Introduction

1.1 About This Document

This reference manual describes the functionality of the i.MX53 multimedia applications processor. The i.MX53 is Freescale Semiconductor's latest addition to a growing family of multimedia-focused products offering high performance processing optimized for lowest power consumption. The i.MX53 processors feature Freescale's advanced implementation of the ARM®Cortex™-A8 core, which operates at speeds as high as 1.2 GHz and interfaces with DDR2-800, LVDDR2-800 and DDR3-800 DRAM memory devices. This product is suitable for applications such as:

- Automotive navigation and entertainment
- High-end Mobile Internet Devices and high-end PDAs
- Netbooks
- Nettops
- High-end portable media players with HD video capability
- Portable navigation devices
- Gaming Consoles

The i.MX53 is a system on a chip (SoC) which integrates on one integrated circuit a complete microcomputer platform based on the ARM Cortex-A8 including an integrated NEON coprocessor, a vector floating point unit, an Execution Trace Module (ETM), separate 32 Kbyte instruction and data L1 caches and a unified 256 Kbyte L2 cache. Supporting the ARM Platform are a large array of system-level components such as system RAM, processor code ROM, Smart DMA controller (SDMA) and system control devices such as a power-on reset controller, voltage regulators, power management, on-board fuse array (FUSEBOX) and clock generation circuitry. Coprocessors including two Graphics Processing Units (GPUs), an Image Processin Unit (IPU), Video Processing Unit (VPU) and Asynchronous Sample Rate Converter (ASRC) accelerate computationally intensive tasks offloading the ARM Platform.

Included in the SoC are I/O devices such as USB controllers, UARTs, Ethernet controllers, General Purpose I/O (GPIO), Multimedia processor, , general purpose and special purpose timers, and system security devices. An integrated memory controller supports the attachment of external DRAM. A Flash controller supports both NAND and NOR Flash devices. Integrated external storage controllers support devices such as SATA hard disks and SD/SDIO/MMC/eMMC memory cards.

1.1.1 Audience

This manual is intended to be used by board-level product designers and product software developers. This manual assumes that the reader has a background in computer engineering and/or software engineering and understands concepts of digital system design, microprocessor architecture, Input / Output (I/O) devices and industry standard communication and device interface protocols.

1.1.2 Organization

This document is organized in two main sections called Book I and Book II.

Book I covers the i.MX53 at a system level and provides an architectural overview. Also covered are system memory map, system-level interrupt events, external pins and pin multiplexing, external memory, system debug, system boot, multimedia subsystem, power management, and system security.

Book II describes the ARM Platform, ARM Platform debug, and an array of internal functional blocks.

1.1.3 Suggested Reading

This section lists additional reading that provides background for the information in this manual as well as general information about the architecture.

1.1.3.1 General Information

The following documentation provides useful background information about the ARM processor and computer architecture in general:

- For information about the ARM Cortex-A8 processor see http://www.arm.com/products/processors/cortex-a/cortex-a8.php

- Computer Architecture: A Quantitative Approach, Fourth Edition, by John L. Hennessy and David A. Patterson
- *Computer Organization and Design: The Hardware/Software Interface*, Second Edition, by David A. Patterson and John L. Hennessy

1.1.3.2 Related Documentation

Freescale documentation is available from the sources listed on the back cover of this manual; the document order numbers are included in parentheses for ease in ordering:

For a current list of documentation, refer to www.freescale.com.

1.1.4 Conventions

This document uses the following notational conventions:

cleared / set
When a bit takes the value zero, it is said to be cleared; when it takes a value of one, it is said to be set.

mnemonics
Instruction mnemonics are shown in lowercase bold

italics
Italics indicate variable command parameters, for example, **bcctr***x*

Book titles in text are set in italics

15
An integer in decimal

0x
Prefix to denote hexadecimal number

0b
Prefix to denote binary number. Binary 0 and 1 are written without the prefix.

n'H4000CA00
n-bit Hexadecimal number

BLK_REG_NAME
Register names are all uppercase. The block mnemonic is prepended with an underscore delimiter (_).

BLK_REG[FIELD]
Fields within registers appear in brackets. For example, ESR[RLS] refers to the Receive Last Slot field of the ESAI Status Register.

BLK_REG[*n*]

Bit number *n* within register BLK.REG. Bit numbering is little endian.

BLK_REG[*l:r*]

Register bit ranges. Ranges are indicated by the left-most bit number *l* and the right-most bit number *r* separated by a colon (:). For example, ESR[15:0] refers to the lower half word in the ESAI Status Register.

x, U

In some contexts, such as signal encodings, an unitalicized x indicates a don't care or uninitialized. The binary value could be 1 or 0.

x

An italicized *x* indicates an alphanumeric variable

n, m

Italicized *n or m* represent integer variables

!

Binary logic operator NOT

&&

Binary logic operator AND

||

Binary logic operator OR

^ or <O+>

Binary logic operator XOR

|

Bit-wise OR. For example, 0b0001 | 0b1000 yields the value 0b1001.

&

Bit-wise AND. For example, 0b0001 & 0b1000 yields the value 0b0000.

{A,B}

Concatenation, where the *n*-bit value A is prepended to the *m*-bit value B to form an (*n* +*m*)-bit value. For example, {0, REG*m* [14:0]} yeilds a 16-bit value with 0 in the most significant bit.

- or grey fill

Indicates a reserved bit field in an register. Although these bits can be written to as ones or zeros, they are always read as zeros.

>>

Shift right logical one position

<<

Shift left logical one posiiton

= <left arrow>

Assignment

==

Compare equal

!=

Compare not equal

>
Greater than
<
Less than

1.1.5 Register Diagram Field Access Type Legend

The following figure provides the interpretation of the notation used in register diagrams for a number of common field access types.

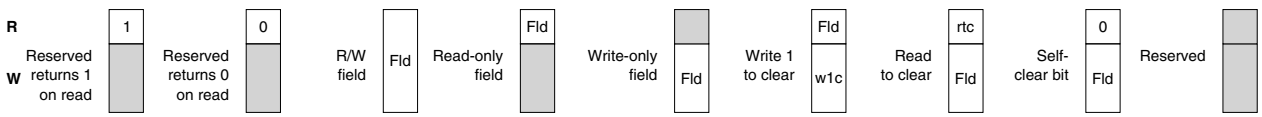

Figure 1-1. Register Field Conventions

NOTE

For reserved register fields, software should mask off the data in the field after read (software can not rely on the contents of data read from a reserved field) and always write all zeros.

1.1.6 Signal Conventions

_b, _B
When appended to a signal name, indicates that a signal is active-low

NEG_ACTIVE
Overbar also denotes a negative active signal

UPPERCASE
Package pin names, Block I/O signals

lowercase
Lowercase is used to indicate internal signals

1.1.7 Acronyms and Abbreviations

Table 1- contains acronyms and abbreviations used in this document.

Acronyms and Abbreviated Terms

Term	Meaning
BIST	Built-in self test
DDR	Double data rate (of Dynamic RAM)

Table continues on the next page...

Term	Meaning
FIFO	First In / First Out (of a queue)
DMA	Direct memory access
DPLL	Digital phase-locked loop
DRAM	Dynamic random access memory
EPROM	Erasable programmable read-only memory
GPIO	General-purpose I/O
GPR	General-purpose register
GPU	Graphicd Processing Unit
I2C or I2C	Inter-integrated circuit
IEEE	Institute of Electrical and Electronics Engineers
IrDA	Infrared Data Association
JTAG	Joint Test Action Group (a serial bus protocol usually used for test purposes)
LIFO	Last-in-first-out
LRU	Least recently used
LSB	Least-significant byte
lsb	Least-significant bit
MSB	Most-significant byte
msb	Most-significant bit
PCI	Peripheral Component Interconnect
PCI-X	PCI extended
PCIe	PCI enhanced
PCMCIA	Personal Computer Memory Card International Association
PIC	Programmable interrupt controller
POR	Power-on reset
RISC	Reduced instruction set computing
RTOS	Real-time operating system
Rx	Receive
SDLC	Synchronous data link control
SDMA	Serial DMA
SPDIF	Sony Phillips Digital Interface
SPI	Serial peripheral interface
SRAM	Static random access memory
Tx	Transmit
UART	Universal asynchronous receiver/transmitter
USB	Universal serial bus

1.2 Overview

This chapter introduces the architecture of the i.MX53 Multimedia Applications Processor. The i.MX53 processor represents Freescale Semiconductor's latest achievement in multimedia integrated applications processors that are part of a growing family of multimedia-focused products offering high performance processing optimized for lowest power consumption.

1.3 Target Applications

The primary market focus of the i.MX53 applications processor is high-end Mobile Internet Devices (MIDs) and Automotive Infotainment. A secondary focus is High End Portable Multimedia Players (PMPs) with HD video capability, as well as markets with similar requirements in terms of package type, thermal limits and I/O. The flexibility of the i.MX53 architecture permits in a wide variety of other applications. The i.MX53 processor provides all of the interfaces for connecting peripherals such as WLAN, Bluetooth, GPS, camera sensors, and dual displays.

The i.MX53 application processor is a follow-on to the i.MX51 with improved performance, power efficiency and multimedia capabilities.

1.4 Features

The i.MX53 ARM Platform (AP) is based on the ARM Cortex A8™ Architecture, which has the following features:

- ARM Cortex A8™ Processor (with TrustZone)
- 32 Kbyte L1 instruction cache
- 32 Kbyte L1 data cache
- 256 Kbyte unified instruction and data L2 cache
- A range of core processor clock speeds (up to 1.2 GHz) based on part number.
- Neon coprocessor
  - SIMD Media Processing Architecture
  - NEON register file with 32x64-bit general-purpose registers
  - NEON Integer execute pipeline (ALU, Shift, MAC)
  - NEON dual, single-precision floating point execute pipeline (FADD, FMUL)
  - NEON load/store and permute pipeline
  - Non-pipelined Vector Floating Point (VFP) coprocessor (VFPv3)

The i.MX53 makes use of dedicated hardware (H/W) accelerators in order to meet specific targeted multimedia performance requirements. The use of H/W accelerators is key factor in obtaining high performance at low power consumption while leaving the ARM platform core relatively free for performing other tasks.

The i.MX53 incorporates the following hardware accelerators:

- VPU-Video Processing Unit
- IPU-Image Processing Unit, version 3M
- GPU3D-3D Graphics Processing Unit (OpenGL ES 2.0), version 3
- GPU2D-2D Graphics accelerator, (OpenVG 1.1), version 1
- ASRC-Asynchronous Sample Rate Converter

Security features are enabled and accelerated by the following hardware:

- ARM TrustZone including the TZ architecture (separation of interrupts, memory mapping, etc.)
- SJC-System JTAG Controller. Protects JTAG from debug port attacks by regulating or blocking access to the system debug features
- SRTC-Secure Real-Time Clock (RTC). Tamper resisted RTC with it's own power domain and mechanism to detect voltage and clock glitches
- RTIC-Real-Time Integrity Checker, version 3, RTIC type 1, enhanced with SHA-256 engine
- SAHARA-Cryptographic accelerator that includes true random number generator (TRNG)
- SCC-Security Controller, type 2. Improved SCC v1 with AES engine, Secure/Non-Secure RAM and support for multiple keys as well as TZ/non-TZ separation
- CSU-Central Security Unit. Enhancement for the IC Identification Module (IIM) configured during boot using e-fuses. Determines the security level operation mode as well as the TZ policy
- AHAB-Advanced High Assurance Boot, with the next embedded enhancements: SHA-256, 2048-bit RSA key, version control mechanism, warm boot, CSU and TZ initialization

Integrated memory system:

- Boot ROM, including High Assurance Boot (HAB) (64 KB)
- Internal multimedia / shared, fast access RAM (128 KB)
- Secure/non-secure RAM (16 KB)

The i.MX53 SoC is built around the following System buses:

- 64-bit AMBA AXI v1.0 (AXI). Provides high-bandwidth, low-latency connectivity for the ARM Platform, major multimedia accelerators (VPU, IPU, GPU3D, GPU2D) and the External Memory Controller (EXTMC)

- 32-bit AMBA AHB 2.0 (AHB). Provides connectivity for bus master peripherals, such as SDMA, RTIC, SCC, and SAHARA. (See block diagram for the complete list.)
- 32-bit Internal Peripheral (IP) Bus. Provides control and data communication for lower speed integrated peripheral devices.

The i.MX53 enables following interfaces to external devices (some of which are not available simultaneously):

- Hard Disk Drives
  - PATA, supports U-DMA mode 5 at transfer rates up to 100 MByte/sec.
  - SATA II protocol with a peak transfer rate of 3.0 Gbits per second.
- Displays
  - 5 interfaces available. Total rate of all interfaces is up to 180 Mpixels/sec, 24 bits per pixel. Up to two interfaces may be active at once.
  - Two Parallel 24-bit display ports supporting up to 165 Mpixels/sec (UXGA @ 60Hz)
  - LVDS serial ports: One port up to 165 Mpixels/sec or two ports up to 85 Mpixels/sec (WXGA @ 60Hz) each
  - One TV-out/VGA port up to 150 Mpixels/sec (1080p at 60 Hz)
- Camera sensors
  - Two parallel camera ports
    - Primary port only: up to 20 bits/pixel, up to 180 MHz peak pixel clock rate
    - Simultaneous use: 8-bit primary and 8-bit secondary.
- Expansion cards
  - Four SD/MMC card ports:
    - Two of which support 208 Mbps (4-bit)
    - One 416 Mbits/sec
    - One enhanced port - supports 832 Mbps, (8-bit, eMMC 4.4).
- External memory interfaces
  - 16/32-bit DDR2-800, LV-DDR2-800 and DDR3-800
  - 8/16-bit NAND SLC/MLC Flash, 4/8/14/16-bit ECC.
  - Supports Samsung OneNAND™ (in muxed I/O mode)
  - 8/16/32-bit NOR Flash (8-bit is not supported at byte D[23:16]). Interface is provided via the External Interface Module (EIM), all EIM pins are muxed with other interfaces (data with NAND Flash Controller (NFC) pins). I/O muxing logic selects the EIM port as primary muxing at system boot.
  - 8/16/32-bit Pseudostatic RAM (PSRAM), Cellular RAM.
- USB
  - High Speed (HS) USB 2.0 OTG (Up to 480 Mbps), with integrated HS USB Phy
  - Three USB 2.0 (480 Mbps) hosts:
    - HS host, with integrated High Speed Phy.

    - HS host for external HS/FS Transceivers via ULPI / Serial, supports IC-USB
    - HS host for external HS/FS Transceivers via ULPI / Serial, supports IC-USB
- Low Power modes
    - Supporting DVFS techniques for low power modes
    - Uses SRPG (State Retention Power Gating) for ARM and Neon
    - Support for various levels of system power modes
    - Flexible clock gating control scheme
- Other interfaces:
    - OWIRE
    - Three I2S/SSI/AC97, up to 1.4 Mbps each connected to Audio Multiplexer (AUDMUX) providing four external ports
    - Enhanced Serial Audio Interface (ESAI), up to 1.4 Mbps each channel
    - Five UART, up to 4.0 Mbps each
        - One of the five supports 8-wire (uart1) while others four supports 4-wire.
    - One CSPI; refer to the data sheet for performance parameters.
    - Two eCSPI (enhanced CSPI); refer to the data sheet for performance parameters.
    - Three I2C, supports 400 Kbps
    - Fast Ethernet Controller (FEC) IEEE1588 compliant, 10/100 Mbps
    - Two Pulse Width Modulators (PWM)
    - JTAG Controller (SJC)
    - GPIO with interrupt capabilities
    - Key Pad Port (KPP)
    - Sony Phillips Digital Interface (SPDIF), Rx and Tx
    - Two Controller Area Network (FLEXCAN), 1 Mbps each
    - Two Watchdog timers (WDOG)
    - Media Local Bus controller (MLB) provides interface to Media Oriented Systems Transport (MOST) Networks (50Mbps)

1.5 Architectural Overview

This section contains i.MX53 architectural details.

A simplified block diagram is provided in the following section.

1.5.1 Simplified Block Diagram

A high-level block diagram of the i.MX53 is shown in Figure 1-2. It provides a view of the major sub-systems (processor domains, shared peripherals domain, memories, etc.) and logical connectivity.

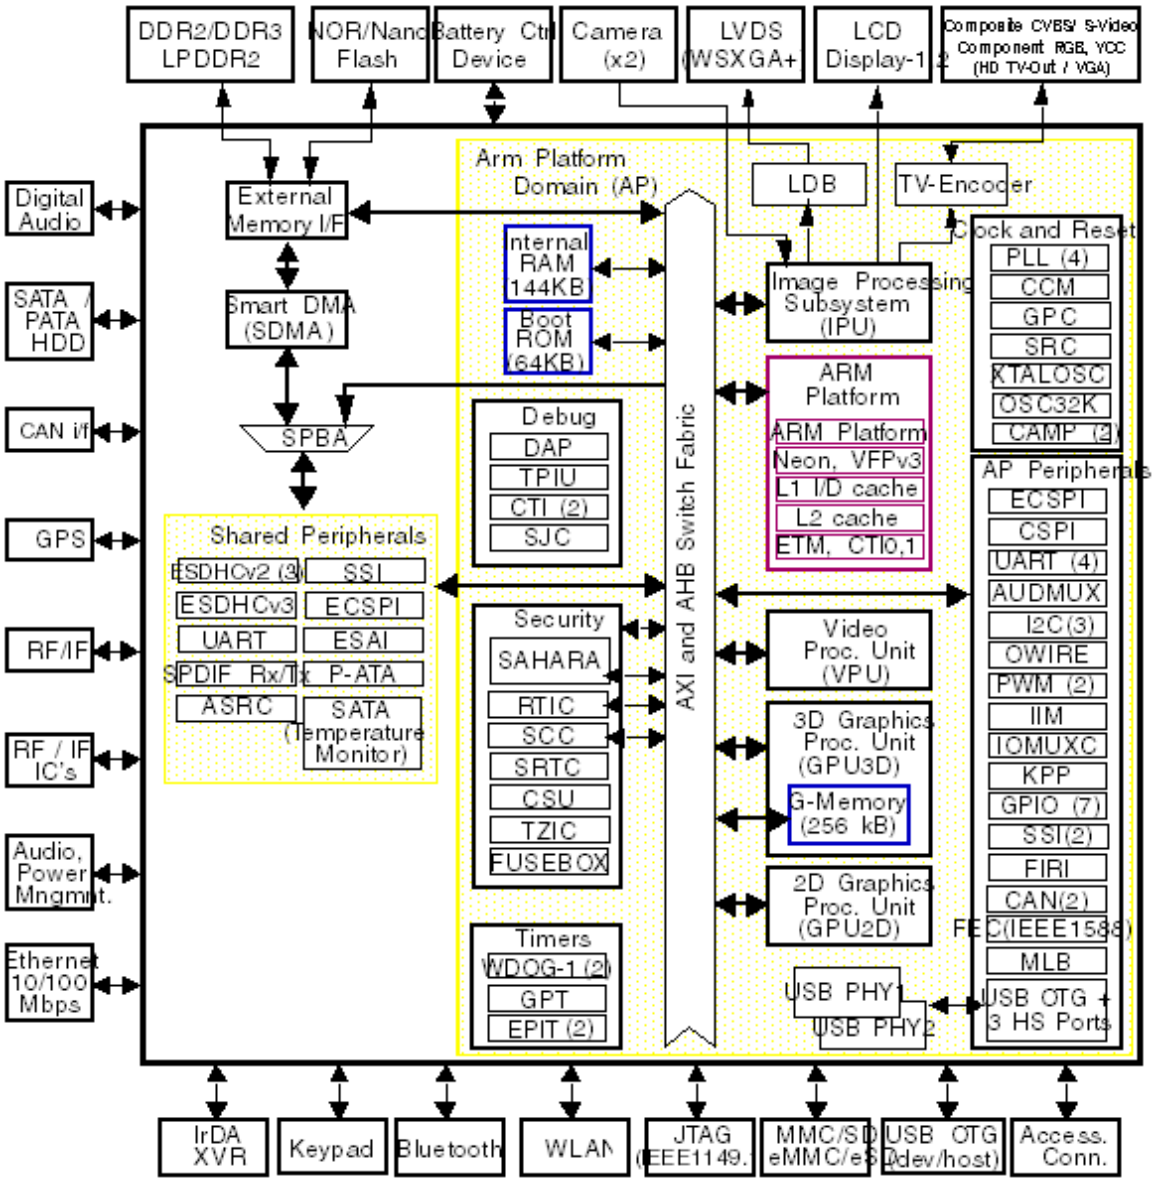

Figure 1-2. i.MX53 Simplified Block Diagram

1.5.2 Major Subsystems

i.MX53 consists of the following major subsystems:

- Core (ARM Cortex A8) Platform, L1/L2 memories
- SDMA controller and the shared peripheral domain
- System Control-Boot Flow control, Clocks distribution, "Reset" control and Low Power logic
- Multimedia
- Security

- Connectivity peripherals and timers
- External Memory Interface

1.5.3 Architectural Partitioning

The i.MX53 Architecture may be functionally organized in terms of five sub-systems. These are:

- The ARM Platform is the central processing unit for the SoC and runs the following software:
  - Power-on-Reset (POR) boot code
  - Boot-strap loader
  - Operating system and application program loader
  - User applications (including control over hardware accelerators and non-accelerated functions)
  - TrustZone applications
- Smart DMA enables data transfer between non-mastering (slave) peripherals and external or internal memories
- System Control
  - Clock Control Block (CCM)
  - Four PLLs
  - XTALOSC- 24MHz Crystal oscillator source support
  - XTALOSC32k- 32k Crystal oscillator support
  - System Reset Controller (SRC)
  - Global Power Controller (GPC)
  - Two Clock Amplifier (CAMP) blocks on CKIH and CKIH2 pins
  - Temperature Sensor, for monitoring and acting on high temperature situations.

NOTE

Refer to SATA Temperature Sensor application note (AN4380) for more details regarding programming and its usage.

- Multimedia
  - Image Processing Unit-IPU
    - Connectivity to displays, display controllers, cameras and auxiliary graphics coprocessors.
    - Display Processing: video/graphics combining, image enhancement
    - Image conversions: resizing, rotation/inversion, color conversion, deinterlacing
    - Synchronization and control capabilities, allowing autonomous operation
  - Video Processing Unit (VPU):

        - Various decoding/encoding formats in HW
        - Up to 1080i/p resolution (H.264, VC1, RV10, DivX)
        - Up to 720p encode (MPEG4, H.264)
        - TV-Encoder (TVE) for HD720p/1080p, PAL/NTSC or VGA output
    - Graphics Processing Unit (GPU3D), 3D graphics processing compliant with the following:
        - OpenGL ES Common Profile v1.0
        - OpenGL ES Common Profile v1.1/Direct3D Mobile
        - OpenGL ES Profile v2.0
    - Graphics Processing Unit (GPU2D), 2D graphics processing:
        - OpenVG 1.1
    - Audio
        - Audio codecs are provided by SW, which runs on ARM core, supporting (but not limited to) MP3, WMA, AAC, HE-AAC and Pro10
        - 3x SSIs
        - ESAI
        - SPDIF Tx/Rx
        - Audio Mux
        - ASRC (for sample rate conversion)
- Security
    - High Assurance Boot (HAB) System
    - ARM TrustZone (TZ) Trusted Execution environment
    - IC Identification Module (IIM) and Central Security Unit (CSU)
    - On-chip One-Time programmable electrical fuse array (FUSEBOX)
    - RTIC: Real-Time Integrity Checker
    - SAHARA Version 4 Lite (SAHARA) cryptographic acceleration engine
    - System JTAG controller (SJC)
    - Secure Real Time Clock (SRTC)
    - Security Controller version 2 (SCC) with 16KByte of secure/non-secure RAM
    - Tamper Detection
    - TrustZone Watchdog (WDOG-2)
- Connectivity peripherals and timers
    - Low level communication protocols
    - Embedded DMAs
    - 3.3V IO voltage for seamless integration
    - Four USB 2.0 ports, including two integrated PHYs
    - TV-Out Video codecs for HD, NTSC/PAL or VGA output
    - DDR2/3, LPDDR2 (PoP package), Nand (MLC 4/8/14/16-bit ECC) and NOR Flash memory interface via EMC

- Timers: 2xEPIT, GPT and Watch Dog timer (WDOG)
- Miscellaneous connectivity support-I2C, SPI, UART, PWM and Keypad interface

- External Memory Controller (EXTMC)
  - External Memory Interface
  - Integrated DRAM controller
    - Support for DDR2, DDR3, LV-DDR and LPDRAM
  - Other external storage devices
    - Support for NAND and NOR Flash
    - Support for PSRAM and Cellular RAM

1.5.4 Endianness Support

i.MX53 supports Little Endian mode only.

1.6 Block List

Table 1-1 provides listing of the blocks used by the various subsystems of the i.MX53.

Table 1-1. Digital and Analog Blocks

Block Mnemonic	Block Name	Subsystem	Brief Description
ARM Platform	ARM Cortex A8™ Platform	ARM	The ARM Platform consists of the ARM Cortex A8™ processor and its essential sub-blocks, the Level 2 Cache Controller and memory, event monitor, and debug blocks.
7x4 AHB MAX	7x4 AHB MAX	Data Path	7x4 AHB Cross-Bar Switch
AIPSTZ-1 AIPSTZ-2	AHB to IP Bridge	Data Path	AHB to IP Bridge (TrustZone)
ASRC	Asynchronous Sample Rate Converter	Multimedia Peripherals	The Asynchronous Sample Rate Converter (ASRC) converts the sampling rate of a signal associated to an input clock into a signal associated to a different output clock.The ASRC supports concurrent sample rate conversion of up to 10 channels. The sample rate conversion of each channel is associated to a pair of incoming and outgoing sampling rates.The ASRC supports up to 3 sampling rate pairs.
AUDMUX	Digital Audio Mux	Multimedia Peripherals	The AUDMUX is a programmable interconnect for voice, audio, and synchronous data routing between host serial interfaces (for example, SSI1, SSI2, and SSI3) and peripheral serial interfaces (audio and voice codecs). The AUDMUX has seven ports with identical functionality and programming models. A desired connectivity is achieved by configuring two or more AUDMUX ports.

Table continues on the next page...

Table 1-1. Digital and Analog Blocks (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
CAMP-1 CAMP-2	Clock Amplifier	Clocks, Resets, and Power Control	Clock Amplifier
CCM GPC SRC SRPGC	Clock Control Module, General Power Controller, System Reset Controller, State Retention Power Gate Control	Clocks, Resets, and Power Control	These blocks are responsible for clock and reset distribution in the system, and also for the system power management. The blocks include four PLLs.
CSPI ECSPI-1 ECSPI-2	Configurable SPI	Connectivity Peripherals	Full-duplex enhanced Synchronous Serial Interface (SSI), with data rate up to 26/52Mbit/s (CSPI/ECSPI). It is configurable to support Master/Slave modes, four chip selects to support multiple peripherals.
CSU	Central Security Unit	Security	The Central Security Unit (CSU) is responsible for setting comprehensive security policy within the i.MX53 platform and for sharing security information between the various security blocks. The Security Control Registers (SCR) of the CSU are set during boot time by the HAB and are locked to prevent further writing.
DPLLC-1 DPLLC-2 DPLLC-3 DPLLC-4	Digital Phase-Locked Loop Controller	System Control Peripherals	This chapter describes DPLLC. The chapter is intended for a block driver software developer. It describes block-level operation and programming.
DVFSC DVFSP	Dynamic Voltage and Frequency Scaling for Core and Peripherals	System Control Peripherals	The DVFS/DVFSP allows simple dynamic voltage frequency scaling. The frequency of the clock and the voltage of the power domain can be changed on the fly while all blocks continue their normal operation.
EIM	External Interface Module	System Control Peripherals	The EIM handles the interface to devices external to the chip, including generation of chip selects, clock and control for external peripherals and memory. It provides asynchronous access to devices with SRAM-like interface and synchronous access to devices with Nor-Flash like or PSRAM like interface.
EPIT-1 EPIT-2	Enhanced Periodic Interrupt Timer	Timer Peripherals	Each EPIT is a 32-bit "set and forget" timer that starts counting after the EPIT is enabled by software. It is capable of providing precise interrupts at regular intervals with minimal processor intervention. It has a 12-bit prescaler for division of input clock frequency to get the required time setting for the interrupts to occur, and counter value can be programmed on the fly.

Table continues on the next page...

Table 1-1. Digital and Analog Blocks (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
ESAI	Enhanced Serial Audio Interface	Connectivity Peripherals	The Enhanced Serial Audio Interface (ESAI) provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, SPDIF transceivers, and other processors. The ESAI consists of independent transmitter and receiver sections, each section with its own clock generator. All serial transfers are synchronized to a clock. Additional synchronization signals are used to delineate the word frames. The normal mode of operation is used to transfer data at a periodic rate, one word per period. The network mode is also intended for periodic transfers; however, it supports up to 32 words (time slots) per period. This mode can be used to build time division multiplexed (TDM) networks. In contrast, the on-demand mode is intended for non-periodic transfers of data and to transfer data serially at high speed when the data becomes available. The ESAI has 12 pins for data and clocking connection to external devices.
ESDCTL	Enhanced SDRAM Controller	Memory Control	The ESDCTL is a configurable high performance and optimized SDRAM controller that supports DDR2, DDR3, and so on.

Table 1-1. Digital and Analog Blocks (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
ESDHCV2-1 ESDHCV2-2 ESDHCV2-4	Enhanced Multi-Media Card / Secure Digital Host Controller	Connectivity Peripheral	i.MX53 specific SoC characteristics: • Ports 1, 2, and 4 are Compatible with the "MMC System Specification" version 4.3, full support. • In i.MX53 SoC, ports 1 and 2 are limited to 4-bit data width interface. The generic features of the eSDHC block (ESDHCv2), when serving as SD/MMC host, include the following: • Conforms to "SD Host Controller Standard Specification" version 2.0, full support. • Compatible with the SD Memory Card Specification version 1.1 • Compatible with the SDIO Card Specification version 1.2 • Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC and MMC RS cards • Configurable to work in one of the following modes: - SD/SDIO 1-bit, 4-bit - MMC 1-bit, 4-bit, 8-bit (possibly restricted per SoC integration) • Full/High speed mode • Host clock frequency variable between 32kHz to 52 MHz • Up to 200 Mbps data transfer for SD/SDIO cards using 4 parallel data lines • Up to 416 Mbps data transfer for MMC cards using 8 parallel data lines for MMC 4.3, and 832Mbps for eMMC 4.4 cards. • eSDHC-2 is limited to bus width of 4-bits, so not recommended for HD use. See separate section below. • Can be configured either as SD/MMC controller • Support eSD and eMMC standard, for SD/MMC embedded type cards
ESDHCV3-3 (EMMC 4.4)	Ultra-High-Speed eMMC/SD host controller.	Connectivity Peripherals	Ultra High-Speed eSDHC, enhanced to support eMMC 4.4 standard specification, for 832 MBps. Block is backward compatible to eSDHCv2. See complete features listing in eSDHCv2 entry below. i.MX53 SoC specific characteristics: • Port 3 - enhanced, to support eMMC 4.4 specification, for double data rate (832Mbps, 8-bit port).

Table 1-1. Digital and Analog Blocks (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
EXTMC	External Memory Controller	Connectivity Peripherals	The EXTMC is an external and internal memory interface. It performs arbitration between multi-AXI masters to multi-memory controllers, divided into four major channels, fast memories (DDR2/DDR3/LPDDR2) channel, slow memories (NOR-FLASH / PSRAM / NAND-FLASH etc.) channel, Internal Memory (RAM, ROM) channel and Graphical Memory (GMEM) channel. In order to increase the bandwidth performance, the EXTMC separates the buffering and the arbitration between different channels, preventing interference between slow and fast accesses. EXTMC Features: • 64-bit and 32-bit AXI ports • Enhanced arbitration scheme for fast channel, including dynamic master priority, and taking into account which pages are open or closed and what type (Read or Write) was the last access • Flexible bank interleaving • Support 16/32-bit DDR2-800 or DDR3-800 or LPDDR2 • Support up to 2 GByte DDR memories • Support NFC, EIM signal muxing scheme • Support 8/16/32-bit Nor-Flash/PSRAM memories (sync and async operating modes), at slow frequency, (8bit is not supported on D[23]-D[16]) • Support 4/8/14/16-bit ECC, page sizes of 512B, 2KB and 4KB Nand-Flash (including MLC) • Multiple chip selects (up to 4) • Enhanced DDR memory controller, supporting access latency hiding • Support Watermark for security (Internal and External memories)
FEC	Fast Ethernet Controller	Connectivity Peripherals	The Ethernet Media Access Controller (MAC) is designed to support both 10 and 100 Mbps Ethernet/IEEE 802.3 networks. An external transceiver interface and transceiver function are required to complete the interface to the media. The i.MX53 also consists of HW assist for IEEE1588 standard. Refer to IEEE1588 section for more details.
FIRI	Fast Infra-Red Interface	Connectivity Peripherals	Fast Infra-Red Interface
FLEXCAN-1 FLEXCAN-2	Flexible Controller Area Network	Connectivity Peripherals	The CAN protocol was primarily, but not only, designed to be used as a vehicle serial data bus, meeting the specific requirements of this field: real-time processing, reliable operation in the EXTMC environment of a vehicle, cost-effectiveness and required bandwidth. The FLEXCAN is a full implementation of the CAN protocol specification, Version 2.0 B, which supports both standard and extended message frames.
FUSEBOX	Electrical Fuse Array	Security	Electrical Fuse Array (splitted to banks). Enables to setup Boot Modes, Security Levels, Security Keys and many other system parameters.

Table continues on the next page...

Table 1-1. Digital and Analog Blocks (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
GPIO-1 GPIO-2 GPIO-3 GPIO-4 GPIO-5 GPIO-6 GPIO-7	General Purpose I/O	System Control Peripherals	Used for general purpose input/output to external ICs. Each GPIO block supports 32 bits of I/O. The AP side has four GPIO blocks supporting up to 128 GPIO functions.
GPT	General Purpose Timer	Timer Peripherals	Each GPT is a 32-bit "free-running" or "set and forget" mode timer with programmable prescaler and compare and capture register. A timer counter value can be captured using an external event and can be configured to trigger a capture event on either the leading or trailing edges of an input pulse. When the timer is configured to operate in "set and forget" mode, it is capable of providing precise interrupts at regular intervals with minimal processor intervention. The counter has output compare logic to provide the status and interrupt at comparison. This timer can be configured to run either on an external clock or on an internal clock.
GPU2D	Graphics Processing Unit-2D, ver 1	Multimedia Peripherals	The GPU provides hardware acceleration for 2D graphics algorithms with sufficient processor power to run desk-top quality interactive graphics applications on displays up to HD1080 resolution.
GPU3D	Graphics Processing Unit, ver.3	Multimedia Peripherals	The GPU provides hardware acceleration for 2D and 3D graphics algorithms with sufficient processor power to run desk-top quality interactive graphics applications on displays up to HD1080 resolution. It supports color representation up to 32 bits per pixel. GPUv3 enables High Performance Mobile 3D and 2D Vector Graphics at rates up to 33 M triangles/sec, 200 Mpixels/sec, 800 MPixels/sec (Z) (as per IP vendor).
I2C-1 I2C-2 I2C-3	I^2C Interface	Connectivity Peripherals	I^2C provide serial interface for external devices. Data rates of up to 400 kbps are supported.

Table continues on the next page...

Table 1-1. Digital and Analog Blocks (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
IIM	IC Identification Module	Security	The IC Identification Module (IIM) provides an interface for reading, programming and/or overriding identification and control information stored in on-chip fuse elements. The block supports electrically-programmable poly fuses (e-Fuses) or Laser Fuses (L-fuses). The IIM also provides a set of volatile software-accessible signals which can be used for software control of hardware elements, not requiring non-volatility. The IIM provides the primary user-visible mechanism for interfacing with on-chip fuse elements. Among the uses for the fuses are unique chip identifiers, mask revision numbers, cryptographic keys, JTAG secure mode, boot characteristics and various control signals requiring permanent non-volatility. The IIM also provides up to 28 volatile control signals. The IIM consists of a master controller, a software fuse value shadow cache, and a set of registers to hold the values of signals visible outside the block
IOMUXC	IOMUX Controller	System Control Peripherals	This block enables flexible IO multiplexing. Each IO pad has default and several alternate functions. The alternate functions are software configurable.
IPTP	IEEE1588 HW Assist to Ethernet controller (FEC).	Connectivity Peripherals	The IEEE 1588-2002 standard defines a Precision Time Protocol (PTP) - which is a time-transfer protocol that enables synchronization of networks (e.g., Ethernet), to a high degree of accuracy and precision. The IEEE1588 hardware assist, is composed of the two IPs - TSU (Time Stamp Unit) and CE_RTC (Real Time Clock), which provides the time stamping protocol's functionality. (generating / reading) the needed timestamps. The hardware-assisted implementations deliver more precise clock synchronization, at significantly lower CPU load, than pure SW implementation.
IPU	Image Processing Unit, ver.3M	Multimedia Peripherals	IPUv3M enables connectivity to displays, relevant processing and synchronization. It supports two display ports and two camera ports, through the following interfaces. • Legacy Parallel Interfaces • Single/dual channel LVDS display interface • Analog TV or VGA interfaces The processing includes • Image enhancement: color adjustment and gamut mapping, gamma correction and contrast enhancement • Video/graphics combining • Support for display backlight reduction • Image conversion-resizing, rotation, inversion and color space conversion • Hardware de-interlacing support • Synchronization and control capabilities, allowing autonomous operation.

Table continues on the next page...

Table 1-1. Digital and Analog Blocks (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
KPP	Key Pad Port	Connectivity Peripherals	KPP Supports 8 x 8 external key pad matrix. KPP features are: • Open drain design • Glitch suppression circuit design • Multiple keys detection • Standby key press detection
LDB	LVDS Display Bridge	Connectivity Peripherals	LVDS Display Bridge is used to connect the IPU (Image Processing Unit) to External LVDS Display Interface. LDB supports two channels; each channel has following signals: • 1 clock pair • 4 data pairs Each signal pair contains - LVDS special differential pad (PadP, PadM).
LDO	Low-Dropout Regulator	Clocks, Resets and Power Control	LDO is an integrated 1.8 V/1.2 V linear regulator.
M4IF	Multi Master Multi Memory Interface	Memory Control	M4IF controls memory accesses from one or more masters through different port interfaces to different external memory controllers ESDCTL, NFC, and EIM, and to some 2 internal memories in the system as well.
MLB	Media Local Bus Controller	Connectivity / Multimedia Peripherals	The MLB interface block provides a link to a MOST® data network, using the standardized MediaLB protocol (up to 50 Mbps)
NFC	NAND Flash Controller	Memory Control	NFC is composed of various control logic units, a 4.5-Kbyte internal RAM and an internal ECC engine. The NFC can interface standard NAND Flash memory devices.
OCRAM	On-Chip Memory controller	Data Path	The On-Chip Memory controller (OCRAM) block, is designed as an interface between the system's AXI bus, to the internal (on-chip) SRAM memory block. In i.MX53, the OCRAM is used for controlling the 128KB multimedia RAM, via a 64-bit AXI bus.
OWIRE	One-Wire Interface	Connectivity Peripherals	OWIRE support provided for interfacing with an on board EEPROM, and smart battery interfaces, for example: Dallas DS2502
PATA	Parallel ATA	Connectivity Peripherals	The P-ATA block is a AT attachment host interface. Its main use is to interface with hard disc drives and optical disc drives. It interfaces with the ATA-6 compliant device over a number of ATA signals. It is possible to connect a bus buffer between the host side and the device side.
PFD	Power Fail Detector	Clocks, Resets, and Power Control	PFD circuit generates a reset signal till its supply vdd reaches a predetermined voltage level.The PFD circuit works only when the chip is in the Non-DSM mode
PLARB2 PLARB1	PL301 Arbiter (2x2) and (4x1)	Data Path	ARM (Ltd.) PL301 AXI arbiters to bridge between several AXI masters accessing several AXI slaves.

Table continues on the next page...

Table 1-1. Digital and Analog Blocks (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
POR	Power on Reset	Clocks, Resets, and Power Control	The POR is designed for use in SoC applications which require low voltage, low power consumption. POR circuit generates a reset signal till its supply VDD reaches a predetermined voltage level.
PWM-1 PWM-2	Pulse Width Modulation	Connectivity Peripherals	The pulse-width modulator (PWM) has a 16-bit counter and is optimized to generate sound from stored sample audio images and it can also generate tones. It uses 16-bit resolution and a 4x16 data FIFO to generate sound.
ROMC	ROM Controller with Patch	Data Path	ROM Controller with ROM Patch support
RTIC	Run Time Integrity Checker	Security	Protecting read only data from modification is one of the basic elements in trusted platforms. The Run-Time Integrity Checker (RTIC), is a data monitoring device responsible for ensuring that memory content is not corrupted during program execution. The RTICv3 mechanism periodically checks the integrity of code or data sections during normal OS run-time execution without interfering with normal operation. The purpose of the RTIC is to ensure the integrity of the peripheral memory contents, protect against unauthorized external memory elements replacement and assist with boot authentication.
SAHARA	SAHARA security accelerator	Security	SAHARA (Symmetric/Asymmetric Hashing and Random Accelerator) version 4 is a security coprocessor. It implements symmetric encryption algorithms, (AES, DES, 3DES, RC4 and C2), hashing algorithms (MD5, SHA-1, SHA-224 and SHA-256), and a hardware true random number generator. It has a slave IPBus interface for the host to write configuration and command information, and to read status information. It also has a DMA controller, with an AHB bus interface, to reduce the burden on the host to move the required data to and from memory.
SATA	Serial ATA	Connectivity Peripherals	The SATA controller and PHY is a complete mixed-signal block solution designed to implement SATA HDD connectivity in a i.MX53 design.
SCC	Security Controller	Security	The SCC-AES is the second generation of the Security Controller. It implements secure RAM that can be used either as general-purpose memory for storing data and software, or as special confidentiality-preserving memory that protects disclosure-sensitive data such as cryptographic keys, passwords, code, or PIN numbers. It also incorporates cryptographic logic and a DMA engine that can be used to safely export the data stored within a partition to external RAM or non-volatile memory

Table continues on the next page...

Table 1-1. Digital and Analog Blocks (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
SDMA	Smart Direct Memory Access	System Control Peripherals	The SDMA is multi-channel flexible DMA engine. It helps in maximizing system performance by off-loading the various cores in dynamic data routing. Features List: • Powered by a 16-bit Instruction-Set micro-RISC engine • Multi-channel DMA supporting up to 32 time-division multiplexed DMA channels • 48 events with total flexibility to trigger any combination of channels • Memory accesses including linear, FIFO, and 2D addressing • Shared peripherals betweenARM Cortex A8™ and SDMA • Very fast Context-Switching with 2-level priority based preemptive multi-tasking • DMA units with auto-flush and prefetch capability • Flexible address management for DMA transfers (increment, decrement, and no address changes on source and destination address) • DMA ports can handle unidirectional and bidirectional flows (copy mode) • Up to 8-word buffer for configurable burst transfers for EXTMC • Support of byte-swapping and CRC calculations • Library of Scripts and API is available
SJC	System JTAG Interface	System Control Peripherals	JTAG manipulation is one of the known hackers' ways of executing unauthorized program code, getting control over secure applications and running code in privileged modes. The JTAG port provides a debug access to several hardware blocks including the ARM processor and the system bus. The JTAG port must be accessible during platform initial laboratory bring-up, manufacturing tests and troubleshooting, as well as for software debugging by authorized entities. However, in order to properly secure the system, unauthorized JTAG usage should be strictly forbidden. In order to prevent JTAG manipulation while allowing access for manufacturing tests and software debugging, i.MX53 incorporates a mechanism for regulating JTAG access. i.MX53 System JTAG Controller provides four different JTAG security modes that can be selected via e-fuse configuration.
SPBA	Shared Peripheral Bus Arbiter	System Control Peripherals	SPBA (Shared Peripheral Bus Arbiter) is a three-to-one IP Bus interfaces (IP Bus) arbiter.
SPDIF	Sony Phillips Digital Interface	Multimedia Peripherals	A standard audio file transfer format. Developed jointly by the Sony and Phillips corporations. Transmitter and Receiver functionality.

Table continues on the next page...

Table 1-1. Digital and Analog Blocks (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
SRTC	Secure Real Time Clock	Security	The SRTC incorporates a special System State Retention Register (SSRR) that stores system parameters during system shut down modes. This register (as all SRTC counters) is power backed up by a coin-cell backup battery. This register is helpful for storing warm boot parameters. The SSRR also stores the system security state. In case of a security violation, the SSRR will mark the event (security violation indication).
SSI-1 SSI-2 SSI-3	I2S/SSI/AC97 Interface	Connectivity Peripherals	The SSI is a full-duplex synchronous interface which is used on the AP to provide connectivity with off-chip audio peripherals. The SSI supports a wide variety of protocols (SSI normal, SSI network, I2S, and AC-97), bit depths (up to 24 bits per word), and clock / frame sync options. The SSI has two pairs of 8x24 FIFOs and hardware support for an external DMA controller in order to minimize its impact on system performance. The second pair of FIFOs provides hardware interleaving of a second audio stream which reduces CPU overhead in use cases where two time slots are being used simultaneously.
TVE	TV-Encoder Ver 2.1	Multimedia	The TVEv2.1 which consists of the Digital Video Encoder (DVE) and a Triple Video Digital-to-Analog Converter (TVDAC); supports HD720p/1080p, PAL/NTSC or VGA output for direct connection to TV or LCD projector
TZIC	TrustZone Aware Interrupt Controller	ARM/Control	The TrustZone Interrupt Controller (TZIC) collects interrupt requests from all i.MX53 sources and routes them to the ARM core. Each interrupt can be configured as a normal or a secure interrupt. Software Force Registers and software Priority Masking are also supported.
UART-1 UART-2 UART-3 UART-4 UART-5	UART Interface	Connectivity Peripherals	Each of the UART supports the following serial data transmit/ receive protocols and configurations: • 7 or 8 bit data words, 1 or 2 stop bits, programmable parity (even, odd or none) • Programmable baud rates up to 4 MHz. This is a higher max baud rate relative to the 1.875 MHz which is stated by the TIA/EIA-232-F standard and the i.MX53 UART. • 32-byte FIFO on Tx and 32 half-word FIFO on Rx supporting auto-baud • IrDA 1.0 support (up to SIR speed of 115200 bps) • Option to operate as 8-pins full UART, DCE or DTE.

Table 1-1. Digital and Analog Blocks (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
USB	USB 2.0 High Speed OTG and 3x HS Hosts	Connectivity Peripherals	USBO HS (2.0 480MHz) contains one hi-speed OTG block, which is internally connected to the HS USB PHY, while still equipped with Transceiver-Less Logic to enable on-board USB connectivity without USB TransceiversUSBOH3 contains: • One high-speed OTG block with integrated HS USB PHY • One high-speed Host block with integrated HS USB PHY • Two identical high-speed Host blocks All the USB ports are equipped with standard digital interfaces (ULPI, HS IC-USB) and Transceiver-Less Logic to enable on-board USB connectivity without USB Transceivers.
VPU	Video Processing Unit	Multimedia Peripherals	A high-performing video processing unit (VPU), which covers many SD-level and HD-level video decoders and SD-level encoders as a multi-standard video codec engine as well as several important video processing such as rotation and mirroring. Refer to Table 9-2 for complete list of VPU's decoding/ encoding capabilities.
WDOG-1	Watch Dog	Timer Peripherals	The Watch Dog Timer supports 2 comparison points during each counting period. Each of the comparison points is configurable to evoke an interrupt to the ARM core, and a second point evokes an external event on the WDOG line.
XTALOSC XTALOSC_32K	Crystal Oscillator I/ F	Clocking	The XTALOSC is 24 MHz crystal oscillator and XTALOSC_32K is a 32.768 kHz crystal oscillator.
RAM 128 KB	Internal RAM	Internal Memory	Internal RAM, shared with VPU
RAM 16 KB	Secure/non-secure RAM	Secured Internal Memory	Secure/non-secure Internal RAM, controlled by SCC
ROM 64 KB	Boot ROM	Internal Memory	Supports secure and regular Boot Modes

1.7 Memory Interfaces

i.MX53 EXTMC supports the following memory interfaces:

- DDR2/LV-DDR2-800, 16/32 -bit, 400 MHz clock
- DDR3-800, 16/32 -bit, 400 MHz clock
- LPDDR2, 32bit on PoP package only, 400 MHz clock

- NAND (MLC/SLC) Flash, 8-bit/16-bit
- NOR Flash, SRAM and PSRAM, 8/16/32-bit (8-bit is not supported at byte D[23]-D[16])

63FF_C000	63FF_FFFF	16K	PTP
6400_0000	6FFF_BFFF	256M (minus 512K)	Reserved (aliased slots)
On Chip AHB Accessed IPs			
6FFF_C000	6FFF_FFFF	16K	Reserved
Off Chip Memories (HW connection via EXTMC)			
7000_0000	AFFF_FFFF	1G	CSD0 DDR
B000_0000	EFFF_FFFF	1G	CSD1 DDR
F000_0000 F000_0000 F400_0000	F7FE_FFFF F3FF_FFFF F7FE_FFFF	128M-64K 64M 64M-64k	CS0 (128M NOR/SRAM) - Default Configuration CS1, CS2, CS3 - Not Active. In case of 2 active CS. CS0(64M) CS1(64M) Via IOMUXC (GPRR1) register, 4CS of 32M are supported. The sum of all CS spaces must equal 128M, and can be splitted between maximum 4 CSs. The biggest region is CS0. No holes are supported. The supported configurations are: CS0(128M), CS1 (0M), CS2 (0M), CS3(0M) CS0(64M), CS1(64M), CS2(0M), CS3(0M) CS0(64M), CS1(32M), CS2(32M), CS3(0M) CS0(32M), CS1(32M), CS2(32M), CS3(32M)
On Chip Memories (HW connection via EXTMC)			
F7FF_0000	F7FF_FFFF	64K	NAND FLASH (internal buffer)
F800_0000	F801_FFFF	128K	iRAM (OCRAM)
F802_0000	F805_FFFF	256K	GPU3D GMEM
F806_0000	FFFF_FFFF	128M-384K	Reserved

NOTE

User should not address reserved memory regions. Access to reserved memory regions can cause unpredictable behavior.

2.2 DMA Memory Map

The Smart DMA memory map is defined in Table 2-2.

Table 2-2. SDMA Peripheral Memory Map

Peripheral	Base Address	Size	Comments
Reserved for SDMA internal memory	0x0000	4KB	Reserved
ESDHCv2-1	0x1000	4KB	
ESDHCv2-2	0x2000	4KB	
UART-3	0x3000	4KB	
ECSPI-1	0x4000	4KB	
SSI-2	0x5000	4KB	
Enhanced Serial Audio Interface (ESAI)	0x6000	4KB	
Reserved for SDMA internal registers	0x7000	4KB	Reserved
ESDHCv2-3 (CE-ATA)	0x8000	4KB	
ESDHCv2-4	0x9000	4KB	
SPDIF	0xA000	4KB	
ASRC	0xB000	4KB	
PATA	0xC000	4KB	
Reserved	0xD000	4KB	Reserved
Reserved	0xE000	4KB	Reserved
SPBA Registers	0xF000	4KB	

NOTE

User should not address reserved memory regions. Access to reserved memory regions can cause unpredictable behavior.

Chapter 3
Interrupts and SDMA Events

3.1 Overview

The Interrupts and SDMA Events chapter provides information on the assignments of the interrupts of the ARM platform domain in ARM Platform Interrupts and of the DMA events in SDMA Event Mapping.

3.2 ARM Platform Interrupts

The TrustZone Aware Interrupt Controller (TZIC) collects up to 128 interrupt requests from all MCIMX53 sources and provides an interface to the core. Each interrupt can be configured as a normal or a secure interrupt. Software force registers and software priority masking are also supported. Table 3-1 details the ARM Cortex A8^{tm} Platform (ARM) interrupt sources.

Table 3-1. ARM Domain Interrupt Summary

IRQ	Interrupt Source	Interrupt Description
0	Reserved	Reserved
1	ESDHCV2-1	Enhanced SDHC Interrupt Request
2	ESDHCV2-2	Enhanced SDHC Interrupt Request
3	ESDHCV3-3	CE-ATA Interrupt Request based on ESDHCV3-3
4	ESDHCV2-4	Enhanced SDHC Interrupt Request
5	DAP	
6	SDMA	AND of all 48 interrupts from all the channels
7	IOMUXC	POWER FAIL interrupt. This is a power fail indicator interrupt from on board power management IC via GPIO_16 PAD on ALT2, PWRFAIL_INT signal.

Table continues on the next page...

Table 3-1. ARM Domain Interrupt Summary (continued)

IRQ	Interrupt Source	Interrupt Description
8	EXTMC	NFC interrupt
9	VPU	VPU Interrupt Request
10	IPU	IPU Error Interrupt
11	IPU	IPU Sync Interrupt
12	GPU3D	GPU Interrupt Request
13	UART-4	UART-4 ORed interrupt
14	USB	USB Host 1
15	EXTMC	Consolidated EXTMC Interrupt
16	USB	USB Host 2
17	USB	USB Host 3
18	USB	USB OTG
19	SAHARA	SAHARA Interrupt for Host 0
20	SAHARA	SAHARA Intr for Host 1
21	SCC	Security Monitor High Priority Interrupt Request.
22	SCC	Secure (TrustZone) Interrupt Request.
23	SCC	Regular (Non-Secure) Interrupt Request.
24	SRTC	SRTC Consolidated Interrupt. Non TZ.
25	SRTC	SRTC Security Interrupt. TZ.
26	RTIC	RTIC (Trust Zone) Interrupt Request. Indicates that the RTIC has completed hashing the selected memory block(s) during single-hash/boot mode.
27	CSU	CSU Interrupt Request 1. Indicates to the processor that one or more alarm inputs were asserted
28	SATA	SATA interrupt request
29	SSI-1	SSI-1 Interrupt Request
30	SSI-2	SSI-2 Interrupt Request
31	UART-1	UART-1 ORed interrupt
32	UART-2	UART-2 ORed interrupt
33	UART-3	UART-3 ORed interrupt
34	IPTP	RTC (IEEE1588) interrupt request
35	IPTP	PTP (IEEE1588) interrupt request
36	ECSPI-1	ECSPI-1 interrupt request line to the core.
37	ECSPI-2	ECSPI-2 interrupt request line to the core.
38	CSPI	CSPI interrupt request line to the core.

Table continues on the next page...

Table 3-1. ARM Domain Interrupt Summary (continued)

IRQ	Interrupt Source	Interrupt Description
39	GPT	OR of GPT Rollover interrupt line, Input Capture 1 & 2 lines, Output Compare 1, 2 &3 Interrupt lines
40	EPIT-1	EPIT-1 output compare interrupt
41	EPIT-2	EPIT-2 output compare interrupt
42	GPIO-1	Active HIGH Interrupt from INT7 from GPIO
43	GPIO-1	Active HIGH Interrupt from INT6 from GPIO
44	GPIO-1	Active HIGH Interrupt from INT5 from GPIO
45	GPIO-1	Active HIGH Interrupt from INT4 from GPIO
46	GPIO-1	Active HIGH Interrupt from INT3 from GPIO
47	GPIO-1	Active HIGH Interrupt from INT2 from GPIO
48	GPIO-1	Active HIGH Interrupt from INT1 from GPIO
49	GPIO-1	Active HIGH Interrupt from INT0 from GPIO
50	GPIO-1	Combined interrupt indication for GPIO-1 signal 0 throughout 15
51	GPIO-1	Combined interrupt indication for GPIO-1 signal 16 throughout 31
52	GPIO-2	Combined interrupt indication for GPIO-2 signal 0 throughout 15
53	GPIO-2	Combined interrupt indication for GPIO-2 signal 16 throughout 31
54	GPIO-3	Combined interrupt indication for GPIO-3 signal 0 throughout 15
55	GPIO-3	Combined interrupt indication for GPIO-3 signal 16 throughout 31
56	GPIO-4	Combined interrupt indication for GPIO-4 signal 0 throughout 15
57	GPIO-4	Combined interrupt indication for GPIO-4 signal 16 throughout 31
58	WDOG-1	Watchdog Timer reset
59	WDOG-2	TrustZone Watchdog Timer reset
60	KPP	Keypad Interrupt
61	PWM-1	Cumulative interrupt line. OR of Rollover Interrupt line, Compare Interrupt line and FIFO Waterlevel crossing interrupt line.
62	I2C-1	I2C-1 Interrupt
63	I2C-2	I2C-2 Interrupt
64	I2C-3	I2C-3 Interrupt
65	MLB	NOR of all interrupts, mlb_cint and mlb_sint

Table continues on the next page...

Table 3-1. ARM Domain Interrupt Summary (continued)

IRQ	Interrupt Source	Interrupt Description
66	ASRC	ASRC Interrupt for core 1
67	SPDIF	SPDIF Tx interrupt OR SPDIF Rx interrupt
68	Reserved	Reserved
69	IIM	Interrupt request to the processor. Indicates to the processor that program or explicit sense cycle is completed successfully or in case of error. This signal is low-asserted.
70	PATA	Parallel ATA host controller interrupt request
71	CCM	CCM, Interrupt Request 1
72	CCM	CCM, Interrupt Request 2
73	GPC	GPC, Interrupt Request 1
74	GPC	GPC, Interrupt Request 2
75	SRC	SRC interrupt request
76	P_PLATFORM_NE_32K_256K	Neon Monitor Interrupt
77	P_PLATFORM_NE_32K_256K	Performance Unit Interrupt (nPMUIRQ). This is an interrupt generated by the ARMCORE and used for system profiling and debug. GPIO_16 PAD in ALT3 mode acts as nPMUIRQ signal (also named PMU_IRQ_B signal).
78	P_PLATFORM_NE_32K_256K	CTI IRQ
79	P_PLATFORM_NE_32K_256K	Debug Interrupt, from Cross-Trigger 1 Interface 1
80	P_PLATFORM_NE_32K_256K	Debug Interrupt, from Cross-Trigger 1 Interface 0
81	ESAI	ESAI interrupt
82	FLEXCAN-1	NOR of all interrupts; ipi_int_mbor, ipi_int_wakein, ipi_int_busoff and ipi_int_error.
83	FLEXCAN-2	NOR of all interrupts; ipi_int_mbor, ipi_int_wakein, ipi_int_busoff and ipi_int_error.
84	OPENVG	General Interrupt
85	OPENVG	Busy signal (for S/W power gating feasibility)
86	UART-5	UART-5 ORed interrupt
87	FEC	Fast Interrupt Request (OR of 13 interrupt sources)
88	OWIRE	1-Wire Interrupt Request
89	P_PLATFORM_NE_32K_256K	Debug Interrupt, from Cross-Trigger 1 Interface 2
90	SJC	
91	Reserved	Reserved
92	TVE	
93	FIRI	FIRI Intr (OR of all 4 interrupt sources)

Table continues on the next page...

Table 3-1. ARM Domain Interrupt Summary (continued)

IRQ	Interrupt Source	Interrupt Description
94	PWM-2	Cumulative interrupt line. OR of Rollover Interrupt line, Compare Interrupt line and FIFO Waterlevel crossing interrupt line.
95	Reserved	Reserved for SLM
96	SSI-3	SSI-3 Interrupt Request
97	Reserved	
98	P_PLATFORM_NE_32K_256K	Debug Interrupt, from Cross-Trigger 1 Interface 3
99	Reserved	Was belong to SLM
100	VPU	Idle interrupt from VPU (for S/W power gating)
101	EXTMC	Indicates all pages have been transferred to NFC during an auto_prog operation
102	GPU3D	Idle interrupt from GPU (for S/W power gating)
103	GPIO-5	Combined interrupt indication for GPIO-5 signal 0 throughout 15
104	GPIO-5	Combined interrupt indication for GPIO-5 signal 16 throughout 31
105	GPIO-6	Combined interrupt indication for GPIO-6 signal 0 throughout 15
106	GPIO-6	Combined interrupt indication for GPIO-6 signal 16 throughout 31
107	GPIO-7	Combined interrupt indication for GPIO-7 signal 0 throughout 15
108	GPIO-7	Combined interrupt indication for GPIO-7 signal 16 throughout 31
109_128	Reserved	Reserved

3.3 SDMA Event Mapping

Table 3-2 shows the DMA request signals for peripherals in i.MX53.

Table 3-2. SDMA Event Mapping

Event Number	DMA Source	Description
0	VPU	VPU DMA request
1	GPC	Will be used for power management.
2	UART-4 PATA	UART-4RX muxed with PATA RX (selector IOMUXC GPR0 register bit [7]).

Table continues on the next page...

Table 3-2. SDMA Event Mapping (continued)

Event Number	DMA Source	Description
3	UART-4 PATA	UART-4TX muxed with PATA TX (selector IOMUXC GPR0 register bit [8]).
4	PATA	PATA Transfer End
5	IPU	IPU DMA Event
6	ECSPI	DMA Rx request
7	ECSPI-1	DMA Tx request
8	ECSPI-2	DMA Rx request
9	ECSPI-2	DMA Tx request
10	I2C-3 ESDHCV3-3	I2C-3 muxed with ESDHCV3-3
11	ESDHCV2-4 CTI2	ESDHC4 muxed with CTI2 (SDMA_CTI) trigger_out[0] connected to SDMA event.
12	UART-2 FIRI	UART-2RX muxed with FIRI REQ[0] (selector IOMUXC GPR0 register bit [9]).
13	UART-2 FIRI	UART-2TX muxed with FIRI REQ[1] (selector IOMUXC GPR0 register bit [10]).
14	SPDIF IOMUXC	SPDIF RX DMA request Muxed with External DMA request #0 from PAD DISP0_DAT16 or GPIO_17 (using daisy chain selector). The event selector is in IOMUXC GPR0 register bit [4].
15	SPDIF	SPDIF TX DMA request
16	UART-5	Rx FIFO of UART-5
17	UART-5	Tx FIFO of UART-5
18	UART-1	Rx FIFO of UART-1
19	UART-1	Tx FIFO of UART-1
20	I2C-1 ESDHCV2-1	I2C-1 muxed with ESDHCV2-1
21	I2C-2 ESDHCV2-2	I2C-2 muxed with ESDHCV2-2
22	SSI-2	SSI-2 receive 2 DMA request
23	SSI-2	SSI-2 transmit 2 DMA request
24	SSI-2	SSI-2 receive 1 DMA request
25	SSI-2	SSI-2 transmit 1 DMA request
26	SSI-1	SSI-1 receive 2 DMA request
27	SSI-1	SSI-1 transmit 2 DMA request
28	SSI-1	SSI-1 receive 1 DMA request
29	SSI-1	SSI-1 transmit 1 DMA request
30	EXTMC	Asserts every time NFC finishes reading a page
31	EXTMC	Asserts at the beginning of auto-program sequence, and every time the NFC finishes transferring data from the RAM to the NAND (Meaning, the SDMA can write to the RAM the next page).

Table continues on the next page...

Table 3-2. SDMA Event Mapping (continued)

Event Number	DMA Source	Description
32	ASRC	ASRC dma1 request (Pair A input Request)
33	ASRC	ASRC dma2 request (Pair B input Request)
34	ASRC	ASRC dma3 request (Pair C input Request)
35	ASRC	ASRC dma4 request (Pair A output Request)
36	ASRC	ASRC dma5 request (Pair B output Request)
37	ASRC	ASRC dma6 request (Pair C output Request)
38	CSPI EPIT-2	CSPI DMA Rx request Muxed with EPIT-2 DMA request
39	CSPI IOMUXC	CSPI DMA Tx request Muxed with External DMA request #1 from PAD DISP0_DAT17 or GPIO_18 (using daisy chain selector). The event selector is in IOMUXC GPR0 register bit [6].
40	ESAI	ESAI Rx FIFO DMA request
41	ESAI	ESAI Tx FIFO DMA request
42	UART-3	Rx FIFO of UART-3
43	UART-3	Tx FIFO of UART-3
44	SSI-3	SSI-3 receive 2 DMA request
45	SSI-3	SSI-3 transmit 2 DMA request
46	SSI-3	SSI-3 receive 1 DMA request
47	SSI-3	SSI-3 transmit 1 DMA request

As shown in the table, some of the events are shared through a multiplexer. The select of shared DMA event sources is controlled by DMAREQ_MUX_SELn fields of the IOMUXC.IOMUXC_GPRO Register.

For other shared connectivity peripherals that do not have dedicated DMA request signals, the ARM platform interrupt service routines have the option to program the SDMA to move data between the peripheral and memory.

Chapter 4
External Signals and Pin Multiplexing

4.1 Overview

Internal signals are connected to external components via package-level electrical connections. In this document, these physical connections will be referred to as pins even though in specific products they may be implemented as solder balls or some other package specific means. Pins, in turn, are connected internally to SoC driver / receiver circuitry called pads.

The i.MX53 contains a number of functional blocks that present input / output signals (block I/Os) that are suitable for connection to components external to the SoC. There are many more block I/Os than there are package pins. To provide flexibility in routing block I/Os to external pins, the Input-Output Multiplexer Controller (IOMUXC) block provides a number of software configurable multiplexers that allow different internal block I/O signals to be routed to the available pins.

In addition to this function, IOMUXC allows software to configure pad electrical characteristics, such as output/output function, voltage level, drive strength, and hysteresis. Not all voltage and ground pins are considered here. For information on these pins, consult the appropriate data sheet for the specific product.

4.2 Controlling Pin Multiplexing

Some block I/Os are routed to dedicated package pins, but the majority of block I/O signals are routed through the IOMUXC. This allows internal blocks to share pins to drive or receive signals. Block I/Os are selected for routing to and from external package pins via the MUX_MODE field in the MUX_CTL registers. These selections are called ALT modes.

Some block input signals can be driven from alternate pins. This function is called a daisy chain. SELECT_INPUT registers allow software to chose between two to six different pins to provide input signals to some blocks.

Drive strength and direction (input or output) of many package pins may be selected by fields within PAD_CTL registers. Some pins have dedicated PAD_CTL_PAD registers. Most pins that are used in their default mode to interface to external DRAM are configured for drive strength and direction by PAD_CTL_GRP register although some have PAD_CTL_PAD registers as well.

Multiplexing and Pad Control below lists those registers used to control package pin drive characteristics and pin to internal block I/O connections.

Daisy Chain Control below lists registers involved in controlling daisy chaining.

See the IOMUXC chapter for more details.

4.2.1 Multiplexing and Pad Control

This section covers the multiplexing and pad control regitsters.

Table 4-1 shows the multiplexing control register and pad driver control register(s) for each package pin.

Table 4-1. Pin Control Registers

Pin Name	Mux Control	Pad / Group Control
GPIO_19	IOMUXC_SW_MUX_CTL_PAD_GPIO_19	IOMUXC_SW_PAD_CTL_PAD_GPIO_19
KEY_COL0	IOMUXC_SW_MUX_CTL_PAD_KEY_COL0	IOMUXC_SW_PAD_CTL_PAD_KEY_COL0
KEY_ ROW0	IOMUXC_SW_MUX_CTL_PAD_KEY_ROW0	IOMUXC_SW_PAD_CTL_PAD_KEY_ROW0
KEY_COL1	IOMUXC_SW_MUX_CTL_PAD_KEY_COL1	IOMUXC_SW_PAD_CTL_PAD_KEY_COL1
KEY_ ROW1	IOMUXC_SW_MUX_CTL_PAD_KEY_ROW1	IOMUXC_SW_PAD_CTL_PAD_KEY_ROW1
KEY_COL2	IOMUXC_SW_MUX_CTL_PAD_KEY_COL2	IOMUXC_SW_PAD_CTL_PAD_KEY_COL2
KEY_ ROW2	IOMUXC_SW_MUX_CTL_PAD_KEY_ROW2	IOMUXC_SW_PAD_CTL_PAD_KEY_ROW2
KEY_COL3	IOMUXC_SW_MUX_CTL_PAD_KEY_COL3	IOMUXC_SW_PAD_CTL_PAD_KEY_COL3
KEY_ ROW3	IOMUXC_SW_MUX_CTL_PAD_KEY_ROW3	IOMUXC_SW_PAD_CTL_PAD_KEY_ROW3
KEY_COL4	IOMUXC_SW_MUX_CTL_PAD_KEY_COL4	IOMUXC_SW_PAD_CTL_PAD_KEY_COL4
KEY_ ROW4	IOMUXC_SW_MUX_CTL_PAD_KEY_ROW4	IOMUXC_SW_PAD_CTL_PAD_KEY_ROW4

Table continues on the next page...

1. If the LVDS Display Bridge (LDB) block is disabled, then each LVDS output pin pair is available to be used as a pair of general purpose CMOS inputs (controlled by the GPIO blocks).

4.2.2 Daisy Chain Control

To increase the flexibility of routing signals from package pins to certain block I/Os, the IOMUXC provides multiplexers that can be programmed to receive inputs from a number of different package pins. This is called daisy chaining. This selection is controlled by daisy chain control registers. These are described below.

Table 4-4 shows the daisy chain control registers sorted by package pin.

Table 4-4. Daisy Chain Multiplexer Control Registers (by pin)

Pin Name	Daisy Chain Control Registers
GPIO_19	IOMUXC_KPP_IPP_IND_COL_5_SELECT_INPUT

4.3 Special Package Pins

In addition to the package pins discussed above, i.MX53 has other dedicated pins that serve special purposes. These are generally pins that convey signals with special voltage or drive characteristics or are used for test purposes.

Table 4-6 lists package analog and power pins and their characteristics.

Chapter 5
External Memory

5.1 Overview

The External Memory Controller (EXTMC) is the block that services all i.MX53 external memory accesses requests (read/write/erase/program) from all the AXI bus masters in the system. All accesses are arbitrated by the Multi Master Multi Memory Interface (M4IF) block and controlled by the respective memory controller. The high level block diagram is presented in Figure 5-1.

Each AXI bus master interface port is an AXI interface with separated input bus for read and write access, so masters that handle separated buses for read and write access can access the EXTMC. The data width can be 32 or 64 bits. All ports support 32 or 64-bit IF.

NOTE

The following is a summary of the EXTMC used in i.MX53. This summary takes precedence if any discrepancy between the information here and the information in the EXTMC (and related sub-blocks) block guide arises. Please note that in case of conflict, the information related to frequencies of operation supersedes that of the block chapters and is superseded by that of the data sheet.

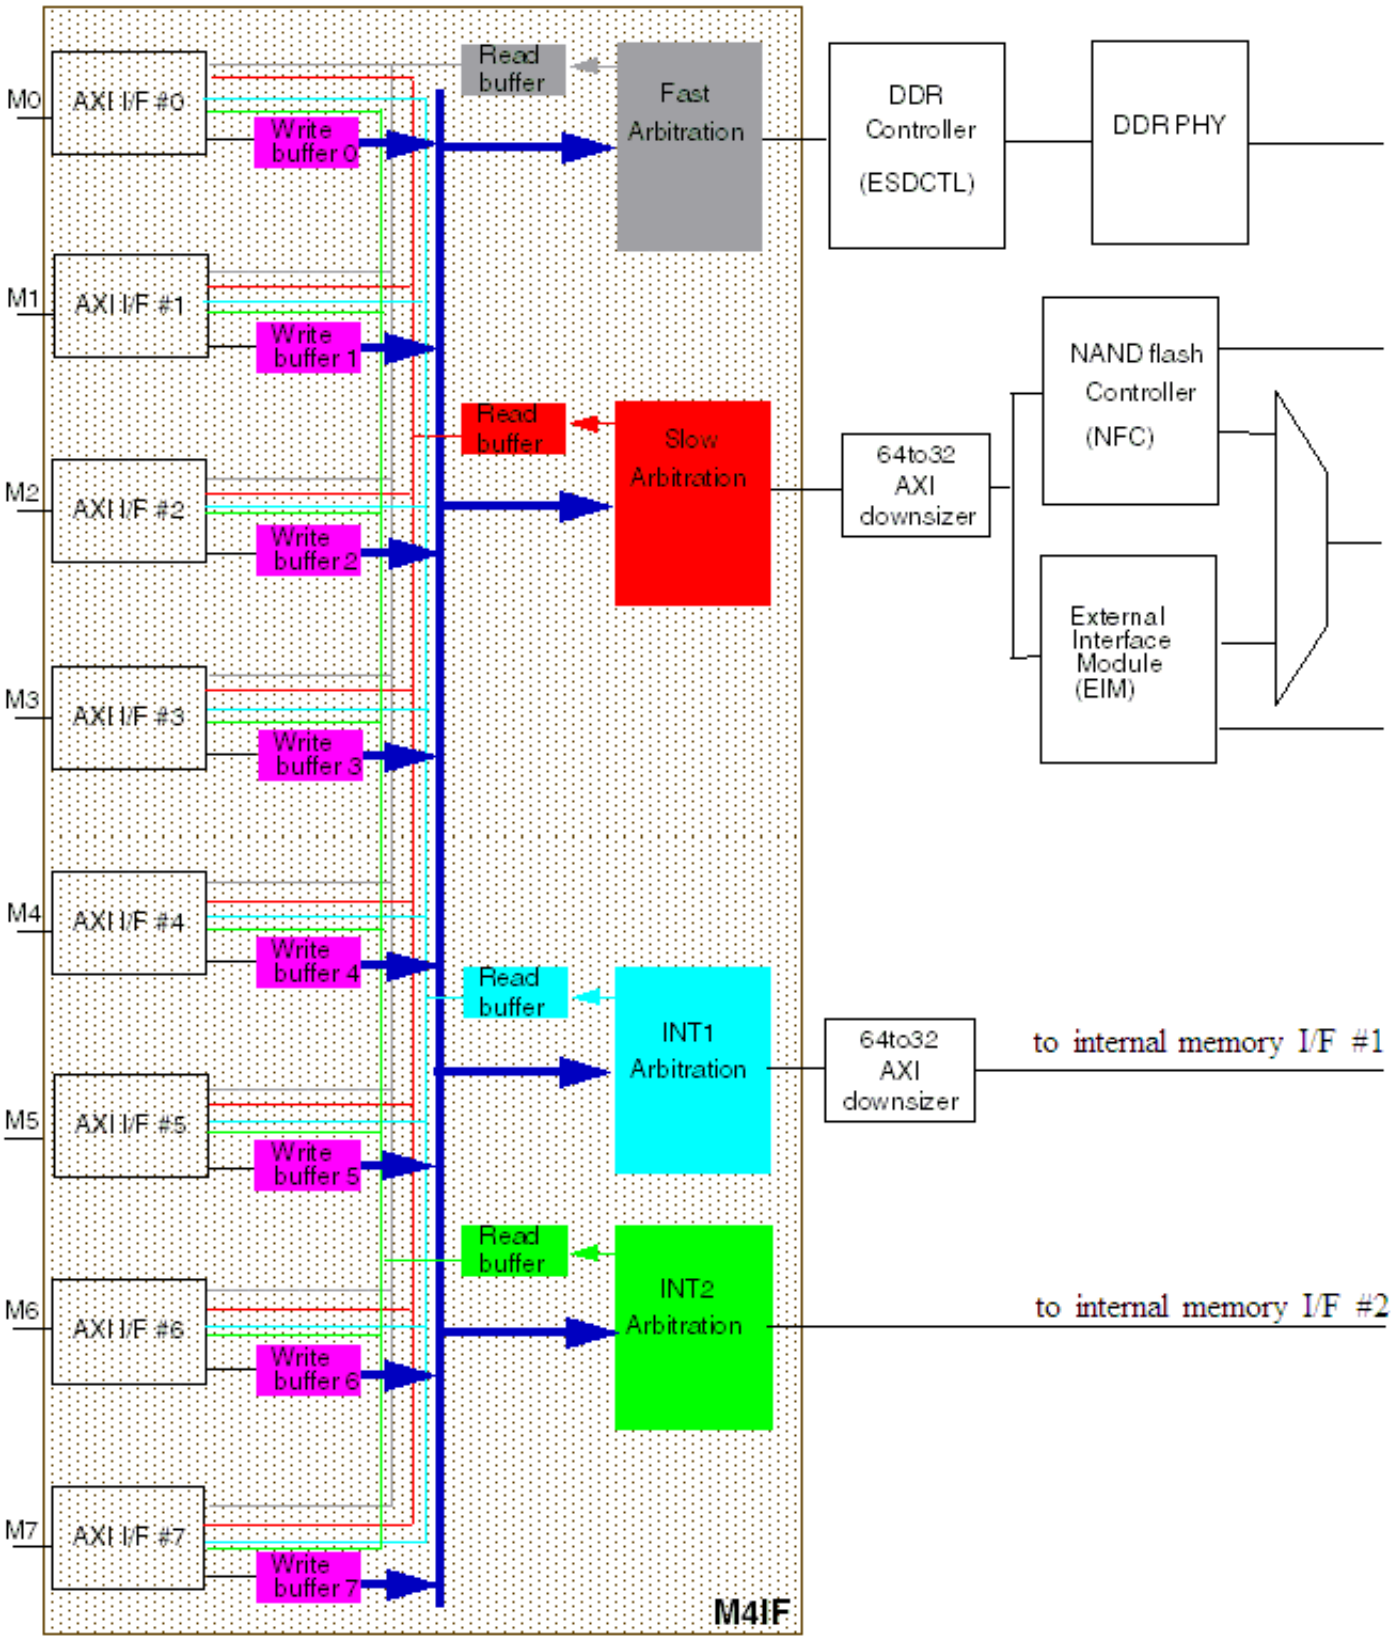

Figure 5-1. EXTMC High Level Block Diagram

5.2 External Memory Interface - i.MX53 Specific Configuration

The EXTMC provides the ability to connect to a wide variety of memory devices. This chapter contains the technical information about the operation and configuration of the EXTMC in the chip to allow the designer to quickly integrate external memory devices into new and existing designs. Pin sharing is done between the data bus of the external interface module (EIM) and the NAND Flash Controller (NFC) in order to reduce the total number of pins needed for the EXTMC.

The EXTMC is an External Memory Interface and arbitration between multi AXI masters to multi memory controllers, divided into three major channels: fast memories (DDR2, DDR3, LPDDR2) channel, slow memories (NOR-FLASH/PSRAM/NAND-FLASH etc.) channel, Internal Memory (RAM, ROM) channel, and Internal GMEM memory.

In order to increase the bandwidth performance, the EXTMC separates the buffering and the arbitration between accesses to fast channel slow channel and Internal Memory channels, so parallel accesses can occur. By separating the three channels slow accesses don't interfere with fast accesses.

The EXTMC contains the arbitration interface and different external memory controllers in order to support several memory devices:

- M4IF - Multi Master Multi Memory Interface.
- ESDRAMC - Enhanced DDR2/DDR3/LPDDR2 memory controller.
- NFC - NANDFlash memory controller.
- EIM - SRAM/PSRAM/NOR FLASH memory controller

5.2.1 EXTMC - AXI Bus Masters

The table below provides details on AXI bus masters and the AXI bus master interface port associated with each master. Please refer to the M4IF chapter for buffer sizes for each master.

Table 5-1. AXI Bus Masters

Block	Direct Bus	Master Port	Buffered	Boundary Crossing	Max frequency Mhz
IPU	AXI	0	y	4K	200MHz
VPU	AXI	1	y	4K	200MHz

Table continues on the next page...

Table 5-1. AXI Bus Masters (continued)

Block	Direct Bus	Master Port	Buffered	Boundary Crossing	Max frequency Mhz
DAP	AHB via AHBMAX	2	n	1K	133MHz

GPU2D (OpenVG)	AXI	6	y	4K	200MHz
USB	AXI	7	n	4K	133MHz

5.2.2 Features

Each of the EXTMC memory controller block guide specify detailed information on the supported features, programming model. However, in i.MX53 some of those feature are disabled or not supported.

The EXTMC in the i.MX53 includes these distinctive features:

- Multi Master Multi Memory Interface (M4IF)
  - Supports multiple accesses from 8 masters through different input ports interfaces. Each port can support either of the following two data width options:
    - x32 AXI port.
    - x64 AXI port.
  - Supports different clock domain for each AXI port master.
  - Configurable memory watermark protection per DDR2/DDR3/LPDDR2 CS.
  - Enhanced arbitration scheme for fast channel, consider page hit/miss, last access details (read/write) and fixed priority configuration.

- Enhanced DDR Controller (ESDRAMC)
  - Up to 2 chip selects support up to 1GByte each.
  - x64 AXI port.
  - Supports x16/x32 DDR2 memories up to 400MHz (800 MHz data rate)
  - Supports x16/x32 DDR3 memories up to 400MHz (800 MHz data rate)
  - Supports x32 LPDDR2 memory (Please refer to the i.MX53 Data Sheet for target frequencies)
  - Supports latency hiding logic.
- NANDFlash Controller - (NFC)
  - x8/x16 NAND interface.
  - Up to 8 chip selects support up to 8Gbit in 1/2K page mode, 64Gbit in 2K page mode and 256Gbit in 4K page mode each.
  - 4.5K RAM Internal Buffer
  - MLC and SLC memory support.
  - Configurable operation mode - symmetric and asymmetric.
  - Configurable page mode, 1/2K, 2K or 4K.
  - ECC support up to 16 bit.
  - Supports up to 8 mutually exclusive, yet interleaved nand devices.
  - Automatic Common NAND Operations
- External Interface Memory Controller - (EIM)
  - Up to 4 chip selects, programmable using the General Purpose Register in IOMUXC.
  - Supports x32/x16/x8 PSRAM/NOR (at slow frequency).
- Supports DVFS, voltage and frequency change.
- Supports automatic shut-down (power saving features)
- Enhanced debug capabilities (trace mode).

Table 5-2. EIM multiplexing

Setup	Non Multiplexed Address/Data Mode						Multiplexed Address/ Data mode	
	8 Bit			16 Bit		32 Bit	16 Bit	32 Bit
	MUM = 0, DSZ = 100	MUM = 0, DSZ = 101	MUM = 0, DSZ = 111	MUM = 0, DSZ = 001	MUM = 0, DSZ = 010	MUM = 0, DSZ = 011	MUM = 1, DSZ = 001	MUM = 1, DSZ = 011
A[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]
A[25:16]	EIM_A[25:16]	EIM_A[25:16]	EIM_A[25:16]	EIM_A[25:16]	EIM_A[25:16]	EIM_A[24:16][1]	EIM_A[25:16]	EIM_A[8:0]
D[7:0], EIM_EB0	NANDF_D[7:0]	-	-	NANDF_D[7:0][2]	-	NANDF_D[7:0]	EIM_DA[7:0]	EIM_DA[7:0]
D[15:8], EIM_EB1	-	NANDF_D[15:8]	-	NANDF_D[15:8][3]	-	NANDF_D[15:8]	EIM_DA[15:8]	EIM_DA[15:8]

Table continues on the next page...

Table 5-2. EIM multiplexing (continued)

Setup	Non Multiplexed Address/Data Mode						Multiplexed Address/ Data mode	
	8 Bit			16 Bit		32 Bit	16 Bit	32 Bit
	MUM = 0, DSZ = 100	MUM = 0, DSZ = 101	MUM = 0, DSZ = 111	MUM = 0, DSZ = 001	MUM = 0, DSZ = 010	MUM = 0, DSZ = 011	MUM = 1, DSZ = 001	MUM = 1, DSZ = 011
D[23:16], EIM_EB2	-	-	-	-	EIM_D[23:16]	EIM_D[23:16]	-	NANDF_D[7:0]
D[31:24], EIM_EB3	-	-	EIM_D[31:24]	-	EIM_D[31:24]	EIM_D[31:24]	-	NANDF_D[15:8]

1. For 32-bit, the address range is A[24:0], due to address space allocation in memory map.
2. NANDF_D[7:0] multiplexed on ALT3 mode of PATA_DATA[7:0]
3. NANDF_D[15:8] multiplexed on ALT3 mode of PATA_DATA[15:8]

5.3 EXTMC Setup

The following section describes i.MX53 specific requirements in order to use the EXTMC.

5.3.1 Clock Domains

EXTMC contains the following clock domains:

- EXTMC IP Bus clock.
- ESDCTLV2 main clock (up to 400MHz)
- Slow arbitration clock. (up to 133MHz)
- Internal memory arbitration 1 & 2 clocks. (up to 133MHz)
- 8 x master clocks, can be asynchronous to EXTMC arbitration clocks (up to 200MHz) see Table 5-3.
- NFC main clock - should be integer divided from slow arbitration clock. (up to 50MHz)
- SDCLK - SDR/DDR clock to SDR/DDR SDRAM device.
- BCLK - NOR Flash/PSRAM clock WEIMv2 in synchronous mode.

5.3.2 Boot Scenarios

The EXTMC memory controllers allow booting from the following memories: NOR Flash devices (through the EIM) and NAND Flash devices (through the NFC) special signals coming from the SoC define the different booting options to those memories like

the memory data width, memory page size and other specific parameters for the initial access of the boot. For more details refer to the memory controllers detailed chapters and boot chapter.

5.3.3 Watermark Ports

Watermark regions are supported in the EXTMC while the configuration is handled by the CSU. The external memory spaces will have trust zone area's that only trust zone accesses will be able to reach. Non trust zone accesses will be blocked. The central security unit (CSU) has the registers that define those regions and send the indication of the region and if specific access is trust zone or not to the EXTMC.

The watermark indication is dynamic and can change for each access.

For details on the watermark configuration refer to the CSU chapter.

5.3.4 EXTMC I/O Multiplexing

The EXTMC gives the system the ability to multiplex some of its signals in the SoC to allow pin sharing between the different memory controllers. Multiplexing is possible on the "slow" channel only because of timing limitations.

Only shared i.MX53 pins signals/busses are routed through the IOMUXC toward the external devices. Signals (mainly controls) that have dedicated pins are directly routed from the memory controllers to the external devices.

5.4 External Memory Controller (EXTMC) Restrictions

5.4.1 Exclusive Access Support

EXTMC does not include an exclusive access monitor. Master 3 (M3) connected to ARM platform at i.MX53 returns EXOKAY for any exclusive access coming from ARM platform. For write accesses this means that the memory location is updated but exclusivity is not guaranteed.

5.4.2 Software LPMD

On i.MX53 Software LPMD done by using control bits on M4IF is not supported.

5.4.3 Data Paths

5.4.4 NAND Flash Restrictions/Limitations

- NFC does not support WRAP access type, so for example FEC accesses to NAND Flash are not supported.
- Using 'Read-Status' Command (that is, not using R/B signals at all, RBB_MODE=0)
  - To work with interleaved (and non-interleaved) schemes, this is the preferred operating mode.
  - In this mode, the status of each device is tested using the 'read-status' command. In interleaved mode, each device status is checked prior to accessing it.
  - This mode, enables use of "Number of Iterations" > "Number of devices", with no impact on performance.
- Using wired OR of device's R/B signals. (RBB_MODE=1)
  - It implies use of R/B signal, with all NAND devices R/B signals are connected in Wired-OR scheme.
  - In non-interleave mode - this mode works just as well as with 'read-status' command.
  - In interleave mode the performance degrades for "Number of Iterations" > "Number of devices" because each new round of accesses (that is, returning to first device), implies that all other devices return to their 'ready' state. This occurs because the NFC checks for 'ready' on the 'OR' R/B signal before re-accessing the first device in the next round. (For example, if using two devices and Number of Iterations = 6, the R/B checks on accesses 1,3 and 5, and the

controller waits for the other device to finish before allowing access to the first device.)

5.4.5 OneNAND Restrictions/Limitations

- For OneNAND devices the following limitation exists (since int_rdy is not in use); The modes described in the EXTMC spec allowing faster wakeup, or getting the interrupt from the EXTMC are not supported.
  - Poll the device and see that it is ready (SW performs read from the device).
  - Connect the RDY signal of the device to any GPIO pin and use it as an interrupt indicating on ready state.

Chapter 6
System Debug

6.1 Overview

This chapter describes the debug architecture of the i.MX53.

6.1.1 Introduction

This chapter describes the hardware and software debug and application development features and resources of i.MX53. There are core/platform-specific resources, resources associated with some of the more complex blocks, and chip-wide resources. Also discussed is the interface to external debug and development tools.

The debug architecture of i.MX53 is based on that of previous members of the i.MX application processor family. A small number of changes and extensions were necessary to accommodate new blocks.

An overview i.MX53's primary debug capabilities and features include:

- JTAG-based access (control, monitoring), built around the System JTAG Controller (SJC)
- Trace Port
- Real-time and Halt-mode debug and profiling capabilities of the ARM platform
- Real-time and Halt-mode debug capabilities of the SDMA core
- An SoC-wide cross-trigger system built around ARM's Embedded Cross Trigger (ECT)
- Visibility of pre-selected critical internal signals via pin muxing
- External memory interface/controller arbitration profiling

Each of these features are described in detail in the following sections of this chapter. i.MX53 also supports ARM CoreSight architecture for system debug and trace capabilities

6.1.2 Debug Strategy

- Software debug - (MSFT kernel)
- Trace the ARM platform activity via ETM trace port or ETB (ARM only)
- Control and monitor via JTAG
- Monitor pre-selected critical internal signals via pin multiplexing - scope

6.2 System JTAG Controller - SJC

The System JTAG Controller (SJC) block is the bridge between external development and test instrumentation and the internal JTAG-accessible debug and test resources. It implements and manages the daisy-chained topology consisting of its own TAP and those of the SDMA, a DSP core (not implemented on i.MX53), the ARM Core, and the ARM DAP. The ARM Core is not part of a daisy-chain. The DSP TAP is excluded by the SJC configuration tie-off, so there is no need to use the BYPASS IR.

6.2.1 JTAG Topology

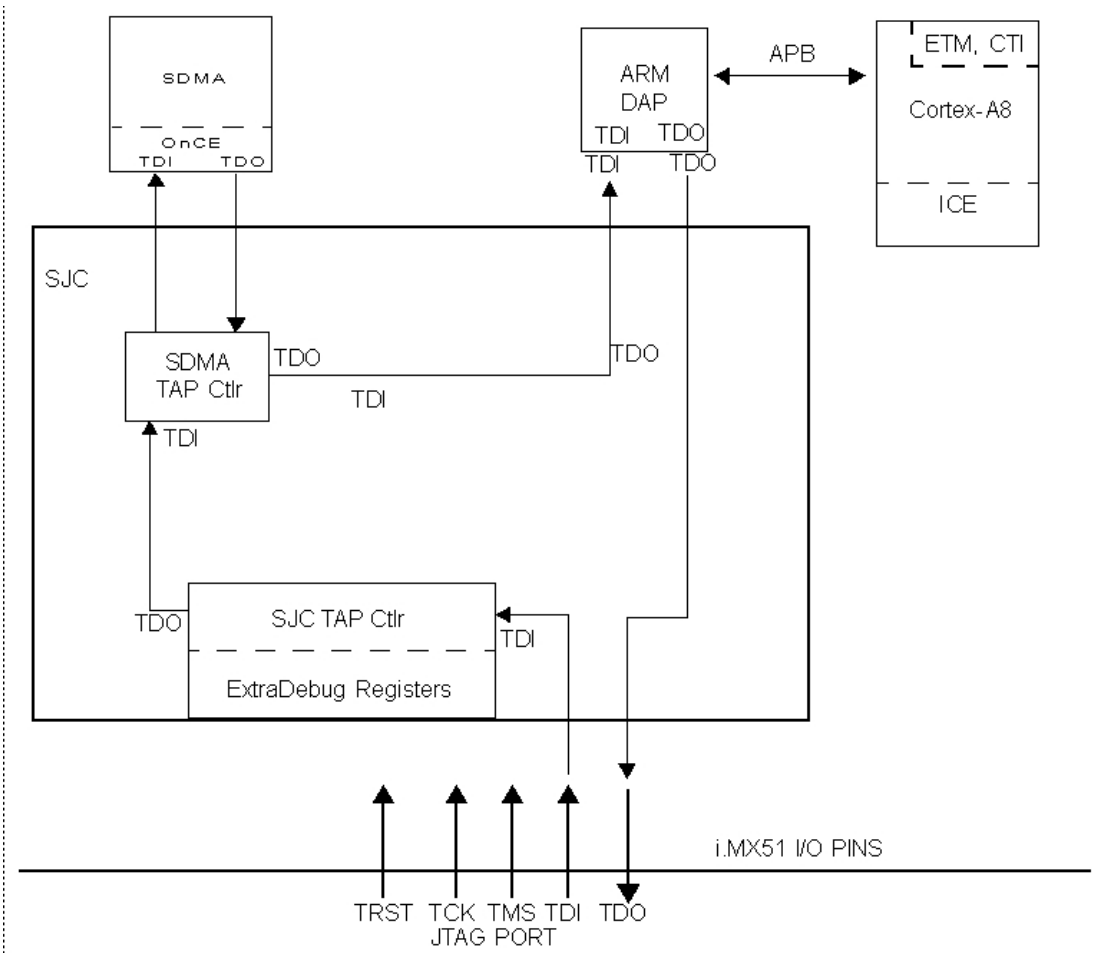

Figure 6-1. JTAG Connectivity

6.2.2 System JTAG Controller Main Feature

- IEEE P1149.1 (standard JTAG) interface to off-chip test and development equipment
  - includes an SJC-only mode for true IEEE 1149.1 compliance, used primarily for board-level implementation of boundary scan.
- Debug-related control and status, such as putting selected cores into reset and/or debug mode and the ability to monitor individual core status signals via JTAG.
- System status, such as the state of the PLLs (locked or not locked)
- Generic status and control, defined on a per-SoC basis by the architecture team
- Factory test related control/status such as PLL bypass and memory BIST
- Four levels of security, ranging from no security to no JTAG accessibility to the chip

6.2.3 SJC TAP Port

The SJC in i.MX53 supports the following standard JTAG pins: TRSTB, TDI, TDO, TCK, and TMS.

6.2.4 SJC Main Blocks

- Interface to the outside world via the standard JTAG pins
- Interface to the external Debug_Event pin
- A master TAP controller, which implements the standard JTAG state machine.
- Implementation of the mandatory and optional IEEE P1149.1 (JTAG) instructions
  - Mandatory: "EXTEST", "SAMPLE/PRELOAD", and "BYPASS"
  - Optional: "ID_CODE" (SoC JTAG ID register), "HIGHZ"
- Supports the SDMA's DR-path-only JTAG architecture by implementing the controller portion of it's TAP (including "BYPASS" as the default state) within the SJC
- Provides the serial interfaces to various DSP-domain JTAG resources (not implemented on i.MX53)
- The ExtraDebug registers, which implement a variety of control and status features
  - Three 32-bit insecure general purpose status registers
  - Two 32-bit secure status registers - one predefined, one general purpose
  - Control and status registers for debug, core, charge pump, PLL, and BIST related functions
  - Control bits for memory timing control (not used on i.MX53)
- Four levels of fuse-defined security, ranging from no security to no access.

Both predefined and user-defined (SoC integration team) Control and Status functions are supported by the SJC. The user-defined functions are defined and documented by the SoC integration team.

6.2.5 i.MX53 Specific SJC Features

6.2.5.1 JTAG Disable Mode

In addition to four different JTAG security modes that are implemented internally in the System JTAG Controller (SJC), there is an option to disable the SJC functionality by e-fuse configuration. This creates additional JTAG mode "JTAG Disabled" with highest

level of JTAG protection. In this mode all JTAG features are disabled. Specifically, the following debug features are disabled in addition to the features that were already disabled in "No Debug" JTAG mode:

- Memory BIST
- Boundary scan register (BSR)
- Non-Secure JTAG control registers (PLL configuration, Deterministic Reset, PLL bypass)
- Non-Secure JTAG status registers (Core status)
- Chip Identification Code (IDCODE)

Please see System Debug SJC Memory Map/Register Definition for i.MX53 specific SJC registers.

6.2.5.2 PROD ID and JTAG ID

i.MX53 PROD_ID=11111010 and JTAG_ID=0x1190_D01D.

Product revision (hw_rev[7:4] in IC Identification Module (IIM)) is = 4'b0000 accordingly.

6.3 CoreSight Design Kit

i.MX53 include ARM CoreSight component for multi core debug and trace solution. CoreSight component can be found in few hierarchy level: ARM Core, ARM platform and top level.

- ARM Core: include the following CoreSight components: ETM, CTI0
- ARM platform: include the following CoreSight components: ETB, ATB Replicator, CTI1, CTM
- Top level: include the following CoreSight components: debug access port (DAP), CTI2, CTI3, TPIU

6.3.1 Memory Map and Register Definition

Each CSDK component has a 4KB location block in the CoreSight memory map. The base address of the CoreSight location block is not fixed but the address offsets are fixed. Each CSDK component has a 4KB memory map, that is, 1K words.

Components connected to the DAP internal bus appear as part of a memory mapped structure with parallel address and two data busses, read data and write data. The bus master, JTAG-DP, controls the ARM platform in this structure the slaves, using normal bus transactions. The JTAG-DP reads and writes registers within this bus.

6.3.2 CoreSight Clock Enable

By default the CoreSight component clocks are enabled, the system get out from reset with all clocks enabled. The CoreSight clocks gating are controlled by programmable Clock Control Module (CCM) registers and DBGEN. The CCM allows control of each CoreSight component separately (by default allowed) and DBGEN that allow and disable all debug clocks. DBGEN is raised when detecting activity on JTAG ports (TMS) and descend on reset (by dap_sys) or controlled by ARM. If both CCM registers bits and DBGEN are high then clock is propagate to CoreSight component.

6.3.3 CoreSight DAP and DAP_SYS

ARM's DAP has several functions. DAP_SYS is a wrapper around DAP and is the FSL block that is actually instantiated in a design (DAP is contained within DAP_SYS). The following list is a summary of the features provided by DAP_SYS.

- Enables debug-related communication between various parts of the system
  - It is a modular block
  - Slave-side support for JTAG and APB (ARM Peripheral Bus) protocols.
  - Debug master can access many debug resources in real time without having to halt the core
  - Enabling of system access to anything connected to the Debug-APB via the APB multiplexer.
- ROM Table - provides a list of memory locations of CoreSight components connected to the Debug APB. Visible from both tools and system access.
- AHB to APB gasket to translate System AHB accesses to APB (input as system APB to the DAP).
- APB Decode to issue select signals to CoreSight components on APB, and handle the PSLVERR and PREADY signals from the components to the DAP.
- AHB-Lite to AHB converter, to translate DAP's AHB-Lite accesses to system's AHB protocol.
- Debug and Reset logic to generate DBGEN signal and reset signals.

The CoreSight components that reside on the Debug-APB include all Embedded Cross Trigger blocks, the ETM, and the ETB.

6.3.4 Embedded Cross Trigger (ECT)

System events, such as a debug request, a core entering or exiting debug mode, the occurrence of a breakpoint or watch point, the occurrence of a particular error, the state of a buffer, etc., can be useful or even essential for debugging or profiling system performance. Whatever the source of the event, the embedded cross trigger implements a flexible, programmable mechanism to transport these events from a source to one or multiple destinations. This includes handling handshake requirements with both the source and the destination as needed and synchronization of signals from different clock domains. The end result is that events of interest that occur in one domain, such as in the ARM Cortex A8 domain, can be recognized and responded to be a destination domain, such as the Smart Direct Memory Access (SDMA).

i.MX53 uses the CoreSight ECT (provided by ARM as part of their full CoreSight Debug Support package) and a custom wrapper to accommodate the various necessary interface scenarios. The ECT (as delivered by ARM) consists of two major blocks - a central Cross Trigger Matrix (CTM) and a Cross Trigger Interface (CTI) block. A Freescale-custom wrapper is added to the CTI to accommodate a variety of different input and output interface scenarios. The wrapped CTI is called the Extended CTI and is configured on a signal by signal basis with port tie-offs.

i.MX53's ECT architecture consists of a single CTM and three wrapped CTIs covering 3 basic groups of functionality as follows:

- CTI0 - is in the Cortex A8 core
- CTI1 - is in the ARM Cortex-A8 core platform, 2 trigger in and 2 trigger out is used by the platform and the others by the device peripherals
- CTI2 - is in the SoC level, is by SDMA
- CTI3 - is in the SoC level, is used by ARM platform peripherals (IPU, GPU, VPU)

Detail CTI pin assignment can be found in CoreSight CTI.

Figure 6-2 is a simple illustration of the relationship between the two processor domains, the SJC and peripherals, and the ARM CoreSight DAP. APB is an AMBA bus used for debugging. It defines what debug and trace components are required and how they are connected. The DAP is the Debug-APB master of the following debug units: 4 CTI blocks, ETM, ETB, TPIU and Cortex A8 debug unit. The Debug-APB bus differs from system-level APB's in that it can be directly accessed via JTAG as well as from the ARM Core. Block selects for each slave module on the Debug-APB are generated by the DAP_SYS.

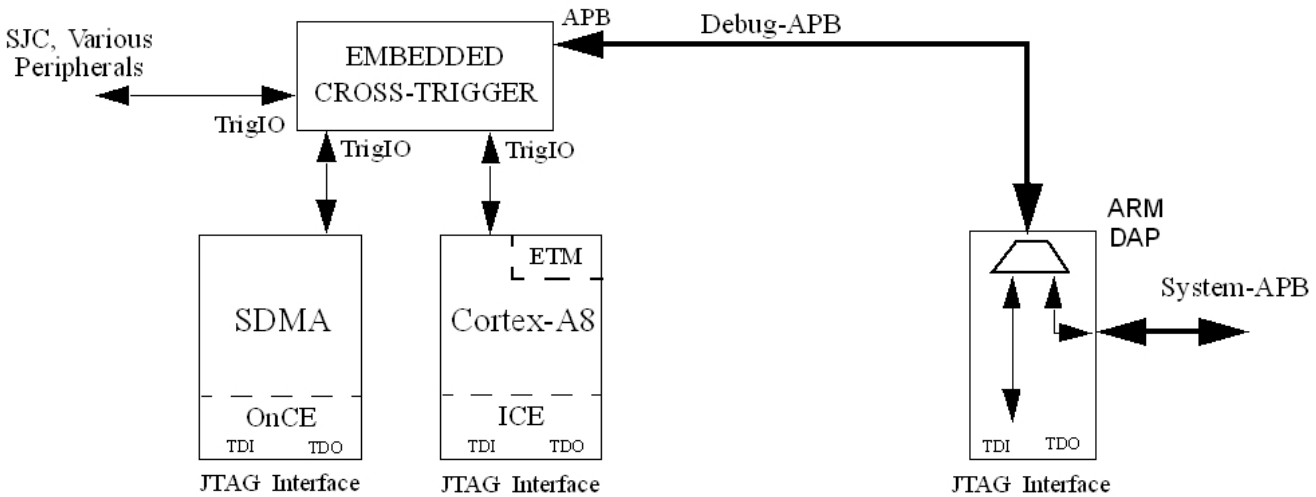

Figure 6-2. Embedded Cross Trigger Topology

Figure 6-3 illustrates the connectivity between the CTM and CTIO components of the CoreSight ECT.

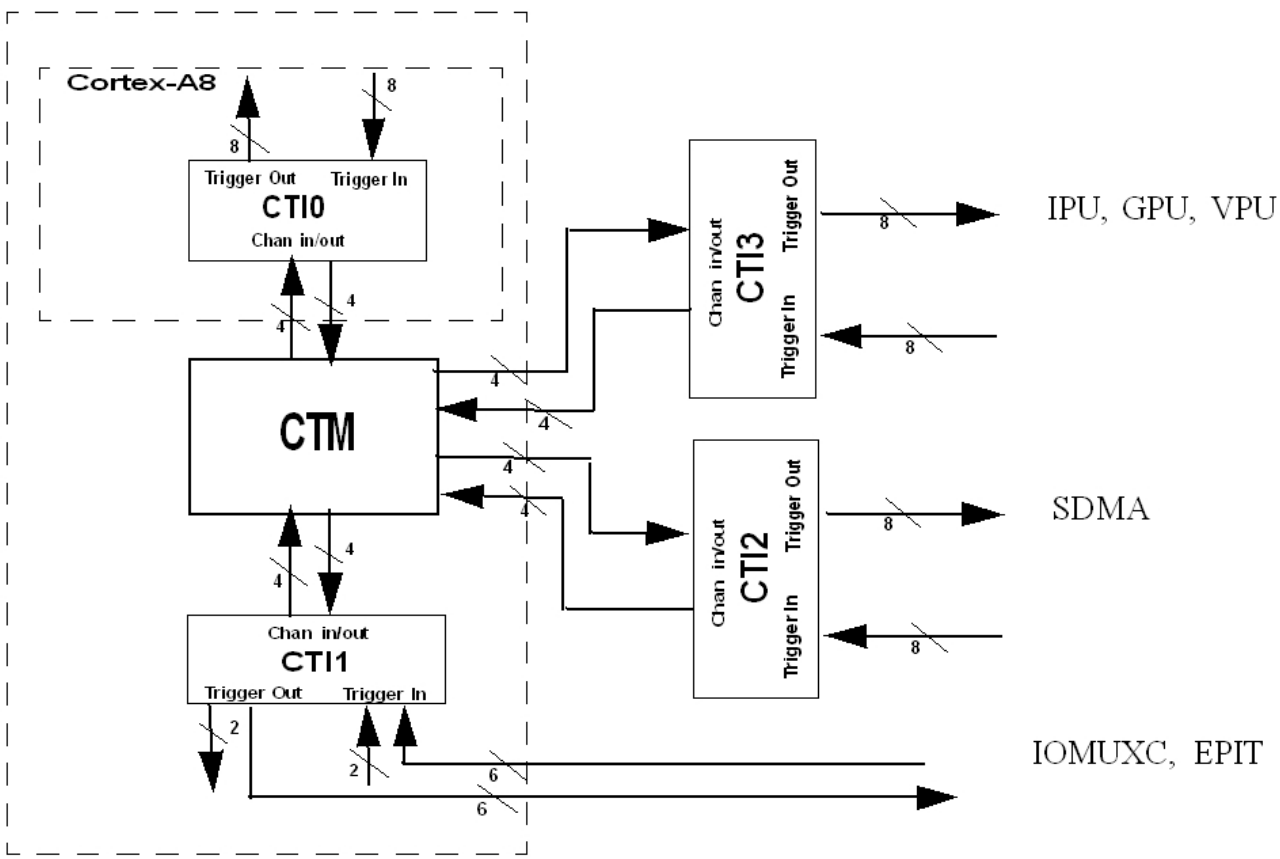

Figure 6-3. Embedded Cross Trigger - Basic Architecture

6.3.4.1 CoreSight CTM

The Cross Trigger Matrix (CTM) is provided by ARM. The CTM is a relatively simple block with no programmability. On i.MX53, it's configured to have 4 input and 4 output channels. Whatever comes in on an input channel is simply routed to all corresponding output channels. For instance, if a trigger input comes in on input channel 0 from CTI0, it is routed to output channel 0 to CTI1, CTI2 & CTI3. All selection of drivers and receivers for an event is done in the individual CTI blocks.

The final feature provided by the CTM is handshake with each CTI. This insures that as trigger signals cross different clock domain boundaries, they won't be lost due to slower downstream sampling frequencies. It is a simple mechanism in which a CTI holds an output until it receives the acknowledgement from the CTM. Handshake is also implemented in the reverse direction, insuring that a trigger signal propagating from the CTM to a CTI won't be missed by the CTI.

6.3.4.2 CoreSight CTI

The CTI (Cross Trigger Interface) is also provided by ARM. A summary description of the CTI is provided here, but please refer to ARM documentation for detailed information. As mentioned earlier, there are 3 CTI's in i.MX53. Each of these has 8 trigger inputs and 8 trigger outputs that connect to logic in the domain to be debugged or profiled. Each CTI also includes a 4 channel interface to the CTM (4 inputs and 4 outputs). The CTIs are wrapped with additional logic to from the Extended CTI, which is described in the next section.

6.3.4.3 Extended CTI (CTI Wrapper)

This wrapper consists of additional logic for each input and each output trigger to implement several features that can be selected or enabled with hard tie-off's on the block's boundary. It is combined with ARM's CTI to form the CTI_Extended block. A functional diagram of the input wrapper is shown in Figure 6-3. A summary of the extended input features implemented by logic in the wrapper is as follows:

- Invert the incoming signal
  - The ARM CTI assumes all inputs are active-high. An active-low input must first be inverted before going into the ARM CTI
- Sample the incoming trigger signal with a clock synchronous to the incoming signal
  - Samples the incoming trigger with it's own clock
- Convert the incoming signal to a pulse
  - Used when an input trigger has a long assertion time. Destinations may be sensitive to a long assertion time and may see it as multiple input triggers.
- Implement holding logic to insure that the ARM CTI captures and acknowledges the incoming signal. The holding logic clock must be synchronous to the clock that generated the input trigger.
- Provides a synchronized or asynchronous acknowledge signal back to the origin of the trigger.
  - If the asynchronous trigger source requires an ACK signal back from the CTI, but a clock from that source is not available to the CTI, the source must first synchronize the received ACK before using it in the trigger source logic.

6.3.5 CoreSight Trace Port Interface (TPIU)

The TPIU is one of the CoreSight trace sink components it acts as a bridge between the on-chip trace data to a data stream that is then driven out the trace port. ATB interface is used by the TPIU accepts trace data from a trace source, either direct from a trace source or using a Trace Funnel. The TPIU has 32 bit connected to the Chip pad. The APB interface is the programming interface for the TPIU configuration.

6.4 Cortex A8 Core and Platform

Cortex A8 Debug architecture includes support for TrustZone and CoreSight. The memory-mapped external debug interface replaces the coprocessor interface defined in the previous version of the Debug architecture. A full access to the processor debug capability available by Cortex A8 debug register map through the *Advanced Peripheral Bus* (APB) slave port. The core include Processor Debug Unit allow: stop program execution, examine and alter processor and coprocessor state, examine and alter memory and input/output peripheral state and restart the processor core.

6.4.1 Cortex A8 Core Debug Support Features

- CoreSight Embedded Trace Macro (ETM11) - trace generator for the Cortex A8 core
- Support for a TrustZone-related 3-level debug scheme:
  - Debug everywhere
  - Debug in Non-Secure privileged and user, and Secure user
  - Debug in Non-Secure only
- Embedded ICE-RT logic
  - Support for both monitor-mode and halt-mode debugging.
  - Core run/halt control, debug status/control
  - Breakpoint/watch point control
  - Core- and memory-mapped resource examination/modification
- Data communication channel between ARM Core and host debugger via JTAG
- PMU - Performance Metrics Unit used for system profiling and debug.
- CP15 register for debugging the MMU, I & D L1 cache, and TLB
- EVTMON - L2 Event Monitor - Supports debug and profiling of the ARM's L2 cache activity

6.4.2 Embedded Cross Trigger Interface

Please refer to the Embedded Cross Trigger section of this chapter for detailed information about the Core and platform interface to that subsystem.

6.4.3 Additional Platform Debug Functionality

- CoreSight Embedded Trace Buffer (ETB11) - 4 Kbyte RAM array to be used for on-chip capture of trace data output from the ETM11
- ATB Replicator to connect the trace data to TPIU (Trace Port Interface) and ETB (Embedded Trace Buffer).
- Debug Visibility - select critical signals routed to the I/O pads as alternate outputs for external visibility

6.5 Smart Direct Memory Access (SDMA) Core

The Smart Direct Memory Access (SDMA) is a dedicated, programmable DMA engine. It is an integration of a 32-bit RISC core and DMA-specific hardware, and includes ports for the ARM platform domain and a peripheral domain, along with a burst-capable port for direct external memory access. The SDMA and it's integration in i.MX53 is unchanged from previous SoCs.

The main SDMA debug features:

- OnCE - On Chip Emulator, provides the following capabilities:
  - SDMA core control - run/halt/single-step
  - SDMA core register/memory-map access
  - Event detection, watch points, and hardware breakpoints
  - Real time buffer and PC trace buffer capability
- Trace buffer
  - Contains information to identify the 32 last changes of flow detected during a program execution
- Context dump
  - include information about all the channel dump activity
  - Current contents of SDMA RAM
- ROMPATCH

6.5.1 SDMA On Chip Emulation Module (OnCE) Feature Summary

The SDMA debug features are primarily defined by the OnCE portion of it's design, which are summarized as follows:

- Memory And Register Access - dedicated logic enables user-access to SDMA memory and register locations. These accesses are supported only when the processor is in debug mode.
- Event Detection Unit - watches signals from the data memory bus (DMBus) which is used by the RISC core to access its RAM, ROM, and memory-mapped registers
- Watch points - one output signal is available to watch event matching conditions at the chip level. Match conditions are defined by programming memory-mapped registers.
- Hardware Breakpoint - a counter is decremented after an event detection. A debug request is sent to the SDMA core only when the counter reaches the value of zero. It is possible to program the initial value of the counter or to disable the use of the counter if a debug request must be generated after each event detection.
- Real Time Buffer - The Real Time Buffer Register (RTB) is a single 32-bit memory-mapped register which can be accessed as a regular memory location during program execution. It is used to store and retrieve run time information without putting the SDMA in debug mode. Each write to this register causes an event. This register is, in fact, located in the OnCE. Executing through JTAG, a buffer command exports the content of this register through the JTAG port.
- Core Control (Core Status / Single Stepping) - Commands are provided to monitor and control processor activity. The commands can halt the core, rerun the core from another address location, and get processor status.
- Trace Buffer - a 32x32 buffer which records the last 32 changes of flow during program execution. The buffer stores data in a modulo fashion (that is, the 33rd instruction change replaces the 1st). Captured trace information is retrieved via reads to the Trace Buffer Register.

6.5.2 Other SDMA Debug Functionality

- Core Trace - basic core trace capability is available through debug visibility functionality only. ETM/Nexus trace capability does not exist.
- ROM Patch - can be accomplished by manipulating the CHN0ADDR register through JTAG or via the ARM platform's ability to write to SDMA OnCE registers. This must be done right after reset and before the SDMA core is enabled to begin processing events.
- Additional debug control/status interaction with the SJC

- SJC-controlled Debug Request
- SJC-readable Debug Acknowledge (in debug mode)
- Debug clock control - allows SJC to force clocks on for debug purposes
- Debug core state (SDMA RISC Core State) - 4 bits accessible from the SJC via JTAG

- Debug Visibility - observable outputs as alternate (programmable) output functions of I/O pins
  - Debug Request, Debug Mode
  - Debug Yield
  - Debug Event Channel[5:0] (indicates requesting event or channel being processed)
  - Debug PC [13:0] (for SDMA core trace)
  - Debug core state [3:0]
  - Debug Real-time Buffer write
  - Debug Addr/Data match
  - Debug bus error
  - Debug bus device
  - Debug bus r/w
  - Debug Event Channels[7:0]
  - Debug Core Run (active when core is running)

6.5.3 Embedded Cross Trigger Interface (SDMA)

Please refer to the Embedded Cross Trigger section of this chapter for detailed information about the SDMA interface to that subsystem.

6.6 External Memory Controller (EXTMC)

The second-generation External Memory Controller (EXTMC) contains an arbitration profiling unit. This can be used to monitor and profile the dynamic arbitration behavior during operation. Several internal signals would be routed out by EXTMC debug unit to give SoC the capability to track the internal logic mainly for the arbitration mechanism and memory served accesses. In addition, the debug unit gives the ability to profile a master connected to EXTMC and get the bus performance of the arbitration.

Signals routed to 51-bit ipp_do_emi_debug bus are routed to the PAD.

Profiling unit include

- Register that saves the maximal time that a selected master was pending without getting the bus - MDSR0

- The maximum value of the dynamic priority which was selected - MDSR0
- Counters to record the number of access that each master performed through each channel - MDSR2-5
- Counter of the total number of accesses a specific request (or type of request) has accessed the bus can be fast, slow or intr - MDSR6
- Register that sums of "time for bus" the time it took a specified request (or type of request) to get the bus - MDSR7
- Register that sums the time it took each access to get the bus (pending time) - MDSR8
- Ability to reset all the counters

The EXTMC profiling logic includes a START signal, which comes from the ECT. Thus, any definable ECT condition can be used to initiate profiling.

6.7 Debug Visibility - IOMUX

Certain predefined, internal signals can be viewed at the package pins. The pad logic for most pins includes an IOMUX, allowing that pad to be shared across multiple functions. Each pad has a primary function that is selected at reset. The alternate functions, such as displaying the state of an internal signal for debug purposes, is selected by reprogramming the IOMUX.

Table 6-7. Debug Visibility

Block	Signals
SDMA	debug_mode, debug_bus_error, debug_bus_device[4:0], debug_bus_rwb, debug_matched_dmbus, debug_rtbuffer_write, debug_evt_chn_lines[7:0]
EXTMC	ipp_do_emi_debug[50:0]
IPU	ipu_diagbus[15:0]
GPU3D	SYS_GC_debug_out[16:0]
TPIU	TRACEDATA[31:0]

The ARM Platform Chapter of the i.MX53 Block Guide contains a complete listing of debug visibility signals and their assigned pins.

6.8 ARM Platform Peripherals

6.8.1 Image Processing Unit (IPU)

The Image Processing Unit (IPU) block includes a debug unit that allows routing of its signals to the SoC level. The signals muxing to be routed to top are controlled by DP Debug Control register (DP_DEBUG_CNT) and are connected to 16 bit diagnostic bus (ipu_diagbus). The IPU also include status register (DP_DEBUG_STAT) that can be used for debug.

The IPU can enter the system into debug mode by the cross trigger system.Three of the IPU signals are input to ETC: IPU general interrupt, IPU error interrupt and IPU end of frame; those signals can trigger the system to enter debug mode.

More details on signal muxing and IPU debug registers can be found in the IPU chapter.

6.8.2 Video Processing Unit (VPU)

The Video Processing Unit (VPU) can enter the system into debug mode by the cross trigger system. Three of the VPU signals are input to ETC: VPU idle, VPU interrupt and VPU underrun; those signals can trigger the system to enter debug mode.

The VPU internal register can be approach the AHB bus for further analysis.

6.8.3 GPU3D

The GPU3D support propagating debug information from the core over a 32b wide debug bus. The debug outputs are directed to only 16 visible ports. GPU3D include debug control bus SYS_GC_gpio[15:0] that selects which debug signals are exposed on the debug out bus GC_SYS_debug_out[31:0].

GPU3D can enter the system into debug mode by the cross trigger system. 2 of GPU3D signals are input to ETC: GPU3D error interrupt and GPU3D end of frame; those signals can trigger the system to enter debug mode.

6.9 Supported Tools

i.MX53 support RealView ARM Debugger, the debugger should be connect to i.MX53 from host by RealView ICE protocol converter.

6.10 Interrupt Visibility

Similar to debug visibility, i.MX53 includes multiplexrs that allow users to view selected internal interrupts. Up to five pads support this as alternate pad output functions, allowing the user to view up to five different interrupt sources simultaneously. These five signals also route to ECT inputs, allowing them to generate ECT trigger events as desired.

6.11 Miscellaneous

6.11.1 SoC-level Bus Trace

There is no SoC-level bus trace capability on i.MX53.

6.11.2 Clock / Reset / Power

The interaction between the debug system and the system clock, reset, and power control blocks includes enhancements to insure that status of critical system components can be monitored at all times, and that a debugger can insure that all critical clocks and power are enabled when needed. Specifically, a master signal coming from an SJC control bit and going to the Clock/PLL logic is implemented for each major clock domain. The same is done for each power domain. Historically, JTAG based operations have not been possible under certain system conditions. For i.MX53, the debugger must have the ability to determine the status of all critical system elements and to override any condition that would prevent the desired debug resources from operating properly.

6.11.3 RVI connection Settings

The RVI connection settings are shown in the figures below.

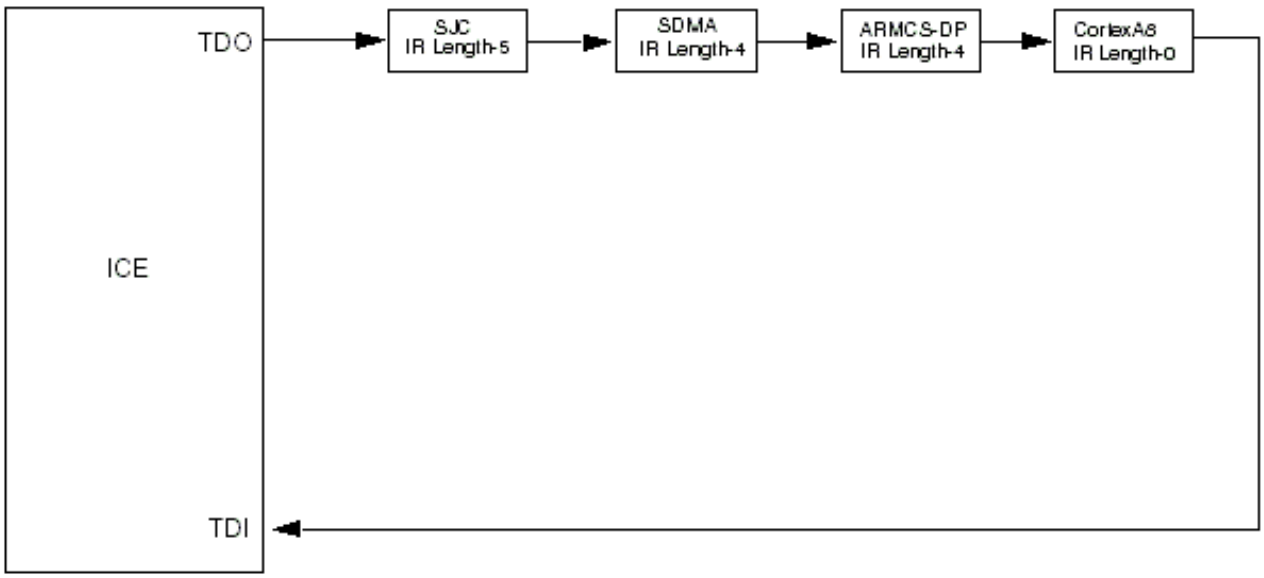

Figure 6-4. JTAG chain configuration

Table 6-8. CoreSight-A8 Base Address Configuration

Item	Value
CoreSight AP index	0x00000001
CoreSight base address	0xC0008000
Code Sequences Enabled	--
Code Sequence Address	0x0007FF80
Code Sequence Size (bytes)	0x00000080
Code Sequence Timeout (ms)	100
Bypass memory protection when in debug	True/False
Clear breakpoint hardware on connect	TrueFalse
Unwind vector when halt on SWI	True/False
Ignore debug priviledge errors when starting core	--
JTAG timeouts enabled	True/False

6.12 System Debug SJC Memory Map/Register Definition

The following a summary of the SJC registers used in i.MX53. This summary takes precedence is any discrepancy between the information found here, and the information in the SJC register summary arises.

SJC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0000_0000	General Purpose Unsecured Status Register 1 (SJC_GPUSR1)	32	R	0000_0000h	6.12.1/438
0000_0001	General Purpose Unsecured Status Register 2 (SJC_GPUSR2)	32	R	0000_0000h	6.12.2/440
0000_0002	General Purpose Unsecured Status Register 3 (SJC_GPUSR3)	32	R	0000_0000h	6.12.3/441
0000_0003	General Purpose Secured Status Register (SJC_GPSSR)	32	R	0000_0000h	6.12.4/442
0000_0004	Debug Control Register (Secured) (SJC_DCR)	32	R/W	0000_0000h	6.12.5/442
0000_0005	Security Status Register (SJC_SSR)	32	R	0000_0000h	6.12.6/444
0000_0006	Charge Pump Configuration Register (SJC_CPCR)	32	R	0000_0000h	6.12.7/446
0000_0007	General Purpose Clocks Control Register (SJC_GPCCR)	32	R/W	0000_0000h	6.12.8/446
0000_0008	PLL Bypass Register (SJC_PLLBR)	32	R/W	0000_0000h	6.12.9/448
0000_0009	General Purpose Unsecured Control Register 1 n (SJC_GPUCR1)	32	R/W	0002_0000h	6.12.10/ 450
0000_000A	General Purpose Unsecured Control Register 2 n (SJC_GPUCR2)	32	R/W	0511_0981h	6.12.11/ 452
0000_000B	General Purpose Unsecured Control Register 3 n (SJC_GPUCR3)	32	R/W	0000_0000h	6.12.12/ 453
0000_000C	General Purpose Secured Control Register (SJC_GPSCR)	32	R/W	0000_0000h	6.12.13/ 456
0000_000D	Test Register (SJC_TESTREG)	16	R/W	0000h	6.12.14/ 456
0000_000E	Serial Access Select Register (SJC_SASR)	32	R/W	0000_0000h	6.12.15/ 457
0000_000F	BIST Configuration Register 1 (SJC_BISTCR1)	32	R/W	0000_0000h	6.12.16/ 457
0000_0010	BIST Configuration Register 2 (SJC_BISTCR2)	32	R/W	0000_0000h	6.12.17/ 459
0000_0011	BIST Configuration Register 3 (SJC_BISTCR3)	32	R/W	0000_0000h	6.12.18/ 460
0000_0012	BIST Configuration Register 4 n (SJC_BISTCR4)	32	R/W	0000_0000h	6.12.19/ 461
0000_0013	BIST Configuration Register 5 (SJC_BISTCR5)	32	R/W	0000_0000h	6.12.20/ 463
0000_0014	Bist Configuration Register 6 (SJC_BISTCR6)	32	R/W	0000_0000h	6.12.21/ 464
0000_0015	Bist Configuration Register 7 (SJC_BISTCR7)	32	R/W	0000_0000h	6.12.22/ 464
0000_0016	Memory BIST Pass-Fail Register 1 (reserved for Test) (SJC_MBISTPASSR1)	32	R	0000_0000h	6.12.23/ 465

Table continues on the next page...

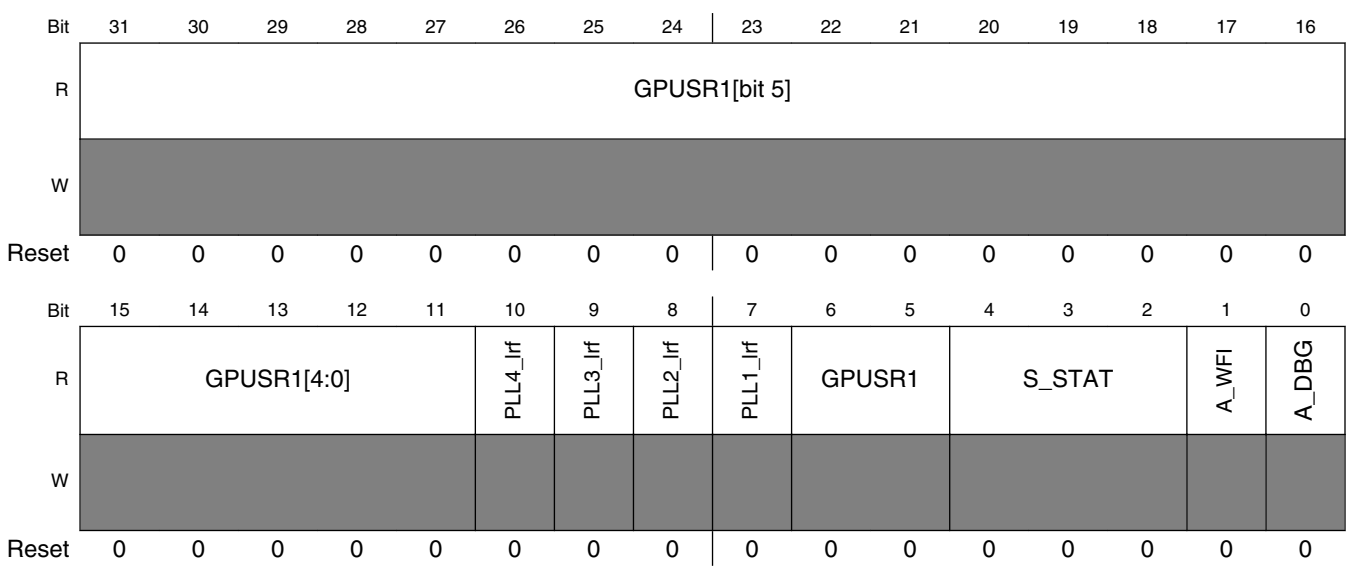
SJC memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0000_0017	Memory BIST Pass-Fail Register 2 (SJC_MBISTPASSR2)	32	R	0000_0000h	6.12.24/ 467
0000_0018	Memory BIST Done Register 1 (SJC_MBISTDONER1)	32	R	0000_0000h	6.12.25/ 468
0000_0019	Memory BIST Done Register 2 (SJC_MBISTDONER2)	32	R	0000_0000h	6.12.26/ 470
0000_001B	Memory BIST Mask Register 2 (SJC_MBISTMASKR2)	16	R/W	0000h	6.12.27/ 470
0000_001C	BIST Pass-Fail Register (SJC_BISTPASSR)	32	R	0000_0000h	6.12.28/ 471
0000_001D	BIST Done Register (SJC_BISTDONER)	32	R	0000_0000h	6.12.29/ 471
0000_001E	Monitor BIST Select Register (SJC_MONBISTSELR)	32	R/W	0000_0000h	6.12.30/ 472
0000_001F	RVAL/WVAL Control Register (SJC_RWVALCR)	32	R/W	0000_0000h	6.12.31/ 472

6.12.1 General Purpose Unsecured Status Register 1 (SJC_GPUSR1)

The General Purpose Unsecured Status Register 1 is a read only register used to check the status of the different Cores and of the DPLL. The rest of its bits are for general purpose use.

Address: SJC_GPUSR1 is 0h base + 0h offset = 0000_0000h

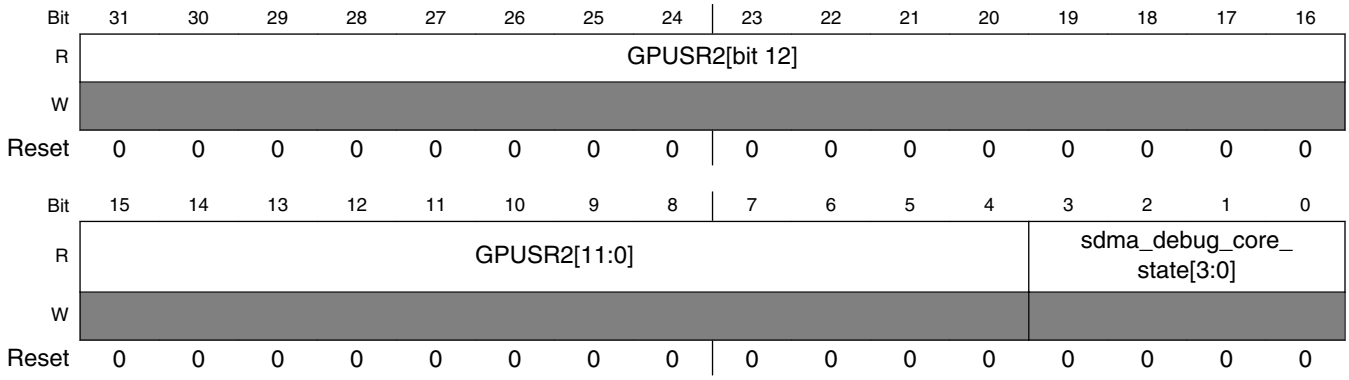


SJC_GPUSR1 field descriptions

Field	Description
31–11 GPUSR1	General Purpose Unsecured Status Register Register is used for testing and debug.
10 PLL4_lrf	Status bit indicating if dpll4 is locked 0 LL not locked 1 LL locked
9 PLL3_lrf	Status bit indicating if dpll3 is locked 0 LL not locked 1 LL locked
8 PLL2_lrf	Status bit indicating if dpll2 is locked 0 LL not locked 1 LL locked
7 PLL1_lrf	Status bit indicating if dpll1 is locked 0 LL not locked 1 LL locked
6–5 GPUSR1	General Purpose Unsecured Status Register Register is used for testing and debug.
4–2 S_STAT	3 LSBits of SDMA core statusH.
1 A_WFI	ARM core wait-for interrupt bit Bit 1 is the ARM core standbywfi (stand by wait-for interrupt). When this bit is HIGH, ARM core is in wait for interrupt mode.
0 A_DBG	ARM core debug status bit Bit 0 is the ARM core DBGACK (debug acknowledge) DBGACK can be overwritten in the ARM core DCR to force a particular DBGACK value. Consequently interpretation of the DBGACK value is highly dependent on the debug sequence. When this bit is HIGH, ARM core is in debug.

6.12.2 General Purpose Unsecured Status Register 2 (SJC_GPUSR2)

Address: SJC_GPUSR2 is 0h base + 1h offset = 0000_0001h

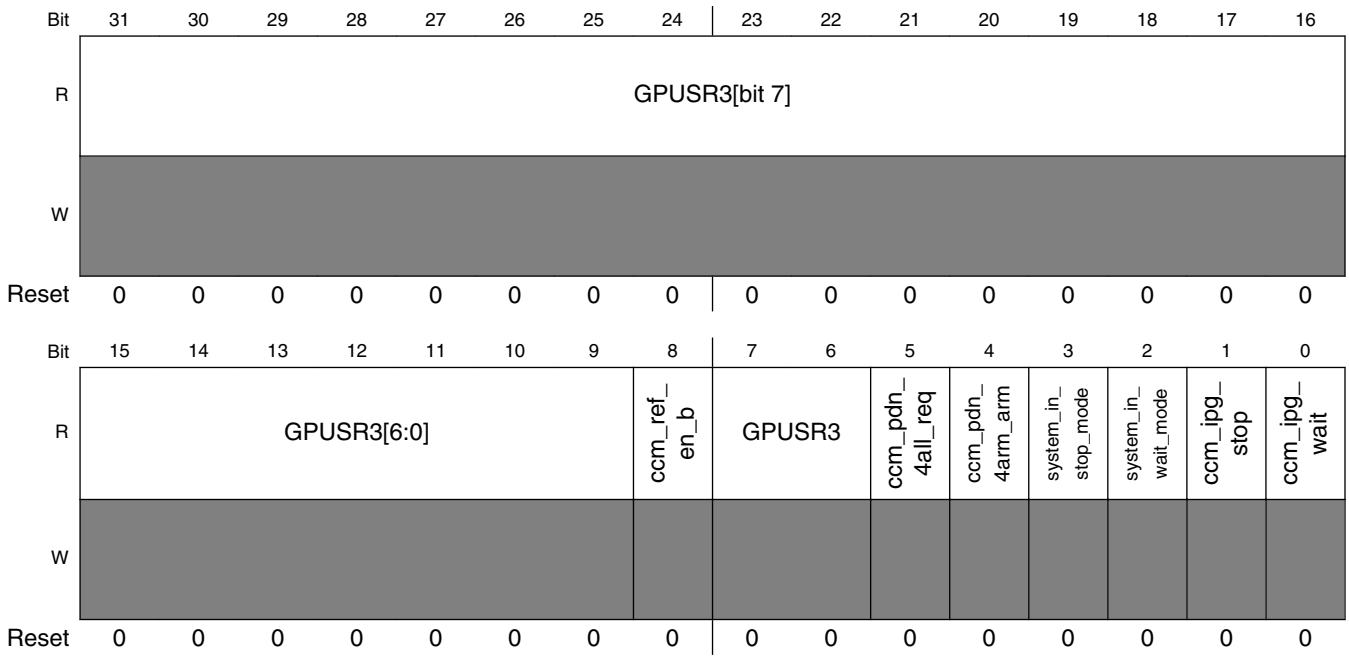


SJC_GPUSR2 field descriptions

Field	Description
31–4 GPUSR2	General Purpose Unsecured Status Register Register is used for testing and debug.
3–0 sdma_debug_ core_state[3:0]	SDMA core status (ipc_cstatus[3:0]). NOTE-The bits are read '0' unless visibility of SDMA Debug signals is enabled (SDMA Config Register, RTDOBS bit). Settings: 0000 PGM 0001 DATA 0010 Change Flow 0011 Set Wakeup 0100 DEBUG 0101 FU Bus 0110 SLEEP 0111 Save 1000 Program in Sleep 1001 Data in Sleep 1010 Change Of Flow in Sleep 1011 Error in Loop in Sleep 1100 Debug in Sleep 1101 Functional Unit in Sleep 1110 Sleep After Reset 1111 Restore See SDMA spec for details.

6.12.3 General Purpose Unsecured Status Register 3 (SJC_GPUSR3)

Address: SJC_GPUSR3 is 0h base + 2h offset = 0000_0002h



SJC_GPUSR3 field descriptions

Field	Description
31–9 GPUSR3	General Purpose Unsecured Status Register Register is used for testing and debug.
8 ccm_ref_en_b	Indicates if external oscillator is enabled. Settings 0 external oscillator disabled 1 external oscillator enabled
7–6 GPUSR3	
5 ccm_pdn_4all_req	Indicates a request to Global Power Controller (GPC) to power down all units Settings 0 no power down request to GPC 1 power down request sent to GPC
4 ccm_pdn_4arm_arm	Indicates a request to GPC to power down ARM Settings 0 no power down request to GPC 1 power down request sent to GPC
3 system_in_stop_mode	Indicates system is in stop mode Settings 0 system not in stop mode 1 system in stop mode
2 system_in_wait_mode	Indicates system is in wait mode Settings 0 system not in stop mode 1 system in stop mode
1 ccm_ipg_stop	Indicates CCM started stop entrance procedure Settings 0 CCM did not start stop entrance procedure 1 CCM started stop entrance procedure

Table continues on the next page...

SJC_GPUSR3 field descriptions (continued)

Field	Description
0 ccm_ipg_wait	Indicates CCM started wait entrance procedure Settings 0 CCM did not start wait entrance procedure 1 CCM started wait entrance procedure

6.12.4 General Purpose Secured Status Register (SJC_GPSSR)

The General Purpose Secured Status Register is a read only register used to check the status of the different critical information in the SoC. This register cannot be accessed in insecure modes.

Address: SJC_GPSSR is 0h base + 3h offset = 0000_0003h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SJC_GPSSR field descriptions

Field	Description
31–0 GPSSR	General Purpose Secured Status Register Register is used for testing and debug.

6.12.5 Debug Control Register (Secured) (SJC_DCR)

This register is used to control propagation of the debug request from the DE_B pad to the cores and debug signals from the embedded cross-trigger block to the DE_B pad. For more details see the SJC block guide.

Address: SJC_DCR is 0h base + 4h offset = 0000_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	DCR[bit 9]															
W

R	DCR[8:0]									direct_arm_req_en	direct_sdma_req_en	direct_dsp_req_en	debug_obs	de_to_DSP	de_to_SDMA	de_to_ARM
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0				

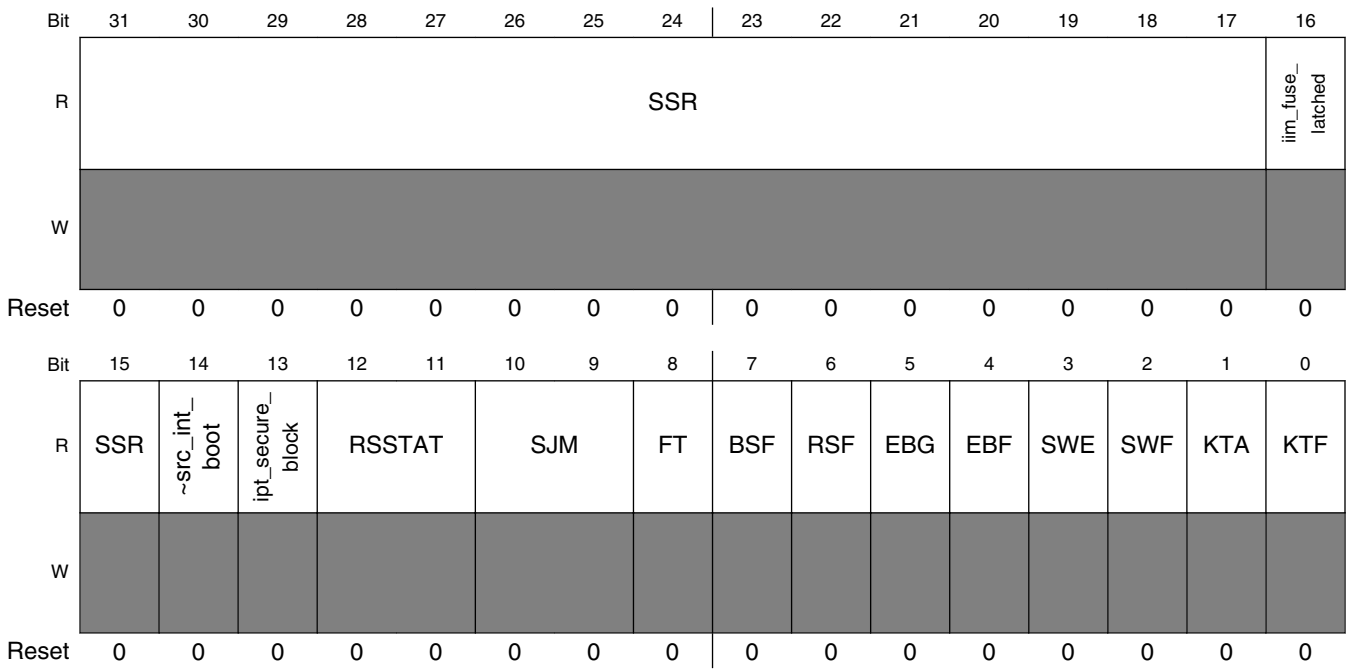
SJC_DCR field descriptions

Field	Description
31–7 DCR	General Purpose Unsecured Status Register Register is used for testing and debug.
6 direct_arm_req_en	Debug enable of the arm debug request This bit controls the propagation of debug request DE_B to the arm. Settings 0 - Disable propagation of system debug to (DE pin) to arm. 1 - Enable propagation of system debug to (DE pin) to arm. 0 Disable propagation of system debug to (DE pin) to arm. 1 Enable propagation of system debug to (DE pin) to arm.
5 direct_sdma_req_en	Debug enable of the SDMA debug request This bit controls the propagation of debug request DE_B to the SDMA. Settings 0 - Disable propagation of system debug to (DE pin) to SDMA. 1 - Enable propagation of system debug to (DE pin) to scam. 0 Disable propagation of system debug to (DE pin) to sdma. 1 Enable propagation of system debug to (DE pin) to sdma.
4 direct_dsp_req_en	Debug enable of the dsp debug request - This bit controls the propagation of debug request DE_B to the dsp. - No DSP in i.MX53 - so this bit is not connected outside. Settings 0 - Disable propagation of system debug to (DE pin) to dsp 1 - Enable propagation of system debug to (DE pin) to dsp
3 debug_obs	Debug observability This bit controls propagation of the system debug signal from Embedded Cross Trigger Block (ECT) to DE_B pad (can propagate debug acknowledge for example). Settings 0 - disable sjc_debug_b_oe 1 - enable sjc_debug_b_oe (when system is in debug) 0 Disable propagation of system debug to DE pin 1 Enable propagation of system debug to DE pin
2 de_to_DSP	DSP debug request input propagation - This bit controls propagation of the debug request to the DSP . - No DSP in i.MX53 - so this bit is not connected outside. Settings 0 - Disable propagation of debug request to DSP 1- Enable propagation of debug request to DSP
1 de_to_SDMA	SDMA debug request input propagation This bit controls propagation of the debug request to the SDMA. Settings 0 - Disable propagation of debug request to SDMA 1- Enable propagation of debug request to SDMA 0 Disable propagation of debug request to SDMA 1 Enable propagation of debug request to SDMA
0 de_to_ARM	ARM platform debug request input propagation This bit controls propagation of the debug request to the ARM platform. Settings 0 - Disable propagation of debug request to ARM platform 1- Enable propagation of debug request to ARM platform 0 Disable propagation of debug request to ARM 1 Enable propagation of debug request to ARM

6.12.6 Security Status Register (SJC_SSR)

This register is used to reflect IC security status and is accessible in all the security modes. The assumption is that the information contained in this register does not pose any security breach for the system.

Address: SJC_SSR is 0h base + 5h offset = 0000_0005h



SJC_SSR field descriptions

Field	Description
31–17 SSR	Security Status Register Register is used for testing and debug.
16 iim_fuse_latched	Indicates that fuse values have been latched. Settings 0 = fuses have not yet been latched 1 = fuses have been latched
15 SSR	Reserved
14 ~src_int_boot	System Reset Controller (SRC) internal boot
13 ipt_secure_block	Indicate if invasive/non-invasive debug can be done to the ARM Settings 0 =invasive and non-invasive debug cannot be done 1= invasive and non-invasive debug can be done
12–11 RSSTAT	SJC internal registers reserved - see SJC block guide 00 Response wasn't entered 01 Response was entered but not verified

Table continues on the next page...

SJC_SSR field descriptions (continued)

Field	Description
	10 Response was entered and is incorrect 11 Response is correct
10–9 SJM	SJC internal registers reserved - see SJC block guide 00 No debug (#1) 01 Secure JTAG (#2) 10 JTAG enabled (#3) 11 Reserved
8 FT	SJC internal registers reserved - see SJC block guide 0 E-fuse technology 1 Laser fuse technology
7 BSF	SJC internal registers reserved - see SJC block guide 0 (intact) - no bypass 1 (burned) - bypass security
6 RSF	SJC internal registers reserved - see SJC block guide 0 (intact) - no re-enable 1 (burned) - secure JTAG is re-enabled
5 EBG	SJC internal registers reserved - see SJC block guide 1 granted 0 not granted
4 EBF	SJC internal registers reserved - see SJC block guide 0 (intact) - external boot is allowed 1 (burned) - external boot is disabled
3 SWE	SJC internal registers reserved - see SJC block guide 1 enabled 0 disabled
2 SWF	SJC internal registers reserved - see SJC block guide 0 (intact) - SW enable possible 1 (intact) - no SW enable possible
1 KTA	SJC internal registers reserved - see SJC block guide 1 active 0 not active

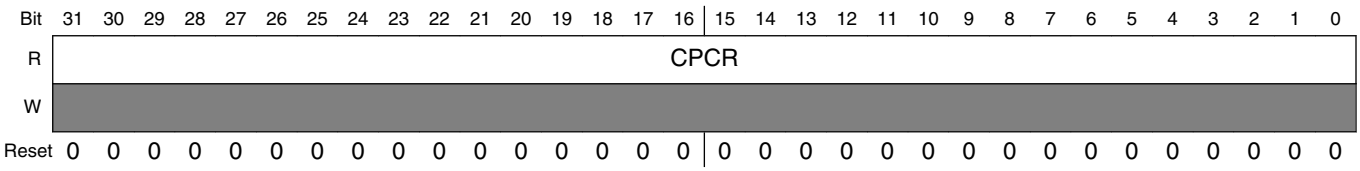
6.12.7 Charge Pump Configuration Register (SJC_CPCR)

This register is used to enable controlling charge pump configuration for Manufacturing Test via SJC. Note that the multiplexing is handled externally to SJC.

Address: SJC_CPCR is 0h base + 6h offset = 0000_0006h



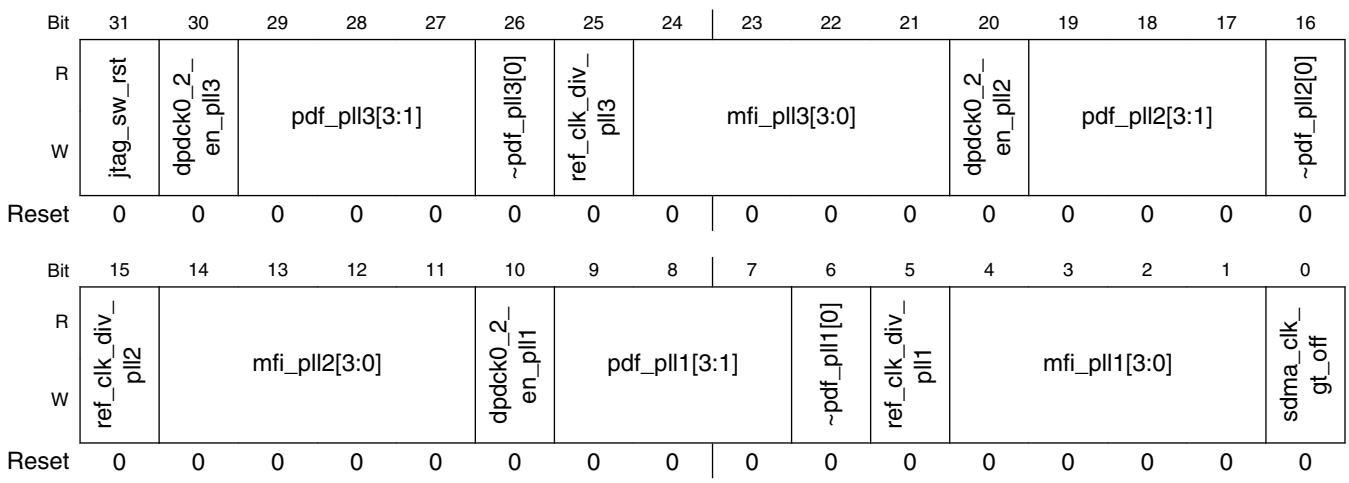
SJC_CPCR field descriptions

Field	Description
31–0 CPCR	Charge Pump Configuration Register-Register is used for testing and debug.

6.12.8 General Purpose Clocks Control Register (SJC_GPCCR)

This register is used to configure clock related modes in SoC. Those bits are directly connected to JTAG outputs.

Address: SJC_GPCCR is 0h base + 7h offset = 0000_0007h



SJC_GPCCR field descriptions

Field	Description
31 jtag_sw_rst	Provides software reset to SRC

Table continues on the next page...

SJC_GPCCR field descriptions (continued)

Field	Description
30 dpdck0_2_en_pll3	Enables double frequency dock for dpllip3 Settings: 0 double frequency clock disabled 1 double frequency clock enabled
29–27 pdf_pll3[3:1]	Pre division factor for dpllip3 Note: This is the actual value of the pre-division factor. (after the PLL adds 1) See DPLLC config spec for more details Settings: 0001 PDF = 1 0000 PDF = 2 0011 PDF = 3 0010 PDF = 4 0101 PDF = 5 0100 PDF = 6 0111 PDF = 7 0110 PDF = 8 1001 PDF = 9 1000 PDF = 10 1011 PDF = 11 1010 PDF = 12 1101 PDF = 13 1100 PDF = 14 1111 PDF = 15 1110 PDF = 16
26 ~pdf_pll3[0]	Pre division factor for dpllip3 Note: This is the actual value of the pre-division factor. (after the PLL adds 1) See DPLLC config spec for more details Settings: 0001 PDF = 1 0000 PDF = 2 0011 PDF = 3 0010 PDF = 4 0101 PDF = 5 0100 PDF = 6 0111 PDF = 7 0110 PDF = 8 1001 PDF = 9 1000 PDF = 10 1011 PDF = 11 1010 PDF = 12 1101 PDF = 13 1100 PDF = 14 1111 PDF = 15 1110 PDF = 16
25 ref_clk_div_pll3	Divides pll3 reference clock for dpllc3 Settings: 0 reference clock not divided by 2 1 reference clock divided by 2
24–21 mfi_pll3[3:0]	Multiplication factor for dpllc3 If MFI is written a value less than 5, it is defaulted to 5 This is also valid for ac scan mode Settings: 0000 MFI is 5 0001 MFI is 5 ... 0101 MFI is 5 0110 MFI is 6 0111 MFI is 7 ...
20 dpdck0_2_en_pll2	Ena ble double frequency clock for dpllc2 Settings: 0 double frequency clock disabled 1 double frequency clock enabled
19–17 pdf_pll2[3:1]	Pre division factor for dpllc2 Settings: See above bits 29:26
16 ~pdf_pll2[0]	Pre division factor for dpllc2 Settings: See above bits 29:26
15 ref_clk_div_pll2	Divides pll2 reference clock for dpll2 Settings: 0 reference clock not divided by 2 1 reference clock divided by 2
14–11 mfi_pll2[3:0]	Multiplication factor for dpllc2 If MFI is written a value less than 5, it is defaulted to 5 This is also valid for ac scan mode Settings: 0000 MFI is 5 0001 MFI is 5 ... 0101 MFI is 5 0110 MFI is 6 0111 MFI is 7 ...
10 dpdck0_2_en_pll1	Enables double frequency clock for dpllc1 Settings: 0 double frequency clock disabled 1 double frequency clock enabled
9–7 pdf_pll1[3:1]	Pre division factor for dpllc1 Settings: See above bits 29:26
6 ~pdf_pll1[0]	Pre division factor for dpllc1 Settings: See above bits 29:26
5 ref_clk_div_pll1	Divides pll1 reference clock for dpllc1 Settings: 0 reference clock not divided by 2 1 reference clock divided by 2
4–1 mfi_pll1[3:0]	Multiplication factor for dpllc1 If MFI is written a value less than 5, it is defaulted to 5 This is also valid for ac scan mode

Table continues on the next page...

Chapter 7
System Boot

7.1 Introduction

The i.MX53 boot process begins at Power On Reset (POR) where the hardware reset logic forces the ARM core to begin execution starting from the on-chip boot ROM. Boot ROM code uses the statet of the internal register BOOT_MODE[1:0] as well as the state of various eFUSEs and/or GPIO settings to determine the boot flow behavior of the i.MX53.

The main features of the ROM include:

- Support for booting from various boot devices
- Serial Downloader support (UART and USB)
- Device Configuration Data (DCD)
- Digital signature based High Assurance Boot (HAB)

The i.MX53 boot ROM supports the following boot devices:

- NOR Flash
- NAND Flash
- OneNAND Flash
- SD/MMC
- Parallel ATA (PATA)/Serial ATA (SATA) HDD
- Serial ROM devices

In normal operation, the boot ROM uses the state of the BOOT_MODE register and eFUSEs to determine the boot device. For development purposes eFUSEs used to determine the boot device may be overridden using GPIO pin inputs.

Boot ROM code also allows the downloading of programs to be run on the i.MX53. An example is a provisioning program that can make further use of the serial connection to provision a boot device with a new image. Typically the provisioning program is

downloaded to internal RAM and allows the programming boot devices such as a NAND Flash. The ROM Serial Downloader uses either a high speed USB in non-stream mode or a UART connection.

The Device Configuration Data (DCD) feature allows boot ROM code to obtain IC configuration data from an external Program Image residing on the boot device. For example, DCD can be used to program the SDRAM controller for optimal settings improving the boot performance. DCD is restricted to memory areas and peripheral addresses that are considered essential for boot purposes.

A key feature of the i.MX53 BOOT ROM is the ability to perform a secure or High Assurance Boot (HAB). This is supported by the HAB security library which is a subcomponent of the MCIMX35 ROM code. HAB uses a combination of hardware and software together with a Public Key Infrastructure (PKI) protocol to protect the system from executing unauthorized programs. Before the HAB allows a user's image to execute, the image must be signed. The signing process is done during the image build process by the private key holder and the signatures are then included as part of the final Program Image. If configured to do so, the i.MX53 verifies the signatures using the public keys included in the Program Image. A secure boot with HAB can be performed on all boot devices supported on i.MX53 in addition to the Serial Downloader. The HAB library in the i.MX53 boot ROM also provides API functions, allowing additional boot chain components (bootloaders) to extend the secure boot chain. The out-of-fab setting for SEC_CONFIG is the Open configuration in which the ROM/HAB performs image authentication but all authentication errors are ignored and the image is still allowed to execute.

NOTE

Contact your local Freescale representative for further details on using the i.MX53 system boot feature.

The remainder of this chapter provides the details on how to configure and use the boot features of the i.MX53.

7.2 Boot Modes

7.2.1 Boot Mode Pin Settings

The i.MX53 has four boot modes (one is reserved for Freescale use). Boot mode is selected based on the binary value stored in the internal BOOT_MODE register. BOOT_MODE is initialized by sampling the BOOT_MODE0 and BOOT_MODE1 pins on the rising edge of RESET_B. After these pins are sampled, their subsequent state does

not affect the contents of the BOOT_MODE internal register. The state of the internal BOOT_MODE register may be read from the BMOD[1:0] field of the SRC Boot Mode Register (SRC_SBMR) register SRC Boot Mode Register (SRC_SBMR). The available boot modes are: Internal Boot, Boot From Fuses, and serial boot through USB/UART. Refer to Table 7-1 for settings.

Table 7-1. Boot MODE Pin Settings

BOOT_MODE[1:0][1]	Boot Type
00	Internal Boot (Development)
01	Reserved
10	Boot From Fuses
11	Serial Downloader

1. BOOT_MODE[1:0] <- {BOOT_MODE1,BOOT_MODE0} (at rising edge of RESET_B)

7.2.2 High Level Boot Sequence

Figure 7-1 shows the High Level boot ROM code flow followed in the i.MX53.

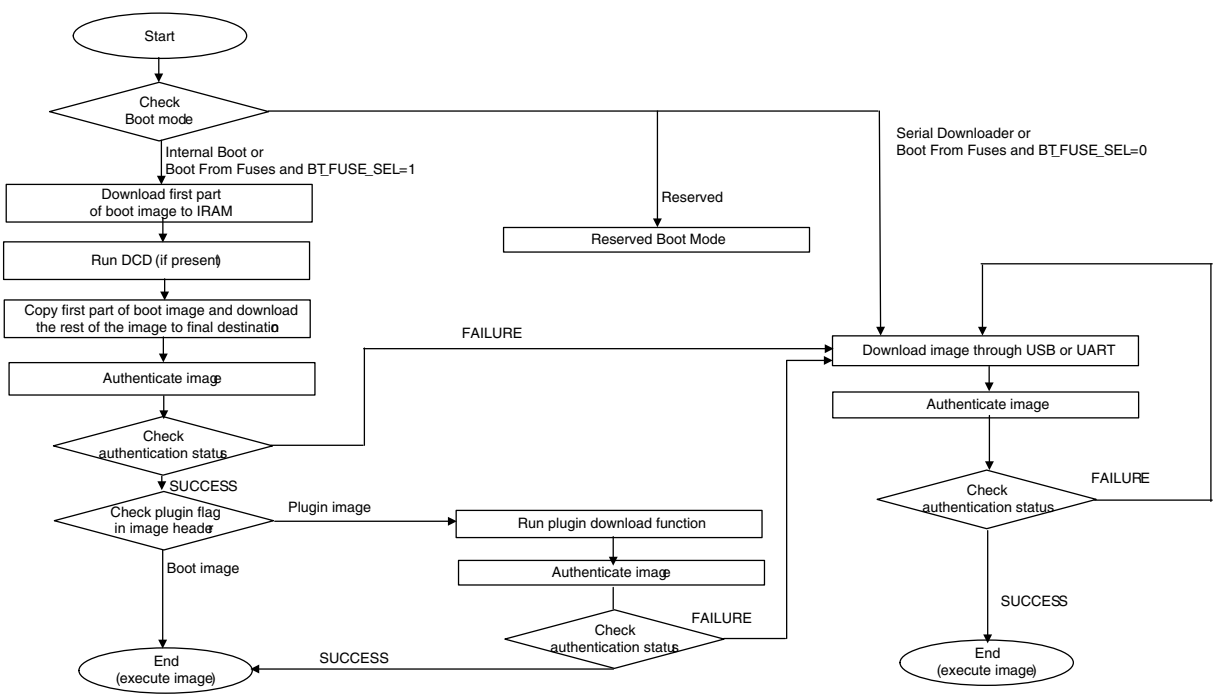

Figure 7-1. Boot Flow

NOTE

For External Interface Module (EIM) boot devices, downloading initial load region to IRAM is skipped. IVT is read from EIM address space (see IVT description Image Vector Table and Boot Data). Copying initial load region and the rest of the program image is done only if the absolute start address of the image is not equal to EIM CS0 start address.

7.2.3 Internal Boot (BOOT_MODE[1:0] = 0b00)

A value of 0b00 in the BOOT_MODE[1:0] register selects the internal Boot mode. In this mode, the processor continues to execute boot code from the internal boot ROM. The boot code performs hardware initialization, loads the Program Image from the chosen boot device, performs image validation using the HAB library (see Boot Security Settings), and then jumps to an address derived from the Program Image. If any error occurs during internal boot, the boot code jumps to the Serial Downloader (see Serial Downloader (BOOT_MODE[1:0] = 0b11)). A secure boot using the HAB on the i.MX53 is possible in all the three boot modes.

When set to Internal Boot, the boot flow may be controlled by a combination of eFUSE settings with an option of overriding the fuse settings using General Purpose I/O (GPIO) pins. Whether the ROM uses GPIO pins for a select number of configuration parameters or eFUSEs in this mode is determined by the GPIO Boot Select (BT_FUSE_SEL) eFUSE.

- If BT_FUSE_SEL = 1, all boot options are controlled by the eFUSEs described in Table 7-2.
- If BT_FUSE_SEL = 0, specific boot configuration parameters may be set using GPIO pins rather than eFUSES. The fuses that can be overridden when in this mode are indicated in the GPIO column of Table 7-2. Table 7-3 provides the details on the GPIO pins.

The use of GPIO overrides is intended for development as these pads are used for other purposes in deployed products. Freescale recommends controlling the boot configuration by eFUSEs in deployed products and reserve the use of the GPIO mode for development and testing purposes only.

7.2.4 Boot From Fuses (BOOT_MODE[1:0] = 0b10)

A value of 0b10 in the BOOT_MODE[1:0] register selects the Boot From Fuses mode. This mode is similar to the Internal Boot mode, with one difference. In this mode the GPIO boot override pins are ignored. The boot ROM code uses the boot eFUSE settings only. This mode also supports a secure boot using HAB.

If set to Boot From Fuses, the boot flow is controlled by the BT_FUSE_SEL eFUSE value. If BT_FUSE_SEL = 0, indicating that the boot device (for example, Flash, SD/MMC) has not yet been programmed, the boot flow jumps directly to the Serial Downloader. If BT_FUSE_SEL = 1, then the normal boot flow is followed, where the ROM attempts to boot from the selected boot device.

The first time a board is used, the default eFUSES may be configured incorrectly for the hardware on the platform. In such a case, the Boot ROM code may try to boot from a device that does not exist. This may cause an electrical/logic violation on some pads. Using Boot From Fuses Boot mode solves this problem. The first time the BT_FUSE_SEL eFUSE is encountered, it is not blown (thus setting BT_FUSE_SEL). This forces the ROM code to jump directly to the Serial Downloader. This allows a bootloader to be downloaded which can then provision the boot device with a Program Image and blow the BT_FUSE_SEL and the other boot configuration eFUSEs. After reset, the Boot ROM code determines that BT_FUSE_SEL is blown (BT_FUSE_SEL = 1) and the ROM code performs internal boot according to the new eFUSE settings. This allows a user to set BOOT_MODE[1:0]=0b10 on a production device and burn fuses on the same device (by forcing entry to the Serial Downloader), without changing the value of BOOT_MODE[1:0] or pull-ups/pull-downs on the BOOT_MODE pins.

7.2.5 Mode: Serial Downloader (BOOT_MODE[1:0] = 0b11)

The serial downloader is invoked if the external Flash device is not programmed, when a failure is encountered during the boot flow process or any of the following conditions are met:

- BOOT_MODE[1:0] = 0b11 (serial downloader mode)
- BOOT_MODE[1:0] = 0b10 (boot from fuses) and the eFUSE BT_FUSE_SEL = 0
- BOOT_MODE[1:0] = 0b00 or 0b10 (internal or boot from fuses) and there is not a valid image in the Flash device
- Internal failure
- Runtime exception occurs
- Error returned by the HAB functions while in Closed security configuration. Errors are ignored in Open security configuration.See Boot Security Settings.

To determine the active serial port, either UART or USB, the processor ROM program polls the UART and USB status register for approximately 32 seconds. If there is no activity on either port within the predefined polling time, then the ROM program will power down the SoC using Watchdog Timer (WDOG-1). When the serial bootloader is active WDOG-1 is reset periodically. If the communication between the serial Host and the i.MX53 is idle for more than 32 seconds or the processor goes into an endless loop, then WDOG-1 expires and powers down the device. For details on the Serial Downloader see Serial Downloader (BOOT_MODE[1:0] = 0b11).

7.2.6 Boot Security Settings

Internal boot modes use one of two security configurations:

- Closed: This level is intended for use with shipping products. All HAB functions are executed and security hardware is initialized (the Security Controller, or SCC, enters Secure state), DCD is processed if present, and the program image is authenticated by HAB prior to its execution. All detected errors will be logged, and the boot flow aborted with control passing to the serial downloader. At this level, execution does not leave the internal ROM unless the target executable image has been authenticated.
- Open: This level is intended for use in non-secure products or during the development phases of a product. All HAB functions are executed as for a production device. Security hardware is initialized (except the SCC is left in Non-Secure state), DCD is processed if present, and the program image is authenticated by HAB prior to its execution. All detected errors will be logged, but have no influence on the boot flow, which continues as if the errors did not occur. This configuration is useful for secure product development, as the Program Image will run even if the authentication data is missing or incorrect, and the error log can be examined to determine the cause of authentication failure.

NOTE

If DIR_BT_DIS eFuse is not blown, authentication may be bypassed.

7.3 Device Configuration

This section describes the external inputs defined that control the behavior of the i.MX53 Boot ROM code. This includes boot device selection (NAND, NOR, MMC), boot device configuration (NAND address cycles), and so on. In general, the source for this

configuration comes from eFUSES embedded inside the i.MX53. However, certain configuration parameters can be sourced from GPIO pins allowing further flexibility during the development process.

7.3.1 Boot eFUSE Descriptions

Table 7-2 below is a comprehensive list of the configuration parameters that the i.MX53 ROM uses.

Table 7-2. Boot eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings[2]
DIR_BT_DIS	OEM	Reserved Mode Disable	NA	0	0 Reserved Mode is allowed 1 Reserved Mode is not allowed
OSC_FREQ_SEL	OEM	OSC Frequency Select. Used by boot code for DPLLC programming.	Yes	0	0 19.2, 24, 26, 27 MHz - auto detection 1 OSC Frequency is 24MHz
BT_FUSE_SEL	OEM	In internal Boot mode, the BT_FUSE_SEL fuse determines weather the boot settings indicated by a Yes in the GPIO column are controlled by GPIO pins or eFUSE settings in the IC Identification Module (IIM). In Boot From Fuse mode, BT_FUSE_SEL fuse BOOT_MODE[1:0] = 10 indicates weather biit configuration eFuses have been programmed.	NA	0	If BOOT_MODE[1:0] = 0b00 0 Bits of SBMR are overridden by GPIO pins. 1 Specific bits of SBMR are controlled by eFUSE settings. If BOOT_MODE[1:0] = 0b10 0 BOOT configuration eFuses are not yet programmed. Boot flow jumps to serial downloader. 1 BOOT configuration eFuses have been programmed. Regular boot flow is performed.
SEC_CONFIG[1:0]	OEM	Security Configuration as defined in Boot Security Settings	NA	01	00 Reserved 01 Open (allows any program image, even if authentication fails) 1x Closed (Program image executes only if authenticated)
SRK_HASH[255:0]	OEM	256-bit hash value of super root key (SRK_HASH)	NA	0	Settings vary - used by HAB

Table continues on the next page...

Table 7-2. Boot eFUSE Descriptions (continued)

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings[2]
DIE-X-CORDINATE[7:0] DIE-Y-CORDINATE[7:0] WAFER_NO[4:0] LOT_NO_ENC[42:40] LOT_NO_ENC[39:32] LOT_NO_ENC[31:24] LOT_NO_ENC[23:16] LOT_NO_ENC[15:8] LOT_NO_ENC[7:0]	FSL	Device Unique ID, 64-bit UID.	NA	Unique ID	Settings vary - used by HAB
SRTC_SECMODE[1:0]	OEM	Security Mode for Secure RTC. Determines the level of security of the Secure Real Time Clock (SRTC) block.	No	00	00 Low Security 01 Medium Security 10 High Security 11 Reserved
BT_MMU_ENABLE	OEM	MMU/Cache enable bit used by boot ROM for fast HAB processing	Yes	0	0 MMU/Cache is disabled by ROM during the boot 1 MMU/Cache is enabled by ROM during the boot
BT_FREQ	OEM	ARM Frequency Selection	Yes	0	0 800MHz 1 400MHz
AXI/DDR Freq	OEM	AXI/DDR Frequency Selection	Yes	0	0 200MHz AXI/400MHz DDR 1 166MHz AXI/333MHz DDR
BOOT_CFG1[7:2]	OEM	Boot Configuration1	Yes	0	Specific to selected boot mode
BOOT_CFG2[7:5,2]	OEM	Boot Configuration2	Yes	0	Specific to selected boot mode

WDOG_ENABLE	OEM	Watchdog reset counter enable	No	0	0 - watchdog reset counter is disabled during serial downloader 1 - watchdog reset counter is enabled during serial downloader
NFC_DLL_DLY[2:0]	OEM	NFC Delay Line settings	No	0	NFC Delay Line settings
MMC_DLL_DLY[2:0]	OEM	eMMC4.4 Delay Line settings	No	0	eMMC4.4 Delay Line settings
SRK_REVOKE[2:0]	OEM	SRK revocation mask	No	0	SRK revocation mask

1. Setting can be overridden by GPIO settings when GPIO_FUSE_SEL fuse is intact. See Table 7-3 for corresponding GPIO pin.
2. 0 = intact fuse and 1= blown fuse

7.3.2 GPIO Boot Overrides

Table 7-3 provides a list of GPIO boot overrides. These input pins are sampled at boot, and can be used to override corresponding eFUSE values, depending on the setting of the BT_FUSE_SEL fuse. The GPIO override feature is only available when BT_FUSE_SEL is 0 (fuse is unblown) and BOOT_MODE[1:0] = 00.

Table 7-3. GPIO Override Contact Assignments

Package Pin	Direction on reset	eFuse
BOOT_MODE1	Input	Boot Mode Selection
BOOT_MODE0	Input	
EIM_A22	Input	BOOT_CFG1[7]
EIM_A21	Input	BOOT_CFG1[6]
EIM_A20	Input	BOOT_CFG1[5]

7.3.3 Device Configuration Data

See Device Configuration Data (DCD), for more details on Device Configuration Data.

7.4 Device Initialization

This section describes the details on the i.MX53 ROM and the provides initialization details. This includes details on:

- The iROM Memory Map
- The iRAM Memory Map
- On-chip blocks that the ROM should make use of or change POR register default values
- Clock initialization
- Enabling the MMU/L2 cache when performing a secure boot (SEC_CONFIG = Closed)
- Exception handling, and interrupt handling

7.4.1 Internal ROM /RAM Memory Map

Figure 7-2 below shows the iROM memory map for the i.MX53.

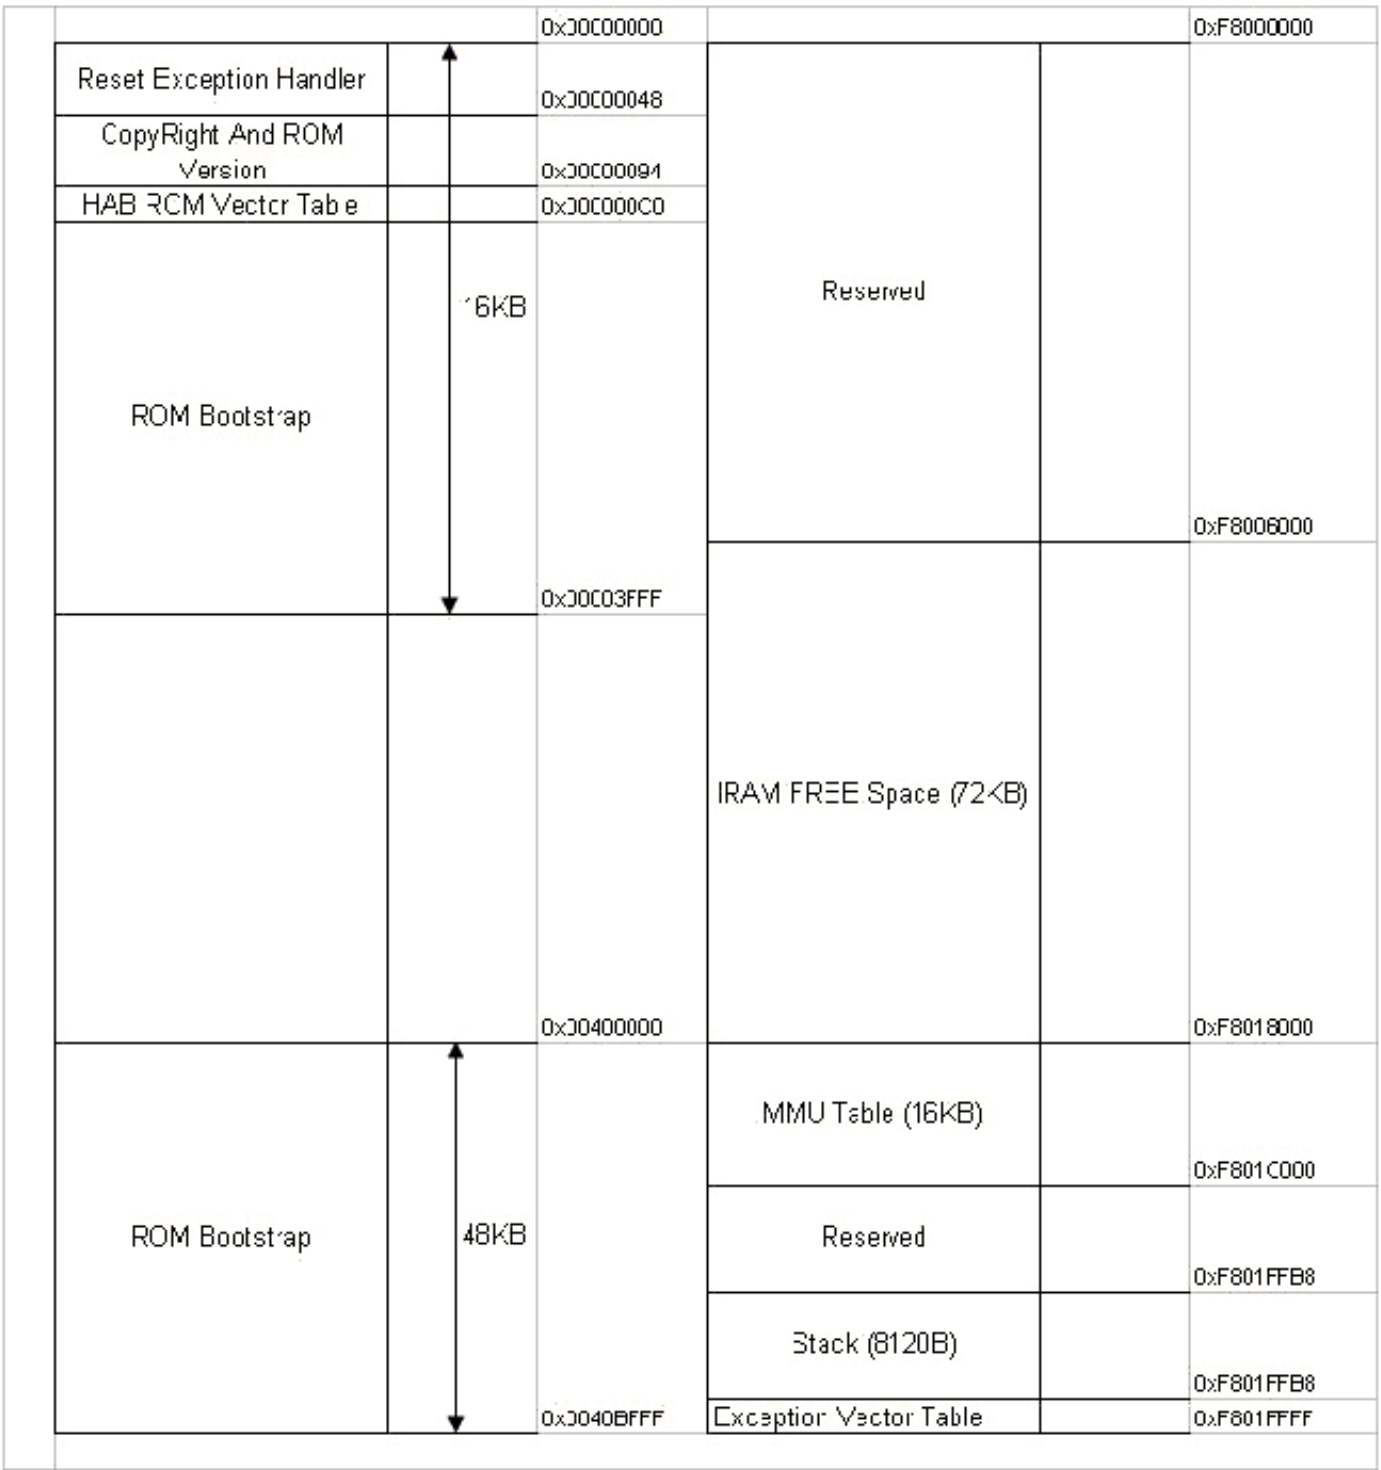

Figure 7-2. Internal ROM and RAM Memory Map

7.4.2 Boot Block Activation

The i.MX53 boot ROM affects a number of different hardware blocks which are activated and play a vital role in the boot flow. The i.MX53 ROM configures and uses the following blocks (listed in alphabetical order) during the boot process. Note that the blocks actually used depend on the boot mode and boot device selection:

- CCM - Clock Control Module
- CSU - Central Security Unit.
- ECSPI - Enhanced Configurable Serial Peripheral Interface
- EXTMC (EIM/NFC/ESDCTL) - External Memory Controller
- ESDHCV2/ESDHCV3- Enhanced Secure Digital Host Controller
- I2C - I2C Controller
- IIM - IC Identification Module. The IIM contains the eFUSEs.
- IOMUXC - I/O Multiplexer Control allows GPIO use to override eFUSE boot settings
- DPLLC - Digital Phase-Locked Loop Controller
- RTIC - Real Time Integrity Checker
- SAHARA- SAHARA Security Accelerator
- SCC-Security Controller
- SRC - System Reset Controller
- SRTC - Secure Real Time Clock
- UART and USB - Used for serial download of a boot device provisioning program
- WDOG-1 - Watchdog Timer

7.4.3 Clocks at Boot Time

The following frequencies are available as input clock to DPLLC1-4 blocks. Selection of these frequencies is accomplished as follows:

- If OSC_FREQ is 0, then ROM automatically detects one of the following frequencies - 26MHz, 19.2MHz, 27MHz or 24MHz.
- If OSC_FREQ is 1, then 24MHz oscillator.

NOTE

If OSC_FREQ is 0, then automatic detection will take approximately 10ms. For 24MHz input clock it is recommended to set OSC_FREQ=1 to save boot time.

Table 7-4 shows DPLLC1-DPLLC4 with their associated frequencies. Table 7-5 shows the various clocks and their sources used by ROM. The BOOT ROM has the capability to change the out of reset frequencies with the values shown in Table 7-5. (See "Reset values for DPLLC")

Table 7-4. DPLLC Frequencies

Clock	Frequency (MHz)
DPLLC-1	800/400
DPLLC-2	400/333
DPLLC-3	216
DPLLC-4	595

Table 7-5. Normal Frequency Clocks Configuration

Clock	CCM signal	Source	Frequency(MHz) AXI/DDR Freq=0, BT_FREQ=0	Frequency(MHz) AXI/DDR Freq=0, BT_FREQ=1	Frequency(MHz) AXI/DDR Freq=1, BT_FREQ=0	Frequency(MHz) AXI/DDR Freq=1, BT_FREQ=1
ARM core clock	arm_clk_root	DPLLC1	800	400	800	400
EXTMC	emi_slow_clk_root	DPLLC2	100		83.25	
NFCv2	enfc_clk_root	DPLLC2	33.3(NFC_FREQ_SEL=0) 14.29(NFC_FREQ_SEL=1)		27.75(NFC_FREQ_SEL=0) 11.9(NFC_FREQ_SEL=1)	
AHB	ahb_clk_root	DPLLC2	133		110	
IPG	ipg_clk_root	DPLLC2	66.5		55	
AXI_A	axi_a	DPLLC2	400		333	
AXI_B	axi_b	DPLLC2	200		166.5	
USB	usboh3_clk_root	DPLLC2	66.5		55	
UART	uart_clk_root	DPLLC3	21.6		21.6	
ESDHC	esdhc1_clk_root esdhc2_clk_root	DPLLC2	80		66.6	
CSPI	ecspi_clk_root	DPLLC3	54		54	
I2C	per_clk_root	DPLLC2	20		16.6	

On reset the processor has access to all peripherals. ROM code will disable the clocks listed in Table 7-6, except for the boot devices listed in the second column.

Table 7-6. List Of Disabled Clocks

7.4.4 Enabling MMU and Caches

Boot ROM includes a feature of enabling the Memory Management Unit (MMU) and caches to improve boot speed when performing a secure boot with SEC_CONFIG=Closed (High Assurance Boot (HAB)). L1 instruction cache is enabled at the start of image download. L1 data cache, L2 cache and MMU are enabled during image authentication.

Enabling the MMU when booting non-securely by setting, SEC_CONFIG=Open and setting the CSF pointer in the Image Vector Table set to NULL, has no impact on the boot performance. With this configuration it is recommended not to blow the MMU_EN fuse.

7.4.5 Exception Handling

The exception vectors located at the start of iROM are used to map all the ARM exceptions (except the reset exception) to a duplicate exception vector table in internal RAM.

During the boot phase, the iRAM vectors point to the serial downloader in iROM. After boot the OS loader can overwrite the vectors as required. The code shown in is used to map the ROM exception vector table to the duplicate one in iRAM.

Mapping ROM Exception Vector Table

```
;; Define linker area for iROM exception vector table
AREA IROM_VECTORS, CODE, READONLY
LDR     PC, Reset_Addr
LDR     PC, Undefined_Addr
LDR     PC, SWI_Addr
LDR     PC, Prefetch_Addr
LDR     PC, Abort_Addr
NOP                         ; Reserved vector
LDR     PC, IRQ_Addr
LDR     PC, FIQ_Addr
LDR       PC, SW_monitor_addr
;; Define exception vector table
Reset_Addr      DCD     start_address
Undefined_Addr  DCD     iRAM_Undefined_Handler
SWI_Addr        DCD     iRAM_SWI_Handler
Prefetch_Addr   DCD     iRAM_Prefetch_Handler
Abort_Addr      DCD     iRAM_Abort_Handler
                DCD     0               ; Reserved vector
IRQ_Addr        DCD     iRAM_IRQ_Handler
FIQ_Addr        DCD     iRAM_FIQ_Handler
SW_monitor_add  DCD                 SW monitor exception
start_address DCD start ;reset handler vector
```

7.4.6 Interrupt Handling During Boot

No special interrupt handling routines are required during the boot process. Interrupts are disabled during boot ROM execution and may be enabled in a later boot stage.

7.4.7 Persistent Bits

Some modes of boot ROM require registers that keep their values even after a reset. SRTC LP General Purpose register is used for this purpose. See Table 7-7 for persistent bits list and description.

Table 7-7. Persistent Bits

Bit Name	Bit Location	Description
PERSIST_SECONDARY_BOOT	SRTC_LPGR[30]	This bit is identifies which image must be used - primary and secondary. Used only for boot modes that support redundant boot.
PERSIST_BLOCK_REWRITE	SRTC_LPGR[29]	This bit is used as warning. It identifies that there are errors in NAND blocks that hold the application image. See NAND Flash for more details.
PERSIST_WDOG_BOOT	SRTC_LPGR[28]	This bit is set for enabling SBMR shadow register during Watchdog Reset Boot Mode. See Watchdog Reset Boot Mode for more details.
PERSIST_SBMR_SHADOW	SRTC_LPGR[25:0]	These bit s are used as shadow SBMR registers during Watchdog Reset Boot Mode. See Watchdog Reset Boot Mode for more details.

7.5 Boot Devices (Internal Boot)

The i.MX53 supports the following boot Flash devices:

- NOR Flash with External Interface Module (EIM), located on CS0, 16-bits bus width.
- OneNAND Flash with EIM interface, located on CS0, 16-bits bus width.
- MLC NAND, SLC NAND, and LBA NAND Flash via NAND Flash Controller (NFC) interface. Page sizes of 512 bytes, 2 Kbytes or 4 Kbytes. Bus widths of 8-bit or 16-bit, with 4/8/14/16-bit Error Checking (ECC) are supported.
- SD/MMC/eMMC and eSD through ESDHC interface, supporting high capacity cards.eMMC4.3/eMMC4.4 "boot mode (FAST BOOT)" through ESDHCV3-3 interface.
- eSD FAST BOOT mode through all the ESDHC ports.
- EEPROM boot through SPI (serial flash) and I2C/HS- I2C (via CSPI, HS- I2C, and I2C blocks respectively)
- PATA boot through PATA interface
- Serial ATA (SATA) boot through SATA interface

The selection of external boot device type is controlled by BOOT_CFG1[7:4] eFUSEs. See Table 7-8 for more details.

Table 7-8. Boot Device Selection

BOOT_CFG1[7:4]	Boot Device
0000	NOR/OneNand (EIM)
0001	Reserved
0010	Hard Disk (PATA/SATA)
0011	Serial ROM (I2C/SPI)
010x	SD/eSD
011x	MMC/eMMC
1xxx	NAND

7.5.1 NOR Flash/OneNand using EIM Interface

The External Interface Module (EIM) works in the asynchronous mode, and supports either muxed, Address/Data, or non-muxed schemes based on fuse settings:

Table 7-9. EIM Boot eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG1[7:4]	OEM	Boot Device Selection	Yes	0000	0000 - Boot from EIM Interface
BOOT_CFG1[3]	OEM	NOR/OneNand Selection	Yes	0	0 - NOR 1 - OneNand
BOOT_CFG2[7:6]	OEM	Muxing Scheme	Yes	00	00 - Muxed, 16-bit data (low half) interface 01 - Not muxed, 16-bit data (high half) interface 10 - Reserved 11 - Reserved
BOOT_CFG3[7:6]	OEM	OneNAND Page Size	Yes	00	00 - 1K 01 - 2K 10 - 4K 11 - Reserved

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 7-3 for corresponding GPIO pin.

7.5.1.1 NOR Flash Boot Operation

Booting from the NOR Flash is supported via EIM interface. The ROM reads Image Vector Table and Boot Data structures to determine if the image can be executed directly from EIM address space or should be copied to other memory. The start field of Boot Data Structure specifies the final location of the image (see Image Vector Table and Boot Data).

7.5.1.2 OneNAND Flash Boot Operation

At system power-up, the OneNAND device automatically copies an Initial Load Region of 1 Kbyte from the start of the flash array (sector 0 and sector 1, page 0, block 0) to its Boot RAM (oneNAND's internal RAM).

NOTE

The OneNAND boot RAM memory containing the Initial 1K Load Region must contain the IVT, DCD and the Boot Data structures.

Next, the i.MX53 ROM processes the DCD and then proceeds to copy the Program Image contents to the application destination pointer (located in the start entry of Boot Data (see Image Vector Table and Boot Data). The ROM determines the size of the

Program Image by the length specified by size entry in Boot Data structure (see Image Vector Table and Boot Data). A failure loading data from the OneNAND device for any reason forces the i.MX53 Boot ROM to enter the Serial Downloader, otherwise the booting from the OneNAND device continues.

Figure 7-3 illustrates the layout of the Program Image on a OneNand boot device.

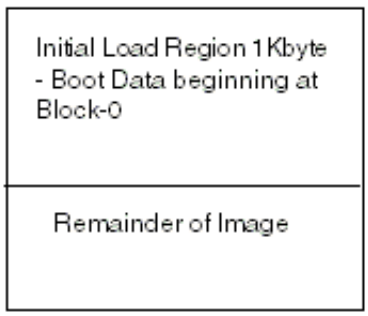

Figure 7-3. Program Image Layout on a OneNand Flash Device

Prior to accessing the OneNAND device the i.MX53 ROM waits approximately 500 µs after Power On Reset. This delay is required for the OneNAND device to become ready. After this initial 500 µs delay it can take an addition 70 µs for the OneNAND device to load the Initial Load Region of 1 Kbyte into its boot RAM. The i.MX53 ROM polls the OneNAND device Interrupt Status Register to confirm that the first 1 Kbytes has been loaded to the OneNAND boot RAM before continuing with the boot flow.

7.5.1.3 IOMUX Configuration for EIM Devices

The EIM interface signals are not configured in the IOMUX for 16-bit muxed mode. The EIM interface uses dedicated contacts on the IC. The contacts assigned to the data signals used by EIM in non-muxed mode is shown in Table 7-10.

Table 7-10. EIM Non-Muxed Mode IOMUX Pin Configuration

Signal	EIM
DATA0	EIM_DA0.alt0
DATA1	EIM_DA1.alt0
DATA2	EIM_DA2.alt0
DATA3	EIM_DA3.alt0
DATA4	EIM_DA4.alt0

DATA13	EIM_DA13.alt0
DATA14	EIM_DA14.alt0
DATA15	EIM_DA15.alt0

7.5.2 NAND Flash

A number of MLC/SLC NAND Flash devices from different vendors and LBA NAND Flash devices are supported by the boot ROM. The Error Correction and Control (ECC) sub-block is used to detect the errors.

7.5.2.1 NAND eFUSE Configuration

The boot ROM determines the configuration of external the NAND flash by parameters, either provided by eFUSE, or sampled on GPIO pins, during boot. See the Table 7-11 for parameters details.

Table 7-11. NAND Boot eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG1[7]	OEM	Boot Device Selection	Yes	0	1 - Boot from Nand Interface
BOOT_CFG1[6]	OEM	Muxed On	Yes	0	0 - PATA Pads 1 - EIM Pads
BOOT_CFG1[5:4]	OEM	Interleaving Scheme	Yes	00	00 - No Interleaving 01- 2 device 10- 4 device 11- Reserved

Table continues on the next page...

BOOT_CFG2[7:6]	OEM	Page Size	Yes	00	00 - 512 + 16 Bytes (4-bit ECC) 01 - 2KB + 64 Bytes (4-bit ECC) 10 - 4KB + 128 Bytes (4-bit ECC) 11 - 4KB + 218 Bytes (8/14/16-bit ECC)
BOOT_CFG2[5]	OEM	NAND Interface Bus Width	Yes	0	0 - 8 bit 1- 16 bit
BOOT_CFG2[2]	OEM	NFC_FREQ_SEL	Yes	0	0 - AXI DDR divide by 12 1 - AXI DDR divide by 28
BOOT_CFG3[7]	OEM	Stride Size (Bad Block skip step)	Yes	0	0 - 1 Block 1 - 8 Blocks
BOOT_CFG3[6]	OEM	LBA-Nand Select	Yes	0	0 - Non LBA (11ms delay) 1 - LBA (22ms delay)
BOOT_CFG3[5]	OEM	NAND Use R/B Signals:	Yes	0	0 - No 1 - Yes
BOOT_CFG3[4:3]	OEM	ECC / Spare select:	Yes	00	Page Size=00/01/10 00 - 4-bit ECC 01 - 4-bit ECC 10 - 4-bit ECC 11 - ECC OFF Page Size=11 00 - 8-bit ECC 01 - 14-bit ECC 10 - 16-bit ECC 11 - ECC OFF
BOOT_CFG3[2:1]	OEM	Pages In Block	Yes	00	00 - 32 01 - 64 10 - 128 11 - 256

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 7-3 for corresponding GPIO pin.See Table 7-47 for NAND eFuse configuration in DCD Example.

7.5.2.2 NAND Flash Boot Flow

On device power on the boot ROM will start searching for the Firmware Configuration Block (FCB). FCB is used by the ROM to find the program images and Discovered Bad Blocks Table (DBBT) for redundant boot and bad block management purposes. It has pointers to Primary and Secondary images, and to DDBT.

See the flow of FCB search in Figure 7-4

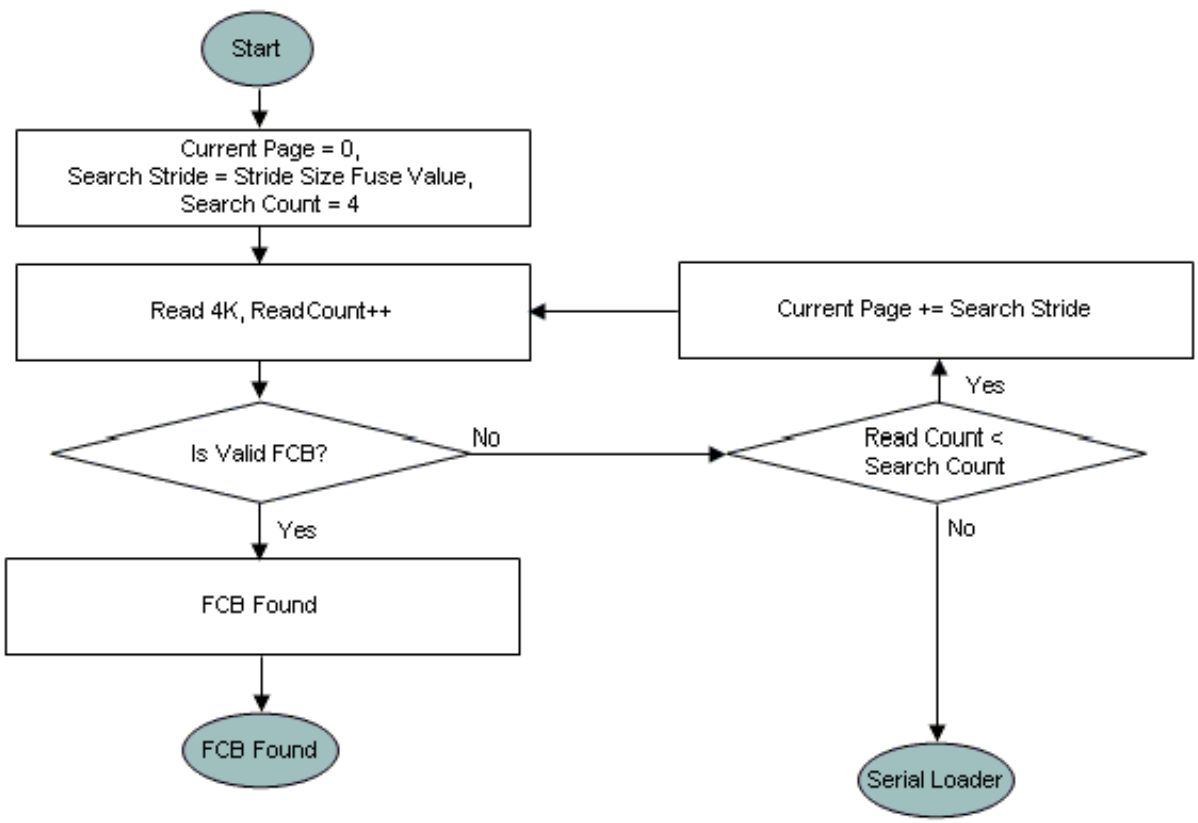

Figure 7-4. FCB Search Flow

See Table 7-12 for FCB format.

Table 7-12. NAND FCB Format

Byte Index	Byte0	Byte1	Byte2	Byte3	Comments
0x0000	Reserved				

Table continues on the next page...

Table 7-12. NAND FCB Format (continued)

Byte Index	Byte0	Byte1	Byte2	Byte3	Comments
0x0004	0x46	0x43	0x42	0x20	Fingerprint #2 (ASCII Code, FCB)
0x0008	0x01	0x00	0x00	0x00	Fingerprint #3 (FCB Version)
0x000C-0x0067	Reserved				
0x0068	Primary Image Starting Page Number				Start page number of primary firmware on the media
0x006C	Secondary Image Starting Page Number				Start page number of secondary firmware on the media
0x0070-0x0077	Reserved				Reserved
0x0078	DBBT Search Area Starting Page Number				Start page address of DBBT Search Area
0x007C	Bad Block Marker Offset				Band Block Marker Offset in page data buffer
0x0080-0x00AB	Reserved				
0x00AC	Bad Block Marker Swapping Enable				Bad Block Marker Swapping Enable
0x00BO	Bad Block Marker Offset to Spare Byte				Bad Block Marker Offset to Spare Byte
0x00B4-0x01FF	Reserved				

Once FCB found the boot ROM starts searching for Discovered Bad Blocks Table (DBBT). If DBBT Search Area is 0 in FCB, then ROM assumes that there are no bad blocks on NAND device. See Figure 7-5 for DBBT search flow.

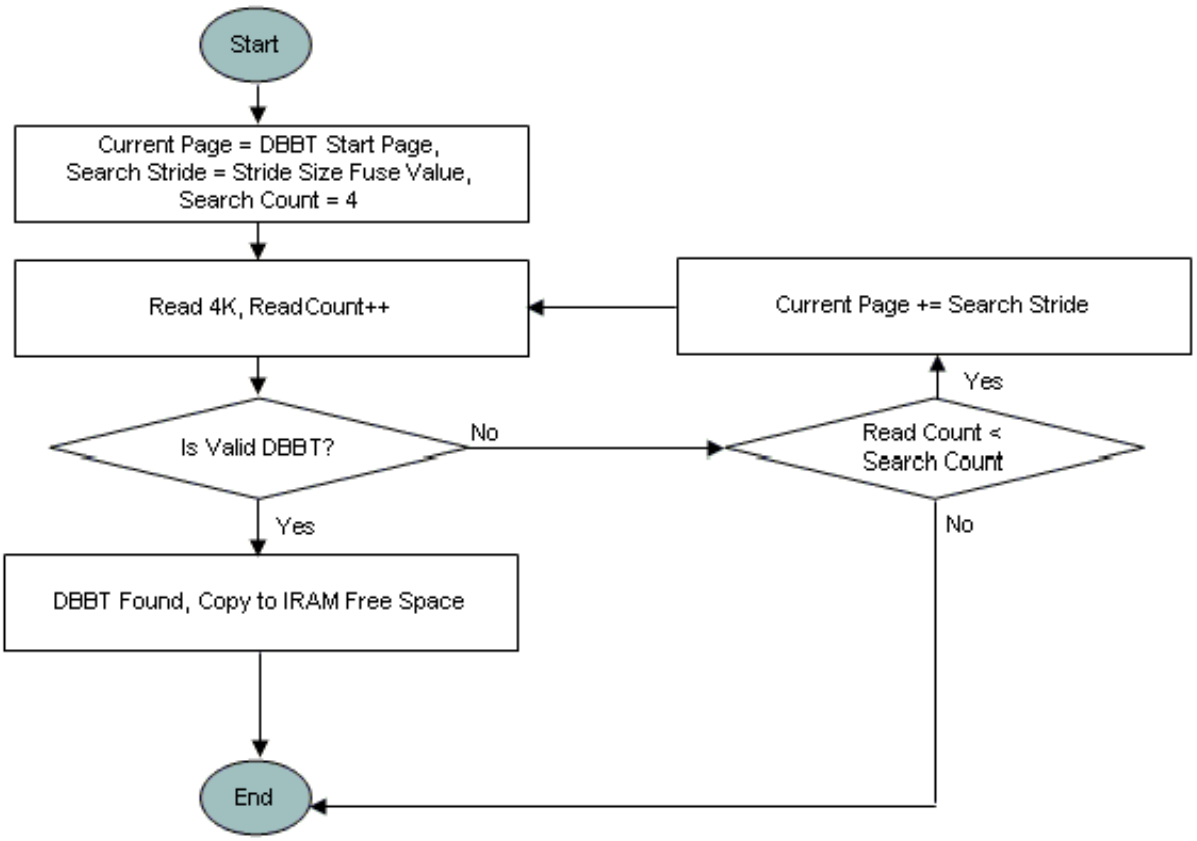

Figure 7-5. DBBT Search Flow

See Table 7-13 for DBBT format.

Table 7-13. NAND DBBT Format

Byte Index	Byte0	Byte1	Byte2	Byte3	Comments
0x0000	Reserved				
0x0004	0x54	0x42	0x42	0x44	Fingerprint #2 (ASCII Code for TBBD)[1]
0x0008	0x01	0x00	0x00	0x00	Fingerprint #3 (DBBT Version)
0x000C	Reserved				
0x0010	Reserved				
0x0014-4*PageSize	Reserved				
4*PageSize + 0x0000	Reserved				
4*PageSize + 0x0004	Number of Entries (N<425)				
4*PageSize + 0x0008	Bad Block Number				

Table continues on the next page...

Table 7-13. NAND DBBT Format (continued)

Byte Index	Byte0	Byte1	Byte2	Byte3	Comments
4*PageSize + 0x000C	Bad Block Number				
.....					
4*PageSize + 0x06A4	Bad Block Number				
4*PageSize + 4*425	Bad Block Number				

1. It should have been DBBT, but it is actually coded as TBBD due to a typo.

From that point ROM will start reading the image and copy it to final destination. If PERSIST_SECONDARY_BOOT (see Table 7-7) bit is 0, then ROM will use primary image start page from FCB for reading the image. Otherwise it will use the secondary image.

NOTE

The Initial 4K of Program Image must contain the IVT, DCD and the Boot Data structures.

ROM will skip blocks marked as bad in DBBT.

If during read there was a page with number of errors that ECC can correct, ROM will turn on PERSIST_BLOCK_REWRITE bit (see Table 7-7). This is done as warning for maintenance task of higher layer software.

If during primary image read there are uncorrected ECC errors or authentication failures (for Closed mode only), the boot ROM will turn on PERSIST_SECONDARY_BOOT bit (see Table 7-7) and perform software reset. (After software reset secondary image will be used).

If during secondary image read there was a page with number of errors higher than ECC can correct, the boot ROM will go to serial loader.

7.5.2.3 Bad Block Marker Swapping

NAND vendors mark bad blocks during production. All device locations are erased (FFh) except locations where the initial invalid block(s) information is written prior to shipping. The initial invalid block(s) status is defined by the one byte in the spare area. As vendors' layout of data and spare area on NAND flash page is different from MCIMX53 NAND Flash Controller layout, swapping one byte between data and spare area is required, in order to preserve Bad Block marker at the original location on NAND flash page.

Bad Block swapping is enabled depending on Bad Block Swapping Enable FCB parameter (see Table 7-12). The swapping is done between one byte in data area with offset specified in FCB, and one byte in spare area segment of the page. The offset to spare area segment byte is specified in FCB.

7.5.2.4 IOMUX Configuration for NAND

The NAND Flash Controller (NFC) signals can use 2 sets of pins, selected by eFuse BOOT_CFG1[6] (MUXED_ON), see Table 7-11. The contacts assigned to the signals used by NFC is shown in Table 7-14

Table 7-14. NAND IOMUX Pin Configuration

Signal	MUXED_ON=0 (PATA)	MUXED_ON=1 (EIM)
CLE	NANDF_CLE.alt0	NANDF_CLE.alt0

7.5.3 Expansion Device

The i.MX53 ROM supports booting from MMC/eMMC and SD/eSD compliant devices.

7.5.3.1 Expansion Device eFUSE Configuration

SD/MMC/eSD/eMMC boot can be performed using either ESDHCV2-1, ESDHCV2-2, ESDHCV3-3, or ESDHCV2-4 ports, based on setting of the BOOT_CFG3[5:4] (Port Select) fuse or its associated GPIO input value at boot. For eMMC4.3 and eMMC4.4 with BOOT ACK support boot mode, only ESDHCV3-3 can be used. Refer to Table 7-15 for details. The boot flow for expansion devices is shown in Figure 7-6 through Figure 7-10, beginning Figure 7-6.

Table 7-15. ESDHC Boot eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG1[7:6]	OEM	Boot Device Selection	Yes	00	01 - Boot from ESDHC Interfaces
BOOT_CFG1[5]	OEM	SD/MMC Selection	Yes	0	0 - SD/eSD 1 - MMC/eMMC
BOOT_CFG1[4]	OEM	Fast Boot Support	Yes	0	0 - Normal Boot 1 - Fast Boot
BOOT_CFG1[3]	OEM	SD/MMC Speed Mode	Yes	0	0 - High Speed Mode 1 - Normal Speed Mode
BOOT_CFG2[7:5]	OEM	Bus Width	Yes	000	SD/eSD (BOOT_CFG1[5]=0) xx0 - 1-bit xx1 - 4-bit MMC/eMMC (BOOT_CFG1[5]=1) 000 - 1-bit 001 - 4-bit 010 - 8-bit 101 - 4-bit DDR (MMC 4.4) 110 - 8-bit DDR (MMC 4.4) Else - reserved.
BOOT_CFG3[5:4]	OEM	Port Select	Yes	00	00 - ESDHCV2-1 01 - ESDHCV2-2 10 - ESDHCV3-3 11 - ESDHCV2-4

Table continues on the next page...

Table 7-15. ESDHC Boot eFUSE Descriptions (continued)

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG3[3]	OEM	DLL Override	Yes	0	0 - Boot ROM default. 1 - Apply value per fuse field MMC_DLL_DLY[3:0]
BOOT_CFG3[2]	OEM	Boot Acknowledge Disable	Yes	0	0 - Boot Acknowledge Enabled. 1 - Boot Acknowledge Disabled.
MMC_DLL_DLY[3:0]	OEM	MMC DLL Value	No	0000	MMC DLL Value

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 7-3 for corresponding GPIO pin.

Boot code supports following standards.

- MMCv4.4 or less
- eMMCv4.4 or less
- SDv2.0 or less
- eSDv2.10 rev-0.9, with or without FAST_BOOT.

MMC/SD/eSD/eMMC can be connected to any of ESDHCV2-1,2,4/V3-3 blocks and can be booted by copying 2 Kbyte of data from MMC/SD/eSD/eMMC device to internal RAM. After checking the Image Vector Table header value (0xD1) from Program Image, the ROM code performs a DCD check. After successful DCD extraction, the Rom code extracts from Boot Data Structure the destination pointer and length of image to be copied to RAM device from where code execution occurs.

NOTE

The Initial 2Kbyte of Program Image must contain the IVT, DCD and the Boot Data structures.

Table 7-16. SD/MMC Frequencies

Frequency	AXI/DDR Freq=0	AXI/DDR Freq=0
Identification (KHz)	357.143	297.321
Normal Speed Mode (MHz)	20	16.6
High Speed Mode (MHz)	40	33.3

NOTE

The application image length and destination pointer should be specified in image as the Boot ROM code reads application image length as well as application destination pointer from image.

7.5.3.2 MMC and eMMC Boot

During initialization (normal boot mode) the MMC frequency is set to 357.143 KHz. When the MMC card enters the identification portion of the initialization, voltage validation is performed and the ROM boot code checks high voltage settings and card capacity. The ROM boot code supports both high capacity and low capacity MMC/eMMC cards. After initialization phase is complete, the ROM boot code switches to a higher frequency (20 MHz in Normal boot mode or 40MHz in High Speed mode). eMMC is also interfaced through ESDHC and follows same flow as does by MMC.

The boot partition can be selected for an MMC4.x card after the card initialization is complete. The ROM code reads the BOOT_PARTITION_ENABLE field in the Ext_CSD[179] to get the boot partition to be set. If there is no boot partition mentioned in BOOT_PARTITION_ENABLE field or the user partition has been mentioned, ROM boots from the user partition.

If using an eMMC4.3 or eMMC4.4 device supporting special "Boot mode", it can be initiated by pulling the CMD line low. If BOOT ACK is enabled, the eMMC4.3/eMMC4.4 device sends the BOOT ACK via DATA lines and ROM can read the BOOT ACK [S010E] to identify the eMMC4.3/eMMC4.4 device. eMMC4.3/eMMC4.4 device with "Boot mode" feature can only be supported via ESDHCV3-3 and with or without BOOT ACK. If BOOT ACK is enabled ROM waits 50 ms to get the BOOT ACK and if BOOT ACK is received by ROM. If BOOT ACK is disabled ROM waits 1 second for data. If BOOT ACK or data was received then eMMC4.3/eMMC4.4 is booted in "Boot mode", otherwise eMMC4.3/eMMC4.4 boots as a normal MMC card from the selected boot partition. This boot mode can be selected by BOOT_CFG1[4] (Fast Boot) fuse. BOOT ACK is selected by BOOT_CFG2[2].

If using eMMC4.4 device, Double Data Rate (DDR) mode can be used. This mode can be selected by BOOT_CFG2[7:5] (Bus Width) fuse.

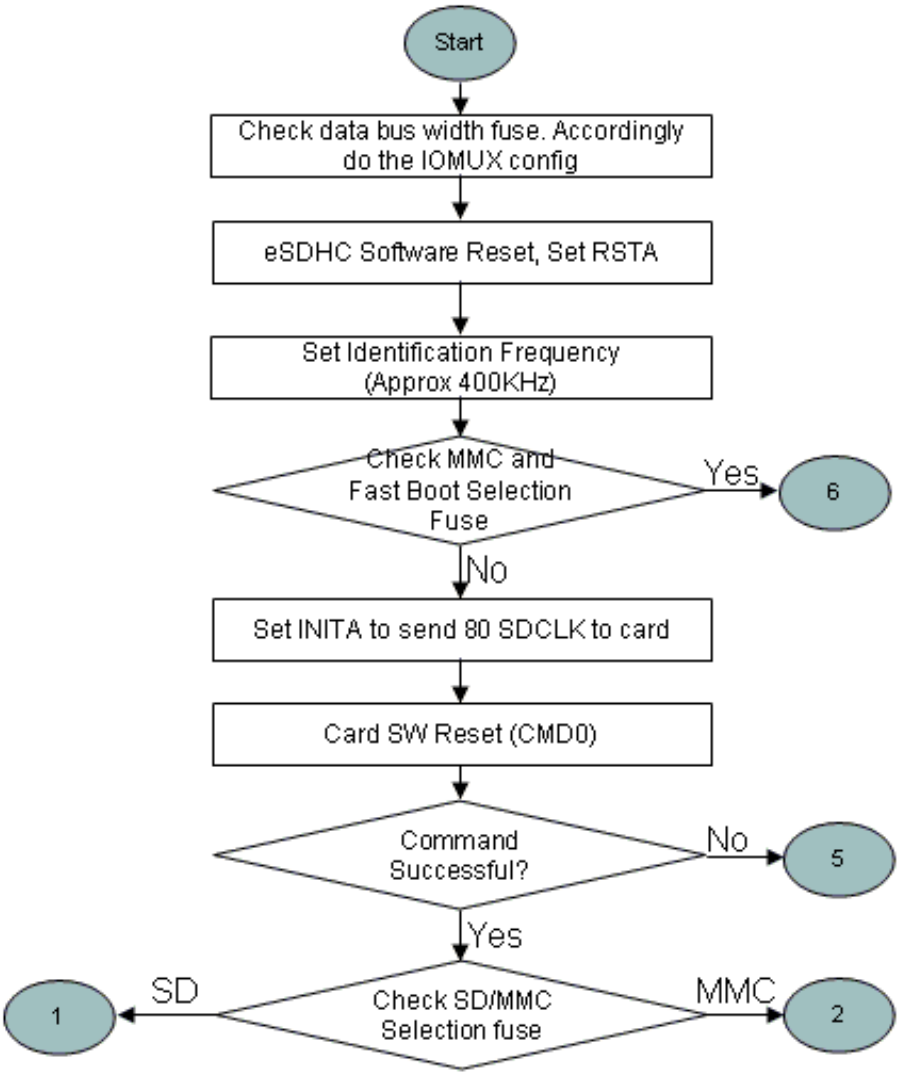

Figure 7-6. Expansion Device Boot Flow (1 of 5)

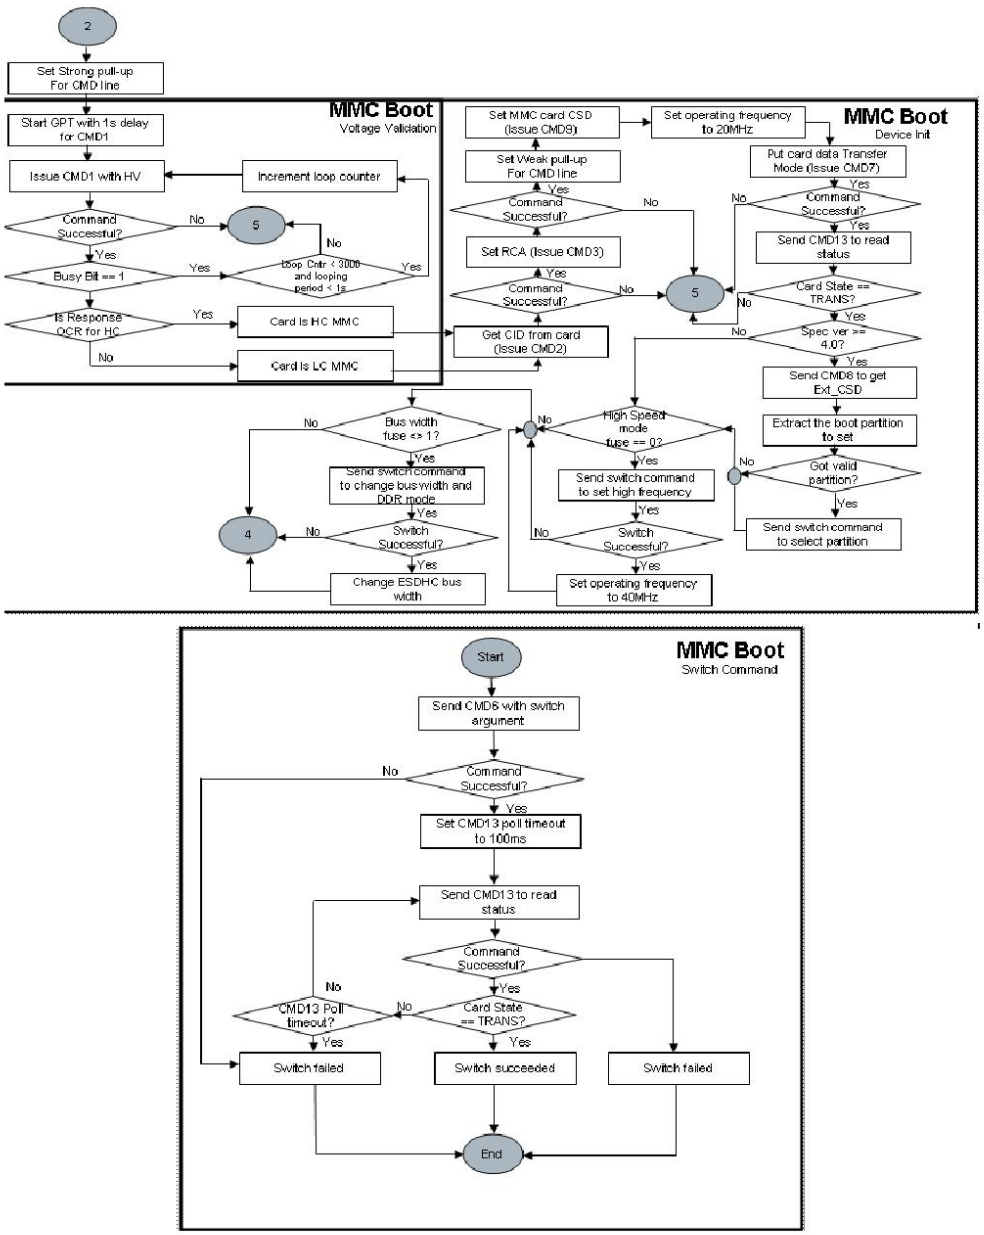

Figure 7-7. Expansion Device (MMC) Boot Flow (2 of 5)

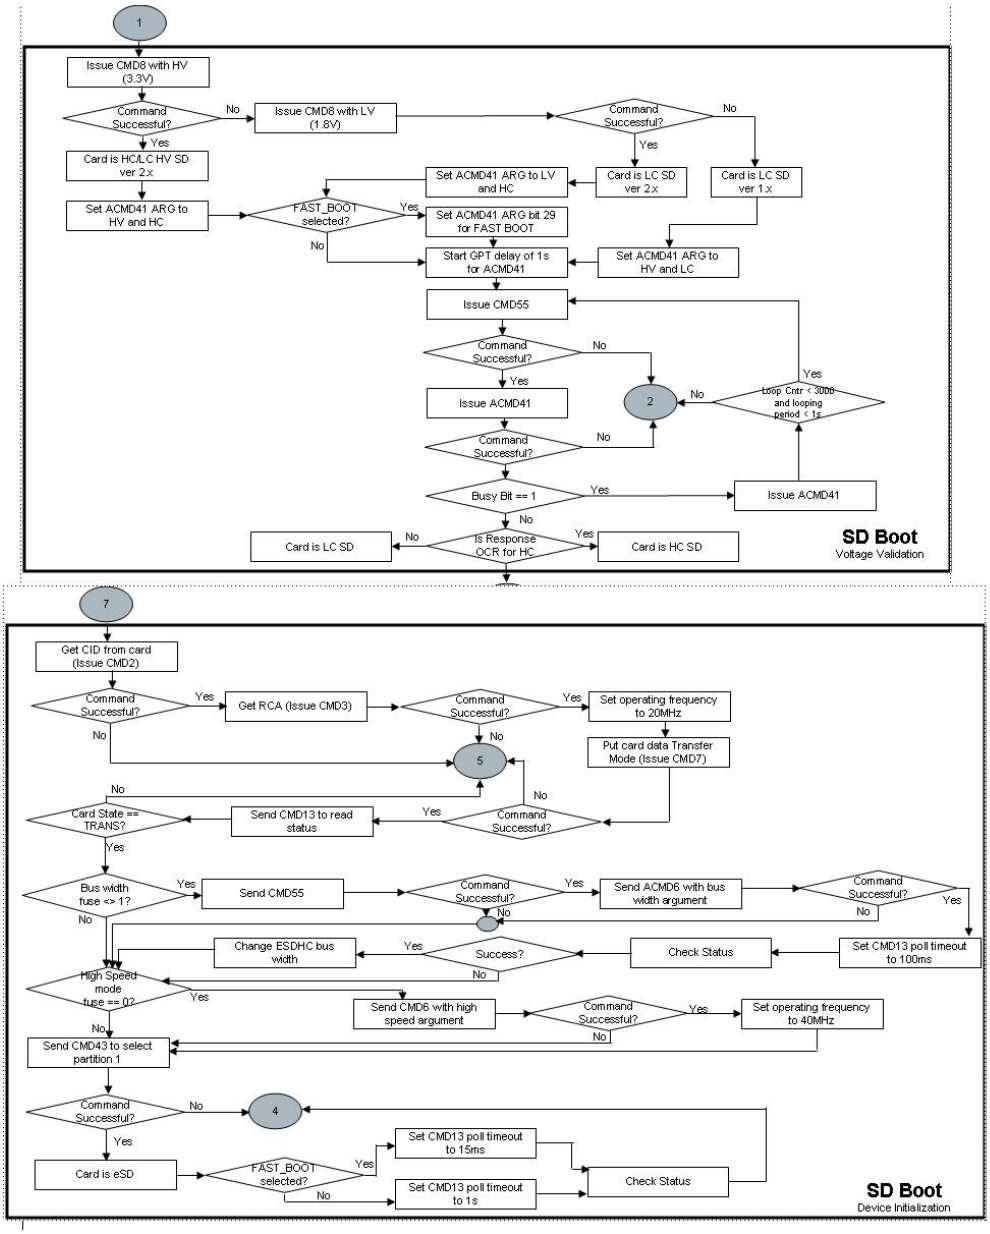

Figure 7-8. Expansion Device (SD/eSD) Boot Flow (3 of 5)

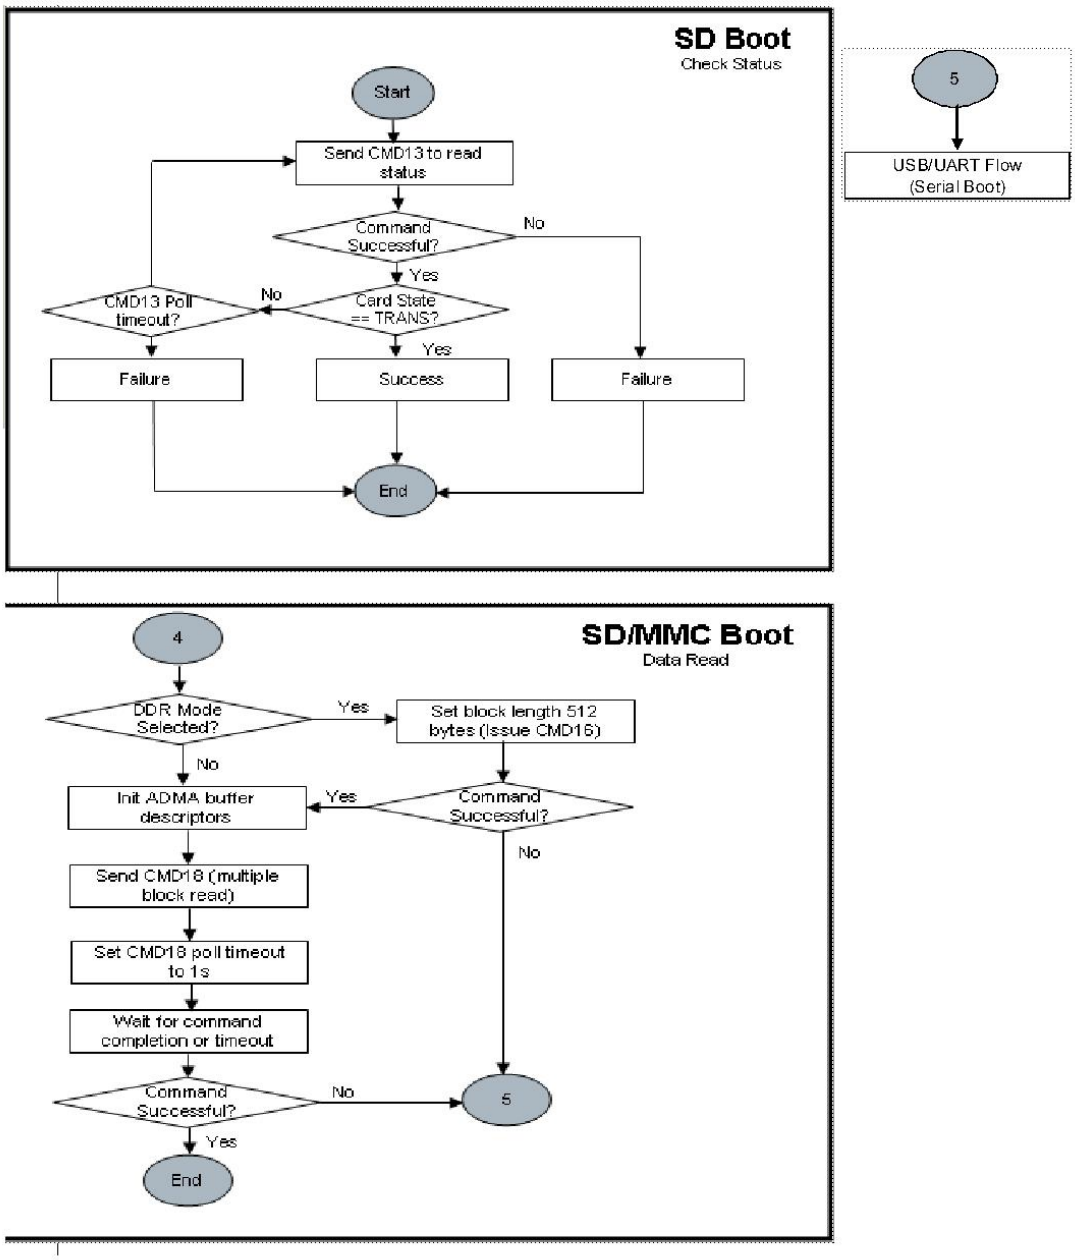

Figure 7-9. Expansion Device Boot Flow (4 of 5)

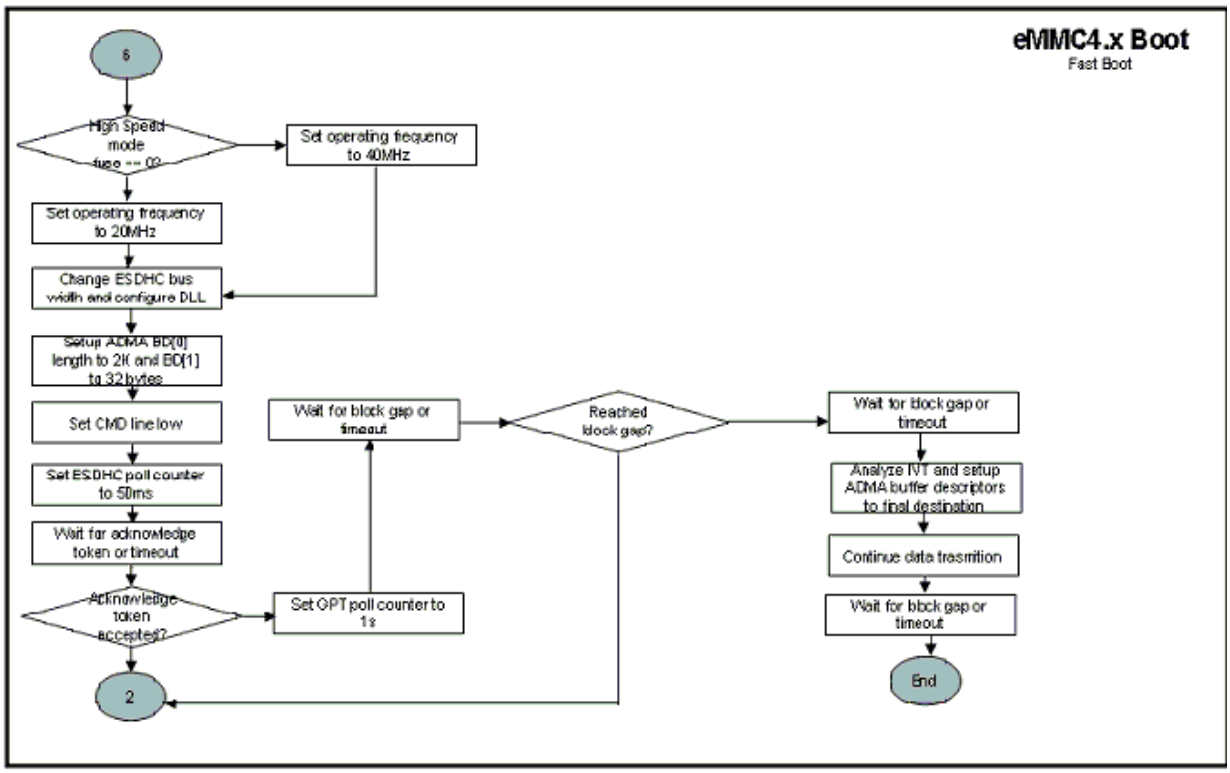

Figure 7-10. Expansion Device Boot Flow (5 of 5)

7.5.3.3 SD and eSD

After the normal boot mode initialization begins, the SD and eSD frequency is set to 357.143 KHz. During the identification phase SD and eSD card voltage validation is performed. During voltage validation, boot code first checks with high voltage settings and if it fails it checks with low voltage settings. Capacity of card is also checked. Boot code supports high capacity and low capacity SD and eSD cards. After voltage validation card initialization is done.

During card initialization the ROM boot code attempts to set the boot partition (both SD and eSD devices). If this fails, the boot code assumes card is a normal SD card otherwise as eSD card. After initialisation phase is over, boot code switches to a higher frequency (20 MHz in Normal Speed mode or 40 MHz in High Speed Mode). ROM also supports FAST_BOOT mode booting from eSD card. This mode can be selected by BOOT_CFG1[4] (Fast Boot) fuse described in Table 7-15.

7.5.3.4 IOMUX Configuration for SD/MMC

Table 7-17. SD/MMC IOMUX Pin Configuration

Signal	ESDHCV2-1	ESDHCV2-2	ESDHCV3-3	ESDHCV2-4
CLK	SD1_CLK.alt0	SD2_CLK.alt0	PATA_RESET_B.alt2	PATA_DA_1.alt2
CMD	SD1_CMD.alt0	SD2_CMD.alt0	PATA_IORDY.alt2	PATA_DA_2.alt2

DAT6	PATA_DATA10.alt2	PATA_DATA14.alt2	PATA_DATA2.alt4	PATA_DATA6.alt4
DAT7	PATA_DATA11.alt2	PATA_DATA15.alt2	PATA_DATA3.alt4	PATA_DATA7.alt4

7.5.3.5 Redundant Boot Support for Expansion Device

i.MX53 ROM supports redundant boot for expansion device. Primary or Secondary image is selected depending on PERSIST_SECONDARY_BOOT setting (see Table 7-7).

If PERSIST_SECONDARY_BOOT is 0, the boot ROM uses address 0x0 for primary image.

If PERSIST_SECONDARY_BOOT is 1, the boot ROM will read secondary image table from address 0x200 on boot media and will use address specified in the table

.

Table 7-18. Secondary Image Table Format

Reserved (chipNum)
Reserved (driveType)
tag
firstSectorNumber
Reserved (sectorCount)

Where:

- tag: used as indication of valid secondary image table. Must be 0x00112233.
- firstSectorNumber is the first 512B sector number of the secondary image.

For secondary image support, the primary image must reserve space for secondary image table. See Figure 7-11 for typical structures layout on expansion devic

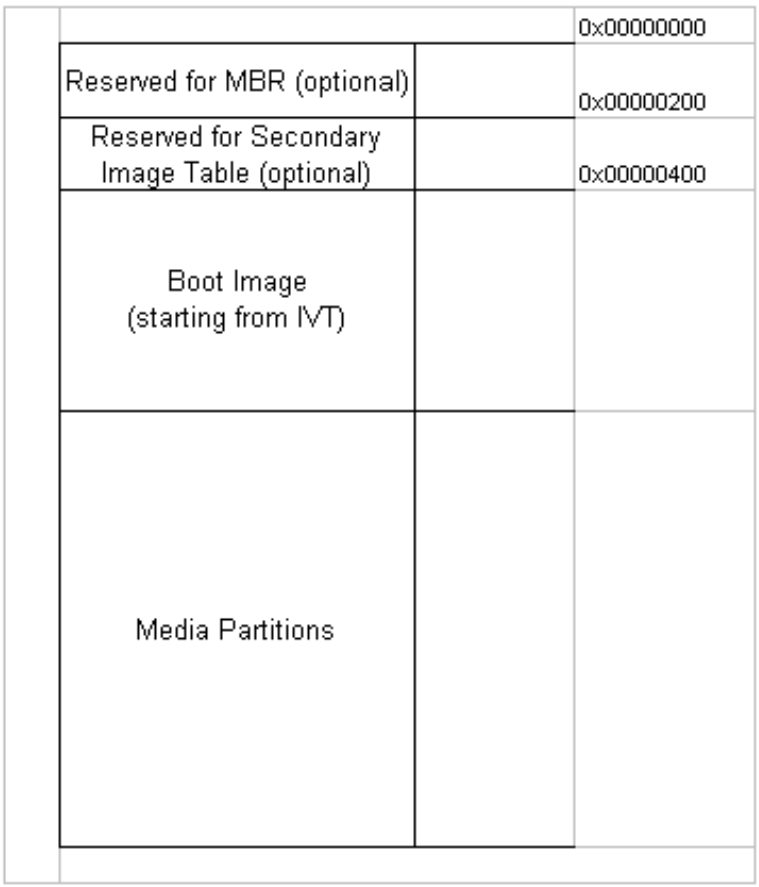

Figure 7-11. Expansion Device Structures Layout

For Closed mode, if there are failures during primary image authentication, the boot ROM will turn on PERSIST_SECONDARY_BOOT bit (see Table 7-7) and perform software reset. (After software reset secondary image will be used).

7.5.4 Hard Disk and SSD

The i.MX53 supports boot from Hard Disk and SSD devices using the PATA and SATA interfaces.

7.5.4.1 Hard Disk and SSD eFUSE Configuration

The boot ROM code determines the type of device using the following parameters, either provided by eFUSE settings or sampled on the I/O pins, during boot (See Table 7-19 for details):

Table 7-19. HDD eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG1[7:4]	OEM	Boot Device Selection	Yes	0000	0010 - Boot from Hard Disk
BOOT_CFG1[3]	OEM	HD Type	Yes	0	0 - PATA 1- SATA

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 7-3 for corresponding GPIO pin.

The boot ROM will send IDENTIFY command to hard disk during initialization. When identification block received, boot ROM assumes that the device is ready. The boot ROM sends separate command for each sector of 512 bytes in PIO mode.

The boot ROM will copy 2 Kbyte of data from Hard Disk or SSD device to internal RAM. After checking the Image Vector Table header value (0xD1) from Program Image, the ROM code performs a DCD check. After successful DCD extraction, the Rom code extracts from Boot Data Structure the destination pointer and length of image to be copied to RAM device from where code execution occurs.

NOTE

The Initial 2 Kbyte of Program Image must contain the IVT, DCD and the Boot Data structures.

7.5.4.2 IOMUX Configuration for PATA

Table 7-20 below provides the IOMUX configuration details for Parallel ATA (PATA).

Table 7-20. PATA IOMUX Pin Configuration

Signal	PATA
DIOW	PATA_DIOW.alt0

D14	PATA_DATA14.alt0
D15	PATA_DATA15.alt0

7.5.4.3 IOMUX Configuration for SATA

The interface signals of the SATA PHY are not configured in the IOMUX. The SATA PHY interface uses dedicated contacts on the IC. See the i.MX53 data sheet for details.

7.5.4.4 Redundant Boot Support for Hard Disk and SSD

i.MX53 ROM supports redundant boot for hard disk and SSD. Primary or Secondary image is selected depending on PERSIST_SECONDARY_BOOT setting (see Table 7-7).

If PERSIST_SECONDARY_BOOT is 0, the boot ROM uses address 0x0 for primary image.

If PERSIST_SECONDARY_BOOT is 1, the boot ROM will read secondary image table from address 0x200 on boot media and will use address specified in the table.

Table 7-21. Secondary Image Table Format

Table continues on the next page...

Table 7-21. Secondary Image Table Format (continued)

Reserved (driveType)
tag
firstSectorNumber
Reserved (sectorCount)

Where:

- tag: used as indication of valid secondary image table. Must be 0x00112233.
- firstSectorNumber is the first 512B sector number of the secondary image.

For secondary image support, the primary image must reserve space for secondary image table. See Figure 7-12 for typical structures layout on expansion device.

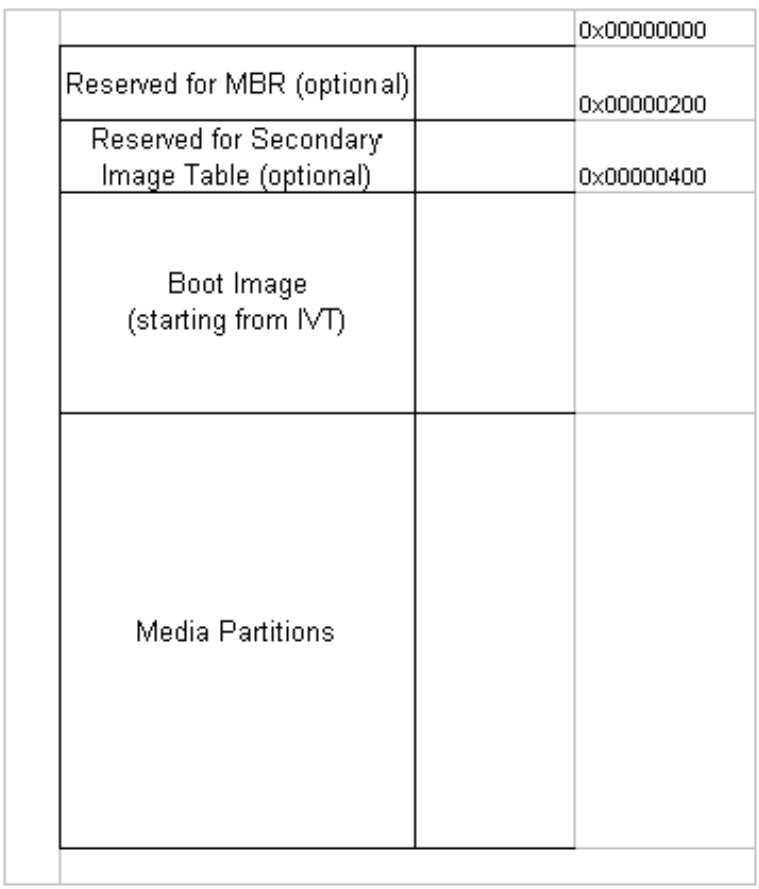

Figure 7-12. Hard Disk Structures Layout

For Closed mode, if there are failures during primary image authentication, the boot ROM will turn on PERSIST_SECONDARY_BOOT bit (see Table 7-7) and perform software reset. (After software reset secondary image will be used).

7.5.5 Serial ROM through SPI and I2C

The i.MX53 supports boot from serial memory devices, such as EEPROM, and Serial Flash using the SPI

(CSPI, ECSPI-1, ECSPI-2), and I2C Controller (I2C-1, I2C-2 and I2C-3) interfaces.

7.5.5.1 Serial ROM eFUSE Configuration

The boot ROM code determines the type of device using the following parameters, either provided by eFUSE settings or sampled on the I/O pins, during boot (See Table 7-22 for details):

Table 7-22. Serial ROM Boot eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG1[7:4]	OEM	Boot Device Selection	Yes	0000	0011 - Boot from Serial ROM
BOOT_CFG1[3]	OEM	Serial ROM select	Yes	0	0 - I2C 1- SPI
BOOT_CFG2[5]	OEM	SPI Addressing	Yes	0	0 - 2-bytes (16-bit) 1 - 3-bytes (24-bit)
BOOT_CFG3[5:4]	OEM	Port Select	Yes	00	00 - I2C-1 / ECSPI-1 01 - I2C-2 / ECSPI-2 10 - I2C-3 / CSPI 11 - Reserved
BOOT_CFG3[3:2]	OEM	CS select (SPI only)	Yes	00	00 - CS#0 01 - CS#1 10 - CS#2 11 - CS#3

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 7-3 for corresponding GPIO pin.

The I2C-1/I2C-2/I2C-3 block can be used as boot device using I2C interface, for serial ROM boot. The I2C interface is configured to operate at 384 Kbps.

The boot ROM will copy 2 Kbyte of data from Serial ROM device to internal RAM. After checking the Image Vector Table header value (0xD1) from Program Image, the ROM code performs a DCD check. After successful DCD extraction, the Rom code extracts from Boot Data Structure the destination pointer and length of image to be copied to RAM device from where code execution occurs.

NOTE

The Initial 2K of Program Image must contain the IVT, DCD and the Boot Data structures.

7.5.5.2 I2C Boot

The boot flow when booting from an I2C device is shown in Figure 7-13. The boot ROM code reads the fuses BOOT_CFG1[7:4] (Boot Device Selection) and BOOT_CFG1[3] (Serial ROM select) to detect EEPROM device type. The ROM program copies 2K data from the EEPROM device to internal RAM. The boot ROM code next copies the initial 2 Kbyte of data as well as rest of image directly to application destination extracted from application image.

The i.MX53 uses the Device Select Code/Device Address in Table 7-23 to boot from an EEPROM.

Table 7-23. EEPROM via I2C Device Select Code

Bits	Device Type Identifier				Chip Enable Address[1]			R/W
	7	6	5	4	3	2	1	0
Device Select Code	1	0	1	0	0	0	0	R/W

1. These address bits, should be configured at the memory device, to match this '000' value.

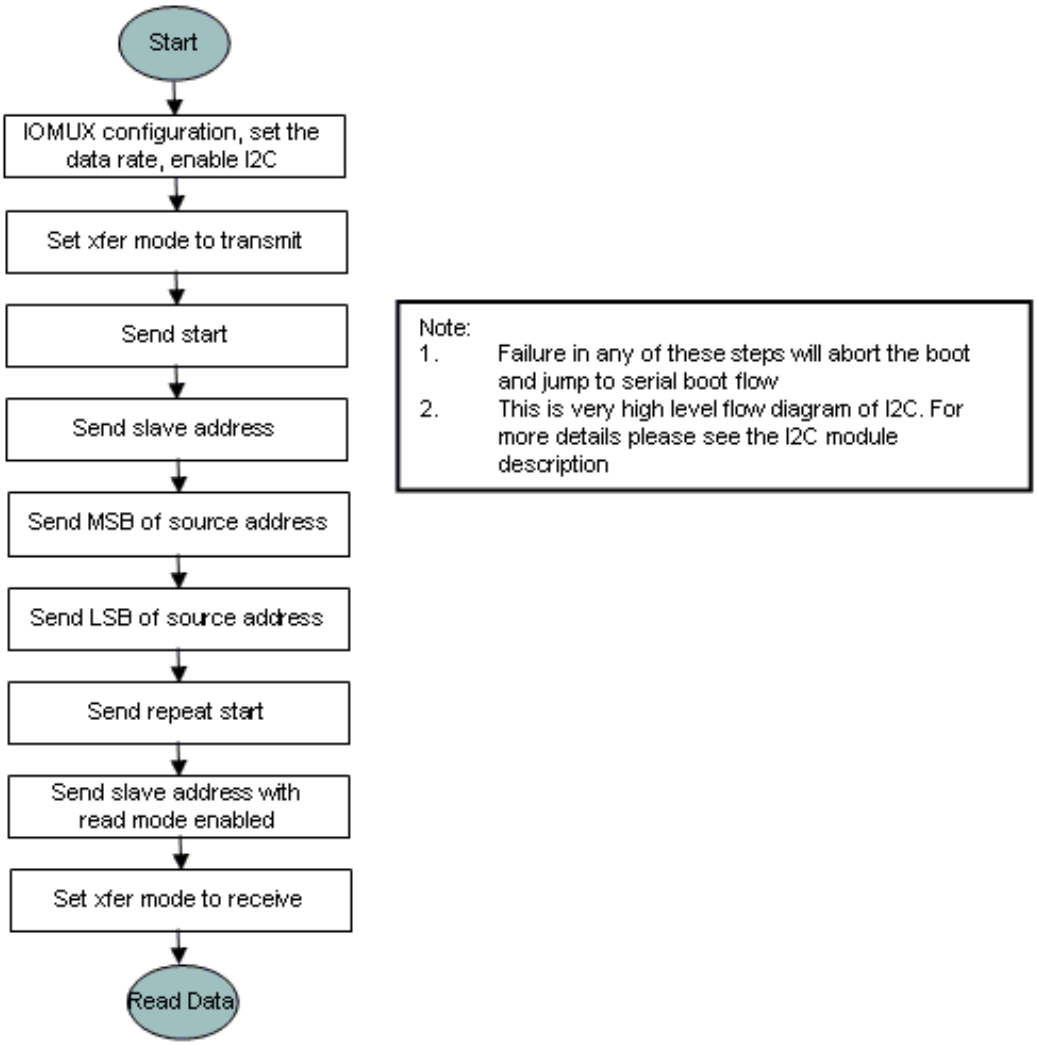

Figure 7-13. I2C Flow Chart

7.5.5.2.1 I2C IOMUX Pin Configuration

The contacts assigned to the signals used by the three I2C blocks is shown in Table 7-24.

Table 7-24. I2C IOMUX Pin Configuration

Signal	I2C-1	I2C-2	I2c-3
SDA	EIM_D28.alt5	EIM_D16.alt5	EIM_D18.alt5
SCL	EIM_D21.alt5	EIM_EB2.alt5	EIM_D17.alt5

7.5.5.3 CSPI Boot

The Configurable SPI (CSPI) interface is configured in Master mode and the EEPROM device is connected to CSPI interface as slave. The boot ROM code copies 2 Kbyte data from EEPROM device to the internal RAM. If DCD verification is successful, the ROM code copies the initial 2 Kbyte data as well as the rest of image directly to application destination extracted from application image. The CSPI can read data from EEPROM using 2 or 3 byte addressing and its burst length is 32 bytes.

NOTE

The Serial ROM Chip Select Number is determined by BOOT_CFG3[3:2] (Chip Select) fuse

When using the SPI as boot device, the i.MX53 supports booting from both Serial EEPROMS and Serial Flash devices. The boot code determines which device is being used by reading the appropriate eFUSE/I/O values at boot (See Table 7-22 for details).

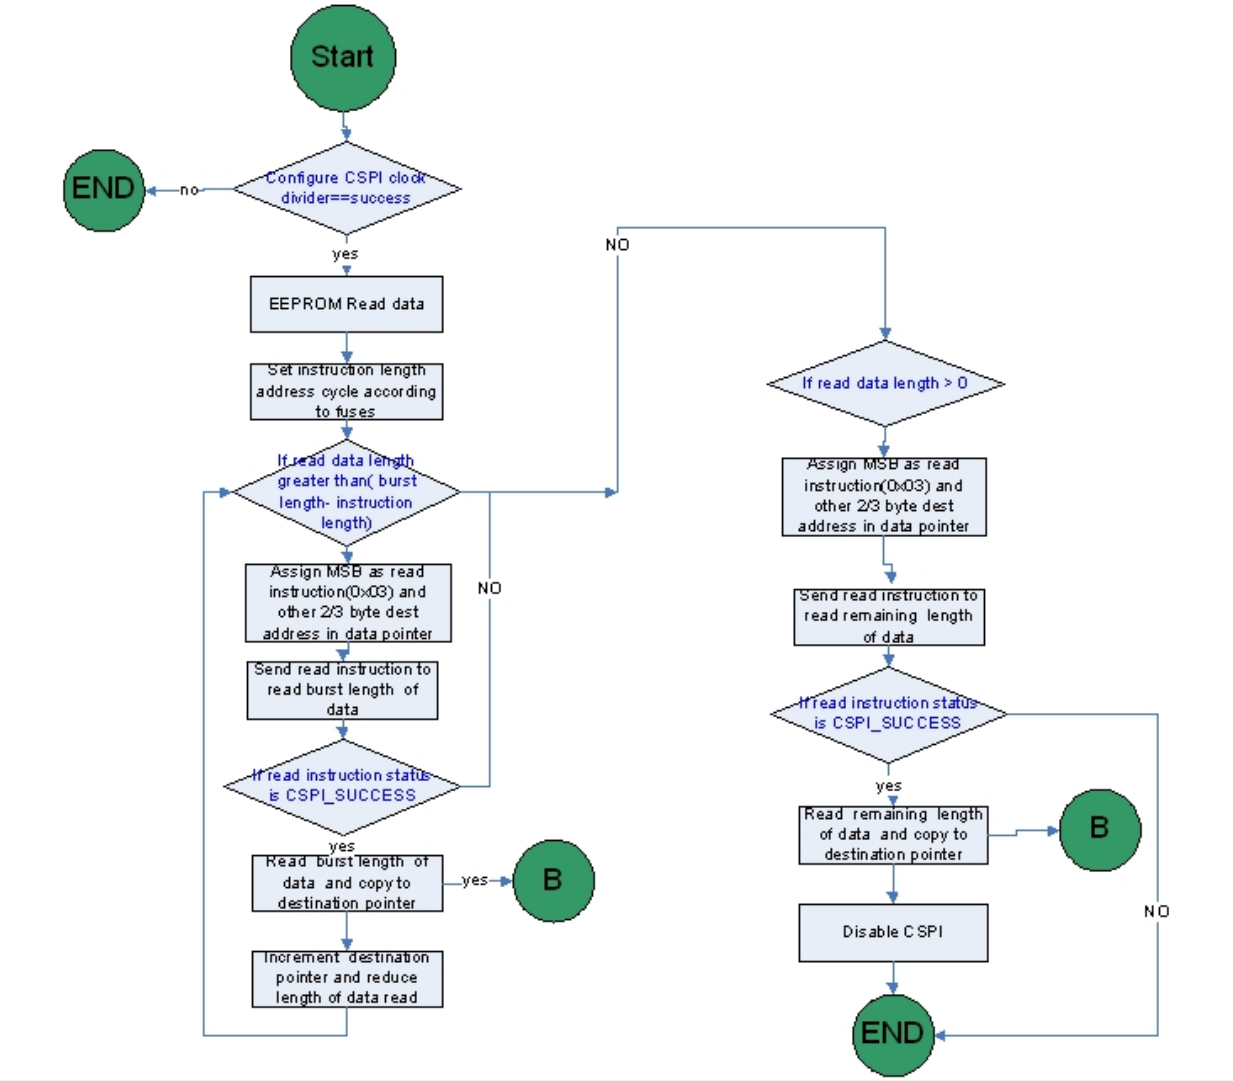

Figure 7-14. CSPI Flow chart

7.5.5.3.1 ECSPI/CSPI IOMUX Pin Configuration

The contacts assigned to the signals used by the three CSPI blocks is shown in Table 7-25.

Table 7-25. SPI IOMUX Pin Configuration

Signal	ECSPI-1	ECSPI-2	CSPI
MISO	EIM_D17.alt4	CSI0_DAT9.alt3	EIM_D22.alt4
MOSI	EIM_D18.alt4	CSI0_DAT10.alt3	EIM_D28.alt4
RDY	N/A[1]	N/A	N/A
SCLK	EIM_D16.alt4	CSI0_DAT8.alt3	EIM_D21.alt4
SS0	EIM_EB2.alt4	CSI0_DAT11.alt3	EIM_D20.alt4

Table continues on the next page...

Table 7-25. SPI IOMUX Pin Configuration (continued)

SS1	EIM_D19.alt4	EIM_LBA.alt2	EIM_A25.alt4
SS2	EIM_D25.alt3	EIM_D25.alt6	EIM_D24.alt4
SS3	EIM_D26.alt3	EIM_D26.alt6	EIM_D24.alt4

1. N/A in the ROM code indicates the pins are not available.

7.6 Program Image

This section describes the data structures that are required to be included in a user's Program Image. A Program Image consists of:

- Image Vector Table- A list of pointers located at a fixed address that the ROM examines to determine where other components of the Program Image are located.
- Boot Data- A table indicating the Program Image Location, Program Image size in bytes and plugin flag.
- Device Configuration Data- IC configuration data.
- User code and data

7.6.1 Image Vector Table and Boot Data

The Image Vector Table (IVT) is the data structure that the ROM reads from the boot device supplying the program image containing the required data components to perform a successful boot. The IVT includes the program image entry point, a pointer to Device Configuration Data (DCD) and other pointers used by the ROM during the boot process. The ROM locates the IVT at a fixed address that is determined by the boot device connected to i.MX53. The IVT offset from the base address and initial load region size for each boot device type is defined in Table 7-26. The location of the IVT is the only fixed requirement by the ROM. The remainder or the image memory map is flexible and is determined by the contents of the IVT.

Table 7-26. Image Vector Table Offset and Initial Load Region Size

Boot Device Type	Image Vector Table Offset	Initial Load Region Size
NOR	4 Kbyte = 0x1000 bytes	Entire Image Size
NAND	1 Kbyte = 0x400 bytes	4 Kbyte
OneNAND	256 bytes = 0x100 bytes	1 Kbyte
SD/MMC/eSD/eMMC	1 Kbyte = 0x400 bytes	2 Kbyte
I2C/HS-I2C/SPI EEPROM	1 Kbyte = 0x400 bytes	2 Kbyte

Table continues on the next page...

Table 7-26. Image Vector Table Offset and Initial Load Region Size (continued)

PATA/SATA	1 Kbyte = 0x400 bytes	2 Kbyte

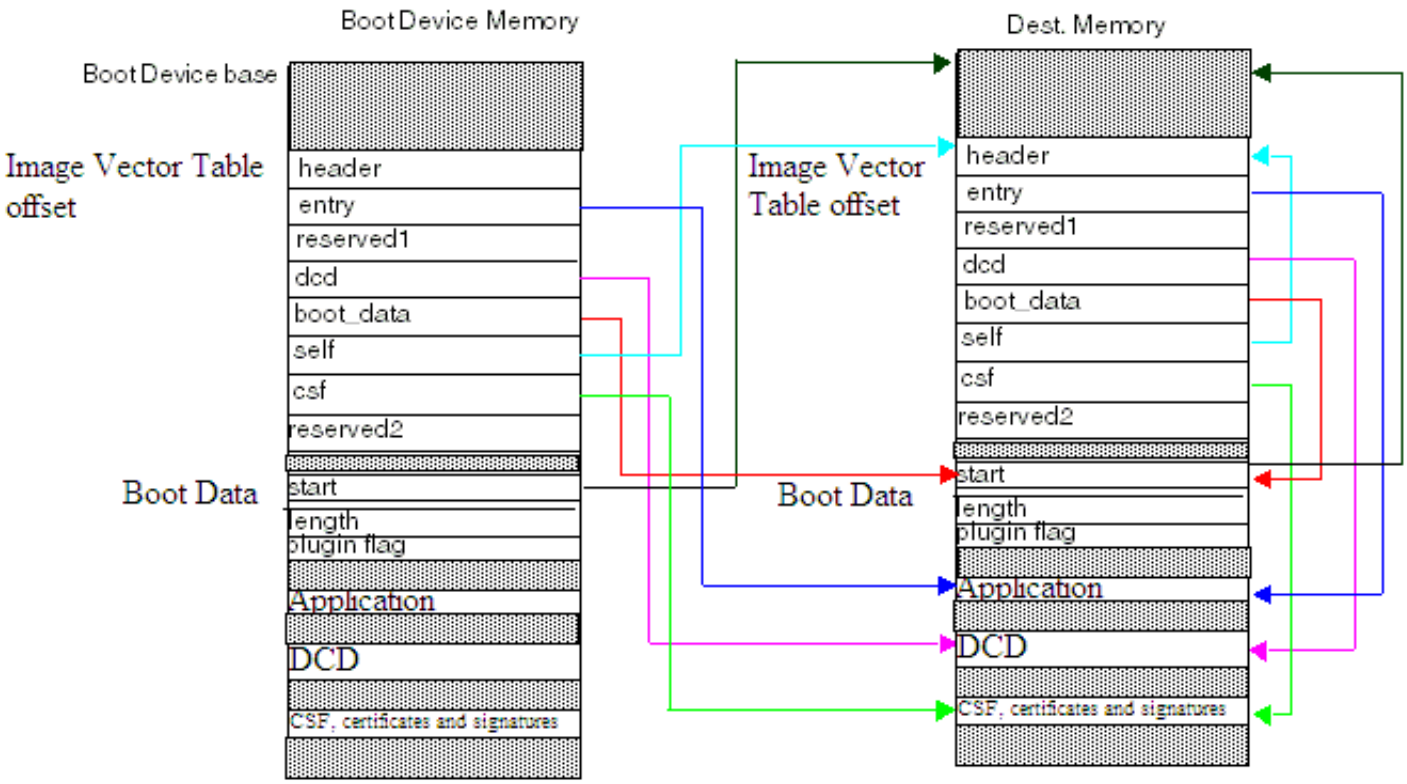

Figure 7-15. Image Vector Table

7.6.1.1 Image Vector Table Structure

The IVT has the following format (each entry is a 32 bit word):

Table 7-27. i.MX53 IVT Format

header
entry
reserved1
dcd
boot data
self
csf
reserved2

- header: The IVT header has the following format:

Table 7-28. IVT Header Format

Tag	Length	version

where:

```
Tag: A single byte field set to 0xD1
Length: a two byte field in big endian format containing the overall length of the IVT,
in bytes, including the header. (the length is fixed and must have a value of
32 bytes)
Version: A single byte field set to 0x40
```

- entry: Absolute address of the first instruction to execute from the image.
- reserved1: Reserved and should be zero.
- dcd: Absolute address of the image DCD. The DCD is optional so this field may be set to NULL if no DCD is required. See Device Configuration Data (DCD) for further details on DCD.
- boot data: Absolute address of the Boot Data
- self: Absolute address of the IVT. Used internally by the ROM.
- csf: Absolute address of Command Sequence File (CSF) used by the HAB library. See High Assurance Boot (HAB) for details on secure boot using HAB. This field must be set to NULL when not performing a secure boot.
- reserved2: Reserved and should be zero.

7.6.1.2 Boot Data Structure

The Boot Data must follow the format defined in Table 7-29, each entry is a 32-bit word.

Table 7-29. i.MX53 Boot Data Format

start
length
plugin

Where:

- start: Absolute address of the image
- length: Size of the program image
- plugin: Plugin flag

7.6.2 Device Configuration Data (DCD)

Upon reset the i.MX53 uses the default register values for all peripherals in the system. However, these settings typically are not ideal for achieving optimal system performance and there are even some peripherals that must configured before they can be used. The DCD is configuration information contained in a Program Image, external to the ROM, that the ROM interprets to configure various peripherals on i.MX53. For example, the EIM default settings allow core to interface to a NOR flash device immediately out of reset. This allows i.MX53 to interface with any NOR flash device, but has the cost of slow performance. Additional, some components such as SDRAM require some sequence of register programming as part of configuration before it is ready to be used. The DCD feature can be used to program the EIM registers and Enhanced SDRAM Controller (ESDCTL) registers to the optimal settings.

The ROM determines the location of the DCD table based on information located in the Image Vector Table (IVT). See Image Vector Table and Boot Data for more details. The DCD table shown in Table 7-30 is a big endian byte array of the allowable DCD commands. The maximum size of the DCD limited to 1768 bytes.

Table 7-30. DCD Data format

Header
[CMD]
[CMD]
...

The DCD header is 4 bytes with the following format:

Table 7-31. DCD Header

Tag	Length	Version

where:

```
Tag: A single byte field set to 0xD2
Length: a two byte field in big endian format containing the overall length of the DCD,
in bytes, including the header
Version: A single byte field set to 0x40
```

7.6.2.1 Write Data Command

The Write Data Command is used to write a list of given 1, 2 or 4-byte values or bitmasks to a corresponding list of target addresses. The format of Write Data Command, again a big endian byte array, is shown in Table 7-32.

Table 7-32. Write Data Command Format

Tag	Length	Parameter
Address		
Value/Mask		
[Address]		
[Value/Mask]		
...		
[Address]		
[Value/Mask]		

where:

```
Tag: A single byte field se to 0xCC
Length: A two byte field in big endian format containing the length of the Write Data
Command, in bytes, including the header
Address: target address to which data should be written
Value/Mask: data value or bitmask to be written to preceding address
```

The Parameter field is a single byte divided into bitfields as follows:

Table 7-33. Write Data Command Parameter field

7	6	5	4	3	2	1	0
flags					bytes		

where

```
bytes: width of target locations in bytes. Either 1, 2 or 4
flags: control flags for command behavior.
Data Mask = bit 3: if set, only specific bits may be overwritten at target address
(otherwise all bits may be overwritten)
Data Set = bit 4: if set, bits at the target address overwritten with this flag
(otherwise it is ignored)
```

One or more target address and value/bitmask pairs can be specified. The same bytes and flags parameters apply to all locations in the command.

When successful, this command writes to each target address in accordance with the flags as follows:

Table 7-34. Interpretation of Write Data Command Flags

"Mask"	"Set"	Action	Interpretation
0	0	*address = val_msk	Write value
0	1	*address = val_msk	Write value
1	0	*address &= ~val_msk	Clear bitmask
1	1	*address |= val_msk	Set bitmask

NOTE

If any of the target addresses does not have the same alignment as the data width indicated in the parameter field, none of the values are written.

If any of the values is larger or any of the bitmasks is wider than permitted by the data width indicated in the parameter field, none of the values are written.

If any of the target addresses do not lie within an allowed region, none of the values are written. The list of allowable blocks and target addresses for i.MX53 are given below.

Table 7-35. Valid DCD Address Ranges

Address range	Start address	Last Address
CCM register set	0x53FD4000	0x53FD7FFF
EIM register set	0x63FDA000	0x63FDAFFF
NANDFC register set	0xF7FF0000	0xF7FFFFFF
IOMUX Control (IOMUXC) registers	0x53FA8000	0x53FABFFF
DPLLC1 register	0x63F80000	0x63F83FFF
DPLLC2 register	0x63F84000	0x63F87FFF
DPLLC3 register	0x63F88000	0x63F8BFFF
DPLLC4 register	0x63F8C000	0x63F8FFFF
ESD RAM controller register	0x63FD9000	0x63FD9FFF
M4IF register	0x63FD8000	0x63FD8FFF
DDR	0x70000000	0xEFFFFFFF
EIM	0xF0000000	0xF7FEFFFF
NANDFC Buffers	0xF7FF0000	0xF7FFFFFF
IRAM Free Space	0xF8006000	0xF8017FF0
GPU Memory	0xF8020000	0xF805FFFF

7.6.2.2 Check Data Command

The Check Data Command is used to test for a given 1, 2 or 4-byte bitmasks from a source address. The Check Data Command is a big endian byte array with format shown in Table 7-36.

Table 7-36. Check Data Command Format

Tag	Length	Parameter

Table continues on the next page...

Table 7-36. Check Data Command Format (continued)

Address
Mask
[Count]

where:

```
Tag: A single byte field se to 0xCF
Length: A two byte field in big endian format containing the length of the Check Data
Command, in bytes, including the header
Address: source address to test
Mask: bit mask to test
Count: optional poll count. If count is not specified this command will poll indefinitely
until the exit condition is met. If count = 0, this command behaves as for NOP.
```

The Parameter field is a single byte divided into bitfields as follows:

Table 7-37. Check Data Command Parameter field

7	6	5	4	3	2	1	0
flags					bytes		

where

```
bytes: width of target locations in bytes. Either 1, 2 or 4
flags: control flags for command behavior.
Data Mask = bit 3: if set, only specific bits may be overwritten at target address
(otherwise all bits may be overwritten)
Data Set = bit 4: if set, bits at the target address overwritten with this flag
(otherwise it is ignored)
```

This command polls the source address until either the exit condition is satisfied, or the poll count is reached. The exit condition is determined by the flags as follows

Table 7-38. Interpretation of Check Data Command Flags

"Mask"	"Set"	Action	Interpretation
0	0	(*address & mask) == 0	All bits clear
0	1	(*address & mask) == mask	All bits set
1	0	(*address & mask)!= mask	Any bit clear
1	1	(*address & mask)!= 0	Any bit set

NOTE

If the source address does not have the same alignment as the data width indicated in the parameter field, the value is not read.

If the bitmask is wider than permitted by the data width indicated in the parameter field, the value is not read.

See DCD Table Structure of Device Configuration Data in DCD Example

7.6.2.3 NOP Command

This command has no effect. The format of Check Data Command is a little endian four byte array as shown in Table 7-36

Table 7-39. NOP Command Format

Tag	Length	Undefined

where:

```
Tag: A single byte field se to 0xC0
Length: A two byte field containing the length of the NOP Command in bytes. Fixed to a
value of 4.
Undefined: This byte is ignored and can be set to any value.
```

7.7 Plugin Image

i.MX53 ROM supports a limited number of boot devices. For using other devices as boot source (for example, ethernet, CDROM, or USB), the supported boot device must be used (typically serial ROM) for firmware with the missing boot drivers.

Boot ROM will detect the image type by plugin flag of boot data structure (see Boot Data Structure). If the plugin flag is 1, then ROM will use the image as plugin function. The function must initialize boot device and copy program image to final location. At the end the plugin function must return with the parameters of program image.

The boot ROM will authenticate the plugin image prior running plugin function and then will authenticate the program image.

The plugin function must follow the API described below:

typedef unsigned char (*) plugin_download_f(void **start, size_t *bytes, UINT32 *ivt_offset)

ARGUMENTS PASSED:

- start - Image load address on exit.
- bytes - Image size on exit.
- ivt_offset - Offset in bytes of the IVT from the image start address on exit.

RETURN VALUE:

- 1 - on success
- 0 - on failure

7.8 Serial Downloader (BOOT_MODE[1:0] = 0b11)

The Serial Downloader provides a means to download a Program Image to i.MX53 over a UART or USB serial connection. In this mode the ROM programs WDOG-1 for a 32-second time-out if WDOG_ENABLE eFuse is 1, and then continuously polls for USB and UART actively in an alternating fashion. If no activity is found on either USB or UART and the watchdog timer expires the ARM core is reset.

NOTE

The downloaded image must continue to service the watchdog timer to avoid an undesired reset from occurring.

The USB/UART boot flow is shown in Figure 7-16.

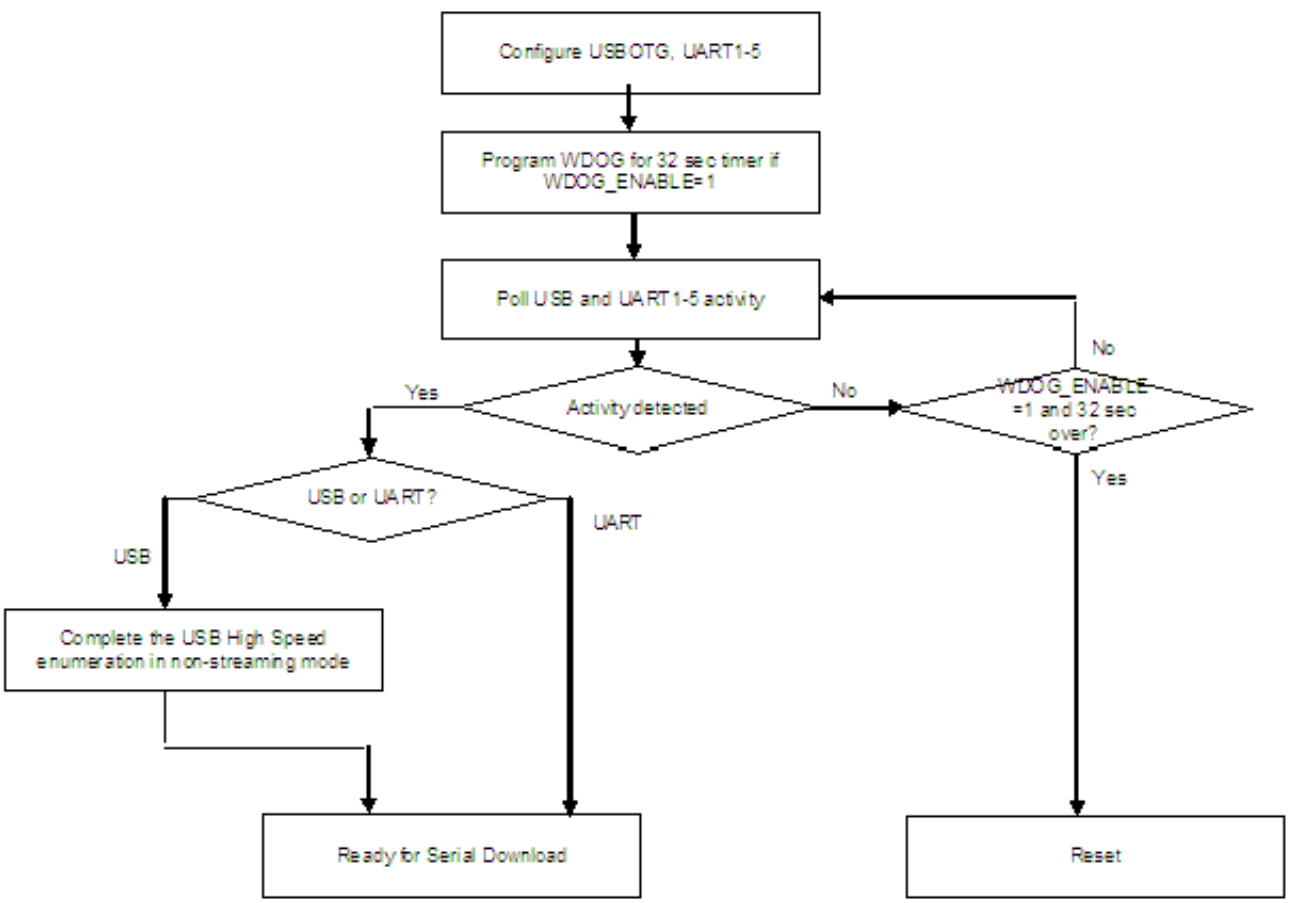

Figure 7-16. USB/UART Boot Flow

7.8.1 USB

The USB support is composed of the USBOH3 (USB OTG core controller, compliant with the USB 2.0 specification and three additional USB hosts) and the USBPHY (HS USB transceiver).

The USB OTG port is the bootable USB device. Additional USB hosts are intended for the intraplatform communication and not bootable.

To enumerate the ROM boot USB function the host PC needs a compatible windows driver and a specific application "Manufacturing Tool". Once enumerated, the USB boot device uses a specific protocol "Download protocol" to download and launch the application.

For USB boot, the USB controller is used, with the integrated PHY. The Boot ROM USB driver configures the USB controller to function in High Speed non-stream bulk mode with 512B maximal packet size. The control endpoints EP0IN and EP0OUT are configured for control transfer and for data transfer in bulk mode EP1OUT and EP2IN are configured as IN and OUT transactions respectively. The supported transceivers are in Table 7-40.

Table 7-40. Supported USB Transceivers

Transceiver	Speed	Interface	USB Controller Mode
Internal PHY	High Speed (HS)	UTMI	High Speed (HS) non-stream bulk mode with a maximal packet size 512B

7.8.1.1 USB Configuration Details

The USB OTG function device driver supports a high speed (HS for UTMI) non-stream mode with a maximal packet size of 512 B and a low-level USB OTG function.

The VID/PID and strings for USB device driver are listed in Table 7-41.

Table 7-41. VID/PID and Strings for USB Device Driver

Descriptor	Value
VID	0x15A2 (Freescale vendor ID)
PID[1]	0x004E
Screen Descriptor1 (manufacturer)	Freescale Semiconductor, Inc.

Table continues on the next page...

Table 7-41. VID/PID and Strings for USB Device Driver (continued)

Descriptor	Value
Screen Descriptor2 (product)	S Blank RITA SE Blank RITA NS Blank RITA
Screen Descriptor4	Freescale Flash
Screen Descriptor5	Freescale Flash

1. Allocation based on BPN (Before Part Number)

7.8.1.2 IOMUX Configuration for USB

The interface signals of the UTMI PHY are not configured in the IOMUX. The UTMI PHY interface uses dedicated contacts on the IC. See the i.MX53 data sheet for details.

7.8.2 UART

All the UART (UART-1, UART-2, UART-3, UART-4 and UART-5) ports can be used as a boot device. The ROM boot functions polls all the ports for data activity indication. Once indicated, the UART boot device uses a specific protocol, called the Serial Downloader Protocol, to download and launch a program image. The UART driver uses the communication parameters listed in Table 7-42.

Table 7-42. UART Communication Parameters

Parameter	Value
Baud rate	115.2 kbaud
Parity check	Disabled
Word size	8 bits
Stop bits	1 bit
RTS	Ignored
CTS	Controlled by host
Receive pin	RXD1
Transmit pin	TXD1

7.8.2.1 IOMUX Configuration for UART

The contacts assigned to the signals used by the three UART blocks is shown in Table 7-43.

Table 7-43. UART IOMUX Pin Configuration

Signal	UART-1	UART-2	UART-3	UART-4	UART-5
TXD	CSI0_DAT10.alt2	PATA_DMARQ.alt 3	EIM_D25.alt2	CSI0_DAT12.alt2	CSI0_DAT14.alt2
RXD	CSI0_DAT11.alt2	PATA_BUFFER_EN.alt3	EIM_D24.alt2	CSI0_DAT13.alt2	CSI0_DAT15.alt2

NOTE

ROM polls activity on all UART ports.When activity is detected on one of these ports, ROM starts waiting for data on this particular port and never goes to another port. UART pads can be muxed with different devices, therefore board design should take this into account and don't connect to UART RX pads devices that can drive these pads during boot.

7.8.3 Serial Download Protocol

This section describes the serial download protocol used for all boot devices in the serial bootloader on the i.MX53.

Each stage in the protocol begins with a command issued by the host to the device, followed by a response from the device to the host. For most commands, that completes the protocol stage. The exception is the Write File command, which has an additional data stream sent from the host to the device after the response.

The protocol is terminated by the host issuing a Write File command with application file type. After processing the Write File commands, the device interprets the next command as a Completed command, and resumes execution of the boot flow in order to authenticate the downloaded application (if required) and then execute it.

7.8.3.1 Get Status

The Get Status command retrieves the error log stored during a failed boot (or the success code when the Serial bootloader is selected deliberately).

Table 7-44. Get Status Command

Command	0x05	0x05	-	-	-	-	-	-	-	-	-
Response	SC	SC	SC	SC	SC						

The fields have the following interpretation:

- SC Status Code. Four copies of the status code are sent.
- - Don't Care (but must be present)

7.8.3.2 Read Memory

The Read Memory command reads a stream of bytes, half-words or words of data starting from a given address in memory. For Closed security configuration, this command is ignored.

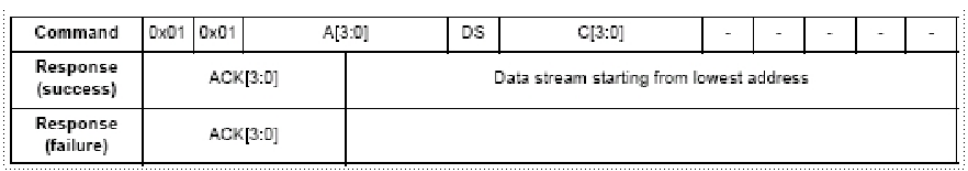

Figure 7-17. Read Memory Command

The fields have the following interpretation:

- A[3:0] = Target address (most-significant byte first).
- DS = Data Size (0x08 = byte, 0x10 = half-word, 0x20 = word). Unsupported DS values result in a failure response.
- C[3:0] = Number of data elements (bytes, half-words or words as appropriate) in data stream (most-significant byte first).
- ACK[3:0] = 0x56, 0x78, 0x78, 0x56.
- - = Don't Care (but must be present)

7.8.3.3 Write Memory

The Write Memory command writes a byte, half-word or word of data to a given address in memory.

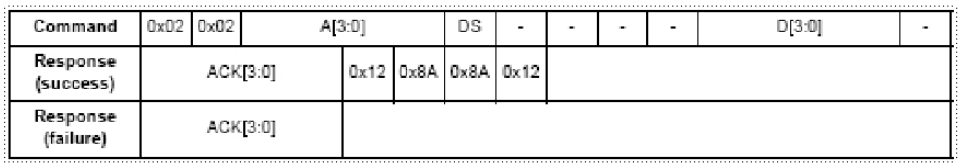

Figure 7-18. Write Memory Command

The fields have the following interpretation:

- A[3:0] = Target address (most-significant byte first).
- DS = Data Size (0x08 = byte, 0x10 = half-word, 0x20 = word). Unsupported DS values result in a failure response.
- D[3:0] = Data to write(most-significant byte first). For DS = 0x08, only D[0] is used. For DS = 0x10, only D[1:0] is used.
- ACK[3:0] = 0x12, 0x34, 0x34, 0x12 for Closed security configuration, and 0x56, 0x78, 0x78, 0x56 otherwise.
- - = Don't Care (but must be present)

For Closed security configuration, the address ranges which may be written are restricted to those listed for DCD, DDR memory space and internal memory regions (IRAM, GMEM and NFC buffer). Attempts to write outside of the valid ranges are ignored and result in the failure response. For other security levels, no restrictions apply to the target address.

7.8.3.4 Re-enumerate

The Re-enumerate command resets the USB connection with an updated descriptor.

Table 7-45. Re-enumerate Command

Command	0x09	0x09	-	-	-	-	-	-	-	SN[3:0]	-
Response	0x89	0x23	0x23	0x89							

The fields have the following interpretation:

- SN[3:0] = Serial number for enumeration descriptor.
- - = Don't Care (but must be present)

7.8.3.5 Write File

The Write File command writes a stream of bytes to a given address in memory. The byte stream may be assigned a file type in order to distinguish CSF, DCD and application files. An application file type leads to the termination the serial download protocol, with the next command (whatever the command byte values) being treated as the Completed command.

Command	0x04	0x04	A[3:0]	-	C[3:0]	-	-	-	-	FT
Response	ACK[3:0]									
Data	Byte stream with data for lowest address first									

Figure 7-19. Write File Command

The fields have the following interpretation:

- A[3:0] = Target address (most-significant byte first).
- C[3:0] = Number of bytes in data stream (most-significant byte first).
- FT= File Type (0xAA = application (terminates protocol), 0xCC = CSF, 0xEE = DCD). With unrecognized FT values, the file is still downloaded, but the pointers to the three essential files are not modified.
- ACK[3:0] = 0x12, 0x34, 0x34, 0x12 for Closed security configuration, and 0x56, 0x78, 0x78, 0x56 otherwise.
- - = Don't Care (but must be present)

For Closed security configuration, the address ranges which may be written are restricted to those listed for DCD DDR memory space and internal memory regions (IRAM, GMEM and NFC buffer). Attempts to write outside of the valid ranges are ignored and result in the failure response. For other security levels, no restrictions apply to the target address.

7.8.3.6 Completed

The Completed command is required after the Write File command with application file type in order to terminate the protocol. The content of the command is irrelevant, but a command must be sent. This command triggers authentication and DCD processing (if required) followed by execution of the application using entry pointer from IVT (see Image Vector Table Structure). For Closed security configuration, if application authentication fails, the serial download protocol resumes, with the status code for authentication failure available through the Get Status command.

Table 7-46. Completed Command

Command	-	-	-	-	-	-	-	-	-	-	-
Response	0x88	0x88	0x88	0x88							

The fields have the following interpretation:

- - = Don't Care (but must be present)

7.9 Watchdog Reset Boot Mode

For testing purposes, shadow SBMR register and SW watchdog reset can be used. SW can write to PERSIST_SBMR_SHADOW register value to select override boot mode settings. Then PERSIST_WDOG_RESET must be set and SW reset must be performed (see Table 7-7).

In case of SW reset the ROM code checks if PERSIST_WDOG_RESET is set. If it is set it uses PERSIST_SBMR_SHADOW register. Otherwise it uses SRC shadow register.

This mode is disabled if DIR_BT_DIS eFuse is blown.

7.10 High Assurance Boot (HAB)

The High Assurance Boot (HAB) component of the ROM protects against the potential threat of attackers modifying areas of code or data in programmable memory to make it behave in an incorrect manner. The HAB also prevents attempts to gain access to features which should not be available. The integration of the HAB feature with the ROM code ensures that i.MX53 does not enter an operational state if the existing hardware security blocks have detected a condition that may be a security compromise or areas of memory deemed to be important have been modified. The HAB uses RSA digital signatures to enforce these policies.

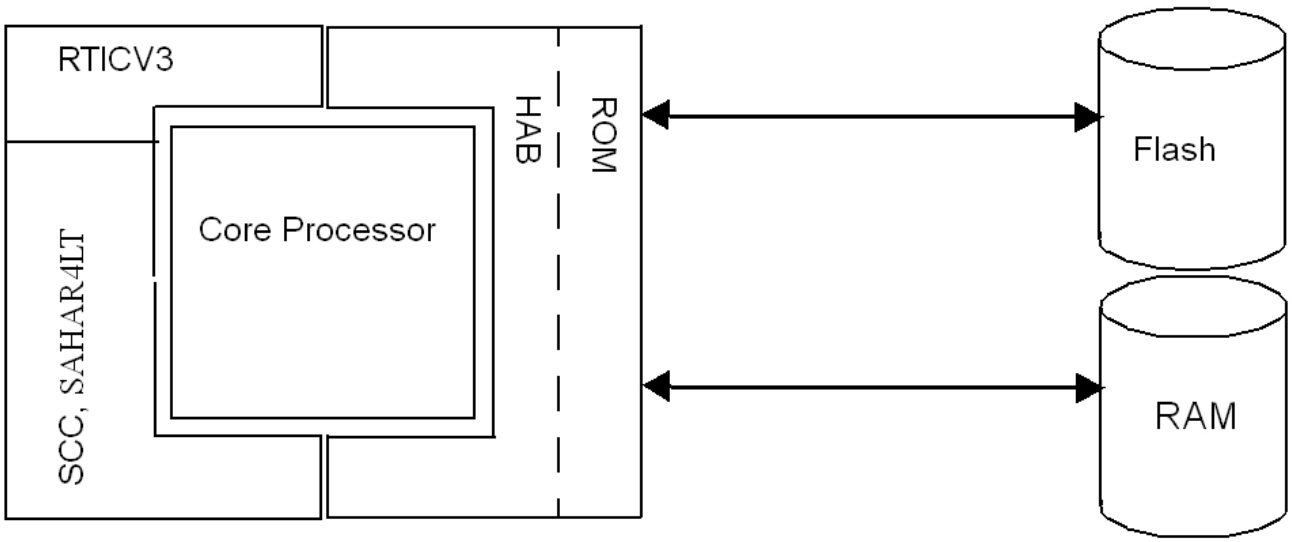

Figure 7-20. Secure Boot Components

Figure 7-20 illustrates the components used during a secure boot using HAB. The HAB interfaces with the SCC to ensure the system security state is as expected. The HAB also makes use of SAHARA and/or RTIC hardware blocks to accelerate SHA-256 message digest operations performed during signature verifications. The HAB also includes a software implementation of SHA-256 for cases where a hardware accelerator cannot be used. The core RSA signature verification operations are performed by a software implementation contained in the HAB library. The main features supported by HAB are:

- X.509 Public key certificate support
- CMS signature format support

NOTE

For further details on making use of the i.MX53 secure boot feature using HAB contact your local Freescale representative.

7.10.1 ROM Vector Table Addresses

For devices that perform a secure boot, the HAB library may be called by boot stages that execute after ROM code. The RVT table contains the pointers to the HAB API functions and is located at 0x00000094

NOTE

For additional information on secure boot on i.MX53 including the HAB API contact your local Freescale representative

7.10.2 SRTC Initialization

NOTE

Refer to the i.MX53 Security Reference Manual for information on Secure Real Time Clock (SRTC) initialization. For details on SRTC initialization when performing a secure boot with HAB contact your local Freescale representative.

7.11 Examples

7.11.1 NAND eFuse Configuration Example

Table 7-47. NAND eFuse Configuration Example

Fuse	Definition	Setting	Description
BOOT_CFG1[7]	Boot Device Selection	1	NAND device is used
BOOT_CFG1[6]	Muxed On	1	NAND data bus uses EIM pads EIM_DA[16:0]
BOOT_CFG1[5:4]	Interleaving Scheme	00	No Interleaving. ROM code will use CS0 only for reading data from NAND device.
BOOT_CFG1[3:2]	Address Cycles	10	5 address cycles
BOOT_CFG2[7:6]	Page Size	01	Page size is 2KB + 64 Bytes spare area, 4-bit ECC is used
BOOT_CFG2[5]	NAND Interface Bus Width	0	8 bit device is used
BOOT_CFG2[2]	NFC_FREQ_SEL	1	NAND frequency will be (AXI DDR divide by 28): 14.29MHz if AXI/DDR Freq eFuse is 0 11.9MHz if AXI/DDR Freq eFuse is 1).
BOOT_CFG3[7]	Stride Size (Bad Block skip step)	1	FCB search stride is 8 blocks
BOOT_CFG3[6]	LBA-Nand Select	0	Non LBA device. 11ms delay will be used after device reset.
BOOT_CFG3[5]	NAND Use R/B Signals:	1	Use R/B signals.
BOOT_CFG3[4:3]	ECC / Spare select:	00	4-bit ECC
BOOT_CFG3[2:1]	Pages In Block	01	NAND device has 64 pages in block

7.11.2 DCD Example

Chapter 8
Multimedia

8.1 The Video/Graphics Sub-System

NOTE

The information in this chapter takes precedence if any discrepancy between the information here, and the information in the mentioned block guides (like IPU, GPU2D, GPU3D, VPU and so on) arises.

The video-graphics sub-system includes the following dedicated blocks (see Figure 8-1):

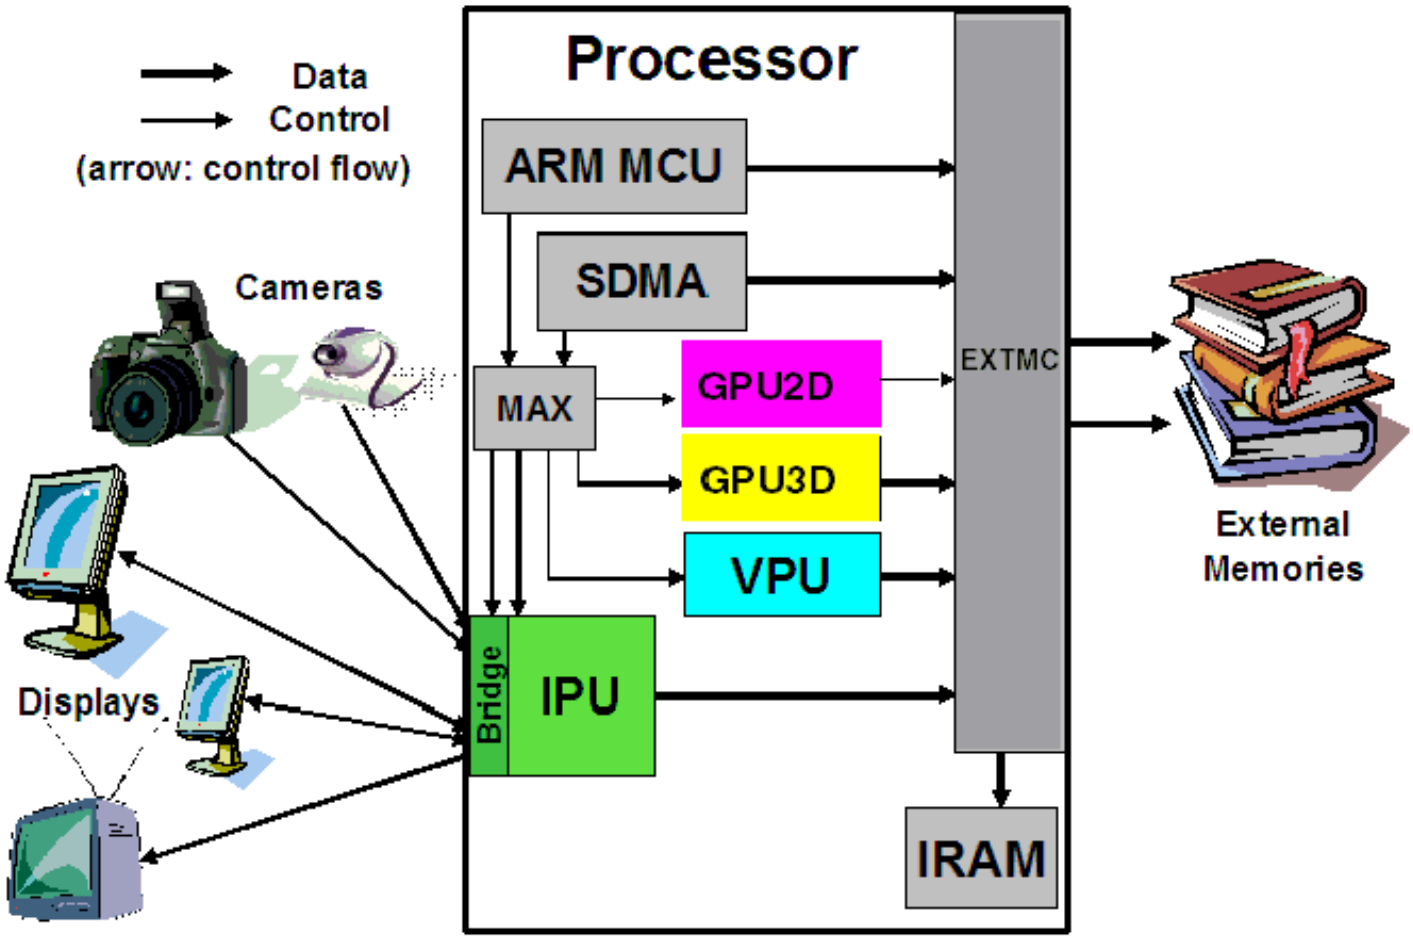

Figure 8-1. The Video-Graphics Subsystem

- Video Processing Unit (VPU): a multi-standard video/image codec
- Two Graphics Processing Units (GPUs): one for accelerating 3D graphics (OpenGL/ES), and one for accelerating vector graphics (OpenVG and 2D graphics BitBLT)
- Image Processing Unit (IPU): providing connectivity to cameras and displays, related processing, synchronization and control
- Display interface bridges: providing optional translation from the digital display interface supported by the IPU to other interfaces:
  - TV Encoder (TVE) bridge: composite, S-video, component and VGA interfaces
  - LVDS bridge: up to two LVDS interfaces

These blocks are connected to the other parts of the system as follows:

- The display ports are described in Figure 8-1.

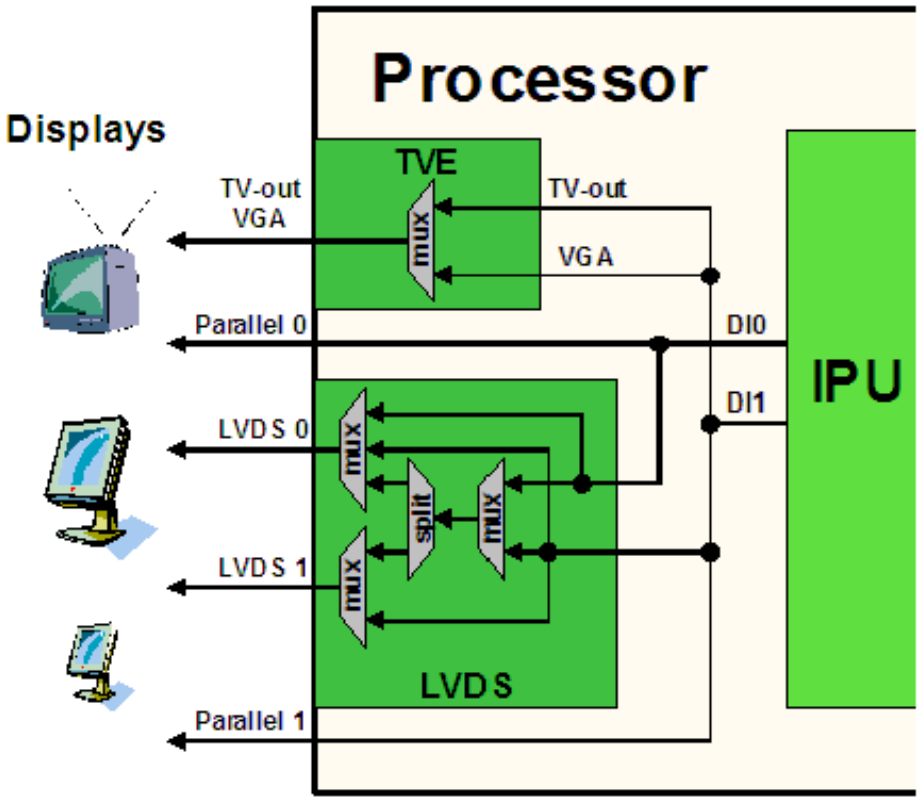

Figure 8-2. The Display Ports

There are five ports:

- Two parallel - driven directly by the IPU
- One analog (TV-out or VGA) - driven by the TVE
- Two LVDS channels, driven by the LVDS bridge

IPU has 2 display ports, so only up to two external ports can be active at any given time.

(Additional asynchronous data flows can be sent though the parallel ports.)

- IPU has 2 camera ports, used to connect to relevant external devices.
- The IPU, VPU and the GPUs have a master AXI port, providing access to system memory.
- The blocks are controlled by the ARM Cortex A8TM Platform (ARM) or the Smart Direct Memory Access (SDMA) as follows
  - The LVDS bridge is controlled by signals connected to top-level registers
  - All other blocks have host interfaces. The VPU and TVE blocks use slave IP ports and the GPU and IPU blocks use slave AHB ports.
- The slave AHB port of the GPUs also allows a direct access of the host to the GPUs internal memory, for the transfer of graphics commands, for example.

- The slave AHB port of the IPU also provides a direct access of the host to an external display controller, connected to the parallel display port.
- There is an interface between the IPU and the GPUs, allowing direct synchronization between them, to transfer graphics data from the GPUs to the IPU (through system memory) while avoiding tearing.

Further aspects of these blocks are outlined in the following sub-sections.

8.2 Image Processing Unit (IPU)

Table 8-1. IPU Block Parametric Table

Name	IPU
Function	Connectivity to cameras and displays; related processing; synchronization and control
External I/O Pins Notes: This is the pinout of the IPU block At chip level, some of the pins are muxed and some are omitted. Additional General Purpose I/O Module (GPIO) pins are required to construct the connection. This is not included in this list.	Parallel Display port: 24-bit data, ~18 clocks and controls. Regular CMOS IO type, 180 MHz max. May be also connected to the TVE or LVDS internal connectivity bridges. Slow Serial Display port: 2 bit data, 3 clocks and controls. Regular CMOS IO type, 120 MHz max. Parallel Sensor port: 20 bit data inputs, 5-6 clocks and controls. Regular CMOS IO type, 180 MHz max. Camera strobe port: 6 camera control outputs. Regular CMOS IO type, 180 MHz max.
SoC Buses	AXI master - for accessing the memory AHB slave - for programming, control and direct access of the ARM Core to the display
Interrupts	Two types of interrupts: one triggered by selected completion events and a second triggered by selected internal error events
DMA Requests	An integral DMA controller, with an AXI master port One DMA request to the SDMA
Number of instantiations	1
Clock sources and range	HSP_CLK - Internal high-speed processing clock: up to 200 MHz DI_CLK0, DI_CLK1 - Display interface clocks: up to 180 MHz In addition, a sensor may require a "master" clock source: 2-180 MHz

The goal of the IPU is to provide comprehensive support for the flow of data from an image sensor and/or a display device. This support covers all aspects of these activities:

- Connectivity to relevant devices - cameras, displays, graphics coprocessors, TV encoders and decoders.
- Related image processing and manipulation: image enhancements and conversions, etc.
- Synchronization and control capabilities (for example, to avoid tearing artifacts)

This integrative approach leads to several significant advantages:

- Automation:

  The involvement of the ARM Core in image management is minimized. In particular, display refresh/update and a camera preview (displaying the input from an image sensor) can be performed completely autonomously. The resulting benefits are reducing the overhead due to SW-HW synchronization, freeing the ARM Core to perform other tasks and reducing the power consumption (when the ARM Core is idle and can be powered down).

- Optimal data path:

  Access to system memory is minimized. In particular, significant processing can be performed on-the-fly while receiving data from an image sensor and/or sending data to a display. System memory is used essentially only when a change in pixel order or frame rate is needed. The resulting benefits are reduced load on the system bus and further reduction of power consumption.

- Resource sharing:

  Maximal HW reuse for different applications, resulting with the support of a wide range of requirements with minimal HW

The HW reuse mentioned above is enabled by a sophisticated configurability of each HW block. This configurability also allows the support of a wide range of external devices, data formats and operation modes. The resulting flexibility is important because the support requirements are evolving significantly, so expected future changes need to be anticipated and accounted for.

A simplified block diagram of the IPU is given in Figure 8-3. The role of each block is described in Table 8-2.

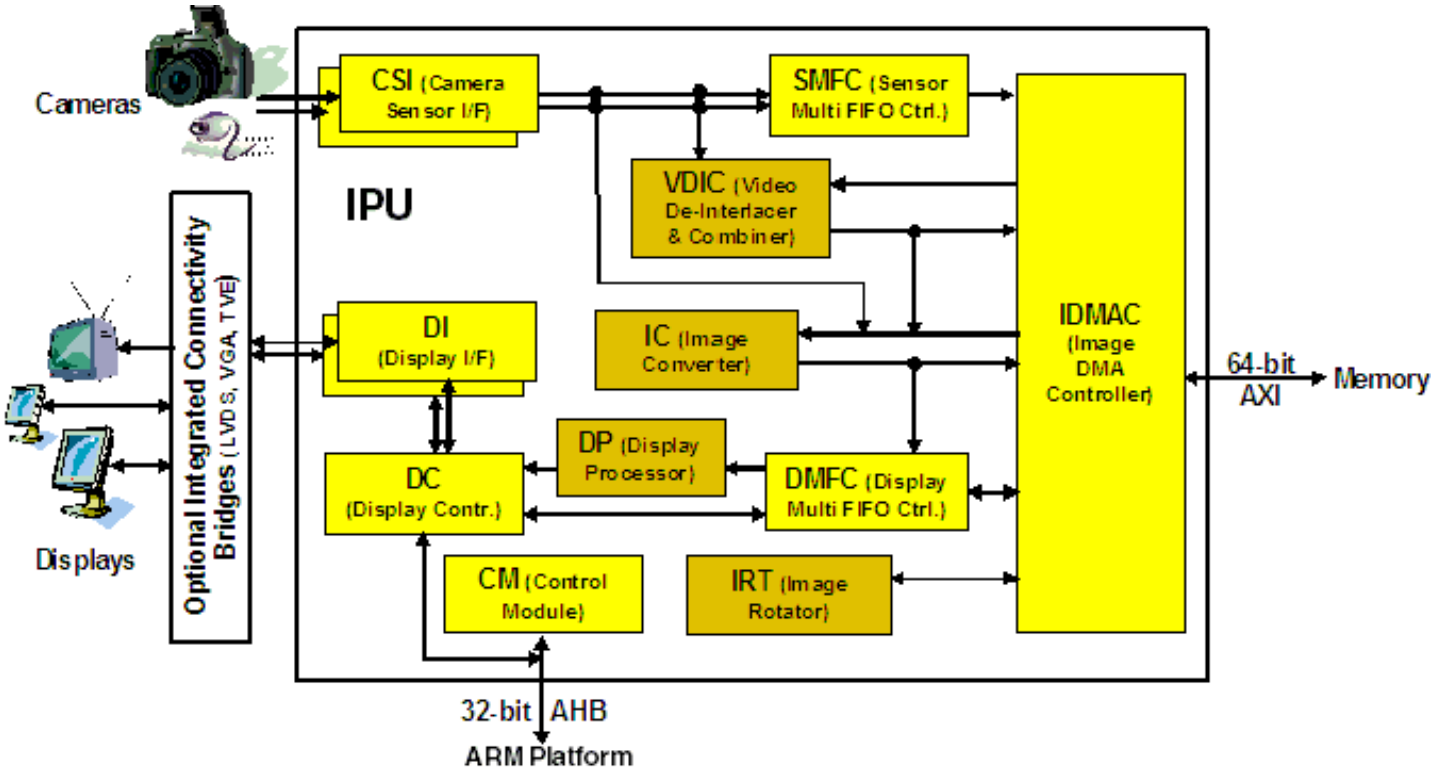

Figure 8-3. IPU - Block Diagram

Table 8-2. IPU - Block Description

Block	Description
CSI - Camera Sensor Interface	Controls a camera port; provides interface to an image sensor or a related device. IPU includes 2 such blocks
DI - Display Interface	Provides interface to displays, display controllers and related devices. IPU includes 2 such blocks
DC - Display Controller	Controls the display ports.
VDIC - Video De-Interlacer and Combiner	Performs deinterlacing - converting interlaced video to progressive - or combining
IC - Image Converter	Performs resizing, color conversion/correction, combining with graphics, and horizontal inversion
DP - Display Processor	Performs the processing required for data sent to display
IRT - Image Rotator	Performs rotation (90 or 180 degrees) and inversion (vertical/horizontal)
IDMAC - Image DMA Controller	Controls the memory port; transfers data to/from system memory
SMFC - Sensor Multi FIFO Controller	Controls FIFO's for output from the CSI's to system memory
DMFC - Display Multi FIFO Controller	Controls FIFO's for IDMAC channels related to the display system
CM - Control Module	Provides control and synchronization.

In the following, the main features of the IPU are listed.

8.2.1 External Ports-IPU

The IPU has the following ports:

- Two camera port - controlled by a CSI sub-block - providing a connection to image sensors and related devices.
- Two display ports - each controlled by a DI sub-block - providing a connection to displays and related devices.
- Memory port - AXI (AHB V3.0) master, controlled by the IDMAC - providing connection to the system memory.
- AHB-Lite slave port, providing connection to the ARM (and to any other master connected to the ARM's cross-bar switch)

8.2.1.1 Camera Port

The role of these ports is to receive input from image sensors (or TV decoders) and to provide support for time-sensitive control signals to the camera. Non-time-sensitive controls - such as configuration, reset - are performed by the ARM Core through an I2C interface or General Purpose I/O Module (GPIO) signal.

Each of the camera ports includes the following features:

- Direct connectivity to most relevant image sensors and to TV decoders.
- Parallel interface - up to 20-bit data bus
- Frame size: up to 8192 x 4096 pixels (including blanking intervals)
- Data formats supported include Raw (Bayer), RGB, YUV 4:4:4, YUV 4:2:2 and grayscale, up to 16 bits per value (component).
- Synchronization - video mode
  - The sensor is the master of the pixel clock (PIXCLK) and synchronization signals
  - Synchronization signals are received using either of the following methods:
    - Dedicated control signals -VSYNC, HSYNC - with programmable pulse width and polarity
    - Controls embedded in the data stream, following loosely the BT.656 protocol, with flexibility in code values and location.
- Synchronization - still image capture

- The image capture is triggered by the ARM Core or by an external signal (for example, a mechanical shutter)
- Synchronized strobes are generated for up to 6 outputs - the sensor and camera peripherals (flash, mechanical shutter...)

- Additional features
  - Frame rate reduction, by periodic skipping of frames
  - Window-of-interest selection
  - Pre-flash - for red-eye reduction and for measurements (such as focus) in low-light conditions

Several sensors can be connected to each of the CSIs. Simultaneous functionality (sending data) is supported as follows:

- Two sensors can send data independently, each through a different port.
- Only one of the streams can be transferred to the VDIC or IC for on-the-fly processing, while the other one is sent directly to system memory.

The input rate supported by the camera port is as follows:

- Peak: up to 180 MHz (values/sec)
- Average (assuming 35% blanking overhead), for YUV 4:2:2
  - Pixel in one cycle (BT.1120): up to 135 MP/sec, e.g. 9M pixels @ 15 fps
  - Pixel on two cycles (BT.656): up to 67 MP/sec, e.g. 4.5M pixels @ 15 fps.
- On-the-fly processing may be restricted to a lower input rate.

8.2.1.2 Display Ports

The role of these ports is to communicate with display devices, either directly or through a controller (such as a graphics accelerator) or a bridge (such as a TV encoder or an LVDS interface bridge).

8.2.1.2.1 Access Modes

Two access modes are supported.

8.2.1.2.1.1 Synchronous Access

In this mode, the IPU transfers a two-dimensional block of pixels to the display device, in synchronization with the screen refresh cycle.

This mode has a dual role:

- For a RAM-less display or a TV screen, this mode is used to perform the screen refresh process from a display buffer in system memory.
- For a "smart" display, this mode is used to transfer a rectangular block of pixels to the display's screen and, in some cases, also to the display buffer

In both cases, the IPU sends all the synchronization signals controlling the screen refresh to the display, and the block transfer is synchronized with these signals. This synchronization means that tearing effects are avoided when using this mode.

8.2.1.2.1.2 Asynchronous Access

This is the main mode used for communicating with an external display controller (possibly in a smart display or a graphics accelerator). In this mode, the IPU performs random access - read/write - to the memory and registers of the controller.

The following access types are provided:

- Data transfer to the external device, after on-the-fly processing in the IPU.
- Data transfer (DMA) - read/write - between the host's system memory and the external device, through the IPU's memory port (controlled by the IDMAC); the transfer of a rectangular block of pixels (possibly full screen).
- Host access - read/write - to an external device, through the slave AHB port
  - Access types
    - Direct access - emulating a directly-addressed access (see below)

      This includes burst access (incremental; up to 8 words/burst)

    - Low-level access - leaving to the host the explicit generation of the access protocol
  - The possible accessing blocks include the ARM Core and the system DMA controller (as well as any other AHB master connected to the ARM Core's cross-bar switch).

The asynchronous access requires the specification of an address. The display interface uses "indirect addressing", namely, there is no address bus, and the address, as well as control and configuration commands, are embedded in the data stream. The access procedure - including writing addresses and commands - can be managed autonomously by the interface, using an access template generated by the ARM Core.

8.2.1.2.2 The Interface

The display interface is very flexible and supports a wide variety of devices from major manufacturers. The following interface types are provided (in each of the two display ports)

- A parallel video interface (for synchronous access) - up to 24-bit data bus.
  - Supports BT.656 (8-bit) and BT.1120 (16-bit) protocols
  - Supports HDTV standards SMPTE274 (1080i/p) and SMPTE296 (720p)
- A parallel bidirectional bus interface (for asynchronous access) - up to 32-bit data bus.
- A serial interface - 3-wire, 4-wire and 5-wire (two flavors) (for asynchronous access)

The supported formats for pixel data are: RGB and YUV 4:2:2 (for TV encoder).

For the interface clock, there are the following options (independently for each port)

- Derived from the IPU internal clock (master mode)
- Provided by an external source (slave mode)

Transfer rates supported:

- Pixel clock frequency up to 200MHz when a single port is active.
- With both ports active
  - Each pixel clock may be up to170 MHz
  - The sum of pixel clock rates may not exceed 180 MHz

8.2.1.2.2.1 Connecting To Display Devices

IPU allows the connectivity to multiple display devices. In particular, it supports the following setup:

- Primary LCD display: can be smart, dumb (RAM-less) or dual-port; may use the parallel interface, or (through an integrated bridge) LVDS interface.
- Second LCD display: can be smart or dumb (RAM-less); may use parallel or legacy serial interface, or (through an integrated bridge) LVDS interface.
- TV Output: either digital parallel output, or (through the integrated TV encoder bridge) analog output.

Simultaneous functionality of the above devices is possible in each of the following ways:

- Two devices can be accessed (synchronously or asynchronously) independently, each through a different port: each using any of the available interfaces.
- Two devices can time-share asynchronous accesses through the legacy serial and parallel interfaces, using the CS signals.
- An asynchronous access can be performed during vertical blanking intervals of a synchronous access (screen refresh; to the same or other device).

8.2.2 Processing-IPU

The IPU processes rectangular blocks of pixels. The processing is performed in four sub-blocks - VDI, IC, DP and IRT (see Figure 8-3 and Table 8-2). Several time-shared data flows are supported, as described in Table 8-3.

Table 8-3. Time-Shared Data Flows through the IPU

Name	Number	Type	Flow	Target	Restrictions
Display Refresh/ Update	5 flows (at most two of them of type DS1)	DS1	Fmem -> DP -> Display	Synchronous Access (such as display refresh; controlled by the DI)	-
		DS2	Fmem -> DP -> Display	Asynchronous Access (such as display update)	-
		DS3	Fmem <-> Display	Generic Data Transfer	-
	1 flow	DS4	ARM Core<-> Display	Direct Access	-
Video Playback	1 flow	PL1	Bmem -> VDI -> IC -> Bmem -> IRT -> Fmem + DSx	Main option	-
		PL2	Fmem -> IRT -> Bmem -> IC -> DP	Low power (branching to DSx, as a video plane)	Progressive source No other video flows
		PL3	Fmem -> VDI -> IC -> DP	Low power (branching to DSx, as a video plane)	Interlaced source No other video flows
Camera Pre-view	2 flows (VF2 may be used also as a playback flow)	VF1	Sensor -> IC -> Bmem -> IRT -> Fmem + DSx	main option	Single progressive input
		VF2	Sensor -> Fmem -> VDI -> IC -> Bmem -> IRT -> Fmem + DSx	two inputs and/or interlaced input	When the VDI is used, one of the three input fields can go directly from the sensor to the VDI
		VF3	Sensor -> IC -> DP	Low power Smart Display Tearing-less (branching to DS2, as a video plane)	Single progressive input Refresh rate = 2x sensor frame rate No other video flows
		VF4	Sensor -> IC -> Fmem + DS1	Low power RAM-less Display Single Display Buffer (in internal memory) Tearing-less	Single progressive input Refresh rate = 2x sensor frame rate No other video flows
Video Record	2 flows	RCx	IC -> Bmem -> IRT -> Fmem	(branching from VFx)	-

Table continues on the next page...

Table 8-3. Time-Shared Data Flows through the IPU (continued)

Name	Number	Type	Flow	Target	Restrictions
Graphic Overlays	2 flows	GF1	Fmem -> IC	(combining with the main flow	-
	2 flows	GF2	Fmem -> DP		-

Comments

- System memory usage - legend
  - Fmem: frame double-buffer (page-flip) in system memory (typically external)
  - Bmem: two possibilities
    - A frame double buffer, as above
    - A band (4-256 rows) double-buffer (page-flip) in system memory (could be internal)
  - Direct arrow between two processing stages represents an internal pipelining
- Time-sharing
  - IC can time-share tightly three flows: one VFx, one RCx and one PLx (with independent processing parameters)
  - DP can time-share one DS1 flow and a one DS2 flow (each with different destinations and independent processing parameters)
  - Direct access to display (DS4) time-shares tightly the display port with other active DSx flows.
  - Other time-sharing (between PLx; between DS2&DS3; in IRT) is frame-by-frame
- Any of the processing stages in the above flows can be skipped.

8.2.2.1 Display Processor (DP)

The Display Processor performs all the processing required for data sent to a display:

- Combining 2 video/graphics planes
- Overlaying a simple HW cursor
- 32 x 32 pixels, uniform color; may be combined logically with the background.
- Color conversion/correction - linear (multiplicative and additive)
- Programmable; including:
  - YUV <-> RGB, YUV<->YUV conversions
  - where YUV stands for any one of the color formats defined in the MPEG-4 standard
  - Adjustments: brightness, contrast, color saturation...
  - Special effects: gray-scale, color inversion, sephia, blue-tone...

    - Hue-preserving gamut mapping - for minimal color distortion
    - Applied to the output of combining or to one of the inputs
- Gamma correction and contrast stretching - programmable piecewise-linear map

The DP processes a single data flow at any given time but it supports up to three data flows by time sharing. One of them may be synchronous.

The data throughput is up to 200M pixels/sec (peak; including blanking intervals)

8.2.2.2 Video Deinterlacer (VDIC)

The Video Deinterlacer and Combiner has two operation modes

- Deinterlacing: converts an interlaced video stream to progressive order.
- Combining: combines two video/graphics planes and a background color

The input and output to/from the VDIC is as follows:

- Input for deinterlacing: three consecutive fields
    - Source
        - The most recent field may come from the CSI or from system memory
        - The other two fields are read from memory
    - Field size: up to 968x600 pixels (may be a vertical stripe of a wider field; for example, 1920 pixels)
    - Pixel format: YUV 4:2:2/4:2:0, 8 bits/value
    - Typical video sources - SDTV: 480i30 (720x480 @ 30 fps) or 576i25 (720x576 @ 25 fps) and HDTV: 1080i30 (1920x1080 @ 30 fps)
- Input for combining: two progressive video/graphics planes
    - Source: system memory
    - Plane size: up to 1920x1200 pixels.
    - Pixel format: RGB/YUV 4:2:2, 8 bits/value
- Output: progressive frame
    - Destination: to system memory or to the Image Converter.
    - Frame size: up to 1920x1200 pixels.
    - Rate: up to 180 MP/sec.
    - Format: same as input format.

The deinterlacing is performed using a high-quality 3-field filter which is motion adaptive:

- For slow motion - retains the full resolution (of both top and bottom fields)
- For fast motion - prevents motion artifacts

The VDIC supports a single video stream at any given time.

8.2.2.3 Image Converter (IC)

The Image Converter performs various operations on a video stream. The operations performed are:

- Resizing
  - Fully flexible resizing ratio
  - Maximal downsizing ratio: 16:1
  - Subject to this limitation, any N->M resizing can be performed
  - Independent horizontal and vertical resizing ratios.
- Color conversion/correction - linear (multiplicative and additive)

  Programmable; including:

  - YUV <-> RGB, YUV<->YUV conversions where YUV stands for any one of the color formats defined in the MPEG-4 standard
  - Adjustments: brightness, contrast, color saturation...
  - Special effects: gray-scale, color inversion, sephia, blue-tone
- Combining with a graphics plane (application-specific overlay)
- Horizontal inversion

The IC supports three time-shared data flows: record, camera preview and playback (the first two share a common input).

The frame resolution supported is up to 4096x4096 for input and up to 1024x1024 for output. Wider frames can be processed by the IC by splitting them to vertical stripes.

The data throughput

- Up to 180M pixels/sec for input and up to 90M pixels/sec for output - for a single active task case.
- Up to 150M pixels/sec for input and up to 75M pixels/sec for output - for several active tasks case.

8.2.2.4 Image Rotator (IRT)

The Image Rotator performs any combination of the following:

- 90-degree rotation
- Horizontal inversion
- Vertical inversion

The data throughput

- When a single task is active: up to 90M pixels/sec.
- When more tasks are active: up to 75M pixels/sec.

8.2.3 Automatic Procedures

The IPU is equipped with powerful control and synchronization capabilities to perform its tasks with minimal involvement of ARM and minimal use of memory. In particular, it includes:

- An integrated DMA controller with an AXI master port, allowing autonomous access to the system memory.
- An integrated display controller, performing screen refresh of a RAM-less display.
- A page-flip double buffering mechanism, synchronizing read and write access to system memory, to prevent tearing effects.
- A double/triple buffer synchronization mechanism with a video/graphics source.
- Internal synchronization, such as that between input from sensor and output to display.

In most cases, the ARM Core is involved only when it also performs part of the processing (such as video coding). In particular, the following procedures are performed by the IPU completely autonomously:

- Screen refresh for RAM-less displays
- Camera preview (displaying a view finder - a video-stream from the image sensor to the display).

Typically, there are extended periods of time in which there is no other activity in the system. The ARM Core can be put into a low-power mode (idle), reducing the power consumption and significantly extending the battery life.

The IPU supports several techniques to reduce further the power consumption of the display system:

- Optimized update of the display buffer, using a "snooping" signal from the memory controller, indicating a modification of the source buffer.
- Dynamic backlight control, with low-light compensation by image enhancement

Further features and capabilities of the automatic procedures include:

- Automatic display of a changing image (animation) or moving image (scrolling).
- The timing of the display update can be adjusted to avoid tearing.
- The video stream from an image sensor can be sent directly to the display buffer used for screen refresh, while avoiding tearing.

The IPU supports direct synchronization with a video/graphics source. Up to three frame buffers are supported for this synchronization. It is performed using the following signals

- The source instructs the IPU which frame should be transferred to the display
- The IPU notifies the source which frame is currently transferred to the display
- The IPU provides to the source an end-of-frame trigger (after which it switches to the frame indicated by the source).

This mechanism is provided for up to two sources, each can be connected to any of the DP/DC channels supporting a synchronous flow.

The clock sources received by the IPU are listed in Table 8-4.

Table 8-4. IPU Clock Sources

Name	Symbol	Source	Rate	Comments
High-Speed Processing Clock	HSP_CLK	Clock Control Module	Up to 200 MHz	-
Display Interface Clocks	DI_CLK0 DI_CLK1	Clock Control Module or an external DPLL	up to 150 MHz	Optional; needed for synchronization with interface bridges

8.3 LVDS Display Bridge (LDB)

LVDS Display Bridge (LDB) will be used to connect the Image Processing Unit (IPU) to External LVDS Display Interface.

Relevant Standards:

- ANSI EIA-644-A. Electrical Characteristics of Low Voltage Differential Signaling (LVDS) Interface Circuits.
- SPWG Notebook Panel Specification (V3.8 from 03/2007)

  http://www.spwg.org/specifications.htm .
- PSWG standards (Panel Standardization Working Group) - set of standards for panels using LVDS.

  All available from http://www.vesa.org/.
- DISM Standard JEIDA-59-1999

Table 8-5. IP Parametric Table

Name	IPU
Function	Connectivity to displays with LVDS interface

Table continues on the next page...

Table 8-5. IP Parametric Table (continued)

Name	IPU
External I/O Pins Notes: Those are LVDS IO pads	LVDS Display port: 2 channels. Each channel consists of: • 1 clock pair • 4 data pairs Each pair contains - LVDS special differential pad (PadP, PadM). total of 20 IO pads.
SoC Buses	None. Only configuration signals.
Interrupts	None
DMA Requests	None
Number of instantiations	1
Clock sources and range	DI0_CLK, DI1_CLK- Display interface clock: 20-170 MHz DI0_SER_CLK, DI1_SER_CLK - Serializer clock: 140-595 MHz

The purpose of the LDB is to support flow of synchronous RGB data from the IPU to external display devices through the LVDS interface. This support covers all aspects of these activities:

- Connectivity to relevant devices - Displays with LVDS receivers.
- Arranging the data as required by the external display receiver and by LVDS display standards.
- Synchronization and control capabilities.

A block diagram of the LDB is given in the following figure.

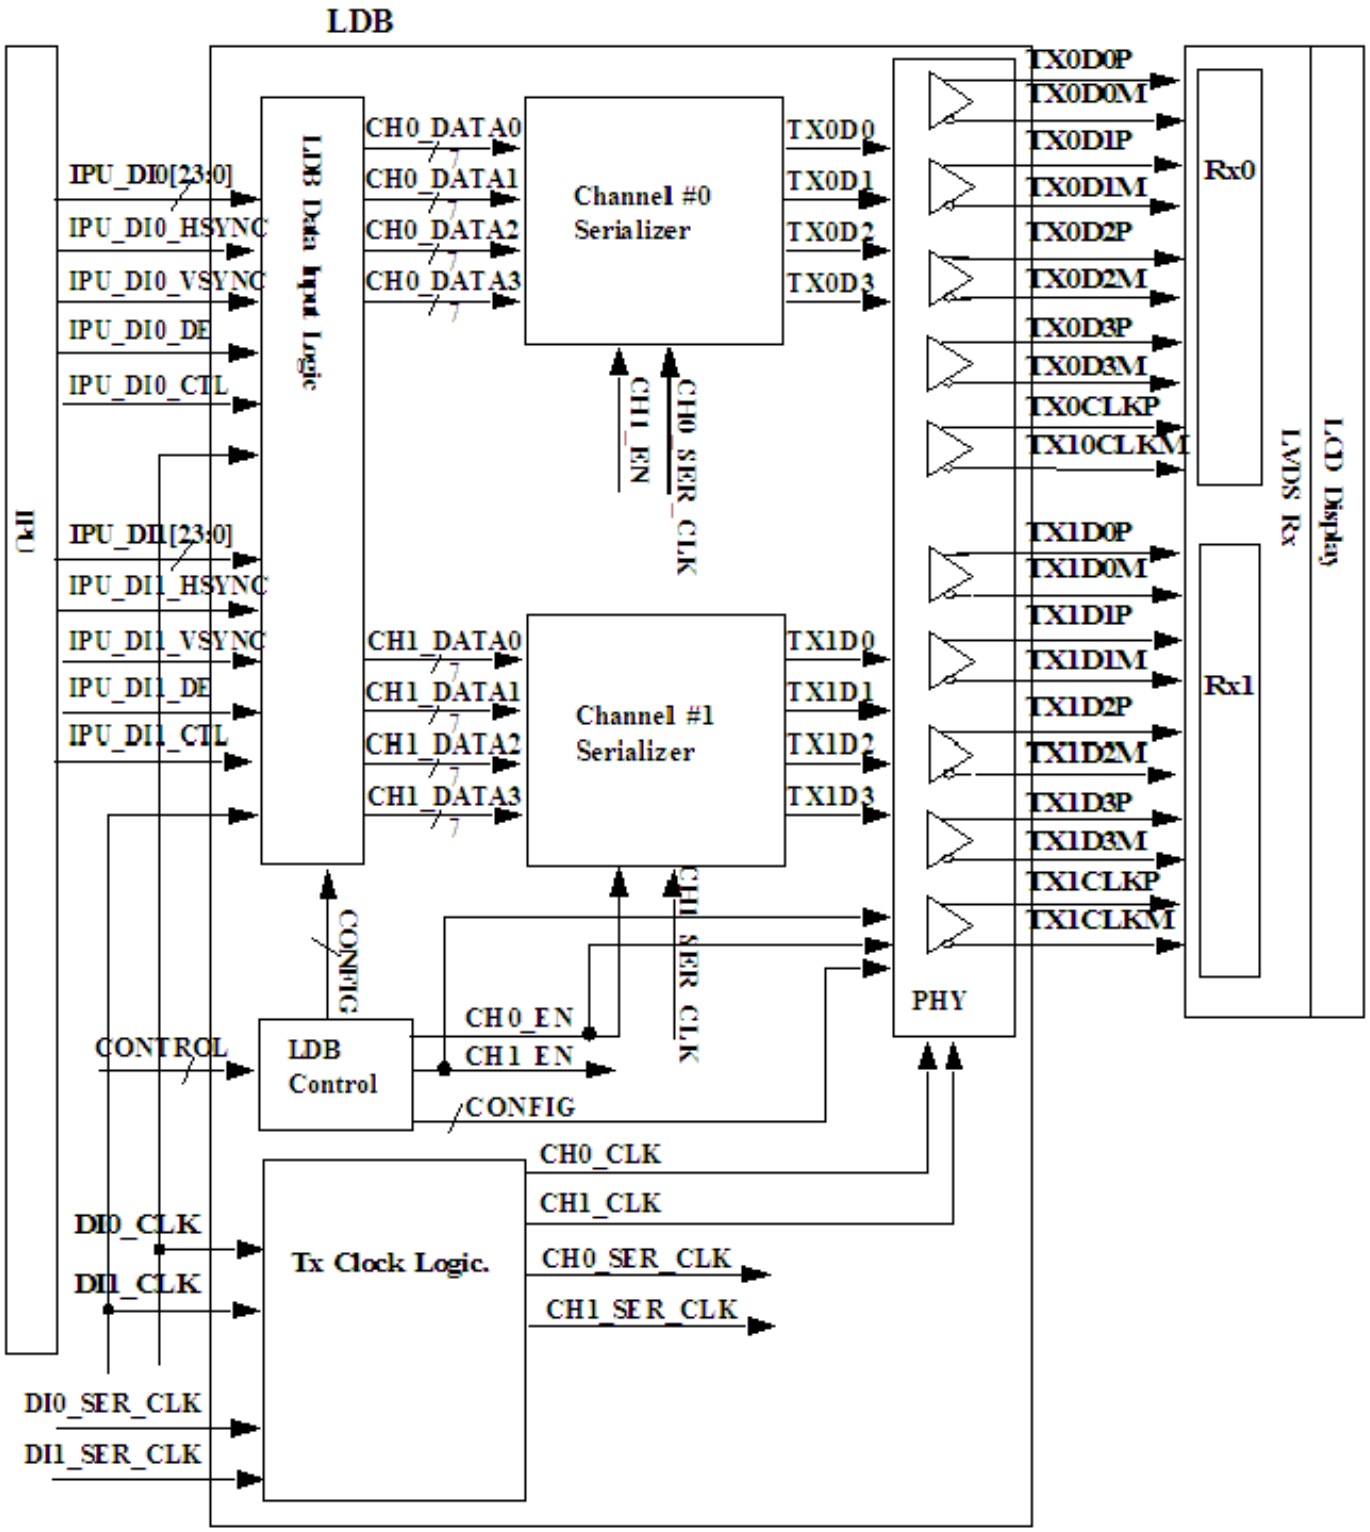

Figure 8-4. LDB - Block Diagram

Table 8-6. LDB - Block Description

Block	Description
LDB Data Input Logic	Rearranges input DI data from IPU according to configuration, and sends output to serializers. Is also responsible on Input bus split to Odd/Even busses.
Channel Serializers	LDB has 2 channel serializers. Each serializer does parallel to serial conversion 7:1 to 3 or 4 data lines
LDB Control	Gets control signals from SoC and determines parameters of LDB
Tx Clock Logic	Mux input clocks to Serializers and PHY.
PHY	Converts digital signals to analog LVDS signals.

8.3.1 External Ports-LDB

The LDB has the following ports:

- Two input parallel display ports.
- Two Output LVDS channels - Each channel consisting of 4 data pair, and 1 clock pair (pair =LVDS pad contains PadP, PadM).
- Control signals - to configure LDB parameters and operations.
- Clocks from SoC DPLLs.

8.3.1.1 Input Parallel Display Ports

One or Two (DI0, DI1) parallel RGB input ports are supported (configurable). Only synchronous access mode is supported.

Each RGB data interface contains the following:

- RGB Data of 18 or 24 bits
- Pixel clock
- Control signals: HSYNC, VSYNC, DE, and 1 additional optional general purpose control.

Total of up to 28 bits per data interface are transferred per pixel clock cycle.

Rates supported:

- For dual-channel output: Up to 170 MHz pixel clock (for example, UXGA - 1600x1200 @ 60 Hz + 35% blanking)
- For single-channel output: Up to 85 MHz per interface (for example, WXGA - 1366x768 @ 60 Hz + 35% blanking).

8.3.1.2 Output LVDS Ports

There are 2 LVDS channels. These inputs are used to communicate RGB data and controls to external LCD displays with LVDS interface, or through LVDS receivers.

The LVDS ports may be used as follows:

- One single-channel output
- One dual channel output: single input, split to two output channels
- Two identical outputs: single input sent to both output channels
- Two independent outputs: two inputs sent, each, to a different output channel

The output LVDS port must comply to #d346e12a1310.

8.3.1.3 Control Signals

Control signals are used to configure LDB operation. Needed configuration parameters are:

Table 8-7. LDB - Configuration Description

Parameter	Description
CHANNEL_MAPPING	Mapping of Parallel input interfaces (DI0, DI1) to output LVDS channels (Channel 1, Channel 2).
D0_DATA_WIDTH	18/24 bit (use 3/4 data pairs)
D1_DATA_WIDTH	18/24 bit (use 3/4 data pairs)
DI0_BIT_MAPPING	Bit mapping/ordering for DI0. Used only on modes where DI0 is enable. See muxing modes on "Processing"
DI1_BIT_MAPPING	Bit mapping/ordering for DI1. Used only on mods where DI1 is enabled. See muxing modes on "Processing"

8.3.1.4 Clock Sources

The clock sources received by the LDB are listed in Table 8-8.

Table 8-8. LDB Clock Sources

Name	Symbol	Source	Rate	Comments
IPU DI0 interface pixel clock	IPU_DI0_CLK	Clock Control Module	Up to 170 MHz	See note below [1, 1]
IPU DI1 interface pixel clock	IPU_DI1_CLK	Clock Control Module	Up to 170 MHz	This input also goes to IPU DI1 as input. See note below [1]

Table continues on the next page...

Table 8-8. LDB Clock Sources (continued)

Name	Symbol	Source	Rate	Comments
DI0 interface serializer clock	DI0_SER_CLK	Clock Control Module	Up to 595 MHz	This is x7 or x3.5 the rate of the DI0 interface pixel clock. See note below.
DI1 interface serializer clock	DI1_SER_CLK	Clock Control Module	Up to 595 MHz	This is x7 or x3.5 the rate of the DI1 interface pixel clock. See note below

1. LVDS DI_CLK should always be identical to the relevant IPU DI_CLK. In case of single-channel of separate-channels use-case - the serializer clock will be x7 faster than the DI_CLK. In case of dual-channel use-case - the serializer clock will be x3.5 faster than the DI_CLK

8.3.2 Processing-LDB

LDB data processing stages are as follows:

- Get input data from 1 or 2 (configurable) parallel input interfaces. 18/24 RGB data + up to 4 controls and map them to LVDS channels.
  - If needed (dual-channel) split the input bus to two half-rate busses.
- Re-arrange the input data according to channel configuration, and muxing scheme.
- Serialize the 22/28 bit input bus (per channel) on 3-4 output serial data lines (7:1)
- PHY converts the serial digital data to analog LVDS signals

8.3.2.1 LDB Data Input Logic

The Data Input Logic does the following processing on the 1-2 input busses:

8.3.2.1.1 Mapping of Input Data Busses

8.3.2.1.1.1 Channel Mapping

Mapping of Parallel input interfaces (DI0, DI1) to output LVDS channels (Channel 0, Channel 1). See Table 8-5.

Channel Mapping

Use Case	LVDS Channel 0	LVDS Channel 1
Single channel from DI0	DI0	Disabled
Single channel from DI1 to channel 1	Disabled	DI1
Single channel from DI1 to channel 0	DI1	Disabled
Dual Channel from DI0	DI0 (first pixel)	DI0 (second pixel)
Dual Channel from DI1	DI1 (first pixel)	DI1 (second pixel)

Table continues on the next page...

Use Case	LVDS Channel 0	LVDS Channel 1
Two single channels with identical content - from DI0	DI0	DI0
Two single channels with identical content - from DI1	DI1	DI1
Two independent single channels	DI0	DI1

8.3.2.1.1.2 Input Bus Split

For the dual-channel case, it is required to split the input bus into two half-rate busses (Odd/Even pixels).

- First pixel is mapped to Channel 0
- Second pixel is mapped to Channel 1

8.3.2.1.2 Bit Mapping

Several bit mapping options should be supported. The 22/28 bit bus is mapped into on 3/4 groups of 7 bits each.

SPWG/PSWG/VESA 18/24 bpp Data Mapping

Serializer input	Slot 0	Slot 1	Slot 2	Slot 3	Slot 4	Slot 5	Slot 6
CHx_DATA0	G0	R5	R4	R3	R2	R1	R0
CHx_DATA1	B1	B0	G5	G4	G3	G2	G1
CHx_DATA2	DE	VS	HS	B5	B4	B3	B2
CHx_DATA3 (for 24 bpp only)	CONT	B7	B6	G7	G6	R7	R6

JEIDA 24bpp Data Mapping

Serializer input	Slot 0	Slot 1	Slot 2	Slot 3	Slot 4	Slot 5	Slot 6
CHx_DATA0	G2	R7	R6	R5	R4	R3	R2
CHx_DATA1	B3	B2	G7	G6	G5	G4	G3
CHx_DATA2	DE	VS	HS	B7	B6	B5	B4
CHx_DATA3	CONT	B1	B0	G1	G0	R1	R0

NOTE

Several options of control usage can be available. Some display devices use only DE, some others use all three controls, and some use only HS and VS. "CONT" is an optional general purpose control which is usually unused by the display.

8.3.2.2 LDB Control

Receives control signals from SoC and configures LDB unit accordingly.

See also Control Signals.

8.3.2.3 LDB Tx Clock

The input pixel clock is used to mark pixel boundaries.

The serializer clock is needed to enable the 7:1 muxing on the channel serializers.

Following operations should be supported:

- Map input clocks to channel clocks
- Map serializer clocks to channel serializers
- Generate hold-rate channel clock and align it to the required timing by LVDS standards

See also Clock Sources.

LDB uses 2 Channel serializers. One per LVDS channel.

- Input: 3-4 busses of 7 bit each.
- Clock: serializer clock
- Processing: 7:1 muxing.
- Output 3-4 serial lines

8.3.2.4 PHY

PHY translates the digital serializer outputs to LVDS signals.

PHY consists of 2 channels (1 or 2 may be used according to use case).

Each channel consists of:

- 4 data pairs (LVDS pads) - 3 or 4 may be used according to use case
- 1 clock pair

The PHY output must comply with ANSI EIA-644-A.

Clock/data timing must comply with display standards such as mentioned in the LVDS Display Bridge (LDB).

Spread spectrum support - only as enabled by SoC DPLL's features.

8.4 Video Processing Unit (VPU)

The Video Processing Unit (VPU) is a multi-standard video codec (encoder/decoder) capable of handling multiple streams simultaneously through time multiplexing. The VPU is a very flexible block consisting of a programmable core surrounded by hardware accelerators. The VPU presents to the system a register mapped interface that is controlled by the embedded processor. Because this interface can be updated by the firmware it will not appear in this document; instead the designer should consult the documentation released with the firmware used. End users should only interface with the VPU using the API that is made available with each firmware release. This API isolates the user from possible changes in the register level interface.

Table 8-9 is a summary of the VPU specs. The VPU has its own DMA driven AXI masters that allow it to retrieve the required data directly from system memory (DDR and iRAM). The load in the host ARM platform is negligible because it only needs to interact with the VPU at the frame level.

Table 8-9. VPU Spec Summary

Name	VPU
Function	Decode video streams including optional video processing such as rotation, deringing and mirroring.
Supported encoders	MPEG-4 SP H.263 V2 + Annex J, K (RS=0 and ASO=0), and T H.264 BP MJPEG Baseline
Supported decoders	MPEG-2 MP VC-1 SP, MP, AP MPEG-4 SP, ASP H.263 V2 + Annex J, K (RS=0 and ASO=0), and T Sorenson H263 H.264 BP, MP, HP DivX v3,4,5 Real Video 8, 9, 10 MJPEG Baseline
External I/O Pins (List, Type, Schmidt Trigger, Speed)	No external I/O pins are needed
SoC Buses (List, Type, Bandwidth)	64 bit AXI master for accessing the system memory and search RAM IP Bus slave for host control
Interrupts	one interrupt

Table continues on the next page...

Table 8-9. VPU Spec Summary (continued)

Name	VPU
DMA Requests	Integrated DMA controller on the AXI master port
Number of instantiations	1
Clock sources and range	Core clock: up to 200 MHz AXI bus clock: up to 200 MHz IP Bus clock: up to 66.5 MHz

The i.MX53 processor has a high-performance Video Processing Unit (VPU) which covers many standard and high definition video decoders and encoders as a multi-standard video codec engine, as well as several important video processes such as rotation, mirroring and de-ringing. VPU is a licensed block provided by Chips&Media. The overview of VPU is summarized above.

8.4.1 Basic Structure

The following figure shows the basic structure of the VPU. The VPU is self-contained except for memory accesses. It is connected to the memory subsystem through two AXI master ports. The ARM configures the VPU operation through the IP Bus that is converted to APB in a gasket.

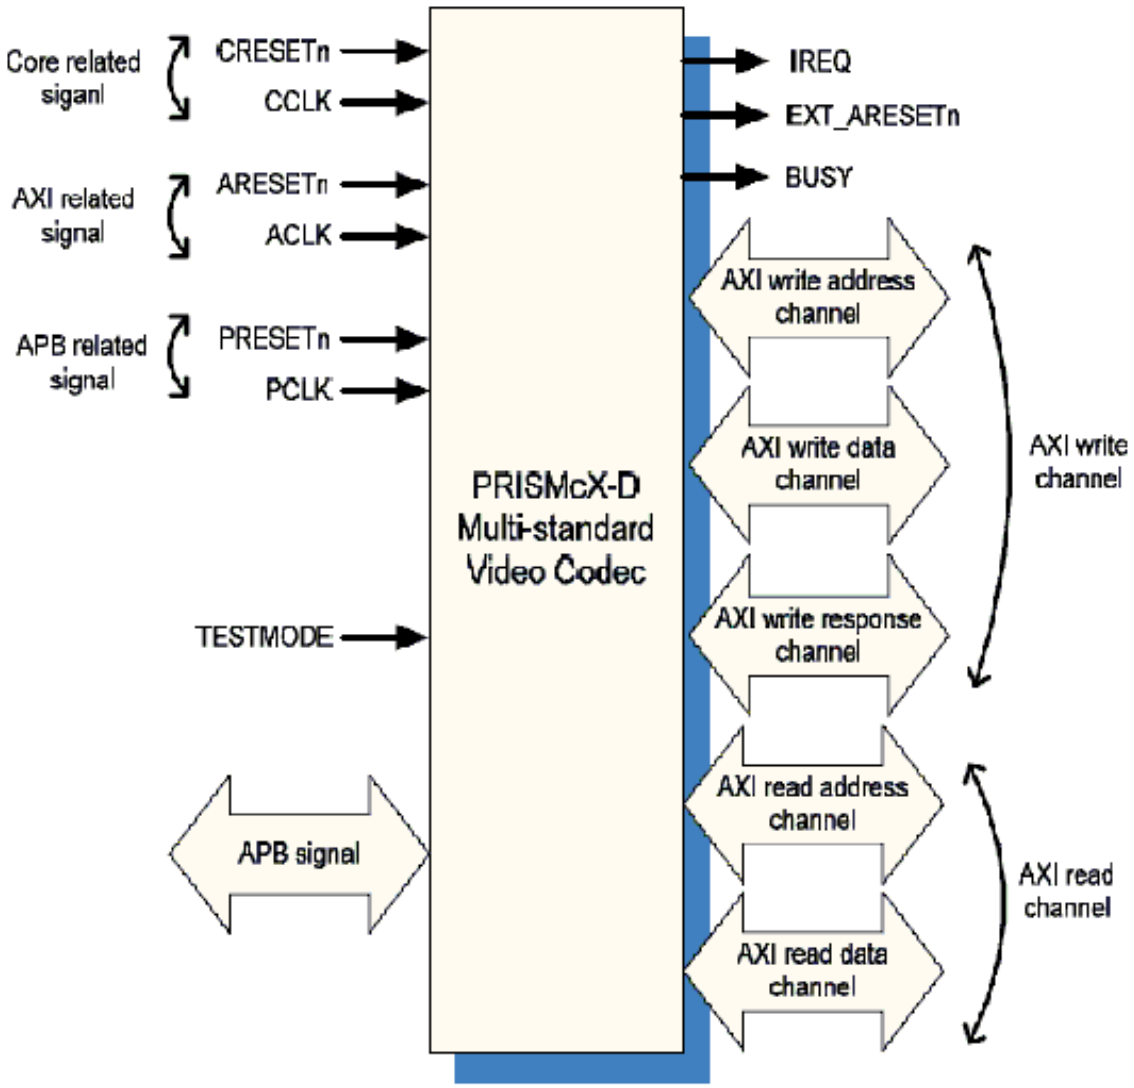

Figure 8-5. The Block Diagram of the VPU

8.4.2 Feature Summary

Table 8-10 below lists the VPU's encoding / decoding capabilities.

Table 8-10. VPU Decoding / Encoding Capabilities

Dec/Enc	Standard	Profile	Resolution	Bitrate	Comments
HW Decoder	MPEG-2	Main-High	1080 i/p	40Mbps	
	MPEG4/XviD	SP/ASP	1080 i/p	40Mbps	-
	H.263	P0/P3	16CIF	20Mbps	i.MX53 Platform may support up to D1@30fps
	Sorenson H.263	N/A	16CIF	20Mbps	i.MX53 Platform may support up to D1@30fps
	H.264	BP/MP/HP	1080 i/p	40Mbps	-
	VC1	SP/MP/AP	1080 i/p	40Mbps	-
	RealVideo	8/9/10	1080p	40Mbps	-
	DivX	3/4/5/6	1080 i/p	40Mbps	-
	MJPEG	Baseline	8192x8192	40Mpixel/sec (Up to YUV444)	40MP/sec is at YUV444 format and it will be higher for 422 and 420 formats
HW Encoder	MPEG2[1]	Main-Main	D1	15Mbps	-
	MPEG4	Simple	720p	20Mbps	VPU can generate higher bitrate than the maximum specified by the corresponding standard.
	H.263	P0/P3	4CIF	20Mbps	
	H.264	Baseline	720p	20Mbps	
	MJPEG	Baseline	8192x8192	80Mpixel/sec (Up to YUV422)	80MP/sec is for 422 format, and it will be higher for 420 format

1. Video partially performed in HW (70%)

8.4.3 Other Features of VPU

- Rotation and Mirroring: on-the-fly (90 x n) degree simultaneous rotation and mirroring (n = 0,1,2,3)
- Post-processing: de-blocking filtering for MPEG-4 and de-ringing filtering for MPEG-4 and H.264 decoder
- De-ringing support: de-ringing filtering is supported in VPU

8.4.4 Architectural Overview

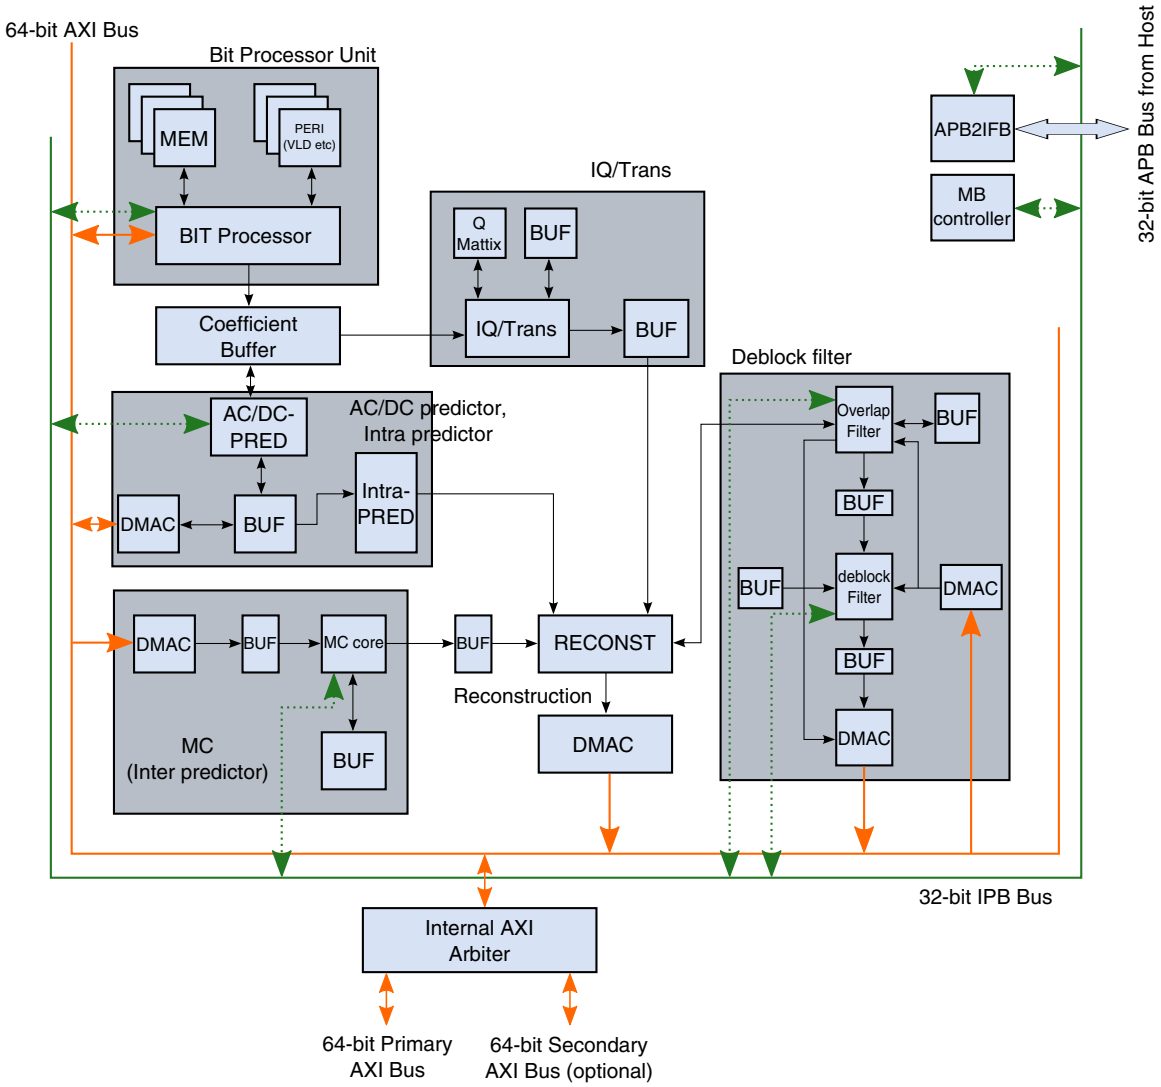

Figure 8-6. VPU Architectural Block Diagram

8.4.5 Interfaces

- Bus Interface
  - Primary AXI master: to System memory, 64-bit
  - Secondary AXI master: to iRAM, 64-bit
  - Host control: IP Bus slave, 32-bit
- Input/output Interface: partially interleaved 4:2:0 data format (YYY... CbCrCbCrCbCr...)
- Others

- One interrupt
- Integral DMA controller, with an AXI master port

(A)WID	Block	Description	External bus
0	BIT Processor	FW code, FW data, and bitstream	Primary for data related to FW.
1	Overlap Filter	Temporal buffer for overlap smoothing filtering processor (VC-1 only)	Either primary or secondary
2	Deblocking Filter	Temporal buffer for deblocking filtering process	Either primary or secondary
3	AC/DC prediction	Temporal buffer for AC/DC prediction(VC-1 only)	Either primary or secondary
4	Reconstruction	Reconstructed pixel row(s) for intra-prediction	Either primary or secondary
5	Deblocking Filter	Decoded frame	Primary
6	Range remapper	VC-1 range remapping/reduction	Primary
7	BIT Processor	MB information	Either primary or secondary

Figure 8-7. AXI Write Channel Traffic Sources

(A)RID	Block	Description	External bus
0	BIT Processor	FW code & data, bitstream	Primary for data related to FW
1	Overlap Filter	Temporal buffer for overlap smoothing filtering processor (VC-1 only)	Either primary or secondary
2	Deblocking Filter	Temporal buffer for deblocking filtering process	Either primary or secondary
3	ACDC –prediction	Temporal buffer for AC/DC prediction(VC-1 only)	Either primary or secondary
4	BIT Processor	MB information	Either primary or secondary
5	NA		
6	Range remapper	VC-1 range remapping/reduction	

Figure 8-8. AXI Read Channel Traffic Sources

8.4.6 Operating Frequencies

VPU operating frequency depends on the block task - decoder / encoder, standard, profile, resolution, bit rate, etc. Below are few estimations of operating frequencies:

- H.264 HP, 720p, 30fps, 14Mbps - 100MHz
- H.264 HP, 1080p, 30fps, 40Mbps - 200MHz

8.4.7 Architectural Features

- Ability to decode entire frames on a per frame basis.
- Upgradeable firmware.
- Multiple decoders and/or encoders can operate simultaneously in a time multiplex mode on frame-basis.
- Partial acceleration for any non-standard decoders is required as seen below

8.4.8 Memory Requirements

8.4.9 Internal Memory (iRAM)

The internal memory or iRAM is used for providing a temporal buffer video encoding and decoding process for the purpose of external memory bandwidth reduction. The iRAM can be accessed through the secondary AXI bus. The size of the iRAM should be determined by the video coding standard which uses the largest iRAM. This is the VC-1 as shown in the table below.

temporal buffer type		QCIF	CIF	VGA	525SD	625SD	720p	1080p
MB information		1,408	2,816	5,120	5,760	5,760	10,240	15,360
AC/DC prediction		1,408	2,816	5,120	5,760	5,760	10,240	15,360
Intra-prediction		704	1,408	2,560	2,880	2,880	5,120	7,680
overlap filter	VC-1	880	1,760	3,200	3,600	3,600	6,400	9,600
deblock filter	VC-1 MP	2,816	5,632	10,240	11,520	11,520	20,480	30,720
	VC-1 AP	5,632	11,264	20,480	23,040	23,040	40,960	61,440
	H.264 BP, H.263P3	1,408	2,816	5,120	5,760	5,760	10,240	15,360
	H.264 MP/HP	2,816	5,632	10,240	11,520	11,520	20,480	30,720

8.4.10 External Memory (SDRAM)

The following two tables present the typical amounts of external DRAM required by each specific encoder or decoder. For encoders, it can be seen that the total amount of SDRAM used for H264 and MPEG4 are the same. This is because only one reference frame is used for both encoders. For decoders, the worse case is for H264 and VC-1, which uses more amount of memory than other video coding standards.

		H.264		MPEG4

8.4.11 VPU Integration into SoC

Figure 8-13 shows the method of connecting the VPU core in the i.MX53 processor.

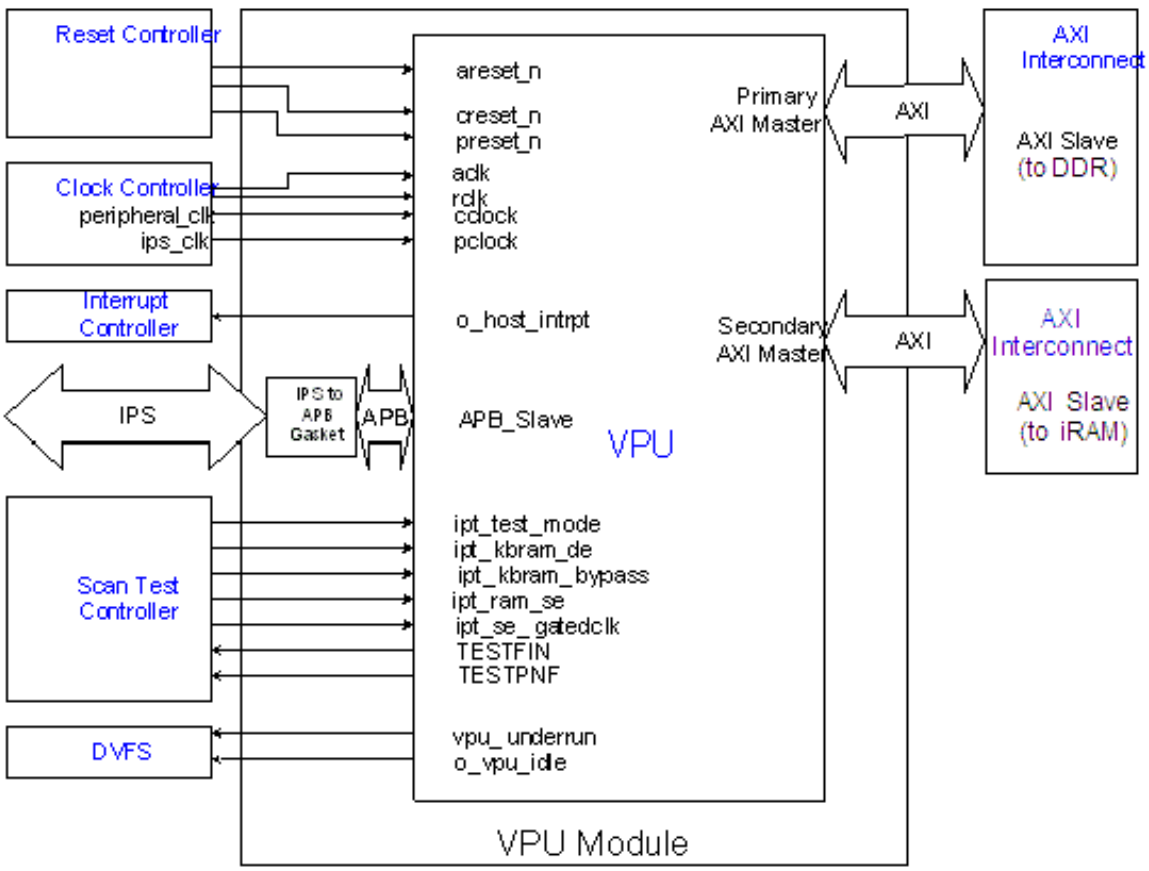

Figure 8-13. VPU System Connectivity

8.4.12 External Bus Connection

The VPU has the following interfaces:

- The first one is the Integrated Peripheral Bus (IP Bus) interface slave port. It serves as a configuration and programming interface. This interface has a maximum clock frequency of 66 MHz.
- There are two (2) AXI interfaces. The first one allows the VPU to access the main system memory (DDR). The second AXI interface allows the VPU to be connected directly to internal low-latency memory (iRAM) for bandwidth reduction purposes.

8.4.13 Other Signals Connection

Table 8-11 describes the other miscellaneous signals of the VPU.

Table 8-11. VPU Miscellaneous Signals

Name	Type	Source/ destination	Description
VPUNTRn	Output	Interrupt controller	Interrupt output from the VPU core. Active LOW.
VPUCLK	Input	Clock controller	Main input clock to the VPU core. That signal has a maximal frequency of 200 MHz
VPUCLKGATE	Output	Clock/power control logic	Signal permits gate the VPUCLK clock input.
ACLK	Input	Clock controller	AXI BUS clock. That signal has a maximal frequency of 200 MHz
ACLKGATE		Clock/power control logic	Signal permits gate the ACLK clock input of VPU.
SCANMODE	Input	Scan test controller	Test scan mode. A 1 on this pin forces scan mode.
SCANEN	Input	Scan test controller	Test scan enable. Active HIGH.
TESTSTRT	Input	Test controller	Embedded memory BIST test start/resume: 1 start/resume 0 normal operation.
TESTFIN	Output	Test controller	Embedded memory BIST test finished: 1 finished 0 test in progress or idle.
TESTPNF	Input	Test controller	Embedded memory BIST test pass/fail: 1 pass 0 fail
VPU_IDLE	Output	DVFS controller	Indicates Idle state of VPU. Could be used by DVFS controller.
VPU_UNDERRUN	Output	DVFS controller	Indicates that the VPU has taken longer to process a frame than the deadline established by rclock.
RCLCK	Input	Clock Controller	Low frequency clock used to determine the underrun condition

8.4.14 Clocking Architecture

The VPU uses four clock sources:

- AXI bus clock domain (aclk)
- Decoding core clock domain (cclk)
- IP bus clock domain (ipg_clk_s)
- Reference clock domain (rclk)

The VPU is designed following a Globally Asynchronous Locally Synchronous (GALS) architecture. As a result, there are no requirements to these clocks in terms of coherency, frequency or phase. Only the rising edges of the clocks are used. These clocks are not gated inside the VPU.

In i.MX53, the core clock (cclk) and axi (aclk) clocks are not tied together to the peripheral domain clock. The ipg_clk_s used in order to control VPU registers read/write function, ipg_clk_s is a gated clock of IP green-line clock (ipg_clk) with ips_module_en, it is turned off when there is no registers read/write, for power saving. The reference clock (rclk) is only used as reference clock for vpu_idle related logic.

8.4.15 Power Management

The Video Processing Unit (VPU)'s power is managed by two mechanisms: clock gating and frequency/voltage adjustments. The VPU core is connected to the peripheral power domain, therefore its voltage and frequency are controlled by the Dynamic Voltage Frequency Scaling for Peripherals (DVFSP) together with rest of the peripheral domain.

The DVFSP does not monitor the VPU directly to decide on entering the power saving mode. It monitors the signal VPU_UNDERRUN as an alarm signal that indicates the need to increase the clock frequency. VPU_UNDERRUN is generated as a count of rclock cycles and indicates that the processing of a frame has taken longer than the programmed time, usually 30 ms.

The ACLK_VPU and CCLK_VPU clocks are gated at the Clock Control Module (CCM) as soon as VPU_IDLE goes high to indicate that the current frame has been completed. To continue to work on the next frame the host re-enables the clockx by writing to the CCM directly.

8.4.16 Interrupt

The VPU has an interrupt request signal, o_host_intrpt, that is connected to the interrupt controller. The o_host_intrpt is synchronized to the rising edge of the cclk and goes to high when its asserted. The interrupt is cleared by system SW writing a '1' to the interrupt clear register of the VPU. The o_host_intrpt is HIGH until it is cleared.

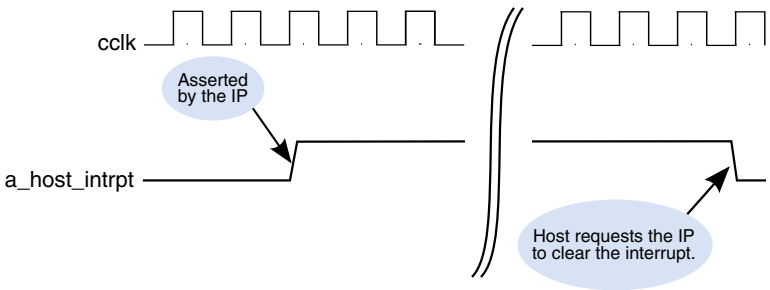

Figure 8-14. Interrupt Timing Diagram

8.4.17 Reset

The VPU has three reset signals areset_n, creset_n, preset_n that have to be synchronous to the corresponding clock. areset_n and creset_n are tied together to the peripheral domain reset. areset_n is tied to the ips bus reset.

In addition to these resets, the VPU can be reset under software control by writing to registers in the VPU memory-mapped register area. Three logical blocks are reset within the design:

- IP to APB gasket
- AXI interfaces
- Core logic

In SCANMODE the soft reset controls are bypassed and the system reset is connected directly to block resets to ensure observability.

All pending transactions are discarded after VPU core stop or reset in the AXI.

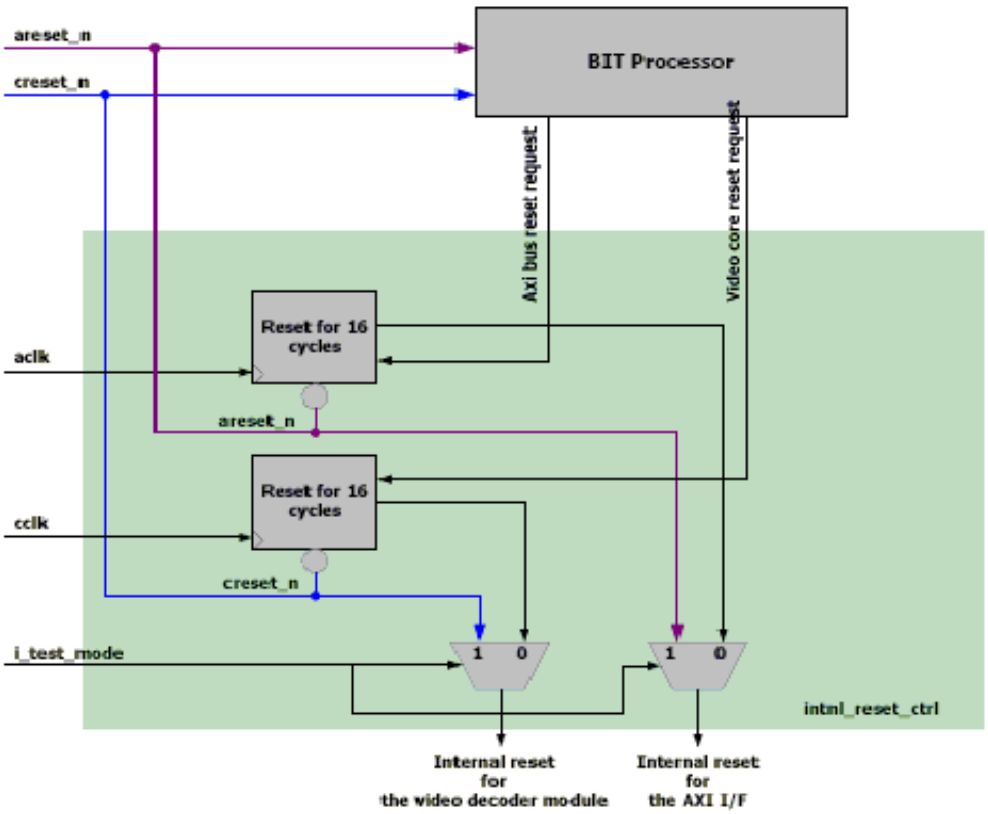

Figure 8-15. VPU Reset

8.5 OpenGL/ES Graphics Processing Unit 3D (GPU3D)

8.5.1 GPU3D Overview

The 3D Graphics Processing Unit (GPU3D) is based on the AMD Z430 IP core (also known as ATI Yamato DX). The core is an embedded engine capable of DirectX9 Shader Model 3.0+ program execution. The design is based on the ATI Xenos core, which is found in the Microsoft XBox 360 and has been extrapolated into recent PC video card designs. The block is focused on accelerating user level graphics APIs such as OpenGL ES 2.0 & 1.1, OpenVG 1.0, and Direct3D Mobile.

8.5.2 GPU3D Features

- Built to accelerate OpenGL ES 2.0

- Uses dynamically shared shader ALU/memory resources between vertex and pixel shaders.
  - Unified Shading Architecture
- Command Processor:
  - Advanced packet based command stream manager allowing for efficient and flexible transfer of graphics commands and host data from the host system to the graphics processor core
- Integrated Power Management
  - Block-level clock gating managed automatically in the IP.
- Graphics Memory Controller and Graphics Memory
  - Customer configurable on-chip memory used to accelerate 3D rendering using a binning architecture significantly reducing external system bandwidth requirements.

8.5.2.1 Capabilities

- Supports 2 & 4-sample MSAA at full rendering speed.
- Compressed Texture Support: ETC, DXTC, and ATI_TC
- Supports general purpose exports to system memory from Vertex and Pixel shaders.
- Uses indexed vertex data fetches from the Vertex Shader as a high-bandwidth vertex data path.
- Latency hiding via FIFOs and multi-threading
- Sophisticated Shader support
  - 512 4-Component constants
  - 1024 Shader Instructions
  - 16 Textures
  - 16 4-Component Interpolants
  - 64 General Purpose Registers
- Rich texture format and type
  - Compressed
  - 16 bit Floating point
  - Cube map
  - Volume textures
  - Non power-of-2
  - Anisotropic
- 1 Primitive (Triangle/Line/Point) every 6 clocks
- 1 Vector (4 component) and 1 Scalar (single component) ALU instruction per clock
- 2 Control Flow Instructions (Jumps, loops) per clock
- 1 Export per clock
- 1 4 component Pixel Shader input interpolant per clock
- Early-Z testing at up to 4 pixels per clock

- 1 pixel (at 4 sample MSAA) per clock with alpha blending and depth test
- 32 bit FP Internal Shader Precision

8.5.3 GPU3D Block Diagram

The Z430 contains three primary blocks:

- Graphics Core (GC)
  - Programmable graphics engine that performs all of the data processing and memory transactions
- Graphics Arbiter (GARB)
  - Controls the GMEM and arbitrates between requests from the GC and the system
- Graphics Memory (GMEM)
  - Local SRAM buffers (four 32KB buffers) that are used to data for the tile / bin of pixels the GC is working on

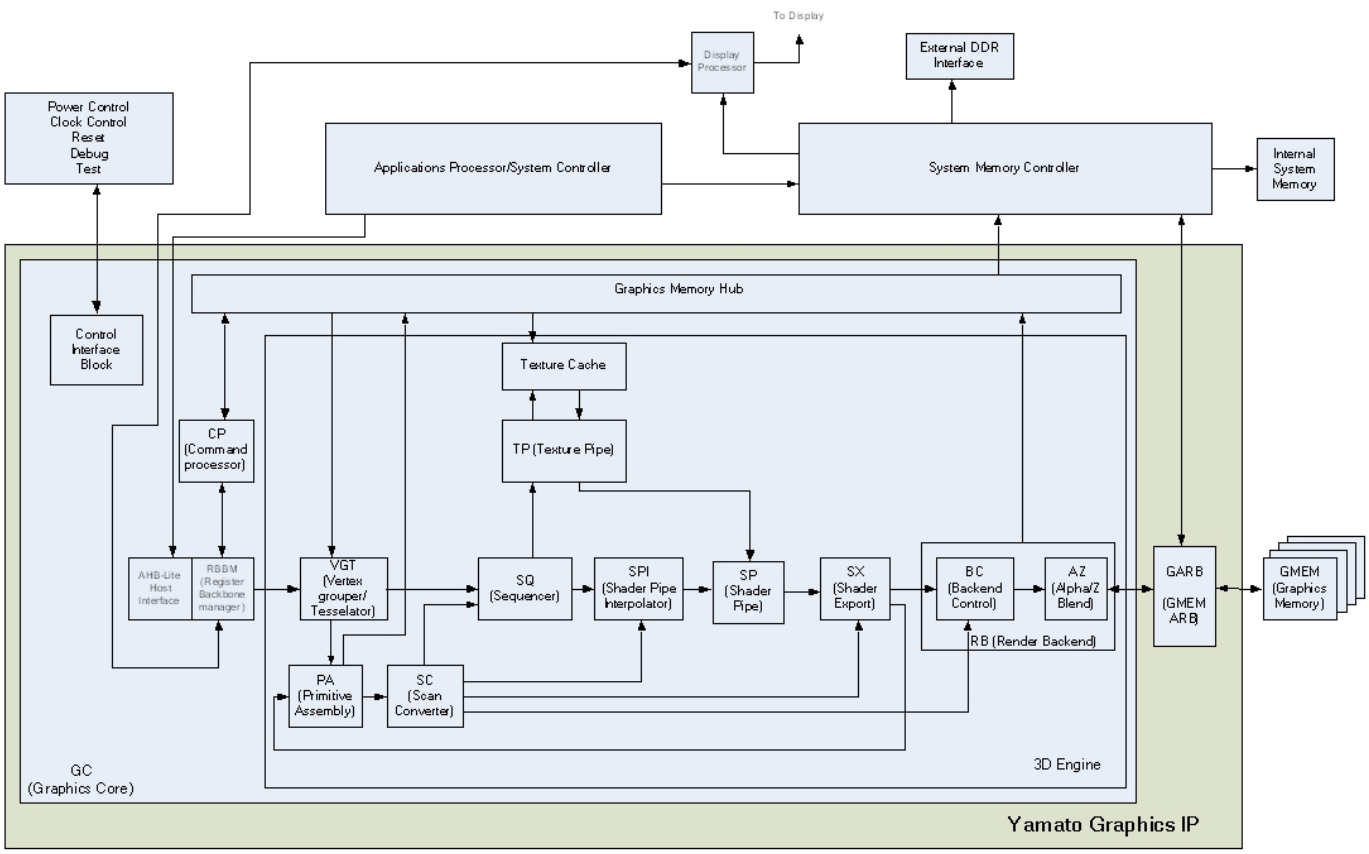

Figure 8-16. GPU3D (Z430) Internal Block Diagram

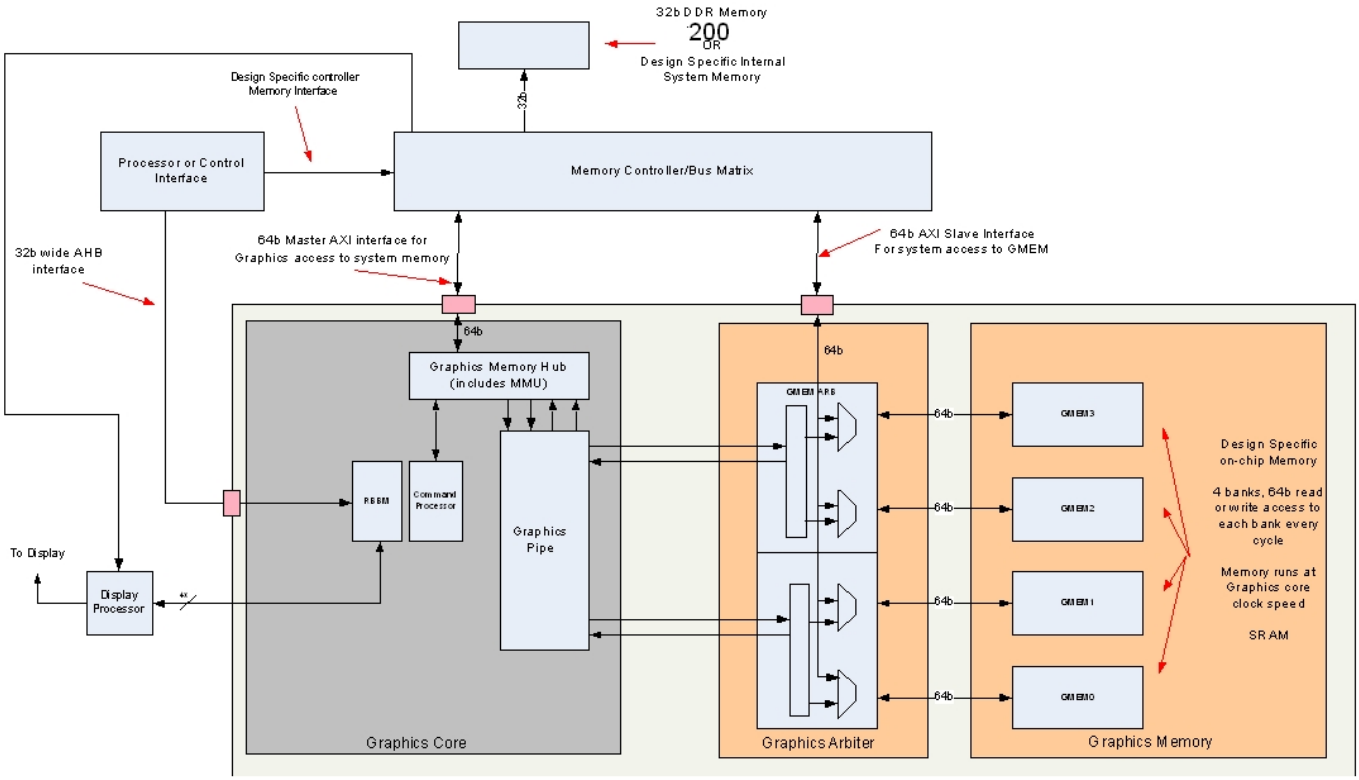

Figure 8-17. GPU3D (Z430) Interface Diagram

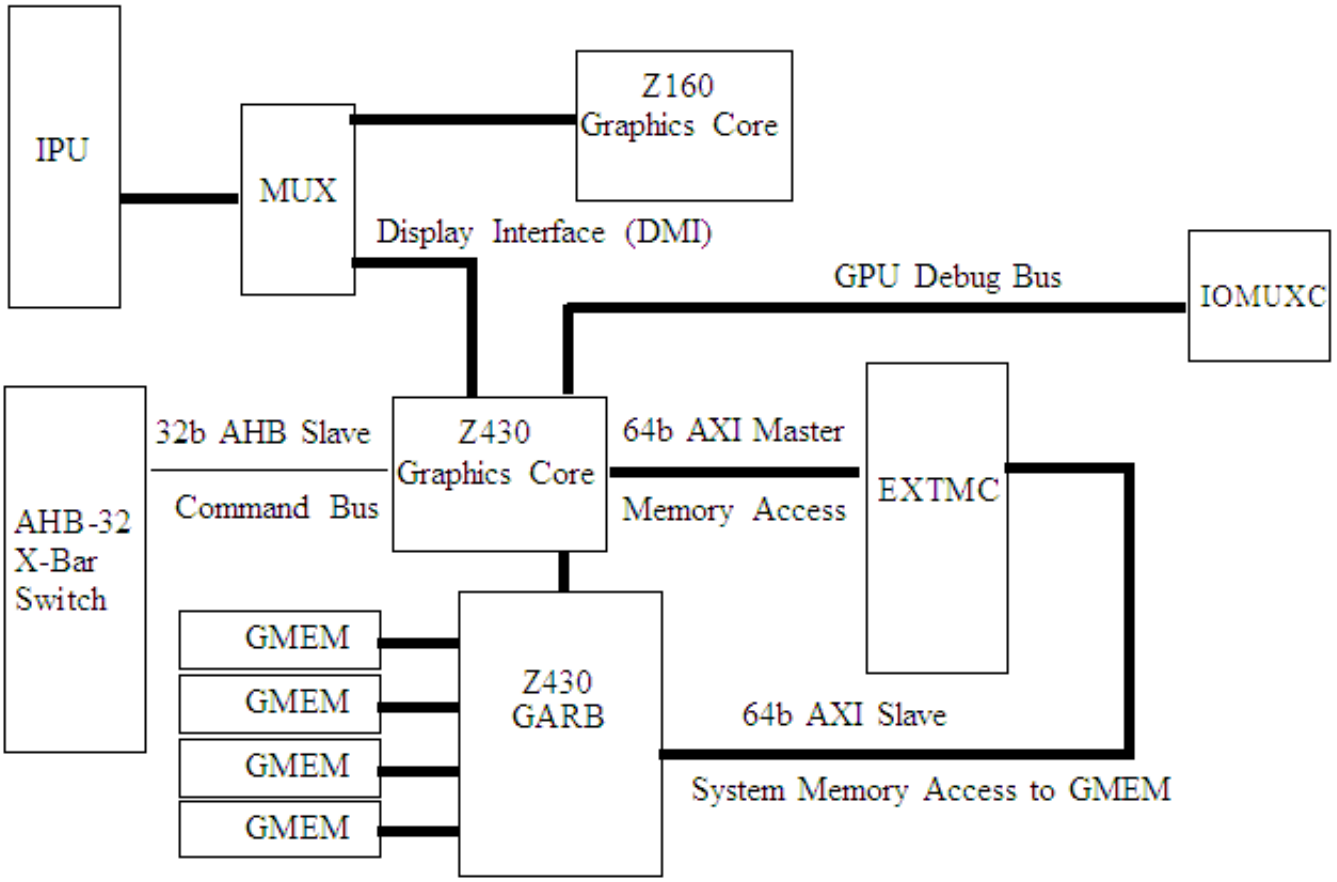

Figure 8-18. GPU3D System Integration Diagram

Interface Summary:

- Slave Interface to ARM platform or controller interface
  - Peripheral AMBA 2.0 AHB-Lite Host Interface
    - Provides host access to graphics core from the system processor.
    - 32b wide, synchronous with core.
    - Support for clock gating for phase removal on AHB clock.
- Memory Master Interface
  - AXI Master Interface into memory system (AXI V1.0)
  - 64b wide, synchronous
    - Provides access to system memory from the graphics core.
  - Programmable number of read and write requests to the memory system
    - Number of outstanding requests is limited by system resources (i.MX53 can support one request).
- Memory Slave Interface (GARB)
  - AXI slave interface for system access to graphics memory (AXI V1.0)
  - 64b wide, synchronous interface
  - 1 outstanding read and write request
- Display Module Interface (DMI)

- For synchronization with the display processor.
- Provides indication to display processor from graphics core that a newly rendered frame is ready and that the display must perform a buffer flip at the next vertical blank.

Table 8-12. DMI Output Clocking Signals

Signal Name	Type	Width	Description
USE_BUFID0	Output	1	When active, indicates that frame buffer 0 should be displayed next
USE_BUFID1	Output	1	When active, indicates that frame buffer 1 should be displayed next
USE_BUFID2	Output	1	When active, indicates that frame buffer 2 should be displayed next

- Provides indication to graphics core from the display processor that the buffer identified by buffer ID has been displayed at least once.

Table 8-13. DMI Input Clocking Signals

Signal Name	Type	Width	Description
VSYNC_VALID	Input	1	Vertical sync signal from display controller for indicating vertical blanking period
ACTIVE_BUFID0	Input	1	When active, indicates that frame buffer 0 is currently being displayed by the display controller
ACTIVE_BUFID1	Input	1	When active, indicates that frame buffer 1is currently being displayed by the display controller
ACTIVE_BUFID2	Input	1	When active, indicates that frame buffer 2is currently being displayed by the display controller

- The DISP signals support up to 4 display channels. For each channel, there is a set of signals for the GPU3D to signal the newest available buffer (supporting up to 3 frame buffers), a set of signals for the system display controller (IPU) to signal the buffer currently being displayed, and a vertical sync.
- The vertical sync (VSYNC) from the display controller occurs after each frame is displayed, during the vertical blanking period. One-hot encoded USE_BUFID signals are updated by Z430 whenever there is a new rendered buffer available (and the previous value of USE_BUFID has already been sampled by the IPU/

display controller), so it can change anywhere in the frame. It is resynchronized and sampled a few cycles before the start of the vertical blanking period (rising edge of VSYNC) in display controller, while the currently displayed buffer (ACTIVE_BUFID signals) is updated by display controller at the rising edge of VSYNC with these values that were just sampled from Z430 a few clock cycles before the VSYNC. Signals ACTIVE_BUFF are then re synchronized and sampled in Z430 after synchronizing to VSYNC rising edge.
    - At least one of the display channel interfaces must be directly connected to the system display controller (IPU) to achieve the lowest delay between frame renderings.
    - The IPU must have controls to enable the interface, to utilize the double and triple buffering mechanisms, and to lock and unlock the rendering to the display's vertical sync.
- Control and Power Management
    - Control Interface Block (CIB)
        - Holding block for clock gating, reset etc.
        - Interrupt Interface (INT)
        - Error and status interrupts to the controller.
        - Activity Halt Interface (AHI)
        - Debug bus outputs
        - GPIO bus for miscellaneous control functions
    - Design For Test Interface (DFT)
        - Memory test collar access.
        - Scan/BIST access.
- Debug
    - Set of signals OR chained between internal masters for debug purposes
    - 32b bus multiplexed to 16b

8.5.4 GPU3D Performance

Graphics primitive rendering speed

- 1 Primitive (Triangle/Line/Point) every 6 clocks.
- Up to 1 Vertex Shader Instruction per clock (shared with Pixel Shader)
- Up to 4 Pixel per clock Z only processing (in Single Sample). 2 Pixels/clk in 2x MSAA mode.
    - 1 pixel (at 4 sample MSAA) per clock with alpha blending and depth test
- 1 Pixel Shader Input Interpolant (4-D IEEE 32-bit float) per clock + 4 Z samples generated/clock
- 1 Pixel Shader Instructions per clock (shared with Vertex Shader)

- 1 Bilinear-filtered Texel fetches per clock.
- 1 Pixel per clock with alpha blending and depth test at up to 4 samples/clk

8.5.4.1 GPU3D Memory Accesses

The Z430 generates 128 and 256 bit bursts to memory from its internal masters, which are arbitrated by a Memory Hub (MH). The MH supports up to 64 outstanding transactions, 8 AXI IDs, and contains a MMU.

Typical graphics use cases (usually games) will utilize approximately 400 to 500 MB/s and require a memory latency of less that 90ns (70ns is preferred).

The Memory Hub selects between the following clients in the graphics core:

- CP - (Command Processor) Read/Write
- VGT - (Vertex Grouper and Tesselator) Read Only
- TC - (Texture Cache) Read only
- RB - (Render Block) Write Only

Sub-Client	Sub-Client Designation	AXI ID	Operation	Transaction Size (Bytes)	Sub-Client Outstanding Transaction Limit
Ring Buffer	CPr0	0	Read	32	Programmable (Note 1)
Indirect Buffer #1	CPr1	1	Read	32	Programmable (Note 1)
Indirect Buffer #2	CPr2	2	Read	32	Programmable (Note 1)
State Sub-Block, Constant, & Shader Instruction Data	CPr3	3	Read	32	Programmable (Note 1)
Micro-Engine & Write Pointer Polling	CPr4	4	Read	32	1 Micro-engine read & 1 write pointer read
VGT Indices	VGTr0	5	Read	32	5 (Note 2)
VGT Bin ID	VGTr1	6	Read	32	8
Texture/Vertex Read	TCr	7	Read	16/32	9
Synchronization Semaphores, Micro-Engine Semaphores, Constant State Data	CPw	Programmable	Write	16/32	8 Unconfirmed writes, unlimited writes past point of confirmation
RB Copy	RBw	Programmable	Write	32	No client limit
PA	PAw	Programmable	Write	32	1
MMU TLB Miss	MMUr	Programmable	Read	32	1

All transactions are incrementing address bursts. The starting address is always aligned to the burst size, for example all 16 Byte bursts start at a 16-Byte aligned address; all 32 Byte bursts start at a 32-Byte aligned address.

Command stream and vertex data is read in bursts of 256 bits.

The Burst cache combines color accesses from several smaller objects to 4x4 pixel (16-bit), or 4x2 pixel (32-bit), which are transferred to memory in bursts of 256 bits.

Color writes use byte enables when incomplete pixel blocks are written to the memory

8.5.5 GPU3D Clocking

Yamato design uses a single synchronous clock SYS_GC_sclk. There is a single time domain, and no multicycle paths, latches or negative edge flops are used in the design. (The CKGATER uses a negative latch, but that is a special cell).

The SYS_GC_sclk should be implemented with programmable dividers to run at full speed, synchronous bus speed, and half bus speed to meet system power use cases.

The Control Interface Block (CIB) provides clocks, internal clock gating and reset the rest of the internal blocks. The Graphics Core (GC) and Graphics Arbiter (GARB) are provided with two versions of the core clock (SYS_GC_sclk and SYS_GA_sclk from the CIB). Both clocks are synchronous and in phase with core clock. Two versions are supplied so that clocks to the GC can be removed independently of the GARB.

8.5.5.1 GPU3D Clock Gating

Yamato supports three levels of clock gating:

- Explicit removal of clocks to the GC core by the system under software control
- Designer controlled removal of clocks to logic blocks
- Power compiler instantiated clock gating.

Explicit clock gating is invoked under system control and as such is transparent to the GC. All clocks (GC, AXI, AHB) are removed. Prior to clock removal, the system should ensure that the GC is idle (no outstanding bus traffic, no outstanding command activity in command buffer). Removing the clocks to the GC does not impact GC state (unless power is also removed).

Designers can chose to remove clocks to blocks or sections of blocks based on those functions becoming idle. To facilitate a clean mechanism for transition to idle state, all block clock control signals are propagated to the top level where they are combined and flopped in the CIB. Outputs from the CIB at the top level are used to control clock gaters which are used to remove clocks in a glitch free manner. All CIB clock-gater control signals come directly from a flop.

Blocks may chose to implement a gated and a non-gated version of the clock. Non-gated versions of the clock are fed through clock gaters which are always enabled. This will help with PD balancing of gated vs. non-gated clocks.

8.5.6 GPU3D Resets

The Yamato core uses an asynchronous reset strategy. This signal is propagated throughout the block by the Control Interface Block. The GPU3D takes 64 clock cycles to complete a reset.

8.5.7 GPU3D Interrupts

The graphics core provides a single interrupt pin to the system. Once asserted the interrupt pin remains asserted until the ARM platform clears the IRQ bit in the RBBM_IRQ register.

In general interrupts are used to signal error conditions or to support frame buffer swap.

8.5.8 Debug

The GPU3D has a 32b debug bus that is controlled by a 16b GPIO bus. The GPU3D GPIO bus should be memory mapped (as a single register) and provides byte enables to select debug information and soft reset of blocks. The 32b debug bus should be mapped to system GPIO. There is also an option of using a 32b debug input bus that is logically ORed with the debug output.

- 00 - output lower 16 bits
- 01 - output upper 16 bits
- 10 - toggle between outputing lower and upper 16 bits per 83MHz clock
- 11 - unused

In addition, the interface is limited to a 83MHz clock due to the max pin frequency.

8.5.9 Software

This figure shows the general software stack utilized by applications using the Z430 GPU3D (shown as Yamato GPU3D in the diagram). The stack is here for background purposes and details will be expanded in a separate section.

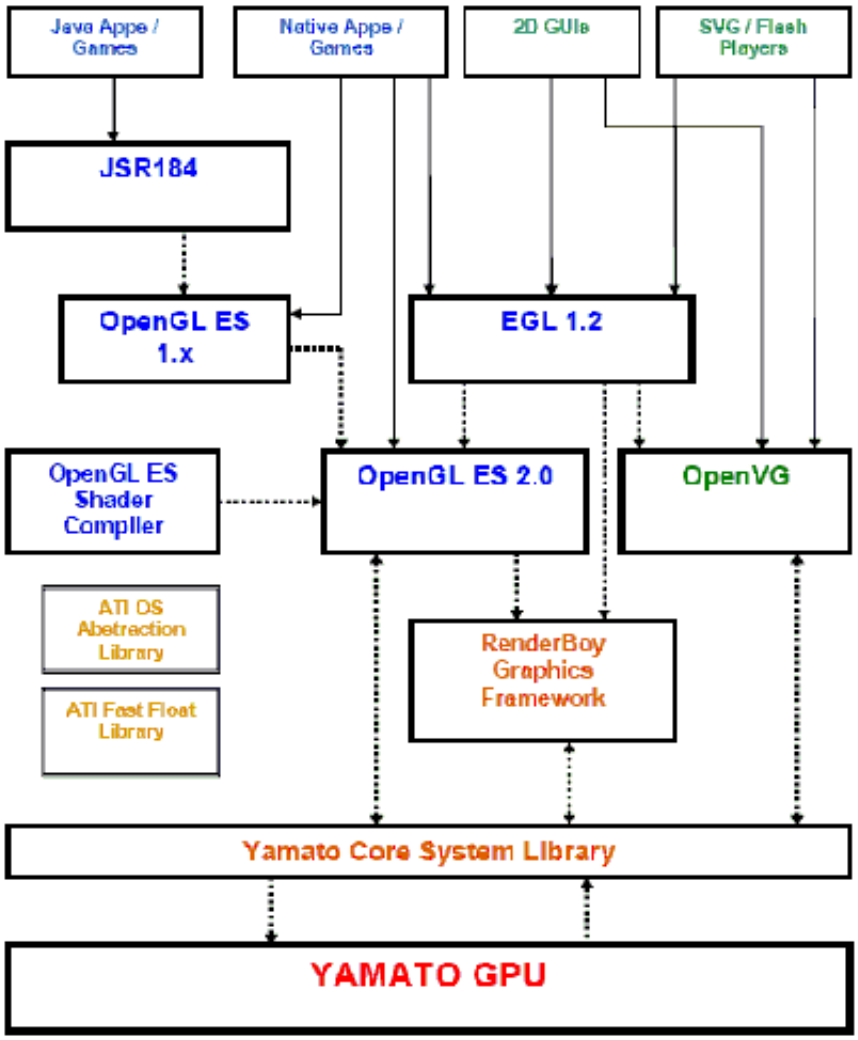

Figure 8-19. Graphics Software Stack

8.6 Graphics Processing Unit 2D (GPU2D)

8.6.1 GPU2D Overview

The 2D graphics processing unit is based on the AMD Z160 IP core (also known as ATI / Bitboys G12). The core is an embedded, 2D and vector graphics accelerator targeting the OpenVG 1.0 graphics API and feature set. The core is divided into two segments. The first accelerates 2D bitmap graphics operations, such as BitBlt, fill and raster operations using a separate 2D graphics acceleration unit. Vector graphics rendering is accelerated by a separate anti-aliasing polygon rasterizer. The core has a rich, but well-chosen set of features, with emphasis being on very high image quality and low memory bandwidth consumption.

8.6.2 GPU2D Features

- Frame buffer sizes supported up-to 2048x2048
- ARGB4444, RGB565, ARGB1555, ARGB5551, ARGB8888 frame buffer modes
- Configurable ARGB order in frame buffer: ARGB, BGRA, ABGR, RGBA
- Linear and block-based (4x4 pixels) frame buffer modes
- Fast buffer clears
- Support for OpenVG render to Image

8.6.2.1 2D Bitmap Graphics (Separate 2D unit)

- BitBlt (surface-to-surface copy)
  - Format conversion from monochrome/ARGB/YUV to ARGB during BitBlt
- Block fill
- Internal 32-bit color precision
- Source bitmap format:
  - 1/4/8-bit monochrome
  - ARGB4444, RGB565, ARGB1555, RGBA5551, and ARGB8888
  - Configurable ARGB order: ARGB, BGRA, ABGR, RGBA
  - Packed YUV 4:2:2 formats (FOURCC codes YUY2, UYVY, YVYU), two pixels per 32 bits of data
  - 1-bit bitmap maps to foreground and background colors
  - 4-bit bitmap is optionally gamma corrected to 8-bit alpha values and can be combined with foreground color to draw anti-aliased fonts
- Destination bitmap format:
  - ARGB4444, RGB565, ARGB1555, RGBA5551, and ARGB8888
  - Configurable ARGB order: ARGB, BGRA, ABGR, RGBA
- Supports three source bitmaps for separate mask/pattern/alpha bitmap support plus reading destination for ROP, blend and color key operations
- Supports masking source coordinates for wrapping patterns
- Supports ROP4 (ROP3 with separate ROPs for masked and unmasked pixels) logical operations
- Supports inverting mask and alpha values from source
- Supports destination rotation by 0/90/180/270 degrees
- Supports programmable blending with optional alpha un-premultiply
- Supports per pixel and constant alpha with optional modulation by source color alpha for OpenVG alpha masking
- Supports color keying by source and destination colors, with optional ignoring of alpha channel

- Supports one scissor rectangle for destination coordinates
- Dithering (ordered)
- Color component masking
- sRGB reads and writes
- Non-power of two source and destination bitmap sizes supported (stride must be a multiple of 32-bits)
- BitBlt with scaling, bilinear filtering with texture lookups, programmable filter kernels possible with the programmable Pixel processor

8.6.2.2 Vector Graphics

- Rasterization of convex and concave polygons with anti-aliasing
- Efficient native polygon rendering (no tessellation to triangles)
- Non-zero and odd-even fill rules
- Primitives supported:
  - Polygons
  - OpenVG path primitives (except Elliptical Arcs): Horizontal/vertical lines, generic lines, curves, smooth curves, moveto, path closing
  - Curve types supported: cubic and quadratic Bézier
  - Strokes with thickness, joints and end caps, unlimited stroke thickness
  - Special case handling of singularities for thick strokes
  - Supports paths with a maximum of 256 crossings along a horizontal or a vertical line
- Input coordinates:
  - Absolute and relative coordinate input in floating point
  - Fixed-point (byte, short, int) and floating-point coordinate input - 0.8, 0.16, 16.16 formats
- Geometry
  - User to surface transform for vertices and stroke shape
  - Hardware curve tessellation
  - Adjustable accuracy for curve and round cap splitting
  - OpenVG/SVG join types: Miter (with miter limit), round, bevel
  - OpenVG/SVG cap types: Butt, round, square
- Pixel processing:
  - Programmable gradient and texturing processor
  - Linear and radial gradients (with focal point)
  - Perspective texture mapping with filtering
  - Two textures supported
  - sRGB and pre-multiply support for textures
  - 16-sample anti-aliasing

- Per-pixel alpha-masking
- Maximum texture size: 1024x1024 pixels

- Vector graphics rendering system AR M platform load:
  - Display list generation during path creation - commands and vertices are stored to an internal format/buffer, no format conversion is performed
  - Filling or stroking a path only requires a few register writes to start the operation in hardware
  - Display lists are transferred to the vector graphics rasterizer using DMA without ARM platform interaction

8.6.3 GPU2D Block Diagram

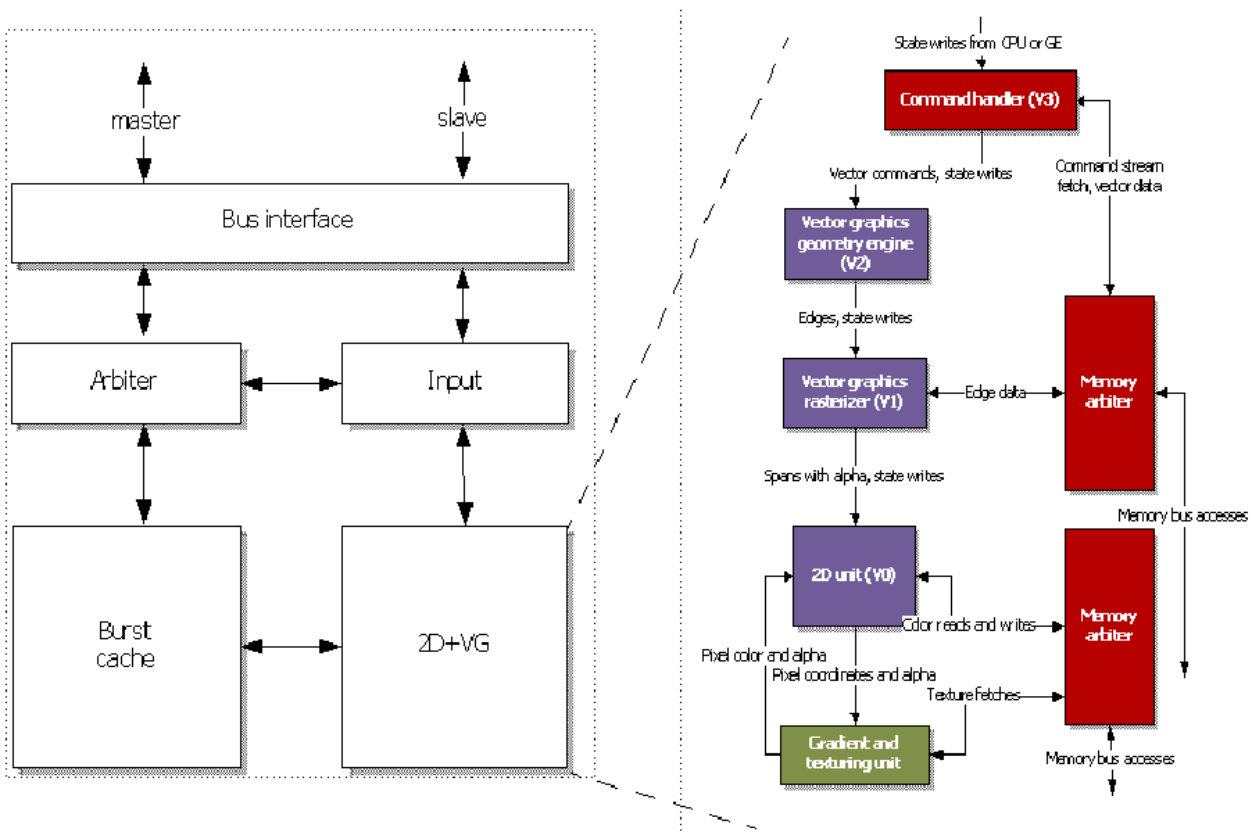

Figure 8-20. GPU2D (Z160) Internal Block Diagram

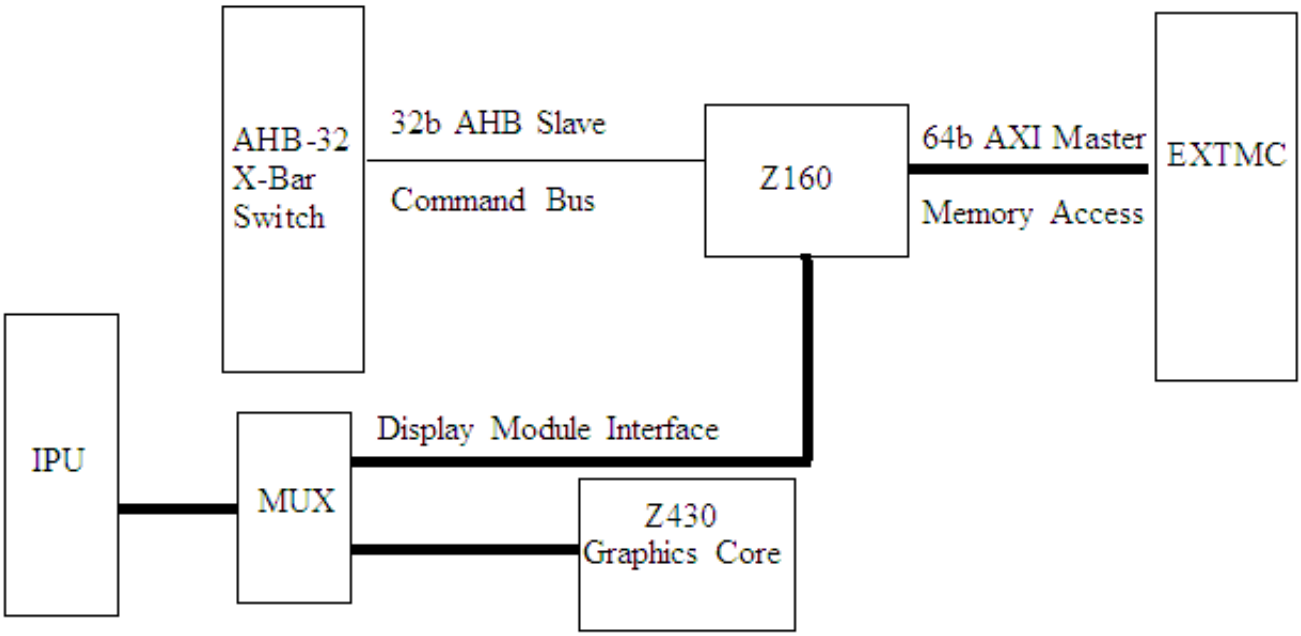

Figure 8-21. GPU2D (Z160) Interface Diagram

Details on the Display Module Interface (DMI) can be found in the GPU3D chapter.

8.6.4 GPU2D Performance

Graphics primitive rendering speed

- 5 clock cycles per vertex (includes transformation)
- 1 pixel / clock (solid color or linear gradient)
- 2 clocks / pixel (affine texture mapping)
- 4 clocks / pixel (with texturing with perspective transformation and radial gradients without separate focal point)
- 8 clocks / pixel (radial gradient with separate focal point)

8.6.4.1 GPU2D Memory Accesses

Command stream and vertex data is read in bursts of 256 bits.

The Burst cache combines color accesses from several smaller objects to 4x4 pixel (16-bit), or 4x2 pixel (32-bit), which are transferred to memory in bursts of 256 bits.

Color writes use byte enables when incomplete pixel blocks are written to the memory

8.6.5 GPU2D Clocking

Table 8-14. Z160 Clocking Signals

Signal Name	Description
busclk	BusIF clock signal
clk_0	Continuos core clock, arbiter and input (not gated)
clk_1	Bcache clock signal
clk_2	2d and VG_V3 clock signal
clk_3	VG_V2 and VG_V1 clock signal
clock_1_ena_o	clock enable for clk_1 (0=clock disabled, 1=clock activated)
clock_2_ena_o	clock enable for clk_2 (0=clock disabled, 1=clock activated)
clock_3_ena_o	clock enable for clk_3 (0=clock disabled, 1=clock activated)

8.6.5.1 GPU2D Clock Gating

There are two different clock gating modes in the GPU2D:

- G12_POWER_OFF - In this mode all the clocks to the G12 are switched off. This mode is only used when the graphics core is totally idle.
- G12_POWER_SW - In this mode the clock gating is controlled by the driver. Appropriate clock gating commands are interleaved into the command stream between render state changes. This is the default state after the core has been reset.

8.6.6 GPU2D Resets

The Z160 has two reset signals:

- *busrst_n* for the bus reset signal
- *rst_n* for reset of all clocks

8.6.7 GPU2D Interrupts

The core has a single general purpose programmable interrupt called *irq_o*.

8.7 Audio Subsystem

8.7.1 Overview

The blocks that belong to the audio subsystem are the SSI-1, SSI-2, SSI-3, AUDMUX, ESAI, SPDIF and ASRC. In addition, the IOMUXC must be appropriately configured to get signals in and out of the chip.

SSI-1,2,3 are synchronous serial interfaces used to transfer audio data. SSI-1,3 are on the peripheral bus and SSI-2 is on the shared peripheral bus. Instead of connecting to the IOMUXC directly, their serial lines connect to the Digital Audio Multiplexer (AUDMUX).

The AUDMUX provides flexible, programmable routing of the serial interfaces (SSI-1 or SSI-2) to and from off-chip devices. The AUDMUX routes audio data (and even splices together multiple time-multiplexed audio streams) but does not decode or process audio data itself. The AUDMUX is controlled by the ARM but can route data even when the ARM is in a low-power mode.

The Enhanced Serial Audio Interface (ESAI) provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, SPDIF transceivers, and other processors. The ESAI consists of independent transmitter and receiver sections, each section with its own clock generator. The ESAI is connected to the IOMUXC and to the ESAI_BIFIFO sub-block.

The ESAI Bus Interface and FIFO (ESAI_BIFIFO) is the interface between the ESAI block and the shared peripheral bus. It contains the FIFOs used to buffer data to/from the ESAI, as well as providing the data word alignment and padding necessary to match the 24-bit data bus of the ESAI to the 32-bit data bus of the shared peripheral bus.

The Sony/Philips Digital Interface (SPDIF) audio block is a stereo transceiver that allows the processor to receive and transmit digital audio over it. The SPDIF receiver section includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency. A recovered clock is provided by the SPDIF receiver section and may be used to drive both internal and external components in the system. The SPDIF is connected to the shared peripheral bus.

The Asynchronous Sample Rate Converter (ASRC) converts the sampling rate of a signal associated to an input clock into a signal associated to a different output clock.The ASRC supports concurrent sample rate conversion of up to 10 channels of over 120dB THD+N. The sample rate conversion of each channel is associated to a pair of incoming and outgoing sampling rates.The ASRC supports up to 3 sampling rate pairs. The ASRC is connected to the shared peripheral bus.

8.7.2 Audio Subsystem Block Diagram

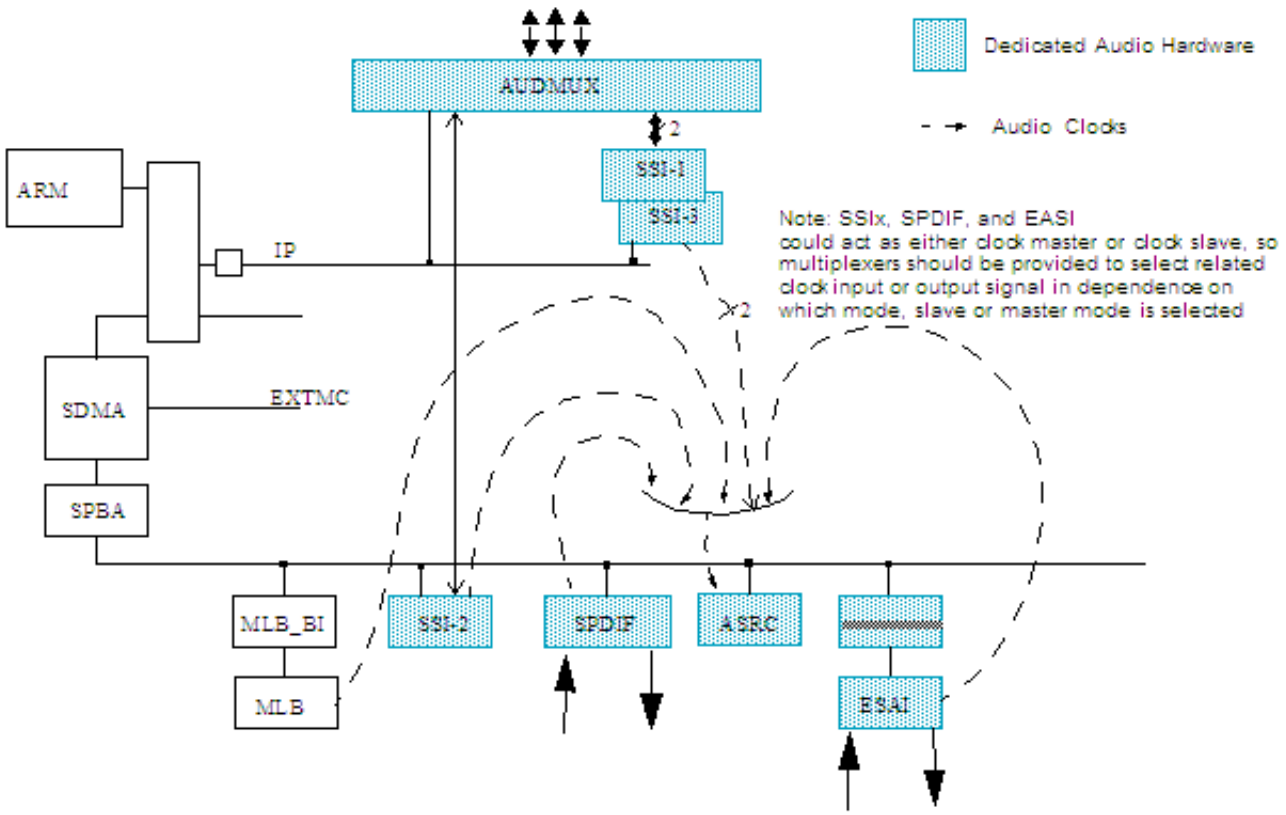

Figure 8-22. Audio Subsystem Block Diagram

8.7.2.1 Standard Serial Interface Controller (SSI)

The Standard Serial Interface Controller (SSI) is a full-duplex serial port that allows communication with external devices using a variety of serial protocols. The SSI supports a wide variety of protocols (SSI normal, SSI network, I2S, and AC-97), bit depths (up to 24 bits per word), and clock/frame sync options.

The SSI has two pairs of 8x24 FIFOs and hardware support for an external DMA controller in order to minimize its impact on system performance. The second pair of FIFOs provides hardware interleaving of a second audio stream which reduces ARM platform overhead in use cases where two timeslots are being used simultaneously.

The three SSIs may support three audio streams (possibly at different sample rates) simultaneously. SSI-1 and SSI-3 are located on the IP Bus, while SSI-2 is located on the Shared Peripheral Bus. Because the SDMA can directly access SSI-2 (being on the Shared Peripheral Bus), it is recommended that SSI-2 be used for high-bandwidth data transfers in order to optimize bus bandwidth consumption. SSI-1 and SSI-3 can then be used for lower bandwidth applications.

8.7.2.2 Digital Audio MUX (AUDMUX)

The Digital Audio Multiplexer (AUDMUX) provides a programmable interconnect fabric for voice, audio, and synchronous data routing between host serial interfaces, such as SSI, and peripheral serial interfaces-that is, audio and voice codecs.

The AUDMUX includes two types of interfaces. Host ports connect to the processor serial interfaces, and peripheral ports connect to off-chip audio devices. A desired connectivity is achieved by configuring the appropriate host and peripheral ports.

The AUDMUX provides flexible, programmable routing of the on-chip serial interfaces to and from off-chip audio devices. The AUDMUX routes audio data (and even splices together multiple time-multiplexed audio streams) but does not decode or process audio data itself.

Figure 8-23 illustrates how the AUDMUX is connected in the system.

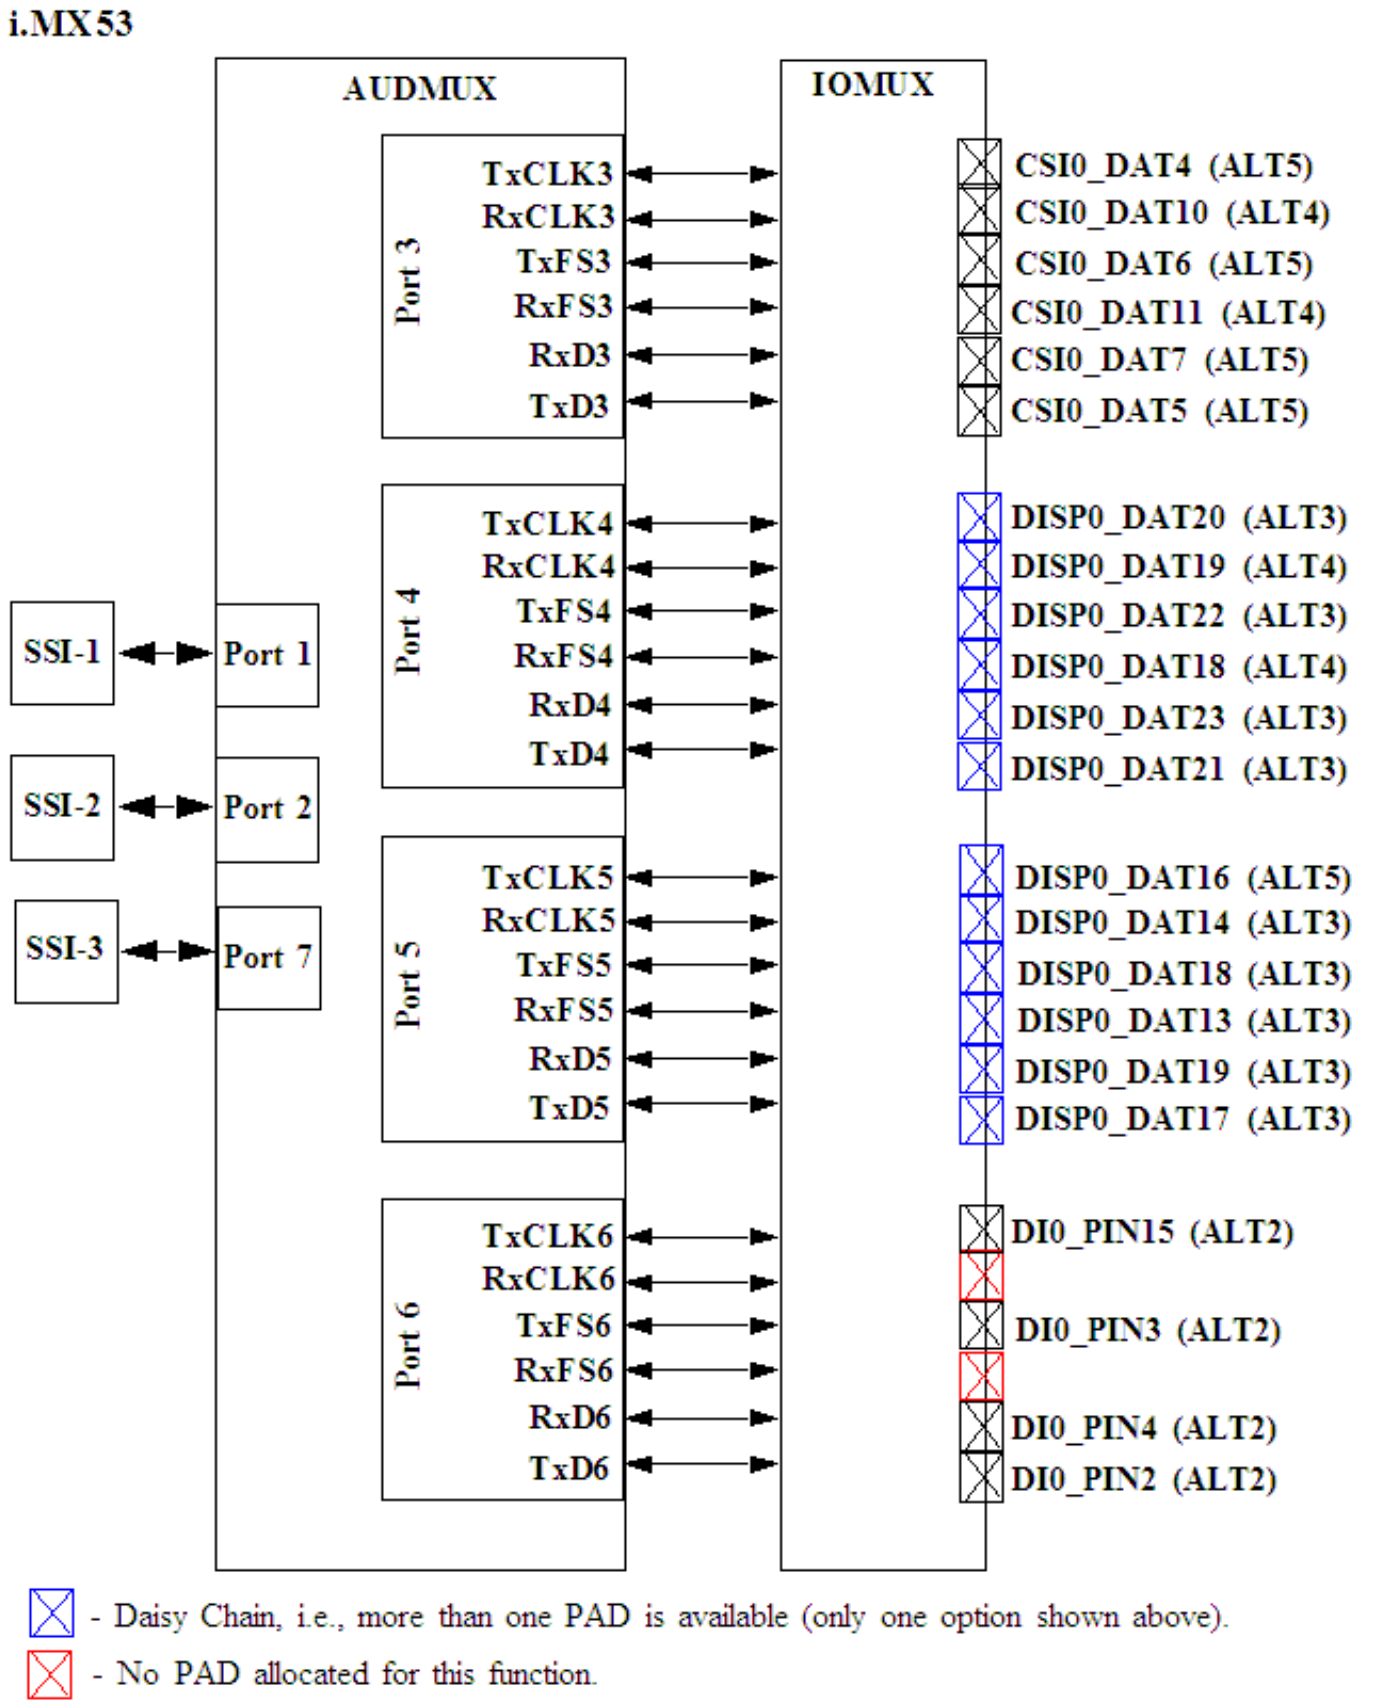

Figure 8-23. AUDMUX System Block Diagram

8.7.3 Enhanced Serial Audio Interface (ESAI)

The Enhanced Serial Audio Interface (ESAI) provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, SPDIF transceivers, and other processors.

The ESAI consists of independent transmitter and receiver sections, each section with its own clock generator. All serial transfers are synchronized to a clock. Additional synchronization signals are used to delineate the word frames. The normal mode of operation is used to transfer data at a periodic rate, one word per period. The network mode is also intended for periodic transfers; however, it supports up to 32 words (time slots) per period. This mode can be used to build time division multiplexed (TDM) networks. In contrast, the on-demand mode is intended for non-periodic transfers of data and to transfer data serially at high speed when the data becomes available.

The ESAI has 12 pins for data and clocking connection to external devices. The ESAI is internally connected to the ESAI Bus Interface and FIFO (ESAI_BIFIFO), and does not connect directly to the shared peripheral bus. The ESAI interface is designed for a 24-bit data bus, while the shared peripheral data bus is 32-bit wide. Also, the ESAI data paths are only double buffered, not allowing efficient DMA service in the applications processor environment. The ESAI_BIFIFO allows increasing the data buffering and data width matching to the shared peripheral bus.

8.7.4 Sony/Philips Digital Interface (SPDIF)

The Sony/Philips Digital Interface (SPDIF) block is a stereo that allows the processor to transmit digital audio over it using the IEC60958 standard, consumer format. i.MX53 provides one SPDIF transmitter with one output. The SPDIF allows the handling of both SPDIF channel status (CS) and User (U) data. Although i.MX53 includes SPDIF receiver part, it is likely not be used for the intended use-cases of i.MX53.

The SPDIF transmit clock is generated by the SPDIF internal clock generator sub-block and the clock sources are from outside of the SPDIF block. The ESAI, SSI and Media Local Bus (MediaLB) Controller (MLB) clock sources should provide a clock that is at least 64 x Fs, where Fs is the sampling frequency. The external clock source should provide at least 128 x Fs. Clocks of higher frequency may be provided as long as the multiplication factor is a power of 2 (for example, 128x, 256x or 512x). Also, clock frequency precision of 100ppm or better should be provided. The SPDIF transmit clock sources should come from the ESAI HCKT block I/O, SSI-1 TXCLK signal, SSI-2

TXCLK signal and MLB clock, as well as from a dedicated audio clock source (either a quartz oscillator or an external clock input). The SPDIF transmit clock can be one of the ASRC clock output sources.

Figure 8-24 shows the clock structure of the SPDIF transceiver.

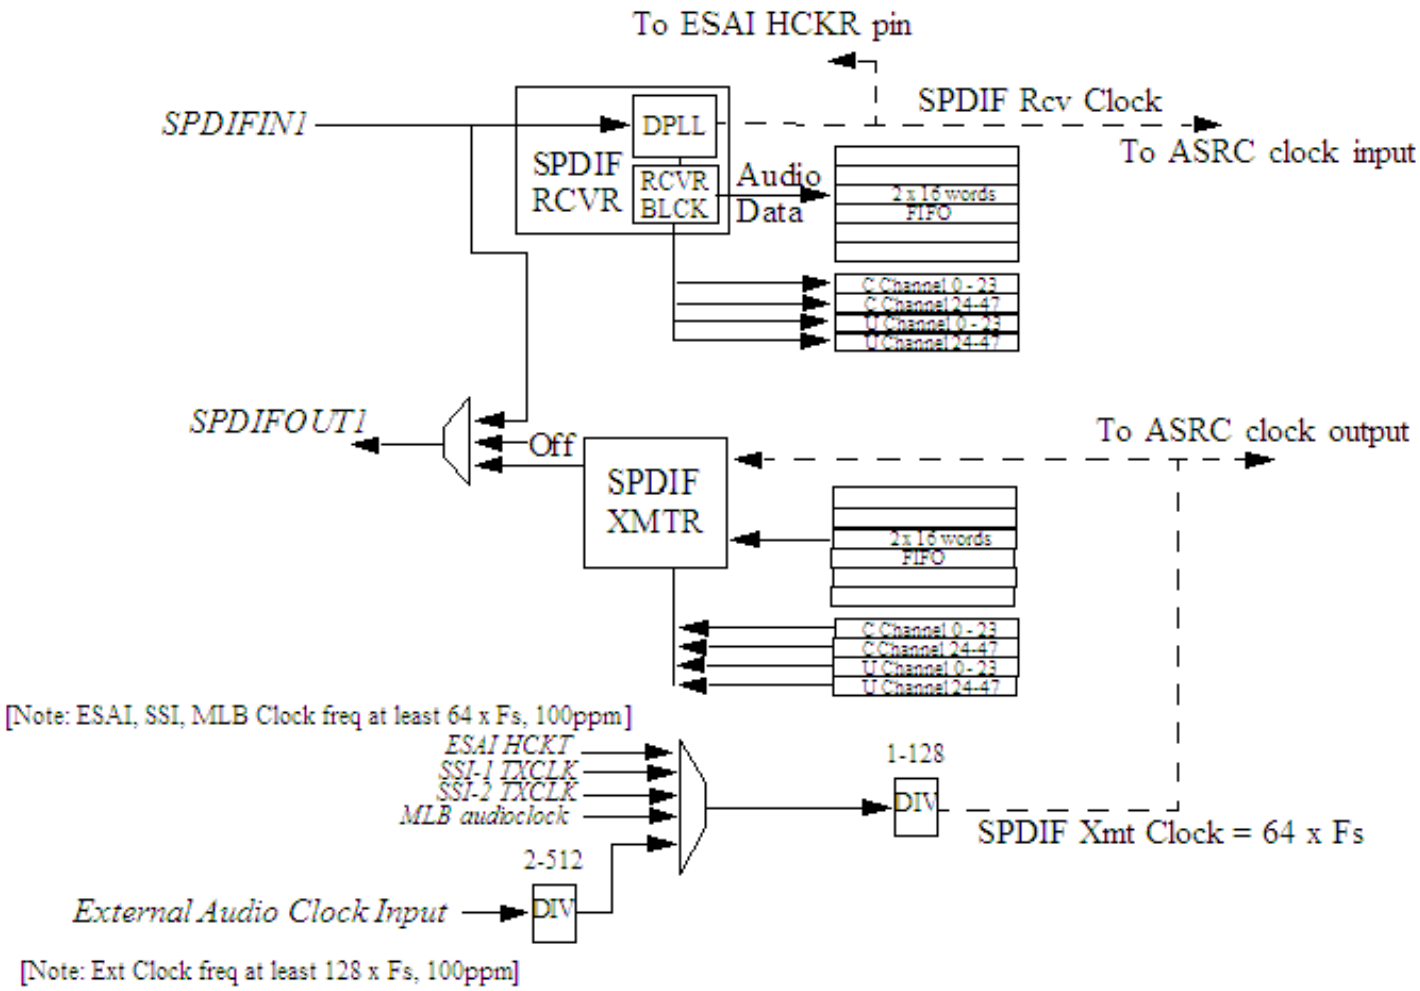

Figure 8-24. SPDIF Transceiver Clock Diagram

8.7.5 Asynchronous Sample Rate Converter (ASRC)

The incoming audio data may be received from various sources at different sampling rates. Also the outgoing audio data may have different sampling rates and it can also be associated to output clocks that are asynchronous to the input clocks.

The Asynchronous Sample Rate Converter (ASRC) converts the sampling rate of a signal associated to an input clock into a signal associated to a different output clock. The ASRC supports concurrent sample rate conversion of up to 10 channels of about -120dB THD+N. The sampling rate conversion of each channel is associated to a pair of incoming and outgoing sampling rates. The ASRC supports up to three sampling rate pairs.

In the real-time audio use case, both input/output sampling rate clocks are activated. Both sampling rate clocks are directly connected to the ASRC, and the ratio estimation of the input clocks to output clocks is used to perform the sample rate conversion in ASRC hardware.

Several audio blocks (namely SSI-1, SSI-2, SSI-3, S/PDIF and ESAI) can act as either clock master or clock slave. Multiplexers are provided on the SoC level to select which of the block's clock signals (clock in or clock out) can be connected to the ASRC input. This depends on the block's operational mode as shown in Figure 8-25 and Table 8-15. Figure 8-25 presents the multiplexer cell used for all ASRC input clocks. Table 8-15 shows the detailed clocks, multiplexer control and data bits for each ASRC input clock. For the audio block clocks that are directly connected to ASRC (without the multiplexer scheme) see Table 8-16.

In the non-real-time streaming audio use case, the input sampling rate clock does not need to be provided. Instead, the ideal-ratio value conversion is set in the ASRC interface registers. In this case only the output sampling rate clock must be provided, and the fixed ratio of the input to the output in the register is used to perform the sample rate conversion.

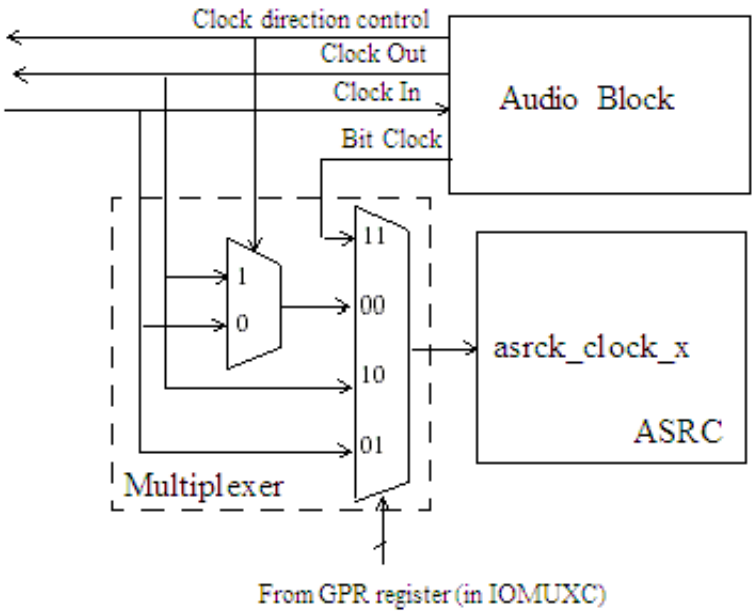

Figure 8-25. Muxing scheme template for ASRC input clocks

Table 8-15. ASRC Muxed Input Clocks

ASRC Clock Input	Audio block source	MUX2:1 Control	MUX2:1 Input 0	MUX2:1 Input 1	MUX4:1 Control	MUX4:1 Input 00	MUX4:1 Input 01	MUX4:1 Input 10	MUX4:1 Input 11

Chapter 9
Power Management

9.1 Overview

The i.MX53 has several voltage domains.

- Peripheral domain: The peripheral domain consists of the i.MX53 peripherals and ARM asynchronous interface. The nominal voltage is 1.3V. This domain has Dynamic Voltage and Frequency Scaling (DVFS). When the chip is in STOP mode, the voltage can be reduced to LP STOP voltage.
- ARM domain: The ARM domain consists of the ARM Cortex A8. The nominal voltage is 1V. This domain has DVFS. When the chip is in STOP, the voltage can be reduced to GP STOP voltage.
- Memory array domain: The memory array domain consists of all the memory arrays, including the L1 and L2 caches. The nominal voltage is 1.3V.
- Secure Real Time Clock (SRTC) domain: The SRTC domain consists of the SRTC. The operating voltage is 1.3V. The voltage to this domain must always remain on. This domain is not affected by STOP mode.
- PLL domain: This domain consists of 2 supplies for the PLLs of i.MX53. The first supply is for the digital domain of the DPLLs' nominal voltage, 1.3V. The second supply is for the analog domain of the PLLs and its nominal voltage is 1.8V. This domain is not affected by STOP mode.
- FUSE program domain: this domain consists of the supply needed to program the e-fuses. The nominal voltage of this domain is 3.3 V. This supply should be connected to ground once programming has been completed. This domain is not affected by STOP mode. Table 9-1 shows the power domains.

Table 9-1. Power domains

Domain name	Description	Nominal Voltage	DVFS	Comments
VCC	i.MX53 peripheral including Cortex A8 LP side	1.3V	1V	

Table continues on the next page...

Table 9-1. Power domains (continued)

Domain name	Description	Nominal Voltage	DVFS	Comments
VCCGP	Cortex A8 cmos065gp side	1V	0.8V	
VDDA/VDDAL1	memory arrays including Cortex A8 L2 memory arrays and L1 memories.	1.3V	NA	See restrictions in Dynamic Voltage and Frequency Scaling (DVFS)
SRTC_POW	SRTC	1.3V	NA	
PLL_DIG	DPLL digital side and FPM	1.3V	NA	
PLL_ANA	PLL analog side	1.8V	NA	

NOTE

* Please note that the power values defined in this table are for reference only. For the validated numbers please see i.MX53 datasheet.

9.2 Power Saving Methodology

Several power management features are supported in i.MX53 to reduce active and static power consumption.

9.2.1 Active Power Savings

The main active power savings techniques applied to i.MX53 are listed below:

- Clock gating - i.MX53 implements three levels of clock gating. These levels are:
  - Clock tree roots (in the CCM)
  - Clock tree branches (in the LPCG)
  - Clock tree leaf nodes (in the blocks)
- DVFS - Dynamic Frequency Voltage Scaling. There are 2 DVFS engines. One for the peripheral domain and one for the ARM domain.

9.2.2 Leakage Power Savings

The main leakage control mechanisms on i.MX53 are reduced voltage in STOP mode and SRPG power gating.

- SRPG - State Retention Power Gating. The state of the flip flops are preserved with a continuously powered on supply, while the combinatorial logic be

are powered down, using internal switch cells. This is available on the Cortex A8 platform. There is also a possibility to SRPG only the NEON floating point inside the Cortex A8.

The power gating sequencing is controlled by the Global Power Controller (GPC) block on i.MX53. The following power gating options exist:

- SRPG of the Cortex A8 platform in WAIT mode.
- SRPG of the Cortex A8 platform in STOP mode.
- SRPG of the NEON floating unit when it's not needed, by SW control.

9.3 Block Connectivity for Low Power Modes

Figure 9-1 shows the connectivity of the blocks for low power modes.

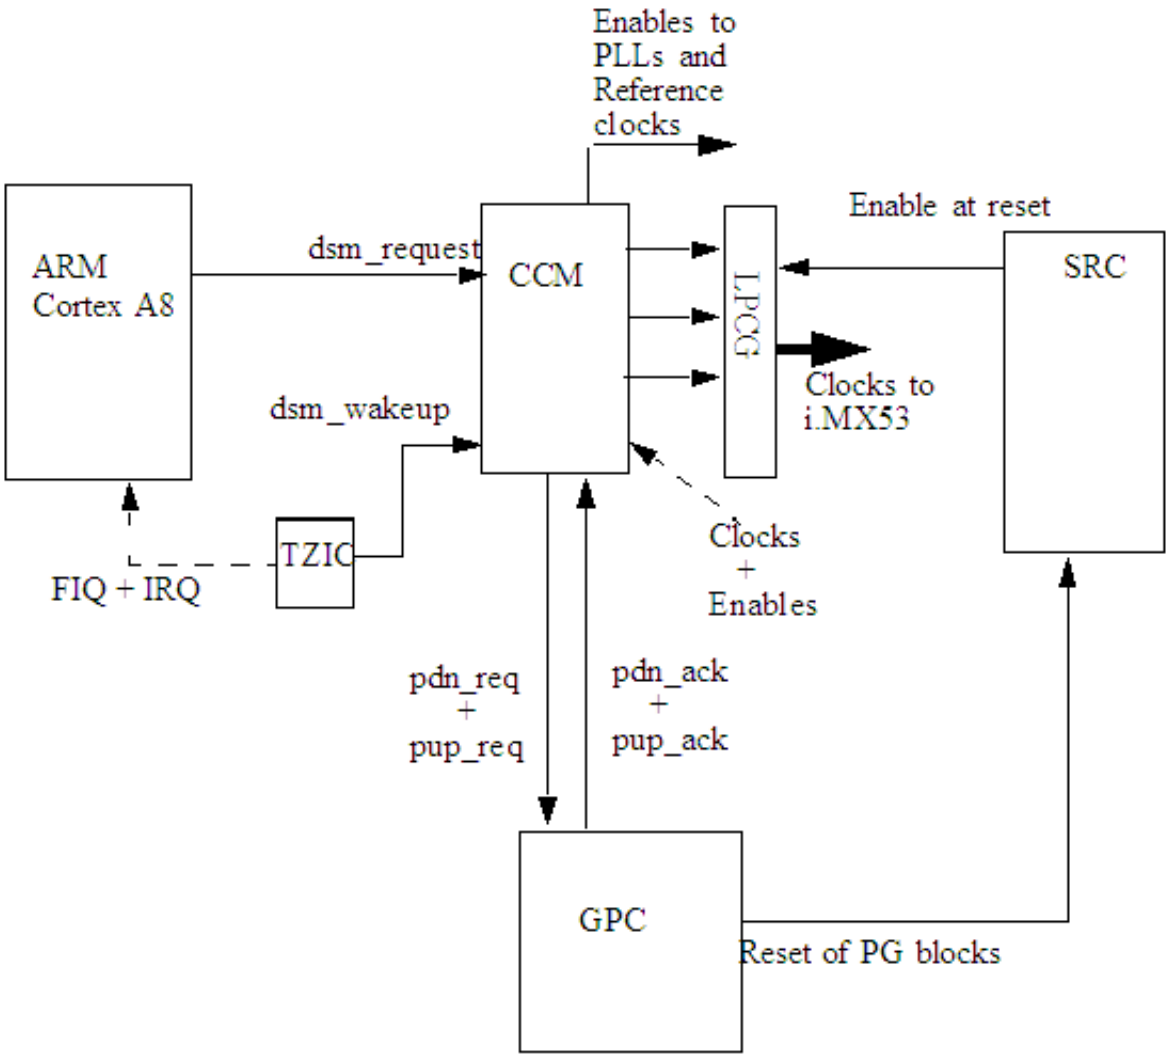

Figure 9-1. Connectivity of module in low power modes

9.4 Low Power Modes

i.MX53 can be put into different low power modes. The different power modes are:

- RUN - Core is active, clocks are on, the peripheral blocks required are active. SW can close clocks of blocks that are not in use.
- WAIT - Core is disabled and clock gated, bus clocks to peripherals can be on as required. SRPG can be applied to Cortex A8 as described on the section above.
- STOP - Core is disabled, peripherals are disabled, bus clocks are off, DPLLs are off. SRPG can be applied to Cortex A8 as described on the section above.

The different power modes of the individual blocks are:

- Active - Operational and doing work with clocks on.
- Idle - Not doing work, but clocks on.
- Disabled - Not doing work and clocks off.

The block modes can be mapped onto the domain modes as shown in Table 9-2.

Table 9-2. Low Power Modes

Mode	Core	Modules	PLL	CKIH	CKIL
RUN	Active	Active, Idle, or Disabled [1]	On	On	On
WAIT	Disabled	Active, Idle, or Disabled [1]	On	On	On
STOP	Disabled	Disabled [2]	Off	Off	On

[1] During RUN and WAIT modes, the peripherals can be active, but not all must be active. The blocks that are not required for the use case can be Idle or Disabled in the RUN and WAIT modes.

[2] Some blocks can operate from CKIL in STOP mode.

9.4.1 Low Power Mode Inputs to Blocks in i.MX53

Many of the peripherals have the following signals:

- ipg_stop - this signal indicates to the block that system is entering stop mode - will be connected to ipg_stop signal from the CCM
- ipg_wait - this signal indicates to the block that system is entering wait mode -will be connected to ipg_wait signal from CCM
- ipg_doze - legacy pin used for doze mode indication - there are a few blocks in i.MX53 that have this pin and they will be connected as follows:
  - uart: ipg_doze is connected to ipg_wait from CCM. Since uart does not have an ipg_wait signal.
  - sim: ipg_doze is connected to ipg_wait from CCM. Since sim does not have an ipg_wait signal.
  - epit: ipg_doze is grounded.
  - gpt: ipg_doze is grounded.
  - pwm: ipg_doze is grounded.
  - wdog: ipg_doze is grounded.

9.4.2 Power Down Sequence

1. SW prepares the LPM bits in the CCM see #clock_control_module_ccm as well as the ARM SRPG power gate bits in the GPC see #general_power_controller_gpc. The

information if the ARM platform can be SRPG power gated is stored in the GPC block.
2. ARM starts the LPM sequence. Resulting in the CCM raising request for power down for ARM and peripherals.
3. Power down sequence, following ARM sequence as described in the #state_retention_power_gating_controller_srpgc, PGC and EMPGC specs.
4. A combined power down acknowledge signal is issued to the CCM from the GPC block.

9.4.3 Power Up Sequence

1. An interrupt is received and as a result after returning clocks is needed then a power up request signal is issued from the CCM to the GPC.
2. The power up of the ARM.

9.5 RAM Memory Supply Connections

The memories in i.MX53 have 3 supply pins:

- VDD - The memory periphery supply.
- VDDA/VDDAL1 - The memory array supply.
- VDD_STATE - The supply to keep the value of the outputs during power down and the redundancy information for redundant memories.

Each memory periphery supply is connected to the supply of the block the memory is placed in.

All the memories' array supply (VDDA/VDDAL1) and VDD_STATE are connected to a dedicated supply pin on i.MX53 this is done due to the fact that the memories array supply does not support a voltage lower then 1.08V. So during DVFS the periphery supply is lowered along with the rest of the chip.

VDDAL1 is dedicated pin used for the memory arrays of the cortex_A8 L1 array. It can be tied to VDDA.

NOTE

The dedicated array supply needs to be lowered to support a maximal difference between VDDA/VDDAL1 and VDD of 300mV.

9.6 Dynamic Voltage and Frequency Scaling (DVFS)

i.MX53 IC has DVFS that is one of the active power saving methodologies. The i.MX53 will support the following voltages:

- Peripheral side (cmos065lp process): 1.3V to 1V.
- Cortex A8 side (cmos065gp process): 1V to 0.8V.

DVFS is supported for both the ARM and the peripherals using 2 different load monitors:

1. DVFSC - uses weighing signals relevant to the ARM platform (cmos065gp) and affecting only the ARM platform.
2. DVFSP - uses weighing signal relevant to the i.MX53 peripherals and affecting only the peripheral side.

While in DVFS each clock will be divided by 2, 3 or 4 all across the peripheral domain, depending on the definition in the CCM. For a restriction table please refer to the #clock_control_module_ccm.

Chapter 10
System Security

10.1 Introduction

Security is a common requirement for platforms built using the i.MX53, although the specific needs vary greatly depending on the platform and market. The type and cost of assets to be protected on a portable consumer device are very different from those to be protected on automotive or industrial platforms, and the same applies to the kind of attacks and level of resources threatening those assets. The platform designer must select an appropriate set of counter measures to meet the relevant platform security needs.

For the platform designer to meet the requirements for each market, the i.MX53 incorporates a range of security features which can be used individually or in concert to underpin the platform security architecture. Most of the i.MX53 security features provide protection against particular kinds of attack and can be configured at various levels according to the required degree of protection. These features are designed to work together and can be integrated with appropriate software to create defensive layers. In addition to protection features, the i.MX53 includes a general purpose accelerator to enhance the performance of selected industry standard cryptographic algorithms.

Main i.MX53 security features:

Secure High Assurance Boot

- Security library embedded in tamper-proof on-chip ROM
- Based on established cryptography: Public Key Infrastructure (PKI), SHA-256 and RSA 2048
- Run every time chip is reset
- Image Version Control (on-chip OTP-based)
- Secure signing services

HW Cryptographic Accelerators

- Symmetric: AES, DES/ 3DES, ARC4

- Asymmetric: RSA, ECC
- Message Digest and HMAC: SHA-1, SHA-224, SHA-256, MD-5

Run-time Integrity Checker and Security Controller (including Security Monitor)

- Run-time monitoring of the critical SW integrity

Secure Storage

- On-chip zeroizable Secure RAM
- Off-chip storage protected using AES-256 and chip's unique hardware-only key

True Random Number Generator Accelerator (RNGA)

Secure JTAG Controller (with electrical fuses)

- JTAG access can be permanently disabled by an on-chip OTP element
- Alternatively, JTAG access can be controlled (by secret keys)

Secure real-time clock

- On-chip, self-powered real-time clock
- Monotonic counter

Universal Unique ID

ARM TrustZone and hardware Firewall

- The Firewall controls access to all hardware resource from DMA bus masters

Physical Tamper Detection

- Clock and power supply tamper detection
- Device's cover seal break detection

The following are the i.MX53 security components.

- TrustZone (TZ) Architecture in the Cortex A8 Platform, TrustZone Aware Interrupt Controller (TZIC) and TrustZone Watchdog Timer (WDOG-2)
- High Assurance Boot (HAB) feature in the System Boot
- Security Controller (SCC) with 16 Kbyte of on-chip Secure RAM
- Symmetric/Asymmetric Hashing and Random Accelerator (SAHARA)
- Real Time Integrity Checker (RTIC)
- Secure Real Time Clock (SRTC)
- IC Identification Module (IIM) with on-chip electrical fuses
- Central Security Unit (CSU)
- Secure JTAG Controller (SJC)

- Watermark mechanism in the Multi Master Multi Memory Interface (M4IF)
- Locked mode in the Smart Direct Memory Access (SDMA) controller

Detailed descriptions of each component are found in *MCIMX53 Multimedia Applications Processor Security Reference Manual* (MCIMX53SRM).

Chapter 11
ARM Cortex A8 Platform (ARM Platform)

11.1 Introduction

This chapter discusses the architecture and design of the ARM™Cortex® A8 platform. Detailed design information of each block within the platform is not covered in this document.

11.2 Overview

A block diagram of the ARM platform is shown in Figure 11-1. The ARM Platform consists of the ARM Ltd. ARM processor which includes a NEON™ co-processor, L1 cache, L2 cache, Embedded Trace Macrocell (ETM) and a Cross Trigger Interface (CTI). The platform includes the essential sub-blocks: platform control, test logic and debug (Cross trigger Matrix (CTM), Embedded Trace Buffer (ETB), and a second CTI).

The ARM processor instruction and data read/write AXI master port is connected from the non-ARM Platform side of the Level 2 Cache. The L2 can access external L3 memory through this port.

The core platform supports static debug through the debug logic to SoC. This includes the capability of real time trace through ARM's Coresight ETM, ETB and CTM sub-blocks. The second CTI sub-block allows cross triggering of internal and external trigger sources.

The ARM platform has two power domains (LP & GP) which are separated by level shifters. The LP power domain serves as a interface to the rest of the SoC. The GP power domain is completely contained within the platform and allows the ARM core and subsystem to run at much higher frequencies than the rest of the SoC.

The boundary of the two power domains is also an asynchronous boundary between the ARM platform and the rest of the SoC. Synchronizers in both the GP and LP power domains of the platform allow the ARM core and subsystem to run asynchronously from the rest of the SoC.

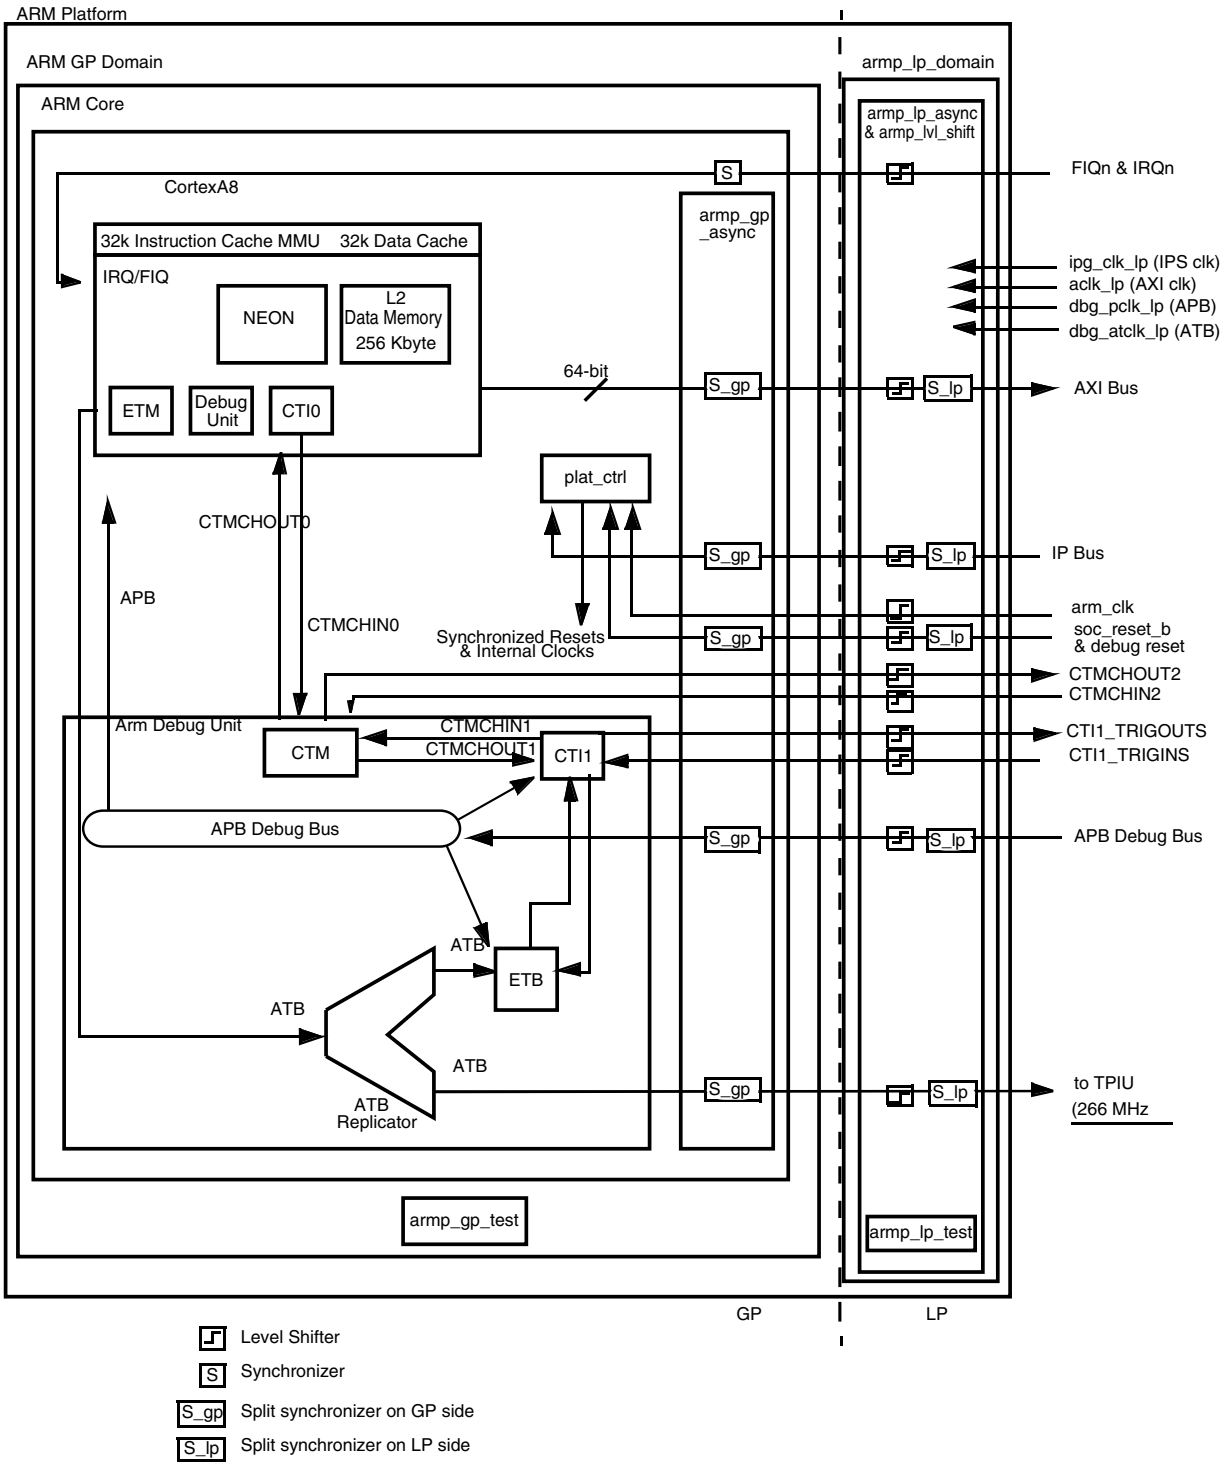

Figure 11-1. ARM platform Block Diagram

11.2.1 Core Platform Sub-Blocks

11.2.1.1 ARM platform

The information presented in this section focuses on design aspects of the ARM platform in the ARM platform subsystem. The ARM platform is ARM's first superscalar processor featuring technology for enhanced code density and performance, NEON™technology for multimedia and signal processing, and Jazelle®RCT (Runtime Compilation Target) technology for efficient support of ahead-of-time and just-in-time compilation of Java and other bytecode languages.

The ARM platform incorporates an integer core that implements the ARMv7-A architecture instruction set. It supports the ARMv7 and Thumb® -2 instruction sets. A NEON sub-block is included to accelerate the performance of multimedia applications. Included Vector Floating Point v3 architecture is IEEE 754 compliant. The processor includes an AMBA® 3 AXI high-performance 64-bit SoC interconnect.

The following are the features of ARM platform:

- The ARM platform's sophisticated pipeline architecture is based on dual, symmetric, in-order issue, 13-stage pipelines with advanced dynamic branch prediction achieving 2.0 DMIPS/MHz. The instruction execute unit consists of two symmetric Arithmetic Logical Unit (ALU) pipelines and the multiply pipeline.
  - In-order, dual-issue, superscalar microprocessor core
  - 13-stage main integer pipeline
  - 10-stage NEON media pipeline for executing NEON and VFP instruction sets
  - Dedicated L2 cache with programmable wait states
  - Global history based branch prediction
- Works in conjunction with a power optimized load store pipeline to deliver 2.0 DMIPS/MHz for power sensitive applications
- ARMv7 architecture compliant including:
  - Thumb-2 technology for greater performance, energy efficiency, and code density
  - NEON signal processing extensions to accelerate media codecs such as H.264 and MP3
  - Jazelle RCT Java-acceleration technology to optimize Just In Time (JIT) and Dynamic Adaptive Compilation (DAC), and reduce memory footprint by up to three times
- Integrated Level 2 Cache
  - Built using standard compiled LP RAMs

    - Sized at 256 Kb
    - Programmable delay
- Optimized Level 1 Caches
    - Customized design for performance and power optimization
    - Sized at 32 Kb Instruction and 32 Kb Data
    - Combine minimal access latency with hash way determination to maximize performance and minimize power consumption.
- Dynamic Branch Prediction
    - Enabled by branch target and global history buffers
    - Achieves 95% accuracy across industry benchmarks.
    - Replay mechanism minimizes miss-predict penalty
- Memory System
    - Single-cycle load-use penalty for access to the L1 cache
    - Hash array in the L1 cache limits activation of the memories to when they are likely to be needed.
    - Direct interface between the integrated, configurable L2 cache and the NEON media unit for data streaming
    - Banked L2 cache design that enables only one bank at a time
- Memory Management Unit (MMU) and separate instruction and data Translation Look-aside Buffers (TLBs) of 32 entries each
- Embedded Trace Macrocell (ETM) support for nonintrusive debug
- ARMv7 debug with watchpoint and breakpoint registers and a 32-bit Advanced Peripheral Bus (APB) interface to the CoreSight debug system.

11.2.1.2 Instruction Fetch

The instruction fetch unit predicts the instruction stream, fetches instructions from the L1 instruction cache, and places the fetched instructions into a buffer for consumption by the decode pipeline. The instruction fetch unit also includes the L1 instruction cache.

11.2.1.3 Instruction Decode

The instruction decode unit decodes and sequences all ARM and Thumb-2 instructions including the debug control coprocessor, CP14, and the system control coprocessor, CP15 instructions.

The instruction decode unit handles the sequencing of:

- Exceptions
- Debug Events
- Reset Initialization

- Memory Built-In Self Test (MBIST) for L1 cache
- Wait-for-interrupt
- Other Unusual Events
- Instruction Cycle Timing

11.2.1.4 Instruction Execute

The instruction execute unit consists of two symmetric Arithmetic Logical Unit (ALU) pipelines and the multiply pipeline. The execute pipelines also perform register write back.

The instruction execute unit:

- executes all integer ALU and multiply operations including flag generation
- generates the virtual addresses for loads and stores and the base write-back value, when required
- supplies formatted data for stores and also forwards data and flags
- processes branches and other changes of instruction stream and evaluates instruction condition codes.

11.2.1.5 Load/Store

The load/store unit encompasses the entire L1 data side memory system and the integer load/store pipeline. This includes the:

- L1 data cache.
- data side TLB.
- integer store buffer.
- NEON store buffer.
- integer load data alignment and formatting.
- integer store data alignment and formatting.

The pipeline accepts one load or store per cycle that can be present in either pipeline 0 or pipeline 1. This gives the processor flexibility when scheduling load and store instructions.

11.2.1.6 L2 Cache

The L2 cache unit includes the L2 cache and the Buffer Interface Unit (BIU). It services L1 cache misses from both the instruction fetch unit and the load/store unit.

11.2.1.7 NEON

The NEON unit includes the full 10-stage NEON pipeline that decodes and executes the NEON media instruction set. The NEON unit includes:

- the NEON instruction queue
- the NEON load data queue
- two pipelines of NEON decode logic
- three execution pipelines for NEON integer instructions
- two execution pipelines for NEON floating-point instructions
- one execution pipeline for NEON and VFP load/store instructions
- the VFP engine for full execution of the VFPv3 data-processing instruction set.

11.2.1.8 Processor Debug Unit

The processor debug unit assists in debugging software running on the processor. In combination with a software debugger program, the debug unit enables debugging the following:

- application software
- operating systems
- hardware systems based on an ARM processor

The debug unit enables:

- stopping program execution
- examining and altering processor and coprocessor states
- examining and altering memory and input/output peripheral states
- restarting the processor core

11.2.1.9 Embedded Trace Marcocell (ETM)

The ETMv3.3 unit is a nonintrusive trace macrocell that filters and compresses an instruction and data trace for use in system debugging and system profiling. The ETM unit has an external interface outside of the processor called the Advanced Trace Bus (ATB) interface.

The ARM platform ETM provides real time instruction trace for the ARM platform. It is designed to be used with the CoreSight Design Kit. Unlike previous versions of the ARM platforms, this ETM is embedded inside the Processor Core.

Real time tracing is controlled by specifying a set of filtering and triggering resources which include address and data comparators, counters and sequencers. Though data trace can not be enabled, the ETM can still trigger based on data values. Also, the ETM can trace data address values.

The ARM platform ETM contains the following main components:

- Core interface
- Trace generation
- Filtering and triggering resources
- Main FIFO
- AMBA 3 ATB interface
- AMBA 3 APB interface

11.2.1.10 Cross Trigger Interface 0 (CTI0)

This block controls the Trigger Interface (TI). The CTI combines and maps the trigger requests, and broadcasts them to all other interfaces on the embedded cross trigger (ECT) as channel events. When the CTI receives a channel event it maps this onto a trigger output. This enables subsystems to cross trigger with each other. The receiving and transmitting of triggers is performed through the TI.

Each CTI has 8 trigger inputs, 8 trigger outputs and 4 sets of 4 channel I/O(s).

11.2.2 Summary of Remaining Platform Components

11.2.2.1 Platform Controller

The Platform Control contains all the miscellaneous logic required for the platform. The main purpose of the Platform Control Module within the ARM platform is to implement a set of control and/or status registers and associated logic for the management of certain platform functions such as internally generated clocks, debug enable/status, low power control, platform version ID, etc.

The Platform Control Module provides these main features:

- Internal clock generation with the ability to programatically set the frequency (divide-by) for each clock independently.
- Ability to force (down-counter) preload for any one or more clocks at anytime independent of preload set.
- Provides a gated clock for the IP Bus asynchronous bridge for power savings

- Provides 16 bits of General Purpose register bits for routing out to Platform boundary.
- Provides 8 bits of Platform Internal Control register bits for external Platform (SoC) use.
- Provides a set of Low Power control and status bits.
- Control bit to enable Debug along with Debug active status bit.
- NEON activity monitor which can be used in determining when to disable NEON thus saving power.

11.2.2.2 Debug Sub-Blocks

The ARM platform debug blocks are part of the overall Coresight debug system which include the ETB, CTM, CTI1, ATB replicator and APB address decode. It is expected that a DAP block and one or more additional CTI will be included at the SoC level. This section gives a brief overview of the sub-blocks that are implemented within the ARM platform. For details of the full Coresight debug subsystem, please refer to the SoC debug section.

11.2.2.2.1 Embedded Trace Buffer (ETB)

The ETB provides on-chip storage of trace data using 32-bit RAM. The ETB accepts trace data from the ARM ETM through an ATB port (passing through a replicator in between). Providing an on-chip buffer alleviates the pin count, bandwidth, and pad design requirements associated with sending trace data to a debugger directly through package pins in a real-time fashion.

Features:

- 4Kbyte compiled memory for the trace buffer and optionally can be used as a general purpose memory
- Only 32-bit accesses to the 4Kbyte buffer is supported
- AMBA Peripheral Bus programming interface for configuration and memory access

11.2.2.2.2 AMBA Trace Bus (ATB) Replicator

The ATB Replicator enables two trace sinks (ETB and an off platform port generally connected to a Trace Port Interface Unit - TPIU) to be wired together and receive ATB trace data from the same trace source (ETM). There are no programable registers. It takes incoming trace data from a single source (ETM) and replicates it as multiple masters.

The CSREPLICATOR is part of the armp_gp_platform block. Two output master ports are required for this design - one for the on-platform ETB and one for the off-platform TPIU. Placing the TPIU off platform allows future debug trace sources to connect to the TPIU via a FUNNEL, without the need to modify the ARM platform.

11.2.2.2.3 Cross Trigger Interface 1 (CTI1)

This block controls the Trigger Interface (TI). The CTI combines and maps the trigger requests, and broadcasts them to all other interfaces on the ECT as channel events. When the CTI receives a channel event it maps this onto a trigger output. This enables subsystems to cross trigger with each other. The receiving and transmitting of triggers is performed through the TI.

Each CTI has 8 trigger inputs, 8 trigger outputs and 4 sets of 4 channel I/O(s).

11.2.2.2.4 Cross Trigger Matrix - CTM

This block controls the distribution of channel events. It provides channel interfaces to the CTIs. The CTM can also connect to another CTM via a channel interface. This allows multiple CTMs to be connected.

The ARM platform has one CTM inside the platform to handle events between the platform's CTI, the processor's CTI and the rest of the ECT system outside the platform. Placing a CoreSight cross trigger matrix (CSCTM) on platform minimizes the event cycle time between the ETB and the ETM. The handshaking between the CTIs on-platform and the on-platform CTM are not enabled. This requires the ARM's CTI, the on-platform CTI1 and the on-platform CTM to all be in the same clock domain. The on-platform CTM connects to the ECT system via an off-platform CTM and the respective channels require synchronizing and handshaking enabled.

11.2.2.2.5 Advanced Peripheral Bus - APB Debug Bus

The APB originates off platform generally from a Debug Access Port (DAP) block. This bus allows access to the registers in all of the debug blocks which have addressable registers.

11.2.2.3 Asynchronous Wrapper

The ARM platform hard macro contains synchronizers for most signals into and out of the platform where synchronization is required. This means the ARM platform can function asynchronously from the rest of the SoC.

11.2.3 Configuration

There are several configuration options associated with the ARM platform. These are determined at the platform level and selected as follows:

- The L1 cache size is 32 Kb instruction and 32 Kb data
- There is parity on the L1 cache
- There is no error correction on the L1 cache
- The L2 cache size is 256 Kb
- There is no parity on the L2 cache
- There is no error correction on the L2 cache
- There are 2 L2 tag banks and 4 data banks per tag bank
- The AXI data bus width out of the platform is 64-bit

11.2.4 Endian Modes

The ARM platform supports Little Endian mode only.

11.2.5 Bus Interfaces

This section will discuss the major bus interfaces of the ARM platform. The ARM platform has the following bus interfaces:

- AMBA AXI interface
- APB CoreSight interface
- ATB CoreSight interface
- Peripheral Interface (IP Bus)

11.2.5.1 AMBA AXI Interface

The AXI bus interface is the main interface to the system bus. It performs L2 cache fills and noncacheable accesses for both instructions and data. The AXI interface utilizes a 64-bit wide input and output data bus. It also supports multiple outstanding requests on the AXI bus. The AXI bus is allowed to be asynchronous between the platform and SoC domains. This provides maximum flexibility at the SoC level.

11.2.5.2 APB CoreSight Interface

The APB is an AMBA bus used for debugging. The CoreSight interface is the ARM architecture for multi-processor trace and debug. It defines what debug and trace components are required and how they are connected. The platform Debug APB should be connected to the SoC DAP APB mux. The APB is allowed to be asynchronous between the platform and SoC domains. This provides maximum flexibility at the SoC level.

11.2.5.3 ATB CoreSight Interface

The ATB is a trace output bus used for debugging. The CoreSight components are programmed with the DAP using the APB programming bus. Trace is output over the ATB trace bus. The ATB is allowed to be asynchronous between the platform and SoC domains. This provides maximum flexibility at the SoC level.

11.2.5.4 Peripheral Interface (IP Bus)

The IP Bus interface to the platform connects the on-chip registers to the memory map and internal buses at the SoC level. Location (addresses of the registers) is determined at the SoC level. The platform acts as a slave to an SoC based IP Bus controller.

11.3 Memory Map and Register Definition

The memory map for ARM platform specific registers is shown below. This does not include coprocessor registers contained in the ARM platform or the ARM Coresight Debug. For documentation of registers contained in those blocks, please refer to the appropriate technical reference manual.

This register block address space uses five address lines which are fully decoded. The space includes nine registers and 23 unimplemented locations. The unimplemented locations will return an error if they are accessed. Depending on how the SoC decodes the register block, the entire 32-word register block could alias in the larger memory space.

ARM memory map

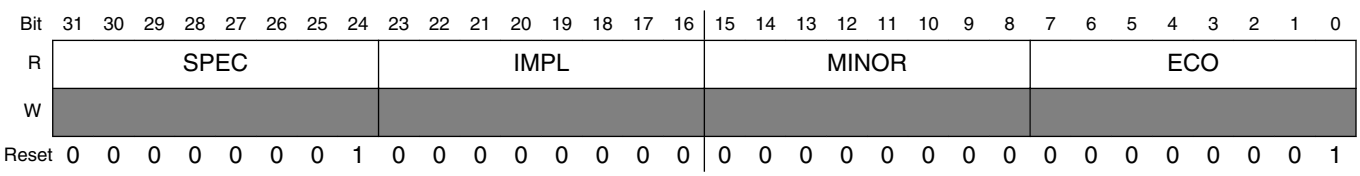
Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FA_0000	Platform Version ID (ARM_PVID)	32	R	0100_0001h	11.3.1/ 623
63FA_0004	General Purpose Control (ARM_GPC)	32	R/W	0004_FF00h	11.3.2/ 624
63FA_000C	Low Power Control (ARM_LPC)	32	R/W	0000_0000h	11.3.3/ 625
63FA_0010	NEON Low Power Control (ARM_NLPC)	32	R/W	0000_0000h	11.3.4/ 626
63FA_0014	Internal Clock Generation Control (ARM_ICGC)	32	R/W	0000_7777h	11.3.5/ 627
63FA_0018	ARM Memory Configuration (ARM_AMC)	32	R/W	0000_0003h	11.3.6/ 629
63FA_0020	NEON Monitor Control (ARM_NMC)	32	R/W	000F_F000h	11.3.7/ 630
63FA_0024	NEON Monitor Status (ARM_NMS)	32	w1c	0000_0000h	11.3.8/ 631

11.3.1 Platform Version ID (ARM_PVID)

The platform version ID register (ARM_PVID) contains a 32-bit version ID which can be used to link the silicon to a specific version of the platform database. The version ID should match our release label applied to the platform database.

This register can be accessed by a 32-bit secure/non-secure, user/supervisor, read transaction. Writes return an error.

Address: ARM_PVID is 63FA_0000h base + 0h offset = 63FA_0000h



ARM_PVID field descriptions

Field	Description
31–24 SPEC	Major architectural or significant spec changes
23–16 IMPL	Implementation changes
15–8 MINOR	Minor changes (bug fixes, I/O changes)

Table continues on the next page...

ARM_PVID field descriptions (continued)

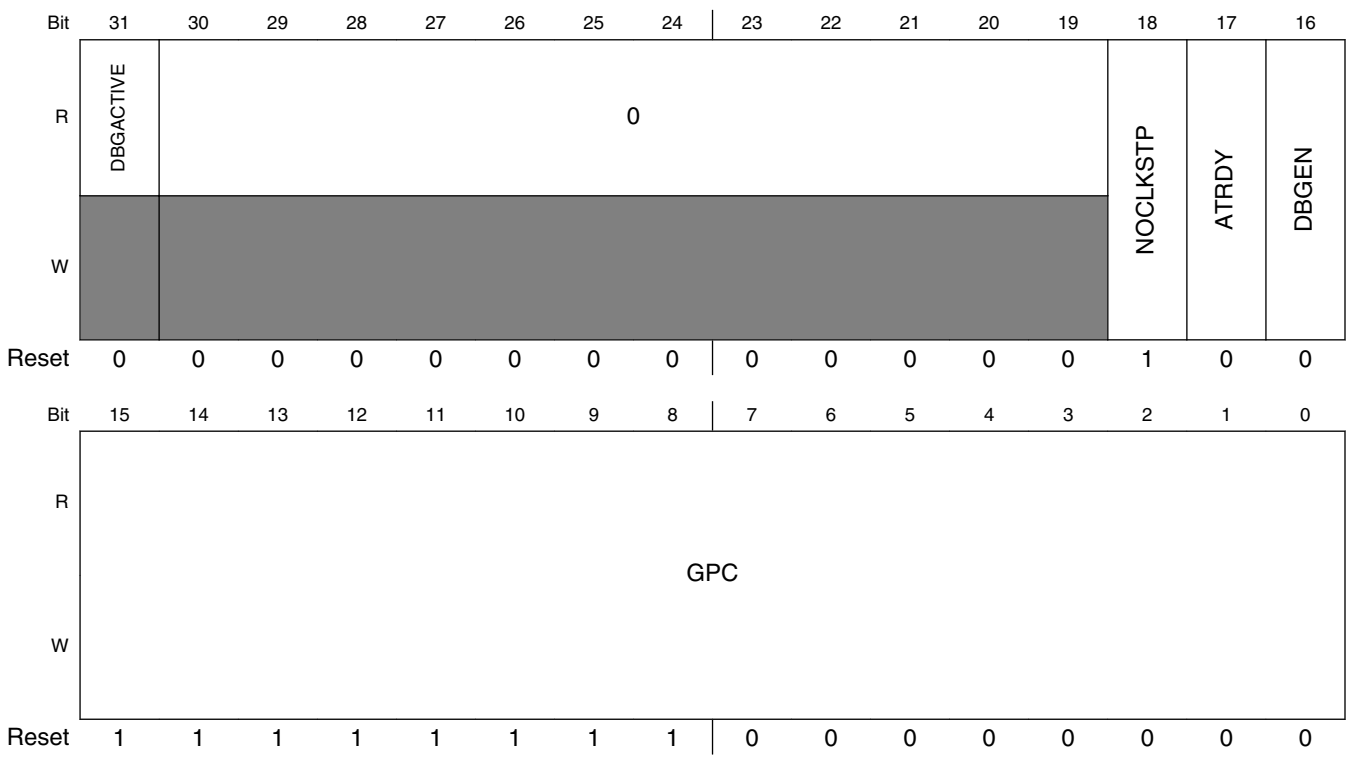
Field	Description
7–0 ECO	ECO changes

11.3.2 General Purpose Control (ARM_GPC)

This register contains 16-bits of general purpose control which drive core platform outputs that can be used within the SoC for general purpose control. This register also contains the DBG_ACTIVE status bit and DBG_EN control bit for entering Debug mode via a software access to this register.

This register can only be accessed by 32-bit secure supervisor transactions.

Address: ARM_GPC is 63FA_0000h base + 4h offset = 63FA_0004h



ARM_GPC field descriptions

Field	Description
31 DBGACTIVE	This bit indicates the status of debug. This allows the user to determine if debug has been enabled either from off platform, via the external DAP_SYS JTAG interface (dbgen_in platform input), or via software accesses to the DBGEN bit in this register.

Table continues on the next page...

ARM_GPC field descriptions (continued)

Field	Description
	0 debug is not enabled. Debug clocks are off and debug registers are inaccessible. 1 debug is enabled. Debug clocks are on and the debug system is ready to be used.
30–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18 NOCLKSTP	This bit is used to control clock-gating within the CORTEX-A8n. Note that this is distinctly different than the higher-level (platform-level) clock-gating/low-power control afforded by the other Plat_Ctrl low-power functionality (dsm_request along with the DSM and DBG_DSM control bits within the Low Power Control register). 1 All normal clock-gating activity (WFI, NEON, and so on) will be overridden and no clock gating will occur within the CORTEX-A8n. NOCLKSTP, however, has no affect on the higher-level platform clock-gating, and the low-power functions discussed in the LPC register will work as architected. 0 clock-gating within the CORTEX-A8n will be enabled. This is the recommended setting in order to reduce run mode power consumed by the clocking network within the Integer core as well as the Neon co-processor.
17 ATRDY	1 this bit disables the platform boundary ATB interface. In most SoCs this will be connected to a TPIU. This prevents traces to the ETB from stalling due to the ASYNCATB FIFO overflowing. 0 this bit allows the platform boundary ATB interface to be active. In this case, traces to the ETB could stall due to ASYNCATB FIFO becoming full. This may cause the ETM data loss.
16 DBGEN	Debug enable. This allows the user to manually activate clocks within the debug system. This register bit directly controls the platform's dbgen_out output signal which connects to the DAP_SYS to enable all debug clocks. Once enabled, the clocks cannot be disabled except by asserting the disable_trace input of the DAP_SYS.
15–0 GPC	General Purpose Control bits directly control the general_purpose_outs[15:0] output ports of the ARM Platform. These bits will be connected at the SoC level and therefore will control functions decided by the SoC architects, and must be documented by the SoC team.

11.3.3 Low Power Control (ARM_LPC)

This register is used to control entry to low power mode and can only be accessed by 32-bit secure supervisor transactions.

There exists a platform output, dsm_request, that when asserted, requests the SoC to turn off clocks to the platform, and optionally deactivate one or more power supplies. DSM can only be entered after the ARM Platform has executed a WFI instruction, completed all outstanding bus transactions, and all activity at the L2 level has completed. Assertion of either irq_b, fiq_b, or dbg_edbgrq platform inputs will cause the ARM platform to complete the WFI instruction and will result in the negation of dsm_request.

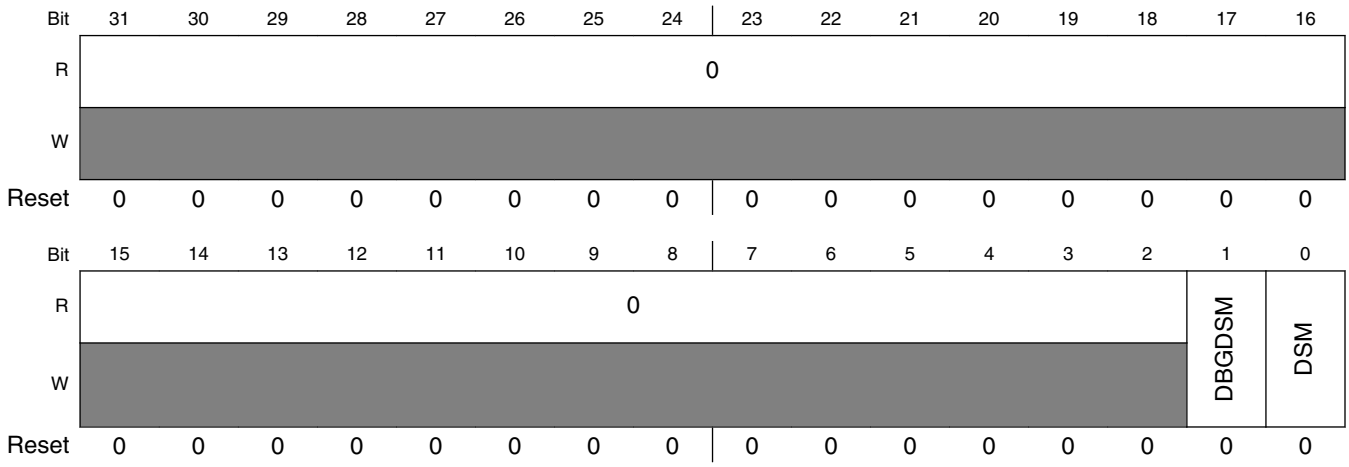
The DSM bit configures the platform to either: block deep sleep mode entry (default), or allow DSM entry when requested.

The DBG_DSM bit configures the platform to block deep sleep mode entry when debug mode is enabled (dbgen_in platform input is asserted high). This will allow the user to ensure deep sleep mode is not entered when debug is enabled.

The NEON_RST bit is used for placing the ARM NEON processor into, or releasing it from, reset.

This register can only be accessed by 32-bit secure supervisor transactions.

Address: ARM_LPC is 63FA_0000h base + Ch offset = 63FA_000Ch



ARM_LPC field descriptions

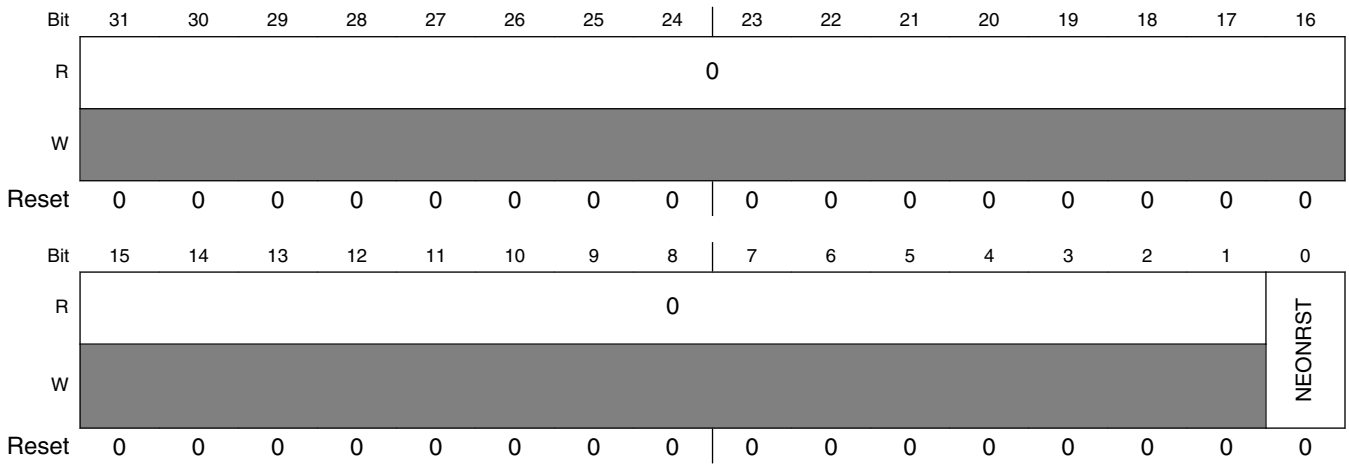
Field	Description
31–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 DBGDSM	Debug Deep Sleep Mode Enable 1 DSM can be entered (dsm_request will not be blocked) regardless if debug is enabled or not. 0 DSM can NOT be entered (dsm_request will be blocked) if debug is enabled
0 DSM	Deep Sleep Mode Enable is used to gate the platform's dsm_request signal, preventing the platform from issuing a deep sleep mode request. 1 DSM can be entered (dsm_request will not be blocked). 0 DSM can NOT be entered (dsm_request will be blocked).

11.3.4 NEON Low Power Control (ARM_NLPC)

This register is used to place the ARM NEON processor into, or releasing it from, reset. Refer to the table below for a description of this control bit.

This register can only be accessed by 32-bit secure supervisor transactions.

Address: ARM_NLPC is 63FA_0000h base + 10h offset = 63FA_0010h



ARM_NLPC field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 NEONRST	Hold the ARM NEON in its reset state in preparation for a low power mode. 1 ARESETNEONn input to the ARM is driven low - placing NEON into reset. 0 ARESETNEONn input to the ARM is driven high - releasing NEON from reset.

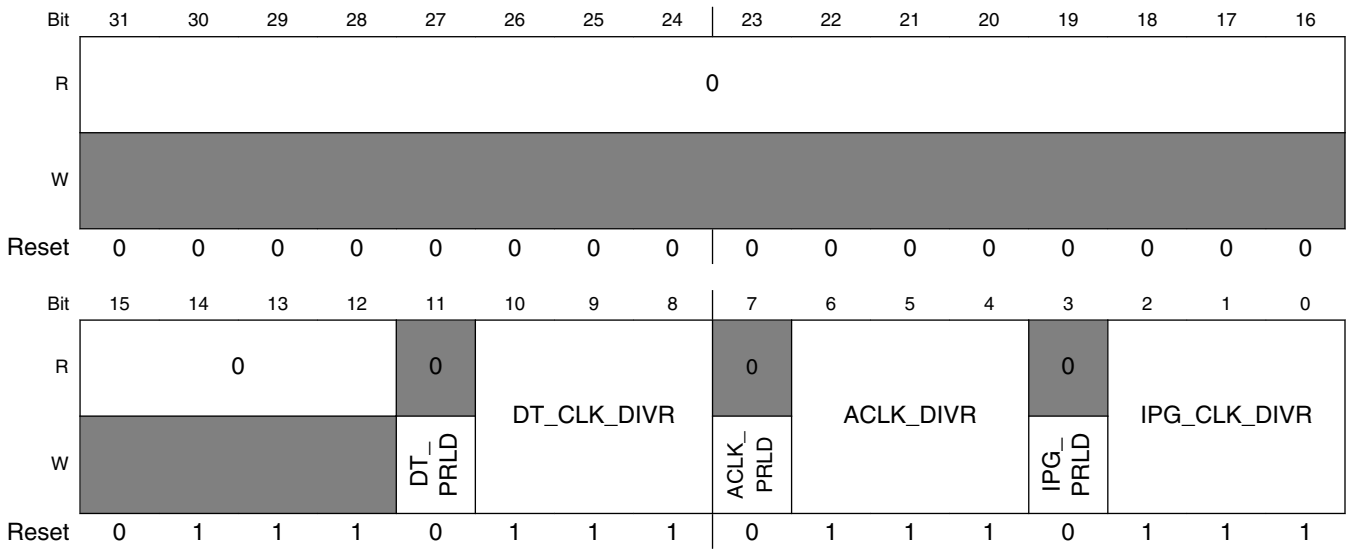
11.3.5 Internal Clock Generation Control (ARM_ICGC)

This register is used to control the clock generation circuitry for all derived clocks used within the ARM platform (ipg_clk, aclk, dbg_atclk, and dbg_pclk). The dbg_pclk clock is generated as a straight divide-by-2 of dbg_atclk.

Note: At reset, all generated clocks are edge aligned and are generated at 8:1. dbg_pclk will require 1 dbg_atclk clock cycle before it begins clocking as a divided dbg_atclk.

This register can only be accessed by 32-bit secure supervisor transactions.

Address: ARM_ICGC is 63FA_0000h base + 14h offset = 63FA_0014h



ARM_ICGC field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11 DT_PRLD	Debug AMBA Trace Bus Clock Down Counter Preload Reads always return 0 0 has no effect. If preload is 0 during a write of a new divide ratio, the down counter will not be loaded with the new value until it reaches 0 (rolls over). 1 A write of 1 will force the DBG_ATCLK down counter to preload on the next arm_clk.
10–8 DT_CLK_DIVR	Debug AMBA Trace Bus Clock Divide Ratio These bits control the clock divide ratio for the debug AMBA trace bus (ATB) and GP async interface clocks. The ATB bus is used to transfer trace messages from the ETM to the ETB or TPIU. When ETM trace data is being transferred over the ATB to the embedded trace buffer (ETB), the ATB is capable of running up to half the ARM Platform frequency. However, when ETM trace data is being transferred to the TPIU to be sent out the trace port, the ATB should be slowed to some appropriate SoC frequency. DT_CLK_DIVR[2:0] = 0b000 results in a 1:1 clock ratio DT_CLK_DIVR[2:0] = 0b001 results in a 2:1 clock ratio DT_CLK_DIVR[2:0] = 0b010 results in a 3:1 clock ratio DT_CLK_DIVR[2:0] = 0b011 results in a 4:1 clock ratio DT_CLK_DIVR[2:0] = 0b100 results in a 5:1 clock ratio DT_CLK_DIVR[2:0] = 0b101 results in a 6:1 clock ratio DT_CLK_DIVR[2:0] = 0b110 results in a 7:1 clock ratio DT_CLK_DIVR[2:0] = 0b111 results in a 8:1 clock ratio
7 ACLK_PRLD	AXI Master Port Clock Down Counter Preload Reads always return 0

Table continues on the next page...

ARM_ICGC field descriptions (continued)

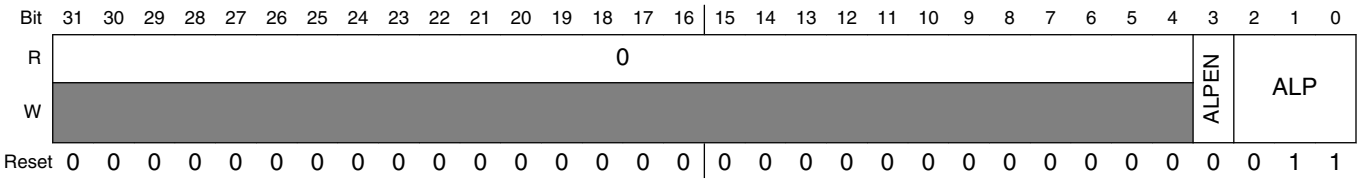
Field	Description
	0 has no effect. If preload is 0 during a write of a new divide ratio, the down counter will not be loaded with the new value until it reaches 0 (rolls over). 1 will force the ACLK down counter to preload on the next arm_clk
6–4 ACLK_DIVR	AXI Master Port Clock Divide Ratio Controls the clock divide ratio for the ARM Platform AXI bus and GP AXI async interface clocks and clock enable. The ratio of clock cycles generated for arm_clk to aclk is: ACLK[2:0] +1 : 1 ACLK_DIVR[2:0] = 0b000 results in a 1:1 clock ratio ACLK_DIVR[2:0] = 0b001 results in a 2:1 clock ratio ACLK_DIVR[2:0] = 0b010 results in a 3:1 clock ratio ACLK_DIVR[2:0] = 0b011 results in a 4:1 clock ratio ACLK_DIVR[2:0] = 0b100 results in a 5:1 clock ratio ACLK_DIVR[2:0] = 0b101 results in a 6:1 clock ratio ACLK_DIVR[2:0] = 0b110 results in a 7:1 clock ratio ACLK_DIVR[2:0] = 0b111 results in a 8:1 clock ratio
3 IPG_PRLD	Platform IP Bus Port Clock Down Counter Preload Reads always return 0 0 has no effect. If preload is 0 during a write of a new divide ratio, the down counter will not be loaded with the new value until it reaches 0 (rolls over). 1 will force the ACLK down counter to preload on the next arm_clk
2–0 IPG_CLK_DIVR	Platform IP Bus Port Clock Divide Ratio Controls the clock divide ratio for the Platform Controller and GP async IP Bus clock and clock enable. The ratio of clock cycles generated for arm_clk to ipg_clk is: IPG_CLK[2:0] +1 : 1 IPG_CLK_DIVR[2:0] = 0b000 results in a 1:1 clock ratio IPG_CLK_DIVR[2:0] = 0b001 results in a 2:1 clock ratio IPG_CLK_DIVR[2:0] = 0b010 results in a 3:1 clock ratio IPG_CLK_DIVR[2:0] = 0b011 results in a 4:1 clock ratio IPG_CLK_DIVR[2:0] = 0b100 results in a 5:1 clock ratio IPG_CLK_DIVR[2:0] = 0b101 results in a 6:1 clock ratio IPG_CLK_DIVR[2:0] = 0b110 results in a 7:1 clock ratio IPG_CLK_DIVR[2:0] = 0b111 results in a 8:1 clock ratio

11.3.6 ARM Memory Configuration (ARM_AMC)

This register is used to configure the ALP inputs to the ARM platform memories. These bits are used to set the leakage configuration bits on the memories.

This register can only be accessed by 32-bit secure supervisor transactions.

Address: ARM_AMC is 63FA_0000h base + 18h offset = 63FA_0018h



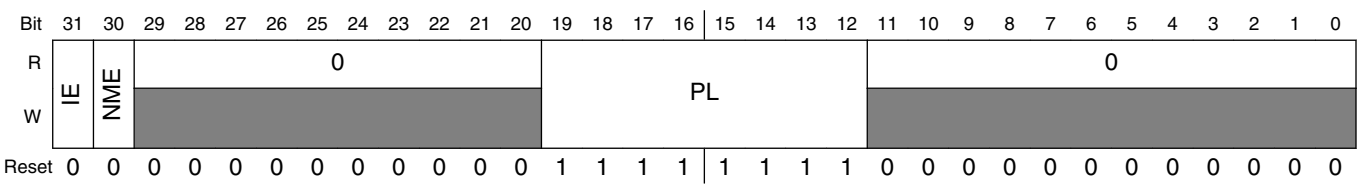
ARM_AMC field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3 ALPEN	ALPEN - ALP Enable is used to activate the ALP bits in this register to override the default memory leakage configuration setting. 1 ALP bits of the memory are over-written with the ALP bits of this register. 0 ALP bits of the memory are driven to the default (reset) value of 3'b000.
2–0 ALP	ALP Memory leakage configuration bits

11.3.7 NEON Monitor Control (ARM_NMC)

This register is used to control the NEON monitor and can only be accessed by 32-bit secure/non-secure supervisor transactions.

Address: ARM_NMC is 63FA_0000h base + 20h offset = 63FA_0020h



ARM_NMC field descriptions

Field	Description
31 IE	Interrupt Enable 1 The monitor interrupt output is enabled and plat_ctrl_nm_irq_b is asserted when the monitor counter expires. 0 The monitor interrupt output is disabled.
30 NME	NEON Monitor Enable
29–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19–12 PL	Preload value for the upper 8 bits of the 16 bit NEON activity counter.

Table continues on the next page...

ARM_NMC field descriptions (continued)

Field	Description
11–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

11.3.8 NEON Monitor Status (ARM_NMS)

This register is used to read the status of the NEON monitor and can only be accessed by 32-bit secure/non-secure supervisor transactions.

Address: ARM_NMS is 63FA_0000h base + 24h offset = 63FA_0024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NI	0														
W	w1c															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ARM_NMS field descriptions

Field	Description
31 NI	NEON Idle Status 1 Indicates that the NEON activity counter has expired. plat_ctrl_nm_irq_b will assert if the IE bit is set. 0 Indicates that the NEON activity counter has not expired.
30–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

11.4 Platform Clocks

The clocking strategy of the ARM platform can be summarized by the following bullets:

- The ARM platform will receive one functional clock from the clock control module (CCM), **arm_clk**, and several SoC clocks for boundary synchronization purposes (**arm_clk** can be completely asynchronous from any other SoC clocks).
- The ARM platform, in conjunction with an external CCM, will support dynamic clock frequency scaling.

- Divided clocks based on **arm_clk** will be generated within the platform for clocking buses which cannot operate at the high **arm_clk** frequencies. These divided clock ratios can be configured by on-platform registers.
  - Derived Clocks:
    - ipg_clk: This clock is used for IP Bus logic.
    - aclk: This clock is used for AXI bus logic.
    - dbg_atclk: This clock is used for the Debug AMBA Trace logic.
    - dbg_pclk: This clock is used for the Debug synchronizer logic.
- Two-level clock gating will be employed.
  - Block level clock gating will be used when possible. A specific block's clock will be gated off when it is not in use.
  - Register level clock gating will be used throughout the platform via power design tools.
- **arm_clk** may be turned off for various low-power use cases by an external CCM which will monitor the **DSM_request** output.

11.5 Platform Power Management

The ARM platform contains low voltage logic elements, an asynchronous and level shifted interface, state retention latches, low leakage power switches, and floating node isolation circuits. These elements each serves a specific purpose in the power management scheme implemented in the ARM platform. The power management capabilities of the ARM platform are summarized in this section.

11.5.1 Voltage and Frequency Scaling

The ARM platform contains structures necessary for the independent voltage scaling of the GP supply. Voltage and frequency scaling control systems are implemented at the chip level with the ARM platform acting as an object of the control. Asynchronous Interface Logic and Level-shifting between SoC-logic and ARM-logic have been implemented in the ARM platform to support the voltage and frequency scaling capabilities of the integrated system.

11.5.1.1 Asynchronous Interface Logic

Voltage and frequency scaling is most effective when there is a continuum of available frequencies at which the ARM platform may be clocked. Asynchronous Interface Logic removes the clock ratio dependencies between the ARM platform and the system in which it operates.

11.5.1.2 Level Shifting between SoC-logic and ARM-logic

Independent voltage scaling of the ARM platform requires a distinct power supply for the GP logic. Level shifters exist at the interface of the SoC logic and the ARM logic to allow independent voltage control of the SoC power supply and the ARM power supply.

11.5.2 Power Gating in the ARM platform

To reduce standby leakage power consumption, the ARM platform contains internal power supplies that may be completely power gated during wait for interrupt modes. Entry and exit sequences of power gating modes are completely controlled by programmed operation of the General Power Controller, so this section will only serve to describe what is possible in terms of how the ARM platform may be powered down during wait for interrupt modes.

11.5.2.1 Isolation Circuitry at the ARM platform Interface

In order to power down digital logic correctly, a special interface must exist which will protect the system from floating signals. Such isolation circuitry has been carefully designed in order to allow glitch-free power down modes of the ARM platform.

11.5.2.2 Power Gating the Memory Peripheries

Once the STANDBYWFI mode has been invoked, all of the ARM platform memory peripheries may be power gated by the assertion of both the l1_pwrdwn and the l2_pwrdwn signals. This will significantly reduce the amount of leakage from the GP supply.

11.5.2.3 Retaining the State of the ARM platform Registers

The ARM platform has been implemented using State Retention Power Gating (SRPG) register elements. In order to safely enter a power gated mode that includes power gating of the ARM platform high performance logic gates, a sequenced assertion of signals must occur. Similarly, a sequenced deassertion is necessary when emerging from power gated states. The required sequences are automatically provided to the ARM platform by the General Power Controller.

11.5.2.4 Power Gating the ARM platform High Performance Logic Gates

Once the STANDBYWFI mode has been invoked, the ARM platform high performance logic gates are power gated by assertion and negation of signals by internal Power management sub-blocks. This will turn off a portion of the leakage from the GP supply.

11.5.2.5 Power Gating the L2 Bit Arrays

If the L2 cache has been flushed, the L2 bit array may be power gated during the subsequent STANDBYWFI mode. Once the STANDBYWFI mode has been invoked, the L2 memory bit arrays may be power gated. This will turn off a portion of the leakage from the LP supply.

11.5.2.6 Controlling Power Gating using the General Power Controller (GPC)

Specific details concerning the power gating entry and exit sequence may be obtained from the block guide of the General Power Controller (GPC). This high level summary is intended to provide some overview.

Code must be formed that will take advantage of low workloads by putting the ARM platform into a STANDBYWFI state whenever possible. Prior to entering the STANDBYWFI state, the code should assess several things about the workload and the battery conservation requirements:

- What is the maximum acceptable interrupt service latency?
- What is the expected time to be spent in STANDBYWFI?

Once these time requirements are understood, then Table 11-10 can be used to determine the appropriate STANDBYWFI mode to invoke. The GPC registers can be programmed with the appropriate values to invoke the appropriate STANDBYWFI mode. After GPC programming is complete, the code should execute the STANDBYWFI instruction.

The GPC will enforce the appropriate sequence for entering and exiting the programmed power gated modes.

11.5.2.7 Power Gating the NEON Block

The NEON co-processor in the ARM platform can be put into a state retention mode and powered down to reduce current consumption when it is not needed. The sequence is shown in the flow diagram of Figure 11-10. Each box in the diagram is numbered to correspond to the following more thorough description:

1. User Selects NEON to be Powered Down

   The NEON Coprocessor is enabled out of reset and will remain powered up unless the user decides to power it down. This method will power down NEON after a user programmable time of NEON inactivity. The current state of the NEON is held in SRPG flops. To select this operation:

   The user code will program the amount of time that the NEON needs to be inactive before powerdown in the NEON Monitor Control Register. Effectively, the user programs the upper 8 bits of a 20-bit counter. This counter runs at the arm_clk rate and so the user can program a timeout from 4K to 1M arm_clk rising edges.

   In the same register, the user code enables the NEON Monitor and enables the NEON Monitor Interrupt.

2. Pre-Set Timer Count

   The timer is loaded (automatically by hardware) with the count value chosen by the user.

3. Decision: NEON Instruction Encountered?

   If a NEON instruction is encountered the sequence is aborted until the NEON is no longer in use. As long as NEON Instructions are executing, the NEON status bit will remain in the active state and the counter gets forced with the pre-set count.

4. Decrement Timer

   When no NEON instructions are encountered, the timer will count towards the timeout.

5. Decision: Timed Out?

   If the user selected time has lapsed without any NEON activity, then the hardware will generate an interrupt.

6. Exception Sequence: Power Down NEON

   The interrupt service routine disables the NEON sub-block with the following sequence:

   A. Software must disable access to the NEON unit using the Coprocessor Access Control Register, see c1, Coprocessor Access Control Register on page 3-64 of the ARM TRM. All outstanding NEON instructions retire and all subsequent NEON instruction cause an Undefined instruction exception.

```
MRC p15, 0, <Rd>, c1, c0, 2; Read Coprocessor Access Control Register
BIC <Rd>, <Rd>, #0xF00000; Disable access to CP10 and CP11
MCR p15, 0, <Rd>, c1, c0, 2; Write Coprocessor Access Control Register
```

   B. Activate the NEON output clamps.

   C. Place NEON into state retention.

   D. Prepare the NEON memory for power down keeping the state of its bits.

   E. Separate the NEON power supplies so that the ones that retain state can continue to have power.

   F. Remove power from the NEON power domain.

7. Decision: NEON Instruction Attempted

   The part will continue running regular ARM Platform instructions with the NEON in low power state as long as no NEON instructions are attempted. When a NEON instruction is attempted, an unimplemented instruction exception occurs.

8. Exception Sequence: Power Up NEON

   An exception is taken when a NEON instruction is attempted with the NEON is disabled. The exception routine will determine that this is indeed what occurred, enable the NEON block and wait for the NEON to power up. Returning from the exception will cause the NEON instruction to be restarted and run successfully. This is a more detailed description of the sequence:

   A. Power is turned on to the NEON power domain.

   B. Reconnect the NEON power supplies together.

   C. Restore the NEON memory power maintaining the state of it's saved bits.

   D. Reload the flops with the SRPG saved contents.

E. Release the NEON output clamps.

F. Software must enable access to the NEON unit using the Coprocessor Access Control Register, see c1, Coprocessor Access Control Register on page 3-64 of the ARM TRM.

```
MRC p15, 0, <Rd>, c1, c0, 2; Read Coprocessor Access Control Register
ORR <Rd>, <Rd>, #0xF00000; Enable access to CP10 and CP11
MCR p15, 0, <Rd>, c1, c0, 2; Write Coprocessor Access Control Register
```

G. Return from the exception causing the NEON instruction to be reloaded and executed.

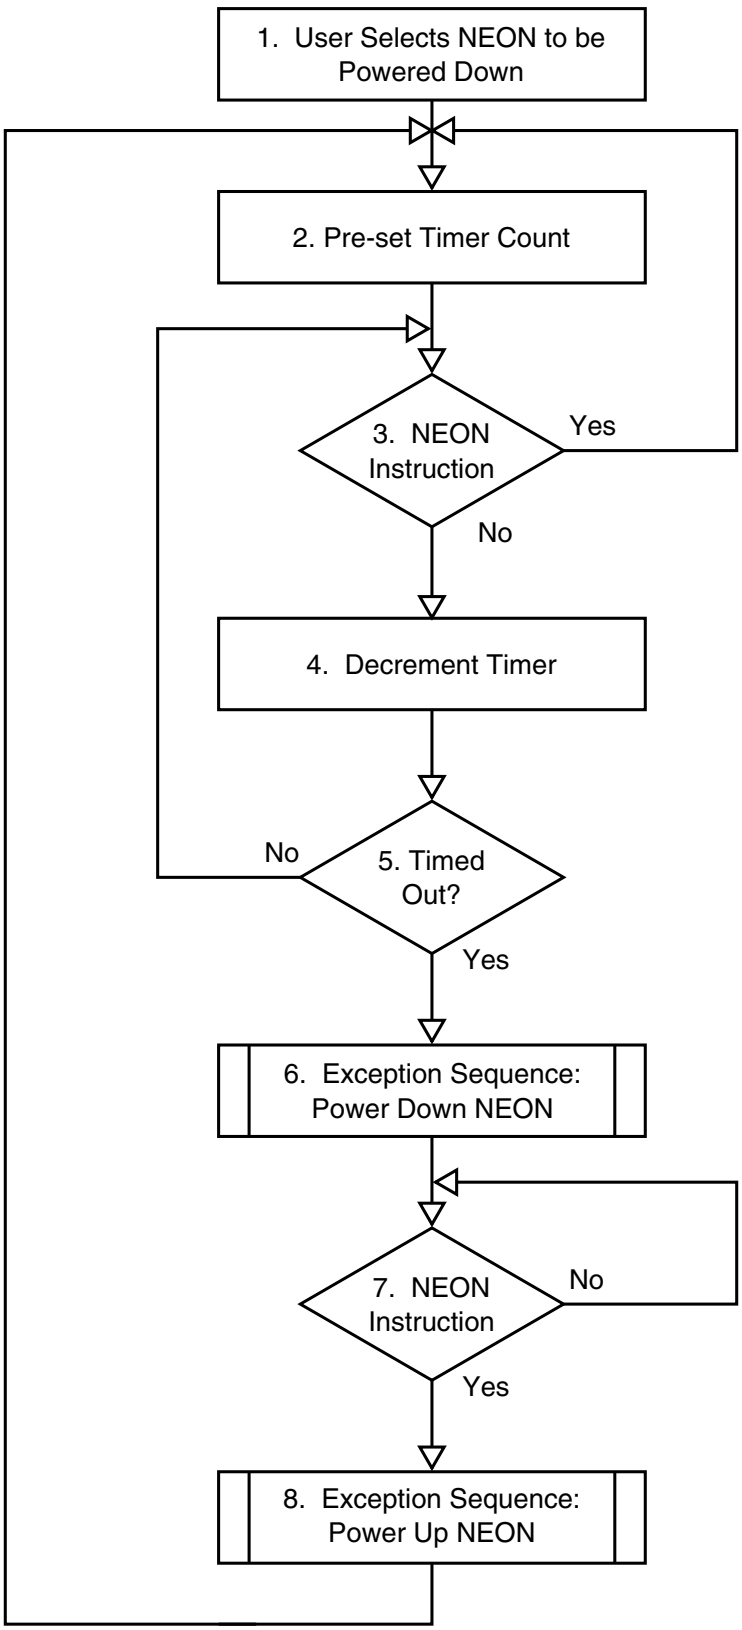


Figure 11-10. Flow Diagram of NEON Power Down Sequence

11.5.3 Modes of Operation

There are several basic low power modes of the ARM platform.

Table 11-10. Modes of Operation of the ARM platform

MODE	Description
RUN	ARM_CLK running, code executing
CLOCKED_WAIT	ARM_CLK running, STANDBYWFI=TRUE
UNCLOCKED_WAIT	ARM_CLK off, STANDBYWFI=TRUE
STOP1	UNCLOCKED_WAIT plus L1 and L2 peripheries power gated
STOP2	UNCLOCKED_WAIT plus L1 and L2 peripheries power gated, ARM_HiP_logic power gated
STOP3	UNCLOCKED_WAIT plus L1 and L2 peripheries power gated, ARM_HiP_logic power gated, L2 cache flushed, and L2 bit arrays power gated

There are several combinations of reduced power in which one of more portions of the platform are in a power saving mode.

Table 11-11. Platform Power Modes

Core and Platform	NEON	L1	L2
Powered Up	Powered Up	Powered Up	Powered Up
Powered Up	Reset (ARM Mode)	Powered Up	Powered Up
State Retention	State Retention	State Retention	State Retention
State Retention	State Retention	Powered Down	State Retention
State Retention	State Retention	State Retention	Powered Down
State Retention	State Retention	Powered Down	Powered Down

Chapter 12
ARM Platform Debug

12.1 Introduction

The purpose of this document is to provide an overview of the ARM platform debug. It will cover the sub-blocks inside the armp_gp_debug block and also the blocks that support the platform debug within the SOC, but external to the ARM platform.

Debug for the ARM platform uses ARM's DK11 CoreSight Debug Kit. The following CoreSight blocks are used: Debug Access Port (DAP) , Embedded Trace Macrocell v 3.3 (ETM), CoreSight replicator (CSREPLICATOR), CoreSight trace port interface unit (CSTPIU), CoreSight embedded trace buffer (CSETB), CoreSight cross trigger interface (CSCTI) and the CoreSight cross trigger matrix (CSCTM). In this introduction, a brief description of each block will be given. For more in depth information, please refer to the CoreSight_DK_TRM and other relative documentation from ARM.

12.1.1 Overview

ARM's CoreSight Design Kit (CSDK) provides a single solution for multi core and bus trace. The CSDK provides the following capabilities for system-wide trace:

- debug and trace visibility of the entire system
- cross triggering support between SOC subsystems
- multi-source trace in a single stream
- higher data compression than previous solutions
- standard programmer's models for standard tools solutions

The CoreSight Design Kit comprises the following main components: Control and access, sources, links and sinks.

- Control and access components configure, access and control the generation of trace. They do not generate, nor process trace data. Examples include the debug access port (DAP) and the embedded cross trigger (ECT) interface.

- Source components generate trace data. Example source components are the ETM and the future AXI trace macrocell (XTM).
- Link components provide connection, triggering and flow of trace data. Link examples include the ATB replicator and the CoreSight Trace funnel.
- Sink components are the end point for trace data on an SOC. Example sinks are the trace port interface unit (TPIU) and the embedded trace buffer (ETB).

The figure below shows the ARM Platform debug block diagram. Further detail of the sub-blocks will be provided in the sections that follow.

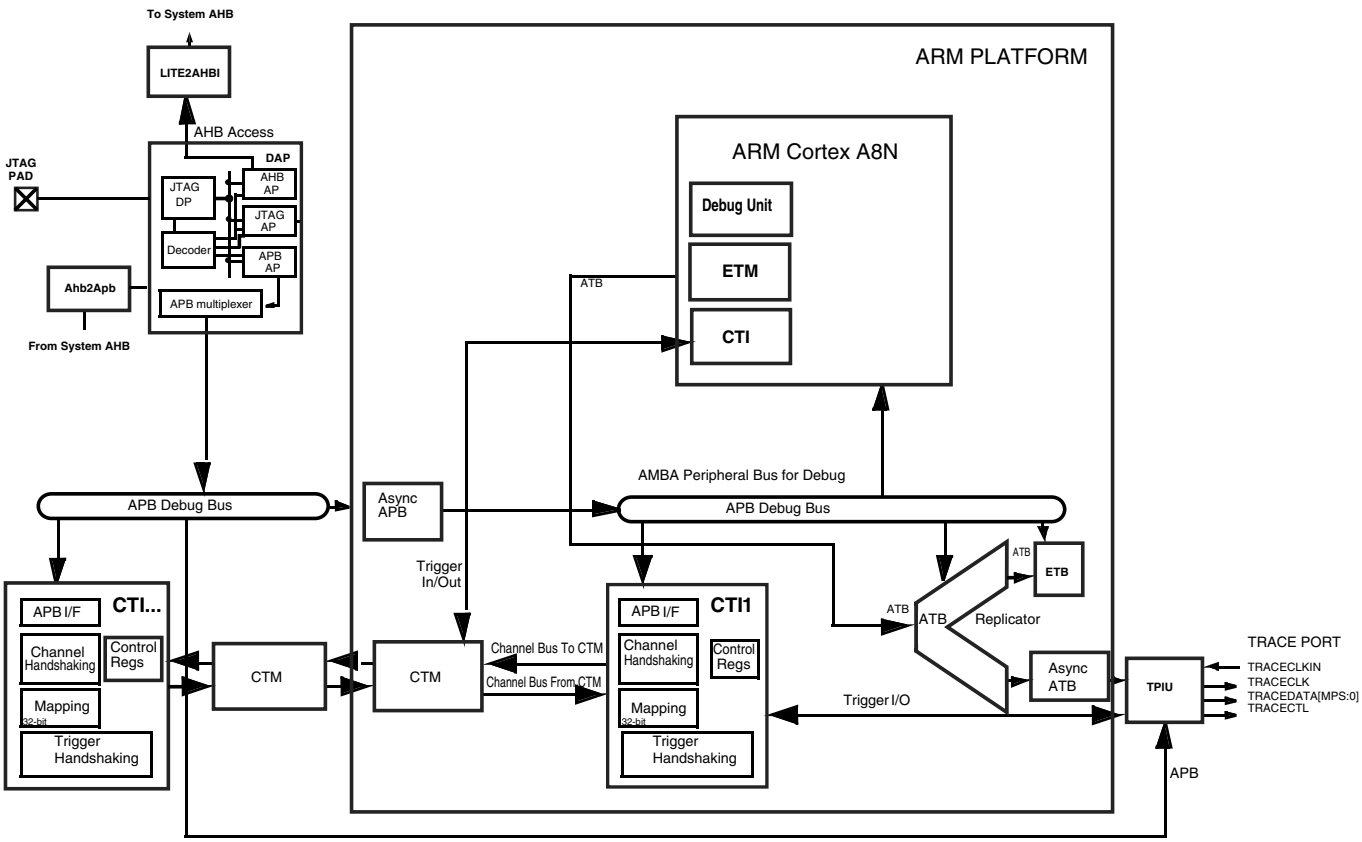

Figure 12-1. Block Diagram

12.1.2 ARM Debug Blocks

This section gives an overview of the Debug blocks used in the ARM platform and also the blocks outside the platform that are included in the CoreSight debug system.

The following blocks are included in the ARM platform debug block: CSETB, CSCTI, CSCTM, CSREPLICATOR and APB address decode logic.

The following blocks are part of the ARM platform, outside the debug block: ETM (embedded in the Cortex), CTI (also embedded in the Cortex), the Processor Debug Unit and two asynchronous bridges - the asyncapb and the asyncatb.

Also included in this block guide is an overview of the DAP and TPIU which reside outside the ARM platform, yet are key components to the debug system.

12.1.2.1 Processor Debug Unit

The processor debug unit assists in debugging software running on the processor. In combination with a software debugger program, the debug unit enables debugging the following:

- application software
- operating systems
- hardware systems based on an ARM processor

The debug unit enables:

- stopping program execution
- examining and altering processor and coprocessor states
- examining and altering memory and input/output peripheral states
- restarting the processor core

There are three ways to debug software running on the processor:

- Halt debug-mode debugging
- Monitor debug-mode debugging
- Trace debugging (ETM) - covered in a different section

12.1.2.1.1 Halting Debug-Mode Debugging

Halting debug-mode debugging is invasive. The processor halts when a debug event, such as a break point, occurs. An external debugger can examine and modify the processor state via the APB while the processor is halted.

12.1.2.1.2 Monitor Debug-Mode Debugging

When a debug event occurs during monitor debug-mode debugging, instead of halting the processor, the processor takes an exception. Special software can then take control to examine or alter the processor state. When execution of a monitor target starts, the state of the processor is preserved in the same manner as all ARM exceptions.

12.1.2.1.3 Programming the Debug Unit

The processor unit is programmed using the APB slave port. Features that can be accessed using the memory-mapped APB registers are:

- instruction address comparators for triggering break points
- data address comparators for triggering watchpoints
- a bidirectional Debug Communication Channel (DCC)
- all other state information associated with the debug unit

12.1.2.2 ARM embedded trace macrocell (ARM ETM)

The ARM ETM provides real time instruction trace for the Cortex A8N processor. It is designed to be used with the CoreSight Design Kit. Unlike previous versions of the ARM platforms, this ETM is embedded inside the ARM Core.

Real time tracing is controlled by specifying a set of filtering and triggering resources which include address and data comparators, counters and sequencers.

NOTE

Though data trace can not be enabled, the ETM can still trigger based on data values. The ETM can also trace data address values.

The ARM ETM contains the following main components:

- Core interface
- Trace generation
- Filtering and triggering resources
- Main FIFO
- AMBA 3 ATB interface
- AMBA 3 APB interface

The ETMv3.3 provides a number of configurations. The table below shows the options implemented in the ETM.

Table 12-1. ETMv3.3 Configurations

Resource Description	Configuration
Instruction trace	Yes
Data address trace	Yes
Data value trace	No
Jazelle trace	-

Table continues on the next page...

Table 12-1. ETMv3.3 Configurations (continued)

Resource Description	Configuration
Address comparator pairs	2
Data comparator	4
Context ID comparators	1
Sequencer	Yes
Start/stop sub-block	Yes
Embedded ICE comparators	0
External inputs	4
External outputs	2
Extended external inputs	49
Extended external input selectors	2
Instrumentation resources	4
FIFO full	No
FIFO full level setting	N/A
Branch broadcasting	Yes
ASIC control register (bits)	8
Data suppression	Yes
Software access to registers	Memory
Readable registers	Yes
FIFO size	128 bytes
Minimum port size	32
Maximum port size	32
Port modes	Dynamic
Asynchronous ATB	Yes
Load pc first	No
Fetch comparisons	No

12.1.2.3 CoreSight Embedded Trace Buffer (CSETB)

The ETB provides on chip storage of trace data. The ARM platform implements a 32-bit 4K RAM.

The ETB accepts trace data from a CoreSight replicator via an ATB write port. The ETB is configurable through an APB port.

Features:

- 4kB compiled memory for the trace buffer. Note: It can no longer be used as a general purpose memory.
- Only 32-bit accesses to the 4kB buffer is supported (Note: RAM size is 4K "bytes" - i.e. 1Kx32)
- Amba Peripheral Bus interface for configuration and memory access

12.1.2.4 CoreSight Replicator (CSREPLICATOR)

The ATB Replicator enables two trace sinks (TPIU and ETB) to be wired together and receive ATB trace data from the same trace source (ETM). There are no programable registers. It takes incoming trace data from a single source (ETM) and replicates it to two master ports.

The CSREPLICATOR is part of the armp_gp_debug block. Two output master ports are required for this design - one for the on-platform ETB and one for the off-platform TPIU. Placing the TPIU off platform allows future debug trace sources to connect to the TPIU through a FUNNEL, without the need to modify the ARM platform. The figure below shows a block diagram for the CSREPLICATOR.

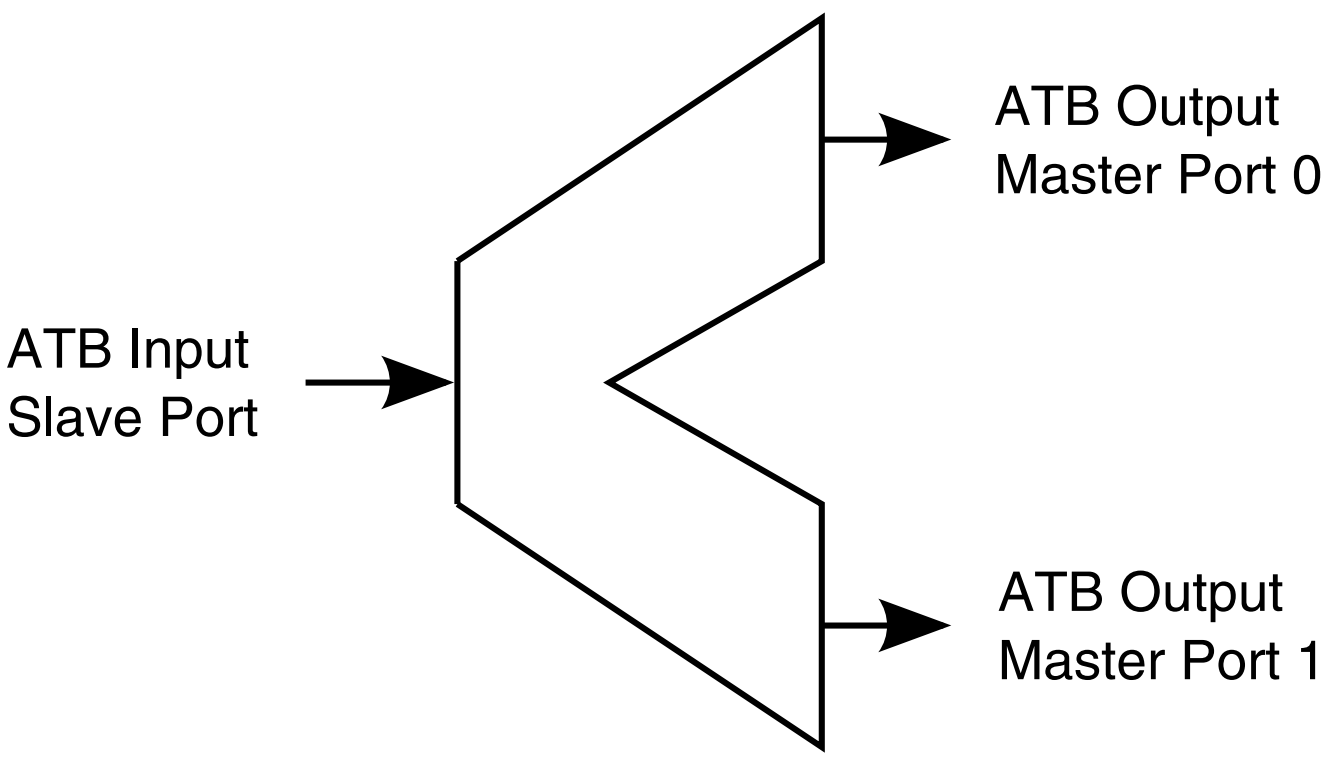

Figure 12-2. CSREPLICATOR Block Diagram

12.1.2.5 CoreSight trace port interface unit (CSTPIU)

The TPIU acts as a bridge between on-chip trace data, ID distinguishable, and a TPA. It receives ATB trace data and sends it off chip via ARM's standard trace signals TRACECLK, TRACEDATA and TRACECTL. The following sub-blocks are included in the TPIU (see the figure below): ATB interface, APB interface, Formatter, Asynchronous FIFO, Register bank, Trace out serializer and a Pattern generator. Further information on the TPIU can be found in ARM's technical reference manuals.

The TPIU is not on the ARM platform and is configurable via the APB.

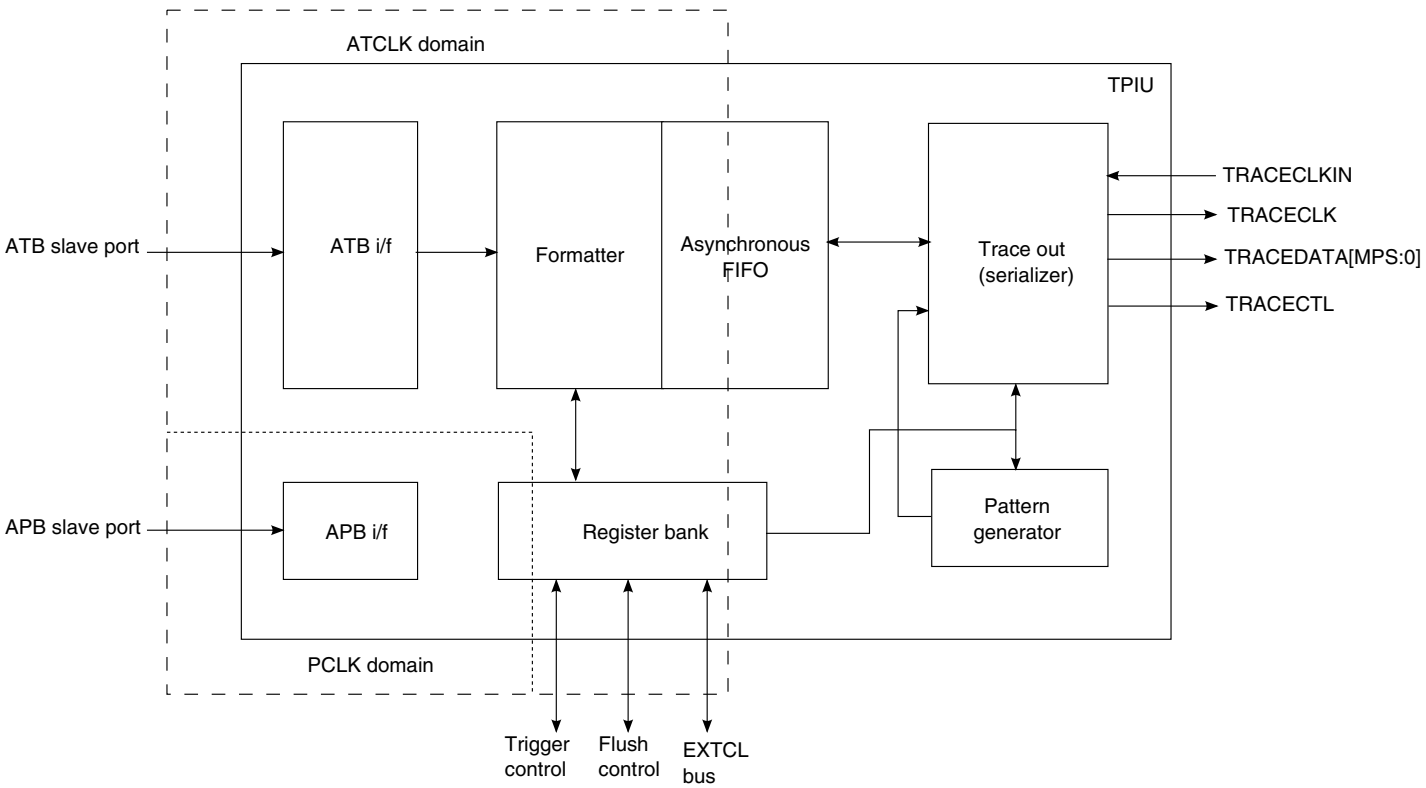

Figure 12-3. TPIU Block Diagram

All signal paths to the pads are subject to wire delays. Special consideration should be taken to re-balance the paths, removing the relative skews between the signals. An extra delay must be added on the TRACECLK path to ensure its rising and falling edge are during the stable part of TRACEDATA and TRACECTL.

12.1.2.6 CoreSight cross trigger interface (CSCTI)

The CSCTI is the CoreSight cross trigger interface component of an Embedded Cross Trigger (ECT) system. The CSCTI combines and maps trigger requests, broadcasting them to all other interfaces on the ECT as channel events. This enables subsystems to cross trigger with each other.

Each CTI has 8 trigger inputs, 8 trigger outputs and 4 sets of 4 channel I/Os. There are also acknowledge signals, configurable on/off, for the trigger and channel outputs. The channels connect to a CoreSight Cross Trigger Matrix (CSCTM). The CSCTM is off-platform, so special consideration should be taken when enabling the synchronizers and handshaking features on both the CSCTI and the CSCTM.

The platform requires one CTI block in addition to the embedded CTI in the ARM core. CTI0 resides in the Core and handles triggers/events from the CSETM and the CORE; CTI1 handles the triggers/events for the TPIU (off platform) and the CSETB. Since the TPIU is outside the platform (asynchronous), the TRIGIN synchronizers are enabled and handshaking is turned on.

The on-platform CTI1 is synchronous and at the same clock speed as the on-platform CTM. This allows the channel handshaking and channel synchronizers to be bypassed.

The figure below shows the recommended connections for CSCTI1.

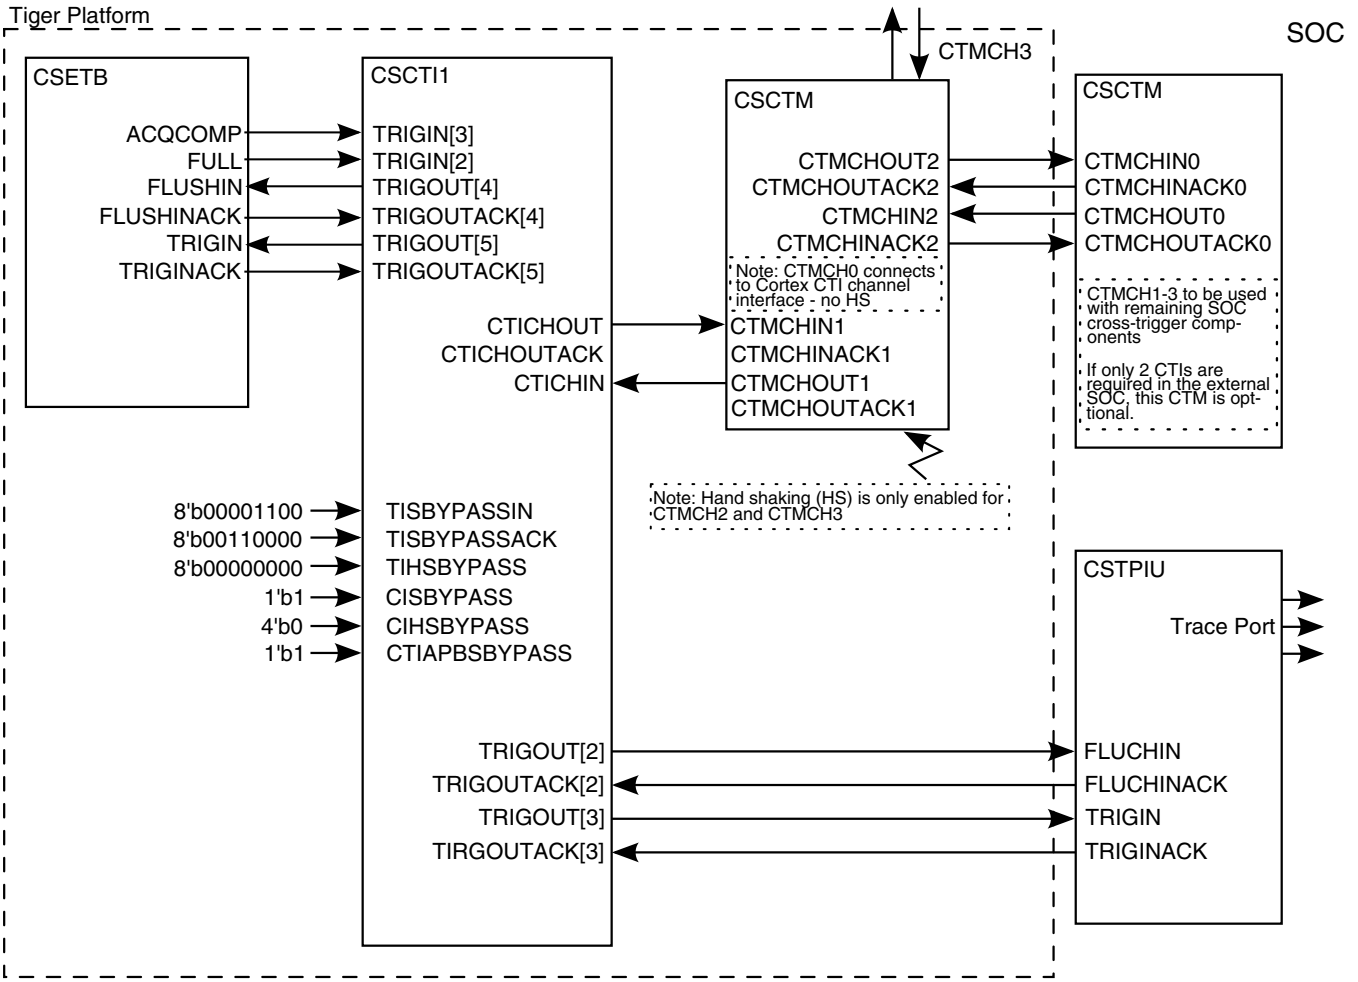

Figure 12-4. CSCTI1 Connections

The SOC CTIs require additional logic to support asynchronous trigger sources/ destinations. The cscti_extended sub-block includes logic, in addition to the CSCTI block, to support triggering across asynchronous boundaries where the source/destination might not have the necessary logic to support asynchronous boundaries.

12.1.2.7 CoreSight Cross Trigger Matrix (CSCTM)

This block controls the distribution of channel events. It provides channel interfaces to the CSCTIs. The CSCTM can also connect to another CSCTM via a channel interface. This allows multiple CSCTMs to be connected.

The ARM has one CSCTM inside the platform to handle events between the platform's CSCTIs and the rest of the ECT system outside the platform. Placing a CSCTM on platform minimizes the event cycle time between the ETB and the ETM. The handshaking between the CTIs on-platform and the on-platform CTM are not enabled.

This requires the Cortex's CTI, the on-platform CTI1 and the on-platform CTM to all be in the same clock domain. The on-platform CTM connects to the ECT system via an off-platform CTM and the respective channels require synchronizing and handshaking enabled.

If only two CTIs are required in the SOC, they can be connected directly to the on-platform CTM eliminating the need for a CTM outside the platform.

More information on the CoreSight ECT system can be found in ARM's Technical Reference manuals.

12.1.2.8 Debug Access Port (DAP)

The DAP provides multiple master driving ports, all accessible via a single external interface port. Components that access the DAP are called Debug Ports (DP) and components that access internal interfaces are called Access Ports.

The DAP provides real time access for the debugger without halting the core to:

- All debug configuration registers
- AMBA system memory and peripheral registers.

The DAP enables debug access to the complete SOC through a number of access ports. Access to the CoreSight Debug APB is enabled through the APB access port (APB-AP). System access can be accomplished via an AHB access port (AHB-AP). An APB multiplexer allows system accesses to debug CoreSight components connected to the APB.

There is also a JTAG access port (JTAG-AP) providing accesses to on-chip JTAG components. The DAP acts as a JTAG master. This feature will not be used for the ARM platform since the core's debug logic is now accessible through the APB.

The figure below shows a block diagram of the DAP.

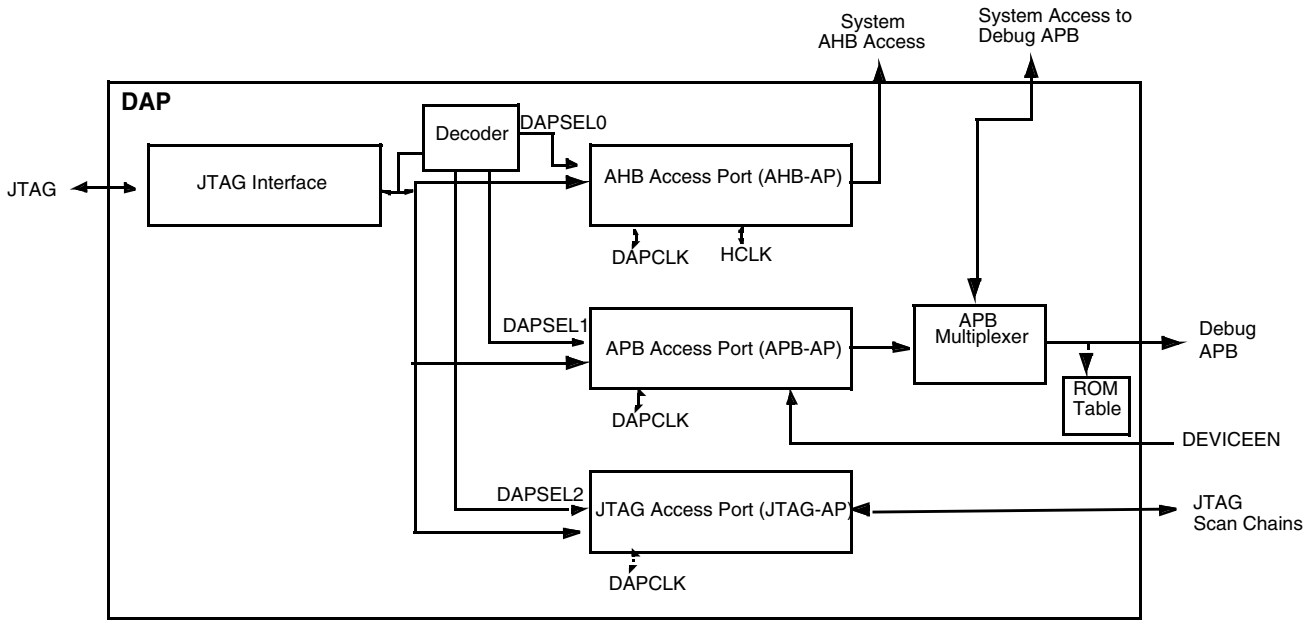

Figure 12-5. DAP Block Diagram

12.1.2.8.1 DAP_SYS

The DAP also requires decode logic for the CoreSight component PSEL signals, an AHB to APB bridge, an AHB lite to AHB bridge, detect logic to enable debug and reset synchronization logic. The dap_sys sub-block wraps these components with the DAP. The figure below shows a block diagram of the DAP_SYS.

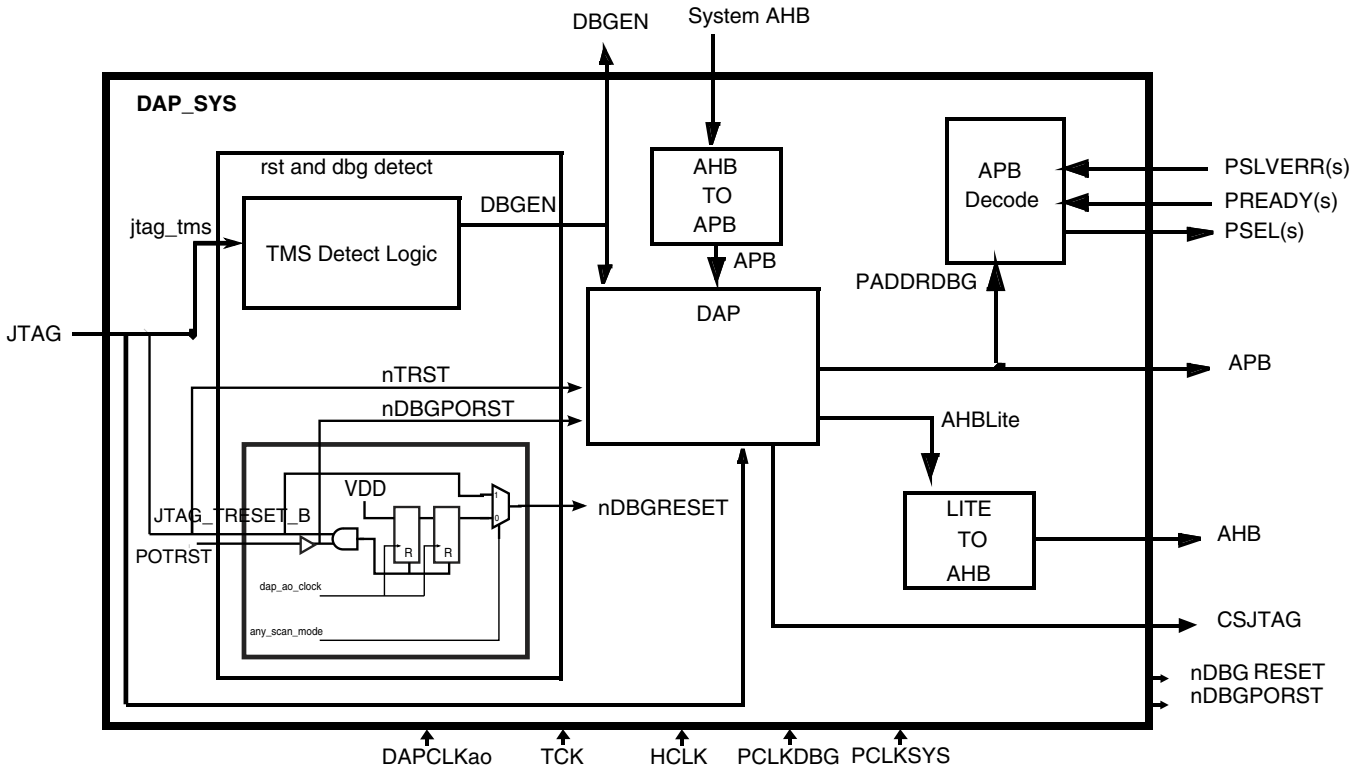

Figure 12-6. DAP_SYS Block Diagram

12.1.3 Modes of Operation

12.1.3.1 ARM Invasive Debug Mode

ARM Invasive Debug mode is usually entered through the JTAG port. Inside the dap_sys there is logic to assert DBGEN high when jtag_tms is active. The user can also invoke DBGEN by writing to a register inside the ARM plat_ctrl sub-block.

It is required that NIDEN is asserted while DBGEN is asserted. Otherwise, CTI functionality is limited when TINIDENSEL is tied to 0. Due to this requirement, NIDEN into the Core and the Debug block is a combination of dbg_niden ored with dbgen_in.

12.1.3.2 ARM Non-Invasive Debug Mode (Real-time Trace)

There are two methods to enter non-invasive debug mode - through JTAG or via memory mapped accesses. For memory mapped accesses, non-invasive debug can be enabled by writing to two secure supervisor registers, one within the Central Security Unit (CSU) and one within the ARM platform.

12.1.3.3 Normal Operating Modes

During normal operating mode, debug is not enabled.

12.1.3.4 Low Power Modes

During deep sleep mode (DSM) all debug is disabled. The platform_ctl sub-block has a bit allocated to overriding DSM when debug is enabled. This bit currently resets to a state disabling DSM while debug is enabled. For more information, refer to the platform control block guide.

The core has an input, DBGNOCLKSTOP (from ARM_GPC[NOCLKSTOP]), allowing the core's debug clocks to stay on while in WFI. The same bit used to override DSM should be connected to DBGNOCLKSTOP (inverted). Another solution is to allocated separate bit for this function in the platform_ctl sub-block. Make note that if the dsm override bit is not set and the platform goes into DSM, it doesn't matter what DBGNOCLKSTOP is set to.

12.2 Memory Map and Register Definition

Each CoreSight component has an allocated 4K. CoreSight components are part of either CoreSight Class or ROM Class. The figure below shows the CoreSight class layout for a 4KB block.

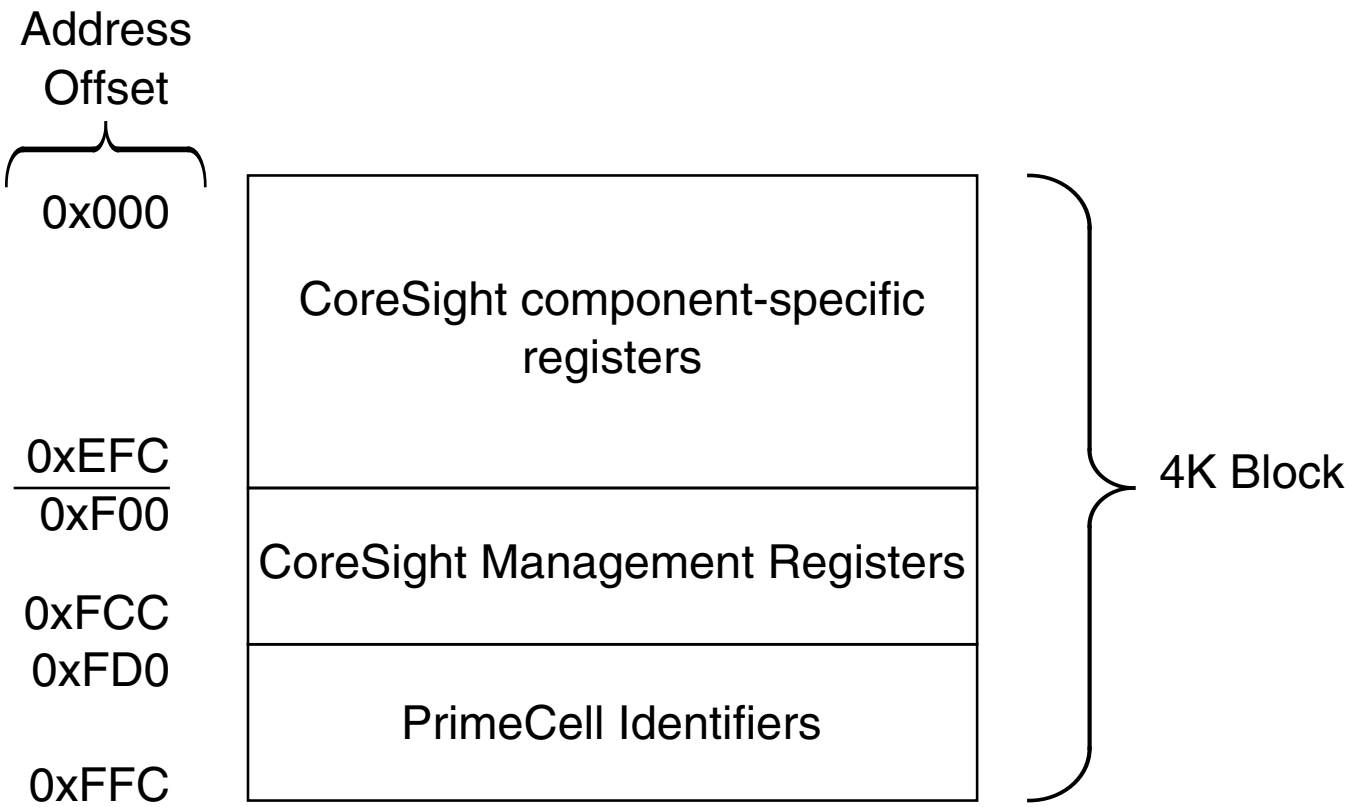

Figure 12-7. CoreSight Component Memory Map

The following table shows an example Debug memory map. The most significant half-word of the address will change based on the chip level memory map.

Table 12-2. Block Memory Map

Start Address	End Address	Size	Target IP	Comments
B0C00000	B0C00FFF	4K	Debug ROM	Located inside DAP
B0C01000	B0C01FFF	4K	ETB	
B0C02000	B0C02FFF	4K	ETM	
B0C03000	B0C03FFF	4K	TPIU	
B0C04000	B0C04FFF	4K	CTI0	On platform
B0C05000	B0C05FFF	4K	CTI1	On platform
B0C06000	B0C06FFF	4K	CTI2	Off platform
B0C07000	B0C07FFF	4K	CTI3	Off platform

12.2.1 Register Summary

This section summarizes the CoreSight Component registers in a table format. The tables are divided by Components. For a more detailed description of each register, refer to the CoreSight_DK_TRM.

The conventions in the table below serve as a key for the register summary.

Table 12-3. Register Conventions

Register Field Types	
RO	Read only. Writing this bit has no effect.
WO	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
RAZ	Read-as-zero
WI	Writes ignored
Self-clearing bit	Writing a one has some effect on the Block, but it always reads as zero. (Previously designated slfclr)

12.2.1.1 DAP JTAG DP Registers

Accessing a JTAG DP register depends on both the instruction register (IR) value of the DAP access and the address field of the DAP access.

The following table shows a register summary table for the DAP DP. Detailed register descriptions can be found inside the CoreSight_DK_TRM provided by ARM.

Table 12-4. DAP JTAG DP Registers

Address Field	IR Contents	Type	Register Name
1	IDCODE	RO	Identification Control Register
0x0	DAPACC	RAZ/WI	Reserved
0x4	DAPACC	R/W	DP Control/Status Register
0x8	DAPACC	R/W	Select Register
0x0	ABORT	WO	DAP Abort Register
0x4-0xC	ABORT	2	Reserved

1. There is no address associated with the ID code register. For more information, see the CoreSight_DK_TRM.
2. The value read on the abort scan chain is unpredictable. The result of accessing the abort scan chain without the address set to 0x0 is unpredictable.

12.2.1.2 DAP ROM Register Summary

The ROM table stores the locations of components on the debug APB. The DAP ROM is read only and configurable through the DAPROM.v and DapRomDefs.v RTL files. Writes are ignored.

The following table shows a register summary table for the DAP Rom. Detailed descriptions can be found inside the CoreSight_DK_TRM provided by ARM.

Table 12-5. DAP ROM Registers

Offset	Name	Type	Description
0xFD0	Peripheral ID4	RO	See CoreSight_DK_TRM
0xFD4	Peripheral ID5	RAZ	Reserved
0xFD8	Peripheral ID6	RAZ	Reserved
0xFDC	Peripheral ID7	RAZ	Reserved
0xFE0	Peripheral ID0	RO	See CoreSight_DK_TRM
0xFE4	Peripheral ID1	RO	See CoreSight_DK_TRM
0xFE8	Peripheral ID2	RO	See CoreSight_DK_TRM
0xFEC	Peripheral ID3	RO	See CoreSight_DK_TRM
0xFF0	Component ID0	RO	Set to 0x0D
0xFF4	Component ID1	RO	Set to 0x10
0xFF8	Component ID2	RO	Set to 0x05
0xFFC	Component ID3	RO	Set to 0xB1

12.2.1.3 Processor Debug Unit Register Summary

Most of the debug unit registers are accessible through the APB. There are some registers that can also be accessed through a coprocessor interface - CP14.

By default, CP14 registers can be accessed from a non-privileged mode. However, the processor can be programmed to disable user access modes using bit [12] of the Debug Status and Control Register (DSCR). For more information on the DSCR and access to CP14 registers, refer to the CortexA8 TRM document.

12.2.1.3.1 Coprocessor Registers Summary

The table below shows the valid debug instructions for accessing the debug registers.

Table 12-6. CP14 Debug Registers Summary

Instruction	Mnemonic	Description
MRC p14, 0, <Rd>, c0, c0, 0	DIDR	Debug Identification Register
MRC p14, 0, <Rd>, c1, c0, 0	DRAR	Debug ROM Address Register
MRC p14, 0, <Rd>, c2, c0, 0	DSAR	Debug Self Address Register
MRC p14, 0, <Rd>, c0, c5, 0 STC p14, c5, <addressing mode>	DTRRX	Data Transfer Register - Receive
MCR p14, 0, <Rd>, c0, c5, 0 LDC p14, c5, <addressing mode>	DTRTX	Data Transfer Register - Transmit
MRC p14, 0, <Rd>, c0, c1, 0 MRC p14, 0, PC, c0, c1, 0	DSCR	Debug Status and Control Register

12.2.1.3.2 Memory Mapped Registers Summary

The table below shows a complete list of memory mapped registers accessible using the APB slave port.

Table 12-7. Debug Unit APB Accessible Registers Summary

Offset	Register Number	Mnemonic	Type	Description
0x000	c0	DIDR	R	CP14 c0, Debug ID Register
0x004-0x014	c1-c5	-	R	RAZ
0x018	c6	WFAR	R/W	Watchpoint Fault Address Register
0x01C	c7	VCR	R/W	Vector Catch Register
0x020	c8	-	R	RAZ
0x024	c9	ECR	R/W	Event Catch Register
0x028	c10	DSCCR	R/W	Debug State Cache Control Register
0x02C	c11	-	R	RAZ

12.2.2 Clocks

The list below describes the Debug clocks within the ARM platform.

- ATCLK - This is the AMBA Trace Bus (ATB) clock. This clock is also used to clock the on-platform CTICLK and on-platform CTMCLK. ATCLK needs to be synchronous (equivalent or faster) to PCLKDBG.
- CTICLK - This is the main clock for the CTI block. The current ARM configuration requires this clock to be synchronous to the on-platform CTM clock.
- PCLKDBG - This is the Debug APB clock. It must be synchronous (equivalent or slower) to the ATCLK.
- TRACECLKIN - This is the Trace Port Interface Unit trace clock input. Since the trace port pads are limited to 133 mhz, TRACECLKIN is pad limited to less than or equal to 266 mhz.
- TRACECLK - This is the clock for the external trace port. It's a DDR clock and runs at 1/2 the speed of TRACECLKIN.

The platform control block generates the debug clocks from the arm clock. The requirement above states that the PCLKDBG needs to be synchronous to the ATCLK. When configuring the divide by settings, make sure this requirement is followed. PCLKDBG is a divide by 2 of ATCLK.

12.2.3 Reset

All debug resets are derived from JTAG_TRST_B and POR. These two resets go into the DAP_SYS to be combined and de-asserted synchronously to the DAPCLKao (always on clock). They also go into the ARM platform, being synchronously de-asserted inside the plat_cntrl block, generating resets for the debug logic inside the platform. Debug resets

that do not require synchronous de-assertion are routed directly to their destination, such as por for the Core and ETM. The figure below shows a diagram of the ARM platform debug reset strategy.

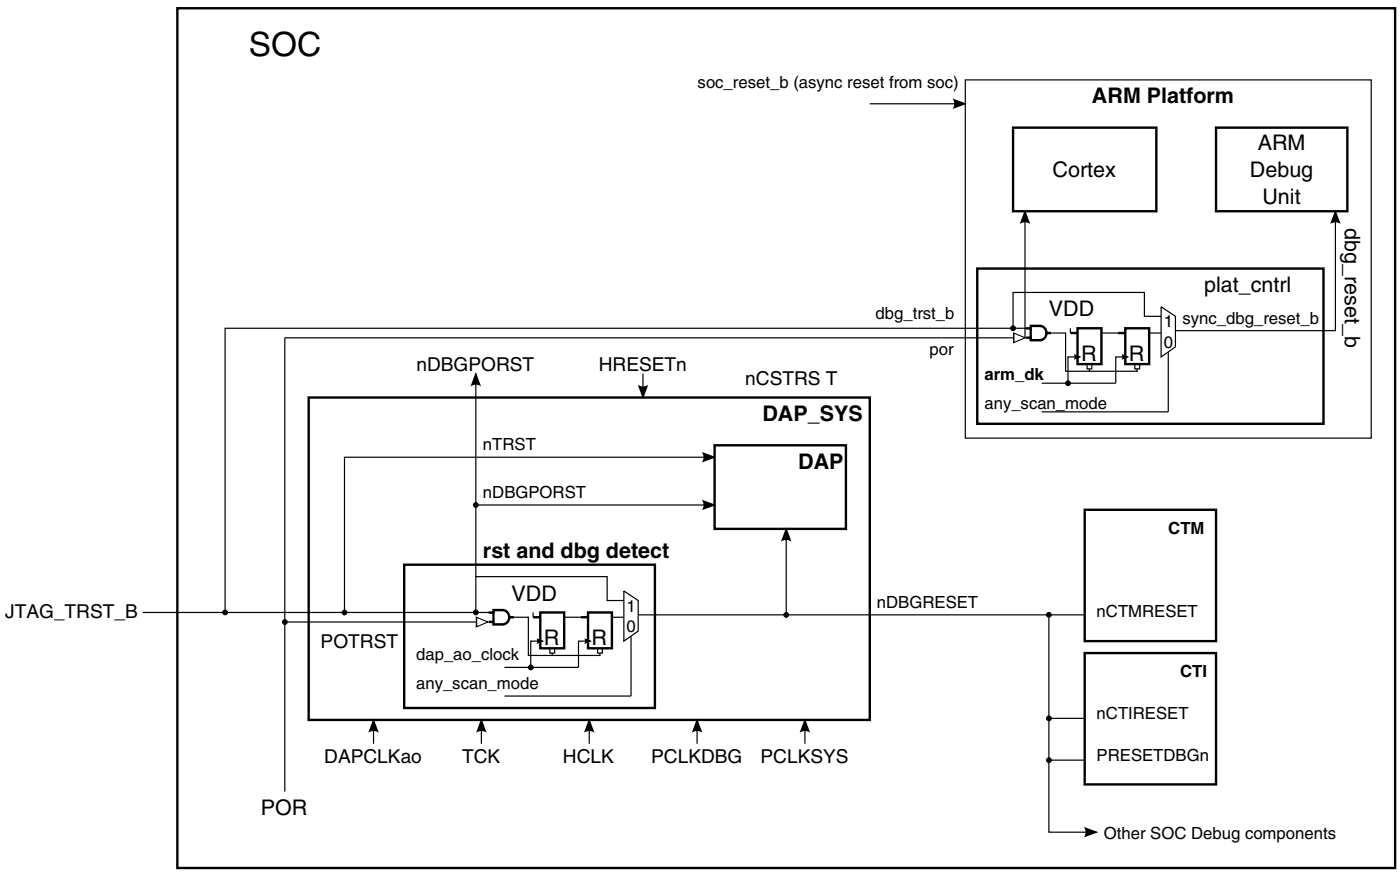

Figure 12-8. ARM Debug Reset Strategy

Chapter 13
Multi-Layer AHB Crossbar Switch (AHBMAX)

13.1 Overview

This section provides an overview of the Multi-Layer AHB Crossbar Switch (AHBMAX). The purpose of the AHBMAX is to concurrently support up to four simultaneous connections between master ports and slave ports. The AHBMAX supports a 32-bit address bus width and a 32-bit data bus width at all master and slave ports. A simplified block diagram is shown in Figure 13-1.

NOTE

The AHBMAX implements a 7 master by 4 slave configuration.

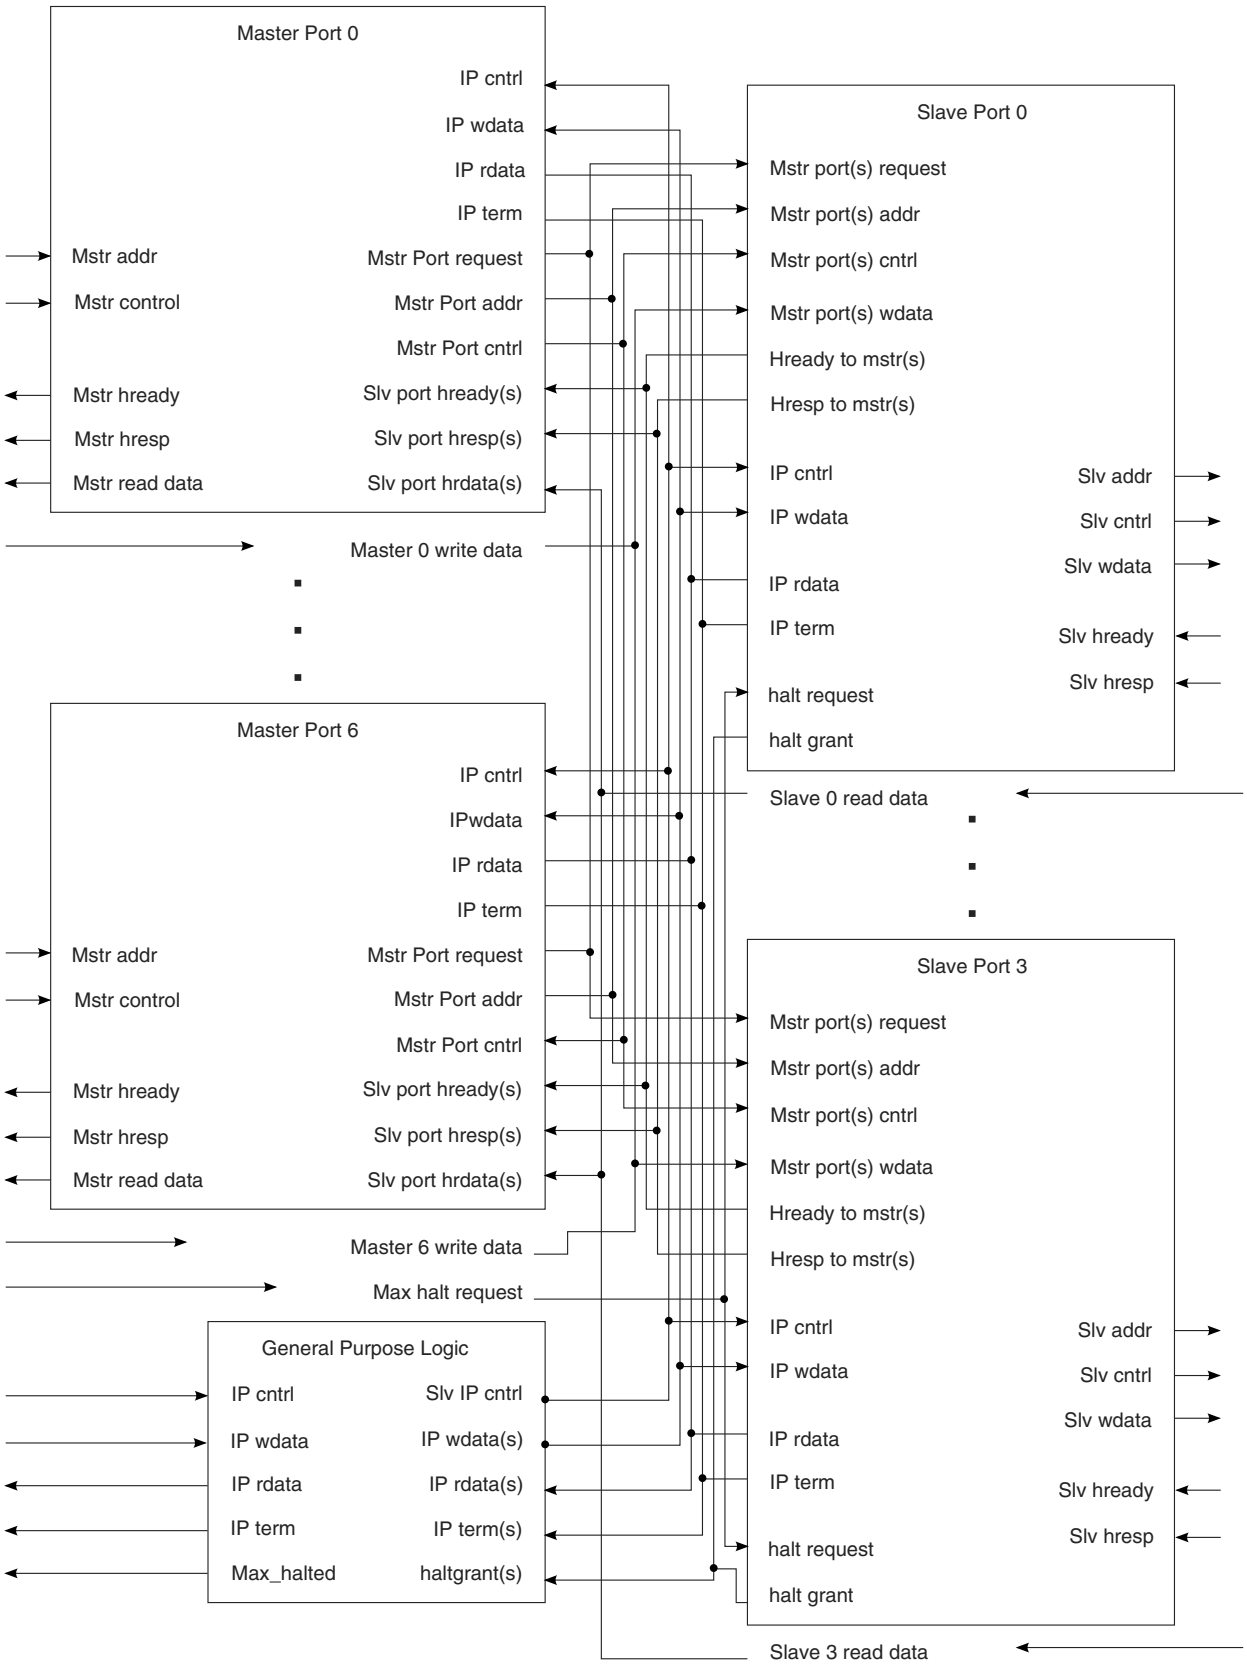

Figure 13-1. AHBMAX Block Diagram

13.2 System Connectivity

This section provides information on system connectivity of AHBMAX.

Table 13-1. Masters of AHBMAX

Table 13-2. Slaves of AHBMAX

S0	DAP, IPU, OpenVG, GPU3D, SATA
S1	IPMUX2
S2	IPMUX1
s3	Output to EMI (M4IF) port #2

13.3 Features

The AHBMAX has the ability to gain control of all the slave ports and prevent any masters from making accesses to the slave ports. This feature is useful when the user wishes to turn off the clocks to the system and needs to ensure that no bus activity will be interrupted.

The AHBMAX can put each slave port into a low power park mode so that slave port will not dissipate any power transitioning address, control or data signals when not being actively accessed by a master port.

Each slave port can also support multiple master priority schemes. Each slave port has a hardware input which selects the master priority scheme so the user can dynamically change master priority levels on a slave port by slave port basis.

The AHBMAX will allow for concurrent transactions to occur from any master port to any slave port. It is possible for four master ports and all slave ports to be in use at the same time as a result of independent master requests. If a slave port is simultaneously

requested by more than one master port, arbitration logic will select the higher priority master and grant it ownership of the slave port. All other masters requesting that slave port will stalled until the higher priority master completes its transactions.

13.3.1 Limitations

The AHBMAX routes bus transactions initiated on the master ports to the appropriate slave ports. There is no provision included to route transactions initiated on the slave ports to other slave ports or to master ports. Simply put, the slave ports do not support the bus request/bus grant protocol, the AHBMAX assumes it is the sole master of each slave port.

Because the AHBMAX does not support the bus request/bus grant protocol, if multiple masters are to be connected to a single master port an external arbiter will need to be used. In the case of a single master connecting to a master port the single master's bus grant signal must be tied off in the asserted state.

Each master and slave port is fully AHB-Lite + AMBA V6 extensions compliant. The ports are not fully AHB compliant because the AHBMAX does not support SPLITs or RETRYs.

13.3.2 General Operation

When a master makes an access to the AHBMAX the access will be immediately taken by the AHBMAX. If the targeted slave port of the access is available then the access will be immediately presented on the slave port. It is possible to make single clock (zero wait state) accesses through the AHBMAX. If the targeted slave port of the access is busy or parked on a different master port the requesting master will simply see wait states inserted (hready held negated) until the targeted slave port can service the master's request. The latency in servicing the request will depend on each master's priority level and the responding peripheral's access time.

Because the AHBMAX appears to be just another slave to the master device, the master device will have no knowledge of whether or not it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting it will simply be wait stated.

A master will be given control of the targeted slave port only after a previous access to a different slave port has completed, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when a master has an outstanding request to

one slave port that has a long response time, has a pending access to a different slave port, and a lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

Once the master has control of the slave port it is targeting the master will remain in control of that slave port until it gives up the slave port by running an IDLE cycle or by leaving that slave port for its next access. The master could also lose control of the slave port if another higher priority master makes a request to the slave port; however, if the master is running a locked or fixed length burst transfer it will retain control of the slave port until that transfer is completed. Based on the AULB bit in the MGPCR (Master General Purpose Control Register) the master will either retain control of the slave port when doing undefined length incrementing burst transfers or will lose the bus to a higher priority master.

The AHBMAX will terminate all master IDLE transfers (as opposed to allowing the termination to come from one of the slave busses). Additionally, when no master is requesting access to a slave port the AHBMAX will drive IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port. When the AHBMAX is controlling the slave bus (i.e. during low power park or halt mode) the hmaster field will indicate 4'b0000.

When a slave bus is being IDLEd by the AHBMAX it can park the slave port on the master port indicated by the PARK bits in the AHBMAX_SGPCR (Slave General Purpose Control Register). This can be done in an attempt to save the initial clock of arbitration delay that would otherwise be seen if the master had to arbitrate to gain control of the slave port. The slave port can also be put into low power park mode in attempt to save power.

13.4 AHBMAX Interface Signals

This section provides information on AHBMAX interface signals, including AHB master and slave interface signals as well as IP bus interface signals.

13.4.1 AHBMAX Signal Descriptions

Please reference the AMBA Specification Rev 2.0 for a description of the AHB signals in the AHBMAX and the IP Bus Specification Rev 2.0 for a description of the IP Bus signals in the AHBMAX.

13.4.1.1 max_halt_request

This input signal is a request to halt all slave port bus activity (run AHBMAX originated IDLE cycles on each slave port bus, blocking all master port accesses). This signal can be used to gracefully shut down the AHBMAX so the system clock can be stopped for low power mode. This signal is captured by a flop inside the AHBMAX before use.

Once the AHBMAX is halted it will remain halted until max_halt_request is negated.

13.4.1.2 max_halted

This output is asserted once the AHBMAX is in control and running IDLE cycles on each slave port.

13.5 Coherency

Since the content of the registers has a real time effect on the operation of the AHBMAX it is important for the user to understand that any register modifications take effect as soon as the register is written. The values of the registers do not track with slave port related AHB accesses but instead track only with IP bus accesses.

The exception to this rule are the AULB bits in the AHBMAX_MGPCR*n*. The update of these bits is only recognized when the master on that master port runs an IDLE cycle, even though the IP bus cycle to write them will have long since terminated successfully. If the AULB bits in the AHBMAX_MGPCR*n* are written in between two burst accesses the new AULB encodings will not take effect until an IDLE cycle has been initiated by the master on that master port.

13.6 Detailed Functional Description

This section describes the functionality of the AHBMAX in greater detail.

13.6.1 Arbitration

The AHBMAX supports two arbitration schemes; a simple fixed-priority comparison algorithm, and a simple round-robin fairness algorithm. The arbitration scheme is independently programmable for each slave port.

13.6.1.1 Arbitration During Undefined Length Bursts

Arbitration points during an undefined length burst are defined by the current master's AHBMAX_MGPCR*n*[AULB] field setting. When a defined length is imposed on the burst via the AULB bits the undefined length burst will be treated as a single or series of single back to back fixed length burst accesses.

Example: A master runs an undefined length burst and the AULB bits in the AHBMAX_MGPCR*n* indicate arbitration will occur after the fourth beat of the burst. The master runs two sequential beats and then starts what will be an 12 beat undefined length burst access to a new address within the same slave port region as the previous access. The AHBMAX will not allow an arbitration point until the fourth overall access (second beat of the second burst). At that point all remaining accesses will be open for arbitration until the master loses control of the slave port.

Assume the master loses control of the slave port after the fifth beat of the second burst. Once the master regains control of the slave port no arbitration point will be available until after the master has run four more beats of its burst. After the fourth beat of the (now continued) burst (ninth beat of the second burst from the master's perspective) is taken all beats of the burst will once again be open for arbitration until the master loses control of the slave port.

Assume the master again loses control of the slave port on the fifth beat of the third (now continued) burst (10th beat of the second burst from the master's perspective). Once the master regains control of the slave port it will be allowed to complete its final two beats of its burst without facing arbitration.

Note that fixed length burst accesses will not be affected by the AULB bits. All fixed length burst accesses will lock out arbitration until the last beat of the fixed length burst.

13.6.1.2 Fixed Priority Operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the AHBMAX_MPR*n* (Master Priority Register). If two masters both request access to a slave port the master with the highest priority in the selected priority register will gain control over the slave port.

Any time a master makes a request to a slave port the slave port checks to see if the new requesting master's priority level is higher than that of the master that currently has control over the slave port (unless the slave port is in a parked state). The slave port does an arbitration check at every clock edge to ensure that the proper master (if any) has control of the slave port.

If the new requesting master's priority level is higher than that of the master that currently has control of the slave port the new requesting master will be granted control over the slave port at the next clock edge. The exception to this rule is if the master that currently has control over the slave port is running a fixed length burst transfer or a locked transfer. In this case the new requesting master will have to wait until the end of the burst transfer or locked transfer before it will be granted control of the slave port. If the master is running an undefined length burst transfer the new requesting master must wait until an arbitration point for the undefined length burst transfer before it will be granted control of the slave port. Arbitration points for an undefined length burst are defined in the MGPCR for each master.

If the new requesting master's priority level is lower than that of the master that currently has control of the slave port the new requesting master will be forced to wait until the master that currently has control of the slave port either runs an IDLE cycle or runs a non IDLE cycle to a location other than the current slave port.

13.6.1.3 Round-Robin Priority Operation

When operating in round-robin mode, each master is assigned a relative priority based on the master number. This relative priority is compared to the ID of the last master to perform a transfer on the slave bus. The highest priority requesting master will become owner of the slave bus as the next transfer boundary (accounting for locked and fixed-length burst transfers). Priority is based on how far ahead the ID of the requesting master is to the ID of the last master (ID is defined by master port number, not the hmaster field).

Once granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line will be granted access to the slave port at the next assertion of slave "n" hready, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the AHBMAX is implemented with master ports 0, 1, 2, 3, 4 and 5. If the last master of the slave port was master 1, and master 0, 4 and 5 make simultaneous requests, (master ports 2 and 3 make no requests), they will be serviced in the order 4, 5 and then 0.

Parking may still be used in a round-robin mode, but will not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff will occur to the next master in line after one cycle of arbitration. If the slave port is put into low power park mode the round-robin pointer will be reset to point at master port 0, giving it the highest priority.

13.6.2 Priority Assignment

Each master port needs to be assigned a unique 3 bit priority level. If an attempt is made to program multiple master ports with the same priority level within a register (MPR) the AHBMAX will respond with an error and the registers will not be updated.

13.6.3 Master Port Functionality

13.6.3.1 Master Port General Information

Each master port consists of two decoders, a capture unit, a register slice, a mux and a small state machine.

The first decoder is used to decode the haddr and control signals coming directly from the master, telling the state machine where the master's next access will be and if it is in fact a legal access. The second decoder gets its input from the capture unit, so it may be looking directly at the signals coming from the master or it may be looking at captured signals coming from the master, depending entirely on the state of the targeted slave port. The second decoder is then used to generate the access requests that go to the slave ports.

The capture unit is used to capture the address and control information coming from the master in the event that the targeted slave port cannot immediately service the master. The capture unit is controlled by outputs from the state machine which tell it to either pass through the original master signals or the captured signals.

The register slice contains the registers associated with the specific master port. The registers have a quasi-IP bus interface at this level for reads and writes and the outputs feed directly into the state machine.

The mux is used simply to select which slave's read data is sent back to the master. The mux is controlled by the state machine.

The state machine controls all aspects of the master port. It knows which slave port the master wants to make a request to and controls when that request is made. It also has knowledge of each slave port, knowing whether or not the slave port is ready to accept an access from the master port. This will determine whether or not the master may immediately have its request taken by the slave port or whether the master port will have to capture the master's request and queue it at the slave port boundary.

For a block diagram of a master port see Figure 13-2.

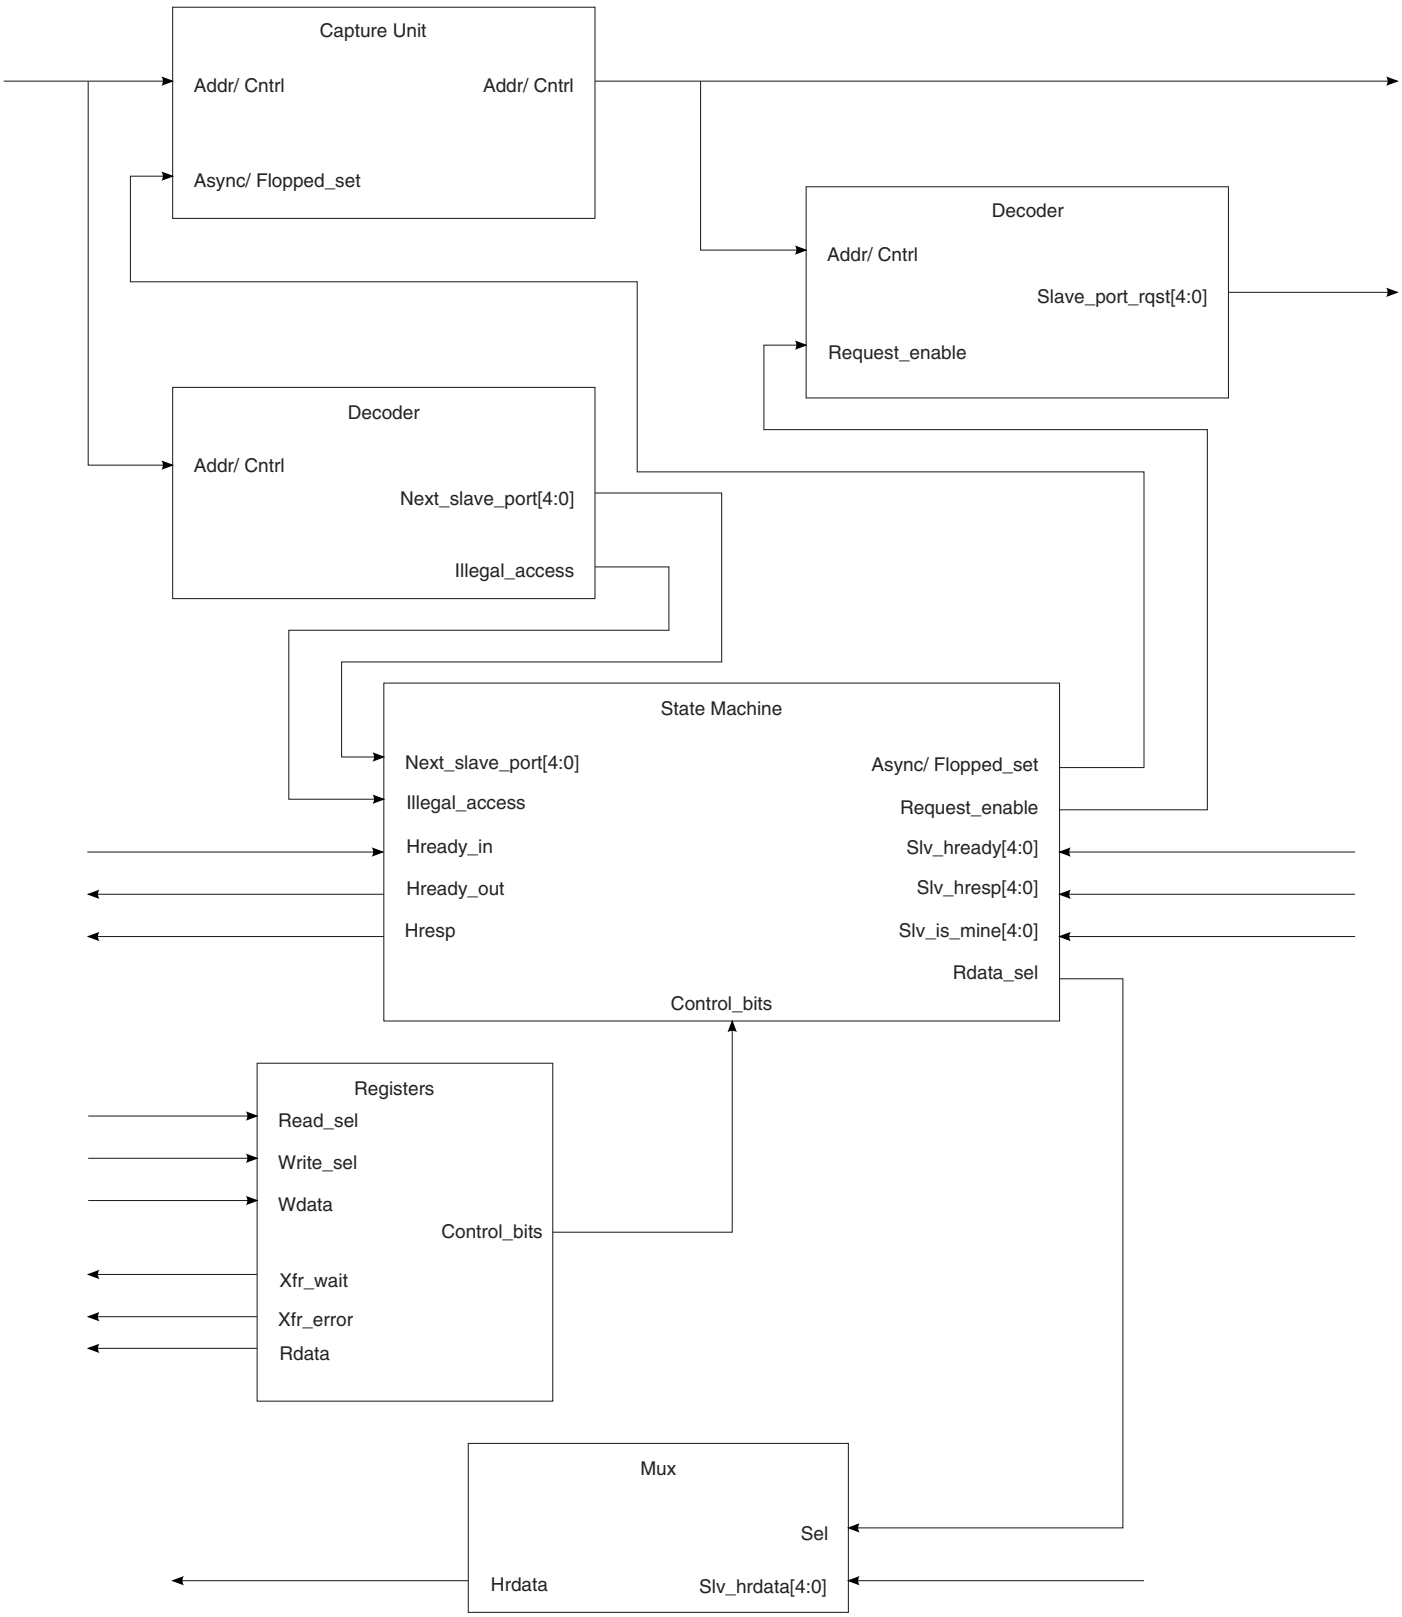

Figure 13-2. AHBMAX Master Port Block Diagram

13.6.3.2 Master Port Decoders

The decoders are very simple as they ensure an access request is allowed to be made and that the slave port targeted is actually present in the design. The decoders feeding the state machine are always enabled. The decoders that select the slave are enabled only when the master port controlling state machine wants to make a request to a slave port. This is necessary so that if a master port is making an access to a slave port and is being wait stated, and its next access is to a different slave port, the request to the second slave port can be held off until the access to the first slave port is terminated.

The decoders also output a "hole decode" or illegal access signal which tells the state machine that the master is trying to access a slave port that does not exist.

13.6.3.3 Master Port Capture Unit

The capture unit simply captures the state of the master's address and control signals if the AHBMAX cannot immediately pass the master's request through to the proper slave port. The capture unit consists of a set of flops and a mux which selects either the asynchronous path from address and control or the flopped (captured) address and control information.

13.6.3.4 Master Port Registers

The registers in the master port are only those registers associated with this particular master port. The read and write interface for the registers is a quasi-IP bus interface. It is not a full IP bus interface at this level because not all the IP bus signals are routed this deep in the design.

There is a register control block at the same level of the master port and slave port instantiations in the AHBMAX. This control block ensures that all accesses are 32-bit supervisor accesses before passing them on to the master ports.

The register outputs are connected directly to the state machine.

13.6.3.5 Master Port State Machine

13.6.3.5.1 Master Port State Machine States

The master side state machine's main function is to monitor the activities of the master port. The state machine has six states: busy, idle, stalled, steady state, first cycle error response and second cycle error response.

The busy state is used when the master runs a BUSY cycle to the master port. The master port maintains its request to the slave port if it currently owns the slave port; however, if it loses control of the slave port it will no longer maintain its request. If the master port loses control of the slave port it will not be allowed to make another request to the slave port until it runs a NSEQ or SEQ cycle.

The idle state is used when the master runs a valid IDLE cycle to the master port. The master port makes no requests to the slave ports (disables the slave port decoder) and terminates the IDLE cycle.

The stalled state is used when the master makes a request to a slave port that is not immediately ready to receive the request. In this case the state machine will direct the capture unit to send out the captured address and control signals and will enable the slave port decoder to indicate a pending request to the appropriate slave port.

The steady state is used when the master port and slave port are in fully asynchronous mode, making the AHBMAX completely transparent in the access. The state machine selects the appropriate slave's hresp0, hready and hrdata to pass back to the master.

The first cycle error response and second cycle error response states are self explanatory. The AHBMAX will respond with an error response to the master if the master tries to access an unimplemented memory location through the AHBMAX (i.e. a slave port that does not exist).

13.6.3.5.2 Master Port State Machine Slave Swapping

The design of the master side state machine is fairly straight forward. The one real decision to be made is how to handle the master moving from one slave port access to another slave port access. The approach that was taken was to minimize or eliminate, when possible, any "bubbles" that would get inserted into the access due to switching slave ports.

The state machine will not allow the master to request access to another slave port until the current access being made is terminated. This prevents a single master from owning two slave ports at the same time (the slave port it is currently accessing and the slave port it wishes to access next).

The state machine also maintains watch on the slave port the master is accessing as well as the slave port the master wishes to switch to. If the new slave port is parked on the master then the master will be able to make the switch without incurring any delays. The termination of the current access will also act as the launch of the new access on the new slave port. If the new slave port is not parked on the master then the master will incur a minimum one clock delay before it can launch its access on the new slave port.

This is the same for switching from the busy or idle state to actively accessing a slave port. If the slave port is parked on the master the state machine will go to the steady state and the access will begin immediately. If the slave port is not parked on the master (serving another master, parked on another master or in low power park mode) then the state machine will transition to the stalled state and at least a one clock penalty will be paid.

13.6.4 Slave Port Functionality

13.6.4.1 Slave Port General Information

Each slave port consists of a register slice, a bank of muxes and a state machine.

The register slice contains the registers associated with the specific slave port. The registers have a quasi-IP bus interface at this level for reads and writes and the outputs feed directly into the state machine.

The muxes are a series of 6 to 1 multiplexers that take in all the address, control and write data information from each of the master ports and then pass the correct master's signals to the slave port. The state machine controls all the muxes.

The state machine is where the main slave port arbitration occurs, it decides which master is in control of the slave port and which master will be in control of the slave port in the next bus cycle.

For a block diagram of a slave port see Figure 13-3.

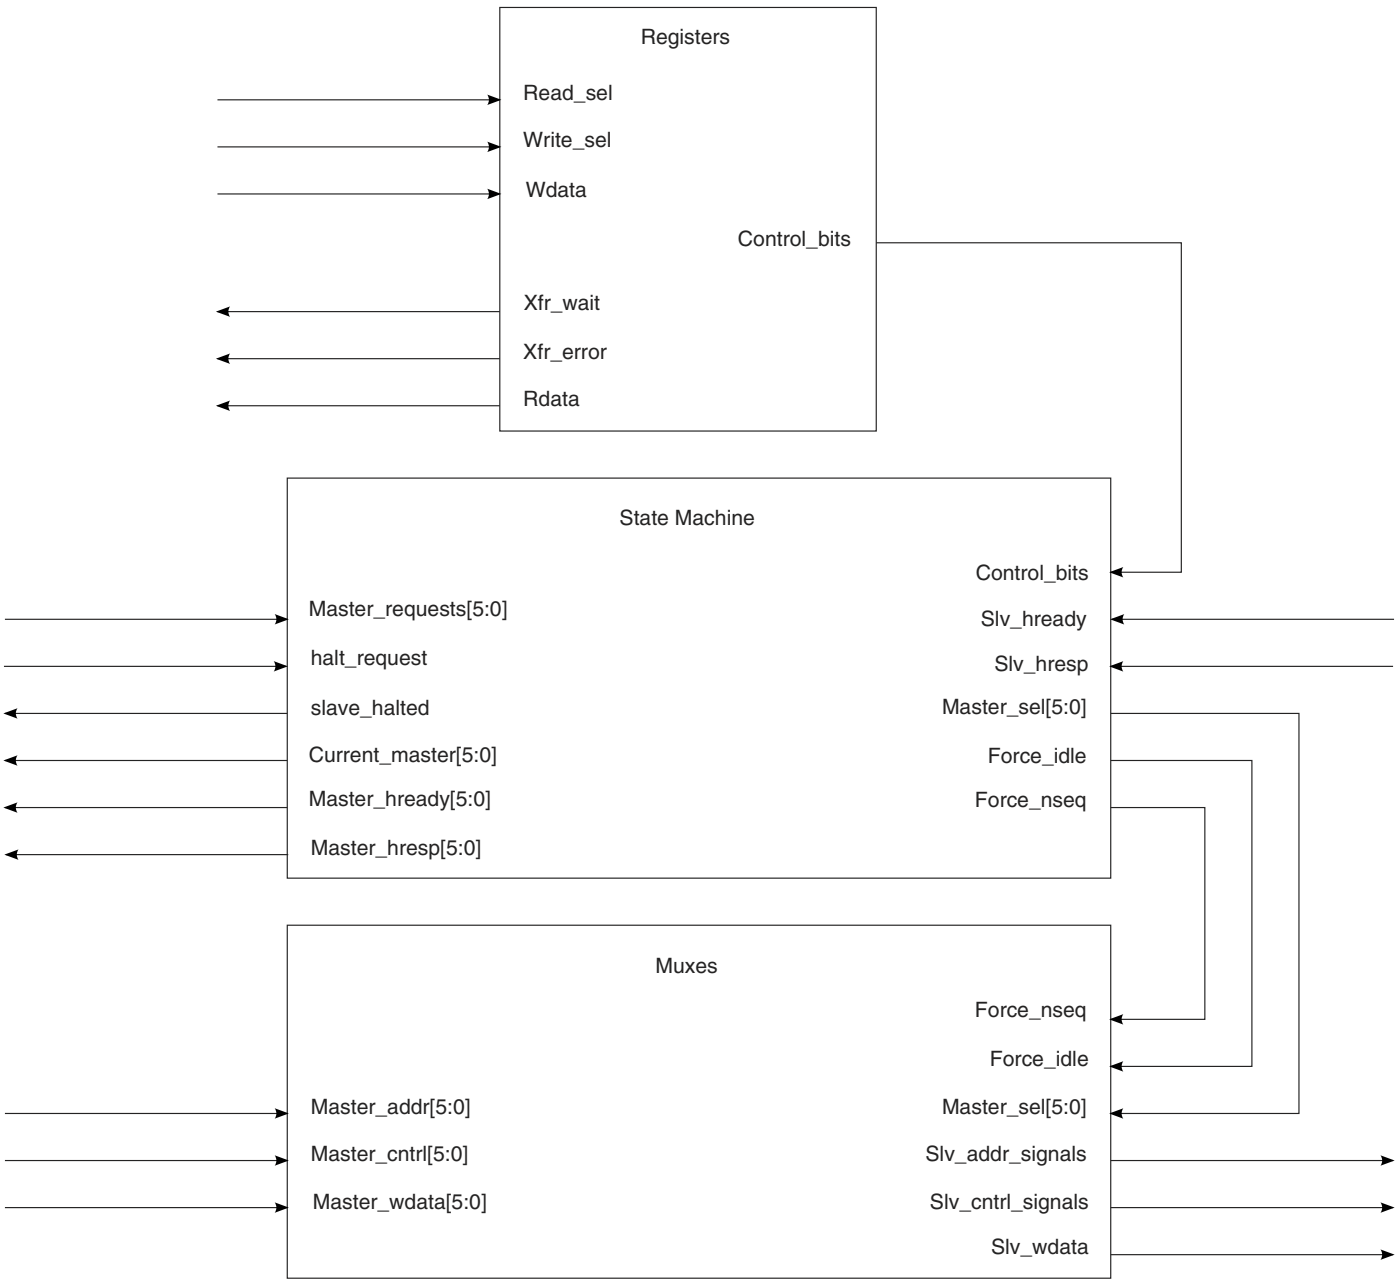

Figure 13-3. AHBMAX Slave Port Block Diagram

13.6.4.2 Slave Port Muxes

The block diagram (Figure 13-3) shows only one block for all the muxes. In reality that block instantiates many 6 to 1 muxes, one for each master-to-slave signal in fact. All the muxes are designed in an AND - OR fashion, so that if no master is selected the output of the muxes will be zero. (This is an important feature for low power park mode.)

The muxes also have an override signal which is used by the slave port to asynchronously force IDLE cycles onto the slave bus. When the state machine forces an IDLE cycle it zeros out htrans and hmastlock, making sure the slave bus sees a valid IDLE cycle being run by the AHBMAX.

The enable to the mux controlling htrans also contains an additional control signal from the state machine so that a NSEQ transaction can be forced. This is done any time the slave port switches masters to ensure that no IDLE-SEQ, BUSY-SEQ or NSEQ-SEQ transactions are seen on the slave port when they shouldn't be. If the state machine indicates to run both an IDLE and an NSEQ cycle, the IDLE directive will have priority.

NOTE

IDLE-SEQ is in fact an illegal access, but a possible scenario given the multi-master environment in the AHBMAX unless corrected by the AHBMAX.

13.6.4.3 Slave Port Registers

There is a register control block at the same level of the master port and slave port instantiations in the AHBMAX. This control block ensures that all accesses are 32-bit supervisor accesses before passing them on to the master and slave ports.

The registers in the slave port are only those registers associated with this particular slave port. The read and write interface for the registers is a quasi-IP bus interface. It is not a full IP bus interface at this level because not all the IP bus signals are routed this deep in the design.

The register outputs are connected directly to the slave state machine. The registers can be read from an unlimited number of times. The registers can only be written to as long as the RO bit is written to 0 in the AHBMAX_SGPCRn, once it is written to a 1 only a hardware reset will allow the registers to be written again.

13.6.4.4 Slave Port State Machine

13.6.4.4.1 Slave Port State Machine States

At the heart of the slave port is the state machine. The state machine is simplicity itself, requiring only four states - steady state, transition state, transition hold state and hold state. Either the slave port is owned by the same master it was in the last clock cycle (either by active use or by parking), it is transitioning to a new master (either for active use or parking), it is transitioning to a new master during wait states or it is being held on the same master pending a transition to a new master.

13.6.4.4.2 Slave Port State Machine Arbitration

The real work in the state machine is determining which master port will be in control of the slave port in the next clock cycle, the arbitration. Each master is programmed with a fixed 3 bit priority level. The AHBMAX uses these bits in determining priority levels when programmed for fixed priority mode of operation.

Arbitration always occurs on a clock edge, but only occurs on edges when a change in mastership will not violate AHB-Lite protocols. Valid arbitrations points include any clock cycle in which slave n hready is asserted (provide the master is not performing a burst or locked cycle) and any wait state in which the master owning the bus indicates a transfer type of IDLE (provided the master is not performing a locked cycle).

Since arbitration can occur on every clock cycle the slave port masks off all master requests if the current master is performing a locked transfer or a protected burst transfer, guaranteeing that no matter how low its priority level it will be allowed to finish its locked or protected portion of a burst sequence.

13.6.4.4.3 Slave Port State Machine Master Handoff

The only times the slave port will switch masters when programmed for fixed priority mode of operation is when a higher priority master makes a request or when the current master is the highest priority and it gives up the slave port by either running and IDLE cycle to the slave port or running a valid access to a location other than the slave port.

If the current master loses control of the slave port because a higher priority master takes it away the slave port will not incur any wasted cycles. The current master will get its current cycle terminated by the slave port at the same time the new master's address and control information will be recognized by the slave port. This will look like a seamless transition on the slave port.

If the current master is being wait stated when the higher priority master makes its request, then the current master will be allowed to make one more transaction on the slave bus before giving it up to the new master. Figure 13-4 illustrates the effect of a higher priority master taking control of the bus when the slave port is programmed for a fixed priority mode of operation.

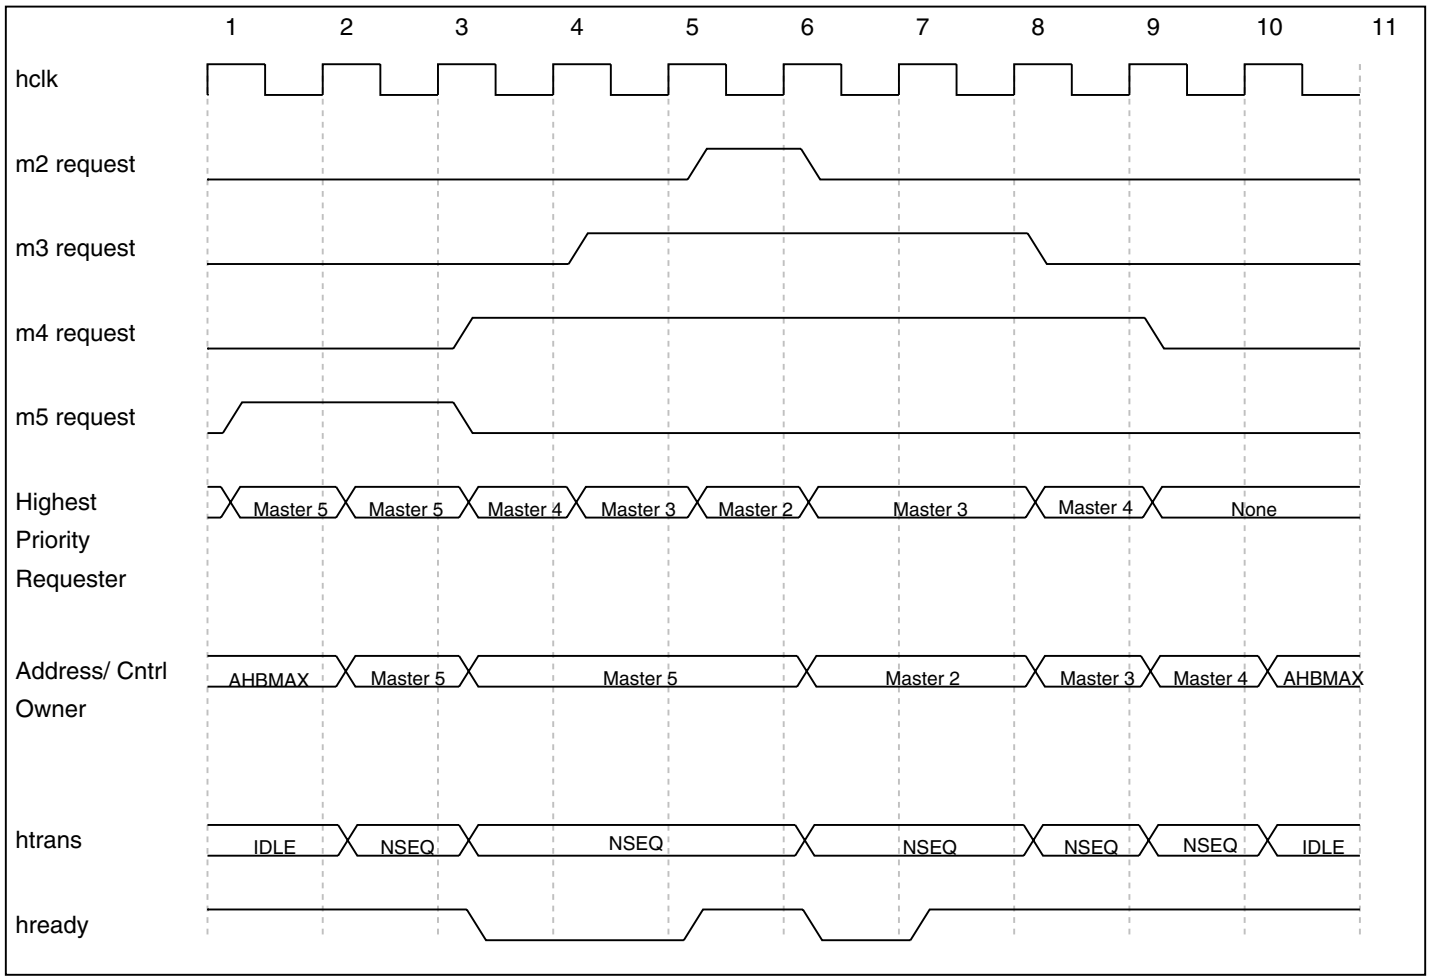

Figure 13-4. Low to High Priority Mastership Change

If the current master is the highest priority master and it gives up the slave port by running an IDLE cycle or by running a valid cycle to another location other than the slave port the next highest priority master will gain control of the slave port. If the current access incurs any wait states then the transition will be seamless and no bandwidth will be lost; however, if the current transaction is terminated without wait states then one IDLE cycle will be forced onto the slave bus by the AHBMAX before the new master will be able to take control of the slave port. If no other master is requesting the bus then IDLE cycles will be run by the AHBMAX but no bandwidth will truly be lost since no master is making a request.

Figure 13-5 illustrates the effect of a higher priority master giving up control of the bus.

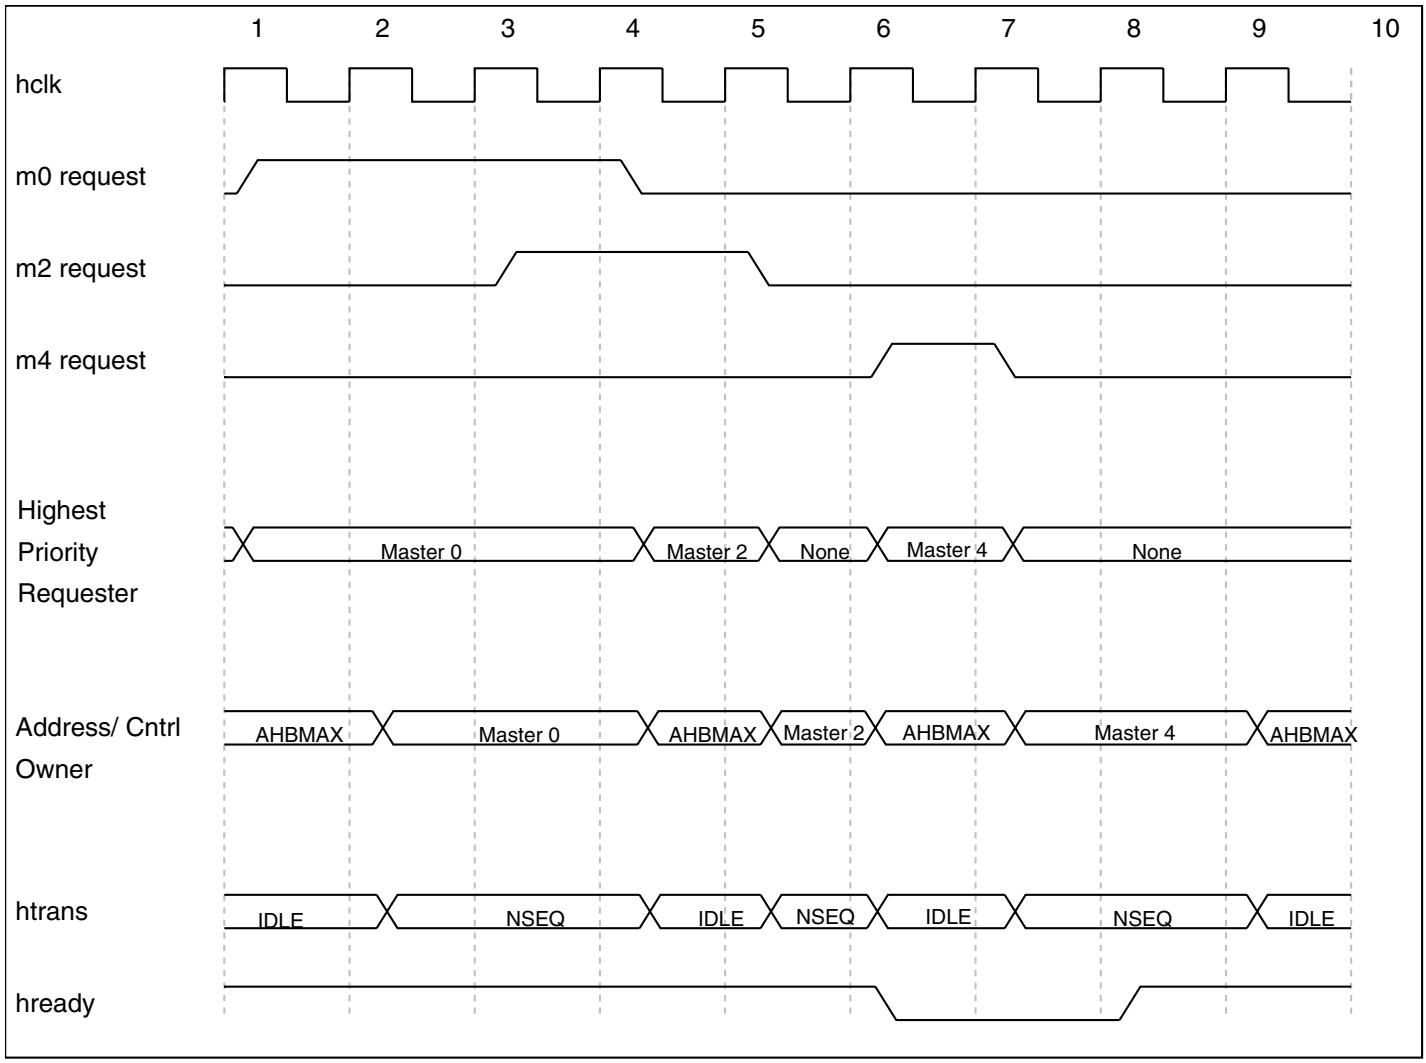

Figure 13-5. High to Low Priority Mastership Change

When the slave port is programmed for round-robin mode of arbitration then the slave port will switch masters any time there is more than one master actively making a request to the slave port. This will happen because any master other than the one which presently owns the bus will be considered to have higher priority.

Figure 13-6 shows an example of round-robin mode of operation.

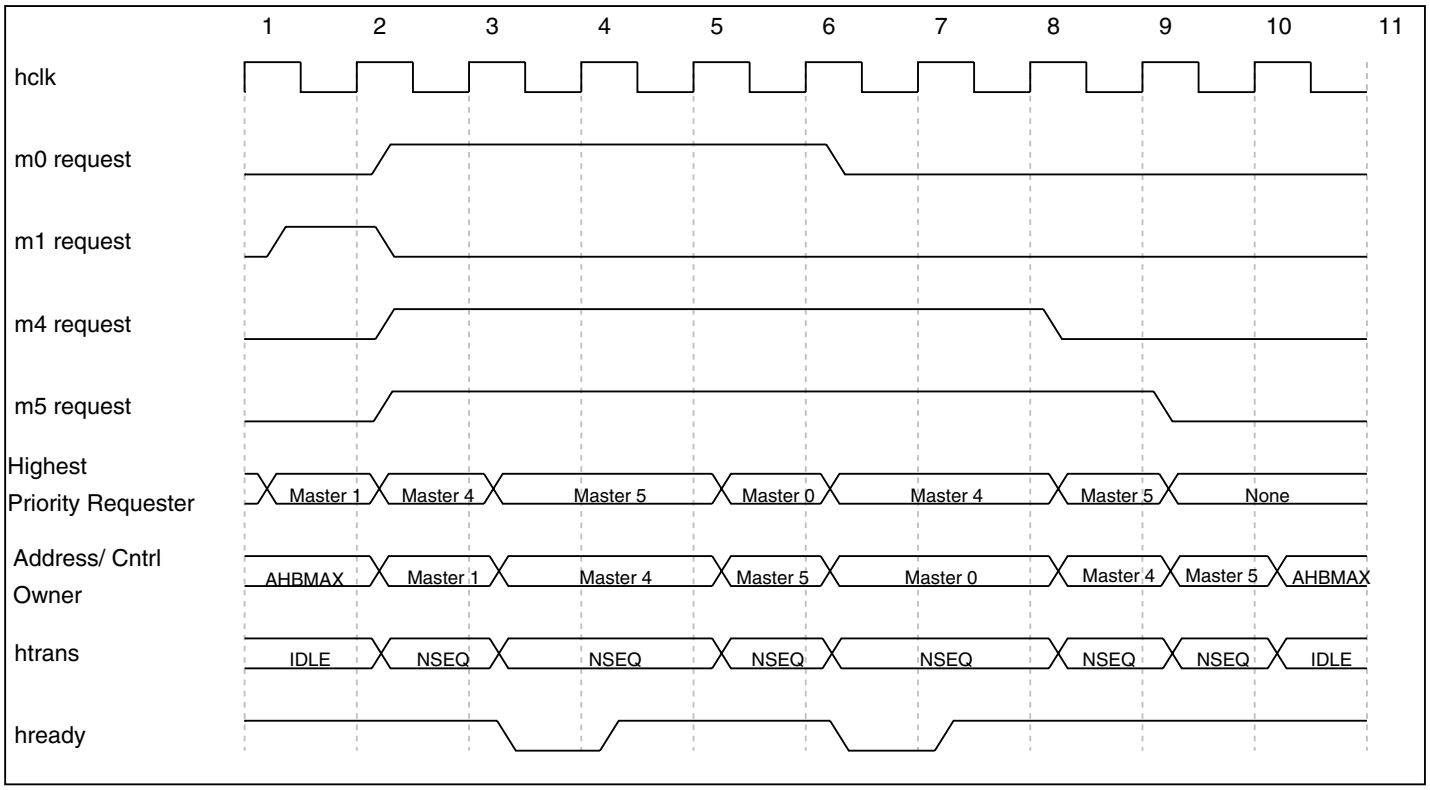

Figure 13-6. Round-robin Mastership Change

13.6.4.4.4 Slave Port State Machine Parking

If no master is currently making a request to the slave port then the slave port will be parked. It will park in one of four places, dictated by the PCTL and PARK bits in the AHBMAX_SGPCR and the locked state of the last master to access it.

If the last master to access the slave port ran a locked cycle and continues to run locked cycles even after leaving the slave port the slave port will park on that master without regard to the bit settings in the AHBMAX_SGPCR and without regard to pending requests from other masters. This is done so a master can run a locked transfer to the slave port, leave it, and return to it and be guaranteed that no other master has had access to it (provided the master maintains all transfers are locked transfers). If locking is not an issue for parking the AHBMAX_SGPCR bits will dictate the parking method.

If the PCTL bits are set for "low power park" mode then the slave port will enter low power park mode. It will not recognize any master as being in control of it and it will not select any master's signals to pass through to the slave bus. In this case all slave bus activity will effectively halt because all slave bus signals being driven from the AHBMAX will be 0. This of course can save quite a bit of power if the slave port will not

be in use for some time. The down side is that when a master does make a request to the slave port it will be delayed by one clock since it will have to arbitrate to acquire ownership of the slave port.

If the PCTL bits are set to "park on last" mode then the slave port will park on the last master to access it, passing all that masters signals through to the slave bus. The AHBMAX will asynchronously force htrans[1:0], hmaster[3:0], hburst[2:0] and hmastlock to 0 for all access that the master does not run to the slave port. When that master access the slave port again it will not pay any arbitration penalty; however, if any other master wishes to access the slave port a one clock arbitration penalty will be imposed.

If the PCTL bits are set to "use PARK" mode then the slave port will park on the master designated by the PARK bits. The behavior here is the same as for the "park on last" mode with the exception that a specific master will be parked on instead of the last master to access the slave port. If the master designated by the PARK bits tries to access the slave port it will not pay an arbitration penalty while any other master will pay a one clock penalty. Figure 13-7 illustrates parking on a specific master.

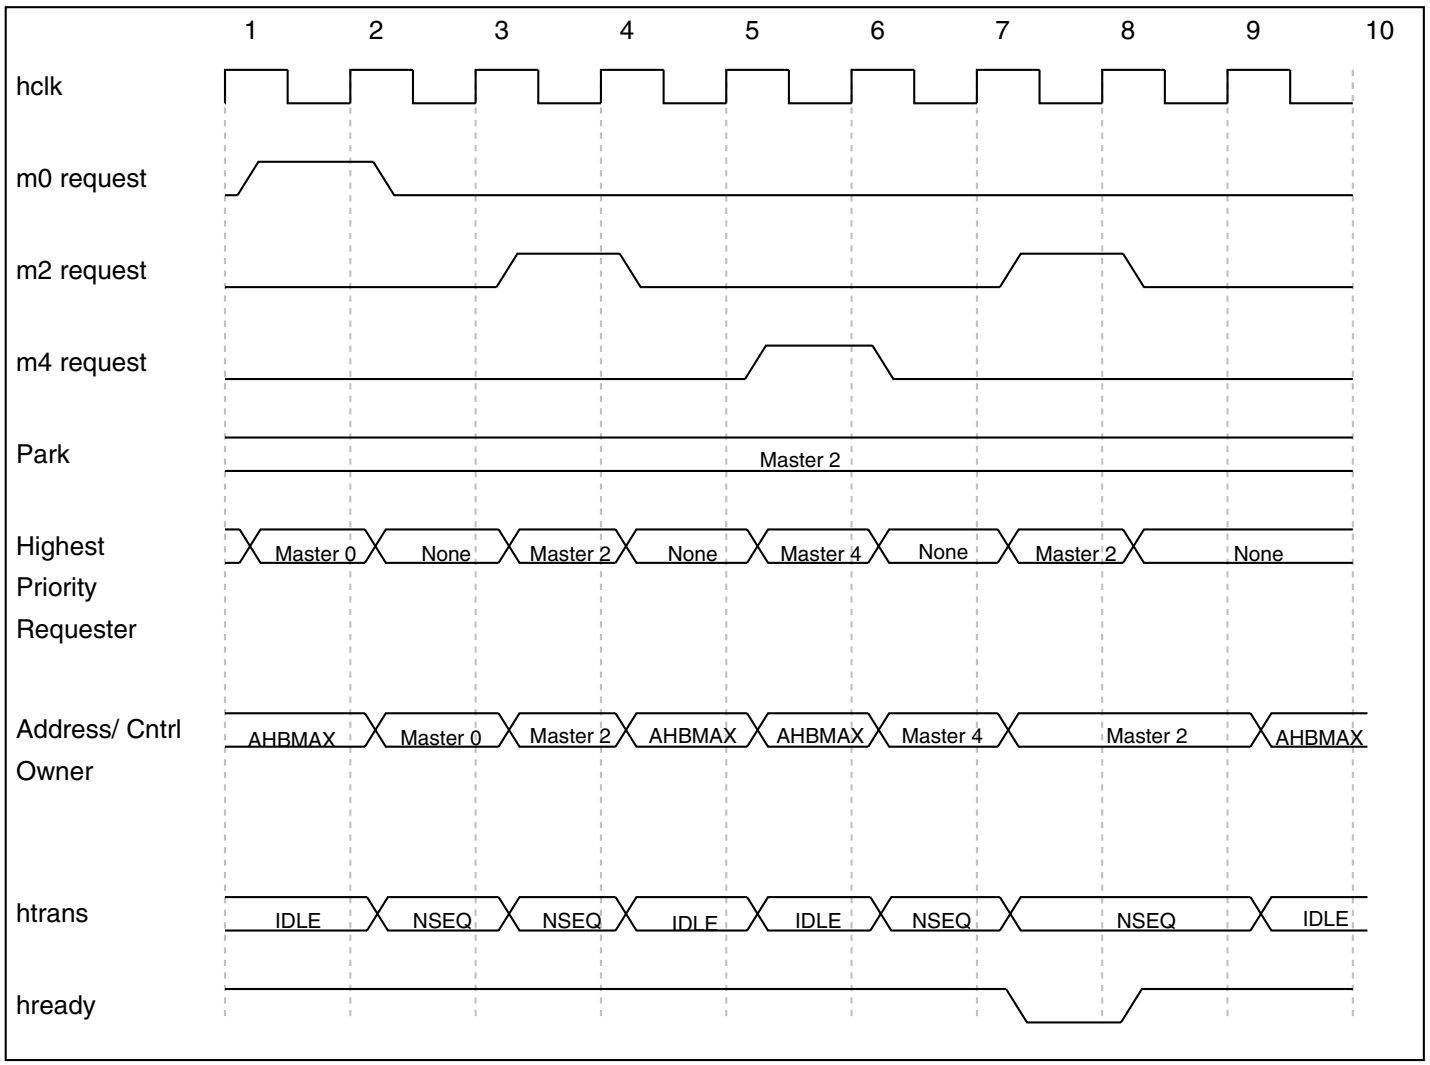

Figure 13-7. Parking on a Specific Master

Figure 13-8 illustrates parking on the last master. Note that in cycle 6 simultaneous requests are made by master 2 and master 4. Although master 2 has higher priority, the slave bus is parked on master 4 so master 4's access will be taken first. The slave port parks on master 2 once it has given control to master 2. This same situation can occur when parking on a specific master as well.

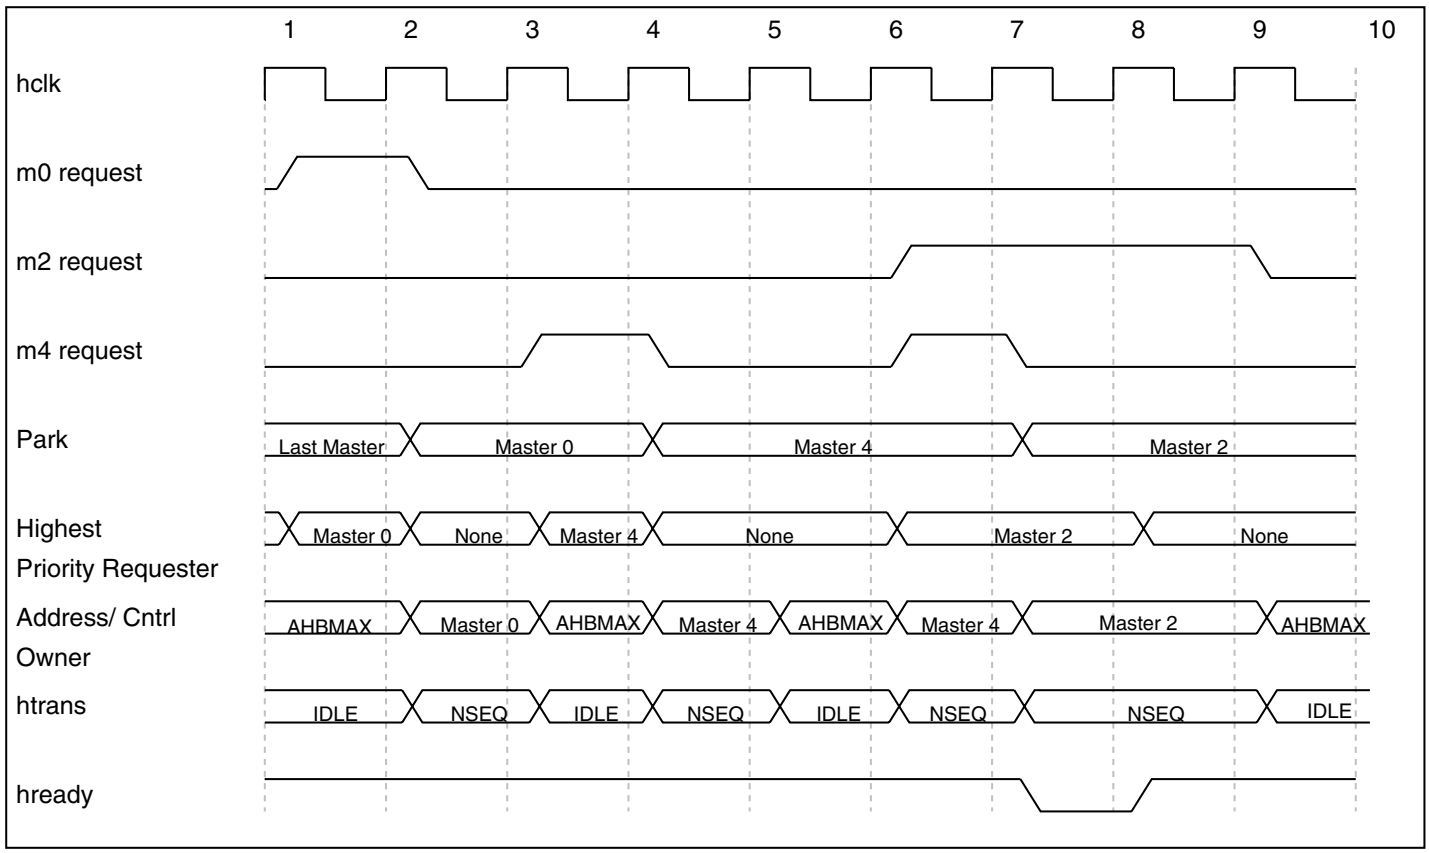

Figure 13-8. Parking on Last Master

13.6.4.4.5 Slave Port State Machine Halt Mode

If the max_halt_request input is asserted the slave port will eventually halt all slave bus activity and go into halt mode, which is almost identical to low power park mode. The HLP bit in the AHBMAX_SGPCR controls the priority level of the max_halt_request in the arbitration algorithm. If the HLP bit is cleared then the max_halt_request will have the highest priority of any master and will gain control of the slave port at the next arbitration point (most likely the next bus cycle, unless the current master is running a locked or fixed length burst transfer). If the HLP bit is set then the slave port will wait until no masters are actively making requests before moving to halt mode.

Regardless of the state of the HLP bit, once the slave port has gone into halt mode as a result of max_halt_request being asserted, it will remain in halt mode until max_halt_request is negated, regardless of the priority level of any masters that may make requests.

In halt mode no master is selected to own the slave port so all the outputs of the slave port are set to 0.

13.7 Initialization/Application Information

No initialization is required by or for the AHBMAX. Hardware reset ensures all the register bits used by the AHBMAX are properly initialized.

13.8 AHBMAX Interface

This section provides information on the AHBMAX interface.

13.8.1 AHBMAX Interface Overview

The main goal of the AHBMAX is to increase overall system performance by allowing multiple masters to communicate in parallel with multiple slaves. In order to maximize data throughput it is essential to keep arbitration delays to a minimum.

This section examines data throughput from the point of view of masters and slaves, detailing when the AHBMAX will stall the masters or insert bubbles on the slave side.

13.8.2 Master Ports-AHBMAX Interface

Master accesses will receive one of four responses from the AHBMAX. They will either be terminated, taken, stalled or responded to with an error.

13.8.2.1 Terminated Accesses

A master access will be terminated if the transfer type is IDLE. The AHBMAX will terminated the access and it will not be allowed to pass through the AHBMAX.

13.8.2.2 Taken Accesses

A master access will be taken if the transfer type is non IDLE and the slave port to which the access decodes is either currently servicing the master or is parked on the master. In this case the AHBMAX will be completely transparent and the master's access will be immediately seen on the slave bus and no arbitration delays will be incurred.

13.8.2.3 Stalled Accesses

A master access will be stalled if the transfer type is non IDLE and the access decodes to a slave port that is busy serving another master, parked on another master or is in low power park mode. The AHBMAX will indicate to the master that the address phase of the access has been taken but will then queue the access to the appropriate slave port to enter into arbitration for access to that slave port.

If the slave port is currently parked on another master or is in low power park mode and no other master is requesting access to the slave port then only one clock of arbitration will be incurred. If the slave port is currently serving another master of a lower priority and the master has a higher priority than all other requesting masters then the master will gain control over the slave port as soon as the data phase of the current access is completed (burst and locked transfers excluded). If the slave port is currently servicing another master of a higher priority then the master will gain control of the slave port once the other master releases control of the slave port if no other higher priority master is also waiting for the slave port.

13.8.2.4 Error Response Terminated Accesses

A master access will be responded to with an error if the transfer type is non IDLE and the access decodes to a location not occupied by a slave port.

13.8.3 Slave Ports-AHBMAX Interface

The goal of the AHBMAX with respect to the slave ports is to keep them 100% saturated when masters are actively making requests. In order to do this the AHBMAX must not insert any bubbles onto the slave bus unless absolutely necessary.

There is only one instance when the AHBMAX will force a bubble onto the slave bus when a master is actively making a request. This occurs when a higher priority master has control of the slave port and is running single clock (zero wait state) accesses while a lower priority master is stalled waiting for control of the slave port. When the higher priority master either leaves the slave port or runs an IDLE cycle to the slave port the AHBMAX will take control of the slave bus and run a single IDLE cycle before giving the slave port to the lower priority master that was waiting for control of the slave port.

The only other times the AHBMAX will have control of the slave port is when the AHBMAX is halting or when no masters are making access requests to the slave port and the AHBMAX is forced to either park the slave port on a specific master or put the slave port into low power park mode.

In most instances when the AHBMAX has control of the slave port it will indicate IDLE for the transfer type, negate all control signals and indicate ownership of the slave bus via the hmaster encoding of b0000. One exception to this rule is when a master running locked cycles has left the slave port but continues to run locked cycles. In this case the AHBMAX will control the slave port and will indicate IDLE for the transfer type but it will not affect any other signals.

NOTE

When a master runs a locked cycle through the AHBMAX, the master will be guaranteed ownership of all slave ports it accesses while running locked cycles for one cycle beyond when the master finishes running locked cycles.

13.9 Programmable Registers

There are four registers that reside in each slave port of the AHBMAX and one register that resides in each master port of the AHBMAX. These registers are IP bus compliant registers. Read and write transfers both require two IP bus clock cycles. The registers can only be read from and written to in supervisor mode. Additionally, these registers can only be read from or written to by 32-bit accesses.

The registers are fully decoded and an error response is returned if an unimplemented location is accessed within the AHBMAX.

The slave registers also feature a bit, which when written with a 1, will prevent the registers from being written to again. The registers will still be readable, but future write attempts will have no effect on the registers and will be terminated with an error response.

AHBMAX memory map

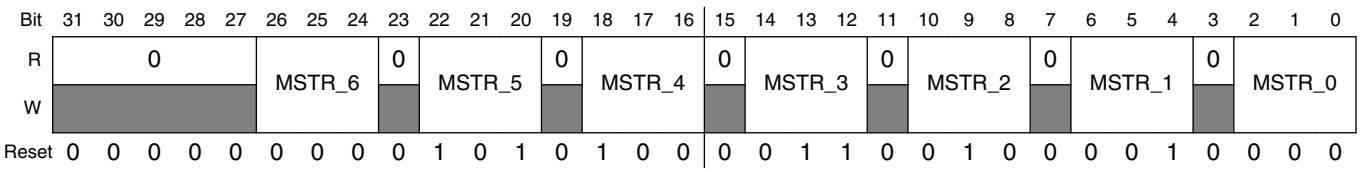
13.9.1 Master Priority Register for Slave port n (AHBMAX_MPR*n*)

The Master Priority Register (MPR) sets the priority of each master port on a per slave port basis and resides in each slave port.

The Master Priority Register can only be accessed in supervisor mode with 32-bit accesses. Once the RO (Read Only) bit has been set in the Slave General Purpose Control Register the Master Priority Register (MPR) can only be read from, attempts to write to it will have no effect on the MPR and result in an error response.

Additionally, no two available master ports may be programmed with the same priority level. Attempts to program two or more available masters with the same priority level will result in an error response and the MPR will not be updated.

Addresses: AHBMAX_MPR0 is 63F9_4000h base + 0h offset = 63F9_4000h
AHBMAX_MPR1 is 63F9_4000h base + 100h offset = 63F9_4100h
AHBMAX_MPR2 is 63F9_4000h base + 200h offset = 63F9_4200h
AHBMAX_MPR3 is 63F9_4000h base + 300h offset = 63F9_4300h



AHBMAX_MPR*n* field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.
26–24 MSTR_6	Master 6Priority. These bits set the arbitration priority for master port 6 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
23 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.
22–20 MSTR_5	Master 5 Priority. These bits set the arbitration priority for master port 5 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
19 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.
18–16 MSTR_4	Master 4 Priority. These bits set the arbitration priority for master port 4 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
15 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.
14–12 MSTR_3	Master 3 Priority. These bits set the arbitration priority for master port 3 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
11 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.

Field	Description
10–8 MSTR_2	Master 2 Priority. These bits set the arbitration priority for master port 2 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
7 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.
6–4 MSTR_1	Master 1 Priority. These bits set the arbitration priority for master port 1 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
3 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.
2–0 MSTR_0	Master 0 Priority. These bits set the arbitration priority for master port 0 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.

13.9.2 General Purpose Control Register for Slave port n (AHBMAX_SGPCR*n*)

The Slave General Purpose Control Register (AHBMAX_SGPCR*n*) controls several features of each slave port.

The Read Only (RO) bit will prevent any registers associated with this slave port from being written to once set. This bit may be written with 0 as many times as the user desires, but once it is written to a 1 only a reset condition will allow it to be written again.

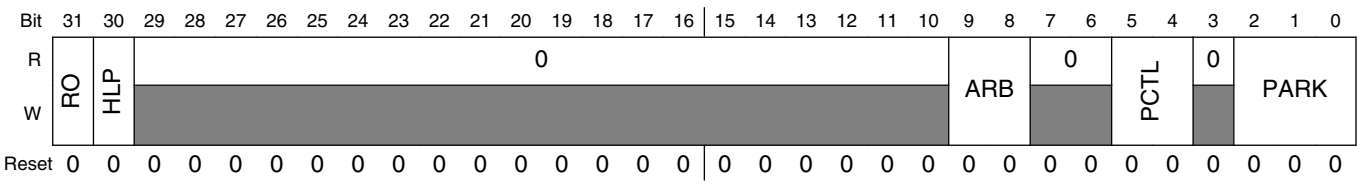
The Halt Low Priority (HLP) bit will set the priority of the max_halt_request input to the lowest possible priority for initial arbitration of the slave ports. By default it is the highest priority. Please note, setting this bit will not effect the max_halt_request from attaining highest priority once it has control of the slave ports.

The PCTL bits determine how the slave port will park when no master is actively making a request. The available options are to park on the master defined by the PARK bits, park on the last master to use the slave port, or go into a low power park mode which will force all the outputs of the slave port to inactive states when no master is requesting an access. The low power park feature can result in an overall power savings if a the slave port is not saturated; however, it will force an extra clock of latency whenever any master tries to access it when it is not in use because it will not be parked on any master

The PARK bits determine which master the slave will park on when no master is making an active request and the max_halt_request input is negated. Please use caution to only select master ports that are actually present in the design. If the user programs the PARK bits to a master not present in the current design implementation undefined behavior will result.

The AHBMAX_SGPCR*n* can only be accessed in supervisor mode with 32-bit accesses. Once the RO (Read Only) bit has been set in the AHBMAX_SGPCR*n* the AHBMAX_SGPCR*n* can only be read, attempts to write to it will have no effect on the AHBMAX_SGPCR*n* and result in an error response.

Addresses: AHBMAX_SGPCR0 is 63F9_4000h base + 10h offset = 63F9_4010h
AHBMAX_SGPCR1 is 63F9_4000h base + 110h offset = 63F9_4110h
AHBMAX_SGPCR2 is 63F9_4000h base + 210h offset = 63F9_4210h
AHBMAX_SGPCR3 is 63F9_4000h base + 310h offset = 63F9_4310h



AHBMAX_SGPCR*n* field descriptions

Field	Description
31 RO	Read Only. This bit is used to force all of a slave port's registers to be read only. Once written to 1 it can only be cleared by hardware reset. This bit is initialized by hardware reset. 0 All this slave port's registers can be written. 1 All this slave port's registers are read only and cannot be written (attempted writes have no effect and result in an error response).
30 HLP	Halt Low Priority. This bit is used to set the initial arbitration priority of the max_halt_request input. This bit is initialized by hardware reset. 0 The max_halt_request input has the highest priority for arbitration on this slave port 1 The max_halt_request input has the lowest initial priority for arbitration on this slave port.
29–10 Reserved	This read-only field is reserved and always has the value zero. Reserved. They read as zero and should be written with zero for upward compatibility.
9–8 ARB	Arbitration Mode. These bits are used to select the arbitration policy for the slave port. These bits are initialized by hardware reset. 00 Fixed Priority. 01 Round Robin (rotating) Priority. 10 Reserved 11 Reserved
7–6 Reserved	This read-only field is reserved and always has the value zero. Reserved. They read as zero and should be written with zero for upward compatibility.

Field	Description
5–4 PCTL	Parking Control.These bits determine the parking control used by this slave port. These bits are initialized by hardware reset. 00 When no master is making a request the arbiter will park the slave port on the master port defined by the PARK bit field. 01 When no master is making a request the arbiter will park the slave port on the last master to be in control of the slave port. 10 When no master is making a request the arbiter will park the slave port on no master and will drive all outputs to a constant safe state. 11 Reserved
3 Reserved	This read-only field is reserved and always has the value zero. Reserved. They read as zero and should be written with zero for upward compatibility.
2–0 PARK	PARK. These bits are used to determine which master port this slave port parks on when no masters are actively making requests and the PCTL bits are set to 00. These bits are initialized by hardware reset. 000 Park on Master Port 0 001 Park on Master Port 1 010 Park on Master Port 2 011 Park on Master Port 3 100 Park on Master Port 4 101 Park on Master Port 5 110 Park on Master Port 6 111 Reserved

13.9.3 General Purpose Control Register for Master port n (AHBMAX_MGPCR*n*)

The Master General Purpose Control Register (AHBMAX_MGPCR*n*) presently controls only whether or not the master's undefined length burst accesses will be allowed to complete uninterrupted or whether they can be broken by requests from higher priority masters.

The AULB (Arbitrate on Undefined Length Bursts) bit field determines whether (and when) or not the AHBMAX will arbitrate away the slave port the master owns when the master is performing undefined length burst accesses.

The AHBMAX_MGPCR*n* can only be accessed in supervisor mode with 32-bit accesses.

Addresses: AHBMAX_MGPCR0 is 63F9_4000h base + 800h offset = 63F9_4800h
AHBMAX_MGPCR1 is 63F9_4000h base + 900h offset = 63F9_4900h
AHBMAX_MGPCR2 is 63F9_4000h base + A00h offset = 63F9_4A00h

These bits are initialized by hardware reset. 000 No arbitration will be allowed during an undefined length burst. 001 Arbitration will be allowed at any time during an undefined length burst. 010 Arbitration will be allowed after four beats of an undefined length burst. 011 Arbitration will be allowed after eight beats of an undefined length burst. 100 Arbitration will be allowed after 16 beats of an undefined length burst. 101 Reserved 110 Reserved 111 Reserved

Chapter 14
AHB to IP Bridge (AIPSTZ)

14.1 Introduction

This section provides an overview of the AHB to IP Bridge (AIPSTZ). The peripheral bridge acts as an interface between the system bus and lower bandwidth IP Slave (IPS) bus peripherals.

14.1.1 Features

The following list summarizes the key features of the bridge:

- The bridge supports the IPS slave bus signals. This interface is only meant for slave peripherals.
- The bridge supports 8-, 16-, and 32-bit IPS peripherals. (Accesses larger than the size of a peripheral are not supported, except to 32-bit memory.)
- The bridge supports a pair of IPS accesses for 64-bit and certain misaligned AHB transfers to 32-bit memory in 64-bit platforms.
- The bridge directly supports up to 32 16-Kbyte external IPS peripherals, and 2 global external IPS peripheral spaces. The bridge occupies 64 MBytes of total address space.
- The bridge provides configurable per-block and per-master access protections.
- Peripheral read transactions require a minimum of 2 hclk clocks, and unbuffered write transactions require a minimum of 3 hclk clocks.
- The bridge uses one single asynchronous reset and one global clock.

14.2 General Operation

The AHB to IP bridge is the interface between the AHB and on-chip IPS peripherals, which are sub-blocks containing readable/writable control and status registers.

The AHB master reads and writes these registers through the AIPSTZ. The bridge generates block enables, the block address, transfer attributes, byte enables and write data as inputs to the IPS peripherals. The bridge captures read data from the IPS interface and drives it on the AHB.

It occupies a 64-Mbyte portion of the address space. 63.5 Mbytes are available for off-platform devices. The register maps of the IPS peripherals are located on 16-Kbyte boundaries. Each IPS peripheral is allocated one 16K-byte block of the memory map, and is activated by one of the block enables from the bridge. Up to thirty-two 16-Kbyte external IPS peripherals may be implemented, occupying contiguous blocks of 16 Kbytes. Two global external IPS block enables are available for the remaining 63 Mbytes of address space to allow for customization and expansion of addressed peripheral devices. In addition, a single "non-global" block enable is also asserted whenever any of the thirty-two non-global block enables is asserted.

The bridge is responsible for indicating to IPS peripherals if an access is in supervisor or user mode. It may block user mode accesses to certain IPS peripherals or it may allow the individual IPS peripherals to determine if user mode accesses are allowed. In addition, peripherals may be designated as write-protected.

The bridge supports the notion of "trusted" masters for security purposes. Masters may be individually designated as trusted for reads, trusted for writes, or trusted for both reads and writes, as well as being forced to look as though all accesses from a master are in user-mode privilege level. Refer to Control Registers for more information.

All peripheral devices are expected to only require aligned accesses equal to or smaller in size than the peripheral size. An exception to this rule is supported for 32-bit peripherals to allow memory to be placed on the IPS.

14.2.1 AIPSTZ Registers

This section provides information on the registers of the AIPS bridge.

In i.MX53 there are 2 blocks named AIPSTZ-1 and AIPSTZ-2. The registers shown in the parathyroids below are identical in both blocks, unless otherwise specified.

14.2.2 Overview

There are eleven registers that control the AIPS bridge. All registers are 32-bit registers and can only be accessed in supervisor mode by specifically configured bus masters such as the core processor. Additionally, these registers must only be read from or written to by a 32-bit aligned access. The bridge registers are mapped into the PACR0 address space.

Two system clocks are required for read accesses and three system clocks are required for write accesses to the bridge registers.

14.2.3 Control Registers

The memory map for the AIPS program-visible registers is shown in the table below.

The MPROT fields of the AIPSTZ_MPR and the AIPSTZ_PACR and AIPSTZ_OPACR registers are 4 bits in width. Some bits may be reserved depending on device.

Table 14-1. AIPSTZ Register Memory Map

PACR0_ Offset	[31:28]	[27:24]	[23:20]	[19:16]	[15:12]	[11:8]	[7:4]	[3:0]

14.3 Register Descriptions

14.3.1 Master Privilege Registers

Each AIPSTZ_MPR specifies eight 4-bit fields defining the access privilege level associated with a bus master in the platform, as well as specifying whether write accesses from this master are bufferable.

The registers provide one field per bus master, where field 15 corresponds to master 15, field 14 to master 14,... field 0 to master 0 (typically the processor core). The master index allocation is shown in Table 14-4.

Table 14-2. MPROT Field

Bit	3	2	1	0
Field	MBW	(MTR)	(MTW)	MPL
Reset	*	*	*	*
Read/Write	Read/Write			

Table 14-3. Master Protection Field Descriptions

Name	Description	Settings
3 (MBW)	**Master Buffer Writes** - This bit determines whether the AIPSTZ is enabled to buffer writes from this master.	0 Write accesses from this master are not bufferable 1 Write accesses from this master are allowed to be buffered
2 (MTR)	**Master Trusted for Reads**- This bit determines whether the master is trusted for read accesses.	0 This master is not trusted for read accesses. 1 This master is trusted for read accesses.
1 (MTW)	**Master Trusted for Writes**- This bit determines whether the master is trusted for write accesses.	0 This master is not trusted for write accesses. 1 This master is trusted for write accesses.
0 (MPL)	**Master Privilege Level** - This bit determines how the privilege level of the master is determined.	0 Accesses from this master are forced to user-mode (**ips_supervisor_access** is forced to zero) regardless of the **hprot[1]** access attribute. 1 Accesses from this master are not forced to user-mode. The **hprot[1]** access attribute is used directly to determine **ips_supervisor_access**.

NOTE

The reset value is set to 0000_0000_0700_0000, which makes master 1 (ARM CORE) the only trusted master. Trusted software can change the settings after reset.

Table 14-4. Master index allocation

Master index	Master name	Comments
Master 0	All masters excluding ARM core, SDMA and CAAM	Share the same number allocation.
Master 0	Reserved	
Master 1	ARM CORE	
Master 2	SDMA, SATA, FEC, MLB	Share the same number allocation.
Master 2	CAAM	
Master 3	GPU3D, GPU2D, VPU, IPU	Share the same number allocation.
Master 3	SDMA	
Master 4-15	Reserved	
Master 4	USB	
Master 5	PATA	
Master 6	Reserved	
Master 7	SAHARA	
Master 8	SCC	
Master 9	RTIC	
Master 10	ESDCHV2-4	
Master 11	Reserved	
Master 12	DAP	
Master 13	ESDHCV2-1	
Master 14	ESDHCV2-2	
Master 15	ESDHCV3-3	

14.3.2 Off-Platform Peripheral Access Control Registers (AIPSTZ_OPACRs)

Each of the off-platform peripherals have an Off-platform Peripheral Access Control Register (AIPSTZ_OPACR) which defines the access levels supported by the given block.

Each AIPSTZ_PACR has the following format:

Table 14-5. AIPSTZ_OPACR Fields

Bit	3	2	1	0
Field	BW	SP	WP	TP
Reset	0	1	0	0
Read/Write	Read/Write			

Table 14-6. Peripheral Access Control Register Field Descriptions

Name	Description	Settings
3 **(BW)**	**Buffer Writes** - This bit determines whether write accesses to this peripheral are allowed to be buffered.[1]	0 Write accesses to this peripheral are not bufferable by the AIPSTZ. 1 Write accesses to this peripheral are allowed to be buffered by the AIPSTZ.
2 **(SP)**	**Supervisor Protect** - This bit determines whether the peripheral requires supervisor privilege level for access.	0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses. The master privilege level must indicate supervisor via the hprot[1] access attribute, and the MPROTx[MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated on the IPS bus.
1 (WP)	**Write Protect** - This bit determines whether the peripheral allows write accesses	0 This peripheral allows write accesses. 1 This peripheral is write protected. If a write access is attempted, the access is terminated with an error response and no peripheral access is initiated on the IPS bus.
0 **(TP)**	**Trusted Protect** - This bit determines whether the peripheral allows accesses from an untrusted master.	0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed. If an access is attempted by an untrusted master, the access is terminated with an error response and no peripheral access is initiated on the IPS bus.

1. Buffered writes are not available for AIPSTZ. This bit should be set to '0'.

The AIPSTZ_OPACR index allocation for AIPSTZ-1 and AIPSTZ-2 are shown in Table 14-7 and Table 14-8 respectively.

14.4 Functional Description

The AIPS bridge serves as a protocol translator between the AHB system bus and the IP bus. Support is provided for generating a pair of 32-bit IP bus accesses when targeted by a 64-bit system bus access, or a misaligned access which crosses a 32-bit boundary. No other bus-sizing access support is provided.

14.5 Access Protections

The AIPS bridge provides programmable access protections for both masters and peripherals. It allows the privilege level of a master to be overridden, forcing it to user-mode privilege, and allows masters to be designated as trusted or untrusted. Peripherals may require supervisor privilege level for access, may restrict access to a trusted master only, and may be write-protected.

14.6 Access Support

Aligned 64-bit accesses, aligned and misaligned word and half word accesses, as well as byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the IPS. Peripheral registers must not be misaligned, although no explicit checking is performed by the AIPS bridge.

The bridge will perform two IPS transfers for 64-bit accesses, word accesses with byte offsets of 1, 2, or 3, and for half word accesses with a byte offset of 3. All other accesses will be performed with a single IPS transfer.

Only aligned half word and byte accesses are supported for 16-bit peripherals. All other accesses types are unsupported, and results of such accesses are undefined. They are not terminated with an error response.

Only byte accesses are supported for 8-bit peripherals. All other accesses types are unsupported, and results of such accesses are undefined. They are not terminated with an error response.

14.7 Initialization Information

The AIPS bridge should be programmed before use. The following registers should be initialized: the Master Privilege Registers (AIPSTZ_MPRs), the Peripheral Access Control registers (AIPSTZ_PACRs), and the Off-platform Peripheral Access Control registers (AIPSTZ_OPACRs) described in 3.2 Control Registers.

Chapter 15
Asynchronous Sample Rate Converter (ASRC)

15.1 Introduction

The figure below is a system view of the connection between the ASRC block and other blocks.

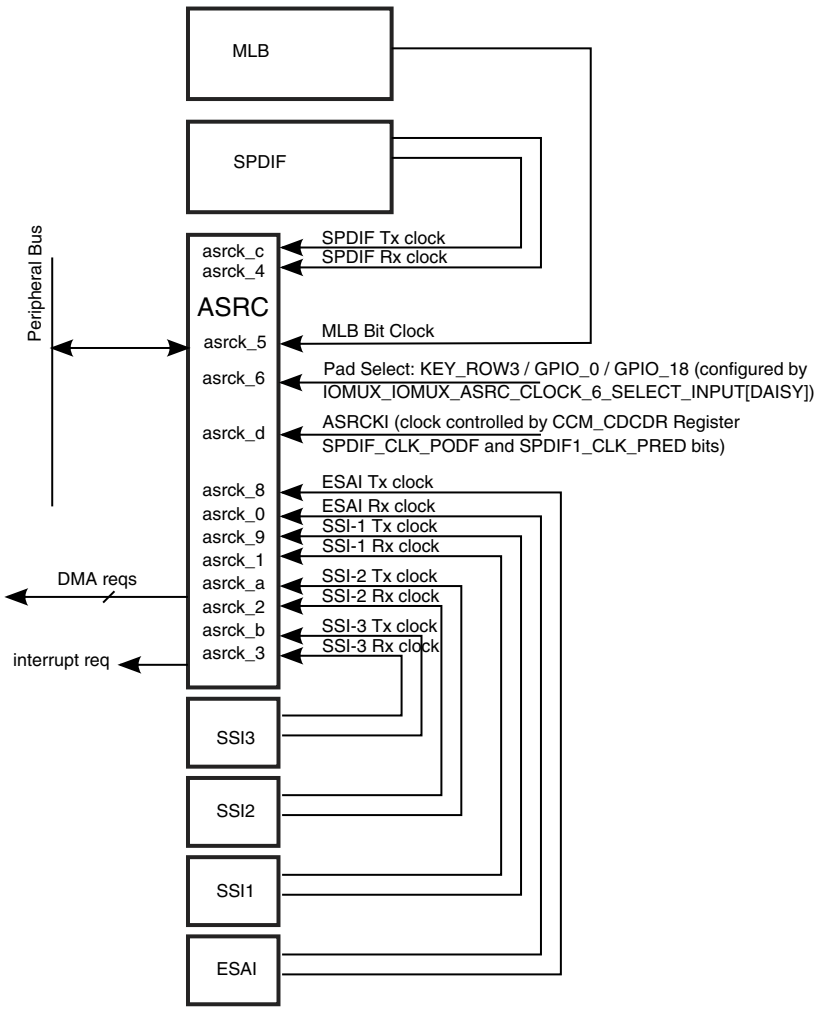

Figure 15-1. General System Overview

The following figure is the ASRC block diagram.

The red dotted line designates the ASRC block. Objects outside the dotted line represent SoC-level resources.

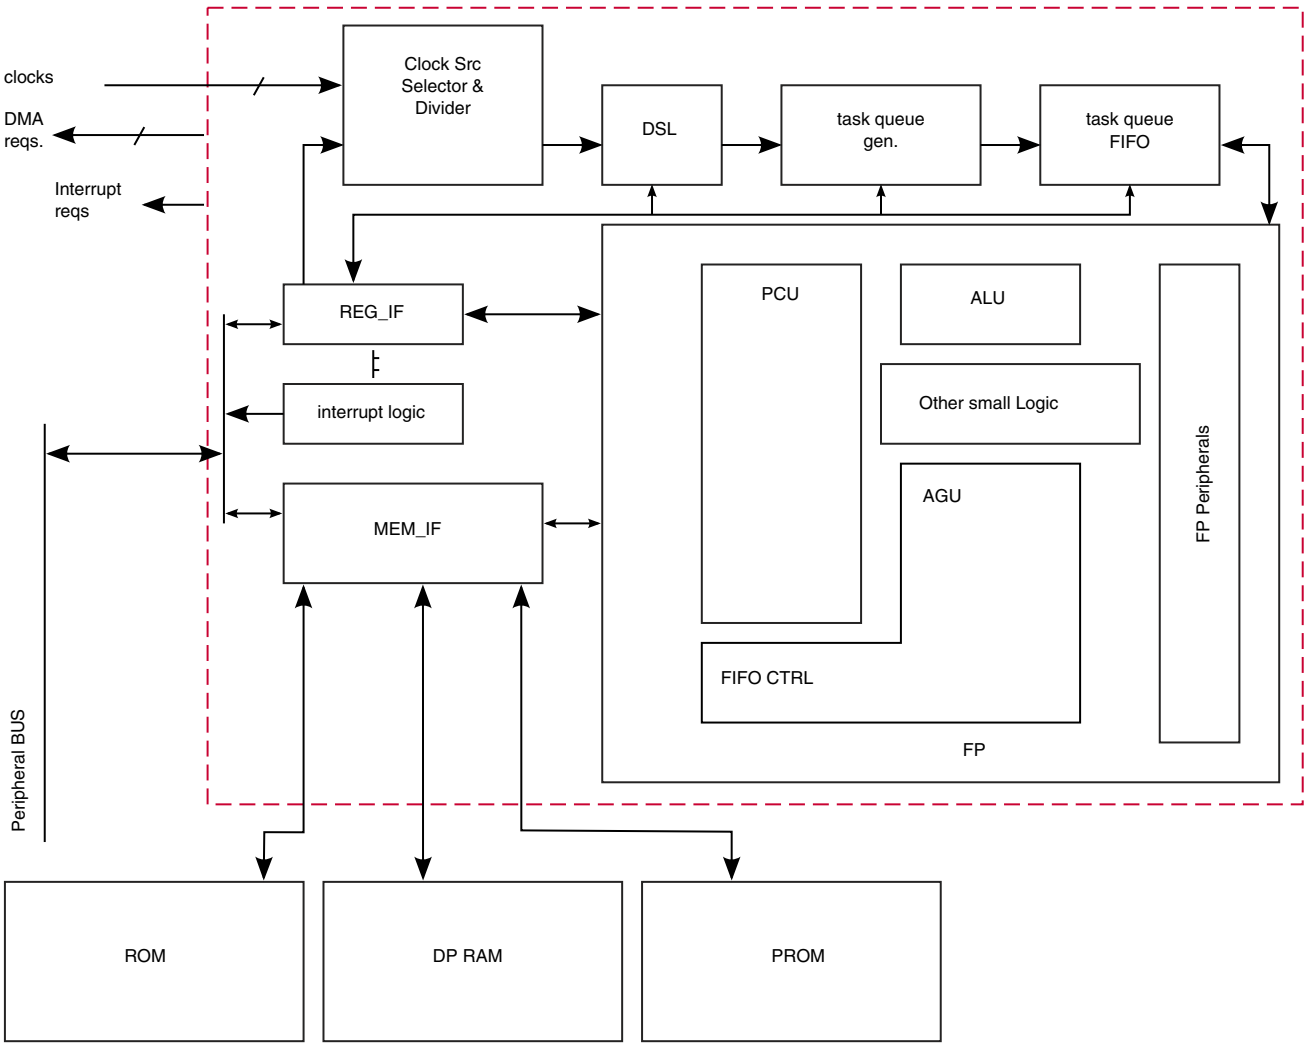

Figure 15-2. ASRC block diagram

15.1.1 Overview

The Asynchronous Sample Rate Converter (ASRC) converts the sampling rate of a signal associated with an input clock into a signal associated with a different output clock. The ASRC supports concurrent sample rate conversion of up to 10 channels of about -120dB THD+N. The ASRC supports up to three sampling rate pairs.

The incoming audio data to this chip may be received from various sources at different sampling rates. The outgoing audio data of this chip may have different sampling rates and it can also be associated with output clocks that are asynchronous to the input clocks.

The ASRC is implemented as a co-processor in hardware, with minimal ARM Platform intervention required.

15.1.2 Features

Table 15-1. ASRC Specifications

Parameters	Test Conditions	Minimum	Typical	Maximum	Unit
Channels Supported		01		10	
Pairs of Rate Conversion		1	-	3	
THD+N	120MHz < Fs_{ASRC}[2] <160MHz		-120		dB
Dynamic Range				144	dB
Settling Time			40		ms
Comment:					

1. When a pair has zero channels, the pair will be disabled, although the pair enable bit may be set in ASRCTR register.
2. Fs_{ASRC} is the processing clock of ASRC block.

Other Features:

- Support user-programmable threshold for the input/output FIFOs.
- Support flexible 8/16/24 bit width of input data, and 16/24 bit width of output data.
- Designed for rate conversion between 44.1kHz, 32kHz, 48kHz, 96kHz, and 192kHz. The useful signal bandwidth is below 24kHz.
- Other input sampling rates in the range of 8kHz to 200kHz is also supported, but possibly with less desirable bandwidth.
- Other output sampling rates in the range of 30kHz to 200kHz is also supported, but possibly with less desirable bandwidth.
- Automatic accommodation to slow variations in the incoming and outgoing sampling rates.
- Linear phase
- Tolerant to sample clock jitter

Clock/Data Connections

- The sampling rate clocks are directly connected to the ASRC block, the ratio estimation of the input clocks with output clocks are done in ASRC hardware.
- The clock signals come from the following blocks, for example:
  - ESAI, receiving bit clock and transmitting bit clock
  - SPDIF, receiving bit clock and transmitting bit clock
  - other audio peripherals etc.
- The exchange of audio data is done by the processor accessing ASRC block through registers defined on shared peripheral bus.

15.1.3 Modes of Operation

See the Programmable Registers section for a definition of the registers and parameters used in ASRC.

15.1.3.1 Data Transfer Schemes

15.1.3.1.1 Data Input Modes

The input mode for each of the three channel sets may be set independently. Three modes of supplying data to the ASRC input FIFOs are available:

- Polling
- Interrupt
- DMA

In all input-data transfer schemes, the ASRC fetches data from each enabled FIFO and processes the data sample-by-sample after each rising edge of the associated input sampling clock until the FIFO level reaches a threshold.

After the threshold is reached, the ASRC requests data. The FIFO size for each channel set is 64 samples and the threshold is set at 32 samples. The threshold can be defined by interface registers ASRMCRx, x=A, B or C.

If the ASRC attempts to fetch data from an empty FIFO, an error is generated and the ASRSTR_AOLE bit is set. If the ASRC overload interrupt is enabled (ASRIER_AOLIE bit is set), an interrupt is generated.

When writing data to an input FIFO, you must ensure that it is in a predefined sequence. For example, when writing to an input FIFO, the sequence should be: channel_0, channel_1, channel_2,..., channel_n, channel_0, channel_1, channel_2, etc. Here channel_n stands for the data intended for the n-th channel. The hardware will re-allocate each data to its corresponding channel FIFO. The channel being re-allocated is shown by ASRCCR_ACIA.

Mode 1 (Polling Mode)

Polling mode is the default mode following power-on or individual reset, and is selected by clearing the associated channel set A, B, or C data-input interrupt enable bit (ASRIER_ADIEx, where x=A, B or C). In this mode, data-input interrupts are disabled. When the FIFO level is below the threshold, the associated status bit (ASRSTR_AIDEx, where x=A, B, or C) is set. To clear the status bit, the FIFO must be written with enough data to raise the level above the threshold.

Mode 2 (Interrupt Mode)

The ASRC input FIFOs can also be serviced by interrupts. To enable interrupts, the corresponding data-input interrupt enable bits (ASRIER_ADIEx, where x=A, B, or C) should be set. An interrupt is automatically generated any time the input FIFO level is below the threshold. The interrupt is cleared when enough data is written to the FIFO to raise the level above the threshold.

Mode 3 (DMA Mode)

The ASRC input FIFOs can also be filled using DMA. In this mode, the data-input interrupt-enable bits (ASRIER_ADIEx, where x=A, B, or C) should be cleared and the DMA controller should be configured to use the ASRC as a request source.

15.1.3.1.2 Data Output Modes

The output mode for each of the 3 channel sets (A, B, and C) may be set independently.

Three modes of retrieving data from the ASRC output FIFOs are available:

- Polling
- Interrupt
- DMA

In all output-data transfer schemes, the ASRC places a processed sample into the associated output FIFO. After a threshold is reached, the ASRC requests that data be transferred out of the FIFO.

The FIFO size for each channel set is 64 samples and the threshold is set at 32 samples. The threshold can be defined by interface registers ASRMCRx, x=A, B or C.

If the ASRC attempts to place data into a FIFO that is already full, an error is generated and the ASRSTR_AOLE bit is set. If the ASRC overload interrupt is enabled (ASRIER_AOLIE bit is set), an interrupt is generated.

Each output FIFO is organized in the same channel order in which the associated input FIFO was written.

Two transfer modes are supported by Interface Block.

Mode 1 (Polling Mode)

The ASRC output FIFOs can be serviced by polling. In this mode, ensure the associated output-data interrupt enable bit (ASRIER_ADOEx, where x=A, B, or C) is cleared. In this mode, all output-data interrupts are disabled. Any time the output FIFO exceeds the threshold the associated status bit (ASRSTR_AODFx, where x=A, B, or C) is set. To clear the status bit, enough data must be read from the associated output FIFO to lower the level below the threshold.

Mode 2 (Interrupt Mode)

The ASRC output FIFOs may also be serviced using interrupts. To enable this mode, the corresponding output-data interrupt-enable bits (ASRIER_ADOEx, where x=A, B, or C) should be set. Any time the output FIFO level exceeds the threshold, an interrupt is automatically generated. The interrupt is cleared when enough data is read from the FIFO to lower the level below the threshold.

Mode 3 (DMA Mode)

The ASRC output FIFOs can also be read using DMA. In this mode, the output-data interrupt-enable bits (ASRIER_ADOEx, where x=A, B, or C) should be cleared and the DMA controller should be configured to use the ASRC as a request source.

15.1.3.2 Word Alignment Supported

15.1.3.2.1 Input Data Alignment Modes

The position and length of input data word to the input data FIFOs ASRDIA, ASRDIB, ASRDIC are programmable. The control bits are defined in ASRMCR1x {x=A, B, or C}. It supports the following modes.

Table 15-2. Input Data Alignment

Format	Bit Number																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15.2 Interrupts

ASRC has several interrupts events.

Priority	Description
lowest	ASRC Pair A input data needed
	ASRC Pair B input data needed
	ASRC Pair C input data needed
	ASRC Pair A output data ready
	ASRC Pair B output data ready
	ASRC Pair C output data ready
	ASRC Overload

15.3 DMA requests

ASRC has six DMA requests. They are directly connected to the lowest six status bits in the ASRSTR register.

Table 15-5. DMA requests

Type	Description
0	ASRC Pair A input data needed
1	ASRC Pair B input data needed
2	ASRC Pair C input data needed
3	ASRC Pair A output data ready
4	ASRC Pair B output data ready
5	ASRC Pair C output data ready

15.4 Functional Description

15.4.1 Algorithm Description

15.4.1.1 Signal Processing Flow

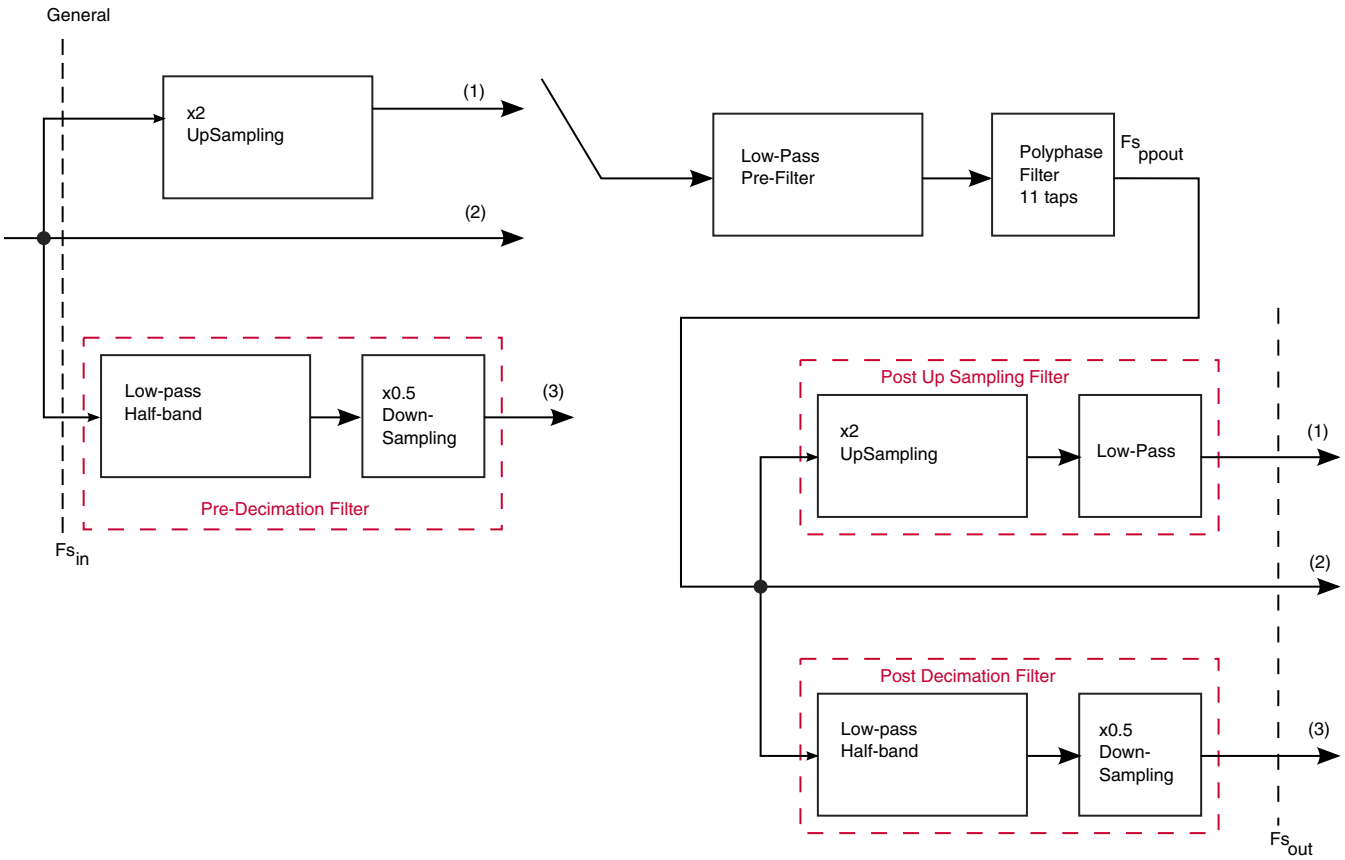

Figure 15-3. Signal processing configurations

The figure above shows the possible configurations of the ASRC. Each configuration consists of 2 to 4 stages.

- x2 up-sampling rate expander (zero insertion only) (Input Branch 1), or direct connection (Input Branch 2), or low-pass pre decimation filter (consisting of a low-pass half-band FIR filter with x0.5 downsampling rate decimator) (Input Branch 3),
- low-pass pre-filter, the low-pass bandwidth is at most 0.25 x Fs, where Fs is the sampling rate of the input signal to this low-pass pre-filter,
- polyphase filter,
- x2 post upsampling filter (consisting of a x2 up-sampling rate expander (zero insertion only) with low-pass half-band FIR filter) (Output Branch 1), or direct connection (Output Branch 2), or low-pass post decimation filter (consisting of a low-pass half-band FIR filter with x0.5 downsampling rate decimator) (Output Branch 3).

By flowing through different processing branches, and different setup of the pre-filter, this ASRC scheme can be used to handle different requirement of rate conversion.

Configuration (a): Input Branch 1+Output Branch 1: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/2$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}/2$.

Configuration (b): Input Branch 1+Output Branch 2: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/2$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}$.

Configuration (c): Input Branch 1+Output Branch 3: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/2$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = 2Fs_{out}$.

Configuration (d): Input Branch 2+Output Branch 1: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/4$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}/2$.

Configuration (e): Input Branch 2+Output Branch 2: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/4$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}$.

Configuration (f): Input Branch 2+Output Branch 3: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/4$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = 2Fs_{out}$.

Configuration (g): Input Branch 3+Output Branch 1: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/8$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}/2$.

Configuration (h): Input Branch 3+Output Branch 2: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/8$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}$.

Configuration (i): Input Branch 3+Output Branch 3: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/8$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = 2Fs_{out}$.

Comments:

In the {Pre_Proc, Post_Proc} pair, the meaning of the values are:

Pre_Proc:

- 0 --- Pre-processing Branch 1 as shown in Figure 15-3
- 1 --- Pre-processing Branch 2 as shown in Figure 15-3
- 2 --- Pre-processing Branch 3 as shown in Figure 15-3, decimation-by-2

Post_Proc:

- 0 --- Post-processing Branch 1 as shown in Figure 15-3
- 1 --- Post-processing Branch 2 as shown in Figure 15-3
- 2 --- Post-processing Branch 3 as shown in Figure 15-3

15.4.1.2 Operation of the Filter

15.4.1.2.1 Support of Physical Clocks

This design supports physical sampling clocks. The clocks can be provided by Sony/ Phillips digital interface (SPDIF), enhanced serial audio interface (ESAI), standard serial interface (media local bus controller (, Core master clock derivative as ASRCK1 .

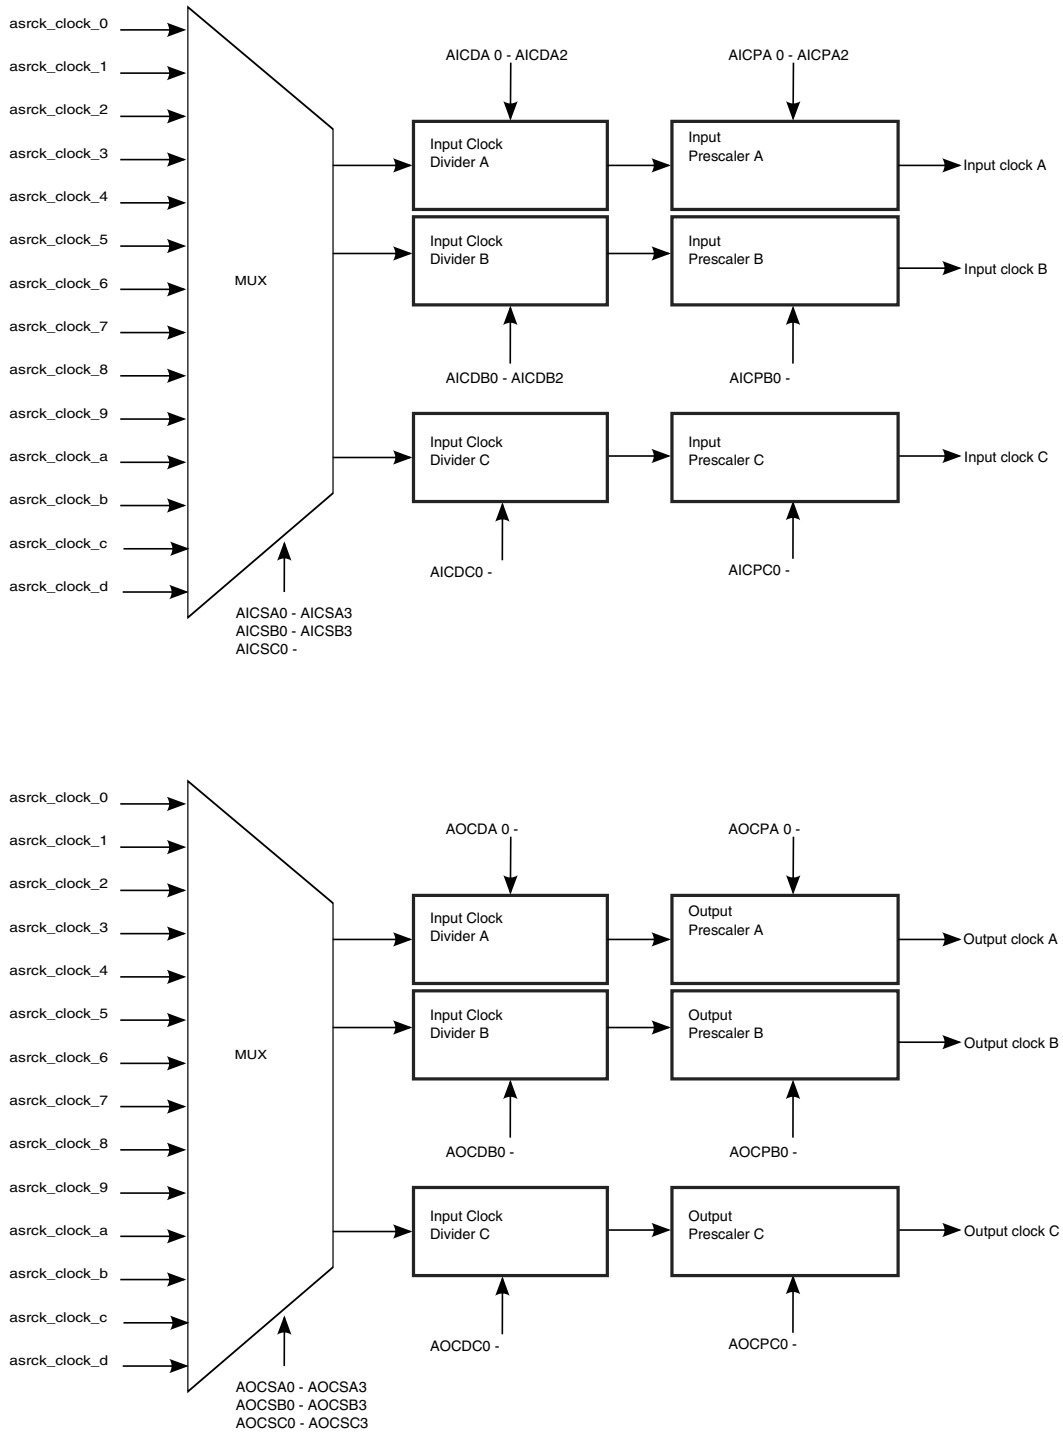

Figure 15-4. Clock Source Selector & Divider

Software can set the ASRC Clock Source Register (ASRCSR) and the Clock Divider Register to select the desired clock source and divide it to the needed sample rate clock for use by the ASRC. The clocks have the following restriction. If the prescaler is set to 1, the clock divider can only be set to 1 and the clock source must have a 50% duty cycle.

15.5 Startup Procedure

The following example shows the normal setup procedure for the ASRC block.

```
#include "asrc_common.h"

#include "stdio.h"

#include "soc_api.h"

errors
              }
           }
        reg32clrbit(ASRC_ASRCTR,0); // disable ASRC
   }
```

15.6 Programmable Registers

All useful registers are listed in the memory map below. The access of undefined registers will behave as normal registers.

All the interface registers are LSB aligned except the input FIFOs and the output FIFOs, and each register has only 24 effective bits.

The input FIFO and output FIFO word alignment can be defined using ASRMCR1{A,B,C} registers in 32-bit interface system.

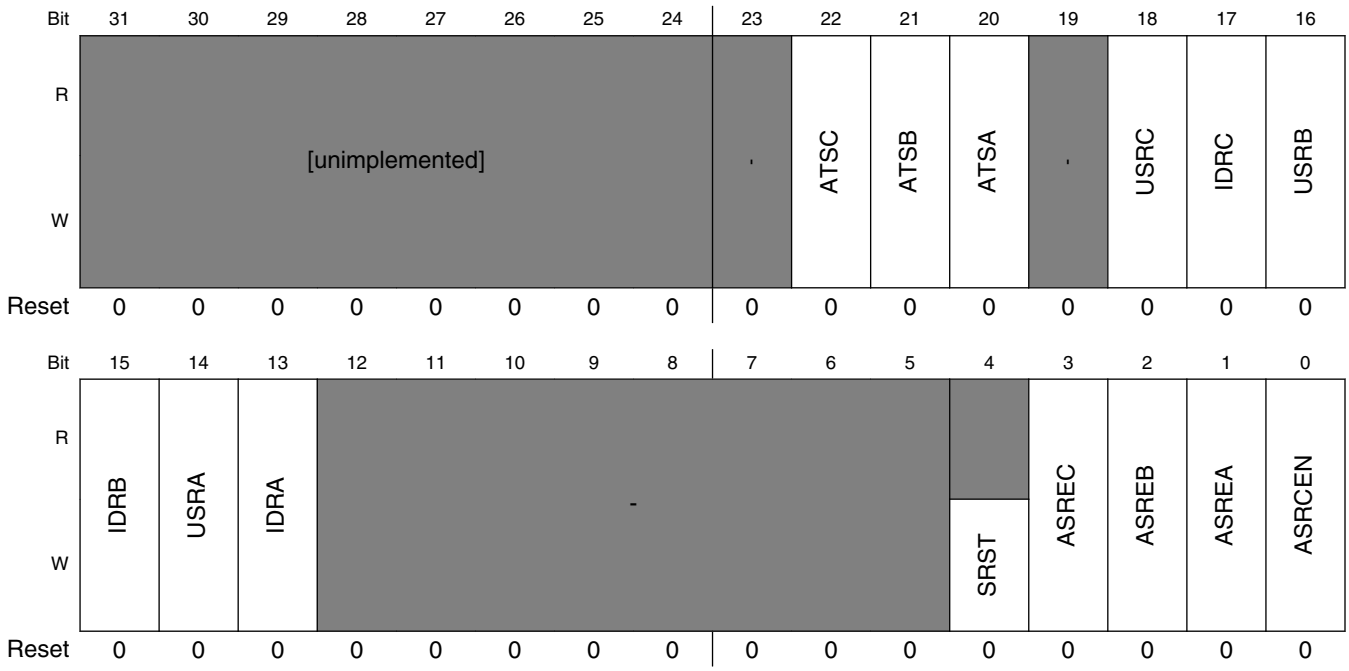
15.6.1 ASRC Control Register (ASRC_ASRCTR)

The ASRC control register (ASRCTR) is a 24-bit read/write register that controls the ASRC operations.

Address: ASRC_ASRCTR is 5002_C000h base + 0h offset = 5002_C000h



ASRC_ASRCTR field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23 -	Reserved. Should be written as zero for compatibility.
22 ATSC	ASRC Pair C Automatic Selection For Processing Options When this bit is 1, pair C will automatic update its pre-processing and post-processing options (ASRCFG: PREMODC, ASRCFG:POSTMODC see ASRC Misc Control Register 1 for Pair CASRC Filter Configuration Status Register) based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly (see ASRC Misc Control Register 1 for Pair CASRC 76kHz Period in terms of ASRC processing clock and ASRC Misc Control Register 1 for Pair CASRC 56kHz Period in terms of ASRC processing clock). When this bit is 0, the user is responsible for choosing the proper processing options for pair C. This bit should be disabled when {USRC, IDRC}={1,1}.
21 ATSB	ASRC Pair B Automatic Selection For Processing Options When this bit is 1, pair B will automatic update its pre-processing and post-processing options (ASRCFG: PREMODB, ASRCFG:POSTMODB see ASRC Misc Control Register 1 for Pair CASRC Filter Configuration Status Register) based on the frequencies it detected. To use this option, the two

Field	Description
	parameter registers(ASR76K and ASR56K) should be set correctly (see ASRC Misc Control Register 1 for Pair CASRC 76kHz Period in terms of ASRC processing clock and ASRC Misc Control Register 1 for Pair CASRC 56kHz Period in terms of ASRC processing clock). When this bit is 0, the user is responsible for choosing the proper processing options for pair B. This bit should be disabled when {USRB, IDRB}={1,1}.
20 ATSA	ASRC Pair A Automatic Selection For Processing Options When this bit is 1, pair A will automatic update its pre-processing and post-processing options (ASRCFG: PREMODA, ASRCFG:POSTMODA see ASRC Misc Control Register 1 for Pair CASRC Filter Configuration Status Register) based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly (see ASRC Misc Control Register 1 for Pair CASRC 76kHz Period in terms of ASRC processing clock and ASRC Misc Control Register 1 for Pair CASRC 56kHz Period in terms of ASRC processing clock). When this bit is 0, the user is responsible for choosing the proper processing options for pair A. This bit should be disabled when {USRA, IDRA}={1,1}.
19 -	Reserved. Should be written as zero for compatibility.
18 USRC	Use Ratio for Pair C Use ratio as the input to ASRC. This bit is used in conjunction with IDRC control bit.
17 IDRC	Use Ideal Ratio for Pair C When USRC=0, this bit has no usage. When USRC=1 and IDRC=0, ASRC internal measured ratio will be used. When USRC=1 and IDRC=1, the idea ratio from the interface register ASRIDRHC, ASRIDRLC will be used. It is suggested to manually set ASRCFG:POSTMODC, ASRCFG:PREMODC according to Table 15-6 in this case.
16 USRB	Use Ratio for Pair B Use ratio as the input to ASRC. This bit is used in conjunction with IDRB control bit.
15 IDRB	Use Ideal Ratio for Pair B When USRB=0, this bit has no usage. When USRB=1 and IDRB=0, ASRC internal measured ratio will be used. When USRB=1 and IDRB=1, the idea ratio from the interface register ASRIDRHB, ASRIDRLB will be used.It is suggested to manually set ASRCFG:POSTMODB, ASRCFG:PREMODB according to Table 15-6 in this case.
14 USRA	Use Ratio for Pair A Use ratio as the input to ASRC. This bit is used in conjunction with IDRA control bit.
13 IDRA	Use Ideal Ratio for Pair A When USRA=0, this bit has no usage. When USRA=1 and IDRA=0, ASRC internal measured ratio will be used. When USRA=1 and IDRA=1, the idea ratio from the interface register ASRIDRHA, ASRIDRLA will be used. It is suggested to manually set ASRCFG:POSTMODA, ASRCFG:PREMODA according to Table 15-6 in this case.
12–5 -	Reserved. Should be written as zero for compatibility.

Table continues on the next page...

ASRC_ASRCTR field descriptions (continued)

Field	Description
4 SRST	Software Reset This bit is self-clear bit. Once it is been written as 1, it will generate a software reset signal inside ASRC. After 9 cycles of the ASRC processing clock, this reset process will stop, and this bit will be cleared automatically.
3 ASREC	ASRC Enable C Enable the operation of the conversion C of ASRC. When ASREC is cleared, operation of conversion C is disabled.
2 ASREB	ASRC Enable B Enable the operation of the conversion B of ASRC. When ASREB is cleared, operation of conversion B is disabled.
1 ASREA	ASRC Enable A Enable the operation of the conversion A of ASRC. When ASREA is cleared, operation of conversion A is disabled.
0 ASRCEN	ASRC Enable Enable the operation of ASRC.

15.6.2 ASRC Interrupt Enable Register (ASRC_ASRIER)

0 ADIEA	Data Input A Interrupt Enable Enables the data input A Interrupt. 1 interrupt enabled 0 interrupt disabled

15.6.3 ASRC Channel Number Configuration Register (ASRC_ASRCNCR)

The ASRC channel number configuration register (ASRCNCR) is a 24-bit read/write register that sets the number of channels used by each ASRC conversion pair.

There are 10 channels available for distribution among 3 conversion pairs, they are ordered as 0,1,...,9. The bottom [0, ANCA-1] channels are used for pair A, the top [10-ANCC, 9] channels are used for pair C, and the [ANCA, ANCA+ANCB-1] channels are allocated for pair B. In case that ANCA=0, then the [0, ANCB-1] channels are assigned for pair B.

Address: ASRC_ASRCNCR is 5002_C000h base + Ch offset = 5002_C00Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

In this case, POSTMODA[1-0] have no use.
5–0 -	Reserved. Should be written as zero for compatibility.

15.6.5 ASRC Clock Source Register (ASRC_ASRCSR)

The ASRC clock source register (ASRCSR) is a 24-bit read/write register that controls the sources of the input and output clocks of the ASRC.

The clock connections are shown in ASRC Misc Control Register 1 for Pair CASRC Clock Source Register, also shown in Figure 15-1 :

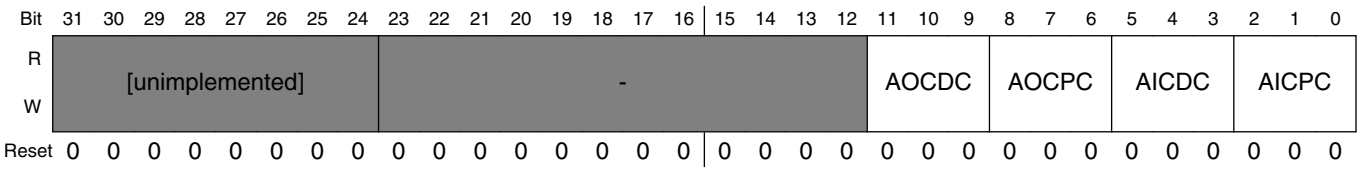
ASRC_ASRCDR1 field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–21 AOCDB	Output Clock Divider B Specify the divide ratio of the output clock divider B. The divide ratio may range from 1 to 8 (AOCDB[2:0] = 000 to 111).
20–18 AOCPB	Output Clock Prescaler B Specify the prescaling factor of the output prescaler B. The prescaling ratio may be any power of 2 from 1 to 128.
17–15 AOCDA	Output Clock Divider A Specify the divide ratio of the output clock divider A. The divide ratio may range from 1 to 8 (AOCDA[2:0] = 000 to 111).
14–12 AOCPA	Output Clock Prescaler A Specify the prescaling factor of the output prescaler A. The prescaling ratio may be any power of 2 from 1 to 128.
11–9 AICDB	Input Clock Divider B Specify the divide ratio of the input clock divider B. The divide ratio may range from 1 to 8 (AICDB[2:0] = 000 to 111).
8–6 AICPB	Input Clock Prescaler B Specify the prescaling factor of the input prescaler B. The prescaling ratio may be any power of 2 from 1 to 128.
5–3 AICDA	Input Clock Divider A Specify the divide ratio of the input clock divider A. The divide ratio may range from 1 to 8 (AICDA[2:0] = 000 to 111).
2–0 AICPA	Input Clock Prescaler A Specify the prescaling factor of the input prescaler A. The prescaling ratio may be any power of 2 from 1 to 128.

15.6.7 ASRC Clock Divider Register 2 (ASRC_ASRCDR2)

The ASRC clock divider register (ASRCDR2) is a two 24-bit read/write register that controls the division factors of the ASRC input and output clock sources.

Address: ASRC_ASRCDR2 is 5002_C000h base + 1Ch offset = 5002_C01Ch



ASRC_ASRCDR2 field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–12 -	Reserved. Should be written as zero for compatibility.
11–9 AOCDC	Output Clock Divider C Specify the divide ratio of the output clock divider C. The divide ratio may range from 1 to 8 (AOCDC[2:0] = 000 to 111).
8–6 AOCPC	Output Clock Prescaler C Specify the prescaling factor of the output prescaler C. The prescaling ratio may be any power of 2 from 1 to 128.
5–3 AICDC	Input Clock Divider C Specify the divide ratio of the input clock divider C. The divide ratio may range from 1 to 8 (AICDC[2:0] = 000 to 111).
2–0 AICPC	Input Clock Prescaler C Specify the prescaling factor of the input prescaler C. The prescaling ratio may be any power of 2 from 1 to 128.

15.6.8 ASRC Status Register (ASRC_ASRSTR)

The ASRC status register (ASRSTR) is a 24-bit read-write register used by the processor core to examine the status of the ASRC block and clear the overload interrupt request and AOLE flag bit. Read the status register will return the current state of ASRC.

Address: ASRC_ASRSTR is 5002_C000h base + 20h offset = 5002_C020h

ASRC_ASRSTR field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–22 -	Reserved. Should be written as zero for compatibility.
21 DSLCNT	DSL Counter Input to FIFO ready When set, this bit indicates that new DSL counter information is stored in the internal ASRC FIFO.When clear, this bit indicates that new DSL counter information is in the process of storage into the internal ASRC FIFO. When ASRIER:AFPWE=1, the rising edge of this signal will propose an interrupt request. Writing any value with this bit set will clear the interrupt request proposed by the rising edge of this bit.
20 ATQOL	Task Queue FIFO overload When set, this bit indicates that task queue FIFO logic is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.

Table continues on the next page...

ASRC_ASRSTR field descriptions (continued)

Field	Description
19 AOOLC	Pair C Output Task Overload When set, this bit indicates that pair C output task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
18 AOOLB	Pair B Output Task Overload When set, this bit indicates that pair B output task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
17 AOOLA	Pair A Output Task Overload When set, this bit indicates that pair A output task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
16 AIOLC	Pair C Input Task Overload When set, this bit indicates that pair C input task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
15 AIOLB	Pair B Input Task Overload When set, this bit indicates that pair B input task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
14 AIOLA	Pair A Input Task Overload When set, this bit indicates that pair A input task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
13 AODOC	Output Data Buffer C has overflowed When set, this bit indicates that output data buffer C has overflowed. When clear, this bit indicates that output data buffer C has not overflowed
12 AODOB	Output Data Buffer B has overflowed When set, this bit indicates that output data buffer B has overflowed. When clear, this bit indicates that output data buffer B has not overflowed
11 AODOA	Output Data Buffer A has overflowed When set, this bit indicates that output data buffer A has overflowed. When clear, this bit indicates that output data buffer A has not overflowed
10 AIDUC	Input Data Buffer C has underflowed When set, this bit indicates that input data buffer C has underflowed. When clear, this bit indicates that input data buffer C has not underflowed.
9 AIDUB	Input Data Buffer B has underflowed When set, this bit indicates that input data buffer B has underflowed. When clear, this bit indicates that input data buffer B has not underflowed.

Table continues on the next page...

ASRC_ASRSTR field descriptions (continued)

Field	Description
8 AIDUA	Input Data Buffer A has underflowed When set, this bit indicates that input data buffer A has underflowed. When clear, this bit indicates that input data buffer A has not underflowed.
7 FPWT	FP is in wait states This bit is for debug only. When set, this bit indicates that ASRC is in wait states. When clear, this bit indicates that ASRC is not in wait states. If ASRCTR:AFPWE=1 and ASRCTR:ASDBG=1, an interrupt will be proposed when this bit is set.
6 AOLE	Overload Error Flag When set, this bit indicates that the task rate is too high for the ASRC to handle. The reasons for overload may be: - too high input clock frequency, - too high output clock frequency, - incorrect selection of the pre-filter, - low ASRC processing clock, - too many channels, - underrun, - or any combination of the reasons above. Since the ASRC uses the same hardware resources to perform various tasks, the real reason for the overload is not straight forward, and it should be carefully analyzed by the programmer. If ASRCTR:AOLIE=1, an interrupt will be proposed when this bit is set. Write any value with this bit set as one into the status register will clear this bit and the interrupt request proposed by this bit.
5 AODFC	Number of data in Output Data Buffer C is greater than threshold When set, this bit indicates that number of data already existing in ASRDORC is greater than threshold and the processor can read data from ASRDORC. When AODFC is set, the ASRC generates data output C interrupt request to the processor, if enabled (that is, ASRCTR:ADOEC = 1). A DMA request is always generated when the AODFC bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
4 AODFB	Number of data in Output Data Buffer B is greater than threshold When set, this bit indicates that number of data already existing in ASRDORB is greater than threshold and the processor can read data from ASRDORB. When AODFB is set, the ASRC generates data output B interrupt request to the processor, if enabled (that is, ASRCTR:ADOEB = 1). A DMA request is always generated when the AODFB bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
3 AODFA	Number of data in Output Data Buffer A is greater than threshold When set, this bit indicates that number of data already existing in ASRDORA is greater than threshold and the processor can read data from ASRDORA. When AODFA is set, the ASRC generates data output A interrupt request to the processor, if enabled (that is, ASRCTR:ADOEA = 1). A DMA request is always generated when the AODFA bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.

Table continues on the next page...

ASRC_ASRSTR field descriptions (continued)

Field	Description
2 AIDEC	Number of data in Input Data Buffer C is less than threshold When set, this bit indicates that number of data still available in ASRDIRC is less than threshold and the processor can write data to ASRDIRC. When AIDEC is set, the ASRC generates data input C interrupt request to the processor, if enabled (that is, ASRCTR:ADIEC = 1). A DMA request is always generated when the AIDEC bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
1 AIDEB	Number of data in Input Data Buffer B is less than threshold When set, this bit indicates that number of data still available in ASRDIRB is less than threshold and the processor can write data to ASRDIRB. When AIDEB is set, the ASRC generates data input B interrupt request to the processor, if enabled (that is, ASRCTR:ADIEB = 1). A DMA request is always generated when the AIDEB bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
0 AIDEA	Number of data in Input Data Buffer A is less than threshold When set, this bit indicates that number of data still available in ASRDIRA is less than threshold and the processor can write data to ASRDIRA. When AIDEA is set, the ASRC generates data input A interrupt request to the processor, if enabled (that is, ASRCTR:ADIEA = 1). A DMA request is always generated when the AIDEA bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.

15.6.9 ASRC Parameter Register n (ASRC_ASRPMn*n*)

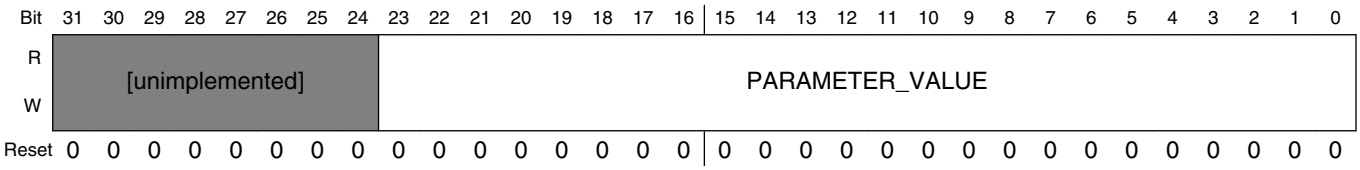
Parameter registers determine the performance of ASRC.

The parameter registers must be initialized by software before ASRC is enabled. Recommended values are given in ASRC Misc Control Register 1 for Pair CASRC Parameter Register n below,

Table 15-18. ASRC Parameter Registers (ASRPM1~ASRPM5)

Register	Offset	Access	Reset Value	Recommend Value
asrcpm1	0x40	R/W	0x00_0000	0x7fffff
asrcpm2	0x44	R/W	0x00_0000	0x255555
asrcpm3	0x48	R/W	0x00_0000	0xff7280
asrcpm4	0x4C	R/W	0x00_0000	0xff7280
asrcpm5	0x50	R/W	0x00_0000	0xff7280

Addresses: ASRC_ASRPMn1 is 5002_C000h base + 40h offset = 5002_C040h
ASRC_ASRPMn2 is 5002_C000h base + 44h offset = 5002_C044h
ASRC_ASRPMn3 is 5002_C000h base + 48h offset = 5002_C048h
ASRC_ASRPMn4 is 5002_C000h base + 4Ch offset = 5002_C04Ch
ASRC_ASRPMn5 is 5002_C000h base + 50h offset = 5002_C050h



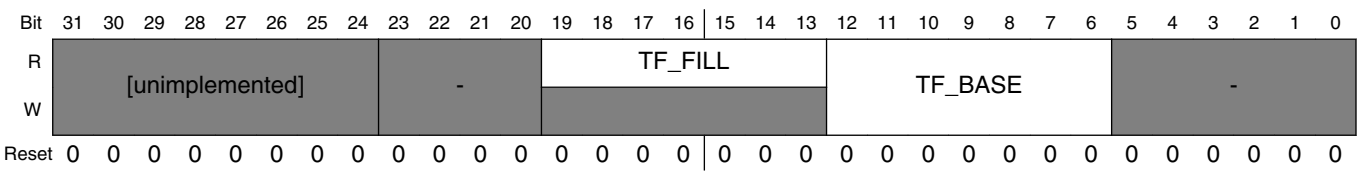
ASRC_ASRPMn*n* field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 PARAMETER_ VALUE	See recommended values table.

15.6.10 ASRC ASRC Task Queue FIFO Register 1 (ASRC_ASRTFR1)

The register defines and shows the parameters for ASRC inner task queue FIFOs.

Address: ASRC_ASRTFR1 is 5002_C000h base + 54h offset = 5002_C054h



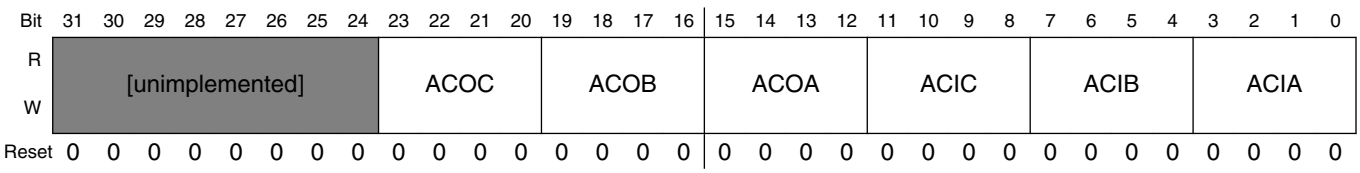
ASRC_ASRTFR1 field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–20 -	Reserved. Should be written as zero for compatibility.
19–13 TF_FILL	Current number of entries in task queue FIFO.
12–6 TF_BASE	Base address for task queue FIFO. Set to 0x7C.
5–0 -	Reserved. Should be written as zero for compatibility.

15.6.11 ASRC Channel Counter Register (ASRC_ASRCCR)

The ASRC channel counter register (ASRCCR) is a 24-bit read/write register that sets and reflects the current specific input/output FIFO being accessed through shared peripheral bus for each ASRC conversion pair.

Address: ASRC_ASRCCR is 5002_C000h base + 5Ch offset = 5002_C05Ch



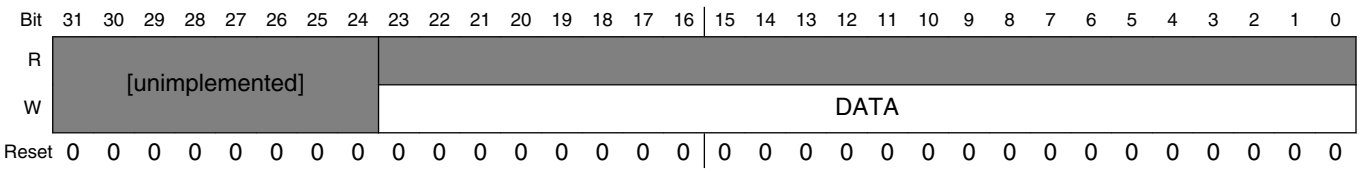
ASRC_ASRCCR field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–20 ACOC	The channel counter for Pair C's output FIFO These bits stand for the current channel being accessed through shared peripheral bus for Pair C's output FIFO's usage. The value can be any value between [0, ANCC-1]
19–16 ACOB	The channel counter for Pair B's output FIFO These bits stand for the current channel being accessed through shared peripheral bus for Pair B's output FIFO's usage. The value can be any value between [0, ANCB-1]
15–12 ACOA	The channel counter for Pair A's output FIFO These bits stand for the current channel being accessed through shared peripheral bus for Pair A's output FIFO's usage. The value can be any value between [0, ANCA-1]
11–8 ACIC	The channel counter for Pair C's input FIFO These bits stand for the current channel being accessed through shared peripheral bus for Pair C's input FIFO's usage. The value can be any value between [0, ANCC-1]
7–4 ACIB	The channel counter for Pair B's input FIFO These bits stand for the current channel being accessed through shared peripheral bus for Pair B's input FIFO's usage. The value can be any value between [0, ANCB-1]
3–0 ACIA	The channel counter for Pair A's input FIFO These bits stand for the current channel being accessed through shared peripheral bus for Pair A's input FIFO's usage. The value can be any value between [0, ANCA-1]

15.6.12 ASRC Data Input Register for Pair *x* (ASRC_ASRDI*n*)

These registers are the interface registers for the audio data input of pair A,B,C respectively. They are backed by FIFOs.

Addresses: ASRC_ASRDIA is 5002_C000h base + 60h offset = 5002_C060h
ASRC_ASRDIB is 5002_C000h base + 68h offset = 5002_C068h
ASRC_ASRDIC is 5002_C000h base + 70h offset = 5002_C070h



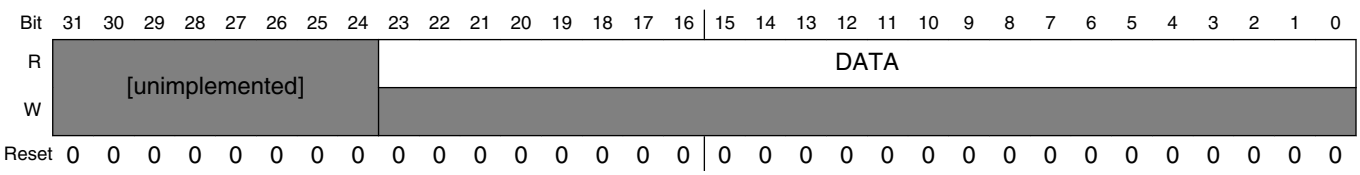
ASRC_ASRDI*n* field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 DATA	Audio data input

15.6.13 ASRC Data Output Register for Pair *x* (ASRC_ASRDO*n*)

These registers are the interface registers for the audio data output of pair A,B,C respectively. They are backed by FIFOs.

Addresses: ASRC_ASRDOA is 5002_C000h base + 64h offset = 5002_C064h
ASRC_ASRDOB is 5002_C000h base + 6Ch offset = 5002_C06Ch
ASRC_ASRDOC is 5002_C000h base + 74h offset = 5002_C074h



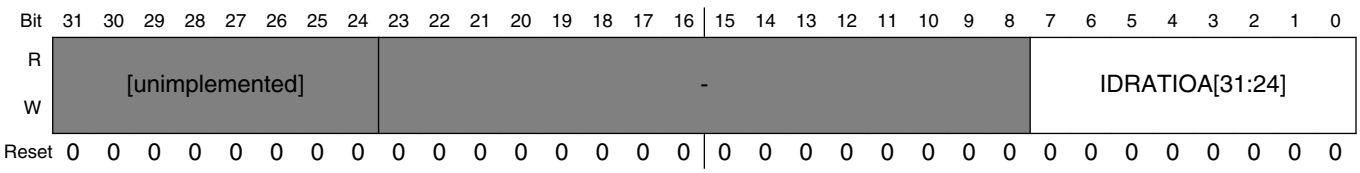
ASRC_ASRDO*n* field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 DATA	Audio data output

15.6.14 ASRC Ideal Ratio for Pair A-High Part (ASRC_ASRIDRHA)

The ideal ratio registers (ASRIDRHA, ASRIDRLA) hold the ratio value IDRATIOA. IDRATIOA = FsinA/FsoutA = TsoutA/TsinA is a 32-bit fixed point value with 26 fractional bits. This value is only useful when ASRCTR:{USRA, IDRA}=2'b11.

Address: ASRC_ASRIDRHA is 5002_C000h base + 80h offset = 5002_C080h



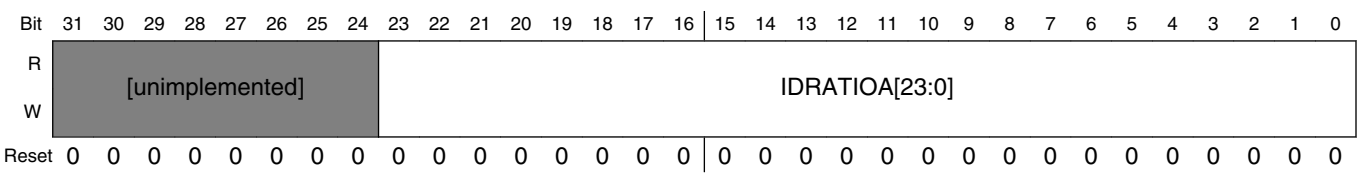
ASRC_ASRIDRHA field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–8 -	Reserved
7–0 IDRATIOA[31:24]	IDRATIOA[31:24]. High part of ideal ratio value for pair A

15.6.15 ASRC Ideal Ratio for Pair A -Low Part (ASRC_ASRIDRLA)

The ideal ratio registers (ASRIDRHA, ASRIDRLA) hold the ratio value IDRATIOA. IDRATIOA = FsinA/FsoutA = TsoutA/TsinA is a 32-bit fixed point value with 26 fractional bits. This value is only useful when ASRCTR:{USRA, IDRA}=2'b11.

Address: ASRC_ASRIDRLA is 5002_C000h base + 84h offset = 5002_C084h



ASRC_ASRIDRLA field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 IDRATIOA[23:0]	IDRATIOA[23:0]. Low part of ideal ratio value for pair A

15.6.16 ASRC Ideal Ratio for Pair B-High Part (ASRC_ASRIDRHB)

The ideal ratio registers (ASRIDRHB, ASRIDRLB) hold the ratio value IDRATIOB. IDRATIOB = FsinB/FsoutB = TsoutB/TsinB is a 32-bit fixed point value with 26 fractional bits. This value is only useful when ASRCTR:{USRB, IDRB}=2'b11.

Address: ASRC_ASRIDRHB is 5002_C000h base + 88h offset = 5002_C088h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

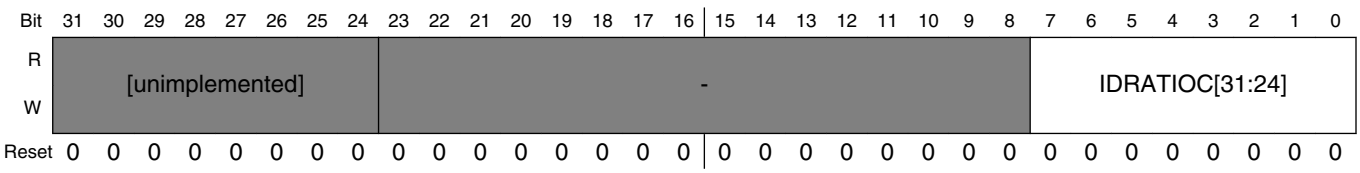
ASRC_ASRIDRLB field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 IDRATIOB[23:0]	IDRATIOB[23:0]. Low part of ideal ratio value for pair B.

15.6.18 ASRC Ideal Ratio for Pair C-High Part (ASRC_ASRIDRHC)

The ideal ratio registers (ASRIDRHC, ASRIDRLC) hold the ratio value IDRATIOC. IDRATIOC = FsinC/FsoutC = TsoutC/TsinC is a 32-bit fixed point value with 26 fractional bits. This value is only useful when ASRCTR:{USRC, IDRC}=2'b11.

Address: ASRC_ASRIDRHC is 5002_C000h base + 90h offset = 5002_C090h



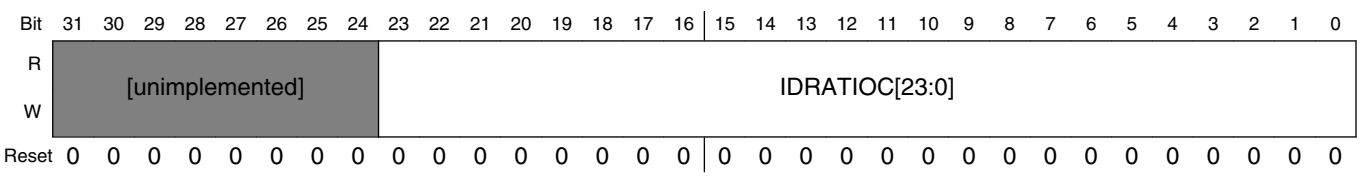
ASRC_ASRIDRHC field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–8 -	Reserved
7–0 IDRATIOC[31:24]	IDRATIOC[31:24]. High part of ideal ratio value for pair C.

15.6.19 ASRC Ideal Ratio for Pair C-Low Part (ASRC_ASRIDRLC)

The ideal ratio registers (ASRIDRHC, ASRIDRLC) hold the ratio value IDRATIOC. IDRATIOC = FsinC/FsoutC = TsoutC/TsinC is a 32-bit fixed point value with 26 fractional bits. This value is only useful when ASRCTR:{USRC, IDRC}=2'b11.

Address: ASRC_ASRIDRLC is 5002_C000h base + 94h offset = 5002_C094h



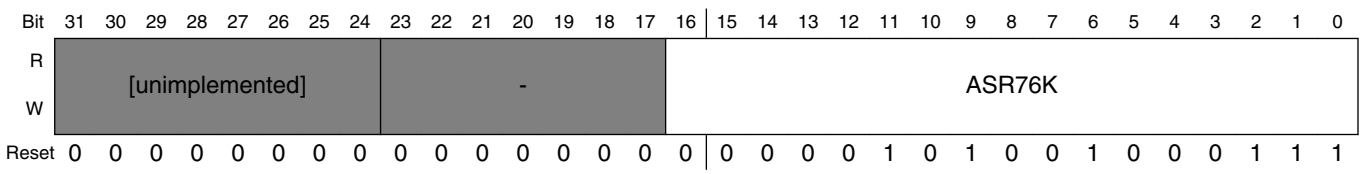
ASRC_ASRIDRLC field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–0 IDRATIOC[23:0]	IDRATIOC[23:0]. Low part of ideal ratio value for pair C.

15.6.20 ASRC 76kHz Period in terms of ASRC processing clock (ASRC_ASR76K)

The register (ASR76K) holds the period of the 76kHz sampling clock in terms of the ASRC processing clock with frequency FsASRC. ASR76K = FsASRC/Fs76k. Reset value is 0x0A47 which assumes that FsASRC=200MHz. This register is used to help the ASRC internal logic to decide the pre-processing and the post-processing options automatically (see ASRC Misc Control Register 1 for Pair CASRC Control Register and ASRC Misc Control Register 1 for Pair CASRC Filter Configuration Status Register). In a system when FsASRC=133MHz, the value should be assigned explicitly as 0x06D6 in user application code.

Address: ASRC_ASR76K is 5002_C000h base + 98h offset = 5002_C098h



ASRC_ASR76K field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23–17 -	Reserved
16–0 ASR76K	Value for the period of the 76kHz sampling clock.

15.6.21 ASRC 56kHz Period in terms of ASRC processing clock (ASRC_ASR56K)

The register (ASR56K) holds the period of the 56kHz sampling clock in terms of the ASRC processing clock with frequency FsASRC. ASR56K = FsASRC/Fs56k. Reset value is 0x0DF3 which assumes that FsASRC=200MHz. This register is used to help the ASRC internal logic to decide the pre-processing and the post-processing options automatically (see ASRC Misc Control Register 1 for Pair CASRC Control Register and ASRC Misc Control Register 1 for Pair CASRC Filter Configuration Status Register). In a system when FsASRC=133MHz, the value should be assigned explicitly as 0x0947 in user application code.

Address: ASRC_ASR56K is 5002_C000h base + 9Ch offset = 5002_C09Ch

ASRC_ASRMCRA field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23 ZEROBUFA	Initialize buf of Pair A when pair A is enabled. Always clear option. This bit is used to control whether the buffer is to be zeroized when pair A is enabled. 1 Don't zeroize the buffer 0 Zeroize the buffer
22 EXTTHRSHA	Use external thresholds for FIFO control of Pair A This bit will determine whether the FIFO thresholds externally defined in this register is used to control ASRC internal FIFO logic for pair A. 1 Use external defined thresholds. 0 Use default thresholds.
21 BUFSTALLA	Stall Pair A conversion in case of Buffer Near Empty/Full Condition This bit will determine whether the near empty/full FIFO condition will stall the rate conversion for pair A. This option can only work when external ratio is used. Near empty condition is the condition when input FIFO has less than 4 useful samples per channel. Near full condition is the condition when the output FIFO has less than 4 vacant sample words to fill per channel. 1 Stall Pair A conversion in case of near empty/full FIFO conditions. 0 Don't stall Pair A conversion even in case of near empty/full FIFO conditions.

Table continues on the next page...

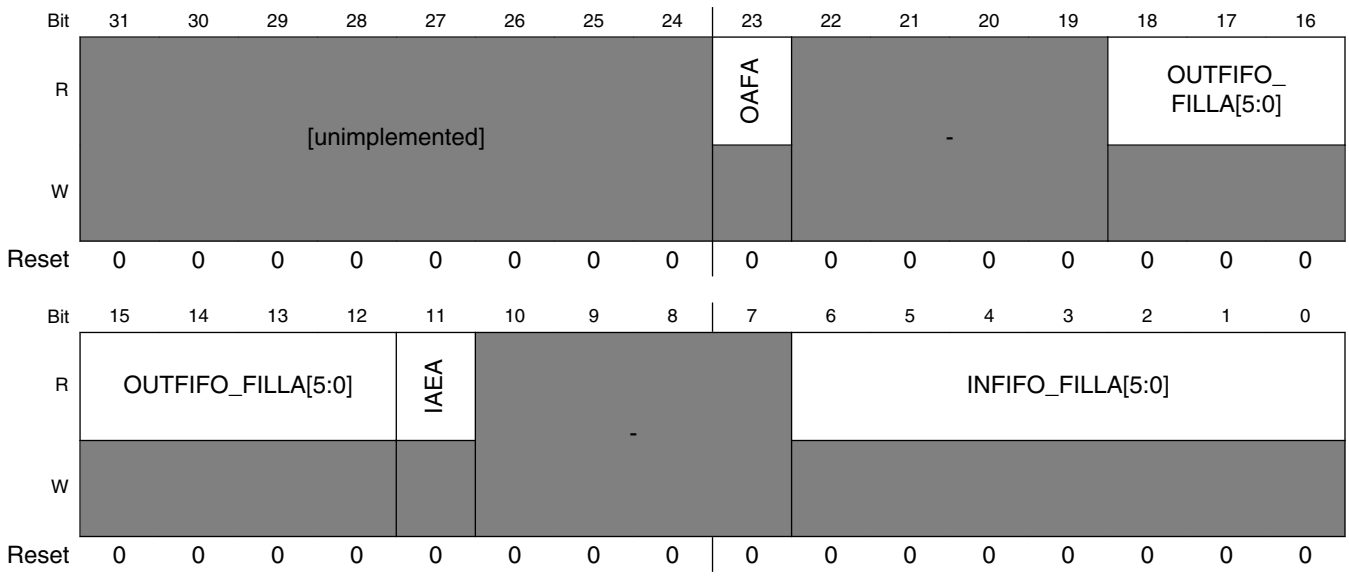
ASRC_ASRMCRA field descriptions (continued)

Field	Description
20 BYPASSPOLYA	Bypass Polyphase Filtering for Pair A This bit will determine whether the polyphase filtering part of Pair A conversion will be bypassed. 1 Bypass polyphase filtering. 0 Don't bypass polyphase filtering.
19–18 -	Reserved. Should be written as zero for future compatibility.
17–12 OUTFIFO_ THRESHOLDA[5:0]	The threshold for Pair A's output FIFO per channel These bits stand for the threshold for Pair A's output FIFO per channel. Possible range is [0,63]. When the value is n, it means that: when the number of output FIFO fillings of the pair is greater than n samples per channel, the output data ready flag is set; when the number of output FIFO fillings of the pair is less than or equal to n samples per channel, the output data ready flag is automatically cleared.
11 RSYNIFA	Re-sync Input FIFO Channel Counter If bit set, force ASRCCR:ACIA=0. If bit clear, untouch ASRCCR:ACIA.
10 RSYNOFA	Re-sync Output FIFO Channel Counter If bit set, force ASRCCR:ACOA=0. If bit clear, untouch ASRCCR:ACOA.
9–6 -	Reserved. Should be written as zero for future compatibility.
5–0 INFIFO_ THRESHOLDA[5:0]	The threshold for Pair A's input FIFO per channel These bits stand for the threshold for Pair A's input FIFO per channel. Possible range is [0,63]. When the value is n, it means that: when the number of input FIFO fillings of the pair is less than n samples per channel, the input data needed flag is set; when the number of input FIFO fillings of the pair is greater than or equal to n samples per channel, the input data needed flag is automatically cleared.

15.6.23 ASRC FIFO Status Register for Pair A (ASRC_ASRFSTA)

The register (ASRFSTA) is used to show Pair A internal FIFO conditions.

Address: ASRC_ASRFSTA is 5002_C000h base + A4h offset = 5002_C0A4h



ASRC_ASRFSTA field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented.
23 OAFA	Output FIFO is near Full for Pair A This bit is to indicate whether the output FIFO of Pair A is near full.
22–19 -	Reserved. Should be written as zero for future compatibility.
18–12 OUTFIFO_ FILLA[5:0]	The fillings for Pair A's output FIFO per channel These bits stand for the fillings for Pair A's output FIFO per channel. Possible range is [0,64].
11 IAEA	Input FIFO is near Empty for Pair A This bit is to indicate whether the input FIFO of Pair A is near empty.
10–7 -	Reserved. Should be written as zero for future compatibility.
6–0 INFIFO_FILLA[5:0]	The fillings for Pair A's input FIFO per channel These bits stand for the fillings for Pair A's input FIFO per channel. Possible range is [0,64].

15.6.24 ASRC Misc Control Register for Pair B (ASRC_ASRMCRB)

The register (ASRMCRB) is used to control Pair B internal logic.

Address: ASRC_ASRMCRB is 5002_C000h base + A8h offset = 5002_C0A8h

Chapter 16
Digital Audio Multiplexer (AUDMUX)

16.1 Overview

The Digital Audio Multiplexer (AUDMUX) provides a programmable interconnect device for voice, audio, and synchronous data routing between host serial interfaces such as the Synchronous Serial Interface Controller (SSI) and peripheral serial interfaces (audio and voice codecs, also known as coder-decoders).

This section includes a top level diagram that shows the functional organization of the block, including all off-chip signals.

AUDMUX allows the audio system connectivity to be modified through programming, as opposed to altering the PCB schematics of the system. The full description of the block is in Functional Description.

Figure 16-1 shows the block diagram.

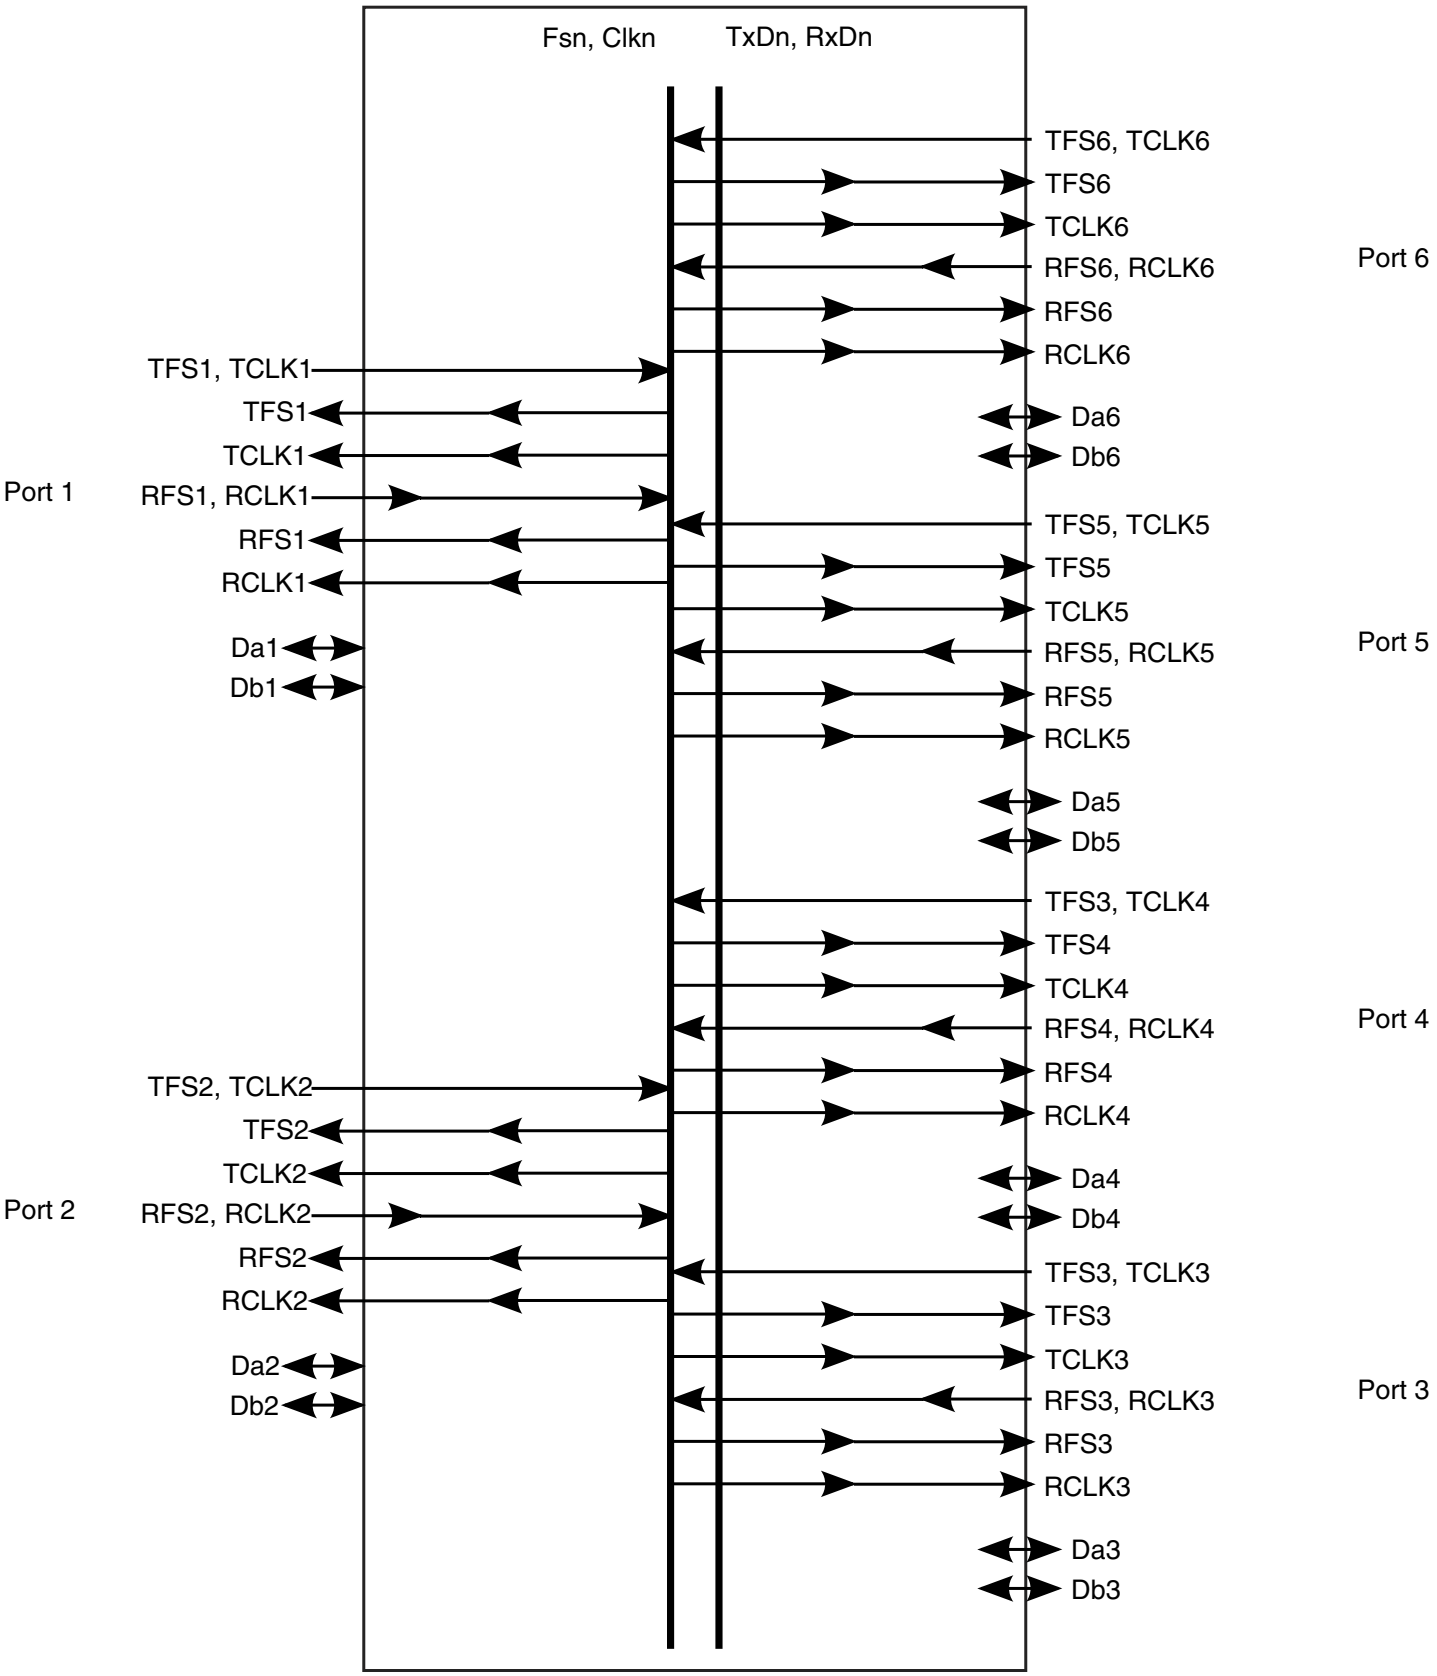

Figure 16-1. AUDMUX Block Diagram

With AUDMUX, resources do not need to be hard-wired and can be effectively shared in different configurations. AUDMUX interconnections allow multiple, simultaneous audio/voice/data flows between the ports in point-to-point or point-to-multipoint configurations.

AUDMUX includes two types of interfaces. Internal ports connect to the processor serial interfaces, and external ports connect to off-chip audio devices and serial interfaces of other processors. The desired connectivity is achieved by configuring the appropriate internal and external ports.

16.1.1 Features

Key features of the block include:

- Two internal ports
- Four external ports
- Three internal ports
- Four external ports
- Full 6-wire SSI interfaces for asynchronous receive and transmit
- Configurable 4-wire (synchronous) or 6-wire (asynchronous) peripheral interfaces
- Independent Tx/Rx Frame sync and clock direction selection for host or peripheral
- Each host interface's capability to connect to any other host or peripheral interface in a point-to-point or point-to-multipoint (network mode)
- Transmit and Receive Data switching to support external network mode

16.1.2 Modes and Operations

The AUDMUX supports the modes described in Operating Modes.

16.2 External Signal Description

The following table lists the off-chip signals of the AUDMUX for the external ports, where P*n* is P4 to P7 and m = (n-3).

Table 16-1. Off-Chip Block Signals

Name	Block Port	I/O	Function	Reset State	Pull-up
AUDm_TXD	P*n*	I/O	Transmit Data from Pn	1	Active
AUDm_RXD	P*n*	I/O	Receive Data at Pn	1	Active

Table continues on the next page...

Table 16-1. Off-Chip Block Signals (continued)

Name	Block Port	I/O	Function	Reset State	Pull-up
AUDm_TXC	P*n*	I/O	Transmit Clock input/output at Pn	1	-
AUDm_RXC	P*n*	I/O	Receive Clock input/output at Pn	1	-
AUDm_TXFS	P*n*	I/O	Transmit Frame sync input/output at Pn	1	-
AUDm_RXFS	P*n*	I/O	Receive Frame sync input/output at Pn	1	-

16.3 Default Register Configuration

There are two configuration registers for each port. Each pair of configuration registers is identical for each port; however, the default values following a reset differ as shown in the Memory Map.

- Default Port Configuration, describes the default configuration of the ports.

16.3.1 Default Port Configuration

After a reset, each port defaults to normal mode (PDCR*n*[MODE] = 0) with synchronous timing mode (PTCR*n*[SYN] = 1) enabled.

The default port-to-port connections are as follows:

- Port 1 to Port 6
  - Port 6 provides the clock and frame sync.
- Port 2 to Port 5
  - Port 5 provides the clock and frame sync.
- Port 3 to Port 4
  - Port 4 provides the clock and frame sync.
- Port 7 to Port 7 (in data loopback mode)
  - Clock and frame syncs are inputs.

16.4 Functional Description

This section provides a complete functional description of the AUDMUX.

16.4.1 Operating Modes

This section describes all functional operation modes of the AUDMUX.

Figure 16-1 shows the AUDMUX block diagram.

All of the ports are essentially identical; there is no functional difference among Ports 1 through 7. The main difference is whether a port is connected to an on-chip serial interface (SSI for example) or connected to the chip's pads to connect to off-chip serial devices (that is, any 4-wire or 6-wire external SSI, voice, I2S, or AC97 codec).

All ports can be configured as four- or six-wire interfaces. When configured as a six-wire interface, the additional RFS and RCLK signals of the interface enable the serial interface to be used in asynchronous mode with separate receive and transmit clocks.

All ports have a Tx/Rx switch to provide flexibility in supporting network mode configurations. The Tx/Rx switch enables the transmit and receive data lines to be swapped so that mastership of the serial bus can be passed among multiple external devices connected to a single port.

In addition to supporting the default external network mode, all ports support an internal network mode:

- With internal network mode, a point-to-multipoint network configuration with an arbitrary number of slaves can be supported if the external slaves are put into the high-impedance state (as defined in the SSI network mode protocol) and have pull-up resistors on their TxD pins. (Alternatively, this can be viewed as requiring a pull-up resistor on the corresponding AUDMUX RxD pin.)

Bit clock direction selection enables each port to be configured as a master or slave in the flow.

Possible scenarios include:

- SSI (internal port) drives a voice codec and a BT (Blue tooth) codec (both on external Port 6Port 5) and the Bottom Connector (on external Port 7Port 6) simultaneously using network mode. SSI is the master.
- An external processor (external port - Port 5Port 4) drives a voice codec and a BT codec (both on external Port 6Port 5) and the Bottom Connector (on Port 7Port 6) simultaneously using network mode. The external processor is the master.

16.4.1.1 Port Receive Data Modes

Each port has logic to select which data lines are used to create the RxD line for the corresponding host interface.

Figure 16-2 shows the logic used to create the RxD line for Port 1. This logic has the following modes of operation (as determined by MODE):

- Normal
- Internal network mode

The subsequent sections describe the various modes of the port receive data logic. The following terms are used to define the operation of the AUDMUX:

- Network mode- Time-Division Multiplexed protocol for sending unique data to multiple devices on a serial bus.
- Internal network mode-Physical bus configuration where multiple serial buses are effectively connected within the AUDMUX via digital logic to create point-to-multipoint connectivity. An arbitrary number of devices are supported. Devices must be put into the high-impedance state as specified by the network mode protocol. TxDATA lines of devices must be pulled high.
- External network mode-Physical bus configuration where multiple serial buses are electrically connected together on a printed circuit board (that is, external to the AUDMUX). Devices must put their TxDATA lines into the high-impedance state as specified by the network mode protocol.

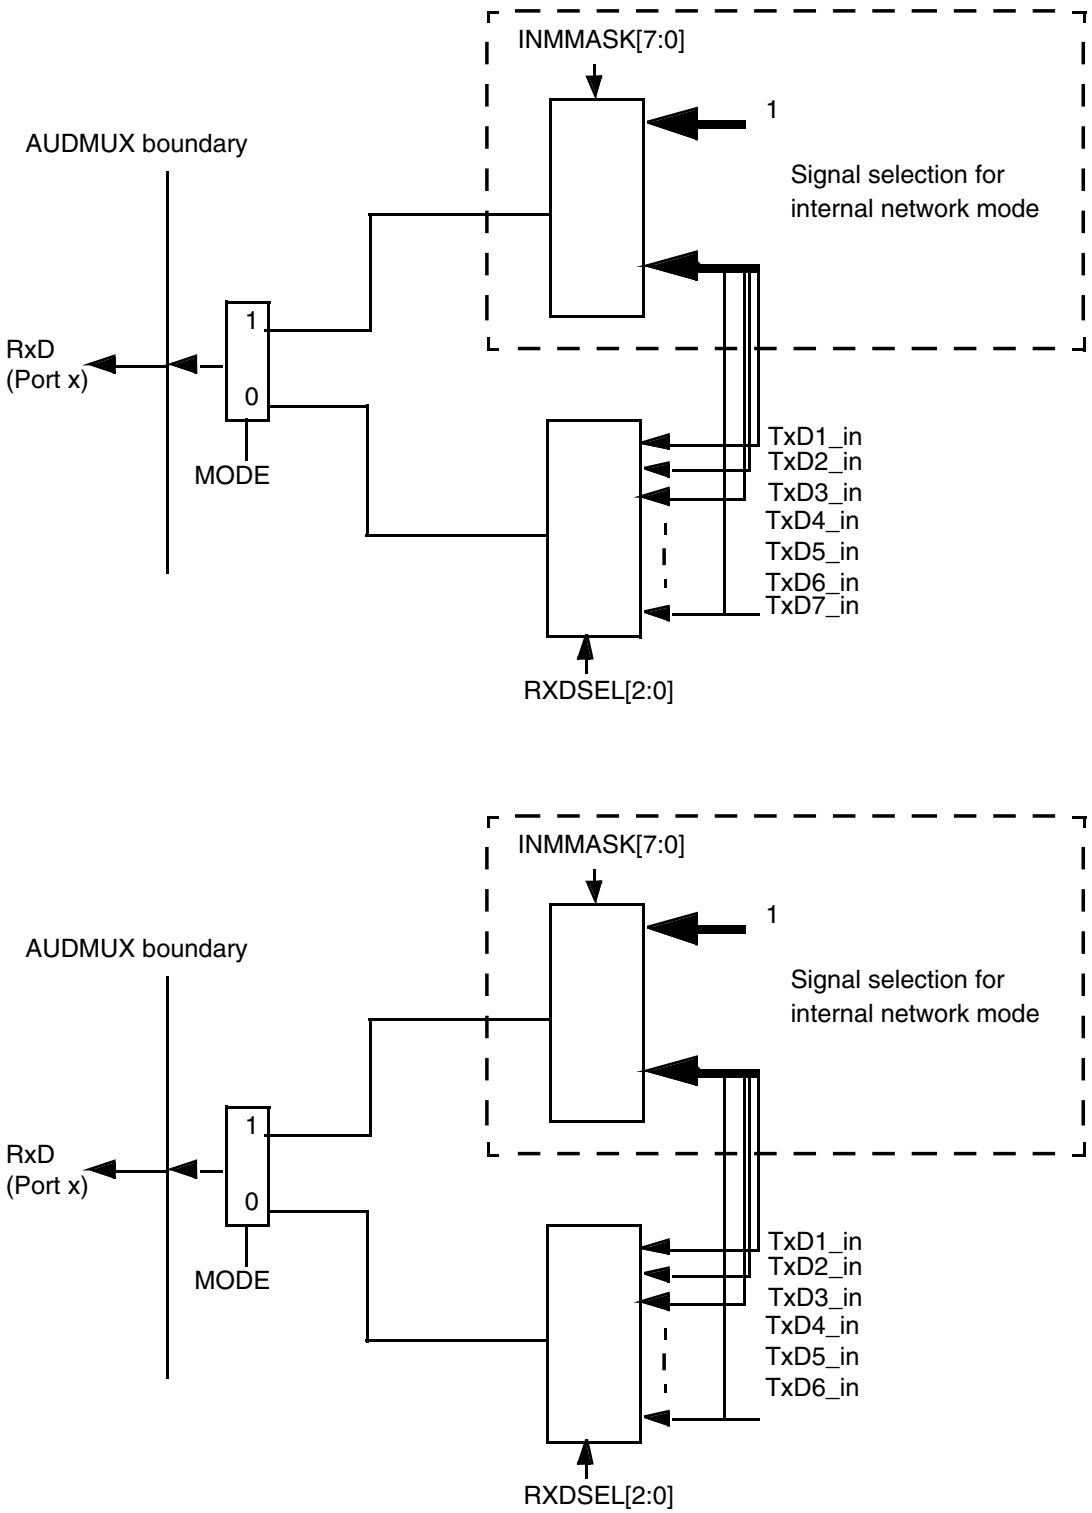

Figure 16-2. Receive Data Logic for Port x

16.4.1.1.1 Normal Mode

In normal mode (MODE = 0) , the port is connected in a point-to-point configuration (as a master or a slave) and the RXDSEL[2:0] setting selects the transmit signal from any port. In normal mode, any data format can be used (that is, SSI normal mode, SSI network mode, AC-97, and others.

16.4.1.1.2 Internal Network Mode

In internal network mode (MODE = 1) , the output of the AND gate is routed (via the output of the port) to the RxD signal of the corresponding host interface.

The INMMASK bit vector selects the transmit signals of the ports that are to be connected in network mode. The transmit signals received at the AUDMUX ports (TxDn_in) are ANDed together to form the output. In internal network mode, only one device can be transmitting in its predesignated timeslot and all other transmit signals must remain high (be in high-impedance state and pulled-up). Therefore, non-active signals in the selection will be high and do not influence the output of the AND gate.

Network mode is a protocol where a master SSI is connected to more than one slave SSI device and communication occurs on a time-slotted frame. Though network mode can allow master-slave and slave-slave communication, internal network mode supports only master-slave communication.

There are two scenarios where internal network mode can be used with external network mode:

1. Slave-only devices are attached to an external port.
2. A master device is attached to an external port and all slave devices connected to the same external port are disabled.

NOTE

When internal network mode is enabled at an external port, RXDSEL[3:0] for RxDn_obe selection is ignored and RxD_obe is always driven high (that is, asserted for all timeslots). All slave devices connected to the same port must be disabled.

Internal Network Mode Example 1

SSI_m and SSI_n are used with Port 4 in internal network mode as shown in Figure 16-3. No pull-up resistors are required because the interfaces combined in internal network mode are on-chip interfaces.

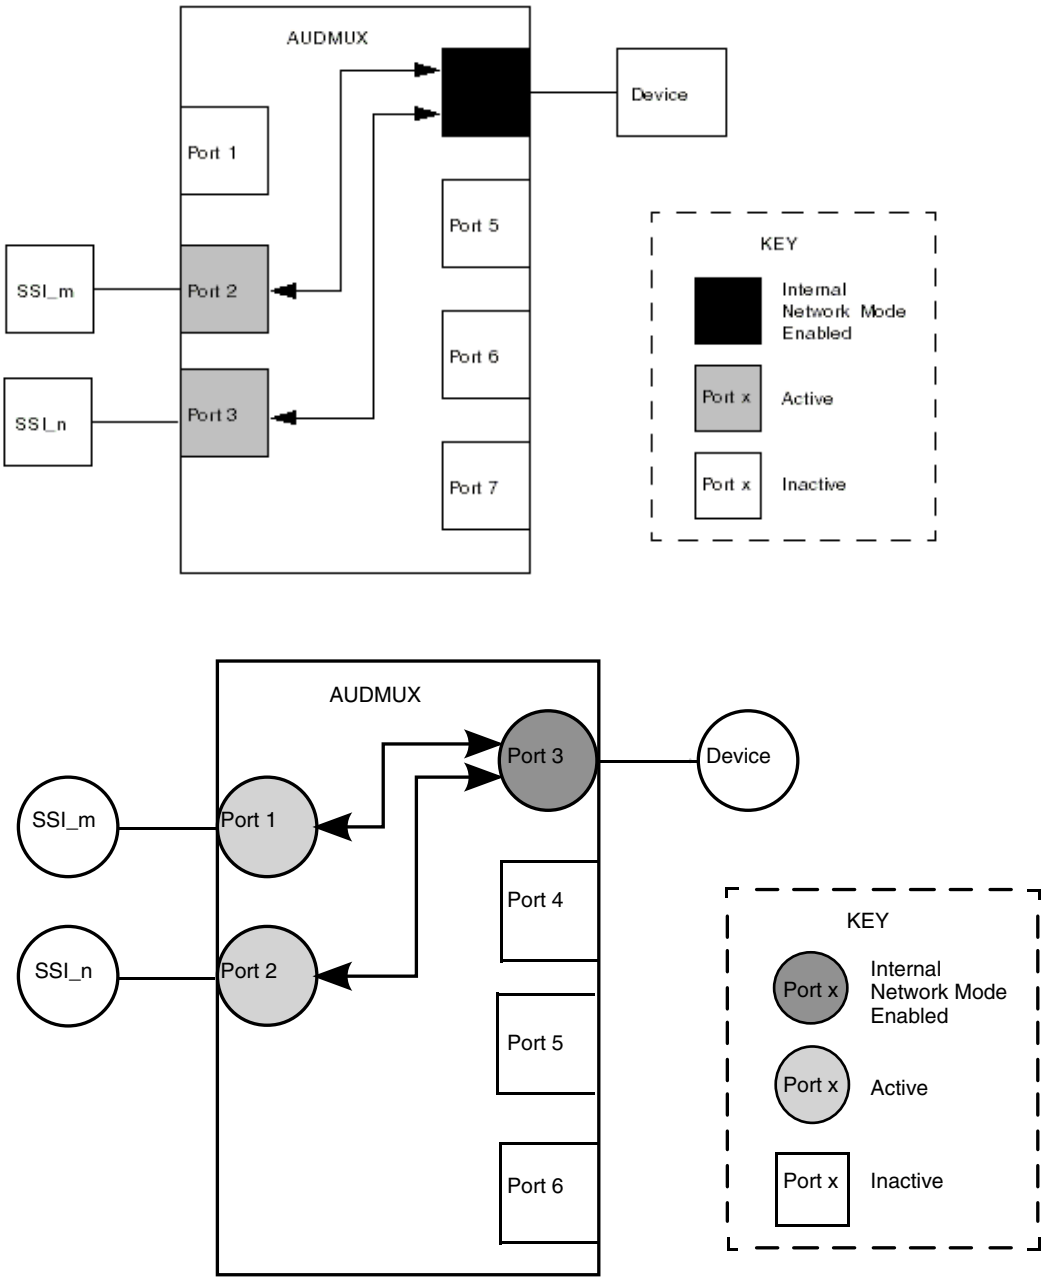

Figure 16-3. Block Diagram For Example 1

See Figure 16-4 for the timing diagram of Example 1. The clock and frame sync signals show the bit and frame timing for the serial bus. The vertical dashed lines divide the frame into four timeslots.

The data lines for SSI_m and SSI_n (as well as their output enables) are shown. Note that the on-chip interfaces drive a logic '1' when their output enables are logic '0'. The combined TxDATA line, which is the logical AND of the individual TxDATA lines, is used for Port 4Port3's TxDATA line.

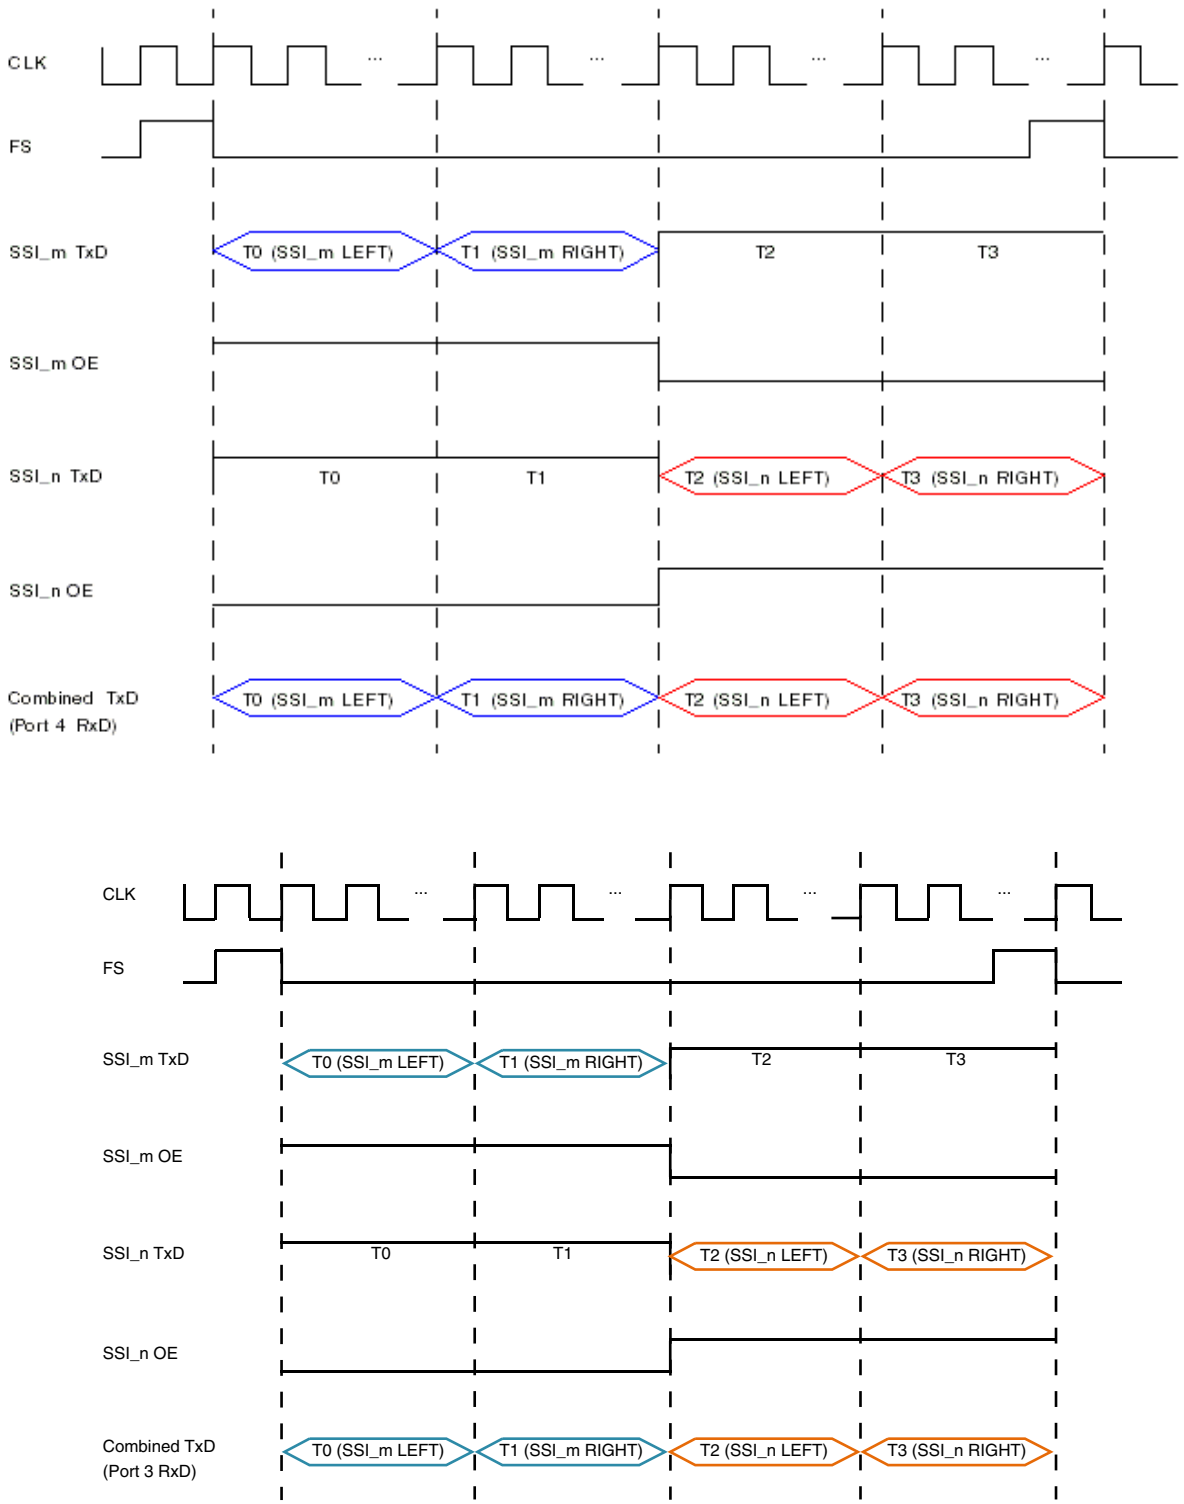

Figure 16-4. Example Using Internal Ports For Transmit Data

Internal Network Mode Example 2

The SSI, Port 4, and Port 5 are used with Port 6Port 3, and Port 4 are used with Port 5 in internal network mode, as shown in the following figure. Note that Port 4 and Port 5Port 3 and Port 4 are external ports. Therefore, pull-up resistors are required on the Port 4 RxDATA and Port 5 RxDATA pins. This example shows the timing associated with using adjacent timeslots for the SSI, Port 4 and Port 5Port 3 and Port 4.

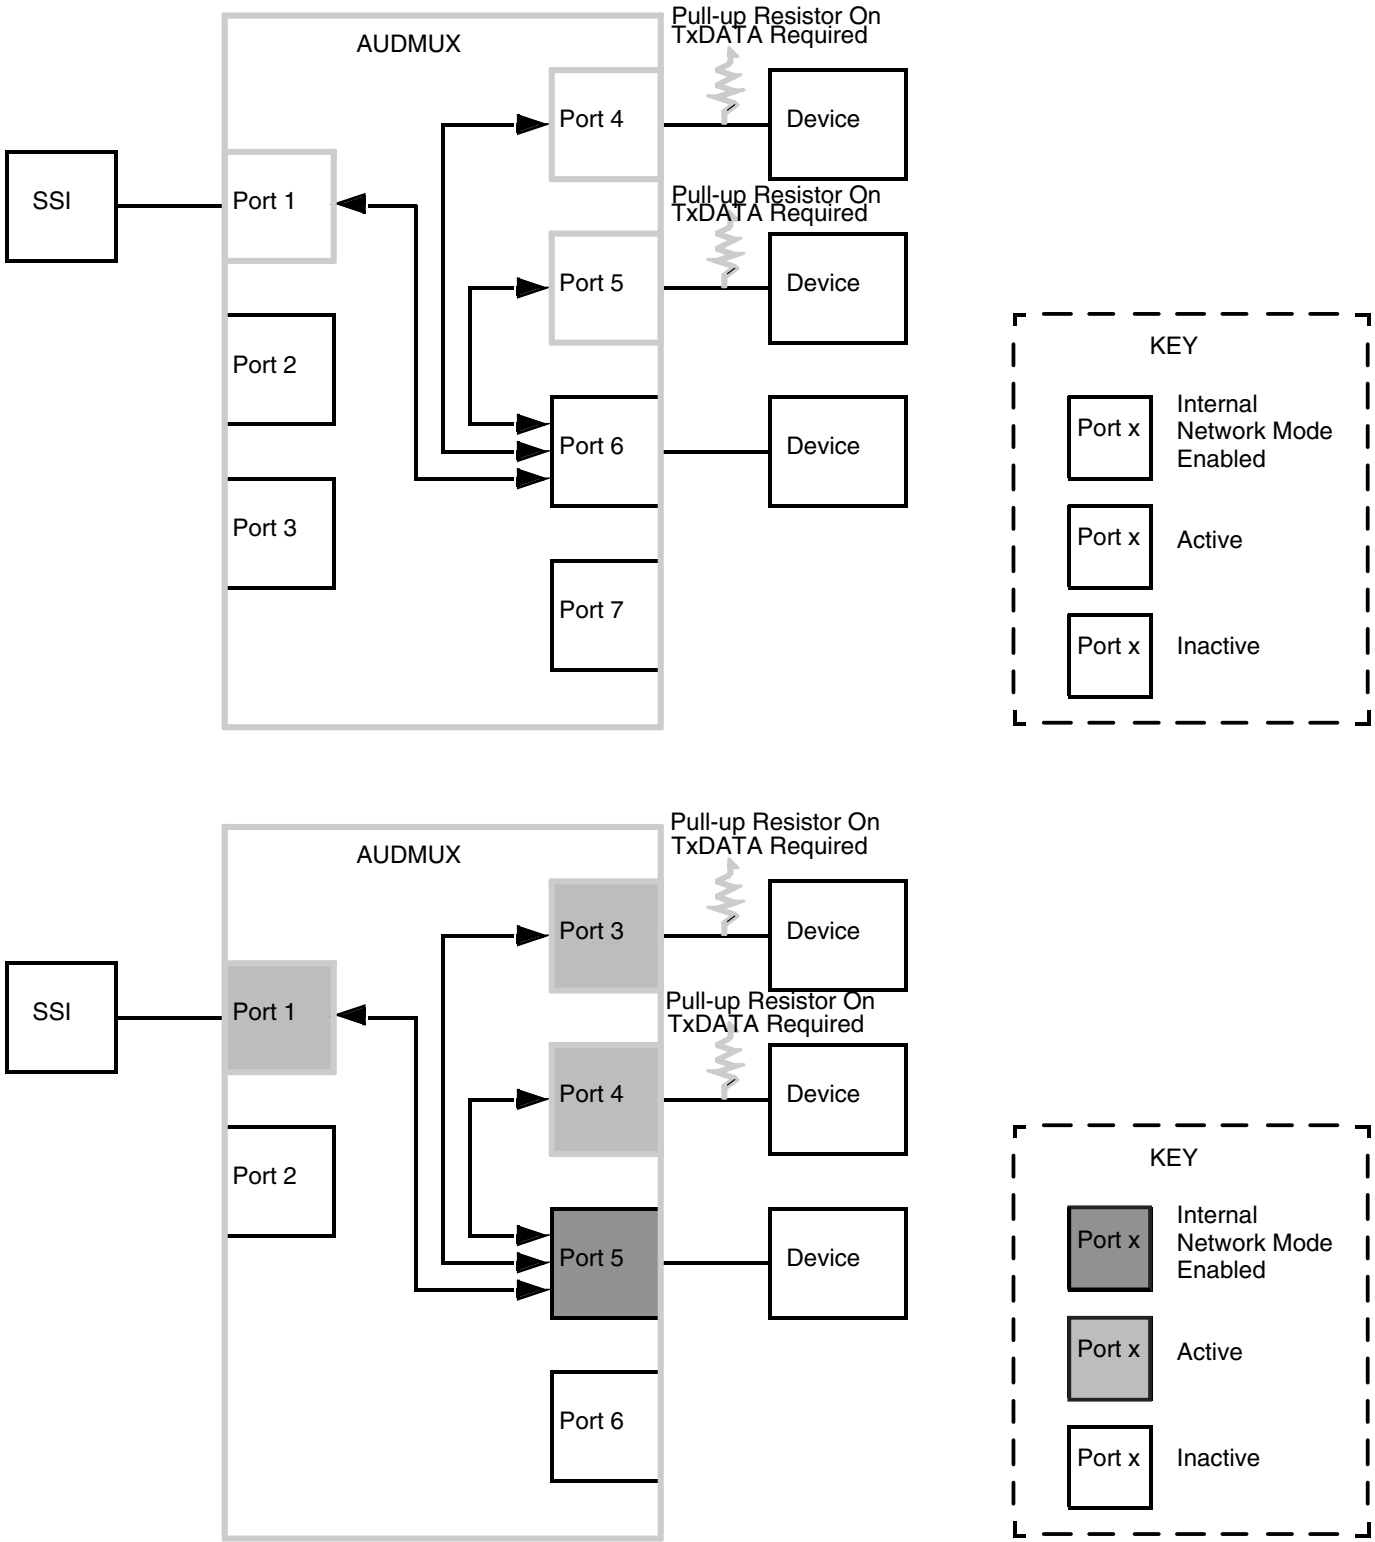

Figure 16-5. Block Diagram For Example 2

The resistance value of the pull-up resistors must be sufficiently high such that a value of '0' can be pulled up to logic '1' within half of a period of the bitclock. The required resistance must be no larger than:

Rmax = 1 / (2 * f_{bc} * C) where:

- f_{bc} is the frequency of the bitclock
- C is the total system capacitance (ICs, board traces, and so on)

The following figure shows the timing diagram for this example. The clock and frame sync signals show the bit and frame timing for the serial bus. The vertical dashed lines divide the frame into four timeslots.

The data lines for the SSI, Port 4 and Port 5Port 3 and Port 4 are shown. Note that the SSI transmits a logic '1' when its corresponding output enable is a logic '0'. The data lines from Port 4 and Port 5Port 3 and Port 4 at the pad are pulled high by pull-up resistors when they are in the high-impedance state. The data lines from Port 4 and Port 5Port 3 and Port 4 at the AUDMUX are pure digital signals and are constantly driven. The combined TxDATA line, which is the logical AND of the SSI, Port 4 and Port 5Port 3 and Port 4's TxDATA lines, is used for Port 6Port 5's TxDATA line.

Note the highlighted areas in the following figure. This shows the transition time that occurs while a TxDATA line is being pulled high. In this example, this transition time is a maximum of 1/2 the period of the serial bitclock. This prevents corruption of the first data bit of the next timeslot. It is critical that the pull-up resistance is sufficient for the given bitclock frequency and system capacitance.

Note that hysteresis should be enabled at Port 4's RxDATA pad and Port 5's RxDATA padPort 3's RxDATA pad and Port 4's RxDATA pad to prevent the digital signals created by the pad from toggling rapidly during the pull-up period. The pads typically require a transition within 25ns unless hysteresis is enabled. Instead of using hysteresis, one could select a pull-up resistor sufficiently high to pull-up the signal at the pad within 25 ns; however, that would result in a higher resistance value and higher current drain.

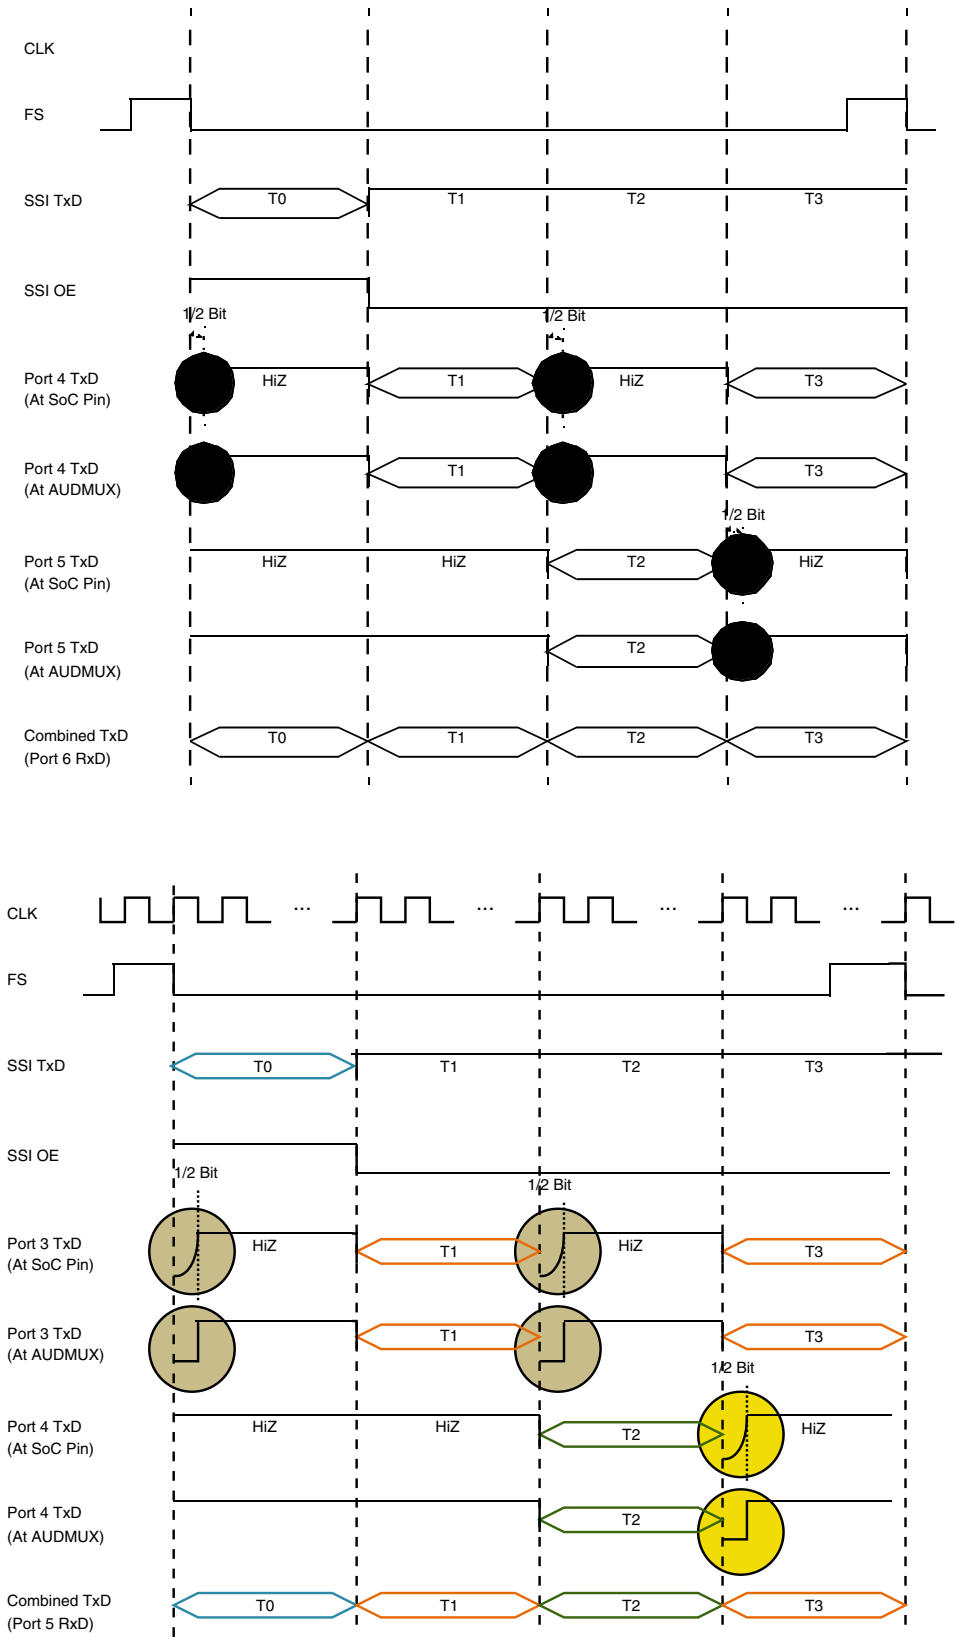

Figure 16-6. Example Using External Ports for Transmit Data in Cons

Internal Network Mode Example 3

The SSI and Port 4 are used with Port 6Port 3 are used with Port 5 in internal network mode as shown in the following figure. Note that Port 4Port 3 is an external port. Therefore, a pull-up resistor is required on the Port 4Port 3 TxDATA pin. This example shows the timing associated with inserting empty timeslots after the timeslots have been used by external ports.

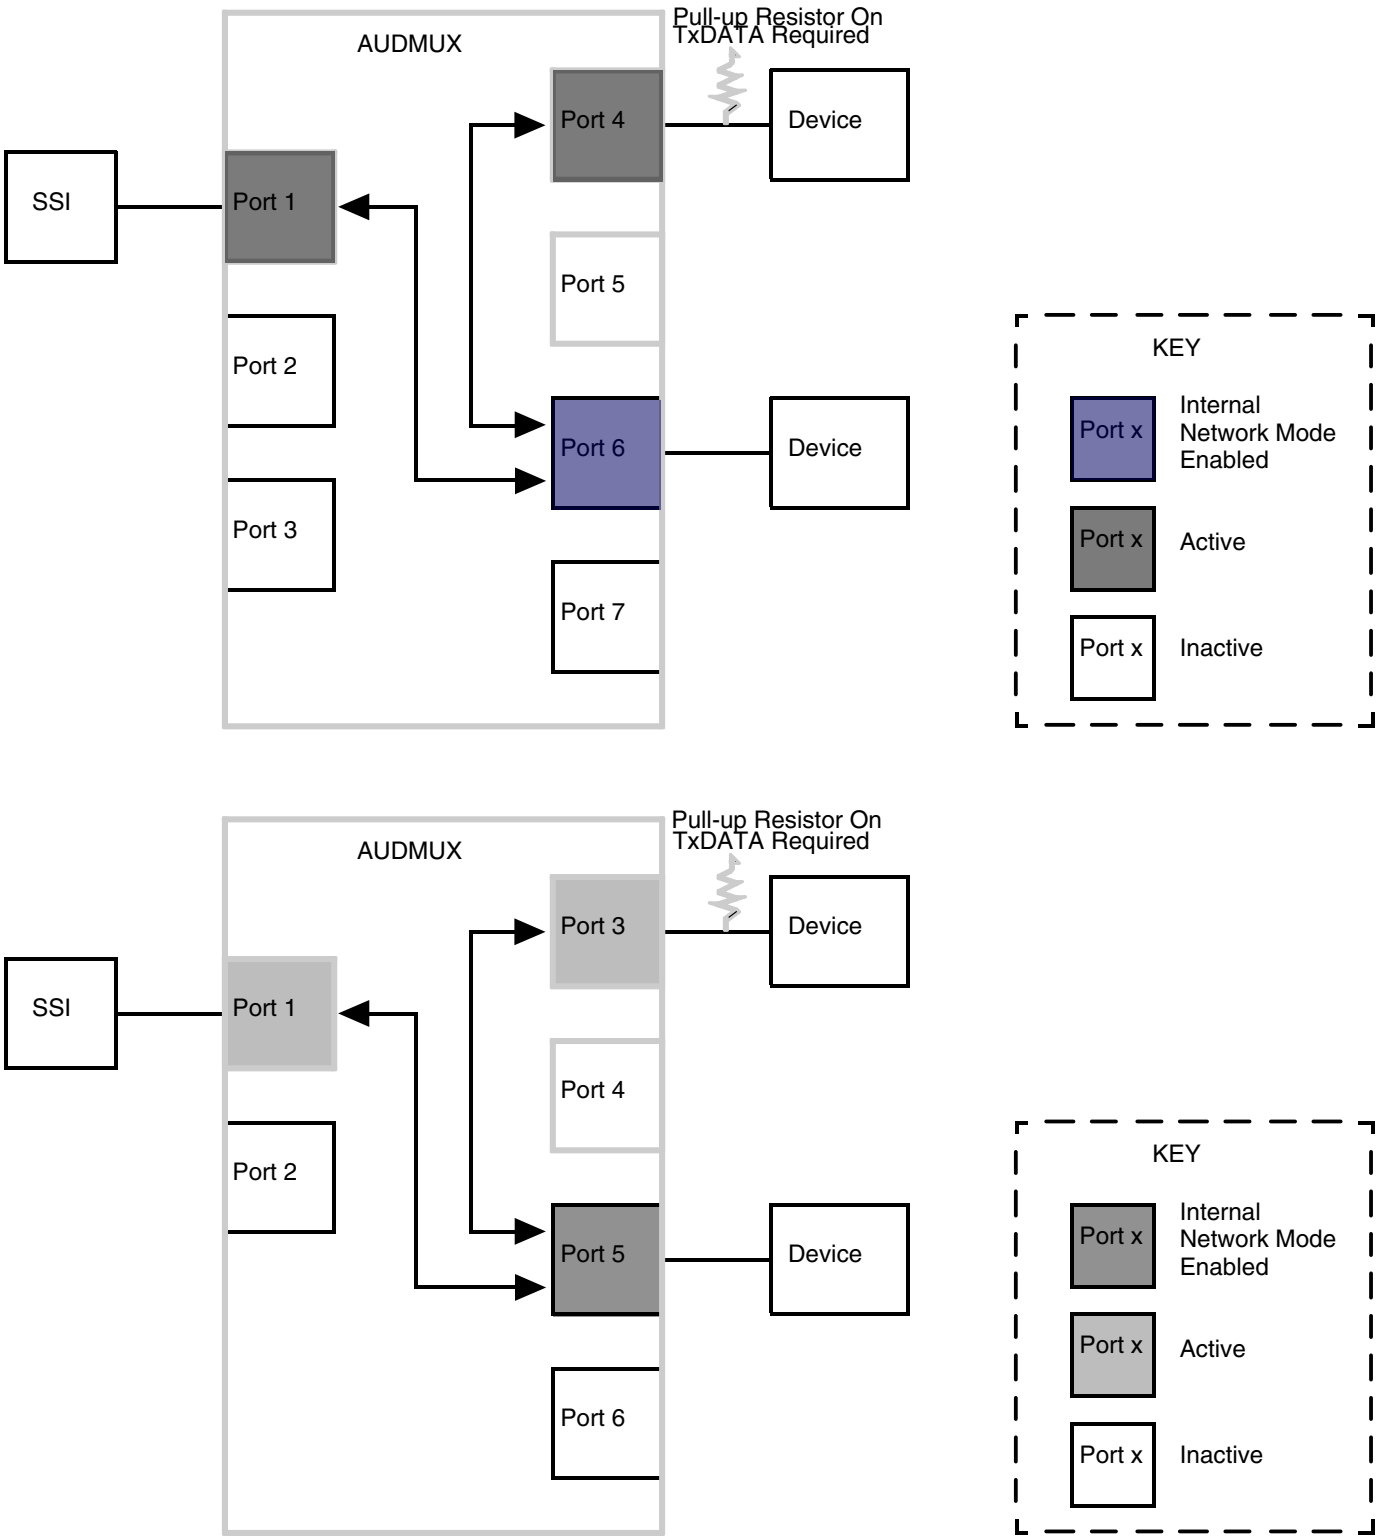

Figure 16-7. Block Diagram For Example 3

The resistance value of the pull-up resistors must be sufficiently high such that a value of '0' can be pulled up to logic '1' by the time that the next occupied timeslot occurs. This allows a much weaker pull-up to be used as compared to Example 2. The required resistance must be no larger than:

Rmax = (4 * n + 1) / (2* f_{bc} * C) where:

- n is the number of bits per timeslot
- f_{bc} is the frequency of the bitclock
- C is the total system capacitance (ICs, board traces, and so on)

The figure below shows the timing diagram for this example. The clock and frame sync signals show the bit and frame timing for the serial bus. The vertical dashed lines divide the frame into four timeslots.

The data lines for the SSI and Port 4Port 3 are shown. Note that the SSI transmits a logic '1' when its corresponding output enable is a logic '0'. The data line from Port 4Port 3 at the pad is pulled high by a pull-up resistor when they are in the high-impedance state. The data line from Port 4Port 3 at the AUDMUX is a pure digital signal and is constantly driven. The combined TxDATA line, which is the logical AND of the SSI and Port 4Port 3's TxDATA lines, is used for Port 6Port 5's RxDATA line.

Note the highlighted area in the following figure. This shows the transition time that occurs while Port 4Port 3's TxDATA line is being pulled high. In this example, this transition time is a maximum of two timeslots plus 1/2 the period of the serial bitclock. This prevents corruption of the first data bit of the next timeslot. It is critical that the pull-up resistance is sufficient for the given bitclock frequency and system capacitance.

Note that hysteresis must be enabled at Port 4Port 3's RxDATA pad to prevent the digital signal created by the pad from toggling rapidly during the extended pull-up period. The pads typically require a transition within 25 ns unless hysteresis is enabled.

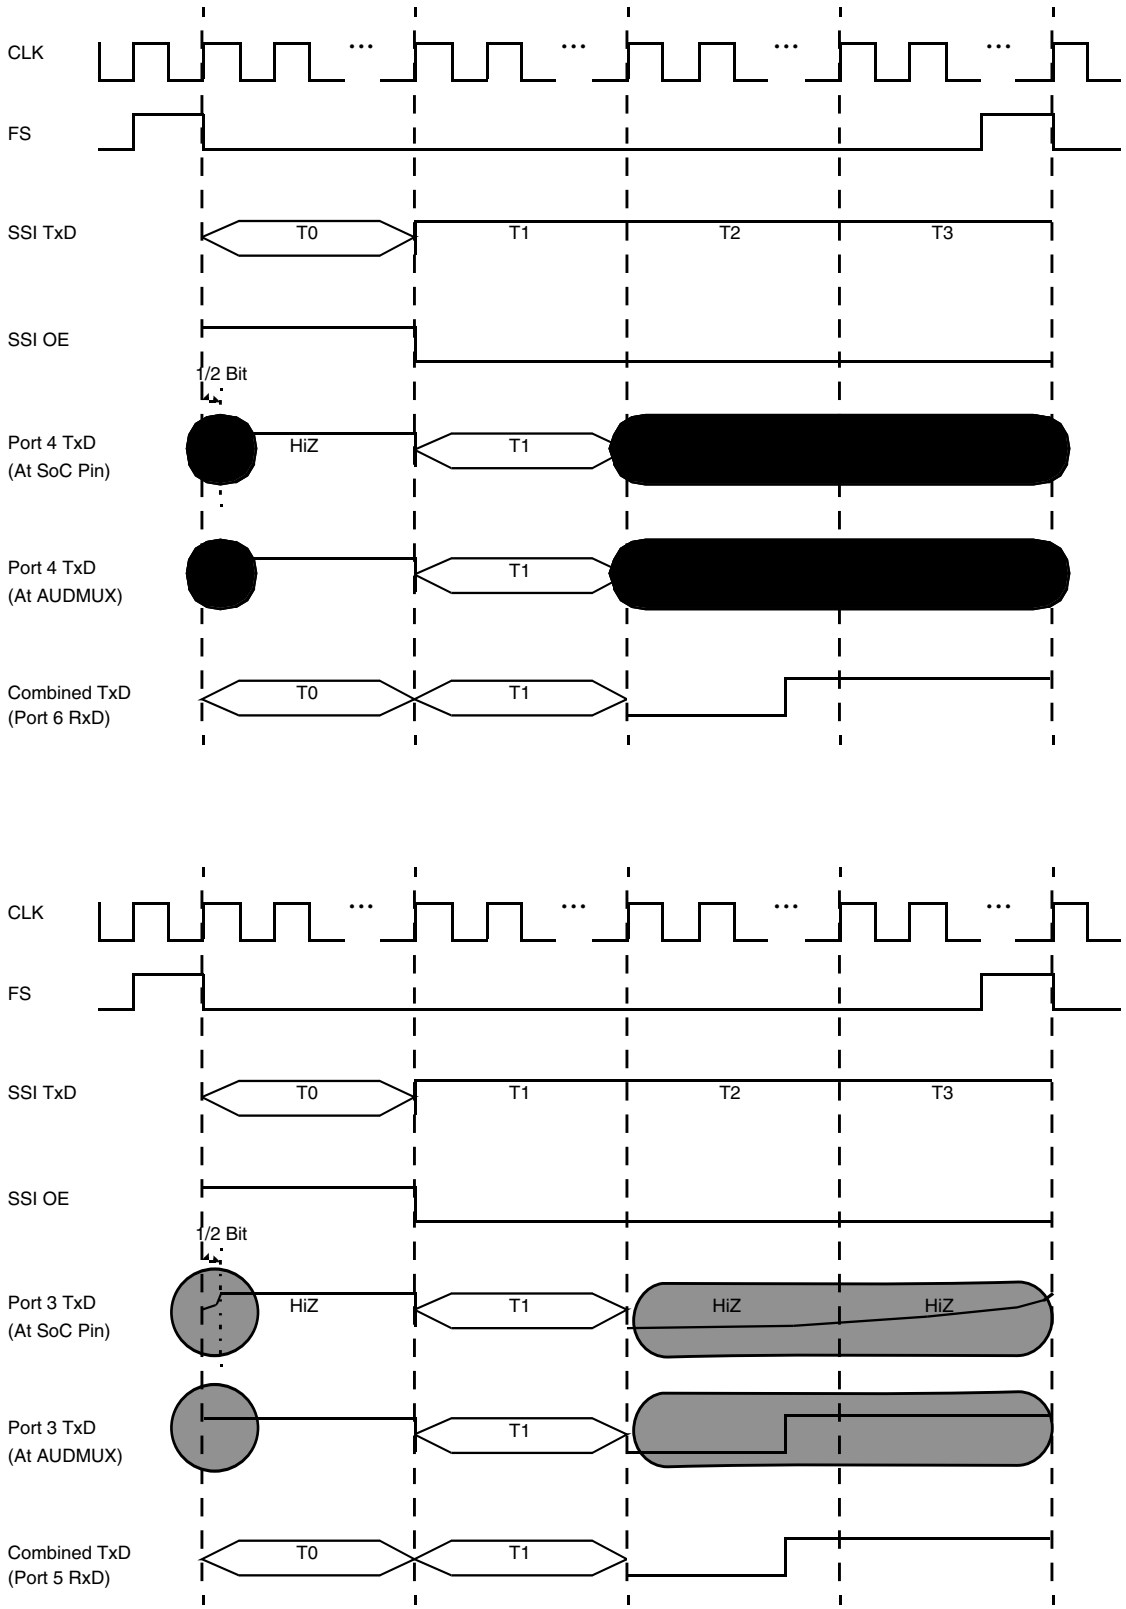

Figure 16-8. Example Using External Ports For Transmit Data In Nonconsecutive Timeslots

16.4.1.1.3 Transmit Data Output Enable Assertion

The TxDATA line from the internal network mode master (connected at any internal port) is put into the high-impedance state at the pad depending upon the assertion or deassertion of TxD_obe, its corresponding output enable generated by the network mode master.

In the case of an external network mode master (connected at an external port), the corresponding TxD_obe is always asserted after the port data register configuration.

16.4.1.2 Tx/Rx Switch and External Network Mode

External network mode is the traditional network mode connection. It is called external network mode to differentiate from the internal network mode. In external network mode, devices are connected to a single external port in a star or multi-drop configuration.

In network mode, there can be only one master (driving the frame sync and clock source) with the other devices configured in normal slave mode or network slave mode. Unlike internal network mode, both master-slave and slave-slave communication can take place in external network mode. Codec devices transmit on a single timeslot while processor serial interfaces (that is, SSI) can process more than one timeslot of data while in network master or slave mode.

The following figure shows the Tx/Rx data switch. RxD_obe is the output buffer enable signal and RxD_out is the data transmit signal from the serial interface. The TxD_in signal is the receive data signal going towards the RXDSEL muxes of all ports.

D_TxRx is the data pin which serves as the chip-level transmit data pin when the TxRx switch is not enabled. D_RxTx is the data pin which serves as the chip-level receive data pin when the TxRx switch is not enabled. The roles of these pins are reversed when the TxRx switch is enabled.

When TXRXEN is disabled (TXRXEN=0), RxD_out is routed to D_TxRx and D_RxTx is routed to TxD_in. The output buffer enable, selected by RXDSEL[2:0], is routed to Db_obe.

When the Tx/Rx switch is enabled (TXRXEN=1), RxD_out is routed to D_RxTx and D_TxRx is routed to TxD_in. The output buffer enable, selected by RXDSEL[2:0], is routed to Da_obe.

If the RXDSELn[2:0] field for any Port *n* is configured to select data from an internal port, the output buffer enable is selected by RXDSELn[2:0] and is routed to Da*n*_obe/ Db*n*_obe. In the case when the RXDSELn[2:0] field for Port *n* is configured to select data from an external port, the output buffer enable is always high and routed to Dan_obe/Dbn_obe, depending on the TXRXENn switch configuration.

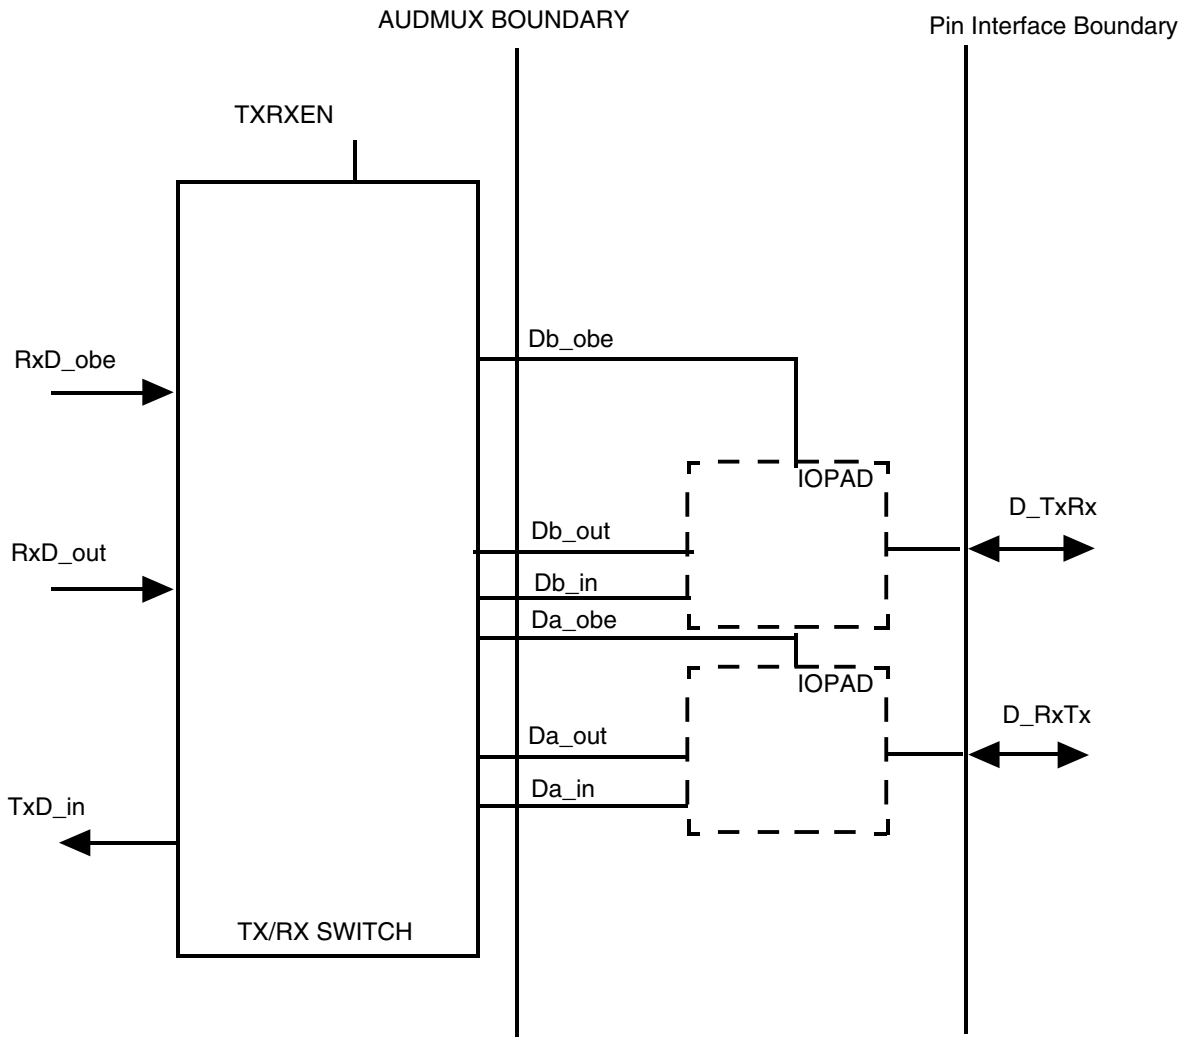

Figure 16-9. Tx/Rx Switch

16.4.1.3 Timing Modes

The AUDMUX ports are constructed as 6-wire interfaces. However, they can be used either in synchronous or asynchronous modes as determined by the SYN bit.

16.4.1.3.1 Synchronous Mode (4-Wire Interface)

In Synchronous mode, the port has a 4-wire interface (that is, RxD, TxD, TxCLK, TxFS). The receive data timing is determined by TxCLK and TxFS.

As shown in the following figure, Port x signals can be routed to Port y, producing 6-wire to 4-wire port connectivity.

TFS_in, RFS_in, TCLK_in, and RCLK_in are the input frame sync and bit clocks from the serial interface (Port x) with their corresponding output buffer enable signals (_obe). TFS_out, RFS_out, TCLK_out, and RCLK_out are the frame sync and bit clocks that are transmitted to the serial interface from the other ports.

The TFS_out and TCLK_out are selected at Port x by the TFSEL and TCSEL mux settings, respectively. RFS_out and RCLK_out are selected at Port x by the RFSEL and RCSEL mux settings, respectively. Similarly, in the external direction, Port y is configured as a 4-wire port; TFSEL selects the FS_obe and FS_out signals. In this mode, the configuration of RFSEL and RCSEL is not used, since the RFS_out and RCLK_out pins at Port y are not available.

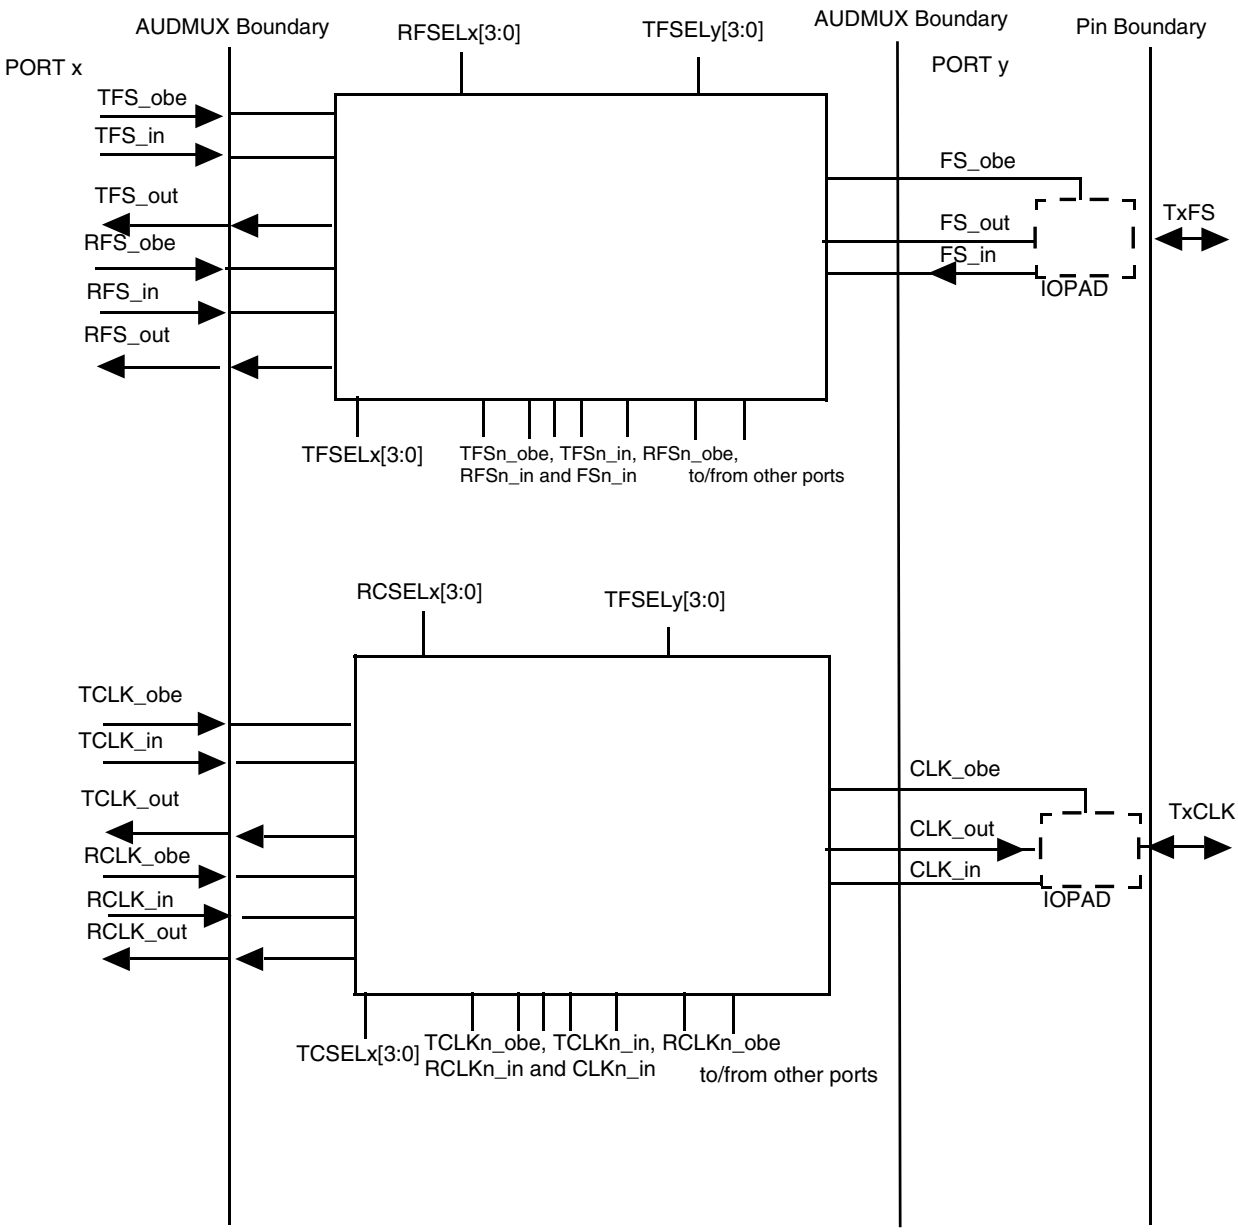

Figure 16-10. Frame Sync and Clock Routing When External Port Is 4-Wire

16.4.1.3.2 Asynchronous Mode (6-Wire Interface)

In Asynchronous mode, the port has a 6-wire interface (meaning RxD, TxD, TxCLK, TxFS, RxCLK, RxFS). This mode has additional receive clock (RxCLK) and frame sync (RxFS) signals as compared to the synchronous or 4-wire interface.

As shown in the figures below, Port x signals can be routed to Port y, producing 6-wire to 6-wire port connectivity.

TFS_in, RFS_in, TCLK_in, and RCLK_in are input frame sync and bit clocks from the serial interface (Port x) with their corresponding output buffer enable signals (_obe). TFS_out, RFS_out, TCLK_out, and RCLK_out are the frame sync and bit clocks that are transmitted to the serial interface from the other ports.

TFS_out and TCLK_out are selected by the TFSEL and TCSEL mux settings, respectively. RFS_out and RCLK_out are selected by the RFSEL and RCSEL mux settings, respectively. Similarly, in the external direction, the TFSEL selects the TxFS_obe and TxFS_out signals and TCSEL selects the TxCLK_obe and TxClk_out signals. The RFSEL selects the RxFS_obe and RxFS_out signals and RCSEL selects the RxCLK_obe and RxCLK_out signals.

NOTE

Because FS_in and CLK_in from external interfaces are also routed to the TFSEL and TCSEL muxes of the external ports, these signals do not have corresponding buffer enable signals. Consequently, their corresponding inputs to the TFSEL and TCSEL mux of the external ports have to be tied high.

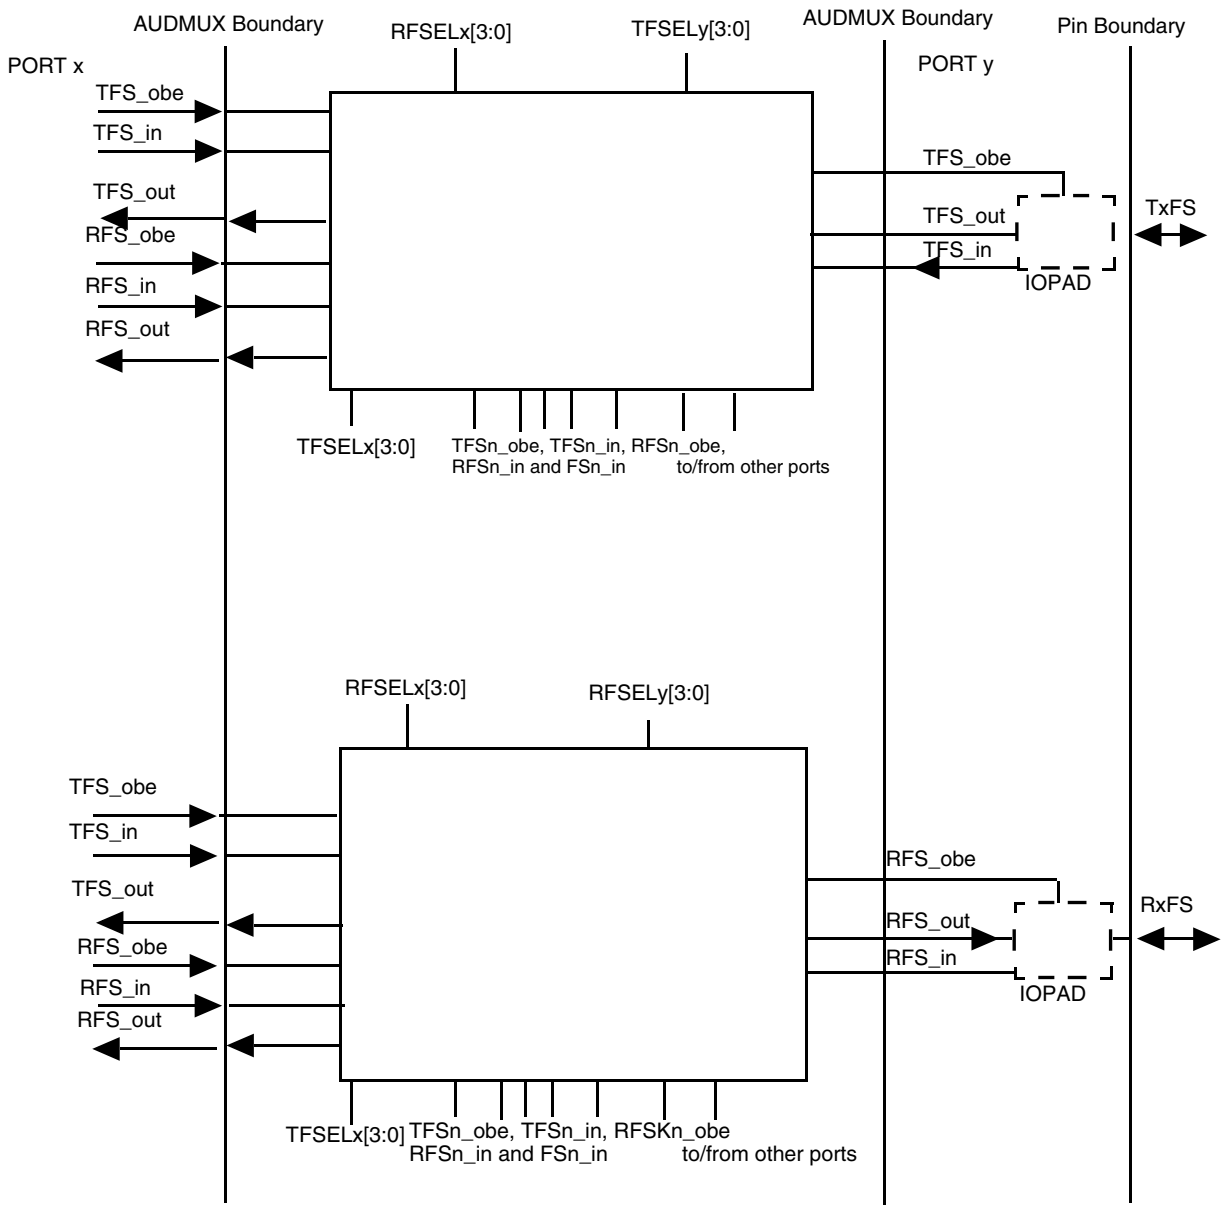

Figure 16-11. Frame Sync Routing When External Port Is 6-Wire

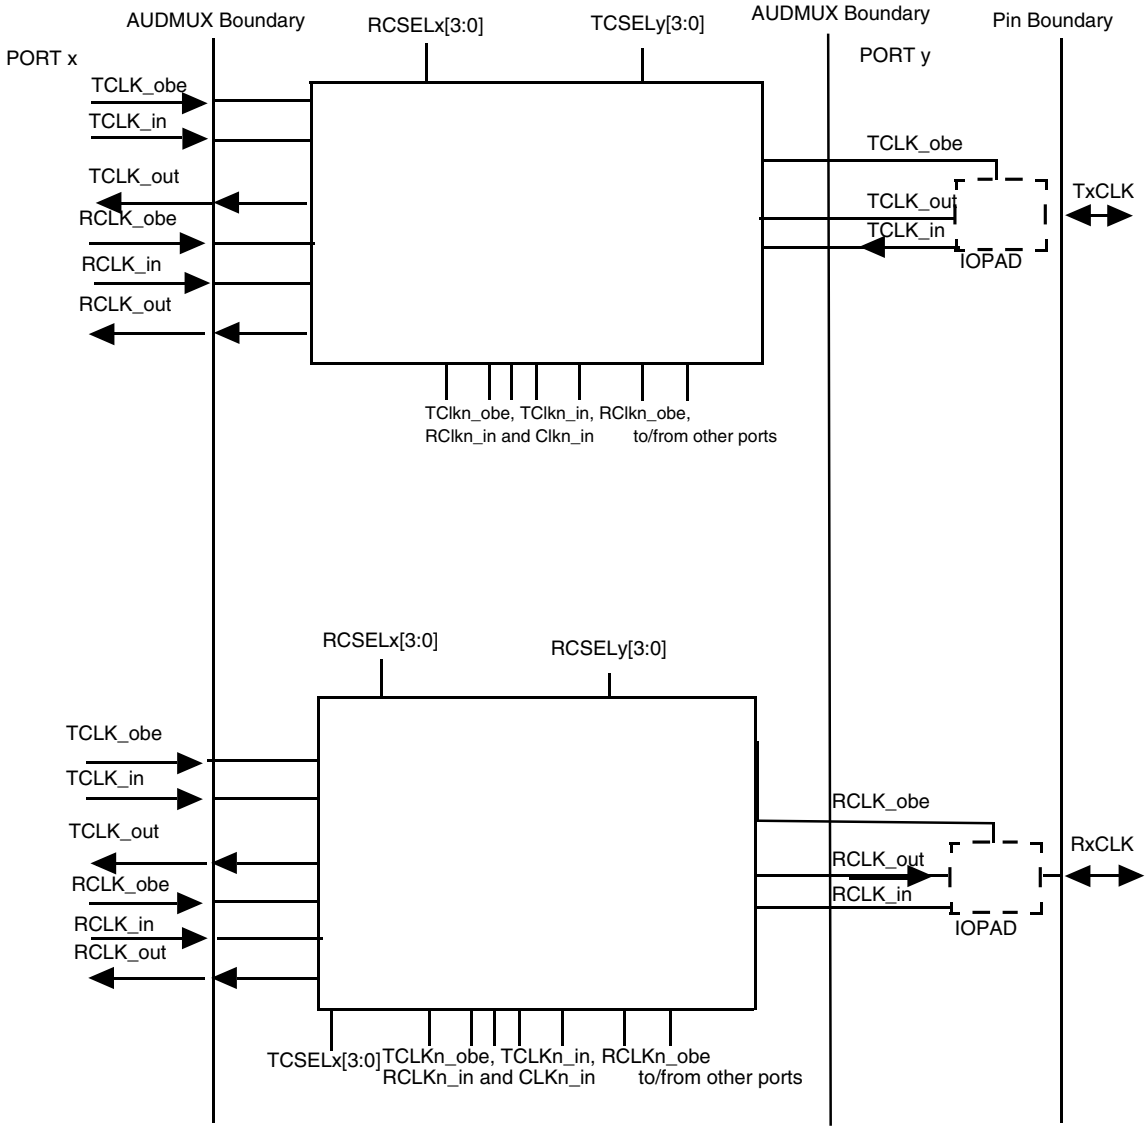

Figure 16-12. Clock Routing When External Port Is 6 Wire

16.4.2 Connectivity Between Ports

Four basic types of connections are provided by the AUDMUX:

- Internal port to external port
- External port to external port
- Internal port to internal port
- Loopback

The corresponding data connections are described in the following sections.

16.4.2.1 Internal Port to External Port Connectivity

The internal port is connected to a processor's serial interface. TxD_obe is the buffer enable signal from the serial interface, TxD_in is the input transmit data from the serial interface to the AUDMUX, and RxD_out is the receive data output from the AUDMUX to the serial interface.

RXDSEL[2:0] of the external port selects the buffer enable signal (TxD_obe) and transmit data output (TxD_out) signal from the TxD_obe and RxD_in signals. RXDSEL[2:0] is a common signal to both selection muxes.

NOTE

Because buffer TxD_in signals from external interfaces do not have corresponding buffer enable signals, their buffer enable signals into the selection mux are tied high. This will ensure that selection of TxD_in, as RxD_out will also drive the RxD_obe output high.

Transmit Data from the serial interface goes into the RXDSEL data mux and comes out as RxD_out. RxD_out is routed to Da_TxRx when TXRXEN is disabled and to D_RxTx when TXRXEN is enabled. Similarly, D_RxTx is routed to TxD_in when TXRXEN is disabled and D_TxRx is routed to TxD_in when TXRXEN is enabled. The routing of frame syncs is shown in Figure 16-11and the routing of interface clocks is shown in Figure 16-9.

If internal network mode is disabled, then RXDSEL selects the TxD_in, which is sent from the AUDMUX to the serial interface connected at Port x. When the internal network mode is selected, RxD_out is constructed by ANDing selected TxD_in signals from the ports (as determined by INMMASK).

If there is more than one device attached to the external port at D_TxRx and D_RxTx and one of the devices is a network master, then two conditions must be noted:

1. When the external master is enabled in network mode, then the serial interface at Port x must be configured as a slave (normal or network mode). No Tx/Rx switching is required.
2. When the external master is disabled and the serial interface at Port x and other slave devices must communicate, then the serial interface at Port x must be configured as a network mode master and the Tx/Rx switch at Port y must be enabled (TXRXEN=1). This will ensure that the transmit and receive paths are connected appropriately.

To communicate with more than one port, internal network mode can be enabled at Port x. In internal network mode, it is possible to communicate with any device attached to the other ports. Internal network mode shall be enabled at the port that is the SSI network mode master.

16.4.2.2 External Port to External Port Connectivity

External ports can communicate with external ports directly.

External ports can communicate together in three ways:

1. Each port's receive logic is configured in normal mode (MODE = 0) . Each port's RXDSEL[2:0] field is configured to select the other port's transmit data. Bit fields associated with clock/frame sync selection and direction are configured for each port. Either port can be the master.
2. One port is configured in internal network mode (MODE = 1) . All desired data lines are combined by the AND gate as determined by INMMASK[7:0]. Since an external port is being used as the internal network mode master, all other devices on the same AUDMUX port as the internal network mode master must be disabled. This configuration can be used with a combination of internal and external ports. All external ports must have a pull-up resistor on its RxDATA pin. Bit fields associated with clock/frame sync selection and direction are configured for each port. Any port can be the master.

16.4.2.3 Internal Port to Internal Port Connectivity

Internal ports can communicate with other internal ports directly, thereby providing a means for synchronous interprocessor communication.

Internal ports can communicate together in two ways:

1. Each port's receive logic is configured in normal mode (MODE = 0) . Each port's RXDSEL[2:0] field is configured to select the other port's transmit data. Bit fields associated with clock/frame sync selection and direction are configured for each port. Either port can be the master.
2. One port is configured in internal network mode (MODE = 1) . All desired data lines are combined by the AND gate as determined by INMMASK[7:0]. This configuration can be used with a combination of internal and external ports. All external ports must have a pull-up resistor on its RxDATA pin. Bit fields associated with clock/frame sync selection and direction are configured for each port. Any port can be the master.

16.4.2.4 Loopback Connectivity

AUDMUX ports can communicate with themselves in order to provide loopback functionality. Port x can route its TxDATA signal to its own RxD_out signal by setting RXDSELx[2:0] to its own port number. This is supported by all ports in the AUDMUX.

In addition, ports can provide loopback support in internal network mode. With internal network mode, the internal network mode master can loop its TxDATA signal (combined with those of other ports, if desired) back into its RxD_out signal. Port x's INMMASK should be set such that bit (x - 1) is clear in order to enable the loopback.

16.4.3 AUDMUX Clocking

This section provides information about AUDMUX clocking including clock inputs and the clock diagram.

16.4.3.1 AUDMUX Clock Inputs

The IP Bus read/write clock-peripheral clock-is an input to the AUDMUX. It is used for all AUDMUX register accesses. It is driven only when there is an AUDMUX access on the IP Bus.

16.4.3.2 AUDMUX Clock Diagram

The figure below shows the clocking used in the AUDMUX.

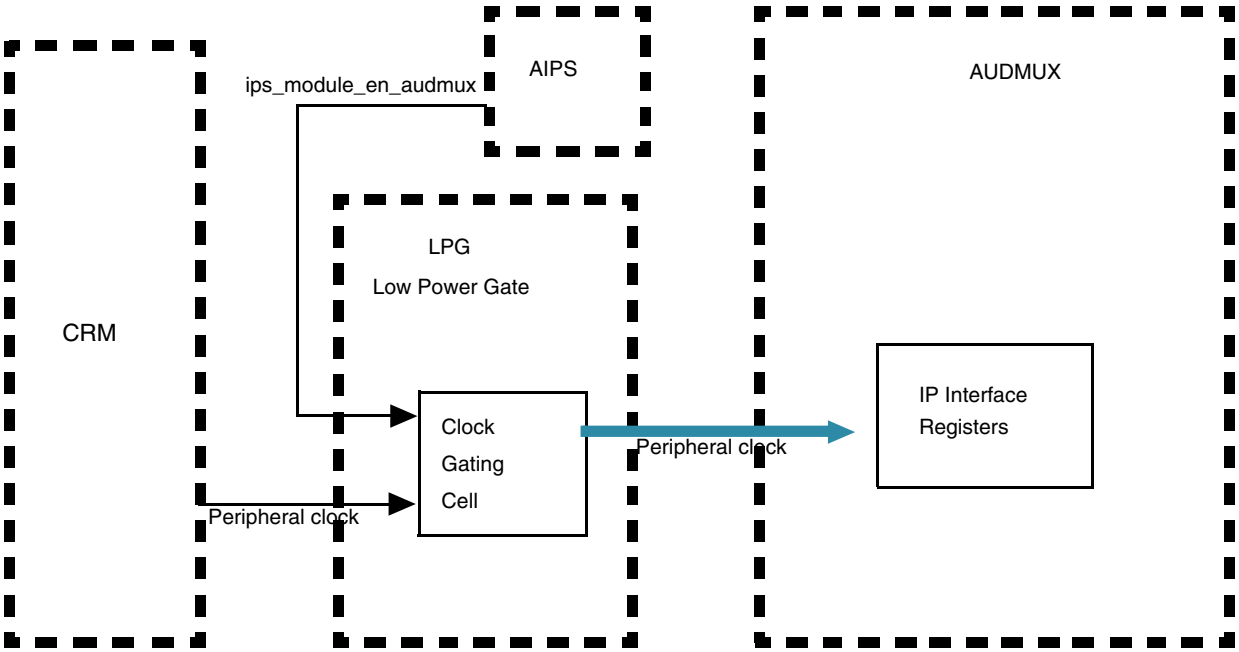

Figure 16-13. AUDMUX Clocking Scheme

16.4.3.3 Clocking Restrictions

16.5 Programmable Registers

This section includes the block memory map and detailed descriptions of all registers. For the base address of a specific sub-block instantiation, see the system memory map in this manual.

The AUDMUX memory map is shown in the following table.

AUDMUX memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FD_0000	Port Timing Control Register 1 (AUDMUX_PTCR1)	32	R/W	AD40_0800h	16.5.1/ 797

Table continues on the next page...

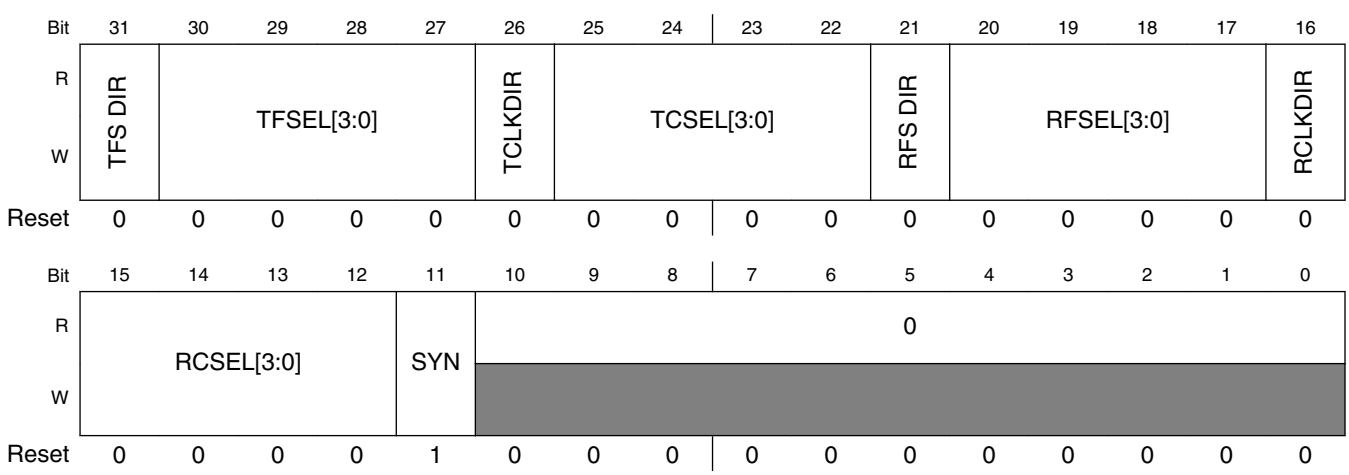
16.5.4 Port Timing Control Register n (AUDMUX_PTCR)

PTCR*n* is the Port Timing Control Register for Port *n*, where *n* ranges from 4 through 7.

Address: AUDMUX_PTCR is 63FD_0000h base + 18h offset = 63FD_0018h



AUDMUX_PTCR*n* field descriptions

Field	Description
31 TFS DIR	Transmit Frame Sync Direction Control. This bit sets the direction of the TxFS pin of the interface as an output or input. When set as an input, the TFSEL settings are ignored. When set as an output, the TFSEL settings determine the source port of the frame sync. 0 TxFS is an input. 1 TxFS is an output.
30–27 TFSEL[3:0]	Transmit Frame Sync Select. Selects the source port from which TxFS is sourced. 0xxx Selects TxFS from port. 1xxx Selects RxFS from port. x000 Port 1 x110 Port 7 x101 Port 6 x111 Reserved x11x Reserved
26 TCLKDIR	Transmit Clock Direction Control. This bit sets the direction of the TxClk pin of the interface as an output or input. When set as an input, the TCSEL settings are ignored. When set as an output, the TCSEL settings determine the source port of the clock. 0 TxClk is an input. 1 TxClk is an output.
25–22 TCSEL[3:0]	Transmit Clock Select. Selects the source port from which TxClk is sourced. 0xxx Selects TxClk from port. 1xxx Selects RxClk from port. x000 Port 1 x110 Port 7 x101 Port 6 x111 Reserved x11x Reserved
21 RFS DIR	Receive Frame Sync Direction Control. This bit sets the direction of the RxFS pin of the interface as an output or input. When set as an input, the RFSEL settings are ignored. When set as an output, the RFSEL settings determine the source port of the frame sync. 0 RxFS is an input. 1 RxFS is an output.
20–17 RFSEL[3:0]	Receive Frame Sync Select. Selects the source port from which RxFS is sourced. RxFS can be sourced from TxFS and RxFS from other ports. 0xxx Selects TxFS from port. 1xxx Selects RxFS from port. x000 Port 1 x110 Port 7 x101 Port 6 x111 Reserved x11x Reserved

Chapter 17
Clock Amplifier (CAMP)

17.1 Introduction

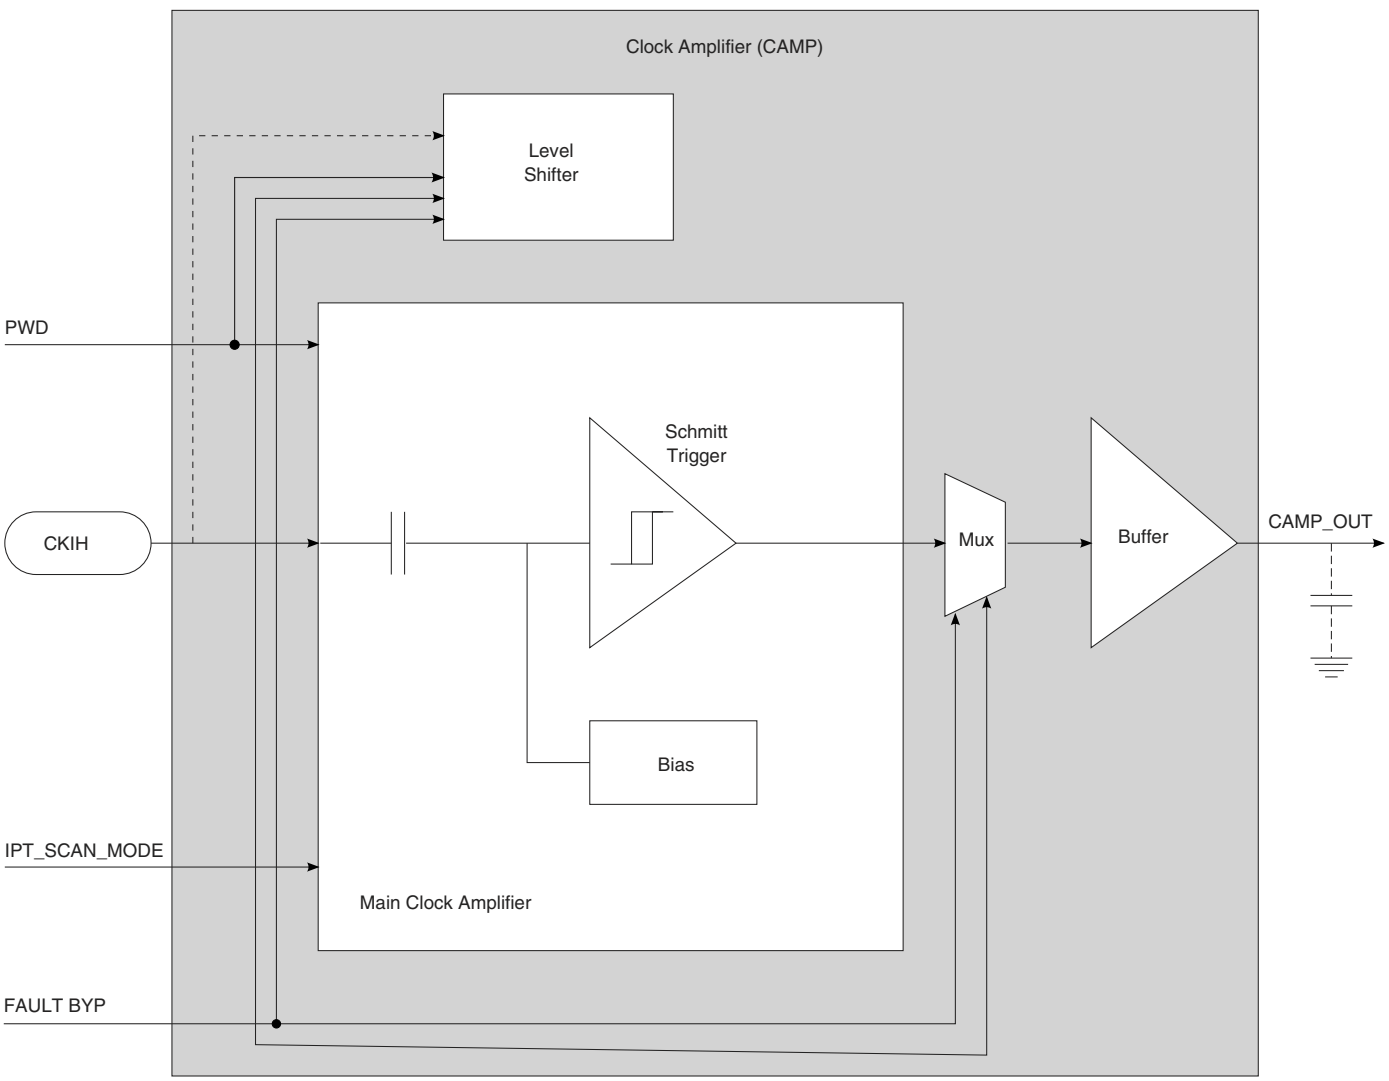

Figure 17-1. Clock Amplifier Block Diagram

17.1.1 Overview

The Clock Amplifier converts a square wave/sinusoidal input of frequency range 8-40 MHz, into a rail to rail square wave (CAMP supply voltage).

The input of the CAMP block is CKIH and the output is CAMP_OUT. The input to CAMP is internally AC coupled (in normal mode); no external coupling is required.

17.1.2 Features

The CAMP includes the following features:

- Converts sinusoidal input to square wave.
- Can accept a square wave of amplitude greater than the supply voltage of the block.

17.1.3 Modes of Operation

The CAMP supports three modes of operation.

17.1.3.1 Normal Mode

In this mode of operation, the Clock Amplifier accepts a sinusoidal/square wave as input and gives a rail to rail square wave output.

17.1.3.2 Power Down Mode

In this mode the CAMP is disabled and put in the low power state. CAMP_OUT remains at logic'0' level during power down.

17.1.3.3 Test Mode (Fault Bypass or Scan)

The Test mode is to be used for testing purpose or during scan. The MAIN CLOCK AMPLIFIER is bypassed in this mode.

17.2 External Signal Description

17.2.1 Signals Overview

Table 17-1. CAMP External Signal Properties

Name	Direction	Function
CKIH	Input	Input clock

Table 17-2. CAMP Interface Signal Properties

Name	Direction	Function
VDD	Input	Power supply
VSS	Input	Ground
PWD	Input	Power down signal
FAULT_BYP	Input	Test mode control signal
IPT_SCAN_MODE	Input	Scan mode signal
CAMP_OUT	Output	Output clock from CAMP

17.2.2 Detailed Signal Description

17.2.2.1 CKIH - External Clock Input

The signal CKIH is the clock input signal to the CAMP. It can be a sinusoidal input with a minimum swing of 400mV p-p or a square wave. It comes directly from the pad.

17.2.2.2 VDD - Power supply

The VDD is the power supply for the CAMP. It supplies the main clock amplifier, buffer and level shifter.

17.2.2.3 VSS - Ground

The VSS input is the ground for the CAMP.

17.2.2.4 IPT_SCAN_MODE - Scan Signal

This signal is active high. When this signal is asserted CAMP is forced to "Test Mode" irrespective of states of fault_byp or pwd signals.

17.2.2.5 PWD - Power Down Signal

This signal when asserted (and ipt_scan_mode = 0), puts the CAMP in the low power mode. This signal is active high.

17.2.2.6 FAULT_BYP - Control Signal for Test Mode

This signal when asserted puts CAMP in test mode. This signal is active high. When this signal is low (and ipt_scan_mode = 0) CAMP works in normal mode.

17.2.2.7 CAMP_OUT - Clock Output from CAMP

This signal is the output of the CAMP.

17.3 Memory Map/Register Definition

The CAMP gets its control signals PWD and FAULT_BYP from registers residing in the CRM. It gets its control signal IPT_SCAN_MODE from TSCM (Test and Scan Control sub-block).

17.4 Functional Description

This section provides a functional description of the Clock Amplifier. The block can be divided into three parts. First the Main Clock Amplifier, second the Output Buffer and third the Level Shifter.

17.4.1 CAMP Sub-Blocks

This section describes the Main Clock amplifier, the Output Buffer and Level Shifter of CAMP. (See Figure 17-1).

17.4.1.1 Main Clock Amplifier

The input clock is ac coupled to the input of a Schmitt trigger. A dc bias generation circuit is used to provide a fixed dc to the input of the Schmitt trigger. The Schmitt trigger converts a sinusoidal signal to a square wave.

17.4.1.2 Output Buffer

The output of the main clock amplifier is buffered by the output buffer.

17.4.1.3 Level Shifter

This is activated in the test mode. It level shifts the input signal to CAMP supply.

17.4.2 CAMP Modes of Operation

Table 17-3. Truth Table for CAMP

IPT_SCAN_MODE	PWD	FAULT_BYP	CAMP_OUT	Main Clock Amplifier Path	Level Shifter Path
0	0	0	Square Wave	Enabled	Disabled
0	0	1	Square Wave	Disabled	Enabled
0	1	X	Logic'0'	Disabled	Disabled
1	X	X	Square Wave	Disabled	Enabled

17.4.2.1 Normal Mode

In this mode of operation the IPT_SCAN_MODE, PWD and FAULT_BYP signals are de-asserted. The sinusoidal (or square wave) clock input (with peak to peak amplitude not exceeding 3 Volts) is converted to square wave with amplitude equal to the Camp supply.

17.4.2.2 Power Down Mode

In this mode of operation, the CAMP is powered down. The supply to Main Clock Amplifier and level shifter is turned off by power gating. The CAMP_OUT is a t logic '0' level.

17.4.2.3 Test Mode

In this mode the MAIN CLOCK AMPLIFIER is bypassed via a level shifter. It accepts only square wave input with voltage swing greater than or equal to CAMP supply voltage. There is no guarantee of output clock duty cycle in this mode. To obtain 45%-55% duty cycle output from CAMP in this mode, the input must be a square wave at CAMP's supply level with slews less than or equal to 2ns.

17.5 Initialization/Application Information

During initialization it has to be ensured that PWD and IPT_SCAN_MODE remain de-asserted.

Chapter 18
Clock Control Module (CCM)

18.1 Overview

The Clock Control Module (CCM) controls the clocks for i.MX53 blocks. This block uses the available clock sources to generate the clock roots. Figure 1-1 shows the CCM block diagram.

The Clock Control Module controls the following functions in i.MX53:

1. Uses the available clock sources to generate clock roots to various parts of the chip.
2. Uses program able bits to control frequencies of the clock roots.
3. Controls the low power mechanism.
4. Provides control signals to low power clock gating (LPCG) for gating clocks.
5. Provides handshake with system reset controller (SRC) for reset performance.
6. Provides handshake with general power controller (GPC) for support of dvfs, dptc and power gating operations.

18.1.1 Features

The CCM includes these distinctive features:

- Clock switcher block to generate four switcher source clocks based on four DPLL's.
- Root clocks generation - provides root clock to i.MX53's blocks based on four switcher source clocks.
- ARM core root clock generated from dedicated switcher source clock.
- Includes separate dividers to control generation of core and bus root clocks (axi's, ahb, ipg).
- Includes separate dividers and clock sources selectors for each serial root clock.
- Option for external clock to bypass DPLL's clocks.
- Selects clock signals to output on CLKO and CLKO2 on to the pads for observability.
- Controllable registers are accessible via IP Bus.

- Manages the Low Power Modes, namely RUN, WAIT, and STOP. The gating of the peripheral clocks is programmable in RUN and WAIT modes.
- Manages frequency scaling procedure for ARM core clock by shifting between DPLL sources, without loss of clocks.
- Manages frequency scaling procedure for peripheral clock roots by programable divider. The division is done on the fly without the loss of clocks.
- DFT feature support.
- Interface for the following block's
  - DPLLC - DPLLC interfaces for each DPLL on the IC.
  - LPCG - Low Power Clock Gating unit
  - SRC - System reset Controller
  - GPC - General Power Controller

18.1.2 CCM Block Diagram

CCM includes the following sub-blocks:

CCM_CLK_IGNITION - This sub-block manages the ignition process. This block functions once the CCM comes out of reset. It starts the Clock Amplifier (CAMP-1 and CAMP-2), the DPLL's and creates stable output root clocks after reset.

CCM_CLK_SWITCHER - This sub-block receives the clock outputs from the four DPLL's, together with the respective bypass clocks from the input and generates four switcher clock outputs (pll1_sw_clk, pll2_sw_clk, pll3_sw_clk, pll4_sw_clk) for the CCM_CLK_ROOT_GEN sub-block.

CCM_CLK_ROOT_GEN - This sub-block receives the four main clocks (pll1_sw_clk, pll2_sw_clk, pll3_sw_clk, pll4_sw_clk) and generates the output root clocks.

CCM_CLK_LOGIC - This sub-block generates the clock enables. It generates the clock enable signals based on information from CCM_LPM and CCM_IP. The clock enables are used by LPCG to turn on and off the clock branches it generates.

CCM_LPM: This sub-block manages the low power modes of the IC.

CCM_GSBI_TOP: This sub-block manages the memory map of CCM. It holds the programable registers and the connectivity to the IP bus. This block is connected to all the sub-blocks that need definition of programmable bits. Note that in the diagram below appears only connectivity to the ccm_clk_logic sub-blocks.

CCM_CLK_SRC_DIV - This sub-block multiplexes different clocks to the two output clocks, CLKO and CLKO2. These output clocks are connected to the pads and can support testing.

CCM_HND_SK - This sub-block manages the handshake when changing root clock dividers that require handshake, and manages the frequency change in case of dvfs scenario.

The following figure describes the CCM boundary.

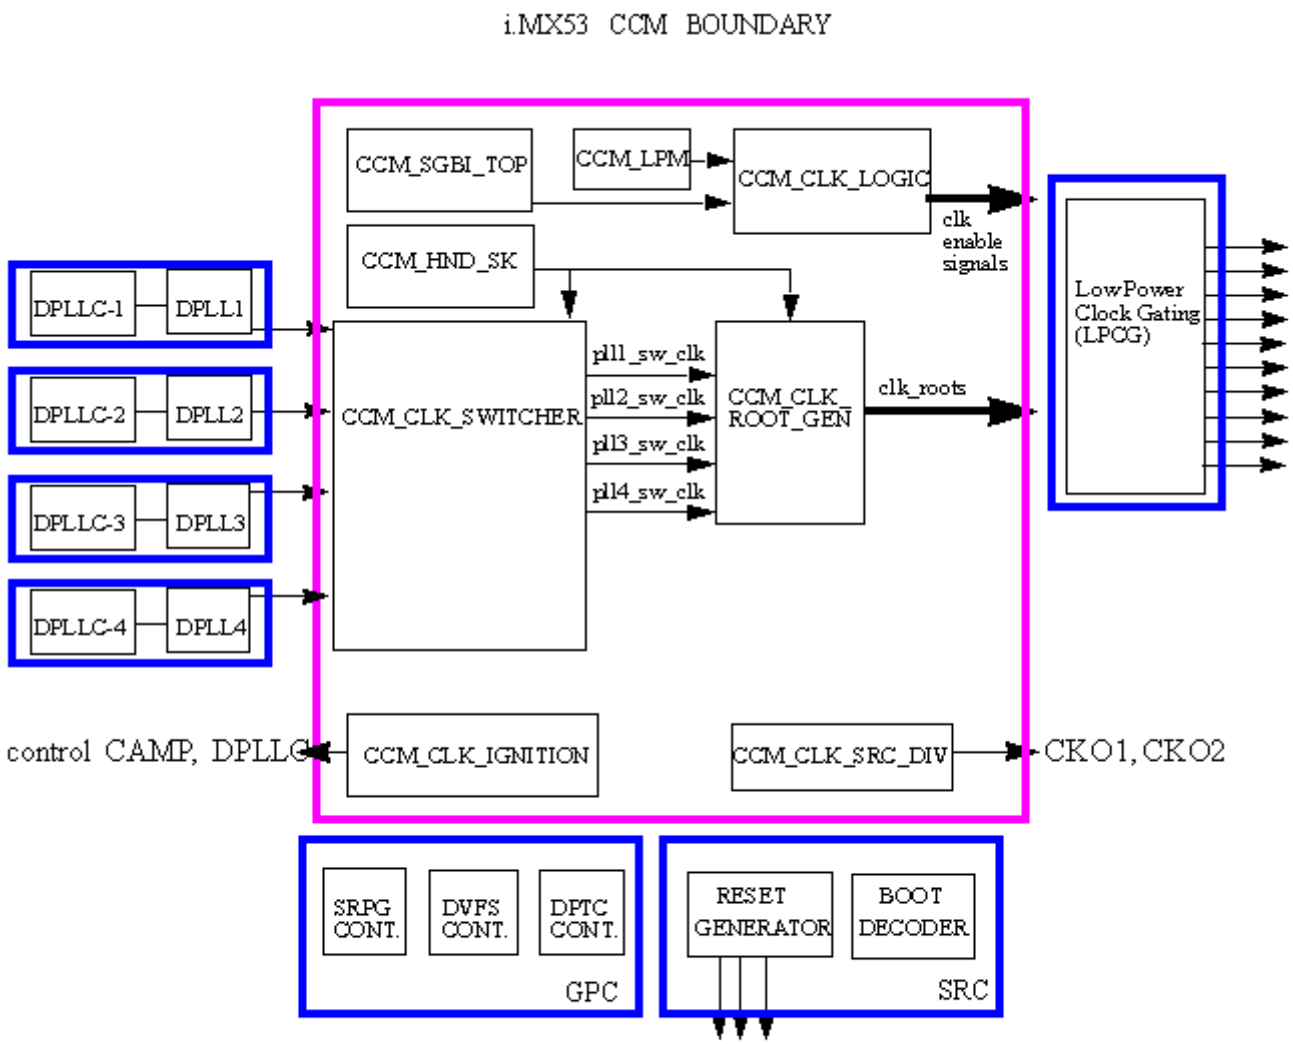

Figure 18-1. CCM Block Diagram

The following figure shows the entire clock tree for i.MX53

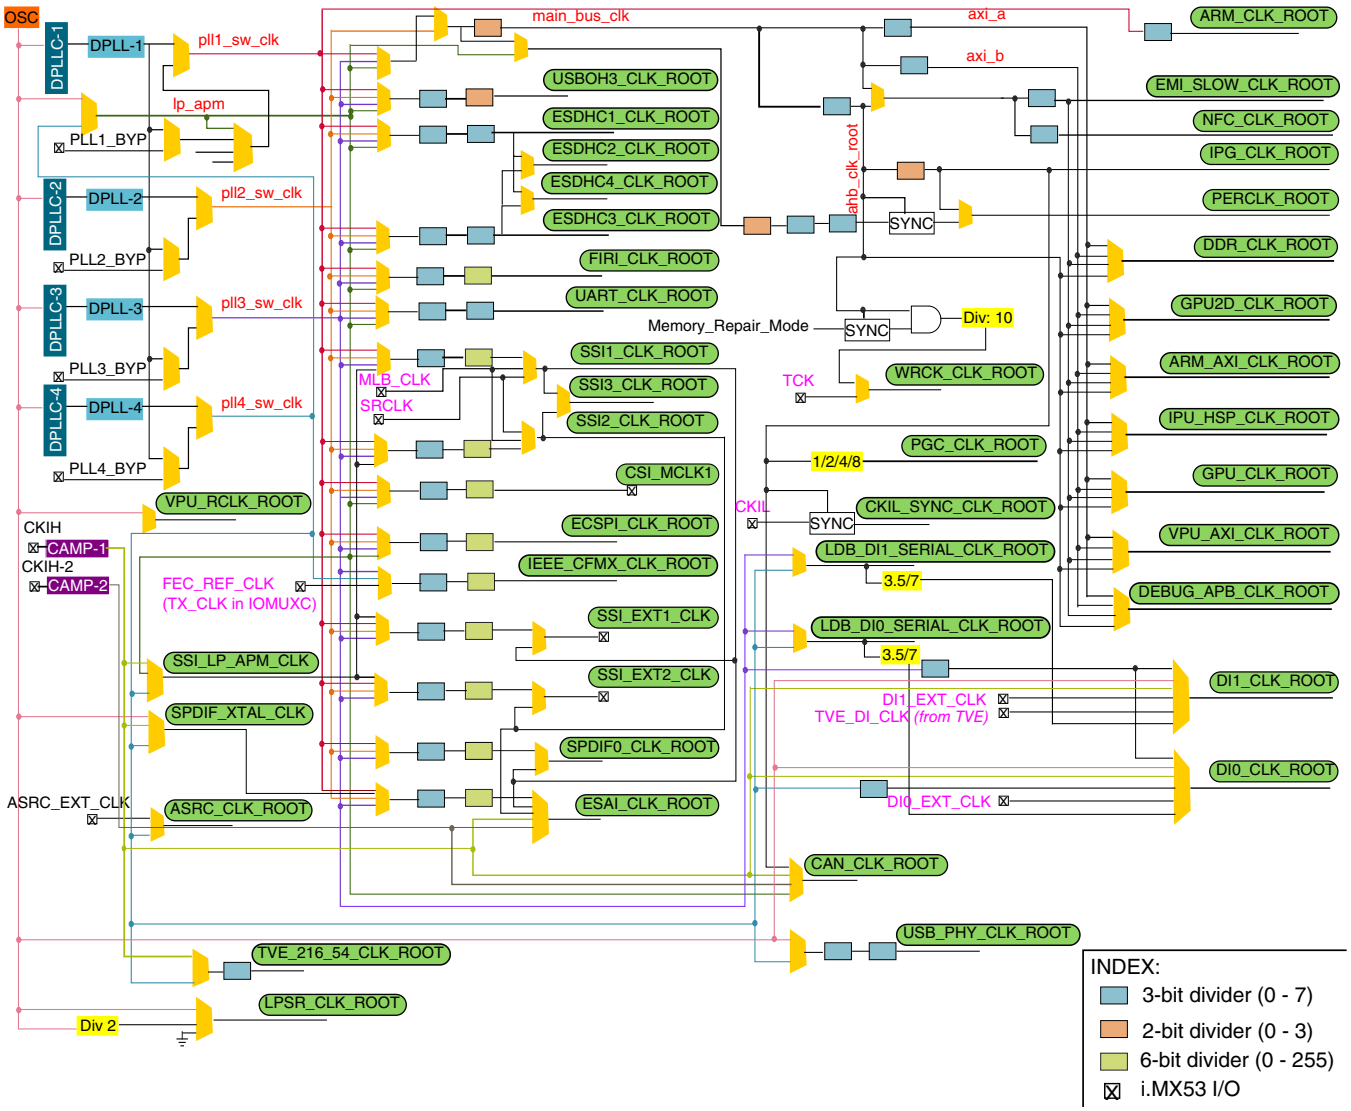

Figure 18-2. CCM Clock Tree

18.2 Functional Description

18.2.1 Clock Generation

18.2.1.1 External Low Frequency Clock - CKIL

i.MX53 can use either a 32 kHz, 32.768 kHz or a 38.4 kHz crystal as the external low frequency source. Throughout this chapter, the low frequency crystal is referred to as the 32 kHz crystal. CMOS input buffer with shmitt trigger feature is used as receiver of

32KHz clock. This clock source should be active all the time i.MX53 is powered on. The 32kHz entering the CCM is referred to as CKIL. It is synchronized to ipg_clk and supplied to blocks that need it.

18.2.1.2 External High Frequency Clock - CKIH and internal oscillator

i.MX53 uses internal oscillator to generate the reference clock. The internal oscillator is connected to an external crystal. The oscillator generates frequencies in the range of 22-27Mhz.

i.MX53 uses CKIH and CKIH2 input pins to generate special serial clock demands (like TVE, SPDIF, etc.) as a backup to the DPLL clocks.

18.2.1.3 DPLL reference clock

There are four DPLL's in i.MX53 project namely:

- DPLL-1 (typical functional frequency 800Mhz)
- DPLL-2 (typical functional frequency 400Mhz)
- DPLL-3 (typical functional frequency 216Mhz)
- DPLL-4 (typical functional frequency 595Mhz)

Each DPLL is controlled by a DPLLC-n interface block. Each DPLLC interface block uses the output of on chip oscillator (typical frequency is 24Mhz) as DPLL reference clock:

18.2.1.4 CCM Internal Clock Generation

The clock generation is comprised of three sub-blocks:

- CCM_CLK_SWITCHER
- CCM_CLK_IGNITION
- CCM_CLK_ROOT_GEN

CCM_CLK_SWITCHER sub-block receives the DPLL output clocks and the DPLL bypass clocks. It generates 4 main switcher clocks to be delivered to CCM_CLK_ROOT_GEN:

- pll1_sw_clk (typical functional frequency 800Mhz - used to supply ARM platform)
- pll2_sw_clk (typical functional frequency 400Mhz - used to supply axi/ahb/ip buses clocks)
- pll3_sw_clk (typical functional frequency 216Mhz - used to supply serial clocks like usb, ssi, etc.)

pll4_sw_clk (typical functional frequency 595Mhz - used to supply LDB clocks)

The figure below describes the generation of the four switcher clocks and a few root clocks.

The figure also includes Frequency Switch Control sub-block that is responsible of frequency change during DVFS operation.

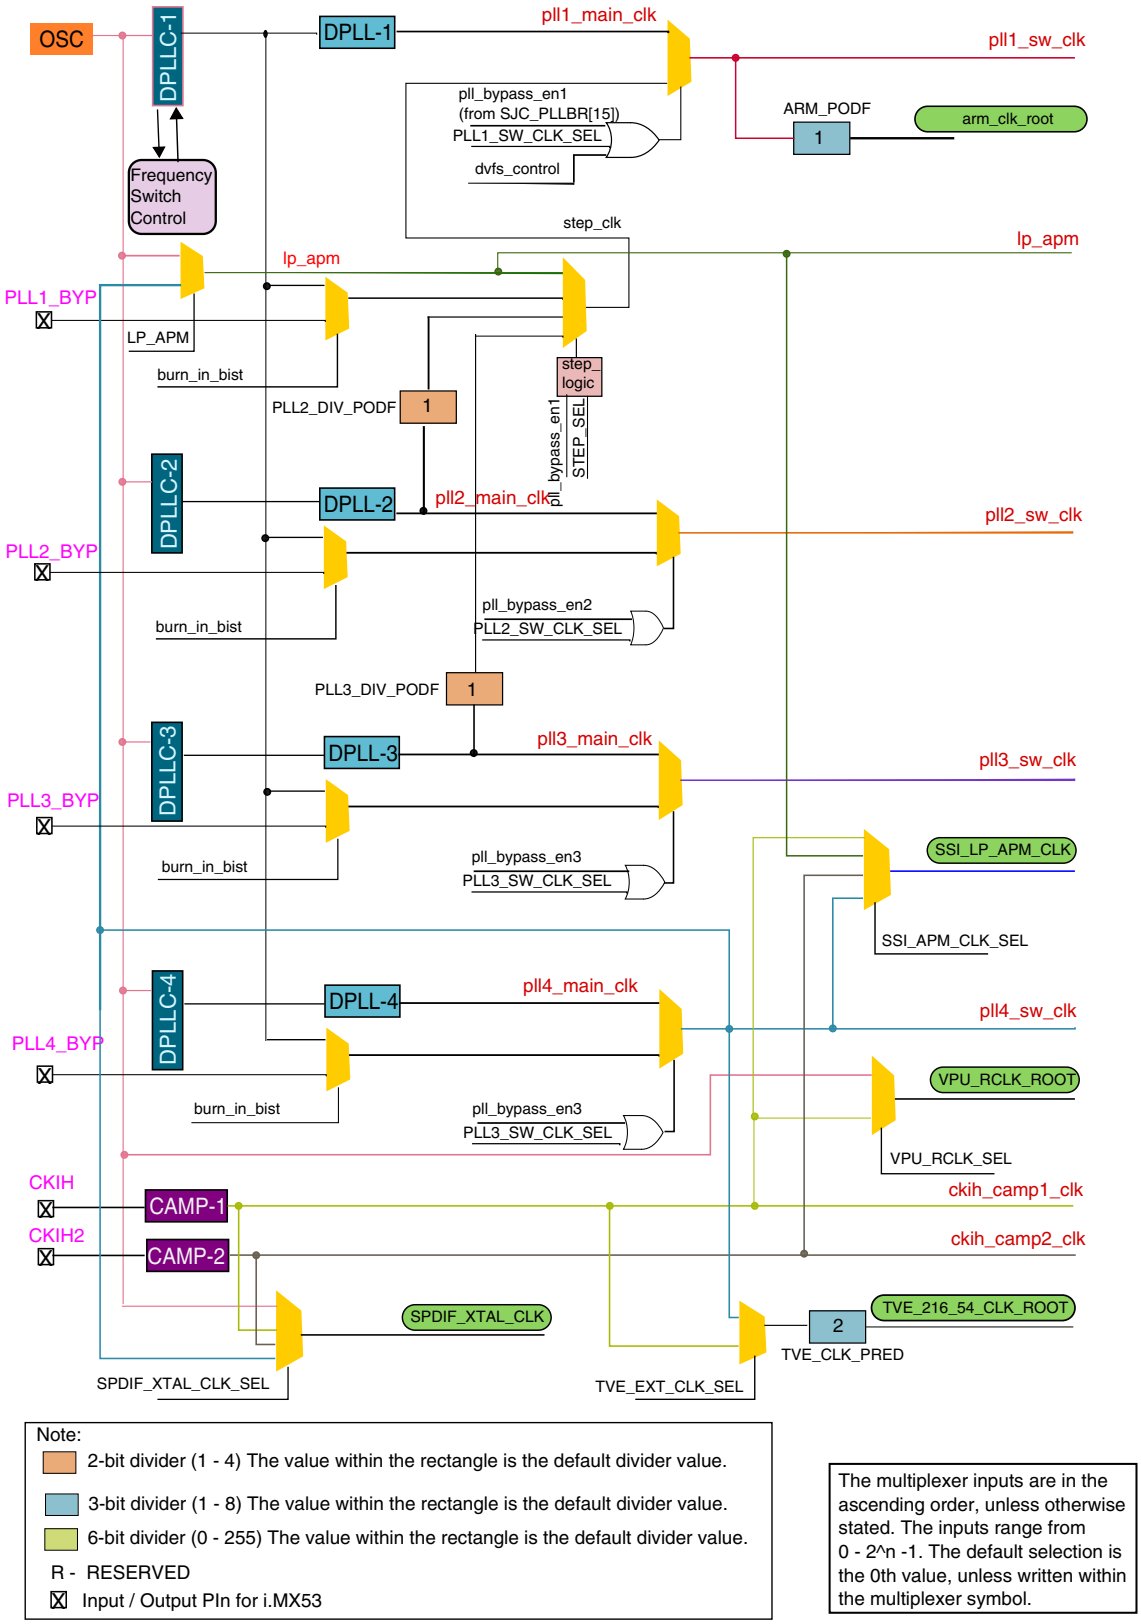

Figure 18-3. Detailed Clock Tree 1

18.2.1.4.1 DPLL Bypass Procedure

CCM_CLK_SWITCHER sub-block includes capability for each of the pll_main_clk's to be bypassed with an external bypass clk. In burn_in_bist mode the DPLL bypass clocks for all DPLLs are supplied from pll1_ref_clk (the output of DPLLC-1).

The decision to shift from pll_main_clk to pll_bypass_clk is done either by programable bits in CCM_CCSR or by pll_bypass_enn signals which are driven from the jtag block. As the switch between the clocks is done by a glitch less multiplexer, both pll_main_clk and pll_bypass_clk should be running to complete the shift glitchlessly. In case the selection is done during reset, then it is not necessary for both clocks to be available simultaneously.

As the bypass clock for pll1_sw_clk is generated from a multiplexer, the bypass clock needs to be set via CCM_CCSR[step_sel] before shifting the glitch less multiplexer via CCM_CCSR[PLL1_SW_CLK_SEL]. Similarly, when returning from pll_bypass, system should first change the glitch less multiplexer via PLL1_SW_CLK_SEL and only after that should it change the STEP_SEL bits.

18.2.1.4.2 Step Logic

The step logic allows the DPLL bypass enable signal to bypass the step_sel bits and to set the 4*1 multiplexer to the pll1_bypass_clk option.

18.2.1.4.3 DPLLC Reference Clock Connectivity

For all four DPLLC's:

The input clk2 is connected to on board oscillator clock output.

The input init_dp_ctl_dpllip [8] is connected to gnd.

The input init_dp_ctl_dpllip [9] is connected to vcc.

The above connections allows DPLLC to choose the on chip oscillator as the reference clock to the DPLL.

18.2.1.4.4 DPLL Clock Change

If the DPLL clock output of a specific DPLL needs to change, or if a specific DPLL needs to be updated, then first move all the clocks generated by the DPLL to another DPLL which is not changed. This should be done via the glitch less multiplexers for the clocks which can not be stopped (core and bus clocks). Then, reprogram the respective DPLLC: First configure DPLLC_CONFIG[1], so that it allows auto restart of the DPLL

on next update of the reference clock. Then change the DPLL values to the new aimed values. In this case the respective DPLL restarts and once its locked, it sends a signal to CCM. This signal can cause an interrupt from CCM (if configured in CCM_CIMR register). This interrupt, notifies that the DPLL is ready with the new reference clocks. Take care while reprograming the DPLL settings to match the new reference clock. At this point the multiplexer can be changed via the glitch less multiplexers to supply clock from the respective DPLL that was updated.

18.2.1.4.5 CCM_CLK_IGNITION

The responsibility of the CCM_CLK_IGNITION sub-block is to manage the wake up after reset of the on chip oscillator, CAMP-1, CAMP-2, DPLLC and DPLL blocks. Its task starts with de-assertion of early_reset from the reset controller and finishes with the assertion of signal that notifies the reset controller that the root clocks are ready.

As the on chip oscillator is the reference clock for the DPLLs, the first step in the ignition process is to assert CCM_CCR[COSC_EN] signal and to de-assert CCM_CLPCR[COSC_PWRDOWN] to start the on chip oscillator. The external oscillator and CAMPs are enabled during ignition proces, that is, CCM_CCR[CAMP1_EN] and CCM_CCR[CAMP2_EN] are asserted (= '1') and CCM_CSR[REF_EN_B] is de-asserted (= '0') so that ckih_camp1 and ckih2_camp2 clocks are started. Next CCM_CLK_IGNITION counts CKIL cycles defined in CCM_CCR[OSCNT]. Once the counter has elapsed, it is assumed that the clock output of the on chip oscillator and CAMP's is ready. In this stage CCM asserts the COSC_READY, CAMP1_READY and CAMP2_READY bits.

Both OSCNT counts for on board oscillator and external oscillator are performed in parallel, so that when the count elapses, it implies that both oscillators are ready. This is done to save time during the ignition process.

Next, CCM_CLK_IGNITION asserts a signal to enable the reference clocks to the DPLL's.

Next, CCM_CLK_IGNITION asserts enable signals for the DPLLCs so that dpllip_cpen is generated.

NOTE

For this to happen, initial value of UPEN should be '1' i.e. init_dp_ctl_dpllip[5] for all DPLL's should be tied to '1'.,

Once the DPLL's are locked, DPLLCs generate DPLL locked signal to CCM_CLK_IGNITION.

Upon assertion of all four DPLL locked signals, CCM_CLK_IGNITION generates a clock ready signal for the reset controller to indicate that DPLL clocks are ready

If DPLL bypass signal is asserted, then clock ready signal to the reset controller is asserted immediately after exiting reset. Once the clock ready signal arrives at the reset controller, the reset sequence continues.

18.2.1.4.6 Reset Values for DPLLC

Reset values that are hard coded as DPLLC initialization values are:

DPLL1 - initial value =192Mhz

DPLL2 - initial value = 192Mhz

DPLL3 - initial value = 168Mhz

DPLL4 - initial value = 168Mhz

These frequencies correspond to the reference clock source of on chip oscillator (24 MHz) as the source for DPLL. For different frequencies, a linear ratio should be applied.

NOTE

The frequencies above are the reset values. The BOOT ROM code can change the DPLL settings according to the configured BOOT mode configuration and FUSE settings.

18.2.1.4.7 CCM_CLK_ROOT_GEN

CCM_CLK_ROOT_GEN sub-block generates the root clocks to be delivered to LPCG.

The following is a list of the root clocks generated by this block. The clocks are supposed to be asynchronous unless mentioned differently:

ARM_CLK_ROOT - generated from pll1_sw_clk.

EMI_SLOW_CLK_ROOT

eNFC_CLK_ROOT - generated by division of EMI_SLOW_CLK_ROOT and balanced with it.

VPU_RCLK_ROOT

AHB_CLK_ROOT

IPG_CLK_ROOT - generated by division of AHB_CLK_ROOT and balanced with it.

PERCLK_ROOT - this clock is synchronized and balanced to AHB_CLK_ROOT. For the synchronization process, peripherals clock pre-divider and post-divider should generate clock with frequency 2.5 times lower than AHB clock. During DVFSP operation, when AHB is reduced, peripherals clock should be configured to be 2.5 times lower than the minimum value of AHB_CLK_ROOT (the DVFS value of ahb_clk).

DDR_CLK_ROOT

ARM_AXI_CLK_ROOT

IPU_HSP_CLK_ROOT

CKIL_SYNC_CLK_ROOT - ckil clock is synchronized to IPG_CLK_ROOT and balanced with it, when not in stop mode. Synchronizer is bypassed, when in stop mode.

USBOH3_CLK_ROOT

ESDHC1_CLK_ROOT

ESDHC2_CLK_ROOT

ESDHC3_CLK_ROOT

UART_CLK_ROOT

SSI1_CLK_ROOT

SSI2_CLK_ROOT

SSI_EXT1_CLK - connected to external pad

SSI_EXT2_CLK - connected to external pad

USB_PHY_CLK_ROOT

TVE_216_54_CLK_ROOT - The default clock frequency is 595MHz. For HDTV the user needs to change the frequency to 594MHz.

DI_CLK_ROOT

SPDIF0_CLK_ROOT

ECSPI_CLK_ROOT

WRCK_CLK_ROOT

LPSR_CLK_ROOT

PGC_CLK_ROOT - generated as division of ipg_clk and balanced to it.

Following figures describe the above clocks generation.

All 6 bit post-dividers in the diagrams above are able to work on frequencies lower than 400MHz. The 6 bit divider should not have an input clock with a frequency higher than this frequency.

The following pre-dividers should use divider values larger than '1'. The option '000' is not allowed for them: USBOH3_CLK_PRED, SSI1_CLK_PRED, SSI2_CLK_PRED, SSI_EXT1_CLK_PRED, SSI_EXT2_CLK_PRED, ECSPI_CLK_PRED.

18.2.1.4.8 Initial Values Controlled by SJC

The initial values of the following dividers and multiplexers can be controlled by SJC. In regular functional mode, the SJC drives the reset values stated in the CCM register memory map. If SJC is programmed to change these values, then the reset value for these

dividers/multiplexers are taken from the SJC programmability. These values can be changed after the reset sequence. The control signals and the dividers/muxes are listed below:

init_perclk_pred1[1:0] to control reset value of PERCLK_PRED1.

init_perclk_pred2[2:0] to control reset value of PERCLK_PRED2.

init_perclk_podf[2:0] to control reset value of PERCLK_PODF.

init_ipg_podf[1:0] to control reset value of IPG_PODF.

init_ahb_podf[2:0] to control reset value of AHB_PODF.

init_axi_a_podf[2:0] to control reset value of AXI_A_PODF.

init_axi_b_podf[2:0] to control reset value of AXI_B_PODF.

init_emi_slow_podf[2:0] to control reset value of EMI_SLOW_PODF.

init_nfc_podf[2:0] to control reset value of NFC_PODF.

init_periph_apm_sel[1:0] to control reset value of PERIPH_APM_SEL.

init_periph_clk_sel to control reset value of PERIPH_CLK_SEL.

init_ssi_apm_clk_sel[1:0] to control reset value of SSI_APM_CLK_SEL.

18.2.1.4.9 Divider Change Handshake

Below list describes the dividers that might involve block handshake on every divider update:

Divider	Handshake with blocks	Comment
emi_slow_podf	EXTMC IPU	Handshake with IPU exists if EMI_SLOW_PODF is chosen as source for ipu_hsp_clk. Handshake with EXTMC is through emi_dvfs_req_slow, emi_dvfs_req_int1,emi_dvfs_req_int2, emi_dvfs_ack_slow, emi_dvfs_ack_int1, emi_dvfs_ack_int2. If emi_slow_podf is chosen as source of gpu_clk,i.e. the change of emi_slow_podf is affect gpu_clk then the handshake of emi_dvfs_req_garb, emi_dvfs_ack_garb should also commence. If this divider is chosen as source of ddr_clk,then the handshake of emi_dvfs_req_fast, emi_dvfs_ack_fast should also commence.
nfc_podf	EXTMC	Handshake with EXTMC is through emi_dvfs_req_slow, emi_dvfs_ack_slow.

Table continues on the next page...

Divider	Handshake with blocks	Comment
axi_a_podf	EXTMC IPU	Handshake with EXTMC exists only if axi_a_podf is chosen as source to ddr_clk. In this case handshake with EXTMC is through emi_dvfs_req_fast, emi_dvfs_ack_fast. If axi_a_podf is chosen as source of gpu_clk,i.e. the change of axi_a_podf is affect gpu_clk then the handshake of emi_dvfs_req_garb, emi_dvfs_ack_garb should also commence. Handshake with IPU exists only if axi_a_podf is chosen as source to ipu_hsp_clk. If this divider is chosen as source of ddr_clk,then the handshake of emi_dvfs_req_fast, emi_dvfs_ack_fast should also commence.
axi_b_podf	EXTMC IPU	Handshake with EXTMC is exist only if axi_b_podf is chosen as source to ddr_clk. In this case handshake with EXTMC is through emi_dvfs_req_fast, emi_dvfs_ack_fast. If axi_b_podf is chosen as source of gpu_clk,i.e. the change of axi_b_podf is affect gpu_clk then the handshake of emi_dvfs_req_garb, emi_dvfs_ack_garb should also commence. Handshake with IPU is exist if axi_b_podf is chosen as source to ipu_hsp_clk. If this divider is chosen as source of ddr_clk,then the handshake of emi_dvfs_req_fast, emi_dvfs_ack_fast should also commence.
ahb_podf	EXTMC IPU	Handshake with EXTMC is exist only if ahb_podf is chosen as source to ddr_clk. In this case handshake with EXTMC is through emi_dvfs_req_fast, emi_dvfs_ack_fast. Handshake with IPU is exist only if ahb_podf is chosen as source to ipu_hsp_clk. If ahb_podf is chosen as source of emi_slow_clk generation, then similar handshake to the emi_slow_podf should take place. If ahb_podf is chosen as source of gpu_clk,i.e. the change of ahb_podf is affect gpu_clk then the handshake of emi_dvfs_req_garb, emi_dvfs_ack_garb should also commence. If this divider is chosen as source of ddr_clk,then the handshake of emi_dvfs_req_fast, emi_dvfs_ack_fast should also commence.

Any update of CCM_CBCDR might involve handshake with blocks based on the above table.

Once the CCM_CBCDR register is updated, CCM checks which of the above dividers were updated. For the updated dividers, CCM is check if a handshake with the respective blocks is needed. If the handshake is needed, CCM is request acknowledge from the respective block for frequency change. Once the acknowledge arrives, CCM is perform the actual frequency change, and is notify the block that the frequency has changed by de

asserting the request. IPU handshake also involves signal to notify it on the frequency change. This signal (periph_dvfs_sw_ack) is held for two clock cycles of ipg_clk on each change.

The handshake with the respective blocks is not be performed in case that the respective handshake is masked through CCDR[bits18-16]. In this case the write to the respective divider is commence immediately after the CBCDR register is updated.

Make sure that the respective blaocks are enabled and have the ablity to acknowledge CCM's request. If the respective block or its clocks are disabled, then it does not have the ability to generate the handshake process, and its handshake capability should be masked (through CCM_CCDR[bits18-16]).

Interrupts can be generated for change in each of the above dividers. See CCM Interrupt Status Register (CCM_CISR) for details on those interrupts.

CCM has divider handshake in process register (CCM_CDHIPR). This register has status bits for each of the above dividers that are involved in the handshake process. When the respective bit is asserted, it means that the divider is being updated, and no attempt to write to this divider should be made, until the bit is de-asserted. Any reads to the divider when it's status bit is asserted, reads the next value to be loaded into the divider, and not the actual value. To make sure that the actual dividers value is read, wait until it's CCM_CDHIPR bit is de-asserted.

For the serial multiplexers, make sure that the block is not using the respective clock before changing multiplexer settings that affect that clock. There is no hardware handshake for changing multiplexer settings.

The multiplexers for AXI buses that are controlled by CCM_CBCDR register, and are not glitchless multiplexers, and hence, should not be used on the fly. That is, make sure that the block is not using the respective clock before changing the multiplexer configuration.

Changing the periph_clk_sel bits in CCM_CBCDR involves handshake with external memory controller (EXTMC) and image processing unit (IPU) - a similar handshake to the one that is performed during load dividers for EXTMC and IPU. These handshakes can be masked by programming CCM_CCDR bits.

Changing the emi_clk_sel bits in CCM_CBCDR involves handshake with EXTMC and IPU - a similar handshake to the one that is performed during load dividers for EXTMC and IPU. The IPU handshake is performed only if IPU_HSP_CLK_ROOT uses EMI_SLOW_CLK_ROOT. These handshakes can be masked by programming CCM_CCDR bits.

NOTE

In case DVFS is enabled (through GPC), frequency changes are not allowed, that is, the frequency of the system should be set prior to DVFS enable, and once the DVFS operation is enabled, no divider from the above handshake group dividers can be changed. This might corrupt the handshake process.

18.2.1.4.10 CKIL Synchronizing to ipg_clk

CKIL is synchronized to ipg_clk when the system is in RUN mode. When system is in STOP mode, i.e. when there is no ipg_clk, the CKIL synchronizer is bypassed, and raw CKIL is supplied to the system.

18.2.1.4.11 Special Considerations for Configuring PERCLK

In addition to ensuring that PERCLK remains at least 2.5 times slower than the AHB clock, certain steps need to be followed to ensure robust operation of PERCLK when reconfiguring the PERCLK clock source.

To properly configure the PERCLK clock source, the following steps are required:

1. In the CCGR registers, gate the clocks to all PERCLK-dependent modules (see below for a list of PERCLK-dependent modules).
2. Select the desired input clock for the PERCLK root clock (to be either source from the peripherals main source clock or the lp_apm clock source). Refer to the CMCBR register, perclk_lp_apm_sel bit.
3. Configure the perclk_pred1, perclk_pred2, and perclk_podf dividers to the desired setting. Refer to the CBCDR register for details.
4. In the CCGR registers, enable the desired clocks for the PERCLK-dependent module clocks.

The following table lists the PERCLK-dependent module clocks and the associated CCGR register. Note that when configuring the PERCLK clock source, these clocks must be gated, however, other unused clock source may also be gated to minimize power consumption.

Table 18-2. PERCLK-dependent Module Clock Sources

PERCLK-dependent Module Clock Sources	Associated CCGR register
uart1_perclk (CG4)	CCGR1
uart2_perclk (CG6)	
uart3_perclk (CG8)	
epit1_highfreq (CG2)	CCGR2

uart5_perclk (CG7)	

18.2.1.5 DPLL's Disabling / Enabling

DPLL enable and disable is done via the DPLLC block. First move all the clocks generated from a specific DPLL to another DPLL before disabling the DPLL through DPLLC. This move of clocks can be done via glitch less multiplexer, for clocks which are critical to the system, i.e. bus clocks. For serial clocks, first disable the block and the clock generated by it. Then move the multiplexer controlling the source of the clocks to another DPLL, and enable the block and its clocks. Only then it is safe to disable the DPLL. The multiplexer for the serial clocks is not glitchless hence the above procedure should be followed.

18.2.1.6 Low Power Clock Gating Module (LPCG)

The LPCG block receives the root clocks and splits them to clock branches for each block. The clock branches are gated clocks and their enables can come from five sources:

1. Clock enable signal from CCM - this signal is generated by configuration of the CGR bits in CCM. It is based on the low power mode.

2. Clock enable signal from the block - this signal is generated by the block based on its internal logic. Not every enable signal from the block is used. For clock enable signals used from the block, CCM generates override signals based on programable bits in CCM_CMEOR.

3. Clock enable signal from Reset controller (SRC) - this signal enables the clock during the reset procedure. Please refer to SRC spec for details on the clock enable signal during reset procedure.

4. Enable or disable clock in bist mode: This is based on bist_en signal. This is applicable for clocks that are not functional and needed only on memory repair or bist sequence (like sms_clk's and wrck).

The above possible enable signals are ANDed to generate the enable signal for the gating cell.

The enable signal for the gating cell is synchronized with the clock it needs to gate. This is done in order to prevent glitches on the gated clock.

Notifications are generated for the CCM, to indicate when to close and to open the clock roots. All notifications that correspond to the same clock root are ORed to generate one notification signal to CCM for clock root gating.

Figure 18-6 describes the implementation for each gating cell:

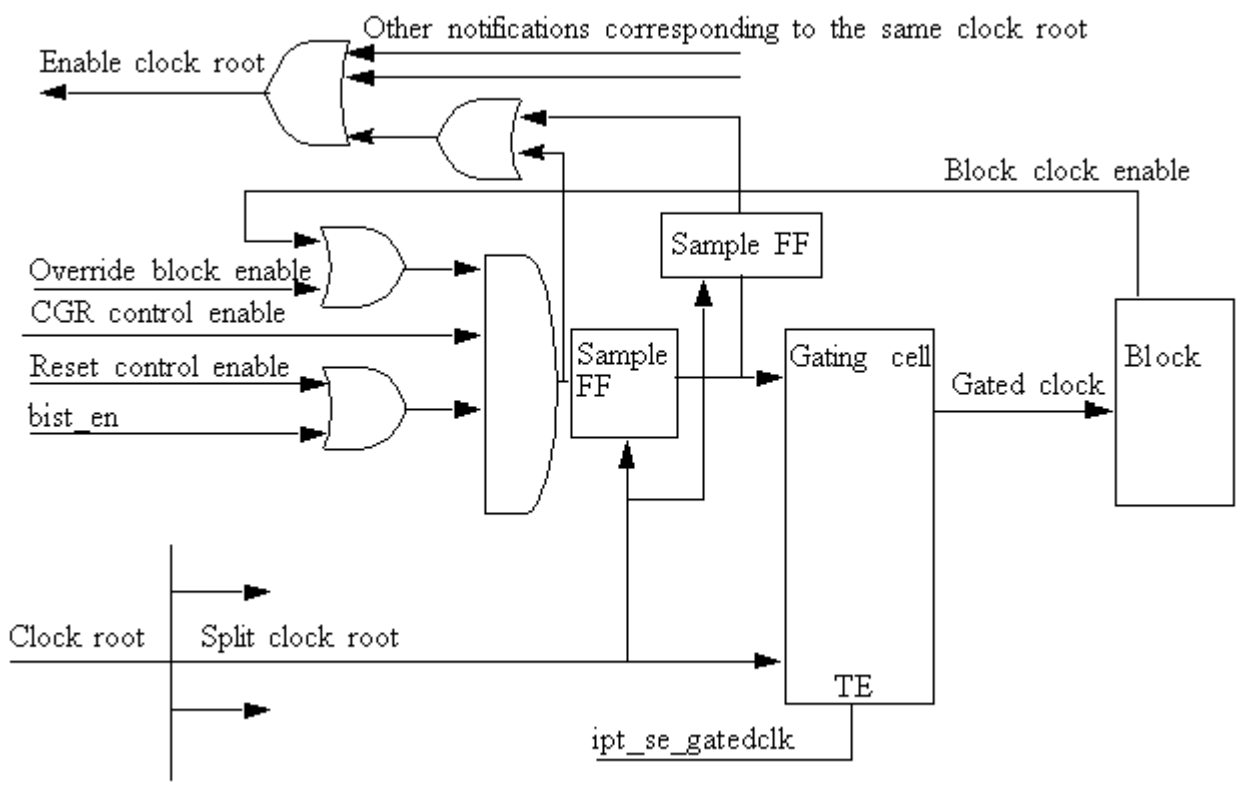

Figure 18-6 describes the clock split inside LPCG. It describes the case of 2 blocks, one block without enable signal and one with enable signal. (SRC enable signals and sync FF's are omitted from this figure).

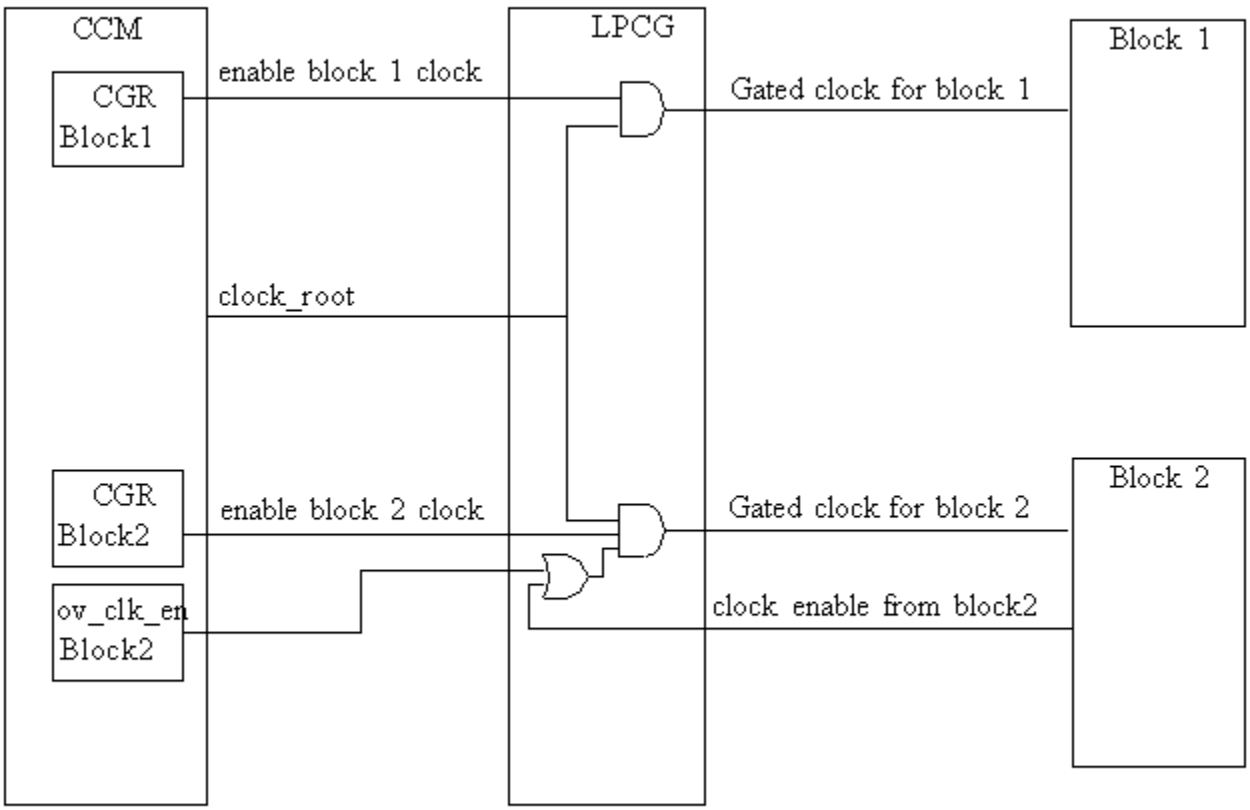

Figure 18-6. Clock split in LPCG

18.2.2 Creation of Sync Signal for IEEE_RTC Module

The IPTP block uses a ipg sync signal to be able to connect to the IP bus. CCM generates ipg_clk_sync_ieee_root signal to be used by LPCG to drive the ipg sync input of IPTP. LPCG gates the ipg sync signal with a same control as the ipg clock input to IPTP.

18.2.3 System clocks connectivity

The following tables show the CCM output clocks system level connectivity per block in i.MX53. The gating option in the table can be either CGR bit or clock enable from the block itself.

Table 18-3. Output clocks from CCM

Instance / Sub-Block	Clock	Root	Override by CCM_CMEOR bits	Gating by CCM_CCGR bits
ARM_Platform	ARM main clock (arm_clk)	arm_clk_root		Yes
	IPG clock (ipg_clk_lp)	ipg_clk_root		Yes
	ACLK (aclk_lp)	arm_axi_clk_root		Yes
	Debug PCLK (dbg_pclk_lp)	debug_apb_clk_root		Yes
	dbg_atclk_lp	debug_apb_clk_root		Yes
DAP	HCLK	ahb_clk_root	Yes	Yes
	HCLKEN	tie to '1'		
	PCLKDBG	debug_apb_clk_root	Yes	Yes
	PCLKENDBG	tie to '1'

18.2.4

Clock roots that affect processing unit (VPU, GPU2D, GPU3D) include BRM capability on their clock root generation. The BRM allows finer granularity of the effective frequency generated on each one of those clock roots, as compared to using a divider. BRM changes the effective frequency by eliminating clock pulses, and hence reducing the average effective frequency over time. The value programed in the control register of the BRM affects the clock cycle that is eliminated. For instance, if the input clock to the BRM is 200Mhz, then the BRM output has the following options:

Table 18-4. BRM Effective Clock Output in case the Input Frequency is 200Mhz

BRM parameter setting	BRM Output frequency (Mhz)
0000	200 (BRM in bypass mode - all clock cycles are passed to the output)

Table continues on the next page...

Table 18-4. BRM Effective Clock Output in case the Input Frequency is 200Mhz (continued)

BRM parameter setting	BRM Output frequency (Mhz)
0001	100
0010	150
0011	166.6
0100	175
0101	180
0110	183.3
0111	185.7
1000	187.5

1011	190.9
1100	191.6
1101	192.3
1110	192.8
1111	193.3

18.2.5 DVFS Support

Frequency shift during DVFS procedure in i.MX53 can be done on two domains:

1. ARM clock domain frequency shift.
2. Peripherals clock domain frequency shift (including buses).

GPC(General Power Controller) initiates the frequency shift procedure. It initiates only one frequency shift at a time. There is no option to commence both frequency shifts simultaneously. GPC is aided by SDMA and CCM to execute the frequency shift.

The following paragraphs explain in detail the frequency shift options.

18.2.5.1 ARM Clock Domain Frequency Shift:

SDMA can request ARM frequency shift by requesting change in ARM_PODF divider, or by DPLL-1 relock.

The following steps are configured by SDMA:

1. SDMA can request ARM frequency shift by dividers, or by DPLL-1 relock. This request is written to CCM_CDCR[ARM_FREQ_SHIFT_DIVIDER] bit. If it is 0, DPLL-1 relock shift is requested.

   If it is 1, ARM_PODF divider shift is requested. In this case any new writes to ARM_PODF is held until change ARM frequency signal is asserted by GPC. CCM holds a status bit to notify that the ARM_PODF divider is being updated. Need to wait until the write finishes before writing any new value to ARM_PODF. See CCM Divider Handshake In-Process Register (CCM_CDHIPR). CCM can also generate an interrupt once the actual ARM_PODF has been written during DVFSC operation. See CCM Interrupt Status Register (CCM_CISR).

2. Configure new ARM domain dividers (if ARM_FREQ_SHIFT_DIVIDER = 1: ARM_PODF divider shift is requested)

   SDMA continues with next steps only if (ARM_FREQ_SHIFT_DIVIDER = 0: DPLL-1 relock shift is requested).

3. Check which frequency mode is active in DPLLC-1, HFS or LFS: DPLLC-1 bit HFSM of DPLLC_CTL register.
4. Configure the non active frequency mode (HFS or LFS) of DPLLC-1, with the new frequency needed for DPLL-1 to relock on: DPLLC-1 registers DPLLC_OP, DPLLC_MFD, DPLLC_MFN, DPLLC_HFS_OP, DPLLC_HFS_MFD, DPLLC_HFS_MFN.
5. Configure the step frequency divider: CCM_CCSR register, bit pll2_div_podf or pll3_div_podf (depending on the decision in the step mux in step 6).
6. Configure the step frequency mux: CCM bit step_sel of CCM_CNT register.

   Once those configurations are done, sdma is notify GPC to continue with the frequency shift procedure.

   The actual shift is start by assertion of arm_clk_switch_req signal from GPC to CCM.

   CCM is commence the following steps upon assertion of arm_clk_switch_req signal:

If arm_freq_shift_divider = 1 dividers shift is requested):

1. Load the ARM domain new dividers.
2. After reloading the dividers (all counters in 0), indicate to GPC that frequency has been updated.

If arm_freq_shift_divider = 0 (DPLL1 relock shift is requested):

1. Switch to the step frequency by a glitch less multiplexer.

2. After the glitchless multiplexer has changed to the step frequency, invert LVS select signal to DPLLC-1 so that DPLL-1 is locked to the new frequency.
3. On pll_lrf_sticky1 assertion move to the new reloaded frequency by the glitch less mux.
4. After actual shift of the mux assert clk_switch_ack for 2 ipg cycle. This is done so GPC is have indication that frequency has been updated.

Upon clk_switch_ack assertion, GPC is de assert arm_clk_switch_req signals.

On this point, ARM has changed frequency and system is ready for a new frequency switch procedure.

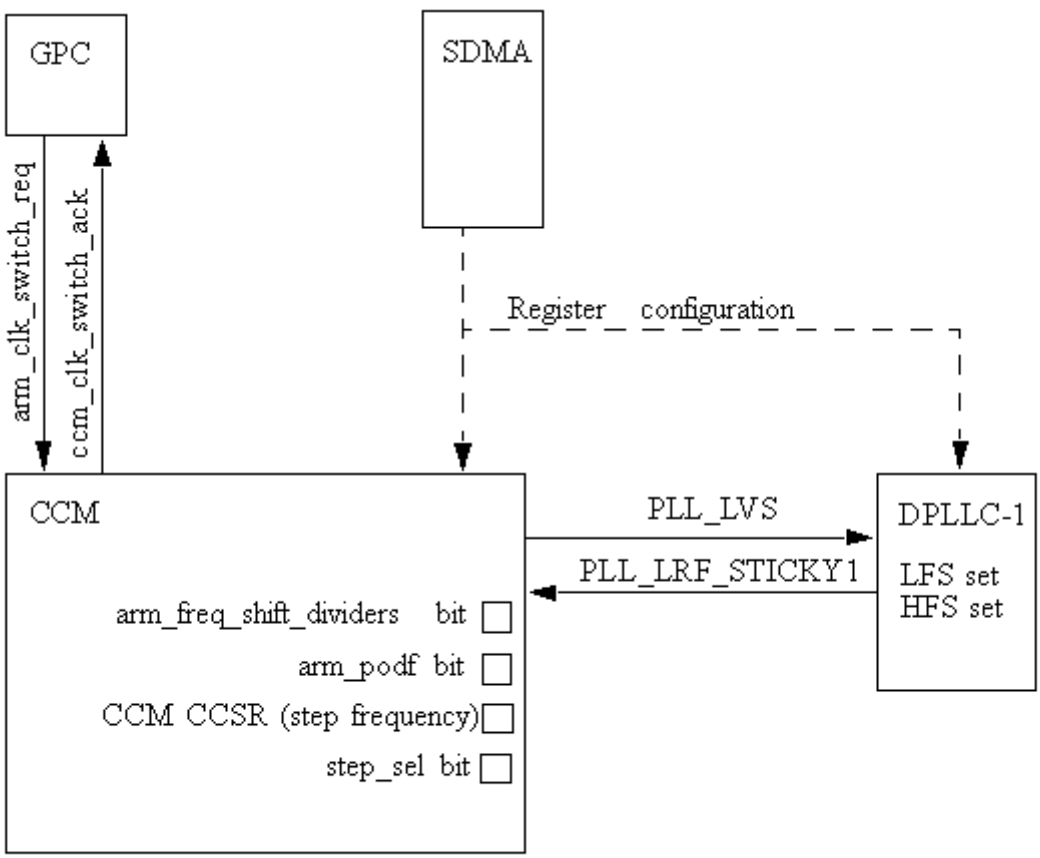

Figure 18-7. ARM dvfs connectivity

18.2.5.2 Peripheral Clock Domain Frequency Shift:

CCM includes capability to divide by 2/3/4 the root of bus clocks (ahb, axi, ipg, int_mem, ddr_clk, nfc_clk).

The actual division factor is defined by the bits in CCM_CDCR[1:0]. Set these bits prior to enabling DVFSP operation. The value written to the DVFSP register divider (CCM_CDCR[1:0]) is not loaded immediately to the actual divider. It waits until DVFSP procedure commences.

During DVFSP operation, the root clocks which are not affected by DVFS divider should be generated from a low frequency DPLL. This frequency should not be higher than 240Mhz. Can use DPLL-3 with frequency 216Mhz for this operation. The setting for the serial clocks is done through CCM_CSCMR1 register.

The blocks whose clock is about to change (IPU,EXTMC, etc.) should be configured with values that determine the frequency of the new clock, prior to the clock switch operation. Please refer to the respective blocks specification for clarification on the needed configuration.

Divide by 2/3/4 procedure (lowering frequency): Upon assertion of Peripherals clock division request signal from GPC, the actual division procedure takes place. The periph_clk_div_req signal from GPC remains asserted as long as GPC requests a division of the peripheral clocks. This signal is de-asserted only when GPC requests frequency multiplication and return to division by '1'.

NOTE

DVFS operation can be started by asserting SW_PERIPH_CLK_DIV_REQ bit in CCM_CDCR. If the bit is asserted, GPC control is ignored and the the acknowledge to GPC is not asserted.

There is no need to synchronize the change in the 3 dividers, because they work on asynchronous clock domains.

Prior to the actual division there is need for acknowledge from peripherals that are sensitive to the frequency change (that is, IPU and EXTMC). The handshakes for IPU and EXTMC are described as follows:

- CCM asserts change frequency request signal to request approval from IPU and EXTMC in order to commence the frequency shift.
- IPU and EXTMC asserts their respective acknowlege signals to notify the time window that its alright to change the frequency.

CCM commences the actual division once both the acknowledge signals (from IPU and EXTMC) are asserted.

After completing the division, CCM notifies GPC by assertion of clock switch acknowledge for 2 ipg cycles (rising on ipg_clk) and notifies IPU by assertion of IPU clock changed signal for at least 2 hsp clock cycles (rising on the edge of the new hsp clock). CCM also negates the frequency change request signals to IPU and EXTMC

Multiply by 2/3/4 procedure (increasing frequency): Upon negation of peripherals clock division request signal from GPC, the actual multiplication procedure takes place by removing the division by 2/3/4 and returning to division by '1'.

NOTE

DVFS operation can be stopped de-asserting SW_PERIPH_CLK_DIV_REQ bit in CCM_CDCR. The GPC control is ignored and the CCM clock switch acknowledge is not asserted.

There is no need to synchronize the 3 dividers change since they work on async clock domains.

Prior to the actual frequency change, CCM requires acknowledge from peripherals that are sensitive to the frequency change. These handshakes are described as follows:

- CCM asserts change frequency request signal to request approval from IPU and EXTMC in order to commence the frequency shift.
- IPU and EXTMC assert their respective acknowlege signals to notify the time window that its alright to change the frequency.

CCM commences the actual division once both the acknowledge signals (from IPU and EXTMC) are asserted.

After completing the frequency change, CCM notifies GPC by assertion of clock switch acknowledge for 2 ipg cycles and notifies IPU by assertion of IPU clock changed for at least 2 hsp clock cycles. CCM also negates the frequency change request signals to IPU and EXTMC.

Following figure describes the connectivity.

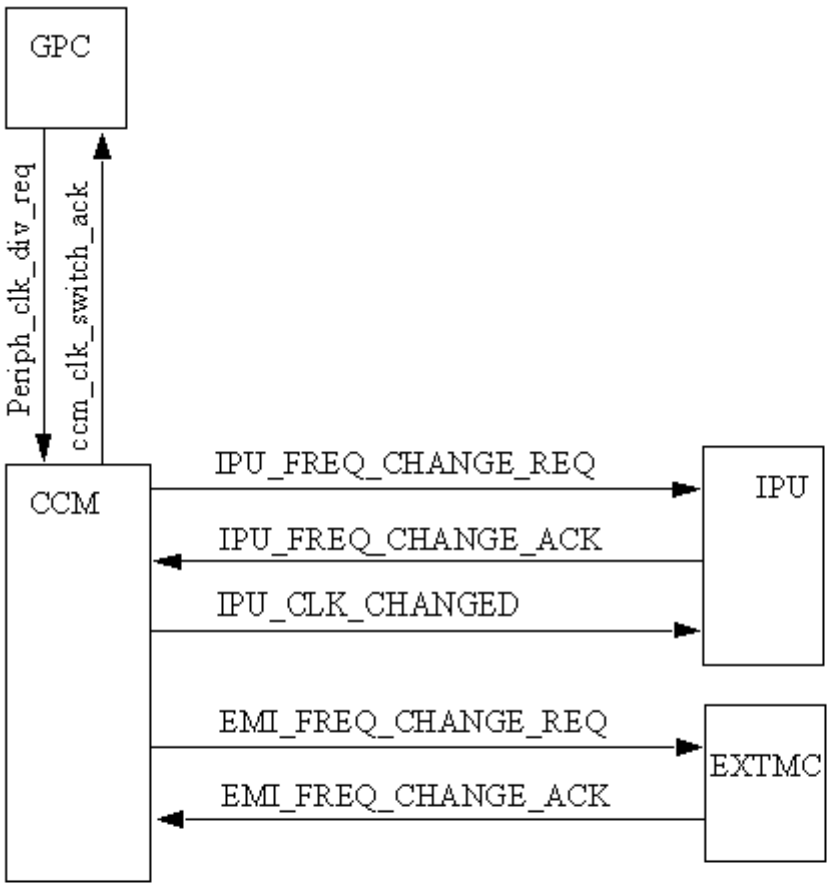

Figure 18-8. DVFSP connectivity

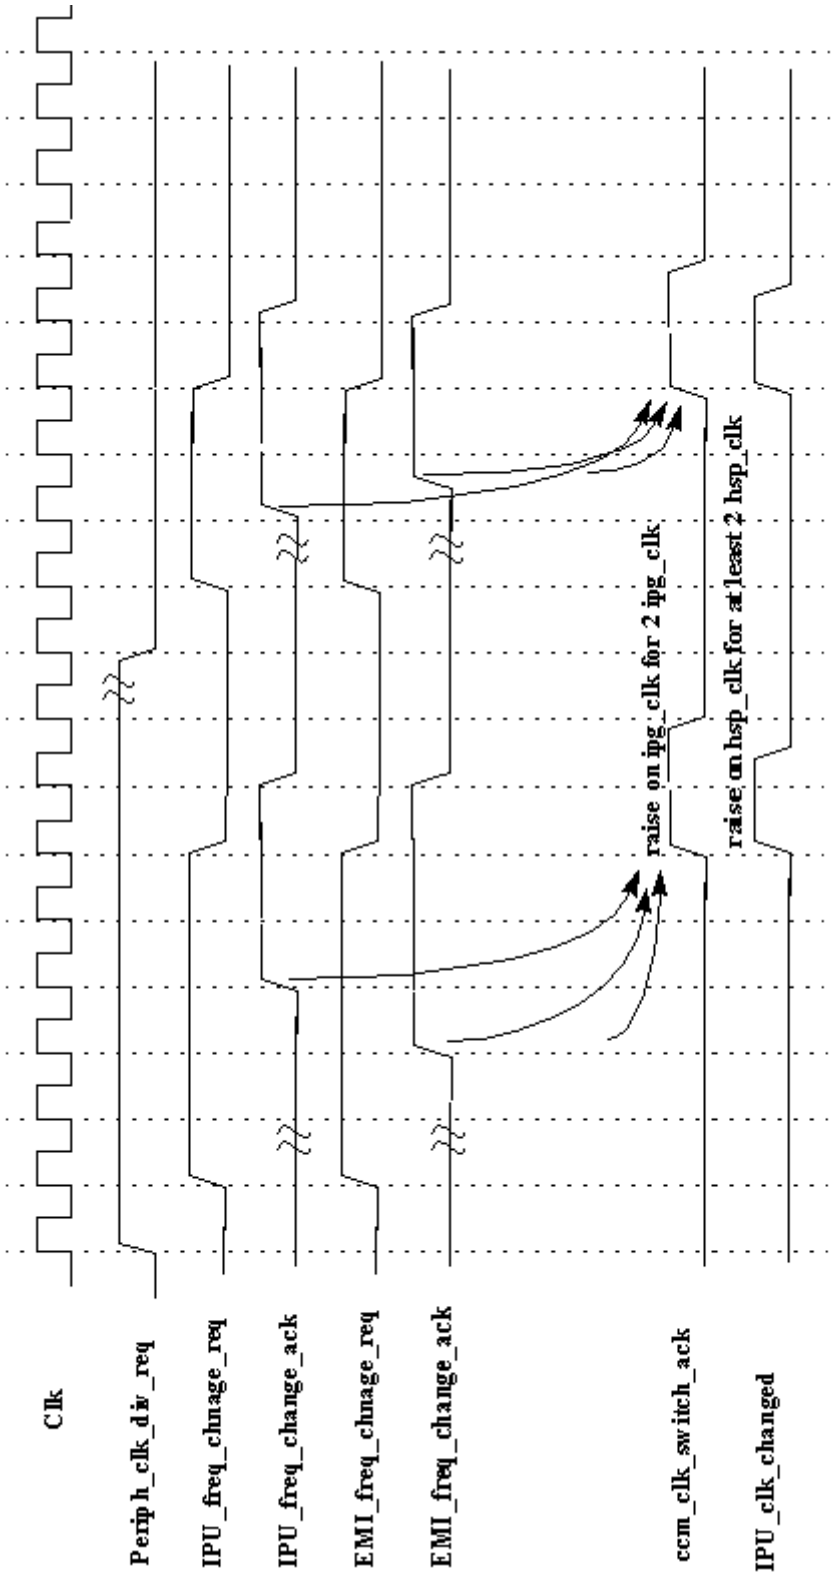

Figure 18-9. DVFSP signals

NOTE

There is an option to generate the EXTMC request only after the acknowledge signals form the EXTMC master (IPU) is received in CCM. This option allows the master to finish it's tasks that require EXTMC performance, and does not interrupt EXTMC performance before the master has acknowledged the frequency change. See CCM DVFS Control Register (CCM_CDCR) for details.

18.2.5.3 Peripherals Restrictions in DVFS Scenario

In DVFSP scenario, ipg and ahb clocks are divided from their nominal frequency.

The serial dividers in the low voltage case, should use a low frequency DPLL input (below 300Mhz) to work correctly.

Listed below are restrictions that need to be followed to support the DVFS frequency shift:

Table 18-5. DVFS restrictions

Block	Support	Restriction
R - blocks that is work with restriction		
UART	R	Need to configure uart rate to be low_frequency_ipg_clk/16. Hence rates of 1.875M and 4M cannot be reached in dvfs scenario.
ESDHC	R	Need to configure card rate to be low_frequency_ahb_clk/2. Hence rated of 52M for SD card cannot be reach in dvfs scenario.
MSHC	R	Need to configure card rate to be low_ipg_clk. Hence rated of 40M for card cannot be reach in dvfs scenario.
SSI	R	Master clock should be generated from ssi_ext1 and ssi_ext2 pads.
CSPI	R	Need to configure spi rate to be low_ipg_clk/4.
DDR memory	R	Under the low frequency limits of DDR memory (125Mhz for DDR2, and 300Mhz for DDR3). Without DLL, DDR3 is able to operate under 125Mhz.
N - blocks that is not work		

Table continues on the next page...

Table 18-5. DVFS restrictions (continued)

Block	Support	Restriction
USB, USB_PHY	N	Needs ipg_clk>60Mhz. Hence is not work under dvfs scenario
FEC	N	Needs ipg_clk>50Mhz. Hence is not work under dvfs scenario
TVE	N	Is not synthesized to twice the frequency
LDB	N	Is not synthesized to twice the frequency
SPDIF	N	Is not synthesized to twice the frequency
SATA	N	Is not synthesized to twice the frequency
P-ATA	N	Needs ipg_clk to be fixed. In case ARM core manages dvfs scenario, it can work only in times ipg_clk is fixed, i.e. before and after dvfs scenario.

18.2.5.4 CCM Handshake with the ESDCTL

When clock frequencies are changed to the DDR memory (either through DVFS or manually), the CCM will issue a handshake with the ESDCTL controller. In turn the ESDCTL will place the external DDR memory in self refresh during the frequency change.

In the case of a manual frequency change, the CCM will issue a handshake to the ESDCTL when changing the main_bus_clk clock MUX (via the PERIPH_CLK_SEL bits[24:22] in the CCM_CBCDR). The CCM will also issue a handshake when changing the post dividers (PODF) that source the DDR clock: AXI_A_PODF, AXI_B_PODF, EMI_SLOW_CLK_ROOT, and AHB_CLK_ROOT.

18.2.6 Power Modes

i.MX53 supports 3 low power modes: RUN mode, WAIT mode, and STOP mode.

18.2.6.1 Run Mode

This is the normal/functional operating mode. In this mode ARM runs in its normal operational mode. The frequency and voltage can be changed by DVFS operation as described in DVFS Support. Clocks to the blocks can be gated by configuring the corresponding CCM_CCGR*n* register bits.

18.2.6.2 Wait Mode

In this mode the ARM clock is gated. All other clocks are functional and can be gated by programing their CCGR bits. Power gating can be done for ARM platform.

18.2.6.2.1 Wait Mode is Entered by the Following Procedure:

ARM asserts the wait mode by writing to CCM_CLPCR[LPM] bits. It then writes to TZIC_DSMINT[0] (asserting DSM interrupt hold off).

DSM interrupt hold off assertion forces the interrupt controller to stop the synchronizer clock for incoming interrupts. Any interrupts that had previously been synchronized by the interrupt controller remain asserted.

If a wakeup event occurrs (an interrupt is serviced) or is pending, the ARM platform aborts the DSM sequence by exiting the main shutdown code sequence and returning to the desired security mode.

Once the L2 cache is inactive, the ARM platform asserts the DSM request signal to the CCM.

If the DSM wakeup signal from TZIC is negated and the DSM request signal from ARM is asserted, the CCM begins the WAIT sequence.

The ARM platform clock is stopped only if CCM_CLPCR[5] = 1 and SJC_GPUCR3[15] = 0. If either value is different, then ARM clocks are not gated off and the CCM continues to next step.

CCM shuts down the clocks to SAHARA,RTIC, IPU, SDMA, SCC, EXTMC and AHBMAX only if their corresponding bits in CCM_CCGR indicate that they should be closed in WAIT mode and if their clocks were functional in RUN mode. The request is issued if the handshake is not bypassed by programing the CLPCR[23:16] register bits. If the corresponding bits are set, then the request signal is not issued to the corresponding block and CCM does not wait for its acknowledge in the process of entering low power mode.

NOTE

Since EXTMC requires the DDR clock to be active for it to answer the handshake request, make sure to enable the clock by setting the appropriate CCM_CCGR bits.

NOTE

The SCC clocks are stopped, only if SAHARA clocks were programmed to be stopped in WAIT made. Hence, the SCC handshake is performed only if the SAHARA clocks were programmed to be closed as well.

Once CCM is in WAIT mode, it is check if TZIC has asserted the DSM wakeup signal, or if ARM DSM request signal has negated during the process of entering wait mode. If it has occurred, CCM exits the WAIT mode.

If neither of the signals have changed, CCM generates a request to GPC to power down the ARM platform. See Figure 18-10 diagram. The GPC sends a power down acknowledge signal at the end of the power down sequence.

NOTE

During WAIT mode, if SCC asserts either of its clock enable signals, CCM enables the SCC clocks. The WAIT mode is not exited due to this assertion.

18.2.6.2.2 Wait mode is Exited by the Following Procedure

As soon as the synchronized TZIC wakeup signal is seen asserted or the ARM DSM request signal is negated, CCM begins the process of exiting WAIT mode.

CCM request GPC to restore power to the ARM platform and then exits from WAIT mode by first resetting the blocks to which the clocks have been stopped. Then it enables all the block clocks (depending on the CCM_CCGR bits).

Once the interrupt propagates through all the synchronization logic, the ARM core recognizes and services it. This forces the negation of the ARM DSM request signal. Prior to this point, ARM DSM request signal and TZIC DSM wakeup signals were simultaneously asserted. Since TZIC DSM wakeup signal has top priority, the system is able to wake up.

Before the ARM exits the ISR, it clears the interrupt source. This is causes the TZIC DSM wakeup signal to be de-asserted. At this point, the two low power control signals (TZIC_DSM_WAKEUP and ARM_DSM_REQUEST) are negated, and the WAIT sequence can be repeated at any time.

18.2.6.3 Stop Mode

In this mode all system clocks and DPLL's are stopped. Power gating can be done on the ARM platform.

18.2.6.3.1 Stop Mode is Entered by the Following Procedure:

ARM asserts the stop mode by writing to CCM_CLPCR[LPM] bits and the TZIC_DSMINT[0] (DSM interrupt hold off) bit.

DSM interrupt hold off assertion forces the interrupt controller to stop the synchronizer clock for incoming interrupts. Any interrupts that had previously been synchronized by the interrupt controller remain asserted.

If a wakeup event occurrs or an interrupt is serviced or is pending, the ARM platform aborts the STOP mode sequence by exiting the main shutdown code sequence and returning to the desired security mode.

Once the L2 cache controller becomes inactive, the ARM platform asserts the ARM DSM request signal to the CCM.

The CCM continuously synchronizes the DSM requests from ARM and TZIC to the clock domain used by its internal state machine.The only time when those signals are not synchronized is when the DPLLs are closed. In this case, exit from STOP mode is done asynchronously. (See Stop Mode is Exited by the Following Procedure:.)

If DSM wakeup signal from TZIC is negated and DSM request from ARM is asserted, CCM begins the STOP (shutdown) sequence.

CCM stops the ARM clock and generates signals to indicate that it has started STOP procedure.

CCM closes SAHARA, RTIC, IPU, SDMA, SCC, EXTMC and AHBMAX clocks. (If they were active in RUN mode.) The request is issued if the handshake is not bypassed by programing the CCM_CLPCR[23:16] register bits. If the corresponding bits are set, then the request signal to the corresponding block is not issued. CCM does not wait for its acknowledge in the process of entering low power mode.

NOTE

Since EXTMC needs the DDR clock to be active for it to answer with handshake signal, make sure to turn on the DDR clock before entering low power mode.

Once the blocks have finished their operation and are ready to enter low power mode, they acknowledge CCM that it is safe to turn off their clocks.

The requests are generated by CCM in stages. CCM continues from stage to stage once all the acknowledges of a present stage are received. The stages are the following:

Stage 1: SAHARA, RTIC, IPU, SDMA, CAN1, CAN2

Stage 2: SCC

Stage 3: AHBMAX

Stage 4: EXTMC

Once CCM receives all the acknowledge signals needed, it enters stop mode and does the following tasks in the order they are written below:

- Closees the system block clocks, not including pgc_clk. The clocks closed include the synchronized clocks of Megamix (all blocks except ARM, IPU, VPU, GPUs, EXTMC and DPLLs) only if GPC indicates that Megamix is powered down.
- Asserts signal indicating that the system is in STOP mode.

Once CCM is in STOP mode, it checks both the DSM request and DSM wakeup signals for a change in value. If ARM DSM request is de-asserted or TZIC DSM wakeup signal is asserted, CCM exits stop mode. Otherwise, CCM generates a request to GPC to power down ARM platform. If in GPC, the ARM platform is programmed to be powered down, GPC powers down the system as follows:

- Closes all the DPLLs and DPLLCs.
- CCM closes the CAMPs.
- If CCM_CLPCR[SBYOS] bit is set, then CCM generates a signal to close the external oscillator and also puts the on board oscillator in power down mode. (If they were not already powered down. If one of them was already closed, then perform the SBYOS operation only on the one that is working. If both of them were closed in run mode, then do nothing.)
- If CCM_CLPCR[VSTBY] bit is set, then assert a signal that indicates to the power management IC, a shift in voltage to standby voltage.

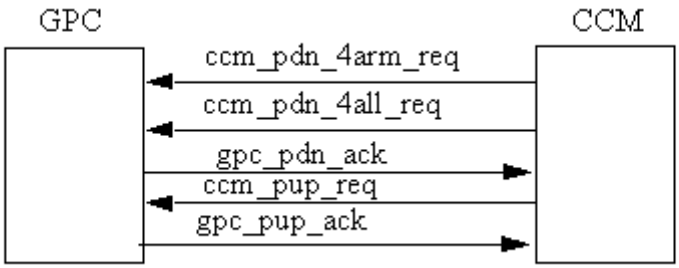

Figure 18-10. CCM-GPC connectivity

18.2.6.3.2 Stop Mode is Exited by the Following Procedure:

As soon as the unsynchronized TZIC DSM wakeup signal is seen asserted or ARM DSM request is seen de-asserted, the CCM start exit from STOP mode.

The following is take place:If CCM_CLPCR[VSTBY] bit is set, notify power management IC to change voltage from standby voltage to functional voltage.

If CCM_CLPCR[SBYOS] is set, and CCM closed either the external oscillator or the on board oscillator, then CCM starts the respective oscillator by asserting ref_en_b signal and deasserting cosc_pwrdown signal respectively.

After a pre-determined amount of CKIL cycles defined in STBY_COUNT, CCM waits until the Power Management IC asserts a signal indicating the voltage is at the "Functional Voltage" level. (Figure Figure 18-12 below describes the pmic signals connectivity.) Once the voltage is ready, CCM continues with the next steps:

- Starts CAMPs (based on definition of CCM_CCR[CAMP1_EN] and CCM_CCR[CAMP2_EN] bits)
- If any CAMP or the on board oscillator is started, waits until CCM_CCR[OSCNT] has finished counting to make sure that the external oscillator, CAMPs output and on board oscillator are ready.
- Start the DPLLs. Only the DPLLs that were configured to be on prior to the entrance to stop mode are started.
- Enable VPU, GPU2D, and GPU clocks.

CCM requests GPC to restore power to the ARM platform. GPC notifys CCM that power to ARM is back on, and it is safe to exit from STOP mode. Only then CCM carries out the following process:

- Once the powered down blocks are reset, CCM negates the low power request signals to all blocks and enables all block clocks including ARM clocks and synchronized CKIL of Megamix (if it was turned off), and returns to RUN mode.

(The clocks whose CCGR bits are set to 2b00, (that is, off in all modes) are not started in RUN mode and continue to be gated in RUN mode).

Once the interrupt propagates through all the synchronization logic, the ARM platform recognizes and services it. This forces the negation of the ARM DSM request. Prior to this point, the ARM DSM request and TZIC DSM wakeup were simultaneously asserted. Since TZIC DSM wakeup has top priority, the system is able to wake up.

Before the ARM exits the ISR, it clears the interrupt source. This causes the TZIC DSM wakeup signal to be negated. At this point, the two low power control signals are negated, and the STOP sequence can be repeated at any time.

Next figure describes connectivity of ARM, CCM and TZIC.

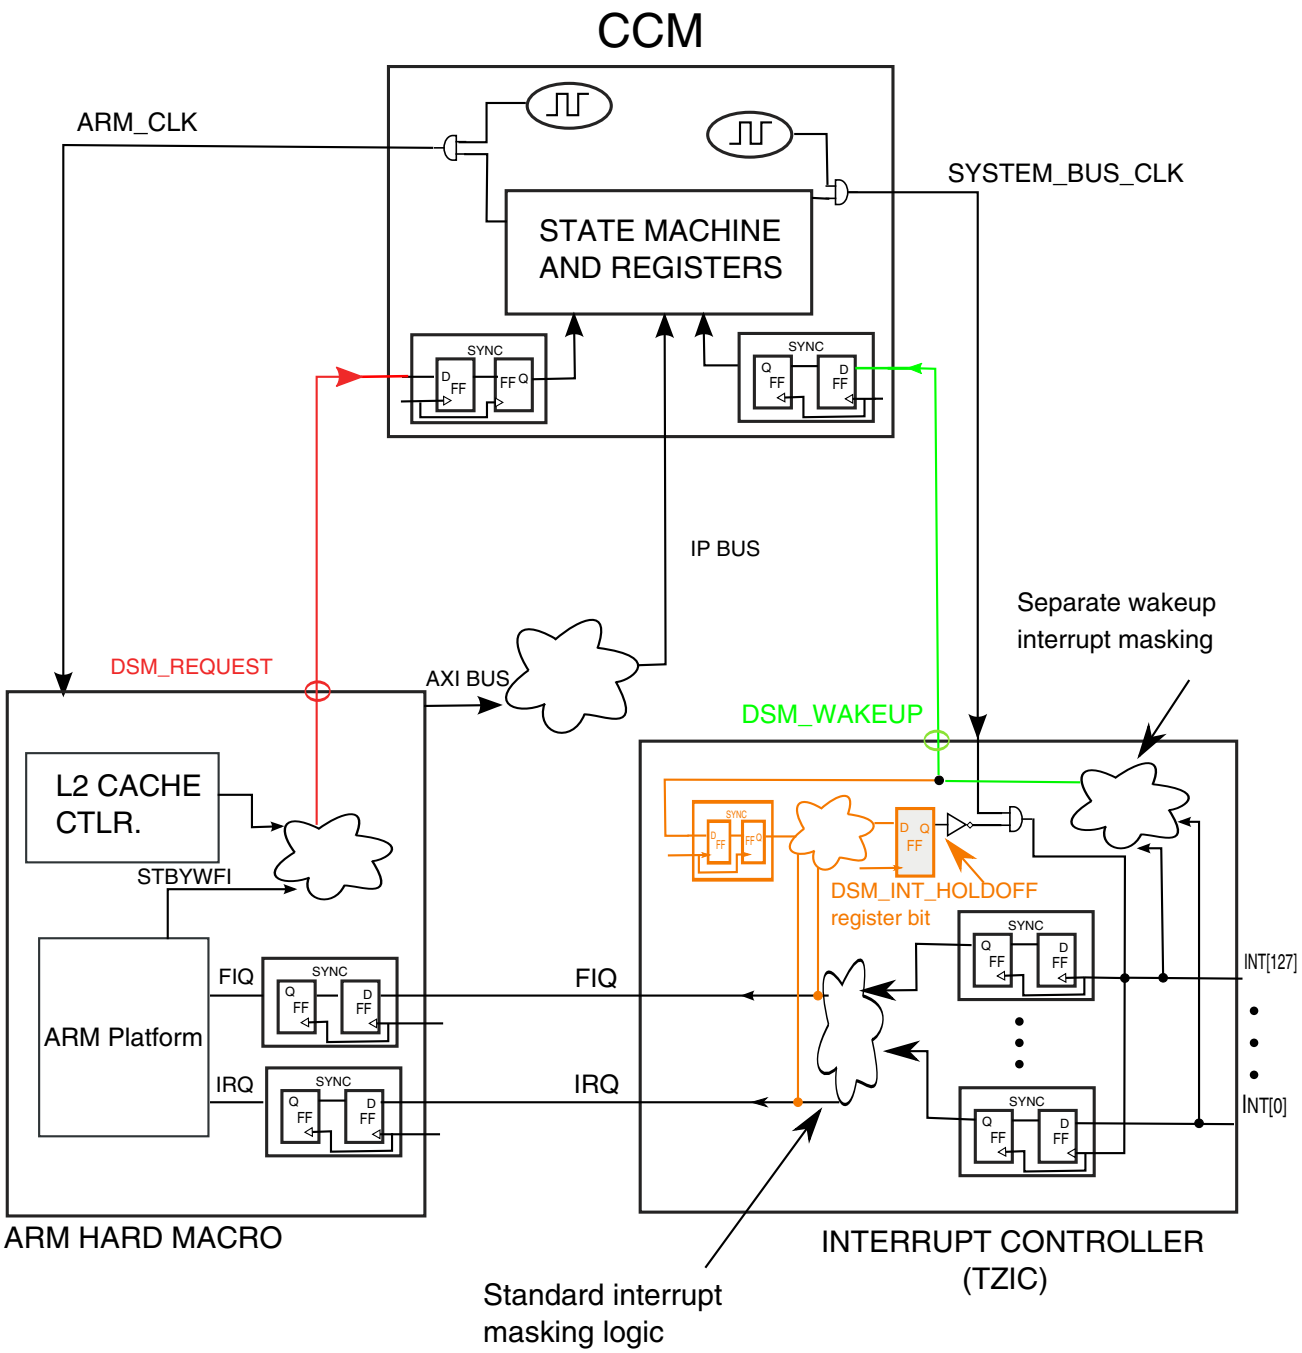

Figure 18-11. ARM Low Power Request

Next figure describes CCM's Low Power State Machine:

18.2.6.3.3 PMIC Signal Description:

stby_count value should be larger than t1 - larger than the amount of time that it takes between CCM's negation of pmic_vstby_req, and the negation of pmic_vfuncional_ready (the signal coming back from PMIC to indicate that the voltage started to change).

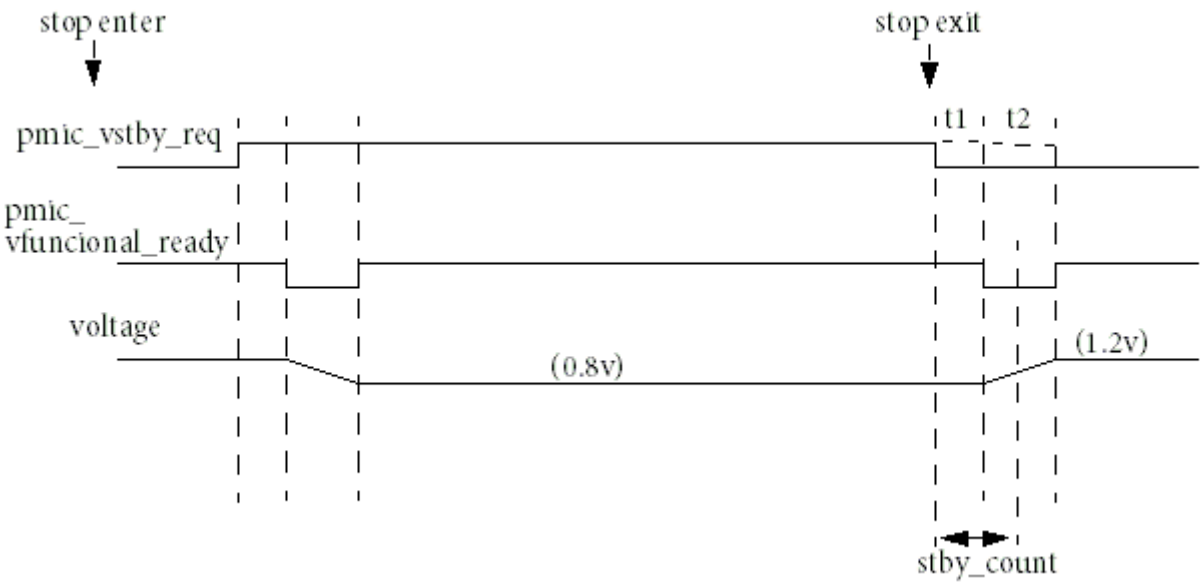

Figure 18-12. PMIC Signal Description

NOTE

Software should configure the IOMUXC so that pmic_vstby_req and pmic_vfuncional_ready is operating in the correct ALT mode, so that they are connected between CCM and the pads.

18.2.6.4 LPMD Request from SRC (Reset Controller)

SRC generates a signal named emi_dvfs_req. This signal is asserted in case of WARM reset to request EXTMC to enter sdram into SELFREFRESH mode. Since CCM is also a generator for the request to EXTMC for entering sdram to selfrefresh, then the SRC request is connected to CCM, and CCM is generate one common request to EXTMC for sdram selfrefresh. This common request is assert either if CCM is the originator of the request or if the SRC is the originator of the request. The SRC request (named emi_dvfs_req) is connected to CCM's input src_warm_dvfs_req. CCM generates the request to EXTMC via dvfs request . This signal generation is combined with the signal coming from SRC (src_warm_dvfs_req) to generate one dvfs request signal to EXTMC.

The acknowledge from EXTMC regarding the selfrefresh of EXTMC is connected to both CCM and SRC.

18.2.6.5 Low Power Audio Playback Mode (LP-APM)

Low Power Audio Playback mode (The term APM is used for this mode, across this document), defines special low power mode, dedicated for Audio only playback mode. It involves DPLL on/off and frequency settings, as well as voltage and clock gating aspects, to enable lowest possible power consumption.

This section covers APM, as well as assumptions, and Enter / Exit flows from the APM mode.

18.2.6.5.1 Low Power APM Mode Definition

1. Only one DPLL of i.MX53 is running - ARM DPLL. This DPLL is set to the maximal frequency that ARM can run at that lowest point, while still ensure ARM and bus system processing needs. Targeting.
2. The peripherals is also work on low voltage (1.0v). The peripherals is work on frequency suitable for this low voltage (about third of the nominal frequency).
3. For i.MX53 used as master on SSI clocks, the ARM platform DPLL frequency has to be set to an integer multiplication of SSI clock

18.2.6.5.2 LP-APM Mode Restrictions

- Entrance and exit to/from Low Power APM mode has effect on Display and SSI clocks. If i.MX53 is master on SSI clocks, audio playback is interrupted during the switch. It is not recommended to switch modes during audio playback.
- Due to impact to Display controller clock, switch to/from LP-APM, SW should take that into consideration. This is not applicable when using Smart Display.

Following diagram describes the possible sequence to be performed to switch from a high power settings (3 DPLL's, high voltage) to the low power APM.

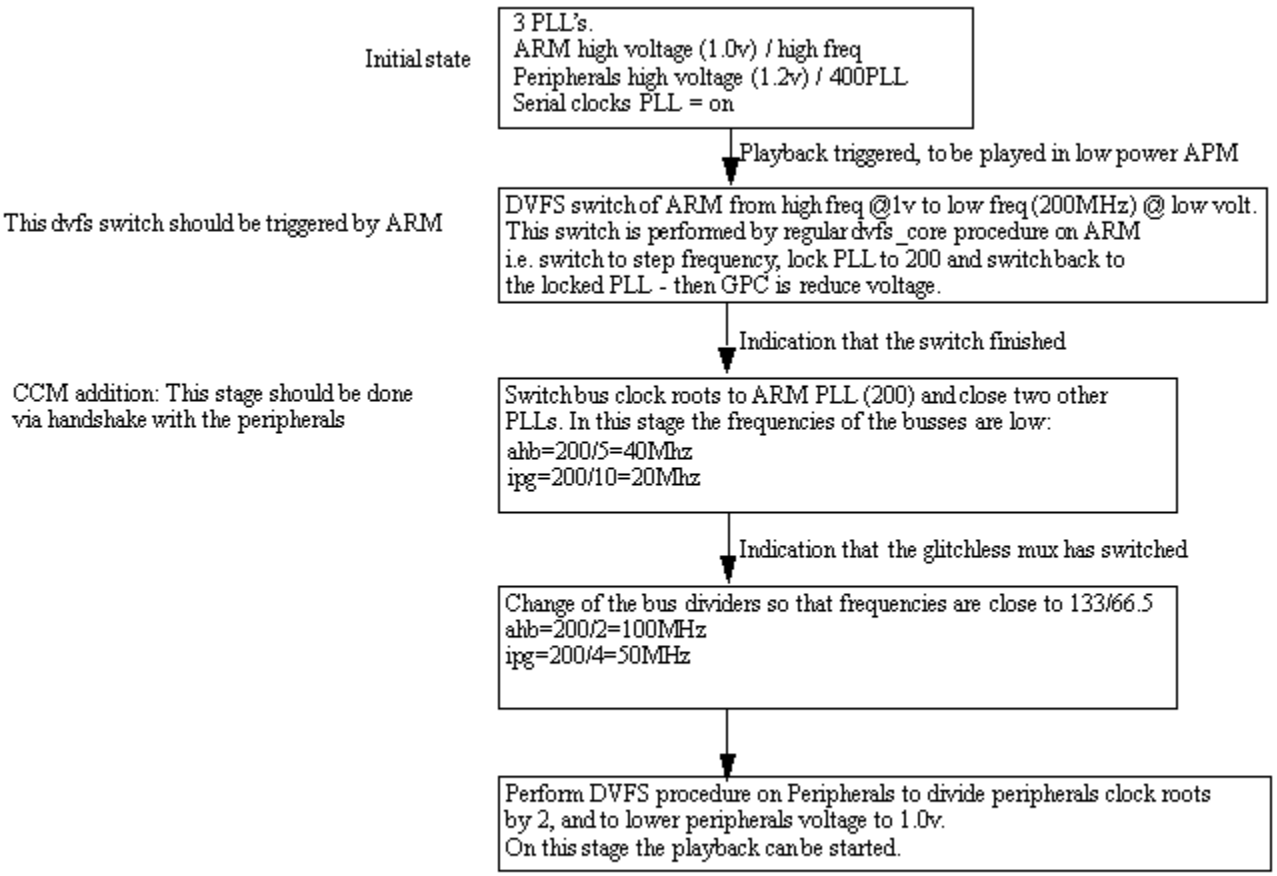

Figure 18-13. Flow of entering low power APM on i.MX53

Table 18-6. LP-APM flow frequencies

Stage	Farm [MHz]	Varm [v]	Fahb [MHz]	Fipg [MHz[	Vper [v]	comments
initial state	800*	1.0*	133	66.5	1.2	run system from 3 PLL's: ARM PLL = 800MHz supplying ARM PERIPH PLL = 665MHz supplying busses (ahb, ipg). Serial PLL = 216MHz supplying USB, TVE etc.
DVFS on ARM	200*	0.8*	133	66.5	1.2	GPC operation triggered by software

Table continues on the next page...

Table 18-6. LP-APM flow frequencies (continued)

Stage	Farm [MHz]	Varm [v]	Fahb [MHz]	Fipg [MHz[	Vper [v]	comments
Switch bus clocks to ARM PLL	200*	0.8*	40	20	1.2	Peripheral dividers are not changed during the shift. The shift should involve EXTMC handshake
change bus dividers	200*	0.8*	100	50	1.2	
DVFS on peripherals	200*	0.8*	50	25	1.0	DVFS on peripherals with div=2

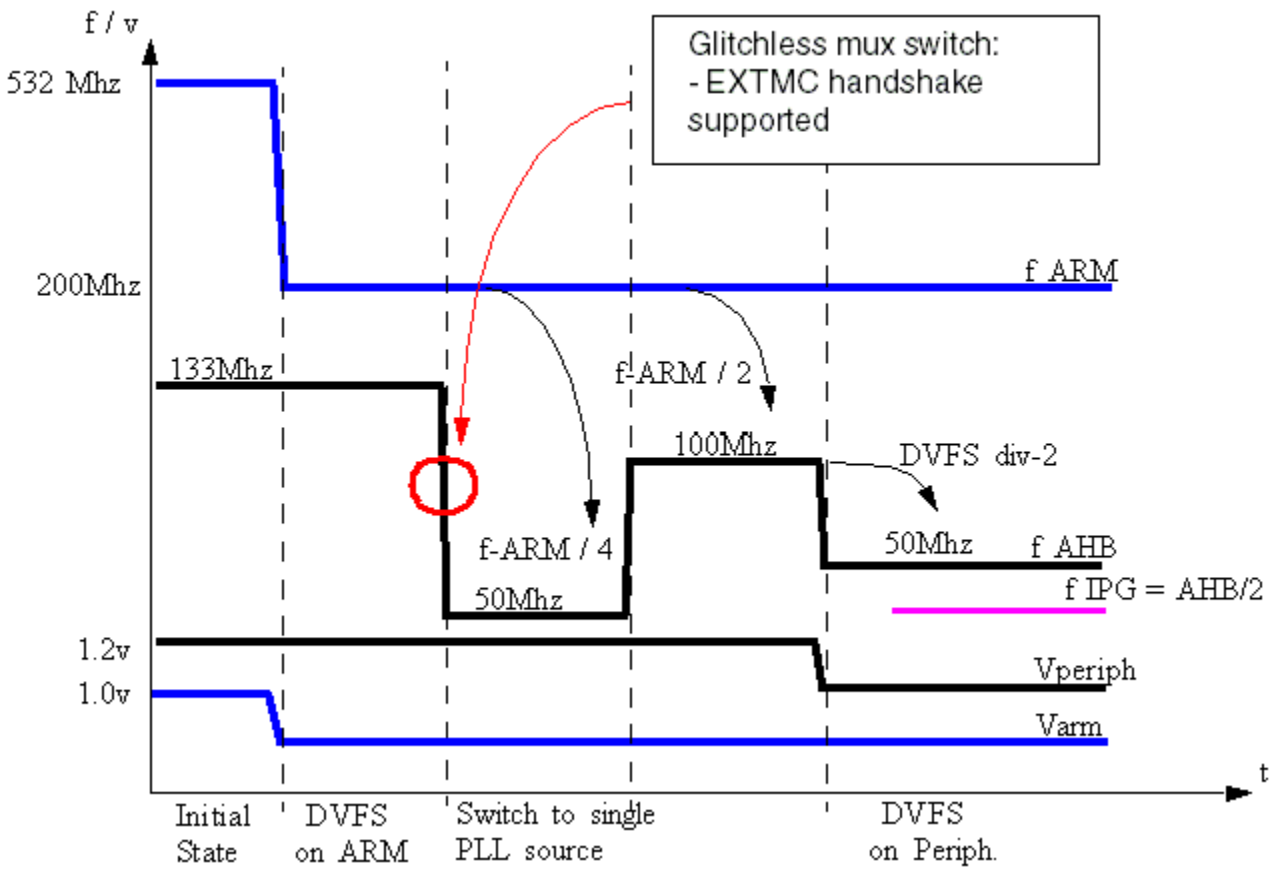

Figure 18-14. Frequency and Voltage flow

Alternative LP-APM clock settings can be applied:

- Entering LPAPM:
  - EXTMC clocks should be enabled.
  - IPU handshake should be masked, since IPU is off during LPAPM mode.
  - Disable DVFSP operation.

- Perform DVFSC procedure to lower the DPLL-1 clock (to ~200 MHz).
- Mask DVFSC operation.
- Set DPLL-1 as source of main_bus_clk.
- Set the AHB and EXTMC dividers to divide by 8, equal to 25MHz. Poll the load dividers bit after EMI_PODF is set.
- EXTMC root clock can be sourced from AHB clock.

- Exiting LP-APM mode
  - Set the AHB and EXTMC dividers to divide by 3.
  - Set DPLL-2 as the source of the main_bus_clk.
  - Perform DVFSC procedure to restore (increase) the DPLL-1 clock.
  - Enable (if required) DVFSP operation.

18.2.6.6 Recommendations for using low power consumption from CCM

In addition to using APM mode for low power, here are recommendations for configuring CCM so that it is consume less power. Those recommendations should be followed when applicable:

1. Using AHB clock source as the source of all AXI buses and VPU core clk: here, the power from the AXI dividers is preserved.
2. Working from one DPLL and disabling the other DPLL's.
3. Generate SSI external clocks from SSI clock roots: here, power consumption by SSI clock dividers is preserved.
4. Generate SPDIF clocks from SSI clock roots: here, the power consumption by SPDIF clock dividers is prevented.

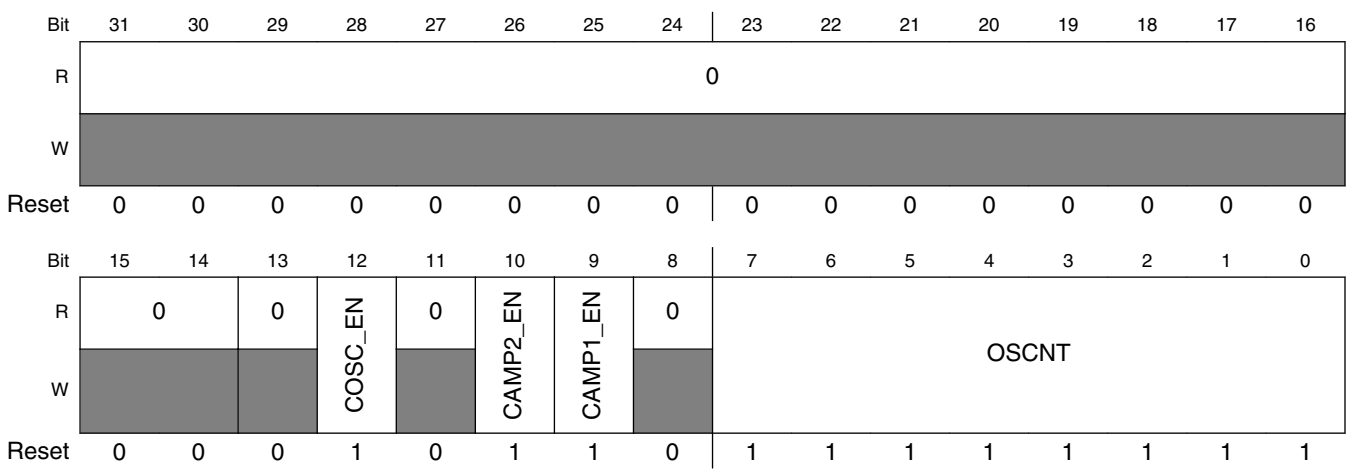
18.3.1 CCM Control Register (CCM_CCR)

Address: CCM_CCR is 53FD_4000h base + 0h offset = 53FD_4000h



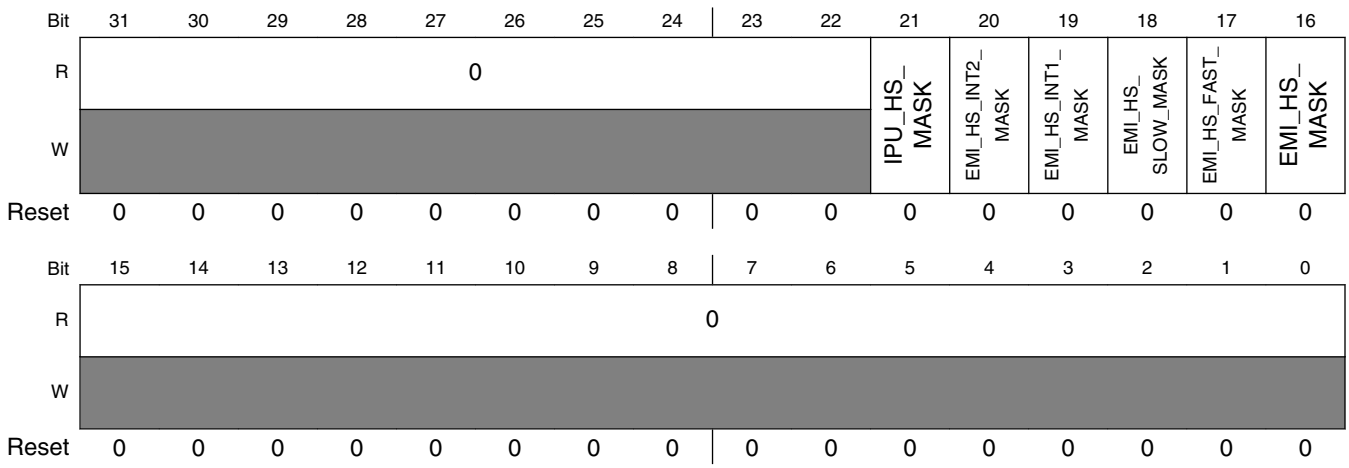
CCM_CCR field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value zero. Reserved
13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12 COSC_EN	On chip oscillator enable bit. This bit value is reflected on the output COSC_EN. The system starts with the on chip oscillator enabled to supply source for the DPLL's. This bit can be changed if a transition to the bypass DPLL clocks is desired for all the DPLLs. In case this bit is changed from '0' to '1', CCM enables the on chip oscillator and after counting OSCNT CKIL clock cycles it notifies that the on chip oscillator is ready by an interrupt cosc_ready and by status bit COSC_READY. The COSC_EN bit can be changed only when the on chip oscillator is not chosen as the clock source. 0 disable on chip oscillator 1 enable on chip oscillator
11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10 CAMP2_EN	CAMP-2 Enable bit. The ignition process always sets this bit. In RUN mode, this bit controls the enable/disable of CAMP-2. If this bit is changed from '0' to '1' then CCM enables CAMP-2 and after counting OSCNT CKILs, it notifies that CAMP-2 is ready by an interrupt camp2_ready and by status bit CAMP2_READY. The CAMP2_EN bit should be changed only when CAMP-2 is not chosen as a clock source. **NOTE:** CCM has an output ccm_camp2_dis. This signal is inverted from the CAMP2_EN bit, i.e. when CAMP2_EN bit is '1' the ccm_camp2_dis signal is '0'. 0 disable CAMP-2 1 enable CAMP-2
9 CAMP1_EN	CAMP-1 Enable bit. The ignition process always sets this bit. In RUN mode, this bit controls the enable/disable of CAMP-1. If this bit is changed from '0' to '1' then CCM enables CAMP-1 and after counting OSCNT CKILs, it notifies that CAMP-1 is ready by an interrupt camp1_ready and by status bit CAMP1_READY. The CAMP1_EN bit should be changed only when CAMP-1 is not chosen as a clock source. **NOTE:** CCM has an output ccm_camp1_dis. This signal is inverted from the CAMP1_EN bit, i.e. when CAMP1_EN bit is '1' the ccm_camp1_dis signal is '0'. 0 disable CAMP-1 1 enable CAMP-1
8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–0 OSCNT	Oscillator ready counter value. These bits define the value of 32KHz counter, that serves as a counter for oscillator lock time. This is used for both the on chip oscillator lock time and the time that CAMP-1 and CAMP-2 require to be ready, since the CAMPs receives the external oscillator clock. Current estimation is ~5ms. This counter is used in ignition sequence and in wake from STOP sequence if SBYOS bit was defined. It notifies that the on chip oscillator output is ready for DPLLC to use.Only then can the gate in DPLLC be opened. 00000000 count 1 ckil 11111111 count 256 ckil's (Default)

18.3.2 CCM Control Divider Register (CCM_CCDR)

The figure below represents the CCM Control Divider Register (CCM_CCDR), which contains bits that control the loading of the dividers that need handshake with the blocks they affect.

Address: CCM_CCDR is 53FD_4000h base + 4h offset = 53FD_4004h



CCM_CCDR field descriptions

Field	Description
31–22 Reserved	This read-only field is reserved and always has the value zero. Reserved
21 IPU_HS_MASK	During the divider ratio change procedure, mask handshake with IPU. 0 allow handshake with IPU. 1 mask handshake with IPU. Request signal is not be generated.
20 EMI_HS_INT2_MASK	During the divider ratio change procedure, mask handshake with EXTMC int2 part only. 0 allow handshake with extermal memory controller (EXTMC). 1 mask handshake with EXTMC. Request signal is not be generated.
19 EMI_HS_INT1_MASK	During the divider ratio change procedure, mask handshake with emi int1 part only. 0 allow handshake with EXTMC 1 mask handshake with EXTMC. Request signal is not be generated.
18 EMI_HS_SLOW_MASK	During the divider ratio change procedure, mask handshake with emi slow part only. 0 allow handshake with EXTMC 1 mask handshake with EXTMC. Request signal is not be generated.
17 EMI_HS_FAST_MASK	During the divider ratio change procedure, mask handshake with emi fast part only. 0 allow handshake with EXTMC 1 mask handshake with EXTMC. Request signal is not be generated.

Table continues on the next page...

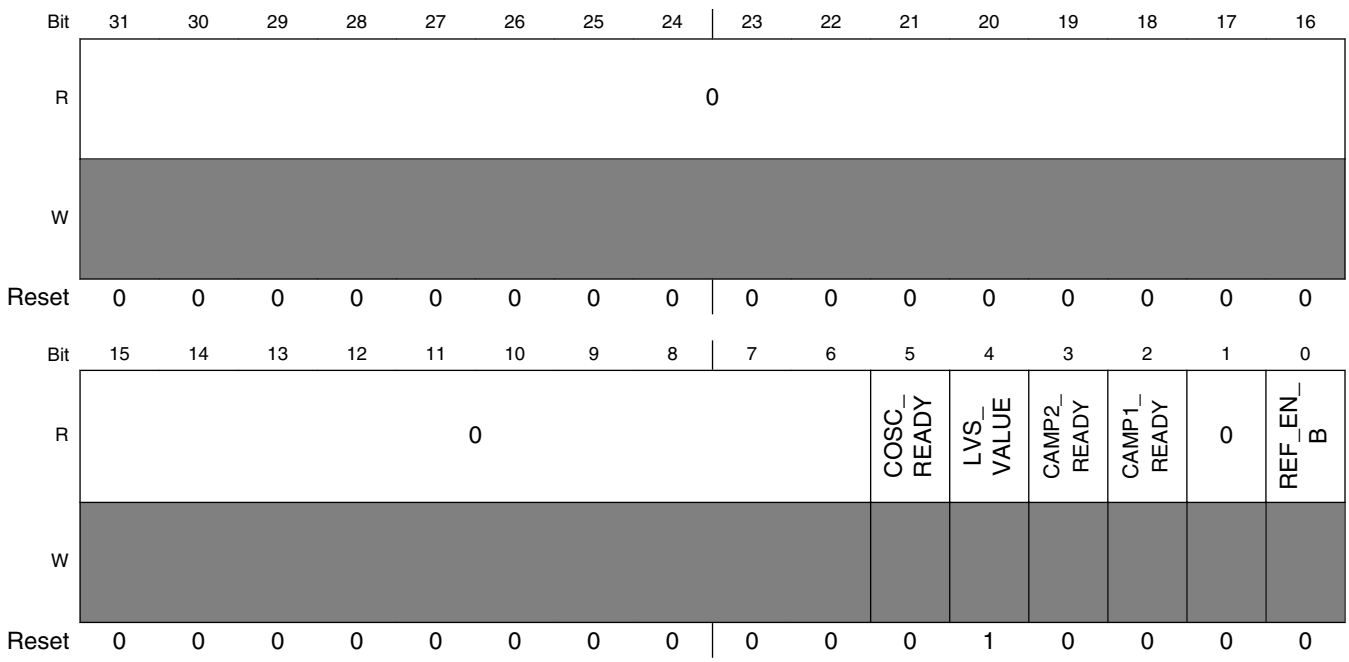
CCM_CCDR field descriptions (continued)

Field	Description
16 EMI_HS_MASK	During the divider ratio change procedure, mask handshake with EXTMC. This is used to mask all the EXTMC frequency change handshakes together. 0 allow handshake with EXTMC 1 mask handshake with EXTMC. Request signal is not be generated.
15–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

18.3.3 CCM Status REgister (CCM_CSR)

The figure below represents the CCM status Register (CCM_CSR). The status bits are read only bits.

Address: CCM_CSR is 53FD_4000h base + 8h offset = 53FD_4008h



CCM_CSR field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 COSC_READY	Status indicator of on board oscillator. This bit is asserted if on chip oscillator is enabled and on chip oscillator is not powered down, and if OSCNT counter has finished counting. 0 on board oscillator is not ready. 1 on board oscillator is ready.

Table continues on the next page...

CCM_CSR field descriptions (continued)

Field	Description
4 LVS_VALUE	Status of the LVS value for DPLL (output from CCM to select between the LVS / HVS frequency configuration) 0 value of LVS select is '0' 1 value of LVS select is '1'
3 CAMP2_READY	Status indication of CAMP-2. This is asserted if CAMP-2 is enabled, and if OSCNT counter has finished counting. 0 CAMP-2 is not ready. 1 CAMP-2 is ready.
2 CAMP1_READY	Status indication of CAMP-1. This is asserted if CAMP-1 is enabled, and if OSCNT counter has finished counting. 0 CAMP-1 is not ready. 1 CAMP-1 is ready.
1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 REF_EN_B	Status of the value of ref_en_b output of CCM 0 value of ref_en_b is '0' 1 value of ref_en_b is '1'

18.3.4 CCM Clock Swither Register (CCM_CCSR)

The figure below represents the CCM Clock Switcher register (CCM_CCSR). The CCM_CCSR register contains bits to control the switcher sub-block dividers and multiplexers.

Address: CCM_CCSR is 53FD_4000h base + Ch offset = 53FD_400Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
	100 divide by 5 101 divide by 6 110 divide by 7 111 divide by 8
9–8 IPG_PODF [1:0]	Selector for ipg clock post-divider. **NOTE:** IPTP block does not support ratio of 1:3 for ahb_clk:ipg_clk. In case IEEE_RTC is used, then the ratio should not be used. **NOTE:** SDMA does not support ratio of 1:3 and 1:4 for ahb_clk:ipg_clk. In case SDMA is used, then these ratios should not be used. 00 divide by 1 01 divide by 2 (Default) 10 divide by 3 11 divide by 4
7–6 PERCLK_ PRED1 [1:0]	Selector for peripherals clock pre-divider1 **NOTE:** Divider should be updated when output clock is gated. 00 divide by 1 01 divide by 2 (default) 10 divide by 3 11 divide by 4
5–3 PERCLK_ PRED2 [2:0]	Selector for peripherals clock pre-divider2. **NOTE:** Divider should be updated when output clock is gated. 000 divide by 1(default) 001 divide by 2 010 divide by 3 011 divide by 4 100 divide by 5 101 divide by 6 110 divide by 7 111 divide by 8
2–0 PERCLK_PODF [2:0]	Selector for peripherals clock post-divider. **NOTE:** Divider should be updated when output clock is gated. 000 divide by 1 001 divide by 2 010 divide by 3 011 divide by 4 100 divide by 5 101 divide by 6(default) 110 divide by 7 111 divide by 8

18.3.7 CCM Bus Clock Multiplexer Register (CCM_CBCMR)

The figure below represents the CCM Bus Clock Multiplexer Register (CCM_CBCMR). The CCM_CBCMR register contains bits to control the multiplexers that generate the bus clocks.

NOTE

Any change on the above multiplexer has to be done while the affected block's clock is not functional and the respective clock is gated in LPCG. If the change is done during operation of the block, it is not guaranteed that the block's operation cannot be harmed.

NOTE

The change for arm_axi_clk_sel should be done through SDMA so that ARM does not use this clock during the change, and the clock is gated in LPCG.

Address: CCM_CBCMR is 53FD_4000h base + 18h offset = 53FD_4018h

Field	Description
13–12 FIRI_CLK_SEL [1:0]	Selector for FIRI clock multiplexer 00 derive clock from pll1_sw_clk 01 derive clock from pll2_sw_clk 10 derive clock from pll3_sw_clk(Default) 11 lp_apm clock
11 LDB_DI1_IPU_ DIV	Selector for division of LDB clock for IPU DI1 0 divide by 3.5 1 divide by 7(Default)
10 LDB_DI0_IPU_ DIV	Selector for division of LDB clock for IPU DI0 0 divide by 3.5 1 divide by 7(Default)
9 LDB_DI1_CLK_ SEL	Selector for LDB DI1 clock multiplexer 0 pll3_sw_clk 1 pll4_sw_clk(Default)
8 LDB_DI0_CLK_ SEL	Selector for LDB DI0 clock multiplexer 0 pll3_sw_clk 1 pll4_sw_clk(Default)
7–6 CAN_CLK_ SEL[1:0]	Selector for FLEXCAN clock multiplexer 00 derive clock from ipg_clk_root (default) 01 derive clock from CKIH pad input 10 derive clock from CKIH2 pad input 11 derive clock from lp_apm clock source
5 Reserved	This read-only field is reserved and always has the value zero. Reserved
4 SPDIF0_COM	Controlls the multiplexer to communize spdif0 clock generation based on ssi1 clock root. 0 generate spdif0_clk_root from dividers 1 generate spdif0_clk_root from ssi1_clk_root.
3–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1–0 SPDIF0_CLK_ SEL [1:0]	Selector for spdif0 clock multiplexer 00 derive clock from pll1_sw_clk 01 derive clock from pll2_sw_clk 10 derive clock from pll3_sw_clk(Default) 11 SPDIF_XTAL_CLK clock

18.3.10 CCM Serial Clock Divider Register 1 (CCM_CSCDR1)

The figure below represents the CCM Serial Clock Divider Register 1 (CCM_CSCDR1). The register contains bits to control the clock generation sub-block dividers.

NOTE

Any change to the above dividers has to be done while the affected block's clock is not functional and the affected clock is gated. If the change is done during operation of the block, it is not guaranteed that the blocks operation will not be harmed.

Address: CCM_CSCDR1 is 53FD_4000h base + 24h offset = 53FD_4024h

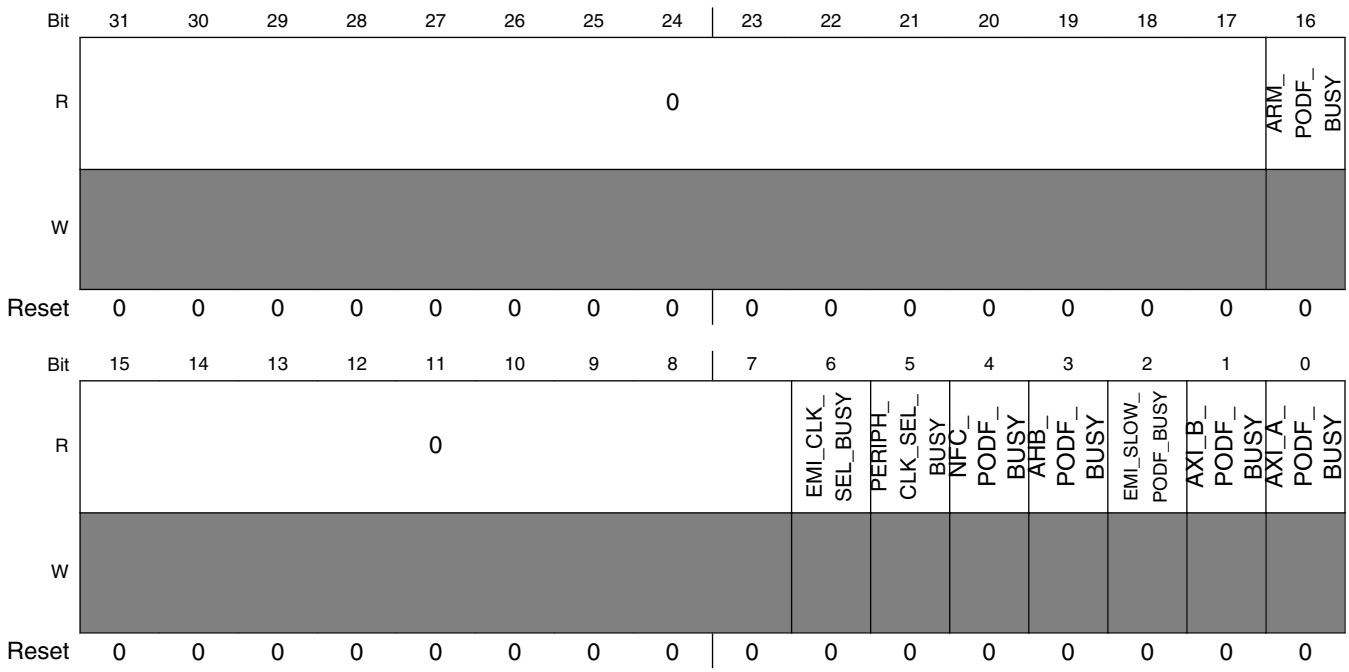
5–0 CSI_MCLK1_ CLK_PODF [5:0]	Selector for CSI mclk1 clock post-divider. **NOTE:** Divider should be updated when output clock is gated. **NOTE:** The input clock to this divider should be lower than 300Mhz, the pre-divider can be used to achieve this. 000000 divide by 1 111111 divide by 2^6

18.3.18 CCM Divider Handshake In-Process Register (CCM_CDHIPR)

The figure below represents the CCM Divider Handshake In-Process Register (CCM_CDHIPR). The register contains read only bits that indicate if the CCM is in the process of updating dividers or multiplexers that might need handshake with blocks.

Address: CCM_CDHIPR is 53FD_4000h base + 48h offset = 53FD_4048h



CCM_CDHIPR field descriptions

Field	Description
31–17 Reserved	This read-only field is reserved and always has the value zero. Reserved
16 ARM_PODF_BUSY	Busy indicator for CCM_CACRR[ARM_PODF]. This bit corresponds to the ARM_PODF divider only if DVFSC operation is done through ARM_PODF change, that is, if CCM_CDCR[ARM_FREQ_SHIFT_DIVIDER] = '1'. If it is not a DVFSC operation, writes to ARM_PODF commence once the divider is written with the new value. **NOTE:** When busy, do not write to this bit. Any reads will return the next value that the divider holds and not the actual value. After the busy signal is de-asserted, CCM can generate an interrupt if it is not masked (see CCM Interrupt Mask Register (CCM_CIMR)) 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process.
15–7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6 EMI_CLK_SEL_BUSY	Busy indicator for emi_clk_sel multiplexer control.

Table continues on the next page...

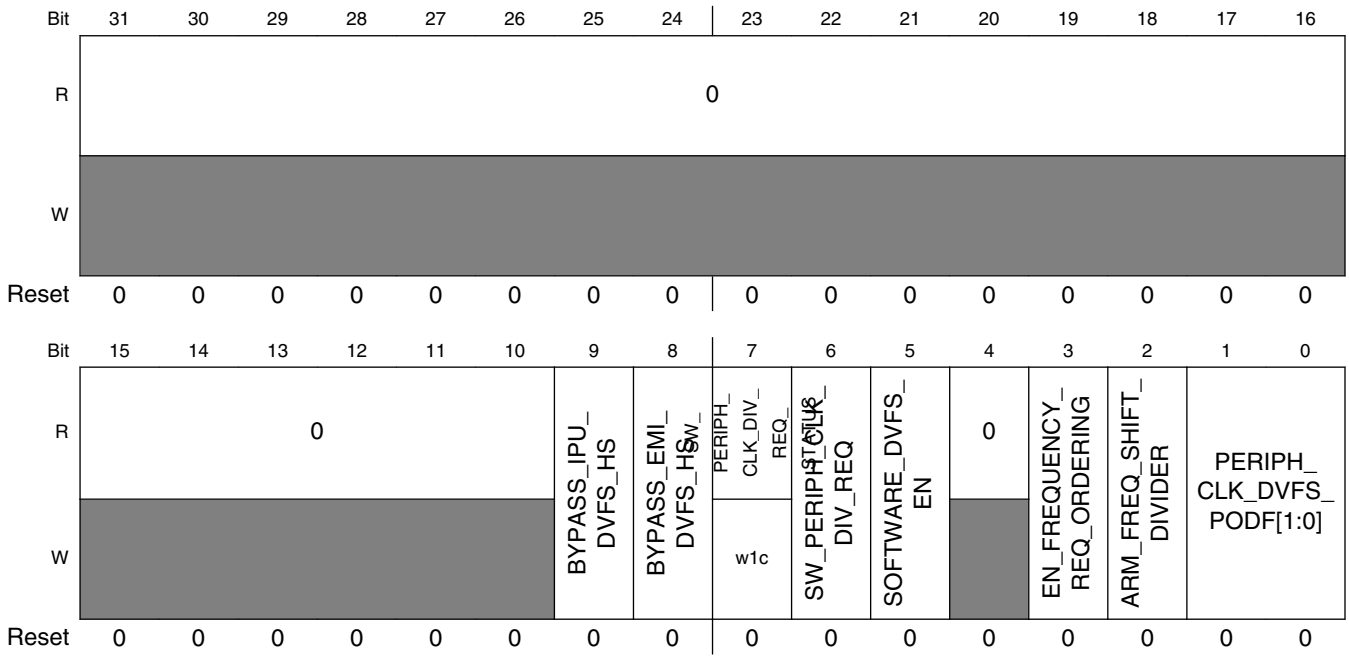
CCM_CDHIPR field descriptions (continued)

Field	Description
	NOTE: When busy, read to the multiplexer will return the next value it holds and not the actual value. After the busy signal is de-asserted, CCM can generate an interrupt if it is not masked (see CCM Module Enable Overide Register CCM Interrupt Mask Register) 0 Multiplexer is not busy and its value represents the actual division. 1 Multiplexer is busy in handshake process with EXTMC. The value read in the divider represents the next value that the divider holds after the handshake.
5 PERIPH_CLK_SEL_BUSY	Busy indicator for periph_clk_sel multiplexer control. **NOTE:** When busy, read to the multiplexer will return the next value it holds and not the actual value. After the busy signal is de-asserted, CCM can also generate an interrupt if it is not masked (see CCM Module Enable Overide Register CCM Interrupt Mask Register) 0 mux is not busy and its value represents the actual division. 1 mux is busy with handshake process with block. The value read in the divider represents the next value that the divider will hold after the handshake.
4 NFC_PODF_BUSY	Busy indicator for nfc_podf. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with block. The value read in the divider represents the next value that the divider will hold after the handshake.
3 AHB_PODF_BUSY	Busy indicator for ahb_podf. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with block. The value read in the divider represents the next value that the divider will hold after the handshake.
2 EMI_SLOW_PODF_BUSY	Busy indicator for emi_slow_podf. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with block. The value read in the divider represents the next value that the divider will hold after the handshake.
1 AXI_B_PODF_BUSY	Busy indicator for axi_b_podf. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with block. The value read in the divider represents the next value that the divider will hold after the handshake.
0 AXI_A_PODF_BUSY	Busy indicator for axi_a_podf. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with block. The value read in the divider represents the next value that the divider will hold after the handshake.

18.3.19 CCM DVFS Control Register (CCM_CDCR)

The figure below represents the CCM DVFS Control Register (CCM_CDCR). The register contains bits to control the dvfs operation.

Address: CCM_CDCR is 53FD_4000h base + 4Ch offset = 53FD_404Ch



CCM_CDCR field descriptions

Field	Description
31–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9 BYPASS_IPU_DVFS_HS	Bypass handshake performed with IPU in case of DVFS frequency division. 1 In case of DVFS. bypass IPU handshake. CCM does not generate the request in this case, and does not wait for the acknowledge from IPU. 0 In case of DVFS, CCM performs handshake with IPU prior to the frequency division.
8 BYPASS_EMI_DVFS_HS	Bypass handshake performed with EXTMC in case of DVFS frequency division. 1 In case of DVFS. bypass EXTMC handshake. CCM does not generate the request in this case, and does not wait for the acknowledge from EXTMC. 0 In case of DVFS, CCM performs handshake with EXTMC prior to the frequency division.
7 SW_PERIPH_CLK_DIV_REQ_STATUS	When software control of DVFS is enabled, that is, SOFTWARE_DVFS_EN = '1' this bit indicates the status of the DVFS frequency switch operation. 1 DVFS frequency switch operation is completed. 0 DVFS frequency switch has not finished, or there is no frequency division request pending.

Table continues on the next page...

CCM_CDCR field descriptions (continued)

Field	Description
6 SW_PERIPH_ CLK_DIV_REQ	Start DVFS frequency division operation. This bit is operational only if SOFTWARE_DVFS_EN bit is set to '1'. 0 Disable DVFS divider operation - DVFS divider divides by '1'. 1 Enable DVFS divider operation. DVFS divider divides by the PERIPH_CLK_DVFS_PODF divider settings.
5 SOFTWARE_ DVFS_EN	Defines if the DVFS frequency division operation commences by software bit SOFTWARE_DVFS_EN or by GPC change frequency request signal. 0 DVFS frequency division operation is controlled by GPC change frequency request signal. 1 DVFS frequency division operation is controlled by software bit SW_PERIPHE_CLK_DIV_REQ.
4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3 EN_ FREQUENCY_ REQ_ ORDERING	Defines if the frequency change request is sent to the EXTMC and to its master (IPU) together, or if CCM sends the request to EXTMC only after an acknowledge from the master (IPU) is received. This programing bit affects every clock change operation (DVFS operation, divider change operation, glitchless multiplexers change operation, etc.). 0 EXTMC request for frequency change is sent together with the request to EXTMC master (IPU). 1 EXTMC request for frequency change is sent after the acknowledge from master (IPU) is received.
2 ARM_FREQ_ SHIFT_DIVIDER	Defines if next DVFSC operation is through CCM_CACRR[ARM_PODF] change or DPLL relock. 0 Next DVFSC operation is done through DPLL relock. The pll relock process starts once GPC request an ARM frequenct change. (in this case any new writes to ARM_PODF commences immediately, without waiting for frequency change request from GPC). 1 Next DVFSC operation is done through ARM_PODF change. CCM holds updates to ARM_PODF until GPC requests for ARM frequency change.
1–0 PERIPH_CLK_ DVFS_ PODF[1:0]	Divider value for next DVFSP operation. This defines the value of the dividers affecting main_bus_clk. This divider takes place only during dvfs operation. Please refer to Peripheral Clock Domain Frequency Shift: for details. 00 divide by 1 (no frequency reduction during dvfs_per engagement, should be used for debug only) 01 divide by 2 (Default) 10 divide by 3 11 divide by 4

18.3.20 CCM Low Power Control Register (CCM_CLPCR)

The figure below represents the CCM Low Power Control Register (CCM_CLPCR). The register contains bits to control the low power modes operation.

Address: CCM_CLPCR is 53FD_4000h base + 54h offset = 53FD_4054h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CCM_CLPCR field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28 BYPASS_CAN2_LPM_HS	Bypass handshake with FLEXCAN-2 on next entrance to stop mode. **NOTE:** If bypass is enabled, CCM does not wait for an acknowledge from the block. 0 handshake with FLEXCAN-2 on next entrance to stop mode is performed. (default). 1 handshake with FLEXCAN-2 on next entrance to stop mode is bypassed.
27 BYPASS_CAN1_LPM_HS	Bypass handshake with FLEXCAN-1 on next entrance to stop mode. **NOTE:** If bypass is enabled, CCM does not wait for an acknowledge from the block. 0 handshake with FLEXCAN-1 on next entrance to stop mode is performed. (default). 1 handshake with FLEXCAN-1 on next entrance to stop mode is bypassed.
26 BYPASS_SCC_LPM_HS	Bypass handshake with scc on next entrance to stop mode. **NOTE:** If bypass is enabled, CCM does not wait for an acknowledge from the block. 0 handshake with SCC on next entrance to stop mode is performed. (default). 1 handshake with SCC on next entrance to stop mode is bypassed.
25 BYPASS_MAX_LPM_HS	Bypass handshake with max on next entrance to low power mode (wait or stop mode). **NOTE:** If bypass is enabled, CCM does not wait for an acknowledge from the block.

Table continues on the next page...

CCM_CLPCR field descriptions (continued)

Field	Description
	0 handshake with max on next entrance to low power mode is performed. (default). 1 handshake with max on next entrance to low power mode is bypassed.
24 BYPASS_ SDMA_LPM_HS	Bypass handshake with sdma on next entrance to low power mode (wait or stop mode). **NOTE:** If bypass is enabled, CCM does not wait for an acknowledge from the block. 0 handshake with sdma on next entrance to low power mode is performed. (default). 1 handshake with sdma on next entrance to low power mode is bypassed.
23 BYPASS_EMI_ INT2_LPM_HS	Bypass handshake with EXTMC int2 controller only on next entrance to low power mode (wait or stop mode). **NOTE:** If bypass is enabled, CCM does not wait for an acknowledge from the block. 0 handshake with EXTMC on next entrance to low power mode is performed. (default). 1 handshake with EXTMC on next entrance to low power mode is bypassed.
22 BYPASS_EMI_ INT1_LPM_HS	Bypass handshake with EXTMC int1 controller only on next entrance to low power mode (wait or stop mode). **NOTE:** If bypass is enabled, CCM does not wait for an acknowledge from the block. 0 handshake with EXTMC on next entrance to low power mode is performed. (default). 1 handshake with EXTMC on next entrance to low power mode is bypassed.
21 BYPASS_EMI_ SLOW_LPM_HS	Bypass handshake with EXTMC slow controller only on next entrance to low power mode (wait or stop mode). **NOTE:** If bypass is enabled, CCM does not wait for an acknowledge from the block. 0 handshake with EXTMC on next entrance to low power mode is performed. (default). 1 handshake with EXTMC on next entrance to low power mode is bypassed.
20 BYPASS_EMI_ FAST_LPM_HS	Bypass handshake with EXTMC fast controller only on next entrance to low power mode (wait or stop mode). **NOTE:** If bypass is enabled, CCM does not wait for an acknowledge from the block. 0 handshake with EXTMC on next entrance to low power mode is performed. (default). 1 handshake with EXTMC on next entrance to low power mode is bypassed.
19 BYPASS_EMI_ LPM_HS	Bypass handshake with EXTMC on next entrance to low power mode (wait or stop mode). This bit is used to bypass all the EXTMC handshakes or low power mode. **NOTE:** If bypass is enabled, CCM does not wait for an acknowledge from the block. 0 handshake with EXTMC on next entrance to low power mode is performed. (default). 1 handshake with EXTMC on next entrance to low power mode is bypassed.
18 BYPASS_IPU_ LPM_HS	Bypass handshake with IPU on next entrance to low power mode (wait or stop mode). **NOTE:** If bypass is enabled, CCM does not wait for an acknowledge from the block. 0 handshake with IPU on next entrance to low power mode is performed. (default). 1 handshake with IPU on next entrance to low power mode is bypassed.
17 BYPASS_RTIC_ LPM_HS	Bypass handshake with RTIC on next entrance to low power mode (wait or stop mode). **NOTE:** If bypass is enabled, CCM does not wait for an acknowledge from the block.

Table continues on the next page...

CCM_CLPCR field descriptions (continued)

Field	Description
	0 handshake with RTIC on next entrance to low power mode is performed. (default). 1 handshake with RTIC on next entrance to low power mode is bypassed.
16 BYPASS_ SAHARA_LPM_ HS	Bypass handshake with SAHARA on next entrance to low power mode (wait or stop mode). **NOTE:** If bypass is enabled, CCM does not wait for an acknowledge from the block. 0 handshake with SAHARA on next entrance to low power mode is performed. (default). 1 handshake with SAHARA on next entrance to low power mode is bypassed.
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11 COSC_ PWRDOWN	In run mode, on chip oscillator can be powered down by programming this bit to '1'. If the on chip oscillator is powered down, then stand-by clock oscillator (SBYOS) functionality for on chip oscillator is bypassed. The onchip oscillator should be powered down only in case the reference oscilator is not the source of all the clocks generation. 0 On chip oscillator is not be powered down.(default) 1 On chip oscillator is powered down.
10–9 STBY_COUNT	Standby counter. In the case of exit from STOP mode, (if VSTBY bit is set), STBY_COUNT defines the amount of time CCM waits between negation of PMIC_VSTBY_REQ and the check for assertion of PMIC_VFUNCIONAL_READY (input to i.MX53). 00 CCM waits 2 ckil clock cycles 01 CCM waits 4 ckil clock cycles 10 CCM waits 8 ckil clock cycles 11 CCM waits 16 ckil clock cycles
8 VSTBY	Voltage standby request bit. This bit defines if PMIC_VSTBY_REQ pin, which notifies external power management IC to change from functional voltage to standby voltage, is asserted in STOP mode. **NOTE:** When returning from STOP mode, the PMIC_VSTBY_REQ is deasserted (if it was asserted when entering STOP mode), and CCM waits for indication that functional voltage is ready (by sampling the assertion of PMIC_VFUNCIONAL_READY) before continuing the process of exiting from STOP mode. Please refer to STBY_COUNT bits (Bits 10-9). 0 voltage is not changed to standby voltage after next entrance to STOP mode. (PMIC_VSTBY_REQ remains negated - '0') 1 voltage is requested to change to standby voltage after next entrance to STOP mode. (PMIC_VSTBY_REQ is asserted - '1').
7 DIS_REF_OSC	In run mode, external reference oscillator clock can be disabled by generating '1' on CCM_CSR[REF_EN_B]. If the external reference clock is disabled by setting REF_EN_B to 1, then SBYOS functionality is bypassed. The external reference oscilator should be closed only in case the reference oscilator is not the source of any clock generation. 0 external high frequency oscillator is enabled, i.e. REF_EN_B = '0'.(default) 1 external high frequency oscillator is disabled, i.e. REF_EN_B = '1'
6 SBYOS	Standby clock oscillator. This bit defines if REF_EN_B pin, which disables external high frequency crystal, and COSC_PWRDOWN, which powers down the on chip oscillator, is asserted in STOP mode. This bit is discarded if DIS_REF_OSC = '1' for external oscillator, and if COSC_PWRDOWN='1' for the on chip oscillator.

Table continues on the next page...

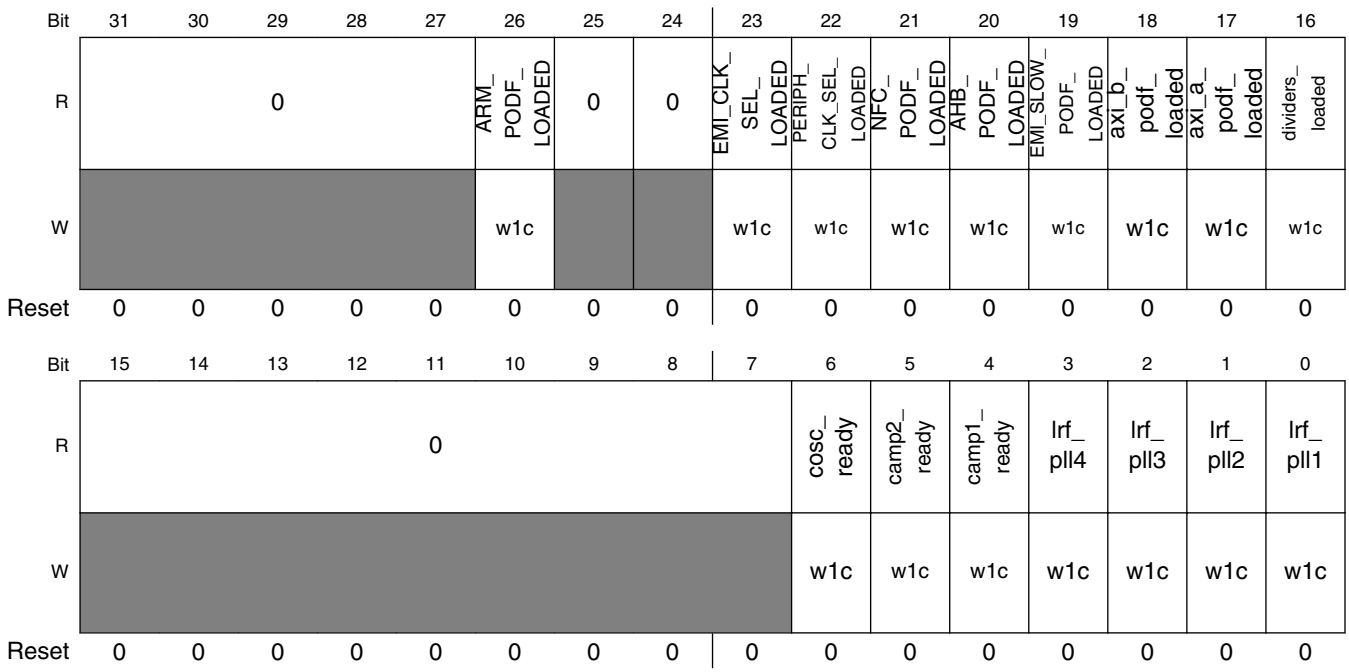
CCM_CLPCR field descriptions (continued)

Field	Description
	0 External high frequency oscillator is not disabled and on chip oscillator is not powered down, after next entrance to STOP mode. (REF_EN_B remains asserted - '0' and COSC_PWRDOWN remains de-asserted - '0') 1 External high frequency oscillator is disabled and on chip oscillator is powered down, after next entrance to STOP mode. (REF_EN_B is deasserted - '1' and COSC_PWRDOWN is asserted - '1'). (default). When returning from STOP mode, external oscillator is enabled again, on chip oscillator is returned to oscillator mode, and after OSCNT counts CCM continues with the exit from STOP mode process.
5 ARM_CLK_DIS_ON_LPM	Defines if ARM clocks are disabled in WAIT mode. This is useful in debug mode, when the user still wants to simulate entering WAIT mode and still keep the ARM clock functioning. **NOTE:** Software should not enable ARM power gating in wait mode if this bit is cleared. 0 ARM clock enabled in WAIT mode. 1 ARM clock disabled in WAIT mode. (default).
4–3 LPSR_CLK_SEL	Controlls the mux to select the lpsr_clk_root generation. Refer to CCM_CLK_ROOT_GEN and to PMIC Signal Description:, for details. 00 Reserved 01 generate clock from on chip oscillator clock. 10 generate clock from on chip oscillator clock/2 11 logical low ('0') - to be set when lpsr is not used, (for power consumption considerations) (default).
2 BYPASS_PMIC_VFUNCTIONAL_READY	By asserting this bit CCM bypasses waiting for pmic_vfunctional_ready signal when coming out of STOP mode. This should be used for PMIC's that don't support the pmic_vfunctional_ready signal. 0 Don't bypass the pmic_vfunctional_ready signal - CCM waits for it's assertion during exit from low power mode if standby voltage is enabled. 1 Bypass the pmic_vfunctional_ready signal - CCM does not wait for it's assertion during exit from low power mode if standby voltage is enabled.
1–0 LPM[1:0]	Setting the low power mode that system enters on next assertion of dsm_request signal. 00 Remain in RUN mode 01 Transfer to WAIT mode 10 Transfer to STOP mode 11 Reserved

18.3.21 CCM Interrupt Status Register (CCM_CISR)

The figure below represents the CCM Interrupt Status Register (CCM_CISR). This is a write one to clear register. Once a interrupt is generated, software should write one to clear it.

Address: CCM_CISR is 53FD_4000h base + 58h offset = 53FD_4058h



CCM_CISR field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26 ARM_PODF_LOADED	Interrupt ipi_int_1 (Interrupt #71) generated due to frequency change of ARM_PODF. The interrupt commences only if ARM_PODF is loaded during a DVFSC operation. 0 interrupt is not genrerated due to frequency change of ARM_PODF 1 interrupt is genrerated due to frequency change of ARM_PODF
25 Reserved	This read-only field is reserved and always has the value zero. Reserved
24 Reserved	This read-only field is reserved and always has the value zero. Reserved
23 EMI_CLK_SEL_LOADED	Interrupt ipi_int_1 (Interrupt #71) generated due to update of EMI_CLK_SEL. 0 interrupt is not genrerated due to update of EMI_CLK_SEL. 1 interrupt is genrerated due to update of EMI_CLK_SEL.

Table continues on the next page...

CCM_CISR field descriptions (continued)

Field	Description
22 PERIPH_CLK_SEL_LOADED	Interrupt ipi_int_1 (Interrupt #71) generated due to update of PERIPH_CLK_SEL. 0 interrupt is not genrerated due to update of PERIPH_CLK_SEL. 1 interrupt is genrerated due to update of PERIPH_CLK_SEL.
21 NFC_PODF_LOADED	Interrupt ipi_int_1 (Interrupt #71) generated due to frequency change of NFC_PODF 0 interrupt is not genrerated due to frequency change of NFC_PODF 1 interrupt is genrerated due to frequency change of NFC_PODF

CCM_CCGR1 field descriptions

Field	Description
31–30 CG15	SCC clocks: affects sccv2_clk_enable. it is not possible to close SCC clocks during RUN mode. Writing '00' to this CCM_CGR register does not affect the clocks of SCC. Closing the clocks of SCC eventually blocks access to the internal memory. In WAIT mode the SCC clocks can be closed only if it is guaranteed that no master is accessing the internal memory during the time spend in WAIT mode. The SCC clocks are closed in WAIT mode only if SAHARA clocks were closed as well. During WAIT mode, if SCC asserts either of it's clock enable signals, CCM enables the SCC clocks. The WAIT mode is not exited due to this assertion.
29–28 CG14	firi serial clock (firi_serial_clk_enable)
27–26 CG13	firi ipg clock (firi_clk_enable)
25–24 CG12	Reserved
23–22 CG11	i2c3 clocks (i2c3_serial_clk_enable)
21–20 CG10	i2c2 clocks (i2c2_serial_clk_enable)

Table continues on the next page...

CCM_CCGR1 field descriptions (continued)

18.3.32 CCM Clock Gating Register 7 (CCM_CCGR7)

The figure below represents the CCM Clock Gating Register 7 (CCM_CCGR7). The clock gating Registers define the clock gating for power reduction of each clock (CG(i) bits). There are 8 CGR registers. The number of registers required is according to the number of peripherals in the system.

CG(i) bits CCGR0-7

NOTE

This bits are used to turn on/off the clock to each block independently.The following table details the possible clock activity conditions for each block

Table 18-40. CG Bit Description

CGR value	Clock Activity Description
00	clock is off during all modes. stop enter hardware handshake is disabled.
01	clock is on in run mode, but off in wait and stop modes
10	Not applicable (Reserved).
11	clock is on during all modes, except stop mode.

NOTE

Blocks should be stopped before it's bits are set to "0", as clocks to the block are stopped immediately.

NOTE

The tables above show the register mappings for the different Clock Gating Registers. The clock connectivity table should be used to match the signal mentioned to the actual clocks going into the blocks.

18.3.33 CCM Module Enable Overide Register (CCM_CMEOR)

The figure below represents the CCM Module Enable Override Register (CCM_CMEOR). The CMEOR register contains bits to override the clock enable signal from the block. This should be used in case that it is decided to bypass the clock enable signals from the blocks. This bit is applicable only for block that their clock enable signal is used.

Address: CCM_CMEOR is 53FD_4000h base + 88h offset = 53FD_4088h

Chapter 19
Configurable Serial Peripheral Interface (CSPI)

19.1 Overview

This chapter describes a block integrated into an SoC. The chapter is intended for a block driver software developer. It describes block-level operation and programming. To understand how the block is integrated at the SoC level, a system software developer should see discussions of the block in the appropriate SoC-level chapter(s).

The Configurable Serial Peripheral Interface (CSPI) block is a full-duplex, synchronous, four-wire serial communication block. The CSPI block contains an 8 x 32 receive buffer (RXFIFO) and an 8 x 32 transmit buffer (TXFIFO). With data FIFOs, the CSPI allows rapid data communication with fewer software interrupts. Figure 19-1 shows a block diagram of the CSPI.

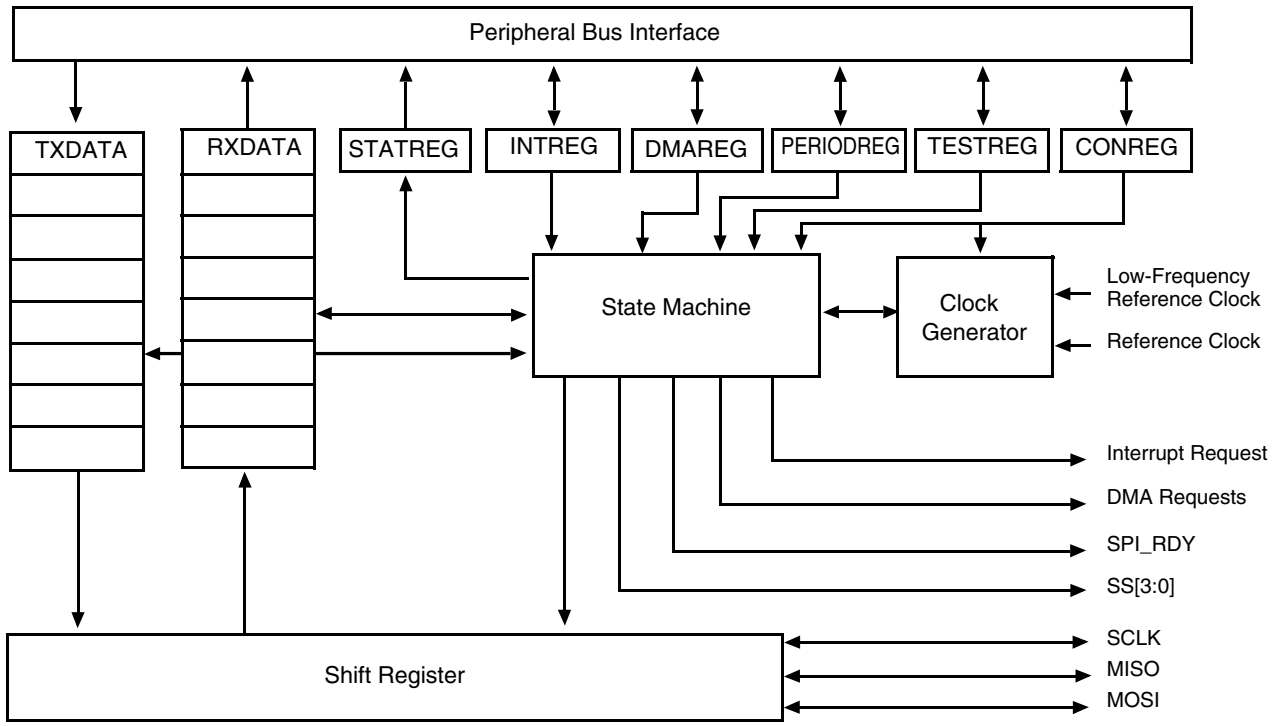

Figure 19-1. CSPI Block Diagram

19.1.1 Features

Key features of the CSPI include:

- Full-duplex synchronous serial interface
- Master/Slave configurable
- Four Chip Select (SS) signals to support multiple peripherals
- Transfer continuation function allows unlimited length data transfers
- 32-bit wide by 8 -entry FIFO for both transmit and receive data
- Polarity and phase of the Chip Select (SS) and SPI Clock (SCLK) are configurable
- Direct Memory Access (DMA) support
- Max operation frequency up to one-quarter of the reference clock frequency.

19.1.2 Modes and Operations

The CSPI supports the modes described in the indicated sections:

As described in Operations, the CSPI supports the operations described in the indicated sections:

19.2 External Signals

The following table lists conventions for representing signals.

Table 19-1. Block Signal Conventions

Category	Convention	Example(s)
Off-chip signal	Uppercase (all capital letters)	TXD
Internal signal[1]	Lowercase italics	*core_int*
Active low signal	_B (_b) suffix or overbar	RESET_EN_B or $\overline{\text{RESET\_EN}}$
Range of bussed or commonly named signals	Beginning and end points of the range are: • Separated by a colon. • Surrounded by square brackets.	ADDR[31:0] CSE_B[7:0] or $\overline{\text{CSE}}$[7:0]
Individual signal in a range of bussed or commonly named signals	Individual number in the range appears without a colon or square brackets	ADDR31 CSE0_B or $\overline{\text{CSE0}}$

1. Internal signals are for reference only in descriptions of internal block or SoC functionality.

The following table describes all CSPI signals that connect off-chip.

Table 19-2. Off-Chip Block Signals

Signal	I/O	Description	Reset State[1]	Pull-Up/ Down[1]
$\overline{\text{SS}}$[3:0]	I/O	Chip selects	1	-
SCLK	I/O	SPI clock	0	Active
MISO	I/O	Master data in; slave data out	0	Passive
MOSI	I/O	Master data out; slave data in	0	-
SPI_RDY	I	Master data out; slave data in	0	Active

1. The reset state values and pull-up/down requirements provided in this table are from the block-level perspective. To understand how the block is integrated at the SoC level, the system software developer must see discussions of the block in the appropriate SoC-level chapter(s). For example, a block signal that requires a pull-up could be integrated with a pull-up option built into the SoC. In this case, the system software developer must ensure the proper programming at the SoC level.

The following figure shows the CSPI in master mode connected to four external devices in a one-way communication link.

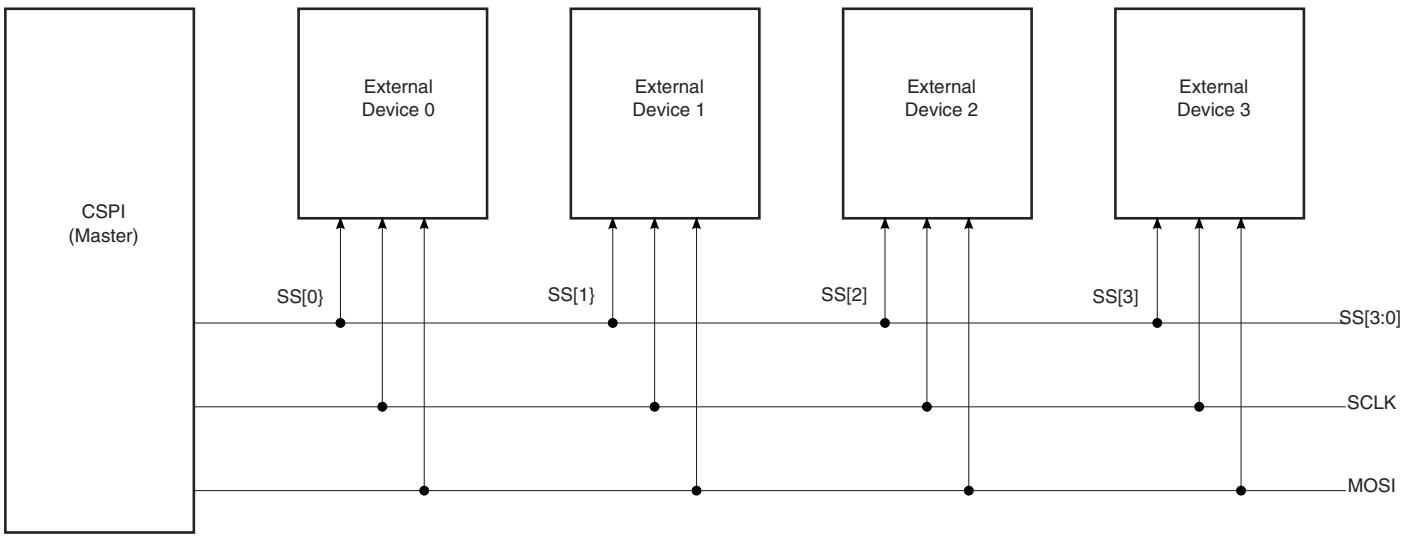

Figure 19-2. Example Connection Diagram

19.3 Functional Description

This section provides a complete functional description of the CSPI. The following figure shows the relationship of SCLK and data lines while CSPI has been configured with different POL and PHA settings.

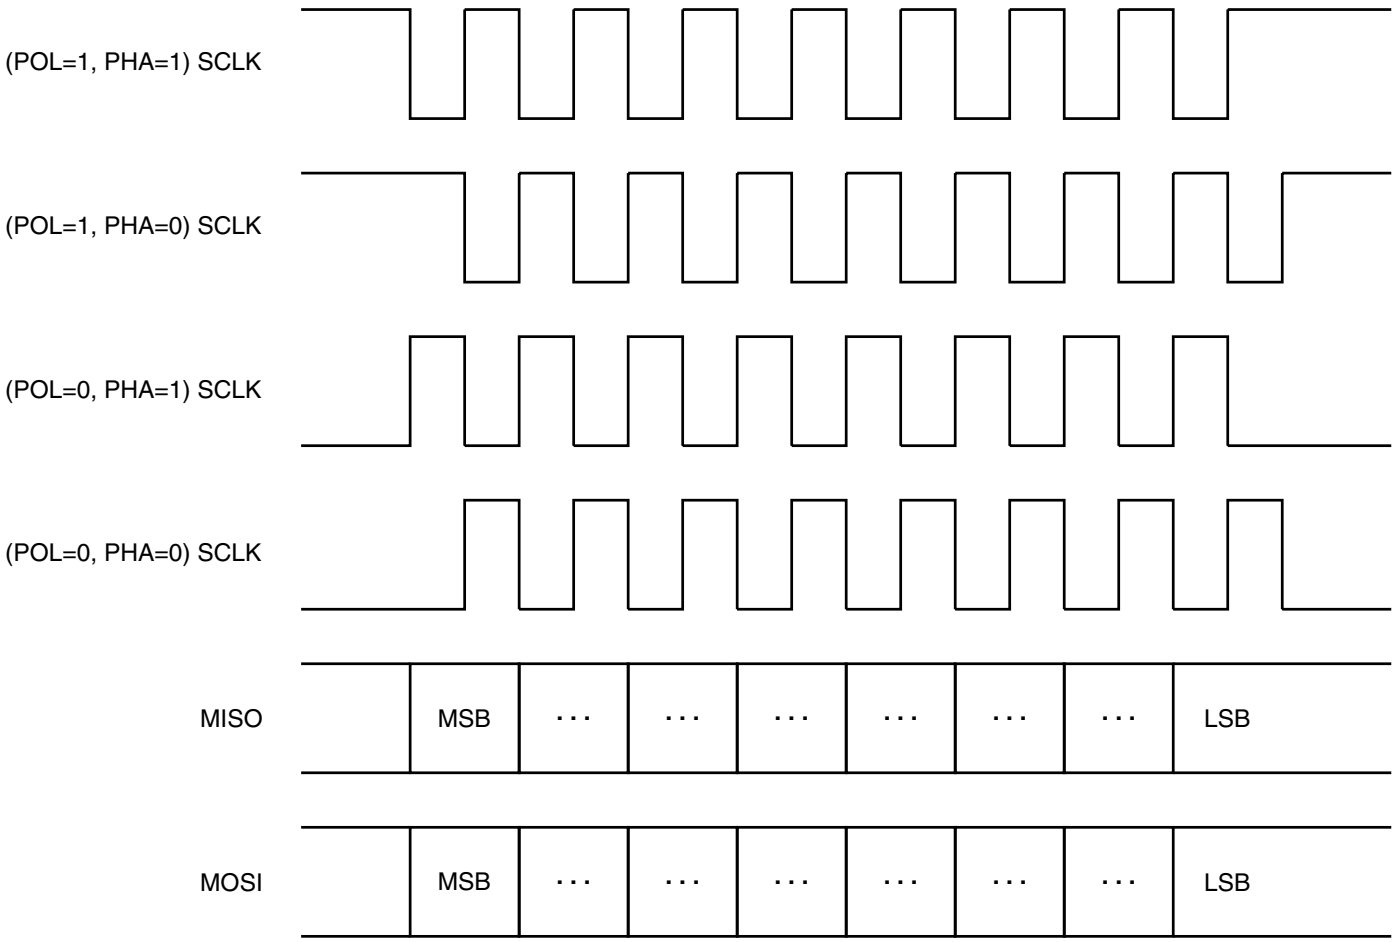

Figure 19-3. CSPI SCLK, MISO, and MOSI Relationship

19.3.1 Operating Modes

CSPI has two operating modes, master mode and slave mode. This section describes all functional operation modes of the CSPI.

19.3.1.1 Master Mode

When the CSPI is configured as a master, it uses a serial link to transfer data between the CSPI and an external slave device. One of the Chip Select (SS) signals and the clock signal (SCLK) are used to transfer data between two devices. If the external device is a transmit-only device, the CSPI master's output port can be ignored and used for other purposes. In order to use the internal TXFIFO and RXFIFO, two auxiliary output signals,

Chip Select (SS) and CSPI_CONREG[DRCTL], are used for data transfer rate control. Software can also configure the sample period control register to a fixed data transfer rate.

19.3.1.2 Slave Mode

When the CSPI is configured as a slave, software can configure the CSPI Control register to match the external SPI master's timing. In this configuration, Chip Select ($\overline{SS}$) becomes an input signal, and is used to control data transfers through the Shift register, as well as to load/store the data FIFO.

19.3.2 Low Power Modes

The CSPI does not operate under low power mode. It holds its operation when its clock is gated off in master mode. In slave mode, the CSPI does not respond when its clock is gated off.

19.3.3 Operations

This section describes the CSPI's operations.

19.3.3.1 Typical Master Mode

The CSPI master uses the Chip Select (SS) signal to enable an external SPI device, and uses the SCLK signal to transfer data in and out of the Shift register. The SPI_RDY enables fast data communication with fewer software interrupts. By programming the CSPI_PERIODREG register accordingly, the CSPI can be used for a fixed data transfer rate.

When the CSPI is in Master mode the SS, SCLK, and MOSI are output signals, and the MISO signal is an input. The following figure shows a typical SPI burst.

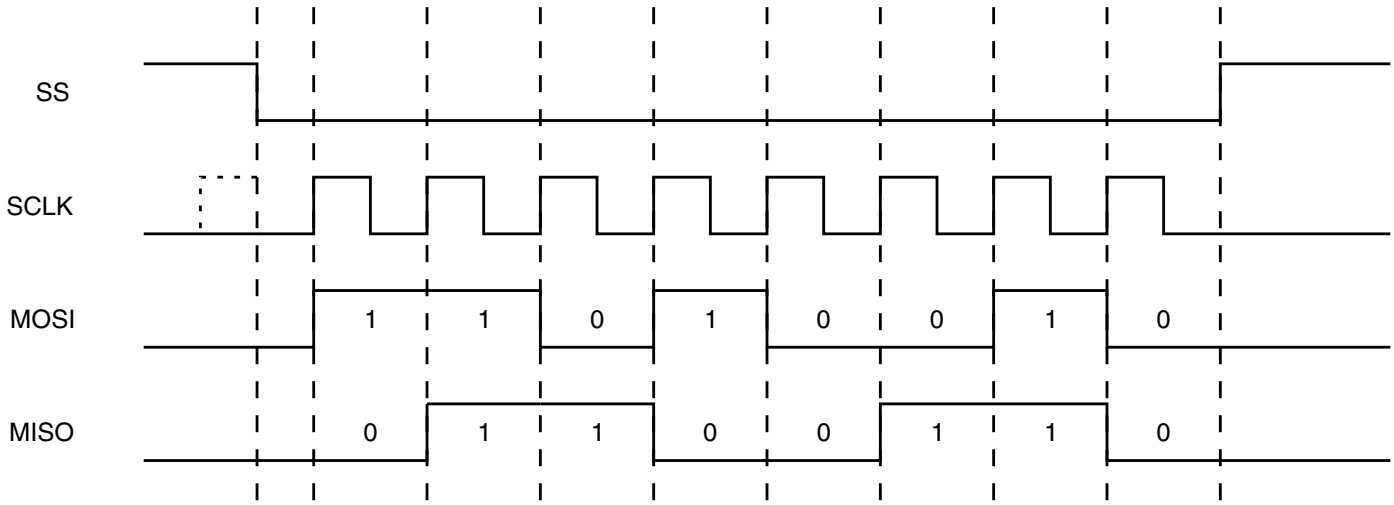

Figure 19-4. Typical SPI Burst (8-bit Transfer)

The Chip Select (SS) signal enables the selected external SPI device, and the SCLK synchronizes the data transfer. The MOSI and MISO signals change on rising edge of SCLK and the MISO signal is latched on the falling edge of the SCLK. The above figure shows a data of 0xD2 is shifted out, and a data of 0x66 is shifted in.

19.3.3.1.1 Master Mode with SPI_RDY

By default, the CSPI does not use the SPI_RDY signal in master mode (MODE =1). A SPI burst begins when the following events happen:

- The CSPI is enabled, TXFIFO has data in it, and CONREG[XCH] bit or the CONREG[SMC] bit is set.
- When the SPI Data Ready Control (CONREG[DRCTL]) bits contains either 01 or 10, the SPI_RDY signal controls when a SPI burst starts.

A SPI burst is defined as a bus transaction that starts when the slave select is asserted and ends when the slave select is negated. The Chip Select (SS) signal will remain asserted until all the bits in a SPI burst are shifted out.

If CONREG[DRCTL] is set to 01, the SPI burst can be triggered only if a falling edge of the SPI_RDY signal from CSPI_CONREG[DRCTL] register has been detected. The following figure shows the relationship between a SPI burst and the falling edge of SPI_RDY signal.

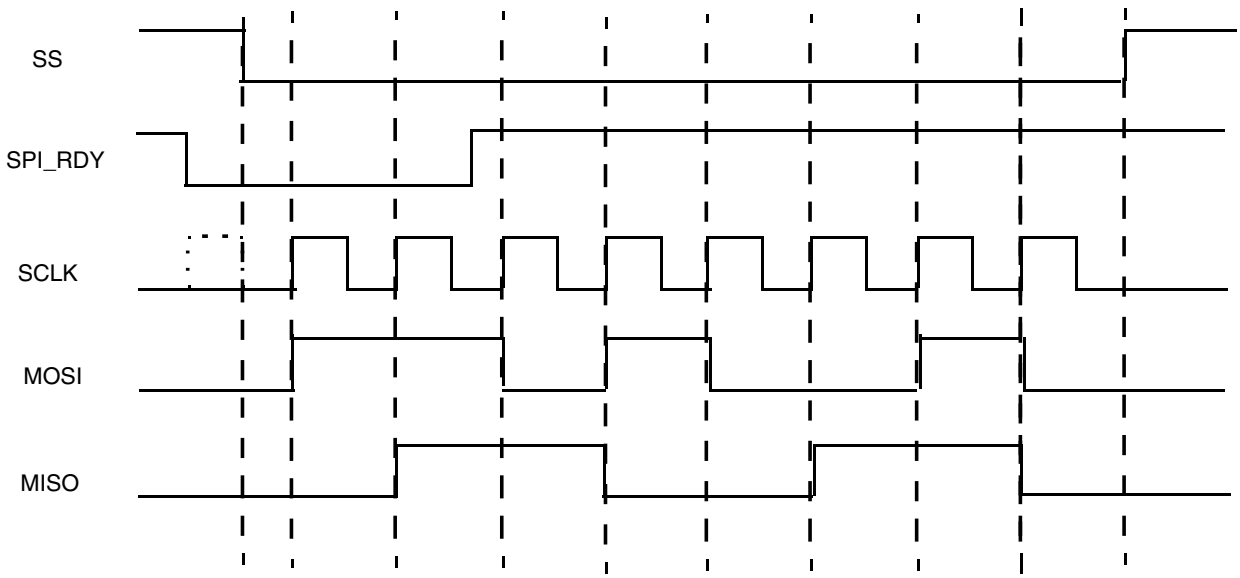

Figure 19-5. Relationship Between a SPI Burst and SPI_RDY: Falling-Edge Triggered

A SPI burst does not start until the falling edge of the SPI_RDY signal is detected. The next SPI burst starts when the next SPI_RDY falling edge is detected, after the last burst has finished.

If SPI Data Ready Control (CONREG[DRCTL]) is set to 10, the SPI burst can be triggered only if the SPI_RDY signal is low. The following figure shows the relationship between a SPI burst and the SPI_RDY signal. The SPI burst does not begin until the SPI_RDY signal goes low. The CSPI will keep transmitting SPI burst if the SPI_RDY signal remains low.

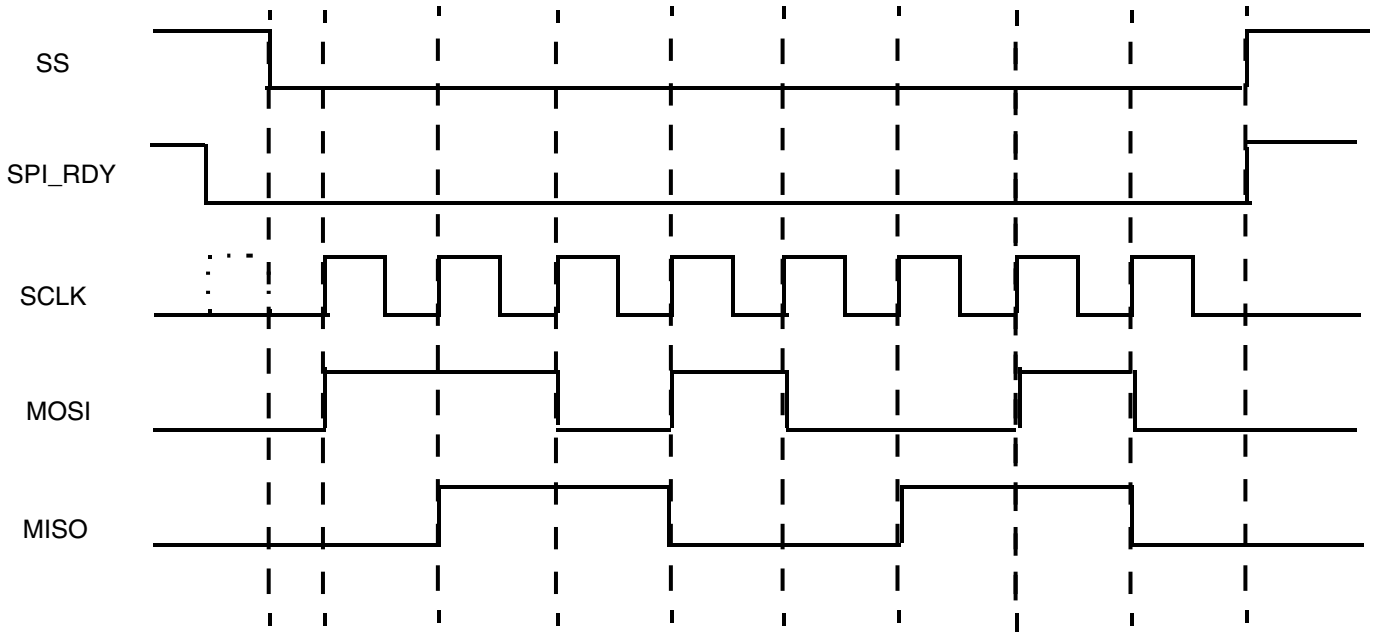

Figure 19-6. Relationship Between a SPI Burst and SPI_RDY: Low-Level Triggered

19.3.3.1.2 Master Mode with Wait States

Wait states can be inserted between SPI bursts. This provides a way for software to slow down the SPI burst to meet the timing requirements of a slower SPI device. The following figure shows wait states inserted between SPI bursts.

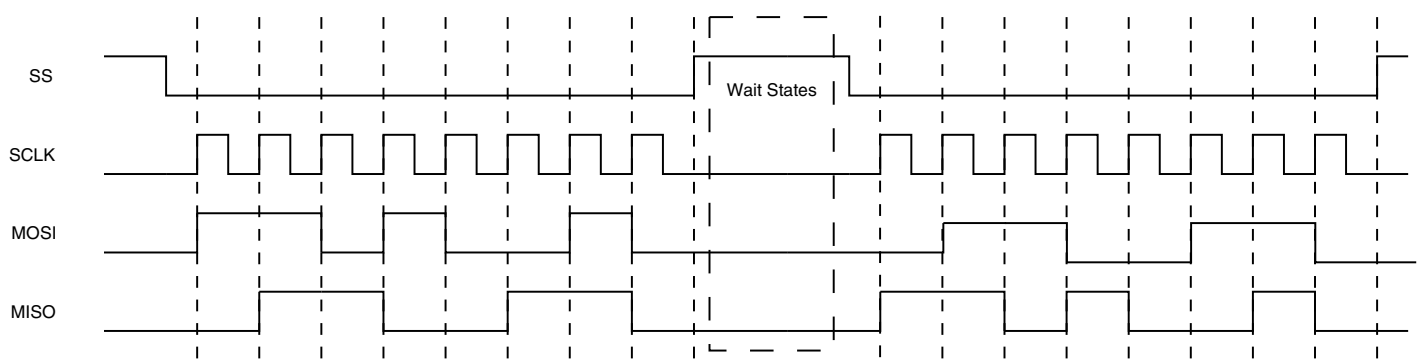

Figure 19-7. SPI Bursts with Wait States

In this case, the number of wait states is controlled by PERIODREG[SAMPLE PERIOD] and the wait states' clock source is selected by PERIODREG[CSRC].

19.3.3.1.3 Master Mode with SSCTL Control

The SPI SS Control (SSCTL) bit controls whether the current operation is single burst or multiple bursts. When the SPI SS Wave Form Select (SSCTL) bit is set, the current operation is multiple bursts transfer. When the SPI SS Wave Form Select (SSCTL) bit is cleared, the current operation is single burst transfer. A SPI burst can contains multiple words as defined in the BURST LENGTH field of the CSPI_CONREG register.

The following figure shows one SPI burst while SSCTL is clear.

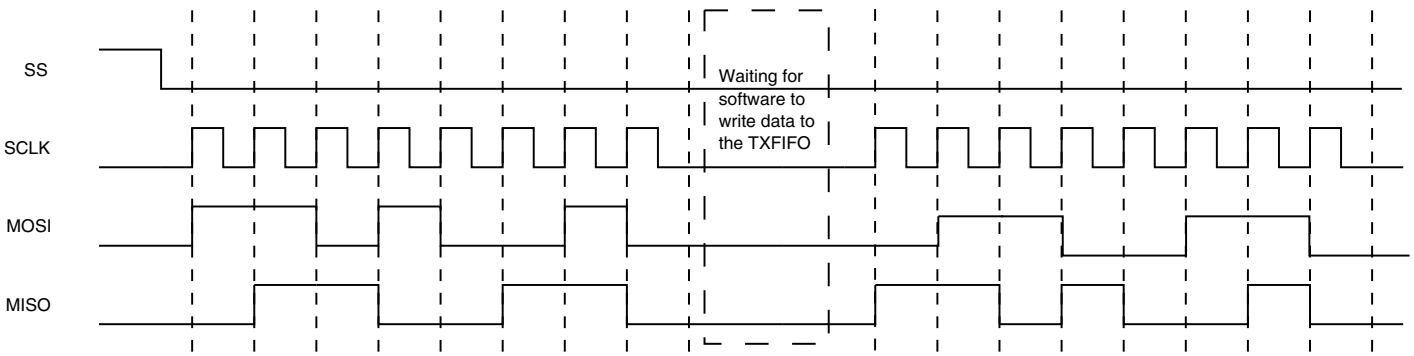

Figure 19-8. SPI Burst While SSCTL is Clear

Two 8-bit bursts in the TXFIFO have been combined and transmitted in one SPI burst. The maximum length of a single SPI burst is defined in the BURST LENGTH field of the CONREG control register. (The above figure corresponds to a BURST LENGTH of 8.) This provides a way for transferring a longer SPI burst by writing data into TXFIFO while the CSPI is transmitting.

The following figure shows two SPI bursts are transmitted while SSCTL is set.

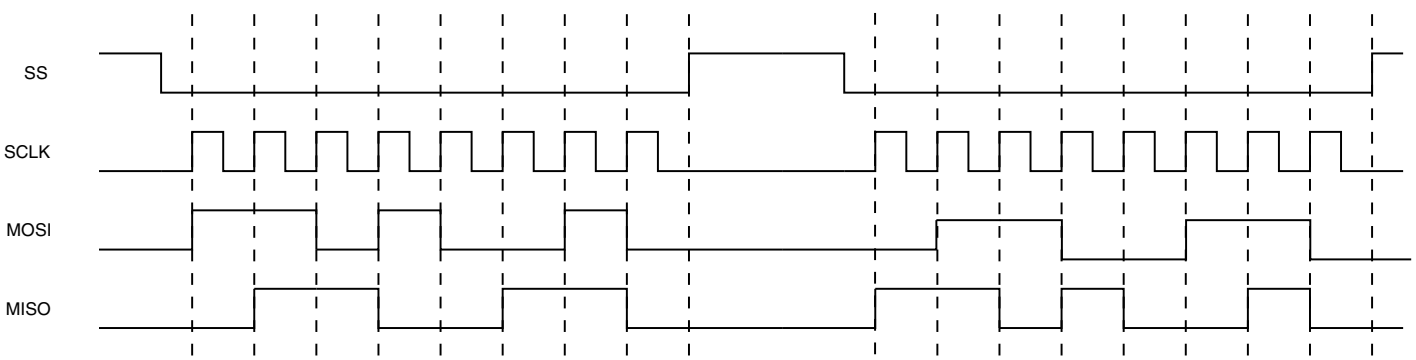

Figure 19-9. SPI Bursts While SSCTL is Set

Two FIFO entries are transmitted, one entry with each SPI burst. The CSPI will continue to transmit SPI bursts until the TXFIFO is empty. When wait states can be inserted between SPI bursts, the SS will negate between SPI bursts until the wait states finish.

19.3.3.1.4 Master Mode with Phase Control

The Phase Control (CSPI_CONREG[PHA]) bit controls how the transmit data shifts out and the receive data shifts in.

When the Phase control (CSPI_CONREG[PHA]) bit is set, the transmit data will shift out on the rising edge of SCLK, and the receive data is latched on the falling edge of SCLK. The most-significant bit is output on the first rising SCLK edge.

When CSPI_CONREG[PHA] is cleared, the transmit data is shifted out on the falling edge of SCLK and the receive data is latched on the rising edge of SCLK. The MSB is output when the host processor loads the transmitted data.

Inverting the SCLK polarity does not impact the edge-triggered operations because they are internal to the serial peripheral interface master.

The following figure shows a SPI burst using different POL and PHA configurations.

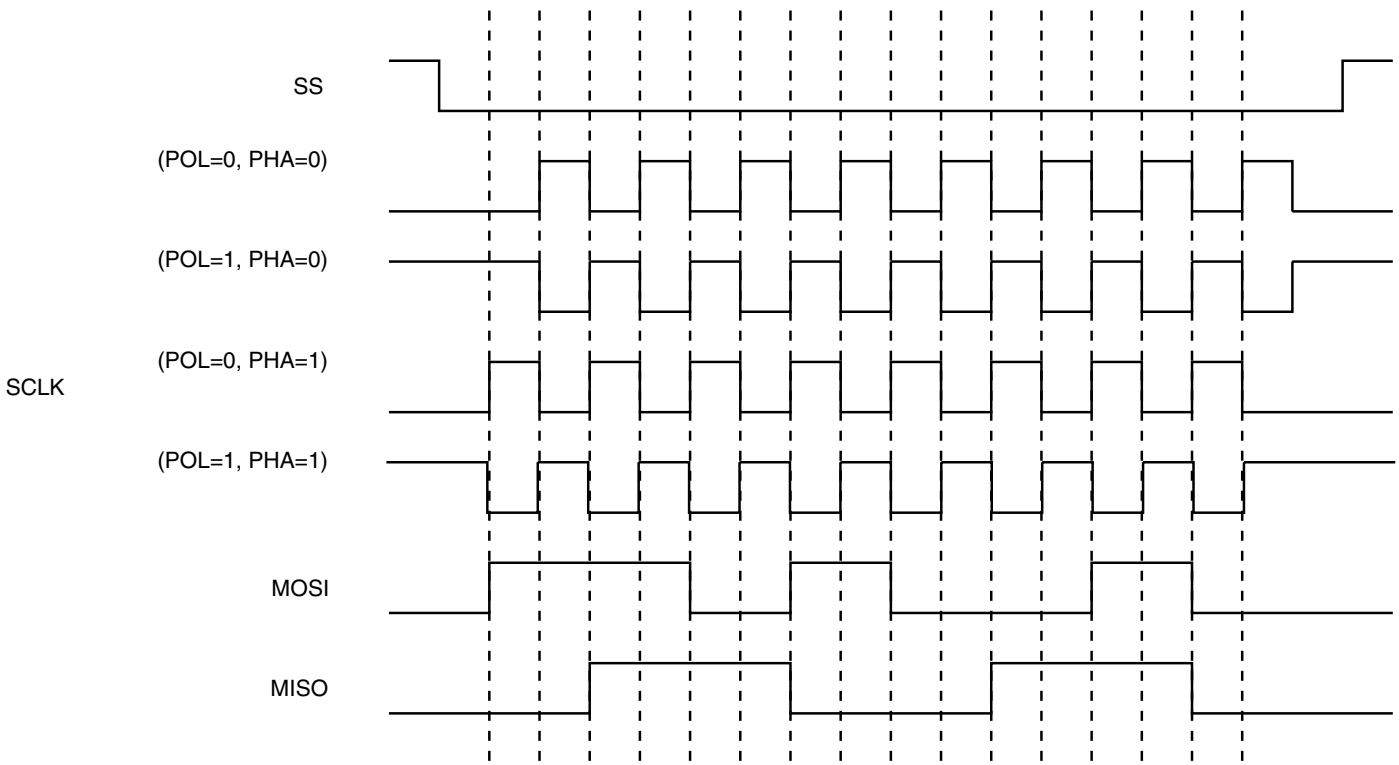

Figure 19-10. SPI Burst with Different POL and PHA Configurations

19.3.3.2 Typical Slave Mode

When the CSPI is configured as a slave (Mode = 0), software can configure the CSPI Control register to match the external SPI master's timing. In this configuration, SS becomes an input signal, and is used to latch data in and out of the internal data Shift registers, as well as to advance the data FIFO.

The SS, SCLK, and MOSI are inputs and MISO is output. Most of the timing diagrams are similar to the diagrams shown previously for the SPI in Master mode (Mode = 1), because the inputs come from a SPI master device.

However, the timing is different when SS is used to advance the data FIFO. When the SSCTL is set while the CSPI is configured in Slave mode, the data FIFO will advance on the rising edge of the SS signal. When the polarity is reversed (SSPOL = 1), the data FIFO will advance on the falling edge of the SS signal.

The following figure shows a SPI burst in which the data FIFO is advanced by the rising edge of the SS signal.

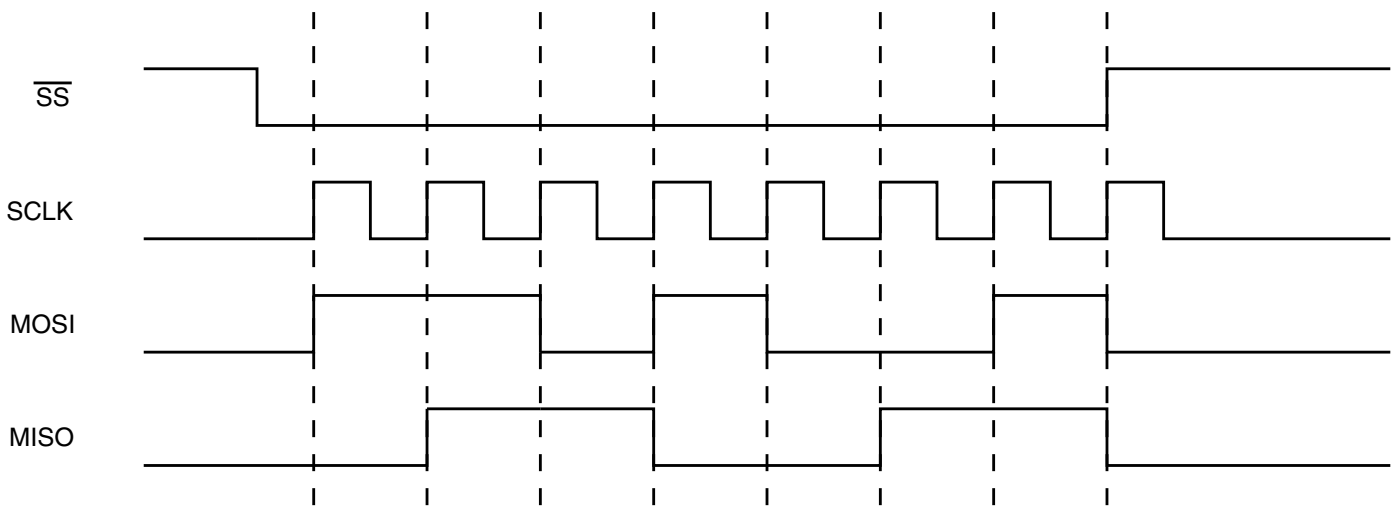

Figure 19-11. Advancing the Data FIFO on the Rising Edge of SS

In the above case, only the most significant 7 bits are loaded to the RXFIFO.

19.3.4 Clocks

This section describes clocks and special clocking requirements of the block.

CSPI has the following clock inputs:

- Reference Clock is the reference clock.
- Low-Frequency Reference Clock is a 32KHz input clock optionally used for counting wait states.

19.3.5 Reset

Whenever a device reset occurs, a reset is performed on the CSPI, resetting all registers to their default values.

Software can reset the block using the CONREG[EN] bit; see Control Register (CSPI_CONREG).

19.3.6 Interrupts

Interrupt control provides a way to manage the CSPI FIFOs:

- For transmitting data, software can enable the TXFIFO empty, TXFIFO half , and TXFIFO full interrupts to maintain the TXFIFO using an interrupt service routine.
- For receiving data, software can enable the RXFIFO ready, RXFIFO half , and RXFIFO full interrupts to retrieve data from the RXFIFO using an interrupt service routine.

Other interrupt sources can be used to control or debug the SPI bursts:

- The transfer-completed interrupt means that there is no data left in the TXFIFO and that the data in the Shift register has been shifted out.
- The RXFIFO overflow interrupt means that the RXFIFO received more than 8 words and will not accept any other words.

The following figure shows a program sequence of SPI bursts using interrupt control.

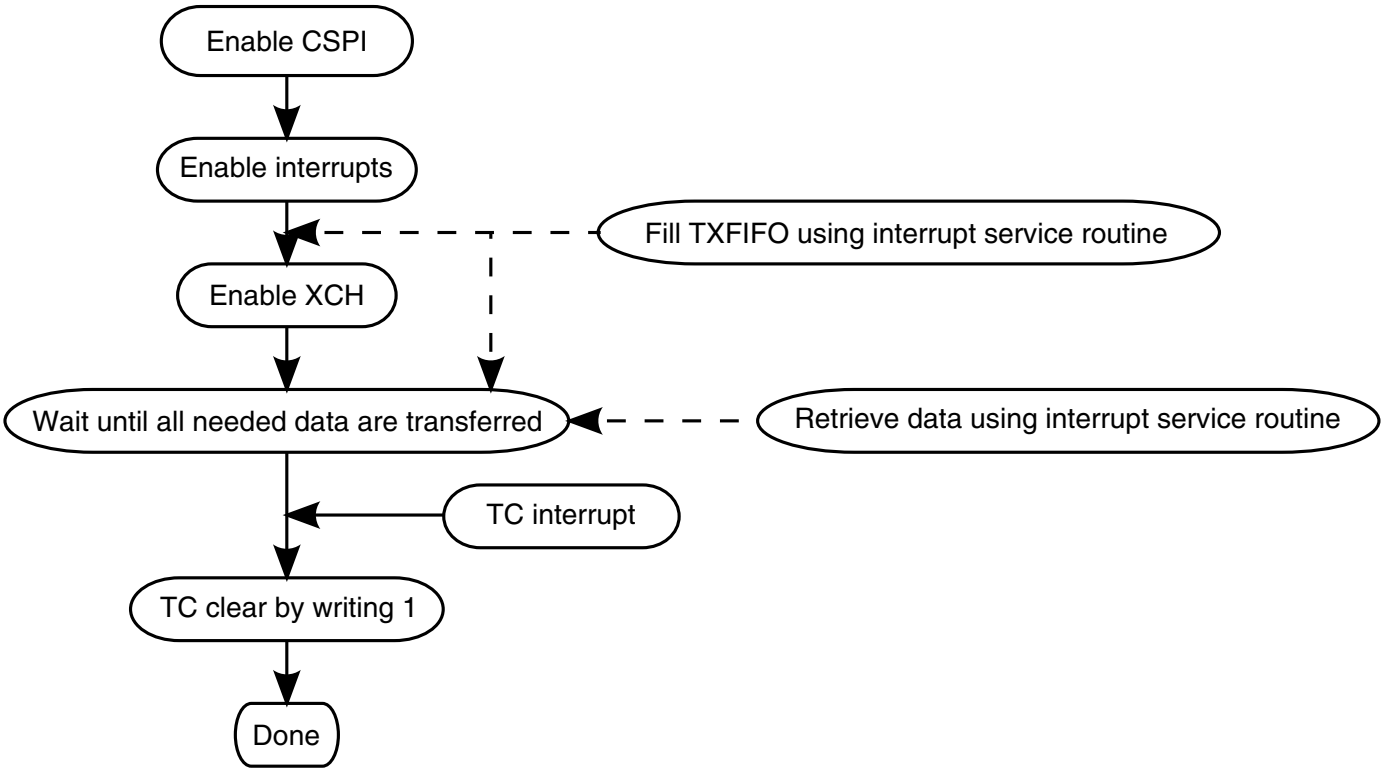

Figure 19-12. Program Sequence of SPI Burst Using Interrupt Control

19.3.7 DMA

DMA control provides another method to utilize the FIFOs in the CSPI. By using DMA request and acknowledge signals, larger amounts of data can be transferred, and will reduce interrupts and host processor loading. When the appropriate conditions are matched, the block will send out a DMA request, and the DMA can deal with the following conditions:

- TXFIFO empty
- TXFIFO half
- RXFIFO half
- RXFIFO full

The following figure shows a program sequence of SPI bursts using DMA control.

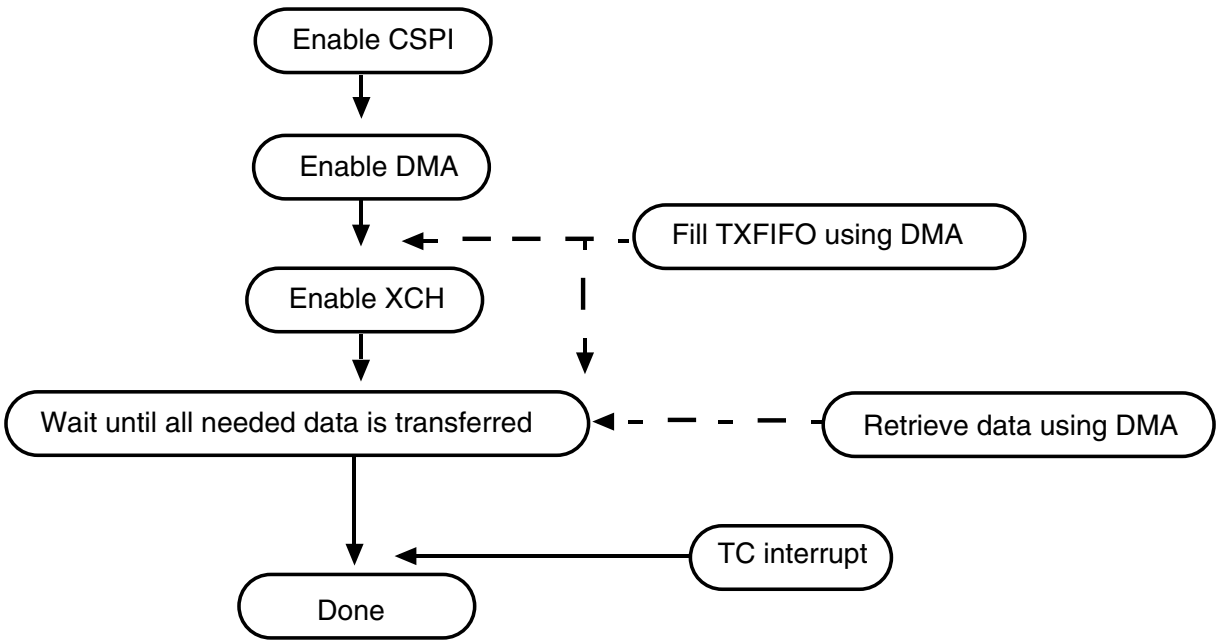

Figure 19-13. Program Sequence of SPI Burst Using DMA

19.3.8 Byte Order

Software can swap bytes for receive data using the TESTREG[SWAP] bit. See Test Control Register (CSPI_TESTREG).

19.4 Initialization

This section provides initialization information for CSPI.

To initialize the block:

1. Clear the EN bit in CSPI_CONREG to reset the block.
2. Enable the clocks for CSPI.
3. Set the EN bit in CSPI_CONREG to put CSPI out of reset.
4. Configure corresponding IOMUX for CSPI external signals.
5. Configure registers of CSPI properly according to the specifications of the external SPI device.

19.5 Applications

The following figure shows two flowcharts for the master and slave mode of operations supported by the CSPI.

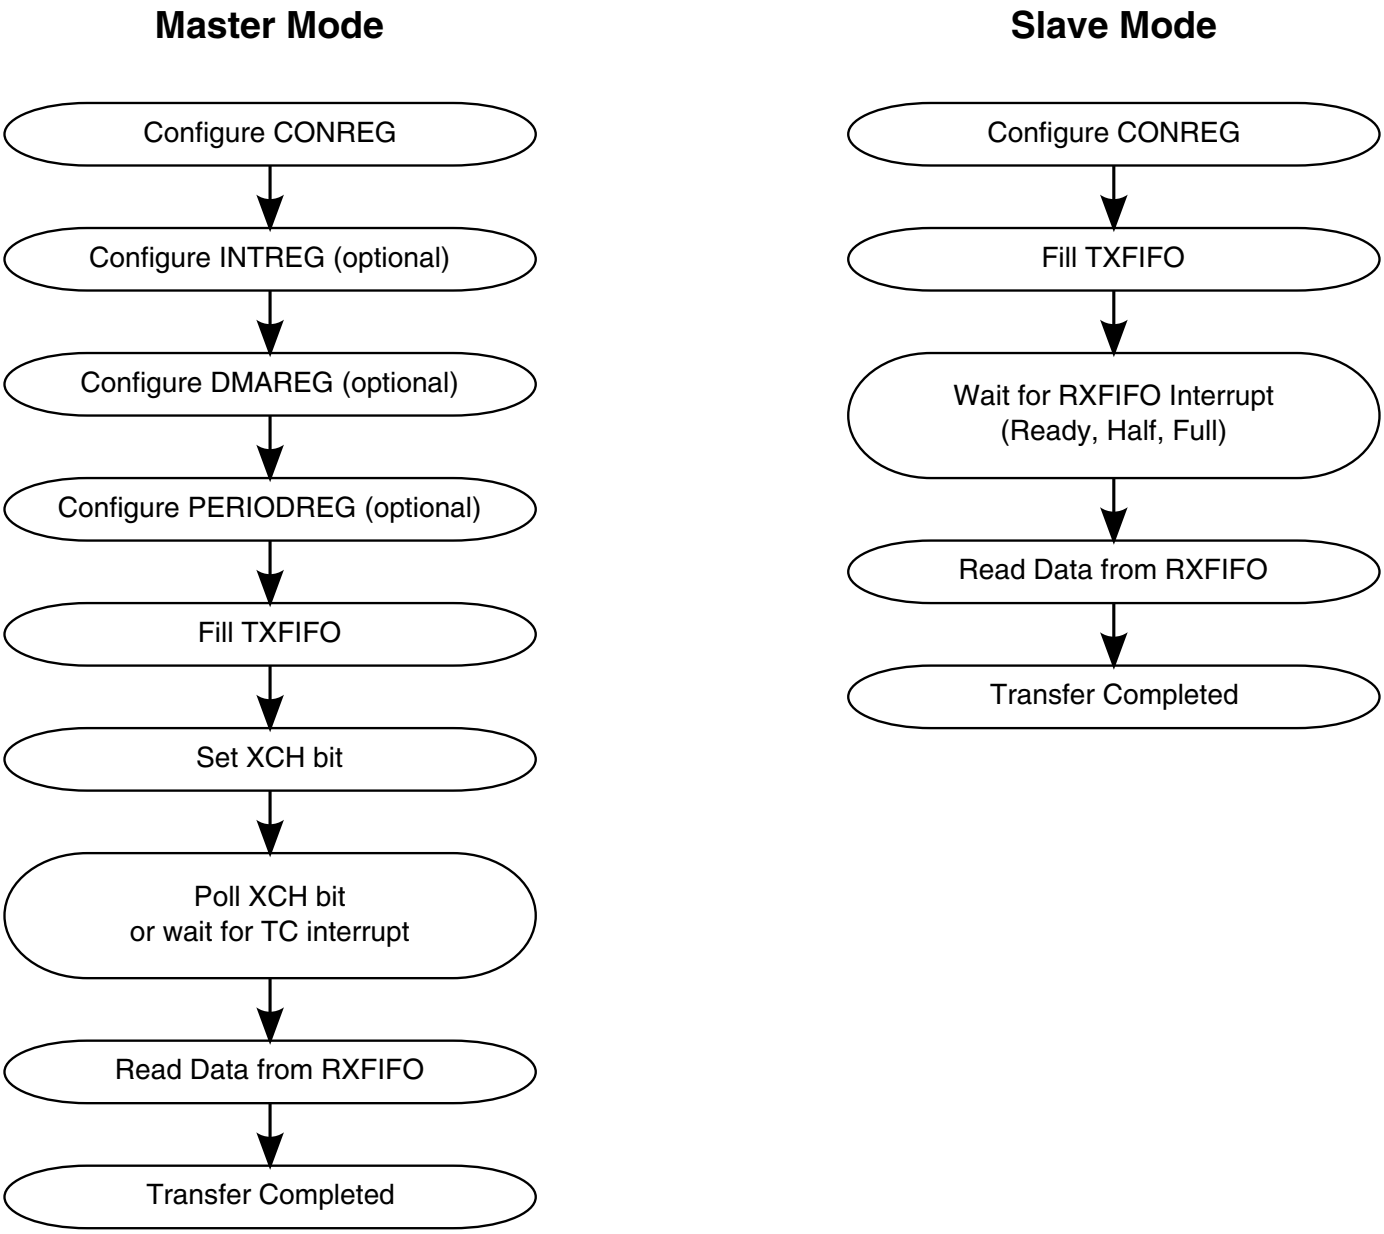

Figure 19-14. Flowchart of the CSPI Operation

The following example shows example code of CSPI operation using ARM instructions.

CSPI Operation using ARM Instructions

```

          LDR R1, [R0, #0x00]                          ; Read data from RXFIFO.
```

19.6 Programmable Registers

This section includes the block memory map and detailed descriptions of all registers. For the base address of a particular block instantiation, see the system memory map.

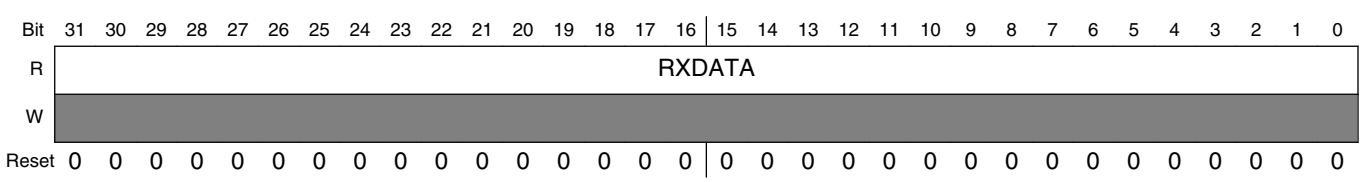
CSPI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FC_0000	Receive Data Register (CSPI_RXDATA)	32	R	0000_0000h	19.6.1/ 944
63FC_0004	Transmit Data Register (CSPI_TXDATA)	32	W (always reads zero)	0000_0000h	19.6.2/ 945
63FC_0008	Control Register (CSPI_CONREG)	32	R/W	0000_0000h	19.6.3/ 946
63FC_000C	Interrupt Control Register (CSPI_CSPI_INTREG)	32	R/W	0000_0000h	19.6.4/ 949
63FC_0010	DMA Control Register (CSPI_CSPI_DMAREG)	32	R/W	0000_0000h	19.6.5/ 950
63FC_0014	Status Register (CSPI_CSPI_STATREG)	32	R/W	0000_0003h	19.6.6/ 951
63FC_0018	Sample Period Control Register (CSPI_PERIODREG)	32	R/W	0000_0000h	19.6.7/ 952
63FC_001C	Test Control Register (CSPI_TESTREG)	32	R/W	0000_0000h	19.6.8/ 953

19.6.1 Receive Data Register (CSPI_RXDATA)

The Receive Data register (CSPI_RXDATA) is a read-only register that forms the top word of the 8 x 32 receive FIFO. This register holds the data received from an external SPI device during a data transaction. Only word-sized read operations are allowed.

Address: CSPI_RXDATA is 63FC_0000h base + 0h offset = 63FC_0000h



CSPI_RXDATA field descriptions

Field	Description
31–0 RXDATA	Receive Data. This register holds the top word of the receive data FIFO. The FIFO is advanced for each read of this register. The data read is undefined when the Receive Data Ready (RR) bit in the Interrupt Control/Status register is cleared. Zeros are read when CSPI is disabled.

19.6.2 Transmit Data Register (CSPI_TXDATA)

The Transmit Data (CSPI_TXDATA) register is a write-only data register that forms the bottom word of the 8 x 32 TXFIFO. The TXFIFO can be written to as long as it is not full, even when the SPI Exchange bit (XCH) in CSPI_CONREG is set. This allows software to write to the TXFIFO during a SPI data exchange process. Writes to this register are ignored when the CSPI block is disabled (CSPI_CONREG[EN] bit is cleared).

Address: CSPI_TXDATA is 63FC_0000h base + 4h offset = 63FC_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																															
W	TXDATA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

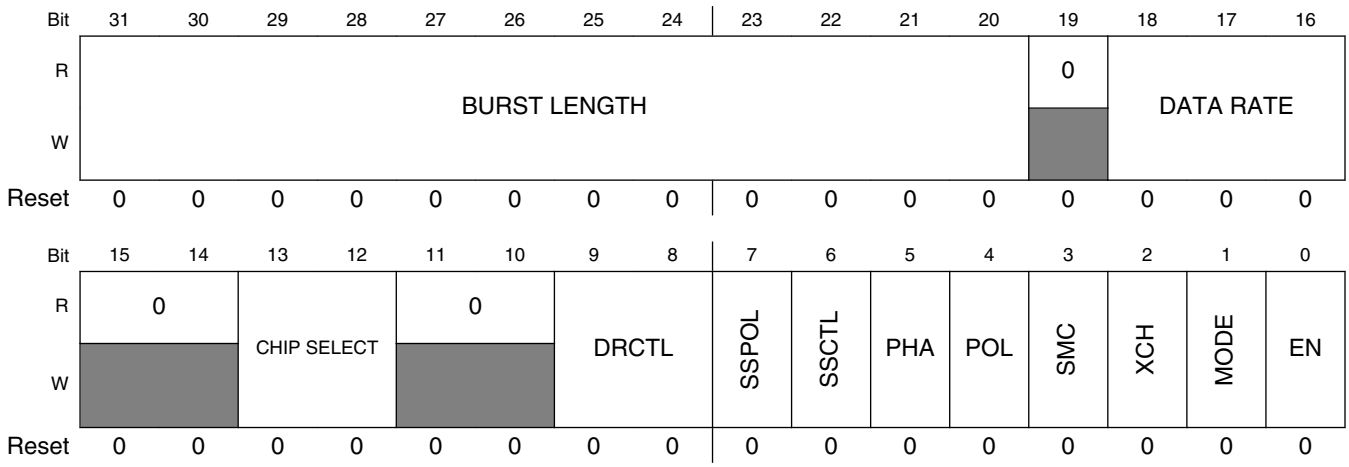
CSPI_TXDATA field descriptions

Field	Description
31–0 TXDATA	Transmit Data. This register holds the top word of data loaded into the FIFO. Data written to this register must be a word operation. The number of bits actually transmitted is determined by the BIT_COUNT field of the corresponding SPI Control register. If this field contains more bits than the number specified by BIT_COUNT, the extra bits are ignored. For example, to transfer 10 bits of data, a 32-bit word must be written to this register. Bits 9-0 are shifted out and bits 31-10 are ignored. When the CSPI is operating in Slave mode, zeros are shifted out when the FIFO is empty. Zeros are read when CSPI is disabled.

19.6.3 Control Register (CSPI_CONREG)

The Control Register (CSPI_CONREG) allows software to enable the CSPI, configure its operating modes, specify the divider value, phase, and polarity of the clock, configure the Chip Select (SS) and SPI_RDY (CSPI_CONREG[DRCTL]) control signal, and define the transfer length.

Address: CSPI_CONREG is 63FC_0000h base + 8h offset = 63FC_0008h



CSPI_CONREG field descriptions

Field	Description
31–20 BURST LENGTH	Burst Length. This field defines the length of a SPI burst to be transferred. The Chip Select (SS) will remain asserted until all bits in a SPI burst are shifted out. A maximum of 2^12 bits can be transferred in a single SPI burst. In master mode, it controls the number of bits per SPI burst. Since the shift register always loads 32-bit data from transmit FIFO, only the n least-significant (n = BURST LENGTH + 1) will be shifted out. The remaining bits will be ignored. In slave mode, only when SSCTL is cleared, this field will take effect in the transfer. Number of Valid Bits in a SPI burst. 0x000 A SPI burst contains the 1 LSB in a word. 0x001 A SPI burst contains the 2 LSB in a word. 0x002 A SPI burst contains the 3 LSB in a word. 0x01F A SPI burst contains all 32 bits in a word. 0x020 A SPI burst contains the 1 LSB in first word and all 32 bits in second word. 0x021 A SPI burst contains the 2 LSB in first word and all 32 bits in second word. 0xFFE A SPI burst contains the 31 LSB in first word and 2^7 -1 words. 0xFFF A SPI burst contains 2^7 words.
19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18–16 DATA RATE	SPI Data Rate Control. This field selects the baud rate of the SCLK based on a division of the reference clock.

Table continues on the next page...

CSPI_CONREG field descriptions (continued)

Field	Description
	These bits allow the CSPI to synchronize with different external SPI devices. The max frequency is one quarter of the reference clock. The divide ratio is determined according to the following table using the equation: $2^{(n+2)}$. SPI Data Rate Control (Master Mode only) 000 Divide by 4. 001 Divide by 8. 010 Divide by 16. 011 Divide by 32. 100 Divide by 64. 101 Divide by 128. 110 Divide by 256. 111 Divide by 512.
15–14 Reserved	This read-only field is reserved and always has the value zero. Reserved
13–12 CHIP SELECT	CHIP SELECT. Select one of four external SPI Master/Slave Devices. In master mode, these two bits select the external slave devices by asserting the Chip Select (SSn) outputs. Only the selected Chip Select (SSn) signal can be active at a given time; the remaining three signals will be negated. Chip Select 00 Chip Select 0 (SS0) will be asserted. 01 Chip Select 1 (SS1) will be asserted. 10 Chip Select 2 (SS2) will be asserted. 11 Chip Select 3 (SS3) will be asserted.
11–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–8 DRCTL	SPI Data Ready Control. This field selects the utilization of the $\overline{\text{SPI\_RDY}}$ signal in master mode. CSPI checks this field before it starts an SPI burst. 00 The $\overline{\text{SPI\_RDY}}$ signal is a don't care. 01 Burst will be triggered by the falling edge of the SPI_RDY signal (edge-triggered). 10 Burst will be triggered by a low level of the SPI_RDY signal (level-triggered). 11 Reserved.
7 SSPOL	SPI SS Polarity Select. In both Master and Slave modes, this bit selects the polarity of the Chip Select (SS) signal. 0 Active low. 1 Active high.
6 SSCTL	SPI SS Wave Form Select. In master mode, this bit controls the output wave form of the Chip Select (SS) signal when SMC is cleared. The SSCTL bit will be ignored if the SMC (Start Mode Control) bit is set. In slave mode, this bit controls when the SPI burst is completed. 0 Only one SPI burst will be transmitted. 1 Negate Chip Select (SS) signal between SPI bursts. Multiple SPI bursts will be transmitted. The SPI transfer will automatically stop when the TXFIFO is empty.

Table continues on the next page...

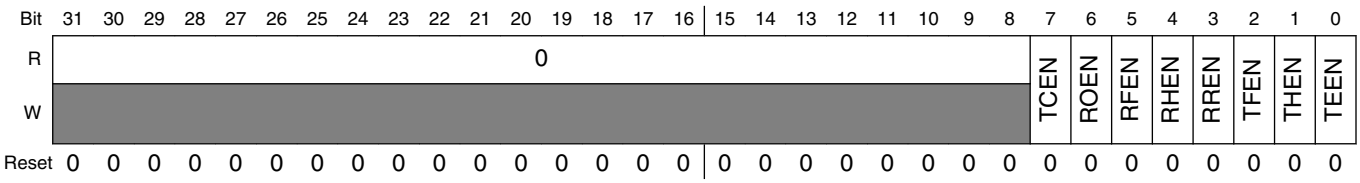
CSPI_CONREG field descriptions (continued)

Field	Description
	0 (slave mode) A SPI burst is completed when the number of bits received in the shift register is equal to BURST LENGTH + 1. Only n least-significant bits (n = BURST LENGTH[4:0] + 1) of the first received word are valid. All bits subsequent to the first received word in RXFIFO are valid. 1 (slave mode) A SPI burst is completed by the Chip Select (SS) signal edges. (SSPOL = 0: rising edge; SSPOL = 1: falling edge) The RXFIFO is advanced whenever a Chip Select (SS) signal edge is detected or the shift register contains 32-bits of valid data.
5 PHA	SPI Clock/Data Phase Control. This bit controls the clock/data phase relationship. See Typical Slave Mode for more information. 0 Phase 0 operation. 1 Phase 1 operation.
4 POL	SPI Clock Polarity Control. This bit controls the polarity of the SCLK signal. See Typical Slave Mode for more information. 0 Active high polarity (0 = Idle). 1 Active low polarity (1 = Idle).
3 SMC	Start Mode Control. This bit applies only when the block is configured in Master mode (MODE = 1). It controls how the CSPI starts a SPI burst, either through the SPI exchange bit, or immediately when the TXFIFO is written to. 0 SPI Exchange Bit (XCH) controls when a SPI burst can start. Setting the XCH bit will start a SPI burst or multiple bursts. This is controlled by the SPI SS Wave Form Select (SSCTL) bit. Refer to XCH and SSCTL bit descriptions. 1 Immediately starts a SPI burst when data is written in TXFIFO.
2 XCH	SPI Exchange Bit. This bit applies only when the block is configured in Master mode (MODE = 1). If the Start Mode Control (SMC) bit is cleared, writing a 1 to this bit starts one SPI burst or multiple SPI bursts according to the SPI SS Wave Form Select (SSCTL bit). The XCH bit remains set while either the data exchange is in progress, or when the CSPI is waiting for an active input if SPIRDY is enabled through DRCTL. This bit is cleared automatically when all data in the TXFIFO and the shift register has been shifted out. 0 Idle. 1 Initiates exchange (write) or busy (read).
1 MODE	SPI Function Mode Select. This bit selects the operating mode of the CSPI. 0 Slave mode. 1 Master mode.
0 EN	SPI Module Enable Control. This bit enables the CSPI. This bit must be set before writing to other registers or initiating an exchange. Writing zero to this bit disables the block and resets the internal logic with the exception of the CONREG. The block's internal clocks are gated off whenever the block is disabled. 0 Disable the block. 1 Enable the block.

19.6.4 Interrupt Control Register (CSPI_CSPI_INTREG)

The Interrupt Control Register (CSPI_INTREG) enables the generation of interrupts to the host processor. If the CSPI is disabled, this register reads zero.

Address: CSPI_CSPI_INTREG is 63FC_0000h base + Ch offset = 63FC_000Ch



CSPI_CSPI_INTREG field descriptions

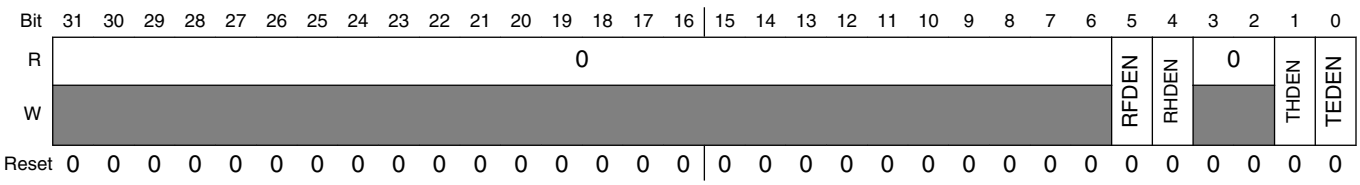
Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 TCEN	Transfer Completed Interrupt enable. This bit enables the Transfer Completed Interrupt. 0 Disable 1 Enable
6 ROEN	RXFIFO Overflow Interrupt enable. This bit enables the RXFIFO Overflow Interrupt. 0 Disable 1 Enable
5 RFEN	RXFIFO Full Interrupt enable. This bit enables the RXFIFO Full Interrupt. 0 Disable 1 Enable
4 RHEN	RXFIFO Half Full Interrupt enable. This bit enables the RXFIFO Half Full Interrupt. 0 Disable 1 Enable
3 RREN	RXFIFO Ready Interrupt enable. This bit enables the RXFIFO Ready Interrupt. 0 Disable 1 Enable
2 TFEN	TXFIFO Full Interrupt enable. This bit enables the TXFIFO Full Interrupt. 0 Disable 1 Enable
1 THEN	TXFIFO Half Empty Interrupt enable. This bit enables the TXFIFO Half Empty Interrupt. 0 Disable 1 Enable
0 TEEN	TXFIFO Empty Interrupt enable. This bit enables the TXFIFO Empty Interrupt. 0 Disable 1 Enable

19.6.5 DMA Control Register (CSPI_CSPI_DMAREG)

The Direct Memory Access Control Register (CSPI_DMAREG) provides software a way to use an on-chip DMA controller for CSPI data. Internal DMA request signals enable direct data transfers between the CSPI FIFOs and system memory. The CSPI sends out DMA requests when the appropriate FIFO conditions are matched.

If the CSPI is disabled, this register is read as 0.

Address: CSPI_CSPI_DMAREG is 63FC_0000h base + 10h offset = 63FC_0010h



CSPI_CSPI_DMAREG field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 RFDEN	RXFIFO Full DMA Request Enable. This bit enables/disables the RXFIFO Full DMA Request. 0 Disable 1 Enable
4 RHDEN	RXFIFO Half Full DMA Request Enable. This bit enables/disables the RXFIFO Half Full DMA Request. 0 Disable 1 Enable
3–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 THDEN	TXFIFO Half Empty DMA Request Enable. This bit enables/disables the TXFIFO Half Empty DMA Request. 0 Disable 1 Enable
0 TEDEN	TXFIFO Empty DMA Request Enable. This bit enables/disables the TXFIFO Empty DMA Request. 0 Disable 1 Enable

19.6.6 Status Register (CSPI_CSPI_STATREG)

The CSPI Status Register (CSPI_STATREG) reflects the status of the CSPI block's operating condition. If the CSPI is disabled, this register reads 0x0000_0003.

Address: CSPI_CSPI_STATREG is 63FC_0000h base + 14h offset = 63FC_0014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CSPI_CSPI_STATREG field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 TC	Transfer Completed Status bit. Writing 1 to this bit clears it. 0 Transfer in progress. 1 Transfer completed.
6 RO	RXFIFO Overflow. When set, this bit indicates that RXFIFO has overflowed. 0 RXFIFO has no overflow. 1 RXFIFO has overflowed.
5 RF	RXFIFO Full. This bit is set when the RXFIFO is full. 0 Not Full. 1 Full.
4 RH	RXFIFO Half Full. This bit is set when the RXFIFO reaches half full. 0 Less than 4 words are stored in RXFIFO. 1 Four or more words are available in RXFIFO.
3 RR	RXFIFO Ready. This bit is set when one or more words are stored in the RXFIFO. 0 No valid data in RXFIFO. 1 More than 1 word in RXFIFO.
2 TF	TXFIFO Full. This bit is set when if the TXFIFO is full. 0 TXFIFO is not Full. 1 TXFIFO is Full.
1 TH	TXFIFO Half empty. This bit is set when the TXFIFO reaches half empty.

Table continues on the next page...

CSPI_CSPI_STATREG field descriptions (continued)

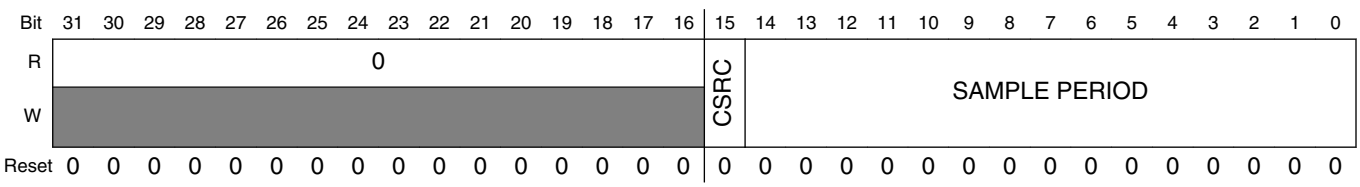
Field	Description
	0 TXFIFO holds more than 4 words. 1 TXFIFO holds 4 or fewer words.
0 TE	TXFIFO Empty. This bit is set if the TXFIFO is empty. 0 TXFIFO contains one or more words. 1 TXFIFO is empty.

19.6.7 Sample Period Control Register (CSPI_PERIODREG)

The Sample Period Control Register (CSPI_PERIODREG) provides software a way to insert delays (wait states) between consecutive SPI transfers. Control bits in this register select the clock source for the sample period counter and the delay count indicating the number of wait states to be inserted between data transfers.

The delay counts apply only when the block is configured in Master mode (CONREG[MODE] = 1).

Address: CSPI_PERIODREG is 63FC_0000h base + 18h offset = 63FC_0018h



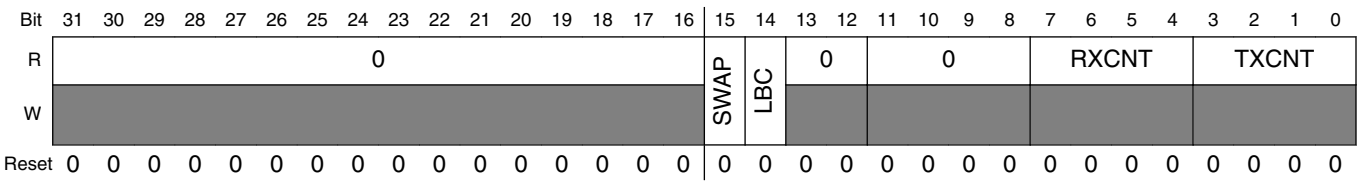
CSPI_PERIODREG field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15 CSRC	Clock Source Control. This bit selects the clock source for the sample period counter. 0 SPI Clock (SCLK) 1 Low-Frequency Reference Clock (32.768 KHz)
14–0 SAMPLE PERIOD	Sample Period Control. These bits control the number of wait states to be inserted in data transfers. During the idle clocks, the state of the SS output will operate according to the SSCTL control field in the CSPI_CONREG register. 0x00000 wait states inserted 0x00011 wait state inserted 0x7FFE32766 wait states inserted 0x7FFF32767 wait states inserted

19.6.8 Test Control Register (CSPI_TESTREG)

The Test Control Register (CSPI_TESTREG) provides software a mechanism to internally connect the receive and transmit devices of the CSPI, swap the byte order for receive data, and monitor the contents of the receive and transmit FIFO.

Address: CSPI_TESTREG is 63FC_0000h base + 1Ch offset = 63FC_001Ch



CSPI_TESTREG field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15 SWAP	Data Swap. This bit is used to swap data as it is read from the RXFIFO. When this bit is set, data read from RXFIFO is swapped. RXDATA[31:0] is swapped as follows: {RXDATA[7:0],RXDATA[15:8], RXDATA[23:16],RXDATA[31:24]} 0 Data read from RXFIFO is unchanged. 1 Data read from RXFIFO is swapped.
14 LBC	Loop Back Control. This bit is used in Master mode only. When this bit is set, the CSPI connects the transmitter and receiver sections internally, and the data shifted out from the most-significant bit of the shift register is looped back into the least-significant bit of the Shift register. In this way, a self-test of the complete transmit/receive path can be made. The output pins are not affected, and the input pins are ignored. 0 Not connected. 1 Transmitter and receiver sections internally connected for Loopback.
13–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11–8 Reserved	This read-only field is reserved and always has the value zero. Reserved, all bits should be ignored.
7–4 RXCNT	RXFIFO Counter. These bits indicate the number of words in RXFIFO. RXFIFO Counter 0000 0 word in RXFIFO 0001 1 word in RXFIFO 0111 7 words in RXFIFO 1000 8 words in RXFIFO
3–0 TXCNT	TXFIFO Counter. These bits indicate the number of words in TXFIFO. TXFIFO Counter

Chapter 20
Central Security Unit (CSU)

20.1 Overview

The CSU enables software for setting comprehensive security policy within the platform and sharing secure information between various secure blocks.

20.2 Features

The Central Security Unit (CSU) sets access control policies between bus masters and bus slaves, allowing peripherals to be separated into distinct security domains. This protects against indirect unauthorized access to data, such as occurs when software programs a DMA bus master to access addresses that the software itself is prohibited from accessing directly. Configuring DMA bus master privileges in the CSU consistently with software privileges defends against such indirect unauthorized access. Additionally, the CSU manges system sucurity alarms.

CSU has the following security related features:

- System alarm routing policy:
  - Type of alarm triggered by the different system security violation indications
  - Type of system event generated by each of the system alarms
  - Security violation indication (Secure Real Time Clock (SRTC)) clearance (fuse driven)
- Setting emergency reset policy
- Peripheral access policy - Master privileges are required to access each peripheral.
- Masters privilege policy - CSU helps those Masters to assert user/supervisor secure/ non-secure signals which can not generate these signals on their own.

20.3 Functional Description

The CSU enables secure software for setting comprehensive security policy within the platform and for sharing secure information between the various secure modules.

Security policies may be set, and optionally locked, in the CSU registers by secure software, including the command sequence file (CSF) processed by the High Assurance Boot (HAB) or a HAB-authenticated image which executes after the boot ROM.

20.3.1 Peripheral Access Policy

The CSU helps secure software in setting the Peripheral Access Policy.

It determines which peripheral can be accessed by what master privileges.

There are four security modes of operation in the system. These security modes are distinguished by security (TrustZone/non-TrustZone) and privilege (Supervisor/User) setting of the module. Below is the list of these security modes from the highest security level to the lowest:

- TrustZone (Secure) Privilege (Supervisor) Mode - Highest Security Level
- TrustZone (Secure) non-Privilege (User) Mode - Medium Security Level
- non-TrustZone (Regular) Privilege (Supervisor) Mode - Medium Security Level
- non-TrustZone (Regular) non-Privilege (User) Mode - Lowest Security Level

This functionality is implemented as follows:

The Configure Slave Level (CSL) Register value for a specified peripheral resource defines the output signal -- csu_sec_level for that peripheral. The value of this signal determines by what master privileges the peripheral can be accessed. The relation between the value of the csu_sec_level signal and execution mode has been shown below in the table.

Table 20-1. Permission Access Table

CSU_SEC_LEVEL[2:0]	Non-Secure User Mode	Non-Secure Spvr Mode	Secure (TZ) User Mode	Secure (TZ) Spvr Mode	CSL register value
(0) 000	RD+WR	RD+WR	RD+WR	RD+WR	8'b1111_1111

Chapter 21
DPLL Controller (DPLLC)

21.1 Overview

The Digital Phase-Locked Loop Control (DPLLC) is the control interface to a DPLL. It generates the control signals required for the DPLL operations.

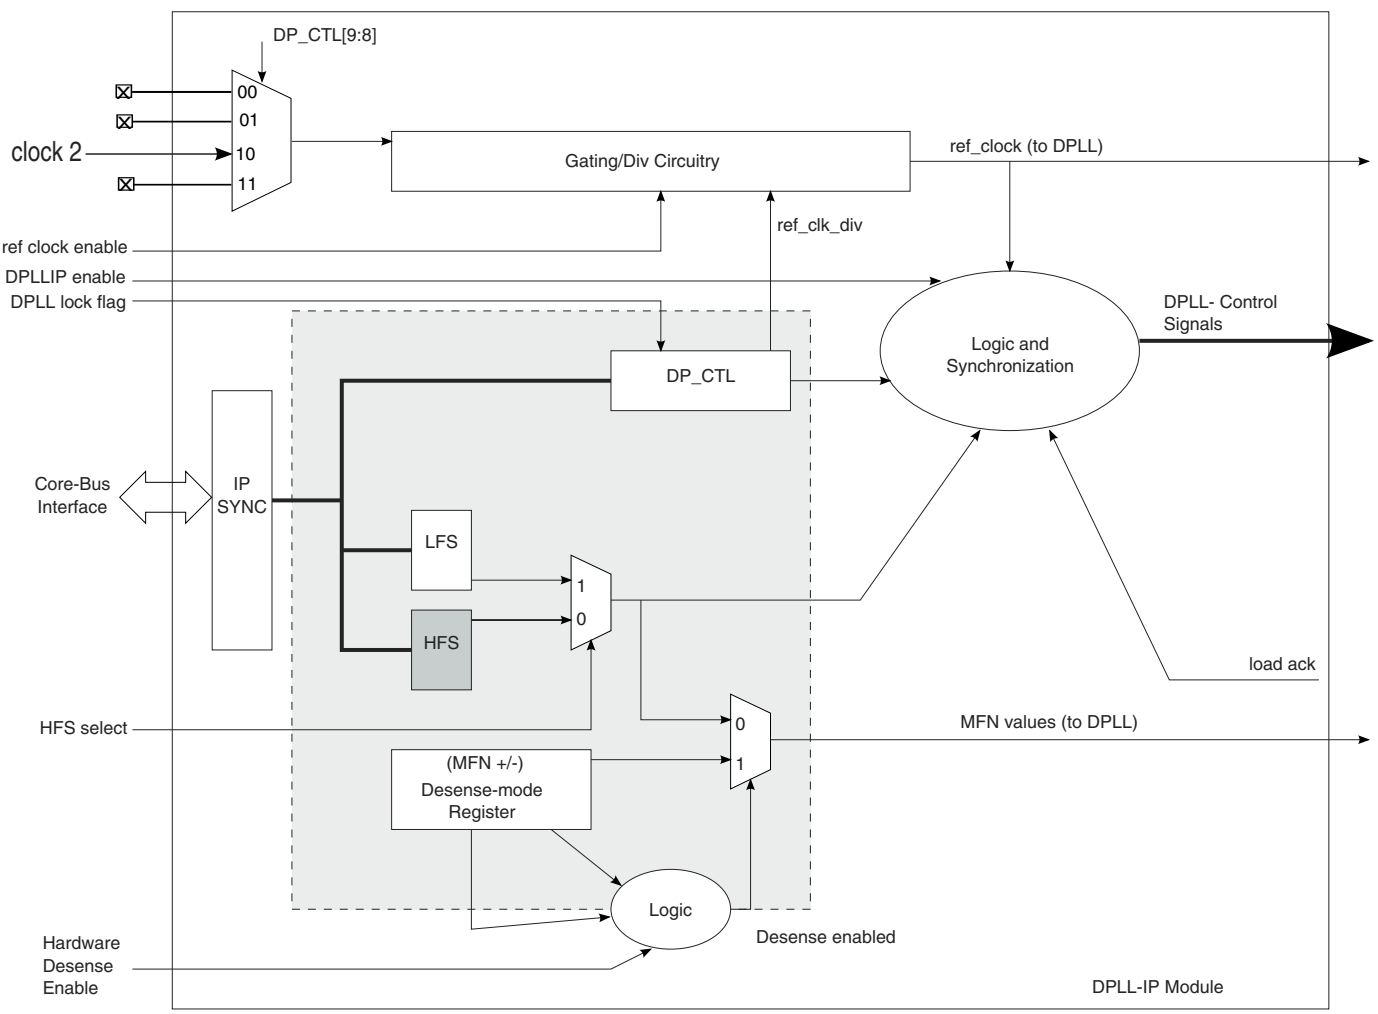

Figure 21-1. Block Diagram of the DPLLC

21.1.1 Feature Description

Key features of this module include:

- Controls the operation of DPLLs.
- Provides controlled phase modulation of clocks to reduce receiver desensitization using desense circuit for DPLLs.
- Selects clock2 input reference clock for DPLL from DPLLC_DP_CTL[ref_clk_sel]. All other setups are Reserved and shall not be changed. See DPLLC Control Register (DPLLC_CTL).
- If auto restart is enabled (AREN bit of the DPLL Config Register is '1'), a restart sequence is issued automatically whenever one of the DPLL registers (DPLLC_DP_CTL, DP_OP, DPLLC_DP_MFD or DPLLC_DP_HFS_OP, DP_HFS_MFD) is written. Otherwise, software needs to set the restart bit of DPLL Control Register manually.

21.1.2 Modes and Operation

The DPLLC supports the following modes of operation:

- Normal Mode
- DPLL Desense Mode
- DVFS Support: HFS Mode

Refer to Operations for DPLLC operations.

21.2 Functional Description

The DPLLC module is mainly divided in the following blocks as shown in Figure 21-1.

- Register read/write: Core bus reads and writes the registers of the module.
- Reference clock selection circuitry: This circuitry comprises of clock selection mux, gating circuit and divide by 2 logic. The reference clock is selected from one of the four external input clocks based on register configuration. This reference clock goes to DPLL. See Figure 21-2 for more details.
- DPLL restart logic and synchronization of data: Based on input signal, registers corresponding to low frequency or high frequency modes are selected. Data goes to the DPLL port, is synchronized on the reference clock.
- Desense mode logic: Desense mode is enabled based on DPLLC configuration. The output to DPLL toggles between predefined values (configured in

which determines the DPLL reference clock frequency. See DPLL Desense Mode for mode details.

- Desense mode logic: Desense mode is enabled based on DPLLC configuration. The output to DPLL toggles between predefined values (configured in DPLLC registers) which determines the DPLL reference clock frequency. See DPLL Desense Mode for mode details.

21.2.1 Operating Modes

21.2.1.1 Normal Mode

In DPLLC normal mode out of the four external input clocks, one is selected depending upon DPLLC register configuration. This is followed by a divider circuitry and then by a gating circuitry as shown below. If reference clock enable signal is HIGH, the clock is passed, else it is gated to a value'1'. Refer to Figure 21-2 for details.

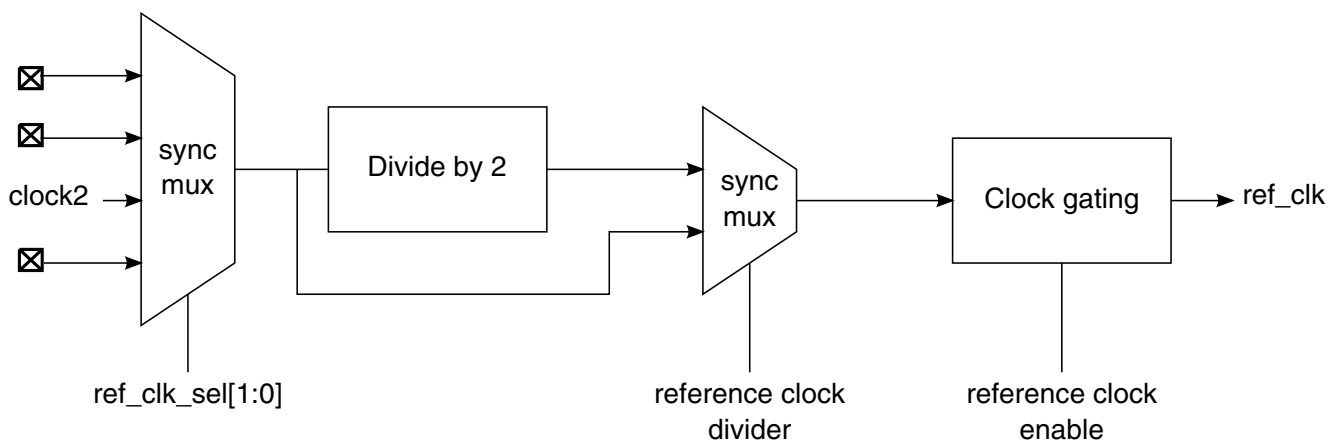

Figure 21-2. Clock MUXing and Gating/Divider Circuitry

21.2.1.2 DPLL Desense Mode

Radiation of clock harmonics causes receiver desensitization. Controlled phase modulation of the clocks coming out of the DPLL will reduce this desensitization. The desense circuit when enabled provides a MFN value that toggles between two programmed MFN_PLUS and MFN_MINUS values for a programmed toggle frequency. This will help achieve the phase modulation of the DPLL clocks.

The disable bit in the DPLLC_DP_MFN_TOGC register should be clear in order to enable the desense logic. Once the disable bit is cleared, desense can be enabled by programming the TOG_EN bit of the DPLLC_DP_MFN_TOGC register for the corresponding PLL. (The desense logic can be activated either by writing to TOG_EN, or by asserting hardware desense enable signal).

Once desense is enabled, the DPLLC module provides the DPLL with a MFN value that switches between MFN_PLUS and MFN_MINUS for n number of correct reference clock cycles. MFN_PLUS and MFN_MINUS are programmed by writing to DPLLC_DP_MFNPLUS and DPLLC_DP_MFNMINUS registers. TOG_CNT (Bits [15:0] of the DPLLC_DP_MFN_TOGC register) determines the toggle rate n. The ref_pll receives a MFN value equal to MFN_PLUS for the first n/2 cycles and MFN_MINUS value for the remaining n/2 cycles.

In the middle of the dither sequence, if the desense mode is disabled through toggle enable (disable) bit or desense hardware request, the circuit completes the ongoing MFN_PLUS, MFN_MINUS cycle before exiting the desense mode. PLL runs on normal MFN after the completion of desense mode. If desense disables and enables again in the middle of the sequence, toggle counter will not stop the current cycle. Only even values for the counter are allowed. If the counter is programmed to an odd value, the counter value will default to a value one less from the odd value.

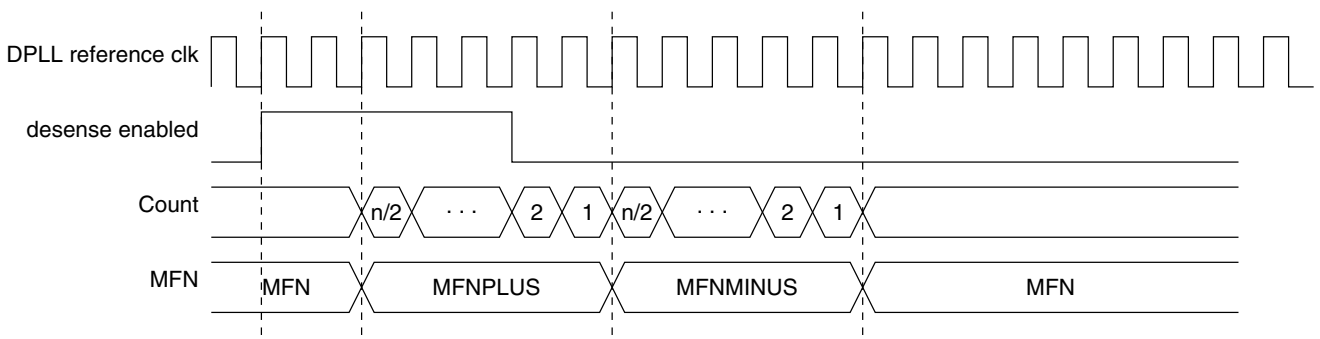

Figure 21-3. Desense Mode MFN Timing

When in desense mode, the DPLLC generates an automatic load request to the PLL whenever the MFN value changes. This signal stays asserted till the load acknowledge signal from the PLL is received. The load request asserts for a minimum of 3 reference clock cycles. Hence for a counter value of 6, where the MFN value toggles between MFN_PLUS and MFN_MINUS every 3 reference clock cycles, the load request may not reflect the updated MFN value and therefore, there is a possibility that the new MFN values are not loaded. Hence it is recommended that the counter be programmed for value greater than 8.

It is required that the toggle counter values not change after the toggle enable is asserted. If toggle counter value changes, the functioning of the desense circuit may be unpredictable.

When any of the 3 MFN values, that is, MFN_PLUS, MFN_MINUS, or MFN values change after the desense mode is enabled, they are buffered till the desense mode is disabled. Therefore to update the MFN_PLUS and MFN_MINUS from the next sequence, desense must be disabled and enabled again.

The desense status register DPLLC Desense Status Register (DPLLC_DESTAT) shows the status of the toggle_enable and the MFN value sent to the DPLL.

21.2.1.3 DVFS Support: HFS Mode

DPLL supports DVFS settings through an alternate set of registers which can be used to store high frequency settings corresponding to high voltage. This alternate set of HFS registers is used to restart the PLL with high frequency settings stored in HFS registers whenever system detects a voltage change from low to high level. Following diagram describes this configuration.

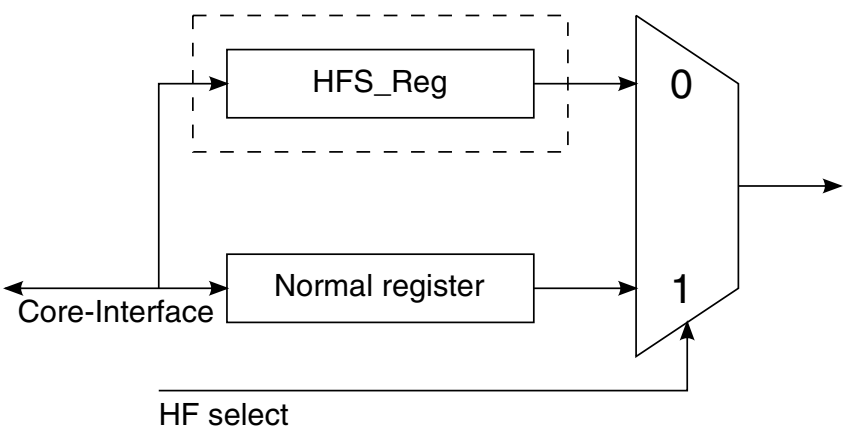

Figure 21-4. DVFS Support for High Frequency Settings

21.2.2 Operations

21.2.2.1 DPLLC_DP_CTL, DPLLC_DP_OP, DPLLC_DP_MFD Register Update

The DPLLs require special timing considerations when updating their ports. Whenever one of the DPLL control register DPLLC_DP_CTL, DPLLC_DP_OP, or DPLLC_DP_MFD, or the shadow registers DPLLC_DP_HFS_OP or DPLLC_DP_HFS_MFD is written (even if the bits don't change), a restart is issued to the DPLL before the actual control bits are sent to the DPLL. The restart assertion and port update will be synchronous to the reference input clock of the DPLL. Writing to any of these registers will cause following procedure to come into effect.

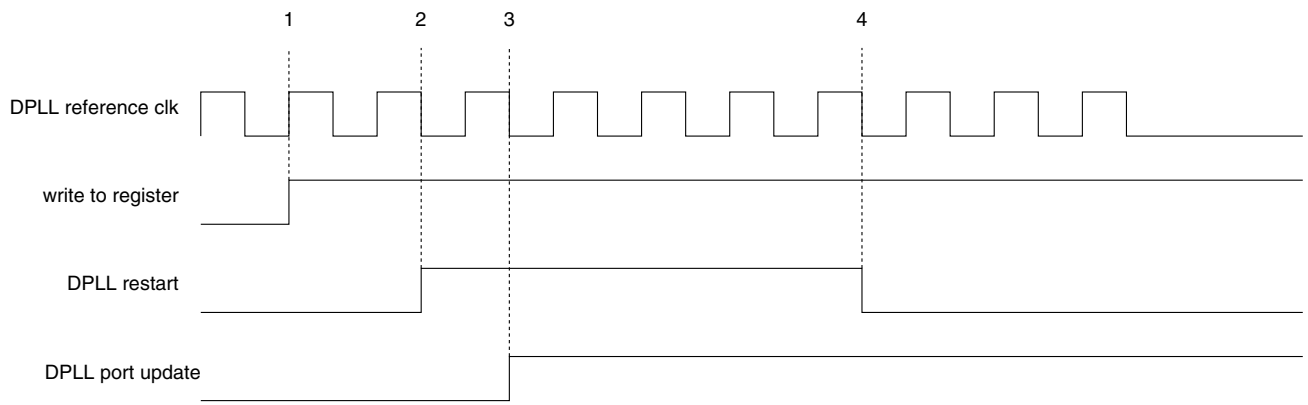

Figure 21-5. DPLL Port Timings

1. Register is written.
2. One clock cycle later restart is asserted.
3. One clock cycle later the appropriate port is updated.
4. Four clock cycles later restart is released.

NOTE

Setting the RST bit of DPLL Control Register will cause the restart (crstrt) signal to assert immediately. In case AREN bit of DPLL Config Register is LOW, the programmer will have to take care of restart of DPLL by setting the RST bit of DPLL Control Register appropriately.

21.2.2.2 DP_MFN Register Update

The MFN bits of DP_MFN register are the only bits in the DPLL that can be changed after the DPLL has been locked without a restart. As shown in diagram below, after writing a new value to MFN, the procedure to update the DPLL is as follows:

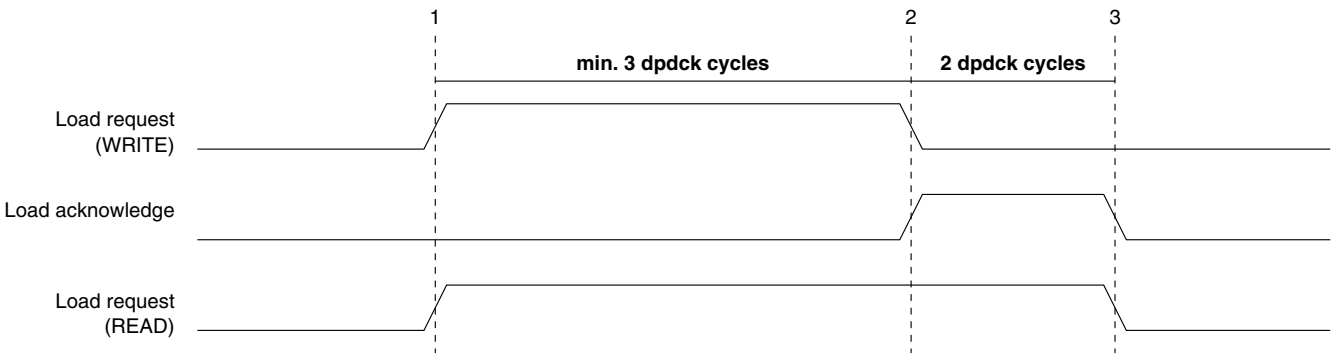

Figure 21-6. MFN Load Request Timings

1. The control bit LDREQ in DP_CONFIG is set. This sends a load request signal to the DPLL.
2. When the DPLL loads the new MFN, it sends a load acknowledge signal back to the DPLL-IP module and clears the write value of load request. At this point load request becomes a status bit, reflecting the state of the acknowledge signal.

NOTE

This write value of load request is a "sticky" bit. When set, it will remain at '1' until a load acknowledgement pulse is received.

3. The read value of load request is automatically cleared when the DPLL has completed updating MFN and has removed the load acknowledge signal, allowing the next load request to take place.

21.2.2.3 Multiple Options for DPLL Control

The DPLLC module provides multiple options for controlling the ON/OFF logic of the DPLLs from the Core and the DSM, making it possible to switch off the PLL by software and still be able to switch it on by DSM. Mul_ctrl (Bit [13]) of DPLLC_DP_CTL register provides this flexibility as shown in the following table.

Table 21-1. Options for DPLL Control

DPLLC Enable	UPEN Bit	mul_ctrl bit (Self Clearing)	DPLL Enable
X	X	1	0
X	0	X	0
posedge	1	0	1
0	X	X	0

As shown in the table above, once the DPLL is switched off by Software using the Mul_ctrl bit, the software cannot turn the PLL on thereafter, unless there is a posedge on the DPLLC enable signal, during DSM entry sequence.

21.2.2.4 Calculating the Output Frequency

The output frequency is given by the formula:

$$f_{dck=2} = 4 \bullet f_{ref} \bullet \left[\frac{\text{MultiplicationFactor}}{\text{PreDividerFactor}} \right]$$

Where:

$$\text{MultiplicationFactor} = MF_I + \frac{MF_N}{MF_D + 1}$$

$$\text{PreDividerFactor} = PDF + 1$$

For normal mode, registers DPLLC_DP_OP, DPLLC_DP_MFN, and DPLLC_DP_MFD are used.

For HFS mode, the shadow registers DPLLC_DP_HFS_OP, DPLLC_DP_HFS_MFN, and DPLLC_DP_HFS_MFD are used.

21.3 Programmable Registers

21.3.1 DPLLC Memory Map/Register Definition

DPLLC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

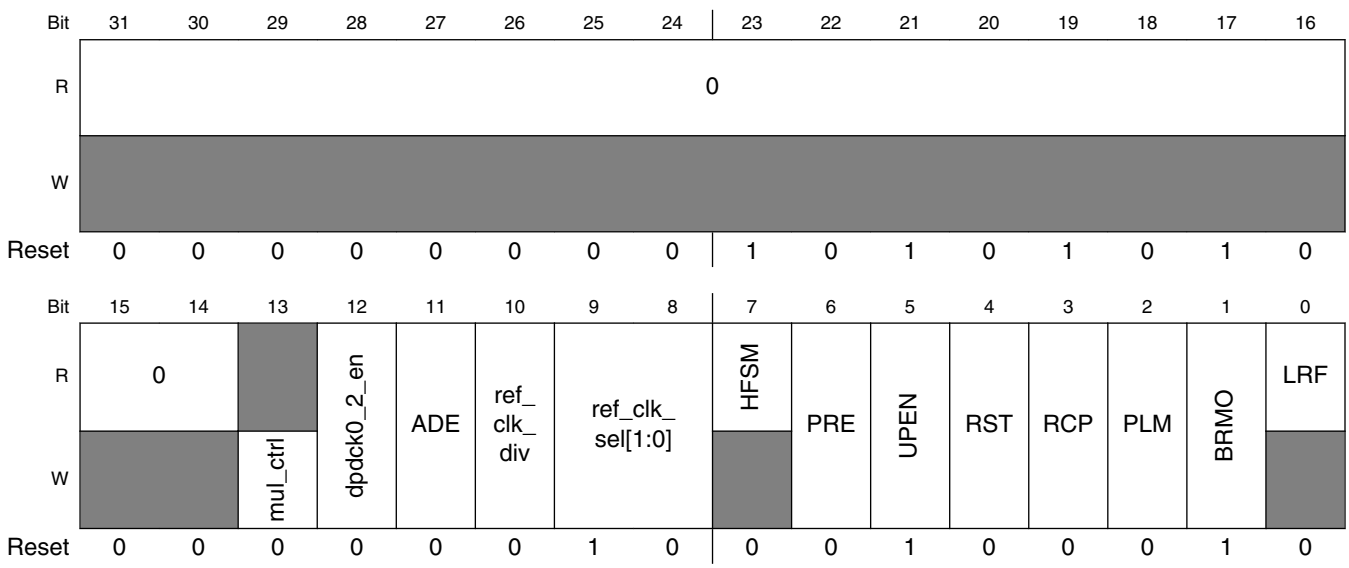
21.31.1 DPLLC Control Register (DPLLCx_CTL)

Addresses: DPLLC-1_CTL is 63F8_0000h base + 0h offset = 63F8_0000h
DPLLC-2_CTL is 63F8_4000h base + 0h offset = 63F8_4000h
DPLLC-3_CTL is 63F8_8000h base + 0h offset = 63F8_8000h
DPLLC-4_CTL is 63F8_C000h base + 0h offset = 63F8_C000h



DPLLCx_CTL field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value zero. Reserved
13 mul_ctrl	Multiple Control. This is a self clearing bit cleared on the next posedge of PLL reference clock. Setting this bit deasserts the enable signal to the DPLL. Using this bit instead of UPEN to disable the DPLL gives DSM the control to independently switch on the DPLL. See Multiple Options for DPLL Control for more details. 0 No Effect 1 DPLL disabled
12 dpdck0_2_en	dpdck0_2 Enable. To enable PLL output before divide by 2 flip-flop. It will enable clock dpdck0_2 which will have double the frequency of dpdck/dpgdck clock. 0 Disable dpdck0_2. 1 Enable dpdck0_2.
11 ADE	The output corresponding to this bit is left unconnected for future use.
10 ref_clk_div	Ref Clk Division factor. Decides whether selected reference clock input needs to be divided by two or one. 0 Divide by 1 1 Divide by 2
9–8 ref_clk_sel[1:0]	ref_clock_select. Used to select the reference clock for DPLL. **NOTE:** Bitfield values 00, 01 and 11 are Reserved and should not be used. 00 Reserved. 01 Reserved. 10 clock2 is selected (24MHz oscillator clock). 11 Reserved.
7 HFSM	HFS-Mode Status bit. Indicates which frequency mode of operation is active. In HFS mode all the shadow registers (DPLLC_DP_HSF_OP, DPLLC_DP_HSF_MFD, DPLLC_DP_HSF_MFN) are used whereas in LFS mode normal registers are used. Reset value of this bit is '0'. 0 LFS mode, normal registers are read. 1 HFS mode is active.
6 PRE	Power Up Reset. Asserts a hard reset to DPLL. 0 Reset cleared. 1 Reset asserted
5 UPEN	PLL Enable. Enables DPLL operation. 0 DPLL disabled. 1 DPLL enabled.
4 RST	Restart. Restarts DPLL. It should not be used as a status bit.

Table continues on the next page...

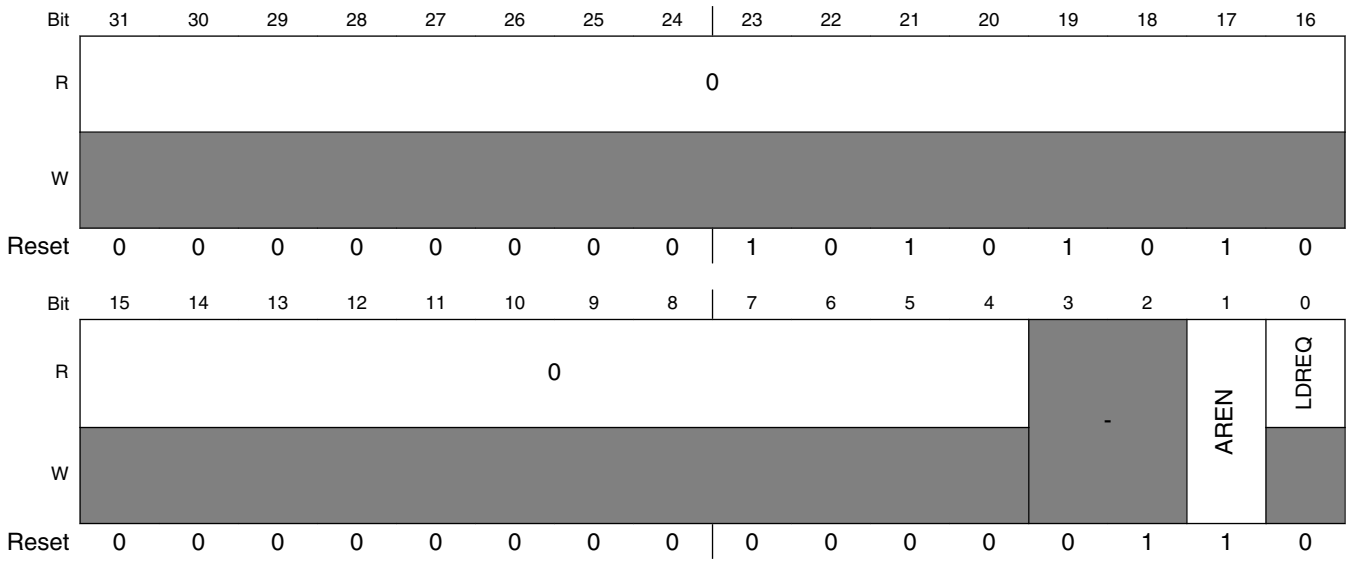
DPLLCx_CTL field descriptions (continued)

Field	Description
	0 DPLL not in restart. 1 DPLL restarted.
3 RCP	Reference Clock Polarity. Selects which edge the chip clock is adjusted to. 0 Positive edge of reference clock. 1 negative edge of reference clock.
2 PLM	Phase Lock Mode. Selects if phase is to be considered (in addition to frequency) during lock-in. 0 DPLL in frequency only lock mode. 1 DPLL in frequency and phase lock mode.
1 BRMO	BRM Order Bit. Binary Rate Modulator order 0 BRM in first order. 1 BRM in second order.
0 LRF	Lock Ready Flag. Shows if the DPLL is in lock. This is a sticky bit. Following events will break the already established lock: (1) DPLLC_DP_CTL, DPLLC_DP_OP, DPLLC_DP_MFD, DPLLC_DP_HSF_OP or DPLLC_DP_HSF_MFD is written (2) Hard reset (3) pll_lvs toggle (4) DPLL enable Reset value of this bit is '0' 0 DPLL not locked. 1 DPLL locked.

21.31.2 DPLLC Configuration Register (DPLLCx_CONFIG)

Writing to this register does not generate an automatic 'restart.'

Addresses: DPLLC-1_CONFIG is 63F8_0000h base + 4h offset = 63F8_0004h
DPLLC-2_CONFIG is 63F8_4000h base + 4h offset = 63F8_4004h
DPLLC-3_CONFIG is 63F8_8000h base + 4h offset = 63F8_8004h
DPLLC-4_CONFIG is 63F8_C000h base + 4h offset = 63F8_C004h



DPLLCx_CONFIG field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3–2 -	Reserved. **NOTE** For FSL testing purposes only. Bit shouldn't be altered and must remain in its default value.
1 AREN	Auto Restart Enable. If auto restart is enabled, then a restart sequence will be issued automatically whenever a write is performed to one of the DPLL registers (DPLLC_DP_CTL, DPLLC_DP_OP, DPLLC_DP_MFD) in normal mode. In HFS mode, same is true if a write is performed to one of the HFS mode registers (DPLLC_DP_CTL, DPLLC_DP_HFS_OP or DPLLC_DP_HFS_MFD). Otherwise, software will need to set the restart bit manually. Bit 4 of DPLL Control Register. Default Value of this bit is '1'. 0 Auto-restart is disabled 1 Auto-restart is enabled
0 LDREQ	Load Request. Notifies the DPLL that the numerator factor of the fractional part (MFN) has changed. This bit is cleared by an acknowledge from the DPLL. Writing a '0' to it has no effect. Default Value of this bit is '0'

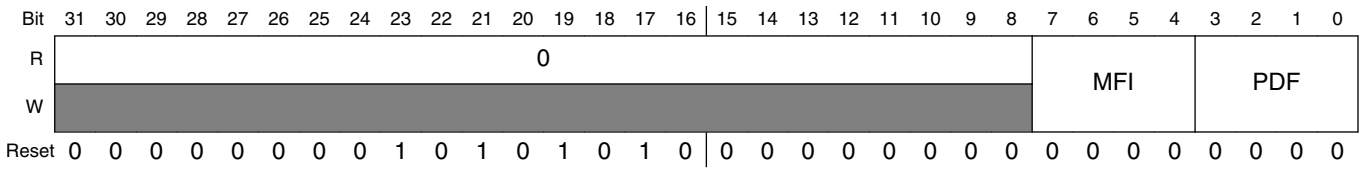
Table continues on the next page...

DPLLCx_CONFIG field descriptions (continued)

Field	Description
	0 DPLL has finished updating MFN. 1 Request that the DPLL updates MFN.

21.31.3 DPLLC Operation Register (DPLLCx_OP)

Addresses: DPLLC-1_OP is 63F8_0000h base + 8h offset = 63F8_0008h
DPLLC-2_OP is 63F8_4000h base + 8h offset = 63F8_4008h
DPLLC-3_OP is 63F8_8000h base + 8h offset = 63F8_8008h
DPLLC-4_OP is 63F8_C000h base + 8h offset = 63F8_C008h

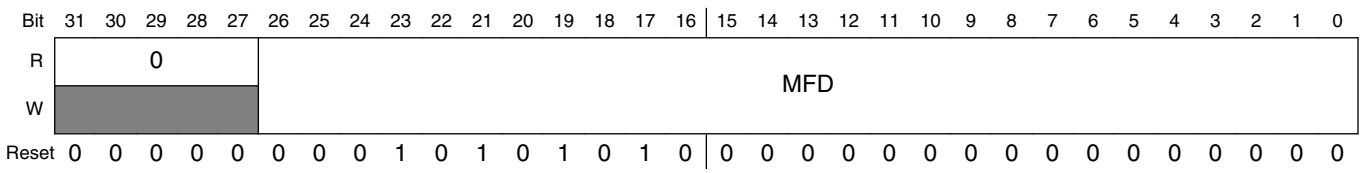


DPLLCx_OP field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–4 MFI	Multiplication Factor, Integer part (MFI). If MFI[3:0] is written with a value of less than 5, MFI will default to 5. See Calculating the Output Frequency Example settings: 0000 Integer part equals 5 0001 Integer part equals 5 0101 Integer part equals 5 0110 Integer part equals 6 1111 Integer part equals 15
3–0 PDF	Pre-division Factor (PDF). PDF determines the value of the PreDividerFactor used in the output frequency formula. See Calculating the Output Frequency Example settings: 0000 PreDividerFactor equals 1 0001 PreDividerFactor equals 2 0010 PreDividerFactor equals 3 1110 PreDividerFactor equals 15 1111 PreDividerFactor equals 16

21.31.4 DPLLC Multiplication Factor Denominator Register (DPLLCx_MFD)

Addresses: DPLLC-1_MFD is 63F8_0000h base + Ch offset = 63F8_000Ch
DPLLC-2_MFD is 63F8_4000h base + Ch offset = 63F8_400Ch
DPLLC-3_MFD is 63F8_8000h base + Ch offset = 63F8_800Ch
DPLLC-4_MFD is 63F8_C000h base + Ch offset = 63F8_C00Ch



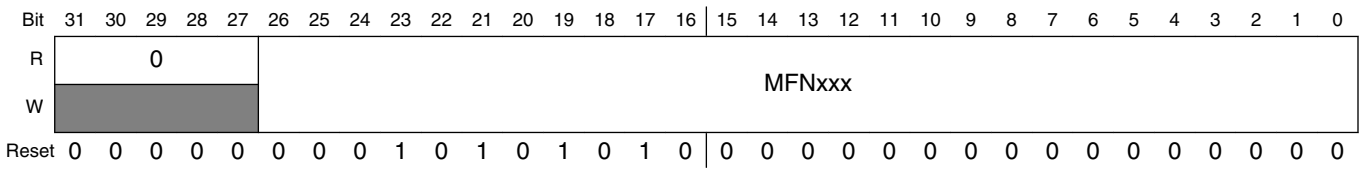
DPLLCx_MFD field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26–0 MFD	Multiplication Factor Denominator Bits. The MFD[26:0] bits, in a 2's complement format, give the denominator of the fractional part. See Calculating the Output Frequency **NOTE:** Bit 26 is always 0. MFD should be in a range from 0 to 67108863; otherwise, the output clock frequency will differ from the desired frequency. Example settings: 0x000000 MFD equals 0 0x000001 MFD equals 1 0x000002 MFD equals 2 0x3FFFFFE MFD equals 67108862 0x3FFFFFF MFD equals 67108863

21.31.5 DPLLC Multiplication Factor Numerator Register (DPLLCx_MFN)

MFNxxx denotes the registers DPLLC_DP_MFN, DPLLC_DP_MFNMINUS and DPLLC_DP_MFNPLUS.

Addresses: DPLLC-1_MFN is 63F8_0000h base + 10h offset = 63F8_0010h
DPLLC-2_MFN is 63F8_4000h base + 10h offset = 63F8_4010h
DPLLC-3_MFN is 63F8_8000h base + 10h offset = 63F8_8010h
DPLLC-4_MFN is 63F8_C000h base + 10h offset = 63F8_C010h



DPLLCx_MFN field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26–0 MFNxxx	Multiplication Factor Numerator Bits (nominal, "MINUS", or "PLUS"). The MFNxxx[26:0] bits, in a 2's complement format, give the numerator of the fractional part. See Calculating the Output Frequency **NOTE:** MFN should be in a range from -67108864 to 67108863. If the absolute value of the MFN is larger than MFD, the output clock frequency will differ from the desired frequency. Example settings: 0x4000000 MFN equals -67108864 0x4000001 MFN equals -67108863 0x4000002 MFN equals -67108862 0xFFFFFFF MFN equals -1 0x0000000 MFN equals 0 (default) 0x0000001 MFN equals 1 0x3FFFFFE MFN equals 67108862 0x3FFFFFF MFN equals 67108863

21.31.6 DPLLC Multiplication Factor Numerator PLUS/MINUS Registers (DPLLC*x*_MFN*n*)

MFNxxx denotes the registers DPLLC_DP_MFN, DPLLC_DP_MFNMINUS and DPLLC_DP_MFNPLUS.

Addresses: DPLLC-1_MFNMINUS is 63F8_0000h base + 14h offset = 63F8_0014h
DPLLC-1_MFNPLUS is 63F8_0000h base + 18h offset = 63F8_0018h
DPLLC-2_MFNMINUS is 63F8_4000h base + 14h offset = 63F8_4014h
DPLLC-2_MFNPLUS is 63F8_4000h base + 18h offset = 63F8_4018h
DPLLC-3_MFNMINUS is 63F8_8000h base + 14h offset = 63F8_8014h
DPLLC-3_MFNPLUS is 63F8_8000h base + 18h offset = 63F8_8018h
DPLLC-4_MFNMINUS is 63F8_C000h base + 14h offset = 63F8_C014h
DPLLC-4_MFNPLUS is 63F8_C000h base + 18h offset = 63F8_C018h

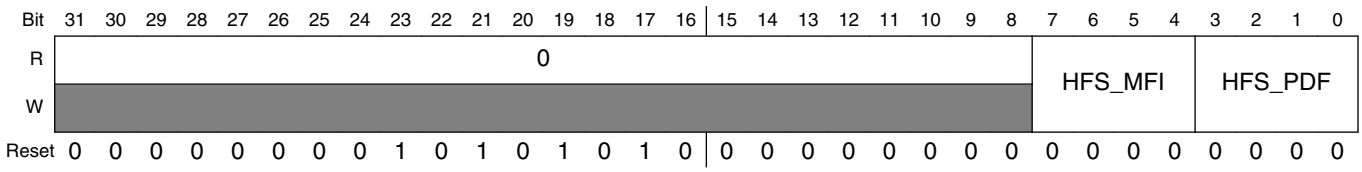
DPLLC*x*_MFN*n* field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26–0 MFNxxx	Multiplication Factor Numerator Bits (nominal, "MINUS", or "PLUS"). The MFNxxx[26:0] bits, in a 2's complement format, give the numerator of the fractional part. See Calculating the Output Frequency **NOTE:** MFN should be in a range from -67108864 to 67108863. If the absolute value of the MFN is larger than MFD, the output clock frequency will differ from the desired frequency. Example settings: 0x4000000 MFN equals -67108864 0x4000001 MFN equals -67108863 0x4000002 MFN equals -67108862 0xFFFFFFF MFN equals -1 0x0000000 MFN equals 0 (default) 0x0000001 MFN equals 1 0x3FFFFFE MFN equals 67108862 0x3FFFFFF MFN equals 67108863

21.31.7 DPLLC High Frequency Support, Operation Register (DPLLCx_HFS_OP)

Addresses: DPLLC-1_HFS_OP is 63F8_0000h base + 1Ch offset = 63F8_001Ch
DPLLC-2_HFS_OP is 63F8_4000h base + 1Ch offset = 63F8_401Ch
DPLLC-3_HFS_OP is 63F8_8000h base + 1Ch offset = 63F8_801Ch
DPLLC-4_HFS_OP is 63F8_C000h base + 1Ch offset = 63F8_C01Ch

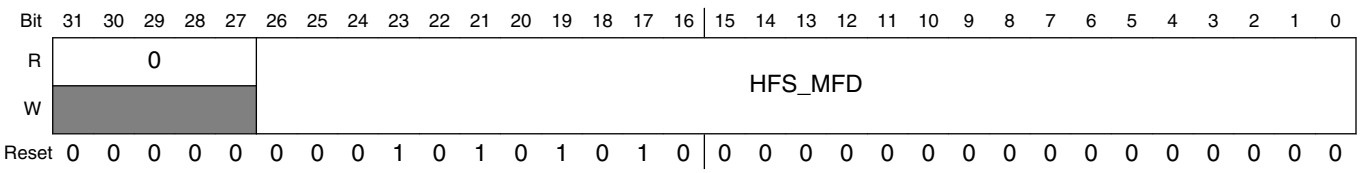


DPLLCx_HFS_OP field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved.
7–4 HFS_MFI	HFS Mode-Multiplication Factor, Integer part (MFI). If HFS_MFI[3:0] is written with a value of less than 5, MFI will default to 5. See Calculating the Output Frequency Example settings: 0000 Integer part equals 5 0101 Integer part equals 5 0110 Integer part equals 6 1111 Integer part equals 15
3–0 HFS_PDF	HFS mode-Pre-division Factor (HFS_PDF). HFS_PDF determines the value of the PreDividerFactor used in the output frequency formula. See Calculating the Output Frequency Example settings: 0000 PreDividerFactor equals 1 0001 PreDividerFactor equals 2 0010 PreDividerFactor equals 3 1110 PreDividerFactor equals 15 1111 PreDividerFactor equals 16

21.31.8 DPLLC High Frequency Support Multiplication Factor Denominator Register (DPLLCx_HFS_MFD)

Addresses: DPLLC-1_HFS_MFD is 63F8_0000h base + 20h offset = 63F8_0020h
DPLLC-2_HFS_MFD is 63F8_4000h base + 20h offset = 63F8_4020h
DPLLC-3_HFS_MFD is 63F8_8000h base + 20h offset = 63F8_8020h
DPLLC-4_HFS_MFD is 63F8_C000h base + 20h offset = 63F8_C020h

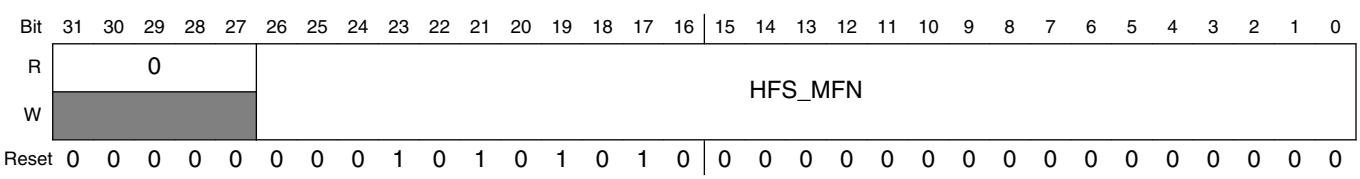


DPLLCx_HFS_MFD field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26–0 HFS_MFD	Multiplication Factor Denominator Bits. The HFS_MFD[26:0] bits, in a 2's complement format, give the denominator of the fractional part. See Calculating the Output Frequency **NOTE:** Bit 26 is always 0. HFS_MFD should be in a range from 0 to 67108863 otherwise the output clock frequency will differ from the desired frequency. Example settings: 0x000000 MFD equals 0 0x000002 MFD equals 1 0x000010 MFD equals 2 0x3FFFFFE MFD equals 67108862 0x3FFFFFF MFD equals 67108863

21.31.9 DPLLC High Frequency Support Multiplication Factor Numerator Register (DPLLCx_HFS_MFN)

Addresses: DPLLC-1_HFS_MFN is 63F8_0000h base + 24h offset = 63F8_0024h
DPLLC-2_HFS_MFN is 63F8_4000h base + 24h offset = 63F8_4024h
DPLLC-3_HFS_MFN is 63F8_8000h base + 24h offset = 63F8_8024h
DPLLC-4_HFS_MFN is 63F8_C000h base + 24h offset = 63F8_C024h

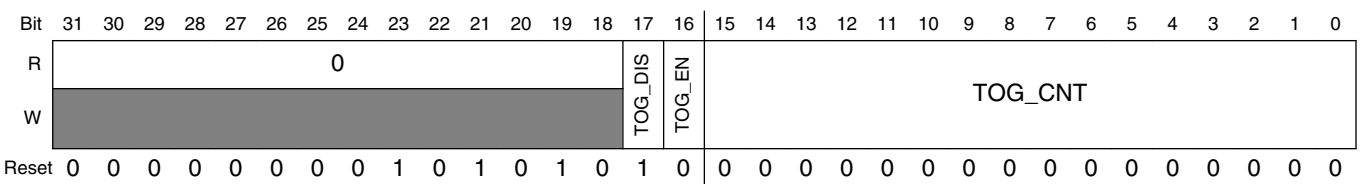


DPLLCx_HFS_MFN field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26–0 HFS_MFN	Multiplication Factor Numerator Bits. The HFS_MFN[26:0] bits, in a 2's complement format, give the numerator of the fractional part. See Calculating the Output Frequency **NOTE:** HFS_MFN should be in a range from -67108864 to 67108863. If the absolute value of the HFS_MFN is larger than HFS_MFD, the output clock frequency will differ from the desired frequency. Example settings: 0x4000000 MFN equals -67108864 0x4000001 MFN equals -67108863 0x4000002 MFN equals -67108862 0xFFFFFFF MFN equals -1 0x0000000 MFN equals 0 (default) 0x0000001 MFN equals 1 0x3FFFFFE MFN equals 67108862 0x3FFFFFF MFN equals 67108863

21.31.10 DPLLC Multiplication Factor Numerator Toggle Control Register (DPLLCx_MFN_TOGC)

Addresses: DPLLC-1_MFN_TOGC is 63F8_0000h base + 28h offset = 63F8_0028h
DPLLC-2_MFN_TOGC is 63F8_4000h base + 28h offset = 63F8_4028h
DPLLC-3_MFN_TOGC is 63F8_8000h base + 28h offset = 63F8_8028h
DPLLC-4_MFN_TOGC is 63F8_C000h base + 28h offset = 63F8_C028h



DPLLCx_MFN_TOGC field descriptions

Field	Description
31–18 Reserved	This read-only field is reserved and always has the value zero. Reserved.
17 TOG_DIS	Desense Global Disable. If TOG_DIS is set, then the desense logic for the DPLL is disabled, and software (TOG_EN) or hardware desense requests to enable the logic will be ignored. (default value of this bit is '1')

Table continues on the next page...

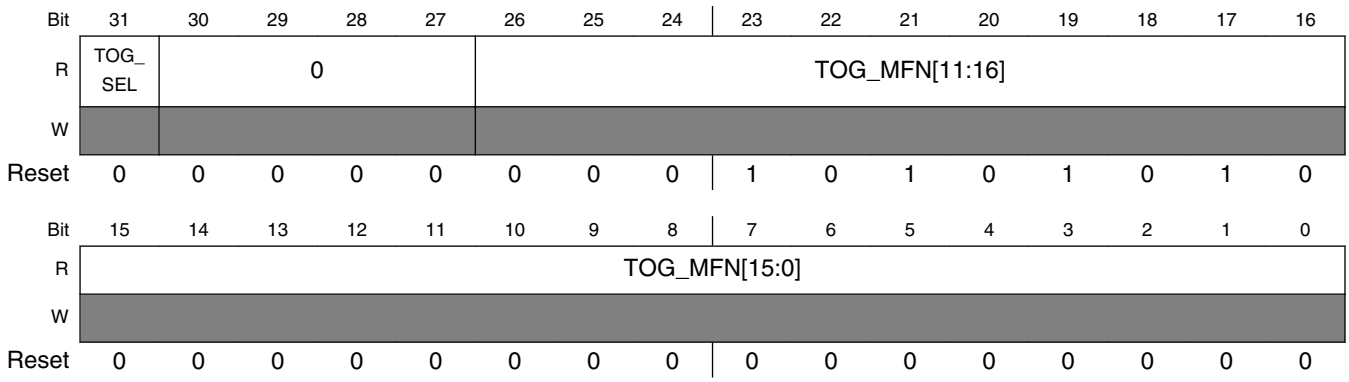
21.31.11 DPLLC Desense Status Register (DPLLCx_DESTAT)

Addresses: DPLLC-1_DESTAT is 63F8_0000h base + 2Ch offset = 63F8_002Ch
DPLLC-2_DESTAT is 63F8_4000h base + 2Ch offset = 63F8_402Ch
DPLLC-3_DESTAT is 63F8_8000h base + 2Ch offset = 63F8_802Ch
DPLLC-4_DESTAT is 63F8_C000h base + 2Ch offset = 63F8_C02Ch



DPLLCx_DESTAT field descriptions

Field	Description
31 TOG_SEL	Toggle set status 0 Desense circuit is inactive. 1 Desense circuit is active.
30–27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26–0 TOG_MFN	Indicates the current MFN value that is sent to the DPLL in desense mode.

Chapter 22
Dynamic Voltage and Frequency Scaling Core (DVFSC)

22.1 Introduction

The DVFSC allows simple dynamic voltage frequency scaling. The frequency of the core clock domain and the voltage of the core power domain can be changed on the fly while all blocks (including the ARM platform) continue their normal operation. The frequency of the core clock domain can be changed by switching temporally to an alternate PLL clock, and then get back to the updated PLL, already locked at a specific frequency, or by merely changing the post dividers division factors.

The DVFSC load tracking block allows hardware tracking on the core load and a generation of an interrupt when a frequency change is requested.

DVFSC is a sub-block of the General Power Controller (GPC). See GPC chapter for more details.

NOTE

DVFSC is a monitor that only provides an interrupt when counting exceeds the predefined value and doesn't actually send request to make a change a change of voltage and frequency. This can be done by the user in the interrupt routine or smart direct memory access (SDMA) code by using GPC or clock control module (CCM) (relocking the PLL or changing the post dividers at the CCM).

22.1.1 Overview

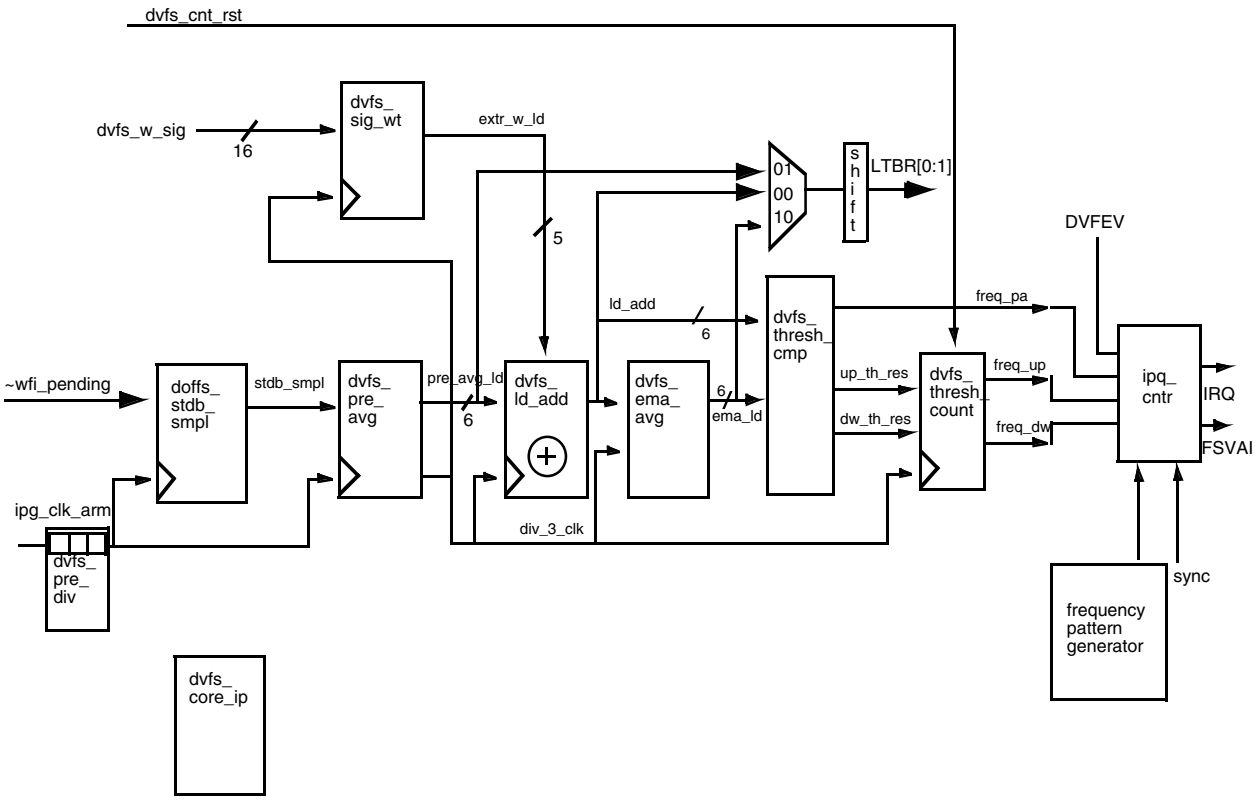


Figure 22-1. Block Diagram

22.1.2 Features

The DVFSC load tracking sub-block includes the following features:

- Configurable include/exclude of input signals:
  - ARM standby signal (idle / non-idle)
  - 16 general purpose bits
    - Configurable weight of each bit.
- Configurable generated clocks and averaging time slicing (respond time).
- Configurable panic mode respond logic (for frequency up).
- Programmable buffer for last 4,8,12, or 16 load tracking samples. Based on value in LBCF in DVFSC_CNTR. There is also a buffer full signal - LBFL.

22.2 Functional Description of DVFS Load Tracking

The DVFS load tracking sub-block includes the following features:

Configurable include/exclude of input signals:

- ARM standby signal (idle / non-idle)
- 16 general purpose load tracking signals
- Configurable weight and (level-sensitive) of GeP signals.
- Configurable generated clocks and averaging time slicing (respond time).
- Configurable panic mode respond logic (for frequency up).
- Programmable buffer for last 4,8,12, or 16 load tracking samples. Two Load Tracking Buffers are working in ping-pong mode with two buffer full signals - LBFL1, LBFL0.

22.3 Component Blocks Description

22.3.1 dvfs_stdb_smpl Block

This block samples the ccm_arm_stdb signal (ARM11 STANDBYWFI signal - idle state indicating) according to the edge of the ipg_clk_arm (ARM11 system clock) signal.

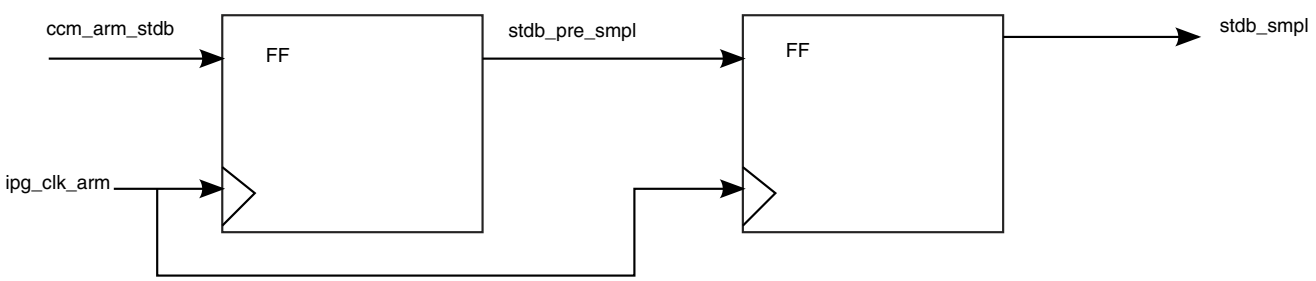

Figure 22-2. dvfs_stdb_smpl block diagram

This block synchronizes the ccm_arm_stdb signal with the ipg_clk_arm clock. The two signals enter the Flip-Flops (twice), and by doing so, are synchronized. The resulting synchronized signal is stdb_smpl.

22.3.2 dvfs_sig_wt Block

The purpose of this block is to sample the 16 GeP (general purpose) load signals, multiply each one of them by appropriate weight and sum products. The sampling is done by the slow clock div_3_clk. These signals have the only options of detection: level sampling.

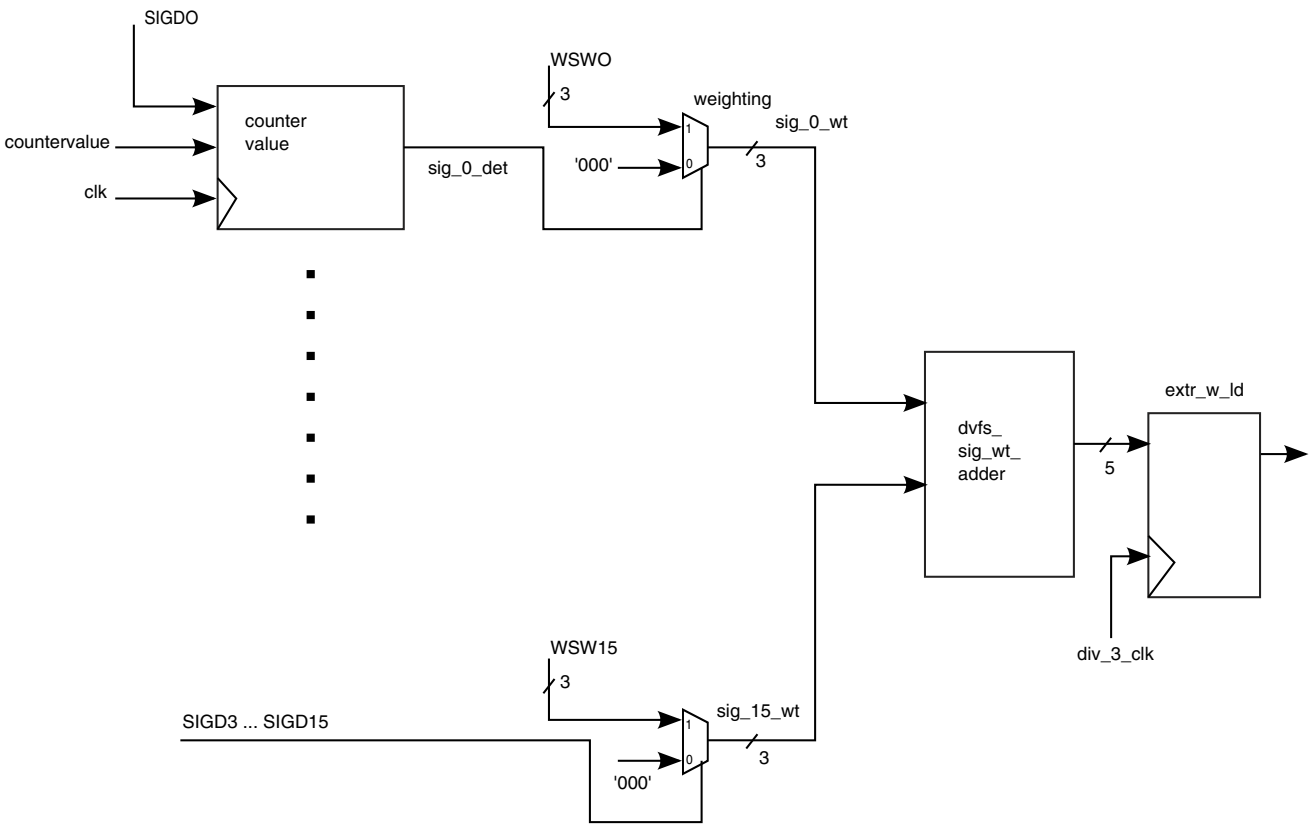

Figure 22-3. dvfs_sig_wt block diagram

There are two paths for weighted general purpose load signals to be calculated.

22.3.3 dvfs_pre_avg Block

The purpose of the dvfs_pre_avg block is to perform simple, non-overlapping averaging, reducing the sampling clock frequency and providing a level-based average index of the tracked ARM Platform load.

External signals:

- stdb_sampl - (input) sampled ARM11 standby signal
- ipg_clk_arm - (input) ARM11 system clk
- pre_avg_ld[4..0] - (output) averaged load

- div_3_clk - (output) clock, generated (reduced) from div_2_clk
- div_2_clk - (output) clock, generated (reduced) from div_1_clk
- div_1_clk - (output) clock, generated (reduced) from ipg_clk_arm

In the current implementation, the averaging is performed in three stages:

1. The first stage IDLE is sampled by divided sys_clock.
2. The second stage (counter2) performs an averaging operation with constant parameters. The counter is an nine (9) bit adder whose output is sampled by the div_2_clk clock. Five (5) highest bits of the sum_2 signal are passed to counter3 (equal to shift right operation).
3. The third (last) stage (counter3) performs an averaging operation with configurable parameters, set by the DIV3CK. The counter3 cell is a fifteen(15) bit adder with output sampled by div_3_clk. The Pre_avg_shifter_5 cell passes configurable bits from the sum_3 signal (see table1_3).

The output 5 bits avg_load signal provides a result with a tolerance of ~3%. (supported values range is 0-0.97)

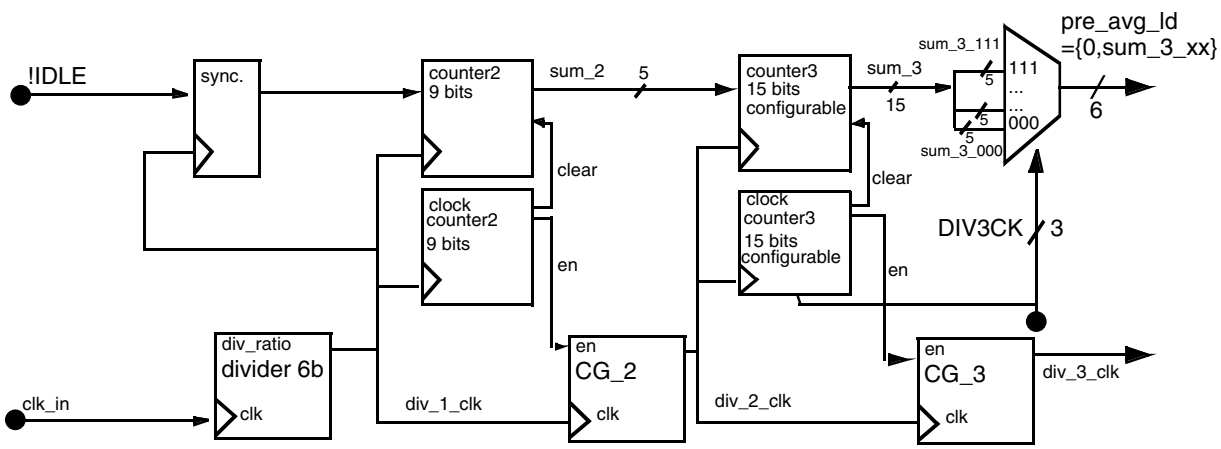

Figure 22-4. dvfs_pre_avg block diagram

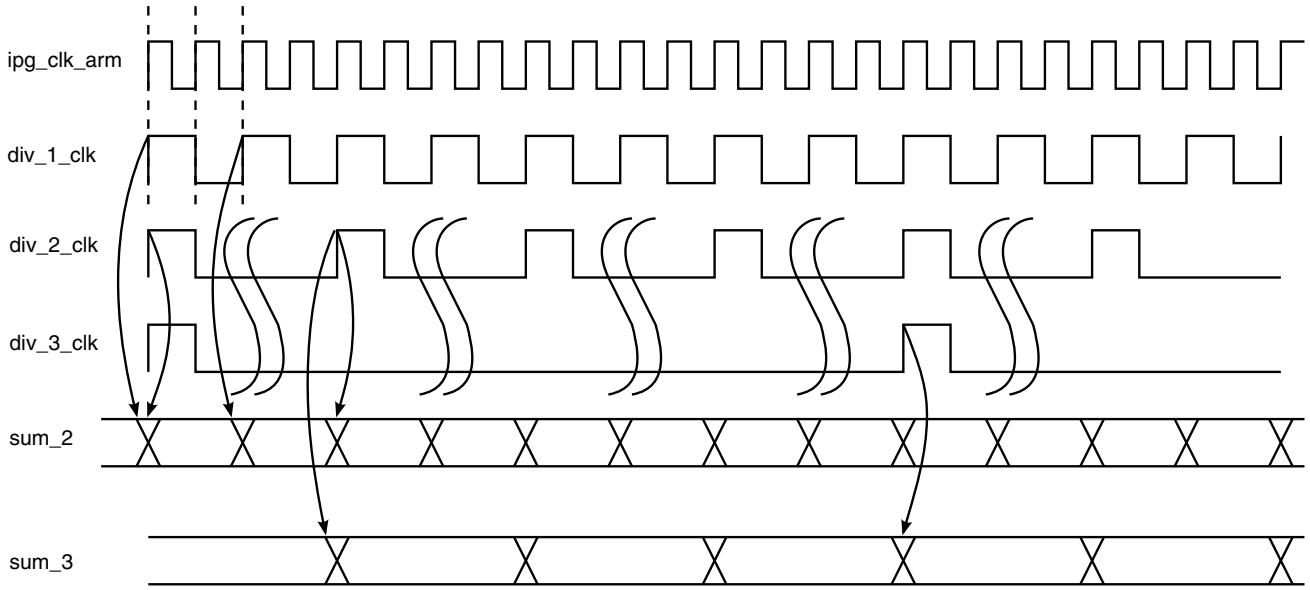

Figure 22-5. dvfs_pre_avg Clocks

The internal clocks in dvfs_avg_pre block are generated from ipg_clk_arm. The details are in the tables below:

Table 22-1. dvfs_pre_avg Signals and its Values

signal	binary max value	binary min value	decimal max value	decimal min value
sum_2	11111	0000	31	0
sum_3	111'1100'0000'0000	000'0000'0000'0000	31744	0
pre_avg_load	11111	0000	31	0

Table 22-2. dvfs_pre_avg generated clocks

clock name	generated from	ratio to source	ratio to ipg_clk_arm	max clk freq.	note
ipg_clk_arm	N/A	N/A	1	66MHz	source clock
div_1_clk	ipg_clk_arm	configurable	configurable	66MHz	configurable
div_2_clk (gated)	div_1_clk	512	configurable	128KHz	none
div_3_clk (gated)	div_2_clk	configurable	configurable	128KHz	configurable

Table 22-3. iv_3_clk Configurable Averaging

DIV3CK setting	dividing ratio	sum_3 passing bits	div_1_clk cumulative divider
00	1	4-0	1*512=512

Table continues on the next page...

Table 22-3. iv_3_clk Configurable Averaging (continued)

DIV3CK setting	dividing ratio	sum_3 passing bits	div_1_clk cumulative divider
001	4	6-2	4*512=2048
010	16	8-4	16*512=8192
011	64	10-6	64*512=32768
100	256	12-8	256*512=131072
101	1024	16-10	1024*512=524288

22.3.4 dvfs_ld_add Block

The dvfs_ld_add block sums the ARM Platform load, tracked by idle/non-idle signal and the load, detected from the additional load signals, weighted by signal_weighting block. The adder should perform the following operation:

extr_w_ld[4..0] + {0,pre_avg_ld[4..0]}

The input signals of five (5) bits produce output signal of six (6) bits, providing 3% resolution in the range of 0-1.97 of load indication. (1 is equal to 100% load tracking with no additional signals include). The output ld_add[5..0] is sampled by div_3_clk signal.

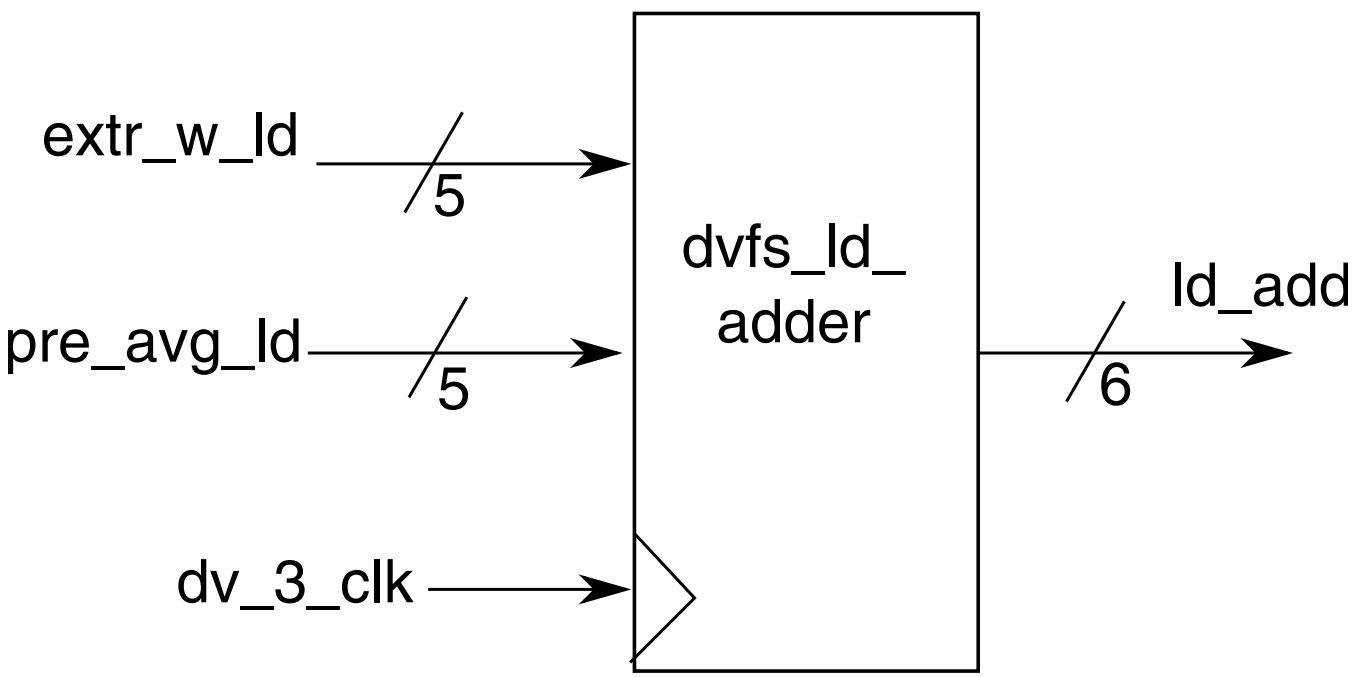

Figure 22-6. dvfs_ld_add block diagram

22.3.5 dvfs_ema_avg Block

The purpose of dvfs_ema_avg (EMA - Exponential Moving Average) block is to calculate an exponential moving average of the tracked ARM Platform load. The parameters of EMA are defined by EMAC field of the DVFSC_EMAC register. These parameters set how many samples of simple average will be taken into account.

The EMA formula is: EMA(i) = a*X(i) + (1-a)*EMA(i-1)

where:

a = 2 / (N+1);

N is the number of samples taken into account.

X(i) = current input sample;

EMA(i-1) = previous value of EMA.

By setting the value of 'a', the behavior of EMA is defined.

In the following table, the parameter 'a' is listed relative to the amount of the X(i) samples taken into account (('N')) in the equation above. (The resolution of the digital multiplier is limited, hence the lowest values of the 'a' can be linked to a range of included samples in EMA instead of single number.)

Also included in the following table is the amount of cycles in which the lower frequency will be masked from the moment the DVFS is enabled (and not between frequency switches), so that enough information about the history can be gained before the frequency is lowered.

EMA settings

samples included in EMA calculation (N)	Number of cycles while lower frequency interrupt is masked	'a' value (decimal)	'a' value, adjusted by binary resolution	'a' value (binary)								
----------		----------	----------	bit 0	bit 1	bit 2	bit 3	bit 4	bit 5	bit 6	bit 7	bit 8

N/A		0.000	0.000	0	0	0	0	0	0	0	0	0

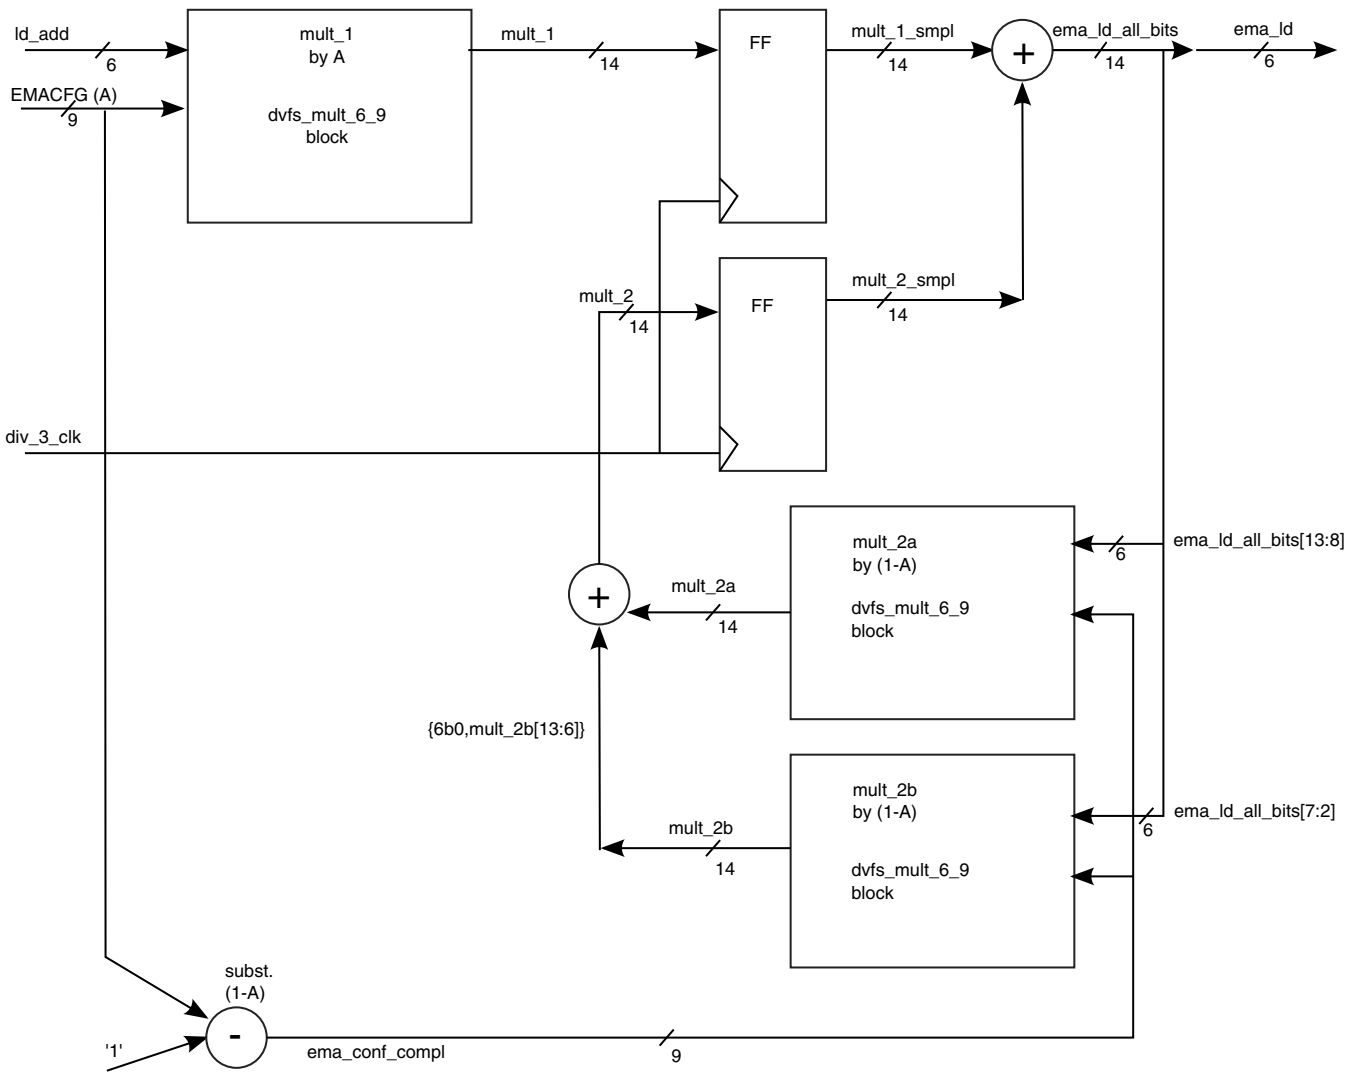

Figure 22-7. dvfs_ema_avg block diagram

The EMA block inputs are as follows:

- ld_add[5..0] - load level
- EMACFG[8..0] - 'a' parameter of EMA algorithm

- div_2_clk - fast clock don't see this in the diagram
- div_3_clk - slow clock

The EMA block outputs the following:

- ema_ld[5..0] - result of EMA algorithm (by div_3_clk)

The mult_a block provides multiplying between comp_load (6 bits) and EMACFG (9 bits). For the multiply operation, a faster clock (for internal sum) is required- this is provided by div_2_clk. Div_2_clk is faster than the div_3_clk by a factor of at least 16, which is enough for 6*9 or 9*6 operations. Only the highest 6 bits are taken from the result of mult_a.

The mult_b block operates in a similar manner.

The adder block's output is sampled with div_3_clk clock.

22.3.6 dvfs_thres_cmp Block

The dvfs_thres_cmp block compares the ARM Platform load value to programmable threshold levels. The comparators as shown in the drawing below are used:

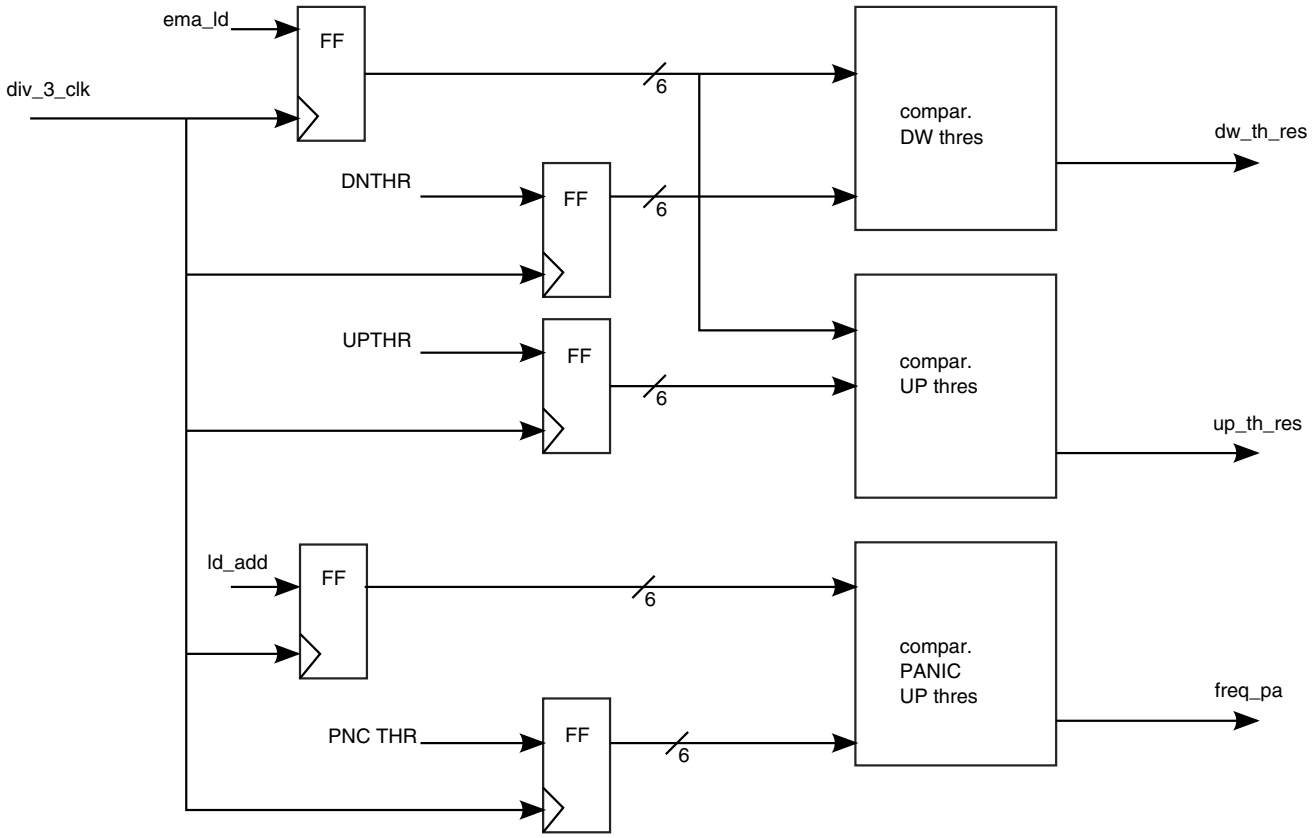

Figure 22-8. dvfs_tresh_cmp Diagram

The block is composed of three (3) comparators:

1. compar_dw_thres comparator, which compares between ema_ld signal (output of EMA block) and DNTHR signal (taken from config register, bits DNTHR).
2. compar_up_thres comparator, which compares between ema_ld signal (output of EMA block) and UPTHR signal (taken from config register, bits UPTHR).
3. compar_panic_up_thres comparator, which compares between ld_add signal (output of load_adder block) and PNCTHR signal (taken from config register, bits PNCTHR).

NOTE

The current implementation of this block enables step-by-step down frequency change. For more advanced option, the number of the DW threshold comparators should be increased (up to three for four-level DVFS).

22.3.7 dvfs_thresh_count Block

The purpose of the dvfs_thres_count block is to count consecutive threshold overcomes of dw_th_res and up_th_res (outputs of threshold_comp block). If any of the counters (see Figure 22-9 below) receives a null (zero) input synchronous with the clk3 signal, the counter is reset.

If the counter reaches a user defined value, its output is set to an active level. These counters are reset each time frequency scaling occurs or if the threshold overcomes are consecutive.

This block's output signals are saved in configuration register 0, bits [3,2].

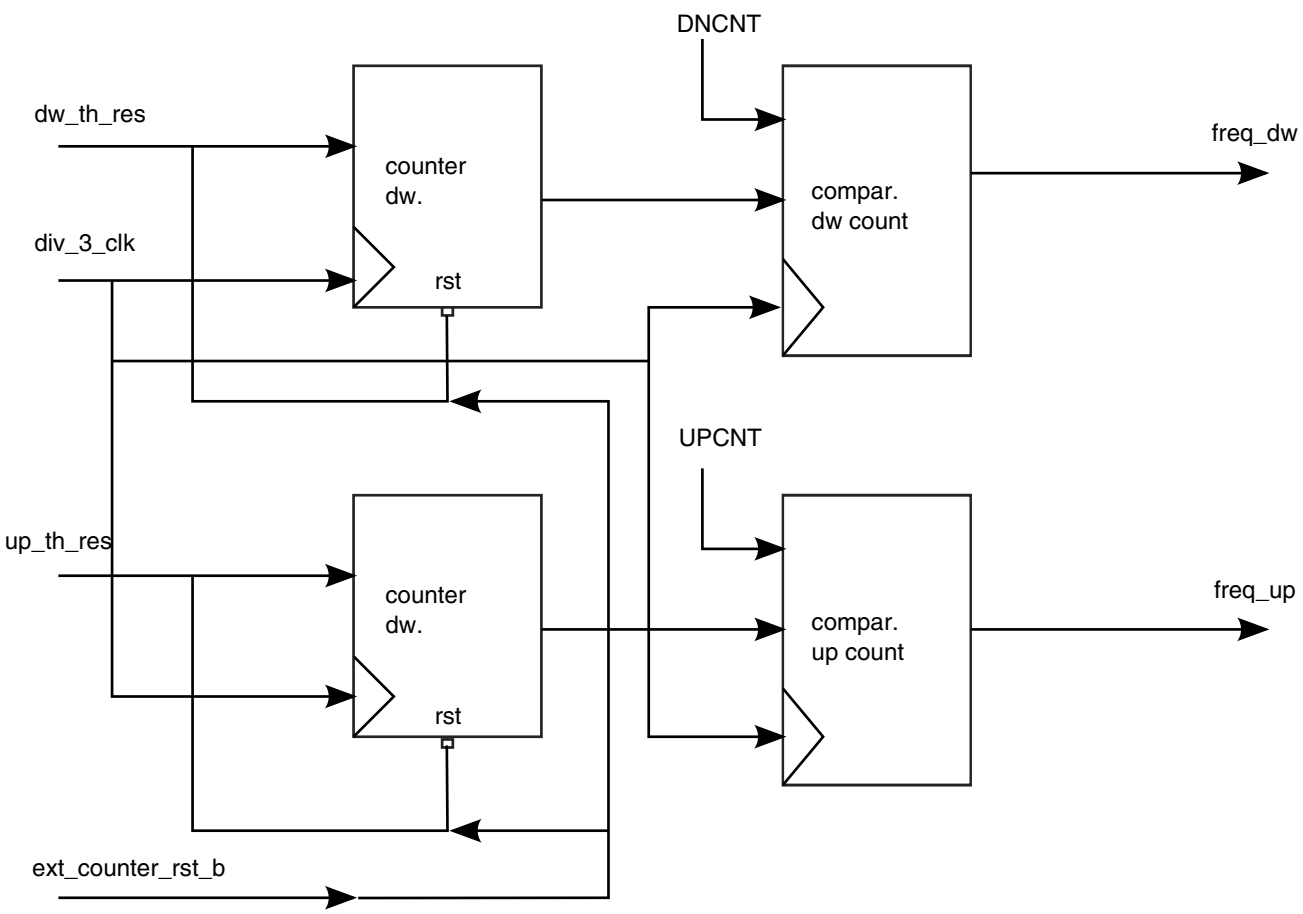

Figure 22-9. Thresh_counters block diagram

22.3.8 Load Tracking Buffer Register

The purpose of the load tracking buffer register is to save last 16 samples of the tracked load (before EMA operation). Hence, the 4 bits of ld_add signal (depending on the LTBRSH) are saved continuously, overwriting each time the latest sample. Each save is carried upon detecting an edge of the div_3_clk signal.

22.3.9 Frequency Pattern Generator

Frequency pattern generator is able to manage the frequency update requests periodically, additionally to main frequency update requests (if bit FPUE is set).

The periodic requests are created following the DVFSPT0, DVFSPT1, DVFSPT2 and DVFSPT3 register values, as described in Figure 22-10.

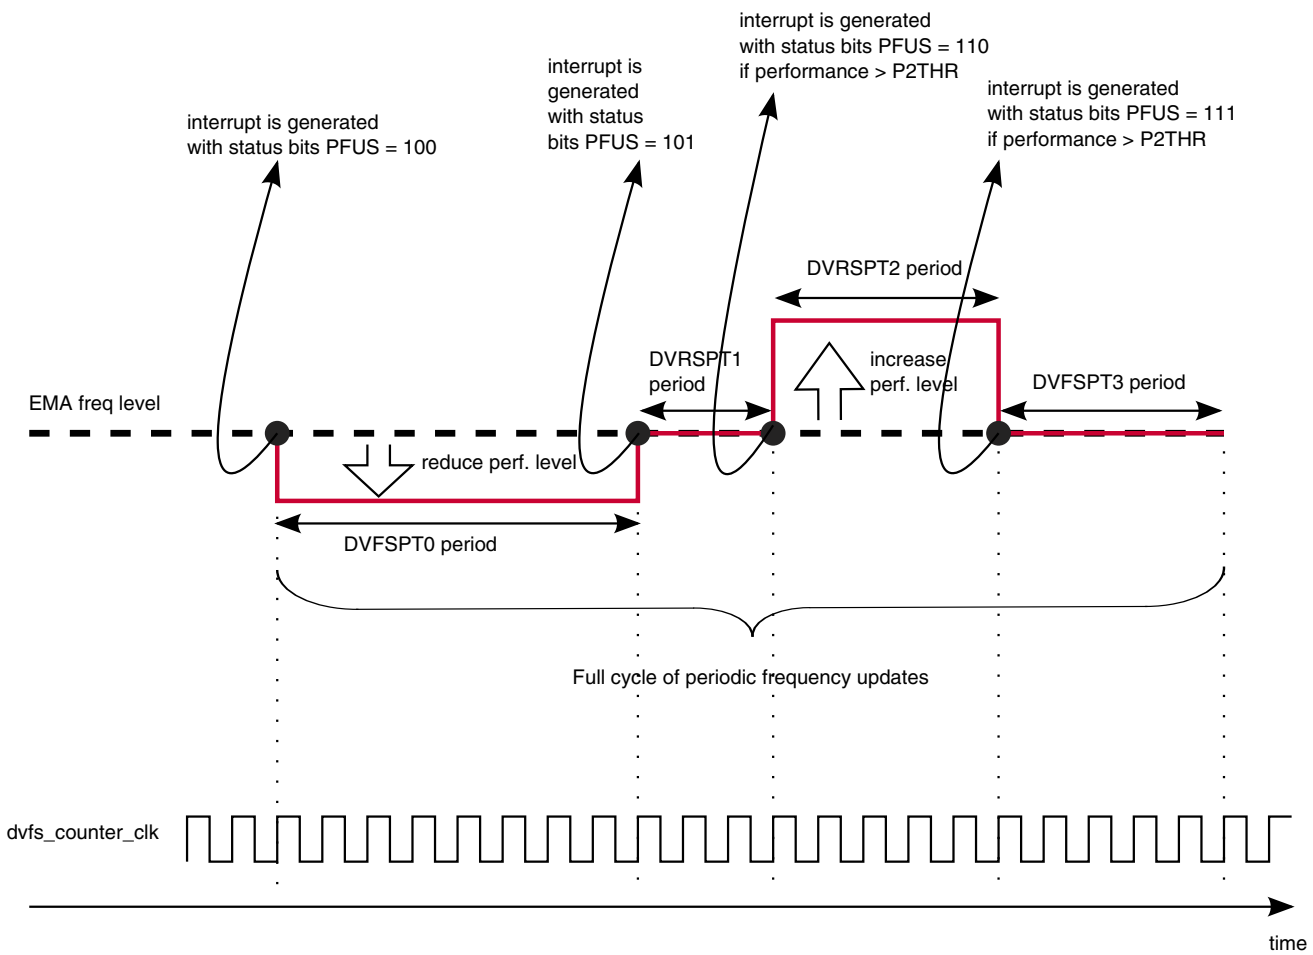

Figure 22-10. DVFS periodic frequency update requests

In case that one of the DVSPT0-DVFSPT3 period is set to "0", such frequency update will be skipped.

The periodic frequency update status is reflected in PFUS bits (reduce/increase performance request is an example - the actual steps taken upon period expiration are defined by s/w routine).

dvfs_counter_clk is ckih divided 64: 26MHz/64=0.40625MHz. The DVFSPT0, DVFSPT1, DVFSPT2 and DVFSPT3 counter are selected for 17 bits each to provide delay of 2^{18}-1=262143 counts, that are equal to 645ms. On the other hand, clk cycle of 0.40625MHz is ~2.46us, that is fast enough to provide high resolution for frequency management for tasks.

The DVFSPT2 and DVFSPT3 begin indication (interrupt) are conditional - only if the current performance is greater than P2THR bits at DVFSPT2 start, the interrupts will be created. Otherwise, the pattern delay will be counted, but without interrupt generation.

22.4 DVFS Output Event/interrupt Configuration

Event/Interrupt will be always high as long as LBFL is'1' and was not cleared by SW. Unless DVFEV (always event) is asserted. Then the event/interrupted will be toggled up and down every toggle of div_3_clk.

22.4.1 Interrupts

DVFS generates an interrupt that indicates that frequency and voltage update is needed. The user has to read the FSVAIM bits in order to know which change needs to be done.

22.5 Initialization Information

The user has to configure threshold values for load tracking and for counters and then enable the DVFS. When an interrupt is received, the user will change the frequency and the voltage in the interrupt handler.

NOTE

DVFS is a monitor that only provides an interrupt when counting exceeds the predefined value and doesn't actually send request to make a change a change of voltage and frequency. This can be done by the user in the interrupt routine or SDMA code by using GPC or CCM (re locking the PLL or changing the post dividers at the CCM).

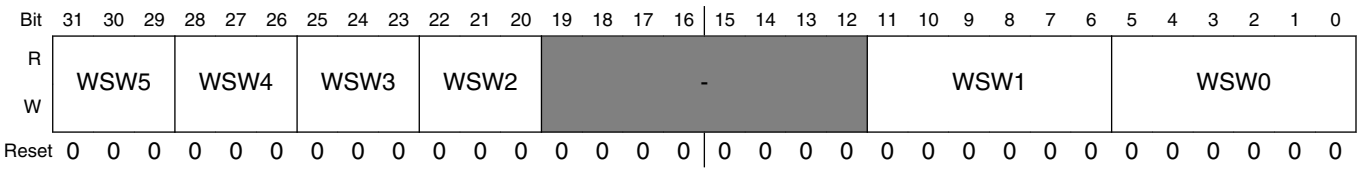
1–0 -	Reserved

22.6.4 DVFSC general purpose bits weight (DVFSC_SIG0)

Address: DVFSC_SIG0 is 53FD_8180h base + Ch offset = 53FD_818Ch



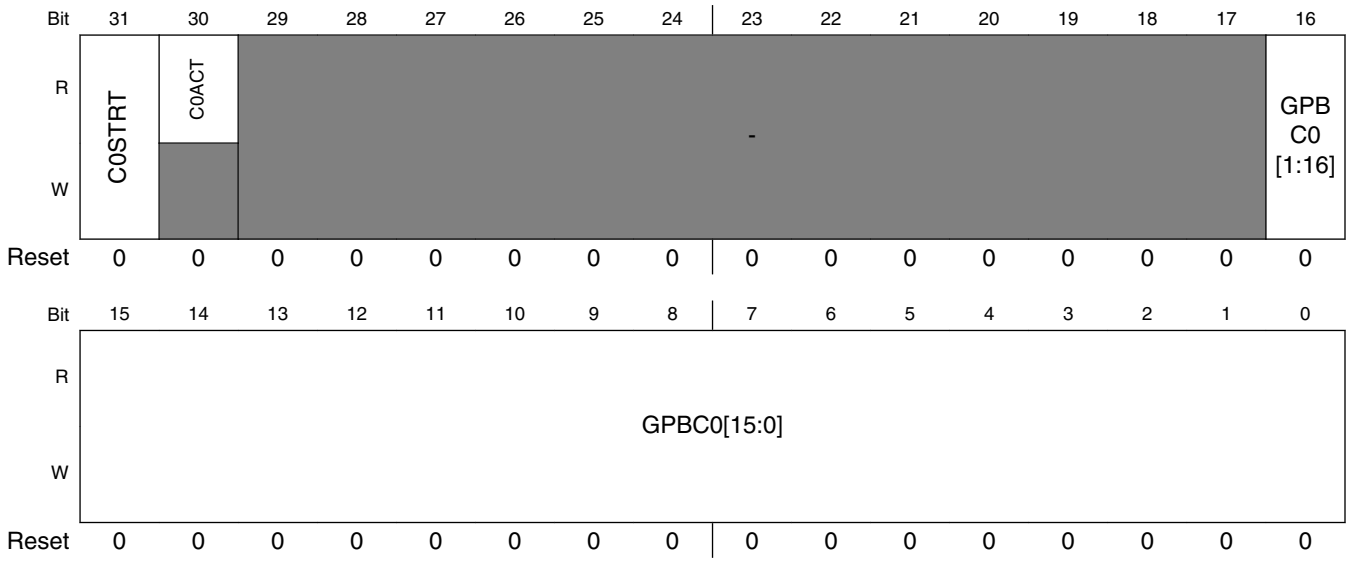
DVFSC_SIG0 field descriptions

Field	Description
31–29 WSW5	General purpose load tracking signal weight dvfs_w_sig[5]
28–26 WSW4	General purpose load tracking signal weight dvfs_w_sig[4]
25–23 WSW3	General purpose load tracking signal weight dvfs_w_sig[3]
22–20 WSW2	General purpose load tracking signal weight dvfs_w_sig[2]
19–12 -	Reserved
11–6 WSW1	General purpose load tracking signal weight dvfs_w_sig[1]. This value is relevant during GPC1 counting period or when GPB1 is set.
5–0 WSW0	General purpose load tracking signal weight dvfs_w_sig[0]. This value is relevant during GPC0 counting period or when GPB0 is set.

22.6.5 DVFSC general purpose bit 0 weight counter (DVFSC_GPC0)

DVFS general purpose bits weight counter.

Address: DVFSC_GPC0 is 53FD_8180h base + 10h offset = 53FD_8190h



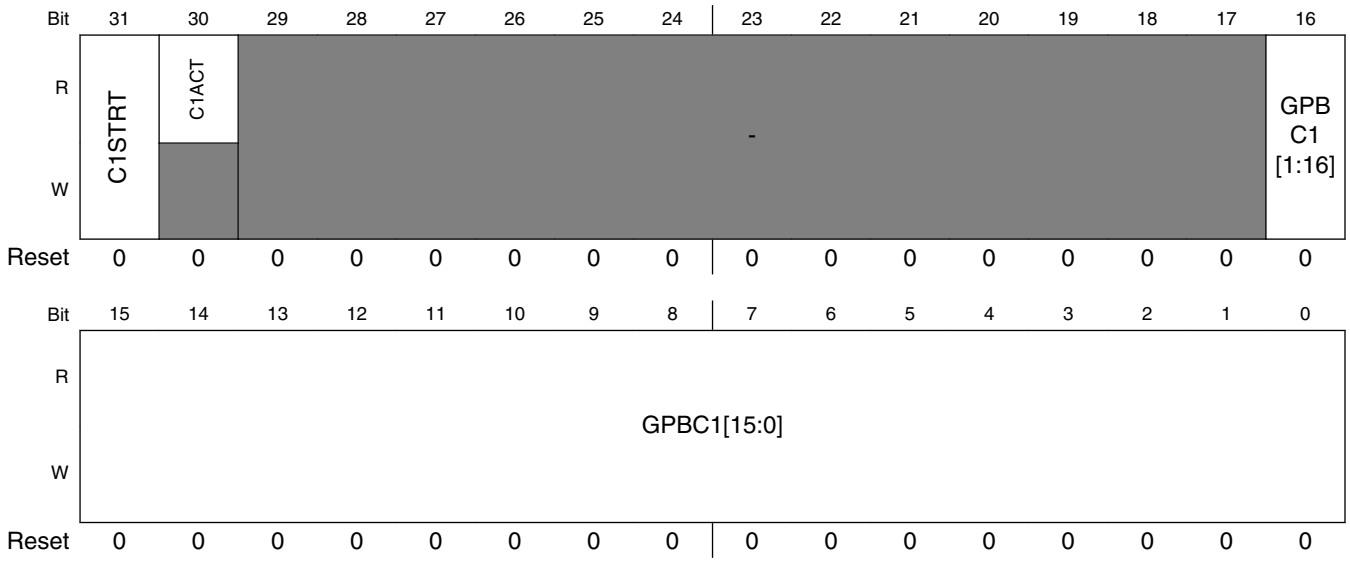
DVFSC_GPC0 field descriptions

Field	Description
31 C0STRT	C0STRT-Counter 0 start Setting of this bit will initialize down counting of the GPC0 value. Bit is self-cleared next cycle after setting. Any setting of this bit will re-start GPC0 counter to the GPC0 value. GPB0 bit disables (overrides) GPC0 counter-WSW0 weight is applicable continuously
30 C0ACT	C0ACT-Counter 0 active indicator 1 General Purpose bit0 counter didn't reach value of "0" - the WSW0 is provided to DVFS calculation 0 General Purpose bit0 counter reached value of "0" - the instead of WSW0, "0" (zero) is provided to DVFS calculation
29–17 -	Reserved
16–0 GPBC0	GPBC0 - General Purpose bits Counter 0 During period of this counter the GeP bit 0 will be set and WSW0 will be added to the calculations.

22.6.6 DVFSC general purpose bit 1 weight counter (DVFSC_GPC1)

DVFS general purpose bits weight counter1.

Address: DVFSC_GPC1 is 53FD_8180h base + 14h offset = 53FD_8194h



DVFSC_GPC1 field descriptions

Field	Description
31 C1STRT	C1STRT - Counter 1start Setting of this bit will initialize down counting of the GPC1 value. Bit is self-cleared next cycle after setting. Any setting of this bit will re-start GPC1 counter to the GPC1 value. GPB1 bit disables (overrides) GPC1 counter - WSW1 weight is applicable continuously
30 C1ACT	C1ACT - Counter 1 active indicator 1 General Purpose bit1 counter didn't reach value of "0" - the WSW1 is provided to DVFS calculation 0 General Purpose bit1 counter reached value of "0" - the instead of WSW1, "0" (zero) is provided to DVFS calculation
29–17 -	Reserved
16–0 GPBC1	GPBC1 - General Purpose bits Counter 1 During period of this counter the GeP bit 1 will be set and WSW1 will be added to the calculations.

22.6.7 DVFSC general purpose bits enables (DVFSC_GPBT)

Address: DVFSC_GPBT is 53FD_8180h base + 18h offset = 53FD_8198h

DVFSC_CNTR field descriptions

Field	Description
31–29 DIV3CK	DIV3CK - div_3_clk division ratio inside the DVFSC. According to the DVFSC Control (DVFSC_CNTR)
28 DVFEV	Always give a DVFS event. 0 Do not give an event always. 1 Always give event.
27 LBMI	Load buffer full mask interrupt. This bit masks the generation of this interrupt. Load buffer full interrupt is masked (LBFL0 and LBFL1 bits still will be updated, but interrupt won't be generated) 0 Load buffer full interrupt is enabled.
26 LBFL1	Load buffer 1 - full status bit. This bit indicates that log buffer registers are full. The bit is set to 1 automatically. An interrupt will be generated if LBMI bit is set to '0' Load buffer0 is full.Write '1' to clear. (write '0' leaves bit unchanged)

Table continues on the next page...

DVFSC_CNTR field descriptions (continued)

Field	Description
	0 Load buffer0 is not full.
25 LBFL0	Load buffer 0 - full status bit. This bit indicates that log buffer registers are full. The bit is set to 1 automatically. An interrupt will be generated if LBMI bit is set to "0" Load buffer1 is full. Write '1' to clear. (write '0' leaves bit unchanged) 0 Load buffer1 is not full.
24 DVFIS	DVFS Interrupt select. These bits define destination of DVFS interrupts. ARM platform interrupt will be generated for DVFS events. 0 SDMA interrupt will be generated for DVFS events.
23 PIRQS	PIRQS - Pattern IRQ Source * write '1' to clear. Writing '1' will clear interrupt if interrupt was from pattern 1 DVFS IRQ source was from pattern 0 DVFS IRQ source was not from pattern
22 FSVAIM	DVFS Frequency adjustment interrupt mask. This bit masks the DVFS frequency adjustment interrupt. FSVAI status bits will be still asserted in relevant cases. interrupt is masked. 0 Interrupt is enabled.
21–20 FSVAI[1:0]	FSVAI DVFS Frequency adjustment interrupt. These status bits indicate that the system frequency should be changed. 00 no interrupt 01 frequency should be increased. Low priority interrupt. Interrupt is asserted, if FSVAIM=0. Interrupt is masked if MAXF = 1 (highest frequency). 10 frequency should be decreased. Interrupt is asserted, if FSVAIM=0. Interrupt is masked if MINF= 1 (lowest frequency). 11 frequency should be increased immediately. High priority interrupt. Interrupt is asserted, if FSVAIM=0. Interrupt is masked if MAXF = 1 (highest frequency).
19 WFIM	DVFS Wait for Interrupt mask bit 0 Wait for interrupt not masked 1 Wait for interrupt masked.
18 MAXF	Maximum frequency reached. Interrupt will not be created in maximum frequency reached and frequency increase required. 1 max frequency reached 0 max frequency not reached
17 MINF	Minimum frequency reached. Interrupt will not be created in minimum frequency reached and frequency decrease required. 1 min frequency reached 0 min frequency not reached

Chapter 23
Dynamic Voltage and Frequency Scaling for Peripherals (DVFSP)

23.1 Introduction

23.1.1 Overview

Dynamic Voltage and Frequency Scaling for Peripherals (DVFSP) enables the frequency of the system and the voltage of the power domain to be changed on the fly while all blocks continue their normal operation on reduced frequency. The frequency of the clock domain is changed by dividing the clock source by DVFSP divider. Serial clocks will remain the same.

The DVFSP load tracking block allows hardware tracking on the system load and a generation of an interrupt when a frequency change is requested.

The statistics for DVFSP are done on peripherals such as External Memory Controller (EXTMC) (PER1), accelerators such as Image Processing Unit (IPU), and so on.

Frequency and voltages changes should comply with the specific limitations of each peripheral, for example lowest allowed frequency of memory device or the ability to change voltages on the fly. Those limitations should be considered when configuring the DVFSP monitors.

DVFSP is sub-block of the Global Power Controller (GPC) block. See GPC chapter for more details.

NOTE

DVFSP is a monitor that provides an interrupt when a count exceeds a predefined value. It does not request a change of voltage and frequency. This can be done by the user in the interrupt routine or Smart Direct Memory Access (SDMA)

code by using GPC or Clock Control Module (CCM) (by locking the PLL or changing the post dividers at the CCM).

A diagram of the DVFSP block is shown in Figure 23-1.

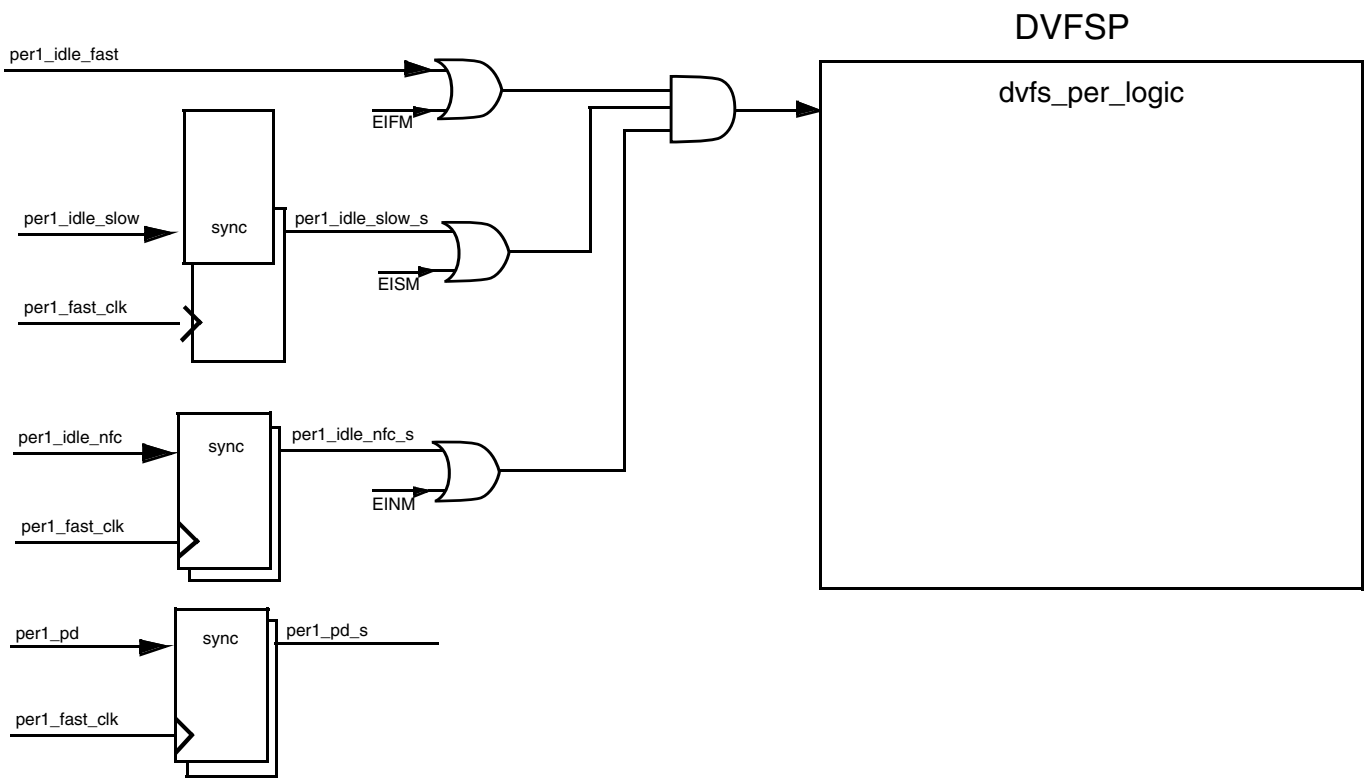

Figure 23-1. DVFSP Block Diagram

The DVFSP logic is shown in Figure 23-2.

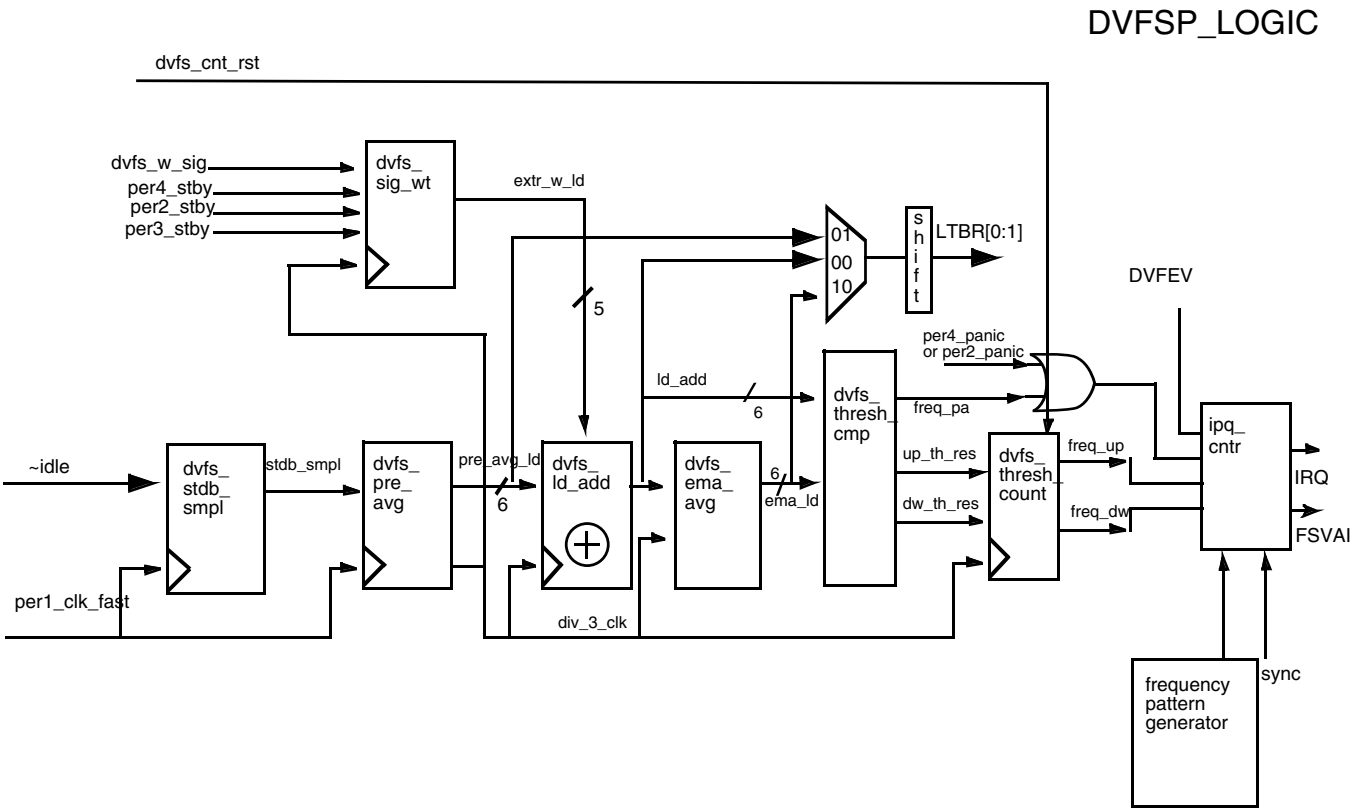

Figure 23-2. DVFSP_LOGIC Block Diagram

23.1.2 Features

The DVFSP load tracking block includes the following features:

- Configurable include/exclude of input signals:
  - Peripheral_1 (PER1) standby signal (idle / non-idle)
  - 10 general purpose bits
  - Peripheral_2 (PER2) standby
  - Peripheral_3 (PER3) standby
  - Peripheral_4 (PER4) standby
    - Configurable weight of each bit.
- Configurable generated clocks and averaging time slicing (respond time).
- Configurable panic mode respond logic (for frequency up).
- Programmable buffer for last 4, 8, 12 or 16 load tracking samples. Based on value in 'LBCF' in DVFSP_PMCR0. There is also a buffer full signal 'LBFL'.

23.2 Functional Description of DVFSP Core Load Tracking

The DVFSP load tracking block includes the following features:

Configurable include/exclude of input signals:

- PER1 standby signal (idle / non-idle)
- 10 general purpose load tracking signals
- per2 idle
- per3 idle
- per4 idle
- per2 panic
- per4 panic
- Configurable weight and (level-sensitive) of GeP signals.
- Configurable generated clocks and averaging time slicing (respond time).
- Configurable panic mode respond logic (for frequency up).
- Programmable buffer for last 4,8,12, or 16 load tracking samples.

23.3 Component Blocks Description

23.3.1 dvfs_stdb_smpl Block

This block samples the per1_non_idle, composed form per1_fast_idle, per1_slo_idle, per1_nfc_idle

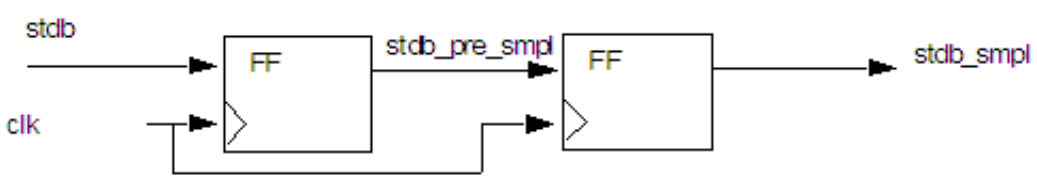

Figure 23-3. dvfs_stdb_smpl block diagram

This block synchronizes the stdb signal with the per1_clk_fast clock. The two signals enter the Flip-Flops (twice), and by doing so, are synchronized. The resulting synchronized signal is stdb_smpl.

23.3.2 dvfs_sig_wt Block

The purpose of this block is to sample the 16 GeP (general purpose) load signals, multiply each one of them by appropriate weight and sum products. The sampling is done by the slow clock div_3_clk. These signals have the only options of detection: level sampling. There are two paths for general purpose bits weight.

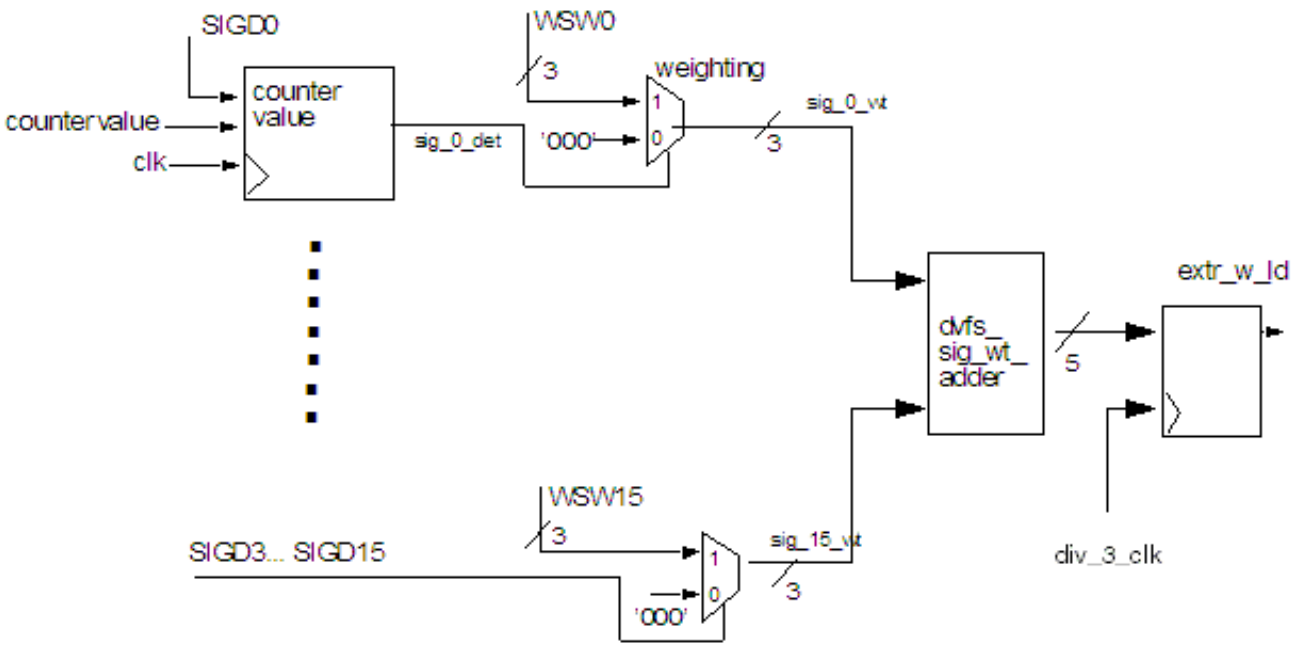

Figure 23-4. dvfs_sig_wt block diagram

23.3.3 dvfs_pre_avg Block

The purpose of the dvfs_pre_avg block is to perform simple, non-overlapping averaging, reducing the sampling clock frequency and providing a level-based average index of the tracked ARM platform load.

The output 5 bits avg_load signal provides a result with a tolerance of ~3%. (Supported values range is 0-0.9.)

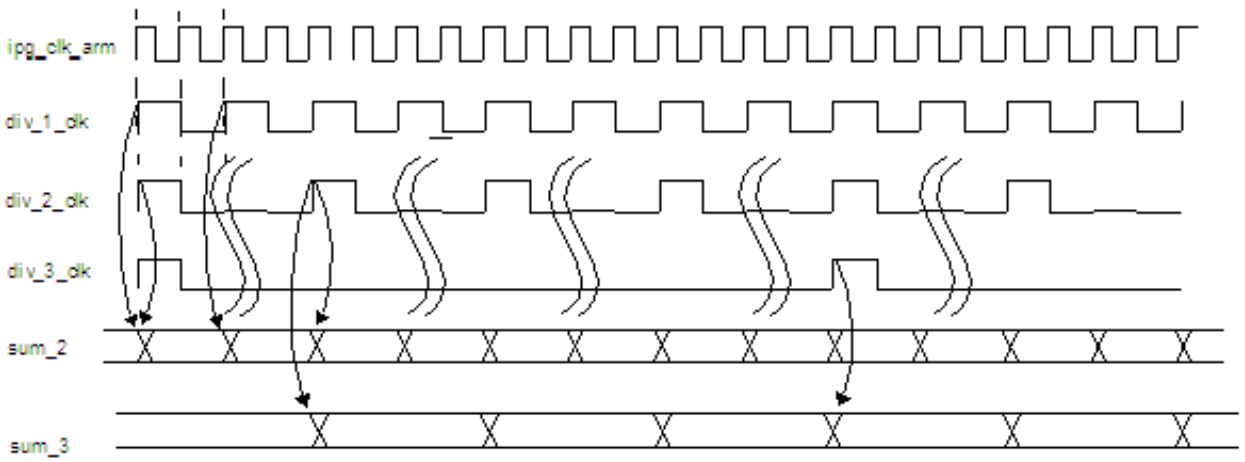

Figure 23-5. dvfs_pre_avg clocks

The internal clocks in dvfs_avg_pre block are generated from ipg_clk_arm.

Table 23-1. Value Ranges of dvfs_pre_avg Signals

signal	binary max value	binary min value	decimal max value	decimal min value

Table 23-2. dvfs_pre_avg Generated Clocks

clock name	generated from	ratio to source	ratio to ipg_clk_arm	max clk freq.	note

23.3.4 dvfs_ld_add Block

The dvfs_ld_add block sums the ARM platform load, tracked by idle/non-idle signal and the load, detected from the additional load signals, weighted by signal_weighting block.

The adder should perform the following operation:

extr_w_ld[4-0] + {0,pre_avg_ld[4-0]}

The input signals of five (5) bits produce output signal of six (6) bits, providing 3% resolution in the range of 0-1.97 of load indication. (1 is equal to 100% load tracking with no additional signals include).

The output ld_add[5-0] is sampled by div_3_clk signal.

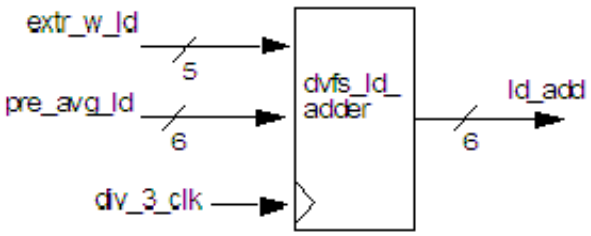

Figure 23-6. dvfs_ld_add block diagram

23.3.5 dvfs_ema_avg Block

The purpose of dvfs_ema_avg, or Exponential Moving Average (EMA), block is to calculate an exponential moving average of the tracked ARM platform load. The parameters of EMA are defined by EMAC field of the LTR2 register. These parameters set how many samples of simple average will be taken into account.

The EMA formula is: EMA(i) = a*X(i) + (1-a)*EMA(i-1)

where:

a = 2 / (N+1);

N is the number of samples taken into account.

X(i) = current input sample;

EMA(i-1) = previous value of EMA.

By setting the value of "a", the behavior of EMA is defined.

In the following table, the parameter "a" is listed relatively to the amount of the X(i) samples taken into account ("N") in the equation above: (the resolution of the digital multiplier is limited, hence the lowest values of the "a" can be linked to a range of included samples in EMA instead of single number).

In the following table there is also the amount of cycles in which the lower frequency will be masked from the moment that DVFSP is enabled (and not between frequency switches), so that enough information about the history can be gained before the frequency is lowered.

EMA settings

samples included in EMA calculation (N)	Number of cycles while lower frequency interrupt is masked	"a" value (decimal)	"a" value, adjusted by binary resolution	"a" value (binary)

dvfs_ema_avg block diagram

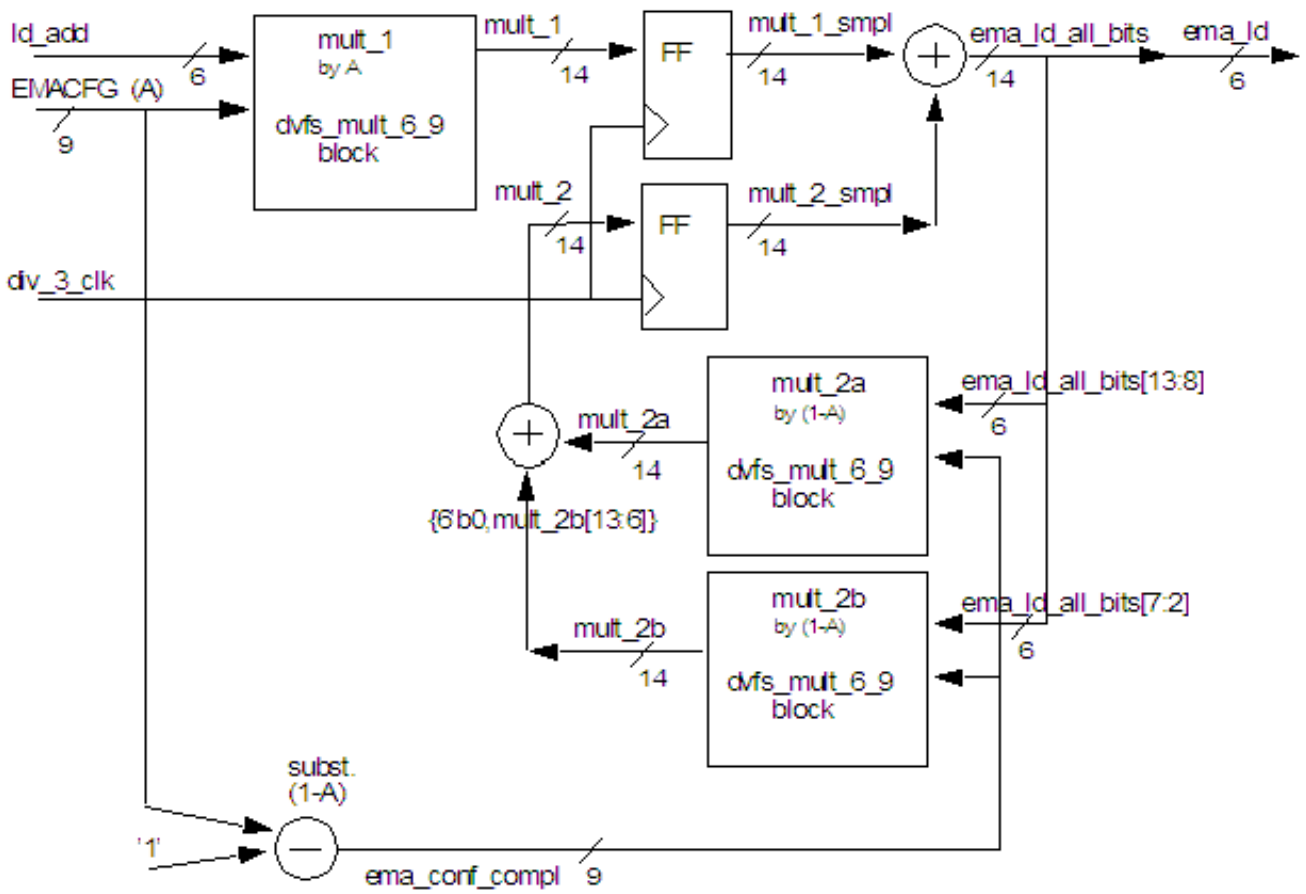

Figure 23-7. dvfs_ema_avg block diagram

The EMA inputs are as follows:

- ld_add[5-0] - load level
- EMACFG[8-0] - "a" parameter of EMA algorithm
- div_2_clk - fast clock don't see this in the diagram
- div_3_clk - slow clock

The EMA outputs the following:

- ema_ld[5-0] - result of EMA algorithm (by div_3_clk)

The mult_a block provides multiplying between comp_load (6 bits) and EMACFG (9 bits). For the multiply operation, a faster clock (for internal sum) is required- this is provided by div_2_clk. Div_2_clk is faster than the div_3_clk by a factor of at least 16, which is enough for 6*9 or 9*6 operations. Only the highest 6 bits are taken from the result of mult_a.

The mult_b block operates in a similar manner.

The adder block's output is sampled with div_3_clk clock.

23.3.6 dvfs_thres_cmp Block

The dvfs_thres_cmp block compares the ARM platform load value to programmable threshold levels. The comparators as shown in the drawing below are used:

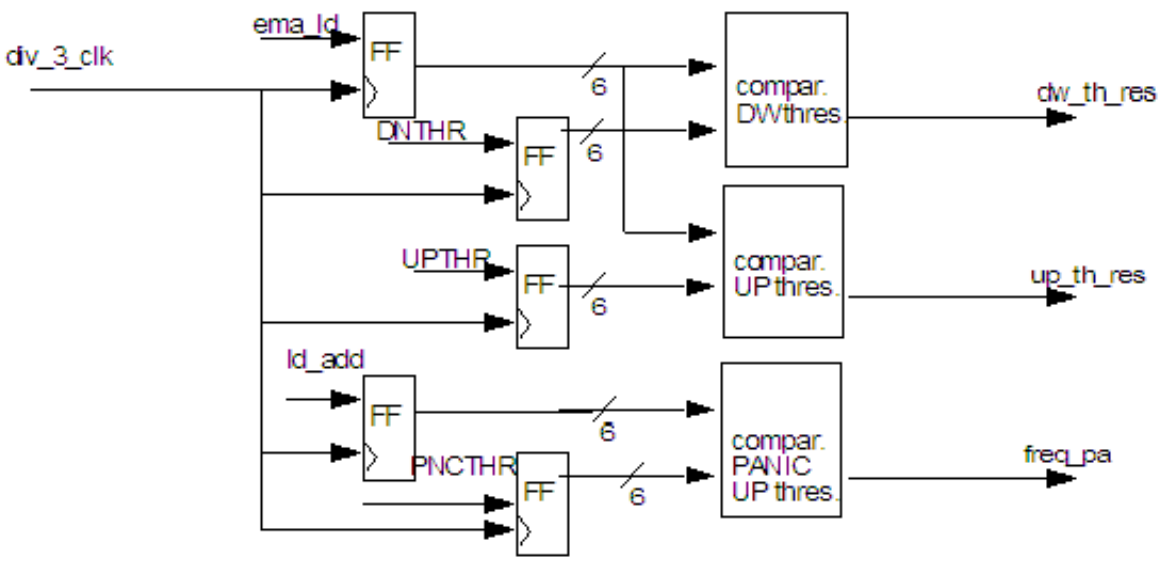

Figure 23-8. dvfs_tresh_cmp diagram

The block is composed of three (3) comparators:

1. compar_dw_thres comparator, which compares between ema_ld signal (output of EMA) and DNTHR signal (taken from config register, bits DNTHR).
2. compar_up_thres comparator, which compares between ema_ld signal (output of EMA) and UPTHR signal (taken from config register, bits UPTHR).
3. compar_panic_up_thres comparator, which compares between ld_add signal (output of load_adder block) and PNCTHR signal (taken from config register, bits PNCTHR).

NOTE

The current implementation of this block enables step-by-step down frequency change. For more advanced option, the number of the DW threshold comparators should be increased (up to three for four-level DVFSP).

23.3.7 dvfs_thresh_count Block

The purpose of the dvfs_thres_count block is to count consecutive threshold overcomes of dw_th_res and up_th_res (outputs of threshold_comp block). If any of the counters (see Figure Figure 23-9 below) receives a null (zero) input synchronous with the clk3 signal, the counter is reset.

If the counter reaches a user defined value, its output is set to an active level. These counters are reset each time frequency scaling occurs or if the threshold overcomes are consecutive.

This block's output signals are saved in configuration register 0, bits [3,2].

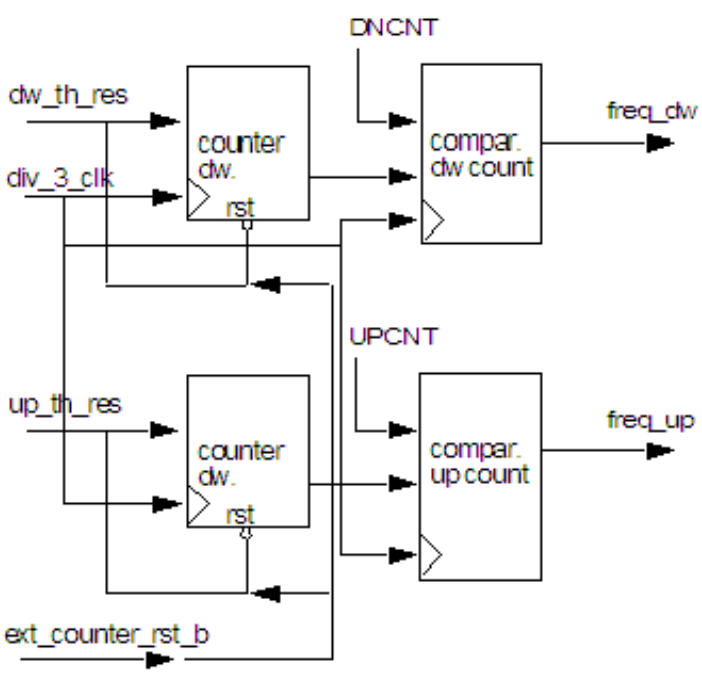

Figure 23-9. Thresh_counters block diagram

23.3.8 Load Tracking Buffer Register

The purpose of the load tracking buffer register is to save last 16 samples of the tracked load (before EMA operation). Hence, the 4 bits of ld_add signal (depending on the LTBRSH) are saved continuously, overwriting each time the latest sample. Each save is carried upon detecting an edge of the div_3_clk signal.

23.4 DVFSP Output Event/Interrupt Configuration

Event/Interrupt will be always high as long as LBFL is'1' and was not cleared by SW. Unless DVFEV (always event) is asserted. Then the event/interrupt will be toggled up and down every toggle of div_3_clk.

23.4.1 Interrupts

DVFSP generates an interrupt that indicates that frequency and voltage update is needed. The FSVAIM bits must be read in order to know which changes should be made.

NOTE

DVFSP is a monitor that provides an interrupt when a count exceeds a predefined value. It does not request a change of voltage and frequency. This can be done by the user in the interrupt routine or SDMA code by using GPC or CCM (by locking the PLL or changing the post dividers at the CCM).

Chapter 24
Enhanced Configurable SPI (ECSPI)

24.1 Overview

This chapter describes a block integrated into an SoC. The chapter is intended for a block driver software developer. It describes block-level operation and programming. To understand how the block is integrated at the SoC level, a system software developer should see discussions of the block in the appropriate SoC-level chapter(s).

The Enhanced Configurable Serial Peripheral Interface (ECSPI) is a full-duplex, synchronous, four-wire serial communication block. The ECSPI contains a 64 x 32 receive buffer (RXFIFO) and a 64 x 32 transmit buffer (TXFIFO). With data FIFOs, the ECSPI allows rapid data communication with fewer software interrupts. The following figure shows a block diagram of the ECSPI.

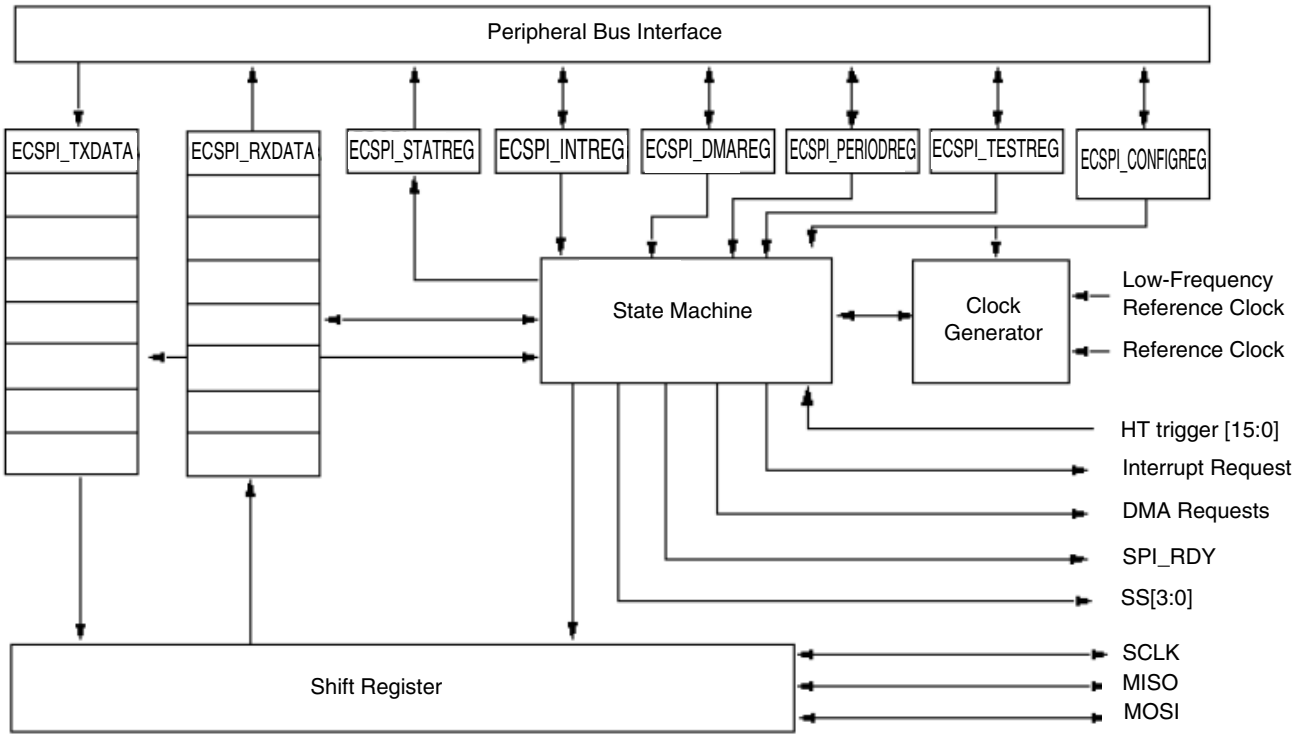

Figure 24-1. ECSPI Block Diagram

24.1.1 Features

Key features of the ECSPI include:

- Full-duplex synchronous serial interface
- Master/Slave configurable
- Four Chip Select (SS) signals to support multiple peripherals
- Transfer continuation function allows unlimited length data transfers
- 32-bit wide by 64-entry FIFO for both transmit and receive data
- 32-bit wide by 16-entry FIFO for HT message data
- Polarity and phase of the Chip Select (SS) and SPI Clock (SCLK) are configurable
- Direct Memory Access (DMA) support
- Max operation frequency up to the reference clock frequency.

24.1.2 Modes and Operations

The ECSPI supports the modes described in the indicated sections:

- Master Mode

- Slave Mode
- Low Power Modes

As described in Operations, the ECSPI supports the operations described in the indicated sections:

- Typical Master Mode
  - Master Mode with SPI_RDY
  - Master Mode with Wait States
  - Master Mode with SS_CTL[3:0] Control
  - Master Mode with Phase Control
- Typical Slave Mode

24.2 External Signals

The table below describes all ECSPI Block I/Os.

Table 24-1. Block I/O Signals

Signal	I/O	Description	Reset State[1]	Pull-Up/ Down[1]
$\overline{SS}$[3:0]	I/O	Chip selects	1	-
SCLK	I/O	SPI clock	0	Active
MISO	I/O	Master data in; slave data out	0	Passive
MOSI	I/O	Master data out; slave data in	0	-
SPI_RDY	I	Master data out; slave data in	0	Active

1. The reset state values and pull-up/down requirements provided in this table are from the block-level perspective. To understand how the block is integrated at the SoC level, the system software developer must see discussions of the block in the appropriate SoC-level chapter(s). For example, a block signal that requires a pull-up could be integrated with a pull-up option built into the SoC. In this case, the system software developer must ensure the proper programming at the SoC level.

The figure below shows the ECSPI in master mode connected to four external devices in a one-way communication link.

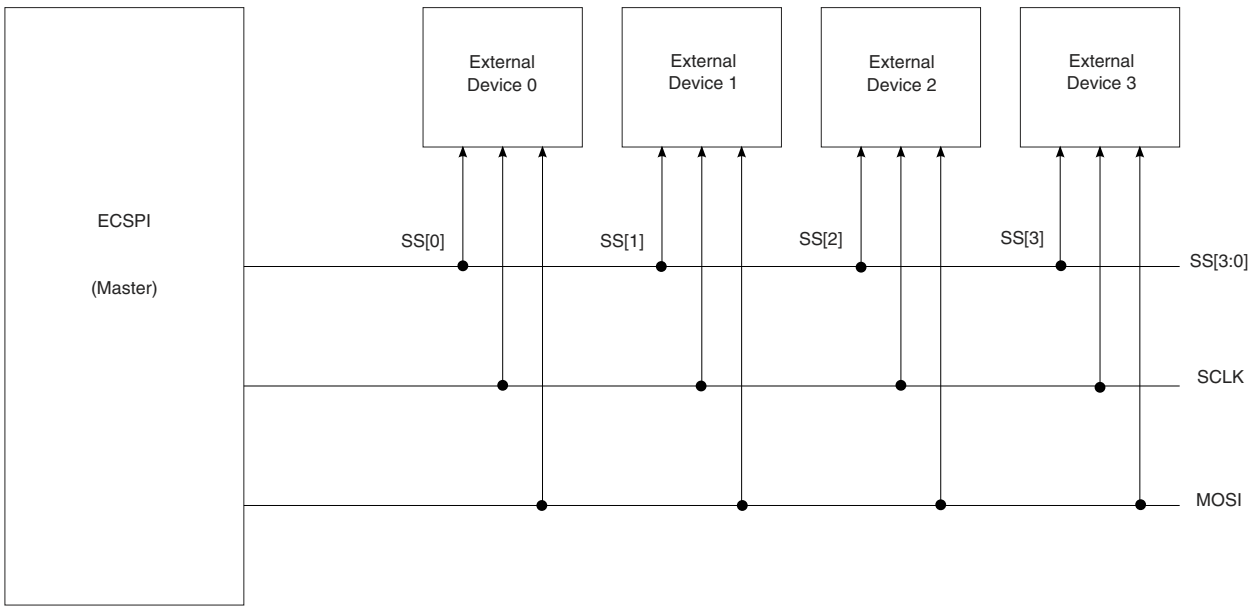

Figure 24-2. Example Connection Diagram

24.3 Functional Description

This section provides a complete functional description of the ECSPI. The figure below shows the relationship of SCLK and data lines while ECSPI has been configured with different POL and PHA settings.

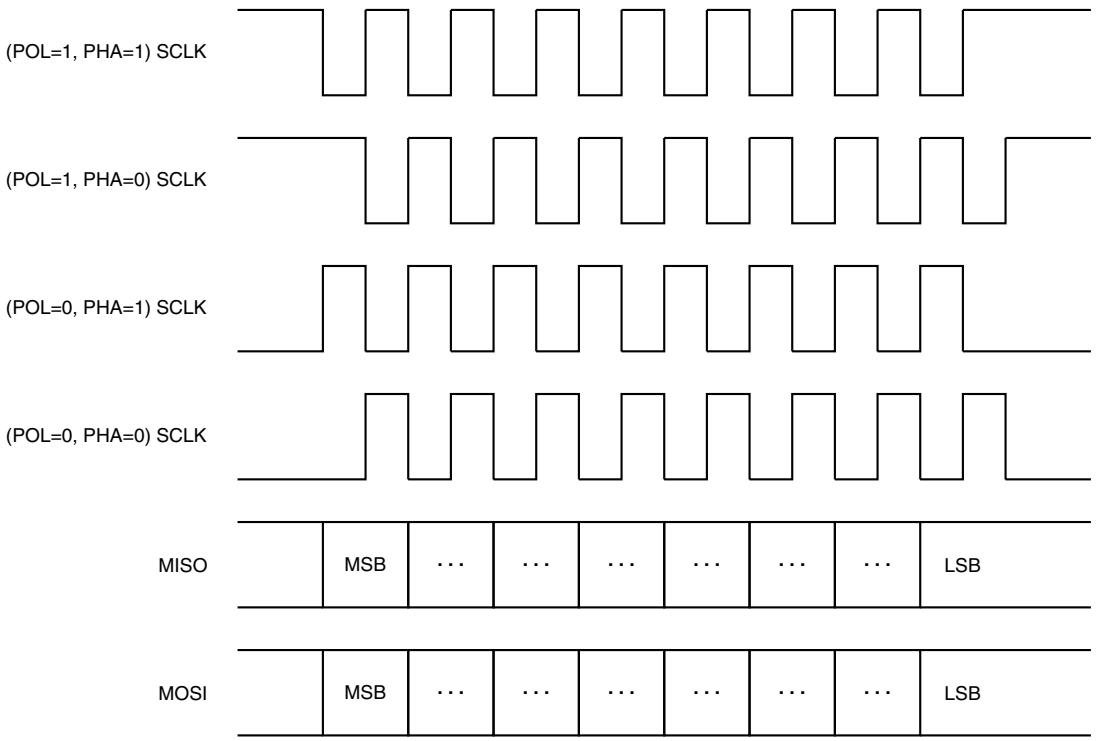

Figure 24-3. ECSPI SCLK, MISO, and MOSI Relationship

24.3.1 Master Mode

When the ECSPI is configured as a master, it uses a serial link to transfer data between the ECSPI and an external slave device. One of the Chip Select (SS) signals and the clock signal (SCLK) are used to transfer data between two devices.

If the external device is a transmit-only device, the ECSPI master's output port can be ignored and used for other purposes. In order to use the internal TXFIFO and RXFIFO, two auxiliary output signals, Chip Select (SS) and SPI_RDY, are used for data transfer rate control. Software can also configure the sample period control register to a fixed data transfer rate.

24.3.2 Slave Mode

When the ECSPI is configured as a slave, software can configure the ECSPI Control register to match the external SPI master's timing. In this configuration, Chip Select ($\overline{SS}$) becomes an input signal, and is used to control data transfers through the Shift register, as well as to load/store the data FIFO.

24.3.3 Hardware Trigger (HT) Mode

In hardware trigger (HT) mode, the behavior of the ECSPI is similar to master mode. The differences are in the trigger mechanism and the burst length.

When the block is in HT mode, the SPI burst is no longer triggered by software, setting the XCH bit or writing to the TXFIFO. Instead, there are 16 input signals HT trigger[15:0] associated with each slot of the 16-entry ECSPI_MSGDATA FIFO, and a positive pulse will trigger the ECSPI to transmit a SPI burst with data in ECSPI_MSGDATA FIFO. And in this case, the burst length is limited in 32-bit, but also configurable. Only SPI channel 0 can be used in HT mode.

24.3.4 Low Power Modes

The ECSPI does not operate under low power mode. It holds its operation when its clock is gated off in master mode. In slave mode, the ECSPI does not respond when its clock is gated off.

24.3.5 Operations

This section describes the ECSPI's operations.

24.3.5.1 Typical Master Mode

The ECSPI master uses the Chip Select (SS) signal to enable an external SPI device, and uses the SCLK signal to transfer data in and out of the Shift register. The SPI_RDY enables fast data communication with fewer software interrupts. By programming the ECSPI_PERIODREG register accordingly, the ECSPI can be used for a fixed data transfer rate.

When the ECSPI is in Master mode the SS, SCLK, and MOSI are output signals, and the MISO signal is an input.

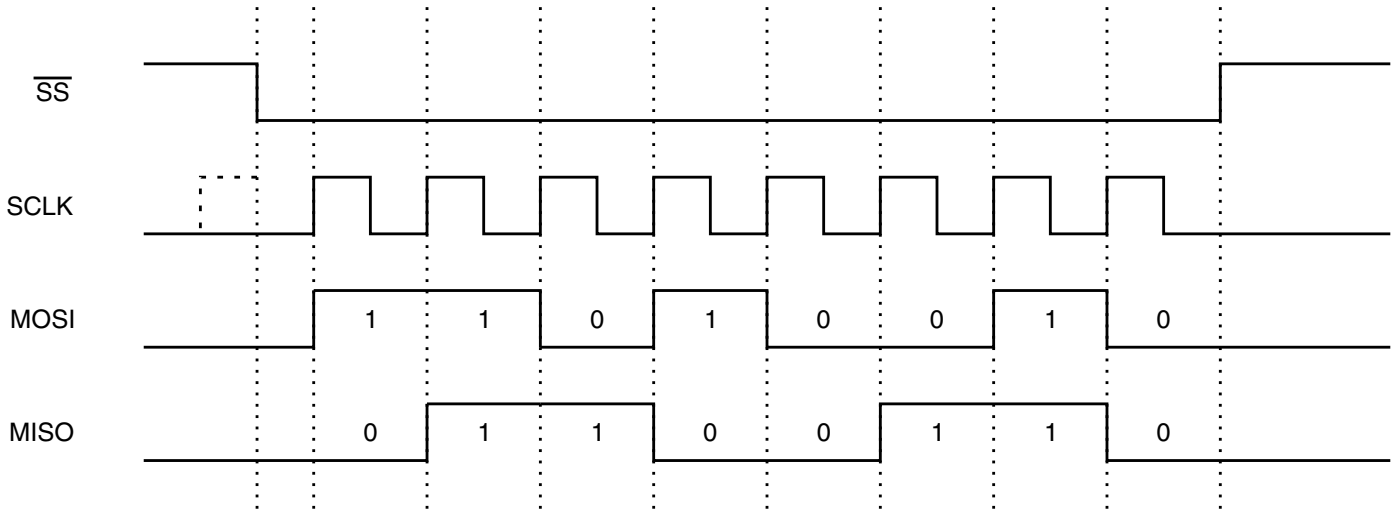

Figure 24-4. Typical SPI Burst (8-bit Transfer)

In the above figure, the Chip Select (SS) signal enables the selected external SPI device, and the SCLK synchronizes the data transfer. The MOSI and MISO signals change on rising edge of SCLK and the MISO signal is latched on the falling edge of the SCLK. The figure above shows a data of 0xD2 is shifted out, and a data of 0x66 is shifted in.

24.3.5.1.1 Master Mode with SPI_RDY

By default, the ECSPI does not use the SPI_RDY signal in master mode (MODE =1).

A SPI burst begins when the following events happen:

- The ECSPI is enabled, TXFIFO has data in it, and ECSPI_CONREG[XCH] bit or the ECSPI_CONREG[SMC] bit is set.
- When the SPI Data Ready Control (ECSPI_CONREG[DRCTL]) bits contains either 01 or 10, the SPI_RDY signal controls when a SPI burst starts.

A SPI burst is defined as a bus transaction that starts when the slave select is asserted and ends when the slave select is negated. The Chip Select (SS) signal will remain asserted until all the bits in a SPI burst are shifted out.

If ECSPI_CONREG[DRCTL] is set to 01, the SPI burst can be triggered only if a falling edge of the SPI_RDY signal has been detected.

The following figure shows the relationship between a SPI burst and the falling edge of SPI_RDY signal.

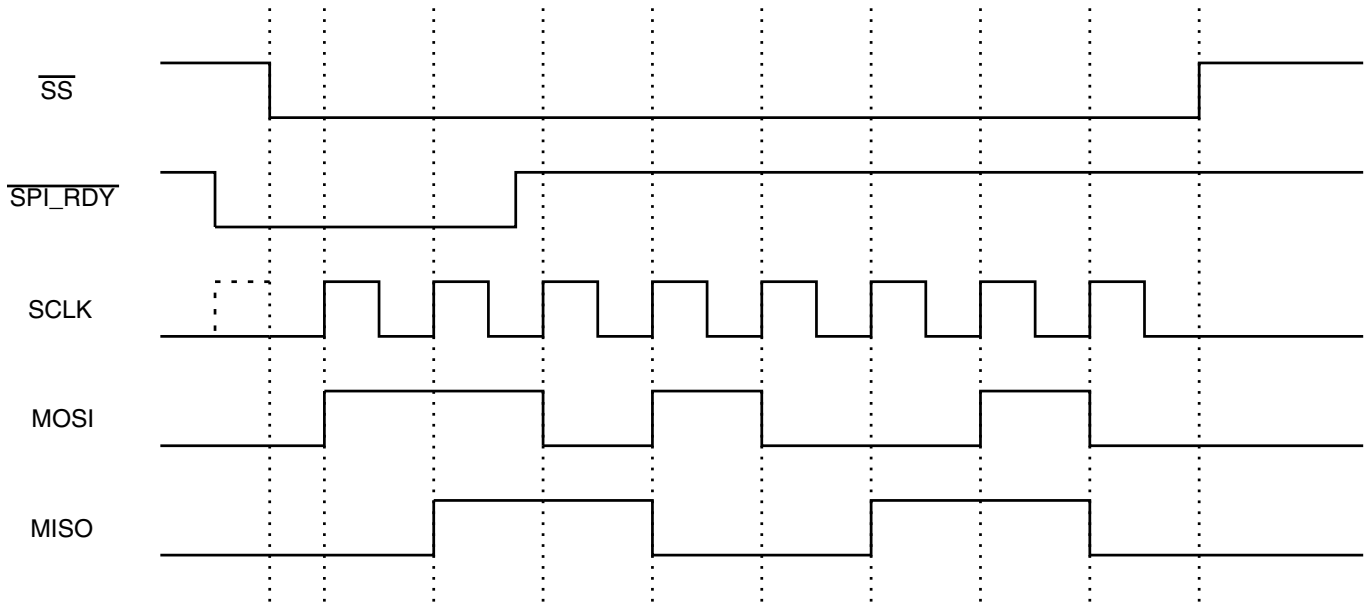

Figure 24-5. Relationship Between a SPI Burst and SPI_RDY: Falling-Edge Triggered

A SPI burst does not start until the falling edge of the SPI_RDY signal is detected. The next SPI burst starts when the next SPI_RDY falling edge is detected, after the last burst has finished.

If SPI Data Ready Control (ECSPI_CONREG[DRCTL]) is set to 10, the SPI burst can be triggered only if the SPI_RDY signal is low.

The following figure shows the relationship between a SPI burst and the SPI_RDY signal. The SPI burst does not begin until the SPI_RDY signal goes low. The ECSPI will keep transmitting SPI burst if the SPI_RDY signal remains low.

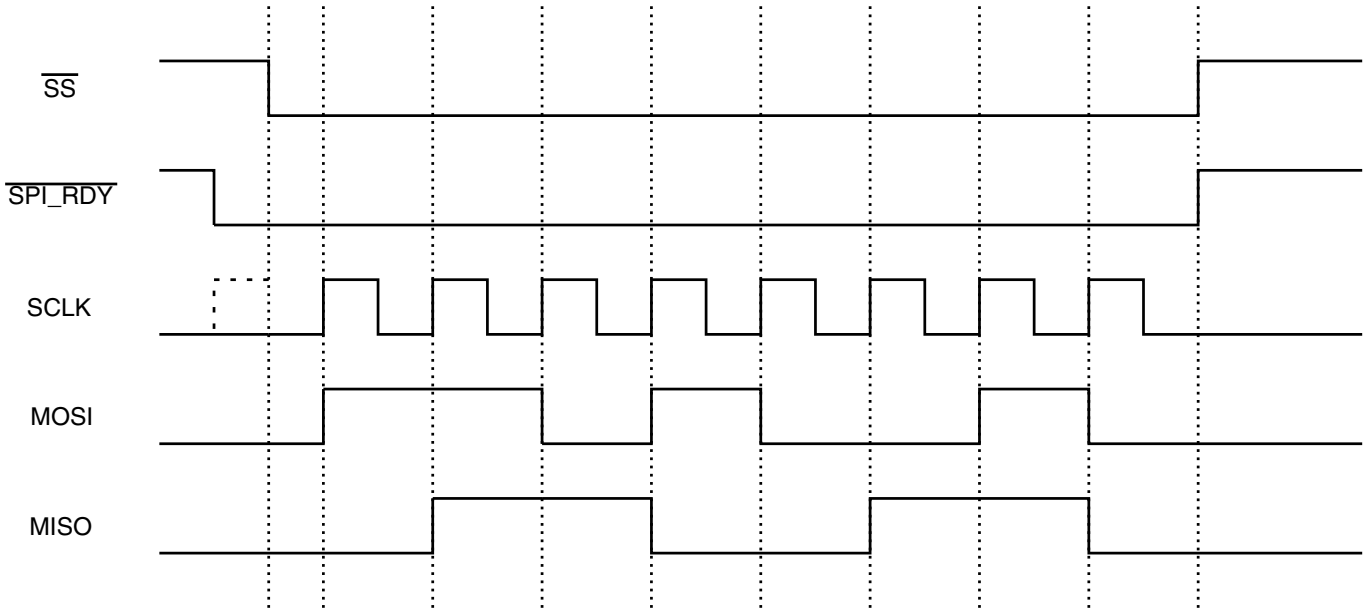

Figure 24-6. Relationship Between a SPI Burst and SPI_RDY: Low-Level Triggered

24.3.5.1.2 Master Mode with Wait States

Wait states can be inserted between SPI bursts. This provides a way for software to slow down the SPI burst to meet the timing requirements of a slower SPI device.

The following figure shows wait states inserted between SPI bursts.

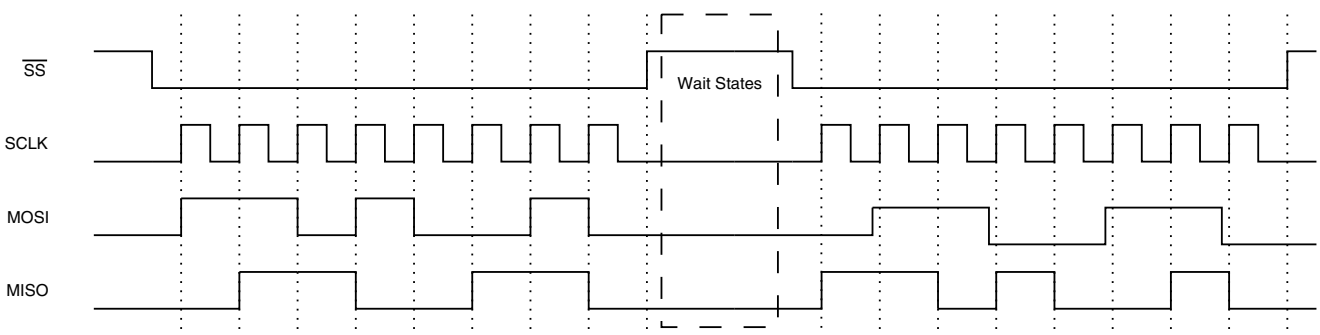

Figure 24-7. SPI Bursts with Wait States

In this case, the number of wait states is controlled by ECSPI_PERIODREG[SAMPLE PERIOD] and the wait states' clock source is selected by ECSPI_PERIODREG[CSRC].

24.3.5.1.3 Master Mode with SS_CTL[3:0] Control

The SPI SS Control (SS_CTL[3:0]) controls whether the current operation is single burst or multiple bursts. When the SPI SS Wave Form Select (SS_CTL[3:0]) is set, the current operation is multiple bursts transfer. When the SPI SS Wave Form Select (SS_CTL[3:0]) bit is cleared, the current operation is single burst transfer. A SPI burst can contains multiple words as defined in the BURST LENGTH field of the ECSPI_CONREG register.

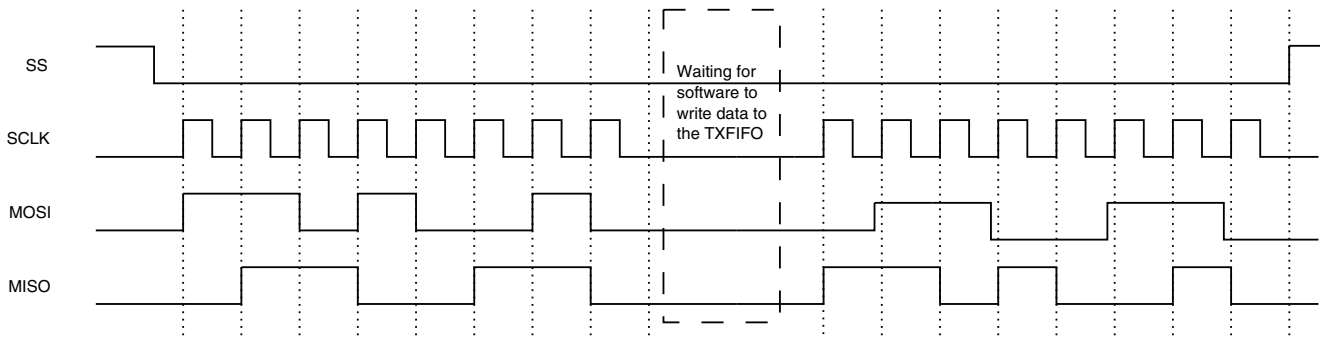

Figure 24-8. SPI Burst While SS_CTL[3:0] is Clear

In Figure 24-8, two 8-bit bursts in the TXFIFO have been combined and transmitted in one SPI burst. The maximum length of a single SPI burst is defined in the BURST LENGTH field of the ECSPI_CONREG control register. (Figure 24-8 corresponds to a BURST LENGTH of 8.) This provides a way for transferring a longer SPI burst by writing data into TXFIFO while the ECSPI is transmitting.

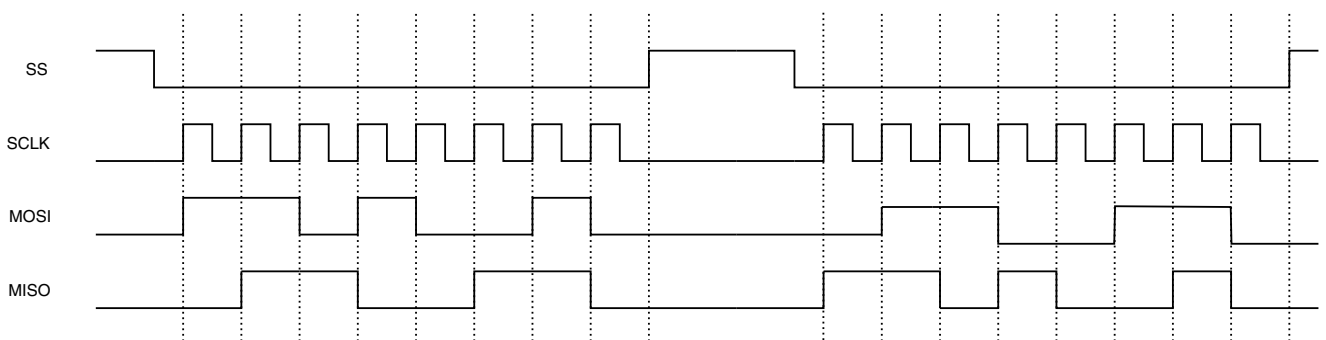

Figure 24-9. SPI Bursts While SS_CTL[3:0] is Set

In Figure 24-9, two FIFO entries are transmitted, one entry with each SPI burst. The ECSPI will continue to transmit SPI bursts until the TXFIFO is empty. When wait states can be inserted between SPI bursts, the SS will negate between SPI bursts until the wait states finish.

24.3.5.1.4 Master Mode with Phase Control

The Phase Control (ECSPI_CONREG[PHA]) bit controls how the transmit data shifts out and the receive data shifts in.

When the Phase control (ECSPI_CONREG[PHA]) bit is set, the transmit data will shift out on the rising edge of SCLK, and the receive data is latched on the falling edge of SCLK. The most-significant bit is output on the first rising SCLK edge.

When ECSPI_CONREG[PHA] is cleared, the transmit data is shifted out on the falling edge of SCLK and the receive data is latched on the rising edge of SCLK. The MSB is output when the host processor loads the transmitted data.

Inverting the SCLK polarity does not impact the edge-triggered operations because they are internal to the serial peripheral interface master.

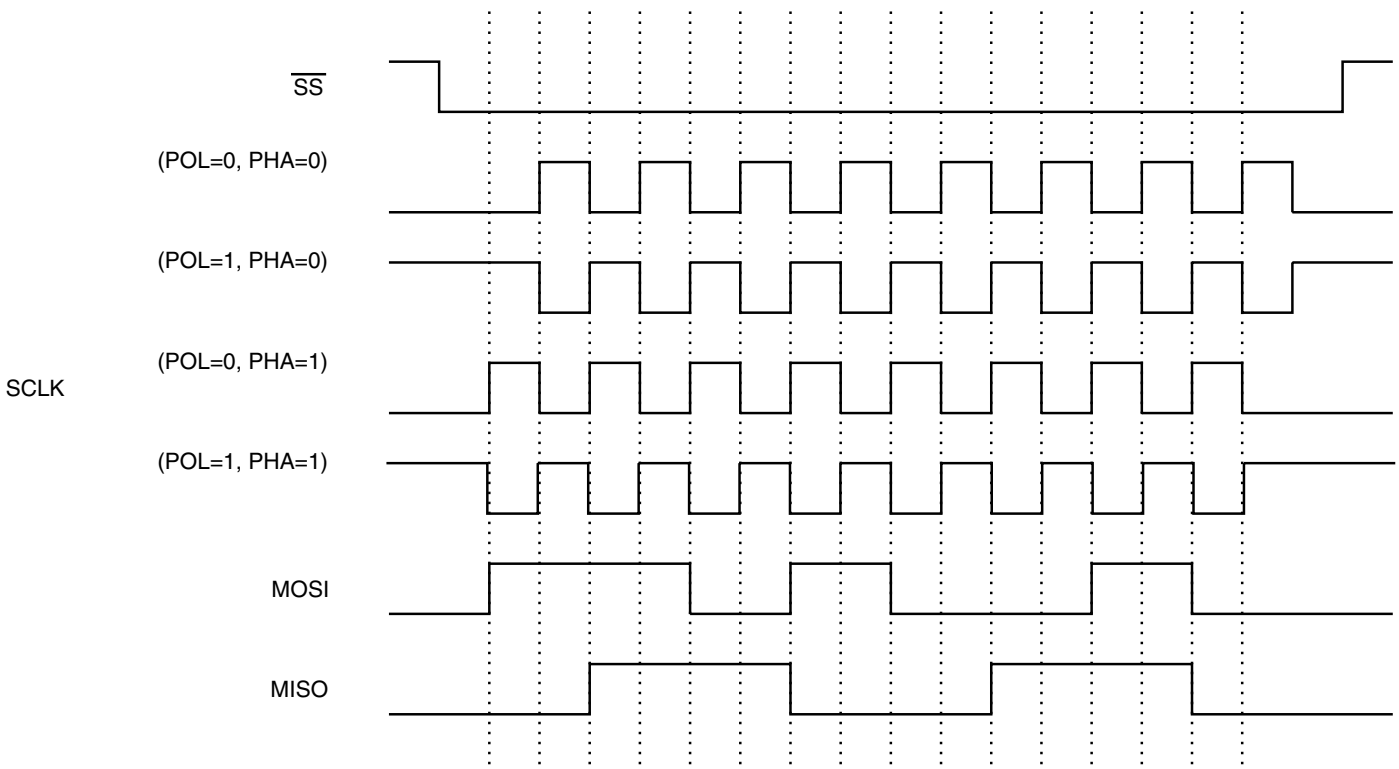

Figure 24-10. SPI Burst with Different POL and PHA Configurations

24.3.5.2 Typical Slave Mode

When the ECSPI is configured as a slave (Mode = 0), software can configure the ECSPI Control register to match the external SPI master's timing. In this configuration, SS becomes an input signal, and is used to latch data in and out of the internal data Shift registers, as well as to advance the data FIFO.

The SS, SCLK, and MOSI are inputs and MISO is output. Most of the timing diagrams are similar to the diagrams shown previously for the SPI in Master mode (Mode = 1), because the inputs come from a SPI master device.

However, the timing is different when SS is used to advance the data FIFO. When the SS_CTL[3:0] is set while the ECSPI is configured in Slave mode, the data FIFO will advance on the rising edge of the SS signal. When the polarity is reversed (SSPOL = 1), the data FIFO will advance on the falling edge of the SS signal.

The figure below shows a SPI burst in which the data FIFO is advanced by the rising edge of the SS signal.

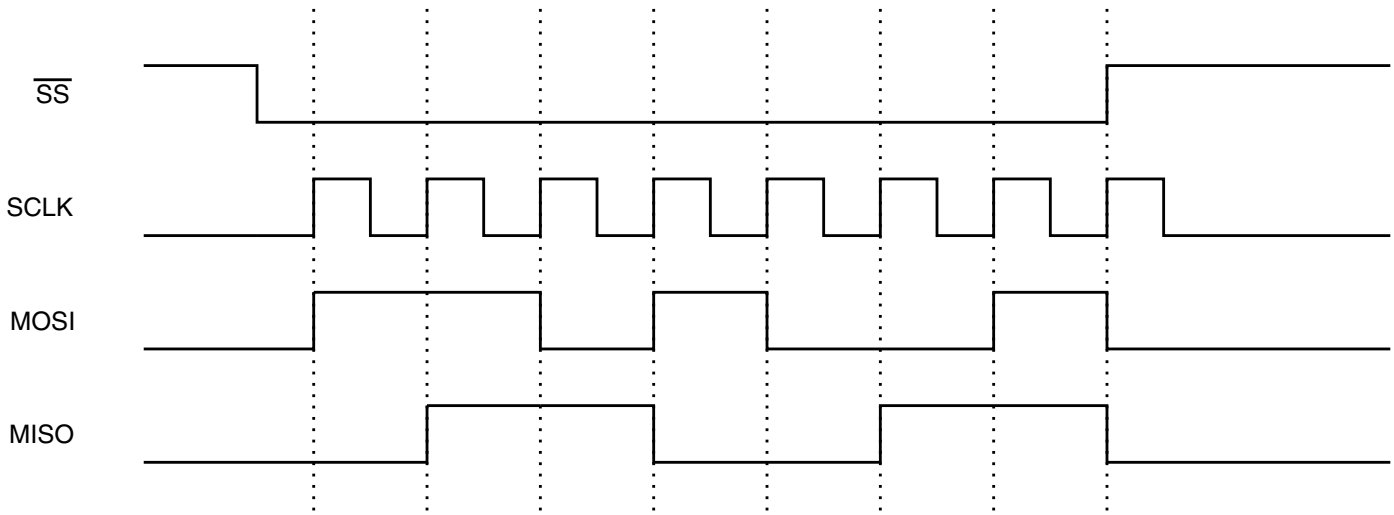

Figure 24-11. Advancing the Data FIFO on the Rising Edge of SS

In the above case, only the most significant 7 bits are loaded to the RXFIFO.

24.3.6 Clocks

This section describes clocks and special clocking requirements of the block.

ECSPI has the following clock inputs:

- Reference Clock is the reference clock.
- Low-Frequency Reference Clock is a 32KHz input clock optionally used for counting wait states.

24.3.7 Reset

Whenever a device reset occurs, a reset is performed on the ECSPI, resetting all registers to their default values.

Software can reset the block using the CONREG[EN] bit; see Control Register (ECSPI_CONREG).

24.3.8 Interrupts

Interrupt control provides a way to manage the ECSPI FIFOs:

- For transmitting data, software can enable the TXFIFO empty, TXFIFO data request, and TXFIFO full interrupts to maintain the TXFIFO using an interrupt service routine.
- For receiving data, software can enable the RXFIFO ready, RXFIFO data request, and RXFIFO full interrupts to retrieve data from the RXFIFO using an interrupt service routine.

Other interrupt sources can be used to control or debug the SPI bursts:

- The transfer-completed interrupt means that there is no data left in the TXFIFO and that the data in the Shift register has been shifted out.
- The RXFIFO overflow interrupt means that the RXFIFO received more than 64 words and will not accept any other words.

.

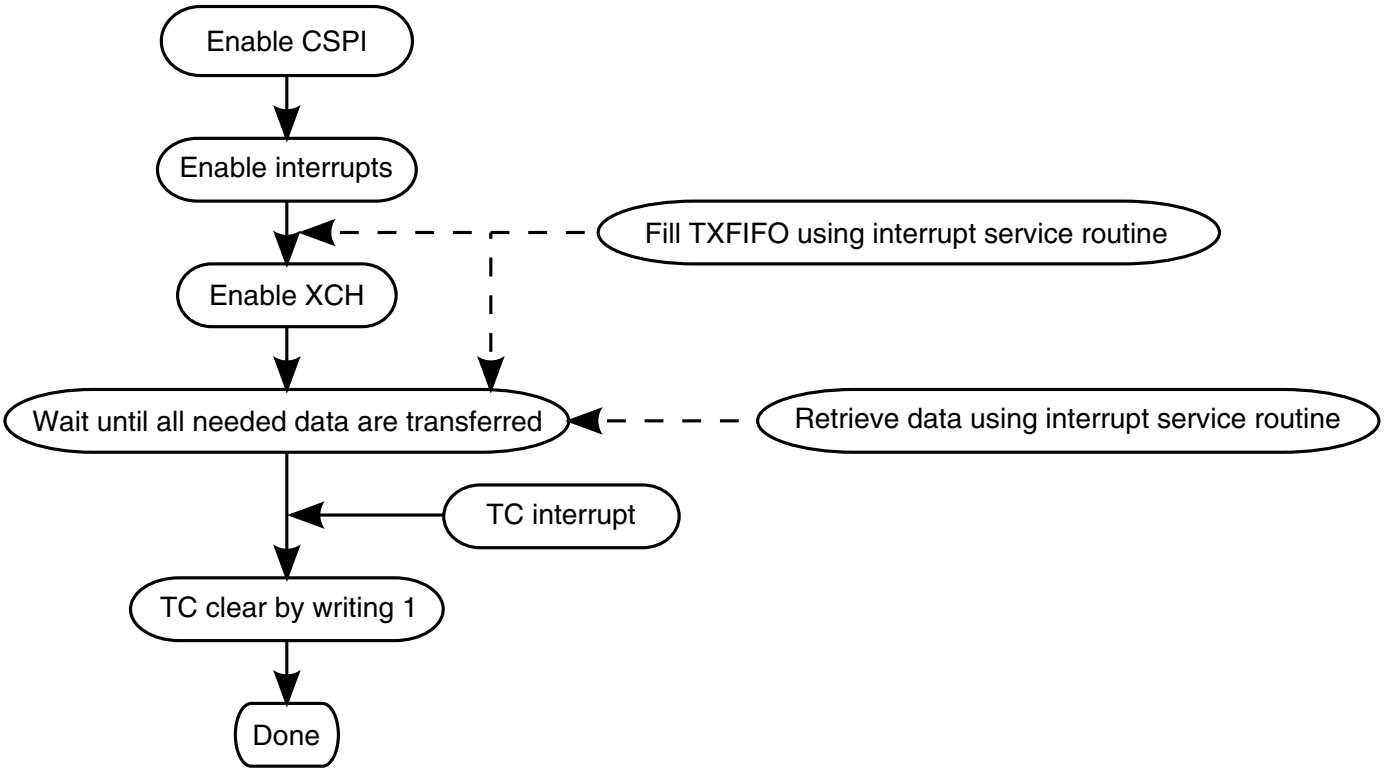

Figure 24-12. Program Sequence of SPI Burst Using Interrupt Control

24.3.9 DMA

DMA control provides another method to utilize the FIFOs in the ECSPI. By using DMA request and acknowledge signals, larger amounts of data can be transferred, and will reduce interrupts and host processor loading. When the appropriate conditions are matched, the block will send out a DMA request.

The DMA can deal with the following conditions:

- TXFIFO empty
- TXFIFO data request
- RXFIFO data request
- RXFIFO full

The figure below shows a program sequence of SPI bursts using DMA control.

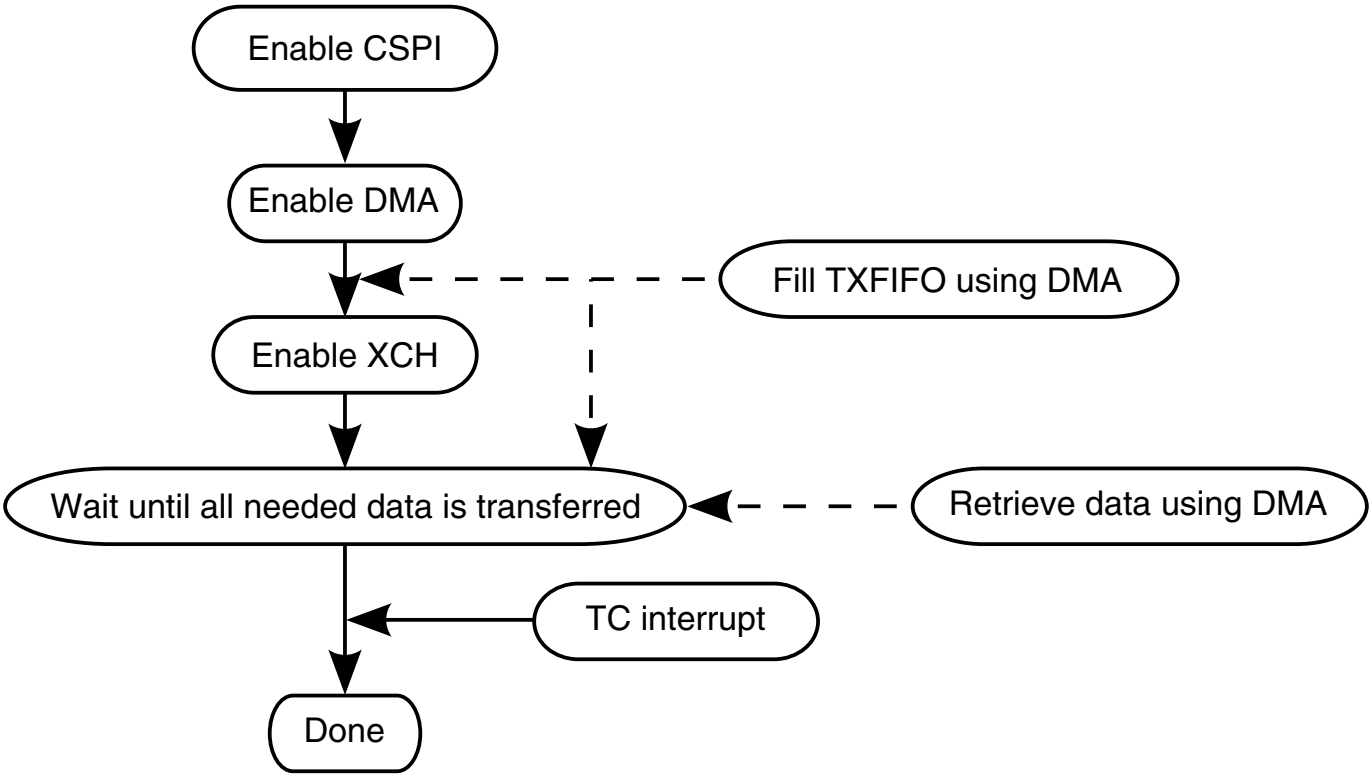

Figure 24-13. Program Sequence of SPI Burst Using DMA

24.3.10 Byte Order

The ECSPI does not support byte re-ordering in hardware.

24.4 Initialization

This section provides initialization information for ECSPI.

To initialize the block:

1. Clear the EN bit in ECSPI_CONREG to reset the block.
2. Enable the clocks for ECSPI.
3. Set the EN bit in ECSPI_CONREG to put ECSPI out of reset.
4. Configure corresponding IOMUX for ECSPI external signals.
5. Configure registers of ECSPI properly according to the specifications of the external SPI device.

24.5 Applications

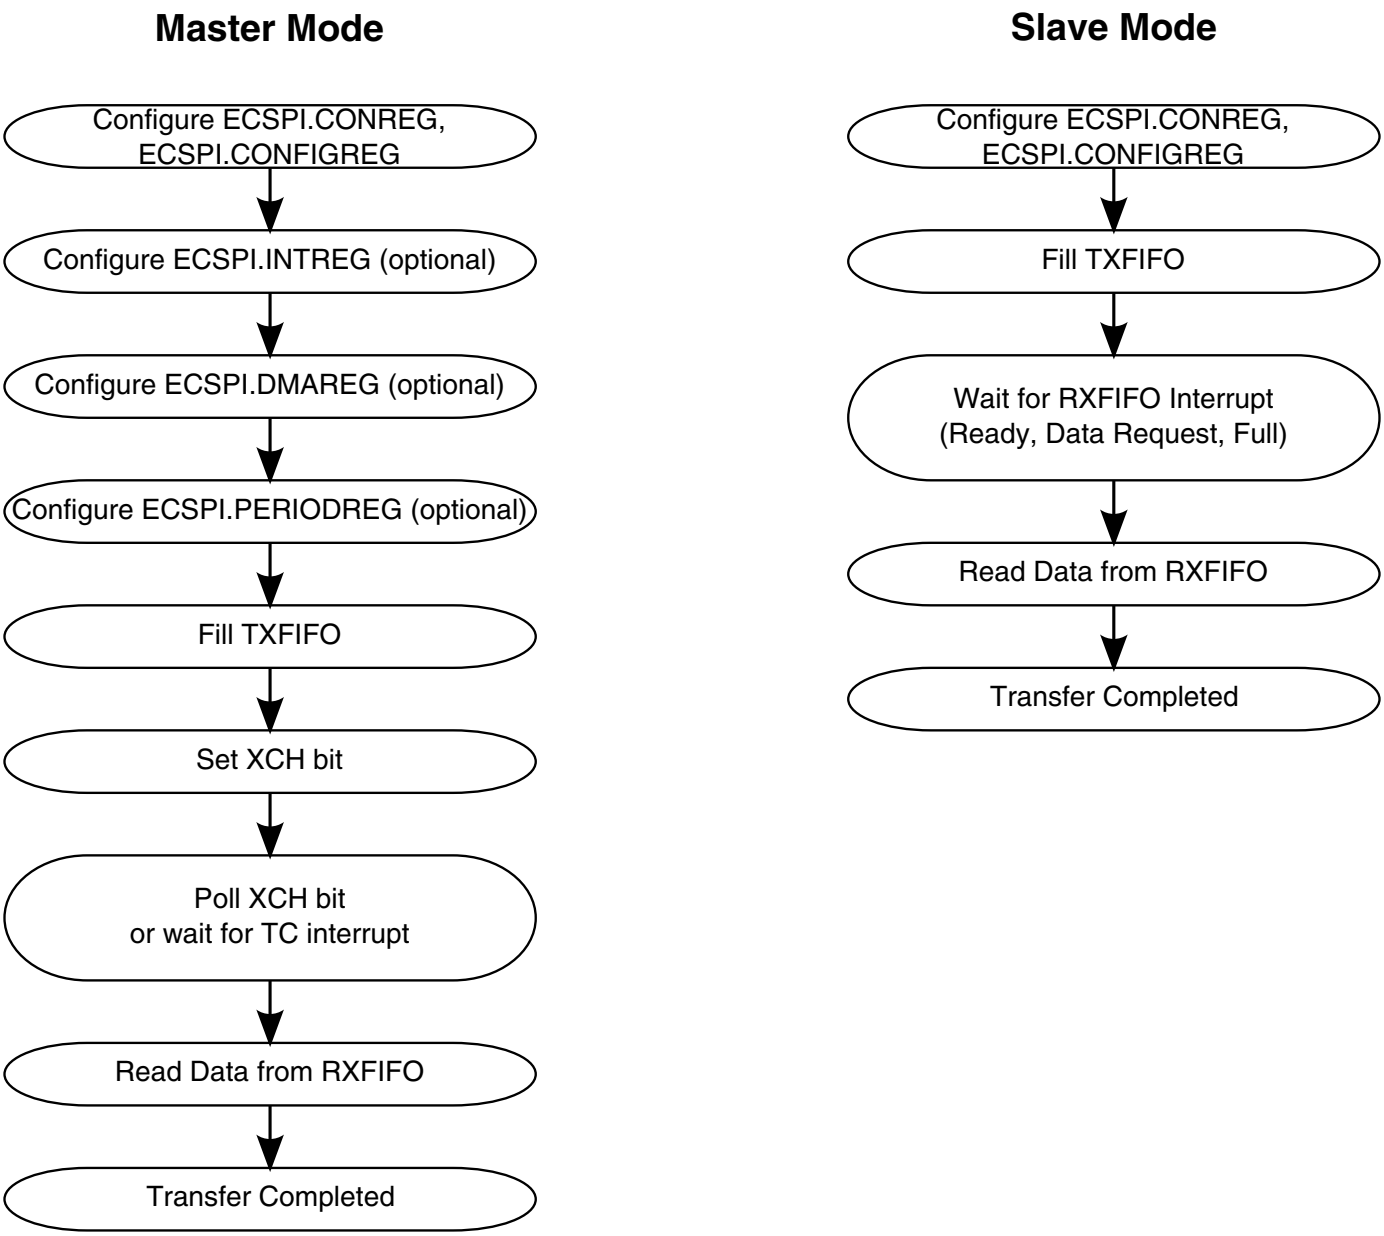

Figure 24-14. Flowchart of the ECSPI Operation

24.6 Programmable Registers

This section includes the block memory map and detailed descriptions of all registers. For the base address of a particular block instantiation, see the system memory map.

ECSPI memory map

24.6.1 Receive Data Register (ECSPIx_RXDATA)

The Receive Data register (ECSPI_RXDATA) is a read-only register that forms the top word of the 64 x 32 receive FIFO. This register holds the data received from an external SPI device during a data transaction. Only word-sized read operations are allowed.

Addresses: ECSPI-1_RXDATA is 5001_0000h base + 0h offset = 5001_0000h

ECSPI-2_RXDATA is 63FA_C000h base + 0h offset = 63FA_C000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ECSPIx_RXDATA field descriptions

Field	Description
31–0 ECSPI_RXDATA	Receive Data. This register holds the top word of the receive data FIFO. The FIFO is advanced for each read of this register. The data read is undefined when the Receive Data Ready (RR) bit in the Interrupt Control/Status register is cleared. Zeros are read when ECSPI is disabled.

24.6.2 Transmit Data Register (ECSPIx_TXDATA)

The Transmit Data (ECSPI_TXDATA) register is a write-only data register that forms the bottom word of the 64 x 32 TXFIFO. The TXFIFO can be written to as long as it is not full, even when the SPI Exchange bit (XCH) in ECSPI_CONREG is set. This allows software to write to the TXFIFO during a SPI data exchange process. Writes to this register are ignored when the ECSPI is disabled (ECSPI_CONREG[EN] bit is cleared).

Addresses: ECSPI-1_TXDATA is 5001_0000h base + 4h offset = 5001_0004h

ECSPI-2_TXDATA is 63FA_C000h base + 4h offset = 63FA_C004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ECSPIx_TXDATA field descriptions

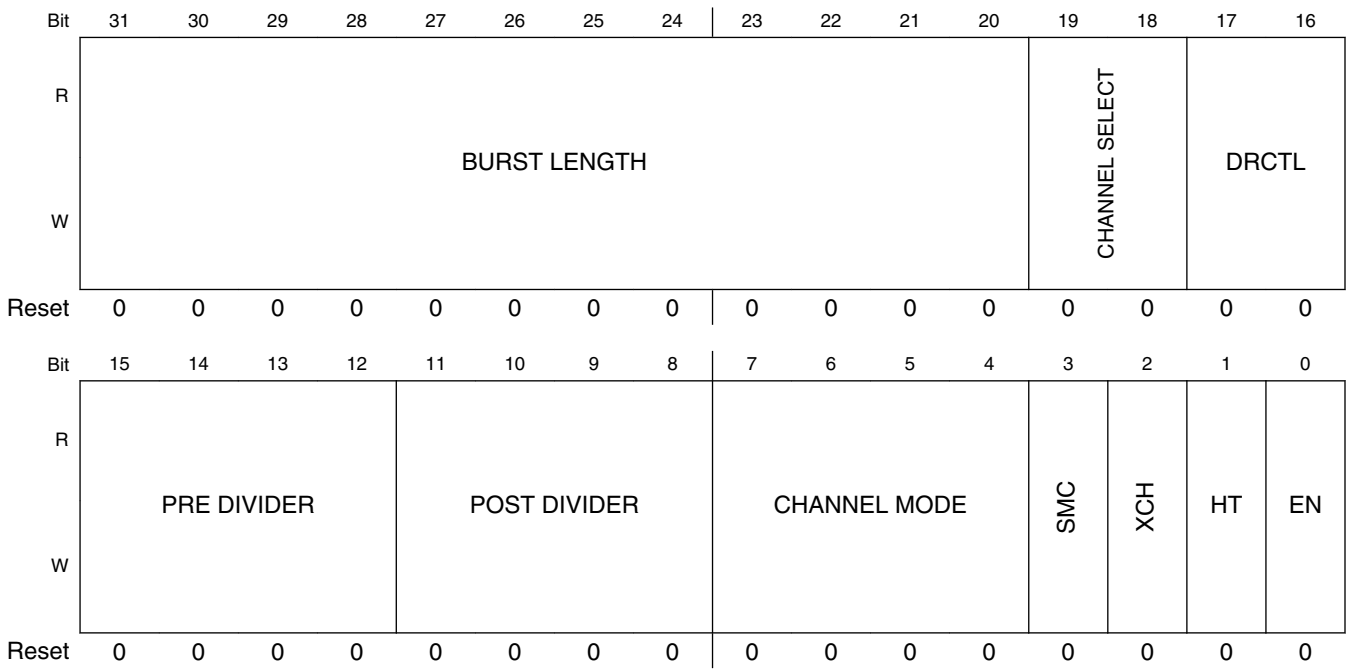
Field	Description
31–0 ECSPI_TXDATA	Transmit Data. This register holds the top word of data loaded into the FIFO. Data written to this register must be a word operation. The number of bits actually transmitted is determined by the BIT_COUNT field of the corresponding SPI Control register. If this field contains more bits than the number specified by BIT_COUNT, the extra bits are ignored. For example, to transfer 10 bits of data, a 32-bit word must be written to this register. Bits 9-0 are shifted out and bits 31-10 are ignored. When the ECSPI is operating in Slave mode, zeros are shifted out when the FIFO is empty. Zeros are read when ECSPI is disabled.

24.6.3 Control Register (ECSPIx_CONREG)

The Control Register (ECSPI_CONREG) allows software to enable the ECSPI , configure its operating modes, specify the divider value, and SPI_RDY control signal, and define the transfer length.

Addresses: ECSPI-1_CONREG is 5001_0000h base + 8h offset = 5001_0008h

ECSPI-2_CONREG is 63FA_C000h base + 8h offset = 63FA_C008h



ECSPIx_CONREG field descriptions

Field	Description
31–20 BURST LENGTH	Burst Length. This field defines the length of a SPI burst to be transferred. The Chip Select (SS) will remain asserted until all bits in a SPI burst are shifted out. A maximum of 2^12 bits can be transferred in a single SPI burst. In master mode, it controls the number of bits per SPI burst. Since the shift register always loads 32-bit data from transmit FIFO, only the n least-significant (n = BURST LENGTH + 1) will be shifted out. The remaining bits will be ignored. In slave mode, only when SS_CTL is cleared, this field will take effect in the transfer. Number of Valid Bits in a SPI burst. 0x000 A SPI burst contains the 1 LSB in a word. 0x001 A SPI burst contains the 2 LSB in a word. 0x002 A SPI burst contains the 3 LSB in a word. 0x01F A SPI burst contains all 32 bits in a word. 0x020 A SPI burst contains the 1 LSB in first word and all 32 bits in second word. 0x021 A SPI burst contains the 2 LSB in first word and all 32 bits in second word.

Table continues on the next page...

ECSPIx_CONREG field descriptions (continued)

Field	Description
	0xFFE A SPI burst contains the 31 LSB in first word and 2^7 -1 words. 0xFFF A SPI burst contains 2^7 words.
19–18 CHANNEL SELECT	SPI CHANNEL SELECT bits. Select one of four external SPI Master/Slave Devices. In master mode, these two bits select the external slave devices by asserting the Chip Select (SSn) outputs. Only the selected Chip Select (SSn) signal can be active at a given time; the remaining three signals will be negated. 00 Channel 0 is selected. Chip Select 0 (SS0) will be asserted. 01 Channel 1 is selected. Chip Select 1 (SS1) will be asserted. 10 Channel 2 is selected. Chip Select 2 (SS2) will be asserted. 11 Channel 3 is selected. Chip Select 3 (SS3) will be asserted.
17–16 DRCTL	SPI Data Ready Control. This field selects the utilization of the $\overline{\text{SPI\_RDY}}$ signal in master mode. ECSPI checks this field before it starts an SPI burst. 00 The $\overline{\text{SPI\_RDY}}$ signal is a don't care. 01 Burst will be triggered by the falling edge of the SPI_RDY signal (edge-triggered). 10 Burst will be triggered by a low level of the SPI_RDY signal (level-triggered). 11 Reserved.
15–12 PRE DIVIDER	SPI Pre Divider. ECSPI uses a two-stage divider to generate the SPI clock. This field defines the pre-divider of the reference clock. 0000 Divide by 1. 0001 Divide by 2. 0010 Divide by 3. 1101 Divide by 14. 1110 Divide by 15. 1111 Divide by 16.
11–8 POST DIVIDER	SPI Post Divider. ECSPI uses a two-stage divider to generate the SPI clock. This field defines the post-divider of the reference clock using the equation: 2^{n} . 0000 Divide by 1. 0001 Divide by 2. 0010 Divide by 4. 1110 Divide by 2^{14} . 1111 Divide by 2^{15} .
7–4 CHANNEL MODE	SPI CHANNEL MODE selects the mode for each SPI channel. CHANNEL MODE[3] is for SPI channel 3. CHANNEL MODE[2] is for SPI channel 2. CHANNEL MODE[1] is for SPI channel 1. CHANNEL MODE[0] is for SPI channel 0. 0 Slave mode. 1 Master mode.
3 SMC	Start Mode Control. This bit applies only to channels configured in Master mode (CHANNEL MODE = 1).

Table continues on the next page...

ECSPIx_CONREG field descriptions (continued)

Field	Description
	It controls how the ECSPI starts a SPI burst, either through the SPI exchange bit, or immediately when the TXFIFO is written to. 0 SPI Exchange Bit (XCH) controls when a SPI burst can start. Setting the XCH bit will start a SPI burst or multiple bursts. This is controlled by the SPI SS Wave Form Select (SS_CTL). Refer to XCH and SS_CTL descriptions. 1 Immediately starts a SPI burst when data is written in TXFIFO.
2 XCH	SPI Exchange Bit. This bit applies only to channels configured in Master mode (CHANNEL MODE = 1). If the Start Mode Control (SMC) bit is cleared, writing a 1 to this bit starts one SPI burst or multiple SPI bursts according to the SPI SS Wave Form Select (SS_CTL). The XCH bit remains set while either the data exchange is in progress, or when the ECSPI is waiting for an active input if SPIRDY is enabled through DRCTL. This bit is cleared automatically when all data in the TXFIFO and the shift register has been shifted out. 0 Idle. 1 Initiates exchange (write) or busy (read).
1 HT	Hardware Trigger Enable. This bit is used in master mode only. It enables hardware trigger (HT) mode. 0 Disable HT mode. 1 Enable HT mode.
0 EN	SPI Block Enable Control. This bit enables the ECSPI. This bit must be set before writing to other registers or initiating an exchange. Writing zero to this bit disables the block and resets the internal logic with the exception of the ECSPI_CONREG. The block's internal clocks are gated off whenever the block is disabled. 0 Disable the block. 1 Enable the block.

24.6.4 Config Register (ECSPIx_CONFIGREG)

The Config Register (ECSPI_CONFIGREG) allows software to configure each SPI channel, configure its operating modes, specify the phase and polarity of the clock, configure the Chip Select (SS), and define the HT transfer length.

Addresses: ECSPI-1_CONFIGREG is 5001_0000h base + Ch offset = 5001_000Ch

ECSPI-2_CONFIGREG is 63FA_C000h base + Ch offset = 63FA_C00Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	-			HT LENGTH					SCLK CTL				DATA CTL				SS POL				SS CTL				SCLK POL				SCLK PHA			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ECSPIx_CONFIGREG field descriptions

Field	Description
31–29 -	Reserved
28–24 HT LENGTH	HT LENGTH. This field defines the message length in HT Mode. The length in bits of one message is (HT LENGTH + 1).
23–20 SCLK CTL	SCLK CTL. This field controls the inactive state of SCLK for each SPI channel. SCLK CTL[3] is for SPI channel 3. SCLK CTL[2] is for SPI channel 2. SCLK CTL[1] is for SPI channel 1. SCLK CTL[0] is for SPI channel 0. 0 Stay high. 1 Stay low.
19–16 DATA CTL	DATA CTL. This field controls inactive state of the data line for each SPI channel. DATA CTL[3] is for SPI channel 3. DATA CTL[2] is for SPI channel 2. DATA CTL[1] is for SPI channel 1. DATA CTL[0] is for SPI channel 0. 0 Stay high. 1 Stay low.
15–12 SS POL	SPI SS Polarity Select. In both Master and Slave modes, this field selects the polarity of the Chip Select (SS) signal. SS POL[3] is for SPI channel 3. SS POL[2] is for SPI channel 2. SS POL[1] is for SPI channel 1. SS POL[0] is for SPI channel 0. 0 Active low. 1 Active high.
11–8 SS CTL	SPI SS Wave Form Select. In master mode, this field controls the output wave form of the Chip Select (SS) signal when the SMC (Start Mode Control) bit is cleared. The SS_CTL are ignored if the SMC bit is set. SS CTL[3] is for SPI channel 3. SS CTL[2] is for SPI channel 2. SS CTL[1] is for SPI channel 1. SS CTL[0] is for SPI channel 0. In slave mode, this bit controls when the SPI burst is completed. 1 An SPI burst is completed by the Chip Select (SS) signal edges. (SSPOL = 0: rising edge; SSPOL = 1: falling edge) The RXFIFO is advanced whenever a Chip Select (SS) signal edge is detected or the shift register contains 32-bits of valid data. 0 In master mode - only one SPI burst will be transmitted.

Table continues on the next page...

ECSPIx_CONFIGREG field descriptions (continued)

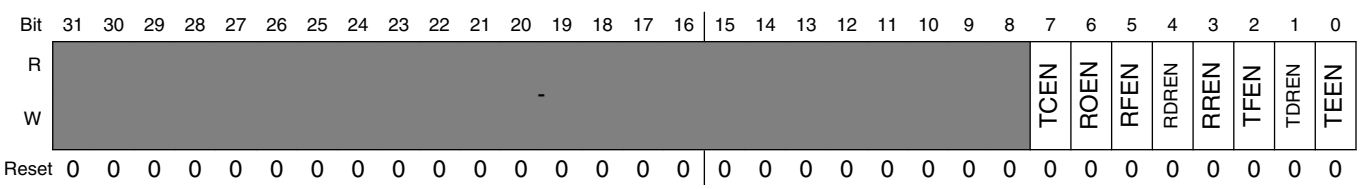
Field	Description
	1 In master mode - Negate Chip Select (SS) signal between SPI bursts. Multiple SPI bursts will be transmitted. The SPI transfer will automatically stop when the TXFIFO is empty. 0 In slave mode - an SPI burst is completed when the number of bits received in the shift register is equal to (BURST LENGTH + 1). Only the n least-significant bits (n = BURST LENGTH[4:0] + 1) of the first received word are valid. All bits subsequent to the first received word in RXFIFO are valid. 1 In slave mode - an SPI burst is completed by the Chip Select (SS) signal edges. (SSPOL = 0: rising edge; SSPOL = 1: falling edge) The RXFIFO is advanced whenever a Chip Select (SS) signal edge is detected or the shift register contains 32-bits of valid data.
7–4 SCLK POL	SPI Clock Polarity Control. This field controls the polarity of the SCLK signal. See Figure 24-10 for more information. SCLK POL[3] is for SPI channel 3. SCLK POL[2] is for SPI channel 2. SCLK POL[1] is for SPI channel 1. SCLK POL[0] is for SPI channel 0. 0 Active high polarity (0 = Idle). 1 Active low polarity (1 = Idle).
3–0 SCLK PHA	SPI Clock/Data Phase Control. This field controls the clock/data phase relationship. See Figure 24-10 for more information. SCLK PHA[3] is for SPI channel 3. SCLK PHA[2] is for SPI channel 2. SCLK PHA[1] is for SPI channel 1. SCLK PHA[0] is for SPI channel 0. 0 Phase 0 operation. 1 Phase 1 operation.

24.6.5 Interrupt Control Register (ECSPIx_INTREG)

The Interrupt Control Register (ECSPI_INTREG) enables the generation of interrupts to the host processor. If the ECSPI is disabled, this register reads zero.

Addresses: ECSPI-1_INTREG is 5001_0000h base + 10h offset = 5001_0010h

ECSPI-2_INTREG is 63FA_C000h base + 10h offset = 63FA_C010h



ECSPIx_INTREG field descriptions

Field	Description
31–8 -	Reserved
7 TCEN	Transfer Completed Interrupt enable. This bit enables the Transfer Completed Interrupt. 0 Disable 1 Enable
6 ROEN	RXFIFO Overflow Interrupt enable. This bit enables the RXFIFO Overflow Interrupt. 0 Disable 1 Enable
5 RFEN	RXFIFO Full Interrupt enable. This bit enables the RXFIFO Full Interrupt. 0 Disable 1 Enable
4 RDREN	RXFIFO Data Request Interrupt enable. This bit enables the RXFIFO Data Request Interrupt when the number of data entries in the RXFIFO is greater than RX THRESHOLD. 0 Disable 1 Enable
3 RREN	RXFIFO Ready Interrupt enable. This bit enables the RXFIFO Ready Interrupt. 0 Disable 1 Enable
2 TFEN	TXFIFO Full Interrupt enable. This bit enables the TXFIFO Full Interrupt. 0 Disable 1 Enable
1 TDREN	TXFIFO Data Request Interrupt enable. This bit enables the TXFIFO Data Request Interrupt when the number of data entries in the TXFIFO is less than or equal to TX THRESHOLD. 0 Disable 1 Enable
0 TEEN	TXFIFO Empty Interrupt enable. This bit enables the TXFIFO Empty Interrupt. 0 Disable 1 Enable

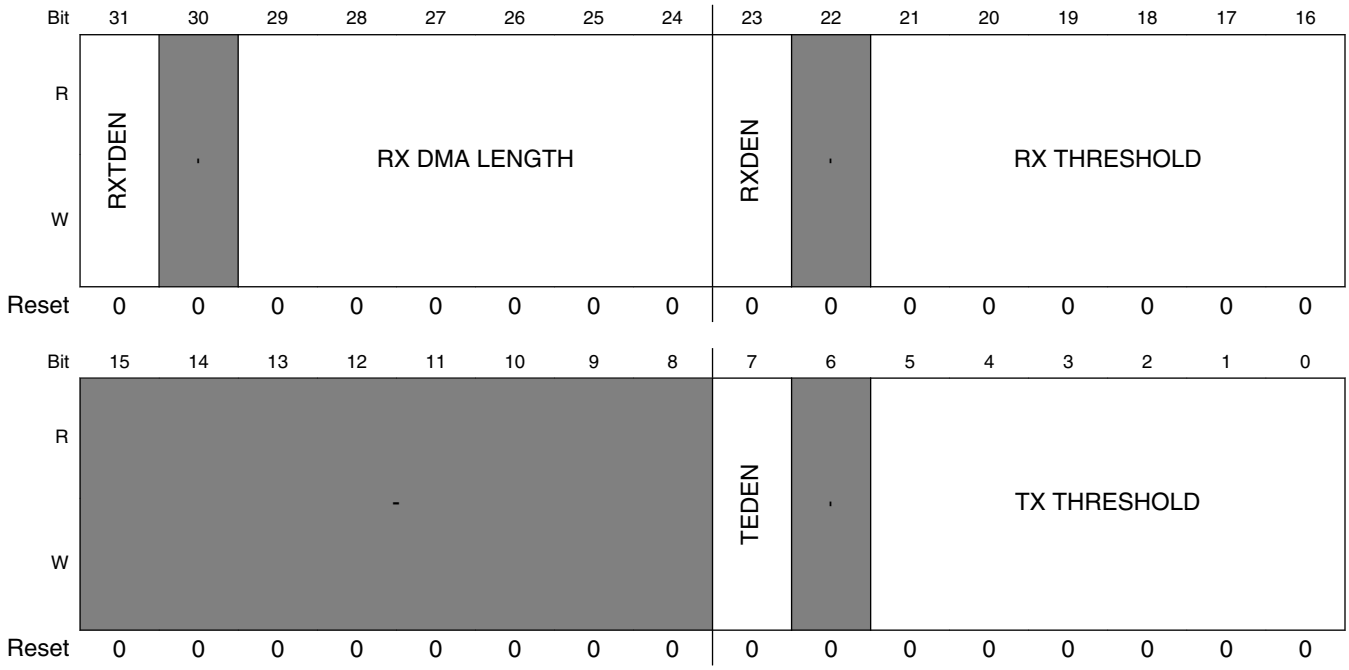
24.6.6 DMA Control Register (ECSPIx_DMAREG)

The Direct Memory Access Control Register (ECSPI_DMAREG) provides software a way to use an on-chip DMA controller for ECSPI data. Internal DMA request signals enable direct data transfers between the ECSPI FIFOs and system memory. The ECSPI sends out DMA requests when the appropriate FIFO conditions are matched.

If the ECSPI is disabled, this register is read as 0.

Addresses: ECSPI-1_DMAREG is 5001_0000h base + 14h offset = 5001_0014h

ECSPI-2_DMAREG is 63FA_C000h base + 14h offset = 63FA_C014h



ECSPIx_DMAREG field descriptions

Field	Description
31 RXTDEN	RXFIFO TAIL DMA Request Enable. This bit enables an internal counter that is increased at each read of the RXFIFO. This counter is cleared automatically when it reaches RX DMA LENGTH. If the number of words remaining in the RXFIFO is greater than or equal to RX DMA LENGTH, a DMA request is generated even if it is less than or equal to RX THRESHOLD. 0 Disable 1 Enable
30 -	Reserved
29–24 RX DMA LENGTH	RX DMA LENGTH. This field defines the burst length of a DMA operation. Applies only when RXTDEN is set.
23 RXDEN	RXFIFO DMA Request Enable. This bit enables/disables the RXFIFO DMA Request. 0 Disable 1 Enable
22 -	Reserved
21–16 RX THRESHOLD	RX THRESHOLD. This field defines the FIFO threshold that triggers a RX DMA/INT request. A RX DMA/INT request is issued when the number of data entries in the RXFIFO is greater than RX THRESHOLD.
15–8 -	Reserved
7 TEDEN	TXFIFO Empty DMA Request Enable. This bit enables/disables the TXFIFO Empty DMA Request.

Table continues on the next page...

ECSPIx_DMAREG field descriptions (continued)

Field	Description
	0 Disable 1 Enable
6 -	Reserved
5–0 TX THRESHOLD	TX THRESHOLD. This field defines the FIFO threshold that triggers a TX DMA/INT request. A TX DMA/INT request is issued when the number of data entries in the TXFIFO is greater than TX THRESHOLD.

24.6.7 Status Register (ECSPIx_STATREG)

The ECSPI Status Register (ECSPI_STATREG) reflects the status of the ECSPI's operating condition. If the ECSPI is disabled, this register reads 0x0000_0003.

Addresses: ECSPI-1_STATREG is 5001_0000h base + 18h offset = 5001_0018h

ECSPI-2_STATREG is 63FA_C000h base + 18h offset = 63FA_C018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	-															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-								TC	RO	RF	RDR	RR	TF	TDR	TE
W									w1c	w1c						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

ECSPIx_STATREG field descriptions

Field	Description
31–8 -	Reserved
7 TC	Transfer Completed Status bit. Writing 1 to this bit clears it. 0 Transfer in progress. 1 Transfer completed.
6 RO	RXFIFO Overflow. When set, this bit indicates that RXFIFO has overflowed. Writing 1 to this bit clears it. 0 RXFIFO has no overflow. 1 RXFIFO has overflowed.
5 RF	RXFIFO Full. This bit is set when the RXFIFO is full. 0 Not Full. 1 Full.

Table continues on the next page...

ECSPIx_STATREG field descriptions (continued)

Field	Description
4 RDR	RXFIFO Data Request. 0 When RXTDE is set - Number of data entries in the RXFIFO is not greater than RX THRESHOLD. 1 When RXTDE is set - Number of data entries in the RXFIFO is greater than RX THRESHOLD or a DMA TAIL DMA condition exists. 0 When RXTDE is clear - Number of data entries in the RXFIFO is not greater than RX THRESHOLD. 1 When RXTDE is clear - Number of data entries in the RXFIFO is greater than RX THRESHOLD.
3 RR	RXFIFO Ready. This bit is set when one or more words are stored in the RXFIFO. 0 No valid data in RXFIFO. 1 More than 1 word in RXFIFO.
2 TF	TXFIFO Full. This bit is set when if the TXFIFO is full. 0 TXFIFO is not Full. 1 TXFIFO is Full.
1 TDR	TXFIFO Data Request. 0 Number of empty slots in TXFIFO is greater than TX THRESHOLD. 1 Number of empty slots in TXFIFO is not greater than TX THRESHOLD.
0 TE	TXFIFO Empty. This bit is set if the TXFIFO is empty. 0 TXFIFO contains one or more words. 1 TXFIFO is empty.

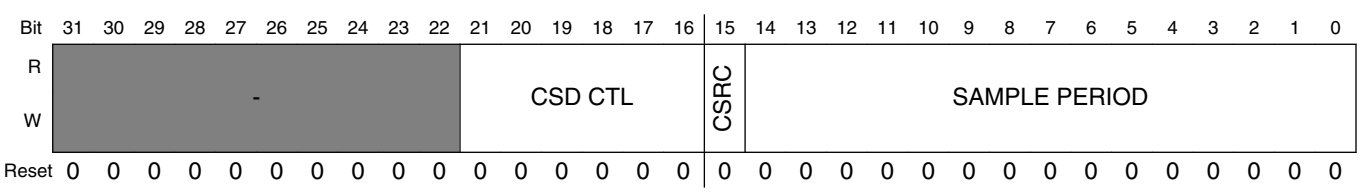
24.6.8 Sample Period Control Register (ECSPIx_PERIODREG)

The Sample Period Control Register (ECSPI_PERIODREG) provides software a way to insert delays (wait states) between consecutive SPI transfers. Control bits in this register select the clock source for the sample period counter and the delay count indicating the number of wait states to be inserted between data transfers.

The delay counts apply only when the current channel is operating in Master mode (ECSPI_CONREG[CHANNEL MODE] = 1).ECSPI_PERIODREG also contains the CSD CTRL field used to insert a delay between the Chip Select's active edge and the first SPI Clock edge.

Addresses: ECSPI-1_PERIODREG is 5001_0000h base + 1Ch offset = 5001_001Ch

ECSPI-2_PERIODREG is 63FA_C000h base + 1Ch offset = 63FA_C01Ch



ECSPIx_PERIODREG field descriptions

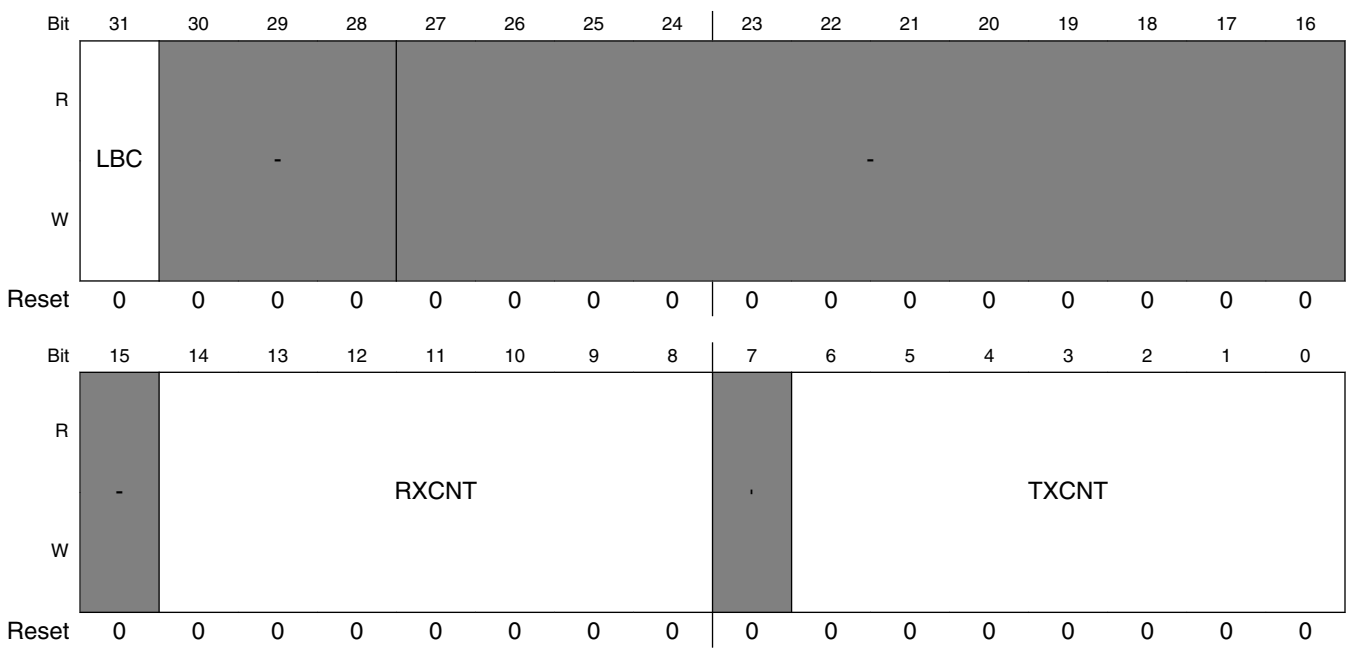
Field	Description
31–22 -	Reserved
21–16 CSD CTL	Chip Select Delay Control bits. This field defines how many SPI clocks will be inserted between the chip select's active edge and the first SPI clock edge. The range is from 0 to 63.
15 CSRC	Clock Source Control. This bit selects the clock source for the sample period counter. 0 SPI Clock (SCLK) 1 Low-Frequency Reference Clock (32.768 KHz)
14–0 SAMPLE PERIOD	Sample Period Control. These bits control the number of wait states to be inserted in data transfers. During the idle clocks, the state of the SS output will operate according to the SS_CTL control field in the ECSPI_CONREG register. 0x0000 0 wait states inserted 0x0001 1 wait state inserted ... ... 0x7FFE 32766 wait states inserted 0x7FFF 32767 wait states inserted

24.6.9 Test Control Register (ECSPIx_TESTREG)

The Test Control Register (ECSPI_TESTREG) provides software a mechanism to internally connect the receive and transmit devices of the ECSPI, and monitor the contents of the receive and transmit FIFOs.

Addresses: ECSPI-1_TESTREG is 5001_0000h base + 20h offset = 5001_0020h

ECSPI-2_TESTREG is 63FA_C000h base + 20h offset = 63FA_C020h



ECSPIx_TESTREG field descriptions

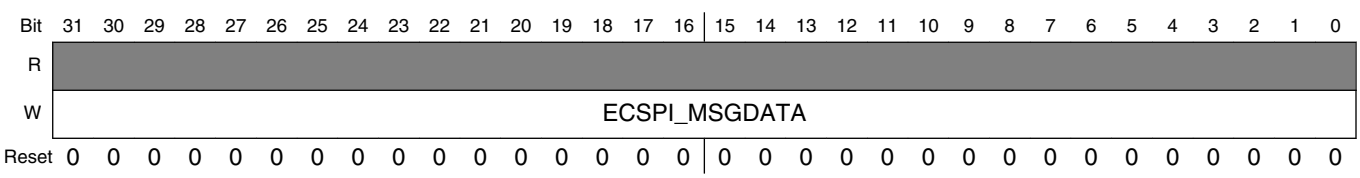
Field	Description
31 LBC	Loop Back Control. This bit is used in Master mode only. When this bit is set, the ECSPI connects the transmitter and receiver sections internally, and the data shifted out from the most-significant bit of the shift register is looped back into the least-significant bit of the Shift register. In this way, a self-test of the complete transmit/receive path can be made. The output pins are not affected, and the input pins are ignored. 0 Not connected. 1 Transmitter and receiver sections internally connected for Loopback.
30–28 -	Reserved, all bits should be ignored.
27–15 -	Reserved
14–8 RXCNT	RXFIFO Counter. This field indicates the number of words in the RXFIFO.
7 -	Reserved
6–0 TXCNT	TXFIFO Counter. This field indicates the number of words in the TXFIFO.

24.6.10 Message Data Register (ECSPIx_MSGDATA)

The Message Data Register (ECSPI_MSGDATA) forms the top word of the 16 x 32 MSG Data FIFO. Only word-size accesses are allowed for this register. Reads to this register return zero, and writes to this register store data in the MSG Data FIFO. See Hardware Trigger (HT) ModeIn hardware trigger (HT) mode, the behavior of the ECSPI is similar to master mode. The differences are in the trigger mechanism and the burst length. .

Addresses: ECSPI-1_MSGDATA is 5001_0000h base + 40h offset = 5001_0040h

ECSPI-2_MSGDATA is 63FA_C000h base + 40h offset = 63FA_C040h



ECSPIx_MSGDATA field descriptions

Field	Description
31–0 ECSPI_ MSGDATA	ECSPI_MSGDATA holds the top word of MSG Data FIFO. The MSG Data FIFO is advanced for each write of this register. The data read is zero. The data written to this register is stored in the MSG Data FIFO.

Chapter 25
External Interface Module (EIM)

25.1 Overview

The EIM handles the interface to devices external to the chip, including generation of chip selects, clock and control for external peripherals and memory. It provides asynchronous access to devices with SRAM-like interface and synchronous access to devices with NOR-Flash-like or PSRAM-like interface.

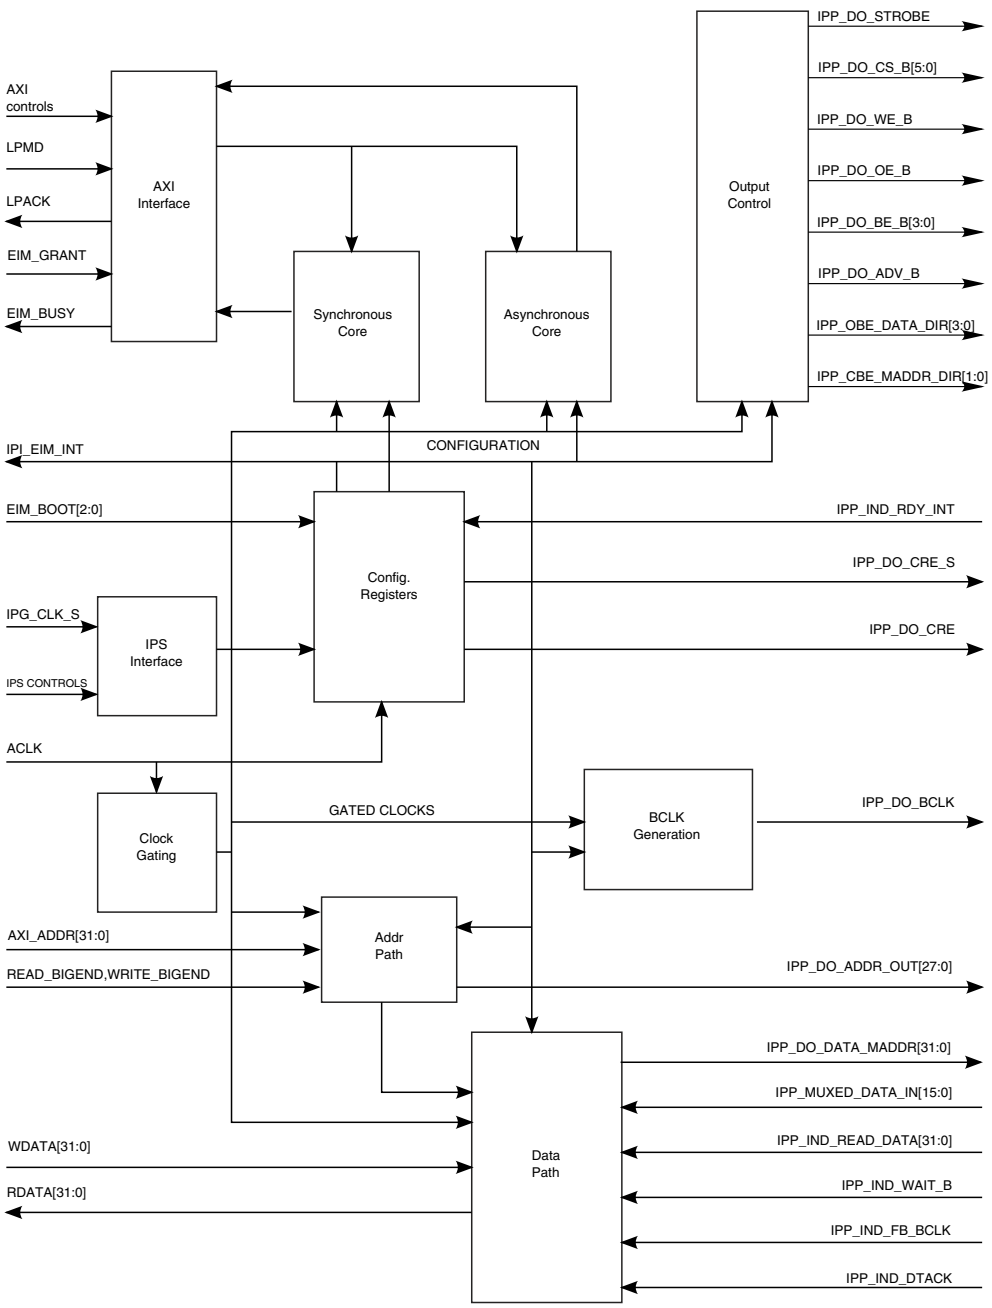


Figure 25-1. EIM Diagram

25.2 Features

- Up to four chip selects for external devices
  - Flexible address decoding. Each chip select memory space determined separately, according to VIA port configuration (see Chip Select Memory Map). Configurable Chip Select 0 base address (by VIA)
  - Individual select signal for each one of the memory space defined. Up to 6 memory spaces may be defined and programmed individually.
  - 28-bit external address bus, max memory size can be 256MByte (2 Gigabit).
- Selectable Write Protection for each Chip Select
- Support for multiplexed address / data bus operation x16 and x32 port size
- Programmable Data Port Size for each Chip Select (x8, x16 and x32)
- Programmable Wait-State generator for each Chip Select, for write and read accesses separately
- Asynchronous accesses with programmable setup and hold times for control signals
- Support for Asynchronous page mode accesses (x16 and x32 port size)
- Independent synchronous Memory Burst Read Mode support for NOR-Flash and PSRAM memories (x16 and x32 port size)
- Independent synchronous Memory Burst Write Mode support for PSRAM and NOR-Flash like memories (CellularRAM™ from Micron, Infineon, and Cypress, OneNAND™ and utRAM™ from Samsung, and COSMORAM™ from Toshiba)
- Support of NAND-Flash devices with NOR-Flash like interface - MDOC™ (M-Systems), OneNAND™ (Samsung)
- Independent programable variable/fix Latency support for read and write synchronous (burst) mode
- Support for Big Endian and Little Endian operation modes per access
- ARM AXI slave interface. One ID at a time support.
- External Interrupt support, RDY_INT signal function as external interrupt
- Boot from external device support according to boot signals, using RDY_INT signal
  - RDY signal support assertion after reset for MDOC™ (M-Systems) device
  - INT signal support assertion after reset for OneNAND™ (Samsung) device

25.3 Modes of Operation

The EIM has the following modes of operation:

- Asynchronous Mode
- Asynchronous Page Mode
- Multiplexed Address/Data mode

- Burst Clock Mode
- Low Power Modes
- Boot Mode

See details in the EIM Operational Modes.

25.3.1 Asynchronous Mode

This is a non-burst mode that is used for SRAM access. In this mode, a single data is read/written with each access (asserted address).

All controls' timings are controlled by preset values in Chip Select Configuration Registers.

25.3.2 Asynchronous Page Read Mode

Setting the APR bit causes the EIM to perform memory burst accesses by emulating page mode operation.

The external address asserts for each piece of data. The initial access timing is according to RWSC field, and the next address assertions timing is according to PAT field. When APR bit is set, RCSN OEN, RADVN and RBEN fields are ignored for burst access to the external device.

The page size can be set via the BL field to 2, 4, 8, 16, or 32 words (the word size is determined by the DSZ field).

25.3.3 Multiplexed Address/Data Mode

In this mode, multiplexing addresses and data bits on the same pins is supported for synchronous/asynchronous accesses to x8/x16/ x32 data width memory devices.

For more information about the pins that drive data/address in 8/16/32 non-muxed mode and 16/32 muxed mode, refer to the EIM Internal Module Multiplexing table in the EIM Internal Pads Allocation chapter of the datasheet.

Table 25-1. EIM multiplexing

Setup	Non Multiplexed Address/Data Mode						Multiplexed Address/ Data mode	
	8 Bit			16 Bit		32 Bit	16 Bit	32 Bit
	MUM = 0, DSZ = 100	MUM = 0, DSZ = 101	MUM = 0, DSZ = 111	MUM = 0, DSZ = 001	MUM = 0, DSZ = 010	MUM = 0, DSZ = 011	MUM = 1, DSZ = 001	MUM = 1, DSZ = 011
A[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]	EIM_DA[15:0]
A[25:16]	EIM_A[25:16]	EIM_A[25:16]	EIM_A[25:16]	EIM_A[25:16]	EIM_A[25:16]	EIM_A[24:16][1]	EIM_A[25:16]	EIM_A[8:0]
D[7:0], EIM_EB0	NANDF_D[7:0]	-	-	NANDF_D[7:0][2]	-	NANDF_D[7:0]	EIM_DA[7:0]	EIM_DA[7:0]
D[15:8], EIM_EB1	-	NANDF_D[15:8]	-	NANDF_D[15:8][3]	-	NANDF_D[15:8]	EIM_DA[15:8]	EIM_DA[15:8]
D[23:16], EIM_EB2	-	-	-	-	EIM_D[23:16]	EIM_D[23:16]	-	NANDF_D[7:0]
D[31:24], EIM_EB3	-	-	EIM_D[31:24]	-	EIM_D[31:24]	EIM_D[31:24]	-	NANDF_D[15:8]

1. For 32-bit, the address range is A[24:0], due to address space allocation in memory map.
2. NANDF_D[7:0] multiplexed on ALT3 mode of PATA_DATA[7:0]
3. NANDF_D[15:8] multiplexed on ALT3 mode of PATA_DATA[15:8]

25.3.4 Burst Clock Mode

The controller has the ability to support a burst synchronous operations in a various frequencies, depending on the frequency of the input clock supplied by the system (EIM clock).

The EIM clock can be divided by one, two, three or four, and its frequency can be changed according to the requirements. Variable and fix latency are supported for this mode, according to the external device requirements.

- Synchronous read mode. This is a burst mode, which is used for reading from Flash/ PSRAM memory devices. In this mode, after address assertion a burst of sequential data can be read. Data exchange is carried out according to BCLK being generated by EIM. An access is delayed according to external WAIT_B signal assertion (signal from the memory device).
- Synchronous write mode. A burst mode used for accessing external devices, which support synchronous write type of access (PSRAM protocol). In this mode, after address assertion a burst of sequential data can be written to the external device. Access may be delayed according to WAIT_B signal assertion (signal from the memory device) before first piece of data arrived to the external device.

NOTE

Maximum frequency of the EIM main clock is 133Mhz. It may be reduced by the system for special cases of external devices, which demand a different frequency then integer division of the 133MHz clock.

25.3.5 Low Power Modes

The Input Clock is gated by ACT_CS bits. When all the ACT_CS are negated (all CS disable) the internal clock is turned off; awready/wready & arready signal are de-asserted and the master can't access the EIM.

25.3.6 Boot Mode

It is possible to perform a boot operation from external device located on CS0. The configuration of the relevant bits are done with boot Mode signals according to the external device parameters (for example, port size and protocol assertion).

See System Boot for more details.

Table 25-2. EIM Boot configuration

EIM_BOOT bits	EIM affected bits	EIM Register	Boot Value
2	MUM OEA	EIM_CS0GCR1 EIM_CS0RCR1	Configurable by fuses; If SRC.SBMR[BOOT_CFG2[7:6]] = 0b00, value = 0x100 If SRC.SBMR[BOOT_CFG2[7:6]] = 0b00, value = 0x010
[1:0]	DSZ[1:0]	EIM_CS0GCR1	

25.4 External Signal Description

25.4.1 Signals Overview

Table 25-3. Block I/Os

Name	Function	Input / Output	Notes
WEIM_A[26:16]	Address Bus MSB	Output	

Table continues on the next page...

Table 25-3. Block I/Os (continued)

Name	Function	Input / Output	Notes
WEIM_DA[15:0]	Address/Data Bus LSB	I/O	NFC data lines can be multiplexed on these lines as well
EIM_NFC_D[15:0]	Data LSB	I/O	The EIM LSB data signals can be shared with the NFC data lines through a multiplexor in the EXTMC module, so the EIM LSB data signals can be routed out through either the EIM_NFC_D[15:0] path OR the EIM_DA[15:0] path
WEIM_BCLK	Burst Clock	Output	
WEIM_CRE	Memory Register Set	Output	
WEIM_CS[5:0]	Chip Selects	Output	
WEIM_DTACK_B	Data Acknowledge	Input	
WEIM_D[31:16]	Data MSB	I/O	
WEIM_EB[3:0]	Enable Byte Signals	Output	
WEIM_LBA	Load Burst Address	Output	
WEIM_OE	Output Enable	Output	
WEIM_RW	Read/Write	Output	
WEIM_WAIT	Memory Ready/Busy/Wait	Input	

25.4.2 Detailed Signal Descriptions

The following is a detailed description of the EIM signals mentioned in Table 25-3.

Table 25-4. Block I/O Descriptions

Name	I/O	Description
WEIM_A[26:16]	O	MSB Address Bus
WEIM_DA[15:0]	I/O	LSB multiplexed Address/Data Bus
EIM_NFC_D[15:0]	I/O	LSB Data Bus (multiplexed with NFC data bus signals)
WEIM_BCLK	O	Burst Clock (BCLK). This active-high output signal is used to clock external burst-capable devices to synchronize the loading and incrementing of addresses and delivery of burst read and write data to/from the EIM. Its behavior is affected by the BCM field in the EIM_WCR and the SWR, SRD, BCD, and BCS fields of the EIM_CSxGCR1.
WEIM_CRE	O	Used as CRE/PS for CellularRam memory. It is used for the Mode Register Set command. This signal can be configured as active low or active high. See CRE and CREP field descriptions of the EIM_CSxGCR1 registers.
WEIM_CS[5:0]	O	Chip Selects. These signals are active-low. Behavior is affected by the RCSA and RCSN fields of the EIM_CSxRCR1 registers and the WCSA and WCSN fields of the EIM_CSxWCR1registers.
WEIM_DTACK_B	I	Data Acknowledge, asynchronous access. This input is used as a data acknowledge signal for single asynchronous accesses.

Table continues on the next page...

Table 25-4. Block I/O Descriptions (continued)

Name	I/O	Description
WEIM_D[31:16]	I/O	MSB Data Bus
WEIM_EB[3:0]	O	Byte Enable. These active-low output signals indicate valid data bytes for the current access. They may be configured to assert for write cycles only. EIM_EB[0] corresponds to DATA_OUT[7:0] EIM_EB[1] corresponds to DATA_OUT[15:8] EIM_EB[2] corresponds to DATA_OUT[23:16] EIM_EB[3] corresponds to DATA_OUT[31:24]. For asynchronous write accesses, behavior is affected by the WBEA and WBEN fields of the EIM_CS1WCR1-EIM_CS5WCR1 Registers. On synchronous or asynchronous read accesses, these signals are always asserted at the start of the access and negated at end of the access.
WEIM_LBA	O	Address Valid. This active-low output signal is asserted during burst mode accesses to cause the external burst capable device to load a new starting burst address. Assertion of LBA indicates that a valid address is present on the address bus. Its behavior is affected by the SWR, SRD, BCD, and BCS fields of the EIM_CSxGCR1 registers, the RADVA and RADVN fields of the EIM_CSxRCR1 registers, and the WADVA and WADVN fields of the EIM_CSxWCR1 registers. In asynchronous mode, LBA length is affected by the RADVA, WADVA, RADVN, and WADVN fields. Minimum length of LBA signal in all modes is one EIM clock cycle.
WEIM_OE	O	Output Enable. This active-low output signal indicates the bus access is a read and enables external devices to drive the data bus with read data. Its behavior is affected by the OEA and OEN bit fields in the Chip Select Configuration Registers.
WEIM_RW	O	Memory Write Enable. This active-low output signal indicates the bus access is a write and enables external devices to sample the data bus. Its behavior is affected by the WEA and WEN bit fields in the Chip Select Configuration Registers.
WEIM_WAIT	I	Ready/Busy/Wait signal. This active-low input signal is asserted by external burst capable devices which support fixed or variable latency of data. It is serviced in synchronous mode only (EIM_CSxGCR1[SWR, SRD] =1). WAIT will have a pull up resistor in I/O. The signal indicates whether the External device is ready for data transaction or not. Busy cycles (or wait cycles) of the external device can occur at the start of a Burst access or at page boundary crossover. **NOTE:** For burst devices, WAIT output should be configured to change one cycle before data is ready (before delay). **NOTE:** Some External devices may not use this input signal for ready state indication (fix latency without WAIT signal monitoring). For these devices EIM should be configured accordingly (see RFL, WFL, and PSZ field descriptions). **NOTE:** This is same as what is shown in IP_IND_WAIT_B

25.4.3 Other Important Block I/O Signals Internal to the SoC

The following table provides a description of other signals which are internal to the i.MX53 that are important to understand the function of EIM.

Name	I/O	Description
WEIM_FB_BCLK	Input	Burst Clock Feedback. This block input is used to sample read data during high transfer speeds. The signal provides feedback from the I/O pad of the BCLK output pin and tends to align more closely with data from the external memory device.
EIM_BOOT[2:0]	Input	EIM Boot Configuration. These block inputs determine the reset state of DSZ[1:0] and MUM. See Table 5-4 for detailed description.
ACLK	Input	AXI clock, maximum frequency 133 Mhz
IPG_CLK_S	Input	EIM module IPG clock
RST_B	Input	Active low HW reset
EIM_WARM_RESET	Input	Warm Reset. If this signal is asserted the rst_b will reset only the internal FF and state machine while S/W registers will keep their current state.This signal is active high signal.

25.5 Chip Select Memory Map

Table 25-6. EIM Chip Select Memory Map

Address	Space Size	Use	Access
EIM_NFC_BASE/ACT_CS/ADDRS0 inputs	0MB-256MB	CS0 memory region	R/W
ACT_CS/ADDRS1 inputs	0MB-256MB	CS1 memory region	R/W
ACT_CS/ADDRS2 inputs	0MB-256MB	CS2 memory region	R/W
ACT_CS/ADDRS3 inputs	0MB-256MB	CS3 memory region	R/W

25.6 Functional Description

This section provides the functional description for the EIM.

25.6.1 Clocks

The EIM has four input clocks.

- ACLK: EIM clock (main clock, AXI clock) with a Max frequency of 133Mhz. Can be gated externally when there is no active AXI access.
- ACLK_SLOW: EIM all time running ACLK. Used for FF that must be active even when EIM is in low power down mode to provide clock for lpack/lpmd registers, IP registers and IP to AXI sync registers.
- IPG_CLK_S: IPG clock for IP accesses. IP registers are activated by ACLK_SLOW clock. BCLK is a clock created from EIM clock for External device usage. Integer division by 1, 2, 3 and 4 of the clock can be use with BCD bit field configuration,

according to external devices demands. EIM clock frequency may be reduced for lower frequency support which cannot be achieved via BCD bit field.
- FB_CLK: BCLK after pads delays.

25.6.2 Bus Sizing Configuration

The EIM supports byte, half word and word operands allowing access to x8, x16, x32 ports. It can be address/data multiplexed in x16, x32 ports. The port size is programmable via the DSZ bit field in the corresponding Chip Select Configuration Register. An 8-bit port can reside in each one of the bytes of the data bus. A 16-bit port can reside on the lower 16 bits of the data bus, DATA_IN/OUT[15:0] or on the higher 16 bits of the data bus, DATA_IN/OUT[31:16] (see Table 25-1).

In the case of a multi-cycle transfer, the lower two address bits (ADDR[1:0]) are incremented appropriately. The EIM address bus is configured according to DSZ bit field and AUS bits. There is either one bit (for x16 port size) or two bits (for x32 port size) right shift of the address bits (only when AUS=0) and no bit shift when AUS = 1 or DSZ[2] = 1.

The EIM has a data multiplexer which takes the four bytes of the AXI data bus and routes them to their required positions to properly interface to memory.

NOTE

A word access to or from a x16 port requires two external bus cycles to complete the transfer.

A word access to or from a x8 port requires four external bus cycles to complete the transfer.

25.6.2.1 8 BIT PORT SUPPORT

EIM has limited support for mot68000 & intel 386 protocols.

25.6.2.1.1 MOTOROLA 68000

EIM has limited support for mot68000 protocol. Only basic read or write asynchronous operations are supported.

The following operations are not supported:

- Read modify write
- Sync access

- All special accesses (ARM platform space, bus arbitration, bus control, bus error & reset operations)
- FC outputs

25.6.2.1.2 INTEL 386

EIM has limited support for intel 386 protocol. Only basic read or write async non-pipelined operations are supported.

The following operations are not supported:

- Other bus cycles (interrupt, halt & refresh)
- Bus lock
- M/IO, DC, LBA, NA, REFRESH & BS8 signals

25.6.3 EIM Operational Modes

EIM has the following main operational modes selected by control bit fields settings. For details, see the bit field descriptions of SWR / SRD / MUM. All modes are supported in with 8-, 16- or 32-bit port configuration, according to DSZ bit field.

Table 25-7. EIM Operation Modes Field Settings

Control bit fields			Brief mode description
MUM	SRD	SWR	
0	0	0	Asynchronous write / Asynchronous read for APR=0 / Asynchronous page read for APR=1, none multiplexed
		1	Synchronous write/ Asynchronous read or APR=0 / Asynchronous page read for APR=1,none multiplexed
	1	0	Asynchronous write/Synchronous read none multiplexed
		1	Synchronous write/read none multiplexed
1	0	0	Asynchronous write/read multiplexed
		1	Synchronous write/ Asynchronous read multiplexed
	1	0	Asynchronous write/Synchronous read multiplexed
		1	Synchronous write/read multiplexed

25.6.4 Burst Mode (Synchronous) Memory Operation

This mode is enabled for read or write access. Bit SWR sets the burst mode for write operations at the corresponding chip select and bit SRD sets it for read operation.

When this mode is set, the controller attempts to translate the Master burst accesses to memory burst accesses, being limited by the memory burst length, predefined by BL value, or memory and Master WRAP/INCR boundary crossing non-matching. Only the first address accessed is displayed by the controller on the external address bus in a memory burst sequence.

EIM may translate from some Master sequential accesses to one or few memory bursts, but not from two Master individual accesses to one memory burst.

For the first access in a memory burst sequence, the EIM asserts $\overline{\text{ADV}}$, causing the external burst device to latch the starting burst address; then toggle the burst clock (BCLK) a predefined number of cycles in order to latch the first unit of data. Subsequent accessed data units can then be burst in fewer clock cycles, realizing an overall increase in bus bandwidth.

NOTE

The BCLK signal toggles only when burst access is executed toward the external device (BCM=1'b0 for normal mode use). It runs with a 50% duty cycle until the end of access is reached. When access is terminated, BCLK stops toggling.

Memory burst accesses are terminated by the EIM whenever it detects the following:

- The specific burst length has executed completely (end of access)
- Write access - missing data in write buffer (Master is delaying the data transfer toward the EIM)
- Next sequential access crosses boundary with unequal condition (wrap/increment, burst length) on the Master and memory
- Current memory burst length reached

25.6.5 Burst Clock Divisor (BCD)

In some cases, it may be necessary to slow the external bus in relation to the internal bus to allow accesses to burst devices that have a maximum operating frequency less than the operating frequency of the internal bus.

The internal bus frequency can be divided by one, two, three or four for presentation on the external bus in burst mode operation.

To achieve frequency of BCLK other then an integer division, the cycle time of the EIM clock entering the controller must be changed accordingly.

By programming the BCD bit field to various values, two signals on the external bus are affected; $\overline{ADV}$ and BCLK. The $\overline{ADV}$ signal is asserted according to RADVA or WADVA bit fields programming, and is negated according to the formula mentioned in RADVN and WADVN bit fields description. The BCLK signal runs with a 50% duty cycle until the end of access is reached.

If BCM = 1, the BCLK runs at frequency according to GBCD bit field settings on every async memory access, regardless of the SWR and SRD bits configuration. Caution should be exercised when using BCM bit; GBCD bit field should be updated once and should not change when BCLK is toggling. The BCM bit is used mainly for system debug mode. It has no functional use of the EIM in normal mode.

25.6.6 Burst Clock Start (BCS)

In an effort to allow greater flexibility in achieving the minimum number of wait states on burst accesses, you can determine when you want the BCLK to start toggling after the start of access. This allows the BCLK to be skewed from point of data capture on the EIM clock by any number of EIM clock cycles.

Care must be exercised when setting BCS bit field in conjunction with the BCD and RWSC/WWSC bit fields. See the external timing diagrams in "Burst Memory Accesses Timing Diagrams" for examples of how to use the BCS, BCD and RWSC/WWSC bit fields together.

25.6.7 Multiplexed Address/Data Mode Support

The control bit MUM allows support memory with multiplexed address/data bus both in asynchronous and in synchronous modes.

Caution should be exercised for using OEA/WEA & ADH bit fields. They should be configured according to the external device requirements, as it determines the time point of end of address phase and start of data phase.

25.6.8 Mixed Master/Memory Burst Modes Support

To provide mixed sequential/wrap accesses with different length, EIM interprets burst signal and generate additional $\overline{ADV}$ signals whenever there appear unequal address or burst boundary crossing condition.

BL bit field is used to notify EIM about current memory burst and wrap condition for properly external address generation. In case of non-matching boundaries in both the memory and Master access, EIM starts a new memory burst access by updating address from Master on address bus and generating $\overline{\text{ADV}}$ signal.

25.6.9 AXI (Master) Bus Cycles Support

The EIM uses an ARM AXI slave interface. It has a 32-bit bus and supports one access (one ID) at a time. No out of order or parallel accesses are supported.

The following AXI protocol signals are not supported:

- AWLOCK
- AWCACHE
- ARLOCK
- ARCACHE

ARID bus is sampled when:

- new read access is valid on the read address channel and is reflected on the RID bus output toward the master.

AWID bus is sampled when:

- new write access is valid on the write address channel and is reflected on the WID/ BID bus output toward the master.

ARPROT and AWPROT signal are partially used. ARPROT[0] and AWPROT[0] bits are used for normal/privileged access detection. ARPROT[2:1] and AWPROT[2:1] are not used.

When sampling a valid access on both of the address channels, the read access will be performed first while write access is pending. After last data transfer completed, the pending write will be executed.

A new access may be executed one cycle after sampling a valid access on the read or write address channels. Assuming there is no current access (back to back) which can cause a recovery or end of access penalty cycles; for write access, data should be present at write buffer for fast execution.

NOTE

- Only 32-bit word size accesses are supported for burst mode accesses.
- Only 8-bit (1 byte), 16-bit (2 byte) and 32-bit (4 byte) word size supported for single access.

- Maximum number of burst length is 16.
- According to AXI protocol, burst access should not cross 4 KB blocks. In case EIM gets an access that crosses the 4 KB, memory address calculation is invalid.

AXI transfers shown in the table below are also supported. These AXI cycles will be translated into the necessary cycles on the memory side. For example, for optimal operation in case ARM cache is configured to 8 beat burst with wrap, a synchronous flash and cellular RAM memory should be configured in 16 word wrap burst mode when using a 16-bit data port, and in 8 word wrap burst mode when using a 32-bit data port. EIM uses BL bit field to support different memory configurations. The controller splits the transaction when needed in some cases. See Table 25-9.

Table 25-8. AXI Burst Cycles Supported

Burst Length - Number of data transfers	Burst size - Bytes in transfer	Burst type	Description
1	1	INCR	Single transfer
1	2	INCR	Single transfer
1	4	INCR	Single transfer
2	4	WRAP	2-beat wrapping burst
4	4	WRAP	4-beat wrapping burst
8	4	WRAP	8-beat wrapping burst
16	4	WRAP	16-beat wrapping burst
2	4	INCR	2-beat incrementing burst
3	4	INCR	3-beat incrementing burst
4	4	INCR	4-beat incrementing burst
5	4	INCR	5-beat incrementing burst
6	4	INCR	6-beat incrementing burst
7	4	INCR	7-beat incrementing burst
8	4	INCR	8-beat incrementing burst
9	4	INCR	9-beat incrementing burst
10	4	INCR	10-beat incrementing burst
11	4	INCR	11-beat incrementing burst
12	4	INCR	12-beat incrementing burst
13	4	INCR	13-beat incrementing burst
14	4	INCR	14-beat incrementing burst
15	4	INCR	15-beat incrementing burst
16	4	INCR	16-beat incrementing burst

Table 25-9. AXI to Memory Burst Splits Number

AXI Burst Type	Memory Burst Type Config.	# of accesses to X8 Memory Port size	# of accesses to X16 Memory Port size	# of accesses to X32 Memory Port size
INC16 Aligned Addr.	WRAP4	16	8	4
	Cont.	1	1	1
INC16 Unaligned Addr.	WRAP4	17	9	5
	Cont.	1	1	1
WRAP16 Aligned Addr.	WRAP16	4	2	1

INC8 Aligned Addr.	WRAP8	4	2	1
	WRAP16	2	1	1
INC8 Unaligned Addr.	WRAP8	4 or 5	2 or 3	2
	WRAP16	2 or 3	2	1 or 2
WRAP8 Aligned Addr.	WRAP16	2	1	1
	Cont.	1	1	1
WRAP8 Unaligned Addr.	WRAP16	2 or 3	1	2
	Cont.	2	2	2

25.6.10 WAIT_B Signal, RWSC and WWSC bit fields Usage

Most of the external devices supporting burst mode for write or read accesses providing signal which indicates for data valid on the memory bus (a.k.a. handshake mode). For this mode, RFL and WFL bits should be cleared and RWSC/ WWSC bit fields indicate when the controller should start sampling this signal from the external device or, in other words, how many BCLK cycles should be masked.

For devices which are not using this signal or have a fixed latency ability, the RFL and WFL bits may be set for internal calculation regarding BCLK cycles penalty until data is valid (memory initial access time). For this mode, RWSC/ WWSC indicates when the data is ready for sampling by the controller (read access) or the external device (write access). There is separation between read and write accesses wait-state control. For read access, RWSC bit field is valid and WWSC bit field is ignored; for write access, WWSC is valid and RWSC is ignored.

25.6.11 IPS Register Interface

Access to the registers of the EIM, read or write, is made with IPS protocol signals. The system should avoid changing the registers while master/memory transaction is valid, as this can cause an unknown behavior of the controller.

Register access size is 32-bit as the register size definition, other size of access (byte or half word) is not supported.

25.6.12 MRS Set for PSRAM

Memory registers of PSRAM devices can be configured according to external signal, which indicates whether the access is to a memory array or memory register domain.

When the CRE bit is set, the following transactions to the external device will assert the CRE signal. The polarity of this signal is determined by the CREP bit for active low or active high assertion of the signal.

25.6.13 EIM Access Termination

EIM is monitoring the corresponding CSx control signal every time variable latency access or dtack access is performed toward the external device.

In variable latency accesses, the Watchdog Timer (WDOG-1) counts BCLK cycles. If it reaches the wdog_limit (according to the WDOG_LIMIT bit field in the WCR) before the device signals can drive/sample new data, the controller will terminate the access and generate an error response transfer toward the Master.

In dtack access, WDOG-1 counts ACLK cycles instead of BCLK and it reaches the wdog_limit before the device asserts the dtack signal, the controller will terminate the access and generate an error response transfer toward the Master.

WDOG-1 can by disabled by WDOG_EN bit in the WCR.

25.6.14 Error Conditions

The following conditions cause an error (AXI error or IPS error) response signal:

- AXI errors
  - Access to a disabled chip select - access to a mapped chip select address space where the CSEN bit in the corresponding chip select Configuration Register is clear

- Access to a non mapped address - access to an address that is not mapped to any CS.
- User access to a supervisor-protected chip select address space (the SP bit in the corresponding chip select Configuration Register is set)
- User access in fixed mode access
- User preform write access to write protected chip select
- First write data ID and write address ID do not match. (No data is written to the memory.)
- First Write Data ID and write address ID match but one or more of the other Write data IDs does not match the First Write data ID (data is written to memory according)
- Access duration to external device from CSx signal assertion is 128/256/512/1024 cycles (access is terminated by the controller) - This error can be disabled be software.

- IPS errors
  - User read or write access to a reserved/non-valid address in the EIM Configuration Register

25.6.15 DTACK Mode

In DTACK mode, the EIM uses DTACK signal as an indication of when to end the access.

DTACK is an asynchronous edge/level sensitive signal. DTACK polarity is configurable by the DAP bit in CsxGCR2 (default value is 0).

In this case, EIM begins the access and after a few cycles (according DAPS field) and waits until DTACK (after synchronization) becomes asserted, then samples the data in read access and completes the current data access (see Figure 25-13, Figure 25-14 & Figure 25-15).

If more than one data is needed, CS will be negated between access (csrec field is not zero) and the AXI burst access will be split into single accesses (see Figure 25-17).

25.6.16 RDY_INT Signal as Interrupt

The EIM has an external interrupt support. When INTEN bit in the WCR is set, signal RDY_INT is used as interrupt; its status is being reflected by INT bit and output signal.

It is cleared by writing one to the INT bit. When INTEN is cleared, the interrupt is disabled. This interrupt is a level interrupt and its polarity can be configured by the INTPOL bit in the WCR.

25.6.17 RDY_INT Signal as Ready After Reset Indication

This feature is used for boot propose from external devices based on NANDFlash array memory with NORFlash interface.

When ERRST bit is set, RDY_INT signal is monitored to determine ready after reset of the external device located on CS0.

The monitoring is taking place when CS0 is accessed for the first time. The access will be pending until assertion of the signal is detected. When detection occurs, ERRST bit is self-cleared and pending access is executed to the external device on CS0.

25.6.18 EIM_GRANT / EIM_BUSY Handshake Description

Prior to executing command to one of the external device (chip select), EIM assert EIM_BUSY signal (1'b1) and checks the EIM_GRANT signal status.

If EIM_GRANT signal is high, it indicates external data bus is not used by other slaves (NAND Flash Controller) and EIM may start to execute the access. If EIM_GRANT is low, EIM waits until it is set (1'b1) before executing the access.

EIM keeps EIM_BUSY signal set until it completes the access toward the external device.

Once EIM_GRANT signal is set, it can not be reset until EIM_BUSY signal is cleared by EIM.

NOTE

In 16-bit Muxed EIM doesn't use the data bus, therefore there is no sharing of the data bus with NFC. EIM doesn't wait for EIM_GRANT signal from NFC and doesn't assert the EIM_BUSY signal.

25.6.19 LPMD / LPACK Handshake Description

These signals are used for frequency and/or voltage change, and for entering low power mode during normal operation of the EIM. Before any change can take place, the controller and all the relevant external devices should be in idle state, which means no access or data transfer is in process.

LPMD input signal is asserted once EIM detects the assertion of LPMD, all ready signals of the AXI channels are negated, and EIM is not sampling new accesses. It finishes all the ongoing accesses and already pending ones. When EIM is in idle state, the LPACK output signal is asserted. EIM will stay in idle state and the LPACK signal will stay asserted until the LPMD signal is negated.

25.6.20 Endianness

Big and Little endianness are supported by the controller according to the following table.

Table 25-10. EIM Out/in Data in Case AXI Out/in Data is 0xB3B2B1B0

Endian mode	AXI access	AXI address [1:0]	Port size and used bits								
			Word port				Half word port			Byte port	
			[31:24]	[23:16]	[15:8]	[7:0]	External address [0]	[31:24] ([15:8])	[23:16] ([7:0])	External address [1:0]	[31:24] ([23:16]) ([15:8]) ([7:0])
Big	Word	0	0xB3	0xB2	0xB1	0xB0	0	0xB3	0xB2	0	0xB3
										1	0xB2
							1	0xB1	0xB0	2	0xB1
										3	0xB0
	Half Word	0			0xB1	0xB0	0	0xB3	0xB2	0	0xB3

		1			0xB1			0xB1		1	0xB1
		2		0xB2			1		0xB2	2	0xB2
		3	0xB3					0xB3		3	0xB3

25.6.21 Strobe Signal Use

The strobe signal is toggling according to address/data valid condition on the external bus for read and write accesses, and for both synchronous and asynchronous modes.

At any time point when address/data is valid on the external bus, the strobe signal will generate a positive edge, which can be used to sample the external data and control signal.

NOTE

Strobe signal for read data is active (RL + 1) cycles after data on external bus is valid.

25.7 Initialization Information

25.7.1 Booting from EIM

EIM is ready to work with CS0 after the hardware reset, but it has been configured for very slow access (for boot purposes), with additional setup and hold time.

Other CSs are disabled by hardware reset. Therefore, all CSs must be properly initialized before use in writing values to the corresponding chip select configuration registers.

DSZ[1:0] and MUM fields are set according to EIM_BOOT [2:0] block inputs.

25.8 Application Note

Application note uses next functions to illustrate EIM and memory accesses:

- WR16(address, data) is a 16 bit write access
- WR32(address, data) is a 32 bit write access
- RD16(address, data) is a 16 bit read access
- RD32(address, data) is a 32 bit read access
- WR_I(address, data, delta, counter) is a write data sequence, there data(i+1) = data(i) + delta
- COMMAND_SEQUENCE as described on page 1-53
- CHECK_STATUS as described on page 1-53

All addresses are byte address. 'CS0 is a Chip Select 0 base address. 'EIM_ is a prefix of EIM's registers. 'h is a prefix of hexadecimal constant. // is a comment beginning. csba[cs] is a dimension of CS base addresses. "addr" means an address offset in current CS address space. Examples use CS0 address space, but it may be any except boot mode functionality.

Configuration examples were checked with some below defined memory models and may require some adjustment for other family members.

25.8.1 Access to AMD Flash

Below mentioned configurations intended for AMD Simultaneous Flash Memory w/ VersatileIO™ Control.

25.8.1.1 AMD Flash Asynchronous Mode Configuration

Next EIM register configuration used for AMD flash asynchronous access:

- WR32('EIM_CS0RCR1,'h0a018000);

- WR32('EIM_CS0WCR1,'h0704a240);
- WR32('EIM_CS0GCR1,'h00430081); // for 32 bit memory or
- WR32('EIM_CS0GCR1,'h00410081); // for 16 bit memory

25.8.1.2 AMD Flash Utility

```
       // Single data word programming to addr, 32-bit memory
           port_size = 32;
           WR32('CS0+('h0555<<2),'h00aa); // command sequence
           WR32('CS0+('h02aa<<2),'h0055);
           WR32('CS0+('h0555<<2),'ha0); // command code
           WR32('CS0+addr, data); // addr & data
// Polling end of programming
          edata = data; // expected data
          data = ~edata;
          errst = 0;
      while(!(data == edata) &&!errst)
             begin: BR_EN
             RD16('CS0+addr, data);          // Read status
             if(data[7]!== edata[7])
                begin
                if(data[5] == 1)
                    begin
                    RD16('CS0+addr, data3);
                    RD16('CS0+addr, data);
                    if(data[6] !== data3[6])
                        begin
                        $display("CHECK_STATUS: Error timout on single data program");
                        errst = 1;
                        disable BR_EN;
                        end
                    end
               end
             else
                begin
                RD16('CS0+addr, data3);
                if(port_size == 32)
                    RD32('CS0+addr, data);
                else
                    begin
                    RD16('CS0+addr, data);
                    edata[31:16] = 16'h0;
                    end
                if(data !== edata)
                    begin
                    $display("CHECK_STATUS: Error in data write on single data program");
                      errst =2;
                    disable BR_EN;
                    end
                end
             end
      // Single data word programming to addr, 16-bit memory
          port_size = 16;
          WR32('CS0+('h0555<<1),'h00aa); // command sequence
          WR32('CS0+('h02aa<<1),'h0055);
          WR32('CS0+('h0555<<1),'ha0); // commund code
          WR32('CS0+addr, data); // addr & data
      // Polling end of programming - the same as for 32 bit
```

25.8.2 Access to Intel Sibley Flash

Below mentioned configurations intended to Sibley family muxed and non-muxed devices.

25.8.2.1 Intel Sibley Flash Asynchronous Mode Configuration

- WR32('EIM_CS0GCR1,'h00210081);
- WR32('EIM_CS0RCR1,'h0e020000);
- WR32('EIM_CS0RCR2,'h00000000);
- WR32('EIM_CS0WCR1,'h0704a040);

25.8.2.2 Intel Sibley Flash Synchronous Mode Configuration

Next configuration used for 133 MHz synchronous access to flash:

```
// Set memory to synchronous read mode
     WR16('CS0+('h5903<<1),'h0060);
     WR16('CS0+('h5903<<1),'h0003);
     WR16('CS0+('h0000<<1),'h00ff);
// Set EIM configuration to synchronous timing
     WR32('EIM_CS0GCR1,'h50214225);                    // 133 MHz
     WR32('EIM_CS0RCR1,'h0c000000);                    // 12 cycles on memory
```

Next configuration used for 66 MHz synchronous access to muxed flash:

```
// Set memory to synchronous read mode
     WR16('CS0+('h3103<<1),'h0060);
     WR16('CS0+('h3103<<1),'h0003);
     WR16('CS0+('h0000<<1),'h00ff);
//-------------------------------------------------------------------------
// Set EIM configuration to synchronous timing
     WR32('EIM_CS0GCR1,'h5021122d);                    // 66 MHz
     WR32('EIM_CS0RCR1,'h07000000);                    // 7cycles on memory
```

25.8.2.3 Intel Sibley Flash Utility

```
// Single data word programming to addr
     WR16('CS0+addr,'h0060);                 // Unlock
     WR16('CS0+addr,'h00d0);
     WR16('CS0+addr, 'h0041);
     WR16('CS0+addr, data);
     WR16('CS0+caddr, 'h0070);                 // Read Status command
     while('CS0+data[7] == 0)                             // Wait / Polling
         RD16('CS0+addr, data);              // Read status
     RD16('CS0+addr, data);                  // Read status
     WR16('CS0+'h0000,'h00ff);
// Write buffer programming
     WR16('CS0+addr,'h0060);                 // Unlock
     WR16('CS0+addr,'h00d0);
     data    = 0;
     WR16('CS0+addr, 'h0070);                // Read Status command
     while(data[7] == 0)                           // Wait
         RD16('CS0+addr, data);              // Read status
```

```
WR16('CS0+'h0000,'h00ff);
           WR16('CS0+addr,'h00e9);           // Write Buffer command
           WR16('CS0+addr,255);              // Word counter (<256)
           for(i=0; i<'h200; i = i + 'h40)
              WR_I('CS0+addr+i, data+((i>2)*'h0010_0001), 'h0010_0001, 16); // Data
           WR16('CS0+addr,'h00d0);           // Write Confirm command
           data  = 0;
           while(data[7] == 0)                     // Wait
              RD16('CS0+addr, data);         // Read status
           RD16('CS0+addr, data);            // Read status
           WR16('CS0+'h0000,'h00ff);
```

25.8.3 Access to MDOC Device

Below mentioned configurations intended to MDOC H3 device.

25.8.3.1 MDOC Device Boot

To boot from the MDOC device the ERRST bit should be configured to 1, so that EIM will hold the first read access to CS0 until the MDOC asserts the RDY signal.

25.8.3.2 MDOC Device Asynchronous Mode Configuration

```
// Non-muxed mode
WR32('EIM_CS0GCR1,'h00410081);
WR32('EIM_CS0RCR1,'h0e121010);
WR32('EIM_CS0RCR2,'h00000000);
WR32('EIM_CS0WCR1,'h12092492);
// Muxed mode
WR32('EIM_CS0GCR1,'h00410081);
WR32('EIM_CS0RCR1,'h0e121010);
WR32('EIM_CS0RCR2,'h00000000);
WR32('EIM_CS0WCR1,'h12092492);
```

25.8.3.3 MDOC Device Utility

```
// Read Manufacturer ID and Device ID
    RE16('CS0+'h9400,'h4833);
    RE16('CS0+'h9422,'hb7cc);
```

25.8.4 Access to Micron PSRAM

Below mentioned configurations intended to mt45w4mw16bfb_706.

25.8.4.1 Micron PSRAM Asynchronous Mode Configuration

```
// 16 bit memory
    WR32('EIM_CS0GCR1,'h403104b1);
    WR32('EIM_CS0RCR1,'h0b010000);
    WR32('EIM_CS0RCR2,'h00000008);
    WR32('EIM_CS0WCR1,'h0b040040);
// 32 bit memory
    WR32('EIM_CS0GCR1,'h403304b1);
    WR32('EIM_CS0RCR1,'h0f010000);
    WR32('EIM_CS0RCR2,'h00000008);
    WR32('EIM_CS0WCR1,'h0f040040);
```

25.8.4.2 Micron PSRAM Synchronous Mode Configuration

```
// 16 bit memory
    WR32('EIM_CS0GCR1,'h403104b1);
    WR32('EIM_CS0WCR1,'h0b040000);
    WR16('CS0+('h85947<<1),'h0040); // memory configuration
    WR32('EIM_CS0GCR1,'h4021_5487);// fixed latency memory wrap 4
    WR32('EIM_CS0RCR1,'h04000000);
    WR32('EIM_CS0RCR2,'h00000008);
    WR32('EIM_CS0WCR1,'h04000000);
// 32 bit memory
    WR32('EIM_CS0GCR1,'h6003_04f1);
    WR32('EIM_CS0WCR1,'h0b04_0000);
    WR32('CS0+('h85947<<2),'h0040); // memory configuration
    WR32('EIM_CS0GCR1,'h4003_1487); // var latency memory inc. page size 128
    WR32('EIM_CS0RCR1,'h04000000);
    WR32('EIM_CS0RCR2,'h00000008);
    WR32('EIM_CS0WCR1,'h04000000);
```

25.8.5 Access to Samsung OneNAND

Mentioned below are the configurations intended for Samsung OneNAND muxed and non-muxed devices.

25.8.5.1 Samsung OneNAND Boot

There are two ways to boot from Samsung OneNAND. In the first way, the ERRST bit is set to 0 and the user has to poll the interrupt status in the OneNAND interrupt register (or set interrupt handler there). In the second way, the ERRST bit is set to 1 and the user should enable the device interrupt output before the first read from CS0 access is issued.

Load sectors 2,3 to DataRAM, page 0 done in the next example:

- WR16('CS0+('hF241<<1),'h0); // Clear interrupt status
- WR16('CS0+('hF100<<1),'h0); // block[8:0] address
- WR16('CS0+('hF107<<1),'h2); // sector[1:0] and page[7:2] addresses
- WR16('CS0+('hF200<<1),'h802); // buffer[11:8] address and counter[1:0]

- WR16('CS0+('hF101<<1),'h0); // DDP choose
- WR16('CS0+('hF220<<1),'h0); // Set command

25.8.5.2 Samsung OneNAND Asynchronous Mode Configuration

```
// Non-muxed memory
    WR32('EIM_CS0GCR1,'h00410081);
    WR32('EIM_CS0RCR1,'h0b010000);
    WR32('EIM_CS0RCR2,'h00000000);
    WR32('EIM_CS0WCR1,'h0c092480);
// Muxed memory
    WR32('EIM_CS0GCR1,'h00410089);
    WR32('EIM_CS0RCR1,'h0b010000);
    WR32('EIM_CS0RCR2,'h00000000);
    WR32('EIM_CS0WCR1,'h0c092480);
```

25.8.5.3 Samsung OneNAND Synchronous Mode Configuration

Set memory and EIM to synchronous read mode is shown in the next example:

```
    WR16('CS0+('hF221<<1),'hc0e0); // Synchronous read, 4 clk latency
    WR32('EIM_CS0GCR1,'h50412405); // 44 MHz (non-muxed)
    WR32('EIM_CS0RCR1,'h05010000);
```

The muxed Samsung OneNAND supports synchronous write, too:

```
// Set memory & EIM to synchronous read and write mode
    WR16('CS0+('hF221<<1),'hc0f2); // Sync. read and write, 4 clk latency
    WR32('EIM_CS0GCR1,'h5041240f); // 44 MHz
    WR32('EIM_CS0RCR1,'h05010000);
    WR32('EIM_CS0WCR1,'h05040000);
```

25.8.5.4 Samsung OneNAND Utility

The following utility algorithms are used on the Samsung OneNAND:

```
// Unlock Block command
    WR16('CS0+('hF100<<1),'h0);         // DFS
    WR16('CS0+('hF100<<1),'h0);         // DBS
    WR16('CS0+('hF24c<<1),'h2);         // SBA - block number (2)
    WR16('CS0+('hF241<<1),'h0);         // Clear interrupt status
    WR16('CS0+('hF220<<1),'h23);        // Unlock command
    data ='h0;
    while(!(data &'h0004))              // Polling
       RD32('WIAR, data); // Read status
// Erase block command
    WR16('CS0+('hF100<<1),'h2);         // DFS and block ([8:0]) address
    WR16('CS0+('hF101<<1),'h0);         // DBS
    WR16('CS0+('hF241<<1),'h0);         // Clear interrupt status
              WR16('CS0+('hF220<<1),'h94);             // Erase command
    data ='h0;
    while(!(data &'h0004))                    // Wait
        RD32('WIAR, data); // Read status
// Program page command
    WR16('CS0+('hF100<<1),'h2);               // DFS and block[8:0] address
    WR16('CS0+('hF107<<1),'h0);               // sector[1:0] and pag
```

```
WR16('CS0+('hF200<<1),'h800);           // buffer[11:8] address and counter[1:0]
WR16('CS0+('hF241<<1),'h0);             // Clear interrupt status
WR16('CS0+('hF220<<1),'h80);            // Program command
data ='h0;
while(!(data &'h0004))                  // Wait
    RD32('WIAR, data); // Read status
```

25.8.6 Access to Samsung UtRAM

Below mentioned configurations are intended for Samsung UtRAM.

25.8.6.1 Samsung UtRAM Asynchronous Mode Configuration

```
WR32('EIM_CS0GCR1,'h400104b1);
WR32('EIM_CS0RCR1,'h0a010000);
WR32('EIM_CS0RCR2,'h00000008);
WR32('EIM_CS0WCR1,'h0b040040);
```

25.8.6.2 Samsung UtRAM Synchronous Mode Configuration

```
RD16('CS0+('hff_ffff<<1),data);             // command sequence
RD16('CS0+('hff_ffff<<1),data);
RD16('CS0+('hff_ffff<<1),data);
RD16('CS0+('hff_feff<<1),data);
RD16('CS0+('h00_82a0<<1),data);             // memory sync. configuration
WR32('EIM_CS0GCR1,'h4021_53b7);            // fixed latency memory wrap 32
WR32('EIM_CS0RCR1,'h0500_0000);
WR32('EIM_CS0WCR1,'h0300_0000);
```

25.8.7 Access to Spansion Flash

Below mentioned configurations are intended for Spansion Flash.

25.8.7.1 Spansion Flash Asynchronous Mode Configuration

```
WR32('EIM_CS0GCR1,'h00410081);
WR32('EIM_CS0RCR1,'h0a018000);
WR32('EIM_CS0RCR2,'h00000000);
WR32('EIM_CS0WCR1,'h0704a240);
WR16('CS0+('hF220<<1),'h94);            // Erase command
data ='h0;
while(!(data &'h0004))                  // Wait
    RD32('WIAR, data); // Read status
// Program page command
WR16('CS0+('hF100<<1),'h2);             // DFS and block[8:0] address
WR16('CS0+('hF107<<1),'h0);             // sector[1:0] and page[7:2] addresses
WR16('CS0+('hF200<<1),'h800);           // buffer[11:8] address and counter[1:0]
WR16('CS0+('hF241<<1),'h0);             // Clear interrupt status
WR16('CS0+('hF220<<1),'h80);            // Program command
data ='h0;
```

```
        while(!(data &'h0004))                  // Wait
            RD32('WIAR, data); // Read status
```

25.8.7.2 Spansion Flash Synchronous Mode Configuration

```
        WR16('CS0+('h0555<<1),'h00aa);   // command sequence
        WR16('CS0+('h02aa<<1),'h0055);
        WR16('CS0+('h0555<<1),'hd0);
        WR16('CS0+('h0000<<1),'h1ec4);   // memory sync. configuration
        WR32('EIM_CS0GCR1,'h50411325); // 66 MHz
        WR32('EIM_CS0RCR1,'h05000000); // 5 cycles on memory
```

25.8.7.3 Spansion Flash Utility

```
    // Single word programming
        COMMAND_SEQUENCE(cs,16,'ha0);           // single word programming
        WR16('CS0+addr, data);
        CHECK_STATUS('CS0+addr,data,16,1,errst);
    // Write buffer programming
        COMMAND_SEQUENCE(0,16,'h25);              // write buffer programming
        WR16('CS0+addr,'h001f);                     // counter-1
        WR_I('CS0+addr, data, 'h0010_0001, 16); // data
        WR16('CS0+addr,'h0029);                     // write buffer to flash
        CHECK_STATUS('CS0+addr+'h3e,data[31:16]+'h00f0,16,1,errst);
```

There COMMAND_SEQUENCE and CHECK_STATUS are next functions:

```
    task COMMAND_SEQUENCE;
        input[2:0]    cs;
        input[7:0]    port_size;
        input[31:0]   code;
    begin
        if(port_size == 16)
           begin
           WR16(csba[cs]+('h0555<<1),'h00aa);
           WR16(csba[cs]+('h02aa<<1),'h0055);
           WR16(csba[cs]+('h0555<<1),code);
           end
        else
           begin
           WR32(csba[cs]+('h0555<<2),'h00aa);
           WR32(csba[cs]+('h02aa<<2),'h0055);
           WR32(csba[cs]+('h0555<<2),code);
           end
    end
    endtask
    task     CHECK_STATUS;
        input[31:0] addr;
        input[31:0] edata;
        input[7:0]   port_size;
        input[7:0]   opcode;
        output[7:0] errst;
        reg[31:0]    data;
        reg[31:0]    data3;
    begin
        errst = 0;
        data  = 0;
        data3 = 0;
while(!(data == edata) && !errst) // Wait operation
      begin: BR_EN
      RD16(addr, data);             // Read status
      if(data[7] !== edata[7])
```

```
            begin
            if(data[5] == 1)
                 begin
                 RD16(addr, data3);
                 RD16(addr, data);
                 if(data[6] !== data3[6])
                      begin
                      $display("CHECK_STATUS: Error timout on single data program");
                      errst = 1;
                      disable BR_EN;
                      end
                 end
            else
                 begin
                 if(opcode == 2)
                      if(data[1] == 1)
                          begin
                          RD16(addr, data3);
                          if(port_size == 32)
                             RD32(addr, data);
                          else
                             RD16(addr, data);
                          if(data[1] == 1 && data !== edata)
                             begin
                             $display("CHECK_STATUS: Error on write buffer");
                             errst =3;
                             disable BR_EN;
                             end
                          end
                 end
            end
        else
            begin
            RD16(addr, data3);
            if(port_size == 32)
                 RD32(addr, data);
            else
                 begin
                 RD16(addr, data);
                 edata[31:16] = 16'h0;
                 end
            if(data !== edata)
                 begin
                 $display("CHECK_STATUS: Error in data write on single data program");
                 errst =2;
                 disable BR_EN;
                 end
            end
        end
end
endtask
```

25.8.8 8 bit support

This section details the pin connections for Intel mode and Motorola mode.

Intel Mode - For intel mode use the following connection:

Table 25-11. Intel Mode pin connections

ARM platform Pin	EIM Pin	Notes
ADS#	IPP_DO_ADV_B	WAL = 1,RAL = 1

Table continues on the next page...

25.10 Programmable Registers

25.10.1 EIM Memory Map/Register Definition

The EIM includes 33 user-accessible 32-bit registers. The the EIM Configuration Register (EIM_WCR) contains control bits that configure the EIM for certain operation modes.

The 160 bits used to control Individual Chip Select are divided into five registers:

- Chip Select x General Configuration Register 1 (EIM_CSxGCR1)
- Chip Select x General Configuration Register 2 (EIM_CSxGCR2)
- Chip Select x Read Configuration Register 1 (EIM_CSxRCR1)
- Chip Select x Read Configuration Register 2 (EIM_CSxRCR2)
- Chip Select x Write Configuration Register (EIM_CSxWCR)

In addition there are 3 general registers: EIM_WCR, EIM_WIAR & EIM_EAR.

NOTE

- All EIM registers are sampled by IPG_CLK_S, therefore IPG_CLK_S must be active when accessing through IP bus.
- Read access from all registers (except EIM_WIAR & EIM_EAR) will generate one IPG_XFR_WAIT cycle.
- Read access from EIM_WIAR & EIM_EAR will generate six IPG_XFR_WAIT cycles.
- Write access to all registers (except EIM_EAR) will generate three IPG_XFR_WAIT cycles.
- Write access to EIM_EAR will generate six IPG_XFR_WAIT cycles.

EIM_CS*n*GCR1 field descriptions

Field	Description
31–28 PSZ	Page Size. This bit field indicates memory page size in words (word is defined by the DSZ field). PSZ is used when fix latency mode is applied, WFL=1 for sync. write accesses, RFL=1 for sync. Read accesses. When working in fix latency mode WAIT signal from the external device is not being monitored, PSZ is used to determine if page boundary is reached and renewal of access is preformed. This bit field is ignored when sync. Mode is disabled or fix latency mode is not being used for write or read access separately. It can be valid for both access type, read or write, or only for one type, according to configuration. PSZ is cleared by a hardware reset. 0000 8 words page size 0001 16 words page size 0010 32 words page size

Table continues on the next page...

EIM_CS*n*GCR1 field descriptions (continued)

Field	Description
	0011 64 words page size 0100 128 words page size 0101 256 words page size 0110 512 words page size 0111 1024 (1k) words page size 1000 2048 (2k) words page size 1001 - 1111 Reserved
27 WP	Write Protect. This bit prevents writes to the address range defined by the corresponding chip select. WP is cleared by a hardware reset. 0 Writes are allowed in the memory range defined by chip. 1 Writes are prohibited. All attempts to write to an address mapped by this chip select result in a error response and no assertion of the chip select output.
26–24 GBC	Gap Between Chip Selects. This bit field, according to the settings shown below, determines the minimum time between end of access to the current chip select and start of access to different chip select. GBC is cleared by a hardware reset. Example settings: 000 minimum of 0 EIM clock cycles before next access from different chip select (async. mode only) 001 minimum of 1 EIM clock cycles before next access from different chip select 010 minimum of 2 EIM clock cycles before next access from different chip select 111 minimum of 7 EIM clock cycles before next access from different chip select
23 AUS	Address UnShifted. This bit indicates an unshifted mode for address assertion for the relevant chip select accesses. AUS bit is cleared by hardware reset. 0 Address shifted according to port size (DSZ config.) 1 Address unshifted
22–20 CSREC	CS Recovery. This bit field, according to the settings shown below, determines the minimum pulse width of CS, OE, and WE control signals before executing a new back to back access to the same chip select. CSREC is cleared by a hardware reset. **NOTE:** The reset value for EIM_CS0GCR1, CSREC[2:0] is 0b110. For EIM_CS1GCR1 - EIM_CS5GCR, the reset value is 0b000. Example settings: 000 0 EIM clock cycles minimum width of CS, OE and WE signals (read async. mode only) 001 1 EIM clock cycles minimum width of CS, OE and WE signals 010 2 EIM clock cycles minimum width of CS, OE and WE signals 111 7 EIM clock cycles minimum width of CS, OE and WE signals
19 SP	Supervisor Protect. This bit prevents accesses to the address range defined by the corresponding chip select when the access is attempted in the User mode. SP is cleared by a hardware reset. 0 User mode accesses are allowed in the memory range defined by chip select. 1 User mode accesses are prohibited. All attempts to access an address mapped by this chip select in User mode results in an error response and no assertion of the chip select output.
18–16 DSZ	Data Port Size. This bit field defines the width of an external device's data port as shown below. **NOTE:** Only async. access supported for 8 bit port.

Table continues on the next page...

EIM_CS*n*GCR1 field descriptions (continued)

Field	Description
	NOTE: The reset value for EIM_CS0GCR1, DSZ[2] = 0, DSZ[1:0] = EIM_BOOT[1:0]. For EIM_CS1GCR1 - EIM_CS5GCR1, the reset value is 0b001. 000 Reserved. 001 16 bit port resides on DATA[15:0] 010 16 bit port resides on DATA[31:16] 011 32 bit port resides on DATA[31:0] 100 8 bit port resides on DATA[7:0] 101 8 bit port resides on DATA[15:8] 110 8 bit port resides on DATA[23:16] 111 8 bit port resides on DATA[31:24]
15–14 BCS	Burst Clock Start. When SRD=1 or SWR=1,this bit field determines the number of EIM clock cycles delay from start of access before the first rising edge of BCLK is generated. When BCD=0 value of BCS=0 results in a half clock delay after the start of access. For other values of BCD a one clock delay after the start of access is applied, not an immediate assertion. BCS is cleared by a hardware reset. 00 0 EIM clock cycle additional delay 01 1 EIM clock cycle additional delay 10 2 EIM clock cycle additional delay 11 3 EIM clock cycle additional delay
13–12 BCD	Burst Clock Divisor. This bit field contains the value used to program the burst clock divisor for BCLK generation. It is used to divide the internal EIMbus frequency. BCD is cleared by a hardware reset. **NOTE:** For other then the mentioned below frequency such as 104 MHz, EIM clock (input clock) should be adjust accordingly. 00 Divide EIM clock by 1 01 Divide EIM clock by 2 10 Divide EIM clock by 3 11 Divide EIM clock by 4
11 WC	Write Continuous. The WI bit indicates that write access to the memory are always continuous accesses regardless of the BL field value. WI is cleared by hardware reset. 0 Write access burst length occurs according to BL value. 1 Write access burst length is continuous.
10–8 BL	Burst Length. The BL bit field indicates memory burst length in words (word is defined by the DSZ field) and should be properly initialized for mixed wrap/increment accesses support. Continuous BL value corresponds to continuous burst length setting of the external memory device. For fix memory burst size, type is always wrap. In case not matching wrap boundaries in both the memory (BL field) and Master access on the current address, EIM update address on the external device address bus and regenerates the access. BL is cleared by a hardware reset. When APR=1, Page Read Mode is applied, BL determine the number of words within the read page burst. BL is cleared by a hardware reset for EIM_CS0GCR1 - EIM_CS5GCR1. 000 4 words Memory wrap burst length (read page burst size when APR = 1) 001 8 words Memory wrap burst length (read page burst size when APR = 1) 010 16 words Memory wrap burst length (read page burst size when APR = 1)

Table continues on the next page...

EIM_CS*n*GCR1 field descriptions (continued)

Field	Description
	011 32 words Memory wrap burst length (read page burst size when APR = 1) 100 Continuous burst length (2 words read page burst size when APR = 1) 101 Reserved 110 Reserved 111 Reserved
7 CREP	Configuration Register Enable Polarity. This bit indicates CRE memory pin assertion state, active-low or active-high, while executing a memory register set command to the external device (PSRAM memory type). CREP is set by a hardware reset. **NOTE:** Whenever PSRAM is connected the CREP value must be correct also for accesses where CRE is disabled. For Non-PSRAM memory CREP value should be 1. 0 CRE signal is active low 1 CRE signal is active high
6 CRE	Configuration Register Enable. This bit indicates CRE memory pin state while executing a memory register set command to PSRAM external device. CRE is cleared by a hardware reset. 0 CRE signal use is disable 1 CRE signal use is enable
5 RFL	Read Fix Latency. This bit field determine if the controller is monitoring the WAIT signal from the External device connected to the chip select (handshake mode - fix or variable data latency) or if it start sampling data according to RWSC field, it only valid in synchronous mode. RFL is cleared by a hardware reset. When RFL=1 Burst access is terminated on page boundary and resume on the following page according to BL bit field configuration, because WAIT signal is not monitored from the external device. 0 the External device WAIT signal is being monitored, and it reflect the external data bus state 1 the state of the External devices is determined internally (Fix latency mode only)
4 WFL	Write Fix Latency. This bit field determine if the controller is monitoring the WAIT signal from the External device connected to the chip select (handshake mode - fix or variable data latency) or if it start data transfer according to WWSC field, it only valid in synchronous mode. WFL is cleared by a hardware reset. When WFL=1 Burst access is terminated on page boundary and resume on the following page according to BL bit field configuration, because WAIT signal is not monitored from the external device 0 the External device WAIT signal is being monitored, and it reflect the external data bus state 1 the state of the External devices is determined internally (Fix latency mode only)
3 MUM	Multiplexed Mode. This bit determines the address/data multiplexed mode for asynchronous and synchronous accesses for 8 bit, 16 bit or 32 bit devices (DSZ config. dependent). **NOTE:** The reset value for EIM_CS0GCR1[MUM] = EIM_BOOT[2]. For EIM_CS1GCR1 - EIM_CS5GCR1 the reset value is 0. 0 Multiplexed Mode disable 1 Multiplexed Mode enable
2 SRD	Synchronous Read Data. This bit field determine the read accesses mode to the External device of the chip select. The External device should be configured to the same mode as this bit implicates. SRD is cleared by a hardware reset. **NOTE:** Sync. accesses supported only for 16/32 bit port.

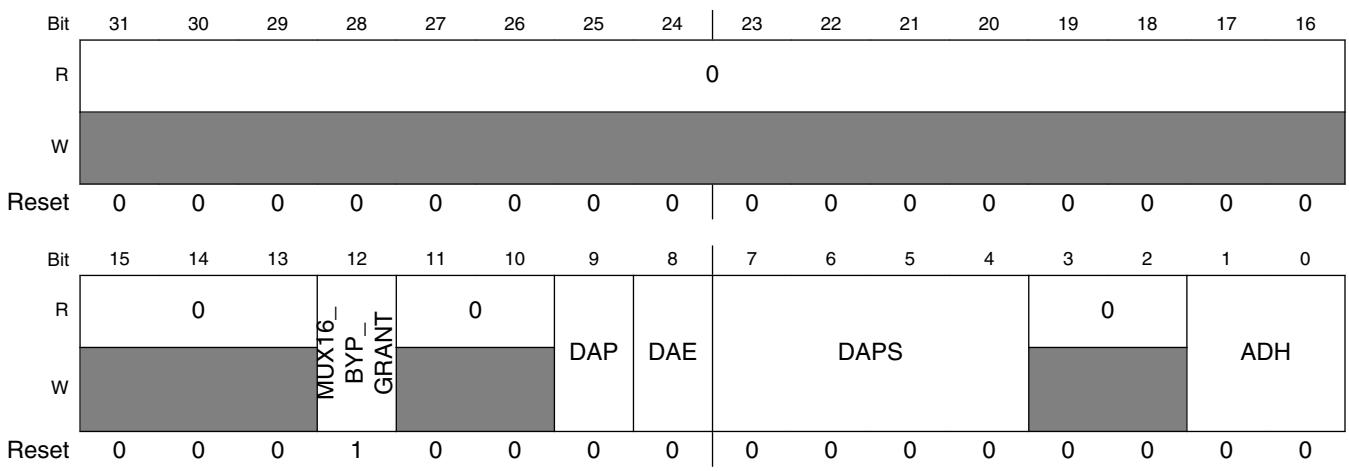
Table continues on the next page...

EIM_CS*n*GCR1 field descriptions (continued)

Field	Description
	0 read accesses are in Asynchronous mode 1 read accesses are in Synchronous mode
1 SWR	Synchronous Write Data. This bit field determine the write accesses mode to the External device of the chip select. The External device should be configured to the same mode as this bit implicates. SWR is cleared by a hardware reset. **NOTE:** Sync. accesses supported only for 16/32 bit port. 0 write accesses are in Asynchronous mode 1 write accesses are in Synchronous mode
0 CSEN	CS Enable. This bit controls the operation of the chip select pin. CSEN is set by a hardware reset for CSGCR0 to allow external boot operation. CSEN is cleared by a hardware reset to CSGCR1-CSGCR5. **NOTE:** Reset value for EIM_CS0GCR1 for CSEN is 1. For EIM_CS1GCR1-CS1GCR5 reset value is 0. 0 Chip select function is disabled; attempts to access an address mapped by this chip select results in an error respond and no assertion of the chip select output 1 Chip select is enabled, and is asserted when presented with a valid access.

25.101.2 Chip Select n General Configuration Register 2 (EIM_CSGCR2)

Addresses: EIM_CS0GCR2 is 63FD_A000h base + 4h offset = 63FD_A004h
EIM_CS1GCR2 is 63FD_A000h base + 1Ch offset = 63FD_A01Ch
EIM_CS2GCR2 is 63FD_A000h base + 34h offset = 63FD_A034h
EIM_CS3GCR2 is 63FD_A000h base + 4Ch offset = 63FD_A04Ch



EIM_CS*n*GCR2 field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

EIM_CS*n*GCR2 field descriptions (continued)

Field	Description
12 MUX16_BYP_GRANT	Muxed 16 bypass grant. This bit when asserted causes EIM to bypass the grant/ack. arbitration with NFC (only for 16 bit muxed mode accesses). 0 EIM waits for grant before driving a 16 bit muxed mode access to the memory. 1 EIM ignores the grant signal and immediately drives a 16 bit muxed mode access to the memory.
11–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9 DAP	Data Acknowledge Polarity. This bit indicates DTACK memory pin assertion state, active-low or active-high, while executing an async access using DTACK signal from the external device. DAP is cleared by a hardware reset. 0 DTACK signal is active high 1 DTACK signal is active low
8 DAE	Data Acknowledge Enable. This bit indicates external device is using DTACK pin as strobe/terminator of an async. access. DTACK signal may be used only in asynchronous single read (APR=0) or write accesses. DTACK poling start point is set by DAPS bit field. polarity of DTACK is set by DAP bit field. DAE is cleared by a hardware reset. 0 DTACK signal use is disable 1 DTACK signal use is enable
7–4 DAPS	Data Acknowledge Poling Start. This bit field determine the starting point of DTACK input signal polling. DAPS is used only in asynchronous single read or write accesses. **NOTE:** Since DTACK is an async. signal the start point of DTACK signal polling is at least 3 cycles after the start of access. DAPS is cleared by a hardware reset. Example settings: 0000 3 EIM clk cycle between start of access and first $\overline{\text{DTACK}}$ check 0001 4 EIM clk cycles between start of access and first $\overline{\text{DTACK}}$ check 0010 5 EIM clk cycles between start of access and first $\overline{\text{DTACK}}$ check 0111 10 EIM clk cycles between start of access and first $\overline{\text{DTACK}}$ check 1011 14 EIM clk cycles between start of access and first DTACK check 1111 18 EIM clk cycles between start of access and first DTACK check
3–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1–0 ADH	Address hold time - This bit field determine the address hold time after ADV negation when mum = 1 (muxed mode). When mum = 0 this bit has no effect. For read accesses the field determines when the pads direction will be switched. **NOTE:** Reset value for EIM_CS0GCR2 for ADH is 10. For EIM_CS1GCR2-EIM_CS5GCR2 reset value is 00. 00 0 cycle after ADV negation 01 1 cycle after ADV negation 10 2 cycle after ADV negation 11 Reserved

25.101.3 Chip Select n Read Configuration Register 1 (EIM_CSRCR1)

Addresses: EIM_CS0RCR1 is 63FD_A000h base + 8h offset = 63FD_A008h
EIM_CS1RCR1 is 63FD_A000h base + 20h offset = 63FD_A020h
EIM_CS2RCR1 is 63FD_A000h base + 38h offset = 63FD_A038h
EIM_CS3RCR1 is 63FD_A000h base + 50h offset = 63FD_A050h

EIM_CS*n*RCR1 field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved
29–24 RWSC	Read Wait State Control. This bit field programs the number of wait-states, according to the settings shown below, for synchronous or asynchronous read access to the external device connected to the chip select. When SRD=1 and RFL=0, RWSC indicates the number of burst clock (BCLK) cycles from the start of an access, before the controller can start sample data.Since WAIT signal can be asserted one cycle before the first data can be sampled, the controller starts evaluating the WAIT signal state one cycle before, this is referred as handshake mode or variable latency mode. When SRD=1 and RFL=1, RWSC indicates the number of burst clock (BCLK) cycles from the start of an access, until the external device is ready for data transfer, this is referred as fix latency mode. When SRD=0, RFL bit is ignored, RWSC indicates the asynchronous access length and the number of EIM clock cycles from the start of access until the external device is ready for data transfer. RWSC is cleared by a hardware reset. **NOTE:** The reset value for EIM_CS0RCR1, RWSC[5:0] = 0b011100. For CG1RCR1 - CS1RCR5 the reset value is 0b000000. Example settings: 000000 Reserved 000001 RWSC value is 1 000010 RWSC value is 2 111101 RWSC value is 61 111110 RWSC value is 62 111111 RWSC value is 63
23 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

EIM_CS*n*RCR1 field descriptions (continued)

Field	Description
22–20 RADVA	ADV Assertion. This bit field determines when ADV signal is asserted for synchronous or asynchronous read modes according to the settings shown below. RADVA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of access and ADV assertion 001 1 EIM clock cycles between beginning of access and ADV assertion 010 2 EIM clock cycles between beginning of access and ADV assertion 111 7 EIM clock cycles between beginning of access and ADV assertion
19 RAL	Read ADV Low. This bit field determine ADV signal negation time. When RAL=1, RADVN bit field is ignored and ADV signal will stay asserted until end of access. When RAL=0 negation of ADV signal is according to RADVN bit field configuration.
18–16 RADVN	ADV Negation. This bit field determines when ADV signal to memory is negated during read accesses. When SRD=1 (synchronous read mode), ADV negation occurs according to the following formula: (RADVN + RADVA + BCD + BCS + 1) EIM clock cycles from start of access. When asynchronous read mode is applied (SRD=0) and RAL=0 ADV negation occurs according to the following formula: (RADVN + RADVA + 1) EIM clock cycles from start of access. RADVN is cleared by a hardware reset. **NOTE:** the reset value for EIM_CS0RCR1[RADVN] = 2. For EIM_CS1RCR1 - EIM_CS5RCR1, the reset value is 0b000. **NOTE:** This field should be configured so ADV negation will occur before the end of access. For ADV negation at the same time with the end of access user should RAL bit.
15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14–12 OEA	OE Assertion. This bit field determines when OE signal are asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. OEA is cleared by a hardware reset. In muxed mode OE assertion occurs (OEA + RADVN + RADVA + ADH +1) EIM clock cycles from start of access. **NOTE:** The reset value for EIM_CS0RCR1[OEA] is 0b000 if EIM_BOOT[2] = 0. If EIM_BOOT[2] is 1, the reset value for EIM_CS0RCR1 is 0b010. The reset value of this field for EIM_CS1RCR1 - EIM_CS5RCR1 is 0b000. Example settings: 000 0 EIM clock cycles between beginning of access and OE assertion 001 1 EIM clock cycles between beginning of access and OE assertion 010 2 EIM clock cycles between beginning of access and OE assertion 111 7 EIM clock cycles between beginning of access and OE assertion
11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10–8 OEN	OE Negation. This bit field determines when OE signal is negated during read cycles in asynchronous single mode only (SRD=0 & APR = 0), according to the settings shown below. This bit field is ignored when SRD=1. OEN is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between end of access and OE negation 001 1 EIM clock cycles between end of access and OE negation

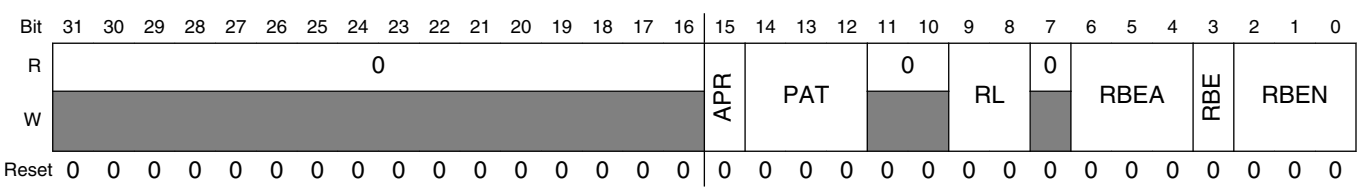
Table continues on the next page...

EIM_CS*n*RCR1 field descriptions (continued)

Field	Description
	010 2 EIM clock cycles between end of access and OE negation 111 7 EIM clock cycles between end of access and OE negation
7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6–4 RCSA	Read CS Assertion. This bit field determines when CS signal is asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. RCSA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of read access and CS assertion 001 1 EIM clock cycles between beginning of read access and CS assertion 010 2 EIM clock cycles between beginning of read access and CS assertion 111 7 EIM clock cycles between beginning of read access and CS assertion
3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2–0 RCSN	Read CS Negation. This bit field determines when CS signal is negated during read cycles in asynchronous single mode only (SRD=0 & APR = 0), according to the settings shown below. This bit field is ignored when SRD=1. RCSN is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between end of read access and CS negation 001 1 EIM clock cycles between end of read access and CS negation 010 2 EIM clock cycles between end of read access and CS negation 111 7 EIM clock cycles between end of read access and CS negation

25.101.4 Chip Select n Read Configuration Register 2 (EIM_CSRCR2)

Addresses: EIM_CS0RCR2 is 63FD_A000h base + Ch offset = 63FD_A00Ch
EIM_CS1RCR2 is 63FD_A000h base + 24h offset = 63FD_A024h
EIM_CS2RCR2 is 63FD_A000h base + 3Ch offset = 63FD_A03Ch
EIM_CS3RCR2 is 63FD_A000h base + 54h offset = 63FD_A054h



EIM_CS*n*RCR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15 APR	Asynchronous Page Read. This bit field determine the asynchronous read mode to the external device. When APR=0, the async. read access is done as single word (where word is defined by the DSZ field).

Table continues on the next page...

EIM_CS*n*RCR2 field descriptions (continued)

Field	Description
	when APR=1, the async. read access executed as page read. page size is according to BL field config., RCSN,RBEN,OEN and RADVN are being ignored. APR is cleared by a hardware reset for EIM_CS1GCR1 - EIM_CS5GCR1. **NOTE:** SRD=0 and MUM=0 must apply when APR=1
14–12 PAT	Page Access Time. This bit field is used in Asynchronous Page Read mode only (APR=1). the initial access is set by RWSC as in regular asynchronous mode. the consecutive address assertions width determine by PAT field according to the settings shown below. when APR=0 this field is ignored. PAT is cleared by a hardware reset for EIM_CS1GCR1 - EIM_CS5GCR1. 000 Address width is 2 EIM clock cycles 001 Address width is 3 EIM clock cycles 010 Address width is 4 EIM clock cycles 011 Address width is 5 EIM clock cycles 100 Address width is 6 EIM clock cycles 101 Address width is 7 EIM clock cycles 110 Address width is 8 EIM clock cycles 111 Address width is 9 EIM clock cycles
11–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–8 RL	Read Latency. This bit field indicates cycle latency when executing a synchronous read operation. The fields holds the feedback clock loop delay in aclk cycle units. This field is cleared by a hardware reset. 00 Feedback clock loop delay is up to 1 cycle for BCD = 0 or 1.5 cycles for BCD != 0 01 Feedback clock loop delay is up to 2 cycles for BCD = 0 or 2.5 cycles for BCD != 0 10 Feedback clock loop delay is up to 3 cycles for BCD = 0 or 3.5 cycles for BCD != 0 11 Feedback clock loop delay is up to 4 cycles for BCD = 0 or 4.5 cycles for BCD != 0
7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6–4 RBEA	Read BE Assertion. This bit field determines when BE signal is asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. RBEA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of read access and BE assertion 001 1 EIM clock cycles between beginning of read access and BE assertion 010 2 EIM clock cycles between beginning of read access and BE assertion 111 7 EIM clock cycles between beginning of read access and BE assertion
3 RBE	Read BE enable. This bit field determines if BE will be asserted during read access. 0 - BE are disabled during read access. 1- BE are enable during read access according to value of RBEA & RBEN bit fields.
2–0 RBEN	Read BE Negation. This bit field determines when BE signal is negated during read cycles in asynchronous single mode only (SRD=0 & APR=0), according to the settings shown below. This bit field is ignored when SRD=1. RBEN is cleared by a hardware reset. Example settings:

* Notes:
- WWSC bitfield: See field descriptions for the reset values.

EIM_CS*n*WCR1 field descriptions

Field	Description
31 WAL	Write ADV Low. This bit field determine ADV signal negation time in write accesses. When WAL=1, WADVN bit field is ignored and ADV signal will stay asserted until end of access. When WAL=0 negation of ADV signal is according to WADVN bit field configuration.
30 WBED	Write Byte Enable Disable. When asserted this bit prevent from IPP_DO_BE_B[x] to be asserted during write accesses.This bit is cleared by hardware reset.
29–24 WWSC	Write Wait State Control. This bit field programs the number of wait-states, according to the settings shown below, for synchronous or asynchronous write access to the external device connected to the chip select. When SWR=1 and WFL=0, WWSC indicates the number of burst clock (BCLK) cycles from the start of an access, before the memory can sample the first data.Since WAIT signal can be asserted one cycle before the first data can be sampled, the controller starts evaluating the WAIT signal state one cycle before, this is referred as handshake mode or variable latency mode. When SWR=1 and WFL=1, WWSC indicates the number of burst clock (BCLK) cycles from the start of an access, until the external device is ready for data transfer, this is referred as fix latency mode. When SWR=0, WFL bit is ignored, WWSC indicates the asynchronous access length and the number of EIM clock cycles from the start of access until the external device is ready for data transfer. WWSC is cleared by a hardware reset. **NOTE:** The reset value for EIM_CS0WCR1, WWSC[5:0] = 0b011100. For EIM_CS1WCR1 - EIM_CS5WCR1, the reset value of this field is 0b000000.

Table continues on the next page...

EIM_CS*n*WCR1 field descriptions (continued)

Field	Description
	Example settings: 000000 Reserved 000001 WWSC value is 1 000010 WWSC value is 2 000011 WWSC value is 3 111111 WWSC value is 63
23–21 WADVA	ADV Assertion. This bit field determines when ADV signal is asserted for synchronous or asynchronous write modes according to the settings shown below. WADVA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of access and ADV assertion 001 1 EIM clock cycles between beginning of access and ADV assertion 010 2 EIM clock cycles between beginning of access and ADV assertion 111 7 EIM clock cycles between beginning of access and ADV assertion
20–18 WADVN	ADV Negation. This bit field determines when ADV signal to memory is negated during write accesses. When SWR=1 (synchronous write mode), ADV negation occurs according to the following formula: (WADVN + WADVA + BCD + BCS + 1) EIM clock cycles. When asynchronous read mode is applied (SWR=0) ADV negation occurs according to the following formula: (WADVN + WADVA + 1) EIM clock cycles. **NOTE:** Reset value for EIM_CS0WCR for WADVN is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. **NOTE:** This field should be configured so ADV negation will occur before the end of access. For ADV negation at the same time as the end of access, S/W should set the WAL bit.
17–15 WBEA	BE Assertion. This bit field determines when BE signal is asserted during write cycles in async. mode only (SWR=0), according to the settings shown below. BEA is cleared by a hardware reset. **NOTE:** Reset value for EIM_CS0WCR for WBEA is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. Example settings: 000 0 EIM clock cycles between beginning of access and BE assertion 001 1 EIM clock cycles between beginning of access and BE assertion 010 2 EIM clock cycles between beginning of access and BE assertion 111 7 EIM clock cycles between beginning of access and BE assertion
14–12 WBEN	BE[3:0] Negation. This bit field determines when BE[3:0] bus signal is negated during write cycles in async. mode only (SWR=0), according to the settings shown below. This bit field is ignored when SWR=1. BEN is cleared by a hardware reset. **NOTE:** Reset value for EIM_CS0WCR for WBEN is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. Example settings: 000 0 EIM clock cycles between end of access and WE negation 001 1 EIM clock cycles between end of access and WE negation 010 2 EIM clock cycles between end of access and WE negation 111 7 EIM clock cycles between end of access and WE negation

Table continues on the next page...

Field	Description
11–9 WEA	WE Assertion. This bit field determines when WE signal is asserted during write cycles (synchronous or asynchronous mode), according to the settings shown below. This bit field is ignored when executing a read access to the external device. WEA is cleared by a hardware reset. **NOTE:** Reset value for EIM_CS0WCR for WEA is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. Example settings: 000 0 EIM clock cycles between beginning of access and WE assertion 001 1 EIM clock cycles between beginning of access and WE assertion 010 2 EIM clock cycles between beginning of access and WE assertion 111 7 EIMclock cycles between beginning of access and WE assertion
8–6 WEN	WE Negation. This bit field determines when WE signal is negated during write cycles in asynchronous mode only (SWR=0), according to the settings shown below. This bit field is ignored when SWR=1. WEN is cleared by a hardware reset. **NOTE:** Reset value for EIM_CS0WCR for WEN is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. Example settings: 000 0 EIM clock cycles between beginning of access and WE assertion 001 1 EIM clock cycles between beginning of access and WE assertion 010 2 EIM clock cycles between beginning of access and WE assertion 111 7 EIM clock cycles between beginning of access and WE assertion
5–3 WCSA	Write CS Assertion. This bit field determines when CS signal is asserted during write cycles (synchronous or asynchronous mode), according to the settings shown below.this bit field is ignored when executing a read access to the external device. WCSA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of write access and CS assertion 001 1 EIM clock cycles between beginning of write access and CS assertion 010 2 EIM clock cycles between beginning of write access and CS assertion 111 7 EIMclock cycles between beginning of write access and CS assertion
2–0 WCSN	Write CS Negation. This bit field determines when CS signal is negated during write cycles in asynchronous mode only (SWR=0), according to the settings shown below. This bit field is ignored when SWR=1. WCSN is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between end of read access and CS negation 001 1 EIM clock cycles between end of read access and CS negation 010 2 EIM clock cycles between end of read access and CS negation 111 7 EIM clock cycles between end of read access and CS negation

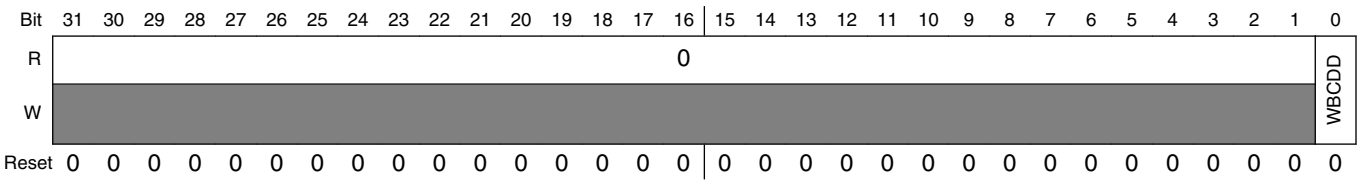
EIM_CS2WCR2 is 63FD_A000h base + 44h offset = 63FD_A044h
EIM_CS3WCR2 is 63FD_A000h base + 5Ch offset = 63FD_A05Ch

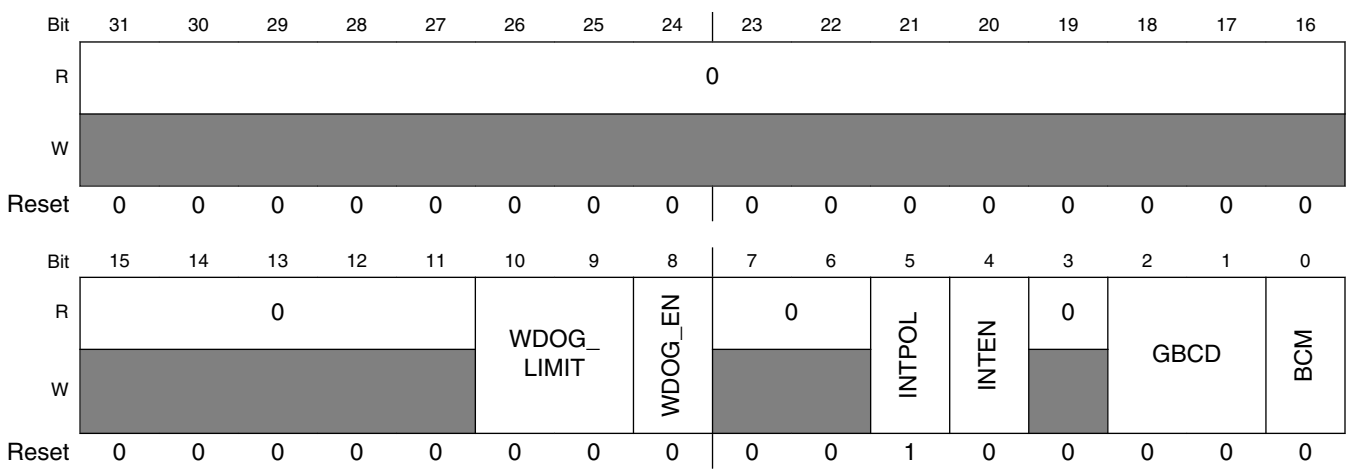


EIM_CS*n*WCR2 field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 WBCDD	Write Burst Clock Divisor Decrement. If this bit is asserted and BCD value is 0 sync. write access will be preformed as if BCD value is 1.When this bit is negated or BCD value is not 0 this bit has no affect. This bit is cleared by hardware reset.

25.101.7 EIM Configuration Register (EIM_WCR)

Address: EIM_WCR is 63FD_A000h base + 90h offset = 63FD_A090h



EIM_WCR field descriptions

Field	Description
31–11 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

EIM_WCR field descriptions (continued)

Field	Description
10–9 WDOG_LIMIT	Memory Watch Dog (WDog) cycle limit. This bit field determines the number of BCLK cycles (ACLK cycles in dtack mode) before the wdog counter terminates the access and send an error response to the master. 00 128 BCLK cycles 01 256 BCLK cycles 10 512 BCLK cycles 11 1024 BCLK cycles
8 WDOG_EN	Memory WDog enable. This bit controls the operation of the wdog counter that terminates the EIM access. 0 Memory WDog is Disabled 1 Memory WDog is Enabled
7–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 INTPOL	Interrupt Polarity. This bit field determines the polarity of the external device interrupt. 0 External interrupt polarity is active low 1 External interrupt polarity is active high
4 INTEN	Interrupt Enable. When this bit is set the External signal RDY_INT as active interrupt. When interrupt occurs, INT bit at the WCR will be set and t EIM_EXT_INT signal will be asserted correspondingly. This bit is cleared by a hardware reset. 0 External interrupt Disable 1 External interrupt Enable
3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2–1 GBCD	General Burst Clock Divisor. When BCM bit is set, this bit field contains the value used to program the burst clock divisor for Continuos BCLK generation. The other BCD bit fields for each chip select are ignored. It is used to divide the internal AXI bus frequency. When BCM=0 GBCD bit field has no influence. GBCD is cleared by a hardware reset. 00 Divide EIM clock by 1 01 Divide EIM clock by 2 10 Divide EIM clock by 3 11 Divide EIM clock by 4
0 BCM	Burst Clock Mode. This bit selects the burst clock mode of operation. It is used for system debug mode. BCM is cleared by a hardware reset. **NOTE:** The BCLK frequency in this mode is according to GBCD bit field. **NOTE:** The BCLK phase is opposite to the EIM clock in this mode if GBCD is 0. **NOTE:** This bit should be used only in async. accesses. No sync access can be executed if this bit is set. **NOTE:** When this bit is set bcd field shouldn't be configured to 0.

Table continues on the next page...

EIM_WCR field descriptions (continued)

Field	Description
	0 The burst clock runs only when accessing a chip select range with the SWR/SRD bits set. When the burst clock is not running it remains in a logic 0 state. When the burst clock is running it is configured by the BCD and BCS bit fields in the chip select Configuration Register. 1 The burst clock runs whenever ACLK is active (independent of chip select configuration)

25.101.8 EIM IP Access Register (EIM_WIAR)

Address: EIM_WIAR is 63FD_A000h base + 94h offset = 63FD_A094h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

EIM_WIAR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value zero. Reserved
4 ACLK_EN	ACLK enable. This bit gates the ACLK for the EIM except from FFs that get ipg_aclk_s. After reset ACLK is enabled. 0 ACLK is disabled 1 ACLK is enabled
3 ERRST	READY After Reset. This bit controls the initial ready/busy status for external devices on CS0 immediately after hardware reset. This is a sticky bit which is cleared once the RDY_INT signal is asserted by the external device. When ERRST = 1 the first fetch access from EIM to the external device located on CS0 will be pending until RDY_INT signal indicates that the external device is ready, then EIM will execute the access. 0 RDY_INT After Reset Disable 1 RDY_INT After Reset Enable
2 INT	Interrupt. This bit indicates interrupt assertion by an external device according to RDY_INT signal. When polling this bit, INT=0 indicates interrupt not occurred and INT=1 indicates assertion of the external device interrupt. This bit is cleared by a hardware reset.

Table continues on the next page...

EIM_WIAR field descriptions (continued)

Field	Description
1 IPS_ACK	IPS ACK. The EIM is ready for ips access. There is no active AXI access and no new AXI access is accepted till this bit is cleared. This bit is cleared by the master after it completes the ips accesses. 0 Master cannot access ips. 1 Master can access ips.
0 IPS_REQ	IPS request. The Master requests to access one of the IPS registers.Dutring such access the EIM should not preform any AXI/memory accesses. The EIM finishes the AXI accesses that already starts and asserts the IPS_ACK bit. 0 No Master requests ips access 1 Master requests ips access

25.101.9 Error Address Register (EIM_EAR)

Address: EIM_EAR is 63FD_A000h base + 98h offset = 63FD_A098h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

EIM_EAR field descriptions

Field	Description
31–0 Error-ADDR	Error Address. This bit field holds the AXI address of the last access that caused error. This register is read only register.

Chapter 26
Enhanced Periodic Interrupt Timer (EPIT)

26.1 Overview

The EPIT is a 32-bit set-and-forget timer that begins counting after the EPIT is enabled by software. It is capable of providing precise interrupts at regular intervals with minimal processor intervention.

The following figure illustrates the block diagram of the EPIT.

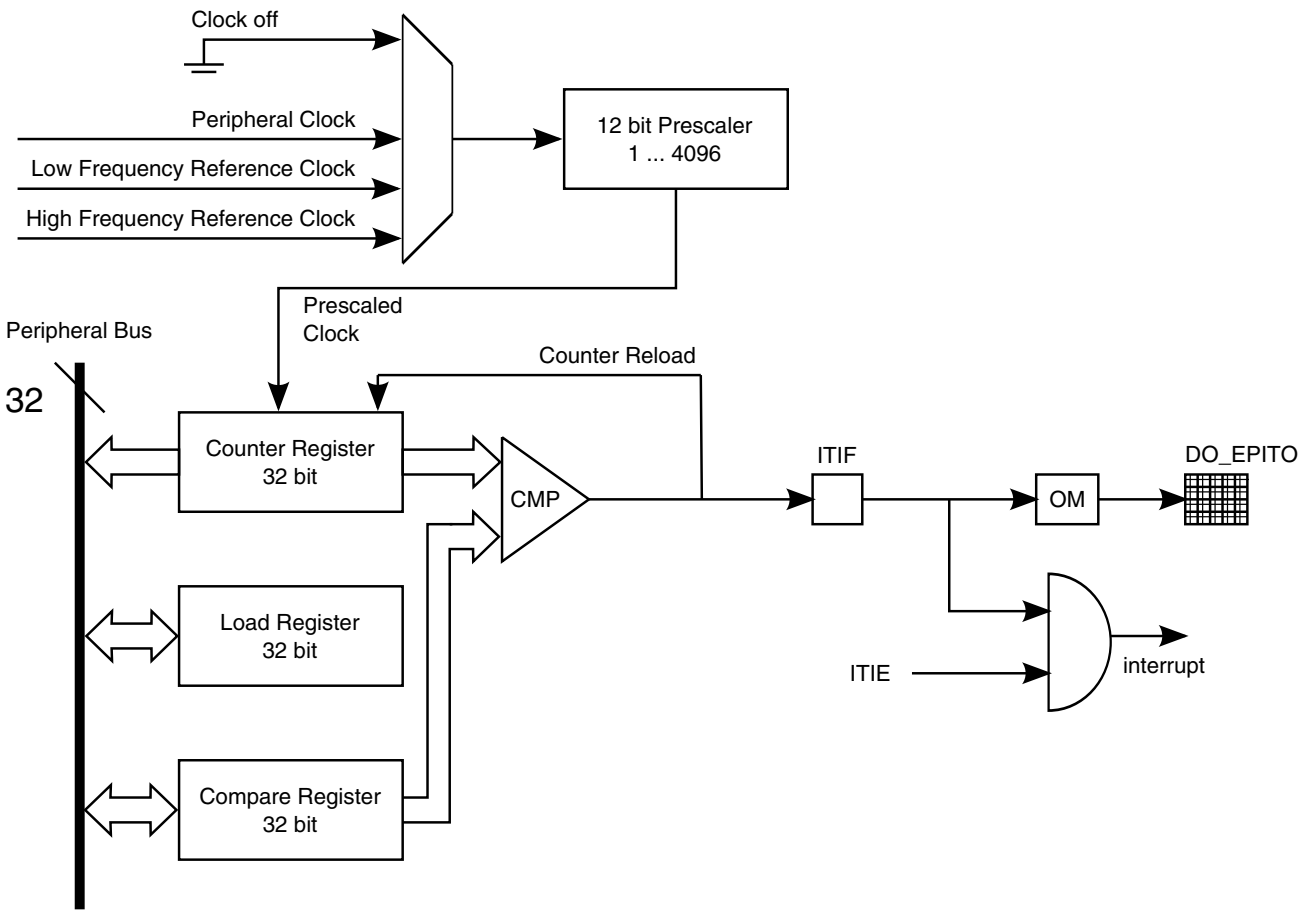

Figure 26-1. EPIT Block Diagram

26.1.1 Features

Key features of the EPIT include:

- 32-bit down counter with clock source selection
- 12-bit prescaler for division of input clock frequency
- Counter value can be programmed on the fly

- Can be programmed to be active during low-power and debug modes
- Interrupt generation when counter reaches the Compare value

26.1.2 Modes and Operations

EPIT supports the modes described in the indicated sections:

- Operating Modes
  - Set-and-Forget Mode
  - Free-Running Mode

EPIT supports the operations as described in Operations.

26.2 External Signals

The following table describes all EPIT's I/O Signals.

Table 26-1. Block I/O Signals

Name	I/O	Description	Reset State	Pull Up
DO_EPITO	O	Output pin at chip boundary for indication of occurrence of output compare event through a specified transition.	0	-

26.3 Functional Description

This section provides a complete functional description of the block.

26.3.1 Operating Modes

This section describes all functional operation modes of the block.

The EPIT can be programmed to function in set-and-forget or free-running modes.

26.3.1.1 Set-and-Forget Mode

This mode of operation is selected when the RLD bit in control register (EPIT_EPITCR) is set to a value of one.

The counter cannot be directly written from the block data bus. Instead, it gets its data from the load register (EPIT_EPITLR). Whenever the counter reaches a count of zero, the value in EPIT_EPITLR is loaded into the counter to be decremented toward zero. The counter may by directly initialized, without having to wait for the count to reach zero, when the EPIT_EPITLR is written with the IOVW bit in EPIT_EPITCR set.

26.3.1.2 Free-Running Mode

This mode of operation is selected when the RLD bit is cleared.

In this mode, the counter rolls over from 0x0000_0000 to 0xFFFF_FFFF without reloading from the modulus register and continues to count down. In this mode when writing to EPIT_EPITLR with the required initialization value after having set the IOVW bit, the counter can also be directly initialized.

26.3.2 Operations

The EPIT has a single 32-bit down counter which starts counting when the block is enabled by software.

The start value of the counter is loaded from the EPIT load register which can be written to at any time by the processor. The value in the compare register determines the time of occurrence of the interrupt.

When EPIT is disabled (EN=0), both the main counter and the prescaler counter freeze their count at current count values. ENMOD bit is a r/w bit which decides the counter value when the EPIT is enabled again by setting EN bit. If ENMOD bit is set, then the main counter is loaded with the load value (If RLD=1)/ 0xFFFF_FFFF (If RLD=0) and the prescaler counter is reset (0x000), when EPIT is enabled (EN=1). If ENMOD is programmed to 0 then both main counter and prescaler counter restart counting from their frozen values, when EPIT is enabled (EN=1). If EPIT is programmed to be disabled in a low-power mode (STOP/WAIT), then both the main counter and the prescaler counter freeze at their current count values when EPIT enters low-power mode. When EPIT exits the low-power mode, both the main counter and the prescaler counter start counting from their frozen values irrespective of the ENMOD bit.

A hardware reset resets all EPIT registers to their respective reset values. There is a software reset which has the same effect on all registers except for the EN, ENMOD, STOPEN and WAITEN bits in the control register. The state of these bits are not affected by software reset. A software reset can be asserted even when the EPIT is disabled.

26.3.3 Clocks

The clock that feeds the prescaler can be selected from among the following sources:

- **High-frequency reference clock**

  This clock is provided by the Clock Control Module (CCM). This clock remains on during low-power mode when the peripheral clock is turned off, allowing EPIT to use this clock in low-power mode. In normal mode, the CCM synchronizes this clock to ahb_clk; in low-power mode, CCM switches to an unsynchronized version.

- **Low-frequency reference clock**

  This 32 kHz reference clock is provided by the CCM. This clock remains on in low-power mode when the peripheral clock is turned off, so EPIT can use this clock during low-power mode. In normal mode, the CCM synchronizes this clock to ahb_clk; in low-power mode, CCM switches to an unsynchronized version. This clock is derived from the external 32kHz crystal.

- **Peripheral clock**

  This is the peripheral clock (PER Clock) which is provided (and optionally gated) by the CCM. This clock is typically used in normal operations. In low-power modes, if the EPIT is programmed to be disabled (via STOPEN or WAITEN), then the peripheral clock can be switched off.

The clock input source is determined by the CLKSRC field in the control register. The clock input to the prescaler can also be disabled by setting CLKSRC to 0b00. **This field value should only be changed after first disabling the EPIT by clearing the EN bit in the EPIT_EPITCR**. For other programming requirements that apply while changing clock source, refer section Change of Clock Source.

The PRESCALER field in the control register is used to select the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by a value between 1 and 4096. A change in the value of the PRESCALER field is immediately reflected on its output clock frequency. The following figure shows the timing for a change in the prescaler value.

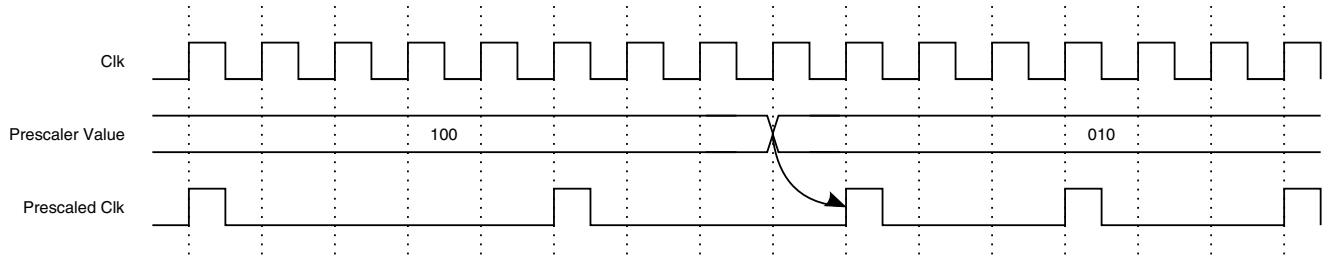

Figure 26-2. Prescaler Value Change Diagram

26.3.4 Compare Event

When the programmed value of EPIT_EPITCMPR matches the value in EPIT_EPITCNR a compare status flag is set, and an interrupt is generated if the OCIEN bit is set in the control register.

The compare output pin is set, cleared, toggled, or not affected at all depending on the setting of the output mode (OM) bits in the control register. If an interrupt is required at rollover (when the counter value reaches 0x0000_0000 and the new value is loaded) then the compare register value should be set equal to the load register value in set-and-forget mode, or equal to 0xFFFF_FFFF in free-running mode.

The following figure shows the timing for a compare event and interrupt.

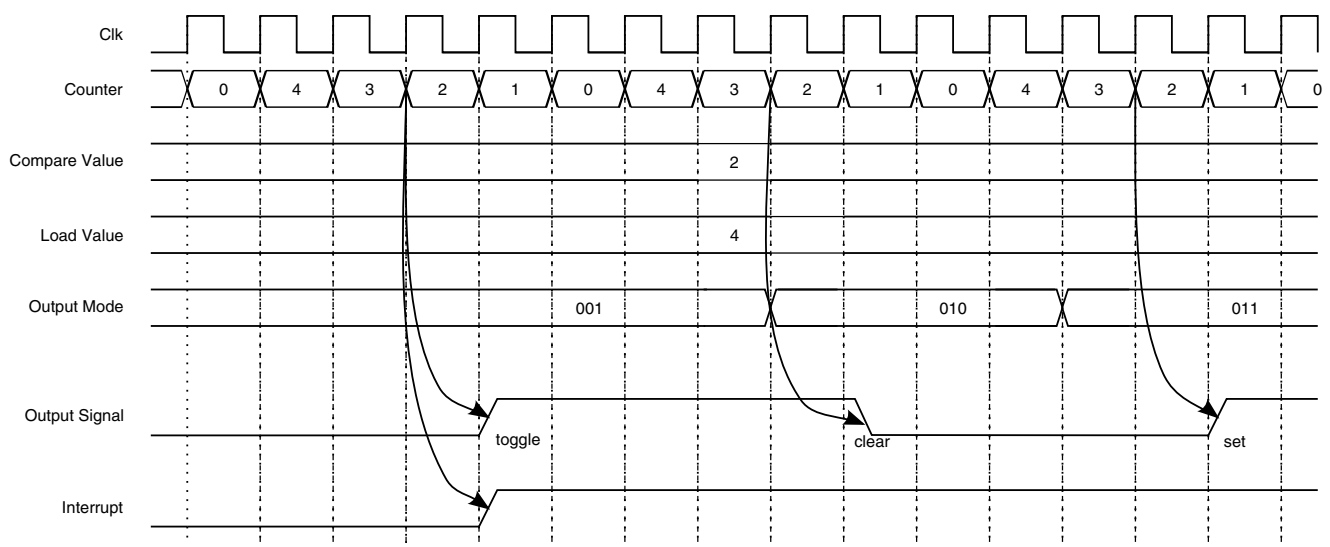

Figure 26-3. Compare Event and Interrupt Timing Diagram

26.3.4.1 Counter Value Overwrite

The EPIT counter value can be overwritten to acquire a desired value at any point of time. The procedure for this is to set the IOVW bit in the control register and then write the desired value into the load register.

This results in the load register acquiring that value and also the counter being overwritten with it. If the EPIT is running the counter resumes counting from the overwritten value.

26.3.4.2 Low-Power Mode Behavior

The EPIT timer's behavior in low-power modes depends on which clock source is being used.

If the selected clock source is available and the corresponding low-power enable bit is set, then the EPIT continues to function in the low-power mode. If the EPIT is programmed to be disabled in a low-power mode (STOP/WAIT), then main counter and the prescaler counter freeze at the current count values when the EPIT enters low-power mode. When the EPIT exits the low-power mode, both main counter and prescaler counter start counting from their frozen values irrespective of the ENMOD bit.

26.3.4.3 Debug Mode Behavior

In debug mode, the user has the option to run or halt the EPIT timers. If the DBGEN bit is reset in the EPIT Control Register, the timer is halted.

When debug mode is exited, the timer operation reverts to what it was prior to entering debug mode.

26.4 Initialization/ Application Information

26.4.1 Change of Clock Source

The CLKSRC field in EPIT_EPITCR determines the clock source. This field value should be changed only after disabling the EPIT (EN = 0).

Below is the software sequence which must be followed while changing clock source.

1. Disable the EPIT by setting EN=0 in EPIT_EPITCR.
2. Program OM=00 in the EPIT_EPITCR.

3. Disable the EPIT interrupts.
4. Program CLKSRC to desired clock source in EPIT_EPITCR.
5. Clear the EPIT status register (EPIT_EPITSR), that is, write "1" to clear (w1c).
6. Enable the EPIT interrupts.
7. Set ENMOD= 1 in the EPIT_EPITCR, to bring the EPIT Counter to defined state (EPIT_EPITLR value or 0xFFFF_FFFF).
8. Enable EPIT (EN=1) in the EPIT_EPITCR

26.5 Programmable Registers

The EPIT includes five user-accessible 32-bit registers. The following table summarizes these registers and their addresses.

Peripheral bus write access to the EPIT control register (EPITCR) and the EPIT load register (EPITLR) results in one cycle of wait state, while other valid peripheral bus accesses are with 0 wait state.

EPIT memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53FA_C000	Control register (EPIT-1_EPITCR)	32	R/W	0000_0000h	26.5.1/ 1141

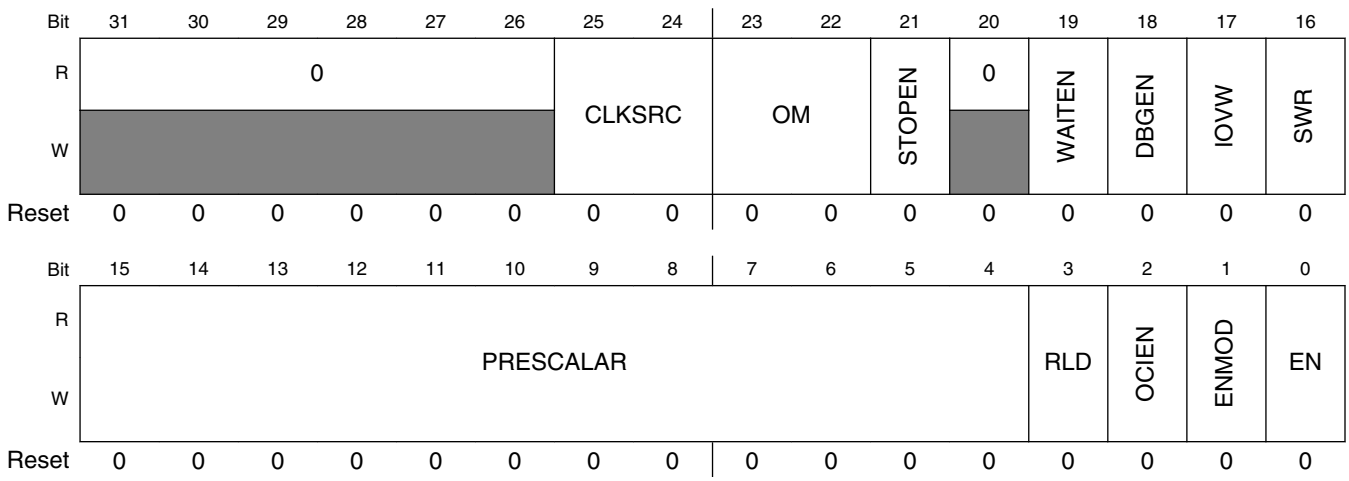
26.5.1 Control register (EPITx_EPITCR)

The EPIT control register (EPIT_EPITCR) is used to configure the operating settings of the EPIT. It contains the clock division prescaler value and also the interrupt enable bit. Additionally it contains other control bit which are outlined below.

Peripheral Bus Write access to EPIT Control Register (EPIT_EPITCR) results in one cycle of the wait state, while other valid peripheral bus accesses are with 0 wait state.

Addresses: EPIT-1_EPITCR is 53FA_C000h base + 0h offset = 53FA_C000h

EPIT-2_EPITCR is 53FB_0000h base + 0h offset = 53FB_0000h



EPITx_EPITCR field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value zero. Reserved. Writing to these bits does not affect the functionality of EPIT. These bits are always read as zero.
25–24 CLKSRC	Select clock source These bits determine which clock input is to be selected for running the counter. This field value should only be changed when the EPIT is disabled by clearing the EN bit in this register. For other programming requirements while changing clock source, refer to Change of Clock Source. 00 Clock is off 01 Peripheral clock 10 High-frequency reference clock 11 Low-frequency reference clock
23–22 OM	EPIT output mode.This bit field determines the mode of EPIT output on the output pin. 00 EPIT output is disconnected from pad 01 Toggle output pin 10 Clear output pin 11 Set output pin

Table continues on the next page...

EPITx_EPITCR field descriptions (continued)

Field	Description
21 STOPEN	EPIT stop mode enable. This read/write control bit enables the operation of the EPIT during stop mode. This bit is reset by a hardware reset and unaffected by software reset. 0 EPIT is disabled in stop mode 1 EPIT is enabled in stop mode
20 Reserved	This read-only field is reserved and always has the value zero. Reserved. Writing to these bits does not affect the functionality of EPIT. These bits are always read as zero.
19 WAITEN	This read/write control bit enables the operation of the EPIT during wait mode. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 EPIT is disabled in wait mode 1 EPIT is enabled in wait mode
18 DBGEN	This bit is used to keep the EPIT functional in debug mode. When this bit is cleared, the input clock is gated off in debug mode.This bit is reset by hardware reset. A software reset does not affect this bit. 0 Inactive in debug mode 1 Active in debug mode
17 IOVW	EPIT counter overwrite enable. This bit controls the counter data when the modulus register is written. When this bit is set, all writes to the load register overwrites the counter contents and the counter starts subsequently counting down from the programmed value. 0 Write to load register does not result in counter value being overwritten. 1 Write to load register results in immediate overwriting of counter value.
16 SWR	Software reset. The EPIT is reset when this bit is set to 1. It is a self clearing bit. This bit is set when the block is in reset state and is cleared when the reset procedure is over. Setting this bit resets all the registers to their reset values, except for the EN, ENMOD, STOPEN, WAITEN and DBGEN bits in this control register 0 EPIT is out of reset 1 EPIT is undergoing reset
15–4 PRESCALAR	Counter clock prescaler value. This bit field determines the prescaler value by which the clock is divided before it goes to the counter 0x000 Divide by 1 0x001 Divide by 2 0xFFFF Divide by 4096
3 RLD	Counter reload control. This bit is cleared by hardware reset. It decides the counter functionality, whether to run in free-running mode or set-and-forget mode. 0 When the counter reaches zero it rolls over to 0xFFFF_FFFF (free-running mode) 1 When the counter reaches zero it reloads from the modulus register (set-and-forget mode)
2 OCIEN	Output compare interrupt enable. This bit enables the generation of interrupt on occurrence of compare event. 0 Compare interrupt disabled 1 Compare interrupt enabled

Table continues on the next page...

EPITx_EPITCR field descriptions (continued)

Field	Description
1 ENMOD	EPIT enable mode. When EPIT is disabled (EN=0), both main counter and prescaler counter freeze their count at current count values. ENMOD bit is a r/w bit that determines the counter value when the EPIT is enabled again by setting EN bit. If ENMOD bit is set, then main counter is loaded with the load value (If RLD=1)/ 0xFFFF_FFFF (If RLD=0) and prescaler counter is reset, when EPIT is enabled (EN=1). If ENMOD is programmed to 0 then both main counter and prescaler counter restart counting from their frozen values when EPIT is enabled (EN=1). If EPIT is programmed to be disabled in a low-power mode (STOP/WAIT/ DEBUG), then both the main counter and the prescaler counter freeze at their current count values when EPIT enters low-power mode. When EPIT exits the low-power mode, both main counter and prescaler counter start counting from their frozen values irrespective of the ENMOD bit. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 Counter starts counting from the value it had when it was disabled. 1 Counter starts count from load value (RLD=1) or 0xFFFF_FFFF (If RLD=0)
0 EN	This bit enables the EPIT. EPIT counter and prescaler value when EPIT is enabled (EN =1), is dependent upon ENMOD and RLD bit as described for ENMOD bit. It is recommended that all registers be properly programmed before setting this bit. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 EPIT is disabled 1 EPIT is enabled

26.5.2 Status register (EPITx_EPITSR)

The EPIT status register (EPIT_EPITSR) has a single status bit for the output compare event. The bit is a write 1 to clear bit.

Addresses: EPIT-1_EPITSR is 53FA_C000h base + 4h offset = 53FA_C004h

EPIT-2_EPITSR is 53FB_0000h base + 4h offset = 53FB_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0

EPITx_EPITSR field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value zero. Reserved. Writing to these bits does not affect the functionality of EPIT. These bits are always read as zero.

Table continues on the next page...

EPITx_EPITSR field descriptions (continued)

Field	Description
0 OCIF	Output compare interrupt flag. This bit is the interrupt flag that is set when the content of counter equals the content of the compare register (EPIT_EPITCMPR). The bit is a write 1 to clear bit. 0 Compare event hasn't occurred 1 Compare event occurred

26.5.3 Load register (EPITx_EPITLR)

The EPIT load register (EPIT_EPITLR) contains the value that is to be loaded into the counter when EPIT counter reaches zero if the RLD bit in EPIT_EPITCR is set. If the IOVW bit in the EPIT_EPITCR is set then a write to this register overwrites the value of the EPIT counter register in addition to updating this registers value. This overwrite feature is active even if the RLD bit is not set.

Addresses: EPIT-1_EPITLR is 53FA_C000h base + 8h offset = 53FA_C008h

EPIT-2_EPITLR is 53FB_0000h base + 8h offset = 53FB_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

EPITx_EPITLR field descriptions

Field	Description
31–0 LOAD	Load value. Value that is loaded into the counter at the start of each count cycle.

26.5.4 Compare register (EPITx_EPITCMPR)

The EPIT compare register (EPIT_EPITCMPR) holds the value that determines when a compare event is generated.

Addresses: EPIT-1_EPITCMPR is 53FA_C000h base + Ch offset = 53FA_C00Ch

EPIT-2_EPITCMPR is 53FB_0000h base + Ch offset = 53FB_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	COMPARE																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EPITx_EPITCMPR field descriptions

Field	Description
31–0 COMPARE	Compare Value. When the counter value equals this bit field value a compare event is generated.

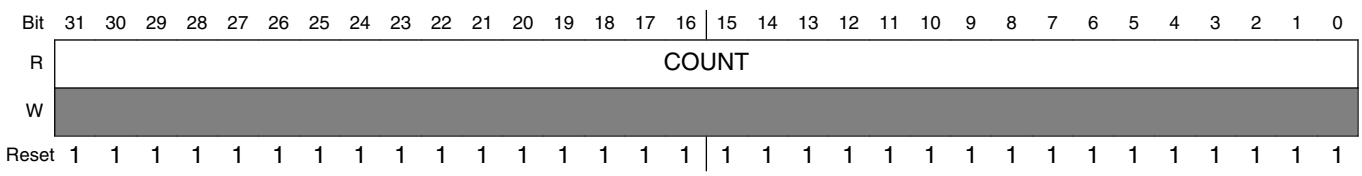
26.5.5 Counter register (EPITx_EPITCNR)

The EPIT counter register (EPIT_EPITCNR) contains the current count value and can be read at any time without disturbing the counter. This is a read-only register and any attempt to write into it generates a transfer error. But if the IOVW bit in EPIT_EPITCR is set, the value of this register can be overwritten with a write to EPIT_EPITLR. This change is reflected when this register is subsequently read.

.

Addresses: EPIT-1_EPITCNR is 53FA_C000h base + 10h offset = 53FA_C010h

EPIT-2_EPITCNR is 53FB_0000h base + 10h offset = 53FB_0010h



EPITx_EPITCNR field descriptions

Field	Description
31–0 COUNT	Counter value. This contains the current value of the counter.

Chapter 27
Enhanced Serial Audio Interface (ESAI)

27.1 Introduction

The Enhanced Serial Audio Interface (ESAI) provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, Sony/Phillips Digital Interface (SPDIF) transceivers, and other DSPs.

The ESAI consists of independent transmitter and receiver sections, each section with its own clock generator. It is a superset of the 56300 Family ESSI peripheral and of the 56000 Family SAI peripheral.

The ESAI block diagram is shown in Figure 27-1. The ESAI is named synchronous because all serial transfers are synchronized to a clock. Additional synchronization signals are used to delineate the word frames. The normal mode of operation is used to transfer data at a periodic rate, one word per period. The network mode is similar in that it is also intended for periodic transfers; however, it supports up to 32 words (time slots) per period. This mode can be used to build time division multiplexed (TDM) networks. In contrast, the on-demand mode is intended for non-periodic transfers of data and to transfer data serially at high speed when the data becomes available.

27.1.1 Overview

The following figure shows the ESAI block diagram.

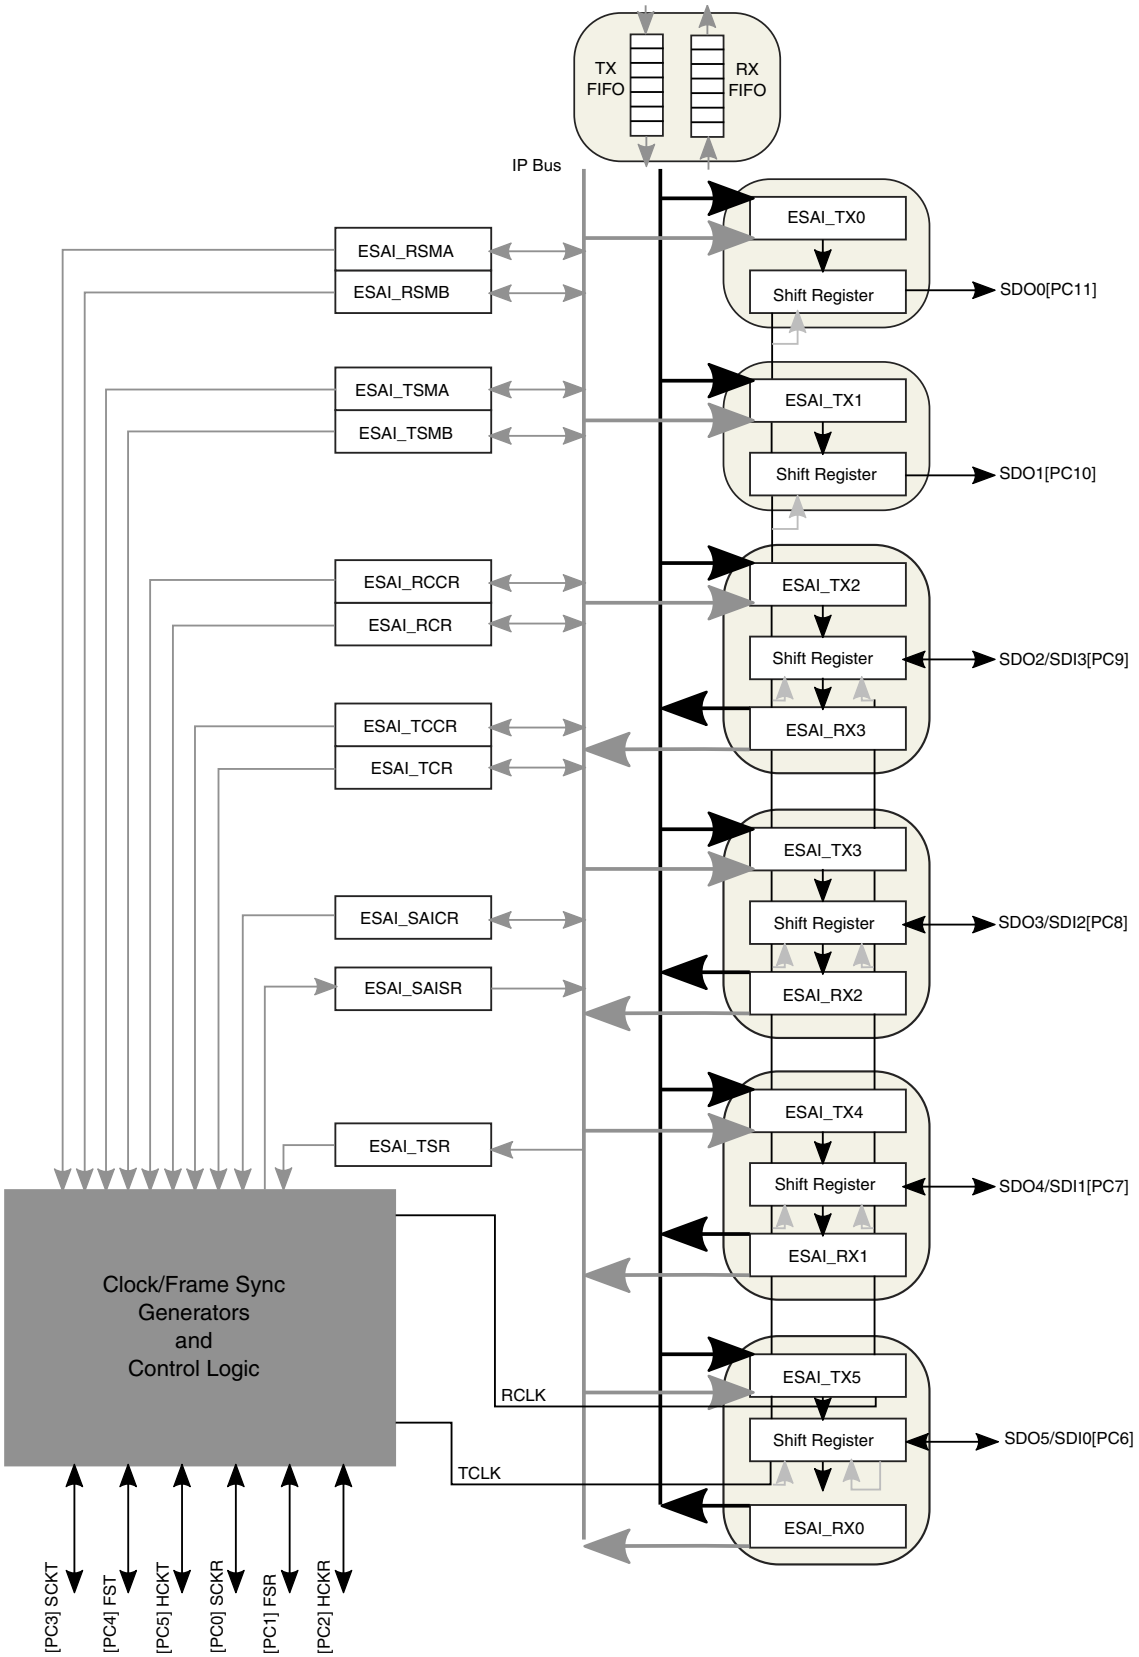


Figure 27-1. ESAI Block Diagram

27.1.2 Features

- Independent (asynchronous mode) or shared (synchronous mode) transmit and receive sections with separate or shared internal/external clocks and frame syncs, operating in Master or Slave mode.
- Up to six transmitters and four receivers with SDO2/SDI3, SDO3/SDI2, SDO4/SDI1 and SDO5/SDI0 pins shared by transmitters 2 to 5 and receivers 0 to 3. SDO0 and SDO1 pins are used by transmitters 0 and 1 only.
- Programmable data interface modes such as I2S, LSB aligned, MSB aligned
- Programmable word length (8, 12, 16, 20 or 24bits)
- Flexible selection between system clock or external oscillator as input clock source, programmable internal clock divider and frame sync generation
- AC97 support
- Time Slot Mask Registers for reduced ARM platform overhead (for both Transmit and Receive)
- 128-word Transmit FIFO shared by six transmitters
- 128-word Receive FIFO shared by four receivers

27.1.3 Modes of Operation

ESAI has three basic operating modes and many data/operation formats.

ESAI operating mode are selected by the ESAI control registers (ESAI_TCCR, ESAI_TCR, ESAI_RCCR, ESAI_RCR, and ESAI_SAICR). The main operating modes are described in the following paragraphs.

27.1.3.1 Normal/Network/On-Demand Mode Selection

Selecting between the normal mode and network mode is accomplished by clearing or setting the TMOD0-TMOD1 bits in the ESAI_TCR register for the transmitter section, as well as in the RMOD0-RMOD1 bits in the ESAI_RCR register for the receiver section.

For normal mode, the ESAI functions with one data word of I/O per frame (per enabled transmitter or receiver). The normal mode is typically used to transfer data to or from a single device.

For the network mode, 2 to 32 time slots per frame may be selected. During each frame, 0 to 32 data words of I/O may be received or transmitted. In either case, the transfers are periodic. The frame sync signal indicates the first time slot in the frame. Network mode is typically used in time division multiplexed (TDM) networks of codecs, DSPs with multiple words per frame, or multi-channel devices.

Selecting the network mode and setting the frame rate divider to zero (DC=00000) selects the on-demand mode. This special case does not generate a periodic frame sync. A frame sync pulse is generated only when data is available to transmit. The on-demand mode requires that the transmit frame sync be internal (output) and the receive frame sync be external (input). Therefore, for simplex operation, the synchronous mode could be used; however, for full-duplex operation, the asynchronous mode must be used. Data transmission that is data driven is enabled by writing data into each TX. Although the ESAI is double buffered, only one word can be written to each TX, even if the transmit shift register is empty. The receive and transmit interrupts function as usual using TDE and RDF; however, transmit underruns are impossible for on-demand transmission and are disabled.

27.1.3.2 Synchronous/Asynchronous Operating Modes

The transmit and receive sections of the ESAI may be synchronous or asynchronous, that is, the transmitter and receiver sections may use common clock and synchronization signals (synchronous operating mode), or they may have their own separate clock and sync signals (asynchronous operating mode).

The SYN bit in the ESAI_SAICR register selects synchronous or asynchronous operation. Because the ESAI is designed to operate either synchronously or asynchronously, separate receive and transmit interrupts are provided.

When SYN is cleared, the ESAI transmitter and receiver clocks and frame sync sources are independent. If SYN is set, the ESAI transmitter and receiver clocks and frame sync come from the transmitter section (either external or internal sources).

Data clock and frame sync signals can be generated internally by the ARM Core or may be obtained from external sources. If internally generated, the ESAI clock generator is used to derive high frequency clock, bit clock and frame sync signals from the ARM Core internal system clock.

27.1.3.3 Frame Sync Selection

The frame sync can be either a bit-long or word-long signal.

The transmitter frame format is defined by the TFSL bit in the ESAI_TCR register. The receiver frame format is defined by the RFSL bit in the ESAI_RCR register.

1. In the word-long frame sync format, the frame sync signal is asserted during the entire word data transfer period. This frame sync length is compatible with codecs, SPI serial peripherals, serial A/D and D/A converters, shift registers and telecommunication PCM serial I/O.
2. In the bit-long frame sync format, the frame sync signal is asserted for one bit clock immediately before the data transfer period. This frame sync length is compatible with Intel and National components, codecs and telecommunication PCM serial I/O.

The relative timing of the word length frame sync as referred to the data word is specified by the TFSR bit in the ESAI_TCR register for the transmitter section and by the RFSR bit in the ESAI_RCR register for the receive section. The word length frame sync may be generated (or expected) with the first bit of the data word, or with the last bit of the previous word. TFSR and RFSR are ignored when a bit length frame sync is selected.

Polarity of the frame sync signal may be defined as positive (asserted high) or negative (asserted low). The TFSP bit in the ESAI_TCCR register specifies the polarity of the frame sync for the transmitter section. The RFSP bit in the ESAI_RCCR register specifies the polarity of the frame sync for the receiver section.

The ESAI receiver looks for a receive frame sync leading edge (trailing edge if RFSP is set) only when the previous frame is completed. If the frame sync goes high before the frame is completed (or before the last bit of the frame is received in the case of a bit frame sync or a word length frame sync with RFSR set), the current frame sync is not recognized, and the receiver is internally disabled until the next frame sync. Frames do not have to be adjacent, that is, a new frame sync does not have to immediately follow the previous frame. Gaps of arbitrary periods can occur between frames. Enabled transmitters are tri-stated during these gaps.

When operating in the synchronous mode (SYN=1), all clocks including the frame sync are generated by the transmitter section.

27.1.3.4 Shift Direction Selection

Some data formats, such as those used by codecs, specify MSB first while other data formats, such as the AES-EBU digital audio interface, specify LSB first.

The MSB/LSB first selection is made by programming RSHFD bit in the ESAI_RCR register for the receiver section and by programming the TSHFD bit in the ESAI_TCR register for the transmitter section.

27.2 External Signal Description

Three to twelve pins are required for operation, depending on the operating mode selected and the number of transmitters and receivers enabled.

The SDO0 and SDO1 pins are used by transmitters 0 and 1 only. The SDO2/SDI3, SDO3/SDI2, SDO4/SDI1 and SDO5/SDI0 pins are shared by transmitters 2 to 5 with receivers 0 to 3. The actual mode of operation is selected under software control. All transmitters operate fully synchronized under control of the same transmitter clock signals. All receivers operate fully synchronized under control of the same receiver clock signals.

27.2.1 Serial Transmit 0 Data Pin (SDO0)

SDO0 is used for transmitting data from the ESAI_TX0 serial transmit shift register.

SDO0 is an output when data is being transmitted from the ESAI_TX0 shift register. In the on-demand mode with an internally generated bit clock, the SDO0 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO0 may be programmed as a disconnected pin (PC11) when the ESAI SDO0 function is not being used.

27.2.2 Serial Transmit 1 Data Pin (SDO1)

SDO1 is used for transmitting data from the ESAI_TX1 serial transmit shift register.

SDO1 is an output when data is being transmitted from the ESAI_TX1 shift register. In the on-demand mode with an internally generated bit clock, the SDO1 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO1 may be programmed as a disconnected pin (PC10) when the ESAI SDO1 function is not being used.

27.2.3 Serial Transmit 2/Receive 3 Data Pin (SDO2/SDI3)

SDO2/SDI3 is used as the SDO2 for transmitting data from the ESAI_TX2 serial transmit shift register when programmed as a transmitter pin, or as the SDI3 signal for receiving serial data to the ESAI_RX3 serial receive shift register when programmed as a receiver pin.

SDO2/SDI3 is an input when data is being received by the ESAI_RX3 shift register. SDO2/SDI3 is an output when data is being transmitted from the ESAI_TX2 shift register. In the on-demand mode with an internally generated bit clock, the SDO2/SDI3 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO2/SDI3 may be programmed as a disconnected pin (PC9) when the ESAI SDO2 and SDI3 functions are not being used.

27.2.4 Serial Transmit 3/Receive 2 Data Pin (SDO3/SDI2)

SDO3/SDI2 is used as the SDO3 signal for transmitting data from the ESAI_TX3 serial transmit shift register when programmed as a transmitter pin, or as the SDI2 signal for receiving serial data to the ESAI_RX2 serial receive shift register when programmed as a receiver pin.

SDO3/SDI2 is an input when data is being received by the ESAI_RX2 shift register. SDO3/SDI2 is an output when data is being transmitted from the ESAI_TX3 shift register. In the on-demand mode with an internally generated bit clock, the SDO3/SDI2 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO3/SDI2 may be programmed as a disconnected pin (PC8) when the ESAI SDO3 and SDI2 functions are not being used.

27.2.5 Serial Transmit 4/Receive 1 Data Pin (SDO4/SDI1)

SDO4/SDI1 is used as the SDO4 signal for transmitting data from the ESAI_TX4 serial transmit shift register when programmed as transmitter pin, or as the SDI1 signal for receiving serial data to the RX1 serial receive shift register when programmed as a receiver pin.

SDO4/SDI1 is an input when data is being received by the ESAI_RX1 shift register. SDO4/SDI1 is an output when data is being transmitted from the ESAI_TX4 shift register. In the on-demand mode with an internally generated bit clock, the SDO4/SDI1 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO4/SDI1 may be programmed as a disconnected pin (PC7) when the ESAI SDO4 and SDI1 functions are not being used.

27.2.6 Serial Transmit 5/Receive 0 Data Pin (SDO5/SDI0)

SDO5/SDI0 is used as the SDO5 signal for transmitting data from the ESAI_TX5 serial transmit shift register when programmed as transmitter pin, or as the SDI0 signal for receiving serial data to the ESAI_RX0 serial shift register when programmed as a receiver pin.

SDO5/SDI0 is an input when data is being received by the ESAI_RX0 shift register. SDO5/SDI0 is an output when data is being transmitted from the ESAI_TX5 shift register. In the on-demand mode with an internally generated bit clock, the SDO5/SDI0 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO5/SDI0 may be programmed as a disconnected pin (PC6) when the ESAI SDO5 and SDI0 functions are not being used.

27.2.7 Receiver Serial Clock (SCKR)

SCKR is a bidirectional pin providing the receivers serial bit clock for the ESAI interface.

The direction of this pin is determined by the RCKD bit in the ESAI_RCCR register.The SCKR operates as a clock input or output used by all the enabled receivers in the asynchronous mode (SYN=0), or as serial flag 0 pin in the synchronous mode (SYN=1).

When this pin is configured as serial flag pin, its direction is determined by the RCKD bit in the ESAI_RCCR register. When configured as the output flag OF0, this pin reflects the value of the OF0 bit in the ESAI_SAICR register, and the data in the OF0 bit shows up at the pin synchronized to the frame sync being used by the transmitter and receiver

sections. When this pin is configured as the input flag IF0, the data value at the pin is stored in the IF0 bit in the ESAI_SAISR register, synchronized by the frame sync in normal mode or the slot in network mode.

SCKR may be programmed as a disconnected pin (PC0) when the ESAI SCKR function is not being used.

NOTE

Although the external ESAI serial clocks can be independent of and asynchronous to the internal 133 MHz ESAI system clock, the external ESAI serial clock frequency cannot exceed 133MHz/4 = 33.25 MHz and each external ESAI serial clock phase must exceed the minimum of 2 x 1/133MHz = 15.04ns.

For SCKR pin mode definitions, see Table 27-37.

The table below provides a list of asynchronous-mode receiver clock sources.

Table 27-1. Receiver Clock Sources (Asynchronous Mode Only)

27.2.8 Transmitter Serial Clock (SCKT)

SCKT is a bidirectional pin providing the transmitters serial bit clock for the ESAI interface.

The direction of this pin is determined by the TCKD bit in the ESAI_TCCR register. The SCKT is a clock input or output used by all the enabled transmitters in the asynchronous mode (SYN=0) or by all the enabled transmitters and receivers in the synchronous mode (SYN=1).

The following table provides a list of asynchronous-mode transmitter clock sources.

Table 27-2. Transmitter Clock Sources (Asynchronous Mode Only)

1	1	1	1	0	EXTAL	HCKT	FST	SCKT
1	1	1	1	1	EXTAL	HCKT	FST	SCKT
Fsys = 133MHz for i.MX25 and i.MX53 EXTAL is the on-chip clock sources other than ESAI system 133MHz clock, and it is from esai_clk_root in CCM								

SCKT may be programmed as a disconnected pin (PC3) when the ESAI SCKT function is not being used.

NOTE

Although the external ESAI serial clocks can be independent of and asynchronous to the internal 133 MHz ESAI system clock, the external ESAI serial clock frequency cannot exceed 133MHz/4 = 33.25 MHz and each external ESAI serial clock phase must exceed the minimum of 2 x 1/133MHz = 15.04ns.

27.2.9 Frame Sync for Receiver (FSR)

FSR is a bidirectional pin providing the receivers frame sync signal for the ESAI interface. The direction of this pin is determined by the RFSD bit in ESAI_RCR register.

In the asynchronous mode (SYN=0), the FSR pin operates as the frame sync input or output used by all the enabled receivers. In the synchronous mode (SYN=1), it operates as either the serial flag 1 pin (TEBE=0), or as the transmitter external buffer enable control (TEBE=1, RFSD=1). For FSR pin mode definitions, see Table 27-38; for receiver clock signals, see Table 27-1.

When this pin is configured as serial flag pin, its direction is determined by the RFSD bit in the ESAI_RCCR register. When configured as the output flag OF1, this pin reflects the value of the OF1 bit in the ESAI_SAICR register, and the data in the OF1 bit shows up at the pin synchronized to the frame sync being used by the transmitter and receiver sections. When configured as the input flag IF1, the data value at the pin is stored in the IF1 bit in the ESAI_SAISR register, synchronized by the frame sync in normal mode or the slot in network mode.

FSR may be programmed as a disconnected pin (PC1) when the ESAI FSR function is not being used.

27.2.10 Frame Sync for Transmitter (FST)

FST is a bidirectional pin providing the frame sync for both the transmitters and receivers in the synchronous mode (SYN=1) and for the transmitters only in asynchronous mode

(SYN=0) (see Table 27-2). The direction of this pin is determined by the TFSD bit in the ESAI_TCR register. When configured as an output, this pin is the internally generated frame sync signal. When configured as an input, this pin receives an external frame sync signal for the transmitters (and the receivers in synchronous mode).

FST may be programmed as a disconnected pin (PC4) when the ESAI FST function is not being used.

27.2.11 High Frequency Clock for Transmitter (HCKT)

HCKT is a bidirectional pin providing the transmitters high frequency clock for the ESAI interface.

The direction of this pin is determined by the THCKD bit in the ESAI_TCCR register. In the asynchronous mode (SYN=0), the HCKT pin operates as the high frequency clock input or output used by all enabled transmitters. In the synchronous mode (SYN=1), it operates as the high frequency clock input or output used by all enabled transmitters and receivers. When programmed as input this pin is used as an alternative high frequency clock source to the ESAI transmitter rather than the ARM Core main clock. When programmed as output it can serve as a high frequency sample clock (to external DACs for example) or as an additional system clock (see Table 27-2).

HCKT may be programmed as a disconnected pin (PC5) when the ESAI HCKT function is not being used.

27.2.12 High Frequency Clock for Receiver (HCKR)

HCKR is a bidirectional pin providing the receivers high frequency clock for the ESAI interface.

The direction of this pin is determined by the RHCKD bit in the ESAI_RCCR register. In the asynchronous mode (SYN=0), the HCKR pin operates as the high frequency clock input or output used by all the enabled receivers. In the synchronous mode (SYN=1), it operates as the serial flag 2 pin. For HCKR pin mode definitions, see Table 27-39; for receiver clock signals, see Table 27-1.

When this pin is configured as serial flag pin, its direction is determined by the RHCKD bit in the ESAI_RCCR register. When configured as the output flag OF2, this pin reflects the value of the OF2 bit in the ESAI_SAICR register, and the data in the OF2 bit shows up at the pin synchronized to the frame sync being used by the transmitter and receiver sections. When configured as the input flag IF2, the data value at the pin is stored in the IF2 bit in the ESAI_SAISR register, synchronized by the frame sync in normal mode or the slot in network mode.

HCKR may be programmed as a disconnected pin (PC2) when the ESAI HCKR function is not being used.

27.2.13 Serial I/O Flags

Three ESAI pins (FSR, SCKR and HCKR) are available as serial I/O flags when the ESAI is operating in the synchronous mode (SYN=1).

Their operation is controlled by RCKD, RFSD, TEBE bits in the ESAI_RCR, ESAI_RCCR and ESAI_SAICR registers.The output data bits (OF2, OF1 and OF0) and the input data bits (IF2, IF1 and IF0) are double buffered to/from the HCKR, FSR and SCKR pins. Double buffering the flags keeps them in sync with the TX and RX data lines.

Each flag can be separately programmed. Flag 0 (SCKR pin) direction is selected by RCKD, RCKD=1 for output and RCKD=0 for input. Flag 1 (FSR pin) is enabled when the pin is not configured as external transmitter buffer enable (TEBE=0) and its direction is selected by RFSD, RFSD=1 for output and RFSD=0 for input. Flag 2 (HCKR pin) direction is selected by RHCKD, RHCKD=1 for output and RHCKD=0 for input.

When programmed as input flags, the SCKR, FSR and HCKR logic values, respectively, are latched at the same time as the first bit of the receive data word is sampled. Because the input was latched, the signal on the input flag pin (SCKR, FSR or HCKR) can change without affecting the input flag until the first bit of the next receive data word. When the received data words are transferred to the receive data registers, the input flag latched values are then transferred to the IF0, IF1 and IF2 bits in the SAISR register, where they may be read by software.

When programmed as output flags, the SCKR, FSR and HCKR logic values are driven by the contents of the OF0, OF1 and OF2 bits in the ESAI_SAICR register respectively, and they are driven when the transmit data registers are transferred to the transmit shift registers. The value on SCKR, FSR and HCKR is stable from the time the first bit of the transmit data word is transmitted until the first bit of the next transmit data word is transmitted. Software may change the OF0-OF2 values thus controlling the SCKR, FSR and HCKR pin values for each transmitted word. The normal sequence for setting output flags when transmitting data is as follows: wait for TDE (transmitter empty) to be set; first write the flags, and then write the transmit data to the transmit registers. OF0, OF1, and OF2 are double buffered so that the flag states appear on the pins when the transmit data is transferred to the transmit shift register, that is, the flags are synchronous with the data.

27.3 Functional Description

27.3.1 ESAI After Reset

Hardware or software reset clears the port control register bits and the port direction control register bits, which configure all ESAI I/O pins as disconnected and both ESAI FIFOs are also in reset state.

The ESAI is in personal reset state while all ESAI pins are programmed as disconnected, and it is active only if at least one of the ESAI I/O pins is programmed as an ESAI pin.

27.3.2 ESAI Interrupt Requests

The ESAI can generate eight different interrupt requests

(ordered from the highest to the lowest priority):

1. **ESAI Receive Data with Exception Status**

   Occurs when the receive exception interrupt is enabled (REIE=1 in the RCR register), at least one of the enabled receive data registers is full (RDF=1) and a receiver overrun error has occurred (ROE=1 in the SAISR register). ROE is cleared by first reading the SAISR and then reading all the enabled receive data registers.

2. **ESAI Receive Even Data**

Occurs when the receive even slot data interrupt is enabled (REDIE=1), at least one of the enabled receive data registers is full (RDF=1), the data is from an even slot (REDF=1) and no exception has occurred (ROE=0 or REIE=0).

Reading all enabled receiver data registers clears RDF and REDF.

3. **ESAI Receive Data**

   Occurs when the receive interrupt is enabled (RIE=1), at least one of the enabled receive data registers is full (RDF=1), no exception has occurred (ROE=0 or REIE=0) and no even slot interrupt has occurred (REDF=0 or REDIE=0). Reading all enabled receiver data registers clears RDF.

4. **ESAI Receive Last Slot Interrupt**

   Occurs, if enabled (RLIE=1), after the last slot of the frame ended (in network mode only) regardless of the receive mask register setting. The receive last slot interrupt may be used for resetting the receive mask slot register, reconfiguring the DMA channels and reassigning data memory pointers. Using the receive last slot interrupt guarantees that the previous frame was serviced with the previous setting and the new frame is serviced with the new setting without synchronization problems. Note that the maximum receive last slot interrupt service time should not exceed N-1 ESAI bits service time (where N is the number of bits in a slot).

5. **ESAI Transmit Data with Exception Status**

   Occurs when the transmit exception interrupt is enabled (TEIE=1), at least one transmit data register of the enabled transmitters is empty (TDE=1) and a transmitter underrun error has occurred (TUE=1). TUE is cleared by first reading the SAISR and then writing to all the enabled transmit data registers, or to the TSR register.

6. **ESAI Transmit Last Slot Interrupt**

   Occurs, if enabled (TLIE=1), at the start of the last slot of the frame in network mode regardless of the transmit mask register setting. The transmit last slot interrupt may be used for resetting the transmit mask slot register, reconfiguring the DMA channels and reassigning data memory pointers. Using the transmit last slot interrupt guarantees that the previous frame was serviced with the previous setting and the new frame is serviced with the new setting without synchronization problems. Note that the maximum transmit last slot interrupt service time should not exceed N-1 ESAI bits service time (where N is the number of bits in a slot).

7. **ESAI Transmit Even Data**

Occurs when the transmit even slot data interrupt is enabled (TEDIE=1), at least one of the enabled transmit data registers is empty (TDE=1), the slot is an even slot (TEDE=1) and no exception has occurred (TUE=0 or TEIE=0). Writing to all the TX registers of the enabled transmitters or to TSR clears this interrupt request.

8. **ESAI Transmit Data**

   Occurs when the transmit interrupt is enabled (TIE=1), at least one of the enabled transmit data registers is empty (TDE=1), no exception has occurred (TUE=0 or TEIE=0) and no even slot interrupt has occurred (TEDE=0 or TEDIE=0). Writing to all the TX registers of the enabled transmitters, or to the TSR clears this interrupt request.

27.3.3 ESAI DMA Requests from the FIFOs

1. ESAI Transmit FIFO Empty - Asserts when the number of empty slots in the ESAI transmit FIFO exceeds the threshold programmed in the ESAI Transmit FIFO Configuration Register (TFCR). Automatically negates when the number of empty slots is less than the threshold programmed in the ESAI Transmit FIFO Configuration Register.
2. ESAI Receive FIFO Full - Asserts when the number of data words in the ESAI receive FIFO exceeds the threshold programmed in the ESAI Receive FIFO Configuration Register (RFCR). Automatically negates when the number of words is less than the threshold programmed in the ESAI Receive FIFO Configuration Register.

27.3.4 ESAI Transmit and Receive Shift Registers

27.3.4.1 ESAI Transmit Shift Registers

The transmit shift registers contain the data being transmitted

Data is shifted out to the serial transmit data pins by the selected (internal/external) bit clock when the associated frame sync I/O is asserted.

The number of bits shifted out before the shift registers are considered empty and may be written to again can be 8, 12, 16, 20, 24 or 32 bits (determined by the slot length control bits in the TCR register). Data is shifted out of these registers MSB first if TSHFD=0 and LSB first if TSHFD=1.

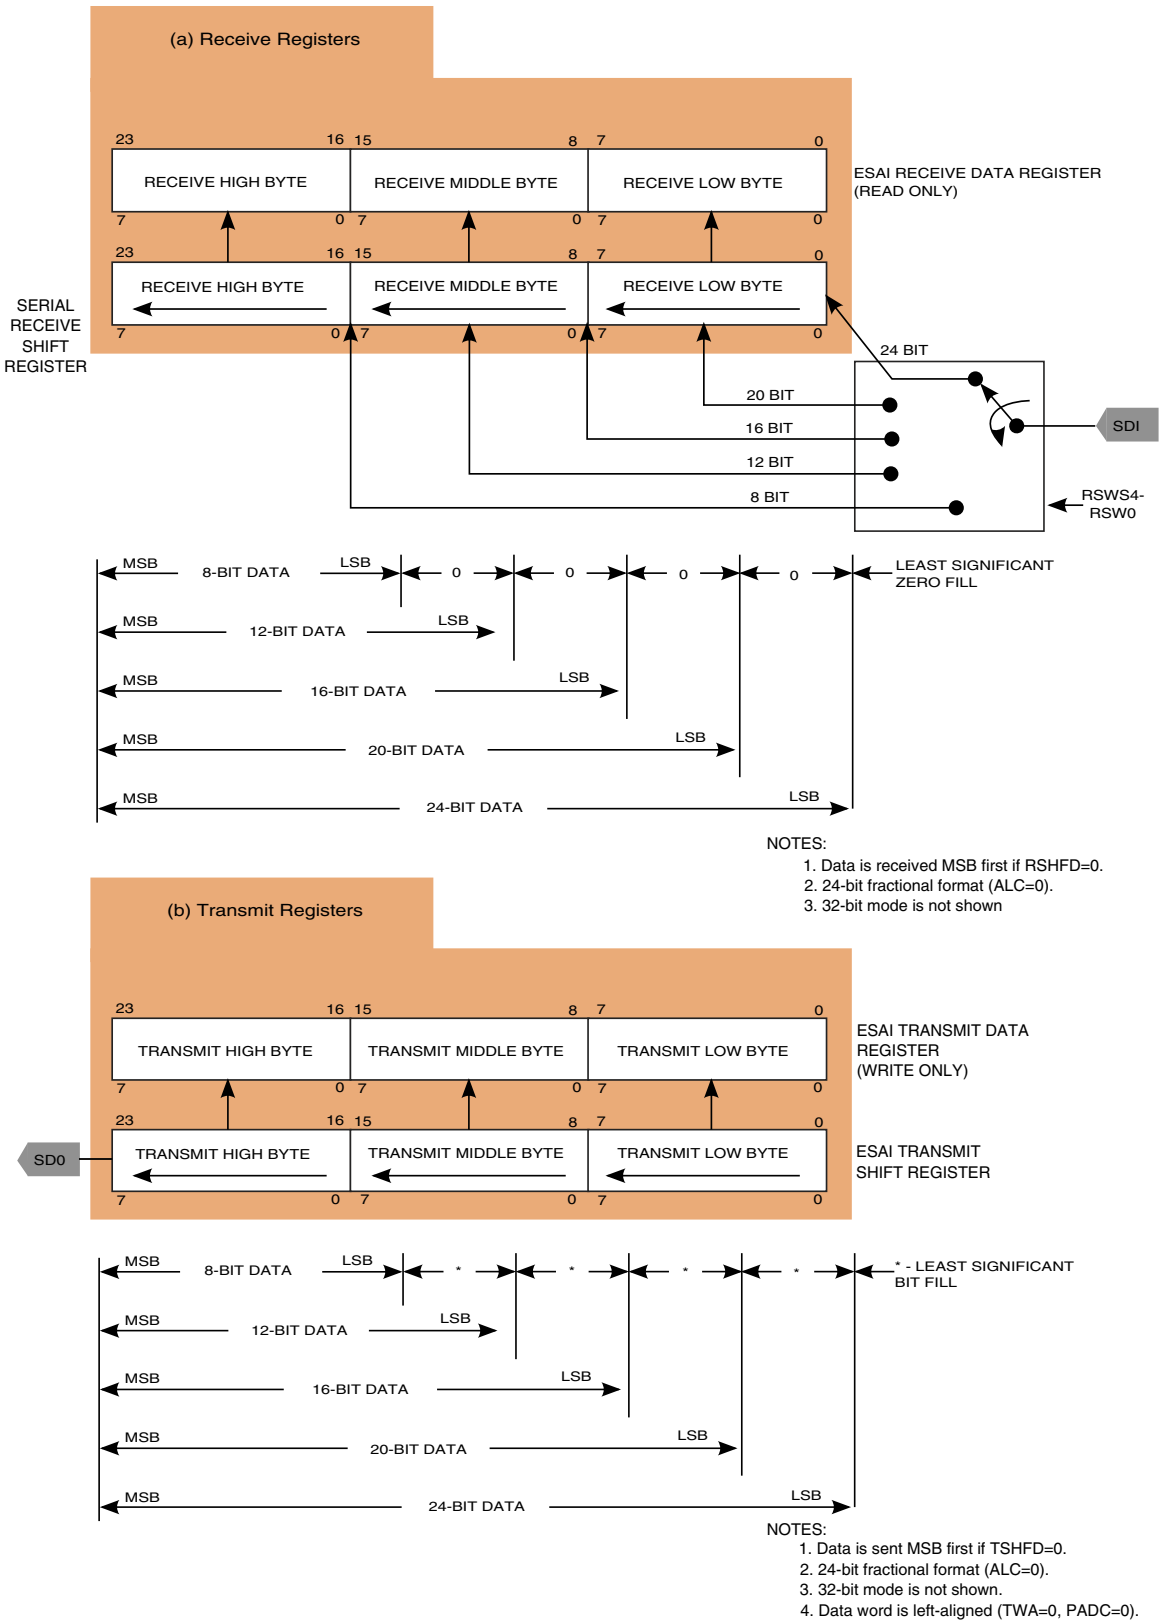

Figure 27-2. ESAI Data Path Programming Model ([R/T]SHFD=0)

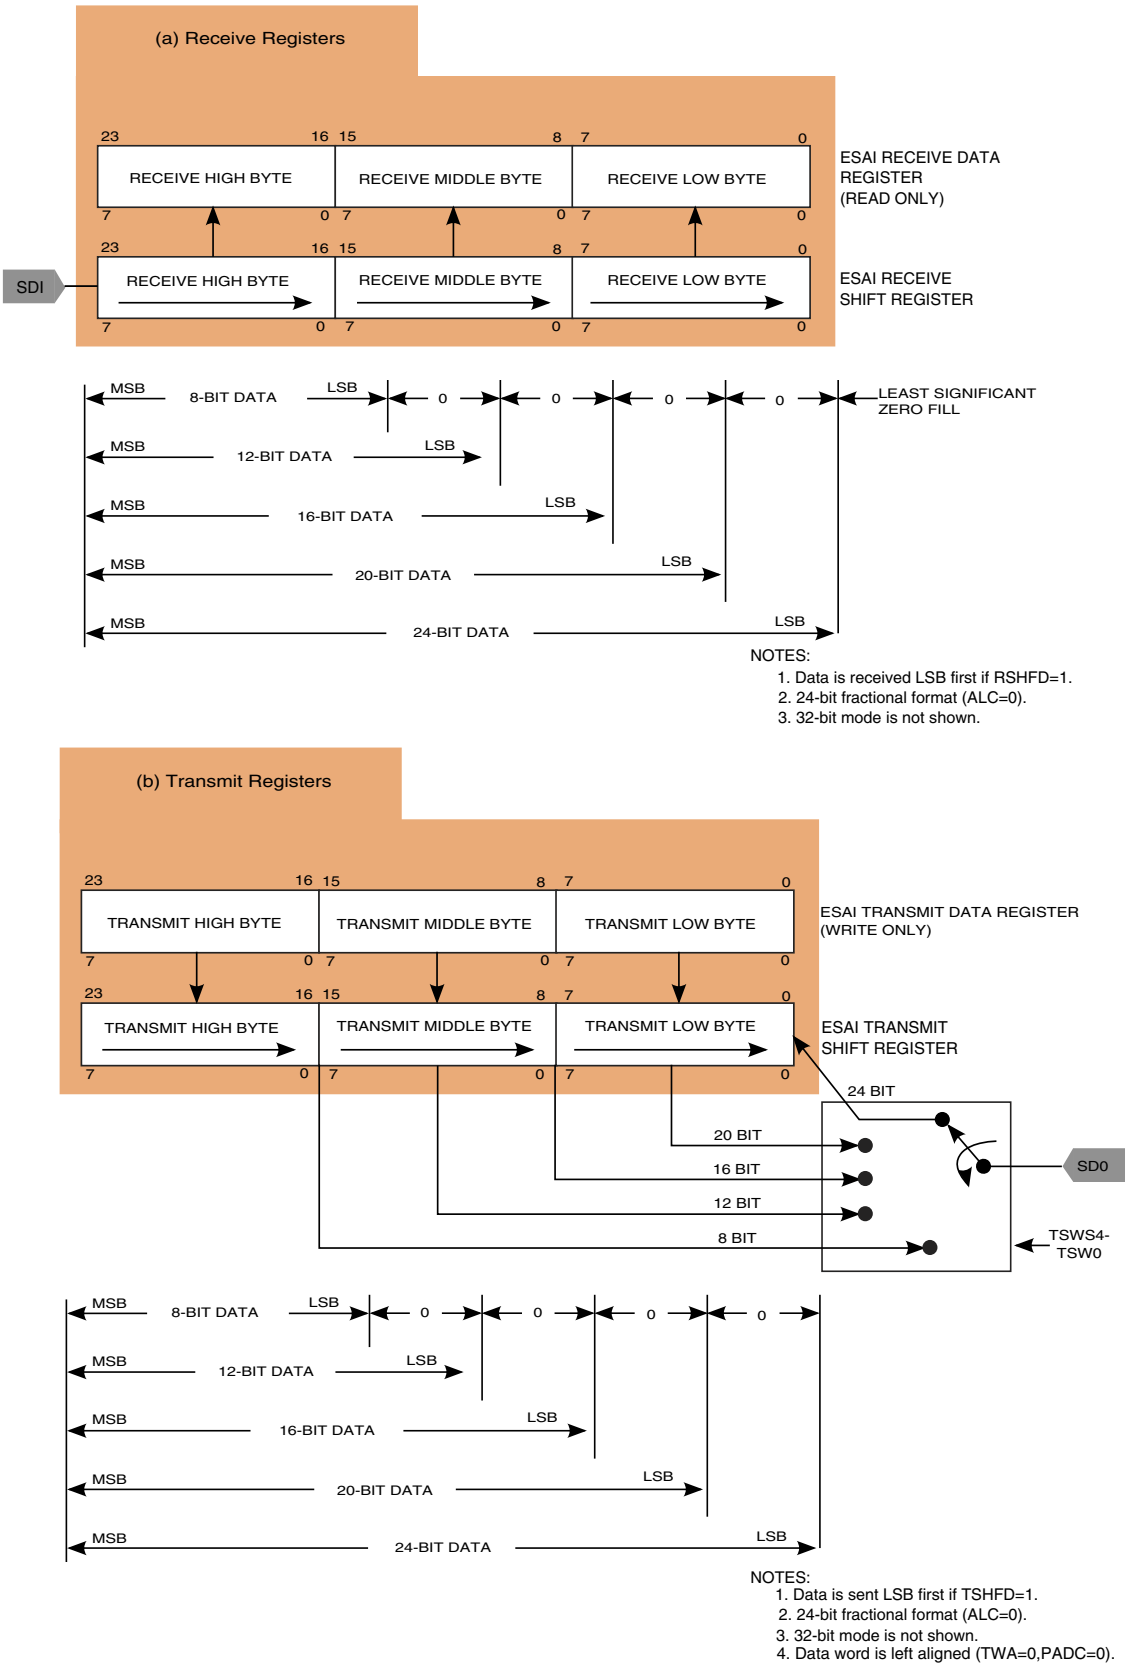

Figure 27-3. ESAI Data Path Programming Model ([R/T]SHFD=1)

27.3.4.2 ESAI Receive Shift Registers

Data is shifted in by the selected (internal/external) bit clock when the associated frame sync I/O is asserted. Data is assumed to be received MSB first if RSHFD=0 and LSB first if RSHFD=1. Data is transferred to the ESAI receive data registers after 8, 12, 16, 20, 24, or 32 serial clock cycles were counted, depending on the slot length control bits in the ESAI_RCR register.

27.4 Initialization Information

27.4.1 ESAI Initialization

The correct way to initialize the ESAI is as follows:

1. Enable the ESAI logic clock by asserting bit 0 of ESAI Control Register (ESAI_ECR[0]).
2. Hardware, software, ESAI individual reset. Note that asserting bit 1 of ESAI Control Register only reset the ESAI core logic, including configuration registers, but not the ESAI FIFOs.
3. Reset ESAI FIFOs by asserting bit 1 of ESAI_TFCR and ESAI_RFCR.
4. Program ESAI control and time slot registers.(The transmit/receive enable bits of TCR/RCR should not be set.)
5. Program ESAI FIFOs via TFCR and RFCR. (Enable Transmit/Receive FIFO, enable transmitters/receivers, transmit initialization and set Transmit FIFO/Receive FIFO watermark.)
6. Write initial words to ESAI Transmit Data Register (ESAI_ETDR), at least one word per enabled transmitter but as many as desired, if Transmit FIFO is used. If not, write initial words to all the enabled transmitters.
7. Remove ESAI personal reset by configuring ESAI_PCRC and ESAI_PRRC.
8. Enabled Transmitters/Receivers in ESAI_TCR/ESAI_RCR.

During program execution, all ESAI pins may be defined disconnected, causing the ESAI to stop serial activity and enter the individual reset state.

All status bits of the interface are set to their reset state however, the control bits are not affected. This procedure allows the programmer to reset the ESAI separately from the other internal peripherals. During individual reset, internal DMA accesses to the data registers of the ESAI are not valid and data read is undefined.

The programmer must use an individual ESAI reset when changing the ESAI control registers (except for TEIE, REIE, TLIE, RLIE, TIE, RIE, TE0-TE5, RE0-RE3) to ensure proper operation of the interface.

NOTE

If the ESAI receiver section is already operating with some of the receivers and enabling additional receivers on the fly, that is, without first putting the ESAI receiver in the personal reset state by setting their REx control bits, it will result in erroneous data being received as the first data word for the newly enabled receivers.

27.4.2 ESAI Initialization Examples

27.4.2.1 Initializing the ESAI using Personal Reset

1. Enable the ESAI logic clock by setting bit 0 of ESAI Control Register(ESAI_ECR[0]).
2. The ESAI should be in its personal reset state (ESAI_PCRC = 0x000 and ESAI_PRRC = 0x000). In the personal reset state, both the transmitter and receiver sections of the ESAI are simultaneously reset. The TPR bit in the ESAI_TCR register may be used to reset just the transmitter section. The RPR bit in the ESAI_RCR register may be used to reset just the receiver section.
3. Configure the control registers (ESAI_TCCR, ESAI_TCR, ESAI_RCCR, ESAI_RCR) and ESAI FIFOs configuration Registers (ESAI_TFCR, ESAI_RFCR) according to the operating mode, but do not enable transmitters (TE5-TE0 = 0x0) or receivers (RE3-RE0 = 0x0). It is possible to set the interrupt enable bits which are in use during the operation (no interrupt occurs).
4. Enable the ESAI by setting the ESAI_PCRC and ESAI_PRRC register bits according to pins which are in use during operation.
5. Write initial words to ESAI Transmit Data Register (ESAI_ETDR) (at least one word per enabled transmitter but as many as you want) if Transmit FIFO is used. If not, just write initial words to all the enabled transmitters which are in use during operation. This step is needed even if DMA is used to service the transmitters.
6. Enable the transmitters and receivers.
7. From now on ESAI can be serviced either by polling, interrupts, or DMA.

Operation proceeds as follows:

- For internally generated clock and frame sync, these signals are active immediately after ESAI is enabled (step 4 above).

- Data is received only when one of the receive enable (REx) bits is set and after the occurrence of frame sync signal (either internally or externally generated).
- Data is transmitted only when the transmitter enable (TEx) bit is set and after the occurrence of frame sync signal (either internally or externally generated). The transmitter outputs remain tri-stated after TEx bit is set until the frame sync occurs.

27.4.2.2 Initializing the ESAI Transmitter Section

1. It is assumed that the ESAI is operational; that is, at least one pin is defined as an ESAI pin.
2. Enable the ESAI logic clock by setting bit 0 of ESAI Control Register(ESAI_ECR[0])
3. The transmitter section should be in its individual reset state (TPR = 1) and also reset the ESAI Transmit FIFO (ESAI_TFCR[1] = 1).
4. Configure the control registers ESAI_TCCR and ESAI_TCR according to the operating mode, configure the Transmit FIFO Configuration Register (bring transmit FIFO out of reset, enable Transmit FIFO, enable transmitters, transmit initialization and set watermark). Make sure to clear the transmitter enable bits (TE0-TE5). TPR must remain set.
5. Take the transmitter section out of the individual reset state by clearing TPR.
6. Write initial words to ESAI Transmit Data Register (ESAI_ETDR) (at least one word per enabled transmitter but as many as you want) if Transmit FIFO is used. If not, just write first words to all the enabled transmitters which are in use during operation. This step is needed even if DMA is used to service the transmitters.
7. Enable the transmitters by setting their TE bits.
8. Data is transmitted only when the transmitter enable (TEx) bit is set and after the occurrence of frame sync signal (either internally or externally generated). The transmitter outputs remain tri-stated after TEx bit is set until the frame sync occurs.
9. From now on the transmitters are operating and can be serviced either by polling, interrupts, or DMA.

27.4.2.3 Initializing the ESAI Receiver Section

1. It is assumed that the ESAI is operational; that is, at least one pin is defined as an ESAI pin.
2. Enable the ESAI logic clock by setting bit 0 of ESAI Control Register (ESAI_ECR[0])
3. The receiver section should be in its individual reset state (RPR = 1) and also reset the ESAI Receive FIFO (ESAI_RFCR[1] = 1).

4. Configure the control registers ESAI_RCCR and ESAI_RCR according to the operating mode, configure the Receive FIFO Configuration Register (bring receive FIFO out of reset, enable Receive FIFO, receivers, and set watermark). Making sure to clear the receiver enable bits (RE0-RE3). RPR must remain set.
5. Take the receiver section out of the individual reset state by clearing RPR.
6. Enable the receivers by setting their RE bits.
7. From now on the receivers are operating and can be serviced either by polling, interrupts, or DMA.

ESAI_ETDR field descriptions

Field	Description
31–0 ETDR	ESAI Transmit Data Register. Writing to this register stores the data written into the ESAI Transmit FIFO. Writing to this register when the Transmit FIFO is full causes the data written to be lost (the existing data within the FIFO is not overwritten). When multiple ESAI transmitters are enabled, the data for each transmitter must be interleaved from lowest transmitter to highest transmitter (for example, if transmitters 0, 2 and 3 are enabled then data must be written as follows: transmitter #0, transmitter #2, transmitter #3, transmitter #0, transmitter #2, transmitter #3, transmitter #0, etc). Data within the ESAI Transmit FIFO is passed to the ESAI transmit shifter registers as defined by the Transmit Word Alignment configuration bits.

27.5.2 ESAI Receive Data Register (ESAI_ERDR)

Address: ESAI_ERDR is 5001_8000h base + 4h offset = 5001_8004h

ESAI_ERDR field descriptions

Field	Description
31–0 ERDR	ESAI Receive Data Register. Reading this register returns the data within the ESAI Receive FIFO. Reading this register when the Receive FIFO is empty returns the last valid data word. When multiple ESAI receivers are enabled, the data for each receiver is interleaved from lowest receiver to highest receiver (for example, if receivers 0, 2 and 3 are enabled then data is returned as follows: receiver #0, receiver #2, receiver #3, receiver #0, receiver #2, receiver #3, receiver #0, etc). Data is passed from the ESAI receive shift registers to the ESAI Receive FIFO as defined by the Receiver Word Alignment configuration bits either zero or sign-extended based on the Receive Extension control bit.

27.5.3 ESAI Control Register (ESAI_ECR)

Address: ESAI_ECR is 5001_8000h base + 8h offset = 5001_8008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ESAI_ESR field descriptions

Field	Description
31–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10 TINIT	Transmit Initialization. Indicates that the Transmit FIFO is writing the first word for each enabled transmitter into the Transmit Data Registers. This bit sets when the Transmit FIFO is enabled (provided Transmit Initialization is enabled) and clears after the Transmit Data Registers have been initialized. The Transmit Enable bits in the Transmit Control Register should not be set until this flag has cleared. 0 Transmitter has finished initializing the Transmit Data Registers (or Transmit FIFO is not enabled or Transmit Initialization is not enabled). 1 Transmitter has not finished initializing the Transmit Data Registers.
9 RFF	Receive FIFO Full. Indicates that the number of data words in the Receive FIFO has equaled or exceeded the Receive FIFO Watermark. This flag also drives the ESAI Receiver DMA request line. ESAI FIFO DMA requests see ESAI DMA Requests from the FIFOs. 0 Number of words in Receive FIFO less than Receive FIFO watermark. 1 Number of words in Receive FIFO is equal to or greater than Receive FIFO watermark.
8 TFE	Transmit FIFO Empty. Indicates that the number of empty slots in the Transmit FIFO has met or exceeded the Transmit FIFO Watermark. This flag also drives the ESAI Transmitter DMA request line. ESAI FIFO DMA request see ESAI DMA Requests from the FIFOs.

Table continues on the next page...

ESAI_ESR field descriptions (continued)

Field	Description
	0 Number of empty slots in Transmit FIFO less than Transmit FIFO watermark. 1 Number of empty slots in Transmit FIFO is equal to or greater than Transmit FIFO watermark.
7 TLS	Transmit Last Slot. Reading this register when TLS is set will negate the Transmit Last Slot interrupt. 0 TLS is not the highest priority active interrupt. 1 TLS is the highest priority active interrupt.
6 TDE	Transmit Data Exception. 0 TDE is not the highest priority active interrupt. 1 TDE is the highest priority active interrupt.
5 TED	Transmit Even Data. 0 TED is not the highest priority active interrupt. 1 TED is the highest priority active interrupt.
4 TD	Transmit Data. 0 TD is not the highest priority active interrupt. 1 TD is the highest priority active interrupt.
3 RLS	Receive Last Slot. Reading this register when RLS is set will negate the Receive Last Slot interrupt. 0 RLS is not the highest priority active interrupt. 1 RLS is the highest priority active interrupt.
2 RDE	Receive Data Exception. 0 RDE is not the highest priority active interrupt. 1 RDE is the highest priority active interrupt.
1 RED	Receive Even Data. 0 RED is not the highest priority active interrupt. 1 RED is the highest priority active interrupt.
0 RD	Receive Data. 0 RD is not the highest priority active interrupt. 1 RD is the highest priority active interrupt.

27.5.5 Transmit FIFO Configuration Register (ESAI_TFCR)

Address: ESAI_TFCR is 5001_8000h base + 10h offset = 5001_8010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESAI_TFCR field descriptions

Field	Description
31–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19 TIEN	Transmitter Initialization Enable. Enables the initialization of the Transmit Data Registers when the Transmitter FIFO is enabled. 0 Transmit Data Registers are not initialized from the FIFO once the Transmit FIFO is enabled. Software must manually initialize the Transmit Data Registers separately. 1 Transmit Data Registers are initialized from the FIFO once the Transmit FIFO is enabled.
18–16 TWA[2:0]	Transmit Word Alignment. Configures the alignment of the data written into the ESAI Transmit Data Register and then passed to the relevant 24 bit Transmit shift register. 000 MSB of data is bit 31. Data bits 7-0 are ignored when passed to transmit shift register. 001 MSB of data is bit 27. Data bits 3-0 are ignored when passed to transmit shift register. 010 MSB of data is bit 23. 011 MSB of data is bit 19. Bottom 4 bits of transmit shift register are zeroed. 100 MSB of data is bit 15. Bottom 8 bits of transmit shift register are zeroed. 101 MSB of data is bit 11. Bottom 12 bits of transmit shift register are zeroed. 110 MSB of data is bit 7. Bottom 16 bits of transmit shift register are zeroed. 111 MSB of data is bit 3. Bottom 20 bits of transmit shift register are zeroed.
15–8 TFWM[7:0]	Transmit FIFO Watermark. These bits configure the threshold at which the Transmit FIFO Empty flag will set. The TFE is set when the number of empty slots in the Transmit FIFO equal or exceed the selected threshold.
7 TE5	Transmitter #5 FIFO Enable. This bit enables transmitter #5 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #5 is not using the Transmit FIFO. 1 Transmitter #5 is using the Transmit FIFO.
6 TE4	Transmitter #4 FIFO Enable. This bit enables transmitter #4 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #4 is not using the Transmit FIFO. 1 Transmitter #4 is using the Transmit FIFO.
5 TE3	Transmitter #3 FIFO Enable. This bit enables transmitter #3 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #3 is not using the Transmit FIFO. 1 Transmitter #3 is using the Transmit FIFO.
4 TE2	Transmitter #2 FIFO Enable. This bit enables transmitter #2 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #2 is not using the Transmit FIFO. 1 Transmitter #2 is using the Transmit FIFO.
3 TE1	Transmitter #1 FIFO Enable. This bit enables transmitter #1 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #1 is not using the Transmit FIFO. 1 Transmitter #1 is using the Transmit FIFO.

Table continues on the next page...

ESAI_TFCR field descriptions (continued)

Field	Description
2 TE0	Transmitter #0 FIFO Enable. This bit enables transmitter #0 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #0 is not using the Transmit FIFO. 1 Transmitter #0 is using the Transmit FIFO.
1 TFR	Transmit FIFO Reset. This bit resets the Transmit FIFO pointers. 0 Transmit FIFO not reset. 1 Transmit FIFO reset.
0 TFE	Transmit FIFO Enable. This bit enables the use of the Transmit FIFO. 0 Transmit FIFO disabled. 1 Transmit FIFO enabled.

27.5.6 Transmit FIFO Status Register (ESAI_TFSR)

Address: ESAI_TFSR is 5001_8000h base + 14h offset = 5001_8014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ESAI_RFCR field descriptions

Field	Description
31–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19 REXT	Receive Extension. Enables the receive data to be returned sign extended when the Receive Word Alignment is configured to return data where the MSB is not aligned with bit 31. 0 Receive data is zero extended. 1 Receive data is sign extended.
18–16 RWA[2:0]	Receive Word Alignment. Configures the alignment of the data passed from the relevant 24 bit Receive shift register and read out the ESAI Receive Data Register. 000 MSB of data is at bit 31. Data bits 7-0 are zeroed. 001 MSB of data is at bit 27. Data bits 3-0 are zeroed. 010 MSB of data is at bit 23. 011 MSB of data is at bit 19. Data bits 3-0 from receive shift register are ignored. 100 MSB of data is at bit 15. Data bits 7-0 from receive shift register are ignored. 101 MSB of data is at bit 11. Data bits 11-0 from receive shift register are ignored. 110 MSB of data is at bit 7. Data bits 15-0 from receive shift register are ignored. 111 MSB of data is at bit 3. Data bits 19-0 from receive shift register are ignored.
15–8 RFWM[7:0]	Receive FIFO Watermark. These bits configure the threshold at which the Receive FIFO Full flag will set. The RFF is set when the number of words in the Receive FIFO equal or exceed the selected threshold. It can be set to a non-zero value.
7–6 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

ESAI_RFCR field descriptions (continued)

Field	Description
5 RE3	Receiver #3 FIFO Enable. This bit enables receiver #3 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled. 0 Receiver #3 is not using the Receive FIFO. 1 Receiver #3 is using the Receive FIFO.
4 RE2	Receiver #2 FIFO Enable. This bit enables receiver #2 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled. 0 Receiver #2 is not using the Receive FIFO. 1 Receiver #2 is using the Receive FIFO.
3 RE1	Receiver #1 FIFO Enable. This bit enables receiver #1 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled. 0 Receiver #1 is not using the Receive FIFO. 1 Receiver #1 is using the Receive FIFO.
2 RE0	Receiver #0 FIFO Enable. This bit enables receiver #0 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled. 0 Receiver #0 is not using the Receive FIFO. 1 Receiver #0 is using the Receive FIFO.
1 RFR	Receive FIFO Reset. This bit resets the Receive FIFO pointers. 0 Receive FIFO not reset. 1 Receive FIFO reset.
0 RFE	Receive FIFO Enable. This bit enables the use of the Receive FIFO. 0 Receive FIFO disabled. 1 Receive FIFO enabled.

27.5.8 Receive FIFO Status Register (ESAI_RFSR)

Address: ESAI_RFSR is 5001_8000h base + 1Ch offset = 5001_801Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

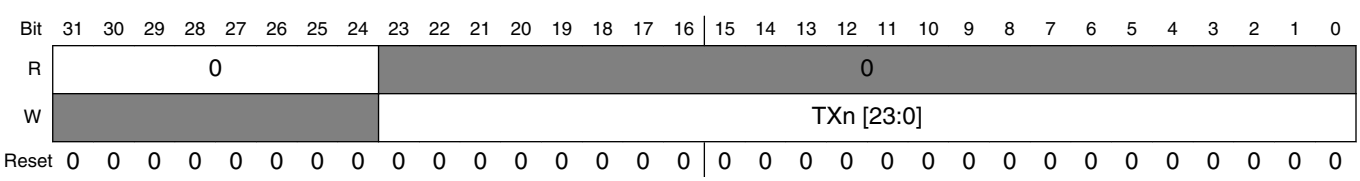
ESAI_RFSR field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value zero. Reserved
13–12 NRFI [1:0]	Next Receiver FIFO In. Indicates which Receiver Data Register the Receive FIFO will load next. This will usually equal the lowest enabled receiver, unless the receive FIFO is full. 00 Receiver #0 returns next word to the Receive FIFO. 01 Receiver #1 returns next word to the Receive FIFO. 10 Receiver #2 returns next word to the Receive FIFO. 11 Receiver #3 returns next word to the Receive FIFO.
11–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–8 NRFO [1:0]	Next Receiver FIFO Out. Indicates which receiver returns the top word of the Receive FIFO. 00 Receiver #0 returns next word from the Receive FIFO. 01 Receiver #1 returns next word from the Receive FIFO. 10 Receiver #2 returns next word from the Receive FIFO. 11 Receiver #3 returns next word from the Receive FIFO.
7–0 RFCNT [7:0]	Receive FIFO Counter. These bits indicate the number of data words stored in the Receive FIFO.

27.5.9 Transmit Data Register n (ESAI_TX)

ESAI_TX5, ESAI_TX4, ESAI_TX3, ESAI_TX2, ESAI_TX1 and ESAI_TX0 are 32-bit write-only registers. Data to be transmitted is written into these registers and is automatically transferred to the transmit shift registers (Figure 1 and Figure 2). The data written (8, 12, 16, 20, or 24 bits) should occupy the most significant portion of the TXn according to the ALC control bit setting. The unused bits (least significant portion and the 8 most significant bits when ALC=1) of the TXn are don't care bits. The Core is interrupted whenever the TXn becomes empty if the transmit data register empty interrupt has been enabled.

Addresses: ESAI_TX0 is 5001_8000h base + 80h offset = 5001_8080h
ESAI_TX1 is 5001_8000h base + 84h offset = 5001_8084h
ESAI_TX2 is 5001_8000h base + 88h offset = 5001_8088h
ESAI_TX3 is 5001_8000h base + 8Ch offset = 5001_808Ch
ESAI_TX4 is 5001_8000h base + 90h offset = 5001_8090h
ESAI_TX5 is 5001_8000h base + 94h offset = 5001_8094h



ESAI_TX*n* field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved
23–0 TXn [23:0]	Stores the data to be transmitted and is automatically transferred to the transmit shift registers. See ESAI Transmit Shift Registers.

27.5.10 ESAI Transmit Slot Register (ESAI_TSR)

Address: ESAI_TSR is 5001_8000h base + 98h offset = 5001_8098h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								0																							
W									TSR [23:0]																							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

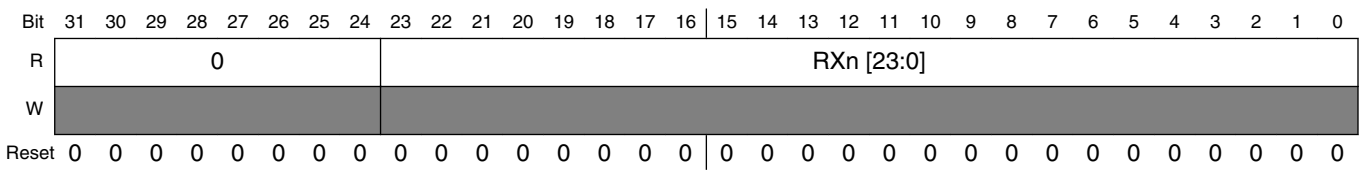
ESAI_TSR field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved
23–0 TSR [23:0]	The write-only Transmit Slot Register (ESAI_TSR) is effectively a null data register that is used when the data is not to be transmitted in the available transmit time slot. The transmit data pins of all the enabled transmitters are in the high-impedance state for the respective time slot where TSR has been written. The Transmitter External Buffer Enable pin (FSR pin when SYN=1, TEBE=1, RFSD=1) disables the external buffers during the slot when the ESAI_TSR register has been written.

27.5.11 Receive Data Register n (ESAI_RX)

ESAI_RX3, ESAI_RX2, ESAI_RX1, and ESAI_RX0 are 32-bit read-only registers that accept data from the receive shift registers when they become full (Figure 1 and Figure 2). The data occupies the most significant portion of the receive data registers, according to the ALC control bit setting. The unused bits (least significant portion and 8 most significant bits when ALC=1) read as zeros. The Core is interrupted whenever RXn becomes full if the associated interrupt is enabled.

Addresses: ESAI_RX0 is 5001_8000h base + A0h offset = 5001_80A0h
ESAI_RX1 is 5001_8000h base + A4h offset = 5001_80A4h
ESAI_RX2 is 5001_8000h base + A8h offset = 5001_80A8h
ESAI_RX3 is 5001_8000h base + ACh offset = 5001_80ACh



ESAI_RX*n* field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved
23–0 RXn [23:0]	Accept data from the receive shift registers when they become full See ESAI Receive Shift Registers

27.5.12 Serial Audio Interface Status Register (ESAI_SAISR)

The Status Register (ESAI_SAISR) is a read-only status register used by the ARM Core to read the status and serial input flags of the ESAI.

Address: ESAI_SAISR is 5001_8000h base + CCh offset = 5001_80CCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0														TODFE	TEDE
W

ESAI_SAISR field descriptions

Field	Description
31–18 Reserved	This read-only field is reserved and always has the value zero. Reserved.
17 TODFE	ESAI_SAISR Transmit Odd-Data Register Empty. When set, TODFE indicates that the enabled transmitter data registers became empty at the beginning of an odd time slot. Odd time slots are all odd-numbered slots (1, 3, 5, and so on). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. This flag is set when the contents of the transmit data register of all the enabled transmitters are transferred to the transmit shift registers; it is also set for a TSR disabled time slot period in network mode (as if data were being transmitted after the TSR was written). When set, TODFE indicates that data should be written to all the TX registers of the enabled transmitters or to the transmit slot register (ESAI_TSR). TODE is cleared when the Core writes to all the transmit data registers of the enabled transmitters, or when the Core writes to the TSR to disable transmission of the next time slot. If TIE is set, an ESAI transmit data interrupt request is issued when TODFE is set. Hardware, software, ESAI individual reset clear TODFE.
16 TEDE	ESAI_SAISR Transmit Even-DataRegister Empty. When set, TEDE indicates that the enabled transmitter data registers became empty at the beginning of an even time slot. Even time slots are all even-numbered slots (0, 2, 4, 6, etc.). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. The zero time slot is considered even. This flag is set when the contents of the transmit data register of all the enabled transmitters are transferred to the transmit shift registers; it is also set for a TSR disabled time slot period in network mode (as if data were being transmitted after the TSR was written). When set, TEDE indicates that data should be written to all the TX registers of the enabled transmitters or to the transmit slot register (ESAI_TSR). TEDE is cleared when the Core writes to all the transmit data registers of the enabled transmitters, or when the Core writes to the TSR to disable transmission of the next time slot. If TIE is set, an ESAI transmit data interrupt request is issued when TEDE is set. Hardware, software, ESAI individual reset clear TEDE.

Table continues on the next page...

ESAI_SAISR field descriptions (continued)

Field	Description
15 TDE	ESAI_SAISR Transmit Data Register Empty. TDE is set when the contents of the transmit data register of all the enabled transmitters are transferred to the transmit shift registers; it is also set for a TSR disabled time slot period in network mode (as if data were being transmitted after the TSR was written). When set, TDE indicates that data should be written to all the TX registers of the enabled transmitters or to the transmit slot register (ESAI_TSR). TDE is cleared when the Core writes to all the transmit data registers of the enabled transmitters, or when the Core writes to the TSR to disable transmission of the next time slot. If TIE is set, an ESAI transmit data interrupt request is issued when TDE is set. Hardware, software, ESAI individual reset clear TDE.
14 TUE	ESAI_SAISR Transmit Underrun Error Flag. TUE is set when at least one of the enabled serial transmit shift registers is empty (no new data to be transmitted) and a transmit time slot occurs. When a transmit underrun error occurs, the previous data (which is still present in the TX registers that were not written) is retransmitted. If TEIE is set, an ESAI transmit data with exception (underrun error) interrupt request is issued when TUE is set. Hardware, software, ESAI individual reset clear TUE. TUE is also cleared by reading the ESAI_SAISR with TUE set, followed by writing to all the enabled transmit data registers or to ESAI_TSR.
13 TFS	ESAI_SAISR Transmit Frame Sync Flar. When set, TFS indicates that a transmit frame sync occurred in the current time slot. TFS is set at the start of the first time slot in the frame and cleared during all other time slots. Data written to a transmit data register during the time slot when TFS is set is transmitted (in network mode), if the transmitter is enabled, during the second time slot in the frame. TFS is useful in network mode to identify the start of a frame. TFS is cleared by hardware, software, ESAI individual reset. TFS is valid only if at least one transmitter is enabled, that is, one or more of TE0, TE1, TE2, TE3, TE4 and TE5 are set. (In normal mode, TFS always reads as a one when transmitting data because there is only one time slot per frame - the "frame sync" time slot)
12–11 Reserved	This read-only field is reserved and always has the value zero. Reserved.
10 RODF	ESAI_SAISR Receive Odd-Data Register Full. When set, RODF indicates that the received data in the receive data registers of the enabled receivers have arrived during an odd time slot when operating in the network mode. Odd time slots are all odd-numbered slots (1, 3, 5, and so on). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. RODF is set when the contents of the receive shift registers are transferred to the receive data registers. RODF is cleared when the Core reads all the enabled receive data registers or cleared by hardware, software, ESAI individual resets.
9 REDF	ESAI_SAISR Receive Even-Data Register Full. When set, REDF indicates that the received data in the receive data registers of the enabled receivers have arrived during an even time slot when operating in the network mode. Even time slots are all even-numbered slots (0, 2, 4, 6, and so on). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. The zero time slot is considered even. REDF is set when the contents of the receive shift registers are transferred to the receive data registers. REDF is cleared when the Core reads all the enabled receive data registers or cleared by hardware, software, ESAI individual resets. If REDIE is set, an ESAI receive even slot data interrupt request is issued when REDF is set.
8 RDF	ESAI_SAISR Receive Data Register Full. RDF is set when the contents of the receive shift register of an enabled receiver is transferred to the respective receive data register. RDF is cleared when the Core reads the receive data register of all enabled receivers or cleared by hardware, software, ESAI individual reset. If RIE is set, an ESAI receive data interrupt request is issued when RDF is set.
7 ROE	ESAI_SAISR Receive Overrun Error Flag. The ROE flag is set when the serial receive shift register of an enabled receiver is full and ready to transfer to its receiver data register (RXn) and the register is already full (RDF=1). If REIE is set, an ESAI receive data with exception (overrun error) interrupt request is issued when ROE is set. Hardware, software, ESAI individual reset clear ROE. ROE is also cleared by reading the SAISR with ROE set, followed by reading all the enabled receive data registers.
6 RFS	ESAI_SAISR Receive Frame Sync Flag. When set, RFS indicates that a receive frame sync occurred during reception of the words in the receiver data registers. This indicates that the data words are from

Table continues on the next page...

ESAI_SAISR field descriptions (continued)

Field	Description
	the first slot in the frame. When RFS is clear and a word is received, it indicates (only in the network mode) that the frame sync did not occur during reception of that word. RFS is cleared by hardware, software, ESAI individual reset. RFS is valid only if at least one of the receivers is enabled (REx=1). (In normal mode, RFS always reads as a one when reading data because there is only one time slot per frame - the "frame sync" time slot)
5–3 Reserved	This read-only field is reserved and always has the value zero. Reserved.
2 IF2	ESAI_SAISR Serial Input Flag 2. The IF2 bit is enabled only when the HCKR pin is defined as ESAI in the Port Control Register, SYN=1 and RHCKD=0, indicating that HCKR is an input flag and the synchronous mode is selected. Data present on the HCKR pin is latched during reception of the first received data bit after frame sync is detected. The IF2 bit is updated with this data when the receive shift registers are transferred into the receiver data registers. IF2 reads as a zero when it is not enabled. Hardware, software, ESAI individual reset clear IF2.
1 IF1	ESAI_SAISR Serial Inout Flag 1. The IF1 bit is enabled only when the FSR pin is defined as ESAI in the Port Control Register, SYN =1, RFSD=0 and TEBE=0, indicating that FSR is an input flag and the synchronous mode is selected. Data present on the FSR pin is latched during reception of the first received data bit after frame sync is detected. The IF1 bit is updated with this data when the receiver shift registers are transferred into the receiver data registers. IF1 reads as a zero when it is not enabled. Hardware, software, ESAI individual reset clear IF1.
0 IF0	ESAI_SAISR Serial Input Flag 0. The IF0 bit is enabled only when the SCKR pin is defined as ESAI in the Port Control Register, SYN=1 and RCKD=0, indicating that SCKR is an input flag and the synchronous mode is selected. Data present on the SCKR pin is latched during reception of the first received data bit after frame sync is detected. The IF0 bit is updated with this data when the receiver shift registers are transferred into the receiver data registers. IF0 reads as a zero when it is not enabled. Hardware, software, ESAI individual reset clear IF0.

27.5.13 Serial Audio Interface Control Register (ESAI_SAICR)

The read/write Common Control Register (ESAI_SAICR) contains control bits for functions that affect both the receive and transmit sections of the ESAI.

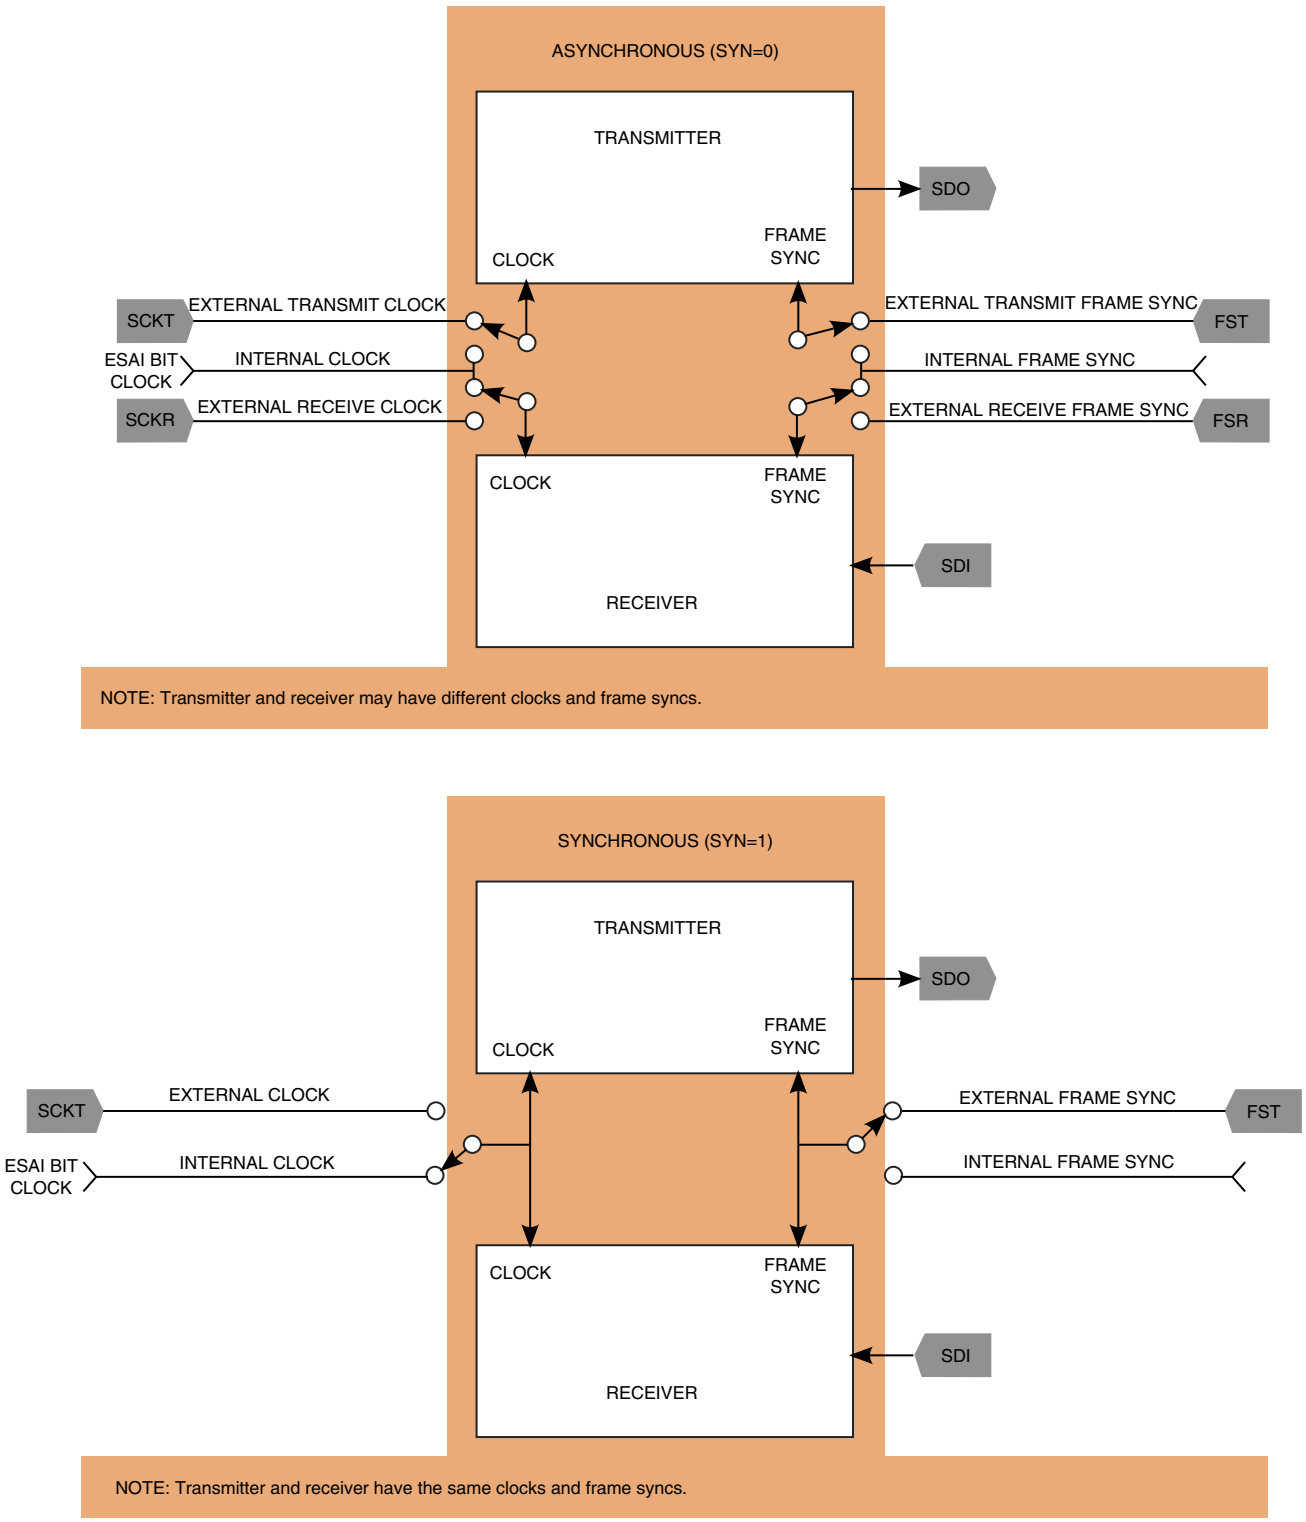

Figure 27-27. SAICR SYN Bit Operation

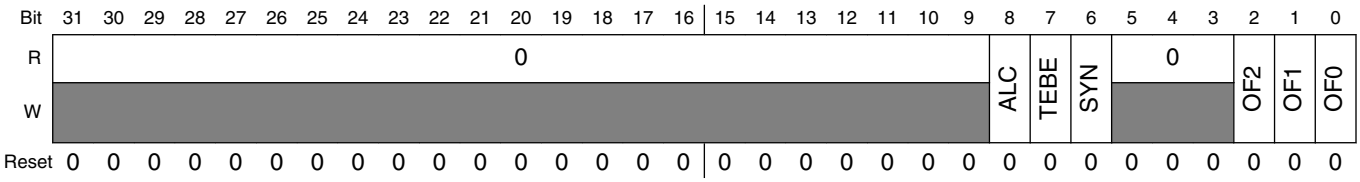
Address: ESAI_SAICR is 5001_8000h base + D0h offset = 5001_80D0h



ESAI_SAICR field descriptions

Field	Description
31–9 Reserved	This read-only field is reserved and always has the value zero. Reserved
8 ALC	ESAI_SAICR Alignment Control. The ESAI is designed for 24-bit fractional data, thus shorter data words are left aligned to the MSB (bit 23). Some applications use 16-bit fractional data. In those cases, shorter data words may be left aligned to bit 15. The Alignment Control (ALC) bit supports these applications. If ALC is set, transmitted and received words are left aligned to bit 15 in the transmit and receive shift registers. If ALC is cleared, transmitted and received word are left aligned to bit 23 in the transmit and receive shift registers. While ALC is set, 20-bit and 24-bit words may not be used, and word length control should specify 8-, 12-, or 16-bit words; otherwise, results are unpredictable.
7 TEBE	ESAI_SAICR Transmit External Buffer Enable. The Transmitter External Buffer Enable (TEBE) bit controls the function of the FSR pin when in the synchronous mode. If the ESAI is configured for operation in the synchronous mode (SYN=1), and TEBE is set while FSR pin is configured as an output (RFSD=1), the FSR pin functions as the transmitter external buffer enable control to enable the use of an external buffers on the transmitter outputs. If TEBE is cleared, the FSR pin functions as the serial I/O flag 1. See Port C Control Register Receive Clock Control Register for a summary of the effects of TEBE on the FSR pin.
6 SYN	ESAI_SAICR Synchronous Mode Selection. The Synchronous Mode Selection (SYN) bit controls whether the receiver and transmitter sections of the ESAI operate synchronously or asynchronously with respect to each other (see Port C Control Register Serial Audio Interface Control Register). When SYN is cleared, the asynchronous mode is chosen and independent clock and frame sync signals are used for the transmit and receive sections. When SYN is set, the synchronous mode is chosen and the transmit and receive sections use common clock and frame sync signals. When in the synchronous mode (SYN=1), the transmit and receive sections use the transmitter section clock generator as the source of the clock and frame sync for both sections. Also, the receiver clock pins SCKR, FSR and HCKR now operate as I/O flags. Refer to Table 27-37, Table 27-38, and Table 27-39 for the effects of SYN on the receiver clock pins.
5–3 Reserved	This read-only field is reserved and always has the value zero. Reserved.
2 OF2	ESAI_SAICR Serial Output Flag 2. The Serial Output Flag 2 (OF2) is a data bit used to hold data to be send to the OF2 pin. When the ESAI is in the synchronous clock mode (SYN=1), the HCKR pin is configured as the ESAI flag 2. If the receiver high frequency clock direction bit (RHCKD) is set, the HCKR pin is the output flag OF2, and data present in the OF2 bit is written to the OF2 pin at the beginning of the frame in normal mode or at the beginning of the next time slot in network mode.
1 OF1	ESAI_SAICR Serial Output Flag 1. The Serial Output Flag 1 (OF1) is a data bit used to hold data to be send to the OF1 pin. When the ESAI is in the synchronous clock mode (SYN=1), the FSR pin is configured as the ESAI flag 1. If the receiver frame sync direction bit (RFSD) is set and the TEBE bit is cleared, the FSR pin is the output flag OF1, and data present in the OF1 bit is written to the OF1 pin at the beginning of the frame in normal mode or at the beginning of the next time slot in network mode.
0 OF0	ESAI_SAICR Serial Output Flag 0. The Serial Output Flag 0 (OF0) is a data bit used to hold data to be send to the OF0 pin. When the ESAI is in the synchronous clock mode (SYN=1), the SCKR pin is

Table continues on the next page...

ESAI_SAICR field descriptions (continued)

Field	Description
	configured as the ESAI flag 0. If the receiver serial clock direction bit (RCKD) is set, the SCKR pin is the output flag OF0, and data present in the OF0 bit is written to the OF0 pin at the beginning of the frame in normal mode or at the beginning of the next time slot in network mode.

27.5.14 Transmit Control Register (ESAI_TCR)

The read/write Transmit Control Register (ESAI_TCR) controls the ESAI transmitter section. Interrupt enable bits for the transmitter section are provided in this control register. Operating modes are also selected in this register.

Table 27-28. Transmit Network Mode Selection

TMOD1	TMOD0	TDC4-TDC0	Transmitter Network Mode

ESAI_TCR field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved.
23 TLIE	ESAI_TCR Transmit Last Slot Interrupt Enable. TLIE enables an interrupt at the beginning of last slot of a frame in network mode. When TLIE is set the Core is interrupted at the start of the last slot in a frame in network mode regardless of the transmit mask register setting. When TLIE is cleared the transmit last slot interrupt is disabled. TLIE is disabled when TDC[4:0]=0x00000 (on-demand mode). The use of the transmit last slot interrupt is described in ESAI Interrupt Requests.
22 TIE	ESAI_TCR Transmit Interrupt Enable. The Core is interrupted when TIE and the TDE flag in the ESAI_SAISR status register are set. When TIE is cleared, this interrupt is disabled. Writing data to all the data registers of the enabled transmitters or to ESAI_TSR clears TDE, thus clearing the interrupt. Transmit interrupts with exception have higher priority than normal transmit data interrupts, therefore if exception occurs (TUE is set) and TEIE is set, the ESAI requests an ESAI transmit data with exception interrupt from the interrupt controller.
21 TEDIE	ESAI_TCR Transmit Even Slot Data Interrupt Enable. The TEDIE control bit is used to enable the transmit even slot data interrupts. If TEDIE is set, the transmit even slot data interrupts are enabled. If TEDIE is cleared, the transmit even slot data interrupts are disabled. A transmit even slot data interrupt request is generated if TEDIE is set and the TEDE status flag in the ESAI_SAISR status register is set. Even time slots are all even-numbered time slots (0, 2, 4, etc.) when operating in network mode. The zero time slot in the frame is marked by the frame sync signal and is considered to be even. Writing data to all the data registers of the enabled transmitters or to ESAI_TSR clears the TEDE flag, thus servicing the interrupt. Transmit interrupts with exception have higher priority than transmit even slot data interrupts, therefore if exception occurs (TUE is set) and TEIE is set, the ESAI requests an ESAI transmit data with exception interrupt from the interrupt controller.
20 TEIE	ESAI_TCR Transmit Exception Interrupt Enable. When TEIE is set, the Core is interrupted when both TDE and TUE in the ESAI_SAISR status register are set. When TEIE is cleared, this interrupt is disabled. Reading the ESAI_SAISR status register followed by writing to all the data registers of the enabled transmitters clears TUE, thus clearing the pending interrupt.
19 TPR	ESAI_TCR Transmit Section Personal Reset. The TPR control bit is used to put the transmitter section of the ESAI in the personal reset state. The receiver section is not affected. When TPR is cleared, the transmitter section may operate normally. When TPR is set, the transmitter section enters the personal reset state immediately. When in the personal reset state, the status bits are reset to the same state as after hardware reset. The control bits are not affected by the personal reset state. The transmitter data

Table continues on the next page...

ESAI_TCR field descriptions (continued)

Field	Description
	pins are tri-stated while in the personal reset state; if a stable logic level is desired, the transmitter data pins should be defined as GPIO outputs, or external pull-up or pull-down resistors should be used. The transmitter clock outputs drive zeroes while in the personal reset state. Note that to leave the personal reset state by clearing TPR, the procedure described in ESAI Initialization Examples should be followed.
18 Reserved	This read-only field is reserved and always has the value zero. Reserved.
17 PADC	ESAI_TCR Transmit Zero Padding Control. When PADC is cleared, zero padding is disabled. When PADC is set, zero padding is enabled. PADC, in conjunction with the TWA control bit, determines the way that padding is done for operating modes where the word length is less than the slot length. See the TWA bit description in bit 7 for more details. Because the data word is shorter than the slot length, the data word is extended until achieving the slot length, according to the following rule: If the data word is left-aligned (TWA=0), and zero padding is disabled (PADC=0), the last data bit is repeated after the data word has been transmitted. If zero padding is enabled (PADC=1), zeroes are transmitted after the data word has been transmitted. If the data word is right-aligned (TWA=1), and zero padding is disabled (PADC=0), the first data bit is repeated before the transmission of the data word. If zero padding is enabled (PADC=1), zeroes are transmitted before the transmission of the data word.
16 TFSR	ESAI_TCR Transmit Frame Sync Relative Timing. TFSR determines the relative timing of the transmit frame sync signal as referred to the serial data lines, for a word length frame sync only (TFSL=0). When TFSR is cleared the word length frame sync occurs together with the first bit of the data word of the first slot. When TFSR is set the word length frame sync starts one serial clock cycle earlier, that is, together with the last bit of the previous data word.
15 TFSL	ESAI_TCR Transmit Frame Sync Length. The TFSL bit selects the length of frame sync to be generated or recognized. If TFSL is cleared, a word-length frame sync is selected. If TFSL is set, a 1-bit clock period frame sync is selected. See Figure 1-21 for examples of frame length selection.
14–10 TSWS [14:10]	ESAI_TCR Tx Slot and Word Length Select (TSWS4-TSWS0). The TSWS4-TSWS0 bits are used to select the length of the slot and the length of the data words being transferred through the ESAI. The word length must be equal to or shorter than the slot length. The possible combinations are shown in Table 27-29. See also the ESAI data path programming model in Figure 27-2 and Figure 27-3.
9–8 TMOD [9:8]	ESAI_TCR Transmit Network Mode Control (TMOD1-TMOD0). The TMOD1 and TMOD0 bits are used to define the network mode of ESAI transmitters, as shown in Table 27-29. In the normal mode, the frame rate divider determines the word transfer rate - one word is transferred per frame sync during the frame sync time slot, as shown in Figure 27-29. In network mode, it is possible to transfer a word for every time slot, as shown in Figure 27-29. For further details, refer to Modes of Operation In order to comply with AC-97 specifications, TSWS4-TSWS0 should be set to 00011 (20-bit slot, 20-bit word length), TFSL and TFSR should be cleared, and TDC4-TDC0 should be set to 0x0C (13 words in frame). If TMOD[1:0]=0b11 and the above recommendations are followed, the first slot and word will be 16 bits long, and the next 12 slots and words will be 20 bits long, as required by the AC97 protocol.
7 TWA	ESAI_TCR Transmit Word Alignment Control. The Transmitter Word Alignment Control (TWA) bit defines the alignment of the data word in relation to the slot. This is relevant for the cases where the word length is shorter than the slot length. If TWA is cleared, the data word is left-aligned in the slot frame during transmission. If TWA is set, the data word is right-aligned in the slot frame during transmission. Because the data word is shorter than the slot length, the data word is extended until achieving the slot length, according to the following rule: If the data word is left-aligned (TWA=0), and zero padding is disabled (PADC=0), the last data bit is repeated after the data word has been transmitted. If zero padding is enabled (PADC=1), zeroes are transmitted after the data word has been transmitted.

Table continues on the next page...

ESAI_TCR field descriptions (continued)

Field	Description
	If the data word is right-aligned (TWA=1), and zero padding is disabled (PADC=0), the first data bit is repeated before the transmission of the data word. If zero padding is enabled (PADC=1), zeroes are transmitted before the transmission of the data word.
6 TSHFD	ESAI_TCR Transmit Shift Direction. The TSHFD bit causes the transmit shift registers to shift data out MSB first when TSHFD equals zero or LSB first when TSHFD equals one (see Figure 27-2 and Figure 27-3 .
5 TE5	ESAI_TCR ESAI Transmit 5 Enable. TE5 enables the transfer of data from ESAI_TX5 to the transmit shift register #5. When TE5 is set and a frame sync is detected, the transmit #5 portion of the ESAI is enabled for that frame. When TE5 is cleared, the transmitter #5 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to ESAI_TX5 when TE5 is cleared but the data is not transferred to the transmit shift register #5. The SDO5/SDI0 pin is the data input pin for ESAI_RX0 if TE5 is cleared and RE0 in the ESAI_RCR register is set. If both RE0 and TE5 are cleared, the transmitter and receiver are disabled, and the pin is tri-stated. Both RE0 and TE5 should not be set at the same time. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE5 and setting it again disables the transmitter #5 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO5/SDI0 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE5 can be left enabled.
4 TE4	ESAI_TCR ESAI Transmit 4 Enable. TE4 enables the transfer of data from ESAI_TX4 to the transmit shift register #4. When TE4 is set and a frame sync is detected, the transmit #4 portion of the ESAI is enabled for that frame. When TE4 is cleared, the transmitter #4 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to ESAI_TX4 when TE4 is cleared but the data is not transferred to the transmit shift register #4. The SDO4/SDI1 pin is the data input pin for ESAI_RX1 if TE4 is cleared and RE1 in the RCR register is set. If both RE1 and TE4 are cleared, the transmitter and receiver are disabled, and the pin is tri-stated. Both RE1 and TE4 should not be set at the same time. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE4 and setting it again disables the transmitter #4 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO4/SDI1 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE4 can be left enabled.
3 TE3	ESAI_TCR ESAI Transmit 3 Enable. TE3 enables the transfer of data from ESAI_TX3 to the transmit shift register #3. When TE3 is set and a frame sync is detected, the transmit #3 portion of the ESAI is enabled for that frame. When TE3 is cleared, the transmitter #3 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to ESAI_TX3 when TE3 is cleared but the data is not transferred to the transmit shift register #3. The SDO3/SDI2 pin is the data input pin for ESAI_RX2 if TE3 is cleared and RE2 in the ESAI_RCR register is set. If both RE2 and TE3 are cleared, the transmitter and receiver are disabled, and the pin is tri-stated. Both RE2 and TE3 should not be set at the same time. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE3 and setting it again disables the transmitter #3 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO3/SDI2 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE3 can be left enabled.

Table continues on the next page...

ESAI_TCR field descriptions (continued)

Field	Description
2 TE2	ESAI_TCR ESAI Transmit 2 Enable. TE2 enables the transfer of data from ESAI_TX2 to the transmit shift register #2. When TE2 is set and a frame sync is detected, the transmit #2 portion of the ESAI is enabled for that frame. When TE2 is cleared, the transmitter #2 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to ESAI_TX2 when TE2 is cleared but the data is not transferred to the transmit shift register #2. The SDO2/SDI3 pin is the data input pin for ESAI_RX3 if TE2 is cleared and RE3 in the ESAI_RCR register is set. If both RE3 and TE2 are cleared, the transmitter and receiver are disabled, and the pin is tri-stated. Both RE3 and TE2 should not be set at the same time. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE2 and setting it again disables the transmitter #2 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO2/SDI3 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE2 can be left enabled.
1 TE1	ESAI_TCR ESAI Transmit 1 Enable. TE1 enables the transfer of data from TX1 to the transmit shift register #1. When TE1 is set and a frame sync is detected, the transmit #1 portion of the ESAI is enabled for that frame. When TE1 is cleared, the transmitter #1 is disabled after completing transmission of data currently in the ESAI transmit shift register. The SDO1 output is tri-stated, and any data present in TX1 is not transmitted, that is, data can be written to TX1 with TE1 cleared, but data is not transferred to the transmit shift register #1. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE1 and setting it again disables the transmitter #1 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO1 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE1 can be left enabled.
0 TE0	ESAI_TCR ESAI Transmit 0 Enable. TE0 enables the transfer of data from ESAI_TX0 to the transmit shift register #0. When TE0 is set and a frame sync is detected, the transmit #0 portion of the ESAI is enabled for that frame. When TE0 is cleared, the transmitter #0 is disabled after completing transmission of data currently in the ESAI transmit shift register. The SDO0 output is tri-stated, and any data present in ESAI_TX0 is not transmitted, that is, data can be written to ESAI_TX0 with TE0 cleared, but data is not transferred to the transmit shift register #0. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE0 and setting it again disables the transmitter #0 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO0 pin remains in the high-impedance state.The on-demand mode transmit enable sequence can be the same as the normal mode, or TE0 can be left enabled.

27.5.15 Transmit Clock Control Register (ESAI_TCCR)

The read/write Transmitter Clock Control Register (ESAI_TCCR) controls the ESAI transmitter clock generator bit and frame sync rates, the bit clock and high frequency clock sources and the directions of the HCKT, FST and SCKT signals. In the synchronous mode (SYN=1), the bit clock defined for the transmitter determines the receiver bit clock as well. ESAI_TCCR also controls the number of words per frame for the serial data. Hardware and software reset clear all the bits of the ESAI_TCCR register.

Care should be taken in asynchronous mode whenever the frame sync clock (FSR, FST) is not sourced directly from its associated bit clock (SCKR, SCKT). Proper phase relationships must be maintained between these clocks in order to guarantee proper operation of the ESAI.

NOTE

ARM Core clock is ipg_clk_esai in block ESAI which is from CCM's ahb_clk_root.

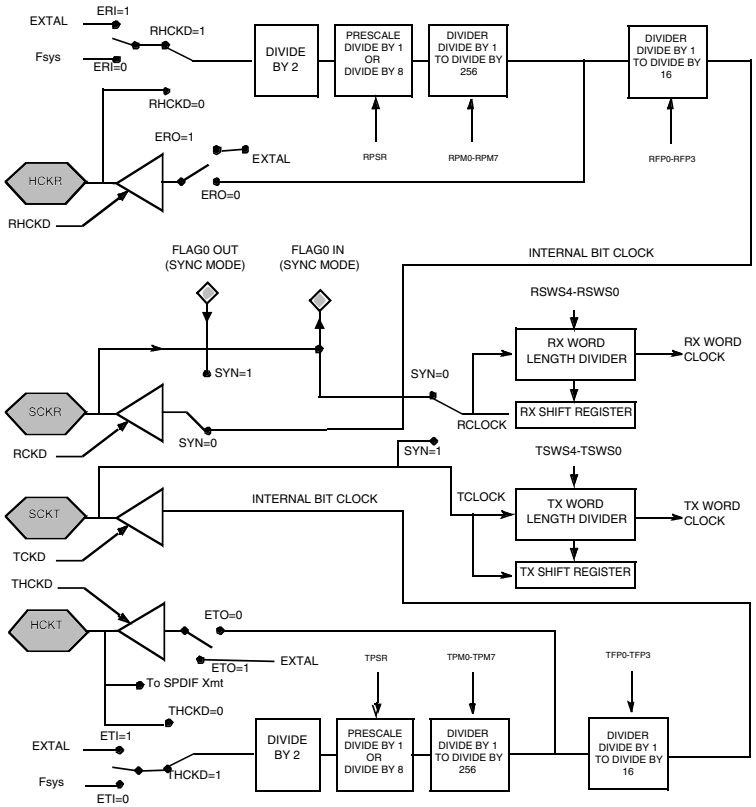

Figure 27-32. ESAI Clock Generator Functional Block Diagram

NOTE

1. ETI, ETO, ERI and ERO bit descriptions are covered in ESAI Control Register (ESAI_ECR). 2. Fsys is the ESAI system 133 MHz clock. 3. EXTAL is the on-chip clock sources other than ESAI system 133MHz clock.

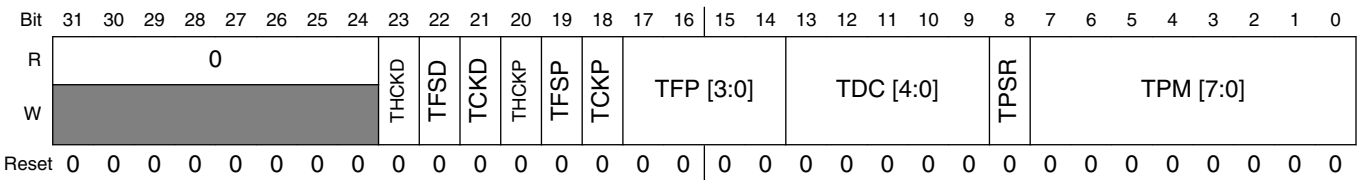
Address: ESAI_TCCR is 5001_8000h base + D8h offset = 5001_80D8h



ESAI_TCCR field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved.
23 THCKD	ESAI_TCCR Transmit High Frequency Clock Direction. THCKD controls the direction of the HCKT pin. When THCKD is cleared, HCKT is an input; when THCKD is set, HCKT is an output (see Table 27-2).
22 TFSD	ESAI_TCCR Transmit Frame Sync Signal Direction. TFSD controls the direction of the FST pin. When TFSD is cleared, FST is an input; when TFSD is set, FST is an output (see Table 27-2).
21 TCKD	ESAI_TCCR Transmit Clock Source Direction. The Transmitter Clock Source Direction (TCKD) bit selects the source of the clock signal used to clock the transmit shift registers in the asynchronous mode (SYN=0) and the transmit shift registers and the receive shift registers in the synchronous mode (SYN=1). When TCKD is set, the internal clock source becomes the bit clock for the transmit shift registers and word length divider and is the output on the SCKT pin. When TCKD is cleared, the clock source is external; the internal clock generator is disconnected from the SCKT pin, and an external clock source may drive this pin (see Table 27-2).
20 THCKP	ESAI_TCCR Transmit High Frequency Clock Polarity. The Transmitter High Frequency Clock Polarity (THCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If THCKP is cleared the data and the frame sync are clocked out on the rising edge of the transmit high frequency bit clock and latched in on the falling edge of the transmit bit clock. If THCKP is set the falling edge of the transmit clock is used to clock the data out and frame sync and the rising edge of the transmit clock is used to latch the data and frame sync in.
19 TFSP	ESAI_TCCR Transmit Frame Sync Polarity. The Transmitter Frame Sync Polarity (TFSP) bit determines the polarity of the transmit frame sync signal. When TFSP is cleared, the frame sync signal polarity is positive, that is, the frame start is indicated by a high level on the frame sync pin. When TFSP is set, the frame sync signal polarity is negative, that is, the frame start is indicated by a low level on the frame sync pin.
18 TCKP	ESAI_TCCR Transmit Clock Polarity. The Transmitter Clock Polarity (TCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If TCKP is cleared the data and the frame sync are clocked out on the rising edge of the transmit bit clock and latched in on the falling edge of the transmit bit clock. If TCKP is set the falling edge of the transmit clock is used to clock the data out and frame sync and the rising edge of the transmit clock is used to latch the data and frame sync in.
17–14 TFP [3:0]	ESAI_TCCR Tx High Frequency Clock Divider. The TFP3-TFP0 bits control the divide ratio of the transmitter high frequency clock to the transmitter serial bit clock when the source of the high frequency clock and the bit clock is the internal ARM Core clock. When the HCKT input is being driven from an external high frequency clock, the TFP3-TFP0 bits specify an additional division ratio in the clock divider chain. Table 27-31 shows the specification for the divide ratio. Figure 27-32 shows the ESAI high frequency clock generator functional diagram.
13–9 TDC [4:0]	ESAI_TCCR Tx Frame Rate Divider Control. The TDC4-TDC0 bits control the divide ratio for the programmable frame rate dividers used to generate the transmitter frame clocks. In network mode, this ratio may be interpreted as the number of words per frame minus one. The divide ratio may range from 2 to 32 (TDC[4:0]=0x00001 to 0x11111) for network mode. A divide ratio of one (TDC[4:0]=0x00000) in network mode is a special case (on-demand mode).

Table continues on the next page...

ESAI_TCCR field descriptions (continued)

Field	Description
	In normal mode, this ratio determines the word transfer rate. The divide ratio may range from 1 to 32 (TDC[4:0]=0x00000 to 0x11111) for normal mode. In normal mode, a divide ratio of 1 (TDC[4:0]=0x00000) provides continuous periodic data word transfers. A bit-length frame sync (TFSL=1) must be used in this case. The ESAI frame sync generator functional diagram is shown in Figure 27-33
8 TPSR	ESAI_TCCR Transmit Prescaler Range. The TPSR bit controls a fixed divide-by-eight prescaler in series with the variable prescaler. This bit is used to extend the range of the prescaler for those cases where a slower bit clock is desired. When TPSR is set, the fixed prescaler is bypassed. When TPSR is cleared, the fixed divide-by-eight prescaler is operational (see Figure 27-32). The maximum internally generated bit clock frequency is Fsys/4; the minimum internally generated bit clock frequency is Fsys/(2 x 8 x 256 x 16)=Fsys/65536. (Do not use the combination TPSR=1, TPM7-TPM0=0x00, and TFP3-TFP0=0x0 which causes synchronization problems when using the internal ARM Core clock as source (TCKD=1 or THCKD=1))
7–0 TPM [7:0]	ESAI_TCCR Transmit Prescale Modulus Select. The TPM7-TPM0 bits specify the divide ratio of the prescale divider in the ESAI transmitter clock generator. A divide ratio from 1 to 256 (TPM[7:0]=0x00 to 0xFF) may be selected. The bit clock output is available at the transmit serial bit clock (SCKT) pin. The bit clock output is also available internally for use as the bit clock to shift the transmit and receive shift registers. The ESAI transmit clock generator functional diagram is shown in Figure 27-32.

27.5.16 Receive Control Register (ESAI_RCR)

The read/write Receive Control Register (ESAI_RCR) controls the ESAI receiver section. Interrupt enable bits for the receivers are provided in this control register. The receivers are enabled in this register (0,1,2 or 3 receivers can be enabled) if the input data pin is not used by a transmitter. Operating modes are also selected in this register.

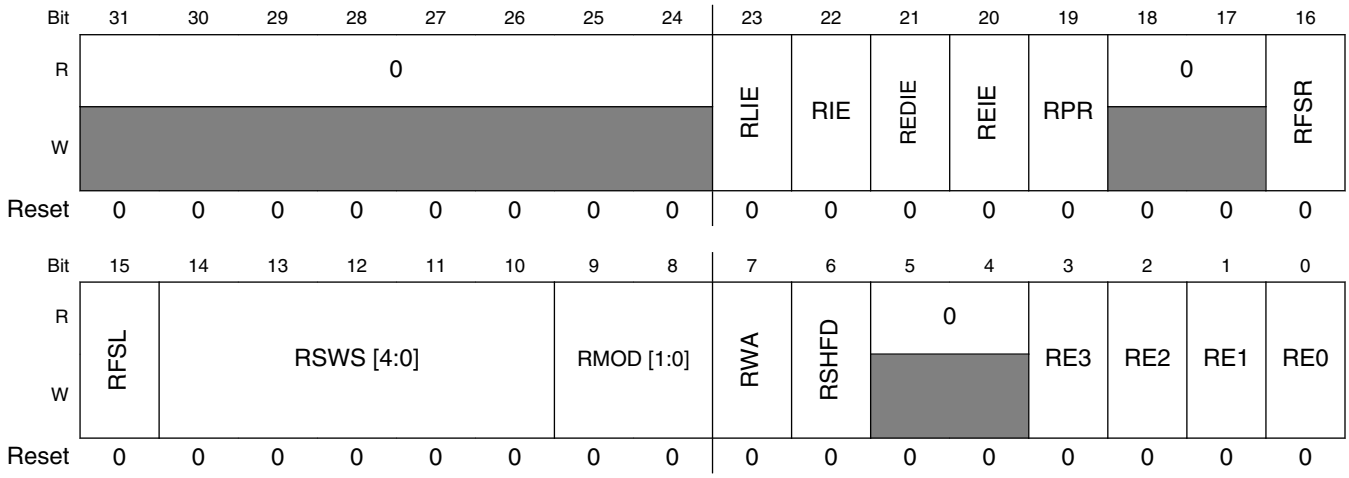
Address: ESAI_RCR is 5001_8000h base + DCh offset = 5001_80DCh



ESAI_RCR field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved.
23 RLIE	ESAI_RCR Receive Last Slot Interrupt Enable. RLIE enables an interrupt after the last slot of a frame ended in network mode only. When RLIE is set the Core is interrupted after the last slot in a frame ended regardless of the receive mask register setting. When RLIE is cleared the receive last slot interrupt is disabled. Hardware and software reset clear RLIE. RLIE is disabled when RDC[4:0]=00000 (on-demand mode). The use of the receive last slot interrupt is described in ESAI Interrupt Requests.
22 RIE	ESAI_RCR Receive Interrupt Enable. The Core is interrupted when RIE and the RDF flag in the ESAI_SAISR status register are set. When RIE is cleared, this interrupt is disabled. Reading the receive data registers of the enabled receivers clears RDF, thus clearing the interrupt. Receive interrupts with exception have higher priority than normal receive data interrupts, therefore if exception occurs (ROE is set) and REIE is set, the ESAI requests an ESAI receive data with exception interrupt from the interrupt controller.
21 REDIE	ESAI_RCR Receive Even Slot Data Interrupt Enable. The REDIE control bit is used to enable the receive even slot data interrupts. If REDIE is set, the receive even slot data interrupts are enabled. If REDIE is cleared, the receive even slot data interrupts are disabled. A receive even slot data interrupt request is generated if REDIE is set and the REDF status flag in the ESAI_SAISR status register is set. Even time slots are all even-numbered time slots (0, 2, 4, etc.) when operating in network mode. The zero time slot is marked by the frame sync signal and is considered to be even. Reading all the data registers of the enabled receivers clears the REDF flag, thus servicing the interrupt. Receive interrupts with exception have higher priority than receive even slot data interrupts, therefore if exception occurs (ROE is set) and REIE is set, the ESAI requests an ESAI receive data with exception interrupt from the interrupt controller.
20 REIE	ESAI_RCR Receive Exception Interrupt Enable. When REIE is set, the Core is interrupted when both RDF and ROE in the ESAI_SAISR status register are set. When REIE is cleared, this interrupt is disabled. Reading the ESAI_SAISR status register followed by reading the enabled receivers data registers clears ROE, thus clearing the pending interrupt.
19 RPR	ESAI_RCR Receiver Section Personal Reset. The RPR control bit is used to put the receiver section of the ESAI in the personal reset state. The transmitter section is not affected. When RPR is cleared, the receiver section may operate normally. When RPR is set, the receiver section enters the personal reset state immediately. When in the personal reset state, the status bits are reset to the same state as after

Table continues on the next page...

ESAI_RCR field descriptions (continued)

Field	Description
	hardware reset.The control bits are not affected by the personal reset state.The receiver data pins are disconnected while in the personal reset state. **NOTE:** To leave the personal reset state by clearing RPR, the procedure described in ESAI Initialization Examples should be followed.
18–17 Reserved	This read-only field is reserved and always has the value zero. Reserved.
16 RFSR	ESAI_RCR Receiver Frame Sync Relative Timing. RFSR determines the relative timing of the receive frame sync signal as referred to the serial data lines, for a word length frame sync only. When RFSR is cleared the word length frame sync occurs together with the first bit of the data word of the first slot. When RFSR is set the word length frame sync starts one serial clock cycle earlier, that is, together with the last bit of the previous data word.
15 RFSL	ESAI_RCR Receiver Frame Sync Length. The RFSL bit selects the length of the receive frame sync to be generated or recognized. If RFSL is cleared, a word-length frame sync is selected. If RFSL is set, a 1-bit clock period frame sync is selected. Refer to Figure 27-30 for examples of frame length selection.
14–10 RSWS [4:0]	ESAI_RCR Receiver Slot and Word Select. The RSWS4-RSWS0 bits are used to select the length of the slot and the length of the data words being received through the ESAI. The word length must be equal to or shorter than the slot length. The possible combinations are shown in Table 27-34. See also the ESAI data path programming model in Figure 27-2 and Figure 27-3.
9–8 RMOD [1:0]	ESAI_RCR Receiver Network Mode Control. The RMOD1 and RMOD0 bits are used to define the network mode of the ESAI receivers, as shown in Table 27-33. In the normal mode, the frame rate divider determines the word transfer rate - one word is transferred per frame sync during the frame sync time slot, as shown in Figure 27-29. In network mode, it is possible to transfer a word for every time slot, as shown in Figure 27-29. For more details, see Modes of Operation. In order to comply with AC-97 specifications, RSWS4-RSWS0 should be set to 0x00011 (20-bit slot, 20-bit word); RFSL and RFSR should be cleared, and RDC4-RDC0 should be set to 0x0C (13 words in frame).
7 RWA	ESAI_RCR Receiver Word Alignment Control. The Receiver Word Alignment Control (RWA) bit defines the alignment of the data word in relation to the slot. This is relevant for the cases where the word length is shorter than the slot length. If RWA is cleared, the data word is assumed to be left-aligned in the slot frame. If RWA is set, the data word is assumed to be right-aligned in the slot frame. If the data word is shorter than the slot length, the data bits which are not in the data word field are ignored. For data word lengths of less than 24 bits, the data word is right-extended with zeroes before being stored in the receive data registers.
6 RSHFD	ESAI_RCR Receiver Shift Direction. The RSHFD bit causes the receiver shift registers to shift data in MSB first when RSHFD is cleared or LSB first when RSHFD is set (see Figure 27-2 and Figure 27-3).
5–4 Reserved	This read-only field is reserved and always has the value zero. Reserved.
3 RE3	ESAI_RCR ESAI Receiver 3 Enable. When RE3 is set and TE2 is cleared, the ESAI receiver 3 is enabled and samples data at the SDO2/SDI3 pin. ESAI_TX2 and ESAI_RX3 should not be enabled at the same time (RE3=1 and TE2=1). When RE3 is cleared, receiver 3 is disabled by inhibiting data transfer into ESAI_RX3. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the ESAI_RX3 data register. If RE3 is set while some of the other receivers are already in operation, the first data word received in ESAI_RX3 will be invalid and must be discarded.
2 RE2	ESAI_RCR ESAI Receiver 2 Enable. When RE2 is set and TE3 is cleared, the ESAI receiver 2 is enabled and samples data at the SDO3/SDI2 pin. ESAI_TX3 and ESAI_RX2 should not be enabled at the same

Table continues on the next page...

ESAI_RCR field descriptions (continued)

Field	Description
	time (RE2=1 and TE3=1). When RE2 is cleared, receiver 2 is disabled by inhibiting data transfer into ESAI_RX2. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the ESAI_RX2 data register. If RE2 is set while some of the other receivers are already in operation, the first data word received in ESAI_RX2 will be invalid and must be discarded.
1 RE1	ESAI_RCR ESAI Receiver 1 Enable. When RE1 is set and TE4 is cleared, the ESAI receiver 1 is enabled and samples data at the SDO4/SDI1 pin. ESAI_TX4 and ESAI_RX1 should not be enabled at the same time (RE1=1 and TE4=1). When RE1 is cleared, receiver 1 is disabled by inhibiting data transfer into ESAI_RX1. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the ESAI_RX1 data register. If RE1 is set while some of the other receivers are already in operation, the first data word received in ESAI_RX1 will be invalid and must be discarded.
0 RE0	ESAI_RCR ESAI Receiver 0 Enable. When RE0 is set and TE5 is cleared, the ESAI receiver 0 is enabled and samples data at the SDO5/SDI0 pin. ESAI_TX5 and ESAI_RX0 should not be enabled at the same time (RE0=1 and TE5=1). When RE0 is cleared, receiver 0 is disabled by inhibiting data transfer into ESAI_RX0. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the ESAI_RX0 data register. If RE0 is set while some of the other receivers are already in operation, the first data word received in ESAI_RX0 will be invalid and must be discarded.

27.5.17 Receive Clock Control Register (ESAI_RCCR)

The read/write Receiver Clock Control Register (ESAI_RCCR) controls the ESAI receiver clock generator bit and frame sync rates, word length, and number of words per frame for the serial data. The ESAI_RCCR control bits are described in the following paragraphs.

NOTE

ARM Core clock is ipg_clk_esai in block ESAI which is from CCM's ahb_clk_root.

ESAI_RCCR field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved.
23 RHCKD	ESAI_RCCR Receiver High Frequency Clock Direction. The Receiver High Frequency Clock Direction (RHCKD) bit selects the source of the receiver high frequency clock when in the asynchronous mode (SYN=0) and the IF2/OF2 flag direction in the synchronous mode (SYN=1).

Table continues on the next page...

ESAI_RCCR field descriptions (continued)

Field	Description
	In the asynchronous mode, when RHCKD is set, the internal clock generator becomes the source of the receiver high frequency clock and is the output on the HCKR pin. In the asynchronous mode, when RHCKD is cleared, the receiver high frequency clock source is external; the internal clock generator is disconnected from the HCKR pin, and an external clock source may drive this pin. When RHCKD is cleared, HCKR is an input; when RHCKD is set, HCKR is an output. In the synchronous mode when RHCKD is set, the HCKR pin becomes the OF2 output flag. If RHCKD is cleared, the HCKR pin becomes the IF2 input flag. Refer to Table 27-1 and Table 27-39.
22 RFSD	ESAI_RCCR Receiver Frame Sync Signal Direction. The Receiver Frame Sync Signal Direction (RFSD) bit selects the source of the receiver frame sync signal when in the asynchronous mode (SYN=0) and the IF1/OF1/Transmitter Buffer Enable flag direction in the synchronous mode (SYN=1). In the asynchronous mode, when RFSD is set, the internal clock generator becomes the source of the receiver frame sync and is the output on the FSR pin. In the asynchronous mode, when RFSD is cleared, the receiver frame sync source is external; the internal clock generator is disconnected from the FSR pin, and an external clock source may drive this pin. In the synchronous mode when RFSD is set, the FSR pin becomes the OF1 output flag or the Transmitter Buffer Enable, according to the TEBE control bit. If RFSD is cleared, the FSR pin becomes the IF1 input flag. Refer to Table 27-1 and Table 27-38 .
21 RCKD	ESAI_RCCR Receiver Clock Source Direction. The Receiver Clock Source Direction (RCKD) bit selects the source of the clock signal used to clock the receive shift register in the asynchronous mode (SYN=0) and the IF0/OF0 flag direction in the synchronous mode (SYN=1). In the asynchronous mode, when RCKD is set, the internal clock source becomes the bit clock for the receive shift registers and word length divider and is the output on the SCKR pin. In the asynchronous mode when RCKD is cleared, the clock source is external; the internal clock generator is disconnected from the SCKR pin, and an external clock source may drive this pin. In the synchronous mode when RCKD is set, the SCKR pin becomes the OF0 output flag. If RCKD is cleared, the SCKR pin becomes the IF0 input flag. Refer to Table 27-1 and Table 27-37.
20 RHCKP	ESAI_RCCR Receiver High Frequency Clock Polarity. The Receiver High Frequency Clock Polarity (RHCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If RHCKP is cleared the data and the frame sync are clocked out on the rising edge of the receive high frequency bit clock and the frame sync is latched in on the falling edge of the receive bit clock. If RHCKP is set the falling edge of the receive clock is used to clock the data and frame sync out and the rising edge of the receive clock is used to latch the frame sync in.
19 RFSP	ESAI_RCCR Receiver Frame Sync Polarity. The Receiver Frame Sync Polarity (RFSP) determines the polarity of the receive frame sync signal. When RFSP is cleared the frame sync signal polarity is positive, that is, the frame start is indicated by a high level on the frame sync pin. When RFSP is set the frame sync signal polarity is negative, that is, the frame start is indicated by a low level on the frame sync pin.
18 RCKP	The Receiver Clock Polarity (RCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If RCKP is cleared the data and the frame sync are clocked out on the rising edge of the receive bit clock and the frame sync is latched in on the falling edge of the receive bit clock. If RCKP is set the falling edge of the receive clock is used to clock the data and frame sync out and the rising edge of the receive clock is used to latch the frame sync in.
17–14 RFP [3:0]	ESAI_RCCR Rx High Frequency Clock Divider. The RFP3-RFP0 bits control the divide ratio of the receiver high frequency clock to the receiver serial bit clock when the source of the receiver high frequency clock and the bit clock is the internal Arm Core clock. When the HCKR input is being driven from an external high frequency clock, the RFP3-RFP0 bits specify an additional division ration in the clock divider chain. Table 27-36 provides the specification of the divide ratio. Figure 27-32 shows the ESAI high frequency generator functional diagram.

Table continues on the next page...

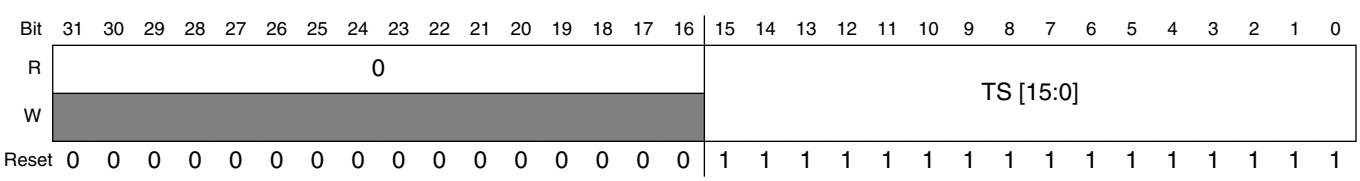
ESAI_RCCR field descriptions (continued)

Field	Description
13–9 RDC [4:0]	ESAI_RCCR Rx Frame Rate Divider Control. The RDC4-RDC0 bits control the divide ratio for the programmable frame rate dividers used to generate the receiver frame clocks. In network mode, this ratio may be interpreted as the number of words per frame minus one. The divide ratio may range from 2 to 32 (RDC[4:0]=0x00001 to 0x11111) for network mode. A divide ratio of one (RDC[4:0]=0x00000) in network mode is a special case (on-demand mode). In normal mode, this ratio determines the word transfer rate. The divide ratio may range from 1 to 32 (RDC[4:0]=0x00000 to 0x11111) for normal mode. In normal mode, a divide ratio of one (RDC[4:0]=0x00000) provides continuous periodic data word transfers. A bit-length frame sync (RFSL=1) must be used in this case. The ESAI frame sync generator functional diagram is shown in Figure 27-33 .
8 RPSP	ESAI_RCCR Receiver Prescaler Range. The RPSR controls a fixed divide-by-eight prescaler in series with the variable prescaler. This bit is used to extend the range of the prescaler for those cases where a slower bit clock is desired. When RPSR is set, the fixed prescaler is bypassed. When RPSR is cleared, the fixed divide-by-eight prescaler is operational (see Figure 27-32). The maximum internally generated bit clock frequency is Fsys/4, the minimum internally generated bit clock frequency is Fsys/(2 x 8 x 256 x 16)=Fsys/65536. (Do not use the combination RPSR=1 and RPM7-RPM0 =0x00, which causes synchronization problems when using the internal Core clock as source (RHCKD=1 or RCKD=1))
7–0 RPM [7:0]	ESAI_RCCR Receiver Prescale Modulus Select. The RPM7-RPM0 bits specify the divide ratio of the prescale divider in the ESAI receiver clock generator. A divide ratio from 1 to 256 (RPM[7:0]=0x00 to 0xFF) may be selected. The bit clock output is available at the receiver serial bit clock (SCKR) pin. The bit clock output is also available internally for use as the bit clock to shift the receive shift registers. The ESAI receive clock generator functional diagram is shown in Figure 27-32.

27.5.18 Transmit Slot Mask Register A (ESAI_TSMA)

The Transmit Slot Mask Register A together with Transmit Slot Mask Register B (ESAI_TSMA and ESAI_TSMB) are two read/write registers used by the transmitters in network mode to determine for each slot whether to transmit a data word and generate a transmitter empty condition (TDE=1), or to tri-state the transmitter data pins. Fields ESAI_TSMA [TS[15:0]] and ESAI_TSMB [TS[31:16]] are concatenated to form the 32-bit field TS[31:0]. Bit number n in TS[31:0] is the enable/disable control bit for transmission in slot number n.

Address: ESAI_TSMA is 5001_8000h base + E4h offset = 5001_80E4h



ESAI_TSMA field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–0 TS [15:0]	When bit number N in ESAI_TSMA is cleared, all the transmit data pins of the enabled transmitters are tri-stated during transmit time slot number N. The data is still transferred from the transmit data registers to the transmit shift registers but neither the TDE nor the TUE flags are set. This means that during a disabled slot, no transmitter empty interrupt is generated. The Core is interrupted only for enabled slots. Data that is written to the transmit data registers when servicing this request is transmitted in the next enabled transmit time slot. When bit number N in ESAI_TSMA register is set, the transmit sequence is as usual: data is transferred from the TX registers to the shift registers and transmitted during slot number N, and the TDE flag is set. Using the slot mask in ESAI_TSMA does not conflict with using TSR. Even if a slot is enabled in ESAI_TSMA, the user may choose to write to TSR instead of writing to the transmit data registers TXn. This causes all the transmit data pins of the enabled transmitters to be tri-stated during the next slot. Data written to the ESAI_TSMA affects the next frame transmission. The frame being transmitted is not affected by this data and would comply to the last ESAI_TSMA setting. Data read from ESAI_TSMA returns the last written data. After hardware or software reset, the ESAI_TSMA register is preset to 0x0000FFFF, which means that all 16 possible slots are enabled for data transmission. When operating in normal mode, bit 0 of the ESAI_TSMA register must be set, otherwise no output is generated.

27.5.19 Transmit Slot Mask Register B (ESAI_TSMB)

The Transmit Slot Mask Register B together with Transmit Slot Mask Register A (ESAI_TSMA and ESAI_TSMB) are two read/write registers used by the transmitters in network mode to determine for each slot whether to transmit a data word and generate a transmitter empty condition (TDE=1), or to tri-state the transmitter data pins. Fields ESAI_TSMA [TS[15:0]] and ESAI_TSMB [TS[31:16]] are concatenated to form the 32-bit field TS[31:0]. Bit number n in TS[31:0] is the enable/disable control bit for transmission in slot number n.

Address: ESAI_TSMB is 5001_8000h base + E8h offset = 5001_80E8h

ESAI_TSMB field descriptions (continued)

Field	Description
15–0 TS [31:16]	When bit number N in ESAI_TSMB is cleared, all the transmit data pins of the enabled transmitters are tri-stated during transmit time slot number N. The data is still transferred from the transmit data registers to the transmit shift registers but neither the TDE nor the TUE flags are set. This means that during a disabled slot, no transmitter empty interrupt is generated. The Core is interrupted only for enabled slots. Data that is written to the transmit data registers when servicing this request is transmitted in the next enabled transmit time slot. When bit number N in ESAI_TSMB register is set, the transmit sequence is as usual: data is transferred from the TX registers to the shift registers and transmitted during slot number N, and the TDE flag is set. Using the slot mask in ESAI_TSMB does not conflict with using TSR. Even if a slot is enabled in TSMB, the user may chose to write to TSR instead of writing to the transmit data registers TXn. This causes all the transmit data pins of the enabled transmitters to be tri-stated during the next slot. Data written to the ESAI_TSMB affects the next frame transmission. The frame being transmitted is not affected by this data and would comply to the last ESAI_TSMB setting. Data read from ESAI_TSMB returns the last written data. After hardware or software reset, the ESAI_TSMB register is preset to 0x0000FFFF, which means that all 16 possible slots are enabled for data transmission.

27.5.20 Receive Slot Mask Register A (ESAI_RSMA)

The Receive Slot Mask Register A together with Receive Slot Mask Register B (ESAI_RSMA and ESAI_RSMB) are two read/write registers used by the receiver in network mode to determine for each slot whether to receive a data word and generate a receiver full condition (RDF=1), or to ignore the received data. Fields ESAI_RSMA [RS[15:0]] and ESAI_RSMB [RS31:16]] are concatenated to form the 32-bit field RS[31:0]. Bit number n in RS[31:0] is an enable/disable control bit for receiving data in slot number n.

Address: ESAI_RSMA is 5001_8000h base + ECh offset = 5001_80ECh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ESAI_RSMA field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–0 RS [15:0]	When bit number N in the ESAI_RSMA register is cleared, the data from the enabled receivers input pins are shifted into their receive shift registers during slot number N. The data is not transferred from the receive shift registers to the receive data registers, and neither the RDF nor the ROE flag is set. This means that during a disabled slot, no receiver full interrupt is generated. The Core is interrupted only for enabled slots.

Table continues on the next page...

ESAI_RSMA field descriptions (continued)

Field	Description
	When bit number N in the ESAI_RSMA is set, the receive sequence is as usual: data which is shifted into the enabled receivers shift registers is transferred to the receive data registers and the RDF flag is set. Data written to the ESAI_RSMA affects the next received frame. The frame being received is not affected by this data and would comply to the last ESAI_RSMA setting. Data read from ESAI_RSMA returns the last written data. After hardware or software reset, the ESAI_RSMA register is preset to 0x0000FFFF, which means that all 16 possible slots are enabled for data reception. When operating in normal mode, bit 0 of the ESAI_RSMA register must be set to one, otherwise no input is received.

27.5.21 Receive Slot Mask Register B (ESAI_RSMB)

The Receive Slot Mask Register B together with Receive Slot Mask Register A (ESAI_RSMA and ESAI_RSMB) are two read/write registers used by the receiver in network mode to determine for each slot whether to receive a data word and generate a receiver full condition (RDF=1), or to ignore the received data. Fields ESAI_RSMA [RS[15:0]] and ESAI_RSMB [RS31:16]] are concatenated to form the 32-bit field RS[31:0]. Bit number n in RS[31:0] is an enable/disable control bit for receiving data in slot number n.

Address: ESAI_RSMB is 5001_8000h base + F0h offset = 5001_80F0h

27.5.22 Port C Direction Register (ESAI_PRRC)

There are two registers to control the ESAI personal reset status: Port C Direction Register (ESAI_PRRC) and Port C Control Register (ESAI_PCRC).

The read/write 32-bit Port C Direction Register (ESAI_PRRC) in conjunction with the Port C Control Register (ESAI_PCRC) controls the functionality of the ESAI personal reset state. Table 27-46 provides the port pin configurations. Hardware and software reset clear all ESAI_PRRC bits.

Address: ESAI_PRRC is 5001_8000h base + F8h offset = 5001_80F8h

Chapter 28
Enhanced SDRAM Controller (ESDCTL)

28.1 Introduction

Figure 28-1 shows the block diagram of the ESDCTL.

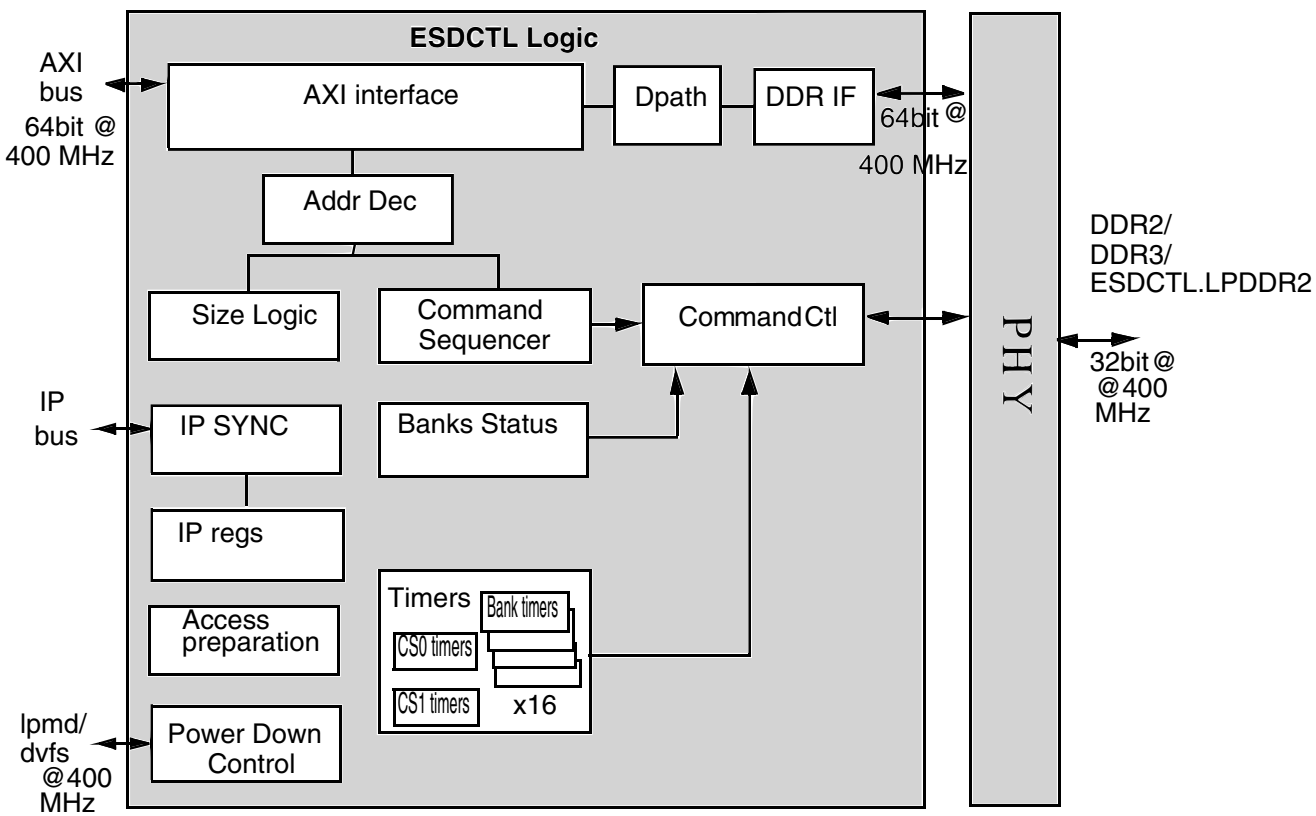

Figure 28-1. ESDCTL Block Diagram

28.2 Overview

The ESDCTL is a configurable high performance and optimized SDRAM controller that supports DDR2, DDR3 and LPDDR2-S memories.

The ESDCTL is composed from the logic part and PHY part. The logic is responsible for the command preparation and data path while the PHY is responsible for the timing adjustment using a special calibration mechanism to ensure data capture margin at clock rate of up to 400MHz.

28.3 Features

28.3.1 ESDCTL Logic Features

- 64bits AXI I/F operating at 400MHz.
- Configurable 2GB memory space (1GB per chip select or 2GB in chip select 0).
- 4/8 banks memory devices.
- Column size between 9 to 11 bits for DDR2/DDR3 and 8 to 12 bits for LPDDR2.
- Row size between 11 to 16 bits.
- x16 or x32 bits memory data width.
- Burst length 4 or 8 for DDR2 devices (best performance for BL4).
- Burst length 4 or 8 for LPDDR2 devices (best performance for BL4).
- Burst length 8 for DDR3 devices.
- DDR2 allowed frequency 125 MHz to 400MHz.
- DDR3 allowed frequency 303 MHz to 400 MHz.
- LPDDR2 allowed frequency 10 MHz to 400 MHz.
- Power down DDR2/DDR3/LPDDR2 memories when inactive (per chip select).
- Several different ODT scheme support (For DDR2/DDR3 only).
- MIF3 - future accesses preparation mechanism (Increase hit rate).
- Bank Interleaving mode.
- Configurable refresh scheme, either by a 32KHz clock or by a special counter.
- Configurable timing parameters.
- Power saving / Frequency change
  - External DVFS / LPMD request.
  - Power down counter per rank after configurable amount of idle cycles.
  - Precharge counter per rank after configurable idle cycles.
- Debug Features

- 32bit Read command counter with reset option (used for bus utilization measurement).
- 32bit Write command counter with reset option (used for bus utilization measurement).
- Latency hiding disable.

28.3.2 PHY Features

- ZQ HW and SW calibration.
- Read data calibration. Adjustment of read DQS with read data byte.
- Read DQS gating calibration. Adjustment of DQS gate with read preamble window.
- Write data calibration. Adjustment of write DQS with write data byte.
- Write leveling calibration. Adjustment of write DQS with SDCLK.
- Read fine tuning. Adjustment of up to 7 delay line units for each read data bit.
- Write fine tuning. Adjustment of up to 3 delay line units for each read data bit.

28.4 AXI Restrictions

- One AXI access is handled at a time (One ID system).
- Out of order accesses are not supported. That means that data interleaving of two different IDs is not allowed in write cycles.
- The controller will not provide data interleaving in the AXI read data bus.
- Exclusive AXI accesses are not supported.
- Atomic/Locked access are not supported.
- All accesses are treated as non-bufferable and non-cachable accesses. Bufferable and cachable accesses should be handeled by the ESDCTL bus master.
- Bursts of up to 8 double-words (64 bits), is supported, for incr and wrap burst types. AWSIZE/ARSIZE are 2 bits wide. AWLEN/ARLEN are 3 bits wide.
- ARRAEDY and AWREADY are all defaulted to high in idle state. Accepting a read or a write will lower the other ready as well until the controller is ready for another address for latency hiding. If both a read and a write are valid at the same cycle, the read is serviced first, then the write, and only after the write is done the readies will go back up.
- The controller BRESP and RRESP signals are returning OKAY by default (No error handling).

28.5 Functional Description

28.5.1 Address Decoding

ESDCTL supports two chip selects, each of which can be used to reach a maximum of 1 GB (a total of 2 GB for both chip selects).

The incoming addresses arrive as 32-bit through the AXI bus, then the ESDCTL Control Register (ESDCTL_ESDCTL) decodes this 32-bit into the following:

- chip select
- bank number
- row number
- column number

For this matter a set of parameters are required:

1. 4 or 8 banks in device - ESDCTL Timing Miscellaneous Register (ESDCTL_ESDMISC) register field: DDR_4_BANK.
2. Memory port size 16 or 32 - ESDCTL Control Register (ESDCTL_ESDCTL) register field: DSIZ.
3. Bank interleaved on or off - ESDCTL Timing Miscellaneous Register (ESDCTL_ESDMISC) register field: BI.
4. Column size - ESDCTL Control Register (ESDCTL_ESDCTL) register field: COL.
5. Row size - ESDCTL Control Register (ESDCTL_ESDCTL) register field: ROW.

In the table below, decoding with no bank interleaving is shown for 16 and 32-bit SDRAM (assuming: bank size = 3, row size = 15, column size = 10).

Table 28-1. Decoding with no bank interleaving for 16 and 32 bit SDRAM

ARM Platform ADDRESS	16-bit SDRAM	32-bit SDRAM
A29	-	BANK[2]
A28	BANK[2]	BANK[1]
A27	BANK[1]	BANK[0]

A4	COL[3]	COL[2]
A3	COL[2]	COL[1]
A2	COL[1]	COL[0]
A1	COL[0]	-
A0	-	-

Selection of Chip select is decoded from the upper 4 bits of the AXI address.

Per the value of 2 vias: 1. sdram_base_cs0_via 2.sdram_base_cs1_via.

Chip select 0 is selected if:

sdram_base_cs0_via <= axi_address[28:31] <= sdram_base_cs0_via +3

Chip select 1is selected if:

sdram_base_cs1_via <= axi_address[28:31] <= sdram_base_cs1_via +3

NOTE

In case of an access to an uninitialized or disconnected chip select, the controller might behave unexpectedly.

28.5.2 Address Mirroring

When enabling this feature, the address bits A3, A4, A5, A6, A7, A8, B0, B1 behave differently according to the referenced chip select.

The mirroring is done in according to the referenced chip select, as shown in table 1-24.

Table 28-3. Address Mirroring

Controller pin	Chip select 0 pin	Chip select 1 pin
A3	A3	A4
A4	A4	A3
A5	A5	A6
A6	A6	A5
A7	A7	A8
A8	A8	A7
B0	B0	B1
B1	B1	B0

28.5.3 MIF3 - Optimization Strategy

The target of this optimization is to increase the data throughput in a certain period of time.

Maximum throughput is achieved when AXI access are back to back hits; in that case the controller issues only RD/WR commands and does not have to issue row preparation commands ACTIVE/ PRECHARGE. The controller does this by looking on the future accesses and, if required, it prepares their bank/row. When the access turn is reached, it is a hit access, and no time is wasted on PRECHARGE/ACTIVE commands.

The controller has 3 levels of pending accesses:

1. Access in first stage of pipeline
2. Valid access on AXI bus either read channel or write channel
3. Valid access on special bus from arbitration, which is chosen by the arbitration as the next miss access in its buffers

The controller can enable/disable this sources by configuration (ESDCTL_ESDMISC register field MIF3_MODE).

28.5.4 Auto Refresh Behavior

The ESDCTL supports various automatic refresh options which can be configured via ESDCTL_ESDREF register.

The periodic auto refresh can be triggered by the following clocks:

- 32KHz clock
- 64KHz clock
- Fast clock which is similar to the frequency which the controller is operated (equal to sdclk frequency).

This flexibility allows the system to choose a desired refresh scheme that will not delay the AXI accesses in each refresh cycle.

The following is an example that specifies 4 options to configure the ESDCTL in order to meet a refresh rate of 3.9us (tREFI):

Option number	Description	REFR	REF_SEL	REF_CNT	DDR hang time
1	Issue 8 refresh commands every 31,250 ns	0x7 (8 refreshes)	0x2 (64KHz)	not needed	tRFC * 8
2	Issue 4 refresh commands every 15,625ns	0x3 (4 refreshes)	0x1(32KHz)	not needed	tRFC * 4
3	Issue 2 refresh commands every 7800ns	0x1(2 refreshes)	0x3 (fast counter)	7800/2.5 = 3120 (0xC30)	tRFC * 2
4	Issue 1 refresh command every 3900 ns	0x0 (1 refresh)	0x3 (fast counter)	3900/2.5 = 1560(0x618)	tRFC

As shown in the table above all options meet the memory requirement of a refresh command every 3.9 us, the difference is how often a refresh cycle occurs and what is the DDR hang time for each refresh cycle.

28.5.5 Initialization Information

The controller gets out of reset while it is disabled, meaning that no clock is driven to the memory and all I/F signals to the memory are at non-active values.

The following are the required steps to activate the controller properly:

1. Set bit 15 on ESDCTL_ESDSCR register - configuration request (because the controller is disabled there is no need to poll configuration acknowledge bit).

2. Configure registers ESDCTL_ESDCFG0, ESDCTL_ESDCFG1, ESDCTL_ESDCFG2 and ESDCTL_ESDOTC- timing parameters.
3. Configure register ESDCTL_ESDMISC with miscellaneous parameters.
4. Configure ESDCTL_ESDOR with requires out of reset delays.
5. Configure ESDCTL with memory parameters and enable the working chip selects. At this point the controller start counting the required time according to configuration. DDR2 and DDR3 has different initialization as described on DDR2 SDRAM Specification JESD79-2E (April 2008) and on DDR3 SDRAM Specification JESD79-3C (April 2008).
6. Issue the required commands for memory initialization (REF,LMR,PRE) by using ESDCTL_ESDSCR register.
7. DDR2 and DDR3 has different command sequence as described on DDR2 SDRAM Specification JESD79-2E (April 2008) and on DDR3 SDRAM Specification JESD79-3C (April 2008).
8. At this point the memory model is ready to be used, but there are still few registers to set.
9. Configure ESDCTL_ESDPDC register - used to enable power saving modes of memory.
10. Enable ODT / ZQ functions - registers can be found in PHY spec.
11. Configure ESDCTL_ESDREF - to enable periodic refreshes.
12. Configure PHY delay parameters (using hardware or software calibrations)
13. Clear bit 15 on ESDCTL_ESDSCR register - configuration request.

Now controller is ready to accept AXI requests.

28.5.6 LPMD/DVFS requests

The controller has LPMD req/ack and DVFS req/ack interface that is used for entering the DDR into self-refresh mode which allow changing/stopping the clock to the memory. At this mode the memory does not need periodic refresh commands.

The controller handles LPMD/DVFS in the same manner.

Upon the assertion of LPMD/DVFS request the controller do the following:

1. Blocks new AXI access from entering the controller.
2. Completing all the acknowledged AXI accesses.
3. If banks are not idle issue precharge all commands when timing allow.
4. Lowers clock enable signal while giving refresh command to the memory, this is done after tRP/tRPA pass from the precharge all command (if issued).
5. Stop clock to the memory after tCKSRE from self refresh entry.

6. Assert LPMD/DVFS ack, which means the clock to the contoller can be shut off or changed.

Upon the deassertion of LPMD/DVFS request the following is done:

1. LPMD/DVFS acknowledge is deasserted.
2. Memory clock turned on again.
3. After tCKSRX pass from clock renewal the CKE signal is asserted again.
4. After tXS pass from CKE assertion a refresh command is given to the memory.
5. If ZQ calibration is disabled skip to step 7.
6. tRFC is counted from the refresh command and a long ZQ command is asserted.
7. tZQoper idle cycles are counted after the ZQ command.
8. tDLLK should pass from the CKE assertion, then the controller return to normal operation.

28.5.7 Writing to ESDCTL configuration registers

In order to modify ESDCTL's internal configuration registers few steps are required as following:

1. Issue configuration request - set bit 15 on ESDCTL_ESDSCR register.
2. Poll configuration acknowledge until high - bit 14 on ESDCTL_ESDSCR register.
3. At this point the controller is in configuration mode and will not treat R/W requests from M4IF.
4. Write to ESDCTL configuration registers.
5. Clear bit 15 on the ESDCTL_ESDSCR register - this will bring the controller back to normal mode.

NOTE

When the controller is in LPMD or DVFS mode, writing to internal configuration registers is prohibited.

NOTE

Controller can enter these modes (LPMD or DVFS) as a result of:

- CCM - Manual DVFS / LPMD.
- M4IF - Manual DVFS / LPMD.
- M4IF - Automatic power saving.

28.5.8 Warm reset

The controller supports warm reset. In case of warm reset all the registers in controller will receive the reset except those that are essential for returning to normal operation without repeating the initialization sequence or losing data stored on the memory.

In order to use warm reset the following should be done:

1. The controller should be brought to self refresh mode. This can be done by either LPMD or DVFS requests.
2. After receiving an acknowledge the warm reset signal can be asserted.
3. While the warm reset signal is asserted it is safe to deassert the rst_b signal.
4. After rst_b is asserted the warm reset signal can be deasserted.
5. LPMD/ DVFS can now be exited by deasserting the LPMD/DVFS request signal.

28.5.9 Software reset

The controller allows the user to issue software reset to FF in controller except FF that are essential for returning to normal operation without repeating the initialization sequence or losing data stored in the memory. Issuing software reset is done as follows:

1. Assert configuration request, bit 15 in ESDCTL_ESDSCR register.
2. Wait for configuration acknowledge assertion, bit 14 in ESDCTL_ESDSCR register.
3. Issue soft reset, bit 1in ESDCTL_ESDMISC register.
4. Deassert configuration request, bit 15 in ESDCTL_ESDSCR register.
5. Normal operation can be resumed.

28.5.10 Power Saving modes

Various DDR power saving modes are supported by the controller as following:

NOTE

Those modes may dramatically decrease the power consumption of DDR memories. At default those modes are disabled.

1. Self refresh entry to the entire DDR device (for both chip selects 0 and 1) can be activated as follows:
   - HW handshaking with the clock module in the system
   - SW handshaking by setting the field MCR0[FLPMD] in the M4IF block.
   - Automatic entry by configuring MCR1[FPST] field in the M4IF block. Define the amount number of idle cycles before entering self refresh automatically.

2. Automatic active/precharge power down entry to a specific chip select (it is possible to enter certain CS to low power consumption while the second chip select is activated). Can be activated by configuring the ESDCTL_ESDPDC register as following:
   - PWDT_0/PWDT_1 - define the number of idle cycles before entering power down, can be different value per chip select.
   - SLOW_PD - In case of DDR2 memory is configured to use slow active power down then this bit should be set as well. In case of DDR3 memory is configured to use slow precharge power down then this bit should be set as well.
   - BOTH_CS_PS - The controller can either set each chip select independently to power down, according to its idle state, or set both chip selects to power down only if both in idle state for the configured period.
   - Few paramters must be configured in addition:
     - Timing parameters at ESDCTL_ESDCFG0[tXP and tXPDLL].
     - ODT timing at ESDCTL_ESDOTC[tAOFPD, tAONPD, tANPD and tAXPD]
3. Automatic precharge of all DDR banks to a specific chip select . Can be activated be configuring ESDCTL_ESDPDC fields: PRCT_0 and PRCT_1. Each field defines a value loaded to a different chip select.

28.5.11 Burst Length options

When connecting DDR3 devices then only burst length 8 can be used.

When connecting DDR2 devices then either burst length 4 or 8 can be used.

Using burst length 4 in DDR2 is recommended as it produces higher throughput.

As mentioned above DDR3 can work only in burst length 8 mode, in this mode read/write accesses to the memory are always align to 8 words in the width of the connected memory (either x16 bit or x32 bit).

In case of AXI INCREMENT accesses that are not aligned the irrelevant data strobes are masked in write and ignored in read. In case of AXI WRAP accesses, even if the access is not aligned the arbitration switches the data so there are no wasted cycles, this method reduce latency in read/write AXI WRAP accesses.

28.6 ZQ calibration

The i.MX ZQ calibration is done in parallel to the DRAM ZQ calibration.There are 2 types of DRAM ZQ calibration: short & long.

The memory long calibration is done during power up sequence, when existing self refresh mode or when exiting slow precharge power down (DLL lock can be done in parallel). Short calibration is done according to a configurable timer defined by ZQ_HW_PER.

28.6.1 PHY ZQ SW calibration sequence

The ZQ calibration can also be done in SW. However because SW ZQ calibration is much slower than HW calibration, it should be used mainly for debugging.

SW should configure the ZQ calibration parameters (Pull-up or Pull-down and their value) and assert the ZQ_SW_FOR bit.Then SW should wait till ZQ_SW_FOR is de-asserted and use ZQ_SW_RES status bit in order to calculate the next ZQ calibration parameters.

28.6.2 Memory ZQ calibration sequence

Before the controller can issue a ZQCL/ZQCS command to the memory, it should precharge all memory banks and wait for tRP. A single ZQ command can be issued to all devices as long as the devices do not share the same ZQ resistor.

When the controller issues the ZQ command, it should also drive A10 (long or short command) and CS (0, 1 or both).

The controller must keep the memory lines quiet (except for CK) for the ZQ calibration time as defined in the Jedec (512 cycles for ZQCL after reset, 256 for other ZQCL and 64 for ZQCS).

28.7 Delay line

The delay line adds a configurable delay of up to 1/2 cycle. The delay is instantiated 8 times (4 for read and 4 for write).

28.7.1 Delay line Calibration

By default the delay in configured to generate 1/4 cycle of delay. However in some systems this may not be the optimal value and an additional calibration should be done.

NOTE

Delay line default configuration value must be a valid value (so data can be write & read in this case) though it might not be the optimal value. The Delay line calibration should be done after dqs gating & write level calibrations.

28.7.1.1 Read Delay Line Calibration

1. If MPR mode is used SW enables the MPR_CMP_BIT in PDCMPR and issues precharge all command to the device followed by MRS command. If pre-defined mode is used the SW issues precharge all command to the device followed by bank 0 ACT command and writes the predefined data to bank 0 address 0 of CS0 and then writes the same pre defined data to the PDCMPR and disables he MPR_CMP_BIT in PDCMPR.
2. SW asserts HW_RD_DL_EN bit.
3. PHY counts for 16 cycles (Tmod+4) (only if MPR mode is used) and asserts the read command request to the controller for one cycle.
4. PHY samples the dl abs default value drive on the delay line inputs.
5. PHY enables the measure signal and wait for 16 cycles.
6. Controller drives read command and data is sampled in the rd FIFO 16/32 cycles (according to HW_RD_DL_CMP_CYC) after read request was acknowledged.
7. PHY compares the data to the pre-defined value if data is incorrect PHY sets the current abs value +1 to be delay line lower boundary.
8. PHY resets the rd FIFO (to the inv. pre-defined value) and its pointers.
9. PHY decrements the rd delay line abs value by 1 and enables the measure signal.
10. PHY asserts the dqs gating read command to the controller for one cycle and data is sampled in the rd FIFO after 16/32 cycles (according to HW_RD_DL_CMP_CYC) after read request was acknowledged.
11. If read data is incorrect, PHY sets the current abs value + 1 to be delay line lower boundary and skip to step 13 if delay line phy_rd_dl_unit_num is 0 PHY sets this value to be delay line lower and skip to step 12 boundary else it repeats steps 7-8.
12. PHY drives the rd delay to abs bypass mode and if compared data is correct, then PHY sets the delay line lower boundary to 0.
13. PHY drives the rd delay line abs value back to it default value.
14. PHY increments the rd delay line abs value by 1 and enables the measure signal.
15. PHY asserts the read command to the controller for one cycle and data is sampled in the rd FIFO 16/32 cycles after read request was acknowledged.
16. If read data is incorrect PHY sets this value - 1 to be delay line upper boundary else it repeats steps 11-12.

17. Upon completion of step 13 PHY drives the values of lower and upper boundaries (HW_RD_DL_LOW & HW_RD_DL_UP) and the average value of those field is written to RD_DL_ABS_OFFSET_x field.
18. PHY enables the measure signal.
19. PHY asserts the hw_rd_dl_finish signal.

28.7.1.2 Write Delay line Calibration

1. SW asserts HW_WR_DL_EN bit
2. Controller drives write command. Wr Dqs should be driven by the controller as in regular write command while data is driven according to the ESDCTL_PDCMPR1/2.
3. Controller drives read command and data is sampled in the rd FIFO16/32 cycles (according to HW_RD_DL_CMP_CYC) after read request was acknowledged.
4. PHY compares the data to the pre-defined value. Every odd (first, third...) access' data is compared to PDV1 while every even (second, fourth...) access' data is compared to PDV2. If read data is incorrect, HW_WR_DL_ERR is asserted and hw_wr_dl_finish is asserted.
5. PHY resets the rd FIFO (to the inv. pre-defined value) and its pointers.
6. PHY decrements the wr delay line abs value by 1 and enables the measure signal of the write delay line.
7. PHY asserts the write command enable to the controller for one cycle and data is written to the DRAM.
8. Controller drives read command and data is sampled in the rd FIFO after 16/32 cycles after read request was acknowledged.
9. If read data is incorrect PHY sets this value + 1 to be delay line lower boundary if delay line qtr_cyc_del is 0 PHY sets this value to be delay line lower boundary else it repeats steps 9-10.
10. PHY drives the wr delay line abs value back to it default value.
11. PHY increments the wr delay line abs value by 1 and enables the measure signal of the write delay line.
12. PHY asserts the write command enable to the controller for one cycle and data is written to the DRAM.
13. PHY asserts the read command enable to the controller for one cycle and data is sampled in the rd FIFO after 16/32 cycles after read request was acknowledged.
14. If read data is incorrect, PHY set this value - 1 to be delay line upper boundary else it repeats steps 13-15.
15. Upon completion of step 16, PHY drives the values of lower and upper boundaries (HW_WR_DL_LOW & HW_WR_DL_UP) and the average value of those fields is written to WR_DL_ABS_OFFSET_x field
16. PHY enables the measure signal.
17. PHY asserts the hw_wr_dl_finish signal.

28.8 Write leveling

The write leveling includes a physical delay of up to 2.875 cycles. The delay is chosen according to a register that holds the configurable value of the delay.

Write leveling can be calibrated by HW or SW. The HW WL calibration points out to the optimal write dqs location inside the cycle but not between cycles. Therefor after completion of the WL HW calibration user should read the HW_WLx_RES and update the HW_WLx_CYC field to the correct value.

Each DQS has a it own delay. In DDR3 the configurable value for each DQS can be different. The write leveling of all DQS is done in parallel.

28.8.1 SW write leveling

Below is the SW write leveling sequence.

1. The SW issues a MRS command to enter write leveling mode.
2. SW asserts WL_SW_CNT_EN & WL_SW_EN bits.
3. PHY enters sw write leveling mode, counts 25 cycles and than asserts the dqs obe.
4. The PHY counts 15 cycles.
5. PHY asserts the dqs_en for one cycle.
6. PHY waits for 16 cycles before sampling prime DQ for each byte.
7. PHY drives the prime DQ's value on the write leveling bits and asserts sw_write_level_finish.
8. Controller sample prime DQ's to write_level_dq status bits.
9. SW read WL_SWx_RES bits.
10. SW clears the WL_SW_CNT_EN bit and de-asserts the WL_SW_EN bit.
11. SW should repeat 2-10(there is no need to assert WL_SW_CNT_EN) till it detects the correct wl value for each byte.
12. SW updates WL_SWx_VAL fields with the new correct values.
13. SW issues a MRS command to exit write leveling mode.

28.8.2 HW write leveling

Below is the HW write leveling sequence.

1. Same as steps 1-3 in SW write leveling (in step 2 SW asserts HW_WL_EN bit and there is no need to assert WL_SW_CNT bit).

2. PHY drives wr_level_delay to 0, asserts the dqs_en for one cycle and samples the DQ prime
3. PHY increments the wr_level_delay by 4, asserts the dqs_en for one cycle and waits for 16 cycles before sampling the DQ prime.
4. PHY decrements the wr_level_delay by 3 and generate measure signal.
5. PHY asserts the dqs_en for one cycle and waits for 16 cycles before sampling the DQ prime.
6. PHY increments the wr_level_delay by 4, asserts the dqs_en for one cycle and waits for 16/32 cycles before sampling the DQ prime.
7. PHY repeats steps 4-6 till all 8 wr_level_delay are calculated.
8. PHY checks the 8 bit prime DQ results for 0 to 1 transition. If 1 transition is found the wr_level_delay is the value of the first 1. If number of transitions isn't 1 HW_WLx_RES is set to 1000 for error indication.
9. Upon completion of this process the PHY asserts the hw_write_level_finish while HW_WLx_RES are valid.
10. PHY enables the measure signal.
11. SW issues a MRS command to exit write leveling mode.

28.9 Write fine tuning

Write fine tuning is an additional circuit that enables the option to fine tune the timing of the dq/dm bits (relative to dqs) by up to +/-100 ps. This is done by reducing the delay between the wl_dqs by 100 ps and adding a configurable delay of up to 200 ps (6 delay units of around 30-35 ps each) for each DQ/DM output. The delay can be configured independently for each DQ/DM. The calibration of this mechanism can be done only by writing & reading data from the memory.

28.10 Read fine tuning

Read fine tuning is an additional circuit that enables the option to fine tune the timing of the coming dq bits (relative to coming dqs) by up to +/-100 ps. This is done by reducing the delay between the incoming rd_dqs by 100 ps and adding a configurable delay of up to 200 ps (6 delay units of around 30-35 ps each) for each DQ input. The delay can be configured independently for each DQ. The calibration of this mechanism can be done only by writing & reading data from the memory.

28.11 DQS Gating

The assertion of the dqs gating is done according to the dqs gating delay, the negation of the dqs gating is done after the negedge of fourth dqs if there is no back to back access.

The dqs gating includes a delay of up to 7.875 cycles (The delay is chosen according to a 6 bit register that holds the configurable value of the delay.

Each DQS has a it own delay. In DDR3 the configurable value for each DQS can be different. The DQS gating training can be done for all DQS is done in parallel.

28.11.1 SW DQS gating training

1. SW writes data to a location that is going to be read in the next steps (the wrutten data should be the same data as in the pre-defined register)or by putting the device in MPR pre-defined mode (SW enables the MPR_CMP_BIT in PDCMPR and send precharge all command to the device followed by MRS command).
2. Generate a burst read access to a pre-defined data location/MPR.
3. Compare the data read from DDR to the pre-defined data to check if data is valid.
4. Reset the read data FIFO pointers and data. (writing 1 to the RST_RD_FIFO bit) and then clear the RST_RD_FIFO bit.
5. Repeat steps 3-4 till the data valid window is found. DQS gating should be configured to the middle of this window.
6. Exit MPR mode (if needed).

28.11.2 HW DQS Gating

Below is the HW DQS gating sequence.

1. If MPR mode is used, SW enables the MPR_CMP_BIT in PDCMPR and issues precharge all command to the device followed by MRS command. If pre-defined mode is used the SW issues precharge all command to the device followed by bank 0 ACT command and then writes data to bank 0 address 0 of CS0 and then writes the same pre defined data to the ESDCTL_PDCMPR1 and disables he MPR_CMP_BIT in ESDCTL_PDCMPR2.
2. SW asserts HW_DG_EN bit.
3. PHY counts for 12 cycles (Tmod) (only if MPR mode is used) and asserts the read command request to the controller for one cycle.

4. Controller drives read command and data is sampled in the rd FIFO 16/32 cycles (according to HW_RD_DL_CMP_CYC) after read request was acknowledged.
5. PHY compares the data to the pre-defined value.
6. PHY resets the rd fifo (to the inv. pre-defined value) and it's pointers.
7. PHY increments the dqs_gating_value by 4 and asserts the dqs gating read command to the controller for one cycle
8. If read data is incorrect PHY repeat step 7 till if finds the correct data. (This value is the used as the lower boundary for stages 10). If no correct data is found till max. DG value DG_HW_ERR is asserted.
9. When the PHY finds correct data it repeats steps 7 till if finds the incorrect data.This value is the used as the upper boundary for stages 13).If no incorrect data is found till lower boundary + 16 DG value DG_HW_ERR is asserted.
10. PHY drives the dqs_gating_value to lower_boundary - 3 and asserts the measure signal.
11. PHY asserts the dqs gating read command to the controller for one cycle.
12. PHY samples the data in rd fifo 16/32 after read request was acknowledged. It data is correct it writes 1 to the dqs_gating result register bit 0 else it write 0 to this bit.
13. If dqs_gating_value + 4 < upper boundary PHY increments dqs_gating_value by 4 and go to step 11 else go to step 14.
14. Phy repeats steps 11-13 for lower boundary -2, lower boundary -1 and lower boundary.
15. Upon completion of step 14 PHY has dqs gating register is ready. HW_DGx_RES is calculated according to the average value of the correct data window.
16. PHY enables the measure signal.
17. Upon completion of the training the PHY asserts hw_dqs_gating_finish (to clear the HW_DG_EN bit) while HW_DGx_RES fields are valid
18. SW should Exit MPR mode.

28.12 Programmable Registers

28.12.1 ESDCTL Memory Map/Register Definition

This section contains the description of the ESDCTL registers. Reset values are according to Micron DDR2-400 device (mt47h128m8_25). When assuming that four x8 bit devices of 1Gbits each are connected to each chip select.

ESDCTL memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FD_9000	ESDCTL Control Register (ESDCTL_ESDCTL)	32	R/W	0311_0000h	28.121.1/ 1233

ESDCTL_ESDCTL field descriptions

Field	Description
31 SDE_0	This should be set if a memory is connected to chip select 0. If SDE0 and SDE1 are both 0, no clock will be issued to the memory. Writing 1 to SDE0 or SDE1 will initiate power up delays as JEDEC defines. Power up delays are a function of the configured memory type (DDR2/DDR3/LPDDR2). 0 Disabled 1 Enabled
30 SDE_1	This should be set if a memory is connected to chip select 1. If SDE0 and SDE1 are both 0, no clock will be issued to the memory. Writing 1 to SDE0 or SDE1 will initiate power up delays as JEDEC defines. Power up delays are a function of the configured memory type (DDR2/DDR3/LPDDR2). 0 Disabled 1 Enabled
29–27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26–24 ROW	Row Address Width. This control field specifies the number of row addresses used by the memory array. It will affect the way an incoming address will be decoded. 000 11 bits Row 001 12 bits Row

ESDCTL_ESDCTL field descriptions (continued)

Field	Description
	010 13 bits Row 011 14 bits Row 100 15 bits Row 101 16 bits Row 110 through 111 are reserved
23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22–20 COL	Column Address Width. The COL control field is used to specify the number of column addresses in the memory array. It will determine how an incoming address will be decoded. 0x0 9 bits column 0x1 10 bits column 0x2 11 bits column 0x3 8 bits column 0x4 12 bits column 0x5-0xF Reserved
19 BL	Burst Length. DDR2 ,LPDDR2 : Controller supports either burst length 8 or 4 (Optimized for BL4). DDR3: Controller supports only burst length 8. 0 Burst Length 4is used. 1 Burst Length 8 is used.
18–17 Reserved	This read-only field is reserved and always has the value zero. Reserved
16 DSIZ	SDRAM Memory Data Width. This field defines the width of the SDRAM memory and its alignment on the external data bus. 16-bit ports aligned to the low half word. Data qualifier mask control outputs must match the selected data bus alignment. Memories aligned to D[15:0] use DQM0 and DQM1. 0 16-bit memory width aligned to D[15:0] 1 32-bit memory width
15–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

28.121.2 ESDCTL Power Down Control Register (ESDCTL_ESDPDC)

Table 28-8. PRCT field encoding

PRCT[2:0]	Precharge Timer
000	Disabled (Bit field reset value)
001	2 clocks
010	4 clocks
011	8 clocks

Table continues on the next page...

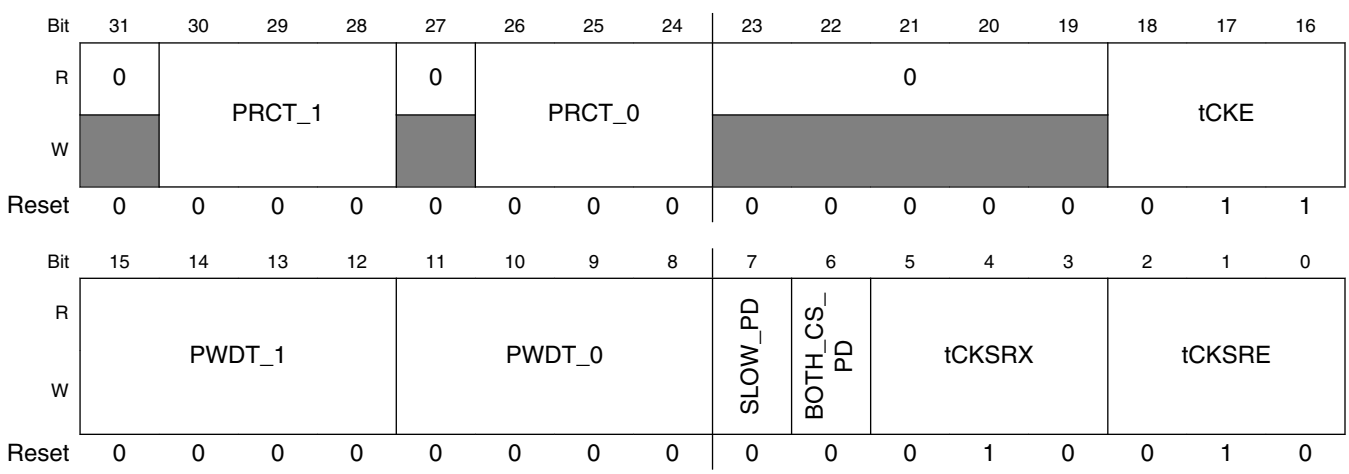
Table 28-8. PRCT field encoding (continued)

PRCT[2:0]	Precharge Timer
100	16 clocks
101	32 clocks
110	64 clocks
111	128 clocks

Table 28-9. PWDT field encoding

PWDT[3:0]	Power Down Time-out
0000	Disabled (bit field reset value)
0001	16 cycles
0010	32 cycles
0011	64 cycles
0100	128 cycles
0101	256 cycles
0110	512 cycles
0111	1024 cycles
1000	2048 cycles
1001	4096 cycles
1010	8196 cycles
1011	16384 cycles
1100	32768 cycles
1101-1111	Reserved

Address: ESDCTL_ESDPDC is 63FD_9000h base + 4h offset = 63FD_9004h



ESDCTL_ESDPDC field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value zero. Reserved
30–28 PRCT_1	Precharge Timer - Chip Select 1. This chip select will be precharged after certain amount of cycles from the last access. The amount of cycles is determined according to Write CA Delay Line controllerESDCTL Power Down Control Register above.
27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26–24 PRCT_0	Precharge Timer - Chip Select 0. This chip select will be precharged after certain amount of cycles from the last access. The amount of cycles is determined according to Write CA Delay Line controllerESDCTL Power Down Control Register above.
23–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18–16 tCKE	CKE minimum pulse width. 0x0 1 cycle 0x1 2 cycles 0x6 7 cycles 0x7 8 cycles
15–12 PWDT_1	Power Down Timer - Chip Select 1. This field determines whether the memory on chip select 1 will be placed in a Power Down condition after a selectable delay from the last access. The amount of cycles is determined according to Write CA Delay Line controllerESDCTL Power Down Control Register above.
11–8 PWDT_0	Power Down Timer - Chip Select 0. This field determines whether the memory on chip select 0 will be placed in a Power Down condition after a selectable delay from the last access. The amount of cycles is determined according to Write CA Delay Line controllerESDCTL Power Down Control Register above.
7 SLOW_PD	DDR3: Slow precharge power-down. DDR2: Slow active power-down. LPDDR2: Not relevant. **NOTE:** Memory should be configured the same. 0 Fast mode. 1 Slow mode.
6 BOTH_CS_PD	When both chip selects are using power down timer, will enter power down only if both chip select 0 and chip select 1 required idle time was reached. 0 Each chip select can enter power down independently according to its configuration. 1 Chip selects can enter power down only if both chip selects idle time was reached.
5–3 tCKSRX	Valid clock requirement before self-refresh exit. 0x0 0 cycle 0x1 1 cycles 0x6 6 cycles 0x7 7 cycles

Table continues on the next page...

ESDCTL_ESDPDC field descriptions (continued)

Field	Description
2–0 tCKSRE	Valid clock requirement after self-refresh entry. 0x0 0cycle 0x1 1 cycles 0x6 6cycles 0x7 7cycles

28.121.3 ESDCTL ODT Timing Control Register (ESDCTL_ESDOTC)

Address: ESDCTL_ESDOTC is 63FD_9000h base + 8h offset = 63FD_9008h

ESDCTL_ESDOTC field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved
29–27 tAOFPD	DDR2: ODT turn-off (power down mode) max value. DDR3: Asynchronous RTT turn-off delay(power down with DLL frozen). LPDDR2: Not relevant. 0x0 1 cycle 0x1 2 cycles 0x6 7 cycles 0x7 8 cycles
26–24 tAONPD	DDR2: ODT turn-on (power down mode) max value. DDR3: Asynchronous RTT turn-on delay(power down with DLL frozen). LPDDR2: Not relevant. 0x0 1 cycle 0x1 2 cycles 0x6 7 cycles 0x7 8 cycles
23–20 tANPD	DDR2: ODT to power down entry latency. DDR3: ODT to power down entry latency (Should be set to tCWL-1). LPDDR2: Not relevant. 0x0 1 clock 0x1 2 clocks

Table continues on the next page...

ESDCTL_ESDOTC field descriptions (continued)

Field	Description
	0x2 3 clocks 0xE 15 clocks 0xF 16 clocks
19–16 tAXPD	DDR2: ODT power down exit latency. DDR3: ODT power down exit latency (Should be set to tCWL-1). LPDDR2: Not relevant. 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF 16 clocks
15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14–12 tODTLon	ODT turn on latency. DDR2: Named 'tAOND' LPDDR2: Not relevant. 0x0 0x1 Reserved 0x2 2 cycles 0x3 3 cycles 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 Reserved
11–9 Reserved	This read-only field is reserved and always has the value zero. Reserved
8–4 tODT_idle_off	Idle period before turning memory ODT off. LPDDR2: Not relevant. 0x0 0 cycle (turned off at the earliest possible time) 0x1 1 cycle 0x2 2 cycles 0x1E 30 cycles 0x1F 31 cycles
3–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

28.121.4 ESDCTL Logic Timing Configuration Register 0 (ESDCTL_ESDCFG0)

Address: ESDCTL_ESDCFG0 is 63FD_9000h base + Ch offset = 63FD_900Ch

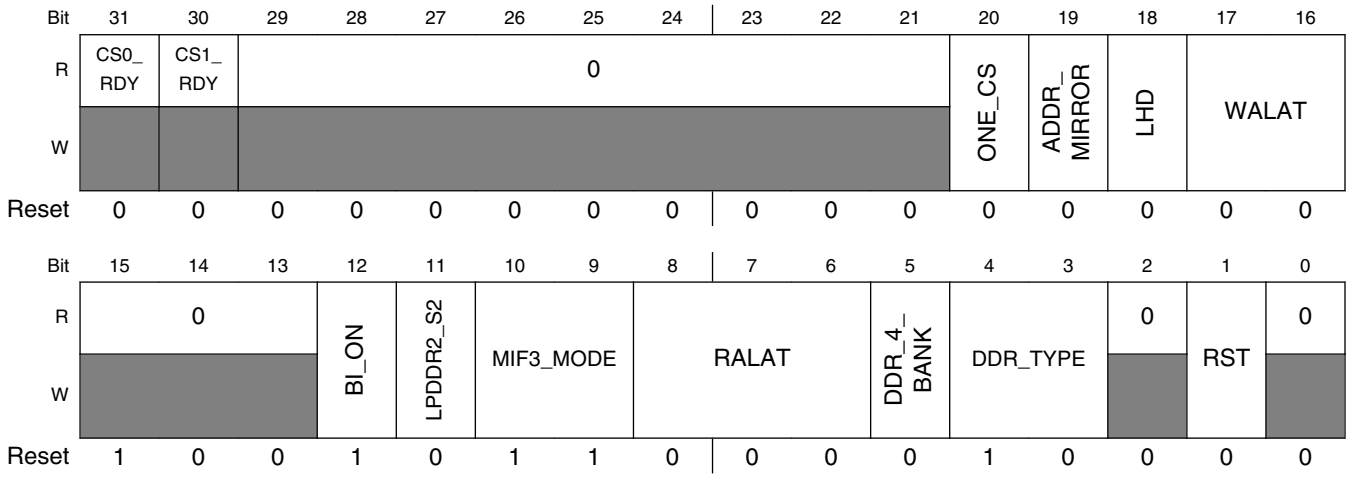
28.121.7 ESDCTL Timing Miscellaneous Register (ESDCTL_ESDMISC)

This register contains the controlling various memory and control settings for the ESDCTL.

.

Address: ESDCTL_ESDMISC is 63FD_9000h base + 18h offset = 63FD_9018h



ESDCTL_ESDMISC field descriptions

Field	Description
31 CS0_RDY	External status device on CS0. This is a read-only status bit, that indicates whether the external memory is in wake-up period. 0 Device in wake-up period. 1 Device is ready for initialization.
30 CS1_RDY	External status device on CS1. This is a read-only status bit, that indicates whether the external memory is in wake-up period. 0 Device in wake-up period. 1 Device is ready for initialization.
29–21 Reserved	This read-only field is reserved and always has the value zero. Reserved
20 ONE_CS	One chip select. This feature enable to use all 2GB of memory space in chip select 0 instead of using 1GB for every chip select. 0x0 Two chip select are used, 1 GB per chip select. 0x1 Chip select 0 is used for entire 2GB memory space.
19 ADDR_MIRROR	Address mirroring. Note: This feature is not supported for LPDDR2 memories. But only for DDR2 or DDR2 memories. See table 1-24 for more details. 0 Address mirroring disabled. 1 Address mirroring enabled.
18 LHD	Latency hiding disable. This is a debug feature. When used the controller handles one read/write at a time. Meaning, the address axi channel waits for the data channel to finish before accepting new access. 0 Latency hiding on. 1 Latency hiding disable.

Table continues on the next page...

ESDCTL_ESDMISC field descriptions (continued)

Field	Description
17–16 WALAT	Write Additional latency. This latency can result from using Write Leveling and causes DQS to arrive later to some memory devices. 0x0 No additional latency required. 0x1 1 cycle additional delay 0x2 2 cycles additional delay 0x3 3 cycles additional delay
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12 BI_ON	Bank Interleaving On: 0 Banks are not interleaved, and address is decoded as bank-row-column 1 Banks are interleaved, and address is decoded as row-bank-column
11 LPDDR2_S2	LPDDR2 S2 device type indication. In case LPDDR2 device is used (DDR_TYPE = 0x1), this bit indicates whether S2 or S4 device is used. 0x0 LPDDR2-S4 device is used. 0x1 LPDDR2-S2 device is used.
10–9 MIF3_MODE	MIF3 working mode: 00 Disable MIF3. 01 Enable treatment for: Valid access on first pipe line stage. 10 Enable treatment for: Valid access on first pipe line stage. Valid access on axi bus. 11 Enable treatment for: Valid access on first pipe line stage. Valid access on axi bus. Predicted next miss access from M4IF.
8–6 RALAT	Read Additional Latency, which determines when the contoller retrieves the data from the ESDCTL internal FIFO. Using this field to compensate on board/chip delays. **NOTE:** On LPDDR2 memories 2 extra cycles are waited internally in order to compensate on tDQSCK delay. 0x0 The data is retrieved from the FIFO at the earliest step possible. 0x1 1 cycle additional latency. 0x2 2 cycles additional latency. 0x3 3 cycles additional latency. 0x4 4 cycles additional latency. 0x5 5 cycles additional latency. 0x6 6 cycles additional latency. 0x7 7 cycles additional latency.
5 DDR_4_BANK	DDR device with 4 Banks: 0 8 banks device is being used. 1 4 banks device is being used
4–3 DDR_TYPE	DDR TYPE: 0x0 DDR3 device is used. 0x1 LPDDR2 device is used.

Table continues on the next page...

ESDCTL_ESDMISC field descriptions (continued)

Field	Description
	0x2 DDR2 device is used. (Default) 0x3 Reserved.
2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 RST	Software Reset. **NOTE:** This bit once asserted gets deasserted automatically. 0 Do nothing. 1 Assert reset to the controller.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved

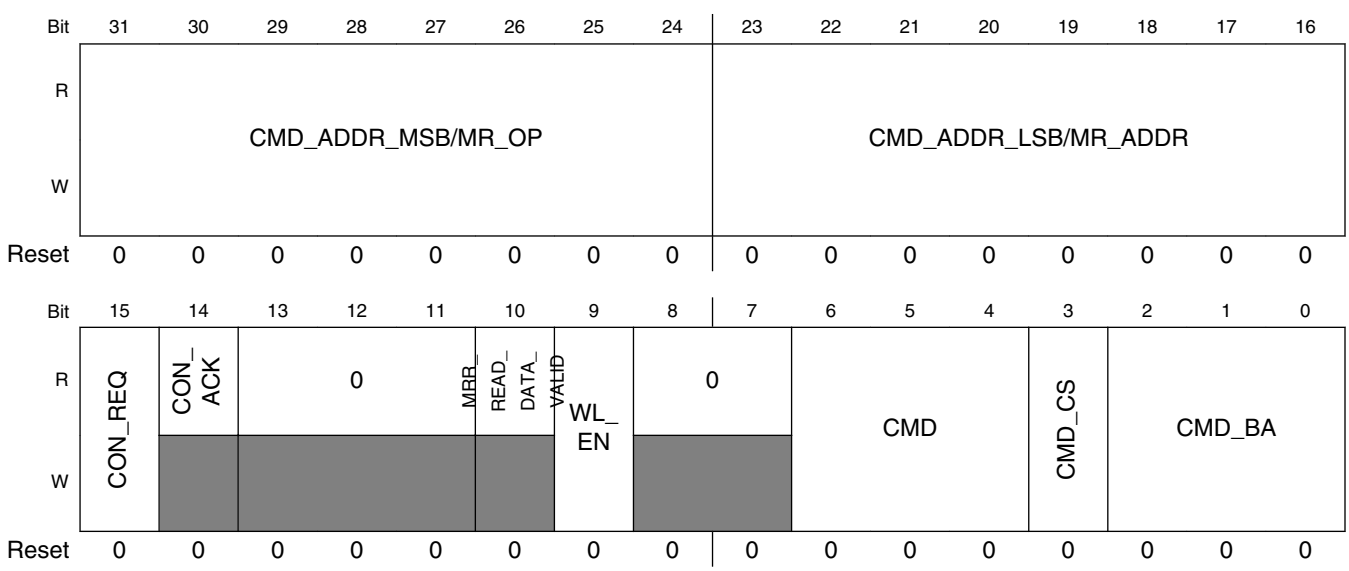
28.121.8 ESDCTL Special Command Register (ESDCTL_ESDSCR)

This register is used to issue special commands on the external device bus (such as load mode register, manual self refresh, manual precharge etc.). Every write to this register is interpreted as a command, and a read from this register will show you the last commands executed.

Every write to this register will result in one special command, and the IP bus will assert ips_xfr_wait as long as the special command is being carried out, thus introducing wait states for the next IP write

.

Address: ESDCTL_ESDSCR is 63FD_9000h base + 1Ch offset = 63FD_901Ch



ESDCTL_ESDSCR field descriptions

Field	Description
31–24 CMD_ADDR_ MSB/MR_OP	DDR2/DDR3: CMD_ADDR_MSB Address 8 LSB bits that match the issued command. ESDCTL.LPDDR2: MRW OPERAND MRR 8 bit operand
23–16 CMD_ADDR_ LSB/MR_ADDR	DDR2/DDR3: CMD_ADDR_MSB Address 8 MSB bits that match the issued command. ESDCTL.LPDDR2: MRR/MRW ADDRESS MRR/MRW 8 bit address
15 CON_REQ	Configuration request. When this bit is set it tells the controller the user would like to configure the IP registers, so in order to prevent a clash with the AXI bus, the controller holds the aready and awready signals at low, and will not accept LPMD request. This bit is high out of reset, meaning the controller is waiting on configuration and initialization of external memory before accepting any AXI accesses. Note that this bit should be held high during subsequent accesses to this register if AXI readies in low state are to be maintained. 1 AXI address readies are being held low 0 AXI address readies are operating normally
14 CON_ACK	Configuration acknowledge. This read only bit indicates that the controller is idle and no AXI accesses are pending execution. It is recommended that the master will wait until both CON_REQ and CON_ACK are 1 before performing any writes on the IP bus. 1 AXI channels state machines are all idle 0 At least one of the AXI state machines is not idle
13–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10 MRR_READ_ DATA_VALID	MRR READ DATA VALID - read only 0 Cleared upon the assertion of MRR command 1 Set after MRR data is valid and stored at ESDCTL_ESDMRR register.
9 WL_EN	Write Level Enable. This bit controls the DQS pads direction. It should be set high when sending write leveling entry command. And should be set low when sending write leveling exit command. 0 Exit write leveling mode or stay in normal mode. 1 Write leveling entry command was sent.
8–7 Reserved	This read-only field is reserved and always has the value zero. Reserved.
6–4 CMD	Command. This field contains the command to be executed: This field is automatically cleared after the command is asserted. 0x0 Normal operation

Table continues on the next page...

ESDCTL_ESDSCR field descriptions (continued)

Field	Description
	0x1 Precharge all, command is sent independently of bank status (set correct CMD_CS). Is issued even if banks are closed. Mainly used for init sequence purpose. 0x2 Auto-Refresh Command (set correct CMD_CS). 0x3 Load Mode Register Command (DDR2/DDR3, set correct CMD_CS, CMD_BA, CMD_ADDR_LSB, CMD_ADDR_MSB), MRW Command (ESDCTL.LPDDR2, set correct CMD_CS, MR_OP, MR_ADDR) 0x4 ZQ calibration (DDR2/DDR3, set correct CMD_CS, {CMD_ADDR_MSB,CMD_ADDR_LSB} = 0x400 or 0x0) 0x5 Precharge all, only if banks open (set correct CMD_CS). 0x6 MRR command (ESDCTL.LPDDR2, set correct CMD_CS, MR_ADDR) 0x7 Reserved
3 CMD_CS	Chip Select. This field determines which chip select the command is directed at. 0 to Chip-select 0 1 to Chip-select 1
2–0 CMD_BA	Bank Address. This field determines which bank within the chip select the command is directed at.

28.121.9 ESDCTL Refresh Control Register (ESDCTL_ESDREF)

This register defines how to refresh the connected memory device. It set how often begins a refresh cycle and how many refreshes are given in every cycle.

Table 28-17. Refresh rate example for REF_SEL = 0

REFR[2:0]	Number of refresh commands every 64KHz	Average periodic refresh rate (tREFI)	System Refresh period
0x0	1	15.6 µs	tRFC
0x1	2	7.8 µs	2*tRFC
0x3	4	3.9µs	4*tRFC
0x7	8	1.95 µs	8*tRFC

Table 28-18. Refresh rate example for REF_SEL = 1

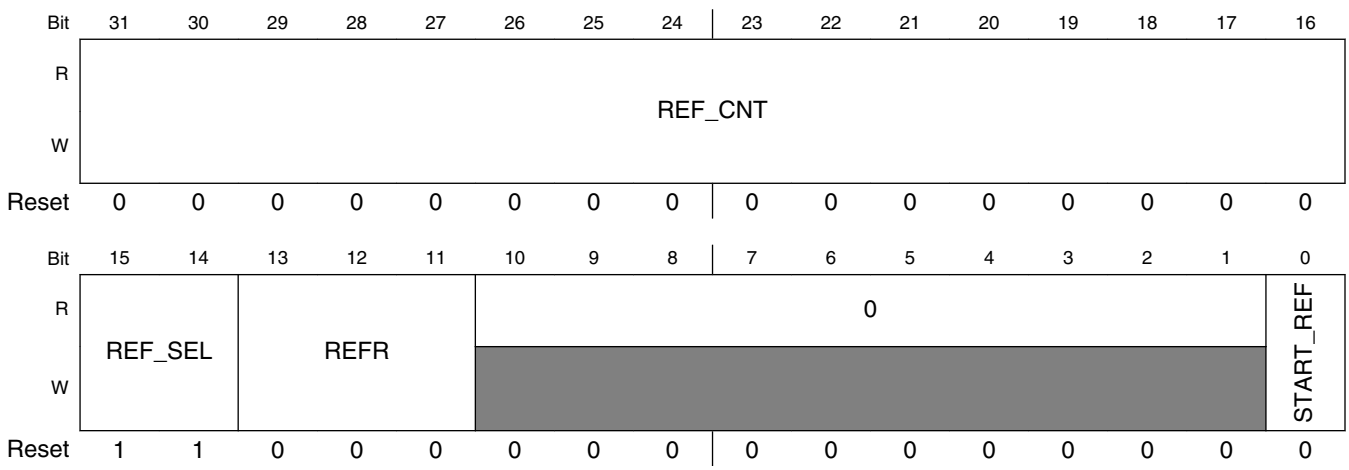
REFR[2:0]	Number of refresh commands every 32KHz	Average periodic refresh rate (tREFI)	System Refresh period
0x1	2	15.6 µs	2*tRFC
0x3	4	7.8 µs	4*tRFC
0x7	8	3.9µs	8*tRFC

Table 28-19. Refresh rate example for REF_SEL = 2@ 400MHz

REFR[2:0]	Number of refresh commands every refresh cycle	REF_CNT	Average periodic refresh rate (tREFI)	System Refresh period
0x0	1	0x618	3.9 µs	tRFC
0x1	2	0xC30	3.9 µs	2*tRFC
0x2	3	0x1248	3.9µs	3*tRFC
0x3	4	0x1860	3.9 µs	4*tRFC

- Other refresh configurations are also allowed, the configuration values in the tables above are only examples for reaching desired average periodic refresh rate.
- If keeping the required average periodic refresh rate (tREFI), all the rows are refreshed every refresh window. It can be seen in memories specifications that regardless of number of rows in the device the tREFI stays the same across this devices. The reason for that is that the memory device issues additional refresh commands for every refresh it receive, this comes into consideration in the tRFC parameter which gets bigger as the density increase.

Address: ESDCTL_ESDREF is 63FD_9000h base + 20h offset = 63FD_9020h



ESDCTL_ESDREF field descriptions

Field	Description
31–16 REF_CNT	Refresh Counter. If REF_SEL equals '2' a refresh cycle begins every amount of cycles defined in this field. (Counts in fast clock cycles) 0x0 Reserved. 0x1 1 cycle. 0xFFFE 65534 cycles. 0xFFFF 65535 cycles.

Table continues on the next page...

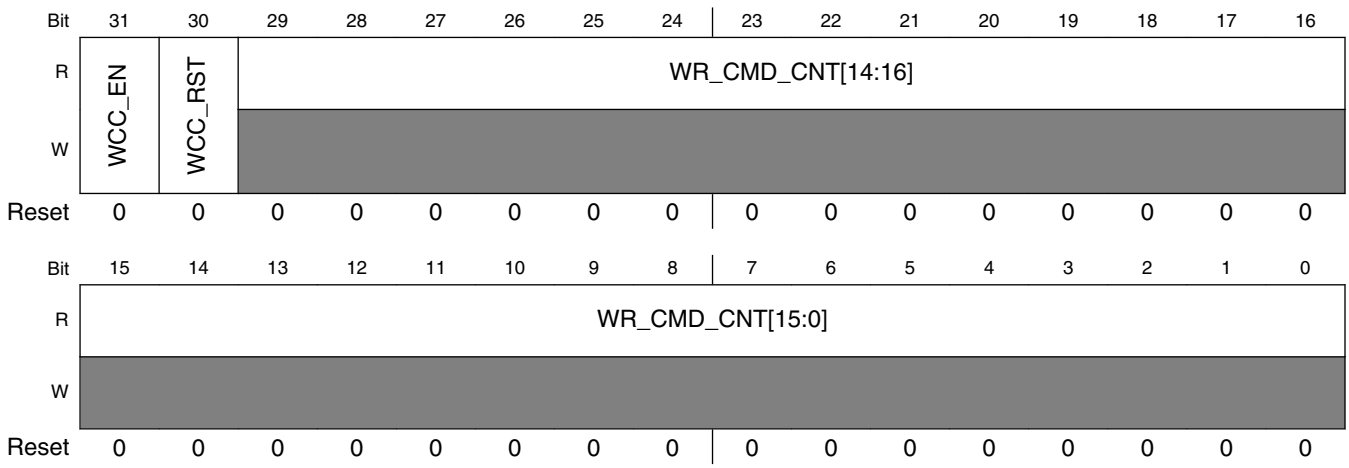
ESDCTL_ESDREF field descriptions (continued)

Field	Description
15–14 REF_SEL	Refresh Selector. This bit choose what will trigger each refresh cycle: 0 Refresh cycles are triggered in frequency of 64KHz. 1 Refresh cycles are triggered in frequency of 32KHz. 2 Refresh cycles are triggered every amount of cycles that is defined in REF_CNT field in this register. 3 No refresh cycles are triggered.
13–11 REFR	Refresh Rate. This field determine how many refresh commands are issued every refresh cycle. After every refresh command a time period of tRFC is kept until next valid command. 0x0 1 refresh 0x1 2 refreshes 0x2 3 refreshes 0x3 4 refreshes 0x4 5 refreshes 0x5 6 refreshes 0x6 7 refreshes 0x7 8 refreshes
10–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 START_REF	Start Refresh cycle. When set to '1' it will start a refresh cycle according to number of refreshes set in 'REFR' field. This bit returns to zero automatically. are0 Do nothing. 1 Start a refresh cycle.

28.121.10 ESDCTL Logic Write Command Counter - Debug (ESDCTL_ESDWCC)

This debug register is used for counting write burst commands that were issued to the memory.

Address: ESDCTL_ESDWCC is 63FD_9000h base + 24h offset = 63FD_9024h



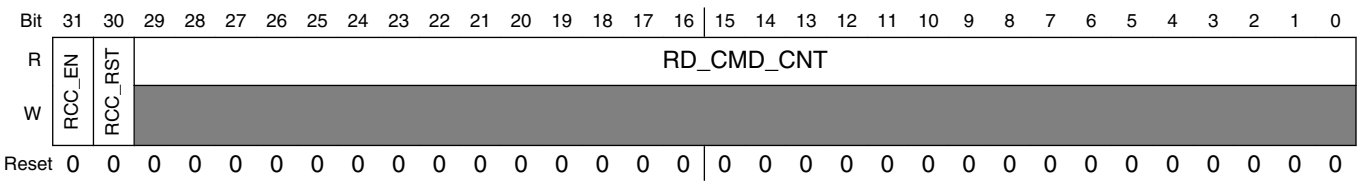
ESDCTL_ESDWCC field descriptions

Field	Description
31 WCC_EN	Write Command Counter Enable. 0 The counter is disabled. 1 The counter is enabled.
30 WCC_RST	Write Command Counter Reset. Note: Once asserted this bit deasserts automatically. 0 Do nothing. 1 The counter is set to zero.
29–0 WR_CMD_CNT	Write Command Counter value. This read-only field will display the number of write burst accesses that were sent to the memory. This is used mainly for bus utilization calculation.

28.121.11 ESDCTL Read Command Counter - Debug (ESDCTL_ESDRCC)

This debug register is used for counting write burst commands that were issued to the memory.

Address: ESDCTL_ESDRCC is 63FD_9000h base + 28h offset = 63FD_9028h



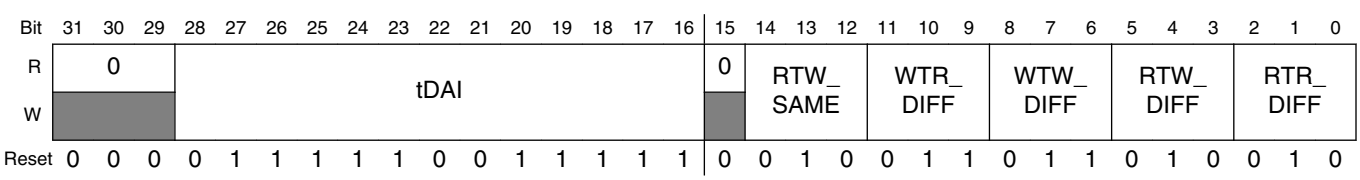
ESDCTL_ESDRCC field descriptions

Field	Description
31 RCC_EN	Read Command Counter Enable. 0 The counter is disabled. 1 The counter is enabled.
30 RCC_RST	Read Command Counter Reset. Note: Once asserted this bit deasserts automatically. 0 DO nothing. 1 The counter is set to zero.
29–0 RD_CMD_CNT	Read Command Counter value. This read-only field will display the number of read burst accesses that were sent to the memory. This is used mainly for bus utilization calculation.

28.121.12 ESDCTL Read/Write Command Delay (ESDCTL_ESDRWD)

This register affects the delay between back to back RD / WR accesses according to the details of each field. The register reset values are set to the minimum required value. The default values are set for achieving the best results and thus not recommended to be changed.

Address: ESDCTL_ESDRWD is 63FD_9000h base + 2Ch offset = 63FD_902Ch



ESDCTL_ESDRWD field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28–16 tDAI	Device auto initialization period.(maximum) Field relevant only to LPDDR2. 0x0 1 cycle 0xF9F 4000 cycles (Default, JEDEC value for LPDDR2, gives 10us at 400MHz clock). 0x1FFF 8192 cycles
15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14–12 RTW_SAME	Controls the cycles delay between Read to Write commands in same chip select. Delay is: BL/2 + RTW_SAME + (tCL-tCWL) + RALAT This field determines the value of RTW_SAME. 0x0 0 cycle 0x1 1 cycle 0x2 2 cycles (Default) 0x3 3 cycles 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles
11–9 WTR_DIFF	Controls the cycles delay between Write to Read commands in different chip select. Delay is: BL/2 + WTR_DIFF - (tCL-tCWL) + WALAT This field determines the value of WTR_DIFF. 0x0 0 cycle 0x1 1 cycle 0x2 2 cycles 0x3 3 cycles (Default) 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles
8–6 WTW_DIFF	Controls the cycles delay between Write to Write commands in different chip select. Delay is: BL/2 + WTW_DIFF This field determines the value of WTW_DIFF. 0x0 0 cycle 0x1 1 cycle 0x2 2 cycles 0x3 3 cycles (Default) 0x4 4 cycles 0x5 5 cycles

Table continues on the next page...

ESDCTL_ESDRWD field descriptions (continued)

Field	Description
	0x6 6 cycles 0x7 7 cycles
5–3 RTW_DIFF	Controls the cycles delay between Read to Write commands in different chip select. Delay is: BL/2 + RTW_DIFF + (tCL - tCWL) + RALAT This field determines the value of RTW_DIFF. 0x0 0 cycle 0x1 1 cycle 0x2 2 cycles (Default) 0x3 3 cycles 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles
2–0 RTR_DIFF	Controls the cycles delay between Read to Read commands in different chip select. Delay is: BL/2 + RTR_DIFF This field determines the value of RTR_DIFF. 0x0 0 cycle 0x1 1 cycle 0x2 2 cycles (Default) 0x3 3 cycles 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles

28.121.13 ESDCTL Out of Reset Delays (ESDCTL_ESDOR)

This register defines some delays that must be kept when controller exit from reset.

Address: ESDCTL_ESDOR is 63FD_9000h base + 30h offset = 63FD_9030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ESDCTL_ESDCFG3_LP field descriptions

Field	Description
31–22 Reserved	This read-only field is reserved and always has the value zero. Reserved
21–16 RC_LP	ACT to ACT or REF command period (same bank). (This field is valid only for LPDDR2 memories)

Table continues on the next page...

ESDCTL_ESDCFG3_LP field descriptions (continued)

Field	Description
	0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0x3E 63 clocks 0x3F Reserved
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11–8 tRCD_LP	ACT command to internal read or write delay time (same bank). (This field is valid only for LPDDR2 memories) 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF Reserved
7–4 tRPpb_LP	PRECHARGE (per bank) command period (same bank). (This field is valid only for LPDDR2 memories) 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF Reserved
3–0 tRPab_LP	PRECHARGE (all banks) command period. (This field is valid only for LPDDR2 memories) 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF Reserved

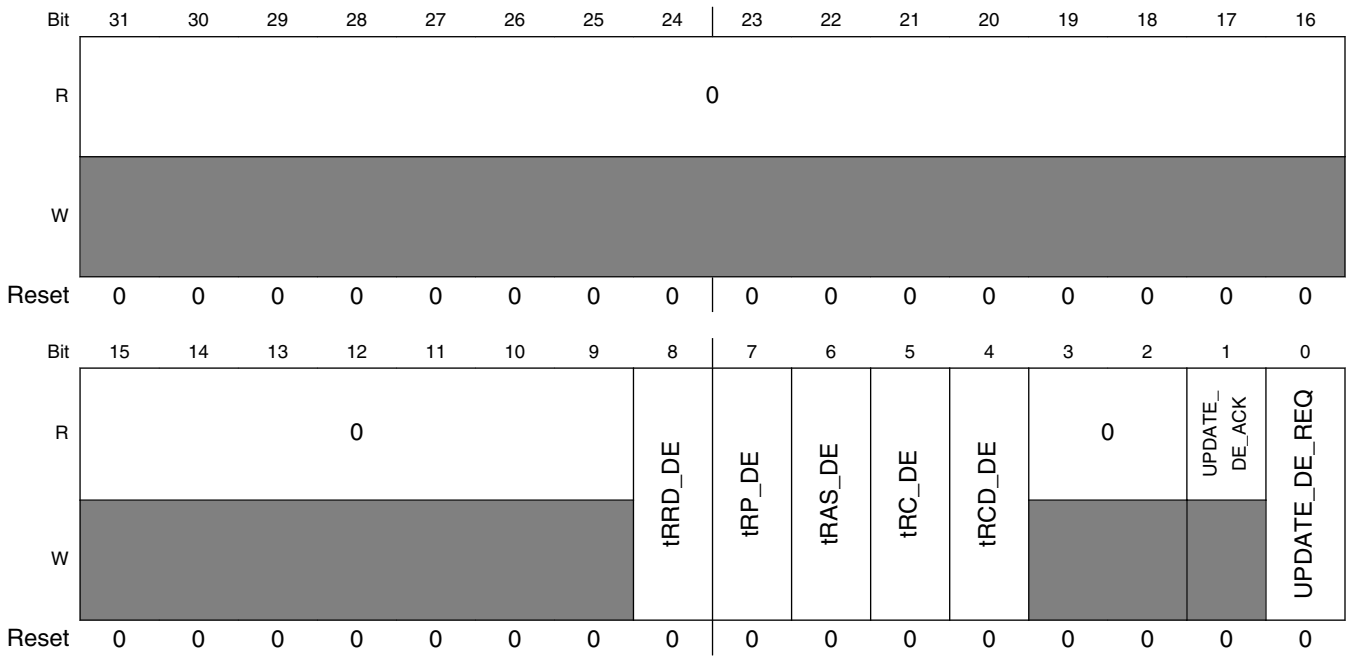
28.121.16 ESDCTL MR4 Derating Register (ESDCTL_ESDMR4)

This register is relevant only to LPDDR2 memories. It is used to dynamically change certain values depending on MR4 read result, which is based on memory temperature sensor result.

NOTE

The temperature sensor is located in the external LPDDR2 memory if supported, it is NOT part of the i.MX53 ESDCTL interface. This Temperature sensor is not the same as the one located within SATA module.

Address: ESDCTL_ESDMR4 is 63FD_9000h base + 3Ch offset = 63FD_903Ch



ESDCTL_ESDMR4 field descriptions

Field	Description
31–9 Reserved	This read-only field is reserved and always has the value zero. Reserved
8 tRRD_DE	tRRD derating value. 0x0 Original tRRD is used. 0x1 tRRD is derated in 1 cycle.
7 tRP_DE	tRP derating value. 0x0 Original tRP is used. 0x1 tRP is derated in 1 cycle.
6 tRAS_DE	tRAS derating value. 0x0 Original tRAS is used. 0x1 tRAS is derated in 1 cycle.
5 tRC_DE	tRC derating value. 0x0 Original tRC is used. 0x1 tRC is derated in 1 cycle.
4 tRCD_DE	tRCD derating value. 0x0 Original tRCD is used. 0x1 tRCD is derated in 1 cycle.
3–2 Reserved	This read-only field is reserved and always has the value zero. Reserved

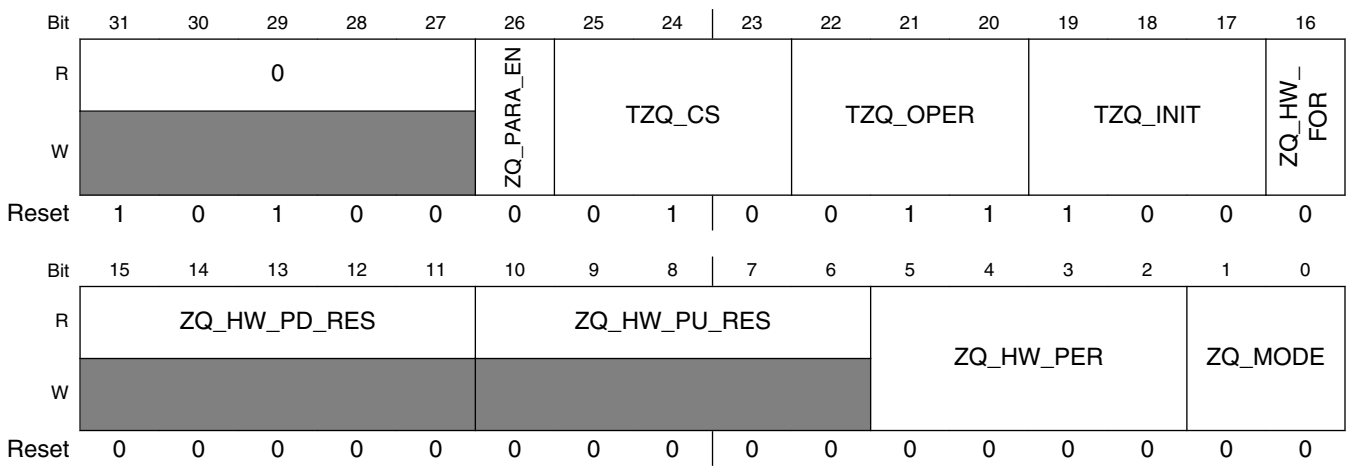
Table continues on the next page...

ESDCTL_ESDMR4 field descriptions (continued)

Field	Description
1 UPDATE_DE_ACK	Update Derated Values Acknowledge. This read only bit is arecleared upon UPDATE_DE_REQ assertion and isare set after the new values are taken.
0 UPDATE_DE_REQ	Update Derated Values Request. This read modify write field is automatically cleared after the request is issued. 0x0 Do nothing. 0x1 Request to update the following values: tRRD, tRCD, tRP, tRC, tRAS and refresh related fields(ESDCTL_ESDREF register): REF_CNT, REF_SEL, REFR

28.121.17 PHY ZQ HW Control Register (ESDCTL_ZQHWCTRL)

Address: ESDCTL_ZQHWCTRL is 63FD_9000h base + 40h offset = 63FD_9040h



ESDCTL_ZQHWCTRL field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26 ZQ_PARA_EN	Device ZQ calibration parallel enable. 0- Device ZQ calibration is done in serial (CS0 first and then CS1). 1- ZQ calibration of both CS is done in parallel
25–23 TZQ_CS	Device ZQ CS time. This field holds the number of cycles that are required by the device to preform ZQ short calibration. **NOTE:** This field should not be update during ZQ calibration. 000 Reserved 001 Reserved 010 128 cycles - Default

Table continues on the next page...

ESDCTL_ZQHWCTRL field descriptions (continued)

Field	Description
	011 256 cycles 100 512 cycles 101 1024 cycles 110-111 Reserved
22–20 TZQ_OPER	Device ZQ oper time. This field holds the number of cycles that are required by the device to preform ZQ oper calibration. **NOTE:** This field should not be update during ZQ calibration. 000 Reserved 001 Reserved 010 128 cycles 011 256 cycles - Default (JEDEC value for DDR3) 100 512 cycles 101 1024 cycles 110-111 Reserved
19–17 TZQ_INIT	Device ZQ init time. This field holds the number of cycles that are required by the device to preform ZQ init calibration. **NOTE:** This field should not be update during ZQ calibration. 000 Reserved 001 Reserved 010 128 cycles 011 256 cycles 100 512 cycles - Default (JEDEC value for DDR3) 101 1024 cycles 110-111 Reserved
16 ZQ_HW_FOR	Force ZQ HW calibration. This bit when asserted force ZQ HW calibration. SW should make sure all access to DDR is finished before asserting this bit. HW should negated this bit upon completion of the ZQ HW calibration.Upon negation of this bit the ZQ HW calibration result is valid
15–11 ZQ_HW_PD_ RES	ZQ HW calibration pull-down result. This field holds the pull-down resistor value calculated by ZQ HW calibration. 00000 Min. resistance. 11111 Max. resistance.
10–6 ZQ_HW_PU_ RES	ZQ HW calibration pull-up result. This field holds the pull-up resistor value calculated by ZQ HW calibration. 00000 Min. resistance. 11111 Max. resistance.
5–2 ZQ_HW_PER	ZQ HW periodic calibration time. This field determines how often ZQ HW calibration time is preformed in regular operation mode. This field is ignored if ZQ_HW_PER_EN is disabled. 0000 ZQ calibration performed every 1 ms sec. 0001 ZQ calibration performed every 2 ms sec.

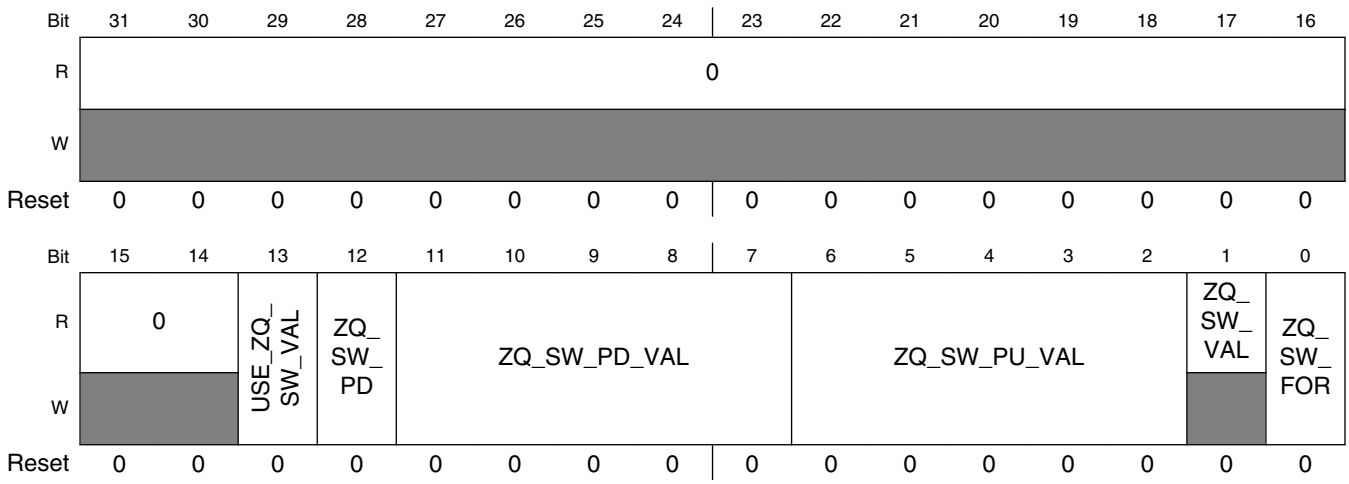
Table continues on the next page...

ESDCTL_ZQHWCTRL field descriptions (continued)

Field	Description
	0010 ZQ calibration performed every 4ms sec. 1111 ZQ calibration performed every 32 sec.
1–0 ZQ_MODE	ZQ calibration mode: 0x0 No ZQ calibration is issued. (Default) 0x1 ZQ calibration is issued to i.MX ZQ pad and external device.(Only when exiting self refresh) 0x2 ZQ calibration is issued to external device only. (Both periodic and when exiting self refresh) 0x3 ZQ calibration is issued to i.MX ZQ pad and external device. (Both periodic and when exiting self refresh)

28.121.18 PHY ZQ SW Control Register (ESDCTL_ZQSWCTRL)

Address: ESDCTL_ZQSWCTRL is 63FD_9000h base + 44h offset = 63FD_9044h



ESDCTL_ZQSWCTRL field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value zero. Reserved
13 USE_ZQ_SW_VAL	Use SW ZQ configured value for I/O pads resistor controls. This bit if asserted causes to DDR PHY to drive SW ZQ configured value on the resistor controls of the I/O pads. By default this bit is cleared and PHY drives the HW ZQ status bits on the resistor controls of the I/O pads. **NOTE:** This bit should not be updated during ZQ calibration. 0 -Fields ZQ_HW_PD_VAL & ZQ_HW_PU_VAL are used for driving I/O pads resistor controls. 1- Fields ZQ_SW_PD_VAL & ZQ_SW_PU_VAL are used for driving I/O pads resistor controls.
12 ZQ_SW_PD	ZQ software PU/PD calibration. This bit determines the calibration stage (PU or PD). 0 PU resistor calibration 1 PD resistor calibration

Table continues on the next page...

ESDCTL_ZQSWCTRL field descriptions (continued)

Field	Description
11–7 ZQ_SW_PD_VAL	ZQ software pull-down resistence.This field determines the value of the PD resistor during SW ZQ calibration. 00000 Max. resistance. 11111 Min. resistance.
6–2 ZQ_SW_PU_VAL	ZQ software pull-up resistence.This field determines the value of the PU resistor during SW ZQ calibration. 00000 Max. resistance. 11111 Min. resistance.
1 ZQ_SW_VAL	ZQ software calibration result. This bit reflects the ZQ calibration voltage comparator value. 0 Current ZQ calibration voltage is less than VDD/2. 1 Current ZQ calibration voltage is more than VDD/2
0 ZQ_SW_FOR	Force ZQ SW calibration. This bit when asserted force ZQ SW calibration. HW should negated this bit upon completion of the ZQ SW calibration.Upon negation of this bit the ZQ SW calibration result is valid

28.121.19 PHY Write Leveling General Control Register (ESDCTL_WLGCR)

Address: ESDCTL_WLGCR is 63FD_9000h base + 48h offset = 63FD_9048h

ESDCTL_WLGCR field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11 WL_HW_ERR3	Byte3 WL HW calibration error. This bit is asserted when an error was found on byte3 during wl hw calibration. This bit is valid only upon completion of the wl HW calibration. (hw_wl_en bit is de-asserted)

Table continues on the next page...

ESDCTL_WLGCR field descriptions (continued)

Field	Description
	0 No error was found on byte3 during wl HW calibration. 1 An error was found on byte3 during wl HW calibration.
10 WL_HW_ERR2	Byte2 WL HW calibration error. This bit is asserted when an error was found on byte2 during wl hw calibration. This bit is valid only upon completion of the wl HW calibration. (hw_wl_en bit is de-asserted) 0 No error was found on byte2 during wl HW calibration. 1 An error was found on byte2 during wl HW calibration.
9 WL_HW_ERR1	Byte1 WL HW calibration error. This bit is asserted when an error was found on byte1 during wl hw calibration. This bit is valid only upon completion of the wl HW calibration. (hw_wl_en bit is de-asserted) 0 No error was found on byte1 during wl HW calibration. 1 An error was found on byte1 during wl HW calibration.
8 WL_HW_ERR0	Byte0 WL HW calibration error. This bit is asserted when an error was found on byte0 during wl hw calibration. This bit is valid only upon completion of the wl HW calibration. (hw_wl_en bit is de-asserted) 0 No error was found on byte0 during wl HW calibration. 1 An error was found on byte0 during wl HW calibration.
7 WL_SW_RES3	Byte3 WL software result. This bit reflects the DQ24 value of the SW WL. 0 DQS3 sampled low CK during SW WL. 1 DQS3 sampled high CK during SW WL.
6 WL_SW_RES2	Byte2 WL software result. This bit reflects the DQ16 value of the SW WL. 0 DQS2 sampled low CK during SW WL. 1 DQS2 sampled high CK during SW WL.
5 WL_SW_RES1	Byte1 WL software result. This bit reflects the DQ8 value of the SW WL. 0 DQS1 sampled low CK during SW WL. 1 DQS1 sampled high CK during SW WL.
4 WL_SW_RES0	Byte0 WL software result. This bit reflects the DQ0 value of the SW WL. 0 DQS0 sampled low CK during SW WL. 1 DQS0 sampled high CK during SW WL.
3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2 SW_WL_CNT_EN	SW WL count down enable.This bit when asserted delay the WL DQS by 25+15 cycles.This bit should be asserted before the issue of the first SW WL request after issuing the write leveling MRS command 0 PHY doesn't count 25+15 cycles before issuing WL DQS. 1 PHY counts 25+15 cycles before issuing WL DQS.
1 SW_WL_EN	Enable WL SW update. This bit when asserted causes the PHY to preform WL SW update. HW negate this bit upon completion of the SW WL .Negation of this bit also points that the WL SW calibration result is valid

Table continues on the next page...

ESDCTL_WLGCR field descriptions (continued)

Field	Description
	NOTE: If this bit and the WL_SW_CNT_EN are enabled the PHY counts 25 + 15 cycles before issuing the SW WL dqs.
0 HW_WL_EN	Enable WL HW update. This bit when asserted causes the PHY to preform WL HW update. HW negate this bit upon completion of the WL HW update. Negation of this bit also points that the WL HW calibration result is valid before issuing the first dqs the PHY counts 25 + 15 cycles.

28.121.20 PHY Write Leveling Delay Control Register 0 (ESDCTL_WLDECTRL0)

Address: ESDCTL_WLDECTRL0 is 63FD_9000h base + 4Ch offset = 63FD_904Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0					WL_CYC_DEL1		WL_HC_DEL1	0	WR_DL_ABS_OFFSET1

R	0					WL_CYC_DEL0		WL_HC_DEL0	0	WR_DL_ABS_OFFSET0						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESDCTL_WLDECTRL0 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26–25 WL_CYC_DEL1	Write level cycle delay. This field holds the number of delay cycles to be added for byte1 write-leveling value This delay is added to the delay that is generated by the write leveling delay line 1. 0 No delay is added. 1 1 cycle delay is added. 2 2 cycles delay is added. 3 Reserved.
24 WL_HC_DEL1	Write level half cycle delay. This field holds the number of half delay cycles to be added for byte1 write-leveling value This delay is added to the delay that is generated by the write leveling delay line 1. 0 No delay is added. 1 Half cycle delay is added.

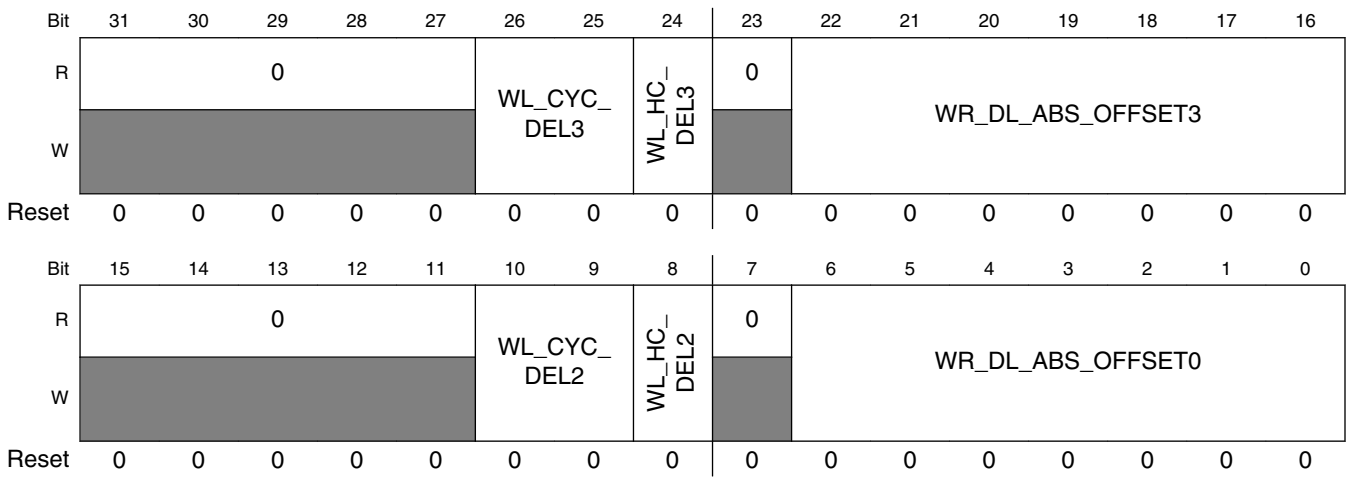
Table continues on the next page...

ESDCTL_WLDECTRL0 field descriptions (continued)

Field	Description
23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22–16 WR_DL_ABS_OFFSET1	Absolute delay offset. This field decides the specific delay line absolute delay in fraction of a cycle terms. The fraction is process and frequency independent.The delay for the delay line would be (WR_DL_ABS_OFFSET1 / 256) * fast_clk. This field can also bit updated by HW. Upon completion of the wl hw calibration this field gets the value of the wl HW calibration result. Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay line resolution (1 delay unit, which varies between 20 pSec in best case to 50 in worst case), then no change will occur.
15–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10–9 WL_CYC_DEL0	Write level cycle delay. This field holds the number of delay cycles to be added for byte0 write-leveling value This delay is added to the delay that is generated by the write leveling delay line 0. 0 No delay is added. 1 1 cycle delay is added. 2 2 cycles delay is added. 3 Reserved.
8 WL_HC_DEL0	Write level half cycle delay. This field holds the number of half delay cycles to be added for byte0 write-leveling value This delay is added to the delay that is generated by the write leveling delay line 0. 0 No delay is added. 1 Half cycle delay is added.
7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6–0 WR_DL_ABS_OFFSET0	Absolute delay offset. This field decides the specific delay line absolute delay in fraction of a cycle terms. The fraction is process and frequency independent.The delay for the delay line would be (WR_DL_ABS_OFFSET0 / 256) * fast_clk. This field can also bit updated by HW. Upon completion of the wl hw calibration this field gets the value of the wl HW calibration result. Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay line resolution (1 delay unit, which varies between 20 pSec in best case to 50 in worst case), then no change will occur.

28.121.21 PHY Write Leveling Delay Control Register 1 (ESDCTL_WLDECTRL1)

Address: ESDCTL_WLDECTRL1 is 63FD_9000h base + 50h offset = 63FD_9050h



ESDCTL_WLDECTRL1 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26–25 WL_CYC_DEL3	Write level cycle delay. This field holds the number of delay cycles to be added for byte3 write-leveling value This delay is added to the delay that is generated by the write leveling delay line 3. 0 No delay is added. 1 1 cycle delay is added. 2 2 cycles delay is added. 3 Reserved.
24 WL_HC_DEL3	Write level half cycle delay. This field holds the number of half delay cycles to be added for byte3 write-leveling value This delay is added to the delay that is generated by the write leveling delay line 3. 0 No delay is added. 1 Half cycle delay is added.
23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22–16 WR_DL_ABS_OFFSET3	Absolute delay offset. This field decides the specific delay line absolute delay in fraction of a cycle terms. The fraction is process and frequency independent.The delay for the delay line would be (WR_DL_ABS_OFFSET3/ 256) * fast_clk. This field can also bit updated by HW. Upon completion of the wl hw calibration this field gets the value of the wl HW calibration result.

ESDCTL_ODTCTRL field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18–16 ODT3_INT_RES	On chip ODT byte3 resistor - This field determines the resistance of the on chip ODT byte3 resistor during read accesses. 000 ODT is Disabled. For the rest of the values, see Table 28-34 .
15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14–12 ODT2_INT_RES	On chip ODT byte2 resistor - This field determines the resistance of the on chip ODT byte2 resistor during read accesses. 000 ODT is Disabled. For the rest of the values, see Table 28-34 .
11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10–8 ODT1_INT_RES	On chip ODT byte1 resistor - This field determines the resistance of the on chip ODT byte1 resistor during read accesses.

Table continues on the next page...

ESDCTL_ODTCTRL field descriptions (continued)

Field	Description
	000 ODT is Disabled. For the rest of the values, see Table 28-34 .
7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6–4 ODT0_INT_RES	On chip ODT byte0 resistor - This field determines the resistance of the on chip ODT byte0 resistor during read accesses. 000 ODT is Disabled. For the rest of the values, see Table 28-34 .
3 ODT_RD_ACT_EN	Active read CS ODT enable. The bit determines if ODT pin of the active CS is areasserted during read accesses. 0 Active CS ODT pin is disabled during read access. 1 Active CS ODT pin is enabled during read access.
2 ODT_RD_PAS_EN	Inactive read CS ODT enable. The bit determines if ODT pin of the inactive CS is asserted during read accesses to other CS. 0 Inactive CS ODT pin is disabled during read accesses to other CS. 1 Inactive CS ODT pin is enabled during read accesses to other CS.
1 ODT_WR_ACT_EN	Active write CS ODT enable. The bit determines if ODT pin of the active CS is asserted during write accesses. 0 Active CS ODT pin is disabled during write access. 1 Active CS ODT pin is enabled during write access.
0 ODT_WR_PAS_EN	Inactive write CS ODT enable. The bit determines if ODT pin of the inactive CS is asserted during write accesses to other CS. 0 Inactive CS ODT pin is disabled during write accesses to other CS. 1 Inactive CS ODT pin is enabled during write accesses to other CS.

28.121.24 PHY Read DQ Byte0 Delay Register (ESDCTL_RDDQBY0DL)

Address: ESDCTL_RDDQBY0DL is 63FD_9000h base + 5Ch offset = 63FD_905Ch

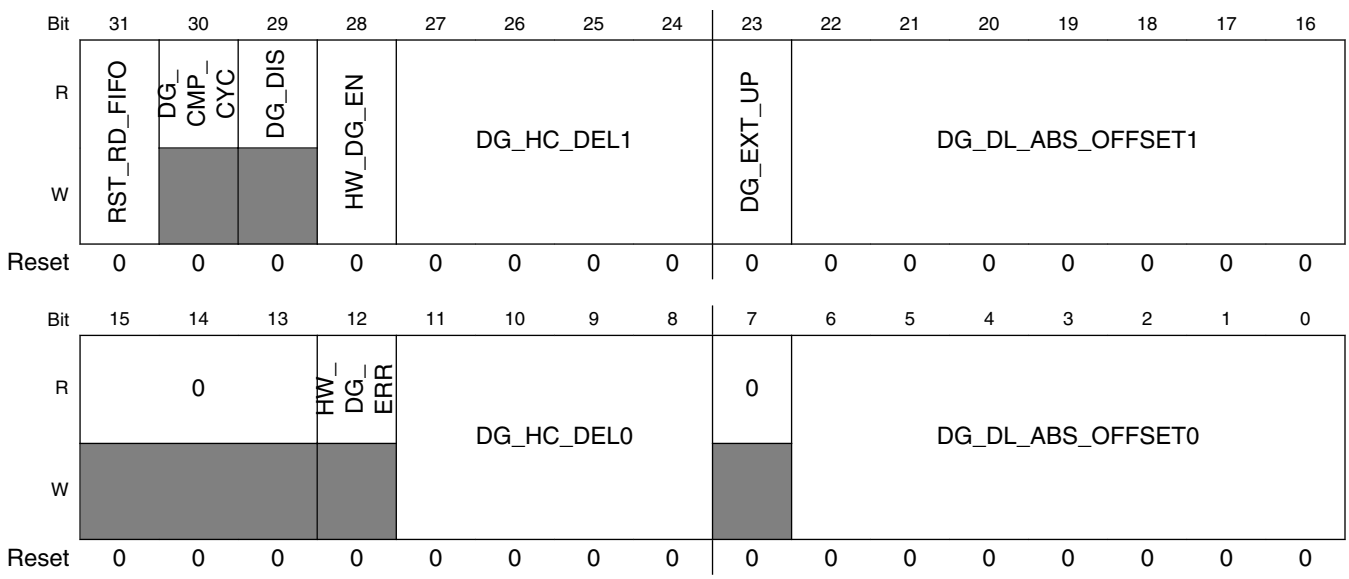
28.121.32 PHY DQS Gating Control Register0 (ESDCTL_DGCTRL0)

Address: ESDCTL_DGCTRL0 is 63FD_9000h base + 7Ch offset = 63FD_907Ch



ESDCTL_DGCTRL0 field descriptions

Field	Description
31 RST_RD_FIFO	Reset Data FIFO & pointers. This bit if asserted causes to DDR PHY reset the data and the pointers of the read data FIFO. This bit is self cleared after the FIFO reset is done.
30 DG_CMP_CYC	DG sample cycle. This bit when asserted causes the PHY to compare the data 32 cycles after the PHY sent the read command enable pulse else it compares the data after 16 cycles.

Table continues on the next page...

ESDCTL_DGCTRL0 field descriptions (continued)

Field	Description
29 DG_DIS	Dqs gating disable. This bit when asserted disable to dqs gating circuit and external dqs is driven directly into phy. This bit can be asserted only when pull down is used in the dqs pads.
28 HW_DG_EN	Enable DG HW update. This bit when asserted causes the PHY to preform DG HW update. HW negates this bit upon completion of the DG HW update. Note: Before issuing the first read command PHY counts 12 cycles.
27–24 DG_HC_DEL1	Dqs1 gating half cycles delay. This field hold the sw delay in half cycles of the dqs1 gating.This delay is added to the delay that is generated by the dqs gating delay line 1. This field can also bit written by HW. Upon completion of the dg hw calibration this field gets the value of the 4 MSB of ((HW_DG_LOW1 + HW_DG_UP1) /2). 0000 0 cycles delay. 0001 Half cycle delay. 0010 1 cycle delay 1101 6.5 cycles delay 1110 Reserved 1111 Reserved
23 DG_EXT_UP	DG extend upper boundary. By default the upper boundary of dqs gating hw calibration is set according to first fail after at least one pass. If this bit is asserted upper boundary is set according to the last pass.
22–16 DG_DL_ABS_ OFFSET1	Absolute delay offset. This field decides the specific delay line absolute delay in fraction of a cycle terms. The fraction is process and frequency independent. The delay for the delay line would be (DG_DL_ABS_OFFSET1 / 256)* fast_clk. This field can also bit written by HW. Upon completion of the dg hw calibration this field gets the value of the 7 LSB of ((HW_DG_LOW1 + HW_DG_UP1) /2). Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay line resolution (1 delay unit, which varies between 20 pSec in best case to 50 in worst case), then no change will occur.
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12 HW_DG_ERR	HW DG error. This bit valid is asserted when an error was found during the DQS HW calibration sequence. Error can occur when no valid value was found during hw calibration. This bit is valid only after HW_DG_EN is de-asserted. 0 No error was found during the DQS gating HW calibration sequence. 1 An error was found during the DQS gating HW calibration sequence.
11–8 DG_HC_DEL0	Dqs0 gating half cycles delay. This field hold the sw delay in half cycles of the dqs0 gating.This delay is added to the delay that is generated by the dqs gating delay line 0. This field can also bit written by HW. Upon completion of the dg hw calibration this field gets the value of the 4 MSB of ((HW_DG_LOW0 + HW_DG_UP0) /2). 0000 0 cycles delay. 0001 Half cycle delay. 0010 1 cycle delay 1101 6.5 cycles delay 1110 Reserved 1111 Reserved

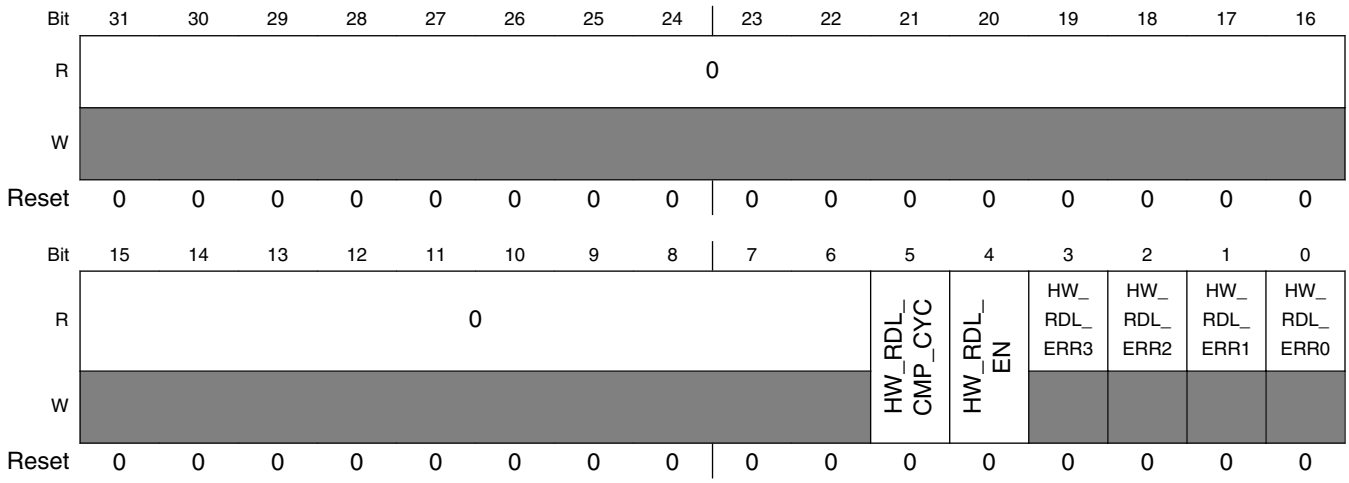
28.121.41 PHY RD DL HW Calibration Control Register (ESDCTL_RDDLHWCTL)

Address: ESDCTL_RDDLHWCTL is 63FD_9000h base + A0h offset = 63FD_90A0h



ESDCTL_RDDLHWCTL field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 HW_RDL_CMP_CYC	HW RD DL sample cycle. This bit when asserted causes the PHY to compare the data 32 cycles after the PHY sent the read command enable pulse else it compares the data after 16 cycles.
4 HW_RDL_EN	Enable HW RD DL calibration. This bit when asserted causes the PHY to preform HW RD DL calibration. HW should negate this bit upon completion of the RD DL HW calibration.Negation of this bit also points that the RD DL HW calibration result is valid **NOTE:** Before issuing the first read command PHY counts 12 cycles.
3 HW_RDL_ERR3	HW RD DL3 error. This bit valid is asserted when an error was found during the HW calibration sequence of read delay line 3. The exact type of error can be found in ESDCTL_RDDLHWST1 register. This bit is valid only after HW_RD_DL_EN is de-asserted. 0 No error was found in read delay line 3 during the HW RD DL calibration sequence of read delay line 3. 1 An error was found in read delay line 3 during the HW RD DL calibration sequence of read delay line 3.
2 HW_RDL_ERR2	HW RD DL2 error. This bit valid is asserted when an error was found during the HW calibration sequence of read delay line 2. The exact type of error can be found in ESDCTL_RDDLHWST1 register. This bit is valid only after HW_RD_DL_EN is de-asserted. 0 No error was found in read delay line 2 during the HW RD DL calibration sequence of read delay line 2. 1 An error was found in read delay line 2 during the HW RD DL calibration sequence of read delay line 2.

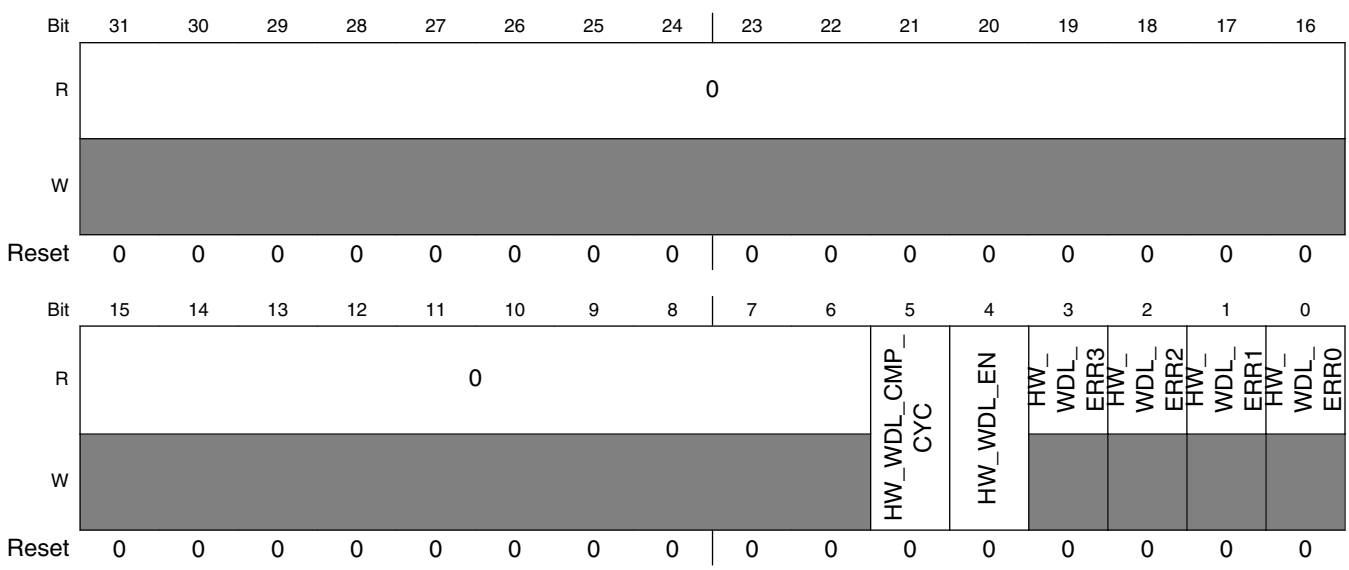
Table continues on the next page...

ESDCTL_RDDLHWCTL field descriptions (continued)

Field	Description
1 HW_RDL_ERR1	HW RD DL1 error. This bit valid is asserted when an error was found during the HW calibration sequence of read delay line 1. The exact type of error can be found in ESDCTL_RDDLHWST0 register. This bit is valid only after HW_RD_DL_EN is de-asserted. 0 No error was found in read delay line 1 during the HW RD DL calibration sequence of read delay line 1. 1 An error was found in read delay line 1 during the HW RD DL calibration sequence of read delay line 1.
0 HW_RDL_ERR0	HW RD DL0 error. This bit valid is asserted when an error was found during the HW calibration sequence of read delay line 0. The exact type of error can be found in ESDCTL_RDDLHWST0 register. This bit is valid only after HW_RD_DL_EN is de-asserted. 0 No error was found in read delay line 0 during the HW RD DL calibration sequence of read delay line 0. 1 An error was found in read delay line 0 during the HW RD DL calibration sequence of read delay line 0.

28.121.42 PHY WR DL HW Calibration Control Register (ESDCTL_WRDLHWCTL)

Address: ESDCTL_WRDLHWCTL is 63FD_9000h base + A4h offset = 63FD_90A4h



ESDCTL_WRDLHWCTL field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

ESDCTL_WRDLHWCTL field descriptions (continued)

Field	Description
5 HW_WDL_ CMP_CYC	WR DL sample cycle. This bit when asserted causes the PHY to compare the data 32 cycles after the PHY sent the read command enable pulse else it compares the data after 16 cycles.
4 HW_WDL_EN	Enable HW WR DL calibration. This bit when asserted causes the PHY to preform HW WR DL calibration. HW should negate this bit upon completion of the WR DL HW calibration.Negation of this bit also points that the WR DL HW calibration result is valid **NOTE:** Before issuing the first read command PHY counts 12 cycles.
3 HW_WDL_ERR3	HW WR DL3 error. This bit valid is asserted when an error was found during the HW calibration sequence of write delay line 3. The exact type of error can be found in HWWDLRES1 register. This bit is valid only after HW_WR_DL_EN is de-asserted. 0 No error was found during the HW calibration sequence of write delay line 3. 1 An error was found during the HW WR DL calibration sequence of write delay line 3.
2 HW_WDL_ERR2	HW WR DL2 error. This bit valid is asserted when an error was found during the HW calibration sequence of write delay line 3. The exact type of error can be found in HWWDLRES1 register. This bit is valid only after HW_WR_DL_EN is de-asserted. 0 No error was found during the HW calibration sequence of write delay line 2. 1 An error was found during the HW WR DL calibration sequence of write delay line 2.
1 HW_WDL_ERR1	HW WR DL1 error. This bit valid is asserted when an error was found during the HW calibration sequence of write delay line 1. The exact type of error can be found in HWWDLRES0 register. This bit is valid only after HW_WR_DL_EN is de-asserted. 0 No error was found during the HW calibration sequence of write delay line 1. 1 An error was found during the HW WR DL calibration sequence of write delay line 1.
0 HW_WDL_ERR0	HW WR DL0 error. This bit valid is asserted when an error was found during the HW calibration sequence of write delay line 0. The exact type of error can be found in HWWDLRES0 register. This bit is valid only after HW_WR_DL_EN is de-asserted. 0 No error was found during the HW calibration sequence of write delay line 0. 1 An error was found during the HW WR DL calibration sequence of write delay line 0.

28.121.43 PHY RD DL HW Calibration Status Register 0 (ESDCTL_RDDLHWST0)

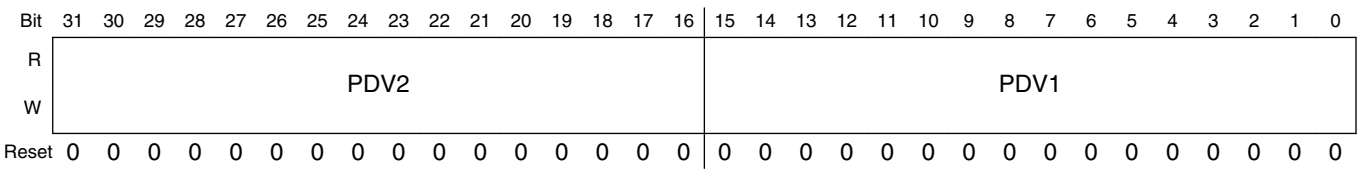
ESDCTL_DGHWST3 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26–16 HW_DG_UP3	HW DG3 upper boundary. This field holds the upper boundary of DG3 calibration sequence. The actual delay in cycles is HW_DG_UP3/256.
15–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10–0 HW_DG_LOW3	HW DG3 lower boundary. This field holds the lower boundary of DG3 calibration sequence. The actual delay in cycles is HW_DG_LOW3/256.

28.121.52 PHY Pre-defined Compare Register 1 (ESDCTL_PDCMPR1)

This set of two registers (ESDCTL_PDCMPR1 & ESDCTL_PDCMPR2) controls the pre-defined compare value.The compare value can be the MPR value (as defined in the ddr3 jedec) or can be programmed by the PDV1 & PDV2 fields.

Address: ESDCTL_PDCMPR1 is 63FD_9000h base + CCh offset = 63FD_90CCh

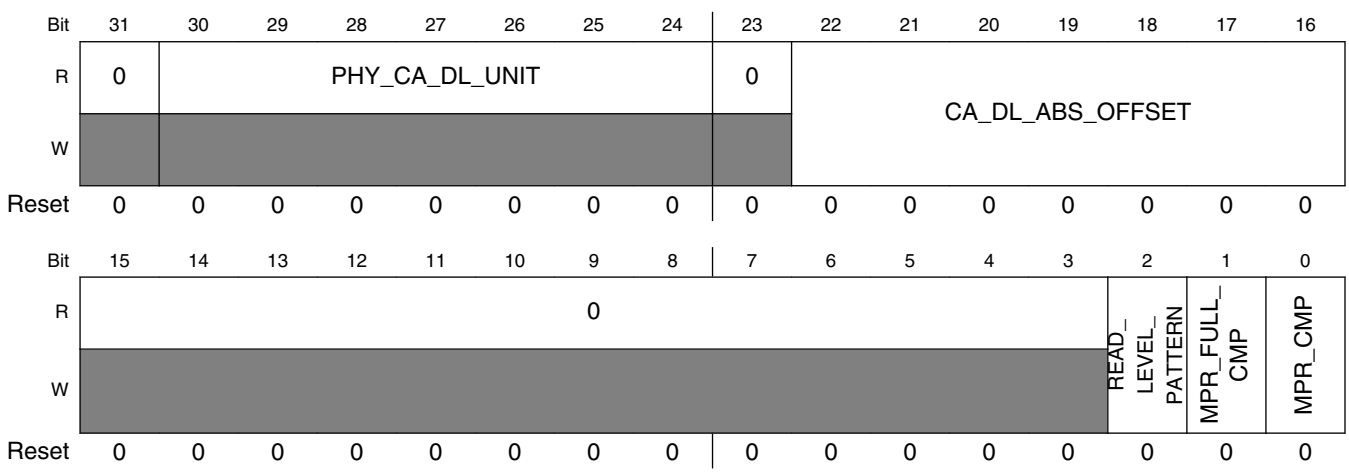


ESDCTL_PDCMPR1 field descriptions

Field	Description
31–16 PDV2	Pre defined compare value2. This field holds data to be compared to the data coming from the ddr device (every second access) during hw write delay line calibration (if MPR_CMP is disabled). Note: The inverted value of this field is used as the reset value for the read fifo when this value is used for comparison
15–0 PDV1	Pre defined compare value1. This field holds that data to be compared to the data coming from the ddr device in all cases except from the one which uses PDV2 (if MPR_CMP is disabled). Note: The inverted value of this field is used as the reset value for the read fifo when this value is used for comparison

28.121.53 PHY Pre-defined Compare Register 2 (ESDCTL_PDCMPR2)

Address: ESDCTL_PDCMPR2 is 63FD_9000h base + D0h offset = 63FD_90D0h

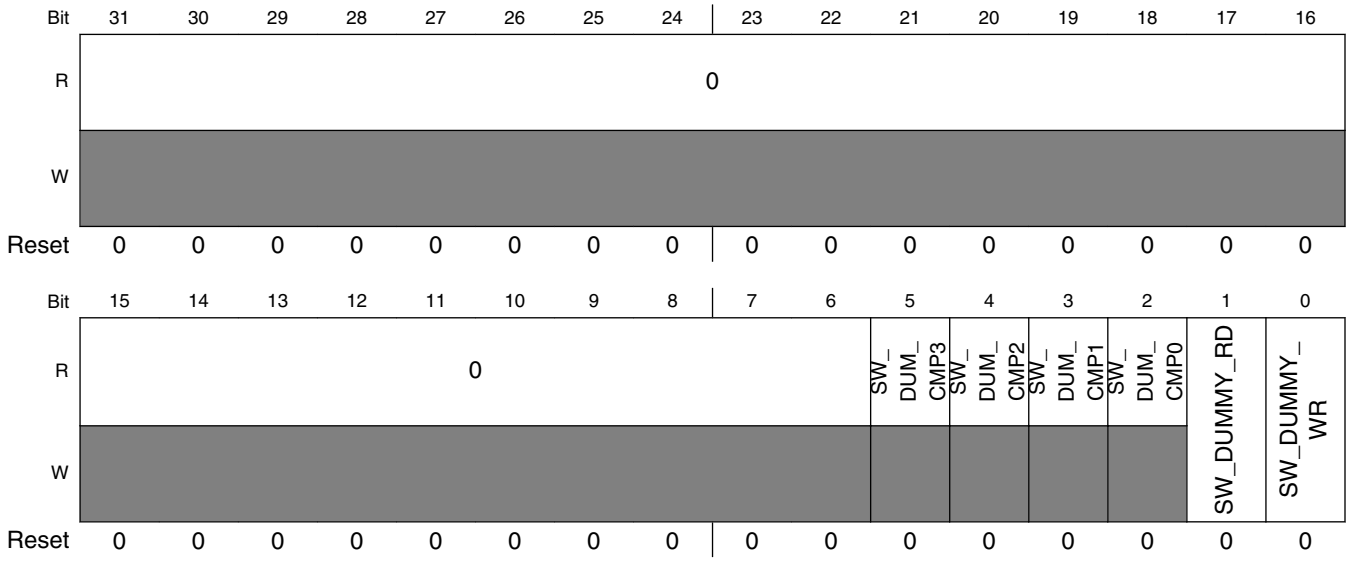


ESDCTL_PDCMPR2 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value zero. Reserved
30–24 PHY_CA_DL_UNIT	This field shows the number of delay units that is actually used by phy CA delay unit
23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22–16 CA_DL_ABS_OFFSET	Absolute delay offset. This field decides the specific delay line absolute delay in fraction of a cycle terms. The fraction is process and frequency independent.The delay for the delay line would be (CA_DL_ABS_OFFSET/ 256) * fast_clk.
15–3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2 READ_LEVEL_PATTERN	in LPDDR2 MPR command is done through MRR command. And there are 2 patterns. Phy will send controller the configured pattern by signal: "read_level_pattern" 0 pattern 1010 1 pattern 0011
1 MPR_FULL_CMP	MPR full compare enable.This bit when asserted (and when MPR_CMP is asserted) causes all hw calibration & sw dummy processes to compare all bit of the data read from the ddr device to the MPR pre-defined value. When this bit is de-asserted only LSB of each byte is compared.
0 MPR_CMP	MPR compare enable. This bit when asserted causes all hw calibration & sw dummy processes to compare the data read from the ddr device to the MPR pre-defined value. When this bit is disabled data is compared to the data of the pre defined compare value field Note: In case of LPDDR2 this bit is used as MRR enable and when asserted causes all hw calibration & sw dummy processes to compare the data read from the ddr device to the MRR pre-defined value, the Pattern type is selected according to READ_LEVEL_PATTERN bit.

28.121.54 PHY SW Dummy Access Register (ESDCTL_SWDAR)

Address: ESDCTL_SWDAR is 63FD_9000h base + D4h offset = 63FD_90D4h



ESDCTL_SWDAR field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 SW_DUM_CMP3	SW dummy read byte3 compare results. This bit reflects the outcome of the dummy read.This bit is valid only after SW_DUMMY_RD is de-asserted. 0 Dummy read fail 1 Dummy read pass
4 SW_DUM_CMP2	SW dummy read byte2 compare results. This bit reflects the outcome of the dummy read.This bit is valid only after SW_DUMMY_RD is de-asserted. 0 Dummy read fail 1 Dummy read pass
3 SW_DUM_CMP1	SW dummy read byte1 compare results. This bit reflects the outcome of the dummy read.This bit is valid only after SW_DUMMY_RD is de-asserted. 0 Dummy read fail 1 Dummy read pass
2 SW_DUM_CMP0	SW dummy read byte0 compare results. This bit reflects the outcome of the dummy read.This bit is valid only after SW_DUMMY_RD is de-asserted. 0 Dummy read fail 1 Dummy read pass
1 SW_DUMMY_RD	SW dummy read. This bit when asserted generate a dummy read sequence. In this succulence there is no axi read access instead data is read from memory and compared to the PDCMPR or MPR default value.Upon completion of the access this bit is de-asserted and the data & compare results are valid.

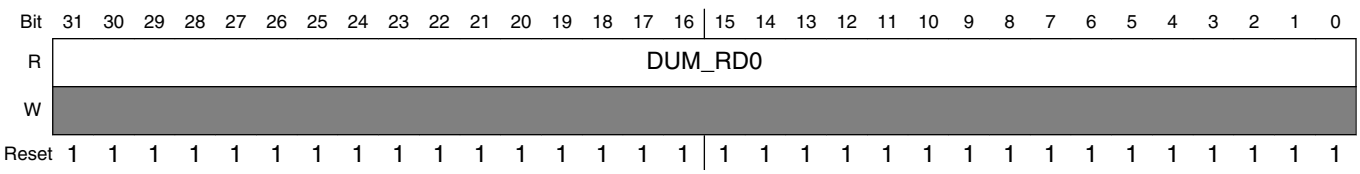
Table continues on the next page...

ESDCTL_SWDAR field descriptions (continued)

Field	Description
0 SW_DUMMY_WR	SW dummy write. This bit when asserted generate a dummy write sequence. In this seqeunce there is no axi write access instead data is written from PDCMPR. The bit is de-asserted upon completion of the access.

28.121.55 PHY SW Dummy Read Data Register n (ESDCTL_SWDRDR*n*)

Addresses: ESDCTL_SWDRDR0 is 63FD_9000h base + D8h offset = 63FD_90D8h
ESDCTL_SWDRDR1 is 63FD_9000h base + DCh offset = 63FD_90DCh
ESDCTL_SWDRDR2 is 63FD_9000h base + E0h offset = 63FD_90E0h
ESDCTL_SWDRDR3 is 63FD_9000h base + E4h offset = 63FD_90E4h
ESDCTL_SWDRDR4 is 63FD_9000h base + E8h offset = 63FD_90E8h
ESDCTL_SWDRDR5 is 63FD_9000h base + ECh offset = 63FD_90ECh
ESDCTL_SWDRDR6 is 63FD_9000h base + F0h offset = 63FD_90F0h
ESDCTL_SWDRDR7 is 63FD_9000h base + F4h offset = 63FD_90F4h

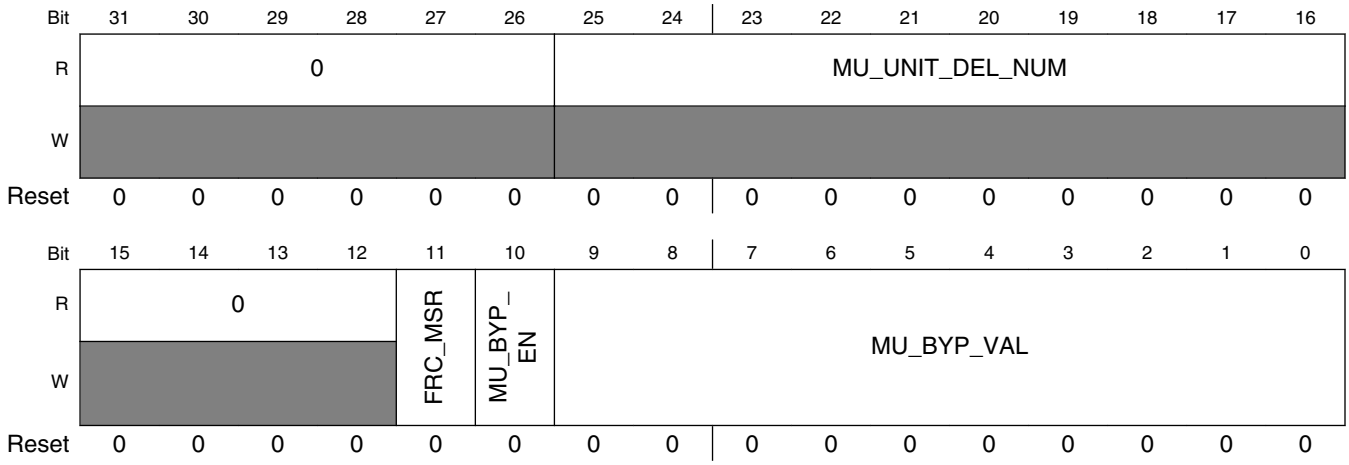


ESDCTL_SWDRDR*n* field descriptions

Field	Description
31–0 DUM_RD0	Dummy read data n. This field holds the nth data read from memory during sw dummy read access.

28.121.56 PHY Measure Unit Register (ESDCTL_MUR)

Address: ESDCTL_MUR is 63FD_9000h base + F8h offset = 63FD_90F8h

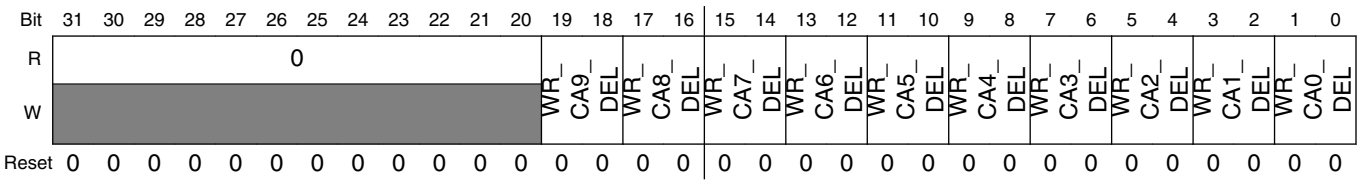


ESDCTL_MUR field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value zero. Reserved
25–16 MU_UNIT_DEL_NUM	Measure unit measured number of unit delay per cycle. This field holds the number of unit delays per cycle measure by the measure unit.
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11 FRC_MSR	Force measurement on delay line.Writing '1' to this bit asserts the measure signal to the delay line and measure unit. Upon completion of the measurement the measure unit & delay line return to functional more.This bit is self cleared. Note: • User should make sure that there is no active accesses to/from DDR before asserting this bit. • This bit is used only for DDR2 / DDR3 (i.e DDR_TYPE = 0x0 or 0x2). In case of LPDDR2 (i.e DDR_TYPE= 0x1) this bit should not be asserted 0 Not forcing delay line to make measurement. 1 Delay line is forced to measure.This bit is cleared upon completion of the measurement process.
10 MU_BYP_EN	Measure unit bypass enable. Selects the num of unit delay per cycle between measure unit measured value and programmable value (MU_BYPASS_VAL). 0 The measured number of delay units is used by the delay lines. 1 MU_BYPASS_VAL value is used by the delay lines.
9–0 MU_BYP_VAL	This field is the measure unit bypass value. The bypass value is used only if MU_BYPASS_EN is set. The bypass value is holds the number of unit delay per cycle.

28.121.57 Write CA Delay Line controller (ESDCTL_WRCADL)

Address: ESDCTL_WRCADL is 63FD_9000h base + FCh offset = 63FD_90FCh



ESDCTL_WRCADL field descriptions

Field	Description
31–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19–18 WR_CA9_DEL	ca9 delay fine tuning.This field holds the del. value that is added to ca9 relative to ca selector delay line. 00 No change in ca9 delay 01 Add ca9 delay of 1 delay units. 10 Add ca9 delay of 2 delay units. 11 Add ca9 delay of 3 delay units
17–16 WR_CA8_DEL	ca8 delay fine tuning.This field holds the del. value that is added to ca8 relative to ca selector delay line. 00 No change in ca8 delay 01 Add ca8 delay of 1 delay units. 10 Add ca8 delay of 2 delay units. 11 Add ca8 delay of 3 delay units
15–14 WR_CA7_DEL	ca7 delay fine tuning.This field holds the del. value that is added to ca7 relative to ca selector delay line. 00 No change in ca7 delay 01 Add ca7 delay of 1 delay units. 10 Add ca7 delay of 2 delay units. 11 Add ca7 delay of 3 delay units
13–12 WR_CA6_DEL	ca6 delay fine tuning.This field holds the del. value that is added to ca6 relative to ca selector delay line. 00 No change in ca6 delay 01 Add ca6 delay of 1 delay units. 10 Add ca6 delay of 2 delay units. 11 Add ca6 delay of 3 delay units
11–10 WR_CA5_DEL	ca0 delay fine tuning.This field holds the del. value that is added to ca5 relative to ca selector delay line. 00 No change in ca5 delay 01 Add ca5 delay of 1 delay units. 10 Add ca5 delay of 2 delay units. 11 Add ca5 delay of 3 delay units
9–8 WR_CA4_DEL	ca4 delay fine tuning.This field holds the del. value that is added to ca4 relative to ca selector delay line. 00 No change in ca4 delay

Table continues on the next page...

ESDCTL_WRCADL field descriptions (continued)

Field	Description
	01 Add ca4 delay of 1 delay units. 10 Add ca4 delay of 2 delay units. 11 Add ca4 delay of 3 delay units
7–6 WR_CA3_DEL	ca3 delay fine tuning.This field holds the del. value that is added to ca3 relative to ca selector delay line. 00 No change in ca3 delay 01 Add ca3 delay of 1 delay units. 10 Add ca3 delay of 2 delay units. 11 Add ca3 delay of 3 delay units
5–4 WR_CA2_DEL	ca2 delay fine tuning.This field holds the del. value that is added to ca2 relative to ca selector delay line. 00 No change in ca2 delay 01 Add ca2 delay of 1 delay units. 10 Add ca2 delay of 2 delay units. 11 Add ca2 delay of 3 delay units
3–2 WR_CA1_DEL	ca1 delay fine tuning.This field holds the del. value that is added to ca1 relative to ca selector delay line. 00 No change in ca1 delay 01 Add ca1 delay of 1 delay units. 10 Add ca1 delay of 2 delay units. 11 Add ca1 delay of 3 delay units
1–0 WR_CA0_DEL	ca0 delay fine tuning.This field holds the del. value that is added to ca0 relative to ca selector delay line. 00 No change in ca0 delay 01 Add ca0 delay of 1 delay units. 10 Add ca0 delay of 2 delay units. 11 Add ca0 delay of 3 delay units

Chapter 29
Enhanced Secured Digital Host Controller (eSDHCv2)

29.1 Overview

The Enhanced Secured Digital Host Controller Version 2 (ESDHCv2, referred to as ESDHC hereafter) provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in Figure 29-1. The ESDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards. It handles the SD/SDIO/MMC protocols at the transmission level.

Two versions of the ESDHC block are utilized in the i.MX53 SoC: Version 2 and Version 3 (ESDHCV2 and ESDHCV3). There are three instances of the block ESDHCV2, and one instance of the block ESDHCV3. The text will use the designation ESDHC when referring to features that are common to both.

The types of cards supported by the ESDHC are described briefly as follows:

The Multi Media Card (MMC) is a universal low cost data storage and communication media that is designed to cover a wide area of applications including mobile video and gaming. Old MMC cards are based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into Memory card, I/O card and Combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O

card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, Figure 29-1 does not show cards with reduced size or mini cards.

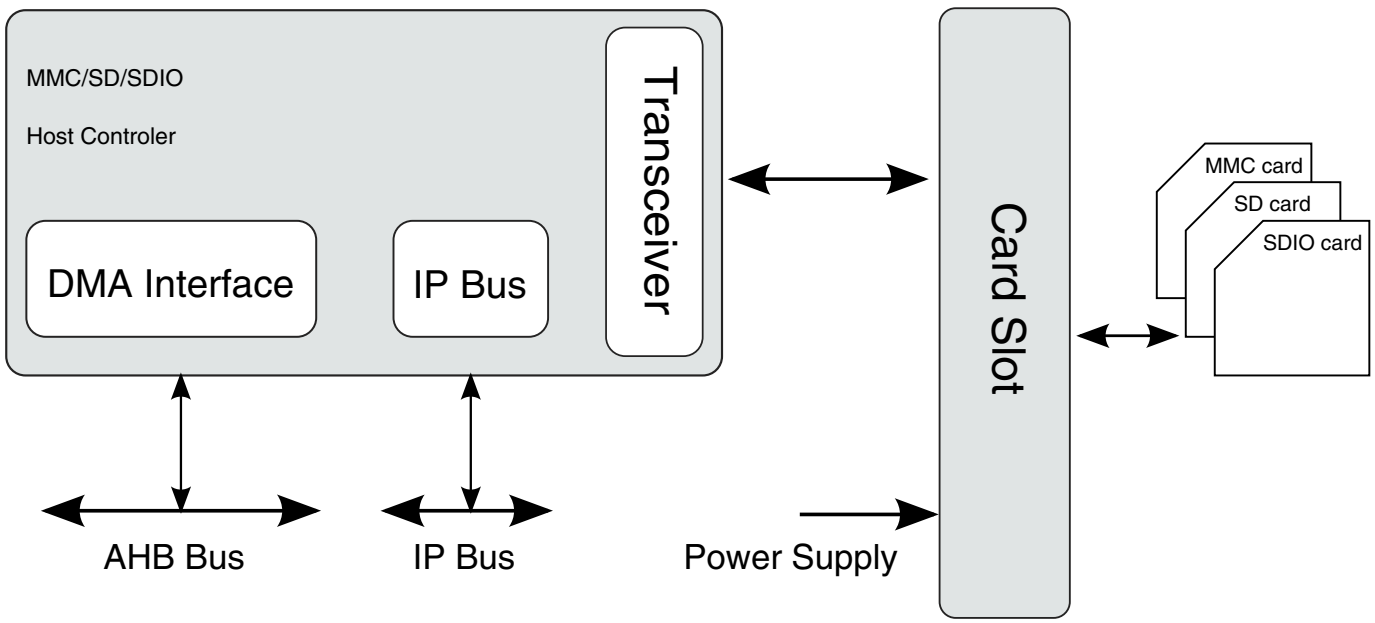


Figure 29-1. System Connection of the ESDHC

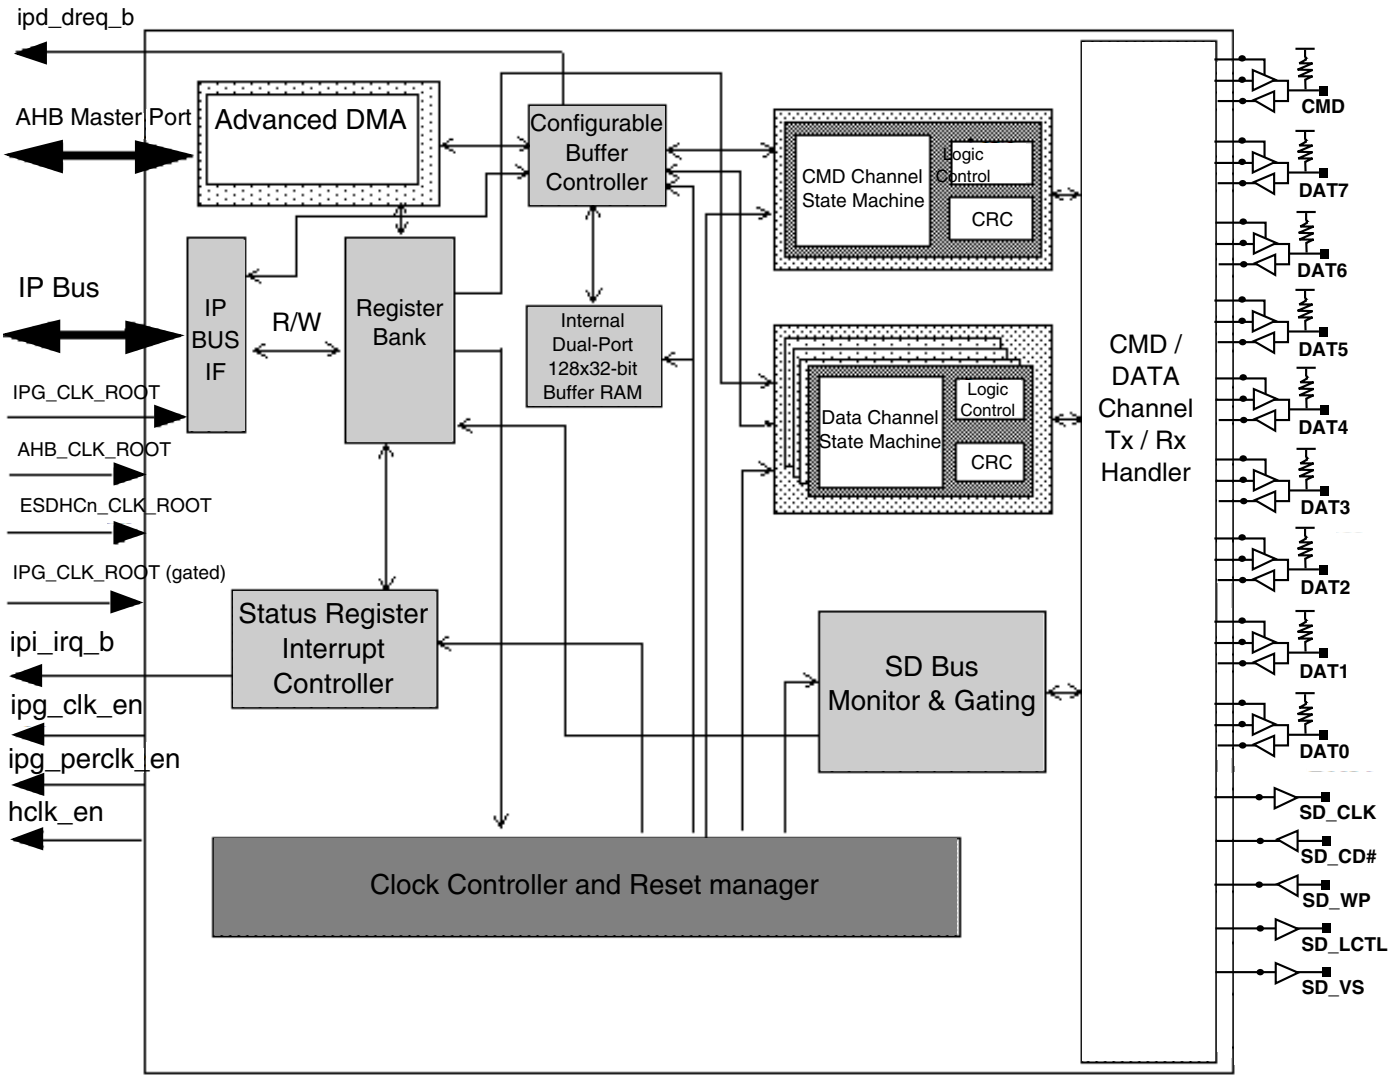

Figure 29-2. enhanced Secure Digital Host Controller Block Diagram

29.1.1 Features

The features of the ESDHC include the following:

- Conforms to the SD Host Controller Standard Specification version 2.0 including Test Event register support
- Compatible with the MMC System Specification version 4.2/4.3
- Compatible with the SD Memory Card Specification version 2.0 and supports the High Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards

- Card bus clock frequency up to 52 MHz
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes devices
  - Up to 200 Mbps of data transfer for SD/SDIO cards using 4 parallel data lines
  - Up to 416 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR (Single Data Rate) mode
- Supports Single Block, Multi Block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal and external DMA capabilities
- Supports Advanced DMA to perform linked memory access

29.1.2 Modes and Operations

29.1.2.1 Data transfer Modes

The ESDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification Mode (up to 400 kHz)
- MMC full speed mode (up to 20 MHz)
- MMC high speed mode (up to 52 MHz)
- SD/SDIO full speed mode (up to 25 MHz)
- SD/SDIO high speed mode (up to 50 MHz)

29.2 External Signals

29.2.1 Signals Overview

The ESDHC has 15 associate I/O signals.

- The SD_CLK is an internally generated clock used to drive the MMC, SD, SDIO cards.
- The CMD I/O is used to send commands and receive responses to/from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the ESDHC and the card.
- The SD_CD# and SD_WP are card detection and write protection signals directly routed from the socket. A low on SD_CD# means that a card is inserted and a high on SD_WP means that the write protect switch is active.
- SD_OD is an output signal generated in SoC level outside ESDHC and is used to select the external open drain resistor.
- SD_LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.

SD_CD#, SD_WP, SD_OD, SD_LCTL are all optional for system implementation. If the ESDHC is desired to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.

29.2.2 Ports Table

See Table 29-1 for the signal properties of the I/Os.

Table 29-1. Properties of I/O Signals

Name	Port	Function	Reset State	Pull up
SD_CLK	O	Clock for MMC/SD/SDIO card	0	N/A
SD_CMD	I/O	CMD line connect to card	1	Pull up
SD_DAT7	I/O	DAT7 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT6	I/O	DAT6 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT5	I/O	DAT5 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT4	I/O	DAT4 line in 8-bit mode Not used in other modes	1	Pull up

Table continues on the next page...

Table 29-1. Properties of I/O Signals (continued)

Name	Port	Function	Reset State	Pull up
SD_DAT3	I/O	DAT3 line in 4/8-bit mode or configured as card detection pin May be configured as card detection pin in 1-bit mode	0	Should be pull-up/pull-down configurable as this port may be used for card detection
SD_DAT2	I/O	DAT2 line or Read Wait in 4-bit mode Read Wait in 1-bit mode	1	Pull up
SD_DAT1	I/O	DAT1 line in 4/8-bit mode Also used to detect interrupt in 1/4-bit mode	1	Pull up
SD_DAT0	I/O	DAT0 line in all modes Also used to detect busy state	1	Pull up
SD_CD#	I	Card detection pin If not used tie high	N/A	N/A
SD_WP	I	Card write protect detect If not used tie low	N/A	N/A
SD_OD	O	Open drain select (not generated within the ESDHC). Optional output	N/A	N/A
SD_LCTL	O	LED control used to drive an external LED Active high Fully controlled by the driver Optional output	0	N/A

29.3 Functional Description

The following sections provide a brief functional description of the major system blocks, including the Data Buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock & reset manager and clock generator.

29.3.1 Data Buffer

The ESDHC uses one configurable data buffer, so that data can be transferred between the system bus (IP Bus or AHB Bus) and the SD card, with an optimized manner to maximize throughput between the two clock domains (that is, the IP peripheral clock, and the master clock). See the table below for illustration of the buffer scheme. The buffer is used as temporary storage for data being transferred between the host system and the

card. The watermark levels for read and write are both configurable, and can be any number from 1 to 128 words. The burst lengths for read and write are also configurable, and can be any number from 1 to 31 words.

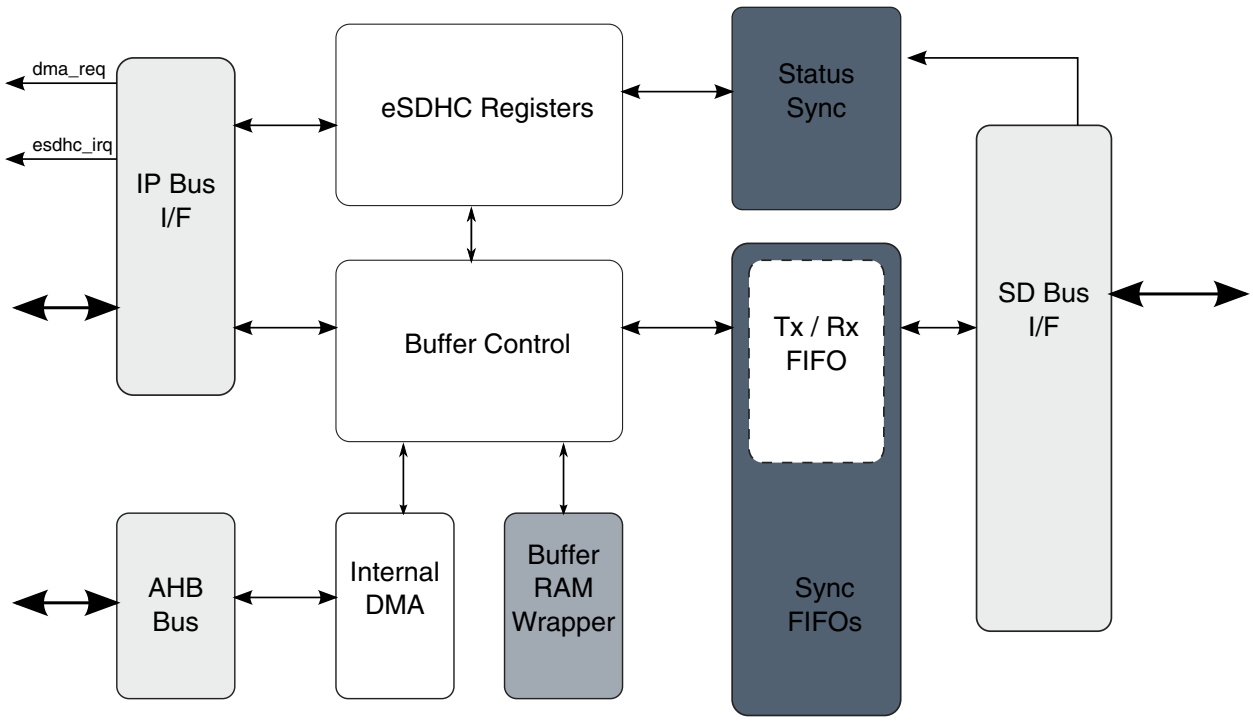

Figure 29-3. ESDHC Buffer Scheme

There are 3 transfer modes to access the data buffer:

- ARM platform polling mode:
  - For a host read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, then by polling the BRR bit the Host Driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar.
- External DMA mode:
  - For a read operation, when there are more words received in the buffer than the amount set in the RD_WML register, a DMA request is sent out to inform the external DMA to fetch the data. The request will be immediately de-asserted when there is an access on the Buffer Data Port register. If the number of words in the buffer after the current burst meets or exceeds RD_WML value, then the DMA request is asserted again. For instance, if there are twice as many words in the buffer than the RD_WML value, there are two successive DMA requests with only one cycle of de-assertion between. The write operation is similar.

NOTE

Data buffer accesses by the ARM platform polling mode and external DMA mode both use the IP Bus. In these mode, if the external DMA is enabled, an external DMA request is sent out every time the buffer is ready.

- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus. For internal DMA access mode, the external DMA request will never be sent out.

    For a read operation, when there are more words in the buffer than the amount set in the RD_WML register, the internal DMA starts fetching data over the AHB bus. Except INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

1. Burst length configured in the burst length field of the Watermark Level register
2. Watermark Level boundary
3. Block size boundary
4. Data boundary configured in the current descriptor (if the ADMA is active)
5. 1 Kbyte address boundary defined in the AHB protocol

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actually byte order is swapped inside the buffer, according to the endian mode configured by software. See Figure 29-4 and Figure 29-5. For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, byte order is swapped before the data is stored into the buffer.

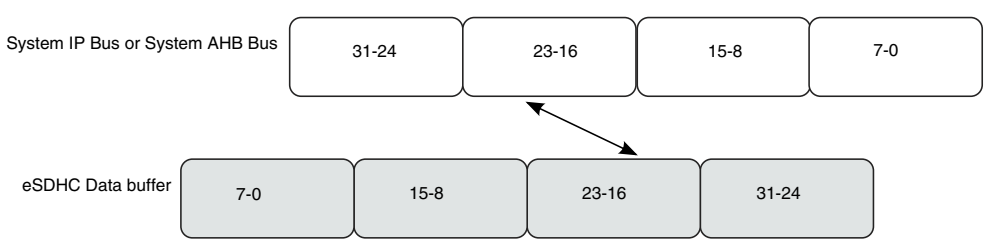

Figure 29-4. Data Swap between System Bus and ESDHC Data Buffer in Byte Little Endian Mode

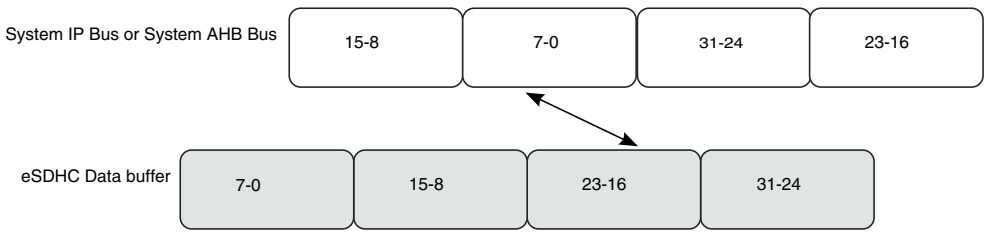

Figure 29-5. Data Swap between System Bus and ESDHC Data Buffer in Half Word Big Endian Mode

29.3.1.1 Write Operation Sequence

There are three ways to write data into the buffer when the user transfers data to the card:

1. By using external DMA through the ESDHC DMA request signal.
2. By processor core polling through the BWR bit in Interrupt Status register (interrupt or polling).
3. By using the internal DMA.

When the internal DMA is not used, (i.e. the DMAEN bit in the Transfer Type register is not set when the command is sent), the ESDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR_WML register, and is ready for receiving new data. At the same time, the ESDHC would set the BWR bit. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the ESDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the ESDHC will abort the data transfer and abandon the current block. The Host Driver should read the contents of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi block mode, the ESDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver shall send CMD12 in this scenario and re-start the write operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started after error recovery.

The ESDHC will not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the Host System does not write data in time, the ESDHC will stop the SD_CLK to avoid the data buffer under-run situation.

29.3.1.2 Read Operation Sequence

There are three ways to read data from the buffer when the user transfers data from the card:

1. By using the external DMA through the ESDHC DMA request signal
2. By processor core polling through the BRR bit in Interrupt Status register (interrupt or polling)
3. By using the internal DMA

When internal DMA is not used (i.e. DMAEN bit in Transfer Type register is not set when the command is sent), the ESDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register (that is, available and ready for system fetching data). At the same time, the ESDHC would set the BRR bit. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the ESDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the ESDHC will abort the data transfer and abandon the current block. The Host Driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi block mode, the ESDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver shall send CMD12 in this scenario and re-start the read operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started after error recovery.

For any read transfer mode, the ESDHC will not start data transmission until the number of words set in the RD_WML register are in the buffer. If the buffer is full and the Host System does not read data in time, the ESDHC will stop the SD_CLK to avoid the data buffer over-run situation.

29.3.1.3 Data Buffer and Block Size

The user needs to know the buffer size, for the buffer operation during a data transfer, to utilize it in the most optimized way. In the ESDHC, the only data buffer can hold up to 128 words (32-bit), and the watermark levels for write and read can be configured respectively. For both read and write, the watermark level can be from 1 word to the maximum of 128 words. For both read and write, the burst length, can be from 1 word to the maximum of 31 words. The Host Driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length may be set to any value between 1 and 4096 bytes inclusive which satisfies the requirements of the external card. The only restriction is from the external card. It might not support that large of a block or it does not support a partial block access (which is not the integer times of 512 bytes).

For block size not times of 4, that is, not word aligned, ESDHC requires stuff bytes at the end of each block, because ESDHC treats each block individually. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write two times for each block. For each block, the ending byte will be abandoned by ESDHC because it only sends 7 bytes to the card and picks data from the following system write, making a total of 24 beats of write access.

29.3.1.4 Dividing Large Data Transfer

This SDIO command CMD53 definition, limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the Host Driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See figure below for an example showing the dividing of large data transfers. Assuming a kind of WLAN SDIO card only supports block size up to 64 bytes. Although the ESDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than64 bytes, so the data must be divided (see example below).

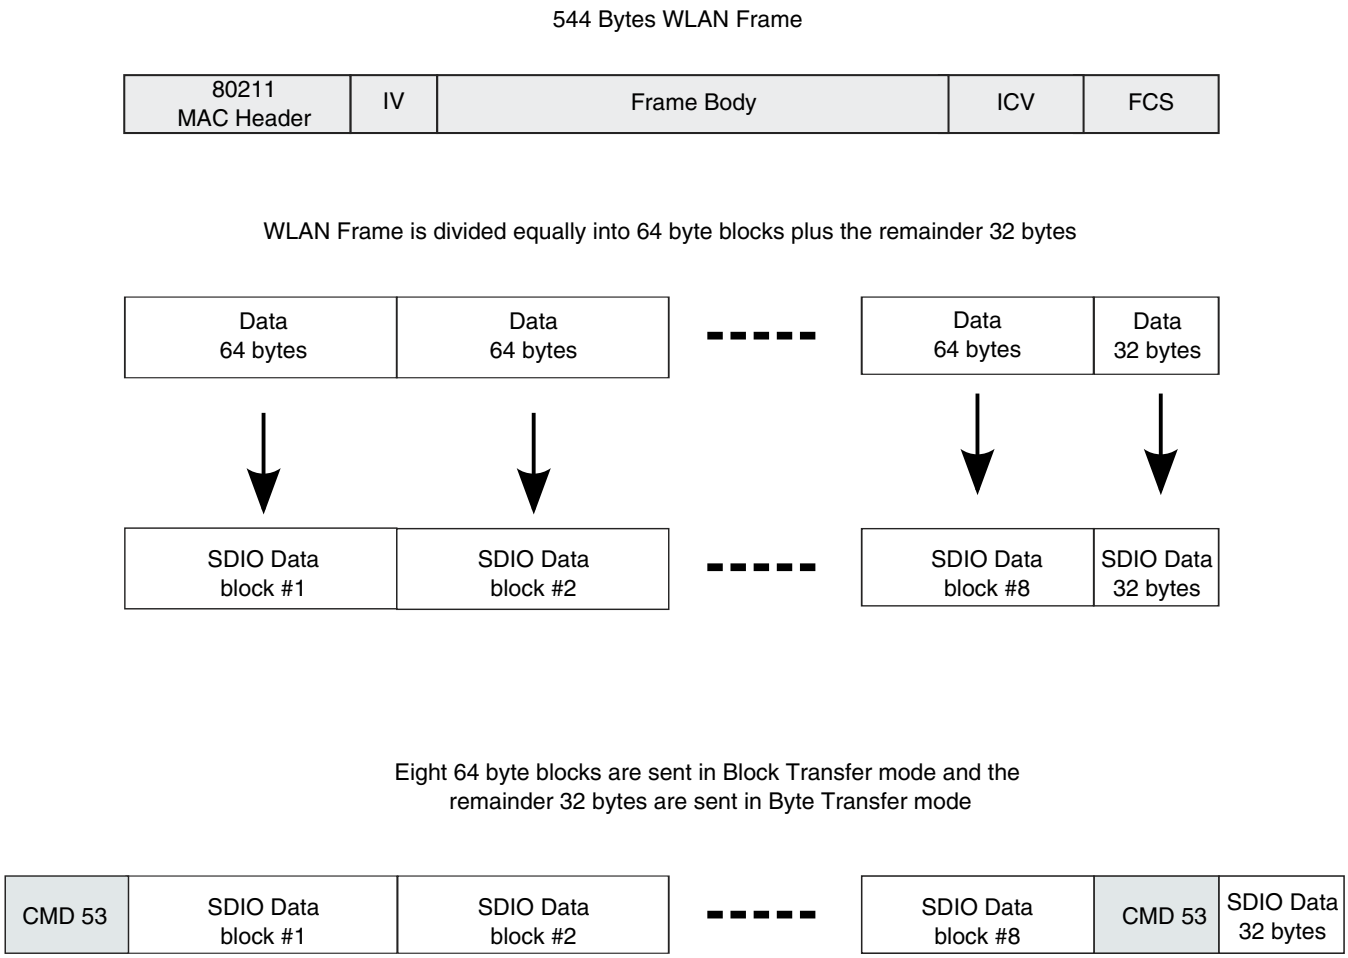

Figure 29-6. Example for Dividing Large Data Transfers

29.3.1.5 External DMA Request

When the internal DMA is not in use, and external DMA request is enabled, the Data Buffer will generate a DMA request to the system. During a write operation, when the number of WR_WML words can be held in the buffer free space, the signal esdhc_dreq_b is asserted to 0, informing the Host System of a DMA write. The BWR bit in the Interrupt Status register is also set, as long as the BWRSEN bit in the Interrupt Status Enable register is set. The DMA request is immediately de-asserted when an access to the Data Port register is made. If the buffer's free space still meets the watermark condition, the DMA request is asserted again after a cycle.

On read operation, when the number of RD_WML words are already in the buffer, the signal esdhc_dreq_b is asserted to 0, informing the Host System for a DMA read. The BRR bit in the Interrupt Status register is also set, as long as the BRRSEN bit in the

Interrupt Status Enable register is set. The DMA request is immediately de-asserted when an access to the Data Port register is made. If the buffer's data still meets the watermark condition, the DMA request is asserted again after a cycle.

Because the DMA burst length can not change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring of the block may cause buffer under-run (read operation) or over-run (write operation). For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of two between 1 and 128. For processor core polling access, as the last access in the block transfer can be controlled by software, there is no such issue. The watermark level can be any value, even larger than the block size (but no greater than 128 words). This is because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The ESDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level should be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of word. For this case, the BLKSIZE bits of the Block Attribute register shall be set as 1fh. For the ARM platform polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the ESDHC will also set the BWR or BRR bits when the remaining data does not violate data buffer. Refer to DMA Burst Length for more details about the dynamic watermark level of the data buffer. For the above example, even though 8 words are transferred through the Data Port register, the ESDHC will transfer only 31 bytes over the SD Bus, as required by the BLKSIZE bits. In this data transfer, with non-word aligned block size, the endian mode should be set cautiously, or invalid data will be transferred to/from the card.

29.3.2 DMA AHB Interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the esdhc_dreq_b will not be asserted during the transfer, but the BWR and BRR bits will be set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register. See the figure below for an illustration of the DMA AHB interface block.

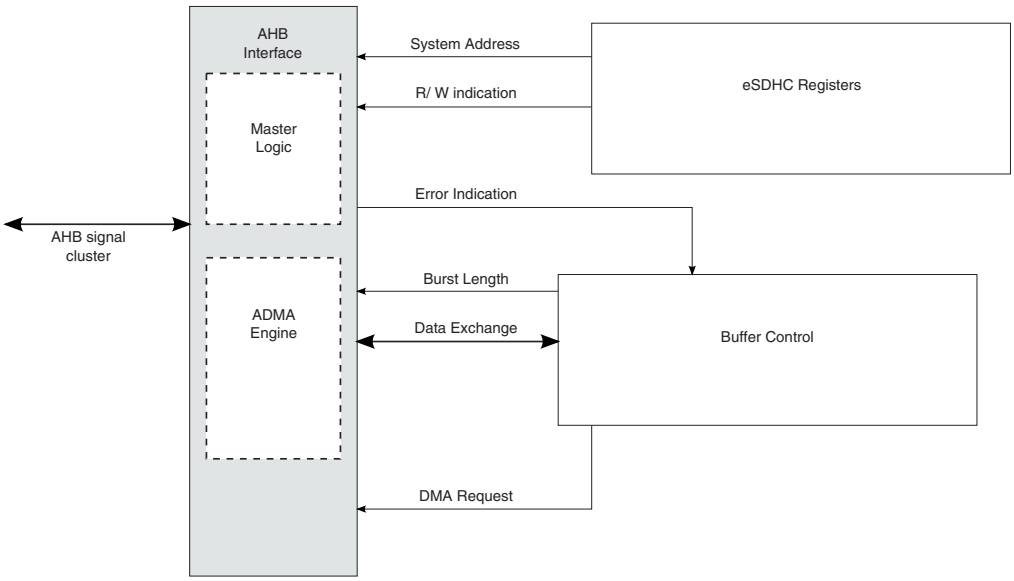

Figure 29-7. DMA AHB Interface Block

29.3.2.1 Internal DMA Request

If the watermark level requirement is met in data transfer, and the Internal DMA is enabled, the Data Buffer block will send a DMA request to AHB interface. Meanwhile, the external DMA request signal (esdhc_dreq_b) is disabled. The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to the ESDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The Data Buffer de-asserts the request once an access to the buffer is made. Upon access to the buffer by internal DMA, the Data Buffer updates its internal buffer pointer, and when the watermark level is satisfied, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer (which might contain some data of the next block), another DMA request read is sent. This is because the remaining number of words to send for the current block is (31 - 6 * 4) / 4 = 2. The ESDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuff byte.

29.3.2.2 DMA Burst Length

Just like a ARM platform polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block. Take the example in Internal DMA Request again. The following burst length after 6 words are read will be 2 words, and the next burst length will be 6 words again. This is because the next block starts, which is 31 bytes, more than 6 words. The Host Driver writer may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

29.3.2.3 AHB Master Interface

It is possible that the internal AHB DMA engine could fail during the data transfer. When this error occurs, the DMA engine stops the transfer and goes to the idle state as well as the internal data buffer stops accepting incoming data. The DMAE bit in the Interrupt Status register is set to inform the driver.

Once the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and re-start the transfer from this address to recover the corrupted block.

29.3.2.4 ADMA Engine

In the SD Host Controller Standard, the new DMA transfer algorithm called the ADMA (Advanced DMA) is defined. For Simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the Host Driver. The ADMA defines the programmable descriptor table in the system memory. The Host Driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized since the Host MCU intervention would not be needed during long DMA based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in Host Controller. ADMA1 can support data transfer of 4KB aligned data in system memory. ADMA2 removes the restriction so that data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA engine can recognize all kinds of descriptors define in SD Host Controller Standard, and if 'End' flag is detected in the descriptor, ADMA engine will stop after this descriptor is processed.

29.3.2.4.1 ADMA Concept and Descriptor Format

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Set data length descriptor.
- Set data address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Rsv descriptor.
- Set data length & address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it will ignore the high 32-bit. Address field shall be set on word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

ADMA will start read/write operation after it reaches the Tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last Set type descriptor before Tran type descriptor. Every Tran type will trigger a transfer, and the transfer data length is extracted from the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length will be the value for previous transfer, or 0 if no Set descriptor is ever met.

For ADMA2, Tran type descriptor contains both data length and transfer data address, so only a Tran type descriptor can start a data transfer.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 29-8. Format of the ADMA1 Descriptor Table

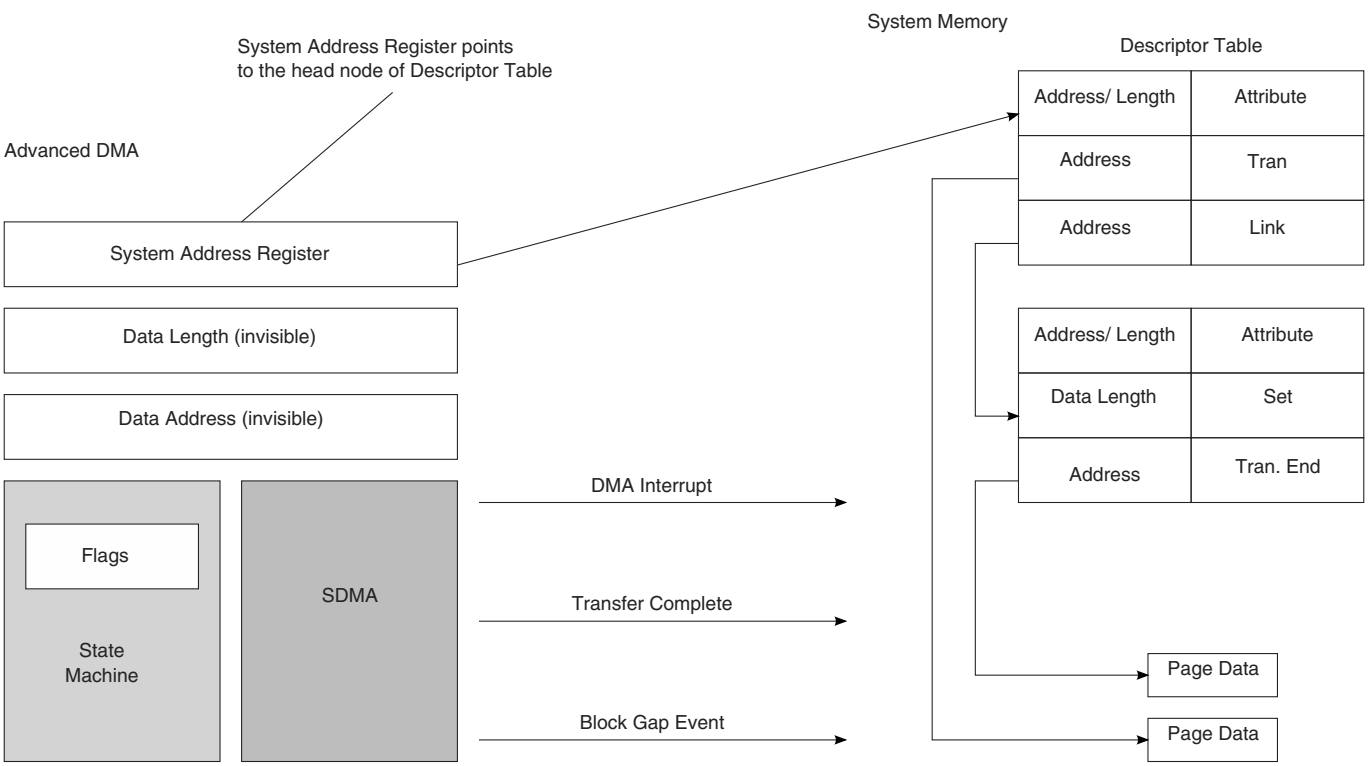

Figure 29-9. Concept and Access Method of ADMA1 Descriptor Table

Address/ Page Field		Address/ Page Field		Address/ Page Field		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit Length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is done.

Figure 29-10. Format of the ADMA2 Descriptor Table

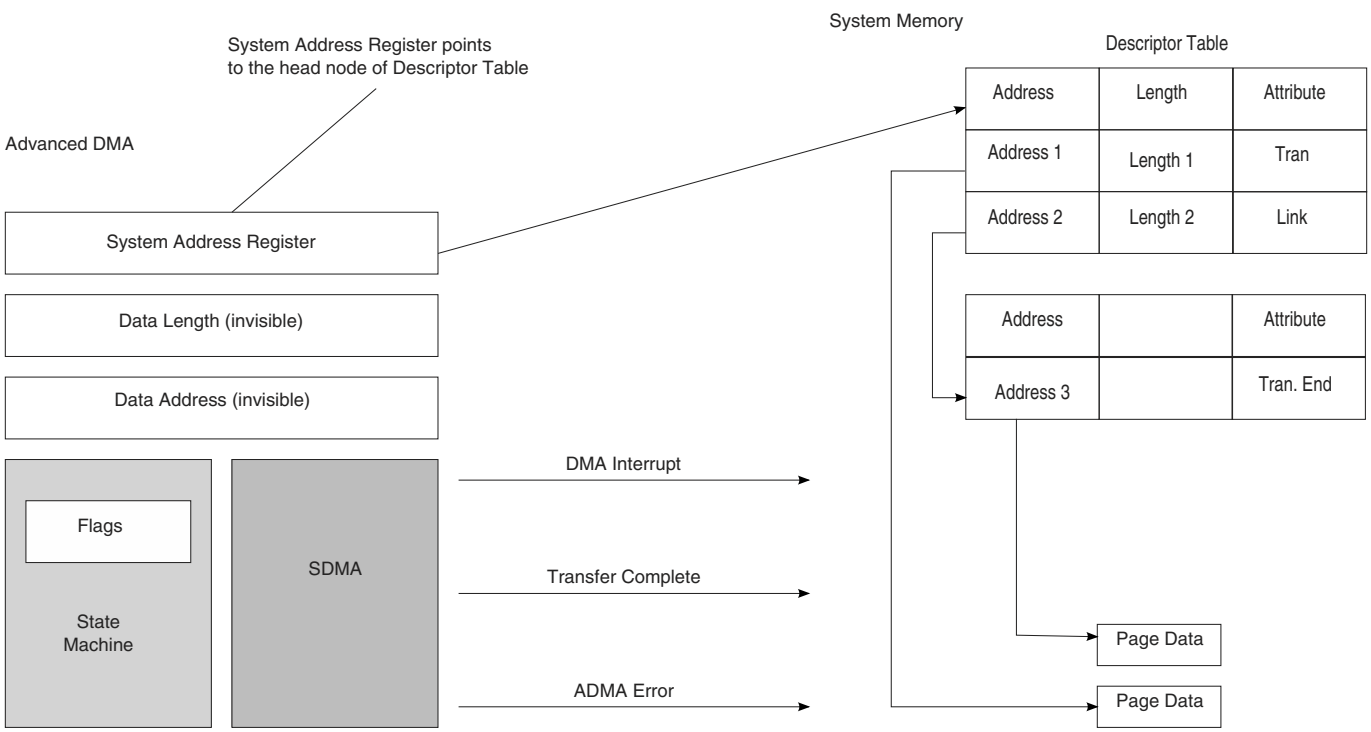

Figure 29-11. Concept and Access Method of ADMA2 Descriptor Table

29.3.2.4.2 ADMA Interrupt

If the 'Interrupt' flag of descriptor is set, ADMA will generate an interrupt according to different type descriptor:

For ADMA1:

- Set type descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop type descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type descriptor: interrupt is generated just after fetch this descriptor.

29.3.2.4.3 ADMA Error-DMA

The ADMA will stop whenever any error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

ADMA descriptor error will be generated when it fails to detect 'Valid' flag in the descriptor. If adma descriptor error occurs, the interrupt is not generated even if the 'Interrupt' flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in Block Attributes register must equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

If BLKCNTEN bit is not set, the whole data length set in descriptor should be times of block length, otherwise, when all data set in the descriptor nodes are done not at block boundary, the data mismatch error will occur.

29.3.3 Register Bank with IP Bus Interface

Register accesses via the IP Bus interface are actually on the Register Bank. See the figure below for the block diagram.

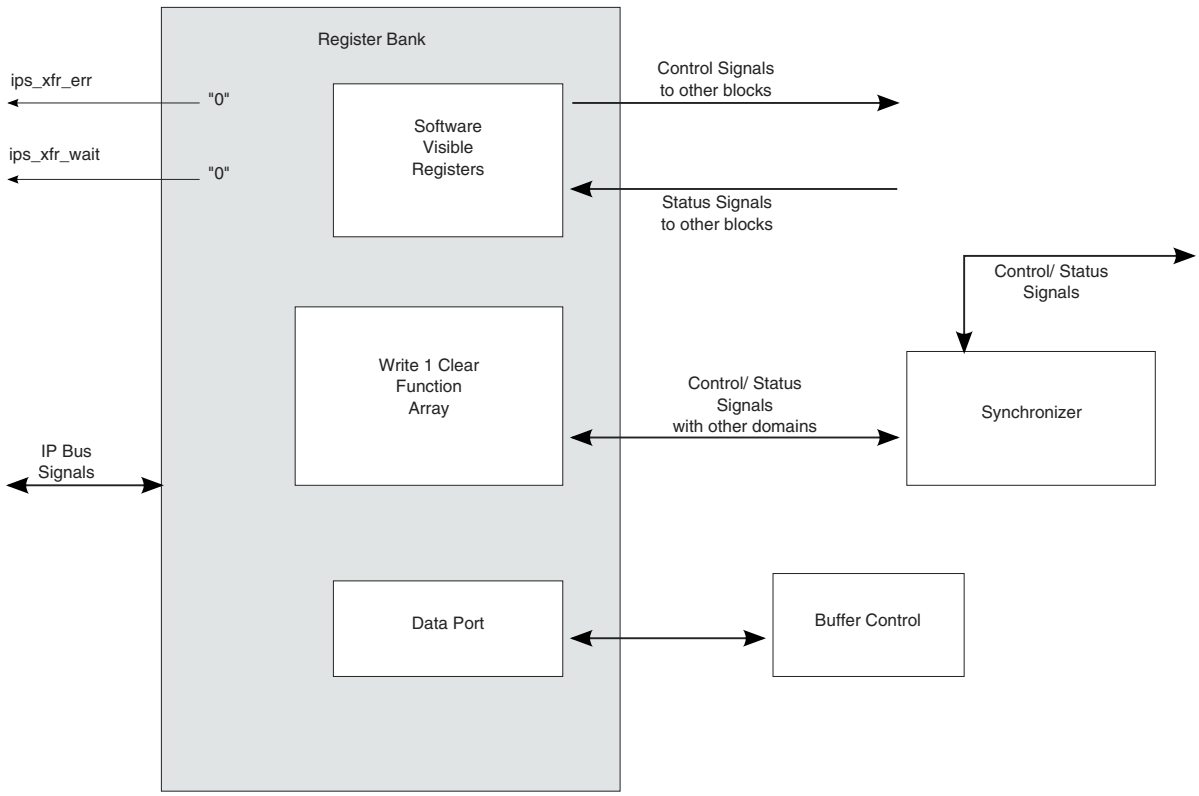

Figure 29-12. Register Bank Diagram

Only 32-bit access is allowed, and no partial read / write is supported, thus all accesses are word aligned.

29.3.4 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs.

The SD Protocol Unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the DAT[0] line
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD Protocol Unit consists of four sub-blocks:

1. SD transceiver.

2. SD clock and monitor.
3. Command agent.
4. Data agent.

29.3.4.1 SD Transceiver

In the SD protocol unit, the transceiver is the main control sub-block. It consists of an FSM and control sub-block, from which the control signals for all other three sub-blocks are generated.

29.3.4.2 SD Clock and Monitor

This sub-block monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the Register Bank. The driver can use this for debug purposes.

The sub-block also detects the Card Detection (CD) line as well as the DAT[3] line. The transceiver reports the card insertion state according to the CD state, or the signal level on the DAT[3] line, when the D3CD bit in the Protocol Control register is set.

The sub-block detects the Write Protect (WP) line. With the information of the WP state, the Register Bank will ignore the command, accompanied by a write operation, when the WP switch is on.

If the internal data buffer is in danger, and the SD clock must be gated off to avoid buffer over/under-run, this sub-block will assert the gate of the output SD clock to shut the clock off. After the buffer danger has recovered, and when the system access of the buffer catches up, the clock gate of this sub-block will open and the SD clock will be active again.

This sub-block also drive SD_LCTL output signal when the LCTL bit is set by the driver.

29.3.4.3 Command Agent

The Command Agent deals with the transactions on the CMD line. See figure below for an illustration of the structure for the Command CRC Shift Register.

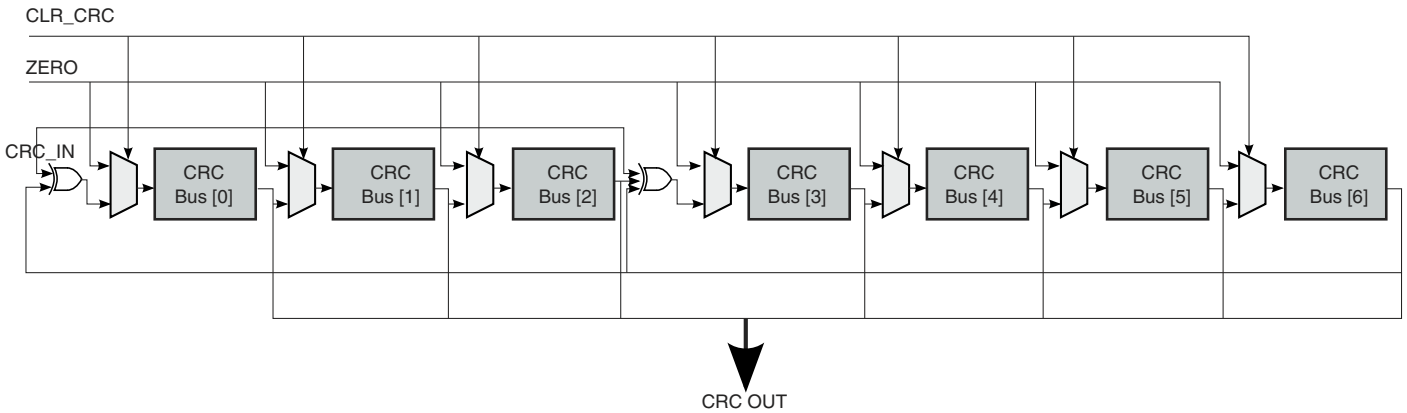

Figure 29-13. Command CRC Shift Register

The CRC polynomials for the CMD are as follows:

```
Generator polynomial: G(x) = x^7 + x^3 + 1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[6:0] = Remainder [(M(x) * x^7) / G(x)]
```

29.3.4.4 Data Agent

The Data Agent deals with the transactions on the eight data lines. Moreover, this sub-block also detects the busy state on the DAT[0] line, and generate the Read Wait state by the request from the Transceiver. The CRC polynomials for the DAT are as follows:

```
Generator polynomial: G(x) = x^16 + x^12 + x^5 +1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[15:0] = Remainder [(M(x) * x^16) / G(x)]
```

29.3.5 Clock and Reset Manager

This sub-block controls all the reset signals within the ESDHC.

There are four kinds of reset signals within ESDHC:

1. Hardware reset.
2. Software reset for all.
3. Software reset for the data part.
4. Software reset for the command part.

All these signals are fed into this sub-block and stable signals are generated inside the module to reset all other modules. The sub-block also gates off all the inside signals.

There are three clocks inside the ESDHC:

1. ipg_clk.

2. ipg_perclk.
3. hclk.

The sub-block monitors the activities of all other sub-blocks, supplies the clocks for them, and when enabled, automatically gates off the corresponding clocks.

29.3.6 Clock Generator

The Clock Generator generates the SD_CLK by peripheral source clock in two stages. Refer to Figure 29-14 for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

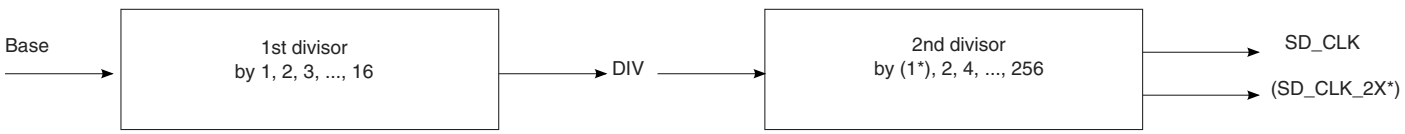

Figure 29-14. Two Stages of the Clock Divider

The first stage outputs an intermediate clock (DIV), which can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler, and outputs the actual clock (SD_CLK).This clock is the driving clock for all sub-blocks of the SD Protocol Unit, and the sync FIFOs (see Figure 29-3) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can beDIV, DIV/2, DIV/4,..., or DIV/256. Thus the highest frequency of the SD_CLK is Base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the Base clock is of equal duty ratio (usually true), the duty cycle of SD_CLK is also 50%, even when the compound divisor is an odd value.

29.3.7 SDIO Card Interrupt

29.3.7.1 Interrupts in 1-bit Mode

In this case the DAT[1] pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DAT[1] low from the SDIO card, until the interrupt service is finished to clear the interrupt.

29.3.7.2 Interrupt in 4-bit Mode

Since the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will only be sent by the card and recognized by the host during a specific time. This is known as the Interrupt Period. The ESDHC will only sample the level on Pin 8 during the Interrupt Period. At all other times, the host will ignore the level on Pin 8, and treat it as the data signal. The definition of the Interrupt Period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the Interrupt Period becomes active two clock cycles after the completion of a data packet. This Interrupt Period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the Interrupt Period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the Interrupt Period. For this case, the Interrupt Period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DAT[1] line will be held low for one clock cycle with the last clock cycle pulling DAT[1] high. On completion of the Interrupt Period, the card releases the DAT[1] line into the high Z state. The ESDHC samples the DAT[1] during the Interrupt Period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

29.3.7.3 Card Interrupt Handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, the ESDHC clears the interrupt request to the Host System. The Host Driver should clear this bit before servicing the SDIO Interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Status bit is cleared by resetting the SDIO interrupt. Writing to this bit would have no effects. In 1-bit mode, the ESDHC will detect the SDIO Interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the Interrupt Period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status has been set, and the Host Driver needs to service this interrupt, so the SDIO bit in the Interrupt Control Register of SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the ESDHC and to stop driving the interrupt signal to the

System Interrupt Controller. The Host Driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Enable bit is set to 1, and the ESDHC starts sampling the interrupt signal again.

See figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

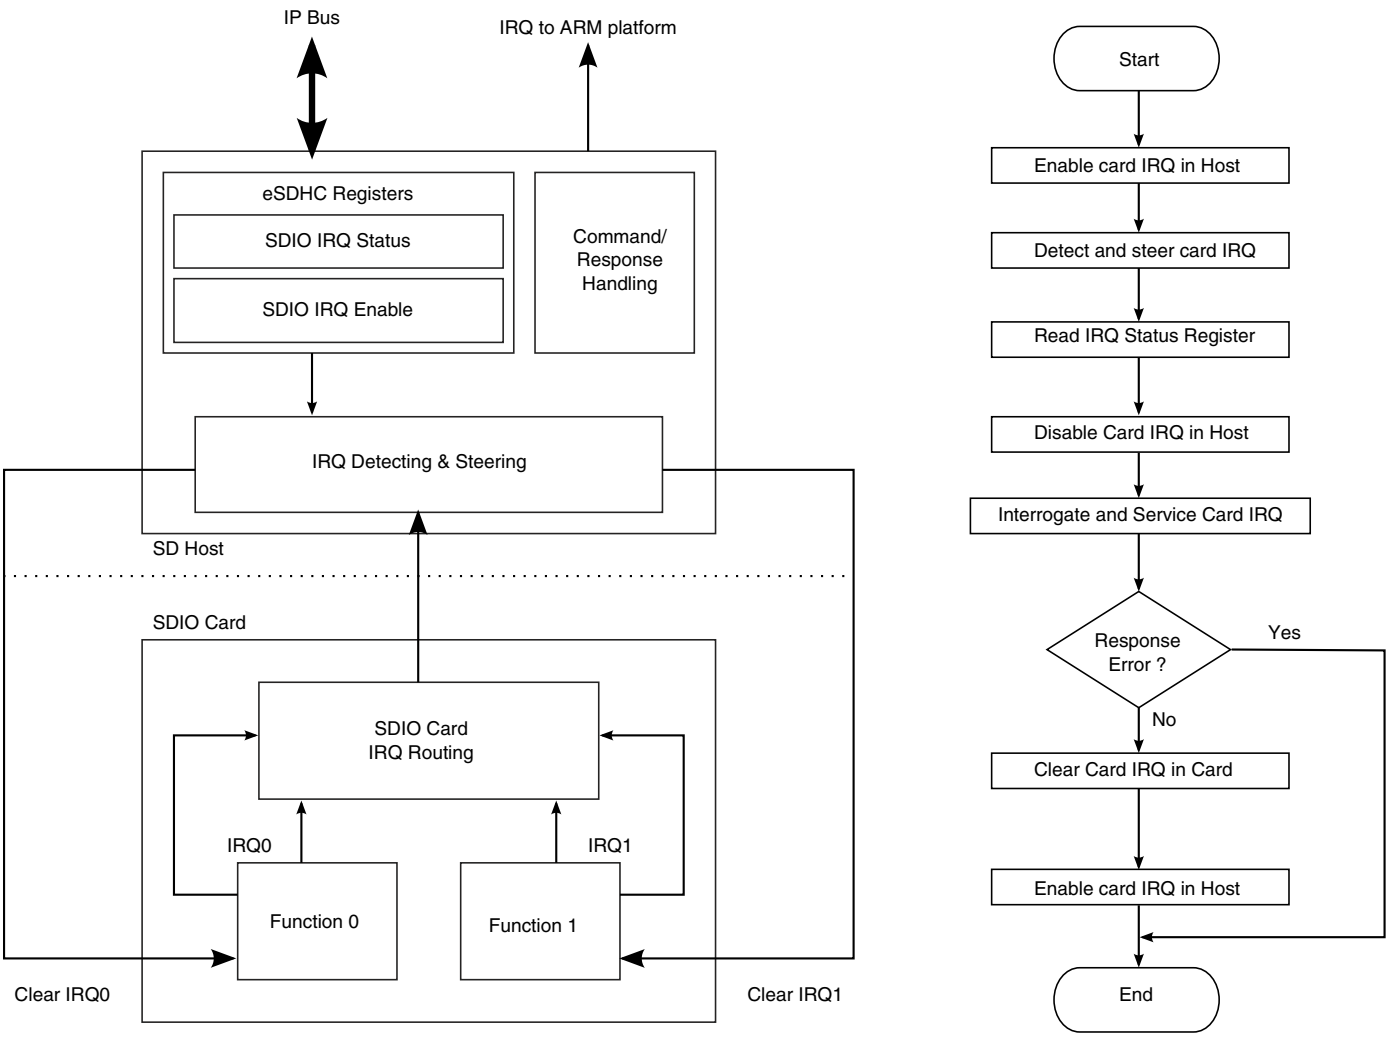

Figure 29-15. Card Interrupt Scheme and Card Interrupt Detection and Handling Procedure

29.3.8 Card Insertion and Removal Detection

The ESDHC uses either the DAT[3] pin or the CD pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DAT[3] will be pulled to a low voltage level by default. When any card is inserted to or removed from the socket, the ESDHC detects the logic value changes on the DAT[3] pin and generates an interrupt. When the DAT[3] pin is not used for card detection (for example, it is implemented in GPIO), the CD pin must be connected for card detection. Whether DAT[3] is configured for card detection or not, the CD pin is always a reference for card detection. Whether the DAT[3] pin or the CD pin is used to detect card insertion, the ESDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

29.3.9 Power Management and Wake Up Events

When there is no operation between the ESDHC and the card through the SD bus, the user can completely disable the ipg_clk and ipg_perclk in the chip level clock control module to save power. When the user needs to use the ESDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the ESDHC are disabled, for instance, when the system is in low power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The ESDHC can generate these interrupt even when there are no clocks enabled. The three interrupts which can be used as wake up events are:

1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

The ESDHC offers a power management feature. By clearing the clock enabled bits in the System Control Register (ESDHC_SYSCTL), the clocks are gated in the low position to the ESDHC. For maximum power saving, the user can disable all the clocks to the ESDHC when there is no operation in progress.

These three wake up events (or wakeup interrupts) can also be used to wake up the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to the ESDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (ESDHCV2_PROCTL) for more information on the ESDHC Protocol Control register.

29.3.9.1 Setting Wake Up Events

For the ESDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the ARM platform enters sleep mode. Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

29.3.10 MMC Fast Boot

The Embedded Multimedia Card (eMMC 4.3) has a fast boot feature. In boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

There are two types of fast boot mode in the eMMC4.3 spec: 'Boot operation' and 'Alternative boot operation.' Each type also has with acknowledge and without acknowledge modes. eSDHCv2 supports both fast boot modes.

NOTE

For the eMMC4.3 card setting, please refer to the eMMC4.3 spec.

29.3.10.1 Boot Operation

NOTE

In this block guide, this fast boot is called normal fast boot mode.

If the CMD line is held LOW for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after the CMD line goes LOW, the slave starts to send the first boot data to the master on the DAT line(s). The master must keep the CMD line LOW to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes LOW. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode with the CMD line HIGH.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

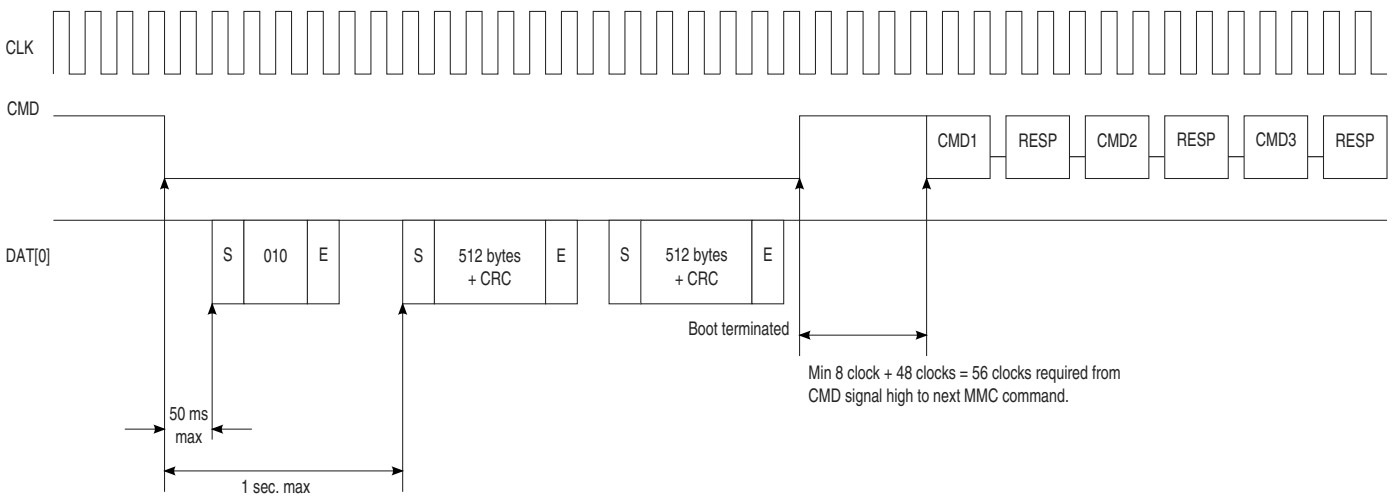

Figure 29-16. MultiMediaCard state diagram (normal boot mode)

29.3.10.2 Alternative Boot Operation

If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

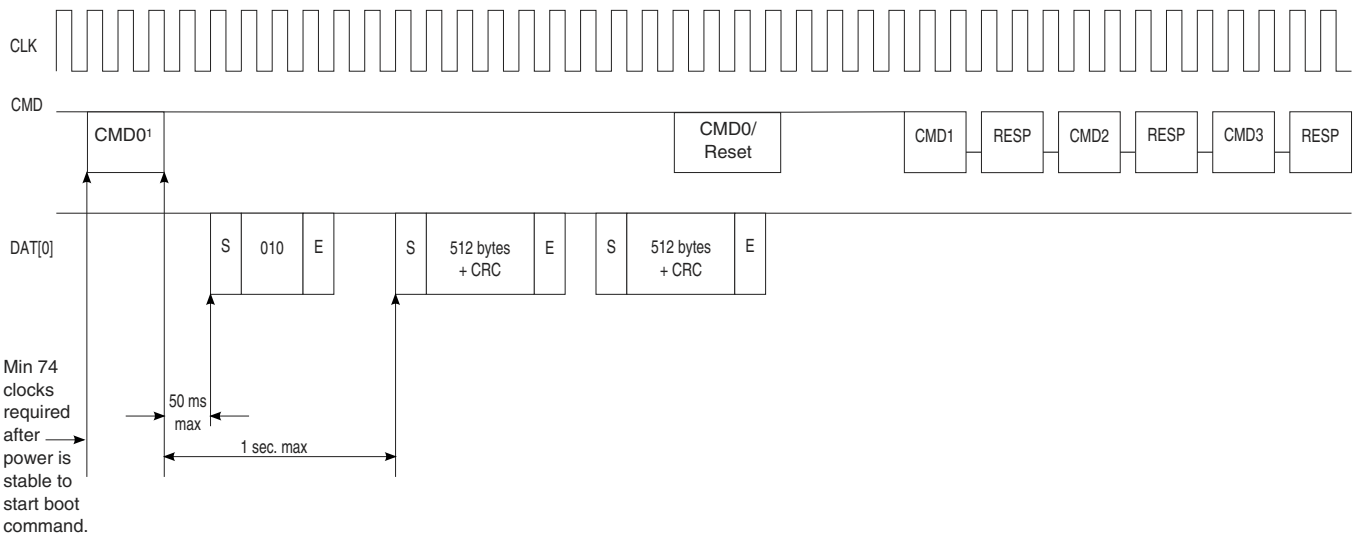
After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DAT line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.



NOTE1. CMD0 with argument 0xFFFFFFFA

Figure 29-17. MultiMediaCard state diagram (alternative boot mode)

29.4 Initialization/Application of ESDHC

All communication between system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as "GO_IDLE_STATE", "SEND_OP_COND", "ALL_SEND_CID" and etc. In Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the Broadcast command CMD3 is issued, the cards enter standby mode. Addressed type commands are used from this point. In this mode, the CMD/DAT I/O pads will turn to push-pull mode, to have the driving capability for maximum frequency operation. Refer to Commands for MMC/SD/SDIO for the commands of ac and adtc categories.

29.4.1 Command Send and Response Receive Basic Operation

Assuming the data type WORD is an unsigned 32-bit integer, the below flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
          set MSBSEL bit;
          if (finite block number) {
                    set BCEN bit;
                    if (auto12 command is to use) set AC12EN bit;
          }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. By doing this, make sure the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the Standby State, no response to the Host when CMD2 is sent. The Host Driver shall deal with 'fake' errors like this with caution.

29.4.2 Card Identification Mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for the MMC cards.

29.4.2.1 Card Detect

See figure below for a flow diagram showing the detection of MMC, SD and SDIO cards using the ESDHC.

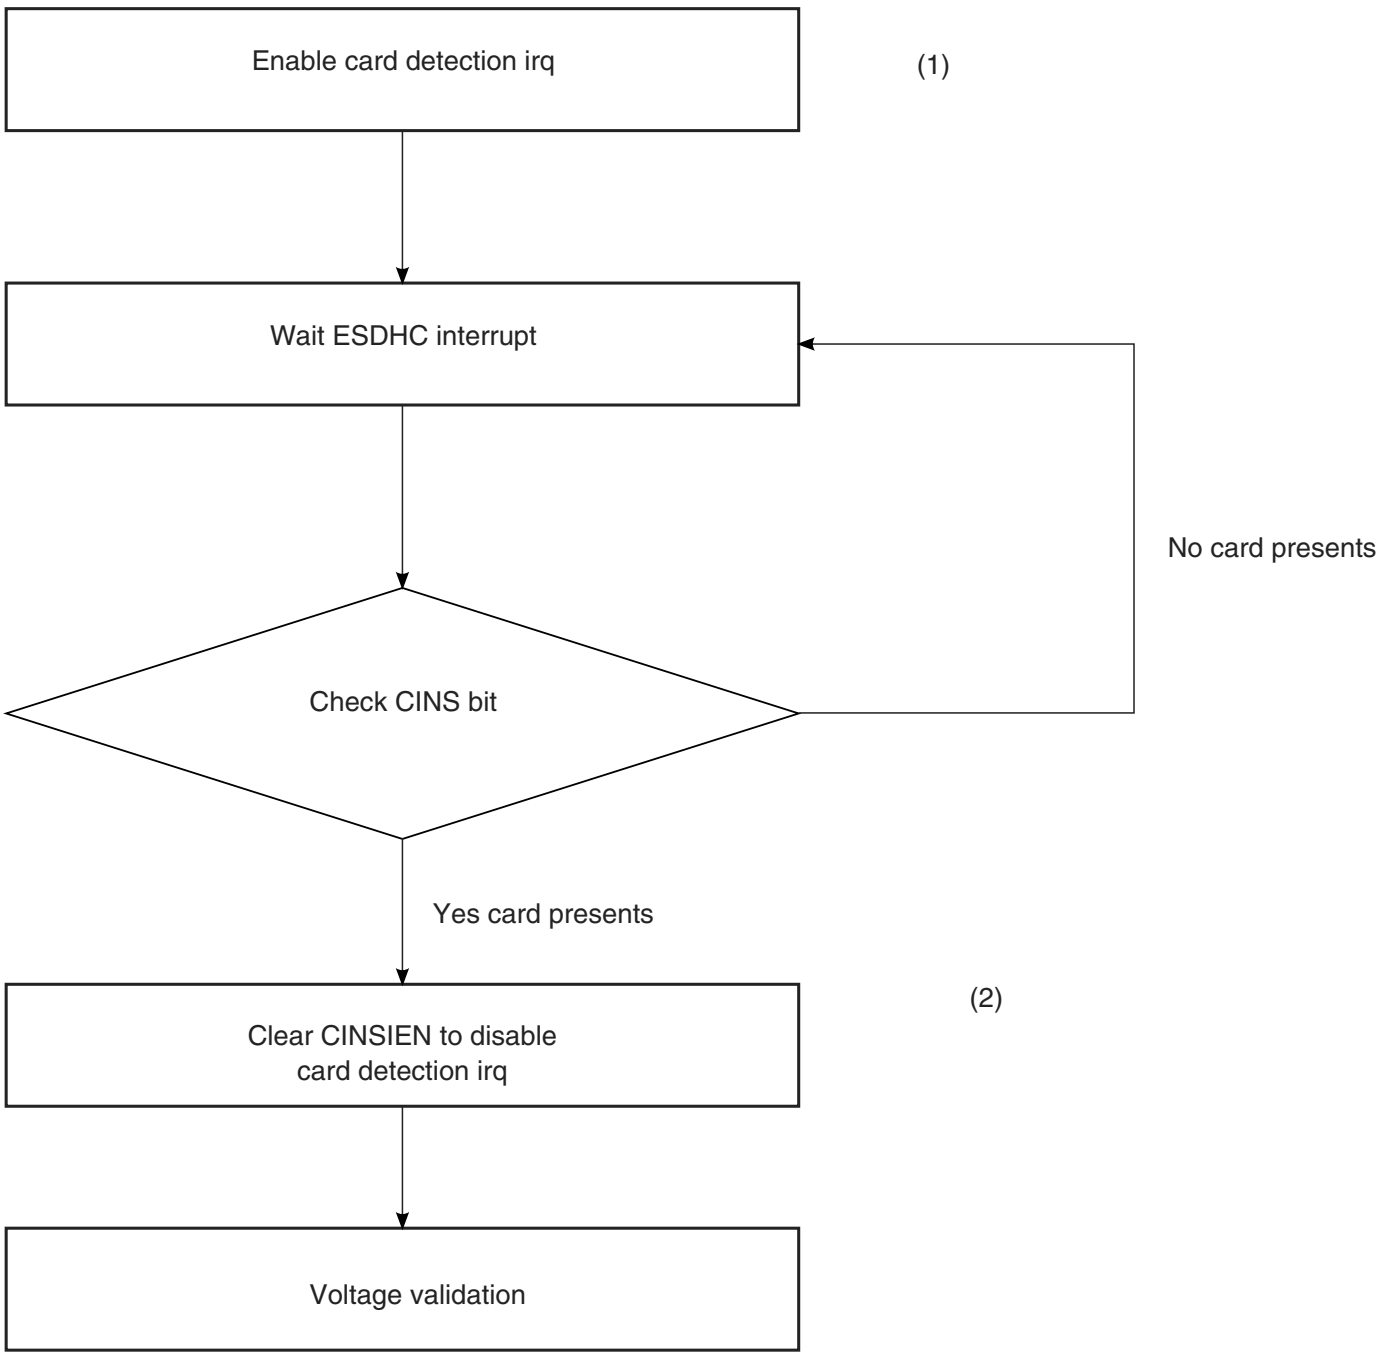


Figure 29-18. Flow Diagram for Card Detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the ESDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

29.4.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) which is driven by POR (Power On Reset)
- Software reset (Host Only) is proceed by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the Host Controller, respectively
- Card reset (Card Only). The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the Idle State regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See figure below for the software flow to reset both the ESDHC and the card.

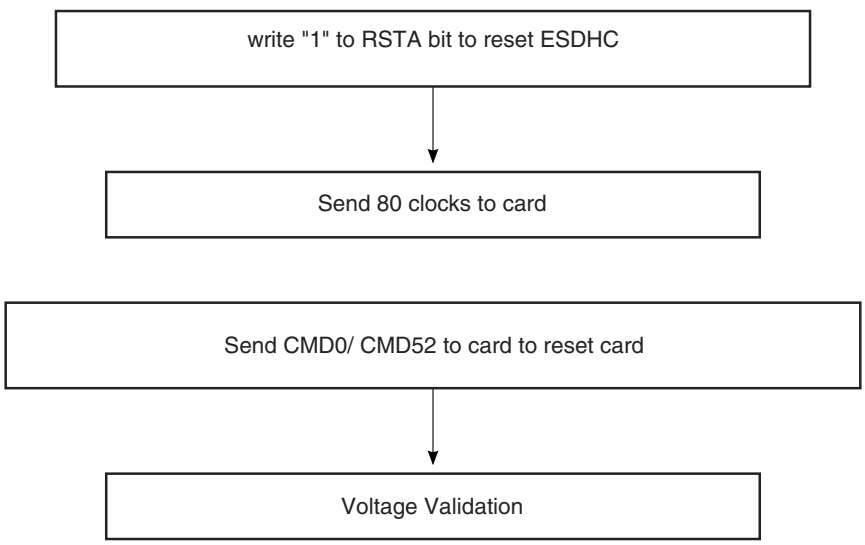

Figure 29-19. Flow Chart for Reset of the ESDHC and SD I/O Card

```
software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set DVS and SDCLKFS bit fields to get the SD_CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

29.4.2.3 Voltage Validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for Vdd are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer Vdd conditions. This means if the host and card have non-common Vdd ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory) and IO_Send_Op_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host. This is accomplished by the host sending the desired Vdd voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive State. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive State. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
          if (0 < number of IO functions) {
                    label the card as SDIO;
                    IORDY = 0;
                    while (!(IORDY in IO OCR response)) { // set voltage range for each IO
function
                              send_command(IO_SEND_OP_COND, <voltage range>, <other
parameter>);
                              wait_for_response(IO_SEND_OP_COND);
                    } // end of while ...
          } // end of if (0 < ...
          if (memory part is present inside SDIO card) Label the card as SDCombo; // this is
an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
          send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41
```

```
range
for memory part or SD card
          wait_for_response(SD_APP_OP_COND); // voltage range is set
          if (card type is UNKNOWN) label the card as SD;
          return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
          deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card           if (card is already labelled as
SDCombo) { // change label
                    re-label the card as SDIO;
                    ignore the error or report it;
                    return; // card is identified as SDIO card
          } // of if (card is ...
          send_command(SEND_OP_COND, <voltage range>, <...>);
          if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
either
                    label the card as UNKNOWN;
                    return;
          } // of if (RESP_TIMEOUT ...
          if (check for CE-ATA signature succeeded) { // the card is CE-ATA
                    store CE-ATA specific info from the signature;
                    label the card as CE-ATA;
          } // of if (check for CE-ATA ...
          else label the card as MMC;
} // of else
}
```

29.4.2.4 Card Registry

Card registry for the MMC and SD/SDIO/SD Combo cards are different.

For the SD Card, the Identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the Card spec). At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the Inactive State. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready State), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification State.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. Once the RCA is received, the card changes its state to the Standby State. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive State. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in Ready State) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Since the CID is unique for each card, only one card can be successfully send its full CID to the host. This card then goes into the Identification State. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received the card state changes to the Stand-by State, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
          if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
                    send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
                    retrieve RCA from response;
          } // end if (card is labelled as SDCombo ...
          else if (card is labelled as SD) { // for SD card
                    send_command(ALL_SEND_CID, <...>);
                    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
                    send_command(SET_RELATIVE_ADDR, <...>);
                    retrieve RCA from response;
          } // else if (card is labelled as SD ...
          else if (card is labelled as MMC or CE-ATA) { // treat CE-ATA as MMC
                    send_command(ALL_SEND_CID, <...>);
                    rca = 0x1; // arbitrarily set RCA, 1 here for example, this RCA is also
the
relative address to access the CE-ATA card
                    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
          } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

29.4.3 Card Access

29.4.3.1 Block Write

29.4.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the DAT line. The transferred data will be discarded and not written, and all further transmitted blocks (in multiple block write mode) will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DAT line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DAT line without interrupting the write operation. When re-selecting the card, it will reactivate the busy indication by pulling DAT to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods (by means of external DMA or ARM platform polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC cards, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the ESDHC block attribute register, block number is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

29.4.3.1.2 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the SD_CLK at any time to pause all the operations, which is also inaccessible to the Host Driver, the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DAT0 line is not required to de-assert to release the busy state, no suspend command is needed.

Like in the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the ESDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.

7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The Driver shall read the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card; when such a command is sent, the ESDHC thinks the System will switch to another function on the SDIO card, and flush the data buffer. The ESDHC takes the Resume Command as a normal command with data transfer, and it is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the ESDHC will automatically send a CMD12 to mark the end of the multi-block transfer.

29.4.3.2 Block Read

29.4.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or ARM platform polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the ESDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set:
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

29.4.3.2.2 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the ESDHC will not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended that the RWCTL bit be set once the Read Wait capability of the SDIO card is recognized.

Like in the flow described in Normal Read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:

a. For SD/MMC, use SET_BLOCKLEN (CMD16)
b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)

5. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
6. Set the ESDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the ESDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. No matter if the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the ESDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the ESDHC will automatically send the CMD12 to mark the end of multi-block transfer.

29.4.3.3 Suspend Resume

The ESDHC supports the Suspend Resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

Suspend

After setting the SABGREQ bit, the Host Driver may send a Suspend command to switch to another function of the SDIO card. The ESDHC does not monitor the content of the response, so it doe not know whether or not the Suspend command has succeeded. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the Driver does not set the ESDHC_XFERTYP[CMDTYP] register to 01, that is, Suspend option. Instead, the Driver sends this command as if it were a normal command (that is, sets CMDTYP to b00). Only when the command succeeds, and the BS bit is set in the response, does the Driver send another command marked as "Suspend" to inform the ESDHC that the current transfer is suspended. This is shown in the following sequence for Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so the ESDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the ESDHC stops driving DAT2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

29.4.3.3.1 Resume

To resume the data transfer, a Resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation above.
2. Send the Resume command. In the Transfer Type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer will be resumed.

29.4.3.4 ADMA1 Usage

To use the ADMA1 in a data transfer, the Host Driver must prepare the correct descriptor chain prior to sending the read/write command. The steps to accomplish this are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4kB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

29.4.3.5 Transfer Error

29.4.3.5.1 CRC Error

It is possible at the end of a block transfer, that a write CRC status error or read CRC error occurs. For this type of error the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the Host Driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, the ESDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 will be sent by the ESDHC. In this case, the Driver shall re-send or re-obtain the last block with a single block transfer.

29.4.3.5.2 Internal DMA Error

During the data transfer with internal Simple DMA, if the DMA engine encounters some error on the AHB bus, the DMA operation is aborted and DMA Error interrupt is sent to the Host System. When acknowledged by such an interrupt, the Driver shall calculate the start address of data block in which the error occurs. The start address can be calculated by either:

1. Read the DMA System Address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.
2. Read the BLKCNT field of the Block Attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register does not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and re-start the transfer from the corrupted block to recover from the error.

29.4.3.5.3 ADMA Error-Card Access

There are three kinds of possible ADMA errors. The AHB transfer, invalid descriptor, and data-length mismatch errors. When these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the Host Driver should recover the error as shown below and re-transfer from the place of interruption.

1. AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and re-create the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
3. Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

29.4.3.5.4 Auto CMD12 Error

After the last block of the multi block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, the ESDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, it is recommended to the Driver to deal with the situations in the following manner:

1. Auto CMD12 response time-out. It is not certain whether the command is accepted by the card or not. The Driver should clear the Auto CMD12 error status bits and re-send the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error. Since card responds to the CMD12, the card will abort the transfer. The Driver may ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The command is not sent, so the Driver shall send a CMD12 manually.

29.4.3.6 Card Interrupt

The external cards can inform the Host Controller by means of some special signals. For the SDIO card, it can be the low level on the DAT[1] line during some special period. The ESDHC only monitors the DAT[1] line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the ESDHC, and the Host System is informed by the ESDHC asserting the ESDHC interrupt line, the interrupt service from the Host Driver is called.

As the interrupt factor is controlled by the external card, the interrupt from the SDIO card must be served before the CINT bit is cleared by written 1. Refer to Card Interrupt Handling for the card interrupt handling flow.

29.4.4 Switch Function

MMC cards transferring data at bus widths other than 1-bit is a feature in MMC spec. The high speed timing mode for all card devices, was also defined in various card specifications. To enable these features, a "switch" command shall be issued by the Host Driver.

For SDIO cards, the high speed mode is enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode is queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards, the high speed mode is queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The 4-bit and 8-bit bus width of the MMC is also enabled by the SWITCH command, but with a different argument.

DDR mode is also selected by setting ddr mode bus width via SWITCH.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following flowcharts do not show current capability check, which is recommended in the function switch process.

29.4.4.1 Query, Enable and Disable SDIO High Speed Mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

29.4.4.2 Query, Enable and Disable SD High Speed Mode

```
enable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFF1 and read 64 bytes of data accompanying the R1 response;
wait data transfer done bit is set;
check if the bit 401 of received 512 bit is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
send CMD6, with argument 0x80FFFFF1 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

29.4.4.3 Query, Enable and Disable MMC High Speed Mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

29.4.4.4 Set MMC Bus Width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

29.4.5 ADMA Operation

29.4.5.1 ADMA1 Operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
```

```
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB align);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

29.4.5.2 ADMA2 Operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

29.4.6 Fast Boot Operation

29.4.6.1 Normal fast boot flow

1. Software must configure INITA bit ESDHC_SYSCTL[27] to make sure 74 card clocks are finished.

2. Software must configure MMC Boot Register (ESDHC_MMCBOOT) (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode or not. If it is necessary to send through DMA mode, bit 7 must be configured to enable automatic stop at block gap feature. And need to configure bit 3-bit0 must be configured to select the ack timeout value according to the sd clk frequence.
3. Software must then configure Block Attributes Register to set block size/no.
4. Software must configure Protocol control register to set DTW (data transfer width).
5. Software must configure Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1.

NOTE

DMAEN should be configured as 0 in polling mode. If BCEN is configured as 1, it is best to configure blk no in Bock Attributes Register to the max value.

7. When step 6 is configured, the boot process will begin. Software must poll the data buffer ready status to read the data from buffer in time. If boot time-out happens (ack time out or the first data read time out), interrupt will be triggered, and software must configure MMC Boot Register, bit 6 to 0 to disable boot. This will make CMD high, and after at least 56 clocks, it is ready to begin normal initialization process.
8. If no time out occurs, the software must decide if the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This will make CMD line high and command completed is asserted. After at least 56 clock cycles, it is ready to begin normal initialization process.
9. Reset the host and then can begin the normal process.

29.4.6.2 Alternative fast boot flow

1. Software must configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software must configure MMC Boot Register (ESDHC_MMCBOOT) (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If it is necessary to send through DMA mode, bit 7 must be configured to enable automatic stop at block gap feature. Bit 3 through bit0 must be configured to select the ack timeout value according to the sd clk frequence.
3. Software must then configure Block Attributes Register to set block size/no.
4. Software mustconfigure Protocol control register to set DTW (data transfer width).

5. Software must configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software must configure Transfer Type Register to start the boot process by CMD0 with 0xFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1.

NOTE

DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in polling mode, it is best to configure blk no in Bock Attributes Register to the max value.

7. When the step 6 is configured, boot process begins. Software must poll the data buffer ready status to read the data from buffer in time. If boot time out (acknowledge data time out in 50ms or data time out in 1s), host will send out the interrupt and software need to send CMD0 with reset and then configure boot enable bit to 0 to stop this process. After command completed, configure MMC Boot Register bit 6 to 0 to disable boot. After at least 8 clocks from command completed, card is ready for identification step.
8. If no time out occurs, software must decide when to stop the boot process, and send out the CMD0 with reset. After this command is completed, configure MMC Boot Register bit 6 to stop the process. After 8 clocks from command are completed, the slave (card) is ready for the identification step.
9. Reset the host and then can begin the normal process.

29.4.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the

beginning of the image, DMA parameters must be switched on the fly during MMC fast boot.

In fast boot, host can use ADMA2 (Advanced DMA2) with two destinations.

The detail flow:

1. Software must configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software must configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the acknowledge mode or not. In DMA mode, configure bit 7 to 1 for enable

automatically stop at block gap feature. Also configure bit31-bit16 to set the VALUE1 (value of block count that need to transfer first time), that host will stop at block gap when card block counter is equal to this value. Bit 3 through bit0 must be configured to select the acknowledge timeout value according to the SD clock frequency.

3. Software must then configure Block Attributes Register to set block size/no. In DMA mode, it is better to set block number to the max value (16'hFFFF).
4. Software must configure Protocol control register to set DTW (data transfer width).
5. Software enbables ADMA2 by configuring protocol control register bit9-bit8.
6. Software must set at least three pairs ADMA2 descriptor in boot memory (i.e. in IRAM, at least 6 words). The first pair descriptor define the start address (i.e. IRAM) and data length (that is, 512 bytes*VALUE1) of first part boot code. Software also must set the second pair descriptor, the second start address (any value that is writeable), data length is suggest to set 1~2word (record as VAULE2).

NOTE

The second couple descriptor also transfers useful data. (At lease 1 word because the ADMA2 can't support a 0 data_length data transfer descriptor.)

7. Software must configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot, and do not need set in normal fast boot.
8. Software must configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in DMA mode. And if BCEN is configured as 1, it is best to configure block no in Bock Attributes Register to the max value.
9. When the step 8 is configured, boot process will begin. The first VAULE1 block number data has transfer. Software must poll TC bit (bit1 in Interrupt Status Register) to determine if the first transfer has ended. Software must poll BGE bit (bit2 in Interrupt Status Register) to determine if first transfer has stopped at block gap.
10. When TC, BGE bit is 1, SW can analyze the first code of VAULE1 block, initialize the new memory device, if required, and set the third pair of descriptors to define the start address and length of the remaining part of boot code (VAULE3 the remain boot code block). Remember to set the last descriptor with END.
11. Software must configure MMC Boot Register (ESDHC_MMCBOOT) (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the acknowledge mode or not. In DMA mode, configure bit 7 to 1 to enable automatic stop at block gap feature. Bit31-bit16 must be configured to set the (VAULE1+1+VAULE3) so that host will stop at block gap when card

block counter is equal to this value. And must configure bit 3-bit0 to select the acknowledge timeout value according to the SD clock frequency.

12. Software must clear TC and BGE bit. It must also clear SABGREQ (bit 16 in Protocol control register), and set CREQ (bit17 Protocol control register) to 1 to resume the data transfer. Host will transfer the VALUE2 and VAULE3 data to the destination that is set by descriptor.
13. Software must poll BGE bit to determine if the fast boot is over.

NOTE

When ADMA boot flow is started, for ESDHC, it is like a normal ADMA read operation. In order to keep descriptor, must have a memory length of at least a few words.For the 1~2 word data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

29.5 Commands for MMC/SD/SDIO

See table below for the list of commands for the MMC/SD/SDIO cards.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. broadcast commands (bc), no response.
2. broadcast commands with response (bcr), response from all cards simultaneously.
3. addressed (point-to-point) commands (ac), no data transfer on the DAT.
4. addressed (point-to-point) data transfer commands (adtc).

The Access Bits for the EXT_CSD Access Modes are shown in table below.

Table 29-2. Commands for MMC/SD/SDIO Cards

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.

Table continues on the next page...

Table 29-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.

Table continues on the next page...

Table 29-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	Reserved				
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.

Table continues on the next page...

Table 29-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.

Table continues on the next page...

Table 29-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather that a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57~59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62~63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.

Table continues on the next page...

Table 29-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac		R1	SET_WR_BLK_ERASE_COUNT	-
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac		R1	SET_CLR_CARD_DETECT	-
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards . The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 29-3.
4. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this block).

Table 29-3. EXT_CSD Access Modes

Bits	Access Name	Operation
00	Command Set	The command set is changed according to the Cmd Set field of the argument
01	Set Bits	The bits in the pointed byte are set, according to the 1 bits in the Value field.
10	Clear Bits	The bits in the pointed byte are cleared, according to the 1 bits in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

29.6 Software Restrictions

29.6.1 Initialization Active

The driver cannot set INITA bit in System Control register when any of the command line or data lines is active, so the driver must ensure both CDIHB and CIHB bits are cleared. In order to auto clear the INITA bit, the SDCLKEN bit must be '1', otherwise no clocks can go out to the card and INITA will never clear.

29.6.2 Softeware Polling Procedure

For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not the times of the value in Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block. For example, for read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

29.6.3 Suspend Operation

In order to suspend the data transfer, the software must inform ESDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform ESDHC that the transfer is suspended.

If software needs to resume the suspended trasnfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending a 'suspend' command, ESDHC will regard the current transfer as aborted and change BLKCNT register to its original value, rather than keeping the remaining number of blocks.

29.6.4 Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

29.6.5 (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register will always update itself with the internal address value to support dynamic address synchronization, so software must make sure TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

29.6.6 Data Port Access

Data Port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the Data Port by ARM platform; or during a ARM read operation, it is also prohibited to write any data to the Data Port, by either ARM or external DMA. Otherwise the data would be corrupted inside the ESDHC buffer.

29.6.7 Change Clock Frequency

ESDHC does not automatically gates off the card clock when the Host Driver changes the clock frequency. To remove possible glitch on the card clock, clear SDCLKEN bit when changing clock divisor value and set SDCLKEN bit to '1' after SDSTB bit is '1' again.

29.6.8 Multi-block Read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by ESDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode. In this case, the card may not respond to this extra abort command and ESDHC will get Response Timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

29.7 Programmable Registers

This section includes the block memory map and detailed descriptions of all registers. Each of these registers support only 32-bit accesses.

NOTE

Addresses greater than 0x44, except 0x50, 0x54, 0x58, 0x60, 0x64, 0xC0, 0xC4 and 0xFC, are reserved and read as all 0s. Write to these registers is ignored.

ESDHCV2 memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
5000_4000	DMA System Address (ESDHCV2-1_DSADDR)	32	R/W	0000_0000h	29.7.1/ 1378

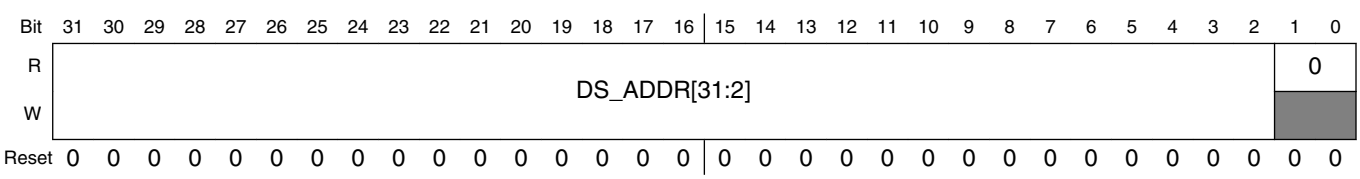
29.7.1 DMA System Address (ESDHCV2x_DSADDR)

This register contains the physical system memory address used for DMA transfers.

Addresses: ESDHCV2-1_DSADDR is 5000_4000h base + 0h offset = 5000_4000h
ESDHCV2-2_DSADDR is 5000_8000h base + 0h offset = 5000_8000h
ESDHCV2-4_DSADDR is 5002_4000h base + 0h offset = 5002_4000h



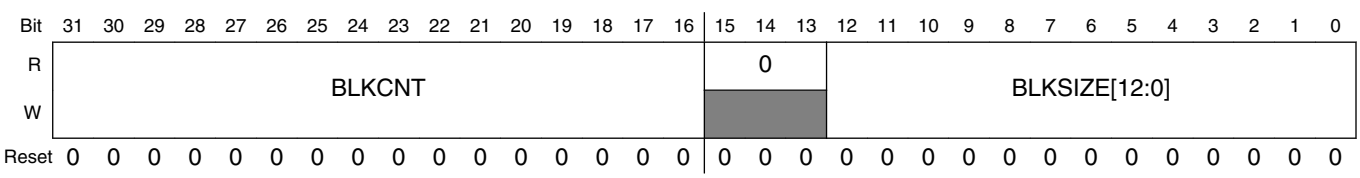
ESDHCV2x_DSADDR field descriptions

Field	Description
31–2 DS_ADDR[31:2]	DMA System Address: This register contains the 32-bit system memory address for a DMA transfer. As the address must be word (4 bytes) align, the least 2 bits are reserved, always 0. When the ESDHC stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The Host Driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The Host driver shall wait, until ESDHCV2_PRSSTAT[DLA] bit is cleared, before writing to this register. The ESDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, ESDHC will automatically change SEQ burst type to NSEQ. As this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions.
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

29.7.2 Block Attributes (ESDHCV2x_BLKATTR)

This register is used to configure the number of data blocks and the number of bytes in each block.

Addresses: ESDHCV2-1_BLKATTR is 5000_4000h base + 4h offset = 5000_4004h
ESDHCV2-2_BLKATTR is 5000_8000h base + 4h offset = 5000_8004h
ESDHCV2-4_BLKATTR is 5002_4000h base + 4h offset = 5002_4004h



ESDHCV2x_BLKATTR field descriptions

Field	Description
31–16 BLKCNT	Blocks Count For Current Transfer: This register is enabled when ESDHCV2_XFERTYP[BCEN] bit is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The Host Driver shall set this register to a value between 1 and the maximum block count. The ESDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. This register should be accessed only when no transaction is executing (that is, after transactions have stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored.

Table continues on the next page...

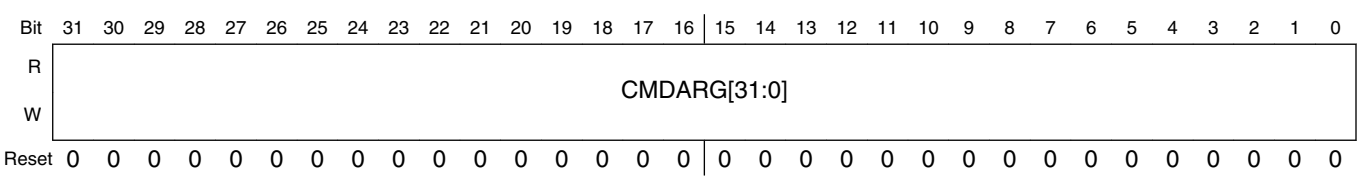
ESDHCV2x_BLKATTR field descriptions (continued)

Field	Description
	When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when Suspend command is sent out, ESDHC will regard the current transfer is aborted and change BLKCNT register back to its original value instead of keeping the dynamical indicator of remained block count. When restoring transfer content prior to issuing a Resume command, the Host Driver shall restore the previously saved block count. 0xFFFF 65535 blocks 0x0002 2 blocks 0x0001 1 block 0x0000 Stop Count
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12–0 BLKSIZE[12:0]	Transfer Block Size: This register specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations will be ignored. 0x1000 4096 Bytes 0x800 2048 Bytes 0x200 512 Bytes 0x1FF 511 Bytes 0x004 4 Bytes 0x003 3 Bytes 0x002 2 Bytes 0x001 1 Byte 0x000 No data transfer

29.7.3 Command Argument (ESDHCV2x_CMDARG)

This register contains the SD/MMC Command Argument.

Addresses: ESDHCV2-1_CMDARG is 5000_4000h base + 8h offset = 5000_4008h
ESDHCV2-2_CMDARG is 5000_8000h base + 8h offset = 5000_8008h
ESDHCV2-4_CMDARG is 5002_4000h base + 8h offset = 5002_4008h



ESDHCV2x_CMDARG field descriptions

Field	Description
31–0 CMDARG[31:0]	Command Argument: The SD/MMC Command Argument is specified as bits 39-8 of the Command Format in the SD or MMC Specification.This register is write protected when the Command Inhibit (CMD) bit in the Present State register is set.

29.7.4 Command Transfer Type (ESDHCV2x_XFERTYP)

This register is used to control the operation of data transfers. The Host Driver sets this register before issuing a command followed by a data transfer, or before issuing a Resume command. To prevent data loss, the ESDHC prevents writing to the bits, that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.

The Host Driver shall check the Command Inhibit DAT bit (CDIHB) and the Command Inhibit CMD bit (CIHB) in the Present State register before writing to this register. When the CDIHB bit in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Besides, block count must also be non-zero, or indicated as single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise ESDHC will ignore the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is '1), otherwise ESDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, that is, response time-out, ESDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver should issue the command again to re-try the transfer. It is also possible that for some reason the card responds the command but ESDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The CMDTYP field of this register is used to initiate three special commands these are:

- Suspend: ESDHC does not monitor the content of the Suspend command response and therefore assumes that the commnand succeeds when issued. It then operates assuming the card bus has been released and that it is permissible to issue the next command using the DAT line. It is the responsibility of S/W to ch[illegible]

the Suspend command and send another command marked as Suspend to inform the ESDHC that a Suspend command was successfully issued. Refer to Suspend Resume for more details. After the end bit of command is sent, ESDHC de-asserts Read Wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the ESDHC will maintain its current state and the Host Driver shall restart the transfer by setting the Continue Request bit in the Protocol Control register.

- Resume: S/W re-starts the data transfer by restoring the registers saved before sending the Suspend Command and then sends the Resume Command. The ESDHC will check for a pending busy state before starting write transfers.
- Abort: If this command is set when executing a read transfer, ESDHC will stop reads to the buffer. If this command is set when executing a write transfer, ESDHC will stop driving the DAT line. After issuing the Abort command, the Host Driver should issue a software reset (Abort Transaction).

Command Transfer Type (ESDHCV2_XFERTYP) shows the summary of how register settings determine the type of data transfer.

Table 29-42. Transfer Type Register Setting for Various Transfer Types

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

Table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, in regards to the Response Type bits and the name of the response type.

Table 29-43. Relationship Between Parameters and the Name of the Response Type

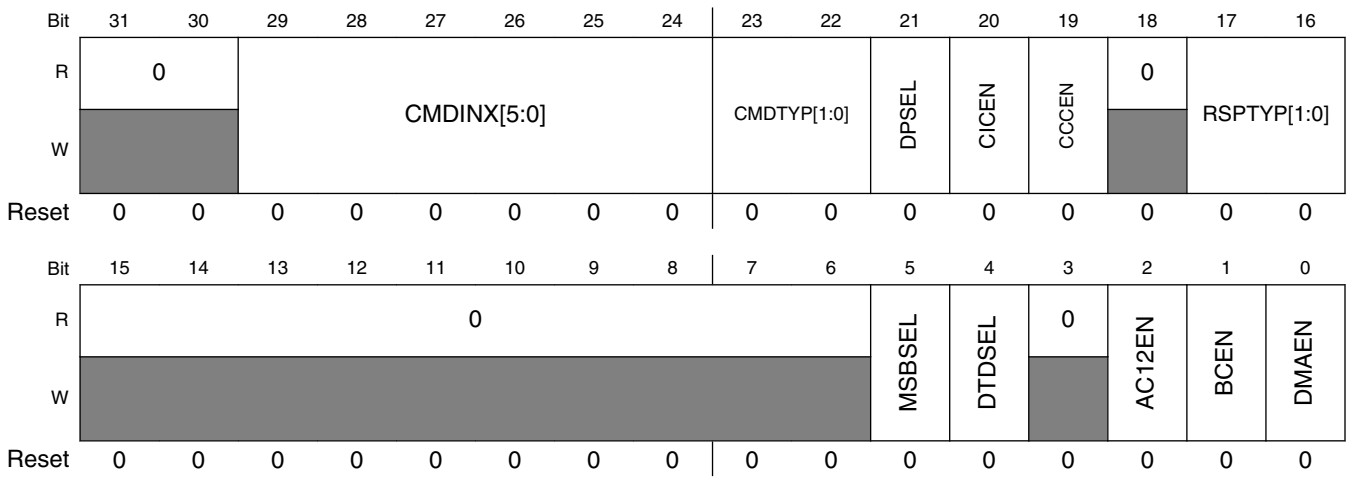
Response Type	Index Check Enable	CRC Check Enable	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3,R4
10	1	1	R1,R5,R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to indicate

that ESDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command will be used with R5b.

- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

Addresses: ESDHCV2-1_XFERTYP is 5000_4000h base + Ch offset = 5000_400Ch
ESDHCV2-2_XFERTYP is 5000_8000h base + Ch offset = 5000_800Ch
ESDHCV2-4_XFERTYP is 5002_4000h base + Ch offset = 5002_400Ch



ESDHCV2x_XFERTYP field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved
29–24 CMDINX[5:0]	Command Index: These bits shall be set to the command number that is specified in bits 45-40 of the Command-Format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23–22 CMDTYP[1:0]	Command Type: 11 Abort CMD12, CMD52 for writing I/O Abort in CCCR 10 Resume CMD52 for writing Function Select in CCCR 01 Suspend CMD52 for writing Bus Suspend in CCCR 00 Normal mode. Used for all other commands
21 DPSEL	Data Present Select: This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52). • Commands with no data transfer, but using the busy signal on DAT[0] line (R1b or R5b such as, CMD38) **NOTE:** In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. When the Write Protect switch is on, (that is, the WPSPL bit is active as '0'), any command with a write operation will be ignored. That is to say, when this bit is set, while the DTDSEL bit is 0, writes to the register Transfer Type are ignored.

Table continues on the next page...

ESDHCV2x_XFERTYP field descriptions (continued)

Field	Description
	1 Data Present 0 No Data Present
20 CICEN	Command Index Check Enable: If this bit is set to 1, the ESDHC will check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked. 1 Enable 0 Disable
19 CCCEN	Command CRC Check Enable: If this bit is set to 1, the ESDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. (Refer to RSPTYP[1:0] and Command Transfer Type (ESDHCV2_XFERTYP).) 1 Enable 0 Disable
18 Reserved	This read-only field is reserved and always has the value zero. Reserved
17–16 RSPTYP[1:0]	Response Type Select: 00 No Response 01 Response Length 136 10 Response Length 48 11 Response Length 48, check Busy after response
15–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 MSBSEL	Multi / Single Block Select: This bit enables multiple block DAT line data transfers. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (See Command Transfer Type (ESDHCV2_XFERTYP).) 1 Multiple Blocks 0 Single Block
4 DTDSEL	Data Transfer Direction Select: This bit defines the direction of DAT line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the ESDHC and is set to 0 for all other commands. 1 Read (Card to Host) 0 Write (Host to Card)
3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2 AC12EN	Auto CMD12 Enable:

Table continues on the next page...

ESDHCV2x_XFERTYP field descriptions (continued)

Field	Description
	Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the ESDHC will issue a CMD12 automatically when the last block transfer has completed. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the ESDHC will ignore this bit no matter if it is set or not. 1 Enable 0 Disable
1 BCEN	Block Count Enable: This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 1 Enable 0 Disable
0 DMAEN	DMA Enable: This bit enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the Host Driver sets the DPSEL bit of this register. Whether the Simple DMA, or the Advanced DMA, is active depends on the DMA Select field of the Protocol Control register. 1 Enable 0 Disable

29.7.5 Command Response 0 (ESDHCV2x_CMDRSP0)

This register is used to store part 0 of the response bits from the card.

Addresses: ESDHCV2-1_CMDRSP0 is 5000_4000h base + 10h offset = 5000_4010h
ESDHCV2-2_CMDRSP0 is 5000_8000h base + 10h offset = 5000_8010h
ESDHCV2-4_CMDRSP0 is 5002_4000h base + 10h offset = 5002_4010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

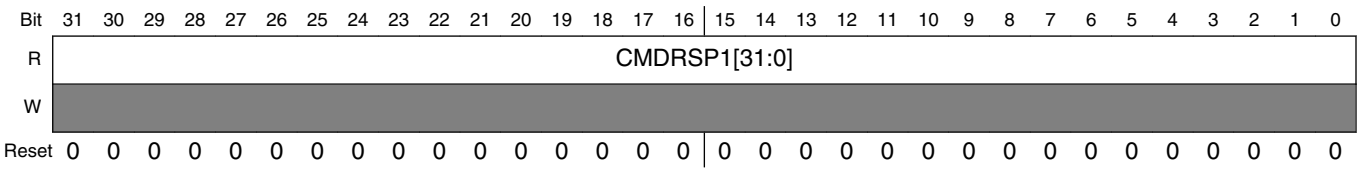
ESDHCV2x_CMDRSP0 field descriptions

Field	Description
31–0 CMDRSP0[31:0]	Command Response 0: Refer to Command Response 3 (ESDHCV2_CMDRSP3) for the mapping of command responses from the SD Bus to this register for each response type.

29.7.6 Command Response 1 (ESDHCV2x_CMDRSP1)

This register is used to store part 1 of the response bits from the card.

Addresses: ESDHCV2-1_CMDRSP1 is 5000_4000h base + 14h offset = 5000_4014h
ESDHCV2-2_CMDRSP1 is 5000_8000h base + 14h offset = 5000_8014h
ESDHCV2-4_CMDRSP1 is 5002_4000h base + 14h offset = 5002_4014h



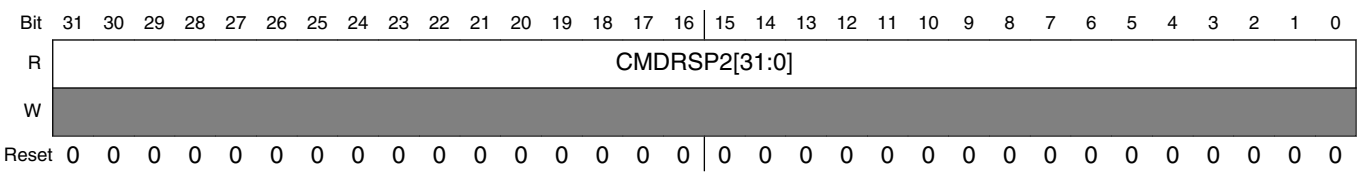
ESDHCV2x_CMDRSP1 field descriptions

Field	Description
31–0 CMDRSP1[31:0]	Command Response 1: Refer to Command Response 3 (ESDHCV2_CMDRSP3) for the mapping of command responses from the SD Bus to this register for each response type.

29.7.7 Command Response 2 (ESDHCV2x_CMDRSP2)

This register is used to store part 2 of the response bits from the card.

Addresses: ESDHCV2-1_CMDRSP2 is 5000_4000h base + 18h offset = 5000_4018h
ESDHCV2-2_CMDRSP2 is 5000_8000h base + 18h offset = 5000_8018h
ESDHCV2-4_CMDRSP2 is 5002_4000h base + 18h offset = 5002_4018h



ESDHCV2x_CMDRSP2 field descriptions

Field	Description
31–0 CMDRSP2[31:0]	Command Response 2: Refer to Command Response 3 (ESDHCV2_CMDRSP3) for the mapping of command responses from the SD Bus to this register for each response type.

29.7.8 Command Response 3 (ESDHCV2x_CMDRSP3)

This register is used to store part 3 of the response bits from the card.

Command Response 3 (ESDHCV2_CMDRSP3) describes the mapping of command responses from the SD Bus to Command Response registers for each response type. In the table, R[] refers to a bit range within the response data as transmitted on the SD Bus.

Table 29-48. Response Bit Definition for Each Response Type

Response Type	Meaning of Response	Response Field	Response Register
R1,R1b (normal response)	Card Status	R[39:8]	ESDHCV2_CMDRSP0
R1b (Auto CMD12 response)	Card Status for Auto CMD12	R[39:8]	ESDHCV2_CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{ESDHCV2_CMDRSP3[23:0], ESDHCV2_CMDRSP2, ESDHCV2_CMDRSP1, ESDHCV2_CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	ESDHCV2_CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	ESDHCV2_CMDRSP0
R5, R5b	SDIO response	R[39:8]	ESDHCV2_CMDRSP0
R6 (Publish RCA)	New Published RCA[31:16] and card status[15:0]	R[39:9]	ESDHCV2_CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the ESDHCV2_CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the ESDHCV2_CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the ESDHCV2_CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the ESDHC only stores part of the response data in the Command Response registers. This enables the Host Driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by the ESDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the ESDHC will check R[47:1], and if the response length is 136 the ESDHC will check R[119:1].

As ESDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, the ESDHC stores the Auto CMD12 response in the ESDHCV2_CMDRSP3 register. The CMD_wo_DAT response is stored in ESDHCV2_CMDRSP0. This allows the ESDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When the ESDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

Addresses: ESDHCV2-1_CMDRSP3 is 5000_4000h base + 1Ch offset = 5000_401Ch
ESDHCV2-2_CMDRSP3 is 5000_8000h base + 1Ch offset = 5000_801Ch
ESDHCV2-4_CMDRSP3 is 5002_4000h base + 1Ch offset = 5002_401Ch

ESDHCV2x_DATPORT field descriptions

Field	Description
31–0 DATCONT[31:0]	Data Content: The Buffer Data Port register is for 32-bit data access by the ARM platform or the external DMA. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s.

29.7.10 Present State (ESDHCV2x_PRSSTAT)

The Host Driver can get status of the ESDHC from this 32-bit read only register. It issues CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DAT lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands will be issued when Command Inhibit (DAT) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

NOTE

The reset value of Present State Register depend on testbench connectivity.

Addresses: ESDHCV2-1_PRSSTAT is 5000_4000h base + 24h offset = 5000_4024h
ESDHCV2-2_PRSSTAT is 5000_8000h base + 24h offset = 5000_8024h
ESDHCV2-4_PRSSTAT is 5002_4000h base + 24h offset = 5002_4024h

Field	Description
	DAT[5]: Data 5 line signal level DAT[4]: Data 4 line signal level DAT[3]: Data 3 line signal level DAT[2]: Data 2 line signal level DAT[1]: Data 1 line signal level DAT[0]: Data 0 line signal level
23 CLSL	CMD Line Signal Level: This status is used to check the CMD line level to recover from errors, and for debugging. The reset value is effected by the external pull-up/pull-down resistor, by default, the read value of this bit after reset is 1'b1, when the command line is pulled up.
22–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19 WPSPL	Write Protect Switch Pin Level: The Write Protect Switch is supported for memory and combo cards.This bit reflects the inverted value of the SD_WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the SD_WP pin is not used, it should be tied low, so that the reset value of this bit is high and write is enabled. 1 Write enabled (SD_WP=0) 0 Write protected (SD_WP=1)
18 CDPL	Card Detect Pin Level: This bit reflects the inverse value of the SD_CD# pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing As it must be debounced by software. A software reset does not effect this bit. A write to the Force Event Register does not effect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the SD_CD# pin (that is, when a card is inserted in the socket, it is 0 on the SD_CD# input, and consequently the CDPL reads 1.) 1 Card present (SD_CD#=0) 0 No card present (SD_CD#=1)
17 Reserved	This read-only field is reserved and always has the value zero. Reserved
16 CINS	Card Inserted: This bit indicates whether a card has been inserted. The ESDHC debounces this signal so that the Host Driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not effect this bit. The Software Reset For All in the System Control register does not effect this bit.A software reset does not effect this bit. 1 Card Inserted 0 Power on Reset or No Card
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

ESDHCV2x_PRSSTAT field descriptions (continued)

Field	Description
11 BREN	Buffer Read Enable: This status bit is used for non-DMA read transfers. The ESDHC may implement multiple buffers to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is high, valid data greater than the watermark level exist in the buffer. A change of this bit from 1 to 0 occurs when any read from the buffer is made. A change of this bit from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 1 Read enable 0 Read disable
10 BWEN	Buffer Write Enable: This status bit is used for non-DMA write transfers. The ESDHC can implement multiple buffers to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, valid data greater than the watermark level can be written to the buffer. A change of this bit from 1 to 0 occurs when any write to the buffer is made. A change of this bit from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled. 1 Write enable 0 Write disable
9 RTA	Read Transfer Active: This status bit is used for detecting completion of a read transfer. This bit is set for either of the following conditions: • After the end bit of the read command. • When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. A Transfer Complete interrupt is generated when this bit changes to 0. This bit is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from ESDHC internal buffer. • When all valid data blocks have been transferred from ESDHC internal buffer to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1. 1 Transferring data 0 No valid data
8 WTA	Write Transfer Active: This status bit indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the ESDHC. This bit is set in either of the following cases: • After the end bit of the write command. • When writing 1 to the Continue Request bit in the Protocol Control register to restart a write transfer. This bit is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple). • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request.

Table continues on the next page...

ESDHCV2x_PRSSTAT field descriptions (continued)

Field	Description
	During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining when to issue commands during Write Busy state. 1 Transferring data 0 No valid data
7 SDOFF	SD Clock Gated Off Internally: This status bit indicates that the SD Clock is internally gated off, because of buffer over/under-run or read pause without read wait assertion, or the driver has cleared SDCLKEN bit to stop the SD clock. This bit is for the Host Driver to debug data transaction on the SD bus. 1 SD Clock is gated off 0 SD Clock is active
6 PEROFF	ipg_perclk Gated Off Internally: This status bit indicates that the ipg_perclk is internally gated off. This bit is for the Host Driver to debug transaction on the SD bus. When INITA bit is set, ESDHC sending 80 clock cycles to the card, the SDCLKEN bit must be '1' to enable the output card clock, otherwise the ipg_perclk will never be gate off, so ipg_perclk and ipg_clk will be always active. 1 ipg_perclk is gated off 0 ipg_perclk is active
5 HCKOFF	hclk Gated Off Internally: This status bit indicates that the hclk is internally gated off. This bit is for the Host Driver to debug during a data transfer. 1 hclk is gated off 0 hclk is active
4 IPGOFF	ipg_clk Gated Off Internally: This status bit indicates that the ipg_clk is internally gated off. This bit is for the Host Driver to debug. 1 ipg_clk is gated off 0 ipg_clk is active
3 SDSTB	SD Clock Stable This status bit indicates that the internal card clock is stable. This bit is for the Host Driver to poll clock status when changing the clock frequency. It is recommended to clear SDCLKEN bit in System Control register to remove glitch on the card clock when the frequency is changing. 1 clock is stable 0 clock is changing frequency and not stable
2 DLA	Data Line Active This status bit indicates whether one of the DAT lines on the SD Bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD Bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This bit will be set in either of the following cases:

Table continues on the next page...

ESDHCV2x_PRSSTAT field descriptions (continued)

Field	Description
	• After the end bit of the read command. • When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. This bit will be cleared in either of the following cases: (1) When the end bit of the last data block is sent from the SD Bus to the ESDHC. (2) When the Read Wait state is stopped by a Suspend command and the DAT2 line is released. The ESDHC will wait at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), the ESDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait in order to use the suspend / resume function. This bit will remain 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD Bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This bit will be set in either of the following cases: • After the end bit of the write command. • When writing to 1 to the Continue Request bit in the Protocol Control register to continue a write transfer. This bit will be cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, the ESDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the ESDHC will assume the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and as a result of a Stop At Block Gap Request. 1 DAT Line Active 0 DAT Line Inactive
1 CDIHB	Command Inhibit (DAT): This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates that the ESDHC can issue the next SD/MMC Command. Commands with a busy signal belong to Command Inhibit (DAT) (for example, R1b, R5b type). Except in the case when the command busy is finished, changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE:** The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0. 1 Cannot issue command which uses the DAT line 0 Can issue command which uses the DAT line
0 CIHB	Command Inhibit (CMD): If this status bit is 0, it indicates that the CMD line is not in use and the ESDHC can issue a SD/MMC Command using the CMD line. This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the Command Inhibit (DAT) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If the ESDHC cannot issue the command because of a command conflict

Table continues on the next page...

ESDHCV2x_PRSSTAT field descriptions (continued)

Field	Description
	error (Refer to Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this bit will remain 1 and the Command Complete is not set. The Status of issuing an Auto CMD12 does not show on this bit. 1 Cannot issue command 0 Can issue command using only CMD line

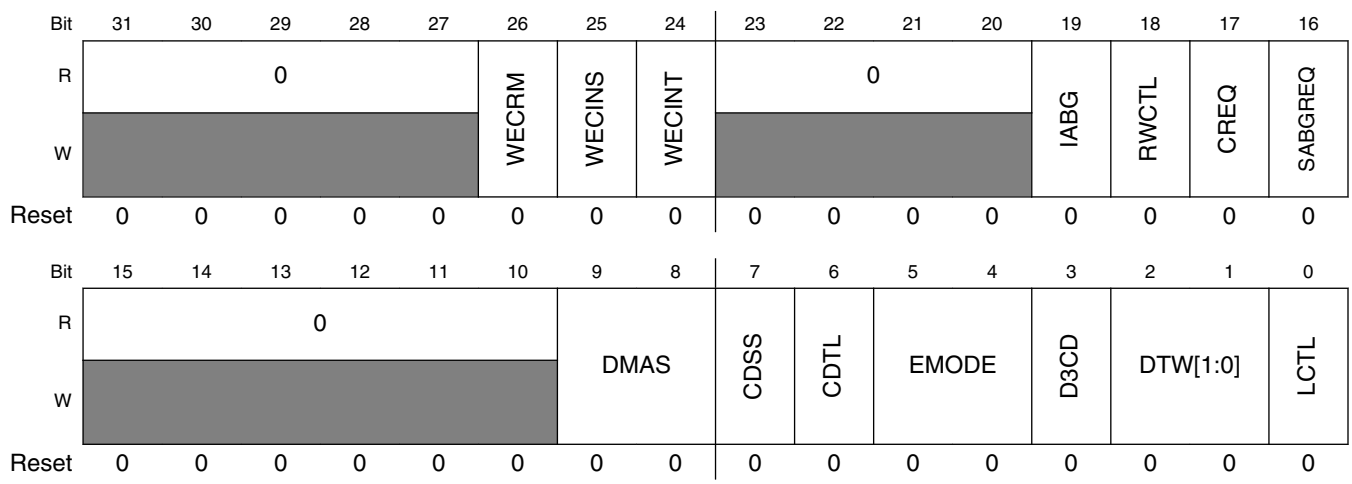
29.7.11 Protocol Control (ESDHCV2x_PROCTL)

There are three cases to restart the transfer after stop at the block gap. The appropriate case depends on whether ESDHC issues a Suspend command or the SD card accepts the Suspend command.

1. If the Host Driver does not issue a Suspend command, the Continue Request will be used to restart the transfer.
2. If the Host Driver issues a Suspend command and the SD card accepts it, a Resume command will be used to restart the transfer.
3. If the Host Driver issues a Suspend command and the SD card does not accept it, the Continue Request will be used to restart the transfer.

Any time Stop At Block Gap Request stops the data transfer, the Host Driver will wait for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the Host Driver will clear the Stop At Block Gap Request before or simultaneously.

Addresses: ESDHCV2-1_PROCTL is 5000_4000h base + 28h offset = 5000_4028h
ESDHCV2-2_PROCTL is 5000_8000h base + 28h offset = 5000_8028h
ESDHCV2-4_PROCTL is 5002_4000h base + 28h offset = 5002_4028h



ESDHCV2x_PROCTL field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26 WECRM	Wakeup Event Enable On SD Card Removal: This bit enables a wakeup event, through a Card Removal, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Removal Status and the ESDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the Card Removal Status and the ESDHC interrupt. 1 Enable 0 Disable
25 WECINS	Wakeup Event Enable On SD Card Insertion: This bit enables a wakeup event, through a Card Insertion, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Insertion Status and the ESDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the Card Insertion Status and the ESDHC interrupt. 1 Enable 0 Disable
24 WECINT	Wakeup Event Enable On Card Interrupt: This bit enables a wakeup event, through a Card Interrupt, in the Interrupt Status register. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the Card Interrupt Status and the ESDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the Card Interrupt Status and the ESDHC interrupt. 1 Enable 0 Disable
23–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19 IABG	Interrupt At Block Gap: This bit is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0 to avoid an inadvertent interrupt. When the Host Driver detects an SDIO card insertion, it sets this bit according to the CCCR of the card. 1 Enabled 0 Disabled
18 RWCTL	Read Wait Control: The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise the ESDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SDIO card insertion, it sets this bit according to the CCCR of the card. If the card does not support read wait, this bit will never be set to 1, otherwise DAT line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the ESDHC will stop the SD Clock to pause reading operation.

Table continues on the next page...

ESDHCV2x_PROCTL field descriptions (continued)

Field	Description
	1 Enable Read Wait Control, and assert Read Wait without stopping SD Clock at block gap when SABGREQ bit is set 0 Disable Read Wait Control, and stop SD Clock at block gap when SABGREQ bit is set
17 CREQ	Continue Request: This bit is used to restart a transaction which was stopped using the Stop At Block Gap Request. When a Suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit to 1 to restart the transfer. The ESDHC automatically clears this bit, therefore it is not necessary for the Host Driver to set this bit to 0. If both Stop At Block Gap Request and this bit are 1, the continue request is ignored. 1 Restart 0 No effect
16 SABGREQ	Stop At Block Gap Request: This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the Transfer Complete is set to 1, indicating a transfer completion, the Host Driver will leave this bit set to 1. Clearing both the Stop At Block Gap Request and Continue Request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The ESDHC will honor the Stop At Block Gap Request for write transfers, but for read transfers it requires that the SDIO card support Read Wait. Therefore, the Host Driver will not set this bit during read transfers unless the SDIO card supports Read Wait and has set the Read Wait Control to 1, otherwise the ESDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the Host Driver writes data to the Data Port register, the Host Driver will set this bit after all block data is written. If this bit is set to 1, the Host Driver will not write data to the Data Port register after a block is sent. Once this bit is set, the Host Driver will not clear this bit before the Transfer Complete bit in Interrupt Status Register is set, otherwise the ESDHCs behavior is undefined. This bit effects Read Transfer Active, Write Transfer Active, DAT Line Active and Command Inhibit (DAT) in the Present State register. 1 Stop 0 Transfer
15–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–8 DMAS	DMA Select: This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00 No DMA or Simple DMA is selected 01 ADMA1 is selected 10 ADMA2 is selected 11 reserved
7 CDSS	Card Detect Signal Selection: This bit selects the source for the card detection. 1 Card Detection Test Level is selected (for test purpose) 0 Card Detection Level is selected (for normal purpose)
6 CDTL	Card Detect Test Level: This is bit is enabled while the Card Detection Signal Selection is set to 1 and it indicates card insertion.

Table continues on the next page...

ESDHCV2x_PROCTL field descriptions (continued)

Field	Description
	1 Card Detect Test Level is 1, card inserted 0 Card Detect Test Level is 0, no card inserted
5–4 EMODE	Endian Mode: The ESDHC supports all four endian modes in data transfer. Refer to Data Buffer for more details. 00 Big Endian Mode 01 Half Word Big Endian Mode 10 Little Endian Mode 11 Reserved
3 D3CD	DAT3 as Card Detection Pin: If this bit is set, DAT3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DAT3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 may set the card into the SPI mode, which the ESDHC does not support. In case of SDIO application, if SD_CD signal is not multiplexed to ESDHC block, S/W should set D3CD bit. 1 DAT3 as Card Detection Pin 0 DAT3 does not monitor Card Insertion
2–1 DTW[1:0]	Data Transfer Width: This bit selects the data width of the SD bus for a data transfer. The Host Driver sets it to match the data width of the card. Possible Data transfer Width is 1-bit, 4-bits or 8-bits. 10 8-bit mode 01 4-bit mode 00 1-bit mode 11 Reserved
0 LCTL	LED Control: This bit, fully controlled by the Host Driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this bit can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the bit once before the first command is sufficient; it is not necessary to reset the bit between commands. 1 LED on 0 LED off

29.7.12 System Control (ESDHCV2x_SYSCTL)

Addresses: ESDHCV2-1_SYSCTL is 5000_4000h base + 2Ch offset = 5000_402Ch
ESDHCV2-2_SYSCTL is 5000_8000h base + 2Ch offset = 5000_802Ch
ESDHCV2-4_SYSCTL is 5002_4000h base + 2Ch offset = 5002_402Ch

ESDHCV2x_SYSCTL field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved
27 INITA	Initialization Active: When this bit is set, 80 SD-Clocks are sent to the card. After the 80 clocks are sent, this bit is self cleared. This bit is very useful during the card power-up period when 74 SD-Clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the CIHB and CDIHB bits in the Present State Register are set, writing 1 to this bit is ignored (that is, when command line or data lines are active, write to this bit is not allowed). On the other hand, when this bit is set, that is, during initialization active period, it is allowed to issue commands, and the command bit stream will appear on the CMD pad after all 80 clock cycles are completer. When this command ends, the driver can make sure that the 80 clock cycles are sent out, which is very useful when the driver needs to send 80 cycles to the card and does not want to wait until this bit is self cleared.
26 RSTD	Software Reset For DAT Line: Only part of the data circuit is reset. DMA circuit is also reset. The following registers and bits are cleared by this bit: • Data Port register • Buffer is cleared and initialized.Present State register • Buffer Read Enable • Buffer Write Enable • Read Transfer Active • Write Transfer Active • DAT Line Active • Command Inhibit (DAT) Protocol Control register • Continue Request

Table continues on the next page...

ESDHCV2x_SYSCTL field descriptions (continued)

Field	Description
	• Stop At Block Gap Request Interrupt Status register • Buffer Read Ready • Buffer Write Ready • DMA Interrupt • Block Gap Event • Transfer Complete 1 Reset 0 No Reset
25 RSTC	Software Reset For CMD Line: Only part of the command circuit is reset. The following registers and bits are cleared by this bit: • Present State register Command Inhibit (CMD) • Interrupt Status register Command Complete 1 Reset 0 No Reset
24 RSTA	Software Reset For ALL: This reset effects the entire Host Controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During its initialization, the Host Driver will set this bit to 1 to reset the ESDHC. The ESDHC will reset this bit to 0 when the capabilities registers are valid and the Host Driver can read them. Additional use of Software Reset For All does not affect the value of the Capabilities registers. After this bit is set, it is recommended that the Host Driver reset the external card and re-initialize it. b Reset 0 No Reset
23–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19–16 DTOCV	Data Timeout Counter Value: This value determines the interval by which DAT line timeouts are detected. Refer to the Data Timeout Error bit in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the base clock SDCLK value by this value. The Host Driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events. 1111 Reserved 1110 SDCLK x 2^{27} 0001 SDCLK x 2^{14} 0000 SDCLK x 2^{13}
15–8 SDCLKFS	SDCLK Frequency Select: This register is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this register holds the prescaler (this register) and divisor (next register) of the Base Clock Frequency register. Setting 00h bypasses the frequency prescaler of the SD Clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits.

Table continues on the next page...

ESDHCV2x_SYSCTL field descriptions (continued)

Field	Description
	The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this bit field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD Clock after reset is 375 kHz. According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD Clock frequency is 50 MHz and will never exceed this limit. Only the following settings are allowed: 0x80 Base clock divided by 256 0x40 Base clock divided by 128 0x20 Base clock divided by 64 0x10 Base clock divided by 32 0x08 Base clock divided by 16 0x04 Base clock divided by 8 0x02 Base clock divided by 4 0x01 Base clock divided by 2 0x00 Base clock (10 MHz-63 MHz)
7–4 DVS[3:0]	Divisor: This register is used to provide a more exact divisor to generate the desired SD clock frequency. **NOTE:** The divider can even support odd divisor without deterioration of duty cycle. The setting are as following: 0x0 Divisor by 1 0x1 Divisor by 2 0xe Divisor by 15 0xf Divisor by 16
3 SDCLKEN	SD Clock Enable The Host Controller will stop SDCLK when writing this bit to 0. SDCLK Frequency can be changed when this bit is 0. Then, the Host Controller will maintain the same clock frequency until SDCLK is stopped (Stop at SDCLK=0). If the Card Inserted in the Present State register is cleared, this bit should be cleared by the Host Driver to save power.
2 PEREN	Peripheral Clock Enable: If this bit is set, ipg_perclk will always be active and no automatic gating is applied. Thus the SDCLK is active except when auto gating-off during buffer danger (buffer about to over-run or under-run). When this bit is cleared, the ipg_perclk will be automatically off when there is no transaction on the SD bus. As this bit is only a feature enabling bit, clearing this bit does not stop SDCLK immediately. The ipg_perclk will be internally gated off, if none of the following factors are met: • The cmd part is reset, or • Data part is reset, or

Table continues on the next page...

ESDHCV2x_SYSCTL field descriptions (continued)

Field	Description
	• A soft reset, or • The cmd is about to send, or • Clock divisor is just updated, or • Continue request is just set, or • This bit is set, or • Card insertion is detected, or • Card removal is detected, or • Card external interrupt is detected, or • 80 clocks for initialization phase is ongoing 1 ipg_perclk will not be automatically gated off 0 ipg_perclk will be internally gated off
1 HCKEN	HCLK Enable: If this bit is set, hclk will always be active and no automatic gating is applied. When this bit is cleared, hclk will be automatically off when no data transfer is on the SD bus. 1 hclk will not be automatically gated off 0 hclk will be internally gated off
0 IPGEN	IPG Clock Enable: If this bit is set, ipg_clk will always be active and no automatic gating is applied. The ipg_clk will be internally gated off, if none of the following factors are met: • The cmd part is reset, or • Data part is reset, or • Soft reset, or • The cmd is about to send, or • Clock divisor is just updated, or • Continue request is just set, or • This bit is set, or • Card insertion is detected, or • Card removal is detected, or • Card external interrupt is detected, or • The ipg_perclk is not gated off **NOTE:** The ipg_clk will not be auto gated off if the ipg_perclk is not gated off. Clearing only this bit has no effect unless the PEREN bit is also cleared. 1 ipg_clk will not be automatically gated off 0 ipg_clk will be internally gated off

29.7.13 Interrupt Status (ESDHCV2x_IRQSTAT)

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. Before clearing the Card Interrupt, make sure that the card stops asserting the interrupt, that is, the Card Driver stops servicing the interrupt condition. Otherwise, the CINT bit will be asserted again.

Interrupt Status (ESDHCV2_IRQSTAT) below shows the relationship between the Command Timeout Error and the Command Complete.

Table 29-54. ESDHC Status for Command Timeout Error/Command Complete Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

Table below shows the relationship between the Transfer Complete and the Data Timeout Error.

Table 29-55. ESDHC Status for Data Timeout Error/Transfer Complete Bit Combinations

Transfer Complete	Data Timeout Error	Meaning of the Status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data Transfer Complete

Table below shows the relationship between the Command CRC Error and Command Timeout Error.

Table 29-56. ESDHC Status for Command CRC Error/Command Timeout Error Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	No error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

Addresses: ESDHCV2-1_IRQSTAT is 5000_4000h base + 30h offset = 5000_4030h
ESDHCV2-2_IRQSTAT is 5000_8000h base + 30h offset = 5000_8030h
ESDHCV2-4_IRQSTAT is 5002_4000h base + 30h offset = 5002_4030h

ESDHCV2x_IRQSTAT field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28 DMAE	DMA Error: Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. This error can be caused by either Simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. As any error corrupts the whole data block, the Host Driver will re-start the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 1 Error 0 No Error
27–25 Reserved	This read-only field is reserved and always has the value zero. Reserved
24 AC12E	Auto CMD12 Error: Occurs when detecting that one of the bits in the Auto CMD12 Error Status register has changed from 0 to 1. This bit is set to 1, not only when the errors in Auto CMD12 occur, but also when the Auto CMD12 is not executed due to the previous command error. 1 Error 0 No Error
23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22 DEBE	Data End Bit Error: Occurs either when detecting 0 at the end bit position of read data, which uses the DAT line, or at the end bit position of the CRC.

Table continues on the next page...

ESDHCV2x_IRQSTAT field descriptions (continued)

Field	Description
	1 Error 0 No Error
21 DCE	Data CRC Error: Occurs when detecting a CRC error when transferring read data, which uses the DAT line, or when detecting the Write CRC status having a value other than 010. 1 Error 0 No Error
20 DTOE	Data Timeout Error: Occurs when detecting one of following time-out conditions. • Busy time-out for R1b,R5b type • Busy time-out after Write CRC status • Read Data time-out. 1 Time out 0 No Error
19 CIE	Command Index Error: Occurs if a Command Index error occurs in the command response. 1 Error 0 No Error
18 CEBE	Command End Bit Error: Occurs when detecting that the end bit of a command response is 0. 1 End Bit Error Generated 0 No Error
17 CCE	Command CRC Error: Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this bit is set when detecting a CRC error in the command response. • The ESDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the ESDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then the ESDHC will abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error will also be set to 1 to distinguish CMD line conflict. 1 CRC Error Generated. 0 No Error
16 CTOE	Command Timeout Error: Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the ESDHC detects a CMD line conflict, in which case a Command CRC Error will also be set (as shown in Interrupt Status (ESDHCV2_IRQSTAT)), this bit will be set without waiting for 64 SDCLK cycles. Because the command will be aborted by the ESDHC. 1 Time out 0 No Error

Table continues on the next page...

ESDHCV2x_IRQSTAT field descriptions (continued)

Field	Description
15–9 Reserved	This read-only field is reserved and always has the value zero. Reserved
8 CINT	Card Interrupt: This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the ESDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the Host System. Writing 1 to this bit will clear it, but as the interrupt factor from the SDIO card is not clear, this bit is set again. In order to clear this bit, reset the interrupt factor from the external card and then clear this bit. When this status bit is set, and the Host Driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be cleared to deactivate the interrupt signal to the Host System. After completion of the card interrupt service, (it should reset the interrupt factors in the SDIO card and the interrupt signal should not be asserted), write 1 to clear this bit, enable the Card Interrupt Signal Enable and start sampling the interrupt signal again. 1 Generate Card Interrupt 0 No Card Interrupt
7 CRM	Card Removal: This status bit is set if the Card Inserted bit (PRSSTNT[CINS]) changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of CINS should be confirmed, because the card state may possibly change when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. In order to leave it cleared, clear the Card Removal Status Enable bit IRQSTATEN[CRMSEN]in Interrupt Status Enable register. 1 Card removed 0 Card state unstable or inserted
6 CINS	Card Insertion: This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if a card is inserted. In order to leave it cleared, clear the Card Inserted Status Enable bit in Interrupt Status Enable register. 1 Card inserted 0 Card state unstable or removed
5 BRR	Buffer Read Ready: This status bit is set if the Buffer Read Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Read Enable bit in the Present State register for additional information. 1 Ready to read buffer 0 Not ready to read buffer
4 BWR	Buffer Write Ready: This status bit is set if the Buffer Write Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Write Enable bit in the Present State register for additional information. 1 Ready to write buffer: 0 Not ready to write buffer

Table continues on the next page...

ESDHCV2x_IRQSTAT field descriptions (continued)

Field	Description
3 DINT	DMA Interrupt: Occurs only when the internal DMA finishes the data transfer successfully. When errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set. Either Simple DMA or ADMA finishes data transferring, this bit will be set. 1 DMA Interrupt is generated 0 No DMA Interrupt
2 BGE	Block Gap Event: If the Stop At Block Gap Request bit in the Protocol Control register is set, this bit is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this bit is not set to 1. In the case of a Read Transaction: This bit is set at the falling edge of the DAT Line Active Status (When the transaction is stopped at SD Bus timing). The Read Wait must be supported in order to use this function. In the case of Write Transaction: This bit is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 1 Transaction stopped at block gap 0 No block gap event
1 TC	Transfer Complete: This bit is set when a read or write transfer is completed. In the case of a Read Transaction: This bit is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request bit in the Protocol Control register (after valid data has been read to the Host System). In the case of a Write Transaction: This bit is set at the falling edge of the DAT Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request bit in the Protocol Control register, and the data transfers are completed. (After valid data is written to the SD card and the busy signal released.) 1 Transfer complete 0 Transfer not complete
0 CC	Command Complete: This bit is set when you receive the end bit of the command response (except Auto CMD12). Refer to the Command Inhibit (CMD) in the Present State register. 1 Command complete 0 Command not complete

29.7.14 Interrupt Status Enable (ESDHCV2x_IRQSTATEN)

Setting the bits in this register to 1 enables the corresponding Interrupt Status to be set by the specified event. If any bit is cleared, the corresponding Interrupt Status bit is also cleared (that is, when the bit in this register is cleared, the corresponding bit in Interrupt Status Register is always 0).

- Depending on IABG bit setting, ESDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the Card Interrupt, asserted from the card, to the time the Host System is informed.
- To detect a CMD line conflict, the Host Driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

Addresses: ESDHCV2-1_IRQSTATEN is 5000_4000h base + 34h offset = 5000_4034h
ESDHCV2-2_IRQSTATEN is 5000_8000h base + 34h offset = 5000_8034h
ESDHCV2-4_IRQSTATEN is 5002_4000h base + 34h offset = 5002_4034h

29.7.15 Interrupt Signal Enable (ESDHCV2x_IRQSIGEN)

This register is used to select which interrupt status is indicated to the Host System as the interrupt. These status bits all share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

Addresses: ESDHCV2-1_IRQSIGEN is 5000_4000h base + 38h offset = 5000_4038h
ESDHCV2-2_IRQSIGEN is 5000_8000h base + 38h offset = 5000_8038h

29.7.16 Auto CMD12 Status (ESDHCV2x_AUTOC12ERR)

When the Auto CMD12 Error Status bit in the Status register is set, the Host Driver will check this register to identify what kind of error the Auto CMD12 indicated. This register is valid only when the Auto CMD12 Error status bit is set.

Table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 29-60. Relationship Between Command CRC Error and Command Timeout Error for Auto CMD12

Auto CMD12 CRC Error	Auto CMD12 Timeout Error	Type of Error
0	0	No Error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

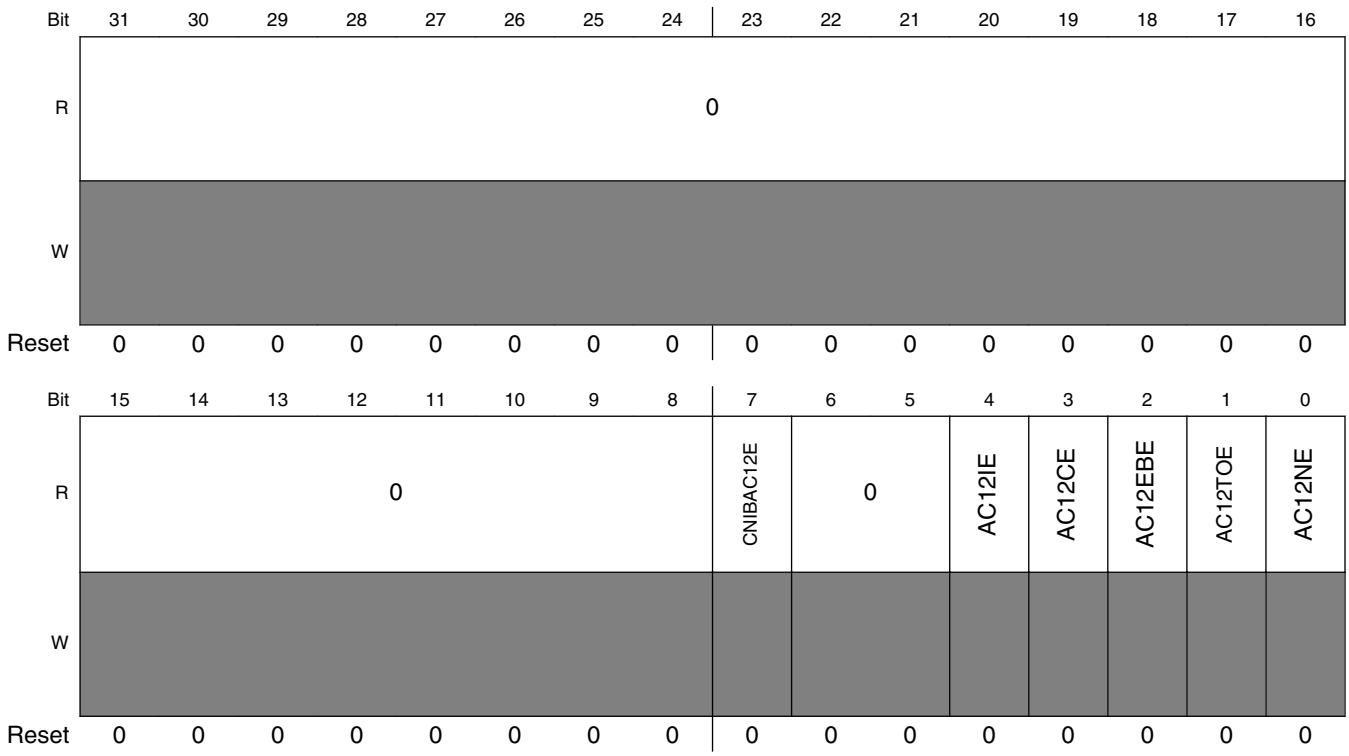
1. When the ESDHC is going to issue an Auto CMD12.
2. Set bit 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
3. Set bit 0 to 0 if the Auto CMD12 is issued
4. At the end bit of an Auto CMD12 response:
   - Check errors correspond to bits 1-4.

- Set bits 1-4 corresponding to detected errors.
- Clear bits 1-4 corresponding to detected errors

5. Before reading the Auto CMD12 Error Status bit 7:
   - Set bit 7 to 1 if there is a command that cannot be issued
   - Clear bit 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, bit 7 will be sampled when the driver is not writing to the Command register. It is suggested to read this register only when the AC12E bit in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error bits (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Addresses: ESDHCV2-1_AUTOC12ERR is 5000_4000h base + 3Ch offset = 5000_403Ch
ESDHCV2-2_AUTOC12ERR is 5000_8000h base + 3Ch offset = 5000_803Ch
ESDHCV2-4_AUTOC12ERR is 5002_4000h base + 3Ch offset = 5002_403Ch



ESDHCV2x_AUTOC12ERR field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 CNIBAC12E	Command Not Issued By Auto CMD12 Error: Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register.

Table continues on the next page...

ESDHCV2x_AUTOC12ERR field descriptions (continued)

Field	Description
	1 Not Issued 0 No error
6–5 Reserved	This read-only field is reserved and always has the value zero. Reserved
4 AC12IE	Auto CMD12 Index Error: Occurs if the Command Index error occurs in response to a command. 1 Error, the CMD index in response is not CMD12 0 No error
3 AC12CE	Auto CMD12 CRC Error: Occurs when detecting a CRC error in the command response. 1 CRC Error Met in Auto CMD12 Response 0 No CRC error
2 AC12EBE	Auto CMD12 End Bit Error: Occurs when detecting that the end bit of command response is 0 which should be 1. 1 End Bit Error Generated 0 No error
1 AC12TOE	Auto CMD12 Timeout Error: Occurs if no response is returned within 64 SDCLK cycles from the end bit of the command. If this bit is set to1, the other error status bits (2-4) have no meaning. 1 Time out 0 No error
0 AC12NE	Auto CMD12 Not Executed: If memory multiple block data transfer is not started, due to a command error, this bit is not set because it is not necessary to issue an Auto CMD12. Setting this bit to 1 means the ESDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (1-4) have no meaning. 1 Not executed 0 Executed

29.7.17 Host Controller Capabilities (ESDHCV2x_HOSTCAPBLT)

This register provides the Host Driver with information specific to the ESDHC implementation. The value in this register is the power-on-reset value, and does not change with a software reset. Any write to this register is ignored.

Addresses: ESDHCV2-1_HOSTCAPBLT is 5000_4000h base + 40h offset = 5000_4040h
ESDHCV2-2_HOSTCAPBLT is 5000_8000h base + 40h offset = 5000_8040h
ESDHCV2-4_HOSTCAPBLT is 5002_4000h base + 40h offset = 5002_4040h

24 VS33	Voltage Support 3.3V: This bit depends on the Host System ability. 1 3.3V supported 0 3.3V not supported

Table continues on the next page...

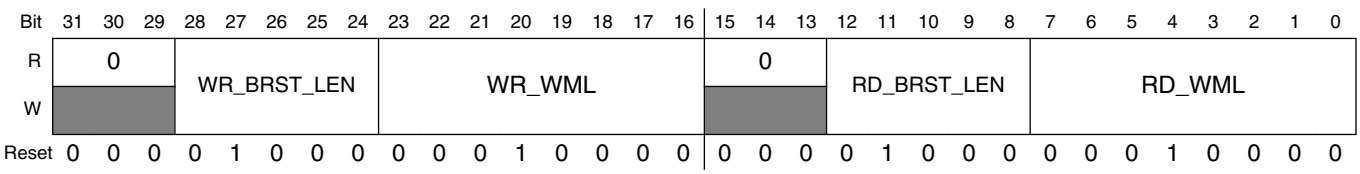
ESDHCV2x_HOSTCAPBLT field descriptions (continued)

Field	Description
23 SRS	Suspend / Resume Support: This bit indicates whether the ESDHC supports Suspend / Resume functionality. If this bit is 0, the Suspend and Resume mechanism, as well as the Read Wait, are not supported, and the Host Driver will not issue either Suspend or Resume commands. 1 Supported 0 Not supported
22 DMAS	DMA Support: This bit indicates whether the ESDHC is capable of using the internal DMA to transfer data between system memory and the data buffer directly. 1 DMA Supported 0 DMA not supported
21 HSS	High Speed Support: This bit indicates whether the ESDHC supports High Speed mode and the Host System can supply a SD Clock frequency from 25 MHz to 50 MHz. 1 High Speed Supported 0 High Speed Not Supported
20 ADMAS	ADMA Support: This bit indicates whether the ESDHC supports the ADMA feature. 1 Advanced DMA Supported 0 Advanced DMA Not supported
19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18–16 MBL[2:0]	Max Block Length: This value indicates the maximum block size that the Host Driver can read and write to the buffer in the ESDHC. The buffer will transfer block size without wait cycles. 000 512 bytes 001 1024 bytes 010 2048 bytes 011 4096 bytes
15–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

29.7.18 Watermark Level (ESDHCV2x_WML)

Both write and read watermark levels (FIFO threshold) are configurable. There value can range from 1 to 128 words. Both write and read burst lengths are also configurable. There value can range from 1 to 31 words.

Addresses: ESDHCV2-1_WML is 5000_4000h base + 44h offset = 5000_4044h
ESDHCV2-2_WML is 5000_8000h base + 44h offset = 5000_8044h
ESDHCV2-4_WML is 5002_4000h base + 44h offset = 5002_4044h



ESDHCV2x_WML field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28–24 WR_BRST_LEN	Write Burst Length:[1] The number of words the ESDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (that is, it is not able to clear this field).
23–16 WR_WML	Write Watermark Level: The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12–8 RD_BRST_LEN	Read Burst Length:[2] The number of words the ESDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (that is, it is not able to clear this field.
7–0 RD_WML	Read Watermark Level: The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.

1. Due to system restriction, the actual burst length may not exceed 16.
2. Due to system restriction, the actual burst length may not exceed 16.

29.7.19 Force Event (ESDHCV2x_FEVT)

The Force Event Register is not a physically implemented register. Rather, it is an address at which the Interrupt Status Register can be written if the corresponding bit of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register sets the corresponding bit of Interrupt Status Register. A read from this register always results in 0's. In order to change the corresponding status bits in the Interrupt Status Register, set IPGEN bit in System Control Register so that ipg_clk is always active.

Forcing a card interrupt will generate a short pulse on the DAT[1] line, and the driver will treat this interrupt as a normal interrupt. The interrupt service routine will skip polling the card interrupt factor as the interrupt is self cleared.

Addresses: ESDHCV2-1_FEVT is 5000_4000h base + 50h offset = 5000_4050h
ESDHCV2-2_FEVT is 5000_8000h base + 50h offset = 5000_8050h
ESDHCV2-4_FEVT is 5002_4000h base + 50h offset = 5002_4050h

29.7.20 ADMA Error Status Register (ESDHCV2x_ADMAES)

When an ADMA Error Interrupt occurrs, the ADMA Error States field (ADMAES) in this register holds the ADMA state and the ADMA System Address register (ADSADDR) holds the address of the error descriptor.

To recover from this error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address
- ST_CADR: This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address

In case of a write operation, the Host Driver should use ACMD22 command (see field descriptions table) to get the number of the written block, because unwritten data may exist in the Host Controller.

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The Host Driver can distinguish this error by reading the Valid bit of the error descriptor.

Table 29-65. ADMA Error State Coding

D01-D00	ADMA Error State (when error has occurred)	Contents of ADMA System Address Register
00	ST_STOP (Stop DMA)	Holds the address of the next executable Descriptor command
01	ST_FDS (Fetch Descriptor)	Holds the valid Descriptor address

Field	Description
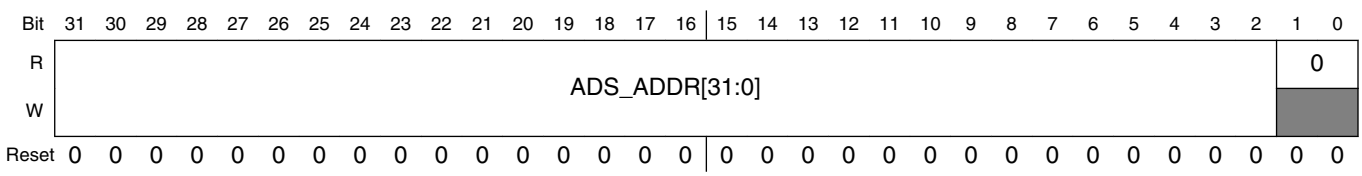
	• While the Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length • Total data length can not be divided by the block length 1 Error 0 No Error
1–0 ADMAES	ADMA Error State (when ADMA Error is occurred.): This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. Refer to ADMA Error Status Register (ESDHCV2_ADMAES) for more details.

29.7.21 ADMA System Address (ESDHCV2x_ADSADDR)

This register contains the physical system memory address used for ADMA transfers.

Addresses: ESDHCV2-1_ADSADDR is 5000_4000h base + 58h offset = 5000_4058h
ESDHCV2-2_ADSADDR is 5000_8000h base + 58h offset = 5000_8058h
ESDHCV2-4_ADSADDR is 5002_4000h base + 58h offset = 5002_4058h



ESDHCV2x_ADSADDR field descriptions

Field	Description
31–2 ADS_ ADDR[31:0]	ADMA System Address: This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the Host Driver will set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register will hold the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned. As this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so this register value cannot be changed when the TC bit is set. Such restriction is also listed in Software Restrictions.
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

29.7.22 Vendor Specific Register (ESDHCV2x_VENDOR)

This register contains the vendor specific control/status register.

Addresses: ESDHCV2-1_VENDOR is 5000_4000h base + C0h offset = 5000_40C0h
ESDHCV2-2_VENDOR is 5000_8000h base + C0h offset = 5000_80C0h
ESDHCV2-4_VENDOR is 5002_4000h base + C0h offset = 5002_40C0h

Chapter 30
Enhanced Secured Digital Host Controller (eSDHCv3)

30.1 Overview

The Enhanced Secured Digital Host Controller Version 3 (ESDHCV3, referred to as ESDHC hereafter) provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in Figure 30-1. The ESDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards. It handles the SD/SDIO/MMC protocols at the transmission level.

Two versions of the ESDHC block are utilized in the i.MX53 SoC: Version 2 and Version 3 (ESDHCV2 and ESDHCV3). There are three instances of the block ESDHCV2, and one instance of the block ESDHCV3. The text will use the designation ESDHC when referring to features that are common to both.

The types of cards supported by the ESDHC are described briefly as follows:

The Multi Media Card (MMC) is a universal low cost data storage and communication media that is designed to cover a wide area of applications including mobile video and gaming. Old MMC cards are based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into Memory card, I/O card and Combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O

card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, Figure 30-1 does not show cards with reduced size or mini cards.

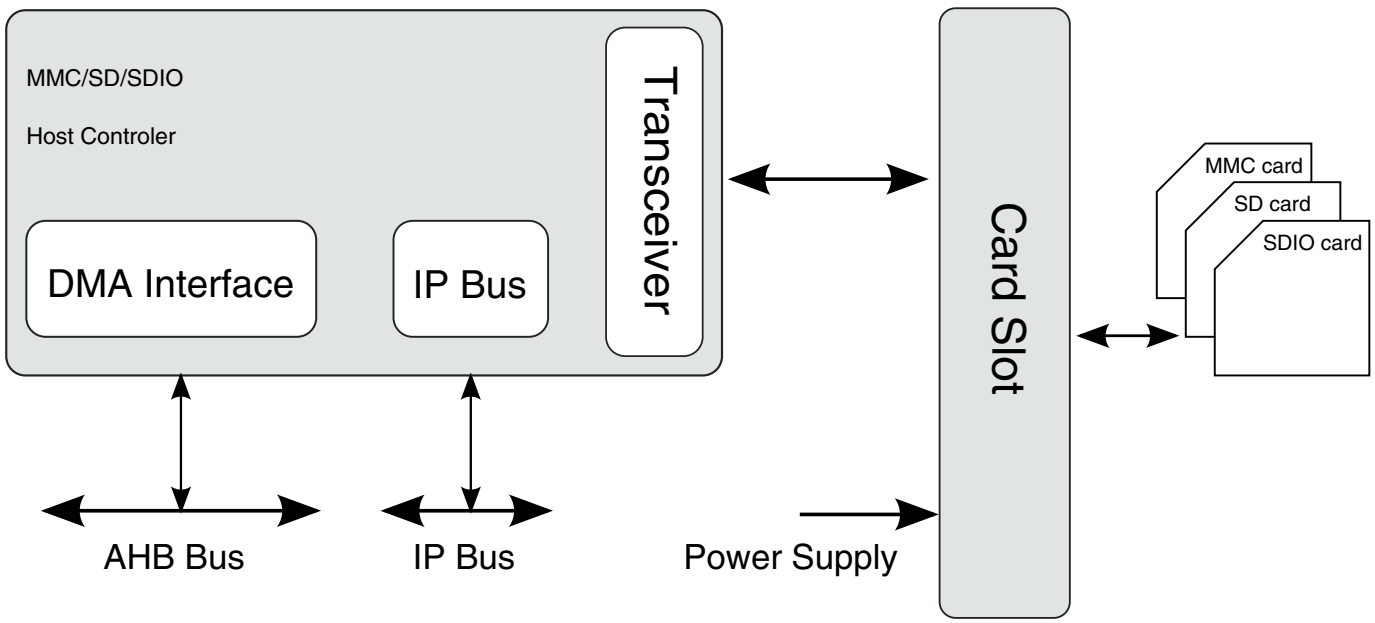

Figure 30-1. System Connection of the ESDHC

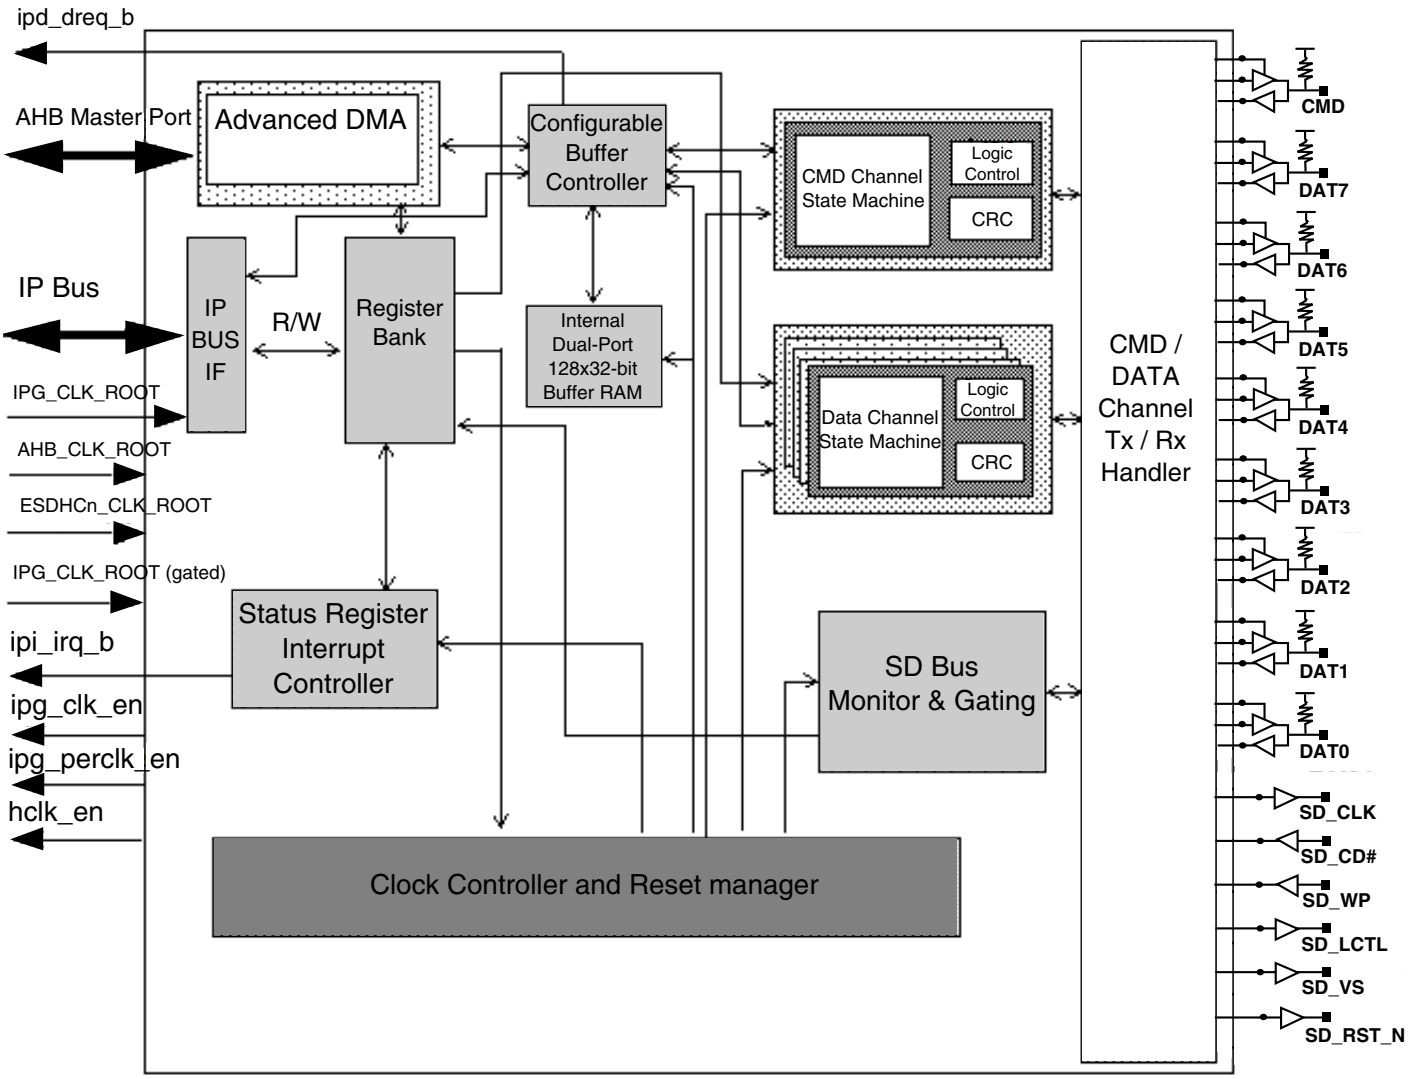

Figure 30-2. enhanced Secure Digital Host Controller Block Diagram

30.1.1 Features

The features of the ESDHC include the following:

- Conforms to the SD Host Controller Standard Specification version 2.0 including Test Event register support
- Compatible with the MMC System Specification version 4.2/4.3/4.4
- Compatible with the SD Memory Card Specification version 2.0 and supports the High Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards

- Card bus clock frequency up to 52 MHz
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes devices
  - Up to 200 Mbps of data transfer for SD/SDIO cards using 4 parallel data lines
  - Up to 416 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR (Single Data Rate) mode
  - Up to 832 Mbps of data transfer for MMC cards using 8 parallel data lines in DDR (Dual Data Rate) mode
- Supports Single Block, Multi Block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal and external DMA capabilities
- Supports Advanced DMA to perform linked memory access

30.1.2 Modes and Operations

30.1.2.1 Data transfer Modes

The ESDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification Mode (up to 400 kHz)
- MMC full speed mode (up to 20 MHz)
- MMC high speed mode (up to 52 MHz)
- MMC DDR mode (up to 52MHz, sampled on both clock edges)
- SD/SDIO full speed mode (up to 25 MHz)
- SD/SDIO high speed mode (up to 50 MHz)

30.2 External Signals

30.2.1 Signals Overview

The ESDHC has 15 associate I/O signals.

- The SD_CLK is an internally generated clock used to drive the MMC, SD, SDIO cards.
- The CMD I/O is used to send commands and receive responses to/from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the ESDHC and the card.
- The SD_CD# and SD_WP are card detection and write protection signals directly routed from the socket. A low on SD_CD# means that a card is inserted and a high on SD_WP means that the write protect switch is active.
- SD_OD is an output signal generated in SoC level outside ESDHC and is used to select the external open drain resistor.
- SD_LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.
- SD_RST_N is an output signal used to reset MMC card. This should be supported by card.

SD_CD#, SD_WP, SD_OD, SD_LCTL and SD_RST_N are all optional for system implementation. If the ESDHC is desired to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.

30.2.2 Ports Table

Table 30-1 shows the signal properties of the I/Os.

Table 30-1. Properties of I/O Signals

Name	Port	Function	Reset State	Pull up
SD_CLK	O	Clock for MMC/SD/SDIO card	0	N/A
SD_CMD	I/O	CMD line connect to card	1	Pull up
SD_DAT7	I/O	DAT7 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT6	I/O	DAT6 line in 8-bit mode Not used in other modes	1	Pull up

Table continues on the next page...

Table 30-1. Properties of I/O Signals (continued)

Name	Port	Function	Reset State	Pull up
SD_DAT5	I/O	DAT5 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT4	I/O	DAT4 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT3	I/O	DAT3 line in 4/8-bit mode or configured as card detection pin May be configured as card detection pin in 1-bit mode	0	Should be pull-up/pull-down configurable as this port may be used for card detection
SD_DAT2	I/O	DAT2 line or Read Wait in 4-bit mode Read Wait in 1-bit mode	1	Pull up
SD_DAT1	I/O	DAT1 line in 4/8-bit mode Also used to detect interrupt in 1/4-bit mode	1	Pull up
SD_DAT0	I/O	DAT0 line in all modes Also used to detect busy state	1	Pull up
SD_CD#	I	Card detection pin If not used tie high	N/A	N/A
SD_WP	I	Card write protect detect If not used tie low	N/A	N/A
SD_OD	O	Open drain select (not generated within the ESDHC). Optional output	N/A	N/A
SD_LCTL	O	LED control used to drive an external LED Active high Fully controlled by the driver Optional output	0	N/A
SD_RST_N	O	Card hardware reset signal, active LOW	1	N/A

30.3 Functional Description

The following sections provide a brief functional description of the major system blocks, including the Data Buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock & reset manager and clock generator.

30.3.1 Data Buffer

The ESDHC uses one configurable data buffer, so that data can be transferred between the system bus (IP Bus or AHB Bus) and the SD card, with an optimized manner to maximize throughput between the two clock domains (that is, the IP peripheral clock, and the master clock). See the table below for illustration of the buffer scheme. The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable, and can be any number from 1 to 128 words. The burst lengths for read and write are also configurable, and can be any number from 1 to 31 words.

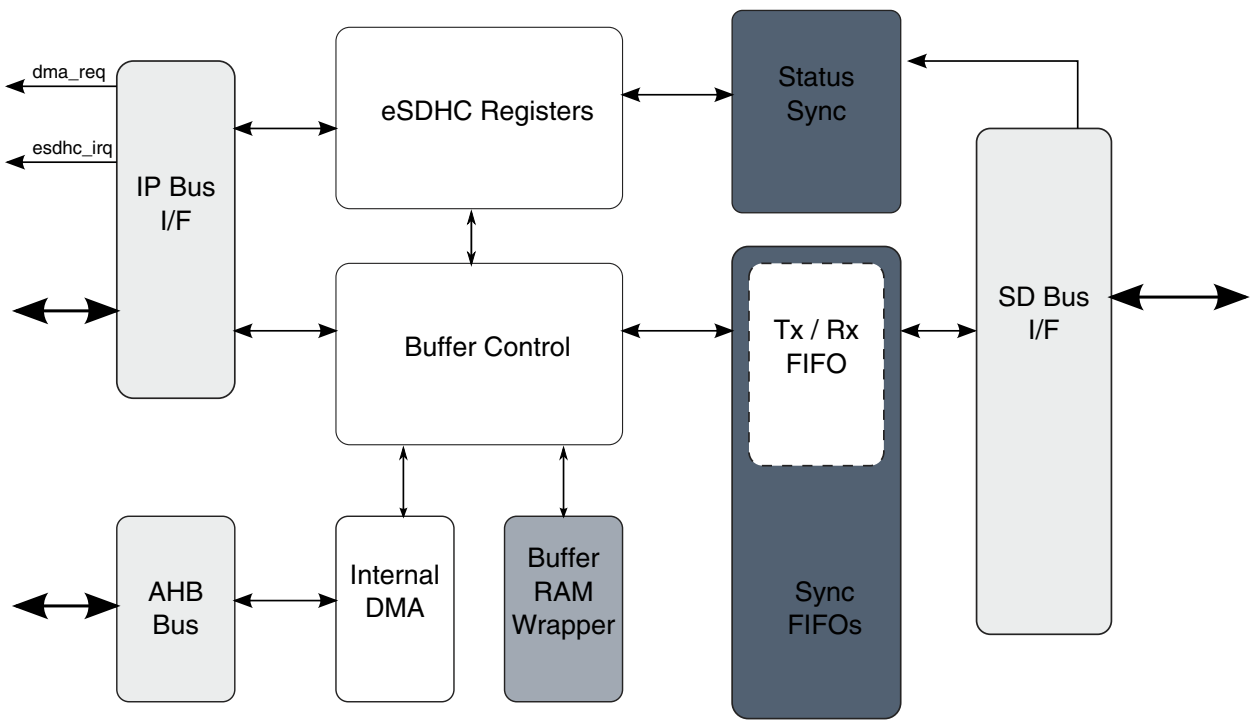

Figure 30-3. ESDHC Buffer Scheme

There are 3 transfer modes to access the data buffer:

- ARM platform polling mode:
  - For a host read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, then by polling the BRR bit the Host Driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar.
- External DMA mode:
  - For a read operation, when there are more words received in the buffer than the amount set in the RD_WML register, a DMA request is sent out to inform the external DMA to fetch the data. The request will be immediately de-asserted

when there is an access on the Buffer Data Port register. If the number of words in the buffer after the current burst meets or exceeds RD_WML value, then the DMA request is asserted again. For instance, if there are twice as many words in the buffer than the RD_WML value, there are two successive DMA requests with only one cycle of de-assertion between. The write operation is similar.

NOTE

Data buffer accesses by the ARM platform polling mode and external DMA mode both use the IP Bus. In these mode, if the external DMA is enabled, an external DMA request is sent out every time the buffer is ready.

- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus. For internal DMA access mode, the external DMA request will never be sent out.

    For a read operation, when there are more words in the buffer than the amount set in the RD_WML register, the internal DMA starts fetching data over the AHB bus. Except INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

1. Burst length configured in the burst length field of the Watermark Level register
2. Watermark Level boundary
3. Block size boundary
4. Data boundary configured in the current descriptor (if the ADMA is active)
5. 1 Kbyte address boundary defined in the AHB protocol

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actually byte order is swapped inside the buffer, according to the endian mode configured by software. See Figure 29-4 and Figure 29-5. For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, byte order is swapped before the data is stored into the buffer.

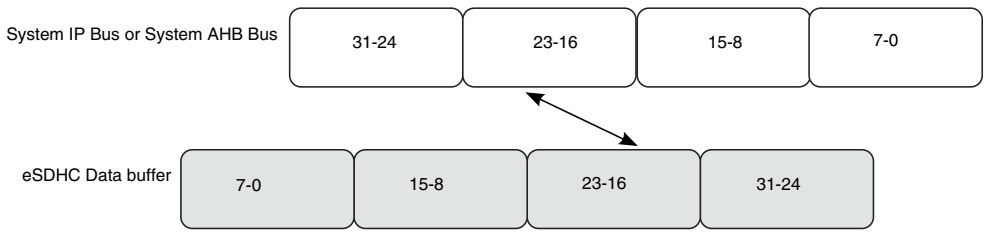

Figure 30-4. Data Swap between System Bus and ESDHC Data Buffer in Byte Little Endian Mode

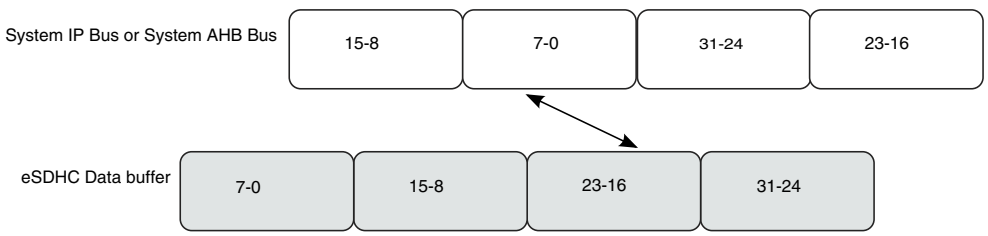

Figure 30-5. Data Swap between System Bus and ESDHC Data Buffer in Half Word Big Endian Mode

30.3.1.1 Write Operation Sequence

There are three ways to write data into the buffer when the user transfers data to the card:

1. By using external DMA through the ESDHC DMA request signal.
2. By processor core polling through the BWR bit in Interrupt Status register (interrupt or polling).
3. By using the internal DMA.

When the internal DMA is not used, (i.e. the DMAEN bit in the Transfer Type register is not set when the command is sent), the ESDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR_WML register, and is ready for receiving new data. At the same time, the ESDHC would set the BWR bit. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the ESDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the ESDHC will abort the data transfer and abandon the current block. The Host Driver should read the contents of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi block mode, the ESDHC will not automatically send CMD12, even though the

AC12EN bit in the Transfer Type register is set. The Host Driver shall send CMD12 in this scenario and re-start the write operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started after error recovery.

The ESDHC will not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the Host System does not write data in time, the ESDHC will stop the SD_CLK to avoid the data buffer under-run situation.

30.3.1.2 Read Operation Sequence

There are three ways to read data from the buffer when the user transfers data from the card:

1. By using the external DMA through the ESDHC DMA request signal
2. By processor core polling through the BRR bit in Interrupt Status register (interrupt or polling)
3. By using the internal DMA

When internal DMA is not used (i.e. DMAEN bit in Transfer Type register is not set when the command is sent), the ESDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register (that is, available and ready for system fetching data). At the same time, the ESDHC would set the BRR bit. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the ESDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the ESDHC will abort the data transfer and abandon the current block. The Host Driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi block mode, the ESDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver shall send CMD12 in this scenario and re-start the read operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started after error recovery.

For any read transfer mode, the ESDHC will not start data transmission until the number of words set in the RD_WML register are in the buffer. If the buffer is full and the Host System does not read data in time, the ESDHC will stop the SD_CLK to avoid the data buffer over-run situation.

30.3.1.3 Data Buffer and Block Size

The user needs to know the buffer size, for the buffer operation during a data transfer, to utilize it in the most optimized way. In the ESDHC, the only data buffer can hold up to 128 words (32-bit), and the watermark levels for write and read can be configured respectively. For both read and write, the watermark level can be from 1 word to the maximum of 128 words. For both read and write, the burst length, can be from 1 word to the maximum of 31 words. The Host Driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length may be set to any value between 1 and 4096 bytes inclusive which satisfies the requirements of the external card. The only restriction is from the external card. It might not support that large of a block or it does not support a partial block access (which is not the integer times of 512 bytes).

For block size not times of 4, that is, not word aligned, ESDHC requires stuff bytes at the end of each block, because ESDHC treats each block individually. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write two times for each block. For each block, the ending byte will be abandoned by ESDHC because it only sends 7 bytes to the card and picks data from the following system write, making a total of 24 beats of write access.

30.3.1.4 Dividing Large Data Transfer

This SDIO command CMD53 definition, limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the Host Driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See figure below for an example showing the dividing of large data transfers. Assuming a kind of WLAN SDIO card only supports block size up to 64 bytes. Although the ESDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than64 bytes, so the data must be divided (see example below).

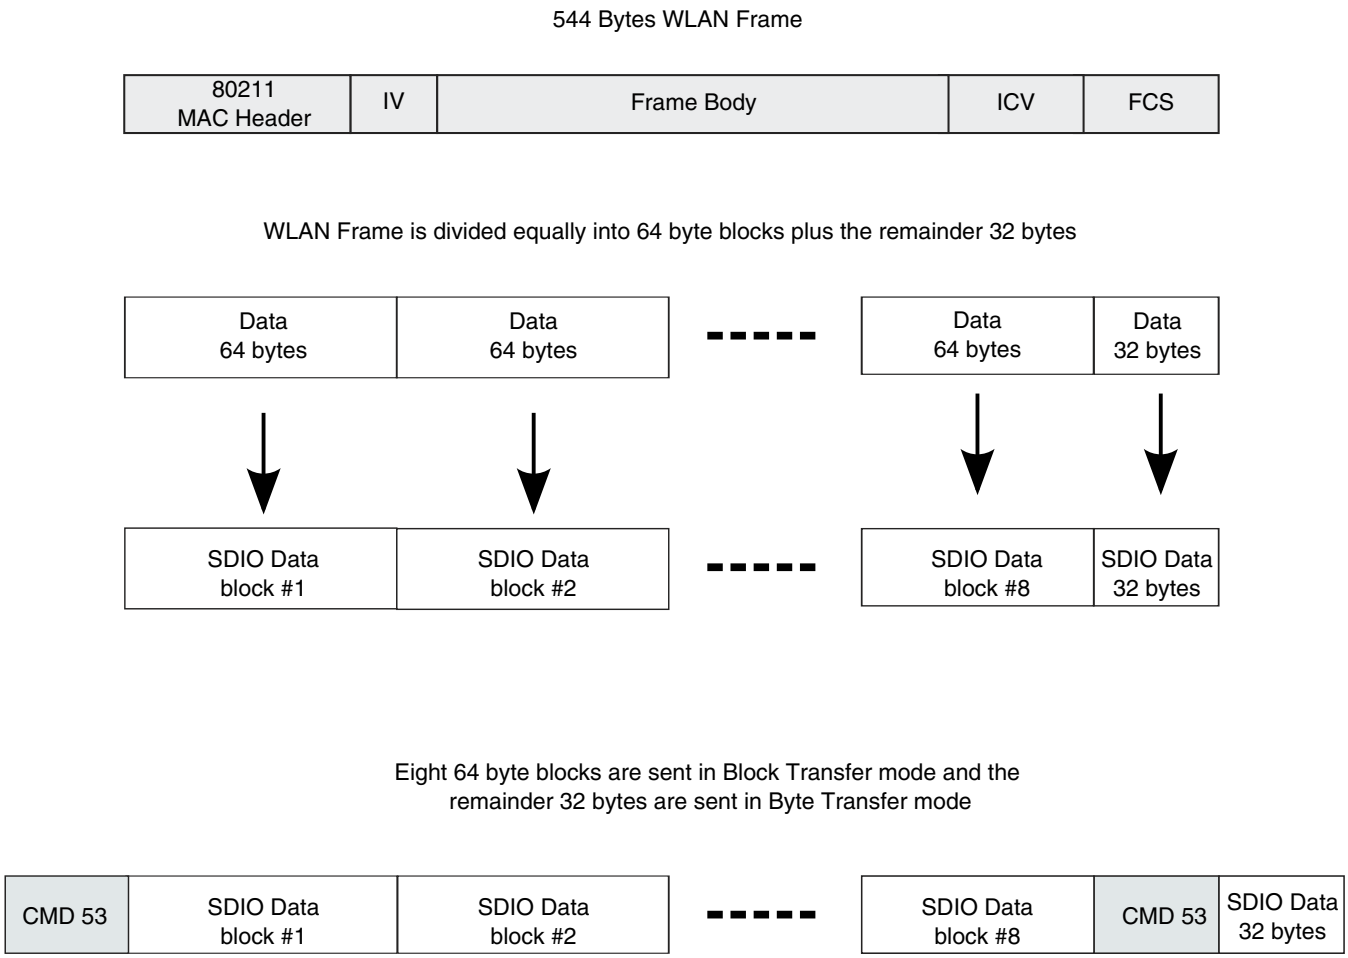

Figure 30-6. Example for Dividing Large Data Transfers

30.3.1.5 External DMA Request

When the internal DMA is not in use, and external DMA request is enabled, the Data Buffer will generate a DMA request to the system. During a write operation, when the number of WR_WML words can be held in the buffer free space, the signal esdhc_dreq_b is asserted to 0, informing the Host System of a DMA write. The BWR bit in the Interrupt Status register is also set, as long as the BWRSEN bit in the Interrupt Status Enable register is set. The DMA request is immediately de-asserted when an access to the Data Port register is made. If the buffer's free space still meets the watermark condition, the DMA request is asserted again after a cycle.

On read operation, when the number of RD_WML words are already in the buffer, the signal esdhc_dreq_b is asserted to 0, informing the Host System for a DMA read. The BRR bit in the Interrupt Status register is also set, as long as the BRRSEN bit in the

Interrupt Status Enable register is set. The DMA request is immediately de-asserted when an access to the Data Port register is made. If the buffer's data still meets the watermark condition, the DMA request is asserted again after a cycle.

Because the DMA burst length can not change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring of the block may cause buffer under-run (read operation) or over-run (write operation). For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of two between 1 and 128. For processor core polling access, as the last access in the block transfer can be controlled by software, there is no such issue. The watermark level can be any value, even larger than the block size (but no greater than 128 words). This is because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The ESDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level should be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of word. For this case, the BLKSIZE bits of the Block Attribute register shall be set as 1fh. For the ARM platform polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the ESDHC will also set the BWR or BRR bits when the remaining data does not violate data buffer. Refer to DMA Burst Length for more details about the dynamic watermark level of the data buffer. For the above example, even though 8 words are transferred through the Data Port register, the ESDHC will transfer only 31 bytes over the SD Bus, as required by the BLKSIZE bits. In this data transfer, with non-word aligned block size, the endian mode should be set cautiously, or invalid data will be transferred to/from the card.

30.3.2 DMA AHB Interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the esdhc_dreq_b will not be asserted during the transfer, but the BWR and BRR bits will be set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register. See the figure below for an illustration of the DMA AHB interface block.

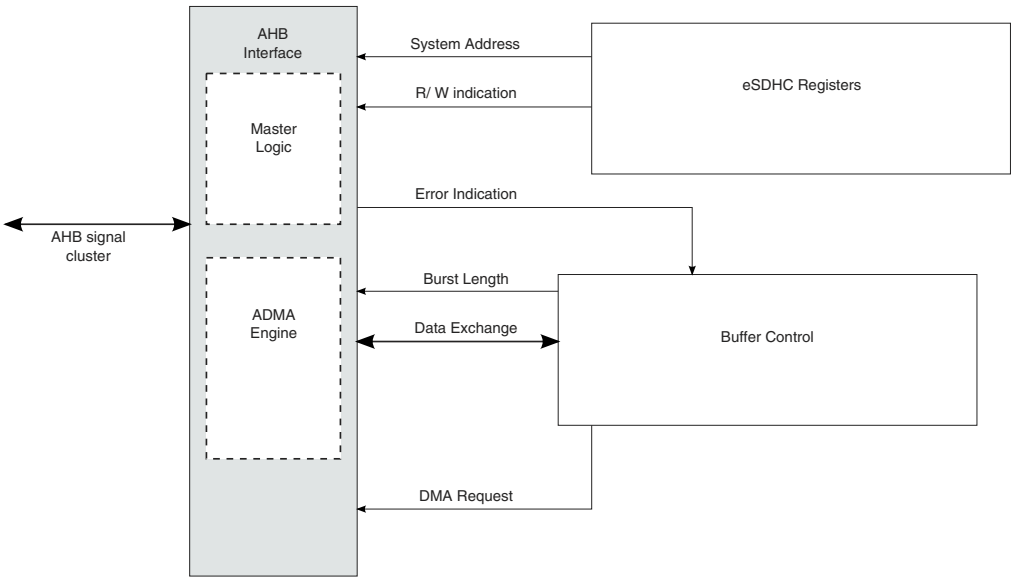

Figure 30-7. DMA AHB Interface Block

30.3.2.1 Internal DMA Request

If the watermark level requirement is met in data transfer, and the Internal DMA is enabled, the Data Buffer block will send a DMA request to AHB interface. Meanwhile, the external DMA request signal (esdhc_dreq_b) is disabled. The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to the ESDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The Data Buffer de-asserts the request once an access to the buffer is made. Upon access to the buffer by internal DMA, the Data Buffer updates its internal buffer pointer, and when the watermark level is satisfied, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer (which might contain some data of the next block), another DMA request read is sent. This is because the remaining number of words to send for the current block is (31 - 6 * 4) / 4 = 2. The ESDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuff byte.

30.3.2.2 DMA Burst Length

Just like a ARM platform polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block. Take the example in Internal DMA Request again. The following burst length after 6 words are read will be 2 words, and the next burst length will be 6 words again. This is because the next block starts, which is 31 bytes, more than 6 words. The Host Driver writer may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

30.3.2.3 AHB Master Interface

It is possible that the internal AHB DMA engine could fail during the data transfer. When this error occurs, the DMA engine stops the transfer and goes to the idle state as well as the internal data buffer stops accepting incoming data. The DMAE bit in the Interrupt Status register is set to inform the driver.

Once the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and re-start the transfer from this address to recover the corrupted block.

30.3.2.4 ADMA Engine

In the SD Host Controller Standard, the new DMA transfer algorithm called the ADMA (Advanced DMA) is defined. For Simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the Host Driver. The ADMA defines the programmable descriptor table in the system memory. The Host Driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized since the Host MCU intervention would not be needed during long DMA based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in Host Controller. ADMA1 can support data transfer of 4KB aligned data in system memory. ADMA2 removes the restriction so that data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA engine can recognize all kinds of descriptors define in SD Host Controller Standard, and if 'End' flag is detected in the descriptor, ADMA engine will stop after this descriptor is processed.

30.3.2.4.1 ADMA Concept and Descriptor Format

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Set data length descriptor.
- Set data address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Rsv descriptor.
- Set data length & address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it will ignore the high 32-bit. Address field shall be set on word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

ADMA will start read/write operation after it reaches the Tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last Set type descriptor before Tran type descriptor. Every Tran type will trigger a transfer, and the transfer data length is extracted from the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length will be the value for previous transfer, or 0 if no Set descriptor is ever met.

For ADMA2, Tran type descriptor contains both data length and transfer data address, so only a Tran type descriptor can start a data transfer.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 30-8. Format of the ADMA1 Descriptor Table

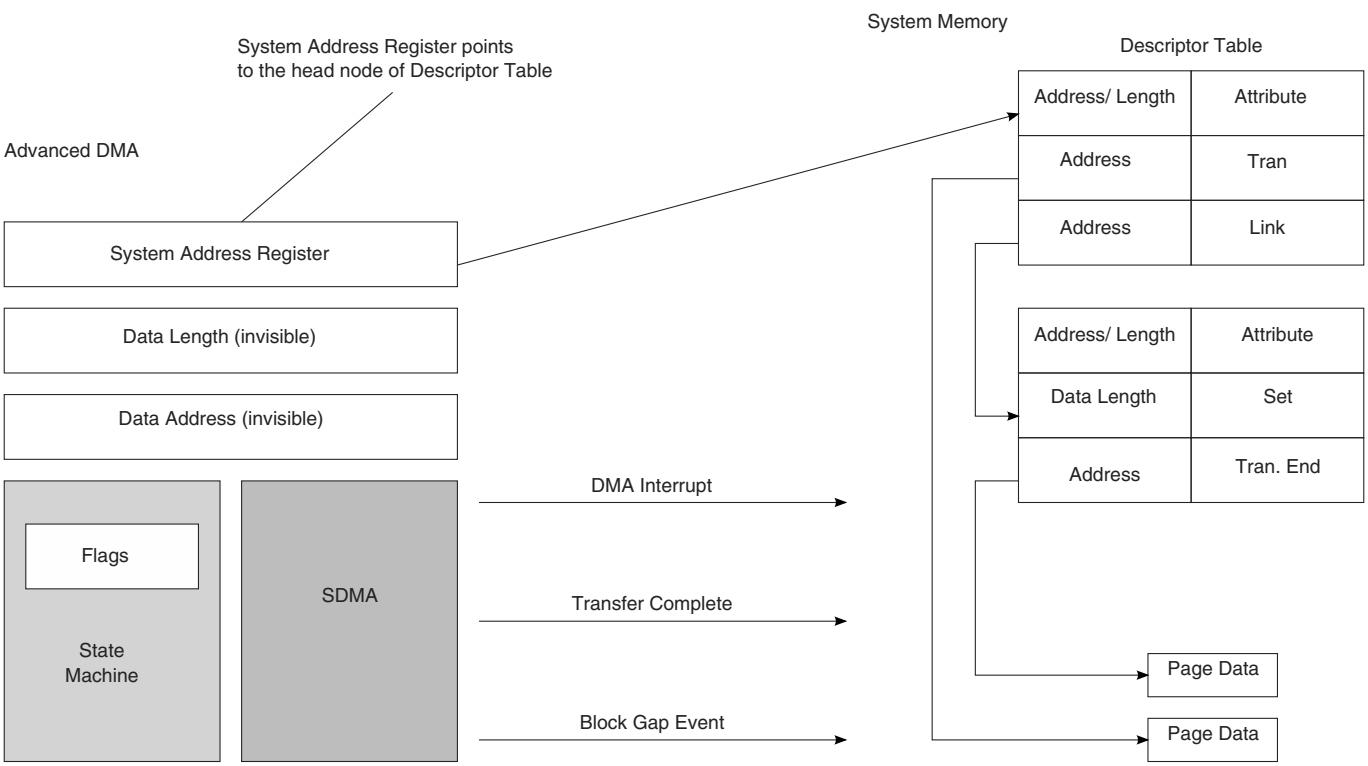

Figure 30-9. Concept and Access Method of ADMA1 Descriptor Table

Address/ Page Field		Address/ Page Field		Address/ Page Field		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit Length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is done.

Figure 30-10. Format of the ADMA2 Descriptor Table

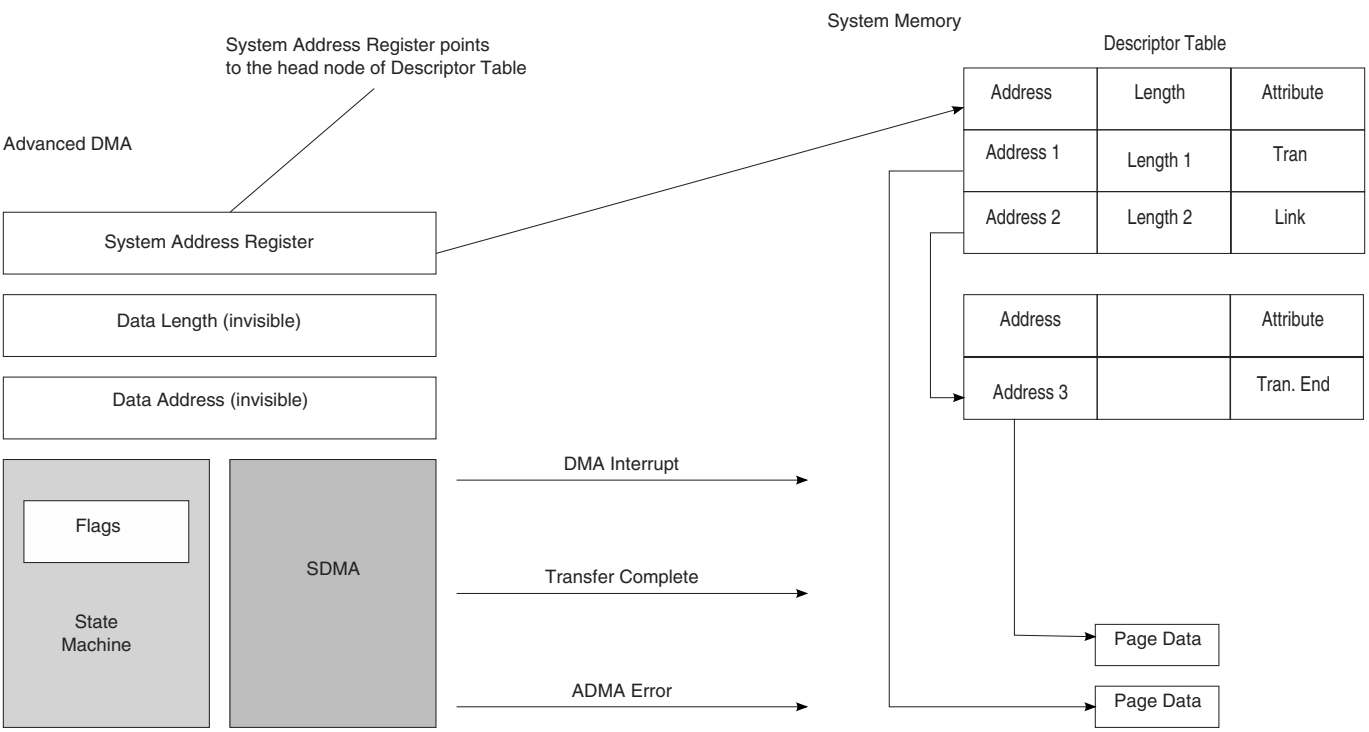

Figure 30-11. Concept and Access Method of ADMA2 Descriptor Table

30.3.2.4.2 ADMA Interrupt

If the 'Interrupt' flag of descriptor is set, ADMA will generate an interrupt according to different type descriptor:

For ADMA1:

- Set type descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop type descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type descriptor: interrupt is generated just after fetch this descriptor.

30.3.2.4.3 ADMA Error-DMA

The ADMA will stop whenever any error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

ADMA descriptor error will be generated when it fails to detect 'Valid' flag in the descriptor. If adma descriptor error occurs, the interrupt is not generated even if the 'Interrupt' flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in Block Attributes register must equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

If BLKCNTEN bit is not set, the whole data length set in descriptor should be times of block length, otherwise, when all data set in the descriptor nodes are done not at block boundary, the data mismatch error will occur.

30.3.3 Register Bank with IP Bus Interface

Register accesses via the IP Bus interface are actually on the Register Bank. See the figure below for the block diagram.

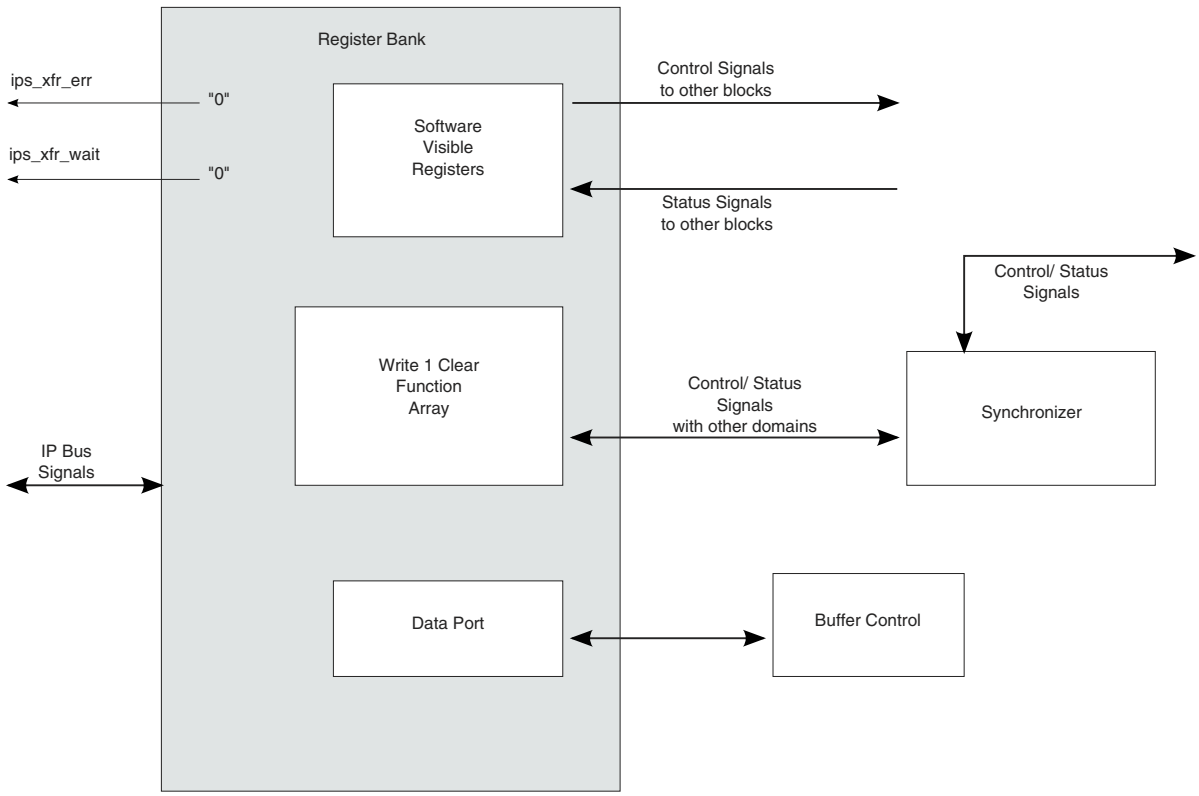

Figure 30-12. Register Bank Diagram

Only 32-bit access is allowed, and no partial read / write is supported, thus all accesses are word aligned.

30.3.4 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs.

The SD Protocol Unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the DAT[0] line
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD Protocol Unit consists of four sub-blocks:

1. SD transceiver.

2. SD clock and monitor.
3. Command agent.
4. Data agent.

30.3.4.1 SD Transceiver

In the SD protocol unit, the transceiver is the main control sub-block. It consists of an FSM and control sub-block, from which the control signals for all other three sub-blocks are generated.

30.3.4.2 SD Clock and Monitor

This sub-block monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the Register Bank. The driver can use this for debug purposes.

The sub-block also detects the Card Detection (CD) line as well as the DAT[3] line. The transceiver reports the card insertion state according to the CD state, or the signal level on the DAT[3] line, when the D3CD bit in the Protocol Control register is set.

The sub-block detects the Write Protect (WP) line. With the information of the WP state, the Register Bank will ignore the command, accompanied by a write operation, when the WP switch is on.

If the internal data buffer is in danger, and the SD clock must be gated off to avoid buffer over/under-run, this sub-block will assert the gate of the output SD clock to shut the clock off. After the buffer danger has recovered, and when the system access of the buffer catches up, the clock gate of this sub-block will open and the SD clock will be active again.

This sub-block also drive SD_LCTL output signal when the LCTL bit is set by the driver.

30.3.4.3 Command Agent

The Command Agent deals with the transactions on the CMD line. See figure below for an illustration of the structure for the Command CRC Shift Register.

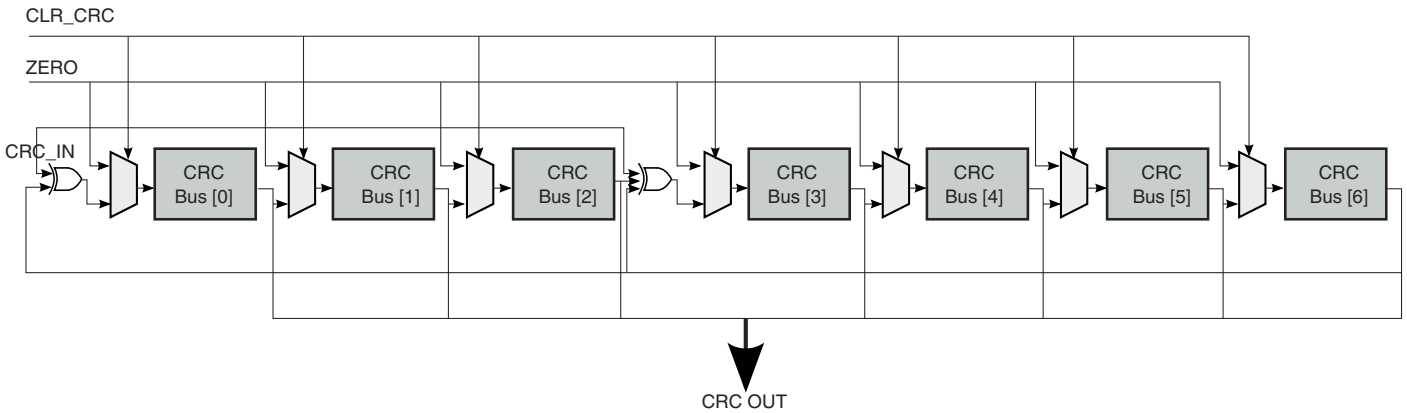

Figure 30-13. Command CRC Shift Register

The CRC polynomials for the CMD are as follows:

Generator polynomial: $G(x) = x^7 + x^3 + 1$
$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \ldots + (\text{last bit}) * x^0$
$CRC[6:0] = \text{Remainder } [(M(x) * x^7) / G(x)]$

30.3.4.4 Data Agent

The Data Agent deals with the transactions on the eight data lines. Moreover, this sub-block also detects the busy state on the DAT[0] line, and generate the Read Wait state by the request from the Transceiver. The CRC polynomials for the DAT are as follows:

Generator polynomial: $G(x) = x^{16} + x^{12} + x^5 + 1$
$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \ldots + (\text{last bit}) * x^0$
$CRC[15:0] = \text{Remainder } [(M(x) * x^{16}) / G(x)]$

30.3.5 Clock and Reset Manager

This sub-block controls all the reset signals within the ESDHC.

There are four kinds of reset signals within ESDHC:

1. Hardware reset.
2. Software reset for all.
3. Software reset for the data part.
4. Software reset for the command part.

All these signals are fed into this sub-block and stable signals are generated inside the module to reset all other modules. The sub-block also gates off all the inside signals.

There are three clocks inside the ESDHC:

1. ipg_clk.

2. ipg_perclk.
3. hclk.

The sub-block monitors the activities of all other sub-blocks, supplies the clocks for them, and when enabled, automatically gates off the corresponding clocks.

30.3.6 Clock Generator

The Clock Generator generates the SD_CLK by peripheral source clock in two stages. Refer to the figure below for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

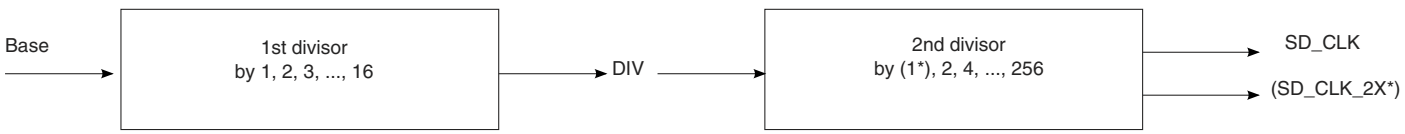

Figure 30-14. Two Stages of the Clock Divider

The first stage outputs an intermediate clock (DIV), which can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler, and outputs the actual clock (SD_CLK). Also it outputs DDR internal processing clock (SD_CLK_2X). These clocks are the driving clock for all sub-blocks of the SD Protocol Unit, and the sync FIFOs (see Figure 29-3) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be DIV/2, DIV/4,..., or DIV/256. Thus the highest frequency of the SD_CLK is Base/2, while the lowest frequency is Base/4096. If the Base clock is of equal duty ratio (usually true), the duty cycle of SD_CLK/SD_CLK_2X is also 50%, even when the compound divisor is an odd value.

30.3.7 SDIO Card Interrupt

30.3.7.1 Interrupts in 1-bit Mode

In this case the DAT[1] pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DAT[1] low from the SDIO card, until the interrupt service is finished to clear the interrupt.

30.3.7.2 Interrupt in 4-bit Mode

Since the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will only be sent by the card and recognized by the host during a specific time. This is known as the Interrupt Period. The ESDHC will only sample the level on Pin 8 during the Interrupt Period. At all other times, the host will ignore the level on Pin 8, and treat it as the data signal. The definition of the Interrupt Period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the Interrupt Period becomes active two clock cycles after the completion of a data packet. This Interrupt Period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the Interrupt Period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the Interrupt Period. For this case, the Interrupt Period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DAT[1] line will be held low for one clock cycle with the last clock cycle pulling DAT[1] high. On completion of the Interrupt Period, the card releases the DAT[1] line into the high Z state. The ESDHC samples the DAT[1] during the Interrupt Period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

30.3.7.3 Card Interrupt Handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, the ESDHC clears the interrupt request to the Host System. The Host Driver should clear this bit before servicing the SDIO Interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Status bit is cleared by resetting the SDIO interrupt. Writing to this bit would have no effects. In 1-bit mode, the ESDHC will detect the SDIO Interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the Interrupt Period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status has been set, and the Host Driver needs to service this interrupt, so the SDIO bit in the Interrupt Control Register of SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the ESDHC and to stop driving the interrupt signal to the

System Interrupt Controller. The Host Driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Enable bit is set to 1, and the ESDHC starts sampling the interrupt signal again.

See figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

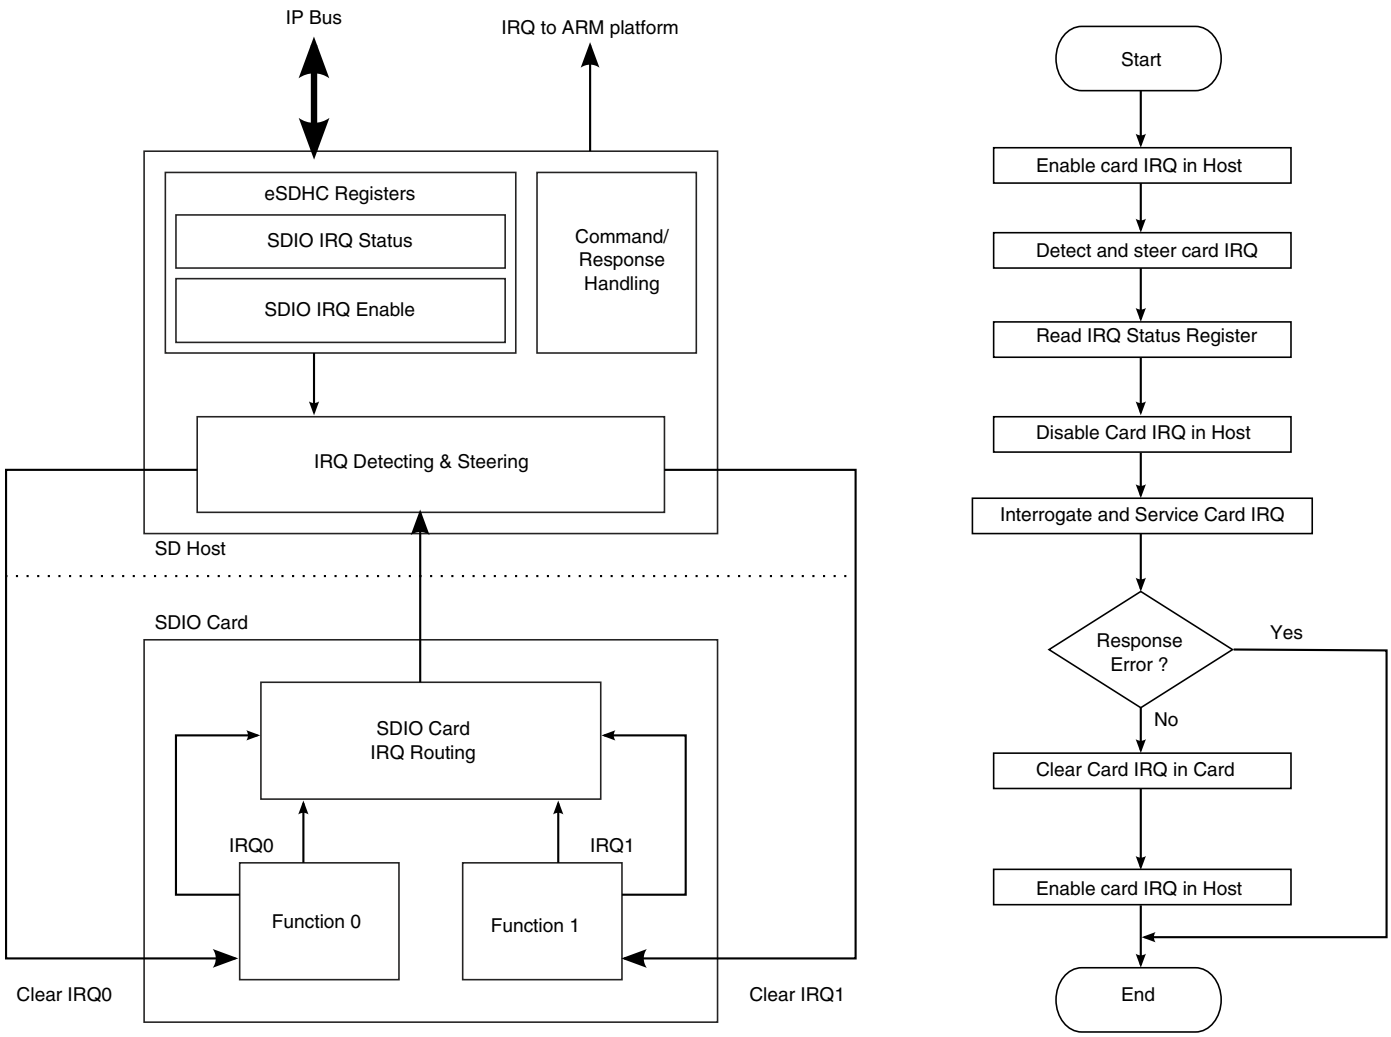

Figure 30-15. Card Interrupt Scheme and Card Interrupt Detection and Handling Procedure

30.3.8 Card Insertion and Removal Detection

The ESDHC uses either the DAT[3] pin or the CD pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DAT[3] will be pulled to a low voltage level by default. When any card is inserted to or removed from the socket, the ESDHC detects the logic value changes on the DAT[3] pin and generates an interrupt. When the DAT[3] pin is not used for card detection (for example, it is implemented in GPIO), the CD pin must be connected for card detection. Whether DAT[3] is configured for card detection or not, the CD pin is always a reference for card detection. Whether the DAT[3] pin or the CD pin is used to detect card insertion, the ESDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

30.3.9 Power Management and Wake Up Events

When there is no operation between the ESDHC and the card through the SD bus, the user can completely disable the ipg_clk and ipg_perclk in the chip level clock control module to save power. When the user needs to use the ESDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the ESDHC are disabled, for instance, when the system is in low power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The ESDHC can generate these interrupt even when there are no clocks enabled. The three interrupts which can be used as wake up events are:

1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

The ESDHC offers a power management feature. By clearing the clock enabled bits in the System Control Register (ESDHC_SYSCTL), the clocks are gated in the low position to the ESDHC. For maximum power saving, the user can disable all the clocks to the ESDHC when there is no operation in progress.

These three wake up events (or wakeup interrupts) can also be used to wake up the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to the ESDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (ESDHCV2_PROCTL) for more information on the ESDHC Protocol Control register.

30.3.9.1 Setting Wake Up Events

For the ESDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the ARM platform enters sleep mode. Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

30.3.10 MMC Fast Boot

The Embedded Multimedia Card (eMMC 4.3) has a fast boot feature. In boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

There are two supported types of fast boot mode, boot operation and alternative boot operation. Each type has with-acknowledge and without-acknowledge modes.

NOTE

For the eMMC 4.3 card setting, please see the eMMC 4.3 spec.

30.3.10.1 Boot Operation

NOTE

In this block guide, this fast boot is called normal fast boot mode.

If the CMD line is held LOW for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after the CMD line goes LOW, the slave starts to send the first boot data to the master on the DAT line(s). The master must keep the CMD line LOW to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes LOW. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode with the CMD line HIGH.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

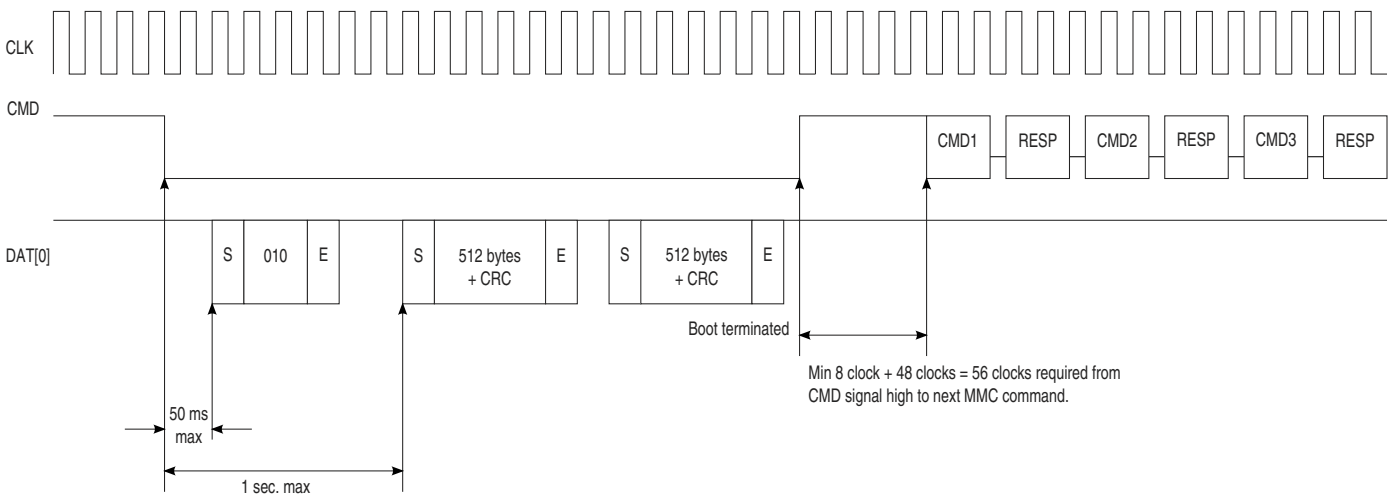

Figure 30-16. MultiMediaCard state diagram (normal boot mode)

30.3.10.2 Alternative Boot Operation

If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

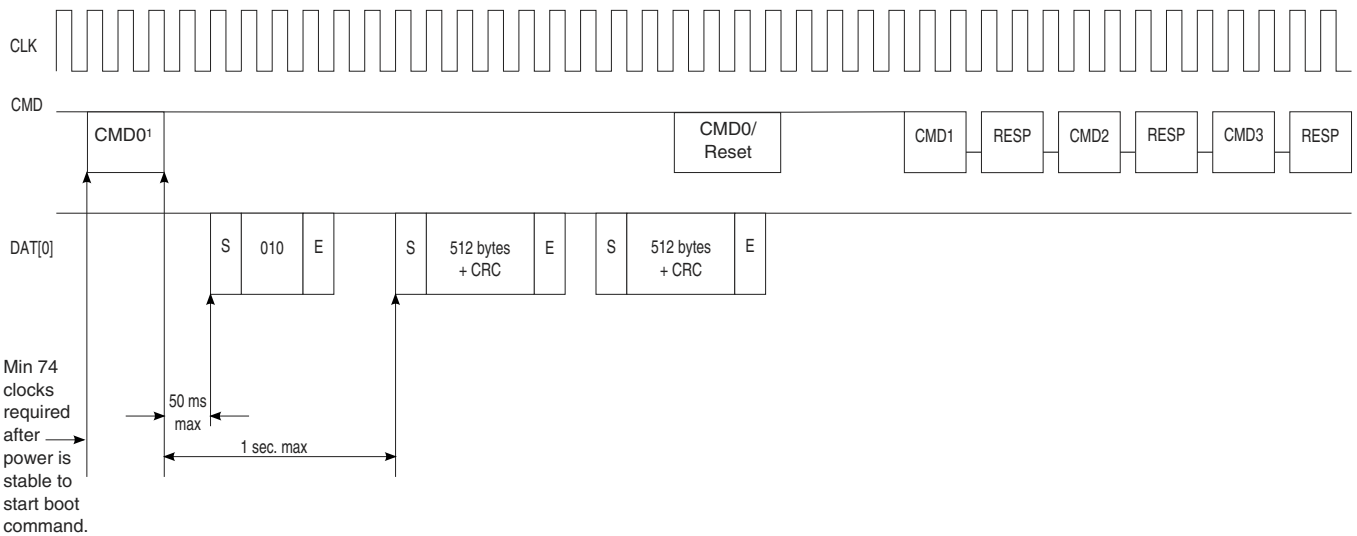
After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DAT line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.



NOTE1. CMD0 with argument 0xFFFFFFFA

Figure 30-17. MultiMediaCard state diagram (alternative boot mode)

30.4 Initialization/Application of ESDHC

All communication between system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as "GO_IDLE_STATE", "SEND_OP_COND", "ALL_SEND_CID" and etc. In Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the Broadcast command CMD3 is issued, the cards enter standby mode. Addressed type commands are used from this point. In this mode, the CMD/DAT I/O pads will turn to push-pull mode, to have the driving capability for maximum frequency operation. Refer to Commands for MMC/SD/SDIO for the commands of ac and adtc categories.

30.4.1 Command Send and Response Receive Basic Operation

Assuming the data type WORD is an unsigned 32-bit integer, the below flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
          set MSBSEL bit;
          if (finite block number) {
                    set BCEN bit;
                    if (auto12 command is to use) set AC12EN bit;
          }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. By doing this, make sure the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the Standby State, no response to the Host when CMD2 is sent. The Host Driver shall deal with 'fake' errors like this with caution.

30.4.2 Card Identification Mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for the MMC cards.

30.4.2.1 Card Detect

See figure below for a flow diagram showing the detection of MMC, SD and SDIO cards using the ESDHC.

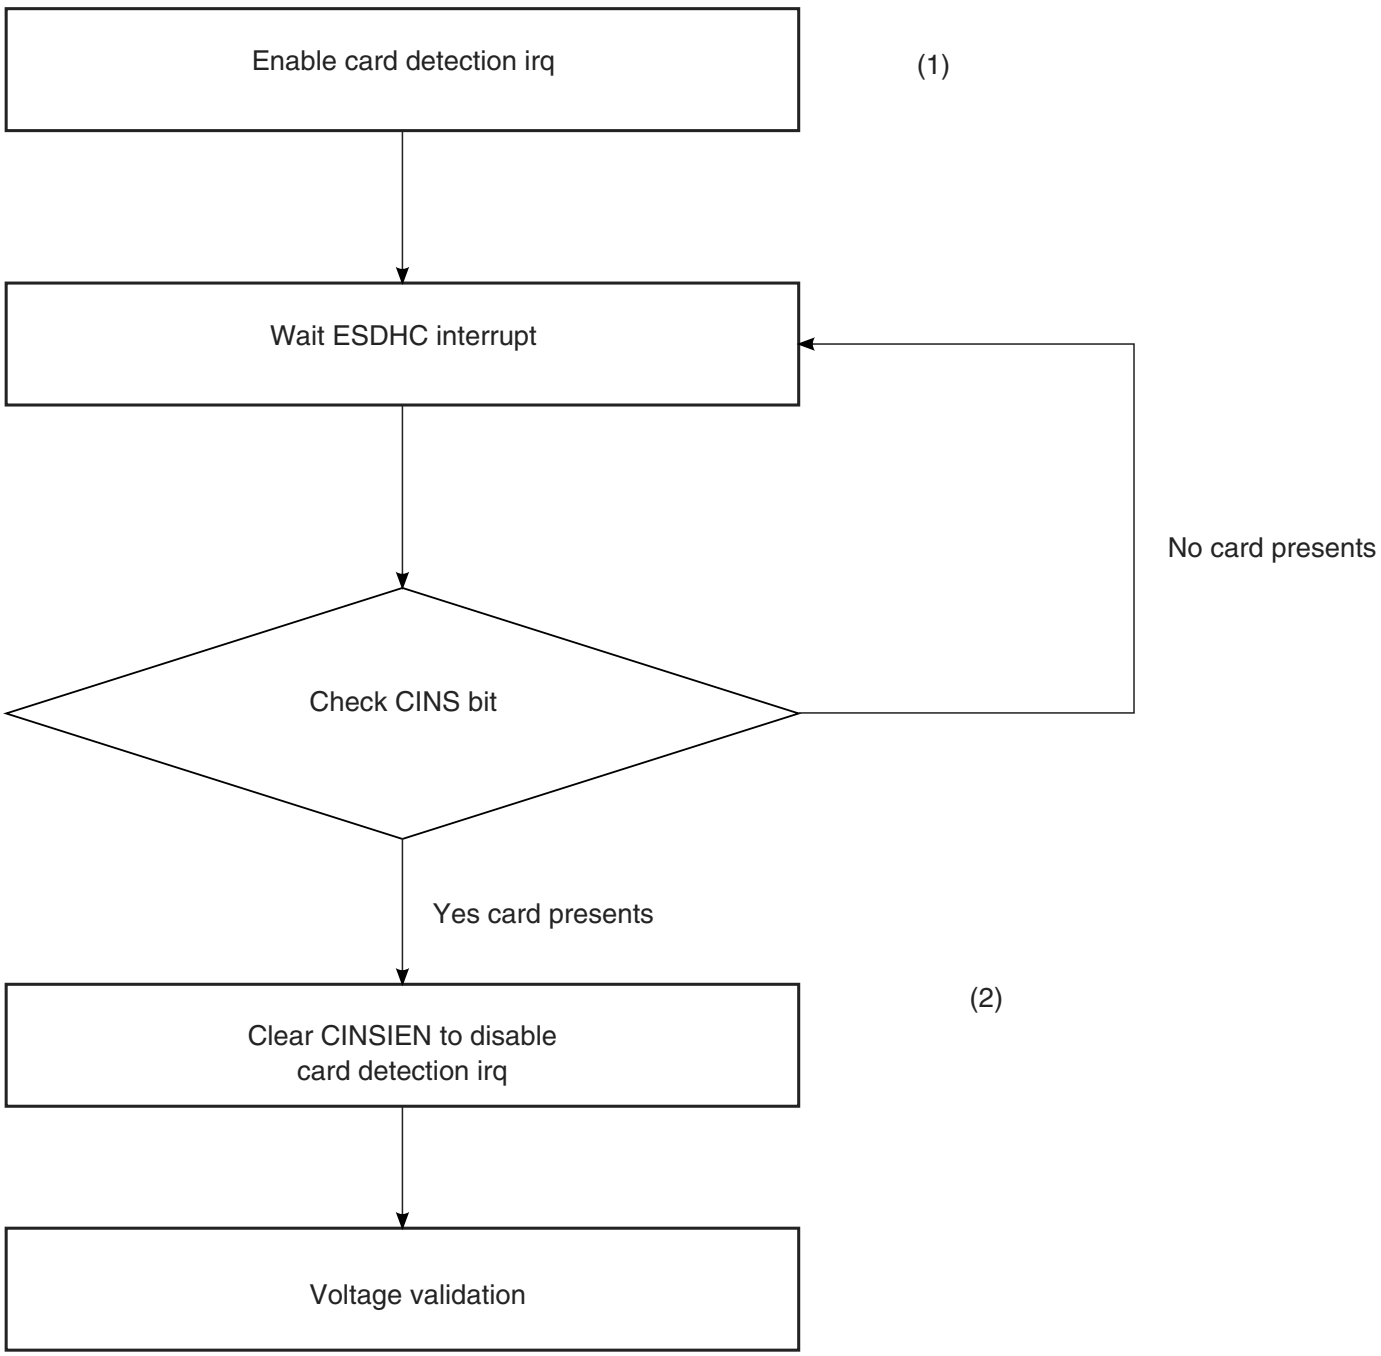


Figure 30-18. Flow Diagram for Card Detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the ESDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

30.4.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) which is driven by POR (Power On Reset)
- Software reset (Host Only) is proceed by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the Host Controller, respectively
- Card reset (Card Only). The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the Idle State regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See figure below for the software flow to reset both the ESDHC and the card.

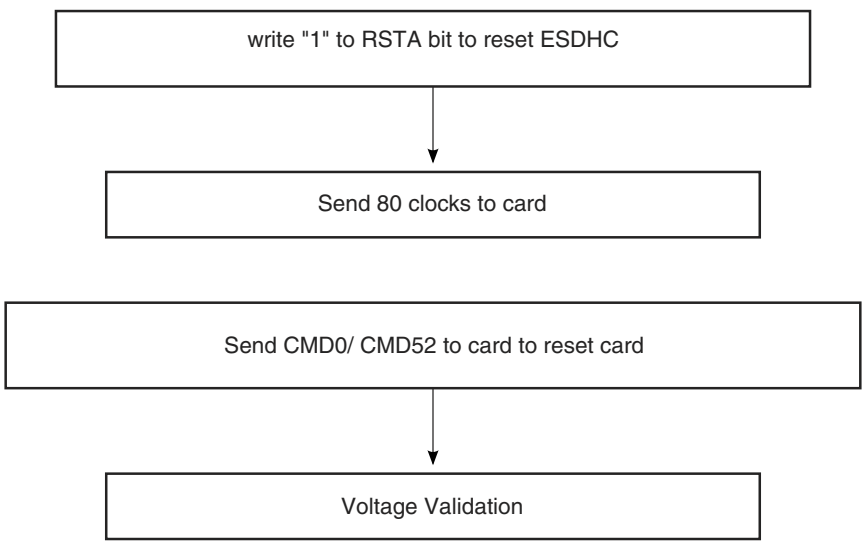

Figure 30-19. Flow Chart for Reset of the ESDHC and SD I/O Card

```
software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set DVS and SDCLKFS bit fields to get the SD_CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

30.4.2.3 Voltage Validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for Vdd are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer Vdd conditions. This means if the host and card have non-common Vdd ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory) and IO_Send_Op_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host. This is accomplished by the host sending the desired Vdd voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive State. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive State. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO

                    label the card as CE-ATA;
          } // of if (check for CE-ATA ...
          else label the card as MMC;
} // of else
}
```

30.4.2.4 Card Registry

Card registry for the MMC and SD/SDIO/SD Combo cards are different.

For the SD Card, the Identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the Card spec). At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the Inactive State. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready State), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification State.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. Once the RCA is received, the card changes its state to the Standby State. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive State. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in Ready State) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Since the CID is unique for each card, only one card can be successfully send its full CID to the host. This card then goes into the Identification State. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received the card state changes to the Stand-by State, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
          if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
                    send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
                    retrieve RCA from response;
          } // end if (card is labelled as SDCombo ...
          else if (card is labelled as SD) { // for SD card
                    send_command(ALL_SEND_CID, <...>);
                    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
                    send_command(SET_RELATIVE_ADDR, <...>);
                    retrieve RCA from response;
          } // else if (card is labelled as SD ...
          else if (card is labelled as MMC or CE-ATA) { // treat CE-ATA as MMC
                    send_command(ALL_SEND_CID, <...>);
                    rca = 0x1; // arbitrarily set RCA, 1 here for example, this RCA is also
the
relative address to access the CE-ATA card
                    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
          } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

30.4.3 Card Access

30.4.3.1 Block Write

30.4.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the DAT line. The transferred data will be discarded and not written, and all further transmitted blocks (in multiple block write mode) will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DAT line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DAT line without interrupting the write operation. When re-selecting the card, it will reactivate the busy indication by pulling DAT to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods (by means of external DMA or ARM platform polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC cards, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the ESDHC block attribute register, block number is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

30.4.3.1.2 DDR Write

ESDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described as below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the ESDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer.The DDR_EN_IPG bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

30.4.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the SD_CLK at any time to pause all the operations, which is also inaccessible to the Host Driver, the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer

between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DAT0 line is not required to de-assert to release the busy state, no suspend command is needed.

Like in the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the ESDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The Driver shall read the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card; when such a command is sent, the ESDHC thinks the System will switch to another

function on the SDIO card, and flush the data buffer. The ESDHC takes the Resume Command as a normal command with data transfer, and it is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the ESDHC will automatically send a CMD12 to mark the end of the multi-block transfer.

30.4.3.2 Block Read

30.4.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or ARM platform polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the ESDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set:
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

30.4.3.2.2 DDR Read

ESDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the ESDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer.The DDR_EN_IPG bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

30.4.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the ESDHC will not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended that the RWCTL bit be set once the Read Wait capability of the SDIO card is recognized.

Like in the flow described in Normal Read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
5. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.

6. Set the ESDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the ESDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. No matter if the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the ESDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the ESDHC will automatically send the CMD12 to mark the end of multi-block transfer.

30.4.3.2.4 DLL (Delay Line) in Read Path

The DLL (Delay Line) is added to assist in sampling read data. As in The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage and temperature (PVT). The reasons why the DLL is needed for ESDHC are 1.) the path of read data traveling from card to host varies. 2.) in MMC DDR mode the minimum input setup and hold time are both at 2.5 ns. The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided perclk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in override mode. The override value set is the number of delay cells. In override mode, the DLL_enable is no need to set. And another working mode of DLL is target value mode. In this mode, DLL will automatically adjust the number of delay cells according to the target value your set value and PVT changes. Be aware that target value is in the unit of 1/32 clock reference period. If the perclk is 100MHz, then the reference clock period is 10ns, setting target value of 16 means 5ns=(16/32)*10ns. Software can disable automatically update by setting dll_gate_update bit. Please refer to Figure 30-20.

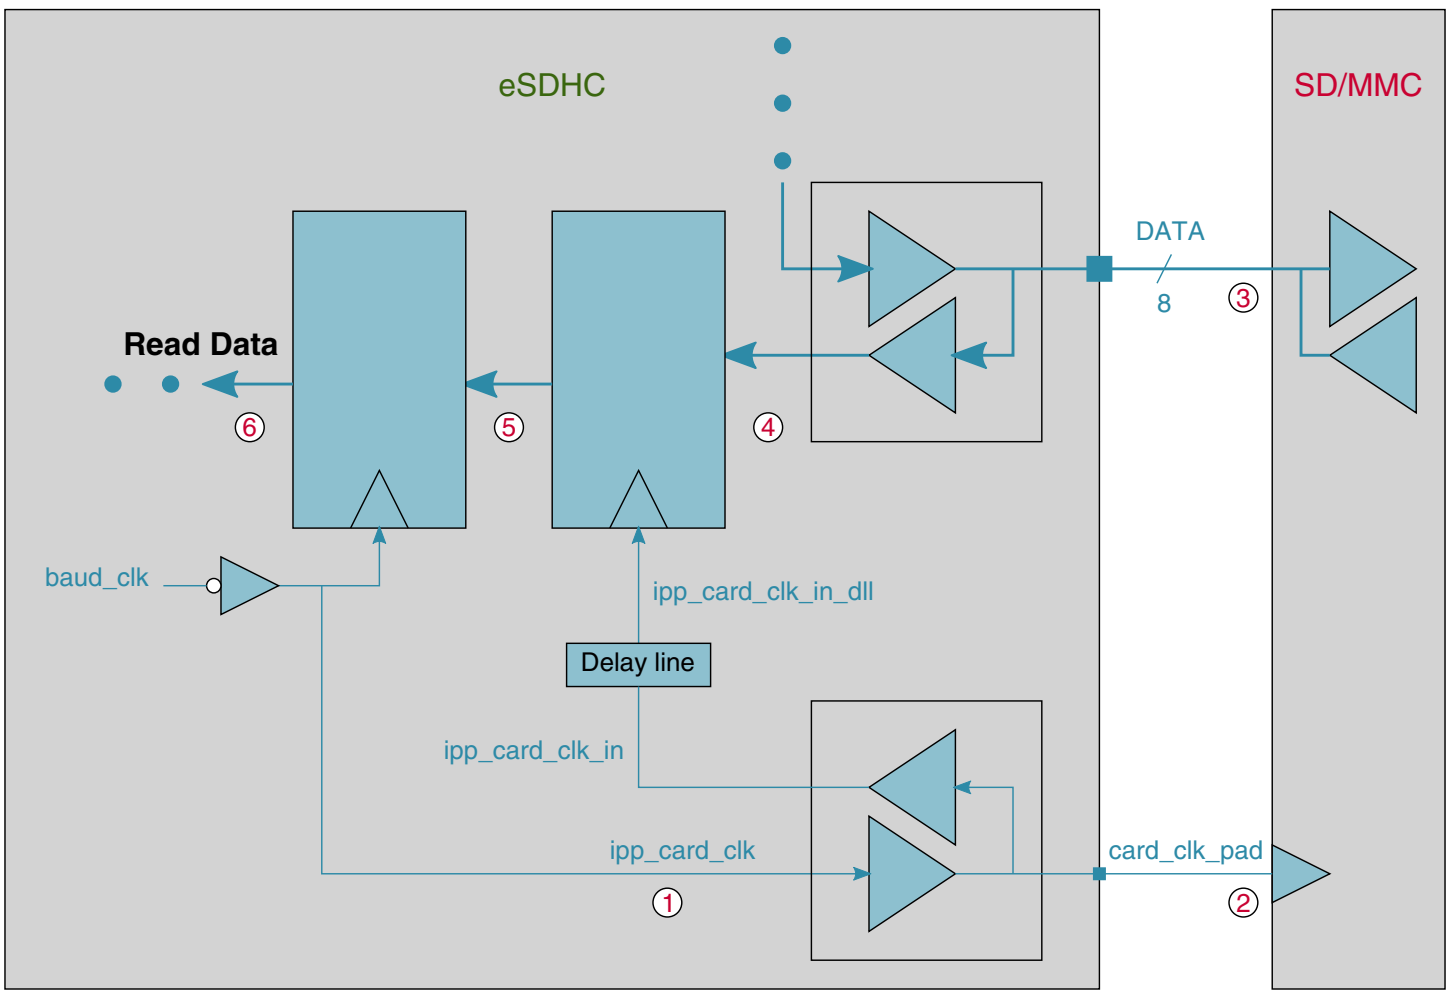

Figure 30-20. DLL (Delay Line) in Read Path

30.4.3.3 Suspend Resume

The ESDHC supports the Suspend Resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

Suspend

After setting the SABGREQ bit, the Host Driver may send a Suspend command to switch to another function of the SDIO card. The ESDHC does not monitor the content of the response, so it doe not know whether or not the Suspend command has succeeded. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the Driver does not set the ESDHC_XFERTYP[CMDTYP] register to 01, that is, Suspend option. Instead, the Driver sends this command as if it were a normal command (that is, sets CMDTYP to b00). Only when the command succeeds, and the BS bit is set in the response, does the Driver send another command marked as "Suspend" to inform the ESDHC that the current transfer is suspended. This is shown in the following sequence for Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so the ESDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the ESDHC stops driving DAT2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

30.4.3.3.1 Resume

To resume the data transfer, a Resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation above.
2. Send the Resume command. In the Transfer Type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer will be resumed.

30.4.3.4 ADMA1 Usage

To use the ADMA1 in a data transfer, the Host Driver must prepare the correct descriptor chain prior to sending the read/write command. The steps to accomplish this are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4kB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

30.4.3.5 Transfer Error

30.4.3.5.1 CRC Error

It is possible at the end of a block transfer, that a write CRC status error or read CRC error occurs. For this type of error the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the Host Driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, the ESDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 will be sent by the ESDHC. In this case, the Driver shall re-send or re-obtain the last block with a single block transfer.

30.4.3.5.2 Internal DMA Error

During the data transfer with internal Simple DMA, if the DMA engine encounters some error on the AHB bus, the DMA operation is aborted and DMA Error interrupt is sent to the Host System. When acknowledged by such an interrupt, the Driver shall calculate the start address of data block in which the error occurs. The start address can be calculated by either:

1. Read the DMA System Address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.
2. Read the BLKCNT field of the Block Attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register does not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and re-start the transfer from the corrupted block to recover from the error.

30.4.3.5.3 ADMA Error-Card Access

There are three kinds of possible ADMA errors. The AHB transfer, invalid descriptor, and data-length mismatch errors. When these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the Host Driver should recover the error as shown below and re-transfer from the place of interruption.

1. AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and re-create the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
3. Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

30.4.3.5.4 Auto CMD12 Error

After the last block of the multi block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, the ESDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, it is recommended to the Driver to deal with the situations in the following manner:

1. Auto CMD12 response time-out. It is not certain whether the command is accepted by the card or not. The Driver should clear the Auto CMD12 error status bits and re-send the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error. Since card responds to the CMD12, the card will abort the transfer. The Driver may ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The command is not sent, so the Driver shall send a CMD12 manually.

30.4.3.6 Card Interrupt

The external cards can inform the Host Controller by means of some special signals. For the SDIO card, it can be the low level on the DAT[1] line during some special period. The ESDHC only monitors the DAT[1] line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the ESDHC, and the Host System is informed by the ESDHC asserting the ESDHC interrupt line, the interrupt service from the Host Driver is called.

As the interrupt factor is controlled by the external card, the interrupt from the SDIO card must be served before the CINT bit is cleared by written 1. Refer to Card Interrupt Handling for the card interrupt handling flow.

30.4.4 Switch Function

MMC cards transferring data at bus widths other than 1-bit is a feature in MMC spec. The high speed timing mode for all card devices, was also defined in various card specifications. To enable these features, a "switch" command shall be issued by the Host Driver.

For SDIO cards, the high speed mode is enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode is queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards, the high speed mode is queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The 4-bit and 8-bit bus width of the MMC is also enabled by the SWITCH command, but with a different argument.

DDR mode is also selected by setting ddr mode bus width via SWITCH.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following flowcharts do not show current capability check, which is recommended in the function switch process.

30.4.4.1 Query, Enable and Disable SDIO High Speed Mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

30.4.4.2 Query, Enable and Disable SD High Speed Mode

```
enable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFF1 and read 64 bytes of data accompanying the R1 response;
wait data transfer done bit is set;
check if the bit 401 of received 512 bit is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
send CMD6, with argument 0x80FFFFF1 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

30.4.4.3 Query, Enable and Disable MMC High Speed Mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

30.4.4.4 Set MMC Bus Width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

30.4.5 ADMA Operation

30.4.5.1 ADMA1 Operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
```

```
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB align);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

30.4.5.2 ADMA2 Operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

30.4.6 Fast Boot Operation

30.4.6.1 Normal fast boot flow

1. Software need to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.

2. Software need to configure MMC Boot Register (offset 0xc4) bit 6 to 1(enable boot), and bit 5 to 0(normal fast boot), and bit 4 to select the ack mode or not. If need to send through DMA mode, need to configure bit 7 to enable automatically stop at block gap feature. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequence.
3. Software then need to configure Block Attributes Register to set block size/no. If in ddr fast boot mode, block size only can be configure to 512byte.
4. Software need to configure Protocol control register to set DTW (data transfer width). If in ddr fast boot mode, DTW only can be configure to 4-bit/8-bit dataline mode.
5. Software need to configure Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software need to configure Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1.

NOTE

DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1, better to configure blk no in Bock Attributes Register to the max value. And if in ddr fast boot mode, DDR_EN need to be set to 1.

7. When the step 6 is configured, boot process will begin. Software need to poll the data buffer ready status to read the data from buffer in time. If boot time-out happened (ack time out or the first data read time out), Interrupt will be triggered, and software need to configure MMC Boot Register to bit 6 to 0 to disable boot. Thus will make CMD high, and then after at least 56 clocks, it is ready to begin normal initialization process.
8. If no time out, software need to decide the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This will make CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
9. Reset the host and then can begin the normal process.

30.4.6.2 Alternative fast boot flow

1. Software need to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software need to configure MMC Boot Register (offset 0xc4) bit 6 to 1(enable boot), and bit 5 to 1(alternative boot), and bit 4 to select the ack mode or not. If need to send through DMA mode, need to configure bit 7 to enable automatically stop at

block gap feature. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequence.

3. Software then need to configure Block Attributes Register to set block size/no. If in ddr fast boot mode, block size only can be configure to 512byte.
4. Software need to configure Protocol control register to set DTW(data transfer width). If in ddr fast boot mode, DTW only can be configure to 4-bit/8-bit dataline mode.
5. Software need to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software need to configure Transfer Type Register to start the boot process by CMD0 with 0xFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1.

NOTE

DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in polling mode, better to configure blk no in Bock Attributes Register to the max value. And if in ddr fast boot mode, DDR_EN need to be set to 1.

7. When the step 6 is configured, boot process will begin. Software need to poll the data buffer ready status to read the data from buffer in time. If boot time out(ack data time out in 50ms or data time out in 1s), host will send out the interrupt and software need to send CMD0 with reset and then configure boot enable bit to 0 to stop this process. After command completed, configure MMC Boot Register bit 6 to 0 to disable boot. After at least 8 clocks from command completed, card is ready for identification step.
8. If no time out, software need to decide when to stop the boot process, and send out the CMD0 with reset and then after command completed, configure MMC Boot Register bit 6 to stop the process. After 8 clocks from command completed, slave(card) is ready for identification step.
9. Reset the host and then can begin the normal process.

30.4.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the

beginning of the image, need to switch DMA parameters on the fly during MMC fast boot.

In fast boot, host can use ADMA2 (Advanced DMA2) with two destinations.

The detail flow:

1. Software need to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software need to configure MMC Boot Register (offset 0xc4) bit 6 to 1(enable boot); and bit 5 to 0(normal fast boot), to 1(alternative boot); and bit 4 to select the acknowledge mode or not. In DMA mode, configure bit 7 to 1 for enable automatically stop at block gap feature. Also configure bit31-bit16 to set the VALUE1 (value of block count that need to transfer first time), that host will stop at block gap when card block counter is equal to this value. And need to configure bit 3-bit0 to select the acknowledge timeout value according to the SD clock frequency.
3. Software then need to configure Block Attributes Register to set block size/no. If in DDR fast boot mode, block size only can be configure to 512byte. In DMA mode, it is better to set block number to the max value (16'hFFFF).
4. Software need to configure Protocol control register to set DTW (data transfer width). If in DDR fast boot mode, DTW can be only configured to 4-bit/8-bit data line mode.
5. Software enbables ADMA2 by configuring protocol control register bit9-bit8.
6. Software need to set at least three pairs ADMA2 descriptor in boot memory (i.e. in IRAM, at least 6 words). The first pair descriptor define the start address (i.e. IRAM) and data length (i.e. 512 bytes*VALUE1) of first part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writeable), data length is suggest to set 1~2word (record as VAULE2).

NOTE

The second couple descriptor also transfer useful data even at lease 1 word. Because our ADMA2 can't support 0 data_length data transfer descriptor.

7. Software need to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot, and don't need set in normal fast boot.
8. Software need to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in DMA mode. And if BCEN is configured as 1, better to configure block no in Bock Attributes Register to the max value. And if in DDR fast boot mode, DDR_EN need to be set to 1.
9. When the step 8 is configured, boot process will begin. The first VAULE1 block number data has transfer. Software need to polling TC bit (bit1 in Interrupt Status Register) to determine first transfer is end. Also software need to polling BGE bit (bit2 in Interrupt Status Register) to determine if first transfer stop at block gap.
10. When TC, BGE bit is 1, SW can analyzes the first code of VAULE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define

the start address and length of the remaining part of boot code(VAULE3 the remain boot code block). Remember set the last descriptor with END.

11. Software need to configure MMC Boot Register (offset 0xc4) again. Set bit 6 to 1(enable boot); and bit 5 to 0(normal fast boot), to 1(alternative boot); and bit 4 to select the acknowledge mode or not. In DMA mode, configure bit 7 to 1 for enable automatically stop at block gap feature. Also configure bit31-bit16 to set the (VAULE1+1+VAULE3), that host will stop at block gap when card block counter is equal to this value. And need to configure bit 3-bit0 to select the acknowledge timeout value according to the SD clock frequency.
12. Software need to clear TC and BGE bit. And software need to clear SABGREQ (bit 16 in Protocol control register), and set CREQ (bit17 Protocol control register) to 1 to resume the data transfer. Host will transfer the VALUE2 and VAULE3 data to the destination that is set by descriptor.
13. Software need to polling BGE bit to determine if the fast boot is over.

NOTE

- When ADMA boot flow is started, for ESDHC, it is like a normal ADMA read operation.
- Need a few words length memory to keep descriptor.
- For the 1~2 word data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

30.5 Commands for MMC/SD/SDIO

See table below for the list of commands for the MMC/SD/SDIO cards.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. broadcast commands (bc), no response.
2. broadcast commands with response (bcr), response from all cards simultaneously.
3. addressed (point-to-point) commands (ac), no data transfer on the DAT.
4. addressed (point-to-point) data transfer commands (adtc).

The Access Bits for the EXT_CSD Access Modes are shown in table below.

Table 30-2. Commands for MMC/SD/SDIO Cards

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.

Table continues on the next page...

Table 30-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	Reserved				
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.

Table continues on the next page...

Table 30-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.

Table continues on the next page...

Table 30-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather that a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57~59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers.

Table continues on the next page...

Table 30-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62~63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac		R1	SET_WR_BLK_ERASE_COUNT	-
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac		R1	SET_CLR_CARD_DETECT	-
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards . The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 29-3.
4. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this block).

Table 30-3. EXT_CSD Access Modes

Bits	Access Name	Operation
00	Command Set	The command set is changed according to the Cmd Set field of the argument
01	Set Bits	The bits in the pointed byte are set, according to the 1 bits in the Value field.
10	Clear Bits	The bits in the pointed byte are cleared, according to the 1 bits in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

30.6 Software Restrictions

30.6.1 Initialization Active

The driver cannot set INITA bit in System Control register when any of the command line or data lines is active, so the driver must ensure both CDIHB and CIHB bits are cleared. In order to auto clear the INITA bit, the SDCLKEN bit must be '1', otherwise no clocks can go out to the card and INITA will never clear.

30.6.2 Softeware Polling Procedure

For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not the times of the value in Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block. For example, for read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

30.6.3 Suspend Operation

In order to suspend the data transfer, the software must inform ESDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform ESDHC that the transfer is suspended.

If software needs to resume the suspended trasnfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending a 'suspend' command, ESDHC will regard the current transfer as aborted and change BLKCNT register to its original value, rather than keeping the remaining number of blocks.

30.6.4 Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

30.6.5 (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register will always update itself with the internal address value to support dynamic address synchronization, so software must make sure TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

30.6.6 Data Port Access

Data Port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the Data Port by ARM platform; or during a ARM read operation, it is also prohibited to write any data to the Data Port, by either ARM or external DMA. Otherwise the data would be corrupted inside the ESDHC buffer.

30.6.7 Change Clock Frequency

ESDHC does not automatically gates off the card clock when the Host Driver changes the clock frequency. To remove possible glitch on the card clock, clear SDCLKEN bit when changing clock divisor value and set SDCLKEN bit to '1' after SDSTB bit is '1' again.

30.6.8 Multi-block Read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by ESDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode. In this case, the card may not respond to this extra abort command and ESDHC will get Response Timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

30.7 Programmable Registers

This section includes the block memory map and detailed descriptions of all registers. Each of these registers support only 32-bit accesses.

NOTE

Addresses greater than 0x44, except 0x50, 0x54, 0x58, 0x60, 0x64, 0xC0, 0xC4 and 0xFC, are reserved and read as all 0s. Write to these

ESDHCV3 memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
5002_0000	DMA System Address (ESDHCV3-3_DSADDR)	32	R/W	0000_0000h	30.7.1/ 1488
