Get the value of the internal flags (SF, DF, T, and LM), of the loop related registers (EPC and SPC), and of the PC-related registers (PC and RPC). Use a done 5, which is the formatting instruction dedicated to the debug. This instruction formats the flags and the values contained in the registers. It also writes the resulting values into the channel context memory. It should not be used when entering debug from the IDLE state (for example, with no active channel script running on the SDMA), because it will update a channel context that may belong to any channel.

```
exec_once("done 5");                    // formatting the value of flags and registers
```

At this point, the channel context should be up-to-date in memory, and debug operations should now be possible. However, the context can be exported with the following instructions:

Exporting the Context

```
dmov(ctx_base_addr);                              // loading GReg[1] with the channel
context base address
exec_once("ld GReg0,(GReg1,0)");                      // get RPC-PC into GReg0
exec_once("ld GReg1, (GReg1,1)");                     // get SPC-EPC into GReg1
Loop_data = dmov(-);                           // read back the value of Loop registers
exec_once("mov GReg1, GReg0");                     // puts the PC info into GReg1
PC_data = dmov(-);                             // reads back the content of the PC registers
```

After this sequence of operations, the entire SDMA context is exported via the OnCE

66.16.5.3 Restoring the Context

At this point in the operation, restore the context of the SDMA. It can be different from the original context located in memory, and the content previously saved into the debugging application via the OnCE.

The following example shows how it is possible to modify the current channel context:

Modifying the Current Channel Context

```
dmov(Loop_data);                                  // put Loop former value into GReg[1]
exec_once("mov GReg0, GReg1");                         // copy to GReg[0]
dmov(PC_data);                                    // put PC former value into GReg[1]
exec_once("mov GReg2, GReg1");                         // copy to GReg[2]
dmov(ctx_base_addr);                                  // put channel context base address into
GReg[1]
exec_once("st GReg0, (GReg1,1)");                          // restore Loop context
exec_once("st GReg2, (GReg1,0)");                          // restore PC context
```

Once the context in memory is the desired context (with or without applying the previous instruction sequence), it can be restored to the *real* PC and loop registers in the SDMA core:

```
exec_once("cpShReg");                    // restore flags and PC & loop related registers
```

After this command, the SDMA core PC, RPC, SPC, EPC registers, as well as the flags contain the same data as what is stored in the context RAM for the current channel.

The following example shows how to restore the context of general registers GReg[0], GReg[1], GReg[2] and GReg[3].

Restoring the General Register Context

```
dmov(GReg3_data);                    // put GReg[3] restore value in GReg[1]
exec_once("mov GReg3, GReg1"); // restore GReg[3]
dmov(GReg2_data);                    // put GReg[2] restore value in GReg[1]
exec_once("mov GReg2, GReg1"); // restore GReg[2]
dmov(GReg0_data);                    // put GReg[0] restore value in GReg[1]
exec_once("mov GReg0, GReg1"); // restore GReg[0]
dmov(GReg1_data);                    // restore GReg[1]
```

At this point, it is possible to restart the normal program execution.

NOTE

Every SDMA core general register value can be modified by a mov instruction, which makes modification of these registers easy during debug. Unfortunately, there is no such instruction as a mov to directly modify the contents of either PCU register or flag (PC, RPC, SPC, EPC, T, LM, SF, or DF). The cpShReg instruction is meant to provide a means for changing these register contents via the context memory.

66.16.5.4 Accessing the Memory

In the following example, it is assumed that the SDMA context is entirely saved. If true, it is permissible to modify the general purpose registers during debugging activity.

To perform a memory read access, the target address is stored via the OnCE in GReg[1], then the load instruction is executed on the SDMA (the data loaded from the memory overwrites the address contained in GReg[1]), and then the result value is read back via the OnCE.

```
macro READ:             dmov(target_addr);                                  // put the target
address in GReg[1]
                    exec_once("ld GReg1,(GReg1,0)");                          // execute the
load instruction
                    res_data = dmov(-);                                 // exports the result
data value
```

For a memory write access, the target address is written in GReg[0], and the value to store is written in GReg[1]. Then the store instruction is executed on the SDMA.

```
macro WRITE:             dmov(target_addr);                                   // puts the
target address in GReg[1]
                    exec_once("mov GReg0,GReg1");                          // puts the target
address in GReg[0]
                    dmov(target_data);                                  // puts the target
data in GReg[1]
                    exec_once("st GReg1,(GReg0,0)");                           // performs the
store operation
```

This sequence is shown as an example; however, many other sequences are possible.

NOTE

This sequence of commands can also be applied to memory-mapped registers.

66.16.5.5 Resuming Program Execution

Before resuming program execution, it is assumed that the SDMA context is properly restored. There are two ways to restart the SDMA.

Start by executing the last instruction fetched before entering debug mode, as follows.

```
run_core(-);                          // resume execution from where we stopped before
```

If necessary, restart the execution from a different address. In this case, use the exec_core command. The data field provided with this command must be the encoding of a jump instruction.

```
exec_core("jmp start_addr"); // rerun the SDMA from another address
```

In these two examples, the SDMA exits debug mode and keeps executing the code fetched from the memory.

66.16.5.6 Single Stepping in RAM

To execute a program step-by-step from the RAM, insert software breakpoints in the program flow at appropriate places so that the SDMA only executes one instruction before returning to debug mode.

First, read the next instruction to execute in the RAM. Then, depending on the value of this instruction, compute the address where a software breakpoint instruction should be inserted. The instruction at the corresponding address must be saved, and, the software breakpoint instruction is inserted. After restarting the SDMA, there is only one instruction executed before meeting the software breakpoint.

The following example shows the macro functions READ and WRITE, which correspond to the sequence of commands (described above) used to access the memory.

NOTE

The data read from the memory are 32-bit values, while the instructions are 16-bit values only. This is why it is best to only use addresses divided by two when accessing the memory.

READ and WRITE Macro Functions

```
next_instr = READ(run_addr/2);                          // read the next instruction to execute
// the tool now has to compute the address where the breakpoint
// instruction should be inserted, this address is the "bkpt_addr"
instr_save = READ(bkpt_addr/2);                          // save the instruction before
overwriting
STORE("bkpt instruction",bkpt_addr/2);                        // store the bkpt instruction
in memory
exec_core("jmp run_addr");                              // rerun the SDMA
rstatus(-);                                           // wait for the SDMA to enter debug mode
...
rstatus(-);
STORE(instr_save,bpkt_addr/2);                           // restore the instruction
overwritten
```

In case of branched conditional instructions, a breakpoint instruction should be written at the two possible target addresses.

66.16.5.7 Single Stepping in ROM

No single-step mechanism is supported in ROM. The program code can be loaded in the RAM, where the single-step mechanism can be executed.

66.16.6 OnCE Event Detection Unit

The event detection unit watches signals from the data memory bus (DMBUS), which the SDMA core uses to access its RAM, ROM, and memory mapped registers.

A debug request is sent to the OnCE controller when user-defined conditions on address and/or data values are true.

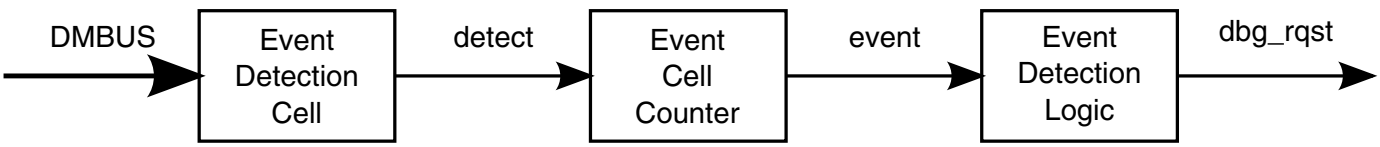

Figure 66-14. Event Detection Unit

A counter, provided with the detection cell, is decreased after an event detection. A debug request is sent to the core only when the counter reaches the value of 0. It is possible to disable the use of the counter if a debug request has to be generated after each event detection.

The event cell is the basic block that supports hardware breakpoints on an address value and/or data values coming from the SDMA memory bus. The trigger condition that generates the debug request is a mixed condition based on those values.

The following figure shows the event cell architecture. The event cell contains the address (stored in the memory address register) and the data (stored in the memory data register) used during the last memory access. There are some user-defined reference values located in memory mapped registers-the event cell addresses, the event cell address mask, the event cell data, and the event cell data mask. These registers are accessed by standard load/store instructions just like regular memory locations.

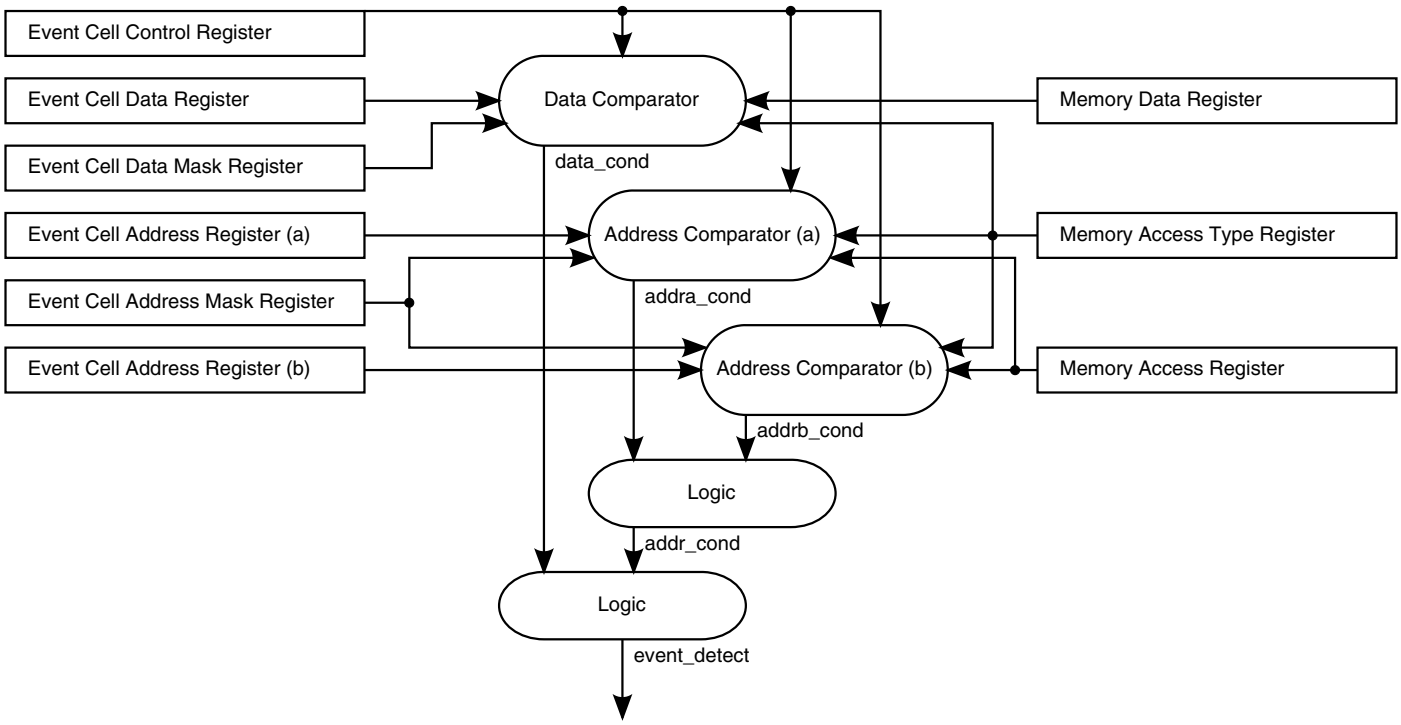

Figure 66-15. Event Cell Architecture

To define a memory breakpoint, three conditions are taken into account: The first two conditions are comparisons of the current memory address with user-defined reference addresses (these conditions are called addressA and addressB). The third condition consists of a comparison between the data received on the DMBUS and a user-defined reference data (this condition is called data). An intermediate address condition is set to express a dependency between addressA and addressB conditions.

66.16.7 Clock Gating and Reset

This section details how to use the clocks and handle the reset signals.

66.16.7.1 Clocks

Because the SDMA uses clock gating to save power, it is necessary to disable the clock gating and force the clocks to be enabled when using the OnCE.

When the OnCE is accessed through its JTAG interface, clock gating must be disabled outside the SDMA via a dedicated SDMA input port clk_gating_off. The reason why detection is not performed automatically by the SDMA internal hardware is that it would cost power to monitor activity on the JTAG interface.

This clk_gating_off input is controlled by a control bit in the System JTAG Controller. Refer to the System JTAG Controller chapter for more information.

When the OnCE is accessed through the ARM platform Control interface, clock gating is automatically turned off. This is done when bit 0 of the ONCE_ENB register (see OnCE Enable (SDMAARM_ONCE_ENB)) is set. A write access to this register is possible even when the OnCE clock is not running. If the ARM platform access is used, the bit in the ONCE_ENB register must be set before any attempt to access any other OnCE register.

66.16.7.2 Resets

The OnCE reset is different from the SDMA main reset. The OnCE reset is connected to the TRST_B pin.

Normally, activating the SDMA reset while keeping the OnCE reset inactive (when possible) enables you to reset the core without having to reprogram the OnCE.

66.16.8 Real Time Features

To rebuild the skeleton of a program execution, it is necessary to store the addresses of the program instructions where jumps are taken: A trace buffer is therefore provided. A real time buffer has also been added to receive data values written during a program execution.

The content of this register may be exported through JTAG ports without stopping the core.

66.16.8.1 Trace Buffer

The Trace Buffer is a 32-stage buffer that contains appropriate information to identify the 32 last changes of flow detected during a program execution.

The following figure shows an overview of the Trace Buffer.

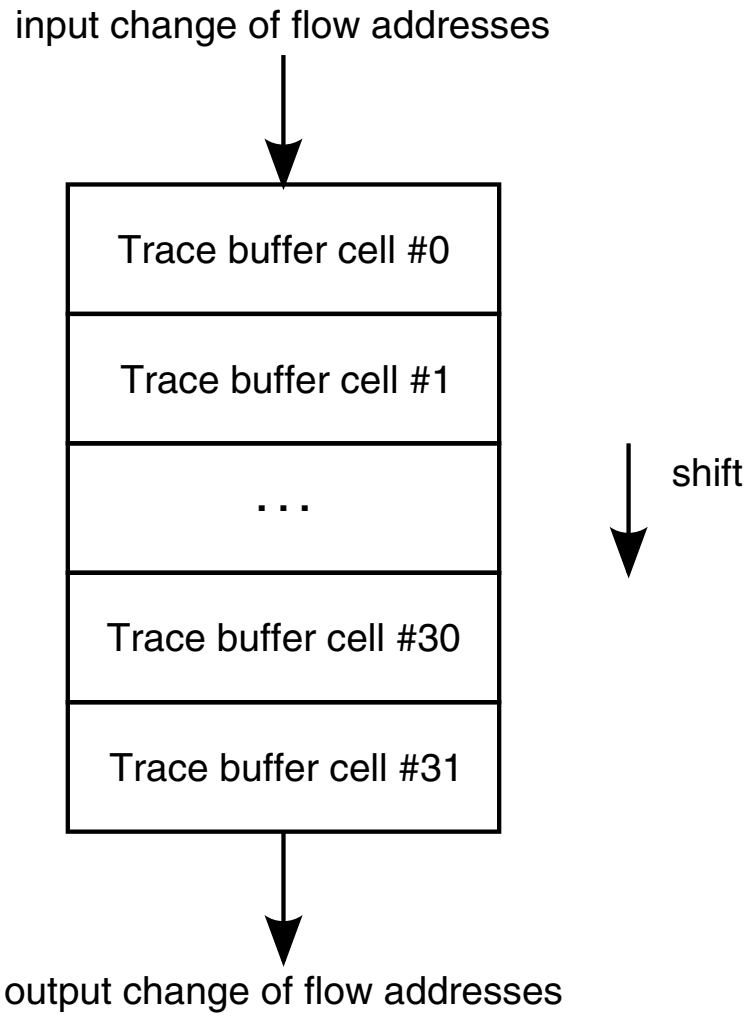

Figure 66-16. Trace Buffer

Each cell of the trace buffer contains two reference addresses and a flag. The flag is set when the addresses stored in the cell correspond to a valid change of flow; otherwise, the flag is cleared. The three most significant bits are unused.

After every change of flow detection, the address of current instruction and the address of the target instruction are stored at the top of the Trace Buffer (cell #0). The flag in the cell is set to indicate that a valid change of flow was detected. Former cell values are shifted one level down. The Trace Buffer contains the 32 last changes of flow. All the flags are reset on a software or a hardware reset, and after each transition from debug mode to user mode.

A memory mapped register of SDMA core, the Trace Buffer register (TB), is provided to read the content of the Trace Buffer. This operation should be done in debug mode. Performing a read access to the Trace Buffer register returns the content of the bottom of the Trace Buffer (cell #31). After every read access, the trace buffer is shifted one level down, and the flag at the top of the trace buffer is cleared.

A typical OnCE command sequence that retrieves the oldest change-of-flow information is a follows:

```
exec_once("mov r1, TB");                              // stores the oldest change-of-flow in
GReg1
dmov(-);                                          // retrieves GReg1 contents
```

This sequence requires the SDMA to be put in debug mode.

66.16.8.2 Real Time Buffer

The Real Time Buffer register (RTB) is a memory mapped register that can be accessed as a regular memory location by the SDMA core during program execution. This register is located in the OnCE.

Executing ar rbuffer command (see The OnCE Controller for further details) exports the content of this register through JTAG ports.

When a write access is performed at the memory location corresponding to the RTB, the receive flag (for example, the RCV bit) is set in the OnCE Status Register (OSR). This flag is cleared at the end of the execution of a rbuffer command.

NOTE

Every write access to the RTB memory location updates the RTB register even if the RCV flag is set. The RTB is cleared on a JTAG reset.

66.16.8.3 Emulation Pin

The debug_matched_event emulation pin reflects the matching condition status detected by the Event Detection Unit.

Since it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

66.16.8.4 Real-Time Debug Outputs

The folloing table shows the debug signals that are available at the SDMA boundaries. Their availability at chip boundaries depends on the project.

Table 66-44. Real-Time Debug Output Pins

Pin	Description
debug_core_state[3:0]	The core_state bits reflect the state of the SDMA core. • The "Program" state is the usual instruction execution cycle. • The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. • The "Debug" state means the SDMA is in debug mode. • The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In "Sleep" modes, no script is running (this is the core idle state); the "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 is executed (boot operation). • The "in Sleep" states are the same as above except they do not have any corresponding channel: they are used when entering debug mode after reset; the reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. 0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Context Switch Saving Channel 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change of Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Context Switch Restoring Channel
debug_yield	Pulse that is active when a yield (done 0) or a yieldge (done 1) instruction is executed. 0 - 1 yield/yieldge executed

Table continues on the next page...

Table 66-44. Real-Time Debug Output Pins (continued)

Pin	Description
debug_core_run	Active when the SDMA core is executing instructions. 0 Debug or sleep mode 1 Run mode
debug_event_channel_sel	Indicates if debug_event_channel displays current channel or last received event 0- debug_event_channel[5:0] gives the number of the current channel 1- debug_event_channel[5:0] gives the number of the last received event
debug_event_channel[5:0]	Gives the number of any DMA request as soon as it is received or the number of the current channel. The value of debug_event_channel_sel indicates if debug_event_channel displays the current channel or last received event. The signal debug_event_channel_sel must be observed to determine what information is provided on debug_event_chanel at any given time.
debug_pc[13:0]	Program Counter value; it has a meaning when the core is in run mode.
debug_mode	Set when the core is in debug. 0 - 1 Core is in debug
debug_bus_error	Set when an error was received during a load or a store (ld, st, ldf, or stf instruction) and registered in SF or DF flag. 0 No error during last load/store 1 Error during last load/store

Table continues on the next page...

Table 66-44. Real-Time Debug Output Pins (continued)

Pin	Description
debug_bus_device[4:0]	Indicates the device or functional unit that is accessed by the current instruction. The debug_bus_device output is always valid when in sleep mode, debug mode, or executing any instruction that does not access the functional units or the memory mapped devices, "no access" is output. 0 No access 1 MSA 2 MDA 3 MD 4 MS 5 PSA 6 PDA 7 PD 8 PS 9 RESERVED 10 RESERVED 11 RESERVED 12 RESERVED 13 CA 14 CS 15 Reserved 16 Memory (RAM or ROM) 17 Memory mapped register 18 Peripheral #1 19 Peripheral #2 20 Peripheral #3 21 Peripheral #4 22 Peripheral #5 23 Peripheral #6 24 Peripheral #7 25 Peripheral #8 26 Peripheral #9 27 Peripheral #10 28 Peripheral #11 29 Peripheral #12 30 Peripheral #13 31 Peripheral #14

Table continues on the next page...

Table 66-44. Real-Time Debug Output Pins (continued)

Pin	Description
debug_bus_rwb	Indicates the direction of the access given by debug_bus_device 0 Write access (st or stf) 1 Read access (ld or ldf)
debug_matched_dmbus	Pulse indicating the OnCE event detection unit has detected a match on the data bus during an access to memory (RAM or ROM), a memory mapped register or a peripheral that is hooked to the SDMA. 0 - 1 data bus match detected
debug_rtbuffer_write	Pulse indicating when the real-time buffer is written by the core. 0 - 1 RTB was modified
debug_evt_chn_lines[7:0]	Eight lines that generate short pulses when DMA requests are received or channels are (re)started. Every line is controlled through two parameters defined in registers Cross-Trigger Events Configuration Register 1 (SDMAARM_XTRIG_CONF1) (as described in SDMAARM). The following two parameters are available for every line: • CNF-Indicates what is monitored on the line: 0 for a channel start, 1 for a DMA request reception • NUM[5:0]-Gives the number of the DMA request or channel to monitor

The matched_event emulation pin reflects the matching condition status detected by the Event Detection Unit. Because it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

All real-time debug outputs are disabled by default (for example, they are stuck to 0) to avoid power consumption when they are not used. They are enabled when bit 11 (RTDOBS) of the Configuration Register (SDMAARM_CONFIG) is set. Signals provided to the system JTAG controller for SDMA debug mode status will also be enabled when the *clk_gating_off* input is asserted.

66.17 Instruction Set

66.17.1 Instruction Encoding

This section presents a short summary of the instruction codes. All context switch instructions are listed for information only; they cannot function properly out of the context switch routine.

```
x...x - don't care

rrr - destination/source general register

sss - additional source general register

bbb - general register used as address base register

ddddd - address displacement

nnnnn - bit number
uuuuuuuu - function unit command bits

pppppppp - branch displacement (signed)

iiiiiiii - 8-bit immediate

jjj - control bit to clear

ff - flag to clear

66.17.2 SDMA Instruction Set

This section describes all the useful instructions from the SDMA set.

Table 66-45. SDMA Instruction List

Instruction	Description	Page
ADD	Addition	ADD (Addition)
ADDI	Add with Immediate Value	ADDI (Add with Immediate Value)
AND	Logical AND	AND (Logical AND)
ANDI	Logical AND with Immediate Value	ANDI (Logical AND with Immediate Value)
ANDN	Logical AND NOT	ANDN (Logical AND NOT)

Table continues on the next page...

Table 66-45. SDMA Instruction List (continued)

Instruction	Description	Page
ANDNI	Logical AND with Negated Immediate Value	ANDNI (Logical AND with Negated Immediate Value)
ASR1	Arithmetic Shift Right by 1 Bit	ASR1 (Arithmetic Shift Right by 1 Bit)
BCLRI	Bit Clear Immediate	BCLRI1 (Bit Clear Immediate)
BDF	Conditional Branch if Destination Fault	BDF (Conditional Branch if Destination Fault)
BF	Conditional Branch if False	Functional Units Programming Model
BSETI	Bit Set Immediate	BSETI (Bit Set Immediate)
BSF	Conditional Branch if Source Fault	BSF (Conditional Branch if Source Fault)
BT	Conditional Branch if True	BT (Conditional Branch if True)
BTSTI	Bit Test immediate	BTSTI (Bit Test immediate)
CLRF	Clear ARM platform flags	CLRF (Clear ARM platform flags)
CMPEQ	Compare for Equal	CMPEQ (Compare for Equal)
CMPEQI	Compare with Immediate for Equal	CMPEQI (Compare with Immediate for Equal)
CMPHS	Compare for Higher or Same	CMPHS (Compare for Higher or Same)
CMPLT	Compare for Less Than	CMPLT (Compare for Less Than)
cpShReg	Update Context of PCU Registers and Flags	cpShReg (Update Context of PCU Registers and Flag)
DONE	DONE, Yield	DONE (DONE, Yield)
ILLEGAL	ILLEGAL Instruction	ILLEGAL (ILLEGAL Instruction)
JMP	Unconditional Jump Immediate	JMP (Unconditional Jump Immediate)
JMPR	Unconditional Jump	JMPR (Unconditional Jump)
JSR	Unconditional Jump to Subroutine Immediate	JSR (Unconditional Jump to Subroutine Immediate)
JSRR	Unconditional Jump to Subroutine	JSRR (Unconditional Jump to Subroutine)

Table continues on the next page...

Table 66-45. SDMA Instruction List (continued)

Instruction	Description	Page
LD	Load Register	LD (Load Register)
LDF	Load Register from Functional Unit	LDF (Load Register from Functional Unit)
LDI	Load Register with Immediate Value	LDI (Load Register with Immediate Value)
LDRPC	Load from RPC to Register	LDRPC (Load from RPC to Register)
LOOP	Hardware Loop	LOOP (Hardware Loop)
LSL1	Logical Shift Left by 1 Bit	LSL1 (Logical Shift Left by 1 Bit)
LSR1	Logical Shift Right by 1 Bit	LSR1 (Logical Shift Right by 1 Bit)
MOV	Logical Move	MOV (Logical Move)
NOTIFY	Notify to ARM platform	NOTIFY (Notify to ARM platform)
OR	Logical OR	OR (Logical OR)
ORI	Logical OR with Immediate Value	ORI (Logical OR with Immediate Value)
RET	Return from Subroutine	RET (Return from Subroutine)
REVB	Reverse Byte Order	REVB (Reverse Byte Order)
REVBLO	Reverse Low Order Bytes	Reverse Low Order Bytes(REVBLO)
ROR1	Rotate Right by 1 Bit	ROR1 (Rotate Right by 1 Bit)
RORB	Rotate Right by 1 Byte	RORB (Rotate Right by 1 Byte)
SOFTBKPT	Software Breakpoint	SOFTBKPT (Software Breakpoint)
ST	Store Register	ST (Store Register)
STF	Store Register in Functional Unit	STF (Store Register in Functional Unit)
SUB	Subtract	SUB (Subtract)
SUBI	Subtract with Immediate	SUBI (Subtract with Immediate)
TST	Test with Zero	TST (Test with Zero)
TSTI	Test Immediate	TSTI (Test Immediate)

Table continues on the next page...

Table 66-45. SDMA Instruction List (continued)

Instruction	Description	Page
XOR	Logical Exclusive OR	XOR (Logical Exclusive OR)
XORI	Exclusive OR with Immediate	XORI (Exclusive OR with Immediate)

66.17.2.1 ADD (Addition)

Operation:

```
GReg[r] ← GReg[s] + GReg[r]

T ← (GReg[r] == 0)
```

Assembler:

```
Syntax: add r,s

Example: add 0,3
```

ADD GReg[3] and GReg[0] and store the result in GReg[0]

CPU Flags: T

Cycles: 1

Description: Performs the ADDition of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*. The T flag is set if the result of the operation is 0. It is cleared if the result is not 0.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]
```

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

66.17.2.2 ADDI (Add with Immediate Value)

Operation:

GReg[r] ← GReg[r] + immediate

T ← (GReg[r] == 0)

Assembler:

Syntax: addi r,immediate

Example: add 6,112

ADD GReg[6] and decimal value 112 and store the result in GReg[6]

CPU Flags: T

Cycles: 1

Description: Adds a 0-extended immediate value to a general register; stores the result in the general register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

```
111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

 ...

11111110 - 254

11111111 - 255
```

66.17.2.3 AND (Logical AND)

Operation:

```
GReg[r] ← GReg[s] & GReg[r]
```

Assembler:

```
Syntax: and r,s

Example: and 1,2
```

AND GReg[1] and GReg[2] and store the result in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]
```

110 - GReg[6]

111 - GReg[7]

66.17.2.4 ANDI (Logical AND with Immediate Value)

Operation:

GReg[r] ← GReg[r] & immediate

Assembler:

Syntax: andi r,immediate

Example: andi 7,45

AND GReg[7] and decimal value 45 and store the result in GReg[7]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between a 0-extended immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiiii - immediate value:

00000000 - 0

```
00000001 - 1

...

11111110 - 254

11111111 - 255
```

66.17.2.5 ANDN (Logical AND NOT)

Operation:

```
GReg[r] ← ~GReg[s] & GReg[r]
```

Assembler:

```
Syntax:andn r,s

Example: andn 3,4
```

AND GReg[3] and NOT GReg[4] (bit inverted) and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the negation of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format:

Table 66-46. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	0	s	s	s

Instruction Fields:

rrr /sss - destination register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.6 ANDNI (Logical AND with Negated Immediate Value)

Operation:

```
GReg[r] ← GReg[r] & ~immediate
```

Assembler:

```
Syntax: andni r,immediate

Example: andni 0,2
```

AND GReg[0] and decimal value -3 (inverted 32-bit value 2) and store the result in GReg[0]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between the negation of a 0-extended 8-bit immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1
```

```
...

11111110 - 254

11111111 - 255
```

66.17.2.7 ASR1 (Arithmetic Shift Right by 1 Bit)

Operation:

```
GReg[r]:{b31,b30,...,b1,b0} ← GReg[r]:{b31,b31,b30,...,b1}
```

Assembler:

```
Syntax: asr1 r

Example: asr1 3
```

divide by 2 the signed value of GReg[3] and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any general register to the right and keep the same sign: The left bit (bit 31) is kept untouched.

Instruction Format:

Table 66-47. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.8 BCLRI1 (Bit Clear Immediate)

Operation:

```
GReg[r]:{b31,...,b(i+1),0,b(i-1),...,b0} ← GReg[r]:{b31,...,b(i+1),b(i),b(i-1),...,b0}
```

Assembler:

```
Syntax: bclri r,i

Example: bclri 1,12
```

clear bit 12 in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Clear the bit of register r specified by the 5-bit immediate field

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	1	i	i	i	i	i

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiii - immediate value:

```
00000 - 0

00001 - 1

...

11110 - 30

11111 - 31
```

66.17.2.9 BDF (Conditional Branch if Destination Fault)

Operation:

```
if (DF == 1) PC ← PC + 1 + displacement else PC ← PC + 1
```

Assembler:

```
Syntax:bdf label

Example: bdf LLL
```

Jump to LLL if DF is set, or go to the next instruction if DF is cleared; the displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: If flag DF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag DF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	1	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0

00000001 - 1

...

01111110 - 126

01111111 - 127

10000000 - (-128)

10000001 - (-127)

...

11111110 - (-2)

11111111 - (-1)
```

66.17.2.10 BF (Conditional Branch if False)

Operation:

```
if (T == 0)

PC ← PC + 1 + displacement

else

PC ← PC + 1
```

Assembler:

```
Syntax: bf label

Example: bf LLL
```

Jump to LLL if T is cleared, or go to the next instruction if T is set. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is cleared, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is set, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	0	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0

00000001 - 1

...

01111110 - 126

01111111 - 127

10000000 - (-128)

10000001 - (-127)

...

11111110 - (-2)

11111111 - (-1)
```

66.17.2.11 BSETI (Bit Set Immediate)

Operation:

```
GReg[r]:{b31,...,b(i+1),1,b(i-1),...,b0} ← GReg[r]:{b31,...,b(i+1),b(i),b(i-1),...,b0}
```

Assembler:

```
Syntax: bseti r,i

Example: bseti 6,5
```

Set bit 5 in GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Sets bit number i in the selected General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	0	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiii - bit number field:

```
00000 - 0

00001 - 1

...

11110 - 30

11111 - 31
```

66.17.2.12 BSF (Conditional Branch if Source Fault)

Operation:

```
if (SF == 1) PC ← PC + 1 + displacement else PC ← PC + 1
```

Assembler:

```
Syntax: bsf label

Example: bsf LLL
```

Jump to LLL if SF is set, or go to the next instruction if SF is cleared. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag SF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag SF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	0	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0

00000001 - 1

...

01111110 - 126

01111111 - 127

10000000 - (-128)

10000001 - (-127)

...

11111110 - (-2)

11111111 - (-1)
```

66.17.2.13 BT (Conditional Branch if True)

Operation

```
if (T == 1)

PC ← PC + 1 + displacement

else

PC ← PC + 1
```

Assembler

```
Syntax: bt label

bt LLL
```

Jump to LLL if T is set, or go to the next instruction if T is cleared. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	1	p	p	p	p	p	p	p	p

pppppppp - signed displacement field:

```
00000000 - 0

00000001 - 1

...

01111110- 126

01111111 - 127

10000000 - (-128)

10000001 - (-127)

...

11111110 -  (-2)

11111111 - (-1)
```

66.17.2.14 BTSTI (Bit Test immediate)

Operation:

```
T ← GReg[r]:b(i)
```

Assembler:

```
Syntax: btsti r,i

Example: btsti 2,29
```

Test bit 29 in GReg[2] and copy its value in flag T

CPU flags: T

Cycles: 1

Description: T is loaded with the value of bit number i from the selected general register.

Instruction Format:

Table 66-48. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	1	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiii - bit number field:

```
0000 - 0

0001 - 1

...

11110 - 30
```

```
11111 - 31
```

66.17.2.15 CLRF (Clear ARM platform flags)

Operation:

```
 if (ff%2 == 0)

SF ← 0

if (ff/2 == 0)

DF ← 0
```

Assembler:

```
Syntax: clrf ff

Example: clrf 2
```

Clear flag SF and keep flag DF unchanged

CPU Flags: SF, DF

Cycles: 1

Description: Clears a selection of the ARM platform fault flags: SF, DF, both SF and DF or none can be cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	f	f	0	0	0	0	0	1	1	1

Instruction Fields:

ff - flags field:

```
00 - clear SF and clear DF

01 - clear DF

10 - clear

SF 11 - no clear
```

66.17.2.16 CMPEQ (Compare for Equal)

Operation:

```
T ← (GReg[s] == GReg[r])
```

Assembler:

```
Syntax: cmpeq r,s

Example: cmpeq 7,5
```

Compare GReg[7] and GReg[5] and set flag T if they are equal

CPU flags: T

Cycles: 1

Description: Subtracts the destination general register *r* from the source general register *s*, and sets T if the result is 0, clears T if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.17 CMPEQI (Compare with Immediate for Equal)

Operation:

```
T ← (GReg[r] == immediate)
```

Assembler:

```
Syntax: cmpeqi r,immediate

Example: cmpeqi 2,13
```

Compare GReg[2] and decimal value 13 and set flag T if they are equal

CPU Flags: T

Cycles: 1

Description: Subtracts the 0-extended 8-bit immediate value from the general register, and sets T if the result is 0, clears T if the result is not 0. The immediate value is the low-order byte of the instruction.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - destination register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

66.17.2.18 CMPHS (Compare for Higher or Same)

Operation:

```
T ← (GReg[r] ≥ GReg[s])
```

Assembler:

```
Syntax: cmphs r,s

Example: cmphs 0,1
```

Compare GReg[0] and GReg[1] and set flag T if GReg[0] is higher than or equal to GReg[1]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is higher than or equal to the source general register *s*, clears T otherwise. The comparison is unsigned.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.19 CMPLT (Compare for Less Than)

Operation:

```
T ← (GReg[r] < GReg[s])
```

Assembler:

```
Syntax: cmplt r,s

Example: cmplt 7,4
```

Compare GReg[7] and GReg[4] and set flag T if GReg[7] is lower than GReg[4]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is lower than the source general register *s*, clears T otherwise. The comparison is signed.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	0	s	s	s

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.20 cpShReg (Update Context of PCU Registers and Flag)

Assembler:

```
Syntax: cpShReg
```

CPU Flags: none

Cycles: 1

Description: SF, RPC, T, PC,LM, EPC, DF, and SPC registers are updated according to the value of their corresponding bits in the context memory. This instruction must only be used in debug mode via the OnCE. It reverses the done *5* operation.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	0	1	1	1	0	0	0	1	0

66.17.2.21 DONE (DONE, Yield)

Operation:

```
if (jjj&6 == 2) HE[CCR] ← 0

if (jjj == 3) HI[CCR] ← 1

if (jjj == 4) EP[CCR] ← 0

if ((jjj == 0) && (NCP > CCP)) CCR ← NCR

else if ((jjj == 1) && (NCP >= CCP))

CCR ← NCR

else

CCR ← NCR
```

(CCR stands for Current Channel Register; NCR stands for Next Channel Register)

Assembler:

```
Syntax: done jjj

Example: done 3
```

Clear HE bit for the current channel, send an interrupt to the ARM platform for the current channel and reschedule.

CPU Flags: Unaffected

Cycles: Variable if a context switch is done, 1 otherwise

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required. Sends an interrupt to the corresponding ARM platform by setting the appropriate flag, if required (HI for the corresponding channel number). Reschedules according to the mode and the NCP (Next Channel Priority) and CCP (Current Channel Priority) values. According to the scheduling decision, the NCR (Next Channel Register) is copied to the CCR (Current Channel Register) and channel contexts are switched. If several channels with the same highest priority are pending, they are ordered by their number from 31 down to 0. The higher number is selected (for example, channel 26 is selected if channels 3, 12, 14, and 26 with the same highest priority are pending). If no flag is modified, the reschedule can allow the replacement of the current channel by another channel with a priority strictly greater than the current channel priority (yield). Or, it can allow the replacement of the current channel by another channel with a priority greater than or equal to the current channel priority (yieldge). In the latter case, the selected channel will always be the first one with the same priority, starting from channel number 31 down to channel 0 (the current channel does not belong to the set of selectable channels).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	0

jjj - Channel Flags field:

000 - No channel flags affected: Reschedule only if the next channel priority is greater than current channel priority (yield)

001 - No channel flags affected: Reschedule only if the next channel priority is greater than or equal to the current channel priority (yieldge)

010 - Clear HE for the current channel and reschedule 011 - Clear HE, set HI for the current channel and reschedule 100 - Clear EP for the current channel and reschedule

101 - Reserved for debug to copy relevant registers into context memory

110 - RESERVED

111 - RESERVED

For the scheduling rules, refer to Scheduler Functional Description. Every possible done instruction is further described as follows:

- done 0/yield is executed by a channel script when it accepts preemption by a higher priority channel;
- done 1/yieldge is executed by a channel script when it accepts preemption by a higher priority channel and it also accepts a roll-up with other channels that have the same priority;
- done 2 is executed by a channel script that was triggered by a ARM platform start via the Channel Start (SDMAARM_HSTART) register, when its task is completed and it requires termination;
- done 3 is executed by a channel script that was triggered by a ARM platform start via the Channel Start (SDMAARM_HSTART) register, when its task is completed, it requires termination and it needs to trigger an interrupt to the ARM platform upon closure;
- done 4 is executed by a channel script that was triggered by a DMA request, when its task is completed and it requires termination;
- done 5 is used in debug mode only; it copies the PCU registers and flags to the context memory of the current channel;

66.17.2.22 ILLEGAL (ILLEGAL Instruction)

Operation:

```
PC ← 0001
```

Assembler:

```
Syntax: illegal
```

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the Illegal instruction routine located at address 0001. All unauthorized instructions result in an Illegal instruction behavior; however, the ILLEGAL instruction must be used to guarantee software compatibility with future versions of the SDMA.

Instruction Format

Table 66-49. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1

66.17.2.23 JMP (Unconditional Jump Immediate)

Operation:

```
PC ← absolute_address
```

Assembler:

```
Syntax: jmp label

Example: jmp LLL
```

The assembler translates the label to the exact address

CPU Flags:Unaffected

Cycles: 2

Description: Jumps to the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	a	a	a	a	a	a	a	a	a	a	a	a	a	a

aaaaaaaaaaaaa - address field:

```
00000000000000 - 0

00000000000001 - 1
```

```
...

11111111111110 - 16382

11111111111111 - 16383
```

66.17.2.24 JMPR (Unconditional Jump)

Operation:

```
PC ← GReg[r]
```

Assembler:

```
Syntax: jmpr r

Example: jmpr 0
```

Jump to address stored in GReg[0]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the absolute address contained in a General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.25 JSR (Unconditional Jump to Subroutine Immediate)

Operation:

```
RPC ← PC + 1

PC ← absolute_address
```

Assembler:

```
Syntax: jsr r

Example:jsr LLL
```

Jumps to subroutine starting at LLL; the assembler translates the label to exact address

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine located at the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	a	a	a	a	a	a	a	a	a	a	a	a	a	a

aaaaaaaaaaaaaa - address field:

```
00000000000000 - 0

00000000000001 - 1

...

11111111111110 - 16382

11111111111111 - 16383
```

66.17.2.26 JSRR (Unconditional Jump to Subroutine)

Operation:

```
RPC ← PC + 1

PC ← GReg[r]
```

Assembler:

```
Syntax: jsrr r

Example:jsrr 5
```

Jumps to subroutine located at address stored in GReg[5]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine at address contained in a General Register

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	1

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.27 LD (Load Register)

Operation:

```
GReg[r] ← [GReg[b] + displacement]

if (transfer_error)

SF ← 1

else

SF ← 0
```

Assembler:

```
Syntax: ld r,(b,displacement)

Example: ld 1,(2,23)
```

Loads data into GReg[1]; the data is located at address obtained by adding decimal value 23 to GReg[2]

CPU Flags: SF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to fetch on the DM bus. The data received from the bus is stored in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	0	r	r	r	d	d	d	d	d	b	b	b

rrr / bbb - register field:

```
000 - GReg[0]

001 - GReg[1]

...

111 - GReg[7]
```

ddddd - displacement value:

```
00000 - 0

00001 - 1

...

11111 - 31
```

66.17.2.28 LDF (Load Register from Functional Unit)

Operation:

```
GReg[r] ← [fu_address]

if (transfer_error)

SF ← 1

else

SF ←0
```

fu_address is an 8-bit field and depends on addressed functional unit

Assembler:

```
Syntax: ldf r,fu_address

Example: ldf 0,13
```

Loads data coming from the Burst DMA register MD into GReg[0]; it is a 32-bit access with no prefetch

CPU Flags: SF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and stores the data received from the bus in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	0	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the LDF instruction usage with each functional unit:

- Burst DMA Read (ldf) for Burst DMA
- Peripheral DMA Read (ldf)-Read Mode for Peripheral DMA
- Read Instruction (ldf) for CRC unit

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

ffffffff - functional unit source register and action (unspecified values are reserved):

```
00000000 - MSA

00000100 - MDA

00001001 - MD byte

00001010 - MD halfword

00001011 - MD word
```

```
00001100 - MS

00101001 - MD byte - prefetch

00101010 - MD halfword - prefetch

00101011 - MD word - prefetch

01000000 - DSA

10000000 - CA

10000100 - CS (CRC checksum)

11000000 - PSA

11001000 - PD

11010000 - PDA

11011000 - PD in copy mode (rrr contents are lost)

11101000 - PD - prefetch next data

11111111 - PS
```

66.17.2.29 LDI (Load Register with Immediate Value)

Operation:

```
GReg[r] ← immediate
```

Assembler:

```
Syntax: ldi r,immediate

Example: ldi 6,1
```

loads decimal value 1 into GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Stores a 0-extended immediate value in a General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

66.17.2.30 LDRPC (Load from RPC to Register)

Operation:

```
GReg[r] ← RPC
```

Assembler:

```
Syntax: ldrpc r

Example: ldrpc 3
```

copies RPC to GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Stores the contents of the RPC in a General Register. That instruction may be used to have more than one level of subroutines.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	1	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.31 LOOP (Hardware Loop)

Operation:

```
if (ff%2 == 0)
   SF ← 0
if (ff/2 == 0)
  DF ← 0
if ((GReg[0] == 0) || (SF == 1) || (DF == 1))
   PC ← PC + loop_size + 1
else
   {
      SPC ← PC + 1
      EPC ← PC + loop_size + 1
      LM ← 1
      PC ← PC + 1
   }
```

during every instruction execution in the loop:

```
if ((SF == 1) || (DF == 1))
 {
    LM ← 0
    PC ← EPC
  }
else if ((PC + 1) == EPC)
```

```
 {
    GReg[0] ← GReg[0] - 1
    if (GReg[0] == 0)
      {
         LM ← 0
         PC ← EPC
       }
     else
         PC ← SPC
   }
else
  PC ← nextPC(instruction)
```

after the execution of the last instruction of the loop body:

```
if (GReg[0] == 0)
   T ← 1
else
   T ← 0
```

Assembler:

```
Syntax: loop n{,ff}
Example: loop 3,1
```

Executes GReg[0] times the instructions comprised between PC+1 and PC+3 (included); ff=1 clears the DF flag before starting the loop. When omitted, the ff field is set to 0 (clearing both SF and DF).

CPU Flags: LM[1:0], T

Cycles: 2 when the loop count (GReg[0]) is 0 or SF or DF is set at loop start, 1+1 when the loop starts but exits abnormally (SF or DF set inside the loop which adds 1 cycle to the offending load or store to jump to EPC), 1 when the loop is executed normally

Description: The loop instruction executes a sequence of instructions several times. The number of times is given by the contents of GReg[0], the loop counter. SDMA will jump to the first instruction after the end of the loop if the value in GReg[0] is 0. Otherwise the SDMA enters loop mode. It sets the most significant bit of the LM flag that will only be reset once the last instruction of the last loop is executed. The instructions in the loop are executed GReg[0] times. The management of fault flags (SF and DF) is as follows. When entering the hardware loop, SF and DF can be cleared according to the ff field of the

instruction. After that operation, if any flag is still set the loop will not be executed. The SDMA will jump to the first instruction after the end of the loop without entering loop mode. During the execution of the loop, if any fault flag is set by a LD, LDF, ST, or STF instruction, the SDMA will immediately exit loop mode and jump to the first instruction after the end of the loop. In that case, GReg0 is not decremented for that last piece of the loop body execution (even if the SF or DF flag is set at the last instruction of the loop body). The T flag reflects the state of GReg[0] after the end of the loop, which is an indicator of the complete execution of the loop. If the loop exited because of an error (SF or DF set), GReg[0] will not be 0 at the end of the loop, hence T will be cleared. If the loop executes without fault, GReg[0] will be 0 at the end of the loop, hence T will be set. The boundary case when a source or destination fault occurs at the last instruction of the last loop is considered as an anticipated exit of the loop, which causes the T flag to be cleared. If the last instruction executed before leaving the hardware loop also tries to modify the T flag, the flag is updated according to the value of GReg[0], NOT according to the result of the last executed instruction.

Limitations:

1. 1. Jump instructions (JMP, JMPR, JSR, JSRR, BF, BT, BSF, BDF) are not allowed inside the hardware loop.
2. 2. GReg[0] cannot be written to inside the hardware loop (it can be read).
3. 3. The empty loop (0 instruction in the body) is forbidden.
4. 4. If GReg[0] == 0 at the start of the loop, which causes a jump to EPC, the T flag is not updated.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	0	f	f	n	n	n	n	n	n	n	n

Instruction Fields:

```
ff - flags field:

00 - clear SF and clear DF

01 - clear DF

10 - clear SF

11 - no clear
```

nnnnnnnn - loop size

```
00000000 - empty loop: forbidden value

00000001 - 1 instruction in the loop

00000010 - 2 instructions in the loop
```

```
...

11111111 - 255 instructions in the loop
```

66.17.2.32 LSL1 (Logical Shift Left by 1 Bit)

Operation:

```
GReg[r]:{b30,...,b1,b0,0} ← GReg[r]:{b31,b30,...,b1,b0}
```

Assembler:

```
Syntax: lsl1 r

Example: lsl1 2
```

multiplies by 2 the value in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the left. The right bit (bit 0) is set to 0. No overflow is detected by the hardware.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	1

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.33 LSR1 (Logical Shift Right by 1 Bit)

Operation:

GReg[r]:{0,b31,b30,...,b1} ← GReg[r]:{b31,b30,...,b1,b0}

Assembler:

Syntax: lsr1 r

Example: lsr1 4

divides by 2 the unsigned value contained in GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the right. The left bit (bit 31) is set to 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	1

Instruction Fields:

rrr - destination register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

66.17.2.34 MOV (Logical Move)

Operation:

GReg[r] ← GReg[s]

Assembler:

Syntax: mov r,s

Example: mov 4,0

copies GReg[0] to GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Move the contents of the source General Register s to the destination General Register r.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.35 NOTIFY (Notify to ARM platform)

Operation:

```
 if (jjj & 4 == 0)
 {
   if (jjj&2 == 2)
      HE[CCR] ← 0
   if (jjj&1== 1)
       HI[CCR] ← 1
  }
else if (jjj == 4)
   EP[CCR] ← 0
else
```

(CCR stands for Current Channel Register)

Assembler:

```
Syntax: notify jjj

Example: notify 3
```

clears the HE bit for the current channel and sends an interrupt to the Host for the current channel

CPU Flags: Unaffected

Cycles: 1

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required, sends an interrupt to the corresponding ARM platform by setting the appropriate flag if required (HI for the corresponding channel number).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	1

jjj - Channel Flags field:

```
000 - unused

001 - set HI for the current channel

010 - clear HE for the current channel

011 - clear HE, set HI for the current channel

100 - clear EP for the current channel

101 - RESERVED

110 - RESERVED

111 - RESERVED
```

66.17.2.36 OR (Logical OR)

Operation:

```
GReg[r] ← GReg[s] | GReg[r]
```

Assembler:

```
Syntax: or r,s

Example: or 3,6
```

ORs GReg[3] and GReg[6] and stores the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the OR of the source General Register s and the destination General Register r, and stores the result in the destination General Register r.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.37 ORI (Logical OR with Immediate Value)

Operation:

```
GReg[r] ← GReg[r] | immediate
```

Assembler:

```
Syntax: ori r,immediate

Example: ori 1,56
```

ORs GReg[1] and the decimal value 56 and stores the result in GReg[1]

CPU Flags: unaffected

Cycles: 1

Description: Performs an OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

66.17.2.38 RET (Return from Subroutine)

Operation:

```
PC ← RPC
```

Assembler:

```
Syntax: ret
```

CPU Flags: Unaffected

Cycles: 2

Description: Return from subroutine.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

66.17.2.39 REVB (Reverse Byte Order)

Operation:

```
GReg[r]:{B3,B2,B1,B0} ← GReg[r]:{B0,B1,B2,B3}
```

Assembler:

```
Syntax: revb r

Example:  revb 5
```

reverses bytes order in GReg[5]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse the byte order of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.40 Reverse Low Order Bytes(REVBLO)

Operation:

```
GReg[r]:{B3,B2,B0,B1} ← GReg[r]:{B3,B2,B1,B0}
```

Assembler:

```
Syntax: revblo r

Example: revblo 0
```

reverses low order bytes in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse both low order bytes of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	1

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.41 ROR1 (Rotate Right by 1 Bit)

Operation:

```
GReg[r]:{b0,b31,b30,...,b1} ← GReg[r]:{b31,b30,...,b1,b0}
```

Assembler:

```
Syntax: ror1 r

Example: ror1 3
```

rotates bits to the right in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Rotate the bits of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.42 RORB (Rotate Right by 1 Byte)

Operation:

```
GReg[r]:{B0,B3,B2,B1} ← GReg[r]:{B3,B2,B1,B0}
```

Assembler:

```
Syntax: rorb r

Example: rorb 2
```

rotates bytes to the right in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Rotate the bytes of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	1	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.43 SOFTBKPT (Software Breakpoint)

Operation:

Stops the current script and enters debug mode

Assembler:

```
softbkpt
```

CPU Flags: Unaffected

Description: When the core executes this instruction, it has the same effect as receiving a debug request from the OnCE or via the external debug request input: the script execution halts, the PCU enters its debug state and waits for the OnCE commands that are described in OnCE and Real-Time Debug.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

66.17.2.44 ST (Store Register)

Operation:

```
[GReg[b] + displacement] ← GReg[r]

if (transfer_error)

 DF ← 1

 else

DF ← 0
```

Assembler:

```
Syntax: st r,(b,displacement)

Example: st 7,(0,9)
```

stores the value from GReg[7] into memory at address obtained by adding decimal value 9 to GReg[0]

CPU Flags: DF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to store on the DM bus. The data sent on the bus comes from the source General Register r. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	r	r	r	d	d	d	d	d	b	b	b

Instruction Fields:

rrr / bbb - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]
```

```
111 - GReg[7]
```

ddddd - displacement value:

```
00000 - 0

00001 - 1

...

11111 - 31
```

66.17.2.45 STF (Store Register in Functional Unit)

Operation:

```
[fu_address] ← GReg[r] 0

if (transfer_error) 0

DF ← 1 0

else 0

DF ← 0
```

fu_address is an 8-bit field

Assembler:

```
Syntax: stf r,fu_address

Example: stf 3,0x2B
```

stores the 32-bit contents of GReg[3] to the Burst DMA register MD; waits until the flush to external memory is completed

CPU Flags: DF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and sends the contents of the source General Register r on the bus. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Table 66-50. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	1	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the STF instruction usage with each functional unit:

- Burst DMA Write (stf) for Burst DMA
- Peripheral DMA Write (stf)-Write Mode for Peripheral DMA
- Write Instruction (stf) for CRC

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

ffffffff - functional unit destination register and action (unspecified values are reserved):

00000000 - MSA in incremented mode

00000100 - MDA in incremented mode

00001001 - MD byte

00001010 - MD halfword

00001011 - MD word

00001100 - clear MS error flag

00001111 - MS

00010000 - MSA in frozen mode

00010100 - MDA in frozen mode

00011000 - MD in copy mode - number of words in rrr

00100000 - MSA in incremented mode - start prefetch

00101000 - MD no data - flush

00101001 - MD byte - flush

00101010 - MD halfword - flush

00101011 - MD word - flush

00110000 - MSA in frozen mode - start prefetch

10000000 - CA

10000100 - init CRC accumulator

10010100 - CS byte - compute CRC

10010101 - CS byte - compute CRC

10010110 - CS halfword - compute CRC

10010111 - CS word - compute CRC

11000001 - PSA in frozen mode - 8-bit data width

11000010 - PSA in frozen mode - 16-bit data width

11000011 - PSA in frozen mode - 32-bit data width

11000101 - PSA in incremented mode - 8-bit data width

11000110 - PSA in incremented mode - 16-bit data width

11000111 - PSA in incremented mode - 32-bit data width

11001000 - PD

11001001 - PSA in decremented mode - 8-bit data width

11001010 - PSA in decremented mode - 16-bit data width

11001011 - PSA in decremented mode - 32-bit data width

11001100 - clear PS error flag

11001101 - PSA data width becomes 8-bit

11001110 - PSA data width becomes 16-bit

11001111 - PSA data width becomes 32-bit

11010001 - PDA in frozen mode - 8-bit data width

11010010 - PDA in frozen mode - 16-bit data width

11010011 - PDA in frozen mode - 32-bit data width

11010101 - PDA in incremented mode - 8-bit data width

11010110 - PDA in incremented mode - 16-bit data width

11010111 - PDA in incremented mode - 32-bit data width

11011001 - PDA in decremented mode - 8-bit data width

11011010 - PDA in decremented mode - 16-bit data width

11011011 - PDA in decremented mode - 32-bit data width

11011101 - PDA data width becomes 8-bit

11011110 - PDA data width becomes 16-bit

11011111 - PDA data width becomes 32-bit

11100001 - PSA in frozen mode - 8-bit data width - prefetch data

11100010 - PSA in frozen mode - 16-bit data width - prefetch data

11100011 - PSA in frozen mode - 32-bit data width - prefetch data

11100101 - PSA in incremented mode - 8-bit data width - prefetch data

11100110 - PSA in incremented mode - 16-bit data width - prefetch data

11100111 - PSA in incremented mode - 32-bit data width - prefetch data

11101001 - PSA in decremented mode - 8-bit data width - prefetch data

11101010 - PSA in decremented mode - 16-bit data width - prefetch data

11101011 - PSA in decremented mode - 32-bit data width - prefetch data

11101101 - PSA data width becomes 8-bit - prefetch data

11101110 - PSA data width becomes 16-bit - prefetch data

11101111 - PSA data width becomes 32-bit - prefetch data

11111111- PS

66.17.2.46 SUB (Subtract)

Operation:

```
GReg[r] ← GReg[r] - GReg[s]

T ← (GReg[r] == 0)
```

Assembler:

```
Syntax: sub r,s

Example: sub 4,7
```

SUBtracts GReg[7] from GReg[4] and stores the result in GReg[4]

CPU Flags: T

Cycles: 1

Description: Subtracts the source General Register s from the destination General Register r, and stores the result in the destination General Register r. The T flag is set if the result of the operation is 0; it is cleared if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	0	s	s	s

Instruction Fields:

rrr / sss - register fields:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.47 SUBI (Subtract with Immediate)

Operation:

```
GReg[r] ← GReg[r] - immediate

T ← (GReg[r] == 0)
```

Assembler:

```
Syntax: sub r,immediate

Example: sub 1,255
```

SUBtracts decimal value 255 from GReg[1] and stores the result in GReg[1]

CPU Flags: T

Cycles: 1

Description: Subtracts a 0-extended 8-bit immediate value from a General Register; stores the result in the General Register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

66.17.2.48 TST (Test with Zero)

Operation:

```
T ← ((GReg[s] & GReg[r]) != 0)
```

Assembler:

```
Syntax: tst r,s

Example: tst 2,3
```

ANDs GReg[2] and GReg[3] and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of the source General Register s and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	0	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.49 TSTI (Test Immediate)

Operation:

```
T ← ((GReg[r] & immediate) != 0)
```

Assembler:

```
Syntax: tsti r,immediate

Example: tsti 5,13
```

ANDs GReg[5] and decimal value 13 and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of a 0-extended 8-bit immediate value and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - destination register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

66.17.2.50 XOR (Logical Exclusive OR)

Operation:

```
GReg[r] ← GReg[s] ^ GReg[r]
```

Assembler:

```
Syntax: xor r,s

Example: xor 0,3
```

XORs GReg[0] and GReg[3] and stores the result in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the eXclusive OR of the source General Register s and the destination General Register r, and stores the result in the destination General Register r.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	0	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

66.17.2.51 XORI (Exclusive OR with Immediate)

Operation:

```
GReg[r] ← GReg[r] ^ immediate
```

Assembler:

```
Syntax: xori r,immediate

Example: xor 7,5
```

XORs GReg[5] and decimal value 5 and stores the result in GReg[7]

CPU Flags: Unaffected

Cycles: 1

Description: Performs an eXclusive OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

66.17.2.52 YIELD, YIELDGE (DONE, Yield)

By default, unsupported assembler syntax. Can be aliased to the corresponding done instructions (yield = done 0; yieldge = done 1). Refer to the done instruction description DONE (DONE, Yield) .

66.18 Software Restrictions

66.18.1 Unsupported Burst DMA Access Sequence

The SDMA does not support triggering a pre-fetch followed by a flush of the Burst DMA without reading or writing any data. If the flush occurs while the background pre-fetch DMA operation is still in progress, it could result in un-defined behavior.

An example of the sequence which could result in undefined results is shown in the following example:

Instruction sequence not supported

```
          stf r1, MSA|PF              ; Update source address, triggers data pre-fetch in the
background
          mov R0,R0                ; Execute multiple assembly instructions, none of which
read
          mov R0,R0                ; or write data to/from MD
          stf MD|SZ0|FL               ; Flush FIFO without writing data. If the pre-fetch is
still in
                                  ; progress when this instruction is executed, there could be
```

; undefined operation.

A work-around to avoid any undesirable results is to first read MD to ensure the pre-fetch is complete before the flush is attempted.

Work-Around to previous example

```
          stf r1, MSA|PF              ; Update source address, triggers data pre-fetch
          mov R0,R0                ; Execute multiple assembly instructions, none of which
read
          mov R0,R0                ; or write data to/from MD
          ldf r2, MD                  ; dummy read of MD to ensure pre-fetch is complete before

66.19 Application Notes

66.19.1 Data Structures for Boot Code and Channel Scripts

SDMA boot code downloads the different channel contexts and the scripts that will be executed on SDMA channels during the application. The boot code is run after reset when channel 0 is started by the ARM platform.

The boot code is also known as channel 0 script.

The boot code is based on the Channel Control Block (CCB) and Buffer Descriptor (BD) mechanisms that are data structures located into the ARM platform memory space. With these data structures, it is possible to instruct SDMA to download scripts and contexts but also to dump a context or a script to a destination data buffer. Channel scripts also use the CCB and BD data structures to pass instructions and/or pointers to data to be copied.

The format, processing, and field definition of the CCB and BD are defined and performed entirely by the software script rather than the SDMA hardware. An overview of the format and structure is provided here, but for complete details refer to the SDMA software documentation (see SDMA Scripts).

The CCB and BD data structures are accessed by SDMA using DMA and processed by the SDMA scripts. The ROM contains common sub-routines for processing these data structures which may be called by the bootload and channel scripts.

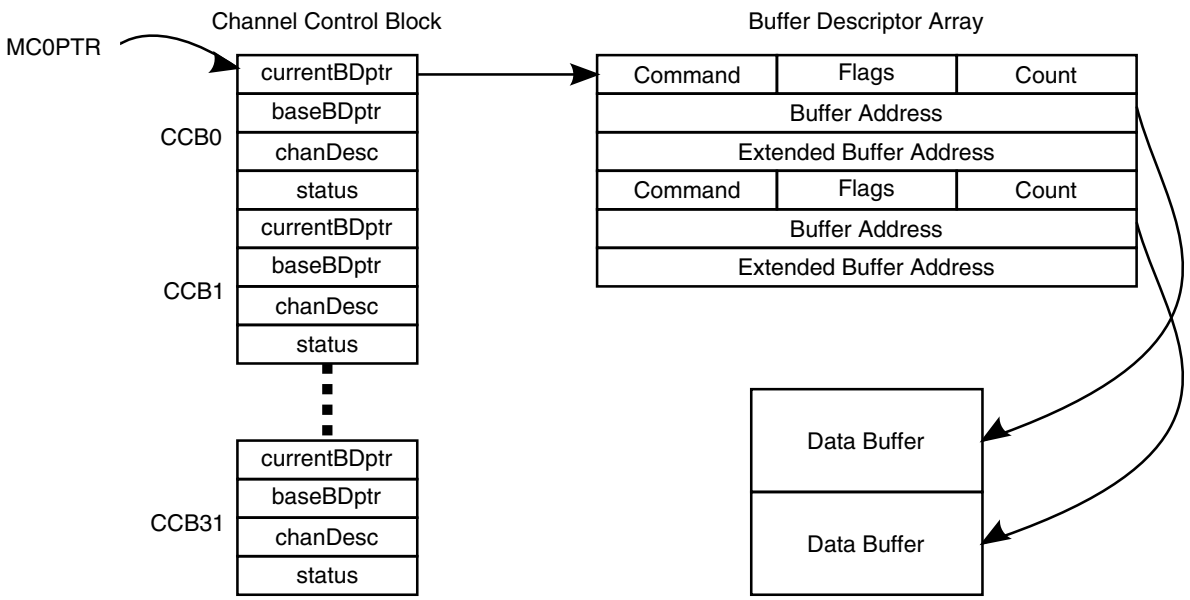

Figure 66-17. Data Structures Layout

The previous figure shows an example how these data structures are linked to pass command and pointers to data buffers. The SDMA's MC0PTR register holds the base address of the Channel 0 Control Block (CCB0). The Channel 0 control block holds a pointer to the array of buffer descriptors. The buffer descriptors are used to tell the channel 0 (boot channel) what to do as described Buffer Descriptor Format.

66.19.1.1 Buffer Descriptor Format

Buffer descriptors are three longs (32-bit words) in size as, shown in the following figure. A buffer descriptor describes the properties of the data buffer it points to. The buffer descriptors can be used for linear or circular data buffers in the ARM platform processor memory. The CCB contains a pointer to the base BD as well as the current BD.

Table 66-51. Buffer Descriptor

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 66-52. Buffer Descriptor Field Descriptions

Field	Description
31-24 Command	Command. The command field is used to differentiate operations performed within a script when the script accesses this particular buffer descriptor. The use of this field can be defined by the script. The command values defined for the bootload script are defined in Buffer Descriptor Commands for Bootload scripts. Refer to the individual script definition in script library documents in SDMA Scripts for command field definitions for other scripts.
23	Reserved
22	Reserved
21 L	Last Buffer Descriptor: This bit is set in SDMA IPC scripts to indicate to the receiving Core that the transfer has ended. Whenever the source finishes transferring the count it wanted to transfer, it sets LAST_BIT in the destination BD, to let the destination know that transfer is over.This bit also tells the destination software that when it processes the destination BDs, they need not process any BD after the BD with the LAST_BIT set.For example, when the DSP prepares a single buffer descriptor with count equals to 25 and ARM platform prepares a single buffer descriptor with count equals 100. When 25 bytes have been transferred from DSP to ARM platform, the DSP buffer descriptor is normally closed while the ARM platform buffer descriptor will have the L bit set and the byte count updated to 25.
20 R	erroR. Indicates an error occurred on the channel's buffer descriptor requested command. Some scripts may overwrite the command field with an error code indicating the source of the error. 0 No Error 1 Error
19 I	Interrupt. When SDMA has finished to process data transfer attached to this buffer descriptor, send an interrupt to the ARM platform. 0 No Interrupt 1 Interrupt the processor when BD is complete
18 C	CONTinuous. This buffer is allowed to receive multiple transmit buffers or is allowed to transmit to multiple receive buffers.The Continuos bit is decoded at the end of the processing of a BD to determine if the SDMA script must open a new BD to potentially continue the data transfer. 0 No further buffer descriptors 1 SDMA should move to the next Buffer descriptor after this one

Table continues on the next page...

Table 66-52. Buffer Descriptor Field Descriptions (continued)

Field	Description
17 W	Wrap. Indicates if this buffer descriptor is the last one for the channel control block. When encountering this bit set, the SDMA scripts updates the CurrentBD pointer to point to the first Buffer Descriptor of the array. This bit is set if the ARM platform wants to organize the array of BD in a circular way (like a ring). When all BD have been processed and if Wrap bit and CONtinuous bit are set in the last BD, the SDMA script will wrap around and it will try to re-open the first BD. 0 No Error 1 Wrap to first buffer descriptor after this one is processed.
16 D	D - "Done": bit 16: indicates the "ownership" of the buffer descriptor. When D=0 the host owns the buffer descriptor; when D=1 SDMA owns the buffer descriptor. In the case of the channel 0, D=1 indicates the SDMA has not yet processed this buffer, D=0 indicates the SDMA has processed this buffer. 0 ARM platform owns the buffer. 1 SDMA owns the buffer
15-0 Count	Count. the count field (bit 15-0) indicates the size of the data to be transmitted, the size of the data buffer pointed to by the buffer descriptor. The SDMA memory structure is different for program memory (16-bits shorts/ half-words) and data memory (32-bits long). For channel 0 buffer descriptors, Count is expressed in 16-bit half-words when PM is addressed and in 32-bit words when DM is addressed. Count is typically expressed in bytes for other channel scripts, but the unit is dependant on the script.
31-0	Buffer address. Address pointer to the data buffer.
31-0	Extended buffer address. Additional pointer or other information required by some scripts.

The buffer descriptors form an array of programmable size. If the last buffer descriptor is marked by the Wrap flag-bit W=1, the array of buffer descriptor is treated as a ring with some logically continuous portion owned by the ARM platform with D=0, and the remainder owned by the SDMA with D=1. The count field of the buffer descriptor indicates how much data has been transmitted.

If ARM platform has prepared 3 buffers to be filled by the SDMA script, it has also prepared 3 BD, one for each buffer. The *Cont* and *Wrap* bits are used to organize the buffers in a circular way. For example, *CONT*inous bit is set to 1 in the 2 first BDs and *Wrap* is set in the 3rd BD. The SDMA script opens and processes BD#1. Since *CONT*inous bit is set for this BD, the SDMA will open the second BD and it will process it. Each time a BD is processed, its *Done* bit is reset by the SDMA. After the 3rd BD, if *CONT*inous is not set but if *Wrap* is set, the SDMA script stops here and the next time the channel will be triggered, the script will open the BD pointed by the currentBDptr pointer of the CCB and it will correspond to the first buffer descriptor.

If the *CONT*inous bit and *Wrap* bits are both set in the 3rd BD, the script will close it and it will try to open the first BD. An error may occur at this point if the BD#1 has already been processed and its *Done* bit is 0. The SDMA script cannot process a BD with a *Done* bit to 0. It means the BD is not ready to be processed. To avoid this situation, the *CONT*inous bit should not be set for the last BD if *Wrap* is set, and the Interrupt flag must set for the last BD. It will warn the owner of the BD that all the BDs have been processed and it has to re-set to 1 the *Done* bit of all the BD's if it desi

fill them again. Basically, if the ARM platform expects the SDMA to fill up the buffers in a circular fashion, then it's the responsibility of the ARM platform to set the *Done* bit of a buffer descriptor at an appropriate time.

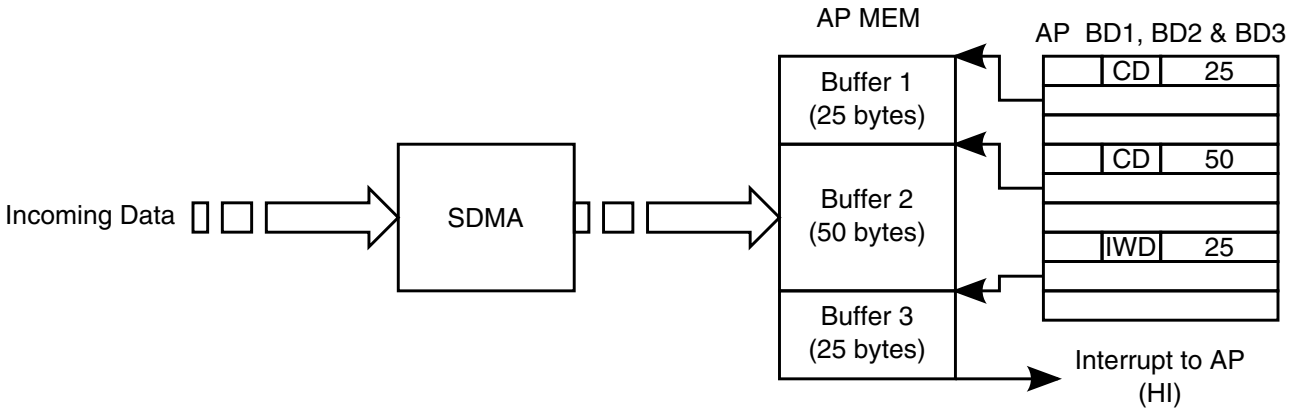

Figure 66-18. Buffer Descriptor Flow

The previous figure shows an example buffer descriptor flow. When the incoming data is stored and fills the first buffer of 25 bytes, the SDMA script opens the second BD because the CONTinuous bit was set. Then next incoming data is put in the second buffer. After receiving 50 bytes, the second buffer descriptor is also closed. The Done bit is reset and the third BD is opened. After receiving another 25 bytes, the third buffer is full and an interrupt is sent to the ARM platform because the Interrupt flag is set in the 3rd BD. The CONTinuous flag is not present the transfer is over. The next time the script will be triggered, the BD to be opened will be the first buffer descriptor since the Wrap flag was set in the 3rd BD. It is the ARM platform responsibility to set the Done bit of all the BD if it wants to use the same buffers.

66.19.1.2 Buffer Descriptor Commands for Bootload scripts

The command field of the buffer descriptor is defined separately for each script.

The following table lists the buffer descriptor commands defined for the channel 0 bootload script.

Table 66-53. Channel Zero Buffer Descriptor Commands

Command Field (binary)	Command	Description	Buffer Address	Extended Buffer Address
0000_0001 (0x01)	C0_SET_DM	Load SDMA data memory (RAM) from ARM platform memory buffer	ARM platform memory source address	SDMA memory destination address
0000_0010 (0x02)	C0_GET_DM	Copy SDMA data memory (RAM) to ARM platform memory buffer	ARM platform memory destination address	SDMA memory source address
0000_0100 (0x04)	C0_SET_PM	Load SDMA program memory (RAM) from ARM platform memory buffer	ARM platform memory source address	SDMA memory destination address
0000_0110 (0x06)	C0_GET_PM	Copy SDMA program memory (RAM) to ARM platform memory buffer	ARM platform memory destination address	SDMA memory source address
cccc_c111 (0x07 | CHN)	C0_SETCTX	Load Context for channel cccc into SDMA RAM from ARM platform memory buffer	ARM Platform memory source address	-
cccc_c011 (0x03 | CHN)	C0_GETCTXT	Copy Context for channel ccccc from SDMA RAM to ARM platform memory buffer	ARM platform memory destination address	-

The Channel 0 bootload commands are summarized as follows:

- C0_SET_[PM-DM]: load the buffer descriptor data in the SDMA local memory at the address pointed to by the "extended buffer address" field. The SDMA RAM can be seen as a Program Memory (PM, 16-bit address) or Data Memory (DM 32-bit address). When C0_SET_PM is used, the count field is expressed in "shorts" (16-bit half words), this command can be used to download scripts. When C0_SET_DM is used, the count field is expressed in "long" (32-bit words), this command can be used to download channel contexts to the context channel area in RAM.
- C0_GET_[PM-DM]: write to the buffer descriptor's data buffer the content of the SDMA local memory from the address pointed to by the "extended buffer address" field for the length defined by the count in the buffer descriptor. C0_GET_PM is used to dump some part of the Program Memory (may be used to dump context of a channel), therefore count is expressed in "shorts"; while C0_GET_DM is used to dump to the buffer descriptor's data buffer, so the count field is in "longs."
- C0_SETCTX: load a context into the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using the channel number the script computes the offset of the context data pointer for the channel relative to the context page base to use as the destination

address in SDMA memory. Then the C0_SET_DM command explained above is invoked to load SDMA RAM from memory. The counter indicates the size in words of the context structure.

- Command value: (in binary) cccc c111, where ccccc is the channel number (5 bits). For instance, 0x0F means set context for channel 1, 0xFF means set context for channel 31.

- C0_GETCTX: write to the buffer descriptor's data buffer the content of the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using this channel number, the script computes the offset of the context data pointer for the channel relative to the context page base to use as the source address for the copy. Then the C0_GET_DM command explained above is invoked to copy the context to memory. The counter indicates the size in words of the context structure.
- Command value: (in binary): cccc c011, where ccccc is the channel number (5 bits). For instance, 0x03 means get context of channel 1, 0xFB means get context of channel 31.

NOTE

To download channel context, C0_SETDM and C0_SETCTXT command can be used but the second one is easier because the channel number is embedded into the command field, whereas with the C0_SETDM, the pointer to the channel context area must be written into the extended buffer address field of the buffer descriptor.

66.19.1.3 Example of Buffer Descriptors for Channel 0.

Figure 66-20 illustrates the buffer descriptors that must be set in ARM platform memory space, before execution of boot code, to download contexts and scripts of channels 1, 4, and 10. After boot code execution, SDMA memory will be populated with the different contexts and scripts as presented in the following figure.

66.19.1.4 Channel Context

There are 32 channel context memory structures pointed to by the local save area pointer. These channel context memory structures are fixed.

The script in the SDMA computes the memory offset for a given channel based on the structure length and channel number. Figure below shows the structure of the channel context as it is saved in the SDMA local memory (RAM).

A channel context consists in 24 words, one per register. A total of 32 words are reserved for every channel. The additional 8 words are called scratch ram and they are dedicated to each channel. This memory area is commonly used for stack management.

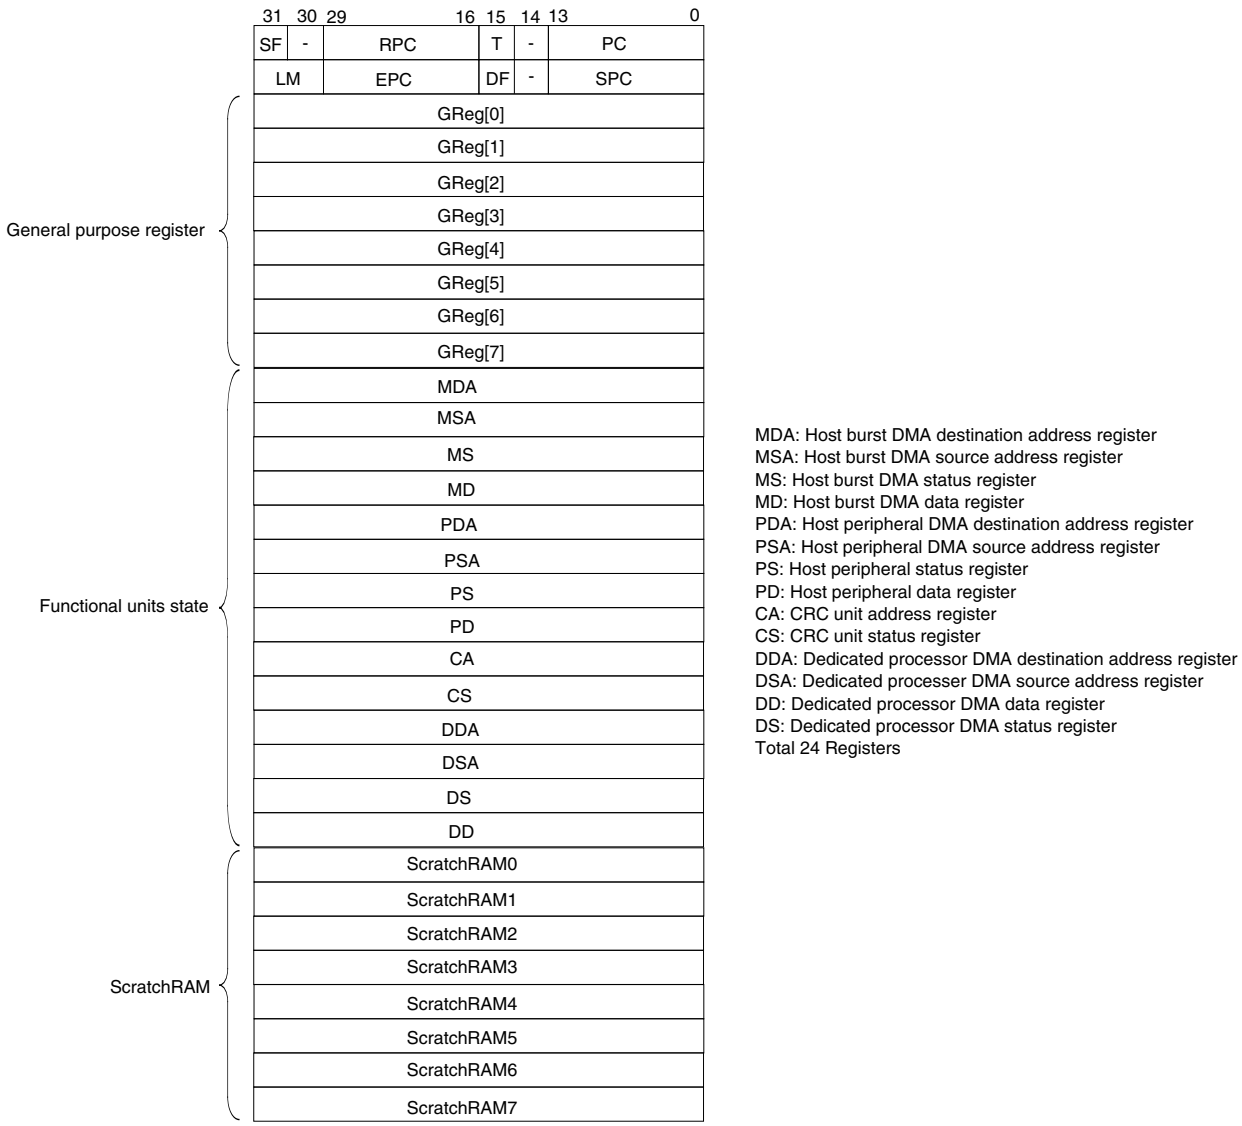

Figure 66-21. Channel Context Memory Structure

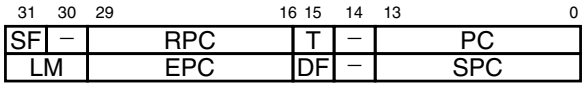
The structure is divided in 4 areas:

- Channel status registers
- General purpose registers
- Functional units state registers reflecting the state of the ARM platform DMAs (Burst and Peripheral DMA) and the CRC unit.
- Scratch RAM

The details of the channel context status registers are described in the following figure.

The PC field of the first long register must point to the SDMA RAM address where the script that will be executed on the channel is located and this value equals the one stored in the extended buffer address of the buffer descriptor with C0_SETPM command.



SF: Source fault while loading data
RPC: Return program counter
T: Test bit: status of arithmetic and test instructions
PC: Program counter
LM: Loop mode
EPC: Loop end program counter
DF: Destination fault while storing data
SPC: Loop Start program counter

Figure 66-22. SDMA State Registers (ShPC, ShLoop)

66.19.2 Typical Data Transfer Supported by SDMA DMA Units

This section presents a library of SDMA scripts that perform data transfers through the peripheral DMA and the burst DMA units.

The ARM platform memory and peripherals are devices that either the peripheral DMA or the burst DMA can access. The scripts are given for a peripheral DMA whose address registers are programmed in incremented mode when internal memory is involved. See the following table for the summary.

Table 66-54. Typical Data Transfers Summary

Data Transfer	Peripheral DMA	Burst DMA	Comments
ARM platform External Memory ↔ ARM platform External Memory		3	Copy mode Script example, see Burst DMA Unit Copy Mode and External Memory to External Memory.
ARM platform Peripheral ↔ ARM platform Peripheral	3		Copy mode if same data path width Script example, see Peripheral to Peripheral Transfer.
ARM platform External Memory ↔ ARM platform Peripheral	3	3	Data transit through SDMA Script example, see Transfer Between Peripheral and External Memory.
ARM platform External Memory ↔ ARM platform Internal Memory		3	Copy mode Script example, see Transfer Between External Memory and Internal Memory.

Table continues on the next page...

Table 66-54. Typical Data Transfers Summary (continued)

Data Transfer	Peripheral DMA	Burst DMA	Comments
ARM platform Internal Memory ↔ ARM platform Internal Memory		3	Copy mode Script example, see Internal Memory to Internal Memory.
ARM platform Internal memory ↔ ARM platform Peripheral	3		Data transit through SDMA Script example, see Transfer Between Peripheral and Internal Memory.

NOTE

These scripts are provided as examples of how to use DMA blocks to perform required data transfers: They are not "official" programs.

66.19.2.1 External Memory to External Memory

This section describes the SDMA script that performs data moves in external memory.

For this particular data transfer, only the burst DMA is used. It is programmed in copy mode, so no data transmits through an SDMA general register.

The SDMA core only monitors data transfer status. It is assumed source and destination address values are already present in two SDMA general registers (r1 and r2). For this example, it is also assumed that a 32-bit word-to-move for source-to-destination address is present in r0 and equals 64.

Data Moves in External Memory

```
1          stf r1,MSA                          // Source address setup

2          stf r2,MDA                          // Destination address setup

3          ldi r0,0x64                         // 64 words must be transferred from MSA to
MDA

4          ldi r1,0x8

MAIN_XFER:

5          cmphs r0,r1                         // Is r0 >= 0x8

6          bf LAST_XFER                      // If not, jump to last transfer label

7          stf r1,MD|CPY                        // Copy 8 words from MSA to MDA address.

8          subi r0,0x8                         // Decrement counter

9          jmp MAIN_XFER                     // return to main transfer loop

LAST_XFER:

10         stf r0,MD|CPY                        // perform last transfer
```

All instructions are performed in one cycle (jumps excepted). Instruction 7 triggers a copy transfer: A read burst access of 8-word starts, data is staged in MD and then a write burst of 8 words is executed. Instruction 8, 9, 5, and 6 are executed while the burst access is in progress. If this access is not complete when instruction 7 is executed a second time, SDMA stalls on this instruction as long as the previous copy transfer is not over. In this case, the instruction is no longer a one-cycle instruction.

During the main loop (MAIN_XFER), r1 always equals 8, so burst lengths are 8 words. On the last ldf |CPY instruction (10), r1 equals the reminder of r0 divided by 8; therefore, the length of bursts triggered in copy mode equal r1 value, which is between 1 and 7.

66.19.2.2 Peripheral to Peripheral Transfer

For this data transfer, only the peripheral DMA is used. It is programmed in copy mode, so no data will transmit through the SDMA general register used in the ldf instruction, but the contents of the general register are lost.

The SDMA core only monitors the transfer.

66.19.2.2.1 Source and Destination Target Have the Same Data Path Width

When the source and destination target have the same data path width, the following is true:

- Source target is a *half-word* (16-bit) peripheral located at address 0x1002.
- Destination is a *half-word* (16-bit) peripheral located at address 0x2006.

It is assumed the address values are already present in two SDMA general registers (r1, r2). The script for a transfer of 10 half-word is as follows:

Same Data Path Width for Source and Destination

```
//SETUP SECTION
1         stf r1, PSA|SZ16|F                    //r1=0x1002 Source address register setup
2         stf r2, PDA|SZ16|F                    //r2=0x2006 Destination address register
setup
3         bdf ERROR_ADDR_SETUP
4         ldi r0,0xa                          //loop counter is 10
//MAIN LOOP TRANFER
copy_loop:

5         loop 2,0
6           ldf r7,PD|CPY                     //Reads 1 half-word from src and writes to
dest.
7           yield
8         bdf ERROR_DURING_XFER
ERROR_ADDR_SETUP:
                    //correction of PSA/PDA setup and jumps to main loop transfer
ERROR_DURING_XFER:
//flag error is set,
//PS can be read to know if error occurs during read or write access.
```

If a data transfer must occur between two word peripherals, only the setup section should be updated. The transfer itself is always performed by the hardware loop instruction.

All instructions are executed in one cycle (change of flow excepted). On instruction 6, a single read access is triggered, read data is staged in PD, and a write-to-destination is executed. When the transfers are in progress, the SDMA can execute he next instructions in parallel. If instruction 6, which performs the copy transfer, is executed while the previous access is not over, SDMA is stalled and instruction ldf is a multi-cycle instruction.

66.19.2.2.2 Source and Destination Target Have a Different Data Path Width

When the source and destination target have a different data path width, copy mode cannot be used, and any attempt to initiate a copy transfer immediately raises an error, which is stored in the SF flag.

The following example shows the SDMA code that could transfer 10 words from a *word* (32-bit) peripheral to a *half-word* peripheral whose addresses are preliminary and stored in r1 and r2.

Different Data Path Width for Source and Destination

```
//SETUP SECTION
1          stf r1, PSA|SZ32|F|PF                    //r1=0x1000 and prefetch data
2          stf r2, PDA|SZ16|F                      //r2=0x2006
3          bdf ERROR_ADDR_SETUP
4          ldi r0,0xa                             //loop counter is 10
//MAIN LOOP TRANFER
main_loop_xfer_16_16:
5          loop 6,0
6            ldf r7,PD                          //copy 32-bit of PD in r7
7            stf r7,PD                           //store 16 LSB of r7 in PD and a flush is
executed
8            rorb r7
9            rorb r7                           //16 MSB --> 16 LSB
10           stf r7,PD                           //store 16 LSB of r6 in PD and a flush.
11           yield
```

On instruction 1, when the source address register is programmed and a data prefetch is required, a read access is executed. In parallel, the SDMA executes instructions 2 to 5. On instruction 6, the SDMA tries to read data that was fetched by instruction 1. If data is ready, the ldf will be a one cycle instruction; otherwise, the SDMA is stalled as long as the read access is not finished. Then, the 16 LSB of the read data is stored in PD and automatically flushed to the destination peripheral. In parallel, the SDMA executes the rotation instructions (8, 9), and stores the 16 MSB of the read data into PD. If a previous write access is finished, instruction 10 will be a one-cycle instruction.

The main loop transfer may appear inefficient, but due to wait states imposed to the peripheral DMA each time an external access is performed, a software pipeline is in place. During the time needed to flush PD, the SDMA executes the move and rotation operations. SDMA executes instructions in parallel with DMA accesses.

66.19.2.3 Transfer Between Peripheral and External Memory

66.19.2.3.1 Peripheral to External Memory Transfer

A transfer from a peripheral to the external memory controller involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from word peripheral to the external memory would be as follows:

Peripheral to External Memory Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1         stf r1, PSA|SZ16|F|PF                  //r1=0x1000 and prefetch 32-bit data
2         stf r2, MDA                          //r2=0x2000, setup burst DMA destination
address
3         bdf ERROR_ADDR_SETUP
4         ldi r0,0x64                           //loop counter is 100
5
          //MAIN LOOP TRANFER
6         loop 3,0
7           ldf r1,PD|PF                        // read 32 bits of PD and initiate a new read
access.
8           stf r1,MD|32                         // store 32 bits of r1 in the MD fifo.
9           yield
10        ldf r1,PD                            // last word data is read
11        stf r1,MD|32|FL                        // to flush all remaining bytes of MD
```

On instruction 1, the source address register of the peripheral DMA is programmed and data is fetched. This data is stored in PD and the SDMA reads PD during instruction 7, which is a one-cycle instruction that is read-access finished. On the same instruction (7), a data prefetch is required and a read access to the source peripheral is executed. In parallel, the SDMA stored the previous read data into the data register of MD. When MD (which is an eight-word FIFO) is full, a burst write access is executed to empty the FIFO. As long as the next SDMA instructions do not access the burst DMA, they will be one-cycle instructions. The following figures show how the peripheral DMA and burst DMA work in parallel.

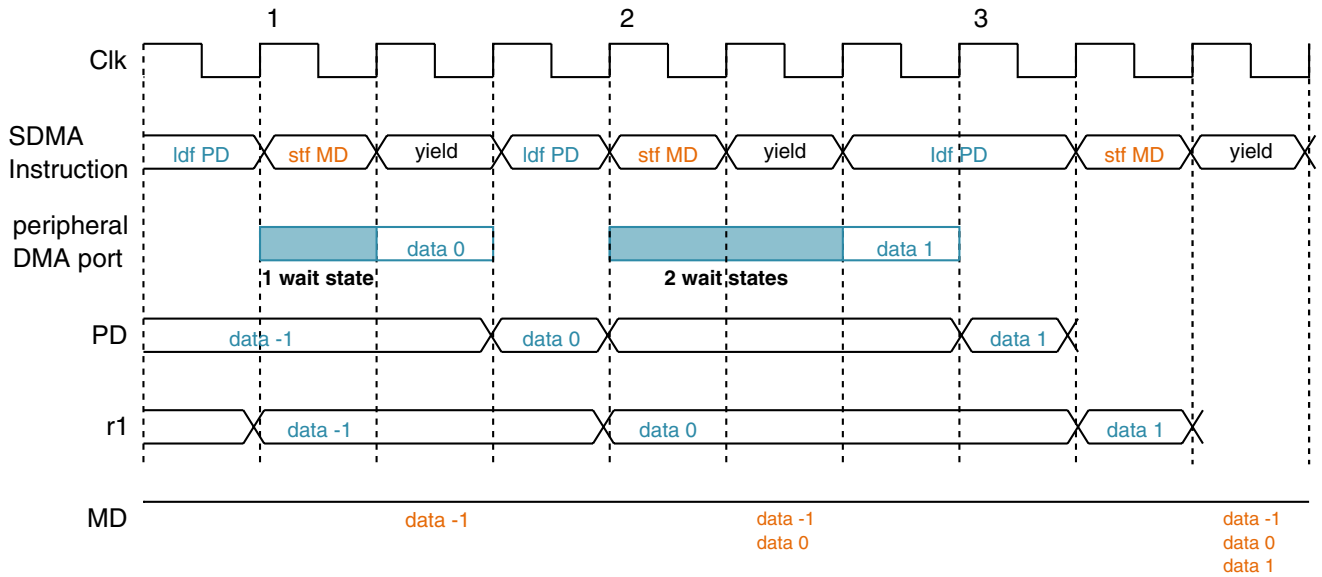


Figure 66-23. Peripheral to External Memory Example (1)

As seen in the figure above, the read access triggered by the ldf PD instruction is symbolized by the blue bar when in progress. After wait states, the read data (data 0, data 1) is stored in PD on the clk rising edge. On edge 2, data 0 is available in PD so it can be transferred to the SDMA general register r1, and then stored in MD FIFO. On edge 3, data 1 is not in PD; therefore, SDMA is stalled on the ldf instruction, which lasts two cycles. The figure below shows an example of when MD FIFO is full with data.

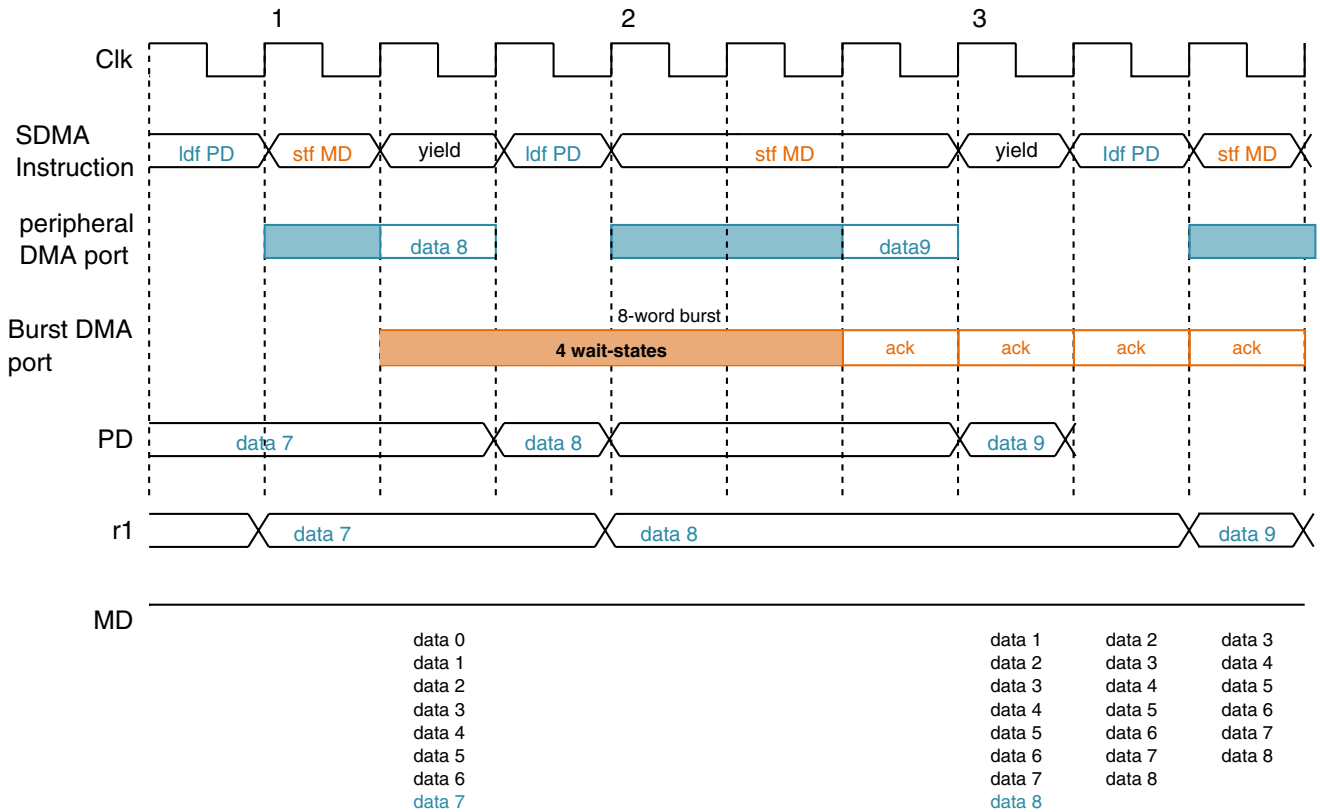

Figure 66-24. Peripheral to External Memory Example (2)

In the previous figure, the write bar means the burst DMA is performing a write burst access. The latency to have the first write acknowledge is four cycles. SDMA is stalled on instruction stf because no acknowledge was received, MD FIFO is full, and there is no empty slot to store data 9. When an acknowledge is sampled by the burst DMA, FIFO is shifted and data 8 is written. As long as there is at least one empty slot in MD FIFO, the stf MD instruction lasts one cycle.

66.19.2.3.2 External Memory to Peripheral Transfer

A transfer from the external memory to a peripheral involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from external memory to a word peripheral would be as follows:

External Memory to Peripheral Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1         stf r1, MSA|PF              //r1=0x1000 and starts a 8-word read burst
2         stf r2, PDA|SZ32|P           //r2=0x2010, setup peripheral DMA destination address
3         bdf ERROR_ADDR_SETUP
4         ldi r0,0x64                 //loop counter is 100
//MAIN LOOP TRANFER
6         loop 3,0
```

```
7           ldf r1,MD|32|PF          // read 32 bits of MD and initiate a new read access
                                  // if MD is empty after this reading.
8           stf r1,PD               // store 32 bits of r1 in the PD.
9           yield
          10 ldf r1,MD|32            // last word data is read
11        stf r1,PD                 // last write access
```

On instruction 1, a read burst of 8 words begins. Read data is staged into MD. On instruction 7 (and if data is available in MD), 32 bits are copied into r1. Then instruction 8 writes them into PD and an automatic flush is executed. The SDMA core, peripheral DMA, and burst DMA can work in parallel as long as no SDMA instruction tries to start a new write access on the peripheral DMA while the previous access is still in progress, or as long as there is data in MD when the SDMA tries to read it.

66.19.2.4 Transfer Between External Memory and Internal Memory

Since the internal memory (ARM platform RAM) is accessed via the peripheral DMA and the external memory is accessed via the burst DMA, the SDMA scripts that are described in Transfer Between Peripheral and External Memory can be reused. The exception is that the peripheral DMA address registers (PSA or PDA, depending on the script) should be programmed in incremented mode rather than frozen mode.

66.19.2.4.1 Internal Memory to Internal Memory

The internal memory can only be accessed via the peripheral DMA, so the script described in Peripheral to Peripheral Transfer can be reused with a different programming of the peripheral DMA address registers.

66.19.2.4.2 Transfer Between Peripheral and Internal Memory

For this transfer, the peripheral DMA is also used in copy mode.

The SDMA script is very similar to the one described in Peripheral to Peripheral Transfer, except for the peripheral DMA address registers programming.

66.20 ARM Platform Memory Map and Control Register Definitions

The ARM platform controls the SDMA by means of several interface registers. Those registers are described in the current section.

All registers are clocked with the SDMA clock (which means the ARM platform must ensure that the SDMA clock is running when it wants to access any register).

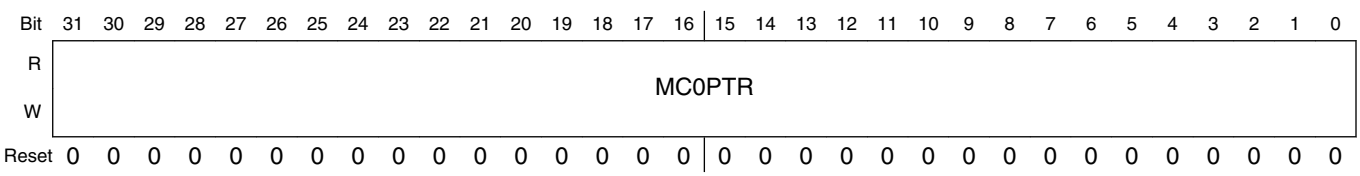
66.20.1 ARM platform Channel 0 Pointer (SDMAARM_MC0PTR)

Address: SDMAARM_MC0PTR is 63FB_0000h base + 0h offset = 63FB_0000h



SDMAARM_MC0PTR field descriptions

Field	Description
31–0 MC0PTR	**Channel 0 Pointer** contains the 32-bit address, in ARM platform memory, of channel 0 control block (the boot channel). Appendix A fully describes the SDMA Application Programming Interface (API). The ARM platform has a read/write access and the SDMA has a read-only access.

66.20.2 Channel Interrupts (SDMAARM_INTR)

Address: SDMAARM_INTR is 63FB_0000h base + 4h offset = 63FB_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARM_INTR field descriptions

Field	Description
31–0 HI[31:0]	The ARM platform Interrupts register contains the 32 HI[i] bits. If any bit is set, it will cause an interrupt to the ARM platform. This register is a "write-ones" register to the ARM platform. When the ARM platform sets a bit in this register the corresponding HI[i] bit is cleared. The interrupt service routine should clear individual channel bits when their interrupts are serviced, failure to do so will cause continuous interrupts. The SDMA is responsible for setting the HI[i] bit corresponding to the current channel when the corresponding `done` instruction is executed.

66.20.3 Channel Stop/Channel Status (SDMAARM_STOP_STAT)

Address: SDMAARM_STOP_STAT is 63FB_0000h base + 8h offset = 63FB_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HE																															
W	w1c

SDMAARM_STOP_STAT field descriptions

Field	Description
31–0 HE	This 32-bit register gives access to the ARM platform Enable bits. There is one bit for every channel. This register is a "write-ones" register to the ARM platform. When the ARM platform writes 1 in bit i of this register, it clears the HE[i] and HSTART[i] bits. Reading this register yields the current state of the HE[i] bits.

66.20.4 Channel Start (SDMAARM_HSTART)

Address: SDMAARM_HSTART is 63FB_0000h base + Ch offset = 63FB_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_HSTART field descriptions

Field	Description
31–0 HSTART/HE	The HSTART/HE registers are 32 bits wide with one bit for every channel. When a bit is written to 1, it enables the corresponding channel. Two physical registers are accessed with that address (HSTART and HE), which enables the ARM platform to trigger a channel a second time before the first trigger is processed. • This register is a "write-ones" register to the ARM platform. Neither HSTART[i] bit can be set while the corresponding HE[i] bit is cleared. • When the ARM platform tries to set the HSTART[i] bit by writing a one (if the corresponding HE[i] bit is clear), the bit in the HSTART[i] register will remain cleared and the HE[i] bit will be set. • If the corresponding HE[i] bit was already set, the HSTART[i] bit will be set. The next time the SDMA channel *i* attempts to clear the HE[i] bit by means of a `done` instruction, the bit in the HSTART[i] register will be cleared and the HE[i] bit will take the old value of the HSTART[i] bit. • Reading this register yields the current state of the HSTART[i] bits. This mechanism enables the ARM platform to pipeline two HSTART commands per channel.

66.20.5 Channel Event Override (SDMAARM_EVTOVR)

Address: SDMAARM_EVTOVR is 63FB_0000h base + 10h offset = 63FB_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARM_HOSTOVR field descriptions

Field	Description
31–0 HO	The Channel ARM platform Override register contains the 32 HO[i] bits. A bit set in this register causes the SDMA to ignore the ARM platform enable bit (HE) when scheduling the corresponding channel.

66.20.8 Channel Event Pending (SDMAARM_EVTPEND)

Address: SDMAARM_EVTPEND is 63FB_0000h base + 1Ch offset = 63FB_001Ch

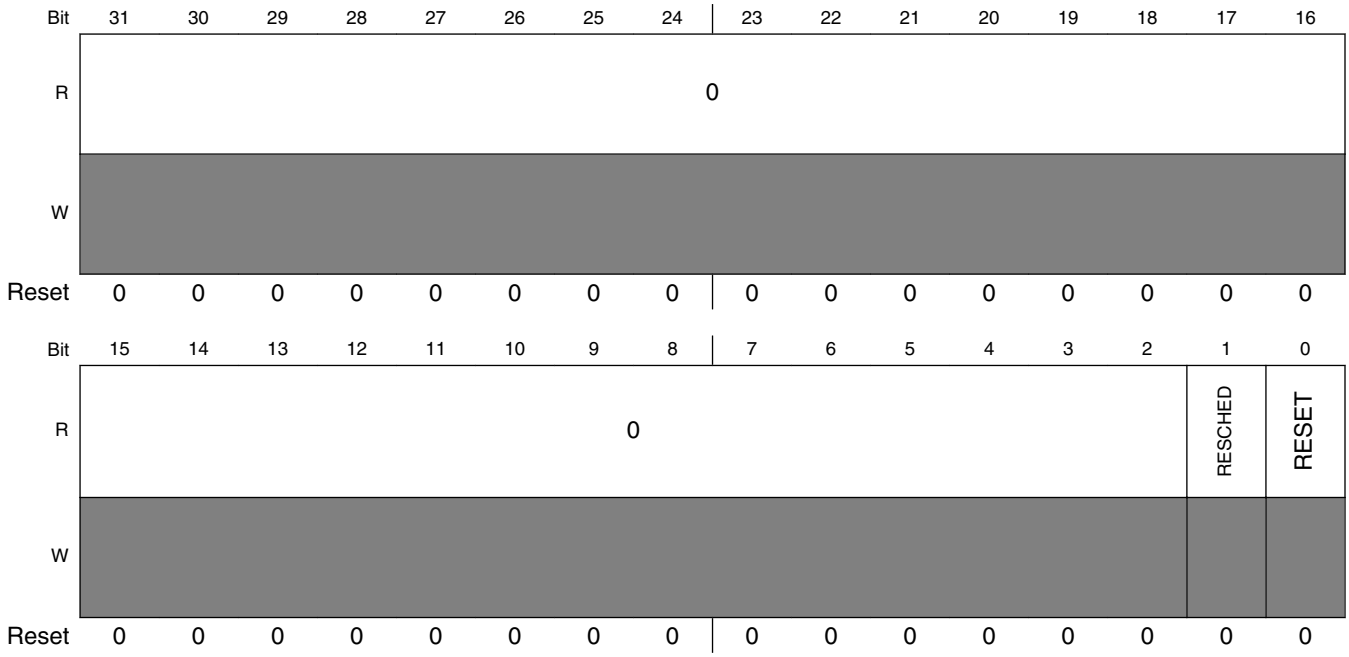
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	EP																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_EVTPEND field descriptions

Field	Description
31–0 EP	The Channel Event Pending register contains the 32 EP[i] bits. Reading this register enables the ARM platform to determine what channels are pending after the reception of a DMA request. • Setting a bit in this register causes the SDMA to reevaluate scheduling as if a DMA request mapped on this channel had occurred. This is useful for starting up channels, so that initialization is done before awaiting the first request. The scheduler can also set bits in the EVTPEND register according to the received DMA requests. • The EP[i] bit may be cleared by the `done` instruction when running the channel *i* script. This a "write-ones" mechanism: Writing a '0' does not clear the corresponding bit.

66.20.9 Reset Register (SDMAARM_RESET)

Address: SDMAARM_RESET is 63FB_0000h base + 24h offset = 63FB_0024h

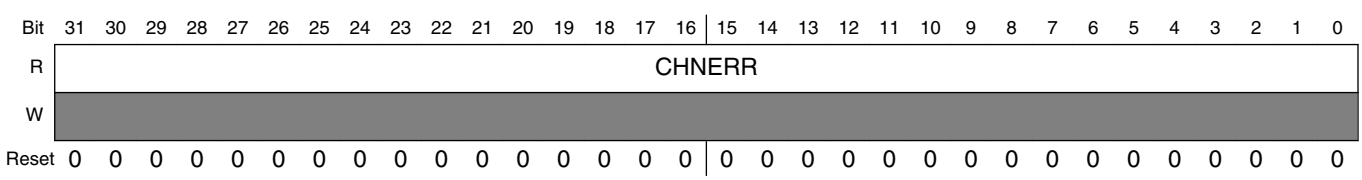


SDMAARM_RESET field descriptions

Field	Description
31–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 RESCHED	When set, this bit forces the SDMA to reschedule as if a script had executed a `done` instruction. This enables the ARM platform to recover from a runaway script on a channel by clearing its HE[i] bit via the STOP register, and then forcing a reschedule via the RESCHED bit. The RESCHED bit is cleared when the context switch starts.
0 RESET	When set, this bit causes the SDMA to be held in a software reset. The internal reset signal is held low 16 cycles; the RESET bit is automatically cleared when the internal reset signal rises.

66.20.10 DMA Request Error Register (SDMAARM_EVTERR)

Address: SDMAARM_EVTERR is 63FB_0000h base + 28h offset = 63FB_0028h



SDMAARM_EVTERR field descriptions

Field	Description
31–0 CHNERR	This register is used by the SDMA to warn the ARM platform when an incoming DMA request was detected and it triggers a channel that is already pending or being serviced. This probably means there is an overflow of data for that channel. • An interrupt is sent to the ARM platform if the corresponding channel bit is set in the INTRMASK register. • This is a "write-ones" register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the ARM platform or during SDMA reset. • The CHNERR[i] bit is set when a DMA request that triggers channel *i* is received through the corresponding input pins and the EP[i] bit is already set; the EVTERR[i] bit is unaffected if the ARM platform tries to set the EP[i] bit, whereas, that EP[i] bit is already set.

66.20.11 Channel ARM platform Interrupt Mask (SDMAARM_INTRMASK)

Address: SDMAARM_INTRMASK is 63FB_0000h base + 2Ch offset = 63FB_002Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARM_PSW field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

SDMAARM_PSW field descriptions (continued)

Field	Description
15–13 NCP[2:0]	The Next Channel Priority gives the next pending channel priority. When the priority is 0, it means there is no pending channel and the NCR value has no meaning. 0 No running channel 1 Active channel priority
12–8 NCR[4:0]	The Next Channel Register indicates the number of the next scheduled pending channel with the highest priority.
7–4 CCP[2:0]	The Current Channel Priority indicates the priority of the current active channel. When the priority is 0, no channel is running: The SDMA is idle and the CCR value has no meaning. In the case that the SDMA has finished running the channel and has entered sleep state, CCP will indicate the priority of previous running channel. 0 No running channel 1 Active channel priority
3–0 CCR[4:0]	The Current Channel Register indicates the number of the channel that is being executed by the SDMA. SDMA. In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel.

66.20.13 DMA Request Error Register (SDMAARM_EVTERRDBG)

Address: SDMAARM_EVTERRDBG is 63FB_0000h base + 34h offset = 63FB_0034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

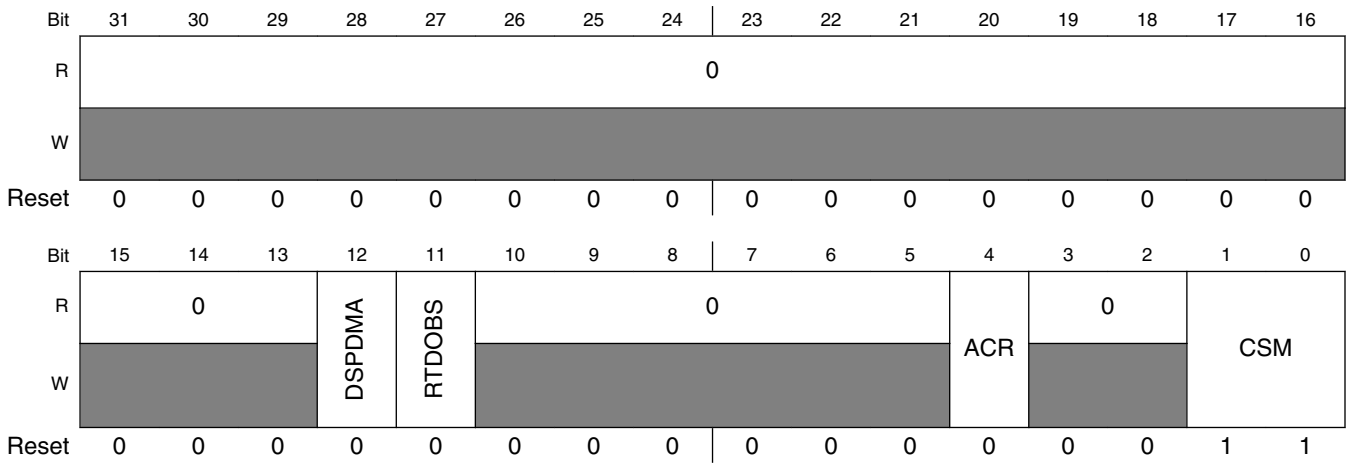
SDMAARM_EVTERRDBG field descriptions

Field	Description
31–0 CHNERR	This register is the same as EVTERR, except reading it does not clear its contents. This address is meant to be used in debug mode. The ARM platform OnCE may check this register value without modifying it.

66.20.14 Configuration Register (SDMAARM_CONFIG)

Address: SDMAARM_CONFIG is 63FB_0000h base + 38h offset = 63FB_0038h



SDMAARM_CONFIG field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12 DSPDMA	This bit's function is reserved and should be configured as zero. 0 - Reset Value 1 - Reserved
11 RTDOBS	Indicates if Real-Time Debug pins are used: They do not toggle by default in order to reduce power consumption. 0 RTD pins disabled 1 RTD pins enabled
10–5 Reserved	This read-only field is reserved and always has the value zero. Reserved
4 ACR	ARM platform DMA / SDMA Core Clock Ratio. Selects the clock ratio between ARM platform DMA interfaces (burst DMA and peripheral DMA) and the internal SDMA core clock. The frequency selection is determined separately by the chip clock controller. This bit has to match the configuration of the chip clock controller that generates the clocks used in the SDMA. 0 ARM platform DMA interface frequency equals twice core frequency 1 ARM platform DMA interface frequency equals core frequency
3–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1–0 CSM	Selects the Context Switch Mode. The ARM platform has a read/write access. The SDMA cannot modify that register. The value at reset is 3, which selects the dynamic context switch by default. That register can be modified at anytime but the new context switch configuration will only be taken into account at the start of the next restore phase.

Table continues on the next page...

SDMAARM_CONFIG field descriptions (continued)

Field	Description
	NOTE: The first call to SDMA's channel 0 Bootload script after reset should use static context switch mode to ensure the context RAM for channel 0 is initialized in the channel SAVE Phase. After Channel 0 is run once, then any of the dynamic context modes can be used. 0 static 1 dynamic low power 2 dynamic with no loop 3 dynamic

66.20.15 SDMA LOCK (SDMAARM_SDMA_LOCK)

Address: SDMAARM_SDMA_LOCK is 63FB_0000h base + 3Ch offset = 63FB_003Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0														SRESET_LOCK_CLR	LOCK
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_SDMA_LOCK field descriptions

Field	Description
31–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 SRESET_ LOCK_CLR	The SRESET_LOCK_CLR bit determine if the LOCK bit is cleared on a software reset triggered by writing to the RESET register. This bit cannot be changed if LOCK=1. SREST_LOCK_CLR is cleared by conditions that clear the LOCK bit. 0 Software Reset does not clear the LOCK bit. 1 Software Reset clears the LOCK bit.
0 LOCK	The LOCK bit is used to restrict access to update SDMA script memory through ROM channel zero scripts and through the OnCE interface under ARM platform control. The LOCK bit is set: • The SDMA_LOCK, ONCE_ENB,CH0ADDR, and ILLINSTADDR registers cannot be written. These registers can be read, but writes are ignored. • SDMA software executing out of ROM or RAM may check the LOCK bit in the LOCK register Lock Status Register (SDMACORE_SDMA_LOCK) to determine if certain operations are allowed, such as up-loading new scripts.

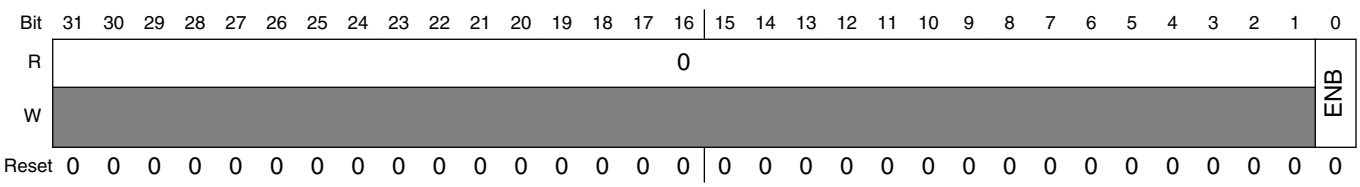
Table continues on the next page...

SDMAARM_SDMA_LOCK field descriptions (continued)

Field	Description
	Once the LOCK bit is set to 1, only a reset can clear it. The LOCK bit is cleared by a hardware reset. LOCK is cleared by a software reset only if SRESET_LOCK_CLR is set. 0 LOCK disengaged. 1 LOCK enabled.

66.20.16 OnCE Enable (SDMAARM_ONCE_ENB)

Address: SDMAARM_ONCE_ENB is 63FB_0000h base + 40h offset = 63FB_0040h

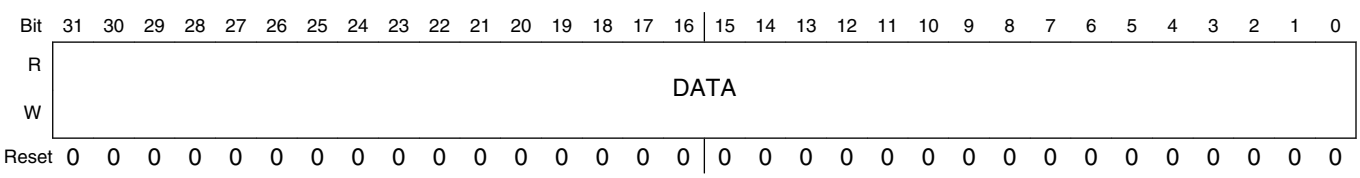


SDMAARM_ONCE_ENB field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 ENB	The OnCE Enable register selects the OnCE control source: When cleared (0), the OnCE registers are accessed through the JTAG interface; when set (1), the OnCE registers may be accessed by the ARM platform through the addresses described, as follows. • After reset, the OnCE registers are accessed through the JTAG interface. • Writing a 1 to ENB enables the ARM platform to access the ONCE_* as any other SDMA control register. • When cleared (0), all the ONCE_xxx registers cannot be written. The value of ENB cannot be changed if the LOCK bit in the SDMA_LOCK register is set.

66.20.17 OnCE Data Register (SDMAARM_ONCE_DATA)

Address: SDMAARM_ONCE_DATA is 63FB_0000h base + 44h offset = 63FB_0044h

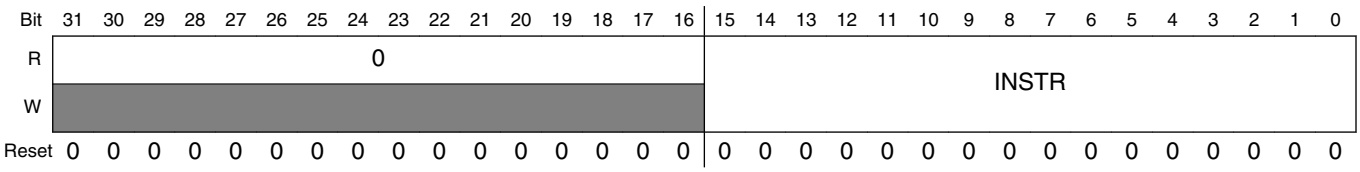


SDMAARM_ONCE_DATA field descriptions

Field	Description
31–0 DATA	Data register of the OnCE JTAG controller. Refer to OnCE and Real-Time Debug for information on this register.

66.20.18 OnCE Instruction Register (SDMAARM_ONCE_INSTR)

Address: SDMAARM_ONCE_INSTR is 63FB_0000h base + 48h offset = 63FB_0048h

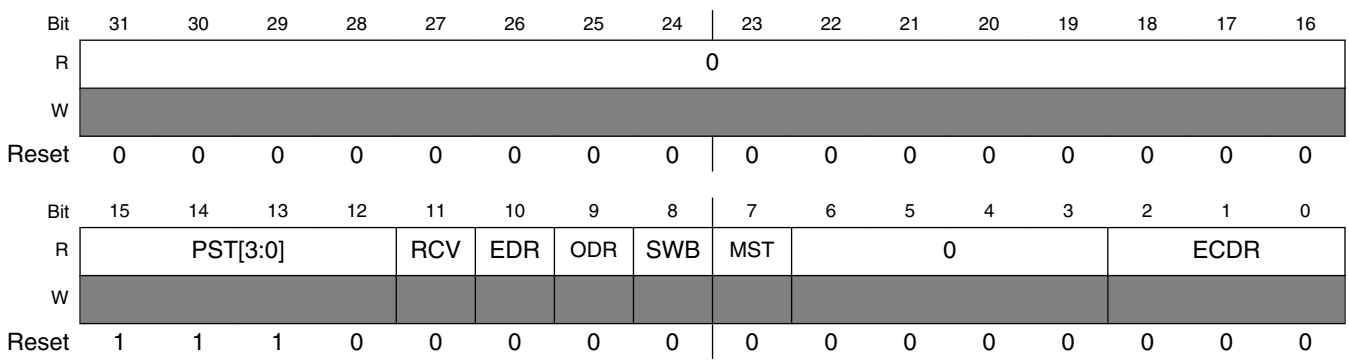


SDMAARM_ONCE_INSTR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–0 INSTR	Instruction register of the OnCE JTAG controller. Refer to OnCE and Real-Time Debug for information on this register.

66.20.19 OnCE Status Register (SDMAARM_ONCE_STAT)

Address: SDMAARM_ONCE_STAT is 63FB_0000h base + 4Ch offset = 63FB_004Ch



SDMAARM_ONCE_STAT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–12 PST[3:0]	The Processor Status bits reflect the state of the SDMA RISC engine. Its states are as follows: • The "Program" state is the usual instruction execution cycle. • The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. • The "Debug" state means the SDMA is in debug mode.

Table continues on the next page...

SDMAARM_ONCE_STAT field descriptions (continued)

Field	Description
	• The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In "Sleep" modes, no script is running (this is the RISC engine idle state). The "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). • The "in Sleep" states are the same as above except they do not have any corresponding channel: They are used when entering debug mode after reset. The reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. 0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Restore
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an `rbuffer` command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	This flag is raised when the OnCE is controlled from the ARM platform peripheral interface. 0 The JTAG interface controls the OnCE. 1 The ARM platform peripheral interface controls the OnCE.
6–3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2–0 ECDR	Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one of the EDR bits is set (the meaning of the encoding is given below). The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addra_cond, addrb_cond, and data_cond conditions. The value of those fields is given by the EDR bits. 0 1 matched addra_cond

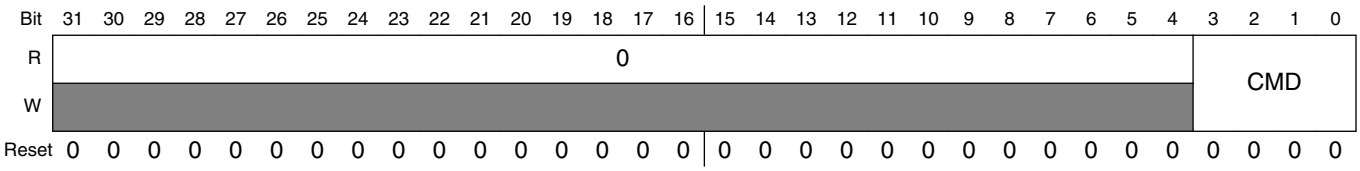
Table continues on the next page...

SDMAARM_ONCE_STAT field descriptions (continued)

Field	Description
	1 1 matched addrb_cond 2 1 matched data_cond

66.20.20 OnCE Command Register (SDMAARM_ONCE_CMD)

Address: SDMAARM_ONCE_CMD is 63FB_0000h base + 50h offset = 63FB_0050h

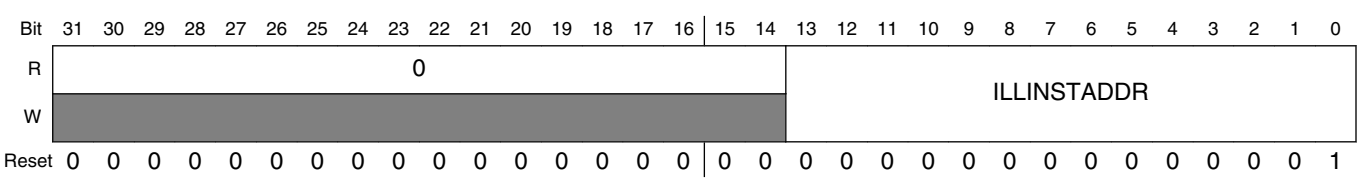


SDMAARM_ONCE_CMD field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3–0 CMD	Writing to this register will cause the OnCE to execute the command that is written. When needed, the ONCE_DATA and ONCE_INSTR registers should be loaded with the correct value before writing the command to that register. For a list of the OnCE commands and their usage, see OnCE and Real-Time Debug. **NOTE:** 7-15 *reserved* 0 rstatus 1 dmov 2 exec_once 3 run_core 4 exec_core 5 debug_rqst 6 rbuffer

66.20.21 Illegal Instruction Trap Address (SDMAARM_ILLINSTADDR)

Address: SDMAARM_ILLINSTADDR is 63FB_0000h base + 58h offset = 63FB_0058h

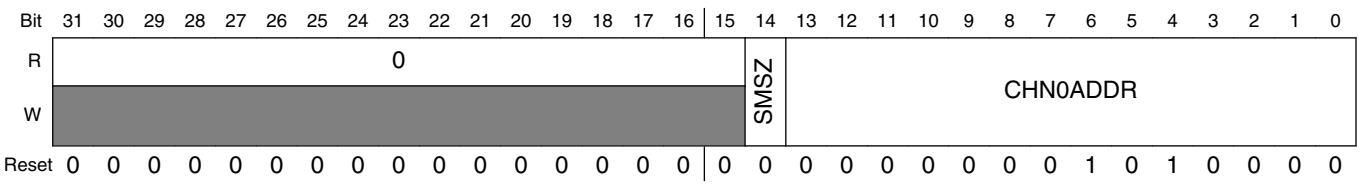


SDMAARM_ILLINSTADDR field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value zero. Reserved
13–0 ILLINSTADDR	The Illegal Instruction Trap Address is the address where the SDMA jumps when an illegal instruction is executed. It is 0x0001 after reset. The value of ILLINSTADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.

66.20.22 Channel 0 Boot Address (SDMAARM_CHN0ADDR)

Address: SDMAARM_CHN0ADDR is 63FB_0000h base + 5Ch offset = 63FB_005Ch



SDMAARM_CHN0ADDR field descriptions

Field	Description
31–15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context, which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism. The value of SMSZ cannot be changed if the LOCK bit in the SDMA_LOCK register is set. 0 24 words per context 1 32 words per context
13–0 CHN0ADDR	This 14-bit register is used by the boot code of the SDMA. After reset, it points to the standard boot routine in ROM (channel 0 routine). By changing this address, you can perform a boot sequence with your own routine. The very first instructions of the boot code fetch the contents of this register (it is also mapped in the SDMA memory space) and jump to the given address. The reset value is 0x0050 (decimal 80). The value of CHN0ADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.

66.20.23 DMA Requests (SDMAARM_EVT_MIRROR)

Address: SDMAARM_EVT_MIRROR is 63FB_0000h base + 60h offset = 63FB_0060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

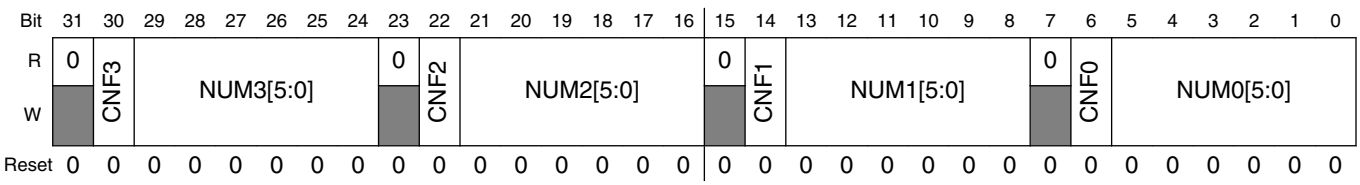
SDMAARM_EVT_MIRROR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–0 EVENTS[47:32]	This register reflects the DMA requests received by the SDMA for events 47-32. The ARM platform and the SDMA have a read-only access. There is one bit associated with each of DMA request events. This information may be useful during debug of the blocks that generate the DMA requests. The EVT_MIRROR2 register is cleared following read access. 0 - DMA request event not pending 1- DMA request event pending

66.20.25 Cross-Trigger Events Configuration Register 1 (SDMAARM_XTRIG_CONF1)

Address: SDMAARM_XTRIG_CONF1 is 63FB_0000h base + 70h offset = 63FB_0070h



SDMAARM_XTRIG_CONF1 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value zero. Reserved
30 CNF3	Configuration of the SDMA event line number *i* that is connected to the cross-trigger. It determines whether the event line pulse is generated by the reception of a DMA request or by the starting of a channel script execution. 0 channel 1 DMA request
29–24 NUM3[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number *i*.
23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22 CNF2	Configuration of the SDMA event line number *i* that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
21–16 NUM2[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number *i*.
15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14 CNF1	Configuration of the SDMA event line number *i* that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
13–8 NUM1[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number *i*.
7 Reserved	This read-only field is reserved and always has the value zero. Reserved

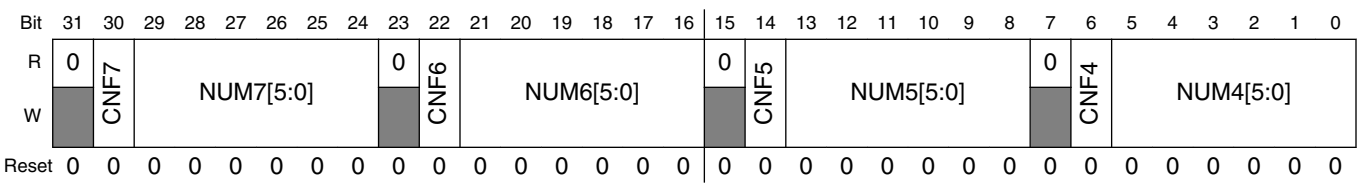
Table continues on the next page...

SDMAARM_XTRIG_CONF1 field descriptions (continued)

Field	Description
6 CNF0	Configuration of the SDMA event line number *i* that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
5–0 NUM0[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number *i*.

66.20.26 Cross-Trigger Events Configuration Register 2 (SDMAARM_XTRIG_CONF2)

Address: SDMAARM_XTRIG_CONF2 is 63FB_0000h base + 74h offset = 63FB_0074h



SDMAARM_XTRIG_CONF2 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value zero. Reserved
30 CNF7	Configuration of the SDMA event line number *i* that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
29–24 NUM7[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number *i*.
23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22 CNF6	Configuration of the SDMA event line number *i* that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
21–16 NUM6[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number *i*.
15 Reserved	This read-only field is reserved and always has the value zero. Reserved

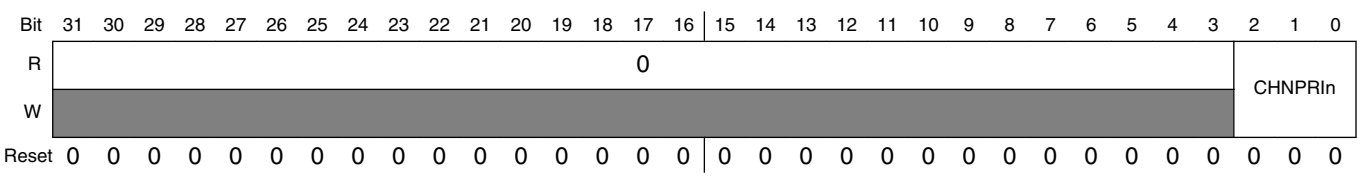
Table continues on the next page...

SDMAARM_XTRIG_CONF2 field descriptions (continued)

Field	Description
14 CNF5	Configuration of the SDMA event line number *i* that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution 0 channel 1 DMA request
13–8 NUM5[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number *i*.
7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6 CNF4	Configuration of the SDMA event line number *i* that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
5–0 NUM4[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number *i*.

66.20.27 Channel Priority Registers (SDMAARM_SDMA_CHNPRI*n*)

Addresses: 63FB_0000h base + 100h offset + (4d × *n*), where *n* = 0d to 31d



SDMAARM_SDMA_CHNPRI*n* field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2–0 CHNPRIn	This contains the priority of channel number *n*. Useful values are between 1 and 7; 0 is reserved by the SDMA hardware to determine when there is no pending channel. Reset value is 0, which prevents the channels from starting.

66.20.28 Channel Enable RAM (SDMAARM_SDMA.CHNENBL*n*)

Addresses: 63FB_0000h base + 200h offset + (4d × *n*), where *n* = 0d to 47d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ENBLn																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_SDMA.CHNENBL*n* field descriptions

Field	Description
31–0 ENBLn	This 32-bit value selects the channels that are triggered by the DMA request number *n*. If ENBLn[i] is set to 1, bit EP[i] will be set when the DMA request *n* is received. These 48 32-bit registers are physically located in a RAM, with no known reset value. It is thus essential for the ARM platform to program them before any DMA request is triggered to the SDMA, otherwise an unpredictable combination of channels may be started.

66.21 BP Memory Map and Control Register Definitions

The following section describes SDMA control registers available to the BP.

NOTE

These registers are physically implemented in all platforms, but are not accessible when the SDMA BP control port is not connected. Reset values are calculated to allow the system to work when those registers cannot be accessed.

All registers are clocked with the SDMA clock (which means the SDMA clock must be running when the BP wants to access any register).

SDMABP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FB_0000	Channel 0 Pointer (SDMABP_DC0PTR)	32	R/W	0000_0000h	66.21.1/ 4249

SDMABP_DC0PTR field descriptions

Field	Description
31–0 DC0PTR	**Channel 0 Pointer** contains the 32-bit address, in BP memory, of the array of channel control blocks starting with the one for channel 0 (the control channel). This register should be initialized by the BP before it enables a channel (for example, channel 0). See the API document i.MX50 SDMA Scripts User Manual for the use of this register. The BP has a read/write access and the SDMA has a read-only access.

66.21.2 Channel Interrupts (SDMABP_INTR)

Address: SDMABP_INTR is 63FB_0000h base + 4h offset = 63FB_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMABP_INTR field descriptions

Field	Description
31–0 DI	The BP Interrupts register contains the 32 DI[i] bits. If any bit is set, it will cause an interrupt to the BP. • This register is a "write-ones" register to the BP. When the BP sets a bit in this register, the corresponding DI[i] bit is cleared.

SDMABP_INTR field descriptions (continued)

Field	Description
	• The interrupt service routine should clear individual channel bits when their interrupts are serviced; failure to do so will cause continuous interrupts. • The SDMA is responsible for setting the DI[i] bit corresponding to the current channel when the corresponding `done` instruction is executed.

66.21.3 Channel Stop/Channel Status (SDMABP_STOP_STAT)

Address: SDMABP_STOP_STAT is 63FB_0000h base + 8h offset = 63FB_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMABP_STOP_STAT field descriptions

Field	Description
31–0 DE	This 32-bit register gives access to the BP (DSP) Enable bits, DE. There is one bit for every channel. • This register is a "write-ones" register to the BP. • When the BP writes 1 in bit *i* of this register, it clears the DE[i] and DSTART[i] bits. • Reading this register yields the current state of the DE[i] bits.

66.21.4 Channel Start (SDMABP_DSTART)

Address: SDMABP_DSTART is 63FB_0000h base + Ch offset = 63FB_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMABP_DSTART field descriptions

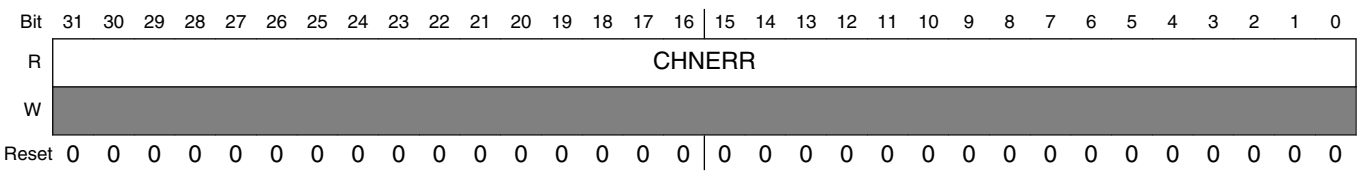
Field	Description
31–0 DSTART/DE	The DSTART/DE registers are 32 bits wide with one bit for every channel. • When a bit is written to 1, it enables the corresponding channel. • Two physical registers are accessed with that address (DSTART and DE), which enables the BP to trigger a channel a second time before the first trigger was processed. • This register is a "write-ones" register to the BP. Neither DSTART[i] bit can be set while the corresponding DE[i] bit is cleared. • When the BP tries to set the DSTART[i] bit by writing a one (if the corresponding DE[i] bit is clear), the bit in the DSTART[i] register will remain cleared and the DE[i] bit will be set. If the corresponding DE[i] bit was already set, the DSTART[i] bit will be set.

SDMABP_DSTART field descriptions (continued)

Field	Description
	• The next time the SDMA channel *i* attempts to clear the DE[i] bit by means of a `done` instruction, the bit in the DSTART[i] register will be cleared and the DE[i] bit will take the old value of the DSTART[i] bit. • Reading this register yields the current state of the DSTART[i] bits. This mechanism enables the BP to pipeline two DSTART commands per channel.

66.21.5 DMA Request Error Register (SDMABP_EVTERR)

Address: SDMABP_EVTERR is 63FB_0000h base + 28h offset = 63FB_0028h

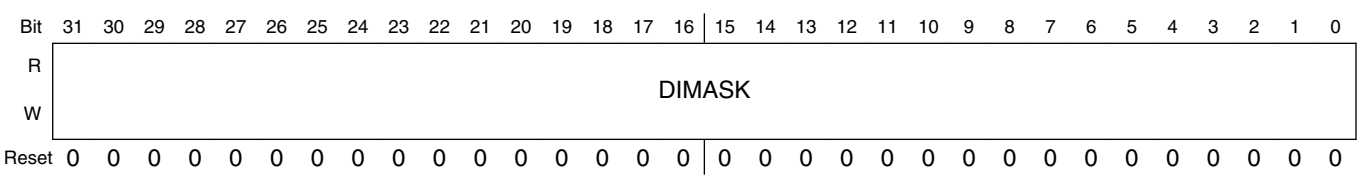


SDMABP_EVTERR field descriptions

Field	Description
31–0 CHNERR	This register is used by the SDMA to warn the BP when an incoming DMA request was detected; it then triggers a channel that is already pending or being serviced, which may mean there is an overflow of data for that channel. An interrupt is sent to the BP if the corresponding channel bit is set in the INTRMASK register. • This is a "write-ones" register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the BP or during an SDMA reset. • The CHNERR[i] bit is set when a DMA request that triggers channel *i* is received through the corresponding input pins and the EP[i] bit is already set. The EVTERR[i] bit is unaffected if the BP tries to set the EP[i] bit when that EP[i] bit is already set.

66.21.6 Channel DSP Interrupt Mask (SDMABP_INTRMASK)

Address: SDMABP_INTRMASK is 63FB_0000h base + 2Ch offset = 63FB_002Ch



SDMABP_INTRMASK field descriptions

Field	Description
31–0 DIMASK	The Interrupt Mask Register contains 32 interrupt generation mask bits. If bit DIMASK[i] is set, the DI[i] bit is set and an interrupt is sent to the BP when a DMA request error is detected on channel *i* (for example, EVTERR[i] is set).

66.21.7 DMA Request Error Register (SDMABP_EVTERRDBG)

Address: SDMABP_EVTERRDBG is 63FB_0000h base + 34h offset = 63FB_0034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMABP_EVTERRDBG field descriptions

Field	Description
31–0 CHNERR	This register is the same as EVTERR except reading it does not clear its contents. This address is meant to be used in debug mode. The BP OnCE may check this register value without modifying it.

66.22 SDMA Internal (Core) Memory Map and Internal Register Definitions

The actual SDMA memory mapped registers are summarized in the following sections; for peripherals' memory maps, refer to the respective chapters.

The following definitions serve as a key for the SDMA internal register summary.

SDMACORE memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FB_0000	ARM platform Channel 0 Pointer (SDMACORE_MC0PTR)	32	R	0000_0000h	66.22.1/ 4253
63FB_0002	Current Channel Pointer (SDMACORE_CCPTR)	32	R	0000_0000h	66.22.2/ 4254
63FB_0003	Current Channel Register (SDMACORE_CCR)	32	R	0000_0000h	66.22.3/ 4254
63FB_0004	Highest Pending Channel Register (SDMACORE_NCR)	32	R	0000_0000h	66.22.4/ 4255
63FB_0005	External DMA Requests Mirror (SDMACORE_EVENTS)	32	R	0000_0000h	66.22.5/ 4256
63FB_0006	Current Channel Priority (SDMACORE_CCPRI)	32	R	0000_0000h	66.22.6/ 4257
63FB_0007	Next Channel Priority (SDMACORE_NCPRI)	32	R	0000_0000h	66.22.7/ 4257

Table continues on the next page...

SDMACORE_CCPTR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–0 CCPTR	Contains the start address of the context data for the current channel: Its value is *CONTEXT_BASE* + 24* *CCR* or *CONTEXT_BASE* + 32* *CCR* where CONTEXT_BASE = 0x0800. The value 24 or 32 is selected according to the programmed channel scratch RAM size in the register shown in Channel 0 Boot Address (SDMAARM_CHN0ADDR) .

66.22.3 Current Channel Register (SDMACORE_CCR)

Address: SDMACORE_CCR is 63FB_0000h base + 3h offset = 63FB_0003h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE_NCR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value zero. Reserved
4–0 NCR	Contains the number of the pending channel that the scheduler has selected to run next.

66.22.5 External DMA Requests Mirror (SDMACORE_EVENTS)

This register is very useful in the case of DMA requests that are active when a peripheral FIFO level is above the programmed watermark. The activation of the DMA request (rising edge) is detected by the SDMA logic and it can enable one or several channels. One of the channels accesses the peripheral and reads or writes a number of data that matches the watermark level (for example, if the watermark is four words, the channel reads or writes four words). If the channel is effectively executed long after the DMA request was received, reading or writing the watermark number of data may not be sufficient to reset the DMA request (for example, if the FIFO watermark is four and at the channel execution it already contains nine pieces of data). This means no new rising edge may be detected by the SDMA, although there still remains transfers to perform. Therefore, if the channel were terminated at that time, it would not be restarted, causing potential overrun or underrun of the peripheral.The proposed mechanism is for the channel to check this register after it has performed the "watermark" number of accesses to the peripheral. If the bit for the DMA request that triggers this channel is set, it means there is still another watermark number of data to transfer. This goes on until the bit is cleared. The same script can be used for multiple channels that require this behavior. The script can determine its channel number from the CCR register and infer the corresponding DMA request bit to check. It needs a reference table that is coherent with the request-channel matrix that the ARM platform programmed.

Address: SDMACORE_EVENTS is 63FB_0000h base + 5h offset = 63FB_0005h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

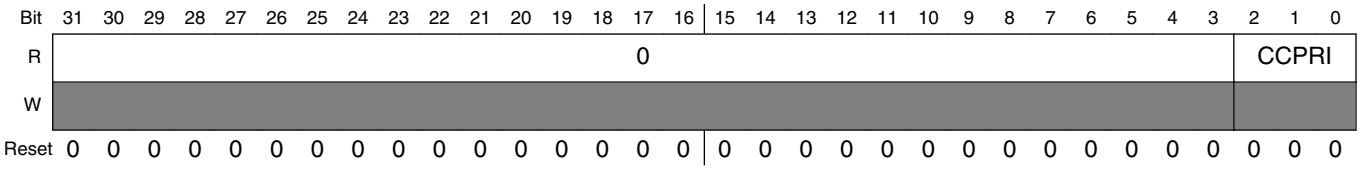
SDMACORE_EVENTS field descriptions

Field	Description
31–0 EVENTS	Reflects the status of the SDMA's external DMA requests. It is meant to allow any channel to monitor the states of these SDMA inputs. This register displays EVENTS 0-31. The EVENTS2 register displays events 32-47.

66.22.6 Current Channel Priority (SDMACORE_CCPRI)

Address: SDMACORE_CCPRI is 63FB_0000h base + 6h offset = 63FB_0006h

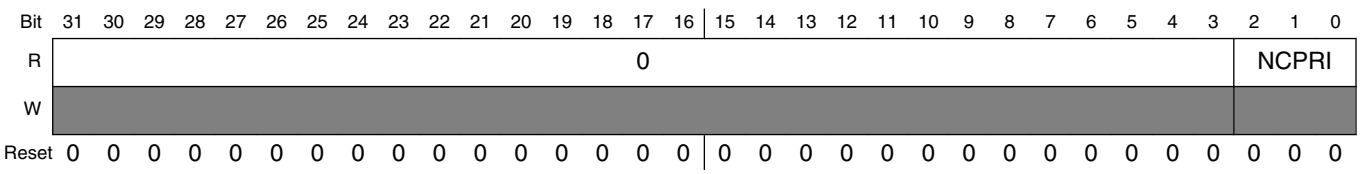


SDMACORE_CCPRI field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2–0 CCPRI	Contains the 3-bit priority of the channel whose context is installed. It is 0 when no channel is running. **NOTE:** 1-7 current channel priority 0 no running channel

66.22.7 Next Channel Priority (SDMACORE_NCPRI)

Address: SDMACORE_NCPRI is 63FB_0000h base + 7h offset = 63FB_0007h

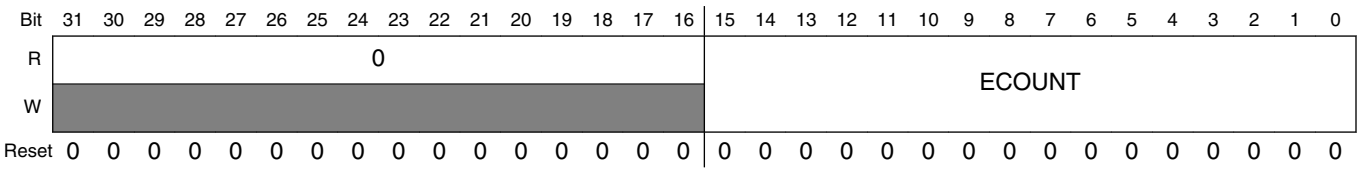


SDMACORE_NCPRI field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2–0 NCPRI	Contains the 3-bit priority of the channel the scheduler has selected to run next. It is 0 when no other channel is pending.

66.22.8 OnCE Event Cell Counter (SDMACORE_ECOUNT)

Address: SDMACORE_ECOUNT is 63FB_0000h base + 9h offset = 63FB_0009h

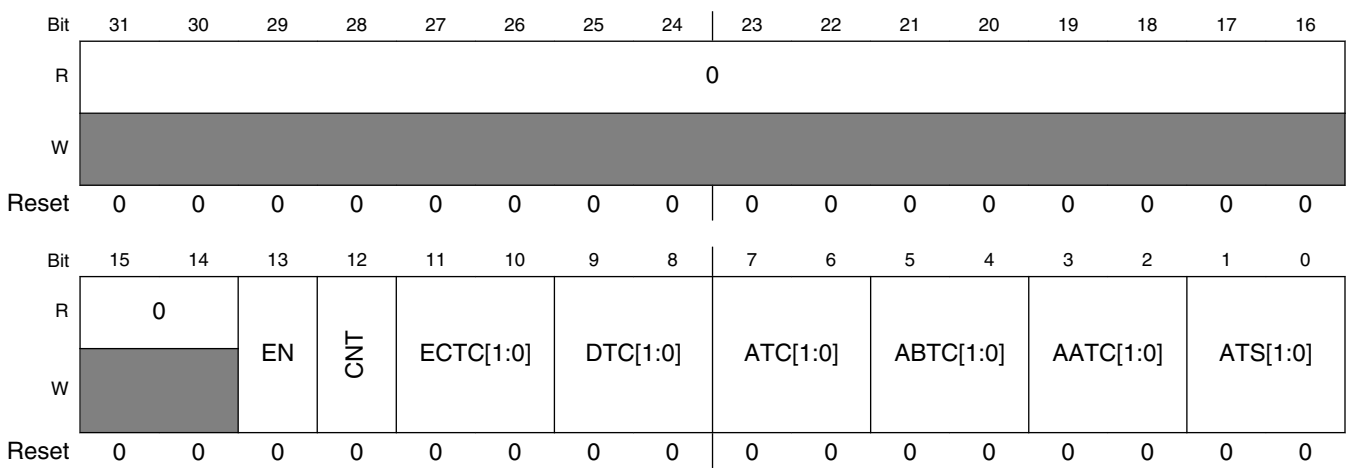


SDMACORE_ECOUNT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–0 ECOUNT	The event cell counter contains the number of times minus one that an event detection must occur before generating a debug request. • This register should be written before any attempt to use the event detection counter during an event detection process. • The counter is cleared on a JTAG reset.

66.22.9 OnCE Event Cell Control Register (SDMACORE_ECTL)

Address: SDMACORE_ECTL is 63FB_0000h base + Ah offset = 63FB_000Ah



SDMACORE_ECTL field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value zero. Reserved
13 EN	Event Cell Enable. If the EN bit is set, the event cell is allowed to generate debug requests (the cell is awakened). If it is cleared, the event detection unit is disabled and no hardware breakpoint is generated, but matching conditions are still reflected on the emulation pin.

Table continues on the next page...

SDMACORE_ECTL field descriptions (continued)

Field	Description
	0 Cell is disabled. 1 Cell is enabled.
12 CNT	Event Counter Enable. The event counter enable bit determines if the cell counter is used during the event detection. In order to use the event counter during an event detection process, the event cell counter register should be loaded with a value equal to the number of times minus one that an event occurs before a debug request is sent. After every event detection, the counter is decreased. When the counter reaches the value 0, the event detection cell sends a debug request to the core. The event counter register should be written and the EN bit should be set before each new event detection process uses the event counter. 0 Counter is disabled. 1 Counter is enabled.
11–10 ECTC[1:0]	The event cell trigger condition bits select the combination of address and data matching conditions that generate the final address/data condition. During program execution, if this event cell trigger condition goes to 1, a debug request is sent to the SDMA. The EN bit must be set to enable the debug request generation. 00 address ONLY 01 data ONLY 10 address AND data 11 address OR data
9–8 DTC[1:0]	The data trigger condition bits define when data is considered matching after comparison with the data register of the event detection unit. The operations are performed on unsigned values. 00 equal 01 not equal 10 greater than 11 less than
7–6 ATC[1:0]	The address trigger condition bits select how the two address conditions (addressA and addressB) are combined to define the global address matching condition. The supported combinations are described, as follows. 00 addressA ONLY 01 addrA AND addrB 10 addrA OR addrB 11 reserved
5–4 ABTC[1:0]	The Address B Trigger Condition (ABTC) controls the operations performed by address comparator B. All operations are performed on unsigned values. This comparator B outputs the addressB condition. 00 equal 01 not equal 10 greater than 11 less than
3–2 AATC[1:0]	The Address A Trigger Condition (AATC) controls the operations performed by address comparator A. All operations are performed on unsigned values. This comparator A outputs the addressA condition. 00 equal 01 not equal

Table continues on the next page...

SDMACORE_ECTL field descriptions (continued)

Field	Description
	10 greater than 11 less than
1–0 ATS[1:0]	The access type select bits define the memory access type required on the SDMA memory bus. 00 read ONLY 01 write ONLY 10 read or write 11 -

66.22.10 OnCE Event Address Register A (SDMACORE_EAA)

Address: SDMACORE_EAA is 63FB_0000h base + Bh offset = 63FB_000Bh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

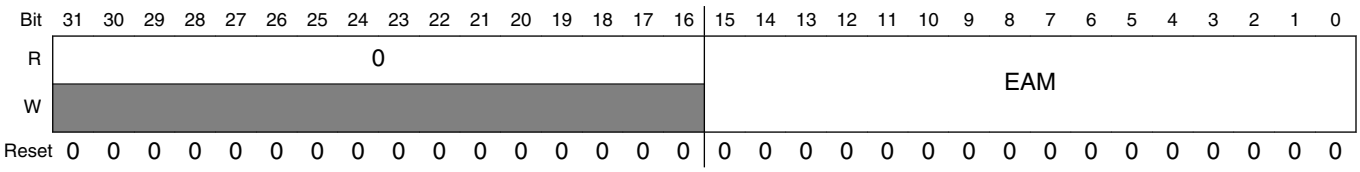
SDMACORE_EAB field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–0 EAB	Event Cell Address Register B computes an address B condition. It is cleared on a JTAG reset.

66.22.12 OnCE Event Cell Address Mask (SDMACORE_EAM)

Address: SDMACORE_EAM is 63FB_0000h base + Dh offset = 63FB_000Dh

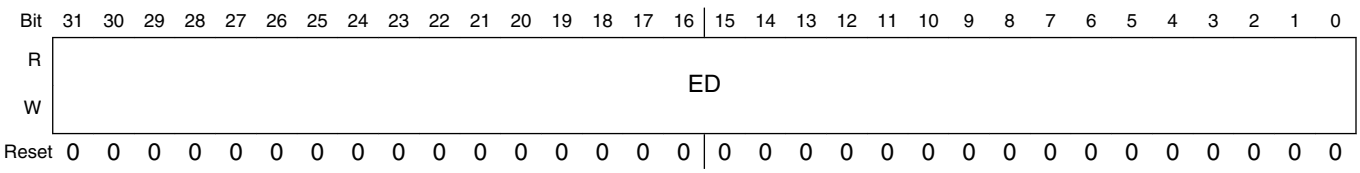


SDMACORE_EAM field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–0 EAM	The Event Cell Address Mask contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before performing the address comparison. **NOTE:** There is a common address mask value for both address comparators. If bit *i* of this register is set, then bit *i* of the address value latched from the memory bus does not influence the result of the address comparison. The register is cleared on a JTAG reset.

66.22.13 OnCE Event Cell Data Register (SDMACORE_ED)

Address: SDMACORE_ED is 63FB_0000h base + Eh offset = 63FB_000Eh

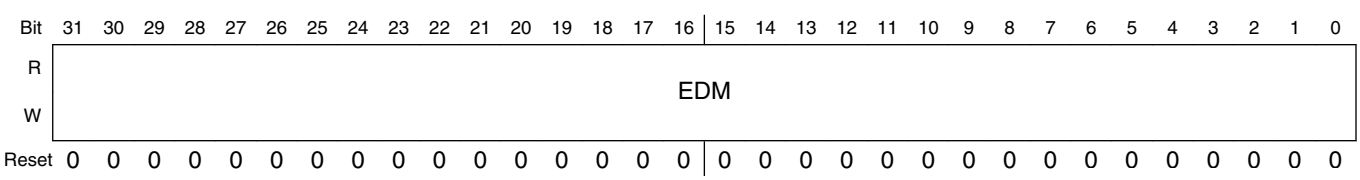


SDMACORE_ED field descriptions

Field	Description
31–0 ED	The event cell data register contains a user defined data value. This data value is an input for the data comparator which generates the data condition. It is cleared on a JTAG reset.

66.22.14 OnCE Event Cell Data Mask (SDMACORE_EDM)

Address: SDMACORE_EDM is 63FB_0000h base + Fh offset = 63FB_000Fh



SDMACORE_EDM field descriptions

Field	Description
31–0 EDM	The event cell data mask register contains the user-defined data mask value. • This mask is applied to the data value latched from the memory bus before performing the data comparison. • Setting bit *i* of the event cell data mask register means that bit *i* of the data value latched from the address bus does not influence the result of the data comparison. • The data mask is cleared on a JTAG reset.

66.22.15 OnCE Real-Time Buffer (SDMACORE_RTB)

Address: SDMACORE_RTB is 63FB_0000h base + 18h offset = 63FB_0018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE_RTB field descriptions

Field	Description
31–0 RTB	The Real Time Buffer register stores and retrieves run time information without putting the SDMA in debug mode. Writing to that register triggers a pulse on a specific real-time debug pin whose connection depends on the chip implementation. The RTB value can be accessed by the OnCE under ARM platform or JTAG control using the rbuffer command.

66.22.16 OnCE Trace Buffer (SDMACORE_TB)

Address: SDMACORE_TB is 63FB_0000h base + 19h offset = 63FB_0019h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0			TBF	TADDR[-2:2]

SDMACORE_OSTAT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–12 PST[3:0]	The Processor Status bits reflect the state of the SDMA RISC engine. • The "Program" state is the usual instruction execution cycle. • The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel-switching instructions). • The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. • The "Debug" state means the SDMA is in debug mode. • The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf).

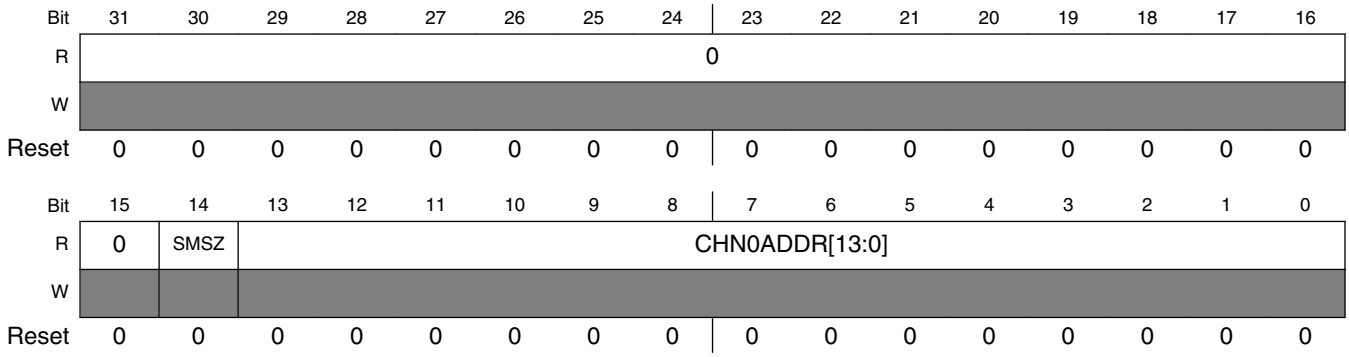
Table continues on the next page...

SDMACORE_OSTAT field descriptions (continued)

Field	Description
	• In "Sleep" modes, no script is running (this is the RISC engine idle state). The "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). • The "in Sleep" states are the same as above except they do not have any corresponding channel. They are used when entering debug mode after reset; the reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. 0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow Loop Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Restore
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an `rbuffer` command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	This flag is raised when the OnCE is controlled from the ARM platform peripheral interface. 0 JTAG interface controls the OnCE. 1 ARM platform peripheral interface controls the OnCE.
6–3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2–0 ECDR[2:0]	Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addressA, addressB, and data conditions; the value of those fields is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one EDR bit is set; the meaning of the encoding is as follows: 0 1 matched addressA condition 1 1 matched addressB condition 2 1 matched data condition

66.22.18 Channel 0 Boot Address (SDMACORE_MCHN0ADDR)

Address: SDMACORE_MCHN0ADDR is 63FB_0000h base + 1Ch offset = 63FB_001Ch

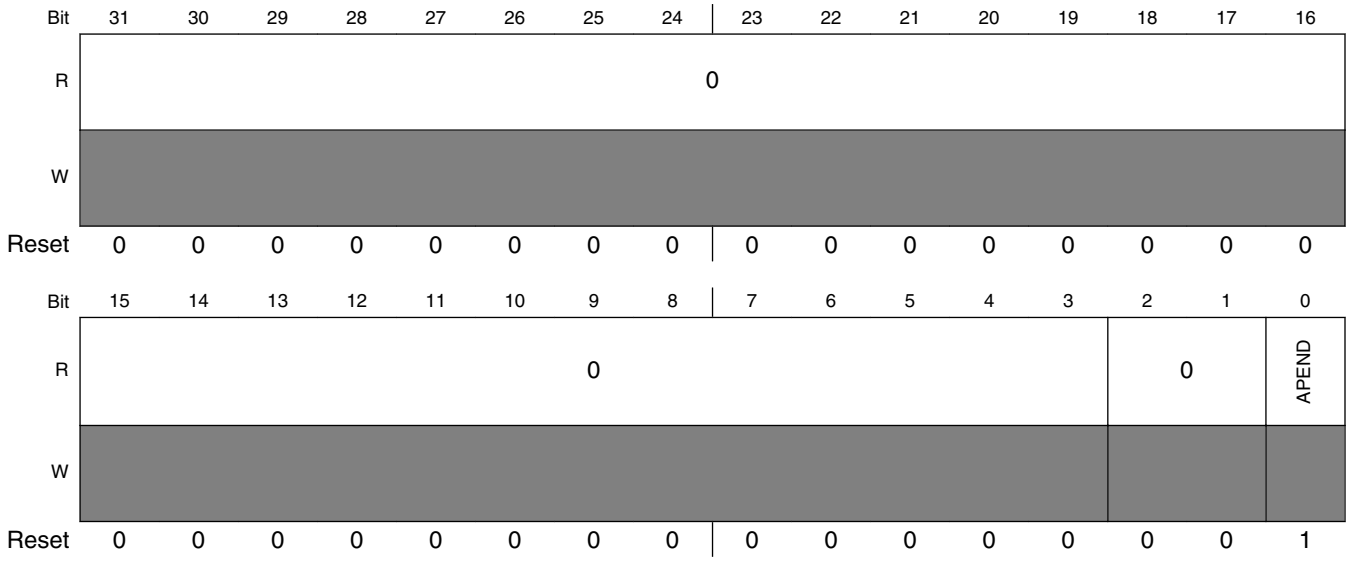


SDMACORE_MCHN0ADDR field descriptions

Field	Description
31–15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context, which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism. 0 24 words per context 1 32 words per context
13–0 CHN0ADDR[13:0]	Contains the address of the channel 0 routine programmed by the ARM platform; it is loaded into a general register at the very start of the boot and the SDMA jumps to the address it contains. By default, it points to the standard boot routine in ROM.

66.22.19 ENDIAN Status Register (SDMACORE_ENDIANNESS)

Address: SDMACORE_ENDIANNESS is 63FB_0000h base + 1Dh offset = 63FB_001Dh

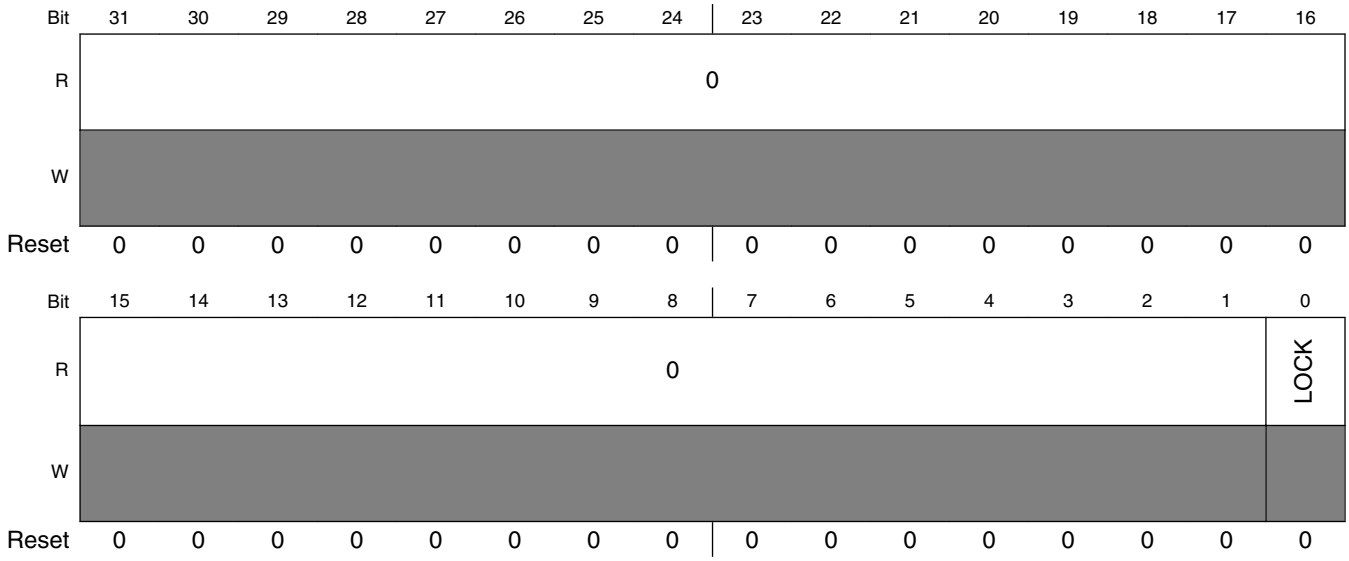


SDMACORE_ENDIANNESS field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 APEND	APEND indicates the endian mode of the Peripheral and Burst DMA interfaces. This bit is tied to logic '1' indicating little-endian mode. 0 - ARM platform is in big-endian mode 1 - ARM platform is in little-endian mode

66.22.20 Lock Status Register (SDMACORE_SDMA_LOCK)

Address: SDMACORE_SDMA_LOCK is 63FB_0000h base + 1Eh offset = 63FB_001Eh

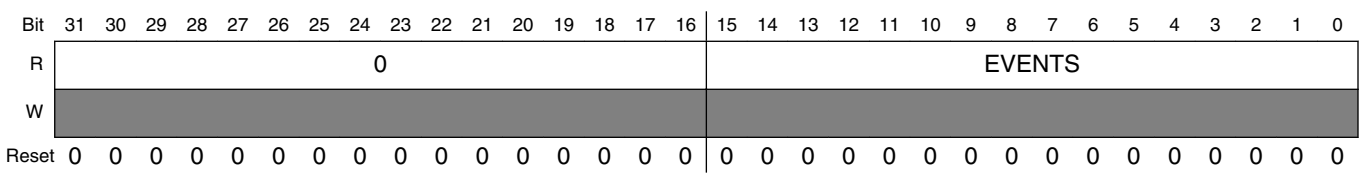


SDMACORE_SDMA_LOCK field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 LOCK	The LOCK bit reports the value of the LOCK bit in the SDMA_LOCK status register. SDMA software may use this value to determine if certain operations such as loading of new scripts is allowed. 0 - LOCK bit clear 1 - LOCK bit set

66.22.21 External DMA Requests Mirror #2 (SDMACORE_EVENTS2)

Address: SDMACORE_EVENTS2 is 63FB_0000h base + 1Fh offset = 63FB_001Fh



SDMACORE_EVENTS2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

SDMACORE_EVENTS2 field descriptions (continued)

Field	Description
15–0 EVENTS	Reflects the status of the SDMA's external DMA requests. It is meant to allow any channel to monitor the states of these SDMA inputs. This register displays EVENTS 32-47. The separate EVENTS register displays events 0-31.

66.23 SDMA Peripheral Registers

Refer to the respective peripherals' chapters more information.

Chapter 67
System JTAG Controller (SJC)

67.1 Introduction

The System JTAG Controller (SJC) provides debug and test control with the maximum security. The test access port (TAP) is designed to support features compatible with the IEEE Standard 1149.1 v2001 (JTAG).

The figure below shows an overview of the JTAG architecture.

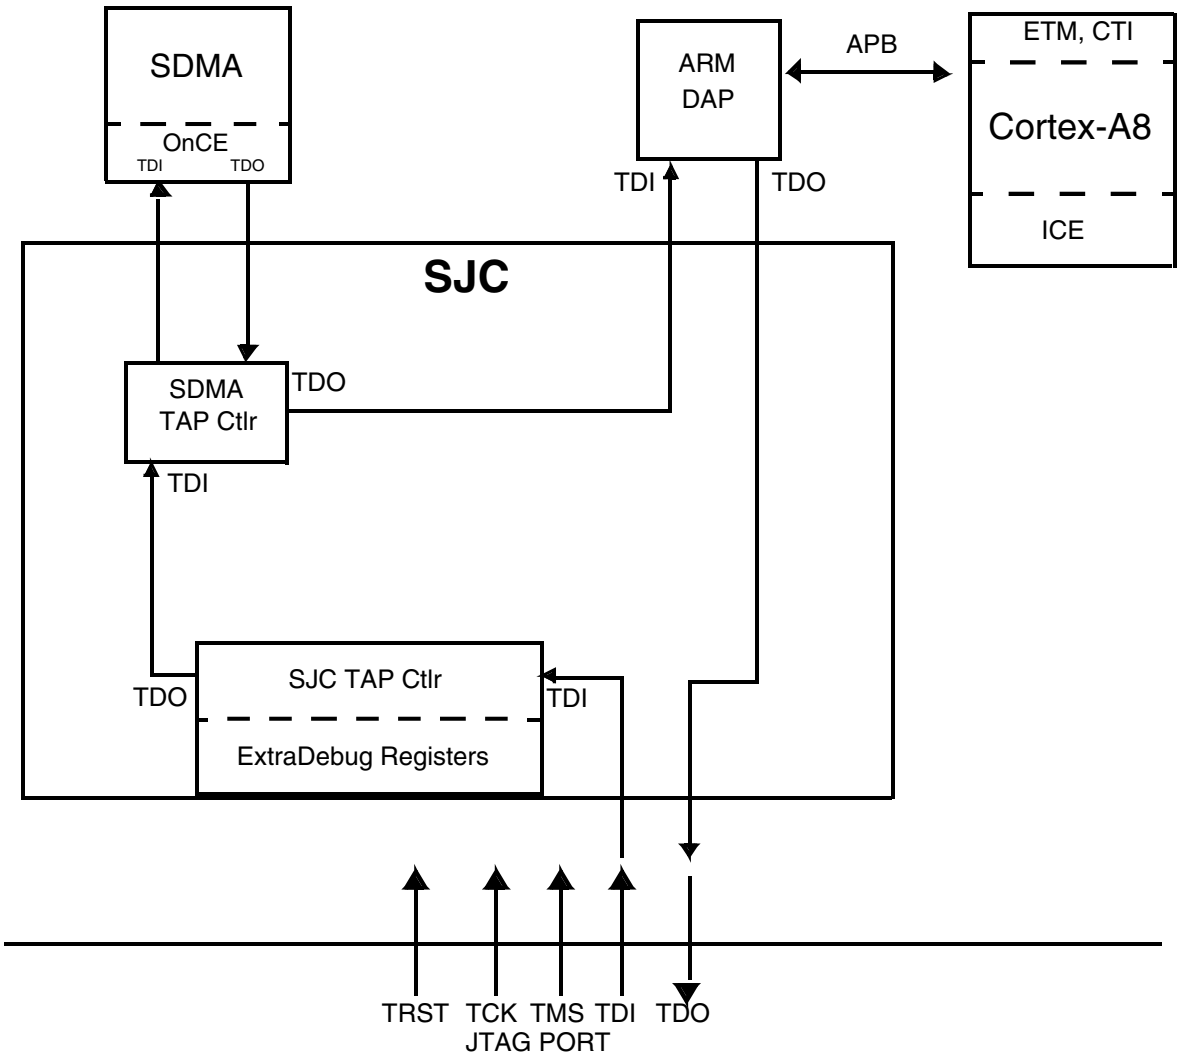


Figure 67-1. System JTAG Controller (SJC) Block Diagram

67.1.1 Overview

The System JTAG Controller (SJC) provides the following capabilities:

- JTAG IEEE1149.1 mandatory instructions, see EXTEST Instruction, SAMPLE/ PRELOAD Instruction, and BYPASS Instruction.
- JTAG IEEE1149.1 optional instructions, see ID_CODE Instruction (IDCODE), and HIGHZ Instruction.
- JTAG IEEE P1149.1 (standard JTAG) interface to off-chip test and development equipment including an SJC-only mode for true IEEE 1149.1 compliance, used primarily for board-level implementation of boundary scan.

- Debug-related control and status, such as putting selected cores into reset and/or debug mode and the ability to monitor individual core status signals via JTAG.
- Provides means for accessing each OnCE/ICE TAP controller independently to control a target system (see Modes of Operation).
- ExtraDebug logic (see ENABLE_ExtraDebug Instruction).
- The maximum clock speed of the SJC is one-eight of the lowest frequency of the accessed OnCE/ICE. For example in normal operation (no core in low-power mode), this frequency is one-eight of the SDMA frequency if this core is present in the TDI-TDO chain (serially connected with other cores or standalone). The user must also consider the 25 MHz frequency limitation on the CE bus.
- Core compliant modes to support standalone core debuggers (see Modes of Operation).
- Multi-cores daisy chained mode (default one) to support multi-core debuggers (see Modes of Operation).

Detailed information about the SJC is provided in the Security Reference Manual. Contact your Freescale representative for information about obtaining this document.

67.2 Modes of Operation

The SJC modes are controlled through both the TAP select register (SJC_TSR) and the "sjc_mod" input port.

The "sjc_mod" port (typically connected to pad of the same name: SJC_MOD) selects between two possible topologies of TAP connections, as seen at SoC level:

- Negating it (this should be the default state) selects all the TAPs (SJC, SDMA and DAP and ARM/ETM) to be connected in the TDI-TDO chain, which is referred to as "daisy chain" mode, throughout this chapter.
- Asserting it only selects the SJC TAP to be connected in the TDI-TDO chain.

IEEE1149.1 standard features are enabled by configuring the SJC input pin: SJC_MOD. Refer to the following table for SJC_MOD settings details:

Table 67-1. SJC Modes

SJC_MOD	Name	Description
0	Daisy chain ALL	For common SW debug (High speed and production)
1	SJC only	IEEE 1149.1 JTAG compliant mode

The following figure shows the SJC mode selection flow. The numbers shown in parenthesis below each block name indicates the TAP's IR length.

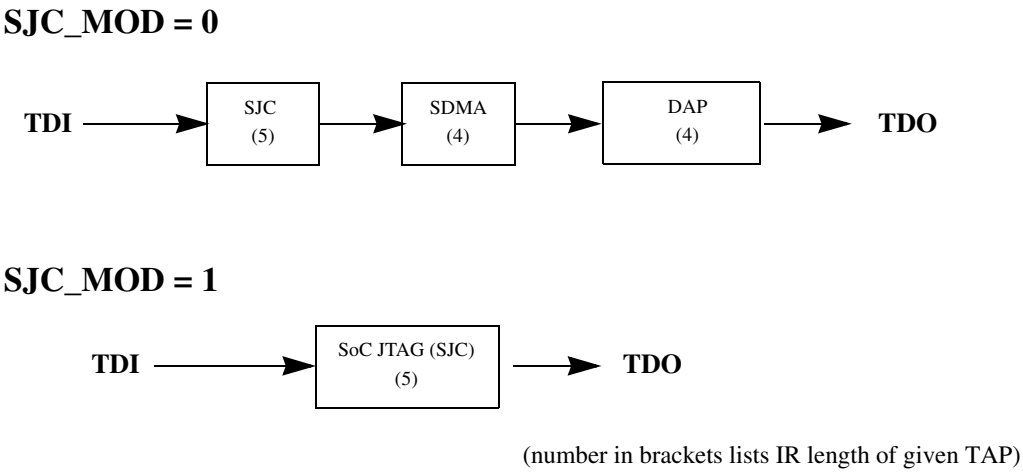

Figure 67-2. SJC Mode Selection Using sjc_mod Pin Sampling

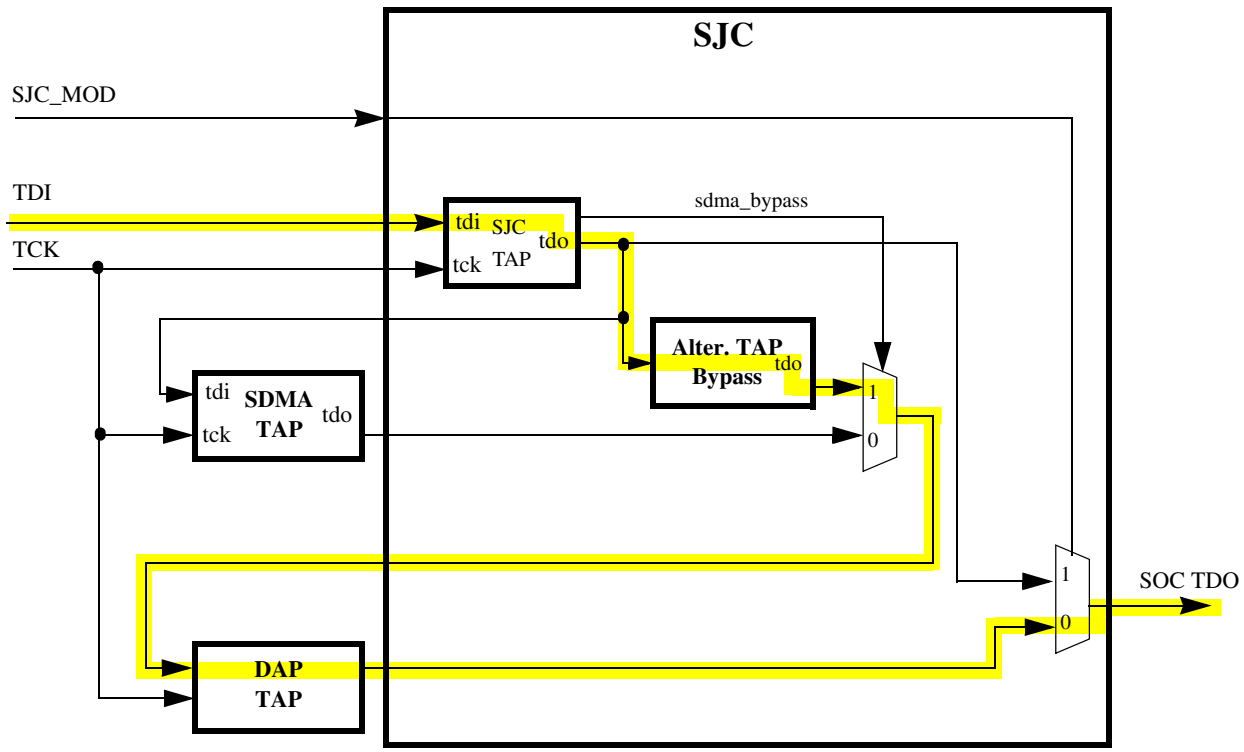
The Connect SDMA bit inside TAP select register controls the SDMA TAP bypass.

- When negated (should be the default state), the SDMA TAP is bypassed with a single D-FF (Flip-flop) during Shift-Dr path
- When asserted SDMA TAP is connected inside the chain
- When taking the SDMA into bypass or out of bypass (by writing to tapsel reg), additional cycle with TMS '0' should be given

The TAP selection block (TSB) provides a simple method of integrating various pieces of IP that have embedded TAPs.

- Provides a way to connect up multiple TAPs within a single SoC
- Identify the SJC TAP as the master TAP which controls the boundary chain (for IEEE 1149.1 standard compliance)
- Follow the state of SJC TAP, and when the Test-Logic-Reset (TLR) state is reached, reset all TAPs

The figure below shows the TAP Selection Block and SOC TAP Chain Scheme.



Note: The default daisy chain connectivity is highlighted in yellow

Figure 67-3. TAP Selection Block and SoC TAP Chain Scheme

NOTE

It is the responsibility of the user to ensure that in any configuration of the TAP controllers chosen, all of the TAPs in the chain comply with the demands of TCK clock frequency as well as the required ratio between TCK clock frequency and that of the core's to which the TAP refers.

67.3 TAP Selection Block (TSB)

As described in Modes of Operation, the SJC can access cores in different modes selected through a TSB.

67.3.1 Select Mode Using Software

Conceptually, the SJC_TSR is a data register which is accessed through Access TSR IR instruction of SJC TAP.

The following figure shows the process of using reserved IR to access the SJC_TSR.

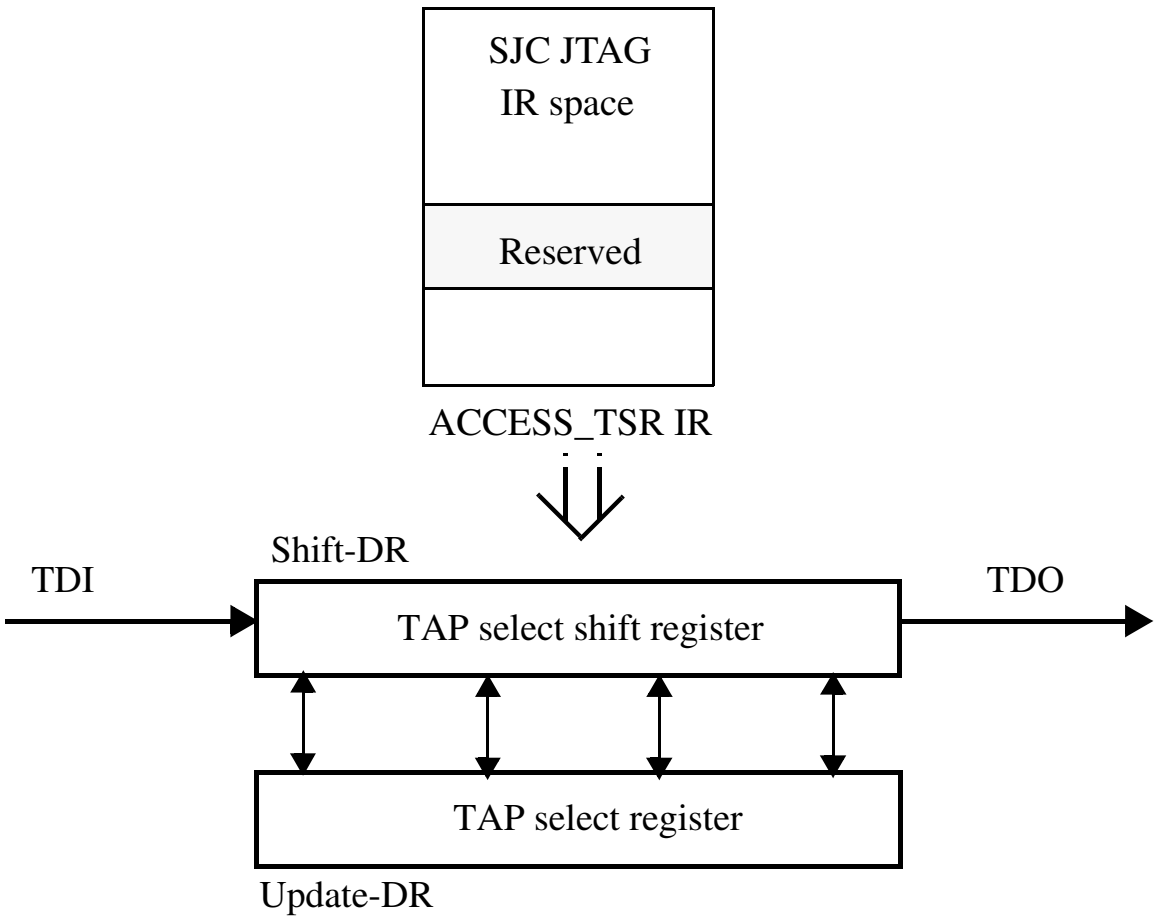


Figure 67-4. Using Reserved IR to Access the TAP Select Register (SJC_TSR)

The SJC_TSR can only be changed during the update-DR state of the TSB JTAG state machine. This is necessary to prevent a TAP that is being selected from losing synchronization with the TSB state machine when the TSB state machine returns to run-test-idle. Therefore, an associated shift register for the SJC_TSR is loaded into the SJC_TSR during the update-DR state (see the figure above). The shift register must also capture the state of the SJC_TSR when in the Capture-DR state for visibility of the contents of the SJC_TSR.

67.4 External Signal Description

67.4.1 External Signal Overview

The SJC provides test and debug control with a minimum number of contacts.

Figure 67-5 shows SJC connections to external contacts and other chip blocks.

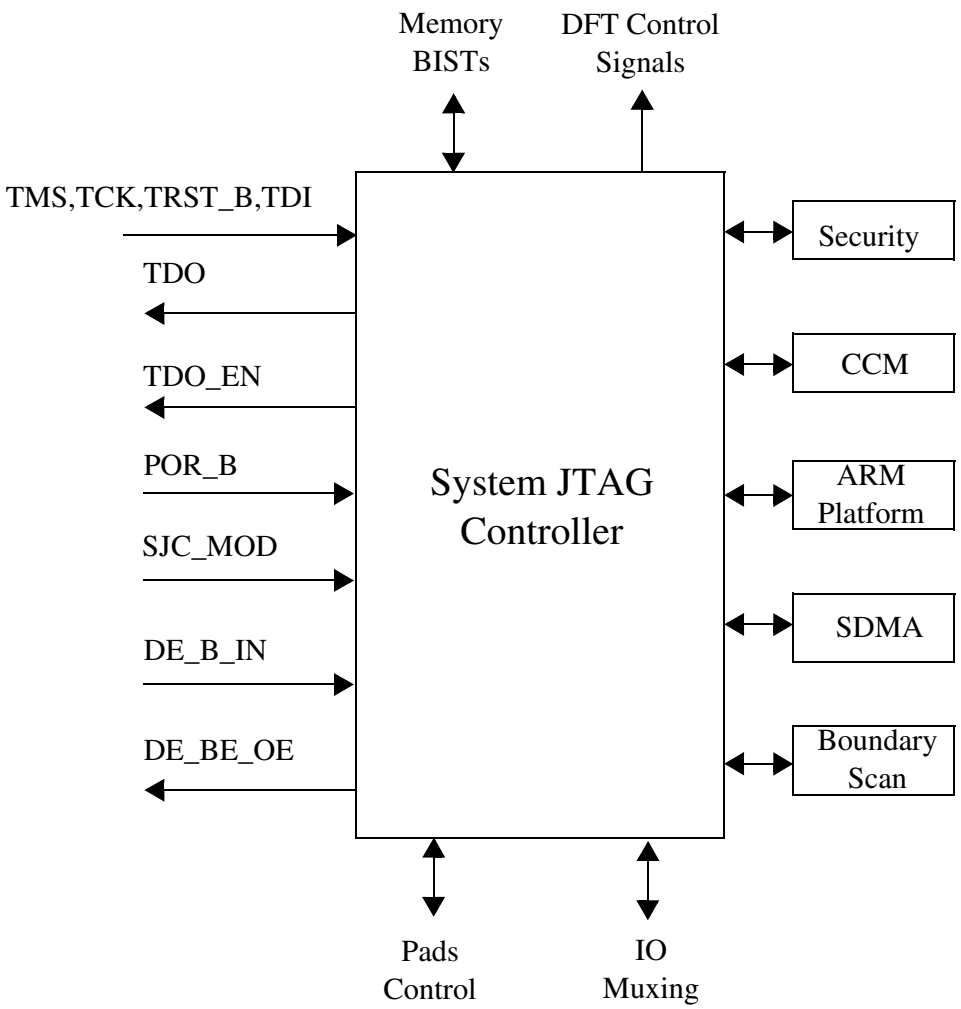

Figure 67-5. SJC Connections

SJC external connections are described along with the signal properties in the table below.

Table 67-2. SJC Signal Properties

Signal	Function	Reset State	Pull up
POR_B	POR reset input. This input can arrive from either pad of IC or from IC's internal logic, for example, Clock Controller.	0	-

Table continues on the next page...

Table 67-2. SJC Signal Properties (continued)

Signal	Function	Reset State	Pull up
TCK	Test Clock (TCK). This is used to synchronize the test logic and includes an internal pull-up resistor	0	-
TDI	Test Data Input (TDI). Serial test instruction and data are received through the test data input (TDI) pin. TDI is sampled on the rising edge of TCK and includes an internal pullup resistor	1	Active
TDO	Test Data Output (TDO). The serial output for test instructions and data. TDO is tri-statable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK	-	-
TDO_EN	Test Data Output Enable (TDO_EN). This signal enables tri-state buffer which output is connected to TDO pad and input connected to IC internal SJC generated TDO signal. Whenever TDO_EN is negated TDO is tri-stated.	-	-
TMS	Test Mode Select (TMS). This is used to sequence the test controller's state machine. TMS is sampled on the rising edge of TCK and includes an internal pullup resistor	1	Active
TRST_B	Test Reset (TRST). This is used to asynchronously initialize the test controller. The TRST pin has an internal pullup resistor	1	Active
SJC_MOD	SJC mode selection. This pin is sampled at TRST reset to determine two possible modes for the TAP connection configuration.	11	Active
DE_IN_B	SoC debug request/acknowledge pin. The DE_IN_B pin is used to propagate an external debug request event to the core(s). This functionality must be enabled first, by set of DE_to_ARM / DE_to_SDMA bits in SJC's DCR register. It is SoC implementation dependent, whether this pin can also be used to reflect the debug acknowledge event back from the cores (in the case where an Open-Drain scheme is used externally).	1	Active

67.4.2 TAP Controller

The TAP controller is responsible for interpreting the sequence of logical values on the TMS signal. It is a synchronous state machine that controls the operation of the JTAG logic. The value shown adjacent to each arc represents the value of the TMS signal sampled on the rising edge of TCK signal. For a description of the TAP controller states, refer to the appropriate IEEE 1149.1 document.

The state machine is shown in the following figure.

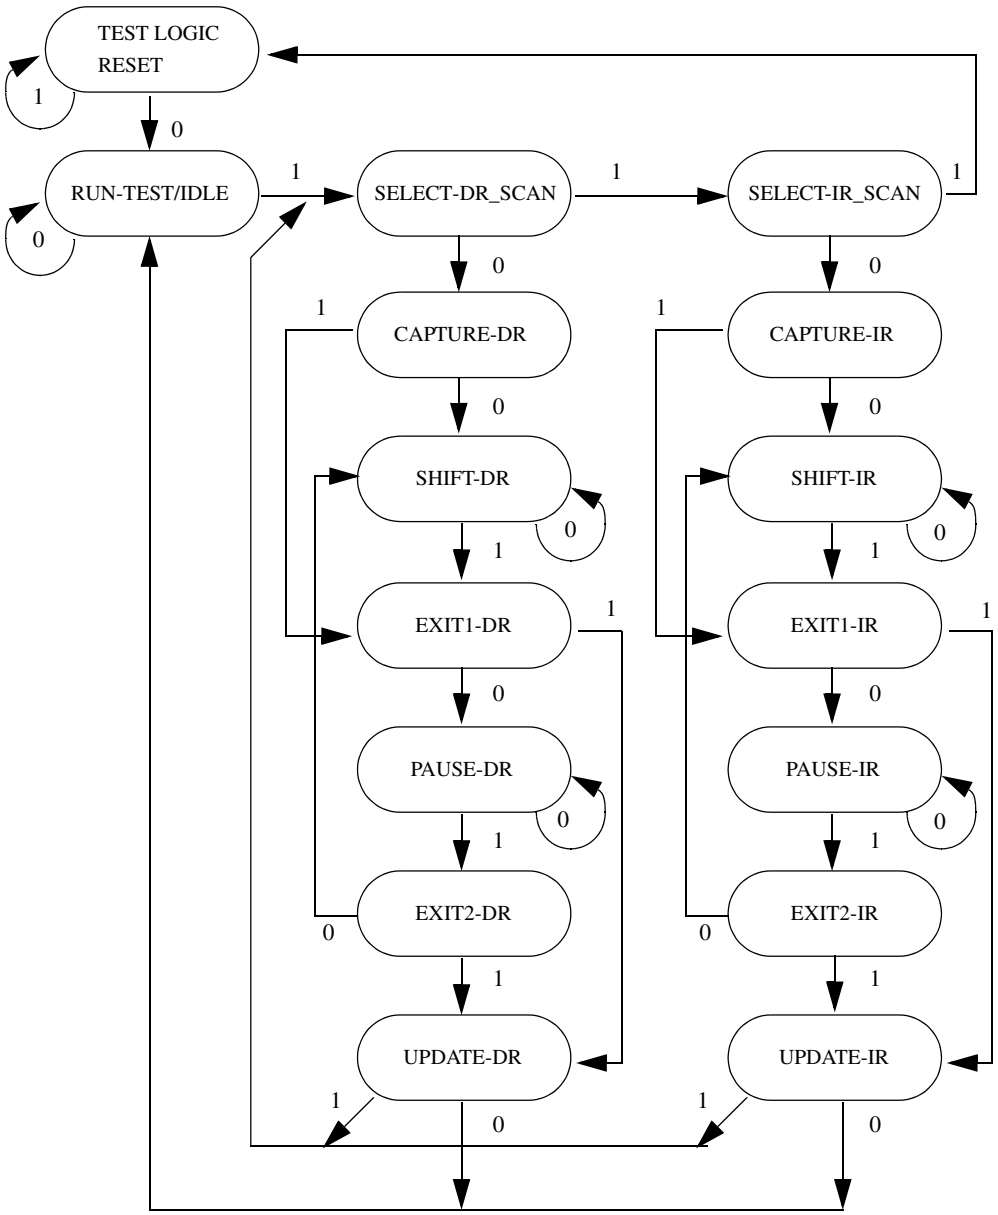

Figure 67-6. TAP Controller State Machine

The change of the JTAG state machine occurs on the rising edge of TCK. TMS and TDI change on the falling edge of TCK. TDO also changes on the falling edge of TCK following entry into the Shift_DR or Shift_IR states (TDO_EN is the enable of the tristate buffer driving the TDO output).

The figure below shows the timings of the SJC signals.

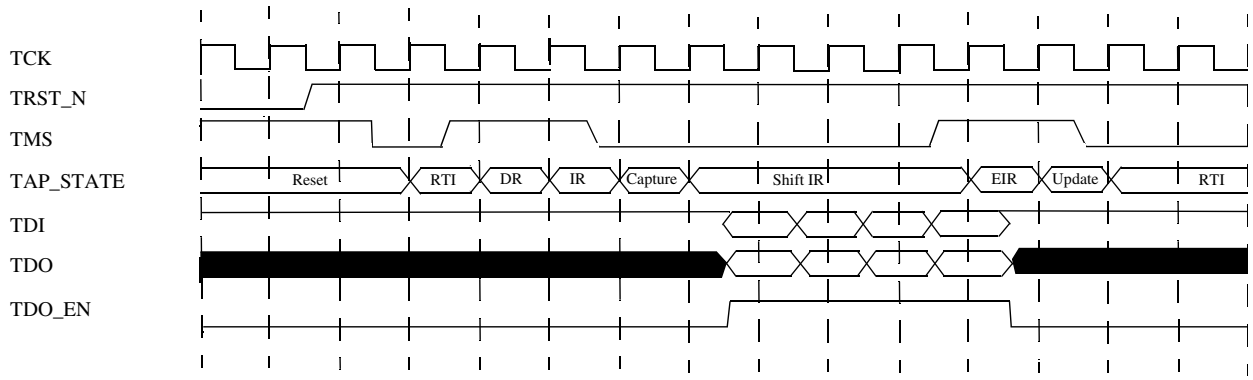

Figure 67-7. SJC Signals Timing Diagram

67.4.3 Accessing ExtraDebug Registers

Accessed through the Select-DR-Scan path, the ExtraDebug shift register consists of 38 bits (maximum) comprising a 32-bit data field (max length, see extradebug register description), a 5 bit address field and read/write bit.

The write actually takes place when the JTAG TAP controller enters the Update-DR state. On a read, the data field is ignored (the user should shift only 5 times to enter Read=1 and the address), the read takes place on the next path through DR at the Capture-DR state, the data is shifted-out during the Shift-DR state.

On the second path for a read access, simultaneous write access is not supported: command converter software shifts in zeros so the TAP decodes a write to the CSR (read-only register) which does not have any effect on the circuit.

The number of shift depends on the width of the accessed register as explained in the following diagrams.

First a write access (one path through Select-DR-Scan):

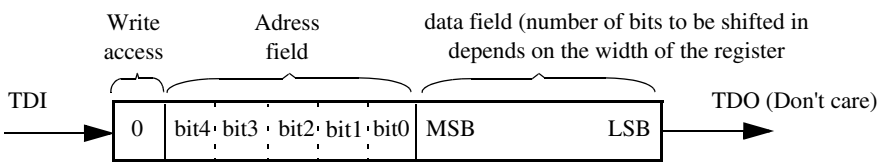

Figure 67-8. TDI/TDO on write access

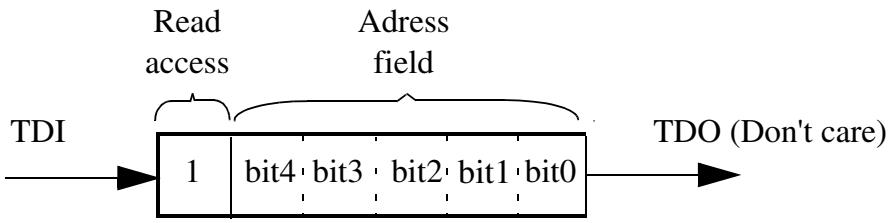
Then a read access (requires two paths through Jtag DR Scan path):

First path



Second path

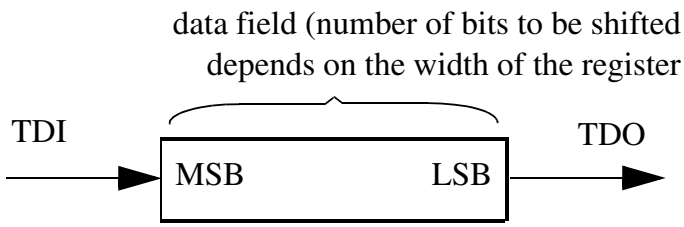


Figure 67-9. TDI/TDO on Read Access

For example, write value 0b1010_1100 to Debug Control Register (address = 0b00110).

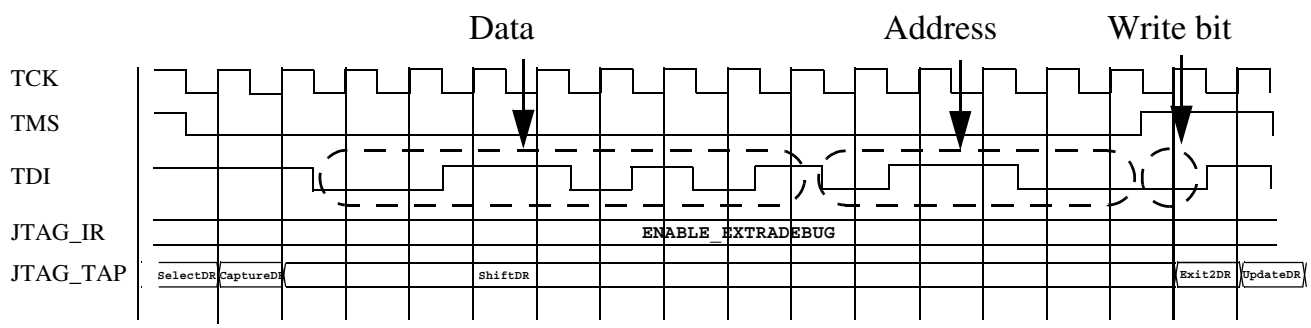

Figure 67-10. Example: Write Access to DCR

The SJC registers have different levels of security:

- Secured- accessible only in mode 2 (supposed correct response entered), mode 3 and mode 4.
- Unsecured- accessible in all modes

The level of security of each register is indicated in its name or description, in "Programmable Registers" section.

A single DE_B pin is dedicated for debug request input/output in bidirectional open drain functionality (including an internal pull-up device).

The main function of the embedded cross trigger is to pass debug events from one core to another. For example this can be programmed to pass debug request from one block as debug request to ARM so that ARM enters debug mode when the debug request is generated. ECT system_debug is connected to SJC and can be programmed for observability on $\overline{DE}$ pad.

Bits 6:4 in DCR register serve as mask bits, controlling the propagation of external debug request to each recipients (ARM Platform, SDMA).

The bits 2:0 define the propagation enable of IR debug request to recipient cores.

Figure 67-11 shows the $\overline{DE}$ Pin Select Logic.

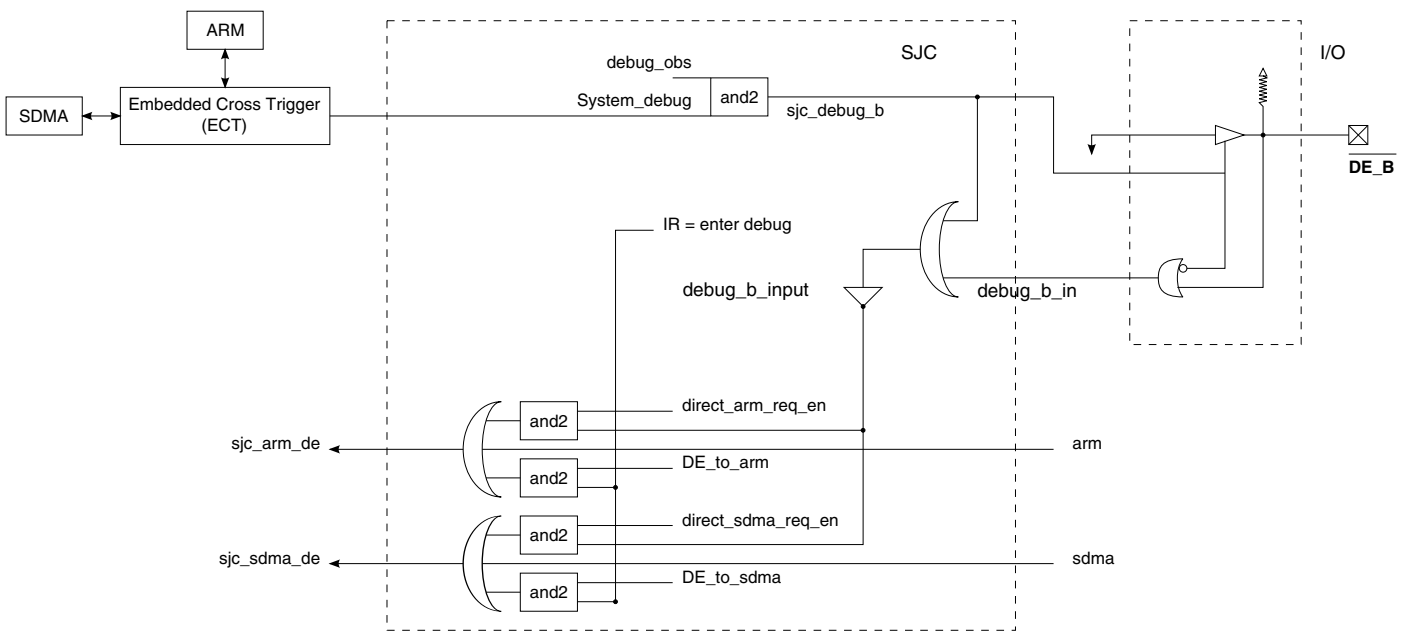

Figure 67-11. $\overline{DE}$ Pin Select Logic

For security reasons, bits for output and input propagation control are at their negated values after reset. A user cannot put the cores in debug mode through $\overline{DE}$ without any Jtag access.

The configuration after reset prevents propagation of debug requests / acknowledges to or from the cores.

67.5 Boundary Scan Register (BSR)

The Boundary Scan Register (BSR) in the JTAG implementation contains bits for all device signal and clock pins and associated control signals. All SoC bidirectional pins have a single register bit in the boundary scan register for pin data, and are controlled by an associated control bit in the boundary scan register.

67.6 SoC JTAG Instruction Register (SJIR)

The SoC JTAG Instruction register is 5 bits wide.

Table 67-3. SoC JTAG Instruction Register (SJIR)

Code					SJC IR
B4	B3	B2	B1	B0	
0	0	0	0	0	IDCODE
0	0	0	0	1	SAMPLE/PRELOAD

The instruction register is reset to 0b00000 in the test-logic-reset controller state which is equivalent to the IDCODE instruction.

During the capture-IR controller state, the parallel inputs to the instruction register are loaded with the code 01 in the least significant bits as required by the standard; the most significant bits are loaded with the values 00, leading to a capture value of 0b00001

67.6.1 ID_CODE Instruction (IDCODE)

Selects the ID register, and the system logic controls the I/O pins. This instruction is provided as a public instruction to allow the manufacturer, part number and version of a component to be determined through the TAP.

The table below shows the ID register configuration.

Table 67-4. ID Configuration Register (IDCODE)

IDCODE				ID Configuration Register												
	BIT 31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	BIT 16
	Version Information[3:0]				Part Number (Bits 27-16)											
TYPE	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
RESET	0	0	0	0	x	x	x	x	x	x	x	x	x	x	x	x
Note:																
	BIT 15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	BIT 0
	Part Number (Bits 15-12)				Manufacturer Identity											1
TYPE	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
RESET	x	x	x	x	0	0	0	0	0	0	0	1	1	1	0	1
Note:																

Table 67-5. ID Configuration Register Description (IDCODE)

Field	Description
31-28 Version Information	IC/SoC Version information number. Initial value: '0000' This number is subject to changes, for new IC/SoC (System On A Chip) revision releases.
27-12 Part Number	Customer Part Number The 16-bit Part Number value is unique for every Freescale's SoC / IC. See "System Configuration" chapter for exact register value for a specific SoC.
11-1 Manufacturer Identity	Manufacturer Identity Freescale's Manufacturer Identity code. Bits [11:1] - 00000001110
0	Tied to logic 1.

One application of the ID register is to distinguish the manufacturer(s) of components on a board when multiple sourcing is used. As more components emerge which conform to the IEEE 1149.1 standard, it is desirable to allow for a system diagnostic controller unit

to blindly interrogate a board design to determine the type of each component in each location. This information is also available for factory process monitoring and for failure mode analysis of assembled boards.

Once the IDCODE instruction is decoded, it selects the ID register which is a 32 Bit data register. Because the bypass register loads a logic 0 at the start of a scan cycle, whereas the ID register loads a logic 1 into its least significant bit, examination of the first bit of data shifted out of a component during a test data scan sequence immediate following exit from Test-Logic-Reset controller state shows whether such a register is included in the design. When the IDCODE instruction is selected, the operation of the test logic has no effect on the operation of the on-chip system logic as required by the IEEE 1149.1 standard.

67.6.2 SAMPLE/PRELOAD Instruction

Selects the boundary scan register and the system logic controls the I/O pins.

The SAMPLE/PRELOAD instruction provides two separate functions:

- First, it provides a means to obtain a snapshot of system data and control signals. The snapshot occurs on the rising edge of TCK in the capture-DR controller state. The data can be observed by shifting it transparently through the boundary scan register.
- The second function of SAMPLE/PRELOAD is to initialize the boundary scan register output cells prior to selection of EXTEST. This initialization ensures that known data appears on the outputs when entering the EXTEST instruction.

NOTE

Because there is no internal synchronization between the JTAG clock (TCK) and the system clock (CLK), the user must provide some form of external synchronization to achieve meaningful results.

For more details on the function and use of SAMPLE/PRELOAD, refer to the appropriate IEEE 1149.1 document.

67.6.3 EXTEST Instruction

Selects the boundary scan register, and the 1149.1 test logic has control of the I/O pins.

By using the TAP controller, the register is capable of:

- Scanning user-defined values into the output buffers,
- Capturing values presented to input pins

- Controlling the direction of bidirectional pins,
- Controlling the output drive of tri-statable output pins.

For more details on the function and use of EXTEST, refer to the appropriate IEEE 1149.1 document.

The EXTEST instruction also asserts internal reset for the cores (through CCM, refer to Figure 67-14) to force a predictable internal state while performing external boundary scan operations.

67.6.4 HIGHZ Instruction

All output drivers, including the two-state drivers, are turned off (that is, high impedance). The instruction selects the bypass register. In this mode, all internal pullup resistors on all the pins (except for the TMS TDI TCK $\overline{\text{TRST}}$ pins) are disabled. This disabling functionality is not built into SJC, but should be implemented by some logic in the SOC/IO Pads.

For more details on the function and use of HIGHZ, refer to the IEEE 1149.1 document.

The HIGHZ instruction also asserts internal reset for the cores (through CCM, refer to Figure 67-14) to force a predictable internal state while performing external boundary scan operations.

67.6.5 BYPASS Instruction

Selects the single Bit bypass register and the system logic controls the I/O pins. This creates a shift-register path from TDI to the bypass register and, finally, to TDO, circumventing the boundary scan register. This instruction is used to enhance test efficiency when a component other than the SoC Core based device becomes the device under test.

When the bypass register is selected by the current instruction, the shift-register stage is set to a logic zero on the rising edge of TCK in the capture-DR controller state. Therefore, the first bit to be shifted out after selecting the bypass register is always a logic zero.

For more details on the function and use of BYPASS, refer to the appropriate IEEE 1149.1 document.

67.6.6 ENABLE_ExtraDebug Instruction

The TDI and TDO pins are connected directly to the ExtraDebug registers, the SJC TAP controller remaining connected to TDI and TMS.

The ExtraDebug shift register consists of 38 bits (maximum) comprising a 32-bits data field, a 5 bits address field and read/write bit. On a register read, the data field does not need to be filled in. The particular ExtraDebug register connected between TDI and TDO at a given time is selected by the ExtraDebug controller depending on the ExtraDebug Address being currently decoded. All communication with the ExtraDebug controller is done through the Select-DR-Scan path of the JTAG TAP Controller.

67.6.7 ENTER_DEBUG instruction

The ENTER_DEBUG instruction is used to generate a debug request event to SDMA and the ARMCore Platform simultaneously (practically, inherited minimal skew is expected, due to difference in event signal propagation in the different modules).

The TDI and TDO are connected to the Instruction Register (IR). After the acknowledgment of the Debug Mode is received (can be checked by reading the Core Status Register part of the ExtraDebug logic), the user can perform system debug functions on the cores.

NOTE

The ENTER_DEBUG event issue to the cores, can be masked, by bits in DCR register.

It is user's responsibility to shift-in another IR value (like IDCODE) before trying to bring the cores out of debug mode, as the debug request signals to the cores remains asserted as long as ENTER_DEBUG IR is in place.

The user need to check that cores are in debug mode (watching debug acknowledge signal) before leaving ENTER_DEBUG instruction, otherwise debug request might not take affect.

67.6.8 TAP Select Instruction

By means of TAP select instruction a user can access TAP select register and by controlling its only bit SDMA Bypass, control whether SDMA TAP is bypassed or not.

Table 67-6. TAP Select Register (TSR)

	TAP Select Register
	BIT 0
	Connect SDMA
TYPE	rw
RESET	0
Note:	

Table 67-7. TAP Select Register Description

Field	Description
0 SDMA Bypass	Connect SDMA Control whether SDMA TAP is bypassed or not: • 0 - SDMA TAP is bypassed by the alternate TAP inside SJC (emulating 4-bit IR and 1-bit bypass path). • 1 - SDMA TAP is connected to the TDI-TDO chain. **NOTE:** Additional cycle with TMS '0' should be inserted, after writing to this register, to allow the SDMA tap be sync before SDMA get into / out of bypass.

67.7 Security

JTAG manipulation is one of the known hackers' ways of executing unauthorized program code, getting control over the OS and run code in privileged modes.

The SJC provides a debug access to several H/W blocks including the ARM processor and the system bus. This allows for program control and manipulation as well as visibility into system peripherals and memory. The ETM and NEXUS interfaces allow bus transactions to be traced. Together these tools provide the hacker all the access needed to completely comprise the system. Means must be provided to block any malicious JTAG access.

The SJC provides a way of regulating the JTAG access.

The following are the different JTAG security modes:

- Mode #1: No Debug-Maximum Security. All security sensitive JTAG features are permanently blocked.

- Mode #2: Secure JTAG-High security. JTAG use is regulated by secret key based authentication mechanism.
- Mode #3: JTAG Enabled-Low security. JTAG always enabled.

The JTAG security modes are configured using eFUSEs which can burned after packaging by applying electrical signals. The fuse burning is irreversible process, once a fuse is burned (e-fuse or laser fuse) it is impossible to change the fuse back to the un-burned state.

67.7.1 JTAG Security Modes

JTAG can be in one of JTAG security modes which is selected by setting the SJC eFUSE configuration. The physical location of the fuses is not in the SJC.

67.7.1.1 Mode 1: No Debug - Maximum Security

No Debug JTAG security mode provides the highest security level.

In this mode, all JTAG features are disabled except for:

- ScanBoundary Scan
- MBIST, all modes except for debug modes which enable controlled memory contents output
- PLL BIST
- BIST monitor mode, allowing routing to external pins BIST pass/fail/invoke information
- PLL bypass- Bypass ARM or/and USB PLL.
- Visibility of the following status bits: power mode - normal, standby, stop, shutdown, and so on

These features do not reduce the security level of the product, and they allows to perform important tests and board connectivity checks.

67.7.1.2 Mode 2: Secure JTAG - High Security

The Secure JTAG mode limits the JTAG access by using challenge/response based authentication mechanism. Any access to JTAG port is being checked. Only authorized debug devices (that is, devices having the right response) can access the JTAG, unauthorized JTAG access attempts are denied.

The intent of this mode is to allow return field testing. When a secured JTAG device is being returned for debugging, this mode allows authorized re-activation of the JTAG.

67.7.1.2.1 Challenge/Response Mechanism in System JTAG Mode

When SJC is in Sysytem JTAG mode the authentication process is as follows:

1. Shift Output Challenge instruction to IR.
2. Passing through Capture-DR state of the SJC and by performing Shift-DR operations Challenge code can be accessed from TDO.
3. Shift Enter Response instruction to IR. By performing Shift-DR, operations enter Response code value through TDI. As Update-DR state is entered, Response code is compared with the correct one.

In Fixed challenge-response pair mode, each part has its individual challenge - response pair which is determined at manufacturing time, and does not change later on. The SJC compares the user's response to the expected response.

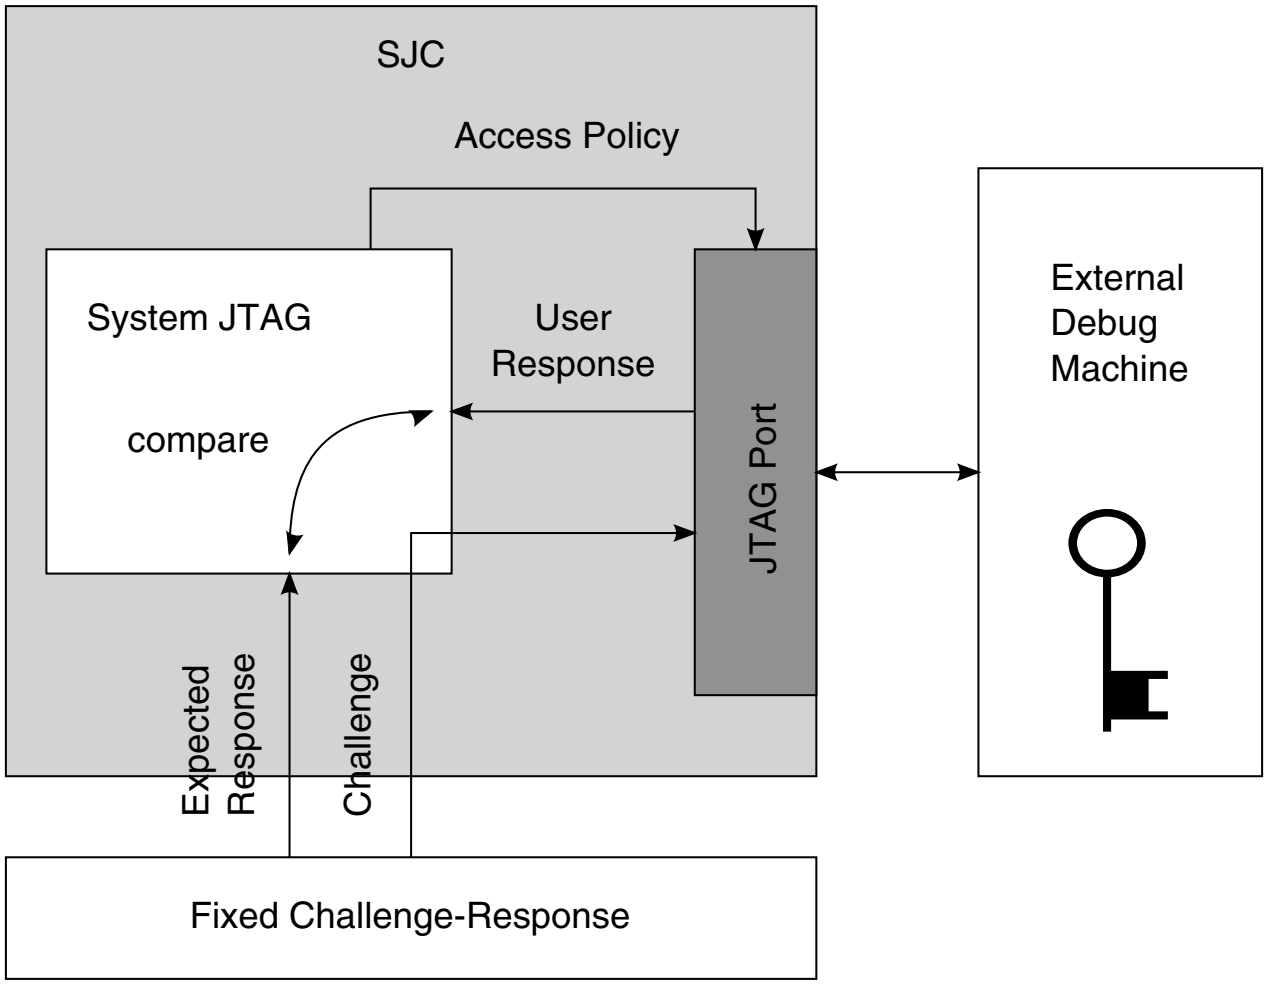

Figure 67-12. Mode #2 - Secure JTAG with Fixed Challenge-response Pair

67.7.1.3 Mode 3: JTAG Enabled - Low Security

In the JTAG Enabled JTAG security mode, all JTAG features are enabled.

67.7.2 Software Enabled JTAG

To increase the flexibility of the SJC, an option to enable the JTAG via software is added and is available only in Secure JTAG mode. By writing '1' to HAB_JDE (HAB JTAG DEBUG ENABLE) bit in the e-fuse controller module (IIM), the JTAG is opened, regardless of its security mode. It is the responsibility of software to assert or negate this bit.

Additionally, a corresponding lock bit is available (in the e-fuse control module) to ensure that only trusted software is able to set the JDE bit. When the LOCK bit is set, no future change of JDE is possible, until the next POR (power-on-reset) cycle.

The platform initialization software should set the LOCK bit for JDE bit before transferring control to the application code.

The S/W JTAG enable allows JTAG enabling without activating the challenge-Response mechanism (which requires JTAG access tool enhancement or special H/W). The JTAG S/W enable does not allow debug in case of boot or memory fault as it requires reset before entering debug.

This feature can be permanently blocked by burning the dedicated e-fuse.

NOTE

The S/W enabled JTAG feature reduces the overall security level of the system as it relies on S/W protections. If this feature is not required, it is strongly recommended to burn the JTAG_HEO e-fuse which disables this feature.

67.7.3 Kill Trace

The kill trace signal disables any output of the ETM block. The ETM can be accessed either via JTAG port and/or by direct software code. Blocking the JTAG port also yields assertion of the kill trace signal. This resulted in blocking of trace port. The intention of this action is to block any attempt to break into the system via software manipulation of the debug modules. The kill trace, when active, prevents trace output even in case where it can be activated via chip pin.

The kill trace feature needs to be activated by burning a dedicated e-fuse. If the fuse is left intact, kill trace is never activated as seen in Figure 67-13.

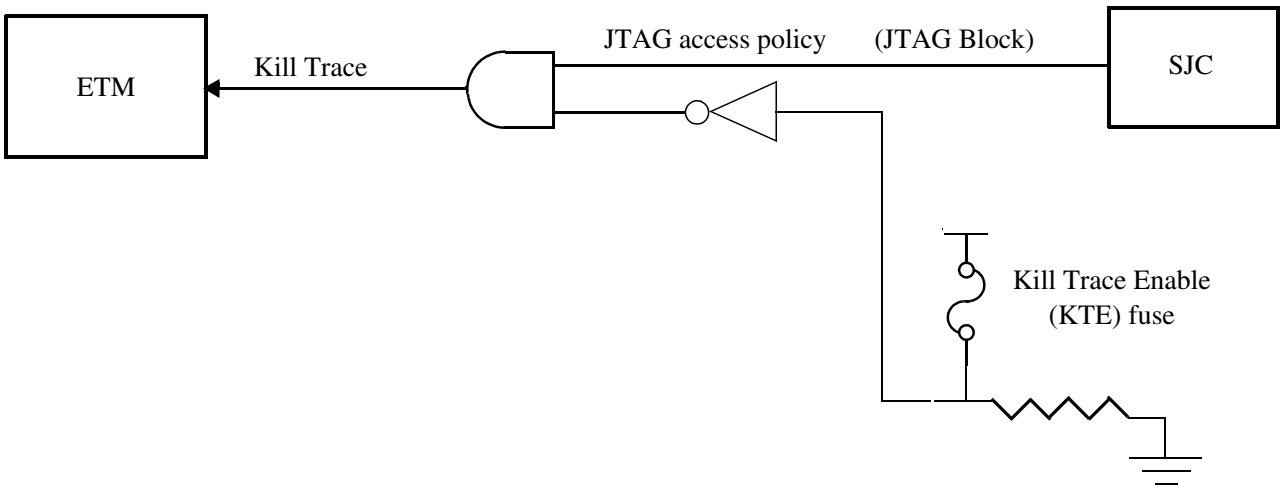

Figure 67-13. Kill Trace eFUSE

The kill trace is asserted when "kill trace enable" fuse is burned and "ipt_secur_block" signal in SJC is asserted, which happens when at least one of the following is true:

- Mode #2 (Secure JTAG) and no code has been entered
- Mode #2 (Secure JTAG) with burned Bypass and Re-enable fuses
- Mode #2 (Secure JTAG) with incorrect response entered
- Mode #1 (No debug)
- TRST_B signal is active
- POR has not ever been asserted

67.7.4 SJC Disable Fuse

In addition to the different JTAG security modes that are implemented internally in the System JTAG Controller (SJC), there is an option to disable the SJC functionality by eFUSE configuration. This creates additional JTAG mode that is, JTAG Disabled with highest level of JTAG protection. In this mode all JTAG features are disabled.

Specifically, the following debug features are disabled in addition to the features that were already disabled in No Debug JTAG mode:

- Memory BIST
- Boundary scan register (SJC_BSR)
- Non-Secure JTAG control registers (PLL configuration, Deterministic Reset, PLL bypass)
- Non-Secure JTAG status registers (Core status)
- Chip Identification Code (IDCODE)

67.8 Functional Description

67.8.1 Static Core Debug

The SJC JTAG TAP controller is fully compatible with the IEEE 1149.1a-2001 Standard Test Access Port and Boundary Scan Architecture specifications.

The ARM platform has an integrated JTAG interface and a TAP controller to manage its own ICE. Also it can access an embedded trace ETM interface, see ARM core and ETM Technical reference guide for more information.

The SDMA has a TAP controller to manage its own OnCE, see SDMA OnCE specifications for more details.

The OnCE and ICE provide a mean of interacting with the cores and their peripherals non-intrusively so that a user may examine registers, memories to facilitate hardware and software development.

67.8.2 Reset Mechanism

The following figure shows the SJC reset logic

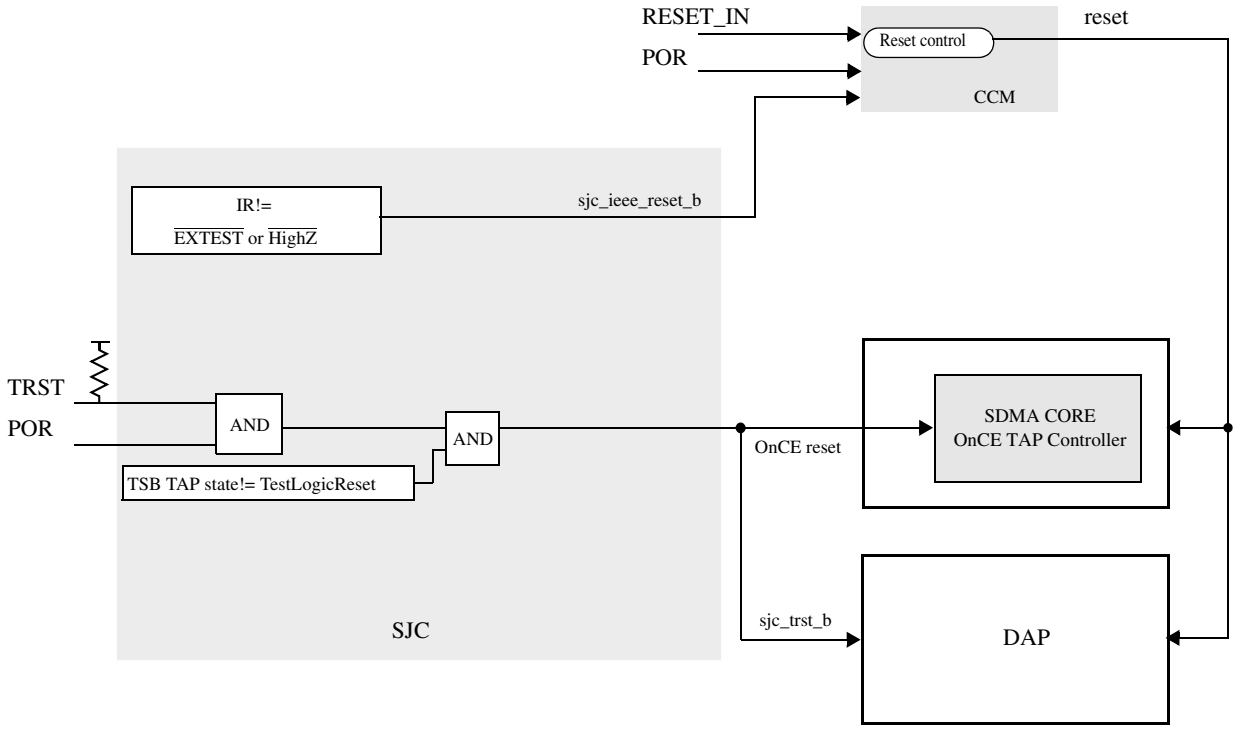

Figure 67-14. SJC Reset Logic

NOTE

- Asserting TRST in any scan mode resets the TCR loosing the testmode configuration and selects default TAP.
- SJC generates an IEEE reset signal to the CCM when in one of the IEEE modes HIGHZ or EXTEST. This signal generates a system reset to the cores until exit from one of these modes.
- The TSB generates Once/ICE reset (either TRST if implemented or other) when its TAP state reaches Test-Logic-Reset (meaning that TAP accessed is also reaching Test-Logic-Reset).
- When the SJC is in scan mode reset lines are controlled from RESET_IN_B for manufacturing test purpose.

67.9 Initialization/Application Information

The control afforded by the output enable signals using the boundary scan register and the EXTEST instruction requires a compatible circuit-board test environment to avoid device-destructive configurations. The user must avoid situations in which the SJC output drivers are enabled into actively driven networks.

There are two constraints related to the JTAG interface:

- Ensure that the JTAG test logic is kept transparent to the system logic by forcing TAP into the Test-Logic-Reset controller state. During power-up, SJC's internal $\overline{\text{TRST}}$ is asserted as IC's $\overline{\text{POR}}$ is asserted which forces the TAP controller into this state. After that, if TMS either remains unconnected or is connected to VCC, then the TAP controller cannot leave the Test-Logic-Reset state, regardless of the state of TCK.
- $\overline{\text{DE\_B}}$ is an IO pin with pullup and care must be taken of the direction when driving this signal.

67.10 Programmable Registers

In addition to the standard accessible JTAG registers (per IEEE1149.1 standard) listed in SoC JTAG Instruction Register (SJIR), the chip contains the following registers accessed using the ExtraDebug mechanism, controlled via "ENABLE_ExtraDebug" IR instruction.

NOTE

SJC registers are only accessible by JTAG interface. They are not memory mapped to processor address space, so the absolute addresses provided by default in the SJC memory map are not valid.

This section assumes the JTAG controller is accessed in standalone mode or daisy chained (defined by TAP Selection Block) using the appropriate TSB configuration.

See "System Debug" chapter for more details about the general purpose register descriptions that are unique to this chip.

SJC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0000_0000	General Purpose Unsecured Status Register 1 (SJC_GPUSR1)	32	R	0000_0000h	67.10.1/ 4295

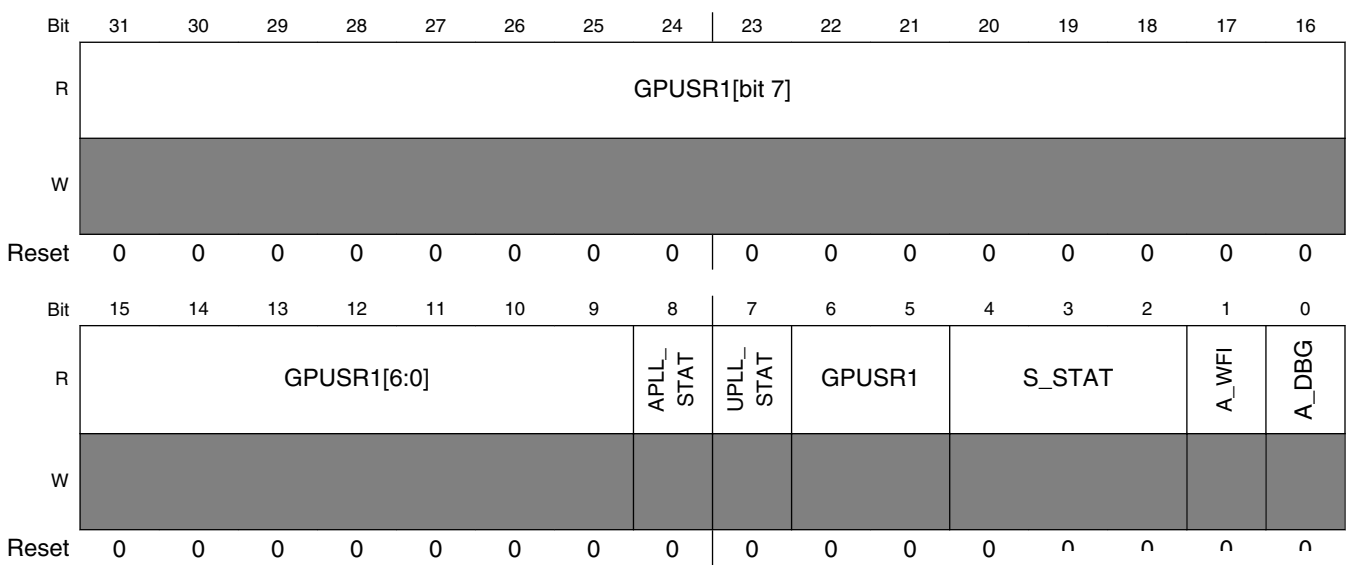
0000_0002	General Purpose Unsecured Status Register 3 (SJC_GPUSR3)	32	R	0000_0000h	67.10.3/ 4297
0000_0003	General Purpose Secured Status Register (SJC_GPSSR)	32	R	0000_0000h	67.10.4/ 4297
0000_0004	Debug Control Register (SJC_DCR)	32	R/W	0000_0000h	67.10.5/ 4298
0000_0005	Security Status Register (SJC_SSR)	32	R	0000_0000h	67.10.6/ 4299
0000_0007	General Purpose Clocks Control Register (SJC_GPCCR)	32	R/W	0000_0000h	67.10.7/ 4301
0000_0008	General Purpose Unsecured Control Register n (SJC_GPUCR)	32	R/W	0000_0000h	67.10.8/ 4302
0000_000B	General Purpose Secured Control Register (SJC_GPSCR)	32	R/W	0000_0000h	67.10.9/ 4302

67.10.1 General Purpose Unsecured Status Register 1 (SJC_GPUSR1)

The General Purpose Unsecured Status Register 1 is a read only registers used to check the status of the different Cores and of the PLL. The rest of its bits are for general purpose use.

Address: SJC_GPUSR1 is 0h base + 0h offset = 0000_0000h



SJC_GPUSR1 field descriptions

Field	Description
31–9 GPUSR1	General Purpose Unsecured Status Register Register is used for testing and debug.
8 APLL_STAT	ARM platform PLL status bit This bits indicates the status of the ARM platform PLL. When this bit is HIGH, the ARM platform PLL is locked.
7 UPLL_STAT	USB PLL status bit This bits indicates the status of the USB PLL. When this bit is HIGH, the USB PLL is locked.
6–5 GPUSR1	General Purpose Unsecured Status Register Register is used for testing and debug.
4–2 S_STAT	3 LSBits of SDMA core statusH.
1 A_WFI	ARM core wait-for interrupt bit Bit 1 is the ARM core standbywfi (stand by wait-for interrupt). When this bit is HIGH, ARM core is in wait for interrupt mode.
0 A_DBG	ARM core debug status bit Bit 0 is the ARM core DBGACK (debug acknowledge) DBGACK can be overwritten in the ARM core DCR to force a particular DBGACK value. Consequently interpretation of the DBGACK value is highly dependent on the debug sequence. When this bit is HIGH, ARM core is in debug.

67.10.2 General Purpose Unsecured Status Register 2 (SJC_GPUSR2)

Address: SJC_GPUSR2 is 0h base + 1h offset = 0000_0001h

67.10.7 General Purpose Clocks Control Register (SJC_GPCCR)

This register is used to configure clock related modes in SOC, see System Configuration chapter for more information. Those bits are directly connected to JTAG outputs. Bit 0 of GPCCR controls SDMA clocks invocation. When out of reset, the SDMA is in sleep mode with no SDMA clock running. Unlike events, debug requests does not wake SDMA if it is in sleep mode. The debug request is recognized by the SDMA only when it exits sleep mode upon reception of an event. To be able to enter debug mode even if no event is triggered, the SDMA clock on bit needs to be set prior to sending the debug request (clear at reset).

Address: SJC_GPCCR is 0h base + 7h offset = 0000_0007h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Chapter 68
Shared Peripheral Bus Arbiter (SPBA)

68.1 Introduction

The Shared Peripheral Bus Arbiter (SPBA) is a three-to-one IP Bus line interface arbiter, with a resource locking mechanism. The masters can access up to thirty one shared peripherals through the SPBA.

The figure below shows the SPBA block diagram

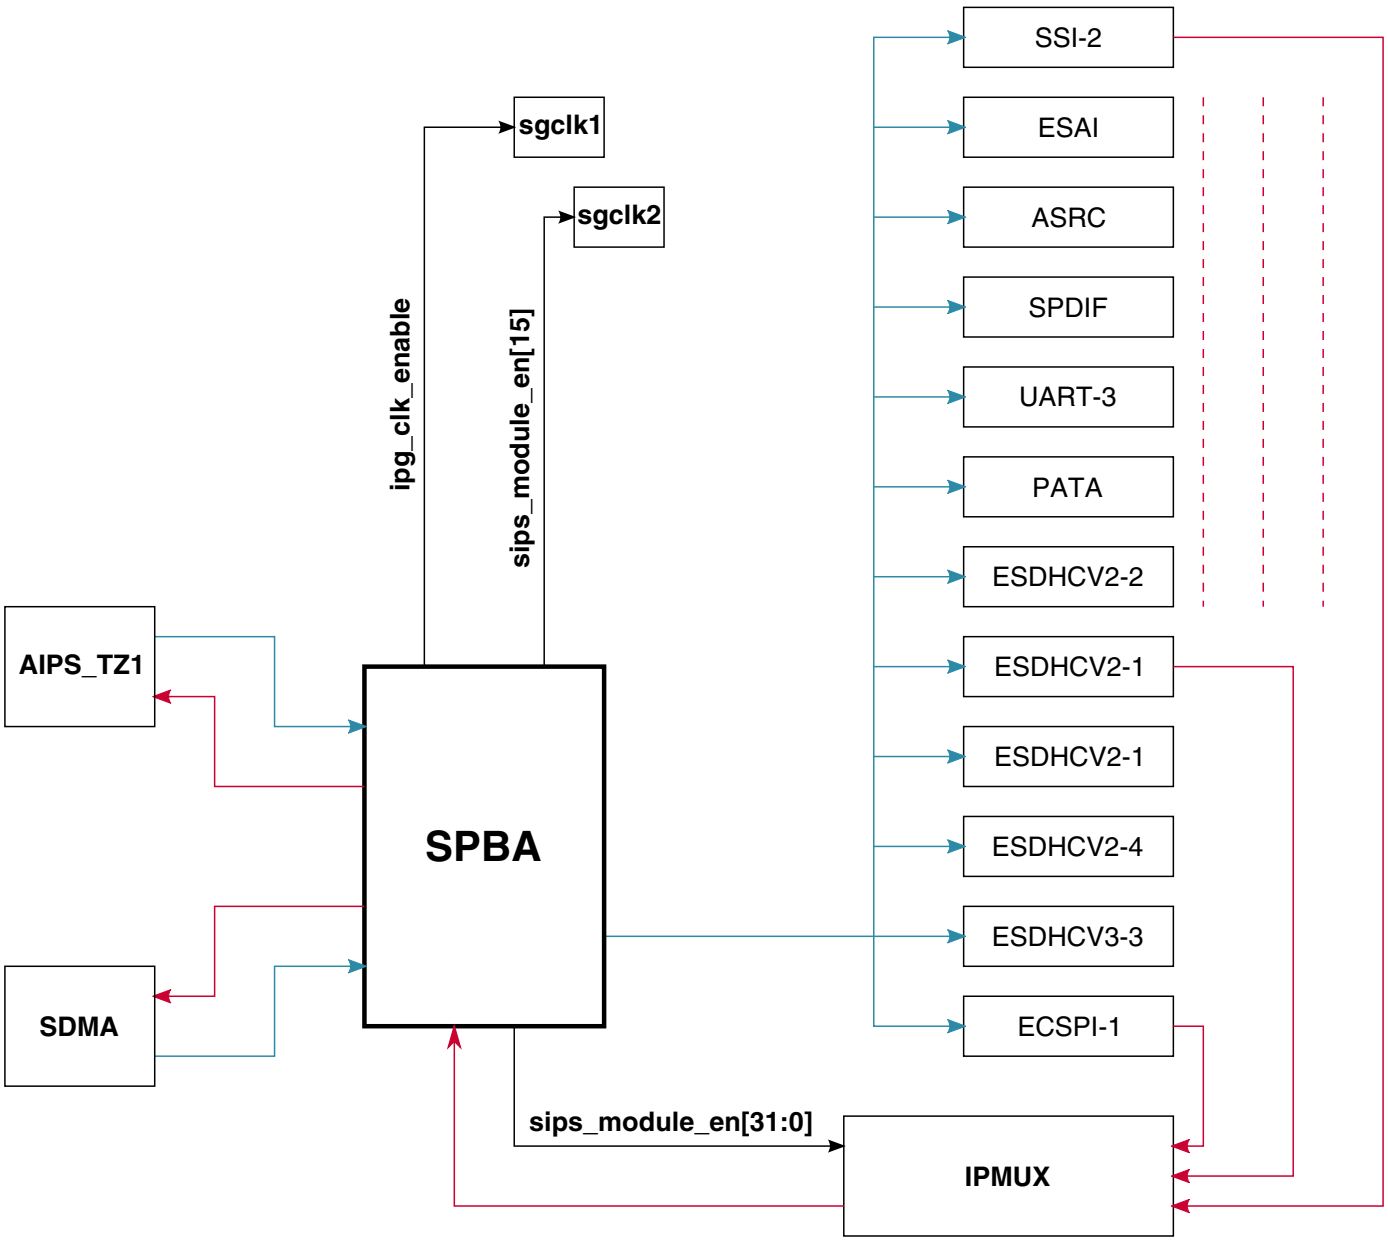

Figure 68-1. i.MX53 SPBA connectivity

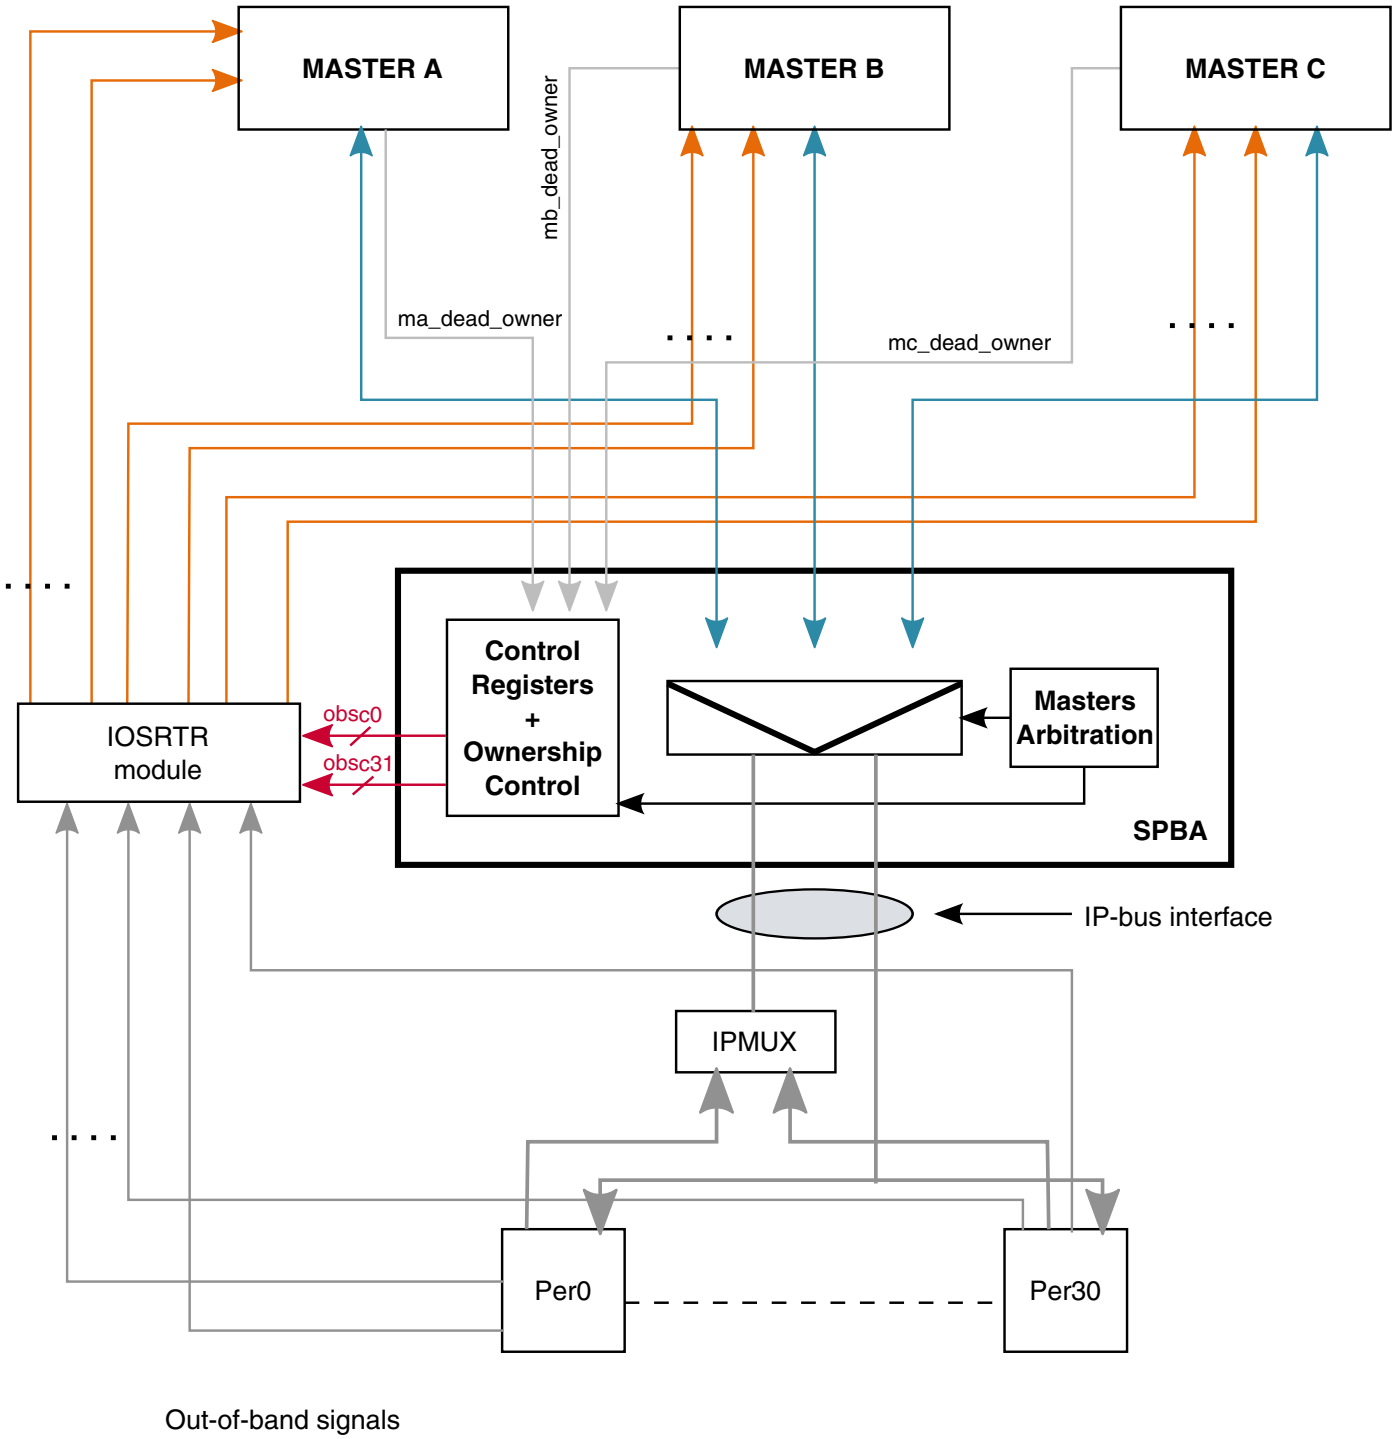

Figure 68-2. SPBA Block Diagram

68.2 General Overview

The Shared Peripheral Bus Arbiter (SPBA) is a three-to-one IP Bus interfaces arbiter. Three masters arbitrate for shared peripherals access through the SPBA.

Indeed three main parts are involved in SPBA.

- The IP Bus Line switches a master to one peripheral.
- The Masters arbiter arbitrates between the three masters to solve concurrent access or restricted access to peripherals.
- The Control Registers and Ownership Control including a set of registers, which are reachable through software, permits the access scheme definition to each peripheral (Resource Ownership and Access Control). It generates signals usable for the external steering logic of interrupts and DMA signals.

68.3 Features

The SPBA includes the following features:

- Three IP Bus masters arbitration, master A, master B and master C
- Support for DMA masters.
- 32 bits data
- Supports up to 31 shared peripherals, each consuming 16 Kilobytes of address space.
- SPBA can be considered as the 32th peripheral, used for resource ownership and access control mechanism to the 31 peripherals,
- Provides 31 sets of Out of Band Steering Control (obsc) signals to the off-block steering logic,
- Operating frequency up to 67 MHz,
- clocks: ipg_clk, ipg_clk_s.

68.4 Modes of Operation

Thus the SPBA behavior is transparent when accessing a peripheral, it can distinguish different modes of operation:

Reset/Abort

The SPBA has a hardware reset which initialize all registers, arbitration and PRR (peripherals rights registers).

Additionally, an abort signal input is provided allowing each master to abort their current access and release their ownership (in case of master reset sequence,...).

Functional

Once a master request is granted, its IP Bus signals are steering to the requested peripheral.

Standby

No clock needed. The SPBA needs clocks only during: access to the PRRs, arbitration and abort phases. It generates two clock enable signals indicating when the clocks must be provided.

Configuration

This is the phase where a master is accessing the SPBA PRRs. Indeed, SPBA memory mapped registers are seen as a shared peripheral.

68.5 Functional Description

The following section intends to describe the main features of the SPBA.

68.5.1 Masters Arbitration

The arbitration mechanism determines which port will control the master port, based on a simple round-robin arbitration scheme.

We can distinguish between different cases:

- Only one master request per different access. So the master is switched to the shared peripheral bus, without arbitration. Figure 68-3 shows the MB request on the global module enable signal, served without wait state.
- If two masters simultaneously access to SPBA, then the last granted master is held-off, using **<master>_ips_xfr_wait** output signal (default value is high). When the master is granted **sips_xfr_wait** from shared IP Bus peripheral is connected to <master>_ips_xfr_wait outputs.
- If three masters simultaneously access to SPBA, then the last two granted masters are held-off, using their <master>_ips_xfr_wait signal. Figure 68-4 shows the case when the last two accesses granted are MA then MB, and how the requests are used even if they are in the same cycle.
- After reset, at the first multiple access, no master has been granted, thus, the priority is static: Master A (MA), Master B (MB) and last Master C (MC) port.
- No master request. No master switch to shared peripherals.

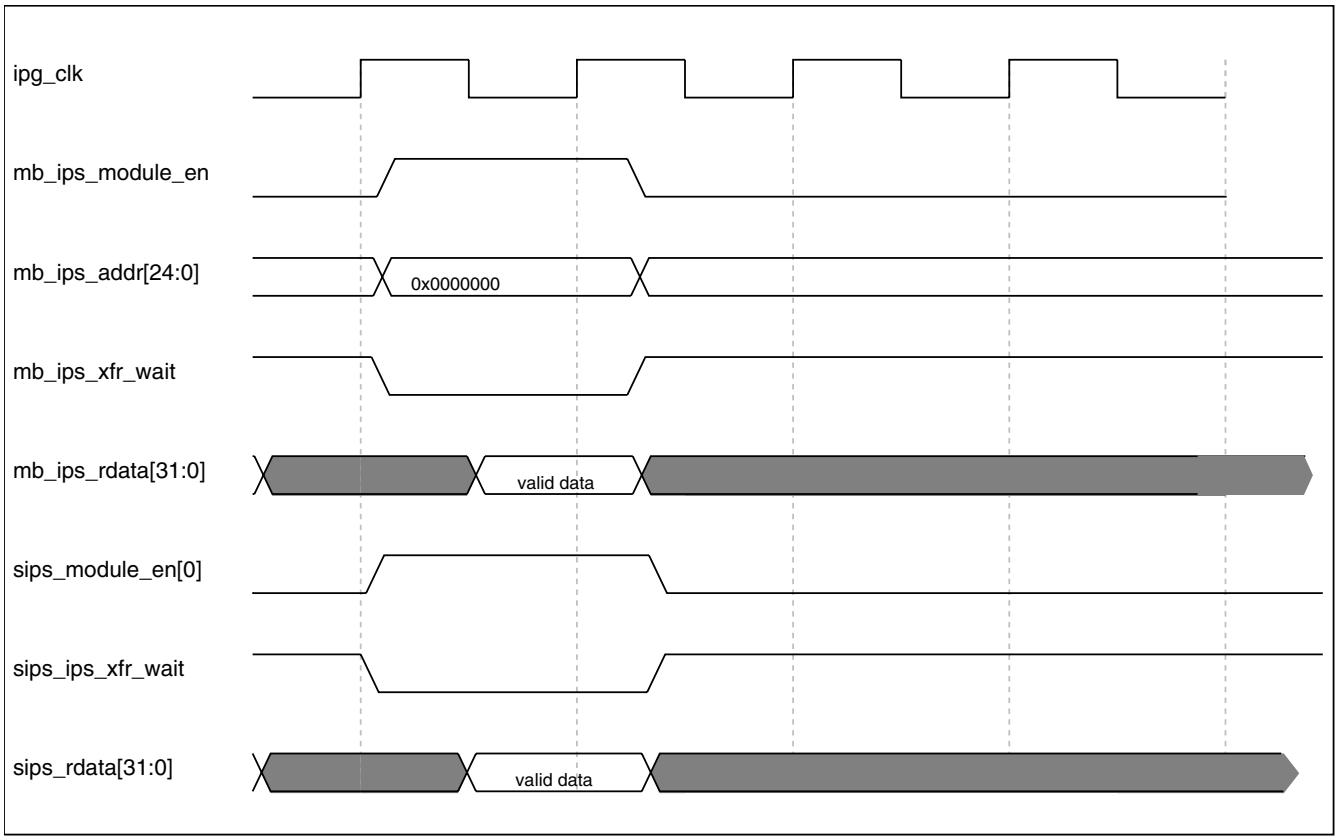

Figure 68-3. Example of one master request: no SPBA Arbitration;

The following figure assumes MA and MB have been the last two masters already granted in the previous transfers (MA then MB).

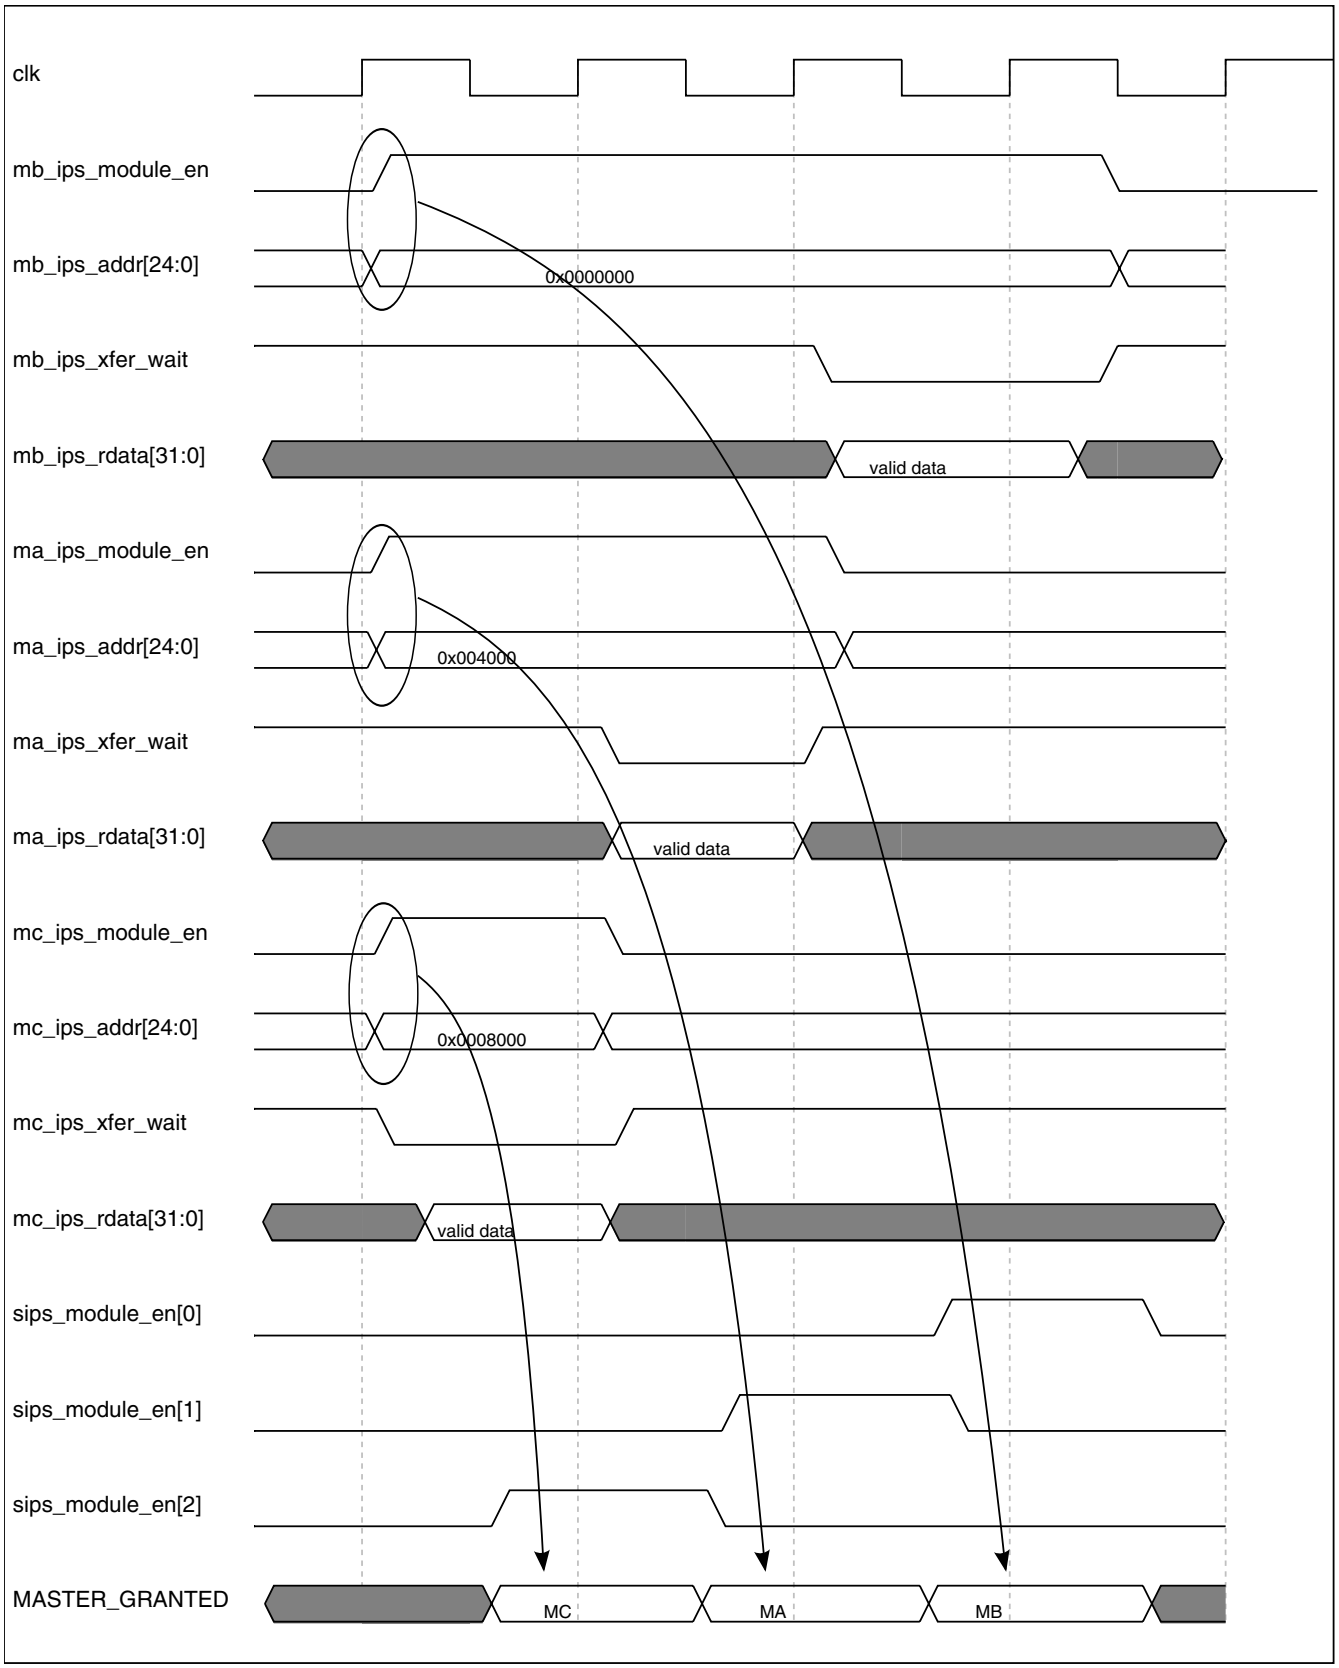

Figure 68-4. Example of three master requests: Masters already granted are "waited";

68.6 Resource Ownership Control

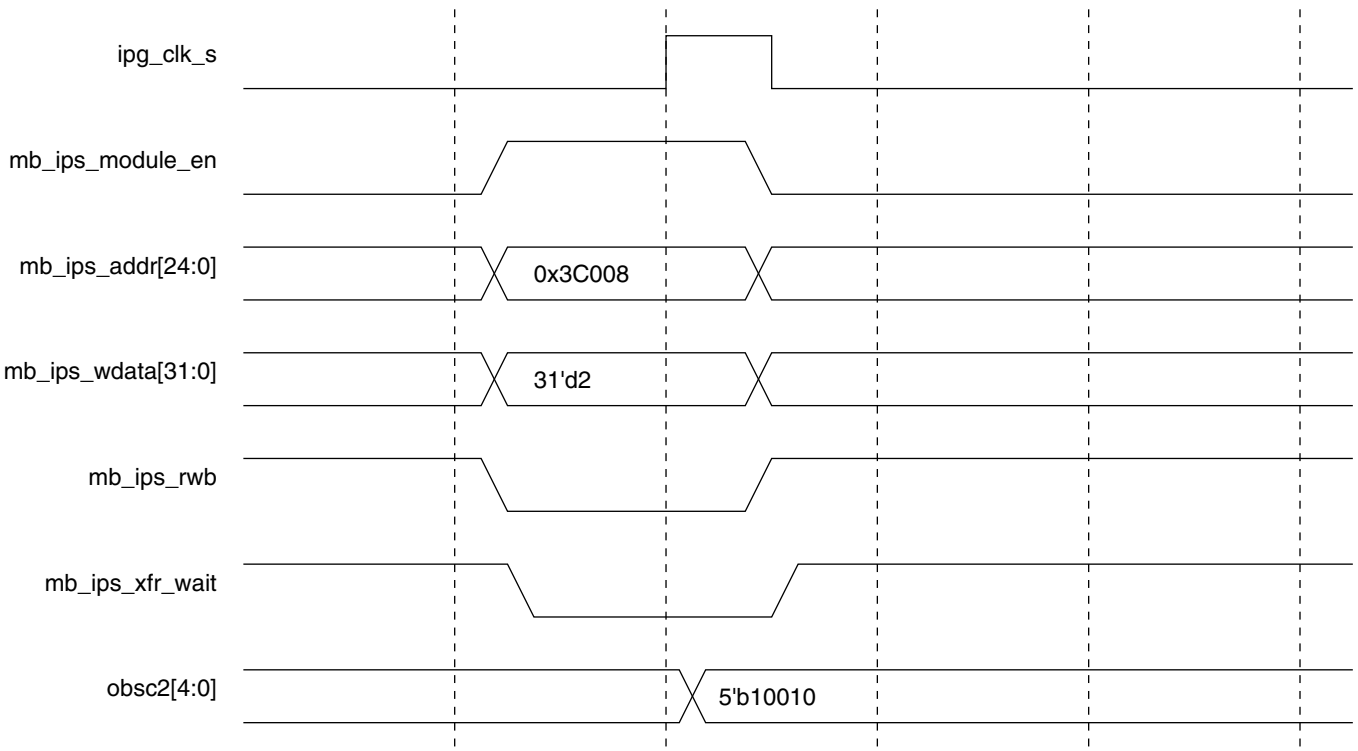
The Resource Ownership Control controls accesses to the shared peripherals and determines steering of out-of-band signals.

68.6.1 Access Control

68.6.1.1 Peripheral Access

The peripheral access (a.k.a resource access) of the requesting master is given by the corresponding RAR bit of the Peripheral Right Register. It determines if the master has access privilege to the resource.

Any attempted access to a resource by a requesting master whose access privilege bit is not set (in the PRR), is terminated with a bus error (**<master>_ips_xfr_err** is asserted by SPBA logic). The master which owns the resource can lock the peripheral for itself and/or grant other masters access to the peripheral by setting the appropriate bit(s) in the RAR field.



Master B is taking ownership of peripheral 2 by writing 3'b010 in the SPBA peripheral 2 right register (rarfield)
This ownership can be checked on obsc2 output as roi2[1:0] = 2'b10 and rar2[2:0] = 3'b010
(obsc[4:0] = {roi2[1], roi2[0], rar2[2], rar2[1], rar2[0]})

Figure 68-5. Example of one master B gaining ownership of peripheral 2

68.6.1.2 Peripheral Right Register Access

The ROI bits of the Peripheral Right Register (PRR) determine which master is allowed to make write access to PRR. The identification of the requesting master is compared to the ROI bits of the Peripheral Right Register to determine if the master has ownership of the corresponding register.

Any attempted write access to a Peripheral Right Register (PRR) already owned by another master will be ignored.

68.6.2 Owner Election

When the peripheral is not owned by any master (ROI="00", such as after coming out of reset), the first master to perform successfully a write to the RAR bits of the PRR is granted ownership of the peripheral and its associated PRR.

After writing to the PRR (RAR bit(s)), the master must read it back to make sure that it was granted ownership. If the RMO field is 2'b11, then the ownership claim is successful. If RMO is 2'b10, then another master claimed ownership before this master was able to complete its write. This resolves the case in which two or more masters attempt to write the PRR at the same time; only the first master will be granted ownership. However all masters must read the PRR to determine if this case occurred, and if so, whether they were the first master which was actually granted ownership.

NOTE

A master which has been granted ownership of the PRR does not automatically have the right access to the peripheral; it must still set its own RAR bits in the PRR to access the peripheral.

68.6.3 Ending Ownership

Ownership may be voluntarily ended by the owning master, or automatically upon assertion of a master-specific dead_owner signal.

The former is appropriate for software-controlled yielding of ownership. The latter is appropriate for automatic yielding of ownership when the owner has gone into reset. Hardware Controlled Ownership Ending

When a master is reset, it clears the ROI bits of the PRRs owned by the corresponding master. When the owner is dead (owner is in reset), all peripherals previously owned by that master must be changed to the un-owned state.

NOTE

It is the programmer's responsibility to make sure the peripherals are placed in an appropriate state before ending ownership.

68.6.3.1 Software Controlled Ownership Ending

The ROI bits will be automatically cleared when the master which owns the PRR access right clears (write) the RAR bits (Table 68-5).

It will then end the ownership of the PRR.

68.6.4 The Un-owned State

During the time when the peripheral is un-owned (i.e the ROI field contains all 0's), all masters have full access to it (RAR bits can then be modified by a master if ROI[1:0] = 2'b0).

In such cases it is necessary for software to ensure any necessary coherency in the resource, there is no hardware protection.

68.7 Memory Map/Register Definition

The following section describes the memory maps and detailed descriptions of all registers which are accessible to the end user within and through SPBA.

From a master side, the absolute address of one peripheral memory map registers is accessible by setting the <master>_ips_addr[24:0]:

- <master>_ips_addr[24:19] to the SPBA master base address (defined by top level parameters SPBA_<MASTER>_BASE_ADDR),
- <master>_ips_addr[18:14] to one of the 32 IP Bus peripherals (including SPBA). Refer to the table below,
- and <master>_ips_addr[13:0] to one of the 16-kilobyte memory mapped registers (16 Kilobytes only if accessing to a shared peripheral, not the same for SPBA PRR access).

The table below describes for each IP Bus peripheral, its absolute memory mapped address range accessible through the SPBA for one master (does not include the <master>_ips_addr[24:19] bits).

Table 68-1. Peripherals Absolute Address

Peripheral	<master>_ips_addr[18:0] start address	<master>_ips_addr[18:0] end address[1]
Peripheral 0	{5'b0_0000, 14'b00_0000_0000_0000}	{5'b0_0000, 14'b11_1111_1111_1111}
Peripheral 1	{5'b0_0001, 14'b00_0000_0000_0000}	{5'b0_0001, 14'b11_1111_1111_1111}

Table continues on the next page...

Table 68-1. Peripherals Absolute Address (continued)

Peripheral	<master>_ips_addr[18:0] start address	<master>_ips_addr[18:0] end address[1]

Peripheral 19	{5'b1_0011, 14'b00_0000_0000_0000}	{5'b1_0011, 14'b11_1111_1111_1111}
Peripheral 20	{5'b1_0100, 14'b00_0000_0000_0000}	{5'b1_0100, 14'b11_1111_1111_1111}
Peripheral 21	{5'b1_0101, 14'b00_0000_0000_0000}	{5'b1_0101, 14'b11_1111_1111_1111}
Peripheral 22	{5'b1_0110, 14'b00_0000_0000_0000}	{5'b1_0110, 14'b11_1111_1111_1111}
Peripheral 23	{5'b1_0111, 14'b00_0000_0000_0000}	{5'b1_0111, 14'b11_1111_1111_1111}
Peripheral 24	{5'b1_1000, 14'b00_0000_0000_0000}	{5'b1_1000, 14'b11_1111_1111_1111}
Peripheral 25	{5'b1_1001, 14'b00_0000_0000_0000}	{5'b1_1001, 14'b11_1111_1111_1111}
Peripheral 26	{5'b1_1010, 14'b00_0000_0000_0000}	{5'b1_1010, 14'b11_1111_1111_1111}
Peripheral 27	{5'b1_1011, 14'b00_0000_0000_0000}	{5'b1_1011, 14'b11_1111_1111_1111}
Peripheral 28	{5'b1_1100, 14'b00_0000_0000_0000}	{5'b1_1100, 14'b11_1111_1111_1111}
Peripheral 29	{5'b1_1101, 14'b00_0000_0000_0000}	{5'b1_1101, 14'b11_1111_1111_1111}
Peripheral 30	{5'b1_1110, 14'b00_0000_0000_0000}	{5'b1_1110, 14'b11_1111_1111_1111}
Peripheral 31	{5'b1_1111, 14'b00_0000_0000_0000}	{5'b1_1111, 14'b11_1111_1111_1111}

1. One of these peripherals must be defined as the SPBA. The end address range given is not valid for SPBA internal registers. If <master>_ips_addr[13:0] is greater than the last PRR location, the SPBA will return a transfer error to the master (report to Table 68-2).

68.7.1 SPBA Register Definition

The SPBA control registers (Peripheral Right Registers) are mapped as a virtual shared peripheral using by default the sips_module_en[15] (or another one using verilog parameter during integration phase) which must not be used for shared blocks.

SPBA can support up to 31 shared peripherals. Each of them has its own Peripheral Right Register (PRR) accessible within the SPBA memory mapped registers, and consists of the Requesting Master Owner, the Resource Owner ID and the Resource Access Right fields (using verilog parameters it can be defined which peripheral is present or not, and so if the corresponding PRR exists or not).

Table 68-2. SPBA PRR Register Summary

Name		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRRn[1] address = ($BASE[2] + n*4)	R	RMOn														ROIn	
	W																
	R														RARn		
	W																

1. for n=0 to 31
2. $BASE = {6'bSPBA_<MASTER>_BASE_ADDR, 5'bx_xxxx, 14'b00_0000_0000_0000}, where 5'bx_xxxx are <master>_ips_addr[18:14] reserved for SPBA registers access. The following table details the value of <master>_ips_addr[13:0] for master access any of the shared PRR

Table 68-3. PRR addresses

1. for n=0 to 31
2. $BASE = {6'bSPBA_MX_BASE_ADDR, 5'bx_xxxx, 14'b00_0000_0000_0000}, where 5'bx_xxxx are the bit [18:14] of master address bus reserved for SPBA access

RMOn[1:0] - Requesting Master Owner

This 2-bit register field indicates if the corresponding resource is owned by the requesting master or not. This register is reset to 2'b0 if ROI[1:0] = 2'b0.

Table 68-4. RMOn Values

Value	Meaning
00	resource un-owned
10	resource owned by another master
11	resource owned by requesting master

ROIn[1:0] - Resource Owner ID

This 2-bits register field indicates which master (one at a time) can access to the PRR for rights modification. This is a Read-Only register.

Table 68-5. ROIn Values

Value	Meaning
00	un-owned resource
01	resource owned by master A port
10	resource owned by master B port
11	resource owned by master C port

After reset, ROI bits are cleared ("00" -> un-owned resource).

A master performing a write access to the an un-owned PRR will get its ID automatically written into ROI, while modifying RAR bits. It can then read back the RMO, RAR, ROI bits to make sure RMO returns the right value, ROI bits contain its ID and RAR bits are correctly asserted. Then no other master (whom ID is different from the one stored in ROI) will be able to modify RAR fields.

Owner master of a peripheral can assert its dead_owner signal, or write 3'b0 in the RAR to release the ownership (ROI[1:0] reset to 2'b0).

RARn[2:0] - Resource Access Right

This 3-bit register field indicates which master can access to the peripheral. From 0 up to 3 masters can have permission to access a resource (all the master can be granted on a peripheral, but only one access at a time will be granted by SPBA).

RARn[0] - Control and Status bit for master A which is connected to port MA,

access to peripheral is granted.

access to peripheral is not allowed.

RARn[1] - Control and Status bit for master B which is connected to port MB,

access to peripheral is granted.

access to peripheral is not allowed.

RARn[2] - Control and Status bit for master C which is connected to port MC,

access to peripheral is granted.

access to peripheral is not allowed.

After reset all RAR registers are set to value 1. So by default all masters have access granted to all the shared peripherals. This is verified until one master modify this default value.

Chapter 69
Sony/Philips Digital Interface (SPDIF)

69.1 Introduction

The Sony/Philips Digital Interface (SPDIF) audio block is a stereo transceiver that allows the processor to receive and transmit digital audio. The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency.

A recovered clock is provided to drive both internal and external components in the system such as ESAI ports, as well as external A/Ds or D/As, with clocking control provided via related registers.

As the SPDIF internal data width is 24-bit, the eight most-significant bits of all registers return zeros.

The figure below shows a block diagram of the SPDIF transceiver data paths (receiver and transmitter) and its interface.

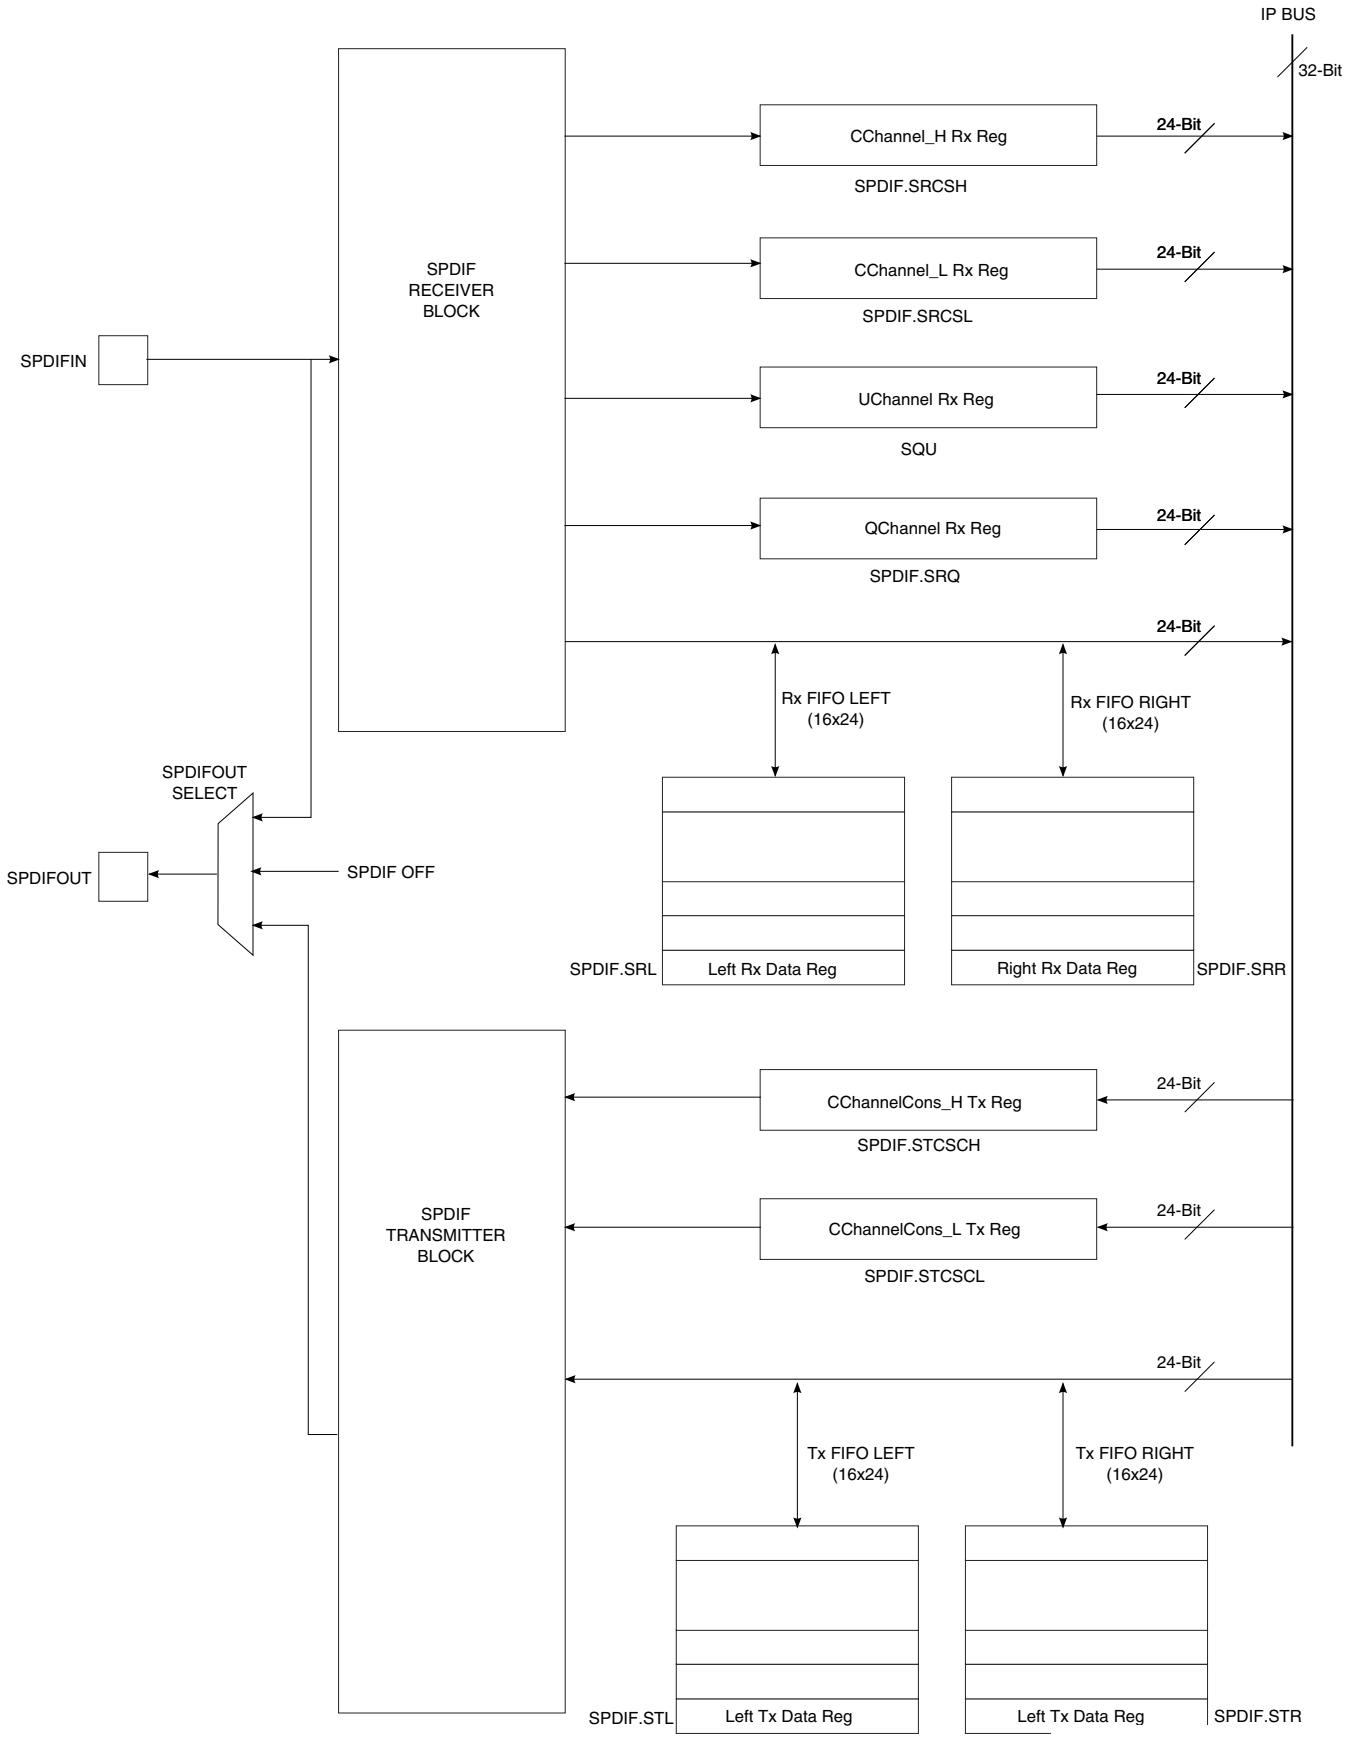

Figure 69-1. SPDIF Transceiver Data Interface Block Diagram

69.1.1 Overview

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter.

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in the SPDIF Rx left and right FIFOs. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates a SPDIF output bitstream in the biphase mark format (IEC60958), which consists of audio data, channel status and user bits.

In the SPDIF transmitter, the IEC60958 biphase bit stream is generated on both edges of the SPDIF Transmit clock. The SPDIF Transmit clock is generated by the SPDIF internal clock generate block and the sources are from outside of the SPDIF block. For the SPDIF receiver, it can recover the SPDIF Rx clock. Both the Rx clock and Tx clock are be sent to the ASRC. shows the clock structure of the SPDIF transceiver.

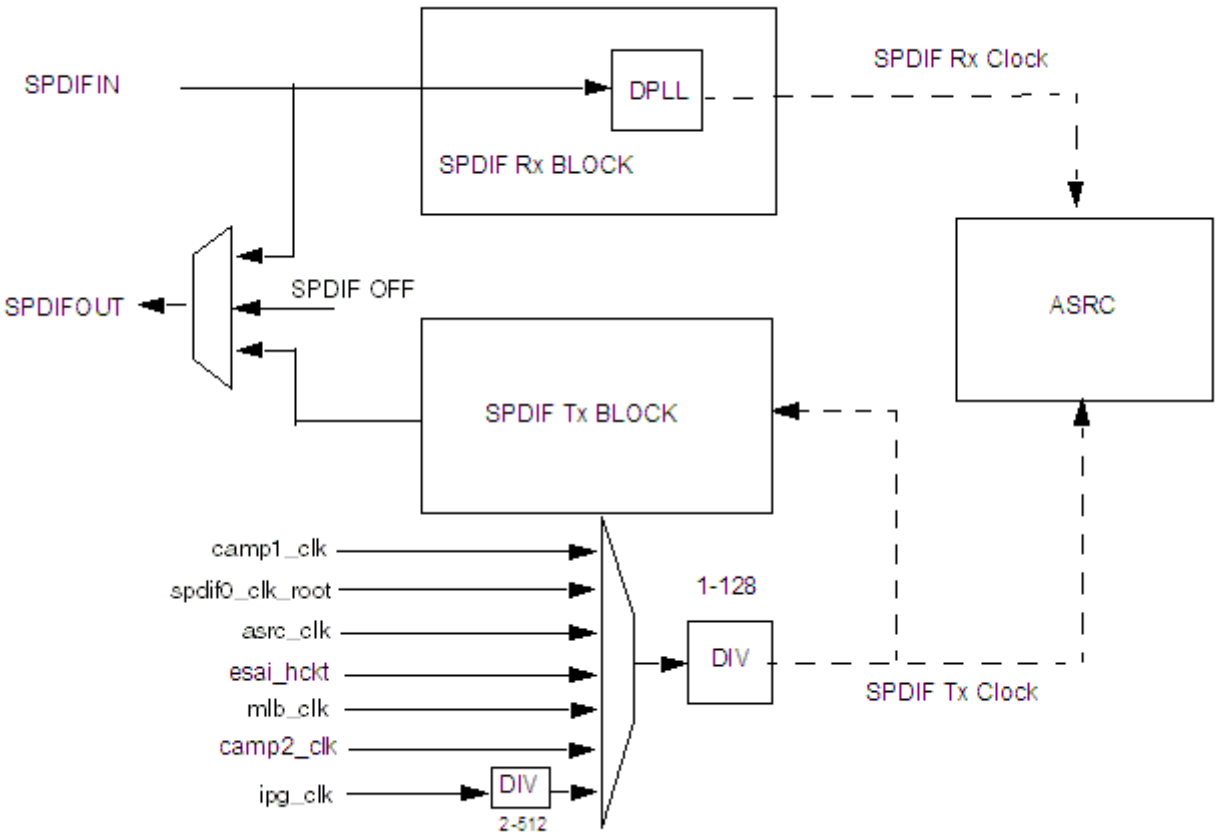

Figure 69-2. SPDIF Transceiver Clock Diagram

69.2 External Signal Description

Table 69-1. Signal Properties

Signal Name	Signal Type	Description
SPDIFIN	input	SPDIF Input Line IEC60958 data in biphase mark format.
SPDIFOUT	output	SPDIF Output Line IEC60958 data in biphase mark format. (Consumer C channel).

69.3 Functional Description

69.3.1 SPDIF Receiver

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in Rx left and right FIFOs.

The Tx left and right FIFOs are 16-deep and 24-wide (equal to the audio data width). The Channel Status and User Bits are also extracted from each frame and placed in corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

The SPDIF receiver handles the main data audio stream and recovers the bit clock from the SPDIF input signal. The sample rate can be determined from the frequency measuring block. Additionally, the receiver supports the SPDIF C and U channels. The SPDIF C and U channel data is interfaced directly to memory-mapped registers.

All the data registers are controlled by the Interrupt Control Block and transferred to the memory-mapped IP bus.

The following functions are performed by the SPDIF receiver:

- Audio Data Reception see Audio Data Reception
- Channel Status bits Reception see Channel Status Reception
- U Channel bits Reception see User Bit Reception
- Validity Flag Reception see Validity Flag Reception
- SPDIF Receiver Exception support see SPDIF Receiver
- SPDIF Lock Detection

69.3.1.1 Audio Data Reception

The SPDIF Receiver block extracts the audio data from the IEC60958 stream, and outputs this via Rx left and right FIFOs to the memory-mapped registers SPDIFRxLeft and SPDIFRxRight. Data from the SPDIF receiver is buffered in receive FIFO, and can be read by the processor from the memory-mapped registers.

- **SPDIF receiver data registers - Behavior on overrun, underrun**

The SPDIF Data Receive registers (SPDIFRxLeft and SPDIFRxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFOs. To prevent this from happening, hardware has been added to the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If a SPDIF Data Rx FIFO overrun occurs on e.g. the right half of the FIFO, the sample that caused the overrun is not written to the right half (due to overrun). Special hardware will make sure the next sample is not written to the left half of the FIFO. If the overrun occurs on the left half of the FIFO, the next sample is not written to the right half of the FIFO.

- **SPDIF receiver data registers - Automatic resynchronization of FIFOs**

An automatic FIFO resynchronization feature is available. It can be enabled and disabled separately for every FIFO. If it is enabled, the hardware will check to see if the left and right FIFOs are in sync. If that is not the case, it will set the filling pointer of the right FIFO to be equal to the filling pointer of the left FIFO.

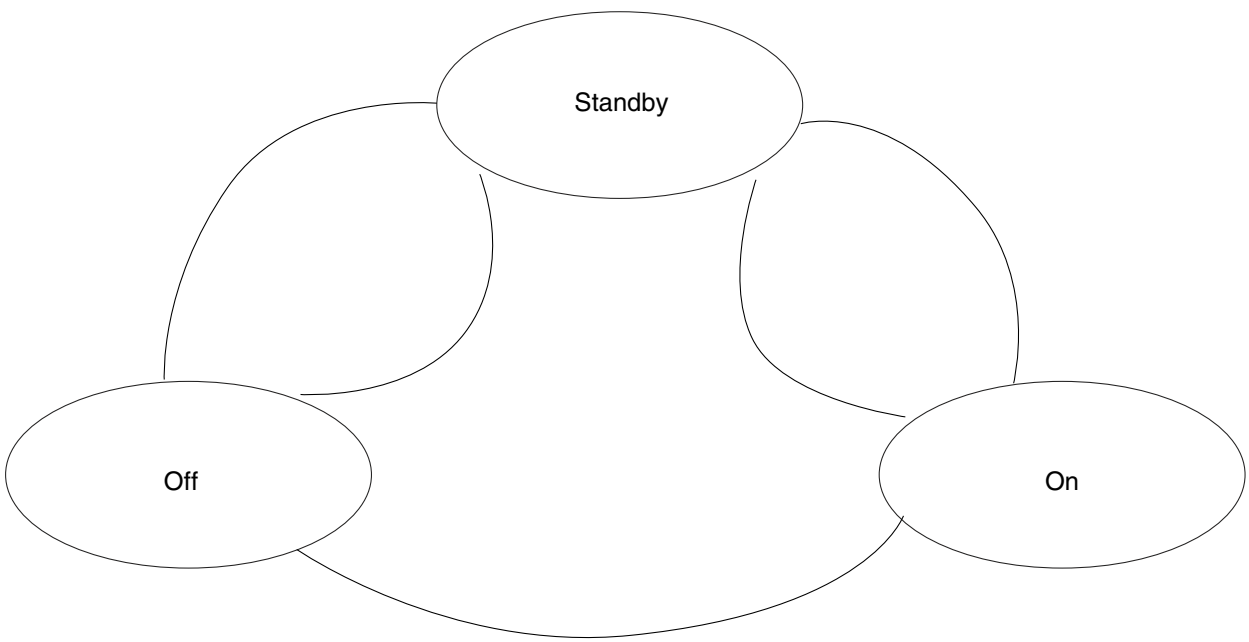

Figure 69-3. FIFO Auto-resync Controller State Machine

The operation is explained from the state diagram shown above. Every FIFO auto-resync controller has a state machine with 3 states: Off, StandBy and On. In the On state, the filling of the left FIFO is compared with the filling of right, and if they are not equal, right is made equal to left, and an interrupt is generated.

The controller will stay in Off state when the feature is disabled. When not disabled, the state machine will go to Off state on any processor read or write to the FIFO. It will go from On or Off to Standby on any left sample read from SPDIF Tx FIFOs, or on any left sample write to SPDIF Rx FIFOs. The controller will go from Standby to On on any right

sample read from SPDIF Tx FIFO, or on any right sample write to SPDIF Rx FIFO. There is a control bit in the SPDIFConfig register to enable/disable the feature for the SPDIF Rx FIFO and SPDIF Tx FIFO.

69.3.1.1.1 Application Note

The automatic FIFO resynchronization can be switched on, and will avoid all mismatches between left and right FIFOs, if the software obeys the following rules: 1. When the left data is read or written to the left FIFO, in the same place of the program, data must be read or written to the right FIFO. Maximum time difference between left and right is 1/2 sample clock. (E.g. if sample frequency is 44 Khz, approximately 10 micro-seconds. For 88 Khz, approximately 5 micro-seconds.) 2. Write/read data to FIFO s at least 2 samples at the time. If there is a mismatch Left-Right, the resync logic may go on only 1 sample clock after last data is read/written to the FIFO. Also acceptable is polling the FIFO, if at least part of the time 2 samples will be read/written to it.

- **SPDIF receiver - Additional features**

There are three exceptions associated with the SPDIF Receivers FIFOs

- full
- under/overrun
- resync

When the "full" condition is set for processor data input registers, the processor should read data from the FIFO, before overrun occurs. When "full" is set, and the FIFO contains e.g. 6 samples, it is acceptable for the software to read first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 6 samples from the RIGHT address, followed by 6 samples from the LEFT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. There is no order specified.

The implementation for SPDIF Rx is a double FIFO, one for left and one for right. "full" is set when both FIFOs are full. "underrun, overrun" are set when one of the FIFOs do underrun or do overrun. The resync interrupt means hardware took special action to resynchronize left and right FIFOs.

The FIFO level at which the "full" interrupt is generated, is programmable via the Full Select field in the SPDIFConfigReg register.

Rx FIFO on and Rx FIFO reset.

Two additional control fields of the SPDIF Rx FIFO are the on/off select and FIFO reset fields.

If on/off select is set to off, all-zero will be read from the FIFO, irrespective of the data received over the SPDIF interface.

If FIFO reset is set, the FIFO is blocked at "1 sample in FIFO". In this, the full interrupt will be on if FullSelect is set to "00". If FullSelect is set to any other value, interrupt will be off. The other interrupts are always off.

69.3.1.2 Channel Status Reception

A total of 48 channel status bits are received in two registers. No interpretation is performed by the SPDIF receiver block.

Channel Status Bits are ordered first bit left. CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFRxCChannel_h. CS-channel bit "23" is considered the LSB bit 0 in the register. C-channel bit 24 to 47 is seen as [23:0] bits of register SPDIFRxCChannel_l.

69.3.1.2.1 Channel Status Interrupt

When the value of a new SPDIF "CS" channel status frame is loaded in the register, an interrupt is generated. The interrupt is cleared when the processor writes the corresponding bit in the InterruptStat register.

69.3.1.3 User Bit Reception

There are two modes for U Channel reception, CD and non-CD. As is decided by USyncMode (bit 1 of CDText_Control register).

- **Behavior of U Channel receive interface on incoming CD U Channel Sub-code in SPDIF receiver**.

This mode is selected if UsyncMode, bit 1 in register CD Text control is set "1".

The CD sub-code stream embedded into the SPDIF U channel consists of a sequence of packets. Every packet is made up 98 "symbols". The first two symbols of every packet are "sync symbols", the other 96 symbols are "data symbols".

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

Data symbols are coming in MSB first. The MSB is the leading one.

When a "long pause" is seen between 2 subsequent "data symbols", the SPDIF receiver will assume the reception of one or more "sync symbols". Table below gives details.

Table 69-2. Sync Control Bits

Number of U Channel zero bits	Corresponding number of sync symbols
0-1	Unpredictable, not allowed
2-10	0
11-22	1
23-34	2
35-46	3
>45	Unpredictable, not allowed

The recognition of the number of sync symbols derives from the fact that the U channel transmitter in the CD channel decoder will transmit one symbol on average every 12 SPDIF channel bits. On this average rate, there is a maximum tolerance of 5%.

The SPDIF receiver is tolerant of symbol errors. Due to the physical nature of the transmission of the data over the CD disc, not more than 1 out of any 5 consecutive user channel symbols may be in error. The error may cause a change in data value, which is not detected by this interface, or it may cause a data symbol to be seen as a sync symbol, or a sync symbol to be seen as a data symbol. However, not more than 1 out of any 5 consecutive user channel symbols should be affected in this way.

The SPDIF U channel circuitry recognizes the 98-symbol packet structure, and sends the 96 symbol payload to the processor application. The 96 symbol payload is transmitted to the processor via 2 registers:

- The SPDIFRxUChannel register. In this register, data is presented 3 symbols at the time to the processor. Every time 3 new valid symbols, received on the SPDIF U Channel are present, the UChannelRxFull interrupt is asserted. For one 98-symbol packet, 96 symbols are carried across SPDIFRxUChannel. To transfer all this data, 32 UChannelRxFull interrupts are generated.
- The QChannelReceive register. In this register, only the Q bit of the packet is accumulated.Operation is similar to UChannelReceive. Because only Q-bit is transferred, only 96 Q-bits are transferred for any 98-symbol packet. To transfer this data, 4 QChannelRxFull interrupts are generated. When QChannelRxFull occurs, it is coincident with UChannelRxFull. There is only one QChannelRxFull for every 8 UChannelRxFull. The convention is that most significant data is transmitted first, and is left-aligned in the registers.
- Timing regarding packet boundary is extracted by hardware. The last UChannelRxFull corresponding to a given packet should be coincident with the last QChannelRxFull. In this last U, Q channel interrupt, symbols 95-98 are received, Q

channel bits 67-98. The interrupts are coincident with UQSyncFound, flagging last symbols of the current frame.
- When the start of the new packet is found before the current packet is complete (less than 98 symbols in the packet), the UQFrameError interrupt is set. The application software should read out UChannelReceive and QchannelReceive registers, discard the value, and assume the start of a new packet.
- As already said, packet sync extraction is tolerant for single-symbol errors. Packet sync detection is based on the recognition of the sequence data-sync-sync-data in the symbol stream, because this is the only syncing sequence that is not affected by single errors. If the sync symbols are not found 98 symbols after the previous occurrence, it is assumed to be destroyed by channel error, and a new sync symbols is interpolated.
- Normally, only data bytes are passed to the application software. Every databyte will have its most significant bit set. If sync symbols are passed to the application software, they are seen as all-zero symbols. Sync symbols can only end up in the data stream due to channel error.

- **Behavior of U Channel receive interface on incoming non-CD data**.

This mode is selected if UsyncMode, bit 1 in register CD Text control is set'0'.

In non-CD mode, the SPDIF U channel stream is recognized as a sequence of "data symbols". No packet recognition is done.

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

3 consecutive data symbols seen in the SPDIF U Channel stream are grouped together into the SPDIFRxUChannel register. First symbol is left, last symbol is right aligned. When SPDIFRxUChannel contains 3 new data symbols, UChannelRxFull is asserted.

In this mode, the operation of QchannelRx and associated interrupt QchannelRxFull is reserved, undefined. And the operation of UQFrameError and UQSyncFound is also reserved, undefined.

The U channel is extracted, and output by the SPDIF Rx on SPDIFRxUChannel-Stream.

When incoming SPDIF data parity error or bit error is detected, and if the next SPDIF word for that channel is error-free, the SPDIF word in error is replaced with the average of the previous word and next word. When incoming SPDIF data parity error or bit error is detected, and the next SPDIF word is in error, the previous SPDIF word is repeated.

69.3.1.4 Validity Flag Reception

An interrupt is associated with the Validity flag. (interrupt 16 - SPDIFValNoGood). This interrupt is set every time a frame is seen on the SPDIF interface with the validity bit set to "invalid".

69.3.1.5 SPDIF Receiver Interrupt Exception Definition

Several SPDIF exceptions can trigger an interrupt.

They are:

- Control Status channel change. Set when SPDIFRxCChannel1 register is updated. The register is updated for every new C-Channel received. The exception is reset on write to InterruptClear register.
- SPDIF Illegal Symbol. Set on reception of illegal symbol during SPDIF receive. Reset by writing register InterruptClear.[1]
- SPDIF bit error. Set on reception of bit error. (Parity bit does not match). Reset on write to InterruptClear register.
- Receive data FIFO full. Set when SPDIF receive data FIFO is full.
- Receive data FIFO underrun/overrun. Set when there is a underrun/overrun on the SPDIF receive data FIFO.
- Receive data FIFO resynchronization. Set when a resynchronization event occurs on the SPDIF receive data FIFO.
- Receive U Channel buffer full. Set when next 24 bits of U channel code are available.
- Receive Q Channel buffer overrun. Set when Q channel buffer overrun.
- Receive U Channel buffer overrun. Set on U channel buffer overrun.
- Receive Q Channel buffer full. Set when next 24 bits of Q channel code are available.
- Receive UQ sync found. Set when UQ channel sync found.
- Receive UQ frame error. Set when UQ frame error found.

1. The SPDIF input is a biphase/mark modulated signal. The time between any two successive transitions of the SPDIF signal is always 1, 2 or 3 SPDIF symbol periods long. The SPDIF receiver will parse the stream, and split it in so-called symbols. It recognizes s1, s2 and s3 symbols, depending on the length of the symbols. Not all sequences of these symbols are allowed. To give an example, a sequence s2-s1-s1-s1-s2 cannot occur in a no-error SPDIF signal. If the receiver finds such an illegal sequence, the illegal symbol interrupt is set. No corrective action is undertaken. When the interrupt occurs, this means that(a) The SPDIF signal is destroyed by noise (b) The SPDIF frequency changed.

69.3.1.6 Standards Compliance

The SPDIF interface is compatible with the Tech 3250-E standard of the European Broadcasting Union, except clause 6.3.3 and the IEC60958-3 Ed2 for relevant topics.

Supported input frequency range is 12 Khz up to 96 Khz. (fully compliant) and 96 Khz up to 176 Khz (Can interface with compliant SPDIF transmitter within same cabinet, making reasonable assumptions on jitter added due to interconnecting wire.)

Tolerated jitter on SPDIF input signals are 0.25 bit peak-peak for high frequencies. There is no jitter limit for low frequencies. The user channel extraction in CD mode is capable of coping with single-symbol errors, and still retrieve U channel frames on correct boundaries. This capability is required for reliable reception of CD-Text from some Philips CD channel decoders. This capability was deemed more important than compliance with the IEC60958 annex A.3 standard, and for this reason user channel reception is not compliant with IEC60958 annex A.3. However, the interface is capable to receive U channel inserted by a typical CD channel decoder. Also, in this case, it is more robust and tolerant for channel error than what is required by IEC60958 annex A.3.

69.3.1.7 SPDIF PLOCK Detection and Rxclk Output

Using the high speed system clock, the internal DPLL can extract the bit clock (advanced pulse) from the input bitstream. When this internal DPLL is locked, the LOCK bit of PhaseConfig Register will be set, and the SPDIF Lock output pin PLOCK will be asserted.

After DPLL has locked, the pulses are generated, and the average pulse rate is 128 x the sampling frequency.(For a 44.1 Khz input sampling frequency, the average pulse rate = 128 x 44.1 Khz.) The pulse signal is used in the FreqMeas circuit to generate the frequency measurement result.

69.3.1.8 Measuring Frequency of SPDIF_RxClk

The internal DPLL can extract the bit clock (advanced plus) from the input bitstream. To do that, it is necessary to measure the frequency of the incoming signal in relationship with the system clock (BUS_CLK).

Associated with it are two registers, PhaseConfig and FreqMeas. The circuit will measure the frequency of the incoming clock as a function of the BUS_CLK. The circuit is a second-order filter. The output is a value represented by an unsigned number stored in the 24-bit FreqMeas register, giving the frequency of the source as a function of the BUS_CLK.

FreqMeas[23:0] = FreqMeas_CLK / BUS_CLK * 2^{10} * GAIN.

For example, if the GAIN is selected as 8*210 (PhaseConfig[5:3] = 3'b011), the actual result

FreqMeas_CLK / BUS_CLK is equal to FreqMeas[23:0] / 2^{23}.

69.3.2 SPDIF Transmitter

Audio data for the SPDIF transmitter is provided by processor via the SPDIFTxLeft and SPDIFTxRight registers.

Clocking for SPDIF transmitter is from either the osc_audio, ipg_baud_spdif_clk, hckt, or spdif_extclk, mlbclk or frequency divided ipg_clk.A multiplexer is used to choose the clock source. The SPDIF transmitter clock source can be divided down as needed using Txclk_DF. The SPDIF transmitter output can be chosen from either the SPDIF transmitter block, directly from the SPDIF receiver (via the output multiplexer), or disabled.

The SPDIF transmitter generates a SPDIF output bitstream in IEC60958 biphase mark format, consisting of audio data, channel status.

69.3.2.1 Audio Data Transmission

Audio data for the SPDIF transmitter is provided by the processor via SPDIFTxLeft and SPDIFTxRight registers. They send audio data to Tx left and right FIFOs. The Tx left and right FIFOs are also 16-deep and 24-width (equal to the audio data width).

- **SPDIF transmitter data registers - Behavior on overrun, underrun**

The SPDIF Data Transmit registers (SPDIFTxLeft and SPDIFTxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFO. To prevent this from happening, hardware has been added on the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If SPDIF Tx FIFO underruns on the right half of the FIFO, no sample leaves that FIFO (because it was already empty). Special hardware will make sure that the next sample read from the left FIFO will not leave the FIFO (no read strobe is generated). If the underrun occurs on the left half of the FIFO, next read strobe to the right FIFO is blocked.

- **SPDIF transmitter data registers - Automatic resynchronization of FIFOs**

See Audio Data Reception.

- **SPDIFTxLeft, SPDIFTxRight details**

With SPDIF Tx FIFOs three exceptions are associated.

- empty
- under/overrun
- resync

When the empty condition is set for processor data output registers, the processor should write data to the FIFO, before underrun occurs. When empty is set and, for instance, 6 samples need to be written, it is acceptable for the software to write first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. Left should be written before right. The implementation of all data out FIFOs is a double FIFO, one for left and one for right. Empty is set when both FIFOs are empty. Underrun, overrun are set when one of the FIFOs do underrun or do overrun. Resync is set when the hardware resynchronizes left and right FIFOs.

On receiving underrun, overrun interrupt, synchronization between Left and Right words in the FIFOs may be lost. Synchronization will not be lost when the underrun or overrun comes from the IEC60958 side of the FIFO. If the processor reads or writes more data from, for example, left than from right, synchronization will be lost. If automatic resynchronization is enabled, and if the software obeys the rules to let this work, resynchronization will be automatic.

69.3.2.2 Channel Status Transmission

A total of 48 Consumer channel status bits are transmitted from two registers. Channel Status Bits are ordered first bit left.

CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFTxCChannelCons_h. CS-channel bit "23" is considered bit 0 in the register. C-channel bits 24-47 are seen as MSB-LSB bits of register SPDIFTxCChannelCons_l.

69.3.2.3 Validity Flag Transmission

The validity bit setting is performed via bit 5 of the SPDIF_SCR register.

69.4 Programmable Registers

SPDIF memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
5002_8000	SPDIF Configuration Register (SPDIF_SCR)	32	R/W	0000_0400h	69.4.1/ 4336

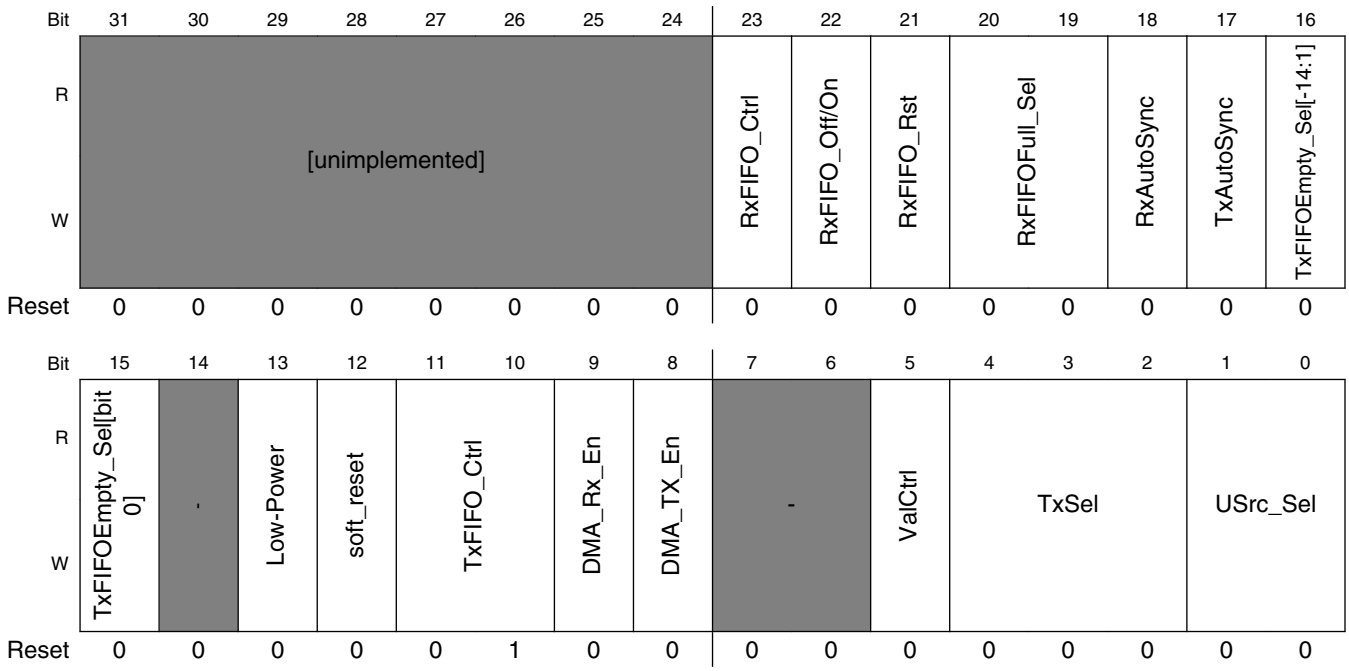
69.4.1 SPDIF Configuration Register (SPDIF_SCR)

Address: SPDIF_SCR is 5002_8000h base + 0h offset = 5002_8000h



SPDIF_SCR field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23 RxFIFO_Ctrl	0 Normal operation 1 Always read zero from Rx data register
22 RxFIFO_Off/On	0 SPDIF Rx FIFO is on 1 SPDIF Rx FIFO is off. Does not accept data from interface
21 RxFIFO_Rst	0 Normal operation 1 Reset register to 1 sample remaining
20–19 RxFIFOFull_Sel	00 Full interrupt if at least 1 sample in Rx left and right FIFOs 01 Full interrupt if at least 4 sample in Rx left and right FIFOs 10 Full interrupt if at least 8 sample in Rx left and right FIFOs 11 Full interrupt if at least 16 sample in Rx left and right FIFO
18 RxAutoSync	0 Rx FIFO auto sync off 1 RxFIFO auto sync on
17 TxAutoSync	0 Tx FIFO auto sync off 1 Tx FIFO auto sync on
16–15 TxFIFOEmpty_Sel	00 Empty interrupt if 0 sample in Tx left and right FIFOs 01 Empty interrupt if at most 4 sample in Tx left and right FIFOs

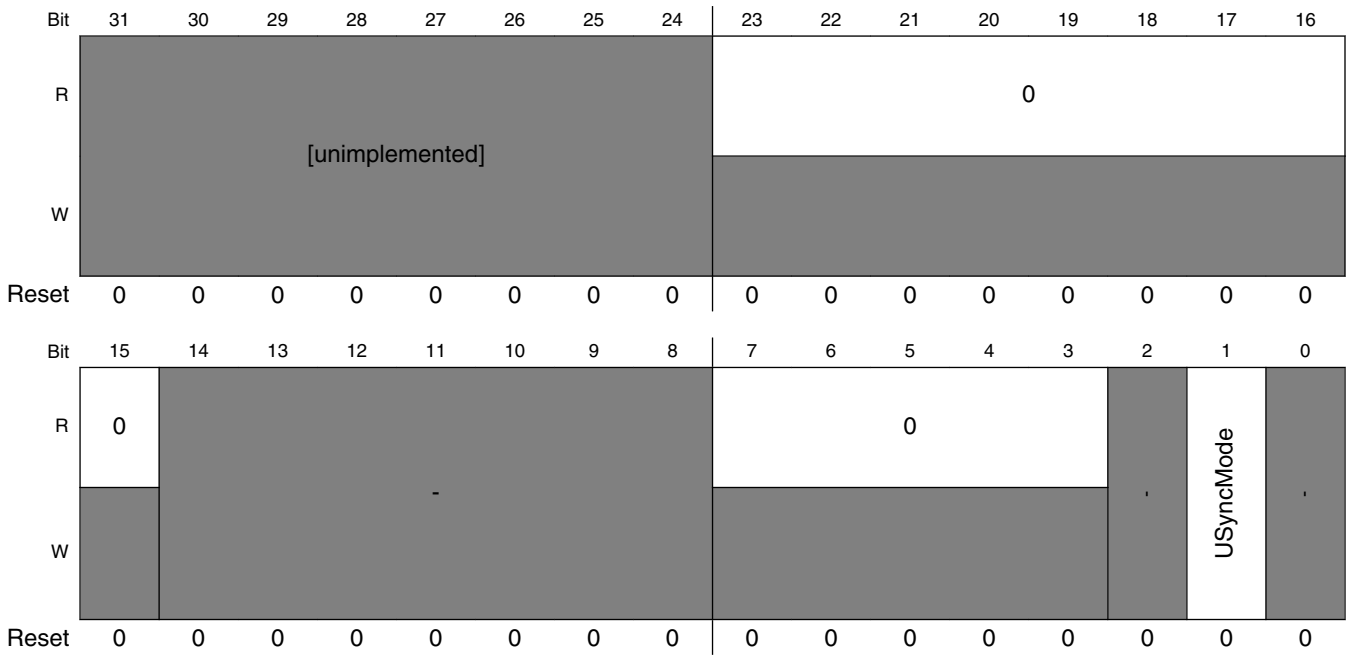
Table continues on the next page...

SPDIF_SCR field descriptions (continued)

Field	Description
	10 Empty interrupt if at most 8 sample in Tx left and right FIFOs 11 Empty interrupt if at most 12 sample in Tx left and right FIFOs
14 -	Reserved
13 Low-Power	When write 1 to this bit, it will cause SPDIF enter low-power mode. return 1 when SPDIF in Low-Power mode.
12 soft_reset	When write 1 to this bit, it will cause SPDIF software reset. The software reset will last 8 cycles. When in the reset process, return 1 when read. else return 0 when read.
11–10 TxFIFO_Ctrl	00 Send out digital zero on SPDIF Tx 01 Tx Normal operation 10 Reset to 1 sample remaining 11 Reserved
9 DMA_Rx_En	DMA Receive Request Enable (RX FIFO full)
8 DMA_TX_En	DMA Transmit Request Enable (Tx FIFO empty)
7–6 -	Reserved
5 ValCtrl	0 Outgoing Validity always set 1 Outgoing Validity always clear
4–2 TxSel	000 Off and output 0 001 Feed-through SPDIFIN 101 Tx Normal operation
1–0 USrc_Sel	00 No embedded U channel 01 U channel from SPDIF receive block (CD mode) 10 Reserved 11 U channel from on chip transmitter

69.4.2 CDText Control Register (SPDIF_SRCD)

Address: SPDIF_SRCD is 5002_8000h base + 4h offset = 5002_8004h

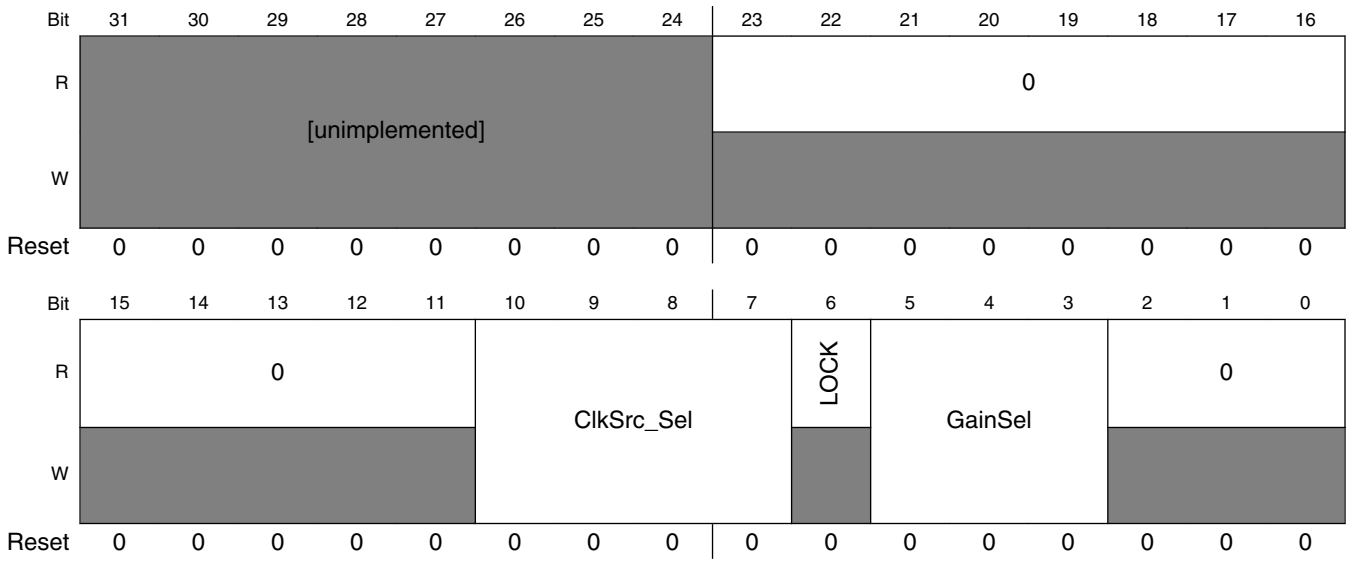


SPDIF_SRCD field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–15 Reserved	This read-only field is reserved and always has the value zero. Return zeros when read
14–8 -	Reserved
7–3 Reserved	This read-only field is reserved and always has the value zero. Return zeros when read
2 -	Reserved
1 USyncMode	0 Non-CD data 1 CD user channel subcode
0 -	Reserved

69.4.3 PhaseConfig Register (SPDIF_SRPC)

Address: SPDIF_SRPC is 5002_8000h base + 8h offset = 5002_8008h



SPDIF_SRPC field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–11 Reserved	This read-only field is reserved and always has the value zero. Reserved, return zeros when read
10–7 ClkSrc_Sel	Clock source selection, all other settings not shown are reserved: 0000 if (DPLL Locked) SPDIF_RxClk else extal 0001 if (DPLL Locked) SPDIF_RxClk else spdif_clk 0011 if (DPLL Locked) SPDIF_RxClk else asrc_clk 0100 if (DPLL Locked) SPDIF_Rxclk else esai_hckt 0101 extal_clk 0110 spdif_clk 1000 asrc_clk 1001 esai_hckt 1010 if (DPLL Locked) SPDIF_RxClk else mlb_clk 1011 if (DPLL Locked) SPDIF_RxClk else camp_clk 1100 mkb_clk 1101 camp_clk
6 LOCK	LOCK bit to show that the internal DPLL is locked, read only
5–3 GainSel	Gain selection: 000 24*2**10 001 16*2**10

Table continues on the next page...

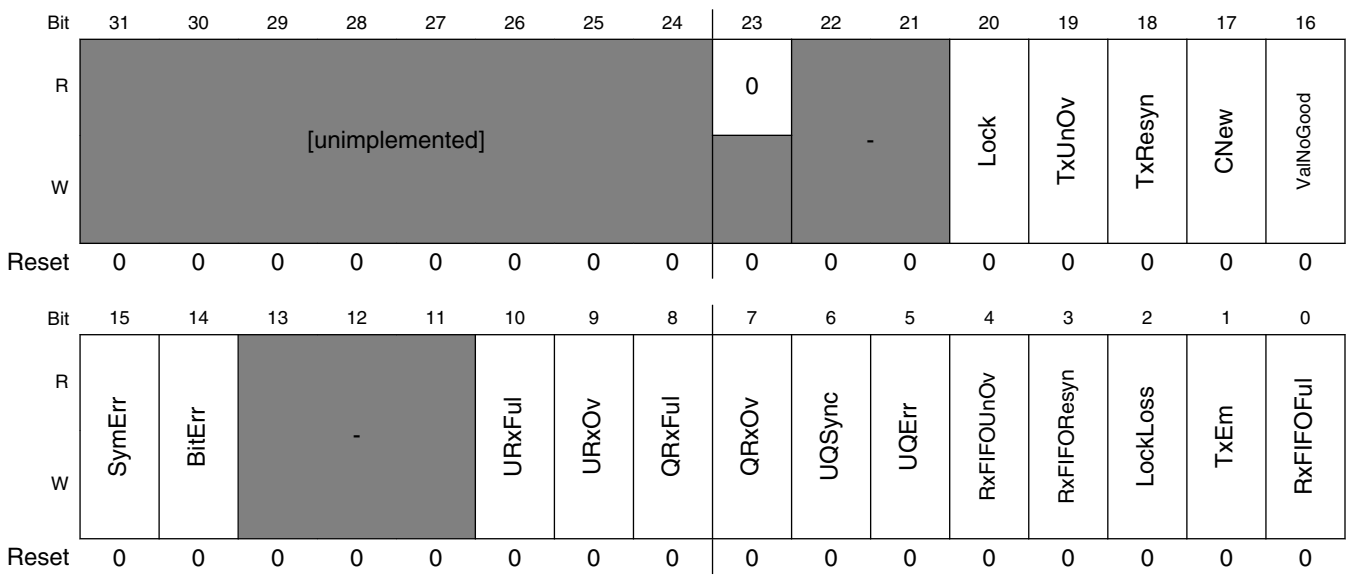
SPDIF_SRPC field descriptions (continued)

Field	Description
	010 12*2**10 011 8*2**10 100 6*2**10 101 4*2**10 110 3*2**10
2–0 Reserved	This read-only field is reserved and always has the value zero. Reserved, return zeros when read

69.4.4 InterruptEn Register (SPDIF_SIE)

The InterruptEn register (SPDIF_SIE) provides control over the enabling of interrupts.

Address: SPDIF_SIE is 5002_8000h base + Ch offset = 5002_800Ch



SPDIF_SIE field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23 Reserved	This read-only field is reserved and always has the value zero. Reserved, for InterruptStat/Clear return zeros when read, for InterruptEn, bit 23 also read zero
22–21 -	Reserved, for InterruptStat/Clear return zeros when read, for InterruptEn, bit 23 also read zero
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overrun

Table continues on the next page...

SPDIF_SIE field descriptions (continued)

Field	Description
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–11 -	Reserved. Return zeros when read
10 URxFul	U Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from U Rx reg.
9 URxOv	U Channel receive register overrun
8 QRxFul	Q Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from Q Rx reg.
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
1 TxEm	SPDIF Tx FIFO empty, can't be cleared with reg. IntClear. To clear it, write toTx FIFO.
0 RxFIFOFul	SPDIF Rx FIFO full, can't be cleared with reg. IntClear. To clear it, read from Rx FIFO.

69.4.5 InterruptStat Register (SPDIF_SIS)

The InterruptStat (SPDIF_SIS) register is a read only register that provides the status on interrupt operations.

Address: SPDIF_SIS is 5002_8000h base + 10h offset = 5002_8010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	[unimplemented]								0			Lock	TxUnOv	TxResyn	CNew	ValNoGood

SPDIF_SIS field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–21 Reserved	This read-only field is reserved and always has the value zero. Reserved, for InterruptStat/Clear return zeros when read.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overrun
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel

Table continues on the next page...

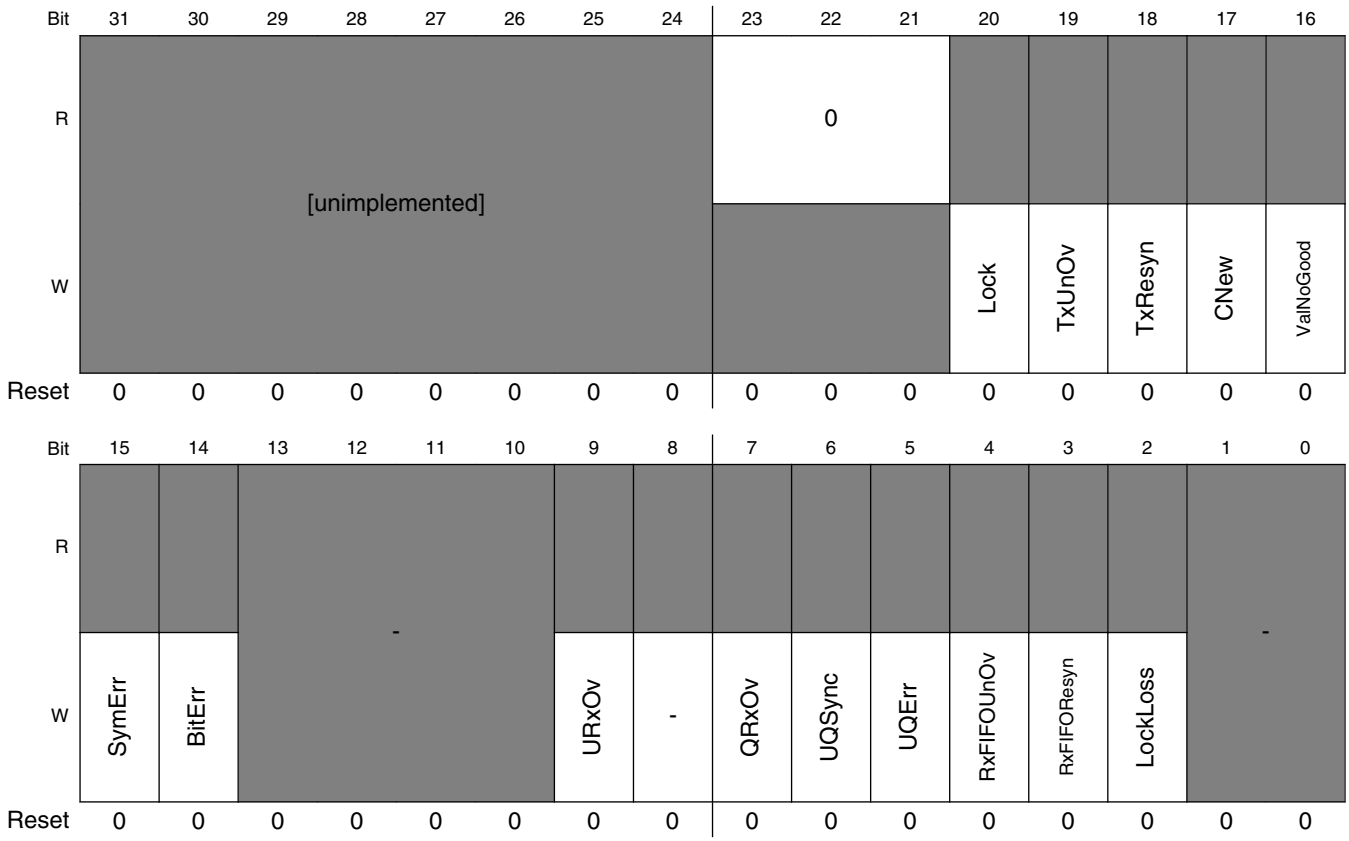
SPDIF_SIS field descriptions (continued)

Field	Description
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–11 Reserved	This read-only field is reserved and always has the value zero. Reserved. Return zeros when read
10 URxFul	U Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from U Rx reg.
9 URxOv	U Channel receive register overrun
8 QRxFul	Q Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from Q Rx reg.
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
1 TxEm	SPDIF Tx FIFO empty, can't be cleared with reg. IntClear. To clear it, write toTx FIFO.
0 RxFIFOFul	SPDIF Rx FIFO full, can't be cleared with reg. IntClear. To clear it, read from Rx FIFO.

69.4.6 InterruptClear Register (SPDIF_SIC)

The InterruptClear (SPDIF_SIC) register is a write only register and is used to clear interrupts.

Address: SPDIF_SIC is 5002_8000h base + 10h offset = 5002_8010h



SPDIF_SIC field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–21 Reserved	This read-only field is reserved and always has the value zero. Reserved, for InterruptStat/Clear return zeros when read.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overrun
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel

Table continues on the next page...

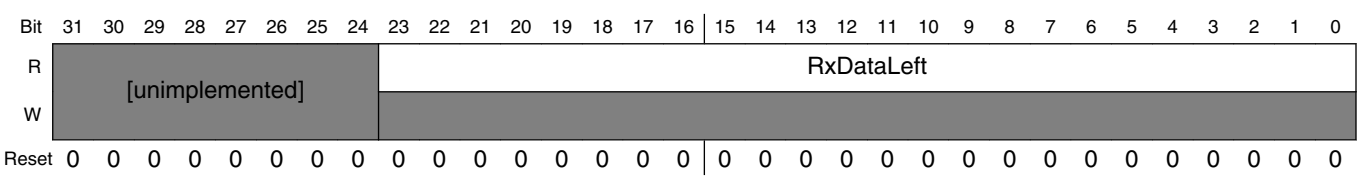
SPDIF_SIC field descriptions (continued)

Field	Description
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–10 -	Reserved.
9 URxOv	U Channel receive register overrun
8 -	Reserved
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
1–0 -	Reserved.

69.4.7 SPDIFRxLeft Register (SPDIF_SRL)

SPDIFRxLeft register is an audio data reception register.

Address: SPDIF_SRL is 5002_8000h base + 14h offset = 5002_8014h



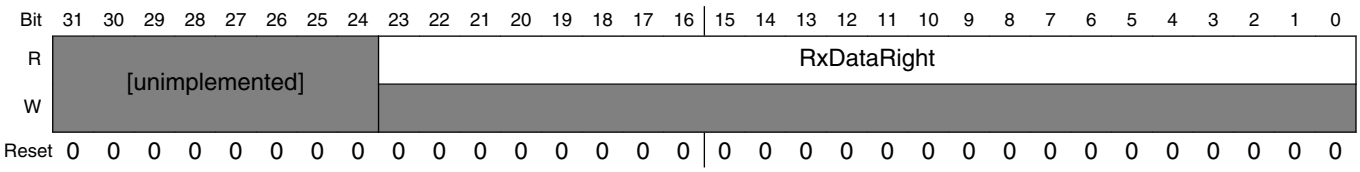
SPDIF_SRL field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 RxDataLeft	Processor receive SPDIF data left

69.4.8 SPDIFRxRight Register (SPDIF_SRR)

SPDIFRxRight register is an audio data reception register.

Address: SPDIF_SRR is 5002_8000h base + 18h offset = 5002_8018h



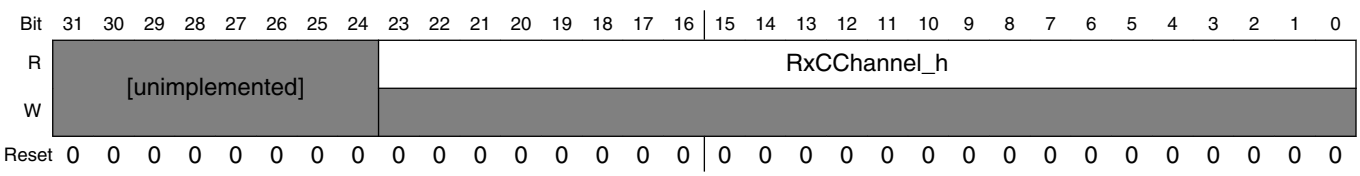
SPDIF_SRR field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 RxDataRight	Processor receive SPDIF data right

69.4.9 SPDIFRxCChannel_h Register (SPDIF_SRCSH)

SPDIFRxCChannel_h register is a channel status reception register.

Address: SPDIF_SRCSH is 5002_8000h base + 1Ch offset = 5002_801Ch



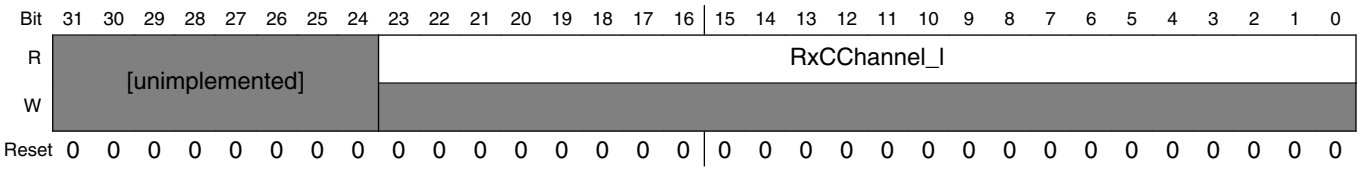
SPDIF_SRCSH field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 RxCChannel_h	SPDIF receive C channel register, contains first 24 bits of C channel without interpretation

69.4.10 SPDIFRxCChannel_l Register (SPDIF_SRCSL)

SPDIFRxCChannel_l register is a channel status reception register.

Address: SPDIF_SRCSL is 5002_8000h base + 20h offset = 5002_8020h



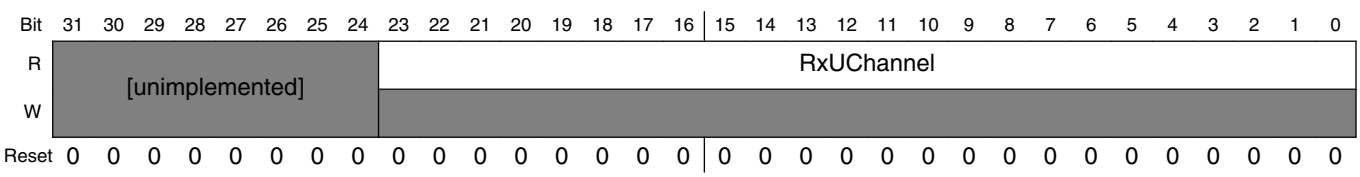
SPDIF_SRCSL field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 RxCChannel_l	SPDIF receive C channel register, contains next 24 bits of C channel without interpretation

69.4.11 UchannelRx Register (SPDIF_SRU)

UChannelRx register is a user bits reception register.

Address: SPDIF_SRU is 5002_8000h base + 24h offset = 5002_8024h



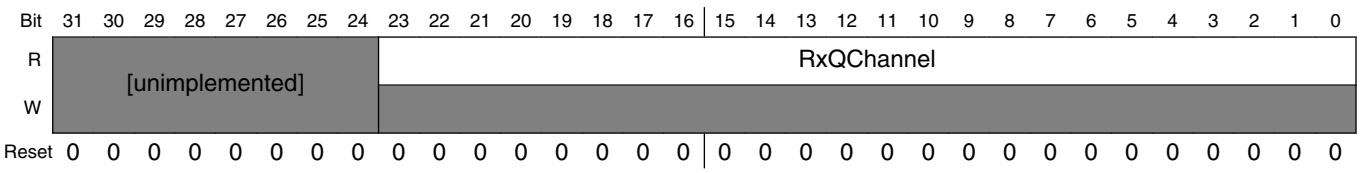
SPDIF_SRU field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 RxUChannel	SPDIF receive U channel register, contains next 3 U channel bytes

69.4.12 QchannelRx Register (SPDIF_SRQ)

QChannelRx register is a user bits reception register.

Address: SPDIF_SRQ is 5002_8000h base + 28h offset = 5002_8028h



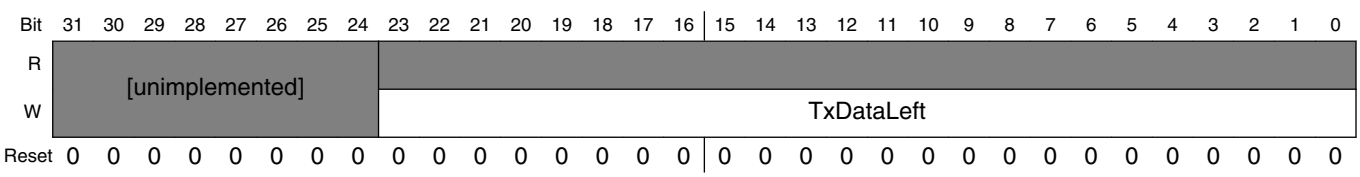
SPDIF_SRQ field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 RxQChannel	SPDIF receive Q channel register, contains next 3 Q channel bytes

69.4.13 SPDIFTxLeft Register (SPDIF_STL)

SPDIFTxLeft register is an audio data transmission register.

Address: SPDIF_STL is 5002_8000h base + 2Ch offset = 5002_802Ch



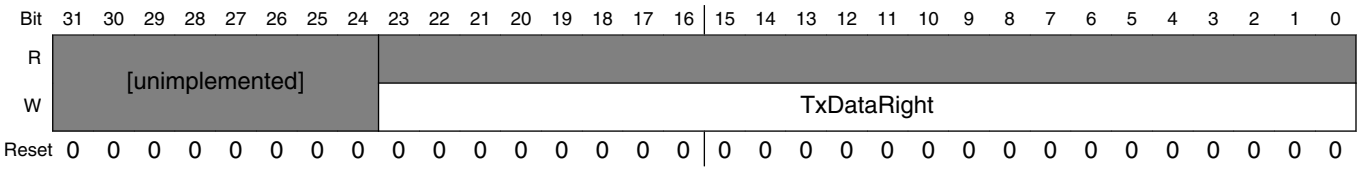
SPDIF_STL field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 TxDataLeft	SPDIF transmit left channel data. It is write-only, and always returns zeros when read

69.4.14 SPDIFTxRight Register (SPDIF_STR)

SPDIFTxRight register is an audio data transmission register.

Address: SPDIF_STR is 5002_8000h base + 30h offset = 5002_8030h



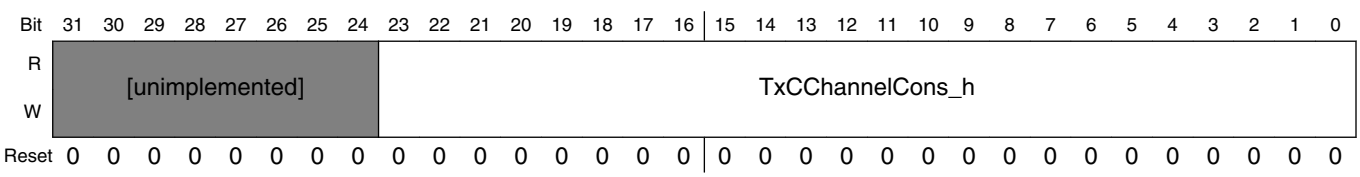
SPDIF_STR field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 TxDataRight	SPDIF transmit right channel data. It is write-only, and always returns zeros when read

69.4.15 SPDIFTxCChannelCons_h Register (SPDIF_STCSCH)

SPDIFTxCChannelCons_h register is a channel status transmission register.

Address: SPDIF_STCSCH is 5002_8000h base + 34h offset = 5002_8034h



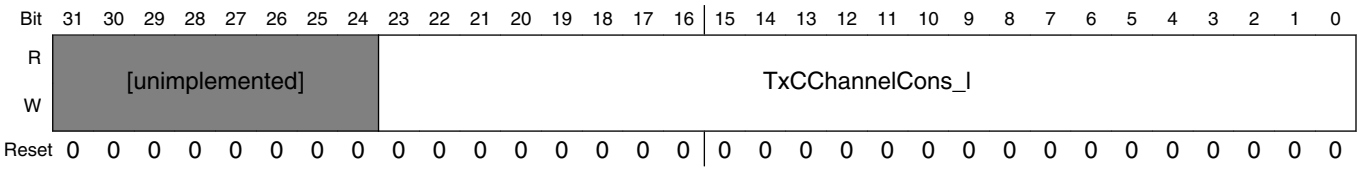
SPDIF_STCSCH field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 TxCChannelCons_h	SPDIF transmit Cons. C channel data, contains first 24 bits without interpretation. When read, it returns the latest data written by the processor

69.4.16 SPDIFTxCChannelCons_l Register (SPDIF_STCSCL)

SPDIFTxCChannelCons_l register is a channel status transmission register.

Address: SPDIF_STCSCL is 5002_8000h base + 38h offset = 5002_8038h

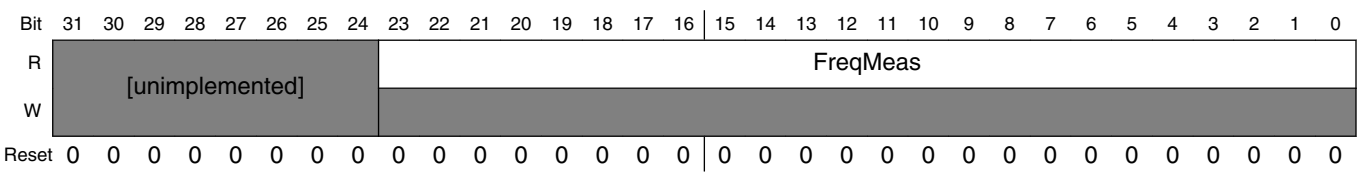


SPDIF_STCSCL field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 TxCChannelCons_l	SPDIF transmit Cons. C channel data, contains next 24 bits without interpretation. When read, it returns the latest data written by the processor

69.4.17 FreqMeas Register (SPDIF_SRFM)

Address: SPDIF_SRFM is 5002_8000h base + 44h offset = 5002_8044h



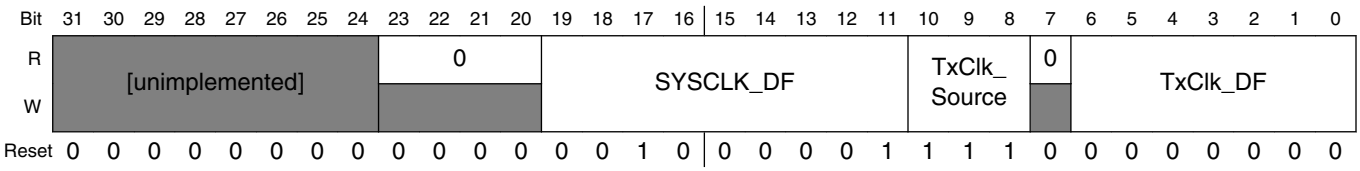
SPDIF_SRFM field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 FreqMeas	Frequency measurement data

69.4.18 SPDIFTxClk Register (SPDIF_STC)

The SPDIFTxClk Control register includes the means to select the transmit clock and frequency division.

Address: SPDIF_STC is 5002_8000h base + 50h offset = 5002_8050h



SPDIF_STC field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–20 Reserved	This read-only field is reserved and always has the value zero. Reserved, return zeros when read
19–11 SYSCLK_DF	system clock divider factor, 2~512. 0 no clock signal 1 divider factor is 2 511 divider factor is 512
10–8 TxClk_Source	000 camp1 clk input 001 CCM spdif0_clk_root input 011 asrc_clk input 100 esai_hckt input 101 frequency divided ipg_clk input 110 mlb_clk input 111 camp2 clk input
7 Reserved	This read-only field is reserved and always has the value zero. Reserved, return zero when read
6–0 TxClk_DF	Divider factor (1-128) 0 divider factor is 1 1 divider factor is 2 127 divider factor is 128

Chapter 70
System Reset Controller (SRC)

70.1 Introduction

SRC generates all reset signals for each block within i.MX53.

70.1.1 Overview

The System Reset Controller (SRC) generates all functional block reset signals. It also determines the boot image device by decoding the BOOT_MODE[1:0] value and the values of several BOOT CFG fields in the register. The reset control determines the source and the type of reset, such as POR, WARM, COLD, and performs the necessary reset qualification and stretching sequences. Based on the type of reset, the reset logic generates the reset sequence for the entire SoC. On initial power on, RESET_B pin signal is asserted (low) and the entire chip is reset.

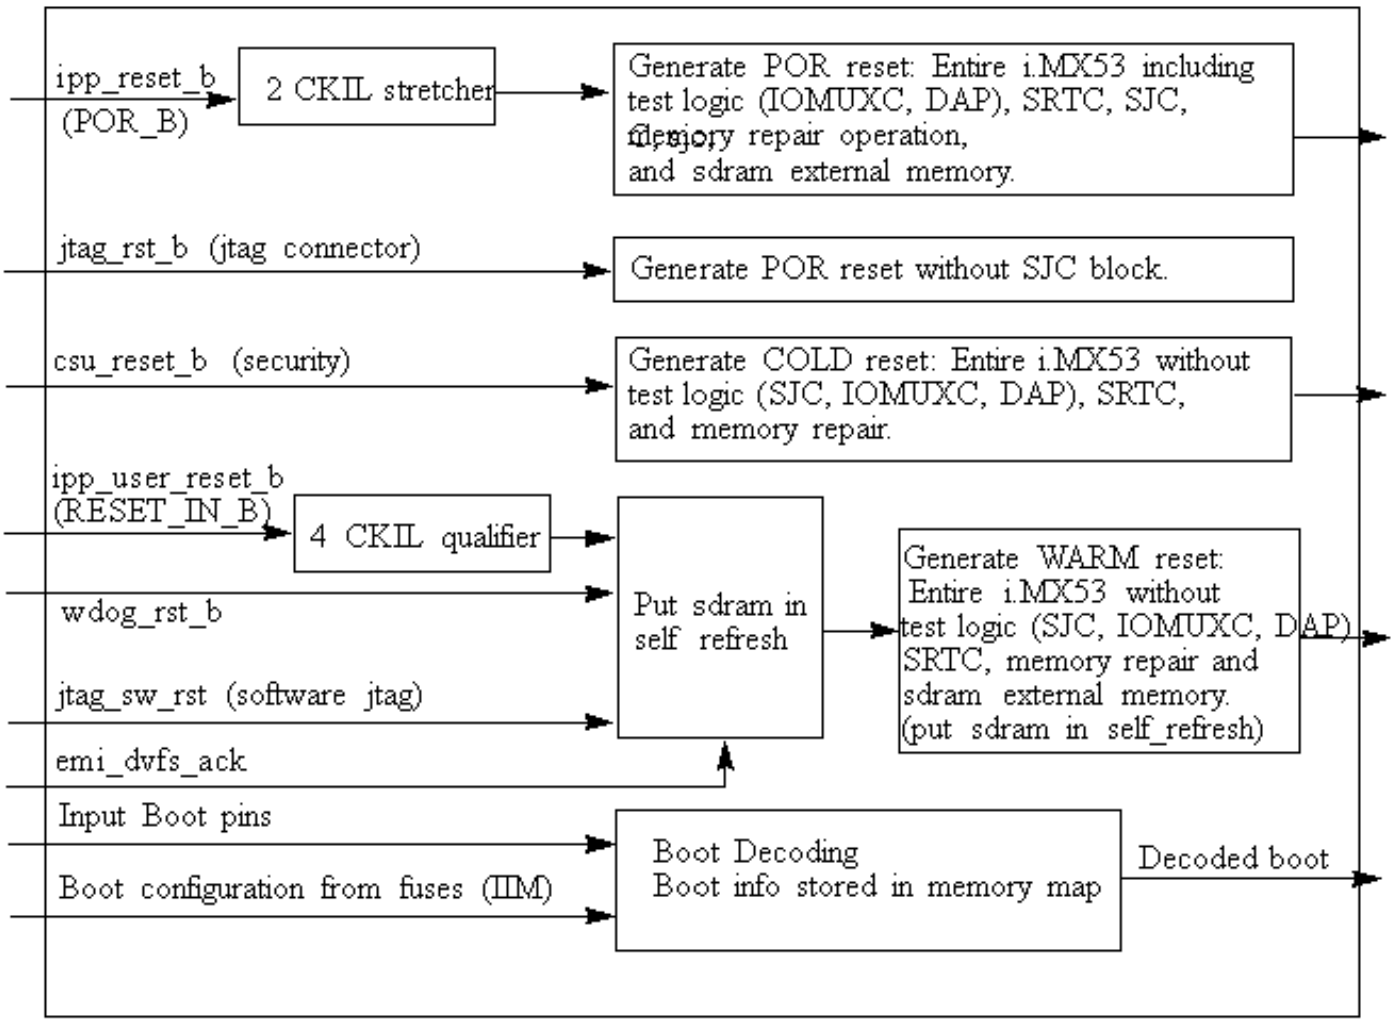


Figure 70-1. SRC High Level diagram

70.1.2 Features

The SRC includes the following features.

- Receives and handles the resets from all the reset sources
- Reset the appropriate domains based upon the resets sources and the nature of the reset.
- Latches the BOOT_MODE pins and common configuration signals from the internal fuse
- The SRC has 32-bit IP Bus interface

70.2 Programmable Registers

SRC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53FD_0000	SRC Control Register (SRC_SCR)	32	R/W	0000_0D21h	70.2.1/ 4355
53FD_0004	SRC Boot Mode Register (SRC_SBMR)	32	R	0000_0000h	70.2.2/ 4357
53FD_0008	SRC Reset Status Register (SRC_SRSR)	32	R/W	0000_0001h	70.2.3/ 4358
53FD_0014	SRC Interrupt Status Register (SRC_SISR)	32	R	0000_0000h	70.2.4/ 4360
53FD_0018	SRC Interrupt Mask Register (SRC_SIMR)	32	R/W	0000_000Fh	70.2.5/ 4361

70.2.1 SRC Control Register (SRC_SCR)

Address: SRC_SCR is 53FD_0000h base + 0h offset = 53FD_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				weim_rst	mask_wdog_rst				warm_rst_ bypass_ count		sw_open_ vg_rst	sw_ipu_rst	sw_vpu_rst	sw_gpu_rst	warm_reset_ enable
W																
Reset	0	0	0	0	1	1	0	1	0	0	1	0	0	0	0	1

SRC_SCR field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11 weim_rst	EIM reset is needed in order to reconfigure the EIM chip select. The software reset bit must deasserted.

Table continues on the next page...

SRC_SCR field descriptions (continued)

Field	Description
	The EIM chip select configuration should be updated. The software bit must be re-asserted since this is not self-refresh.
10–7 mask_wdog_rst	Mask wdog_rst_b source. If these 4 bits are coded from A to 5 then, wdog_rst_b input to SRC will be masked and wdog_rst_b will not create reset to the IC. **NOTE:** any other code will be coded to 1010 i.e. wdog_rst_b is not masked During the time the WDOG event is masked using SRC logic, it is likely that WDOG Reset Status Register (WRSR) bit 1 (which indicates WDOG timeout event) will get asserted. SW / OS developer must prepare for this case. Re-enable WDOG is possible, by un-mask it in SRC, though it must be preceded by servicing the WDOG. However, for the case that the event has been asserted, the status bit (WRSR bit-1) will remain asserted, regardless of servicing the WDOG. (HW reset is the only mean to cause deassertion of that bit). 0101 wdog_rst_b is masked 1010 wdog_rst_b is not masked (default)
6–5 warm_rst_ bypass_count	Defines the CKIL cycles to count before bypassing the EXTMC acknowledge for warm reset. If the EXTMC acknowledge will not be asserted before this counter has elapsed, then a cold reset will be initiated. 00 Counter not to be used - system will wait until EXTMC acknowledge until it is asserted. 01 Wait 16 CKIL cycles before changing warm reset to a cold reset. 10 Wait 32 CKIL cycles before changing warm reset to a cold reset. 11 Wait 64 CKIL cycles before changing warm reset to a cold reset
4 sw_open_vg_rst	Software reset for open_vg **NOTE:** this is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrupt once the software has finished. Please refer to SISR register for details. **NOTE:** the reset process will involve 8 open_vg cycles before negating the open_vg reset, to allow reset assertion to propagate into open_vg. 0 do not assert open_vg reset 1 assert open_vg reset
3 sw_ipu_rst	Software reset for IPU **NOTE:** this is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrupt once the software has finished. Please refer to SISR register for details. 0 do not assert IPU reset 1 assert IPU reset
2 sw_vpu_rst	Software reset for VPU **NOTE:** this is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrupt once the software has finished. Please refer to SISR register for details.

Table continues on the next page...

SRC_SCR field descriptions (continued)

Field	Description
	NOTE: the reset process will involve 8 VPU cycles before negating the VPU reset, to allow reset assertion to propagate into VPU. 0 do not assert VPU reset 1 assert VPU reset
1 sw_gpu_rst	Software reset for GPU **NOTE:** this is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrupt once the software has finished. Please referto SISR register for details. **NOTE:** the reset process will involve 8 GPU cycles before negating the GPU reset, to allow reset assertion to propagate into GPU. 0 do not assert GPU reset 1 assert GPU reset
0 warm_reset_ enable	Warm reset enable bit. Warm reset will be enabled only if warm_reset_enable bit is set. Otherwise all warm reset sources will generate cold reset. 0 Warm reset disabled 1 Warm reset enabled

70.2.2 SRC Boot Mode Register (SRC_SBMR)

The figure below presents the Boot Mode register which contains bits that reflect the status of boot Mode Pins of the chip. The default values for those bits depends on the values of pins/fuses during reset sequence .

Address: SRC_SBMR is 53FD_0000h base + 4h offset = 53FD_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	-		TEST_MODE[2:0]			BT_FUSE_SEL	BMOD[1:0]		BOOT_CFG3[7:0]							
W	0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	BOOT_CFG2[7:0]								BOOT_CFG1[7:0]							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SRC_SBMR field descriptions

Field	Description
31–30 -	
29–27 TEST_ MODE[2:0]	Reserved for test purposes.
26 BT_FUSE_SEL	Please refer to i.MX53 fuse map.
25–24 BMOD[1:0]	BMOD[1:0] reflects the settings of the BOOT_MODE pins at exit from reset. BMOD[1:0] = {BOOT_MODE1, BOOT_MODE0}
23–16 BOOT_ CFG3[7:0]	Please refer to i.MX53 fuse map.
15–8 BOOT_ CFG2[7:0]	Please refer to i.MX53 fuse map.
7–0 BOOT_ CFG1[7:0]	Please refer to i.MX53 fuse map.

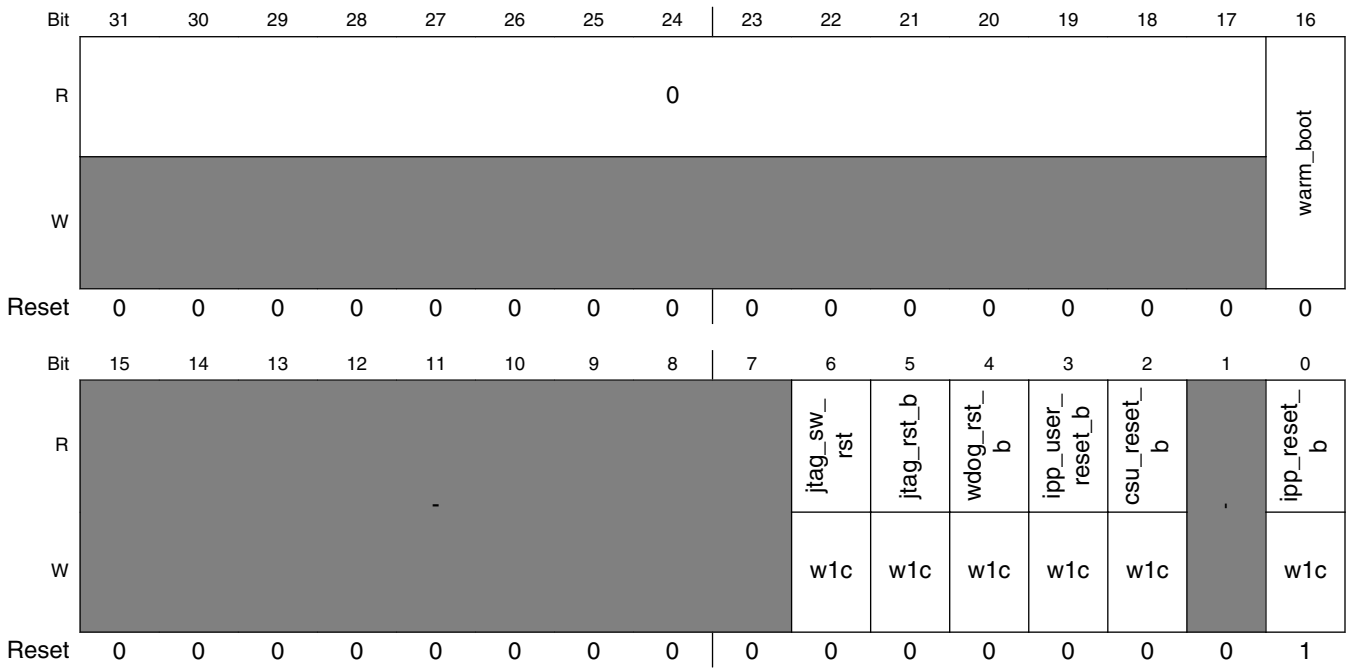
70.2.3 SRC Reset Status Register (SRC_SRSR)

The SRC_SRSR is a write to one clear register which records the source of the reset events for the chip. The SRC reset status register will capture all the reset sources that have occurred.

This register is reset on the rising edge of ipp_reset_b. This is a read-write register,

For bit[6-0] - writing zero does not have any effect. Writing one will clear the corresponding bit. The individual bits can be cleared by writing one to that bit. When the system comes out of reset, this register will have bits set corresponding to all the reset sources that occurred during system reset. Software has to take care to clear this register by writing one after every reset that occurs so that the register will contain the information of recently occurred reset.

Address: SRC_SRSR is 53FD_0000h base + 8h offset = 53FD_0008h



SRC_SRSR field descriptions

Field	Description
31–17 Reserved	This read-only field is reserved and always has the value zero. Reserved
16 warm_boot	Warm boot indication gives software capability to notify that warm boot was initiated by software. This indicates to the software that it saved the needed info in the memory before initiating the warm reset. In this case, software will set this bit to '1', before initiating the warm reset. The warm_boot bit should be used as indication only after a warm_reset sequence. Software should clear this bit after warm_reset to indicate that next warm_reset is not done with warm_boot. Please refer to Reset Sequence and Deassertion for details on warm_reset. 0 warm boot process not initiated by software. 1 warm boot initiated by software.
15–7 -	Reserved
6 jtag_sw_rst	JTAG SW reset. Indicates whether the reset was the result of software reset from JTAG. Connections at chip-level: jtag_sw_rst -> sjc_gpccr_reg_2_b 0 Reset is not a result of software reset from JTAG. 1 Reset is a result of software reset from JTAG.
5 jtag_rst_b	HIGH - Z JTAG reset. Indicates whether the reset was the result of HIGH-Z reset or reset from JTAG. Connections at chip-level: jtag_rst_b -> sjc_ieee_reset_b 0 Reset is not a result of HIGH-Z reset from JTAG. 1 Reset is a result of HIGH-Z reset from JTAG.

70.3 Functional Description

70.3.1 Reset Control

This section details the reset control of this SoC device.

70.3.1.1 Reset Inputs and Outputs

The SRC receives reset requests from all the potential reset sources. All the immediate sources of reset are directly passed to the reset stretching block whereas the resets which require qualification are passed on to the reset qualification logic before they are sent to the reset stretching block.

All reset inputs and outputs are described in the following figure:

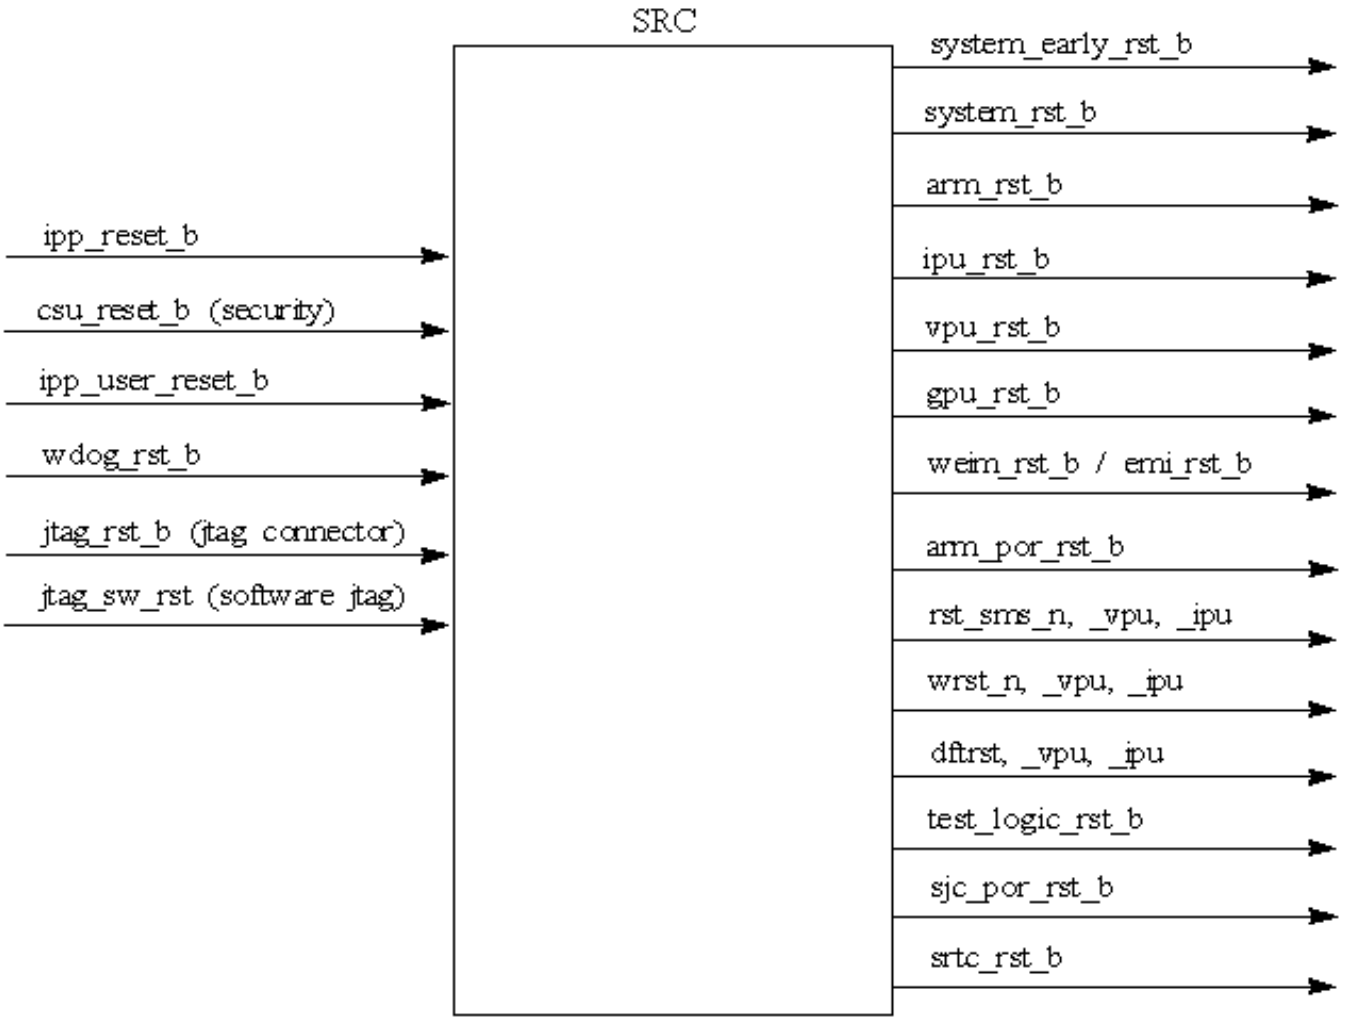

Figure 70-7. SRC Inputs and Outputs

The reset sources, type and behavior are shown in the Table 70-7. As there is no chip POR the $\overline{\text{ipp\_reset\_b}}$ is used to reset the entire chip including test logic and JTAG blocks.

NOTE

All resets are expected to be active low except jtag_sw_rst.

Table 70-7. Reset Priorities, Sources, Types, and Behavior

Priority	Sources	Type	Behavior
4.	$\overline{\text{ipp\_reset\_b}}$	POR	Reset IC = $\overline{\text{system\_early\_rst\_b}}$ + $\overline{\text{system\_rst\_b}}$ + arm_por_rst+ $\overline{\text{arm\_soc\_rst\_b}}$ + $\overline{\text{arm\_dbg\_rst\_b}}$ + $\overline{\text{ipu\_rst\_b}}$ + $\overline{\text{vpu\_rst\_b}}$ + $\overline{\text{gpu\_rst\_b}}$ + $\overline{\text{open\_vg\_rst\_b}}$ + $\overline{\text{emi\_rst\_b}}$ + $\overline{\text{rst\_sms\_n}}$ + $\overline{\text{wrst}}$ + $\overline{\text{dftrst}}$ + $\overline{\text{test\_logic\_rst\_b}}$ + $\overline{\text{srtc\_rst\_b}}$ + $\overline{\text{sjc\_por\_rst\_b}}$ Note: ipp_reset_b is connected to POR_B pin.

Table continues on the next page...

Table 70-7. Reset Priorities, Sources, Types, and Behavior (continued)

Priority	Sources	Type	Behavior
5.	csu_reset_b	Cold	Reset IC - rst_sms_n - wrst - dftrst - test_logic_rst_b - srtc_rst_b - sjc_por_rst_b - arm_por_rst - arm_dbg_rst_b = system_early_rst_b + system_rst_b + arm_soc_rst_b + ipu_rst_b + vpu_rst_b + gpu_rst_b + open_vg_rst_b + emi_rst_b
6.	ipp_user_reset_b (qualified 4 CKIL's)	Warm	Reset IC - rst_sms_n - wrst - dftrst - test_logic_rst_b - srtc_rst_b- arm_por_rst - arm_dbg_rst_b - sjc_por_rst_b + warm_reset_signal = system_early_rst_b + system_rst_b + arm_soc_rst_b + ipu_rst_b + vpu_rst_b + gpu_rst_b + open_vg_rst_b + emi_rst_b+ warm_reset_signal Note: ipp_user_reset_b is connected to RESET_IN_B pin.
7.	wdog_rst_b This reset will not be generated if mask_wdog_rst bits are coded to 5.	Warm	Reset IC - rst_sms_n - wrst - dftrst - test_logic_rst_b - srtc_rst_b - arm_por_rst - arm_dbg_rst_b - sjc_por_rst_b + warm_reset_signal = system_early_rst_b + system_rst_b + arm_soc_rst_b + ipu_rst_b + vpu_rst_b + gpu_rst_b + open_vg_rst_b + emi_rst_b+ warm_reset_signal
8.	jtag_rst_b (jtag connector)	POR - sjc_por_rst_b	Reset IC - sjc_por_rst_b = system_early_rst_b + system_rst_b + arm_por_rst+ arm_soc_rst_b + arm_dbg_rst_b + ipu_rst_b + vpu_rst_b + gpu_rst_b + open_vg_rst_b + emi_rst_b + rst_sms_n + wrst + dftrst + test_logic_rst_b + srtc_rst_b
9.	jtag_sw_rst (software jtag)	Warm	Reset IC - rst_sms_n - wrst - dftrst - test_logic_rst_b - srtc_rst_b - arm_por_rst - arm_dbg_rst_b + warm_reset_signal - sjc_por_rst_b = system_early_rst_b + system_rst_b + arm_rst_b + ipu_rst_b + vpu_rst_b + gpu_rst_b+ open_vg_rst_b + emi_rst_b+ warm_reset_signal

The reset priorities are POR (strongest), COLD and WARM (weakest). If a stronger reset is asserted during the sequence of a wicker reset, then the wicker sequence will be interfered and the stronger reset sequence will commence. There is no priority inside a reset type group. If a reset is asserted during reset sequence of reset from the same type group, then the reset sequence will be interfered and a new reset sequence (from the same type) will commence.

The following lists the functionality of each of these reset outputs:

- system_early_rst_b - Resets the system blocks that need to start first as ccm, pll_ip's, iim, fuseboxes, EXTMC etc.
- system_rst_b - Resets functional blocks.
- arm_rst_b - Resets ARM core (on regular system reset)
- ipu_rst_b - Resets IPU (on regular system reset)
- vpu_rst_b - Resets VPU (on regular system reset)
- gpu_rst_b - Resets GPU (on regular system reset)

- open_vg_rst_b - Resets Open_VG (on regular system reset)
- emi_rst_b - Resets SDRAM controller.
- arm_por_rst - Resets ARM por input.
- arm_soc_rst_b - Reset for arm SoC.
- arm_dbg_rst_b - Reset debug logic of ARM.
- test_logic_rst_b - Reset test logic. (IOMUXC, DAP)
- sjc_por_rst_b - reset to SJC.
- srtc_rst_b - Resets SRTC.

The following are related to SMS(STAR memory system):

- rst_sms_n - Resets SMS
- dftrst - Resets SMS DFT
- wrst - Resets JPC wrapper.

SRC will also generate rst_sms_n dftrst and wrst_n for specific accelerators. Since those blocks are not involved in the memory repair process, then they will be similar to the functional resets of those blocks. Note that dftrst is active high, hence its inverted version equals the functional reset.

- dftrst_ipu = wrst_n_ipu = rst_sms_n_ipu = ipu_rst_b
- dftrst_vpu = wrst_n_vpu = rst_sms_n_vpu = vpu_rst_b

NOTE

It is assumed that each reset source will deassert after its assertion, either due to reset generated to the system from SRC, or either by negation of the reset source (in case it came from an external source to the IC). In the later case, the reset source is assumed to be held for atleast 2 CKIL cycles so that SRC can sample it.

70.3.1.2 Reset Handling

70.3.1.2.1 Reset Qualification

The reset qualification logic qualifies the reset source before sending it out to the chip as a valid reset. Warm resets are in this category. All remaining reset sources are immediate resets and are acknowledged by the reset circuitry the moment they are asserted.

Warm resets are not immediate resets. Warm resets do reset the clock control module (CCM), the source of SDRAMC clock. So, if a Warm reset were to immediately reset the CCM, then the SDRAMC clock would be shut off and this may cause the SDRAM data to be lost. During normal mode of operation of the chip, the protocol that is followed

before shutting off the SDRAMC clock is that an emi_dvfs_req signal is sent to SDRAMC and only after the SDRAMC sends an acknowledge signal, emi_dvfs_ack, are the clock to the SDRAMC gated off.

However, the implication here is that a valid warm reset source condition will not be able to cause a chip reset until the SDRAMC sends the acknowledge signal (emi_dvfs_ack). For example, a JTAG reset event has occurred but the JTAG reset will not be serviced until the emi_dvfs_ack signal is received. So, essentially all Warm reset sources depend on the SDRAMC providing the emi_dvfs_ack acknowledge signal before the reset is performed. When the SDRAM controller is not used, emi_dvfs_ack is defaulted high.

The occurrence of warm reset results in the assertion of warm_reset signal before the system resets are asserted to indicate EXTMC that the reset occurred is a warm reset.

A reset source is updated in the Reset status register when it becomes valid, provided it is asserted for the minimum amount of time after asserting. So, all immediate resets would be immediately updated in the Status register. Warm resets would be updated when the emi_dvfs_ack signal is received from the SDRAMC.

Once the reset is qualified, depending on the source of the reset, internal resets would be asserted appropriately.

70.3.1.2.2 Reset Sequence and Deassertion

The system_early_rst_b and the system_rst_b will assert immediately after any reset source is recognized (except for the case of warm reset when EXTMC needs to answer emi_dvfs_ack first). After all of the reset sources are released, the SRC will start the following set of events depending on the type of reset that occurred.

$\overline{\text{IPP\_RESET\_B}}$ (POR)

This is a external signal from the pads and whenever the chip is powered up the reset signal is passed through this pin indicating power-up sequence and the SRC resets the entire chip including test logic and JTAG. All SRC registers will be reset on POR sequence.

As soon as $\overline{\text{IPP\_RESET\_B}}$ occurs all resets are asserted and the entire chip is reset by SRC. The $\overline{\text{IPP\_RESET\_B}}$ is stretched for 2 CKIL cycles and the stretching sequence takes place after 2 CKIL clocks of $\overline{\text{IPP\_RESET\_B}}$ pin deassertion.

test_logic_rst_b, sjc_por_rst_b and srtc_rst_b signals are deasserted together with IPP_RESET_B signal. Those outputs are also deasserted after the stretching of IPP_RESET_B has deasserted.

After the above resets deasserts, system_early_rst_b reset is deasserted after 2 CKIL clock. The system_early_rst_b is used for the CCM and digital phase-locked loop's (DPLL) to start generating DPLL clock ouputs and the system root clocks.

Once system root clocks are ready, CCM will assert system_clk_ready signal. This signal is generated during the ignition sequence in CCM and it involves the preparation of CKIH/DPLL's to generate clock roots for functional operation. Please refer to Ignition Sequence in CCM chapter.

Once this signal arrives to SRC, it will initiate smart sfp operation. This operation will be finished once the SRC receives the assertion on signal "sfp_ready".

After SFP operation finish, SRC will enable IIM and FUSEBOX clocks, so that fuses can be loaded to IIM. IIM will notify with iim_ready_flag on the finish of the FUSEBOX loading.

SRC will prepare the boot information and then deassert emi_rst_b.

SRC will wait 8 ipg clock cycles, and then SRC will enable EXTMC clocks.

SRC will wait 8 CKIL clocks to allow EXTMC to generate fixed external clock to external memory SDRAM.

SRC will enable VPU and GPU clocks so that reset will penetrate this block.

After 8 ipg cycles, SRC will disable VPU, open_vg and GPU clocks.

After 8 ipg cycles, resets to all blocks will be deasserted (system_rst_b, vpu_rst_b, gpu_rst_b, open_vg_rst_b, ipu_rst_b).

If en_tester_control signal is asserted, SRC will wait for assertion of tester_ack signal to continue. This signal allows tester to receive determinism on the reset sequence.

After 8 ipg cycles, system clocks will be enabled (en_system_clk).

NOTE

The memory repair operation is bypassed when the smart_bypass signal is asserted.

COLD RESET

The sequence is similar to $\overline{\text{IPP\_RESET\_B}}$ except the memory repair operation is not performed and test_logic_reset is not fired.

Once the reset source deasserts, system_early_rst_b reset is deasserted after at least 2 CKIL clock. The system_early_rst_b is used for the CCM and DPLLCs to start generating DPLL clock ouputs and the system root clocks.

Once system root clocks are ready, CCM will assert system_clk_ready signal. This signal is generated during the ignition sequence in CCM and it involves the preparation of CKIH/DPLLs to generate clock roots for functional operation. Please refer to Ignition Sequence in CCM chapter.

Once this signal arrives to SRC, SRC will enable IIM and FUSEBOX clocks, so that fuses can be loaded to IIM. IIM will notify with iim_ready_flag on the finish of the FUSEBOX loading.

SRC will prepare the boot information and then deassert emi_rst_b.

SRC will wait 8 ipg clock cycles, and then SRC will enable EXTMC clocks.

SRC will wait 8 CKIL clocks to allow EXTMC to generate fixed external clock to external memory SDRAM.

SRC will enable VPU and GPU clocks so that reset will penetrate this block.

After 8 ipg cycles, src will disable VPU, open_vg and GPU clocks.

After 8 ipg cycles resets to all blocks will be deasserted (system_rst_b, vpu_rst_b, gpu_rst_b, open_vg_rst_b, ipu_rst_b).

If en_tester_control signal is asserted, SRC will wait for assertion of tester_ack signal to continue. This signal allows tester to receive determinism on the reset sequence.

After 8 ipg cycles, system clocks will be enabled (en_system_clk).

WARM RESET

WARM reset will be enabled only if warm_reset_enable bit is programed. Otherwise all warm reset sources will generate cold reset. This bit will be reset only by por reset.

A WARM reset is similar to a cold reset except that before the reset is fired a signal to EXTMC is asserted emi_dvfs_req (generates DVFS assertion to EXTMC) to request to prepare EXTMC to a WARM reset, i.e. to finish the transactions and to put the sdram in self refresh. Another signal will be asserted to EXTMC (warm_reset) that will wrap the warm reset sequence and will notify EXTMC that a warm reset is in process.

One of the sources of the WARM reset is ipp_user_reset_b. If this is the case, it is qualified for 4 CKIL edges. The WARM reset is initiated immediately after 4 CKIL edges. The system does not come out of reset until the ipp_user_reset_b is released.

During WARM reset, request to put SDRAM in self refresh is sent to SDRAMC. The request is sent threw generation of DVFS signal to EXTMC. The request is passed threw CCM to be combined with CCM's capability to request DVFS. Only after the EXTMC sends an acknowledge signal, emi_dvfs_ack, warm reset is generated. The implication here is that a valid WARM reset source condition will not be able to cause a chip reset

until the EXTMC sends the acknowledge signal (emi_dvfs_ack). For example, a WDOG reset event has occurred but the WDOG reset will not be serviced until the emi_dvfs_ack signal is received. So, essentially all WARM reset sources depend on the EXTMC providing the emi_dvfs_ack acknowledge signal before the reset is performed. When the EXTMC is not used, emi_dvfs_ack is defaulted high.

After the acknowledge signal, emi_dvfs_ack, is received the warm reset is generated. The warm_reset input to SDRAMC reflects the value of the warm_reset_enable bit. This signal indicates to SDRAMC that the upcoming reset is WARM.

In case the handshake mechanism with SDRAMC is stuck meaning no emi_dvfs_ack is received, cold reset will be generated after a number of CKIL clocks. The number of CKIL clocks is defined in register SCR bit warm_rst_bypass_count. the default of this bit is 16 CKIL count.

The following is a basic description of the warm reset sequence:

ARM sets warm_reset_enable bit to enable the WARM Reset functionality. If this bit is not set, all WARM reset sources will result in Cold Reset.

Assertion of one of the WARM reset sources.

The reset source is qualified in the SRC.

If emi_dvfs_ack signal is low, then SRC triggers the SDRAM Ctrl. to switch to self refresh mode using emi_dvfs_req signal. This is done threw CCM to combine with the DVFS sent from CCM in case of frequency change of EXTMC.

Wait for emi_dvfs_ack signal from the EXTMC. If no ack is received during warm_rst_bypass_count number of CKIL clocks, cold reset will be generated.

Assert warm_reset signal to EXTMC.

SRC asserts system resets

The deassertion sequence is exactly the same as in the Cold Reset except waiting for 8 CKIL's for EXTMC to generate fixed external clock to external memory SDRAM. This stage is not needed in WARM reset since SDRAM is held in self refresh in WARM reset and there is no need to reconfigure it when going out of WARM reset.

WARM BOOT

Software can save any needed information in the memory before initiating a warm reset. In this case, software will set warm_boot bit before initiating warm reset. After the system returns to run mode, the warm_boot bit will still be set, indicating the software that data was saved in memory and can be reused.

Figure 70-8, Figure 70-9, Figure 70-10, Figure 70-11 shows the behavior of different resets for POR, Cold and Warm reset cases respectively.

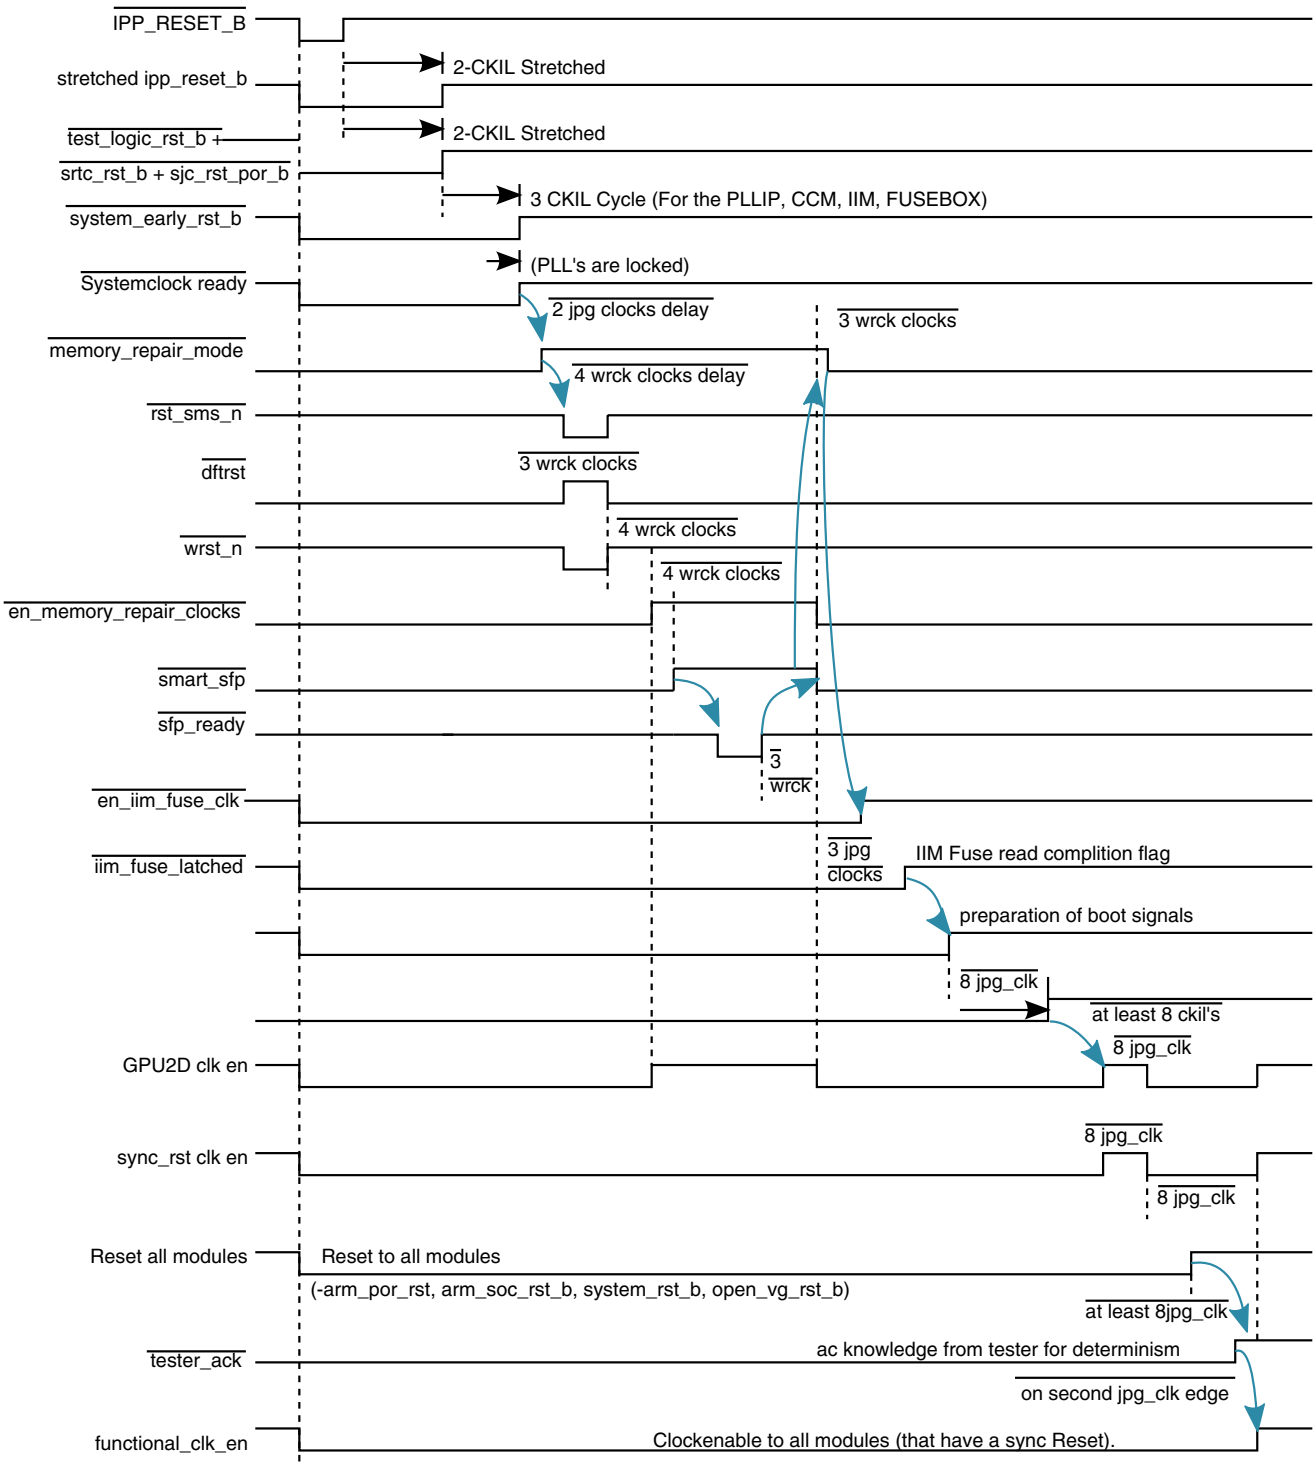

Figure 70-8. Behavior of IPP_RESET_B(POR)

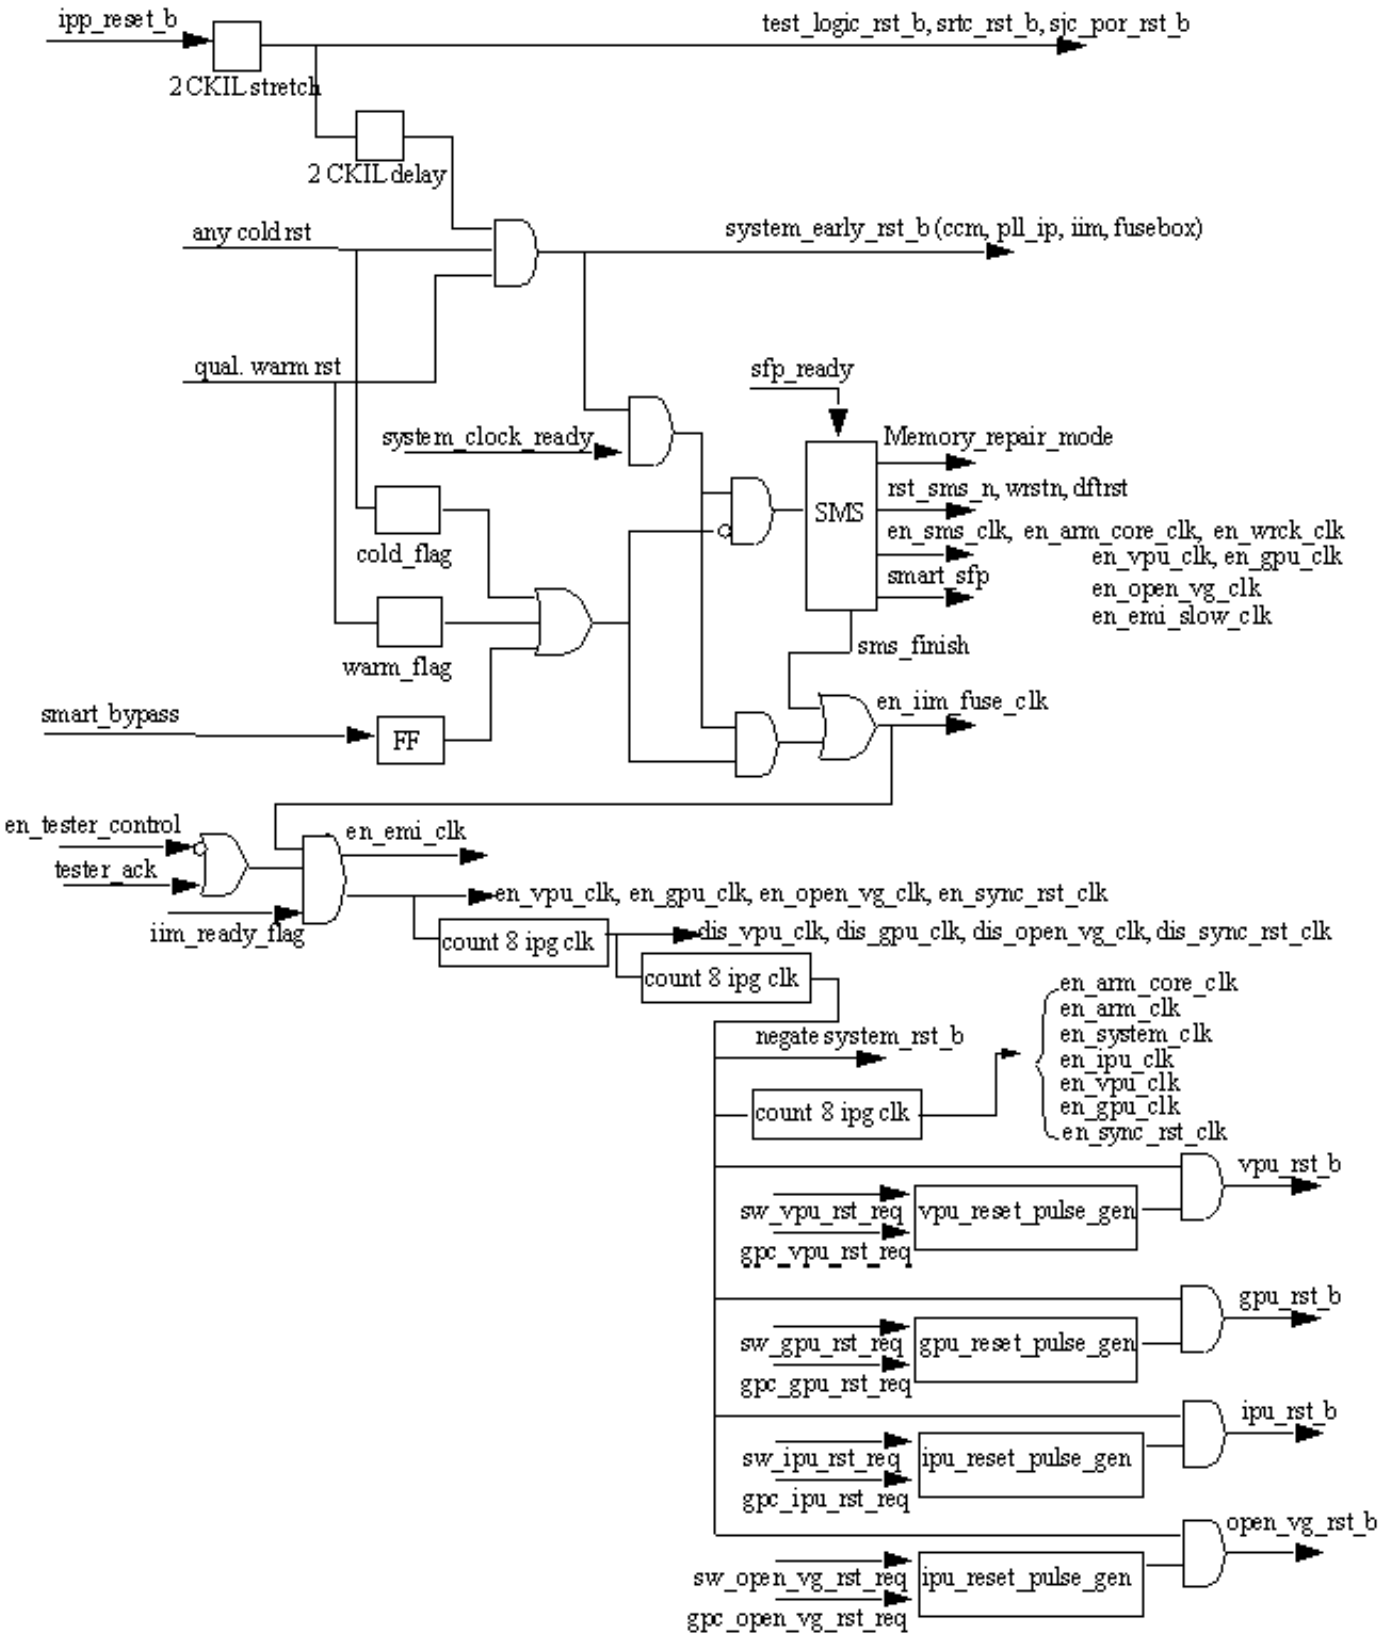

Figure 70-9. Reset Diagram

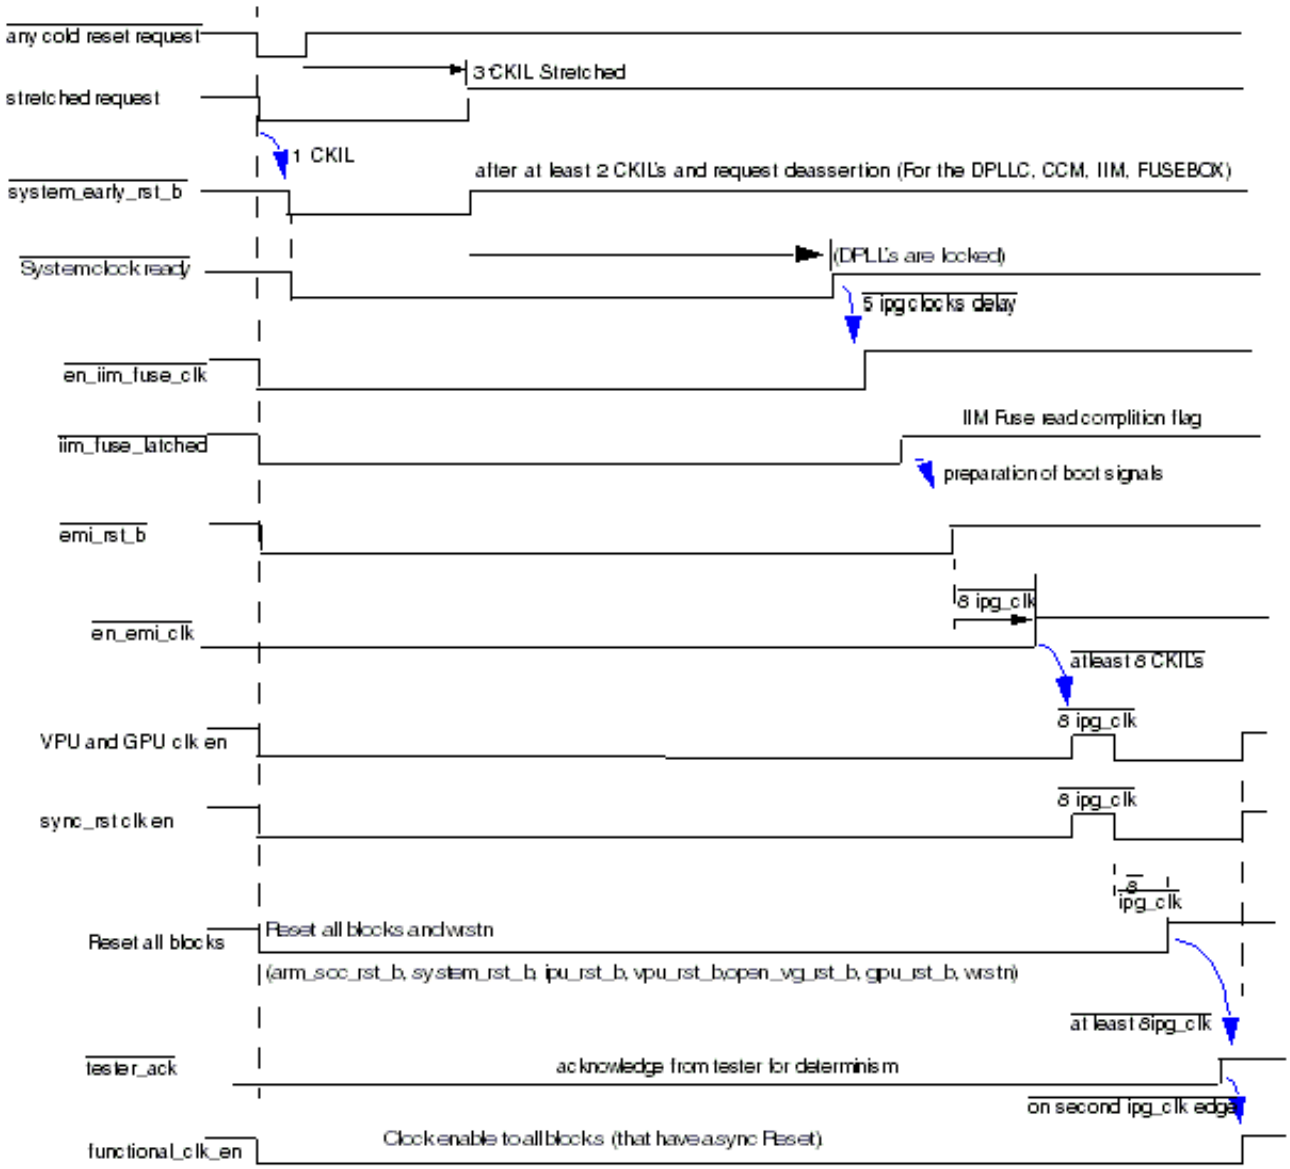

Figure 70-10. Cold reset sequence

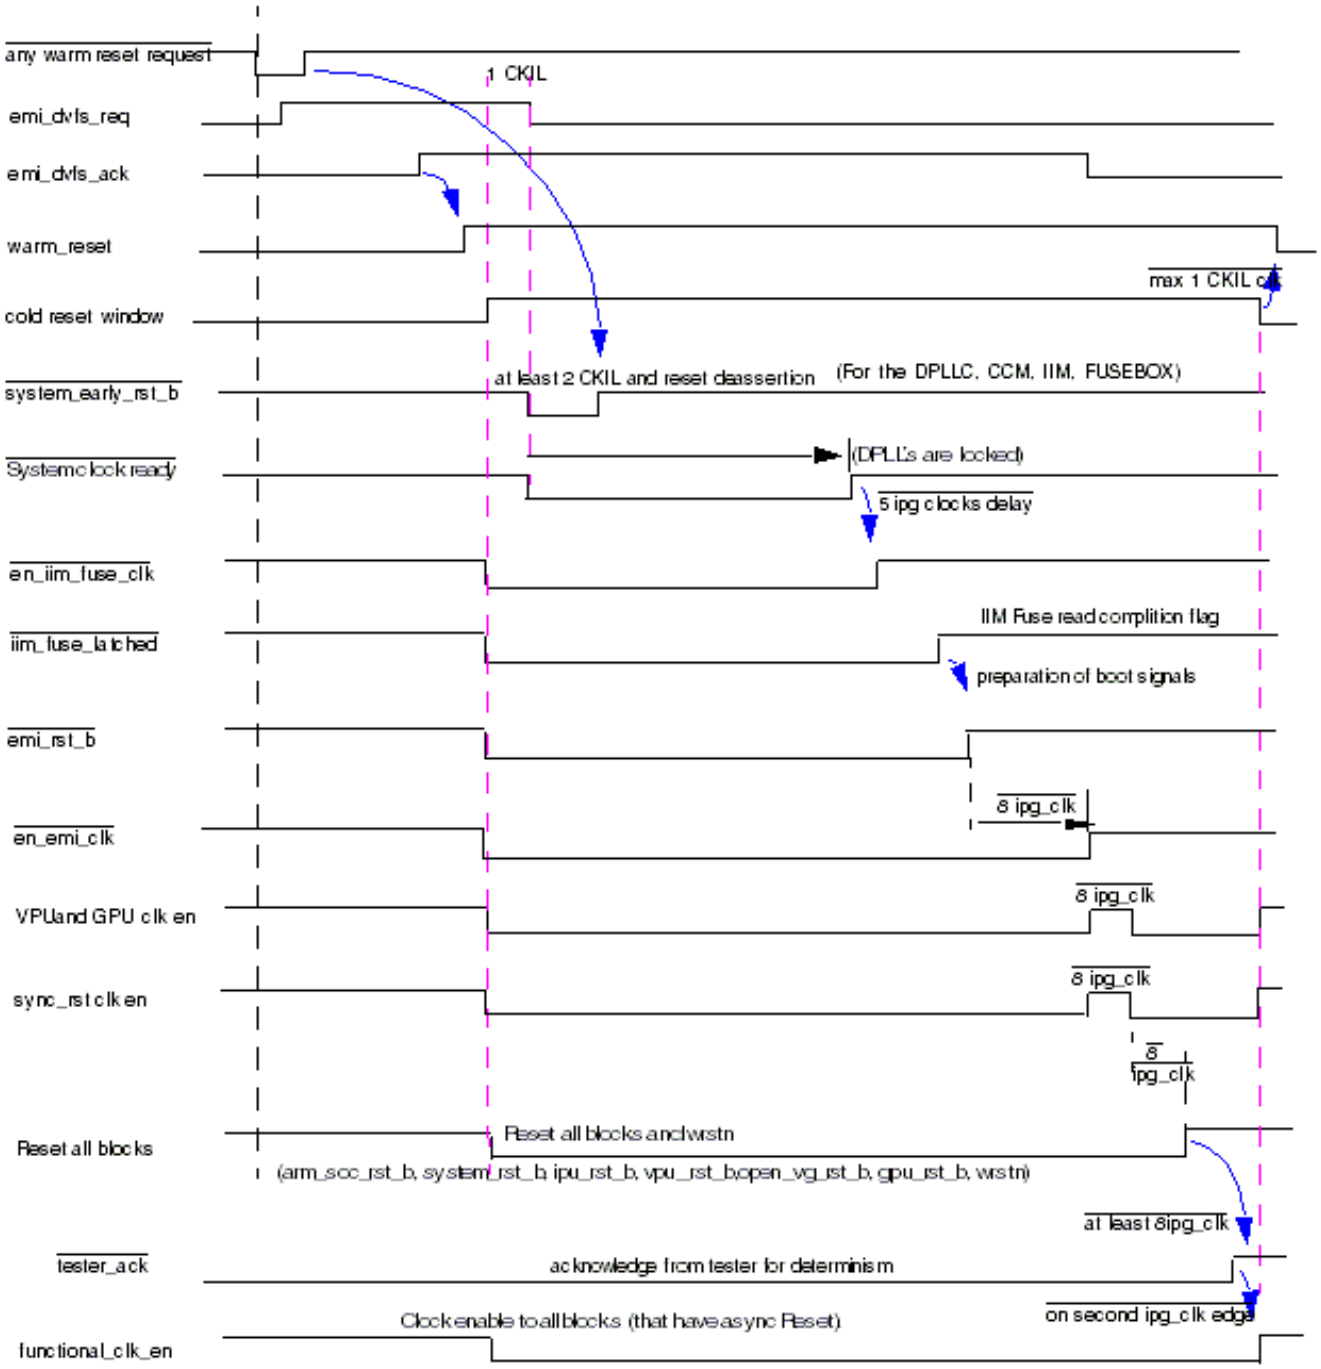

Figure 70-11. Warm reset sequence

70.3.1.2.3 SMS sub-block

The SMS sub-block manages the memory repair signals during por. The SMS sub-block will start its operation after system_clock_ready notification from CCM and only if the reset sequence is due to por sequence (ipp_reset_b). The SMS sub-block operation can be bypassed by smart_bypass assertion signal from the pad. If the smart_bypass is asserted, only the assertion part of SMS reset signals will take place, but smart_sfp - sfp_ready sequence will not be performed.

Following is the sms sequence:

1. Upon assertion of system_clock_ready signal, count 2 ipg clocks and assert the memory_repair_mode signal.
2. Wait 4 wrck clocks.
3. Assert sms reset signals on wrck clock edge:

   rst_sms_n = 0

   wrst_n = 0

   dftrst = 1

4. Wait 3 wrck clocks
5. Deassert the reset signals on wrck clock edge:

   rst_sms_n = 1

   wrst_n = 1

   dftrst = 0

6. Wait 4 wrck clocks
7. Enable memory repair clocks, i.e. en_arm_core_clk=1, en_emi_slow_clk=1, en_vpu_clk=1, en_gpu_clk=1, en_open_vg_clk=1, en_sms_clk=1 and en_wrck_clk=1 on wrck edge.
8. Wait 4 wrck clocks
9. Assert smart_sfp signal on wrck edge.
10. Monitor deassertion and assertion of sfp_ready signal.
11. Once assertion of sfp_ready signal, deassert smart_sfp, deassert clock enables en_arm_core_clk=0, en_emi_slow_clk=0, en_vpu_clk=0, en_gpu_clk=0, en_open_vg_clk=0, en_sms_clk=0 and en_wrck_clk=0 on wrck edge, deassert memory_repair_mode signal. (all on wrck edges).
12. Wait 4 wrck clocks
13. Assert sms_finish to notify that SRC can continue with enable IIM clocks.

Next figure describes the sms flow.

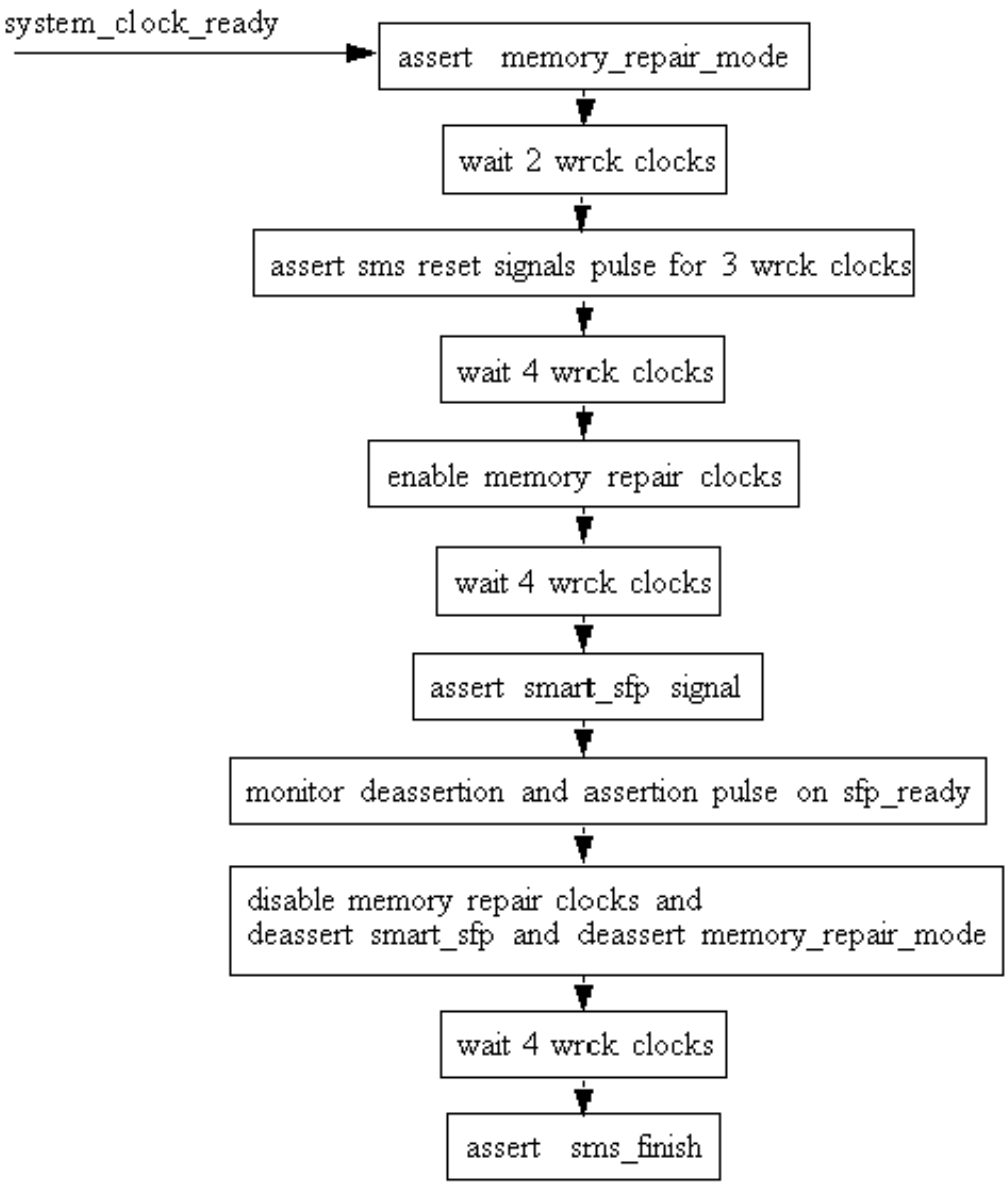

Figure 70-12. sms flow diagram

70.3.1.2.4 SRTC_RST_B generation

SRTC_RST_B will be generated during POR sequence together with test_logic_rst_b.

On the srtc_rst_b path there will be a mux that enables a generation of reset on srtc_rst_b pad from TCU, in case of test_mode. The enable of this mux is test_mode input. When the test_mode input equals '0', the generated srtc_rst_b will be the functional srtc reset (generated during POR scenario). When the test_mode input equals '1' the generated

srtc_rst_b will be connected to the tcu_reset input. In this case, tcu will have complete controlability of srtc_rst_b, and will be able to generate a reset for srtc. Below diagram describes this mux.

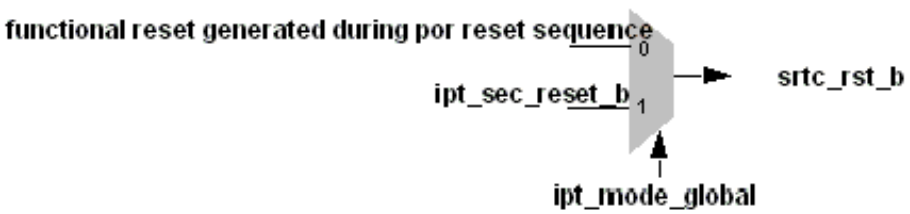

Figure 70-13. srtc_rst_b generation

70.3.2 SJC_POR_RST_B Generation

SJC will be reset by sjc_por_rst_b output of SRC. This output will be toggled only on POR sequence together with test_logic_rst_b. It will not be toggled on IEEE reset (jtag_rst_b).

70.3.3 Parallel Reset Requests

This chapter describes the behavior when parallel reset requests are received. In the parallel reset requests case SRC will follow the following rules:

1. The order of strength of resets is POR - strongest, cold - medium, warm - weakest.
2. If a stronger reset is asserted during weaker reset sequence, then the stronger reset will take over and the stronger reset process will commence. the following cases fall into this category:

   POR reset request in the middle of cold or warm reset process - the cold or warm reset process will be stopped and the POR sequence will start.

   COLD reset request in the middle of warm reset process - the warm reset process will be stopped and the cold sequence will start.

3. If a weaker reset is asserted during stronger reset sequence, then the stronger reset sequence will continue without interference. If at the end of the stronger reset process the weaker request is still asserted then the weaker sequence will commence. The following cases fall into this category:

COLD or WARM reset requests in the middle of POR reset process - the POR process will continue without interference.

WARM reset request in the middle of COLD reset process - the COLD process will continue without interference.

4. If a similar reset request is asserted during the process of reset handling, then the process of reset handling will start over (with the same process). The following cases fall into this category:

   POR reset request in the middle of POR reset process - the POR process will start over.

   COLD reset request in the middle of COLD reset process - the COLD process will start over.

There is one exception to this category - WARM reset request in the middle of WARM reset process - in this case the new WARM reset process cant restart because EXTMC is reset and there can't be a handshake with EXTMC if EXTMC is reset. For this case the first WARM reset will continue, and only if the second WARM reset is still asserted after the first one has finished, then the WARM sequence will start again.

70.3.4 DFT Mux on Reset Outputs

All functional reset output described above are muxed before exiting SRC. The mux is controlled by "ipt_mode_global "signal. The mux chooses between the functional reset and the DFT reset.

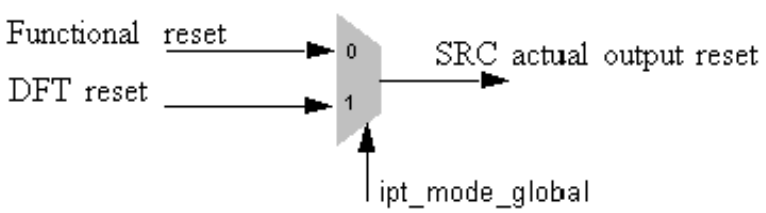

Figure 70-14. MUX between functional reset and DFT reset

Next table describes the DFT reset assigned to each of the reset outputs.

Table 70-8. DFT Reset Assignment

70.3.5 Boot Mode Control

70.3.5.1 BOOT_MODE Pin Latching

The exact boot sequence for i.MX53 is controlled by the values of the BOOT_MODE0 and BOOT_MODE1 pins on this device.

Both BOOT_MODE pins will be sampled at deassertion of system_early_rst_b.

The value of the BOOT_MODE pins will be latched after the IIM asserts the fuse read completion flag. After latching, the values of the BOOT_MODE pins are used to determine the booting options of the core as given in the SBMR register.

The Boot mode general purpose bits can be provided to the SRC from either e-fuses or GPIO signals. The gpio_bt_sel e-fuse defines the source to be used to derive the boot information. When gpio_bt_sel is set, e-fuses are used. When cleared, GPIO signals are used.

When FSL test mode is chosen (BMOD[1:0] = 0b01) then the Fuses signals are used.

When Internal Production Boot Mode is chosen (10 for BMOD[1:0]) then e-fuses signals are used, independent of the gpio_bt_sel e-fuse value.

The Boot information is provided in SBMR register. Figure 70-15 shows the selection of Boot mode information.

NOTE

BOOT_MODE[1:0] inputs of SRC are connected to the BOOT_MODE pins. BOOT_MODE[1:0] = {BOOT_MODE1, BOOT_MODE0}

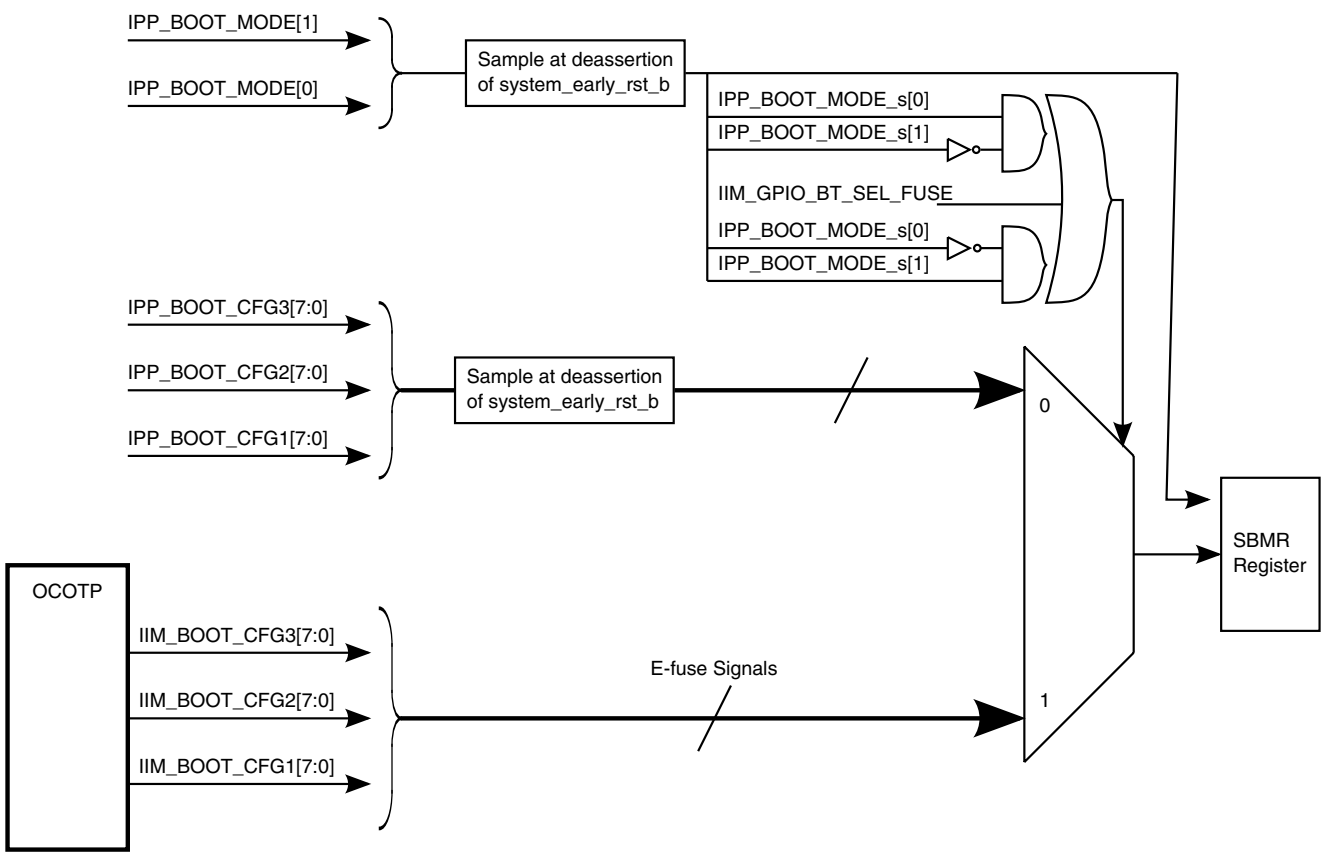

Figure 70-15. Boot Mode Information

NOTE

IPP signals that need to be latched by SRC will be set to the corresponding mode based on system_rst_b signal. When system_rst_b signal equals '0', the IOMUX will shift to the needed mode for transferring boot values on the IO pins. When system_rst_b signal equals '1', the IOMUX will shift to the default mode.

70.3.5.2 Correspondence Table between SRC SBMR bit/signal Names and Fuse Names

The SBMR bit names and boot signals corresponding to those bits were changed in i.MX53 fuse map. Below table describes the matching between the new fuse names and the ones represented above in SBMR register.

70.3.5.3 Boot Output Signals

1. External BOOT is set when the chip is in FSL TEST MODE and BOOT FROM EIM is selected.

   Otherwise, internal boot is selected.

2. EIM_BOOT_CFG bits:

   Used to determine if the chip uses muxed EIM 16 bits low half or unmuxed EIM 16 bits high half data.

   Look at i.MX53 Fuse Map for more details.

3. src_boot_add[31:0] - boot address - output to ARM Platform

   IF src_int_boot=0 then src_boot_add[31:0]=0x0800_0000

   Otherwise src_boot_add[31:0]=0x0000_0000

4. ipp_do_boot_mode_inv[1:0]=NOTBOOT_MODE[1:0]. Once the boot pins (BOOT_MODE[1:0]) are sampled in SRC, SRC will drive ipp_do_boot_mode_inv[1:0] back out on the BOOT_MODE pins. The I/O ring will use SYSTEM_RESET_B to determine when to drive the value ipp_do_boot_mode_inv[1:0] on the BOOT_MODE pins.

When system_rst_b=0, the BOOT_MODE pins will be configured as inputs, allowing boot mode information to propagate to SRC's BOOT_MODE[1:0].

When system_rst_b=1, the boot pads will be configured as outputs, allowing ipp_do_boot_mode_inv[1:0] to be driven out on the BOOT_MODE pins.

Board-level logic can detect the inversion of the BOOT_MODE pin state in order to determine that the system boot sequence has changed. This allows the subsequent use of the boot mode pins for some alternate purpose.

Chapter 71
State Retention Power Gating Controller (SRPGC)

71.1 Introduction

The State Retention Power Gating Controller (SRPGC) is a part of GPC. It controls the save, restore & power gating sequence of a platform implemented using SRPG cells. Power supply to all the logic except the retention latch of the SRPG flop, can be switched off in low power modes. For designs using SRPG flops, a specific sequence of various control signals must be followed in order to save and restore the state of flops correctly. SRPGC provides this sequence based on the various control registers.

71.1.1 Features

The SRPGC features include:

- Provides options to switch power off to a platform.
- Controls the operation of state-retaining/state-restoring circuitry, and stages the retain/restore signals in order to control the IR drop on the power grid during these events.
- Generates Power-up and Power-down control sequences
- Programmable registers to stage the various SRPG and Power control signals
- 32-bit IP Bus interface
- All registers are byte-accessible

71.1.2 Modes of Operation

71.1.2.1 Functional Mode

The SRPGC provides an option to switch OFF power to a platforms. The various power sequence control registers should be programmed to the desired value before powering down a platform.

71.1.2.2 Debug Mode

If the debug bit in the Debug control register is set to one, the SRPGC does not asserts the various outputs in the power down sequence, based on the other control bits in the Debug control register.

71.2 Power Gating Cells

71.2.1 Power Supply Switch Cells

In order to satisfy the power supply requirements of a platform, power switches are placed between the continuous supplies and the gated supplies as shown below. The power switches are composed of parallel power switch cells placed external to the platform.

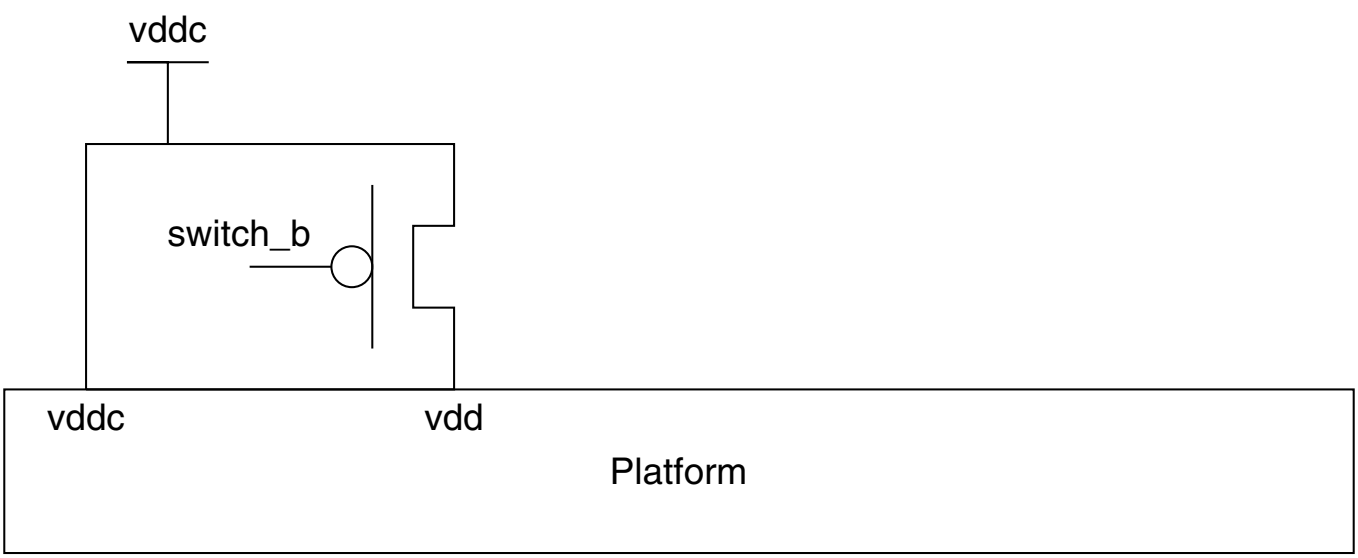

Figure 71-1. Power Switches External to the Platform

The power switch cells are positioned in strategic locations that satisfy the active current requirements of a platform. Table 71-1 describes the pins of the power switch cell

Table 71-1. Power Switch Cell Pins

Name	Type	Description
vddc	SUPPLY	Continuous supply1 connection
vdd	GATED_SUPPLY	Gated supply1 connection that will be placed into a resistive state when power_en_b is negated.
switch_b	INPUT	Active low power control signal that allows high conductivity between vddc and vdd when asserted. Invokes low conductivity between vddc and vdd when negated.

71.2.2 Power Supply Shorting Cells

Internal to a Platform, there are a number of power supply shorting cells. The power supply shorting cells provide local clamping between the continuous and the gated vdd nodes. Internal clamping ensures that the supply1 reference correlates for both the continuous logic (the state retaining circuitry) and the gated logic (the combinational logic). During periods of high switching activity, IR drops on the continuous supply will be transferred to the gated supply and vice versa. A primary purpose of the shorting cells is to give the Vdd supply access to the nwell-psubstrate diode decoupling capacitance on VDDC.

During power up states, the power supply shorting cells will be placed in a high conductivity configuration by assertions on the SHORT_B signal. Consequently, the power supply shorting cells will be held in a high impedance configuration during power down states.

Figure 71-2 shows a block diagram with a platform power supply shorting cells. The power supply shorting cells are instantiated as a parallel array of cells.

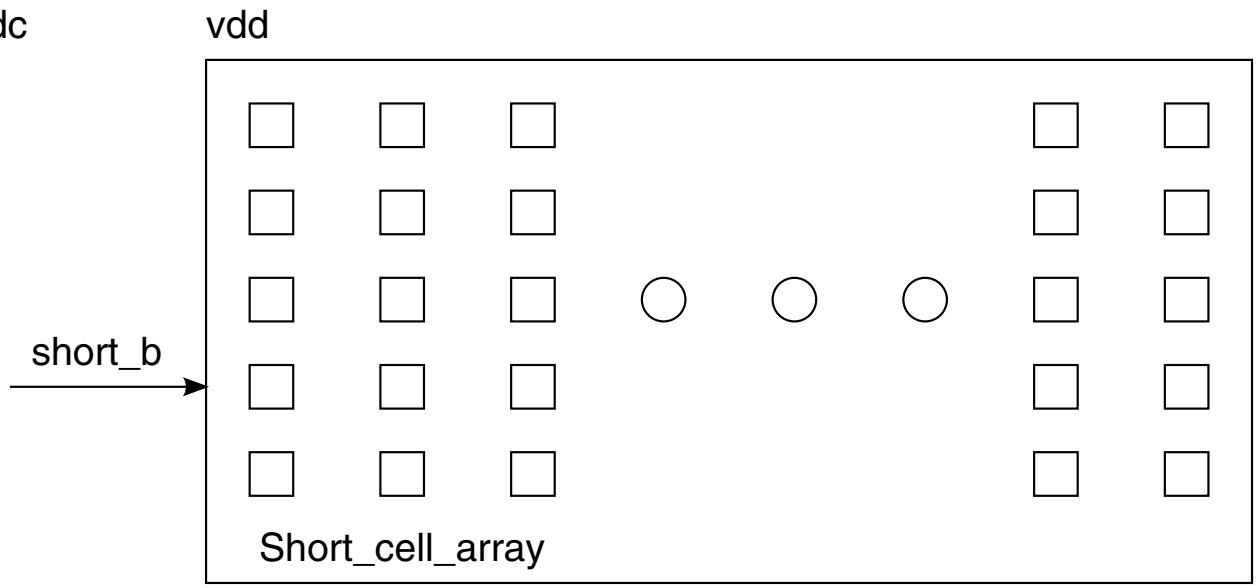

Figure 71-2. Power Supply Shorting Cells Internal to a Platform

Figure 71-3 shows the schematic diagram of power supply shorting cell. This may be combined with a well tie cell.

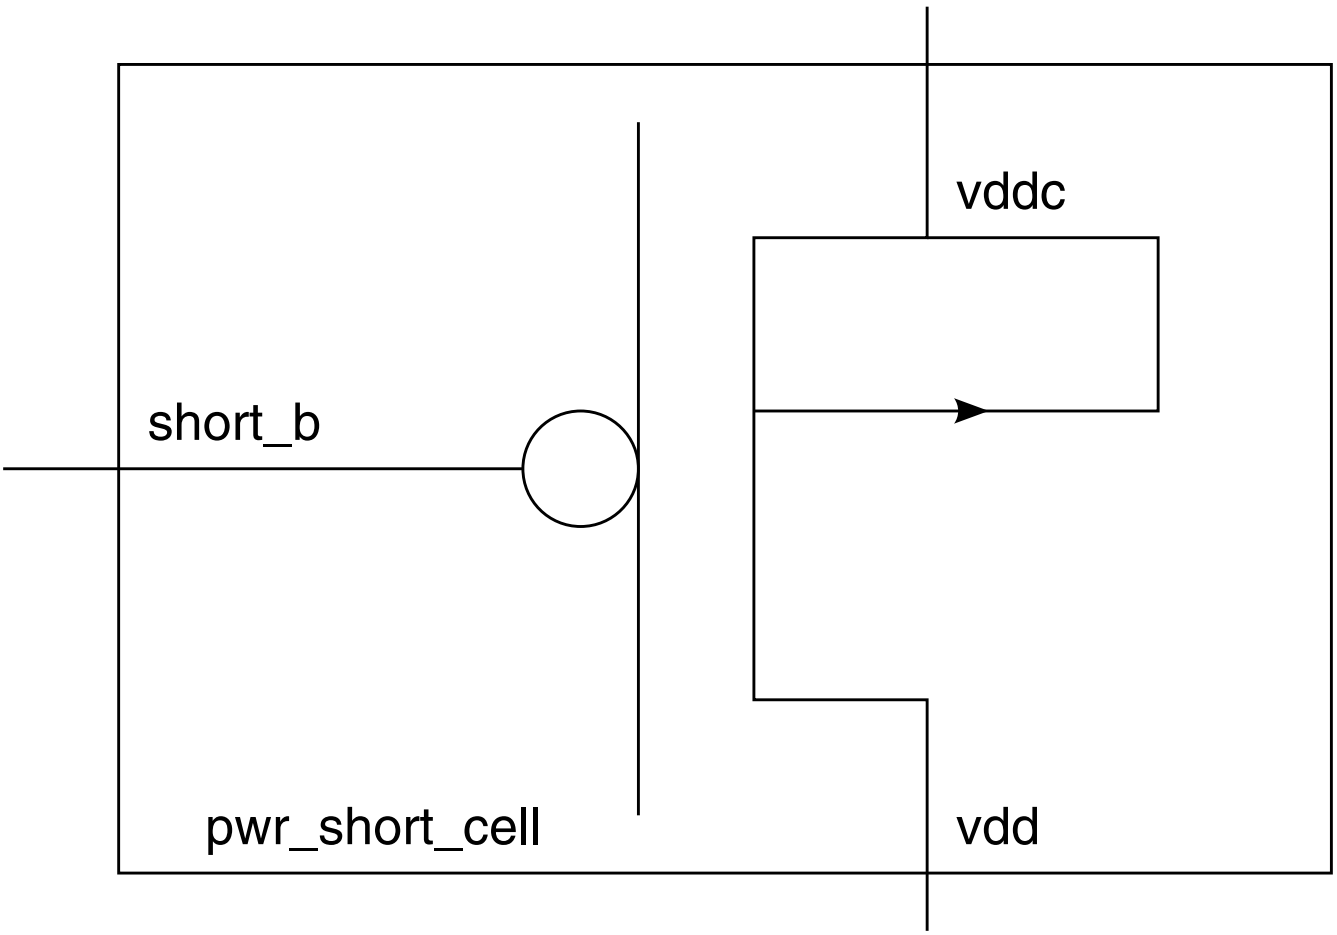

Figure 71-3. Power Supply Shorting Cell Schematic Diagram

Table 71-2 describes the pins of the power supply shorting cell.

Table 71-2. Power Supply Shorting Cell Pins

Name	Type	Description
vddc	SUPPLY	Continuous supply1 connection
vdd	GATED_SUPPLY	Gated supply1 connection that will be placed into a resistive state when short_b is negated.
short_b	INPUT	Active low power control signal that allows high conductivity between vddc and vdd_gtd when asserted. Invokes low conductivity between vddc and vdd_gtd when negated.

71.2.3 State Retention Power Gating (SRPG) Cell

The different platforms have the ability to keep the state of every register element preserved during power gating by using special SRPG flip flop elements. The flip flop consists of a master latch and a slave latch. During active modes, both the master and slave latches are powered up. During power gating, the master latch is completely powered off, but the slave latch remains powered up. This allows the state to be preserved with low leakage. Figure 71-4 shows a simplified version of a normal SRPG flop.

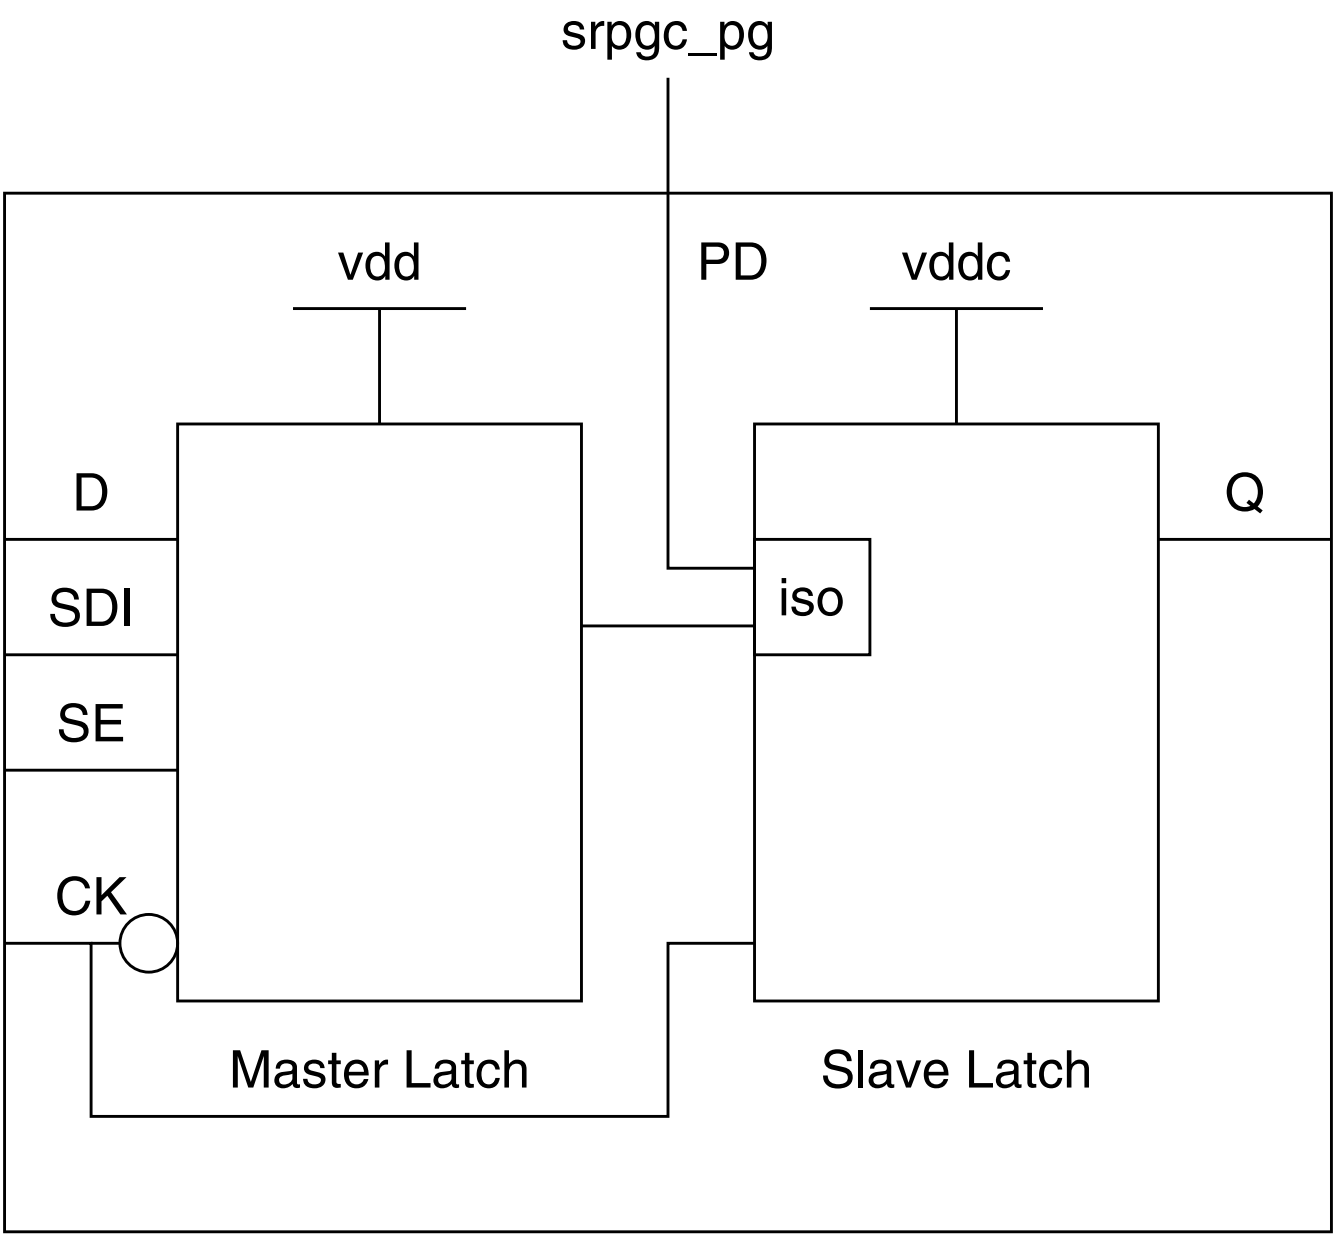

Figure 71-4. Simplified SRPG Cell Diagram

The SRPG flop provides a single extra control signal, PD, that is used to safely isolate the master and the slave latch so that the master latch can be powered down. The PD control signal must remain powered up and asserted during power gating. All other input signals can float including set, reset, clock, etc. The Q output shown in Figure 71-4 and the QN output in an inverted output flop (not shown) will be forced to a value when PD is asserted and vdd is not shut off. This is a result of the internal circuit design and not due to any special requirement. Upon exit from power gating, the PD signal will be deasserted to restore the flip flop to normal operation. For posedge flip-flops, the clock must be low before PD is asserted and held low until PD is deasserted. This also allows for needing only the slave latch state to be saved.

Because there may be many flip flops in a platform, the process of isolating all the flip flops for power gating, and forcing the Q and QN outputs will cause a moment of high instantaneous current, particularly if the Q or QN was previously a different state. Likewise the process of restoring all Q and QN outputs will cause a moment of high instantaneous current. For this reason, the platform must provide multiple PD signals that must be individually asserted/deasserted staged. Staging the negations and assertions on the PD signals provides guard banding against the unacceptable IR drop which might have caused flops to lose state. By transitioning these PD chains at different times during the SRPG_ENTRY and SRPG_EXIT sequences, an acceptable IR drop can be achieved in all cases.

There are several other very important design details which should be adhered to. First, reset synchronizing flops PD signals must be the last PD signals asserted and the first to be deasserted. This ensures proper operation of the reset synchronizing flops which must not have an incorrect Q or QN output prematurely. Second, the PD signals should be asserted/deasserted after the clocks have stopped low for posedge flops. This ensures that the master to slave pass gates are not opened, and is a requirement of the flop design.

The above text describes the SRPG flop architecture called SRPG7. Some variations of the SRPG flop exist. For example, the SRPG2 flop, which is available for LP transistor designs only, does not change Q output when PD is asserted. This lessens the need to stagger PD assertions and eliminates the need to give reset synchronizers their own PD signal. Another flop, applicable only to GP transistor designs, is the SRPG7RS flop. This flop is designed for reset synchronizers and, at the expense of area, does not change the Q output when PD is asserted.

71.3 SRPGC Interface

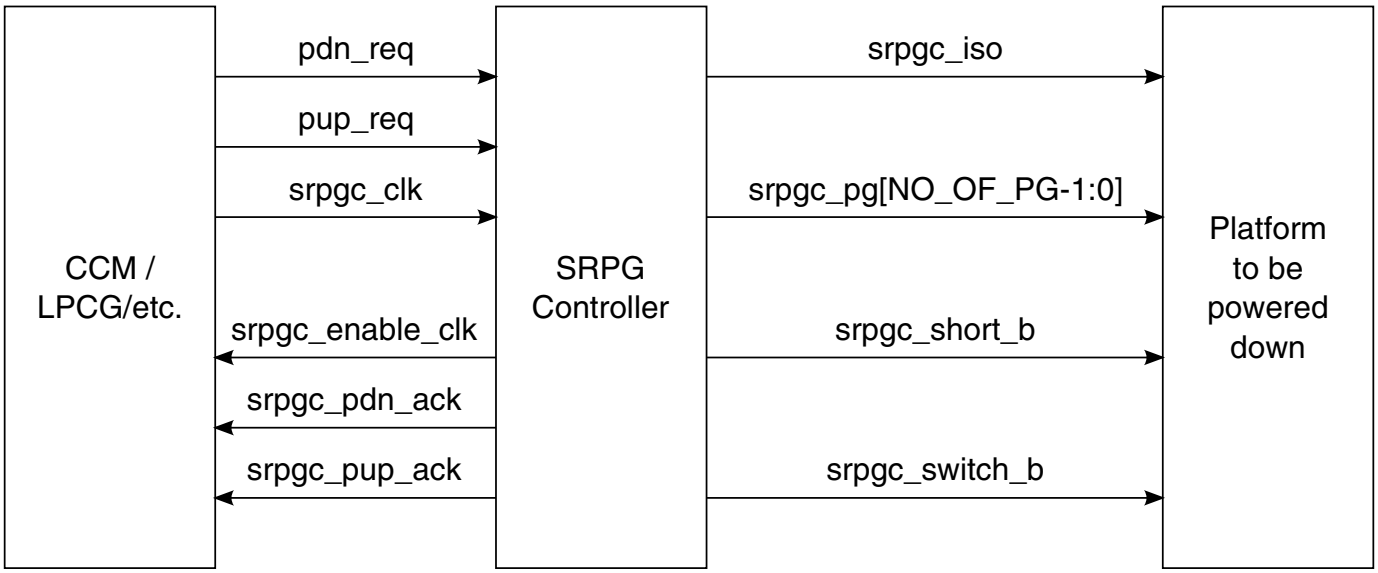

Figure 71-5. SRPGC Interface

71.3.1 Power-Down Sequence (SRPG Entry Sequence)

The power-down sequence control register (SRPGC_PDNSCR) and power-up sequence control register (PUPSCR) must be programmed to the desired value before initiating the "pdn_req" and must not be changed until power up is completed. The SRPG entry sequence is outlined in the following list of steps:

1. Software program PCR bit in the SRPG control register (SRPGC_SRPGCR).
2. CCM stops the clocks to the powering down platform.
3. pdn_req is asserted to SRPGC.
4. Upon detecting the pdn_req assertion, SRPGC asserts "srpgc_enable_clk".
5. SRPGC asserts "srpgc_iso" to isolate the outputs, based on the programming of PDNSCR[5:0].
6. SRPGC asserts "srpgc_pg[0]" to save the state of SRPG flops, based on the programming of PDNSCR[13:8]
7. SRPGC asserts "srpgc_pg[NO_OF_PG-1:1]" to save the state of SRPG flops. "srpgc_pg[1]" is asserted after one "srpgc_clk" of srpgc_pg[0] assertion, "srpgc_pg[2]" is asserted after two "srpgc_clk" of srpgc_pg[0] assertion, "srpgc_pg[NO_OF_PG-1]" is asserted after (NO_OF_PG-1) "srpgc_clk" of srpgc_pg[0] assertion.

8. SRPGC deasserts "srpgc_short_b", based on the programming of PDNSCR[17:16].
9. SRPGC deasserts "srpgc_switch_b", based on the programming of PDNSCR[29:24].
10. SRPGC asserts "srpgc_pdn_ack", one "srpgc_clk" cycle wide pulse.
11. SRPGC deasserts "srpgc_enable_clk".

NOTE

If the "pup_req" is asserted before completion of power down then the SRPGC stops the power down sequence immediately and starts the power-up sequence. "srpgc_pdn_ack" is asserted as soon as the power down sequence stops. If "pup_req" is asserted before or along with "pdn_req" then power down sequence does not start and "srpgc_pdn_ack" is not asserted by SRPGC.

71.3.1.1 Power-Down Sequence Timing Waveforms

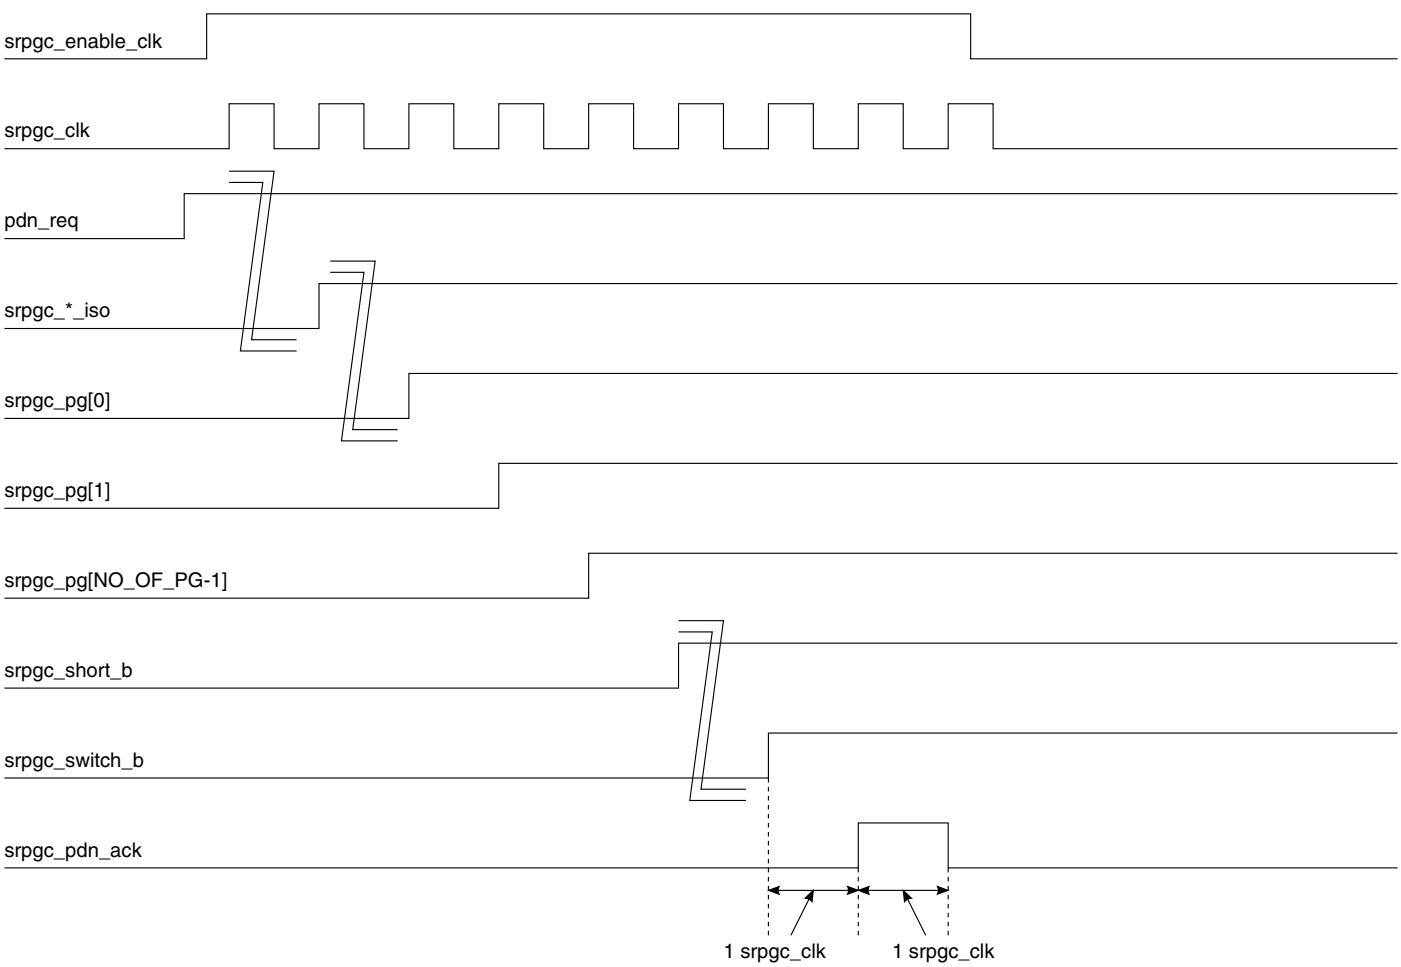

Figure 71-6. Power-down Sequence Timing Waveforms

71.3.2 Power-Up Sequence (SRPG Exit Sequence)

SRPG exit sequence is outlined in the following list of steps:

1. pup_req is asserted to SRPGC.
2. SRPGC asserts "srpgc_enable_clk" to enable the clock.
3. SRPGC asserts "srpgc_switch_b", based on the programming of PUPSCR[5:0].
4. SRPGC asserts "srpgc_short_b", based on the programming of PUPSCR[13:8].
5. SRPGC deasserts "srpgc_pg[NO_OF_PG-1]" to restore the state of SRPG flops, based on the programming of PUPSCR[21:16].
6. SRPGC deasserts "srpgc_pg[NO_OF_PG-2:0]" to restore the state of SRPG flops. "srpgc_pg[NO_OF_PG-2]" is deasserted after one "srpgc_clk" of srpgc_pg[NO_OF_PG-1] deassertion, "srpgc_pg[NO_OF_PG-3]" is deasserted after two "srpgc_clk" of srpgc_pg[NO_OF_PG-1] deassertion, "srpgc_pg[0]" is deasserted after (NO_OF_PG-1) "srpgc_clk" of srpgc_pg[NO_OF_PG-1] deassertion.
7. SRPGC deasserts "srpgc_iso" to remove the isolation from the output of the platform, based on the programming of PUPSCR[25:24].
8. SRPGC asserts "srpgc_pup_ack" after one clock cycles of "srpgc_iso" deassertion. This is a one "srpgc_clk" cycle wide pulse.
9. "pup_req" is deasserted to SRPGC.
10. SRPGC deasserts "srpgc_enable_clk".

NOTE

If the "pup_req" is asserted before completion of power down then the SRPGC stops the power down sequence immediately and starts the power-up sequence. "srpgc_pup_ack" is asserted after completion of power up. If "pup_req" is asserted before "pdn_req" then SRPGC does not initiate the power down sequence and asserts the "srpgc_pup_ack".

71.3.2.1 Power-up Sequence Timing Waveforms

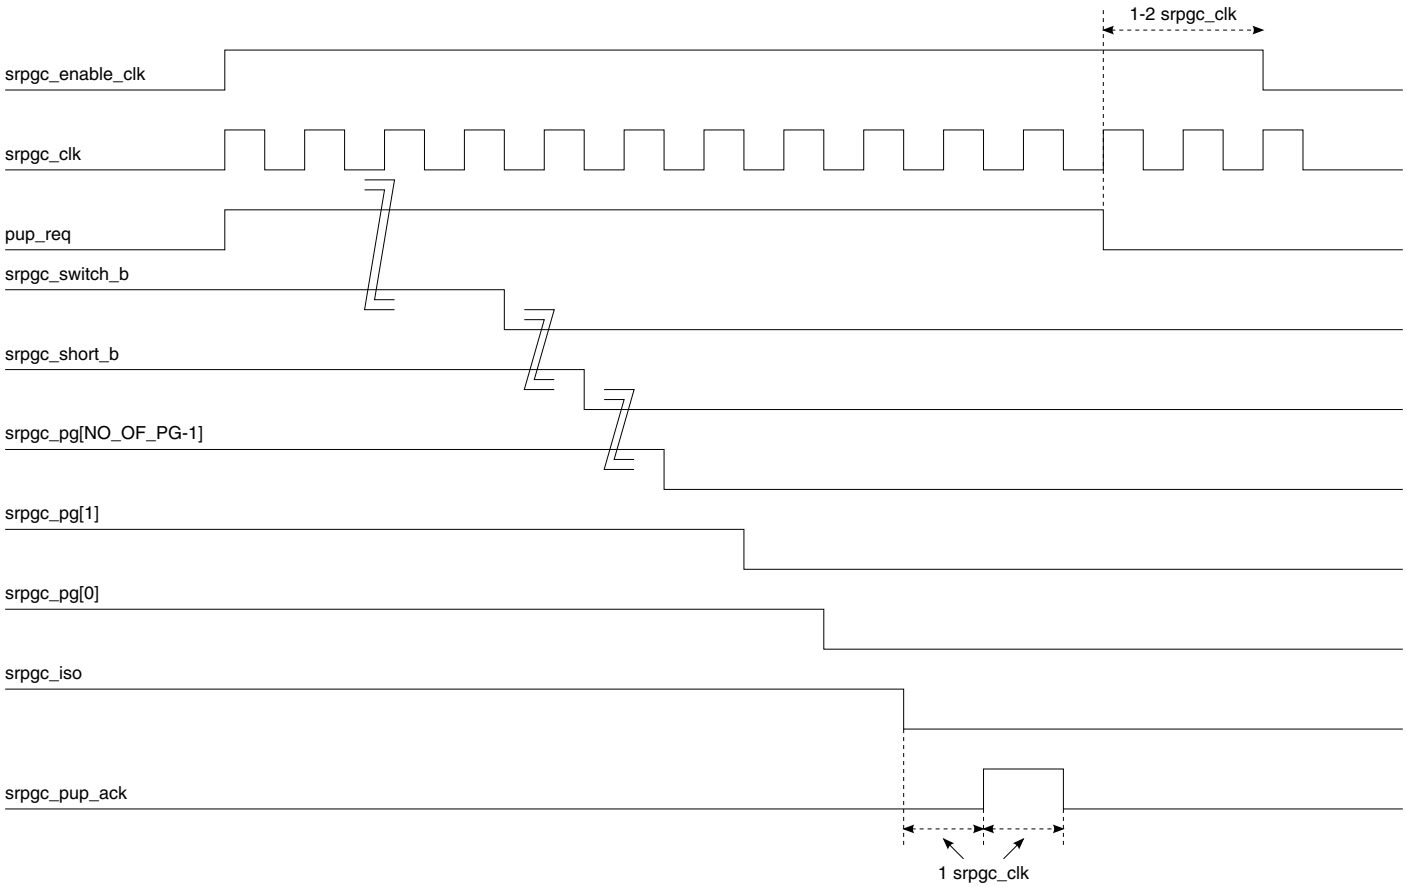

Figure 71-7. Power-up Sequence Timing Waveforms

71.4 Programmable Registers

The SRPGC registers can only be accessed in supervisor mode. Any access in normal mode, or an access to an unimplemented address location can assert transfer error signal "ips_xfr_err", if "resp_sel" is low.

Chapter 72
Secure Real Time Clock (SRTC)

72.1 Overview

This section briefly introduces the block. The full description of the block is in Functional Description.

The SRTC is comprised of two separated sub-blocks:

- Low power domain SRTC (SRTC LP)
- High power domain SRTC (SRTC HP)

SRTC LP is in an always powered up domain and is isolated from the rest of the logic by means of an isolation cell. Isolation cells are library instantiated cells, which insure that the powered up logic does not get corrupted when the power goes down in the rest of the SoC. It is powered by the Coin Cell battery.

SRTC HP is in the normal supply domain. It is powered by the main digital supply powering the SoC.

72.1.1 Low Power SRTC (SRTC LP) Overview

The SRTC LP is a real time clock with enhanced security capabilities. Its purpose is to provide an accurate time read at all times, regardless of the main system power state and without the need to use an external on-board time source such as external RTC. The SRTC LP can wake up the system when preset time alarm is asserted.

It is divided into following units:

- Counters and registers
  - Non-rollover 47-bit time counter
  - 32-bit alarm register

- General purpose registers
- Secured monotonic counter

- SRTC Monitor
  - SRTC state machine
  - SRTC power and clock detectors

Figure 72-1 shows the SRTC partitioning.

72.1.2 High Power SRTC (SRTC HP) Overview

The SRTC HP contains all the interfaces to the core (IP Bus Interface). It contains a counter, an alarm and has the capability of generating a number of user-defined periodic interrupts. Access to SRTC LP registers can only be done through the SRTC HP and when SRTC HP is powered up.

SRTC HP is partitioned into following units.

- Address Decode
- Counters and registers
  - Nonsecure 47-bit time counter
  - Programmable nonsecure 47-bit alarm with interrupt
  - Periodic alarm with interrupt

The nonsecure time counter can be synchronized with the secured time counter by writing to a SRTC HP bit (time_sync-Time Synchronization). When written, the content of the secure counter is automatically copied to the nonsecure counter.

The following figure shows the SRTC partitioning.

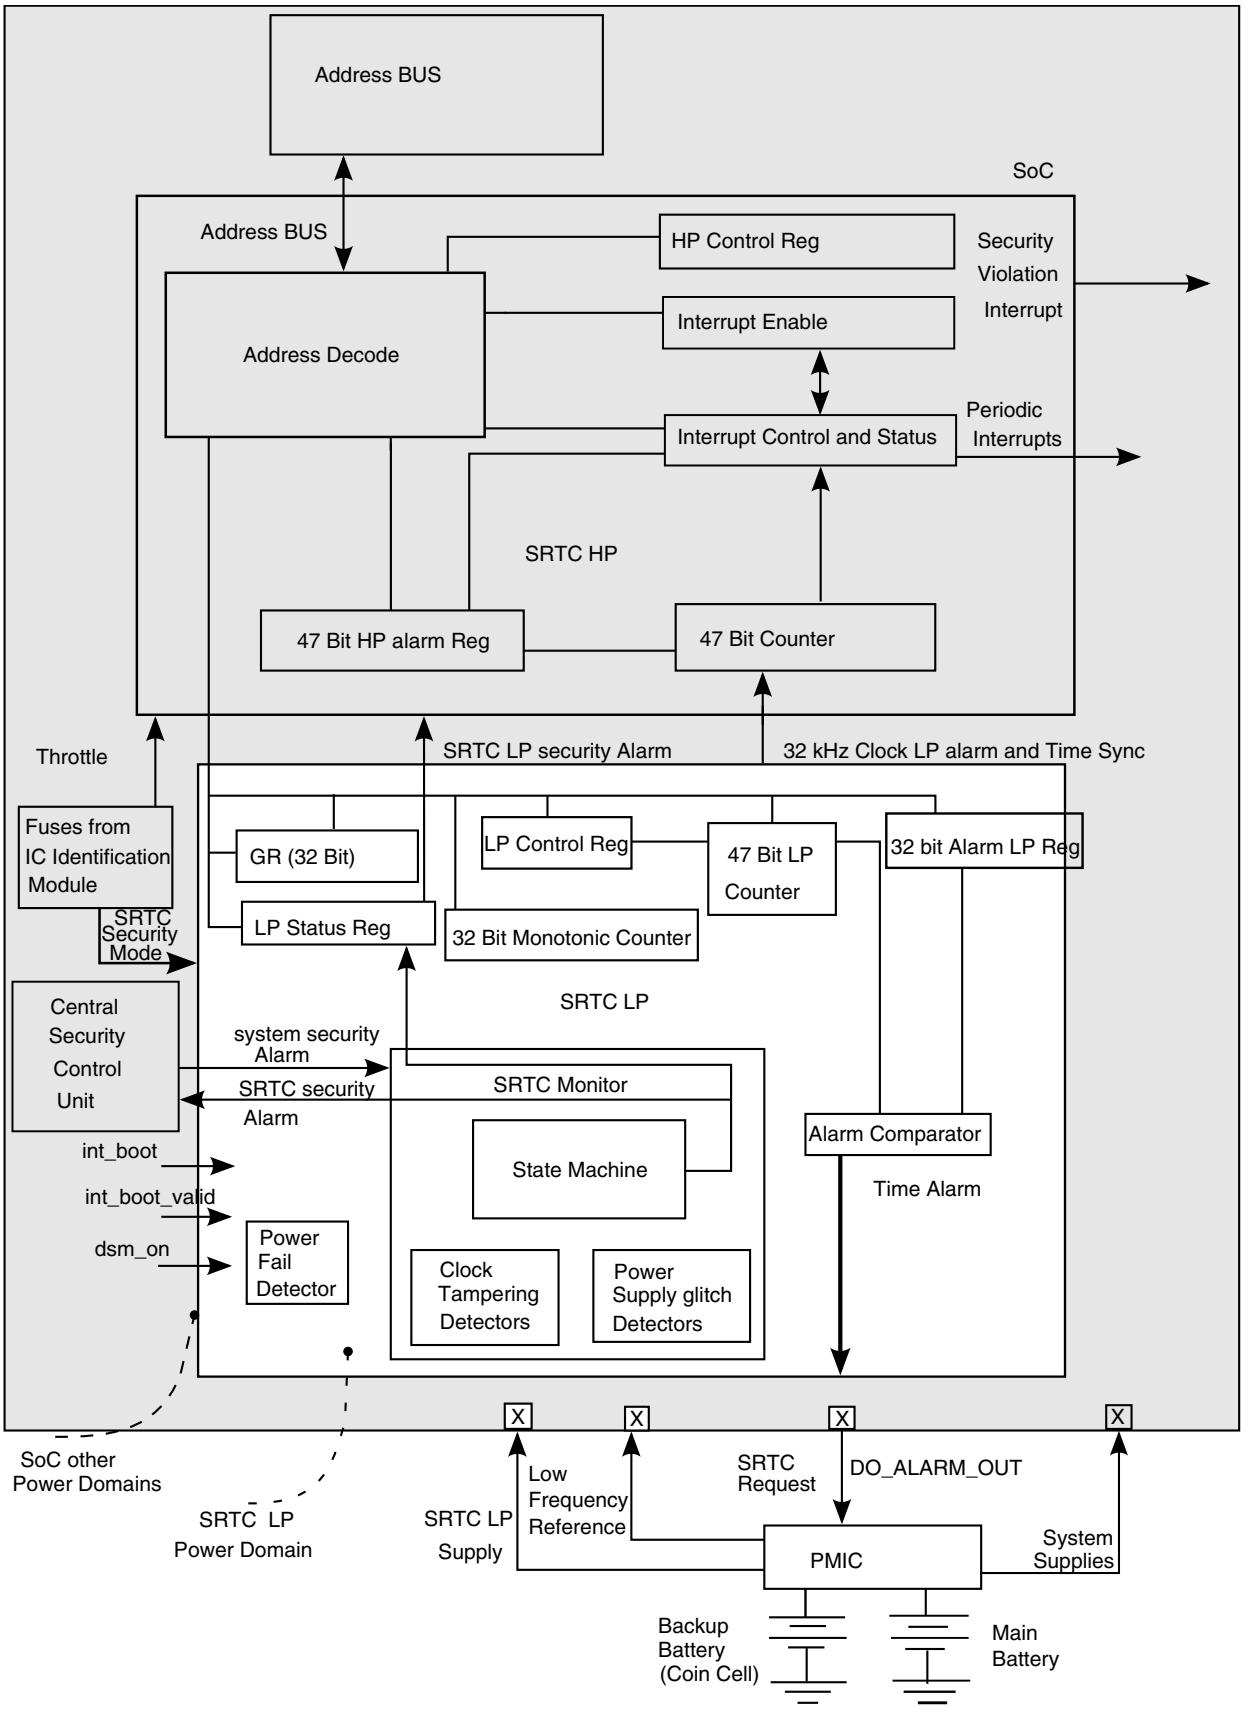

Figure 72-1. Block Diagram

72.1.3 Features

The SRTC includes the following features:

- Secure 47-bit time counter running on 32.768 kHz clock
- Nonsecure 47-bit time counter running on 32.768 kHz clock
- User mode protection and/or ARM's TrustZone mode protection- SRTC secured registers cannot be configured by nonsecured SW (see the Programmable Registers section). A dedicated control bit can allow nonsecured SW to update the secured registers. This bit can be set only by secured SW. In any case, SRTC secured registers cannot be configured when SRTC is locked.
- Re-programming protection:
  - SRTC time cannot be altered after SRTC is locked (when SRTC set to the appropriate security mode)
  - SRTC cannot be disabled after SRTC is locked (when SRTC set to the appropriate security mode)
- Power loss protection:
  - Separated power supply
  - Accurate continuous time is kept during power down system states and main power source losses
  - In the event of a total power loss (main power source and backup power source), SRTC time read is invalidated
  - In the event of unstable voltage power source, SRTC time read is invalidated
  - In the event of low voltage power source that disrupts normal time counting, SRTC time read is invalidated
- Clock source protection:
  - Directly connects to a low frequency crystal (32.768 kHz) or to a PMIC 32.768 kHz clock source
  - In the event that SRTC frequency drops, SRTC time read is invalidated
- SRTC time can be invalidated by a system security alarm
- SRTC can assert a system security alarm and fast interrupt request to alert the processor that time read was invalidated
- Programmable secure 32-bit alarm with interrupt (alarm of the secure- LP section). In case of system power up mode, this alarm generates interrupt to alert the processor. In case of system power down mode, this alarm alerts the power management IC (PMIC) via an external pin to instruct the PMIC to power up the system. Note that this feature does not require any PMIC special support. This signal can be connected to an on-board power on button circuit.
- Programmable nonsecure 47-bit alarm with interrupt (alarm of the nonsecure, HP, section)

- Periodic nonsecure alarm with interrupt
- Secured monotonic counter
- General purpose always powered registers
- Ultra low power consumption. SRTC LP power consumption during system power down state is less than 3 µA.(TYP)
- Separate calibration logic for 47 bit HP and LP counters

72.1.4 Modes of Operations

The SRTC has three functional modes, defined by IC Identification Module dedicated fuses, and can be found in one of four states.

The SRTC modes are as follows:

- Mode #1 - High Security
- Mode #2 - Medium Security
- Mode #3 - Low Security

SRTC states are defined as follows:

- Initialization- SRTC is powered up for the first time or after system POR.
- Nonvalid- SRTC time is not set, time read is not authenticated
- Valid- Valid time was set, time read is authentic
- Failure- SRTC logic detected a failure. Time is invalidated.

See SRTC State Machine, for more details.

NOTE

Detailed information about the SRTC security modes is provided in the Security Reference Manual. Contact your Freescale representative for information about obtaining this document.

72.2 External Signal Description

Table 72-1. Signal Properties[1]

Name	PORT	Function	I/O	Reset	Pull Up
IND_CKIL_IN	CKIL	Input 32.768 kHz Low Frequency Reference clock for the LP Section.	I	0	-
DO_ALARM_OUT	SRTC_ALARM	Output wake up alarm to PMIC on time out. Polarity is active low.	O	0	-

1. This table indicates external signal connected to PAD

72.3 Functional Description

The SRTC is a real time clock with enhanced security capabilities. Its purpose is to provide an accurate time read at all times, regardless of the main system power states and without the need to use an external time source such as external RTC. The following sections describe in detail the theory and basic design principals of the SRTC.

72.3.1 Power and Clock Source

The SRTC is divided into two main sub-blocks based on the power supply.

The SRTC LP is the always powered section of the SRTC. SRTC LP is a separate power domain with its own power supply. No other logical sub-blocks within the SoC boundary share the power supply with this section.

SRTC LP power is supplied by a power management IC (PMIC), such as Freescale MC13783 (Atlas). It is assumed that the power management IC is responsible for supplying a stable voltage level at all times from a main power source or from a back-up power source (for example, a coin-cell battery). The SRTC LP is not connected directly to a backup power source and is not responsible for switching between power sources in case of main power source losses: main battery removals or power cuts (momentary lost of power). It is assumed that the PMIC is responsible for switching between main power source and backup power source as required.

The SRTC LP section is separated from the rest of the SRTC and SoC by means of isolation cells. SRTC receives a signal which indicates a power loss to the SoC, and enables the isolation cells. This signal is deactivated once stable power is restored to the SoC.

Figure 72-2 shows low power domain connectivity. SRTC HP section is in the normal power supply domain and receive power along with the rest of the SoC.

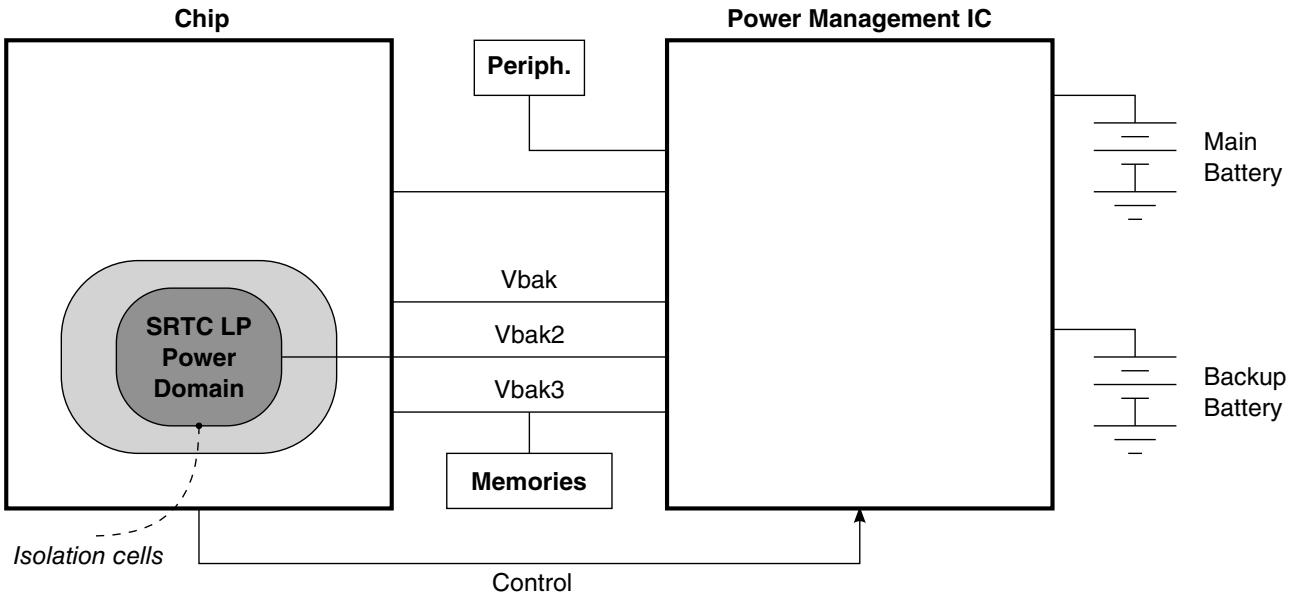

Figure 72-2. SRTC Power Domains

72.3.1.1 Clocks

SRTC runs on two clock sources, high frequency peripherals clock and low frequency timers clock. The high frequency peripheral IP clock is used by the SRTC peripheral bus interface, control and status registers. The low frequency 32.768 kHz clock is the always-active clock used by the SRTC timers and by the PTD and CTD logics. This can be driven directly from an oscillator or from a PMIC clock source.

72.3.2 High Power SRTC (SRTC HP) Description

The SRTC HP contains all the interfaces to the core (IPBus interface). Access to SRTC LP registers can only be done through the SRTC HP and when SRTC HP is powered up. It also contains the following sub- blocks.

72.3.2.1 SRTC HP nonsecured Counter

The SRTC HP incorporates autonomous 47-bit nonsecured time counter. The counter is not active and is reset when system is powered down, however, it remains active during system low-power modes (for example, wait, doze and stop). The nonsecure counter can be used by any application as it has no access restrictions. The SRTC HP counter can be

synchronized with the SRTC LP secure time counter by writing to a specific bit in the SRTC HP control register. After synchronization, time integrity of the nonsecured timer cannot be guaranteed as it has no access limitations

72.3.2.1.1 SRTC HP Counter Calibration

A clock calibration system is provided to adjust the 32,768 cycle counter that generates the 1 Hz timer for SRTC HP timing registers. The general implementation relies on the system processor to measure the 32.768 kHz crystal oscillator against a higher frequency and more accurate system clock such as a TCXO. If the SRTC timer needs a correction, a 5-bit 2-second complement calibration word can be sent via IP to compensate the SRTC for inaccuracy in its reference oscillator as defined in the Table 72-2. The available correction range should be sufficient to ensure that drift accuracy is in compliance with standards for secure time applications like DRM time keeping. Note that the 32.768 kHz oscillator is not affected by SCAL_HP settings; calibration is only applied to the SRTC time base counter. Therefore, the frequency at the clock output Low Frequency Reference Clock is not affected.

The SRTC system calibration is enabled by programming the SCALM_HP for desired behavior by operational mode.

Table 72-2. SRTC HP Calibration Setting

Calibration Settings Code in SCAL_HP[4:0	Correction in Counts per 32768	Relative Correction in ppm
01111	+15	+458
00011	+3	+92
00001	+1	+31
00000	0	0
11111	-1	-31
11101	-3	-92
10001	-15	-458
10000	-16	-488

However, the calibration is only as good as the SCAL_HP data that has been provided, so occasional refreshing is recommended to ensure that any drift-influencing environmental factors have not skewed the clock beyond desired tolerances.

See HP Control Register (SRTC_HPCR), for bit definitions of SCAL_HP and SCALM_HP.

72.3.2.2 SRTC HP nonsecured Counter Alarm

The SRTC HP nonsecured counter has its own 47-bit time alarm register. An alarm is when the 47 bits of HP counter matches with the value of the 47-bit HP alarm register. If X is the value at which the alarm is desired, then this HP Alarm register should be set with value X-1. Note that this register can be updated by any application. The SRTC HP time alarm can generate an interrupt to alert the ARM core to wake it up from one of its low-power modes (for example, wait, doze, stop). Note that this alarm cannot wake up the entire system if it is powered off.

A nonsecure alarm has been provided with mask bit AHP in the SRTC_HPCR.

72.3.2.3 SRTC HP Periodic Alarm

The SRTC HP nonsecure counter can support a generation of a millisecond resolution periodic alarm. The periodic interrupt generation can be set in a range of 1Hz to 32.768 kHz. This interrupt is enabled and set from the SRTC Interrupt enable register. The interrupt source of the periodic alarm is chosen by comparing one of the16 LSB Bits of the 47-bit nonsecured counter (this interrupt is generated when a zero-to-one and one-to-zero transition occurs on the selected bit).

HP SRTC nonsecure counter and its alarms are shown in Figure 72-3.

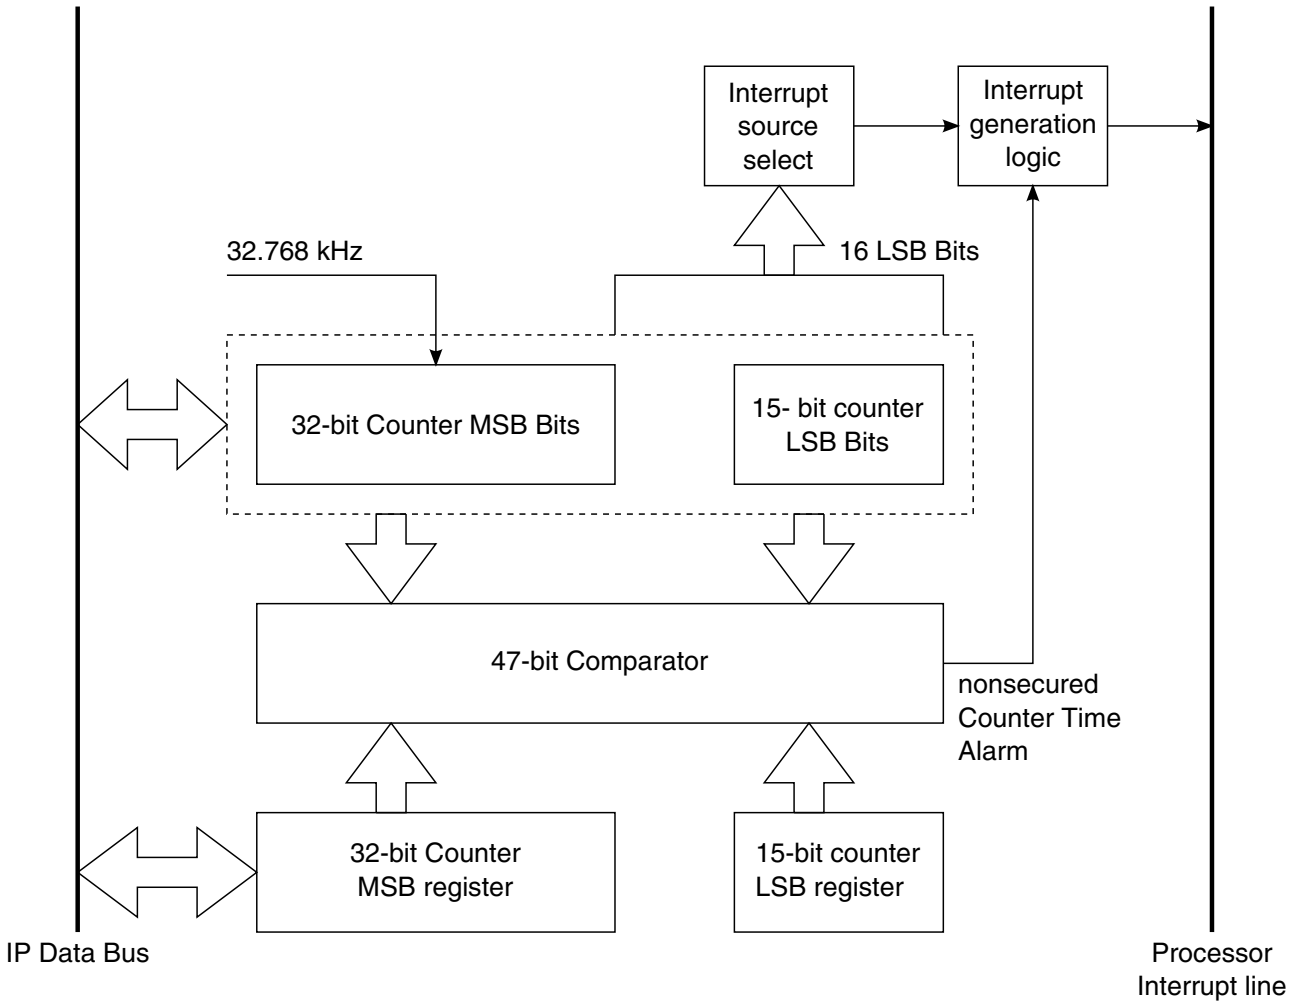

Figure 72-3. SRTC HP nonsecured Counter

72.3.3 Low Power SRTC (SRTC LP) Description

The SRTC LP is a real time clock with enhanced security capabilities. Its purpose is to provide an accurate time read at all times, regardless of the main system power state and without the need to use external on-board time source such as external RTC. The SRTC LP can wake up the system when preset time alarm is asserted. The SRTC LP also contains a monotonic counter and a general purpose register that can be used to store important information while the system is powered down. The following sections describe in detail the theory and basic design principals of the SRTC LP sub-block.

72.3.3.1 SRTC LP Behavior during System Power Down and POR

On system power down the SRTC LP continues to operate normally. It is isolated from the rest of the SoC by means of isolation cells. It keeps the time and retains all parameters stored in its registers. On system power down, the SRTC ignores all system signals (SRTC LP inputs) such as IC Identification Module, SRTC HP, and other input signals. On PoR SRTC LP ignores all system input signals (SRTC LP inputs) until the CCM indicates that the PoR routine ended. This is done to eliminate false signal indications caused by an unstable power state of the system.

72.3.3.2 SRTC LP Secured Counter

The SRTC incorporates autonomous 47-bit secured time counter. Time counter is a non-rollover counter. This means that if the time counter reaches the value of 0xffff_ffff_ffff, it does not rollover. However, the TR bit is set in the SRTC_LPSR and the SRTC enters failure state. This has been done to prevent an attacker from virtually running the time backwards using a higher frequency clock source.

72.3.3.2.1 SRTC LP Counter Calibration

A clock calibration system is provided to adjust the 32,768 cycle counter that generates the 1 Hz timer for SRTC LP timing registers. The general implementation relies on the system processor to measure the 32.768-kHz crystal oscillator against a higher frequency and more accurate system clock such as a TCXO. If the SRTC timer needs a correction, a 5-bit 2-second complement calibration word can be set to compensate the SRTC for inaccuracy in its reference oscillator as defined in the following table.The available correction range should be sufficient to ensure drift accuracy in compliance with standards for secure time applications like DRM time keeping. Note that the 32.768 kHz oscillator is not affected by SCAL_LP settings; calibration is only applied to the SRTC time base counter. Therefore, the frequency at the clock output Low Frequency Reference Clock is not affected.

The SRTC system calibration is enabled by programming the SCALM_LP[1:0] for desired behavior by operational mode.A slight increase in consumption is seen when that calibration circuitry is activated. To minimize consumption and maximize lifetime when the SRTC system is maintained by the coin cell, the SRTC Calibration circuitry can be automatically disabled when main battery contact is lost or if it is so deeply discharged that SRTC power draw is switched to the coin cell (configured with SCALM_LP=01). Because of the low SRTC consumption, SRTC accuracy can be maintained through long periods with the application being shut down, even after the main battery has discharged.

However, calibration is only as good as the SCAL_LP data that has been provided, so occasional refreshing is recommended to ensure that any drift influencing environmental factors have not skewed the clock beyond desired tolerances.

Table 72-3. SRTC LP Calibration Setting

Calibration Settings Code in SCAL_LP[4:0	Correction in Counts per 32768	Relative Correction in ppm
01111	+15	+458
00011	+3	+92
00001	+1	+31
00000	0	0
11111	-1	-31
11101	-3	-92
10001	-15	-458
10000	-16	-488

See LP Control Register (SRTC_LPCR), for bit definition of SCAL_LP and SCALM_LP.

72.3.3.3 SRTC LP Secured Counter Alarm

The SRTC LP section has its own 32-bit time alarm register. An alarm is generated when a 32-bit MSB (bits 46 to 15) value of the LP secure counter (SRTC_LPSCMR) matches with the 32-bit secure alarm register (SRTC_LPSAR). If X is the value at which the alarm is desired, then this SRTC_LPSAR should be set with the value X-1. The alarm register can be updated only by secure application. The SRTC LP time alarm can generate interrupt to alert the core and can wake-up the core from one of its low-power modes (for example, wait, doze, stop). This alarm can also wake-up the entire system by asserting the DO_ALARM_OUT signal to the PMIC. DO_ALARM_OUT is asserted only if the main system is powered off as indicated by power fail circuity or external signal (dsm_on) input to DO_ALARM_OUT is active-low .

The secured alarm has been provided with a separate mask bit, ALP and WAE, in the SRTC_LPCR .

72.3.3.4 Monotonic Counter

Security applications require a monotonic counter that cannot be exhausted or return to any previous value during the life-time of the product.

The monotonic counter is a counter that counts in one direction only. The monotonic counter can never repeat a number implying that it cannot be reset or cycled back to its starting count. The monotonic counter incorporates an innovative mechanism that prevents exhaustive usage of the counter while still allowing short rapid counter increments.

The monotonic counter features are listed below:

- 32-bits counter that can only go up
- Counter increment can only be done by secured SW (by writing any value to the counter's register)
- Average number of updates per predefined period is limited

72.3.3.4.1 Monotonic Counter Roll-Over Protection Mechanism

To prevent a case where a malicious SW rolls over the monotonic counter, a counter update limitation mechanism is implemented. This mechanism assures that the number of updates within a period of 512 seconds is limited. Updates beyond the specified number are ignored and the counter is not incremented.

The number of updates per 512 seconds is set by the IC Identification Module (e-fuse programmed) as follows: (number of updates (average updates per second))

- 8192 (16)
- 4096 (8)
- 2048 (4)
- 1024 (2)
- 512 (1)
- Unlimited

The mechanism gates the increment request signal with output overflow signal of a special 13-bit counter, as shown in the figure below.

Table 72-4 shows the mapping between the IC Identification Module throttle values and number of updates.

Table 72-4. Throttle and Monotonic Counter Updates Mapping

Value of IIM Throttle	Number of Updates per 512 seconds (Average Updates per second)
000	512(1)
001	1024 (2)
010	2048 (4)
011	4096 (8)
100	8192 (16)

Table continues on the next page...

Table 72-4. Throttle and Monotonic Counter Updates Mapping (continued)

Value of IIM Throttle	Number of Updates per 512 seconds (Average Updates per second)
101	8192 (16)
110	8192 (16)
110	8192 (16)
111	Unlimited

On reaching the value of 0xffff_ffff, the monotonic counter does not roll over. The MR bit in SRTC_LPSR is set and SRTC enters failure state.

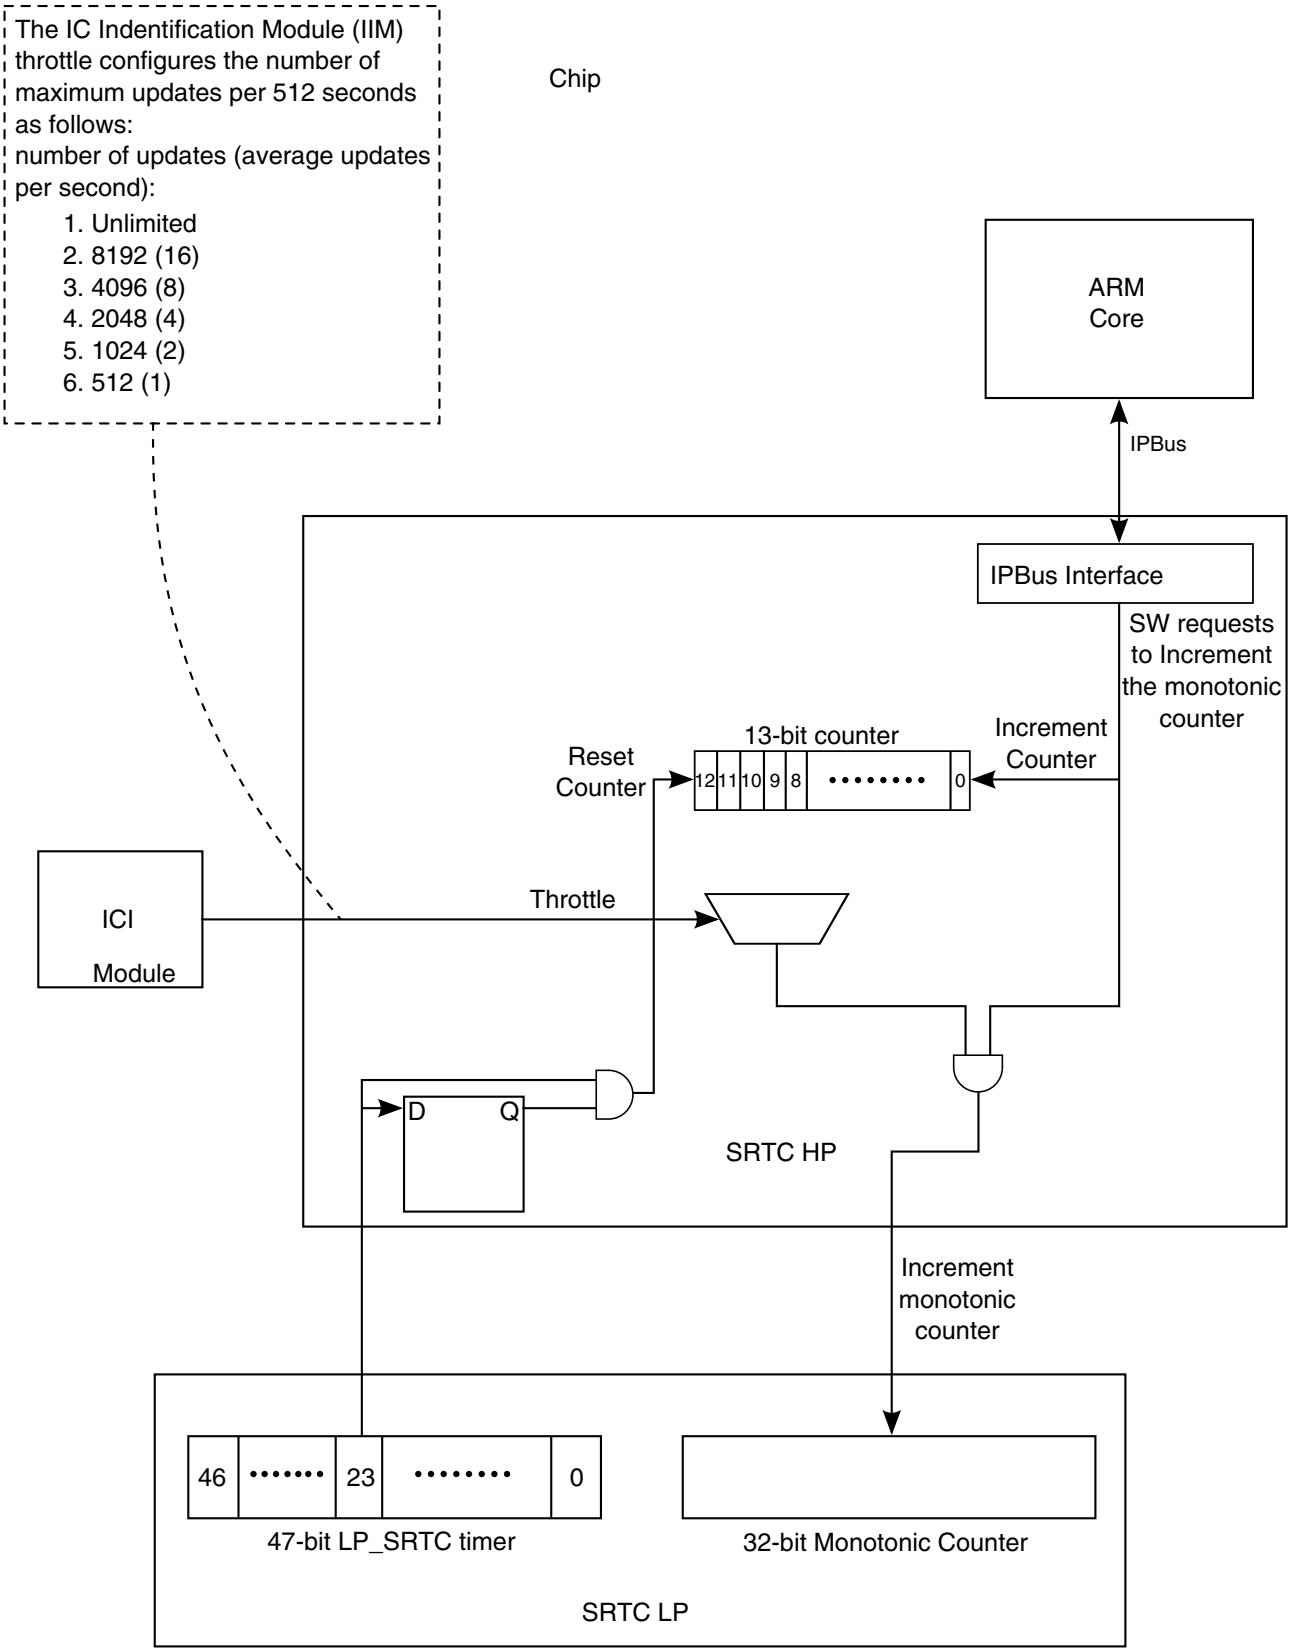

Figure 72-4. Monotonic Counter Roll-Over Protection Mechanism

72.3.3.5 General Purpose Always-Powered Registers

One 32-bits general purpose register that is a part of the SRTC LP and is always powered.

72.3.3.6 SRTC LP Monitor

The SRTC monitor watches for security alarms (SRTC LP and security block alarms) and then shifts the SRTC to failure state, in case of a security violation. The SRTC is comprised of three sub-blocks, SRTC State Machine (SSM), Power Supply Glitch Detector (PGD) and Clock Tampering Detector (CTD).

72.3.3.6.1 SRTC State Machine

The SRTC LP State Machine (SSM) can be found in one of four states:

- Initialization- SRTC failure indication can be cleared. Time read and monotonic counter read are reset and kept reset (except for nonsecure mode). Monotonic counter and secured time cannot be programmed. During this state the power glitch register can be loaded with the 41736166 value. This mode is exited by writing to a IE SRTC control bit. Failure monitors are not active in this state.
- Nonvalid- Time and monotonic counters are not valid and need to be set. Time is not running however time value and monotonic counter can be updated (in nonsecure mode, timer and monotonic counter are not reset and remained active). Failure detectors are active. This mode is exited by writing to a NVE SRTC control bit.
- Valid- Time and monotonic counter read are valid and operational. Re-programing is allowed only in appropriate security mode. Failure detectors are active.
- Failure- SRTC detected a security violation. Time and monotonic read are invalidated. Time and monotonic read operation returns zero (except for nonsecure mode where timer is operational, can be read and reprogrammed).

SRTC states are shown in Figure 72-5.

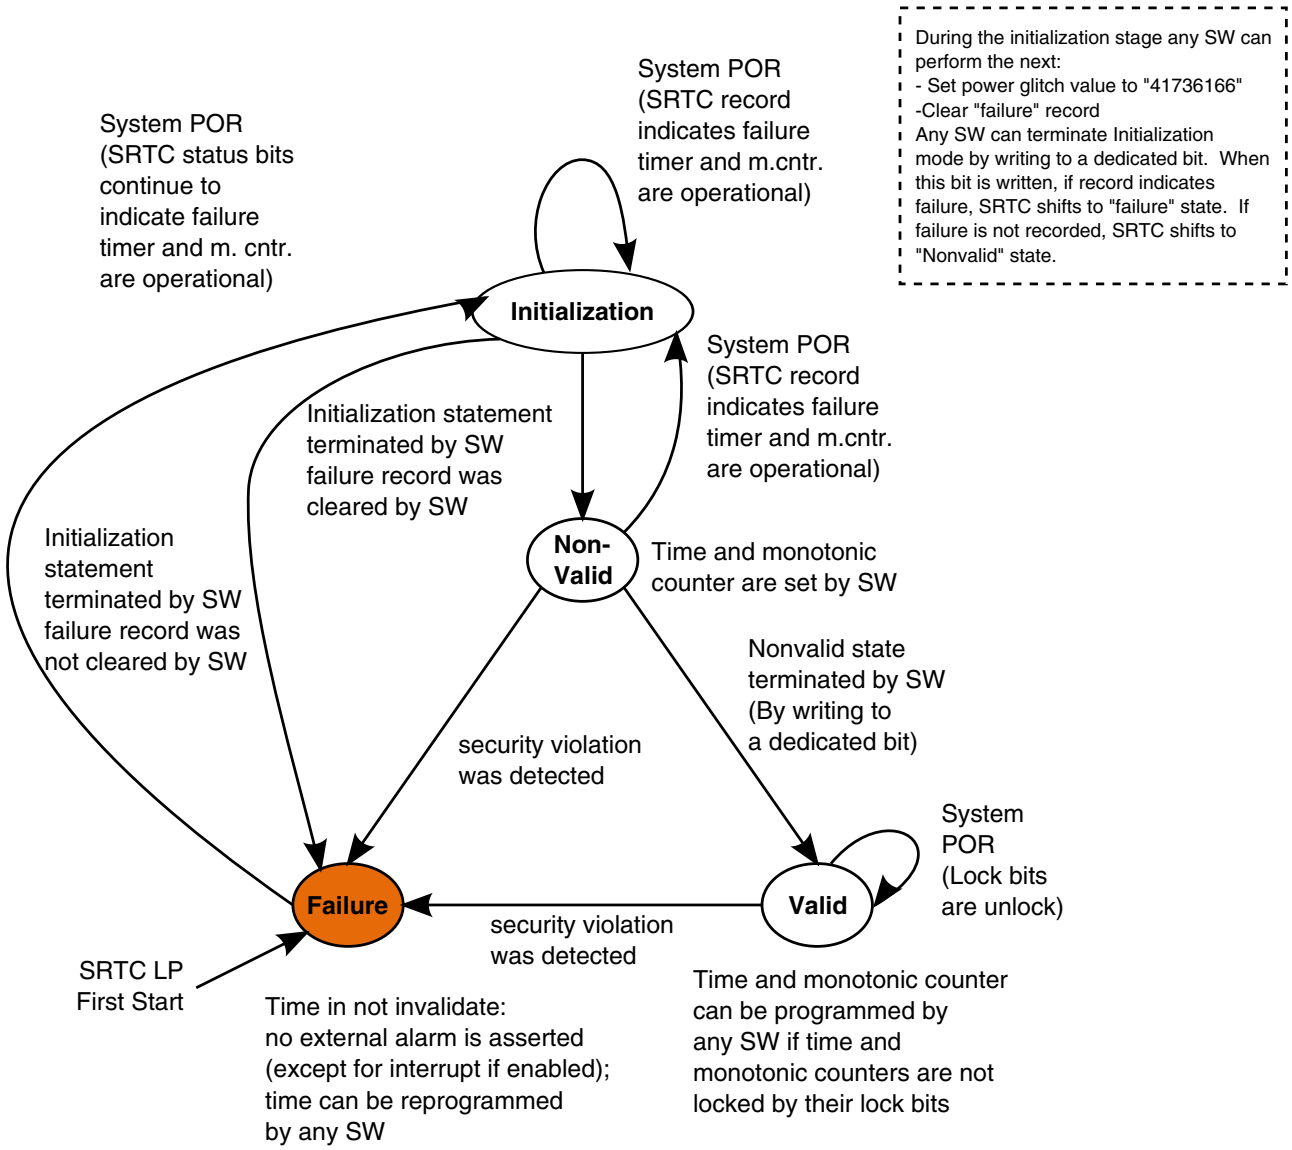

Figure 72-5. SRTC States - Low Security Mode

72.3.3.6.2 Power Supply Glitch Detector (PGD)

SRTC LP power supply can be power gated for short periods to cause state machine or secure counter register value to change. To detect such attack, SRTC incorporates an innovative method to detect and alert the system whenever power supply glitches endanger SRTC registers value. The SRTC glitch detector comprised of a simple register and few logic gates. This register is loaded to a known specific value (41736166) as part of the SRTC initialization process. This register have no reset input and its power-up value is pretty random. Comparing of these register value to a hardened value allow detection of power gating. The power supply glitch detector mechanism is shown in Figure 72-6.

The PGD and the TRI bit are set in the SRTC_LPSR and security alarm is raised to security block on SRTC security alarm (active high) pin and security interrupt (active low) to the core depending upon the SAE bit in the SRTC_LPCR and SI bit HPIENR respectively.

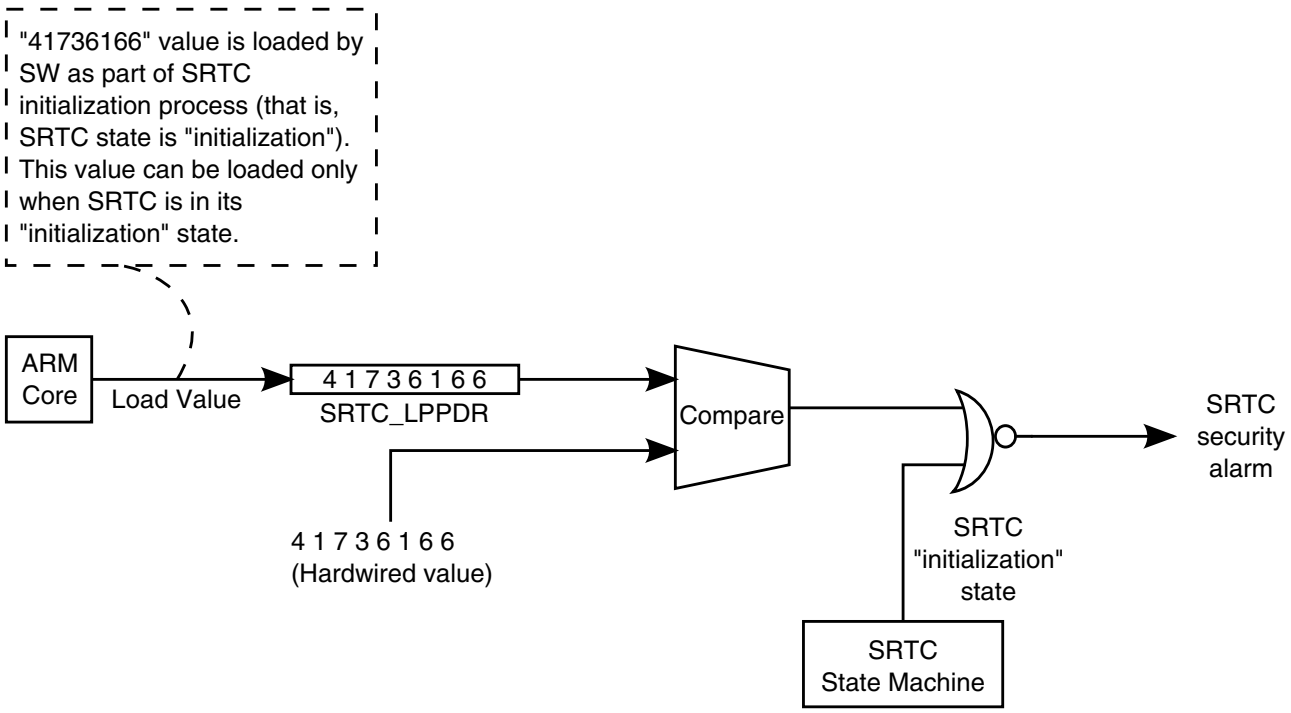

Figure 72-6. Power Supply Glitch Detector

72.3.3.6.3 Clock Tampering Detector (CTD)

External clock removal or frequency reduction can stop or slow down the secure counter time count. Because the clock signal is not generated internally in the SoC, SRTC cannot assure the reliability of the clock source and as consequence, cannot provide absolute assurance of the time read. However, SRTC provides means to detect significant reduction in its clock source frequency. SRTC clock tampering detector can detect frequency drop of 30%-100%. In current SRTC version, only clock frequency drop of 90% or more is detected.

If an attempt to tamper with the SRTC clock is detected, the SRTC enters failure state.

Storing fail indication of the clock monitor is done by SR latch with low, as possible, operating voltage. In this way, even if this register is not functional due to low voltage supply, on system power up, this register recalls the fail indication. The SRTC clock monitor mechanism is shown in Figure 72-7.

The CTD and the TRI bits are set in the SRTC_LPSR, and the security alarm is raised to the security block on the SRTC security alarm (active high) pin and the security interrupt (active low) to the core on the SRTC security Interrupt (Active low) pin SRTC security Interrupt (Active low) depending upon the SAE bit in the SRTC_LPCR and the SI bit in the SRTC_HPIENR, respectively.

72.3.3.6.4 Voltage Level Tampering Detector

Supply voltage of SRTC can be reduced to a value that causes the SRTC FF elements to be stuck at a constant value. Although clock frequency is valid, counter values can be stuck. Such attack has the same effect as clock input removal. Moreover, state machine registers can be also stuck, so even if violation is detected, it is not recorded. To make sure that voltage level is sufficient for proper functionality, the clock monitor does not monitor the raw clock input, but monitors a divided version of the actual real time counter. In this way, the same clock monitor can detect low voltage attack, where time counter LSB FF is stuck. LSB Bit of real time counter should be built from a high threshold transistors (this FF is more sensitive to low voltage than other SRTC FFs).

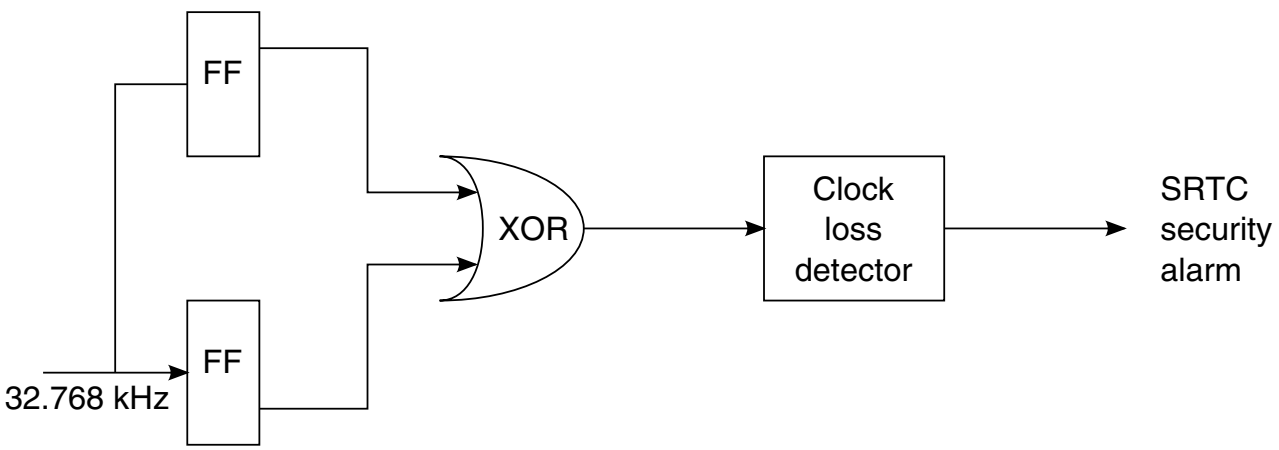

Figure 72-7. Clock Tampering Detector

72.3.3.6.5 Power Fail Detector (PFD)

Power fail detector is provided to detect the power failure in the SoG and isolate the SRTC LP from the rest of the SoG. It is provided with dsm_on input from the SoG. PFD is triggered when the dsm_on is asserted or when the there is power failure in the SoC.

72.4 SRTC Reset and System Power-Up

SRTC LP (always powered up section) is provided with its own POR, which provides power-on-reset as the power is switched on. This POR clears all registers inside SRTC.

SRTC LP section is in the Initialization state of the SRTC state machine upon its POR. Upon System POR the security mode of the SRTC is determined. If the security mode is Low (no security mode) then the SRTC LP counter and monotonic counter can be operational in the Initialization state.

Both the HP and LP section of the SRTC are provided with the their own software reset bit SWR in their respective control registers. The SWR bit of HP section can be set at any time and it resets all the HP section. This is a self clearing bit and always read as zero.

The SWR bit of LP section resets all the LP section. This bit can be set only in the Initialization state of SRTC state machine. This is a self clearing bit and always read as zero.

72.5 SRTC Interrupts and Alarms

The SRTC provides following interrupt and alarm lines

- $\overline{\text{SRTC Interrupt (Active low)}}$: Consolidated (ORed) interrupt pin for the following SRTC interrupts.
  - Periodic interrupt from 1 Hz to 32768 Hz frequency
  - Alarm interrupt of the HP section, see SRTC HP nonsecured Counter Alarm, for more details.
  - Alarm interrupt of the LP section, see SRTC LP Secured Counter Alarm, for more details.
  - Initialization Exit and Non Valid Exit Interrupt. Indicates the exit from the Initialization and Nonvalid state of the SRTC LP state machine.
  - Write done interrupt of the LP and HP section. To take care of the asynchronous Low Frequency Reference Clock, all the write from IP domain is synchronized to the Low Frequency Reference Clock domain. To indicate this delay the write done interrupt are provided for both the LP and HP section. Write done indicates that the consolidated status of the various IP writes and is triggered when all the registers have been updated. A separate interrupt is provided for the IP write to LP and HP section.
- SRTC security interrupt (Active low)- Security interrupt line to the core upon setting of the TRI bit in the LP section.

- SRTC security alarm- Security alarm to the security block upon setting of the TRI bit in the LP section.
- DO_ALARM_OUT- Time alarm of the LP section to the external pad, see SRTC LP Secured Counter Alarm, for more details. This alarm is generated when the system is powered off as indicated by the power fail circuitry or by external signal dsm_on input to the block. DO_ALARM_OUT is active low .

72.6 Initialization Information/Application Information

72.6.1 Flow Chart of SRTC LP Operation

See Figure 72-8 for the illustration of the flow chart of a typical SRTC LP operation.

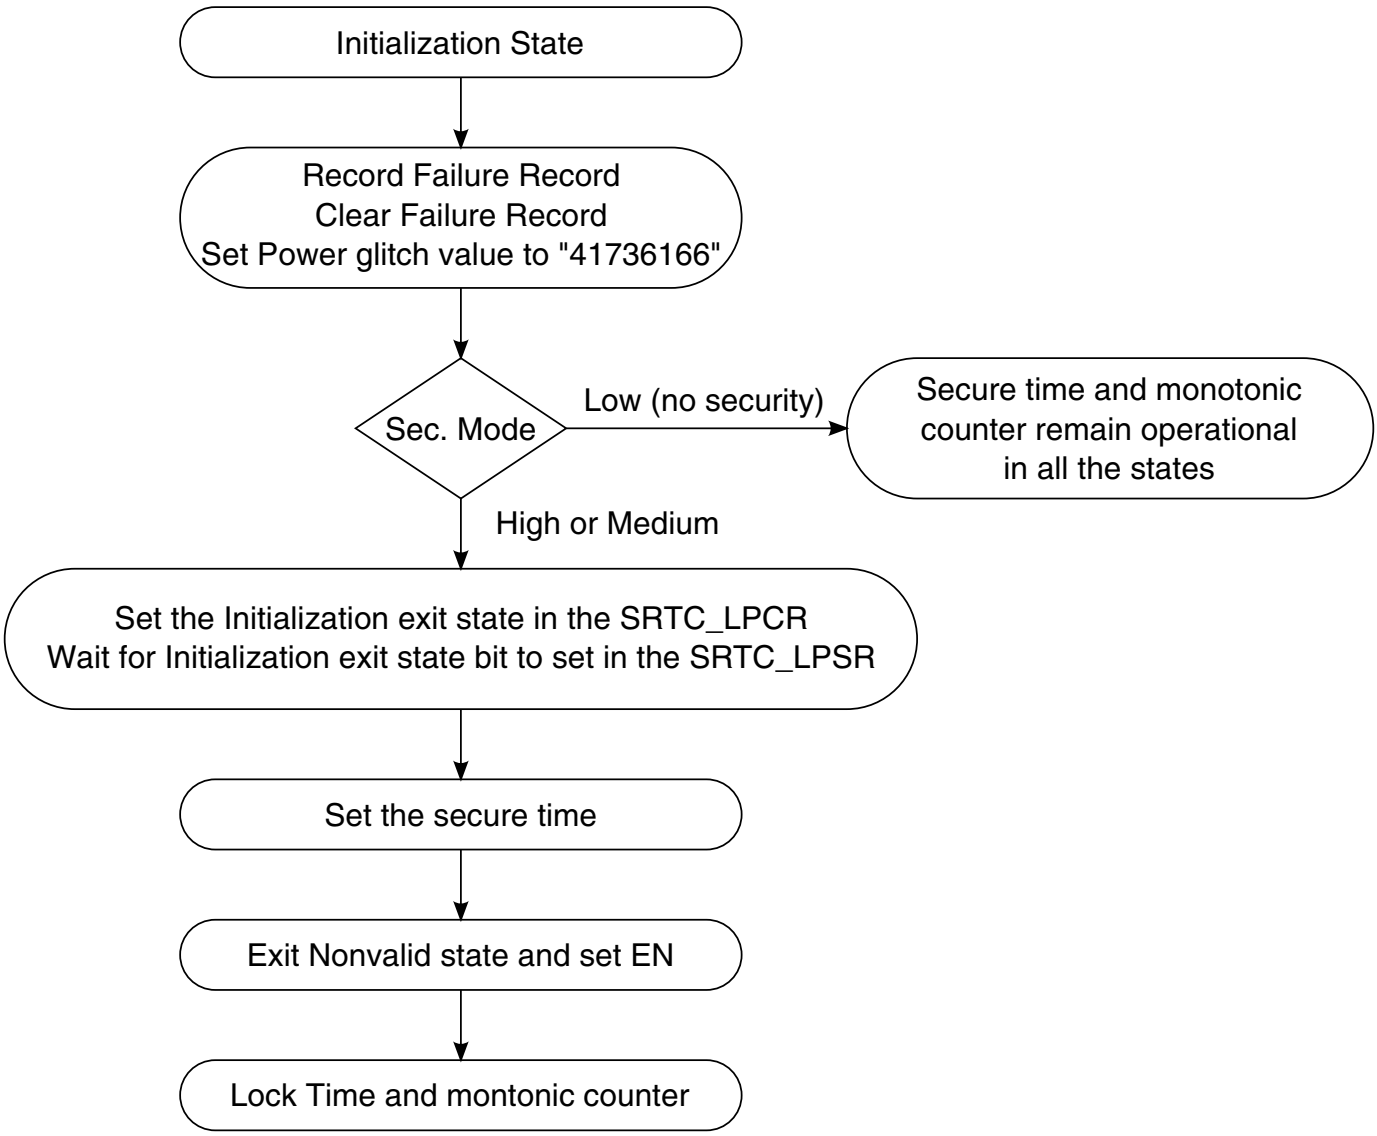

Figure 72-8. Flow Chart of SRTC LP Operations

72.6.2 Flow Chart of SRTC HP Operation

See Figure 72-9 for the illustration of the flow chart of a typical SRTC HP operation.

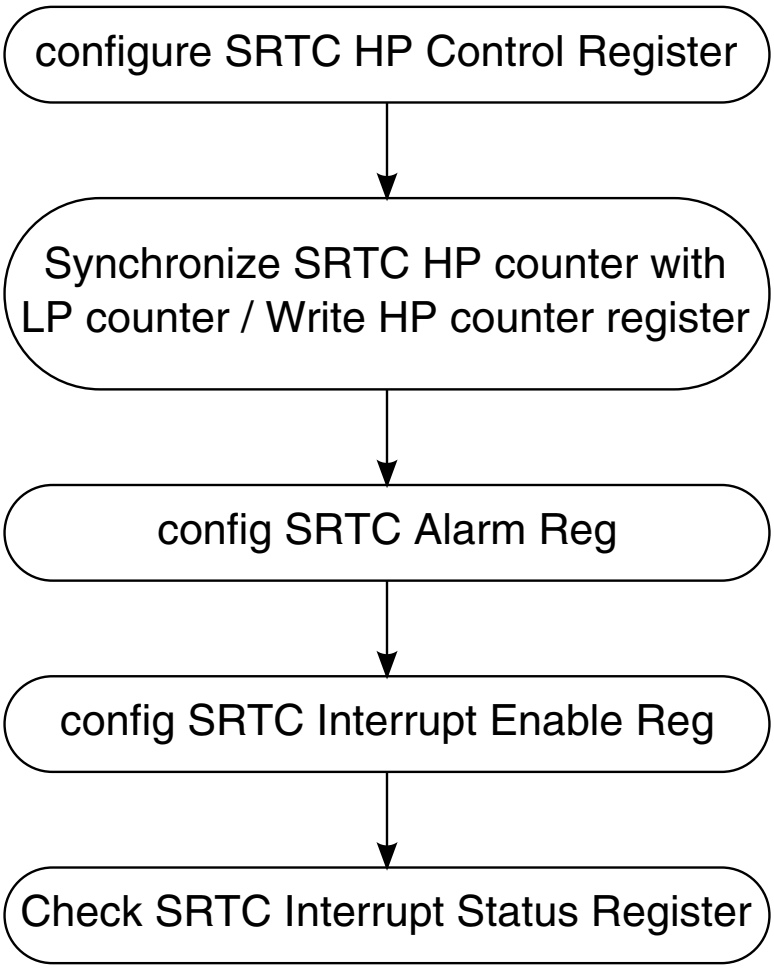

Figure 72-9. Flow Chart of SRTC HP Operations

72.7 Software Restrictions

The SRTC has the following software restrictions.

- The 32-bit MSB part and 15-bit LSB part of all the 47-bit registers should be updated together.
- The registers are not byte-writeable. All Valid byte enable should be asserted high for updating the register.
- LTC bit in the SRTC_LPCR. After it is set, this bit prevents write access to 47 bit SRTC LP secure counter by all application. Once set this bit is reset only upon system POR.

- LMC bit in the SRTC_LPCR. Once set this bit prevents write access to 32 bit SRTC LP secure monotonic counter by all application.Once set this bit is reset only upon system POR.
- SWR bit in the SRTC_LPCR. This bit can set by the secure application only in the Initialization state of the SRTC state machine.
- CTD, PTD and TRI bits in the SRTC_LPSR are unaffected by the System POR and are cleared only in Initialization state of SRTC state machine.
- SRTC LP power supply glitch detector register (SRTC_LPPDR). This register is write accessible only in the Initialization state of the SRTC state machine.
- Security mode. Security mode are retained upon system POR and can only be updated to higher security mode
- HPCR_TS that is, time synchronize operation and write on SRTC_HPCLR and SRTC_HPCMR shall not be performed at the same time. There is one count difference between LP and HP count value after TS has been performed
- There are two Low Frequency Reference Clock delay between the IP write operation on 47 bit counter, and value is updated on these counter.
- For write operation on monotonic counter the SRTC EN shall be enabled by setting the EN_LP. The software then shall wait for write pending LP bit (WPLP in SRTC_HPISR) to be zero before any write operation on Monotonic counter.
- IE and NVE in SRTC_LPCR are used to end the Initialization and Nonvalid states, respectively. They are used in the same sequence, that is, Initialization ends first, followed by Nonvalid exit.

When reading either SRTC_LPSCLR or SRTC_LPSCMR register, the software will read twice. The value of the register is valid when both the read data matches. In case there is mismatch the software will again read it twice.

72.8 Programmable Registers

The SRTC has fifteen 32-bit registers.

SRTC registers are marked with User and Secure access permissions. The distinction between User and Secure accesses does not apply when SRTC is configured for Low Security or the NSA bit is set in the SRTC_LPCR register.

- TrustZone Supervisor mode for TrustZone based systems (ARM1176 or further versions); or
- Supervisor mode for non-TrustZone based systems.

* Notes:
- u = Unaffected by reset.

SRTC_LPSCMR field descriptions

Field	Description
31–0 MLPSC	MSB value of the LP secure counter Contains MSB bits 46 to 15 of the 47 Bit LP secure counter.

72.8.2 LP Secure Counter LSB Register (SRTC_LPSCLR)

The LP secure counter LSB register contains the 15 least significant bits LSB (bits 14 to 0) of the 47-bit LP secure counter.

Address: SRTC_LPSCLR is 53FA_4000h base + 4h offset = 53FA_4004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

- u = Unaffected by reset.

SRTC_LPSAR field descriptions

Field	Description
31–0 LPSALM	LP Secure alarm Contains 32 bit value of LP secure alarm register, see SRTC LP Secured Counter Alarm, for more details.

72.8.4 LP Secure Monotonic Counter Register (SRTC_LPSMCR)

The LP secure monotonic counter register contains the 32-bit value of LP section monotonic counter. The counter is increment by writing any value to the counters register.

Address: SRTC_LPSMCR is 53FA_4000h base + Ch offset = 53FA_400Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

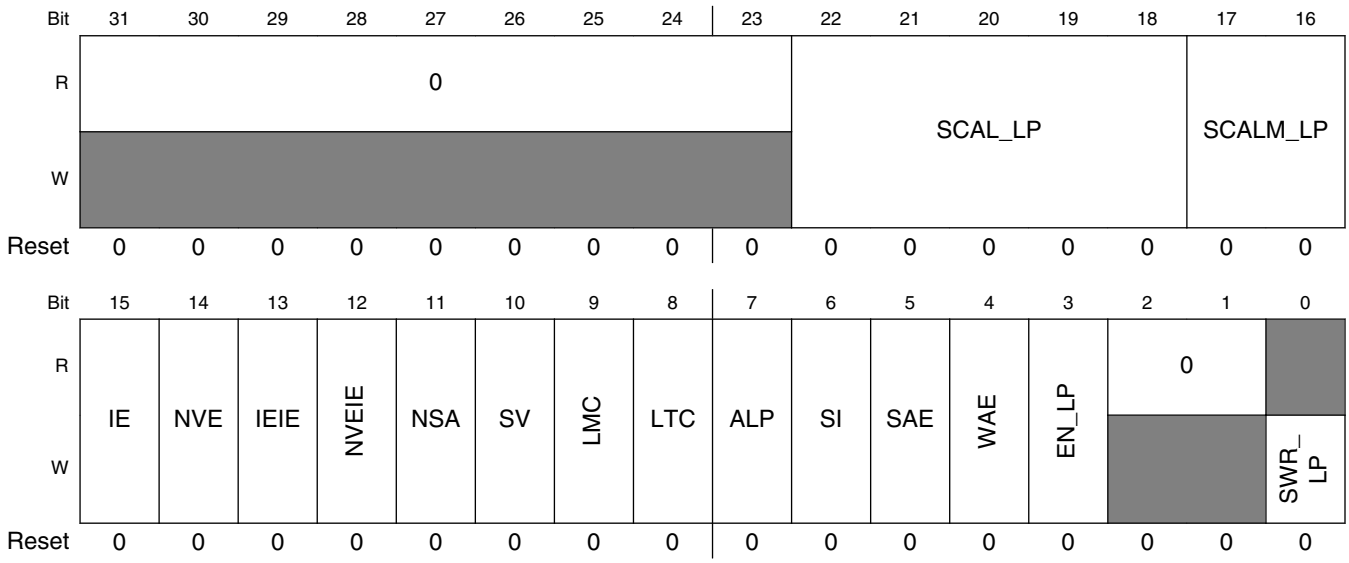
SRTC_LPSMCR field descriptions

Field	Description
31–0 LPSMC	LP Secure Monotonic counter Contains 32 bit value of LP secure monotonic counter.

72.8.5 LP Control Register (SRTC_LPCR)

The LP control register (SRTC_LPCR) contains various control bits of the LP section of SRTC.

Address: SRTC_LPCR is 53FA_4000h base + 10h offset = 53FA_4010h



SRTC_LPCR field descriptions

Field	Description
31–23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22–18 SCAL_LP	SRTC Calibration Value These five bits indicates signed calibration value for SRTC LP timer. In this, SCAL_LP[21:18] represent 4 bit value and SCAL_LP[22] represents the sign. Hence, SCAL_LP[22:18] allow calibration +15 to -16 in SRTC LP timer.
17–16 SCALM_LP	SRTCCALMODEL_LP Decides the SRTC LP calibration mode. 00 SRTC LP Timer calibration disabled. 01 SRTC LP Timer calibration enabled in all modes except coin cell mode 10 SRTC LP calibration disabled (Reserved). 11 SRTC LP Calibration enabled in all modes.
15 IE	Initialization state exit bit When set, this bit ends Initialization state of the SRTC state machine. **NOTE:** IE bit is a control bit to end the Initialization state. For the current state of SRTC LP see the state_lp field in the SRTC_LPSR. **NOTE:** This bit is unaffected by reset.

Table continues on the next page...

SRTC_LPCR field descriptions (continued)

Field	Description
	0 SRTC is in Initialization state. 1 End of Initialization state
14 NVE	Nonvalid state exit bit When set this bit ends the Nonvalid state of the SRTC state machine. **NOTE:** NVE bit is a control bit to end the Non Valid state. For the current state of SRTC LP see the state_lp field in the SRTC_LPSR. **NOTE:** This bit is unaffected by reset. 0 SRTC is in Nonvalid state. 1 End of Nonvalid state.
13 IEIE	Initialization state exit interrupt enable bit This bit enables the interrupt on exit from the Initialization State of the SRTC state machine. **NOTE:** This bit is unaffected by reset. 0 An interrupt is disabled. 1 An interrupt is enabled.
12 NVEIE	Nonvalid state exit interrupt enable bit This bit enables the interrupt on exit from the Nonvalid state of the SRTC state machine. **NOTE:** This bit is unaffected by reset. 0 An interrupt is disabled. 1 An interrupt is enabled.
11 NSA	Nonsecure access When set this bit allows nonsecure application to access secure register. This bit is reset by the system por. 0 Nonsecure access of secure register is not allowed 1 Nonsecure access is allowed
10 SV	Security Violation When set this bit move the SRTC LP to failure state upon termination of Initialization state. Also if the current state is Nonvalid/Valid the SRTC LP is moved to failure state. This bit is reset by the system por. **NOTE:** Setting the SV invalidates the SRTC_LPSCR and SRTC_LPSMCR contents. 0 No security violation 1 Security Violation
9 LMC	Lock monotonic counter When set this bit prevents write access to 32-bit secure LP monotonic counter register (SRTC_LPSMCR) by all application.Once set this bit cannot be reset except by system por. 0 Write access is allowed. 1 Write access is not allowed
8 LTC	Lock time counter

Table continues on the next page...

SRTC_LPCR field descriptions (continued)

Field	Description
	When set this bit prevents write access to secure 47-bit LP counter (SRTC_LPSCMR and SRTC_LPSCLR) by all application.Once set this bit cannot be reset except by system por. 0 Write access is allowed. 1 Write access is not allowed
7 ALP	Alarm Flag of LP Section Enables the alarm interrupt to the core. See SRTC LP Secured Counter Alarm, for more details. **NOTE:** This bit is unaffected by reset. 0 Alarm interrupt disabled. 1 Alarm interrupt enabled.
6 SI	Security Interrupt Enable bit This bit enables the security interrupt to be raised to core on SRTC security Interrupt (Active low). Security interrupt is raised upon setting of the of time read invalidate status bit **NOTE:** This bit is unaffected by reset. 0 Security interrupt disabled. 1 Security interrupt enabled
5 SAE	Security Alarm Enable bit This bit enables the security alarm to be raised to security block on SRTC security alarm (Active high) pin. Security alarm is raised upon setting of the of time read invalidate status bit **NOTE:** This bit is unaffected by reset. 0 Security alarm disabled. 1 Security alarm enabled
4 WAE	Wakeup Alarm Enable bit This bit enables the time alarm to be raised on DO_ALARM_OUT pin. See SRTC LP Secured Counter Alarm, for more details.DO_ALARM_OUT is asserted only if the main system is powered off as indicated by power fail circuity or external signal (dsm_on) input to block. DO_ALARM_OUT's polarity is active low **NOTE:** This bit is unaffected by reset. 0 Time alarm disabled. 1 Time alarm enabled.
3 EN_LP	Enables/Disables the LP secure time and secure monotonic counter When set the secure LP counter and monotonic counter becomes operational. This bit cannot be reset once either of LMC or LTC is set. In high and Medium this bit can only be set in Valid state **NOTE:** This bit is unaffected by reset. 0 Disable the real-time clock and monotonic counter 1 Enable the real-time clock and monotonic counter
2–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 SWR_LP	Software reset

Table continues on the next page...

SRTC_LPCR field descriptions (continued)

Field	Description
	Resets the LP section of the SRTC to its default state.This bit can be set only in the Initialization state of the SRTC state machine. It can be set by a secure application only. This is self clearing bit is always read as zero. 0 No effect 1 Reset the block to its default state

72.8.6 LP Status Register (SRTC_LPSR)

The LP status register (LPSR) register is used by the core to read the status of the various bits.

Address: SRTC_LPSR is 53FA_4000h base + 14h offset = 53FA_4014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SRTC_LPSR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15 IES	Initialization state exit status bit This bit indicates the end of Initialization state of the SRTC state machine. **NOTE:** IES and NVES are w1c status bits corresponding to the Initialization Exit and Nonvalid exit interrupts. **NOTE:** This bit is unaffected by reset. 0 SRTC is in Initialization state. 1 SRTC has exit out of Initialization state
14 NVES	Nonvalid state exit status bit This bit indicate the end of Nonvalid state of the SRTC state machine. **NOTE:** This bit is unaffected by reset. 0 SRTC is in Nonvalid state. 1 SRTC has exit out of Nonvalid state.

Table continues on the next page...

SRTC_LPSR field descriptions (continued)

Field	Description
13–12 STATE_LP	STATE_LP Specify the present state of SRTC LP state machine. These are read-only bits. **NOTE:** This bit is unaffected by reset. 00 Initialize. 01 Nonvalid 10 Valid 11 Failure
11–10 SM	Security Mode Specify the present security mode of the SRTC as determined from the IC Identification Module fuses. These are read-only bits. **NOTE:** This bit is unaffected by reset. 00 Security Mode: Low (no security). Other values: see Security Reference Manual .
9–7 IT	IIM Throttle Specify the 3-bit value of the throttle bits for monotonic counter from the IC Identification Module. These are read-only bits. SeeTable 72-4. **NOTE:** This bit is unaffected by reset.
6 EAD	External alarm detected Indicates that Security alarm generated by the external security block has been detected or external boot is performed in High and Medium security mode. **NOTE:** This bit is unaffected by reset. 0 No security alarm detected. 1 Security alarm detected
5 TR	Time Rollover Indicates that the 47 Bit LP secure counter has reached the value of 0xffff_ffff_ffff. When counter reaches this maximum value, TRI bit is also set and SRTC enters failure state. Once set this bit is not reset by system por, and can be cleared only by secure application in Initialization state of SRTC state machine. **NOTE:** This bit is unaffected by reset. 0 Counter has not reached its maximum value. 1 Counter has reached its maximum value.
4 MR	Monotonic counter Rollover Indicates that the 32 Bit LP secure monotonic counter has reached the value of 0xffff_ffff. When counter reaches this maximum value, TRI bit is also set and SRTC enters failure state. Once set this bit is not reset by system por, and can be cleared only by secure application in Initialization state of SRTC state machine. **NOTE:** This bit is unaffected by reset.

Table continues on the next page...

SRTC_LPSR field descriptions (continued)

Field	Description
	0 Counter has not reached its maximum value. 1 Counter has reached its maximum value
3 ALP	Alarm Flag of LP section Indicates that the SRTC LP secured counter alarm has occured. See SRTC LP Secured Counter Alarm, for more details. **NOTE:** This bit is unaffected by reset. 0 No alarm occurred. 1 An alarm has occurred.
2 CTD	Clock Tampering Detected This bit is set when clock tampering is detected. Once set this bit is not reset by system por, and can be cleared only by secure application in Initialization state of SRTC state machine **NOTE:** This bit is unaffected by reset. 0 No Clock Tampering Detected. 1 Clock Tampering Detected.
1 PGD	Power supply glitch Detected This bit is set when glitch in the power supply is detected. Once set this bit is not reset by system por, and can be cleared only by secure application in Initialization state of SRTC state machine. **NOTE:** This bit is unaffected by reset. 0 No Power supply glitch Detected. 1 Power supply glitch Detected.
0 TRI	Time Read Invalidate This bit is set when SRTC LP state machine is moved to failure by any of the security violation. It indicates the time maintained by the SRTC has been invalidated.Once set this bit is not reset by system por, and can be cleared only by secure application in Initialization state of SRTC state machine. **NOTE:** This bit is unaffected by reset. 0 Time read is validated. 1 Time read is invalidated.

72.8.7 LP Power Supply Glitch Detector Register (SRTC_LPPDR)

The LP power supply glitch detector register (SRTC_LPPDR) provides a 32-bit read write register, which is used for storing power glitch value logic as described in Power Supply Glitch Detector (PGD). This register may be written only in the Initialization state of the SRTC state machine.

Address: SRTC_LPPDR is 53FA_4000h base + 18h offset = 53FA_4018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:
- u = Unaffected by reset.

SRTC_LPPDR field descriptions

Field	Description
31–0 LPPDR	LP power supply glitch detector register Contains 32 bit value of LP power supply glitch detector register.

72.8.8 LP General Purpose Register (SRTC_LPGR)

The LP general purpose register can be used to retain data while the system power is down. Some bits of this register are used by the boot ROM.

NOTE

SW_ISO will not be set by any software except by the power fail routine. Once set it can only be reset by negedge of power fail detector, that is, by removing power from the SoC. This is provided as an additional safeguard over the Power fail detector's late triggering upon power failure in SoC.

NOTE

An alternate way to reset this bit is to assert dsm_on input.

Address: SRTC_LPGR is 53FA_4000h base + 1Ch offset = 53FA_401Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SW_ISO	SW_ROM		LPGR[13:16]

* Notes:
- u = Unaffected by reset.

SRTC_LPGR field descriptions

Field	Description
31 SW_ISO	Software isolation bit When set it isolates the SRTC LP portion from the rest of the SoC. It is reset by the negedge of the power fail output of internal power fail detector. 0 SRTC is not isolated. 1 SRTC is isolated from the rest of the SoC.
30–29 SW_ROM	Reserved for use by boot ROM.
28–0 LPGR	LP general purpose register Contains user-specified data.

72.8.9 HP Counter MSB Register (SRTC_HPCMR)

The HP counter MSB register contains the 32 most significant bits (MSB bits 46 to 15) of the 47-bit HP counter.

Address: SRTC_HPCMR is 53FA_4000h base + 20h offset = 53FA_4020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	MHPC

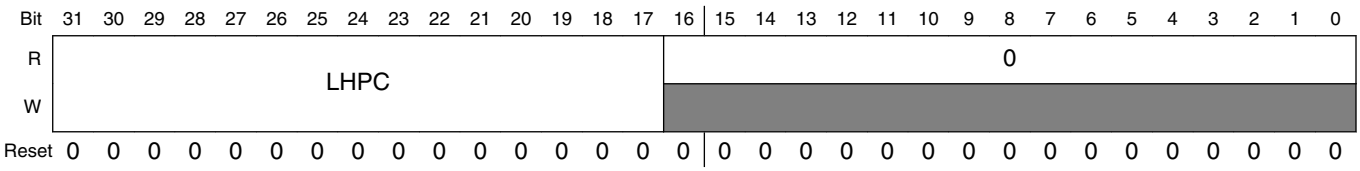
SRTC_HPCMR field descriptions

Field	Description
31–0 MHPC	MSB value of the HP counter Contains MSB bits 46 to 15 of the 47 Bit SRTC HP counter.

72.8.10 HP Counter LSB Register (SRTC_HPCLR)

The HP counter LSB register contains the 15 least significant bits LSB (bits 14 to 0) of the 47-bit SRTC HP counter.

Address: SRTC_HPCLR is 53FA_4000h base + 24h offset = 53FA_4024h



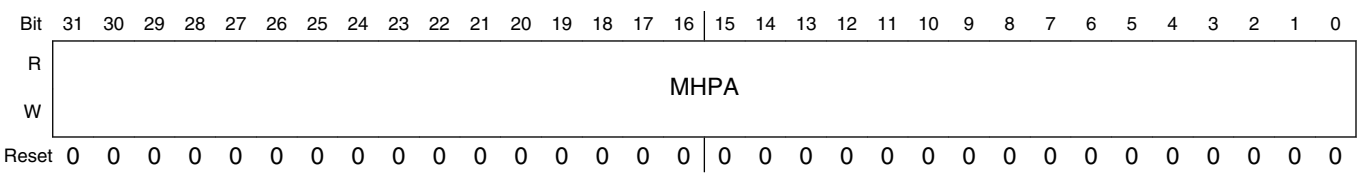
SRTC_HPCLR field descriptions

Field	Description
31–17 LHPC	LSB value of the HP counter Contains LSB bits 14 to 0 of 47 Bit SRTC HP counter.
16–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

72.8.11 HP Alarm MSB Register (SRTC_HPAMR)

The HP alarm MSB register contains the 32 most significant bits (MSB bits 46 to 15) of the 47-bit HP alarm.

Address: SRTC_HPAMR is 53FA_4000h base + 28h offset = 53FA_4028h



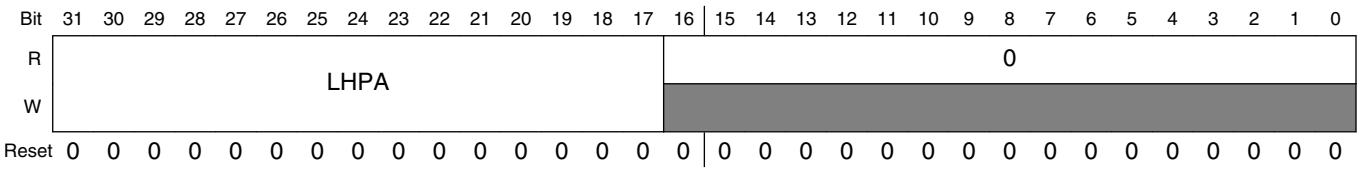
SRTC_HPAMR field descriptions

Field	Description
31–0 MHPA	MSB value of the HP alarm Contains MSB bits 46 to 15 of the 47 Bit SRTC HP alarm. See SRTC HP nonsecured Counter Alarm, for more details.

72.8.12 HP Alarm LSB Register (SRTC_HPALR)

The HP alarm LSB register contains the 15 least significant bits LSB (bits 14 to 0) of the 47-bit SRTC HP alarm.

Address: SRTC_HPALR is 53FA_4000h base + 2Ch offset = 53FA_402Ch



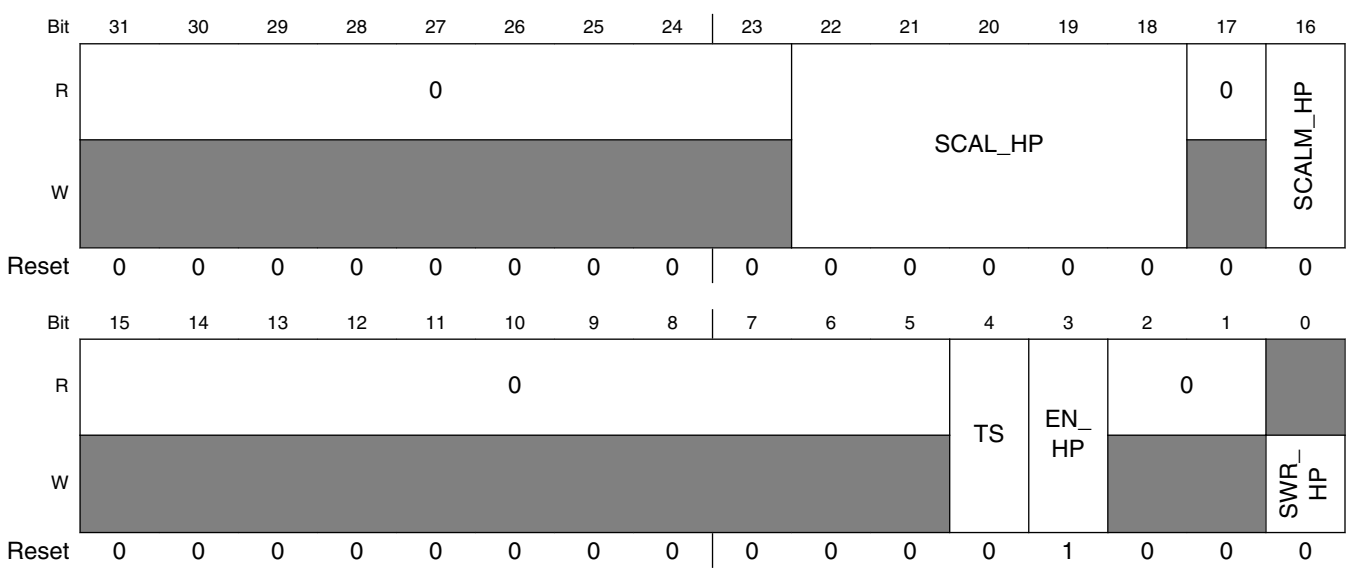
SRTC_HPALR field descriptions

Field	Description
31–17 LHPA	LSB value of the HP alarm Contains LSB bits 14 to 0 of 47 Bit SRTC HP alarm, see SRTC HP nonsecured Counter Alarm, for more details.
16–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

72.8.13 HP Control Register (SRTC_HPCR)

The HP control register (SRTC_HPCR) contains various control bits of the HP section of SRTC.

Address: SRTC_HPCR is 53FA_4000h base + 30h offset = 53FA_4030h



SRTC_HPCR field descriptions

Field	Description
31–23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22–18 SCAL_HP	SRTC Calibration Value These five bits indicates signed calibration value for SRTC HP timer. In this, SCAL_HP[21:18] represent 4 bit value and SCAL_HP[22] represents the sign. Hence, SCAL_HP[22:18] allow calibration +15 to -16 in SRTC HP timer.
17 Reserved	This read-only field is reserved and always has the value zero. Reserved
16 SCALM_HP	SRTCCALMODE_HP Decides the SRTC HP calibration mode. 0 SRTC HP Timer calibration disabled (default). 1 SRTC HP Timer calibration enabled
15–5 Reserved	This read-only field is reserved and always has the value zero. Reserved
4 TS	Time synchronize When set this updates the 47 bit HP counter with the 47 bit LP secure counter. This bit remains set, while the counter is being synchronized, after which it self clears. 0 No Action. 1 Time is synchronized
3 EN_HP	Enables/Disables the HP Time counter 0 Disable the real-time clock 1 Enable the real-time clock
2–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 SWR_HP	Software reset Resets the HP Section of block to its default state. SWR self clears to zero when 0 No effect 1 Reset the block to its default state

72.8.14 HP Interrupt Status Register (SRTC_HPISR)

The HP interrupt status register (SRTC_HPISR) indicates the status of the various periodic, alarm and status interrupts. When an event of the types included in this register occurs, then the bit is set in this register regardless of its corresponding interrupt enable bit. Interrupts may occur while the system clock is idle or in sleep mode. Every interrupt status bit is independent of each other. See SRTC Interrupts and Alarms, for more information on different interrupts.

Address: SRTC_HPISR is 53FA_4000h base + 34h offset = 53FA_4034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
31–22 Reserved	This read-only field is reserved and always has the value zero. Reserved
21 WPLP	Write pending LP Indicates that the write request are pending in the LP section. This is read-only bit. 0 No write requests are pending. 1 Write requests are pending.
20 WPHP	Write pending HP Indicates that the write request are pending in the HP section bit. This is read-only bit. 0 No write requests are pending 1 Write requests are pending
19 WDLP	Write Done LP Indicates that the write request are completed in the LP section. This is w1c bit.

Table continues on the next page...

SRTC_HPISR field descriptions (continued)

Field	Description
	NOTE: The information conveyed by the WPLP and WDLP is about delayed write operation on LP section due to synhronization. WPLP is active high read only bit which indica.tes a pending write operation on LP. WDLP is w1c status bit which is set when the write operation on the LP is completed 0 Write requests are pending. 1 Write requests are completed.
18 WDHP	Write Done HP Indicates that the write request are completed in the HP section. This is w1c bit. **NOTE:** The information conveyed by the WPHP and WDHP is about delayed write operation on HP section due to synhronization. WPHP is active high read only bit which indicates a pending write operation on HP. WDHP is w1c status bit which is set when the write operation on the HP is completed. 0 Write requests are pending. 1 Write requests are completed.
17 Reserved	This read-only field is reserved and always has the value zero. Reserved
16 AHP	Alarm Flag of HP section Indicates that the HP Nonsecured counter alarm has occurred, see SRTC HP nonsecured Counter Alarm, for more details. 0 No alarm interrupt occurred. 1 An alarm interrupt has occurred.
15 PI15	Periodic Interrupt Flag at 32768 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 32768 Hz. 0 No interrupt occurred. 1 An interrupt occurred.
14 PI14	Periodic Interrupt Flag at 16384 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 16384 Hz. 0 No interrupt occurred. 1 An interrupt occurred.
13 PI13	Periodic Interrupt Flag at 8192 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 8192 Hz. 0 No interrupt occurred. 1 An interrupt occurred.
12 PI12	Periodic Interrupt Flag at 4096 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 4096 Hz. 0 No interrupt occurred. 1 An interrupt occurred.
11 PI11	Periodic Interrupt Flag at 2048 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 2048 Hz.

Table continues on the next page...

SRTC_HPISR field descriptions (continued)

Field	Description
	0 No interrupt occurred. 1 An interrupt occurred.
10 PI10	Periodic Interrupt Flag at 1024 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 1024 Hz. 0 No interrupt occurred. 1 An interrupt occurred.
9 PI9	Periodic Interrupt Flag at 512 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 512 Hz. 0 No interrupt occurred. 1 An interrupt occurred.
8 PI8	Periodic Interrupt Flag at 256 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 256 Hz. 0 No interrupt occurred. 1 An interrupt occurred.
7 PI7	Periodic Interrupt Flag at 128 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 128 Hz. 0 No interrupt occurred. 1 An interrupt occurred.
6 PI6	Periodic Interrupt Flag at 64 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 64 Hz. 0 No interrupt occurred. 1 An interrupt occurred.
5 PI5	Periodic Interrupt Flag at 32 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 32 Hz. 0 No interrupt occurred. 1 An interrupt occurred.
4 PI4	Periodic Interrupt Flag at 16 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 16 Hz. 0 No interrupt occurred. 1 An interrupt occurred.
3 PI3	Periodic Interrupt Flag at 8 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 8 Hz. 0 No interrupt occurred. 1 An interrupt occurred.
2 PI2	Periodic Interrupt Flag at 4 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 4 Hz.

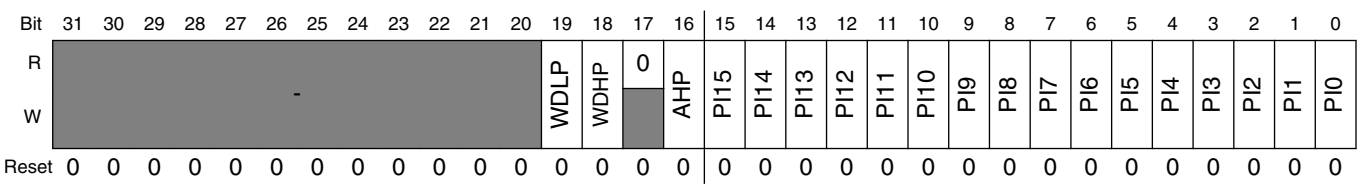
1 PI1	Periodic Interrupt Flag at 2 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 2 Hz. 0 No interrupt occurred. 1 An interrupt occurred.
0 PI0	Periodic Interrupt Flag at 1 Hz Frequency Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 1 Hz. 0 No interrupt occurred. 1 An interrupt occurred.

72.8.15 HP Interrupt Enable Register (SRTC_HPIENR)

The HP interrupt enable register (SRTC_HPIENR) is used to enable/disable the various periodic, alarm and security interrupts. Masking an interrupt bit has no effect on its corresponding status bit. Every interrupt enable bit is independent of the other.

Address: SRTC_HPIENR is 53FA_4000h base + 38h offset = 53FA_4038h



SRTC_HPIENR field descriptions

Chapter 73
Synchronous Serial Interface (SSI)

73.1 Overview

This block guide presents the Synchronous Serial Interface (SSI), and discusses the architecture, the programming model, the operating modes, and initialization of SSI.

The SSI is a full-duplex, serial port that allows the chip to communicate with a variety of serial devices. These serial devices can be standard CODer-DECoder (CODECs), Digital Signal Processors (DSPs), microprocessors, peripherals, and popular industry audio codecs that implement the inter-IC sound bus standard (I2S) and Intel AC97 standard.

SSI is typically used to transfer samples in a periodic manner. The SSI consists of independent transmitter and receiver sections with independent clock generation and frame synchronization.

The figure below illustrates the organization of the SSI. It consists of control registers to set up the port, status register, separate transmit and receive circuits with FIFO registers, and separate serial clock and frame sync generation for the transmit and receive sections. The second set of Tx and Rx FIFOs, replicates the logic used for the first set of FIFOs.

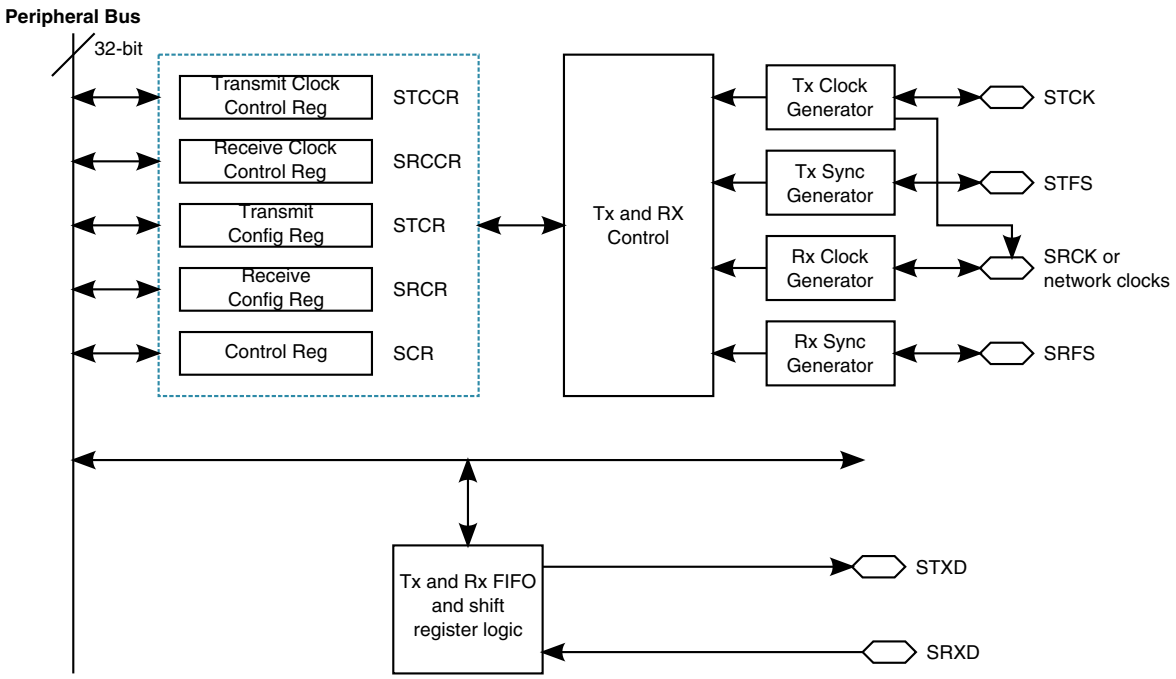

Figure 73-1. SSI Block Diagram

73.1.1 Features

The SSI includes the following features:

- Independent (asynchronous) or shared (synchronous) transmit and receive sections with separate or shared internal/external clocks and frame syncs, operating in Master or Slave mode.
- Normal mode operation using frame sync
- Network mode operation allowing multiple devices to share the port with as many as thirty-two time slots
- Gated Clock mode operation requiring no frame sync
- 2 sets of Transmit and Receive FIFOs. Each of the four FIFOs is 15x32 bits. The two sets of Tx/Rx FIFOs can be used in Network mode to provide 2 independent channels for transmission and reception
- Programmable data interface modes such as I2S, LSB, MSB aligned
- Programmable word length (8, 10, 12, 16, 18, 20, 22 or 24 bits)
- Program options for frame sync and clock generation
- Programmable I2S modes (Master, Slave or Normal). Max audio sampling rate is 196kHz. Min audio sampling rate is 8kHz. Network clock (as an oversampling clock to external device) available as output from SRCK in I2S Master mode
- AC97 support. Max frame rate is 48kHz. Min frame rate is 8kHz.

- Completely separate clock and frame sync selections for the receive and transmit sections. In AC97 standard, the clock is taken from an external source and frame sync is generated internally.
- External network clock input for use in I2S Master mode. Programmable network clock of the sampling frequency available as output in master mode at SRCK, when operated in sync mode.
- Programmable internal clock divider
- Time Slot Mask Registers for reduced ARM platform overhead (for both Tx and Rx)
- SSI power-down feature
- Programmable wait states for ARM platform accesses

73.1.2 Modes of Operation

SSI has the following basic operating modes.

- Normal Mode : Asynchronous protocol, Synchronous protocol
  - Normal Mode Transmit
  - Normal Mode Receive
- Network Mode : Asynchronous protocol, Synchronous protocol
  - Network Mode Transmit
  - Network Mode Receive
- Gated Clock Mode : Synchronous protocol only
- I2S Mode
- AC97 Mode
  - AC97 Fixed Mode (SSI.SACNT[1]=0)
  - AC97 Variable Mode (SSI.SACNT[1]=1)

73.2 External Signal Description

73.2.1 Signals Overview

The Synchronous Serial Interface (SSI) can be connected directly to the external pins or through the Digital Audio Multiplexer (AUDMUX). Refer to the AUDMUX chapter for programming details of the various multiplexing options.

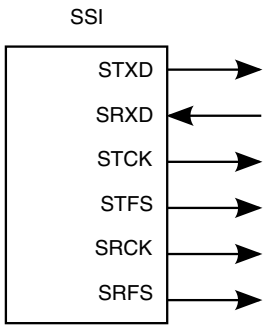
Table 73-1. Off-Chip Block Signals

Name	I/O	Function	Reset State	Pull up
SRCK	I/O	Serial Receive Clock. SRCK can be used as either an input or an output. This clock signal is used by the receiver in asynchronous mode and is always continuos. During synchronous mode, the STCK port is used instead for clocking in data. In SSI synchronous modes, this port can be used as an output for the network clock (oversampling clock) . In I2S master mode, this signal can be used to output the network clock to an external CODEC.	0	Passive
SRFS	I/O	Serial Receive Frame Sync. The SRFS port can be used as either an input or an output. The frame sync is used by the receiver to synchronize the transfer of data. The frame sync signal can be one bit or one word in length and can occur one bit before the transfer of data or right at the transfer of data. If SRFS is configured as an input, the external device should drive SRFS during the rising edge of STCK or SRCK.	0	Passive
SRXD	I	Serial Receive Data. The SRXD port is an input and is used to bring serial data into the Receive Data Shift Register.	-	-
STCK	I/O	Serial Transmit Clock. The STCK port can be used as either an input or an output. This clock signal is used by the transmitter and can be either continuous or gated. During Gated Clock mode, data on the STCK port is valid only during the transmission of data, otherwise it is pulled to the inactive state. In Synchronous mode, this port is used by both the transmit and receive sections.	0	Passive
STFS	I/O	Serial Transmit Frame Sync. The STFS port can be used as either an input or an output. The frame sync is used by the transmitter to synchronize the transfer of data. The frame sync signal can be one bit or one word in length and can occur one bit before the transfer of data or right at the transfer of data. In Synchronous mode, this port is used by both the transmit and receive sections. In Gated Clock mode, frame sync signals are not used. If STFS is configured as an input, the external device should drive STFS during the rising edge of STCK if TSCKP is +ve edge triggered. The external device should drive STFS during the falling edge of STCK if TSCKP is -ve edge triggered.	0	Passive
STXD	O	Serial Transmit Data. The STXD port is an output and transmits data from the Serial Transmit Shift Register. The STXD port is an output port when data is being transmitted and is disabled between data word transmissions and on the trailing edge of the bit clock after the last bit of a word is transmitted.	0	Passive

The following figure shows the main SSI configurations. These ports support all transmit and receive functions with continuous or gated clock as shown.

NOTE

Gated clock implementations do not require the use of the frame sync ports (STFS and SRFS).



SSI Internal Continuous Clock for TX/RX (RXDIR = 1, TXDIR = 1, RFDIR = 1, TFDIR = 1, SYN = 0)

73.3 SSI Transmit FIFO 0 & 1 Registers

The SSI Transmit FIFO registers are 15x32-bit registers. These registers are not directly accessible by the end user. Transmit Shift Register (TXSR) receives its values from these FIFO registers. Transmitted data is first-in-first-out.

When the Transmit Interrupt Enable (TIE) bit in the SIER and either of the Transmit FIFO Empty Enable (TFE0 or 1) bits in the SIER are set, an interrupt is asserted whenever the number of empty slots exceed or are equal to the selected threshold value of corresponding Tx-FIFO. The threshold value is contained in the corresponding Transmit FIFO Watermark (TFWM0 or 1) field in the SSI FIFO Control/Status Register (SFCSR).

73.4 SSI Transmit Shift Register (TXSR)

The SSI Transmit Shift Register (TXSR) is a 24-bit shift register that contains the data being transmitted. This register is not directly accessible by the end user. When a continuous clock is used, data is shifted out to the Serial Transmit Data (STXD) port by

the selected (internal/external) bit clock when the associated (internal/external) frame sync is asserted. When a gated clock is used, data is shifted out to the STXD port by the selected (internal/external) gated clock.

The Word Length control bits (WL[3:0]) in the SSI Transmit and Receive Clock Control Register (STCCR) determine the number of bits to be shifted out of the TXSR before it is considered empty and can be written to again. This word length can be 8, 10, 12, 16, 18, 20, 22 or 24 bits. The data to be transmitted occupies the most significant portion of the shift register if TXBIT0 is '0', otherwise it occupies the least significant portion. The unused portion of the register is ignored. Data is always shifted out of this register with the Most Significant Bit (MSB) first when the SHFD bit of the STCR is cleared. If this bit is set, the Least Significant Bit (LSB) is shifted out first. The figures below show the transmitter loading and shifting operation. The figures show the working for some WL values, the same can be extended for other values.

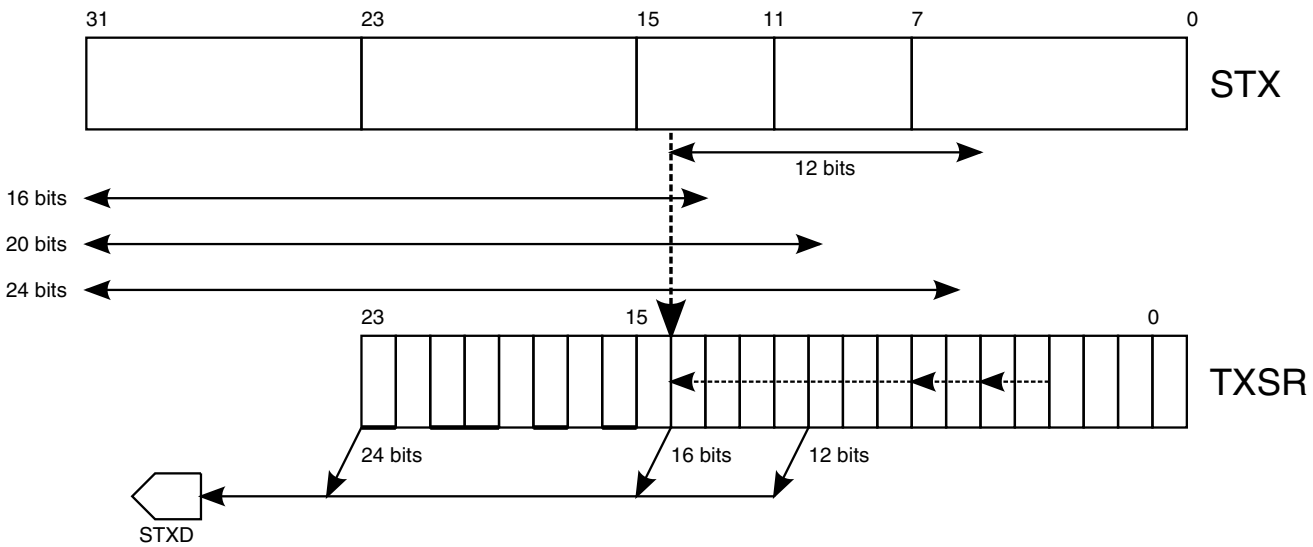

Figure 73-4. Transmit Data Path (TXBIT0=0, TSHFD=0) (MSB Alignment)

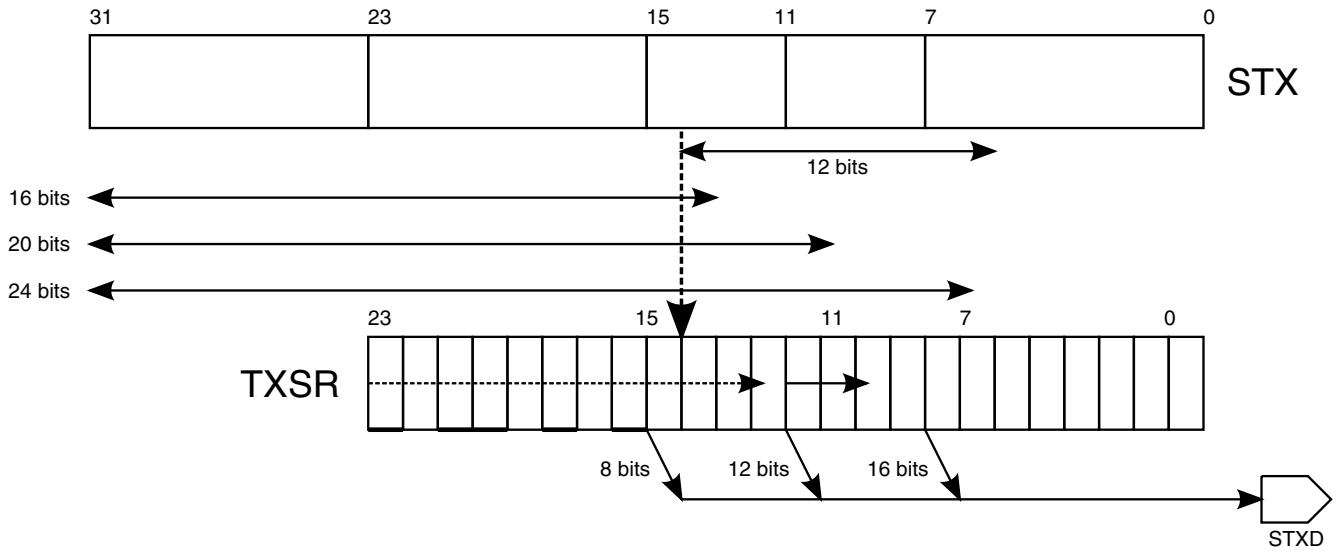

Figure 73-5. Transmit Data Path (TXBIT0=0, TSHFD=1) (MSB Alignment)

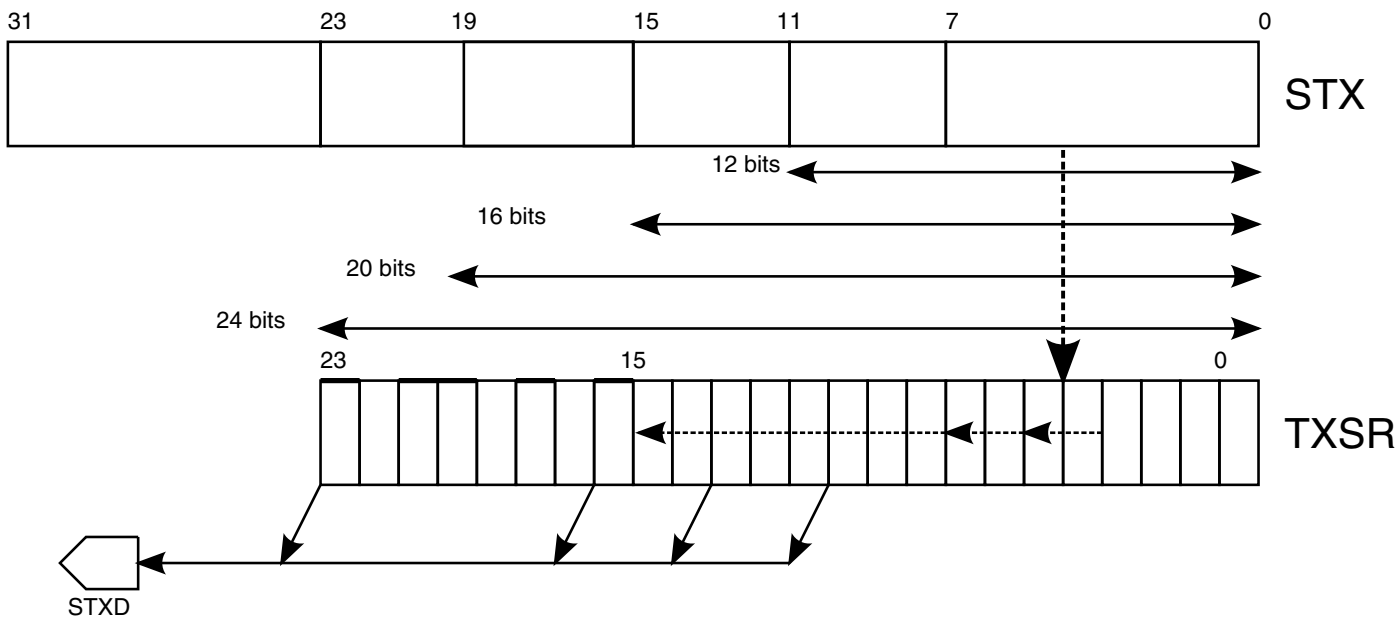

Figure 73-6. Transmit Data Path (TXBIT0=1, TSHFD=0) (LSB Alignment)

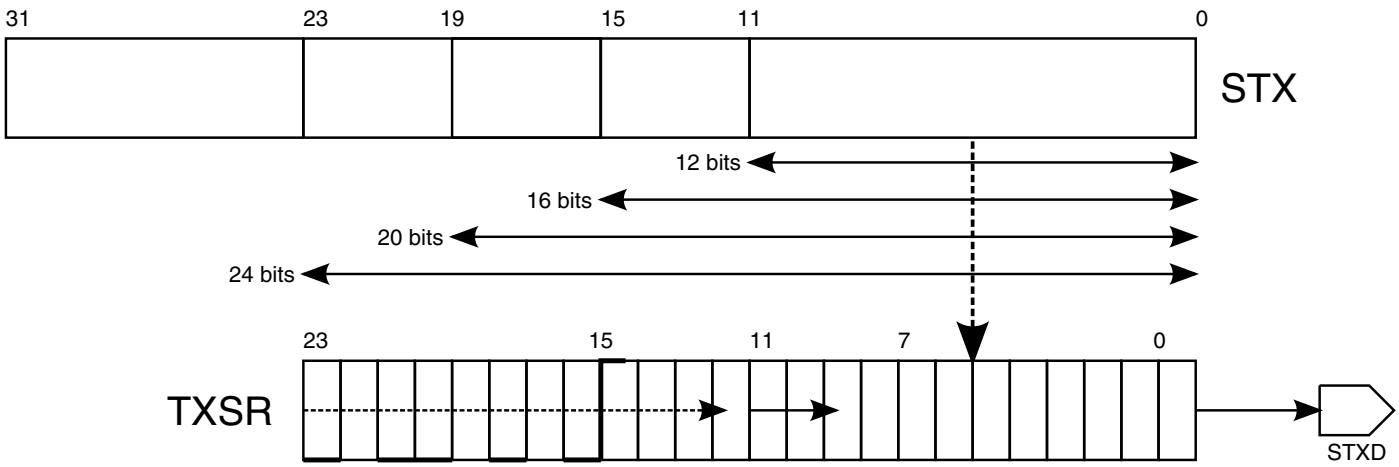

Figure 73-7. Transmit Data Path (TXBIT0=1, TSHFD=1) (LSB Alignment)

73.5 SSI Receive FIFO 0 and 1 Registers

The SSI Receive FIFO registers are 15x32-bit registers. These registers are not directly accessible by the end user. These FIFO registers receive data from the Receive Shift Register (RXSR). Received data is first-in-first-out.

When the Receive Interrupt Enable (RIE) bit in the SIER and either of the Receive FIFO Full Enable (RFF0_EN or RFF1_EN) bits in the SIER are set, an interrupt is asserted whenever the number of full slots exceeds or is equal to the selected threshold value of corresponding Rx-FIFO. The threshold value is contained in the corresponding Receive FIFO Watermark (RFWM0 or 1) field in the SSI FIFO Control/Status Register (SFCSR).

73.6 SSI Receive Shift Register (RXSR)

The SSI Receive Shift Register (RXSR) is a 24-bit, shift register that receives incoming data from the serial receive data SRXD port. This register is not directly accessible by the end user. When a continuous clock is used, data is shifted in by the selected (internal/external) bit clock when the associated (internal/external) frame sync is asserted. When a gated clock is used, data is shifted in by the selected (internal/external) gated clock.

Data is assumed to be received MSB first if the SHFD bit of the SSI.SRCR is cleared. If this bit is set, the data is received LSB first. Data is transferred to the appropriate SSI Receive Data Register (SRX0/1) or Receive FIFOs (if the receive FIFO is enabled and the corresponding SRX is full) after 8, 10, 12, 16, 18, 20, 22 or 24 bits have been shifted in depending on the WL[3:0] control bits. For receiving less than 24 bits of data, LSB bits

are appended with zero. The figures below show the receiver loading and shifting operation. These figures show the operation for several values of WL and the same can be extended for other values.

73.7 Functional Description

73.7.1 Operating Modes

Different modes can be programmed by several bits in the SSI control registers.

See the table below for the list of SSI operating modes and some of the typical applications in which they can be used:

Table 73-3. SSI Operating Modes

TX, RX Sections	Serial Clock	Mode	Typical Application
Asynchronous	Continuous	Normal	Multiple synchronous CODECs
Asynchronous	Continuous	Network	TDM CODEC or DSP networks
Synchronous	Continuous	Normal	Multiple synchronous CODECs
Synchronous	Continuous	Network	TDM CODEC or DSP network
Synchronous	Gated	Normal	SPI-type devices; DSP to ARM platform

The transmit and receive sections of the SSI can be synchronous or asynchronous. In Synchronous mode, the transmitter and the receiver use a common clock and frame synchronization signal. Masking of slots for Transmit and Receive section can differ in synchronous mode. Also the shifting of data in independent and for receive section depends on RXBIT0 and RSHFD bits in SSI.SRCR register. In Asynchronous mode, the transmitter and receiver each has its own clock and frame synchronization signals.

Normal or Network mode can be selected. In Normal mode, the SSI functions with one data word of I/O per frame. In Network mode, any number from two to thirty-two data words of I/O per frame can be used. Network mode is typically used in star time division multiplex networks with other processors or CODECs, allowing interface to time division multiplexed networks without additional logic. Gated clock mode option can be selected in Normal synchronous mode only. During Gated mode the clock is not-continuous and runs only during data-transmission. These distinctions result in the basic operating modes that allow the SSI to communicate with a wide variety of devices.

The SSI supports both Normal and Network modes, and these can be selected independently of whether the transmitter and receiver are synchronous or asynchronous. Typically these protocols are used in a periodic manner, where data is transferred at regular intervals, such as at the sampling rate of an external CODEC. Both modes use the concept of a frame. The beginning of the frame is marked with a frame sync when programmed with continuous clock. The frame sync occurs at a periodic interval. The length of the frame is determined by the DC[4:0] bits in either the SSI.SRCCR or SSI.STCCR register, depending on whether data is being transmitted or received. The number of words transferred per frame depends on the mode of the SSI.

In Normal mode, one data word is transferred per frame. In Network mode, the frame is divided into anywhere between two and thirty-two time slots, where in each time slot one data word can optionally be transferred.

Apart from the above basic modes of operation, SSI supports the following modes which require some specific programming.

- I2S mode
- AC97 mode
  - AC97 Fixed mode
  - AC97 Variable mode

In (non-I2S) slave modes (external frame sync), the programmed word length setting of the SSI should be equal to the word length setting of the master. In I2S slave mode, the programmed word length setting of the SSI can be lesser than or equal to the word length setting of the I2S master (external CODEC).

In slave modes, the programmed frame length setting (DC bits) of the SSI can be lesser than or equal to the frame length setting of the master (external CODEC).

The following sections provide detailed descriptions of the above modes.

73.7.1.1 Normal Mode

Normal mode is the simplest mode of the SSI. It is used to transfer data in one time slot per frame. A time slot is a unit of data and the WL[3:0] bits define the number of bits in a time slot. In Continuous Clock mode, a frame sync occurs at the beginning of each frame.

The length of the frame is determined by the following factors:

- The period of the Serial Bit Clock (DIV2, PSR, PM[7:0] bits for internal clock or the frequency of the external clock on the STCK port)
- The number of bits per time slot (WL[3:0] bits)
- The number of time slots per frame (DC[4:0] bits)

If Normal mode is configured with more than one time slot per frame, data is transferred only in the first time slot. No data is transferred in subsequent time slots. In Normal mode, DC[4:0] values corresponding to more than a single time slot in a frame, only results in lengthening of the frame.

73.7.1.1.1 Normal Mode Transmit

The conditions for data transmission from the SSI in Normal mode are:

- SSI Enabled (SSIEN = 1)
- Write data to Transmit Data Register (STX)
- Transmitter Enabled (TE = 1)
- Frame sync active (for continuous clock case)
- Bit clock begins

When the above conditions occur in Normal mode, the next data word is transferred into the Transmit Shift Register (SSI.TXSR) from the Transmit Data Register 0 (SSI.STX0), or from the Transmit FIFO 0 Register, if transmit FIFO 0 is enabled. The new data word is transmitted on arrival of frame-sync preceded by clocks in continuous clock mode. In gated-external mode, data word in transmitted on arrival of frame-sync. In gated-internal mode, data word is transmitted whenever data is available in Tx-FIFO.

If Transmit FIFO 0 is not enabled and the transmit data register empty enable (TDE0_EN) and transmit interrupt enable (TIE) bits are set, transmit interrupt occurs when the word in SSI_STX0 is shifted to Transmit Shift (SSI.TXSR) register for shifting.

If Transmit FIFO 0 is enabled and the transmit fifo empty enable (TFE0_EN) and transmit interrupt enable (TIE) bits are set, transmit interrupt occurs when the number of empty slots in Transmit Fifo 0 exceed or are equal to the selected threshold value i.e. Transmit Fifo 0 Watermark (TFWM0) value. If transmit FIFO 0 is enabled and filled with data, 15 data words can be transferred before the core must write new data to the SSI.STX0 register.

The STXD port is disabled except during the data transmission period. For a continuous clock, the optional frame sync output and clock outputs are not disabled, even if both receiver and transmitter are disabled.

73.7.1.1.2 Normal Mode Receive

The conditions for data reception from the SSI are:

- SSI enabled (SSIEN = 1)
- Receiver enabled (RE = 1)
- Frame sync active (for continuous clock case)
- Bit clock begins

With the above conditions in Normal mode with a continuous clock, each time the frame sync signal is generated (or detected) a data word is clocked in. With the above conditions and a gated clock, each time the clock begins, a data word is clocked in.

If Receive FIFO 0 is not enabled and Receive Interrupt enable (RIE) and Received Data 0 Ready enable (RDR0_EN) bits are set, receive interrupt occurs when received data word is transferred from the Receive Shift Register (SSI.RXSR) to the Receive Data Register 0 (SSI.SRX0), thus setting the Receive Data Ready 0 (RDR0) flag.

If Receive FIFO 0 is enabled, and Receive Interrupt enable (RIE) and Received Fifo 0 full enable (RFF0_EN) bits are set, receive interrupt occurs when the received data word is transferred to the Receive FIFO 0 and Receive FIFO 0 reaches the selected threshold and results in Receive FIFO Full 0 (RFF0) flag to get set.

The core program has to read the data from the Receive Data Register 0 (SSI.SRX0) (in case Receive FIFO0 is disabled) before a new data word is transferred from the Receive Shift Register (SSI.RXSR), otherwise the Receive Overrun Error 0 (ROE0) bit is set. If receive FIFO 0 is enabled, the Receive Overrun Error 0 (ROE0) bit is set when the Receive FIFO 0 data level reaches the selected threshold and a new data word is ready to be transferred to the Receive FIFO 0.

See the following figure for an illustration of transmitter and receiver timing for an 8-bit word in the first time slot in Normal mode, continuous clock with a late word length frame sync. The Tx Data register is loaded with the data to be transmitted. On arrival of the clock, this data is transferred to the Transmit Shift Register, which gets transmitted on arrival of the frame-sync on the STXD output. Simultaneously, the Receive Shift Register shifts in the received data available on the SRXD input and, at the end of the time slot, this data is transferred to the Rx Data Register.

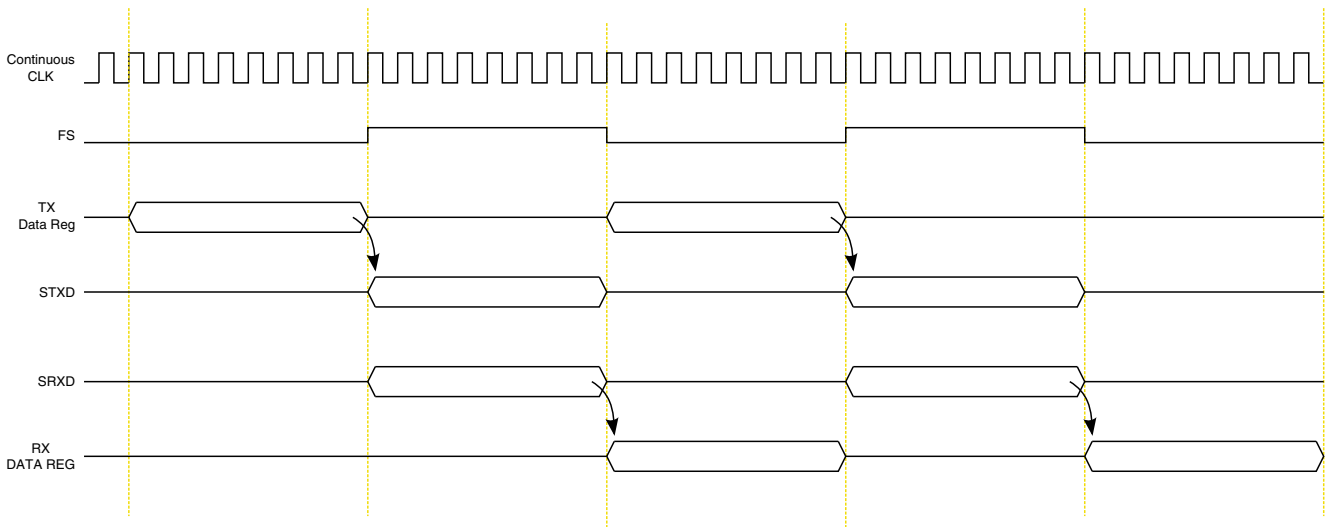

Figure 73-12. Normal Mode Timing - Continuous Clock

The following figure shows a similar case for internal (SSI generates clock) gated clock mode and Figure 73-14 shows a case for external (SSI receives clock) gated clock mode.

NOTE

A pull-down resistor is required in the gated clock case because the clock port is disabled between transmissions.

The Tx Data register is loaded with the data to be transmitted. On arrival of the clock, this data is transferred to the Transmit Shift Register, which gets transmitted on arrival of the frame-sync on the STXD output. Simultaneously, the Receive Shift Register shifts in the received data available on the SRXD input and, at the end of the time slot, this data is transferred to the Rx Data Register. In case of Internal Gated clock mode, the Tx Data line and clock output port are put in the high-impedance state at the end of transmission

of the last bit (at the completion of the complete clock cycle), whereas, in External Gated clock mode, the Tx Data line is tri-stated at the last inactive edge of the incoming bit clock (during the last bit in a data word).

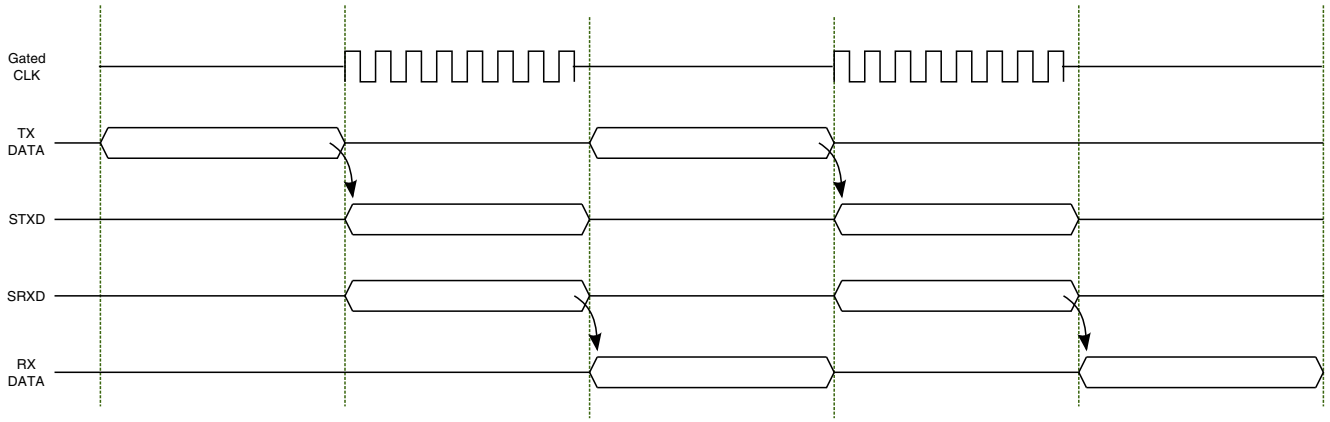

Figure 73-13. Normal Mode Timing - Internal Gated Clock

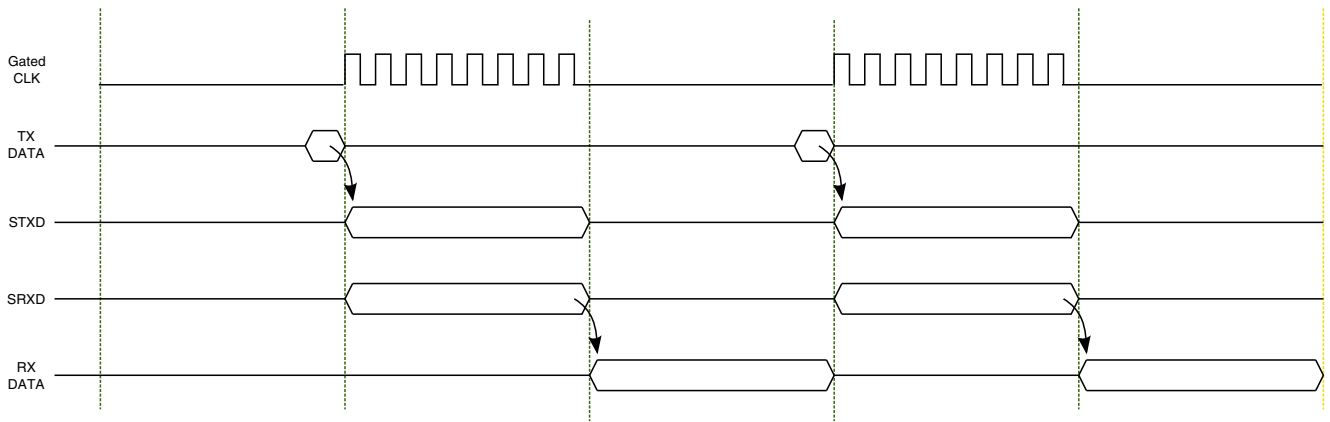

Figure 73-14. Normal Mode Timing - External Gated Clock

73.7.1.2 Network Mode

Network mode is used for creating a Time Division Multiplexed (TDM) network, such as a TDM CODEC network or a network of DSPs. In Continuous Clock mode, a frame sync occurs at the beginning of each frame.

In this mode, the frame is divided into more than one time slot. During each time slot, one data word can be transferred. Each time slot is then assigned to an appropriate CODEC or DSP on the network. The DSP can be a master device that controls its own private network, or a slave device that is connected to an existing TDM network and occupies a few time slots.

The frame sync signal indicates the beginning of a new data frame. Each data frame is divided into time slots and transmission and/or reception of one data word can occur in each time slot (rather than in just the frame sync time slot as in Normal mode). The frame rate dividers, controlled by the DC[4:0] bits, select two to thirty-two time slots per frame. The length of the frame is determined by the following factors:

- The period of the serial bit clock (PSR, PM[7:0] bits for internal clock, or the frequency of the external clock on the STCK port)
- The number of bits per sample (WL[3:0] bits)
- The number of time slots per frame (DC[4:0] bits)

In Network mode, data can be transmitted in any time slot. The distinction of the Network mode is that each time slot is identified with respect to the frame sync (data word time). This time slot identification allows the option of transmitting data during the time slot by writing to the STX registers or ignoring the time slot as determined by SSI.STMSK register bits. The receiver is treated in the same manner and received data is only transferred to the receive data register/fifo if the corresponding time slot is enabled (through SSI.SRMSK).

By utilizing the SSI.STMSK and SSI.SRMSK registers, software only has to service the SSI during valid time slots. This eliminates any overhead associated with unused time slots. Refer to SSI Transmit Time Slot Mask Register (SSI_SSI_STMSK) and SSI Receive Time Slot Mask Register (SSI_SSI_SRMSK) for more information on SSI.STMSK and SSI.SRMSK.

In the Two-Channel mode of operation, the second set of Transmit and Receive FIFOs and Data Registers are used to create two separate channels. These channels are completely independent, with a their own set of Core interrupts and DMA requests, which are identical to the ones available for the default channel. In this mode, data is transmitted/received in enabled time slots alternately from/to FIFO 0 and FIFO 1, starting from FIFO 0. The first data word is taken from FIFO 0 and transmitted in the first enabled time slot and subsequently, data is loaded from FIFO 1 and FIFO 0 alternately and transmitted. Similarly, the first received data is sent to FIFO 0 and subsequent data is sent to FIFO 1 and FIFO 0 alternately. Time slots can be selected through the Transmit and Receive Time Slot Mask registers (SSI.STMSK and SSI.SRMSK). For using this mode of operation, the TCH_EN bit (SCR[8]) needs to be set.

73.7.1.2.1 Network Mode Transmit

The transmit portion of SSI is enabled when the SSIEN and the TE bits in the SSI.SCR are both set. However, for continuous clock, when the TE bit is set, the transmitter is enabled only after detection of a new frame sync (transmission starts from the next frame boundary).

Normal start-up sequence for transmission is to perform the following:

1. Enable Network Mode.
2. Enable SSI
3. Write the data to be transmitted to the SSI.STX register. This clears the TDE flag
4. Set the TE bit to enable the transmitter on the next frame boundary (for continuous clock case).
5. Enable transmit interrupts.

(Alternatively, the programmer may decide not to transmit in a time slot by configuring the STMSK.) TDE flag is set as data is shifted from SSI.STX register to TXSR, but the STXD port remains disabled during the time slots. When the next frame sync is detected or generated (continuous clock), the data word in TXSR and is shifted out (transmitted). When the SSI.STX register is empty, the TDE bit is set, which causes a transmitter interrupt (in case the FIFO is disabled) to be sent if the TIE bit is set. Software can poll the TDE bit or use interrupts to reload the STX register with new data for the next time slot. Failing to reload the SSI.STX register before the TXSR is finished shifting (empty) causes a transmitter underrun and the TUE error bit is set. In case the FIFO is enabled, the TFE flag is set in accordance with the watermark setting and this flag causes the transmitter interrupt to occur.

The operation of clearing the TE bit disables the transmitter after completion of transmission of the current frame. Setting the TE bit enables transmission from the next frame. During that time the STXD port is disabled. The TE bit should be cleared after the TDE bit is set to ensure that all pending data is transmitted.

To summarize, the Network mode transmitter generates interrupts every enabled time slot (when FIFO is disabled) and requires the core program to respond to each enabled time slot. These responses from the core are one of the following:

- Write data in data register to enable transmission in the next time slot.
- Configure the time slot register to disable transmission in the next time slot (unless time slot is already masked by SSI.STMSK register bit).
- Do nothing-transmit underrun occurs at the beginning of the next time slot and the previous data is re-transmitted.

In the Two-Channel mode of operation, both the channels (Data Registers, FIFOs, Interrupts and DMA requests) operate in the same manner, as described above. The only difference in case of the second channel is that the Interrupts related to this channel are generated only in case this mode of operation is selected (TDE1 is low by default).

73.7.1.2.2 Network Mode Receive

The receiver portion of the SSI is enabled when both the SSIEN and the RE bits in the SSI.SCR are set. However, the receive enable only takes place during that time slot if RE is enabled before the second to last bit of the word. If the RE bit is cleared, the receiver is disabled at the end of the current frame.

SSI is capable of finding the start of the next frame automatically. When the word is completely received, it is transferred to the SRX register, which sets the RDR bit (Receive Data Ready). Setting the RDR bit causes a receive interrupt to occur if the receiver interrupt is enabled (the RIE bit is set) and (Receive data ready enable) RDR_EN bit is set. The second data word (second time slot in the frame), begins shifting in immediately after the transfer of the first data word to the SSI.SRX register. The core program has to read the data from the Receive Data Register (which clears RDR) before the second data word is completely received (ready to transfer to RX data register) or a receive overrun error occurs (the ROE bit is set).

An interrupt can occur after the reception of each enabled data word or the programmer can poll the RDR flag. The core program response can be one of the following:

- Read RX and use the data.
- Read RX and ignore the data.
- Do nothing-the receiver overrun exception occurs at the end of the current time slot.

NOTE

For a continuous clock, the optional frame sync output and clock output signals are not affected, even if the transmitter or receiver is disabled. TE and RE do not disable the bit clock or the frame sync generation. To disable the bit clock and the frame sync generation, the SSIEN bit in the SSI.SCR can be cleared or TFR_CLK_DIS/RFR_CLK_DIS bits can be set, or the port control logic external to the SSI (for example, in the IOMUXC) can be re configured.

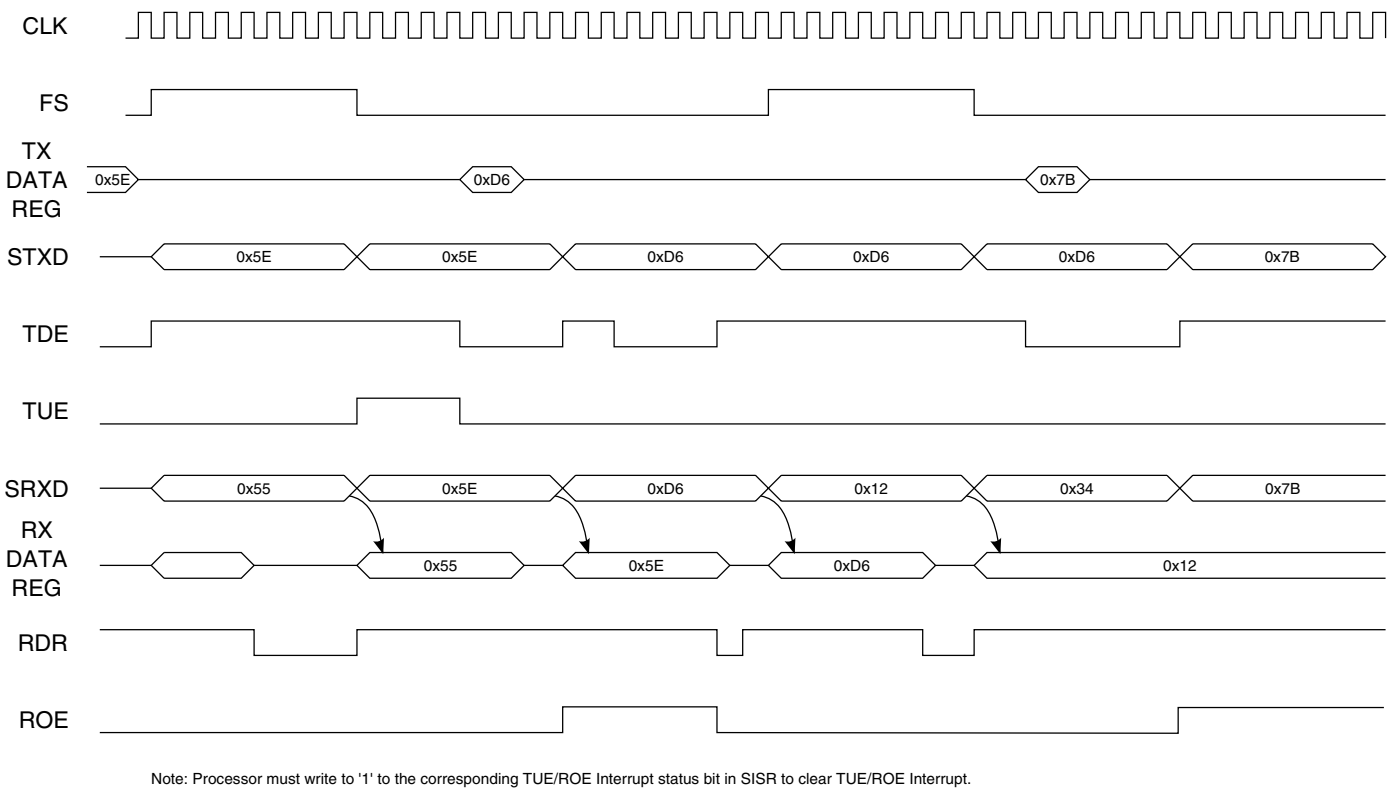
In the Two-Channel mode of operation, both the channels (Data Registers, FIFOs, Interrupts and DMA requests) operate in the same manner, as described above. The only difference in case of the second channel is that the Interrupts related to this channel are generated only in case this mode of operation is selected.

The transmitter and receiver timing for an 8-bit word with continuous clock, FIFO disabled, three words per frame sync in Network mode is shown in the figure below).

NOTE

The transmitter repeats the value 0x5E because of an underrun condition

For the receive section, data received on the SRXD pin gets transferred to the Rx Data register at the end of each time slot. If the FIFO is disabled, the RDR flag gets set and causes a receiver interrupt if RE, RIE and RDR_EN bits are set. If the FIFO is enabled, then the RFF flag is used for interrupt generation (this flag is set in accordance with the watermark settings). Here all time slots are enabled. The receive data ready flag is set after reception of the first data (0x55). Since the flag is not cleared (Rx Data Register is not read by core), the Receive Overrun Error (ROE) flag is set on reception of the next data (0x5E). ROE flag is cleared on writing '1' to the corresponding interrupt status bit in SSI Status Register.



Note: Processor must write to '1' to the corresponding TUE/ROE Interrupt status bit in SISR to clear TUE/ROE Interrupt.

Figure 73-15. Network Mode Timing - Continuous Clock

73.7.1.3 Gated Clock Mode

Gated Clock mode is often used to hook up to SPI-type interfaces on Micro controller Units (MCUs) or external peripheral chips. In Gated Clock mode, the presence of the clock indicates that valid data is on the STXD or SRXD ports. For this reason, no frame sync is needed in this mode.

Once transmission of data has completed, the clock is pulled to the inactive state. Gated clocks are allowed for both the transmit and receive sections with either internal or external clock in Normal mode. Gated clocks are not allowed in Network mode. See Table 73-2 ("Clock Pin Configurations") for SSI configuration for gated-mode operation.

The clock runs when the TE bit and/or the RE bit are appropriately enabled. For the case of internally generated clock, all internal bit clocks, word clocks, and frame clocks continue to operate. When a valid time slot occurs (such as the first time slot in Normal mode), the internal bit clock is enabled onto the appropriate clock port. This allows data to be transferred out in periodic intervals in Gated Clock mode. With an external clock, the SSI waits for a clock signal to be received. Once the clock begins, valid data is shifted in. Care should be taken to clear all DC bits (0x00000) when SSI is used in Gated mode. In gated mode of operation the TFS, RFS, TLS, RLS, TFRC and RFRC bits of SSI.AISR register are not generated.

For Gated clock operated in external clock mode, a proper clock signalling must be applied to the SSI STCK in order for it to function properly. When TSCKP is 0, CLK_IST value should be 1. When TSCKP is 1, CLK_IST value should be 0. If the SSI uses rising edge transition to clock data (TSCKP=0) and the falling edge transition to latch data (RSCKP=0), the clock must be in an active low state when idle. If the SSI uses falling edge transition to clock data (TSCKP=1) and the rising edge transition to latch data (RSCKP=1), the clock must be in a active high state when idle. The figures below illustrate the different edge clocking/latching.

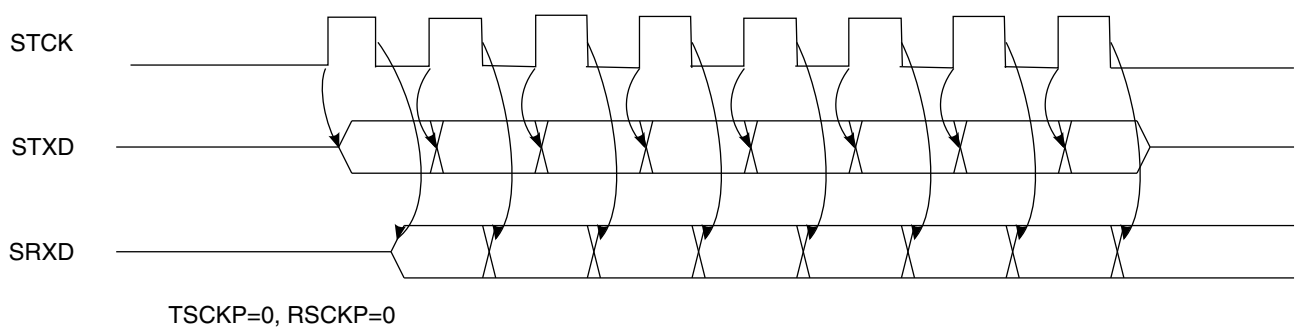


Figure 73-16. Internal Gated Mode Timing - Rising Edge Clocking / Falling Edge Latching

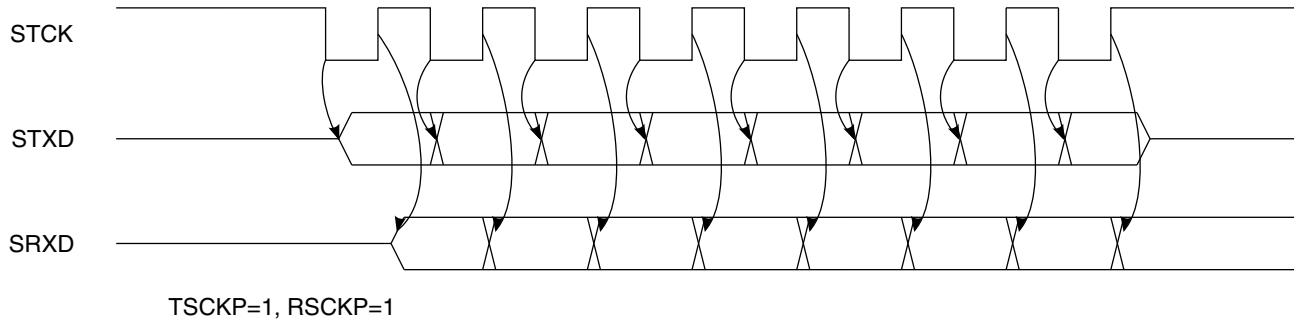

Figure 73-17. Internal Gated Mode Timing - Falling Edge Clocking / Rising Edge Latching

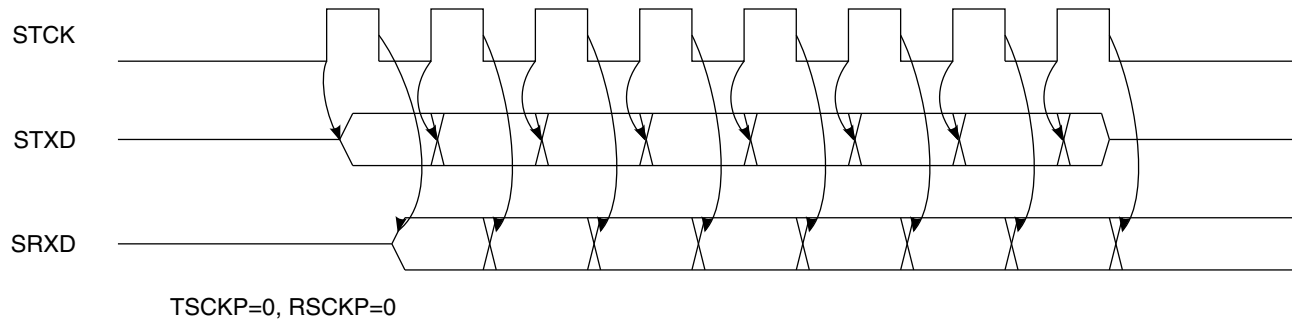

Figure 73-18. External Gated Mode Timing - Rising Edge Clocking / Falling Edge Latching

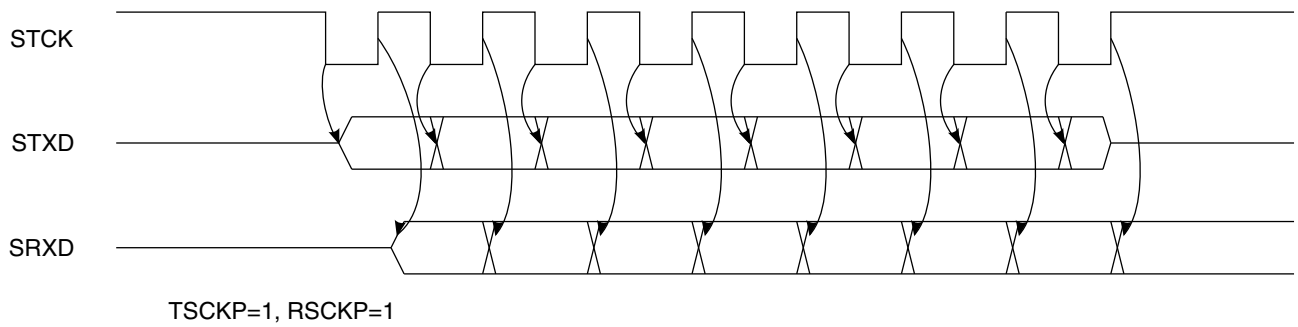

Figure 73-19. External Gated Mode Timing - Falling Edge clocking / Rising Edge Latching

The bit clock ports must be kept free of timing glitches. If a single glitch occurs, all ensuing transfers will be out of synchronization.

In case of External Gated Mode, even though the Tx Data line is put in the high-impedance state at the last non-active edge of the bit clock, the round trip delay should be sufficient to take care of hold time requirements at the external receiver.

73.7.1.4 I2S Mode

The SSI is compliant to the Inter-IC Sound (I2S) bus specification from Philips Semiconductors (February 1986, Revised June 5, 1996). For more information on I2S, refer to the latest version of NXP Semiconductor's I2S specification.

See the following figure for an illustration of the basic I2S protocol timing.

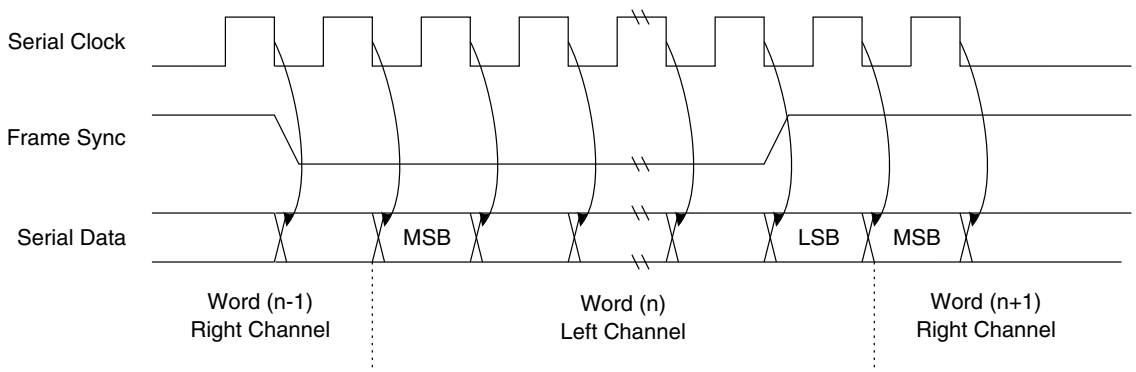

Figure 73-20. I2S Mode Timing - Serial Clock, Frame Sync and Serial Data

Select I2S mode using the options listed in the table below.

Table 73-4. I2S Mode Selection

I2S_MODE[1]	I2S_MODE[0]	Mode Type
0	0	Normal mode
0	1	I2S master mode
1	0	I2S slave mode
1	1	Normal mode

In normal mode operation, no register bits are forced to any particular state internally and the user can program the SSI to work in any operating condition.

When I2S modes are entered (I2S master (01) or I2S slave (10)), the following settings are recommended:

- Sync mode (SSI_SCR[4] =1)
- Tx shift direction: MSB transmitted first (SSI_STCR[4]=0)
- Rx shift direction: MSB received first (SSI_SRCR[4]=0)
- Tx data clocked at falling edge of the clock (SSI_STCR[3]=1)
- Rx data latched at rising edge of the clock (SSI_SRCR[3]=1)
- Tx frame sync active low (SSI_STCR[2]=1)
- Rx frame sync active low (SSI_SRCR[2]=1)

- Tx frame sync initiated one bit before data is transmitted (SSI_STCR[0]=1)
- Rx frame sync initiated one bit before data is received (SSI_SRCR[0]=1)
- TX Frame Rate should be 2 (SSI_STCCR[12:8] = 1)
- RX Frame Rate should be 2 (SSI_SRCCR[12:8] = 1)

In I2S master mode (SSI_SCR[6:5]=01), the following additional settings are recommended:

- TXDIR bit (SSI_STCR[5]) set to 1 to select internal generated bit clock
- TFDIR bit (SSI_STCR[6]) set to 1 to select internal generated frame sync

In I2S master mode(SSI.SCR[6:5]=01), the following settings are internally overridden by the hardware:

- Network mode is selected (SSI_SCR[3]=1)
- Tx frame sync length set to one-word-long-frame (SSI_STCR[1]=0)
- Rx frame sync length set to one-word-long-frame (SSI_SRCR[1]=0)
- Tx shifting w.r.t. bit 0 of TXSR (SSI.STCR[9]=1)
- Rx shifting w.r.t. bit 0 of RXSR (SSI.SRCR[9]=1)

The user needs to set the following control bits to configure the bit clock and frame sync:

- PM (SSI_STCCR[7:0])
- PSR (SSI_STCCR[17])
- DIV2(SSI_STCCR[18]
- WL (SSI_STCCR[16:13]
- DC (SSI_STCCR[12:8])

The word length is fixed to 32 in I2S Master mode and the WL bits determine the number of bits that will contain valid data (out of the 32 transmitted/received bits in each channel).

In I2S slave mode(SSI_SCR[6:5]=10), the following additional settings are recommended:

- TXDIR bit(SSI_STCR[5]) set to 0 to select external generated bit clock
- TFDIR bit(SSI_STCR[6]) set to 0 to select external generated frame sync

In I2S slave mode(SSI_SCR[6:5]=10), the following settings are internally overridden by the hardware:

- Normal mode is selected (SSI_SCR[3]=0)
- Tx frame sync length set to one-bit-long-frame (SSI_STCR[1]=1)
- Rx frame sync length set to one-bit-long-frame (SSI_SRCR[1]=1)
- Tx shifting w.r.t. bit 0 of TXSR (SSI_STCR[9]=1)
- Rx shifting w.r.t. bit 0 of RXSR (SSI_SRCR[9]=1)

The user needs to set the following control bits to configure the data transmission:

- WL (SSI_STCCR[16:13])
- DC (SSI_STCCR[12:8])

The word length is variable in I2S slave mode and the WL bits determine the number of bits that will contain valid data. The actual word length is determined by the external CODEC. The external I2S Master still sends frame sync according to the I2S protocol (early, word wide and active low), the SSI internally operates so that each frame sync transition is the start of a new frame (the WL bits determine the number of bits to be transmitted/received). After one data word has been transferred, the SSI waits for the next frame sync transition to start operation in the next time slot. Transmit (STMSK) and receive (SRMSK) mask bits should not be used in I2S Slave mode of operation. Masking is supported only for network mode of operation.

73.7.1.5 AC97 Mode

In AC97 mode of operation, the SSI transmits a 16-bit Tag Slot at the start of a frame and the rest of the slots (in that frame) are all 20-bits wide. The same sequence is followed while receiving data. Refer to the AC97 specification for details regarding transmit and receive sequences and data formats.

NOTE

The Audio Codec specification released in 1997 [AC '97] defines the Architecture and Digital Interface, specifically designed for implementing audio and modem I/O functionality in personal computers. Companion specifications include the Modem Codec [MC '97], and the combined Audio/Modem Codec standard [AMC '97]. The current version of AC '97 was produced in 2002. The AC-97 specification defines a recommended 48-pin QFP IC package.

Note that the SSI only has one RxDATA pin so the SSI can only support one codec. Secondary codecs are not supported.

When AC97 mode is enabled, the following settings are internally overridden by the hardware. The programmed register values are not changed by entering AC97 mode but they no longer apply to the block's operation. Writing to the programmed register fields will update their values; these updates can be seen by reading back the register fields. However, these settings will not take effect until AC97 mode is turned off.

The register bits within the bracket are the equivalent settings:

- Sync mode is entered (SSI.SCR[4] =1)

- Network mode is selected (SSI.SCR[3]=1)
- Tx shift direction is MSB transmitted first (SSI.STCR[4]=0)
- Rx shift direction is MSB received first (SSI.SRCR[4]=0)
- Tx data is clocked at rising edge of the clock (SSI.STCR[3]=0)
- Rx data is latched at falling edge of the clock (SSI.SRCR[3]=0)
- Tx frame sync is active high (SSI.STCR[2]=0)
- Rx frame sync is active high (SSI.SRCR[2]=0)
- Tx frame sync length is one-word-long-frame (SSI.STCR[1]=0)
- Rx frame sync length is one-word-long-frame (SSI.SRCR[1]=0)
- Tx frame sync initiated one bit before data is transmitted (SSI.STCR[0]=1)
- Rx frame sync initiated one bit before data is received (SSI.SRCR[0]=1)
- Tx shifting w.r.t. bit 0 of TXSR (SSI.STCR[9]=1)
- Rx shifting w.r.t. bit 0 of RXSR (SSI.SRCR[9]=1)
- Tx FIFO is enabled (SSI.STCR[7]=1)
- Rx FIFO is enabled (SSI.SRCR[7]=1)
- TFDIR bit (SSI.STCR[6]) is forced to 1 internally to select internal generated frame sync
- TXDIR bit (SSI.STCR[5]) is forced to 0 internally to select external generated bit clock

Any alteration of these bits individually will not affect the operational conditions of the SSI unless AC97 mode is deselected.

Hence, the only control bits needed to be set by the user to configure the data transmission/reception are the WL (SSI.STCCR[16:13]) and DC (SSI.STCCR[12:8]) bits. In AC97 mode, the WL bits can only legally take the values corresponding to 16-bit (truncated data) or 20-bit time slots. In case WL bits are set to select 16-bit time slots, the SSI pads the transmit data (four least significant bits) with zeros and while receiving, stores only the most significant 16 bits in the Rx FIFO.

Follow the sequence for programming the SSI to work in AC97 mode:

1. Program the WL bits to a value corresponding to either 16 or 20 bits. The WL bit setting is only for the data portion of the AC97 frame (Slots #3 through #12). The Tag slot (Slot #0) is always 16 bits wide and the Command Address and Command Data slots (Slots #1 and #2) are always 20 bits wide.
2. Select the number of time slots by programming the DC bits. For AC97 operation, DC bits should be set to a value of '0xC', resulting in 13 time slots per frame.
3. Write data to be transmitted, in Tx FIFO 0 (through Tx Data Register 0) and Tx FIFO 1 while using Two-Channel Mode (TCH_EN = 1).
4. Program the FV, TIF, RD, WR and FRDIV bits in SSI.SACNT register
5. Update the contents of SSI.SACADD, SSI.SACDAT and SSI.SATAG (for Fixed mode only) registers

6. Enable the AC97 mode of operation (AC97EN bit in SSI.SACNT register)

Once the SSI starts transmitting and receiving data (after being configured in AC97 mode), the programmer needs to service the interrupts, as and when they are raised (updates to command address/data or tag registers, reading of received data and writing more data for transmission). Further details regarding fixed and variable mode implementation are provided in the following sections.

While using AC97 in Two-Channel Mode (TCH_EN=1), it is recommended that the received tag is not stored in the Rx FIFO (TIF=0). In case the programmer needs to update the SSI.SATAG register and also issue a RD/WR command (in a single frame), it is recommended that the SSI.SATAG register be updated prior to issuing a RD/WR command.

73.7.1.5.1 AC97 Fixed Mode (SSI.SACNT[1]=0)

In fixed mode of operation, SSI transmits in accordance with the AC97 Frame Rate Divider bits (i.e. FRDIV in SACNT) which decides the number of frames for which the SSI should be idle, after operating for one frame.

In a valid frame, TAG Value (written by Core) will be transmitted in Slot #0, Command Address will be transmitted in Slot #1 in case of RD/WR Command, and Command Data will be transmitted in Slot #2 in case of a WR Command. The data from TX-FIFO is transmitted in Slot #3 - Slot #12 depending on the valid slots indicated by the TAG value.

While receiving, bit 15 of the TAG Value (Slot #0) is checked to see if the CODEC is ready. If this bit is set, the frame is received. The received TAG provides the information about Slots containing valid data. The the corresponding TAG bit is valid, the Command Address (Slot #1) and Command Data (Slot #2) values are stored in the corresponding registers. The received data (Slot #3 - Slot #12) is then stored in the Rx-FIFO (for valid slots).

73.7.1.5.2 AC97 Variable Mode (SSI.SACNT[1]=1)

In Variable Mode, the transmit slots which should contain data in the current frame are determined by SLOTREQ bits received in the previous frame. While receiving, if the CODEC is ready, the frame is received and the SLOTREQ bits (contained in Slot #1) are stored for scheduling transmission in the next frame.

The SSI.SACCST, SSI.SACCEN and SSI.SACCDIS registers helps in determining which transmit slots are active. This information is used to ensure that SSI does not transmit data for powered-down/inactive channels.

73.7.2 External Frame and Clock Operation

When applying external frame sync and clock signals to SSI, there should be at least 4-bit clock cycles between the enabling of the transmit or receive section and the rising edge of the corresponding frame sync signal. The transition of STFS or SRFS should be synchronized with the rising edge of external clock signal, STCK or SRCK.

73.7.2.1 Data Alignment Formats Supported

The SSI supports three data formats in order to provide flexibility with handling data. These formats dictate how data is written to (and read from) the data registers. Therefore, data can appear in different places in SSI.STX0/1 and SSI.SRX0/1 based on the data format and the number of bits per word. Independent data formats are supported for both the transmitter and receiver (that is, the transmitter and receiver can use different data formats).

The supported data formats are:

- MSB alignment
- LSB alignment
  - Zero-extended (receive data only)
  - Sign-extended (receive data only)

With MSB alignment, the most significant byte is bits 31 through 24 of the data register if the word length is larger than or equal to 16 bits. If the word length is less than 16 bits and MSB alignment is chosen, the most significant byte is bits 15 through 8. With LSB alignment, the least significant byte is bits 7 through 0. Data alignment is controlled by the TXBIT0 bit in the SSI.STCR and the RXBIT0 bit in the SSI.SRCR. See the table below for the bit assignment for all the data formats supported by the SSI.

Table 73-5. Data Alignment

Format	Bit Number																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
8-bit LSB Aligned																									7	6	5	4	3	2	1	0
8-bit MSB Aligned																	7	6	5	4	3	2	1	0								
10-bit LSB Aligned																							9	8	7	6	5	4	3	2	1	0
10-bit MSB Aligned																	9	8	7	6	5	4	3	2	1	0						
12-bit LSB Aligned																					11	10	9	8	7	6	5	4	3	2	1	0

Table continues on the next page...

Table 73-5. Data Alignment (continued)

12-bit MSB Aligned																	11	10	9	8	7	6	5	4	3	2	1	0				
16-bit LSB Aligned																	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
16-bit MSB Aligned	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																
18-bit LSB Aligned															17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
18-bit MSB Aligned	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0														
20-bit LSB Aligned													19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
20-bit MSB Aligned	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0												
22-bit LSB Aligned											21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
22-bit MSB Aligned	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0										
24-bit LSB Aligned									23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
24-bit MSB Aligned	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								

In addition, receive data can either be zero-extended or sign-extended if LSB alignment is selected. With zero-extension, all bits above the most significant bit are 0's. This format is useful when data is stored in a pure integer format. With sign-extension, all bits above the most significant bit are equal to the most significant bit. This format is useful when data is stored in a fixed-point integer format (which implies fractional values). Receive data extension is controlled by the RXEXT bit in the SSI.SRCR. Transmit data used with LSB alignment has no concept of sign/zero-extension. Unused bits above the most significant bit are simply ignored.

When configured in I2S or AC97 mode, the SSI forces the selection of LSB alignment. However, RXEXT still permits a choice between zero-extension and sign-extension.

Refer to SSI Transmit Configuration Register (SSI_SSI_STCR) and SSI Receive Configuration Register (SSI_SSI_SRCR) for more details on the relevant bits in the SSI.STCR and SSI.SRCR registers.

73.7.3 SSI Architecture

The Synchronous Serial Interface (SSI) is connected to chip pads through the Digital Audio Mux (AUDMUX) block or directly as well. The AUDMUX can be configured to connect the SSI to the chip pads in various ways.

Refer to Figure 73-1 for a block diagram of the SSI.

73.7.4 SSI Clocking

The SSI uses the following clocks:

- Bit clock - Used to serially clock the data bits in and out of the SSI port. This clock is either generated internally (from SSI's sys clock) or taken from external clock source (through the Tx/Rx clock ports).
- Word clock - Used to count the number of data bits per word (8, 10, 12, 16, 18, 20, 22 or 24 bits). This clock is generated internally from the bit clock.
- Frame clock (Frame Sync) - Used to count the number of words in a frame. This signal can be generated internally from the bit clock, or taken from external source (from the Tx/Rx frame sync ports).
- Network clock -In master mode, this is an integer multiple of frame clock. This is oversampling clock. It is used in cases when SSI has to provide the clock.

Care should be taken to ensure that the bit clock frequency (either internally generated by dividing the SSI's sys clock or sourced from external device through Tx/Rx clock ports) is never greater than 1/5 of the ipg_clk (from CCM) frequency.

In Normal mode (SCR[6:5]=00), the bit clock, used to serially clock the data, is visible on the Serial Transmit Clock (STCK) and Serial Receive Clock (SRCK) ports. The word clock is an internal clock used to determine when transmission of an 8, 10, 12, 16, 18, 20, 22 or 24 bit word has completed. The word clock in turn then clocks the frame clock, which counts the number of words in the frame. The frame clock can be viewed on the STFS and SRFS frame sync ports, because a frame sync is generated after the correct number of words in the frame have passed. In master and synchronous mode, the unused port SRCK is used as network clock (oversampling clock) enabled by the SCR register bit 15, SYS_CLK_EN. This network clock is an oversampling clock of the frame sync clock (STFS). In this mode, the word length (WL), Prescaler Range (PSR), Prescaler Modulus (PM) and Frame rate (DC) selects the ratio of network clock to sampling clock STFS. In case of I2S mode, the network clock (oversampling clock) can be made available on this port if the SYS_CLK_EN bit is set. The relationship between the clocks and the dividers is shown in the figure below ("SSI Clocking"). The bit clock can be received from an SSI clock port or can be generated from the network clock through a divider, as shown in Figure 73-22 ("SSI Transmit Clock Generator Block Diagram").

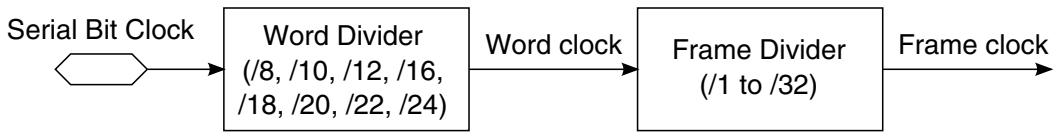

Figure 73-21. SSI Clocking

73.7.4.1 SSI Clock and Frame Sync Generation

Data clock and frame sync signals can be generated internally, or can be obtained from external sources. If internally generated, the SSI clock generator is used to derive bit clock and frame sync signals from the SSI's sys clock. The SSI clock generator consists of a selectable, fixed prescaler and a programmable prescaler for bit rate clock generation.

In Gated Clock mode, the data clock is valid only when data is being transmitted. Otherwise the clock port is pulled to the inactive state. A programmable frame rate divider and a word length divider are used for frame rate sync signal generation.

The following figure shows a block diagram of the clock generator for the transmit section. The serial bit clock can be internal or external, depending on the Transmit Direction (TXDIR) bit in the SSI Transmit Configuration Register (SSI.STCR). The receive section contains an equivalent clock generator circuit.

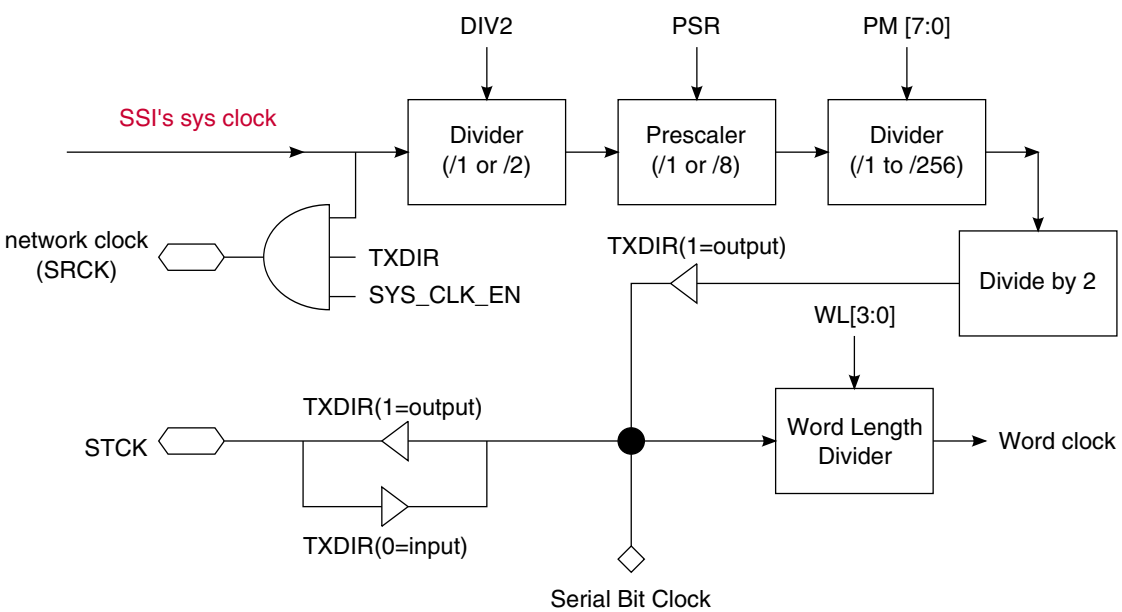

Figure 73-22. SSI Transmit Clock Generator Block Diagram

The figure below shows the Frame Sync Generator block for the transmit section. When internally generated, both receive and transmit frame sync are generated from the word clock and are defined by the Frame Rate Divider (DC[4:0]) bits and the Word Length (WL[3:0]) bits of the SSI Transmit Clock Control Register (SSI.STCCR). The receive section contains an equivalent circuit for the Frame Sync Generator.

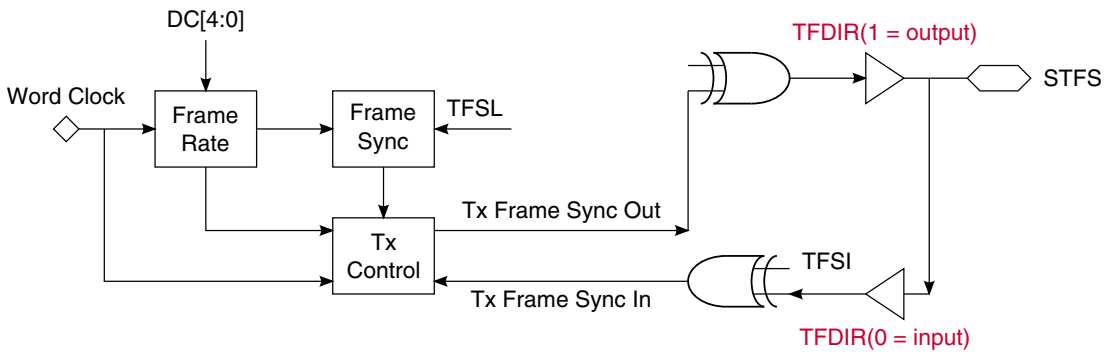

Figure 73-23. SSI Transmit Frame Sync Generator Block Diagram

73.7.4.2 DIV2, PSR and PM Bit Description

The bit clock frequency can be calculated from the SSI's sys clock using the equation in the following figure.

NOTE

You must ensure that the bit-clock frequency must be never greater than 1/5 of the peripheral clock frequency. The oversampling clock frequency can go up to peripheral clock frequency. Bits DIV2, PSR and PM should not be all set to zero at the same time.

$$f_{INT\_BIT\_CLK} = f_{SSI's\ sys\ clock} / [(DIV2 + 1) \times (7 \times PSR + 1) \times (PM + 1) \times 2]$$

where PM = PM[7:0]

$$f_{FRAME\_SYN\_CLK} = (F_{INT\_BIT\_CLK}) / [(DC + 1) \times WL]$$

where DC = DC[4:0] and WL = 8, 10, 12, 16, 18, 20, 22, 24

Figure 73-24. SSI Bit Clock Equation

For example, if the SSI's sys clock is 12.288, in 8-bit word Normal mode with DC[4:0] set to 0(00000), PM[7:0] set to 47 (0010 1111), the PSR bit cleared, DIV2 bit set to 1, a bit clock rate of 12.288 Mhz / [1 x 4 x 48] = 64 kHz is generated. Since the 8-bit word rate is equal to one (i.e. normal mode), the sampling rate (FS rate) would then be 64 kHz / [1 * 8] = 8 kHz.

In next example, SSI's sys clock is 11.2896 Mhz. A 16-bit word Network mode with DC[4:0] set to 1 (00001), PM[7:0] set to 3 (0000 0011), the PSR bit is set to 0, DIV2 bit set to 0, and a 11.2896 MHz oversampling clock, a bit clock rate of 11.2896 Mhz / [1 x 2 x 4] = 1.4112 MHz is generated. Since the 16-bit word rate is equal to two, the sampling rate (FS rate) would be 1.4112 MHz / [2 * 16] = 44.1 kHz.

The table below shows programming examples for the clock dividers in the CCM and the SSI to support various bit clock (STCK) frequencies.

Table 73-6. SSI Bit Clock and Frame Rate as a Function of PSR, PM, and DIV2

Bits/ Word	Words / Frame	Ideal Frame Rate (kHz)	PLL Freq (Mhz)	SSIDIV (in CCM)	SSI's sys clock Freq (Mhz)	DIV 2	PS R	P M	W L	D C	Actual Serial bit clock Freq (kHz) STCK	Target Serial bit clock Freq (kHz) STCK	Erro r (Hz)

NOTE

The table above describes how various frame rates can be achieved with the PLLs supplying a frequency of 294.912 MHz and 270.9504 MHz (with WL and DC settings as shown). These clocks are recommended as convenient starting points but the system allows for other input clock frequencies as well.

Table 73-6 shows programming of the CCM and SSI dividers in order to generate the appropriate network clock and serial bit clock frequencies for various sampling rates. In these examples, the master mode is selected either by setting I2S master bit (SCR[6:5]=01) or individually programming the SSI in network, synchronous, transmit internal mode (the table specifically illustrates the I2S mode frequencies/sample rates). The network clock is oversampling clock.

Note that the I2S master mode requires that a word length of 32 bits be used (regardless of the actual data type). Consequently, the fixed I2S frame rate of 64 bits per frame (word length (WL) can be any value) and DC of 1 are assumed.

73.7.5 Receive Interrupt Enable Bit Description

When the RIE and RE bit are set, the processor is interrupted when either of the SSI Receive FIFO Full (RFF0/1) bits in SSI.SISR is set (if the corresponding Receive FIFO is enabled). If the Receive FIFO is not enabled, the interrupt is generated when the corresponding SSI Receive Data Ready (RDR0/1) bit in the SSI.SISR is set

When the receive FIFO is enabled, a maximum of 15 values are available to be read (15 values per channel in Two-Channel mode). If not enabled, then one value can be read from the SRX register (one each in case of Two-Channel mode). If the RIE bit is cleared, these interrupts are disabled. However, the RFF0/1 and RDR0/1 bits still indicate the receive data register full condition. Reading the SSI.SRX registers clears the RDR bits, thus clearing the pending interrupt. Two receive data interrupts (two per channel in case of Two-Channel mode) are available: receive data with exception status and receive data without exception. The tables below show the conditions under which these interrupts are generated.

Table 73-7. SSI Receive Data 1 Interrupts

Interrupt	RIE	ROE0	RFF0/RDR0
Receive Data 1(with Exception Status)	1	1	1
Receive Data 1(without exception)	1	0	1

Table 73-8. SSI Receive Data 0 Interrupts

Interrupt	RIE	ROE1	RFF1/RDR1
Receive Data 0 (with Exception Status)	1	1	1
Receive Data 0 (without exception)	1	0	1

73.7.6 Transmit Interrupt Enable Bit Description

The SSI Transmit Interrupt Enable (TIE) control bit determines whether the processor is interrupted when the SSI transmitter needs to be serviced.

When the TIE and TE bits are set, the program controller is interrupted when either of the SSI Transmit FIFO Empty (TFE0/1) flags in SISR are set (if corresponding Transmit FIFO is enabled). If the corresponding Transmit FIFO is not enabled, an interrupt is generated when the corresponding SSI Transmit Data Register Empty (TDE0/1) flag in the SISR is set and Transmit Enable (TE) bit is set.

When Transmit FIFO 0 is enabled, a maximum of 15 values can be written to the SSI (15 per channel in case of Two-Channel mode, using Tx FIFO 1). If not enabled, then one value can be written to the SSI.STX0 register (one per channel in case of Two-Channel mode using SSI.STX1). When the TIE bit is cleared, all transmit interrupts are disabled. However, the TDE0/1 bits always indicate the corresponding SSI.STX register empty condition, even when the transmitter is disabled by the Transmit Enable (TE) bit (in the SSI.SCR). Writing data to the STX clears the corresponding TDE bit, thus clearing the interrupt. Two transmit data interrupts are available (four in case of Two-

Channel mode, two per channel): transmit data with exception status and transmit data without exceptions. The tables below show the conditions under which these interrupts are generated.

Table 73-9. SSI Transmit Data 1 Interrupts

Interrupt	TIE	TUE1	TFE1/TDE1
Transmit Data 1 (with Exception Status)	1	1	1
Transmit Data 1 (without exception)	1	0	1

Table 73-10. SSI Transmit Data 0 Interrupts

Interrupt	TIE	TUE0	TFE0/TDE0
Transmit Data 0 (with Exception Status)	1	1	1
Transmit Data 0 (without exception)	1	0	1

73.7.7 Internal Frame and Clock Shutdown

During transmit/receive operation, disabling TE/RE will ensure that data transmission/ reception stops after current frame ends following which TFRC/RFRC Status bits will get set to indicate the Frame Completion State.

If TE is disabled 4 clock cycles before the next frame, extra frame generated are invalid frames. TFR_CLK_DIS/RFR_CLK_DIS bit is set in the current or any of the previous frames, SSI will stop driving the STFS/SRFS and STCK/SRCK signals after the current frame ends.

If TFR_CLK_DIS/RFR_CLK_DIS bit is not set, SSI will continue generating STFS/ SRFS and STCK/SRCK signals (in case direction is from SSI), which then can be disabled by writing '1' to TFR_CLK_DIS/RFR_CLK_DIS bit. SSI will then stop driving these signals after end of frame is reached following which TFRC/RFRC status bits will get set to indicate the Frame Completion State.

The following figure is an illustration of transmission case where TXDIR and TFDIR are both set to '1'. In this case TE is disabled with TFR_CLK_DIS bit set in current or any of the previous frames.

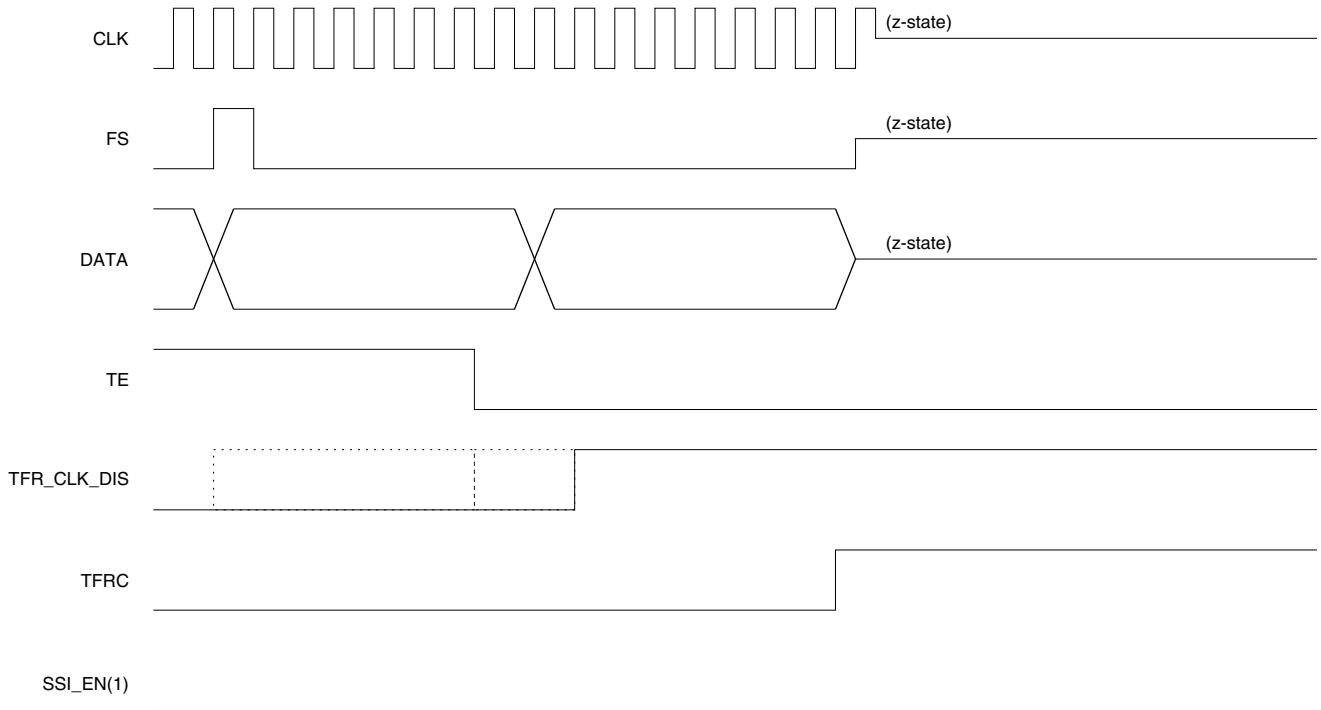

Figure 73-25. TFR_CLK_DIS assertion in current or previous frame as TE disable

The figure below is an illustration of transmission case where TXDIR and TFDIR are both set to '1'. In this case TFR_CLK_DIS bit is set after few frames of disabling TE. TFRC (Transmit Frame Complete) is set at frame boundary after TE is cleared. Once software services this interrupt and sets TFR_CLK_DIS bit later, TFRC bit is again set at next frame boundary.

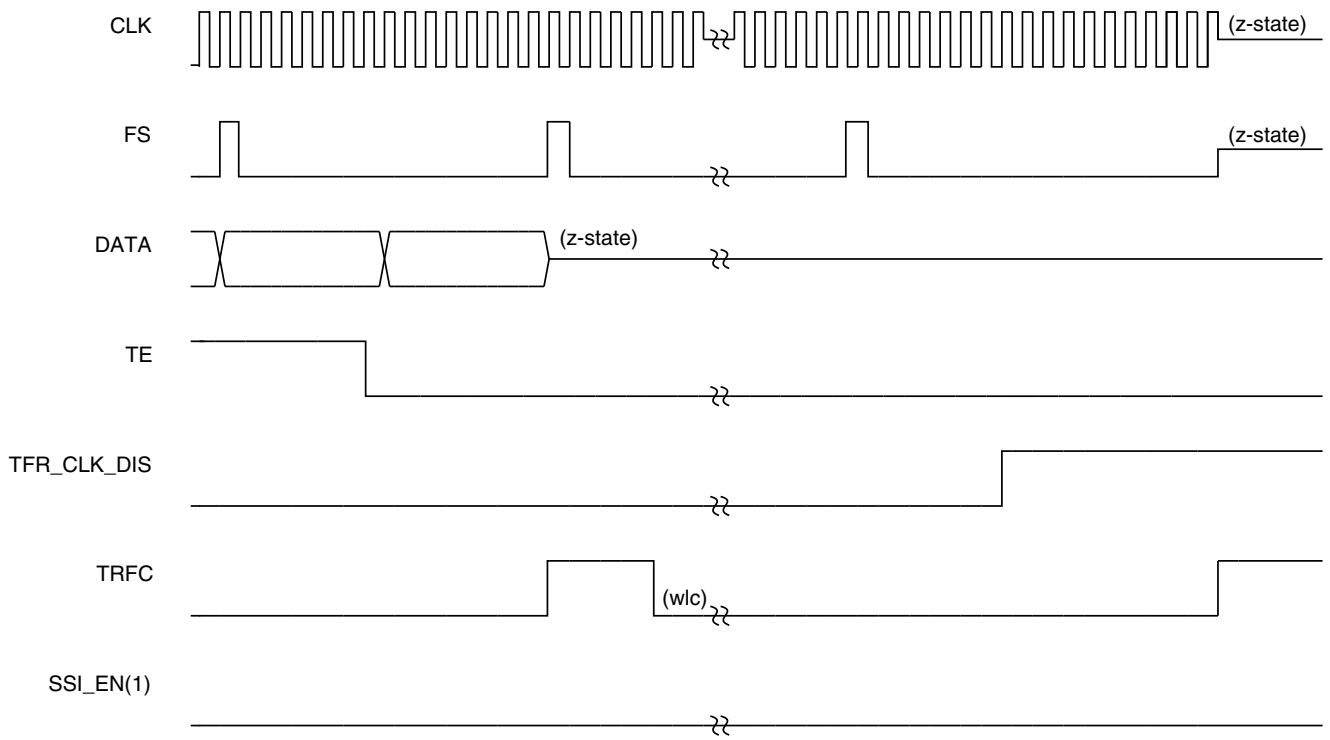

Figure 73-26. TFR_CLK_DIS assertion in subsequent frame after disabling TE

73.7.8 Peripheral Bus Interface

The SSI has a Peripheral Bus interface to provide a control and data interface. This interface is used by both the processor and DMA controller.

73.7.8.1 Transfer Lengths Supported

The Peripheral Bus interface of the SSI only supports 32-bit transfers with all SSI registers other than SSI.STX0, SSI.STX1, SSI.SRX0, and SSI.SRX1 (that is, the data registers).

With the exception of the data registers, using 8-bit and 16-bit transactions could result in undesired behavior but will not result in a transfer bus error. The data registers (SSI.STX0, SSI.STX1, SSI.SRX0, and SSI.SRX1) support 8-bit, 16-bit, and 32-bit transfer lengths without restrictions.

73.7.8.2 Transfer Bus Errors

Transfer bus errors are generated upon response to the following:

- Write transfer to a read-only register.
- Read or write access to a register space beyond the last populated register of the SSI in its memory map (up until the end of the allocated memory address range of the SSI).

73.7.8.3 Clock Rate

The Peripheral Bus clock frequency must be at least five times the serial bit clock frequency.

73.7.9 Reset

The SSI is affected by the following types of reset:

- Power-on Reset-The Power-on reset clears the SSIEN bit in SSI.SCR, which disables the SSI. All other status and control bits in the SSI are affected as described in SSI Programming Model in the "Memory Map and Register Definition section".
- SSI Reset-The SSI reset is generated when the SSIEN bit in the SSI.SCR is cleared. The SSI status bits are preset to the same state produced by the Power-on reset. The SSI control bits are unaffected. The control bits in the SSI.SCR are also unaffected. The SSI reset is useful for selective reset of the SSI without changing the present SSI control bits and without affecting the other peripherals.

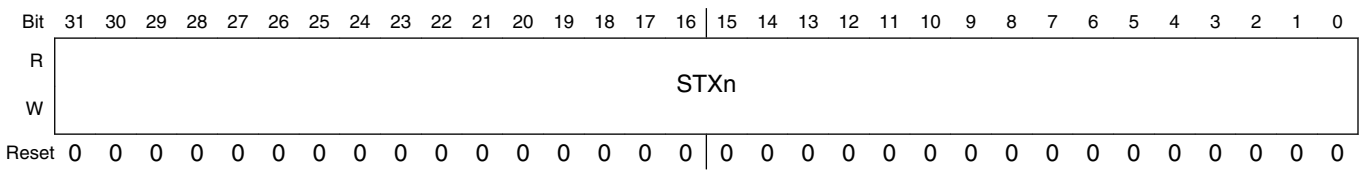
SSI-1_SSI_STX1 is 63FC_C000h base + 4h offset = 63FC_C004h
SSI-3_SSI_STX0 is 63FE_8000h base + 0h offset = 63FE_8000h
SSI-3_SSI_STX1 is 63FE_8000h base + 4h offset = 63FE_8004h

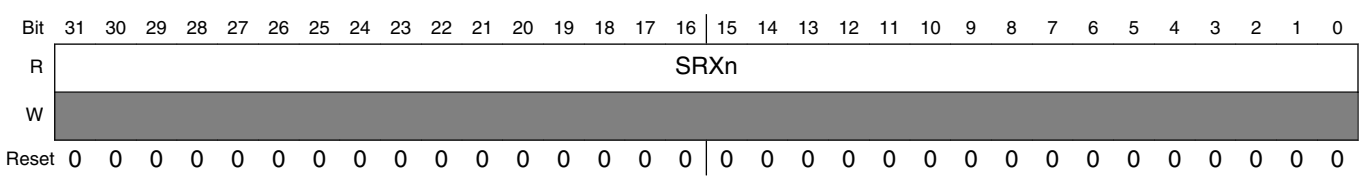


SSIx_SSI_STX*n* field descriptions

Field	Description
31–0 STXn	SSI Transmit Data. These bits store the data to be transmitted by the These are implemented as the first word of their respective Tx FIFOs. Data written to these registers is transferred to the Transmit Shift Register (TXSR), when shifting of the previous data is complete. If both FIFOs are in use, data is alternately transferred from STX0 and STX1, to TXSR. Multiple writes to the STX registers will not result in the previous data being over-written by the subsequent data. STX1 can only be used in Two-Channel mode of operation. Protection from over-writing is present irrespective of whether the transmitter is enabled or not. Example 1: If Tx FIFO0 is in use and user writes Data1...Data16 to STX0,Data16 will not over-write Data1. Data1...Data15 are stored in the FIFO whileData16 is discarded. Example 2: If Tx FIFO0 is not in use and user writes Data1, Data2 to STX0, then Data2 will not over-write Data1 and will be discarded.

73.8.2 SSI Receive Data Register n (SSIx_SSI_SRX*n*)

Addresses: SSI-2_SSI_SRX0 is 5001_4000h base + 8h offset = 5001_4008h
SSI-2_SSI_SRX1 is 5001_4000h base + Ch offset = 5001_400Ch
SSI-1_SSI_SRX0 is 63FC_C000h base + 8h offset = 63FC_C008h
SSI-1_SSI_SRX1 is 63FC_C000h base + Ch offset = 63FC_C00Ch
SSI-3_SSI_SRX0 is 63FE_8000h base + 8h offset = 63FE_8008h
SSI-3_SSI_SRX1 is 63FE_8000h base + Ch offset = 63FE_800Ch



SSIx_SSI_SRX*n* field descriptions

Field	Description
31–0 SRXn	SSI Receive Data. These bits store the data received by the These are implemented as the first word of their respective Rx FIFOs. These bits receive data from the RXSR depending on the mode of operation. In case both FIFOs are in use, data is transferred to each data register alternately. SRX1 can only be used in Two-Channel mode of operation.

73.8.3 SSI Control Register (SSIx_SSI_SCR)

The SSI Control Register (SSI_SCR) sets up the SSI reset is controlled by bit 0 in the SSI_SCR. SSI operating modes are also selected in this register (except AC97 mode which is selected in the SSI_SACNT register).

Addresses: SSI-2_SSI_SCR is 5001_4000h base + 10h offset = 5001_4010h
SSI-1_SSI_SCR is 63FC_C000h base + 10h offset = 63FC_C010h
SSI-3_SSI_SCR is 63FE_8000h base + 10h offset = 63FE_8010h

SSIx_SSI_SCR field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12 SYNC_TX_FS	SYNC_FS_TX bit provides a safe window for TE to be visible to the internal circuit which is just after FS occurrence. When SYNC_TX_FS is set, TE(SCR[1]) gets latched on FS occurrence & latched TE is used to enable/disable SSI transmitter. TE needs setup of 2 bit-clock cycles before occurrence of FS. If TE is changed within 2 bit-clock cycles of FS occurrence, there is high probability that TE will be latched on next FS. Note: With TFR_CLK_DIS feature on, TE is used directly to enable transmitter in following cases (i) Sync mode & Rx disabled (ii) Async Mode. Latched-TE is used to disable the transmitter. This bit has no relevance in gated mode and AC97 mode. 0 - TE not latched with FS occurrence & used directly for transmitter enable/disable. 1 - TE latched with FS occurrence & latched-TE used for transmitter enable/disable.

Table continues on the next page...

SSIx_SSI_SCR field descriptions (continued)

Field	Description
11 RFR_CLK_DIS	Receive Frame Clock Disable. This bit provides the option to keep the Frame-sync and Clock enabled or to disable them after the receive frame in which the receiver is disabled. Writing to this bit has effect only when RE is disabled.The receiver is disabled by clearing the RE bit. 0 Continue Frame-sync/Clock generation after current frame during which RE is cleared. This may be required when Frame-sync and Clocks are required from SSI, even when no data is to be received. 1 Stop Frame-sync/Clock generation at next frame boundary. This will be effective also in case where receiver is already disabled in current or previous frames.
10 TFR_CLK_DIS	Transmit Frame Clock Disable. This bit provide option to keep the Frame-sync and Clock enabled or disabled after current transmit frame, in which transmitter is disabled by clearing TE bit. Writing to this bit has effect only when SSI is enabled TE is disabled. 0 Continue Frame-sync/Clock generation after current frame during which TE is cleared. This may be required when Frame-sync and Clocks are required from SSI, even when no data is to be received. 1 Stop Frame-sync/Clock generation at next frame boundary. This will be effective also in case where transmitter is already disabled in current or previous frames.
9 CLK_IST	Clock Idle State. This bit controls the idle state of the transmit clock port during SSI internal gated mode. Note: When Clock idle state is '1' the clock polarity should always be negedge triggered and when Clock idle = '0' the clock polarity should always be positive edge triggered. 0 Clock idle state is '0'. 1 Clock idle state is '1'.
8 TCH_EN	Two-Channel Operation Enable. This bit allows SSI to operate in the two-channel mode.In this mode while receiving, the RXSR transfers data to SRX0 and SRX1 alternately and while transmitting, data is alternately transferred from STX0 and STX1 to TXSR. For an even number of slots, Two-Channel Operation can be enabled to optimize usage of both FIFOs or disabled as in the case of odd number of active slots. This feature is especially useful in I2S mode, where data for Left Speaker can be placed in Tx-FIFO0 and for Right speaker in Tx-FIFO1. 0 Two-channel mode disabled. 1 Two-channel mode enabled.
7 SYS_CLK_EN	Network Clock (Oversampling Clock) Enable. When set, this bit allows the SSI to output the network clock at the SRCK port, provided that synchronous mode, and transmit internal clock mode are set. The relationship between bit clock and network clock is determined by DIV2, PSR, and PM bits. This feature is especially useful in I2S Master mode to output network clock (oversampling clock) on SRCK port. 0 network clock not output on SRCK port. 1 network clock output on SRCK port.
6–5 I2S MODE[1:0]	I2S Mode Select. These bits allow the SSI to operate in Normal, I2S Master or I2S Slave mode. Refer to I2S Mode for a detailed description of I2S Mode of operation. Refer to Table 73-4 for details regarding settings.
4 SYN	Synchronous Mode. This bit controls whether SSI is in synchronous mode or not. In synchronous mode, the transmit and receive sections of SSI share a common clock port (STCK) and frame sync port (STFS). 0 Asynchronous mode selected. 1 Synchronous mode selected.

Table continues on the next page...

SSIx_SSI_SCR field descriptions (continued)

Field	Description
3 NET	Network Mode. This bit controls whether SSI is in network mode or not. 0 Network mode not selected. 1 Network mode selected.
2 RE	Receive Enable. This control bit enables the receive section of the When this bit is enabled, data reception starts with the arrival of the next frame sync. If data is being received when this bit is cleared, data reception continues until the end of the current frame and then stops. If this bit is set again before the second to last bit of the last time slot in the current frame, then reception continues without interruption. RE should not be toggled in the same frame. 0 Receive section disabled. 1 Receive section enabled.
1 TE	Transmit Enable. This control bit enables the transmit section of the It enables the transfer of the contents of the STX registers to the TXSR and also enables the internal transmit clock. The transmit section is enabled when this bit is set and a frame boundary is detected. When this bit is cleared, the transmitter continues to send data until the end of the current frame and then stops. Data can be written to the STX registers with the TE bit cleared (the corresponding TDE bit will be cleared). If the TE bit is cleared and then set again before the second to last bit of the last time slot in the current frame, data transmission continues without interruption. The normal transmit enable sequence is to write data to the STX register(s) and then set the TE bit. The normal disable sequence is to clear the TE and TIE bits after the TDE bit is set. In gated clock mode, clearing the TE bit results in the clock stopping after the data currently in TXSR has shifted out. When the TE bit is set, the clock starts immediately (for internal gated clock mode). TE should not be toggled in the same frame. After enabling/disabling transmission, SSI expects 4 setup clock cycles before arrival of frame-sync for frame-sync to be accepted/rejected by In case of fewer clock cycles, there is high probability of the frame-sync to get missed. Note: If continuos clock is not provided, SSI expects 6 clock cycles before arrival of frame-sync for frame-sync to be accepted by 0 Transmit section disabled. 1 Transmit section enabled.
0 SSIEN	SSIEN - SSI Enable This bit is used to enable/disable the When disabled, all SSI status bits are preset to the same state produced by the power-on reset, all control bits are unaffected, the contents of Tx and Rx FIFOs are cleared. When SSI is disabled, all internal clocks are disabled (except register access clock). 0 SSI is disabled. 1 SSI is enabled.

73.8.4 SSI Interrupt Status Register (SSIx_SSI_SISR)

The SSI Interrupt Status Register (SSI_SISR) is used to monitor the This register is used by the core to interrogate the status of the In gated mode of operation the TFS, RFS, TLS, RLS, TFRC and RFRC bits of AISR register are not generated. The status bits are described in the following table.

- SSI Status flags are valid when SSI is enabled.
- See Receive Interrupt Enable Bit Description and Transmit Interrupt Enable Bit Description for interrupt source mapping.
- All the flags in the SSI_SISR are updated after the first bit of the next SSI word has completed transmission or reception. Certain status bits (ROE0/1 and TUE0/1) are cleared by writing 1 to the corresponding interrupt status bit in SSI_SISR.

Addresses: SSI-2_SSI_SISR is 5001_4000h base + 14h offset = 5001_4014h
SSI-1_SSI_SISR is 63FC_C000h base + 14h offset = 63FC_C014h
SSI-3_SSI_SISR is 63FE_8000h base + 14h offset = 63FE_8014h

SSIx_SSI_SISR field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value zero. Reserved
24 RFRC	Receive Frame Complete. This flag is set at the end of the frame during which Receiver is disabled. If Receive Frame & Clock are not disabled in the same frame, this flag is also set at the end of the frame in which Receive Frame & Clock are disabled. See description of RFR_CLK_DIS (SSI Control Register (SSI_SSI_SCR)) bit for more details on how to disable Receiver Frame & Clock or keep them enabled after receiver is disabled. 0 End of Frame not reached 1 End of frame reached after disabling RE or disabling RFR_CLK_DIS, when receiver is already disabled.
23 TFRC	Transmit Frame Complete. This flag is set at the end of the frame during which Transmitter is disabled. If Transmit Frame & Clock are not disabled in the same frame, this flag is also set at the end of the frame in which Transmit Frame & Clock are disabled. See description of TFR_CLK_DIS (SSI Control Register (SSI_SSI_SCR)) bit for more details on how to disable Transmit Frame & Clock or keep them enabled after transmitter is disabled.

Table continues on the next page...

SSIx_SSI_SISR field descriptions (continued)

Field	Description
	0 End of Frame not reached 1 End of frame reached after disabling TE or disabling TFR_CLK_DIS, when transmitter is already disabled.
22–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18 CMDAU	Command Address Register Updated. This bit causes the Command Address Updated interrupt (when CMDAU_EN bit is set). This status bit is set each time there is a difference in the previous and current value of the received Command Address. This bit is cleared on reading the SACADD register. 0 No change in SACADD register. 1 SACADD register updated with different value.
17 CMDDU	Command Data Register Updated. This bit causes the Command Data Updated interrupt (when CMDDU_EN bit is set). This status bit is set each time there is a difference in the previous and current value of the received Command Data. This bit is cleared on reading the SACDAT register. 0 No change in SACDAT register. 1 SACDAT register updated with different value.
16 RXT	Receive Tag Updated. This status bit is set each time there is a difference in the previous and current value of the received tag. It causes the Receive Tag Interrupt (if RXT_EN bit is set). This bit is cleared on reading the SATAG register. 0 No change in SATAG register. 1 SATAG register updated with different value.
15 RDR1	Receive Data Ready 1. This flag bit is set when SRX1 or Rx FIFO 1 is loaded with a new value and Two-Channel mode is selected. RDR1 is cleared when the Core reads the SRX1 register. If Rx FIFO 1 is enabled, RDR1 is cleared when the FIFO is empty. If RIE and RDR1_EN are set, a Receive Data 1 interrupt request is issued on setting of RDR1 bit in case Rx FIFO1 is disabled, if the FIFO is enabled, the interrupt is issued on RFF1 assertion. The RDR1 bit is cleared by POR and SSI reset. 0 No new data for Core to read. 1 New data for Core to read.
14 RDR0	Receive Data Ready 0. This flag bit is set when SRX0 or Rx FIFO 0 is loaded with a new value. RDR0 is cleared when the Core reads the SRX0 register. If Rx FIFO 0 is enabled, RDR0 is cleared when the FIFO is empty. If RIE and RDR0_EN are set, a Receive Data 0 interrupt request is issued on setting of RDR0 bit in case Rx FIFO0 is disabled, if the FIFO is enabled, the interrupt is issued on RFF0 assertion. The RDR0 bit is cleared by POR and SSI reset. 0 No new data for Core to read. 1 New data for Core to read.
13 TDE1	Transmit Data Register Empty 1. This flag is set whenever data is transferred to TXSR from STX1 register and Two-Channel mode is selected. If Tx FIFO1 is enabled, this occurs when there is at least one empty slot in STX1 or Tx FIFO1. If Tx FIFO1 is not enabled, this occurs when the contents of STX1 are transferred to TXSR. The TDE1 bit is cleared when the Core writes to STX1. If TIE and TDE1_EN are set, an SSI Transmit Data 1 interrupt request is issued on setting of TDE1 bit. The TDE1 bit is cleared by POR and SSI reset.

Table continues on the next page...

SSIx_SSI_SISR field descriptions (continued)

Field	Description
	0 Data available for transmission. 1 Data needs to be written by the Core for transmission.
12 TDE0	Transmit Data Register Empty 0. This flag is set whenever data is transferred to TXSR from STX0 register. If Tx FIFO 0 is enabled, this occurs when there is at least one empty slot in STX0 or Tx FIFO 0. If Tx FIFO 0 is not enabled, this occurs when the contents of STX0 are transferred to TXSR. The TDE0 bit is cleared when the Core writes to STX0. If TIE and TDE0_EN are set, an SSI Transmit Data 0 interrupt request is issued on setting of TDE0 bit. The TDE0 bit is cleared by POR and SSI reset. 0 Data available for transmission. 1 Data needs to be written by the Core for transmission.
11 ROE1	Receiver Overrun Error 1. This flag is set when the RXSR is filled and ready to transfer to SRX1 register or to Rx FIFO 1 (when enabled) and these are already full and Two-Channel mode is selected. If Rx FIFO 1 is enabled, this is indicated by RFF1 flag, else this is indicated by the RDR1 flag. The RXSR is not transferred in this case. The ROE1 flag causes an interrupt if RIE and ROE1_EN are set. The ROE1 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit. Clearing the RE bit does not affect the ROE1 bit. 0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.
10 ROE0	Receiver Overrun Error 0. This flag is set when the RXSR is filled and ready to transfer to SRX0 register or to Rx FIFO 0 (when enabled) and these are already full. If Rx FIFO 0 is enabled, this is indicated by RFF0 flag, else this is indicated by the RDR0 flag. The RXSR is not transferred in this case. The ROE0 flag causes an interrupt if RIE and ROE0_EN are set. The ROE0 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit. Clearing the RE bit does not affect the ROE0 bit. 0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.
9 TUE1	Transmitter Underrun Error 1. This flag is set when the TXSR is empty (no data to be transmitted), the TDE1 flag is set, a transmit time slot occurs and the SSI is in Two-Channel mode. When a transmit underrun error occurs, the previous data is retransmitted. In Network mode, each time slot requires data transmission (unless masked through STMSK register), when the transmitter is enabled (TE is set). The TUE1 flag causes an interrupt if TIE and TUE1_EN are set. The TUE1 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit. 0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.
8 TUE0	Transmitter Underrun Error 0. This flag is set when the TXSR is empty (no data to be transmitted), the TDE0 flag is set and a transmit time slot occurs. When a transmit underrun error occurs, the previous data is retransmitted. In Network mode, each time slot requires data transmission (unless masked through STMSK register), when the transmitter is enabled (TE is set). The TUE0 flag causes an interrupt if TIE and TUE0_EN are set. The TUE0 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit.

Table continues on the next page...

SSIx_SSI_SISR field descriptions (continued)

Field	Description
	0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.
7 TFS	Transmit Frame Sync. This flag indicates the occurrence of transmit frame sync. Data written to the STX registers during the time slot when the TFS flag is set, is sent during the second time slot (in Network mode) or in the next first time slot (in Normal mode). In Network mode, the TFS bit is set during transmission of the first time slot of the frame and is then cleared when starting transmission of the next time slot. In Normal mode, this bit is high for the first time slot. This flag causes an interrupt if TIE and TFS_EN are set. The TFS bit is cleared by POR and SSI reset. 0 No Occurrence of Transmit frame sync. 1 Transmit frame sync occurred during transmission of last word written to STX registers.
6 RFS	Receive Frame Sync. This flag indicates the occurrence of receive frame sync. In Network mode, the RFS bit is set when the first slot of the frame is being received. It is cleared when the next slot begins to be received. In Normal mode, this bit is always high (When DC = 0). This flag causes an interrupt if RIE and RFS_EN are set. The RFS bit is cleared by POR and SSI reset. 0 No Occurrence of Receive frame sync. 1 Receive frame sync occurred during reception of next word in SRX registers.
5 TLS	Transmit Last Time Slot. This flag indicates the last time slot in a frame. When set, it indicates that the current time slot is the last time slot of the frame. TLS is set at the start of the last transmit time slot and causes the SSI to issue an interrupt (if TIE and TLS_EN are set). TLS is not generated when frame rate is 1 in normal mode of operation. TLS is cleared when the SISR is read with this bit set. The TLS bit is cleared by POR and SSI reset. 0 Current time slot is not last time slot of frame. 1 Current time slot is the last transmit time slot of frame.
4 RLS	Receive Last Time Slot. This flag indicates the last time slot in a frame. When set, it indicates that the current time slot is the last receive time slot of the frame. RLS is set at the end of the last time slot and causes the SSI to issue an interrupt (if RIE and RLS_EN are set). RLS is cleared when the SISR is read with this bit set. The RLS bit is cleared by POR and SSI reset. 0 Current time slot is not last time slot of frame. 1 Current time slot is the last receive time slot of frame.
3 RFF1	Receive FIFO Full 1. This flag is set when Rx FIFO1 is enabled, the data level in Rx FIFO1 reaches the selected Rx FIFO WaterMark 1 (RFWM1) threshold and the SSI is in Two-Channel mode. The setting of RFF1 only causes an interrupt when RIE and RFF1_EN are set, Rx FIFO1 is enabled and the Two-Channel mode is selected. RFF1 is automatically cleared when the amount of data in Rx FIFO1 falls below the threshold. The RFF1 bit is cleared by POR and SSI reset. When Rx FIFO1 contains15 words, the maximum it can hold, all further data received (for storage in this FIFO) is ignored until the FIFO contents are read. 0 Space available in Receive FIFO1. 1 Receive FIFO1 is full.
2 RFF0	Receive FIFO Full 0. This flag is set when Rx FIFO0 is enabled and the data level in Rx FIFO0 reaches the selected Rx FIFO WaterMark 0 (RFWM0) threshold. The setting of RFF0 only causes an interrupt when RIE and RFF0_EN are set and Rx FIFO0 is enabled. RFF0 is automatically cleared when the amount of data in Rx FIFO0 falls below the threshold. The RFF0 bit is cleared by POR and SSI reset. When Rx FIFO0 contains15 words, the maximum it can hold, all further data received (for storage in this FIFO) is ignored until the FIFO contents are read.

Table continues on the next page...

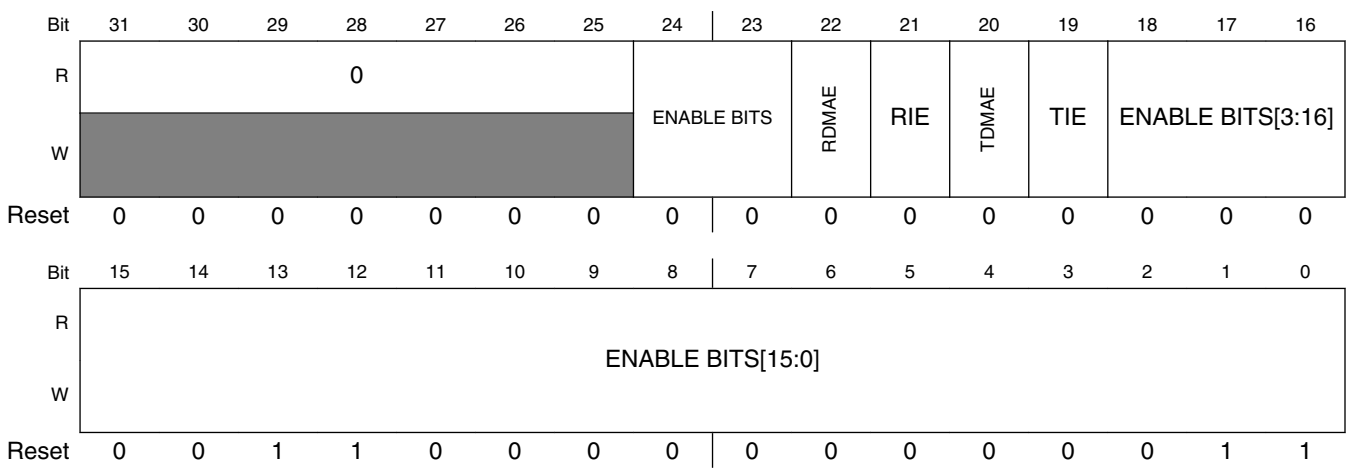
SSIx_SSI_SISR field descriptions (continued)

Field	Description
	0 Space available in Receive FIFO0. 1 Receive FIFO0 is full.
1 TFE1	Transmit FIFO Empty 1. This flag is set when the empty slots in Tx FIFO exceed or are equal to the selected Tx FIFO WaterMark 1 (TFWM1) threshold and the Two-Channel mode is selected. The setting of TFE1 only causes an interrupt when TIE and TFE1_EN are set, Tx FIFO1 is enabled and Two-Channel mode is selected. The TFE1 bit is automatically cleared when the data level in Tx FIFO1 becomes more than the amount specified by the watermark bits. The TFE1 bit is set by POR and SSI reset. 0 Transmit FIFO1 has data for transmission. 1 Transmit FIFO1 is empty.
0 TFE0	Transmit FIFO Empty 0. This flag is set when the empty slots in Tx FIFO exceed or are equal to the selected Tx FIFO WaterMark 0 (TFWM0) threshold. The setting of TFE0 only causes an interrupt when TIE and TFE0_EN are set and Tx FIFO0 is enabled. The TFE0 bit is automatically cleared when the data level in Tx FIFO0 becomes more than the amount specified by the watermark bits. The TFE0 bit is set by POR and SSI reset. 0 Transmit FIFO0 has data for transmission. 1 Transmit FIFO0 is empty.

73.8.5 SSI Interrupt Enable Register (SSIx_SIER)

The SSI Interrupt Enable Register (SIER) is a 25-bit register used to set up the SSI interrupts and DMA requests.

Addresses: SSI-2_SIER is 5001_4000h base + 18h offset = 5001_4018h
SSI-1_SIER is 63FC_C000h base + 18h offset = 63FC_C018h
SSI-3_SIER is 63FE_8000h base + 18h offset = 63FE_8018h



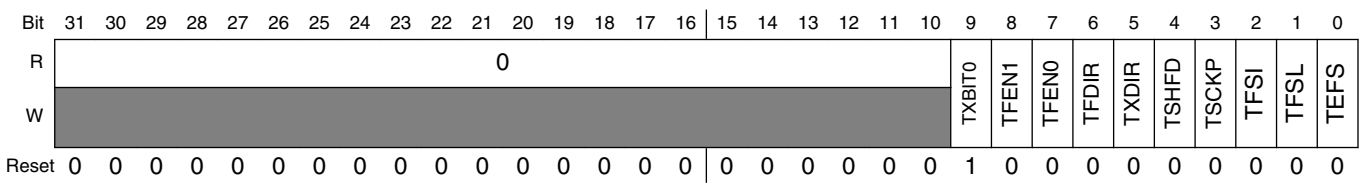
SSIx_SIER field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value zero. Reserved
24–23 ENABLE BITS	Enable Bit. Each bit controls whether the corresponding status bit in SISR can issue an interrupt to the Core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
22 RDMAE	Receive DMA Enable. This bit allows SSI to request for DMA transfers. When enabled, DMA requests are generated when any of the RFF0/1 bits in the SISR are set and if the corresponding RFEN bit is also set. If the corresponding FIFO is disabled, a DMA request is generated when the corresponding RDR bit is set. 0 SSI Receiver DMA requests disabled. 1 SSI Receiver DMA requests enabled.
21 RIE	Receive Interrupt Enable. This control bit allows the SSI to issue receiver related interrupts to the Core. Refer to Receive Interrupt Enable Bit Description for a detailed description of this bit. 0 SSI Receiver Interrupt requests disabled. 1 SSI Receiver Interrupt requests enabled.
20 TDMAE	Transmit DMA Enable. This bit allows SSI to request for DMA transfers. When enabled, DMA requests are generated when any of the TFE0/1 bits in the SISR are set and if the corresponding TFEN bit is also set. If the corresponding FIFO is disabled, a DMA request is generated when the corresponding TDE bit is set. 0 SSI Transmitter DMA requests disabled. 1 SSI Transmitter DMA requests enabled.
19 TIE	Transmit Interrupt Enable. This control bit allows the SSI to issue transmitter data related interrupts to the Core. Refer to Transmit Interrupt Enable Bit Description for a detailed description of this bit. 0 SSI Transmitter Interrupt requests disabled. 1 SSI Transmitter Interrupt requests enabled.
18–0 ENABLE BITS	Enable Bit. Each bit controls whether the corresponding status bit in SISR can issue an interrupt to the Core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.

73.8.6 SSI Transmit Configuration Register (SSIx_SSI_STCR)

The SSI Transmit Configuration Register (SSI_STCR) is a read/write control registers used to direct the transmit operation of the STCR controls the direction of the bit clock and frame sync ports, STCK and STFS. Interrupt enable bit for the transmit sections is provided in this control register. The Power-on reset clears all SSI_STCR bits. However, SSI reset does not affect the SSI_STCR bits. The SSI_STCR bits are described in the following paragraphs. See the Programmable Registers section for the programming model of the SSI. The SSI Control Register (SSI_SCR) must first be set to enable interrupts. Next, the SSI interrupt bit in the Interrupt Enable Register (SSI_SIER) must be set to enable the interrupt. Finally, the interrupt can be enabled from within the

Addresses: SSI-2_SSI_STCR is 5001_4000h base + 1Ch offset = 5001_401Ch
SSI-1_SSI_STCR is 63FC_C000h base + 1Ch offset = 63FC_C01Ch
SSI-3_SSI_STCR is 63FE_8000h base + 1Ch offset = 63FE_801Ch



SSIx_SSI_STCR field descriptions

Field	Description
31–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9 TXBIT0	Transmit Bit 0. This control bit allows SSI to transmit the data word from bit position 0 or 15/31 in the transmit shift register. The shifting data direction can be MSB or LSB first, controlled by the TSHFD bit. 0 Shifting with respect to bit 31 (if word length = 16, 18, 20, 22 or 24) or bit 15 (if word length = 8, 10 or 12) of transmit shift register (MSB aligned). 1 Shifting with respect to bit 0 of transmit shift register (LSB aligned).
8 TFEN1	Transmit FIFO Enable 1. This bit enables transmit FIFO 1. When enabled, the FIFO allows15 samples to be transmitted by the SSI (per channel) (a 9th sample can be shifting out) before TDE1 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is transferred to the transmit shift register (provided the interrupt is enabled). 0 Transmit FIFO 1 disabled. 1 Transmit FIFO 1 enabled.
7 TFEN0	Transmit FIFO Enable 0. This bit enables transmit FIFO 0. When enabled, the FIFO allows15 samples to be transmitted by the SSI per channel (a 9th sample can be shifting out) before TDE0 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is transferred to the transmit shift register (provided the interrupt is enabled). 0 Transmit FIFO 0 disabled. 1 Transmit FIFO 0 enabled.

Table continues on the next page...

SSIx_SSI_STCR field descriptions (continued)

Field	Description
6 TFDIR	Transmit Frame Direction. This bit controls the direction and source of the transmit frame sync signal. Internally generated frame sync signal is sent out through the STFS port and external frame sync is taken from the same port. 0 Frame Sync is external. 1 Frame Sync generated internally.
5 TXDIR	Transmit Clock Direction. This bit controls the direction and source of the clock signal used to clock the TXSR. Internally generated clock is output through the STCK port. External clock is taken from this port. Refer to Table 73-2 for details of clock pin configurations. 0 Transmit Clock is external. 1 Transmit Clock generated internally.
4 TSHFD	Transmit Shift Direction. This bit controls whether the MSB or LSB will be transmitted first in a sample. **NOTE:** The CODEC device labels the MSB as bit 0, whereas the Core labels the LSB as bit 0. Therefore, when using a standard CODEC, Core MSB (CODEC LSB) is shifted in first (TSHFD cleared). 0 Data transmitted MSB first. 1 Data transmitted LSB first.
3 TSCKP	Transmit Clock Polarity. This bit controls which bit clock edge is used to clock out data for the transmit section. Note: TSCKP is 0 CLK_IST = 0; TSCKP is 1CLK_IST = 1 0 Data clocked out on rising edge of bit clock. 1 Data clocked out on falling edge of bit clock.
2 TFSI	Transmit Frame Sync Invert. This bit controls the active state of the frame sync I/O signal for the transmit section of SSI. 0 Transmit frame sync is active high. 1 Transmit frame sync is active low.
1 TFSL	Transmit Frame Sync Length. This bit controls the length of the frame sync signal to be generated or recognized for the transmit section. The length of a word-long frame sync is same as the length of the data word selected by WL[3:0]. 0 Transmit frame sync is one-word long. 1 Transmit frame sync is one-clock-bit long.
0 TEFS	Transmit Early Frame Sync. This bit controls when the frame sync is initiated for the transmit section. The frame sync signal is deasserted after one bit-for-bit length frame sync and after one word-for-word length frame sync. In case of synchronous operation, the frame sync can also be initiated on receiving the first bit of data. 0 Transmit frame sync initiated as the first bit of data is transmitted. 1 Transmit frame sync is initiated one bit before the data is transmitted.

73.8.7 SSI Receive Configuration Register (SSIx_SSI_SRCR)

The SSI Receive Configuration Register (SSI_SRCR) is a read/write control registers used to direct the receive operation of the SSI. SSI.SRCR controls the direction of the bit clock and frame sync ports, SRCK and SRFS. Interrupt enable bit for the transmit sections is provided in this control register. The Power-on reset clears all SSI_SRCR bits. However, SSI reset does not affect the SSI_SRCR bits.

Addresses: SSI-2_SSI_SRCR is 5001_4000h base + 20h offset = 5001_4020h
SSI-1_SSI_SRCR is 63FC_C000h base + 20h offset = 63FC_C020h
SSI-3_SSI_SRCR is 63FE_8000h base + 20h offset = 63FE_8020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SSIx_SSI_SRCR field descriptions

Field	Description
31–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10 RXEXT	Receive Data Extension. This control bit allows SSI to store the received data word in sign extended form. This bit affects data storage only in case received data is LSB aligned (SRCR[9]=1) 0 Sign extension turned off. 1 Sign extension turned on.
9 RXBIT0	Receive Bit 0. This control bit allows SSI to receive the data word at bit position 0 or 15/31 in the receive shift register. The shifting data direction can be MSB or LSB first, controlled by the RSHFD bit. 0 Shifting with respect to bit 31 (if word length = 16, 18, 20, 22 or 24) or bit 15 (if word length = 8, 10 or 12) of receive shift register (MSB aligned). 1 Shifting with respect to bit 0 of receive shift register (LSB aligned).
8 RFEN1	Receive FIFO Enable 1. This bit enables receive FIFO 1. When enabled, the FIFO allows15 samples to be received by the SSI per channel (a 16th sample can be shifting in) before RDR1 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is received by the SSI (provided the interrupt is enabled). 0 Receive FIFO 1 disabled. 1 Receive FIFO 1 enabled.
7 RFEN0	Receive FIFO Enable 0. This bit enables receive FIFO 0. When enabled, the FIFO allows15 samples to be received by the SSI (per channel) (a 16th sample can be shifting in) before RDR0 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is received by the SSI (provided the interrupt is enabled). 0 Receive FIFO 0 disabled. 1 Receive FIFO 0 enabled.

SSIx_SSI_SRCR field descriptions (continued)

Field	Description
6 RFDIR	Receive Frame Direction. This bit controls the direction and source of the receive frame sync signal. Internally generated frame sync signal is sent out through the SRFS port and external frame sync is taken from the same port. 0 Frame Sync is external. 1 Frame Sync generated internally.
5 RXDIR	Receive Clock Direction. This bit controls the direction and source of the clock signal used to clock the RXSR. Internally generated clock is output through the SRCK port. External clock is taken from this port. Refer to Table 73-2 for details on clock pin configurations. 0 Receive Clock is external. 1 Receive Clock generated internally.
4 RSHFD	Receive Shift Direction. This bit controls whether the MSB or LSB will be received first in a sample. **NOTE:** The CODEC device labels the MSB as bit 0, whereas the Core labels the LSB as bit 0. Therefore, when using a standard CODEC, Core MSB (CODEC LSB) is shifted in first (RSHFD cleared). 0 Data received MSB first. 1 Data received LSB first.
3 RSCKP	Receive Clock Polarity. This bit controls which bit clock edge is used to latch in data for the receive section. 0 Data latched on falling edge of bit clock. 1 Data latched on rising edge of bit clock.
2 RFSI	Receive Frame Sync Invert. This bit controls the active state of the frame sync I/O signal for the receive section of SSI. 0 Receive frame sync is active high. 1 Receive frame sync is active low.
1 RFSL	Receive Frame Sync Length. This bit controls the length of the frame sync signal to be generated or recognized for the receive section. The length of a word-long frame sync is same as the length of the data word selected by WL[3:0]. 0 Receive frame sync is one-word long. 1 Receive frame sync is one-clock-bit long.
0 REFS	Receive Early Frame Sync. This bit controls when the frame sync is initiated for the receive section. The frame sync is disabled after one bit-for-bit length frame sync and after one word-for-word length frame sync. 0 Receive frame sync initiated as the first bit of data is received. 1 Receive frame sync is initiated one bit before the data is received.

73.8.8 SSI Transmit Clock Control Register (SSIx_SSI_STCCR)

The SSI Transmit and Receive Control (SSI_STCCR and SSI_SRCCR) registers are 19-bit, read/write control registers used to direct the operation of the SSI. The Clock Controller Module (CCM) can source the SSI clock (SSI's sys clock-from CCM's ssi_clk_root) from multiple sources and perform fractional division to support commonly used audio bit rates. The CCM can maintain the SSI's sys clock frequency at a constant rate even in cases where the ipg_clk (from CCM) frequency changes. These registers control the SSI clock generator, bit and frame sync rates, word length, and number of words per frame for the serial data. The SSI.STCCR register is dedicated to the transmit section, and the SSI_SRCCR register is dedicated to the receive section except in Synchronous mode, in which the SSI_STCCR register controls both the receive and transmit sections. Power-on reset clears all SSI_STCCR and SSI_SRCCR bits. SSI reset does not affect the SSI_STCCR and SSI_SRCCR bits. The control bits are described in the following paragraphs. Although the bit patterns of the SSI_STCCR and SSI_SRCCR registers are the same, the contents of these two registers can be programmed differently.

Table 73-51. SSI Data Length

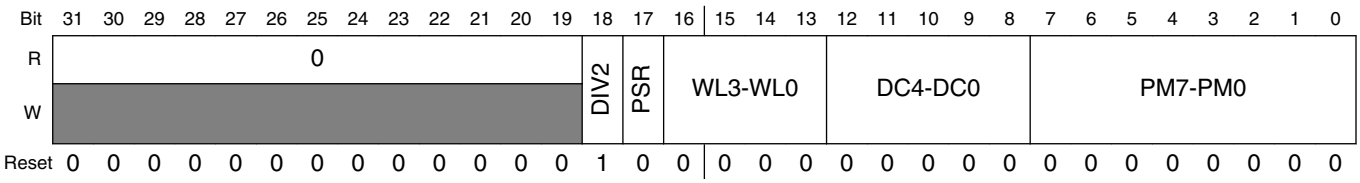
Addresses: SSI-2_SSI_STCCR is 5001_4000h base + 24h offset = 5001_4024h

SSI-1_SSI_STCCR is 63FC_C000h base + 24h offset = 63FC_C024h

SSI-3_SSI_STCCR is 63FE_8000h base + 24h offset = 63FE_8024h



SSIx_SSI_STCCR field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18 DIV2	Divide By 2. This bit controls a divide-by-two divider in series with the rest of the prescalers. 0 Divider bypassed. 1 Divider used to divide clock by 2.
17 PSR	Prescaler Range. This bit controls a fixed divide-by-eight prescaler in series with the variable prescaler. It extends the range of the prescaler for those cases where a slower bit clock is required. 0 Prescaler bypassed. 1 Prescaler used to divide clock by 8.
16–13 WL3-WL0	Word Length Control. These bits are used to control the length of the data words being transferred by the SSI. These bits control the Word Length Divider in the Clock Generator. They also control the frame sync pulse length when the FSL bit is cleared. In I2S Master mode, the SSI works with a fixed word length of 32, and the WL bits are used to control the amount of valid data in those 32 bits. In AC97 Mode of operation, if word length is set to any value other than 16 bits, it will result in a word length of 20 bits.
12–8 DC4-DC0	Frame Rate Divider Control. These bits are used to control the divide ratio for the programmable frame rate dividers. The divide ratio works on the word clock. In Normal mode, this ratio determines the word transfer rate. In Network mode, this ratio sets the number of words per frame. The divide ratio ranges from 1 to 32 in Normal mode and from 2 to 32 in Network mode. In Normal mode, a divide ratio of 1 (DC=00000) provides continuous periodic data word transfer. A bit-length frame sync must be used in this case. These bits can be programmed with values ranging from "00000" to "11111" to control the number of words in a frame.
7–0 PM7-PM0	Prescaler Modulus Select. These bits control the prescale divider in the clock generator. This prescaler is used only in Internal Clock mode to divide the internal clock. The bit clock output is available at the clock port. A divide ratio from 1 to 256 (PM[7:0] = 0x00 to 0xFF) can be selected. Refer to DIV2, PSR and PM Bit Description for details regarding settings.

73.8.9 SSI Receive Clock Control Register (SSIx_SRCCR)

The SSI Transmit and Receive Control (SSI_STCCR and SSI_SRCCR) registers are 19-bit, read/write control registers used to direct the operation of the SSI. The Clock Controller Module (CCM) can source the SSI clock (SSI's sys clock-from CCM's ssi_clk_root) from multiple sources and perform fractional division to support commonly used audio bit rates. The CCM can maintain the SSI's sys clock frequency at a constant rate even in cases where the ipg_clk from CCM frequency changes. These registers control the SSI clock generator, bit and frame sync rates, word length, and number of words per frame for the serial data. The SSI_STCCR register is dedicated to the transmit section, and the SSI_SRCCR register is dedicated to the receive section except in Synchronous mode, in which the SSI_STCCR register controls both the receive and transmit sections. Power-on reset clears all SSI_STCCR and SSI_SRCCR bits. SSI reset does not affect the SSI_STCCR and SSI_SRCCR bits. The control bits are described in the following paragraphs. Although the bit patterns of the SSI_STCCR and SSI_SRCCR registers are the same, the contents of these two registers can be programmed differently.

Field	Description
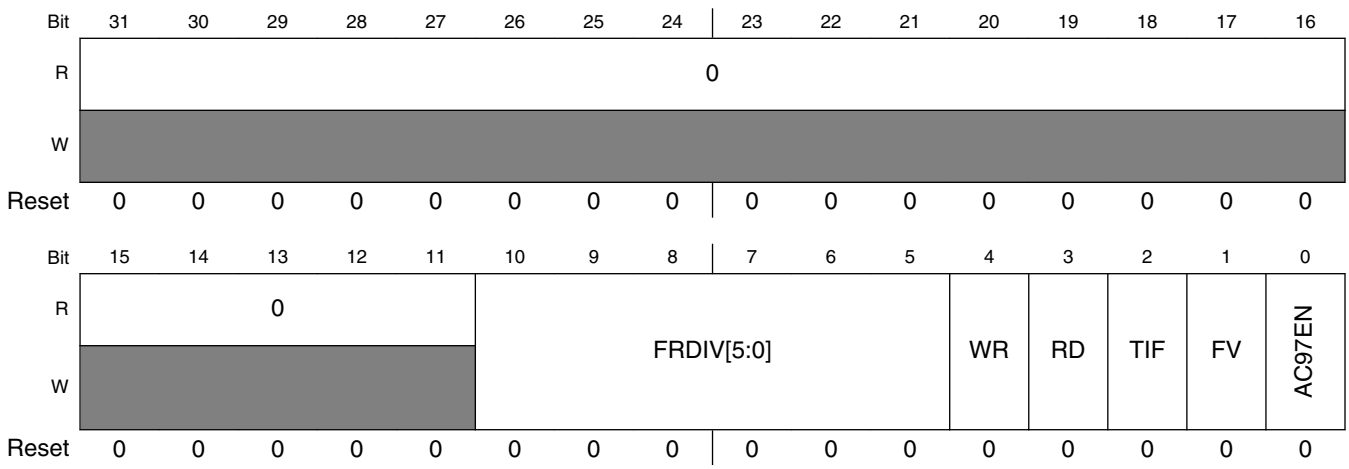
7–4 RFWM0[3:0]	Receive FIFO Full WaterMark 0. These bits control the threshold at which the RFF0 flag will be set. The RFF0 flag is set whenever the data level in Rx FIFO 0 reaches the selected threshold. Refer to RFWM1[3:0] for details regarding settings for receive FIFO watermark bits.
3–0 TFWM0[3:0]	Transmit FIFO Empty WaterMark 0. These bits control the threshold at which the TFE0 flag will be set. The TFE0 flag is set whenever the empty slots in Tx FIFO exceed or are equal to the selected threshold. Refer to TFWM1[3:0] for details regarding settings for transmit FIFO watermark bits.

73.8.11 SSI AC97 Control Register (SSIx_SSI_SACNT)

Addresses: SSI-2_SSI_SACNT is 5001_4000h base + 38h offset = 5001_4038h
SSI-1_SSI_SACNT is 63FC_C000h base + 38h offset = 63FC_C038h
SSI-3_SSI_SACNT is 63FE_8000h base + 38h offset = 63FE_8038h



SSIx_SSI_SACNT field descriptions

Field	Description
31–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10–5 FRDIV[5:0]	Frame Rate Divider. These bits control the frequency of AC97 data transmission/reception. They are programmed with the number of frames for which the SSI should be idle, after operating in one frame. Through these bits, AC97 frequency of operation, from 48 KHz (000000) to 1 KHz (101111) can be achieved. Sample Value: 001010 (10 Decimal) = SSI will operate once every 11 frames.
4 WR	Write Command. This bit specifies whether the next frame will carry an AC97 Write Command or not. The programmer should take care that only one of the bits (WR or RD) is set at a time. When this bit is set, the corresponding tag bits (corresponding to Command Address and Command Data slots of the next Tx frame) are automatically set. This bit is automatically cleared by the SSI after completing transmission of a frame. 0 Next frame will not have a Write Command. 1 Next frame will have a Write Command.

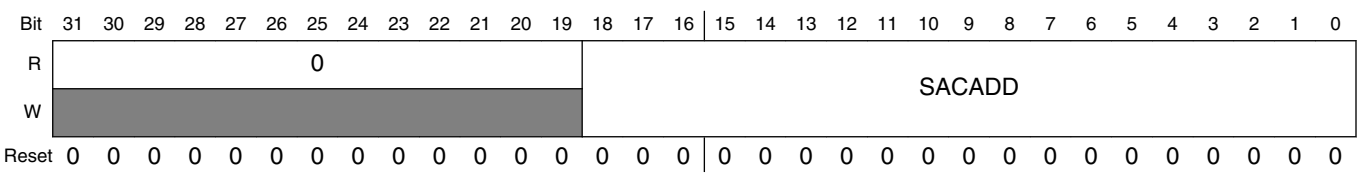
Table continues on the next page...

SSIx_SSI_SACNT field descriptions (continued)

Field	Description
3 RD	Read Command. This bit specifies whether the next frame will carry an AC97 Read Command or not. The programmer should take care that only one of the bits (WR or RD) is set at a time. When this bit is set, the corresponding tag bit (corresponding to Command Address slot of the next Tx frame) is automatically set. This bit is automatically cleared by the SSI after completing transmission of a frame. 0 Next frame will not have a Read Command. 1 Next frame will have a Read Command.
2 TIF	Tag in FIFO. This bit controls the destination of the information received in AC97 tag slot (Slot #0). 0 Tag info stored in SATAG register. 1 Tag info stored in Rx FIFO 0.
1 FV	Fixed/Variable Operation. This bit selects whether the SSI is in AC97 Fixed mode or AC97 Variable mode. 0 AC97 Fixed Mode. 1 AC97 Variable Mode.
0 AC97EN	AC97 Mode Enable. This bit is used to enable SSI AC97 operation. Refer to AC97 Mode for details of AC97 operation. 0 AC97 mode disabled. 1 SSI in AC97 mode.

73.8.12 SSI AC97 Command Address Register (SSIx_SSI_SACADD)

Addresses: SSI-2_SSI_SACADD is 5001_4000h base + 3Ch offset = 5001_403Ch
SSI-1_SSI_SACADD is 63FC_C000h base + 3Ch offset = 63FC_C03Ch
SSI-3_SSI_SACADD is 63FE_8000h base + 3Ch offset = 63FE_803Ch

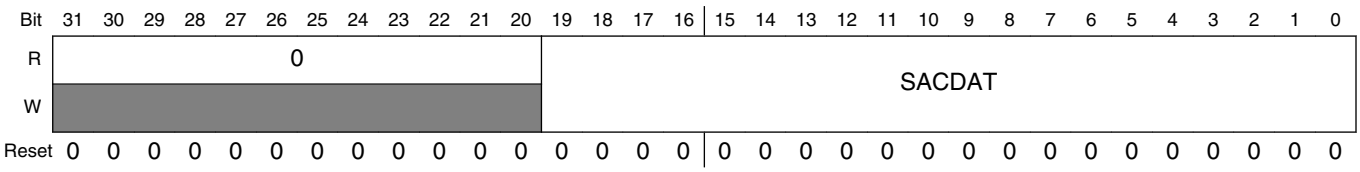


SSIx_SSI_SACADD field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18–0 SACADD	AC97 Command Address. These bits store the Command Address Slot information (bit 19 of the slot is sent in accordance with the Read and Write Command bits in SSI_SACNT register). These bits can be updated by a direct write from the Core. They are also updated with the information received in the incoming Command Address Slot. If the contents of these bits change due to an update, the CMDAU bit in SISR is set.

73.8.13 SSI AC97 Command Data Register (SSIx_SSI_SACDAT)

Addresses: SSI-2_SSI_SACDAT is 5001_4000h base + 40h offset = 5001_4040h
SSI-1_SSI_SACDAT is 63FC_C000h base + 40h offset = 63FC_C040h
SSI-3_SSI_SACDAT is 63FE_8000h base + 40h offset = 63FE_8040h

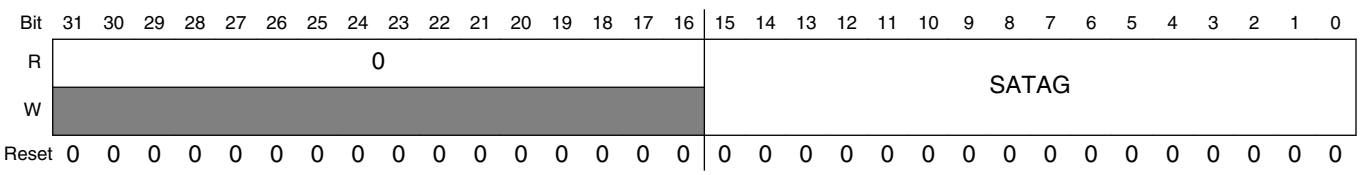


SSIx_SSI_SACDAT field descriptions

Field	Description
31–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19–0 SACDAT	AC97 Command Data. The outgoing Command Data Slot carries the information contained in these bits. These bits can be updated by a direct write from the Core. They are also updated with the information received in the incoming Command Data Slot. If the contents of these bits change due to an update, the CMDDU bit in SISR is set. These bits are transmitted only during AC97 Write Command. During AC97 Read Command, 0x00000 is transmitted in time slot #2.

73.8.14 SSI AC97 Tag Register (SSIx_SATAG)

Addresses: SSI-2_SATAG is 5001_4000h base + 44h offset = 5001_4044h
SSI-1_SATAG is 63FC_C000h base + 44h offset = 63FC_C044h
SSI-3_SATAG is 63FE_8000h base + 44h offset = 63FE_8044h



SSIx_SATAG field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–0 SATAG	AC97 Tag Value. Writing to this register (by the Core) sets the value of the Tx-Tag in AC97 fixed mode of operation. On a read, the Core gets the Rx-Tag Value received (in the last frame) from the Codec. If TIF bit in SSI_SACNT register is set, the TAG value is also stored in Rx-FIFO in addition to SATAG register. When the received Tag value changes, the RXT bit in SISR register is set. Bits SATAG[1:0] convey the Codec -ID. In current implementation only Primary Codecs are supported. Thus writing value 2'b00 to this field is mandatory.

73.8.15 SSI Transmit Time Slot Mask Register (SSIx_SSI_STMSK)

Addresses: SSI-2_SSI_STMSK is 5001_4000h base + 48h offset = 5001_4048h
SSI-1_SSI_STMSK is 63FC_C000h base + 48h offset = 63FC_C048h
SSI-3_SSI_STMSK is 63FE_8000h base + 48h offset = 63FE_8048h

31–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–0 SACCDIS	AC97 Channel Disable. The Core writes a '1' to these bits to disable an AC97 data channel. Writing a '0' has no effect. Bit [0] corresponds to the first data slot in an AC97 frame (Slot #3) and Bit [9] corresponds to the tenth data slot (slot #12). Writes to these bits only have effect in the AC97 Variable mode of operation. These bits are always read as '0' by the Core. 0 Write Has no effect. 1 Write Disables the corresponding data channel.

Chapter 74
Television Encoder (TVEv2)

74.1 Introduction

The Television Encoder (TVE) is designed to provide direct connection between an Application Processor, or ARM platform, and a TV set via analog interfaces. The ARM platform may be both a standalone product and a part of a Wireless Baseband Platform (WBP). Integration of the TVE into the ARM platform and the WBP allows minimizing system complexity and cost. The TV Encoder supports different Standard Definition (SD) and High Definition (HD) television standards.

The block is based on mixed (digital and analog) signal processing. It includes three main components:

- TV Signal Processor (TVSP) is a digital block which is responsible for modulation, filtering, generation synchronization signals, upsampling, cable detection control, copy protection and other processing tasks.
- Triple Video Digital-to-Analog Converter (TVDAC) is an analog block which is designed to convert up to three digital video signals to a current.
- Cable Detection Circuit (CDC) is an analog block which provides monitoring of TVDAC output signals for Cable Detection (CD).

The TVE can operate in two modes:

1. Encoding the video data according to the selected TV standard
2. Generating RGB analog signals according to the VGA specification.

The main features of the TVE in TV encoding mode are:

1. SD mode features:
    - Supported TV standards:
        - NTSC
        - PAL B,D,G,H, I/M/N
        - 480i
        - 576i

- Supported output formats:
  - Composite video (CVBS) - up to two simultaneous identical outputs are supported
  - S-video (Y/C), composite video and S-video signals may be output simultaneously
  - YPrPb component
  - RGB component
- Programmable notch/pre-comb filter for CVBS
- Switchable pedestal
- Copy Generation Management System (CGMS) support according to
  - EIA-608b
  - IEC 61880-1
  - EIA-J CPR-1204-1
- Wide-Screen Signaling (WSS) support according to ITU-R BT.1119, ETSI EN 300 294
- Closed Caption insertion capability according to EIA-608b
- Macrovision™ 7.1 copy protection
- Output oversampling up to x16 for elimination of external analog filters

2. HD mode features:
   - Supported TV standards:
     - 720p 60Hz
     - 720p 50Hz
     - 720p 30Hz
     - 720p 25Hz
     - 720p 24Hz
     - 1080i 60Hz
     - 1080i 50Hz
     - 1035i 60Hz (1920x1035)
     - 1080p 30Hz
     - 1080p 30Hz25Hz
     - 1080p 25Hz24Hz
     - 1080p 50Hz
     - 1080p 60Hz
   - Supported output formats:
     - YPrPb component
     - RGB component
   - CGMS support according to
     - EIAJ CPR-1204-2 (CGMS)
     - CEA-805-A (CGMS type B)
   - Output oversampling up to x4 for elimination of external analog filters
3. Common SD/HD mode features

- Flexible timing and gain control mechanism allowing non-standard parameters ("user mode")
- Programmable Chroma digital filters
- Programmable adaptive Luma digital filters for
  - horizontal and vertical sharpening
  - horizontal and vertical noise reduction
  - de-flickering in interlaced modes
- Programmable YCrCb to RGB color matrix
- Output resolution - 10 bits (single-ended analog output loaded by a double terminated 75-Ohm cable)
- Cable Detection functionality including
  - Separate cable connection monitoring separately for each TVDAC channel both during normal operation and in standby mode
  - Automatic TVE power on when a TV cable has been connected
  - Detection of connection type (composite, S-video, component)
  - Detection of cable short to the ground

In VGA mode, the TVE provides transfer of RGB video data from the ARM platform to a monitor. The Interface supports RGBHV video data format with three analog color signals (RGB) and separate horizontal (HSYNC) and vertical (VSYNC) synchronization signals. The standard VGA DE-15 connector includes signal lines listed in Table 74-1.

Table 74-1. VGA DE-15 Connector Signals

##	Name	Description
Pin 1	**RED**	**Red video**
Pin 2	GREEN	Green video
Pin 3	BLUE	Blue video
Pin 4	N/C	Not connected
Pin 5	GND	Ground (HSync)
Pin 6	RED_RTN	Red return
Pin 7	GREEN_RTN	Green return
Pin 8	BLUE_RTN	Blue return
Pin 9	+5 V	+5 V DC
Pin 10	GND	Ground (VSync, DDC)
Pin 11	N/C	Not connected
Pin 12	SDA	I²C data
Pin 13	HSync	Horizontal sync
Pin 14	VSync	Vertical sync
Pin 15	SCL	I²C clock

Figure 74-1 depicts the TVE integration scheme into the ARM platfor

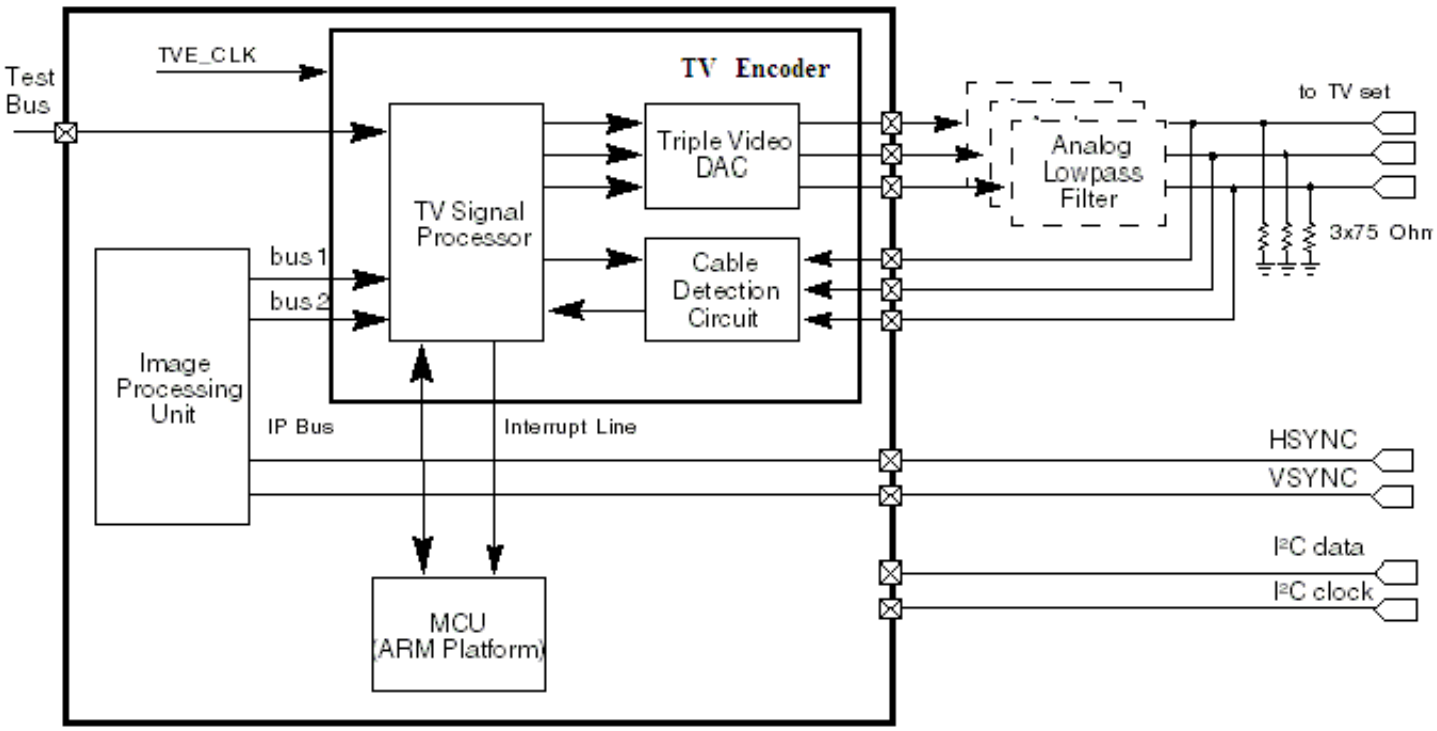

Figure 74-1. TVE Integration in an Application Processor

The TVE receives a 30-bit video data stream either via the VIDEO_DATA_IN_1 bus or via the VIDEO_DATA_IN_2 bus from the Image Processing Unit (IPU). The VIDEO_DATA_IN_1 bus is used for data transfer when the TVE operates in TV encoding mode or in test mode with the IPU driving the test data. The VIDEO_DATA_IN_2 bus is used in VGA mode.

In VGA mode, the IPU transfers data in RGB format (8 bits/component). The 30-bit VIDEO_DATA_IN_2 bus is connected to the 24-bit IPU data output bus as shown in Table 74-2.

Table 74-2. Connection between the IPU Data Output Bus and the VIDEO_DATA_IN_2 Bus

VIDEO_DATA_IN_2 bus pins	Connection	Description
0	ground	
8:1	IPU_DATA_OUT[7:0]	G component
9	ground	
10	ground	
18:11	IPU_DATA_OUT[15:8]	R component
19	ground	
20	ground	

Table continues on the next page...

Table 74-2. Connection between the IPU Data Output Bus and the VIDEO_DATA_IN_2 Bus (continued)

VIDEO_DATA_IN_2 bus pins	Connection	Description
28:21	IPU_DATA_OUT[23:16]	B component
29	ground	

The IPU provides also the sampling clocks VIDEO_DATA_CLK_1 and VIDEO_DATA_CLK_2 for each of the data buses. The clock frequency depends on the mode.

In SD mode, the TVE output is always in the interlaced format. For some TVE configuration, the TVE performs inter-field vertical filtering for de-flickering, fine sharpening and high-frequency noise reduction. In this case, the input data arrives in the progressive format at the doubled frequency Fsx2 = 27 MHz where Fs = 13.5 MHz is the pixel frequency for the interlaced format. In HD mode the input data rate is always Fs = 74.25 MHz or Fs = 74.25/1.001 = 74.1758 MHz. The Y component is sampled at the VIDEO_DATA_CLK_1(2) frequency. For the YCbCr 4:2:2 input format, the Cb/Cr components are sampled at a half of the VIDEO_DATA_CLK_1(2) frequency. For the YCbCr 4:4:4 input format, the Cb/Cr components are sampled at the VIDEO_DATA_CLK_1(2) frequency.

The VIDEO_DATA_CLK_2 clock frequency depends on current resolution of the VGA output. For more details see Operation in VGA Mode-Introduction.

The data stream via the VIDEO_DATA_IN_1 is also accompanied by two separated signals for horizontal synchronization (HSYNC) and vertical synchronization (VSYNC) and by data validness indicator VIDEO_DATA_EN. The existing HSYNC_2, VSYNC_2 and VIDEO_DATA_EN_2 pins are unused for VGA mode.

The second alternative for the TVE input source is the test bus driven by an external device through the chip pins. The test bus can be used for both in functional mode testing or in TVDAC testing. In both cases, the test bus replaces the IPU output.

The TVE generates a TV signal in one of the formats specified above in TV encoding mode. The signal is oversampled before digital-to-analog conversion. The oversampling factor is programmable and can vary from 2x to 16x in SD mode and from x2 to x4 in HD mode. In primary operation mode with maximal output oversampling, the TVDAC sampling frequency is 216 MHz for SD and 297 MHz or 297/1.001 MHz for HD. For SD, there are also 2 additional modes when the TVDAC sampling frequency is 108 or 54 MHz. For HD, there is one additional mode with the TVDAC sampling frequency of 148.5 MHz or 148.5/1.001 MHz. These modes should be used as a reserved option in the case if the performance of the used TVDAC degrades at high sampling frequency.

In VGA mode, the TVE can provide oversampling by 2 or 4. If the pixel rate is less than 75 Mpix/sec, x4 oversampling should be used. For faster pixel rates, x2 oversampling should be used.

The TVDAC is able to drive directly a 75-Ohm double terminated cable (the equivalent load is 37.5 Ohm). External Analog Lowpass Filters are optional. They are recommended in VGA mode with pixel rates faster than 75Mpix/sec when no oversampling can be done. The cutoff frequency of the filters should be 70 MHz.

The TVE is sampled by the TVE_CLK clock. The clock frequency is equal to the TVDAC sampling rate. All required internal clocks are produced by division of the TVE_CLK inside the TVE.

An output voltage of each TVE channel is monitored by Cable Detection (CD) system. The CD is able to distinguish between the following cases:

- Normal load impedance which is equal to 37.5 Ohm when the TVE drives directly a 75-Ohm double terminated cable
- Double load impedance (75 Ohm) when the cable is disconnected
- Zero load impedance when the output is shorted to the ground

The CD monitors each of the output channels separately. The monitoring result is sent to the ARM platform which decides on the TV output mode corresponding to the connected cable type.

The TVE is controlled by the ARM platform via the IP Bus interface. The TVE generates interrupts for the ARM platform via a singe interrupt line corresponding to the Indigo IP Interface.

74.1.1 Overview

This paragraph describes TVE architecture and functionality with focus on TV encoding mode. For more details on operation in VGA mode, see Operation in VGA Mode-Introduction.

The TVE block diagram is shown in Figure 74-2. The TVE consists of three sub-blocks: the TV Signal Processor (TVSP), the Triple Video DAC (TVDAC) and the Cable Detection Circuit (CDC).

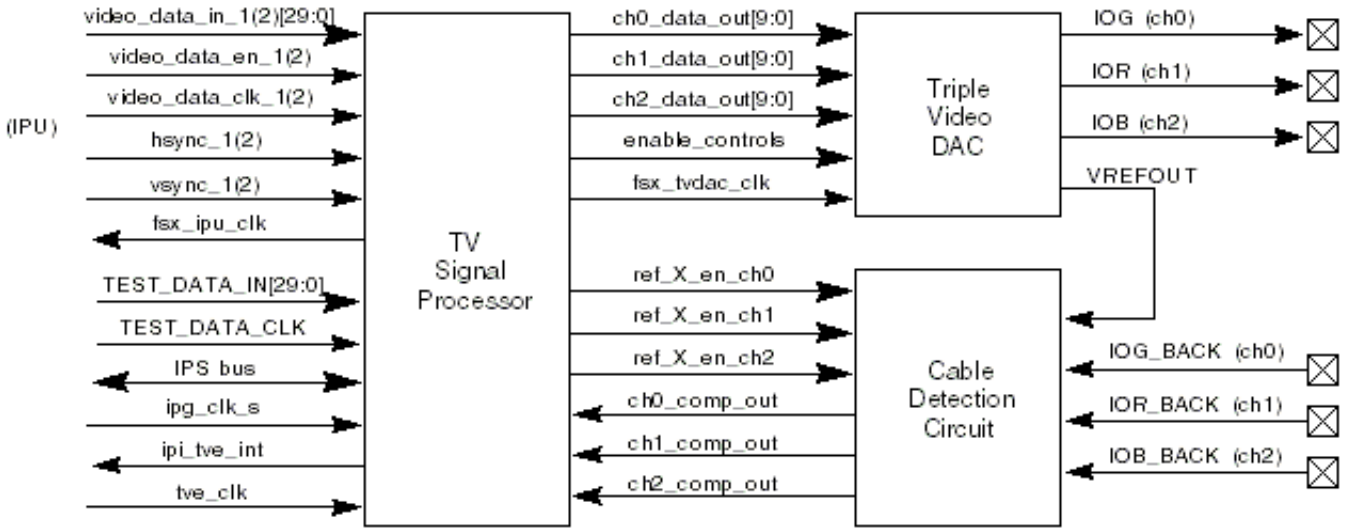

Figure 74-2. TVE Block Diagram

The TVDAC converts an input 10-bit code in the unsigned format to the current. The DAC is able to drive directly a double terminated 75-Ohm cable. The full scale output current is controlled by an external resistor to provide the required full-scale voltage of the video signal on the output load. The nominal sampling rate of the TVDAC is 216 MHz in SD mode and 297 MHz or 297/1.001 MHz in HD mode.

The CDC is an analog block which includes a reference voltage divider and three comparators (one for each TVDAC output). The reference voltage for the CDC is taken from the TVDAC VREFOUT pin. The CDC compares the TVDAC output voltage with the different reference levels derived from the VREFOUT voltage. The result is sent to the TVSP which decides whether a cable is connected.

The TVSP is a digital part of the TVE. The TVSP block diagram is shown in Figure 74-3.

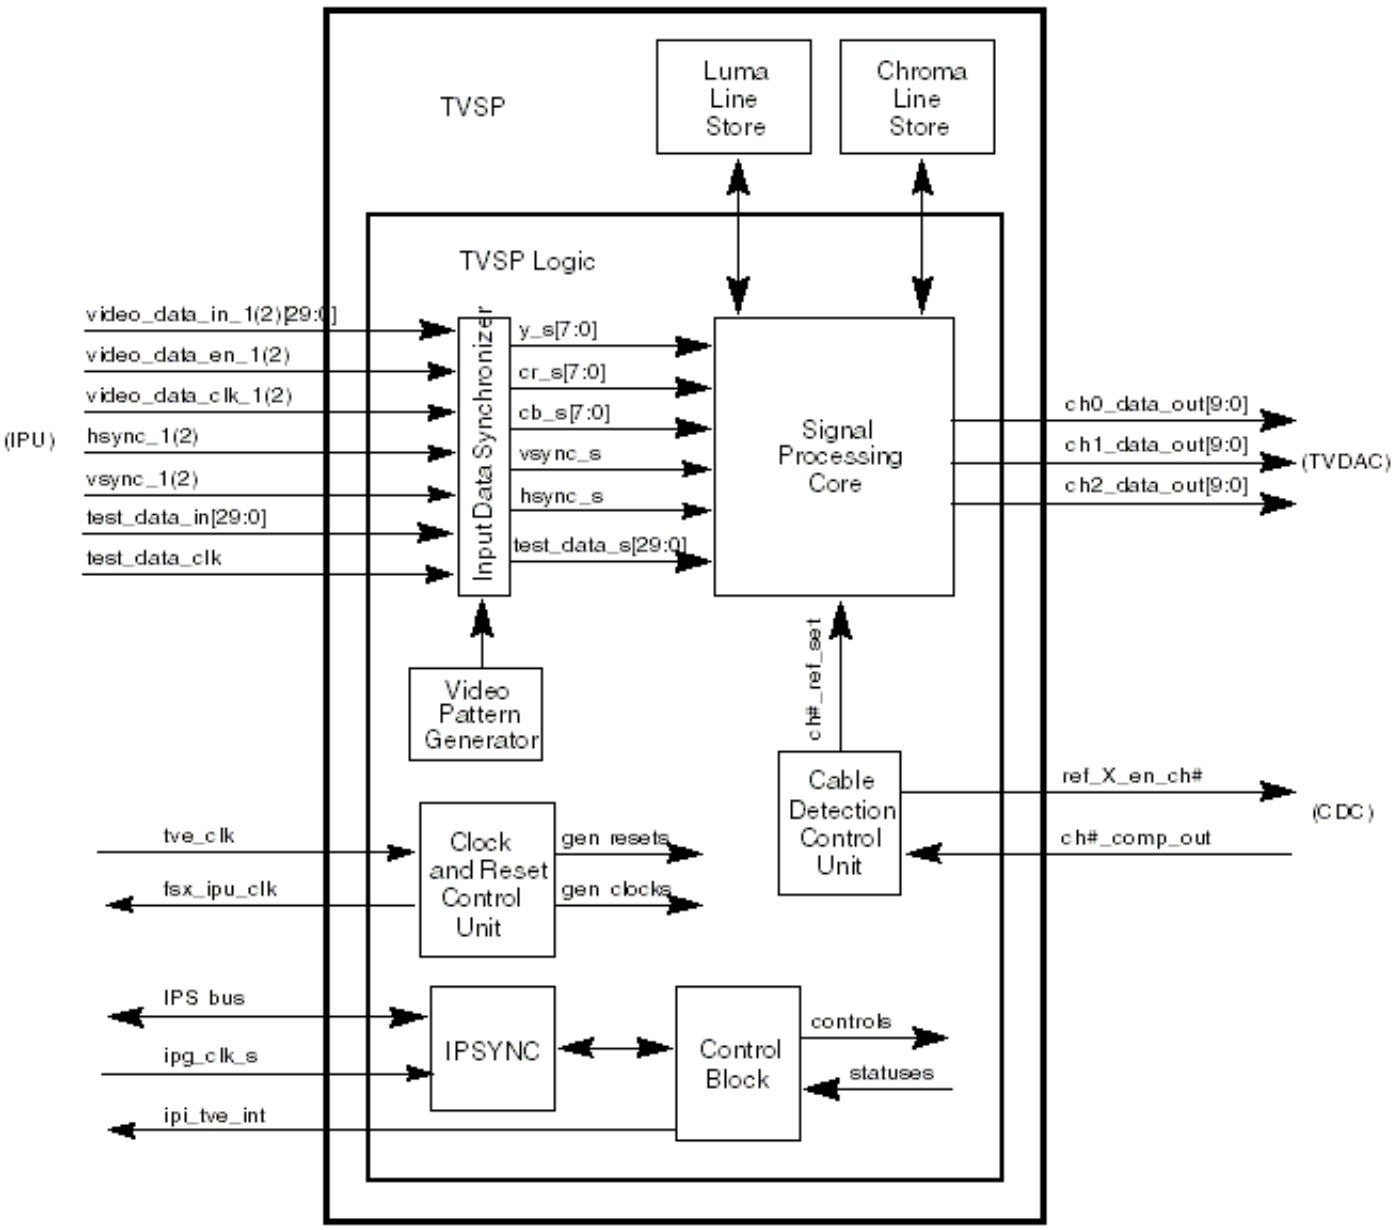

Figure 74-3. TVSP Block Diagram

The TVSP includes two parts: the memory-less TVSP Logic and two memories - the Luma Line Store and the Chroma Line Store.

The central sub-block of the TVSP is based on the Signal Processing Core (SPC) which is responsible for the following TV encoding tasks:

- Synchronization signals generation according to the used TV standard
- Digital non-adaptive and adaptive filtering of video signals
- Sampling rate conversion (upsampling)

- Color conversion YCrCb to RGB and color adjustment
- Color modulation in composite and S-video output modes required by the supported SD standards
- VBI data insertion
- Macrovision^{TM} signals generation for copy protection in SD mode

The SPC receives the input data from the Input Data Synchronizer (IDS) in the YCrCb 4:2:2 or the YCrCb 4:4:4 formats. The IDS is designed to synchronize the IPU output data to the TVE clock.

According to the IPU type used, two synchronization modes are possible:

1. If the IPU supports output data synchronization to an external clock, the TVE should provide the FSx_IPU_CLK clock (27 MHz in SD mode and 74.25 MHz or 74.25/1.001 MHz in HD mode) to the IPU. The IPU uses this clock to generate the output data stream. The IDS is transparent in this case. In functional mode, the sampling rate is 13.5 MHz in SD mode and 74.25 MHz or 74.25/1.001 MHz in HD mode (for the YCrCb 4:2:2 format, the Cb and Cr samples are repeated twice). In TVDAC test mode, the data sampling rate is correspondingly 27 MHz and 74.25 MHz or 74.25/1.001 MHz.
2. If the IPU does not support output data synchronization to an external clock, it should provide the sampling rates mentioned above (for example, to generate the display clock using fractional frequency division). The frequencies of the IPU output and TVE input clocks must be equal, but a phase jitter between two clocks is allowed. The maximal value of this jitter should be less than one period of one pixel clock. Also initial phase difference between two clocks may be unspecified. The IDS is designed to eliminate phase uncertainty and phase jitter between two clocks.

The IDS receives a 30-bit input data from the IPU. In functional mode, the least significant byte of the data bus include the Y component, next two bytes are the Cr and Cb components correspondingly. Six most significant bits are unused in functional mode. In TVDAC test mode 1, each 10 bits are fed to the corresponding TVDAC channel. In TVDAC test mode 2, only 10 least significant bits are fed to all TVDAC channels and 20 most significant bits are unused.

In addition to the data, the IDS resamples the vertical (VSYNC_1(2)) and horizontal (HSYNC_1(2)) synchronization signals from the IPU. It also gates off the invalid IPU output data according to the VIDEO_DATA_EN_1(2) data enable signal from the IPU.

The SPC has three output channels. Each channel is represented by 10 bits. The ouputs can be in composite (CVBS), S-video, YCrCb and RGB component formats according to the TV_OUT_MODE control parameter (see Table 74-3).

Table 74-3. TVE Output Data Formats

Output channel	Output data format (TV_OUT_MODE)							
	Composite (CVBS)				S-video (Y/C)	CVBS and Y/C	YCrCb component	RGB component
	(0)	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Channel #0	0	CVBS	0	CVBS	Y	Y	Y	G
Channel #1	0	0	0	0	C	C	Cr	R
Channel #2	0	0	CVBS	CVBS	0	CVBS	Cb	B

The Cable Detection Control Unit (CDCU) is a digital part of the CD system. It sends periodical requests to the CDC to monitor TVDAC output voltage. The CDC returns the results of load resistance measurement and ground short detection for each of monitored channels. For TVE channels those are inactive for the used TV_OUT_MODE setting (zeros in Table 74-3), the CDCU forces the output current to the value required for the measurement.

The Clock and Reset Control Unit (CRCU) produces internal generated clocks by division of the TVE_CLK clock. The CRCU asserts also reset signals to the sub-blocks which are unused in the current configuration and enable signals for the TVDAC channels.

The Control Module (CM) is responsible for IP Bus interface and interrupt generation support. It contains a set of control and status registers. Because the CM is sampled by the 27-MHz clock in SD mode and by the 74.25-MHz or 74.25/1.001-MHz clock in HD mode, the IP Synchronizer (IPSYNC) is used to synchronize the frequency of the IP Bus interface (typically, 66 MHz) to the CM clock frequency.

The SPC block diagram is depicted in Figure 74-4.

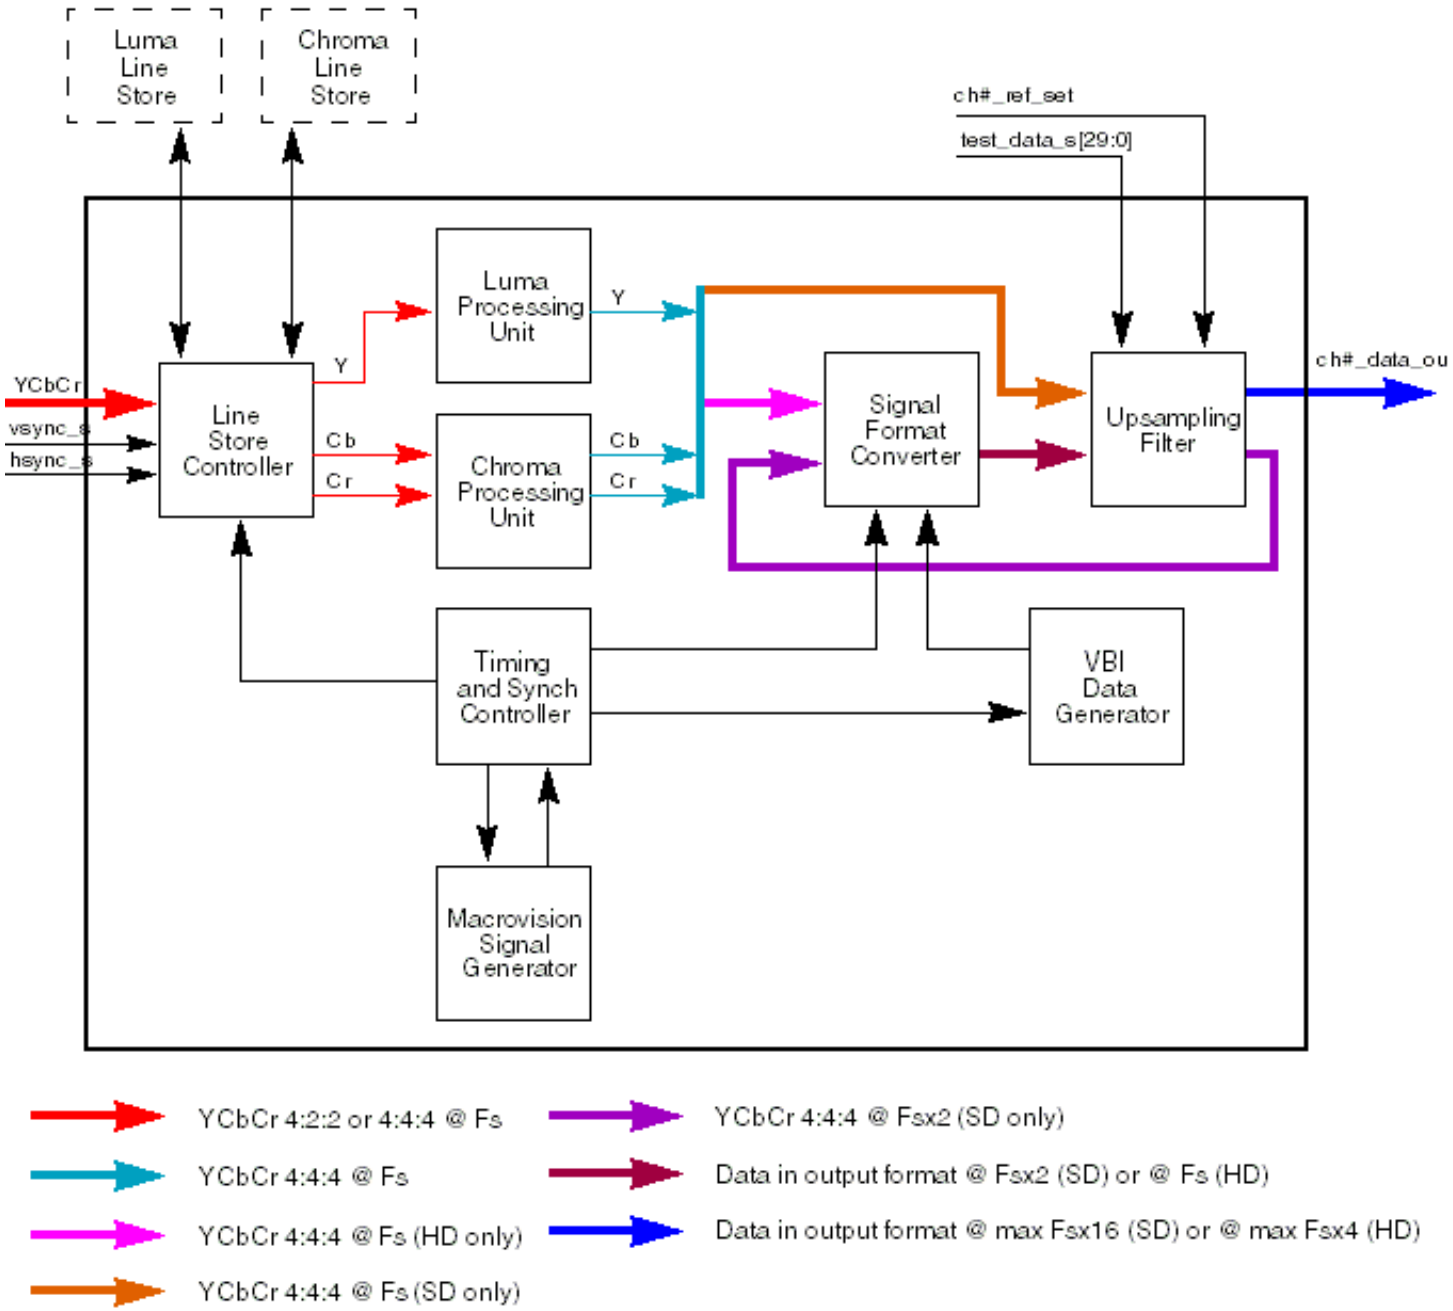

Figure 74-4. SPC Block Diagram

The SPC includes the Line Store Controller (LSC), The Luma Processing Unit (LPU), the Chroma Processing Unit, the Signal Format Converter (SFC), the Upsampling Filter (UF), The Timing and Synchronization Controller (TSC), the Macrovision Signal Generator and the VBI Data Generator (VDG).

The LSC receives the data in the YCbCr 4:0:0 or 4:4:4 format from the IDS. The data is written to the LLS (Y) and the CLS (Cb/Cr) line-by-line. The LLS size is 5 lines of 1920 Y samples. The CLS size is 4 lines of 1920 Cb/Cr pairs. The LSC reads 5 sample

columns of the Y component from the LLS and sends it to the LPU. In parallel, the LSC reads 4-sample columns of the Cb/Cr component from the CLS and sends it to the chroma processing unit.The columns are read sequentially so for generation of one output line, the whole line of pixel columns is read from the line stores.

The LPU contains a set of filters including:

- 5-tap vertical adaptive filter designed for
  - vertical coarse and fine sharpening
  - vertical mid-frequency and high-frequency noise reduction
  - de-flickering (required only for interlaced TV formats)
- 5-tap horizontal adaptive filter designed for
  - horizontal coarse and fine sharpening
  - horizontal mid-frequency and high-frequency noise reduction
  - horizontal de-ringing
- Notch filter for better Luma/Chroma separation in SD composite mode
- Lowpass filter for reducing out-of-band noise (it may enabled instead of the notch filter because both filters are implemented by the same hardware).

The adaptive filters boost (for sharpening) or suppress (for noise reduction, de-ringing and de-flickering) mid and high frequency components in the Luma spectrum. The filter operation (boost or suppression) depends on the Luma gradient in the corresponding spatial direction. The filters behavior is fully programmable. If the filter for vertical fine sharpening /vertical high-frequency noise reduction/de-flickering is enabled, the input data from the IPU should arrive in the progressive format.

The chroma processing unit performs the following operation on the Chroma samples from the CLS:

- Upsampling from Fs/2 to Fs (if the input data format is YCbCr 4:2:2)
- Lowpass filtering for reducing color noise and improving Luma/Chroma separation in SD composite mode
- Comb filtering for improving Luma/Chroma separation in SD composite mode.

The chroma processing unit produces the filtered Cb and Cr components sampled at Fs.

The following processing path of the LPU and chroma processing unit output samples depends on the mode. In SD mode, the samples are fed to the UF. The UF performs upsampling the data to Fsx2 = 27 MHz. The upsampled data enters the SFC. In HD mode, the LPU and chroma processing unit outputs sampled at Fs = 74.25 or 74.25/1.001 MHz are sent directly to the SFC.

The SFC is responsible for the following functions:

- Conversion the YCbCr data to the RGB format for RGB component output

- Subcarrier generation and Chroma modulation according to NTSC and PAL standards in SD composite and S-video modes
- Adjustment of brightness, saturation and hue (in user mode)
- Signal level normalization to the desired values
- Combining the synchronization signals and the VBI data with the video signal
- Composing three output streams according to Table 74-3.

Signal formats and waveforms on three SFC outputs correspond to the final TV signals. The UF provides upsampling of these SFC outputs. The UF consists of three identical channels. Each channel includes the following elements:

- The Gain and Offset Correction (GOC) block is designed to compensate the TVDAC gain and offset deviation from the nominal values. The gain and the offset are adjusted in the range +/-25% and +/-12.5% of the full scale separately for each channel. The TVDAC_#_GAIN and TVDAC_#_OFFSET parameters are responsible for gain and offset control. The GOC includes an input mux used for selection between the functional mode data, the test data and the CD reference levels.
- The Drop Correction Filter (DCF) provides compensation of the gain drop introduced by the TVDAC at high frequencies. The drop compensation factor is programmable via the TVDAC_#_DROP_COMP parameter separately for each channel.
- The Halfband Upsampling Filter 1 (HUF1) performs upsampling from Fs to Fsx2 (27 MHz in SD mode and 148.5 MHz or 148.5/1.001 MHz in HD mode). In SD mode, the HUF1 input is muxed to the LPU and chroma processing unit outputs and the HUF1 output is muxed to the SFC input, so the first upsampling is done before processing in the SFC.
- The Halfband Upsampling Filter 2 (HUF2) performs upsampling from Fsx2 to Fsx4 (54 MHz in SD mode and 297 MHz or 297/1.001 MHz in HD mode). The HUF2 may be bypassed in HD mode if the output sampling frequency is set to Fsx2 via the TVDAC_SAMP_RATE control parameter.
- The 3rd-order Interpolation Comb Filter (ICF) performs upsampling from Fsx4 to Fsx8 or Fsx16 in SD mode. The upsampling factor is controlled by the TVDAC_SAMP_RATE parameter. The ICF may be bypassed also in SD mode if the TVDAC_SAMP_RATE sets the output sampling frequency to 54 MHz.

In test mode, a test data is fed directly to the TVDAC (without upsampling) or through the UF.

The TSC is responsible for the following functions:

- Maintenance vertical and horizontal timing specified by the TV standards
- Generation of the synchronization signals, the color burst envelope, the active video data enable signal, the pedestal
- Control of the blanking level for each of three output channels

- Insertion of the Macrovision signal distortions
- Edge shaping for all generated signals
- Delays between the synchronization signals

The TSC is triggered by the VSYNC and HSYNC signals from the IPU. The TSC provides flexible control on horizontal timings in user mode than allows non-standard timing modes in addition to the standard configurations (including square pixel operation in SD mode). The MSG controls insertion of the Macrovision signal distortions in the TSC. The MSG gets all necessary triggers from the TSC and returns Macrovision controls to the TSC.

The VDG generates the following VBI control sequences:

- Closed Caption
- CGMS
- WSS

The VDG can be configured only to one of them at the moment because a common hardware is used for generation of all these sequences.

74.1.2 Operation in VGA Mode-Introduction

In VGA mode, the most of the processing is bypassed. The data is in the RGB888 format. It is synchronized by the IDS to the internal pixel clock. The IDS output is fed directly to the UF. To provide such data flow, the TVE should be configured to test mode with upsampling and the selected TV standard should be one of HD standards. The UF provides gain correction and upsampling by 2 or 4 depending on required display resolution. The gain should be 548/511=1.072 to provide 0.7V peak-to-peak amplitude on the TVDAC output. Required clock frequencies for some VGA modes are shown in Table 74-4.

Table 74-4. Some VGA Modes and Clock Frequencies

Display resolution	Frame rate, Hz	Pixel clock frequency, MHz	TVE_CLK frequency, MHz	Upsampling factor	TVDAC sampling frequency, MHz
VGA (640x480)	60	25.175	100.7	4	100.7
VGA (640x480)	75	31.5	126	4	126
SVGA (800x600)	60	40	160	4	160
SVGA (800x600)	75	49.5	198	4	198
XGA (1024x768)	60	65	260	4	260
XGA (1024x768)	75	78.8	157.6	2	157.6
WXGA (1368x768)	60	85.86	171.72	2	171.72

Table continues on the next page...

Table 74-4. Some VGA Modes and Clock Frequencies (continued)

Display resolution	Frame rate, Hz	Pixel clock frequency, MHz	TVE_CLK frequency, MHz	Upsampling factor	TVDAC sampling frequency, MHz
SXGA (1280x1024)	60	108	216	2	216
SXGA (1280x1024)	75	135	270	2	270
WSXGA (1440x900)	60	106.47	212.94	2	212.94
WSXGA+ (1680x1050)	60	147.14	294.28	2	294.28

74.1.3 Features

Common TVE features in both SD and HD modes are shown in Table 74-5.

Table 74-5. Common TVE Features in SD and HD Modes

Parameter	Value	Comments	TVEv1
Input data format	YCrCb 4:2:2 YCrCb 4:4:4	The IPU should support 24-bit/pixel parallel data output format	YCrCb 4:2:2
Input interface format and synchronization	Parallel interface with separate HSYNC and VSYNC	Two inputs from the IPU are available to allow transferring video data from one of two IPU display interfaces	Single input from the IPU
Input data resolution	8 bits/component		Same
Output data resolution	10 bits	-	Same
Output interface format	Parallel	-	Same
Non-standard horizontal timings support	Yes	Supported in user mode	No
Programmable adaptive Luma digital filter	Yes. The 5x5 adaptive filter is used for • horizontal and vertical sharpening • horizontal and vertical noise reduction • de-flickering in interlaced modes	The filter is fully programmable. The filter algorithm can be altered in user mode.	No
Programmable YCrCb to RGB color matrix	Yes	Five matrix coefficients are programmable. The can be also used for brightness, saturation and hue adjustment in user mode.	Fixed color matrix

Table continues on the next page...

Table 74-5. Common TVE Features in SD and HD Modes (continued)

Parameter	Value	Comments	TVEv1
Cable Detection functionality	Supported. It includes • separate cable connection monitoring separately for each TVDAC channel both during normal operation and in standby mode • automatic TVE power on when a TV cable has been connected • detection of connection type (composite, S-video, component) • detection of cable short to the ground	-	Same

Main parameters of the TVE in SD mode are given in Table 74-6.

Table 74-6. TVE Features in SD Mode

Parameter	Value	Comments	TVEv1
Supported color standards	PAL (B,D,G,H, I/M/N), NTSC	-	Same plus SECAM
Supported TV standards	480i (29.97Hz), 576i (25Hz)	-	Same
Input frame format	Interlaced if no inter-field filtering is performed. Progressive otherwise.	Inter-field filtering is used for vertical fine sharpening, vertical high-frequency noise reduction and de-flickering	Interlaced only
Input sampling frequency	If no inter-field filtering is performed: Y - 13.5 MHz Cb/Cr - 6.75 MHz for YCbCr 4:2:2 format, Cb/Cr - 13.5 MHz for YCbCr 4:4:4 format. If inter-field filtering is performed: Y - 27 MHz Cb/Cr - 13.5 MHz for YCbCr 4:2:2 format, Cb/Cr - 27 MHz for YCbCr 4:4:4 format.	-	Y - 13.5 MHz Cb/Cr - 6.75 MHz
Square pixel operation	Yes	Also other non-standard timings can be supported in user mode	No
Output data format	Composite (CVBS) or S-video (Y/C) or component (YPrPb or RGB)	Simultaneous output of two identical CVBS as well as CVBS and Y/C is possible	Same

Table continues on the next page...

Table 74-6. TVE Features in SD Mode (continued)

Parameter	Value	Comments	TVEv1
Output sampling frequency	216/108/54 MHz	Lower sampling frequencies should be used if the TVDAC performance degrades at high sampling frequencies	Same plus 27 MHz
Macrovision support	Yes. According to Macrovision 7.1	-	Same
Programmable chroma bandwidth	Yes. The possible bandwidth values are: • for YCbCr 4:2:2 input - 0.6, 1.3, 2 and 3 MHz • for YCbCr 4:4:4 input - 1.3, 2.7, 4 and 5.4 MHz	-	For composite and S-video output formats - 0.7, 1.0, 1.7 MHz For component output format - 1.8 MHz
Switchable pedestal	Yes	-	Same
Copy generation management system (CGMS) support	Yes. According to EIA-608b, IEC 61880-1, EIA-J CPR-1204-1	-	Same
Closed Caption support	Yes. According to EIA-608b	-	Same
Wide Screen Signaling (WSS) support	Yes. According to ITU-R BT.1119, ETSI EN 300 294.	-	Same
Luma notch filter	Yes	For better Luma/Chroma separation in composite mode	No
Chroma comb filter	Yes	For better Luma/Chroma separation in composite mode	No

Main parameters of the TVE in HD mode are given in Table 74-7.

Table 74-7. TVE Features in HD Mode

Parameter	Value	Comments
Supported HD TV standards	720p 60Hz 720p 50Hz 720p 30Hz 720p 25Hz 720p 24Hz 1080i 60Hz 1080i 50Hz 1035i 60Hz (1920x1035) 1080p 30Hz 1080p 25Hz 1080p 24Hz 1080p 50Hz 1080p60Hz	-
Input frame format	Interlaced for 1080i. Progressive otherwise.	No inter-field filtering is available for 1080i
Input sampling frequency	74.25 MHz -for 25/30/60Hz modes 74.176 MHz - for 29.97/59.94Hz modes	-
Output data format	Component (YCrCb or RGB)	-
Output sampling frequency	297 MHz -for 25/30/60Hz modes 296.704 MHz - for 29.97/59.94Hz modes	-
Programmable chroma bandwidth	Yes. The possible bandwidth values are: • for YCbCr 4:2:2 input - 3.3, 7.1, 11 and 16.5 MHz • for YCbCr 4:4:4 input - 6.7, 14.3, 22 and 29.7 MHz	-
Copy generation management system (CGMS) support	Yes. According to EIAJ CPR-1204-2 (CGMS) and CEA-805-A (CGMS type B)	-

Main parameters of the VGA mode are given in Table 74-8.

Table 74-8. TVE Features in VGA Mode

Parameter	Value	Comments
Input data format	RGB	The IPU should support 24-bit/ pixel parallel data output format
Input interface format and synchronization	Parallel interface	The TVE accepts video data only. The HSYNC and VSYNC are fed to the display directly from the IPU
Input color component resolution	8 bits/component	
Maximal screen resolution	Up to WSXGA+ (1680x1050 pixels)	
Output video signal format	RGB analog signals with separate HSYNC and VSYNC	

Table continues on the next page...

Table 74-8. TVE Features in VGA Mode (continued)

Parameter	Value	Comments
Output color component resolution	10 bits	
Output analog levels	0V - min., 0.7V max	
Maximal output signal bandwidth	Up to 150 MHz	
Maximal output sampling rate	Up to 300 MHz	
Output oversampling	2 or 4	

Main parameters of the TVDAC are given in Table 74-9.

Table 74-9. TVDAC Features

Parameter	Value	Comments
Video signal formats	Composite (CVBS) or S-Video (Y/C) or component (YPrPb or RGB)	-
Resolution	10 bits	-
Signal bandwidth	From 0 to 30 MHz	-
Sampling rate	From 54 to 300 MHz	-
Digital input	Parallel 10x3 bits in unsigned format	-
Output type	Single-end current output	-
Output drive characteristics	Full drive - double-terminated 75 Ohm load (equivalent to 37.5 Ohm) Low drive - 100 Ohm load	Drive with standard output video levels
Output Drive Range	Controllable full-scale current	Controlled by an external resistor
Channel enable control	Separate for each channel and common control enabling the voltage reference	-
Voltage reference	Build-in bandgap reference	-
Maximal gain mismatch	2%	Between any DAC
Maximal Integral Nonlinearity (INL)	+/-2 LSB	-
Maximal Differential Nonlinearity (DNL)	+/-1 LSB	-
Spurious-free Dynamic Range	> 50 dBc @ F=15 MHz, Fs=300 MHz	-
Power Supplies	Analog - 2.5-2.75 V, Digital - 1.2 V	-

74.1.4 Modes of Operation

74.1.4.1 Operation in TV Mode

In Normal Operation Mode, the TVE converts the input YCrCb 4:2:2 or 4:4:4 video stream to an analog TV signal. The TVE is in Normal Operation Mode, if the TV_OUT_MODE control parameter is in the range from 1 to 7 (see Table 74-3). This parameter also specifies the output TV signal type. During Normal Operation Mode, inactive TVDAC and UF channels, which outputs should be 0 according to Table 74-3, are disabled to save power.

The TV standard supported is specified by the TV_STAND control parameter as described in Table 74-10.

Table 74-10. TV_STAND Parameter

TV_STAND	Standard
0000	SD NTSC
0001	SD PALM
0010	SD Combination PALN
0011	SD PAL (B,D,G,H,I)
0100	HD 720p60
0101	HD 720p50
0110	HD 720p30
0111	HD 720p25
1000	HD 720p24
1001	HD 1080i60
1010	HD 1080i50
1011	HD 1035i60 (1920x1035)
1100	HD 1080p30
1101	HD 1080p25
1110	HD 1080p24
1111	Reserved

For the TV_STAND values corresponding to HD modes, only the YPbPr and RGB output formats are valid. For SD modes, the input data from the IPU can be in interlaced or progressive formats.

To provide HD 1080p50 and HD 1080p60 modes the following programming should be used:

- The TVDAC_SAMP_RATE should be set to 1 (the oversampling factor is x2).

- The TVE_CLK frequency should be 297 MHz or 297/0.001 MHz and the VIDEO_DATA_CLK frequency should be 148.5 MHz or 148.5/0.001 MHz.
- The rest of control registers should be configured as for HD 1080p25 and HD 1080p30 modes.

74.1.4.2 Operation in VGA Mode

In VGA mode, the most of the processing is bypassed. The data is in the RGB888 format. It is synchronized by the IDS to the internal pixel clock. The IDS output is fed directly to the UF. To provide such data flow, the TVE should be configured to test mode with upsampling and the selected TV standard should be one of HD standards. The UF provides gain correction and upsampling by 2 or 4 depending on required display resolution. The gain should be 548/511=1.072 to provide 0.7V peak-to-peak amplitude on the TVDAC output. Required clock frequencies for some VGA modes are shown in Table 74-4.

Table 74-11. Some VGA Modes and Clock Frequencies

Display resolution	Frame rate, Hz	Pixel clock frequency, MHz	TVE_CLK frequency, MHz	Upsampling factor	TVDAC sampling frequency, MHz
VGA (640x480)	60	25.175	100.7	4	100.7
VGA (640x480)	75	31.5	126	4	126
SVGA (800x600)	60	40	160	4	160
SVGA (800x600)	75	49.5	198	4	198
XGA (1024x768)	60	65	260	4	260
XGA (1024x768)	75	78.8	157.6	2	157.6
WXGA (1368x768)	60	85.86	171.72	2	171.72
SXGA (1280x1024)	60	108	216	2	216
SXGA (1280x1024)	75	135	270	2	270
WSXGA (1440x900)	60	106.47	212.94	2	212.94
WSXGA+ (1680x1050)	60	147.14	294.28	2	294.28

74.1.4.3 Standby Mode

The TVE is in Standby Mode, if the TV_OUT_MODE control parameter is 0. In this case, the most of internally generated clocks are gated off and internal resets are generated for the TVE sub-blocks. The TVDAC is disabled. If the CD is enabled, the UF, the CDC and the TVDAC are periodically turned on for a short time to monitor cable connection.

74.1.4.4 Cable Detection Modes

The CD operation is supported with both hardware and software involvement. Different types of the TV connection are distinguished by a number of cable lines connected to the TV output. If one or several cable lines are connected, the equivalent load impedance for these outputs is close to 37.5 Ohm and the voltage on them matches the nominal video levels. If no cable is connected, the load impedance is elevated to 75 Ohm. In this case, the output voltage is higher than the nominal video levels.

An additional feature of the CD system is detection of output line short to the ground. The short may appear if a headphone jack is plugged into the A/V connector and shorts the CVBS output to the ground.

Some natural limitations exist for CD operation. It is impossible to differentiate the mixed CVBS/S-video, the component YPrPb and the component RGB connections because in all these three cases a three-wire cable is used. So for these cases the software should set a default option or allow user choosing the interface type.

The CD is supported in both full-drive output mode (when the TV cable is connected directly to the TVDAC outputs) and low-drive output mode (when the TVDAC drives a high-resistance load and a buffer/filter is located between the TVDAC output and the TV connector). In both cases, three monitoring input pins should be connected on a board directly to the cable plug.

There are three CD modes:

1. Monitoring the current cable connection when the TVE is in Normal Operation Mode. The mode is enabled if TV_OUT_MODE is not 000 and the CD_TRIG_MODE is 0.
2. Periodical automatic pending the cable connection when the TVE is in Standby Mode. The mode is enabled if TV_OUT_MODE is 000 and the CD_TRIG_MODE is 0.
3. Checking the cable connection 'on demand' (on the trigger control generated by software). The mode is enabled if the CD_TRIG_MODE is 1.

In modes 1 and 2, the CDCU periodically initiates monitoring the output voltage. In mode 3, the ARM platform should set the CD_MAN_TRIG bit.

The CDC measures the voltage in two steps. At the first step, cable connection is checked. The voltage comparison results obtained at the first step are compared with the current TV output mode specified by the TV_OUT_MODE parameter. If the results do

not match the current output mode, an interrupt to the ARM platform is generated. At the second step, output short to ground is checked. If short has been detected, an interrupt to the ARM platform is generated.

The software is able to control for which output channels cable connection and/or output short should be checked. The CD_CH_#_LM_EN and CD_CH_#_SM_EN control bits are used for this. If an output load for one of the channels for which the CD_CH_#_LM_EN=1 is different from the value defined the TV_OUT_MODE, the load monitoring interrupt status bit (CD_LM_INT) is set and the corresponding interrupt is generated. If the output of one of the channels for which the CD_CH_#_SM_EN=1 is shorted to the ground, the short monitoring interrupt status bit (CD_SM_INT) is set and the corresponding interrupt is generated.

In the first CD mode, the monitoring period is a multiple of a TV field duration (for SD mode) or a TV frame duration (for HD mode). It is specified by the CD_MON_PER control parameter. The measurement is performed during the first half-line of the pre-equalization pulse in the vertical blanking period.

In the second CD mode, the monitoring period is a multiple of 0.31 sec. It is also specified by the CD_MON_PER control parameter. For output monitoring, the CDCU enables the monitored channels for a measurement time and forces its input to the desired value.

The reference voltage level used for comparison in the CDC can be equal to the Luma blanking level (about 320 mV) or to the Chroma blanking level (about 670 mV). The specific values of the reference levels depend on the CD_REF_MODE and the CD_CH_2_REF_LVL and the current TV output mode specified by the TV_OUT_MODE parameter. Table 74-12 shows the CD reference levels depending on these control parameters.

Table 74-12. CD Reference Level

Output channel	CD_REF_MODE	CD Reference Level[1] (TV_OUT_MODE)							
		Composite (CVBS)				S-video (Y/C)	CVBS and Y/C	YCrCb component	RGB component
		(0)	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Channel #0	0	CD_CH_0_REF_LVL	0	CD_CH_0_REF_LVL	0	0	0	0	0
	1	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL	CD_CH_0_REF_LVL

Table continues on the next page...

Table 74-12. CD Reference Level (continued)

Output channel	CD_REF_MODE	CD Reference Level[1] (TV_OUT_MODE)							
		Composite (CVBS)				S-video (Y/C)	CVBS and Y/C	YCrCb component	RGB component
		(0)	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Channel #1	0	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	1	1	CD_CH_1_REF_LVL	0
	1	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL	CD_CH_1_REF_LVL
Channel #2	0	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	0	0	CD_CH_2_REF_LVL	0	CD_CH_2_REF_LVL	0
	1	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL	CD_CH_2_REF_LVL

1. Luma Reference Level is 0, Chroma Reference Level is 1

74.2 External Signal Description

74.2.1 Detailed Signal Descriptions

The MMT pins are described in Table 74-13.

Table 74-13. Detailed Signal Descriptions

Signal	I/O	Description	
Clocks and resets			
tve_clk	I	High speed clock input	
		State Meaning	Asserted/Negated-Samples TVE flip-flops on positive edge
		Timing	Assertion/Negation - According to the required operation frequency. The allowed frequencies for SD are 216, 108, 54 MHz, for HD - 297 (297/1.001), 148.5 (148.5/1.001) MHz
ipg_clk_s	I	IPI SOC Sideband Bus gated clock for IP bus	
		State Meaning	According to the IP Bus protocol
		Timing	According to the IP Bus protocol. May be asynchronous with the tve_clk clock

Table continues on the next page...

Table 74-13. Detailed Signal Descriptions (continued)

Signal	I/O	Description	
fsx_ipu_clk	O	Internally generated clock fed to the IPU	
		State Meaning	Used for sampling of the output data interface in the IPU
		Timing	Derived by division of the TVE_CLK clock. Edge-synchronized with TVE_CLK
ipg_hard_async_reset_b	I	System HW reset	
		State Meaning	According to the IP Bus protocol
		Timing	According to the IP Bus protocol
ipg_soft_reset_b	I	System SW reset	
		State Meaning	According to the IP Bus protocol
		Timing	According to the IP Bus protocol
Input Data Interface			
video_data_clk_1	I	Clocking signal for input video data bus 1 from the IPU	
		State Meaning	Negative edge - Indicates that the IPU has updated the video_data_in_1 bus Positive edge - Indicates that the TVE can sample the video_data_in_1 bus
		Timing	The clock frequency is 13.5 MHz or 27 MHz in functional SD mode, 74.25 (74.25/1.001) MHz in functional HD mode. The clock frequency is 27 MHz (SD) and 74.25 (74.25/1.001) MHz (HD) in TVDAC test modes. The clock may be asynchronous with the TVE_CLK but the phase jitter between this clock and the clock generated in the TVE must be less than a half of video_data_clk cycle.
video_data_in_1[29:0]	I	Video data input bus 1 from the IPU	
		State Meaning	In functional mode - video_data_in_1[7:0]: Y video_data_in_1[15:8]: Cr video_data_in_1[23:16]: Cb video_data_in_1[29:24]: unused In TVDAC test modes 1 and 3 - video_data_in_1[9:0]: test data for TVDAC channel #0 video_data_in_1[19:10]: test data for TVDAC channel #1 video_data_in_1[29:20]: test data for TVDAC channel #2 In TVDAC test modes 2 and 4 - video_data_in_1[9:0]: test data for TVDAC channels #0 - #2 video_data_in_1[29:10]: unused
		Timing	The bus is sampled by negative edges of the video_data_clk_1 clock
video_data_en_1	I	Enable signal for input video data bus 1 from the IPU. In TVDAC test modes, the signal is unused.	
		State Meaning	Asserted-Indicates valid input video data on the bus 1 Negated- Indicates no valid input video data on the bus 1
		Timing	Assertion/Negation - Synchronized to negative edges of the video_data_clk_1 clock.

Table continues on the next page...

Table 74-13. Detailed Signal Descriptions (continued)

Signal	I/O	Description	
vsync_1	I	Vertical synchronization signal for input video data bus 1 from the IPU. In TVDAC test modes, the signal is unused.	
		State Meaning	Asserted-Indicates video frame start Negated- Indicates no video frame start
		Timing	Assertion/Negation- Synchronized to negative edges of the video_data_clk_1 clock. Remains asserted for one clock cycle
hsync_1	I	Horizontal synchronization signal for input video data bus 1 from the IPU. In TVDAC test modes, the signal is unused.	
		State Meaning	Asserted-Indicates video line start Negated- Indicates no video line start
		Timing	Assertion/Negation - Synchronized to negative edges of the video_data_clk_1 clock. Remains asserted for one clock cycle
video_data_clk_2	I	Clocking signal for input video data bus 2 from the IPU	
		State Meaning	Negative edge - Indicates that the IPU has updated the video_data_in_2 bus Positive edge - Indicates that the TVE can sample the video_data_in_2 bus
		Timing	The clock frequency is 13.5 MHz or 27 MHz in functional SD mode, 74.25 (74.25/1.001) MHz in functional HD mode. The clock frequency is 27 MHz (SD) and 74.25 (74.25/1.001) MHz (HD) in TVDAC test modes. The clock may be asynchronous with the TVE_CLK but the phase jitter between this clock and the clock generated in the TVE must be less than a half of video_data_clk cycle.
video_data_in_2[29:0]	I	Video data input bus 2 from the IPU	
		State Meaning	In functional TV encoding mode - video_data_in_2[7:0]: Y video_data_in_2[15:8]: Cr video_data_in_2[23:16]: Cb video_data_in_2[29:24]: unused In VGA mode - video_data_in_2[0]: ground video_data_in_2[8:1]: G video_data_in_2[10:9]: ground video_data_in_2[18:11]: R video_data_in_2[20:19]: ground video_data_in_2[28:21]: B video_data_in_2[29]: ground In TVDAC test modes 1 and 3 - video_data_in_2[9:0]: test data for TVDAC channel #0 video_data_in_2[19:10]: test data for TVDAC channel #1 video_data_in_2[29:20]: test data for TVDAC channel #2 In TVDAC test modes 2 and 4 - video_data_in_2[9:0]: test data for TVDAC channels #0 - #2 video_data_in_2[29:10]: unused
		Timing	The bus is sampled by negative edges of the video_data_clk_2 clock

Table continues on the next page...

Table 74-13. Detailed Signal Descriptions (continued)

Signal	I/O	Description	
video_data_en_2	I	Enable signal for input video data bus 2 from the IPU. In VGA mode and TVDAC test modes, the signal is unused.	
		State Meaning	Asserted-Indicates valid input video data on the bus 2 Negated- Indicates no valid input video data on the bus 2
		Timing	Assertion/Negation - Synchronized to negative edges of the video_data_clk_2 clock.
vsync_2	I	Vertical synchronization signal for input video data bus 2 from the IPU. In VGA mode and TVDAC test modes, the signal is unused.	
		State Meaning	Asserted-Indicates video frame start Negated- Indicates no video frame start
		Timing	Assertion/Negation- Synchronized to negative edges of the video_data_clk_2 clock. Remains asserted for one clock cycle
hsync_2	I	Horizontal synchronization signal for input video data bus 2 from the IPU. In VGA mode and TVDAC test modes, the signal is unused.	
		State Meaning	Asserted-Indicates video line start Negated- Indicates no video line start
		Timing	Assertion/Negation - Synchronized to negative edges of the video_data_clk_2 clock. Remains asserted for one clock cycle
External Test Data Interface			
IPP_IND_TEST_DATA_CLK	I	Clocking signal for input data from the external test bus	
		State Meaning	Negative edge - Indicates that an external source has updated the IPP_IND_TEST_DATA_IN bus Positive edge - Indicates that the TVE can sample the IPP_IND_TEST_DATA_IN bus
		Timing	The clock frequency is 13.5 or 27 MHz (SD) and 74.25 (74.25/1.001) MHz (HD) in TVE test mode. The clock frequency is 27-MHz (SD) and 74.25 (74.25/1.001) MHz (HD) in TVDAC test modes. The clock may be asynchronous with the TVE_CLK but the phase jitter between this clock and the clock generated in the TVE must be less than a half the clock cycle.

Table 74-13. Detailed Signal Descriptions (continued)

Signal	I/O	Description	
IPP_IND_TEST_DATA_IN[29:0]	I	Test data input from an external source	
		State Meaning	In TVE test mode - IPP_IND_TEST_DATA_IN[7:0]: Y IPP_IND_TEST_DATA_IN[15:8]: Cr IPP_IND_TEST_DATA_IN[23:16]: Cb IPP_IND_TEST_DATA_IN[24]: data enable IPP_IND_TEST_DATA_IN[25]: hsync IPP_IND_TEST_DATA_IN[26]: vsync IPP_IND_TEST_DATA_IN[29:27]: unused In TVDAC test modes 1 and 3 - IPP_IND_TEST_DATA_IN[9:0]: test data for TVDAC channel #0 IPP_IND_TEST_DATA_IN[19:10]: test data for TVDAC channel #1 IPP_IND_TEST_DATA_IN[29:20]: test data for TVDAC channel #2 In TVDAC test modes 2 and 4 - IPP_IND_TEST_DATA_IN[9:0]: test data for TVDAC channels #0 - #2 IPP_IND_TEST_DATA_IN[29:10]: unused
		Timing	The bus is sampled by negative edges of the IPP_IND_TEST_DATA_CLK clock
IPP_IBE_TEST_DATA_IN	O	Test data bus and clock pins direction control	
		State Meaning	Asserted - Indicates that the test data bus and clock pins direction should be set for test data input from an external source (the external test data is used) Negated - Indicates that the test data bus and clock pins direction should be set according to alternate functions of these pins (the external test data is unused)
		Timing	The signal is sampled by positive edges of the TVE clock
Output Analog Interface and Other Analog Pins			
IPP_ANALOGIO_TVCDC_IOG_BACK	I	Cable detection channel #0 (green) input	
		State Meaning	Voltage range is according to TVDAC specifications
		Timing	na
IPP_ANALOGIO_TVCDC_IOR_BACK	I	Cable detection channel #1 (red) input	
		State Meaning	Voltage range is according to TVDAC specifications
		Timing	na
IPP_ANALOGIO_TVCDC_IOB_BACK	I	Cable detection channel #2 (blue) input	
		State Meaning	Voltage range is according to TVDAC specifications
		Timing	na
IPP_ANALOGIO_TVDAC_VREFIN	I	Reference voltage input	
		State Meaning	Voltage range is according to TVDAC specifications
		Timing	na

IPP_POWER_TVCDC_HVSS	na	Cable detection circuit analog ground	
		State Meaning	na
		Timing	na
IP Interrupt Bus Interface			

Table continues on the next page...

Table 74-13. Detailed Signal Descriptions (continued)

Signal	I/O	Description	
ipi_tve_int	O	Interrupt request	
		State Meaning	Asserted-Indicates TVE interrupt request to the ARM platform. Negated-Indicates no TVE interrupt request to the ARM platform.
		Timing	Assertion-Synchronized to S27_CLK. Remains asserted until the ARM platform will clear the corresponding status bit (according to the IP Bus protocol protocol) Negation- Synchronized to S27_CLK.
Miscellaneous Signals			
via_tvdac_clk_pol	I	TVDAC clock polarity	
		State Meaning	Asserted- Indicates that the TVDAC clock polarity is opposite to the tve_clk polarity. Negated- Indicates that the TVDAC clock polarity is equal to the tve_clk polarity.
		Timing	Assertion/Negation- Static signal assigned by TVE integration into SoC.
via_tvdac_en_pol	I	TVDAC global and channels enable signals polarity	
		State Meaning	Asserted- Indicates that the TVDAC enabling signals are active high. Negated- Indicates that the TVDAC enabling signals are active low.
		Timing	Assertion/Negation- Static signal assigned by TVE integration into SoC.

74.2.2 Interface between the IPU and the TVE

The timing diagrams of the interface signals between the IPU and the TVE are shown in Figure 74-5 and Figure 74-6.

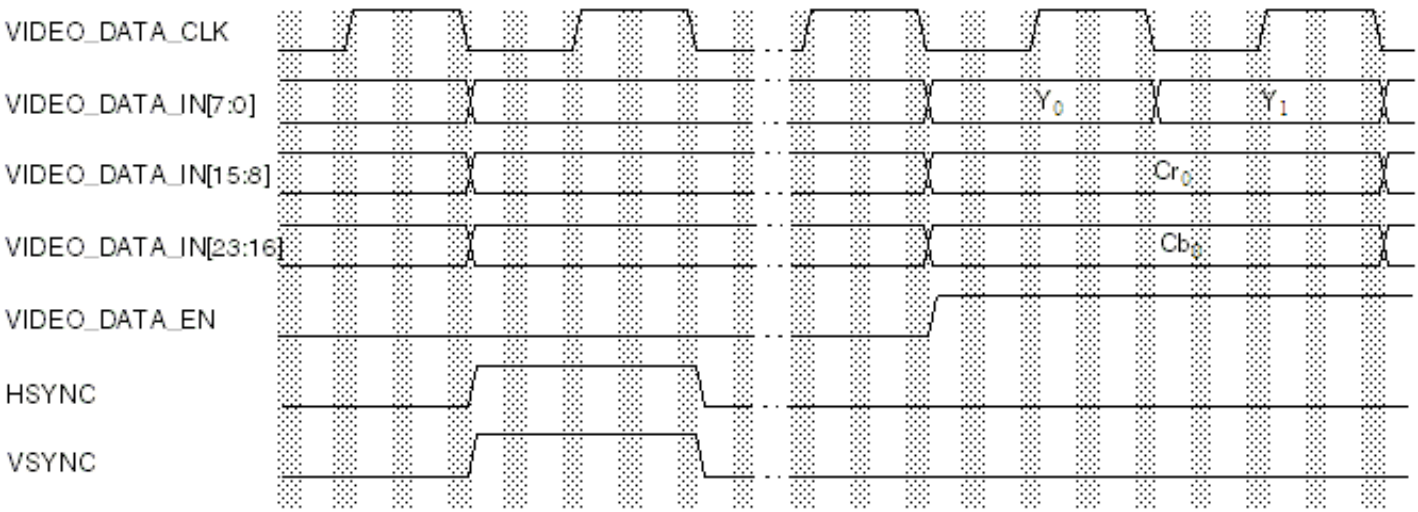

Figure 74-5. Interface between the IPU and the TVE for YCbCr 4:2:2 Input Format

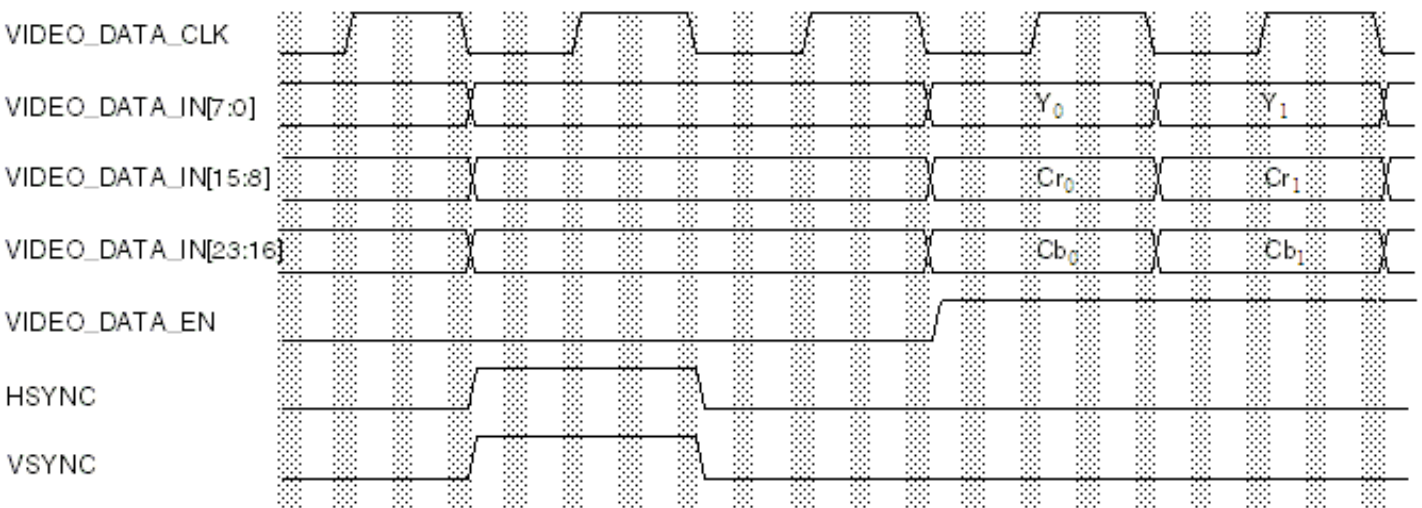

Figure 74-6. Interface between the IPU and the TVE for YCbCr 4:4:4 Input Format

74.2.3 Software Recommendations

74.2.3.1 PLL configuration

In order to obtain the best TV signal quality, the reference clock phase jitter should be minimized. For this purpose the PLL producing the TVE_CLK clock (the DPLLC4 in iMX53) should be configured with pre-divider factor of 1.

74.2.3.2 HSYNC and VSYNC in VGA Mode

GPIO pads driving the HSYNC and VSYNC signals in VGA mode should be configured for maximal driving strength.

74.3 Programmable Registers

Table continues on the next page...

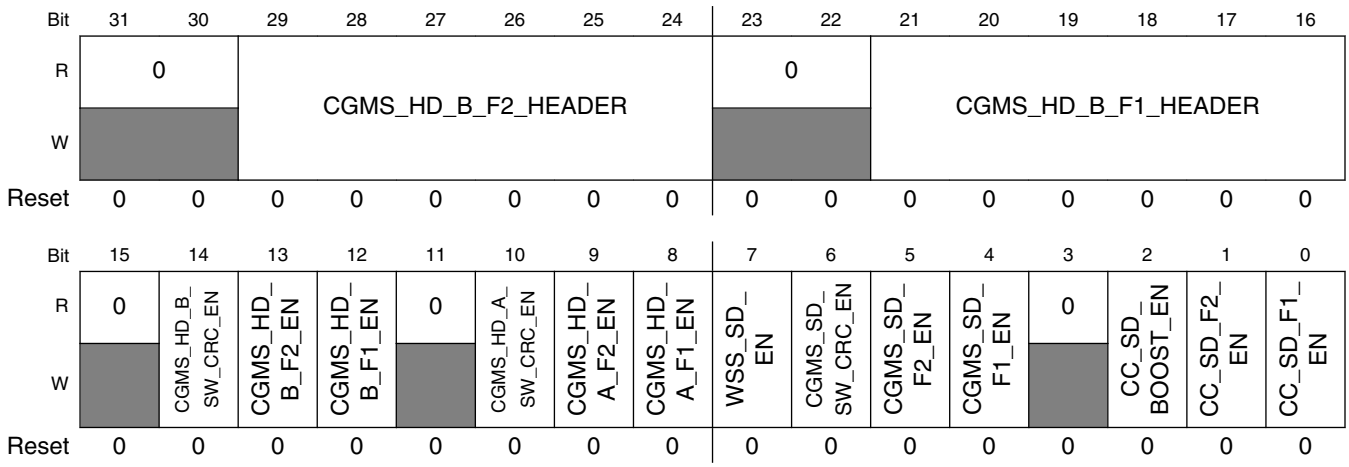
TVE_CD_CONT_REG field descriptions (continued)

Field	Description
	0 Disable 1 Enable
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved.
11 CD_REF_MODE	CD reference mode. Specifies how the reference voltage level for CD comparators is set for active TVDAC channels. The bit is ignored for inactive channels or in standby mode (manual mode assumed). The bit is also ignored for channels# 1 and #2 in YPrPb mode (TV_OUT_MODE=110). 0 Automatic mode when the reference voltage is set according to the channel signal type defined by the TV_OUT_MODE 1 Manual mode when the reference voltage is set according to the CD_CH_#_REF_LVL
10 CD_CH_2_REF_LVL	CD reference level for TVDAC channel #2. Specified the expected level of the channel output voltage when the output is loaded by nominal 37.5-Ohm impedance. This bit is ignored if the channel is active and CD_REF_MODE is 0 excluding YPrPb mode (TV_OUT_MODE=110). 0 The reference level corresponds to the Luma blanking level 1 The reference level corresponds to the Chroma blanking level
9 CD_CH_1_REF_LVL	CD reference level for TVDAC channel #1. Specified the expected level of the channel output voltage when the output is loaded by nominal 37.5-Ohm impedance. This bit is ignored if the channel is active and CD_REF_MODE is 0 excluding YPrPb mode (TV_OUT_MODE=110). 0 The reference level corresponds to the Luma blanking level 1 The reference level corresponds to the Chroma blanking level
8 CD_CH_0_REF_LVL	CD reference level for TVDAC channel #0. Specified the expected level of the channel output voltage when the output is loaded by nominal 37.5-Ohm impedance. This bit is ignored if the channel is active and CD_REF_MODE is 0. 0 The reference level corresponds to the Luma blanking level 1 The reference level corresponds to the Chroma blanking level
7–4 CD_MON_PER	Cable detection monitoring period. If TV_OUT_MODE is not 000 (during normal operation), specified in TV fields for SD or in TV frames for HD. If TV_OUT_MODE is 000 (standby mode), specified in 0.31-sec units. 0000 1 field (SD) or 1 frame (HD) for normal operation or 0.31 sec for standby mode 0001 2 fields (SD) or 2 frames (HD) for normal operation or 0.62 sec for standby mode 1111 16 fields (SD) or 16 frames (HD) for normal operation or 4.96 sec for standby mode
3–2 Reserved	This read-only field is reserved and always has the value zero. Reserved.
1 CD_TRIG_MODE	CD trigger mode. 0 Automatic (periodical) trigger 1 Manual (single shot) trigger
0 CD_EN	Enable cable detection. When low, resets the CD Control Unit and the CD Circuit. 0 Disable 1 Enable

74.3.15 VBI Data Control Register (TVE_VBI_DATA_CONT_REG)

Address: TVE_VBI_DATA_CONT_REG is 63FF_0000h base + 38h offset = 63FF_0038h



TVE_VBI_DATA_CONT_REG field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved.
29–24 CGMS_HD_B_F2_HEADER	HD CGMS Type B header for field 2.
23–22 Reserved	This read-only field is reserved and always has the value zero. Reserved.
21–16 CGMS_HD_B_F1_HEADER	HD CGMS Type B header for field 1.
15 Reserved	This read-only field is reserved and always has the value zero. Reserved.
14 CGMS_HD_B_SW_CRC_EN	Enable HD CGMS Type B CRC value calculated by software. Otherwise the CRC value is calculated by hardware. 0 Disable 1 Enable
13 CGMS_HD_B_F2_EN	Enable HD CGMS Type B data insertion for field 2. 0 Disable 1 Enable
12 CGMS_HD_B_F1_EN	Enable HD CGMS Type B data insertion for field 1. 0 Disable 1 Enable
11 Reserved	This read-only field is reserved and always has the value zero. Reserved.

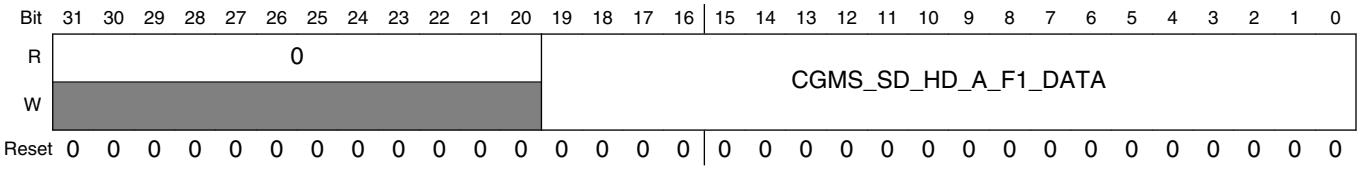
Table continues on the next page...

TVE_VBI_DATA_CONT_REG field descriptions (continued)

Field	Description
10 CGMS_HD_A_SW_CRC_EN	Enable HD CGMS Type A CRC value calculated by software. Otherwise the CRC value is calculated by hardware. 0 Disable 1 Enable
9 CGMS_HD_A_F2_EN	Enable HD CGMS Type A data insertion for field 2. 0 Disable 1 Enable
8 CGMS_HD_A_F1_EN	Enable HD CGMS Type A data insertion for field 1. 0 Disable 1 Enable
7 WSS_SD_EN	Enable SD WSS data insertion. 0 Disable 1 Enable
6 CGMS_SD_SW_CRC_EN	Enable SD CGMS CRC value calculated by software. Otherwise the CRC value is calculated by hardware. 0 Disable 1 Enable
5 CGMS_SD_F2_EN	Enable SD CGMS data insertion for field 2. 0 Disable 1 Enable
4 CGMS_SD_F1_EN	Enable SD CGMS data insertion for field 1. 0 Disable 1 Enable
3 Reserved	This read-only field is reserved and always has the value zero. Reserved.
2 CC_SD_BOOST_EN	Enable SD closed caption level boost by a factor of 1.7. May be used in RGB TV output mode. 0 Disable 1 Enable
1 CC_SD_F2_EN	Enable SD closed caption data insertion for field 2. 0 Disable 1 Enable
0 CC_SD_F1_EN	Enable SD closed caption data insertion for field 1. 0 Disable 1 Enable

74.3.16 VBI Data Register 0 (TVE_VBI_DATA_REG_0)

Address: TVE_VBI_DATA_REG_0 is 63FF_0000h base + 3Ch offset = 63FF_003Ch

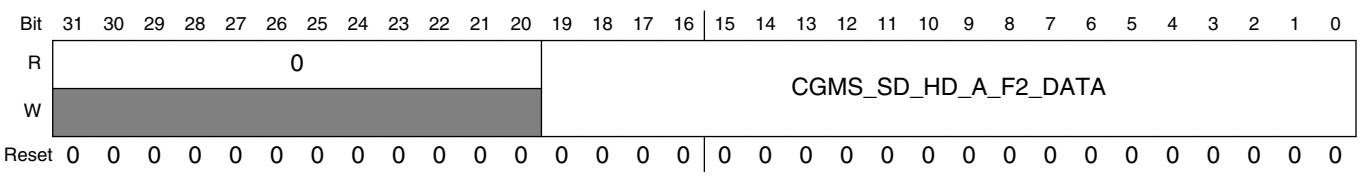


TVE_VBI_DATA_REG_0 field descriptions

Field	Description
31–20 Reserved	This read-only field is reserved and always has the value zero. Reserved.
19–0 CGMS_SD_HD_A_F1_DATA	CGMS data (in SD mode) or CGMS Type A data (in HD mode) for field 1.

74.3.17 VBI Data Register 1 (TVE_VBI_DATA_REG_1)

Address: TVE_VBI_DATA_REG_1 is 63FF_0000h base + 40h offset = 63FF_0040h



TVE_VBI_DATA_REG_1 field descriptions

Field	Description
31–20 Reserved	This read-only field is reserved and always has the value zero. Reserved.
19–0 CGMS_SD_HD_A_F2_DATA	CGMS data (in SD mode) or CGMS Type A data (in HD mode) for field 2.

74.3.18 VBI Data Register 2 (TVE_VBI_DATA_REG_2)

Address: TVE_VBI_DATA_REG_2 is 63FF_0000h base + 44h offset = 63FF_0044h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

TVE_STAT_REG field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value zero. Reserved.
25 BG_READY	Status bit of bandgap reference of the TVDAC. The ready time is set by the BG_RDY_TIME parameter. 0 Bandgap reference is not ready. 1 Bandgap reference is ready
24 CD_MAN_TRIG	Control/status bit for manual (single shot) trigger of CD monitors. Set by the ARM platform, cleared by the TVE. Has no effect if CD_TRIG_MODE is 0. This bit can be set only if CD_EN=1. 0 No CD trigger 1 Trigger CD
23 Reserved	This read-only field is reserved and always has the value zero. Reserved.
22 CD_CH_2_SM_ST	Status bit of TVDAC channel #2 short monitoring by CD. Valid only if CD_CH_2_SM_EN is set. 0 Short detected 1 No short detected
21 CD_CH_1_SM_ST	Status bit of TVDAC channel #1 short monitoring by CD. Valid only if CD_CH_1_SM_EN is set.

Table continues on the next page...

TVE_STAT_REG field descriptions (continued)

Field	Description
	0 Short detected 1 No short detected
20 CD_CH_0_SM_ST	Status bit of TVDAC channel #0 short monitoring by CD. Valid only if CD_CH_0_SM_EN is set. 0 Short detected 1 No short detected
19 Reserved	This read-only field is reserved and always has the value zero. Reserved.
18 CD_CH_2_LM_ST	Status bit of TVDAC channel #2 load impedance monitoring by CD. Valid only if CD_CH_2_LM_EN is set. 0 Cable detected 1 No cable detected
17 CD_CH_1_LM_ST	Status bit of TVDAC channel #1 load impedance monitoring by CD. Valid only if CD_CH_1_LM_EN is set. 0 Cable detected 1 No cable detected
16 CD_CH_0_LM_ST	Status bit of TVDAC channel #0 load impedance monitoring by CD. Valid only if CD_CH_0_LM_EN is set. 0 Cable detected 1 No cable detected
15 Reserved	This read-only field is reserved and always has the value zero. Reserved.
14 SA_MEAS_END_INT	Status bit of the Luma statistic measurement end interrupt. 0 No statistic measurement end event has occurred 1 Statistic measurement end event has occurred
13 TVE_FRAME_END_INT	Status bit of the end-of-frame interrupt. 0 No end-of-frame event has occurred 1 End-of-frame event has occurred
12 TVE_FIELD_END_INT	Status bit of the end-of-field interrupt. 0 No end-of-field event has occurred 1 End-of-field event has occurred
11 CGMS_HD_B_F2_DONE_IEN	Status bit of the HD CGMS Type B done interrupt for field 2. 0 No HD CGMS Type B done 1 HD CGMS Type B done
10 CGMS_HD_B_F1_DONE_IEN	Status bit of the HD CGMS Type B done interrupt for field 1. 0 No HD CGMS Type B done 1 HD CGMS Type B done
9 CGMS_HD_A_F2_DONE_IEN	Status bit of the HD CGMS Type A done interrupt for field 2. 0 No HD CGMS Type B done 1 HD CGMS Type B done

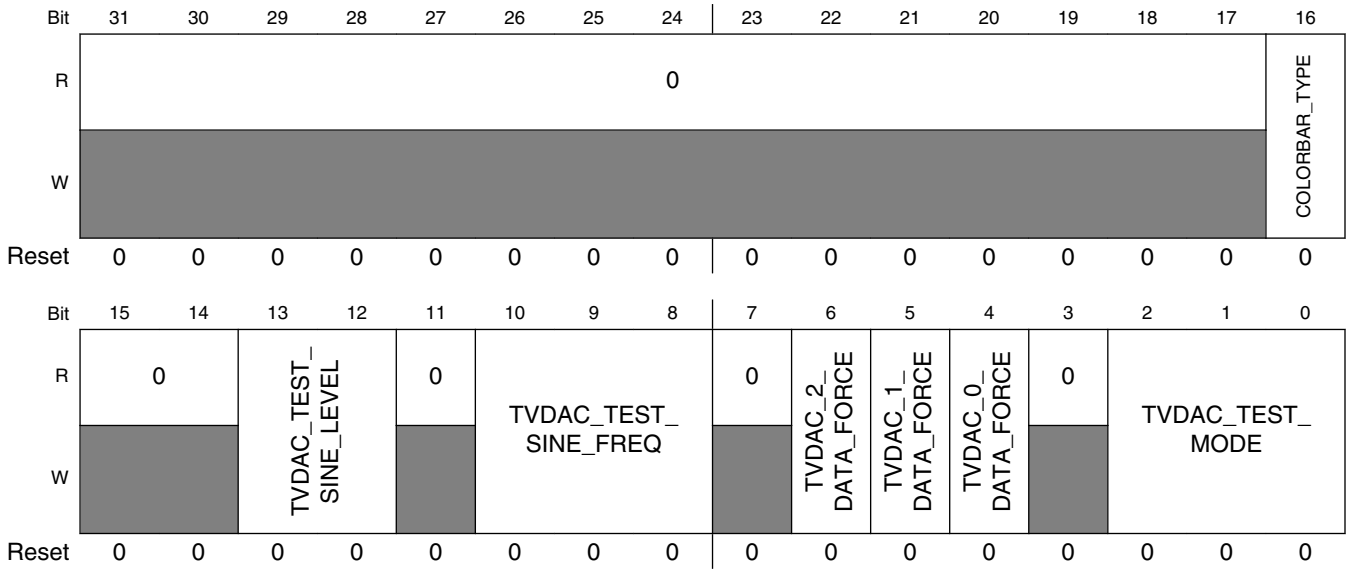
Table continues on the next page...

TVE_STAT_REG field descriptions (continued)

Field	Description
8 CGMS_HD_A_F1_DONE_IEN	Status bit of the HD CGMS Type A done interrupt for field 1. 0 No HD CGMS Type B done 1 HD CGMS Type B done
7 WSS_SD_DONE_IEN	Status bit of the SD WSS done interrupt. 0 No SD WSS done 1 SD WSS done
6 CGMS_SD_F2_DONE_IEN	Status bit of the SD CGMS done interrupt for field 2. 0 No SD CGMS done 1 SD CGMS done
5 CGMS_SD_F1_DONE_IEN	Status bit of the SD CGMS done interrupt for field 1. 0 No SD CGMS done 1 SD CGMS done
4 CC_SD_F2_DONE_IEN	Status bit of the SD Closed Caption done interrupt for field 2. 0 No SD Closed Caption done 1 SD Closed Caption done
3 CC_SD_F1_DONE_IEN	Status bit of the SD Closed Caption done interrupt for field 1. 0 No SD Closed Caption done 1 SD Closed Caption done
2 CD_MON_END_INT	Status bit of the end-of-monitoring interrupt by CD. 0 No end-of-monitoring event has occurred 1 End-of-monitoring event has occurred
1 CD_SM_INT	Status bit of the short monitoring interrupt by CD. 0 No short detected 1 Short detected
0 CD_LM_INT	Status bit of the load impedance monitoring interrupt by CD. 0 No mismatch between current output mode and real output load configuration 1 Current output mode does not match real output load configuration

74.3.28 Test Mode Register (TVE_TST_MODE_REG)

Address: TVE_TST_MODE_REG is 63FF_0000h base + 6Ch offset = 63FF_006Ch



TVE_TST_MODE_REG field descriptions

Field	Description
31–17 Reserved	This read-only field is reserved and always has the value zero. Reserved.
16 COLORBAR_TYPE	Select the type of internally generated color bar. 0 100% 1 75%
15–14 Reserved	This read-only field is reserved and always has the value zero. Reserved.
13–12 TVDAC_TEST_SINE_LEVEL	Select level of internally generated sine wave pattern. 00 Sine wave swing is 100% of TVDAC full scale (from 1 to 1023) 01 Sine wave swing is 75% of TVDAC full scale 10 Sine wave swing is 50% of TVDAC full scale 11 Sine wave swing is 25% of TVDAC full scale
11 Reserved	This read-only field is reserved and always has the value zero. Reserved.
10–8 TVDAC_TEST_SINE_FREQ	Select frequency of internally generated sine wave pattern. Defined ratio (division factor) between the TVDAC sampling frequency and the test sine wave frequency. 000 8 001 16 010 32 011 64 100 128

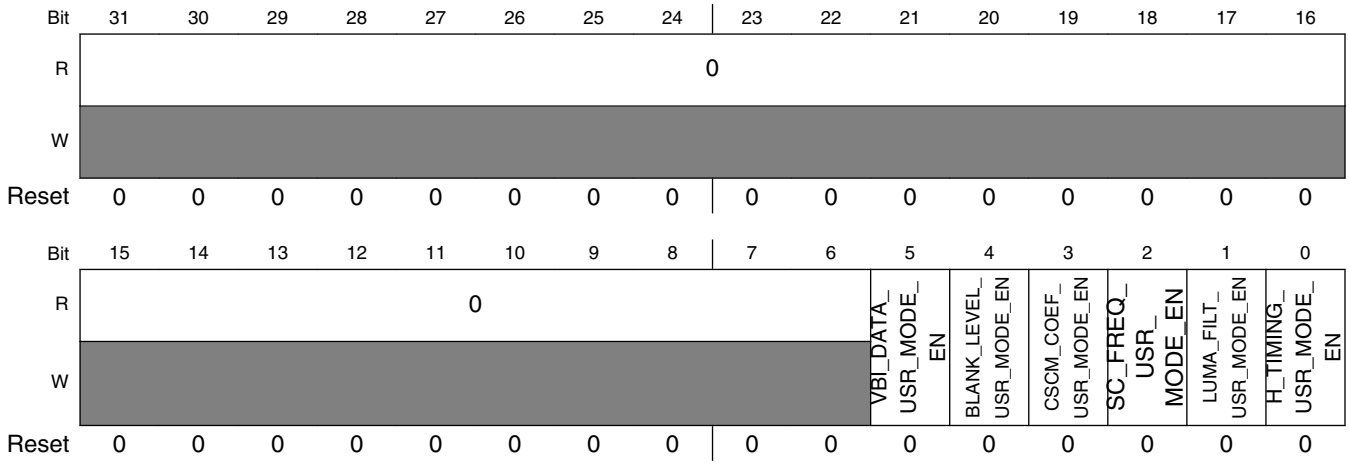
Table continues on the next page...

TVE_TST_MODE_REG field descriptions (continued)

Field	Description
	101 256 110 Reserved 111 Reserved
7 Reserved	This read-only field is reserved and always has the value zero. Reserved.
6 TVDAC_2_ DATA_FORCE	Enable forcing input of TVDAC channel #2 by value defined in BLANKING_CH_2_USR. 0 Disable 1 Enable
5 TVDAC_1_ DATA_FORCE	Enable forcing input of TVDAC channel #1 by value defined in BLANKING_CH_1_USR. 0 Disable 1 Enable
4 TVDAC_0_ DATA_FORCE	Enable forcing input of TVDAC channel #0 by value defined in BLANKING_CH_0_USR. 0 Disable 1 Enable
3 Reserved	This read-only field is reserved and always has the value zero. Reserved.
2–0 TVDAC_TEST_ MODE	Select TVDAC test mode. 000 Disable test mode (functional mode) 001 TVDAC test mode 1 - different data on TVDAC channels and UF is in data path 010 TVDAC test mode 2 - equal data on TVDAC channels and UF is in data path 011 TVDAC test mode 3 - different data on TVDAC channels and UF is bypassed 100 TVDAC test mode 4 - equal data on TVDAC channels and UF is bypassed 101 TVDAC test mode 5 - sine wave data from the internal generator directly to all TVDAC channels 110 Reserved 111 Reserved

74.3.29 User Mode Control Register (TVE_USER_MODE_CONT_REG)

Address: TVE_USER_MODE_CONT_REG is 63FF_0000h base + 70h offset = 63FF_0070h

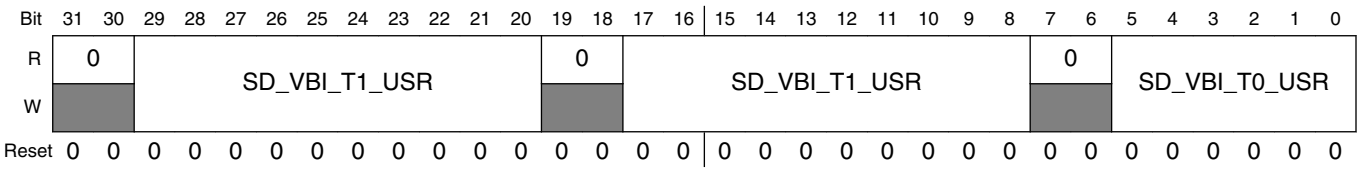


TVE_USER_MODE_CONT_REG field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value zero. Reserved.
5 VBI_DATA_ USR_MODE_EN	Enable user mode for VBI data. 0 Disable 1 Enable
4 BLANK_LEVEL_ USR_MODE_EN	Enable user mode for blank level. 0 Disable 1 Enable
3 CSCM_COEF_ USR_MODE_EN	Enable user mode for color space conversion matrix. 0 Disable 1 Enable
2 SC_FREQ_ USR_MODE_EN	Enable user mode for subcarrier frequency. 0 Disable 1 Enable
1 LUMA_FILT_ USR_MODE_EN	Enable user mode for Luma filtering. 0 Disable 1 Enable
0 H_TIMING_ USR_MODE_EN	Enable user mode for horizontal timing. 0 Disable 1 Enable

74.3.30 SD Timing User Control Register 0 (TVE_SD_TIMING_USR_CONT_REG_0)

Address: TVE_SD_TIMING_USR_CONT_REG_0 is 63FF_0000h base + 74h offset = 63FF_0074h

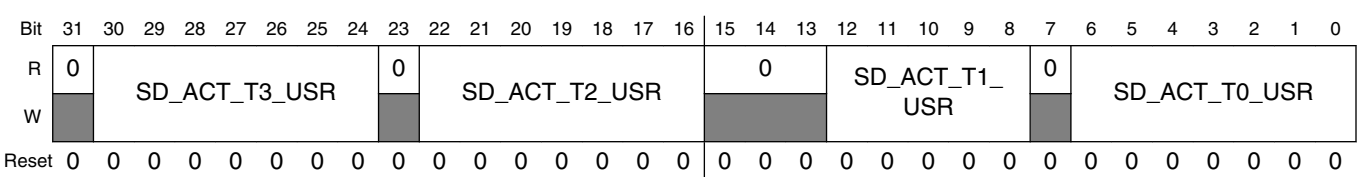


TVE_SD_TIMING_USR_CONT_REG_0 field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved.
29–20 SD_VBI_T1_ USR	User defined horizontal timing interval t2 for VBI lines in SD mode. 0000000000 1 pixels 0000000001 2 pixels 1111111111 1024 pixels
19–18 Reserved	This read-only field is reserved and always has the value zero. Reserved.
17–8 SD_VBI_T1_ USR	User defined horizontal timing interval t1 for VBI lines in SD mode. 0000000000 1 pixels 0000000001 2 pixels 1111111111 1024 pixels
7–6 Reserved	This read-only field is reserved and always has the value zero. Reserved.
5–0 SD_VBI_T0_ USR	User defined horizontal timing interval t0 for VBI lines in SD mode. 000000 1 pixels 000001 2 pixels 111111 64 pixels

74.3.31 SD Timing User Control Register 1 (TVE_SD_TIMING_USR_CONT_REG_1)

Address: TVE_SD_TIMING_USR_CONT_REG_1 is 63FF_0000h base + 78h offset = 63FF_0078h

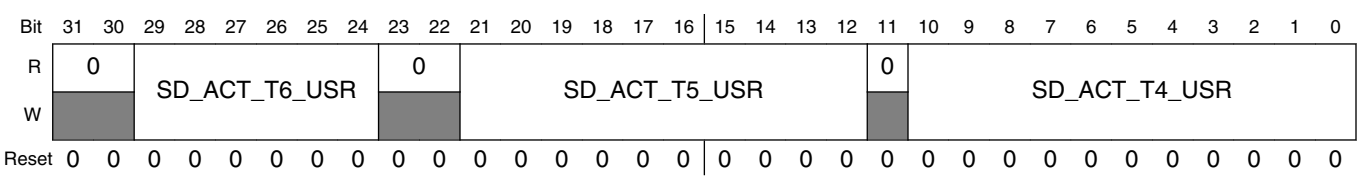


TVE_SD_TIMING_USR_CONT_REG_1 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value zero. Reserved.
30–24 SD_ACT_T3_USR	User defined horizontal timing interval t3 for active data lines in SD mode. 0000000 1 pixels 0000001 2 pixels 1111111 128 pixels
23 Reserved	This read-only field is reserved and always has the value zero. Reserved.
22–16 SD_ACT_T2_USR	User defined horizontal timing interval t2 for active data lines in SD mode. 0000000 1 pixels 0000001 2 pixels 1111111 128 pixels
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved.
12–8 SD_ACT_T1_USR	User defined horizontal timing interval t1 for active data lines in SD mode. 00000 1 pixels 00001 2 pixels 11111 32 pixels
7 Reserved	This read-only field is reserved and always has the value zero. Reserved.
6–0 SD_ACT_T0_USR	User defined horizontal timing interval t0 for active data lines in SD mode. 0000000 1 pixels 0000001 2 pixels 1111111 128 pixels

74.3.32 SD Timing User Control Register 2 (TVE_SD_TIMING_USR_CONT_REG_2)

Address: TVE_SD_TIMING_USR_CONT_REG_2 is 63FF_0000h base + 7Ch offset = 63FF_007Ch



TVE_SD_TIMING_USR_CONT_REG_2 field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved.

Chapter 75
TrustZone Aware Interrupt Controller (TZIC)

75.1 Overview

The interrupt controller is a TrustZone enabled interrupt controller with an AXI interface. It allows complete and independent control over every interrupt connected to the controller, including enable, security, and priority functionality. It provides secure and non-secure transaction access to those interrupts, restricting non-secure read and write transactions to only those interrupts configured as non-secure and allowing secure transactions read and write capability to all interrupts regardless of security configuration. It supports priority masking, overall enable/disable of secure or nonsecure interrupts, and access to raw interrupt state and pending transactions.

NOTE

Chip-specific system interrupts are defined and described in the Interrupts and SDMA Events chapter.

NOTE

On i.MX53 board, power fail indication can be connected to the interrupt controller via GPIO_16 (ALT2) PAD. This can generate an interrupt (IRQ #7, as described in Table 3-1) if properly configured (priority, masking, etc.).

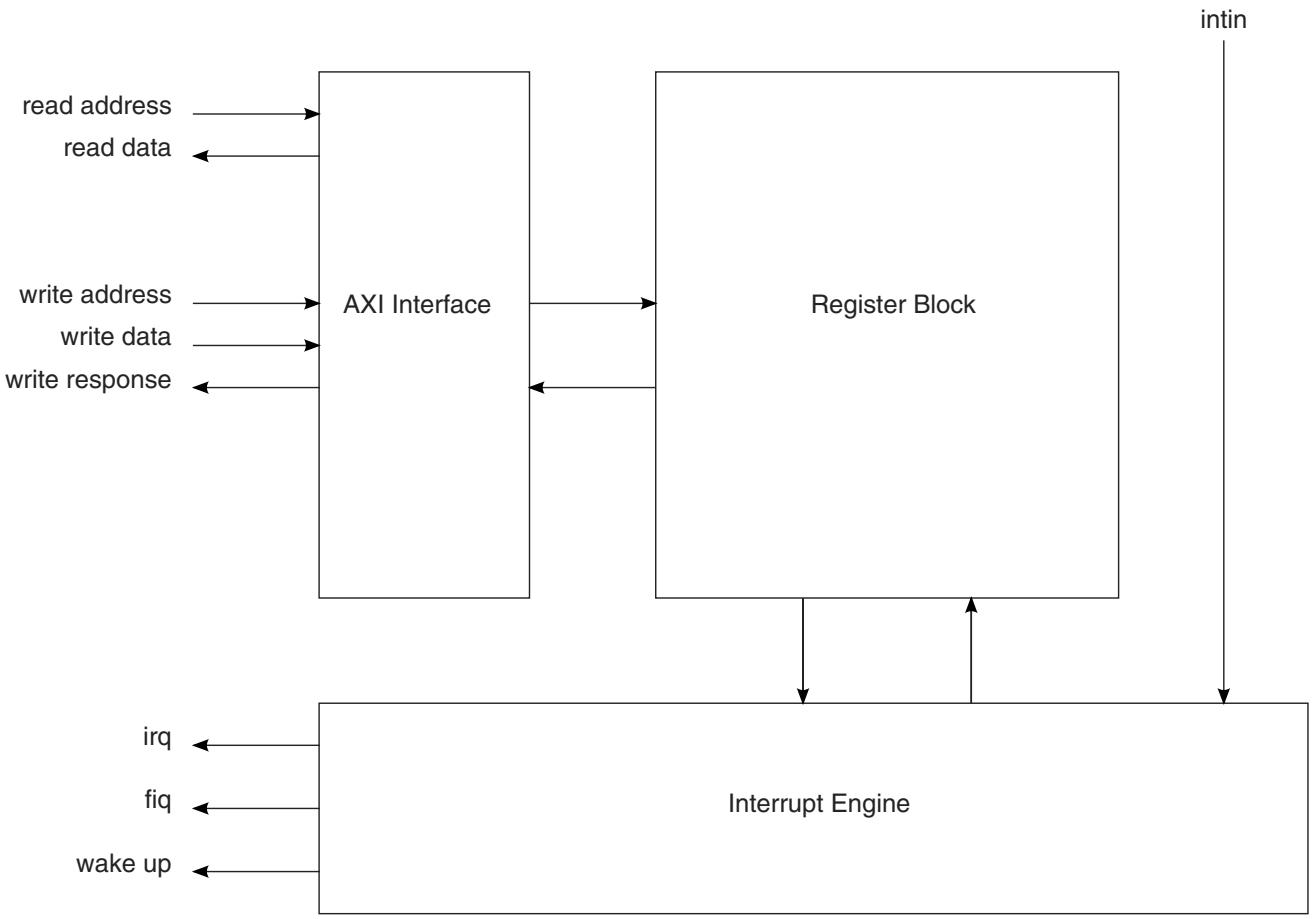

Figure 75-1. Block Diagram

75.2 Features

The following features are included in the interrupt controller

- AXI interface
- Support for up to 128 interrupts
- Secure configuration available on all interrupts
- Software triggered interrupts supported
- High priority pending registers for autovectored interrupt service routines
- Set/Clear registers for interrupt enable, force, and secure registers
- 16/32 programmable priority levels (nonsecure/secure)
- Wakeup configuration available on all interrupts

75.3 External Signal Description

The interrupt controller has no external signals.

75.4 Functional Description

The TZIC is an interrupt controllersupporting trustzone . This implementation allows up to 128 interrupts. It supports autovectoring solutions and provides a high priority pending register for software to directly access the interrupts currently pending at the highest active priority level (based on security configuration).

The interrupt controller is made up of three primary components:

1. The AXI Interface
2. The Register Block
3. The Interrupt Engine

75.4.1 Security Configurability

The TZIC is designed to handle two levels of secure interrupts using trustzone functionality included in the AXI specifications. It is also possible to use it in a single security level, non-trustzone aware system. At integration the TZIC can be connected such that all transactions are treated as secure, providing the ARM platform with full access to all registers. The TZIC_INTSEC registers reset to all interrupts being secure, which translates to all interrupts being available to the system without needing to be configured, therefore the non-secure software running as secure does not need to be aware of the security registers for configuration.

The TZIC_INTSEC registers determine which interrupts are accessible by non-secure transactions. Interrupts configured as secure are not accessible or configurable by non-secure transactions. Any information associated with an interrupt configured as secure is not accessible by non-secure transactions. Read transactions will return reset values for any bits tied to a secure interrupt, writes to these bits will be ignored. This includes all registers. The TZIC_INTSEC registers are not visible to non-secure transactions.

75.4.1.1 TrustZone and Interrupt Priority

The priority scheme implemented in the interrupt controller allows for flexible prioritization of secure and non-secure interrupts, and ease of use with legacy software.

Each interrupt can be assigned a priority value up to 8 bits (depending on the PRIORITY_MASK parameter). The highest priority value is 0, the next is 1, and so on. For designs where not all 8 bits are used, the lower bits are masked off, such that an implementation with only 5 bits would use values 0 (8'h00), 8 (8'h08), 16 (8'h10), 24 (8'h18), and so on. The number of bits available can be discovered by software through writing 8'hFF to a priority register and reading back the resulting value actually stored in the register.

Secure and non-secure transactions have different views of the priority registers. A secure transaction can see all implemented bits and has access to the full range of priority values. A non-secure transaction is limited to the lower half of the possible priorities. This is accomplished through shifting the values written and read during a non-secure transaction.

A non-secure write to a priority register will automatically be shifted one bit to the right, with the MSB assigned 1'b1. This shift is reversed when read, with the priority value shifted one bit to the left and the LSB assigned 1'b0. This is shown in the following equations:

Non-Secure write to priority register: priority_reg[7:0] = {1'b1, wdata[7:1]}

Non-Secure read from priority register: rdata[7:0] = {priority_reg[6:0], 1'b0}

This guarantees the highest priority a non-secure transaction can write is 128 (8'h80), which is the highest priority of the lower half of possible priorities. It also shows the non-secure software will not be aware of this limitation, because reading back a priority register with a value of 128 will result in a read data value of 0.

This scheme will allow for non-secure interrupts to function in their own priority scheme without knowledge of secure interrupt priorities while allowing secure interrupts to guarantee priority over non-secure interrupts. If all secure interrupts are assigned priorities in the upper half of the possible priorities, secure interrupts will always be of higher priority than non-secure interrupts.

Note that this priority value shifting is determined by the security of the transaction, not the security of the interrupt whose priority is being configured. A non-secure transaction will only have access to non-secure interrupt priority values, but a secure transaction will have access to secure and non-secure priority values, and will be accessing the actual value, not the shifted value. This means it is possible for a secure transaction to configure a non-secure interrupt priority to be in the upper half of the priority levels, or to configure a secure interrupt priority to be below a non-secure interrupt. In the first case, the non-

secure interrupt priority will remain set until written again by another secure transaction or a non-secure transaction (which would automatically limit the priority level to 128 or lower). A non-secure read will shift the value as specified above but would not alter the value. This is not recommended because it could impact the non-secure software in an unpredictable manner. In the second case, it may be desirable to configure a secure interrupt to be of lower priority than some non-secure interrupts, although such behavior should be used with care.

75.4.2 AXI Interface

The AXI interface allows access to all functionality of the interrupt controller. It is fully compatible with the AMBA 3 AXI specification from ARM.

Read transactions are generally returned with one initial wait state and two clock cycles per read data. All registers can be read with 32-bit transactions, the priority registers allow 8-bit transactions. 16-bit transactions are not supported and will result in an error. Exclusive reads are not supported. The interrupt controller will accept one read address at a time. If a second read transaction is valid before completion of the previous read, it will be held off until the interrupt controller is finished returning data from the first read.

Write transactions are generally accepted with one initial wait state, the one clock cycle per write data. Registers are word writeable only with the exception of the priority and priority mask registers which support byte writes. Exclusive writes are not supported. The interrupt controller will accept one write address at a time. If a second write transaction is valid before completion of the previous write, it will be held off until the interrupt controller is finished returning the write response from the first write. The interrupt controller will also hold off the write data bus until it receives a write address.

75.4.3 Interrupt Engine

The interrupt engine performs all processing on the raw interrupt information. It receives configuration information from the Register Block, interrupts from the system, and based on that information determines when to assert interrupts to the core.

An interrupt is asserted to the core (IRQ or FIQ) when all the following criteria are met:

- The EN bit in the TZIC_INTCTRL register is enabled, secure for FIQ or non-secure for normal IRQ.
- An interrupt is asserted, either on an interrupt input (intin) or by writing the TZIC_SRCSET or TZIC_SWINT registers.

- The interrupt is configured appropriately for the desired interrupt in the TZIC_INTSEC register, set as secure for FIQ or non-secure for IRQ.
- The asserted interrupt is enabled in the TZIC_ENSET/TZIC_ENCLEAR register.
- The priority of the asserted interrupt is greater than the TZIC_PRIOMASK register value. Note: this requires the actual priority value to be greater than the TZIC_PRIOMASK register value, after taking into account shifting for non-secure transactions.

This interrupt controller can handle up to 128 interrupts (intin). Each interrupt has an associated interrupt ID number 0 - 127.

The interrupt synchronizers are part of the interrupt engine. A two-flop synchronizer is implemented for each interrupt input. Clock gating is available for the synchronizers and is configured through the Synchronizer Control (TZIC_SYNCCTRL) Register. For more information see Synchronizer Control (TZIC_SYNCCTRL).

The interrupt engine handles the wakeup functionality of the interrupt controller, processing the dsm_int_holdoff signal input from the ARM platform and asserting tzic_wakeup_request to the clock controller module as necessary.

tzic_wakeup_request is an asynchronous, combinational output determined by the asynchronous interrupt sources (intin) and the TZIC_WAKEUP registers. It asserts when any interrupt is asserted on the intin input while configured for wakeup. It negates when there are no more interrupts asserted that are configured for wakeup. A software interrupt will not assert this output, because a software interrupt would require a clock to be triggered and the tzic_wakeup_request is intended for enabling clocks and/or power during low power states.

dsm_int_holdoff causes the interrupt synchronizers to stop updating. This is for shutting down clocks in the system. While preparing for low power modes, the ARM platform may be in a position where it expects no more interrupts to be occurring, but has not yet executed a standby-wait-for-interrupt. The ARM platform must write to the dsm_int_holdoff bit, then read it back to verify that it was successfully set. If not set, an interrupt occurred during the process before the synchronizers could be stopped and the ARM platform must process the interrupt and write to the dsm_int_holdoff bit again.

NOTE

Above internal decription is for information only, because the mechanisms are automated through the clock controller module when going into a low power mode.

75.4.4 Auto-Vectored Interrupt Handling

The TZIC is intended to be used with auto-vectored interrupt service routines. Once interrupts have been enabled using the TZIC_ENSET/TZIC_ENCLEAR registers and the TZIC_INTCTRL register, the interrupt engine is live and will signal an interrupt to the ARM platform when an enabled interrupt is asserted. Once the ARM platform interrupt is triggered, a read to the TZIC_PND or TZIC_HIPND registers will determine which interrupts are currently pending.

The TZIC_PND registers will contain information on every interrupt currently pending, whether asserted by the interrupt input or forced by software. This includes interrupts of priority lower than the TZIC_PRIOMASK value. The TZIC_PRIOMASK register limits the assertion of the IRQ/FIQ signals based on priority, it does not affect which interrupts are visible in the pending registers.

The TZIC_HIPND registers will contain information on which interrupts are currently pending at the highest pending priority, allowing autovectoring software to choose between the highest priority interrupts without having to process such information on its own. As with the TZIC_PNDPND register, the TZI.HIPND register will return pending values even if the highest pending priority is of equal or lower priority than the TZIC_PRIOMASK value, although in such a case the interrupt signals will not be asserted.

After choosing a pending interrupt to service, writing the priority of the interrupt being serviced to the TZIC_PRIOMASK register will allow for interrupt pre-emption by a higher priority interrupt being asserted later.

75.4.5 Reset

Coming out of reset, all interrupts are configured as secure, disabled, and set to priority level 0. Also, the TZIC_INTCTRL register is set to disable all secure and non-secure interrupts.

75.5 Initialization Information

Initialization procedures will vary based on whether the interrupt controller is set up in a one or two security domain configuration. This description will handle the case where the interrupt controller is set up to take advantage of both secure and non-secure interrupts, the single security level case is a subset of this scenario.

Note: When writing to any registers affecting the interrupt outputs to the ARM platform it is recommended the ARM platform interrupt inputs be masked to prevent interrupts asserting and negating due to register writes.

When the interrupt controller comes out of reset, all interrupts are disabled and set as secure. It is advised that the TZIC_INTCTRL register enables are not activated until all other configuration options have been set up. To set up the interrupt controller for autovectoring functionality:

1. Secure software sets TZIC_INTSEC registers appropriately - This configures all interrupts as either secure or non-secure, allowing the non-secure software to configure the non-secure interrupts.Until these registers are configured, non-secure software will not be able to configure any registers.

   At this point secure and non-secure software are free to configure their associated interrupts with minimal conflict. Non-secure software cannot affect any register bits associated with secure interrupts. It is the responsibility of the secure software not to overwrite any non-secure interrupt configuration bits.

2. Configure TZIC_ENSET/TZIC_ENCLEAR - Secure and non-secure software must enable all interrupts. At this point interrupt functionality has yet to be enabled in the TZIC_INTCTRL register so this will not cause interrupts to occur during initialization.
3. Configure TZIC_PRIORITY - Secure and non-secure software must set TZIC_PRIORITY registers to appropriate levels, otherwise all interrupts are set to the lowest priority level as determined by the PRIORITY_MASK parameter.
4. Set TZIC_PRIOMASK - The TZIC_PRIOMASK register must be set to allow interrupts to occur, out of reset it is set to the lowest priority level which masks all priority levels.
5. Set TZIC_INTCTRL - Secure and non-secure software must enable interrupt functionality in the TZIC_INTCTRL register. This will enable the interrupt controller to send interrupts to the ARM platform.

At this point the interrupt controller will generate interrupt signals to the ARM platform. The ARM platform itself must enable interrupts as well. In this configuration the interrupt controller is enabled for autovectoring software to access the TZIC_PND or TZIC_HIPND registers and determine which interrupt to service.

75.6 Programmable Registers

This is the memory map for all possible registers in the interrupt controller. The presence of some registers will be dependent upon the implementation configuration. Address space not specified is reserved.

This section contains the detailed register descriptions for the interrupt controler registers.

The read and write behavior of many of the interrupt controller regsiters is impacted by the security configuration of each individual interrupt, as determined by the INTSEC registers. In all cases, non-secure transactions will only read back information about interrupts configured as non-secure and writes will have no effect on secure interrupts. Secure transactions will have full read and write access to all interrupt bits.

Write bursts are taken with one clock per write data after an initial one clock delay. Read bursts are returned with two clocks per read data.

The specific behavior for each register set is described in the field descriptions. In some cases where the register described spans multiple 32-bit addressible locations, the variable X is used to denote which particular register corresponds to which interrupts. For instance, a register with 1 bit associated with each interrupt will have one 32-bit register for each set of 32 interrupts. The registers can be numbered such that REGISTER0 corresponds to interrupts 0-31, REGISTER1 corresponds to interrupts 32-63, and so on. This relationship can be expressed using the following equation:

REGISTER(X)[Y] corresponds to interrupt (32 x (X))+Y

Such that if X is 2 and Y is 17:

REGISTER(2)[17] -> (32 x (2))+17 = 81

The interrupt would be number 81.

This terminology is used to express the location and relationship for several registers in this section.

All registers are accessible with 32-bit accesses. The PRIOMASK register and PRIORITY registers support 8-bit transactions, all others are not supported and will yield unpredictable results. 16-bit transactions are not supported to any registers and will result in a slave error. Any access larger than 32-bit will also result in an error.

All registers are bufferable, non-cacheable, data, supervisor only. Transactions marked as cacheable, allocate, user, or instruction will result in error responses.

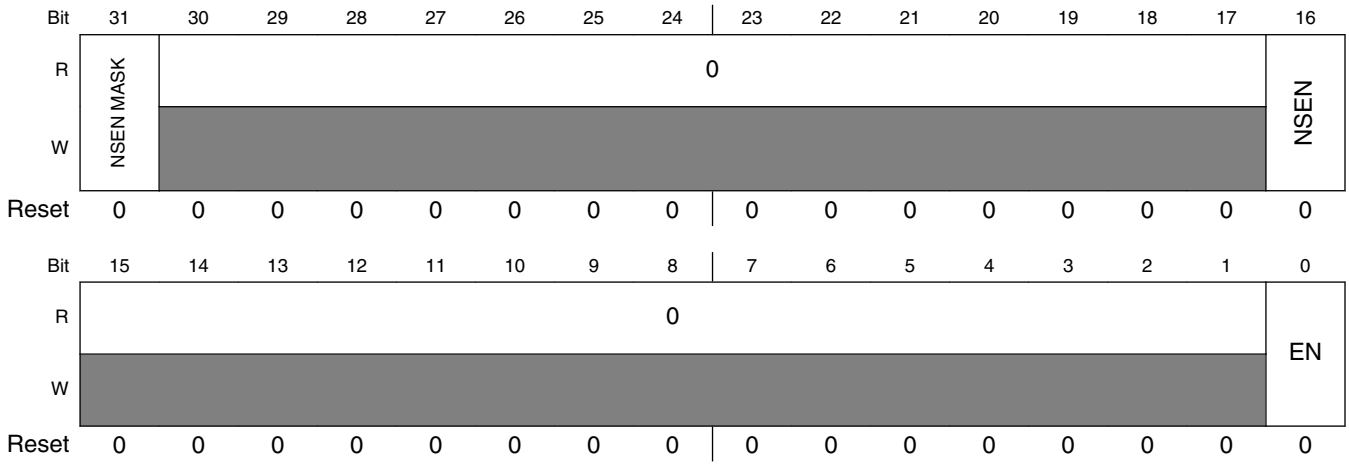
75.6.1 Control Register (TZIC_INTCTRL)

The interrupt control register (INTCTRL) can enable or disable all normal or secure interrupts to the ARM platform, depending on the state of the write transaction used. A secure read or write will access the enable bit for secure interrupts, a non-secure read or write will access the enable bit for non-secure interrupts. This only affects the outputs to the core, it has no impact on which interrupts are pending in the PND and HIPND registers.

A secure read can access the non-secure enable through bit 16, which will only be written if bit 31 is written at the same time. This allows secure software to ignore the non-secure enable bit and update the secure enable bit without a read-modify-write sequence.

This register can only be accessed by a 32-bit supervisor transaction.

Address: TZIC_INTCTRL is FFFC000h base + 0h offset = 0FFF_C000h



TZIC_INTCTRL field descriptions

Field	Description
31 NSEN MASK	Non-Secure Enable Mask - This bit indicates the secure write transaction is updating the NSEN bit. When written as 1'b0 the NSEN bit will not be updated. When written as 1'b1 the NSEN bit will be updated. This allows the secure software to ignore the NSEN bit and update only the Secure EN bit without requiring a read/modify/write to determine the current state of the NSEN. Note: Available for secure transactions only. If written with AWPROT[1] == 1'b0: If written with AWPROT[0] == 1'b1: no effect 0 NSEN bit unaffected 1 NSEN bit updated
30–17 Reserved	This read-only field is reserved and always has the value zero. Reserved
16 NSEN	Non-Secure Enable. This bit is available in secure mode only to enable/disable nonsecure interrupts. This allows for using both security levels in a single security level system where only secure transactions are available. A secure write to this bit will only take effect if the NSEN MASK bit is also set. Note: Available for secure transactions only. If written or read with AxPROT[1] == 1'b1: On reads: 1'b0 On writes: no effect If written or read with AxPROT[1] == 1'b0: 0 Non-Secure interrupts disabled 1 Non-Secure interrupts enabled
15–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 EN	Interrupt Enable. This bit, when set, enables normal or secure interrupts, depending on the secure state of the transaction. If written or read with AxPROT[1] == 1'b0: and If written or read with AxPROT[1] == 1'b1: 0 Secure Interrupts disabled

75.6.2 Interrupt Controller Type Register (TZIC_INTTYPE)

The interrupt controller type register (INTTYPE) contains information about the type of interrupt controller that has been implemented. It can be used to determine the number of interrupts, ARM cores, and if security is enabled for a given instantiation.

The current version only supports configurations with one ARM core and two security domain(s).

This register can only be accessed by a 32-bit supervisor read transaction.

Address: TZIC_INTTYPE is FFFC000h base + 4h offset = 0FFF_C004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

75.6.3 Priority Mask Register (TZIC_PRIOMASK)

The Priority Mask Register (PRIOMASK) is a single register used to mask both secure and non-secure interrupts based on their priority configuration. The ARM platform will only receive an interrupt if there is a pending interrupt with a priority higher than the value in this register. If an interrupt source asserts and its priority is equal to or lower than the priority mask value, it will not cause an interrupt to the ARM platform.

The lowest priority the priority mask value can be set to is the lowest priority level in the controller. Therefore any interrupt set to the lowest allowed priority will never cause an interrupt since it is not possible for its priority to be greater than the mask value.

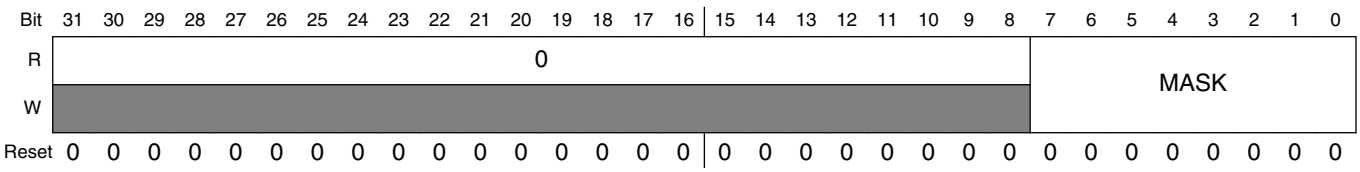
This register is affected by an integration parameter which varies the available resolution of priority values. The number of bits available can vary from four to eight, with the lowest resolution only implementing bits [7:4], and the highest resolution implementing bits [7:0]. Which bits are implemented can be determined by writing 8'hFF to bits [7:0] and reading back the result. The bits set high will indicate which register bits are implemented in this register as well as the PRIORITY registers.

Secure and non-secure transactions to this register will have different behaviors. A secure write will result in the register receiving the write data bits as written. A non-secure write will results in wdata bits [7:1] being shifted to the right one bit and bit [7] being set to 1'b1. A secure read will return the actual value stored in the register while a non-secure read will return the register value shifted to the left one bit and bit [0] being filled with a 1'b0. This is subject to the actual register bits implemented according to the integration parameter.

For more information regarding priorities, see TrustZone and Interrupt Priority.

This register can only be accessed by 8-bit or 32-bit supervisor transactions.

Address: TZIC_PRIOMASK is FFFC000h base + Ch offset = 0FFF_C00Ch



TZIC_PRIOMASK field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–0 MASK	Priority Mask - This field stores the priority mask value. Interrupts with a priority level set equal to or below this value are masked. For READS: 00000000 If ARPROT[1] == 1'b0 (secure), then priority mask is set to 0. If ARPROT[1] == 1'b1 (nonsecure), then priority mask is set to 128. 00000001 If ARPROT[1] == 1'b0 (secure), then the priority mask is set to 1. If ARPROT[1] == 1'b1 (nonsecure), then priority mask is set to 128. 11111111 The priority mask is set to 255.

75.6.4 Synchronizer Control (TZIC_SYNCCTRL)

The Synchronizer Control Register (SYNCCTRL) is used to control latency and power usage in the interrupt synchronizers. There are three configurations for synchronization:

- Low Latency-The synchronizer is clocked continuously and interrupts are synchronized as they arrive.
- Low Power-The synchronizer is not clocked until a difference is detected between the inputs and outputs of the synchronizer. When a difference is detected, the detection result is synchronized and used as a clock enable for the synchronizer, which introduces additional latency. Total latency is four clocks, two for the enable and two for the interrupt.

This register can only be accessed by 32-bit secure supervisor transactions.

Address: TZIC_SYNCCTRL is FFFC000h base + 10h offset = 0FFF_C010h

75.6.5 DSM Interrupt Holdoff (TZIC_DSMINT)

The DSM Interrupt Holdoff Register (DSMINT) is used to stop interrupts to the ARM platform from occuring until a wakeup signal occurs. This is used for entering Deep Sleep Mode. When written, the DSM bit will cause the interrupt synchronizer to stop updating. If an interrupt occurs while this register is being written the bit will not be set and the ARM platform will have to try to write again. If no interrupt to the ARM platform occurs while the register is being written the write will succeed and the interrupt synchronizers will not update until the DSM bit clears. The DSM bit is cleared by either a write to the DSMINT register or assertion of the dsm_wakeup_request output of the interrupt controller. When a wakeup request is asserted, the interrupt controller will remove the DSM interrupt holdoff bit and interrupts will resume.

This register can only be accessed by 32-bit secure supervisor transactions.

Address: TZIC_DSMINT is FFFC000h base + 14h offset = 0FFF_C014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

75.6.6 Interrupt Security (FIQ) Register: Irq 0 to 31 (TZIC_INTSEC*n*)

The Interrupt Security Registers (INTSEC) are used to set interrupts as secure or non-secure. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, if its secure bit is set to 1'b0, the interrupt is secure and will cause a secure interrupt to the ARM platform. When set as secure, a particular interrupt will also be invisible to non-secure accesses, its configuration hidden during non-secure reads. If its bit is set to 1'b1, the interrupt is non-secure and will cause a non-secure interrupt to the ARM platform.

The values read in the INTSEC register represent the interrupts currently set as non-secure. Out of reset, all interrupts are configured as secure, the intention being that when the interrupt controller is used in a system that does not use TrustZone, the secure bit of ARPROT/AWPROT will be tied to secure and the interrupt controller will act as always in secure mode.

These registers can only be accessed by 32-bit secure supervisor transactions.

Addresses: TZIC_INTSEC0 is FFFC000h base + 80h offset = 0FFF_C080h
TZIC_INTSEC1 is FFFC000h base + 84h offset = 0FFF_C084h
TZIC_INTSEC2 is FFFC000h base + 88h offset = 0FFF_C088h
TZIC_INTSEC3 is FFFC000h base + 8Ch offset = 0FFF_C08Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
31–0 SECURE	Interrupt Secure Status. When read, this register returns the status bit values of the associated interrupts. When written, this register sets the configuration for the associated interrupts. The corresponding interrupts for an INTSEC(X) are determined through the following formula: SECURE(X)[31] -> (32*X)+31

TZIC_INTSEC*n* field descriptions (continued)

Field	Description
	SECURE(X)[0] -> (32*X)+0 0 Interrupt is secure 1 Interrupt is non-secure

75.6.7 Enable Set Register: Irq 0 to 31 (TZIC_ENSET*n*)

The Enable Set Registers (ENSET) are used to enable interrupt requests to the core. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, when read, if its enable bit is set to 1'b1, the interrupt is enabled and will be transmitted to the ARM platform. If its bit is set to 1'b0, any activity on that interrupt will have no effect.

Writing a bit to 1'b1 in this register will enable the interrupt associated with that bit. Writing a bit to 1'b0 will have no effect. To clear an enable bit, the Enable Clear Registers must be used.

The values read in the ENSET register represent the currently enabled interrupts.

These registers can only be accessed by 32-bit supervisor transactions.

Addresses: TZIC_ENSET0 is FFFC000h base + 100h offset = 0FFF_C100h
TZIC_ENSET1 is FFFC000h base + 104h offset = 0FFF_C104h
TZIC_ENSET2 is FFFC000h base + 108h offset = 0FFF_C108h
TZIC_ENSET3 is FFFC000h base + 10Ch offset = 0FFF_C10Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
	0 Interrupt is disabled or configured as secure 1 Interrupt is enabled If AWPROT[1] == 1'b0 (secure) 0 no effect 1 Interrupt enable bit set If AWPROT[1] == 1'b1 (nonsecure) 0 no effect 1 Interrupt enable bit set if bit is configured as non-secure

75.6.8 Enable Clear Register: Irq 0 to 31 (TZIC_ENCLEAR*n*)

The Enable Clear Registers (ENCLEAR) are used to disable interrupt requests to the core. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, when read, if its enable bit is set to 1'b1, the interrupt is enabled and will be transmitted to the ARM platform. If its bit is set to 1'b0, any activity on that interrupt will have no effect.

Writing a bit to 1'b1 in this register will disable the interrupt associated with that bit. Writing a bit to 1'b0 will have no effect. To set an enable bit, the Enable Set Registers must be used.

The values read in the ENCLEAR register represent the currently enabled interrupts.

These registers can only be accessed by 32-bit supervisor accesses.

Addresses: TZIC_ENCLEAR0 is FFFC000h base + 180h offset = 0FFF_C180h
TZIC_ENCLEAR1 is FFFC000h base + 184h offset = 0FFF_C184h
TZIC_ENCLEAR2 is FFFC000h base + 188h offset = 0FFF_C188h
TZIC_ENCLEAR3 is FFFC000h base + 18Ch offset = 0FFF_C18Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

TZIC_ENCLEAR*n* field descriptions

Field	Description
31–0 INTENCLEAR	Interrupt Enable Cleared. When written, this register clears the enable bits of the associated interrupts. When read, this register returns the enable bit values of the associated interrupts. The corresponding interrupts for register ENCLEARX are determined through the following formula: INTENCLEAR[31] -> (32*X)+31

TZIC_ENCLEAR*n* field descriptions (continued)

Field	Description
	INTENCLEAR[0] -> (32*X)+0 If ARPROT[1] == 1'b0 (secure) 0 Interrupt is disabled 1 Interrupt is enabled If ARPROT[1] == 1'b1 (nonsecure) 0 Interrupt is disabled or configured as secure 1 Interrupt is enabled If AWPROT[1] == 1'b0 (secure) 0 no effect 1 Interrupt enable bit cleared If AWPROT[1] == 1'b1 (nonsecure) 0 no effect 1 Interrupt enable bit cleared if bit is configured as non-secure

75.6.9 Source Set Register: Irq 0 to 31 (TZIC_SRCSET*n*)

The Source Set Registers (SRCSET) are used to determine which interrupts are currently asserted and to force interrupts to an asserted state regardless of activity on the interrupt lines. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, when read, if its source bit is set to 1'b1, the interrupt is asserted and pending action from the ARM platform. If its bit is set to 1'b0, the interrupt is not asserted.

Writing a bit to 1'b1 in this register will override the interrupt line and force the corresponding interrupt to assert. Writing a bit to 1'b0 will have no effect. To clear a source bit, the Source Clear Registers or SWINT must be used.

If a source bit is set which corresponds to an interrupt not enabled in the ENSET/ ENCLEAR registers, the source bit will be 1'b1 but will not be considered pending and will not cause an interrupt to the core.

The values read in the SRCSET register represent the currently asserted interrupts.

These registers can only be accessed by 32-bit supervisor accesses.

Addresses: TZIC_SRCSET0 is FFFC000h base + 200h offset = 0FFF_C200h
TZIC_SRCSET1 is FFFC000h base + 204h offset = 0FFF_C204h
TZIC_SRCSET2 is FFFC000h base + 208h offset = 0FFF_C208h
TZIC_SRCSET3 is FFFC000h base + 20Ch offset = 0FFF_C20Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

TZIC_SRCSET*n* field descriptions

Field	Description
31–0 SRCSET	Interrupt Source Set. When written, this register forces the source bits of the associated interrupts. When read, this register returns the source bit values of the associated interrupts. The corresponding interrupts for register SRCSETX are determined through the following formula: SRCSET[31] -> (32*X)+31 SRCSET[0] -> (32*X)+0 If ARPROT[1] == 1'b0 (secure) 0 Interrupt is not asserted 1 Interrupt is asserted If ARPROT[1] == 1'b1 (nonsecure) 0 Interrupt is not asserted or configured as secure 1 Interrupt is asserted If AWPROT[1] == 1'b0 (secure) 0 no effect 1 Interrupt source bit set If AWPROT[1] == 1'b1 (nonsecure) 0 no effect 1 Interrupt source bit set if bit is configured as non-secure

75.6.10 Source Clear Register: Irq 0 to 31 (TZIC_SRCCLEAR*n*)

The Source Clear Registers (SRCCLEAR) are used to determine which interrupts are currently asserted and to clear interrupts from the asserted state that were triggered by software, either through the SRCSET or SWINT registers. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, when read, if its source bit is set to 1'b1, the interrupt is asserted and is pending action from the ARM platform. If its bit is set to 1'b0, the interrupt is not asserted.

Writing a bit to 1'b1 in this register will clear an asserted interrupt that was triggered by software. Writing a bit to 1'b0 will have no effect. To set a source bit, the Source Set Registers or Software Triggered Interrupt Register must be used.

The values read in the SRCCLEAR register represent the currently asserted interrupts.

These registers can only be accessed by 32-bit supervisor accesses.

Addresses: TZIC_SRCCLEAR0 is FFFC000h base + 280h offset = 0FFF_C280h
TZIC_SRCCLEAR1 is FFFC000h base + 284h offset = 0FFF_C284h
TZIC_SRCCLEAR2 is FFFC000h base + 288h offset = 0FFF_C288h

TZIC_SRCCLEAR*n* field descriptions

Field	Description
31–0 SRCCLEAR	Interrupt Source Clear. When written, this register forces the source bits of the associated interrupts. When read, this register returns the source bit values of the associated interrupts. The corresponding interrupts for register SRCCLEARX are determined through the following formula: SRCCLEAR[31] -> (32*X)+31 SRCCLEAR[0] -> (32*X)+0 If ARPROT[1] == 1'b0 (secure) 0 Interrupt is not asserted 1 Interrupt is asserted If ARPROT[1] == 1'b1 (nonsecure) 0 Interrupt is not asserted or configured as secure 1 Interrupt is asserted If AWPROT[1] == 1'b0 (secure) 0 no effect 1 Interrupt source bit cleared If AWPROT[1] == 1'b1 (nonsecure) 0 no effect 1 Interrupt source bit cleared if bit is configured as non-secure

75.6.11 Priority Register: Irq 0 to 3 (TZIC_PRIORITY*n*)

The Priority Registers (PRIORITY) are used to configure the priority of each interrupt for masking purposes.

Each eight bit priority field is affected by an integration parameter which determines the available resolution of priority levels. The number of bits available can vary from four to eight, with the lowest resolution only implementing bits [7:4], and the highest resolution implementing bits [7:0]. The implemented number of bits can be found in a manner similar to that described in Priority Mask Register (TZIC_PRIOMASK).

The priority scheme used is such that an interrupt assigned to 0 has the highest priority.

These registers can only be accessed by 32-bit or 8-bit supervisor transactions.

Addresses: FFFC000h base + 400h offset + (4d × *n*), where *n* = 0d to 31d

7–0 PRIO0	Description and settings as for PRIO3.

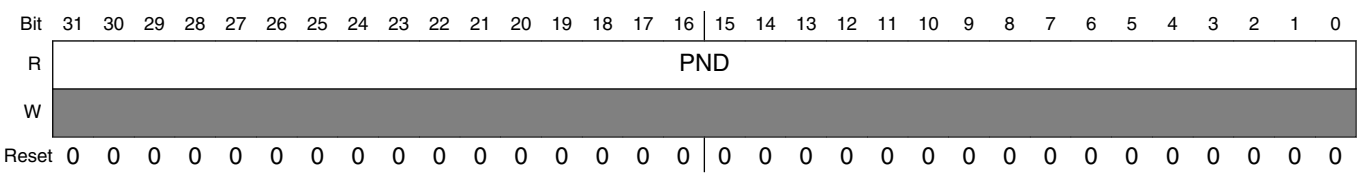
75.6.12 Pending Register: Irq 0 to 31 (TZIC_PND*n*)

The Pending Registers (PND) are used to determine which interrupts are currently pending action from the ARM platform. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, if its pending bit is set to 1'b1, the interrupt is enabled in the ENSET/ENCLEAR registers and asserted either on the interrupt inputs or in the SRCSET/SRCCLEAR registers, and therefore is pending action from the ARM platform. Priority values have no effect on whether an interrupt is pending.

This is a read-only register, writes will be ignored.

These registers can only be accessed by 32-bit supervisor transactions.

Addresses: TZIC_PND0 is FFFC000h base + D00h offset = 0FFF_CD00h
TZIC_PND1 is FFFC000h base + D04h offset = 0FFF_CD04h
TZIC_PND2 is FFFC000h base + D08h offset = 0FFF_CD08h
TZIC_PND3 is FFFC000h base + D0Ch offset = 0FFF_CD0Ch



TZIC_PND*n* field descriptions

Field	Description
31–0 PND	Interrupt Pending Status. When read, this register returns the pending bit values of the associated interrupts, indicating which interrupts are enabled and asserted. The corresponding interrupts for register PNDX are determined through the following formula: PND[31] -> (32*X)+31 PND[0] -> (32*X)+0 If ARPROT[1] == 1'b0 (secure) 0 Interrupt is not pending 1 Interrupt is pending

TZIC_PND*n* field descriptions (continued)

Field	Description
	If ARPROT[1] == 1'b1 (nonsecure) 0 Interrupt is not pending or configured as secure 1 Interrupt is pending

75.6.13 High Priority Pending Register: Irq 0 to 31 (TZIC_HIPND*n*)

The High Priority Pending Registers (HIPND) are used to determine which interrupts are currently pending at the highest active priority. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, if its pending bit is set to 1'b1, the interrupt is pending action from the ARM platform and its priority is the highest level amongst all pending enabled interrupts. See Pending Register: Irq 0 to 31 (TZIC_PND*n*) for more information about pending interrupts.

The highest active priority is determined based on the security state of the read transaction. If the register is read by a non-secure transaction, the pending interrupts returned are those non-secure interrupts that are pending and set to the highest priority of any currently pending non-secure interrupts. If the register is read by a secure transaction, the pending interrupts returned are those interrupts, secure or non-secure, that are pending and set to the highest priority of any currently pending interrupts regardless of security configuration.

This is a read-only register, writes will be ignored.

These registers can only be accessed by 32-bit supervisor transactions.

Addresses: TZIC_HIPND0 is FFFC000h base + D80h offset = 0FFF_CD80h
TZIC_HIPND1 is FFFC000h base + D84h offset = 0FFF_CD84h

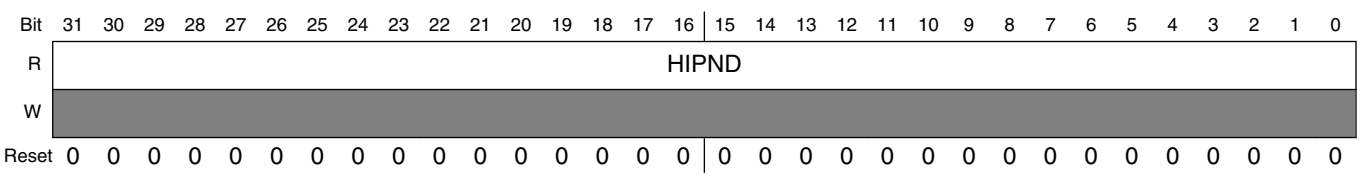
TZIC_HIPND3 is FFFC000h base + D8Ch offset = 0FFF_CD8Ch



TZIC_HIPND*n* field descriptions

Field	Description
31–0 HIPND	High Priority Interrupt Pending Status. When read, this register returns the pending bit values of the associated interrupts which are set to the highest currently active priority level. The corresponding interrupts for register HIPNDX are determined through the following formula: HIPND[31] -> (32*X)+31

TZIC_HIPND*n* field descriptions (continued)

Field	Description
	HIPND[0] -> (32*X)+0 If ARPROT[1] == 1'b0 (secure) 0 Interrupt is not pending at the higest priority level 1 Interrupt is pending at the higest priority level If ARPROT[1] == 1'b1 (nonsecure) 0 Interrupt is not pending at the higest priority level or configured as secure 1 Interrupt is pending at the higest priority level

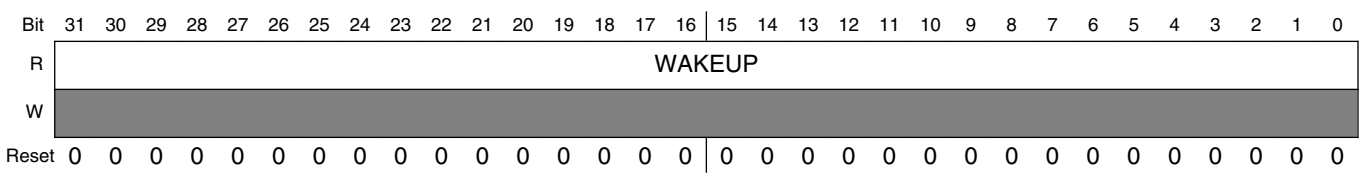
75.6.14 Wakeup Config Register: Irq 0 to 31 (TZIC_WAKEUP*n*)

The Wakeup Conguration Registers (WAKEUP) are used to set which interrupts will assert the tzic_wakeup_request signal. Each bit in the register corresponds to an interrupt source available in the system. For each interrupt, if its wakeup bit is set to 1'b1 assertion of the interrupt will cause the wakeup request signal to assert combinationally. When its wakeup bit is set to 1'b0, the interrupt will not assert the wakeup request signal.

The values read in the WAKEUP register represent interrupts currently set to wake up the system. Out of reset, all interrupts are configured not to wake up the system. Non-secure transactions can only enable or disable wakeup configuration of interrupts configured as non-secure. Secure transactions can enable or disable wakeup configuration of any interrupts.

These registers can only be accessed by 32-bit supervisor transactions.

Addresses: TZIC_WAKEUP0 is FFFC000h base + E00h offset = 0FFF_CE00h
TZIC_WAKEUP1 is FFFC000h base + E04h offset = 0FFF_CE04h
TZIC_WAKEUP2 is FFFC000h base + E08h offset = 0FFF_CE08h
TZIC_WAKEUP3 is FFFC000h base + E0Ch offset = 0FFF_CE0Ch



TZIC_WAKEUP*n* field descriptions

Field	Description
31–0 WAKEUP	Wakeup Configuration. When read, this register returns the wakeup bit values of the associated interrupts. When written, this register sets the configuration for the associated interrupts. The corresponding interrupts for register WAKEUPX are determined through the following formula: WAKEUP[31] -> (32*X)+31

TZIC_WAKEUP*n* field descriptions (continued)

Field	Description
	WAKEUP[0] -> (32*X)+0 If AxPROT[1] == 1'b0 0 Interrupt will not assert tzic_wakeup_request 1 Interrupt will assert tzic_wakeup_request If AxPROT[1] == 1'b1 0 Interrupt will not assert tzic_wakeup_request or is configured as secure and not accessible 1 Interrupt will assert tzic_wakeup_request

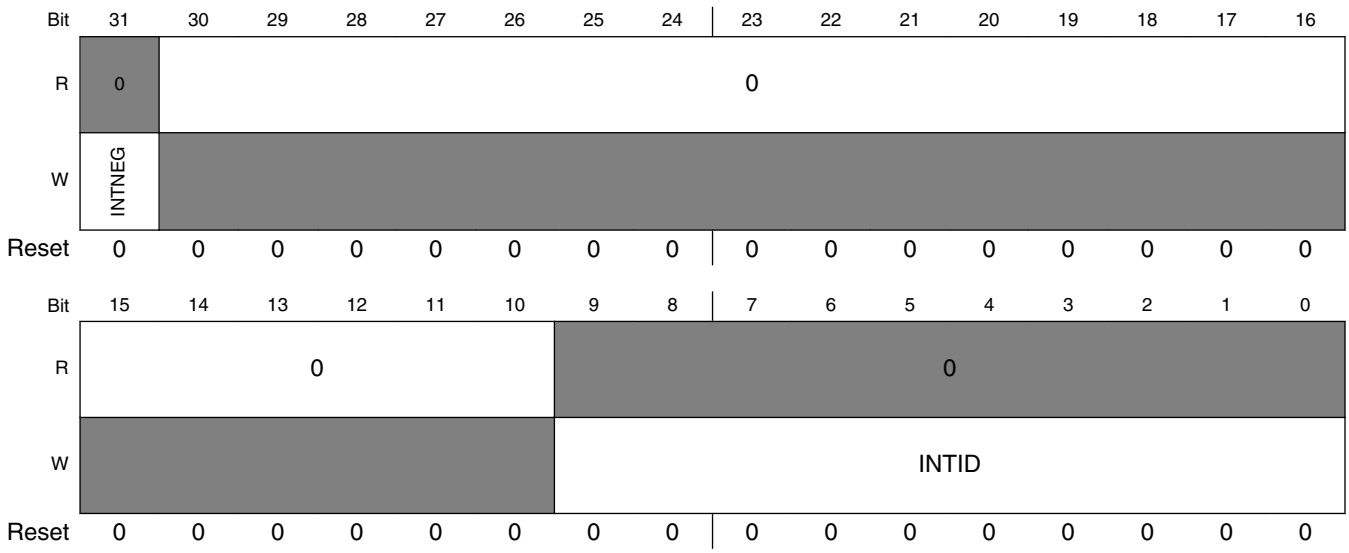
75.6.15 Software Interrupt Trigger Register (TZIC_SWINT)

The interrupt controller software interrupt register (SWINT) can be used by software to assert or negate an interrupt at a specific interrupt number. Writing the number of the desired interrupt will either trigger an interrupt to assert if not already asserted by hardware, or negate an interrupt that was originally asserted by software. An interrupt asserted by hardware cannot be negated by this register. Triggering an interrupt with the SWINT is equivalent to asserting the associated interrupt input pin, except regarding the tzic_wakeup_request output. It will be asserted in the SRCSET/SRCCLEAR regitsers, but will not be pending unless the interrupt is enabled. A software interrupt will not cause a wakeup request.

A secure write can trigger any enabled interrupt. A non-secure write can only trigger non-secure interrupts, an attempt to trigger a secure interrupt with a non-secure write will be ignored. If wbstrb[3] is not asserted to indicate whether asserting or negating an interrupt, the write will be ignored.

This register can only be accessed by 32-bit supervisor transactions.

Address: TZIC_SWINT is FFFC000h base + F00h offset = 0FFF_CF00h



TZIC_SWINT field descriptions

Field	Description
31 INTNEG	Interrupt Negate. This bit indicates whether the interrupt ID in the INTID field is being asserted or negated. Assuming the interrupt is not being asserted by hardware, when 1'b0, an interrupt is asserted, when 1'b1, an interrupt is negated.
30–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–0 INTID	Interrupt ID. This field indicates the number of the interrupt to be triggered (asserted or negated). Triggering an interrupt outside of the maximum number of interrupts will result in UPREDICTABLE behavior. Triggering a secure interrupt with a non-secure write will have no effect.

Chapter 76
Universal Asynchronous Receiver/Transmitter (UART)

76.1 Overview

Universal Asynchronous Receiver/Transmitter (UART) provides serial communication capability with external devices through an RS-232 cable or through use of external circuitry that converts infrared signals to electrical signals (for reception) or transforms electrical signals to signals that drive an infrared LED (for transmission) to provide low speed IrDA compatibility. UART supports NRZ encoding format and IrDA-compatible infrared slow data rate (SIR) format.

The following figure is the UART block diagram.

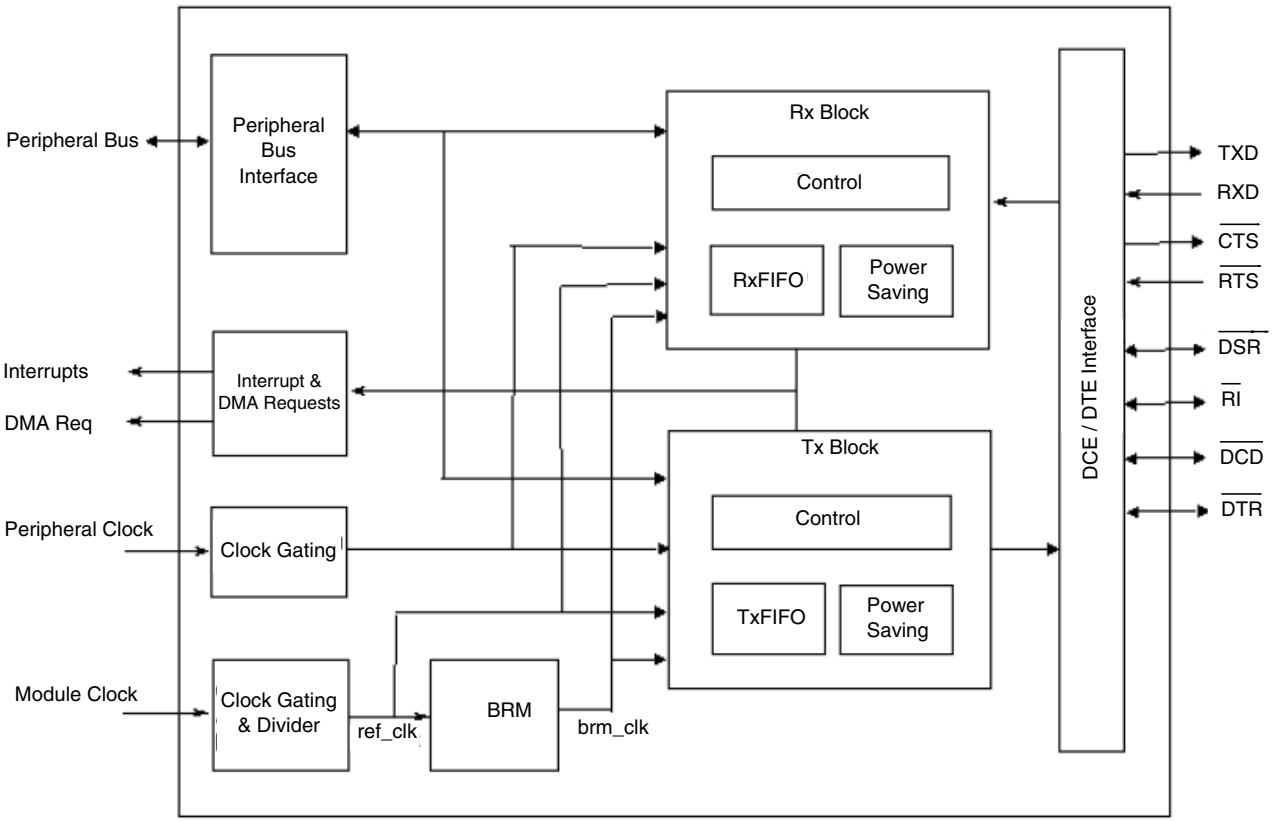


Figure 76-1. UART Block Diagram

76.1.1 Features

The UART includes the following features:

- High-speed TIA/EIA-232-F compatible, up to 4.0 Mbit/s
- Serial IR interface low-speed, IrDA-compatible (up to 115.2 Kbit/s)
- 7 or 8 data bits
- 1 or 2 stop bits
- Programmable parity (even, odd, and no parity)
- Hardware flow control support for request to send ($\overline{RTS}$) and clear to send ($\overline{CTS}$) signals
- Edge-selectable $\overline{RTS}$ and edge-detect interrupts
- Status flags for various flow control and FIFO states
- Voting logic for improved noise immunity (16x oversampling)
- Transmitter FIFO empty interrupt suppression
- UART internal clocks enable/disable
- Auto baud rate detection (up to 115.2 Kbit/s)
- Receiver and transmitter enable/disable for power saving

- DCE/DTE capability
- $\overline{\text{RTS}}$, IrDA asynchronous wake (AIRINT), receive asynchronous wake (AWAKE), $\overline{\text{RI}}$ (DTE only), $\overline{\text{DCD}}$ (DTE only), $\overline{\text{DTR}}$ (DCE only) and $\overline{\text{DSR}}$ (DTE only) interrupts wake the processor from STOP mode
- Maskable interrupts
- Two DMA Requests (TxFIFO DMA Request and RxFIFO DMA Request)
- Escape character sequence detection
- Software reset ($\overline{\text{SRST}}$)
- Two independent, 32-entry FIFOs for transmit and receive
- The peripheral clock can be totally asynchronous with the module clock. The module clock determines baud rate. This allows frequency scaling on peripheral clock (such as during DVFS mode) while remaining the module clock frequency and baud rate.

76.1.2 Modes of Operation

- Serial RS-232NRZ mode
- IrDA mode

76.1.3 UART I/O Configuration in DTE and DCE Modes

The i.MX53 UART interfaces can serve both as DTE or DCE device. This can be configured by the DCEDTE control bit (default 0 – DCE mode). Table 76-1 shows the UART I/O configuration based on the operation mode.

Table 76-1. UART I/O Configuration

Port	DTE Mode		DCE Mode	
	Direction	Description	Direction	Description
RTS	Output	RTS from DTE to DCE	Input	RTS from DTE to DCE
CTS	Input	CTS from DCE to DTE	Output	CTS from DCE to DTE
DTR	Output	DTR from DTE to DCE	Input	DTR from DTE to DCE
DSR	Input	DSR from DCE to DTE	Output	DSR from DCE to DTE
DCD	Input	DCD from DCE to DTE	Output	DCD from DCE to DTE
RI	Input	RING from DCE to DTE	Output	RING from DCE to DTE
TXD_MUX	Input	Serial data from DCE to DTE	Output	Serial data from DCE to DTE
RXD_MUX	Output	Serial data from DTE to DCE	Input	Serial data from DTE to DCE

The UART IP Signals definitions along the chapter are following DCE viewpoint (for which the CTS is output and RTS is input).

The UART pins (at IC boundary) change direction according to UART functionality: data communication equipment (DCE mode) or as data terminal equipment (DTE mode). For example, in DCE mode the TxD pad is set as output and RxD is set as input. In DTE mode the TxD pad is set as input and RxD pad is set as output.

This additional signal multiplexing occurs between the UART IP and the IC pad (at the IOMUX) and sets the pad functionality for the different modes. For information regarding UART I/O routing to IC pads, please refer to Table 4-3.

76.2 External Signals

The following table lists conventions for representing signals.

Table 76-2. Module Signal Conventions

Category	Convention	Example(s
Off-chip signal	Uppercase (all capital letters)	TXD
Internal signal[1]	Lowercase italics	*core_int*
Active low signal	_B (_b) suffix or overbar	RESET_EN_B or $\overline{\text{RESET\_EN}}$
Range of bussed or commonly named signals	Beginning and end points of the range are: • Separated by a colon. • Surrounded by square brackets.	ADDR[31:0] CSE_B[7:0] or $\overline{\text{CSE}}$[7:0]
Individual signal in a range of bussed or commonly named signals	Individual number in the range appears without a colon or square brackets	ADDR31 CSE0_B or $\overline{\text{CSE0}}$

1. Internal signals are for reference only in descriptions of internal module or SoC functionality.

The table below describes all UART signals that connect off-chip.

Table 76-3. Off-Chip Module Signals

Signal name	I/O	Active state	Description	Reset state
Serial / IrDA Signals				
RXD	I		Serial / infrared data receive	
TXD	O		Serial/infrared data transmit	High
Modem Control Signals				
$\overline{\text{CTS}}$	O	Low	Clear to send	High
$\overline{\text{RTS}}$	I	Low	Request to send	
$\overline{\text{DSR}}$	I/O	Low	Data set ready	High

Table continues on the next page...

Table 76-3. Off-Chip Module Signals (continued)

Signal name	I/O	Active state	Description	Reset state
$\overline{DCD}$	I/O	Low	Data carrier detected	High
$\overline{DTR}$	I/O	Low	Data terminal ready	
$\overline{RI}$	I/O	Low	Ring indicator	High
Interrupts				
interrupt_uart	O	Low	UART interrupt	High
DMA Requests				
dma_req_rx	O	Low	Receiver DMA request	High
dma_req_tx	O	Low	Transmitter DMA request	High
Clocks				
peripheral_clock	I		Peripheral clock	
module_clock	I		Clock source for the module's logic	
Special Signals				
stop_req	I	High	Module stop mode	
doze_req	I	High	Module doze mode	
debug_req	I	High	Module debug	

76.2.1 Detailed Signal Descriptions

76.2.1.1 Serial/IrDA Signals

76.2.1.1.1 RXD - Data Receive

Input asynchronous data receive in Serial and IrDA modes.

76.2.1.1.2 TXD - Data Transmit

Output asynchronous data transmit in Serial and IrDA modes.

76.2.1.2 Modem Control Signals

76.2.1.2.1 $\overline{\text{CTS}}$ - Clear To Send

Output in DCE and DTE mode. This signal informs the remote modem that UART is ready to receive data.

76.2.1.2.2 $\overline{\text{RTS}}$ - Request To Send

Input in DCE and DTE mode. This signal informs UART that remote modem is ready to receive data.

76.2.1.2.3 $\overline{\text{DSR}}$ - Data Set Ready

Input in DTE mode. Indicates to UART that remote modem is operational.

Output in DCE mode. Indicates to remote modem that UART is operational.

76.2.1.2.4 $\overline{\text{DCD}}$ - Data Carrier Detected

Input in DTE mode. Indicates to UART that a good carrier is being received from the remote modem.

Output in DCE mode. Indicates to remote device that a good carrier is being received from the UART.

76.2.1.2.5 $\overline{\text{DTR}}$ - Data Terminal Ready

Input in DCE mode. Indicates to UART (in DCE mode) that remote device (in DTE mode) is operational.

Output in DTE mode. Indicates to remote modem (in DCE mode) that UART (in DTE mode) is operational.

76.2.1.2.6 $\overline{\text{RI}}$ - Ring Indicator

Input in DTE mode. Indicates to UART that remote modem is detecting a ringing tone.

Output in DCE mode. Indicates to remote device that UART is detecting a ringing tone.

76.2.1.3 Interrupt Signals

76.2.1.3.1 *interrupt_uart* - UART Interrupt

Output interrupt request.

76.2.1.4 DMA Request Signals

76.2.1.4.1 *dma_req_rx* - Receiver DMA Request

Output DMA Request signal for receiver interface.

76.2.1.4.2 *dma_req_tx* - Transmitter DMA Request

Output DMA Request signal for transmitter interface. Set at 0 when TXDMAEN (UCR1[3]) is at 1 and TRDY (USR1[13]) is also at 1.

76.2.1.5 Clock Signals

76.2.1.5.1 *peripheral_clock* - Peripheral Clock

See Clocks for more information about *peripheral_clock* .

76.2.1.5.2 *module_clock* - Module Clock

See Clocks for more information about *module_clock* .

76.2.1.6 Special Signals

76.2.1.6.1 *stop_req* - Stop Mode

Input stop mode. Indicates to UART that ARM platform is going to enter in Stop Mode and clocks are going to stop running.

See Low Power Modes for more information about Stop Mode.

76.2.1.6.2 *doze_req* - Doze Mode

Input doze mode. ARM platform requests UART to switch in doze mode (power saving mode).

See Low Power Modes for more information about Doze Mode.

76.2.1.6.3 *debug_req* - Debug Mode

Input debug mode. Indicates UART it has to enter in debug mode.

See UART Operation in System Debug State, for more information about Debug Mode.

76.3 Functional Description

This section provides a complete functional description of the block.

76.3.1 Interrupts and DMA Requests

See the following table for the lists of all interrupt and DMA signals and associated interrupt and DMA sources of the UART. See register description section for explanation of interrupt/DMA enable and status.

Table 76-4. Interrupts and DMA

Interrupt/DMA Output	Interrupt/DMA Enable	Enable Register Location	Interrupt/DMA Flag	Flag Register Location
interrupt_uart	RRDYEN	UCR1 (bit 9)	RRDY	USR1 (bit 9)
	IDEN	UCR1 (bit 12)	IDLE	USR2 (bit 12)
	DREN	UCR4 (bit 0)	RDR	USR2 (bit 0)
	RXDSEN	UCR3 (bit 6)	RXDS	USR1 (bit 6)
	ATEN	UCR2 (bit 3)	AGTIM	USR1 (bit 8)
interrupt_uart	TXMPTYEN	UCR1 (bit 6)	TXFE	USR2 (bit 14)
	TRDYEN	UCR1 (bit 13)	TRDY	USR1 (bit 13)
	TCEN	UCR4 (bit 3)	TXDC	USR2 (bit 3)

Table continues on the next page...

Table 76-4. Interrupts and DMA (continued)

Interrupt/DMA Output	Interrupt/DMA Enable	Enable Register Location	Interrupt/DMA Flag	Flag Register Location
interrupt_uart	OREN	UCR4 (bit 1)	ORE	USR2 (bit 1)
	BKEN	UCR4 (bit 2)	BRCD	USR2 (bit 2)
	WKEN	UCR4 (bit 7)	WAKE	USR2 (bit 7)
	ADEN	UCR1 (bit 15)	ADET	USR2 (bit 15)
	ACIEN	UCR3 (bit 0)	ACST	USR2 (bit 11)
	ESCI	UCR2 (bit 15)	ESCF	USR1 (bit 11)
	ENIRI	UCR4 (bit 8)	IRINT	USR2 (bit 8)
	AIRINTEN	UCR3 (bit 5)	AIRINT	USR1 (bit 5)
	AWAKEN	UCR3 (bit 4)	AWAKE	USR1 (bit 4)
	FRAERREN	UCR3 (bit 11)	FRAERR	USR1 (bit 10)
	PARERREN	UCR3 (bit 12)	PARITYERR	USR1 (bit 15)
	RTSDEN	UCR1 (bit 5)	RTSD	USR1 (bit 12)
	RTSEN	UCR2 (bit 4)	RTSF	USR2 (bit 4)
	DTREN (DCE)	UCR3 (bit 13)	DTRF	USR2 (bit 13)
	RI (DTE)	UCR3 (bit 8)	RIDELT	USR2 (bit 10)
	DCD (DTE)	UCR3 (bit 9)	DCDDELT	USR2 (bit 6)
	DTRDEN	UCR3 (bit 3)	DTRD	USR1 (bit 7)
dma_req_rx	RXDMAEN	UCR1 (bit 8)	RRDY	USR1 (bit 9)
	ATDMAEN	UCR1 (bit 2)	AGTIM	USR1 (bit 8)
	IDDMAEN	UCR4 (bit 6)	IDLE	USR2 (bit 12)
dma_req_tx	TXDMAEN	UCR1 (bit 3)	TRDY	USR1 (bit 13)

76.3.2 Clocks

This section describes clocks and special clocking requirements of the UART.

76.3.2.1 Clock requirements

UART module receives 2 clocks, *peripheral_clock* and *module_clock*. The *peripheral_clock* is used as write clock of the TxFIFO, read clock of the RxFIFO and synchronization of the modem control input pins. It must always be running when UART is enabled. There is an exception in stop mode (see Clocking in Low-Power Modes).

The *module_clock* is for all the state machines, writing RxFIFO, reading TxFIFO, etc. It must always be running when UART is sending or receiving characters.This clock is used in order to allow frequency scaling on *peripheral_clock* without changing configuration of baud rate (*module_clock* staying at a fixed frequency).

The constraints on *peripheral_clock* and *module_clock* are as follows:

- *peripheral_clock* and *module_clock* can totally be asynchronous. Off course, they can also be synchronous.
- Due to the 16x oversampling of the incoming characters, *module_clock* frequency must always be greater or equal to 16x the maximum baud rate. For example, if max baud rate is 4 Mbit/s, *module_clock* must be greater or equal to 4 M x 16 = 64MHz.

NOTE

The restriction that *peripheral_clock* frequency must be higher or equal to 16x baud rate has been removed. There is no limitation on *peripheral_clock* frequencyto baud rate.

76.3.2.2 Maximum Baud Rate

The max baud rate the UART can support is determined by the max frequency of the *module_clock* and logic synthesis results.

For example, if the SoC can provide the fastest *module_clock* 66.5 MHz and the UART synthesis timing is acceptable under this constraint, the UART can transmit and receive serial data with the maximum baud rate 66.5M/16 = 4.15 Mbit/s.

The UART supports serial IR interface low speed. In the low speed IrDA mode, the max baud rate is 115.2Kbit/s. To support the 115.2Kbit/s, *module_clock* frequency must be higher or equal to 1.8432MHz.

76.3.2.3 Clocking in Low-Power Modes

The UART supports 2 low-power modes: DOZE and STOP.

In STOP mode (input pin *stop_req* is at '1'), the UART doesn't need any clock. In this mode the UART can wake-up the ARM platform with the asynchronous interrupts (refer to Low Power Modes). An application of this feature is when the system must be waken-up by the arrival of a frame of characters.

- If before entering in Stop mode the software has enabled RTSDEN interrupt, then when RTS will change state (put at '0' by external device started to send), the

asynchronous interrupt will wake-up the system, *peripheral_clock* and *module_clock* will be provided to the UART before first start bit, so that no data will be lost.

- If RTS doesn't change state (already at '0' before entering in Stop mode), then wake-up interrupt (AWAKE) will be sent at the arrival of first Start bit (on falling edge). In this case, the UART must receive the *peripheral_clock* and *module_clock* during the first half of start bit to correctly receive this character (for example, at 115.2 Kbit/s, UART must receive *peripheral_clock* and *module_clock* at maximum 4.3 microseconds after falling edge of Start bit). If the UART receives *peripheral_clock* and *module_clock* too late, first character will be lost, and so should be dropped. Also, if autobaud detection is enabled, the first character won't be correctly received and another autobaud detection will need to be initiated.

In Doze mode, UART behavior is programmable through DOZE bit (UCR1[1]). If DOZE bit is set to '1', then UART is disabled in Doze mode, and in consequence, UART clocks can be switched-off (after being sure UART is not transmitting nor receiving). On the contrary, if DOZE bit is set to '0', UART is enabled and it must receive *peripheral_clock* and *module_clock* .

76.3.3 General UART Definitions

Definitions of terms that occur the following discussions are given in this section.

- Bit Time-The period of time required to serially transmit or receive 1 bit of data (1 cycle of the baud rate frequency).
- Start bit-The bit time of a logic 0 that indicates the beginning of a data frame. A start bit begins with a 1-to-0 transition, and is preceded by at least 1 bit time of logic 1.
- Stop bit-1 bit time of logic 1 that indicates the end of a data frame.
- BREAK-A frame in which all of the data bits, including the stop bit, are logic 0. This type of frame is usually sent to signal the end of a message or the beginning of a new message.
- Mark - When no data is being sent, the serial port's transmit pin's voltage is 1 and is said to be in a MARK state.
- Space - The serial port can also be forced to keep the transmit pin at a 0 and is said to be the SPACE or BREAK state.
- Frame-A start bit followed by a specified number of data or information bits and terminated by a stop bit. The number of data or information bits depends on the format specified and must be the same for the transmitting device and the receiving device. The most common frame format is 1 start bit followed by 8 data bits (least significant bit first) and terminated by 1 stop bit. An additional stop bit and a parity bit also can be included.

- Framing Error-An error condition that occurs when the stop bit of a received frame is missing, usually when the frame boundaries in the received bit stream are not synchronized with the receiver bit counter. Framing errors can go undetected if a data bit in the expected stop bit time happens to be a logic 1. A framing error is always present on the receiver side when the transmitter is sending BREAKs. However, when the UART is programmed to expect 2 stop bits and only the first stop bit is received, this is not a framing error by definition.
- Parity Error-An error condition that occurs when the calculated parity of the received data bits in a frame does not match the parity bit received on the RXD input. Parity error is calculated only after an entire frame is received.
- Idle-One in NRZ encoding format and selectable polarity in IrDA mode.
- Overrun Error-An error condition that occurs when the latest character received is ignored to prevent overwriting a character already present in the UART receive buffer (RxFIFO). An overrun error indicates that the software reading the buffer (RxFIFO) is not keeping up with the actual reception of characters on the RXD input.

76.3.3.1 $\overline{\text{RTS}}$ - UART Request To Send

The UART Request To Send input controls the transmitter. The modem or other terminal equipment signals the UART when it is ready to receive by setting '0' on the RTS pin.

Normally, the transmitter waits until this signal is active (low) before transmitting a character, however when the Ignore RTS (IRTS) bit is set, the transmitter sends a character as soon as it is ready to transmit. An interrupt (RTSD) can be posted on any transition of this pin and can wake the ARM platform from STOP mode on its assertion. When $\overline{\text{RTS}}$ is set to '1' during a transmission, the UART transmitter finishes transmitting the current character and shuts off. The contents of the TxFIFO (characters to be transmitted) remain undisturbed. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode.

76.3.3.2 RTS Edge Triggered Interrupt

The input to the $\overline{\text{RTS}}$ pin can be programmed to generate an interrupt on a selectable edge.

See the table below for summary of the operation of the RTS edge triggered interrupt (RTSF).

To enable the $\overline{\text{RTS}}$ pin to generate an interrupt, set the request to send interrupt enable (RTSEN) bit (UCR2[4]) to 1. Writing 1 to the $\overline{\text{RTS}}$ edge triggered interrupt flag (RTSF) bit (USR2[4]) clears the interrupt flag. The interrupt can occur on the rising edge, falling

edge, or either edge of the RTS input. The request to send edge control (RTEC) field (UCR2[10:9]) programs the edge that generates the interrupt. When RTEC is set to 0x00 and RTSEN = 1, the interrupt occurs on the rising edge (default). When RTEC is set to 0x01 and RTSEN = 1, the interrupt occurs on the falling edge. When RTEC is set to 0x1X and RTSEN = 1, the interrupt occurs on either edge. This is a synchronous interrupt. The RTSF bit is cleared by writing 1 to it. Writing 0 to RTSF has no effect.

Table 76-5. RTS Edge Triggered Interrupt Truth Table

RTS	RTSEN	RTEC [1]	RTEC [0]	RTSF	Interrupt Occurs On...	interrupt_uart
X	0	X	X	0	Interrupt disabled	1
1->0	1	0	0	0	Rising edge	1
0->1	1	0	0	1	Rising edge	0
1->0	1	0	1	1	Falling edge	0
0->1	1	0	1	0	Falling edge	1
1->0	1	1	X	1	Either edge	0
0->1	1	1	X	1	Either edge	0

There is another RTS interrupt that is not programmable. The status bit RTSD asserts the *interrupt_uart* interrupt when the RTS delta interrupt enable = 1. This is an asynchronous interrupt. The RTSD bit is cleared by writing 1 to it. Writing 0 to the RTSD bit has no effect.

76.3.3.3 DTR - Data Terminal Ready

This signal indicates the general readiness of the Data Terminal Equipment (DTE). This signal is an input in DCE mode and an output in DTE mode. If the connection between the DCE and the DTE is established once, the DTR signal must remain active throughout the whole connection time.

In general the DTR and DSR signals are responsible for establishing the connection. RTS and CTS are responsible for the data transfer and the transfer direction in the case of a half-duplex configuration. The DTR signal is like a "main switch". If the DTR signal is inactive the RTS and CTS signals have no effect. In DCE mode, an interrupt (DTRD) can be posted on any transition of this pin and can wake the ARM platform from STOP mode on its assertion.

76.3.3.4 $\overline{\text{DSR}}$ - Data Set Ready

This signal indicates the general readiness of the DCE. This signal is an output in DCE mode and an input in DTE mode. The DCE uses this signal to inform the DTE that it is switched on, has completed all preparations and can communicate with the DTE.

In DTE mode, an interrupt (DTRD) can be posted on any transition of this pin and can wake the ARM platform from STOP mode on its assertion.

76.3.3.5 $\overline{\text{DTR/DSR}}$ Edge Triggered Interrupt

The $\overline{\text{DTR}}$ input pin (DCE mode) or $\overline{\text{DSR}}$ input pin (DTE mode) can be configured to cause an interrupt on a selectable edge.

See the table below for summary of the operation of the DTR/DSR edge triggered interrupt. To enable the interrupt, set the DTREN bit (UCR3[13]) to '1'. Write a "one" to the DTRF bit (USR2[13]) to clear the interrupt flag.

The interrupt can be configured to occur on either the rising, falling, or either edge of the $\overline{\text{DTR/DSR}}$ input. Write to the DPEC[1:0] bits (UCR3[15:14]) to program which edge will cause an interrupt. If the bits are set to 00b and DTREN = 1, the interrupt will occur on the rising edge (default). If the bits are set to 01b and DTREN = 1, the interrupt will occur on the falling edge. If the bits are set to 1Xb and DTREN = 1, the interrupt will occur on either edge.

Table 76-6. $\overline{\text{DTR/DSR}}$ Edge Triggered Interrupt Truth Table

$\overline{\text{DTR}}$ / $\overline{\text{DSR}}$	DTREN	DPEC[1]	DPEC[0]	DTRF	Interrupt occurs on:	interrupt_uart
X	0	X	X	0	turned off	1
1->0	1	0	0	0	rising edge	1
0->1	1	0	0	1	rising edge	0
1->0	1	0	1	1	falling edge	0
0->1	1	0	1	0	falling edge	1
1->0	1	1	X	1	either edge	0
0->1	1	1	X	1	either edge	0

76.3.3.6 $\overline{\text{DCD}}$ - Data Carrier Detect

This signal is an output in DCE mode and an input in DTE mode. If used, the DCE device uses this signal to inform the DTE it has detected the carrier signal and the connection will be set up. This signal remains active while the connection remains established.

In DTE mode this input can trigger an interrupt on changing state. This is achieved by setting to '1' the interrupt enable bit (DCD, UCR3[9]). The change state is reflected in DCDDELT (USR2[6]). Also, the state of the Data Carrier Detect input is mirrored in the status register DCDIN (USR2[5]).

76.3.3.7 $\overline{\text{RI}}$ - Ring Indicator

This signal is an output in DCE mode and an input in DTE mode. If used, the DCE device uses this signal to inform the DTE that a ring just occurred.

In DTE mode this input can trigger an interrupt on changing state. This is achieved by setting to '1' the interrupt enable bit (RI, UCR3[8]). The change state is reflected in RIDELT (USR2[10]). Also, the state of the Ring Indicator input is mirrored in the status register RIIN (USR2[9]).

76.3.3.8 $\overline{\text{CTS}}$ - Clear To Send

This output pin serves two purposes. Normally, the receiver indicates that it is ready to receive data by asserting this pin (low). When the $\overline{\text{CTS}}$ trigger level is programmed to trigger at 32 characters received and the receiver detects the valid start bit of the 33 character, it de-asserts this pin. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode.

76.3.3.9 Programmable $\overline{\text{CTS}}$ Deassertion

The $\overline{\text{CTS}}$ output can also be programmed to deassert when the RxFIFO reaches a certain level. Setting the CTS trigger level (UCR4[15:10]) at any value less than 32 deasserts the $\overline{\text{CTS}}$ pin on detection of the valid start bit of the N + 1 character (where N is the trigger level setting). However, the receiver continues to receive characters until the RxFIFO is full.

76.3.3.10 TXD - UART Transmit

This is the transmitter serial output. When operating in RS-232 mode, NRZ encoded data is . When operating in infrared mode, a 3/16 bit-period pulse is output for each 0 bit transmitted, and no pulse is output for each 1 bit transmitted.

For RS-232 applications, this pin must be connected to an RS-232 transmitter. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode. See Figure 76-2.

76.3.3.11 RXD - UART Receive

This is the receiver serial input. When operating in RS-232 mode, NRZ encoded data is expected. When operating in infrared mode, a narrow pulse is expected for each 0 bit received and no pulse is expected for each 1 bit received.

External circuitry must convert the IR signal to an electrical signal. RS-232 applications require an external RS-232 receiver to convert voltage levels. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode. See the figure below.

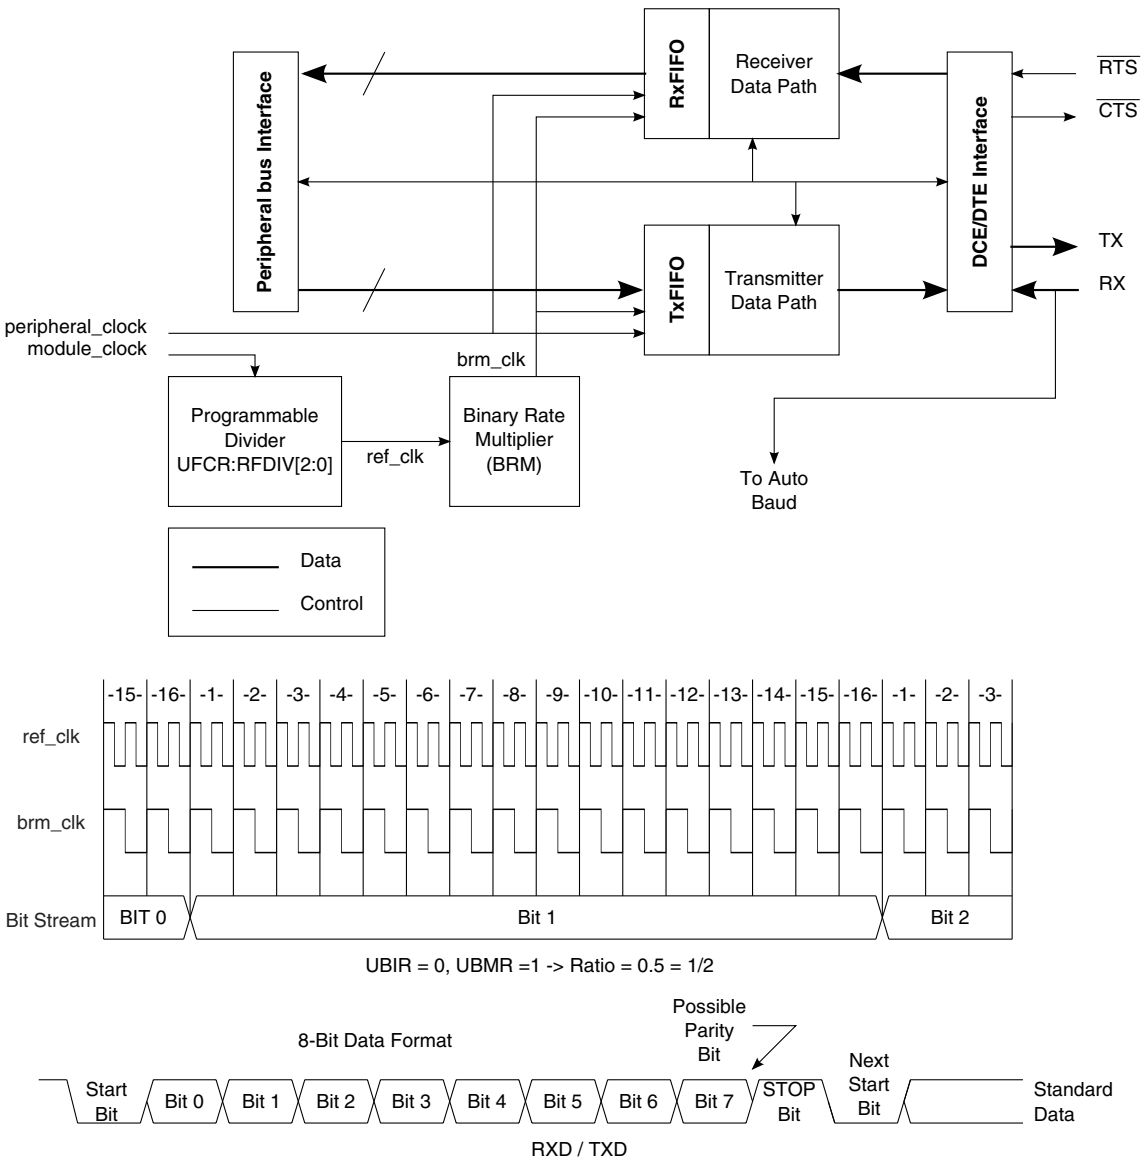

Figure 76-2. UART Simplified Block and Clock Generation Diagrams

76.3.4 Transmitter

The transmitter accepts a parallel character from the ARM platform and transmits it serially. The start, stop, and parity (when enabled) bits are added to the character.

When the ignore RTS bit (IRTS) is set, the transmitter sends a character as soon as it is ready to transmit. $\overline{RTS}$ can be used to provide flow-control of the serial data. When $\overline{RTS}$ is set to '1', the transmitter finishes sending the character in progress (if any), stops, and waits for $\overline{RTS}$ to be set to '0' again. Generation of BREAK characters and parity errors (for debugging purposes) is supported. The transmitter operates from the clock provided by the BRM. Normal NRZ encoded data is transmitted when the IR interface is disabled.

The transmitter FIFO (TxFIFO) contains 32 bytes. The data is written to TxFIFO by writing to the UTXD register with the byte data to the [7:0] bits. The data is written consecutively if the TxFIFO is not full. It is read (internally) consecutively if the TxFIFO is not empty. TXFULL bit (UTS[4]) can be used to control whether TXFIFO is full or not. The TxFIFO can be written regardless of the transmitter is disabled or enabled. If the UART is disabled, user can still write data into the TxFIFO correctly. But in this case the write access will yield to a transfer error.

76.3.4.1 Transmitter FIFO Empty Interrupt Suppression

The transmitter FIFO empty interrupt suppression logic suppresses the TXFE interrupt between writes to the TxFIFO.

When TxFIFO is empty, the software can either send one or several characters. If the software sends one character, it would write the character into the UTXD register, then that character is immediately transferred to the transmitter shift register, assuming the transmitter is already enabled. Without interrupt suppression logic, the TXFE interrupt flag would be set immediately. But, with this logic, the interrupt flag is set when the last bit of the character has been transmitted, for example, before the transmission of the parity bit (if exists) and the stop bit(s).

So, the suppression logic doesn't immediately send the TXFE interrupt flag. It allows the software to write another character to the TxFIFO before the interrupt flag is asserted.

When the transmitter shift register empties before another character is written to the TxFIFO, the interrupt flag is asserted. Writing data to the TxFIFO would release the interrupt flag. The interrupt flag is asserted on the following conditions:

- System Reset
- UART software reset

- When a single character has been written to Transmitter FIFO and then the Transmitter FIFO and the Transmitter Shift Register become empty until another character is written to the Transmitter FIFO
- The last character in the TxFIFO is transferred to the shift register, when TxFIFO contains two or more characters. See the figure below.

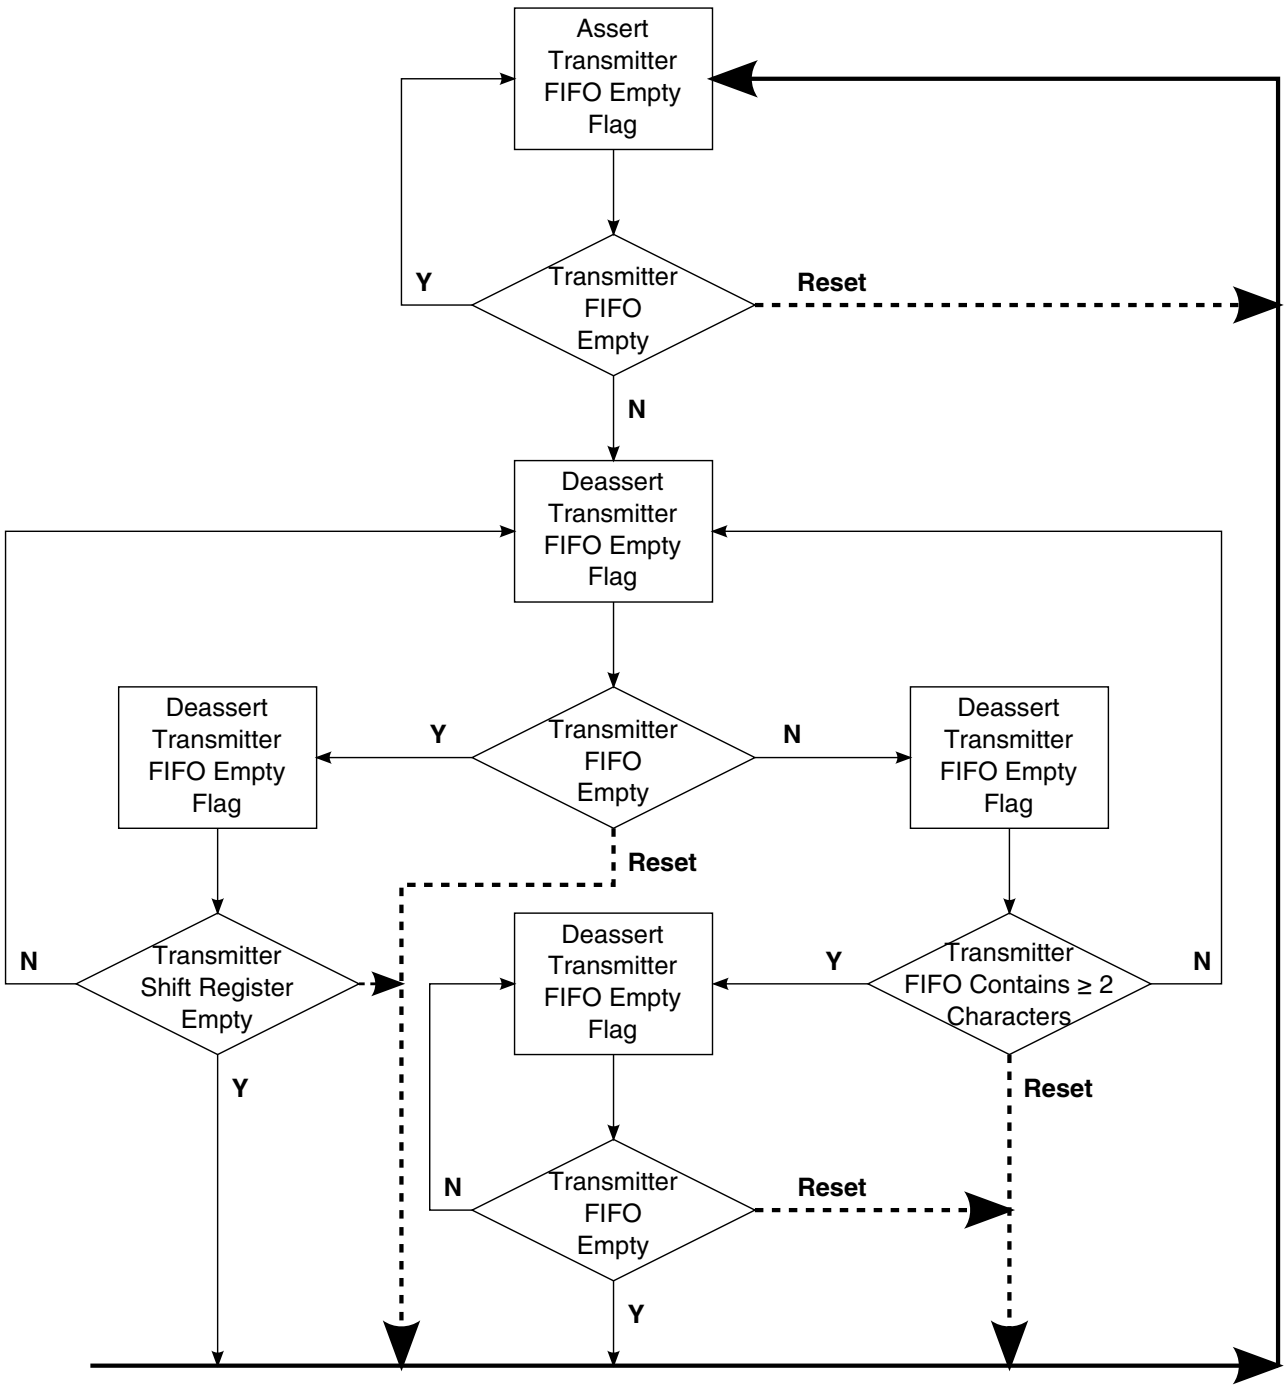

Figure 76-3. Transmitter FIFO Empty Interrupt Suppression Flow Chart

76.3.4.2 Transmitting a Break Condition

Asserting SNDBRK bit of the UCR1 Register forces the transmitter to send a break character (continuous zeros). The transmitter will finish sending the character in progress (if any) before sending break until this bit is reset.

The user is responsible to ensure that this bit is high for long enough to generate a valid BREAK. The transmitter samples SNDBRK after every bit is transmitted. Following completion of the BREAK transmission, the UART will transmit two mark bits. The user can continue to fill the FIFO and any character remaining will be transmitted when the break is terminated.

76.3.5 Receiver

See the figure below for the receiver flow chart.

The receiver accepts a serial data stream and converts it into parallel characters. When enabled, it searches for a start bit, qualifies it, and samples the following data bits at the bit-center. Jitter tolerance and noise immunity are provided by sampling at a 16x rate and using voting techniques to clean up the samples.

Once the start bit is found, the data bits, parity bit (if enabled), and stop bits (either 1 or 2 depending on user selection) are shifted in. Parity is checked and its status reported in the URXD register when parity is enabled. Frame errors and BREAKs are also checked and reported. When a new character is ready to be read by the ARM platform from the RxFIFO, the receive data ready (RDR = USR2[0]) bit is asserted and an interrupt is posted (if DREN = UCR4[0] = 1). If the receiver trigger level is set to 2 (RXTL[5:0] = UFCR[5:0] = 2), and 2 chars have been received into RxFIFO, the receiver ready interrupt flag (RRDY = USR1[9]) is asserted and an interrupt is posted if the receiver ready interrupt enable bit is set (RRDYEN = UCR1[9] = 1). If the UART Receiver Register (URXD) is read once, and in consequence there is only 1 character in the RxFIFO, the interrupt generated by the RDR bit is automatically cleared. The RRDY bit is cleared when the data in the RxFIFO falls below the programmed trigger level.

Normal NRZ encoded data is expected when the IR interface is disabled.The RxFIFO contains 32 half-word entries. Characters received are written consecutively into this FIFO. If the FIFO is full and a 33rd characters is received, this character will be ignored and the USR2[ORE] bit will be set.

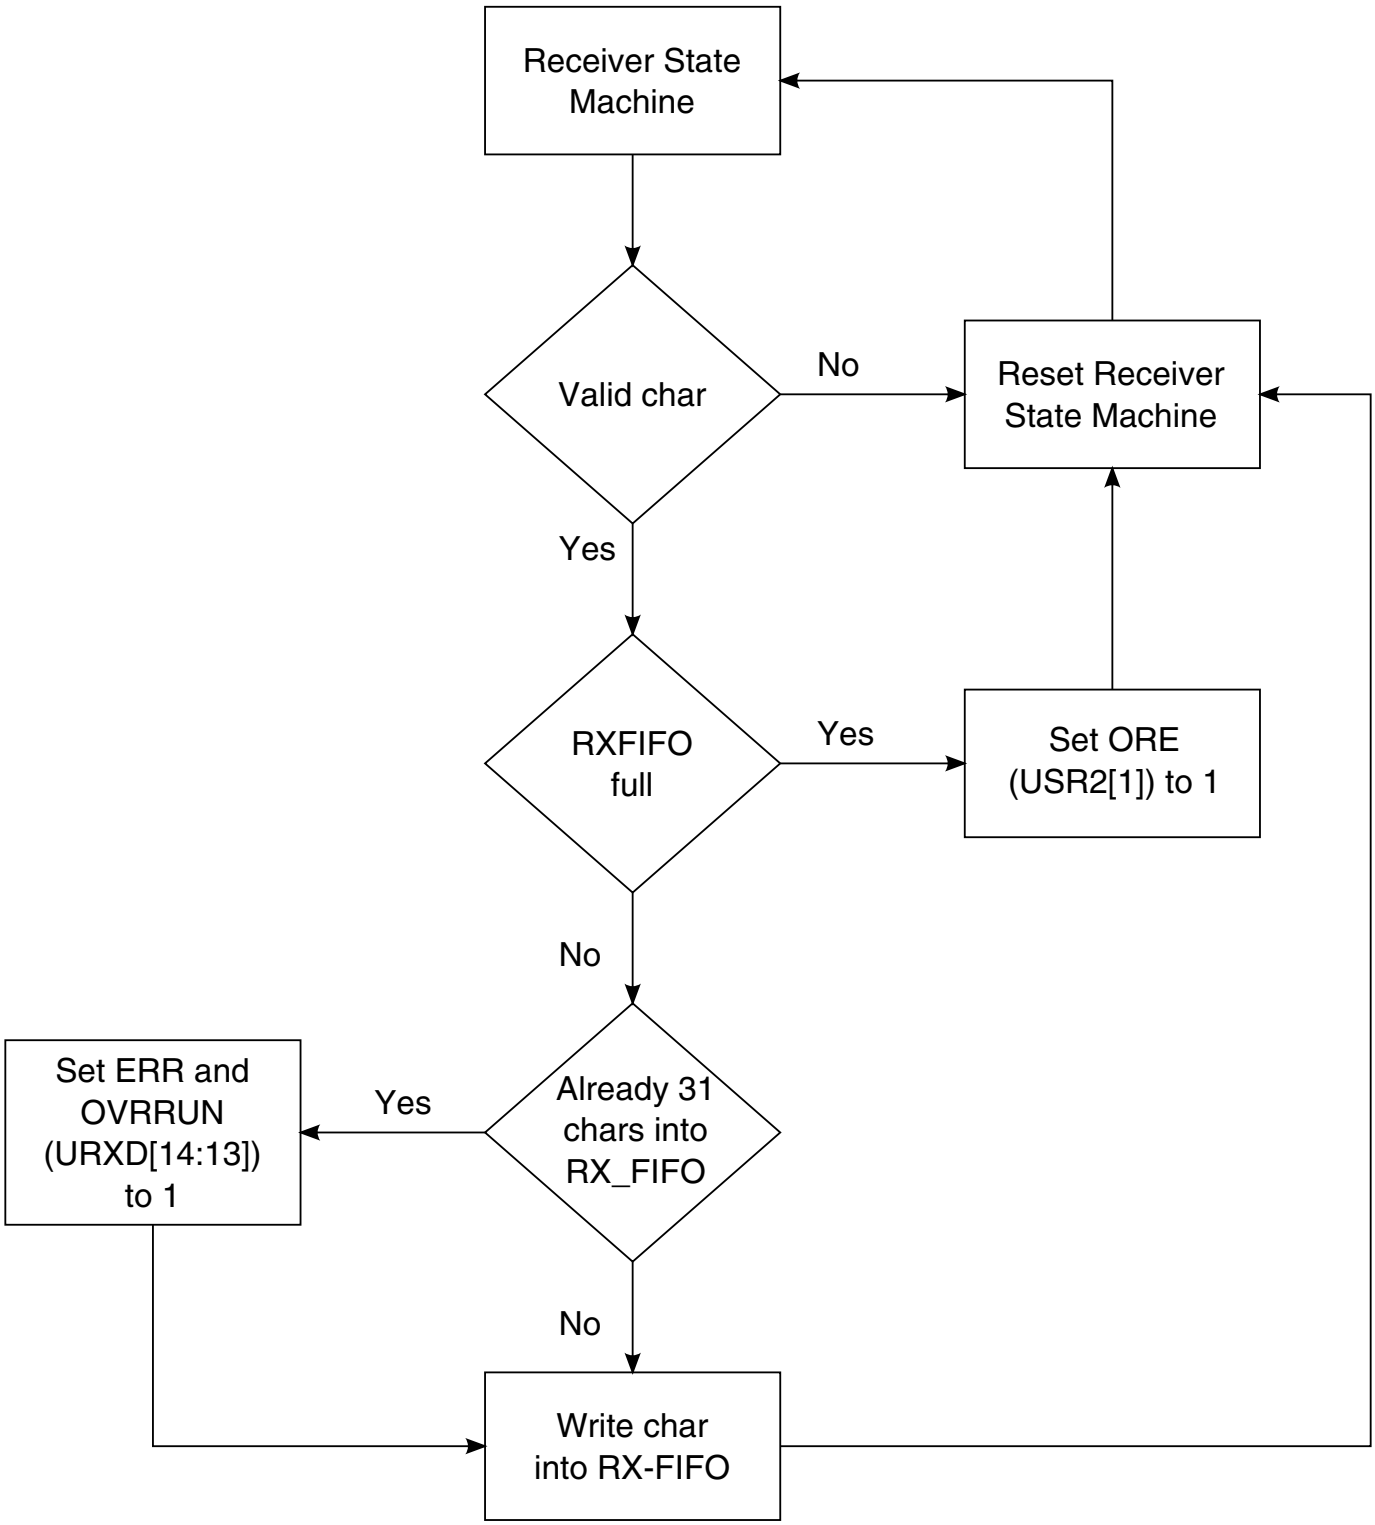

Figure 76-4. Receiver Flow Chart

76.3.5.1 Idle Line Detect

The receiver logic block includes the ability to detect an idle line. Idle lines indicate the end or the beginning of a message.

For an idle condition to occur:

- RxFIFO must be empty and
- RXD pin must be idle for more than a configured number of frames (ICD[1:0] = UCR1[11:10]).

When the idle condition detected interrupt enable (IDEN = UCR1[12]) is set and the line is idle for 4 (default), 8, 16, or 32 (maximum) frames, the detection of an idle condition flags an interrupt (see the table below). When an idle condition is detected, the IDLE (USR2[12]) bit is set. Clear the IDLE bit by writing 1 to it. Writing 0 to the IDLE bit has no effect.

Table 76-7. Detection Truth Table

IDEN	ICD [1]	ICD [0]	IDLE	*interrupt_uart*
0	X	X	0	1
1	0	0	asserted after 4 idle frames	asserted after 4 idle frames
1	0	1	asserted after 8 idle frames	asserted after 8 idle frames
1	1	0	asserted after 16 idle frames	asserted after 16 idle frames
1	1	1	asserted after 32 idle frames	asserted after 32 idle frames
NOTE: This table assumes that no other interrupt is set at the same time this interrupt is set for the *interrupt_uart* signal. This table shows how this interrupt affects the *interrupt_uart* signal.				

During a normal message there is no idle time between frames. When all of the information bits in a frame are logic 1s, the start bit ensures that at least one logic 0 bit time occurs for each frame so that the IDLE bit is not asserted.

76.3.5.2 Aging Character Detect

The receiver block also includes the possibility to detect when at least one character has been sitting into the RxFIFO for a time corresponding to 8 characters. This aging character capability allows the UART to inform the ARM platform that there is less character into the RxFIFO than the Rx trigger and, no new character has been detected on the RXD line.

The aging capability is a timer which starts to count as soon as the RxFIFO is not empty and its trigger level is not reached (RRDY=0). This counter is reset when either a RxFIFO read is performed or another character starts to present on the RXD line. If none of those two events occurs, the bit AGTIM (USR1[8]) is set when the counter has

measured a time corresponding to 8 characters. AGTIM is cleared by writing a 1 to it. AGTIM can flag an interrupt to ARM platform on *interrupt_uart* if ATEN (UCR2[3]) has been set.

To summarize, AGTIM is set when:

- There is at least one character into RxFIFO.
- No read has occurred on RxFIFO and RXD line has stayed high, for a time corresponding to 8 characters.
- The RxFIFO trigger is not reached (RRDY=0)

76.3.5.3 Receiver Wake

The WAKE bit (USR2[7]) is set when the receiver detects a qualified Start bit. For this, two conditions must be fulfilled, firstly a falling edge on RXD line must be detected and secondly the RXD line must stays at low level for more than a half-bit duration.

When the wake interrupt enable WKEN (UCR4[7]) bit is enabled, the receiver flags an interrupt (*interrupt_uart*) if the WAKE status bit is set. The WAKE bit is cleared by writing 1 to it. Writing 0 to the WAKE bit has no effect. The WAKE status bit can be asserted in either serial RS-232 mode or IR mode. The generation of the WAKE interrupt needs the clock *module_clock* .

When the asynchronous wake interrupt (AWAKE) is enabled (AWAKEN = UCR3[4] = 1), and the ARM platform is in STOP mode, and UART clocks have been shut-off, then a falling edge detected on the receive pin (RXD) asserts the AWAKE bit (USR1[4]) and the *interrupt_uart* interrupt to wake the ARM platform from STOP mode. Re-enable UART clocks and clear the AWAKE bit by writing 1 to it. Writing 0 to the AWAKE bit has no effect. When IR interface is enabled (UCR1[7]=1), the AWAKE bit is always not asserted. The generation of the asynchronous AWAKE interrupt does not need any clocks.

In IR mode, if the asynchronous IR WAKE interrupt is enabled (AIRINTEN = UCR3[5] = 1), and if the ARM platform is in STOP mode (UART clocks are off when ARM platform in STOP mode), then the detection of a falling edge on the receive pin (RXD_IR), asserts the AIRINT bit (USR1[5]), and the *interrupt_uart* interrupt. This interrupt wakes the ARM platform from STOP mode. Software re-enables UART clocks and clear the AIRINT bit by writing 1 to it. Writing 0 to the AIRINT bit has no effect. When IR interface is disabled (UCR1[7]=0), the AIRINT bit is always not asserted. The generation of the asynchronous AIRINT interrupt does not need any clocks.

Recommended procedure for programming the asynchronous interrupts is to first clear them by writing 1 to the appropriate bit in the UART Status Register 1 (USR1). Poll or enable the interrupt for the Receiver IDLE Interrupt Flag (RXDS) in the USR1. When asserted, the RXDS bit indicates to the software that the receiver state machine is in the idle state, the next state is idle, and the RXD pin is idle (high). After following this procedure, enable the asynchronous interrupt and enter STOP mode.

76.3.5.4 Receiving a BREAK Condition

A BREAK condition is received when the receiver detects all 0s (including a 0 during the bit time of the stop bit) in a frame. The BREAK condition asserts the BRCD bit (USR2[2]) and writes only the first BREAK character to the RxFIFO. Clear the BRCD bit by writing 1 to it. Writing 0 to the BRCD bit has no effect.

Asserting BRCD would generate an interrupt on *interrupt_uart*. The interrupt generation can be masked using the control bit BKEN (UCR4[2]). Receiving a break condition will also effect the following bits in the receiver register URXD:

URXD(11) = BRK. While high this bit indicates that the current char was detected as a break.

URXD(12) = FRMERR. The frame error bit will always be set when BRK is set.

URXD(10) = PRERR. If odd parity was selected the parity error bit will also be set when BRK is set.

URXD(14) = ERR. The error detect bit indicates that the character present in the rx data field has an error status. This can be asserted by a break.

76.3.5.5 Vote Logic

The vote logic block provides jitter tolerance and noise immunity by sampling with respect to a 16x clock (*brm_clk*) and using voting techniques to clean up the samples. The voting is implemented by sampling the incoming signal constantly on the rising edge of the *brm_clk*.

See Figure 76-5. The receiver is provided with the majority vote value, which is 2 out of the 3 samples. For examples of the majority vote results of the vote logic, see the following table.

Table 76-8. Majority Vote Results

Samples	Vote
000	0
101	1
001	0
111	1

The vote logic captures a sample on every rising edge of *brm_clk*, however the receiver uses 16x oversampling to take its value in the middle of the sample character.

The receiver starts to count when the Start bit is set however it does not capture the contents of the RxFIFO at the time the Start bit is set. The start bit is validated when 0s are received for 7 consecutive 1/16 of bit times following the 1-to-0 transition. Once the counter reaches 0xF, it starts counting on the next bit and captures it in the middle of the sampling frame (see Table 76-8). All data bits are captured in the same manner. Once the stop bit is detected, the receiver shift register (SIPO_OUT) data is parallel shifted to the RxFIFO.

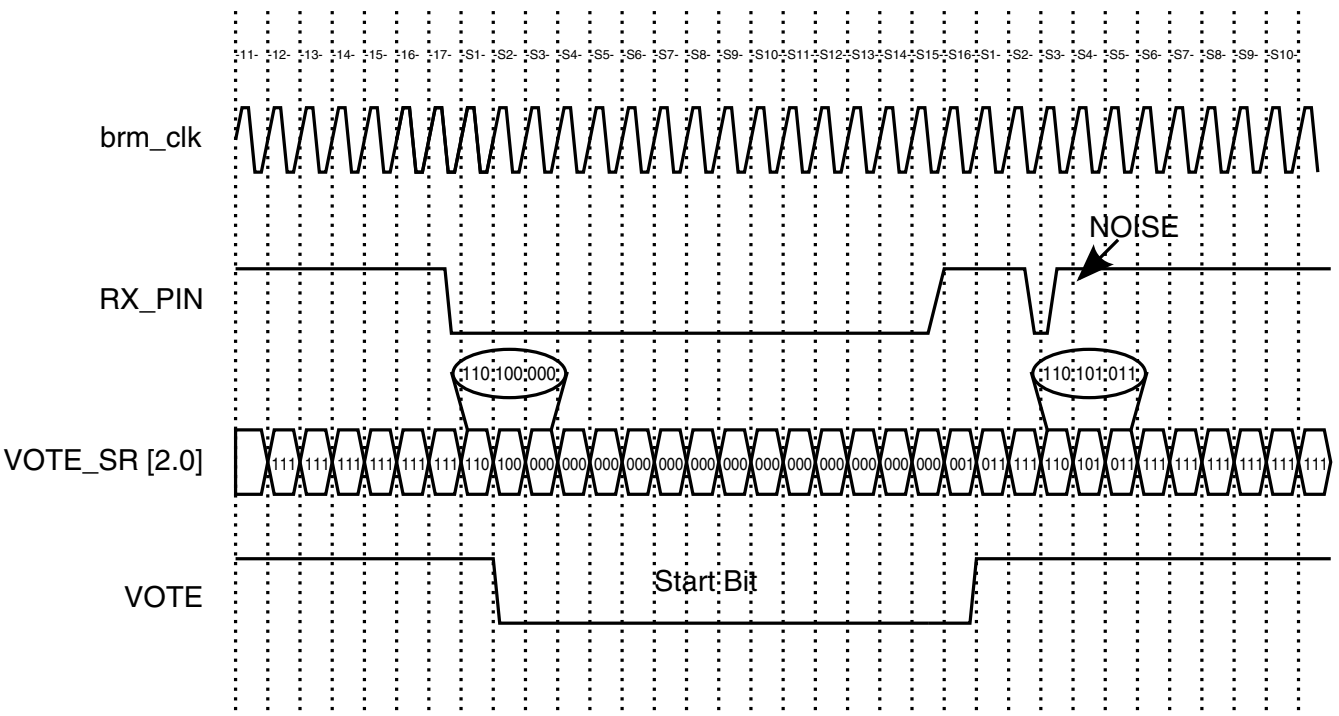

Figure 76-5. Majority Vote Results

A new feature has been recently implemented, it allows to re-synchronize the counter on each edge of RXD line. This is automatic and allows to improve the immunity of UART against signal distortion.

There is a special case when the *brm_clk* frequency is too low and is unable to capture a 0 pulse in IrDA. In this case, the software must set the IRSC (UCR4[5]) bit so that the reference clock (after internal divider) is used for the voting logic. The pulse is validated by counting the length of the pulse.

Refer to Infrared Interface for more details.

76.3.5.6 Baud Rate Automatic Detection Logic

When the baud rate automatic detection logic is enabled, the UART locks onto the incoming baud rate. To enable this feature, set the automatic detection of baud rate bit (ADBR = UCR1[14] = 1) and write 1 to the ADET bit (USR2[15]) to clear it.

When ADET=0 and ADBR =1, the detection starts. Then, once the beginning of start bit (transition from 1-to-0 of RXD) has been detected, UART start a counter (UBRC) working at reference frequency. Once the end of start bit is detected (transition from 0-to-1 of RXD), the value of UBRC - 1 is directly copied into UBMR register. UBIR register is filled with 0x000F.

So, at the end of start bit, registers gets following values:

```
UBRC = number of reference clock periods (after divider) during Start bit.
UBIR = 0x000F
UBMR = UBRC - 1
```

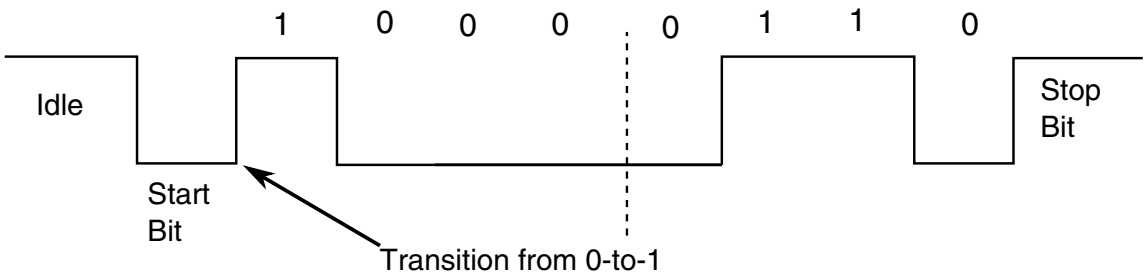
The updated values of the 3 registers can be read.

See Table 76-9 for list of parameters for baud rate detection and Figure 76-6 for baud rate detection protocol diagram.

If any of the UART BRM registers are simultaneously written by the baud rate automatic detection logic and by the peripheral data bus, the peripheral data bus would have lower priority.

Table 76-9. Baud Rate Automatic Detection

ADBR	ADET	Baud Rate Detection	*interrupt_uart*
0	X	Manual Configuration	1
1	0	Auto Detection Started	1
1	1	Auto Detection Complete	0
NOTE: This table assumes that no other interrupt is set at the same time this interrupt is set for the *interrupt_uart* signal.			



Note: LSB Transmitted first.

Figure 76-6. Baud Rate Detection Protocol Diagram

76.3.5.6.1 Baud Rate Automatic Detection Protocol

The receiver must receive an ASCII character "A" or "a" to verify proper detection of the incoming baud rate. When an ASCII character "A" (0x41) or "a" (0x61) is received and no error occurs, the Automatic Detect baud rate bit is set (ADET=1) and if the interrupt is enabled (ADEN=UCR1[15]=1), an interrupt *interrupt_uart* is generated.

When an ASCII character "A" or "a" is not received (because of a bit error or the reception of another character), the auto detection sequence restarts and waits for another 1-to-0 transition.

As long as ADET = 0 and ADBR = 1, the UART continues to try to lock onto the incoming baud rate. Once the ASCII character "A" or "a" is detected and the ADET bit is set, the receiver ignores the ADBR bit and continues normal operation with the calculated baud rate.

The UART interrupt is active (*interrupt_uart* = 0) as long as ADET = 1 and ADBR = 1. This can be disabled by clearing the automatic baud rate detection interrupt enable bit (ADEN = 0). Before starting an automatic baud rate detection sequence, set ADET = 0 and ADBR = 1.

The RxFIFO must contain the ASCII character "A" or "a" following the automatic baud rate detection interrupt.

The 16-bit UART Baud Rate Count Register (UBRC) is reset to 4 and stays at 0xFFFF when an overflow occurs. The UBRC register counts (measures) the duration of start bit. When the start bit is detected and counted, the UART Baud Rate Count Register retains its value until the next automatic baud rate detection sequence is initiated.

The Baud Rate Count Register counts only when auto detection is enabled.

76.3.5.6.2 New Baud Rate Determination

In order to fight against the problems caused by the distortion and the noise on the RXD line, the duration of the baud rate measurement has been extended.

Previously, as described above, this determination was based on the measurement of the START bit duration. Now, this measurement is based on the duration of START bit + bit0. Bit0 is the first bit following the START bit. In fact, the counter which is started at the falling edge of START bit is no longer stopped at next rising edge (end of START bit), but it is stopped at the next falling edge (end of bit0). As the character sent is always a "A" (41h) or a "a" (61h), this second falling edge will always be present and it will indicate the end of bit0. Once this counter is stopped, the result is divided by 2 and used by the BRM to determine the incoming baud rate.

NOTE

UBRC register contains the result of this division by two, in consequence it reflects the measurement of the duration of one bit.

76.3.5.6.2.1 New Autobaud Counter Stopped bit and Interrupt

A new bit has been added in USR2 register: ACST (USR2[11]). This bit is set immediately after the determination of the baud rate.

So,

- if ADNIMP is not set (default), ACST is set to 1 after the end of bit0,
- If ADNIMP is set to 1, ACST is set to 1 at the end of START bit.

If ACIEN (UCR3[0]) is set to 1, ACST will flag an interrupt on *interrupt_uart* signal. This interrupt informs the ARM platform that the BRM has just been set with the result of the bit length measurement. If needed, the ARM platform can perform a read of UBMR (or UBRC) register and determine by itself the baud rate measured. Then the ARM platform has the possibility to correct the BRM registers with the nearest standardized baud rate.

NOTE

ACST is set only if ADBR is set to 1, for example, the UART is autobauding.

Clear the ACST bit by writing 1 to it. Writing 0 to the ACST bit has no effect.

76.3.6 Escape Sequence Detection

An escape sequence typically consists of 3 characters entered in rapid succession (such as +++). Because these are valid characters by themselves, the time between characters determines if it is a valid escape sequence. Too much time between two of the "+" characters is interpreted as two "+" characters, and not part of an escape sequence.

The software chooses the escape character and writes its value to the UART Escape Character Register (UESC). The software must also enable escape detection feature by setting ESCEN (UCR2[11]) to 1. The hardware compares this value to incoming characters in the RxFIFO. When an escape character is detected, the internal escape timer starts to count. The software specifies a time-out value for the maximum allowable time between 2 successive escape characters (see the table below). The escape timer is programmable in intervals of 2 ms to a maximum interval of 8.192 seconds.

Table 76-10. Escape Timer Scaling

UTIM Register	Maximum Time Between Specified Escape Characters
0x000	2 ms
0x001	4 ms
0x002	6 ms
0x003	8 ms
0x004	10 ms
...	...
0F8	498 ms
0F9	500 ms
...	...
9C3	5 s
...	...
FFD	8.188 s
FFE	8.190 s
FFF	8.192 s
NOTE: To calculate the time interval: (UTIM_Value + 1) x 0.002 = Time_Interval Example: (09C3 + 1) x 0.002 = 5 s.	

The escape sequence detection feature is available for all the reference frequencies. Before using Escape Sequence Detection, the user must fill the ONEMS register. This 24-bit register must contain the value of the UART internal frequency divided by 1000. The internal frequency is obtained after the UART internal divider which is applied on *module_clock* clock.

Example I:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 2 with the internal divider: UFCR[9:7] = 3'b100

$$ONEMS = \frac{66.5 \times 10^6}{2 \times 1000} = 33250 = 81E2h$$

Figure 76-7. Calculation of Frequency for ONEMS Register

Example II:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 1with the internal divider: UFCR[9:7] = 3'b101

$$ONEMS = \frac{66.5 \times 10^6}{1000} = 66500 = 103C4h$$

Figure 76-8. Calculation of Frequency for ONEMS Register

The escape sequence detection interrupt is asserted when the escape sequence interrupt enable (ESCI) bit is set and an escape sequence is detected (ESCF set). Clear the ESCF bit by writing 1 to it. Writing 0 to the ESCF bit has no effect.

76.4 Binary Rate Multiplier (BRM)

The BRM sub-block receives *ref_clk* (*module_clock* clock after divider). From this clock, and with integer and non-integer division, BRM generates a 16x baud rate clock whose frequency is 16 times of baud rate.

The uart transmitter will shift data out based on this 16x baud rate clock. The uart receiver will sample the serial data line based on this 16x baud rate clock. The input and output frequency ratio is programmed in the UART BRM Incremental Register (UBIR) and UART BRM MOD Register (UBMR). The output frequency is divided by the input frequency to produce this ratio. For integer division, set the UBIR = 0x000F and write the divisor to the UBMR register. All values written to these registers must be one less than the actual value to eliminate division by 0 (undefined), and to increase the maximum range of the registers.

Updating the BRM registers requires writing to both registers. The UBIR register must be written before writing to the UBMR register. If only one register is written to by the software, the BRM continues to use the previous values.

The following examples show how to determine what values are to be programmed into UBIR and UBMR for a given reference frequency and desired baud rate. The following equation can be used to help determine these values:

$$\text{BaudRate} = \frac{\text{Ref Freq}}{\left(16 \times \frac{\text{UBMR} + 1}{\text{UBIR} + 1}\right)}$$

Figure 76-9. Frequency and Baud Rate for UBIR and UBMR

With:

Reference Frequency (Hz): UART Reference Frequency (*module_clock* after RFDIV divider)

Baud Rate (bit/s): Desired baud rate.

Integer Division ÷ 21

Reference Frequency = 19.44 MHz

UBIR = 0x000F

UBMR = 0x0014

Baud Rate = 925.7 kbit/s

NOTE

Observe that each value written to the registers is one less than the actual value.

Non-Integer Division

```
Reference Frequency = 16 MHz
Desired Baud Rate = 920 Kbits/s
```

$$\frac{UBMR + 1}{UBIR + 1} = \frac{RefFreq}{16 \times BaudRate} = \frac{16 \times 10^6}{16 \times 920 \times 10^3} = 1.087$$

```
Ratio = 1.087 = 1087 / 1000
UBIR = 999 (decimal)= 0x3E7
UBMR = 1086 (decimal)= 0x43E
Non-Integer Division
Reference Frequency = 25 MHz
Desired Baud Rate = 920 kbit/s
Ratio = 1.69837 = 625 / 368
UBIR = 367 (decimal)= 0x16F
UBMR = 624 (decimal)= 0x270
```

Non-Integer Division

```
Reference Frequency: 30 MHz
Desired Baud Rate = 115.2 kbit/s
Ratio = 16.276043 = 65153 / 4003
UBIR = 4002 (decimal) = 0x0FA2
UBMR = 65152 (decimal) = 0xFE80
```

76.5 Infrared Interface

76.5.1 Generalities-Infrared

The Infrared interface is selected when IREN (UCR1[7]) is set to 1.

The Infrared Interface is compatible with IrDA Serial Infrared Physical Layer Specification. In this specification, a "zero" is represented by a positive pulse, and a "one" is represented by no pulse (line remains low).

In the UART:

In TX: For each "zero" to be transmitted, a narrow positive pulse which is 3/16 of a bit time is generated. For each "one" to be transmitted no pulse is generated (output is low). External circuitry has to be provided to drive an Infrared LED.

In RX: When receiving, a narrow negative pulse is expected for each "zero" transmitted while no pulse is expected for each "one" transmitted (input is high).

NOTE

Rx part of IR block expects to receive an inverted signal compared to IrDA specification. Circuitry external to the IC transforms the Infrared signal to an electrical signal.

The IR interface has an edge triggered interrupt (IRINT). This interrupt validates a zero bit being received. This interrupt is enabled by writing a "one" to ENIRI bit.

The behavior of Infrared Interface is determined by 3 bits INVT (UCR3[1]), INVR (UCR4[9]) and IRSC (UCR4[5]).

76.5.2 Inverted Transmission and Reception bits (INVT & INVR)

The values of INVT and INVR depend of the IrDA transceiver connected on the TXD_IR and RXD_IR pins of the UART. If this transceiver is not inverting on both paths Tx and Rx, a Zero is represented by a positive pulse and a One is represented by no pulse (line remains low). In this case, the bit INVT must be set to 0 and the bit INVR must be set to 1 (because Rx IR block expects an inverted signal).

On the contrary user must set INVT=1 and INVR=0 if both paths of the transceiver are inverting, that is, a Zero is represented as a negative pulse and a One is represented by no pulse (line remains high). The transceiver can also be inverting on only one path (Tx or Rx), in this case INVT and INVR must be together equal to 1 or to 0, depending on which path is inverted.

76.5.3 InfraRed Special Case (IRSC) Bit

The value to apply to IRSC bit is based on 2 parameters: the baud rate and the Minimum Pulse Duration (MPD) of the transceiver.

According to IrDA Standard Specification, for SIR (Serial IR) baud rates from 2.4 Kbit/s to 115.2 Kbit/s this nominal pulse duration is equal to 3/16 of a bit duration (at the selected baud rate). But, for all the baud rates a Minimum Pulse Duration is also specified. According to IrDA Standard, a Zero is represented by a light pulse, so the IrDA transceiver can't emit a light pulse shorter than the MPD. For SIR, the MPD is constant and equal to 1.41 us.

But user must take into account the electrical MPD associated to the transceiver on the receiver path. Typically this value is 2.0 us, but for some manufacturers MPD can go down to 1.0 us.

In order to understand the meaning of IRSC bit, one must understand how the RX path work in IrDA mode.

When UART is in IrDA mode, a Zero is not only detected by the state of the RXD_IR line, but also with the duration of the pulse. This pulse duration can be measured with 2 different clocks. In this case, clock is selected with the IRSC bit.

- If IRSC = 0, the clock used is the BRM clock.
- If IRSC = 1, the clock used is the UART internal clock (UART clock after the divider (RFDIV)).

In normal operation, IRSC=0. This means at any time, the user must ensure that the frequency of BRM_clock is high enough to measure the pulse. In the UART and for IRSC=0, the pulse must last at least 2 BRM clock cycles.

If this condition is not fulfilled, IRSC must be set to 1.

Let's take 2 examples, with the Minimum Pulse Duration equals to the MPD of the IrDA specification (in SIR).

Calculation of BRM Clock Period (Clock Period < 1.41 µs)

The user wants to receive IrDA data at 115.2 Kbit/s. The UBIR and UBMR registers are set in order to create the BRM_clock with a frequency of 16*baud rate = 16 * 115.2 = 1.843 MHz. But at the same time, in order to correctly detect the pulse, the user must be sure that 2* BRM_clock period is lower than 1.41 us. Lets check:

BRM_clock period = 1/1843000 = 542 ns

So 2*BRM_clock period = 1.09 us < 1.41 us. It is fine.

Calculation of BRM Clock Period (Clock Period > 1.41 µs)

This time the user wants to receive at 19.2 Kbit/s. So, the BRM_clock is set to 16*19200 = 307.2 kHz. Let's check if 2* BRM_clock period < 1.41 us:

1. BRM_clock period =1/307200 = 3.25 us

   So 2*BRM_clock period = 6.50 us >> 1.41 us. It doesn't work.

   So, in this case, the BRM clock can't be used to measure the pulse duration and the user must select the UART internal clock by setting IRSC =1.

NOTE

Like for Escape character detection, when IR Special Case is enabled (IRSC=1), the UART must measure a duration. In order to do that, the user must fill the ONEMS register. Refer to Escape Sequence Detection.

76.5.4 IrDA interrupt

Serial infrared mode (SIR) uses an edge triggered interrupt flag IRINT (USR2[8]). When INVR =0, detection of a falling edge on the RXD pin asserts the IRINT bit. When INVR=1, detection of a rising edge on the RXD pin asserts the IRINT bit. When IRINT and ENIRI bits are both asserted, the *interrupt_uart* interrupt is asserted. Clear the IRINT bit by writing 1 to it. Writing 0 to the IRINT bit has no effect.

76.5.5 Conclusion about IrDA

Before using the UART in IrDA, the baud rate limit must be calculated. This baud rate limit will inform the user if IRSC bit has to be set or not.

Let's determine this limit:

As already described, if IRSC = 0, the following condition must always be fulfilled

$$2 \times BRMClockPeriod < MinPulseDuration$$

Figure 76-10. Calculation of Baud Rate

So,

$$BRMClockFrequency > \frac{2}{MPD}$$

So, knowing BRM_clock frequency = 16 * Baud Rate, we get:

$$BaudRate > \frac{1}{8 \times MinPulseDuration}$$

So, the user needs to set IRSC = 0 when:

- If Minimum Pulse Duration = 2.5 us and Baud Rate > 50 Kbit/s.
- If Minimum Pulse Duration = 2.0 us and Baud Rate > 62.5 Kbit/s.
- If Minimum Pulse Duration = 1.41 us and Baud Rate > 88.6 Kbit/s.

NOTE

For baud rates lower than the limit, IRSC must be set to1.

76.5.6 Programming IrDA Interface

76.5.6.1 High Speed

As an example, the following sequence can be used to program the IrDA interface in order to send and receive characters at 115.2 Kbit/s.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 115.2 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to ARM platform when 1 char is received into the Rx FIFO (RDR)

Registers values and Programming orders:

```
UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART
UTS = 0x0000
UFCR = 0x0981
TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock  is 30 MHz)
RXTL[5:0] = 0x01: Default value
UBIR = 0x0202
UBMR = 0x20BE Baud rate = 115.2 kbit/s with internal clock = 30 MHz
UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
UCR2[2] = TXEN = 1: Enable Rx path
UCR2 [1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset
UCR3 = 0x0000

         UCR4 = 0x8201
CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)
```

The UART is ready to send a character as soon as there is a write into UTXD register. And an interrupt will be sent to ARM platform when a character is received.

76.5.6.2 Low Speed

This time, we keep the same assumptions but the speed is now 9.6 Kbit/s. So, this baud rate is below the limit (even with a Min. Pulse Duration of 2.5 us) and thus IRSC must be set to 1.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 9.6 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to ARM platform when 1 char is received into the Rx FIFO (RDR).

Registers values and Programming orders:

```
UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART
UFCR = 0x0981
UFCR[15:10] = TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock  is 30 MHz)
UFCR[5:0] = RXTL[5:0] = 0x01: Default value
UBIR = 0x00FF
UBMR = 0xC354 Baud rate = 9.6 kbit/s with internal clock = 30 MHz
UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
UCR2[2] = TXEN = 1: Enable Rx path
UCR2 [1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset
UCR3 = 0x0000
UCR3[1] = INVT = 0: Positive pulse represents 0.
UCR4 = 0x8221
UCR4[15:10] = CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
UCR4[5] = IRSC = 1: Because data rate is below the limit and thus the UART internal clock is
used to measure the pulse duration.
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)
```

The UART is now ready to send a character as soon as there is a write into UTXD register. An interrupt will be sent to ARM platform when a character is received.

76.6 Low Power Modes

These modes are controlled by the signals *doze_req* and *stop_req*. The control/status/data registers won't change when getting into/out of low power modes.

Table 76-11. UART Low Power State Operation

	Normal State (*doze_req* = 1'b0 & *stop_req* = 1'b0)	Doze State (*doze_req* = 1'b1)		Stop State (*stop_req* = 1'b1)
		DOZE bit = 0	DOZE bit = 1	
UART-Clock	ON	ON	ON	OFF
UART Serial / IrDA	ON	ON	OFF	OFF

76.6.1 UART Operation in System Doze Mode

While in Doze State (when *doze_req* input pin is set to 1'b1), the UART behavior depends on the DOZE (UCR1[1]) control bit.

While the DOZE bit is negated, the UART serial interface is enabled. While the system is in the Doze State, and the DOZE bit is asserted, the UART is disabled. If the Doze State is entered with the DOZE bit asserted while the UART serial interface was receiving or transmitting data, it will complete the receive/transmit of the current character and signal to the far-end transmitter/receiver to stop sending/receiving.

76.6.2 UART Operation in System Stop Mode

The internal baud rate clocks of the transmitter and receiver are gated off if the *stop_req* signal to UART is asserted. Even though the clocks at the input of the UART continue to run during system Stop mode, the UART will not do any transmission or reception.

The following UART interrupts wake the ARM platform processor from STOP mode:

- RTS (RTSD)
- IrDA Asynchronous WAKE (AIRINT)
- Asynchronous WAKE (AWAKE)
- RI (RIDELT in DTE mode only)
- DCD (DCDDELT in DTE mode only)
- DTR (DTRD in DCE mode only)
- DSR (DTRD in DTE mode only)

When an asynchronous WAKE (awake) interrupt exits the ARM platform from STOP mode, make sure that a dummy character is sent first because the first character may not be received correctly.

76.6.3 Power Saving Method in UART

The RXEN (UCR2[1]), TXEN (UCR2[2]) and UARTEN (UCR1[0]) bits are set by the user and provide software control of low-power modes.

Setting the UARTEN (UCR1[0]) bit to 0 shuts off the receiver and transmitter logic and the associated clocks.

If the UART is used only in transmit mode, UARTEN and TXEN must be set to 1. If the UART is used only in receive mode, UARTEN and RXEN must be set to 1. Setting TXEN or RXEN to 0 allows to save a lot of power.

76.7 UART Operation in System Debug State

The bit UTS [11] controls whether the UART will respond to the input signal *debug_req*, or whether it will continue to run as normal.

If the UART is programmed to respond to *debug_req*:

1. The UART will halt all operations upon detecting the *debug_req* input.
2. A transfer in progress, either to/from a core (using the IP Bus interface) or to/from an external device, will be completed before halting. This means a single byte/word transfer, not an entire FIFO. Reception of any further data from an external device will be disabled.
3. Internal registers will continue to be writable and readable using the IP Bus interface. A read will leave the contents unaffected.
4. The RX FIFO is affected in debug mode in the following way:
   - All writes into the RX FIFO are prevented.
   - The bit RXDBG (UTS[9]) is used to select the readability of the RX FIFO during debug mode:

     RXDBG = 0: hold the read pointer at the location it had upon entering debug mode, and URXD register returns only the data value at that location, no matter how many reads attempted.

     RXDBG = 1, selectable at any time: Allow to read the characters received in Rx FIFO. It will not be possible to re-read previously read locations, nor will it be possible to readjust the read pointer to the value it had prior to entering debug mode.

76.8 Reset

This section describes how to reset the block and explains special requirements related to reset.

76.8.1 Hardware reset

All of registers, FIFOs, state machines and sequential elements can be reset to their initial values by hardware reset or power on reset.

76.8.2 Software reset

The status registers USR1 and USR2, BRM registers UBIR and UBMR, TxFIFO and RxFIFO, and transmitter and receiver state machines can be reset by software reset. Internal logic will remain the software reset signal at active for about 4 *module_clock* cycles.

Programmer can follow the following software reset sequence:

1. Clear the $\overline{\text{SRST}}$ bit (UCR2[0])
2. Wait for software reset complete: poll SOFTRST bit (UTS[0]) until it is 0.
3. Re-program baud rate registers: Re-write UBIR and UBMR.

76.9 Transfer Error

The UART can generate a transfer error on the peripheral bus in the following cases:

- Core is writing into a read-only register.
- Core is accessing (read or write) an unused location within the assigned address space reserved to UART.
- Core is writing into UTXD register with transmit interface disabled (TXEN=0 or UARTEN=0)
- Core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0)

76.10 Functional Timing

This section includes timing diagrams for functional signaling.

76.10.1 RS-232/RS-485 Mode

When transmitting a byte, the UART first sends a Start Bit which is logic 0, followed by the data (general 8 bits, but could be 7 bits) followed by parity bit (optional in RS-232 mode, replaced by the ninth bit in RS-485 mode) and one or two Stop Bits which is logic 1. The sequence is repeated for each byte sent. The receiver also sample data according to this format.

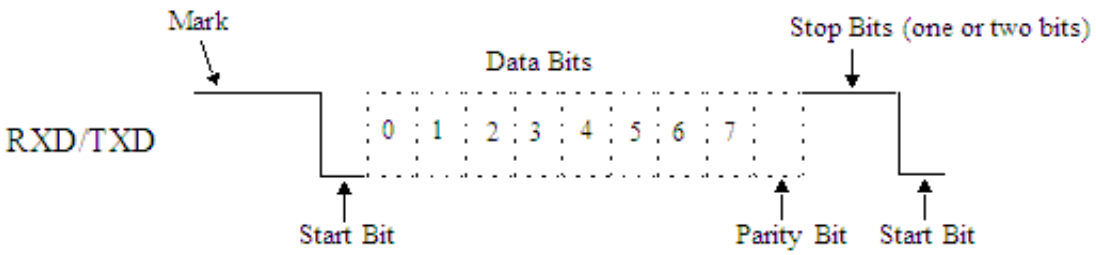


Figure 76-11. Timing Diagram of RS-232 Serial Data Line

76.10.2 IrDA Mode

According to IrDA specification, the low speed (115.2Kbit/s and below) IR frame format is compatible with UART frame.

In this figure, an example data 0x65 is used.

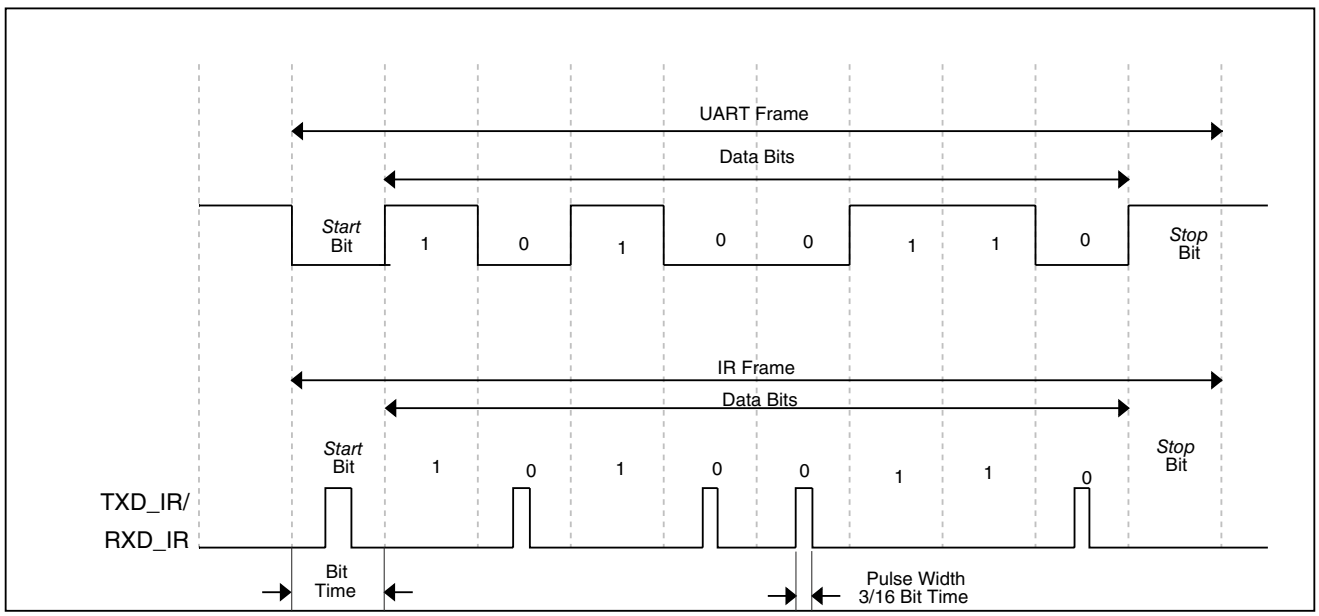

Figure 76-12. Timing diagram of Low Speed IR (<=115.2 Kbit/s) Data Line

76.11 Initialization

76.11.1 Programming the UART in RS-232 mode

As an example, the following sequence can be used to program the UART in order to send and receive characters in RS-232 mode.

Assumptions:

- Input uart clock = 100 MHz
- Baud rate = 921.6Kbps
- Data bits = 8 bits
- Parity = Even
- Stop bits = 1 bit
- Flow control = Hardware

Main program:

1. UCR1 = 0x0001

   Enable the UART.

2. UCR2 = 0x2127

   Set hardware flow control, data format and enable transmitter and receiver.

3. UCR3 = 0x0704

   Set UCR3[RXDMUXSEL] = 1.

4. UCR4 = 0x7C00

   Set CTS trigger level to 31,

5. UFCR = 0x089E

   Set internal clock divider = 5 (divide input uart clock by 5). So the reference clock is 100MHz/5 = 20MHz.

   Set TXTL = 2 and RXTL = 30.

6. UBIR = 0x08FF
7. UBMR = 0x0C34

   In the above two steps, set baud rate to 921.6Kbps based on the 20MHz reference clock.

8. UCR1 = 0x2201>

   Enable the TRDY and RRDY interrupts.

Interrupt service routine for the transmitter:

- Write characters into UTXD

The TRDY interrupt will be automatically de-asserted when the data level of the TxFIFO exceeds the TXTL=2. Note: For the first time the interrupt may be de-asserted after 4 characters are written into the TxFIFO because of the shift register.

Interrupt service routine for the receiver:

- Read characters from URXD

The RRDY interrupt will be automatically de-asserted when the data level of the RxFIFO is below the RXTL=30.

76.13 UART Memory Map/Register Definition

UART supports 8-bit, 16-bit and 32-bit accesses to 32-bit memory-mapped addresses. Any access to unmapped memory location will yield a transfer error.

All registers except the ONEMS described in this section are 16-bit registers. The ONEMS register is a 24-bit register.

- For 32-bit write accesses, the upper two bytes will not be taken into account.
- For 32-bit read accesses the upper two bytes will return 0.

The ONEMS register is expanded from 16 bits to 24 bits in order to support the high frequency of the BRM internal clock *ref_clk* (*module_clock* after divider). The ONEMS register can be accessed as 8 bits, 16 bits or 32 bits.

- For 32-bit write accesses, the most significant byte of the ONEMS will be discarded.
- For 32-bit read accesses, the most significant byte of the ONEMS will be read as 0.

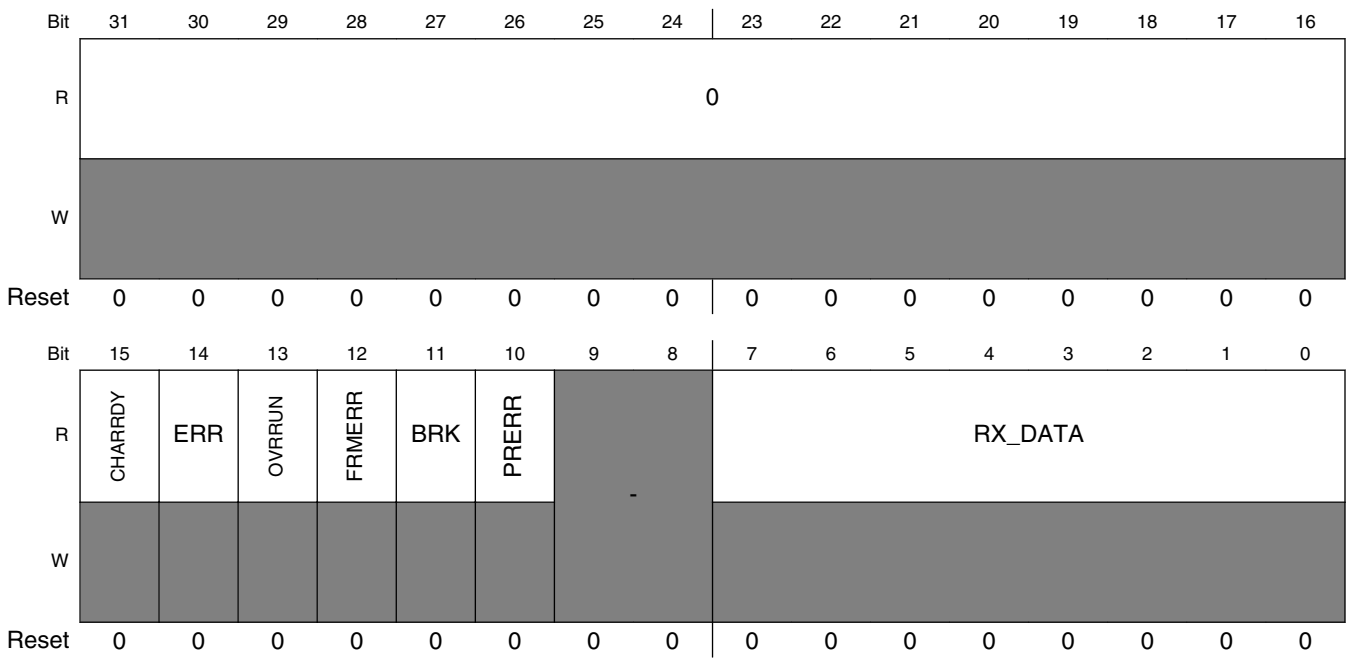
76.13.1 UART Receiver Register (UARTx_URXD)

The UART will yield a transfer error on the peripheral bus when core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0).

Addresses: UART-1_URXD is 53FB_C000h base + 0h offset = 53FB_C000h
UART-2_URXD is 53FC_0000h base + 0h offset = 53FC_0000h
UART-3_URXD is 53FC_4000h base + 0h offset = 53FC_4000h
UART-4_URXD is 53FF_0000h base + 0h offset = 53FF_0000h
UART-5_URXD is 63F9_0000h base + 0h offset = 63F9_0000h



UARTx_URXD field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15 CHARRDY	Character Ready. This read-only bit indicates an invalid read when the FIFO becomes empty and software tries to read the same old data. This bit should not be used for polling for data written to the RX FIFO. 0 Character in RX_DATA field and associated flags are invalid. 1 Character in RX_DATA field and associated flags valid and ready for reading.
14 ERR	**Error Detect.** Indicates whether the character present in the RX_DATA field has an error (OVRRUN, FRMERR, BRK or PRERR) status. The ERR bit is updated and valid for each received character. 0 No error status was detected 1 An error status was detected

Table continues on the next page...

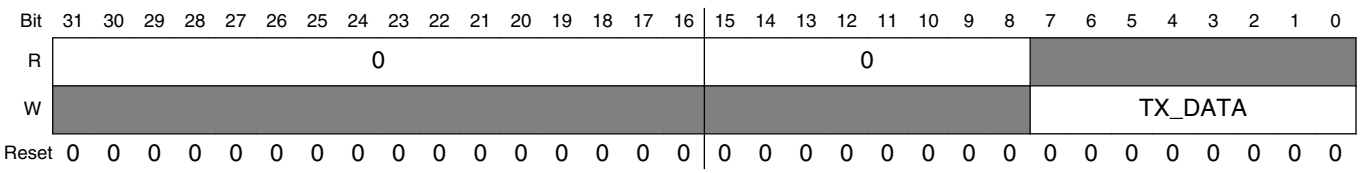
UARTx_URXD field descriptions (continued)

Field	Description
13 OVRRUN	**Receiver Overrun.** This read-only bit, when HIGH, indicates that the corresponding character was stored in the last position (32nd) of the Rx FIFO. Even if a 33rd character has not been detected, this bit will be set to '1' for the 32nd character. 0 No RxFIFO overrun was detected 1 A RxFIFO overrun was detected
12 FRMERR	**Frame Error.** Indicates whether the current character had a framing error (a missing stop bit) and is possibly corrupted. FRMERR is updated for each character read from the RxFIFO. 0 The current character has no framing error 1 The current character has a framing error
11 BRK	**BREAK Detect.** Indicates whether the current character was detected as a BREAK character. The data bits and the stop bit are all 0. The FRMERR bit is set when BRK is set. When odd parity is selected, PRERR is also set when BRK is set. BRK is valid for each character read from the RxFIFO. 0 The current character is not a BREAK character 1 The current character is a BREAK character
10 PRERR	**Parity Error flag**. Indicates whether the current character was detected with a parity error and is possibly corrupted. PRERR is updated for each character read from the RxFIFO. When parity is disabled, PRERR always reads as 0. 0 = No parity error was detected for data in the RX_DATA field 1 = A parity error was detected for data in the RX_DATA field
9–8 -	**Reserved**
7–0 RX_DATA	**Received Data**. Holds the received character. In 7-bit mode, the most significant bit (MSB) is forced to 0. In 8-bit mode, all bits are active.

76.13.2 UART Transmitter Register (UARTx_UTXD)

The UART will yield a transfer error on the peripheral bus when core is writing into UART_URXD register with transmit interface disabled (TXEN=0 or UARTEN=0). Memory space between UART_URXD and UART_UTXD registers is reserved. Any read or write access to this space will be considered as an invalid access and yield a transfer error.

Addresses: UART-1_UTXD is 53FB_C000h base + 40h offset = 53FB_C040h
UART-2_UTXD is 53FC_0000h base + 40h offset = 53FC_0040h
UART-3_UTXD is 53FC_4000h base + 40h offset = 53FC_4040h
UART-4_UTXD is 53FF_0000h base + 40h offset = 53FF_0040h
UART-5_UTXD is 63F9_0000h base + 40h offset = 63F9_0040h



UARTx_UTXD field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–0 TX_DATA	**Transmit Data**. Holds the parallel transmit data inputs. In 7-bit mode, D7 is ignored. In 8-bit mode, all bits are used. Data is transmitted least significant bit (LSB) first. A new character is transmitted when the TX_DATA field is written. The TX_DATA field must be written only when the TRDY bit is high to ensure that corrupted data is not sent.

76.13.3 UART Control Register 1 (UARTx_UCR1)

Addresses: UART-1_UCR1 is 53FB_C000h base + 80h offset = 53FB_C080h
UART-2_UCR1 is 53FC_0000h base + 80h offset = 53FC_0080h
UART-3_UCR1 is 53FC_4000h base + 80h offset = 53FC_4080h
UART-4_UCR1 is 53FF_0000h base + 80h offset = 53FF_0080h
UART-5_UCR1 is 63F9_0000h base + 80h offset = 63F9_0080h

UARTx_UCR1 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15 ADEN	**Automatic Baud Rate Detection Interrupt Enable**. Enables/Disables the automatic baud rate detect complete (ADET) bit to generate an interrupt (*interrupt_uart* = 0). 0 Disable the automatic baud rate detection interrupt 1 Enable the automatic baud rate detection interrupt
14 ADBR	**Automatic Detection of Baud Rate**. Enables/Disables automatic baud rate detection. When the ADBR bit is set and the ADET bit is cleared, the receiver detects the incoming baud rate automatically. The ADET flag is set when the receiver verifies that the incoming baud rate is detected properly by detecting an ASCII character "A" or "a" (0x61 or 0x41). 0 Disable automatic detection of baud rate 1 Enable automatic detection of baud rate
13 TRDYEN	**Transmitter Ready Interrupt Enable**. Enables/Disables the transmitter Ready Interrupt (TRDY) when the transmitter has one or more slots available in the TxFIFO. The fill level in the TXFIFO at which an interrupt is generated is controlled by TxTL bits. When TRDYEN is negated, the transmitter ready interrupt is disabled. **NOTE:** An interrupt will be issued as long as TRDYEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TRDY interrupt. 0 Disable the transmitter ready interrupt 1 Enable the transmitter ready interrupt

Table continues on the next page...

UARTx_UCR1 field descriptions (continued)

Field	Description
12 IDEN	**Idle Condition Detected Interrupt Enable**. Enables/Disables the IDLE bit to generate an interrupt (*interrupt_uart* = 0). 0 Disable the IDLE interrupt 1 Enable the IDLE interrupt
11–10 ICD	**Idle Condition Detect**. Controls the number of frames RXD is allowed to be idle before an idle condition is reported. 00 Idle for more than 4 frames 01 Idle for more than 8 frames 10 Idle for more than 16 frames 11 Idle for more than 32 frames
9 RRDYEN	**Receiver Ready Interrupt Enable**. Enables/Disables the RRDY interrupt when the RxFIFO contains data. The fill level in the RxFIFO at which an interrupt is generated is controlled by the RXTL bits. When RRDYEN is negated, the receiver ready interrupt is disabled. 0 Disables the RRDY interrupt 1 Enables the RRDY interrupt
8 RXDMAEN	**Receive Ready DMA Enable**. Enables/Disables the receive DMA request *dma_req_rx* when the receiver has data in the RxFIFO. The fill level in the RxFIFO at which a DMA request is generated is controlled by the RXTL bits. When negated, the receive DMA request is disabled. 0 Disable DMA request 1 Enable DMA request
7 IREN	**Infrared Interface Enable**. Enables/Disables the IR interface. See the IR interface description in Infrared Interface, for more information. 0 Disable the IR interface 1 Enable the IR interface
6 TXMPTYEN	**Transmitter Empty Interrupt Enable**. Enables/Disables the transmitter FIFO empty (TXFE) interrupt. *interrupt_uart*. When negated, the TXFE interrupt is disabled. **NOTE:** An interrupt will be issued as long as TXMPTYEN and TXFE are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXFE interrupt. 0 Disable the transmitter FIFO empty interrupt 1 Enable the transmitter FIFO empty interrupt
5 RTSDEN	**RTS Delta Interrupt Enable**. Enables/Disables the RTSD interrupt. The current status of the $\overline{\text{RTS}}$ pin is read in the RTSS bit. 0 Disable RTSD interrupt 1 Enable RTSD interrupt
4 SNDBRK	**Send BREAK**. Forces the transmitter to send a BREAK character. The transmitter finishes sending the character in progress (if any) and sends BREAK characters until SNDBRK is reset. Because the transmitter samples SNDBRK after every bit is transmitted, it is important that SNDBRK is asserted high for a sufficient period of time to generate a valid BREAK. After the BREAK transmission completes, the UART transmits 2 mark bits. The user can continue to fill the TxFIFO and any characters remaining are transmitted when the BREAK is terminated.

Table continues on the next page...

UARTx_UCR1 field descriptions (continued)

Field	Description
	0 Do not send a BREAK character 1 Send a BREAK character (continuous 0s)
3 TXDMAEN	**Transmitter Ready DMA Enable**. Enables/Disables the transmit DMA request *dma_req_tx* when the transmitter has one or more slots available in the TxFIFO. The fill level in the TxFIFO that generates the *dma_req_tx* is controlled by the TXTL bits. **NOTE:** A DMA request will be issued as long as TXDMAEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the transmit DMA request. 0 Disable transmit DMA request 1 Enable transmit DMA request
2 ATDMAEN	**Aging DMA Timer Enable**. Enables/Disables the receive DMA request *dma_req_rx* for the aging timer interrupt (triggered with AGTIM flag in USR1[8]). 0 Disable AGTIM DMA request 1 Enable AGTIM DMA request
1 DOZE	**DOZE**. Determines the UART enable condition in the DOZE state. When *doze_req* input pin is at '1', (the ARM Platform executes a doze instruction and the system is placed in the Doze State), the DOZE bit affects operation of the UART. While in the Doze State, if this bit is asserted, the UART is disabled. See the description in Low Power Modes. 0 The UART is enabled when in DOZE state 1 The UART is disabled when in DOZE state
0 UARTEN	**UART Enable**. Enables/Disables the UART. If UARTEN is negated in the middle of a transmission, the transmitter stops and pulls the TXD line to a logic 1. UARTEN must be set to 1 before any access to UTXD and URXD registers, otherwise a transfer error is returned. This bit can be set to 1 along with other bits in this register. There is no restriction to the sequence of programing this bit and other control registers. 0 Disable the UART 1 Enable the UART

76.13.4 UART Control Register 2 (UARTx_UCR2)

Addresses: UART-1_UCR2 is 53FB_C000h base + 84h offset = 53FB_C084h
UART-2_UCR2 is 53FC_0000h base + 84h offset = 53FC_0084h
UART-3_UCR2 is 53FC_4000h base + 84h offset = 53FC_4084h
UART-4_UCR2 is 53FF_0000h base + 84h offset = 53FF_0084h
UART-5_UCR2 is 63F9_0000h base + 84h offset = 63F9_0084h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																ESCI	IRTS	CTSC	CTS	ESCEN	RTEC		PREN	PROE	STPB	WS	RTSEN	ATEN	TXEN	RXEN	SRST
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

UARTx_UCR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15 ESCI	**Escape Sequence Interrupt Enable**. Enables/Disables the ESCF bit to generate an interrupt. 0 Disable the escape sequence interrupt 1 Enable the escape sequence interrupt
14 IRTS	**Ignore RTS Pin**. Forces the RTS input signal presented to the transmitter to always be asserted (set to low), effectively ignoring the external pin. When in this mode, the RTS pin serves as a general purpose input. 0 Transmit only when the RTS pin is asserted 1 Ignore the RTS pin
13 CTSC	CTS **Pin Control**. Controls the operation of the $\overline{CTS}$ output pin. When CTSC is asserted, the $\overline{CTS}$ output pin is controlled by the receiver. When the RxFIFO is filled to the level of the programmed trigger level and the start bit of the overflowing character (TRIGGER LEVEL + 1) is validated, the $\overline{CTS}$ output pin is negated to indicate to the far-end transmitter to stop transmitting. When the trigger level is programmed for less than 32, the receiver continues to receive data until the RxFIFO is full. When the CTSC bit is negated, the $\overline{CTS}$ output pin is controlled by the CTS bit. On reset, because CTSC is cleared to 0, the $\overline{CTS}$ pin is controlled by the CTS bit, which again is cleared to 0 on reset. This means that on reset the $\overline{CTS}$ signal is negated. 0 The $\overline{CTS}$ pin is controlled by the CTS bit 1 The $\overline{CTS}$ pin is controlled by the receiver
12 CTS	**Clear to Send**. Controls the $\overline{CTS}$ pin when the CTSC bit is negated. CTS has no function when CTSC is asserted. 0 The $\overline{CTS}$ pin is high (inactive) 1 The $\overline{CTS}$ pin is low (active)
11 ESCEN	**Escape Enable**. Enables/Disables the escape sequence detection logic. 0 Disable escape sequence detection 1 Enable escape sequence detection
10–9 RTEC	**Request to Send Edge Control**. Selects the edge that triggers the RTS interrupt. This has no effect on the RTS delta interrupt. RTEC has an effect only when RTSEN = 1 (see Table 76-5). 00 Trigger interrupt on a rising edge 01 Trigger interrupt on a falling edge 1X Trigger interrupt on any edge
8 PREN	**Parity Enable**. Enables/Disables the parity generator in the transmitter and parity checker in the receiver. When PREN is asserted, the parity generator and checker are enabled, and disabled when PREN is negated. 0 Disable parity generator and checker 1 Enable parity generator and checker
7 PROE	**Parity Odd/Even**. Controls the sense of the parity generator and checker. When PROE is high, odd parity is generated and expected. When PROE is low, even parity is generated and expected. PROE has no function if PREN is low.

Table continues on the next page...

UARTx_UCR2 field descriptions (continued)

Field	Description
	0 Even parity 1 Odd parity
6 STPB	**Stop**. Controls the number of stop bits after a character. When STPB is low, 1 stop bit is sent. When STPB is high, 2 stop bits are sent. STPB also affects the receiver. 0 The transmitter sends 1 stop bit. The receiver expects 1 or more stop bits. 1 The transmitter sends 2 stop bits. The receiver expects 2 or more stop bits.
5 WS	**Word Size**. Controls the character length. When WS is high, the transmitter and receiver are in 8-bit mode. When WS is low, they are in 7-bit mode. The transmitter ignores bit 7 and the receiver sets bit 7 to 0. WS can be changed in-between transmission (reception) of characters, however not when a transmission (reception) is in progress, in which case the length of the current character being transmitted (received) is unpredictable. 0 7-bit transmit and receive character length (not including START, STOP or PARITY bits) 1 8-bit transmit and receive character length (not including START, STOP or PARITY bits)
4 RTSEN	**Request to Send Interrupt Enable.** Controls the RTS edge sensitive interrupt. When RTSEN is asserted and the programmed edge is detected on the $\overline{\text{RTS}}$ pin (the RTSF bit is asserted), an interrupt will be generated on the *interrupt_uart* pin. (See Table 76-5.) 0 Disable request to send interrupt 1 Enable request to send interrupt
3 ATEN	**Aging Timer Enable**. This bit is used to enable the aging timer interrupt (triggered with AGTIM) 0 AGTIM interrupt disabled 1 AGTIM interrupt enabled
2 TXEN	**Transmitter Enable**. Enables/Disables the transmitter. When TXEN is negated the transmitter is disabled and idle. When the UARTEN and TXEN bits are set the transmitter is enabled. If TXEN is negated in the middle of a transmission, the UART disables the transmitter immediately, and starts marking 1s. The transmitter FIFO cannot be written when this bit is cleared. 0 Disable the transmitter 1 Enable the transmitter
1 RXEN	**Receiver Enable**. Enables/Disables the receiver. When the receiver is enabled, if the RXD input is already low, the receiver does not recognize BREAK characters, because it requires a valid 1-to-0 transition before it can accept any character. 0 Disable the receiver 1 Enable the receiver
0 SRST	**Software Reset**. Once the software writes 0 to $\overline{\text{SRST}}$, the software reset remains active for 4 *module_clock* cycles before the hardware deasserts $\overline{\text{SRST}}$. The software can only write 0 to $\overline{\text{SRST}}$. Writing 1 to $\overline{\text{SRST}}$ is ignored. 0 Reset the transmit and receive state machines, all FIFOs and register USR1, USR2, UBIR, UBMR, UBRC , URXD, UTXD and UTS[6-3]. 1 No reset

76.13.5 UART Control Register 3 (UARTx_UCR3)

Addresses: UART-1_UCR3 is 53FB_C000h base + 88h offset = 53FB_C088h
UART-2_UCR3 is 53FC_0000h base + 88h offset = 53FC_0088h
UART-3_UCR3 is 53FC_4000h base + 88h offset = 53FC_4088h
UART-4_UCR3 is 53FF_0000h base + 88h offset = 53FF_0088h
UART-5_UCR3 is 63F9_0000h base + 88h offset = 63F9_0088h

UARTx_UCR3 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–14 DPEC	**DTR/DSR Interrupt Edge Control**. These bits control the edge of $\overline{\text{DTR}}$ (DCE) or $\overline{\text{DSR}}$ (DTE) on which an interrupt will be generated. An interrupt will only be generated if the DTREN bit is set. 00 interrupt generated on rising edge 01 interrupt generated on falling edge 1X interrupt generated on either edge
13 DTREN	**Data Terminal Ready Interrupt Enable**. When this bit is set, it will enable the status bit DTRF (USR2 [13]) (DTR/DSR edge sensitive interrupt) to cause an interrupt. 0 Data Terminal Ready Interrupt Disabled 1 Data Terminal Ready Interrupt Enabled
12 PARERREN	**Parity Error Interrupt Enable. Enables/Disables the interrupt. When asserted, PARERREN causes the PARITYERR bit to generate an interrupt.** 0 Disable the parity error interrupt 1 Enable the parity error interrupt
11 FRAERREN	**Frame Error Interrupt Enable. Enables/Disables the interrupt. When asserted, FRAERREN causes the FRAMERR bit to generate an interrupt.** 0 Disable the frame error interrupt 1 Enable the frame error interrupt

Table continues on the next page...

UARTx_UCR3 field descriptions (continued)

Field	Description
10 DSR	**Data Set Ready**. This bit is used by software to control the DSR/DTR output pin for the modem interface. In DCE mode it applies to $\overline{DSR}$ and in DTE mode it applies to $\overline{DTR}$. 0 DSR/ DTR pin is logic zero 1 DSR/ DTR pin is logic one
9 DCD	**Data Carrier Detect**. In DCE mode this bit is used by software to control the $\overline{DCD}$ output pin for the modem interface. In DTE mode, when this bit is set, it will enable the status bit DCDDELT (USR2 (6)) to cause an interrupt. 0 $\overline{DCD}$ pin is logic zero (DCE mode) 1 $\overline{DCD}$ pin is logic one (DCE mode) 0 DCDDELT interrupt disabled (DTE mode) 1 DCDDELT interrupt enabled (DTE mode)
8 RI	**Ring Indicator**. In DCE mode this bit is used by software to control the $\overline{RI}$ output pin for the modem interface. In DTE mode, when this bit is set, it will enable the status bit RIDELT (USR2 (10)) to cause an interrupt. 0 $\overline{RI}$ pin is logic zero (DCE mode) 1 $\overline{RI}$ pin is logic one (DCE mode) 0 RIDELT interrupt disabled (DTE mode) 1 RIDELT interrupt enabled (DTE mode)
7 ADNIMP	**Autobaud Detection Not Improved-. Disables new features of autobaud detection (See Baud Rate Automatic Detection Protocol, for more details).** 0 Autobaud detection new features selected 1 Keep old autobaud detection mechanism
6 RXDSEN	Receive Status Interrupt Enable. Controls the receive status interrupt (*interrupt_uart*). When this bit is enabled and RXDS status bit is set, the interrupt *interrupt_uart* will be generated. 0 Disable the RXDS interrupt 1 Enable the RXDS interrupt
5 AIRINTEN	Asynchronous IR WAKE Interrupt Enable. Controls the asynchronous IR WAKE interrupt. An interrupt is generated when AIRINTEN is asserted and a pulse is detected on the RXD pin. 0 Disable the AIRINT interrupt 1 Enable the AIRINT interrupt
4 AWAKEN	Asynchronous WAKE Interrupt Enable. Controls the asynchronous WAKE interrupt. An interrupt is generated when AWAKEN is asserted and a falling edge is detected on the RXD pin. 0 Disable the AWAKE interrupt 1 Enable the AWAKE interrupt
3 DTRDEN	**Data Terminal Ready Delta Enable**. Enables / Disables the asynchronous DTRD interrupt. When DTRDEN is asserted and an edge (rising or falling) is detected on $\overline{DTR}$ (in DCE mode) or on $\overline{DSR}$ (in DTE mode), then an interrupt is generated. 0 Disable DTRD interrupt 1 Enable DTRD interrupt
2 RXDMUXSEL	RXD Muxed Input Selected. Selects proper input pins for serial and Infrared input signal.

Table continues on the next page...

UARTx_UCR3 field descriptions (continued)

Field	Description
	NOTE: In this chip, UARTs are used in MUXED mode, so that this bit should always be set.
1 INVT	In **IrDA mode**, when INVT is cleared, the infrared logic block transmits a positive IR 3/16 pulse for all 0s and 0s are transmitted for 1s. When INVT is set (INVT = 1), the infrared logic block transmits an active low or negative infrared 3/16 pulse for all 0s and 1s are transmitted for 1s. 0 TXDActive low transmission 1 **TXD** Active high transmission
0 ACIEN	**Autobaud Counter Interrupt Enable.** This bit is used to enable the autobaud counter stopped interrupt (triggered with ACST (USR2[11]). 0 ACST interrupt disabled 1 ACST interrupt enabled

76.13.6 UART Control Register 4 (UARTx_UCR4)

Addresses: UART-1_UCR4 is 53FB_C000h base + 8Ch offset = 53FB_C08Ch
UART-2_UCR4 is 53FC_0000h base + 8Ch offset = 53FC_008Ch
UART-3_UCR4 is 53FC_4000h base + 8Ch offset = 53FC_408Ch
UART-4_UCR4 is 53FF_0000h base + 8Ch offset = 53FF_008Ch
UART-5_UCR4 is 63F9_0000h base + 8Ch offset = 63F9_008Ch

UARTx_UCR4 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–10 CTSTL	**CTS Trigger Level**. Controls the threshold at which the $\overline{\text{CTS}}$ pin is deasserted by the RxFIFO. After the trigger level is reached and the $\overline{\text{CTS}}$ pin is deasserted, the RxFIFO continues to receive data until it is full. The CTSTL bits are encoded as shown in the Settings column. Settings 0 to 32 are in use. All other settings are Reserved.

Table continues on the next page...

UARTx_UCR4 field descriptions (continued)

Field	Description
	000000 0 characters received 000001 1 characters in the RxFIFO ... — ... — 100000 32 characters in the RxFIFO (maximum)
9 INVR	**In IrDA mode**,when cleared, the infrared logic block expects an active low or negative IR 3/16 pulse for 0s and 1s are expected for 1s. When INVR is set (INVR 1), the infrared logic block expects an active high or positive IR 3/16 pulse for 0s and 0s are expected for 1s. 0 **RXD** active low detection 1 **RXD** active high detection
8 ENIRI	**Serial Infrared Interrupt Enable**. Enables/Disables the serial infrared interrupt. 0 Serial infrared Interrupt disabled 1 Serial infrared Interrupt enabled
7 WKEN	**WAKE Interrupt Enable**. Enables/Disables the WAKE bit to generate an interrupt. The WAKE bit is set at the detection of a start bit by the receiver. 0 Disable the WAKE interrupt 1 Enable the WAKE interrupt
6 IDDMAEN	**DMA IDLE Condition Detected Interrupt Enable** Enables/Disables the receive DMA request *dma_req_rx* for the IDLE interrupt (triggered with IDLE flag in USR2[12]). 0 DMA IDLE interrupt disabled 1 DMA IDLE interrupt enabled
5 IRSC	**IR Special Case**. Selects the clock for the vote logic. When set, IRSC switches the vote logic clock from the sampling clock to the UART reference clock. The IR pulses are counted a predetermined amount of time depending on the reference frequency. See InfraRed Special Case (IRSC) Bit. 0 The vote logic uses the sampling clock (16x baud rate) for normal operation 1 The vote logic uses the UART reference clock
4 LPBYP	**Low Power Bypass**. Allows to bypass the low power new features in UART. To use during debug phase. 0 Low power features enabled 1 Low power features disabled
3 TCEN	**TransmitComplete Interrupt Enable**. Enables/Disables the TXDC bit to generate an interrupt (*interrupt_uart* = 0) **NOTE:** An interrupt will be issued as long as TCEN and TXDC are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXDC interrupt. 0 Disable TXDC interrupt 1 Enable TXDC interrupt
2 BKEN	**BREAK Condition Detected Interrupt Enable**. Enables/Disables the BRCD bit to generate an interrupt. 0 Disable the BRCD interrupt 1 Enable the BRCD interrupt
1 OREN	**Receiver Overrun Interrupt Enable**. Enables/Disables the ORE bit to generate an interrupt.

UARTx_UFCR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–10 TXTL	**Transmitter Trigger Level**. Controls the threshold at which a maskable interrupt is generated by the TxFIFO. A maskable interrupt is generated whenever the data level in the TxFIFO falls below the selected threshold. The bits are encoded as shown in the Settings column. Settings 0 to 32 are in use. All other settings are Reserved. 000000 Reserved 000001 Reserved 000010 TxFIFO has 2 or fewer characters ... — ... —

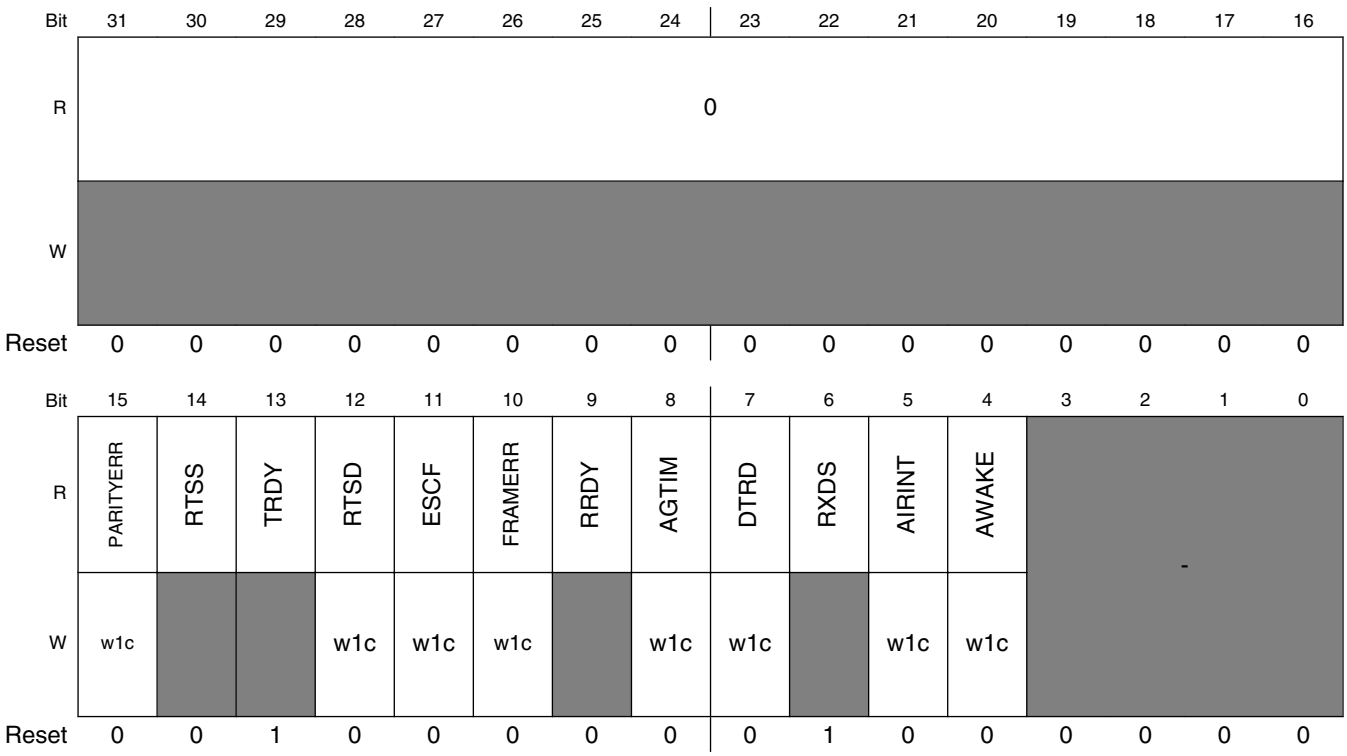
Table continues on the next page...

UARTx_UFCR field descriptions (continued)

Field	Description
	011111 TxFIFO has 31 or fewer characters 100000 TxFIFO has 32 characters (maximum)
9–7 RFDIV	Reference Frequency Divider. Controls the divide ratio for the reference clock. The input clock is *module_clock*. The output from the divider is *ref_clk* which is used by BRM to create the 16x baud rate oversampling clock (*brm_clk*). 000 Divide input clock by 6 001 Divide input clock by 5 010 Divide input clock by 4 011 Divide input clock by 3 100 Divide input clock by 2 101 Divide input clock by 1 110 Divide input clock by 7 111 Reserved
6 DCEDTE	**DCE/DTE mode select**. Select UART as data communication equipment (DCE mode) or as data terminal equipment (DTE mode). 0 DCE mode selected 1 DTE mode selected
5–0 RXTL	**Receiver Trigger Level**. Controls the threshold at which a maskable interrupt is generated by the RxFIFO. A maskable interrupt is generated whenever the data level in the RxFIFO reaches the selected threshold. The RXTL bits are encoded as shown in the Settings column. Setting 0 to 32 are in use. All other settings are Reserved. 000000 0 characters received 000001 RxFIFO has 1 character ... — ... — 011111 RxFIFO has 31 characters 100000 RxFIFO has 32 characters (maximum)

76.13.8 UART Status Register 1 (UARTx_USR1)

Addresses: UART-1_USR1 is 53FB_C000h base + 94h offset = 53FB_C094h
UART-2_USR1 is 53FC_0000h base + 94h offset = 53FC_0094h
UART-3_USR1 is 53FC_4000h base + 94h offset = 53FC_4094h
UART-4_USR1 is 53FF_0000h base + 94h offset = 53FF_0094h
UART-5_USR1 is 63F9_0000h base + 94h offset = 63F9_0094h



UARTx_USR1 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15 PARITYERR	**Parity Error Interrupt Flag**. Indicates a parity error is detected. PARITYERR is cleared by writing 1 to it. Writing 0 to PARITYERR has no effect. When parity is disabled, PARITYERR always reads 0. At reset, PARITYERR is set to 0. 0 No parity error detected 1 Parity error detected (write 1 to clear)
14 RTSS	$\overline{\text{RTS}}$ **Pin Status**. Indicates the current status of the $\overline{\text{RTS}}$ pin. A "snapshot" of the pin is taken immediately before RTSS is presented to the data bus. RTSS cannot be cleared because all writes to RTSS are ignored. At reset, RTSS is set to 0. 0 The $\overline{\text{RTS}}$ pin is high (inactive) 1 The $\overline{\text{RTS}}$ pin is low (active)

Table continues on the next page...

UARTx_USR1 field descriptions (continued)

Field	Description
13 TRDY	**Transmitter Ready Interrupt / DMA Flag**. Indicates that the TxFIFO emptied below its target threshold and requires data. TRDY is automatically cleared when the data level in the TxFIFO exceeds the threshold set by TXTL bits. At reset, TRDY is set to 1. 0 The transmitter does not require data 1 The transmitter requires data (interrupt posted)
12 RTSD	**RTS Delta.** Indicates whether the $\overline{\text{RTS}}$ pin changed state. It (RTSD) generates a maskable interrupt. When in STOP mode, RTS assertion sets RTSD and can be used to wake the processor. The current state of the $\overline{\text{RTS}}$ pin is available on the RTSS bit. Clear RTSD by writing 1 to it. Writing 0 to RTSD has no effect. At reset, RTSD is set to 0. 0 $\overline{\text{RTS}}$ pin did not change state since last cleared 1 $\overline{\text{RTS}}$ pin changed state (write 1 to clear)
11 ESCF	**Escape Sequence Interrupt Flag**. Indicates if an escape sequence was detected. ESCF is asserted when the ESCEN bit is set and an escape sequence is detected in the RxFIFO. Clear ESCF by writing 1 to it. Writing 0 to ESCF has no effect. 0 No escape sequence detected 1 Escape sequence detected (write 1 to clear).
10 FRAMERR	**Frame Error Interrupt Flag**. Indicates that a frame error is detected. The *interrupt_uart* interrupt will be generated if a frame error is detected and the interrupt is enabled. Clear FRAMERR by writing 1 to it. Writing 0 to FRAMERR has no effect. 0 No frame error detected 1 Frame error detected (write 1 to clear)
9 RRDY	**Receiver Ready Interrupt / DMA Flag**. Indicates that the RxFIFO data level is above the threshold set by the RXTL bits. (See the RXTL bits description in UART FIFO Control Register (UART_UFCR) for setting the interrupt threshold.) When asserted, RRDY generates a maskable interrupt or DMA request. RRDY is automatically cleared when data level in the RxFIFO goes below the set threshold level. At reset, RRDY is set to 0. 0 No character ready 1 Character(s) ready (interrupt posted)
8 AGTIM	Ageing Timer Interrupt Flag. Indicates that data in the RxFIFO has been idle for a time of 8 character lengths (where a character length consists of 7 or 8 bits, depending on the setting of the WS bit in UCR2, with the bit time corresponding to the baud rate setting) and FIFO data level is less than RxFIFO threshold level (RXTL in the UFCR). Clear by writing a 1 to it. 0 AGTIM is not active 1 AGTIM is active (write 1 to clear)
7 DTRD	**DTR Delta.** Indicates whether $\overline{\text{DTR}}$ (in DCE mode) or $\overline{\text{DSR}}$ (in DTE mode) pins changed state. DTRD generates a maskable interrupt if DTRDEN (UCR3[3]) is set. Clear DTRD by writing 1 to it. Writing 0 to DTRD has no effect. 0 $\overline{\text{DTR}}$ (DCE) or $\overline{\text{DSR}}$ (DTE) pin did not change state since last cleared 1 $\overline{\text{DTR}}$ (DCE) or $\overline{\text{DSR}}$ (DTE) pin changed state (write 1 to clear)
6 RXDS	Receiver IDLE Interrupt Flag. Indicates that the receiver state machine is in an IDLE state, the next state is IDLE, and the receive pin is high. RXDS is automatically cleared when a character is received. RXDS is active only when the receiver is enabled.

Table continues on the next page...

UARTx_USR1 field descriptions (continued)

Field	Description
	0 Receive in progress 1 Receiver is IDLE
5 AIRINT	Asynchronous IR WAKE Interrupt Flag. Indicates that the IR WAKE pulse was detected on the RXD pin. Clear AIRINT by writing 1 to it. Writing 0 to AIRINT has no effect. 0 No pulse was detected on the RXD IrDA pin 1 A pulse was detected on the RXD IrDA pin
4 AWAKE	Asynchronous WAKE Interrupt Flag. Indicates that a falling edge was detected on the RXD pin. Clear AWAKE by writing 1 to it. Writing 0 to AWAKE has no effect. 0 No falling edge was detected on the RXD Serial pin 1 A falling edge was detected on the RXD Serial pin
3–0 -	Reserved

76.13.9 UART Status Register 2 (UARTx_USR2)

Addresses: UART-1_USR2 is 53FB_C000h base + 98h offset = 53FB_C098h
UART-2_USR2 is 53FC_0000h base + 98h offset = 53FC_0098h
UART-3_USR2 is 53FC_4000h base + 98h offset = 53FC_4098h
UART-4_USR2 is 53FF_0000h base + 98h offset = 53FF_0098h
UART-5_USR2 is 63F9_0000h base + 98h offset = 63F9_0098h

UARTx_USR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15 ADET	**Automatic Baud Rate Detect Complete**. Indicates that an "A" or "a" was received and that the receiver detected and verified the incoming baud rate. Clear ADET by writing 1 to it. Writing 0 to ADET has no effect. 0 ASCII "A" or "a" was not received 1 ASCII "A" or "a" was received (write 1 to clear)
14 TXFE	**Transmit Buffer FIFO Empty**. Indicates that the transmit buffer (TxFIFO) is empty. TXFE is cleared automatically when data is written to the TxFIFO. Even though TXFE is high, the transmission might still be in progress. 0 The transmit buffer (TxFIFO) is not empty 1 The transmit buffer (TxFIFO) is empty
13 DTRF	**DTR edge triggered interrupt flag**. This bit is asserted, when the programmed edge is detected on the $\overline{\text{DTR}}$ pin (DCE mode) or on $\overline{\text{DSR}}$ (DTE mode). This flag can cause an interrupt if DTREN (UCR3[13]) is enabled. 0 Programmed edge not detected on DTR/DSR 1 Programmed edge detected on DTR/DSR (write 1 to clear)
12 IDLE	**Idle Condition**. Indicates that an idle condition has existed for more than a programmed amount frame (see Idle Line Detect. An interrupt can be generated by this IDLE bit if IDEN (UCR1[12]) is enabled. IDLE is cleared by writing 1 to it. Writing 0 to IDLE has no effect. 0 No idle condition detected 1 Idle condition detected (write 1 to clear)
11 ACST	**Autobaud Counter Stopped**. In autobaud detection (ADBR=1), indicates the counter which determines the baud rate was running and is now stopped. This means either START bit is finished (if ADNIMP=1), or Bit 0 is finished (if ADNIMP=0). See New Autobaud Counter Stopped bit and Interrupt, for more details. An interrupt can be flagged on *interrupt_uart* if ACIEN=1. 0 Measurement of bit length not finished (in autobaud) 1 Measurement of bit length finished (in autobaud). (write 1 to clear)
10 RIDELT	**Ring Indicator Delta**. This bit is used in DTE mode to indicate that the Ring Indicator input ($\overline{\text{RI}}$) has changed state. This flag can generate an interrupt if RI (UCR3[8]) is enabled. RIDELT is cleared by writing 1 to it. Writing 0 to RIDELT has no effect. 0 Ring Indicator input has not changed state 1 Ring Indicator input has changed state (write 1 to clear)
9 RIIN	**Ring Indicator Input**. This bit is used in DTE mode to reflect the status if the Ring Indicator input ($\overline{\text{RI}}$). The Ring Indicator input is used to indicate that a ring has occurred. In DCE mode this bit is always zero. 0 Ring Detected 1 No Ring Detected
8 IRINT	**Serial Infrared Interrupt Flag.** When an edge is detected on the RXD pin during SIR Mode, this flag will be asserted. This flag can cause an interrupt which can be masked using the control bit ENIRI: UCR4 [8]. 0 no edge detected 1 valid edge detected (write 1 to clear)

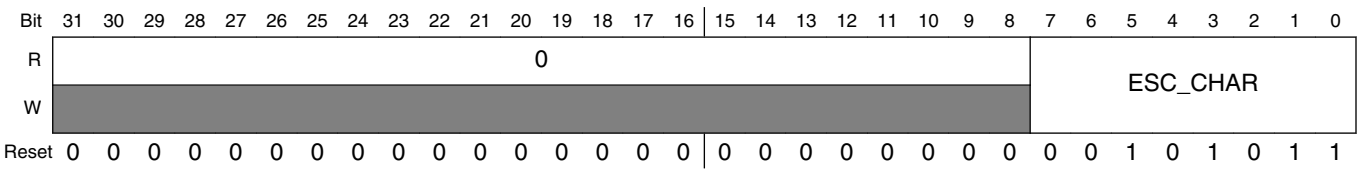
Table continues on the next page...

UARTx_USR2 field descriptions (continued)

Field	Description
7 WAKE	**Wake**. Indicates the start bit is detected. WAKE can generate an interrupt that can be masked using the WKEN bit. Clear WAKE by writing 1 to it. Writing 0 to WAKE has no effect. 0 start bit not detected 1 start bit detected (write 1 to clear)
6 DCDDELT	**Data Carrier Detect Delta**. This bit is used in DTE mode to indicate that the Data Carrier Detect input ($\overline{DCD}$) has changed state. This flag can cause an interrupt if DCD (UCR3[9]) is enabled. When in STOP mode, this bit can be used to wake the processor. In DCE mode this bit is always zero. 0 Data Carrier Detect input has not changed state 1 Data Carrier Detect input has changed state (write 1 to clear)
5 DCDIN	**Data Carrier Detect Input**. This bit is used in DTE mode reflect the status of the Data Carrier Detect input ($\overline{DCD}$). The Data Carrier Detect input is used to indicate that a carrier signal has been detected. In DCE mode this bit is always zero. 0 Carrier signal Detected 1 No Carrier signal Detected
4 RTSF	**RTS Edge Triggered Interrupt Flag. Indicates if** a programmed edge is detected on the $\overline{RTS}$ pin. The RTEC bits select the edge that generates an interrupt (see Table 76-5). RTSF can generate an interrupt that can be masked using the RTSEN bit. Clear RTSF by writing 1 to it. Writing 0 to RTSF has no effect. 0 Programmed edge not detected on $\overline{RTS}$ 1 Programmed edge detected on $\overline{RTS}$ (write 1 to clear)
3 TXDC	**Transmitter Complete**. Indicates that the transmit buffer (TxFIFO) and Shift Register is empty; therefore the transmission is complete. TXDC is cleared automatically when data is written to the TxFIFO. 0 Transmit is incomplete 1 Transmit is complete
2 BRCD	**BREAK Condition Detected**. Indicates that a BREAK condition was detected by the receiver. Clear BRCD by writing 1 to it. Writing 0 to BRCD has no effect. 0 No BREAK condition was detected 1 A BREAK condition was detected (write 1 to clear)
1 ORE	**Overrun Error**. When set to 1, ORE indicates that the receive buffer (RxFIFO) was full (32 chars inside), and a 33rd character has been fully received. This 33rd character has been discarded. Clear ORE by writing 1 to it. Writing 0 to ORE has no effect. 0 No overrun error 1 Overrun error (write 1 to clear)
0 RDR	**Receive Data Ready**-Indicates that at least 1 character is received and written to the RxFIFO. If the URXD register is read and there is only 1 character in the RxFIFO, RDR is automatically cleared. 0 No receive data ready 1 Receive data ready

76.13.10 UART Escape Character Register (UARTx_UESC)

Addresses: UART-1_UESC is 53FB_C000h base + 9Ch offset = 53FB_C09Ch
UART-2_UESC is 53FC_0000h base + 9Ch offset = 53FC_009Ch
UART-3_UESC is 53FC_4000h base + 9Ch offset = 53FC_409Ch
UART-4_UESC is 53FF_0000h base + 9Ch offset = 53FF_009Ch
UART-5_UESC is 63F9_0000h base + 9Ch offset = 63F9_009Ch

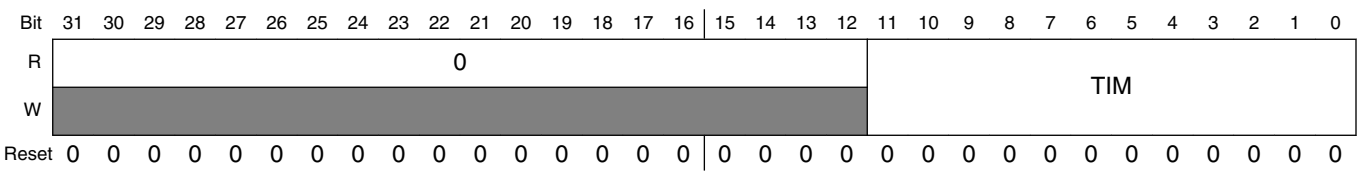


UARTx_UESC field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–0 ESC_CHAR	**UART Escape Character**. Holds the selected escape character that all received characters are compared against to detect an escape sequence.

76.13.11 UART Escape Timer Register (UARTx_UTIM)

Addresses: UART-1_UTIM is 53FB_C000h base + A0h offset = 53FB_C0A0h
UART-2_UTIM is 53FC_0000h base + A0h offset = 53FC_00A0h
UART-3_UTIM is 53FC_4000h base + A0h offset = 53FC_40A0h
UART-4_UTIM is 53FF_0000h base + A0h offset = 53FF_00A0h
UART-5_UTIM is 63F9_0000h base + A0h offset = 63F9_00A0h



UARTx_UTIM field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11–0 TIM	UART Escape Timer. Holds the maximum time interval (in ms) allowed between escape characters. The escape timer register is programmable in intervals of 2 ms. See Escape Sequence Detection and Table 76-10 for more information on the UART escape sequence detection. Reset value 0x000 = 2 ms up to 0xFFF = 8.192 s.

76.13.12 UART BRM Incremental Register (UARTx_UBIR)

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write 0x000F value into the UBIR after finishing detecting baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle[1].

Please note software reset will reset the register to its reset value.

Addresses: UART-1_UBIR is 53FB_C000h base + A4h offset = 53FB_C0A4h
UART-2_UBIR is 53FC_0000h base + A4h offset = 53FC_00A4h
UART-3_UBIR is 53FC_4000h base + A4h offset = 53FC_40A4h
UART-4_UBIR is 53FF_0000h base + A4h offset = 53FF_00A4h
UART-5_UBIR is 63F9_0000h base + A4h offset = 63F9_00A4h

UARTx_UBIR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–0 INC	Incremental Numerator. Holds the numerator value minus one of the BRM ratio (see Binary Rate Multiplier (BRM)). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM will ignore this data until the other register is written to by software. Updating this field using byte accesses is not recommended and is undefined.

1. Note: The write priority in the new design is not same as the original UART. In the orginal design, software has higher priotiry than hardware when writing this register at the same time.

76.13.13 UART BRM Modulator Register (UARTx_UBMR)

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write a proper value into the UBMR based on detected baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle[1].

Please note software reset will reset the register to its reset value.

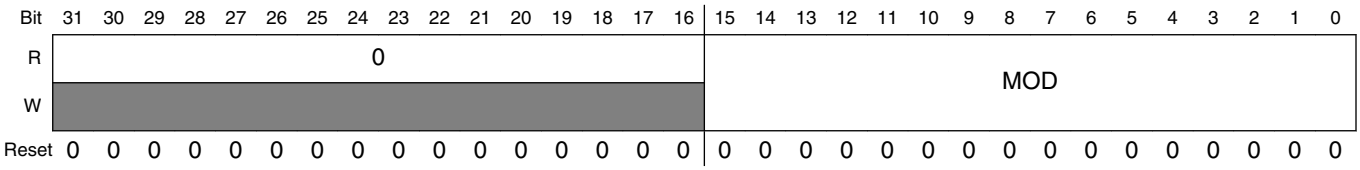
Addresses: UART-1_UBMR is 53FB_C000h base + A8h offset = 53FB_C0A8h

UART-2_UBMR is 53FC_0000h base + A8h offset = 53FC_00A8h

UART-3_UBMR is 53FC_4000h base + A8h offset = 53FC_40A8h

UART-4_UBMR is 53FF_0000h base + A8h offset = 53FF_00A8h

UART-5_UBMR is 63F9_0000h base + A8h offset = 63F9_00A8h



UARTx_UBMR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–0 MOD	**Modulator Denominator.** Holds the value of the denominator minus one of the BRM ratio (see Binary Rate Multiplier (BRM)). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM will ignore this data until the other register is written to by software. Updating this register using byte accesses is not recommended and undefined.

1. Note: The write priority in the new design is not same as the original UART. In the orginal design, software has higher priotiry than hardware when writing this register at the same time.

76.13.14 UART Baud Rate Count Register (UARTx_UBRC)

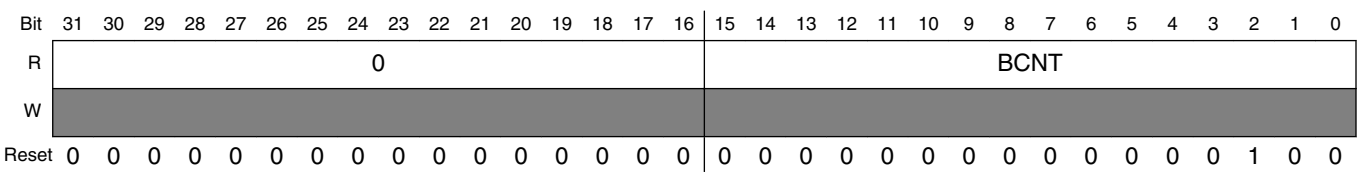
Addresses: UART-1_UBRC is 53FB_C000h base + ACh offset = 53FB_C0ACh

UART-2_UBRC is 53FC_0000h base + ACh offset = 53FC_00ACh

UART-3_UBRC is 53FC_4000h base + ACh offset = 53FC_40ACh

UART-4_UBRC is 53FF_0000h base + ACh offset = 53FF_00ACh

UART-5_UBRC is 63F9_0000h base + ACh offset = 63F9_00ACh



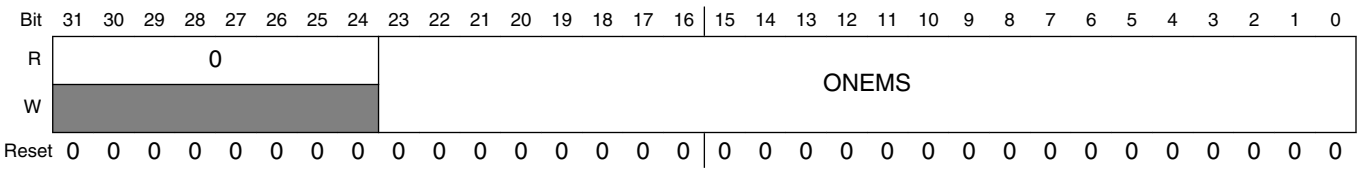
UARTx_UBRC field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–0 BCNT	**Baud Rate Count Register.** This read only register is used to count the start bit of the incoming baud rate (if ADNIMP=1), or start bit + bit0 (if ADNIMP=0). When the measurement is done, the Baud Rate Count Register contains the number of UART internal clock cycles (clock after divider) present in an incoming bit. BCNT retains its value until the next Automatic Baud Rate Detection sequence has been initiated. The 16 bit Baud Rate Count register is reset to 4 and stays at hex FFFF in the case of an overflow.

76.13.15 UART One Millisecond Register (UARTx_ONEMS)

This register has been expanded from 16 bits to 24 bits. In previous versions, the 16-bit ONEMS can only support the maximum 65.535MHz (0xFFFFx1000) ref_clk. To support 4Mbps Bluetooth application with 66.5MHz module_clock, the value 0x103C4 (66.5M/1000) should be written into this register. In this case, the 16 bits are not enough to contain the 0x103C4. So this register was expanded to 24 bits to support high frequency of the ref_clk.

Addresses: UART-1_ONEMS is 53FB_C000h base + B0h offset = 53FB_C0B0h
UART-2_ONEMS is 53FC_0000h base + B0h offset = 53FC_00B0h
UART-3_ONEMS is 53FC_4000h base + B0h offset = 53FC_40B0h
UART-4_ONEMS is 53FF_0000h base + B0h offset = 53FF_00B0h
UART-5_ONEMS is 63F9_0000h base + B0h offset = 63F9_00B0h

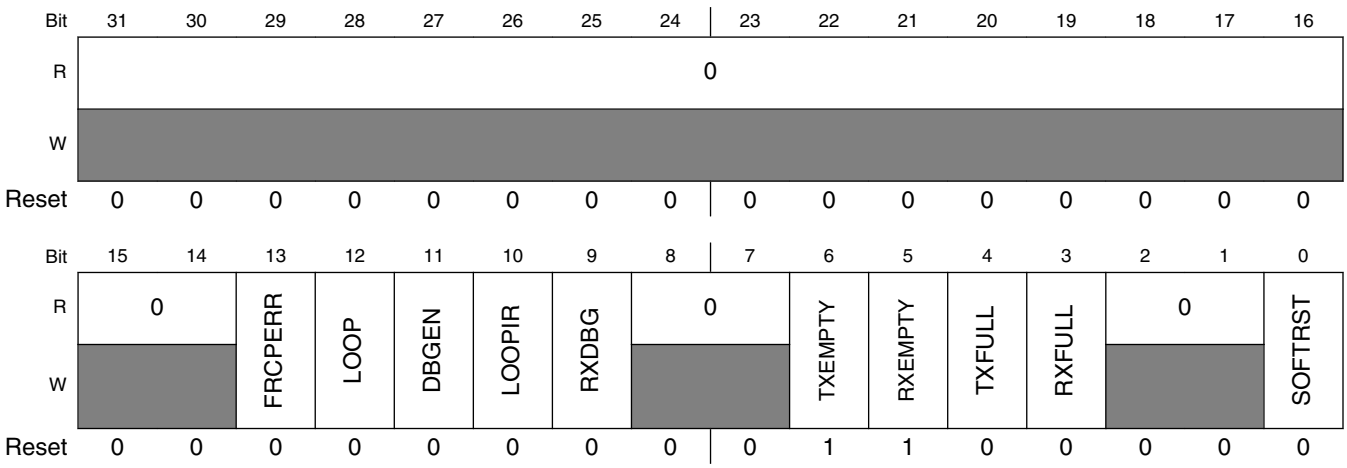


UARTx_ONEMS field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved
23–0 ONEMS	**One Millisecond Register.** This 24-bit register must contain the value of the UART internal frequency (*ref_clk* in Figure 76-1) divided by 1000. The internal frequency is obtained after the UART BRM internal divider (F (*ref_clk*) = F(*module_clock*) / RFDIV). In fact this register contains the value corresponding to the number of UART BRM internal clock cycles present in one millisecond. The ONEMS (and UTIM) registers value are used in the escape character detection feature (Escape Sequence Detection) to count the number of clock cycles left between two escape characters. The ONEMS register is also used in infrared special case mode (IRSC = UCR4[5] = 1'b1), see InfraRed Special Case (IRSC) Bit.

76.13.16 UART Test Register (UARTx_UTS)

Addresses: UART-1_UTS is 53FB_C000h base + B4h offset = 53FB_C0B4h
UART-2_UTS is 53FC_0000h base + B4h offset = 53FC_00B4h
UART-3_UTS is 53FC_4000h base + B4h offset = 53FC_40B4h
UART-4_UTS is 53FF_0000h base + B4h offset = 53FF_00B4h
UART-5_UTS is 63F9_0000h base + B4h offset = 63F9_00B4h



UARTx_UTS field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value zero. Reserved
13 FRCPERR	Force Parity Error. Forces the transmitter to generate a parity error if parity is enabled. FRCPERR is provided for system debugging. 0 Generate normal parity 1 Generate inverted parity (error)
12 LOOP	Loop TX and RX for Test. Controls loopback for test purposes. When LOOP is high, the receiver input is internally connected to the transmitter and ignores the RXD pin. The transmitter is unaffected by LOOP. If RXDMUXSEL (UCR3[2]) is set to 1, the loopback is applied on serial and IrDA signals. If RXDMUXSEL is set to 0, the loopback is only applied on serial signals. 0 Normal receiver operation 1 Internally connect the transmitter output to the receiver input
11 DBGEN	$\overline{\text{debug\_enable}}$. This bit controls whether to respond to the *debug_req* input signal. 0 UART will go into debug mode when *debug_req* is HIGH 1 UART will not go into debug mode even if *debug_req* is HIGH
10 LOOPIR	**Loop TX and RX for IR Test (LOOPIR).** This bit controls loopback from transmitter to receiver in the InfraRed interface.

Table continues on the next page...

UARTx_UTS field descriptions (continued)

Field	Description
	0 No IR loop 1 Connect IR transmitter to IR receiver
9 RXDBG	**RX_fifo_debug_mode.** This bit controls the operation of the RX fifo read counter when in debug mode. 0 rx fifo read pointer does not increment 1 rx_fifo read pointer increments as normal
8–7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6 TXEMPTY	TxFIFO Empty. Indicates that the TxFIFO is empty. 0 The TxFIFO is not empty 1 The TxFIFO is empty
5 RXEMPTY	RxFIFO Empty. Indicates the RxFIFO is empty. 0 The RxFIFO is not empty 1 The RxFIFO is empty
4 TXFULL	TxFIFO FULL. Indicates the TxFIFO is full. 0 The TxFIFO is not full 1 The TxFIFO is full
3 RXFULL	RxFIFO FULL. Indicates the RxFIFO is full. 0 The RxFIFO is not full 1 The RxFIFO is full
2–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 SOFTRST	Software Reset. Indicates the status of the software reset ($\overline{\text{SRST}}$ bit of UCR2). 0 Software reset inactive 1 Software reset active

Chapter 77
Universal Serial Bus Controller (USB)

77.1 Overview

The USB controller block provides high performance USB functionality that conforms to the USB 2.0 specification, and the OTG supplement.

The USB controller consists of four independent USB controller cores: one OTG controller core, and three Host-only controller cores. Each controller core can support ULPI, Serial, UTMI, IC-USB or HSIC interface according to its feature. All four controller cores are single-port cores. For the OTG core, there is only one port. It is used as both a downstream and upstream port. For the Host-only core, there is also only one port which is used as a downstream port.

The following figure is a block diagram of USB.

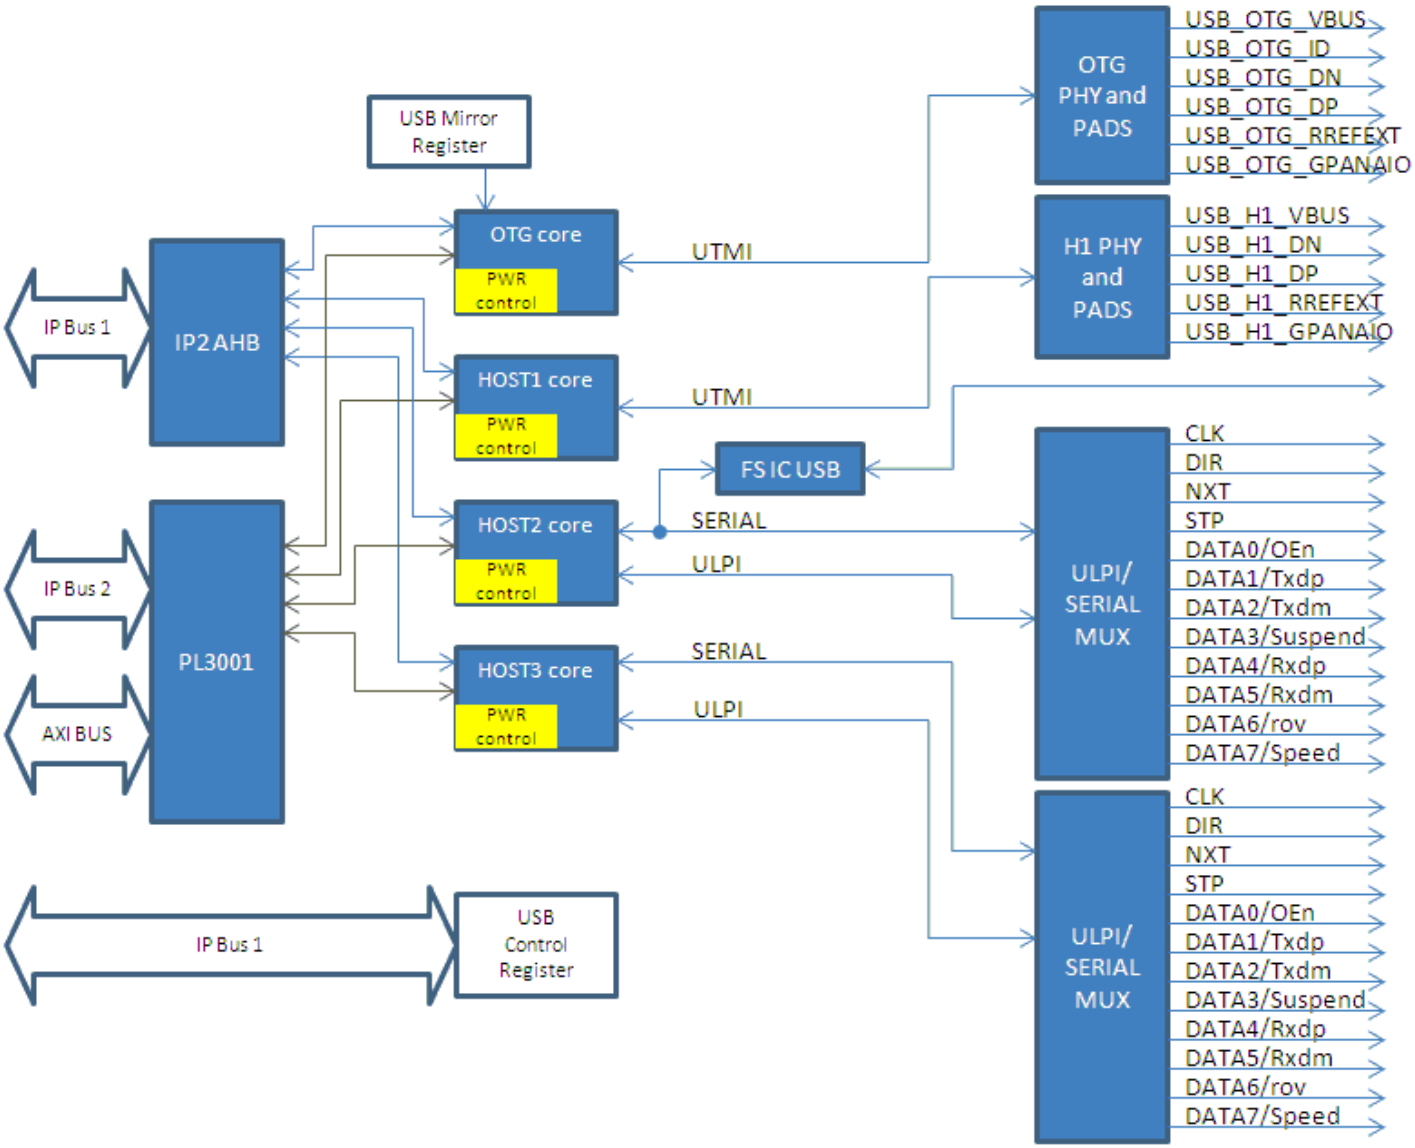


Figure 77-1. USBOH3 Block Diagram

77.2 Features

The USB includes the following features:

- High-speed/full-speed/low-speed host only core (Host1)
  - HS/FS/LS UTMI compliant interface
- High-speed/full-speed/low-speed host only core (Host2)
  - HS/FS/LS ULPI compliant interface
  - Software configurable for full speed/low speed interface for Serial transceiver
  - Full Speed Inter-Chip USB compliant interface (IC-USB)

- High-speed/full-speed/low-speed Host-only core (Host3)
  - HS/FS/LS ULPI compliant interface
  - Software configurable for full-speed/low-speed interface for Serial transceiver
- High-speed/full-speed/low-speed OTG core
  - HS/FS/LS UTMI compliant interface
  - High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
  - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
  - Hardware support for OTG signaling, session request protocol, and host negotiation protocol
  - Up to 8 bidirectional endpoints
- Low-power mode with local and remote wake-up capability
- Serial PHY interfaces configurable for bidirectional/unidirectional and differential/ single ended
- Embedded DMA controller

77.2.1 Modes of Operation

The USB has two main modes of operation: normal mode and low power mode.

Each USB controller core can be configured for High Speed operation (480 Mbps), Full Speed operation (12Mbps) and Low Speed operation (1.5 Mbps).

This chapter explains the operation modes.

77.2.1.1 Normal Mode

For OTG controller core, it could work in Host mode, or Device (Peripheral) mode; for Host-only controller core, it could work in Host mode only.

Each USB controller core has its corresponding port, which could work in one or more interface modes.

- Host1 Port
  - This port supports on-chip UTMI transceivers only.
- Host2 Port
  - This port supports ULPI, Serial and IC-USB interface.
  - Serial interface mode

    For connections to external Serial transceivers.

- ULPI interface mode

  For connections to external ULPI compatible transceivers.

- IC-USB interface mode

  For connection to USB peripherals with IC-USB interface.

- Host3 Port
  - This port supports ULPI and Serial interface.
  - Serial interface mode

    For connections to external Serial transceivers.

  - ULPI interface mode

    For connections to external ULPI compatible transceivers.

- OTG port
  - This port supports on-chip UTMI transceiver only.

NOTE

As the ULPI and Serial mode do not work at the same time, the ULPI_DATA[7:0] signals are shared as the Serial interface signals.

The signal mapping for serial interface in 4 different serial modes are given in Table 77-1.

Table 77-1. Serial Interface Signal Mapping

	Unidirection & Differential	Unidirection & Single-End	Bidirection & Differential	Bidirection & Single-End
ULPI_DATA[0]	oen	oen	oen	oen
ULPI_DATA[1]	txdp	tx_dat	dp	dat
ULPI_DATA[2]	txdm	tx_se0	dm	se0
ULPI_DATA[3]	suspend	suspend	suspend	suspend
ULPI_DATA[4]	rxdp	rxdp	-	-
ULPI_DATA[5]	rxdm	rxdm	-	-
ULPI_DATA[6]	rcv	rcv	rcv	-
ULPI_DATA[7]	speed	speed	speed	speed

77.2.1.2 Low Power Mode

Each USB controller core has a low power mode (Suspend Mode) to save power consumption.

As described in USB 2.0 specification, devices can go into the Suspend state after they see a constant Idle state on their upstream facing bus. The OTG controller core could enter Suspend Mode after there is no bus activity for 3ms on port when it is in Device operation mode. Host1, Host2 and Host3 controller core do not have this function because they support host mode only.

Either the local ARM platform or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication. For details about Suspend/Resume, please see .

77.3 Functional Description

These sections describe the functionality of the various building blocks of the USB.

77.3.1 USB Host Controller 1

Host Controller 1 is an instantiation of EHCI-compatible core which supports High Speed / Full Speed / Low Speed operation.

77.3.1.1 Pins Used for Host Controller 1

USB Host Controller 1 signals do not multiplex with other pins on the i.MX53. Therefore it is not necessary to port IOMUX settings for this particular interface.

- Supply USB_H1_VDDA33 with 3.3V
- Supply USB_H1_VDDA25 with 2.5V

USB H1 PHY pins used:

- USB_H1_VBUS (D15)
- USB_H1_VDDA25 (F13)
- USB_H1_DN (B17)
- USB_H1_VDDA33 (G13)
- USB_H1_DP (A17)
- USB_H1_RREFEXT (B16)
- USB_H1_GPANAIO (A16)

77.3.2 USB Host Controller 2

Host Controller 2 is an instantiation of the EHCI-compatible core which supports High Speed / Full Speed / Low Speed operation.

The Host 2 core USB signals do not connect directly to the Host2 I/O pins. Instead, the signals pass through the Serial and ULPI Mux to allow for additional functionality on Host2 Port. Host controller 2 is configured for operation with a FS/LS serial transceiver or a parallel ULPI transceiver (HS/FS/LS). The selection between transceiver type is software programmable. The block defaults to serial mode.

77.3.3 USB Host Controller 3

Host Controller 3 is an instantiation of EHCI-compatible core which supports High Speed / Full Speed / Low Speed operation.

The Host 3 core USB signals do not connect directly to the Host3 I/O pins. Instead, the signals pass through the Serial and ULPI Mux to allow for additional functionality on Host3 Port. Host controller 3 is configured for operation with a FS/LS serial transceiver or a parallel ULPI transceiver (HS/FS/LS). The selection between transceiver type is software programmable. The block defaults to serial mode.

77.3.4 USB OTG Controller

OTG Controller 3 is an instantiation of EHCI-compatible OTG core which supports High Speed / Full Speed / Low Speed operation.

The OTG controller core supports HS/FS/LS operation in Host mode and HS/FS operation in device mode.

77.3.4.1 Host Mode

The controller supports direct connection of a HS/FS/LS device with on-chip UTMI transceiver.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a USB 2.0 high speed hub has been implemented within the DMA and protocol engine blocks to support connection to full and low speed devices.

77.3.4.2 Peripheral (Device) Mode

- Up to 8 bidirectional endpoints
- High/Full speed operation
- Supports HNP and SRP
- Remote wake-up capable

77.3.4.3 Pins Used for OTG

USB OTG signals do not multiplex with other pins on the i.MX53. Therefore it is not necessary to port IOMUX settings for this particular interface.

The only required setup is to:

- supply USB_OTG_VDDA33 with 3.3V
- supply USB_OTG_VDDA25 with 2.5V

USB OTG PHY pins used:

- USB_OTG_VBUS (E15)
- USB_OTG_ID (C16)
- USB_OTG_VDDA25 (F14)
- USB_OTG_DN (A19)
- USB_OTG_VDDA33 (G14)
- USB_OTG_DP (B19)
- USB_OTG_RREFEXT (D16)
- USB_OTG_GPANAIO (F15)

77.3.5 Interrupts

77.3.5.1 USB Core Interrupts

Each USB core uses one dedicated vector in the Interrupt Table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB Cores. Refer to the Register Interface for details.

77.3.5.2 USB Wake-Up Interrupts

Each USB Core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but use the same vector as the corresponding USB controller cores' interrupt.

These interrupts are generated by the Power Control blocks which run on the 32KHz standby clock. The wake-up interrupt is designed to work even when the USB and ARM platform clocks are disabled, such that a wake-up condition on the USB bus can re-activate the ARM platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 KHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the ARM platform clock. The software should than wait for at least three 32 KHz clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

77.3.6 USB Clock System

This section describes the clock diagram of USB.

The figure below shows the clock system of USB.

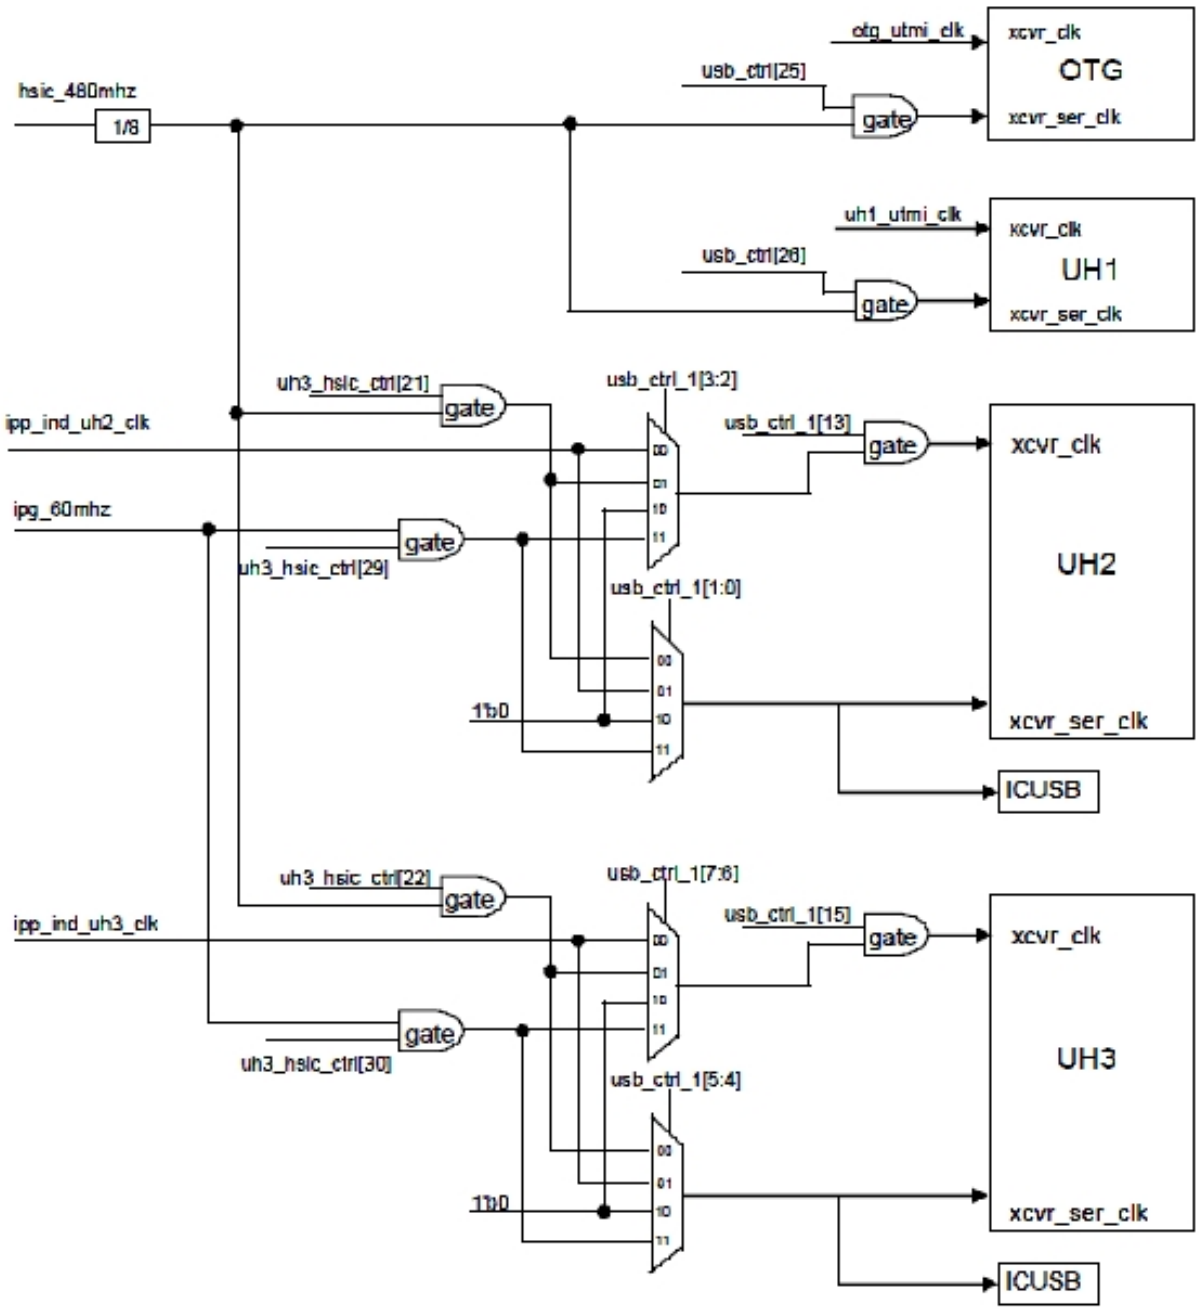

Figure 77-2. USB Clock System

- HSIC_480MHz: this clock comes from on-chip OTG UTMI PHY DPLL, its freq is 480 MHz.
- otg_utmi_clk: this clock comes from on-chip OTG UTMI PHY sieclock port, its freq is 30 MHz.
- uh1_utmi_clk: this clock comes from on-chip Host1 UTMI PHY sieclock port, its freq is 30 MHz.
- ipg_60mhz: this clock comes from system DPLL, its freq is 60MHz.
- ipp_ind_uh2_clk: this clock is from Host2 port external ULPI PHY clock pad

- ipp_ind_uh3_clk: this clock is from Host3 port external ULPI PHY clock pad.
- usb_ctrl: this register is the USB Control Register 0 (Base+0x800).
- usb_ctrl_1: this register is the USB Control Register 1 (Base+0x810).
- usb_uh2_ctrl: this register is the USB Host2 Control Register (Base+0x814).
- usb_uh3_ctrl: this register is the USB Host3 Control Register (Base+0x818).
- uh3_hsic_ctrl: this register is the USB Host3 HS_IC Control Register (Base+0x824).
- otg_ser_mode/uh1_ser_mode: these signals are used to enable the serial mode of OTG/Host1

77.4 USB Operation Model

This section describes the detailed application knowledge for Host1, Host2, Host3 and OTG ports. It can be generally divided in two parts, one is for Host and the other is for Device.

Host part applies to all three host ports, and to OTG port when operating in Host mode. Device part only applies to OTG port when operating in Device mode.

77.4.1 Register Interface

Slave accesses from the controlling processor enables access to the configuration, control, and status registers. One function of the system address map is the registers base address, which must begin on a DWord (32-bit) boundary.

Register offset definitions are listed in the table below.

Configuration, control and status registers are divided into three categories, identification, capability and operational registers.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are comprised of dynamic control or status registers that may be read only, read/write, or read/write to clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

The following table describes the Interface register sets.

Table 77-2. Interface Register Sets

Offset	Register Set	Explanation
000h-07Ch	Identification Registers	Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.
100h-124h	Capability Registers	Capability registers specify the limits, restrictions, and capabilities of a host/device controller implementation. These values are used as parameters to the host/device controller driver.
080h-0FCh 140h-1FCh	Operational Registers	Operational registers are used by the system software to control and monitor the operational state of the host/device controller.

77.4.1.1 Configuration, Control and Status Register Set

The following table describes the Device/Host capability registers.

NOTE

Depending on implementation, "*x*" can have the following values: UOG, UH1, UH2 or UH3.

.

Table 77-3. Device/Host Capability Registers

Offset	Size (Bytes)	Mnemonic	Register Name	Device Mode	Host Mode
000h	4	USB_*x*_ID	Identification Register	O	O

77.4.1.2 Identification Registers

Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.

77.4.1.3 OTG Operations

77.4.1.3.1 Register Bits

In the previous section, the Register interface has behaviors described for device mode and behaviors described for host mode. However, during OTG operations it is necessary to perform tasks independent of the controller mode.

Note also from Endpoint Control0 (USB_UOG_ENDPTCTRL0), that the only way to transition the controller mode out of host or device mode is with the controller reset bit. Therefore, it is also necessary for the OTG tasks to be performed independent of a controller reset as well as independent of the controller mode.

The following figure shows the controller mode.

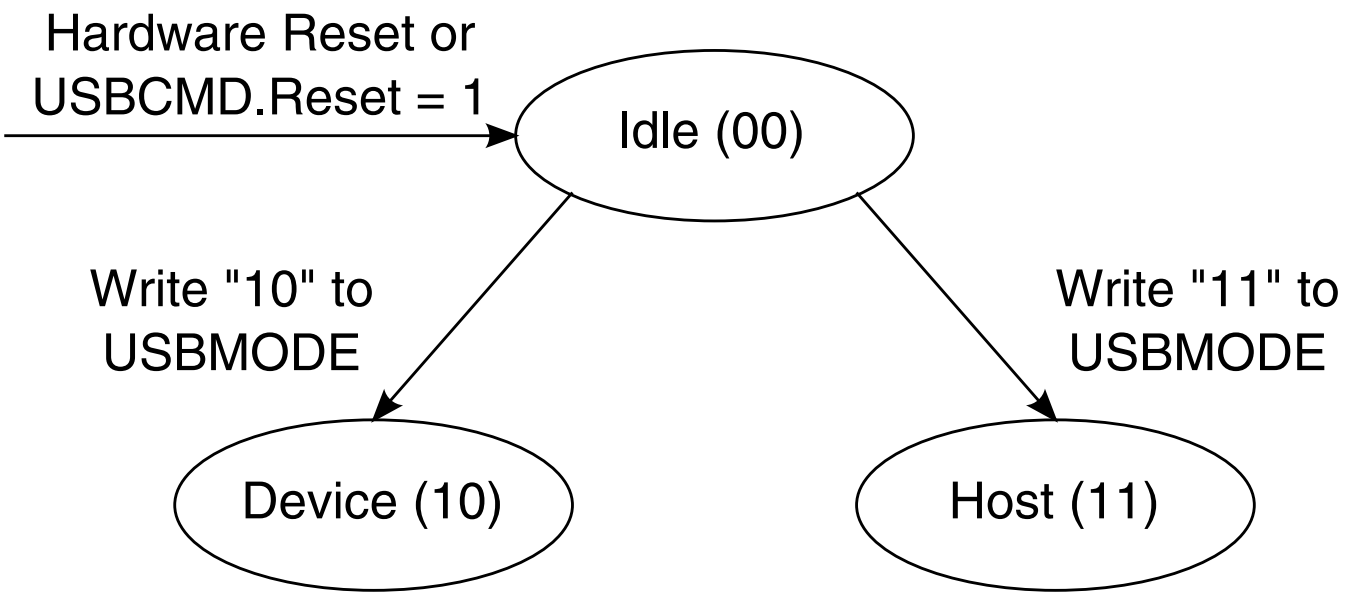

Figure 77-3. Controller Mode

To this end, the listed below are the register bits that are used for OTG operations, which are independent of the controller mode and are also not affected by a write to the reset bit in the USBCMD register:

All Identification Registers

All Device/Host Capability Registers

OTGSC: All bits

PORTSC1:

Physical Interface Select

Physical Interface Serial Select

Physical Interface Data Width

Physical Interface Low Power

Physical Interface Wake Signals

Port Indicators

Port Power

77.4.1.3.2 Hardware Assist

The hardware assist provides automated response and sequencing that may not be possible to software with significant interrupt latency response times.

The use of this additional circuitry is optional and can be used to assist the 3 sequences below.

77.4.1.3.2.1 Auto-Reset

When the HAAR is set to one, the host automatically starts a reset after a connect event. This shortcuts the normal process where software is notified of the connect event and starts the reset.

Software still receives notification of the connect event but should not write the reset bit when the HAAR is set. Software is notified again after the reset is complete via the enable change bit in the USB_PORTSC1 register which cause a port change interrupt.

This assist ensures the OTG parameter TB_ACON_BSE0_MAX = 1ms is met.

77.4.1.3.2.2 Data-Pulse

Writing one to HADP starts a data pulse of approximately 7ms in duration and then automatically cease the data pulsing. During the data pulse, the DP is set and then cleared. This automation relieves software from accurately controlling the data-pulse duration.

During the data pulse, the HCD can poll to see that the HADP and DP bit have returned low to recognize the completion or simply launch the data pulse and wait to see if a VBUS Valid interrupt occurs when the A-side supplies bus power.

This assist ensures data pulsing meets the OTG requirement of > 5ms and < 10ms.

77.4.1.3.2.3 B-Disconnect to A-Connect

During HNP, the B-disconnect occurs from the OTG A_suspend state and within 3 ms, the A device must enable the pullup on the DP leg in the A-peripheral state.

When HABA is set, the Host Controller port is in suspend mode, and the device disconnects, then this hardware assist begins.

1. Reset the OTG core.
2. Write the OTG core into device mode.
3. Write the device run bit to 1 and enable necessary interrupts including:

USB Reset Enable (URE); enables interrupt on usb bus reset to device

Sleep Enable (SLE); enables interrupt on device suspend

Port Change Detect Enable (PCE); enables interrupt on device connect

When software has enabled this hardware assist, it must not interfere during the transition and should not write any register in the core until it gets an interrupt from the device controller signifying that a reset interrupt has occurred or at least first verify that the core has entered device mode. HCD/DCD must not activate the core soft reset at any time because this action is performed by hardware. During the transition, the software may see an interrupt from the disconnect and/or other spurious interrupts (that is SOF, and so on) that may or may not cascade and my be cleared by the soft reset depending on the software response time.

After the core has entered device mode by the hardware assist, the DCD must ensure that the USB_ENDPTLISTADDR is programmed properly before the host sends a setup packet. Because the end of the reset duration, which may be initiated quickly (a few microseconds) after connect, will require at a minimum 50 ms, this is the time for which the DCD must be ready to accept setup packets after having received notification that the reset has been detected or simply that the OTG is in device mode which ever occurs first.

In the case where the A-peripheral fails to see a reset after the controller enters device mode and engages the DP-pullup, the device controller interrupt the DCD signifying that a suspend has occurred.

This assist ensures the parameter TA_BDIS_ACON_MAX = 3ms is met.

77.4.2 Host Data Structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the Enhanced Host Controller (hardware). The data structure definitions in this chapter support a 32-bit memory buffer address space.

The interface consists of a Periodic Schedule, Periodic Frame List, Asynchronous Schedule, Isochronous Transaction Descriptors, Split-transaction Isochronous Transfer Descriptors, Queue Heads, and Queue Element Transfer Descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) support for the host controller interface. The asynchronous list is the root for all the bulk and control transfer type support. Isochronous data streams are managed using Isochronous Transaction Descriptors. Isochronous split-transaction data streams are managed with Split-transaction Isochronous Transfer Descriptors. All Interrupt, Control, and Bulk data streams are managed via queue heads and Queue Element Transfer

Descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI host controller spans a 4 K-page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

77.4.2.1 Periodic Frame List

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the USB_PERIODICLISTBASEaddress register and the USB_FRINDEX register.

The periodic schedule is based on an array of pointers called the Periodic Frame List. The USB_PERIODICLISTBASE address register is combined with the USB_FRINDEX register to produce a memory pointer into the frame list. The Periodic Frame List implements a sliding window of work over time.

The following figure shows the organization of periodic schedule.

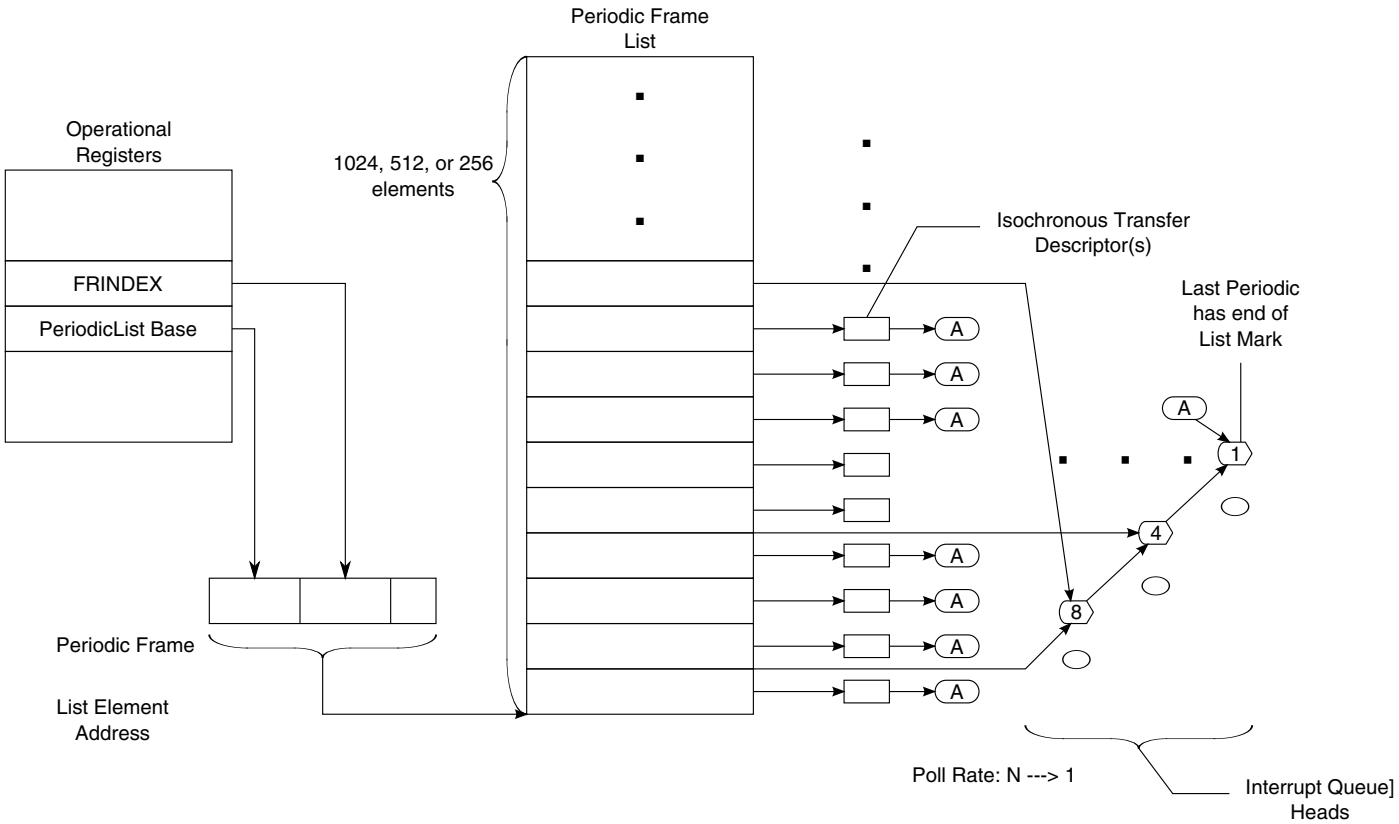

Figure 77-4. Periodic Schedule Organization

Split transaction Interrupt, Bulk and Control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4 K-page aligned array of Frame List Link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to system software via the USB_HCCPARAMS register. If non-programmable, the length is 1024 elements. If programmable, the length can be selected by system software as one of 256, 512, or 1024 elements. An implementation must support all three sizes. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into Frame List Size field in the USB_USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current micro-frame. The link pointers are aligned on DWord boundaries within the Frame List.

The table below illustrates the format of the Frame list element pointer.

Table 77-4. Format of Frame List Element Pointer

Table continues on the next page...

Table 77-4. Format of Frame List Element Pointer (continued)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Frame List Link Pointer																											0		Typ			03-00 H

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing.

The least significant bit is the T-Bit (bit 0). When this bit is set to a one, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field is used to indicate the exact type of data structure being referenced by this pointer. The value encodings are.

Table 77-5. Typ Field Value Definitions

Value	Meaning
00b	Isochronous Transfer Descriptor
01b	Queue Head
10b	Split Transaction Isochronous Transfer Descriptor.
11b	Frame Span Traversal Node.

77.4.2.2 Asynchronous List Queue Head Pointer

The Asynchronous Transfer List (based at the USB_ASYNCLISTADDR register) is where all of the control and bulk transfers are managed. Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty.

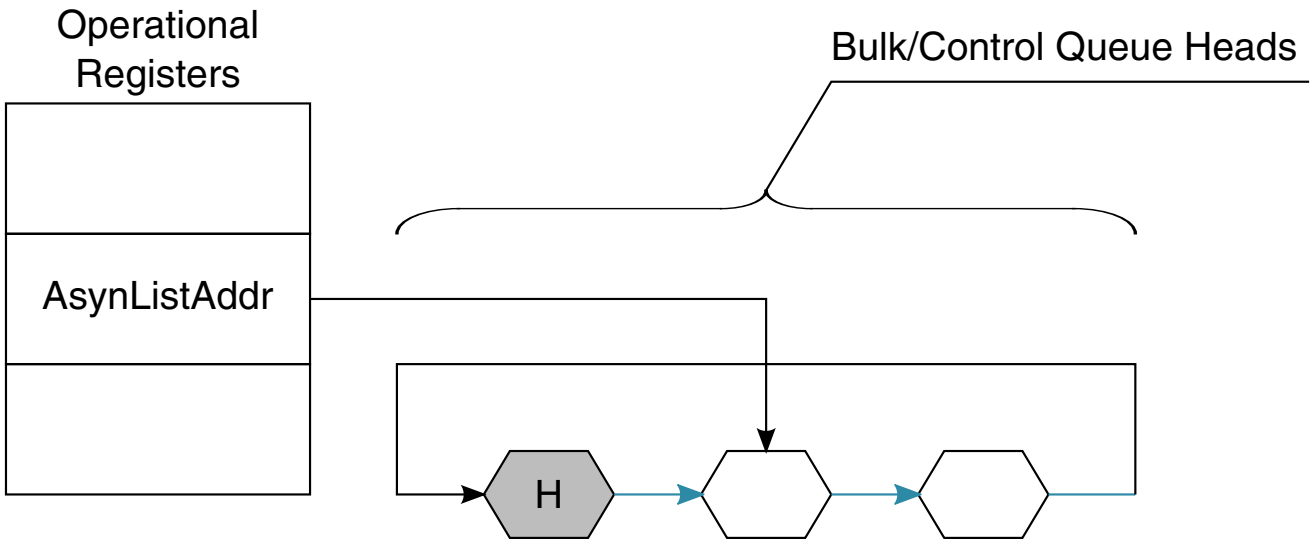

Figure 77-5. Asynchronous Schedule Organization

The Asynchronous list is a simple circular list of queue heads. The USB_ASYNCLISTADDR register is simply a pointer to the next queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

77.4.2.3 Isochronous (High-Speed) Transfer Descriptor (iTD)

The format of an isochronous transfer descriptor is shown in the table below.

This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

Table 77-6. Isochronous Transaction Descriptor (iTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Buffer Pointer (Page 6)				-	3F-3CH

	Host Controller Read/Write		Host Controller Read Only.

These fields may be modified by the host controller if the I/O field indicates an OUT.

77.4.2.3.1 Next Link Pointer-Host Data Structures

The first DWord of an iTD is a pointer to the next schedule data structure.

The following table describes the Next Schedule Element pointer field.

Table 77-7. Next Schedule Element Pointer

Bit	Description

Table continues on the next page...

Table 77-7. Next Schedule Element Pointer (continued)

31-5	Link Pointer (LP). These bits correspond to memory address signals [31:5], respectively. This field points to another Isochronous Transaction Descriptor (iTD/siTD) or Queue Head (QH).
4-3	Reserved. These bits are reserved and their value has no effect on operation. Software should initialize this field to zero.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0	Terminate (T). 1= Link Pointer field is not valid. 0= Link Pointer field is valid.

77.4.2.3.2 iTD Transaction Status and Control List

DWords 1 through 8 are eight slots of transaction control and status.

Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The PG and Transaction X Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list, to execute a transaction on the

The following table describes iTD Transaction Status and Control fields.

Table 77-8. iTD Transaction Status and Control

Bit	Description	
31-28	Status. This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:	
	Bit	Definition
	31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.
	30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.
	29	Babble Detected. Set to one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.

Table continues on the next page...

Table 77-8. iTD Transaction Status and Control (continued)

Bit	Description	
	28	Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.
27-16	Transaction X Length. For an OUT, this field is the number of data bytes the host controller sends during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (0‡zero length data, 1‡one byte, 2‡two bytes, etc.). The maximum value this field may contain is 0xC00 (3072).	
15	Interrupt On Complete (IOC). If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.	
14-12	Page Select (PG). These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.	
11-0	Transaction X Offset. This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent *PG* field to produce the starting buffer address for this transaction.	

77.4.2.3.3 iTD Buffer Page Pointer List (Plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4 K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous.

Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) * 1024 (maximum packet size) * 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Because each pointer is a 4 K aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

The tables below illustrate the field descriptions.

Table 77-9. iTD Buffer Pointer Page 0 (Plus)

Bit	Description
31-12	Buffer Pointer (Page 0). This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit reserved for future use and should be initialized by software to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

Table 77-10. iTD Buffer Pointer Page 1 (Plus)

Bit	Description
31-12	Buffer Pointer (Page 1). This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11	Direction (I/O). 0 = OUT; 1 = IN. This field encodes whether the high-speed transaction should use an IN or OUT PID.
10-0	Maximum Packet Size. This directly corresponds to the maximum packet size of the associated endpoint *(wMaxPacketSize)*. This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (per micro-frame). This field is used with the *Multi* field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (400h). Any value larger yields undefined results.

Table 77-11. iTD Buffer Pointer Page 2 (Plus)

Bit	Description
31-12	Buffer Pointer. This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-2	Reserved. This bit reserved for future use and should be set to zero.
1-0	Multi. This field is used to indicate to the host controller the number of transactions that should be executed per transaction description (per micro-frame). The valid values are: Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro- frame 10b Two transactions to be issued for this endpoint per micro-frame 11b Three transactions to be issued for this endpoint per micro- frame

Table 77-12. iTD Buffer Pointer Page 3-6

Bit	Description
31-12	Buffer Pointer. This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-0	Reserved. These bits reserved for future use and should be set to zero.

77.4.2.4 Split Transaction Isochronous Transfer Descriptor (siTD)

All Full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure. This data structure satisfies the operational requirements for managing the split transaction protocol.

The table below shows the Split Transaction Isochronous Transfer Descriptor (siTD).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 77-13. Split-transaction Isochronous Transaction Descriptor (siTD)

	Host Controller Read/Write		Host Controller Read Only.

77.4.2.4.1 Next Link Pointer

DWord0 of a siTD is a pointer to the next schedule data structure.

The following table describes the Next Link Pointer fields.

Table 77-14. Next Link Pointer

Bit	Description
31-5	Next Link Pointer (LP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved. These bits must be written as zeros.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD/siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0	Terminate (T). 1=Link Pointer field is not valid. 0=Link Pointer is valid.

77.4.2.4.2 siTD Endpoint Capabilities/Characteristics

DWords 1 and 2 specify static information about the full-speed endpoint, the addressing of the parent Companion Controller, and micro-frame scheduling control.

The tables below describe the Endpoint and transaction translator characteristics and micro-frame schedule control fields.

Table 77-15. Endpoint and Transaction Translator Characteristics

Bit	Description
31	Direction (I/O).0 = OUT; 1 = IN. This field encodes whether the full-speed transaction should be an IN or OUT.
30-24	Port Number. This field is the port number of the recipient Transaction Translator.
23	Reserved. Bit reserved and should be set to zero.
22-16	Hub Address. This field holds the device address of the Companion Controllers' hub.
15-12	Reserved. Field reserved and should be set to zero.
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit is reserved for future use. It should be set to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

Table 77-16. Micro-frame Schedule Control

Bit	Description
31-16	Reserved. This field reserved for future use. It should be set to zero.
15-8	Split Completion Mask (mFrame C-Mask). This field (along with the *Active* and *SplitX- state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute complete-split transactions. When the criteria for using this field is met, an all zeros value has undefined behavior. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the m*Frame C-Mask* field is a one, then this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Split Start Mask (mFrame S-mask). This field (along with the *Active* and *SplitX-state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the m*Frame S-mask* field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

77.4.2.4.3 siTD Transfer State

DWords 3-6 are used to manage the state of the transfer.

The following table describes siTD transfer state fields.

Table 77-17. siTD Transfer Status and Control

Bit	Description
31	Interrupt On Complete (ioc). 0 = Do not interrupt when transaction is complete. 1 = Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it asserts a hardware interrupt at the next interrupt threshold.
30	Page Select (P). Used to indicate which data page pointer should be concatenated with the *CurrentOffset* field to construct a data buffer pointer (0 selects *Page 0* pointer and 1 selects *Page 1*). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero).
29-26	Reserved. This field reserved for future use and should be set to zero.

Table continues on the next page...

Table 77-17. siTD Transfer Status and Control (continued)

Bit	Description	
25-16	Total Bytes To Transfer. This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)	
15-8	µFrame Complete-split Progress Mask (C-prog-Mask). This field is used by the host controller to record which split-completes has been executed.	
7-0	Status. This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:	
	Bit	Definition
	7	Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.
	6	ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.
	5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overrun condition occurs, no action is necessary.
	4	Babble Detected. Set to a one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.
	3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit is set only for IN transactions.
	2	Missed Micro-Frame. The host controller detected that a host-induced hold- off caused the host controller to miss a required complete-split transaction.
	1	Split Transaction State (SplitXstate). The bit encodings are: Value Meaning 00b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint when a match is encountered in the S-mask. 01b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint when a match is encountered in the C-mask.
	0	Reserved. Bit reserved for future use and should be set to zero.

77.4.2.4.4 siTD Buffer Pointer List (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4 K (page) aligned buffer pointers.

The least significant 12 bits of each DWord are used as additional transfer state. The following table describes the siTD buffer pointer fields.

Table 77-18. Buffer Page Pointer List (plus)

Bit	Description	
31-12	Buffer Pointer List. Bits [31:12] of DWords 4 and 5 are 4 K paged aligned, physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field *P* specifies the *current* active pointer	
11-0	Page 0: Current Offset. The 12 least significant bits of the Page 0 pointer is the current byte offset for the current page pointer (as selected with the page indicator bit (*P* field)). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero). The least significant bits of Page 1 pointer is split into three sub-fields Page 1:	
	Bits	Description
	11-5	Reserved
	4-3	Transaction position (TP). This field is used with T-count to determine whether to send *all*, *first*, *middle*, or *last* with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are: Value Meaning 00b All. The entire full-speed transaction data payload is in this transaction (that is, less than or equal to 188 bytes). 01b Begin. This is the first data payload for a full- speed that is greater than 188 bytes.transaction 10B Mid. This is the *middle* payload for a full-speed OUT transaction that is larger than 188 bytes. 11b End. This is the *last* payload for a full-speed OUT transaction that was larger than 188 bytes.
	2-0	Transaction count (T-Count). Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

77.4.2.4.5 siTD Back Link Pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD, and it cannot reference any other schedule data structure.

The following table describes the siTD back link pointer fields

.

Table 77-19. siTD Back Link Pointer

Bit	Description
31-5	siTD Back Pointer. This field is a physical memory pointer to a siTD.
4-1	Reserved. This field is reserved for future use. It should be set to zero.
0	Terminate (T). 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.

77.4.2.5 Queue Element Transfer Descriptor (qTD)

This data structure is only used with a queue head. It is used for one or more USB transactions, as well as to transfer up to 20480 (5*4096) bytes.

The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers. It is 32 bytes (or one 32-byte cache line). Also, this data structure must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a queue head.

The following table shows the Queue head data structure.

Table 77-20. Queue Head Data Structure

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Buffer Pointer (page 0)	-	1B-18H
Buffer Pointer (page 0)	-	1F-1CH

	Host Controller Read/Write		Host Controller Read Only.

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

77.4.2.5.1 Next qTD Pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor.

The following table describes Next qTD pointer fields.

Table 77-21. qTD Next Element Transfer Pointer (DWord 0)

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

77.4.2.5.2 Alternate Next qTD Pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next client buffer on short packet. To be more explicit the host controller always uses this pointer when the current qTD is retired due to short packet.

The following table describes the TD Alternate Next Element Transfer Pointer field descriptions.

Table 77-22. TD Alternate Next Element Transfer Pointer (DWord 1)

Bit	Description
31-5	Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

77.4.2.5.3 qTD Token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

NOTE

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

The following table describes the TD Token fields.

Table 77-23. TD Token (DWord 2)

Bit	Description
31	Data Toggle. This is the data toggle sequence bit. The use of this bit depends on the setting of the *Data Toggle Control* bit in the queue head.
30-16	Total Bytes to Transfer. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 * 4K (5000H). This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that *Total Bytes To Transfer* be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction is always less than QHD.Maximum Packet Length. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16 K(4000H).
15	Interrupt On Complete (IOC). If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.
14-12	Current Page (C_Page). This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0H to 4H. The host controller is not required to write this field back when the qTD is retired.

Table continues on the next page...

Table 77-23. TD Token (DWord 2) (continued)

Bit	Description	
11-10	Error Counter (CERR). This field is a 2-bit down counter that keeps track of the number of consecutive Errors detected while executing this qTD. If this field is programmed with a non-zero value during set-up, the Host Controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the *Halted* bit to a one, and error status bit for the error that caused *CERR* to decrement to zero. An interrupt is generated if the *USB Error Interrupt Enable* bit in the USBINTR register is set to a one. If HCD programs this field to zero during set-up, the Host Controller does not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD. Error Decrement Counter Transaction Error Yes Data Buffer Error No[3] Stalled No[1] Babble Detected No[1] No Error No[2]	
	Error	Decrement Counter Error Decrement Counter
	1	Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented
	2	If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and *PIDCode* indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset *CERR* to extend the total number of errors for this transaction. For example, *CERR* should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b. See Split Transaction Interrupt for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See Asynchronous - Do Complete Split for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the *PIDCode* indicates a SETUP.
	3	Data buffer errors are host problems. They don't count against the device's retries.
	NOTE: Software must not program CERR to a value of zero when the EPS field is programmed with a value indicating a Full- or Low-speed device. This combination could result in undefined behavior.	
9-8	PID Code. This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. Encodings are:	
	00b	OUT Token generates token (E1H)
	01b	IN Token generates token (69H)
	10b	SETUP Token generates token (2DH) (undefined if endpoint is an interrupt, the queue head is non-zero) transfer type, for example, µ*Frame S-mask* field in
	11b	Reserved
7-0	Status. This field is used by the Host Controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. The bit encodings are:	
	Bit	Status Field Description
	7	Active. Set to one by software to enable the execution of transactions by the Host Controller.
	6	Halted. Set to one by the Host Controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set to a one, the Active bit is also set to zero.

Table continues on the next page...

Table 77-23. TD Token (DWord 2) (continued)

Bit		Description
	5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, the Host Controller forces a timeout condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	4	Babble Detected. Set to a one by the Host Controller during status update when" babble" is detected during the transaction. In addition to setting this bit, the Host Controller also sets the *Halted* bit to a one. Because "babble" is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
	3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	2	Missed Micro-Frame. This bit is ignored unless the *QH.EPS* field indicates a full- or low-speed endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	1	Split Transaction State (SplitXstate). This bit is ignored by the host controller unless the *QH.EPS* field indicates a full- or low-speed endpoint. When a Full- or Low-speed device, the host controller uses this bit to track the state of the split- transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the endpoint is in the periodic or asynchronous schedule. The bit encodings are: Value Meaning 0b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint. 1b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint.
	0	Ping State (P)/ERR. If the *QH.EPS* field indicates a High-speed device and the *PID_Code* indicates an OUT endpoint, then this is the state bit for the Ping protocol. The bit encodings are: Value Meaning 0b Do OUT. This value directs the host controller to issue an OUT PID to the endpoint. 1b Do Ping. This value directs the host controller to issue a PING PID to the endpoint. If the *QH.EPS* field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.

77.4.2.5.4 qTD Buffer Page Pointer List

The last five DWords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes Current Offset field to the starting offset into the current page, where current page is selected through the value in the C_Page field.

The following table describes the qTD Buffer Pointer(s) (DWords 3-7) fields.

Table 77-24. qTD Buffer Pointer(s) (DWords 3-7)

Bit	Description
31-12	Buffer Pointer List. Each element in the list is a 4 K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4 K page. The field C_Page specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using C_Page (similar to an array index to select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment C_Page and advance to the next buffer pointer in the list, and conclude the transaction through the new buffer pointer.
11-0	Current Offset (Reserved). This field is reserved in all pointers except the first one (for example Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by C_Page). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zero.

77.4.2.6 Queue Head

The following table shows the Queue head structure layout.

Table 77-25. Queue Head Structure Layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	Host Controller Read/Write		Host Controller Read Only.

77.4.2.6.1 Queue Head Horizontal Link Pointer

The first DWord of a Queue Head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

The following table describes the Queue head DWord 0 fields.

Table 77-26. Queue Head DWord 0

Bit	Description
31-5	Queue Head Horizontal Link Pointer (QHLP). This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD Select (Typ). This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

77.4.2.6.2 Queue Head Endpoint Capabilities/Characteristics

The second and third DWords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint.

There are three types of information in this region:

- Endpoint Characteristics. These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.
- Endpoint Capabilities. These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- Split Transaction Characteristics. This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

The following table describes the Endpoint characteristics: Queue head DWord 1 fields.

Table 77-27. Endpoint Characteristics: Queue Head DWord 1

Bit	Description	
31-28	Nak Count Reload (RL). This field contains a value, which is used by the host controller to reload the Nak Counter field.	
27	Control Endpoint Flag (C). If the *QH.EPS* field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to zero.	
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (*wMaxPacketSize*). The maximum value this field may contain is 0x400 (1024).	
15	Head of Reclamation List Flag (H). This bit is set by System Software to mark a queue head as being the head of the reclamation list.	
14	Data Toggle Control (DTC). This bit specifies where the host controller should get the initial data toggle on an overlay transition. 0b Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head. 1b Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD.	
13-12	Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are:	
	Value	Meaning
	00b	Full-Speed (12 Mbits/sec)
	01b	Low-Speed (1.5 Mbits/sec)
	10b	High-Speed (480 Mbits/sec)
	11b	Reserved
	This field must not be modified by the host controller.	

Table continues on the next page...

Table 77-27. Endpoint Characteristics: Queue Head DWord 1 (continued)

11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Inactivate on Next Transaction (I). This bit is used by system software to request that the host controller set the Active bit to zero. See Rebalancing the Periodic Schedule , for full operational details. This field is only valid when the queue head is in the Periodic Schedule and the *EPS* field indicates a Full or Low-speed endpoint. Setting this bit to one when the queue head is in the Asynchronous Schedule or the *EPS* field indicates a high-speed device yields undefined results.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

The table below describes the Endpoint capabilities: Queue head DWord 2 field descriptions.

Table 77-28. Endpoint Capabilities: Queue Head DWord 2

Bit	Description
31-30	High-Bandwidth Pipe Multiplier (Mult). This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). The valid values are: Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro-frame 10b Two transactions to be issued for this endpoint per micro-frame 11b Three transactions to be issued for this endpoint per micro-frame
29-23	Port Number. This field is ignored by the host controller unless the *EPS* field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address *Hub Addr* below), below which the full- or low-speed device associated with this endpoint is attached. This information is used in the split-transaction protocol.
22-16	Hub Addr. This field is ignored by the host controller unless the *EPS* field indicates a full-or low-speed device. The value is the USB device address of the USB 2.0 Hub below which the full- or low-speed device associated with this endpoint is attached. This field is used in the split-transaction protocol.
15-8	Split Completion Mask (µFrame C-Mask). This field is ignored by the host controller unless the *EPS* field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the *Active* and *SplitX-state* fields) is used to determine during which micro-frames the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the µ*Frame C- Mask* field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Interrupt Schedule Mask (µFrame S-mask). This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the µ*Frame S-mask* field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the *EPS* field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the *PID_Code* field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the *EPS* field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.

77.4.2.6.3 Transfer Overlay-Queue Head

The nine DWords in this area represent a transaction working space for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the Queue Head Horizontal Link Pointer to the next queue head. The host controller will never follow the Next Transfer Queue Element or Alternate Queue Element pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

The following table describes the current qTD link pointer field descriptions.

Table 77-29. Current qTD Link Pointer

Bit	Description
31-5	Current Element Transaction Descriptor Link Pointer. This field contains the address Of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4-0	Reserved (R). These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves an execution cache for the transfer.

The table below describes the Host-controller rules for bits in overlay.

Table 77-30. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9)

DWord	Bit	Description
5	4-1	Nak Counter (NakCnt)µRW. This field is a counter the host controller decrements whenever a transaction for the endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from *RL* before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from RL during an overlay.
6	31	Data Toggle. The *Data Toggle Control* controls whether the host controller preserves this bit when an overlay operation is performed.

Table continues on the next page...

Table 77-30. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9) (continued)

6	15	Interrupt On Complete (IOC). The IOC control bit is always inherited from the source qTD when the overlay operation is performed.
6	11-10	Error Counter (C_ERR). This two-bit field is copied from the qTD during the overlay and written back during queue advancement.
6	0	Ping State (P)/ERR. If the *EPS* field indicates a high-speed endpoint, then this field should be preserved during the overlay operation.
8	7-0	Split-transaction Complete-split Progress (C-prog-mask). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4-0	Split-transaction Frame Tag (Frame Tag). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	11-5	S-bytes. Software must ensure that the *S-bytes* field in a *qTD* is zero before activating the *qTD*. This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.

77.4.2.7 Periodic Frame Span Traversal Node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary.

See Host Controller Operational Model for FSTNs for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose USB_HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use yields undefined results.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	Normal Path Link Pointer																											0		Typ		T	03-00H
	Back Path Link Pointer																											0		Typ		T	07-04H

Table 77-31. Frame Span Traversal Node Structure Layout

	Host Controller Read/Write		Host Controller Read Only.

77.4.2.7.1 FSTN Normal Path Pointer

The first DWord of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

The following table describes the FSTN normal path pointer fields.

Table 77-32. FSTN Normal Path Pointer Field Descriptions

Bit	Description
31-5	Normal Path Link Pointer (NPLP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD/FSTN Select (Typ). This field indicates to the Host Controller whether the item referenced is a iTD/siTD, a QH or an FSTN. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (Frame Span Traversal Node)
0	Terminate (T). 1=Link Pointer field is not valid. 0=Link Pointer is valid.

77.4.2.7.2 FSTN Back Path Link Pointer

The second DWord of an FTSN node contains a link pointer to a queue head.

If the T-bit in this pointer is zero, then this FSTN is a Save-Place indicator. Its Typ field must be set by software to indicate the target data structure is a queue head. If the T-bit in this pointer is set to one, then this FSTN is the Restore indicator. When the T-bit is one, the host controller ignores the Typ field.

The following table describes the FSTN back path link pointer fields.

Table 77-33. FSTN Back Path Link Pointer Field Descriptions

Bit	Description
31-5	Back Path Link Pointer (BPLP). This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	Typ. Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.
0	Terminate (T). 1=Link Pointer field is not valid (that is the host controller must not use bits [31:5] as a valid memory address). This value also indicates that this FSTN is a Restore indicator. 0=Link Pointer is valid (that is the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.

77.4.3 Host Operational Model

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (generally referred to as system software).

Each significant operational feature of the EHCI host controller is discussed in a separate section. Each section presents the operational model requirements for the host controller hardware. Where appropriate, recommended system software operational models for features are also presented.

77.4.3.1 Host Controller Initialization

When the system boots, the host controller is enumerated, assigned a base address for the register space and BIOS sets the USB_FLADJ register to a system-specific value.

After initial power-on or HCReset (hardware or through HCReset bit in the USB_USBCMD register), all of the operational registers are at their default values. After a hardware reset, only the operational registers not contained in the Auxiliary power well are at their default values.

The following table describes the default values of operational registers.

.

Table 77-34. Default Values of Operational Register Space

Operational Register	Default Value (after Reset)
USB_USBCMD	00080000h (00080B00h, if *Asynchronous Schedule Park Capability is one*)
USB_USBSTS	00001000h
USB_USBINTR	00000000h
USB_FRINDEX	00000000h
USB_CTRLDSSEGMENT	00000000h
USB_PERIODICLISTBASE	Undefined
USB_ASYNCLISTADDR	Undefined
USB_CONFIGFLAG	00000000h
USB_PORTSC1	00002000h (w/*PPC* set to one); 00003000h (w/*PPC* set to zero)

To initialize the host controller, software should perform the following steps:

- Program the USB_CTRLDSSEGMENT register with 4-Gbyte segment where all of the interface data structures are allocated.

- Write the appropriate value to the USB_USBINTR register to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to the USB_PERIODICLIST BASE register. If no work items are in the periodic schedule, all elements of the Periodic Frame List should have their T-Bits set to one.
- Write the USB_USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller ON through setting the Run/Stop bit.
- Write 1 to USB_CONFIGFLAG register to route all the ports to the EHCI controller.

At this point, the host controller is up and running and the port registers begin reporting device connects, and so on. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled port enabled High-speed ports, but the schedules have not enabled. The EHCI Host controller do not transmit SOFs to enabled Full- or Low-speed ports. To communicate with devices through the asynchronous schedule, system software must write the USB_ASYNDLISTADDR register with the address of a control or bulk queue head. Software must then enable the asynchronous schedule by writing one to the Asynchronous Schedule Enable bit in the USB_USBCMD register. To communicate with devices through the periodic schedule, system software must enable the periodic schedule by writing one to the Periodic Schedule Enable bit in the USB_USBCMD register.

NOTE

The schedules can be turned on before the first port is reset (and enabled).

When the USB_USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

77.4.3.2 Port Routing and Control

A USB 2.0 Host controller is comprised of one high-speed host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion host controllers. Companion host controllers (cHCs) may be implementations of either Universal or Open host controller specifications.

This configuration is used to deliver the required full USB 2.0-defined port capability; for example, Low-, Full-, and High-speed capability for every port.

NOTE

The USB controller on i.MX parts do not require nor support companion controllers to support Full Speed/Low Speed device.Therefore, no port routing is present in the controller.

Please refer to Embedded Transaction Translator Function for detail!

The following figure illustrates a simple block diagram of the port routing logic and its relationship to the high-speed and companion host controllers within a USB 2.0 host controller.

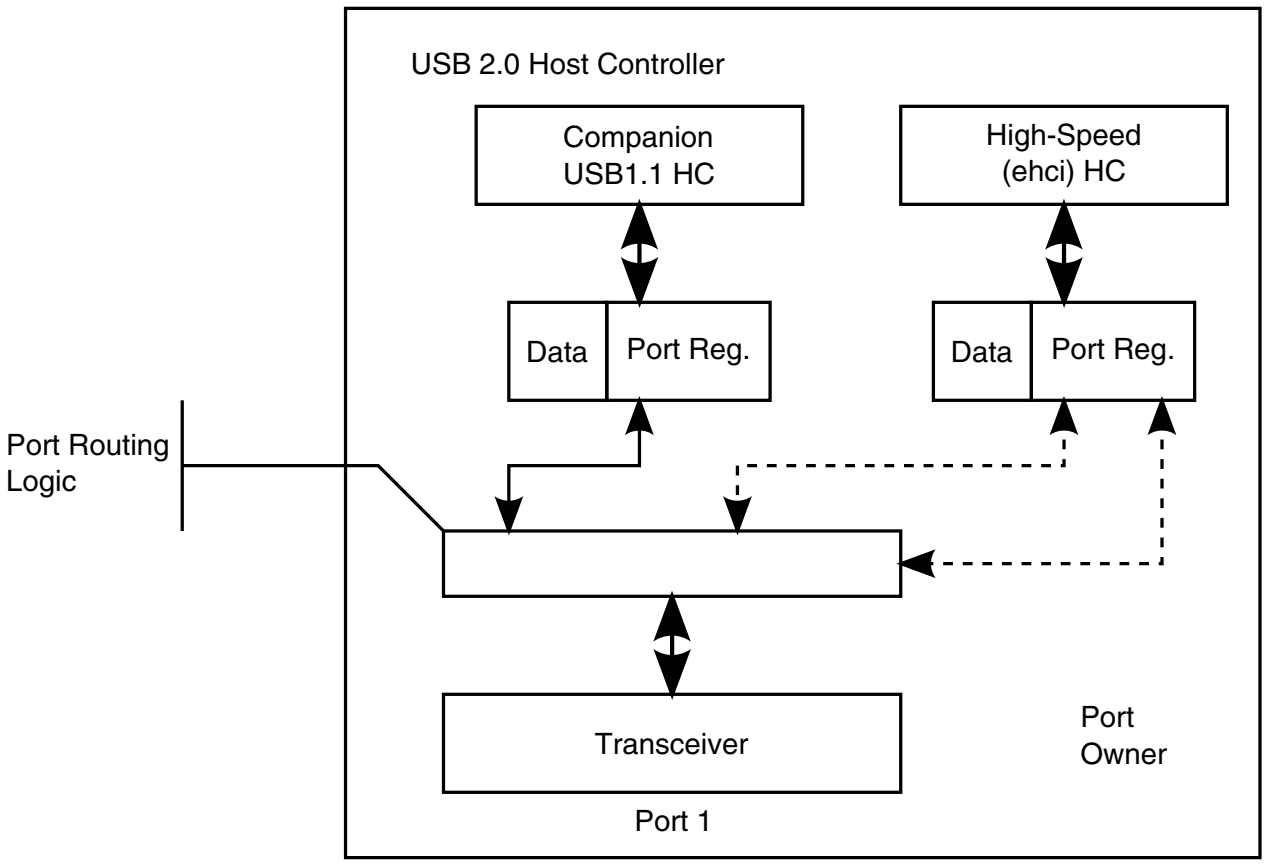

Figure 77-6. Example USB 2.0 Host Controller Port Routing Block Diagram

There exists one transceiver per physical port and each host controller block has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each companion host controller has only the port control and status registers it is required to operate. Either the EHCI host controller or one companion host controller controls each transceiver. Routing logic lies between the transceiver, the port status and control registers.[1]

The port routing logic is controlled from signals originating in the EHCI host controller. The EHCI host controller has a global routing policy control field and per-port ownership control fields. The Configured Flag (CF) bit is the global routing policy control. At power-on or reset, the default routing policy is to the companion controllers (if they

1. The routing logic should not be implemented in the 480 MHz clock domain of the transceiver.

exist). If the system does not include a driver for the EHCI host controller and the host controller includes Companion Controllers, then the ports still work in Full- and Low-speed mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the companion host controllers' port registers do not see a connect indication from the transceiver. Similarly, when a companion host controller owns a port, the EHCI controller's port registers do not see a connect indication from the transceiver. The details on the rules for the port routing logic are described in the following sections. The USB 2.0 host controller must be implemented as a multi-function PCI device if the implementation includes companion controllers. The companion host controllers' function numbers must be less than the EHCI host controller function number. The EHCI host controller must be a larger function number with respect to the companion host controllers associated with this EHCI host controller. If a PCI device implementation contains only an EHCI controller (that is no companion controllers or other PCI functions), then the EHCI host controller must be function zero, in accordance with the PCI Specification. The N_CC field in the Structural Parameter register (HCSPARAMS) indicates whether the controller implementation includes companion host controllers. When N_CC has a non-zero value there exists companion host controllers. If N_CC has a value of zero, then the host controller implementation does not include companion host controllers. If the host controller root ports are exposed to attachment of full- or low-speed devices, the ports always fails the high-speed chirp during reset and the ports are not enabled. System software can notify the user of the illegal condition. This type of implementation requires a USB 2.0 hub be connected to a root port to provide full and low-speed device connectivity.

System software uses information in the host controller capability registers to determine how the ports are routed to the companion host controllers. See Host Controller Structural Parameters (USB__HCSPARAMS).

77.4.3.2.1 Port Routing Control through EHCI Configured (CF) Bit

Each port in the USB 2.0 host controller are routed either to a single companion host controller or to the EHCI host controller.

The port routing logic is controlled by two mechanisms in the EHCI HC: a host controller global flag and per-port control. The Configured Flag (CF) bit, is used to globally set the policy of the routing logic. Each port register has a Port Owner control bit which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever the CF bit transitions from zero to one (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all Port Owner bits go to zero). While the CF-bit is one, the EHCI Driver controls individual ports' routing through the Port Owner control bit. Likewise, whenever the CF bit transitions from one to zero (as a result of Aux power application, HCRESET, or

software writing zero to CF-bit), the port routing unconditionally routes all of the port registers to the appropriate companion HC. The default value for the EHCI HC's CF bit (after Aux power application or HCRESET) is zero.

The *view* of the port depends on the current owner. A Universal or Open companion host controller will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI host controllers are not visible to companion host controllers.

The following table summarizes the default routing for all the ports, based on the value of the EHCI HC's CF bit.

Table 77-35. Default Port Routing Depending on EHCI HC CF Bit

HS CF Bit	Default Port Ownership	Explanation
0B	Companion HCs	The companion host controllers own the ports and only Full- and Low-speed devices are supported in the system. The exact port assignments are implementation dependent. The ports behave only as Full- and Low-speed ports in this configuration
1B	EHCI HC	The EHCI host controller has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs' port status and control registers when the port owner is the EHCI HC.The EHCI HC has access to the additional port status and control bits defined in this specification (see Port Status & Control (USB__PORTSC1)). The EHCI HC can temporarily release control of the port to a companion HC by setting the *PortOwner* bit in the PORTSC1 register to one.

77.4.3.2.2 Port Routing Control through PortOwner and Disconnect Event

Manipulating the port routing through the CF-bit is an extreme process and not intended to be used during normal operation.

The normal mode of port ownership transferal is on the granularity of individual ports using the Port Owner bit in the EHCI HC's USB_PORTSC1 register (for hand-offs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI *CF-bit* is set to one), the typical port enumeration sequence proceeds as illustrated below:

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.
- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the LineStatus bits in the USB_PORTSC1 register. If they indicate the attached device is a full-speed device (for example, D+ is asserted), then the EHCI Driver sets the PortReset control bit to one (and sets the PortEnable bit to zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing zero to the port reset bit. The reset process is actually complete when software reads zero in the PortReset bit. The EHCI Driver checks the PortOwner bit in the USB_PORTSC1 register. If set to one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.
- At the time the EHCI Driver receives the port reset and enable request the LineStatus bits might indicate a low-speed device. Additionally, when the port reset process is complete, the PortEnable field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the USB_PORTSC1 register to one to release port ownership to a companion host controller.
- When the EHCI Driver sets PortOwner bit to one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The EHCI USB_PORTSC1 register observes and reports a disconnect event through the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to one, a connect change set to one and a connect status set to zero. This information is derived directly from the EHCI port register. This allows the hub driver to assume the device was disconnected during reset. It acknowledges the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's CF-bit transitions from1b to 0b). When a disconnect occurs, the disconnect

event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects is detected by the EHCI port register and the process repeats.

77.4.3.2.3 Example Port Routing State Machine

The following figure illustrates an example of how the port ownership should be managed. The following sections describe the entry conditions to each state.

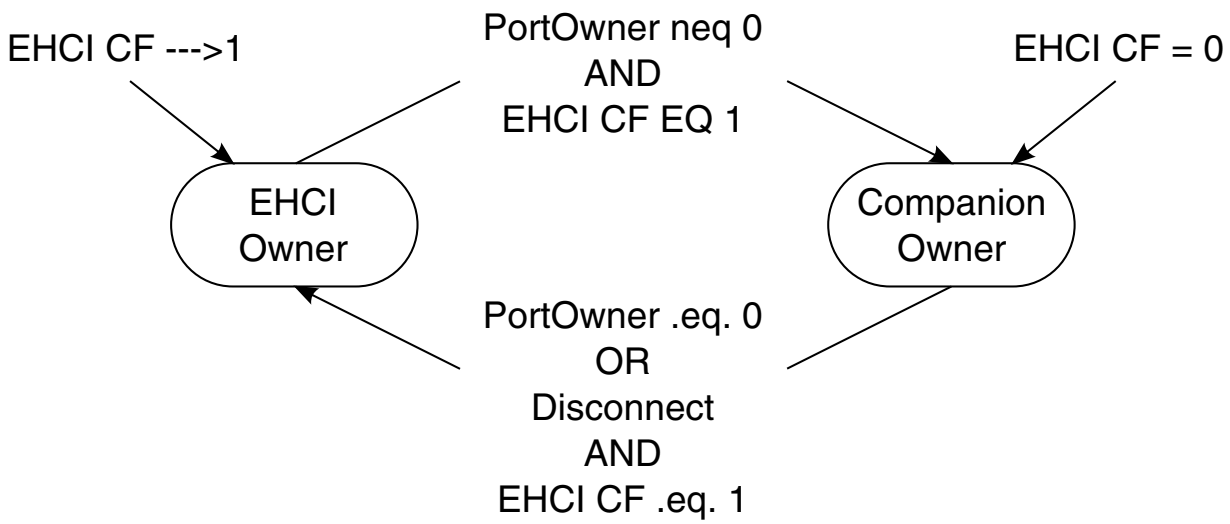

Figure 77-7. Port Owner Handoff State Machine

77.4.3.2.3.1 EHCI HC Owner

Entry to this state occurs when one of the following events occur:

- When the EHCI HC's Configure Flag (CF) bit in the USB_CONFIGFLAG register transitions from zero to one. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.
- When the port is owned by a companion HC and the device is disconnected from the port. The EHCI port routing control logic is notified of the disconnect, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver acknowledges the disconnect by setting the connect status change bit to zero. This allows the

companion HC's driver to interact with the port completely through the disconnect process.

- When system software writes zero to the PortOwner bit in the USB_PORTSC1 register. This allows software to take ownership of a port from a companion host controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.

77.4.3.2.3.2 Companion HC Owner

Entry to this state occurs whenever one of the following events occur:

- When the PortOwner field transitions from zero to one.
- When the HS-mode HC's Configure Flag (CF) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

77.4.3.2.4 Port Power

The Port Power Control (PPC) bit in the USB_HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (see Host Controller Structural Parameters (USB__HCSPARAMS)).

When this bit is zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the *PPC* bit is one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is referred to in this discussion as PortPowerOutputEnable (PPE). PPE is controlled based on the state of the combination bits PPC bit, EHCI Configured (CF)-bit and individual Port Power (PP) bits.

The following table describes the summary behavioral model.

Table 77-36. Port Power Enable Control Rules

CF	CHC[1] (PP)	EHC[2] (PP)	Owner	PPE[3]	Description
0	0	X	CHC	0	When the EHCI controller is not configured, the port is owned by the companion host controller. When the companion HC's port power select is off, then the port power is off.
0	1	X	CHC	1	Similar to previous entry. When the companion HC's port power select is on, then the port power is on.

Table continues on the next page...

Table 77-36. Port Power Enable Control Rules (continued)

1	0	0	CHC	0	Port owner has port power turned off, the power to port is off.
1	0	0	EHC	0	Port owner has port power turned off, the power to port is off.
1	0	1	EHC	1	Port owner has port power on, so power to port is on.
1	0	1	CHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	EHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	EHC	1	Port owner has port power on, so power to port is on.

1. CHC (Companion Host Controller).
2. EHC (EHCI Host Controller).
3. PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists).

77.4.3.2.5 Port Reporting Over-Current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI USB_PORTSC1 register has an over-current status and over-current change bit.

The functionality of these bits are specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document.

The over-current condition effects the following bits in the USB_PORTSC1 register on the EHCI port:

- Over-current Active bits are set to one. When the over-current condition goes away, the Over-current Active bit transitions from one to zero.
- Over-current Change bits are set to one. On every transition of the Over-current Active bit the host controller sets the Over-current Change bit to one. Software sets the Over-current Change bit to zero by writing one to this bit.

- Port Enabled/Disabled bit is set to zero. When this change bit gets set to one, then the Port Change Detect bit in the USB_USBSTS register is set to one.
- Port Power (PP) bits may optionally be set to zero. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to limit the current and leave power applied. When the Over-current Change bit transitions from zero to one, the host controller also sets the Port Change Detect bit in the USB_USBSTS register to one. In addition, if the Port Change Interrupt Enable bit in the USB_USBINTR register is one, then the host controller issues an interrupt to the system. Refer to Table 77-37 for summary behavior for over-current detection when the host controller is halted (suspended from a device component point of view).

77.4.3.3 Suspend/Resume-Host Operational Model

The EHCI host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub.

Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely through software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wake-up events. The classes of wake-up events are:

- Remote-wake-up enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake-up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the USB_PORTSC1 registers.

Selective suspend is a feature supported by every USB_PORTSC1 register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the Run/Stop bit in the USB_USBCMD register to zero. The EHCI sub-block can then be placed into a lower device state through the PCI power management interface (see Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com).

When a wake event occurs, the system resumes operation and system software eventually set the Run/Stop bit to one and resume the suspended ports. Software must not set the Run/Stop bit to one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the ARM platform is restarted. So, by definition, if software is running, clocks in the system are stable and the Run/Stop bit in the USB_USBCMD register can be set to one. Minimum system software delays are also defined in the PCI Power Management Specification. Refer to PCI Power Management Specification for more information.

77.4.3.3.1 Port Suspend/Resume

System software places individual ports into suspend mode by writing one into the appropriate USB_PORTSC1 Suspend bit. Software must only set the Suspend bit when the port is in the enabled state (Port Enabled bit is one) and the EHCI is the port owner (PortOwner bit is zero).

The host controller may evaluate the Suspend bit immediately or wait until a micro-frame or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several micro-frames of activity on the port until the host controller evaluates the Suspend bit. The host controller must evaluate the Suspend bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing one to the Force Port Resume bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see Port Status & Control (USB__PORTSC1)). If system software sets Force Port Resume bit to one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 ms after a port indicates that it is suspended (Suspend bit is one) before initiating a port resume through the Force Port Resume bit. When Force Port Resume bit is one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 ms) then sets the Force Port Resume bit to zero. When the host controller receives the write to transition Force Port Resume to zero, it completes the resume sequence as defined in the USB specification, and sets both the Force Port Resume and Suspend bits to zero. Software-initiated port resumes do not affect the Port Change Detect bit in the USB_USBSTS register nor do they cause an interrupt if the Port Change Interrupt Enable bit in the USB_USBINTR register is one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100 µsec. The port's

Force Port Resume bit is set to one and the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit in the USB_USBINTR register is one the host controller issues a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 ms), then terminates the resume sequence by writing zero to the Force Port Resume bit in the port. The host controller receives the write of zero to Force Port Resume, terminates the resume sequence and sets Force Port Resume and Suspend port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the USB_PORTSC1 register and observing that the Suspend and Force Port Resume bits are zero. Software must ensure that the host controller is running (that is HCHalted bit in the USB_USBSTS register is zero), before terminating a resume by writing zero to a port's Force Port Resume bit. If HCHalted is one when Force Port Resume is set to zero, then SOFs do not occur down the enabled port and the device returns to suspend mode in a maximum of 10 msec.

The table below summarizes the wake-up events. Whenever a resume event is detected, the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit is one in the USB_USBINTR register, the host controller generates an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the Port Change Detect status bit in the USB_USBSTS register.

Table 77-37. Behavior During Wake-up Events

Port Status and Signaling Type	Signaled Port Response	Device State	
		D0	Not D0
Port disabled, resume K-State received	No Effect	N/A	N/A
Port suspended, resume K-State received	Resume reflected downstream on signaled port. Force Port Resume status bit in USB_PORTSC1 register is set to one. Port Change Detect bit in USB_USBSTS register set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is one. A disconnect is detected.	Depending in the initial port state, theUSB_ PORTSC1 Connected Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is zero. A disconnect is detected.	Depending on the initial port state, the USB_PORTSC1 Connect and Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is not connected and the port's WKCNNT_E bit is one. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is not connected and the port's WKCNNT_E bit is zero. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]

Table continues on the next page...

Table 77-37. Behavior During Wake-up Events (continued)

Port is connected and the port's WKOC_E bit is one. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one	[1], [2]	[2]
Port is connected and the port's WKOC_E bit is zero. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]

[1] Hardware interrupt issued if Port Change Interrupt Enable bit in the USB_USBINTR register is one.

[2] PME# asserted if enabled (Note: PME Status must always be set to one).

[3] PME# not asserted.

77.4.3.4 Schedule Traversal Rules

The host controller executes transactions for devices using a simple, shared-memory schedule. The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the USB_PERIODICLISTBASE register (see Frame List Base Address (USB__PERIODICLISTBASE))/Device Address (USB_UOG_DEVICEADDR). The USB_PERIODICLISTBASE register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in Host Data Structures. In each micro-frame, if the periodic schedule is enabled (see Periodic Scheduling Threshold) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It only executes from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the USB_PERIODICLISTBASE and the USB_FRINDEX registers (see the following figure). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a next link pointer of a schedule data structure having its T-bit set to one. When the host controller encounters a T-Bit set to one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic

schedule and transitions immediately to traversing the asynchronous schedule. After the transition, the host controller executes from the asynchronous schedule until the end of the micro-frame.

The following figure illustrates the derivation of pointer into frame list array.

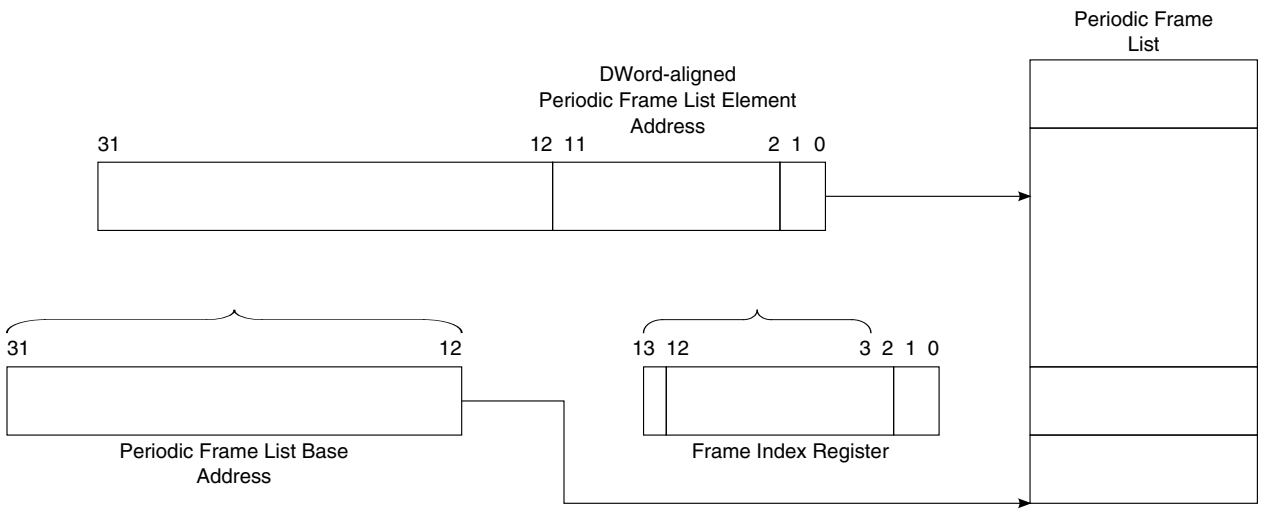

Figure 77-8. Derivation of Pointer into Frame List Array

When the host controller determines that it is the time to execute from the asynchronous list, it uses the operational register USB_ASYNCLISTADDR to access the asynchronous schedule, see the figure below.

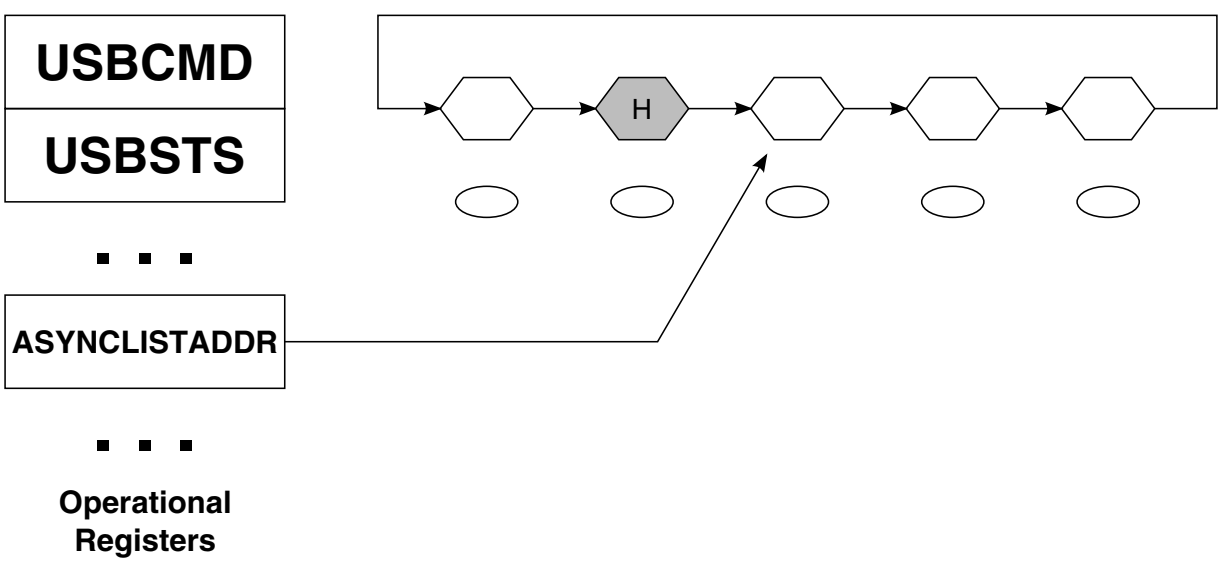

Figure 77-9. General Format of Asynchronous Schedule List

The USB_ASYNCLISTADDR register contains a physical memory pointer to the next queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the USB_ASYNCLISTADDR register. Software must set queue head horizontal pointer T-bits to zero for queue heads in the asynchronous schedule. See Asynchronous Schedule for complete operational details.

77.4.3.4.1 Example - Preserving Micro-Frame Integrity

One of the requirements of a USB host controller is to maintain Frame Integrity. This means that the HC must preserve the micro-frame boundaries.

For example, SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of micro-frame timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One implication of this responsibility is that the HC must ensure that it does not start transactions that do not complete before the end of the micro-frame. More precisely, no transactions should be started by the host controller, which do not complete in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it completes before the end of the micro-frame.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction takes. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch all of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers can allow the host controller to know exactly whether there is enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the micro-frame. It is a reasonable assumption that software never over-commits the micro-frame to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some

circumstances a transaction is not executed that could have been executed. However, under all circumstances, a transaction is never started unless there is enough time in the frame to complete the transaction.

77.4.3.4.1.1 Transaction Fit - A Best-Fit Approximation Algorithm

A curve is calculated which represents the latest start time for every packet size, at which software schedules the start of a periodic transaction.

This curve is the 80% bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each packet size can be started and completed, in the micro-frame. A plot of these two curves are illustrated in the following figure. The plot Y-axis represents the number of byte-times left in a frame.

The space between the 80% and the Last Start plots is bandwidth reclamation area. In this algorithm the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function ($f(x)$) between the 80% and Last Start curves. The function $f(x)$ adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land above the function curve. The host controller will not start transactions whose results land below the function curve.

The following figure illustrates the Best-Fit Approximation.

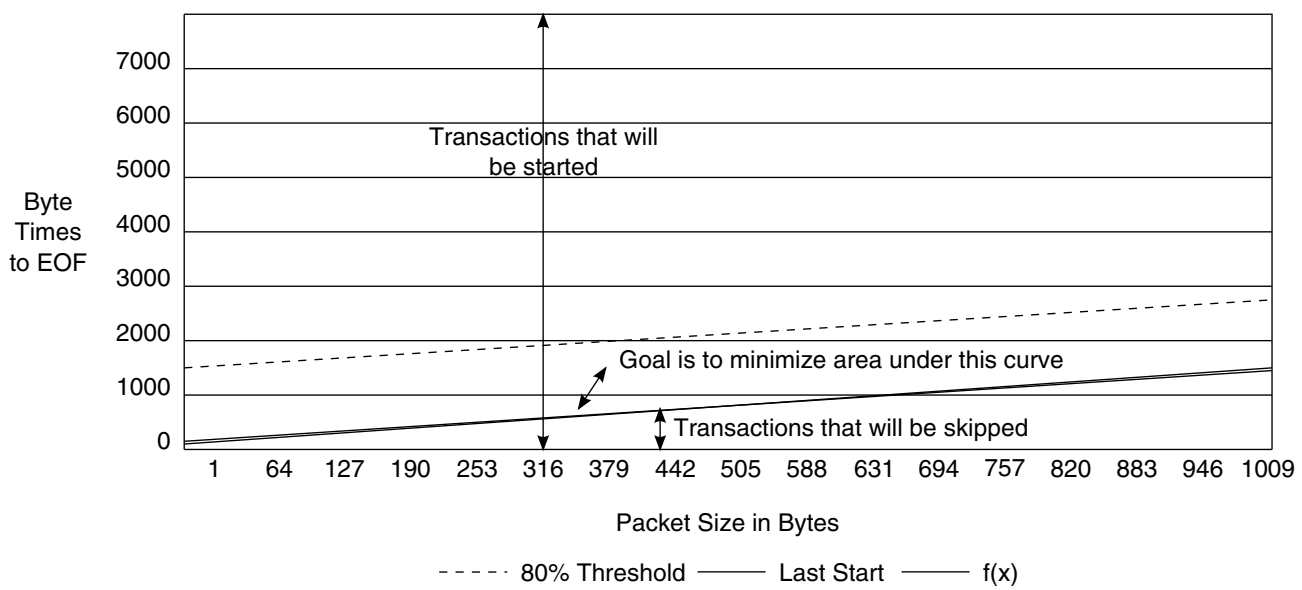

Figure 77-10. Best Fit Approximation

The LastStart line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used is a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in the table below. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

Table 77-38. Example Worse-case Transaction Timing Components

Component	Bit time	Byte Time	Explanation
Split Token	76	9.5	Split token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Number of bit times required between consecutive host packets.
Token	67	8.375	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Token as defined in USB core specification. Includessync, token, eop, and so on.
Data Packet (0 data bytes)	66.7	8.34	Zero-length data packet. Includes sync, PID, crc16, eop, and so on.
Turnaround time	721	90.125	Time for packet initiator (Host) to see the beginning of a response to a transmitted packet.
Handshake packet	48	6	Handshake packet as defined in USB core specification. Includes sync, PID, eop, and so on.
		144	Total

The exact details of the function (f(x)) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the Last Start curve, without dipping below the LastStart line, while at the same time keeping the check as simple as possible for hardware implementation. The f(x) in Figure 77-10 was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```
Alorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)
Begin
Local Temp = MaximumPacketSize + 192
Local rvalue = TRUE
If MaximumPacketSize >= 128 then
     Temp += 128
End If
If Temp > HC_BytesLeftInFrame then
     Rvalue = FALSE
End If
Return rvalue
End
```

This algorithm takes two inputs, the current maximum packet size of the transaction and the hardware counter of the number of bytes left in the current micro-frame. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is

greater than or equal to 128 bytes, then an additional constant of 128 is added to the running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the $f(x)$ plot was getting close to the LastStart line.

77.4.3.5 Periodic Schedule Frame Boundaries vs Bus Frame Boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned.

Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions through a micro-frame pipeline (see start- (SS) and complete- (CS) splits illustrated in the following figure). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

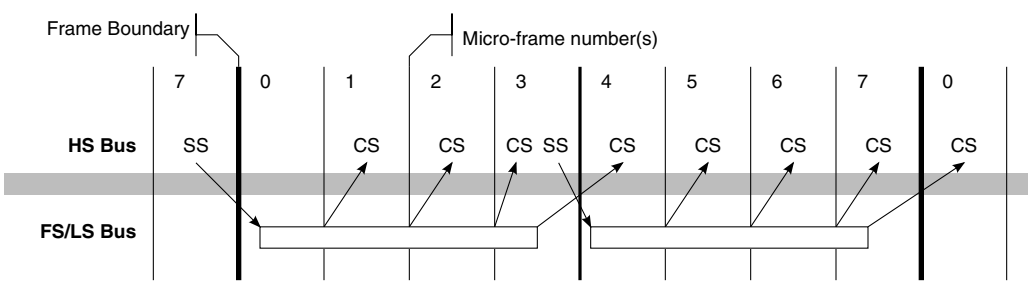

Figure 77-11. Frame Boundary Relationship between HS bus and FS/LS Bus

The simple projection, as the above figure illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement one micro-frame phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed through the Frame List Index Register (USB_FRINDEX) documented in USB Frame Index (USB__FRINDEX) and initially illustrated in Schedule Traversal Rules . Bits FRINDEX[2:0], represent the micro-frame number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and

increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one micro-frame. The one micro-frame delay yields host controller periodic schedule and bus frame boundary relationship as illustrated in the following figure. This adjustment allows software to trivially schedule the periodic start and complete-split transactions for full-and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

The following figure illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined: The host controller's view of the 1 msec boundaries is called H-Frames. The high-speed bus's view of the 1 msec boundaries is called B-Frames.

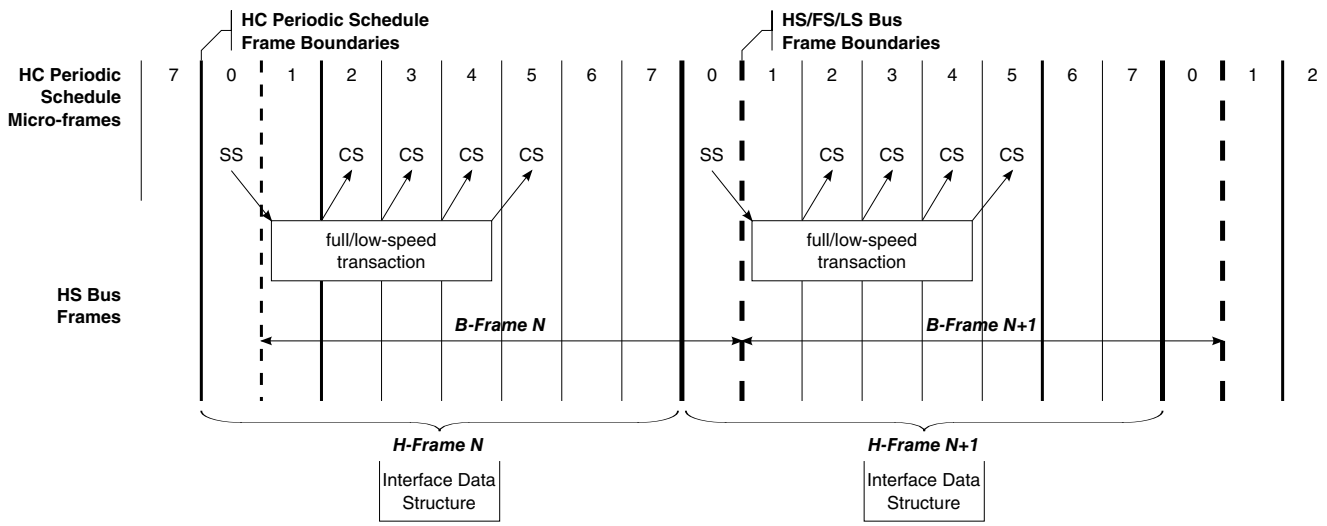

Figure 77-12. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries

H-Frame boundaries for the host controller correspond to increments of FRINDEX[13:3]. Micro-frame numbers for the H-Frame are tracked by FRINDEX[2:0]. B-Frame boundaries are visible on the high-speed bus through changes in the SOF token's frame number. Micro-frame numbers on the high-speed bus are only derived from the SOF token's frame number (that is the high-speed bus sees eight SOFs with the same frame number value). H-Frames and B-Frames have the fixed relationship (that is B-Frames lag H-Frames by one micro-frame time) illustrated in the figure above. The host controller's periodic schedule is naturally aligned to H-Frames. Software schedules transactions for full- and low-speed periodic endpoints relative the H-Frames. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in USB Frame Index (USB__FRINDEX), the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the FRINDEX register bits [13:3] by one micro-frame count. This lag behavior can be

accomplished by incrementing FRINDEX[13:3] based on carry-out on the 7 to 0 increment of FRINDEX[2:0] and incrementing SOFV based on the transition of 0 to 1 of FRINDEX[2:0].

Software is allowed to write to FRINDEX. USB Frame Index (USB__FRINDEX) provides the requirements that software should adhere when writing a new value in FRINDEX.

The table below illustrates the required relationship between the value of FRINDEX and the value of SOFV.

Table 77-39. Operation of FRINDEX and SOFV (SOF Value Register)

Current			Next		
FRINDEX[F]	SOFV	FRINDEX[mF]	FRINDEX[F]	SOFV	FRINDEX[mF]

77.4.3.6 Periodic Schedule

The periodic schedule traversal is enabled or disabled through the Periodic Schedule Enable bit in the USB_USBCMD register.

If the Periodic Schedule Enable bit is set to zero, then the host controller simply does not try to access the periodic frame list through the USB_PERIODICLISTBASE register. Likewise, when the Periodic Schedule Enable bit is one, then the host controller does use the USB_PERIODICLISTBASE register to traverse the periodic schedule. The host controller will not react to modifications to the Periodic Schedule Enable immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the Periodic Schedule Enable bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b micro-frame. These work items must be removed from the schedule before the Periodic Schedule Enable bit is written to zero. The Periodic

Schedule Status bit in the USB_USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing one (or zero) to the Periodic Schedule Enable bit in the USB_USBCMD register. Software then can poll the Periodic Schedule Status bit to determine when the periodic schedule has made the desired transition. Software must not modify the Periodic Schedule Enable bit unless the value of the Periodic Schedule Enable bit equals that of the Periodic Schedule Status bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions on the

The following figure illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

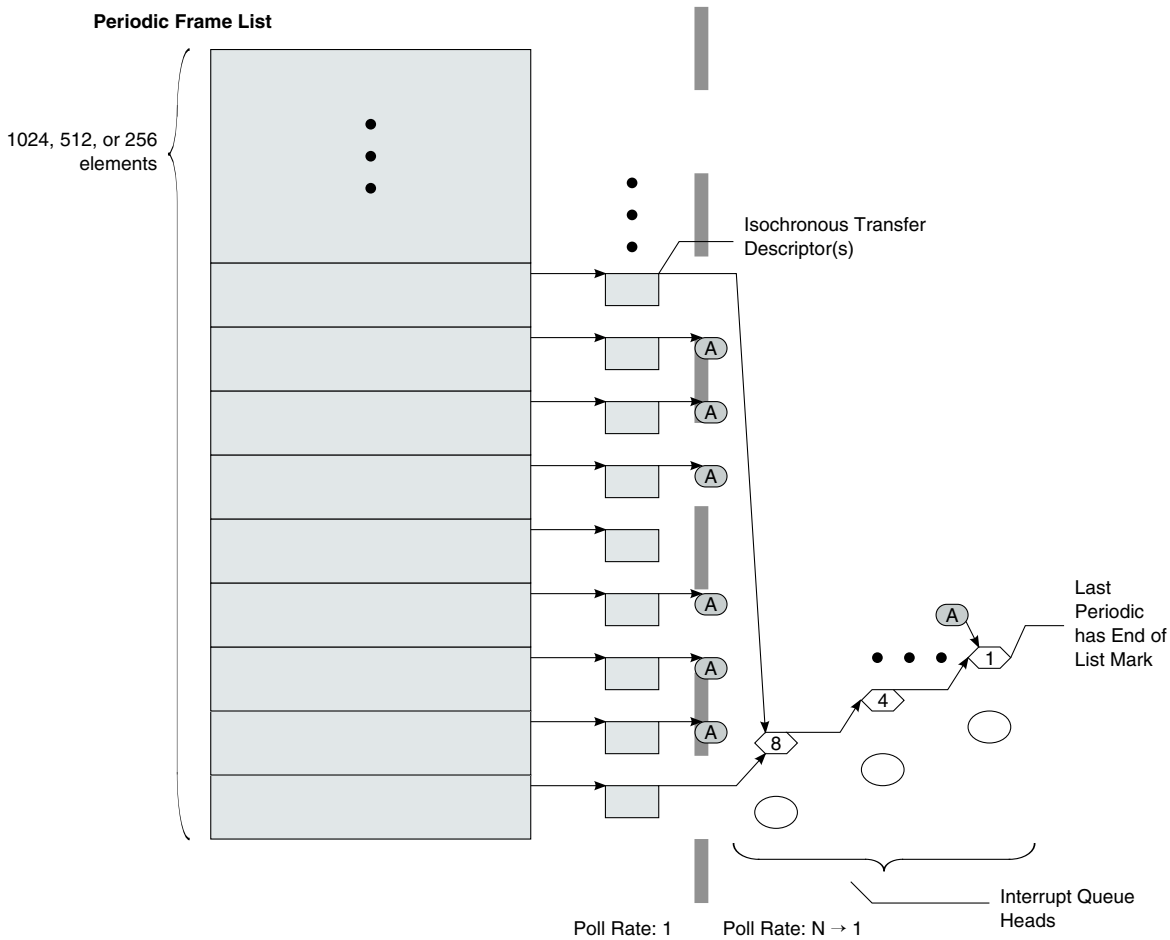

Figure 77-13. Example Periodic Schedule

77.4.3.7 Managing Isochronous Transfers Using iTDs

The structure of an iTD is presented in Isochronous (High-Speed) Transfer Descriptor (iTD). The four distinct sections to an iTD:

- The first field is the Next Link Pointer. This field is for schedule linkage purposes only.
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one micro-frame's worth of transactions for a single high-speed isochronous endpoint.
- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4 K aligned pointers to physical memory.
- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

77.4.3.7.1 Host Controller Operational Model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Each iTD can span 8 micro-frames worth of transactions.

When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array.

If the active bit in the Status field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the Next pointer to the next schedule data structure.

When the indexed active bit is one, the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, and so on.). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if PG field is 0, then the host controller stores Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses the endpoint addressing information and I/O-bit to execute a transaction to the appropriate endpoint. When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (for example, page 0 pointer) selected by the active transaction descriptions' PG (for example, value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer crosses a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (for example, page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes through the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of Maximum Packet sized bus transactions for the endpoint in the current micro-frame. In

other words, the Mult field represents a transaction count for the endpoint in the current micro-frame. If the Mult field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers, the value of the Transaction X Length field represents the total bytes to be sent during the micro-frame. The Mult field must be set by software to be consistent with Transaction X Length and Maximum Packet Sixe. The host controller sends the bytes in Maximum Packet Size'd portions. After each transaction, the host controller decrements its local copy of Transaction X Length by Maximum Packet Size. The number of bytes the host controller sends is always Maximum Packet Size or Transaction X Length, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues Mult transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use Maximum Packet Size to detect packet babble errors. The host controller keeps the sum of bytes received in the Transaction X Length field. After all transactions for the endpoint have completed for the micro-frame, Transaction X Length contains the total bytes received. If the final value of Transaction X Length is less than the value of Maximum Packet Size, then less data than was allowed for was received from the associated endpoint. This short packet condition does not set the USBINT bit in the USB_USBSTS register to one. The host controller will not detect this condition. If the device sends more than Transaction X Length or Maximum Packet Size bytes (whichever is less), then the host controller sets the Babble Detected bit to one and set the Active bit to zero. Note, that the host controller is not required to update the iTD field Transaction X Length in this error scenario. If the Mult field is greater than one, then the host controller automatically executes the value of Mult transactions. The host controller will not execute all Mult transactions if:

- The endpoint is an OUT and Transaction X Length goes to zero before all the Mult transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed. The end of micro-frame may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next micro-frame. Refer to Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

77.4.3.7.2 Software Operational Model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N micro-frames. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

The following figure illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (that is the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one micro-frame's worth of transactions. The EHCI controller does not provide per-transaction results within a micro-frame. It treats the per-micro-frame transactions as a single logical transfer. On the left is the host controller's frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

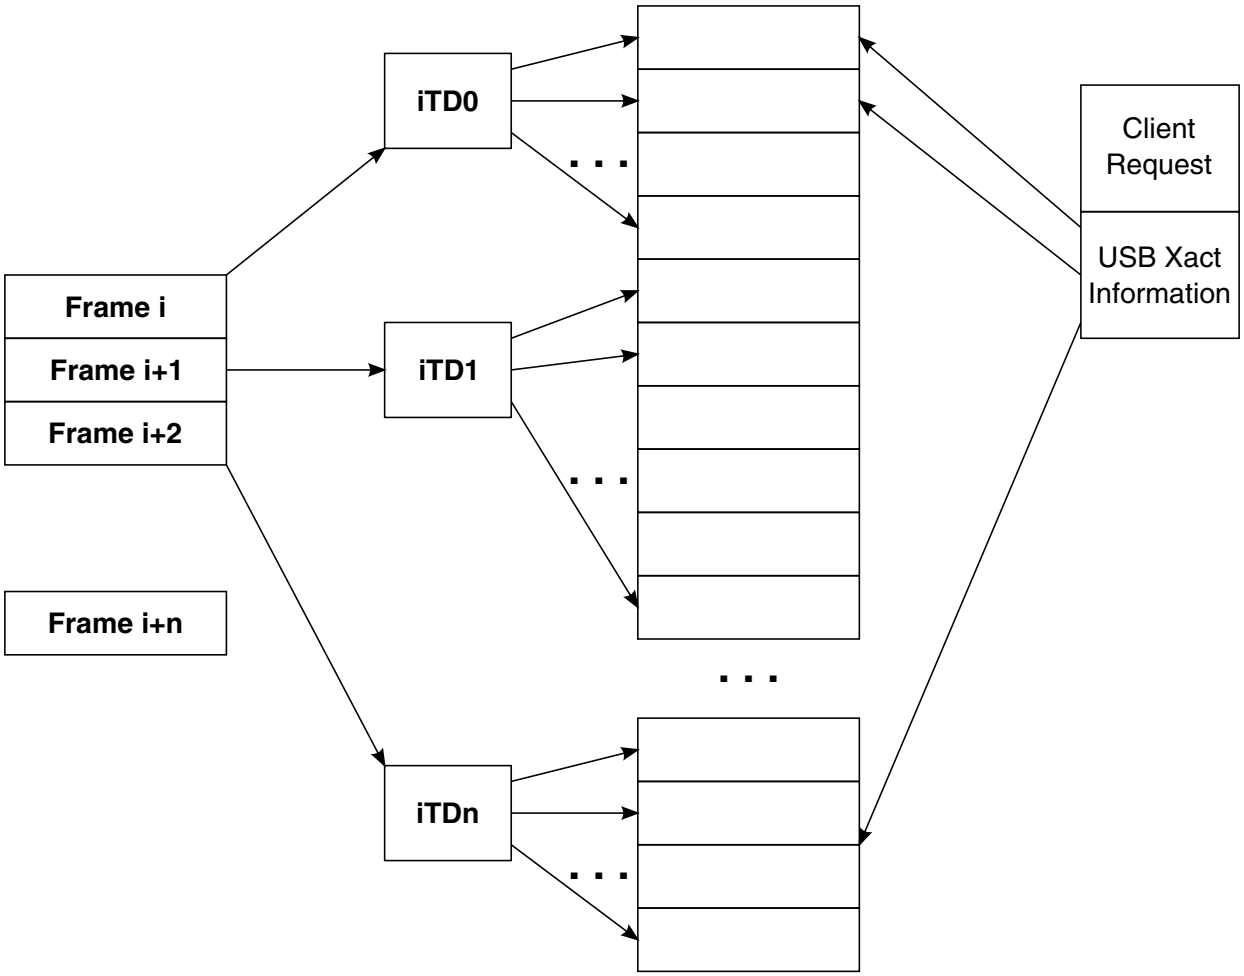

Figure 77-14. Example Association of iTDs to Client Request Buffer

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page (for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the transaction offset field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer wraps a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to 'alias' the page selector to Page zero. USB 2.0 isochronous

endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to one.

77.4.3.7.2.1 Periodic Scheduling Threshold

The Isochronous Scheduling Threshold field in the USB_HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures. It is used by system software when adding isochronous work items to the periodic schedule.

The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 micro-frames worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. Three basic caching models that account for the fact the isochronous data structures span 8 micro-frames. The three caching models are: no caching, micro-frame caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the USB_FRINDEX register to determine the current frame and micro-frame the host controller is currently executing. Of course, there is no information about where in the micro-frame the host controller is, so a constant uncertainty-factor of one micro-frame has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the Isochronous Scheduling Threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per micro-frame) but always dumps any accumulated schedule state at the end of the micro-frame. At the appropriate time relative to the beginning of every micro-frame, the host controller always begins schedule traversal from the frame list. Software can use the value of the USB_FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 micro-frames in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the Isochronous Scheduling Threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 micro-frames). Software uses the value of the USB_FRINDEX register (plus the constant 1

uncertainty) to determine the current micro-frame/frame (assume modulo 8 arithmetic in adding the constant 1 to the micro-frame number). For any current frame N, if the current micro-frame is 0 to 6, then software can safely add isochronous transactions to Frame N + 1. If the current micro-frame is 7, then software can add isochronous transactions to Frame N + 2.

Micro-frame caching is indicated with a non-zero value in the least-significant 3 bits of the Isochronous Scheduling Threshold field. System software assumes the host controller caches one or more periodic data structures for the number of micro-frames indicated in the Isochronous Scheduling Threshold field. For example, if the count value were 2, then the host controller keeps a window of 2 micro-frames worth of state (current micro-frame, plus the next) on-chip. On each micro-frame boundary, the host controller releases the current micro-frame state and begins accumulating the next micro-frame state.

77.4.3.8 Asynchronous Schedule

The Asynchronous schedule traversal is enabled or disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

If the Asynchronous Schedule Enable bit is set to zero, then the host controller simply does not try to access the asynchronous schedule through the USB_ASYNCLISTADDR register. Likewise, when the Asynchronous Schedule Enable bit is one, then the host controller does use the USB_ASYNCLISTADDR register to traverse the asynchronous schedule. Modifications to the Asynchronous Schedule Enable bit are not necessarily immediate. Rather the new value of the bit is taken into consideration the next time the host controller needs to use the value of the USB_ASYNCLISTADDR register to get the next queue head.

The Asynchronous Schedule Status bit in the USB_USBSTS register indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing one (or zero) to the Asynchronous Schedule Enable bit in the USB_USBCMD register. Software then can poll the Asynchronous Schedule Status bit to determine when the asynchronous schedule has made the desired transition. Software must not modify the Asynchronous Schedule Enable bit unless the value of the Asynchronous Schedule Enable bit equals that of the Asynchronous Schedule Status bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the USB_ASYNCLISTADDR register. The default value of the USB_ASYNCLISTADDR register after reset is undefined and the schedule is disabled when the Asynchronous Schedule Enable bit is zero.

Software may only write this register with defined results when the schedule is disabled. For example, Asynchronous Schedule Enable bit in the USB_USBCMD and the Asynchronous Schedule Status bit in the USB_USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting the Asynchronous Schedule Enable bit is set to one. The asynchronous schedule is actually enabled when the Asynchronous Schedule Status bit is one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the USB_ASYNCLISTADDR register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller completes processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the USB_ASYNCLISTADDR register. Next time the asynchronous schedule is accessed, this is the first data structure that is serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller completes processing the asynchronous schedule when one of the following events occur:

- The end of a micro-frame occurs.
- The host controller detects an empty list condition (see Empty Asynchronous Schedule Detection)
- The schedule has been disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in Figure 77-9. Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iTD or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

77.4.3.8.1 Adding Queue Heads to Asynchronous Schedule

This is a software requirement section.

There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the USB_ASYNCLISTADDR register, then enables the list by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example, qTD pointers have T-Bits set to one or reference valid qTDs and the Horizontal Pointer references a valid queue head data structure. The following algorithm represents the functional requirements:

```
InsertQueueHead (pQHeadCurrent, pQueueHeadNew)
          --
          -- Requirement: all inputs must be properly initialized.
          --
          -- pQHeadCurrent is a pointer to a queue head that is
          -- already in the active list
          -- pQHeadNew is a pointer to the queue head to be added
          --
          -- This algorithm links a new queue head into a existing
          -- list
          --
          pQueueHeadNew.HorizontalPointer  =  pQueueHeadCurrent.HorizontalPointer
          pQueueHeadCurrent.HorizontalPointer =  physicalAddressOf(pQueueHeadNew)
End InsertQueueHead
```

77.4.3.8.2 Removing Queue Heads from Asynchronous Schedule

This is a software requirement section.

There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list.

Software deactivates the asynchronous schedule by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to zero. Software can determine when the list is idle when the Asynchronous Schedule Status bit in the USB_USBSTS register is zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list through the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```
UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)
          --
```

```
        -- Requirement: all inputs must be properly initialized.
        --
        -- pQHeadPrevious is a pointer to a queue head that
        -- references the queue head to remove
        -- pQHeadToUnlink is a pointer to the queue head to be
        -- removed
        -- pQheadNext is a pointer to a queue head still in the
        -- schedule. Software provides this pointer with the
        -- following strict rules:
        --          if the host software is one queue head, then
        --          pQHeadNext must be the same as
        --          QueueheadToUnlink.HorizontalPointer. If the host
        --          software is unlinking a consecutive series of
        --          queue heads, QHeadNext must be set by software to
        --          the  queue head remaining in the schedule.
        --
        -- This algorithm unlinks a queue head from a circular list
        --
        pQueueHeadPrevious.HorizontalPointer =  pQueueHeadToUnlink.HorizontalPointer
                            pQueueHeadToUnlink.HorizontalPointer = pQHeadNext
End UnlinkQueueHead
```

If software removes the queue head with the H-bit set to one, it must select another queue head still linked into the schedule and set its H-bit to one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its H-bit set to one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, and so on). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (Interrupt on Async Advance Doorbell bit in the USB_USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (Interrupt on Async Advance bit in the USB_USBSTS register) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to one, it also sets the command bit to zero. The third bit is an interrupt enable (Interrupt on Async Advance bit in the USB_USBINTR register) that is matched with the status bit. If the status bit is one and the interrupt enable bit is one, then the host controller asserts a hardware interrupt.

The figure below illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that remains in the asynchronous schedule.

When the host controller observes that doorbell bit being set to one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A and B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (that is traversed beyond queue head (B) in this example). The following figure illustrates the generic queue head unlink scenario.

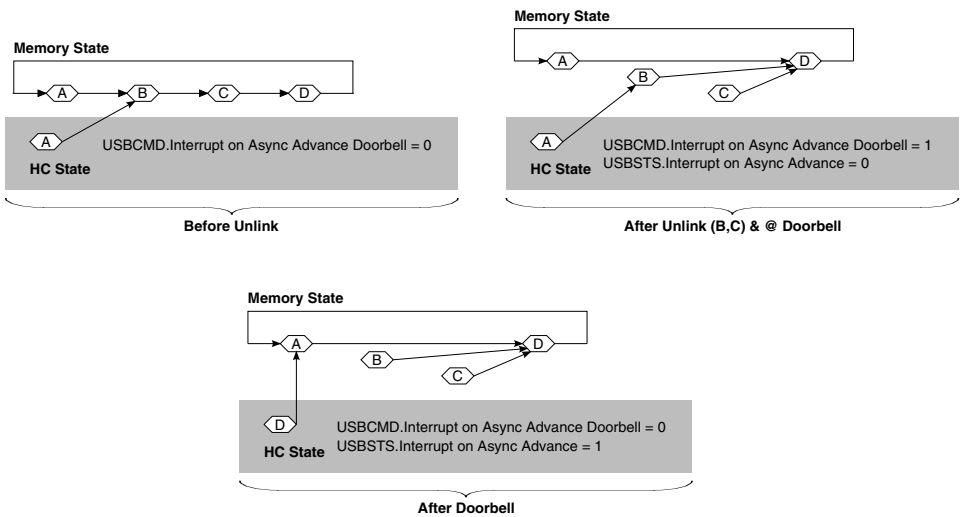

Figure 77-15. Generic Queue Head Unlink Scenario

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting the Advance on Async status bit to one.

Software may re-use the memory associated with the removed queue heads after it observes the Interrupt on Async Advance status bit is set to one, following assertion of the doorbell. Software should acknowledge the Interrupt on Async Advance status as indicated in the USB_USBSTS register, before using the doorbell handshake again.

77.4.3.8.3 Empty Asynchronous Schedule Detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty.

The queue head data structure (see Table 77-25) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USB_USBSTS register (*Reclamation*) that is set to zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see Asynchronous Schedule Traversal: *Start Event*).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is shown in the following figure.

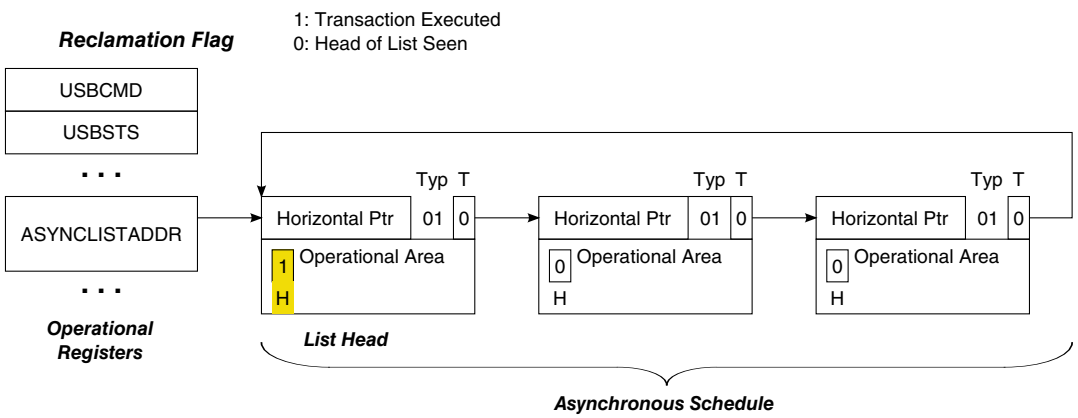

Figure 77-16. Asynchronous Schedule List w/Annotation to Mark Head of List

Software must ensure there is at most one queue head with the *H-bit* set to one, and that it is always coherent with respect to the schedule.

77.4.3.8.4 Restarting Asynchronous Schedule Before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the micro-frame.

It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the micro-frame. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the host controller ceases traversal of the Asynchronous schedule very early in the micro-frame. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current micro-frame, instead of waiting

until the next micro-frame. When the reason for host controller idling asynchronous schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

77.4.3.8.4.1 Example Method for Restarting Asynchronous Schedule Traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: *how long should the host controller stay idle before restarting*?

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called *AsyncSchedSleepTime*, and has a value of 10 µsec. The value is derived based on the analysis in Example Derivation for *AsyncSchedSleepTime*, The traversal algorithm is simple:

- Traverse the Asynchronous schedule until the either an End-Of-micro-Frame event occurs, or an empty list is detected. If the event is an End-of-micro-Frame, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a *schedule sleep* state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to *schedule active* state. The start context allows the HC to reload *Nakcnt* fields, and so on. So the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each micro-frame. The figure below illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.

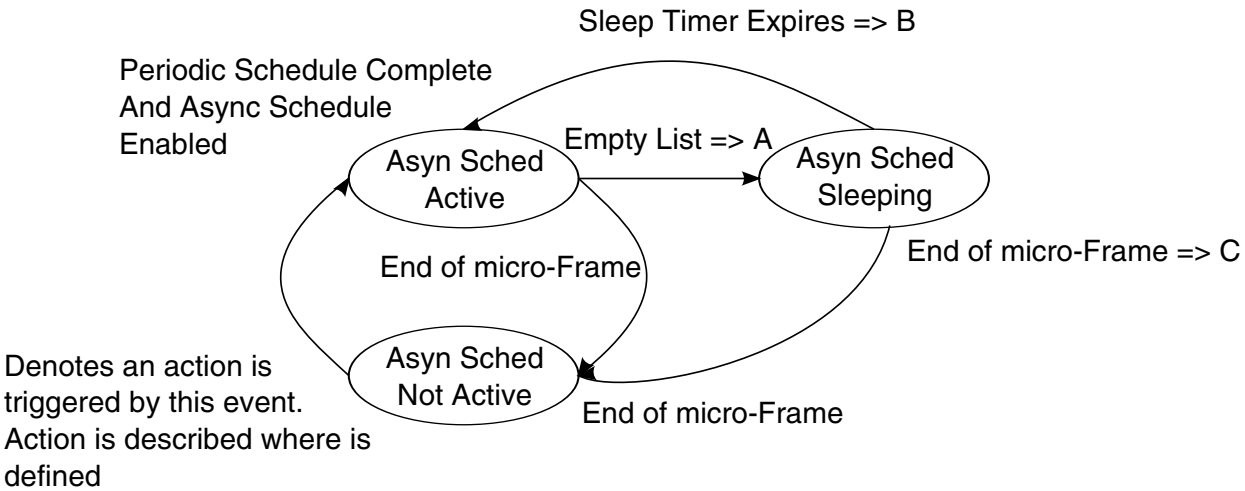

Figure 77-17. Example State Machine for Managing Asynchronous Schedule Traversal

The actions referred to in the figure above are defined in the following table.

Table 77-40. Asynchronous Schedule SM Transition Actions

Action	Action Description Label
A	On detection of the empty list, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.
B	When the *AsynchronousTraversalSleepTimer* expires, the host controller sets the *Reclamation* bit in the USBSTS register to one and moves the Nak Counter reload state machine to WaitForListHead (see Nak Count Reload Control).
C	The host controller cancels the sleep timer (*AsynchronousTraversalSleepTimer*).

77.4.3.8.4.2 Async Sched Not Active

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine does not leave this state when the *Asynchronous Schedule Enable* bit in the USB_USBCMD register is zero.

This state is entered from Async Sched Active or Async Sched Sleeping states when the end-of-micro-frame event is detected.

77.4.3.8.4.3 Async Sched Active

This state is entered from the Async Sched Not Active state when the periodic schedule is not active. It is also entered from the Async Sched Sleeping states when the *AsyncrhonousTraversalSleepTimer* expires. On every transition into this state, the host controller sets the *Reclamation* bit in the USB_USBSTS register to one.

While in this state, the host controller continually traverses the asynchronous schedule until either the end of micro-frame or an empty list condition is detected.

77.4.3.8.4.4 Async Sched Sleeping

The state is entered from the Async Sched Active state when a schedule empty condition is detected. On entry to this state, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.

77.4.3.8.4.5 Example Derivation for *AsyncSchedSleepTime*

The derivation is based on analysis of what work the host controller could be doing next.

It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests.

The table below summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (for example *footprint*, or *wall clock*) the transaction takes to complete.

Table 77-41. Typical Low-/Full-speed Transaction Times

Transaction Attributes		Footprint (time)	Description
Speed	HS	11.9 ms	Maximum foot print for a worst-case, full-sized bulk data transaction.
Size	512	9.45 ms	Maximum footprint for an approximate best-case, full-sized bulk data transaction.
Type	Bulk		
Speed	FS	~50 ms	Approximate typical for full-sized bulk data. An 8-byte low-speed is about 2x, or between 90 and 100 ms.
Size	64		
Type	Bulk		
Speed	FS	~12 ms	Approximate typical for 8-byte bulk/control (that is setup)
Size	8		
Type	Cntrl		

A *AsyncSchedSleepTime* value of 10 µs provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller gets the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10 µs sleep period would allow the host controller to get the NAK results on the first complete-split.

77.4.3.8.5 Asynchronous Schedule Traversal: *Start Event*

Once the HC has *idled* itself through the empty schedule detection (Section 0), it will naturally *activate* and begin processing from the Periodic Schedule at the beginning of each micro-frame. In addition, it may have idled itself early in a micro-frame.

When this occurs (idles early in the micro-frame) the HC must occasionally *re-activate* during the micro-frame and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in Restarting Asynchronous Schedule Before EOF . Asynchronous schedule *Start Event*s are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the micro-frame is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state (see Restarting Asynchronous Schedule Before EOF).

77.4.3.8.6 Reclamation Status Bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (see Empty Asynchronous Schedule Detection) depends on the proper management of the *Reclamation* bit in the USB_USBSTS register.

The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (see Fetch Queue Head).

It is required that the host controller sets the *Reclamation* bit to one whenever an asynchronous schedule traversal *Start Event*, as documented inAsynchronous Schedule Traversal: *Start Event*, occurs. The *Reclamation* bit is also set to one whenever the host controller executes a transaction while traversing the asynchronous schedule (see Execute Transaction). The host controller sets the *Reclamation* bit to zero whenever it finds a queue head with its *H-bit* set to one. Software should only set a queue head's *H-bit* if the queue head is in the asynchronous schedule. If software sets the *H-bit* in an interrupt queue head to one, the resulting behavior is undefined. The host controller may set the *Reclamation* bit to zero when executing from the periodic schedule.

77.4.3.9 Operational Model for Nak Counter

This section describes the operational model for the *NakCnt* field defined in a queue head (see Queue Head Initialization). Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control through the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced through the same asynchronous schedule. The time between the *Start-split* transaction and the first *Complete-split* transaction could be very short (that is like when the endpoint is the only one in the asynchronous schedule). The hub NYETs (effectively Naks) the *Complete-split* transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which does not complete until after the transaction on the classic bus completes.

The two component fields in a queue head to support the throttling feature: a counter field (*NakCnt*), and a counter reload field (*RL*). *NakCnt* is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. The two operational modes associated with this counter:

- Not Used- This mode is set when the *RL* field is zero. The host controller ignores the *NakCnt* field for any execution of transactions through a queue head with an *RL* field of zero. Software must use this selection for interrupt endpoints.
- Nak Throttle Mode- This mode is selected when the *RL* field is non-zero. In this mode, the value in the *NakCnt* field represents the maximum number of Nak or Nyet responses the host controller tolerates on each endpoint. In this mode, the HC decrements the *NakCnt* field based on the token/handshake criteria listed in the table below. The host controller must reload *NakCnt* when the endpoint successfully moves data (for example, policy to reward device for moving data).

The following table describes the NakCnt field adjustment rules.

Table 77-42. NakCnt Field Adjustment Rules

Token	Handshake	
	Handshake NAK	NYET
IN/PING	decrement *NakCnt*	N/A (protocol error)
OUT	decrement *NakCnt*	No Action[1, 1] Start
Split	decrement *NakCnt*	N/A (protocol error)
Complete Split	No Action	Decrement *NakCnt*

1. Recommended behavior on this response is to reload *NakCnt*

In summary, system software enables the counter by setting the reload field (*RL*) to a non-zero value. The host controller may execute a transaction if *NakCnt* is non-zero. The host controller does not execute a transaction if *NakCnt* is zero. The reload mechanism is described in detail in Nak Count Reload Control .

NOTE

When all queue heads in the Asynchronous Schedule either exhausts all transfers or all NakCnt's go to zero, then the host controller detects an empty Asynchronous Schedule and idle schedule traversal (see Empty Asynchronous Schedule Detection).

Any time the host controller begins a new traversal of the Asynchronous Schedule, a *Start Event* is assumed, see Asynchronous Schedule Traversal: *Start Event*. Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

77.4.3.9.1 Nak Count Reload Control

When the host controller reaches the *Execute Transaction* state for a queue head (meaning that it has an active operational state), it checks to determine whether the *NakCnt* field should be reloaded from *RL* (see Execute Transaction). If the answer is yes, then *RL* is copied into *NakCnt*. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (*NakCnt* see Table 77-25) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see Asynchronous Schedule Traversal: *Start Event* for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see Figure 77-16).

The following figure illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: Execute Transaction (see the figure below). The host controller does not perform the nak counter reload operation if the RL field (see Table 77-25) is set to zero.

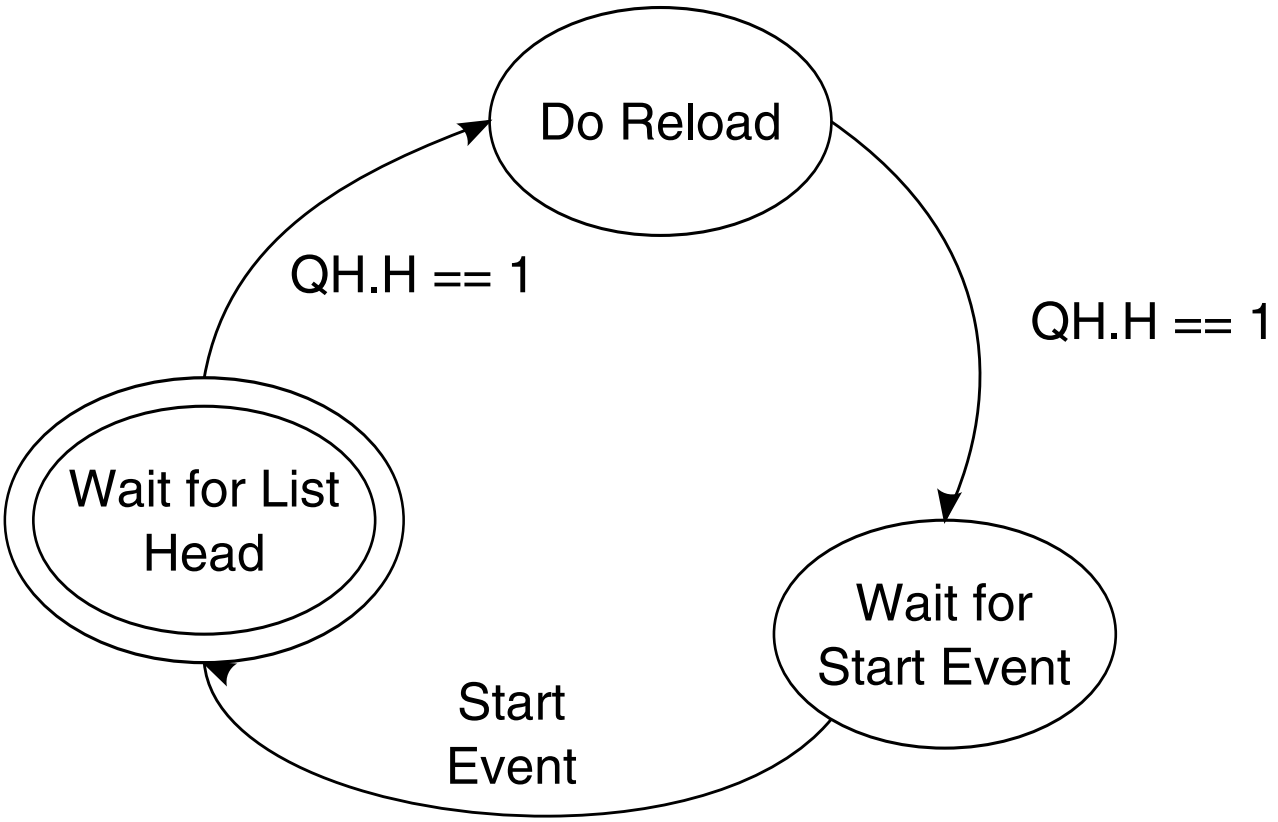

Figure 77-18. Example HC State Machine for Controlling Nak Counter Reloads

77.4.3.9.1.1 Wait for List Head

This is the initial state.

The state machine enters this state from Wait for Start Event when a start event as defined in Asynchronous Schedule Traversal: *Start Event*occurs.

The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule.

This occurs when the host controller fetches a queue head whose *H-bit* is set to one.

77.4.3.9.1.2 Do Reload

This state is entered from the Wait for List Head state when the host controller fetches a queue head with the *H-bit* set to one. While in this state, the host controller performs nak counter reloads for every queue head visited that has a non-zero nak reload value (*RL*) field.

77.4.3.9.1.3 Wait for Start Event

This state is entered from the *Do Reload* state when a queue head with the *H-bit* set to one is fetched. While in this state, the host controller does not perform nak counter reloads.

77.4.3.10 Managing Control/Bulk/Interrupt Transfers through Queue Heads

This section presents an overview of how the host controller interacts with queuing data structures.

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in Table 77-25). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a *transfer*.

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,
- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area,
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller sets one (or more) of the error reporting bits in the queue head's *Status* field. The *Status* field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the queue head *Status* field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions occurs for the endpoint and the host controller does not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in the following figure. This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the *Fetch QH* state in order to avoid all hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and *activate* them, then the host controller always *find* them if/when they are reachable. The figure below illustrates the Host Controller Queue Head Traversal State Machine.

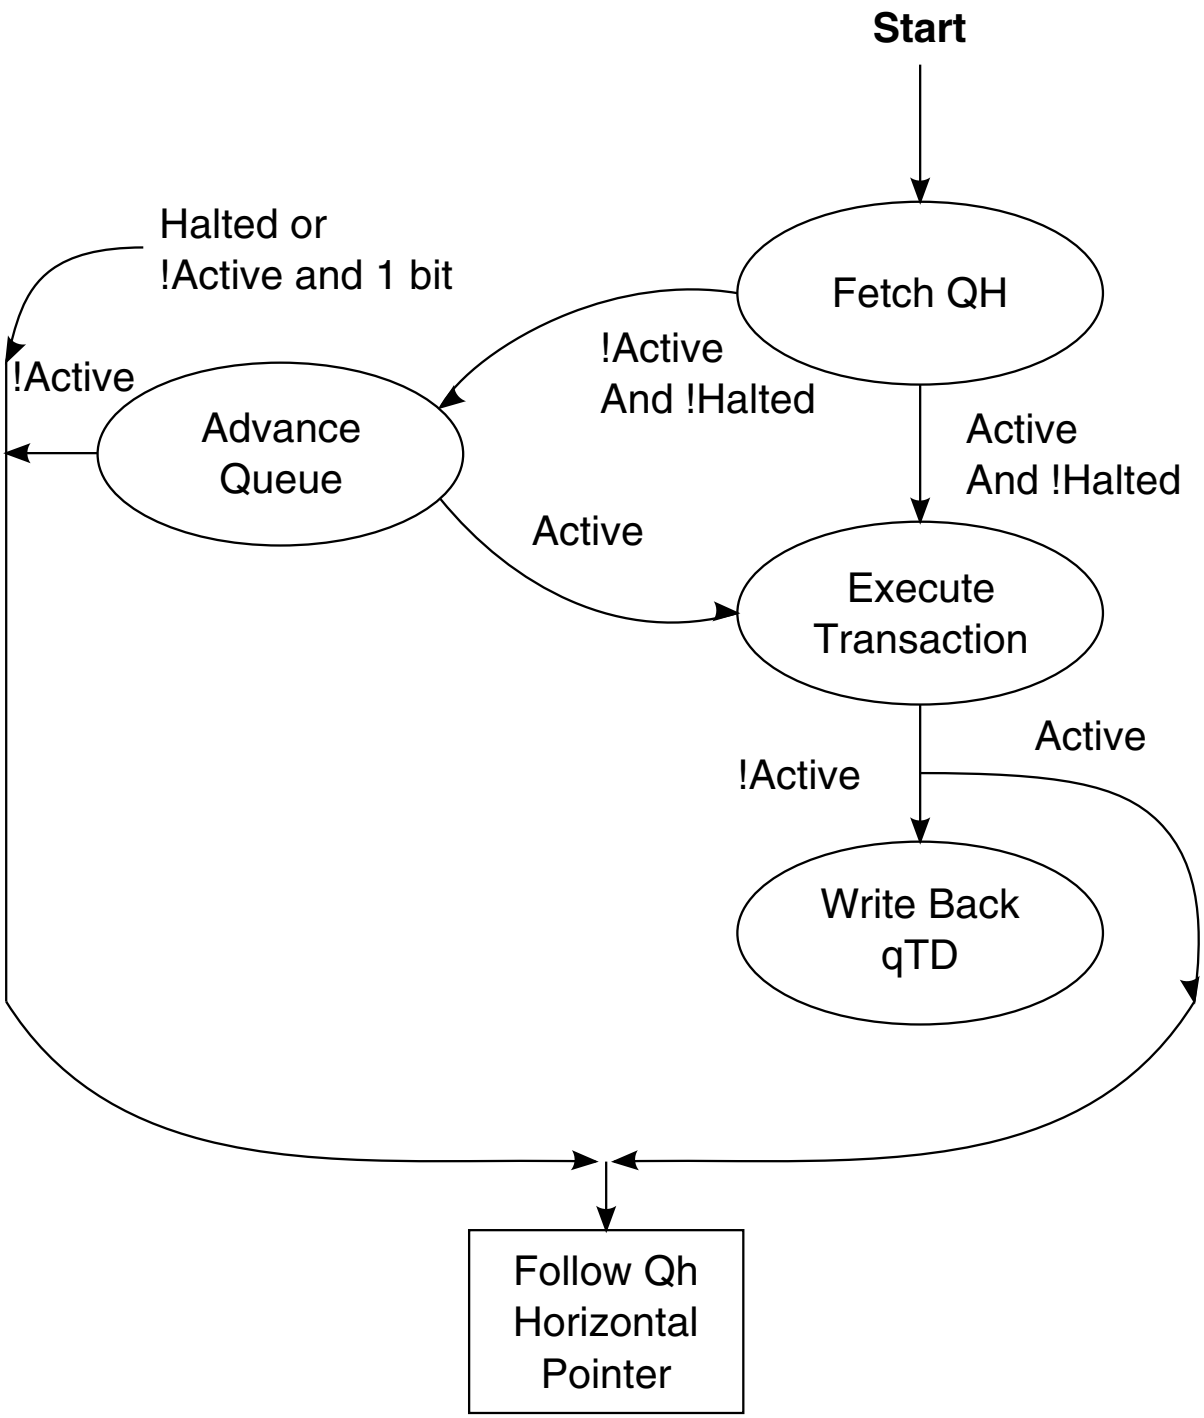

Figure 77-19. Host Controller Queue Head Traversal State Machine

This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The Execute Transaction state (see Execute

Transaction) describes the basic requirements for all endpoints. Split Transactions for Asynchronous Transfers and Split Transaction Interrupt describe details of the required extensions to the Execute Transaction state for endpoints requiring split transactions.

NOTE

Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see Section Queue Head for layout of a queue head):

Valid static endpoint state.

- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the *Next qTD Pointer* field value to reference a valid qTD.

77.4.3.10.1 Fetch Queue Head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register (see Next Asynch. Address (USB__ASYNCLISTADDR))/ Endpoint List Address (USB_UOG_ENDPTLISTADDR) Additionally, it may be referenced from the *Next LinkPointer* field of an iTD, siTD, FSTN or another Queue Head. If the referencing link pointer has the *Typ* field set to indicate a queue head, it is assumed to reference a queue head structure as defined in Table 77-25.

While in this state, the host controller performs operations to implement empty schedule detection (see Empty Asynchronous Schedule Detection) and Nak Counter reloads (see Operational Model for Nak Counter). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (that is *S-mask* is zero), and
- The *H-bit* is one, and
- The *Reclamation* bit in the USBSTS register is zero.

When these criteria are met, the host controller stops traversing the asynchronous list (as described in Empty Asynchronous Schedule Detection). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the *H-bit* is one and the *Reclamation* bit is one, then the host controller sets the *Reclamation* bit in the USBSTS register to zero before completing this state. The operations for reloading of the Nak Counter are described in detail in Operational Model for Nak Counter.

This state is complete when the queue head has been read on-chip.

77.4.3.10.2 Advance Queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the FetchQHD state if the overlay *Active* and *Halt* bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and determines whether or not to perform an overlay.

NOTE

If the *I-bit* is one and the *Active* bit is zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field *Bytes to Transfer* is not zero and the *T-bit* in the *Alternate Next qTD Pointer* is set to zero, then the host controller uses the *Alternate Next qTD Pointer*. Otherwise, the host controller uses the *NextqTD Pointer*. If *NextqTD Pointer's T-bit* is set to one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has its *Active* bit set to one, the host controller moves the pointer value used to reach the qTD (*Next* or *Alternate Next*) to the *Current qTD Pointer* field, then performs the overlay. If the fetched qTD has its *Active* bit set to zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure.

The host controller performs the overlay based on the following rules:

- The value of the data toggle (*dt*) field in the overlay area depends on the value of the *data toggle control* (*dtc*) bit (see Table 77-27).
- If the *EPS* field indicates the endpoint is a high-speed endpoint, the *Ping* state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- *C-prog-mask* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *Frame Tag* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *NakCnt* field in the overlay area is loaded from the *RL* field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.

77.4.3.10.3 Execute Transaction

The host controller enters this state from the Fetch Queue Head state only if the *Active* bit in *Status* field of the queue head is set to one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's *S-mask* field contains a non-zero value. It is the responsibility of software to ensure the *S-mask* field is appropriately initialized based on the transfer type. There are other criteria that must be met if the *EPS* field indicates that the endpoint is a low- or full-speed endpoint, see Split Transactions for Asynchronous Transfers and Split Transaction Interrupt .

77.4.3.10.3.1 Interrupt Transfer Pre-condition Criteria

If the queue head is for an interrupt endpoint (for example, non-zero *S-mask* field), then the FRINDEX[2:0] field must identify a bit in the *S-mask* field that has one in it.

For example, an *S-mask* value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction.

77.4.3.10.3.2 Asynchronous Transfer Pre-operations and Pre-condition Criteria

If the queue head is not for an interrupt endpoint (for example, zero *S-mask* field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria.

The pre-operation is:

Checks the Nak counter reload state (Operational Model for Nak Counter). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the *NakCnt* field has been reloaded, the host controller checks the value of the *NakCnt* field in the queue head. If *NakCnt* is non-zero, or if the *Reload Nak Counter* field is zero, then the host controller considers this queue head for a transaction.

77.4.3.10.3.3 Transfer Type Independent Pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter *qHTransactionCounter* is loaded from the queue head's *Mult* field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the *Mult* field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the micro-frame to complete this transaction (see Transaction Fit - A Best-Fit Approximation Algorithm for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of *qHTransactionCounter* for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the *Reclamation* bit in the USBSTS register to one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates *qHTransactionCounter* times in this state executing transactions. After each transaction is executed, *qHTransactionCounter* is decremented by one. The host controller exits this state when one of the following events occurs:

- The *qHTransactionCounter* decrements to zero, or
- The endpoint responds to the transaction with any handshake other than an ACK,[4] or
- The transaction experiences a transaction error, or
- The *Active* bit in the queue head goes to zero, or
- There is not enough time in the micro-frame left to execute the next transaction(see Transaction Fit - A Best-Fit Approximation Algorithm) for example method for implementing the frame boundary test).

NOTE

For a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the *Total Bytes to Transfer* field is decremented by the number of bytes moved in the transaction, the data toggle bit (*dt*) is toggled, the current page offset is advanced to the next appropriate value (for example,

advanced by the number of bytes successfully moved), and the *C_Page* field is updated to the appropriate value (if necessary). See Buffer Pointer List Use for Data Streaming with qTDs .

NOTE

The *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller executes zero-length transaction to the endpoint. If the *PID_Code* field indicates an IN transaction and the device delivers data, the host controller detects a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement *qHTransactionCounter*). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of *qHTransactionCounter* is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and *RL* is non-zero, *NakCnt* is decremented by one. If *RL* is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of *CErr* did not change). Software should set the *RL* field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly *NakCnt*, the host controller writes back the results of the transaction to the queue head's overlay area in main memory).

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *MaximumPacket Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The *CErr* field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in Transaction Error .

The following events causes the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from one to zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to zero. When this occurs the *Halted* bit is set to one and *Active* is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to one and the *Active* bit is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The *Total Bytes to Transfer* field is zero after the transaction completes.
  - For a zero length transaction, it was zero before the transaction was started. When this condition occurs, the *Active* bit is set to zero.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to zero and a short packet condition exists. The short-packet condition is detected during the Advance Queue state. Refer to Split Transactions for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (for example *Maximum Packet Length* or *Total Bytes to Transfer* bytes, whichever is less) (for example a packet babble). This results in the host controller setting the *Halted* bit to one.

- NakCnt, dt, Total Bytes to Transfer, C_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

77.4.3.10.3.4 Halting a Queue Head

A halted endpoint is defined only for the transfer types that are managed through queue heads (control, bulk and interrupt).

The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USB.USBSTS register to one. To halt the queue head, the *Active* bit is set to zero and the *Halted* bit is set to one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller does not advance the transfer state on a transaction that results in a *Halt* condition (for example no updates necessary for *Total Bytes to Transfer*, *C_Page*, *Current Offset,* and *dt*). The host controller must update *CErr* as appropriate. When a queue head is halted, the *USB Error Interrupt* bit in the USB.USBSTS register is set to one. If the *USB Error Interrupt Enable* bit in the USB.USBINTR register is set to one, a hardware interrupt is generated at the next interrupt threshold.

77.4.3.10.3.5 Asynchronous Schedule Park Mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule.

This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the *Mult* feature that is used in the Periodic schedule. Where-as the *Mult* feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in Execute Transaction apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the *Asynchronous Schedule Park Capability* bit in the USB.HCCPARAMs register to one. This information keys system software that the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USB.USBCMD register are modifiable. System software enables the feature by writing a one to the *Asynchronous Schedule Park Mode Enable* bit.

When park-mode is not enabled (for example *Asynchronous Schedule Park Mode Enable* bit in the USB.USBCMD register is zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose *EPS* field indicates a Low/Full-speed device (for example only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose *EPS* field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose *EPS* field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the *Asynchronous Schedule Park Mode Count* field in the USB.USBCMD register. Software must not set *Asynchronous Schedule Park Mode Enable* bit to one and also set *Asynchronous Schedule Park Mode Count* field to zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in Execute Transaction . It only effects how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the *Mult* field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter *PM-Count* from *Asynchronous Schedule Park Mode Count* when *Asyncrhonous Schedule Park Mode Enable* bit is one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, *PM-Count* is decremented. The host controller may continue to execute bus transactions from the current queue head until *PM-Count* goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake.

The following table summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

Table 77-43. Actions for Park Mode, based on Endpoint Response and Residual Transfer State

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	

Table continues on the next page...

Table 77-43. Actions for Park Mode, based on Endpoint Response and Residual Transfer State (continued)

IN	DATA[0,1] w/ Maximum Packet sized data	Not zero	Not Zero	Allowed to perform another bus transaction. [1],, [2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.
	DATA[0,1] w/short packet	Don't care	Don't care	Retire qTD and move to next QH.
	NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH.
OUT	ACK	Not zero	Not Zero	Allowed to perform another bus transaction. [2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't' care	Move to next QH.
	NYET, NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not Zero	Not Zero	Allowed to perform another bus transaction. [2]
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

1. The host controller may continue to execute bus transactions from the current high-speed queue head (if *PM-Count* is not equal to zero), if a PID mismatch is detected (for example expected DATA1 and received DATA0, or visa-versa).
2. This specification does not *require* that the host controller execute another bus transaction when *PM-Count* is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

77.4.3.10.4 Write Back qTD

This state is entered from the Execute Transaction state when the *Active* bit is set to zero.

The source data for the write-back is the transfer results area of the queue head overlay area (see Table 77-43).

The host controller uses the *Current qTD Pointer* field as the target address for the qTD.

The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include *Total Bytes to Transfer*, *Cerr*, and *Status*.

The duration of this state depends on when the qTD write-back is committed.

77.4.3.10.5 Follow Queue Head Horizontal Pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the *Active* bit is one on exit from the Execute Transaction state, or

- When the host controller exits the Write Back qTD state, or
- If the Advance Queue state fails to advance the queue because the target qTD is not active, or
- If the *Halted* bit is one on exit from the Fetch QH state.

There is no functional requirement that the host controller wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

77.4.3.10.6 Buffer Pointer List Use for Data Streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be *virtually contiguous*.

This means: if the buffer spans more than one physical page, it must obey the following rules (the figure below illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4 K chunk beyond the first page, each buffer portion matches to a full 4 K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20 K bytes. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16 Kbyte buffer with any starting buffer alignment.

The host controller uses the field *C_Page* field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing *C_Page* and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the *Bytes to Transfer* field.

The following figure illustrates a nominal example of how System software would initialize the buffer pointers list and the *C_Page* field for a transfer size of 16383 bytes. *C_Page* is set to zero. The upper 20-bits of Page 0 references the start of the physical

page. *Current Offset* (the lower 12-bits of queue head Dword 7) holds the offset in the page for example 2049 (for example 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4 K page.

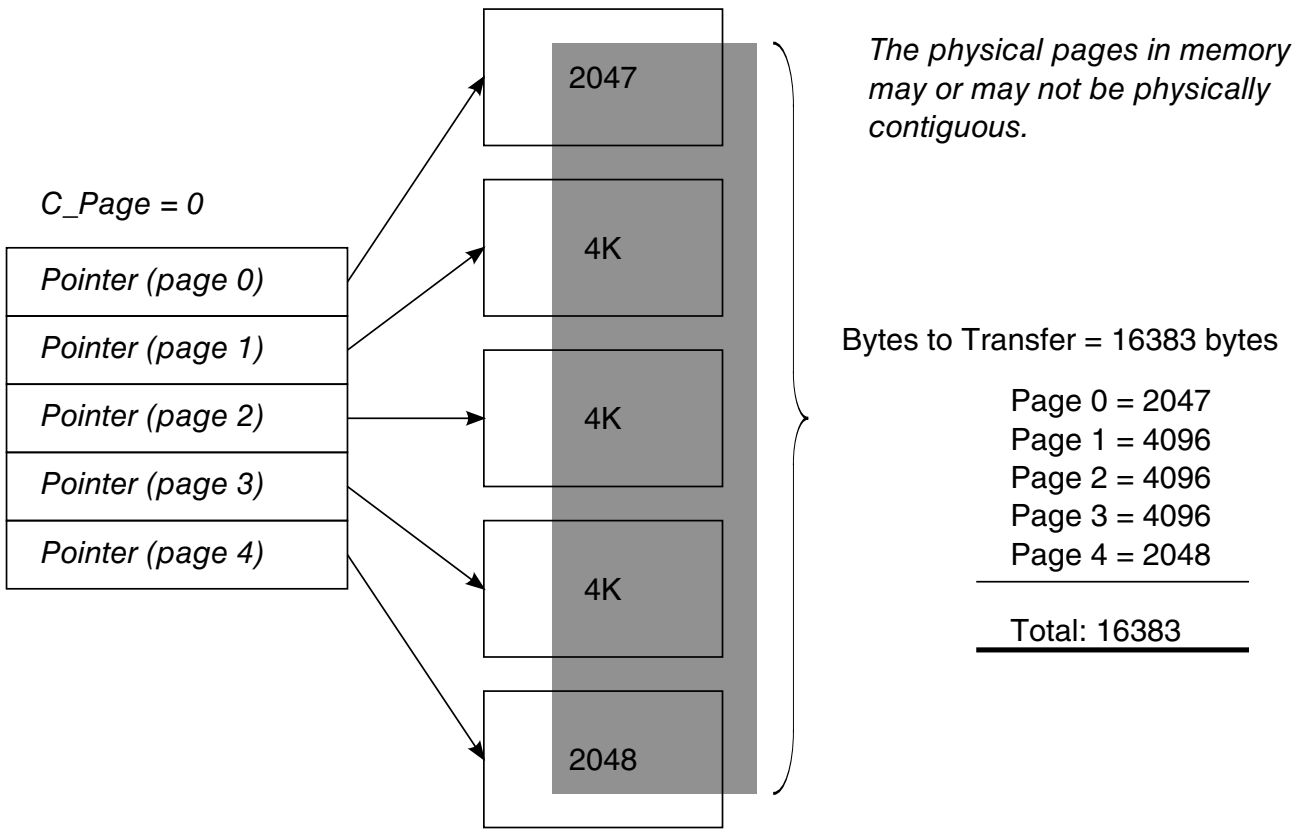

Figure 77-20. Example Mapping of qTD Buffer Pointers to Buffer Pages

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because *C_Page* is set to zero) and concatenates the *Current Offset* field. The 512 bytes are moved during the transaction, the *Current Offset* and *Total Bytes to Transfer* are adjusted by 512 and written back to the queue head working area.

During the 4th transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller increments *C_Page* (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4th transaction, the active page pointer is the page 1 pointer and *Current Offset* has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is *C_Page*) when necessary. The three conditions for how the host controller handles *C_Page*:

- The current transaction does not span a page boundary. The value of *C_Page* is not adjusted by the host controller.

- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (that is the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment *C_Page* before writing back status for the transaction.

NOTE

The only valid adjustment the host controller may make to *C_Page* is to increment by one.

77.4.3.10.7 Adding Interrupt Queue Heads to the Periodic Schedule

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate.

System software sets a bit in a queue head's *S-Mask* to indicate which micro-frame within 1 msec period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have *S-Mask* set to a non-zero value. An *S-mask* with zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and *S-Mask* values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in the following table.

Table 77-44. Example Periodic Reference Patterns for Interrupt Transfers with 2ms Poll Rate

Frame # Reference Sequence	Description
0, 2, 4, 6, 8, and so on *S-Mask* = 01h	A queue head for the *bInterval* of 2 msec (16 micro-frames) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the *S-Mask* field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during micro-frame 0 of the frame.
0, 2, 4, 6, 8, and so on *S-Mask* = 02h	Another example of a queue head with a *bInterval* of 2 msec is linked into the periodic frame list at exactly the same interval as the previous example. However, the *S-Mask* is set to 02h indicating that the transaction for the endpoint should be executed on the bus during micro-frame 1 of the frame.

77.4.3.10.8 Managing Transfer Complete Interrupts from Queue Heads

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an *Interrupt on Complete* (*IOC*) bit set to one, or whenever a transfer (qTD) completes with a short packet.

If system software needs multiple qTDs to complete a client request (that is like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

77.4.3.11 Ping Control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints.

Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The *Status* field has a *Ping State* bit, which the host controller uses to determine the *next* actual PID it uses in the next transaction to the endpoint (see the table below).

The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt and
- *EPS* field equals High-Speed and
- *PIDCode* field equals OUT

The following table illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

Table 77-45. Ping Control State Transition Table

Event			
Current	Host	Device	Next
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr[1]	Do Ping
Do Ping	PING	Stall	N/C[2] Do
OUT	OUT	Nak	Do Ping

Table continues on the next page...

Table 77-45. Ping Control State Transition Table (continued)

Do OUT	OUT	Nyet	Do Ping
Do OUT	OUT	Ack	Do OUT
Do OUT	OUT	XactErr[1]	Do Ping
Do OUT	OUT	Stall	N/C[2]

1. Transaction Error (XactErr) is any time the host misses the handshake.
2. No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (for example Active set to zero and Halt set to one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to Do Ping. The Ping State bit has the following encoding:

Table 77-46. Ping State bit Encoding

Value	Meaning
0B	Do OUT The host controller uses an OUT PID during the next bus transaction to this endpoint.
1B	Do Ping The host controller uses a PING PID during the next bus transaction to this endpoint.

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (that is start in *Do OUT* when we don't know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

77.4.3.12 Split Transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs.

This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol.

Refer to USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.

The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see Split Transaction Isochronous Transfer Descriptor (siTD)). Control, Bulk and Interrupt are managed using the queuing data structures (see Queue Head). The interface data structures need to be programmed with the device address and the Transaction Translator number of the USB 2.0 Hub operating as the Low-/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

77.4.3.12.1 Split Transactions for Asynchronous Transfers

A queue head in the asynchronous schedule with an *EPS* field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head.

All full-speed bulk and full-, low-speed control are managed through queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit (*SplitXState*) to Do-Start-Split. Finally, if the endpoint is a control endpoint, then system software must set the *Control Transfer Type* (*C*) bit in the queue head to one. If this is not a control transfer type endpoint, the *C* bit must be initialized by software to be zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the *C* bit is zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the *C* bit is one, the split transaction token's ET field is set to indicate a control endpoint. Refer to Chapter 8 of USB Specification Revision 2.0 for details.

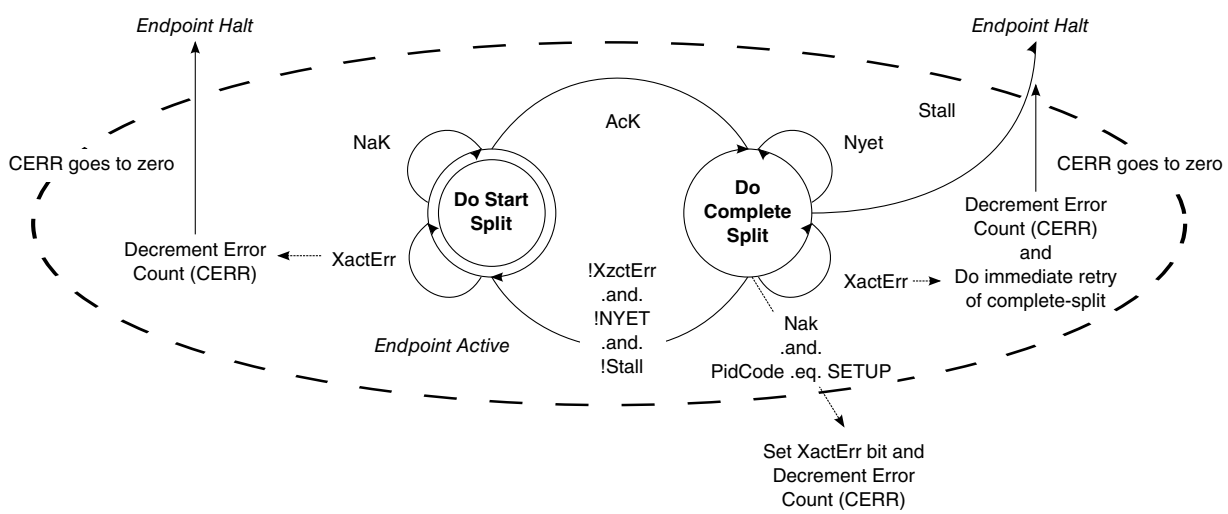

Figure 77-21. Host Controller Asynchronous Schedule Split-Transaction State Machine

77.4.3.12.1.1 Asynchronous - Do Start Split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the Do Complete Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller executes a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and *PidCode* indicates an IN or OUT transaction, then the host controller reloads the error counter (*CErr*). If it is a successful bus transaction and the *PidCode* indicates a SETUP, the host controller does not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements *Cerr* and proceeds to the next queue head in the asynchronous schedule.

77.4.3.12.1.2 Asynchronous - Do Complete Split

This state is entered from the Do Start Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller executes a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's *PidCode* indicates an IN or OUT, the host controller reloads the error counter (*CErr*). When a Nyet handshake is received for a complete-split bus transaction where the queue head's *PidCode* indicates a SETUP, the host controller must not adjust the value of *CErr*.

Independent of *PIDCode*, the following responses have the effects:

- Transaction Error (XactErr). Timeout or data CRC failure, and so on. The error counter (*Cerr*) is decremented by one and the complete split transaction is *immediately* retried (if possible). If there is not enough time in the micro-frame to execute the retry, the host controller MUST ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to

accomplish this behavior is to not advance the asynchronous schedule. When the host controller returns to the asynchronous schedule in the next micro-frame, the first transaction from the schedule is the retry for this endpoint.

If *Cerr* went to zero, the host controller must halt the queue.

- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the *PidCode* is a SETUP, then the Nak response is a protocol error. The *XactErr* status bit is set to one and the *CErr* field is decremented.
- STALL. The target endpoint responded with a STALL handshake. The host controller sets the *halt* bit in the status byte, retires the qTD but does not attempt to advance the queue.

If the *PidCode* indicates an IN, then any of following responses are expected:

- DATA0/1. On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is *good*, the host controller advances the state of the transfer, for example move the data pointer by the number of bytes received, decrement *BytesToTransfer* field by the number of bytes received, and toggle the *dt* bit. The host controller then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the *PidCode* indicates an OUT/SETUP, then any of following responses are expected:

- ACK. The target endpoint accepted the data, so the host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount and the data toggle bit (*dt*) is toggled. The host controller then exit this state.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Managing Control/Bulk/Interrupt Transfers through Queue Heads).

77.4.3.12.2 Split Transaction Interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed through the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule.

Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller visits a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the *execution* phase are different (that is takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, and so on, occurs as defined in Managing Control/Bulk/Interrupt Transfers through Queue Heads, but only occurs on the completion of a split transaction.

77.4.3.12.2.1 Split Transaction Scheduling Mechanisms for Interrupt

Full- and low-speed Interrupt queue heads have an *EPS* field indicating full- or low-speed and have a non-zero *S-mask* field.

The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each endpoint occurs. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit micro-frames, or the data or response information in the pipeline is lost.

The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The S and ^{C}X labels indicate micro-frames where software can schedule start-splits and complete splits (respectively).

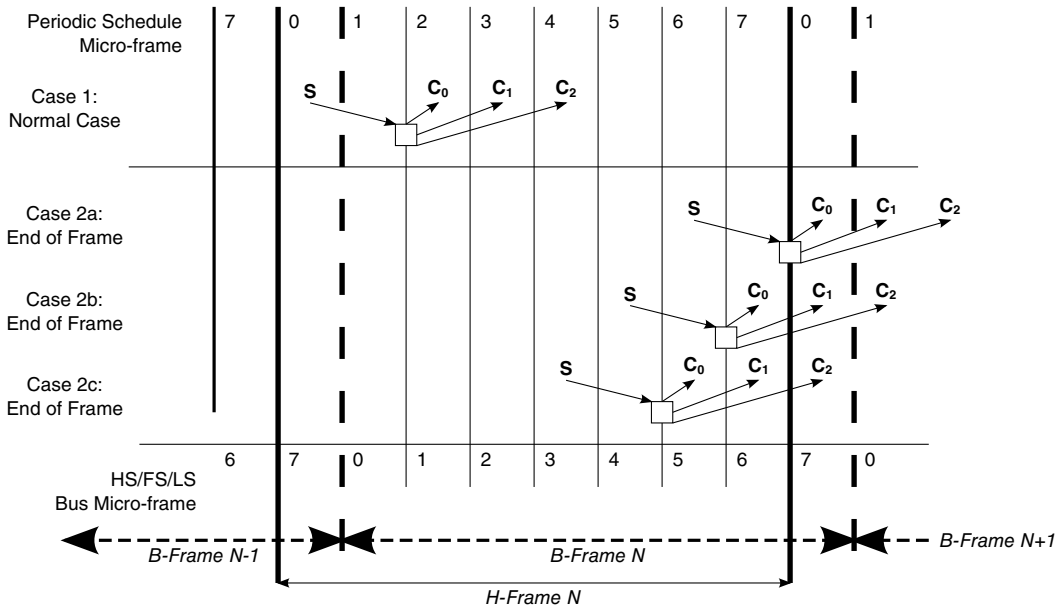

Figure 77-22. Split Transaction, Interrupt Scheduling Boundary Conditions

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in micro-frame 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

The figure below illustrates the general layout of the periodic schedule.

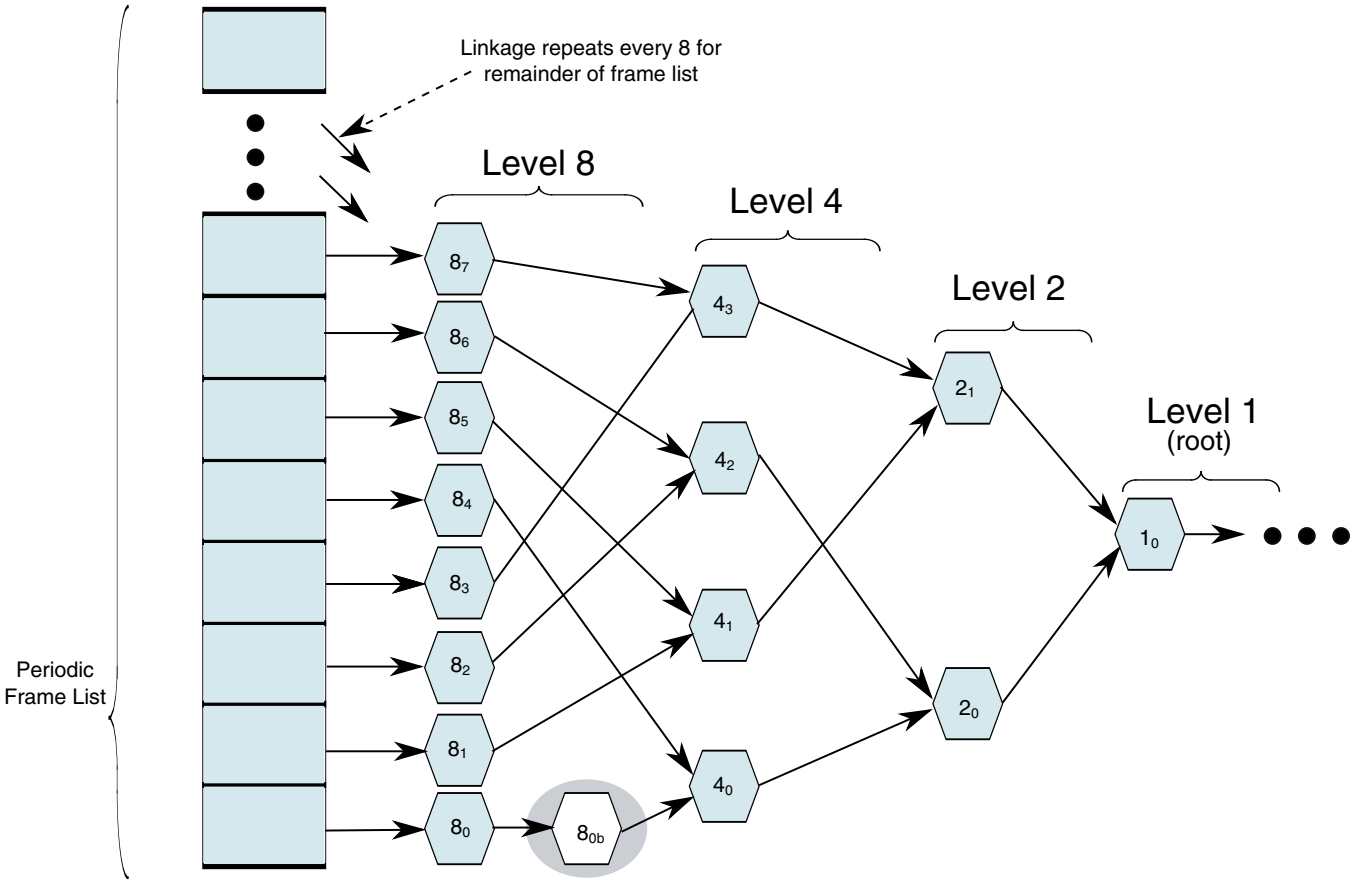

Figure 77-23. General Structure of EHCI Periodic Schedule Utilizing Interrupt Spreading

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a 2^N poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if 8_{0b} where such an endpoint. Without additional support on the interface, to get 8_{0b} reachable at the correct time, software would have to link 8_1 to 8_{0b}. It would then have to move 4_1 and everything linked after into the same path as 4_0. This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. Host Controller Operational Model for FSTNs defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol:

- *SplitXState*. This is single bit residing in the *Status* field of a queue head (see Table 77-23). This bit is used to track the current state of the split transaction.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 77-22, case one, the *S-mask* would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Start, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask.* This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 77-22, case one, the *C-mask* would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Complete, and the current micro-frame as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between *H-Frames* and *B-Frames* is correctly performed when setting bits in *S-mask* and *C-mask*

77.4.3.12.2.2 Host Controller Operational Model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (that is boundary cases 2a through 2c).

An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see siTD Back Link Pointer).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

The four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to zero.

- A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to one.
- Host controller FSTN traversal rules.

When the host controller encounters an FSTN during micro-frames 2 through 7 it simply follows the node's *Normal Path Link Pointer* to access the next schedule data structure.

NOTE

The FSTN's *Normal Path Link Pointer.T-bit* may set to one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in micro-frames 0 or 1, it saves the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller's rules for how it traverses the schedule and limits which data structures is considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the micro-frame (see details in the list below).

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

- Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN's *Back Path Link Pointer*.
- Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer*.
- Do not process a QH (Queue Head) whose *EPS* field indicates a high-speed device. Simply follow its *Horizontal Link Pointer*.
- When a QH's *EPS* field indicates a Full/Low-speed device, the host controller considers only it for execution if its *SplitXState* is DoComplete (note: this applies whether the *PID Code* indicates an IN or an OUT). See Execute Transaction and Tracking Split Transaction Progress for Interrupt Transfers for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction.
  - The host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See Periodic Isochronous - Do Complete Split for special handling when in *Recovery Path* mode.
- Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The

host controller must clear the context of executing a *Recovery Path* when it restores schedule traversal to the *Save-Place* FSTN's *Normal Path Link Pointer*.

- If the host controller determines that there is not enough time left in the micro-frame to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive micro-frame, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in the following figure.

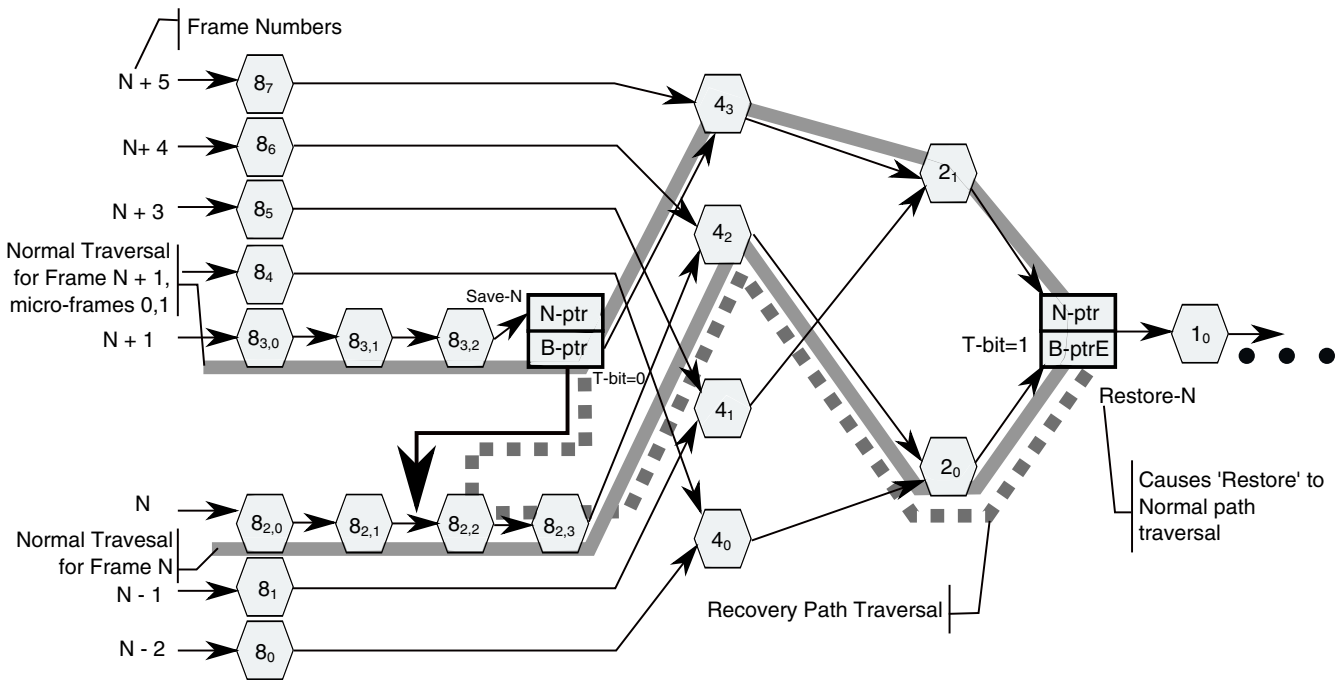

Figure 77-24. Example Host Controller Traversal of Recovery Path via FSTNs

In frame N+1 (micro-frames 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in *Recovery Path* mode (the recovery path is annotated in the figure above with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to one (definition of a Restore indicator), so the host controller exits *Recovery Path* mode by clearing the internal *Recovery Path* mode flag and commences (restores) schedule traversal using the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* (for example Save-N.Normal Path Link Pointer). The nodes traversed during these micro-frames include: {$8_{3,0}$, $8_{3,1}$, $8_{3,2}$, Save-A, $8_{2,2}$, $8_{2,3}$, 4_2,

2_0, Restore-N, 4_3, 2_1, Restore-N, 1_0 …}. The nodes on the recovery-path are in bold. In frame N (micro-frames 0-7), for this example, the host controller traverses all of the schedule data structures utilizing the *Normal Path Link Pointers* in any FSTNs it encounters. This is because the host controller has not yet encountered a *Save-Place* FSTN so it not executing in *Recovery Path* mode. When it encounters the *Restore* FSTN, (Restore-N), during micro-frames 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (that is normal schedule traversal). This is because the host controller must use a Restore FSTN's *Normal Path Link Pointer* when not executing in a *Recovery-Path* mode. The nodes traversed during frame N include: {$8_{2.0}$, $8_{2.1}$, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 1_0 …}.

In frame N+1 (micro-frames 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these micro-frames include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, 4_3, 2_1, Restore-N, 1_0 …}.

77.4.3.12.2.3 Software Operational Model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse.

When using FSTNs, system software must adhere to the following rules:

- Each *Save-Place* indicator requires a matching *Restore* indicator.
  - The *Save-Place* indicator is an FSTN with a valid *Back Path Link Pointer and T-bit* equal to zero.
    - *Back Path Link Pointer.Typ* field must be set to indicate the referenced data structure is a queue head. The *Restore* indicator is an FSTN with its *Back Path Link Pointer.T-bit* set to one.
  - A *Restore* FSTN may be matched to one or more *Save-Place* FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a *Restore* FSTN at the beginning of this list in order to match all possible *Save-Place* FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more *Save-Place* FSTNs are used, then System Software must ensure the *Restore* FSTN's *Normal Path Link Pointer*'s *T-bit* is set to one, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a *Restore* FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that *Recovery Path* mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A *Save-Place* FSTN's *Back Path Link Pointer* must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list

location. In other words, if the *Save-Place* FSTN is reachable from frame list offset N, then the FSTN's *Back Path Link Pointer* must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one *Save-Place* FSTN reachable in any single frame. Note there is times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth re-balance causes system software to move the *Save-Place* FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

77.4.3.12.2.4 Tracking Split Transaction Progress for Interrupt Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost.

For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline.

When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets one of the *C-prog*-mask bits for each complete-split executed. The bit position is determined by the micro-frame number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a

complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.

- *FrameTag*. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame* number) when the next complete split must be executed.
- *S-bytes*. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

77.4.3.12.2.5 Split Transaction Execution State Machine for Interrupt

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame.*

As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence. Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- *cMicroFrameBit*. This is a single-bit encoding of the current micro-frame number. It is an eight-bit value calculated by the host controller at the beginning of every micro-frame. It is calculated from the three least significant bits of the *FRINDEX* register (that is, *cMicroFrameBit* = (1 shifted-left(*FRINDEX*[2:0])). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current micro-frame number. For example, if the current micro-frame is 0, then *cMicroFrameBit* will equal 00000001b. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start- or complete-splt transaction for the current micro-frame.

The following figure illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at Do_Start and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to Do_Complete. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the Do_Complete state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the Do_Complete state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (for example, after the host tries the same transaction three times, and each

encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

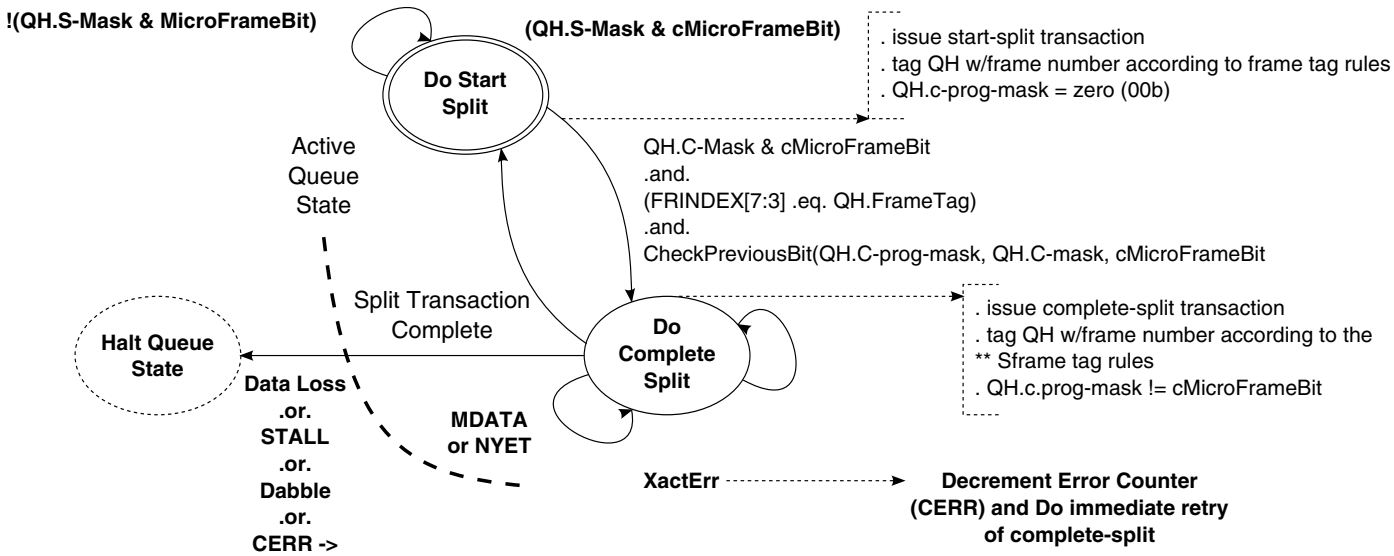

Figure 77-25. Split Transaction State Machine for Interrupt

See Previous Section for the frame tag management rules.

Periodic Interrupt - Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head *StartXState* bit. This state is entered from the Do_Complete Split state only after the split transaction is complete. This occurs when one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- NAK. A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- ACK. An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- DATA 0/1. Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- ERR. The transaction on the low-/full-speed link below the transaction translator had a failure (for example, timeout, bad CRC, etc.).
- NYET (and Last). The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section Periodic Isochronous - Do Complete Split for the definition of 'Last'.

Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it performs the following test to determine whether to execute a start-split.

- *QH.S-mask* is bit-wise anded with *cMicroFrameBit*.

If the result is non-zero, then the host controller will issue a start-split transaction. If the *PIDCode* field indicates an IN transaction, the host controller must zero-out the *QH.S-bytes* field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into *QH.FrameTag* field (see Section), set *C-prog-mask* to zero (00h), and exits this state. Note that the host controller must not adjust the value of *CErr* as a result of completion of a start-split transaction.

Periodic Interrupt - Do Complete Split

This state is entered unconditionally from the Do Start Split state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- Test A. *cMicroFrameBit* is bit-wise anded with *QH.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame.
- Test B. *QH.FrameTag* is compared with the current contents of *FRINDEX*[7:3]. An equal indicates a match.
- Test C. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)
Begin
-- Return values:
-- TRUE - no error
-- FALSE - error
--
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous micro-frame. So,
-- if the
-- 'previous bit' is set in C-mask, check C-prog-mask to
-- make sure it
-- happened.
If (previousBit bitAND QH.C-mask)then
                                If not(previousBit bitAND QH.C-prog-mask) then
                    rvalue = FALSE;
          End if
End If
-- If the C-prog-mask already has a one in this bit position,
```

```
-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
 rvalue = FALSE;
End if
return (rvalue)
End Algorithm
```

- Test D. Check to see if a start-split should be executed in this micro-frame. Note this is the same test performed in the Do Start Split state (see Section Periodic Isochronous - Do Start Split). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a *Recovery Path* mode, it means a start-split should occur in this micro-frame. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. On completion of the complete-split transaction, the host controller records the result of the transaction in the queue head and sets *QH.FrameTag* to the expected *H-Frame* number (see Section). The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the *CErr* will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the clompete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the Last complete split can be performed by XOR *QH.C-mask* with *QH.C-prog-mask*. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the *XactErr* status bit is set to a one and the *CErr* field is decremented.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask* and *FrameTag*) and stay in this state. The host controller must not adjust *CErr* on this response.

- Transaction Error (XactErr). Timeout, data CRC failure, etc. The *CErr* field is decremented and the *XactErr* bit in the *Status* field is set to a one. The complete split transaction is *immediately* retried (if *Cerr* is non-zero).If there is not enough time in the micro-frame to complete the retry and the endpoint is an IN, or *CErr* is decremented to a zero from a one, the queue is halted. If there is not enough time in the micro-frame to complete the retry and the endpoint is an OUT and *CErr* is not zero, then this state is exited (that is, return to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section full- and low-speed Interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.
- ACK. This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount. And the data toggle bit (*dt*) is toggled. The host controller will then exit this state for this queue head. The host controller must reload *CErr* with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers through Queue Heads).
- MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in *QH.S-bytes*. The host controller must not adjust *CErr* on this response.
- DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in *QH.S-bytes*. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers through Queue Heads).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload *CErr* with maximum value on this response.

- ERR. There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, *Cerr* is decremented, the state of the transfer is not advanced, and this state is exited.
- STALL. The queue is halted (an exit condition of the Execute Transaction state). The status field bits: *Active* bit is set to zero and the *Halted* bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. The table below lists the possible combinations and the appropriate action.

Table 77-47. Interrupt IN/OUT Do Complete Split State Execution Criteria

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current micro-frame.Host controller should continue walking the schedule.
A not(C)	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	Progress bit check failed. These means a complete-split has been missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A not(B) C	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	*QH.FrameTag* test failed. This means that exactly one or more *H-Frames* have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.

Table continues on the next page...

Table 77-47. Interrupt IN/OUT Do Complete Split State Execution Criteria (continued)

D	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CERR*. In either case, set the *Missed Micro-frame* bit in the status field to a one. Note: When executing in the context of a *Recovery Path* mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a *Recovery Path* mode.

Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see Figure 77-22).
- Rule 2: If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c (Figure 77-22).
- Rule 3: If transitioning from Do_Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is not 6, or currently in Do Complete Split and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases (Figure 77-22).

77.4.3.12.2.6 Rebalancing the Periodic Schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation. This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction* (*I*) bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then

wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.
- If the *Active* bit is a one and the *SplitXState* is DoStart (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed its final bus-transaction and set *Active* to a zero.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Because the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

1. Set the *Halted* bit to a one, then
2. Set the *I-bit* to a zero, then
3. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

77.4.3.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions.

This data structure uses the scheduling model of isochronous TDs (iTD, Section Isochronous (High-Speed) Transfer Descriptor (iTD)) (see Section Managing Isochronous Transfers Using iTDs for the operational model of iTDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

77.4.3.12.3.1 Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur.

The requirements described in Section Split Transaction Scheduling Mechanisms for Interrupt apply. The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The ^{S}X and ^{C}X labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

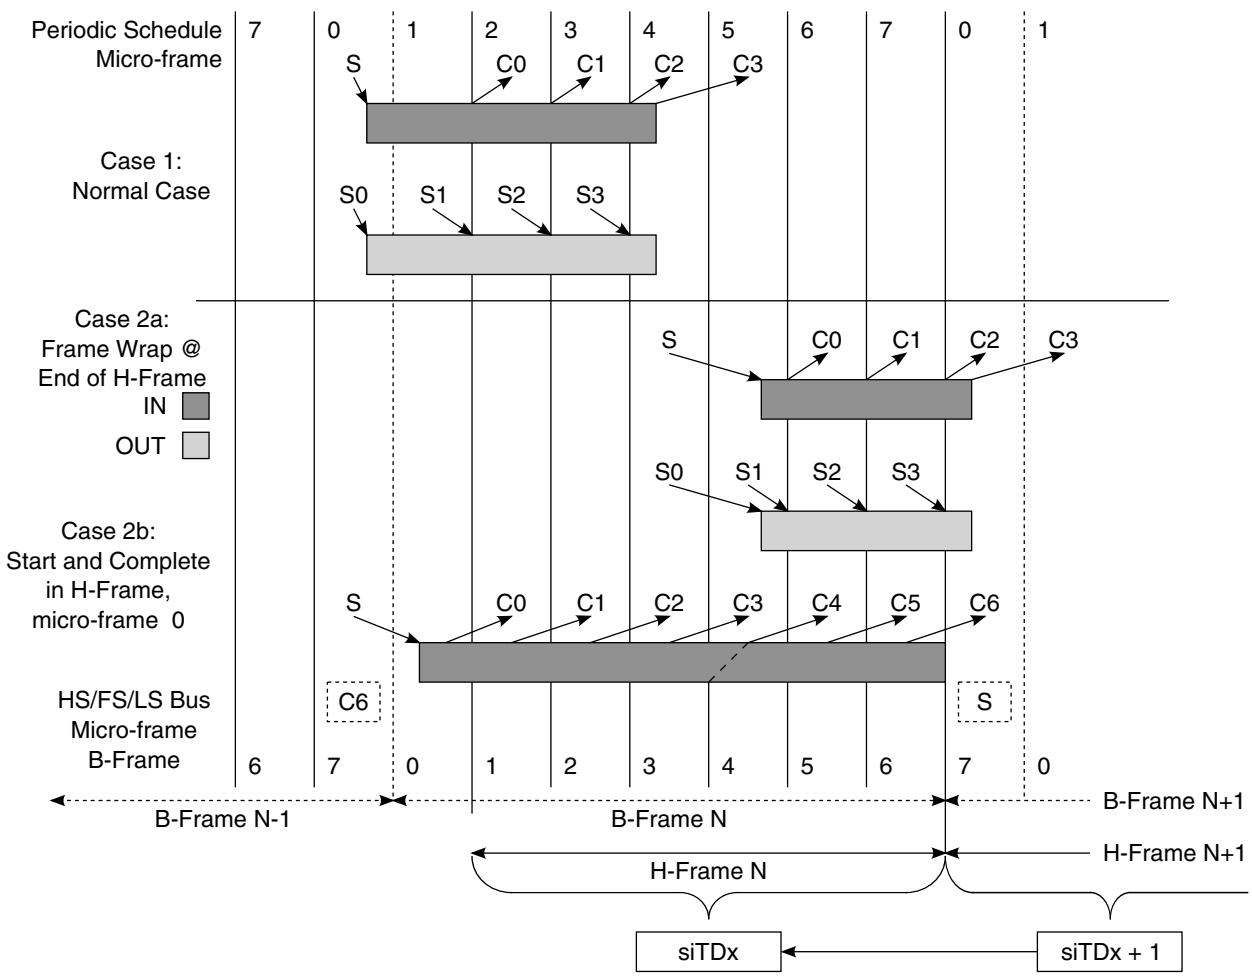

Figure 77-26. Split Transaction, Isochronous Scheduling Boundary Conditions

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to *N* complete-splits. The scheduling boundary cases are:

- *Case 1*: The entire split transaction is completely bounded by an *H-Frame*. For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.
- *Case 2a*: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame,* micro-frames 6 or 7 (*H-Frame* micro-frame 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list.(For example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see Figure 77-27). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in Section Split Transaction Execution State Machine for Interrupt .
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 77-26, case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Start Split, and the current micro-frame as indicated by USB.FRINDEX[2:0] is 0, then execute a start-split transaction.

- *Frame C-mask.* This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 77-26, case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Complete Split, and the current micro-frame as indicated by *USB.FRINDEX*[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.
- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN an OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. The figure below illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

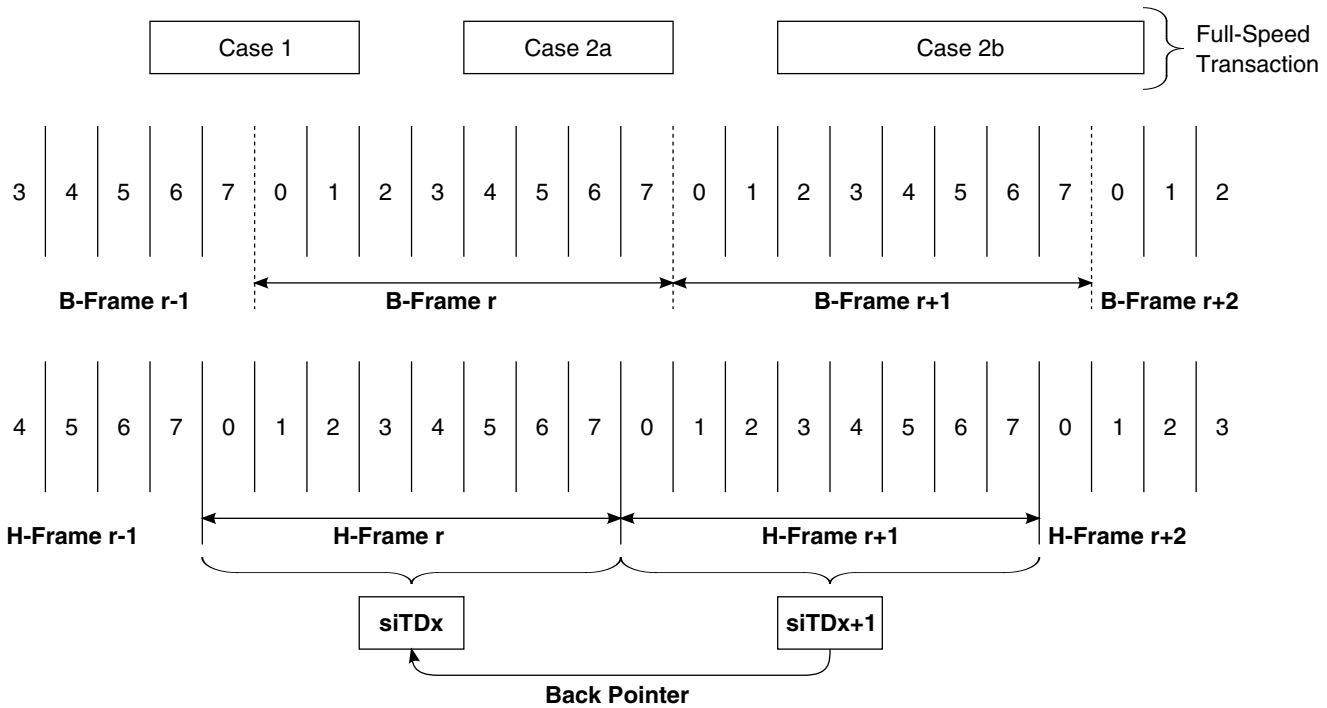

Figure 77-27. siTD Scheduling Boundary Examples

Each case is described below:

- *Case 1*: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.
- *Case 2a, 2b*: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction $siTD_X$ is used to always issue the start-split and the first *N* complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of $H\text{-}Frame_{Y+1}$, or micro-frame 0 of $H\text{-}Frame_{Y+2}$. The complete splits are scheduled using $siTD_{X+2}$ (not shown). The complete-splits to extract this data must use the buffer pointer from $siTD_{X+1}$. The only way for the host controller to reach $siTD_{X+1}$ from $H\text{-}Frame_{Y+2}$is to use $siTD_{X+2}$'s back pointer. The host controller rules for when to use the back pointer are described is Section Periodic Isochronous - Do Complete Split .

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, micro-frame 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of *H-Frame* N and the last complete-split would need to occur in micro-frame 1 of H-Frame N+1. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

77.4.3.12.3.2 Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction N are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields *Transaction Position* (*TP*) and *Transaction Count* (*T-count*). If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section Periodic Isochronous - Do Start Split for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction

isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the micro-frame (USB.FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section Asynchronous - Do Complete Split for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the

remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement its *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

77.4.3.12.3.3 Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section Tracking Split Transaction Progress for Interrupt Transfers , plus the variable *cMicroFrameBit* defined in Section Split Transaction Execution State Machine for Interrupt to track the progress of an isochronous split transaction. The figure below illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

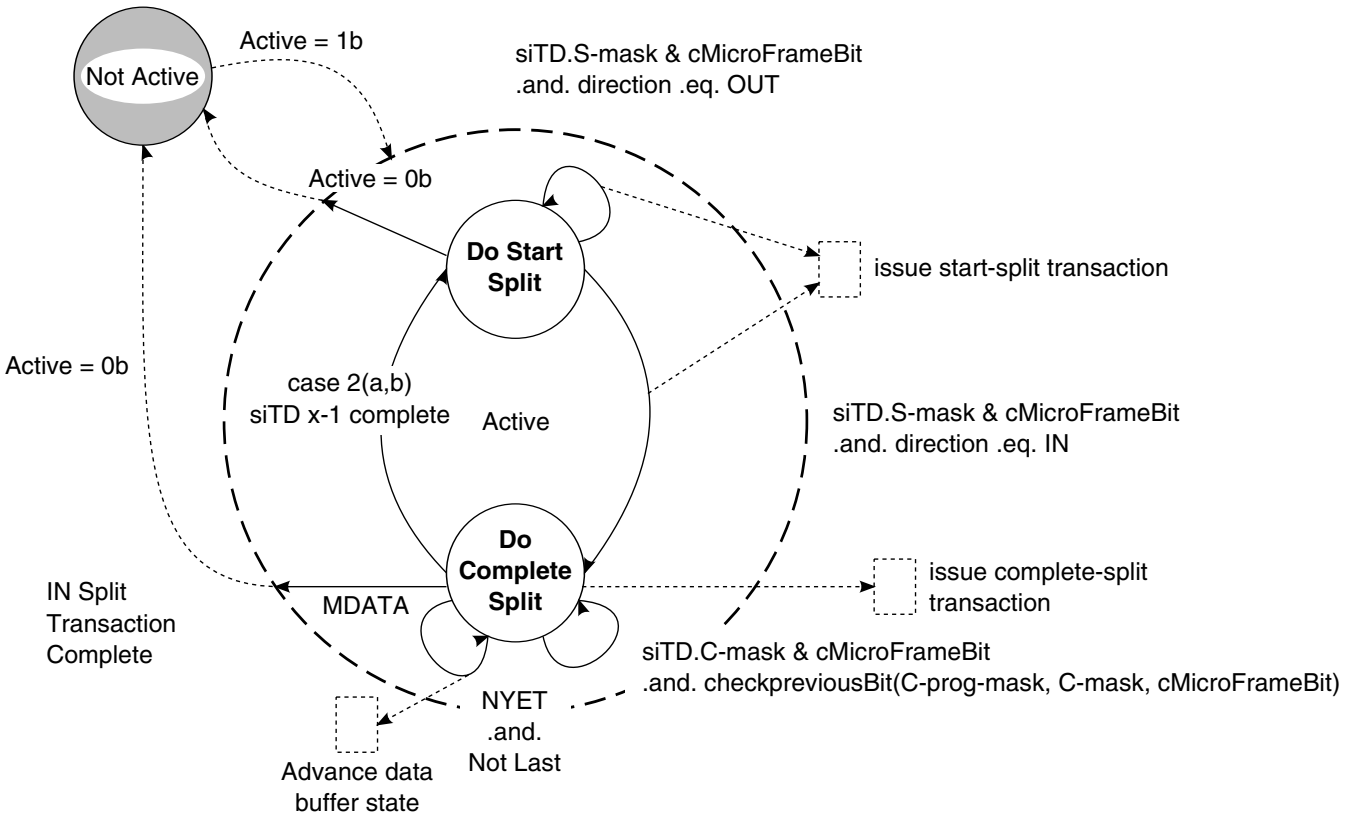

Figure 77-28. Split Transaction State Machine for Isochronous

77.4.3.12.3.4 Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state. An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from Do Complete Split when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the siTD will execute a start-split transaction. By definition, the host controller cannot *reach* an siTD at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory buffer address for the data payload is constructed by concatenating *siTD.Current Offset*

with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

T-Count is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see Figure 77-27) is used to determine the initial value of *TP*. The initial cases are summarized in the following table.

Table 77-48. Initial Conditions for OUT siTD's TP and T-count Fields

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated.

The table below illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

.

Table 77-49. Transaction Position (TP)/Transaction Count (T-Count) Transition Table

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when *T-count* starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when *T-count* starts at greater than 2.
MID	!=1	MID	*TP* stays at MID while *T-count* is not equal to 1 (that is, greater than 1). This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in Table 77-49.

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count* and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in Section Split Transaction for Isochronous - Processing Examples .

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit*() algorithm defined in Periodic Isochronous - Do Complete Split can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

77.4.3.12.3.5 Periodic Isochronous - Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint. This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint.

Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- Test B. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section Periodic Isochronous - Do Complete Split). The sequence in which this test is applied depends on the current value of USB.FRINDEX[2:0]. If USB.FRINDEX[2:0] is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

```
Algorithm Boolean CheckPreviousBit(siTD.C-prog-mask, siTD.C-mask, cMicroFrameBit)
Begin
          Boolean rvalue = TRUE;
          previousBit = cMicroFrameBit rotate-right(1)
          -- Bit-wise anding previousBit with C-mask indicates whether there was an intent
          -- to send a complete split in the previous micro-frame. So, if the
          -- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
          -- happened.
          if previousBit bitAND siTD.C-mask then
                    if not (previousBit bitAND siTD.C-prog-mask) then
                              rvalue = FALSE
                    End if
          End if
          Return rvalue
End Algorithm
```

If Test A is true and USB.FRINDEX[2:0] is zero or one, then this is a case 2a or 2b scheduling boundary (see Figure 77-26). See Section Periodic Isochronous - Do Complete Split for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer,*
- Adjust *siTD.Current Offset* by the number of bytes received,

- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives and MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, etc. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the *Active* bit is set to zero.
- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section Periodic Isochronous - Do Complete Split . If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled clompete-splits with NYETs

meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.

- MDATA (and Last). See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-mask*s incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- MDATA (and not Last). The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame X to X+1 and during micro-frame X, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the *Active* bit to a zero.

77.4.3.12.3.6 Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see Figure 77-26) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. The table below enumerates the transaction state fields.

Table 77-50. Summary siTD Split Transaction State

Buffer State	Status	Execution Progress
Total Bytes To Transfer P (page select) Current Offset TP (transaction position) T-count (transaction count)	All bits in the status field	C-prog-mask

NOTE

TP and *T-count* are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the *siTD.Back Pointer* field to reference a valid siTD and will have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer*

field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is Do Complete Split.

- When cMicroFrameBit is a 1h and the siTDX.Back Pointer.T-bit is a zero, or
- If cMicroFrameBit is a 2h and siTDX.S-mask[0] is a zero

When either of these conditions apply, then the host controller must use the transaction state from $siTD_{X-1}$.

In order to access $siTD_{X-1}$, the host controller reads on-chip the siTD referenced from $siTD_X$.*Back Pointer*.

The host controller must save the entire state from $siTD_X$ while processing $siTD_{X-1}$. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers*.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see Table 77-50) of $siTD_{X-1}$ is appropriately advanced based on the results and written back to memory. If the resultant state of $siTD_{X-1}$'s *Active* bit is a one, then the host controller returns to the context of $siTD_X$, and follows its next pointer to the next schedule item. No updates to $siTD_X$ are necessary.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is Do Start Split), then the host controller must set *Active* bit to a zero and *Missed Micro-Frame* status bit to a one and the resultant status written back to memory.

If $siTD_{X-1}$*'sActive* bit is a zero, (because it was zero when the host controller first visited $siTD_{X-1}$ via $siTD_X$*'s* back pointer, it transitioned to zero as a result of a detected error, or the results of $siTD_{X-1}$*'s* complete-split transaction transitioned it to zero), then the host controller returns to the context of $siTD_X$ and transitions its *SplitXState* to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if *cMicroframeBit* is a 1b and $siTD_X$.*S-mask*[0] is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of $siTD_X$, then follows $siTD_X$.*Next Pointer* to the next schedule item. If the criterion is not met, the host controller simply follows $siTD_X$.*Next Pointer* to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of $siTD_{X-1}$ will have its *Active* bit set to zero when the host controller returns

to the context of $siTD_X$. Also, note that software should not initialize an siTD with *C-mask* bits 0 and 1 set to a one and an *S-mask* with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

77.4.3.12.3.7 Split Transaction for Isochronous - Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines. The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the Execute Transaction queue head traversal state machine (see Figure 77-19).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, the table below illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

Table 77-51. Example Case 2a - Software Scheduling siTDs for an IN Endpoint

siTDX		Micro-Frames								Initial
#	Masks	0	1	2	3	4	5	6	7	SplitXState
X	S-Mask	-	-	-	-	1	-	-	-	Do Start Split
	C-Mask	1	1	-	-	-	-	1	1	
X+1	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Because this is the case-2a frame-wrap case, *S-masks* of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and *C-mask* value of C3h (one-bits in micro-frames 0,1, 6 and 7). Additionally, sofware ensures that the *Back Pointer* field of each siTD references the appropriate siTD data structure (and the *Back PointerT-bits* are set to zero).

The initial *SplitXState* of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is Do Start Split. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to Do Complete Split. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has its *SplitXState* initialized to Do Complete Split. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, micro-frame 0, the host controller detects that $siTD_{X+1}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+1}$ and fetches $siTD_X$. It executes the complete split transaction using the transaction state of $siTD_X$. If the $siTD_X$ split transaction is complete, siTD's *Active* bit is set to zero and results written back to $siTD_X$. The host controller retains the fact that $siTD_X$ is retired and transitions the *SplitXState* in the $siTD_{X+1}$ to Do Start Split. At this point, the host controller is prepared to execute the start-split for $siTD_{X+1}$ when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section Periodic Isochronous - Do Complete Split), that is, before all the scheduled complete-splits have been executed, the host controller will transition $siTD_X$.*SplitXState* to Do Start Split early and naturally skip the remaining scheduled complete-split transactions. For this example, $siTD_{X+1}$ does not receive a DATA0 response until *H-Frame* X+2, micro-frame 1.

During *H-Frame X+2,* micro-frame 0, the host controller detects that $siTD_{X+2}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the *Active* bit. The host controller returns to the context of $siTD_{X+2}$, and traverses its next pointer without any state change updates to $siTD_{X+2}$. S

During *H-Frame X+2*, micro-frame 1, the host controller detects $siTD_{X+2}$'s *S-mask[0]* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of $siTD_{X+2}$ and changes its *SplitXState* to Do Start Split. At this point, the host controller is prepared to execute start-splits for $siTD_{X+2}$ when it

reaches micro-frame 4. <TBD… describe how software detects that there was missing micro-frames (don't think we care about missing out micro-frames. There is enough residual state to identify than not all transactions were executed.).

77.4.3.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports.

When the schedules are enabled, the EHCI host controller will access the schedules in main memory each micro-frame. This constant pinging of main memory is known to create ARM platform power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the ARM platform, based on recent history usage. In the more aggressive power saving modes, the ARM platform can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the ARM platform power management software can detect this activity over time and inhibit the transition of the ARM platform into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they access their memory-based schedules keeps the ARM platform power management software from placing the ARM platform into its lowest power savings state.

USB Host controllers don't access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the ARM platform power management to get the ARM platform into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the ARM platform to reach its low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the ARM platform will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing its shared memory based data structures (schedule lists or otherwise).

77.4.3.14 Port Test Modes -Host Operational Model

EHCI host controllers must implement the port test modes Test J_State, Test K_State, Test_Packet, Test Force_Enable, and Test SE0_NAK as described in the USB Specification Revision 2.0. The system is only allowed to test ports that are owned by the EHCI controller (for example, *CF-bit* is a one and *PortOwner* bit is a zero).

System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the *CF-bit* in the USB.CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate USB.PORTSC register to a one.
- Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
- Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test_Force_Enable, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting *HCReset* to a one.

77.4.3.15 Interrupts-Host Operational Model

The EHCI Host Controller hardware provides interrupt capability based on a number of sources.

There are several general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions),
- Host controller events (Port change events, etc.), and
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR, see Section Interrupt Enable Register (USB__USBINTR)). Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight micro-frames. This means that the host controller will not generate interrupts any more frequently than once every eight micro-frames.

Section Host System Error details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, ARM platform control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to reads the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINR register, see Section Interrupt Enable Register (USB__USBINTR)) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register (Section USB Status Register (USB__USBSTS)) from a one to a zero.

77.4.3.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

77.4.3.15.1.1 Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully.

The table below lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

Table 77-52. Summary of Transaction Errors

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1[1]
Timeout	-1	XactErr set to a one.	1[1]
Bad PID[2]	-1	XactErr set to a one.	1[1]
Babble	N/A	Section Serial Bus Babble	1
Buffer Error	N/A	Section Data Buffer Error	

1. If occurs in a queue head, then *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted, see Halting a Queue Head .
2. The host controller received a response from the device, but it could not recognize the PID as a valid PID.

77.4.3.15.1.2 Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*.

When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see Halting a Queue Head). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the USB.USBSTS register is set to a one and if the *USB Error Interrupt Enable* bit in the USB.USBINTR register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

NOTE

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

77.4.3.15.1.3 Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction. This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements.

These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

77.4.3.15.1.4 USB Interrupt (Interrupt on Completion (IOC))

Transfer Descriptors (iTDs, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USB.USBSTS register to be set to a one.

In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USB.USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USB.USBSTS register is also set to a one.

77.4.3.15.1.5 Short Packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USB.USBSTS register is set to a one.

If the *USB Interrupt Enable* bit is set in the USB.USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

77.4.3.15.2 Host Controller Event Interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section Interrupt on Async Advance).

77.4.3.15.2.1 Port Change Events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one.

If the *Port Change Interrupt Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

77.4.3.15.2.2 Frame List Rollover

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs.

If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USB.USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USB.USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

77.4.3.15.2.3 Interrupt on Async Advance

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USB.USBCMD register.

If it is a one, it sets the *Interrupt on Async Advance* bit in the USB.USBSTS register to a one. If the *Interrupton Async Advance Enable* bit in the USB.USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section Removing Queue Heads from Asynchronous Schedule .

77.4.3.15.2.4 Host System Error

The host controller is a bus master and any interaction between the host controller and the system may experience errors. The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to continue in a coherent fashion.

In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USB.USBCMD register is set to a zero.
- The following bits in the USB.USBSTS register are set:
  - *Host System Error* bit is to a one.
  - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. The following table summarizes the required actions taken on the various host errors.

Table 77-53. Summary Behavior of EHCI Host Controller on Host System Errors

Cycle Type	Master Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]
iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

NOTE

After a *Host System Error*, Software must reset the host controller through *HCReset* in the USB.USBCMD register before re-initializing and restarting the host controller.

77.4.4 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specificationEnhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com. Device operation & On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is proprietary. The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

77.4.4.1 Embedded Transaction Translator Function

The USB-HS OTG High-Speed USB On-The-Go OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

77.4.4.1.1 Capability Registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N_TT added to USB.HCSPARAMS - Host Control Structural Parameters
- N_PTT added to USB.HCSPARAMS - Host Control Structural Parameters

77.4.4.1.2 Operational Registers

The following additions have been added to the operational registers to support the embedded TT:

- is a new register.
- Addition of two-bit Port Speed (PSPD) to the Port Status & Control (USB__PORTSC1) register.

77.4.4.1.3 Discovery-EHCI Deviation

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation.

The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in the following table.

Table 77-54. Summary of EHCI

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (ie. Split target hub)]	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (ie. Split target hub is the root hub)]

77.4.4.1.4 Data Structures

The same data structures used for FS/LS transactions though a HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator.

Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) - Async. (Bulk/Control Endpoints) Periodic (Interrupt)
   - Hub Address = 0
   - Transactions to direct attached device/hub.
     - QH.EPS = Port Speed
   - Transactions to a device downstream from direct attached FS hub.
     - QH.EPS = Downstream Device Speed

NOTE

When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

Maximum Packet Size must be less than or equal 64 or undefined behaviour may result.

2. siTD (for direct attach FS) - Periodic (ISO Endpoint)
   - All FS ISO transactions:
     - Hub Address = 0
     - siTD.EPS = 00 (full speed)
       - Maximum Packet Size must less than or equal to 1023 or undefined behaviour may result.

77.4.4.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specificationUniversal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

77.4.4.1.5.1 Micro- frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

77.4.4.1.5.2 Split State Machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator.

Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. The following table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 77-55. Summary of the Conditons of Handshakes[1]

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET

Table continues on the next page...

Table 77-55. Summary of the Conditons of Handshakes[1] (continued)

Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

1. The un-shaded cells represent Start-Splits and the shaded cells represent Complete-Splits

77.4.4.1.5.3 Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

77.4.4.1.5.4 USB 2.0 - 11.17.3

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

77.4.4.1.5.5 USB 2.0 - 11.17.4

- Transaction tracking for 2 data pipes.

77.4.4.1.5.6 Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

77.4.4.1.5.7 USB 2.0 - 11.18.6.[1-2]

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 micro-frames

77.4.4.1.5.8 USB 2.0 - 11.18.[7-8]

- Transaction tracking for up to 16 data pipes.
- Some applications may not require transaction tracking up to a maximum of 16 periodic data pipes. The option to limit the tracking to only 4 periodic data pipes exists in the by changing the configuration constant VUSB_HS_TT_PERIODIC_CONTEXTS to 4. The result is a significant gate count savings to the core given the limitations implied.

NOTE

Limiting the number of tracking pipes in the EMBedded -TT to four (4) will impose the restriction that no more than 4 pe

transactions (INTERRUPT/ISOCHRONOUS) can be scheduled through the embedded-tt per frame. the number 16 was chosen in the USB specification because it is sufficient to ensure that the high-speed to full-speed periodic pipeline can remain full. keeping the pipeline full puts no constraint on the number of periodic transactions that can be scheduled in a frame and the only limit becomes the flight time of the packets on the bus.

- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

77.4.4.1.5.9 Multiple Transaction Translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N_TT field in the Host Controller Structural Parameters (USB__HCSPARAMS) register.

77.4.4.2 Device Operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

77.4.4.3 USB.USBMODE Register

Given that the dual-role controller is initialized in neither host nor device mode, the USB Device Mode (USB__USBMODE) register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

77.4.4.3.1 Non-Zero Fields the Register File

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode .

77.4.4.3.2 SOF Interrupt

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode.

EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See USB Status Register (USB__USBSTS) and Interrupt Enable Register (USB__USBINTR) registers.

77.4.4.4 Embedded Design Interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

77.4.4.4.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 Mhz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

77.4.4.5 Miscellaneous variations from EHCI

77.4.4.5.1 Programmable Physical Interface Behaviour

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes.

Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase.

The control bits for selecting the Physical Interface operating mode have been added to the Port Status & Control (USB__PORTSC1) register providing a capability that is not defined by EHCI.

77.4.4.5.2 Discovery

77.4.4.5.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the Port Status & Control (USB__PORTSC1) register for a duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to the reset the device.
- Software shall write a '0' to the reset the device after 10 ms.
  - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device in now operational and at this point the port speed has been determined.

77.4.4.5.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices.

Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - *This information is redundant with the 2-bit Port Speed indicator above.*

77.4.4.5.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI since the release of revision 3.2.1. In earlier product revisions, the test packet mode was not EHCI compatible. An alternate host controller driver procedure is no longer necessary or supported.

77.4.5 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller.

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writable fields. The device controller must preserve the read-only fields on all data structure writes.

The USB-HS OTG High-Speed USB On-The-Go core includes DCD Software called the USB 2.0 Device API. The Device API provides an easy to use Application Program Interface for developing device (peripheral) applications using the USB-HS OTG High-Speed USB On-The-Go core. The Device API incorporates and abstracts for the application developer all of the elements of the program interface.

The figure below shows the organization of the End Point Queue Head.

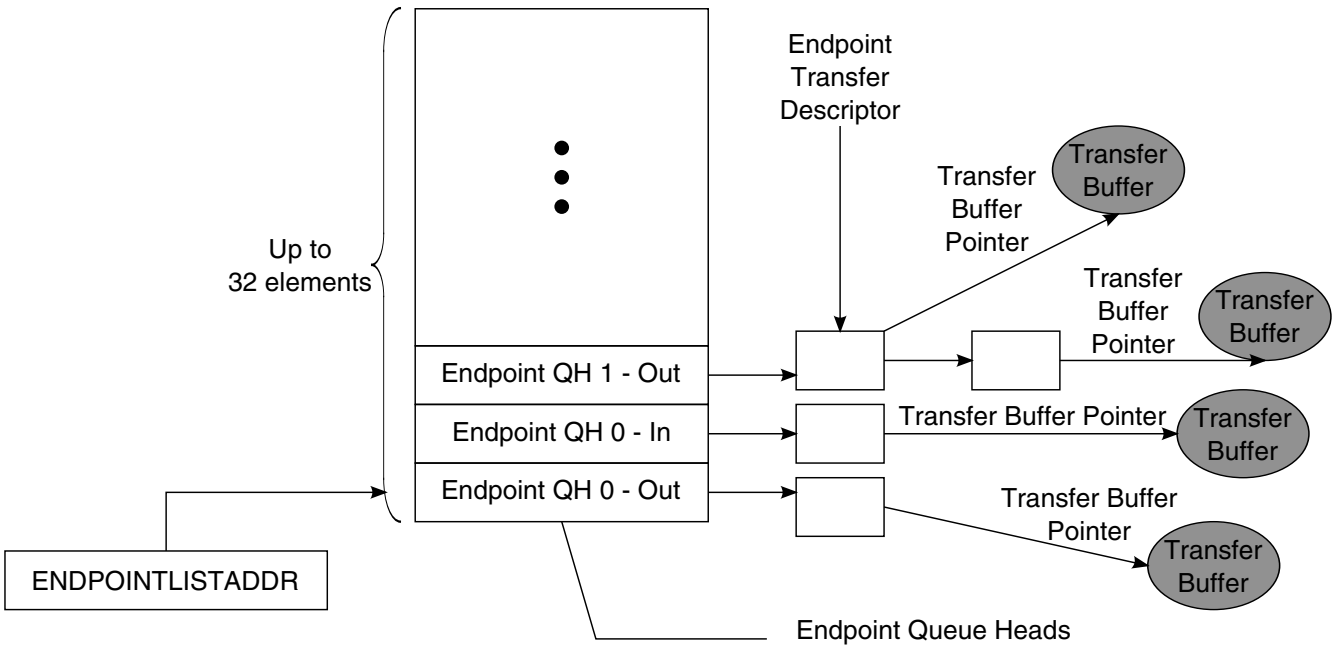

Figure 77-29. End Point Queue Head Organization

Device queue heads are arranged in an array in a continuous area of memory pointed to by the USB.ENDPOINTLISTADDR pointer. The even -numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

NOTE

The Endpoint Queue Head List must be aligned to a 2k boundary.

77.4.5.1 Endpoint Queue Head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD

status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

Table 77-56. Endpoint Queue Head (dQH)

77.4.5.1.1 Endpoint Capabilities/Characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

Table 77-57 describes the endpoint capabilities.

Table 77-57. Endpoint Capabilities/Characteristics

Bit	Description

Table continues on the next page...

Table 77-57. Endpoint Capabilities/Characteristics (continued)

31-30	Mult. This field is used to indicate the number of packets executed per transaction description as given by the following: 00 - Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD) 01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions. **NOTE:** Non-ISO endpoints must set Mult="00". ISO endpoints must set Mult="01", "10", or "11" as needed.
29	Zero Length Termination Select. This bit is used to indicate when a zero length packet is used to terminate transfers where to total transfer length is a multiple . This bit is not relevant for Isochronous 0 - Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default). 1 - Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28-27	Reserved. These bit reserved for future use and should be set to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	Interrupt On Setup (IOS). This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14-0	Reserved. Bits reserved for future use and should be set to zero.

77.4.5.1.2 Transfer Overlay-Endpoint Queue Head

The seven DWords in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

77.4.5.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

The following table describes the dTD Pointer.

Table 77-58. Next dTD Pointer

Bit	Description
31-5	Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved. Bit reserved for future use and should be set to zero.

77.4.5.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

The following table describes the Multiple Mode Control.

Table 77-59. Multiple Mode Control (HCCPARAMS)

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

77.4.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/ received for given transfer.

The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in section Managing Transfers with Transfer Descriptors.

Table below shows the Endpoint Transfer Descriptor (dTD).

Table 77-60. Endpoint Transfer Descriptor (dTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Next Link Pointer																											0				T	
0	Total Bytes															ioc	0			MultO		0		Status								

Table continues on the next page...

Buffer Pointer (Page 0)	Current Offset	
Buffer Pointer (Page 1)	0 Frame Number	
Buffer Pointer (Page 2)	-	
Buffer Pointer (Page 3)	-	
Buffer Pointer (Page 4)	Reserved	

	Device Controller Read/Write		Device Controller Read Only.

The following table describes the dTD Pointer.

Table 77-61. Next dTD Pointer

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved. Bits reserved for future use and should be set to zero.
0	Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

The following table describes the dTD Token.

Table 77-62. dTD Token

Bit	Description
31	Reserved. Bit reserved for future use and should be set to zero.
30-16	Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction. The maximum value software may store in the field is 5*4K(5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K(4000H). If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of *Maximum Packet Length*. If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less that *Maximum Packet Length*.
15	Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14-12	Reserved. Bits reserved for future use and should be set to zero.

Table continues on the next page...

Table 77-62. dTD Token (continued)

11-10	Multiplier Override (MultO). This field can be used for transmit ISO's (ie. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO. Example: if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default] Three packets are sent: {Data2(8); Data1(7); Data0(0)} if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2 Two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, software should compute MultO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultO should be 1. Note: Non-ISO and Non-TX endpoints must set MultO="00".
9-8	Reserved. Bits reserved for future use and should be set to zero.
7-0	Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are: Bit Status Field Description 7 Active. 6 Halted. 5 Data Buffer Error. 3 Transaction Error. 4,2,0 Reserved.

The table below describes the dTD Buffer Page Pointer List.

Table 77-63. dTD Buffer Page Pointer List

Bit	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0,11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.
1,10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

77.4.6 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus.

Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

77.4.6.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs.

Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

1. Set Controller Mode in the USB.USBMODE register to device mode.
2. Allocate and Initialize device queue heads in system memory.

NOTE

Transitioning from host mode to device mode requires a device controller reset before modifying USB.USBMODE.

- Minimum: Initialize device queue heads 0 Tx & 0 Rx.
- For information on device queue heads, refer to section Device Data Structures.

NOTE

All device queue heads must be initialized for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

3. Configure USB.ENDPOINTLISTADDR Pointer.
   - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
4. Enable the microprocessor interrupt associated with the USB-HS OTG High-Speed USB On-The-Go core.
   - Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
   - For a list of available interrupts refer to the Interrupt Enable Register (USB__USBINTR) and the USB Status Register (USB__USBSTS) register tables.
5. Set Run/Stop bit to Run Mode.
   - After the Run bit is set, a device reset will occur. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the following Port State and Control section below.

NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to initially prime Endpoint 0 because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

77.4.6.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'.

After receiving a reset on the bus, the port will enter the *defaultFS or defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0.

The following state diagram depicts the state of a USB 2.0 device.

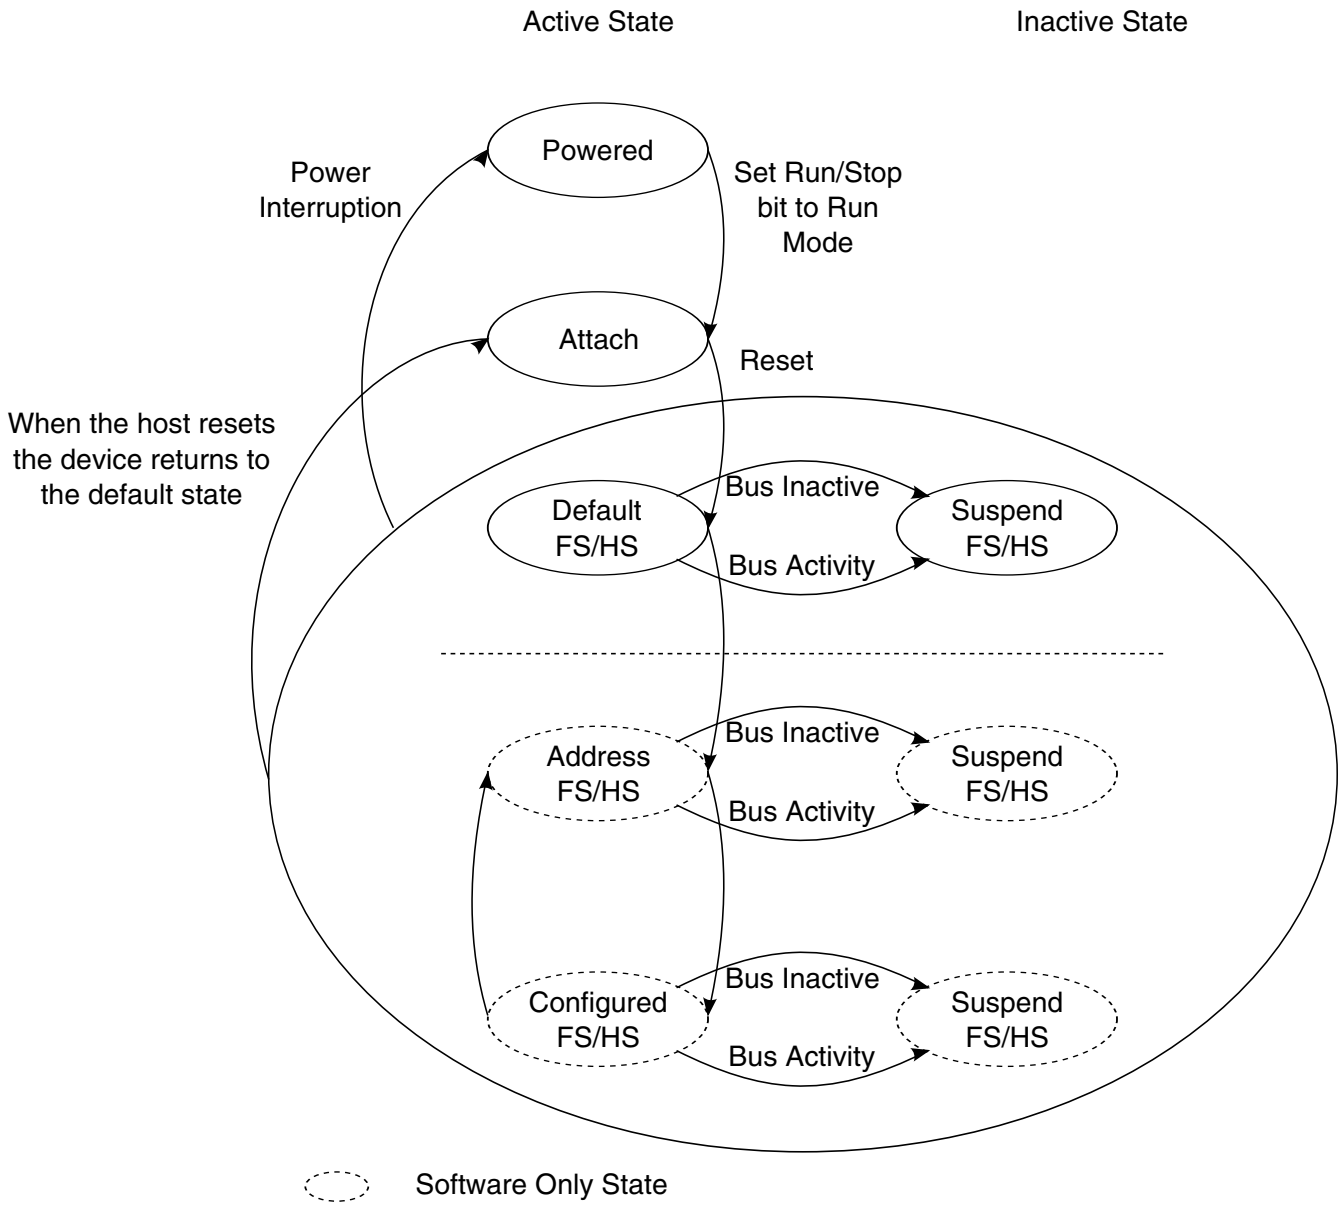

Figure 77-30. Device State Diagram

States *powered, attach, defaultFS/HS, suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

The following table describes the Device Controller State Information Bits.

Table 77-64. Device Controller State Information Bits

Bit	Register
DCSuspend	USB Status Register (USB__USBSTS)
USB Reset Received	USBSTS

Table continues on the next page...

Table 77-64. Device Controller State Information Bits (continued)

Port Change Detect	USBSTS
High-Speed Port	Port Status & Control (USB__PORTSC1)

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the ENDPTCTRLx registers and initializing the associated queue heads.

77.4.6.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices.

When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the Endpoint Status (USB_UOG_ENDPTSTAT) register and writing the same value back to the Endpoint Status (USB_UOG_ENDPTSTAT) register.

Clear all the endpoint complete status bits by reading the Endpoint Complete (USB_UOG_ENDPTCOMPLETE) register and writing the same value back to the Endpoint Complete (USB_UOG_ENDPTCOMPLETE) register.

Cancel all primed status by waiting until all bits in the Endpoint Initialization (USB_UOG_ENDPTPRIME) are 0 and then writing 0xFFFFFFFF to Endpoint De-Initialize (USB_UOG_ENDPTFLUSH).

Read the reset bit in the Port Status & Control (USB__PORTSC1) register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the Port Status & Control (USB__PORTSC1) to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

77.4.6.2.2 Suspend/Resume

77.4.6.2.2.1 Suspend

Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the Port Status & Control (USB__PORTSC1) is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

NOTE

Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

77.4.6.2.2.2 Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port.

Resume signaling is sent upstream by writing a '1' to the Resume bit in the in the Port Status & Control (USB__PORTSC1) while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

NOTE

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

77.4.6.2.2.3 Port Test Modes

Contact ARC International for port test mode capabilities.

77.4.6.2.3 Managing Endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk, interrupt*, and *isochronous*. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The USB-HS OTG High-Speed USB On-The-Go device controller hardware supports up to the USB 2.0 maximum of 32 endpoint specified numbers. Each additional endpoint beyond the required endpoint position adds additional hardware logic. The maximum number of endpoint numbers available to the DCD is configured at hardware synthesis timer. After synthesis, the DCD can enable, disable and configure endpoint type up to the maximum selected during synthesis.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. If the maximum of 16 endpoint numbers, one for each endpoint direction are being used by the device controller, then 32 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

77.4.6.2.4 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the ENDPTCTRLx register.

Each 32-bit ENDPTCTRLx is split into an upper and lower half. The lower half of ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the ENDPTCTRLx

register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. The following table shows the fields and values for the Device Controller Endpoint initialization.

Table 77-65. Device Controller Endpoint Initialization

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk 11 Interrupt
Endpoint Stall	0

77.4.6.2.5 Stalling

There are two occasions where the device controller may need to return to the host a STALL.

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

NOTE

Any write to the ENDPTCTRLx register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

The following table shows the response matrix for the Device Controller Stall.

Table 77-66. Device Controller Stall Response Matrix

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response

Table continues on the next page...

Table 77-66. Device Controller Stall Response Matrix (continued)

SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL
IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET

77.4.6.2.6 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe.

For more information on data toggle, refer to the USB 2.0 specification.

77.4.6.2.6.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the ENDPTCTRLx register.

This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

77.4.6.2.6.2 Data Toggle Inhibit

NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

77.4.6.2.6.3 Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH).

After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the USB.ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section .

77.4.6.2.6.4 Priming Receive Endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

77.4.6.3 Operational Model For Packet Transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification.

At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

77.4.6.3.1 Interrupt/Bulk Endpoint Operational Model

The behaviors of the device controller for interrupt and bulk endpoints are identical. All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

N = INT(Number Of Bytes/Max. Packet Length) + 1

With Zero Length Termination (ZLT) = 1

N = MAXINT(Number Of Bytes/Max. Packet Length)

Table 77-67. Variable Length Transfer Protocol Example (ZLT = 0)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	3	256	256	0
512	512	2	512	0	

Table 77-68. Variable Length Transfer Protocol Example (ZLT = 1)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

NOTE

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. *** Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. *** Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. *** This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). *** This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

NOTE

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

77.4.6.3.1.1 Interrupt/Bulk Endpoint Bus Response Matrix

The table below shows the response matrix for Interrput/Bulk Endpoint Bus.

Table 77-69. Interrupt/Bulk Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

NOTE

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

77.4.6.3.2 Control Endpoint Operation Model

77.4.6.3.2.1 Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

In hardware versions 2.3 and later, the setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted be an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

Setup Packet Handling (Pre-2.3 hardware)

- After receiving an interrupt and inspecting USB Device Mode (USB__USBMODE) to determine that a setup packet was received on a particular pipe:

1. Duplicate contents of dQH.SsetupBuffer into local software byte array.
2. Write '1' to clear corresponding Endpoint Setup Status (USB_UOG_ENDPTSETUPSTAT) bit and thereby disabling Setup Lockout. (That is, the Setup Lockout activates as soon as a setup arrives. By writing to the Endpoint Setup Status (USB_UOG_ENDPTSETUPSTAT), the device controller will accept new setup packets.)
3. Process setup packet using local software byte array copy and execute status/ handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

NOTE

To limit the exposure of setup packets to the setup lockout mechanism (if used), the DCD should designate the priority of responding to setup packets above responding to other packet completions.

Setup Packet Handling (2.3 hardware and later)

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in USB Device Mode (USB__USBMODE). (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

NOTE

Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting Endpoint Setup Status (USB_UOG_ENDPTSETUPSTAT) to determine that a setup packet was received on a particular pipe:
  a. Write 1 to clear corresponding bit Endpoint Setup Status (USB_UOG_ENDPTSETUPSTAT).
  b. Write 1 to Setup Tripwire (SUTW) in USB Command Register (USB__USBCMD) register.
  c. Duplicate contents of dQH.SetupBuffer into local software byte array.
  d. Read Setup TripWire (SUTW) in USB Command Register (USB__USBCMD) register. (if set - continue; if cleared - goto 2)
  e. Write 0 to clear Setup Tripwire (SUTW) in USB Command Register (USB__USBCMD) register.
  f. Process setup packet using local software byte array copy and execute status/ handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

77.4.6.3.2.2 Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the Endpoint Initialization (USB_UOG_ENDPTPRIME) register is zero and the associated bit in the Endpoint Status (USB_UOG_ENDPTSTAT) register is a one. If a prime fails, ie. The Endpoint Initialization (USB_UOG_ENDPTPRIME) bit goes to zero and the Endpoint Status (USB_UOG_ENDPTSTAT) bit is not set, then the prime has failed. This can only

be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status (Endpoint Status (USB_UOG_ENDPTSTAT)) to enforce data coherency with the setup packet.

NOTE

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

77.4.6.3.2.3 Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase.

The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

NOTE

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

77.4.6.3.2.4 Control Endpoint Bus Response Matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

The table below shows the response matrix for the Control Endpoint Bus.

Table 77-70. Control Endpoint Bus Response Matrix

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A
Out	STALL	NAK	Receive + NYET/ ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

77.4.6.3.3 Isochronous Endpoint Operational Model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes.

Real time delivery by the device controller will is accomplished by the following:

- Exactly MULT Packets per (micro)Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets and sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro)frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
  - MULT counter reaches zero.
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT

NOTE

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
  - MULT counter reaches zero.
  - Non-MDATA Data PID is received**
    - ** Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
  - Overflow Error:
    - Packet received is > maximum packet length. [*Buffer Error* bit is set]
    - Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT
  - CRC Error [*Transaction Error* bit is set

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame

operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

77.4.6.3.3.1 Isochronous Pipe Synchronization

When it is necessary to synchronize an isochroous data pipe to the host, the (micro)frame number (USB.FRINDEX register) can be used as a marker.

To cause a packet transfer to occur at a specific (micro)frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB.FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro)frame N-1 so that the device controller will execute delivery during (micro)frame N.

NOTE

Priming an endpoint towards the end of (micro)frame N-1 will not guarantee delivery in (micro)frame N. The delivery may actually occur in (micro)frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

77.4.6.3.3.2 Isochronous Endpoint Bus Response Matrix

The following table shows the response matrix for the Isochronous Endpoint Bus.

Table 77-71. Isochronous Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. BS Error = Force Bit Stuff Error

   NULL Packet = Zero Length Packet

77.4.6.4 Managing Queue Heads

The following figure shows the End Point Queue Head.

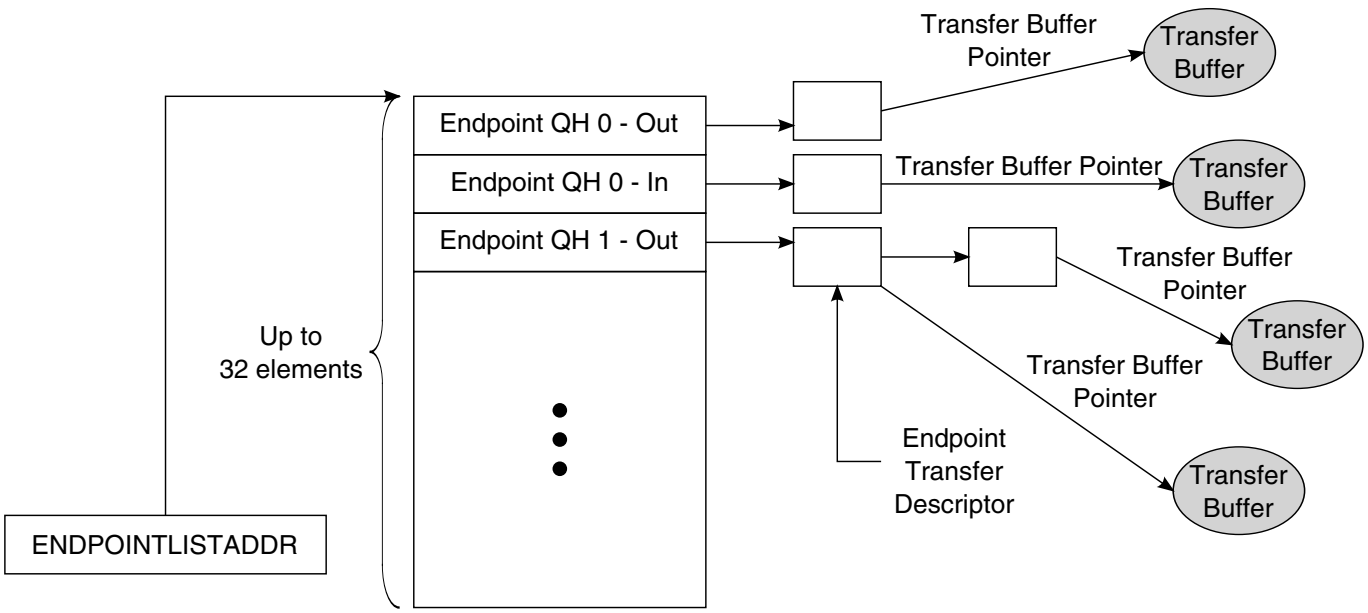

Figure 77-31. End Point Queue Head Diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by USB.ENDPOINTLISTADDR contains a group of all dQH's in a sequential list as shown in Figure 77-31. The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTD is retired (see section Software Link Pointers).

In addition to the current and next pointers and the dTD overlay examined in section Operational Model For Packet Transfers, the dQH also contains the following parameters for the associated endpoint: Multipler, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

77.4.6.4.1 Queue Head Initialization

One pair of device queue heads must be initialized for each active endpoint.

To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1,2, or 3 as required bandwidth an in conjunction with the USB Chapter 9 protocol.

NOTE

In FS mode, the multiplier field can only be 1 for ISO endpoints.

- Write the next dTD Terminate bit field to 1.
- Write the Active bit in the status field to 0.
- Write the Halt bit in the status field to 0.

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTD's.

77.4.6.4.2 Operational Model For Setup Transfers

As discussed in section Control Endpoint Operation Model, setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in ENDPTSETUPSTAT.

NOTE

- The acknowledge must occur before continuing to process the setup packet.
- After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH - RX. Only the local software copy should be examined.

3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in section Flushing/De-priming an Endpoint.
4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

77.4.6.5 Managing Transfers with Transfer Descriptors

77.4.6.5.1 Software Link Pointers

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. The following figure shows the Software Link Pointers.

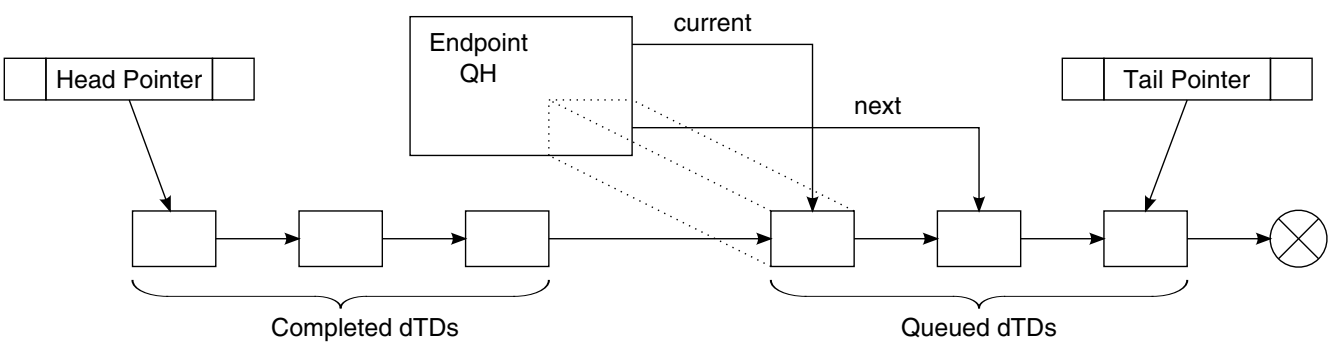

Figure 77-32. Software Link Pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

77.4.6.5.2 Building a Transfer Descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer.

Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

77.4.6.5.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must be follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty:

- Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding)
- Case 1: Link list is empty
  - 1. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
  - 2. Clear active & halt bit in dQH (in case set from a previous error).
  - 3. Prime endpoint by writing 1 to correct bit position in Endpoint Initialization (USB_UOG_ENDPTPRIME).
- Case 2: Link list is not empty
  - 1. Add dTD to end of linked list.
  - 2. Read correct prime bit in Endpoint Initialization (USB_UOG_ENDPTPRIME)- if 1 DONE.
  - 3. Set ATDTW bit in USBCMD register to 1.
  - 4. Read correct status bit in Endpoint Status (USB_UOG_ENDPTSTAT). (store in tmp. variable for later)
  - 5. Read ATDTW bit in USBCMD register.
  - If 0 goto 3.
  - If 1 continue to 6.

- 6. Write ATDTW bit in USBCMD register to 0.
- 7. If status bit read in (3) is 1 DONE.
- 8. If status bit read in (3) is 0 then Goto Case 1: Step 1.

77.4.6.5.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the Device Error Matrix.

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

77.4.6.5.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer. There may also be application specific requirements to stop transfers in progress.

The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in Endpoint De-Initialize (USB_UOG_ENDPTFLUSH).
2. Wait until all bits in Endpoint De-Initialize (USB_UOG_ENDPTFLUSH) are '0'.
   - Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read Endpoint Status (USB_UOG_ENDPTSTAT) to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
   - Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using Endpoint De-Initialize (USB_UOG_ENDPTFLUSH). A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush be repeating steps 1-3 until each endpoint is successfully flushed.

77.4.6.5.6 Device Error Matrix

The following table summarizes packet errors that are not automatically handled by the Device Controller.

Table 77-72. Device Error Matrix

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. The table below describes the errors.

Table 77-73. Error Descriptions

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length.
	** This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.

Table continues on the next page...

Table 77-73. Error Descriptions (continued)

Error	Description
ISO Fulfillment Error	Hst failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

77.4.6.6 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

77.4.6.6.1 High-Frequency Interrupts

High frequency interrupts in particular should be handed in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

The table below describes the High frequency interrupt events.

Table 77-74. High Frequency Interrupt Events

Execution Order	Interrupt	Action
1a	USB Interrupt - USB.ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in Figure 77-31 shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt[1] - USB.ENDPTCOMPLETE	Handle completion of dTD as indicated in Figure 77-31 shows the End Point Queue Head.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

77.4.6.6.2 Low-Frequency Interrupts

The low frequency events include the following interrupts. These interrupt can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

The table below shows the Low frequency interrupt events.

Table 77-75. Low Frequency Interrupt Events

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

77.4.6.6.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

The following table shows the error interrput events

.

Table 77-76. Error Interrupt Events

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

77.5 USB Non-Core Memory Map/Register Definition

There are two kinds of registers in the USB module: USB core registers and USB non-core registers.

USB core registers are used to control USB core functions, and more independent of USB features. Each USB controller core has its own core registers.

USB non-core registera are additional to USB core registers, and more dependent on USB features. Therefore, these registers could be very different in different i.MX products.

This section describes only the USB non-core registers. For detailed descriptions of USB core registers, please refer to Register Interface .

NOTE

For reserved bits, please preserve the value when writing (read its reset value, then write this value back).

"USB_UOG_", "USB_UH1_", "USB_UH2_", "USB_UH3_" prefix in register name indicates it is a core register for OTG/ Host1/Host2/Host3 controller core respectively.

"USB_USB_" prefix in register name indicates it is a USB non-core register.

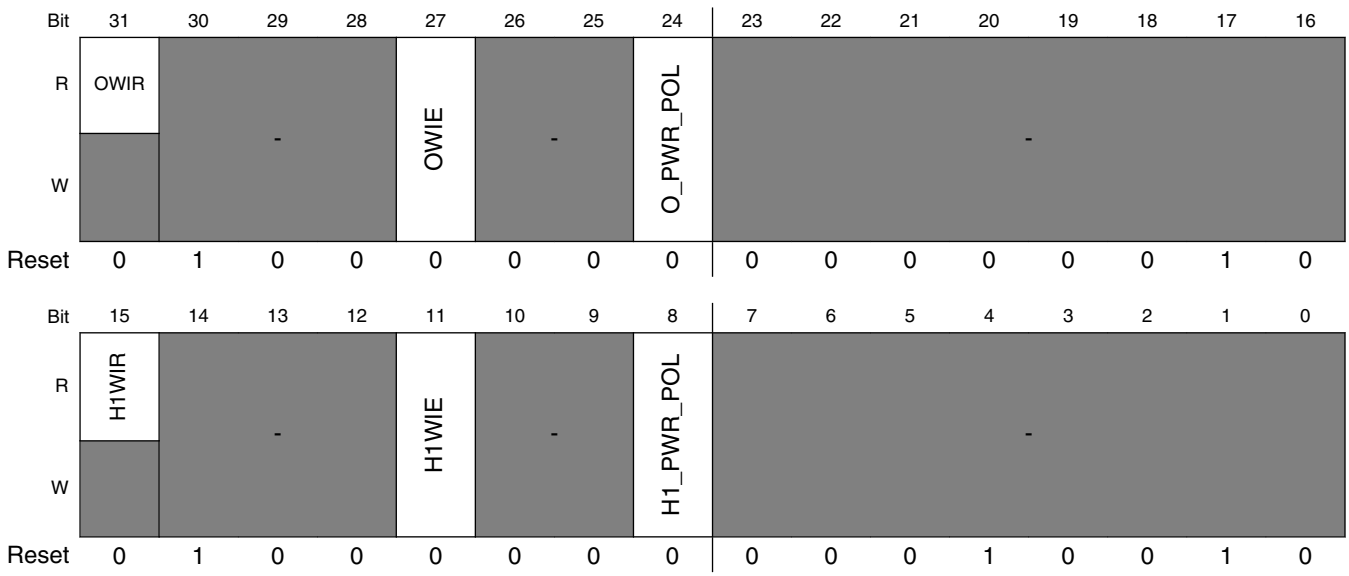
USB memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53F8_0800	USB Control Register 0 (USB_USB_CTRL_0)	32	R/W	4002_4012h	77.5.1/ 4881
53F8_0808	USB OTG UTMI PHY Control Register 0 (USB_USB_OTG_PHY_CTRL_0)	32	R/W	8000_1400h	77.5.2/ 4883
53F8_080C	USB OTG UTMI PHY Control Register 1 (USB_USB_OTG_PHY_CTRL_1)	32	R/W	0054_1402h	77.5.3/ 4885
53F8_0810	USB Control Register 1 (USB_USB_CTRL_1)	32	R/W	0000_0000h	77.5.4/ 4888
53F8_0814	USB Host2 Control Register (USB_USB_UH2_CTRL)	32	R/W	0000_1402h	77.5.5/ 4890
53F8_0818	USB Host3 Control Register (USB_USB_UH3_CTRL)	32	R/W	0000_1402h	77.5.6/ 4892
53F8_081C	USB Host1 UTMI PHY Control Register 0 (USB_USB_UH1_PHY_CTRL_0)	32	R/W	8000_1408h	77.5.7/ 4895
53F8_0820	USB Host1 UTMI PHY Control Register 1 (USB_USB_UH1_PHY_CTRL_1)	32	R/W	0054_1401h	77.5.8/ 4897
53F8_0824	USB Clock on/off control Register (USB_USB_CLKONOFF_CTRL)	32	R/W	8980_1042h	77.5.9/ 4899

77.5.1 USB Control Register 0 (USB_USB_CTRL_0)

The USB control register 0 controls the integration specific features of the USB. These features are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wake-up functionality.

Address: USB_USB_CTRL_0 is 53F8_0000h base + 800h offset = 53F8_0800h



USB_USB_CTRL_0 field descriptions

Field	Description
31 OWIR	OTG Wake-up Interrupt Request This bit indicates that a wake-up interrupt request is issued by the OTG port. This bit is cleared when disabling the wake-up interrupt (clearing bit "OWIE"). 1 Wake-up interrupt request detected 0 No wake-up interrupt request detected
30–28 -	Reserved
27 OWIE	OTG Wake-up Interrupt Enable This bit enables or disables the OTG wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit "OWIR". Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to entering suspend mode 1 Interrupt Enabled 0 Interrupt Disabled (Default)
26–25 -	Reserved
24 O_PWR_POL	OTG power Pin polarity The polarity of OTG Power pin (to enable external PMIC to drive VBUS)

Table continues on the next page...

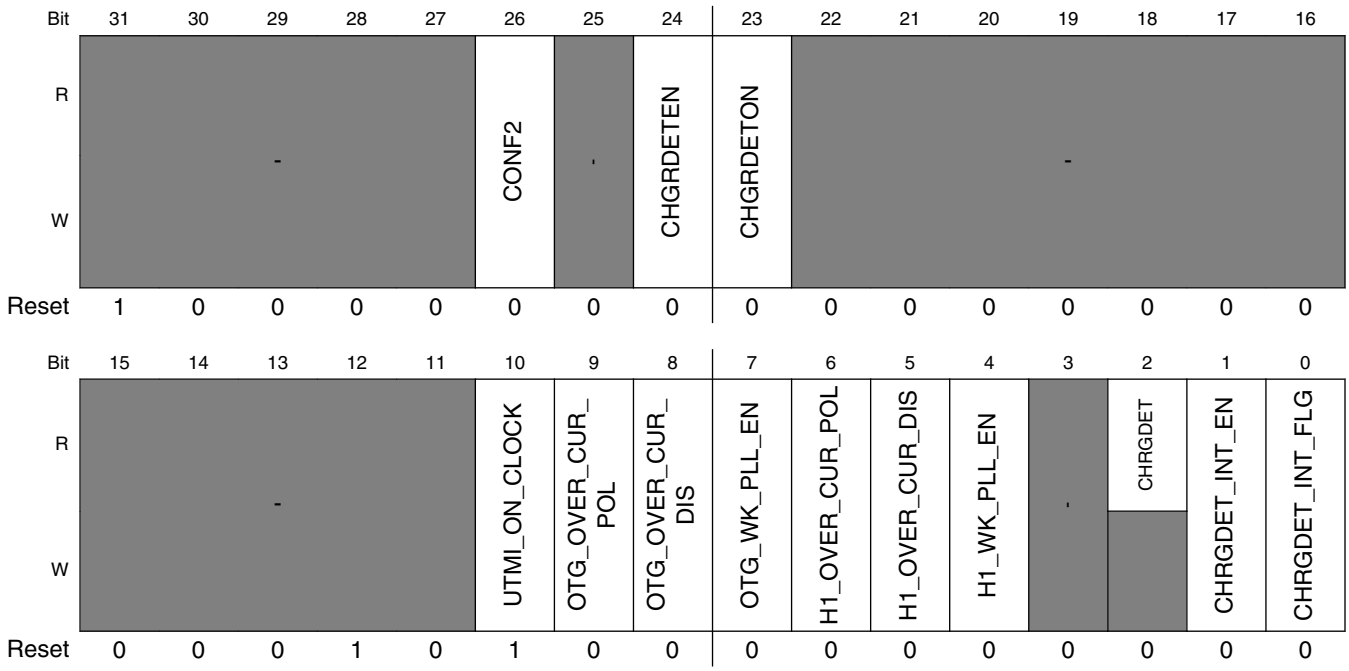
USB_USB_CTRL_0 field descriptions (continued)

Field	Description
	1 High active 0 Low active
23–16 -	Reserved
15 H1WIR	Host1 Wake-up Interrupt Request This bit indicates that a wake-up interrupt request is issued by the Host1 port. This bit is cleared when disabling the wake-up interrupt (clearing bit "H1WIE"). 1 Wake-up interrupt request detected 0 No wake-up interrupt request detected (Default)
14–12 -	Reserved
11 H1WIE	Host1 Wake-up Interrupt Enable This bit enables or disables the Host1 wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit "H1WIR". Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to entering suspend mode 1 Interrupt Enabled 0 Interrupt Disabled
10–9 -	Reserved
8 H1_PWR_POL	Host1 power Pin polarity The polarity of Host1 Power pin (to enable external PMIC to drive VBUS) 1 High active 0 Low active
7–0 -	Reserved

77.5.2 USB OTG UTMI PHY Control Register 0 (USB_USB_OTG_PHY_CTRL_0)

USB OTG UTMI PHY control register 0 controls the on-chip UTMI PHY.

Address: USB_USB_OTG_PHY_CTRL_0 is 53F8_0000h base + 808h offset = 53F8_0808h



USB_USB_OTG_PHY_CTRL_0 field descriptions

Field	Description
31–27 -	Reserved
26 CONF2	UTMI PHY CONF2 When this bit is active, OTG comparators are turn on during suspend. 1 Turns on OTG comparators during suspend 0 Inactive
25 -	Reserved
24 CHGRDETEN	UTMI PHY Charger Detector Enable This bit should be set for 300 ms (or more) after CHGRDETON bit is set to '1b'. 1 Active 0 Inactive
23 CHGRDETON	UTMI PHY Charger Detector Power On This bit controls the internal current mirrors used for charger detection. When this bit is set '1b', internal current mirrors are powered on.

Table continues on the next page...

USB_USB_OTG_PHY_CTRL_0 field descriptions (continued)

Field	Description
	This bit should be set to '1b' at least 20 ms before CHGRDETEN bit is set to '1b'.
22–11 -	Reserved
10 UTMI_ON_CLOCK	UTMI PHY Clock On When this bit is set to '1b', The DPLL in OTG UTMI PHY will be force on even if the PHY is in suspend mode. When this bit is set to '0b', DPLL clock will stop when the PHY entering suspend mode. This feature is used when Host2 controller core and/or Host3 controller core use the PHY DPLL as clock source. 1 Enable 0 Disable
9 OTG_OVER_CUR_POL	OTG Polarity of Overcurrent This bit sets the active level of OTG port overcurrent detector output. 1 Low active 0 High active
8 OTG_OVER_CUR_DIS	OTG Disable Overcurrent Detector This bit enables/disables OTG overcurrent detector. 1 Disables the overcurrent detector 0 Enables the overcurrent detector
7 OTG_WK_PLL_EN	OTG PHY 480MHz DPLL automatic power-up by OTG wake-up event enable. If set '1b', the OTG UTMI DPLL will automatically be enabled when a wake-up event is detected on OTG port. 1 Enable automatic power-up of OTG PHY DPLL 0 Disable automatic power-up of OTG PHY DPLL
6 H1_OVER_CUR_POL	Host1 Polarity of Overcurrent This bit sets the active level of Host1 port overcurrent detector output. 1 Low active 0 High active
5 H1_OVER_CUR_DIS	Host1 Disable Overcurrent Detector This bit enables/disables Host1 overcurrent detector. 1 Disables the overcurrent detector 0 Enables the overcurrent detector
4 H1_WK_PLL_EN	Host1 PHY 480MHz DPLL automatic power-up by Host1 wake-up event enable. If set '1b', the Host1 UTMI DPLL will automatically be enabled when a wake-up event is detected on Host1 port.

Table continues on the next page...

USB_USB_OTG_PHY_CTRL_0 field descriptions (continued)

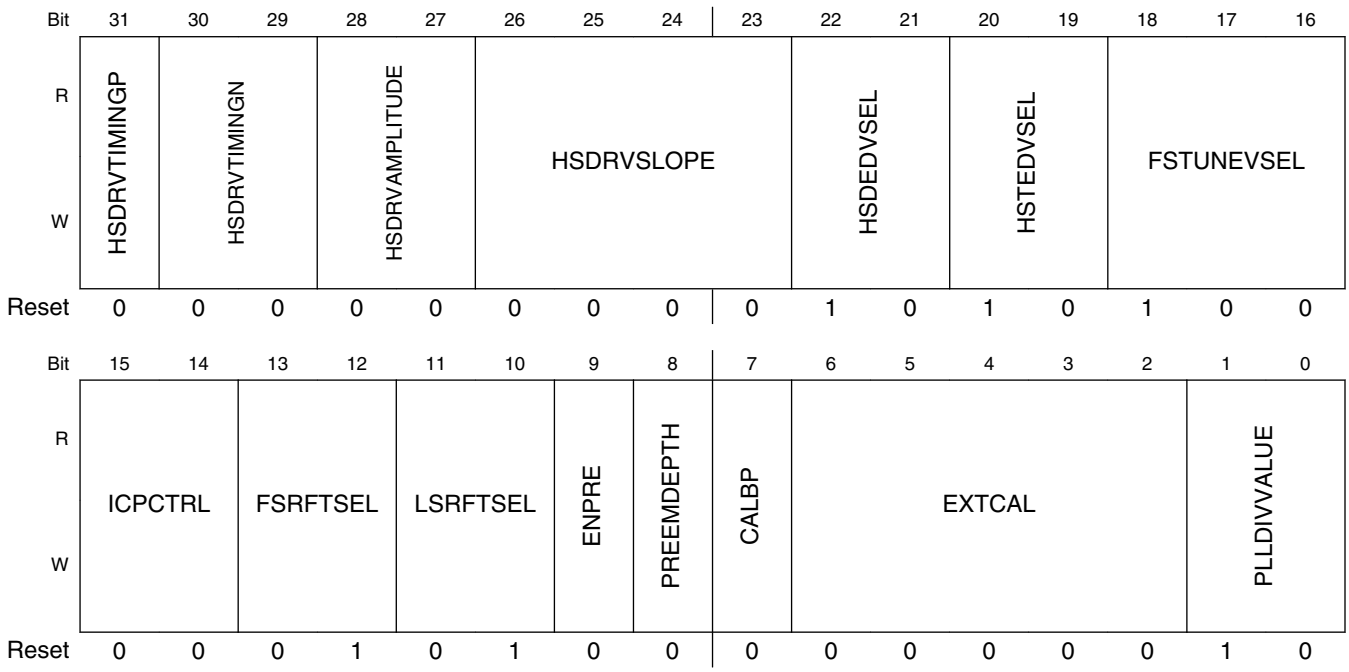
Field	Description
	1 Enable automatic power-up of Host1 PHY DPLL 0 Disable automatic power-up of Host1 PHY DPLL
3 -	Reserved
2 CHRGDET	OTG UTMI PHY Charger Detector Output. **NOTE:** Maximum response time = 1ms 1 Detected 0 not detected
1 CHRGDET_INT_EN	OTG UTMI PHY Charger detected interrupt enable 1 Enable 0 Disable
0 CHRGDET_INT_FLG	OTG UTMI PHY Charger detected interrupt flag This bit is cleared when CHRGDET_INT_EN is set '0b'. 1 Interrupt generated 0 No interrupt

77.5.3 USB OTG UTMI PHY Control Register 1 (USB_USB_OTG_PHY_CTRL_1)

USB OTG UTMI PHY control register 1 also controls the on-chip UTMI PHY.

.

Address: USB_USB_OTG_PHY_CTRL_1 is 53F8_0000h base + 80Ch offset = 53F8_080Ch



USB_USB_OTG_PHY_CTRL_1 field descriptions

Field	Description
31 HSDRVTIMINGP	HS driver timing control for PMOS 1 8x 0 2x
30–29 HSDRVTIMINGN	HS driver timing control for NMOS 00 2x 01 4x 10 6x 11 8x
28–27 HSDRVAMPLITUDE	HS driver amplitude control 00 I (I = 17.78 mA) 01 I + 2.5% 10 I + 5% 11 I + 7.5%
26–23 HSDRVSLOPE	HS driver slope control The HS Driver may have its rise/fall times controlled using the hsdrvslope[3:0] control pins. Additional charge is injected, so the HS driver Rise/Fall times change (RC constant changes).
22–21 HSDEDVSEL	Reference voltage for high speed disconnect envelope detector 00 (46 + 2)/100 x vbg (556.8 mV) 01 (46 + 3)/100 x vbg (568.4 mV) 10 (46 + 4)/100 x vbg (580 mV) 11 (46 + 5)/100 x vbg (591.6 mV)

20–19 HSTEDVSEL	Reference voltage for high speed transmission envelope detector 00 vbg x (9)/100 (104.4 mV) 01 vbg x (9+1)/100 (116 mV) 10 vbg x (9+2)/100 (127.6 mV) 11 vbg x (9+3)/100 (139.2 mV)
18–16 FSTUNEVSEL	Reference voltage control for Calibration circuit 000 (46)/100 x vbg (533.6 mV) 001 (46 + 1)/100 x vbg (545.2 mV) 010 (46 + 2)/100 x vbg (556.8 mV) 011 (46 + 3)/100 x vbg (568.4 mV) 100 (46 + 4)/100 x vbg (580 mV) 101 (46 + 5)/100 x vbg (591.6 mV) 110 (46 + 6)/100 x vbg (603.2 mV) 111 (46 + 7)/100 x vbg (614.8 mV)
15–14 ICPCTRL	PLL charge pump current control 00 Icp (Icp = 40 mA) 01 Icp x 0.5 10 Icp x 1.5 11 Icp x 2
13–12 FSRFTSEL	FS driver rise/fall time control 00 Nominal FS rise time - 30% 01 Nominal FS rise time 10 Nominal FS rise time 11 Nominal FS rise time + 30%
11–10 LSRFTSEL	LS driver rise/fall time control 00 Nominal LS rise time - 30% 01 Nominal LS rise time 10 Nominal LS rise time 11 Nominal LS rise time + 30%
9 ENPRE	HS driver pre-emphasis Enable 1 Enable 0 Disable
8 PREEMDEPTH	HS driver pre-emphasis depth 00 I (I = 17.78 mA) 01 I + 5% 10 I + 10% 11 I + 20%
7 CALBP	Calibration Bypass Enable for both dp and dn lines

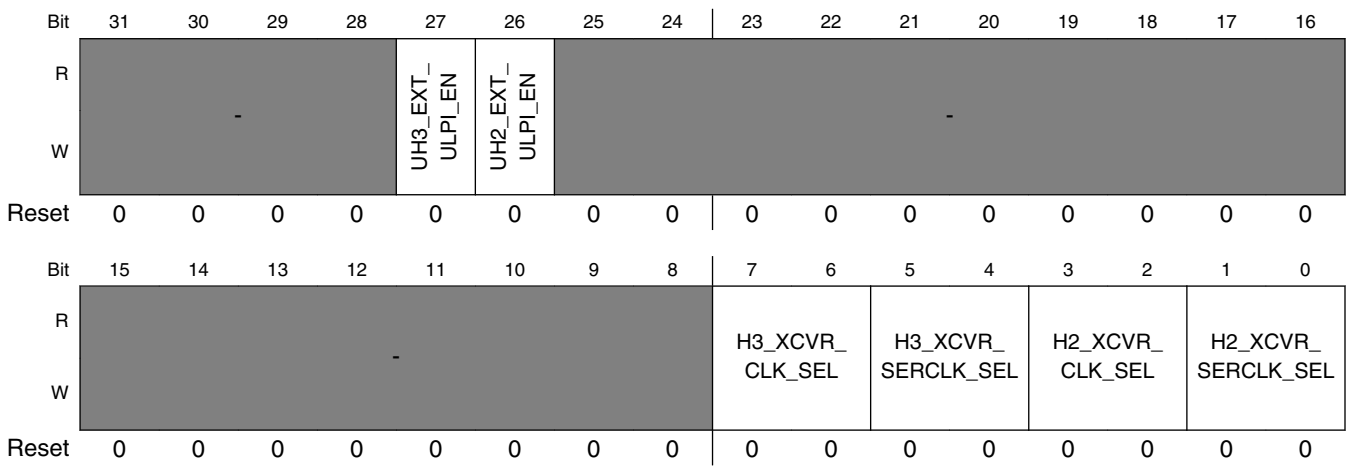
Table continues on the next page...

USB_USB_OTG_PHY_CTRL_1 field descriptions (continued)

Field	Description
6–2 EXTCAL	Controls calibration value externally. This bit is valid only if calbp bit is set to '1b'.
1–0 PLLDIVVALUE	Selects reference clock frequence 00 sysclock uses 19.2 MHz 01 sysclock uses 24 MHz 10 sysclock uses 26 MHz 11 sysclock uses 27 MHz

77.5.4 USB Control Register 1 (USB_USB_CTRL_1)

Address: USB_USB_CTRL_1 is 53F8_0000h base + 810h offset = 53F8_0810h



USB_USB_CTRL_1 field descriptions

Field	Description
31–28 -	Reserved
27 UH3_EXT_ULPI_EN	Host3 selects ULPI data interface or Serial interface This bit must be set to '1b' before Host3 core is set to ULPI mode. It should be clear to '0b' before Host3 core is set to FS/LS serial mode. 1 Select ULPI data interface 0 Select Serial data interface
26 UH2_EXT_ULPI_EN	Host2 selects ULPI data interface or Serial interface This bit must be set to '1b' before Host2 core is set to ULPI mode. It should be clear to '0b' before Host2 core is set to FS/LS serial mode. 1 Select ULPI data interface 0 Select Serial data interface

Table continues on the next page...

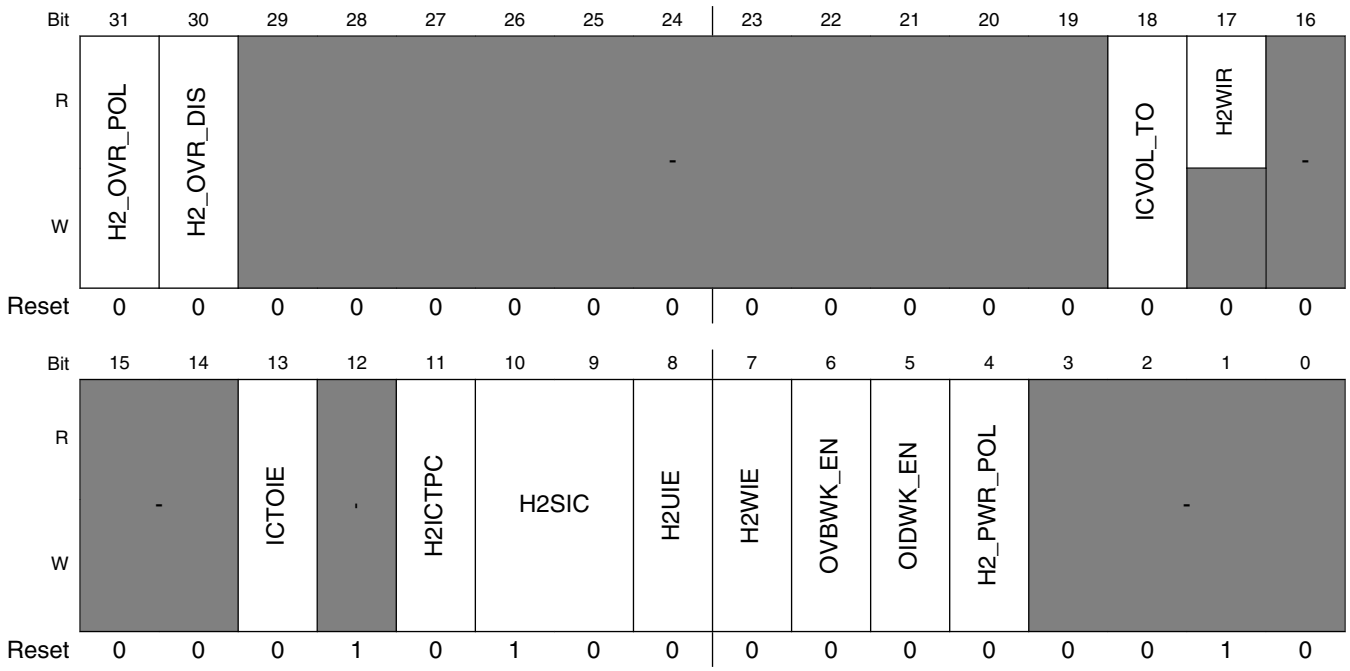
USB_USB_CTRL_1 field descriptions (continued)

Field	Description
25–8 -	Reserved
7–6 H3_XCVR_CLK_SEL	Select the clock source for Host3 Transceiver clock. Host3 can support Serial and ULPI transceivers. When used with ULPI PHY, the ULPI PHY clock must be used as source. For Serial PHY either settings 00 or 11 can be used. 00 Clock sourced from OTG UTMI PHY DPLL 01 Clock from ULPI PHY (Host3 ULPI clock PAD) 10 Reserved 11 Clock from on-chip system DPLL (less accurate)
5–4 H3_XCVR_SERCLK_SEL	Select the clock source for Host3 with serial transceiver. In general, the OTG UTMI PHY DPLL sould be used as it is more accurate.However, the system DPLL can be used if needed in special cases. 00 Clock sourced from OTG UTMI PHY DPLL 01 Reserved 10 Reserved 11 Clock from on-chip system DPLL (less accurate)
3–2 H2_XCVR_CLK_SEL	Select the clock source for Host2 Transceiver clock. Host2 can support Serial and ULPI transceivers. When used with ULPI PHY, the ULPI PHY clock must be used as source. For Serial PHY either settings 00 or 11 can be used. 00 Clock sourced from OTG UTMI PHY DPLL 01 Clock from ULPI PHY (Host2 ULPI clock PAD) 10 Reserved 11 Clock from on-chip system DPLL (less accurate)
1–0 H2_XCVR_SERCLK_SEL	Select the clock source for Host2 with serial transceiver. In general, the OTG UTMI PHY DPLL sould be used as it is more accurate.However, the system DPLL can be used if needed in special cases. 00 Clock sourced from OTG UTMI PHY DPLL 01 Reserved 10 Reserved 11 Clock from on-chip system DPLL (less accurate)

77.5.5 USB Host2 Control Register (USB_USB_UH2_CTRL)

The USB Host2 control register controls the integration specific features of the USB host2 block. These features are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wake-up functionality.

Address: USB_USB_UH2_CTRL is 53F8_0000h base + 814h offset = 53F8_0814h



USB_USB_UH2_CTRL field descriptions

Field	Description
31 H2_OVR_POL	Host2 Polarity of Overcurrent This bit sets the active level of Host2 port overcurrent detector output. 1 Low active 0 High active
30 H2_OVR_DIS	Host2 Disable Overcurrent Detector This bit enables/disables Host2 overcurrent detector. 1 Disables the overcurrent detector 0 Enables the overcurrent detector
29–19 -	Reserved
18 ICVOL_TO	Host2 IC-USB voltage detection time out interrupt 1 Interrupt generated 0 No interrupt

Table continues on the next page...

USB_USB_UH2_CTRL field descriptions (continued)

Field	Description
17 H2WIR	Host2 Wake-up Interrupt Request This bit indicates that a wake-up interrupt request is issued by the OTG port. This bit is cleared when disabling the wake-up interrupt (clearing bit "H2WIE"). 1 Wake-up interrupt request detected 0 No wake-up interrupt request detected
16–14 -	Reserved
13 ICTOIE	Host2 IC-USB voltage detection time out interrupt enable 1 Enable 0 Disable
12 -	Reserved
11 H2ICTPC	Host2 Clear IC-USB TP interrupt Flag 1 Clear 0 Not clear (Default)
10–9 H2SIC	Host2 Serial Interface Configuration These bits control the interface type of the Host2 port when used with a serial transceiver. These bit fields allow for configuring the serial interface for single-ended or differential operation combined with bidirectional or unidirectional operation. The available settings are described below. **NOTE:** When using bidirectional mode, the IOMUX must be configured to place the DP/DM pad into loopback mode. 00 Differential/unidirectional (6-wire) 01 Differential/bidirectional (4-wire) 10 Single ended/unidirectional (6-wire) (Default) 11 Single ended/unidirectional (6-wire)
8 H2UIE	Host2 Waku-up by ULPI transceiver Interrupt Enable This bit controls whether Host2 controller core will be wake-up by interrupts from the ULPI transceiver. This bit is only meaningful when a ULPI transceiver is selected. 1 Enable 0 Disable (Default)
7 H2WIE	Host 2 Wake-up Interrupt Enable This bit enables or disables the Host 2 wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit. Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to going in suspend mode 1 Interrupt Enabled 0 Interrupt Disabled
6 OVBWK_EN	OTG VBUS Wake-up Enable This bit enables or disables the interrupt which is caused OTG VBUS Change.

Table continues on the next page...

USB_USB_UH2_CTRL field descriptions (continued)

Field	Description
	1 Interrupt Enabled 0 Interrupt Disabled
5 OIDWK_EN	OTG ID change Wake-up Enable This bit enables or disables the interrupt which is caused OTG ID Change. 1 Interrupt Enabled 0 Interrupt Disabled
4 H2_PWR_POL	Host2 power Pin polarity The polarity of Host2 Power pin(to enable external PMIC to drive VBUS) 1 High active 0 Low active
3–0 -	Reserved

77.5.6 USB Host3 Control Register (USB_USB_UH3_CTRL)

The USB Host3 control register controls the integration specific features of the USB host3 block. These features are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wake-up functionality.

Address: USB_USB_UH3_CTRL is 53F8_0000h base + 818h offset = 53F8_0818h

USB_USB_UH3_CTRL field descriptions

Field	Description
31 H3_OVR_POL	Host3 Polarity of Overcurrent This bit sets the active level of Host3 port overcurrent detector output. 1 Low active 0 High active
30 H3_OVR_DIS	Host3 Disable Overcurrent Detector This bit enables/disables Host3 overcurrent detector. 1 Disables the overcurrent detector 0 Enables the overcurrent detector
29–21 -	Reserved
20 H2_SER_DRV_EN	Host2 Serial Interface Drive Enable Host2 core serial interface output enable. By default all serial interface output pins are not driven by the controller. This bit should be enabled after Host2 core switches to serial mode and should be disabled before Host2 core switches to ULPI mode. 1 Serial interface drive enable 0 Serial interface drive disable (Default)
19 H3_SER_DRV_EN	Host3 Serial Interface Drive Enable Host3 core serial interface output enable. By default all serial interface output pins are not driven by the controller. This bit should be enabled after Host3 core switches to serial mode and should be disabled before Host3 core switches to ULPI mode. 1 Serial interface drive enable 0 Serial interface drive disable (Default)
18 -	Reserved
17 H3WIR	Host3 Wake-up Interrupt Request This bit indicates that a wake-up interrupt request is issued by the Host3 port. This bit is cleared when disabling the wake-up interrupt (clearing bit "H3WIE"). 1 Wake-up interrupt request detected 0 No wake-up interrupt request detected
16–11 -	Reserved
10–9 H3SIC	Host3 Serial Interface Configuration These bits Control the interface type of the Host3 port when used with a serial transceiver. These bit fields allow for configuring the serial interface for single-ended or differential operation combined with bidirectional or unidirectional operation. The available settings are described below. **NOTE:** In case of Bidirectional mode, IOMUX must set the DP/DM pad into loopback mode. 00 Differential / Unidirectional (6-wire) 01 Differential / Bidirectional (4-wire) 10 Single Ended / Unidirectional (6-wire) (Default) 11 Single Ended / Bidirectional (3-wire)

Table continues on the next page...

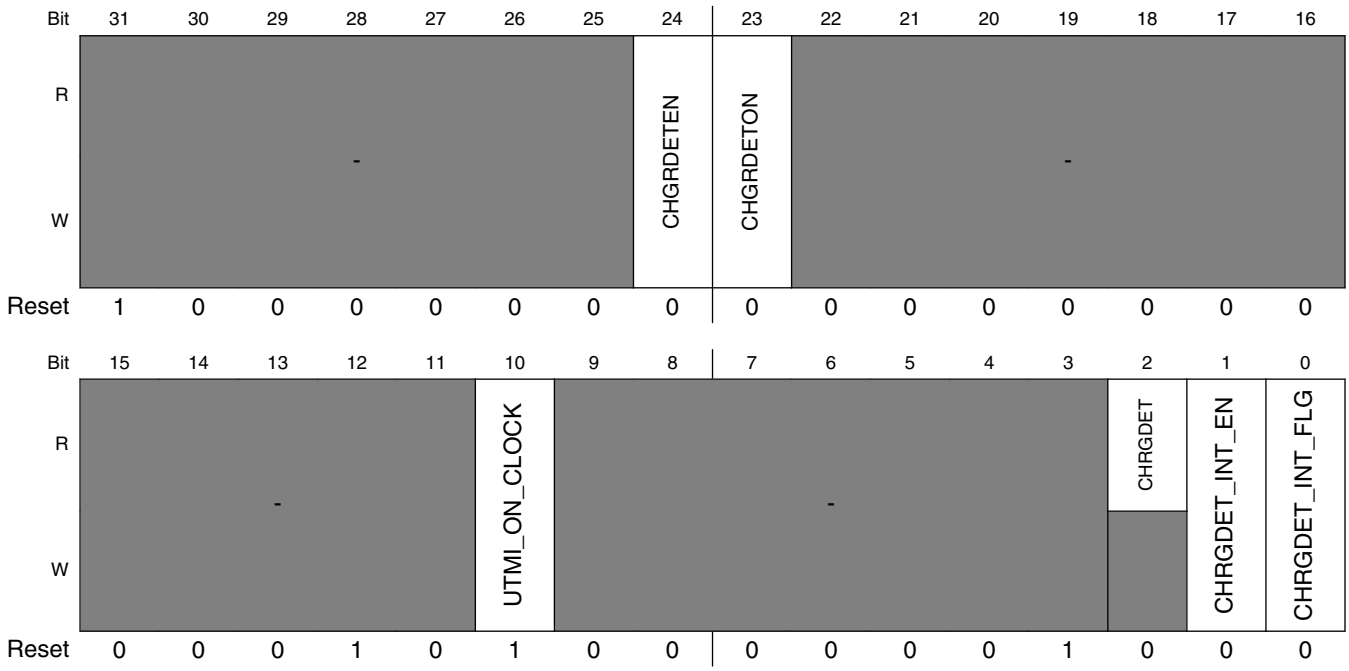
USB_USB_UH3_CTRL field descriptions (continued)

Field	Description
8 H3UIE	Host3 Waku-up by ULPI transceiver Interrupt Enable This bit controls whether Host3 controller core will be wake-up by interrupts from the ULPI transceiver. This bit is only meaningful when a ULPI transceiver is selected. 1 Enable 0 Disable (Default)
7 H3WIE	Host3 Wake-up Interrupt Enable This bit enables or disables the Host3 wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit "H3WIR". Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to entering suspend mode 1 Interrupt Enabled 0 Interrupt Disabled (Default)
6–5 -	Reserved
4 H3_PWR_POL	Host3 power Pin polarity The polarity of Host3 Power pin (to enable external PMIC to drive VBUS) 1 High active 0 Low active
3–0 -	Reserved

77.5.7 USB Host1 UTMI PHY Control Register 0 (USB_USB_UH1_PHY_CTRL_0)

USB Host1 UTMI PHY Control Register 0 are used to control the on-chip UTMI PHY.

Address: USB_USB_UH1_PHY_CTRL_0 is 53F8_0000h base + 81Ch offset = 53F8_081Ch



USB_USB_UH1_PHY_CTRL_0 field descriptions

Field	Description
31–25 -	Reserved
24 CHGRDETEN	UTMI PHY Charger Detector Enable This bit should be set for 300 ms (or more) after CHGRDETON bit is set to '1b'. 1 Active 0 Inactive
23 CHGRDETON	UTMI PHY Charger Detector Power On This bit controls the internal current mirrors used for charger detection. When this bit is set '1b', internal current mirrors are powered on. This bit should be set to '1b' at least 20 ms before CHGRDETEN bit is set to '1b'.
22–11 -	Reserved
10 UTMI_ON_ CLOCK	UTMI PHY Clock On When this bit is set to '1b', The PLL in OTG UTMI PHY will be force on even if the PHY is in suspend mode. When this bit is set to '0b', PLL clock will stop when the PHY entering suspend mode.

Table continues on the next page...

USB_USB_UH1_PHY_CTRL_0 field descriptions (continued)

Field	Description
	This feature is used when Host2 controller core and/or Host3 controller core use the PHY PLL as clock source. 1 Enable 0 Disable
9–3 -	Reserved

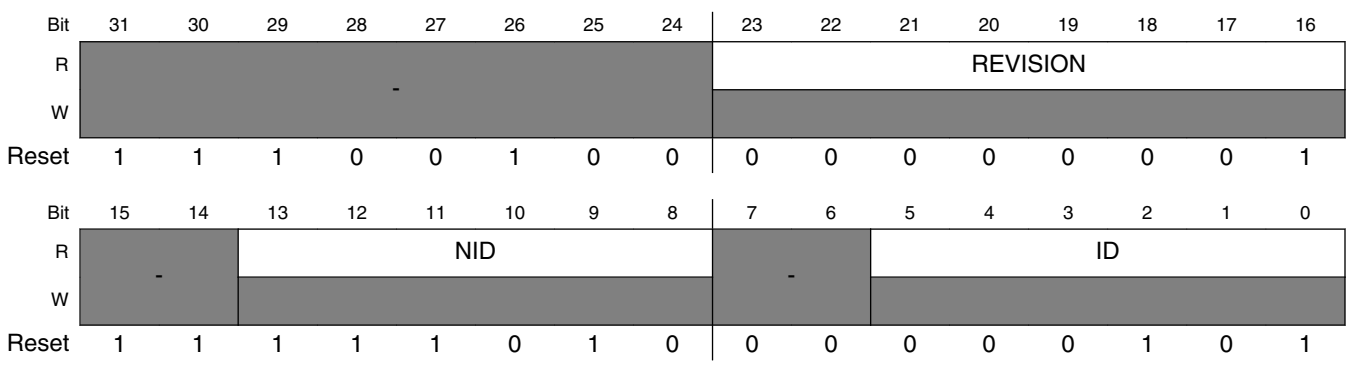
77.6.1 Identification register (USB__ID)

The ID register identifies the USB 2.0 OTG High-Speed core and its revision.

Addresses: USB_UOG_ID is 53F8_0000h base + 0h offset = 53F8_0000h
USB_UH1_ID is 53F8_0000h base + 200h offset = 53F8_0200h
USB_UH2_ID is 53F8_0000h base + 400h offset = 53F8_0400h
USB_UH3_ID is 53F8_0000h base + 600h offset = 53F8_0600h



USB_*n*_ID field descriptions

Field	Description
31–24 -	Reserved

Table continues on the next page...

USB_*n*_ID field descriptions (continued)

Field	Description
23–16 REVISION	Revision number of the controller core.
15–14 -	Reserved
13–8 NID	Complement version of ID
7–6 -	Reserved
5–0 ID	Configuration number. This number is set to 0x05 and indicates that the peripheral is USB 2.0 OTG High-Speed core.

77.6.2 Hardware General (USB__HWGENERAL)

General hardware parameters as defined in System Level Issues and Core Configuration.

Addresses: USB_UOG_HWGENERAL is 53F8_0000h base + 4h offset = 53F8_0004h
USB_UH1_HWGENERAL is 53F8_0000h base + 204h offset = 53F8_0204h
USB_UH2_HWGENERAL is 53F8_0000h base + 404h offset = 53F8_0404h
USB_UH3_HWGENERAL is 53F8_0000h base + 604h offset = 53F8_0604h

USB_*n*_GPTIMER0LD field descriptions

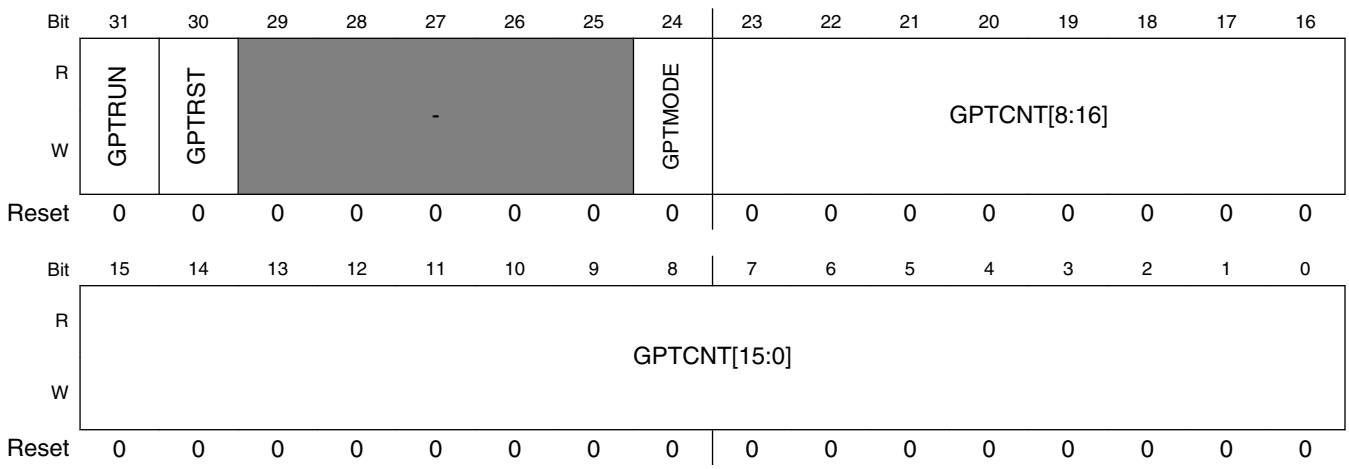
Field	Description
31–24 -	Reserved
23–0 GPTLD	General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. **NOTE:** Max value is 0xFFFFFF or 16.777215 seconds.

77.6.8 General Purpose Timer #0 Controller (USB__GPTIMER0CTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI0 bit in n_USBSTS register (See USB Status Register (USB__USBSTS)), interrupt enable bit is TIE0 bit in n_USBINTR register. (See Interrupt Enable Register (USB__USBINTR) .)

Addresses: USB_UOG_GPTIMER0CTRL is 53F8_0000h base + 84h offset = 53F8_0084h
USB_UH1_GPTIMER0CTRL is 53F8_0000h base + 284h offset = 53F8_0284h
USB_UH2_GPTIMER0CTRL is 53F8_0000h base + 484h offset = 53F8_0484h
USB_UH3_GPTIMER0CTRL is 53F8_0000h base + 684h offset = 53F8_0684h



USB_*n*_GPTIMER0CTRL field descriptions

Field	Description

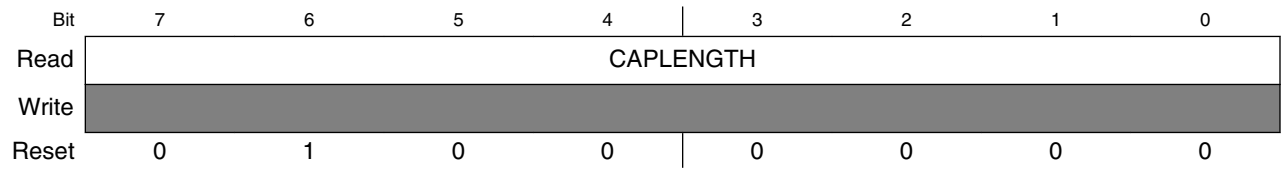
USB_*n*_SBUSCFG field descriptions

Field	Description
31–3 -	Reserved
2–0 AHBBRST	AHB master interface Burst configuration These bits controls AHB master transfer type sequence (or priority). **NOTE:** This register overrides n_BURSTSIZE register when its value is not zero. 000 Incremental burst of unspecified length only 001 INCR4 burst, then single transfer 010 INCR8 burst, INCR4 burst, then single transfer 011 INCR16 burst, INCR8 burst, INCR4 burst, then single transfer 100 Reserved, don't use 101 INCR4 burst, then incremental burst of unspecified length 110 INCR8 burst, INCR4 burst, then incremental burst of unspecified length 111 INCR16 burst, INCR8 burst, INCR4 burst, then incremental burst of unspecified length

77.6.12 Capability Register Length (USB__CAPLENGTH)

The following figure Capability Register Length (n_CAPLENGTH) indicates the offset that should be added to the register base address at the beginning of the Operational Register.

Addresses: USB_UOG_CAPLENGTH is 53F8_0000h base + 100h offset = 53F8_0100h
USB_UH1_CAPLENGTH is 53F8_0000h base + 300h offset = 53F8_0300h
USB_UH2_CAPLENGTH is 53F8_0000h base + 500h offset = 53F8_0500h
USB_UH3_CAPLENGTH is 53F8_0000h base + 700h offset = 53F8_0700h



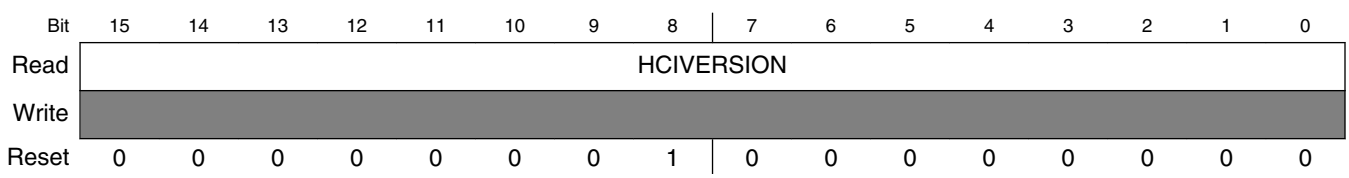
USB_n_CAPLENGTH field descriptions

Field	Description
7–0 CAPLENGTH	These bits are used as an offset to add to register base to find the beginning of the Operational Register. Default value is '40h'.

77.6.13 Host Controller Interface Version (USB__HCIVERSION)

The following figure shows the Host Interface version number (n_HCIVERSION), which is a 2-byte register containing a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision.

Addresses: USB_UOG_HCIVERSION is 53F8_0000h base + 102h offset = 53F8_0102h
USB_UH1_HCIVERSION is 53F8_0000h base + 302h offset = 53F8_0302h
USB_UH2_HCIVERSION is 53F8_0000h base + 502h offset = 53F8_0502h
USB_UH3_HCIVERSION is 53F8_0000h base + 702h offset = 53F8_0702h



USB_n_HCIVERSION field descriptions

Field	Description
15–0 HCIVERSION	Host Controller Interface Version Number Default value is '10h', which means EHCI rev1.0.

77.6.14 Host Controller Structural Parameters (USB__HCSPARAMS)

The following figure shows the port steering logic capabilities of Host Control Structural Parameters (n_HCSPARAMS).

Addresses: USB_UOG_HCSPARAMS is 53F8_0000h base + 104h offset = 53F8_0104h
USB_UH1_HCSPARAMS is 53F8_0000h base + 304h offset = 53F8_0304h
USB_UH2_HCSPARAMS is 53F8_0000h base + 504h offset = 53F8_0504h
USB_UH3_HCSPARAMS is 53F8_0000h base + 704h offset = 53F8_0704h

USB_*n*_HCSPARAMS field descriptions

Field	Description
31–28 -	Reserved
27–24 N_TT	Number of Transaction Translators (N_TT). Default value '0000b' This field indicates the number of embedded transaction translators associated with the USB2.0 host controller. These bits would be set to '0001b' for Multi-Port Host, and '0000b' for Single-Port Host.
23–20 N_PTT	Number of Ports per Transaction Translator (N_PTT). Default value '0000b' This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. These bits would be set to equal N_PORTS for Multi-Port Host, and '0000b' for Single-Port Host.
19–17 -	Reserved
16 PI	Port Indicators (P INDICATOR) This bit indicates whether the ports support port indicator control. When set to one, the port status and control registers include a read/writeable field for controlling the state of the port indicator This bit is "1b" in all 4 controller core.
15–12 N_CC	Number of Companion Controller (N_CC). This field indicates the number of companion controllers associated with this USB2.0 host controller. These bits are '0000b' in all 4 controller core.

Table continues on the next page...

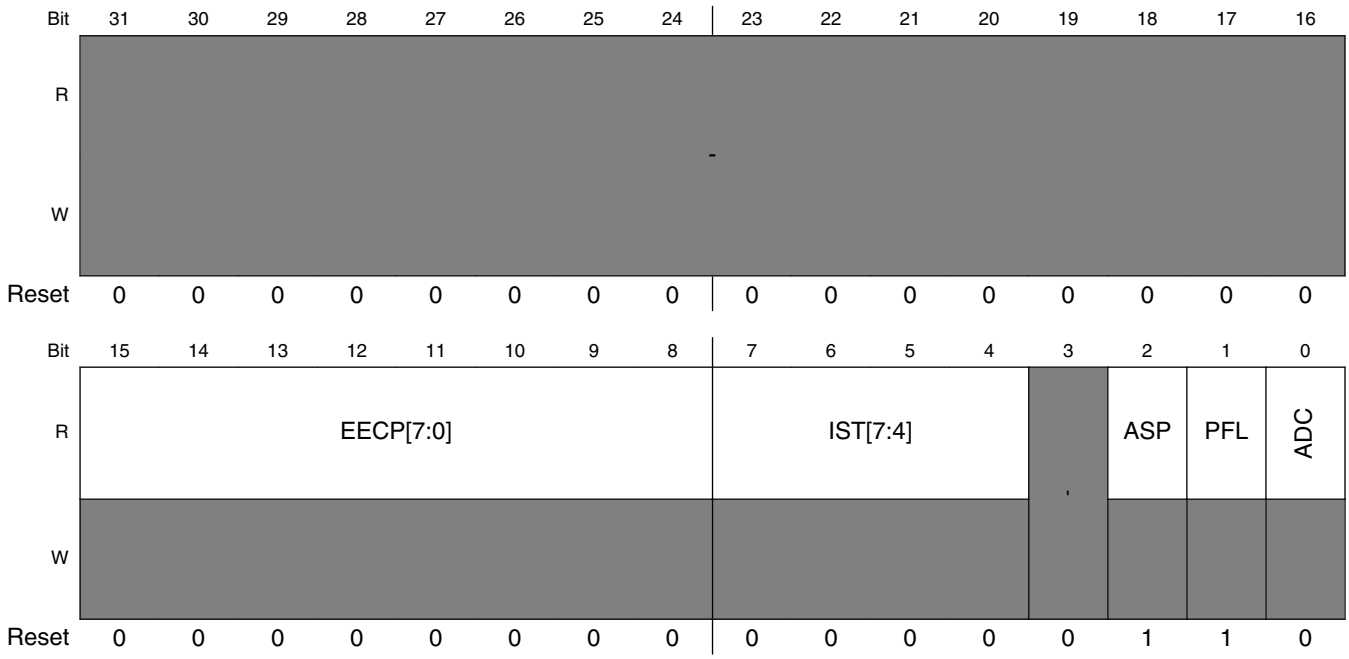
USB_*n*_HCSPARAMS field descriptions (continued)

Field	Description
	0 There is no internal Companion Controller and port-ownership hand-off is not supported. 1 There are internal companion controller(s) and port-ownership hand-offs is supported.
11–8 N_PCC	Number of Ports per Companion Controller This field indicates the number of ports supported per internal Companion Controller. It is used to indicate the port routing configuration to the system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC. These bits are '0000b' in all 4 controller core.
7–5 -	Reserved
4 PPC	Port Power Control This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register
3–0 N_PORTS	Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register. Valid values are in the range of 1h to Fh. A zero in this field is undefined. These bits are always set to '0001b' because all 4 controller cores are Single-Port Host.

77.6.15 Host Controller Capability Parameters (USB__HCCPARAMS)

This register identifies multiple mode control (time-base bit functionality), addressing capability.

Addresses: USB_UOG_HCCPARAMS is 53F8_0000h base + 108h offset = 53F8_0108h
USB_UH1_HCCPARAMS is 53F8_0000h base + 308h offset = 53F8_0308h
USB_UH2_HCCPARAMS is 53F8_0000h base + 508h offset = 53F8_0508h
USB_UH3_HCCPARAMS is 53F8_0000h base + 708h offset = 53F8_0708h



USB_*n*_HCCPARAMS field descriptions

Field	Description
31–16 -	Reserved
15–8 EECP[7:0]	EHCI Extended Capabilities Pointer. This field indicates the existence of a capabilities list. A value of 00h indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. The pointer value must be 40h or greater if implemented to maintain the consistency of the PCI header defined for this class of device. These bits are set '00h' in all 4 controller core.
7–4 IST[7:4]	Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. These bits are set '00h' in all 4 controller core.

Table continues on the next page...

USB_*n*_HCCPARAMS field descriptions (continued)

Field	Description
3 -	Reserved
2 ASP	Asynchronous Schedule Park Capability If this bit is set to a one, then the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USBCMD register. This bit is set '1b' in all 4 controller core.
1 PFL	Programmable Frame List Flag If this bit is set to zero, then the system software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. If set to a one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This bit is set '1b' in all 4 controller core.
0 ADC	64-bit Addressing Capability This bit is set '0b' in all 4 controller core, no 64-bit addressing capability is supported.

77.6.16 Device Controller Interface Version (USB_UOG_DCIVERSION)

This register indicates the two-byte BCD encoding of the device controller interface version number.

Address: USB_UOG_DCIVERSION is 53F8_0000h base + 120h offset = 53F8_0120h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

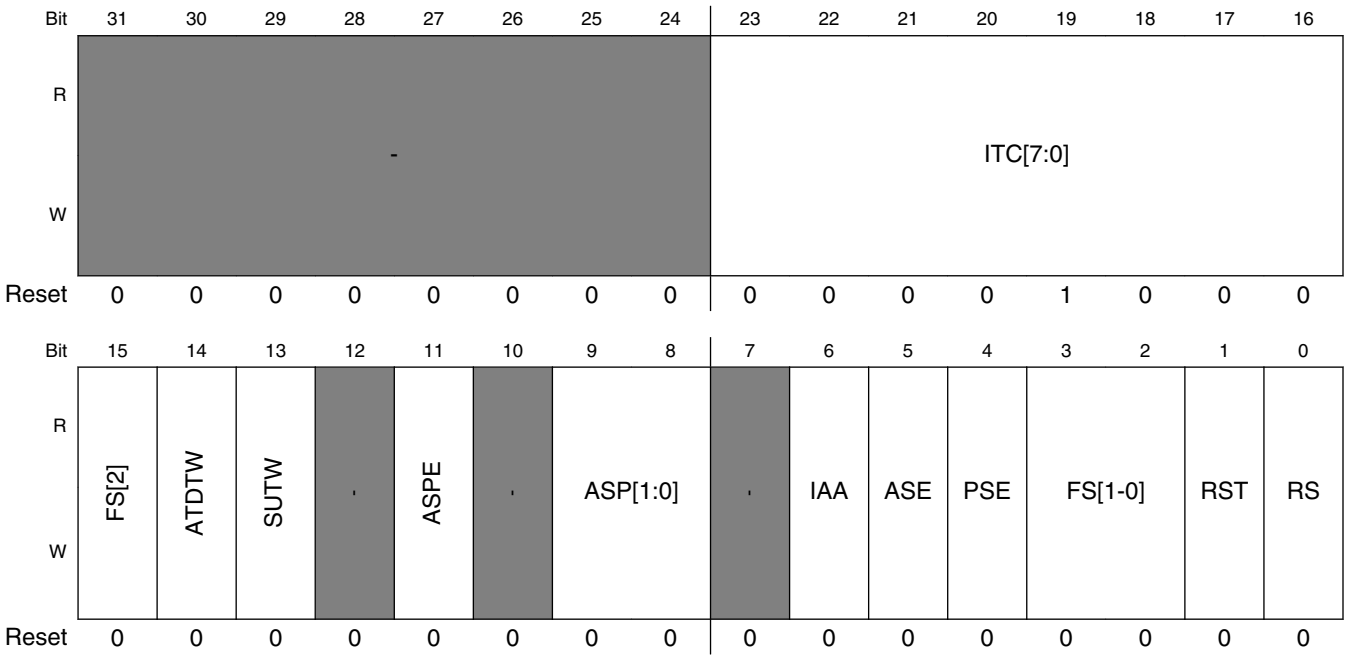
7 DC	Device Capable When this bit is 1, this controller is capable of operating as a USB 2.0 device.
6–5 -	Reserved
4–0 DEN[4:0]	Device Endpoint Number This field indicates the number of endpoints built into the device controller. If this controller is not device capable, then this field will be zero. Valid values are 0 - 15.

77.6.18 USB Command Register (USB__USBCMD)

The Command Register indicates the command to be executed by the serial bus host/device controller. Writing to the register causes a command to be executed.

*: ASPE,ASP[1],ASP[0] reset value: '0b' for OTG core; '1b' for Host1/Host2/Host3 core.

Addresses: USB_UOG_USBCMD is 53F8_0000h base + 140h offset = 53F8_0140h
USB_UH1_USBCMD is 53F8_0000h base + 340h offset = 53F8_0340h
USB_UH2_USBCMD is 53F8_0000h base + 540h offset = 53F8_0540h
USB_UH3_USBCMD is 53F8_0000h base + 740h offset = 53F8_0740h



USB_*n*_USBCMD field descriptions

Field	Description
31–24 -	Reserved
23–16 ITC[7:0]	Interrupt Threshold Control -Read/Write. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 0x00 Immediate (no threshold) 0x01 1 micro-frame 0x02 2 micro-frames 0x04 4 micro-frames 0x08 8 micro-frames 0x10 16 micro-frames 0x20 32 micro-frames 0x40 64 micro-frames
15 FS[2]	See also bits 3-2 Frame List Size - (Read/Write or Read Only). [host mode only] This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index.

Table continues on the next page...

USB_*n*_USBCMD field descriptions (continued)

Field	Description
	NOTE: This field is made up from USBCMD bits 15, 3 and 2. Value Meaning 000 1024 elements (4096 bytes) Default value 001 512 elements (2048 bytes) 010 256 elements (1024 bytes) 011 128 elements (512 bytes) 100 64 elements (256 bytes) 101 32 elements (128 bytes) 110 16 elements (64 bytes) 111 8 elements (32 bytes)
14 ATDTW	Add dTD TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software. This bit would also be cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.
13 SUTW	Setup TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (SLOM bit in USB core register n_USBMODE, see USB Device Mode (USB__USBMODE)) then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software. This bit would also be cleared by hardware when a hazard detected.
12 -	Reserved
11 ASPE	Asynchronous Schedule Park Mode Enable - Read/Write. If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. This field is set to '1b' in this implementation.
10 -	Reserved
9–8 ASP[1:0]	Asynchronous Schedule Park Mode Count - Read/Write. If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is Read-Only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when *Park Mode Enable* is a one as this will result in undefined behavior. This field is set to 3h in all 4 controller core.
7 -	Reserved
6 IAA	Interrupt on Async Advance Doorbell - Read/Write.

Table continues on the next page...

USB_*n*_USBCMD field descriptions (continued)

Field	Description
	This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results.
5 ASE	Asynchronous Schedule Enable - Read/Write. Default 0b. This bit controls whether the host controller skips processing the Asynchronous Schedule. Only the host controller uses this bit. Values Meaning 0 Do not process the Asynchronous Schedule. 1 Use the ASYNCLISTADDR register to access the Asynchronous Schedule.
4 PSE	Periodic Schedule Enable- Read/Write. Default 0b. This bit controls whether the host controller skips processing the Periodic Schedule. Only the host controller uses this bit. Values Meaning 0 Do not process the Periodic Schedule 1 Use the PERIODICLISTBASE register to access the Periodic Schedule.
3–2 FS[1-0]	See description at bit 15
1 RST	Controller Reset (RESET) - Read/Write. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host operation mode: When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. Device operation mode: When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, because the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.
0 RS	Run/Stop (RS) - Read/Write. Default 0b. 1=Run. 0=Stop. Host operation mode:

Table continues on the next page...

USB_*n*_USBCMD field descriptions (continued)

Field	Description
	When set to '1b', the Controller proceeds with the execution of the schedule. The Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the controller is in the Halted state (that is, HCHalted in the USBSTS register is a one). Device operation mode: Writing a one to this bit will cause the controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the controller has been properly initialized. Writing a 0 to this will cause a detach event.

77.6.19 USB Status Register (USB__USBSTS)

This register indicates various states of the Host/Device Controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

*HCH bit reset value: '0b' for OTG core, '1b' for Host1/Host2/Host3 core.

Addresses: USB_UOG_USBSTS is 53F8_0000h base + 144h offset = 53F8_0144h
USB_UH1_USBSTS is 53F8_0000h base + 344h offset = 53F8_0344h
USB_UH2_USBSTS is 53F8_0000h base + 544h offset = 53F8_0544h
USB_UH3_USBSTS is 53F8_0000h base + 744h offset = 53F8_0744h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USB_*n*_USBSTS field descriptions

Field	Description
31–26 -	Reserved
25 TI1	General Purpose Timer Interrupt 1(GPTINT1)--R/WC. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero, writing a one to this bit will clear it.
24 TI0	General Purpose Timer Interrupt 0(GPTINT0)--R/WC. This bit is set when the counter in the GPTIMER0CTRL register transitions to zero, writing a one to this bit clears it.
23–17 -	Reserved
16 NAKI	NAK Interrupt Bit--RO. This bit is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all Enabled TX/RX Endpoint NAK bits are cleared.
15 AS	Asynchronous Schedule Status - Read Only. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
14 PS	Periodic Schedule Status - Read Only. This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
13 RCL	Reclamation - Read Only. This is a read-only status bit used to detect an empty asynchronous schedule. Only used in the host operation mode.
12 HCH	HCHalted - Read Only. This bit is a zero whenever the Run/Stop bit is a one. The Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Controller hardware (for example, an internal error). Only used in the host operation mode. Default value is '0b' for OTG core, and '1b' for Host1/Host2/Host3 core. This is because OTG core is not operating as host in default. Please see CM bit in UOG_USBMODE register.
11 -	Reserved
10 ULPII	ULPI Interrupt - R/WC.

Table continues on the next page...

USB_*n*_USBSTS field descriptions (continued)

Field	Description
	This bit will be set '1b' by hardware when there is an event completion in ULPI viewport. This bit is usable only if the controller support UPLI interface mode.
9 -	Reserved
8 SLI	DCSuspend - R/WC. When a controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state. Only used in device operation mode.
7 SRI	SOF Received - R/WC. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125ms in HS mode and will be synchronized to the actual SOF that is received. Because the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp. In host mode, this bit will be set every 125us and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it.
6 URI	USB Reset Received - R/WC. When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used in device operation mode.
5 AAI	Interrupt on Async Advance - R/WC. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the n_USBCMD register. This status bit indicates the assertion of that interrupt source. Only used in host operation mode.
4 SEI	System Error- R/WC. This bit is will be set to '1b' when an Error response is seen to a read on the system interface.
3 FRI	Frame List Rollover - R/WC. The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the UOG_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles. Only used in host operation mode.
2 PCI	Port Change Detect - R/WC. The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/ Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively.

Table continues on the next page...

USB_*n*_USBSTS field descriptions (continued)

Field	Description
1 UEI	USB Error Interrupt (USBERRINT) - R/WC. When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set The device controller detects resume signaling only.
0 UI	USB Interrupt (USBINT) - R/WC. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.

77.6.20 Interrupt Enable Register (USB__USBINTR)

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt source is active. The USB Status register (n_USBSTS) still shows interrupt sources even if they are disabled by the n_USBINTR register, allowing polling of interrupt events by the software.

Addresses: USB_UOG_USBINTR is 53F8_0000h base + 148h offset = 53F8_0148h
USB_UH1_USBINTR is 53F8_0000h base + 348h offset = 53F8_0348h
USB_UH2_USBINTR is 53F8_0000h base + 548h offset = 53F8_0548h
USB_UH3_USBINTR is 53F8_0000h base + 748h offset = 53F8_0748h

USB_*n*_USBINTR field descriptions

Field	Description
31–26 -	Reserved
25 TIE1	General Purpose Timer #1 Interrupt Enable When this bit is one and the TI1 bit in n_USBSTS register is a one the controller will issue an interrupt.
24 TIE0	General Purpose Timer #0 Interrupt Enable When this bit is one and the TI0 bit in n_USBSTS register is a one the controller will issue an interrupt.
23–20 -	Reserved
19 UPIE	USB Host Periodic Interrupt Enable When this bit is one, and the UPI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
18 UAIE	USB Host Asynchronous Interrupt Enable When this bit is one, and the UAI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
17 -	Reserved
16 NAKE	NAK Interrupt Enable When this bit is one and the NAKI bit in n_USBSTS register is a one the controller will issue an interrupt.
15–11 -	These bits are reserved and should be set to zero.
10 ULPIE	ULPI Interrupt Enable When this bit is one and the UPLII bit in n_USBSTS register is a one the controller will issue an interrupt. This bit is usable only if the controller support UPLI interface mode.
9 -	Reserved
8 SLE	Sleep Interrupt Enable When this bit is one and the SLI bit in n_n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
7 SRE	SOF Received Interrupt Enable When this bit is one and the SRI bit in n_USBSTS register is a one the controller will issue an interrupt.
6 URE	USB Reset Interrupt Enable When this bit is one and the URI bit in n_UOG_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
5 AAE	Async Advance Interrupt Enable When this bit is one and the AAI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
4 SEE	System Error Interrupt Enable When this bit is one and the SEI bit in n_USBSTS register is a one the controller will issue an interrupt.

Table continues on the next page...

USB_*n*_USBINTR field descriptions (continued)

Field	Description
	Only used in host operation mode.
3 FRE	Frame List Rollover Interrupt Enable When this bit is one and the FRI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
2 PCE	Port Change Detect Interrupt Enable When this bit is one and the PCI bit in n_USBSTS register is a one the controller will issue an interrupt.
1 UEE	USB Error Interrupt Enable When this bit is one and the UEI bit in n_USBSTS register is a one the controller will issue an interrupt.
0 UE	USB Interrupt Enalbe When this bit is one and the UI bit in n_USBSTS register is a one the controller will issue an interrupt.

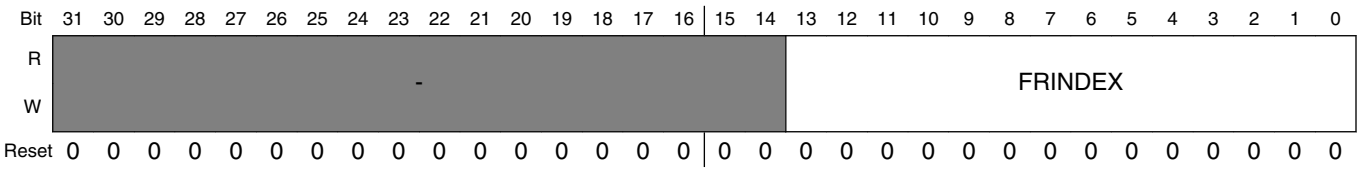
77.6.21 USB Frame Index (USB__FRINDEX)

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the n_USBCMD register.

This register must be written as a DWord. Byte writes produce-undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop hit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (that is, SOF for 125 us micro-frame.).

Addresses: USB_UOG_FRINDEX is 53F8_0000h base + 14Ch offset = 53F8_014Ch
USB_UH1_FRINDEX is 53F8_0000h base + 34Ch offset = 53F8_034Ch
USB_UH2_FRINDEX is 53F8_0000h base + 54Ch offset = 53F8_054Ch
USB_UH3_FRINDEX is 53F8_0000h base + 74Ch offset = 53F8_074Ch



USB_*n*_FRINDEX field descriptions

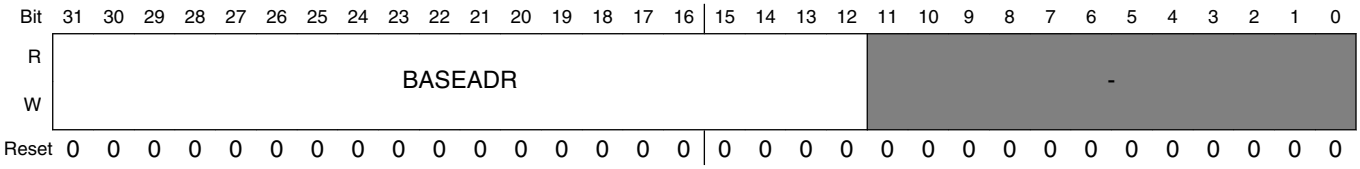
Field	Description
31–14 -	Reserved
13–0 FRINDEX	Frame Index. The value, in this register, increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. This means that each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD [Frame List Size] Number Elements N In device mode the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode bits 2:0 indicate the current microframe. 000 (1024) 12 001 (512) 11 010 (256) 10 011 (128) 9 100 (64) 8 101 (32) 7 110 (16) 6 111 (8) 5

77.6.22 Frame List Base Address (USB__PERIODICLISTBASE)

Host Controller only

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (UOG_FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

Addresses: USB_UOG_PERIODICLISTBASE is 53F8_0000h base + 154h offset = 53F8_0154h
USB_UH1_PERIODICLISTBASE is 53F8_0000h base + 354h offset = 53F8_0354h
USB_UH2_PERIODICLISTBASE is 53F8_0000h base + 554h offset = 53F8_0554h
USB_UH3_PERIODICLISTBASE is 53F8_0000h base + 754h offset = 53F8_0754h



USB_*n*_PERIODICLISTBASE field descriptions

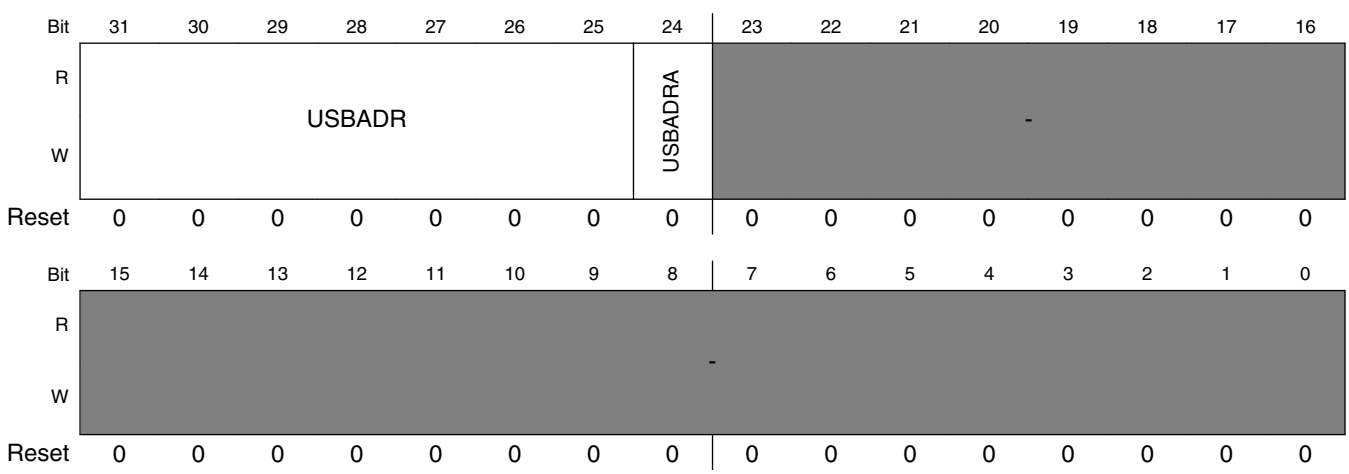
Field	Description
31–12 BASEADR	Base Address (Low). These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.
11–0 -	Reserved

77.6.23 Device Address (USB_UOG_DEVICEADDR)

Device Controller only

The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS descriptor.

Address: USB_UOG_DEVICEADDR is 53F8_0000h base + 154h offset = 53F8_0154h



USB_UOG_DEVICEADDR field descriptions

Field	Description
31–25 USBADR	Device Address. These bits correspond to the USB device address
24 USBADRA	Device Address Advance. Default=0. When this bit is '0', any writes to USBADR are instantaneous. When this bit is written to a '1' at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). **NOTE:** After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
23–0 -	Reserved

77.6.24 Next Asynch. Address (USB__ASYNCLISTADDR)

Host Controller only

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits [4:0] of this register cannot be modified by the system software and will always return a zero when read.

Addresses: USB_UOG_ASYNCLISTADDR is 53F8_0000h base + 158h offset = 53F8_0158h
USB_UH1_ASYNCLISTADDR is 53F8_0000h base + 358h offset = 53F8_0358h
USB_UH2_ASYNCLISTADDR is 53F8_0000h base + 558h offset = 53F8_0558h
USB_UH3_ASYNCLISTADDR is 53F8_0000h base + 758h offset = 53F8_0758h

USB_*n*_BURSTSIZE field descriptions

Field	Description
31–17 -	Reserved
16–8 TXPBURST	Programmable TX Burst Size. Default value is determined by TXBURST bits in n_HWTXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from system memory to the USB bus.
7–0 RXPBURST	Programmable RX Burst Size. Default value is determined by TXBURST bits in n_HWRXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory.

77.6.27 TX FIFO Fill Tuning (USB__TXFILLTUNING)

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_{ff} = Time to fetch packet into TX FIFO up to specified level.

T_s = Total Packet Flight Time (send-only) packet

$T_s = T_0 + T_1$

T_p = Total Packet Time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure T_p remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is < T_s then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a mark will be made the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the n_TSCHHEALTH (T_{ff}) described below.

Addresses: USB_UOG_TXFILLTUNING is 53F8_0000h base + 164h offset = 53F8_0164h
USB_UH1_TXFILLTUNING is 53F8_0000h base + 364h offset = 53F8_0364h
USB_UH2_TXFILLTUNING is 53F8_0000h base + 564h offset = 53F8_0564h
USB_UH3_TXFILLTUNING is 53F8_0000h base + 764h offset = 53F8_0764h

USB_*n*_TXFILLTUNING field descriptions

Field	Description
31–22 -	Reserved
21–16 TXFIFOTHRES	FIFO Burst Threshold. (Read/Write) This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in UOG_USBMODE register is set. Default value is '00h' for OTG controller core, and '02h' for Host1/Host2/Host3 controller core.
15–13 -	Reserved
12–8 TXSCHHEALTH	Scheduler Health Counter. (Read/Write To Clear) This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31. Default value is '08h' for OTG controller core, and '00h' for Host1/Host2/Host3 controller core.

Table continues on the next page...

USB_*n*_TXFILLTUNING field descriptions (continued)

Field	Description
7–0 TXSCHOH	Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode. Default value is '08h' for OTG controller core, and '00h' for Host1/Host2/Host3 controller core.

77.6.28 IC_USB enable and voltage negotiation (USB__IC_USB)

This register enable and controls the IC-USB FS/LS transceiver.

Addresses: USB_UOG_IC_USB is 53F8_0000h base + 16Ch offset = 53F8_016Ch
USB_UH1_IC_USB is 53F8_0000h base + 36Ch offset = 53F8_036Ch
USB_UH2_IC_USB is 53F8_0000h base + 56Ch offset = 53F8_056Ch

77.6.31 Port Status & Control (USB__PORTSC1)

Host Controller

A host controller could implement one to eight port status and control registers. The number is determined by N_PORTs bits in HWSPARAMs register (please see Host Controller Structural Parameters (USB__HCSPARAMS)). Software could read this parameter register to determine how many ports need service.

All 4 controller cores are Single-Port Host, so there is only one port status and control register for each controller core.

This register is only reset by power on reset or controller core reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port supports power control, this state remains until port power is supplied (by software).

Device Controller

A device controller has only port register one (PORTSC1) and it does not support power control. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

Addresses: USB_UOG_PORTSC1 is 53F8_0000h base + 184h offset = 53F8_0184h
USB_UH1_PORTSC1 is 53F8_0000h base + 384h offset = 53F8_0384h
USB_UH2_PORTSC1 is 53F8_0000h base + 584h offset = 53F8_0584h
USB_UH3_PORTSC1 is 53F8_0000h base + 784h offset = 53F8_0784h

USB_*n*_PORTSC1 field descriptions

Field	Description
31–30 PTS[1:0]	Parallel Transceiver Select (bit25, bit31, bi30). These register bits are implementation dependent. For OTG core, it's Read-Only. Reset value is 000b. For Host1/Host2/Host3 core, it's Read/Write. Reset value is 011b. Bit field {bit25, bit31, bit30}: "000b" UTMI/UTMI+ "001b" Reserved "010b" ULPI "011b" Serial/USB 1.1 PHY/IC-USB (FS Only) "100b" HSIC **NOTE:** All USB port interface modes are listed in this field description, but not all are supported. For detail feature of each controller core, please see Features . The behaviour is unknown when unsupported interface mode is selected.
29 STS	Serial Transceiver Select - Read/Write. Reset value is 0b. 1 Serial Interface Engine is selected 0 Parallel Interface signals is selected Serial Interface Engine can be used in combination with UTMI+/ULPI physical interface to provide FS/LS signaling instead of the parallel interface signals. When this bit is set '1b', serial interface engine will be used instead of parallel interface signals. This bit has no effect unless PTS bits is set to select UTMI+/ULPI interface. The Serial/USB1.1 PHY/IC-USB will use the serial interface engine for FS/LS signaling regardless of this bit value.
28 PTW	Parallel Transceiver Width

Table continues on the next page...

USB_*n*_PORTSC1 field descriptions (continued)

Field	Description
	This bit has no effect if serial interface engine is used. These register bits are implementation dependent. For OTG/Host1/Host2/Host3 core, it is Read/Write. Reset value is '1b'. 1 Select the 8-bit UTMI interface [60MHz] 2 Select the 16-bit UTMI interface [30MHz]
27–26 PSPD	Port Speed - Read Only. This register field indicates the speed at which the port is operating. 00 Full Speed 01 Low Speed 10 High Speed 11 Undefined
25 PTS	See description at bits 31-30
24 PFSC	Port Force Full Speed Connect - Read/Write. Default = 0b. When this bit is set to '1b', the port will be forced to only connect at Full Speed, It disables the chirp sequence that allows the port to identify itself as High Speed. 1 Forced to full speed 0 Normal operation
23 PHCD	PHY Low Power Suspend - Clock Disable (PLPSCD) - Read/Write. Default = 0b. When this bit is set to '1b', the PHY clock is disabled. Reading this bit will indicate the status of the PHY clock. **NOTE:** The PHY clock cannot be disabled if it is being used as the system clock. In device mode, The PHY can be put into Low Power Suspend when the device is not running (USBCMD Run/Stop=0b) or the host has signaled suspend (PORTSC1 SUSPEND=1b). PHY Low power suspend will be cleared automatically when the host initials resume. Before forcing a resume from the device, the device controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software. 1 Disable PHY clock 0 Enable PHY clock
22 WKOC	Wake on Over-current Enable (WKOC_E) - Read/Write. Default = 0b. Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if *Port Power(*Port Status & Control (USB__PORTSC1)*)* is zero.
21 WKDC	Wake on Disconnect Enable (WKDSCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if *Port Power(*Port Status & Control (USB__PORTSC1)*)* is zero or in device mode.
20 WKCN	Wake on Connect Enable (WKCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if *Port Power(*Port Status & Control (USB__PORTSC1)*)* is zero or in device mode.

Table continues on the next page...

USB_*n*_PORTSC1 field descriptions (continued)

Field	Description
19–16 PTC[3:0]	Port Test Control - Read/Write. Default = 0000b. Refer to Section 4.14 for the operational model for using these test modes and the USB Specification Revision 2.0, Chapter 7 for details on each test mode. The FORCE_ENABLE_FS and FORCE ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point. **NOTE:** *Low speed operations are not supported as a peripheral device.* Any other value than zero indicates that the port is operating in test mode. Value Specific Test 0000 TEST_MODE_DISABLE 0001 J_STATE 0010 K_STATE 0011 SE0 (host) / NAK (device) 0100 Packet 0101 FORCE_ENABLE_HS 0110 FORCE_ENABLE_FS 0111 FORCE_ENABLE_LS 1000-1111 Reserved
15–14 PIC[1:0]	Port Indicator Control - Read/Write. Default = Ob. Writing to this field has no effect if the P_INDICATOR bit in the HCSPARAMS register is a zero. Refer to the USB Specification Revision 2.0 for a description on how these bits are to be used. This field is zero if *Port Power* is zero. Bit Value Meaning 00 Port indicators are off 01 Amber 10 Green 11 Undefined
13 PO	Port Owner-Read/Write. Default = 0. This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port. Port owner handoff is not supported in all 4 controller cores, therefore this bit will always be 0.
12 PP	Port Power (PP)-Read/Write or Read Only. The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0 1b *Read Only - Host controller does not have port power control switches. Each port is hard-wired to power.*

Table continues on the next page...

USB_*n*_PORTSC1 field descriptions (continued)

Field	Description
	1 1b/0b - *Read/Write. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, etc.* When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port). This feature is implemented in all 4 controller cores (PPC = 1).
11–10 LS[1:0]	Line Status-Read Only. These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of linestate by the device controller driver is not necessary. The encoding of the bits are: Bits [11:10] Meaning 00 SE0 10 J-state 01 K-state 11 Undefined
9 HSP	High-Speed Port - Read Only. Default = 0b. When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode. **NOTE:** HSP is redundant with PSPD(bit 27, 26) but remained for compatibility.
8 PR	Port Reset - Read/Write or Read Only. Default = 0b. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. Default 0. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. *This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.* In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. This field is zero if *Port Power(*Port Status & Control (USB__PORTSC1)*)* is zero.
7 SUSP	Suspend - Read/Write or Read Only. Default = 0b. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend

Table continues on the next page...

USB_*n*_PORTSC1 field descriptions (continued)

Field	Description
	When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the The host controller will unconditionally set this bit to zero when software sets the *Force Port Resume* bit to zero. The host controller ignores a write of zero to this bit. If host software sets this bit to a one when the port is not enabled (that is, *Port enabled* bit is a zero) the results are undefined. This field is zero if *Port Power(*Port Status & Control (USB__PORTSC1)*)* is zero in host mode. In Device Mode: Read Only. In device mode this bit is a read only status bit.
6 FPR	Force Port Resume -Read/Write. 1= Resume detected/driven on port. 0=No resume (K-state) detected/ driven on port. Default = 0. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the *Port Change Detect* bit in the USBSTS register is also set to one. *This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.* Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no affect because the port controller will time the resume operation clear the bit the port control state switches to HS or FS idle. This field is zero if *Port Power(*Port Status & Control (USB__PORTSC1)*)* is zero in host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition detected, the *Port Change Detect* bit in the USBSTS register is also set to one.
5 OCC	Over-current Change-R/WC. Default=0. This bit is set '1b' by hardware when there is a change to Over-current Active. Software can clear this bit by writing a one to this bit position.
4 OCA	Over-current Active-Read Only. Default 0. This bit will automatically transition from one to zero when the over current condition is removed. 1 This port currently has an over-current condition 0 This port does not have an over-current condition.
3 PEC	Port Enable/Disable Change-R/WC. 1=Port enabled/disabled status has changed. 0=No change. Default = 0. In Host Mode:

Table continues on the next page...

USB_*n*_PORTSC1 field descriptions (continued)

Field	Description
	For the root hub, this bit is set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if *Port Power(*Port Status & Control (USB__PORTSC1)*)* is zero. In Device mode: The device port is always enabled, so this bit is always '0b'.
2 PE	Port Enabled/Disabled-Read/Write. 1=Enable. 0=Disable. Default 0. In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if *Port Power(*Port Status & Control (USB__PORTSC1)*)* is zero in host mode. In Device Mode: The device port is always enabled, so this bit is always '1b'.
1 CSC	Connect Status Change-R/WC. 1 =Change in Current Connect Status. 0=No change. Default 0. In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it. This field is zero if *Port Power(*Port Status & Control (USB__PORTSC1)*)* is zero in host mode. In Device Mode: This bit is undefined in device controller mode.
0 CCS	Current Connect Status-Read Only. In Host Mode: 1=Device is present on port. 0=No device is present. Default = 0. This value reflects the current state of the port, and may not correspond directly to the event that caused the *Connect Status Change* bit (Bit 1) to be set. This field is zero if *Port Power(*Port Status & Control (USB__PORTSC1)*)* is zero in host mode. In Device Mode: 1=Attached. 0=Not Attached. Default=0. A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended.

77.6.32 On-The-Go Status & control (USB_UOG_OTGSC)

This register is availabe only in OTG controller core. It has four sections:

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms does not cause an update of the status input register, or cause an OTG interrupt.

See also USB Device Mode (USB__USBMODE) register.

Address: USB_UOG_OTGSC is 53F8_0000h base + 1A4h offset = 53F8_01A4h

USB_UOG_OTGSC field descriptions

Field	Description
31 -	Reserved
30 DPIE	Data Pulse Interrupt Enable
29 1msE	1 millisecond timer Interrupt Enable - Read/Write

Table continues on the next page...

USB_UOG_OTGSC field descriptions (continued)

Field	Description
28 BSEIE	B Session End Interrupt Enable - Read/Write. Setting this bit enables the B session end interrupt.
27 BSVIE	B Session Valid Interrupt Enable - Read/Write. Setting this bit enables the B session valid interrupt.
26 ASVIE	A Session Valid Interrupt Enable - Read/Write. Setting this bit enables the A session valid interrupt.
25 AVVIE	A VBus Valid Interrupt Enable - Read/Write. Setting this bit enables the A VBus valid interrupt.
24 IDIE	USB ID Interrupt Enable - Read/Write. Setting this bit enables the USB ID interrupt.
23 -	Reserved
22 DPIS	Data Pulse Interrupt Status - Read/Write to Clear. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC1(0)[PP] = 0. Software must write a one to clear this bit.
21 1msS	1 millisecond timer Interrupt Status - Read/Write to Clear. This bit is set once every millisecond. Software must write a one to clear this bit.
20 BSEIS	B Session End Interrupt Status - Read/Write to Clear. This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit
19 BSVIS	B Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the B session valid threshold (0.8 VDC). Software must write a one to clear this bit.
18 ASVIS	A Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the A session valid threshold (0.8 VDC). Software must write a one to clear this bit.
17 AVVIS	A VBus Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the VBus valid threshold (4.4 VDC) on an A device. Software must write a one to clear this bit.
16 IDIS	USB ID Interrupt Status - Read/Write. This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.
15 -	Reserved

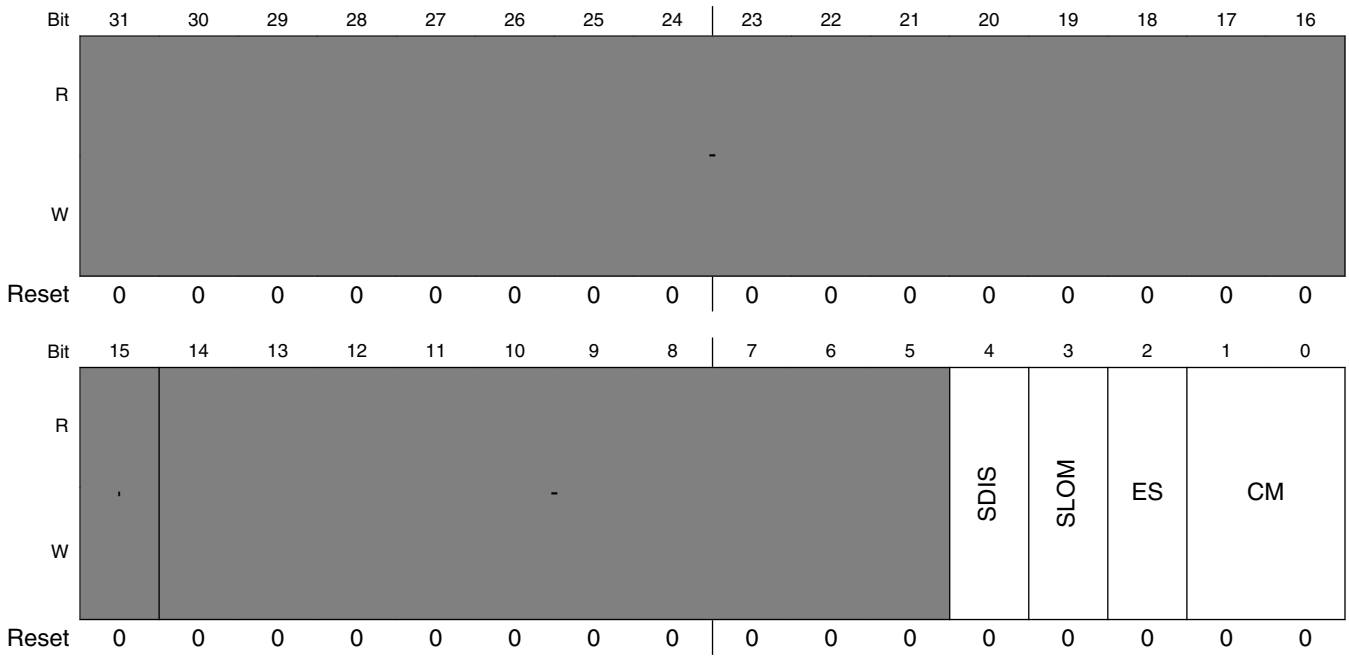
Table continues on the next page...

USB_UOG_OTGSC field descriptions (continued)

Field	Description
14 DPS	Data Bus Pulsing Status - Read Only. A '1' indicates data bus pulsing is being detected on the port.
13 1msT	1 millisecond timer toggle - Read Only. This bit toggles once per millisecond.
12 BSE	B Session End - Read Only. Indicates VBus is below the B session end threshold.
11 BSV	B Session Valid - Read Only. Indicates VBus is above the B session valid threshold.
10 ASV	A Session Valid - Read Only. Indicates VBus is above the A session valid threshold.
9 AVV	A VBus Valid - Read Only. Indicates VBus is above the A VBus valid threshold.
8 ID	USB ID - Read Only. 0 = A device, 1 = B device
7–6 -	Reserved
5 IDPU	ID Pullup - Read/Write This bit provide control over the ID pull-up resister; 0 = off, 1 = on [default]. When this bit is 0, the ID input will not be sampled.
4 DP	Data Pulsing - Read/Write. Setting this bit causes the pullup on DP to be asserted for data pulsing during SRP.
3 OT	OTG Termination - Read/Write. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.
2 -	Reserved
1 VC	VBUS Charge - Read/Write. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP.
0 VD	VBUS_Discharge - Read/Write. Setting this bit causes VBus to discharge through a resistor.

77.6.33 USB Device Mode (USB__USBMODE)

Addresses: USB_UOG_USBMODE is 53F8_0000h base + 1A8h offset = 53F8_01A8h
USB_UH1_USBMODE is 53F8_0000h base + 3A8h offset = 53F8_03A8h
USB_UH2_USBMODE is 53F8_0000h base + 5A8h offset = 53F8_05A8h
USB_UH3_USBMODE is 53F8_0000h base + 7A8h offset = 53F8_07A8h



USB_*n*_USBMODE field descriptions

Field	Description
31–16 -	Reserved
15 -	Reserved
14–5 -	Reserved
4 SDIS	Stream Disable Mode. (0 - Inactive [default]; 1 - Active) Device Mode: Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received are responded to with a NYET handshake when stream disable is active. Host Mode: Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB.

Table continues on the next page...

USB_*n*_USBMODE field descriptions (continued)

Field	Description
	NOTE: Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TX FIFO Fill Tuning (USB__TXFILLTUNING) and TXTTFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature. **NOTE:** The use of this feature substantially limits of the overall USB performance that can be achieved.
3 SLOM	Setup Lockout Mode. In device mode, this bit controls behavior of the setup lock mechanism. See Control Endpoint Operation Model . 0 Setup Lockouts On (default); 1 Setup Lockouts Off (DCD requires use of Setup Data Buffer Tripwire in USB Command Register (USB__USBCMD) .
2 ES	Endian Select - Read/Write. This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The bit fields in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word. Bit Meaning 0 Little Endian [Default] 1 Big Endian
1–0 CM	Controller Mode - R/WO. Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host & device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the *RESET* bit in the USBCMD register before reprogramming this register. For OTG controller core, reset value is '00b'. For Host1/Host2/Host3 controller core, reset value is '11b'. Bit Meaning 00 Idle [Default for combination host/device] 01 Reserved 10 Device Controller [Default for device only controller] 11 Host Controller [Default for host only controller]

77.6.34 Endpoint Setup Status (USB_UOG_ENDPTSETUPSTAT)

Address: USB_UOG_ENDPTSETUPSTAT is 53F8_0000h base + 1ACh offset = 53F8_01ACh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

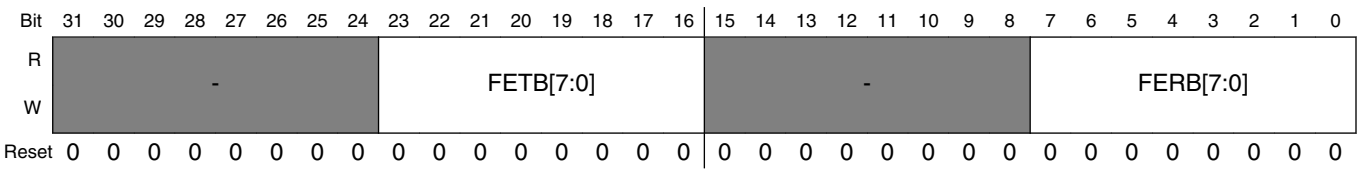
USB_UOG_ENDPTPRIME field descriptions

Field	Description
31–24 -	Reserved
23–16 PETB[7:0]	Prime Endpoint Transmit Buffer - R/WS. For each endpoint a corresponding bit is used to request that a buffer prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction. Software should write a one to the corresponding bit when posting a new transfer descriptor to an endpoint. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. **NOTE:** These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PETB[N] - Endpoint #N, N is in 0..7
15–8 -	Reserved
7–0 PERB[7:0]	Prime Endpoint Receive Buffer - R/WS. For each endpoint, a corresponding bit is used to request a buffer prepare for a receive operation for when a USB host initiates a USB OUT transaction. Software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. **NOTE:** These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PERB[N] - Endpoint #N, N is in 0..7

77.6.36 Endpoint De-Initialize (USB_UOG_ENDPTFLUSH)

This register is only used in device mode.

Address: USB_UOG_ENDPTFLUSH is 53F8_0000h base + 1B4h offset = 53F8_01B4h



USB_UOG_ENDPTFLUSH field descriptions

Field	Description
31–24 -	Reserved
23–16 FETB[7:0]	Flush Endpoint Transmit Buffer - R/WS. Writing one to a bit(s) in this register causes the associated endpoint(s) to clear any primed buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FETB[N] - Endpoint #N, N is in 0..7
15–8 -	Reserved
7–0 FERB[7:0]	Flush Endpoint Receive Buffer - R/WS. Writing one to a bit(s) causes the assocUOGiated endpoint(s) to clear any primed buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FERB[N] - Endpoint #N, N is in 0..7\

77.6.37 Endpoint Status (USB_UOG_ENDPTSTAT)

This register is only used in device mode.

Address: USB_UOG_ENDPTSTAT is 53F8_0000h base + 1B8h offset = 53F8_01B8h

USB_UOG_ENDPTSTAT field descriptions (continued)

Field	Description
23–16 ETBR[7:0]	Endpoint Transmit Buffer Ready -- Read Only. One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There is always a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. **NOTE:** These bits are momentarily cleared by hardware during hardware endpoint re-priming operations when a dTD is retired, and the dQH is updated. ETBR[N] - Endpoint #N, N is in 0..7
15–8 -	Reserved
7–0 ERBR[7:0]	Endpoint Receive Buffer Ready -- Read Only. One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPRIME register. There is always a delay between setting a bit in the ENDPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. **NOTE:** These bits are momentarily cleared by hardware during hardware endpoint re-priming operations when a dTD is retired, and the dQH is updated. ERBR[N] - Endpoint #N, N is in 0..7

77.6.38 Endpoint Complete (USB_UOG_ENDPTCOMPLETE)

This register is only used in device mode.

Address: USB_UOG_ENDPTCOMPLETE is 53F8_0000h base + 1BCh offset = 53F8_01BCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USB_UOG_ENDPTCTRL0 field descriptions

Field	Description
31–24 -	Reserved
23 TXE	TX Endpoint Enable 1 Enabled Endpoint0 is always enabled.
22–20 -	Reserved
19–18 TXT	TX Endpoint Type - Read/Write 00 - Control

Table continues on the next page...

USB_UOG_ENDPTCTRL0 field descriptions (continued)

Field	Description
	Endpoint0 is fixed as a Control End Point.
17 -	Reserved
16 TXS	TX Endpoint Stall - Read/Write 0 End Point OK [Default] 1 End Point Stalled Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request.
15–8 -	Reserved
7 RXE	RX Endpoint Enable 1 Enabled Endpoint0 is always enabled.
6–4 -	Reserved
3–2 RXT	RX Endpoint Type - Read/Write 00 Control Endpoint0 is fixed as a Control End Point.
1 -	Reserved
0 RXS	RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request.

77.6.40 Endpoint ControlIn (USB_UOG_ENDPTCTRL*n*)

There is a UOG_ENDPTCTRLx register for each endpoint in a device.

NOTE

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

Addresses: USB_UOG_ENDPTCTRL1 is 53F8_0000h base + 1C4h offset = 53F8_01C4h
USB_UOG_ENDPTCTRL2 is 53F8_0000h base + 1C8h offset = 53F8_01C8h
USB_UOG_ENDPTCTRL3 is 53F8_0000h base + 1CCh offset = 53F8_01CCh
USB_UOG_ENDPTCTRL4 is 53F8_0000h base + 1D0h offset = 53F8_01D0h
USB_UOG_ENDPTCTRL5 is 53F8_0000h base + 1D4h offset = 53F8_01D4h
USB_UOG_ENDPTCTRL6 is 53F8_0000h base + 1D8h offset = 53F8_01D8h
USB_UOG_ENDPTCTRL7 is 53F8_0000h base + 1DCh offset = 53F8_01DCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	-								TXE	TXR	TXI	-	TXT		TXD	TXS

R	-								RXE	RXR	RXI	-	RXT		RXD	RXS
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USB_UOG_ENDPTCTRL*n* field descriptions

Field	Description
31–24 -	Reserved
23 TXE	TX Endpoint Enable 0 Disabled [Default] 1 Enabled An Endpoint should be enabled only after it has been configured.
22 TXR	TX Data Toggle Reset (WS) Write 1 - Reset PID Sequence Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the Host and device.
21 TXI	TX Data Toggle Inhibit 0 PID Sequencing Enabled. [Default] 1 PID Sequencing Disabled. This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet.

Table continues on the next page...

USB_UOG_ENDPTCTRL*n* field descriptions (continued)

Field	Description
20 -	Reserved
19–18 TXT	TX Endpoint Type - Read/Write 00 Control 01 Isochronous 10 Bulk 11 Interrupt
17 TXD	TX Endpoint Data Source - Read/Write 0 Dual Port Memory Buffer/DMA Engine [DEFAULT] Should always be written as 0.
16 TXS	TX Endpoint Stall - Read/Write 0 End Point OK 1 End Point Stalled This bit is set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It is cleared automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues to returning STALL until this bit is either cleared by software or automatically cleared as above. **NOTE:** For CONTROL type endpoint, there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. Take care that the STALL bit is not set immediately after writing a '1' to it. Please follow this procedure: continually write this STALL bit until it is set or until a new setup has ben received by checking the associated ENDPTSETUPSTAT bit.
15–8 -	Reserved
7 RXE	RX Endpoint Enable 0 Disabled [Default] 1 Enabled An Endpoint should be enabled only after it has been configured.
6 RXR	RX Data Toggle Reset (WS) Write 1 - Reset PID Sequence Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the host and device.
5 RXI	RX Data Toggle Inhibit 0 Disabled [Default] 1 Enabled This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always accept data packet regardless of their data PID.
4 -	Reserved.

Table continues on the next page...

USB_UOG_ENDPTCTRL*n* field descriptions (continued)

Field	Description
3–2 RXT	RX Endpoint Type - Read/Write 00 Control 01 Isochronous 10 Bulk 11 Reserved
1 RXD	RX Endpoint Data Sink - Read/Write - TBD 0 Dual Port Memory Buffer/DMA Engine [Default] Should always be written as zero.
0 RXS	RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled This bit is set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It is cleared automatically upon receipt a SETUP request if this Endpoint is configured as a Control Endpoint, Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues to returning STALL until this bit is either cleared by software or automatically cleared as above.

77.6.41 ULPI Viewport (USB__ULPIVIEW)

The register provides indirect access to the ULPI PHY register set. Although the core performs access to the ULPI PHY register set, there may be extraordinary circumstances where software may need direct access.

NOTE

Writes to the ULPI through the ULPI Viewport can substantially harm standard USB operations. Most of the ULPI register settings are under direct control of the USB core and should not be changed by software through viewport writes as this may harm USB operations.

NOTE

Executing read operations though the ULPI Viewport should have no harmful side effects to standard USB operations.

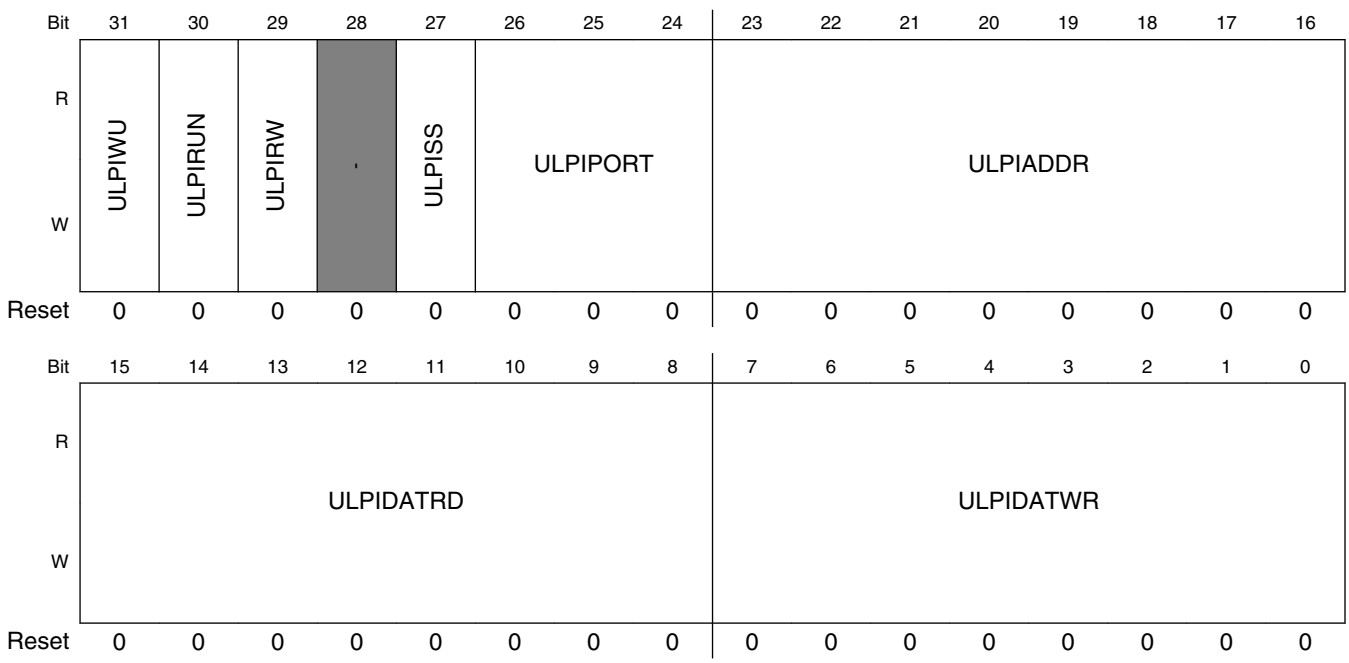
There are two operations that can be performed with the ULPI Viewport, wake-up and read /write operations. The wake-up operation is used to put the ULPI interface into normal operation mode and re-enable the clock if necessary. A wake-up operation is required before accessing the registers when the ULPI interface is operating in low power mode, serial mode, or carkit mode. The ULPI state can be determined by reading the sync. state bit (ULPISS). If this bit is a one, then ULPI interface is run

operation mode and can accept read/write operations. If the ULPISS indicates a '0' then read/write operations will not be able execute. Undefined behavior will result if ULPISS = 0 and a read or write operation is performed. To execute a wake-up operation, write all 32-bits of the ULPI Viewport where ULPIPORT is constructed appropriately and the ULPIWU bit is a '1' and ULPIRUN bit is a '0'. Poll the ULPI Viewport until ULPIWU is zero for the operation to complete.

To execute a read or write operation, write all 32-bits of the ULPI Viewport where ULPIDATWR, ULPIADDR, ULPIPORT, ULPIRW are constructed appropriately and the ULPIRUN bit is a '1'. Poll the ULPI Viewport until ULPIRUN is zero for the operation to complete. Once ULPIRUN is zero, the ULPIDATRD will be valid if the operation was a read.

The polling method above could also be replaced and interrupt driven using the ULPI interrupt defined in the USB Status Register (USB__USBSTS) and Interrupt Enable Register (USB__USBINTR) registers. When a wake-up or read/write operation complete, the ULPI interrupt will be set.

Addresses: USB_UOG_ULPIVIEW is 53F8_0000h base + 770h offset = 53F8_0770h
USB_UH1_ULPIVIEW is 53F8_0000h base + 970h offset = 53F8_0970h
USB_UH2_ULPIVIEW is 53F8_0000h base + B70h offset = 53F8_0B70h
USB_UH3_ULPIVIEW is 53F8_0000h base + D70h offset = 53F8_0D70h



USB_*n*_ULPIVIEW field descriptions

Field	Description
31 ULPIWU	ULPI wake-up - Read/Write.

Table continues on the next page...

USB_*n*_ULPIVIEW field descriptions (continued)

Field	Description
	Writing the 1 to this bit will begin the wake-up operation. The bit will automatically transition to 0 after the wake-up is complete. Once this bit is set, the driver can not set it back to 0. Note: The driver must never execute a wake-up and a read/write operation at the same time.
30 ULPIRUN	ULPI Read/Write Run - Read/Write. Writing the 1 to this bit will begin the read/write operation. The bit will automatically transition to 0 after the read/write is complete. Once this bit is set, the driver can not set it back to 0. **NOTE:** The driver must never execute a wake-up and a read/write operation at the same time.
29 ULPIRW	ULPI Read/Write Control - Read/Write. (0) - Read; (1) - Write. This bit selects between running a read or write operation.
28 -	Reserved
27 ULPISS	ULPI Sync State - Read Only. (1) - Normal Sync. State. (0) In another state (that is, carkit, serial, low power) This bit represents the state of the ULPI interface. Before reading this bit, the ULPIPORT field should be set accordingly if used with the multi-port host. Otherwise, this field should always remain 0.
26–24 ULPIPORT	ULPI Port Number - Read/Write. For the wake-up or read/write operation to be executed, this value selects the port number the ULPI PHY is attached to in the multi-port host. The range is 0 to 7. This field should always be written as a 0 for the non-multi port products.
23–16 ULPIADDR	ULPI Data Address - Read/Write. When a read or write operation is commanded, the address of the operation is written to this field.
15–8 ULPIDATRD	ULPI Data Read - Read Only. After a read operation completes, the result is placed in this field.
7–0 ULPIDATWR	ULPI Data Write - Read/Write. When a write operation is commanded, the data to be sent is written to this field.

Chapter 78
Video Processing Unit (VPU)

78.1 Introduction

The Video Processing Unit (VPU) is the multi-media video processing block in i.MX 6Dual/6Quad.

The following figure shows VPU top-level diagram.

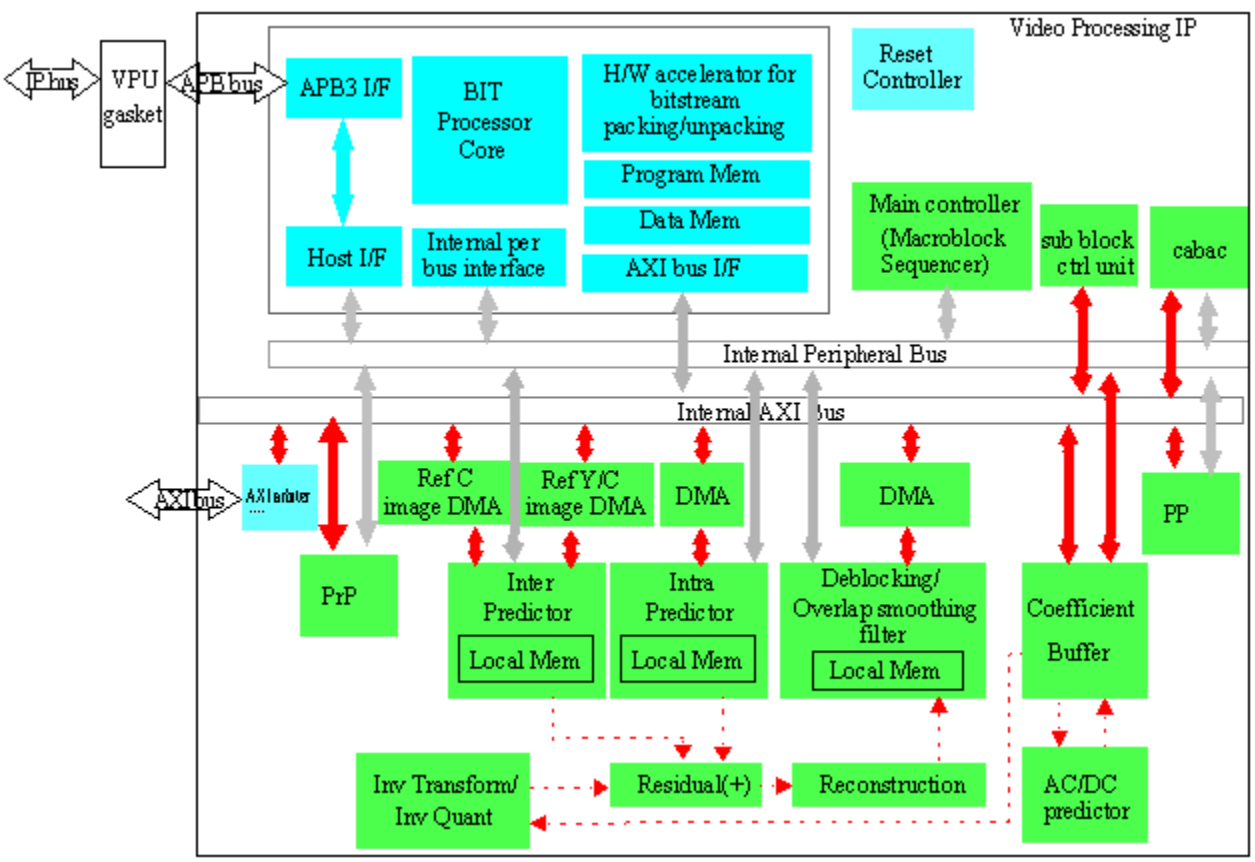


Figure 78-1. VPU Block Diagram

78.1.1 Overview

Video Processing Unit of i.MX53 is a high performance multi-standard video codec which can decode H.264 BP/MP/HP, VC-1 SP/MP/AP, MPEG-4 SP/ASP, H.263 P0/P3, MPEG-1/2 MP, Divx (Xvid) HP/PP/HTP/HDP, RV8/9/10, Sorenson Spark, VP8 (1280x720), AVS, H.264-MVC (1280x720), MJPEG BP (max. 8192x8192) up to full-HD 1920x1088 @30fps.

It can also perform H.264 BP/CBP, MPEG-4 SP, H.263 P0/P3, MJPEG BP (max. 8192x8192) encoding up to 1280x720 @30fps. VPU can support encode or decode multiple video clips with multiple standards simultaneously.

VPU has two bus interface: IP bus for register access controlling and AXI bus for data throughput.

VPU makes use of external memory space for bitstream buffer, parameter buffer, bit code buffer, working buffer and frame buffer. VPU has 51Kbyte internal memories to achieve high performance decoding.

VPU has an embedded BIT processor controlling internal video processing sub-blocks and communicating with host processor through host interface. Very low resources of the ARM platform is required to support VPU. Host processor only need to access VPU registers for initializing VPU or setting parameters during frame gap. In application, it is done through VPU API called by host processor. Large part of video codec (except BIT processor) is optimally shared which enables to achieve low power and low gate count.

VPU combined with processing capabilities of Image Processing Unit (IPU) can support high quality video processing applications for i.MX 6Dual/6Quad.

78.1.2 Features

VPU supports H.264 BP/MP/HP, VC-1 SP/MP/AP, MPEG-4 SP/ASP, H.263 P0/P3, MPEG-1/2 MP/HP, Divx (Xvid) HP/PP/HTP/HDP, RV8/9/10, Sorenson Spark, MJPEG BP decoding and H.264 BP/CBP, MPEG-4 SP, H.263 P0/P3, MJPEG BP encoding. The supported resolution is up to full-HD 1920x1088@30fps for decoding and 1280x720 @30fps for encoding except MJPEG codec (up to 8192x8192). VPU can support various error resilience tools and also support multiple decoding and full duplex multi-party-call simultaneously.

And the VPU provides programmability, flexibility and ease of upgrade in decoding/encoding or host interface because all the controls in decoding/encoding process and host interface are implemented as firmware in a programmable BIT processor

NOTE

The capabilities of VPU listed here is measured with a nearly ideal bus and memory system. But in real SOC, the capabilities of VPU are also depends on the bus and memory system of SOC.

The detailed feature of VPU is as follows:

Table 78-1. Supported Decoding/Encoding Standards

	Standard	Profile	Level	Resolution
Encoder	H.264	BP	3/3.1	1280x720
	MPEG-4	SP	5/6	1280x720
	H.263	P0/P3	70	1280x720
	MJPEG	BP		8192x8192
Decoder	H.264	BP/MP/HP	3/3.1/4.1	1920x1088
	MPEG-4	SP/ASP	5/6	1920x1088
	H.263	P0/3	70	1920x1088
	VC-1	SP/MP/AP	ML/L1,2,3	1920x1088
	MPEG-2	MP/HP	ML/HL	1920x1088
	DivX/Xvid	HP/PP/HTP/HDP		1920x1088
	RV	8/9/10		1920x1088
	H.264-MVC	BP/MP/HP		1280x720
	MJPEG	BP		8192x8192

- Multi-standard video codec
  - H.264/AVC decoder for baseline profile, main profile and high profile
  - VC-1 decoder for simple profile, main profile and advanced profile
  - MPEG-4 decoder for simple profile, advanced simple profile except GMC
  - H.263 decoder for baseline profile
  - Divx decoder for home theater and high definition profile (version 3.x, 4.x, 5.x, 6.x) and Xvid
  - MPEG-2 decoder for main profile @ main and high level
  - RV decoder for profile 8/9/10
  - MJPEG decoder for Baseline profile
  - H.264/AVC encoder for baseline profile
  - MPEG-4 encoder for simple profile
  - H.263 encoder for baseline profile
  - MJPEG encoder for baseline profile
  - Multiple codec: supports up to 4 decoding/encoding processes simultaneously, each process can have a different format.
- Other features

- Pre/Post rotator and mirror
- Built-in de-ringing filter.
- Built-in de-blocking filter for MPEG-2/MPEG-4/Divx.
- MPEG-2 encoder partial acceleration.
- Simultaneous multi-stream and multi-standard processing capability.
- Robust error detection/concealment.

- Programmability
  - Embeds 16-bit BIT processor that is dedicated to processing bitstream and controlling the hardware.
  - General purpose registers and interrupt generation for communication between host processor and VPU.

78.1.3 Modes of Operation

The VPU has two kinds of operating modes: normal operating mode and low power mode.

78.1.3.1 Normal Operating Mode

Normal operating mode is the video codec processing mode, which can be MPEG-4 encoding/decoding, Divx decoding, H.264 encoding/decoding, VC-1 decoding, or multiple bitstream encoding/decoding in multiple standards simultaneously.

VPU supports up to 4 decoding/encoding processes simultaneously. Each process can have a different format. The host processor creates and executes the specified process by sending parameters and commands to the BIT processor through the VPU API.

78.1.3.2 Low Power Mode

When VPU is in idle state, VPU interface signal vpu_idle is asserted and system can gate off its clock source according to this signal.

If the clock source is gated off and system wants to wake it up, it just re-enable the clock and send command to VPU. If power is off when the system wants to wake it up, VPU has to be re-initialized.

78.2 Functional Description

VPU is a high-performance multi-standard video processing block that supports up to full HD 1920 x 1088 at 30 fps decoding and 1280 x 720 at 30 fps encoding.

78.2.1 VPU Architecture

VPU is a high performance multi-standard video codec that can decode

- H.264 BP/MP/HP
- VC-1 SP/MP/AP
- MPEG-4 SP/ASP
- H.263 P0/P3
- MPEG-1/2 MP/HP
- Divx (Xvid) HP/PP/HTP/HDP
- RV8/9/10
- Sorenson Spark
- MJPEG BP (max. 8192x8192) up to full-HD 1920 x 1088 at 30 fps

It can also perform H.264 BP, MPEG-4 SP, H.263 P0/P3, and MJPEG BP (max. 8192x8192) encoding up to 1280 x 720 at 30 fps. VPU can support encode or decode multiple video clips with multiple standards simultaneously.

It connects with the system via the 32-bit IP bus for system control and 64-bit AMBA3 AXI for data throughput. It uses on-chip memories to achieve high performance.

VPU has a 16-bit DSP called a BIT processor. The BIT processor controls the internal video codec sub blocks and communicates with a host processor through the host interface. The required resource for the host ARM platform to control the VPU is very low, under 1 MIPS, because all functions such as rate control, FMO, ASO, video codec control and error resilience are implemented in the BIT processor. The majority of sub-blocks in VPU are optimally shared, which enables the ultra low power and low gate count.

VPU mainly consists of an embedded 16-bit BIT processor, video codec hardware, and bus arbiter/interface. Refer to for the block diagram of VPU.

78.2.1.1 Embedded BIT processor

The embedded BIT processor is used for parsing or forming bitstreams. It includes some hardware accelerators to speed up bitstream processing.

In addition to handling bitstreams, the BIT processor controls the video decoding hardware and communicates with host processor through IP bus and AXI bus interface.

78.2.1.2 Video CODEC Hardware

All video decoding processing, except handling coefficients for VLD, are implemented in hardware.

The video codec hardware is designed to reduce logic gate count by sharing parts of sub-blocks for multi-standard video decoding.

It mainly includes the following hardware components.

78.2.1.2.1 Inter-Predictor

The Inter-Predictor sub-block uses a reconstructed motion vector that represents the displacement between the block currently being decoded and the corresponding location in the reference frame, to calculate interpolated pixel data for motion compensation.

78.2.1.2.2 AC/DC and Intra-Predictor

There are two intra-prediction sub-blocks in the video decoding hardware. One is for the MPEG-4/H.263 P3/VC-1 AC/DC prediction and another for the H.264 intra-prediction.

In case of VC-1 decoding, the hardware prediction mode decision is used. It brings high performance and low power consumption. The coefficient data of decoding is re-ordered automatically based on the detected prediction mode. For H.264 intra-prediction mode in decoding, hardware mode decision or software based made decision is used.

78.2.1.2.3 Inverse transform/Inverse quantization

VPU has only one transform/quantization sub-block. It operates in several types of inverse transform/quantization for MPEG-2, VC-1 and H.264.

Each inverse transform/quantization for decoding uses different coefficients and different data processes, but it uses same control and data flow in many cases.

78.2.1.2.4 De-blocking/Overlap-smoothing filter

>De-blocking filter removes blocking artifacts resulted from quantization, different motion vectors. The filter processing is applied in both decoder and encoder.

The VPU de-blocking filter supports H.264/H.263/MPEG4/VC-1. Overlap-smoothing filter supports VC-1 overlap-smoothing feature. For H.264, H.263 and VC-1, the de-blocking filter operates within coding loop. Filtered frames are used as reference frames for motion compensation of subsequent coded frames. But for MPEG4, the de-blocking filter operates outside coding loop for only display.

78.2.1.2.5 Coefficient buffer interface

The coefficient buffer interface provides a channel for BIT processor to read quantized coefficients resulted from encoding process or to send variable-length-decoded coefficients to the video codec for decoding process.

78.2.1.2.6 Macroblock controller

VPU has a complex and large number of pipeline for high-performance. To manage it wholly by BIT processor is not suitable, so VPU embeds the macroblock controller to control all sub-blocks of the video codec based on the configuration of pipelining by BIT processor. This scheme reduces the load on BIT processor and guarantees the programmability of the block. Before the video codec encodes or decodes a macroblock, BIT processor configures how the pipeline of the codec is structured. If all processes are completed for encoding/decoding a macroblock, the macro-block controller indicates its completion. In summary,

BIT processor configures which sub-blocks are enabled for current macroblock processing, and the macroblock controller manages corresponding sub-blocks based on the configuration.

The figure below shows the connectivity of macroblock controller.

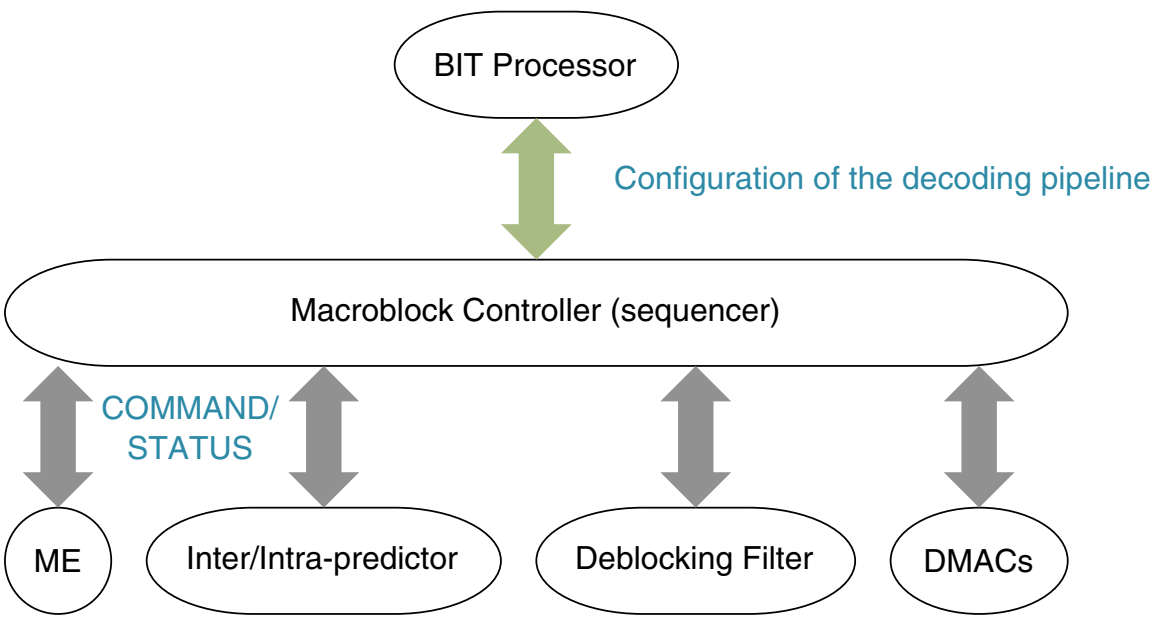

Figure 78-2. The connectivity of macroblock controller

78.2.1.2.7 Rotation/Mirroring

VPU supports rotation together with mirroring function for decoding output image to display. It is done by rotator/mirror sub-block.

The rotation/mirroring process in decoding process requires additional bandwidth because VPU has to re-use the un-rotated image for decoding the next image. So the rotated image is written to other memory space. In this scheme, the display I/F has not to change memory space for displaying the decoded image because subsequent rotated image is written to the same space.

The rotator sub-blocks support 8-types mode of 90 x n degree(n=0, 1, 2, 3) rotating and mirroring. The figure below gives architecture diagram of post rotation/mirroring sub-block.

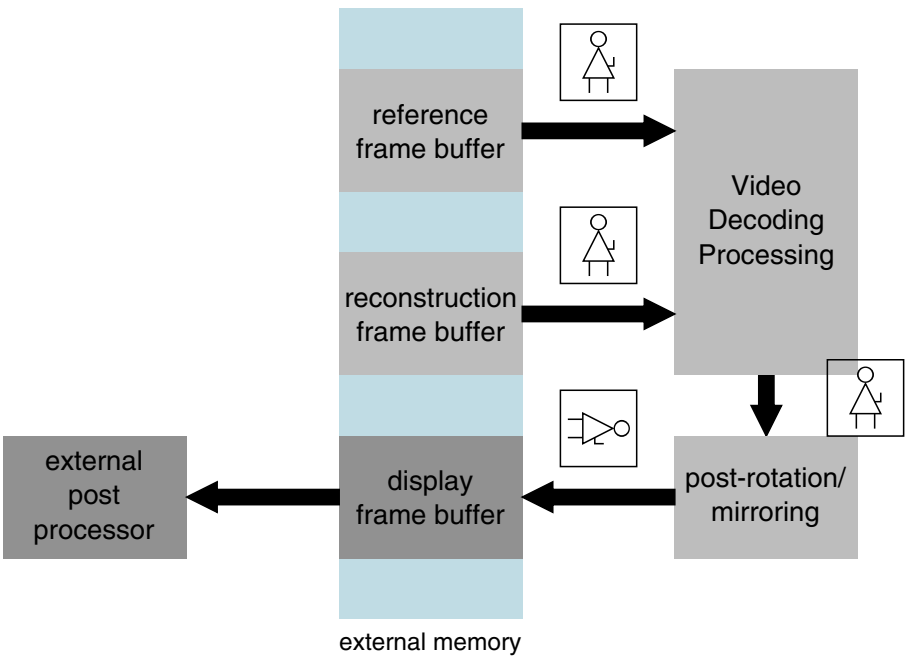

Figure 78-3. Post rotation/mirroring

78.2.2 Clocks

There are four clock domains in VPU.

- AXI bus clock domain (aclk): Controls all AXI bus related functions. Maximum frequency is 200MHz. The aclk derives from the same clock as other blocks performing AXI bus access in i.MX 6Dual/6Quad, the frequency is determined by the whole system performance requirement.
- Decoding core clock domain (cclk): This is VPU functional clock. It controls all VPU decoding functionality, with a maximum frequency of 200MHz. The actual value of the core clock is dependent upon the maximum use case. Clock frequency scaling will be done through the VPU API.

- IP bus clock domain (ipg_clk_s): Controls VPU registers read/write function, with a maximum frequency of 66.5 MHz. ipg_clk_s is a gated clock of IP green-line clock (ipg_clk) with ips_module_en, it is turned off when there is no registers read/write, for power saving.
- Reference clock domain (rclk): Used as reference clock for vpu_idle related logic.

VPU has all four clock domains because it involves in AXI signal generation, functional calculation, IP bus configuration, vpu_idle control logic. Only positive edge clocks is used in VPU design. Each clock is fully asynchronous with other clocks and separated from other clocks.

All clocks can be gated off when VPU is in the idle state to reduce power consumption. There is no restriction about the value of aclk and cclk. The actual frequency of aclk and cclk affects bus bandwidth and video decoding processing capability.

78.2.3 Reset

There are four reset signals going into VPU, corresponding to four clock domains, active low.

- areset_n: used in AXI bus interface. Corresponding clock is aclk.
- creset_n: used in BIT processor and video codec hardware. Corresponding clock is cclk.
- ipg_hard_pos_async_reset_b: used in IP bus interface. Corresponding clock is ipg_clk_s.
- rreset_n: used in reference counter for vpu_idle or vpu_underrun. Corresponding clock is rclk.

The number of cycles for each reset signal must be at least 16 cycles.

VPU embeds an internal reset controller for feature of the software reset from the BIT processor. If any of the VPU blocks except the BIT processor is needed to reset (software reset), the host processor can enable this software reset by setting the software reset register through VPU API. But, the BIT processor cannot be reset by this software reset scheme, because the reset signal of the BIT processor is connected directly from external reset signal.

If reset fires when VPU is processing a transaction through the AXI bus, there is no guarantee that the AXI will complete the transaction normally, because VPU will be reset. If there are any corrupted data in memory, it can be discarded by software. Basically, if the host processor needs to issue a reset, it must check that there is no

transaction on AXI bus between the VPU and external memory interface. In general, the AXI bus is free of VPU transactions when one frame decoding is completed. The start of next frame processing need software configuration

78.2.4 Interrupts

There isone interrupt signal output from VPU. Basically, this interrupt is used to indicate completion of decoding or encoding one frame.

It is generated when VPU interrupt is enabled and as well as the interrupt condition is met. The interrupt signal is active high and retains till the host processor clears it by writing "1" to the interrupt clear register. This signal is synchronized to the positive edge of cclk.

When getting frame completion interrupt, the software can set the parameters for next frame processing and start the BIT processor again. The parameters are mainly the source/destination frame buffer base address. It can be different from the previous frame buffer because the previous completed frame of data may be needed for other image block like display block or IPU in the system.

Basically, the following operation responding to interrupt is dependent upon the application. For example, the software can send the decoded frame to the Image Processing Unit for post-processing and display, at the same time the software should prepare the next bitstream to be processed to the external memory before starting a new processing. This can be done through VPU driver.

78.2.5 Endianness

VPU supports both little and big endian memory system.

User should specify the endianness of the bitstream buffer and frame buffer corresponding to the application scenario. The endianness configuration can be done through VPU API.

78.3 Initialization Information

VPU embedded BIT processor is highly optimized to handle bitstream data.

In addition to processing bitstreams, the BIT processor also controls the communication between VPU and host processor.

The BIT processor firmware to drive video decoding is divided into 2 parts.

One is boot code, which is downloaded by host processor through the IP bus to BIT processor internal memory, it is loaded only once at the VPU initialization stage. The size of the boot code is 1Kbyte. This boot code has also to be written to a region of external memory, and the base address of the firmware region is written through VPU API.

The other is a package of firmware for driving decoding processing. Before starting decoding, firmware has to be written to the continuous region of external memory following the boot code. At run-time, the BIT processor will self-download firmware into internal memory corresponding to the activated decoding standard. It is loaded through the AXI bus.

The VPU initialization process is shown in the figure below.

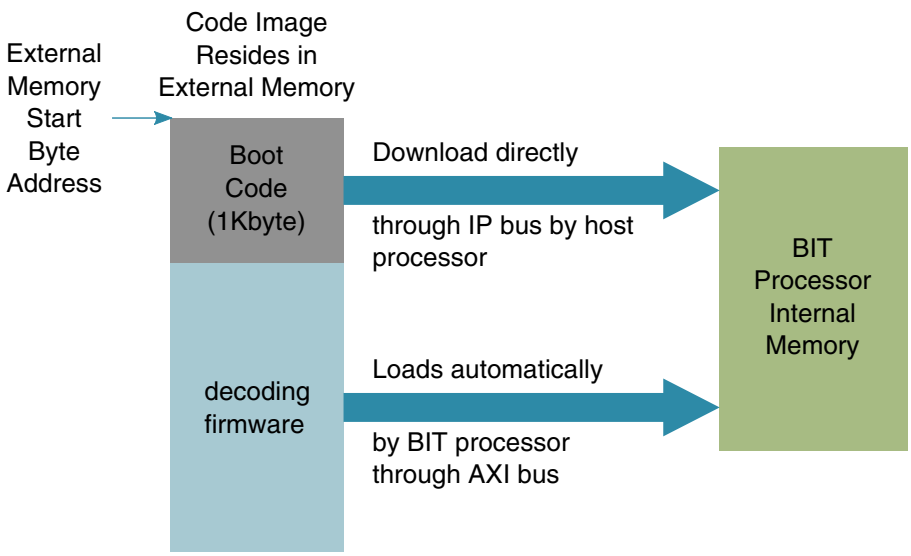

Figure 78-4. VPU initialization process

78.4 Application Information

The figure below shows roles of the BIT processor and VPU video processing core sub-block and how to interface with application software. Basically, at the frame level, host processor communicates with VPU through the provided API's. To give the video decoding more flexibility and debugging capability, all processes related to the bitstream are assigned to the BIT processor.

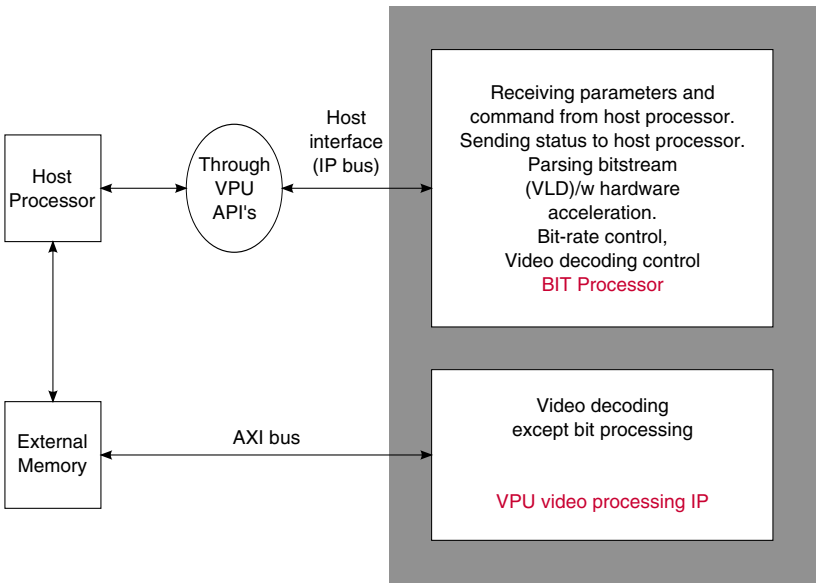

Figure 78-5. VPU interface with application software diagram

78.4.1 Video Decoding Processing Control

This section describes how BIT processor controls the video decoding and communicates with the host.

78.4.1.1 Video Decoding Process Flow

VPU can handle a maximum of 4 processes simultaneously. Each process can have a different format - MPEG-4, MPEG-2, H.264, VC-1 and etc. The figure below shows a simplified state diagram for running decoding process.

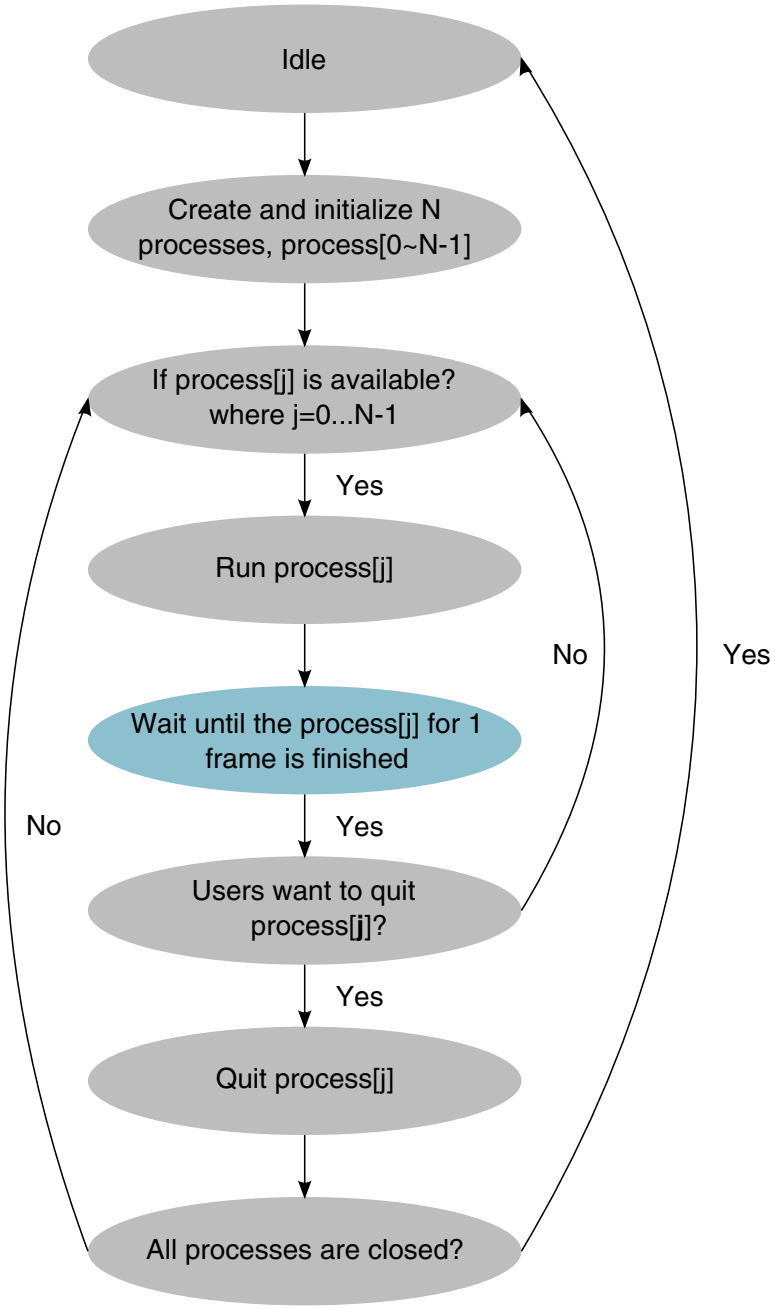

Figure 78-6. Decoding process state diagram

Each decoding process consists of three categories:

- Create processes- Software creates and configures processes.
- Running processes- At a proper time instance, software will begin a specific process. The proper time instance means when the decoding is in idle state and bitstream to be decoded is ready in the external memory.
- Quit Processes- Software can quit a specific process

If more than one process are ready to run, each process must be assigned to different process ID - RunIndex, which is range from 0 to 3. Basically, the ID is assigned based on the order of creation. For example, when 1 MPEG-4 Decoding + 1 H.264 Decoding + 1 MPEG-2 Decoding + 1 VC1 Decoding are running simultaneously, MPEG-4 Decoding is assigned to process index "0", H.264 Decoding is assigned to process index "1", MPEG-2 Decoding is assigned to index "2", and VC1 decoding is assigned to process index "3".

There is no priority rules for executing processes, after creating all processes at the initialization step, the host enables the BIT processor to execute process specified with the RunIndex. All processes are executed in time-division like mechanism, after one process finishes decoding or encoding a frame, another process then can be executed.

In conjunction with the process ID, the RunCodStd needs to be set, to define which coding standard is used with the created process and whether the created process will decode a bitstream. The table below shows the dedicated RunCodStd value for each decoding standard. All this can be done through VPU API.

Table 78-2. RuncCodStd Register Value for Coding Standard

Coding standard	RunCodStd
MPEG-4/H.263 decoding	0
MPEG-4/H.263 encoding	1
H.264 decoding	2
H.264 encoding	3
VC-1 decoding	4

78.4.1.2 Video Decoding Process Command

There are 7 execution commands to initialize, run, quit, set frame and set parameter processes. A command is sent by writing the command value to the RunCommand register through VPU API.

- DEC_SEQ_INIT- This command is to initiate a decoding process. At DEC_SEQ_INIT command, BIT processor finds sequence header and parses the header to extract bitstream information such as picture size then the information is reported to DEC_SEQ_INIT return registers. API should set following configuration parameters before sending this command to VPU.
  - Bitstream buffer base address and size
  - Frame buffers base addresses and stride lines
- DEC_SEQ_END- This command is to terminate a decoding process.
  - After this command, no more PICTURE_RUN commands will be accepted for this process.

- DEC_PIC_RUN- This command is to decode one picture.
  - In decoding case, frame destination address should be set before executing.
- SET_FRAME_BUF- This command informs frame buffer addresses to be used as a decoding/reconstructing image to the BIT processor. Total 63 frame buffers may be used for decoding/reconstructing.
  - The decoding image must be reserved for motion compensation reference until it is not used for reference. So the decoded frame buffer is re-used carefully. The BIT processor receives the whole frame buffer address by this command before picture decoding is started. Then the BIT processor manages the frame buffer allocation for next storage area for decoding.
  - The frame buffer addresses are stored to external memory address. The luminance and one/two chrominance buffer addresses for each frame index must be stored.
- DEC_PARA_SET- This command adds a sequence parameter set or a picture parameter set in H.264 decoder case.
  - The sequence parameter set or the picture parameter set may be conveyed via "out-of-band". In that case, the host must transfer the sequence parameter set or picture parameter set to decoder by this command.
  - The sequence parameter set or picture parameter set must be written to the Parameter buffer of the BIT processor in RBSP format prior to executing this command. The BIT processor decodes the transferred sequence/the picture parameter and stores decoded contents. The decoded sequence/picture parameter set will be activated at decoding slice header with the matched sequence/picture parameter set id.
  - Multiple sequence/picture parameter sets may be delivered to decoder. They are distinguished by different sequence/picture parameter set id. BIT processor can process 32 sequence parameter sets and 256 picture parameter sets.
  - The type (sequence or picture) and size (byte count) of conveyed sequence/ picture parameter set must be delivered to BIT processor by command argument register.
- DEC BUF FLUSH- Flush data in bitstream buffer.
  - After this command finished, bitstream buffer read pointer will be 0. So host must set bitstream buffer write pointer as 0.
- GET F/W VERSION- Get firmware version.

There is a busy status register in the VPU to show whether the BIT processor is executing a command. The busy status keeps "1" until the command is finished, then the BIT processor can accept a new command.

78.4.1.3 Video Decoding Process Finish Detection

VPU raises the interrupt signal or busy state is asserted when a process finishes decoding a frame. So there are three ways of detecting whether the process is finished:

- Polling VPU interrupt status register. When interrupt is generated, the interrupt status register can indicate that.
- Polling VPU busy status register. When a DEC_PIC_RUN command is issued to BIT processor and the process is under operation, the busy status keeps "1", as soon as the busy status becomes "0", the decoding process is finished.
- Capture the interrupt signal from system level, respond to interrupt request within system interrupt service routine.

There is a single busy status register for all processes, user knows which process is finished by the specified running process ID - RunIndex. Interrupt status can be cleared by writing 1 to interrupt clear register. Busy state can be self cleared after read out.

78.4.1.4 Video Decoding Process Flow Example

The figure below shows a process flow example for decoding an H.264 bitstream and decoding an MPEG4 bitstream simultaneously. At first both decoding process are created and initialized, then each process is executed with DEC_PIC_RUN command alternately. More details are described as below.

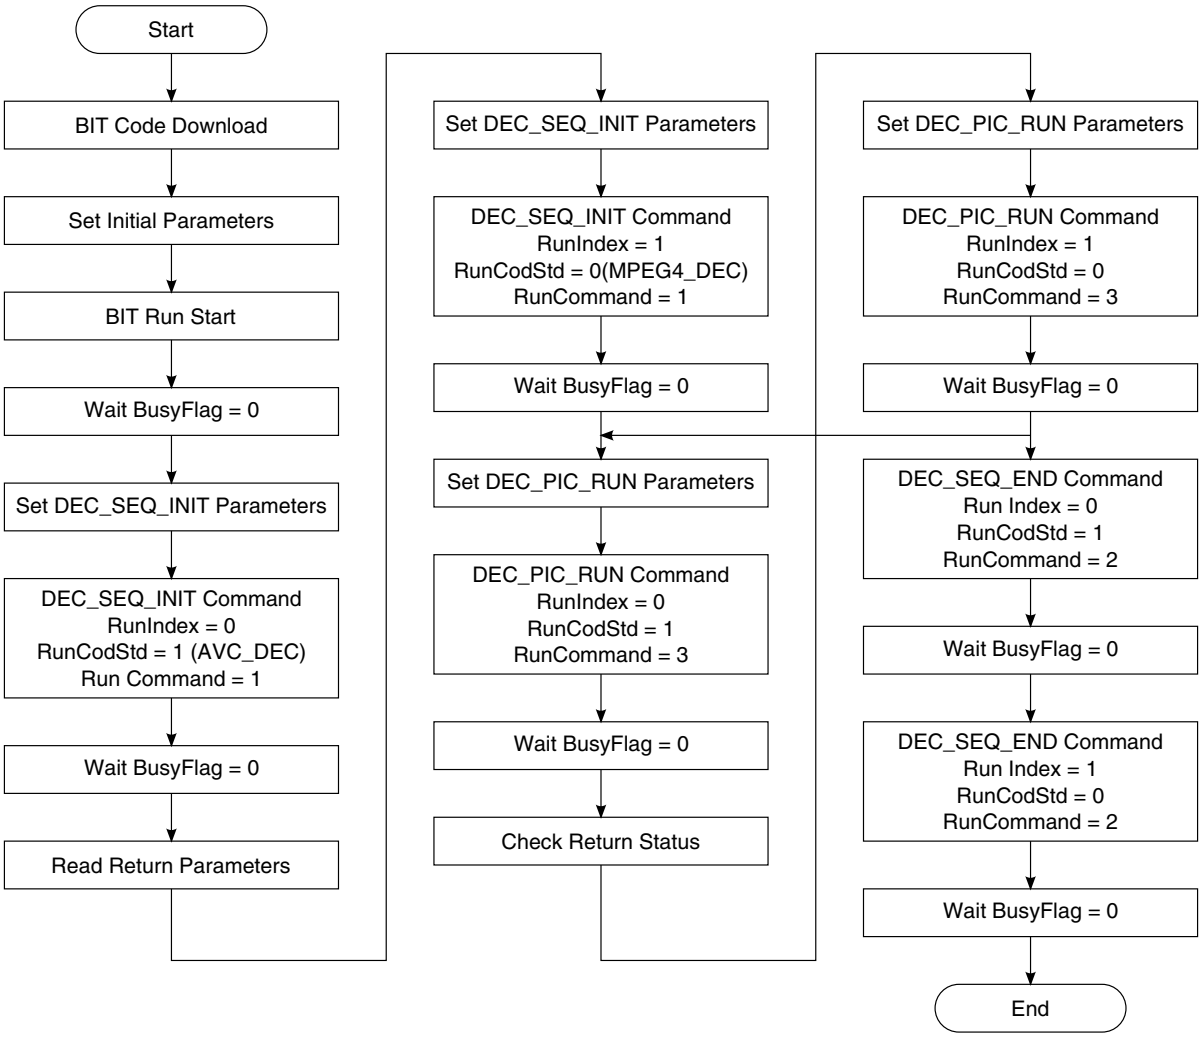

Figure 78-7. H.264 decoding and MPEG4 decoding process flow

NOTE

*RunCommand = 1 (DEC_SEQ_INIT); RunCommand = 2 (DEC_SEQ_END); RunCommand = 3 (DEC_PIC_RUN)

1. Initialize VPU
   - BIT Code Download: Load BIT Processor firmware to memory.
   - Set Initial Parameters: General configuration for BIT processor, setting working buffer base address, BIT Code memory address, bitstream buffer control and so on.
   - BIT Run Start: Run BIT processor to initialize VPU.
2. Create and initialize an H.264 decoding process
   - Set DEC_SEQ_INIT parameters: Configure base address and size of bitstream buffer, base address of frame buffers and so on.
   - Run DEC_SEQ_INIT command: Initiate an H.264 decoding process.

- Wait BusyFlag=0: Wait BIT processor completes DEC_SEQ_INIT command execution.
- Read Return Parameters: Read the features of decoded bitstream, such as the picture resolution and number of reference frames, this can be done by reading the RetSrcFormat and Ret264Info register through VPU API. In this way, the host can prepare the required frame buffers.

3. Create and initialize an MPEG4 decoding process
   - The flow is similar to the H.264 decoding process except the run standard setting.
4. Run the H.264 decoding process
   - Set DEC_PIC_RUN Parameters: Configure the frame destination address.
   - Run DEC_PIC_RUN command: Start the H.264 decoding process.
   - Wait BusyFlag=0: Wait the BIT processor completes DEC_PIC_RUN command execution. It also means one frame process is finished. (The finish detection can be implemented in other way described in Video Decoding Process Finish Detection.) The decoded frame can be sent to the Image Processing Unit for post-processing and display. The actual operation is dependant on the application.
5. Run the MPEG4 decoding process
   - The flow is similar to the H.264 decoding process. The decoding process should configure frame source address in addition to destination address.
6. Execute step 4 and step 5 alternately.
   - Before running decoding process, the host should load new bitstream to the bitstream buffer if it is empty, and update the frame destination address according to the application.
7. Stop the decoding processes
   - Run DEC_SEQ_END command to each process to terminate it.

Basically, the process flow for decoding is similar, though it may have minor change for different firmware version. The detailed implementation is done in the VPU driver.

78.4.2 Video Encoding Processing Control

This section describes how BIT processor controls the video encoding and communicates with the host.

78.4.2.1 The Pipeline for Encoding

The following figure shows the 6 pipeline stages for H.264 encoding.

In encoding, there are two separate data paths. The upper four stages form the encoding path, and the lower four stages form the reconstruction path. .

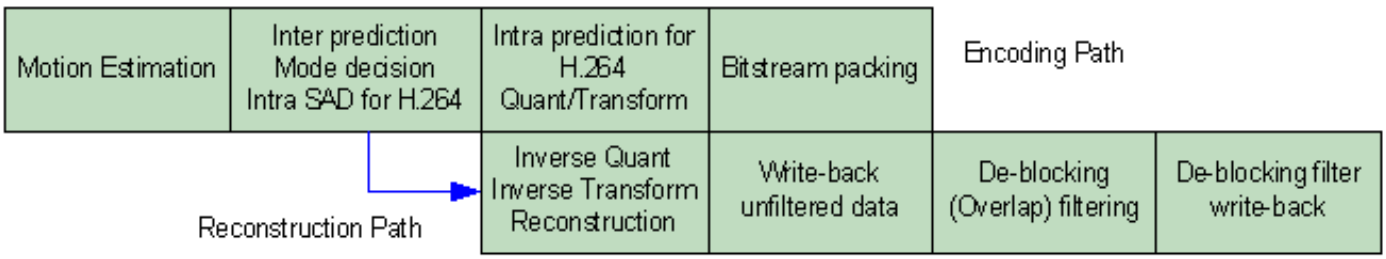

Figure 78-8. Encoding pipeline stages for H.264 Encoding

The sub-block in each stage is controlled by BIT processor and main controller (macroblock sequencer). The detailed H.264 encoding pipeline stage is as follows.

- Pipeline Stage 1
  a. The Motion Estimation (ME) block searches the motion vectors.
  b. The BIT processor reads the motion vectors from ME.
  c. The used data (reference luminance and current macroblock luminance data) is moved to the MC block for reuse.
- Pipeline Stage 2
  a. The MC block writes the predicted data from ME motion vector.
  b. The Intra predictor calculates the Intra SAD and cost for the mode decision.
  c. The Inter/Intra prediction block writes the predicted data to predicted local memory for subtraction in the next pipeline stage.
- Pipeline Stage 3
  a. Execute Intra Prediction and transfer the results to Quantizer/Transform.
  b. Quantized and transformed data are written to the residual buffer for bitstream packing.
  c. Quantized and transformed data are transferred to Inverse Quantizer/ Inverse Transform.
  d. Inverse quantized and inverse transformed data are added (reconstructed) with prediction block data in order to make a reconstructed frame.
- Pipeline Stage 4
  a. The BIT processor reads the residual buffer and makes the bitstream.
  b. Write back the un-filtered pixel data
- Pipeline Stage 5
  a. The deblocking filter reads the reconstructed data from its local memory and runs deblocking filtering for H.264/VC-1 or overlap smoothing for VC-1 intra block.

b. The filtered pixel data, that is the final reconstructed picture, is stored in the local memory of deblocking filter block for write-back.

- Pipeline Stage 6
  a. The write-back DMA writes the decoded picture into external frame buffer and it will be the reference picture of next picture decoding.

shows the 5 pipeline stages for MPEG-4/H.263 encoding when the deblocking filter is disabled and shows the 6 pipeline stages for H.263 when the deblocking filter is enabled. The encoding data path in MPEG-4/H.263 is similar to the H.264 encoding data path, except for the addition of an AC/DC prediction step.

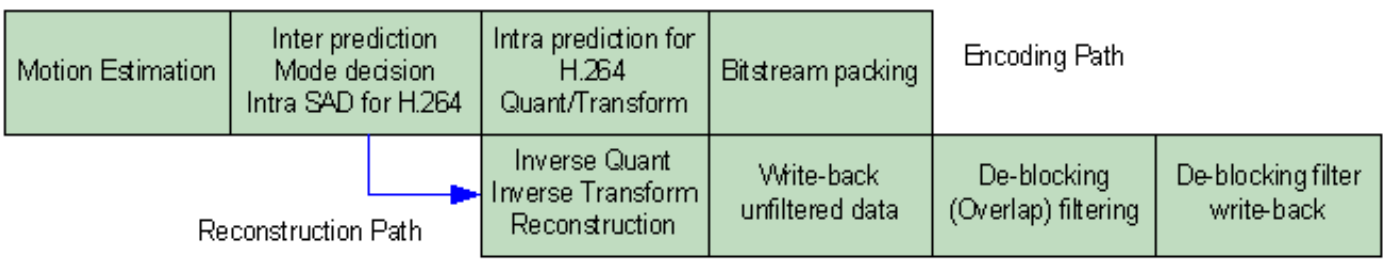

Figure 78-9. Encoding pipeline stages for H.264 encoding

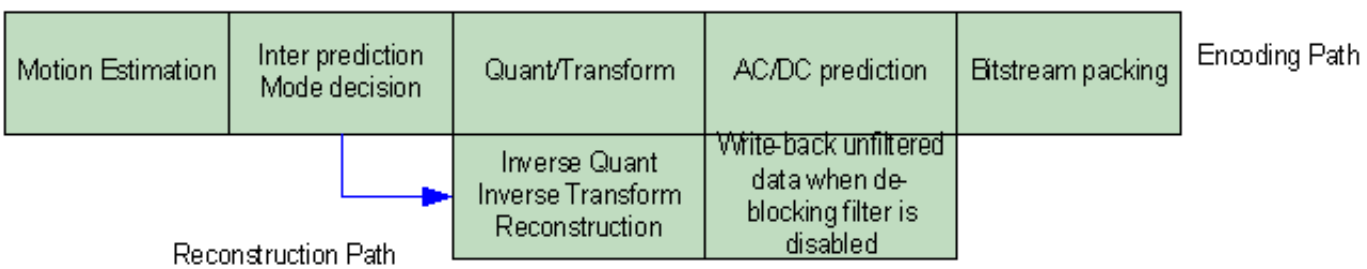

Figure 78-10. MPEG-4/H.263 encoding pipeline stage when deblocking filter is disabled

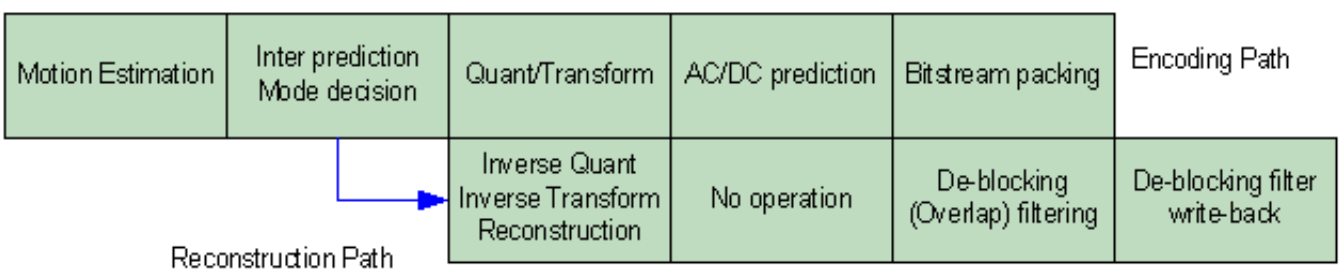

Figure 78-11. H.263 encoding pipeline stage when deblocking filter is enabled

78.4.3 Video Codec Processing Buffer Requirement

VPU has full access to the entire external memory. It uses external memory to load or store image frame, bitstream, program and data for the BIT processor.

AC/DC predication and de-blocking filtering also uses external memory. The buffer size requirement is dependent on the standard and target applications. For example, the H.264 decoding uses multiple reference frames up to 16. MPEG-4 and H.263 decoding uses only one reference frame. Each standard requires a different temporary memory size when it processes de-blocking or overlap-smoothing filtering.

VPU uses five kinds of buffers, as follows:

- Frame Buffer: for storing image frame.
- BIT processor program memory: for boot code and firmware.
- Working Buffer: for intermediate data from the BIT processor and the video decoding hardware.
- Bitstream Buffer: for loading bitstream.
- Parameter Buffer: for BIT processor command execution argument and return data.
- Search RAM: for the use of ME to reduce SDRAM bus loading.

Different buffers can be noncontiguous in external memory, though each buffer must be contiguous.

VPU also supports an optional secondary AXI bus which is connected to internal SRAM for storing temporal data of some sub-blocks, such as de-blocking filter and intra prediction. This decreases the total bandwidth to the external memory.

78.4.3.1 Memory Map Types of Frame Buffer

There are 7 map types of frame buffer:

- Type 0 : linear map
- Type 1 : Frame based tiled map, horizontal addressing
- Type 2 : Frame based tiled map, vertical addressing
- Type 3 : Field based tiled map, vertical addressing
- Type 4 : Frame/Field mixed tiled map, vertical addressing
- Type 5 : Tiled MB Raster Frame Map
- Type 6 : Tiled MB Raster Field Map

In i.MX 6Dual/6Quad, only Type 0, 5 and 6 are supported.

In the linear map, a pixel is read out from or written to the frame buffer in a raster scan order for a frame. However, VPU requires pixels on an MB basis and such address access cannot be continuous on the physical memory. Meanwhile in the tiled

memory region is logically split into a specific number of tile-shaped segments. A tile can be an access unit in which addresses are sequential and have efficiently accessible structure. The size of tile can be configurable according to applications. It might be an MB at least or a group of MBs whose addresses belong to the same row and bank address and are consecutive column address in SDRAM.

Meanwhile in the tiled map, the whole memory region is logically split into a specific number of tile-shaped segments. A tile can be an access unit in which addresses are sequential and have efficiently accessible structure. The size of tile can be configurable according to applications. It might be an MBat least or a group of MBs whose addresses belong to the same row and bank address and are consecutive column address in SDRAM. For more details, please refer to VPU API document.

78.4.3.2 Frame Buffer

This section describes the memory map of the frame buffer and the size requirement.

- Only 4:2:0 for all standards except (M)JPEG codec: in case of MJPEG, 4:0:0, 4:2:0, 4:2:2, and 4:4:4 are supported.
- Luminance, Cb and Cr frame buffer base addresses in 16-byte alignment. In case of the interleaved Cb/Cr map, a base address for Cr is ignored because a base address for the Cb is used to store or load the interleaved Cb/Cr samples.
- Stride for the width of the luminance frame buffer should be equal or greater than the width of picture and multiple of 16.
- Endian of the frame buffers is configurable as little or big endian.
- Both the interleaved Cb/Cr map and the separate Cb/Cr map are supported.
- A field pair is stored in a single frame buffer.

As shown in Figure 78-12, a frame buffer is specified with the base address and the stride line. A complete image consists of Y, U, and V components. There are two kinds of configuration, separate Cb/Cr map and interleaved Cb/Cr map.

For the separate Cb/Cr configuration, each chroma component has its own buffer. Therefore, one frame buffer needs 3 buffers for Y, U, and V components, and these buffers can be noncontiguous in memory.

For the interleaved Cb/Cr configuration, only one buffer is needed for chroma components. Therefore, one frame buffer needs 2 buffers for Y, U, and V components, and these buffers can be noncontiguous in memory.

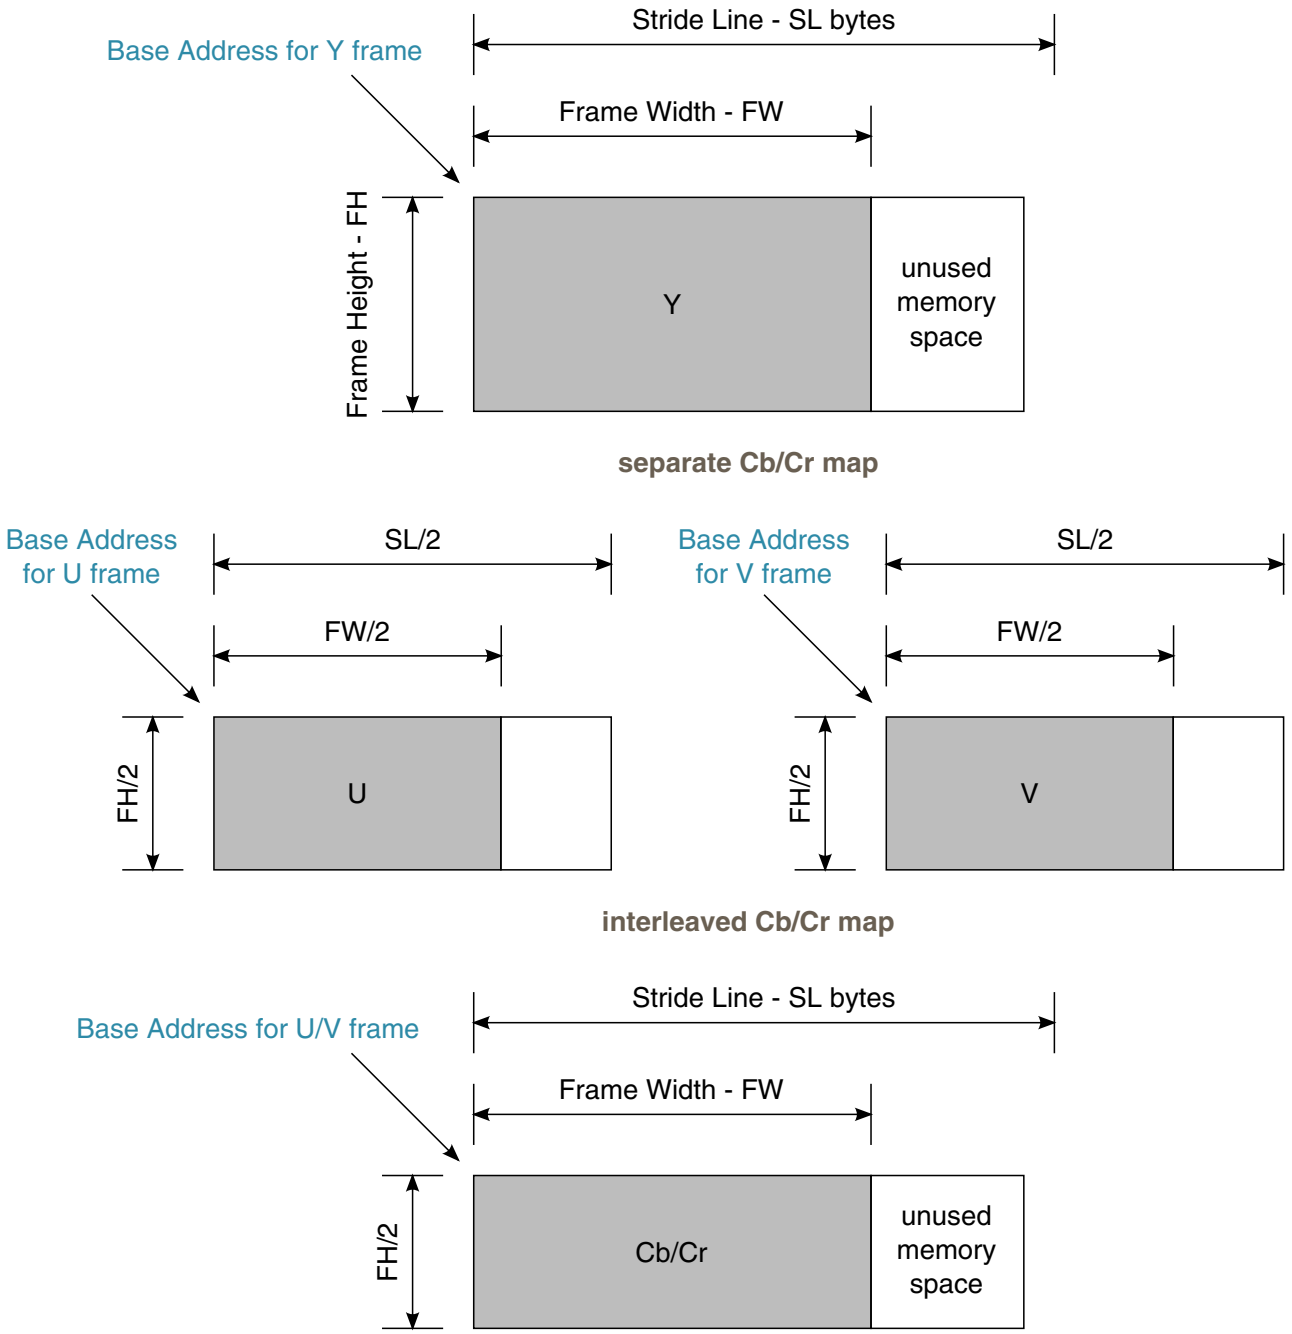

Figure 78-12. Frame Buffer configuration

Figure 78-13 shows the memory map of the frame buffer. In separate Cb/Cr map, for V frame buffer, the memory map is the same as the U frame buffer except for the base address.

VPU supports both little and big endian systems. Y(0,0) could be located in the bit[31:24]. User can specify the endianness through VPU API.

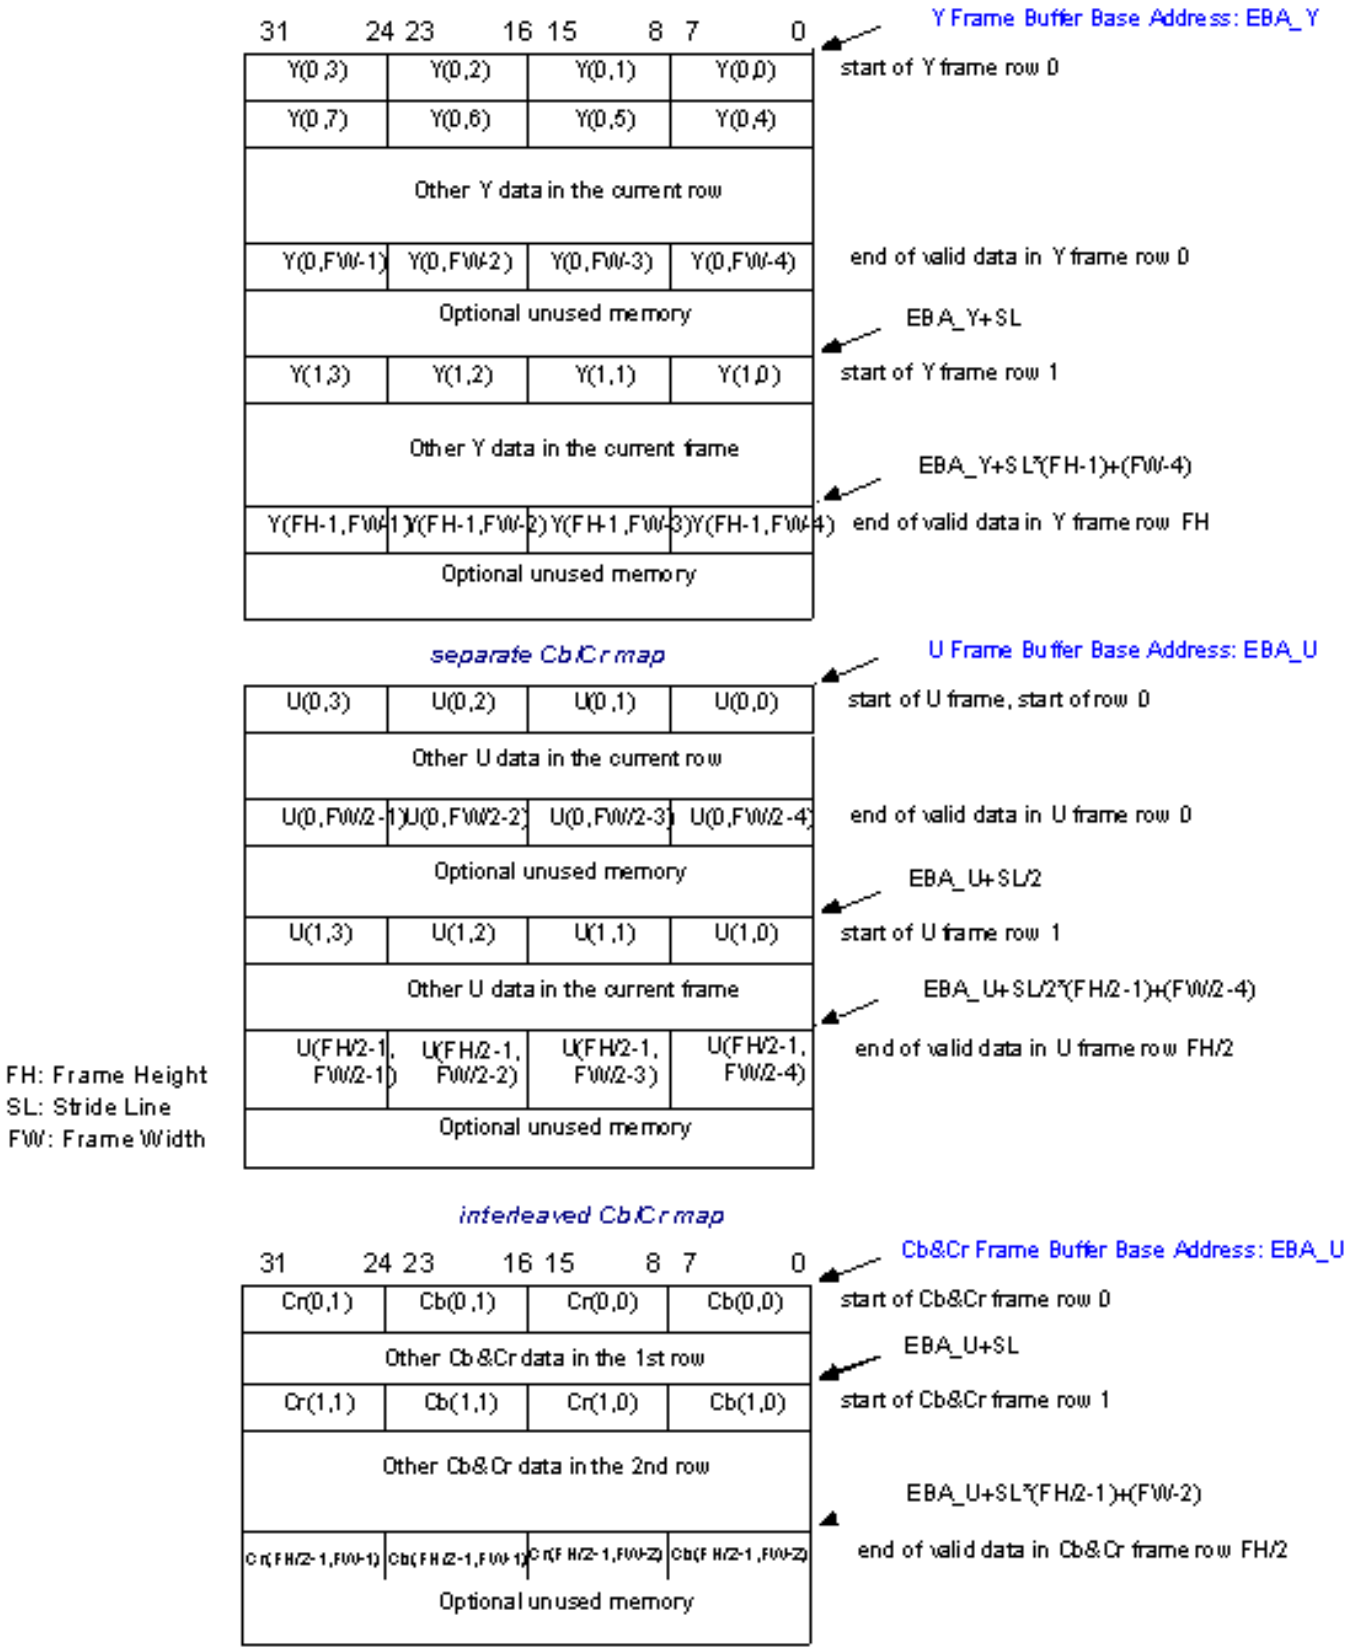

Figure 78-13. Frame Buffer address map in little endian

The table below shows the frame buffer requirement for MPEG-4, H.264 and VC-1. The H.264 decoder requires multiple reference frames up to 16. In the case of VC-1 main profile, the decoder needs two reference frames to decode a B picture. Also, VC-1 requires two more frames that it stores for range reduction or multi-resolution.

The table below also shows the memory requirement in case of QCIF/CIF/VGA resolution image. In the case of H.264 decoding, the required size for the reference frame is dependent on the level being supported. The VPU supports up to H.264 decoding level 3.0, which the maximum decoded picture buffer size is defined as 3037.5Kbyte in the standard. To support H.264 CIF at level 3.0, 2524Kbyte is needed if 16 reference frames are used.

Table 78-3. Frame Buffer Requirement

		MEPG-4 Decoder	H.264 Decoder	VC-1 Decoder
QCIF	Reference Frames	2	16	2
	Instant Frames	1	1	2
	Display Frames	1	1	2
	Total Frames	4	18	6
	Picture Size[1]	37Kbyte	37Kbyte	37Kbyte
	Total Frame Size	148Kbyte	668Kbyte	222Kbyte
CIF	Reference Frames	2	16	2
	Instant Frames	1	1	2
	Display Frames	1	1	2
	Total Frames	4	18	6
	Picture Size	148Kbyte	148Kbyte	148Kbyte
	Total Frame Size	592Kbyte	2672Kbyte	891Kbyte
VGA	Reference Frames	2	5	2
	Instant Frames	1	1	2
	Display Frames	1	1	2
	Total Frames	4	7	6
	Picture Size	450Kbyte	450Kbyte	450Kbyte
	Total Frame Size	1800Kbyte	3150Kbyte	2700Kbyte

1. The Picture Size is the minimum size of one frame buffer with assumption that the picture is YUV 4:2:0 format and the stride line is equal to frame width.

78.4.3.3 BIT Processor Program Buffer

At the initialization stage of VPU, the host processor must download boot code to the BIT processor. After initialization, the BIT processor loads a program corresponding to the activated standard.

The program size of the boot code is 1Kbyte. There are total 48 Kbyte sizes for the current version of BIT firmware to support multi-standards decoding.

78.4.3.4 Working Buffer

Besides buffers for frames and firmware, additional working buffer for intermediate data from the BIT processor and decoding is needed.

The buffers are such as the reconstructed pixel row buffer for MPEG-4 AC/DC prediction or H.264 intra-prediction, context saving buffer for running multiple processes and various temporal storage buffer for decoding process.

The required working buffer size varies according to decode size, decoding standard, decoding capability. For example, AC/DC prediction buffer size is determined by picture width and the maximum bitstream re-ordering buffer for data partition is determined by the maximum bitstream size of one picture. Working buffer size may change for different firmware version. The current version of firmware requires max 256 Kbyte for working. Its size can be set through VPU API. The detailed working buffer is organized as indicated in the table below.

Table 78-4. Working buffer organization

Working Buffer Type	Name	Description	size
static buffer	STATIC_PRC_DMEM	BIT processor data memory of each process for context switching.	5Kbyte for each process
	STATIC_PRC_SEQ	static data storage of each sequence.	8Kbyte for each process

Table continues on the next page...

Table 78-4. Working buffer organization (continued)

Working Buffer Type	Name	Description	size
temp mpeg-4 decoding/encoding buffer	MP4_DEC_ACDC	AC/DC prediction buffer of Y/Cb/Cr	204Kbyte
	MP4_DEC_DP	bitstream reordering buffer for data partition.	
	MP4_ENC_ACDC	AC/DC prediction buffer of Y/Cb/Cr	
	MP4_ENC_DP	bitstream reordering buffer for data partition.	
temp avc decoding/ebcidubg buffer	AVC_DEC_FMO	FMO group status buffer	
	AVC_DEC_IP	intra-prediction buffer of Y/Cb/Cr	
	AVC_DEC_SLICE_INFO	slice information buffer. maximum 1280 slices per picture.	
	AVC_DEC_SLICE	slice data RBSP buffer. All slice data RBSP of one picture is stored.	
	AVC_ENC_IP	intra-prediction buffer of Y/Cb/Cr	

78.4.3.5 Bitstream Buffer

The host processor has to assign buffers for bitstreams on a per instance basis.

If VPU handles N-bitstreams simultaneously in an application, the host should assign N bitstream buffers, and specify the base address and size. The External bitstream buffer is "ring buffer" type. The start address of ring buffer and buffer size must be written by host to BIT processor. The current read or write address of ring buffer is automatically wrapped-around by firmware.

In decoding case, the host writes the bitstream to be decoded then BIT processor reads bitstream. In this case, the bitstream overwriting or underflow may occur and if it occurs, decoding will fail. To prevent overwriting or underflow, current bitstream read/write pointer must be exchanged between the host and the BIT processor.

The BIT processor writes current read pointer of ring buffer to internal register and the host must write current write pointer of ring buffer to internal register. The BIT processor checks the bit buffer empty (underflow) status by comparing current read pointer and write pointer. If no more bitstream data is available to be decoded (buffer empty status), the BIT processor stops bitstream decoding to prevent mis-reading the bitstream and waits until the host writes more bitstream data and updates write pointer. The host must check the current read pointer and write pointer before writing more bitstream data to ring buffer to prevent overwriting bitstream data.

78.4.3.6 Parameter Buffer

Host processor must reserve parameter buffer in external memory for BIT processor command execution argument and return data.

78.4.3.7 Search RAM

VPU's motion estimation sub-block uses a search RAM to reduce the bandwidth on the external SDRAM.

Generally, motion estimation reads a reference pixel data several times. To avoid this B/W overhead, the motion estimation sub-block loads the reference pixel data form the external SDRAM one time and stores them to the search RAM through AXI bus. The stored reference pixel data is loaded several times to search the motion vector, but these operations are conducted through AMBA AXI bus. Therefore the B/W of loading reference pixel data will be reduced using search RAM in AXI bus.

The size of search RAM is (# of horizontal pixel x 36 + 8 macroblocks) bytes.

For example, in CIF encoding, the search RAM size is 352x36 + 2048 = 14720 bytes = 14.375Kbyte.

78.4.3.8 Buffer Requirement Summary

Table 78-5 shows a summary of buffer requirement for each decoding instance, where bitstream buffer size is not considered because the size is not limited. The total size may change for different firmware version. Except the BIT processor program memory, other kinds of buffer has to be assigned on a per instance basis. The overall buffer size for a multiparty call application is nearly the sum of each instanced decoding.

Table 78-5. Summary of Buffer Requirement

		MEPG-4 Decoder	H.264 Decoder	VC-1 Decoder
QCIF	Frames buffer	148KB	668Kbyte	222Kbyte
	BIT processor program buffer	128Kbyte		
	Parameter buffer	8Kbyte		
	Bitstream buffer	1000Kbyte		
	Working Buffer	13Kbyte	256Kbyte	13Kbyte
	Total	1297Kbyte	2060Kbyte	1371Kbyte

Table continues on the next page...

Table 78-5. Summary of Buffer Requirement (continued)

		MEPG-4 Decoder	H.264 Decoder	VC-1 Decoder
CIF	Frames Size	592Kbyte	2672Kbyte	891Kbyte
	BIT processor program buffer	128Kbyte		
	Parameter buffer	8Kbyte		
	Bitstream buffer	1000Kbyte		
	Working Buffer	13Kbyte	256Kbyte	13Kbyte
	Total	1741Kbyte	4064Kbyte	2040Kbyte
VGA	Frame Size	1800Kbyte	3150Kbyte	2700Kbyte
	BIT processor program buffer	128Kbyte		
	Parameter buffer	8Kbyte		
	Bitstream buffer	1000Kbyte		
	Working Buffer	13Kbyte	256Kbyte	13Kbyte
	Total	2949Kbyte	4542Kbyte	3849Kbyte

78.5 Programmable Registers

VPU registers are all 32-bit wide, support only 32bit aligned read/write operation. VPU registers are grouped into several regions corresponding to different decoding process step. They are used for decoding process configuration and control. They can only be accessed through IP bus interface.

Please note that there are some undefined address space in VPU memory map, any read/write accessing to this register address space is ignored in the VPU. Read accessing to write only register returns ZERO value. Write accessing to read only register is ignored.

The BIT processor registers' memory map in VPU is 0xBASE_0000~0xBASE_01FC. The BIT processor registers are divided into 2 categories.

- Address 0xBASE_0000~0xBASE_00FC (64 registers address space) are hardware registers. These registers have reset values and their functions are fixed (not configurable).
- Address 0xBASE_0100~0xBASE_01FC (64 registers address space) are software registers. They have no reset values and can be configured by internal BIT processor. Their definitions may change for different firmware version, so they are not provided

here. This type of registers can be used as general parameter registers between host processor and BIT processor.

- The first 32 parameter registers (address 0xBASE_0100~0xBASE_017C) are used as static parameters. Definition and functions of those registers are same for all kinds of run commands.
- The second 32 parameter registers (address 0xBASE_0180~0xBASE_01FC) are used as temporal parameters. The definition and functions of those registers may differ in different run commands.

The memory map for the hardware registers of VPU is shown in the table below.

Please refer to the VPU API document for descriptions on software registers access.

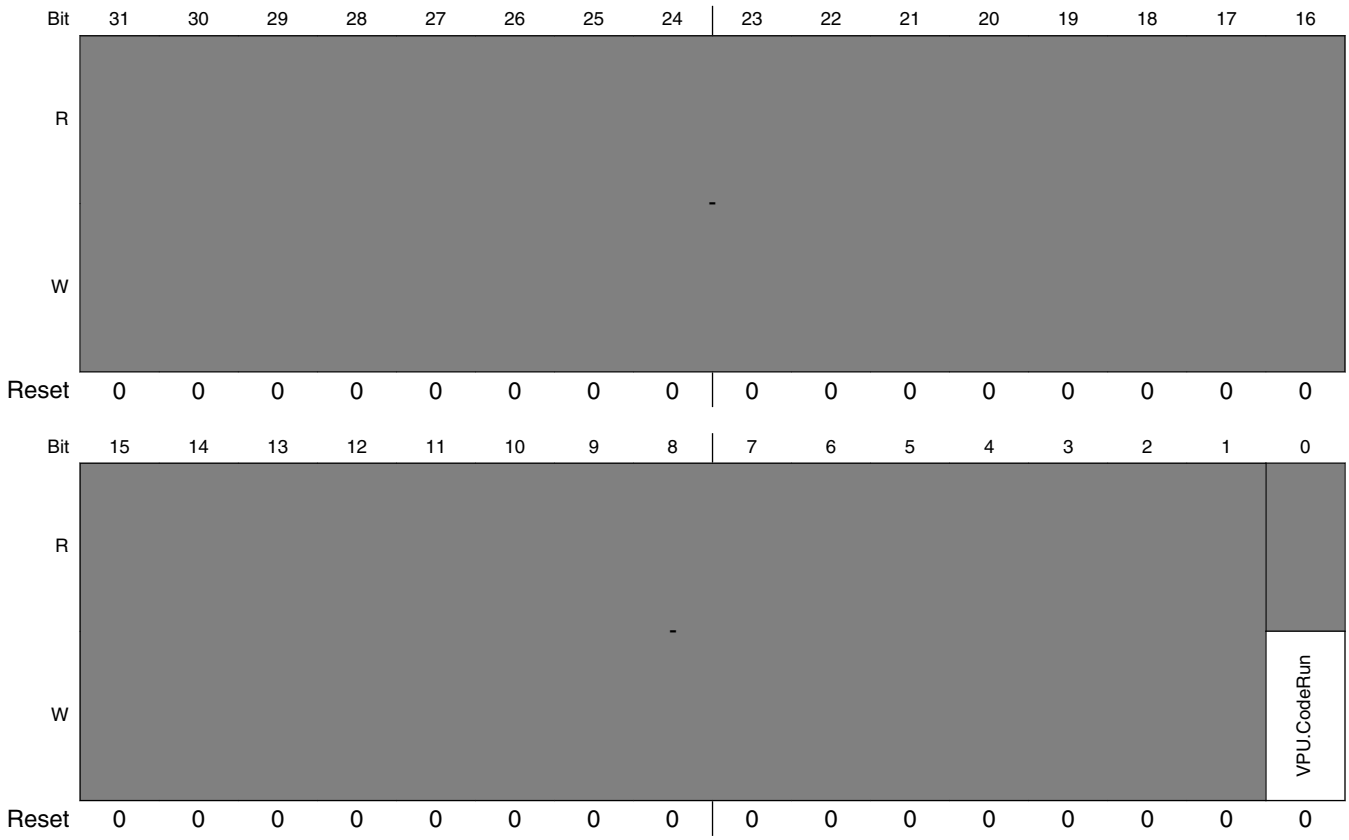
VPU memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FF_4000	BIT Processor run start (VPU_CodeRun)	32	W	0000_0000h	78.5.1/ 4994
63FF_4004	BIT Boot Code Download Data register (VPU_CodeDown)	32	W	0000_0000h	78.5.2/ 4994
63FF_4008	Host Interrupt Request to BIT (VPU_HostIntReq)	32	W	0000_0000h	78.5.3/ 4995
63FF_400C	BIT Interrupt Clear (VPU_BitIntClear)	32	W	0000_0000h	78.5.4/ 4996
63FF_4010	BIT Interrupt Status (VPU_BitIntSts)	32	R	0000_0000h	78.5.5/ 4997
63FF_4014	BIT Code Reset (VPU_BitCodeReset)	32	W	0000_0000h	78.5.6/ 4998
63FF_4018	BIT Current PC (VPU_BitCurPc)	32	R	0000_0000h	78.5.7/ 4999
63FF_4020	BIT CODEC Busy (VPU_BitCodecBusy)	32	R	0000_0000h	78.5.8/ 5000

78.5.1 BIT Processor run start (VPU_CodeRun)

See the figure below for illustration of valid bits in VPU Code Run Register and the table below for description of the bit fields in the register.

Address: VPU_CodeRun is 63FF_4000h base + 0h offset = 63FF_4000h



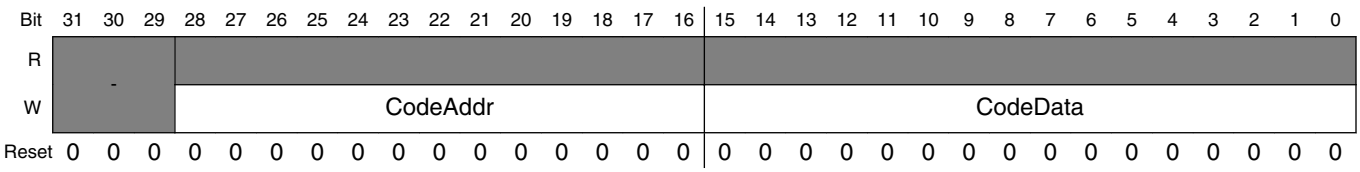
VPU_CodeRun field descriptions

Field	Description
31–1 -	Reserved
0 VPU.CodeRun	VPU_CodeRun. BIT processor run start bit. 0 BIT Processor stop execution. 1 BIT Processor start execution.

78.5.2 BIT Boot Code Download Data register (VPU_CodeDown)

See the figure below for illustration of valid bits in VPU BIT Boot Code Download Data Register and the following table for description of the bit fields in the register.

Address: VPU_CodeDown is 63FF_4000h base + 4h offset = 63FF_4004h



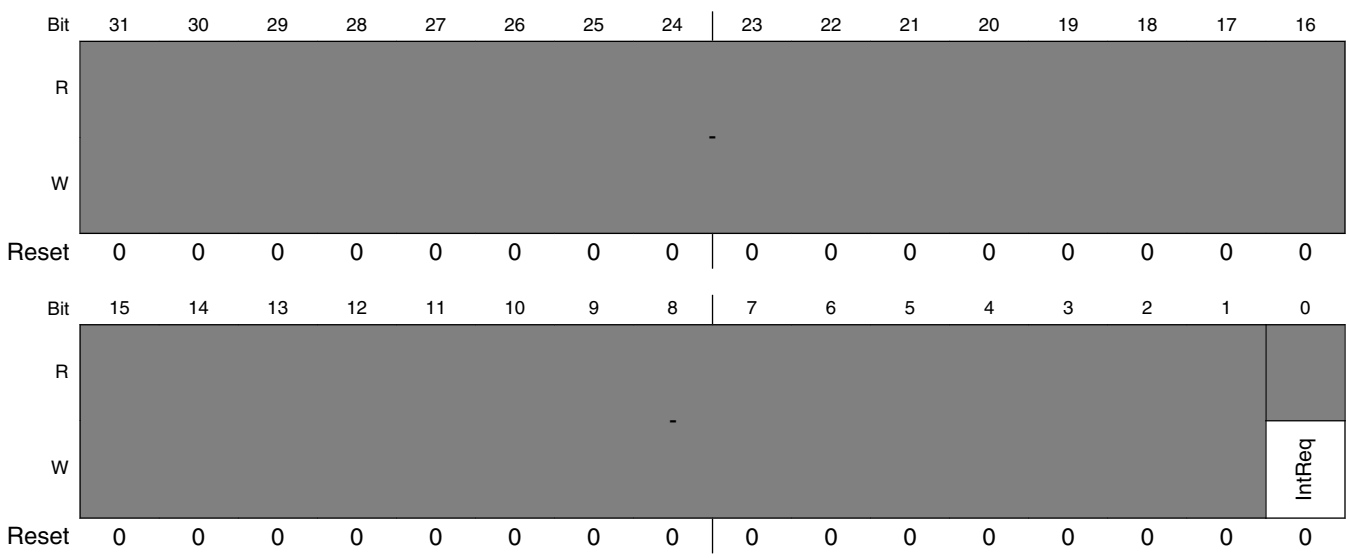
VPU_CodeDown field descriptions

Field	Description
31–29 -	Reserved
28–16 CodeAddr	CodeAddr[12:0] Download address of VPU BIT boot code, which is VPU internal address of BIT processor.
15–0 CodeData	CodeData[15:0] Download data of VPU BIT boot code.

78.5.3 Host Interrupt Request to BIT (VPU_HostIntReq)

See the figure below for illustration of valid bits in VPU Host Interrupt Request Register and the following table for description of the bit fields in the register.

Address: VPU_HostIntReq is 63FF_4000h base + 8h offset = 63FF_4008h



VPU_HostIntReq field descriptions

Field	Description
31–1 -	Reserved

Table continues on the next page...

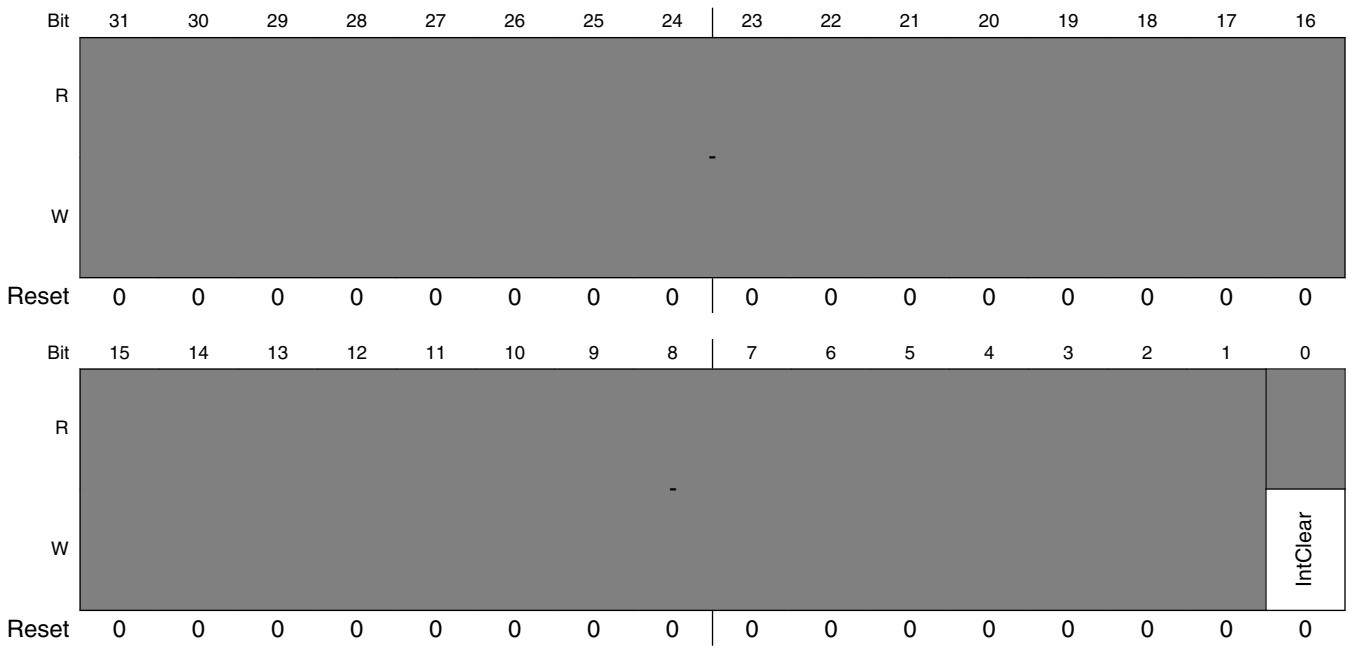
VPU_HostIntReq field descriptions (continued)

Field	Description
0 IntReq	IntReq. The host interrupt request bit. 0 No host interrupt is requested. 1 The host processor request interrupt to the BIT processor.

78.5.4 BIT Interrupt Clear (VPU_BitIntClear)

See the figure below for illustration of valid bits in VPU BIT Interrupt Clear Register and the following table for description of the bit fields in the register.

Address: VPU_BitIntClear is 63FF_4000h base + Ch offset = 63FF_400Ch



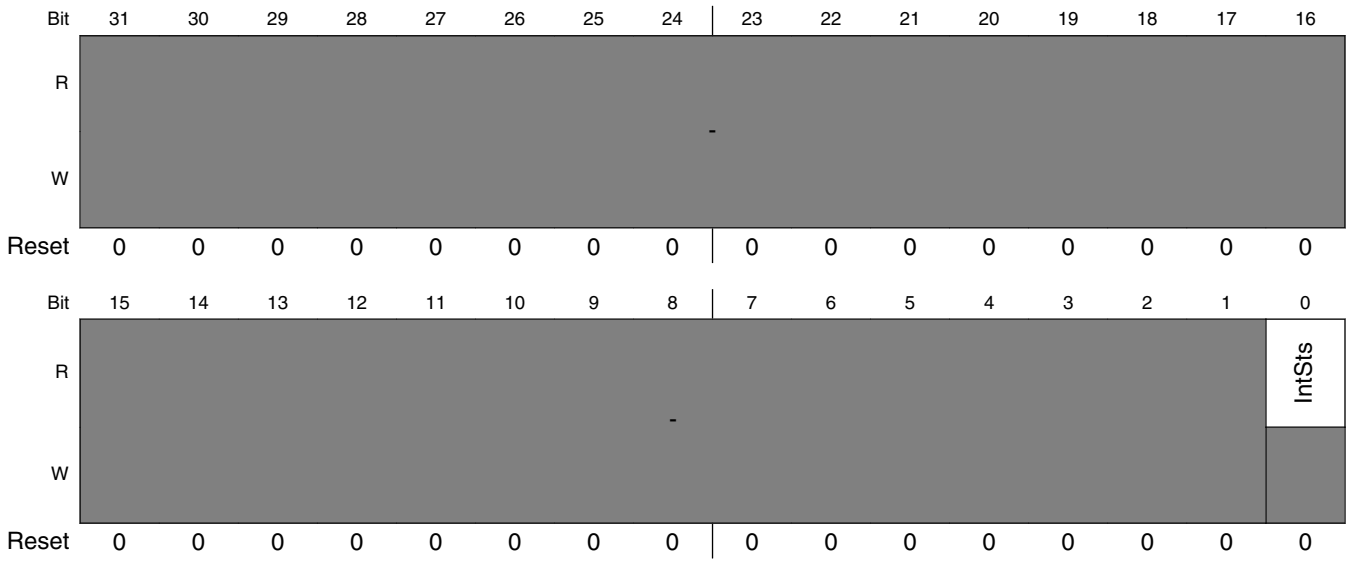
VPU_BitIntClear field descriptions

Field	Description
31–1 -	Reserved
0 IntClear	IntClear. BIT interrupt clear bit. 0 No operation is issued. 1 Clear the BIT interrupt to the host.

78.5.5 BIT Interrupt Status (VPU_BitIntSts)

See the figure below for illustration of valid bits in VPU BIT Interrupt Status Register and the following table for description of the bit fields in the register.

Address: VPU_BitIntSts is 63FF_4000h base + 10h offset = 63FF_4010h



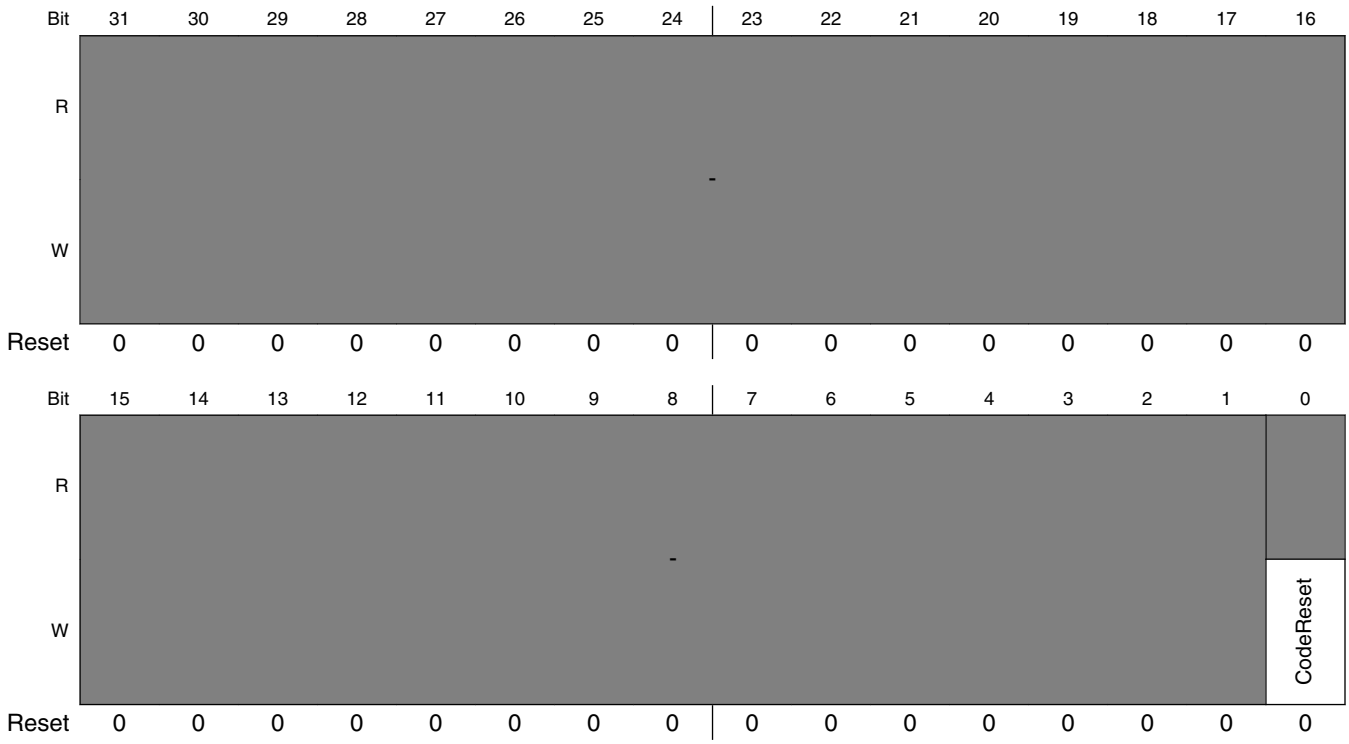
VPU_BitIntSts field descriptions

Field	Description
31–1 -	Reserved
0 IntSts	IntSts. BIT interrupt status bit. 0 No BIT interrupt is asserted. 1 The BIT interrupt is asserted to the host. It is cleared when the host processor write "1" to VPU_BitIntClear register.

78.5.6 BIT Code Reset (VPU_BitCodeReset)

See the figure below for illustration of valid bits in VPU BIT Code Reset Register and the following table for description of the bit fields in the register.

Address: VPU_BitCodeReset is 63FF_4000h base + 14h offset = 63FF_4014h



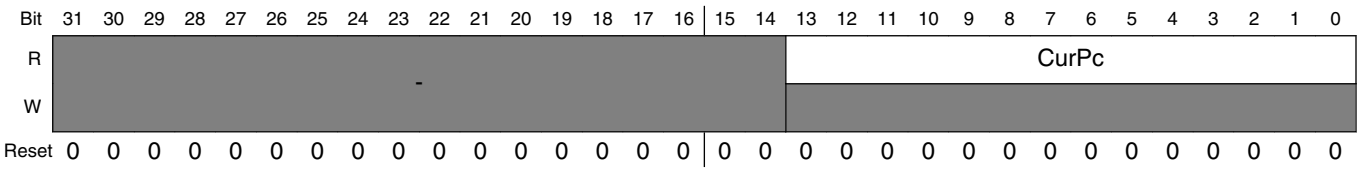
VPU_BitCodeReset field descriptions

Field	Description
31–1 -	Reserved
0 CodeReset	CodeReset. BIT code reset bit. 0 No operation is issued. 1 The program counter of BIT processor is set to "0", BIT processor restart at initial routine.

78.5.7 BIT Current PC (VPU_BitCurPc)

See the figure below for illustration of valid bits in VPU BIT Current PC Register and the following table for description of the bit fields in the register.

Address: VPU_BitCurPc is 63FF_4000h base + 18h offset = 63FF_4018h



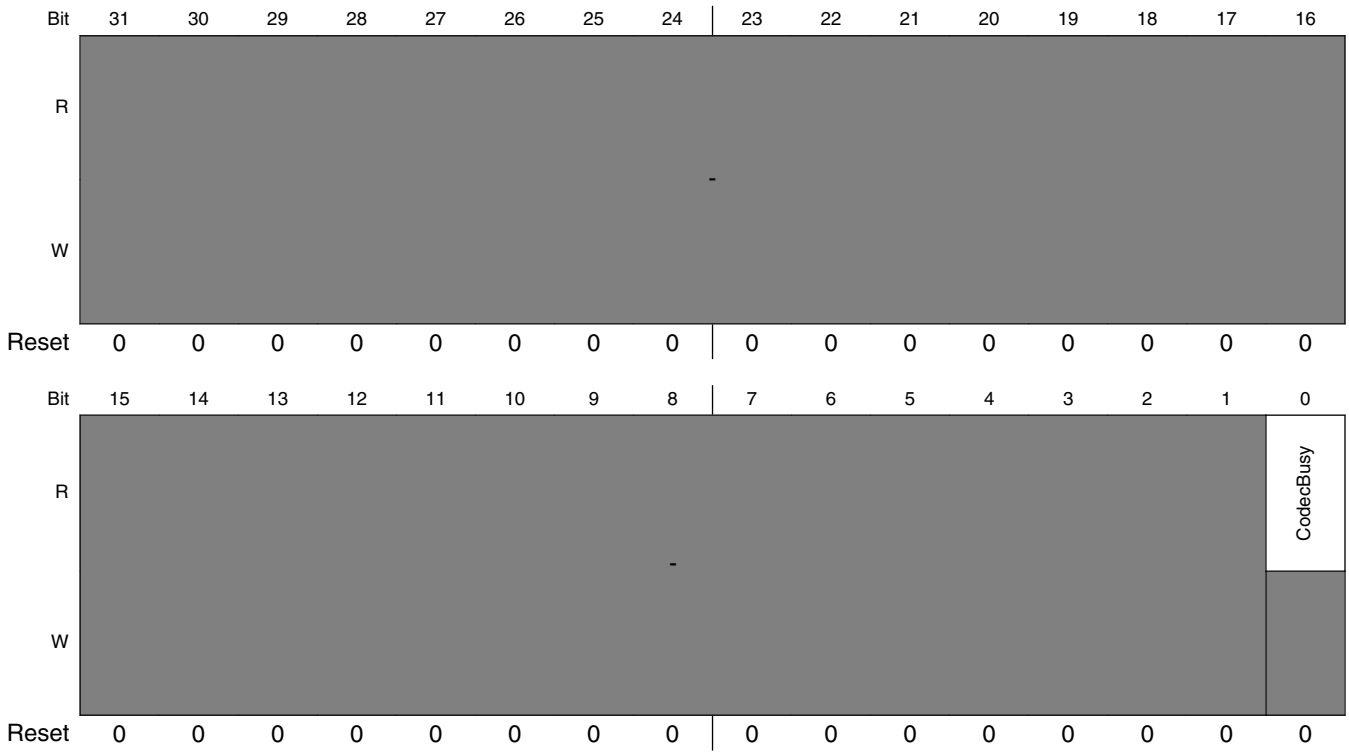
VPU_BitCurPc field descriptions

Field	Description
31–14 -	Reserved
13–0 CurPc	CurPc[13:0]. BIT current PC value. Returns the current program counter of BIT processor by reading this register.

78.5.8 BIT CODEC Busy (VPU_BitCodecBusy)

See the figure below for illustration of valid bits in VPU BIT Codec Busy Register and the following table for description of the bit fields in the register.

Address: VPU_BitCodecBusy is 63FF_4000h base + 20h offset = 63FF_4020h



VPU_BitCodecBusy field descriptions

Field	Description
31–1 -	Reserved
0 CodecBusy	Codec busy flag for Bit processor.BIT processor write "1"to this register when the processor is running."0"means processor is waiting for a command.This value is connected to the o_vpu_idle.

Chapter 79
Watchdog Timer (WDOG-1)

79.1 Introduction

This chapter describes a block integrated into an SoC. The chapter is intended for a block driver software developer. It describes block-level operation and programming. To understand how the block is integrated at the SoC level, a system software developer should see discussions of the block in the appropriate SoC-level chapter(s).

79.2 Overview

This section briefly introduces the block. The full description of the block is in Functional Description.

This section includes a top level diagram that shows the functional organization of the block, including all off-chip signals. The figure below is the block diagram.

The Watchdog Timer (WDOG-1) protects against system failures by providing a method of escaping from unexpected events or programming errors. Once the WDOG-1 is activated, it must be serviced by the software on a periodic basis. If servicing does not take place, the timer times out. Upon a time-out, the WDOG-1 asserts the internal system reset signal, $\overline{\text{wdog\_rst}}$ which will be going to System Reset Controller . There is also a provision for WDOG-1 signal assertion by time-out counter expiration.There is an option of programmable interrupt generation before the counter actually times out. The time at which the interrupt needs to be generated prior to counter time-out is programmable. There is a power down counter which gets enabled out of any reset (POR, Warm / Cold). This counter has a fixed time out period of 16 seconds upon which it will assert the WDOG-1signal. Flow diagrams for the time-out counter, power down counter and interrupt operations are shown in Figure 79-6, Figure 79-7 and Figure 79-8.

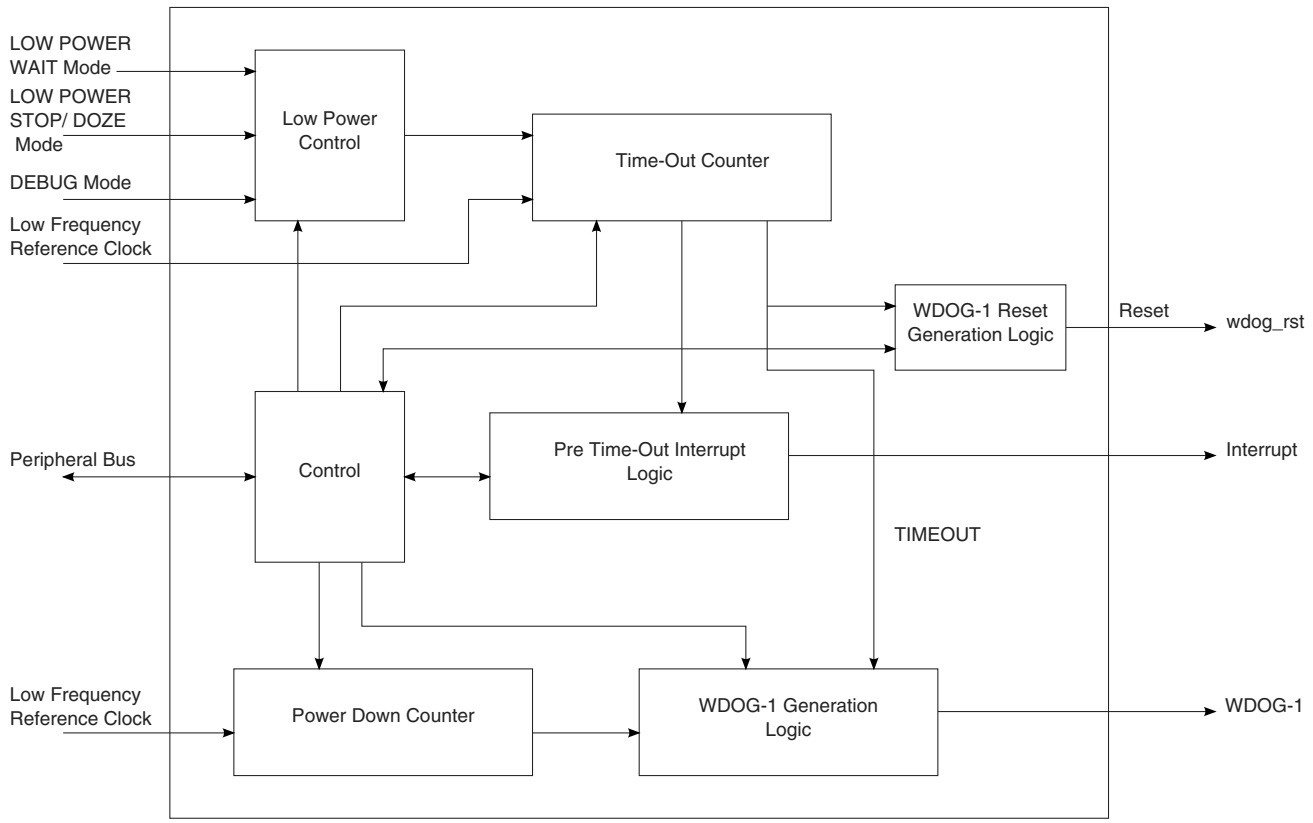


Figure 79-1. WDOG-1 Diagram

79.2.1 Features

The WDOG-1 features are as follows:

- A Configurable time-out counter with Time-out periods from 0.5 seconds up to 128 seconds and after time-out expiration results in assertion of $\overline{\text{wdog\_rst}}$ Reset signal .
- Time resolution of 0.5 seconds.
- Configurable time-out counter that can be programmed to run or stop during low-power modes.
- Configurable time-out counter that can be programmed to run or stop during DEBUG mode.
- Programmable Interrupt generation prior to time-out.
- The time duration between interrupt and time-out events can be programmed from 0 to 127.5 seconds in steps of 0.5 seconds.
- A power down counter with fixed time-out period of 16 seconds which if not disabled after reset will assert $\overline{\text{WDOG-1}}$ signal low.
  - Power down counter will be enabled out of any reset (POR, Warm / Cold reset) by default.

79.2.2 Modes and Operations

The WDOG-1 supports the following modes described in the indicated sections:

- Low Power Modes
- Debug Mode

As described in Operations, the WDOG supports the operations described in the indicated sections:

- Watchdog Reset Generation
- WDOG_B Generation

79.3 External Signals

Table 79-1. Off-Chip Block Signals

Signal	I/O	Description	Reset State[1]	Pull-Up/Down[1]
WDOG-1	O	This signal will powerdown the Chip. Refer to WDOG_B Generation.	1	-
wdog_rst	O	This signal is a reset source for the chip. Refer to Watchdog Reset Generation.	1	-

1. The reset state values and pull-up/down requirements provided in this table are from the block-level perspective. To understand how the block is integrated at the SoC level, the system software developer must see discussions of the block in the appropriate SoC-level chapter(s). For example, a block signal that requires a pull-up could be integrated with a pull-up option built into the SoC. In this case, the system software developer must ensure the proper programming at the SoC level.

79.4 Functional Description

79.4.1 Time-Out Event

The WDOG-1 provides time-out periods from 0.5 seconds up to 128 seconds with a time resolution of 0.5 seconds.

The user can determine the time-out period by writing to the WDOG-1 Time-out field (WT[7:0]) in the Watchdog Control Register (WDOG_WCR). The WDOG-1 has to be enabled by setting the WDE bit of Watchdog Control Register (WDOG_WCR) for the time-out counter to start running. After the WDOG-1 is enabled, the counter is activated, loads the time-out value and begins to count down from this programmed value. The

timer will time-out when the counter reaches zero and the WDOG-1 outputs a system reset signal, wdog_rst and asserts WDOG-1 (WDT bit should be set in Watchdog Control Register (WDOG_WCR)).

However, the Time-out condition can be prevented by reloading the counter with the new time-out value (WT[7:0] of WDOG-1.WCR) if a service routine is performed before the counter reaches zero. If any system errors occur that prevent the software from servicing the Watchdog Service Register (WDOG_WSR), then the time-out condition occurs. By performing the service routine, the WDOG-1 reloads its counter to the time-out value indicated by bits WT[7:0] of the Watchdog Control Register (WDOG_WCR) and it restarts the countdown.

A system reset will reset the counter and place it in the idle state at any time during the countdown. The counter flow diagram is shown in Figure 79-6.

NOTE

The time-out value is reloaded to the counter at the time when WDOG-1 is enabled or after the service routine has been performed.

79.4.1.1 Servicing WDOG-1 To Reload The Counter

The proper service sequence to reload a time-out value to the counter begins by writing 0x 5555 followed by 0x AAAA to the Watchdog Service Register (WDOG_WSR). Any number of instructions can be executed between the two writes. If the WDOG-1.WSR is not loaded with 0x 5555 prior to writing 0x AAAA to the WDOG-1.WSR, the counter is not reloaded. If any value other than 0x AAAA is written to the WDOG-1.WSR after 0x 5555, the counter is not reloaded. This service sequence will reload the counter with the time-out value WT[7:0] of Watchdog Control Register (WDOG_WCR). The time-out value can be changed at any point of the time and the counter reloads this value whenever the core services the Watchdog.

79.4.2 Interrupt Event

Prior to time-out the WDOG-1 can generate an interrupt which can be considered a warning signal to indicate that the time-out will occur shortly.

The time duration between interrupt event and time-out event can be controlled by writing to the WICT field of Watchdog Interrupt Control Register (WDOG_WICR). It can vary between 0 and 127.5 seconds. If the WDOG-1 is serviced before the interrupt generation then the counter will be reloaded with the time-out value WT[7:0] of Watchdog Control Register (WDOG_WCR) and interrupt will not be t

79.4.3 Power-Down Counter Event

The Power down Counter inside WDOG-1 will be enabled out of reset. This counter has a fixed time-out value of 16 seconds, after which it will drive the $\overline{\text{WDOG-1}}$ signal low.

To prevent this, the software must disable this counter by clearing the PDE bit of Watchdog Miscellaneous Control Register (WDOG_WMCR) within 16 seconds of reset de-assertion. Once disabled, this counter cannot be enabled again until the next system reset occurs. This feature is provided to prevent the hanging up of cores after reset, as WDOG-1 is not enabled out of reset.

79.4.4 Low Power Modes

79.4.4.1 STOP and DOZE Mode

If the WDOG-1 Timer Disable bit for Low power STOP and DOZE mode (WDZST) bit in the Watchdog Control Register (WDOG_WCR), is '0", the WDOG-1 Timer continues to operate using the Low Frequency Reference clock. If Low power Enable (WDZST) bit is set to "1", then the WDOG-1 Timer operation will be suspended in Low power STOP or DOZE mode. Upon exiting Low power STOP or DOZE mode, the WDOG-1 operation returns to what it was prior to entering the STOP or DOZE mode.

79.4.4.2 WAIT Mode

If the WDOG-1 Timer Disable bit for low power WAIT mode (WDW) bit in the Watchdog Control Register (WDOG_WCR), is '0", the WDOG-1 Timer continues to operate using the Low Frequency Reference clock . If low power WAIT Enable (WDW) bit is set to "1", then the WDOG-1 Timer operation will be suspended. Upon exiting low power WAIT mode, the WDOG-1 operation returns to what it was prior to entering the WAIT mode.

NOTE

WDOG-1 Timer will not be able to detect events which happen for periods less than one Low Frequency Reference clock cycle. For example in repeated WAIT mode entry/exit, if the RUN mode time is less than one Low Frequency Reference clock cycle and if WDW bit is set then WDOG-1 Timer may never time out even though the system is in RUN mode for a finite

duration because WDOG-1 may not see any Low Frequency Reference clock edge during its wake time.

79.4.5 Debug Mode

The WDOG-1 Timer can be configured for continual operation, or the operation can be suspended during debug mode. If the WDOG-1 debug enable (WDBG) bit is set to "1" in the Watchdog Control Register (WDOG_WCR), the WDOG-1 Timer operation is suspended in debug mode. In-case of WDBG bit being set to "1" and the Debug mode is entered, WDOG-1 Timer operation is suspended after 2 Low Frequency Reference clocks and similarly WDOG-1 Timer operation is continued after 2 Low frequency reference clocks of Debug mode Exit. Register read and write accesses in Debug mode continue to function normally. Also, while in DEBUG mode, the WDE bit of Watchdog Control Register (WDOG_WCR) can be enabled-disabled directly. If the WDOG-1 debug enable (WDBG) bit is cleared then Watchdog Timer operation is not suspended. Power-down counter is not affected by debug mode entry/exit.

NOTE

If the WDE bit of Watchdog Control Register (WDOG_WCR) is set/cleared while in DEBUG mode, it remains set/cleared even after exiting DEBUG mode.

79.4.6 Operations

This section describes the block's operations.

79.4.6.1 Watchdog Reset Generation

The WDOG-1 generated reset signal $\overline{\text{wdog\_rst}}$ is asserted by the following operations:

- A software write to the Software Reset Signal (SRS) bit of the Watchdog Control Register (WDOG_WCR).
- WDOG-1 time-out.

The $\overline{\text{wdog\_rst}}$ will be asserted for one clock cycle of Low frequency Reference clock for both the time-out Condition and software write occurrence. It remains asserted for 1 clock cycle of Low frequency Reference clock even if a system reset is asserted in between. Figure 79-3 shows the timing diagram of this signal due to time-out condition.

79.4.6.2 $\overline{\text{WDOG\_B}}$ Generation

The WDOG-1 asserts $\overline{\text{WDOG}}$ under the following scenarios:

- Software write to WDA bit of Watchdog Control Register (WDOG_WCR). $\overline{\text{WDOG}}$ Signal remains asserted as long as the WDA bit is "0".
- WDOG-1 time-out condition, WDT bit of Watchdog Control Register (WDOG_WCR) must be set for this scenario. $\overline{\text{WDOG-1}}$ Signal remains asserted until a Power-on Reset (POR) occurs. It gets cleared after the POR occurs and not due to any other system reset. Figure 79-4 shows the timing diagram of $\overline{\text{WDOG-1}}$ due to time-out condition.
- WDOG-1 Power down Counter time-out, PDE bit of Watchdog Miscellaneous Control Register (WDOG_WMCR) should not be cleared for this scenario. $\overline{\text{WDOG-1}}$ Signal remains asserted for one clock cycle of Low frequency Reference clock.

Figure 79-2 shows the scenarios under which $\overline{\text{WDOG-1}}$ gets asserted.

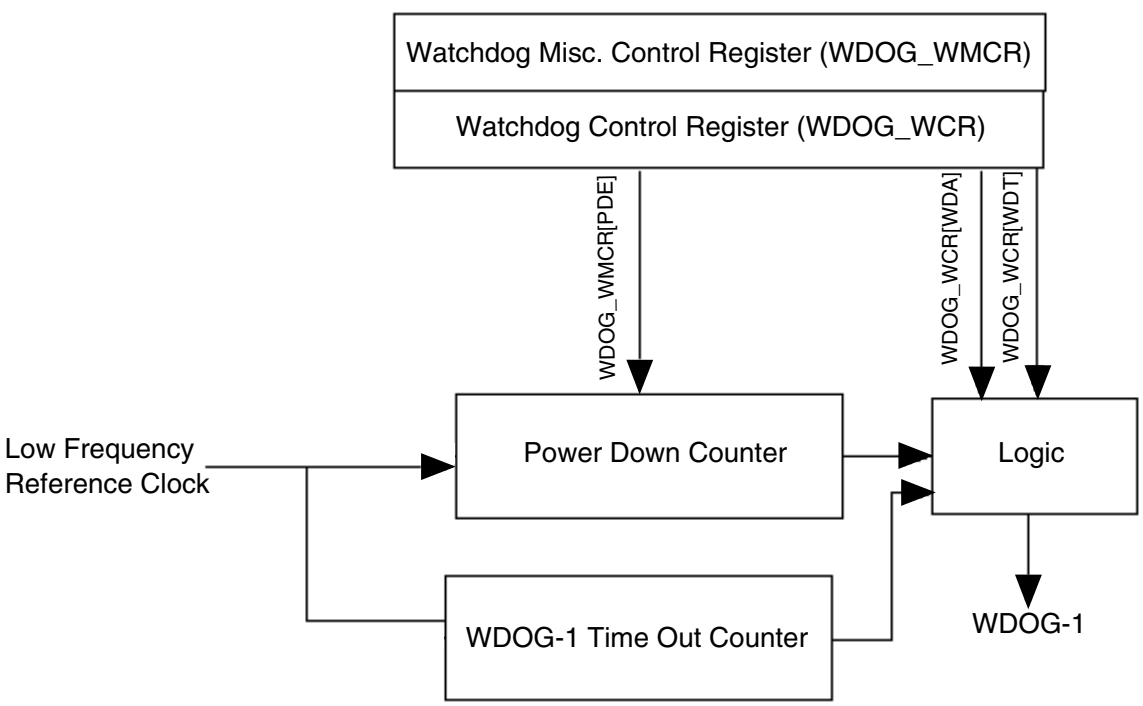

Figure 79-2. $\overline{\text{WDOG-1}}$ Generation

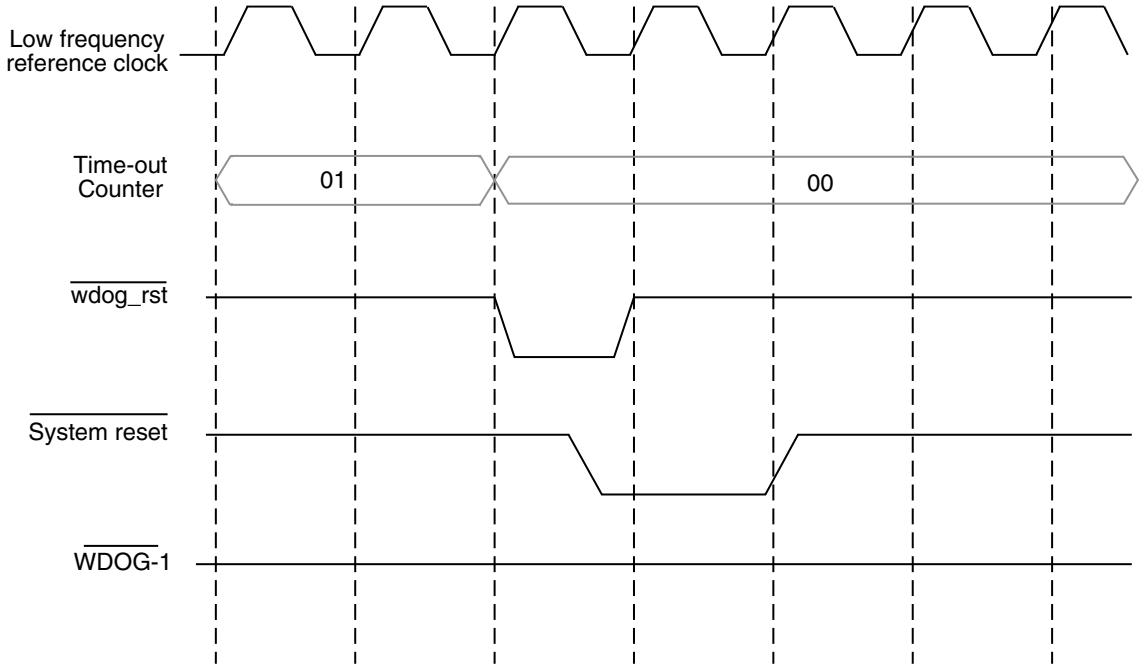

Figure 79-3. WDOG-1 Time-Out Condition/WDT Bit Is Not Set

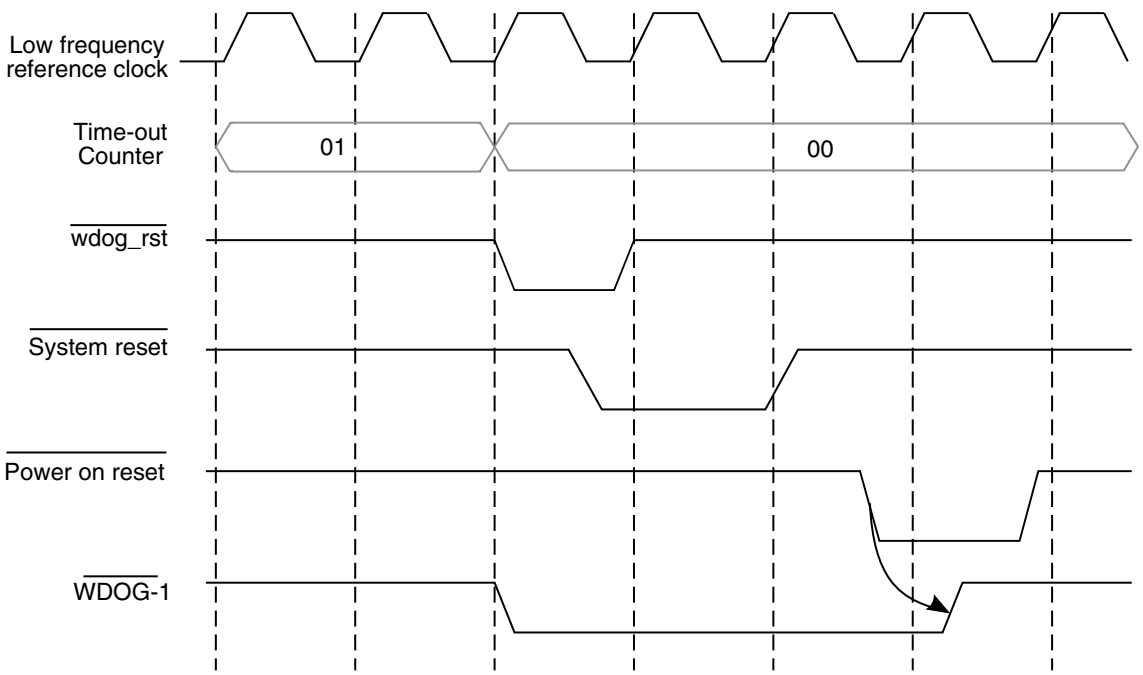

Figure 79-4. WDOG-1 Time-Out Condition/WDT Bit Is Set

79.4.7 Clocks

This section describes clocks and special clocking requirements of the block.

The WDOG-1 uses the Low frequency Reference clock for its counter and control operations. Peripheral Bus clock is used for register Read/Write operations.

Low frequency Reference clock is a free running clock and cannot be gated. Peripheral Bus clock cannot be gated and is selectively switched ON whenever Read/Write operations takes place.

79.4.8 Reset

This section describes how to reset the block and explains special requirements related to reset.

The block is reset by a system reset and will have the following consequences: WDOG-1 counter is disabled.

Power-Down counter is enabled and starts counting.

79.4.9 Interrupt

The WDOG-1 has the feature of Interrupt generation before time-out.

The interrupt will be generated only if the WIE bit in Watchdog Interrupt Control Register (WDOG_WICR) is set. The exact time at which the interrupt should occur prior to time-out depends on the value of WICT field of Watchdog Interrupt Control Register (WDOG_WICR). As an example if the WICT field has a value 0x04, then the interrupt will be generated 2 seconds prior to time-out. Once the interrupt is triggered the WTIS bit in Watchdog Interrupt Control Register (WDOG_WICR) will be set. The software need to clear this bit to de-assert the Interrupt. If the WDOG-1 is serviced before the interrupt generation then the counter will be reloaded with the time-out value WT[7:0] of Watchdog Control Register (WDOG_WCR) and interrupt would not be triggered.

79.4.10 Flow Diagrams

A flow diagram of watchdog operation is shown in Figure 79-6, Figure 79-7 and Figure 79-8.

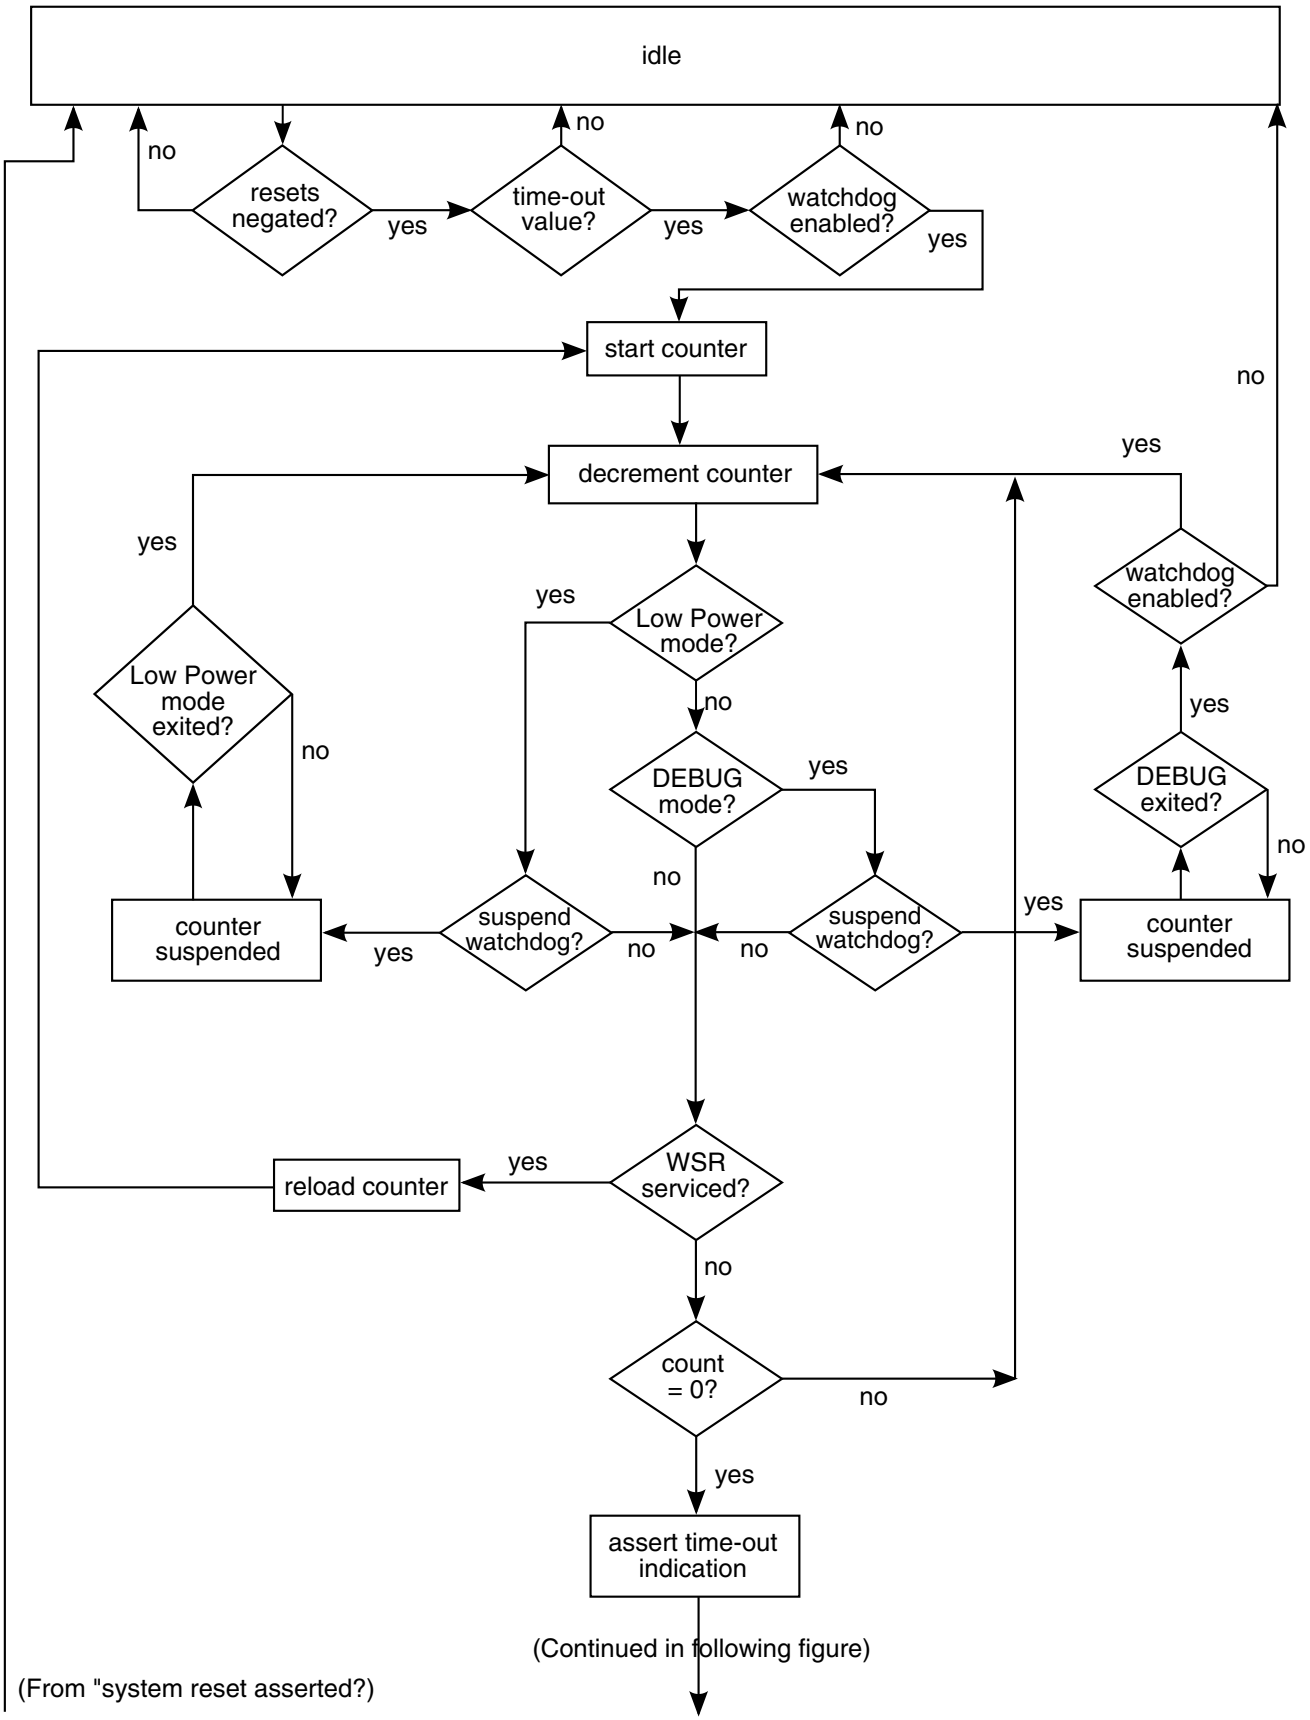

Figure 79-5. Time-Out Counter Flow Diagram

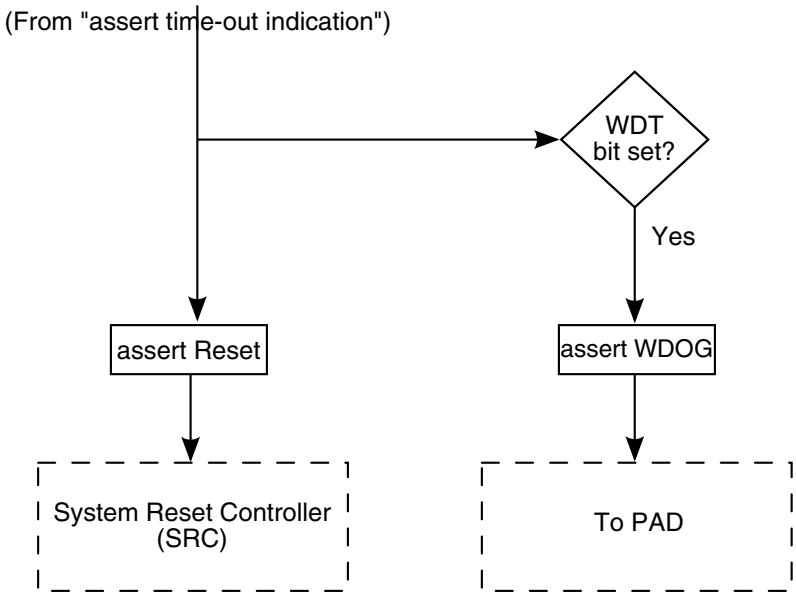

Note: A system reset will force the state machine to "idle" at any time during countdown.

Figure 79-6. Time-Out Counter Flow Diagram

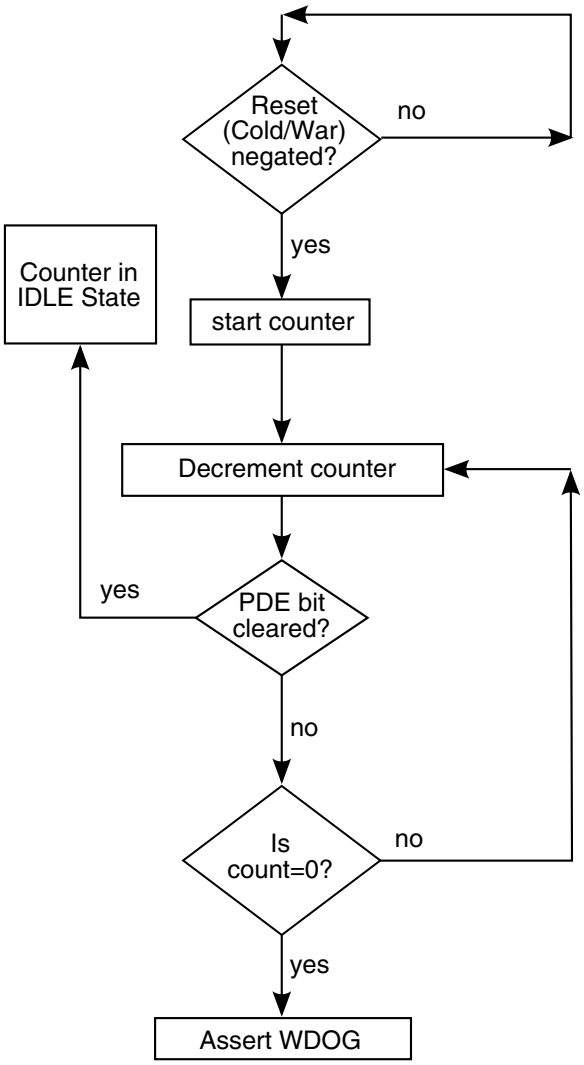

Figure 79-7. Power-Down Counter Flow Diagram

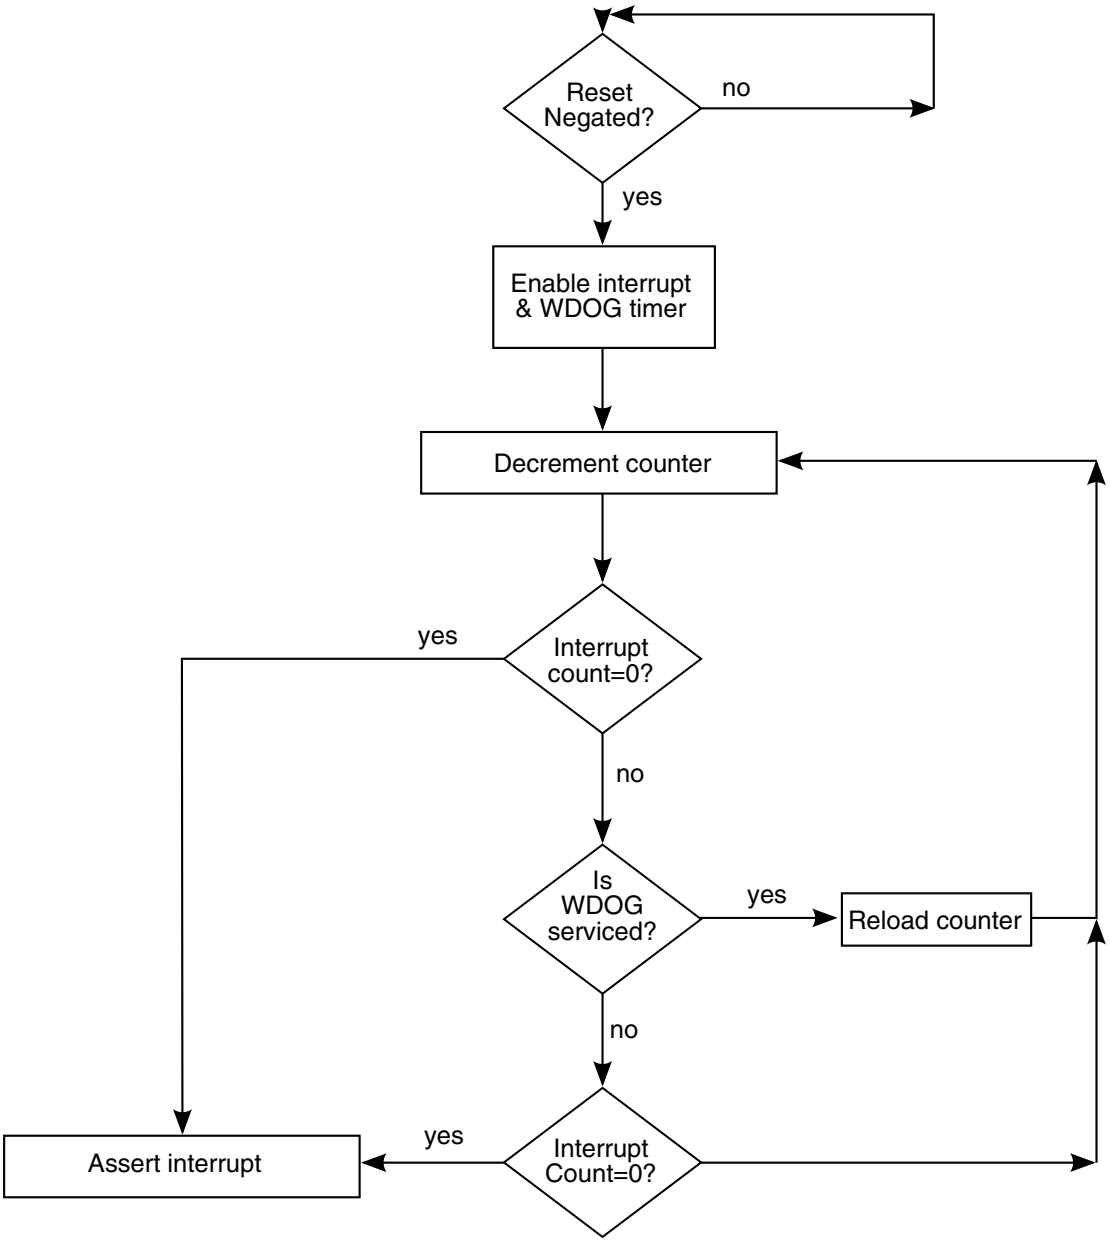

Figure 79-8. Interrupt Generation Flow Diagram

79.5 Initialization

The following sequence of programming should be performed for WDOG-1 initialization:

- PDE bit of Watchdog Miscellaneous Control Register (WDOG_WMCR) should be cleared for disabling the power down counter.

- WDT field of Watchdog Control Register (WDOG_WCR) should be programmed for sufficient time-out value.
- WDOG-1 should be enabled by setting WDE bit of Watchdog Control Register (WDOG_WCR) so that the Time-out counter loads the WDT field value of Watchdog Control Register (WDOG_WCR) and starts counting.

79.6 Programmable Registers

The WDOG-1 has user-accessible, 16-bit registers used to configure, operate, and monitor the state of the Watchdog Timer. Byte operations can be performed on these registers. If a 32-bit access is performed on these registers then the WDOG-1 will not generate any Peripheral Bus error and will behave normally, like a 16-Bit access, making Read/Write possible. A 32-Bit access should be avoided, as the system might go to an unknown state.

WDOG memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53F9_8000	Watchdog Control Register (WDOG_WCR)	16	R/W	0030h	79.6.1/ 5014
53F9_8002	Watchdog Service Register (WDOG_WSR)	16	R/W	0000h	79.6.2/ 5016
53F9_8004	Watchdog Reset Status Register (WDOG_WRSR)	16	R	0000h	79.6.3/ 5017
53F9_8006	Watchdog Interrupt Control Register (WDOG_WICR)	16	R/W	0004h	79.6.4/ 5018
53F9_8008	Watchdog Miscellaneous Control Register (WDOG_WMCR)	16	R/W	0001h	79.6.5/ 5019

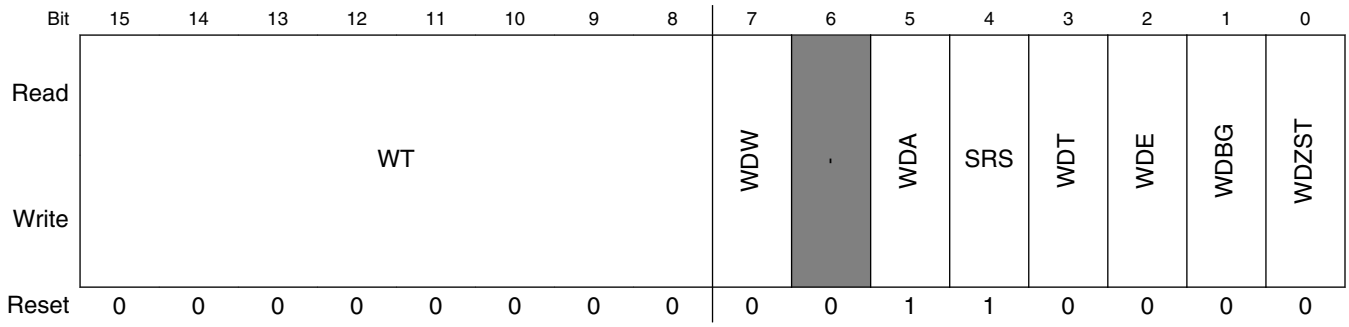
79.6.1 Watchdog Control Register (WDOG_WCR)

The Watchdog Control Register (WDOG_WCR) controls the WDOG-1 operation.

- WDZST, WDBG and WDW bits are write-once only bits. Once the software does a write access to these bits, all these bits will get locked and cannot be reprogrammed till the next system reset assertion.

- WDE is a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared till the next system reset.
- WDT is also a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared till the next POR (Power-on Reset). This bit does not gets reset/cleared due to any system reset.

Address: WDOG_WCR is 53F9_8000h base + 0h offset = 53F9_8000h



WDOG_WCR field descriptions

Field	Description
15–8 WT	Watchdog Time-out Field. This 8-bit field contains the time-out value that is loaded into the Watchdog counter after the service routine has been performed or after the Watchdog is enabled. After reset, WT[7:0] must have a value written to it before enabling the Watchdog otherwise count value of zero which is 0.5 seconds is loaded into the counter. **NOTE:** The time-out value can be written at any point of time but it is loaded to the counter at the time when WDOG-1 is enabled or after the service routine has been performed. For more information see Time-Out Event . 0x00 - 0.5 Seconds (Default). 0x01 - 1.0 Seconds. 0x02 - 1.5 Seconds. 0x03 - 2.0 Seconds. 0xff - 128 Seconds.
7 WDW	Watchdog Disable for Wait. This bit determines the operation of WDOG-1 during Low Power WAIT mode. This is a write once only bit. 0 Continue WDOG-1 timer operation (Default). 1 Suspend WDOG-1 timer operation.
6 -	Reserved adopt Reserved
5 WDA	$\overline{\text{WDOG}}$ assertion. Controls the software assertion of the $\overline{\text{WDOG}}$ signal. 0 Assert $\overline{\text{WDOG}}$ output. 1 No effect on system (Default).
4 SRS	Software Reset Signal. Controls the software assertion of the WDOG-generated reset signal $\overline{\text{wdog\_rst}}$. This bit automatically resets to "1" after it has been asserted to "0". **NOTE:** This bit does not generate the software reset to the block.

Table continues on the next page...

WDOG_WCR field descriptions (continued)

Field	Description
	0 Assert system reset signal. 1 No effect on the system (Default).
3 WDT	$\overline{\text{WDOG}}$ Time-out assertion. Determines if the $\overline{\text{WDOG}}$ gets asserted upon a Watchdog Time-out Event. This is a write-one once only bit. **NOTE:** There is no effect on $\overline{\text{wdog\_rst}}$ (WDOG Reset) upon writing on this bit. $\overline{\text{WDOG}}$ gets asserted along with $\overline{\text{wdog\_rst}}$ if this bit is set. 0 No effect on $\overline{\text{WDOG}}$ (Default). 1 Assert $\overline{\text{WDOG}}$ upon a Watchdog Time-out event.
2 WDE	Watchdog Enable. Enables or disables the WDOG-1 block. This is a write one once only bit. It is not possible to clear this bit by a software write, once the bit is set. **NOTE:** This bit can be set/reset in debug mode (exception). 0 Disable the Watchdog (Default). 1 Enable the Watchdog.
1 WDBG	Watchdog DEBUG Enable. Determines the operation of the WDOG-1 during DEBUG mode. This bit is write once-only. 0 Continue WDOG-1 timer operation (Default). 1 Suspend the watchdog timer.
0 WDZST	Watchdog Low Power. Determines the operation of the WDOG-1 during low-power modes. This bit is write once-only. **NOTE:** The WDOG-1 can continue/suspend the timer operation in the low-power modes (STOP and DOZE mode). 0 Continue timer operation (Default). 1 Suspend the watchdog timer.

79.6.2 Watchdog Service Register (WDOG_WSR)

When enabled, the WDOG-1 requires that a service sequence be written to the Watchdog Service Register (WSR) to prevent the time-out condition.

NOTE

Executing the service sequence will reload the WDOG-1 time out counter.

Address: WDOG_WSR is 53F9_8000h base + 2h offset = 53F9_8002h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	WSR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WDOG_WSR field descriptions

Field	Description
15–0 WSR	Watchdog Service Register. This 16-bit field contains the Watchdog service sequence. Both writes must occur in the order listed prior to the time-out, but any number of instructions can be executed between the two writes. The service sequence must be performed as follows: 0x5555 Write to the Watchdog Service Register (WDOG_WSR). 0xAAAA Write to the Watchdog Service Register (WDOG_WSR).

79.6.3 Watchdog Reset Status Register (WDOG_WRSR)

The WRSR is a read-only register that records the source of the output reset assertion. It is not cleared by a hard reset. Therefore, only one bit in the WRSR will always be asserted high. The register will always indicate the source of the last reset generated due to WDOG-1. Read access to this register is with one wait state. Any write performed on this register will generate a Peripheral Bus Error .

A reset can be generated by the following sources, as listed in priority from highest to lowest:

- Watchdog Time-out
- Software Reset

Address: WDOG_WRSR is 53F9_8000h base + 4h offset = 53F9_8004h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0											POR	0		TOUT	SFTW
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WDOG_WRSR field descriptions

Field	Description
15–5 Reserved	This read-only field is reserved and always has the value zero. Reserved.
4 POR	Power On Reset. Indicates whether the reset is the result of a power on reset. 0 Reset is not the result of a power on reset. 1 Reset is the result of a power on reset.
3–2 Reserved	This read-only field is reserved and always has the value zero. Reserved.
1 TOUT	Time-out. Indicates whether the reset is the result of a WDOG-1 time-out. 0 Reset is not the result of a WDOG-1 time-out. 1 Reset is the result of a WDOG-1 time-out.

Table continues on the next page...

WDOG_WRSR field descriptions (continued)

Field	Description
0 SFTW	Software Reset. Indicates whether the reset is the result of a WDOG-1 software reset by asserting SRS bit 0 Reset is not the result of a software reset. 1 Reset is the result of a software reset.

79.6.4 Watchdog Interrupt Control Register (WDOG_WICR)

The WDOG_WICR controls the WDOG-1 interrupt generation.

Address: WDOG_WICR is 53F9_8000h base + 6h offset = 53F9_8006h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	WIE	WTIS	0						WICT							
Write		w1c														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

WDOG_WICR field descriptions

Field	Description
15 WIE	Watchdog Timer Interrupt enable bit. Reset value is 0. **NOTE:** This bit is a write once only bit. Once the software does a write access to this bit, it will get locked and cannot be reprogrammed till the next system reset assertion 0 Disable Interrupt (Default). 1 Enable Interrupt.
14 WTIS	Watchdog TImer Interrupt Status bit will reflect the timer interrupt status, whether interrupt has occurred or not.Once the interrupt has been triggered software must clear this bit by writing 1 to it. 0 No interrupt has occurred (Default). 1 Interrupt has occurred
13–8 Reserved	This read-only field is reserved and always has the value zero. Reserved.
7–0 WICT	Watchdog Interrupt Count Time-out (WICT) field determines, how long before the counter time-out must the interrupt occur. The reset value is 0x04 implies interrupt will occur 2 seconds before time-out. The maximum value that can be programmed to WICT field is 127.5 seconds with a resolution of 0.5 seconds. **NOTE:** This field is write once only. Once the software does a write access to this field, it will get locked and cannot be reprogrammed till the next system reset assertion. 0x00 WICT[7:0] = Time duration between interrupt and time-out is 0 seconds. 0x01 WICT[7:0] = Time duration between interrupt and time-out is 0.5 seconds. 0x04 WICT[7:0] = Time duration between interrupt and time-out is 2 seconds (Default). 0xff WICT[7:0] = Time duration between interrupt and time-out is 127.5 seconds.

79.6.5 Watchdog Miscellaneous Control Register (WDOG_WMCR)

WDOG_WMCR Controls the Power Down counter operation.

Address: WDOG_WMCR is 53F9_8000h base + 8h offset = 53F9_8008h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0															PDE
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

WDOG_WMCR field descriptions

Field	Description
15–1 Reserved	This read-only field is reserved and always has the value zero. Reserved.
0 PDE	Power Down Enable bit. Reset value of this bit is 1, which means the power down counter inside the WDOG-1 is enabled after reset. The software must write 0 to this bit to disable the counter within 16 seconds of reset de-assertion. Once disabled this counter cannot be enabled again. See Power-Down Counter Event for operation of this counter. **NOTE:** This bit is write-one once only bit. Once software sets this bit it cannot be reset till the next system reset. 0 Power Down Counter of WDOG-1 is disabled. 1 Power Down Counter of WDOG-1 is enabled (Default).

Chapter 80
Crystal Oscillator 24 MHz (XTALOSC)

80.1 Introduction

The crystal oscillator contains an Automatic Level Controller (ALC), which detects the amplitude of the oscillation and adjusts the amount of current sourced to the crystal accordingly.

NOTE

As the oscillator is initially turned on there is no oscillation. The oscillator will source its maximum current of a few milliamps (mA) to kick-start the crystal.

NOTE

Once the oscillation starts and the amplitude of oscillation is detected and monitored by the ALC circuitry, the oscillator slowly cuts back its current to a stable value of a few hundreds microamps (uA).

80.1.1 Interface Specification

Most signals in the XTALOSC interface are either analog in nature or clock signals with no specific timing.

They are represented in the figure and table below.

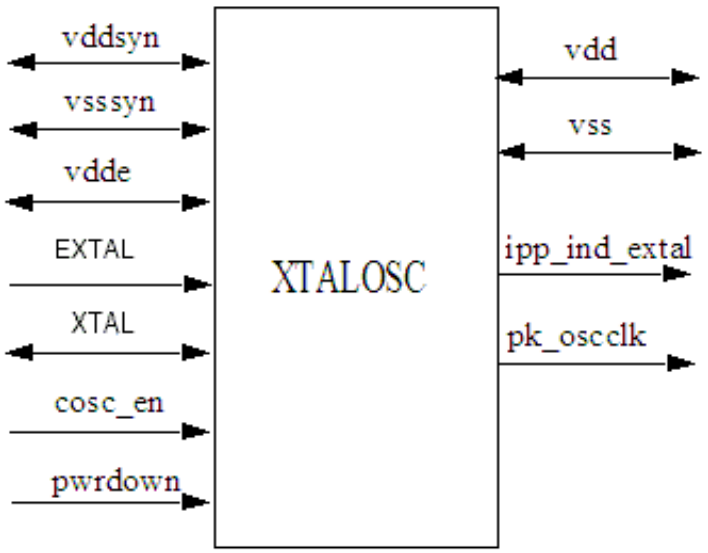


Figure 80-1. XTALOSC Interface

Table 80-1. Block I/O Signals

Signal	I/O	Description
XTALI	I/O	Crystal inout or 24MHz clock source input
XTALO	O	XTAL out pin to crystal

NOTE

If wish to use a single ended source, drive input on XTALI and float XTALO. (XTALI refers to the input of the integrated amplifier while XTALO is the output). Please refer to part data sheet, for max voltage limitation on XTALI.

80.1.2 Crystal Operating Frequency

This oscillator uses crystals with fundamental frequency 24MHz.

80.1.3 Power Supply

This oscillator is powered by a 2.5V power supply +/-10% tolerance. The core supply is 1.2V +/-10% tolerance.

80.1.4 Operating Temperature

For safety application, the temperature range is from -20C to 125C. The same temperature range applies when choosing a crystal for the oscillator.

80.1.5 Input Clock in Bypass Mode

Input clock voltage range in bypass mode is from 1.8V to 2.5V (50% duty cycle). It is recommended that the input clock voltage be the same as Vdde for proper output clock duty cycle.

80.1.6 Input Control Signal

To prevent voltage mismatch problem, input control voltage range can be high (2.5V) or low voltage (1.2V for cmos065lp)

80.1.7 Output Clock

The output clocks that are the same as the 2.5V power supply are pk_oscclk. The output clocks that are the same as the core logic voltage are ipp_ind_extal. All output clocks, either 2.5V or 1.2V, are required to have duty cycle in the range of 45% to 55% for 50% clock inputs

80.2 External Signals

The following table describes all XTALOSC (24MHz) I/Os.

Table 80-2. Block I/O Signals

Signal	I/O	Description
XTALI	I/O	Crystal input or 24 MHz clock source input
XTALO	O	XTAL out pin to crystal

80.3 Operation Modes

80.3.1 Crystal Osc Mode

In this mode, both extal and xtal are connected to a crystal and "cosc_en" is asserted with "pwrdown" deasserted. Two output clocks are available: "pk_oscclk" at 2.5V for 2.5V PLL and ipp_ind_extal at 1.2V for 1.2V PLL.

80.3.2 Bypass Mode

In this mode, the crystal oscillator amplifier is off with "cosc_en" deasserted. Only "extal" can be driven by an external clock source.

Any clock at voltage level of 1.2V to 2.5V is level-shifted to 2.5 V for 2.5 V PLL or 1.2 V for 1.2 V logic. The level shifters are actually comparators.

80.3.3 Low Power Mode

The "pwrdown" signal turns most of the circuitry in the osc, including the bias circuit.

80.3.4 Oscillator Safety Margin Requirements

Oscillator safety margin requirements are normally 5 or 10 times the maximum crystal ESR, depending on the crystal vendor. NDK requires 5x and KDS requires 10x.

The oscillator safety margin depends heavily on the capacitive loads on "extal" and "xtal" pins, so care must be taken when doing simulation to include parasitic loads on-chip as well as parasitic caps on boards.

Chapter 81
Crystal Oscillator 32K (XTALOSC32K)

81.1 Introduction

The Crystal Oscillator 32K (XTALOSC32K) is an integrated building block, that, when coupled with pads and an external crystal and load capacitors, can implement a crystal oscillator.

The cell features a power multiplexer allowing it to switch between a NiMH battery source and a nominal 1.2 V source. The multiplexer is controlled by the vdd1p2good signal from the Low-dropout regulator (LDO).

81.2 Features

Table 81-1. Features

	Min	Typ	Max	Comments
Fosc		32.768KHz		This frequency is nominal and determined mainly by the crystal selected. 32.0K would work as well.
Supply Voltage	1.0V	1.2V	1.4V	The target battery is a 1.2V NiMH button cell.
Temperature range	- 40C		120C	This is the simulated junction temperature. Battery specifications may practically limit this to a smaller range when used in an oscillator.

Table continues on the next page...

Table 81-1. Features (continued)

	Min	Typ	Max	Comments
Current consumption		1.5uA		This is the consumption of the oscillator alone (osc32k). Total supply consumption will depend on what the digtal portion of the RTC consumes. Target is for an additional 2uA. TBD
Bias resistor		14Mohm		This the integrated bias resistor that sets the amplifier into a high gain state. Any leakage through the ESD network, external board leakage, or even a scope probe that is significant relative to this value will debias the amp. The debiasing will result.
Crystal Properties				
Cload		10pF		Usually crystals can be purchased tuned for different Cloads. A higher Cload with decrease oscillation margin, but increases current oscillating through the crystal. See graph below.
ESR		50KHz		Equivalent series resistance of the crystal. Choosing a crystal with a higher value will decrease the oscillating margin. See graph below.

81.3 External Signals

Table below describes all XTAL32K Block I/Os.

Table 81-2. Block I/O Signals

Signal	I/O	Description
RTC_XTALI	I/O	Crystal inout or 32KHz clock source input
RTC_XTALO	O	XTAL out pin to crystal

NOTE

If wish to use a single ended source, drive input on RTC_XTALI and float RTC_XTALO . (RTC_XTALI refers to the input of the integrated amplifier while RTC_XTALO is the output). Please refer to part data sheet, for max voltage limitation on RTC_XTALI.

81.4 Memory Map/Register Definition

No programming model exists.

81.5 Functional Description

The following figure shows the Simulated Oscillator Gain Margin Vs Input Leakage Resistor referred to in Table 81-1.

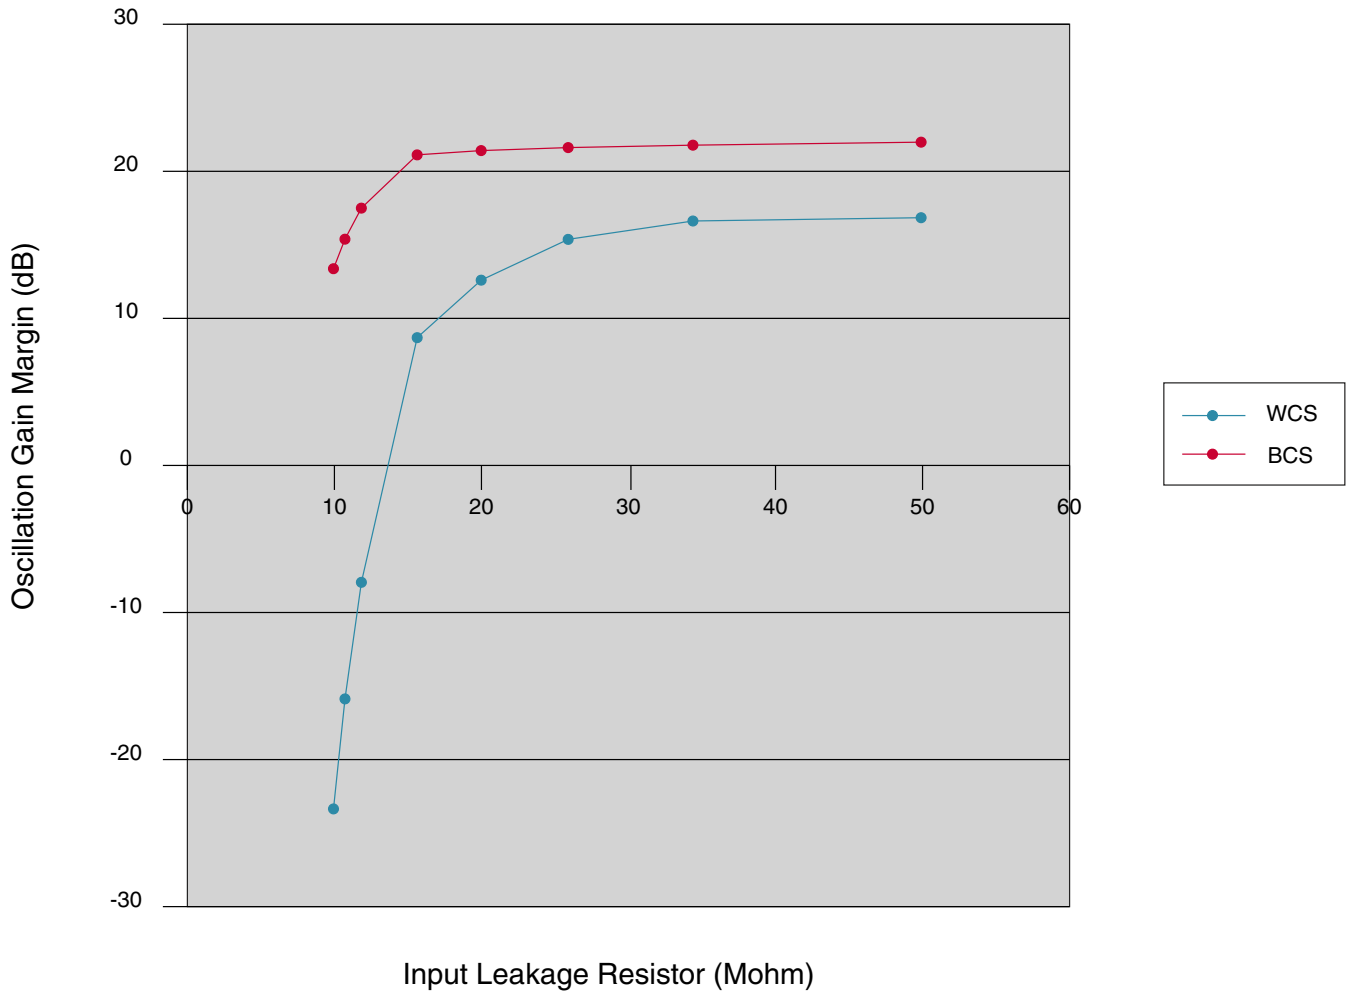

Figure 81-1. Simulated Oscillator Gain Margin Vs Input Leakage Resistor

The following figure shows the Simulated Oscillator Gain Margin Vs Crystal ESR referred to in Table 81-1.

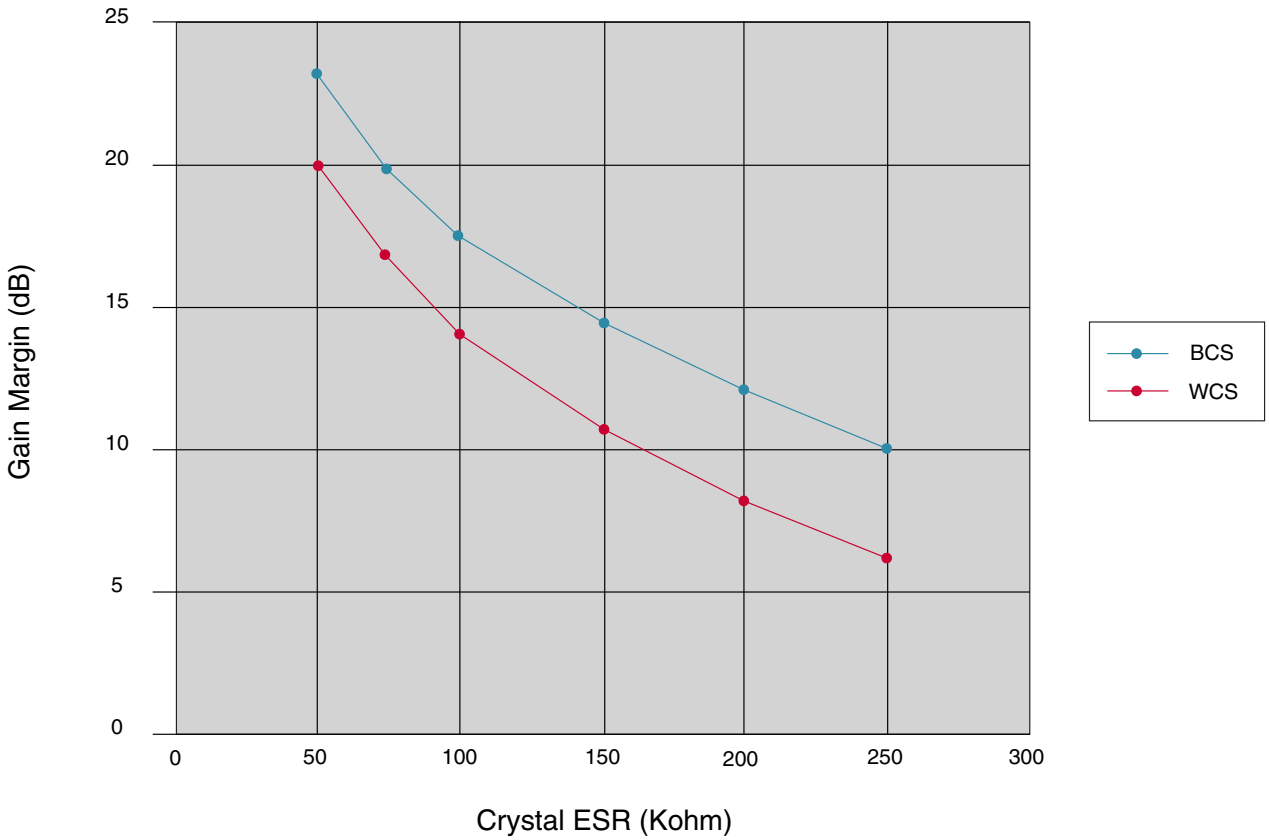

Figure 81-2. Simulated Oscillator Gain Margin Vs Crystal ESR

Appendix A
SDMA Scripts

A.1 Introduction

This appendix provides descriptions of scripts that may be used to perform data transfers using the Smart DMA (SDMA) block of the SoC. The SDMA block supports data transfer from core memory space to core memory, from core memory space to peripherals, and vice versa.

A.2 SDMA Scripts Overview

Table A-1 gives an overview of the SDMA scripts.

Table A-1. SDMA Scripts Overview

Data Transfer	Script to Use	Use Case	Parameters Through Context	Parameters Through Buffer Descriptor
Memory	ap_2_ap	Memory Copy	None	Word length (2'b01 or 2'b10 or 2'b11 or 2'b00), Counter Fist address is memory source address, second address is memory destination address
FIRI	mcu_2_firi	Firi Tx	FIRI Tx FIFO address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size (2'b01 or 2'b10 or 2'b11 or 2'b00), Counter Memory source address, Second address not used
	firi_2_mcu	Firi Rx	FIRI Tx FIFO address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size(2'b01 or 2'b10 or 2'b11 or 2'b00), Counter Memory source address, Second address not used
Shared UART	uartsh_2_mcu	Uart Rx	UART Rx FIFO address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size (2'b01), Counter Mem destination address, Second address not used

Table continues on the next page...

Table A-1. SDMA Scripts Overview (continued)

Data Transfer	Script to Use	Use Case	Parameters Through Context	Parameters Through Buffer Descriptor
UART	uart_2_mcu	Uart Rx	Uart Rx FIFO address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size (2'b01), Counter Memory source address, Second address not used
SPDIF	mcu_2_spdif	Spdif Playback	SPDIF Tx FIFO address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size (2'b10 or 2'b00), Counter Memory source address, Second address not used
	spdif_2_mcu	Spdif Record	SPDIF Rx FIFO address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size (2'b10 or 2'b00), Counter Memory source address, Second address not used
SSI	mcu_2_app, mcu_2_shp	Audio Playback	SSI Tx FIFO address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size (2'b01 or 2'b10 or 2'b11 or 2'b00), Counter Memory source address Second address not used
	app_2_mcu, shp_2_mcu	Audio Record	SSI Rx FIFO address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size (2'b01 or 2'b10 or 2'b11 or 2'b00), Counter, Memory source address Second address not used
	mcu_2_ssiapp, mcu_2_ssish	Audio Playback	SSI Tx FIFO 0 address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size (2'b01 or 2'b10 or 2'b11 or 2'b00), Counter Memory source address, Second address not used
	ssiapp_2_mcu, ssish_2_mcu	Audio Record	SSI Rx FIFO 0 address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size (2'b01 or 2'b10 or 2'b11 or 2'b00), Counter, Memory source address Second address not used
Peripheral	p_2_p	Peripheral Transfer	Destination address (r6) Event_mask (r1) Event2_mask (r0) Source address (r2) Information (r7)	Counter, First address and Second address not used

In Table A-1, the data transfer column lists the possible types of DMA channels that involve the SDMA and a specific script is attached to each channel. It must be noted that some scripts cover several DMA channels. The scripts deal with the channels that have generic peripherals where only the watermark level is needed (no aging timer, no end_of_packet feature, and so on). The location refers to whether a script resides in ROM or in RAM and the size of the script is given in the instructions. The parameters columns are explained in the next section.

The following terms are used in Table A-1 which lists all the supported data transfers.

EMI or External Memory:

The external memories are connected to the External Memory Interface. Thus, a data transfer to EMI means a data transfer to any of the external memories (NAND Flash, NOR Flash, PSRAM, SDRAM, and so on).

Host mem or ARM internal memory:

The memory space accessible through the MAX of the ARM platform. It does not correspond to the peripherals, although they are accessible through the MAX as well. A data transfer from Host mem means data is read from the internal memory of the ARM or from the external memory. It is possible to point to an external memory through the MAX because it is also connected to EMI module. The next diagram replaces the SDMA and its DMA port in the hardware architecture. The Host mem is accessible through the Per DMA port of the SDMA, the EMI is accessible through the Burst DMA and the DSP mem through the DSP port.

Shared Peripheral:

A same peripheral can be connected to the shared peripheral bus (output of SPBA module) and to the ARM platform. This is the case for some UART, CSPI, and SSI. Therefore, "shared UART" indicates that the UART is connected to the shared peripheral, whereas "UART" means the UART is connected to the ARM platform.

Figure A-1 gives an overview of the SDMA in its hardware environment.

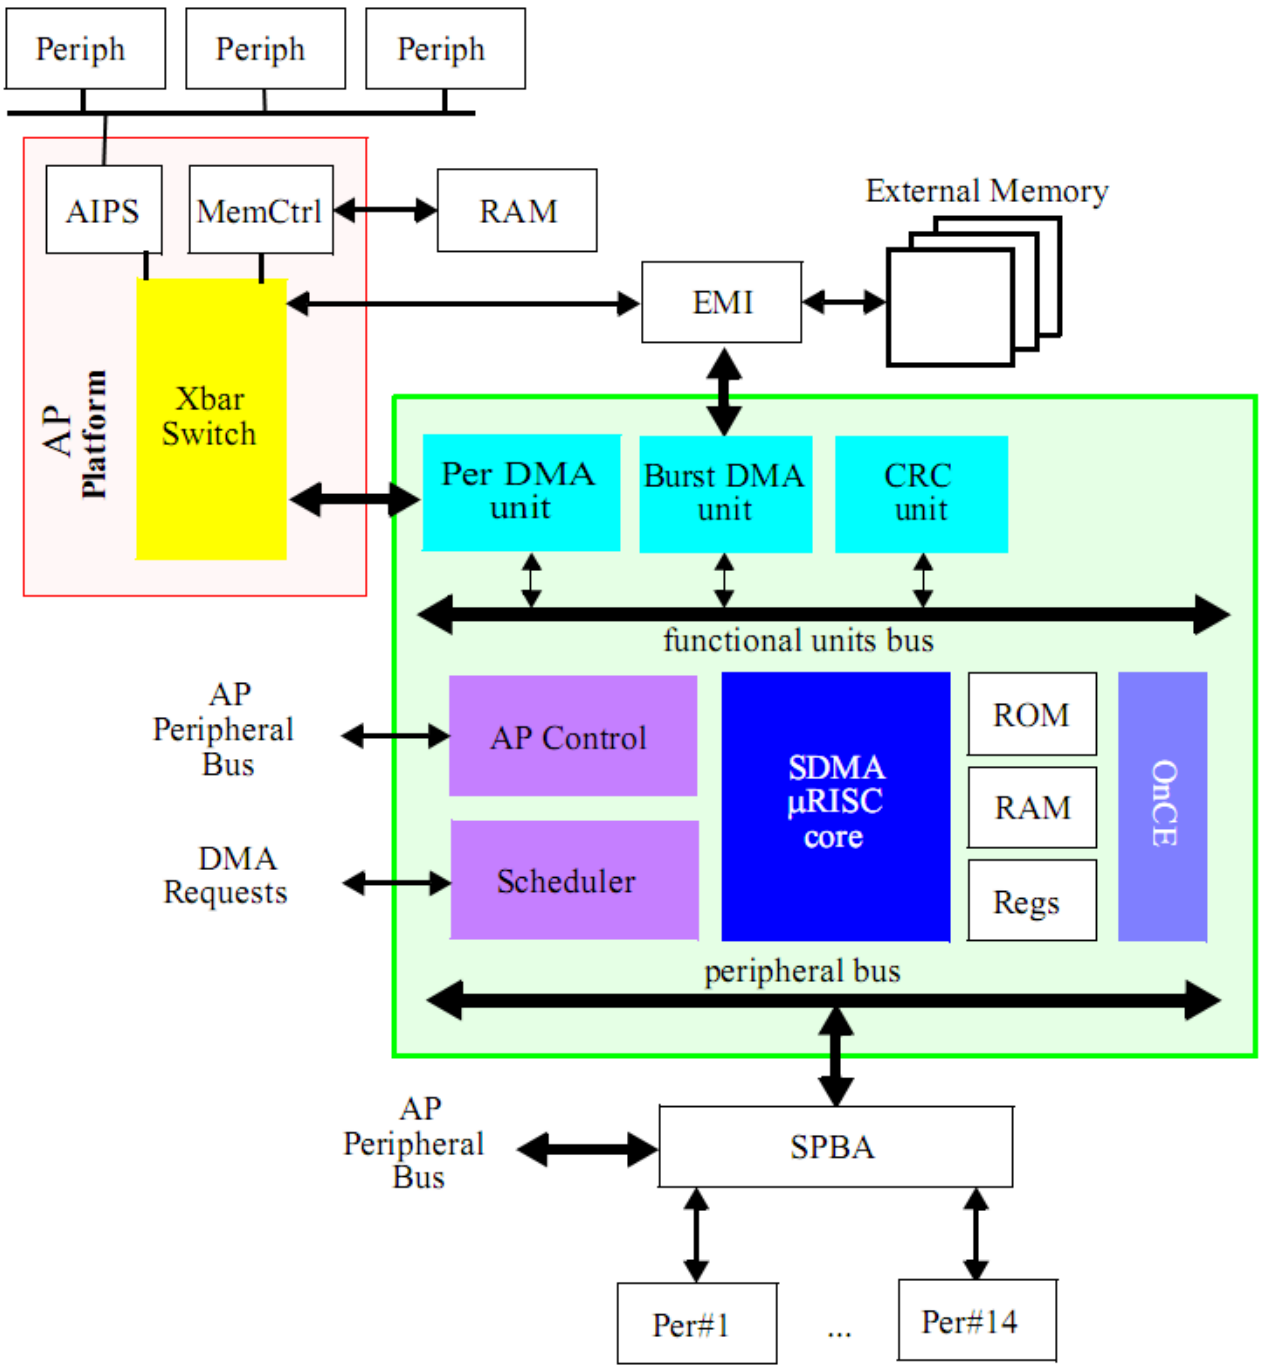

Figure A-1. SDMA Connections

A.3 Scripts Parameters: Definition

A.3.1 Parameters Definition

A.3.1.1 Parameters Required by Data Transfer Script Involving a Peripheral

The scripts that have a peripheral as a player in the transfer of data need to have the following input parameters:

A.3.1.1.1 Watermark Level (WML)

It is the upper or the lower threshold of the receive or transmit FIFO of the peripheral that triggers a DMA request to the SDMA. The WML determines the data transfer loop size, meaning the number of bytes that will be read/write from/to the receive/transmit FIFO. This parameter must be a multiple of the peripheral FIFO data size. As an example, if UART1 is the data transfer destination, data must be written to the Tx FIFO of the peripheral. For instance, the watermark level can be set to 8 bytes (the UART is a 1 byte FIFO data size), meaning the UART_TX DMA request will be sent to the SDMA each time there are more than 8 free locations in the FIFO; therefore SDMA loop size will be set to 8 and 8 bytes will be written to the UART_TX FIFO. In fact, the loop size is the minimum between the WML and the count field of the buffer descriptor attached to the channel. This concept is explained later on in the chapter. Similarly, if the UART is the source of a data transfer and if the WML is set to 16, each time the DMA request is received by the SDMA, which triggers the associated channel, the data transfer loop size is set to 16. This means 16 bytes will be read from the UART_RX FIFO. The watermark level is a "long" (32-bit data) programmed by the ARM and is not supposed to evaluate a lot during application. The WML is always given in bytes.

NOTE

For the transmit FIFO, the WML = FIFO_SIZE - FIFOTX_THRESHOLD For the receive FIFO, the WML = FIFORX_THRESHOLD The FIFOTX_THRESHOLD/ FIFORX_THRESHOLD are the values of the peripheral transmit and receive FIFO level at which a DMA request is triggered. For instance, if TX FIFO is 32 bytes depth and if the DMA request is sent when the number of bytes present in the FIFO is below a threshold of 10, the WML will be 22. It means that when the SDMA will receive the DMA request from the peripheral, it will be possible to store 22 bytes in the TX FIFO. For the receive FIFO, the WML equals the threshold.

A.3.1.1.2 Event_mask and Event2_mask

As previously said, when the WML threshold is over or under passed, a DMA request is sent to the scheduler part of the SDMA. The SDMA scheduler has 48 input pins, called "events", which are connected to the different DMA request. The mapping between the DMA request name and the event number is SoC dependent and defined in the "Interrupts and SDMA Events" chapter. For instance, in SoC A, the UART_RX DMA request is connected to events pin 5; whereas for SoC B, it may be connected to events pin 15. The script reads the EVENTS(32 events requests) and EVENTS2(remaining 16 events requests) register to check if the received DMA request is compliant with the expected one and it guaranteed that a second DMA request sent during the data transfer is not lost.

For instance, while SDMA is reading the UART_RX FIFO (again, the number of data to be read is given by WML value), the peripheral may receive new data from its input ports. Therefore after the first data transfer, the number of data available in the UART received FIFO can be still higher than the WML threshold, so a second DMA request may be sent.

The event_mask value is generally a 1-bit high value, which means that if the script attached to the channel must be triggered by DMA request number I, event_mask[I] must be set to 1, if the script attached to the channel must be triggered by DMA request number 32+I, event2_mask[I] must be set to 1. Some scripts (like ata_2_mcu) may be triggered by several DMA requests; in that case several bits of the event_mask must be asserted. The event_mask and event2_mask are long (32-bit) data.

A.3.1.1.3 Request sources

The SDMA has 48 sources of hardware requests coming from various peripherals either integrated inside the SoC, or connected outside the SoC (external DMA requests). Each request, or event, is able to trigger a single or several channels. A channel transfer can be also simply triggered in software if the script does not use the even_mas/event_mask2 variables or if the user wants to force a transfer.

Typically, the scripts (like uart_2_mcu) working with peripherals FIFO use the event_mask/event_mask2 variables to perform a data burst upon FIFO requests until count is reached. Whereas other scripts (like ap_2_ap) are just triggered once through an event (hardware or software request), and do not stop until count is reached.

A.3.1.1.4 Peripheral Address

The scripts of the SDMA scripts library are SoC independent but as their goal is to address peripheral, they required the base address or the FIFO address of the peripheral. Passing FIFO or peripheral base address depends on the scripts.

A.3.1.1.5 Data Length

The scripts whose name contains the key word "app" or "shp" are generic: they are used to transfer data from/to a 8, 16, 24 or 32-bit peripheral data size. Some jumps to some routines of these scripts depend on this peripheral size. This parameter is required as input of these scripts. This parameter is passed through the command field of the buffer descriptor and is coded on bits 25 and 24 of the mode:

00: 32-bit data transfer.

01: 8-bit data transfer.

10: 16-bit datatransfer.

11: 24-bit data transfer.

A.4 SDMA Scripts on i.MX53

The following scripts are all based on buffer descriptor mechanism.

A.4.1 SDMA ROM Scripts

The ROM holds the generic memory to memory scripts (ap_2_ap, ap_2_bp, bp_2_ap, bp_2_bp) and the peripheral most useful scripts (app_2_mcu, mcu_2_app, uart_2_mcu, uartsh_2_mcu, mcu_2_shp, shp_2_mcu).

In these memory to memory scripts, the number of bytes to transfer from the source memory to the destination is divided by 4 to get the number of 32-bit words that can be transferred. Most of the time, the transfer will be a transfer of words. There will be a byte or half data transfer at the end of the transfer if the total number of bytes to transfer is not an multiple of 4.

A.4.1.1 ap_2_ap

This script is used to transfer data inside the application processor memory using BurstDMA.

Using this script there is no restriction on the number of bytes to transmit, the source address and destination address alignment, or on the source memory and destination memory type. But word alignment and source/destination memory type will impact performance. In case that the source and destination are in the same memory type, being word aligned allows the SDMA to use the copy capability of the DMA units. When it is not the case the SRAM of the SDMA is used as temporary buffer.

A.4.1.1.1 Parameters Transmitted Through the Context ap_2_ap

None.

A.4.1.1.2 Parameters Transmitted Through the Buffer Descriptor ap_2_ap

The number of bytes to transmit is stored in the first Buffer descriptor word

The source address is stored in the second Buffer descriptor word (address field).

The destination address is stored in the Extended Buffer address

A.4.1.1.3 Use of the General Register During the Execution ap_2_ap

- r0: nb of bytes to transfer, counter during loop
- r2: channel cb address, scratch
- r3: current buffer descriptor pointer, AP destination address, scratch
- r4: mode
- r5: source address loaded by getbd,
- r6: destination address loaded by getcb, scratch
- r7:

A.4.1.1.4 Overview of Script Functionality ap_2_ap

The parameters of the transfer (number of bytes to transfer, source address and destination address) are retrieved from the buffer descriptor.

Depending on the address alignment and the DMA units involved, if possible, the transfer is performed using the copy capability of the DMA unit, or using the SDMA SRAM as a temporary buffer.

When the transfer is finished, this algorithm restarts (a new buffer descriptor is read).

The count in the BD mode word after the script is over is meaningful only if error was reported, else it has the same value as was fed as input to the script.

A.4.1.2 uartsh_2_mcu

This script is used to transfer data from the shared UART to the External memory. The UART is connected to the ARM platform. The UART is an 8-bit peripheral, but when reading the FIFO, 16 bits are retrieved. In fact, the 8 MSB are the status bytes for the current data. At each access the value of this byte is checked to verify that a valid data was retrieved. If an error is detected the transfer is stopped and the information is sent back to the Host through the buffer descriptor with the byte count field updated.

A.4.1.2.1 Parameters Transmitted Through the Context uartsh_2_mcu

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check event - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: address of the peripheral Rx FIFO (project dependent)

r7: Watermark level - Used to determine the maximum of data that can be sent to the peripheral each time the channel is started.

A.4.1.2.2 Parameters Transmitted Through the Buffer Descriptor uartsh_2_mcu

The number of bytes to transmit is stored in the first Buffer descriptor word

The destination address is stored in the second Buffer descriptor word (address field).

The Extended Buffer address is not used

A.4.1.2.3 Use of the General Register During the Execution uartsh_2_mcu

r0 = mask to check events2

r1 = mask to check events

r2 = AP M3 destination address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.4.1.2.4 Overview of Script Functionality uartsh_2_mcu

When the UART sends a DMA request, it can be for three different reasons:

When the RX threshold is over passed. It deals with the most frequent event.

When the AGEING timer has reached its final value, meaning there is less data than the RX threshold in the RX FIFO, and they have been present for too long. It is called the aging DMA request.

When IDLE timer reached its final value; meaning the RX FIFO has been empty for too long. It is called the iddle dma request. The IDLE timer is not used, so only normal and AGEING DMA requests are supported by the script.

The first time the script is executed, a buffer descriptor is opened, the buffer destination address and its size are retrieved from the BD. Then the script checks if the RRDY bit of USR1 is set. If yes, it means that the Watermark level has been reached, there are "WML" bytes in RX FIFO. If the count field of the opened BD is higher than WML-1, the SDMA script will perform WML-1 read accesses to the RX FIFO and WML write access to the destination buffer (a read access then a write access is call a data transfer loop). If the count field is lesser than the WML-1 value, the count field will be the data transfer loop size. So the data transfer loop size equals min(WML-1,BD count)

So there will be always one data remaining in the UART RX FIFO after every data transfer loop and the ageing timer will always trigger a DMA request. It means that the channel on which the script is run will be always closed on an AGEING DMA request.

Now assume the script is triggered by a DMA request, but RRDY is not set. It means that it deals with an AGEING DMA request; there is at least one data in the RX FIFO. The data is read and written into the destination buffer, and then the RDR is checked again. If it is set and if the destination data buffer is not full (BD count is not 0), a new data is read and so on until RDR is 0. When RDR is 0, the ageing timer interrupt flag is disabled by setting the AGTIM bit, the count field of BD is updated and the current BD is closed. Then the script tries to open the next BD if the Continuous bit of the current BD was set, if there is no more BD to open, the channel is stopped.

When reading a data from the UART RX FIFO, the MSB are check to verify that a valid data has been retrieved. If an error is detected the transfer is stopped, the error bit is set in the BD, the count is updated, the BD is closed and an interrupt is sent to the ARM.

When the buffer is full, this algorithm restarts (a new buffer descriptor is read, if it exists).

The next diagram illustrates the script algorithm, it is quite complex but things become more obvious when we notice that there is a loop for the normal DMA request (in sky-blue) and on when the AGEING DMA request was detected (in yellow).

A.4.1.3 shp_2_mcu

This generic script is used to transfer data from a 8, 16, 24 or 32-bit peripheral connected to the shared peripheral bus accessed through the SPBA to memories accessed by the BurstDMA (External memories). It can be used for SSI (8, 16, 24 or 32-bit data size), for CSPI (32-bit data size) or for SDHC(MMC)/SIM (16-bit data size), these peripherals being connected to the shared peripheral bus.

A.4.1.3.1 Parameters Transmitted Through the Context shp_2_mcu

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check event - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: address of the peripheral Rx FIFO (project dependent)

r7: Watermark level - Used to determine the maximum of data that can be sent to the peripheral each time the channel is started.

A.4.1.3.2 Parameters Transmitted Through the Buffer Descriptor shp_2_mcu

The peripheral size/data length is set in the command field of the first Buffer descriptor word, specially bits 24 and 25.

The number of bytes to transmit is stored in the first Buffer descriptor word (count field)

The destination address in the external memory is stored in the second Buffer descriptor word (address field).

The Extended Buffer address is not used.

A.4.1.3.3 Use of the General Register During the Execution shp_2_mcu

r0 = mask to check events2

r1 = mask to check events

r2 = BD destination address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.4.1.3.4 Overview of Script Functionality shp_2_mcu

The parameters of the transfer (peripheral size, number of bytes to transfer and source address) are retrieved from the buffer descriptor.

When the peripheral sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" data in the FIFO.

During this data transfer loop, the number of bytes that are transferred from the RX FIFO of the peripheral to the EMI is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory write access is fixed by the parameter peripheral size.

The necessary number of transfer loops are executed in order to fill the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is filled, this algorithm restarts (a new buffer descriptor is read).

A.4.1.4 mcu_2_shp

This generic script is used to transfer data from memories accessed by the BurstDMA (External memories) to a 8, 16, 24 or 32-bit peripheral connected to the shared peripheral bus accessed through the SPBA. It can be used for SSI (8, 16, 24 or 32-bit data size), for CSPI (32-bit data size), for SDHC(MMC)/SIM (16-bit data size) or for UART3,4 (8-bit data size), these peripherals being connected to the shared peripheral bus.

A.4.1.4.1 Parameters Transmitted Through the Context mcu_2_shp

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check events - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: address of the peripheral Tx FIFO (project dependent)

r7: Watermark level - Used to determine the maximum of data that can be retrieved from the peripheral each time the channel is started.

A.4.1.4.2 Parameters Transmitted Through the Buffer Descriptor mcu_2_shp

The peripheral size/data length is set in the command field of the first Buffer descriptor word, specially bits 24 and 25.

The number of bytes to transmit is stored in the first Buffer descriptor word (count field)

The source address in the external memory is stored in the second Buffer descriptor word (address field).

The Extended Buffer address is not used.

A.4.1.4.3 Use of the General Register During the Execution mcu_2_shp

r0 = mask to check events2

r1 = mask to check events

r2 = EVENTS / EVENTS2

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.4.1.4.4 Overview of Script Functionality mcu_2_shp

The parameters of the transfer (peripheral size, number of bytes to transfer and source address) are retrieved from the buffer descriptor.

When the peripheral sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" empty rooms in the FIFO.

During this data transfer loop, the number of bytes that are transferred from the EMI to the TX FIFO of the peripheral is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory read access is fixed by the parameter peripheral size.

The necessary number of transfer loops are executed in order to empty the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is empty, this algorithm restarts (a new buffer descriptor is read).

A.4.1.5 uart_2_mcu

This script is similar to uartsh_2_mcu script. The only difference between these scripts is the way SDMA access UART RX FIFO. In case of uartsh_2_mcu, the UART RX FIFO can directly be accessed by SDMA as it is on Shared Peripheral Bus. In case of uart_2_mcu, SDMA script uses one of its DMA (Peripheral DMA) to access UART RX FIFO.

A.4.1.6 app_2_mcu

This generic script is used to transfer data from a 8, 16, 24 or 32-bit peripheral connected to the AIPS accessed through the Periphera DMA of SDMA, to memories accessed by the BurstDMA (External memories). It can be used for SSI (8, 16, 24 or 32-bit data size), for CSPI (32-bit data size) or for SDHC(MMC)/SIM (16-bit data size).

A.4.1.6.1 Parameters Transmitted Through the Context app_2_mcu

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check event - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: address of the peripheral Rx FIFO (project dependent)

r7: Watermark level - Used to determine the maximum of data that can be sent to the peripheral each time the channel is started.

A.4.1.6.2 Parameters Transmitted Through the Buffer Descriptor app_2_mcu

The Data Length peripheral size/data length is set in the command field of the first buffer descriptor word, specially bits 24 and 25.

The number of bytes to transmit is stored in the first buffer descriptor word (count field)

The destination address in the external memory is stored in the second buffer descriptor word (address field).

The Extended Buffer address is not used.

A.4.1.6.3 Use of the General Register During the Execution app_2_mcu

r0 = mask to check events2

r1 = mask to check events

r2 = AP M3 destination address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.4.1.6.4 Overview of Script Functionality app_2_mcu

The parameters of the transfer (peripheral size, number of bytes to transfer and source address) are retrieved from the buffer descriptor.

When the peripheral sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" data in the FIFO.

During this data transfer loop, the number of bytes that are transferred from the RX FIFO of the peripheral to the EMI is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory write access is fixed by the parameter peripheral size.

The necessary number of transfer loops are executed in order to fill the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is filled, this algorithm restarts (a new buffer descriptor is read).

A.4.1.7 mcu_2_app

This generic script is used to transfer data from memories accessed by the BurstDMA (External memories), to a 8, 16, 24 or 32-bit peripheral connected to the AIPS accessed through the Periphera DMA of SDMA. It can be used for SSI (8, 16, 24 or 32-bit data size), for CSPI (32-bit data size) or for SDHC(MMC)/SIM (16-bit data size).

A.4.1.7.1 Parameters Transmitted Through the Context mcu_2_app

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check event - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: address of the peripheral Tx FIFO (project dependent)

r7: Watermark level - Used to determine the maximum of data that can be sent to the peripheral each time the channel is started.

A.4.1.7.2 Parameters Transmitted Through the Buffer Descriptor mcu_2_app

The peripheral size/data length is set in the command field of the first buffer descriptor word, specially bits 24 and 25.

The number of bytes to transmit is stored in the first buffer descriptor word (count field).

The source address in the external memory is stored in the second buffer descriptor word (address field).

The Extended Buffer address is not used.

A.4.1.7.3 Use of the General Register During the Execution mcu_2_app

r0 = mask to check events2

r1 = mask to check events

r2 = TX FIFO address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.4.1.7.4 Overview of Script Functionality mcu_2_app

The parameters of the transfer (peripheral size, number of bytes to transfer and source address) are retrieved from the buffer descriptor.

When the peripheral sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" empty room in the FIFO.

During this data transfer loop, the number of bytes that are transferred from the EMI to the TX FIFO of the peripheral is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory read access is fixed by the parameter peripheral size.

The necessary number of transfer loops are executed in order to fill the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is filled, this algorithm restarts (a new buffer descriptor is read).

A.4.1.8 mcu_2_spdif

This script performs a data move from AP buffer to 24 bits FIFO of the SPDIF. This peripheral is on the peripheral bus, the SDMA accesses it through the SPBA. The MCU buffer is accessed through the burst DMA.

A.4.1.8.1 Parameters Transmitted Through the Context mcu_2_spdif

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check events - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: Address of SPDIF STL register

r7: Watermark level - Used to determine the maximum data that can be sent to the peripheral each time the channel is started.

A.4.1.8.2 Parameters Transmitted Through the Buffer Descriptor mcu_2_spdif

The data length (Either 32-bit or 16-bit) is set in the command field of the first Buffer descriptor word, especially bits 24, 25.

The number of bytes to transmit is stored in the first Buffer descriptor word (count field)

The source address in the external memory is stored in the second Buffer descriptor word (address field).

The Extended Buffer address is not used.

A.4.1.8.3 Use of the General Register During the Execution mcu_2_spdif

r0 = mask to check events2

r1 = mask to check events

r2 = EVENTS / EVENTS2

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.4.1.8.4 Overview of Script Functionality mcu_2_spdif

The parameters of the transfer (data length, number of bytes to transfer and source address) are retrieved from the buffer descriptor.

When the spdif sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" of empty room in the FIFO (Sum of left and right FIFO's).

During this data transfer loop, the number of bytes that are transferred from the EMI to the TX FIFO of the spdif is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory read access is fixed by the parameter data length.

The necessary numbers of transfer loops are executed in order to empty the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is empty, this algorithm restarts (a new buffer descriptor is read).

A.4.1.9 spdif_2_mcu

This script performs a data move from 24 bits FIFO of the SPDIF to AP buffer. This peripheral is on the peripheral bus, the SDMA accesses it through the SPBA. The MCU buffer is accessed through the burst DMA.

A.4.1.9.1 Parameters Transmitted Through the Context spdif_2_mcu

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check events - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: Address of SPDIF SRL register

r7: Watermark level - Used to determine the maximum data that can be sent to the peripheral each time the channel is started.

A.4.1.9.2 Parameters Transmitted Through the Buffer Descriptor spdif_2_mcu

The data length (Either 32 bit or 16 bit) is set in the command field of the first Buffer descriptor word, especially bits 24, 25.

The number of bytes to transmit is stored in the first Buffer descriptor word (count field)

The destination address in the external memory is stored in the second Buffer descriptor word (address field).

The Extended Buffer address is not used.

A.4.1.9.3 Use of the General Register During the Execution spdif_2_mcu

r0 = mask to check events2

r1 = mask to check events

r2 = EVENTS / EVENTS2

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.4.1.9.4 Overview of Script Functionality spdif_2_mcu

The parameters of the transfer (data length, number of bytes to transfer and destination address) are retrieved from the buffer descriptor.

When the spdif sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" date in the FIFO (Sum of left and right FIFO's).

During this data transfer loop, the number of bytes that are transferred from the RX FIFO of the spdif to the EMI is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory write access is fixed by the parameter data length.

The necessary numbers of transfer loops are executed in order to empty the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is empty, this algorithm restarts (a new buffer descriptor is read).

A.4.1.10 mcu_2_firi

This script performs a data move from AP buffer to 8, 16, 24 or 32-bit FIFO of the FIRI. Both MCU buffer and FIRI are accessed through the burst DMA.

A.4.1.10.1 Parameters Transmitted Through the Context mcu_2_firi

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check events - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: Address of FIRI Transmit FIFO register

r7: Watermark level - Used to determine the maximum data that can be sent to the peripheral each time the channel is started.

A.4.1.10.2 Parameters Transmitted Through the Buffer Descriptor mcu_2_firi

The data length (8, 16, 24 or 32-bit) is set in the command field of the first buffer descriptor word, especially bits 24, 25.

The number of bytes to transmit is stored in the first buffer descriptor word (count field)

The source address in the memory is stored in the second buffer descriptor word (address field).

The Extended Buffer address is not used.

A.4.1.10.3 Use of the General Register During the Execution mcu_2_firi

r0 = mask to check events2

r1 = mask to check events

r2 = EVENTS / EVENTS2

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.4.1.10.4 Overview of Script Functionality mcu_2_firi

The parameters of the transfer (data length, number of bytes to transfer and source address) are retrieved from the buffer descriptor.

When the firi sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" of empty room in the FIFO (Sum of left and right FIFO's).

During this data transfer loop, the number of bytes that are transferred from the EMI to the TX FIFO of the firi is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory read access is fixed by the parameter data length.

The necessary numbers of transfer loops are executed in order to empty the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is empty, this algorithm restarts (a new buffer descriptor is read).

A.4.1.11 firi_2_mcu

This script performs a data move from 8, 16, 24, 32-bit FIFO of the FIRI to the AP buffer. Both the MCU buffer and FIRI are accessed through the burst DMA.

A.4.1.11.1 Parameters Transmitted Through the Context firi_2_mcu

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check event - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: address of the FIRI RX FIFO

r7: Watermark level - Used to determine the maximum of data that can be sent to the peripheral each time the channel is started.

A.4.1.11.2 Parameters Transmitted Through the Buffer Descriptor firi_2_mcu

The data length (8, 16, 24 or 32 bits) is set in the command field of the first buffer descriptor word, especially bits 24 and 25.

The number of bytes to transmit is stored in the first buffer descriptor word (count field)

The destination address is stored in the second buffer descriptor word (address field).

The Extended Buffer address is not used

A.4.1.11.3 Use of the General Register During the Execution firi_2_mcu

r0 = mask to check events2

r1 = mask to check events

r2 = AP M3 destination address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.4.1.11.4 Overview of Script Functionality firi_2_mcu

When the FIRI sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" of data in the FIFO.

During this data transfer loop, the number of bytes that are transferred from the RX FIFO of the FIRI to the EMI is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory write access is fixed by the parameter data length.

The necessary numbers of transfer loops are executed in order to fill the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is full, this algorithm restarts (a new buffer descriptor is read).

A.4.2 SDMA RAM scripts

A.4.2.1 mcu_2_ssiapp

This script performs a data move from AP buffer to 8, 16, 24 or 32-bit FIFO of the SSI in the AP region with 2 FIFOs enabled. The MCU buffer is accessed through the burst DMA, while SSI is accessed with Per DMA.

A.4.2.1.1 Parameters Transmitted Through the Context mcu_2_ssiapp

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check events - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: Address of SSI Transmit FIFO 0 register

r7: Watermark level - Used to determine the maximum data that can be sent to the peripheral each time the channel is started.

A.4.2.1.2 Parameters Transmitted Through the Buffer Descriptor mcu_2_ssiapp

The data length (8, 16, 24 or 32-bit) is set in the command field of the first buffer descriptor word, especially bits 24 and 25.

The number of bytes to transmit is stored in the first buffer descriptor word (count field).

The source address in the memory is stored in the second buffer descriptor word (address field).

The Extended Buffer address is not used.

A.4.2.1.3 Use of the General Register During the Execution mcu_2_ssiapp

r0 = mask to check events2

r1 = mask to check events

r2 = Tx FIFO address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.4.2.1.4 Overview of Script Functionality mcu_2_ssiapp

The parameters of the transfer (data length, number of bytes to transfer and source address) are retrieved from the buffer descriptor.

When the SSI sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" of empty room in the FIFO (Sum of left and right FIFO's).

During this data transfer loop, the number of bytes that are transferred from the EMI to the TX FIFO of the SSI is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory read access is fixed by the parameter data length.

The necessary numbers of transfer loops are executed in order to empty the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is empty, this algorithm restarts (a new buffer descriptor is read).

A.4.2.2 ssiapp_2_mcu

This script performs a data move from the 8, 16, 24 or 32-bit FIFO of the SSI to the AP buffer. The SSI is in the AP region and 2 FIFO enabled. The MCU buffer is accessed through the burst DMA while the SSI is accessed through Per DMA.

A.4.2.2.1 Parameters Transmitted Through the Context ssiapp_2_mcu

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check event - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: address of the SSI RX FIFO 0

r7: Watermark level - Used to determine the maximum of data that can be sent to the peripheral each time the channel is started.

A.4.2.2.2 Parameters Transmitted Through the Buffer Descriptor ssiapp_2_mcu

The data length (8, 16, 24, 32 bits) is set in the command field of the first buffer descriptor word, especially bits 24 and 25.

The number of bytes to transmit is stored in the first buffer descriptor word (count field)

The destination address is stored in the second buffer descriptor word (address field).

The Extended Buffer address is not used

A.4.2.2.3 Use of the General Register During the Execution ssiapp_2_mcu

r0 = mask to check events2

r1 = mask to check events

r2 = AP M3 destination address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.4.2.2.4 Overview of Script Functionality ssiapp_2_mcu

When the SSI sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" of data in the FIFO(sum of left and right FIFOs).

During this data transfer loop, the number of bytes that are transferred from the RX FIFO of the SSI to the EMI is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory write access is fixed by the parameter data length.

The necessary numbers of transfer loops are executed in order to fill the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is full, this algorithm restarts (a new buffer descriptor is read).

A.4.2.3 mcu_2_ssish

This script is similar to mcu_2_ssiapp. The only difference is the way SDMA core accesses the SSI TX FIFO. For script of mcu_2_ssiapp, SDMA core accesses the TX FIFO through Functional Unit Bus and regards it as the peripheral DMA, whereas for the mcu_2_ssish, the access is through the Shared Peripheral Bus and SSI can be directly accessed by SDMA.

A.4.2.4 ssish_2_mcu

This script is similar to ssiapp_2_mcu. The only difference is the way SDMA core accesses the SSI RX FIFO. For script of ssiapp_2_mcu, SDMA core accesses the RX FIFO through Functional Unit Bus and regards it as the peripheral DMA, whereas for the ssish_2_mcu, the access is through the Shared Peripheral Bus and SSI can be directly accessed by SDMA.

A.4.2.5 p_2_p

This script performs a data move of 32 bits from the peripheral's FIFO connected either on SPBA or AIPS bus to another. If destination FIFO belongs to ASRC then pad adding is performed after every N samples from the source device. If the source FIFO belongs to ASRC then after transmitting N samples a pad is swallowed. In case there is a transaction between ASRC(source) and SPDIF (destination) no pad adding or swallowing is required because SPDIF expects even number of samples.

This script presently does not deal with the transactions involving two devices connected to AIPS bus.

A.4.2.5.1 Parameters Transmitted Through the Context p_2_p

r0: LWML event mask

r1: HWML event mask

r2: source address

r6: destination address

r7: INFO. See details in Table A-1 :

p_2_p (r7 INFO)

Bits	Name	Description
0-7	Lower WML	Watermark Level
8	PS	1 : Pad Swallowing 0 : No Pad swallowing
9	PA	1 : Pad Adding 0 : No Pad swallowing
10	SPDIF	If this bit is set both source and destination are on SPBA
11	Source Bit(SP)	1 : Source on SPBA 0 : Source on AIPS

Table continues on the next page...

Bits	Name	Description
12	Destination Bit (DP)	1 : Destination on SPBA 0 : Destination on AIPS
13-15	----------	MUST BE 0
16-23	Higher WML	HWML
24-27	N	Total number of samples after which Pad adding/Swallowing must be done. It must be odd.
28	Lower WML Event (LWE)	SDMA events reg to check for LWML event mask 0 : LWE in EVENTS register 1 : LWE in EVENTS2 register
29	Higher WML Event(HWE)	SDMA events reg to check for HWML event mask 0 : HWE in EVENTS register 1 : HWE in EVENTS2 register
30	----------	MUST BE 0
31	CONT	1 : Amount of samples to be transferred is unknown and script will keep on transferring samples as long as both events are detected and script must be manually stopped by the application 0 : The amount of samples to be is equal to the count field of mode word

A.4.2.5.2 Parameters Transmitted Through the Buffer Descriptor p_2_p

In the first buffer descriptor word, the mode and number of types to transfer is included.

The Buffer address and Extended Buffer address are not used.

A.4.2.5.3 Use of the General Register During the Execution p_2_p

The register usage for each case(spba_2_spba, asrc_2_spba) are different, so don't present here.

A.4.2.5.4 Overview of Script Functionality p_2_p

The script get the number of data to transfer per event according to the bit 31(CONT) of INFO. If CONT is 0, each transfer loop will transmit the number of data as in the mode count; Or else, it means the number of samples to be transferred is not known and the transfer must take place as long as both events are detected and the script must be manually stopped by the application in case the transfer needs to be stopped.

When PS or PA is set, then after each N words transfer, a pad swallowing or pad adding will be done. This is to handle the ASRC involved transfer.

The transfer is executed only when the event is set. After each transfer for the event, the script will try to obtain a new BD.

Appendix B
i.MX53 Revision History

B.1 Arch Overview Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Block List	In Table 1-1, "Digital and Analog Blocks," removed "(Pop Only)" in the description of the EXTMC row.
Features	In Section "Features," replaced the text "One CSPI, up to 26 Mbps in master mode (up to 10MHz in slave mode)" with "One CSPI; refer to data sheet for performance parameters."
Features	In Section "Features," replaced the text "Two ECSPI (enhanced CSPI), up to 52 Mbps each" with "Two eCSPI (enhanced CSPI); refer to data sheet for performance parameters."
Block List	In Table 1-1, "Digital and Analog Blocks," updated the description of the SAHARA row.
Architectural Partitioning	In Section, "Architectural Partitioning, added a NOTE referring to SATA Temperature Sensor application note.

B.2 Memory Map Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
ARM Platform System Memory Map	In Table 2-1 "System Memory Map," removed "(TBD)."

B.3 Interrupts Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
ARM Platform Interrupts	In Table 3-1, "ARM Domain Interrupt Summary," added the PWRFAIL_INT signal in the description of IOMUXC row.
ARM Platform Interrupts	In Table 3-1, "ARM Domain Interrupt Summary," updated the description of P_PLATFORM_NE_32K_256K row.

B.4 External Memory Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Features	Updated Table 5-2, "EIM multiplexing," as per i.MX53 datasheet.
Features	Removed "EIM/NANDF multiplexing diagram."
Overview	Replaced "Each AXI bud master" with "Each AXI bus master."
Features	In Table 5-2, "EIM multiplexing," corrected the DSZ values in 8 bit columns.

B.5 Multimedia Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Clocking Architecture	Updated Section "Clocking Architecture."
Software	Updated first sentence of Section "Software."

B.6 AHBMAX Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
System Connectivity	Added Section "System Connectivity."

B.7 ASRC Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Introduction	In Section "Introduction ," updated Figure "General System Overview."

B.8 AUDMUX Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Internal Network Mode	In Section "Internal Network Mode," corrected the dimensions of images.
Port Receive Data Modes	In Section "Port Receive Data Modes," corrected the dimensions of images.

B.9 CSU Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Features	In Section "Features," added an introductory paragrah.
Features	In Section "Features," updated the bullet point related to peripheral access policy and added a note.
Features	In Section "Features," added a note.
Peripheral Access Policy	Changed the title of the Section "Execution Mode Access Policy" to " Peripheral Access Policy."

B.10 DPLLC Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
DPLLC Memory Map/Register Definition	In Section "DPLLC Memory Map/Register Definition," corrected the positions of bits.
DPLLC Memory Map/Register Definition	In Section "DPLLC Control Register," corrected restes of UPEN and ref_clk_sel[1:0]. Also, replaced "10 clock2 is selected" with "10 clock2 is selected (24MHz oscillator clock)." in the field description of ref_clk_sel[1:0].
Overview	In Section "Overview," updated Figure "Block Diagram of the DPLLC."
Feature Description	In Section "Feature Description," updated the third bullet point.
DPLLC Memory Map/Register Definition	In Table "DPLLC_CTL field descriptions," updated the description of ref_clk_sel[1:0].
Normal Mode	In Section "Normal Mode," updated Figure "Clock MUXing and Gating/Divider Circuitry."

B.11 EIM Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Features	Changed six chip selects to four chip selects.
Multiplexed Address/Data Mode	Updated second sentence of Section "Multiplexed Address/ Data Mode"
Multiplexed Address/Data Mode	Updated Table 25-1 as per the IMX53 Data sheet.
EIM Memory Map/Register Definition	In Section "EIM Memory Map/Register Definition" updated offset/base addresses for "Programmable Registers."
EIM Memory Map/Register Definition	In Table "EIM_CSnWCR1 field descriptions," updated WWSC row.
Boot Mode	In Section "Boot Mode," added a cross reference to Chapter "System Boot."
Boot Mode	In Table "Table 25-2," removed first 7 rows.
Other Important Block I/O Signals Internal to the SoC	Updated EIM_BOOT row of the table in Section "Other Important Block I/O Signals Internal to the SoC."

Table continues on the next page...

Topic Cross-Reference	Customer-facing Description
EIM Memory Map/Register Definition	Updated NOTEs in AUS, CSREC, DSZ in EIM_CSnGCR1 field descriptions in Table "EIM_CSnGCR1 field descriptions."
EIM Memory Map/Register Definition	Removed the NOTE in ERRST row of Table "EIM_WIAR field descriptions."
Booting from EIM	Updated second paragraph of Section "Booting from EIM."
Access to AMD Flash	Removed Section "AMD Flash Boot."
Access to Intel Sibley Flash	Removed Section "Intel Sibley Flash Boot."
MDOC Device Boot	Updated Section "MDOC Device Boot."
Samsung OneNAND Boot	Updated Section "Samsung OneNAND Boot."
Access to Spansion Flash	Removed Section "Spansion Flash Boot."
Overview	Replaced "EIM_BOOT[12:0]" with "EIM_BOOT[2:0]" in Figure "EIM Diagram."
EIM Memory Map/Register Definition	In Section "Chip Select n Read Configuration Register 1," added footnotes for RWSC and OEA bit fields.
EIM Memory Map/Register Definition	In Section "Chip Select n Write Configuration Register 1," added a footnote for WWSC bit field.
EIM Memory Map/Register Definition	In Section "Chip Select n General Configuration Register 1," added a footnotes for CSREC, DSZ, and MUM bit fields.
EIM Memory Map/Register Definition	In Section "Chip Select n General Configuration Register 1," updated the NOTE in in the field description of CSREC row.
Initialization Information	Removed Section "Active Chip Selects and Address Space Configuration."
EIM Memory Map/Register Definition	Removed note in WIAR row EIM IP Access Register.
EIM Memory Map/Register Definition	Removed note in WAL row of Chip Select n Write Configuration Register 1.
EIM Memory Map/Register Definition	Updated note in WWSC row of Chip Select n Write Configuration Register 1.
EIM Memory Map/Register Definition	Removed note in RAL row of Chip Select n Read Configuration Register 1.
EIM Memory Map/Register Definition	Updated note in RWSA row of Chip Select n Read Configuration Register 1.
EIM Memory Map/Register Definition	Removed note in MUX16_BYP_GRANT row of Chip Select n General Configuration Register 2.
EIM Memory Map/Register Definition	Removed note in AUS row of Chip Select n General Configuration Register 1.

B.12 ESDCTL Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
ESDCTL	Added a NOTE to Section "ESDCTL MR4 Derating Register (ESDCTL_ESDMR4)."
ESDCTL	Added Table 28-34, "ODT Values," and updated the descriptions of ODT3_INT_RES, ODT2_INT_RES, ODT1_INT_RES, and ODT0_INT_RES bits with references to the same table.
ESDCTL	Added a line in the NOTE to Section "ESDCTL MR4 Derating Register (ESDCTL_ESDMR4)," clarifying the temperature sensor location.
ESDCTL Memory Map/Register Definition	Updated definitions for bit fields "SDE_0" and "SDE_1" in the ESDCTL register.

B.13 ESDHCv2 Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
ESDHCV2	Removed the text "In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DAT0 line is released." from DLA bit field row of Table "ESDHCV2x_PRSSTAT field descriptions."

B.14 EXTMC Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
EIM and NFC IO pin sharing	Updated Section "EIM and NFC IO pin sharing."
EIM and NFC IO pin sharing	Updated Table 31-1, "EIM multiplexing."
EIM and NFC IO pin sharing	Removed Figure "EIM/NANDF multiplexing diagram."
IP Bus Memory Map	In Table 31-3, "EXTMC Block memory map," updated Start ADDR and End ADDR columns for base addresses.

B.15 GPIO Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
External Signal Description	Removed Sections "External Signal Description" and "Signals Overview", which described only internal signals.

B.16 IOMUXC Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
CH0_MODE[10]	In Section "General Purpose Register 2," changed "29kOhm" to "28 kOhms," for BGREF_ RRMODE in Table "IOMUXC_GPR2 field descriptions."
DDR_SEL	In Section "IOMUXC_SW_PAD_CTL_GRP_DDR_TYPE," updated the field description for DR_SEL.
IOMUXC_memoryMap	In Section "Programmable Registers," Added Table 43-2, "DDR Output Driver Average Impedance," and placed cross references to it in DSE field descriptions of DQM3, SDQS3, DQM2, SDODT1, SDQS2, RESET, SDCLK_1, CAS, SDCLK_0, SDQS0, SDODT0, DQM0, RAS, SDQS1, DQM1, ADDDS, B0DS, B1DS, CTLDS, B2DS, and B3DS registers, replacing existing field description.

B.17 IPU Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
IPU Memory Map/Register Definition	In Section, "Programmable Registers," added the missing text in the last sentence."
IPU Memory Map/Register Definition	The register base address for IPU has been changed from "0x1800_0000" to "0x1E00_0000".
IPU Memory Map/Register Definition	Updated duplicate bit 22 offset in IPU_INT_CTRL_1, 3, 5, 13, IPU_SDMA_EVENT_1, 3, 13, IPU_CH_DB_MODE_SEL0, IPU_INT_STAT_1, 3, 5, 13, IPU_CUR_BUF_0, and IPU_CH_BUF0_RDY0 to correct offsets.
IPU Memory Map/Register Definition	Updated bit names in IPU_IDMAC_CH_EN_2 and IPU_CH_BUF0_RDY0 registers.

B.18 KPP Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Ghost Key Problem and Correction	In Section "Ghost Key Problem and Correction," updated the Figure "Matrix with "Ghost" Key Protections."

B.19 M4IF Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
M4IF	In Table Watermark Interrupt and Status 0 Register (M4IF_WMIS0), corrected typos in the descriptions of WS0_7 and WS0_6 rows.

B.20 NFC Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
NFC	In Section "AXI Memory Map," corrected the base addresses of NFC registers.

B.21 OCRAM Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Memory Map	Removed Section "Memory Map."

B.22 PLARB1 Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Overview	Added Section System Connectivity

B.23 PWM Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
PWM	In Section "PWM Period Register," replaced "Writing 0xFFFF to this register will achieve the same result as writing 0xFFFE," with "Maximum allowed value for this register is 0xFFFE."
PWM	In Section "PWM Sample Register," replaced "The FIFO can be written and read when the PWM is disabled" with "The FIFO can be written at any time, but can be read only when the PWM is enabled."
FIFO	In Section "FIFO," replaced "The FIFO can be written and read when the PWM is disabled" with "The FIFO can be written at any time, but can be read only when the PWM is enabled."
Overview	In Section "Overview," updated Figure "Pulse-Width Modulator Block Diagram."

B.24 SAHARA Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Features	Updated Section "Features."
Overview	In Section "Overview," updated Figure "Block Diagram of SAHARA."

B.25 SATA Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
-	Restructured presentation of information in this chapter.
	Added Section "."
Features	In Section, "Features," updated the bullet point related to SATA speeds.
Hot Plug	In Section, "Hot Plug," removed last two bullet points.
Link Layer Tx OOB Sequence Generation	In Section, "Link Layer Tx OOB Sequence Generation," removed second sentence of the NOTE.
PHY Initialization Details	In Section, "PHY Initialization Details," removed footnote.
Port DMA	In Section, "Port DMA," removed NOTE.
Bus Interface Unit	Removed Section "AMBA AXI Interface."
Features	Updated Section "Features."
Block Diagram	Updated Section "Block Diagram."

B.26 SATA PHY Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
-	Removed "Top metal options for active section", "Naming conventions", "Static timing constraint files and setup", and "Core sizes" sections.
-	Removed "Signaling completion of an operation" and "Digital scan operation" sections.
-	Removed "Boundary scan and jtag interface connections", "SoC layout considerations", "Back-to-back diodes", and "Using deliverables in physical design tools" sections.
-	Removed "Simulation", "Verilog model files and simulators", "Gate-level models", "Macros affecting simulation", "Running example tests", "Spice models descriptions", and "Using the spice models" sections.
Overview	Added Chapter "DesignWare Cores SATA2 PHY."
ID Code	In Table "Table 64-29" replaced value "0011" with "1017."
Control Register Bus Interface	In Section "Control Register Bus Interface," corrected a crossreference.
Signal Descriptions Information	Removed "Section Boundary Scan Port Signals," and its references in sections "Common Signals" and "Signal Descriptions Overview."

B.27 SDMA Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
ARM Platform Memory Map and Control Register Definitions	In Section "ARM platform Channel 0 Pointer (SDMAARM_MC0PTR)," replaced the text "Refer to the API document i.MX53 SDMA Scripts User Manual for the use of this register" with "Appendix A fully describes the SDMA Application Programming Interface (API) in SDMAARM_MC0PTR field descriptions."
Standard Boot Sequence	In Section "Standard Boot Sequence," replaced the text "4. Perform any necessary setup as required by the standard boot script in ROM (this is described in i.MX53 SDMA Scripts User Manual)" with "4. Perform any necessary setup as required by the standard boot script in ROM (this is described in Appendix A)."
SDMA Initialization	In Section "SDMA Initialization," replaced the text "The API document i.MX53 SDMA Scripts User Manual describes the setup of the SDMA" with "The Appendix A describes the setup of the SDMA."
SDMA Internal (Core) Memory Map and Internal Register Definitions	Changed reset value of SDMACORE_ENDIANNESS[APEND] to 1 and added that bit is tied to logic '1'.
Overview	Removed Section "References," and pointed cross references directly to appendix Section "SDMA Scripts Overview."

B.28 SJC Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
External Signal Overview	In Section "External Signal Overview," removed a duplicate Figure "SJC Connections."
	Various updates to figures in several sections.

B.29 SPBA Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Introduction	In Section "Introduction," updated Figure "SPBA Block Diagram."

B.30 SRC Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Boot Output Signals	In Section "Boot Output Signals ," updated the boot address from F000_0000 to 0800_0000.

B.31 SSI Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Features	Added min/max audio sampling rates for I2S. Added min/max frame rates for AC97.

B.32 USB Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Queue Head	Updated C bit field position at offset 07-04H.
USB	In "Non-core Registers" section, removed the duplicate rows of USBNC memory map.
USB	In "Core Registers" section, updated the base addresses of USB_UOG_ENDPTCTRL1-7 registers.
	Updated Section "."
Entering Low Power Suspend Mode	Updated Section "Entering Low Power Suspend Mode."
Wake-Up Events	Updated Section "Wake-Up Events."
	Updated Section "."
USB Non-Core Memory Map/Register Definition	Added bit UH1_PHY_CTRL_0[UTMI_ON_CLOCK] entry and description
USB Non-Core Memory Map/Register Definition	Added bit USB_OTG_PHY_CTRL_0[conf2] entry and description
Peripheral (Device) Mode	Added Section "Peripheral (Device) Mode."

Table continues on the next page...

Topic Cross-Reference	Customer-facing Description
Pins Used for Host Controller 1	Added Section "Pins Used for Host Controller 1."
Overview	In Section "Overview."

B.33 WDOG Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
WDOG_B Generation	In Section, "WDOG_B Generation," updated Figure "WDOG-1 Generation."

B.34 XTALOSC Revision History

The following table contains changes made to this block guide.

Topic Cross-Reference	Customer-facing Description
Introduction	Updated Section "Introduction."

Chapter 1
Introduction

1.1 About This Document

The following chapter is a supplement to the *i.MX53 Multimedia Applications Processor Reference Manual, Rev. 2*.

Chapter 2
Fusemap

2.1 Fusemap

Table 2-1 is a summary of the fuse locks used in the chip.

Table 2-1. Fuse Lock Summary

Fuse Name	Fuse Bank	Rows Affected
LOCK	0, 1, 3	0800, 0C00, 1400
BOOT_LOCK	0	0804 - 0818, 0840-0844
TESTER_LOCK	0	0820 - 083C
GP_LOCK	0	0860 - 087C
SRK_LOCK	1	0C04
SJC_RESP_LOCK	1	0C08 - 0C20
MAC_ADDR_LOCK	1	0C24 - 0C38
SRK_LOCK88	3	1404 - 142C
SRK_LOCK160	3	1430 - 147C
Bank 4 Locks	4	1808 - 1814

Table 2-2 details the lock fuses, which control the fuse accessibility in an irreversible mode.

NOTE

Setting the lock fuses irreversibly locks the affected rows against any further modification.

Table 2-2. Lock Fuses

FB	Addr	7	6	5	4	3	2	1	0
0	0800	FBWP	FBOP	FBRP	TESTER_LOCK	FBESP	TESTER_LOCK2	GP_LOCK	BOOT_LOCK
0	0804	Reserved	JTAG_SMODE[1:0]		BT_FUSE_SEL	JTAG_HEO	KTE	SEC_JTAG_RE	JTAG_BP

The following section details the various modes and selection of the required boot devices. A separate map is given for each and every boot device. The device select is specified by BOOT_CFG1[7:4] fuses listed in Table 2-3.

Table 2-3. Boot Device Select

Boot Device	BOOT _CFG1[7]	BOOT_CFG1[6]	BOOT_CFG1[5]	BOOT_CFG1[4]
WEIM (Table 2-4)	0	0	0	0
HD (SATA/PATA) (Table 2-5)	0	0	1	0

2.2 Fusemap Description Table

This section covers the fusemap descriptions of the chip.

Table 2-11. Fusemap Descriptions

IIM addr	IIM Bank	Fuses Name	Number of Fuses	Fuses Function	Setting	Locked by/Is Lock?
0800[0]	0	BOOT_LOCK	1	Boot fuses Locking rows 0804 080C-0818 0840-0844 0854 fusebank0.	0 - Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded IIM register) 1 - Lock (The controlled field can be read or sensed only)	LOCK
0800[1]	0	GP_LOCK	1	Locking rows 0860-087C, fusebank0	0 - Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded IIM register) 1 - Lock (The controlled field can be read or sensed only)	LOCK
0804[0]	0	JTAG_BP	1	JTAG Debug Security Bypass. Blowing this fuse semi-permanently returns the device to the “JTAG Enable mode”	0 - JTAG Security bypass is not active 1 - JTAG Security bypass is active	BOOT_LOCK
0804[1]	0	SEC_JTAG_RE	1	Secure JTAG Re-enable. Overrides the Secure JTAG Bypass fuse (JTAG_BP, in this register), to limit JTAG access according to the JTAG_SMODE. The JTAG_RE signal permanently overrides JTAG security bypass, returning the device to “Secure JTAG mode.	0 - Secure JTAG Bypass fuse is not overridden (secure JTAG bypass is allowed) 1 - Secure JTAG Bypass fuse is overridden (secure JTAG bypass is not allowed)	BOOT_LOCK
0804[2]	0	KTE	1	Kill Trace Enable. Enables tracing capability on ETM, and other modules.	0 - Bus tracing is allowed 1 - Bus tracing is allowed in case security state as defined by Secure JTAG allows it (for example, JTAG_ENABLE or NO_DEBUG)	BOOT_LOCK
0804[3]	0	JTAG_HEO	1	JTAG HAB Enable Override. Disallows HAB JTAG enabling. The HAB may normally enable JTAG debugging by means of the HAB_JDE-bit in the IIM SCS0 register. The JTAG_HEO-bit can override this behavior.	0 - HAB may enable JTAG debug access 1 - HAB JTAG enable is overridden (HAB may not enable JTAG debug access)	BOOT_LOCK

Table continues on the next page...

Table 2-11. Fusemap Descriptions (continued)

IIM addr	IIM Bank	Fuses Name	Number of Fuses	Fuses Function	Setting	Locked by/Is Lock?
0804[4]	0	BT_FUSE_SEL	1	Determines, whether using fuses for boot configuration, or GPIO /Serial loader.	If boot_mode=""00"" (Development) 0=Boot mode configuration is taken from GPIOs. 1=Boot mode configuration is taken from fuses. If boot_mode=""10"" (Production) 0 - Boot using Serila Loader (UART/USB) 1- Boot mode configuration is taken from fuses.	BOOT_LOCK
0804[6:5]	0	JTAG_SMODE[1:0]	2	JTAG Security Mode. Controls the security mode of the JTAG debug interface	00 - JTAG enable mode 01 - Secure JTAG mode 11 - No debug mode	BOOT_LOCK
080C[0]	0	BT_MMU_ENABLE (BOOT_CFG1[0])	1	Option to enable MMU initializing during the HAB boot. (Include L2 cache enable), Enable L1 during start of boot processing. Have a corresponded GPIO pin.	0 - Not initializing MMU during the boot 1 - Initializing MMU with L1 cache (write through) during the boot	BOOT_LOCK
080C[1]	0	BT_FREQ (BOOT_CFG1[1])	1	ARM core frequency at boot time.	0 - 800MHz 1 - 400MHz	BOOT_LOCK
080C[7:4]	0	BOOT_CFG1[7:2]	4	Defines specific boot mode configurations. Refer to the respective boot fusemap tables for details.	0x0000 - WEIM (NOR/OneNAND) boot 0x0010 - HD (PATA/SATA) boot 0x0011 - Serial ROM (I2C/SPI) boot 0x1XXX - NAND FLASH boot 0x01XX - SD/MMC (eSD/eMM) boot 0x0001 - Reserved Refer to the respective boot fusemap tables for details.	BOOT_LOCK
0810[1:0]	0	SEC_CONFIG[1:0] (BOOT_CFG2[1:0])	2	Security Configuration	00 - FAB (Open) 01 - Open - allows any code to be flashed and executed, even if it has no valid signature. 1x - Closed (Security On)	BOOT_LOCK

Table continues on the next page...

Table 2-11. Fusemap Descriptions (continued)

IIM addr	IIM Bank	Fuses Name	Number of Fuses	Fuses Function	Setting	Locked by/Is Lock?
0810[2]	0	NFC_FREQ_SEL	1	NFC Clock Freq selection, to meet device speed characteristics. (Delay line set to '0' delay)	NAND Flash clock frequency, (in brackets freq for 400MHz / 300MHz DDR AXI clock setting respectively): 0 - AXI DDR divide by 12, (33.33MHz / 27.75MHz) 1 - AXI DDR divide by 28 (14.28MHz / 11.89MHz)	BOOT_LOCK
0810[3]	0	OSC_FREQ_SEL (BOOT_CFG2[3])	1	Oscillator frequency select. It is used by boot code for PLL programming.	0 - Auto detect (~10ms cost in boot time) Selects between 19.2, 24, 26 and 27 MHz. 1 - Oscillator frequency is 24 MHz	BOOT_LOCK
0810[4]	0	AXI / DDR Freq (BOOT_CFG2[4])	1	DDR / AXI default frequency settings	0 - PLL2: 400MHz 1 - PLL2: 333MHz	BOOT_LOCK
0810[7:5]	0	BOOT_CFG2[7:5]	3	Various boot options configurations, specific to the selected boot device. Refer to the respective boot fusemap tables for details.	Refer to the respective boot fusemap tables for details.	BOOT_LOCK
0814[0]	0	DIR_BT_DIS	1	Direct External Memory Boot Disable	0 - Direct boot from external memory is allowed 1 - Direct boot from external memory is not allowed	BOOT_LOCK
0814[7:1]	0	BOOT_CFG3[7:1]	7	Various boot options configurations, specific to the selected boot device. Refer to the respective boot fusemap tables for details.	Refer to the respective boot fusemap tables for details.	BOOT_LOCK
0818[0]	0	WDOG_ENABLE	1	Watchdog Enable	Used to specify whether to enable / not watchdog at boot. 0 - Watch-Dog is disabled. 1 - Watch-Dog is enabled.	BOOT_LOCK
0818[3]	0	BT_LPB_POLARITY	1	Select polarity of GPIO pin used for LPB indication.	0 - Positive logic ('1' on GPIO - means LPB boot) 1 - Inverse logic ('0' on GPIO - means LPB boot)	BOOT_LOCK
0818[4]	0	BT_LPB	1	Options for Low Power Boot mode. Have a corresponded GPIO pin.	0 - Low power boot is not activated 1 - Low Power boot is enabled	BOOT_LOCK

Table continues on the next page...

Table 2-11. Fusemap Descriptions (continued)

IIM addr	IIM Bank	Fuses Name	Number of Fuses	Fuses Function	Setting	Locked by/Is Lock?
0818[7:6]	0	BT_LPB_DIV	2	In Low Power Boot mode - control of DVFS divider factors.	00 – Divide by 1 (No devision) 01 – Divide by 2 10 – Divide by 3 11 – Divide by 4	BOOT_LOCK
0820[7:0]	0	SJC_CHALL[63:56] / UNIQUE_ID[63:56]	8	SJC CHALLENGE/ Unique ID	Burned by Freescale	TESTER_LOCK
0824[7:0]	0	SJC_CHALL[55:48] / UNIQUE_ID[55:48]	8	SJC CHALLENGE/ Unique ID	Burned by Freescale	TESTER_LOCK
0828[7:0]	0	SJC_CHALL[47:43] / UNIQUE_ID[47:40]	8	SJC CHALLENGE/ Unique ID	Burned by Freescale	TESTER_LOCK
082C[7:0]	0	SJC_CHALL[39:32] / UNIQUE_ID[39:32]	8	SJC CHALLENGE/ Unique ID	Burned by Freescale	TESTER_LOCK
0830[7:0]	0	SJC_CHALL[31:24] / UNIQUE_ID[31:24]	8	SJC CHALLENGE/ Unique ID	Burned by Freescale	TESTER_LOCK
0834[7:0]	0	SJC_CHALL[23:16] / UNIQUE_ID[23:16]	8	SJC CHALLENGE/ Unique ID	Burned by Freescale	TESTER_LOCK
0838[7:0]	0	SJC_CHALL[15:8] / UNIQUE_ID[15:8]	8	SJC CHALLENGE/ Unique ID	Burned by Freescale	TESTER_LOCK
083C[7:0]	0	SJC_CHALL[7:0] / UNIQUE_ID[7:0]	8	SJC CHALLENGE/ Unique ID	Burned by Freescale	TESTER_LOCK
0840[1:0]	0	SRTC_SECMODE[1:0]	2	Security Mode for Secure RTC. Determines the level of security for Secure Real Time Clock (SRTC) module	00 - Low Security 01 - Medium Security 10 - High Security 11 - Reserved	BOOT_LOCK

Table continues on the next page...

Table 2-11. Fusemap Descriptions (continued)

IIM addr	IIM Bank	Fuses Name	Number of Fuses	Fuses Function	Setting	Locked by/Is Lock?
0840[3:2]	0	LDO_DIS[1:0]	2	LDO_DIS[0]: Controls vddpllana - Analog PLL supply. LDO_DIS[1]: Controls vddplldig - Digital PLL supply.	The two bits controls the Analog and Digital supplies of the DPLL's: 0 - PLL supply is provided by internal LDO source. 1 - PLL supply is provided by the external pad.	BOOT_LOCK
0840[4]	0	SJC_DISABLE	1	Disable/Enable the Secure JTAG Controller module. This fuse is used to create highest JTAG security level, where JTAG is totally blocked.	0 - Secure JTAG Controller is enabled 1 - Secure JTAG Controller is disabled	BOOT_LOCK
0840[7:5]	0	SRTC_MCOUNT[2:0]	3	Monotonic Counter Roll-Over Protection Mechanism. In order to prevent a case, where a malicious SW rolls over the monotonic counter, counter update limitation mechanism is implemented. Updates beyond the specified number is ignored and counter is not incremented.	The number of updates per 512 second: 000 - 512 (1 per second in average) 001 - 1024 (2 per second in average) 010 - 2048 (4 per second in average) 011 - 4096 (8 per second in average) 100 - 8192 (16 per second in average) 101 - reserved 110 - reserved 111 - No restriction	BOOT_LOCK
0844[0]	0	CSU_FA_COUNT	1	CSU Force Alarm Counter. When set, the Alarm Counter is always enabled (can not be disabled by SW) and the option to stop the Counter by SW is disabled.	0 - CSU alarm counter can be disabled and stoped by SW 1 - CSU alarm counter can't be disabled or stoped by SW	BOOT_LOCK
0844[1]	0	CSU_AM_DIS[0]	1	CSU Alarm Mask Disable 0. When this fuse is set, the first half of the CSU alarm input signals can't be masked. Note that the first two alarm input signals can't be masked by definition as this fuse has no effect on them.	0 - CSU alarm inputs, csu_alarm_in[N/2-1:2], can be masked 1 - CSU alarm inputs, csu_alarm_in[N/2-1:2], cannot be masked	BOOT_LOCK

Table continues on the next page...

Table 2-11. Fusemap Descriptions (continued)

IIM addr	IIM Bank	Fuses Name	Number of Fuses	Fuses Function	Setting	Locked by/Is Lock?
0844[2]	0	CSU_AM_DIS[1]	1	CSU Alarm Mask Disable 1. When this fuse is set, the second half of the CSU alarm input signals can't be masked.	0 - CSU alarm inputs, csu_alarm_in[N:N/2], can be masked 1 - CSU alarm inputs, csu_alarm_in[N:N/2], can't be masked	BOOT_LOCK
0844[3]	0	CSU_FA_OUT[0]	1	CSU Force Alarm Output 0. When this fuse is set, all CSU alarm inputs are routed to csu_alarm_out0 regardless of settings in Alarm Routing Registers. Note that this fuse doesn't affect routing policy of other alarm outputs.	0 - The CSU alarm inputs that routed to csu_alarm_out0 are specified by Alarm Routing Registers 1 - All CSU alarm inputs are routed to csu_alarm_out0	BOOT_LOCK
0844[4]	0	CSU_FA_OUT[1]	1	CSU Force Alarm Output 1. When this fuse is set, all CSU alarm inputs are routed to csu_alarm_out1 regardless of settings in Alarm Routing Registers. Note that this fuse doesn't affect routing policy of other alarm outputs.	0 - The CSU alarm inputs that routed to csu_alarm_out1 are specified by Alarm Routing Registers 1 - All CSU alarm inputs are routed to csu_alarm_out1	BOOT_LOCK
0860	0	GP[63:56]	8	General Purpose user fuses	0	GP_LOCK
0864	0	GP[55:48]	8	General Purpose user fuses	0	GP_LOCK
0868	0	GP[47:40]	8	General Purpose user fuses	0	GP_LOCK
086C	0	GP[39:32]	8	General Purpose user fuses	0	GP_LOCK
0870	0	GP[31:24]	8	General Purpose user fuses	0	GP_LOCK
0874	0	GP[23:16]	8	General Purpose user fuses	0	GP_LOCK
0878	0	GP[15:8]	8	General Purpose user fuses	0	GP_LOCK
087C	0	GP[7:0]	8	General Purpose user fuses	0	GP_LOCK
0C00[4]	1	MAC_ADDR_LOCK	1	Lock for rows 0024-0038, fusebank1.	0 - Unlock 1 - Lock	LOCK
0C00[2]	1	SRK_LOCK	1	Locking row 0004, fusebank1 SRK_HASH[255:248]	0 - Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded IIM register) 1 - Lock (The controlled field can be read or sensed only)	LOCK
0C00[1]	1	SJC_RESP_LOCK	1	Locking 0008-0020, fusebank1. SJC_RESP[55:0] When locked, the fuses cannot be read, sensed, overridden nor programmed	0 - Unlock (SJC_RESP[55:0] can be read, sensed, burned or overridden in the corresponded IIM register) 1 - Lock (SJC_RESP[55:0] cannot be read, sensed, overridden nor written)	LOCK

Table continues on the next page...

Table 2-11. Fusemap Descriptions (continued)

IIM addr	IIM Bank	Fuses Name	Number of Fuses	Fuses Function	Setting	Locked by/Is Lock?
0C04	1	SRK_HASH[255:248]	8	Most Significant Byte of the AP super root key hash	0	SRK_LOCK
0C08	1	SJC_RESP[55:48]	8	Response reference value for the secure JTAG controller	0	SJC_RESP_LOCK
0C0C	1	SJC_RESP[47:40]	8	Response reference value for the secure JTAG controller	0	SJC_RESP_LOCK
0C10	1	SJC_RESP[39:32]	8	Response reference value for the secure JTAG controller	0	SJC_RESP_LOCK
0C14	1	SJC_RESP[31:24]	8	Response reference value for the secure JTAG controller	0	SJC_RESP_LOCK
0C18	1	SJC_RESP[23:16]	8	Response reference value for the secure JTAG controller	0	SJC_RESP_LOCK
0C1C	1	SJC_RESP[15:8]	8	Response reference value for the secure JTAG controller	0	SJC_RESP_LOCK
0C20	1	SJC_RESP[7:0]	8	Response reference value for the secure JTAG controller	0	SJC_RESP_LOCK
0C24	1	MAC_ADDR[47:40]	8	Reserved for users/SW	0	MAC_ADDR_LOCK
0C28	1	MAC_ADDR[39:32]	8	Reserved for users/SW	0	MAC_ADDR_LOCK
0C2C	1	MAC_ADDR[31:24]	8	Reserved for users/SW	0	MAC_ADDR_LOCK
0C30	1	MAC_ADDR[23:16]	8	Reserved for users/SW	0	MAC_ADDR_LOCK
0C34	1	MAC_ADDR[15:8]	8	Reserved for users/SW	0	MAC_ADDR_LOCK
0C38	1	MAC_ADDR[7:0]	8	Reserved for users/SW	0	MAC_ADDR_LOCK
1400[1]	3	SRK_LOCK88	1	Lock for SRK_HASH[247:160] fuses in rows 1404-142C, fusebank3	0 - Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded IIM register) 1 - Lock (The controlled field can be read or sensed only)	LOCK
1400[0]	3	SRK_LOCK160	1	Lock for SRK_HASH[159:0] fuses in rows 1430-147C	0 - Unlock (The controlled field can be read, sensed, burned or overridden in the corresponded IIM register) 1 - Lock (The controlled field can be read or sensed only)	LOCK
1404-142C	3	SRK_HASH[247:160]	88	AP Super Root Key hash, bits [247:160] Most significant byte SRK_HASH[255:248] is in the fuse bank #1, 1428	0	SRK_LOCK88

Table continues on the next page...

Table 2-11. Fusemap Descriptions (continued)

IIM addr	IIM Bank	Fuses Name	Number of Fuses	Fuses Function	Setting	Locked by/Is Lock?
1430-147C	3	SRK_HASH[159:0]	160	AP Super Root Key hash, bits [159:0] Most significant byte SRK_HASH[255:248] is in the fuse bank #1, 1428	0	SRK_LOCK160
1808[7:4]	4	MMC_DLL_DLY[3:0]	3	eMMC 4.4 delay line default value (set by boot rom), used in conjunction with "DLL Override" = 1 (BOOT_CFG3[3])	Connected to LVDS module.	Bank4 Locks
180C[0]	4	SATA_RST_SRC	1	Controls mux to select 'herset' to SATA, from either SATA reset controller, or SRC module.	SATA_RST_SRC 0 - SRC reset 1 - Orig SATA reset controller	Bank4 Locks
180C[2:1]	4	SATA_ALT_REF_CLK[1:0]	2	SATA PHY source clock and frequency select	00 - 100 MHz (External) 01 - 50 MHz (External) 10 - 120 MHz, internal (USB PHY) 11 - Reserved	Bank4 Locks
180C[5:3]	4	NFC_DLL_DLY	3	NFC read-status timing (NFC status_samp_sel control)	000 - Zero delay (default) XXX - TBD	Bank4 Locks
1810[3]	4	NFC_RD_ST_TIME	1	NFC read-status timing (NFC status_samp_sel control)	0 - Use new (fast) read status timing. (status_samp_sel=1) 1 - Old / Legacy implementation (status_samp_sel=0)	Bank4 Locks
1810[2:0]	4	SRK_REVOKE[2:0]	3	SRK keys revocation	000 - Key 1 001 - Key 2 011 - Key 3 111 - Key 4 Else - TBD	
1814	0	GP[87:80]	8	General purpose user fuses	0	Bank4 Locks
1818	0	GP[79:72]	8	General purpose user fuses	0	Bank4 Locks
181C	0	GP[71:64]	8	General purpose user fuses	0	Bank4 Locks

How to Reach Us:

Home Page:
www.freescale.com

Web Support:
http://www.freescale.com/support

USA/Europe or Locations Not Listed:
Freescale Semiconductor
Technical Information Center, EL516
2100 East Elliot Road
Tempe, Arizona 85284
+1-800-521-6274 or +1-480-768-2130
www.freescale.com/support

Europe, Middle East, and Africa:
Freescale Halbleiter Deutschland GmbH
Technical Information Center
Schatzbogen 7
81829 Muenchen, Germany
