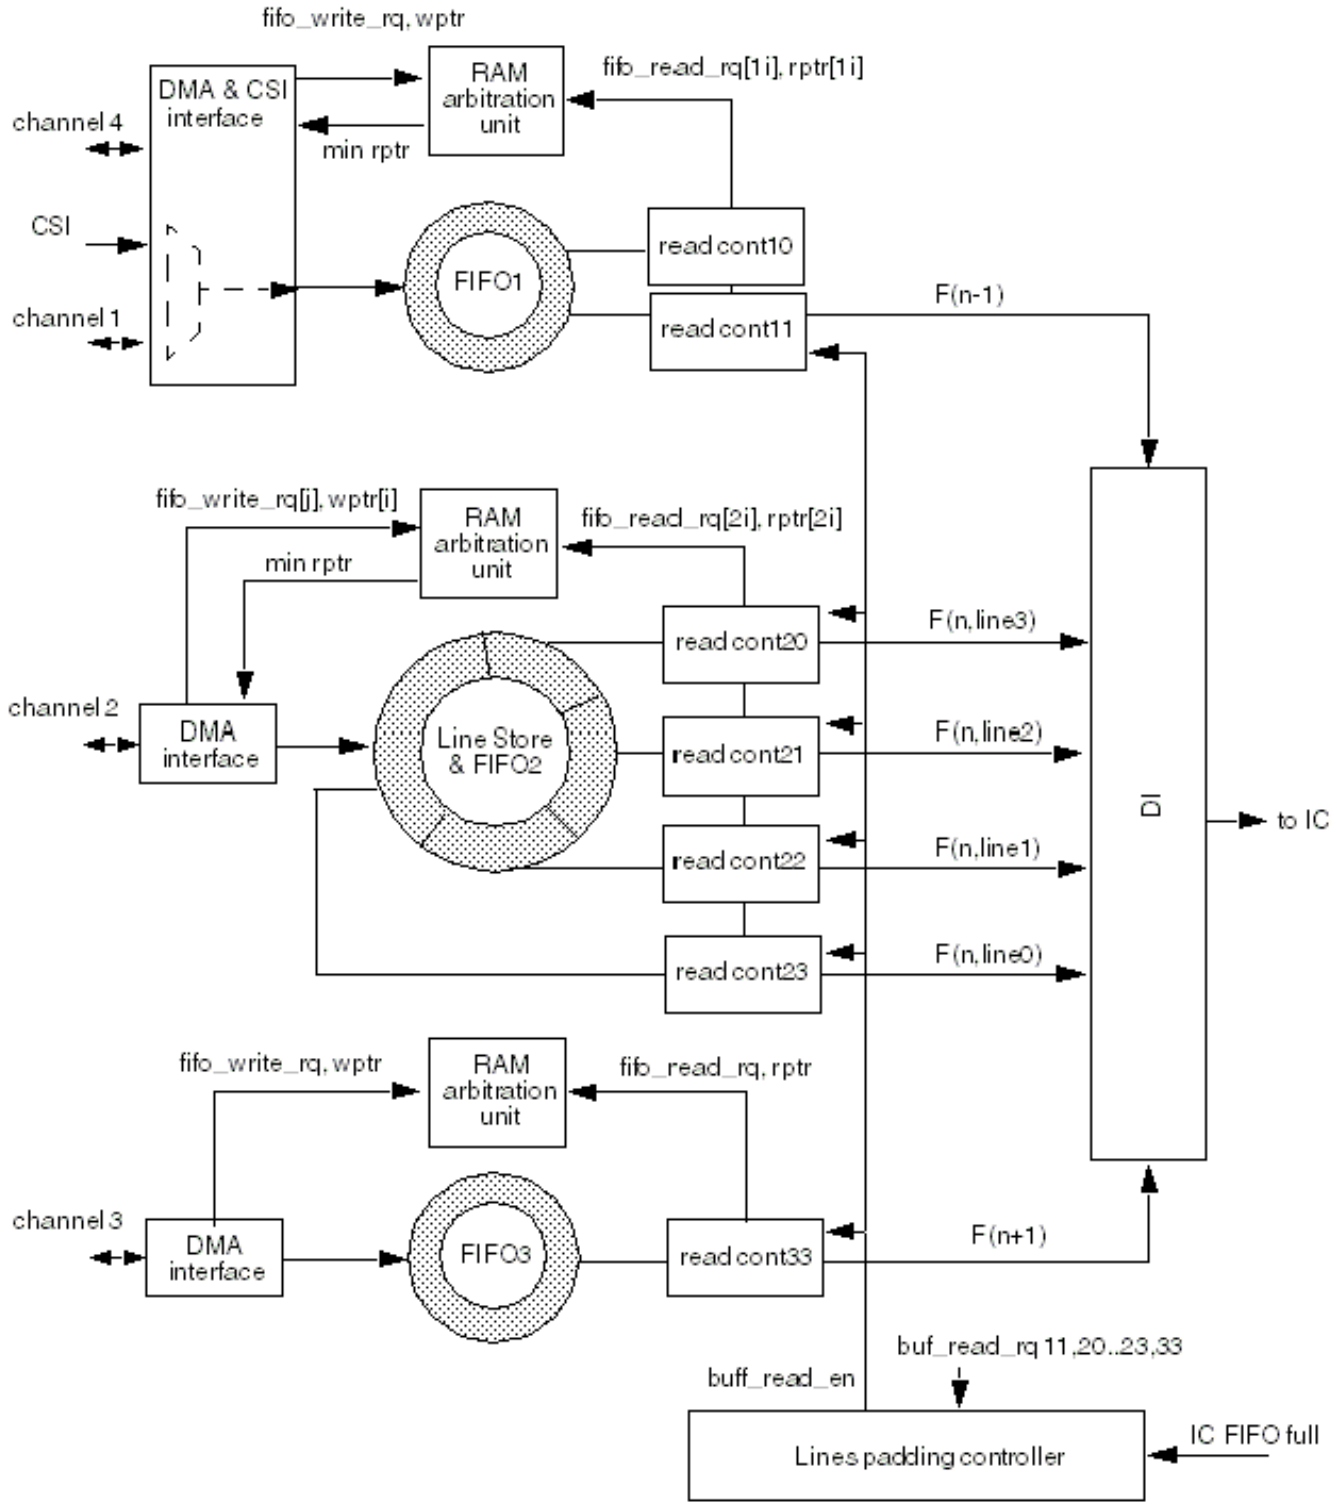

Figure 45-51. VDIC Block Diagram

45.4.11.1 VDIC FeaturesVDI Features

Key features of the VDIC block include:

Key features of the VDI block include:

- Deintarlacing
  - maximum horizontal resolution 968 pixels
  - maximum pixel rate 75MP
  - Support YUV422 and YUV420 formats
- CSI FIFO mode
- Combining

45.4.11.2 De interlacer (DI) sub-block

The block diagram of the DI block is shown in figure below.

Pipelining is inserted at all stages, so that the design may run at a fast clock speed, if needed.

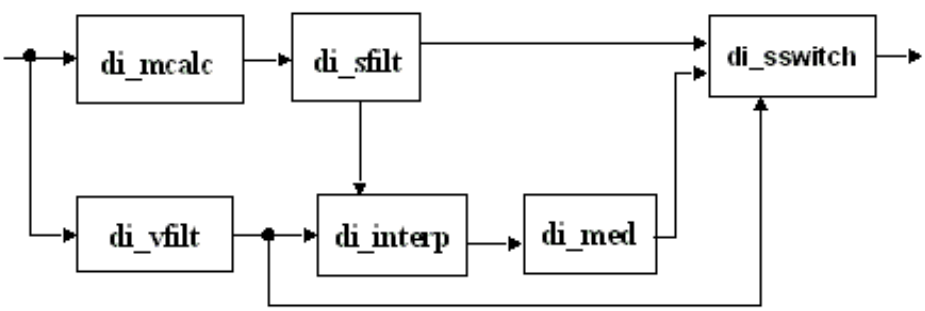

Figure 45-52. DI block diagram

45.4.11.2.1 Vertical Filter Block (di_vfilt)

The di_vfilt block performs spatial vertical filtering of pixels.

It is a four tap vertical filter:

vfilt_out = (-3.0*pix1 + 19.0*pix2 + 19.0*pix3 - 3.0*pix4)/32.0

Where pix1, pix2, pix3, pix4 are four pixels in same horizontal location on four consecutive lines of a field.

vfilt_out is pixel being predicted (between pix2 and pix3)

45.4.11.2.2 Motion Calculator Block (di_mcalc)

The mcalc block estimates the amount of motion for any given pixel by looking at pixel values in current, previous and next fields.

The generic formula used to calculate the estimated motion is:

m = SAT(Ks*(|e-w|/(|e-w|+|n-s|+SPA_DETAIL)))

- Where, n is the pixel above the pixel being predicted
- s is the pixel below the pixel being predicted
- e is the pixel in previous field at same spatial location as the pixel being predicted
- w is the pixel in next field at same spatial location as the pixel being predicted
- m is motion estimation for the pixel being predicted (range from 0 to 1)
- Ks is slope control and decides how quickly the algorithm switches from no motion (m=0) to full motion (m=1)
- SPA_DETAIL is a constant (50) that is added to |n-s|.
- SAT() is saturate at 1 function

The motion calculator block is simplified in a certain respect, by removing the need for a divider, while providing a degree of flexibility. The main motivators for this are the following observations:

1. the above equation defines a set of curves based on the value of |n-s|, but the curves are fairly closely spaced, so that using a granularity of 8 in |n-s| to define specific curves to use gives pretty much the same quality of picture as using all of the curves; and once |n-s| reaches about 120, the effect of an increased |n-s| value is hard to observe
2. once |e-w| gets to about 15, the motion is usually saturated to a value of 1

Based on the above observations, the motion calculator is now implemented with the use of two "ROM"s, using the 4 LSBs of |e-w| and bits 6:3 of |n-s|.

The motion calculator has 3 modes of operation. These modes are defined by the VDI_MOT_SEL field. In case that the user has an information about the motion (For example SW analyzing motion vectors provided by a video decoder) he can select one of the modes listed below. Changing the value of the VDI_MOT_SEL has an affect only on the next frame.

- When VDI_MOT_SEL==2'b01, m_calc is 0 (no motion - use weave)

- When VDI_MOT_SEL==2'b10, We assume high motion and use min(15,delta_t).
- When VDI_MOT_SEL==2'b00, We assume low motion and use sat([0,15],delta_t-8) (delta_t-8 is signed operation).

45.4.11.2.3 Spatial Motion Filter (di_sfilt)

The di_sfilt block spreads motion signal over five pixels:

Mspread = MAX(m3, (0.5*m1 + m2 + m3 + m4 + 0.5*m5)/4.0)

- Where, m3 is motion estimate for current pixel
- m2 is motion estimate for previous pixel
- m4 is motion estimate for next pixel
- m1 is motion estimate for pixel before previous pixel
- m5 is motion estimate for pixel after next pixel

45.4.11.2.4 Interpolated Pixel Calculator Block (di_interp)

The di_interp block uses the motion estimated by the di_sfilt block and computes an interpolated pixel that is weighted sum of the surrounding four pixels (n, s, e, w).

The block performs the following calculations:

```
          if (Mspread <= 0.5) {
i = (1-2*Mspread)*(e+w)/2 + 2*Mspread*vfilt_out
} else {
          i = vfilt_out
}
```

Where, i is the interpolated pixel

n, s, e, w are surrounding pixels as explained earlier

45.4.11.2.5 Median Filter Block (di_med)

The di_med block performs a 5-point median of n, s, e, w and i pixels.

It should be noted that the median required here is not a true 5-point, but can be implemented more efficiently as a 3-point median:

med = MEDIAN(min(max(n,s),max(e,w)), max(min(n,s),min(e,w)), i)

45.4.11.2.6 Soft Switch Block (di_sswitch)

The final output of the deinterlacer is a blend of the median value and the vertical filter, assuming that the pixel data n,s are uncorrelated with the pixel data e,w. By uncorrelated, we mean (max(n,s) < min(e,w)) or (min(n,s) > max(e,w)).

```
          if (Mspread <= 0.5 || not(F)) {
pix_out =    med
} else { /* Mspread > 0.5 */
pix_out = (1-2*(Mspread-0.5))*med + 2*(Mspread-0.5)*vfilt_out
}
```

45.4.11.3 DMA only Mode

In DMA only mode the data is coming from IDMAC only.

45.4.11.4 Real Time Mode

In Real Time Mode the F(n-1) are coming from CSI. The CSI write to FIFO1. The DI sub-block read F(n-1) from processing. In addition IDMAC read the field from FIFO1 and store in external memory. Then stored frames are used as F(n) and F(n+1).

45.4.11.5 CSI only Mode

In CSI only mode VDIC do not perform any processing and used as FIFO only. The data arrived from CSI written to FIFO1. The IDMAC read data from the FIFO1. The FIFO3 and Line store memory are not used. The ID sub-blocks are turned OFF. The CSI only mode can be used as alternative to SMFC, when appropriate.

45.4.11.6 Using Combining in the VDIC

As an alternate function to the de interacing function, the VDIC can perform combining of two planes.

- Both planes have to be at the same color space.
- Overlaying of a single plane over a unified background is supported.
- The planes can be at a different sizes - one plane can be smaller than the other.
- Combining requires a single cycle per output pixel.
- Alpha blending (global or local) is supported.
- Color keying is supported.

The plane's location and size is programmable as shown in the following figure.

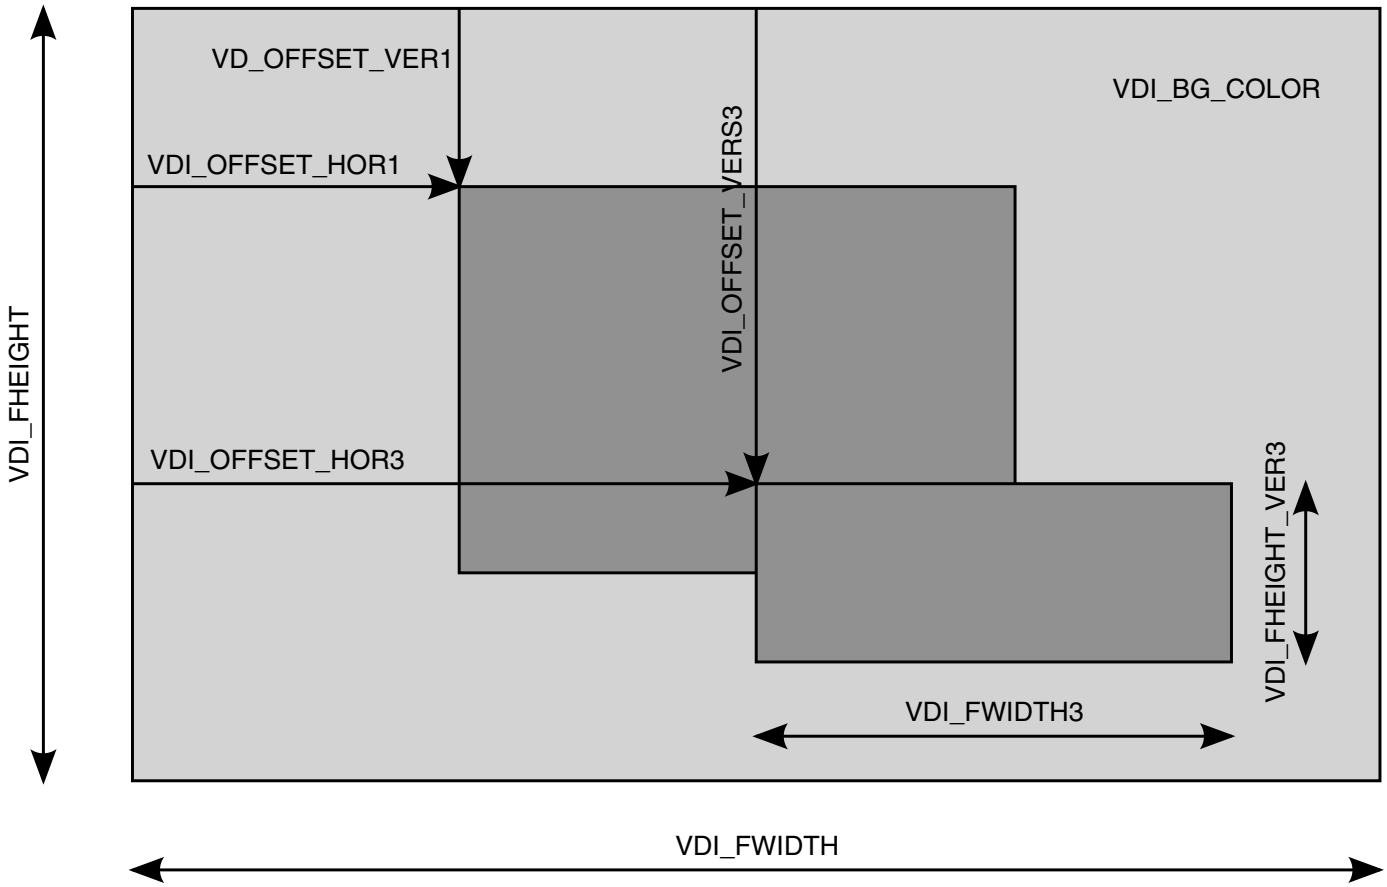

Figure 45-53. The relations between planes of the combining unit

When local alpha is used it should be arrived through channel3 of the VDIC.

The combining equation is:

OP = BG*(1 - alpha) + FG*alpha

Where "OP" is output pixel, "FG" is input pixel of foreground plan arrived thought channel3, BG is input pixel of background plan arrived thought channel1, "alpha" is global or local transparency.

45.4.11.7 VDIC Restrictions

- Maximum output pixel rate is 75 MP.
- The output pixel format (YUV422 or YUV420) are equal to input format.
- The VDIC can perform combining or de interlacing. It cannnot perform both functions at the same time.

45.4.12 Control Module (CM)

45.4.12.1 Block Diagram

The CM Block Diagram is shown in the figure below.

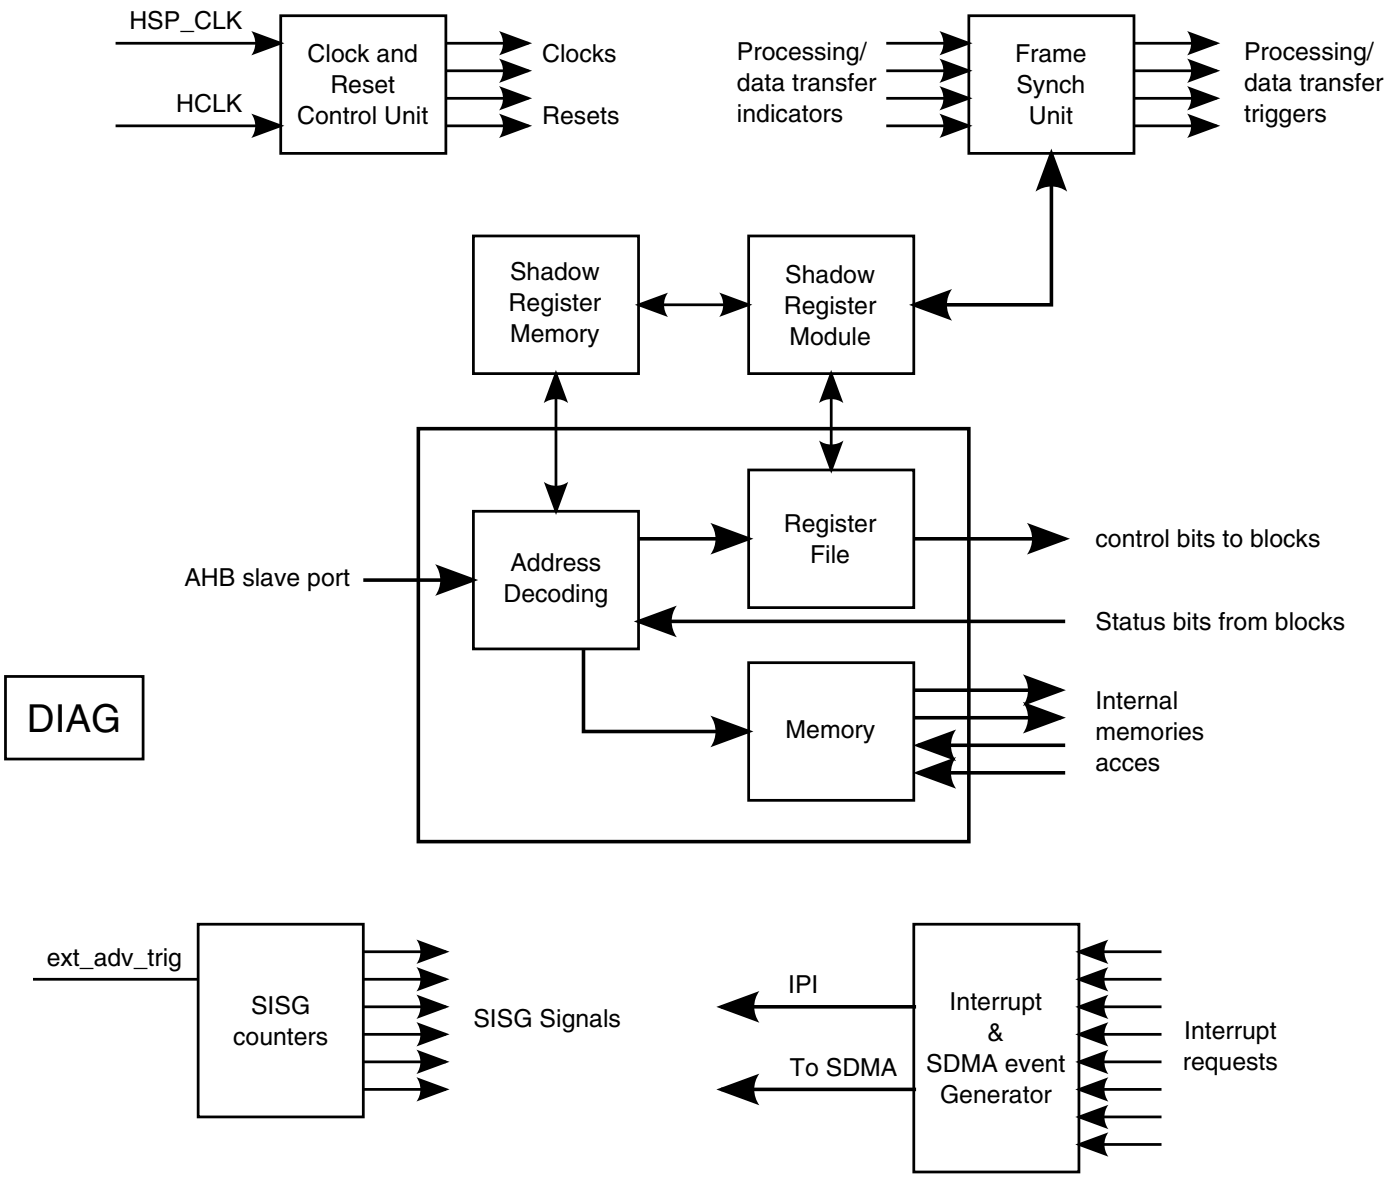

Figure 45-54. CM Block Diagram

The CM consists of the Frame Synchronization Unit (FSU), the Interrupt Generator (IG), the General Configuration Registers (GCR), the Clock and Reset Control Unit (CRCU) and the Shadow Registers Block (SRM).

45.4.12.2 Frame Synchronization Unit

This section details the frame synchronization unit.

45.4.12.2.1 General Description

The FSU provides synchronization of tasks performed by different IPU sub-blocks and ARM platform tasks. This allows to build complex processing flows which are performed automatically (without ARM platform involvement in synchronization of the IPU's tasks).

The FSU supports double buffering of image frames stored in the external memory and allows chaining IPU processing flows in automatic mode.

45.4.12.2.2 Frame Synchronization Flow

1. Initialization

   The ARM platform initializes all the parameters for a task by writing to the GCR and to the parameters memories of each IPU sub-blocks. The initialization must occur before the ARM platform enables the task.

2. Enabling

   After the initialization step has been completed, the ARM platform enables the task by setting its enable bit in an appropriate register.

3. Triggering

   After the task is enabled, the FSU waits for triggering signal. The triggering signals is a combination of the enable bit and the buffer ready signal which can be driven by the ARM platform (DMA_CH_BUF<0/1>_RDY_<#>) and/or by the preceding task (IDMAC_EOF_# or Frame Complete signal from the DC).

   The trigger causes the FSU to invoke the relevant unit to start by assertion of the NEW_FRM_RDY signal. In some cases triggering occurs at the enabling step (when the enable bit is the trigger for the task).

4. Operating

   The triggering step cause the task to move to active mode, this is the operating step. In this step, the FSU monitors the synchronization signals from ARM platform, IDMAC and the corresponding processing units, and controls the units operation. The FSU also controls the IDMAC buffer toggling when double buffer page flipping is used.

The FSU checks at end of each frame if the next frame can be served. If the answer is yes, the FSU stays in active mode with re-sending the <TASK>_NEW_FRM_RDY signal and updating the relevant flags (e.g. DMA<BL>_<#>_CUR_BUF and DMA<BL>_<#>_BUF_RDY). If the answer is no, the FSU moves to pause mode and pauses the task waiting until the next frame can be served.

5. Disabling

   When the task is disabled by the ARM platform (by negating the enable bit), it moves back to non-active mode.

45.4.12.2.3 FSU's fundamentals

Trigger source select

A flow is triggered by a trigger. The trigger may be asserted manually by the ARM platform or may be a result of the completion of the preceding task. Trigger's source select choose the source of the trigger. The trigger means that the data is ready to be processed by the sub-blocks. The trigger source select is defined by the corresponding SRC_SEL bits of the block or task.

Trigger destination select

A block or task that process data needs to know that the following task in the chain is ready to receive the processed data. The user needs to specify what is the destination of the processed data. This is done by setting the corresponding DEST_SEL bits of the block or task.

Double buffering

The IPU supports double buffering in the system's memory. When a flow is processed frame by frame the first frame will be read from one location (BUF0) in the memory, the next frame will be read from another location in the memory (BUF1). The location in the memory of the buffers is defined by the EBA0 and EBA1 parameters of the corresponding channel in the CPMEM. The IDMAC use the correct buffer according to the DMA_CH_CUR_BUF_# signal. The FSU automatically toggles the DMA_CH_CUR_BUF_# to point on the correct buffer to be used by the channel. In order to work in double buffer mode the corresponding DMA_CH_DB_MODE_SEL_# needs to be set.

Alternative flow

Some of the IPU sub-blocks can handle 2 flows via them one is the main flow and the other is the alt flow. In order to support an alternate flow via the same sub-block an alternative configuration should be used by the sub-block. This includes

- Alternate registers including an alternative sub-block's setup - this is handled by the SRM
- Alternate IDMAC settings: parameters in the CPMEM, separate alpha
- Alternate SRC_SEL as the source of the trigger may come from a different function.
- Alternate FSU settings (CUR_BUF, BUF_RDY, DB_MODE_SEL)
- Some of the display sub-blocks alternate settings are handled by programming an alternative set of registers.

The FSU handles the switch to the alternate flow, it controls the update of the alternate configuration and send the appropriate signals to other sub-blocks in the IPU indicating about a need to switch to the alternate configuration.

Once a frame is completed there is a chance that there are 2 buffers ready. One is the next buffer of the current flow and the other is the a buffer in an alternate flow. The FSU will automatically select between the next buffer to handle in a round-robin fashion.

IPU task chaining - Single flow

The diagram below illustrates task chaining in the In this example a single flow is handled

The Frames are coming from the same camera sub-block. The frames are handled frame by Frame. The first frame arriving Frame0 is stored in BUF0 of the "INPUT BUFFER". Once the Frame0 is ready in BUF0, the processing sub-block is triggered and data is read from BUF0 to the processing sub-block. In the meantime, Frame1 coming from the camera is written to BUF1 of the "INPUT BUFFER". The processing sub-block processes the data and stores the first frame on BUF0 of the "OUTPUT BUFFER". Once the processing is done and the frame is ready, the display sub-block is triggered to pick the data and send it to the display. The processing sub-block will start working on the next frame once the data is ready in the "INPUT_BUFFER" and there's a free buffer in the "OUTPUT_BUFFER".

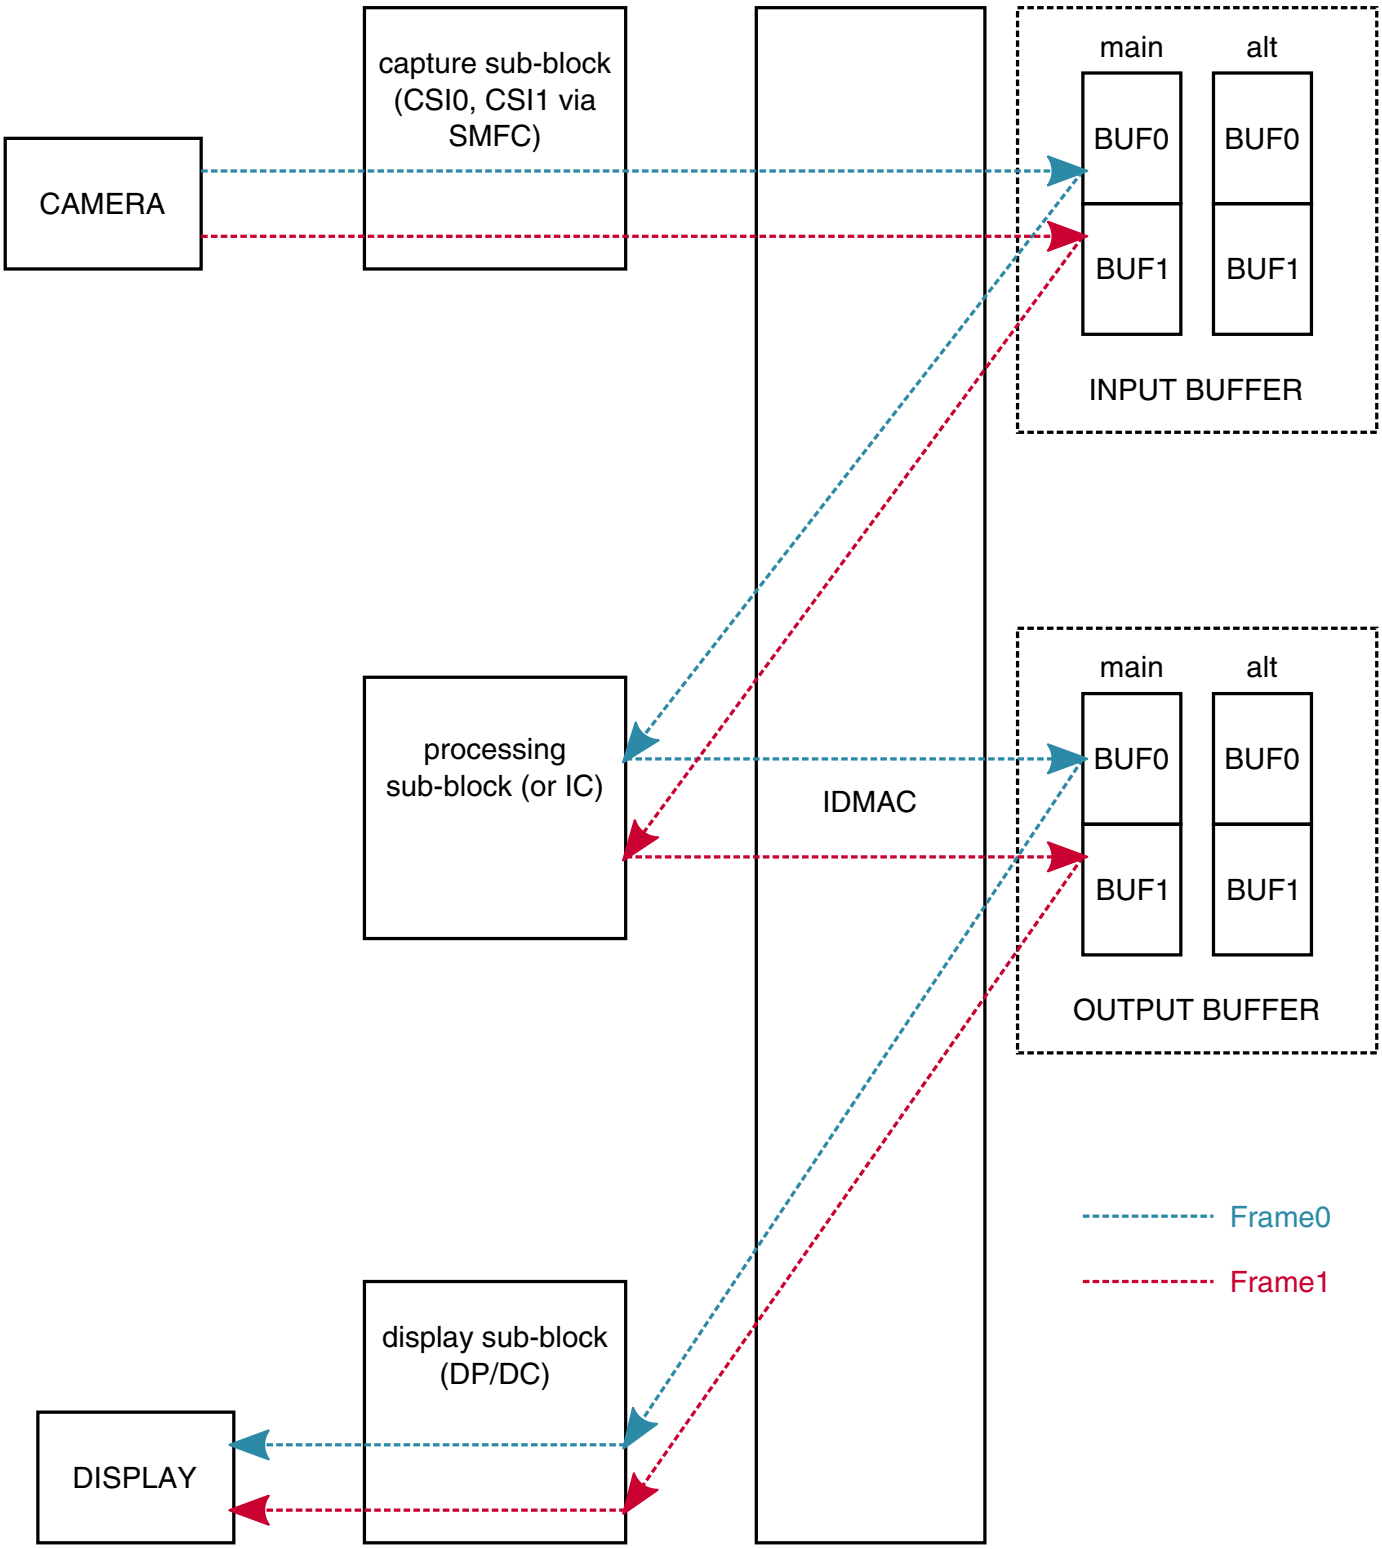

Figure 45-55. IPU tasks' chaining illustration - single flow

IPU task chaining - double flow

The diagram below illustrates task chaining in the In this example double flow is handled. In addition to the flow described on the previous example, another flow is handled via the display sub-blocks. In that case the DC will handle 2 flows. Once sending Frame0 to the display is complete, the FSU will decide in whether to handle Frame1 or Frame0_ALT. The decision is made according the readiness of the other buffers in the memory, in case of 2 ready buffers (main flow and alternate) the FSU will switch between them in a round robin fashion.

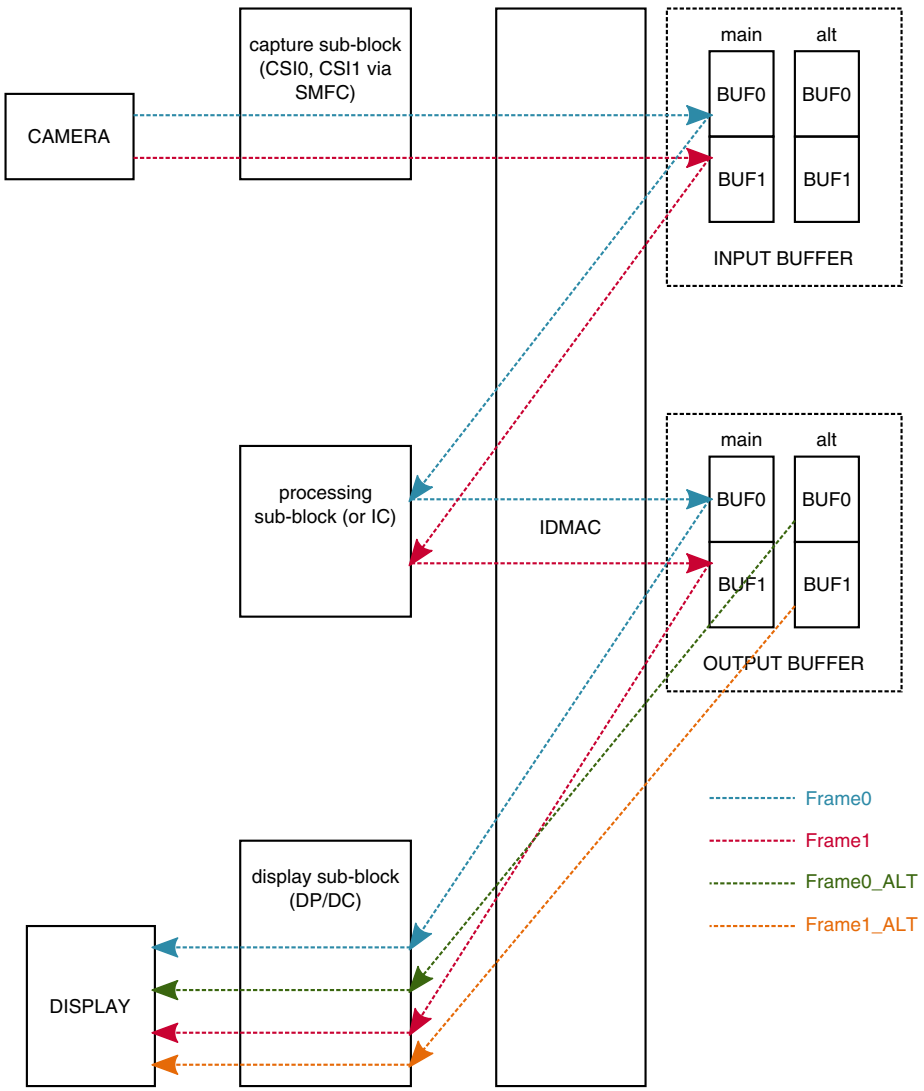

Figure 45-56. IPU tasks' chaining illustration - double flow

45.4.12.2.4 IPU main flows

IPU's flows can be partitioned into 5 groups.

- CF - capture flows

- PF - processing flows
- SF - synchronous display flows
- AF - Asynchronous display flows
- DF - Direct flow from IC to the display

Tasks from different groups can be chained as illustrated below.

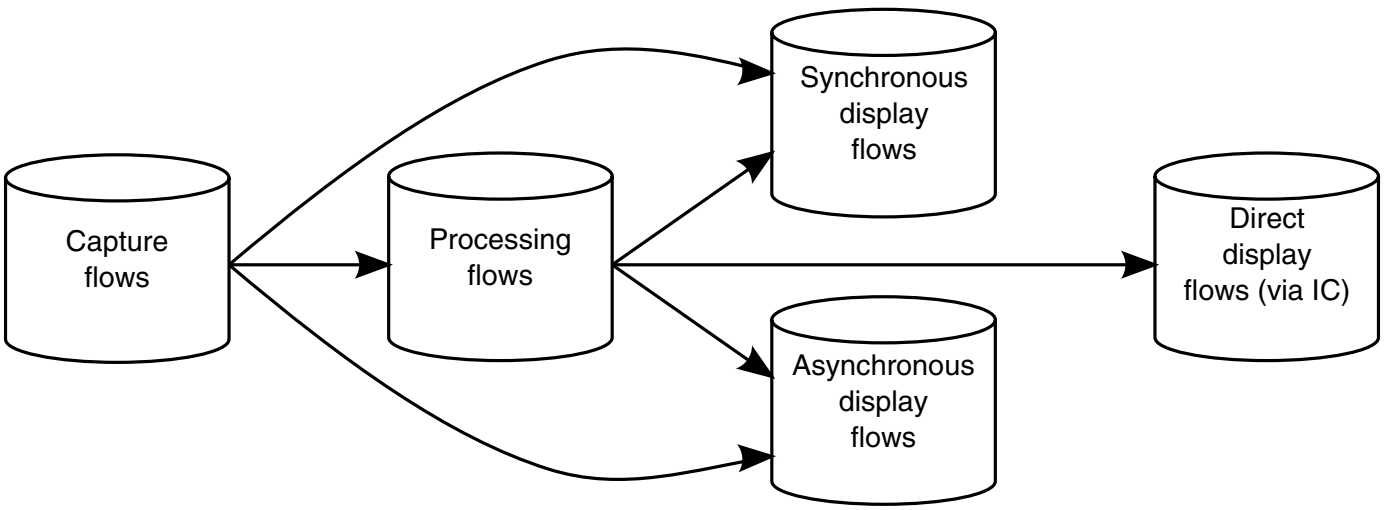

Figure 45-57. IPU task flows chaining

The tables below describe the most important use cases of chaining the IPU tasks. The tables show the main task for each group.

The physical DMA channel is the DMA channel that is used for the main flow - this is the IDMAC channel that is physically connected to the block - the CPMEM parameters should be configured according to the physical channel number. In case of an alternate flow then an alternate entry in the CPMEM should be configured as well

The following table describes capturing flows where data is captured from the sensor and sent to the memory without processing. This flows can be chained to the processing and display flows described on: Table 45-29, Table 45-30, Table 45-31 and on Table 45-32.

Table 45-28. IPU's capture flows

	Flow	Tasks chain	Physical DMA Channels		
			Video Input	Other Input	Output
	Capturing image from sensor and storing it in the memory (via SMFC) without processing	CSI0 or CSI1 --> SMFC --> MEM	---	---	IDMAC_CH_0 IDMAC_CH_1 IDMAC_CH_2 IDMAC_CH_3

Table continues on the next page...

Table 45-28. IPU's capture flows (continued)

	Flow	Tasks chain	Physical DMA Channels		
			Video Input	Other Input	Output
	Capturing image from sensor and storing it in the memory (via IC) without processing	CSI0 or CSI1 --> MEM	---	---	IDMAC_CH_5
	Capturing interlaced input and storing it in the memory (via VDIC) while performing video de-interlacing in the VDIC.	CSI0 or CSI1 -> VDIC --> MEM		IDMAC_CH_9 IDMAC_CH_10	IDMAC_CH_5 IDMAC_CH_13
		Interlaced input coming from one of the CSIs is sent to the memory without processing via channel #13. In addition 2 more inputs are read from the memory via channels 9 and 10. The processed image is written to the memory via ch 5 in progressive scan mode.			

The following table describe processing flows via the IC . This flows can start from the memory, can be chained to a capturing flow described on Table 45-28. The target of this flow can be chained to the display flows described on Table 45-30 and on Table 45-31.

Table 45-29. IPU's Processing flows

	Flow	Tasks chain	Physical DMA Channels		
			Video Input	Other Input	Output
	Preprocessing image from sensor for encoding	CSI0 or CSI1 --> SMFC --> MEM	---	---	IDMAC_CH_0 IDMAC_CH_1 IDMAC_CH_2 IDMAC_CH_3
		MEM --> IC (PRP ENC) --> MEM	IDMAC_CH_12	---	IDMAC_CH_20

	Flow	Tasks chain	Physical DMA Channels		
			Video Input	Other Input	Output
	Rotation and preprocessing of image from sensor for viewfinder and displaying it on asynchronous display via DP	CSI0 or CSI1 --> SMFC --> MEM	---	---	IDMAC_CH_0 IDMAC_CH_1 IDMAC_CH_2 IDMAC_CH_3
		MEM --> IC (ROT VF) --> MEM	IDMAC_CH_46	---	IDMAC_CH_49
		MEM --> IC (PRP VF) --> DMFC	IDMAC_CH_12	IDMAC_CH_14	Direct to the DMFC
		MEM --> DP SYNC (BG/FG)	IDMAC_CH_24 / IDMAC_CH_29	command channel	---
	Preprocessing image from sensor for viewfinder and direct displaying it on asynchronous display	CSI0 or CSI1 --> SMFC --> MEM	---	---	IDMAC_CH_0 IDMAC_CH_1 IDMAC_CH_2 IDMAC_CH_3
		MEM --> IC (PRP VF) --> DC	IDMAC_CH_12	IDMAC_CH_14	---
	Preprocessing image from sensor for viewfinder and direct displaying it on asynchronous display	CSI0 or CSI1 --> IC (PRP VF) --> DC	---	IDMAC_CH_14	IDMAC_CH_21
	Preprocessing image from sensor for viewfinder and direct displaying it on asynchronous display via DP	CSI0 or CSI1 --> IC (PRP VF) --> DP ASYNC	---	IDMAC_CH_14	IDMAC_CH_21
	Capturing interlaced input via CSI, then perform video de-interlacing in the VDIC. Then processing in the IC and direct displaying it on asynchronous display via DP	CSI0 or CSI1 -> VDIC --> IC (PRP VF) --> DP ASYNC	--	IDMAC_CH_9 IDMAC_CH_10 IDMAC_CH_14	IDMAC_CH_13 IDMAC_CH_21
		Interlaced input coming from one of the CSIs is sent to the memory without processing via channel #13. In addition 2 more inputs are read from the memory via channels 9 and 10. The processed image is sent to the IC for further processing then it is sent to the display			
	Capturing interlaced input via CSI, then perform video de-interlacing in the VDIC. Then processing in the IC and direct displaying it on asynchronous display	CSI0 or CSI1 -> VDIC --> IC (PRP VF) --> DC	--	IDMAC_CH_9 IDMAC_CH_10 IDMAC_CH_14	IDMAC_CH_13 IDMAC_CH_21
		Interlaced input coming from one of the CSIs is sent to the memory without processing via channel #13. In addition 2 more inputs are read from the memory via channels 9 and 10. The processed image is sent to the IC for further processing then it is sent to the display			

45.4.12.2.5 Sub-Frame Double-Buffering (Band Mode)

Page-flip double buffering is performed using full-frame buffers. In addition IPU supports also page-flip double buffering using smaller buffers, each containing 4/8/16/32/64/128/256 rows of pixels. This allows the use of internal memory for buffering.

This mode can be supported by the following modifications (relative to full-frame buffers):

The address in system memory is generated by the same formula, but inserting the full row number, only k LSB's (for a band of 2^k rows) are inserted (e.g. [2:0] for 8 rows).

Page flip is triggered at the end of each band (when the k LSB's are all 1) and not only at the end of the frame. This flip may be accompanied by an ARM/SDMA interrupt, if synchronization with other modules (e.g. VPU or ARM) is needed.

The channels that can work in this mode are controlled by the corresponding IDMAC_BNDM_EN_<i>

bit. The BNDM parameter of the corresponding IDMAC channel has to be set as well.

45.4.12.2.6 Snooping

This function allows to reduce the rate of write accesses from the system memory to a smart display. When snooping is enabled, writing to the display is performed only if the corresponding system memory buffers has been changed. Any change of data in the system memory buffers is registered by the External Memory Controller of the chip.

When writing to the system memory is performed, the External Memory Controller asserts the emi_snooping1 or emi_snooping2 pins of the After receiving these signals, the CM initiates transfer of the corresponding buffer to a display buffer, either in system's memory or in a smart display. Selecting the snooping mechanism as the trigger for the flow is done by setting the <>_SRC_SEL bits of the corresponding flow to snoop1 or snoop2 mode.

The emi_snooping1 and emi_snooping2 signals are synchronized to the IPU's clock. The synchronize on the emi_snooping2 signal can be bypassed by setting the bit SNOOP2_SYNC_BYP bit.

45.4.12.2.7 Automatic Window Refresh

By programming the <>_SRC_SEL bits of the corresponding flow to autoref mode, automatic refresh of a window on the smart display is enabled. This means that the flow is triggered any time the refresh counter completes its counting. The refresh period is defined via the AUTOREF_PER field (the time unit is 2^{17} periods of the HSP_CLK clock).

The actual value of refresh period is equal to:

THSP*2^17 *(AUTO_REF_PER+1).

45.4.12.2.8 Auto-refresh and snooping

Auto-refresh can be conditional. In this case, it is accomplished emi_snooping1 or emi_snooping2 pins of the IPU are asserted. This is defined by setting the <>_SRC_SEL bits to autoref+snoop1 or autoref_snoop2 mode.

45.4.12.2.9 Synchronization with A Video/Graphics source

The IPU supports direct synchronization with a video/graphics source (e.g. an integrated graphics accelerator, rendering graphics frames). Up to three frame buffers are supported for this synchronization. It is performed using the following signals

- The source instructs the i.MX53EX which frame should be transferred to the display by providing a 3 bit one-hot vector.
- The IPU notifies the source which frame is currently transferred to the display by providing a 3 bit one-hot vector.
- The IPU provides to the source an end-of-frame trigger (after which it switches to the frame indicated by the source).

This mechanism is provided for the main plane of the primary flow to the DP (ch 23). The SRC_SEL of this channel has to be defined as external source.

Triple buffer mode is enabled by setting the channel's corresponding bit on IPU_CH_TRB_MODE_SEL register. Setting this bit overrides the channel's corresponding settings on the IPU_CH_DB_MODE_SEL register. The CPMEM's settings of the corresponding channel can hold 2 pointers for 2 buffers (EBA0 and EBA1). The third pointer resides on an alternate entry in the CPMEM. The pointer to the alternate entry is defined by the channel's corresponding IDMAC_SUB_ADDR field. EBA0 of the alternate entry in the CPMEM is used as a third pointer. All the other settings of alternate entry in the CPMEM must be the same as the channel's standard entry in the CPMPM.

Once the channel reached end-of-frame event, the FSU automatically switch between pointers according to the signals coming from the source and notifies the source that the IPU reached the end-of-frame.

IPU has 2 identical bridges allowing direct synchronization with 2 sources. The 2 bridges support exactly the same protocol.

45.4.12.3 Interrupt Generator

The IG produces two interrupts to the ARM platform - the functional interrupt and the error interrupt. All of the interrupts are maskable.

The following table describes the functional interrupts.

Table 45-33. Functional Interrupts Summary

Location	Sub-blocks	Interrupt status bit name	Description

The table below describes the error interrupts. The panic column indicates if this signal is part of the logic generating the ipu_panic signal. The ipu_panic signal can be used for indicating about errors that are result of data rate problems. Such problems may be a result of the IPU running in slower clock then required by the use case. This signal can be used in order to indicate the system that the IPU can't handle the desired data rate. In that case the system may need to increase the clock to the IPU or simplify the use case.

45.4.12.4 SDMA event generator

The IPU provides an SDMA event signal that can be used as trigger to the SoC's SDMA. IPU routes an internal event to the SDMA event signal. The internal event causing the assertion of the SDMA signal is enabled by setting the corresponding bit on the SDMA_EVENT_# registers.

The user is allowed to enable multiple events. When one of these events occurs the ipu_sdma_event signal will be asserted. Similar to interrupts, the ipu_sdma_event signal is cleared by writing one to the corresponding bit in the INT_STAT_# registers.

It is not recommended to use the same internal event for a simultaneous generation of an interrupt signal and an SDMA event. This will require special software care when clearing the corresponding bit in the INT_STAT_# registers.

45.4.12.5 General Configuration Registers

The GCR contains a set of control/status/data registers. It provides IPU interface to the AHB slave bus.

The HCLK rate is equal to the HSP_CLK rate. The detail description of the registers is found in the Programmable Registers section.

45.4.12.6 Shadow Registers Module (SRM)

IPU supports frame by frame task switching. This means that a sub-block can handle a frame with one configuration and handle the following frame with different configuration. Changing the configuration is done by updating the sub-block's parameters.

In order to allow automatic flow without a need of the SW to update all the parameters at the frame boundaries. A Register of a sub-block that has the shadowing capabilities has a shadow register file that resides in the Shadow Register Memory.

The sub-blocks supporting this function may use it in one of the following ways:

45.4.12.6.1 Switching between 2 flows

Upon request from the FSU the SRM switches between the registers and the content in the Shadow Register Memory. When a sub-block uses one of the configuration SW, it is allowed to update the parameters in the memory. This is normally used when 2 flows are supported via one module.

- The current flow's configuration is stored in the module's registers
- The alternate flow configuration is stored in the SRM.
- When switching between flows the current flow's configuration is stored in the SRM. The alternate flow's configuration is written to the module's registers. When the alternate flow ends the configurations are swapped again.

This process is fully controlled by the FSU

45.4.12.6.2 Updating parameters between frames

This mode is used when the user needs to update the parameters of the current task being processed by the module. The updates can't affect the frame that is currently being processed. The update is effective only on the next frame. The SRM performs the parameters update only when there's a specific request by the user.

- The current frame's configuration is stored in the sub-block's registers
- The next frame's configuration is stored in the SRM.
- On frame's boundary the SRM reads the new configuration from the SRM and writes it to the sub-block's registers. The old configuration is lost.

45.4.12.6.3 Updating the memory

In order to avoid data coherency problems, the user should set a flag indicating that he is currently updating the memory region of a specific sub-block. When the flag is set the SRM will not attempt to replace the parameters relevant to the specific sub-block currently being updated by the user.

The user should clear this flag when he completes the update, and the parameters are ready to be used.

The flag is the corresponding **SRM_MODE** field for each sub-block. This field controls the SRM logic that handles the sub-blocks registers

- 00 - ARM platform is allowed to access the sub-block's region in the RAM; The automatic swapping mechanism is disabled.
- 01 - The SRM logic is controlled by the FSU. The update will be done of the next frame.
- 10 - The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame
- 11 - Update now. The SRM is controlled by the ARM platform. The Register will be update now

Each sub-block uses the SRM mechanism according to the sub-block's behavior, the table below summarizes the SRM support for each sub-block

Table 45-35. SRM support per Sub-block

Sub-block	Switching between 2 flows support	Updating parameters between frames	Comment
CSI1, CSI0	NO	YES	SRM_MODE can be 00 or 01. The update will happen only once. When set to 01: after the update the state machine is automatically moved to 00 mode. It is recommended to make sure that the first frame has started by polling the corresponding NFACK bit before setting the SRM_MODE
DI1, DI0	NO	YES	DI0, DI1 parameters are needed when clock change is performed (Clock Change procedure). SRM_MODE can be 00 or 01. The update will happen only once. When set to 01: after the update the state machine is automatically moved to 00 mode
DC	YES	NO	SRM_MODE can be 00 or 10.
DP	YES	NO	SRM_MODE can be 00, 10 or 11. When set to 11: after the update the state machine is automatically moved to 10 mode 10 is not supported for SYNC flows

In order to update parameters the user should monitor the SRM_BUSY bit of the corresponding sub-block. When the SRM is not busy the user should set the **SRM_MODE to 00. The user will now update the register file in the memory. When done the user should switch the SRM_MODE field to the desired mode.**

45.4.12.6.4 SRM priority

The SRM updates the registers according to a pre defined priority. The priority is set according to the SRM_PRI bits of each sub-block. The user must set a unique value for each sub-block.

45.4.12.6.5 SRM entries mapping

The table below maps any IPU register to an address in the SRM. The registers marked as NONE do not have an SRM entry

PG column indicates if this register is saved during power gating mode

LPSR column indicates if this register is swapped during low power screen refresh mode (LPSR)

Table 45-36. IPU SRM entries mapping

45.4.12.7 Memory Access Unit

The Memory Access Unit (MA) supports ARM platform access to the IPU internal memories.

Some of the IPU internal memories are memory mapped. This unit handles accessing these memories. The table below describe the accessible memories and their limitations.

Table 45-39. Internal Memories Access Support and Limitations

Memory	Function	Support and Limitations
lut	IDMAC's look up table	Accessible only when All the IDMAC channels that use the LUT are disabled
cpmem	IDMAC's Channel parameter Memory	This memory can be accessed while tasks are enabled. Must be configured before enabling processing tasks. IDMAC channel parameters must not be changed in the CPM when the corresponding DMA channel is enabled excluding the base addresses (EBA0 and EBA1). One of these parameters can be changed during channel operation if it relates to the non-active double buffer.
tpm	IC's task parameter memory	Must be configured before enabling processing tasks. This memory can be accessed while tasks are enabled. IC task parameters must not be changed in the TPM when the corresponding task is active.
dc_template	DC's template memory	Can be configured before enabling tasks. Must not be accessed while operation. Both read and write access to the DC's template memory are forbidden when there is any enabled channel which can use the template

45.4.12.8 SISG - Still Image Synchronization Generator

The IPU incudes a "Still Image Synchronization Generator" (SISG), providing time-sensitive control signals synchronizing the image sensor with camera peripherals, such as a flash lamp and a mechanical shutter.

The SISG is implemented using a single time base counter, and six Time Compare Units - as described in the following figure.

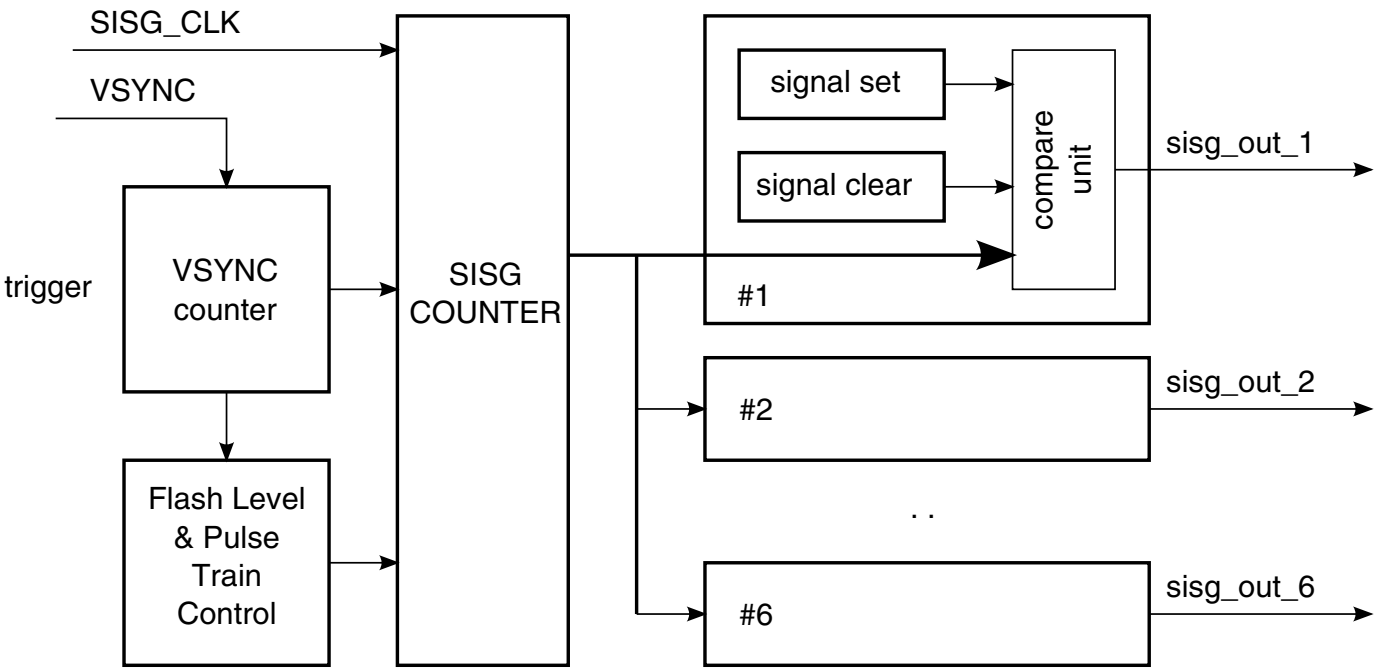

Figure 45-58. Still Image Signal Generator

The SISG inputs are:

- Activation trigger
- VSYNC: the frame-boundary signal from the sensor

The SISG is activated by one of the following triggers:

- The ARM platform by setting the MCU_ACTV_TRIG bit
- An external signal (GPIO pin)

Upon activation, the counter is reset and then there are the following two possibilities:

- Counting starts immediately
- Counting start is delayed until one of the next 7 VSYNC signals (programmable via the NO_OF_VSYNC bits)

During the counting period, the SISG can generate up to 6 output strobes:

- Each strobe can be individually enabled or disabled and has a programmable polarity
- The edges of the strobes are generated at specified counter values - to achieve pixel-level resolution - as specified by programmable SISG_SET& SISG_CLR time tag registers
- The clock has 25 bits, to allow strobe generation during a time period of up to two 12M pixel frames

The SISG can repeat the above sequence for up to 32 cycles (this is provided to generate a train of flash pulses, for anti-red-eye or for measurements in low-light conditions). The repetition is implemented by resetting the counter, which can be triggered by one of the following events:

- A VSYNC signal
- A pre-defined value reached by the counter

After the last sequence, when the counter reaches its maximal value, it stops counting and the SISG remains in idle mode until the next activation.

45.4.12.9 Clock Change procedure

The IPU supports dynamic clock rate changes.

Types of change:

- DVFS transitions: frequent, initiated by the SoC's power modes controller (GPC) and the SoC's clock controller module (CCM)
- Other: infrequent, initiated by SW.

IPU may have on-going activities at this stage.

The display interface clocks may either change or remain unchanged. During screen refresh, the display clock would typically not change. During asynchronous access, it may be appropriate to change also the display interface clock. The choice between these options would be made in advance by the user

If the IPU display interface uses the external clock (ipp_di_0_ext_clk or ipp_di_1_ext_clk) source, it remains unchanged. A change in the rate of this clock is performed fully by SW, without the special HW support described below. In particular, the SW may have to stop explicitly any interaction with the display (e.g. screen refresh) before performing the change.

The user is responsible to make sure that the lowest planned clock (in DVFS transitions) is still high enough to support the expected activities (e.g. data rate through the display bus)

The procedure below describes the IPU handshaking with the CCM.

1. The user prepares 2 sets of clock modes CLOCK_MODE_0 is the default clock mode, CLOCK_MODE_1 is the alternate clock mode. The IPU toggles between these two settings following the next assertion of ipg_clk_change_rq. If the user sets the SRM_CLOCK_CHANGE_MODE bit then he should also prepare the registers in the SRM for each of the DIs. These registers include all the DI settings adjusted to the new clock.
2. CCM asserts the ipg_clk_change_rq signal when a clock change is needed
3. The CM calculates the new clock frequency and send it to the DI (signals are di0_clk_freq, and di1_clk_freq). These signals should be sent to the DI only after getting the di_clk_change_ack signal from the DIs. The values of this field could be.
   - 00 - 1/4 of full frequency
   - 01 - 1/2 of full frequency
   - 10 - full frequency
   - 11 - illegal
4. The CM sends a cm_clk_change_rq signal to the DIs.
5. The DI stops the clock to the display (freeze mode) according to DI0_CLOCK_STOP_MODE & DI1_CLOCK_STOP_MODE bits. If the DI is disable, the ACK from the DI is not needed and the CM will assume that the DI sent an ACK.
6. Once the clock to the display is stopped, the DI sends a signal to the CM called di_clk_change_ack
7. The CM wait for the clock change signals from both of the DIs
8. If the SRM_CLOCK_CHANGE_MODE bit is set the CM should read the new DI settings from the SRM and override the previous DI settings. Then the CM clears the SRM_CLOCK_CHANGE_MODE bit
9. Once the above is complete the CM asserts the ipg_clk_change_ack signal to the CCM
10. The CM sends the signals di0_clk_freq, and di1_clk_freq to the DIs.
11. The CCM will negate the cm_clk_change_rq
12. The CCM will now change the clocks
13. When the new clock arrives the ipu_clk_changed signal will be asserted.
14. The state machine on each DI will now move out of freeze mode and continue working with the new clock.

45.4.12.10 Low Power Modes - Stop, PG and LPSR modes

IPU supports 3 low power modes.

- STOP: on this mode the clock to the IPU is stopped

- PG: power gating, where the clock to the IPU is stopped and the power is for the IPU is turned off. Some of the memories are kept powered, so the wake up from this mode will be faster.
- LPSR: low power screen refresh.The clock to the IPU is changed to a slower frequency, the IPU performs only screen refresh.

The user should not request both LPSR and PG. at the same time. This case is not supported and the results are not predictable.

The CCM may assert one of the 2 signals: stop_clk_at_stop_req OR stop_clk_at_wait_req

The IPU OR them internally as there's no difference between them with regards to IPU's behavior.

In all these modes the clock to the IPU is going to be stopped (assertion of stop_clk_at_stop_req).

IPU should complete all his tasks:

- CSIs complete transferring the last frame. Wait for csi_busy = 0
- IDMAC completes all the flows (all CH_BUSY = 0)
- All the flows in the FSU are complete. New ones do not start.
- CM sends stop request to the DIs
- Once the DI sent all the data to the display, it asserts an ACK signal

Only when all the above occurs, the CM can assert an internal signal called "IPU_IDLE"

IPU_IDLE is the starting point for any of the low power modes.

Note that if the VDIC was in use prior to entrance the low power mode the viewfinder task of the IC will be in WAIT_FOR_READY state (the task's status is reflected in the VF_TSTAT field). The user will need to manually switch that task to IDLE. This is done by performing the following steps:

- Wait for EOF of the viewfinder output channel (IDMAC_EOF_21)
- Set RSW_EN bit
- resume one frame via the viewfinder task.
- Disable the VDI and IC and the corresponding IDMAC channels

45.4.12.10.1 STOP Mode

In this mode the IPU sends the ipu_stby_ack after getting to IPU_IDLE state. The CCM will gate off the clock to the IPU.

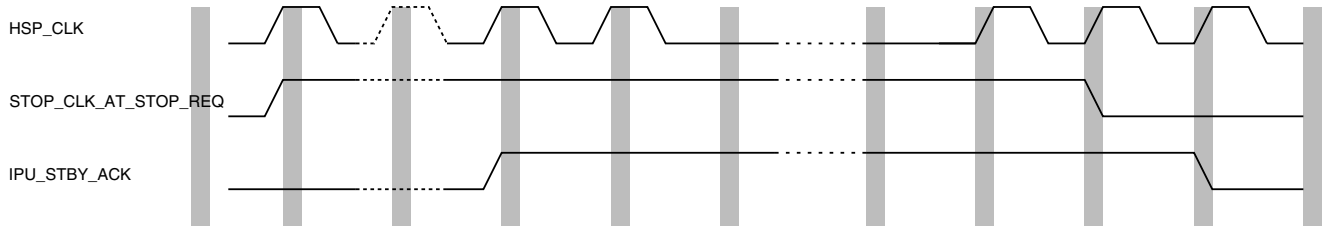

Figure 45-59. Entering and Exiting STOP Mode

Wake up from STOP mode

When the SoC decides to wake up from STOP mode it should:

- Resume the clock to the IPU.
- Negate the stop_clk_at_stop_req or stop_clk_at_wait_req signal.
- The IPU will then negate the ipu_stby_ack signal.
- The IPU will resume screen refresh.

45.4.12.10.2 Power Gating

In power gating mode the clock to the IPU is stopped and part of the IPU is powered down. Only the memories that are essential for a quick and smooth wake up are kept powered.

The procedure for entering PG mode is the similar to the procedure for entering STOP mode.

1. If the stop request is asserted and the "gpc_pg_ipu" signal is asserted then we are entering PG mode.
2. The IPU follows the same process as on STOP mode till getting into IPU_IDLE state.
3. The IPU saves in the SRM the content of the registers of the sub-blocks participating in screen refresh. The sub-blocks are:
   - DI0 & DI1
   - DC
   - DP
   - DMFC
   - IDMAC
   - IC
   - CM
4. After saving the registers the IPU will send the ipu_stby_ack signal to the CCM.
5. The CCM will gate off the clock to the IPU.

6. The GPC will gate off the power to the IPU. The memories listed below are needed for quick and smooth wake up, therefore the memories listed below are kept powered

Table 45-40. Memories that are Powered at PG mode

Sub-blocks	Instance name	Description
IDMAC	ipu_memories_lut0 ipu_memories_lut1	Look UP table memory
IDMAC	ipu_memories_cpmem	Channel parameter memory
CM shadow	ipu_memories_srm	Shadow registers memory
IC + IRT	ipu_memories_tpm	IC's task's parameters memory
DC	ipu_memories_dc_template	DC's template

Wake up from PG mode

1. The GPC resumes power to the IPU
2. The GPC drives the signal gpc_ipu_pwgtd, indicating that the IPU wakes up from PG mode.
3. The SoC's reset controller resets the IPU by asserting the ipg_hard_async_reset_b signal.
4. The CCM resumes the clock to the IPU.
5. The IPU reads the registers from the SRM and writes the content to the sub-block's registers.
6. The IPU sends the ipu_wakeup_ack to the CCM, indicating that the wake up procedure is complete. This signal is negated when gpc_ipu_pwgtd is negated.
7. The IPU resumes screen refresh.

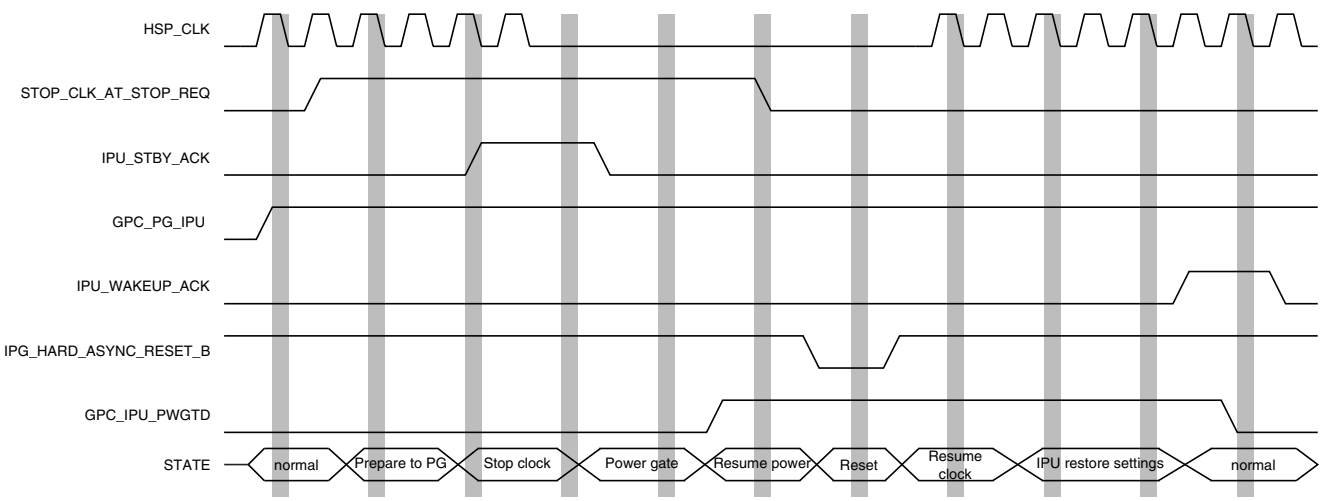

Figure 45-60. Entering and Exiting PG mode

45.4.12.10.3 Low Power Screen Refresh mode - LPSR

In Low Power Screen Refresh mode, the clock to the IPU is changed to a slower frequency, the IPU performs only screen refresh to a single display via the DP (channels 23 & 27).

Preparations

1. The user sets the LPSR_MODE bit indicating that the next assertion of stop_clk_at_stop_req OR stop_clk_at_wait_req activates the LPSR procedure.
2. The user moves the IPU to screen refresh flow. This means that if other tasks are active (flows via CSI or multiple flows to multiple displays) - this tasks needs to be complete and disabled. This is step is fully done by the user (SW). The only flow that remains active is screen refresh to a single display done via the DP (channels 23 & 27)
3. The user stores in the SRM the planned configuration for the sub-blocks involved in the LPSR flow. These configuration will e switched with the active registers' settings on later stage. The relevant sub-blocks are:
   - DI0 & DI1
   - DC
   - DP
   - DMFC
   - IDMAC
   - CM

Entering LPSR

The flow for entering LPSR is the same as stop mode.

1. The IPU follows the same procedure as on STOP mode till getting into IPU_IDLE state.
2. IPU swaps the registers of the relevant blocks with the pre stored content from the SRM. The content of the registers of the current flow is stored in the SRM. The IPU will switch back to this configuration after exiting from LPSR.
3. The IPU sends the ipu_stby_ack
4. The CCM will gate off the clock to the IPU.
5. The CCM will switch to the new clock
6. After changing the clock, the CCM asserts ccm_lpsr_ipu, this signal is synched inside the IPU to the hsp_clk
7. The IPU will resume screen refresh with the new settings.

Exit from LPSR

1. The CCM negates ccm_lpsr_ipu
2. The CM sends standby request to the DI

3. The DI should complete processing the current frame and stop the clock to the display and send an acknowledge signal to the CM.
4. The SRM swaps the registers' configuration. current configuration (LPSR) is saved in the SRM, the previous (original) configuration is stored in the blocks' registers.
5. IPU asserts the ipu_wakeup_ack signal indicating that it is now safe to leave LPSR mode.
6. CCM stops the clocks to IPU
7. CCM resumes the clock to the IPU - This clock is the same clock used prior to entering the LPSR mode.
8. CCM negates the stop_clk_at_stop_req (or stop_clk_at_wait_req)
9. IPU negates the ipu_stby_ack and the ipu_wakeup_ack signals
10. The IPU resumes screen refresh with the original settings.

The diagram below illustrates the procedure for entering and leaving LPSR mode

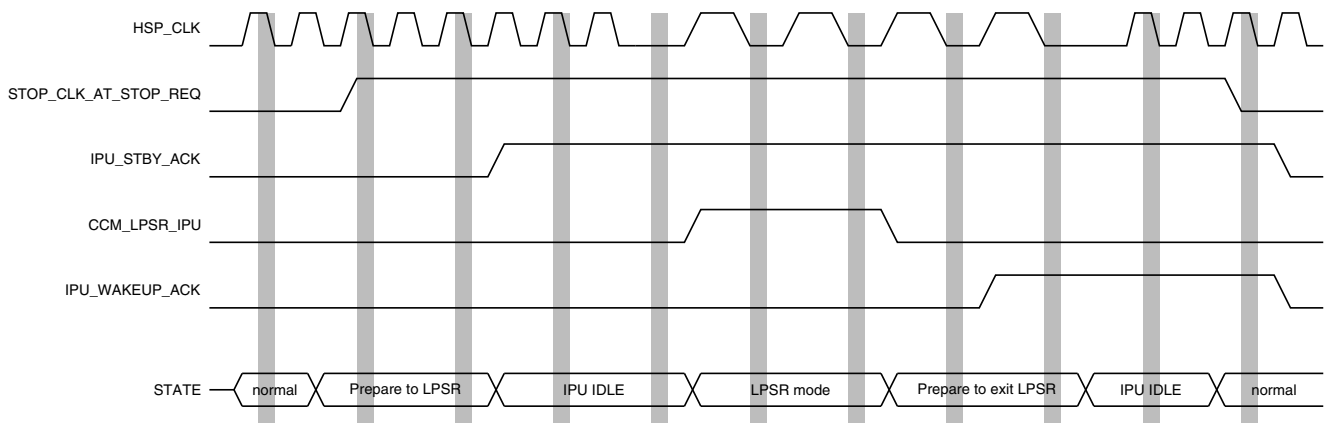

Figure 45-61. Entering and Exiting LPSR mode

45.4.13 IPU diagnostics unit

The IPU has a 16 bit diagnostic bus called ipu_diagbus. This bus can be connected at SoC level so these 16 outputs of the IPU can be routed to the SoC's pins and used for signals monitoring during debug.

The internal signals that can be monitored are internal status signals. There are 18 groups of signals. In order to route the selected group the user need to set the IPU_DIAGBUS_MODE and select the correct group. The sub-blocks are arranged in groups as described on the tables below.

Table 45-41. IPU diag bus groups 0-3

	group0	group1	group2	group3
0	IDMAC_NFACK_6	DC_TEARING_ERR_6	IDMAC_EOF_40	IDMAC_EOF_5

45.5 Programmable Registers

45.5.1 IPU Memory Map/Register Definition

The address space for accesses through the AHB-lite slave port is 128 MB and it is split internally (with 32MB resolution) according to bits[28:25] of the address. Using the following notation

Address = (IPU_ID[31:29], MSB[28:25], LSB[24:0])

the address is used as follows ("T" is a configurable integer between12and 13 by configuring the MCU_T parameter):

1. MSB<T: access to an external device, with address = (MSB, LSB)
2. T<=MSB<14: access to an external device, with address (MSB-T, LSB)
3. MSB=14: Low-level access to an external device, with LSB[3:0] = (Lock, CS, RS[1:0])

- LSB[5:4] = RS[1:0] (the address on the display interface)
- LSB[6] = Choice of display's channel (0=channel 8, 1=channel 9)
- LSB[7] = Lock (Lock=1 prevents the use of the display port until the next ARM platform access)

1. MSB=15: access to internal IPU registers, with address LSB

The display port has 2 channels dedicated for ARM platform accesses via the AHB bus. Channel 8 is dedicated to the accesses where MSB<T. Channel 9 is dedicated to the accesses where MSB>T. When only a single channel is used, channel 8 should be used. The usage of channel 9 requires the usage of channel 8 as well.

The table below shows the register file of the block (addresses 0x1E000000 to 0x1FFFFFFF) and how the memory space allocation for each sub-block of the IPU.

NOTE

The addresses given in the table are relative to the IPU base address defined at SoC's level.

IPU_CONF field descriptions

Field	Description
31 CSI_SEL	CSI select bit; This bit selects manually between the 2 CSI's. This bit defines which CSI is the input to the IC. This bit is effective only if IC_INPUT is bit cleared 0 CSI0 is selected 1 CSI1 is selected
30 IC_INPUT	IC Input select bit. This bit selects manually between the 2 inputs to the IC 1 VDI
29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28 Reserved	This read-only field is reserved and always has the value zero. Reserved
27 VDI_DMFC_SYNC	This bit enables the direct path VDIC -> IC_VF -> DMFC for sync flow. If this bit is set IC_DMFC_SEL must be set. 0 the flow is disabled 1 the flow is enabled
26 IC_DMFC_SYNC	IC to DMFC Sync flow This bit defines if the direct flow between IC to DMFC is synchronous or asynchronous 0 async flow 1 Sync flow
25 IC_DMFC_SEL	IC to DMFC select Selects the DMAIC_1 (channel 21) channel's connectivity between the IC and the DMFC

Table continues on the next page...

IPU_CONF field descriptions (continued)

Field	Description
	0 DMAIC_1 (channel 21) is routed to the IDMAC 1 DMAIC_1 (channel 21) is routed to DMFC In case DMFC was selected the IDMAC_CH_EN[21] must be clear.
24 Reserved	This read-only field is reserved and always has the value zero. Reserved
23 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
22 IDMAC_ DISABLE	Image DMA controller (IDMAC) disable bit. This bit allows the user to turn off the clock of the IDMAC if the use case permits it. By default the IDMAC is enabled. 0 IDMAC is enabled 1 IDMAC is disabled
21 IPU_DIAGBUS_ ON	IPU Diagnostics bus on This bit is connected to the IPU's output. it can be used by the SoC in order to control the IOMUX and bring the IPU's diagnostics bus to the SoC's pins. 1 diagnostics bus is on 0 diagnostics bus is off
20–16 IPU_DIAGBUS_ MODE	IPU diagnostic bus mode. This 5 bits select one of 16 groups of signals to be routed to the IPU's diagnostics bus 00000 Route group 0 to the IPU's diagnostics bus 00001 Route group 1 to the IPU's diagnostics bus 01111 Route group 15 to the IPU's diagnostics bus 10000 Route group 16 to the IPU's diagnostics bus 10001 Route group 17 to the IPU's diagnostics bus 10010-11111 Reserved
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
12 VDI_EN	VDI enable bit. This bit must be cleared if the ISP_EN bit is set. 0 VDIC is disabled 1 VDIC is enabled
11 SISG_EN	Still Image Synchronization Generator (SISG) Enable bit 0 SISG is disabled 1 SISG is enabled
10 DMFC_EN	Display's Multi FIFO Controller sub-block (DMFC) Enable bit 0 DMFC is disabled 1 DMFC is enabled
9 DC_EN	Display Controller sub-block (DC) Enable bit 0 DC is disabled 1 DC is enabled

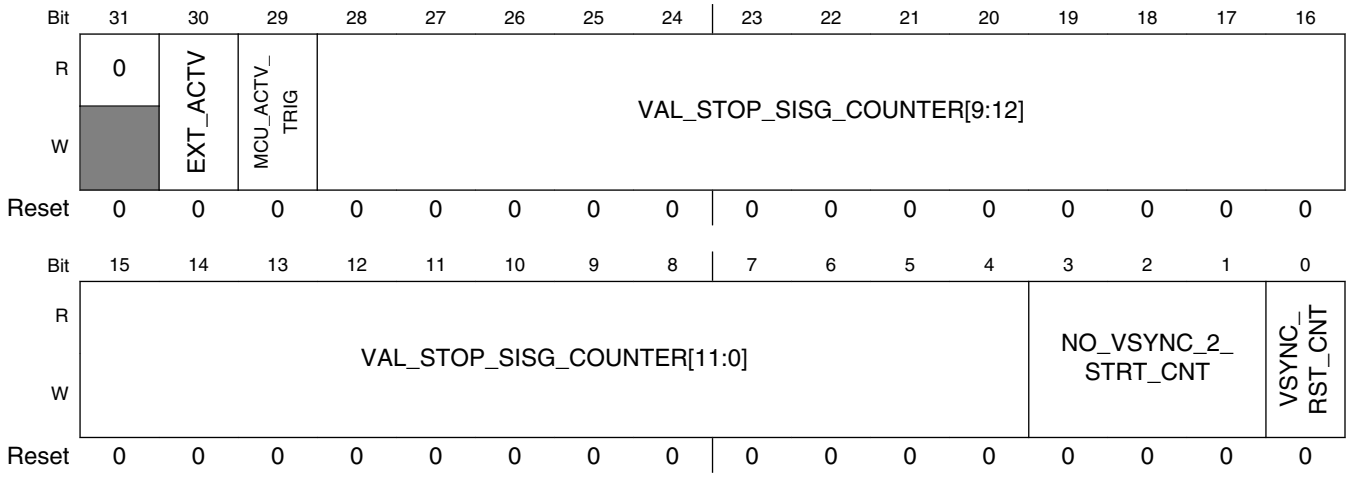
Table continues on the next page...

IPU_CONF field descriptions (continued)

Field	Description
8 SMFC_EN	Sensor's Multi FIFO Controller Sub-block (SMFC) Enable bit 0 SMFC is disabled 1 SMFC is enabled
7 DI1_EN	Display Interface Sub-block 1 Enable bit 0 DI1 is disabled 1 DI1 is enabled
6 DI0_EN	Display interface Sub-block 0 Enable bit 0 DI0 is disabled 1 DI0 is enabled
5 DP_EN	Display processor Sub-block Enable bit 0 DP is disabled 1 DP is enabled
4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3 IRT_EN	Image Rotation Sub-Block Enable bit 0 IRT is disabled 1 IRT is enabled
2 IC_EN	Image Conversion Sub-Block Enable bit 0 IC is disabled 1 IC is enabled
1 CSI1_EN	Camera Sensor Interface 1 Enable bit 0 CSI1 is disabled 1 CSI1 is enabled
0 CSI0_EN	Camera Sensor Interface 0 Enable bit 0 CSI0 is disabled 1 CSI0 is enabled

45.51.2 SISG Control 0 Register (IPU_SISG_CTRL0)

Address: IPU_SISG_CTRL0 is 1E00_0000h base + 4h offset = 1E00_0004h

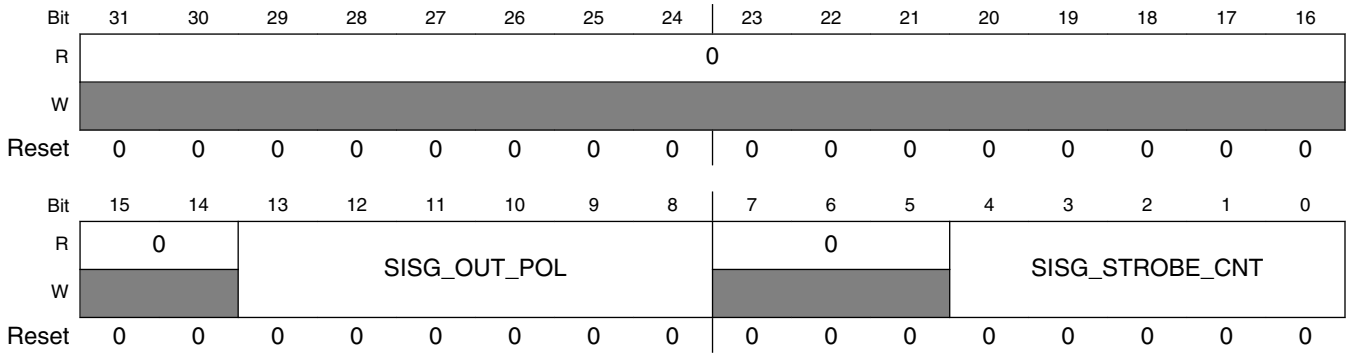


IPU_SISG_CTRL0 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value zero. Reserved
30 EXT_ACTV	External Active Define if an external active trigger will start the counters. The external active trigger is an input signal to the IPU called ext_actv_trig
29 MCU_ACTV_TRIG	Reserved, should be cleared.
28–4 VAL_STOP_SISG_COUNTER	SISG Stop Counters value. This is a predefined value that stops the SISG counters. The user should write to this field the N-1 value of the desired value.
3–1 NO_VSYNC_2_STRT_CNT	VSYCs to Start Counter This bits define how many VSYNCs signals will be counter before activating the SISG counters. If set to 0 starts immediately. If set to N (1..7) starts after N VSYNCs.
0 VSYNC_RST_CNT	VSYNC Resets counters Defines if the counters are stooped following VSYNC or when the counters reach a pre defined value (VAL_STOP_SISG_COUNTER) 1 The counters are stopped at VSYNC 0 The counters are stooped when the counters reach the VAL_STOP_SISG_COUNTER value.

45.51.3 SISG Control 1 Register (IPU_SISG_CTRL1)

Address: IPU_SISG_CTRL1 is 1E00_0000h base + 8h offset = 1E00_0008h

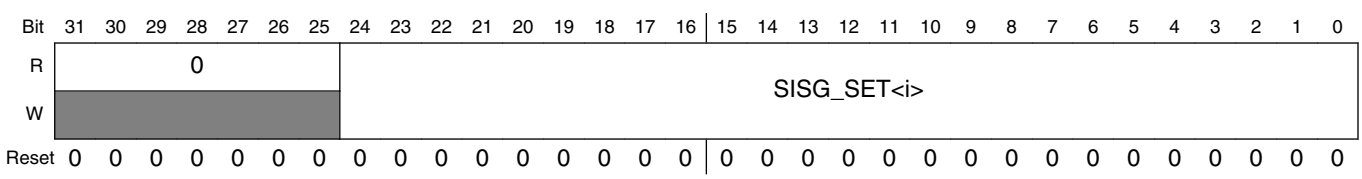


IPU_SISG_CTRL1 field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
13–8 SISG_OUT_POL	SISG_OUT_POL This bits defines the polarity of the SISG output signals 1 active high 0 active low
7–5 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
4–0 SISG_STROBE_CNT	SISG Strobe Count The SISG can repeat the sequence for up to 32 cycles; this is used for generating a train of pulses.

45.51.4 SISG Set<i> Register (IPU_SISG_SET_i)

Address: IPU_SISG_SET_i is 1E00_0000h base + Ch offset = 1E00_000Ch



IPU_SISG_SET_i field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.

Table continues on the next page...

IPU_SISG_SET_i field descriptions (continued)

Field	Description
24–0 SISG_SET<i>	SISG SET <i> value These bits define the set value of the SISG counter #<i>

45.51.5 SISG Clear <i> Register (IPU_SISG_CLR_i)

Address: IPU_SISG_CLR_i is 1E00_0000h base + 24h offset = 1E00_0024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

IPU_INT_CTRL_3 field descriptions (continued)

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
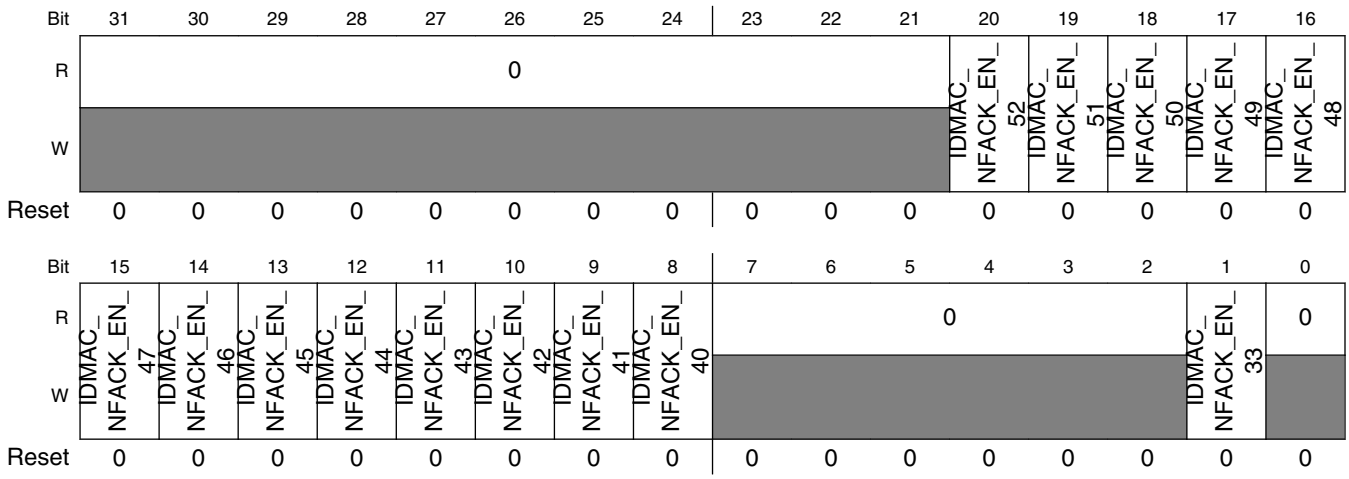
8 IDMAC_ NFACK_EN_8	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
7–6 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.
5 IDMAC_ NFACK_EN_5	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
4 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.
3 IDMAC_ NFACK_EN_3	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
2 IDMAC_ NFACK_EN_2	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
1 IDMAC_ NFACK_EN_1	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
0 IDMAC_ NFACK_EN_0	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.

45.51.9 Interrupt Control Register 4 (IPU_INT_CTRL_4)

This register contains part of IPU interrupts controls. The controls of NFACK (New Frame Ack) of DMA Channels interrupts [63:32] can be found in this register.

Address: IPU_INT_CTRL_4 is 1E00_0000h base + 48h offset = 1E00_0048h



IPU_INT_CTRL_4 field descriptions

Field	Description
31–21 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.
20 IDMAC_ NFACK_EN_52	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
19 IDMAC_ NFACK_EN_51	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
18 IDMAC_ NFACK_EN_50	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
17 IDMAC_ NFACK_EN_49	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number.

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
16 IDMAC_ NFACK_EN_48	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
15 IDMAC_ NFACK_EN_47	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 IDMAC_ NFACK_EN_46	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
13 IDMAC_ NFACK_EN_45	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
12 IDMAC_ NFACK_EN_44	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
11 IDMAC_ NFACK_EN_43	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
10 IDMAC_ NFACK_EN_42	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
9 IDMAC_ NFACK_EN_41	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
8 IDMAC_ NFACK_EN_40	Enable New Frame Ack of Channel interrupt. This bit is the control of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number.

IPU_INT_CTRL_5 field descriptions

Field	Description
31 IDMAC_ NFB4EOF_EN_ 31	New Frame before end-of-frame error indication of Channel interrupt. This bit is the control of New Frame before end-of-frame error interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
30 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.
29 IDMAC_ NFB4EOF_EN_ 29	New Frame before end-of-frame error indication of Channel interrupt. This bit is the control of New Frame before end-of-frame error interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
28 IDMAC_ NFB4EOF_EN_ 28	New Frame before end-of-frame error indication of Channel interrupt. This bit is the control of New Frame before end-of-frame error interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
27 IDMAC_ NFB4EOF_EN_ 27	New Frame before end-of-frame error indication of Channel interrupt. This bit is the control of New Frame before end-of-frame error interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
26 IDMAC_ NFB4EOF_EN_ 26	New Frame before end-of-frame error indication of Channel interrupt. This bit is the control of New Frame before end-of-frame error interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
25 IDMAC_ NFB4EOF_EN_ 25	New Frame before end-of-frame error indication of Channel interrupt. This bit is the control of New Frame before end-of-frame error interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
24 IDMAC_ NFB4EOF_EN_ 24	New Frame before end-of-frame error indication of Channel interrupt. This bit is the control of New Frame before end-of-frame error interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
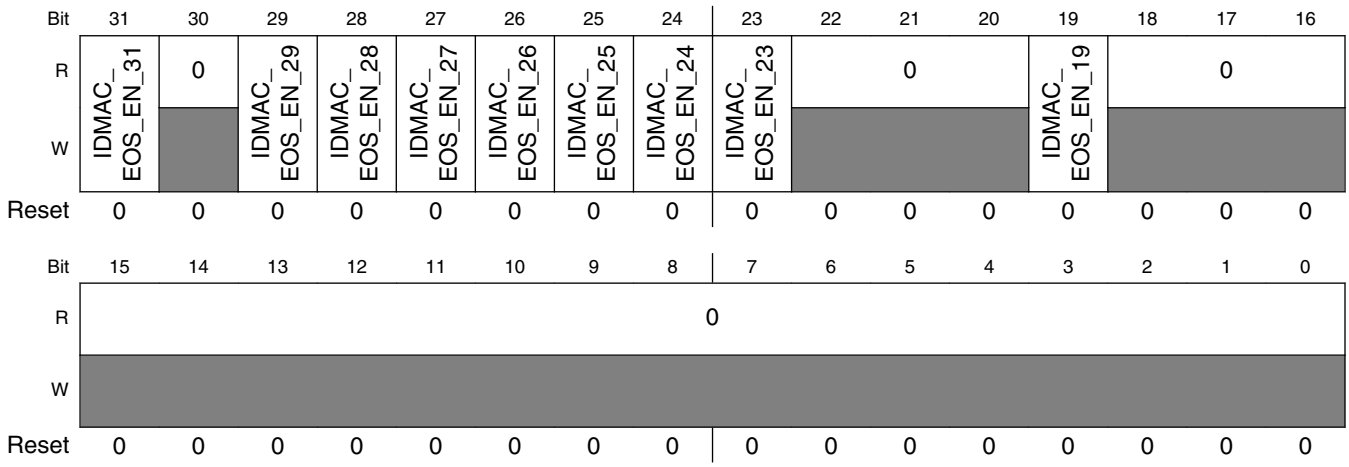
9 IDMAC_ NFB4EOF_EN_ 41	New Frame before end-of-frame error indication of Channel interrupt. This bit is the control of New Frame before end-of-frame error interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
8 IDMAC_ NFB4EOF_EN_ 40	New Frame before end-of-frame error indication of Channel interrupt. This bit is the control of New Frame before end-of-frame error interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
7–2 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.
1 IDMAC_ NFB4EOF_EN_ 33	New Frame before end-of-frame error indication of Channel interrupt. This bit is the control of New Frame before end-of-frame error interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.

45.51.12 Interrupt Control Register 7 (IPU_INT_CTRL_7)

This register contains part of IPUIPU interrupts controls. The controls of the End-of-Scroll indication (EOS) of DMA Channels interrupts [31:0] can be found in this register.

Address: IPU_INT_CTRL_7 is 1E00_0000h base + 54h offset = 1E00_0054h



IPU_INT_CTRL_7 field descriptions

Field	Description
31 IDMAC_EOS_EN_31	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
30 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.
29 IDMAC_EOS_EN_29	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
28 IDMAC_EOS_EN_28	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
27 IDMAC_EOS_EN_27	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number.

Table continues on the next page...

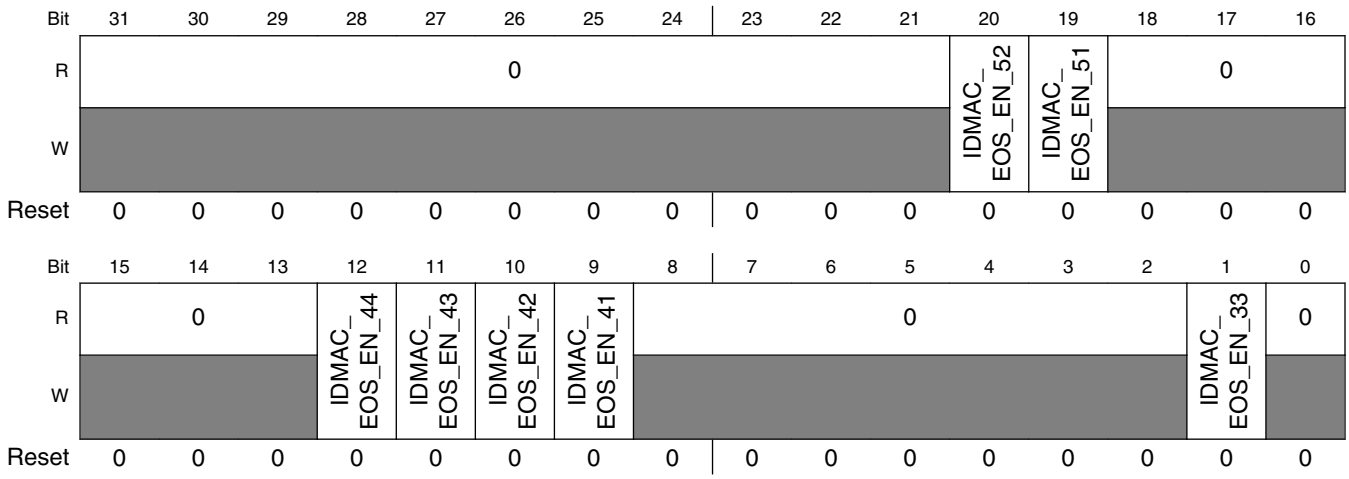
IPU_INT_CTRL_7 field descriptions (continued)

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
26 IDMAC_EOS_EN_26	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
25 IDMAC_EOS_EN_25	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
24 IDMAC_EOS_EN_24	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
23 IDMAC_EOS_EN_23	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
22–20 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.
19 IDMAC_EOS_EN_19	End of Scroll indication of Channel interrupt. This bit is the control of End of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
18–0 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.

45.51.13 Interrupt Control Register 8 (IPU_INT_CTRL_8)

This register contains part of IPU interrupts controls. The controls of the End of Scroll indication (EOS) of DMA Channels interrupts [63:32] can be found in this register.

Address: IPU_INT_CTRL_8 is 1E00_0000h base + 58h offset = 1E00_0058h



IPU_INT_CTRL_8 field descriptions

Field	Description
31–21 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.
20 IDMAC_EOS_EN_52	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
19 IDMAC_EOS_EN_51	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
18–13 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.
12 IDMAC_EOS_EN_44	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number.

Table continues on the next page...

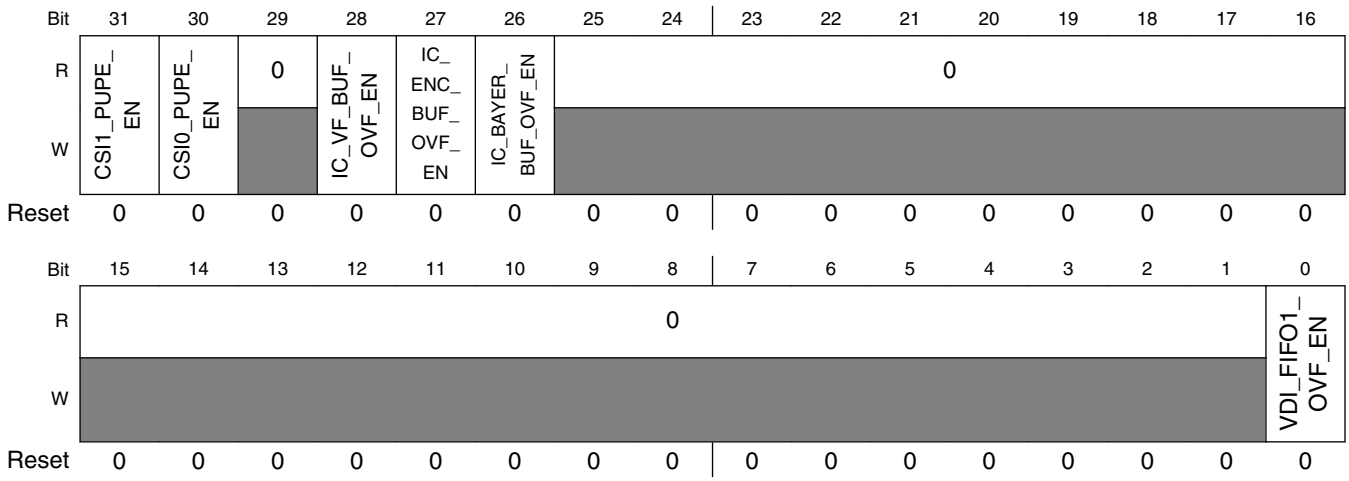
Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
11 IDMAC_EOS_EN_43	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
10 IDMAC_EOS_EN_42	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
9 IDMAC_EOS_EN_41	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
8–2 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.
1 IDMAC_EOS_EN_33	End of Scroll of Channel interrupt. This bit is the control of End Of Scroll interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.

45.51.14 Interrupt Control Register 9 (IPU_INT_CTRL_9)

This register contains part of IPU interrupts controls. This register controls error interrupt signals coming from different sub-blocks within

Address: IPU_INT_CTRL_9 is 1E00_0000h base + 5Ch offset = 1E00_005Ch



IPU_INT_CTRL_9 field descriptions

Field	Description
31 CSI1_PUPE_EN	CSI1_PUPE_EN - CSI1 parameters update error interrupt enable. This bit enables an interrupt that is a result of an error generated by the CSI1. The error is generated in case where new frame arrived from the CSI1 before the completion of the CSI1's parameters update by the SRM 0 Interrupt is disabled. 1 Interrupt is enabled.
