30 CSI0_PUPE_EN	CSI0_PUPE_EN - CSI0 parameters update error interrupt enable. This bit enables an interrupt that is a result of an error generated by the CSI0. The error is generated in case where new frame arrived from the CSI0 before the completion of the CSI0's parameters update by the SRM 0 Interrupt is disabled. 1 Interrupt is enabled.
29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28 IC_VF_BUF_OVF_EN	This bit enables an interrupt that is a result of the IC Buffer overflow for view finder coming from the IC. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is disabled. 1 Interrupt is enabled.
27 IC_ENC_BUF_OVF_EN	This bit enables an interrupt that is a result of the IC Buffer overflow for encoding coming from the IC. The user needs to write 1 to this bit in order to clear it.

Table continues on the next page...

IPU_INT_CTRL_9 field descriptions (continued)

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
26 IC_BAYER_ BUF_OVF_EN	This bit enables an interrupt that is a result of the IC Buffer overflow for bayer coming from the IC. The user needs to write 1 to this bit in order to clear it. 0 Interrupt is disabled. 1 Interrupt is enabled.
25–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 VDI_FIFO1_ OVF_EN	FIFO1 overflow Interrupt1 Enable The VDIC generates FIFO1 overflow interrupt1 when the write pointer of FIFO1 overruns read pointer. 0 Interrupt is disabled. 1 Interrupt is enabled.

45.51.15 Interrupt Control Register 10 (IPU_INT_CTRL_10)

This register contains part of IPU interrupts controls. This register controls error interrupt signals coming from different modules within

Address: IPU_INT_CTRL_10 is 1E00_0000h base + 60h offset = 1E00_0060h

IPU_INT_CTRL_10 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

IPU_INT_CTRL_10 field descriptions (continued)

Field	Description
30 AXIR_ERR_EN	This bit enables an interrupt that is a result of AXI read access resulted with error response. 0 Interrupt is disabled. 1 Interrupt is enabled.
29 AXIW_ERR_EN	This bit enables an interrupt that is a result of AXI write access resulted with error response. 0 Interrupt is disabled. 1 Interrupt is enabled.
28 NON_ PRIVILEGED_ ACC_ERR_EN	Non Privileged Access Error interrupt enable. The CPMEM and the DP can be accessed by the ARM platform in privileged mode only HPROT[1] =1. An attempt to access these regions in user mode will issue an interrupt. This bit enables the interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26 IC_BAYER_ FRM_LOST_ ERR_EN	This bit enables an interrupt that is a result of IC's Bayer frame lost. 0 Interrupt is disabled. 1 Interrupt is enabled.
25 IC_ENC_FRM_ LOST_ERR_EN	This bit enables an interrupt that is a result of IC's encoding frame lost. 0 Interrupt is disabled. 1 Interrupt is enabled.
24 IC_VF_FRM_ LOST_ERR_EN	This bit enables an interrupt that is a result of IC's view finder frame lost. 0 Interrupt is disabled. 1 Interrupt is enabled.
23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22 DI1_TIME_ OUT_ERR_EN	DI1 time out error interrupt enable This bit enables the interrupt that is a result of a time out error during a read access via DI1 0 Interrupt is disabled. 1 Interrupt is enabled.
21 DI0_TIME_ OUT_ERR_EN	DI0 time outwore interrupt enable This bit enables the interrupt that is a result of a time out error during a read access via DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
20 DI1_SYNC_ DISP_ERR_EN	DI1 Synchronous display error enable This bit enables the interrupt that is a result of an error during access to a synchronous display via DI1 0 Interrupt is disabled. 1 Interrupt is enabled.

Table continues on the next page...

IPU_INT_CTRL_10 field descriptions (continued)

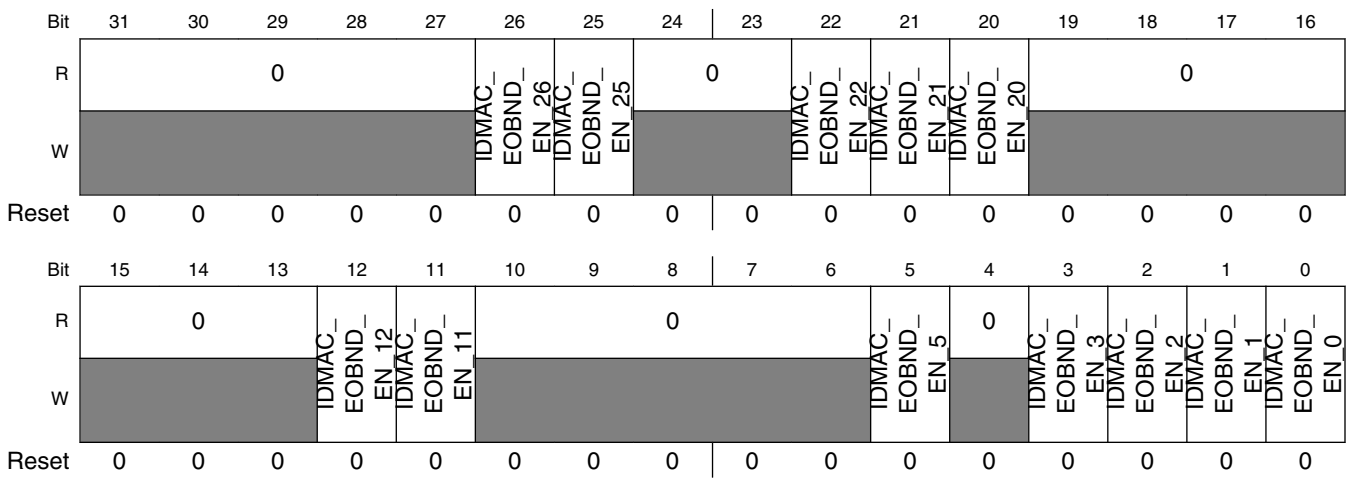
Field	Description
19 DI0_SYNC_ DISP_ERR_EN	DI0 Synchronous display error enable This bit enables the interrupt that is a result of an error during access to a synchronous display via DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
18 DC_TEARING_ ERR_6_EN	Tearing Error #6 enable This bit enables the interrupt that is a result of tearing error while the anti tearing mechanism is activated for DC channel 6 0 Interrupt is disabled. 1 Interrupt is enabled.
17 DC_TEARING_ ERR_2_EN	Tearing Error #2 enable This bit enables the interrupt that is a result of tearing error while the anti tearing mechanism is activated for DC channel 2 0 Interrupt is disabled. 1 Interrupt is enabled.
16 DC_TEARING_ ERR_1_EN	Tearing Error #1 enable This bit enables the interrupt that is a result of tearing error while the anti tearing mechanism is activated for DC channel 1 0 Interrupt is disabled. 1 Interrupt is enabled.
15–4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3 SMFC3_FRM_ LOST_EN	Frame Lost of SMFC channel 3 interrupt enable bit This bit enables an interrupt that is a result of a Frame Lost of SMFC channel 3. 0 Interrupt is disabled. 1 Interrupt is enabled.
2 SMFC2_FRM_ LOST_EN	Frame Lost of SMFC channel 2 interrupt enable bit This bit enables an interrupt that is a result of a Frame Lost of SMFC channel 2. 0 Interrupt is disabled. 1 Interrupt is enabled.
1 SMFC1_FRM_ LOST_EN	Frame Lost of SMFC channel 1 interrupt enable bit This bit enables an interrupt that is a result of a Frame Lost of SMFC channel 1. 0 Interrupt is disabled. 1 Interrupt is enabled.
0 SMFC0_FRM_ LOST_EN	Frame Lost of SMFC channel 0 interrupt enable bit This bit enables an interrupt that is a result of a Frame Lost of SMFC channel 0. 0 Interrupt is disabled. 1 Interrupt is enabled.

45.51.16 Interrupt Control Register 11 (IPU_INT_CTRL_11)

This register contains part of IPU interrupts controls. The controls of the end-of-band indication (EOBND) of DMA Channels interrupts [31:0] can be found in this register.

- Hide VDOA_SYNC for all versions
- Show VDOA_SYNC for IPUv3H version.
- The table below tagged with other settings (like IPU3M_only) should be hidden in IPUv3H version.

Address: IPU_INT_CTRL_11 is 1E00_0000h base + 64h offset = 1E00_0064h



IPU_INT_CTRL_11 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is disabled. 1 Interrupt is enabled.
26 IDMAC_ EOBND_EN_26	end-of-band indication of Channel interrupt. This bit is the control of end-of-band interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
25 IDMAC_ EOBND_EN_25	end-of-band indication of Channel interrupt. This bit is the control of end-of-band interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is disabled. 1 Interrupt is enabled.
24–23 Reserved	This read-only field is reserved and always has the value zero. Reserved.

Table continues on the next page...

IPU_INT_CTRL_15 field descriptions

Field	Description
31 DI1_CNT_EN_PRE_8_EN	This bit enables the interrupt that is a result of a trigger generated by counter #8 of DI1 0 Interrupt is disabled. 1 Interrupt is enabled.
30 DI1_CNT_EN_PRE_3_EN	This bit enables the interrupt that is a result of a trigger generated by counter #3 of DI1 0 Interrupt is disabled. 1 Interrupt is enabled.
29 DI1_DISP_CLK_EN_PRE_EN	DI1_DISP_CLK_EN_PRE_EN 0 Interrupt is disabled. 1 Interrupt is enabled.

Table continues on the next page...

IPU_INT_CTRL_15 field descriptions (continued)

Field	Description
28 DI0_CNT_EN_ PRE_10_EN	This bit enables the interrupt that is a result of a trigger generated by counter #10 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
27 DI0_CNT_EN_ PRE_9_EN	This bit enables the interrupt that is a result of a trigger generated by counter #9 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
26 DI0_CNT_EN_ PRE_8_EN	This bit enables the interrupt that is a result of a trigger generated by counter #8 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
25 DI0_CNT_EN_ PRE_7_EN	This bit enables the interrupt that is a result of a trigger generated by counter #7 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
24 DI0_CNT_EN_ PRE_6_EN	This bit enables the interrupt that is a result of a trigger generated by counter #6 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
23 DI0_CNT_EN_ PRE_5_EN	This bit enables the interrupt that is a result of a trigger generated by counter #5 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
22 DI0_CNT_EN_ PRE_4_EN	This bit enables the interrupt that is a result of a trigger generated by counter #4 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
21 DI0_CNT_EN_ PRE_3_EN	This bit enables the interrupt that is a result of a trigger generated by counter #3 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
20 DI0_CNT_EN_ PRE_2_EN	This bit enables the interrupt that is a result of a trigger generated by counter #2 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
19 DI0_CNT_EN_ PRE_1_EN	This bit enables the interrupt that is a result of a trigger generated by counter #1 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
18 DI0_CNT_EN_ PRE_0_EN	This bit enables the interrupt that is a result of a trigger generated by counter #0 of DI0 0 Interrupt is disabled. 1 Interrupt is enabled.
17 DC_ASYNC_ STOP_EN	This bit enables the interrupt asserted anytime the DP stops an async flow and moves to a sync flow

Table continues on the next page...

IPU_INT_CTRL_15 field descriptions (continued)

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
16 DC_DP_ START_EN	This bit enables the interrupt asserted anytime the DP start a new sync or async flow or when an async flow is interrupted by a sync flow 0 Interrupt is disabled. 1 Interrupt is enabled.
15 DI_VSYNC_ PRE_1_EN	This bit enables the DI1 interrupt indicating of a VSYNC signal asserted 2 rows before the VSYNC sent to the display 0 Interrupt is disabled. 1 Interrupt is enabled.
14 DI_VSYNC_ PRE_0_EN	This bit enables the DI0 interrupt indicating of a VSYNC signal asserted 2 rows before the VSYNC sent to the display 0 Interrupt is disabled. 1 Interrupt is enabled.
13 DC_FC_6_EN	This bit enables the DC Frame Complete on channel #6 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
12 DC_FC_4_EN	This bit enables the DC Frame Complete on channel #4 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
11 DC_FC_3_EN	This bit enables the DC Frame Complete on channel #3 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
10 DC_FC_2_EN	This bit enables the DC Frame Complete on channel #2 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
9 DC_FC_1_EN	This bit enables they'd Frame Complete on channel #1 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
8 DC_FC_0_EN	This bit enables they'd Frame Complete on channel #0 interrupt 0 Interrupt is disabled. 1 Interrupt is enabled.
7 DP_ASF_ BRAKE_EN	DP Async Flow Brake enable bit. This bit enables the interrupt that is a result of the async flow brake at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.

Table continues on the next page...

IPU_INT_CTRL_15 field descriptions (continued)

Field	Description
6 DP_SF_ BRAKE_EN	DP Sync Flow Brake enable bit. This bit enables the interrupt that is a result of the Sync flow brake at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
5 DP_ASF_END_ EN	DP Async Flow End enable bit. This bit enables the interrupt that is a result of the Async flow end at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
4 DP_ASF_ START_EN	DP Async Flow Start enable bit. This bit enables the interrupt that is a result of the Async flow start at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
3 DP_SF_END_ EN	DP Sync Flow End enable bit. This bit enables the interrupt that is a result of the Sync flow end at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
2 DP_SF_START_ EN	DP Sync Flow Start enable bit. This bit enables the interrupt that is a result of the Sync flow start at the DP 0 Interrupt is disabled. 1 Interrupt is enabled.
1 SNOOPING2_ INT_EN	IPU snooping 2 interrupt enable bit. This bit enables the interrupt that is a result of the detection of a snooping 2 signal assertion coming to the IPU 0 Interrupt is disabled. 1 Interrupt is enabled.
0 SNOOPING1_ INT_EN	IPU snooping 1 interrupt enable bit. This bit enables the interrupt that is a result of the detection of a snooping 1 signal assertion coming to the IPU 0 Interrupt is disabled. 1 Interrupt is enabled.

45.51.21 SDMA Event Control Register 1 (IPU_SDMA_EVENT_1)

This register contains part of IPU SDMA events controls. The controls of EOF (end of frame) of DMA Channels SDMA events [31:0] can be found in this register.

Address: IPU_SDMA_EVENT_1 is 1E00_0000h base + 78h offset = 1E00_0078h

IPU_SDMA_EVENT_3 field descriptions (continued)

Field	Description
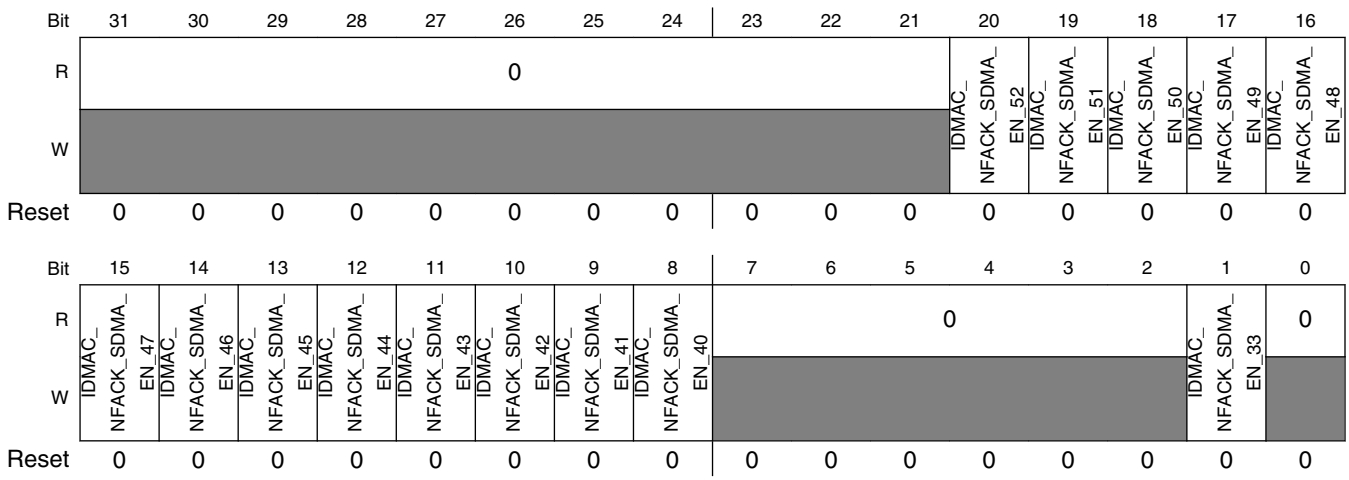
	0 SDMA event is disabled. 1 SDMA event is enabled.
7–6 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.
5 IDMAC_ NFACK_SDMA_ EN_5	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
4 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.
3 IDMAC_ NFACK_SDMA_ EN_3	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
2 IDMAC_ NFACK_SDMA_ EN_2	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
1 IDMAC_ NFACK_SDMA_ EN_1	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
0 IDMAC_ NFACK_SDMA_ EN_0	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.

45.51.24 SDMA Event Control Register 4 (IPU_SDMA_EVENT_4)

This register contains part of IPU SDMA events controls. The controls of NFACK (New Frame Acknowledge) of DMA Channels SDMA events [63:32] can be found in this register.

Address: IPU_SDMA_EVENT_4 is 1E00_0000h base + 84h offset = 1E00_0084h



IPU_SDMA_EVENT_4 field descriptions

Field	Description
31–21 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.
20 IDMAC_ NFACK_SDMA_ EN_52	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
19 IDMAC_ NFACK_SDMA_ EN_51	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
18 IDMAC_ NFACK_SDMA_ EN_50	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.

Table continues on the next page...

IPU_SDMA_EVENT_4 field descriptions (continued)

Field	Description
17 IDMAC_ NFACK_SDMA_ EN_49	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
16 IDMAC_ NFACK_SDMA_ EN_48	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
15 IDMAC_ NFACK_SDMA_ EN_47	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
14 IDMAC_ NFACK_SDMA_ EN_46	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
13 IDMAC_ NFACK_SDMA_ EN_45	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
12 IDMAC_ NFACK_SDMA_ EN_44	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
11 IDMAC_ NFACK_SDMA_ EN_43	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
10 IDMAC_ NFACK_SDMA_ EN_42	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number.

Table continues on the next page...

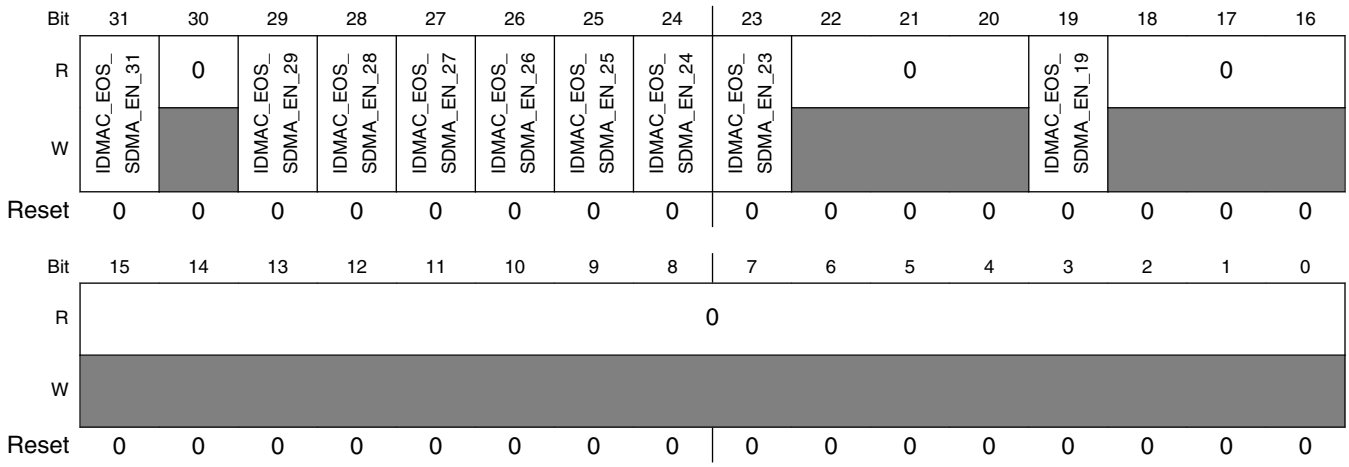
Field	Description
	0 SDMA event is disabled. 1 SDMA event is enabled.
9 IDMAC_ NFACK_SDMA_ EN_41	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
8 IDMAC_ NFACK_SDMA_ EN_40	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
7–2 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.
1 IDMAC_ NFACK_SDMA_ EN_33	Enable New Frame Acknowledge of Channel SDMA event. This bit is the control of New Frame Acknowledge of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.

45.51.25 SDMA Event Control Register 7 (IPU_SDMA_EVENT_7)

This register contains part of IPU SDMA events controls. The controls of EOS (End of Scroll) of DMA Channels SDMA events [31:0] can be found in this register.

Address: IPU_SDMA_EVENT_7 is 1E00_0000h base + 88h offset = 1E00_0088h



IPU_SDMA_EVENT_7 field descriptions

Field	Description
31 IDMAC_EOS_SDMA_EN_31	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
30 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.
29 IDMAC_EOS_SDMA_EN_29	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
28 IDMAC_EOS_SDMA_EN_28	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
27 IDMAC_EOS_SDMA_EN_27	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number.

Table continues on the next page...

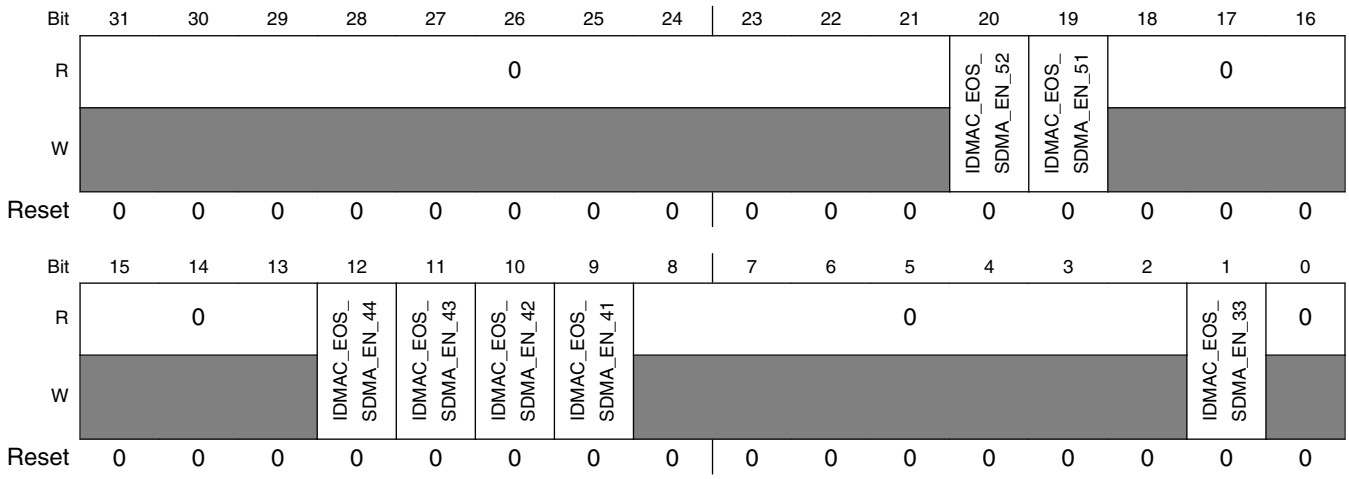
IPU_SDMA_EVENT_7 field descriptions (continued)

Field	Description
	0 SDMA event is disabled. 1 SDMA event is enabled.
26 IDMAC_EOS_ SDMA_EN_26	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
25 IDMAC_EOS_ SDMA_EN_25	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
24 IDMAC_EOS_ SDMA_EN_24	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
23 IDMAC_EOS_ SDMA_EN_23	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
22–20 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.
19 IDMAC_EOS_ SDMA_EN_19	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
18–0 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.

45.51.26 SDMA Event Control Register 8 (IPU_SDMA_EVENT_8)

This register contains part of IPU SDMA events controls. The controls of EOS (End of Scroll) of DMA Channels SDMA events [63:32] can be found in this register.

Address: IPU_SDMA_EVENT_8 is 1E00_0000h base + 8Ch offset = 1E00_008Ch



IPU_SDMA_EVENT_8 field descriptions

Field	Description
31–21 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.
20 IDMAC_EOS_SDMA_EN_52	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
19 IDMAC_EOS_SDMA_EN_51	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
18–13 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.
12 IDMAC_EOS_SDMA_EN_44	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number.

Table continues on the next page...

IPU_SDMA_EVENT_8 field descriptions (continued)

Field	Description
	0 SDMA event is disabled. 1 SDMA event is enabled.
11 IDMAC_EOS_SDMA_EN_43	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
10 IDMAC_EOS_SDMA_EN_42	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
9 IDMAC_EOS_SDMA_EN_41	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
8–2 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.
1 IDMAC_EOS_SDMA_EN_33	Enable End of Scroll of Channel SDMA event. This bit is the control of End Of Scroll of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.

45.51.27 SDMA Event Control Register 11 (IPU_SDMA_EVENT_11)

This register contains part of IPU SDMA events controls. The controls of EOBND (End of Band) of DMA Channels SDMA events [31:0] can be found in this register.

- Hide VDOA_SYNC for all versions
- Show VDOA_SYNC for IPUv3H version.
- The table below tagged with other settings (like IPU3M_only) should be hidden in IPUv3H version.

8 IDMAC_TH_ SDMA_EN_8	Enable Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
7–6 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.
5 IDMAC_TH_ SDMA_EN_5	Enable Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
4 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.
3 IDMAC_TH_ SDMA_EN_3	Enable Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
2 IDMAC_TH_ SDMA_EN_2	Enable Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
1 IDMAC_TH_ SDMA_EN_1	Enable Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
0 IDMAC_TH_ SDMA_EN_0	Enable Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.

45.51.30 SDMA Event Control Register 14 (IPU_SDMA_EVENT_14)

This register contains part of IPU SDMA events controls. The controls of TH (Threshold) of DMA Channels SDMA events [63:32] can be found in this register.

Address: IPU_SDMA_EVENT_14 is 1E00_0000h base + 9Ch offset = 1E00_009Ch

IPU_SDMA_EVENT_14 field descriptions

Field	Description
31–21 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.
20 IDMAC_TH_SDMA_EN_52	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
19 IDMAC_TH_SDMA_EN_51	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
18 IDMAC_TH_SDMA_EN_50	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.

Table continues on the next page...

IPU_SDMA_EVENT_14 field descriptions (continued)

Field	Description
17 IDMAC_TH_ SDMA_EN_49	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
16 IDMAC_TH_ SDMA_EN_48	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
15 IDMAC_TH_ SDMA_EN_47	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
14 IDMAC_TH_ SDMA_EN_46	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
13 IDMAC_TH_ SDMA_EN_45	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
12 IDMAC_TH_ SDMA_EN_44	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
11 IDMAC_TH_ SDMA_EN_43	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
10 IDMAC_TH_ SDMA_EN_42	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number.

Table continues on the next page...

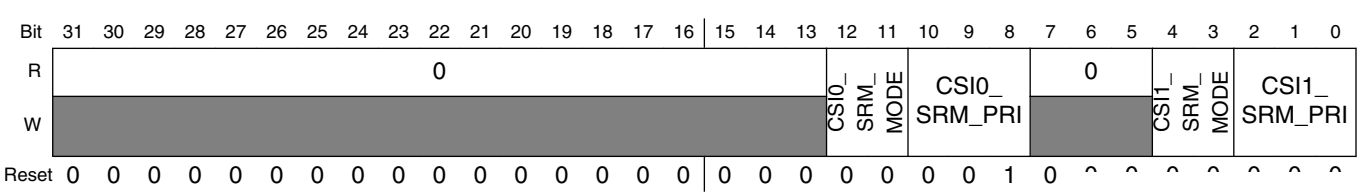
IPU_SDMA_EVENT_14 field descriptions (continued)

Field	Description
	0 SDMA event is disabled. 1 SDMA event is enabled.
9 IDMAC_TH_ SDMA_EN_41	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
8 IDMAC_TH_ SDMA_EN_40	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
7–2 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.
1 IDMAC_TH_ SDMA_EN_33	Threshold of Channel SDMA event. This bit is the control of Threshold of Channel #n. n Indicates the corresponding DMA channel number. *n* Indicates the corresponding DMA channel number. 0 SDMA event is disabled. 1 SDMA event is enabled.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 SDMA event is disabled. 1 SDMA event is enabled.

45.51.31 Shadow Registers Memory Priority 1 Register (IPU_SRM_PRI1)

The register controls the priority of SRM updates. The priority level for each block that has a shadow of its registers in the SRM should be unique. The priority level defines the order of SRM updates. A block with priority set to 010 will be updated before a block with priority set to 001.

Address: IPU_SRM_PRI1 is 1E00_0000h base + A0h offset = 1E00_00A0h



IPU_SRM_PRI1 field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12–11 CSI0_SRM_ MODE	CSI0 SRM Mode This field controls the SRM logic that handles the CSI0 registers 00 Automatic swapping is disabled; ARM platform is allowed to access the CSI1's region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM Platform. The Register will be update now
10–8 CSI0_SRM_PRI	CSI0 SRM priority This bits define the priority of the CSI1 block
7–5 Reserved	This read-only field is reserved and always has the value zero. Reserved
4–3 CSI1_SRM_ MODE	CSI1 SRM Mode This field controls the SRM logic that handles the CSI1 registers 00 Automatic swapping is disabled; ARM platform is allowed to access the CSI0's region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
2–0 CSI1_SRM_PRI	CSI1 SRM priority This bits define the priority of the CSI0 module

45.51.32 Shadow Registers Memory Priority 2 Register (IPU_SRM_PRI2)

The register controls the priority of SRM updates. The priority level for each block that has a shadow of its registers in the SRM should be unique. The priority level defines the order of SRM updates. a block with priority set to 010 will be updated before a block with priority set to 001.

Address: IPU_SRM_PRI2 is 1E00_0000h base + A4h offset = 1E00_00A4h

IPU_SRM_PRI2 field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28–27 DI1_SRM_ MODE	DCI1 SRM Mode This field controls the SRM logic that handles the DI1 registers 00 Automatic swapping is disabled; ARM platform is allowed to access the DI1 region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
26–24 DI1_SRM_PRI	DI1 SRM priority This bits define the priority of the DI1 module
23–21 Reserved	This read-only field is reserved and always has the value zero. Reserved
20–19 DI0_SRM_ MCU_USE	DI0 SRM is used by ARM platform This bit indicates that the registers of the DI0 are currently being updated by the ARM platform. The ARM platform should set this bit before accessing the SRM part that is relevant to the DI0. The ARM platform should clear this bit when the update procedure is finished. When this bit is set the SRM mechanism will not update the DI0's registers to avoid data coherency problems. 1 DI0 SRM is currently updated by the ARM platform 0 DI0 SRM s currently not updated by the ARM platform
18–16 DI0_SRM_PRI	DI0 SRM priority This bits define the priority of the DI0 module
15–14 DC_6_SRM_ MODE	DC Group #6 SRM Mode This field controls the SRM logic that handles the DC Group #6 registers 00 Automatic swapping is disabled; ARM platform is allowed to access the DC Group #6's region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
13–12 DC_2_SRM_ MODE	DC Group #2 SRM Mode This field controls the SRM logic that handles the DC Group #2 registers 00 Automatic swapping is disabled; ARM platform is allowed to access the DC Group #2's region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
11–9 DC_SRM_PRI	DC SRM priority This bits define the priority of the DC module
8–7 DP_A1_SRM_ MODE	DP Async flow #1 SRM Mode This field controls the SRM logic that handles the DP Async flow #1 registers

Table continues on the next page...

IPU_SRM_PRI2 field descriptions (continued)

Field	Description
	00 Automatic swapping is disabled; ARM platform is allowed to access the DP Async flow #1 region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
6–5 DP_A0_SRM_MODE	DP Async flow #0 SRM Mode This field controls the SRM logic that handles the DP Async flow #0 registers 00 Automatic swapping is disabled; ARM platform is allowed to access the DP Async flow #0 region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done of the next frame. 10 The SRM logic is controlled by the FSU. Registers are swapped continuously frame by frame 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
4–3 DP_S_SRM_MODE	DP sync flow SRM Mode This field controls the SRM logic that handles the DP sync flow registers 00 Automatic swapping is disabled; ARM platform is allowed to access the DP sync flow region in the RAM 01 The SRM logic is controlled by the FSU. The update will be done on the next frame. 10 Reserved 11 Update now. The SRM is controlled by the ARM platform. The Register will be update now
2–0 DP_SRM_PRI	DP SRM priority This bits define the priority of the DP module

45.51.33 FSU Processing Flow 1 Register (IPU_FS_PROC_FLOW1)

This register contain controls for IPU's tasks.

Address: IPU_FS_PROC_FLOW1 is 1E00_0000h base + A8h offset = 1E00_00A8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

45.51.35 FSU Processing Flow 3 Register (IPU_FS_PROC_FLOW3)

This register contains controls for IPU's tasks.

- Hide VPU_SUB_FRAME_SYNC for all versions
- Show VPU_SUB_FRAME_SYNC for IPUv3H version.
- The table below tagged with other settings (like IPU3M_only) should be hidden in IPUv3H version.
- This requires some sophisticated conditional tag settings

Address: IPU_FS_PROC_FLOW3 is 1E00_0000h base + B0h offset = 1E00_00B0h

45.51.38 SKIP Register (IPU_SKIP)

This register controls the different frame skipping supported by the IPU.

Address: IPU_SKIP is 1E00_0000h base + BCh offset = 1E00_00BCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	VDI_SKIP												VDI_MAX_RATIO_SKIP			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CSI_SKIP_IC_VF					CSI_MAX_RATIO_SKIP_IC_VF			CSI_SKIP_IC_ENC					CSI_MAX_RATIO_SKIP_IC_ENC		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_SKIP field descriptions

Field	Description
31–20 VDI_SKIP	VDI_SKIP These 12 bits define the skipping pattern of the frames send from the VDIC. The VDIC avoids reading fields from the memory if the output frame is skipped. Skipping is relevant only if the source to the VDIC is coming from the CSI. Skipping is done for a set of frames. The number of frames in a set is defined at VDI_MAX_RATIO_SKIP. when VDI_MAX_RATIO_SKIP = 1 => VDI_SKIP[1:0] is used; other bits are ignored when VDI_MAX_RATIO_SKIP = 2 => VDI_SKIP[2:0] are used; other bits are ignored .. .. when VDI_MAX_RATIO_SKIP = 11 => VDI_SKIP[11:0] are used;
19–16 VDI_MAX_ RATIO_SKIP	Maximum Ratio Skip for VDIC These bits define the number of frames in a skipping set. The maximum value of this bits is 11. When set to 0 the skipping is disabled.
15–11 CSI_SKIP_IC_ VF	CSI SKIP IC_VF These 5 bits define the skipping pattern of the frames send to the IC for view finder task from one of the CSIs as defined on the CSI_SEL and IC_INPUT bits Skipping is done for a set of frames. The number of frames in a set is defined at CSI_MAX_RATIO_SKIP_IC_VF. when CSI_MAX_RATIO_SKIP_IC_VF = 1 => CSI_SKIP_IC_VF[1:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_VF = 2 => CSI_SKIP_IC_VF[2:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_VF =3 => CSI_SKIP_IC_VF[3:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_VF = 4 => CSI_SKIP_IC_VF[4:0] are used; Setting bit #n of CSI_SKIP_IC_VF means that the #n frame in the set is skipped. For example: if CSI_MAX_RATIO_SKIP_IC_VF = 4 and CSI_SKIP_IC_VF = 11010 Frames #0 & Frame #2 will not be skipped as bit0 and bit2 are cleared Frames #1 & Frame #3 will be skipped as bit1 and bit3 are set

Table continues on the next page...

IPU_SKIP field descriptions (continued)

Field	Description
	bit #4 is ignored as CSI_MAX_RATIO_SKIP_IC_VF is set to 4
10–8 CSI_MAX_ RATIO_SKIP_ IC_VF	CSI Maximum Ratio Skip for IC (view finder task) These bits define the number of frames in a skipping set. The maximum value of this bits is 4. When set to 0 the skipping is disabled.
7–3 CSI_SKIP_IC_ ENC	CSI SKIP IC_ENC These 5 bits define the skipping pattern of the frames send to the IC for encoding task from one of the CSIs as defined on the CSI_SEL and IC_INPUT bits Skipping is done for a set of frames. The number of frames in a set is defined at CSI_MAX_RATIO_SKIP_IC_ENC. when CSI_MAX_RATIO_SKIP_IC_ENC = 1 => CSI_SKIP_IC_ENC[1:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_ENC = 2 => CSI_SKIP_IC_ENC[2:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_ENC = 3 => CSI_SKIP_IC_ENC[3:0] are used; other bits are ignored when CSI_MAX_RATIO_SKIP_IC_ENC = 4 => CSI_SKIP_IC_ENC[4:0] are used; Setting bit #n of CSI_SKIP_IC_ENC means that the #n frame in the set is skipped. For example: if CSI_MAX_RATIO_SKIP_IC_ENC = 4 and CSI_SKIP_IC_ENC = 11010 Frames #0 & Frame #2 will not be skipped as bit0 and bit2 are cleared Frames #1 & Frame #3 will be skipped as bit1 and bit3 are set bit #4 is ignored as CSI_MAX_RATIO_SKIP_IC_ENC is set to 4
2–0 CSI_MAX_ RATIO_SKIP_ IC_ENC	CSI Maximum Ratio Skip for IC (encoding task) These bits define the number of frames in a skipping set. The maximum value of this bits is 4. When set to 0 the skipping is disabled.

45.51.39 Display General Control Register (IPU_DISP_GEN)

This register controls various aspects of the display port.

Address: IPU_DISP_GEN is 1E00_0000h base + C4h offset = 1E00_00C4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0						DI1_COUNTER_RELEASE	DI0_COUNTER_RELEASE	CSI_VSYNC_DEST	MCU_MAX_BURST_STOP	MCU_T				MCU_DI_ID_9	MCU_DI_ID_8
W																
Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0									0	DP_FG_EN_ASYNC1	DP_FG_EN_ASYNC0	DP_ASYNC_DOUBLE_FLOW_DC2_	DOUBLE_FLOW	DI1_DUAL_MODE	DI0_DUAL_MODE
W										DP_PIPE_CLR						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_DISP_GEN field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value zero. Reserved
25 DI1_COUNTER_RELEASE	DI1 Counter release By default the DI0 counters responsible for waveform generation for sync flow are frozen. For the first attempt to use the DI in sync flow the user should set this bit 1 counter is released and running 0 counter is cleared and stopped
24 DI0_COUNTER_RELEASE	DI1 Counter release By default the DI0 counters responsible for waveform generation for sync flow are frozen. For the first attempt to use the DI in sync flow the user should set this bit 1 counter is released and running 0 counter is cleared and stopped
23 CSI_VSYNC_DEST	CSI_VSYNC destination This bit defines the destination of the VSYNC coming from the CSI's 1 csi1_vsync is connected to DI0; csi0_vsync is connected to DI1 0 csi0_vsync is connected to DI0; csi1_vsync is connected to DI1
22 MCU_MAX_BURST_STOP	ARM platform Maximal burst This bit limit the maximal unspecified length burst. 1 The maximum unspecified burst length is 8-beat 0 The unspecified burst length is unlimited
21–18 MCU_T	The address space for accesses through the AHB-lite slave port is 128MB and it is split internally (with 32MB resolution) according to bits [28:25] of the address. Using the following notation: Address = (ID[31:29], MSB[28:25], LSB[24:0]) The address is used as follows ("T" is a configurable integer between 0 and 13): MSB<T: access to an external device, with address = (MSB, LSB) T<=MSB<14: access to an external device, with address (MSB-T, LSB)
17 MCU_DI_ID_9	MCU_DI_ID_9 - DI ID via DC channel 9. This bit defines the DI that the ARM platform DC's access via channel #9 1 ARM platform accesses DC's channel #9 via DI1. 0 ARM platform accesses DC's channel #9 via DI0.
16 MCU_DI_ID_8	MCU_DI_ID_8 - DI ID via DC channel 8. This bit defines the DI that the ARM platform DC's access via channel #8 1 ARM platform accesses DC's channel #8 via DI1. 0 ARM platform accesses DC's channel #8 via DI0.
15–7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6 DP_PIPE_CLR	DP Pipe Clear This bit clears the internal pipe of the DP. The user may use this bit in case of an error condition

Table continues on the next page...

IPU_DISP_GEN field descriptions (continued)

Field	Description
	This is a self clear bit 1 Clear the internal pipe of the DP 0 Idle - does nothing
5 DP_FG_EN_ASYNC1	FG_EN - partial plane Enable for async flow 1. This bit enables the partial plane channel. 1 partial plane channel is enabled. 0 partial plane channel is disabled.
4 DP_FG_EN_ASYNC0	FG_EN - partial plane Enable for async flow 0. This bit enables the partial plane channel. 1 partial plane channel is enabled. 0 partial plane channel is disabled.
3 DP_ASYNC_DOUBLE_FLOW	DP Async Double Flow. This bit define how many async flows are currently handles via DP channel (ch24+29) 1 2 flows are handled via DP 0 single flow is handled via DP
2 DC2_DOUBLE_FLOW	DC2 Double Flow. This bit define how many flows are currently handles via DC2 channel (ch41) 1 2 flows are handled via DC2 0 single flow is handled via DC2
1 DI1_DUAL_MODE	DI1 dual mode control 1 DI1 operates in dual mode 0 DI1 is not in dual mode
0 DI0_DUAL_MODE	DI0 dual mode control 1 DI0 operates in dual mode 0 DI0 is not in dual mode

45.51.40 Display Alternate Flow Control Register 1 (IPU_DISP_ALT1)

This register controls various aspects of the display port.

Address: IPU_DISP_ALT1 is 1E00_0000h base + C8h offset = 1E00_00C8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	sel_alt_0				step_repeat_alt_0											
W																
Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	cnt_auto_reload_alt_0	cnt_clr_sel_alt_0			run_value_m1_alt_0											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_DISP_ALT1 field descriptions

Field	Description
31–28 sel_alt_0	Select alternative parameters instead of DI Sync Wave Gen counter#. The DI is selected according to DP's synchronous channel destination 0000-disable 0001 instead of counter 1 0010 instead of counter 2 1000 instead of counter 8
27–16 step_repeat_alt_0	This fields defines the amount of repetitions that will be performed by the counter
15 cnt_auto_reload_alt_0	Counter auto reload mode 1 The counter will automatically be reloaded forever, ignoring the value of the step_repeat_alt_0 field 0 The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the step_repeat_alt_0 field
14–12 cnt_clr_sel_alt_0	Counter Clear select This field defines the source of the signals that clears the counter. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 Reserved 011 Reserved 100 Reserved 101 CSI VSYNC. The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. —

Table continues on the next page...

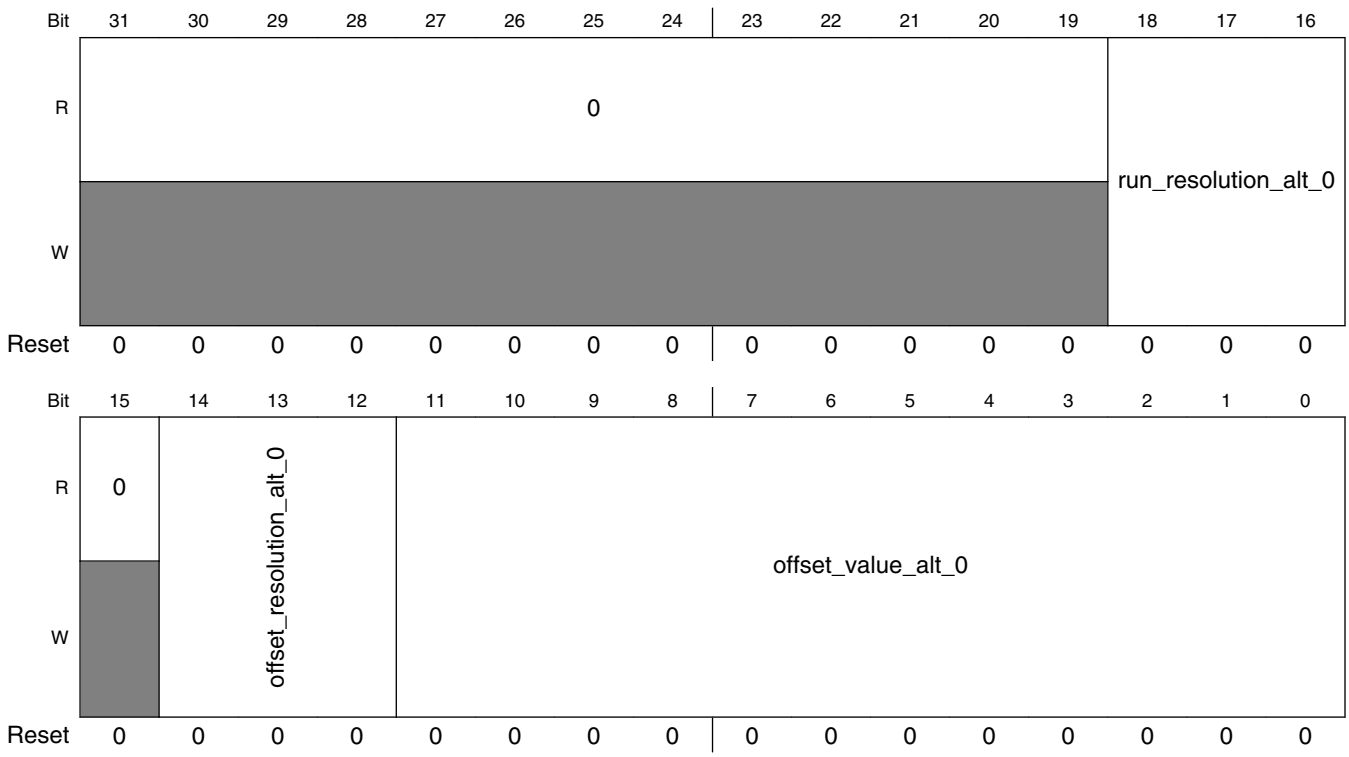
IPU_DISP_ALT1 field descriptions (continued)

Field	Description
	110 External VSYNC 111 Counter is always on.
11–0 run_value_m1_alt_0	Counter pre defined value This fields defines the counter pre defines value. real value- 1

45.51.41 Display Alternate Flow Control Register 2 (IPU_DISP_ALT2)

This register controls various aspects of the display port.

Address: IPU_DISP_ALT2 is 1E00_0000h base + CCh offset = 1E00_00CCh



IPU_DISP_ALT2 field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18–16 run_resolution_alt_0	Counter Run Resolution This field defines the trigger causing the counter to increment. The counter run resolution should be defined in the same way as in original DI's counter#
15 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

IPU_DISP_ALT2 field descriptions (continued)

Field	Description
14–12 offset_ resolution_alt_0	Counter offset Resolution This field defines the trigger causing the offset counter to increment The counter offset resolution should be defined in the same way as in original DI's counter#
11–0 offset_value_alt_ 0	Counter offset value The counter can start counting after a pre defined delay This field defines the amount of cycles that the counter will be delayed by

45.51.42 Display Alternate Flow Control Register 3 (IPU_DISP_ALT3)

This register controls various aspects of the display port.

Address: IPU_DISP_ALT3 is 1E00_0000h base + D0h offset = 1E00_00D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_DISP_ALT3 field descriptions

Field	Description
31–28 sel_alt_1	Select alternative parameters instead of DI Sync Wave Gen counter#. The DI is selected according to DP's synchronous channel destination 0000 disable 0001 instead of counter 1 0010 instead of counter 2 1000 instead of counter 8
27–16 step_repeat_alt_ 1	This fields defines the amount of repetitions that will be performed by the counter
15 cnt_auto_ reload_alt_1	Counter auto reload mode

Table continues on the next page...

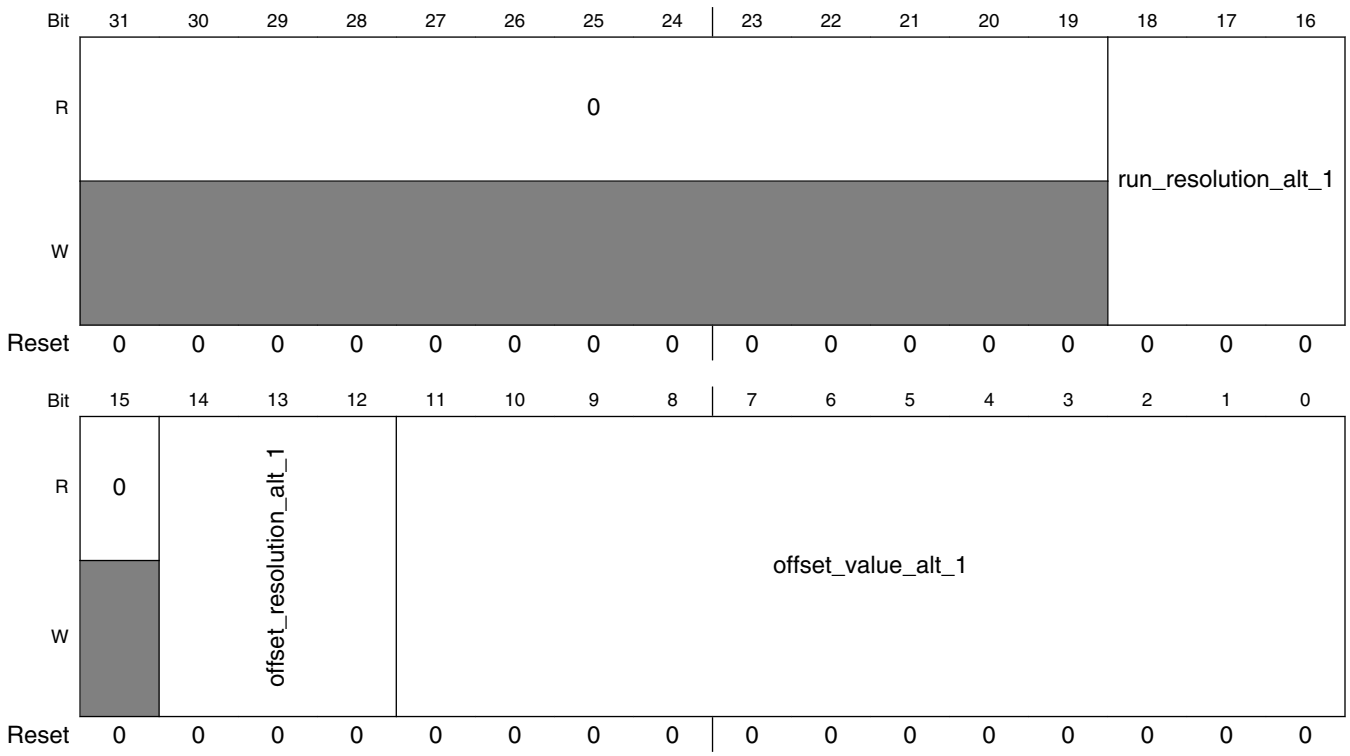
IPU_DISP_ALT3 field descriptions (continued)

Field	Description
	1 The counter will automatically be reloaded forever, ignoring the value of the step_repeat_alt_0 field 0 The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the step_repeat_alt_0 field
14–12 cnt_clr_sel_alt_1	Counter Clear select This field defines the source of the signals that clears the counter. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 Reserved 011 Reserved 100 Reserved 101 CSI VSYNC. The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. — 110 External VSYNC 111 Counter is always on.
11–0 run_value_m1_alt_1	Counter pre defined value This fields defines the counter pre defines value. real value- 1

45.51.43 Display Alternate Flow Control Register 4 (IPU_DISP_ALT4)

This register controls various aspects of the display port.

Address: IPU_DISP_ALT4 is 1E00_0000h base + D4h offset = 1E00_00D4h



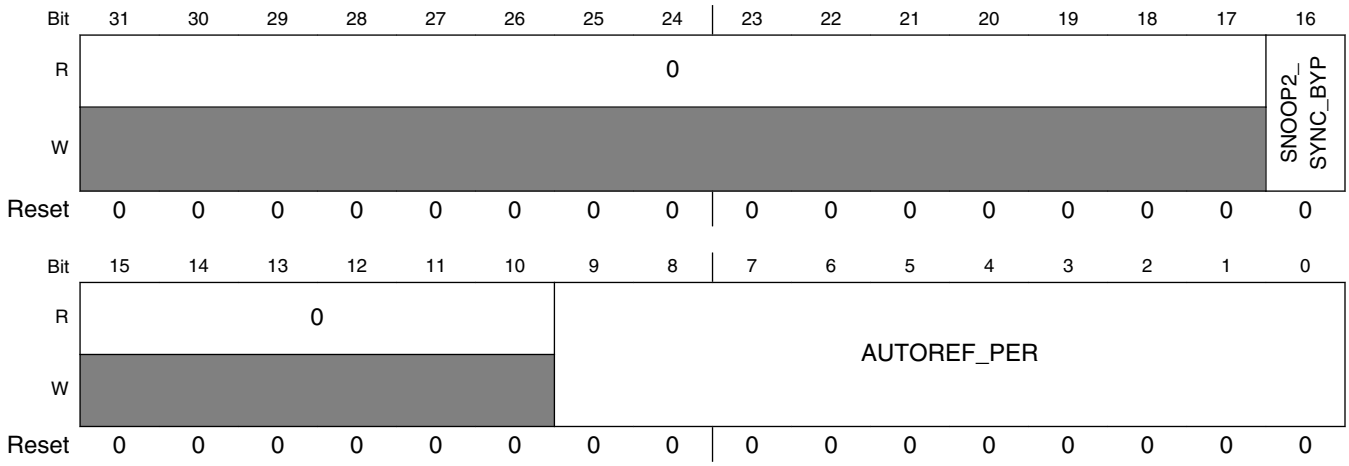
IPU_DISP_ALT4 field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18–16 run_resolution_alt_1	Counter Run Resolution This field defines the trigger causing the counter to increment. The counter run resolution should be defined in the same way as in original DI's counter#
15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14–12 offset_resolution_alt_1	Counter offset Resolution This field defines the trigger causing the offset counter to increment The counter offset resolution should be defined in the same way as in original DI's counter#
11–0 offset_value_alt_1	Counter offset value The counter can start counting after a pre defined delay This field defines the amount of cycles that the counter will be delayed by

45.51.44 Autorefresh and Snooping Control Register (IPU_SNOOP)

This register controls the snooping mechanism

Address: IPU_SNOOP is 1E00_0000h base + D8h offset = 1E00_00D8h



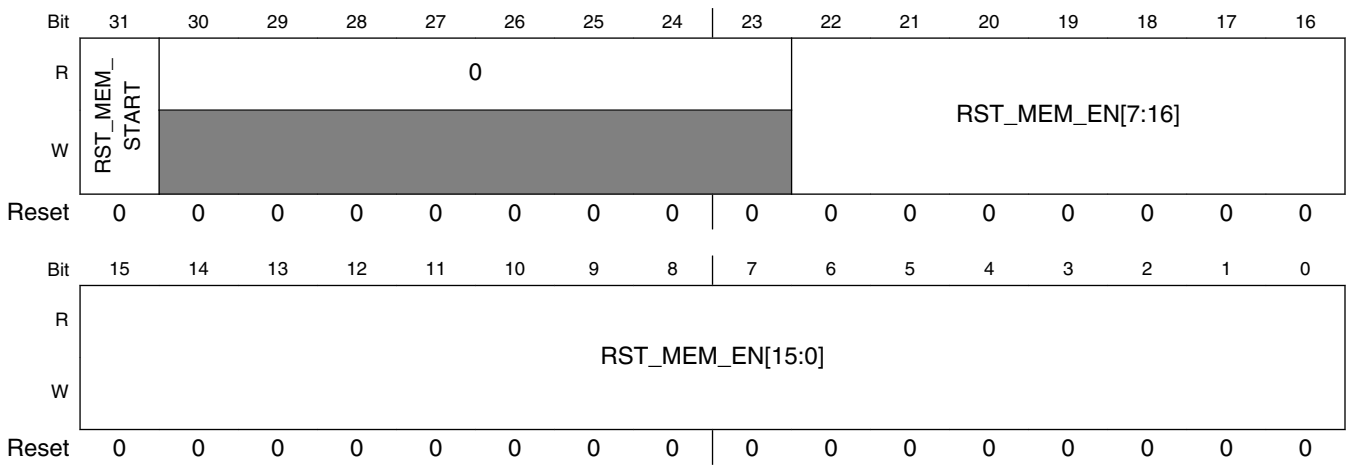
IPU_SNOOP field descriptions

Field	Description
31–17 Reserved	This read-only field is reserved and always has the value zero. Reserved
16 SNOOP2_ SYNC_BYP	This bits control the bypass of the synchronizer on emi_snooping2 signal. This bit is for test purposes only. The user should not set this bit 1 bypass the emi_snooping2 synchronizer 0 normal mode emi_snooping2 is internally synchronized
15–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–0 AUTOREF_PER	Autorefresh period minus 1. The actual value of autorefresh period is equal to the high speed clock (HSP_CLK) period multiplied by 2^17*(AUTO_REF_PER+1).

45.51.45 Memory Reset Control Register (IPU_MEM_RST)

This register controls the memory reset mechanism. IPU has a hardware mechanism for clearing the content of the internal memories. This allows the user to clear the content of or more of the internal memories without the need to perform write accesses to the memories.

Address: IPU_MEM_RST is 1E00_0000h base + DCh offset = 1E00_00DCh



IPU_MEM_RST field descriptions

Field	Description
31 RST_MEM_START	Memory Reset Start Writing one to this bit activate the memory reset mechanism. The memories that their corresponding RST_MEM_EN bit is set will be cleared. When the memory reset mechanism completes the memory clearing procedure this bit will be automatically cleared. 1 The memory reset mechanism is activated and busy 0 Idle, the memory reset mechanism is not working.
30–23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22–0 RST_MEM_EN	Reset Memory Enable Each bit on this field enables the memory reset mechanism for a specific memory. The user should set the relevant bits for the memories that need to be cleared. Below is the list of memories and their corresponding bit. srm = rst_mem_en[0] alpha = rst_mem_en[1] cpmem = rst_mem_en[2] tpm = rst_mem_en[3] mpm = rst_mem_en[4] bm = rst_mem_en[5] rm = rst_mem_en[6]

Table continues on the next page...

45.51.46 Power Modes Control Register (IPU_PM)

This register controls the automatic transitions of the IPU between different power modes of the SoC and handles the clock change modes.

Address: IPU_PM is 1E00_0000h base + E0h offset = 1E00_00E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IPU_PM field descriptions

Field	Description
31 LPSR_MODE	LPSR Mode This bit indicates that the next attempt for entering low power mode is an attempt to move to LPST mode. Setting this bit by the user is essential in order to assure proper response of the IPU to the assertion of the stop request from the CCM. 1 Next low power mode will be LPSR 0 Next low power mode is not LPSR
30 DI1_SRM_ CLOCK_ CHANGE_ MODE	SRM clock change mode When the clock is going to be changed to any new ratio other then 1:1, 1:2. 1:4. The user needs to prepare an alternate set of DI setting in the SRM. This bit enable this mode. This bit is self cleared. 1 SRM clock change mode is enabled; the next clock change will be done by updating the DI settings from the SRM 0 SRM clock change mode is disabled.
29–23 DI1_CLK_ PERIOD_1	DI1_CLK period option 1. This parameter defines the period of the clock that the DI1 works with. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]). Setting this value to 1.0 (default) means that the DI1 works on the fastest possible clock. Setting a value smaller than 1.0 is not allowed. The value to be programmed to the DI1_CLK_PERIOD_1 field is equal to: Fast_freq/Target_freq Where: Target_freq = The frequency that the DI clock works with Fast_freq = fastest possible clock that the DI can work with
22–16 DI1_CLK_ PERIOD_0	DI1_CLK period option 0. This parameter defines the period of the clock that the DI1 works with. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]). Setting this value to 1.0 (default) means that the DI1 works on the fastest possible clock. Setting a value smaller than 1.0 is not allowed. The value to be programmed to the DI1_CLK_PERIOD_1 field is equal to: Fast_freq/Target_freq Where: Target_freq = The frequency that the DI clock works with Fast_freq = fastest possible clock that the DI can work with
15 CLCOK_MODE_ STAT	Clock mode status This is a read only bit indicating what is the current clock mode 1 current clock mode is 1 0 current clock mode is 0

Table continues on the next page...

IPU_PM field descriptions (continued)

Field	Description
14 DI0_SRM_ CLOCK_ CHANGE_ MODE	SRM clock change mode When the clock is going to be changed to any new ratio other then 1:1, 1:2. 1:4. The user needs to prepare an alternate set of DI setting in the SRM. This bit enable this mode. This bit is self cleared. 1 SRM clock change mode is enabled; the next clock change will be done by updating the DI settings from the SRM 0 SRM clock change mode is disabled.
13–7 DI0_CLK_ PERIOD_1	DI0_CLK period option 1. This parameter defines the period of the clock that the DI0 works with. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]). Setting this value to 1.0 (default) means that the DI0 works on the fastest possible clock. Setting a value smaller than 1.0 is not allowed. The value to be programmed to the DI0_CLK_PERIOD_1 field is equal to: Fast_freq/Target_freq Where: Target_freq = The frequency that the DI clock works with Fast_freq = fastest possible clock that the DI can work with
6–0 DI0_CLK_ PERIOD_0	DI0_CLK period option 0. This parameter defines the period of the clock that the DI0 works with. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]). Setting this value to 1.0 (default) means that the DI0 works on the fastest possible clock. Setting a value smaller than 1.0 is not allowed. The value to be programmed to the DI0_CLK_PERIOD_1 field is equal to: Fast_freq/Target_freq Where: Target_freq = The frequency that the DI clock works with Fast_freq = fastest possible clock that the DI can work with

45.51.47 General Purpose Register (IPU_GPR)

The register contains general purpose bits.

Address: IPU_GPR is 1E00_0000h base + E4h offset = 1E00_00E4h

Field	Description
	0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.

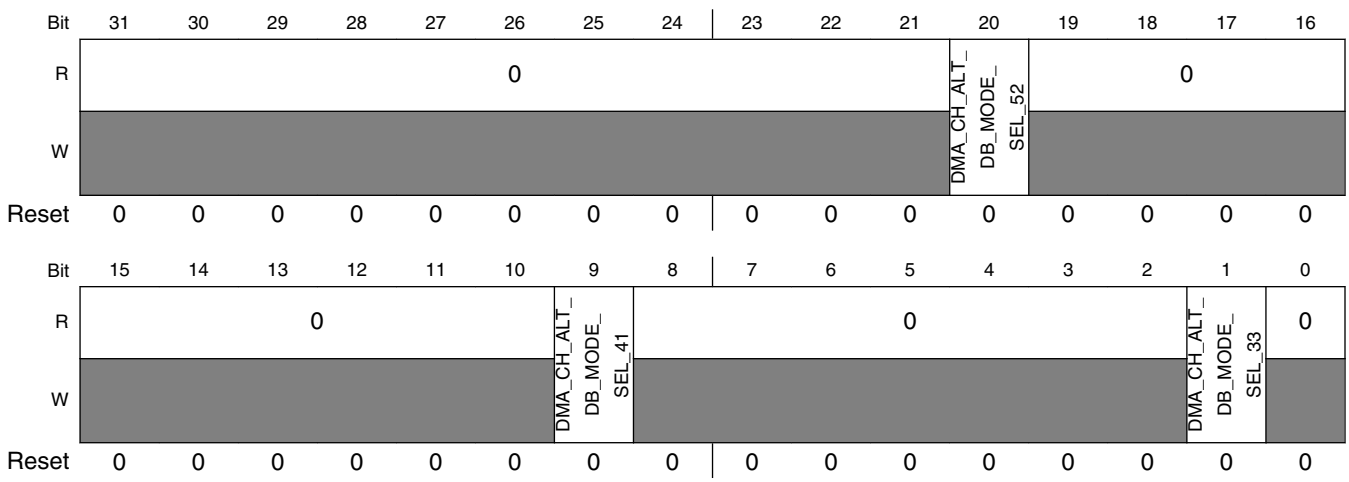
45.51.51 Alternate Channel Double Buffer Mode Select1 Register (IPU_ALT_CH_DB_MODE_SEL1)

The register contains double buffer mode select control information for 32 IPU's DMA channels.

Address: IPU_ALT_CH_DB_MODE_SEL1 is 1E00_0000h base + 16Ch offset = 1E00_016Ch



IPU_ALT_CH_DB_MODE_SEL1 field descriptions

Field	Description
31–21 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
20 DMA_CH_ALT_DB_MODE_SEL_52	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
19–10 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.

Table continues on the next page...

IPU_ALT_CH_DB_MODE_SEL1 field descriptions (continued)

Field	Description
9 DMA_CH_ALT_DB_MODE_SEL_41	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
8–2 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
1 DMA_CH_ALT_DB_MODE_SEL_33	Double Buffer Mode Select. This bit indicates if a double buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Double buffer is not used for this channel. 1 Double buffer is used for this channel.

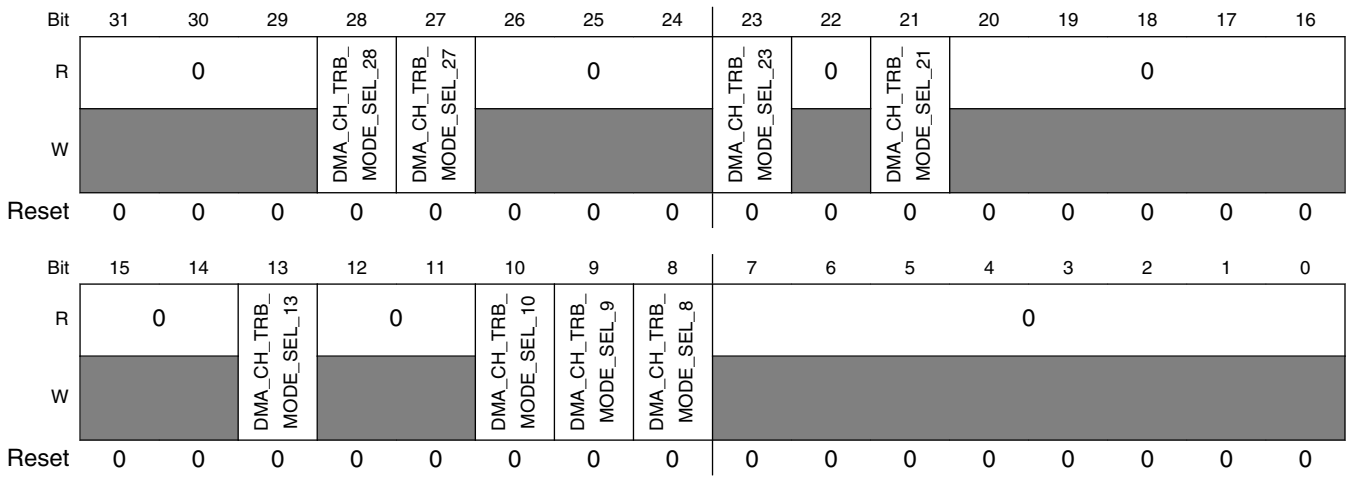
45.51.52 Alternate Channel Triple Buffer Mode Select 0 Register (IPU_ALT_CH_TRB_MODE_SEL0)

The register contains triple buffer mode select control information for 32 IPU's DMA channels.

When the channel is configured for triple buffer mode. The double buffer mode settings configured on the corresponding DB_MODE_SEL bit are overridden.

- Hide VPU_SUB_FRAME_SYNC for all versions
- Show VPU_SUB_FRAME_SYNC for IPUv3H version.
- The table below tagged with other settings (like IPU3M_only) should be hidden in IPUv3H version.
- This requires some sophisticated conditional tag settings

Address: IPU_ALT_CH_TRB_MODE_SEL0 is 1E00_0000h base + 178h offset = 1E00_0178h



IPU_ALT_CH_TRB_MODE_SEL0 field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Triple buffer is not used for this channel. 1 Triple buffer is used for this channel.
28 DMA_CH_TRB_MODE_SEL_28	Triple Buffer Mode Select. This bit indicates if a triple buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Triple buffer is not used for this channel. 1 Triple buffer is used for this channel.
27 DMA_CH_TRB_MODE_SEL_27	Triple Buffer Mode Select. This bit indicates if a triple buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Triple buffer is not used for this channel. 1 Triple buffer is used for this channel.
26–24 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Triple buffer is not used for this channel. 1 Triple buffer is used for this channel.
23 DMA_CH_TRB_MODE_SEL_23	Triple Buffer Mode Select. This bit indicates if a triple buffer is used for this channel. *n* Indicates the corresponding DMA channel number. 0 Triple buffer is not used for this channel. 1 Triple buffer is used for this channel.
22 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Triple buffer is not used for this channel. 1 Triple buffer is used for this channel.

Table continues on the next page...

Field	Description
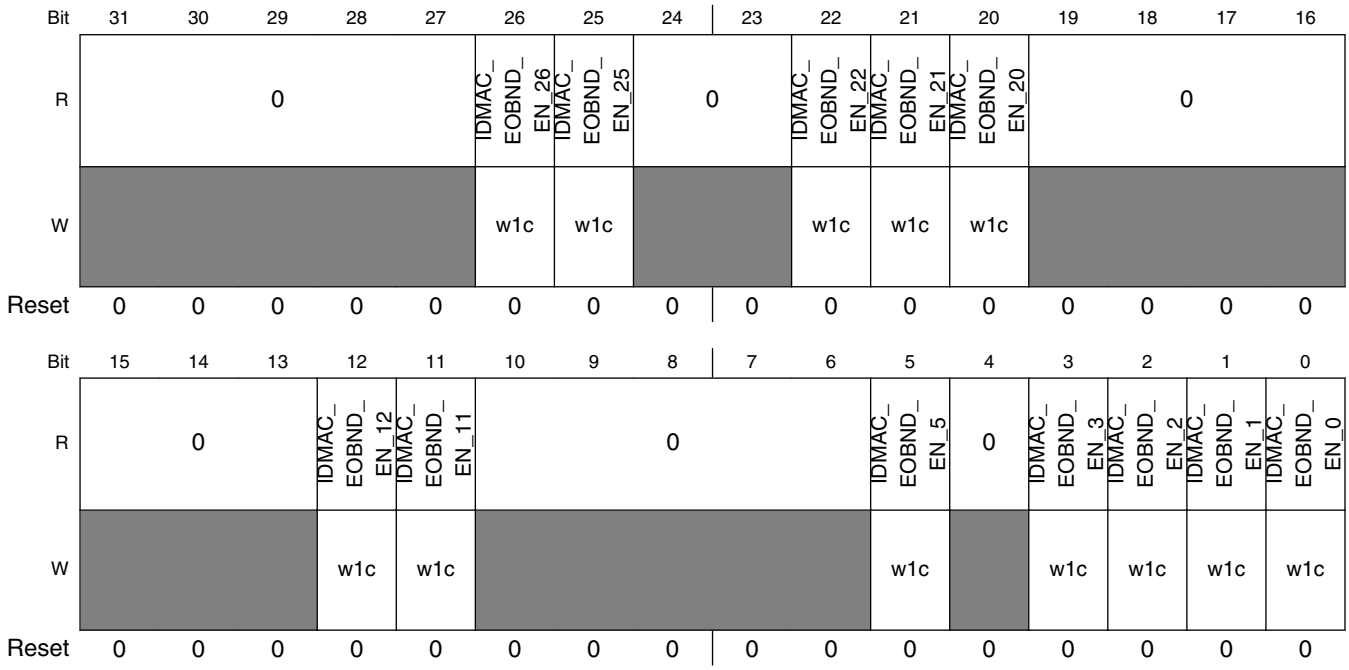
3 SMFC3_FRM_LOST	Frame Lost of SMFC channel 3 interrupt. This bit indicates on an interrupt that is a result of a result of a Frame Lost of SMFC channel 3 0 Interrupt is cleared. 1 Interrupt is requested.
2 SMFC2_FRM_LOST	Frame Lost of SMFC channel 2 interrupt. This bit indicates on an interrupt that is a result of a result of a Frame Lost of SMFC channel 2 0 Interrupt is cleared. 1 Interrupt is requested.
1 SMFC1_FRM_LOST	Frame Lost of SMFC channel 1 interrupt. This bit indicates on an interrupt that is a result of a result of a Frame Lost of SMFC channel 1 0 Interrupt is cleared. 1 Interrupt is requested.
0 SMFC0_FRM_LOST	Frame Lost of SMFC channel 0 interrupt. This bit indicates on an interrupt that is a result of a result of a Frame Lost of SMFC channel 0 0 Interrupt is cleared. 1 Interrupt is requested.

45.51.62 Interrupt Status Register 11 (IPU_INT_STAT_11)

IPU status registers are not stored in the SRM during power gating mode.This register contains part of IPU interrupts status bits. The status bits of the end-of-band indication (EOBND) of DMA Channels interrupts [31:0] can be found in this register.

- Hide VDOA_SYNC for all versions
- Show VDOA_SYNC for IPUv3H version.
- The table below tagged with other settings (like IPU3M_only) should be hidden in IPUv3H version.

Address: IPU_INT_STAT_11 is 1E00_0000h base + 228h offset = 1E00_0228h



IPU_INT_STAT_11 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is cleared. 1 Interrupt is requested.
26 IDMAC_ EOBND_EN_26	end-of-band indication of Channel interrupt. This bit is the status bit of end-of-band interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
25 IDMAC_ EOBND_EN_25	end-of-band indication of Channel interrupt. This bit is the status bit of end-of-band interrupt of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
24–23 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is cleared. 1 Interrupt is requested.
22 IDMAC_ EOBND_EN_22	end-of-band indication of Channel interrupt. This bit is the status bit of end-of-band interrupt of Channel #n. *n* Indicates the corresponding DMA channel number.

Table continues on the next page...

IPU_CUR_BUF_0 field descriptions

Field	Description
31 DMA_CH_CUR_BUF_31	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
30 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
29 DMA_CH_CUR_BUF_29	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
28 DMA_CH_CUR_BUF_28	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.

Table continues on the next page...

Field	Description
27 DMA_CH_CUR_BUF_27	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
26 DMA_CH_CUR_BUF_26	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
25 DMA_CH_CUR_BUF_25	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
24 DMA_CH_CUR_BUF_24	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
23 DMA_CH_CUR_BUF_23	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
22 DMA_CH_CUR_BUF_22	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
21 DMA_CH_CUR_BUF_21	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
20 DMA_CH_CUR_BUF_20	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
19 DMA_CH_CUR_BUF_19	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.

Field	Description
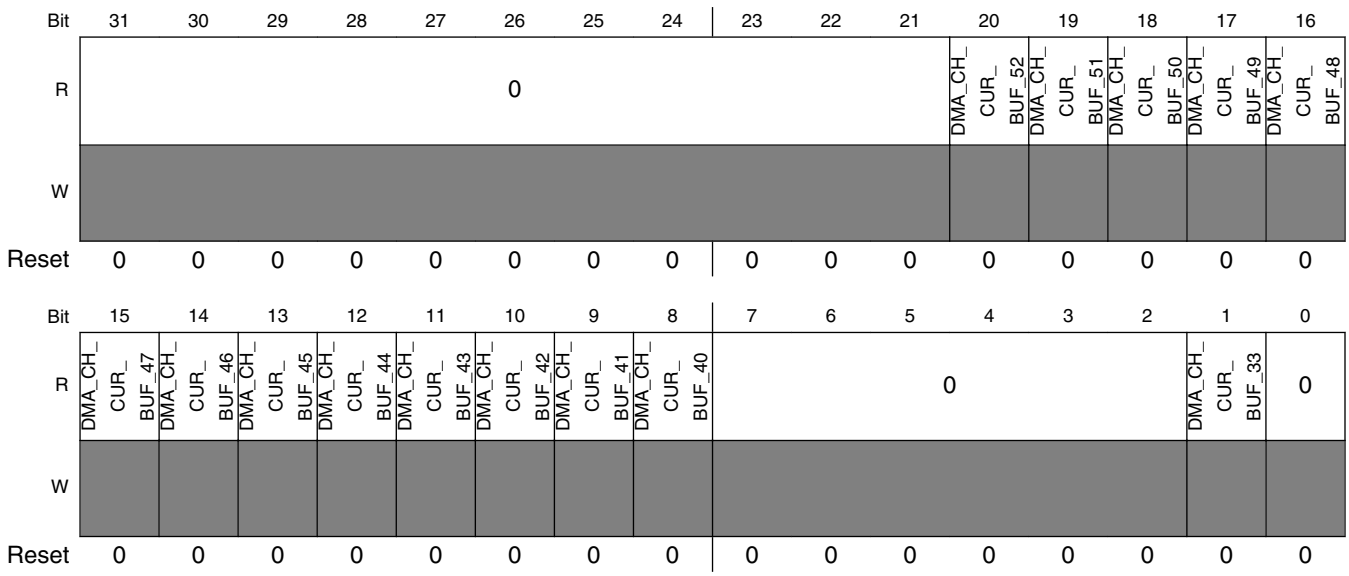
9 DMA_CH_CUR_BUF_9	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
8 DMA_CH_CUR_BUF_8	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
7–6 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
5 DMA_CH_CUR_BUF_5	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
4 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
3 DMA_CH_CUR_BUF_3	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
2 DMA_CH_CUR_BUF_2	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
1 DMA_CH_CUR_BUF_1	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
0 DMA_CH_CUR_BUF_0	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.

45.51.68 Current Buffer Register 1 (IPU_CUR_BUF_1)

This register contains the current buffer status information bit for each DMA channel.

Address: IPU_CUR_BUF_1 is 1E00_0000h base + 240h offset = 1E00_0240h



IPU_CUR_BUF_1 field descriptions

Field	Description
31–21 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
20 DMA_CH_CUR_BUF_52	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
19 DMA_CH_CUR_BUF_51	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
18 DMA_CH_CUR_BUF_50	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.

Table continues on the next page...

IPU_CUR_BUF_1 field descriptions (continued)

Field	Description
17 DMA_CH_CUR_BUF_49	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
16 DMA_CH_CUR_BUF_48	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
15 DMA_CH_CUR_BUF_47	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
14 DMA_CH_CUR_BUF_46	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
13 DMA_CH_CUR_BUF_45	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
12 DMA_CH_CUR_BUF_44	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
11 DMA_CH_CUR_BUF_43	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
10 DMA_CH_CUR_BUF_42	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
9 DMA_CH_CUR_BUF_41	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.

Table continues on the next page...

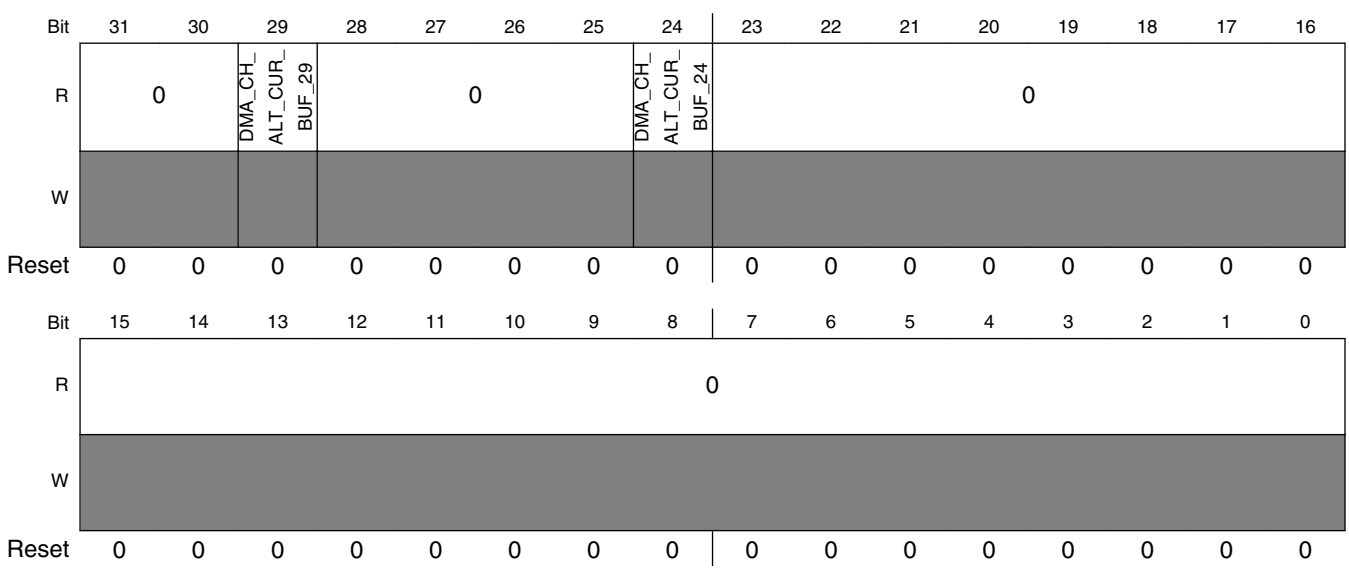
IPU_CUR_BUF_1 field descriptions (continued)

Field	Description
8 DMA_CH_CUR_BUF_40	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
7–2 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
1 DMA_CH_CUR_BUF_33	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.

45.51.69 Alternate Current Buffer Register 0 (IPU_ALT_CUR_0)

This register contains the current buffer status information bit for each DMA channel.

Address: IPU_ALT_CUR_0 is 1E00_0000h base + 244h offset = 1E00_0244h



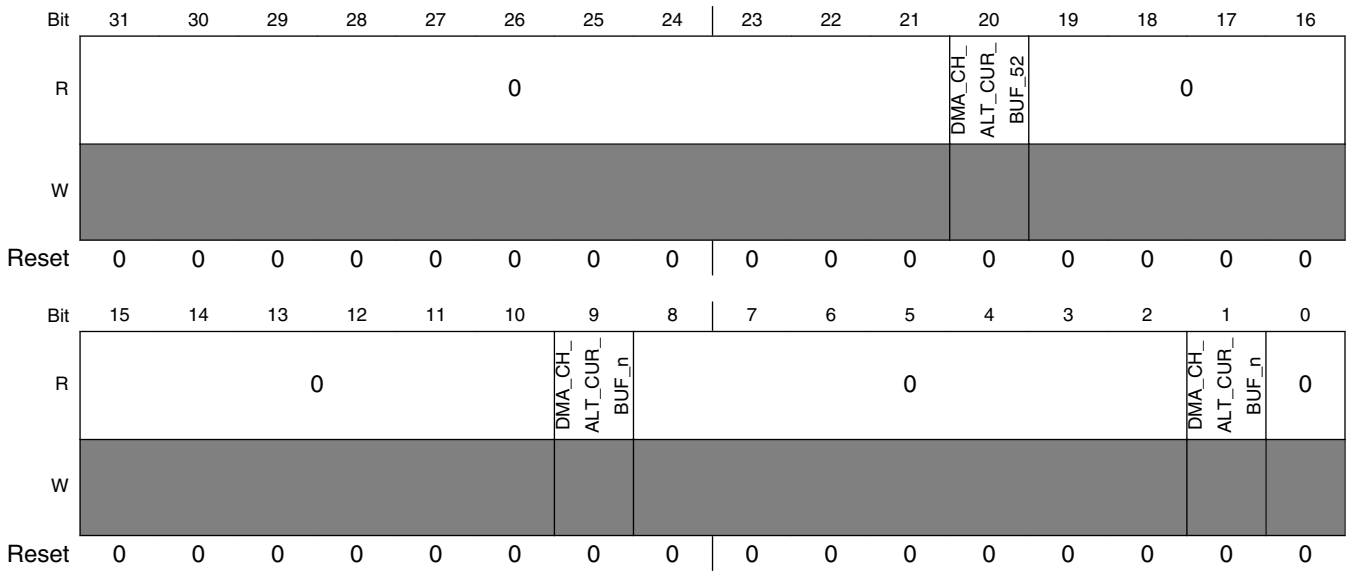
IPU_ALT_CUR_0 field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
29 DMA_CH_ALT_ CUR_BUF_29	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
28–25 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
24 DMA_CH_ALT_ CUR_BUF_24	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
23–0 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.

45.51.70 Alternate Current Buffer Register 1 (IPU_ALT_CUR_1)

This register contains the current buffer status information bit for each DMA channel. The register is shown in VDI Plane Size Register 4 Alternate Current Buffer Register 1, and the register fields are described in VDI Plane Size Register 4 Alternate Current Buffer Register 1.

Address: IPU_ALT_CUR_1 is 1E00_0000h base + 248h offset = 1E00_0248h



IPU_ALT_CUR_1 field descriptions

Field	Description
31–21 Reserved	This read-only field is reserved and always has the value zero. Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
20 DMA_CH_ALT_ CUR_BUF_52	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
19–10 Reserved	This read-only field is reserved and always has the value zero. Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.

Table continues on the next page...

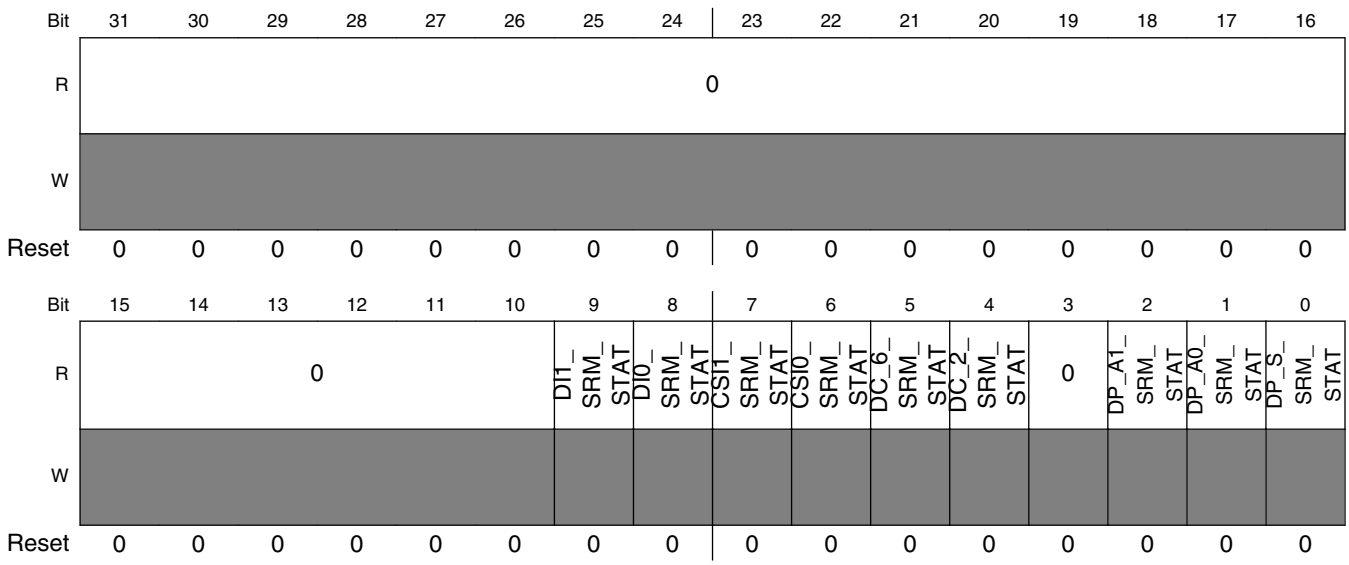
IPU_ALT_CUR_1 field descriptions (continued)

Field	Description
9 DMA_CH_ALT_ CUR_BUF_n	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
8–2 Reserved	This read-only field is reserved and always has the value zero. Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
1 DMA_CH_ALT_ CUR_BUF_n	Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.
0 Reserved	This read-only field is reserved and always has the value zero. Current Buffer. This bit indicates which buffer is in use by DMA when double buffer mode is selected. *n* Indicates the corresponding DMA channel number. 0 Current buffer used by DMA is buffer 0. 1 Current buffer used by DMA is buffer 1.

45.51.71 Shadow Registers Memory Status Register (IPU_SRM_STAT)

The register contains status bits of SRM updates. There is a bit for each block. The bit is set when the SRM is currently updating the module's registers. When the SRM completes updating the registers of the block the bit is cleared. SW should not update the block's registers while it is being updated by the SRM.

Address: IPU_SRM_STAT is 1E00_0000h base + 24Ch offset = 1E00_024Ch



IPU_SRM_STAT field descriptions

Field	Description
31–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9 DI1_SRM_STAT	DI1 SRM STAT This bit indicates that the SRM is currently updating the DI1 registers 1 SRM is busy updating the DI1 registers 0 SRM is not updating the DI1 registers
8 DI0_SRM_STAT	DI0 SRM STAT This bit indicates that the SRM is currently updating the DI0 registers 1 SRM is busy updating the DI0 registers 0 SRM is not updating the DI0 registers
7 CSI1_SRM_STAT	CSI1_SRM_STAT

Table continues on the next page...

IPU_SRM_STAT field descriptions (continued)

Field	Description
6 CSI0_SRM_ STAT	CSI1_SRM_STAT
5 DC_6_SRM_ STAT	DC group #6 SRM STAT This bit indicates that the SRM is currently updating the DC group #6 registers 1 SRM is busy updating the DC registers 0 SRM is not updating the DC registers
4 DC_2_SRM_ STAT	DC group #2 SRM STAT This bit indicates that the SRM is currently updating the DC group #2 registers 1 SRM is busy updating the DC group #6 registers 0 SRM is not updating the DC group #2 registers
3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2 DP_A1_SRM_ STAT	DP ASYNC1 FLOW SRM STAT This bit indicates that the SRM is currently updating the DP async flow 1 registers 1 SRM is busy updating the DP sync flow registers 0 SRM is not updating the DP sync flow registers
1 DP_A0_SRM_ STAT	DP ASYNC0 FLOW SRM STAT This bit indicates that the SRM is currently updating the DP async flow 0 registers 1 SRM is busy updating the DP async flow 0 registers 0 SRM is not updating the DP async flow 0 registers
0 DP_S_SRM_ STAT	DP SYNC FLOW SRM STAT This bit indicates that the SRM is currently updating the DP sync flow registers 1 SRM is busy updating the DP sync flow registers 0 SRM is not updating the DP sync flow registers

45.51.72 Processing Status Tasks Register (IPU_PROC_TASKS_STAT)

This register contains status bits for IPU's tasks.

Address: IPU_PROC_TASKS_STAT is 1E00_0000h base + 250h offset = 1E00_0250h

5–4 DC_ASYNC1_ STAT	Status of the Asynchronous flow #1 through the DC (ch 28) 00 IDLE - The task is idle 01 ACTIVE - This task is currently active 10 WAIT_FOR_ READY - The task is waiting for a buffer to be ready
3 DP_ASYNC_ CUR_FLOW	Current asynchronous flow via the DP 1 alternate flow 0 main flow
2–0 DP_ASYNC_ STAT	Status of the Asynchronous flow through the DP 000 IDLE - the task is idle 001 PRIM_ACTIVE - The primary flow of this task is currently active 010 ALT_ACTIVE - The alternate flow of this task is currently active 011 UPDATE_PARAM - The FSU is busy updating parameters from the SRM 100 PAUSE - The task is paused 101 Reserved 110 Reserved 111 Reserved

45.51.74 Triple Current Buffer Register 0 (IPU_TRIPLE_CUR_BUF_0)

This register contains the current buffer status information for triple buffer mode for each DMA channel.

- Hide VPU_SUB_FRAME_SYNC for all versions
- Show VPU_SUB_FRAME_SYNC for IPUv3H version.

- The table below tagged with other settings (like IPU3M_only) should be hidden in IPUv3H version.
- This requires some sophisticated conditional tag settings

Address: IPU_TRIPLE_CUR_BUF_0 is 1E00_0000h base + 258h offset = 1E00_0258h

IPU_TRIPLE_CUR_BUF_1 field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value zero. Reserved.

Table continues on the next page...

IPU_TRIPLE_CUR_BUF_1 field descriptions (continued)

Field	Description
25–24 DMA_CH_ TRIPLE_CUR_ BUF_28	Current Buffer for triple buffer mode. This bits indicate which buffer is in use by the DMA when triple buffer mode is selected. Each pair of bits indicate the corresponding DMA channel (bits [1:0] correspond to ch #0; (bits [3:2] correspond to ch #1, etc.) 11 NA 00 Current buffer used by DMA is buffer 0. 01 Current buffer used by DMA is buffer 1. 10 Current buffer used by DMA is buffer 2.
23–22 DMA_CH_ TRIPLE_CUR_ BUF_27	Current Buffer for triple buffer mode. This bits indicate which buffer is in use by the DMA when triple buffer mode is selected. Each pair of bits indicate the corresponding DMA channel (bits [1:0] correspond to ch #0; (bits [3:2] correspond to ch #1, etc.) 11 NA 00 Current buffer used by DMA is buffer 0. 01 Current buffer used by DMA is buffer 1. 10 Current buffer used by DMA is buffer 2.
21–16 Reserved	This read-only field is reserved and always has the value zero. Reserved.
15–14 DMA_CH_ TRIPLE_CUR_ BUF_23	Current Buffer for triple buffer mode. This bits indicate which buffer is in use by the DMA when triple buffer mode is selected. Each pair of bits indicate the corresponding DMA channel (bits [1:0] correspond to ch #0; (bits [3:2] correspond to ch #1, etc.) 11 NA 00 Current buffer used by DMA is buffer 0. 01 Current buffer used by DMA is buffer 1. 10 Current buffer used by DMA is buffer 2.
13–12 Reserved	This read-only field is reserved and always has the value zero. Reserved.
11–10 DMA_CH_ TRIPLE_CUR_ BUF_21	Current Buffer for triple buffer mode. This bits indicate which buffer is in use by the DMA when triple buffer mode is selected. Each pair of bits indicate the corresponding DMA channel (bits [1:0] correspond to ch #0; (bits [3:2] correspond to ch #1, etc.) 11 NA 00 Current buffer used by DMA is buffer 0. 01 Current buffer used by DMA is buffer 1. 10 Current buffer used by DMA is buffer 2.
9–0 Reserved	This read-only field is reserved and always has the value zero. Reserved.

45.51.76 IPU Channels Buffer 0 Ready 0 Register (IPU_CH_BUF0_RDY0)

The register contains buffer 0 ready control information for 32 IPU's DMA channels (31-0). This register can be a write one to set or a write one to clear according to the **IPU_CH_BUF0_RDY0_CLR bit**.

The register is shown in IPU Channels Buffer 0 Ready 0 Register (IPU_CH_BUF0_RDY0), and the register fields are described in IPU Channels Buffer 0 Ready 0 Register (IPU_CH_BUF0_RDY0).

Address: IPU_CH_BUF0_RDY0 is 1E00_0000h base + 268h offset = 1E00_0268h

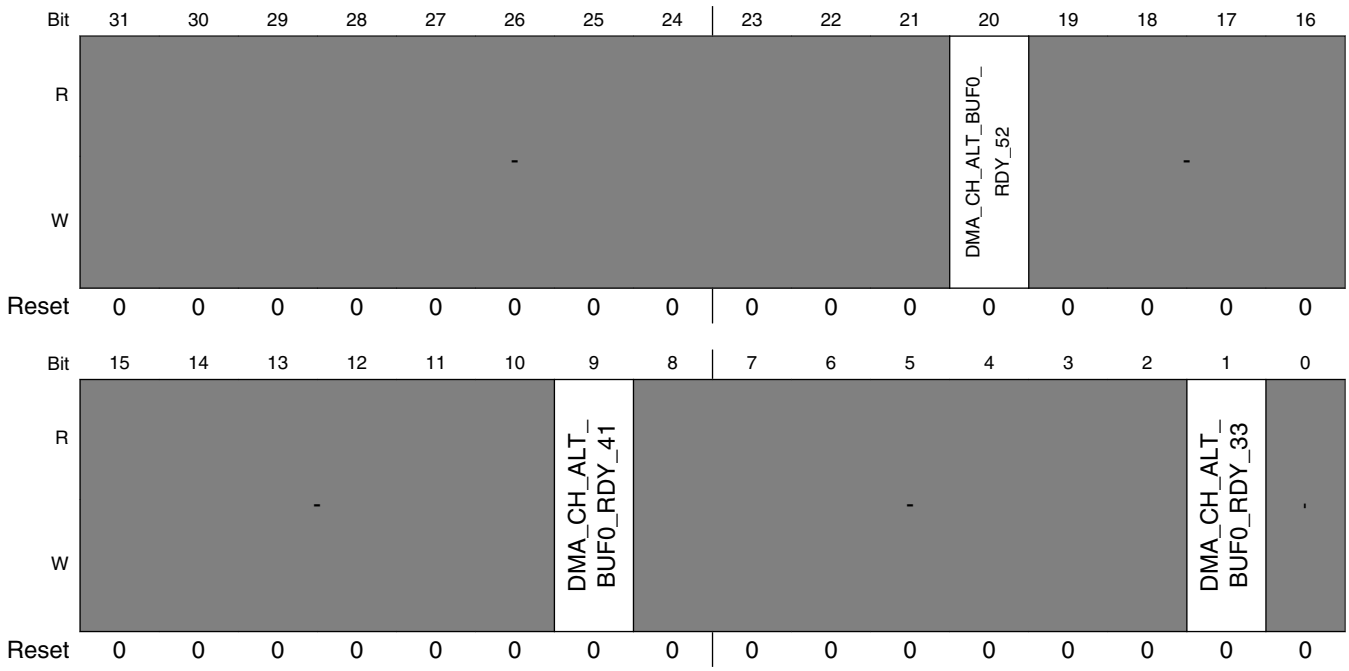
IPU_ALT_CH_BUF0_RDY0 field descriptions

Field	Description
31–30 -	Reserved.
29 DMA_CH_ALT_BUF0_RDY_29	Buffer 0 is ready. This bit indicates that ARM platform finished/writing reading buffer 0 in memory. 0 Buffer 0 is not ready. 1 Buffer 0 is ready.
28–25 -	Reserved.
24 DMA_CH_ALT_BUF0_RDY_24	Buffer 0 is ready. This bit indicates that ARM platform finished/writing reading buffer 0 in memory. 0 Buffer 0 is not ready. 1 Buffer 0 is ready.
23–0 -	Reserved.

45.51.81 IPU Alternate Channels Buffer 0 Ready 1 Register (IPU_ALT_CH_BUF0_RDY1)

The register contains buffer 0 ready control information for 32 IPU's DMA channels (63-32). Writing "1" to each field will set each bit. Writing "0" to each field simultaneously will clear all the bits.

Address: IPU_ALT_CH_BUF0_RDY1 is 1E00_0000h base + 27Ch offset = 1E00_027Ch



IPU_ALT_CH_BUF0_RDY1 field descriptions

Field	Description
31–21 -	Reserved.
20 DMA_CH_ALT_BUF0_RDY_52	Buffer 0 is ready. This bit indicates that ARM platform finished/writing reading buffer 0 in memory. 0 Buffer 0 is not ready. 1 Buffer 0 is ready.
19–10 -	Reserved.
9 DMA_CH_ALT_BUF0_RDY_41	Buffer 0 is ready. This bit indicates that ARM platform finished/writing reading buffer 0 in memory. 0 Buffer 0 is not ready. 1 Buffer 0 is ready.
8–2 -	Reserved.

Table continues on the next page...

IPU_ALT_CH_BUF0_RDY1 field descriptions (continued)

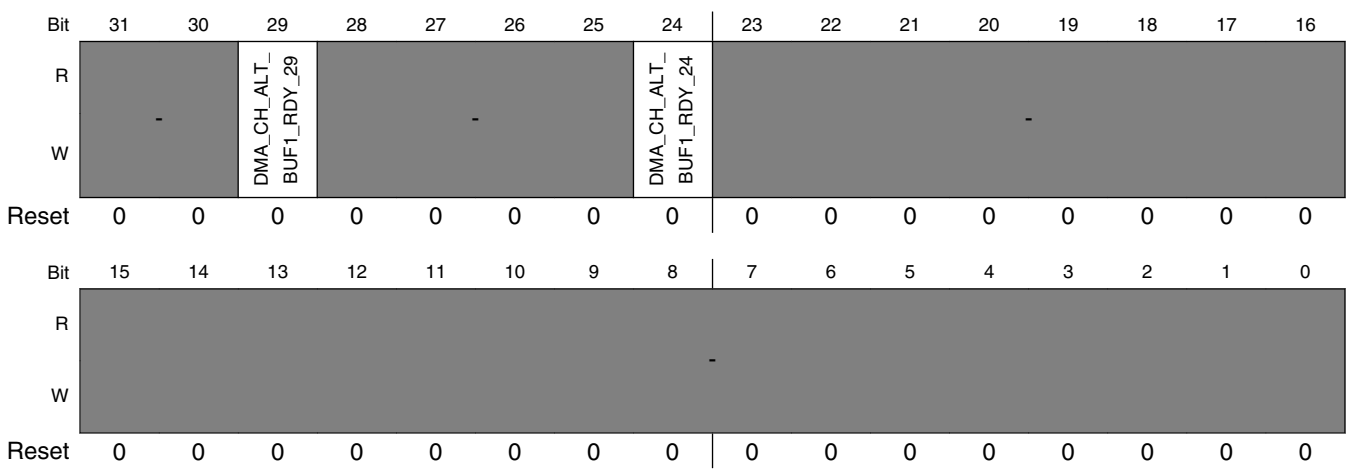
Field	Description
1 DMA_CH_ALT_ BUF0_RDY_33	Buffer 0 is ready. This bit indicates that ARM platform finished/writing reading buffer 0 in memory. 0 Buffer 0 is not ready. 1 Buffer 0 is ready.
0 -	Reserved.

45.51.82 IPU Alternate Channels Buffer1 Ready 0 Register (IPU_ALT_CH_BUF1_RDY0)

The register contains buffer 1 ready control information for 32 IPU's DMA channels (31-0). Writing "1" to each field will set each bit. Writing "0" to each field simultaneously will clear all the bits.

The register is shown in IPU Alternate Channels Buffer1 Ready 0 Register (IPU_ALT_CH_BUF1_RDY0), and the register fields are described in IPU Alternate Channels Buffer1 Ready 0 Register (IPU_ALT_CH_BUF1_RDY0).

Address: IPU_ALT_CH_BUF1_RDY0 is 1E00_0000h base + 280h offset = 1E00_0280h



IPU_ALT_CH_BUF1_RDY0 field descriptions

Field	Description
31–30 -	Reserved.
29 DMA_CH_ALT_ BUF1_RDY_29	Buffer 1 is ready. This bit indicates that ARM platform finished/writing reading buffer 1 in memory. 0 buffer 1 is not ready. 1 buffer 1 is ready.

Table continues on the next page...

IPU_ALT_CH_BUF1_RDY0 field descriptions (continued)

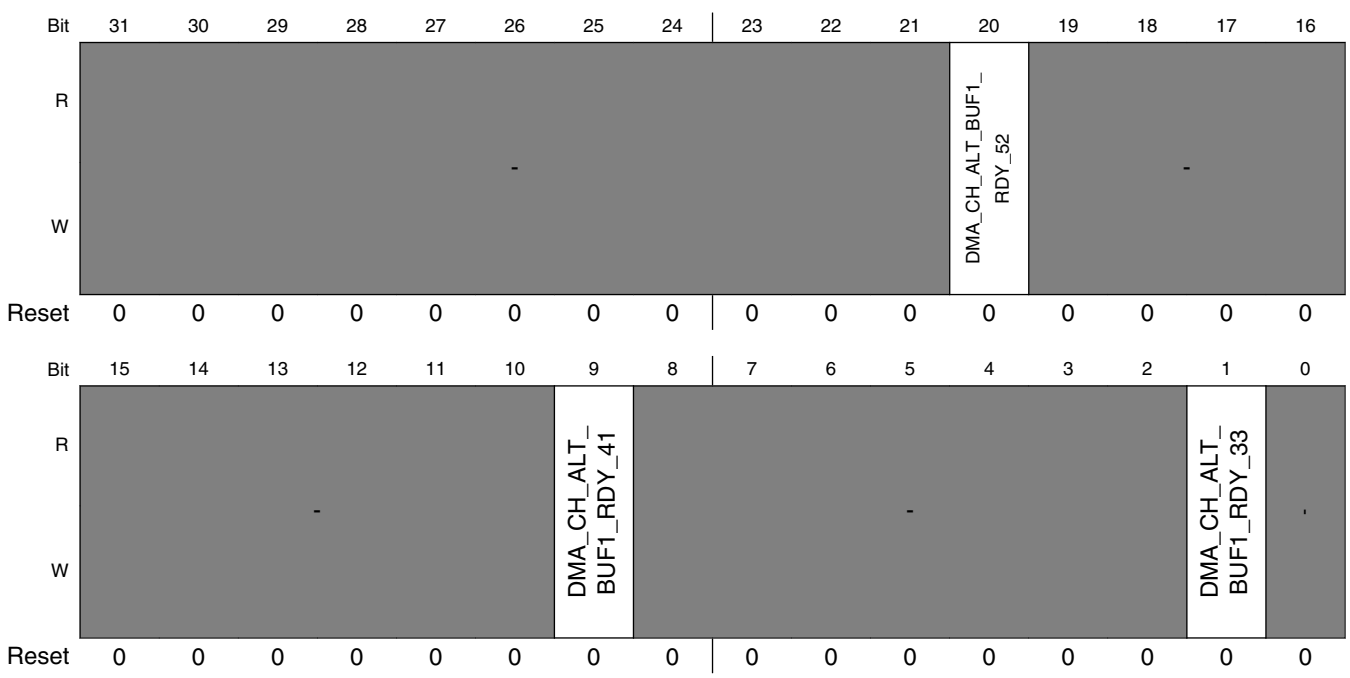
Field	Description
28–25 -	Reserved.
24 DMA_CH_ALT_BUF1_RDY_24	Buffer 1 is ready. This bit indicates that ARM platform finished/writing reading buffer 1 in memory. 0 buffer 1 is not ready. 1 buffer 1 is ready.
23–0 -	Reserved.

45.51.83 IPU Alternate Channels Buffer 1 Ready 1 Register (IPU_ALT_CH_BUF1_RDY1)

The register contains buffer 0 ready control information for 32 IPU's DMA channels (63-32). Writing "1" to each field will set each bit. Writing "0" to each field simultaneously will clear all the bits.

The register is shown in IPU Alternate Channels Buffer 1 Ready 1 Register (IPU_ALT_CH_BUF1_RDY1), and the register fields are described in IPU Alternate Channels Buffer 1 Ready 1 Register (IPU_ALT_CH_BUF1_RDY1).

Address: IPU_ALT_CH_BUF1_RDY1 is 1E00_0000h base + 284h offset = 1E00_0284h



IPU_ALT_CH_BUF1_RDY1 field descriptions

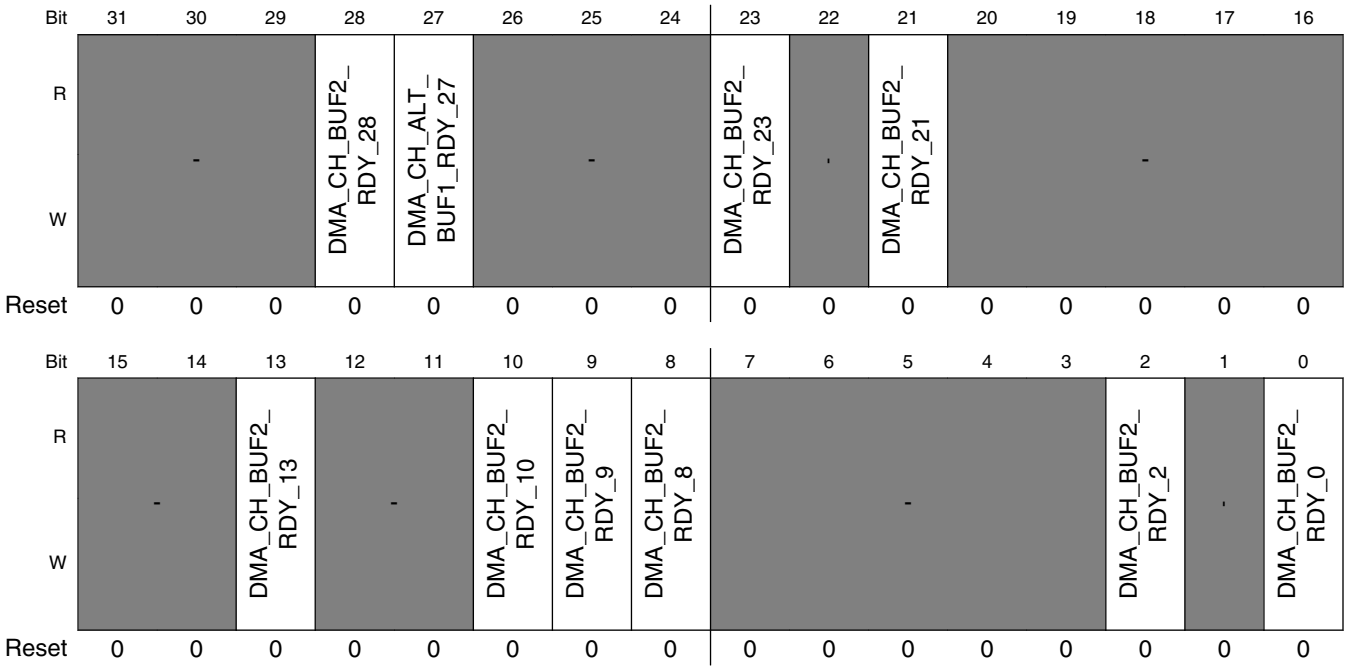
Field	Description
31–21 -	Reserved.
20 DMA_CH_ALT_ BUF1_RDY_52	Buffer 1 is ready. This bit indicates that ARM platform finished/writing reading buffer 1 in memory. 0 buffer 1 is not ready. 1 buffer 1 is ready.
19–10 -	Reserved.
9 DMA_CH_ALT_ BUF1_RDY_41	Buffer 1 is ready. This bit indicates that ARM platform finished/writing reading buffer 1 in memory. 0 buffer 1 is not ready. 1 buffer 1 is ready.
8–2 -	Reserved.
1 DMA_CH_ALT_ BUF1_RDY_33	Buffer 1 is ready. This bit indicates that ARM platform finished/writing reading buffer 1 in memory. 0 buffer 1 is not ready. 1 buffer 1 is ready.
0 -	Reserved.

45.51.84 IPU Channels Buffer 2 Ready 0 Register (IPU_CH_BUF2_RDY0)

The register contains buffer 2 ready control information for 32 IPU's DMA channels (31-0). This register can be a write one to set or a write one to clear according to the **IPU_CH_BUF2_RDY0_CLR bit**.

The register is shown in IPU Channels Buffer 2 Ready 0 Register (IPU_CH_BUF2_RDY0), and the register fields are described in IPU Channels Buffer 2 Ready 0 Register (IPU_CH_BUF2_RDY0).

Address: IPU_CH_BUF2_RDY0 is 1E00_0000h base + 288h offset = 1E00_0288h



IPU_CH_BUF2_RDY0 field descriptions

Field	Description
31–29 -	Reserved.
28 DMA_CH_ BUF2_RDY_28	Buffer 2 is ready. This bit indicates that ARM platform finished/writing reading buffer 2 in memory. 0 Buffer 2 is not ready. 1 Buffer 2 is ready.
27 DMA_CH_ALT_ BUF1_RDY_27	buffer 2 is ready. This bit indicates that ARM platform finished/writing reading buffer 2 in memory. 0 buffer 2 is not ready. 1 buffer 2 is ready.
26–24 -	Reserved.
23 DMA_CH_ BUF2_RDY_23	Buffer 2 is ready. This bit indicates that ARM platform finished/writing reading buffer 2 in memory. 0 Buffer 2 is not ready. 1 Buffer 2 is ready.
22 -	Reserved.
21 DMA_CH_ BUF2_RDY_21	Buffer 2 is ready. This bit indicates that ARM platform finished/writing reading buffer 2 in memory. 0 Buffer 2 is not ready. 1 Buffer 2 is ready.
20–14 -	Reserved.

Table continues on the next page...

IPU_CH_BUF2_RDY0 field descriptions (continued)

Field	Description
13 DMA_CH_ BUF2_RDY_13	Buffer 2 is ready. This bit indicates that ARM platform finished/writing reading buffer 2 in memory. 0 Buffer 2 is not ready. 1 Buffer 2 is ready.
12–11 -	Reserved.
10 DMA_CH_ BUF2_RDY_10	Buffer 2 is ready. This bit indicates that ARM platform finished/writing reading buffer 2 in memory. 0 Buffer 2 is not ready. 1 Buffer 2 is ready.
9 DMA_CH_ BUF2_RDY_9	Buffer 2 is ready. This bit indicates that ARM platform finished/writing reading buffer 2 in memory. 0 Buffer 2 is not ready. 1 Buffer 2 is ready.
8 DMA_CH_ BUF2_RDY_8	Buffer 2 is ready. This bit indicates that ARM platform finished/writing reading buffer 2 in memory. 0 Buffer 2 is not ready. 1 Buffer 2 is ready.
7–3 -	Reserved.
2 DMA_CH_ BUF2_RDY_2	Buffer 2 is ready. This bit indicates that ARM platform finished/writing reading buffer 2 in memory. 0 Buffer 2 is not ready. 1 Buffer 2 is ready.
1 -	Reserved.
0 DMA_CH_ BUF2_RDY_0	Buffer 2 is ready. This bit indicates that ARM platform finished/writing reading buffer 2 in memory. 0 Buffer 2 is not ready. 1 Buffer 2 is ready.

45.51.85 IPU Channels Buffer 2 Ready 1 Register (IPU_CH_BUF2_RDY1)

The register contains buffer 2 ready control information for 32 IPU's DMA channels (63-32). This register can be a write one to set or a write one to clear according to the **IPU_CH_BUF2_RDY1_CLR bit.**

The register is shown in IPU Channels Buffer 2 Ready 1 Register (IPU_CH_BUF2_RDY1), and the register fields are described in IPU Channels Buffer 2 Ready 1 Register (IPU_CH_BUF2_RDY1).

Address: IPU_CH_BUF2_RDY1 is 1E00_0000h base + 28Ch offset = 1E00_028Ch

IPU_INT_STAT_4 field descriptions (continued)

Field	Description
	0 Interrupt is cleared. 1 Interrupt is requested.
20 IDMAC_ NFACK_52	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
19 IDMAC_ NFACK_51	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
18 IDMAC_ NFACK_50	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
17 IDMAC_ NFACK_49	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
16 IDMAC_ NFACK_48	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
15 IDMAC_ NFACK_47	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
14 IDMAC_ NFACK_46	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
13 IDMAC_ NFACK_45	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
12 IDMAC_ NFACK_44	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number.

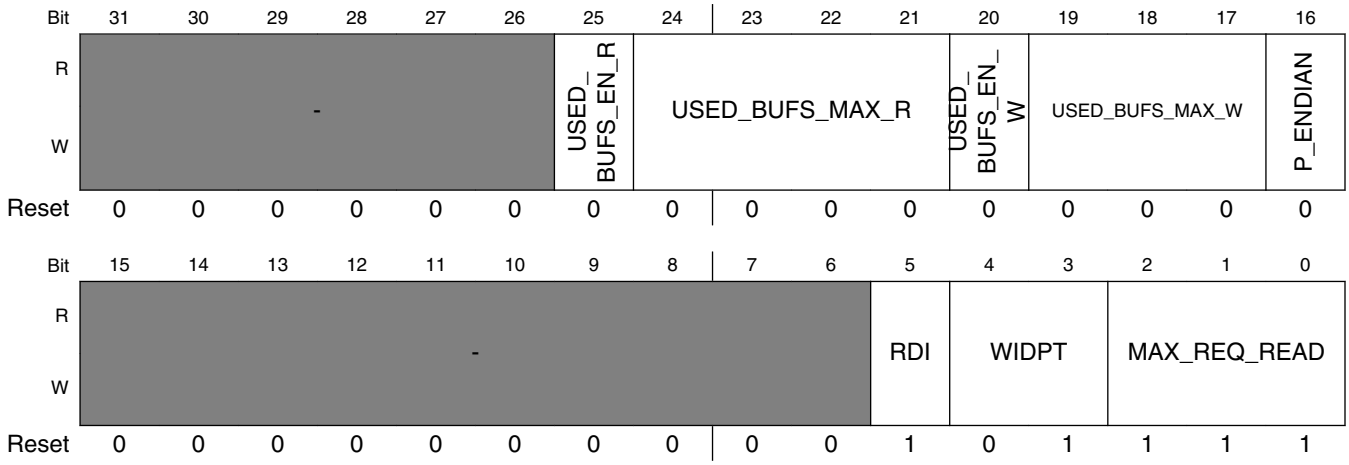
Table continues on the next page...

IPU_INT_STAT_4 field descriptions (continued)

Field	Description
	0 Interrupt is cleared. 1 Interrupt is requested.
11 IDMAC_ NFACK_43	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
10 IDMAC_ NFACK_42	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
9 IDMAC_ NFACK_41	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
8 IDMAC_ NFACK_40	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
7–2 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is cleared. 1 Interrupt is requested.
1 IDMAC_ NFACK_33	Enable New Frame Ack of Channel interrupt. This bit is the status bits of New Frame Ack of Channel #n. *n* Indicates the corresponding DMA channel number. 0 Interrupt is cleared. 1 Interrupt is requested.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved. 0 Interrupt is cleared. 1 Interrupt is requested.

45.51.87 IDMAC Configuration Register (IPU_IDMAC_CONF)

Address: IPU_IDMAC_CONF is 1E00_0000h base + 8000h offset = 1E00_8000h



IPU_IDMAC_CONF field descriptions

Field	Description
31–26 -	Reserved, should be cleared.
25 USED_BUFS_EN_R	Enables the limit on the number of pending non real time read requests.
24–21 USED_BUFS_MAX_R	Limit the number of pending non real time read requests. The value can be between 0 to 8. This field has no affect if USED_BUFS_EN_R is cleared
20 USED_BUFS_EN_W	Enables the limit on the number of pending non real time write requests.
19–17 USED_BUFS_MAX_W	Limit the number of pending non real time write requests. The value can be between 0 to 6. This field has no affect if USED_BUFS_EN_W is cleared
16 P_ENDIAN	Pixel Endianness. The pixel Endianness must not be changed while any of the IDMAC channels is enabled. 0 little endian 1 Big endian
15–6 -	Reserved, should be cleared.
5 RDI	Read Data Interleaving. This bit must match the slave read data interleaving support. If the AXI slave connected to the IPU supports read data interleaving then this bit must be set. If the AXI slave does not support read data interleaving then the IDMAC can utilize this and issue more address phases on read. In that case it is recommended to have this bit cleared. 0 The AXI slave does not support read data interleaving

Table continues on the next page...

IPU_IDMAC_CONF field descriptions (continued)

Field	Description
	1 The AXI slave supports read data interleaving
4–3 WIDPT	Write Interleaving Depth These 2 bits define the Write Interleaving Depth of the AXI port. This bits should be configured by the user according to the AXI slave's Write Interleaving Depth. WIDPT defines the maximal number of active bursts (yet to be responded) with different IDs. IDMAC will block data phase if the next data's ID is new (no such ID active) and the number of active IDs is equal to WIDPT. 00 Write Interleaving Depth of 1 01 Write Interleaving Depth of 2 10 Write Interleaving Depth of 3 11 Write Interleaving Depth of 4
2–0 MAX_REQ_ READ	Maximum Read Requests. This fields sets the maximum pending requests allowed in the AXI Read requests queue.

45.51.88 IDMAC Channel Enable 1 Register (IPU_IDMAC_CH_EN_1)

Field	Description
31–30 -	Reserved.
29 IDMAC_ALT_SEP_AL_29	IDMAC Alternate Separate alpha indication bit [i] A sub block may need to read data from the system's memory where the pixel data and the alpha transparency data are located in separate buffers. In that case the Alpha transparency data is read by the special Alpha channel. In a case where the alpha should be read from a separate buffer, the user should set the channels corresponding. For channels that may have alternate flow and may use separate alpha. This bit indicates the mode of the alpha for the alternate flow 0 Channel [i] does not read Alpha transparency data from a separate buffer. 1 Channel [i] reads Alpha transparency data from a separate buffer.
28–25 -	Reserved.

Field	Description
	0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
13 IDMAC_CH_BUSY_13	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
12 IDMAC_CH_BUSY_12	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
11 IDMAC_CH_BUSY_11	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
10 IDMAC_CH_BUSY_10	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
9 IDMAC_CH_BUSY_9	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
8 IDMAC_CH_BUSY_8	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
7–6 -	Reserved.
5 IDMAC_CH_BUSY_5	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC.

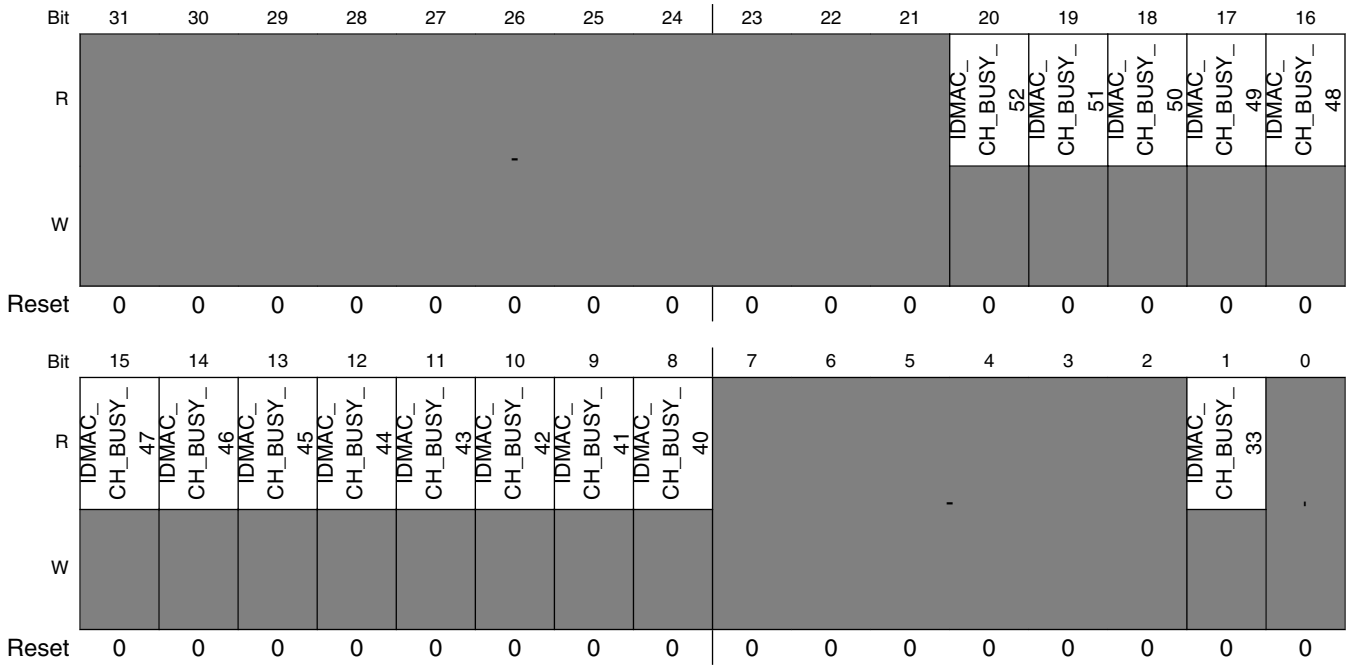
Table continues on the next page...

IPU_IDMAC_CH_BUSY_1 field descriptions (continued)

Field	Description
	0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
4 -	Reserved.
3 IDMAC_CH_ BUSY_3	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
2 IDMAC_CH_ BUSY_2	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
1 IDMAC_CH_ BUSY_1	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
0 IDMAC_CH_ BUSY_0	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy

45.51.98 IDMAC Channel Busy 2 Register (IPU_IDMAC_CH_BUSY_2)

Address: IPU_IDMAC_CH_BUSY_2 is 1E00_0000h base + 8104h offset = 1E00_8104h



IPU_IDMAC_CH_BUSY_2 field descriptions

Field	Description
31–21 -	Reserved.
20 IDMAC_CH_BUSY_52	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
19 IDMAC_CH_BUSY_51	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
18 IDMAC_CH_BUSY_50	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy

Table continues on the next page...

IPU_IDMAC_CH_BUSY_2 field descriptions (continued)

Field	Description
17 IDMAC_CH_ BUSY_49	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
16 IDMAC_CH_ BUSY_48	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
15 IDMAC_CH_ BUSY_47	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
14 IDMAC_CH_ BUSY_46	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
13 IDMAC_CH_ BUSY_45	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
12 IDMAC_CH_ BUSY_44	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
11 IDMAC_CH_ BUSY_43	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy

Table continues on the next page...

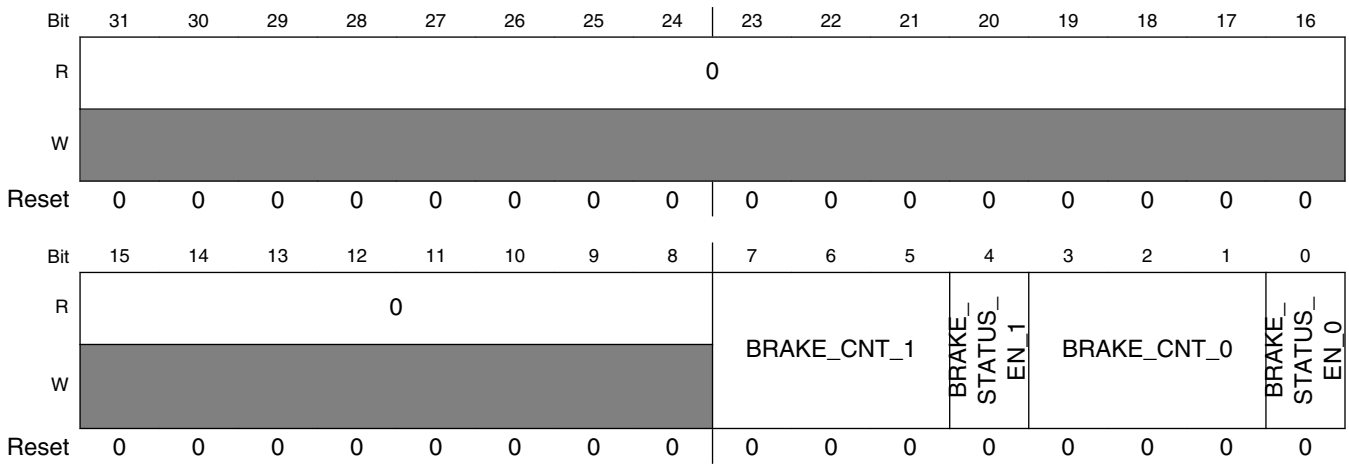
IPU_IDMAC_CH_BUSY_2 field descriptions (continued)

Field	Description
10 IDMAC_CH_ BUSY_42	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
9 IDMAC_CH_ BUSY_41	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
8 IDMAC_CH_ BUSY_40	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
7–2 -	Reserved.
1 IDMAC_CH_ BUSY_33	IDMAC Channel busy bit [i] This bit indicates if the channel is currently served by the IDMAC. This bit is self cleared by the IDMAC. 0 IDMAC channel [i] is not busy 1 IDMAC channel [i] is busy
0 -	Reserved.

45.51.99 DP Debug Control Register (IPU_DP_DEBUG_CNT)

This is the debug unit control register. This register is not stored in the SRM.

Address: IPU_DP_DEBUG_CNT is 1E00_0000h base + 180BCh offset = 1E01_80BCh

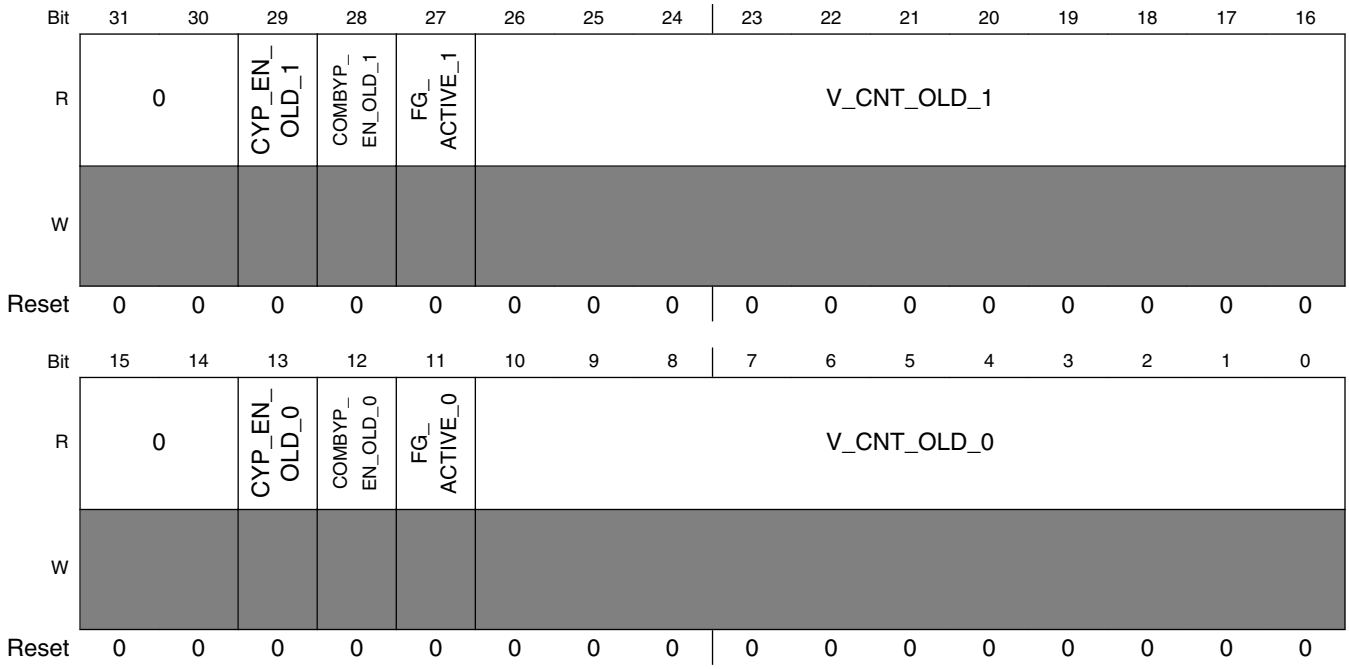


IPU_DP_DEBUG_CNT field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–5 BRAKE_CNT_1	The async flow can be broken multiple times. It possible to control which breaking event will cause the interrupt. This field counts the breaking events for unit #1
4 BRAKE_ STATUS_EN_1	This bit enables the break/status unit #1
3–1 BRAKE_CNT_0	The async flow can be broken multiple times. It possible to control which breaking event will cause the interrupt. This field counts the breaking events for unit #0
0 BRAKE_ STATUS_EN_0	This bit enables the break/status unit #0

45.51.100 DP Debug Status Register (IPU_DP_DEBUG_STAT)

Address: IPU_DP_DEBUG_STAT is 1E00_0000h base + 180C0h offset = 1E01_80C0h



IPU_DP_DEBUG_STAT field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved
29 CYP_EN_OLD_1	The async flow has been broken in the middle of a cursor (This filed is relevant for debug unit #1)
28 COMBYP_EN_OLD_1	the async1 flow has been broken in the middle of combining (This filed is relevant for debug unit #1)
27 FG_ACTIVE_1	Displaying the partial frame has been started (This filed is relevant for debug unit #1)
26–16 V_CNT_OLD_1	The exact row where the async flow has been broken (This filed is relevant for debug unit #0)
15–14 Reserved	This read-only field is reserved and always has the value zero. Reserved
13 CYP_EN_OLD_0	The async flow has been broken in the middle of a cursor (This filed is relevant for debug unit #0)
12 COMBYP_EN_OLD_0	the async flow has been broken in the middle of combining (This filed is relevant for debug unit #0)

Table continues on the next page...

IPU_DP_DEBUG_STAT field descriptions (continued)

Field	Description
11 FG_ACTIVE_0	Displaying the partial frame has been started for async flow (This filed is relevant for debug unit #0)
10–0 V_CNT_OLD_0	The exact row where the async flow has been broken (This filed is relevant for debug unit #0)

45.51.101 IC Configuration Register (IPU_IC_CONF)

This register contains control parameter for IC 3 tasks (pre-processing for encoding, pre-processing for view-finder and post processing).

Address: IPU_IC_CONF is 1E00_0000h base + 20000h offset = 1E02_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_IC_CONF field descriptions

Field	Description
31 CSI_MEM_WR_EN	CSI direct memory write enable. This bit enables writing data from sensor directly to memory even when a raw sensor is not attached. 0 CSI direct writing to memory is disabled. 1 CSI direct writing to memory is enabled.
30 RWS_EN	Raw sensor enable. This bit indicate if a Raw sensor is attached (Bayer format). This bit is used together with the CSI_MEM_WR_EN bit as follows: CSI_MEM_WR_EN=0, RWS_EN=0 - data is fed from the CSI to the IC for processing; CSI_MEM_WR_EN=1, RWS_EN=0 - data is fed from the CSI to the IC for processing and also for writing to the system memory; CSI_MEM_WR_EN=0, RWS_EN=1 - data is fed from the CSI to the system memory (via the IC) and from the system memory to the IC for processing; CSI_MEM_WR_EN=1, RWS_EN=1 - non-valid configuration.

Table continues on the next page...

IPU_IC_CONF field descriptions (continued)

Field	Description
	0 Raw sensor is not attached. 1 Raw sensor is attached.
29 IC_KEY_ COLOR_EN	Key Color enable. This bit enables the key color feature. 0 Key color is disabled. 1 Key color is enabled.
28 IC_GLB_LOC_A	Global Alpha. This bit select the source of Alpha parameter. 0 Alpha parameter is local. 1 Alpha parameter is global.
27–21 Reserved	This read-only field is reserved and always has the value zero. Reserved
20 PP_ROT_EN	Post-Processing Rotation Task enable. This bit enable Post-Processing Rotation Task. 0 Rotation is disabled. 1 Rotation is enabled.
19 PP_CMB	Post-Processing Task combining enable. This bit enables combining. 0 Combining is disabled. 1 Combining is enabled.
18 PP_CSC2	Post-Processing Task color conversion RGB-->YUV enable. This bit enables YUV-->RGB. Reserved 0 RGB-->YUV is disabled. 1 RGB-->YUV is enabled.
17 PP_CSC1	Post-Processing Task color conversion YUV-->RGB enable. This bit enables YUV-->RGB. 0 YUV-->RGB is disabled. 1 YUV-->RGB is enabled.
16 PP_EN	Post-Processing Task enable. This bit enables the Post-Processing task. 0 Task is disabled. 1 Task is enabled.
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12 PRPVF_ROT_ EN	Preprocessing Rotation Task for viewfinder enable. This bit enable Preprocessing Rotation Task for viewfinder. 0 Rotation is disabled. 1 Rotation is enabled.
11 PRPVF_CMB	Preprocessing Task for View-Finder combining enable. This bit enables combining. 0 Combining is disabled. 1 Combining is enabled.
10 PRPVF_CSC2	Reserved

Table continues on the next page...

IPU_IC_CONF field descriptions (continued)

Field	Description
9 PRPVF_CSC1	Pre-processing task for view-finder first color conversion enable. This bit enables first color conversion. 0 First color conversion is disabled. 1 First color conversion is enabled.
8 PRPVF_EN	Preprocessing Task for View-Finder enable. This bit enables the View-Finder task. 0 Task is disabled. 1 Task is enabled.
7–3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2 PRPENC_ROT_EN	Preprocessing Rotation Task for encoding enable. This bit enable Preprocessing Rotation Task for encoding. 0 Rotation is disabled. 1 Rotation is enabled.
1 PRPENC_CSC1	Preprocessing Task for encoding color conversion enable. This bit enables color conversion. 0 Color conversion is disabled. 1 Color conversion is enabled.
0 PRPENC_EN	Preprocessing Task for encoding enable. This bit enables the encoding task. 0 Task is disabled. 1 Task is enabled.

45.51.102 IC Preprocessing Encoder Resizing Coefficients Register (IPU_IC_PRP_ENC_RSC)

This register contains the resizing and downsizing parameters for Preprocessing task for encoding.

Address: IPU_IC_PRP_ENC_RSC is 1E00_0000h base + 20004h offset = 1E02_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	PRPENC_DS_R_V		PRPENC_RS_R_V

Reset	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_IC_PRP_ENC_RSC field descriptions

Field	Description
31–30 PRPENC_DS_R_V	Preprocessing task for encoding Downsizing vertical Ratio. This field contains the downsizing vertical coefficient of Preprocessing for Encoding.
29–16 PRPENC_RS_R_V	Preprocessing task for encoding Resizing vertical Ratio. This field contains the resizing vertical coefficient of Preprocessing for Encoding. Resizing Ratio is equal to PRPENC_RS_R_V: M Where M = 2^13; SI - input size; SO - output size PRPENC_RS_R_V = floor(M*(SI-1)/(SO-1));
15–14 PRPENC_DS_R_H	Preprocessing task for encoding Downsizing horizontal Ratio. This field contains the downsizing horizontal coefficient of Preprocessing for Encoding. Values: 00 1 01 2 10 4 11 RSV

Table continues on the next page...

IPU_IC_PRP_ENC_RSC field descriptions (continued)

Field	Description
13–0 PRPENC_RS_R_H	Preprocessing task for encoding Resizing horizontal Ratio. This field contains the resizing horizontal coefficient of Preprocessing for Encoding. Resizing Ratio is equal to PRPENC_RS_R_H: M Where M = 2^13; SI - input size; SO - output size PRPENC_RS_R_H = floor(M*(SI-1)/(SO-1));

45.51.103 IC Preprocessing View-Finder Resizing Coefficients Register (IPU_IC_PRP_VF_RSC)

This register contains the resizing and downsizing parameters for preprocessing task for display.

Address: IPU_IC_PRP_VF_RSC is 1E00_0000h base + 20008h offset = 1E02_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

IPU_IC_PRP_VF_RSC field descriptions

Field	Description
31–30 PRPVF_DS_R_V	Preprocessing task for encoding Downsizing vertical Ratio. This field contains the downsizing vertical coefficient of Preprocessing for View-Finder.
29–16 PRPVF_RS_R_V	Preprocessing task for encoding Resizing vertical Ratio. This field contains the resizing vertical coefficient of Preprocessing for View-Finder. Resizing Ratio is equal to PRPVF_RS_R_V: M Where M = 2^13; SI - input size; SO - output size PRPVF_RS_R_V = floor(M*(SI-1)/(SO-1));
15–14 PRPVF_DS_R_H	Preprocessing task for encoding Downsizing horizontal Ratio. This field contains the downsizing horizontal coefficient of Preprocessing for View-Finder. Values: 00 1 01 2 10 4 11 RSV
13–0 PRPVF_RS_R_H	Preprocessing task for view-finding resizing horizontal ratio. This field contains the resizing horizontal coefficient of preprocessing Task For View-finder. Resizing Ratio is equal to PRPVF_RS_R_H: M Where M = 2^13; SI - input size; SO - output size

Table continues on the next page...

IPU_IC_PRP_VF_RSC field descriptions (continued)

Field	Description
	PRPVF_RS_R_H = floor(M*(SI-1)/(SO-1));

45.51.104 IC Postprocessing Encoder Resizing Coefficients Register (IPU_IC_PP_RSC)

This register contains the resizing and downsizing parameters for Post-Processing task for display.

Address: IPU_IC_PP_RSC is 1E00_0000h base + 2000Ch offset = 1E02_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

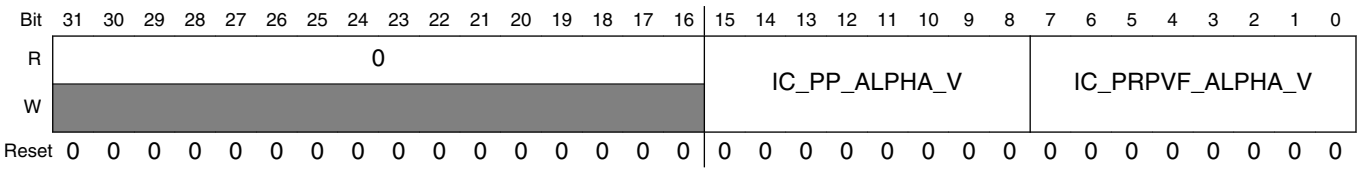
Reset	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_IC_PP_RSC field descriptions

Field	Description
31–30 PP_DS_R_V	Post-Processing task Downsizing vertical Ratio. This field contains the downsizing vertical coefficient of Post-Processing.
29–16 PP_RS_R_V	Post-Processing task Resizing vertical Ratio. This field contains the resizing vertical coefficient of Post-Processing. Resizing Ratio is equal to PP_RS_R_V: M Where M = 2^13; SI - input size; SO - output size PP_RS_R_V = floor(M*(SI-1)/(SO-1));
15–14 PP_DS_R_H	Post-Processing task Downsizing horizontal Ratio. This field contains the downsizing horizontal coefficient of Post-Processing. 00 1 01 2 10 4 11 RSV
13–0 PP_RS_R_H	Post-Processing task Resizing horizontal Ratio. This field contains the resizing horizontal coefficient of Post-Processing. Resizing Ratio is equal to PP_RS_R_H: M Where M = 2^13; SI - input size; SO - output size PP_RS_R_H = floor(M*(SI-1)/(SO-1));

45.51.105 IC Combining Parameters Register 1 (IPU_IC_CMBP_1)

Address: IPU_IC_CMBP_1 is 1E00_0000h base + 20010h offset = 1E02_0010h

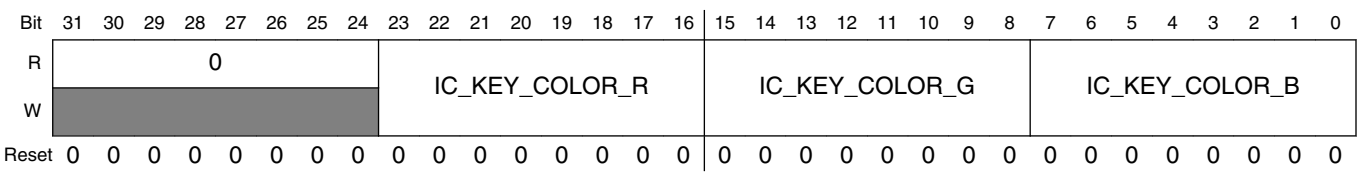


IPU_IC_CMBP_1 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved.
15–8 IC_PP_ALPHA_V	Post-Processing task Global Alpha. This field contains the Global Alpha value of Post-Processing.
7–0 IC_PRPVF_ALPHA_V	Preprocessing task for viewfinder Global Alpha. This field contains the Global Alpha value of Preprocessing for viewfinder.

45.51.106 IC Combining Parameters Register 2 (IPU_IC_CMBP_2)

Address: IPU_IC_CMBP_2 is 1E00_0000h base + 20014h offset = 1E02_0014h

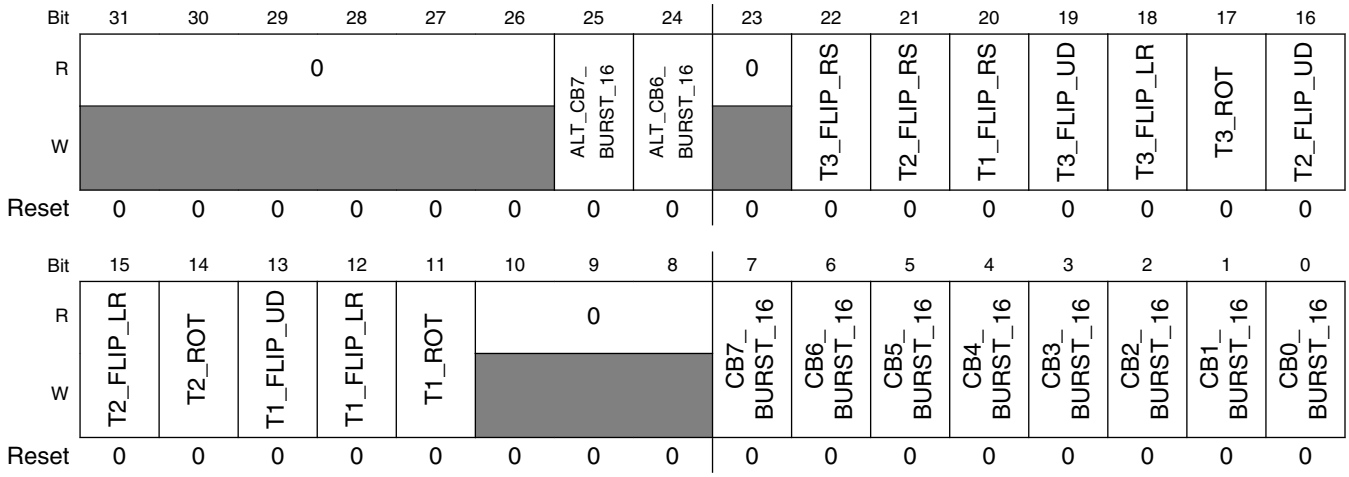


IPU_IC_CMBP_2 field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved.
23–16 IC_KEY_COLOR_R	Key Color Red.
15–8 IC_KEY_COLOR_G	Key Color Green.
7–0 IC_KEY_COLOR_B	Key Color Blue.

45.51.107 IC IDMAC Parameters 1 Register (IPU_IC_IDMAC_1)

Address: IPU_IC_IDMAC_1 is 1E00_0000h base + 20018h offset = 1E02_0018h



IPU_IC_IDMAC_1 field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value zero. Reserved
25 ALT_CB7_ BURST_16	Reserved
24 ALT_CB6_ BURST_16	Reserved
23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22 T3_FLIP_RS	LEFT/RIGHT flip for Post Processing (PP) task; his bit affect the flipping done on the resizing unit. The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 horizontal flip enabled 0 no flip
21 T2_FLIP_RS	LEFT/RIGHT flip for View Finder (VF) task; this bit affect the flipping done on the resizing unit. The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 horizontal flip enabled 0 no flip
20 T1_FLIP_RS	LEFT/RIGHT flip for Encoding (ENC) task; this bit affect the flipping done on the resizing unit. The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM

Table continues on the next page...

IPU_IC_IDMAC_1 field descriptions (continued)

Field	Description
	1 horizontal flip enabled 0 no flip
19 T3_FLIP_UD	UP/DOWN flip for Post Processing (PP) task The value of this field must be identical to the corresponding channel's VF parameters in the IDMAC's CPMEM 1 Vertical flip enable 0 no flip
18 T3_FLIP_LR	LEFT/RIGHT flip for Post Processing (PP) task; this bit affect the flipping done on the rotation unit The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 horizontal flip enabled 0 no flip
17 T3_ROT	Rotation for Post Processing (PP) task The value of this field must be identical to the corresponding channel's ROT parameters in the IDMAC's CPMEM 1 90 degree rotation clockwise 0 no rotation
16 T2_FLIP_UD	UP/DOWN flip for View Finder (VF) task The value of this field must be identical to the corresponding channel's VF parameters in the IDMAC's CPMEM 1 Vertical flip enable 0 no flip
15 T2_FLIP_LR	LEFT/RIGHT flip for View Finder (VF) task; this bit affect the flipping done on the rotation unit The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 horizontal flip enabled 0 no flip
14 T2_ROT	Rotation for View Finder (VF) task The value of this field must be identical to the corresponding channel's ROT parameters in the IDMAC's CPMEM 1 90 degree rotation clockwise 0 no rotation
13 T1_FLIP_UD	UP/DOWN flip for Encoding (ENC) task The value of this field must be identical to the corresponding channel's VF parameters in the IDMAC's CPMEM 1 Vertical flip enable 0 no flip
12 T1_FLIP_LR	LEFT/RIGHT flip for Encoding (ENC) task; this bit affect the flipping done on the rotation unit

Table continues on the next page...

IPU_IC_IDMAC_1 field descriptions (continued)

Field	Description
	The value of this field must be identical to the corresponding channel's HF parameter in the IDMAC's CPMEM 1 horizontal flip enabled 0 no flip
11 T1_ROT	Rotation for Encoding (ENC) task The value of this field must be identical to the corresponding channel's ROT parameters in the IDMAC's CPMEM 1 90 degree rotation clockwise 0 no rotation
10–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 CB7_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB7 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
6 CB6_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB6 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
5 CB5_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB5 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
4 CB4_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB4 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
3 CB3_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB3 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
2 CB2_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB2 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM

Table continues on the next page...

IPU_IC_IDMAC_1 field descriptions (continued)

Field	Description
	0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
1 CB1_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB1 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111
0 CB0_BURST_16	This bit defines the number of active cycles within a burst (burst size) coming from the IDMAC for IC's CB0 For pixel data the number of pixels should match the NPB[6:2] value on the IDMAC's CPMEM 0 Burst size is 8 pixels; The Matching NPB[6:2] should be 00111 1 Burst size is 16 pixels; The Matching NPB[6:2] should be 01111

45.51.108 IC IDMAC Parameters 2 Register (IPU_IC_IDMAC_2)

Address: IPU_IC_IDMAC_2 is 1E00_0000h base + 2001Ch offset = 1E02_001Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

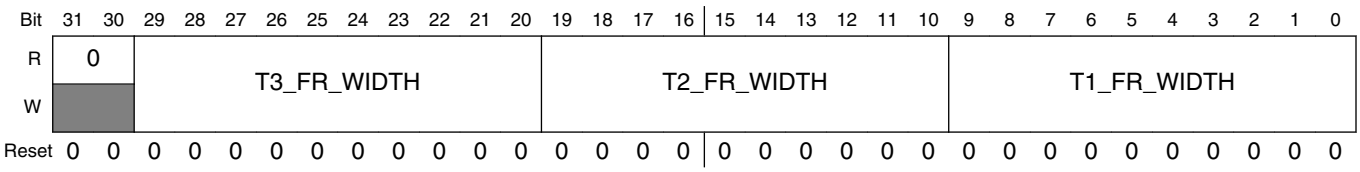
IPU_IC_IDMAC_2 field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved
29–20 T3_FR_HEIGHT	Frame Height for Post Processing (PP) task The value of this field must be identical to the corresponding FH channel's parameters in the IDMAC's CPMEM. This parameter refers to the output's size -1
19–10 T2_FR_HEIGHT	Frame Height for View Finder (VF) task The value of this field must be identical to the corresponding FH channel's parameters in the IDMAC's CPMEM. This parameter refers to the output's size -1
9–0 T1_FR_HEIGHT	Frame Height for Encoding (ENC) task The value of this field must be identical to corresponding FH channel's parameters in the IDMAC's CPMEM. This parameter refers to the output's size -1

45.51.109 IC IDMAC Parameters 3Register (IPU_IC_IDMAC_3)

Address: IPU_IC_IDMAC_3 is 1E00_0000h base + 20020h offset = 1E02_0020h

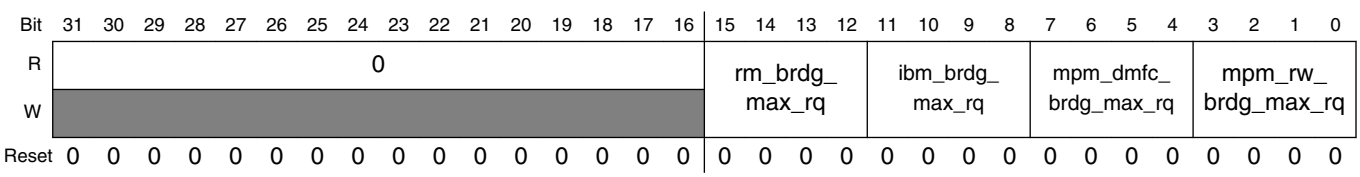


IPU_IC_IDMAC_3 field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved
29–20 T3_FR_WIDTH	Frame Width for Post Processing (PP) task The value of this field must be identical to the corresponding FW channel's parameters in the IDMAC's CPMEM. This parameter refers to the output's size -1
19–10 T2_FR_WIDTH	Frame Width for View Finder (VF) task The value of this field must be identical to the corresponding FW channel's parameters in the IDMAC's CPMEM. This parameter refers to the output's size -1
9–0 T1_FR_WIDTH	Frame Width for Encoding (ENC) task The value of this field must be identical to corresponding FW channel's parameters in the IDMAC's CPMEM. This parameter refers to the output's size -1

45.51.110 IC IDMAC Parameters 4 Register (IPU_IC_IDMAC_4)

Address: IPU_IC_IDMAC_4 is 1E00_0000h base + 20024h offset = 1E02_0024h



IPU_IC_IDMAC_4 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–12 rm_brdg_max_rq	RM memory Bridge Max Requests 0000 Feature is disabled 0001 Max request is 1 1111 Max request are15

Table continues on the next page...

IPU_IC_IDMAC_4 field descriptions (continued)

Field	Description
11–8 ibm_brdg_max_rq	IBM memory Bridge Max Requests 0000 Feature is disabled 0001 Max request is 1 1111 Max request are15
7–4 mpm_dmfc_brdg_max_rq	MPM memory Bridge Max Requests for the IC DMFC interface 0000 Feature is disabled 0001 Max request is 1 1111 Max request are15
3–0 mpm_rw_brdg_max_rq	MPM memory Bridge Max Requests between MPM's read and writes 0000 Feature is disabled 0001 Max request is 1 1111 Max request are15

45.51.111 CSI0 Sensor Configuration Register (IPU_CSI0_SENS_CONF)

Address: IPU_CSI0_SENS_CONF is 1E00_0000h base + 30000h offset = 1E03_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_CSI0_SENS_CONF field descriptions

Field	Description
31 CSI0_DATA_EN_POL	Invert IPP_IND_SENSB_DATA_EN input. This bit selects the polarity of IPP_IND_SENSB_DATA_EN signal. 0 IPP_IND_SENSB_DATA_EN is directly applied to internal circuitry. 1 IPP_IND_SENSB_DATA_EN is inverted before applied to internal circuitry.
30 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.

Table continues on the next page...

IPU_CSI0_SENS_CONF field descriptions (continued)

Field	Description
29 CSI0_FORCE_EOF	Force End of frame This is a self clear bit allowing the user to force an End-of-frame event; This bit can be used in cases where the frame sent by the sensor was not completed. 1 force end of frame 0 no action
28 CSI0_JPEG_MODE	JPEG Mode - this bit defines the mode of the control signals when working in JPEG mode 1 The data is valid as long as HSYNC and VSYNC signals are active; HSYNC is valid for single frame 0 The frame starts withe the assertion of VSYNC. The frame ends on the next VSYNC or by setting the **CSI0_FORCE_EOF bit.**
27 CSI0_JPEG8_EN	JPEG8 enable bit 1 JPEG8 detection is enabled 0 JPEG8 is disabled
26–24 CSI0_DATA_DEST	These bits enable the destination of the data coming from the CSI. CSI0_DATA_DEST[0] - Reserved CSI0_DATA_DEST[1] - destination is IC CSI0_DATA_DEST[2] - destination is IDMAC via SMFC
23–16 CSI0_DIV_RATIO	DIV Ratio Clock division ratio minus 1. This field defines the division ratio of HSP_CLK into SENSB_MCLK: SENSB_MCLK rate = HSP_CLK rate /(DIV_RATIO+1)
15 CSI0_EXT_VSYNC	External VSYNC enable. This bits select between external and internal VSYNC. 0 Internal VSYNC mode. 1 External VSYNC mode.
14–11 CSI0_DATA_WIDTH	Data width. This field defines the number of bits per color. Values: 0000 4 bits per color 0000 Reserved 0001 8 bits per color 0010 9 bits per color 0010 Reserved 0011 10 bits per color 0100 11 bits per color 0100 Reserved 0101 12 bits per color 0101 Reserved 0110 13 bits per color 0110 Reserved 0111 14 bits per color 0111 Reserved 1000 15 bits per color 1000 Reserved 1001 16 bits per color

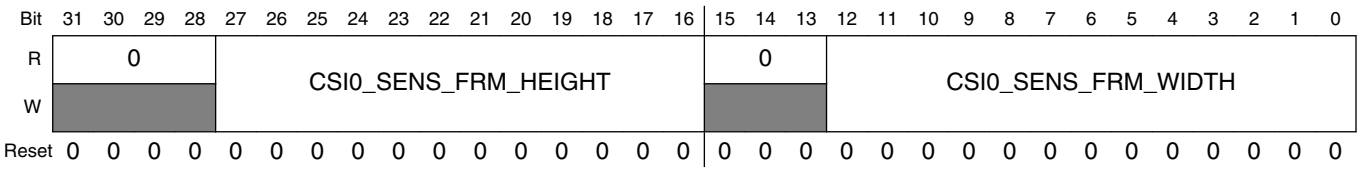
Table continues on the next page...

IPU_CSI0_SENS_CONF field descriptions (continued)

Field	Description
10–8 CSI0_SENS_ DATA_FORMAT	Data format from the sensor. This field defines the data format for the input of the CSI sensor. Values: 000 full RGB or YUV444 001 YUV422 (YUYV...) 010 YUV422 (UYVY...) 011 Bayer or Generic data 100 RGB565 101 RGB555 110 RGB444 111 JPEG
7 CSI0_PACK_ TIGHT	CSI0 Pack Tight When the data format is YUV or RGB and the component's width is 9-16 bits, it can be sent to the memory in 2 different ways. 1 Three 10 bits components are packed into a 32 bit word. Color extension/reduction is performed 0 Each component is written as a 16 bit word where the MSB is written to bit #15, color extension is done for the remaining least significant bits.
6–4 CSI0_SENS_ PRTCL	Sensor Protocol. This bit defines the Sensor timing/data mode protocol. Values: 000 Gated clock mode 001 Non-gated clock mode 010 CCIR progressive mode (BT.656) 011 CCIR interlaced mode (BT.656) 100 CCIR progressive (BT.1120 DDR mode: data arrives on every edge of the clock) 101 CCIR progressive (BT.1120 SDR mode: data arrives only on the positive edge of the clock) 110 CCIR interlaced mode (BT.1120 DDR mode: data arrives on every edge of the clock) 111 CCIR interlaced mode (BT.1120 SDR mode: data arrives only on the positive edge of the clock)
3 CSI0_SENS_ PIX_CLK_POL	Invert Pixel clock input. This bit selects the polarity of pixel clock. 0 pixel clock is directly applied to internal circuitry. 1 pixel clock is inverted before applied to internal circuitry.
2 CSI0_DATA_ POL	Invert data input. This bit selects the polarity of data input. 0 data lines are directly applied to internal circuitry. 1 data lines are inverted before applied to internal circuitry.
1 CSI0_HSYNC_ POL	Invert IPP_IND_SENSB_HSYNC input. This bit selects the polarity of IPP_IND_SENSB_HSYNC signal. 0 IPP_IND_SENSB_HSYNC is directly applied to internal circuitry. 1 IPP_IND_SENSB_HSYNC is inverted before applied to internal circuitry.
0 CSI0_VSYNC_ POL	Invert IPP_IND_SENSB_VSYNC input. This bit selects the polarity of IPP_IND_SENSB_VSYNC signal. 0 IPP_IND_SENSB_VSYNC is not inverted before applied to internal circuitry. 1 IPP_IND_SENSB_VSYNC is inverted before applied to internal circuitry.

45.51.112 CSI0 Sense Frame Size Register (IPU_CSI0_SENS_FRM_SIZE)

Address: IPU_CSI0_SENS_FRM_SIZE is 1E00_0000h base + 30004h offset = 1E03_0004h

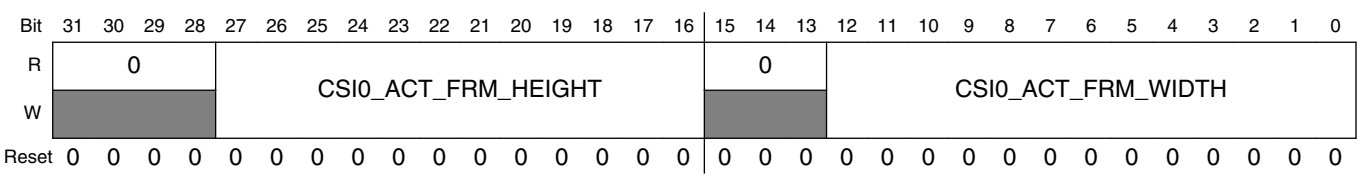


IPU_CSI0_SENS_FRM_SIZE field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
27–16 CSI0_SENS_ FRM_HEIGHT	Sensor frame height minus 1. This field defines the sensor frame rows number minus 1.
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
12–0 CSI0_SENS_ FRM_WIDTH	Sensor frame width minus 1. This field defines the sensor frame column number minus 1.

45.51.113 CSI0 Actual Frame Size Register (IPU_CSI0_ACT_FRM_SIZE)

Address: IPU_CSI0_ACT_FRM_SIZE is 1E00_0000h base + 30008h offset = 1E03_0008h



IPU_CSI0_ACT_FRM_SIZE field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
27–16 CSI0_ACT_ FRM_HEIGHT	Actual frame height minus 1. This field defines the CSI output frame rows number minus 1.
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.

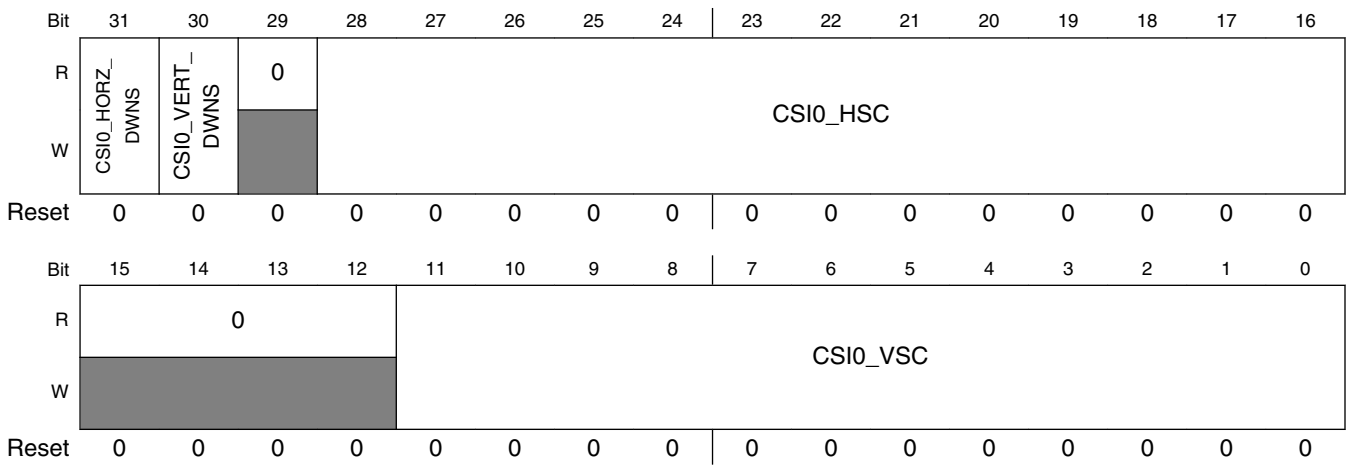
Table continues on the next page...

IPU_CSI0_ACT_FRM_SIZE field descriptions (continued)

Field	Description
12–0 CSI0_ACT_ FRM_WIDTH	Actual frame width minus 1. This field defines the CSI output frame columns number minus 1.

45.51.114 CSI0 Output Control Register (IPU_CSI0_OUT_FRM_CTRL)

Address: IPU_CSI0_OUT_FRM_CTRL is 1E00_0000h base + 3000Ch offset = 1E03_000Ch

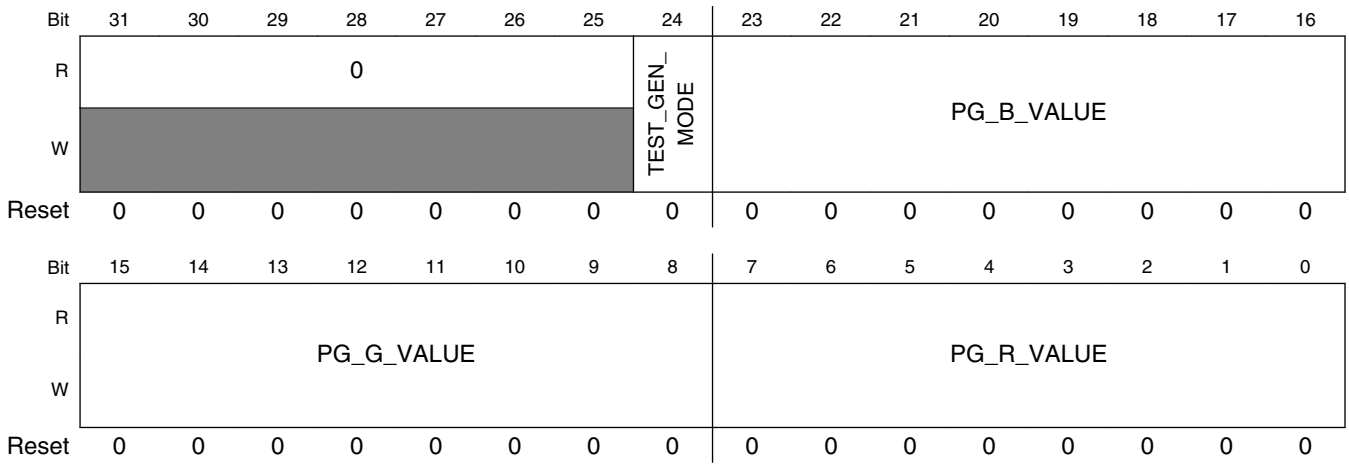


IPU_CSI0_OUT_FRM_CTRL field descriptions

Field	Description
31 CSI0_HORZ_ DWNS	Enable horizontal downsizing (decimation) by 2. 0 Downsizing disabled 1 Downsizing enabled
30 CSI0_VERT_ DWNS	Enable vertical downsizing (decimation) by 2. 0 Downsizing disabled 1 Downsizing enabled
29 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
28–16 CSI0_HSC	Horizontal skip. This field defines the number of columns to skip. In Interlaced mode this number refers to the number of lines per field.
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
11–0 CSI0_VSC	Vertical skip. This field defines the number of rows to skip.

45.51.115 CSIO Test Control Register (IPU_CSI0_TST_CTRL)

Address: IPU_CSI0_TST_CTRL is 1E00_0000h base + 30010h offset = 1E03_0010h

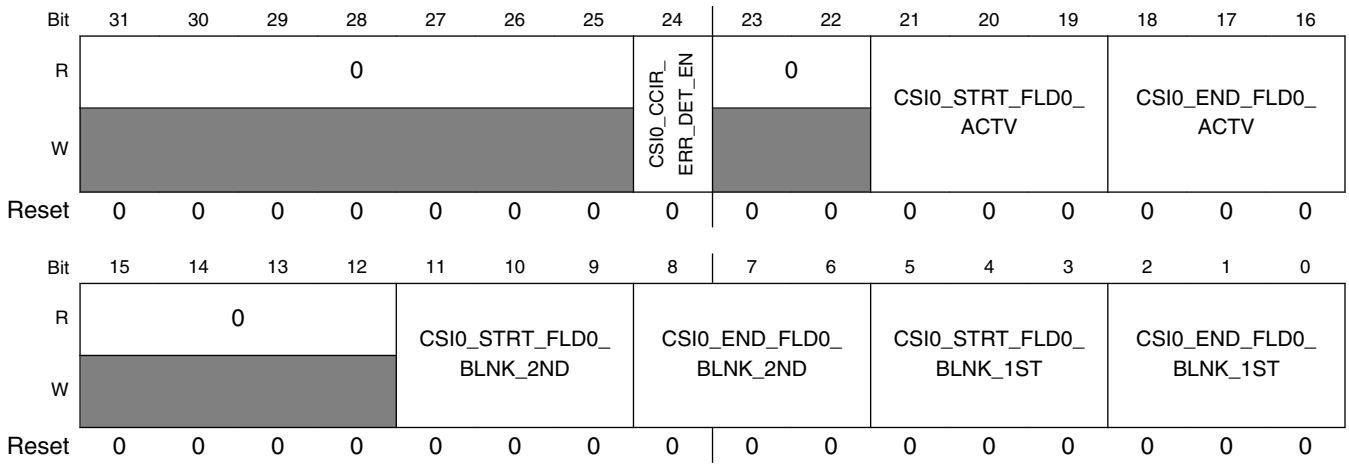


IPU_CSI0_TST_CTRL field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
24 TEST_GEN_ MODE	Test generator mode. This bit activates the signal generation. 0 Test signal generator is inactive. 1 Test signal generator is active.
23–16 PG_B_VALUE	Pattern generator B value. This field selects the B value for the generated pattern of even pixel.
15–8 PG_G_VALUE	Pattern generator G value. This field selects the G value for the generated pattern of even pixel.
7–0 PG_R_VALUE	Pattern generator R value. This field selects the R value for the generated pattern of even pixel.

45.51.116 CSIO CCIR Code Register 1 (IPU_CSI0_CCIR_CODE_1)

Address: IPU_CSI0_CCIR_CODE_1 is 1E00_0000h base + 30014h offset = 1E03_0014h



IPU_CSI0_CCIR_CODE_1 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
24 CSI0_CCIR_ERR_DET_EN	Enable error detection and correction for CCIR interlaced mode with protection bit. 0 Error detection and correction is disabled. 1 Error detection and correction is enabled.
23–22 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
21–19 CSI0_STRT_FLD0_ACTV	Start of field 0 active line command (interlaces mode). (In progressive mode, start of active line command mode).
18–16 CSI0_END_FLD0_ACTV	End of field 0 active line command (interlaces mode). (In progressive mode, end of active line command mode).
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
11–9 CSI0_STRT_FLD0_BLNK_2ND	Start of field 0 second blanking line command (interlaces mode). (In progressive mode this field is ignored).
8–6 CSI0_END_FLD0_BLNK_2ND	End of field 0 second blanking line command (interlaces mode). (In progressive mode this field is ignored).

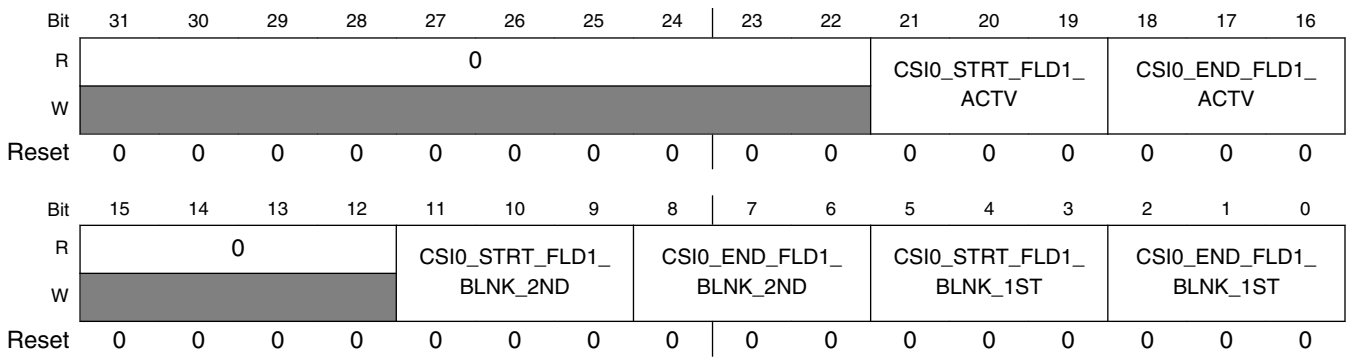
Table continues on the next page...

IPU_CSI0_CCIR_CODE_1 field descriptions (continued)

Field	Description
5–3 CSI0_STRT_FLD0_BLNK_1ST	Start of field 0 first blanking line command (interlaces mode). (In progressive mode this field indicates start of blanking line command).
2–0 CSI0_END_FLD0_BLNK_1ST	End of field 0 first blanking line command (interlaces mode). (In progressive mode this field is ignored).

45.51.117 CSIO CCIR Code Register 2 (IPU_CSI0_CCIR_CODE_2)

Address: IPU_CSI0_CCIR_CODE_2 is 1E00_0000h base + 30018h offset = 1E03_0018h



IPU_CSI0_CCIR_CODE_2 field descriptions

Field	Description
31–22 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
21–19 CSI0_STRT_FLD1_ACTV	Start of field 1 active line command (interlaces mode). (In progressive mode this field is ignored).
18–16 CSI0_END_FLD1_ACTV	End of field 1 active line command (interlaces mode). (In progressive mode this field is ignored).
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
11–9 CSI0_STRT_FLD1_BLNK_2ND	Start of field 1 second blanking line command (interlaces mode). (In progressive mode this field is ignored).
8–6 CSI0_END_FLD1_BLNK_2ND	End of field 1 second blanking line command (interlaces mode). (In progressive mode this field is ignored).

Table continues on the next page...

IPU_CSI0_CCIR_CODE_2 field descriptions (continued)

Field	Description
5–3 CSI0_STRT_FLD1_BLNK_1ST	Start of field 1 first blanking line command (interlaces mode). (In progressive mode this field is ignored).
2–0 CSI0_END_FLD1_BLNK_1ST	End of field 1 first blanking line command (interlaces mode). (In progressive mode this field is ignored).

45.51.118 CSIO CCIR Code Register 3 (IPU_CSI0_CCIR_CODE_3)

Address: IPU_CSI0_CCIR_CODE_3 is 1E00_0000h base + 3001Ch offset = 1E03_001Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

IPU_CSI0_DI field descriptions

Field	Description
31–24 CSI0_MIPI_DI3	Reserved

Table continues on the next page...

IPU_CSI0_DI field descriptions (continued)

Field	Description
23–16 CSI0_MIPI_DI2	Reserved
15–8 CSI0_MIPI_DI1	Reserved
7–0 CSI0_MIPI_DI0	Reserved

45.51.120 CSI0 SKIP Register (IPU_CSI0_SKIP)

This register controls the frame skipping supported between CSI0 and the SMFC.

Address: IPU_CSI0_SKIP is 1E00_0000h base + 30024h offset = 1E03_0024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0								CSI0_SKIP_ISP					CSI0_MAX_RATIO_SKIP_ISP		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0						CSI0_ID_2_SKIP		CSI0_SKIP_SMFC					CSI0_MAX_RATIO_SKIP_SMFC		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_CSI0_SKIP field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved
23–19 CSI0_SKIP_ISP	Reserved
18–16 CSI0_MAX_RATIO_SKIP_ISP	Reserved
15–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–8 CSI0_ID_2_SKIP	Reserved
7–3 CSI0_SKIP_SMFC	CSI0 SKIP SMFC These 5 bits define the skipping pattern of the frames send to the SMFC. Skipping is done for a set of frames. The number of frames in a set is defined at CSI0_MAX_RATIO_SKIP_SMFC. when CSI0_MAX_RATIO_SKIP_SMFC = 1 => CSI0_SKIP_SMFC[0] is used; other bits are ignored

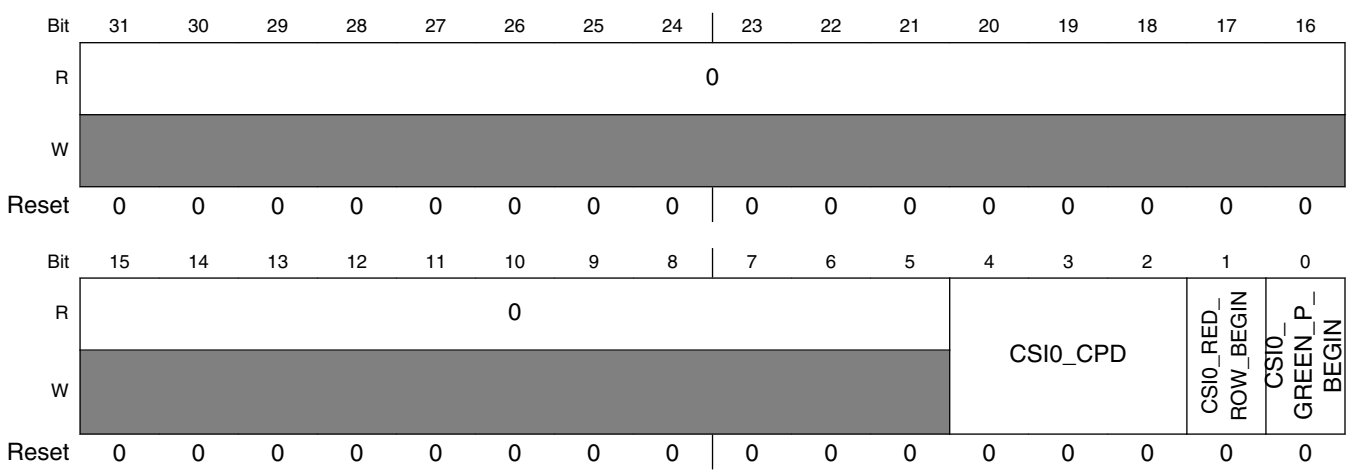
Table continues on the next page...

IPU_CSI0_SKIP field descriptions (continued)

Field	Description
	when CSI0_MAX_RATIO_SKIP_SMFC = 2 => CSI0_SKIP_SMFC[1:0] are used; other bits are ignored when CSI0_MAX_RATIO_SKIP_SMFC = 3 => CSI0_SKIP_SMFC[2:0] are used; other bits are ignored when CSI0_MAX_RATIO_SKIP_SMFC = 4 => CSI0_SKIP_SMFC[3:0] are used; other bits are ignored when CSI0_MAX_RATIO_SKIP_SMFC = 5 => CSI0_SKIP_SMFC[4:0] are used; Setting bit #n of CSI0_SKIP_SMFC means that the #n frame in the set is skipped. For example: if CSI0_MAX_RATIO_SKIP_SMFC = 4 and CSI0_SKIP_SMFC = 11010 Frames #0 & Frame #2 will not be skipped as bit0 and bit2 are cleared Frames #1 & Frame #3 will be skipped as bit1 and bit3 are set bit #4 is ignored as CSI0_MAX_RATIO_SKIP_SMFC is set to 4
2–0 CSI0_MAX_ RATIO_SKIP_ SMFC	CSI0 Maximum Ratio Skip for SMFC These bits define the number of frames in a skipping set. The skipping number is equal to CSI0_MAX_RATIO_SKIP_SMFC+1; The maximum value of this bits is 5. When set to 0 the skipping is disabled.

45.51.121 CSI0 Compander Control Register (IPU_CSIO_CPD_CTRL)

Address: IPU_CSIO_CPD_CTRL is 1E00_0000h base + 30028h offset = 1E03_0028h



IPU_CSIO_CPD_CTRL field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
4–2 CSI0_CPD	CSI0_CPD These bits enable the compander in the path to different destination. CSI0_CPD[0] - CSI0_CPD[1] - Enable for the compander for data sent to the IC

Table continues on the next page...

IPU_CSIO_CPD_CTRL field descriptions (continued)

Field	Description
	CSI0_CPD[2] - Enable for the compander for data sent to the IDMAC via SMFC If all the 3 bits are zero the compander is disabled Reserved
1 CSI0_RED_ROW_BEGIN	Color of first row in the frame. Reserved 0 First row in the frame is GBGB. 1 First row in the frame is GRGR.
0 CSI0_GREEN_P_BEGIN	Color of first component in the frame. Reserved 0 First component in the frame is blue or red, depending from RED_ROW bit. 1 First component in the frame is green

45.51.122 CSI0 Red Component Compander Constants Register <i> (IPU_CSIO_CPD_RC_i)

These registers contain CONSTANT <i> parameters used for companding of red component.

Address: IPU_CSIO_CPD_RC_i is 1E00_0000h base + 3002Ch offset = 1E03_002Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_CSI1_SENS_CONF field descriptions

Field	Description
31 CSI0_DATA_EN_POL	Invert IPP_IND_SENSB_DATA_EN input. This bit selects the polarity of IPP_IND_SENSB_DATA_EN signal. 0 IPP_IND_SENSB_DATA_EN is directly applied to internal circuitry. 1 IPP_IND_SENSB_DATA_EN is inverted before applied to internal circuitry.
30 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
29 CSI1_FORCE_EOF	Force End of frame This is a self clear bit allowing the user to force an End-of-frame event; This bit can be used in cases where the frame sent by the sensor was not completed. 1 force end of frame 0 no action
28 CSI1_JPEG_MODE	JPEG Mode - this bit defines the mode of the control signals when working in JPEG mode 1 The data is valid as long as HSYNC and VSYNC signals are active; HSYNC is valid for single frame 0 The frame starts withe the assertion of VSYNC. The frame ends on the next VSYNC or by setting the **CSI0_FORCE_EOF bit**
27 CSI1_JPEG8_EN	JPEG8 enable bit 1 JPEG8 detection is enabled 0 JPEG8 is disabled
26–24 CSI1_DATA_DEST	These bits enable the destination of the data coming from the CSI. CSI1_DATA_DEST[0] - Reserved CSI1_DATA_DEST[1] - destination is IC

Table continues on the next page...

IPU_CSI1_SENS_CONF field descriptions (continued)

Field	Description
	CSI1_DATA_DEST[2] - destination is IDMAC via SMFC
23–16 CSI1_DIV_RATIO	DIV Ratio Clock division ratio minus 1. This field defines the division ratio of HSP_CLK into SENSB_MCLK: SENSB_MCLK rate = HSP_CLK rate /(DIV_RATIO+1)
15 CSI1_EXT_VSYNC	External VSYNC enable. This bits select between external and internal VSYNC. 0 Internal VSYNC mode. 1 External VSYNC mode.
14–11 CSI1_DATA_WIDTH	Data width. This fields defines the number of bits per color. Values: 0000 4 bits per color 0000 Reserved 0001 8 bits per color 0010 9 bits per color 0010 Reserved 0011 10 bits per color 0100 11 bits per color 0100 Reserved 0101 12 bits per color 0101 Reserved 0110 13 bits per color 0110 Reserved 0111 14 bits per color 0111 Reserved 1000 15 bits per color 1000 Reserved 1001 16 bits per color
10–8 CSI1_SENS_DATA_FORMAT	Data format from the sensor. This field defines the data format for the input of the CSI sensor. Values: 000 full RGB or YUV444 001 YUV422 (YUYV...) 010 YUV422 (UYVY...) 011 Bayer or Generic data 100 RGB565 101 RGB555 110 RGB444 111 JPEG
7 CSI1_PACK_TIGHT	**CSI1 Pack Tight** When the data format is YUV or RGB and the component's width is 9-16 bits, it can be sent to the memory in 2 different ways 1 Three 10 bits components are packed into a 32 bit word. Color extension/reduction is performed 0 Each component is written as a 16 bit word where the MSB is written to bit #15, color extension is done for the remaining least significant bits.

Table continues on the next page...

IPU_CSI1_SENS_CONF field descriptions (continued)

Field	Description
6–4 CSI1_SENS_ PRTCL	Sensor Protocol. This bit defines the Sensor timing/data mode protocol. Values: 000 Gated clock mode 001 Non-gated clock mode 010 CCIR progressive mode (BT.656) 011 CCIR interlaced mode (BT.656) 100 CCIR progressive (BT.1120 DDR mode: data arrives on every edge of the clock) 101 CCIR progressive (BT.1120 SDR mode: data arrives only on the positive edge of the clock) 110 CCIR interlaced mode (BT.1120 DDR mode: data arrives on every edge of the clock) 111 CCIR interlaced mode (BT.1120 SDR mode: data arrives only on the positive edge of the clock)
3 CSI1_SENS_ PIX_CLK_POL	Invert Pixel clock input. This bit selects the polarity of pixel clock. 0 pixel clock is directly applied to internal circuitry. 1 pixel clock is inverted before applied to internal circuitry.
2 CSI1_DATA_ POL	Invert data input. This bit selects the polarity of data input. 0 data lines are directly applied to internal circuitry. 1 data lines are inverted before applied to internal circuitry.
1 CSI1_HSYNC_ POL	Invert IPP_IND_SENSB_HSYNC input. This bit selects the polarity of IPP_IND_SENSB_HSYNC signal. 0 IPP_IND_SENSB_HSYNC is directly applied to internal circuitry. 1 IPP_IND_SENSB_HSYNC is inverted before applied to internal circuitry.
0 CSI1_VSYNC_ POL	Invert IPP_IND_SENSB_VSYNC input. This bit selects the polarity of IPP_IND_SENSB_VSYNC signal. 0 IPP_IND_SENSB_VSYNC is not inverted before applied to internal circuitry. 1 IPP_IND_SENSB_VSYNC is inverted before applied to internal circuitry.

45.51.133 CSI1 Sense Frame Size Register (IPU_CSI1_SENS_FRM_SIZE)

Address: IPU_CSI1_SENS_FRM_SIZE is 1E00_0000h base + 38004h offset = 1E03_8004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

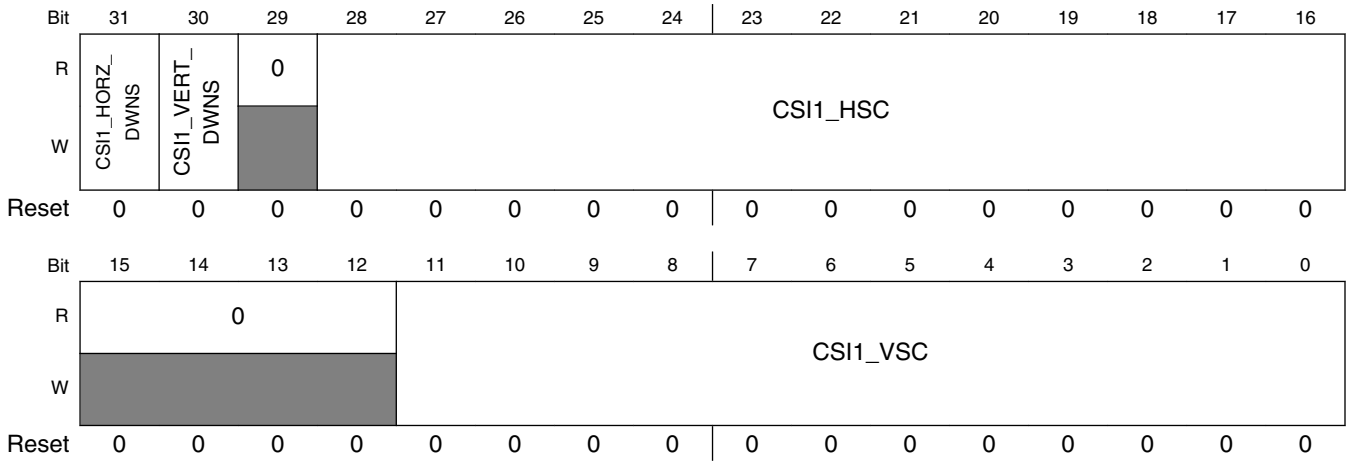
IPU_CSI1_ACT_FRM_SIZE field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
27–16 CSI1_ACT_ FRM_HEIGHT	Actual frame height minus 1. This field defines the CSI output frame rows number minus 1.
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
12–0 CSI1_ACT_ FRM_WIDTH	Actual frame width minus 1. This field defines the CSI output frame columns number minus 1.

45.51.135 CSI1 Output Control Register (IPU_CSI1_OUT_FRM_CTRL)

Address: IPU_CSI1_OUT_FRM_CTRL is 1E00_0000h base + 3800Ch offset = 1E03_800Ch

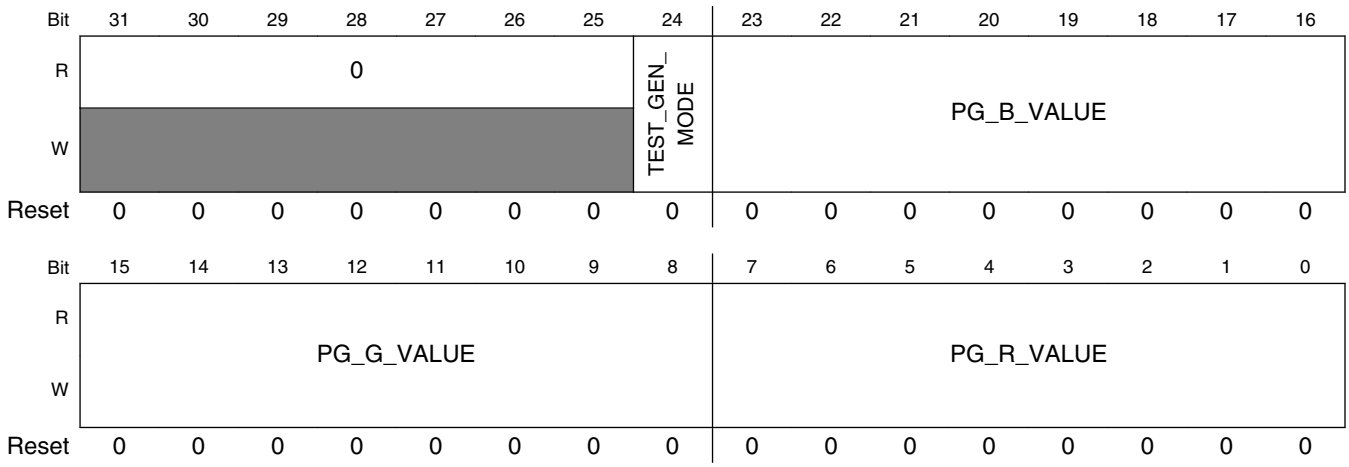


IPU_CSI1_OUT_FRM_CTRL field descriptions

Field	Description
31 CSI1_HORZ_DWNS	Enable horizontal downsizing (decimation) by 2. 0 Downsizing disabled 1 Downsizing enabled
30 CSI1_VERT_DWNS	Enable vertical downsizing (decimation) by 2. 0 Downsizing disabled 1 Downsizing enabled
29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28–16 CSI1_HSC	Horizontal skip. This field defines the number of columns to skip. In Interlaced mode this number refers to the number of lines per field
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
11–0 CSI1_VSC	Vertical skip. This field defines the number of rows to skip.

45.51.136 CSI1 Test Control Register (IPU_CSI1_TST_CTRL)

Address: IPU_CSI1_TST_CTRL is 1E00_0000h base + 38010h offset = 1E03_8010h



IPU_CSI1_TST_CTRL field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared.
24 TEST_GEN_ MODE	Test generator mode. This bit activates the signal generation. 0 Test signal generator is inactive. 1 Test signal generator is active.
23–16 PG_B_VALUE	Pattern generator B value. This field selects the B value for the generated pattern of even pixel.
15–8 PG_G_VALUE	Pattern generator G value. This field selects the G value for the generated pattern of even pixel.
7–0 PG_R_VALUE	Pattern generator R value. This field selects the R value for the generated pattern of even pixel.

45.51.137 CSI1 CCIR Code Register 1 (IPU_CSI1_CCIR_CODE_1)

Address: IPU_CSI1_CCIR_CODE_1 is 1E00_0000h base + 38014h offset = 1E03_8014h

15–8 CSI0_MIPI_DI1	Reserved
7–0 CSI1_MIPI_DI0	Reserved

45.51.141 CSI1 SKIP Register (IPU_CSI1_SKIP)

This register control the frame skipping supported between CSI1 and the SMFC.

Address: IPU_CSI1_SKIP is 1E00_0000h base + 38024h offset = 1E03_8024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0								CSI1_SKIP_ISP					CSI1_MAX_RATIO_SKIP_ISP		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0						CSI1_ID_2_SKIP		CSI1_SKIP_SMFC					CSI1_MAX_RATIO_SKIP_SMFC		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_CSI1_SKIP field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved
23–19 CSI1_SKIP_ISP	Reserved
18–16 CSI1_MAX_RATIO_SKIP_ISP	Reserved
15–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–8 CSI1_ID_2_SKIP	Reserved
7–3 CSI1_SKIP_SMFC	CSI1 SKIP SMFC These 5 bits define the skipping pattern of the frames send to the SMFC. Skipping is done for a set of frames. The number of frames in a set is defined at CSI1_MAX_RATIO_SKIP_SMFC. when CSI1_MAX_RATIO_SKIP_SMFC = 1 => CSI1_SKIP_SMFC[0] is used; other bits are ignored

Table continues on the next page...

IPU_CSI1_SKIP field descriptions (continued)

Field	Description
	when CSI1_MAX_RATIO_SKIP_SMFC = 2 => CSI1_SKIP_SMFC[1:0] are used; other bits are ignored when CSI1_MAX_RATIO_SKIP_SMFC = 3 => CSI1_SKIP_SMFC[2:0] are used; other bits are ignored when CSI1_MAX_RATIO_SKIP_SMFC = 4 => CSI1_SKIP_SMFC[3:0] are used; other bits are ignored when CSI1_MAX_RATIO_SKIP_SMFC = 5 => CSI1_SKIP_SMFC[4:0] are used; Setting bit #n of CSI1_SKIP_SMFC means that the #n frame in the set is skipped. For example: if CSI1_MAX_RATIO_SKIP_SMFC = 4 and CSI1_SKIP_SMFC = 11010 Frames #0 & Frame #2 will not be skipped as bit0 and bit2 are cleared Frames #1 & Frame #3 will be skipped as bit1 and bit3 are set bit #4 is ignored as CSI1_MAX_RATIO_SKIP_SMFC is set to 4
2–0 CSI1_MAX_ RATIO_SKIP_ SMFC	CSI1 Maximum Ratio Skip for SMFC These bits define the number of frames in a skipping set. These bits define the number of frames in a skipping set. The skipping number is equal to CSI1_MAX_RATIO_SKIP_SMFC+1; The maximum value of this bits is 5. When set to 0 the skipping is disabled.

45.51.142 CSI1 Compander Control Register (IPU_CSI1_CPD_CTRL)

Address: IPU_CSI1_CPD_CTRL is 1E00_0000h base + 38028h offset = 1E03_8028h

IPU_DI0_GENERAL field descriptions

Field	Description
31 di0_pin8_pin15_sel	This bit routes PIN8 over PIN15 1 PIN8 is routed to PIN15, PIN8 is also routed to PIN8 0 PIN15 is routed to PIN15, PIN8 is routed to PIN8
30–28 di0_disp_y_sel	DI0 Display Vertical coordinate (Y) select. This field defines which one of the 8 counters will be used as a display's line counter. 000 counter #1 is selected 111 counter #8 is selected
27–24 DI0_CLOCK_STOP_MODE	DI clock stop mode When performing a clock change. The DI stops the clock to the display. These field defines when the clock will be stopped. Stopping at EOL/EOF is supported for the case where the data is coming from the IDMAC (DMA access). In case that only direct accesses is performed, the user should set this field to 0000 0001-1001 stop at the next event of one of the counters (counter #1 to counter #9) 0000 stop at the next edge of the display clock 1100 stop at EOL (end of a line), but if stop request is during blanking interval, stop now 1101 stop at EOF (end of a frame), but if stop request is during blanking interval, stop now 1110 stop at EOL (end of a line), but if stop request is during blanking interval, stop at the end of the next line 1111 stop at EOF (end of a frame), but if stop request is during blanking interval, stop at the end of the next frame
23 DI0_DISP_CLOCK_INIT	Display clock's initial mode For synchronization error conditions the display clock can be stopped on the next VSYNC

Table continues on the next page...

IPU_DI0_GENERAL field descriptions (continued)

Field	Description
	1 The display's clock is running after the next VSYNC (indicating new frame) 0 The display's clock is stopped after the next VSYNC (indicating new frame)
22 di0_mask_sel	DI0 Mask select. IPP_PIN_2 output of the DI that functions as MASK signal can come from 2 sources: counter #2 or extracted from the MASK data coming from the memory. 1 IPP_PIN_2 is coming from extracted MASK data coming from the memory 0 IPP_PIN_2 is coming from counter #2
21 di0_vsync_ext	DI0 External VSYNC. This bit selects the source of the VSYNC signal 1 External to the IPU 0 Internally generated by the IPU
20 di0_clk_ext	DI0 External Clock. This bit selects the source of the DI0's clock 1 The source of the clock is external to the IPU 0 The clock is internally generated by the IPU
19–18 DI0_ WATCHDOG_ MODE	DI0 watchdog mode In case of a display error where the DI clock is stopped (defined at di0_err_treatment). An internal watchdog counts DI clocks. If this timer reached its pre defined value the DI will skip the current frame and restart on the frame. This 2 bits define the number of DI clock cycles that the timer counts. 00 The timer counts 4 DI cycles 01 The timer counts 16 DI cycles 10 The timer counts 64 DI cycles 11 The timer counts 128 DI cycles
17 di0_polarity_ disp_clk	DI0 Output Clock's polarity This bits define the polarity of the DI0's clock. 1 The output clock is active high 0 The output clock is active low
16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–12 di0_sync_count_ sel	For synchronous flow error: selects synchronous flow synchronization counter in DI:
11 di0_err_ treatment	In case of synchronous flow error there are 2 ways to handle the display 1 to wait (stop clock) 0 Drive the last component
10 di0_erm_vsync_ sel	DI0 error recovery block's VSYNC source select The error recovery block detect a case where the DI's VSYNC is asserted before the EOF. This bit selects the source of the VSYNC signal monitored by this mechanism.

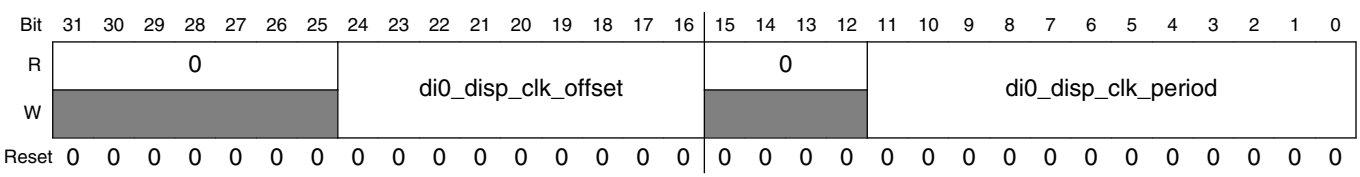
Table continues on the next page...

IPU_DI0_GENERAL field descriptions (continued)

Field	Description
	1 vsync_post - an internal VSYNC signal asserted 2 lines after the DI's VSYNC 0 vsync_pre - an internal VSYNC signal asserted 2 lines before the DI's VSYNC
9 di0_polarity_cs1	DI0 Chip Select's 1 polarity This bits define the polarity of the DI's CS1. 1 The CS1 is active high 0 The CS1 is active low
8 di0_polarity_cs0	DI0 Chip Select's 0 polarity This bits define the polarity of the DI's CS0. 1 The CS0 is active high 0 The CS0 is active low
7–0 di0_polarity_<i+1>	DI0 output pin's polarity This bits define the polarity of each of the DI's outputs. 1 The output pin is active high 0 The output pin is active low

45.51.154 DI0 Base Sync Clock Gen 0 Register (IPU_DI0_BS_CLKGEN0)

Address: IPU_DI0_BS_CLKGEN0 is 1E00_0000h base + 40004h offset = 1E04_0004h

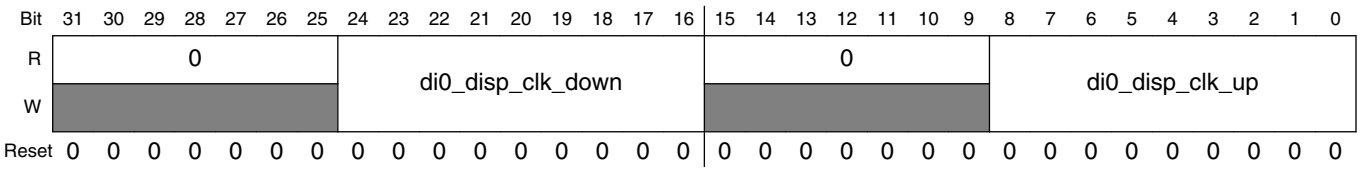


IPU_DI0_BS_CLKGEN0 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value zero. Reserved.
24–16 di0_disp_clk_offset	DI0 Display Clock Offset The DI has the ability to delay the display's clock This field defines the amount of IPU's clock cycles added as delay on this clock.
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved.
11–0 di0_disp_clk_period	DI0 Display Clock Period This field defines the Display interface clock period for display write access. This parameter contains an integer part (bits 11:4) and a fractional part (bits 3:0). It defines a fractional division ratio of the HSP_CLK clock for generation of the display's interface clock.

45.51.155 DI0 Base Sync Clock Gen 1 Register (IPU_DI0_BS_CLKGEN1)

Address: IPU_DI0_BS_CLKGEN1 is 1E00_0000h base + 40008h offset = 1E04_0008h

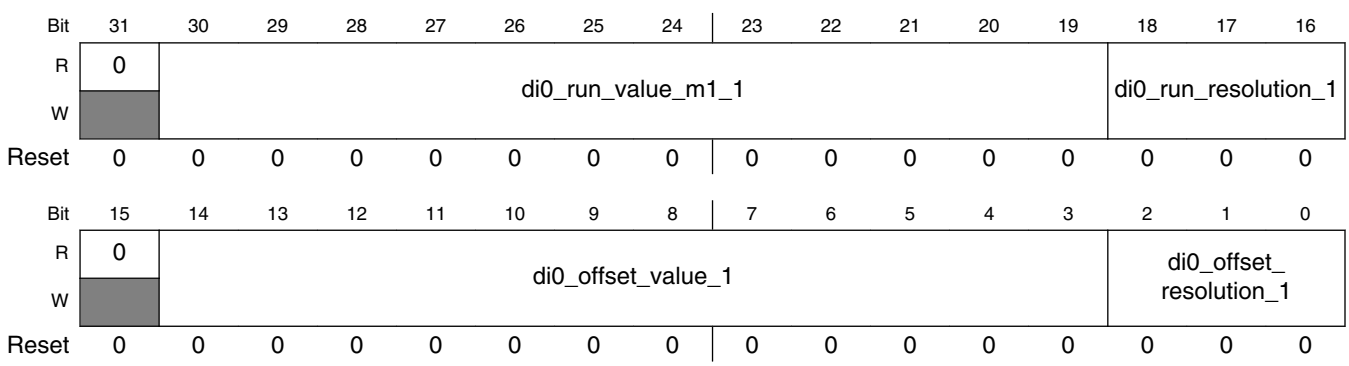


IPU_DI0_BS_CLKGEN1 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value zero. Reserved.
24–16 di0_disp_clk_down	DI0 display clock falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is a time interval between display's access start point and display's interface clock falling edge.
15–9 Reserved	This read-only field is reserved and always has the value zero. Reserved.
8–0 di0_disp_clk_up	DI0 display clock rising edge position This parameter contains an integer part (bits 8:1) and a fractional part (bit 0). The position value is a time interval between display's access start point and display's interface clock rising edge.

45.51.156 DI0 Sync Wave Gen 1 Register 0 (IPU_DI0_SW_GEN0_1)

Address: IPU_DI0_SW_GEN0_1 is 1E00_0000h base + 4000Ch offset = 1E04_000Ch



IPU_DI0_SW_GEN0_1 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value zero. Reserved.
30–19 di0_run_value_m1_1	DI0 counter #1 pre defined value This fields defines the counter #1 pre defines value. When the counter is auto reload mode (di0_cnt_auto_reload_1 bit is set), the counter automatically restarts. otherwise the counter restarts for the amount of time defined on the corresponding di0_step_repeat field.
18–16 di0_run_resolution_1	DI0 counter #1 Run Resolution This field defines the trigger causing the counter to increment. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 NA 011 NA 100 NA 101 CSI VSYNC. The VSYNC is a trigger coming from one of the CSIs according to the CSI_VSYNC_DEST bit. — 110 External VSYNC 111 Counter is always on.
15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14–3 di0_offset_value_1	DI0 counter #1 offset value The counter can start counting after a pre defined delay This field defines the amount of cycles that the counter will be delayed by
2–0 di0_offset_resolution_1	DI0 counter #1 offset Resolution This field defines the trigger causing the offset counter to increment 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock 010 NA 011 NA 100 NA 101 CSI VSYNC. The VSYNC is a trigger coming from one of the CSIs according to the CSI_VSYNC_DEST bit. — 110 External VSYNC 111 Counter is always on.

45.51.157 DI0 Sync Wave Gen 2 Register 0 (IPU_DI0_SW_GEN0_2)

Address: IPU_DI0_SW_GEN0_2 is 1E00_0000h base + 40010h offset = 1E04_0010h

IPU_DI0_SW_GEN1_2 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value zero. Reserved.
30–29 di0_cnt_polarity_ gen_en_2	DI0 Counter polarity generator enable The counter's output polarity can be changed on the fly. 00 Dynamic polarity change is disabled 01 The counters UP and DOWN value are calculated according to the trigger selected by cnt_polarity_trigger_sel field. When selecting this mode the UP and DOWN values has to be a multiple of 2. 10 Dynamic polarity change is enabled 11 Outputs polarity is dynamically changed every time the counter reaches its pre defined value
28 di0_cnt_auto_ reload_2	Counter auto reload mode 1 The counter will automatically be reloaded forever, ignoring the value of the di0_step_repeat_<i> field 0 The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the di0_step_repeat_<i> field
27–25 di0_cnt_clr_sel_ 2	Counter Clear select This field defines the source of the signals that clears the counter. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock.

IPU_DI0_SW_GEN1_9 field descriptions

Field	Description
31–29 di0_gentime_sel_9	Counter #9 main waveform select This field defines the counter that counter #9's auxiliary waveform will be attached too. 000 Counter #9's waveform is attached to counter #1's waveform 001 Counter #9's waveform is attached to counter #2's waveform 010 Counter #9's waveform is attached to counter #3's waveform 011 Counter #9's waveform is attached to counter #4's waveform 100 Counter #9's waveform is attached to counter #5's waveform 101 Counter #9's waveform is attached to counter #6's waveform 110 Counter #9's waveform is attached to counter #7's waveform 111 Counter #9's waveform is attached to counter #8's waveform
28 di0_cnt_auto_reload_9	Counter auto reload mode 1 The counter will automatically be reloaded forever, ignoring the value of the di0_step_repeat_<i> field 0 The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the di0_step_repeat_<i> field
27–25 di0_cnt_clr_sel_9	Counter Clear select This field defines the source of the signals that clears the counter. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 The Counter is triggered by counter #1 011 The Counter is triggered by counter #2 100 The Counter is triggered by counter #3 101 The Counter is triggered by counter #4 110 The Counter is triggered by counter #5 111 Counter is always on.

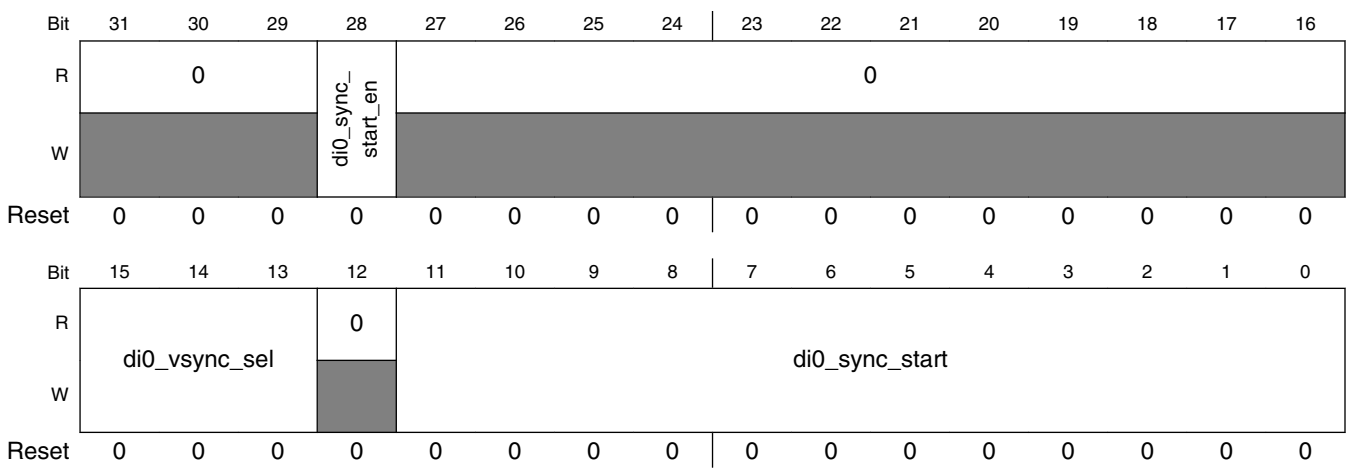
Table continues on the next page...

IPU_DI0_SW_GEN1_9 field descriptions (continued)

Field	Description
24–16 di0_cnt_down_9	Counter falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's falling edge.
15 di0_tag_sel_9	Counter #9 can send a synchronous tag when counter #9 reach its predefined value or when it's triggering counter reaches its pre defined value. 1 tag source is counter #9 0 Tag's source is the triggering counter.
14–9 Reserved	This read-only field is reserved and always has the value zero. Reserved
8–0 di0_cnt_up_9	Counter rising edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's rising edge.

45.51.174 DI0 Sync Assistance Gen Register (IPU_DI0_SYNC_AS_GEN)

Address: IPU_DI0_SYNC_AS_GEN is 1E00_0000h base + 40054h offset = 1E04_0054h



IPU_DI0_SYNC_AS_GEN field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28 di0_sync_start_en	di0_sync_start_en

Table continues on the next page...

IPU_DI0_SYNC_AS_GEN field descriptions (continued)

Field	Description
27–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–13 di0_vsync_sel	VSYNC select This field defines which of the counters functions as VSYNC signal 000 VSYNC is coming from counter #1 001 VSYNC is coming from counter #2 111 VSYNC is coming from counter #8
12 Reserved	This read-only field is reserved and always has the value zero. Reserved.
11–0 di0_sync_start	DI0 Sync start This field defines the number of low (including blanking rows) on the which the DI0 starts preparing the data for the next frame.

45.51.175 DI0 Data Wave Gen <i> Register (IPU_DI0_DW_GEN_i)

The DI0_DW_GEN_<i> register holds pointers for the waveform generators.

These registers have different bit arrangements for parallel and serial display. When using a parallel display VDI Plane Size Register 4 DI0 Data Wave Gen <i> Register is applicable. When using a serial interface VDI Plane Size Register 4 DI0 Data Wave Gen <i> Register is applicable.

Table 45-223. Register Field Descriptions for Serial Display

Field	Description
31-24 di0_serial_period_<i>	DI0 Serial Period <i> This field defines the period of the time base serial display clock. The units are the internal DI clock
23-16 di0_start_period_<i>	DI0 start period This field defines the amount of cycles between the point where the access is ready to be launched to the actual point where the time base serial display clock restarts. The units are the internal DI clock
15-14 di0_cst_<i>	DI0 Chip Select pointer for waveform <i> This field points to a register that defines the waveform of the CS pin. For serial displays the down value as defined on DI0_DW_SET*_<i> is measured from the assertion of the last serial display time base clock. 00 The waveform is defined according to the settings on DI0_DW_SET0_<i> 01 The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 The waveform is defined according to the settings on DI0_DW_SET3_<i>

Table continues on the next page...

Table 45-223. Register Field Descriptions for Serial Display (continued)

Field	Description
13-9	Reserved
8-4 di0_serial_valid_bits<i>	DI0 Serial valid bits. This field defines the amount of valid bits to be transmitted within the 32 bits internal word aligned to bit[0]. The actual amount of valid bits is di0_serial_valid_bits_<i> + 1
3-2 di0_serial_rs_<i>	DI0 Serial RS This field points to a register that defines the waveform of the RS pin. For serial displays the down value as defined on DI0_DW_SET*_<i> is measured from the assertion of the last serial display time base clock. 00 The waveform is defined according to the settings on DI0_DW_SET0_<i> 01 The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 The waveform is defined according to the settings on DI0_DW_SET3_<i>
1-0 di0_serial_clk_<i>	DI0 serial clock<i> This field points to a register that defines the waveform of the Serial clock pin. 00 The waveform is defined according to the settings on DI0_DW_SET0_<i> 01 The waveform is defined according to the settings on DI0_DW_SET1_<i> 10 The waveform is defined according to the settings on DI0_DW_SET2_<i> 11 The waveform is defined according to the settings on DI0_DW_SET3_<i>

IPU_DI0_SSC field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved.
23 DI0_PIN17_ERM	DI0 PIN17 error recovery mode. This bit defines the error recovery mode of the PIN17 pin. 1 The PIN17 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN17 pin following a display error detection
22 DI0_PIN16_ERM	DI0 PIN16 error recovery mode. This bit defines the error recovery mode of the PIN16 pin. 1 The PIN16 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN16 pin following a display error detection
21 DI0_PIN15_ERM	DI0 PIN15 error recovery mode. This bit defines the error recovery mode of the PIN15 pin. 1 The PIN15 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN15 pin following a display error detection
20 DI0_PIN14_ERM	DI0 PIN14 error recovery mode. This bit defines the error recovery mode of the PIN14 pin. 1 The PIN14 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN14 pin following a display error detection
19 DI0_PIN13_ERM	DI0 PIN13 error recovery mode. This bit defines the error recovery mode of the PIN13 pin. 1 The PIN13 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN13 pin following a display error detection
18 DI0_PIN12_ERM	DI0 PIN12 error recovery mode. This bit defines the error recovery mode of the PIN12 pin. 1 The PIN12 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN12 pin following a display error detection
17 DI0_PIN11_ERM	DI0 PIN11 error recovery mode. This bit defines the error recovery mode of the PIN11 pin. 1 The PIN11 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC 0 Nothing is done to the PIN11 pin following a display error detection
16 DI0_CS_ERM	DI0 GLUELOGIC error recovery mode. This bit defines the error recovery mode of the GLUELOGIC.

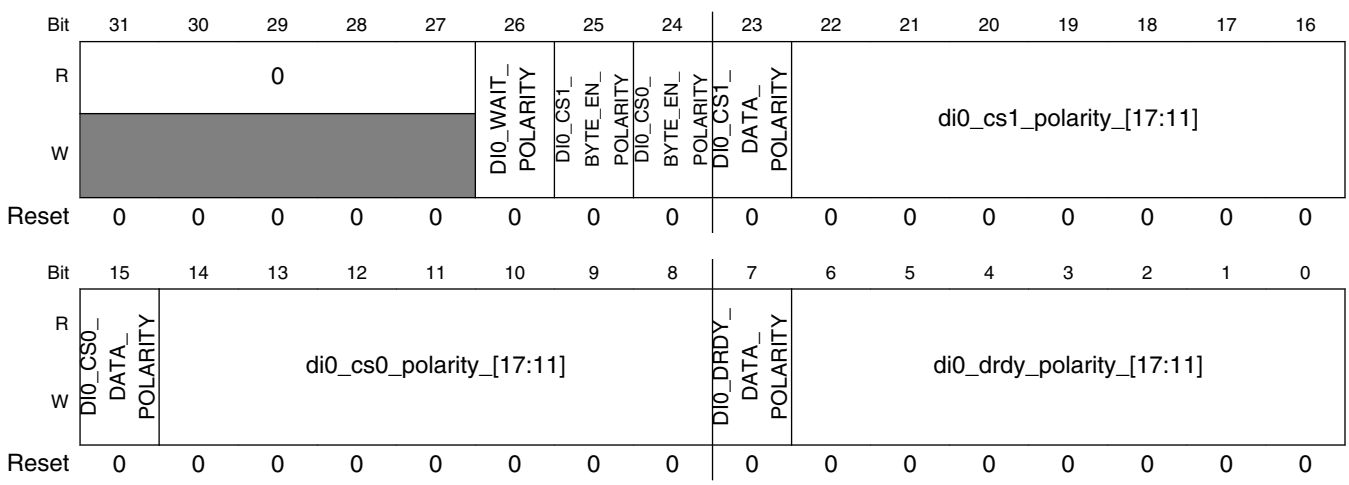
Table continues on the next page...

IPU_DI0_SSC field descriptions (continued)

Field	Description
	1 The GLUELOGIC is release in case of a synchronous display error. The release will be done on the next VSYNC 0 Nothing is done to the GLUELOGIC following a display error detection
15–6 Reserved	This read-only field is reserved and always has the value zero. Reserved.
5 DI0_WAIT_ON	Wait On This field defines the DC's response to WAIT signal 1 The DC holds the flow as long as WAIT is asserted 0 The DC continues the flow regardless the WAIT signal
4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3 DI0_BYTE_EN_RD_IN	Byte Enable Read In This bit selects the source of the byte enable pins 1 The write byte enable signals are routed via bits [17:16] of the display's data, The read byte enable signals are routed via bits [19:18 of the display's data 0 The byte enable signals are routed via bits [17:16] of the display's data for both read and write
2–0 DI0_BYTE_EN_PNTR	Byte Enable Pointer This pointer selects the pin asserted along with the byte enables signals 000 wave form of byte enable as pin_11 001 wave form of byte enable as pin_12 111 wave form of byte enable as suitable CS pin

45.51.184 DI0 Polarity Register (IPU_DI0_POL)

Address: IPU_DI0_POL is 1E00_0000h base + 40164h offset = 1E04_0164h



IPU_DI0_POL field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26 DI0_WAIT_ POLARITY	WAIT polarity This bit defines the polarity of the wait signal input coming from the displa1 1 active high 0 active low
25 DI0_CS1_ BYTE_EN_ POLARITY	Byte Enable associated with CS1 polarity This bit defines the polarity of the byte enable signals to the display 1 active high 0 active low
24 DI0_CS0_ BYTE_EN_ POLARITY	Byte Enable associated with CS0 polarity This bit defines the polarity of the byte enable signals to the display 1 active high 0 active low
23 DI0_CS1_ DATA_ POLARITY	Data Polarity associated with CS1
22–16 di0_cs1_ polarity_[17:11]	DI0 output pin's polarity for CS1 This bits define the polarity of each of the DI's outputs when CS1 is asserted 1 The output pin is active high 0 The output pin is active low
15 DI0_CS0_ DATA_ POLARITY	Data Polarity associated with CS0
14–8 di0_cs0_ polarity_[17:11]	DI0 output pin's polarity for CS1 This bits define the polarity of each of the DI's outputs when CS1 is asserted 1 The output pin is active high 0 The output pin is active low
7 DI0_DRDY_ DATA_ POLARITY	Data Polarity associated with DRDY
6–0 di0_drdy_ polarity_[17:11]	DI0 output dynamic pin's polarity for synchronous access This bits define the polarity of each of the DI's outputs when synchronous display access is asserted The pins' default polarity is the same as defined in the di0_drdy_polarity_[17:11] bits 1 The output pin is active high 0 The output pin is active low

45.51.185 DI0 Active Window 0 Register (IPU_DI0_AW0)

Address: IPU_DI0_AW0 is 1E00_0000h base + 40168h offset = 1E04_0168h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_DI0_AW0 field descriptions

Field	Description
31–28 DI0_AW_TRIG_SEL	This field selects the trigger for sending data during the display's active window 000 disabled 001 The trigger is the same trigger that triggers the displays clock. 010 The trigger is counter #1 011 The trigger is counter #2 100 The trigger is counter #3 101 The trigger is counter #4 110 The trigger is counter #5 111 The trigger is always on.
27–16 DI0_AW_HEND	This field defines the horizontal end of the active window
15–12 DI0_AW_HCOUNT_SEL	GM: This field selects the counter that counts the horizontal position of the display's active window 0000 disabled 0001 reserved 0010 The counter is counter #1 0011 The counter is counter #2 0100 The counter is counter #3 0101 The counter is counter #4 0110 The counter is counter #5 1001 The counter is counter #8
11–0 DI0_AW_HSTART	This field defines the horizontal start of the active window DI0_AW_HSTART < DI0_AW_HEND

45.51.186 DI0 Active Window 1 Register (IPU_DI0_AW1)

Address: IPU_DI0_AW1 is 1E00_0000h base + 4016Ch offset = 1E04_016Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				DI0_AW_VEND												DI0_AW_VCOUNT_SEL				DI0_AW_VSTART											
W

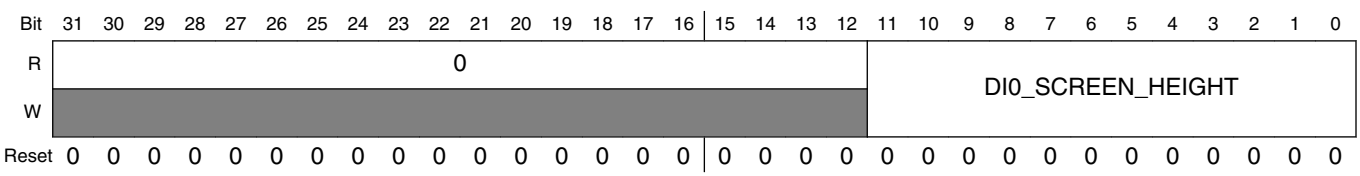
IPU_DI0_AW1 field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved
27–16 DI0_AW_VEND	This field defines the vertical end of the active window
15–12 DI0_AW_ VCOUNT_SEL	This field selects the counter that counts the vertical position of the display's active window 0000 disabled 0001 reserved 0010 The counter is counter #1 0011 The counter is counter #2 0100 The counter is counter #3 0101 The counter is counter #4 0110 The counter is counter #5 1001 The counter is counter #8
11–0 DI0_AW_ VSTART	This field defines the vertical start of the active window DI0_AW_VSTART < DI0_AW_VEND

45.51.187 DI0 Screen Configuration Register (IPU_DI0_SCR_CONF)

Address: IPU_DI0_SCR_CONF is 1E00_0000h base + 40170h offset = 1E04_0170h

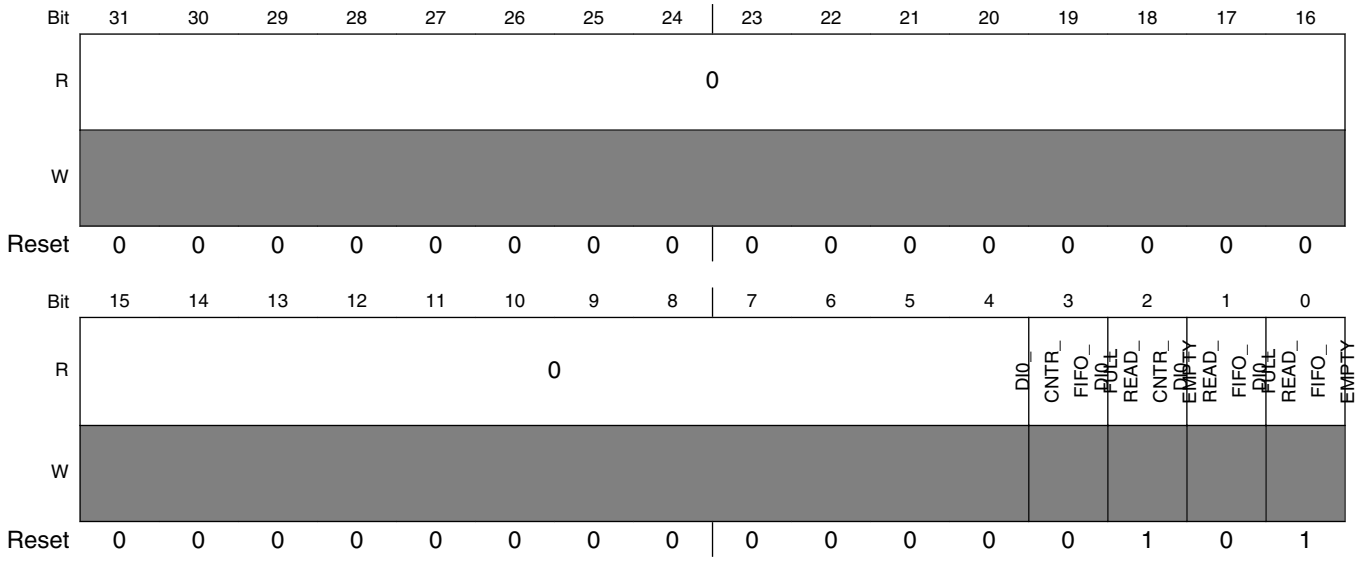


IPU_DI0_SCR_CONF field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value zero. Reserved.
11–0 DI0_SCREEN_ HEIGHT	This field defines the number of display rows (Number_of_ROWS = DI0_SCREEN_HEIGHT+1) This field is used for VSYNC calculation and for anti-tearing

45.51.188 DI0 Status Register (IPU_DI0_STAT)

Address: IPU_DI0_STAT is 1E00_0000h base + 40174h offset = 1E04_0174h

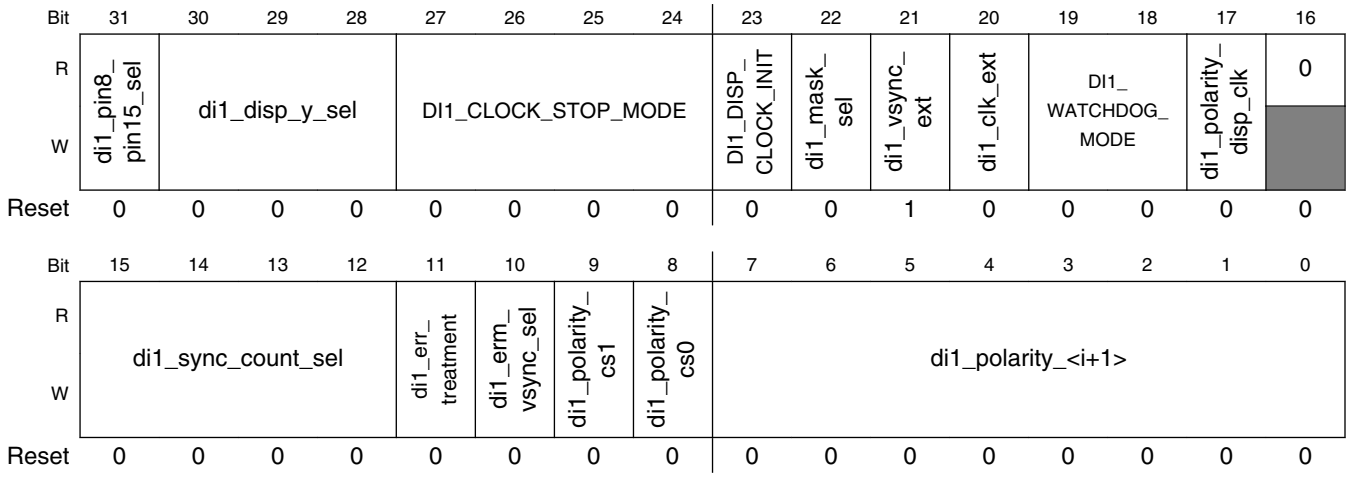


IPU_DI0_STAT field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3 DI0_CNTR_ FIFO_FULL	This bit indicates a full state of the DI0 FIFO. This FIFO is part of the DI0 synchronizer.
2 DI0_READ_ CNTR_EMPTY	This bit indicates an empty state of the DI0 FIFO. This FIFO is part of the DI0 synchronizer.
1 DI0_READ_ FIFO_FULL	This bit indicates a full state of the DI0 FIFO when performing a read. This FIFO is part of the DI0 synchronizer.
0 DI0_READ_ FIFO_EMPTY	This bit indicates an empty state of the DI0 FIFO when performing a read. This FIFO is part of the DI0 synchronizer.

45.51.189 DI1General Register (IPU_DI1_GENERAL)

Address: IPU_DI1_GENERAL is 1E00_0000h base + 48000h offset = 1E04_8000h



IPU_DI1_GENERAL field descriptions

Field	Description
31 di1_pin8_pin15_sel	This bit routes PIN8 over PIN15 1 PIN8 is routed to PIN15, PIN8 is also routed to PIN8 0 PIN15 is routed to PIN15, PIN8 is routed to PIN8
30–28 di1_disp_y_sel	DI1 Display Vertical coordinate (Y) select. This field defines which one of the 8 counters will be used as a display's line counter. 000 counter #1 is selected 111 counter #8 is selected
27–24 DI1_CLOCK_STOP_MODE	DI clock stop mode When performing a clock change. The DI stops the clock to the display. These field defines when the clock will be stopped Stopping at EOL/EOF is supported for the case where the data is coming from the IDMAC (DMA access). In case that only direct accesses is performed, the user should set this field to 0000 0001-1001 stop at the next event of one of the counters (counter #1 to counter #9) 0000 stop at the next edge of the display clock 1100 stop at EOL (end of a line), but if stop request is during blanking interval, stop now 1101 stop at EOF (end of a frame), but if stop request is during blanking interval, stop now 1110 stop at EOL (end of a line), but if stop request is during blanking interval, stop at the end of the next line 1111 stop at EOF (end of a frame), but if stop request is during blanking interval, stop at the end of the next frame
23 DI1_DISP_CLOCK_INIT	Display clock's initial mode For synchronization error conditions the display clock can be stopped on the next VSYNC

Table continues on the next page...

IPU_DI1_GENERAL field descriptions (continued)

Field	Description
	1 The display's clock is running after the next VSYNC (indicating new frame) 0 The display's clock is stopped after the next VSYNC (indicating new frame)
22 di1_mask_sel	DI1 Mask select. IPP_PIN_2 output of the DI that functions as MASK signal can come from 2 sources: counter #2 or extracted from the MASK data coming from the memory. 1 IPP_PIN_2 is coming from extracted MASK data coming from the memory 0 IPP_PIN_2 is coming from counter #2
21 di1_vsync_ext	DI1 External VSYNC. This bit selects the source of the VSYNC signal 1 External to the IPU 0 Internally generated by the IPU
20 di1_clk_ext	DI1 External Clock. This bit selects the source of the DI's clock 1 The source of the clock is external to the IPU 0 The clock is internally generated by the IPU
19–18 DI1_ WATCHDOG_ MODE	DI1 watchdog mode In case of a display error where the DI clock is stopped (defined at di0_err_treatment). An internal watchdog counts DI clocks. If this timer reached its pre defined value the DI will skip the current frame and restart on the frame. This 2 bits define the number of DI clock cycles that the timer counts. 00 The timer counts 4 DI cycles 01 The timer counts 16 DI cycles 10 The timer counts 64 DI cycles 11 The timer counts 128 DI cycles
17 di1_polarity_ disp_clk	DI1 Output Clock's polarity This bits define the polarity of the DI's clock. 1 The output clock is active high 0 The output clock is active low
16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–12 di1_sync_count_ sel	For synchronous flow error: selects synchronous flow synchronization counter in DI:
11 di1_err_ treatment	In case of synchronous flow error there are 2 ways to handle the display 1 to wait (i.e. stop clock) 0 Drive the last component
10 di1_erm_vsync_ sel	DI1 error recovery module's VSYNC source select The error recovery block detect a case where the DI's VSYNC is asserted before the EOF. This bit selects the source of the VSYNC signal monitored by this mechanism.

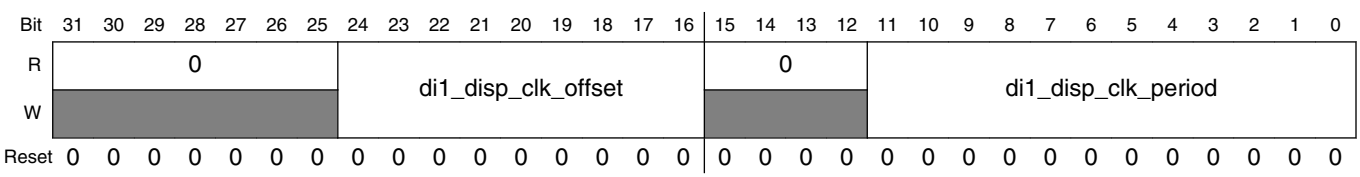
Table continues on the next page...

IPU_DI1_GENERAL field descriptions (continued)

Field	Description
	1 vsync_post - an internal VSYNC signal asserted 2 lines after the DI's VSYNC 0 vsync_pre - an internal VSYNC signal asserted 2 lines before the DI's VSYNC
9 di1_polarity_cs1	DI1 Chip Select's 1 polarity This bits define the polarity of the DI's CS1. 1 The CS1 is active high 0 The CS1 is active low
8 di1_polarity_cs0	DI1 Chip Select's 0 polarity This bits define the polarity of the DI's CS0. 1 The CS0 is active high 0 The CS0 is active low
7–0 di1_polarity_<i+1>	DI1 output pin's polarity This bits define the polarity of each of the DI's outputs. 1 The output pin is active high 0 The output pin is active low

45.51.190 DI1 Base Sync Clock Gen 0 Register (IPU_DI1_BS_CLKGEN0)

Address: IPU_DI1_BS_CLKGEN0 is 1E00_0000h base + 48004h offset = 1E04_8004h

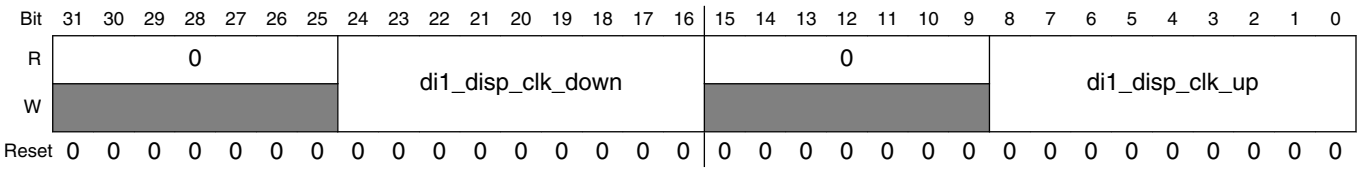


IPU_DI1_BS_CLKGEN0 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value zero. Reserved.
24–16 di1_disp_clk_offset	DI1 Display Clock Offset The DI has the ability to delay the display's clock This field defines the amount of IPU's clock cycles added as delay on this clock.
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved.
11–0 di1_disp_clk_period	DI1 Display Clock Period This field defines the Display interface clock period for display write access. This parameter contains an integer part (bits 11:4) and a fractional part (bits 3:0). It defines a fractional division ratio of the HSP_CLK clock for generation of the display's interface clock.

45.51.191 DI1 Base Sync Clock Gen 1 Register (IPU_DI1_BS_CLKGEN1)

Address: IPU_DI1_BS_CLKGEN1 is 1E00_0000h base + 48008h offset = 1E04_8008h

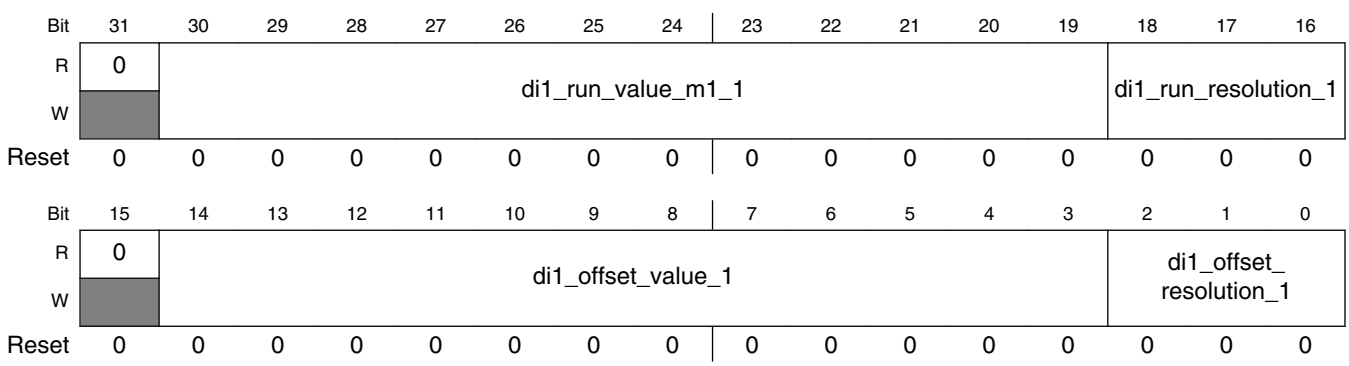


IPU_DI1_BS_CLKGEN1 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value zero. Reserved.
24–16 di1_disp_clk_down	DI1 display clock falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is a time interval between display's access start point and display 's interface clock falling edge.
15–9 Reserved	This read-only field is reserved and always has the value zero. Reserved.
8–0 di1_disp_clk_up	DI1 display clock rising edge position This parameter contains an integer part (bits 8:1) and a fractional part (bit 0). The position value is a time interval between display's access start point and display 's interface clock rising edge.

45.51.192 DI1 Sync Wave Gen 1 Register 0 (IPU_DI1_SW_GEN0_1)

Address: IPU_DI1_SW_GEN0_1 is 1E00_0000h base + 4800Ch offset = 1E04_800Ch



IPU_DI1_SW_GEN0_1 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value zero. Reserved.
30–19 di1_run_value_m1_1	DI1 counter #1 pre defined value This fields defines the counter #1 pre defines value. When the counter is auto reload mode (di1_cnt_auto_reload_1 bit is set), the counter automatically restarts. otherwise the counter restarts for the amount of time defined on the corresponding di1_step_repeat field.
18–16 di1_run_resolution_1	DI1 counter #1 Run Resolution This field defines the trigger causing the counter to increment. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 NA 011 NA 100 NA 101 CSI VSYNC. The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. — 110 External VSYNC 111 Counter is always on.
15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14–3 di1_offset_value_1	DI1 counter #1 offset value The counter can start counting after a pre defined delay This field defines the amount of cycles that the counter will be delayed by
2–0 di1_offset_resolution_1	DI1 counter #1 offset Resolution This field defines the trigger causing the offset counter to increment 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 NA 011 NA 100 NA 101 CSI VSYNC. The VSYNC is a trigger coming from one of the CSI's according to the CSI_VSYNC_DEST bit. — 110 External VSYNC 111 Counter is always on.

45.51.193 DI1 Sync Wave Gen 2 Register 0 (IPU_DI1_SW_GEN0_2)

Address: IPU_DI1_SW_GEN0_2 is 1E00_0000h base + 48010h offset = 1E04_8010h

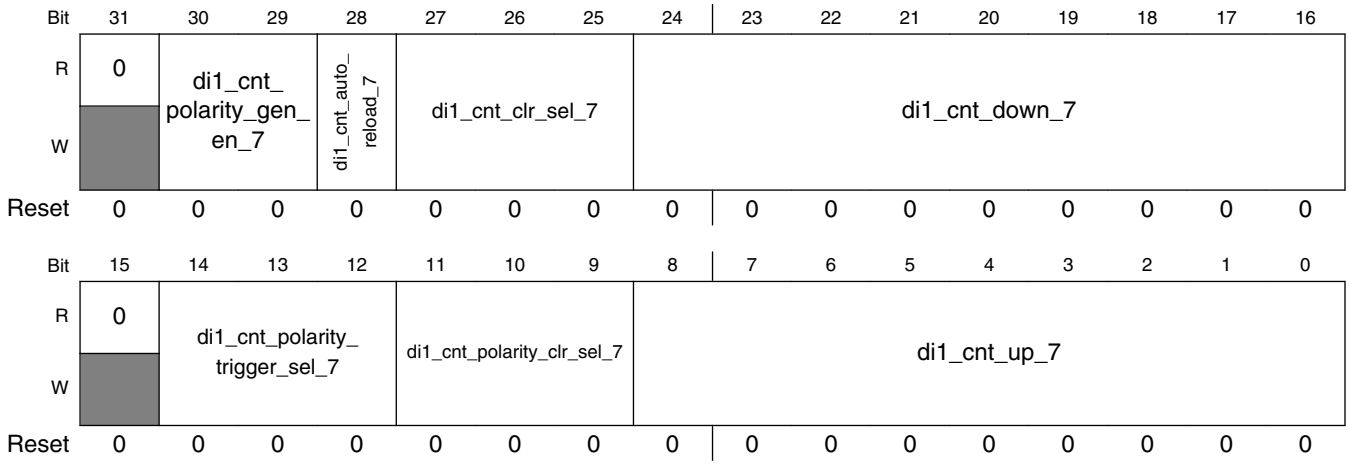
IPU_DI1_SW_GEN1_6 field descriptions (continued)

Field	Description
24–16 di1_cnt_down_6	Counter falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's falling edge.
15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14–12 di1_cnt_polarity_trigger_sel_6	DI1 Counter's toggling trigger select This field selects the counter's trigger causing the output to toggle 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 The Counter is triggered by counter #1 011 The Counter is triggered by counter #2 100 The Counter is triggered by counter #3 101 The Counter is triggered by counter #4 110 The Counter is triggered by counter #5 111 Counter is always on.
11–9 di1_cnt_polarity_clr_sel_6	DI1 counter's polarity Clear select This field selects the input to the counter telling the counter wether to invert the output 000 Output is always inverted 001 Output is kept the same (no inversion) 010 Output is inverted if the output of counter #1 is set 011 Output is inverted if the output of counter #2 is set 100 Output is inverted if the output of counter #3 is set 101 Output is inverted if the output of counter #4 is set 110 Output is inverted if the output of counter #5 is set 111 Reserved
8–0 di1_cnt_up_6	Counter rising edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's rising edge.

45.51.207 DI1Sync Wave Gen 7 Register 1 (IPU_DI1_SW_GEN1_7)

Address: IPU_DI1_SW_GEN1_7 is 1E00_0000h base + 48048h offset = 1E04_8048h



IPU_DI1_SW_GEN1_7 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value zero. Reserved.
30–29 di1_cnt_polarity_gen_en_7	DI1 Counter polarity generator enable The counter's output polarity can be changed on the fly. 00 Dynamic polarity change is disabled 01 The counters UP and DOWN value are calculated according to the trigger selected by cnt_polarity_trigger_sel field. When selecting this mode the UP and DOWN values has to be a multiple of 2. 10 Dynamic polarity change is enabled 11 Outputs polarity is dynamically changed every time the counter reaches its pre defined value
28 di1_cnt_auto_reload_7	Counter auto reload mode 1 The counter will automatically be reloaded forever, ignoring the value of the di1_step_repeat_<i> field 0 The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the di1_step_repeat_<i> field
27–25 di1_cnt_clr_sel_7	Counter Clear select This field defines the source of the signals that clears the counter. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 The Counter is triggered by counter #1 011 The Counter is triggered by counter #2 100 The Counter is triggered by counter #3 101 The Counter is triggered by counter #4 110 The Counter is triggered by counter #5 111 Counter is always on.

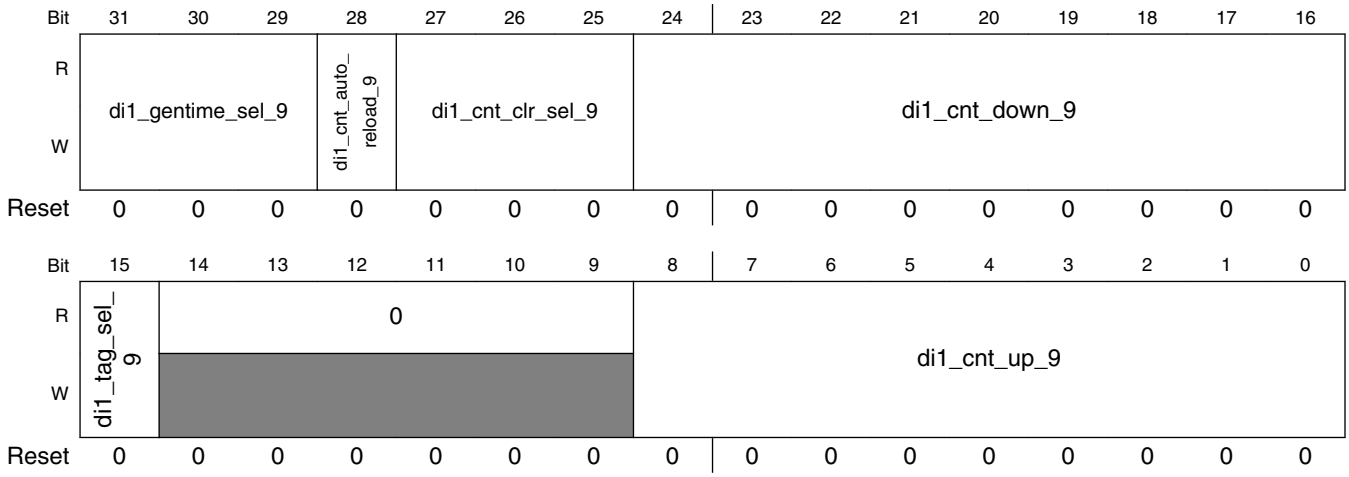
45.51.209 DI1 Sync Wave Gen 9 Register 1 (IPU_DI1_SW_GEN1_9)

Address: IPU_DI1_SW_GEN1_9 is 1E00_0000h base + 48050h offset = 1E04_8050h



IPU_DI1_SW_GEN1_9 field descriptions

Field	Description
31–29 di1_gentime_sel_9	Counter #9 main waveform select This field defines the counter that counter #9's auxiliary waveform will be attached too. 000 Counter #9's waveform is attached to counter #1's waveform 001 Counter #9's waveform is attached to counter #2's waveform 010 Counter #9's waveform is attached to counter #3's waveform 011 Counter #9's waveform is attached to counter #4's waveform 100 Counter #9's waveform is attached to counter #5's waveform 101 Counter #9's waveform is attached to counter #6's waveform 110 Counter #9's waveform is attached to counter #7's waveform 111 Counter #9's waveform is attached to counter #8's waveform
28 di1_cnt_auto_reload_9	Counter auto reload mode 1 The counter will automatically be reloaded forever, ignoring the value of the di1_step_repeat_<i> field 0 The counter will not be automatically reloaded, It will be reloaded for the amount of repeat times defined on the di1_step_repeat_<i> field
27–25 di1_cnt_clr_sel_9	Counter Clear select This field defines the source of the signals that clears the counter. 000 Counter is disabled 001 The counter is triggered by the same trigger that triggers the displays clock. 010 The Counter is triggered by counter #1 011 The Counter is triggered by counter #2 100 The Counter is triggered by counter #3 101 The Counter is triggered by counter #4 110 The Counter is triggered by counter #5 111 Counter is always on.

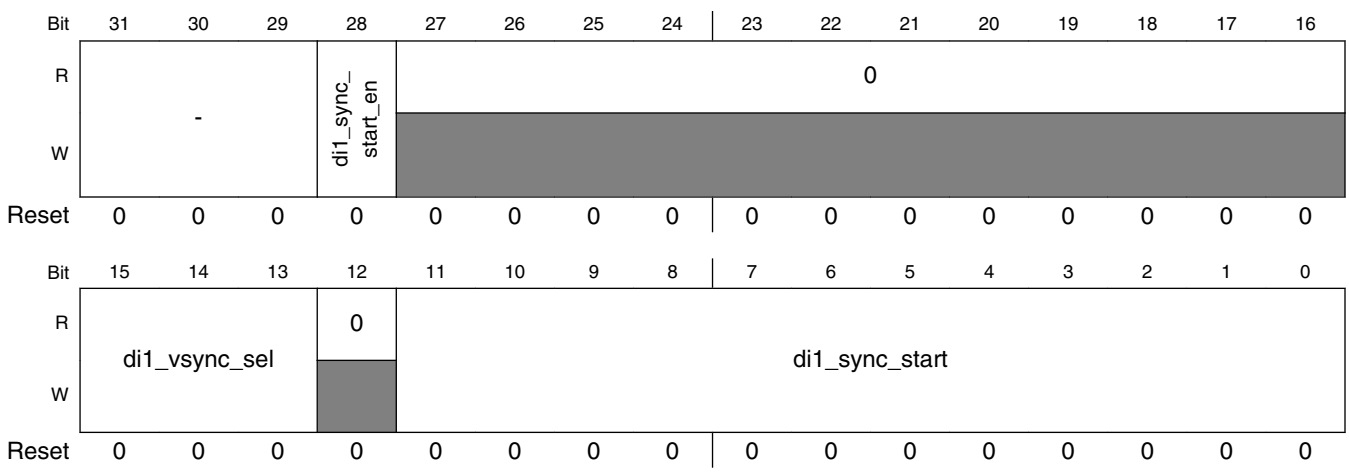
Table continues on the next page...

IPU_DI1_SW_GEN1_9 field descriptions (continued)

Field	Description
24–16 di1_cnt_down_9	Counter falling edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's falling edge.
15 di1_tag_sel_9	Counter #9 can send a synchronous tag when counter #9 reach its predefined value or when it's triggering counter reaches its pre defined value. 1 tag source is counter #9 0 Tag's source is the triggering counter.
14–9 Reserved	This read-only field is reserved and always has the value zero. Reserved
8–0 di1_cnt_up_9	Counter rising edge position This parameter contains an integer part (bits 24:17) and a fractional part (bit 16). The position value is the amount of cycles between the trigger's start point and the waveform's rising edge.

45.51.210 DI1 Sync Assistance Gen Register (IPU_DI1_SYNC_AS_GEN)

Address: IPU_DI1_SYNC_AS_GEN is 1E00_0000h base + 48054h offset = 1E04_8054h



IPU_DI1_SYNC_AS_GEN field descriptions

Field	Description
31–29 -	Reserve
28 di1_sync_start_en	di1_sync_start_en

Table continues on the next page...

IPU_DI1_SYNC_AS_GEN field descriptions (continued)

Field	Description
27–16 Reserved	This read-only field is reserved and always has the value zero. Reserved.
15–13 di1_vsync_sel	VSYNC select This field defines which of the counters functions as VSYNC signal 000 VSYNC is coming from counter #1 001 VSYNC is coming from counter #2 111 VSYNC is coming from counter #8
12 Reserved	This read-only field is reserved and always has the value zero. Reserved.
11–0 di1_sync_start	DI1 Sync start This field defines the number of low (including blanking rows) on the which the DI1 starts preparing the data for the next frame.

45.51.211 DI1 Data Wave Gen <i> Register (IPU_DI1_DW_GEN_i)

The DI1_DW_GEN_<i> register holds pointers for the waveform generators.

These registers have different bit arrangements for parallel and serial display. When using a parallel display VDI Plane Size Register 4 DI1 Data Wave Gen <i> Register is applicable. When using a serial interface VDI Plane Size Register 4 DI1 Data Wave Gen <i> Register is applicable.

Table 45-260. Register Field Descriptions for Serial display

Field	Description
31-24 di1_serial_period_<i>	DI1 Serial Period <i> This field defines the period of the time base serial display clock. The units are the internal DI clock
23-16 di1_start_period_<i>	DI1 start period This field defines the amount of cycles between the point where the access is ready to be launched to the actual point where the time base serial display clock restarts. The units are the internal DI clock.
15-14 di1_cst_<i>	DI1 Chip Select pointer for waveform <i> This field points to a register that defines the waveform of the CS pin. For serial displays the down value as defined on DI1_DW_SET*_<i> is measured from the assertion of the last serial display time base clock. 00 The waveform is defined according to the settings on DI1_DW_SET0_<i> 01 The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 The waveform is defined according to the settings on DI1_DW_SET3_<i>

Table continues on the next page...

Table 45-260. Register Field Descriptions for Serial display (continued)

Field	Description
13-9	Reserved
8-4 di1_serial_valid_bits_<i>	DI1 Serial valid bits. This field defines the amount of valid bits to be transmitted within the 32 bits internal word aligned to bit[0]. The actual amount of valid bits is di1_serial_valid_bits_<i> + 1
3-2 di1_serial_rs_<i>	DI1 Serial RS This field points to a register that defines the waveform of the RS pin. For serial displays the down value as defined on DI1_DW_SET*_<i> is measured from the assertion of the last serial display time base clock. 00 The waveform is defined according to the settings on DI1_DW_SET0_<i> 01 The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 The waveform is defined according to the settings on DI1_DW_SET3_<i>
1-0 di1_serial_clk_<i>	DI1 serial clock<i> This field points to a register that defines the waveform of the Serial clock pin. 00 The waveform is defined according to the settings on DI1_DW_SET0_<i> 01 The waveform is defined according to the settings on DI1_DW_SET1_<i> 10 The waveform is defined according to the settings on DI1_DW_SET2_<i> 11 The waveform is defined according to the settings on DI1_DW_SET3_<i>

IPU_DI1_SER_CONF field descriptions (continued)

Field	Description
27–24 DI1_SERIAL_LLA_PNTR_RS_R_0	RS 2 waveform pointer for low level access This pointer defines which waveform set will be chosen when the read low level access is targeted to RS group 0. 0000 Waveform set #1 0001 Waveform set #2 1011 Waveform set #12 1100 Reserved 1101 Reserved 1100 Reserved
23–20 DI1_SERIAL_LLA_PNTR_RS_W_1	RS 1 waveform pointer for write low level access This pointer defines which waveform set will be chosen when the write low level access is targeted to RS group 1. 0000 Waveform set #1 0001 Waveform set #2 1011 Waveform set #12 1100 Reserved 1101 Reserved 1100 Reserved
19–16 DI1_SERIAL_LLA_PNTR_RS_W_0	RS 0 waveform pointer for write low level access This pointer defines which waveform set will be chosen when the write low level access is targeted to RS group 0. 0000 Waveform set #1 0001 Waveform set #2 1011 Waveform set #12 1100 Reserved 1101 Reserved 1100 Reserved
15–8 DI1_SERIAL_LATCH	DI1 Serial Latch This field defines how many cycles to insert between serial read accesses start to data sampling in the
7–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 DI1_LLA_SER_ACCESS	Direct Low Level Access to Serial display 1 ARM platform access is performed via a direct path to the serial display in LLA mode, in this mode only the ARM platform in LLA mode can access the serial port 0 ARM platform access to the serial display port is not done directly, hence other source are allowed to access the serial port. The arbitration is done automatically
4 DI1_SER_CLK_POLARITY	Serial Clock Polarity The output polarity of the SER_CLK pin 1 The clock is inverted 0 The clock is not inverted

Table continues on the next page...

IPU_DI1_SER_CONF field descriptions (continued)

Field	Description
3 DI1_SERIAL_ DATA_ POLARITY	Serial Data Polarity The output polarity of the SER_DATA pin 1 The data is inverted 0 The data is not inverted
2 DI1_SERIAL_ RS_POLARITY	Serial RS Polarity The output polarity of the SER_RS pin 1 The RS is inverted 0 The RS is not inverted
1 DI1_SERIAL_ CS_POLARITY	Serial Chip Select Polarity The output polarity of the SER_CS pin 1 The CS is inverted 0 The CS is not inverted
0 DI1_ WAIT4SERIAL	Wait for Serial When the parallel display share pins with the serial port. Accessing the parallel port is not allowed till the serial port completes its access. 1 The parallel port should wait to the serial port as the pins are shared 0 The parallel port should not wait to the serial port as the pins are not shared

45.51.219 DI1 Special Signals Control Register (IPU_DI1_SSC)

Address: IPU_DI1_SSC is 1E00_0000h base + 48160h offset = 1E04_8160h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IPU_DI1_SSC field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved.
23 DI1_PIN17_ERM	DI1 PIN17 error recovery mode. This bit defines the error recovery mode of the PIN17 pin. 1 The PIN17 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN17 pin following a display error detection.
22 DI1_PIN16_ERM	DI1 PIN16 error recovery mode. This bit defines the error recovery mode of the PIN16 pin. 1 The PIN16 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN16 pin following a display error detection.
21 DI1_PIN15_ERM	DI1 PIN15 error recovery mode. This bit defines the error recovery mode of the PIN15 pin. 1 The PIN15 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN15 pin following a display error detection.
20 DI1_PIN14_ERM	DI1 PIN14 error recovery mode. This bit defines the error recovery mode of the PIN14 pin. 1 The PIN14 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN14 pin following a display error detection.
19 DI1_PIN13_ERM	DI1 PIN13 error recovery mode. This bit defines the error recovery mode of the PIN13 pin. 1 The PIN13 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN13 pin following a display error detection.
18 DI1_PIN12_ERM	DI1 PIN12 error recovery mode. This bit defines the error recovery mode of the PIN12 pin. 1 The PIN12 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN12 pin following a display error detection.
17 DI1_PIN11_ERM	DI1 PIN11 error recovery mode. This bit defines the error recovery mode of the PIN11 pin. 1 The PIN11 pin is cleared in case of a synchronous display error. The clear will be done on the next VSYNC. 0 Nothing is done to the PIN11 pin following a display error detection.
16 DI1_CS_ERM	DI1 GLUELOGIC error recovery mode. This bit defines the error recovery mode of the GLUELOGIC.

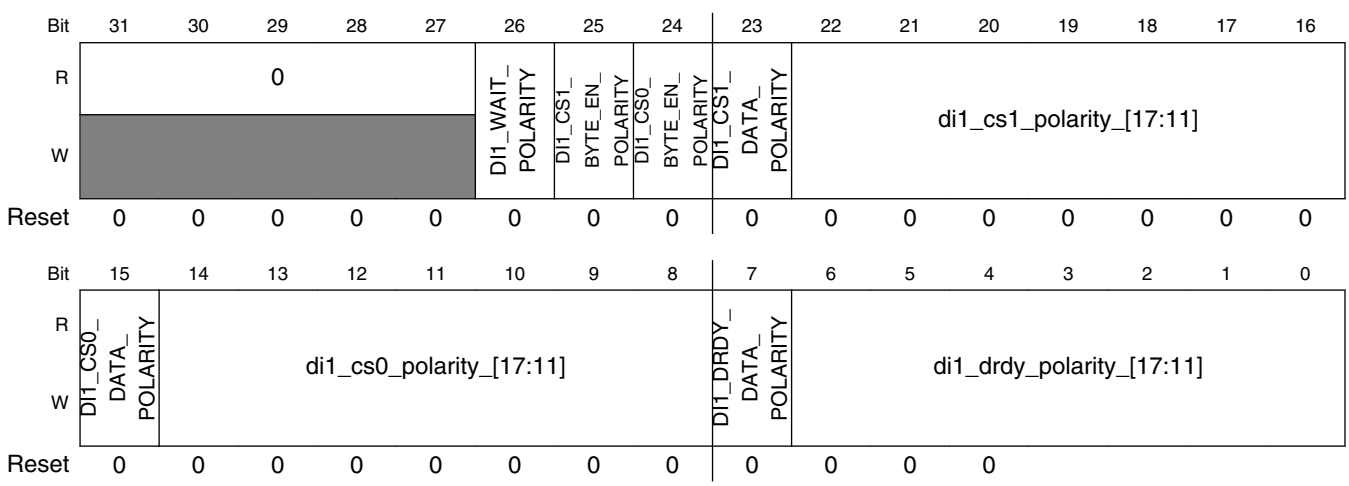
Table continues on the next page...

IPU_DI1_SSC field descriptions (continued)

Field	Description
	1 The GLUELOGIC is release in case of a synchronous display error. The release will be done on the next VSYNC. 0 Nothing is done to the GLUELOGIC following a display error detection.
15–6 Reserved	This read-only field is reserved and always has the value zero. Reserved.
5 DI1_WAIT_ON	Wait On This field defines the DC's response to WAIT signal 1 The DC holds the flow as long as WAIT is asserted. 0 The DC continues the flow regardless the WAIT signal.
4 DI1_BYTE_EN_POLARITY	Byte Enable polarity This bit defines the polarity of the byte enable signals to the display. 1 active high. 0 active low.
3 DI1_BYTE_EN_RD_IN	Byte Enable Read In This bit selects the source of the byte enable pins 1 The write byte enable signals are routed via bits [17:16] of the display's data, The read byte enable signals are routed via bits [19:18 of the display's data 0 The byte enable signals are routed via bits [17:16] of the display's data for both read and write
2–0 DI1_BYTE_EN_PNTR	Byte Enable Pointer This pointer selects the pin asserted along with the byte enables signals 000 wave form of byte enable as pin_11 001 wave form of byte enable as pin_12 111 wave form of byte enable as suitable CS pin

45.51.220 DI1 Polarity Register (IPU_DI1_POL)

Address: IPU_DI1_POL is 1E00_0000h base + 48164h offset = 1E04_8164h



IPU_DI1_POL field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26 DI1_WAIT_ POLARITY	WAIT polarity This bit defines the polarity of the wait signal input coming from the displa1 1 active high 0 active low
25 DI1_CS1_ BYTE_EN_ POLARITY	Byte Enable associated with CS1 polarity This bit defines the polarity of the byte enable signals to the display 1 active high 0 active low
24 DI1_CS0_ BYTE_EN_ POLARITY	Byte Enable associated with CS0 polarity This bit defines the polarity of the byte enable signals to the display 1 active high 0 active low
23 DI1_CS1_ DATA_ POLARITY	Data Polarity associated with CS1
22–16 di1_cs1_ polarity_[17:11]	DI1 output pin's polarity for CS1 This bits define the polarity of each of the DI's outputs when CS1 is asserted 1 The output pin is active high 0 The output pin is active low
15 DI1_CS0_ DATA_ POLARITY	Data Polarity associated with CS0
14–8 di1_cs0_ polarity_[17:11]	DI1 output pin's polarity for CS1 This bits define the polarity of each of the DI's outputs when CS1 is asserted 1 The output pin is active high 0 The output pin is active low
7 DI1_DRDY_ DATA_ POLARITY	Data Polarity associated with DRDY
6–0 di1_drdy_ polarity_[17:11]	DI1 output dynamic pin's polarity for synchronous access This bits define the polarity of each of the DI's outputs when synchronous display access is asserted The pins' default polarity is the same as defined in the di0_drdy_polarity_[17:11] bits 1 The output pin is active high 0 The output pin is active low

45.51.221 DI1Active Window 0 Register (IPU_DI1_AW0)

Address: IPU_DI1_AW0 is 1E00_0000h base + 48168h offset = 1E04_8168h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DI1_AW_TRIG_SEL				DI1_AW_HEND												DI1_AW_HCOUNT_SEL				DI1_AW_HSTART											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_DI1_AW0 field descriptions

Field	Description
31–28 DI1_AW_TRIG_SEL	This field selects the trigger for sending data during the display's active window 000 disabled 001 The trigger is the same trigger that triggers the displays clock. 010 The trigger is counter #1 011 The trigger is counter #2 100 The trigger is counter #3 101 The trigger is counter #4 110 The trigger is counter #5 111 The trigger is always on.
27–16 DI1_AW_HEND	This field defines the horizontal end of the active window
15–12 DI1_AW_HCOUNT_SEL	This field selects the counter that counts the horizontal position of the display's active window 0000 disabled 0001 reserved 0010 The counter is counter #1 0011 The counter is counter #2 0100 The counter is counter #3 0101 The counter is counter #4 0110 The counter is counter #5 1001 The counter is counter #8
11–0 DI1_AW_HSTART	This field defines the horizontal start of the active window DI1_AW_HSTART < DI1_AW_HEND

45.51.222 DI1 Active Window 1 Register (IPU_DI1_AW1)

Address: IPU_DI1_AW1 is 1E00_0000h base + 4816Ch offset = 1E04_816Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

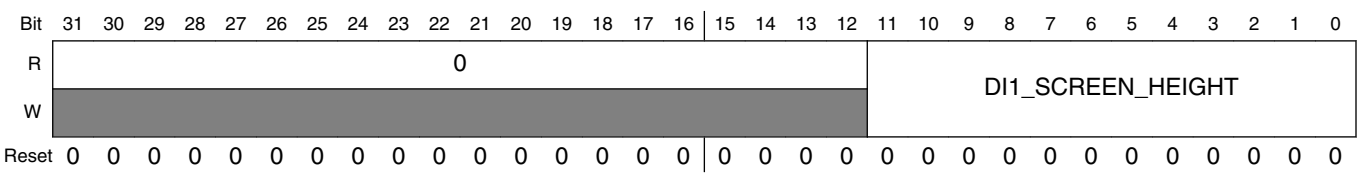
IPU_DI1_AW1 field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved
27–16 DI1_AW_VEND	This field defines the vertical end of the active window
15–12 DI1_AW_ VCOUNT_SEL	This field selects the counter that counts the vertical position of the display's active window 0000 disabled 0001 reserved 0010 The counter is counter #1 0011 The counter is counter #2 0100 The counter is counter #3 0101 The counter is counter #4 0110 The counter is counter #5 1001 The counter is counter #8
11–0 DI1_AW_ VSTART	This field defines the vertical start of the active window DI1_AW_VSTART < DI1_AW_VEND

45.51.223 DI1 Screen Configuration Register (IPU_DI1_SCR_CONF)

Address: IPU_DI1_SCR_CONF is 1E00_0000h base + 48170h offset = 1E04_8170h

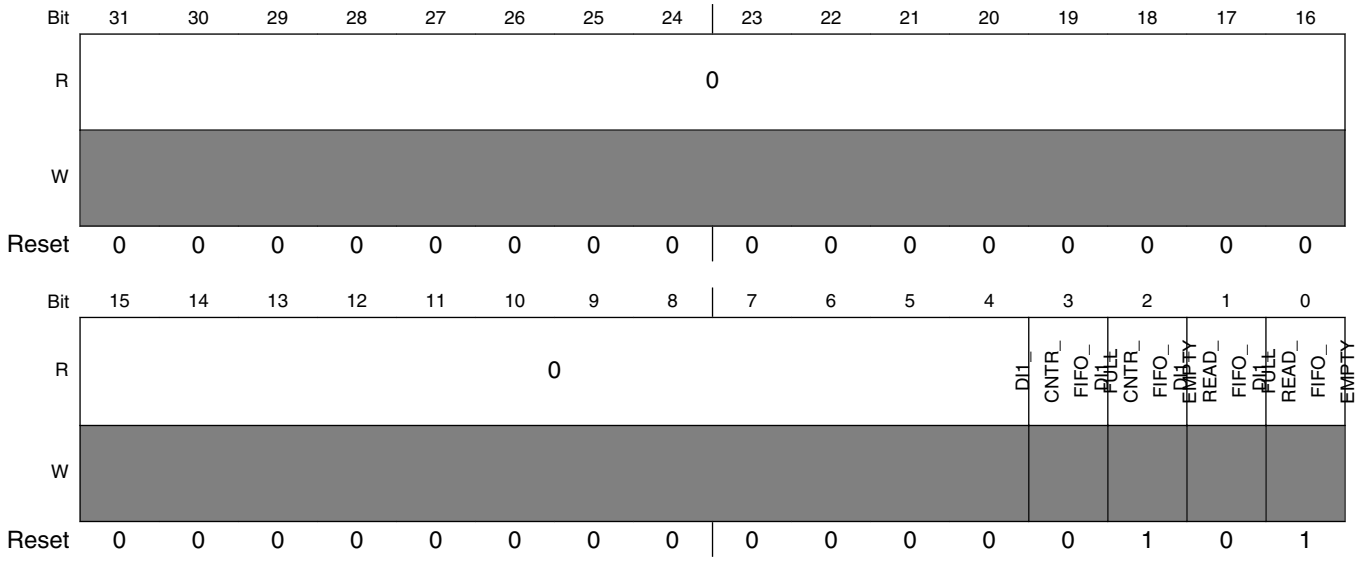


IPU_DI1_SCR_CONF field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value zero. Reserved.
11–0 DI1_SCREEN_ HEIGHT	This field defines the number of display rows (Number_of_ROWS = DI1_SCREEN_HEIGHT+1) This field is used for VSYNC calculation and for anti-tearing

45.51.224 DI1 Status Register (IPU_DI1_STAT)

Address: IPU_DI1_STAT is 1E00_0000h base + 48174h offset = 1E04_8174h



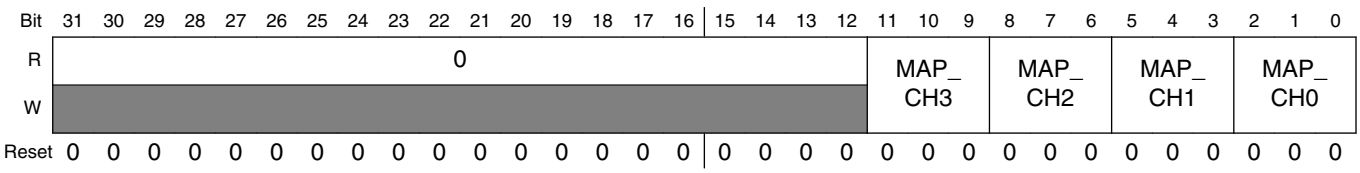
IPU_DI1_STAT field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3 DI1_CNTR_ FIFO_FULL	This bit indicates a full state of the DI1 FIFO. This FIFO is part of the DI1 synchronizer.
2 DI1_CNTR_ FIFO_EMPTY	This bit indicates an empty state of the DI1 FIFO. This FIFO is part of the DI1 synchronizer.
1 DI1_READ_ FIFO_FULL	This bit indicates a full state of the DI1 FIFO when performing a read. This FIFO is part of the DI1 synchronizer.
0 DI1_READ_ FIFO_EMPTY	This bit indicates an empty state of the DI1 FIFO when performing a read. This FIFO is part of the DI1 synchronizer.

45.51.225 SMFC Mapping Register (IPU_SMFC_MAP)

The purpose of this register is to map CSI frames to IDMAC channels.

Address: IPU_SMFC_MAP is 1E00_0000h base + 50000h offset = 1E05_0000h



IPU_SMFC_MAP field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value zero. Reserved.
11–9 MAP_CH3	DMASMFC channel 3mapping bits. 000 CSI0, ID=0 mapped to DMASMFC channel 3. 001 CSI0, ID=1 mapped to DMASMFC channel 3. 010 CSI0, ID=2 mapped to DMASMFC channel 3. 011 CSI0, ID=3 mapped to DMASMFC channel 3. 100 CSI1, ID=0 mapped to DMASMFC channel 3. 101 CSI1, ID=1 mapped to DMASMFC channel 3. 110 CSI1, ID=2 mapped to DMASMFC channel 3. 111 CSI1, ID=3 mapped to DMASMFC channel 3.
8–6 MAP_CH2	DMASMFC channel 2 mapping bits. 000 CSI0, ID=0 mapped to DMASMFC channel 2. 001 CSI0, ID=1 mapped to DMASMFC channel 2. 010 CSI0, ID=2 mapped to DMASMFC channel 2. 011 CSI0, ID=3 mapped to DMASMFC channel 2. 100 CSI1, ID=0 mapped to DMASMFC channel 2. 101 CSI1, ID=1 mapped to DMASMFC channel 2. 110 CSI1, ID=2 mapped to DMASMFC channel 2. 111 CSI1, ID=3 mapped to DMASMFC channel 2.
5–3 MAP_CH1	DMASMFC channel 1 mapping bits. 000 CSI0, ID=0 mapped to DMASMFC channel 1. 001 CSI0, ID=1 mapped to DMASMFC channel 1. 010 CSI0, ID=2 mapped to DMASMFC channel 1. 011 CSI0, ID=3 mapped to DMASMFC channel 1. 100 CSI1, ID=0 mapped to DMASMFC channel 1. 101 CSI1, ID=1 mapped to DMASMFC channel 1. 110 CSI1, ID=2 mapped to DMASMFC channel 1. 111 CSI1, ID=3 mapped to DMASMFC channel 1.
2–0 MAP_CH0	DMASMFC channel 0 mapping bits.

Table continues on the next page...

IPU_SMFC_MAP field descriptions (continued)

Field	Description
	000 CSI0, ID=0 mapped to DMASMFC channel 0. 001 CSI0, ID=1 mapped to DMASMFC channel 0. 010 CSI0, ID=2 mapped to DMASMFC channel 0. 011 CSI0, ID=3 mapped to DMASMFC channel 0. 100 CSI1, ID=0 mapped to DMASMFC channel 0. 101 CSI1, ID=1 mapped to DMASMFC channel 0. 110 CSI1, ID=2 mapped to DMASMFC channel 0. 111 CSI1, ID=3 mapped to DMASMFC channel 0.

45.51.226 SMFC Watermark Control Register (IPU_SMFC_WMC)

The purpose of this register is to control watermarks levels of DMA channels. The bit setting given relative to FIFO size and not in number of words since FIFO size depend from number of enabled DMA channels.

Address: IPU_SMFC_WMC is 1E00_0000h base + 50004h offset = 1E05_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

IPU_SMFC_WMC field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved.
27–25 WM3_CLR	Watermark "clear" level of DMASMFC channel 3. 000 clear watermark level when FIFO is full on 1/8 of their size. 001 clear watermark level when FIFO is full on 2/8 of their size. 110 clear watermark level when FIFO is full on 7/8 of their size. 111 clear watermark level when FIFO is full.
24–22 WM3_SET	Watermark "set" level of DMASMFC channel 3 000 set watermark level when FIFO is full on 1/8 of their size. 001 set watermark level when FIFO is full on 2/8 of their size. 110 set watermark level when FIFO is full on 7/8 of their size. 111 set watermark level when FIFO is full.
21–19 WM2_CLR	Watermark "clear" level of DMASMFC channel 2. 000 clear watermark level when FIFO is full on 1/8 of their size. 001 clear watermark level when FIFO is full on 2/8 of their size. 110 clear watermark level when FIFO is full on 7/8 of their size. 111 clear watermark level when FIFO is full.

Table continues on the next page...

IPU_SMFC_WMC field descriptions (continued)

Field	Description
18–16 WM2_SET	Watermark "set" level of DMASMFC channel 2. 000 set watermark level when FIFO is full on 1/8 of their size. 001 set watermark level when FIFO is full on 2/8 of their size. 110 set watermark level when FIFO is full on 7/8 of their size. 111 set watermark level when FIFO is full.
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved.
11–9 WM1_CLR	Watermark "clear" level of DMASMFC channel 1. 000 clear watermark level when FIFO is full on 1/8 of their size. 001 clear watermark level when FIFO is full on 2/8 of their size. 110 clear watermark level when FIFO is full on 7/8 of their size. 111 clear watermark level when FIFO is full.
8–6 WM1_SET	Watermark "set" level of DMASMFC channel 1. 000 set watermark level when FIFO is full on 1/8 of their size. 001 set watermark level when FIFO is full on 2/8 of their size. 110 set watermark level when FIFO is full on 7/8 of their size. 111 set watermark level when FIFO is full.
5–3 WM0_CLR	Watermark "clear" level of DMASMFC channel 0. 000 clear watermark level when FIFO is full on 1/8 of their size. 001 clear watermark level when FIFO is full on 2/8 of their size. 110 clear watermark level when FIFO is full on 7/8 of their size. 111 clear watermark level when FIFO is full.
2–0 WM0_SET	Watermark "set" level of DMASMFC channel 0. 000 set watermark level when FIFO is full on 1/8 of their size. 001 set watermark level when FIFO is full on 2/8 of their size. 110 set watermark level when FIFO is full on 7/8 of their size. 111 set watermark level when FIFO is full.

45.51.227 SMFC Burst Size Register (IPU_SMFC_BS)

This register holds the burst size value for each DMASMFC channel. The burst size is the number of IDMAC's active accesses that will done for each IDMAC's burst. This number is a function of PFS, BPP & NPB parameters in the IDMAC's CPMEM. These are the parameters corresponding to the IDMAC's channel used. The table below describes what should be the burst size according to PFS, BPP & NPB settings

Table 45-277. SMFC Burst Size

BPP	PFS	BURST_SIZE
8	6	NPB[6:4]
16	6	NPB[6:4]
All other	All other	NPB[6:2]

Address: IPU_SMFC_BS is 1E00_0000h base + 50008h offset = 1E05_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

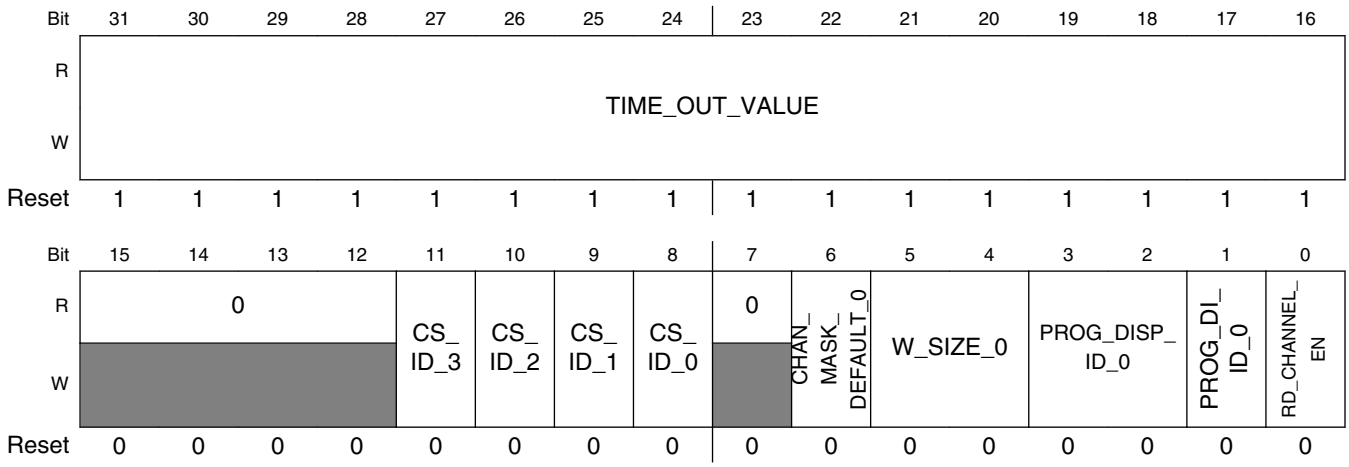
IPU_SMFC_BS field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved.
15–12 BURST3_SIZE	Burst Size of SMFCDMA channel 3. The value programed here should be BURST_SIZE-1 (for example: for a burst size of 1, write 0 to these bits)
11–8 BURST2_SIZE	Burst Size of SMFCDMA channel 2. The value programed here should be BURST_SIZE-1 (for example: for a burst size of 1, write 0 to these bits)
7–4 BURST1_SIZE	Burst Size of SMFCDMA channel 1. The value programed here should be BURST_SIZE-1 (for example: for a burst size of 1, write 0 to these bits)
3–0 BURST0_SIZE	Burst Size of SMFCDMA channel 0. The value programed here should be BURST_SIZE-1 (for example: for a burst size of 1, write 0 to these bits)

45.51.228 DC Read Channel Configuration Register (IPU_DC_READ_CH_CONF)

Address: IPU_DC_READ_CH_CONF is 1E00_0000h base + 58000h offset = 1E05_8000h



IPU_DC_READ_CH_CONF field descriptions

Field	Description
31–16 TIME_OUT_ VALUE	Time out value. In case of a error during read accesses to the display, where no response from the display was received. A time-out counter will terminate the current access and perform the next commend defined in the microcode. This field defines the amount of the hsp_clk cycles counted before the time-out event is issued. This event is tied to the interrupt controller and can generate an error interrupt.
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11 CS_ID_3	This bit maps an asynchronous display to a chip select 1 display #3 is connected to CS1 0 display #3 is connected to CS0
10 CS_ID_2	This bit maps an asynchronous display to a chip select 1 display #2 is connected to CS1 0 display #2 is connected to CS0
9 CS_ID_1	This bit maps an asynchronous display to a chip select 1 display #1 is connected to CS1 0 display #1 is connected to CS0
8 CS_ID_0	This bit maps an asynchronous display to a chip select 1 display #0 is connected to CS1 0 display #0 is connected to CS0

Table continues on the next page...

IPU_DC_READ_CH_CONF field descriptions (continued)

Field	Description
7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6 CHAN_MASK_DEFAULT_0	Event mask bit for the read channel When more then one event is used during a flow (EOF, EOL, NL, NF, EOFIELD, etc.) masks all the event besides the event that is defined as the highest priority event 1 All the events are used - no mask 0 Only the highest priority event is used, the rest are masked
5–4 W_SIZE_0	Word Size The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used
3–2 PROG_DISP_ID_0	The field defines which one of the 4 displays can be read. 00 display #0 01 display #1 10 display #2 11 display #3
1 PROG_DI_ID_0	This bit select the DI which a read transaction can be performed through 1 DI #1 0 DI #0
0 RD_CHANNEL_EN	This bit enables the read channel. 1 The Read channel is enabled 0 The Read channel is disabled

45.51.229 DC Read Channel Start Address Register (IPU_DC_READ_SH_ADDR)

Address: IPU_DC_READ_SH_ADDR is 1E00_0000h base + 58004h offset = 1E05_8004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																ST_ADDR_0															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_DC_READ_SH_ADDR field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved.
28–0 ST_ADDR_0	This field defines the start address within the display's memory space where the read transactions will be done from.

45.51.230 DC Routine Link Register 0 Channel 0 (IPU_DC_RL0_CH_0)

Address: IPU_DC_RL0_CH_0 is 1E00_0000h base + 58008h offset = 1E05_8008h

IPU_DC_RL0_CH_0 field descriptions

Field	Description
31–24 COD_NL_START_CHAN_0	This field is a pointer to the address within the microcode memory where the routine that handles the new line event (NL) resides
23–20 Reserved	This read-only field is reserved and always has the value zero. Reserved.
19–16 COD_NL_PRIORITY_CHAN_0	This field defines the priority of the new line (NL) event The priority between the events should be set to a unique value. i.e. two events must not have the same priority (except 0000 - disable) 0000 disable 0001 Priority #1 (lowest) 0010 Priority #2 1101 Priority #13 (highest) 1110 Reserved 1111 Reserved
15–8 COD_NF_START_CHAN_0	This field is a pointer to the address within the microcode memory where the routine that handles the new Frame event (NF) resides
7–4 Reserved	This read-only field is reserved and always has the value zero. Reserved.
3–0 COD_NF_PRIORITY_CHAN_0	This field defines the priority of the new frame (NF) event The priority between the events should be set to a unique value. i.e. two events must not have the same priority (except 0000 - disable) 0000 disable

Field	Description
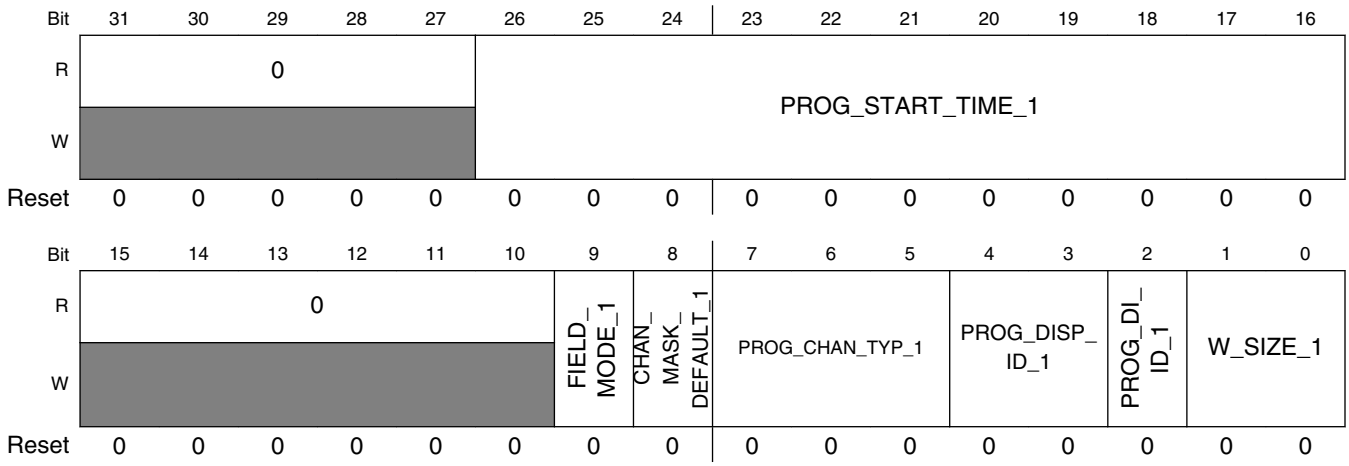
	0010 Priority #2 1101 Priority #13 (highest) 1110 Reserved 1111 Reserved

45.51.234 DC Write Channel 1 Configuration Register (IPU_DC_WR_CH_CONF_1)

Address: IPU_DC_WR_CH_CONF_1 is 1E00_0000h base + 5801Ch offset = 1E05_801Ch



IPU_DC_WR_CH_CONF_1 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26–16 PROG_START_TIME_1	This field defines the delay between display 's vertical synchronization pulse and the start time point of DC's channel 1 window. The delay is defined in pairs of rows. It is used for tearing elimination
15–10 Reserved	This read-only field is reserved and always has the value zero. Reserved.
9 FIELD_MODE_1	Field mode bit for channel #1 This bit defines if the channel works in field mode or frame mode; This bit is relevant if the flow is sync flow 1 Field mode 0 Frame mode
8 CHAN_MASK_DEFAULT_1	Event mask bit for channel #1 When more then one event is used during a flow (EOF, EOL, NL, NF, EOFIELD, etc.) masks all the event besides the event that is defined as the highest priority event

Table continues on the next page...

IPU_DC_WR_CH_CONF_1 field descriptions (continued)

Field	Description
	1 All the events are used - no mask 0 Only the highest priority event is used, the rest are masked
7–5 PROG_CHAN_TYP_1	This field define the mode of operation of channel #1 000 Disable 001 Reserved 010 Reserved 100 Normal mode without anti-tearing. For sync display this is the only mode allowed 101 Normal mode with anti-tearing 110 Reserved 111 Additional command channel is added to the flow handled by DC channel #1
4–3 PROG_DISP_ID_1	The field defines which one of the 4 displays is associated with channel #1. 00 display #0 01 display #1 10 display #2 11 display #3
2 PROG_DI_ID_1	This bit select the DI which a transaction associated with channel #1 can be performed to 1 DI #1 0 DI #0
1–0 W_SIZE_1	Word Size associated with channel #1 The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used

IPU_DC_WR_CH_CONF_2 field descriptions (continued)

Field	Description
15–9 Reserved	This read-only field is reserved and always has the value zero. Reserved.
8 CHAN_MASK_DEFAULT_2	Event mask bit for channel #2 When more then one event is used during a flow (EOF, EOL, NL, NF, EOFIELD, etc.) masks all the event besides the event that is defined as the highest priority event 1 All the events are used - no mask 0 Only the highest priority event is used, the rest are masked
7–5 PROG_CHAN_TYP_2	This field define the mode of operation of channel #2 000 Disable 001 Reserved 010 Reserved 100 Normal mode without anti-tearing. For sync display this is the only mode allowed 101 Normal mode with anti-tearing 110 Reserved 111 Additional command channel is added to the flow handled by DC channel #2
4–3 PROG_DISP_ID_2	The field defines which one of the 4 displays is associated with channel #2. 00 display #0 01 display #1 10 display #2 11 display #3
2 PROG_DI_ID_2	This bit select the DI which a transaction associated with channel #2 can be performed to 1 DI #1 0 DI #0
1–0 W_SIZE_2	Word Size The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used

45.51.244 DC Write Channel 2 Address Configuration Register (IPU_DC_WR_CH_ADDR_2)

Address: IPU_DC_WR_CH_ADDR_2 is 1E00_0000h base + 5803Ch offset = 1E05_803Ch

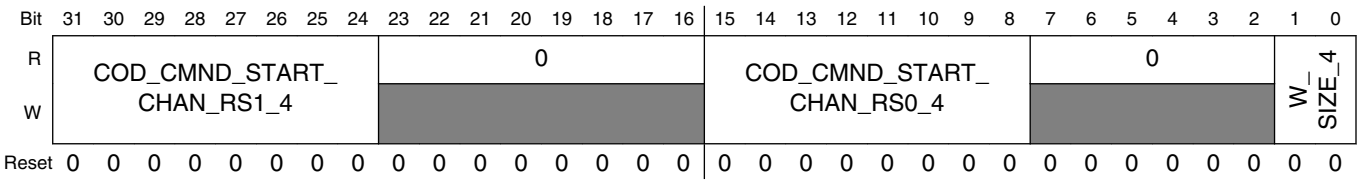
IPU_DC_CMD_CH_CONF_3 field descriptions

Field	Description
31–24 COD_CMND_START_CHAN_RS1_3	This field is a pointer to the address within the microcode memory where the routine that handles the command start event resides (associated with channel #3); This field is relevant when RS is equal to 1
23–16 Reserved	This read-only field is reserved and always has the value zero. Reserved.
15–8 COD_CMND_START_CHAN_RS0_3	This field is a pointer to the address within the microcode memory where the routine that handles the command start event resides (associated with channel #3); This field is relevant when RS is equal to 0
7–2 Reserved	This read-only field is reserved and always has the value zero. Reserved.
1–0 W_SIZE_3	Word Size associated with channel #3 The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used

45.51.250 DC Command Channel 4 Configuration Register (IPU_DC_CMD_CH_CONF_4)

Address: IPU_DC_CMD_CH_CONF_4 is 1E00_0000h base + 58058h offset = 1E05_8058h

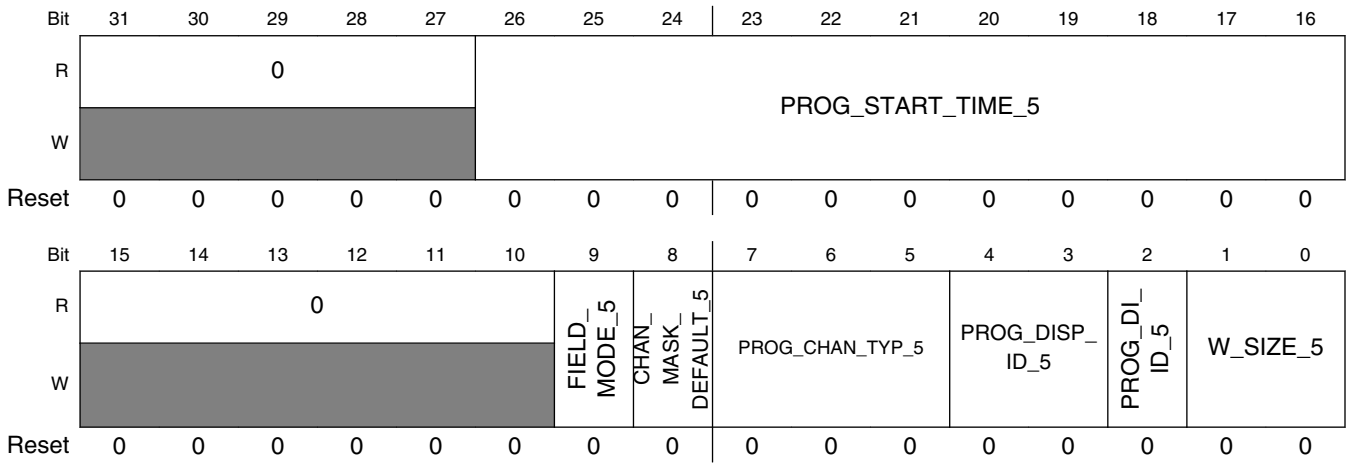


IPU_DC_CMD_CH_CONF_4 field descriptions

Field	Description
31–24 COD_CMND_START_CHAN_RS1_4	This field is a pointer to the address within the microcode memory where the routine that handles the command start event resides (associated with channel #4); This field is relevant when RS is equal to 1
23–16 Reserved	This read-only field is reserved and always has the value zero. Reserved.
15–8 COD_CMND_START_CHAN_RS0_4	This field is a pointer to the address within the microcode memory where the routine that handles the command start event resides (associated with channel #4); This field is relevant when RS is equal to 0
7–2 Reserved	This read-only field is reserved and always has the value zero. Reserved.
1–0 W_SIZE_4	Word Size associated with channel #4 The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used

45.51.251 DC Write Channel 5Configuration Register (IPU_DC_WR_CH_CONF_5)

Address: IPU_DC_WR_CH_CONF_5 is 1E00_0000h base + 5805Ch offset = 1E05_805Ch



IPU_DC_WR_CH_CONF_5 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26–16 PROG_START_TIME_5	This field defines the delay between display 's vertical synchronization pulse and the start time point of DC's channel 5 window. The delay is defined in pairs of rows. It is used for tearing elimination
15–10 Reserved	This read-only field is reserved and always has the value zero. Reserved.
9 FIELD_MODE_5	Field mode bit for channel #5 This bit defines if the channel works in field mode or frame mode; This bit is relevant if the flow is sync flow 1 Field mode 0 Frame mode
8 CHAN_MASK_DEFAULT_5	Event mask bit for channel #5 When more then one event is used during a flow (EOF, EOL, NL, NF, EOFIELD, etc.) masks all the event besides the event that is defined as the highest priority event 1 All the events are used - no mask 0 Only the highest priority event is used, the rest are masked
7–5 PROG_CHAN_TYP_5	This field define the mode of operation of channel #5 000 Disable 001 Reserved 010 Reserved 100 Normal mode without anti-tearing. For sync display this is the only mode allowed

Table continues on the next page...

IPU_DC_WR_CH_CONF_5 field descriptions (continued)

Field	Description
	101 Normal mode with anti-tearing 110 Reserved 111 Additional command channel is added to the flow handled by DC channel #5
4–3 PROG_DISP_ID_5	The field defines which one of the 4 displays is associated with channel #5. 00 display #0 01 display #1 10 display #2 11 display #3
2 PROG_DI_ID_5	This bit select the DI which a transaction associated with channel #5 can be performed to. When channel 28 is connected to DI0, channel 23 must be connected to DI1 even if ch23 is not used. This is done by writing 1 to this bit. 1 DI #1 0 DI #0
1–0 W_SIZE_5	Word Size associated with channel #5 The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used

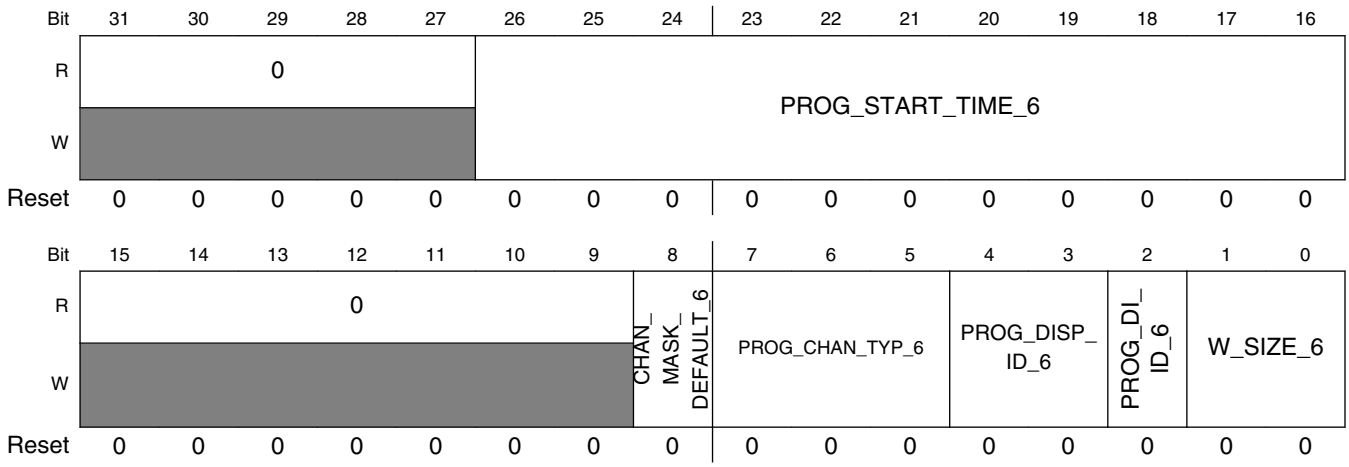
3–0 COD_NEW_DATA_PRIORITY_CHAN_5	This field defines the priority of the new line event (associated with channel #5) The priority between the events should be set to a unique value. i.e. two events must not have the same priority (except 0000 - disable) 0000 disable 0001 Priority #1 (lowest) 0010 Priority #2 1101 Priority #13 (highest) 1110 Reserved 1111 Reserved

45.51.258 DC Write Channel 6 Configuration Register (IPU_DC_WR_CH_CONF_6)

Address: IPU_DC_WR_CH_CONF_6 is 1E00_0000h base + 58078h offset = 1E05_8078h



IPU_DC_WR_CH_CONF_6 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26–16 PROG_START_TIME_6	This field defines the delay between display 's vertical synchronization pulse and the start time point of DC's channel 6 window. The delay is defined in pairs of rows. It is used for tearing elimination
15–9 Reserved	This read-only field is reserved and always has the value zero. Reserved.
8 CHAN_MASK_DEFAULT_6	Event mask bit for channel #6 When more then one event is used during a flow (EOF, EOL, NL, NF, EOFIELD, etc.) masks all the event besides the event that is defined as the highest priority event 1 All the events are used - no mask 0 Only the highest priority event is used, the rest are masked
7–5 PROG_CHAN_TYP_6	This field define the mode of operation of channel #6 000 Disable 001 Reserved 010 Reserved 100 Normal mode without anti-tearing. For sync display this is the only mode allowed 101 Normal mode with anti-tearing 110 Reserved 111 Additional command channel is added to the flow handled by DC channel #6
4–3 PROG_DISP_ID_6	The field defines which one of the 4 displays is associated with channel #6. 00 display #0 01 display #1

Table continues on the next page...

IPU_DC_WR_CH_CONF_6 field descriptions (continued)

Field	Description
	10 display #2 11 display #3
2 PROG_DI_ID_6	This bit select the DI which a transaction associated with channel #6 can be performed to 1 DI #1 0 DI #0
1–0 W_SIZE_6	Word Size associated with channel #6 The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used

45.51.259 DC Write Channel 6 Address Configuration Register (IPU_DC_WR_CH_ADDR_6)

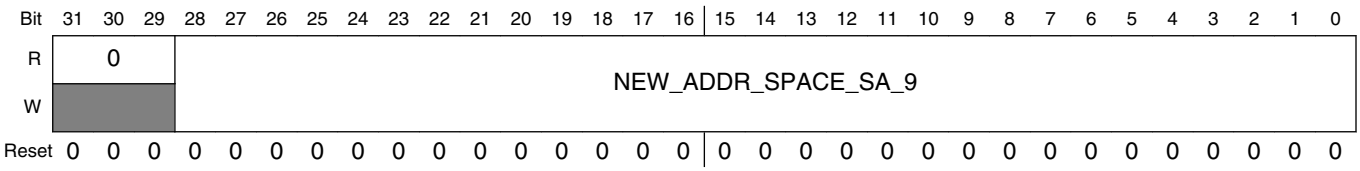
4–3 MCU_DISP_ID_9	The field defines which one of the 4 displays is associated with channel #9. 00 display #0 01 display #1 10 display #2 11 display #3
2 CHAN_MASK_DEFAULT_9	Event mask bit for channel #9 When more then one event is used during a flow (EOF, EOL, NL, NF, EOFIELD, etc.) masks all the event besides the event that is defined as the highest priority event 1 All the events are used - no mask 0 Only the highest priority event is used, the rest are masked
1–0 W_SIZE_9	Word Size associated with channel #9 The data coming from the IDMAC is 32bit wide. This field defines the size of the word used by the DC 00 8 bits are used - a 32 bit words includes 4X8bit valid words. 01 16 LSB bits - a 32 bit words includes 2 X16bit valid words. 10 24 MSB bits are used (RGB) - 8 LSB bits are ignored by the DC 11 32 bits are used

45.51.274 DC Write Channel 9Configuration 2Register (IPU_DC_WR_CH_CONF2_9)

Address: IPU_DC_WR_CH_CONF2_9 is 1E00_0000h base + 580B8h offset = 1E05_80B8h

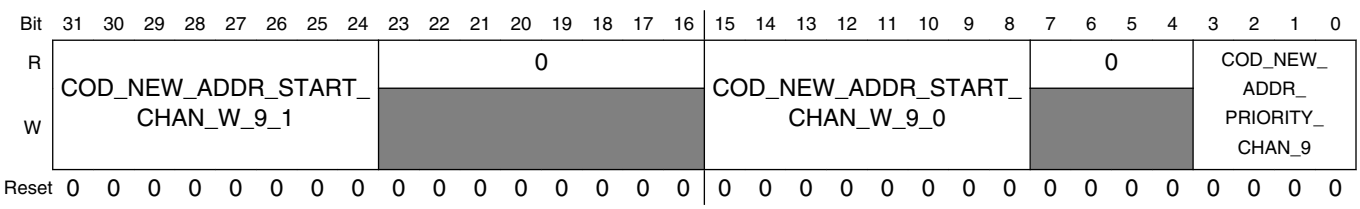


IPU_DC_WR_CH_CONF2_9 field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved.
28–0 NEW_ADDR_SPACE_SA_9	Channel #8 is used for ARM platform direct access to the display. This field defines the base address of the second region accessible on the display

45.51.275 DC Routine Link Register 1 Channel 9 (IPU_DC_RL1_CH_9)

Address: IPU_DC_RL1_CH_9 is 1E00_0000h base + 580BCh offset = 1E05_80BCh



IPU_DC_RL1_CH_9 field descriptions

Field	Description
31–24 COD_NEW_ADDR_START_CHAN_W_9_1	This field is a pointer to the address within the microcode memory where the routine that handles the new address event resides (associated with channel #9, second region)
23–16 Reserved	This read-only field is reserved and always has the value zero. Reserved.
15–8 COD_NEW_ADDR_START_CHAN_W_9_0	This field is a pointer to the address within the microcode memory where the routine that handles the new address event resides (associated with channel #9, first region)
7–4 Reserved	This read-only field is reserved and always has the value zero. Reserved.

Table continues on the next page...

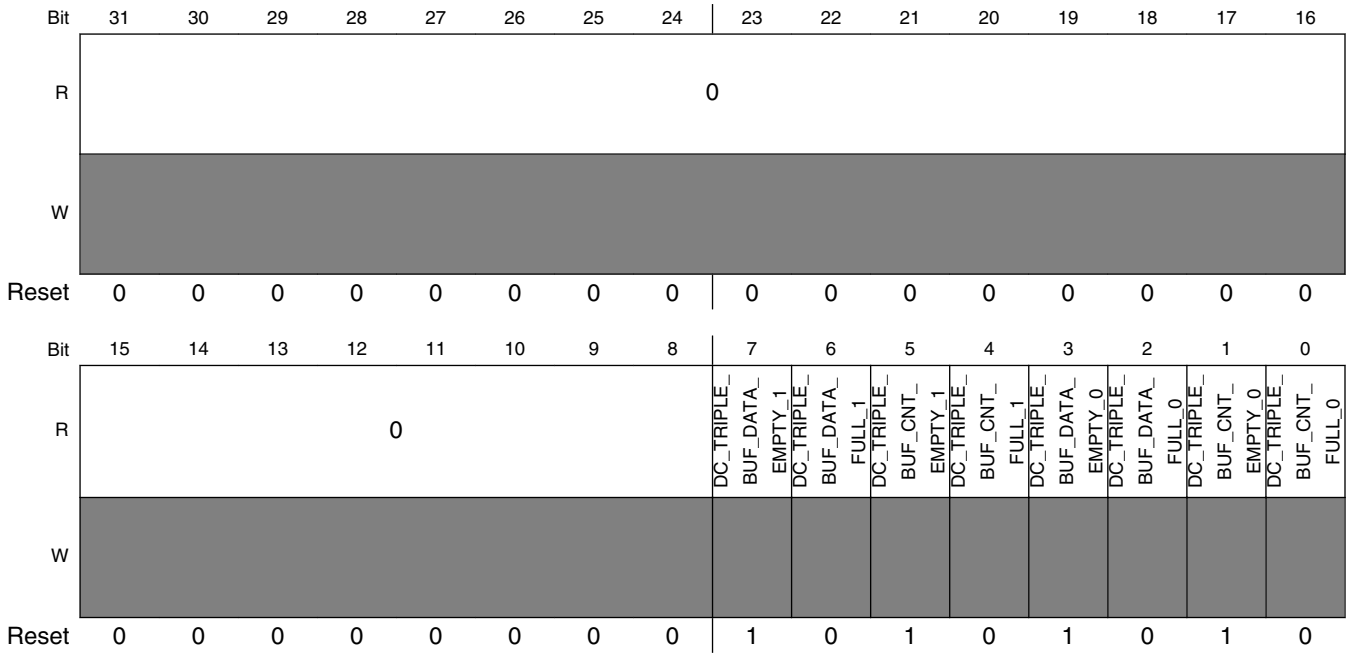
IPU_DC_WR_CH_ADDR_5_ALT field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved.
28–0 ST_ADDR_5_ALT	This field defines the start address within the display's memory space where the write transactions will be done to for channel #5, when alternate flow is performed via channel #5

45.51.341 DC Status Register (IPU_DC_STAT)

Address: IPU_DC_STAT is 1E00_0000h base + 581C8h offset = 1E05_81C8h



IPU_DC_STAT field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved.
7 DC_TRIPLE_BUF_DATA_EMPTY_1	This bit indicates a FIFO full state on the DC FIFO accessing DI1 when write to the display flow is used
6 DC_TRIPLE_BUF_DATA_FULL_1	This bit indicates a FIFO empty state on the DC FIFO accessing DI1 when read from the display flow is used
5 DC_TRIPLE_BUF_CNT_EMPTY_1	This bit indicates a FIFO empty state on the DC FIFO accessing DI1 when write to the display flow is used
4 DC_TRIPLE_BUF_CNT_FULL_1	This bit indicates a FIFO full state on the DC FIFO accessing DI1 when write to the display flow is used
3 DC_TRIPLE_BUF_DATA_EMPTY_0	This bit indicates a FIFO empty state on the DC FIFO accessing DI0 when read from the display flow is used

Table continues on the next page...

IPU_DC_STAT field descriptions (continued)

Field	Description
2 DC_TRIPLE_BUF_DATA_FULL_0	This bit indicates a FIFO full state on the DC FIFO accessing DI0 when read from the display flow is used
1 DC_TRIPLE_BUF_CNT_EMPTY_0	This bit indicates a FIFO empty state on the DC FIFO accessing DI0 when write to the display flow is used
0 DC_TRIPLE_BUF_CNT_FULL_0	This bit indicates a FIFO full state on the DC FIFO accessing DI0 when write to the display flow is used

45.51.342 DC Display Configuration 2 Register 1 (IPU_DC_DISP_CONF2_1)

Address: IPU_DC_DISP_CONF2_1 is 1E00_0000h base + 590ECh offset = 1E05_90ECh

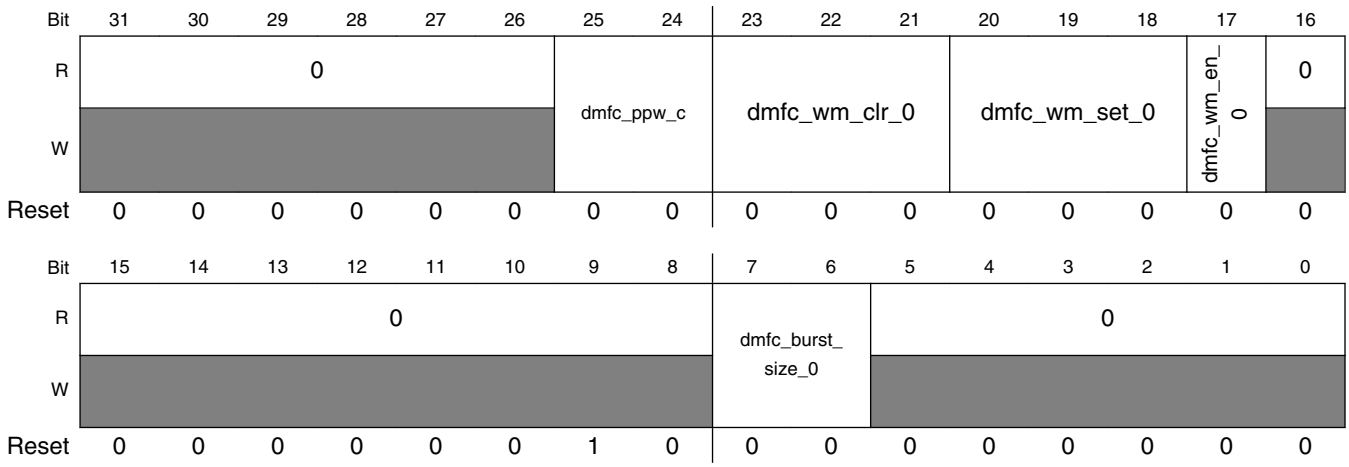
IPU_DC_DISP_CONF2_1 field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved.
28–0 SL_1	Stride line of display 1

45.51.343 DMFC Read Channel Register (IPU_DMFC_RD_CHAN)

Address: IPU_DMFC_RD_CHAN is 1E00_0000h base + 60000h offset = 1E06_0000h



IPU_DMFC_RD_CHAN field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value zero. Reserved.
25–24 dmfc_ppw_c	Pixel Per Word coded. This field defines the size of the read data from the display. 00 8 bit per pixel 01 16 bit per pixel 10 24 (rgb) bit per pixel or 32 bit per pixel 11 Reserved
23–21 dmfc_wm_clr_0	Watermark Clear This field defines the watermark's level of the DMFC read FIFO. Crossing this level will clear the watermark signal to the IDMAC. The WM level is the amount of free bursts at the FIFO (dmfc_wm_clr_0 > dmfc_wm_set_0)
20–18 dmfc_wm_set_0	Watermark Set This field defines the watermark's level of the DMFC read FIFO. Crossing this level will send the watermark signal to the IDMAC. The WM level is the amount of free bursts at the FIFO (dmfc_wm_clr_0 > dmfc_wm_set_0)
17 dmfc_wm_en_0	Watermark enable. This bit enables the watermark feature of the FIFO 1 WM feature is enabled 0 WM feature is disabled
16–8 Reserved	This read-only field is reserved and always has the value zero. Reserved.

Table continues on the next page...

IPU_DMFC_RD_CHAN field descriptions (continued)

Field	Description
7–6 dmfc_burst_size_0	Read burst Size This field defines the burst size of the DMFC's read accesses. This settings must match the settings in the corresponding IDMAC channel's settings. 00 32 words of 128 bit (4 pixels of 32 bit each, going to the IDMAC) 01 16 words of 128 bit 10 8 words of 128 bit 11 4 words of 128 bit
5–0 Reserved	This read-only field is reserved and always has the value zero. Reserved.

45.51.344 DMFC Write Channel Register (IPU_DMFC_WR_CHAN)

Field	Description
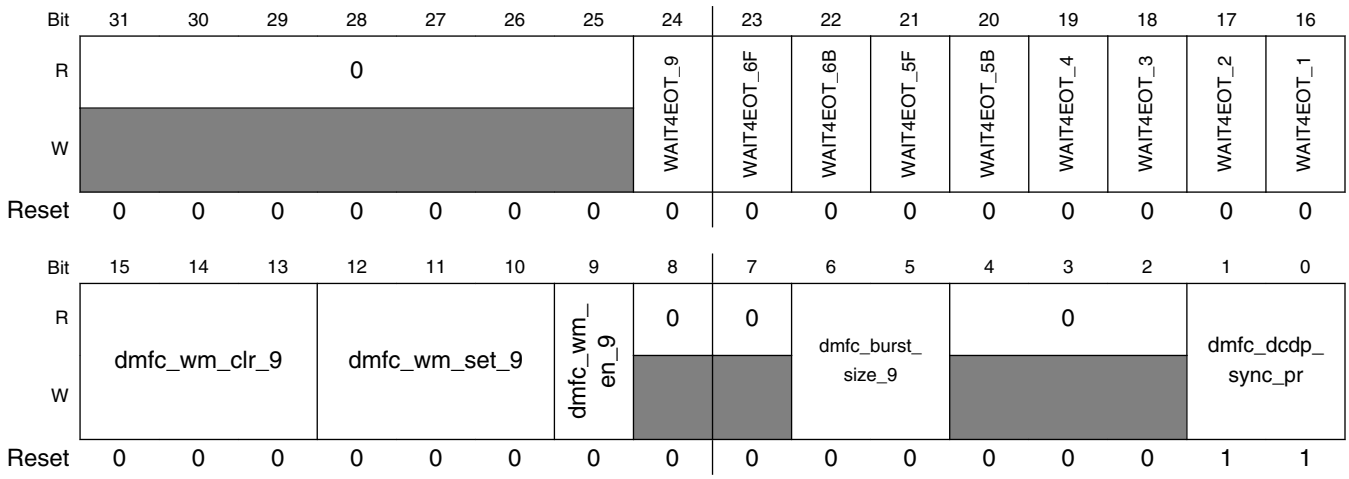
17 dmfc_wm_en_6b	Watermark enable. This bit enables the watermark feature of the FIFO 1 WM feature is enabled 0 WM feature is disabled
16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–13 dmfc_wm_clr_5f	Watermark Clear This field defines the watermark's level of the DMFC's write FIFO. Crossing this level will clear the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set)
12–10 dmfc_wm_set_5f	Watermark Set This field defines the watermark's level of the DMFC write FIFO. Crossing this level will send the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set
9 dmfc_wm_en_5f	Watermark enable. This bit enables the watermark feature of the FIFO 1 WM feature is enabled 0 WM feature is disabled
8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–5 dmfc_wm_clr_5b	Watermark Clear This field defines the watermark's level of the DMFC's write FIFO. Crossing this level will clear the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set)
4–2 dmfc_wm_set_ 5b	Watermark Set This field defines the watermark's level of the DMFC write FIFO. Crossing this level will send the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set
1 dmfc_wm_en_5b	Watermark enable. This bit enables the watermark feature of the FIFO 1 WM feature is enabled 0 WM feature is disabled
0 Reserved	This read-only field is reserved and always has the value zero. Reserved

45.51.348 DMFC General 1 Register (IPU_DMFC_GENERAL_1)

Address: IPU_DMFC_GENERAL_1 is 1E00_0000h base + 60014h offset = 1E06_0014h



IPU_DMFC_GENERAL_1 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value zero. Reserved.
24 WAIT4EOT_9	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #9 is in wait4eot mode 0 FIFO #9 is in normal mode
23 WAIT4EOT_6F	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #6F is in wait4eot mode 0 FIFO #6F is in normal mode
22 WAIT4EOT_6B	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #6B is in wait4eot mode 0 FIFO #6B is in normal mode
21 WAIT4EOT_5F	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO.

Table continues on the next page...

IPU_DMFC_GENERAL_1 field descriptions (continued)

Field	Description
	When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #5F is in wait4eot mode 0 FIFO #5F is in normal mode
20 WAIT4EOT_5B	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #5B is in wait4eot mode 0 FIFO #5B is in normal mode
19 WAIT4EOT_4	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #4 is in wait4eot mode 0 FIFO #4 is in normal mode
18 WAIT4EOT_3	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #3 is in wait4eot mode 0 FIFO #3 is in normal mode
17 WAIT4EOT_2	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #2 is in wait4eot mode 0 FIFO #2 is in normal mode
16 WAIT4EOT_1	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #1 is in wait4eot mode 0 FIFO #1 is in normal mode
15–13 dmfc_wm_clr_9	Watermark Clear This field defines the watermark's level of the DMFC's write FIFO. Crossing this level will clear the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set)

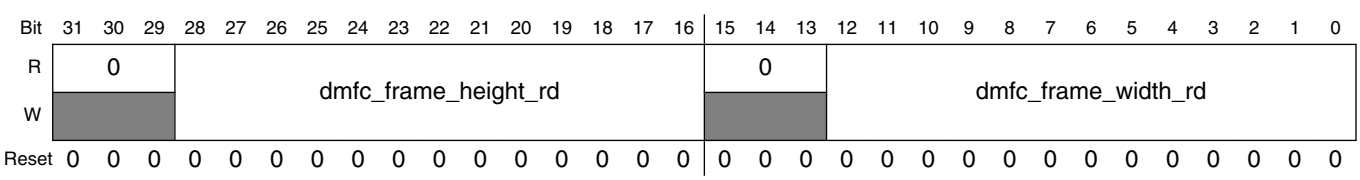
Table continues on the next page...

IPU_DMFC_GENERAL_1 field descriptions (continued)

Field	Description
12–10 dmfc_wm_set_9	Watermark Set This field defines the watermark's level of the DMFC write FIFO. Crossing this level will send the watermark signal to the IDMAC. The WM level is the amount of occupied bursts at the FIFO (dmfc_wm_clr > dmfc_wm_set
9 dmfc_wm_en_9	Watermark enable. This bit enables the watermark feature of the FIFO 1 WM feature is enabled 0 WM feature is disabled
8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6–5 dmfc_burst_size_9	Burst size of IDMAC's channel 44 This field defines the burst size of the IDMAC's channel 44 write accesses. This settings must match the settings in the corresponding IDMAC channel's settings. This channel is targeted for MASK - the FIFO size is always 32X128; The base address is always the upper half of the 8th segment 00 32 words of 128 bit (4 pixels of 32 bit each, coming from the IDMAC) 01 16 words of 128 bit 10 8 words of 128 bit 11 4 words of 128 bit
4–2 Reserved	This read-only field is reserved and always has the value zero. Reserved.
1–0 dmfc_dcdp_sync_pr	DMFC's memory access priority settings for simultaneous synchronous flows from DC & DP 00 Forbidden - should not be used. 01 DC has higher priority over DP 10 DP has higher priority over DC 11 Round Robin

45.51.349 DMFC General 2 Register (IPU_DMFC_GENERAL_2)

Address: IPU_DMFC_GENERAL_2 is 1E00_0000h base + 60018h offset = 1E06_0018h



IPU_DMFC_GENERAL_2 field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved.
28–16 dmfc_frame_height_rd	Frame height for read channel from the display to the IDMAC; Units are pixels
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved.
12–0 dmfc_frame_width_rd	Frame width for read channel from the display to the IDMAC; Units are pixels

45.51.350 DMFC IC Interface Control Register (IPU_DMFC_IC_CTRL)

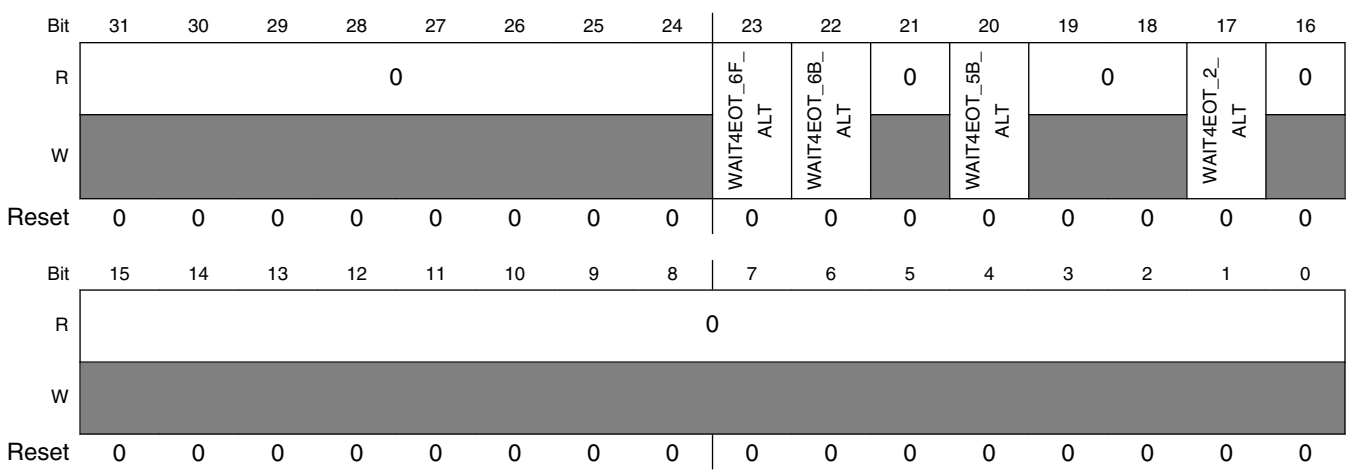
45.51.355 DMFC General 1 Alternate Register (IPU_DMFC_GENERAL1_ALT)

Address: IPU_DMFC_GENERAL1_ALT is 1E00_0000h base + 60030h offset = 1E06_0030h



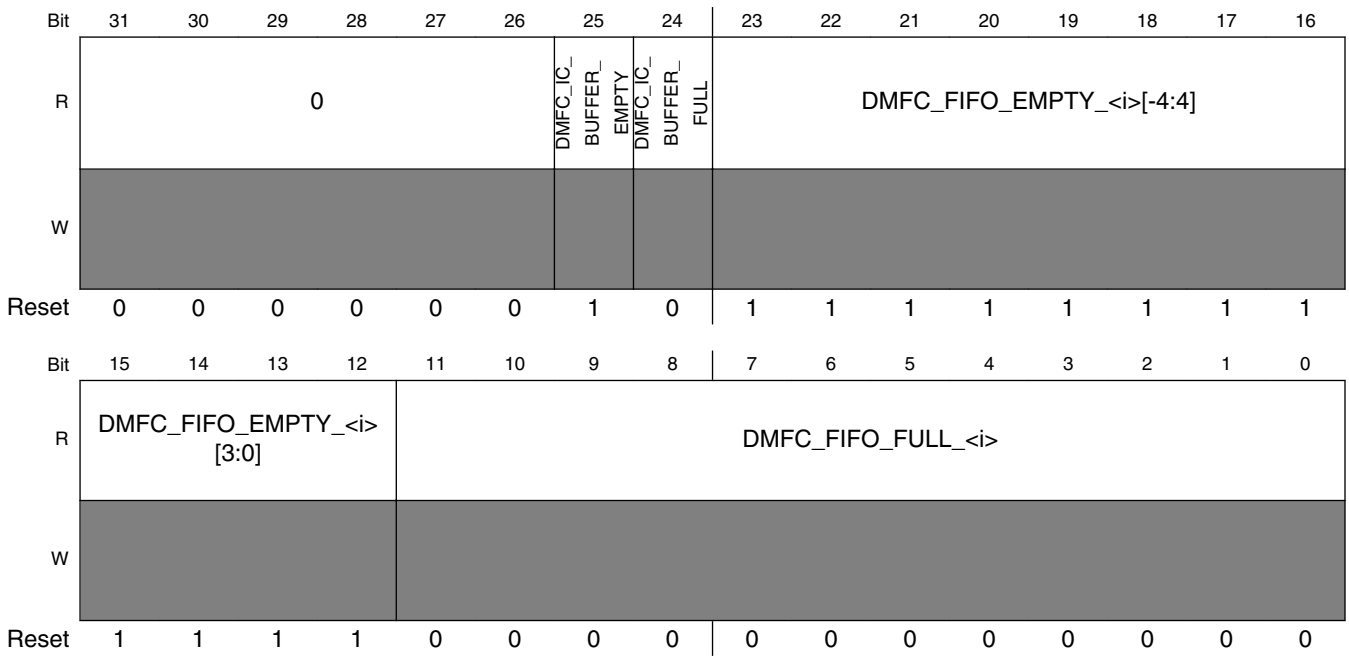
IPU_DMFC_GENERAL1_ALT field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved.
23 WAIT4EOT_6F_ALT	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #6F is in wait4eot mode (for alternate flow) 0 FIFO #6F is in normal mode (for alternate flow)
22 WAIT4EOT_6B_ALT	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #6B is in wait4eot mode (for alternate flow) 0 FIFO #6B is in normal mode (for alternate flow)
21 Reserved	This read-only field is reserved and always has the value zero. Reserved
20 WAIT4EOT_5B_ALT	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #5B is in wait4eot mode (for alternate flow) 0 FIFO #5B is in normal mode (for alternate flow)
19–18 Reserved	This read-only field is reserved and always has the value zero. Reserved
17 WAIT4EOT_2_ALT	In normal operation the DMFC sends requests to the IDMAC whenever there is room in the FIFO. When this bit is set the DMFC sends the request only after the current transfer is terminated, (wait4eot mode) When the FIFO is larger then the size of the line, the user should work in wait4eot mode. 1 FIFO #2 is in wait4eot mode (for alternate flow) 0 FIFO #2 is in normal mode (for alternate flow)
16–0 Reserved	This read-only field is reserved and always has the value zero. Reserved.

45.51.356 DMFC Status Register (IPU_DMFC_STAT)

This register contains DMFC's status bits. All the bits in this register are read-only.

Address: IPU_DMFC_STAT is 1E00_0000h base + 60034h offset = 1E06_0034h



IPU_DMFC_STAT field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value zero. Reserved
25 DMFC_IC_BUFFER_EMPTY	This bit indicates on a IC FIFO, inside the DMFC, empty condition. 0 IC FIFO not empty 1 IC FIFO is empty
24 DMFC_IC_BUFFER_FULL	This bit indicates on a IC FIFO, inside the DMFC, full condition. 0 IC FIFO not full 1 IC FIFO is full
23–12 DMFC_FIFO_EMPTY_<i>	This bit indicates on a DMFC FIFO#<i> empty condition. Mapping of these bit to an actual FIFO number is as follows: bit 0 => 0 bit 1=> 1 bit 2 => 2 bit 3 =>1c bit 4 => 2c bit 5 => 5b bit 6 => 5f bit 7 => 6b bit 8 => 6f bit 9 => 9 bit 10 => 10 (ARM platform access) bit 11 => 11 (ARM platform access) 0 FIFO #<i> is not empty 1 FIFO #<i> is empty
11–0 DMFC_FIFO_FULL_<i>	This bit indicates on a DMFC FIFO#<i> full condition.

Table continues on the next page...

IPU_DMFC_STAT field descriptions (continued)

Field	Description
	Mapping of these bit to an actual FIFO number is as follows: bit 0 => 0 bit 1=> 1 bit 2 => 2 bit 3 =>1c bit 4 => 2c bit 5 => 5b bit 6 => 5f bit 7 => 6b bit 8 => 6f bit 9 => 9 bit 10 => 10 (ARM platform access) bit 11 => 11 (ARM platform access) 0 FIFO #<i> is not full 1 FIFO #<i> is full

45.51.357 VDI Field Size Register (IPU_VDI_FSIZE)

The register used to control size of VDIC input fields.

Address: IPU_VDI_FSIZE is 1E00_0000h base + 68000h offset = 1E06_8000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0					VDI_FHEIGHT											0					VDI_FWIDTH										
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_VDI_FSIZE field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26–16 VDI_FHEIGHT	Frame height The value to be written to this register is the frame's height minus 1. The frame height should not be smaller than 16. When VDI_CMB_EN bit is clear: • The frame height should not be greater than 1080. • The frame's height must be even (which means that both fields have the same height) • The frame's height in 4:2:0 format, must be multiple of 4 (which means that both chroma fields have the same height) When VDI_CMB_EN bit is set: • The frame height should not be greater than 1200.
15–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10–0 VDI_FWIDTH	Frame width. The value to be written to this register is the frame's width minus 1. The Frame width should not be smaller than 16. The width must be even. When VDI_CMB_EN bit is clear • The Frame width should not be greater than 720968.

Table continues on the next page...

IPU_VDI_FSIZE field descriptions (continued)

Field	Description
	When VDI_CMB_EN bit is set: • The Frame width should not be greater than 1920.

45.51.358 VDI Control Register (IPU_VDI_C)

The register used to control modes of operations of VDIC module.

Address: IPU_VDI_C is 1E00_0000h base + 68004h offset = 1E06_8004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IPU_VDI_C field descriptions

Field	Description
31 -	VDIC top filed (automatic) This defines what would be the top field to be processed when the data is coming from the CSI 0 top field is field 0 1 top field is field 1
30 -	VDIC top filed (manual) This defines what would be the next top field to be processed when the data is coming from the memory 0 top field is field 0 1 top field is field 1
29–28 Reserved	This read-only field is reserved and always has the value zero. Reserved
27–25 VDI_VWM3_CLR	VDIC WaterMark "clear" level for channel 3. 0 clear watermark level when FIFO3 is full on 1/8 of their size.

Table continues on the next page...

IPU_VDI_C field descriptions (continued)

Field	Description
	1 clear watermark level when FIFO3 is full on 2/8 of their size. 7 clear watermark level when FIFO3 is full.
24–22 VDI_VWM3_ SET	VDIC WaterMark "set" level for channel 3. 0 set watermark level when FIFO3 is full on 1/8 of their size. 1 set watermark level when FIFO3 is full on 2/8 of their size. 7 set watermark level when FIFO3 is full.
21–19 VDI_VWM1_ CLR	VDIC WaterMark "clear" level for channel 1 or channel 4 (channels 1 and 4 are not working simultaneously). 0 clear watermark level when FIFO1 is full on 1/8 of their size. 1 clear watermark level when FIFO1 is full on 2/8 of their size. 7 clear watermark level when FIFO1 is full.
18–16 VDI_VWM1_ SET	VDIC WaterMark "set" level for channel 1 or channel 2 (channels 1 and 4 are not working simultaneously). 0 set watermark level when FIFO1 is full on 1/8 of their size. 1 set watermark level when FIFO1 is full on 2/8 of their size. 7 set watermark level when FIFO1 is full.
15–12 VDI_BURST_ SIZE3	Burst Size for channel 3. The VDIC's burst size is restrict by the IDMAC's restriction - This value must match the IDMAC settings and follow the IDMAC's restrictions 0 Burst size is 1 access. 1 Burst size is 2 accesses. 15 Burst size is 16 accesses.
11–8 VDI_BURST_ SIZE2	Burst Size for channel 2. The VDIC's burst size is restrict by the IDMAC's restriction - This value must match the IDMAC settings and follow the IDMAC's restrictions 0 Burst size is 1 access. 1 Burst size is 2 accesses. 15 Burst size is 16 accesses.
7–4 VDI_BURST_ SIZE1	Burst Size for channels 1 or 4 (channels 1 and 4 are not working simultaneously). The VDIC's burst size is restrict by the IDMAC's restriction - This value must match the IDMAC settings and follow the IDMAC's restrictions 0 Burst size is 1 access. 1 Burst size is 2 accesses. 15 Burst size is 16 accesses.
3–2 VDI_MOT_SEL	Motion select. 0 Motion determined by ROM "1" (shared toward medium/high motion). 1 Motion determined by ROM "2" (This option will not work well for high motion). 2 Full motion, only vertical filter is used 3 Forbidden.

Table continues on the next page...

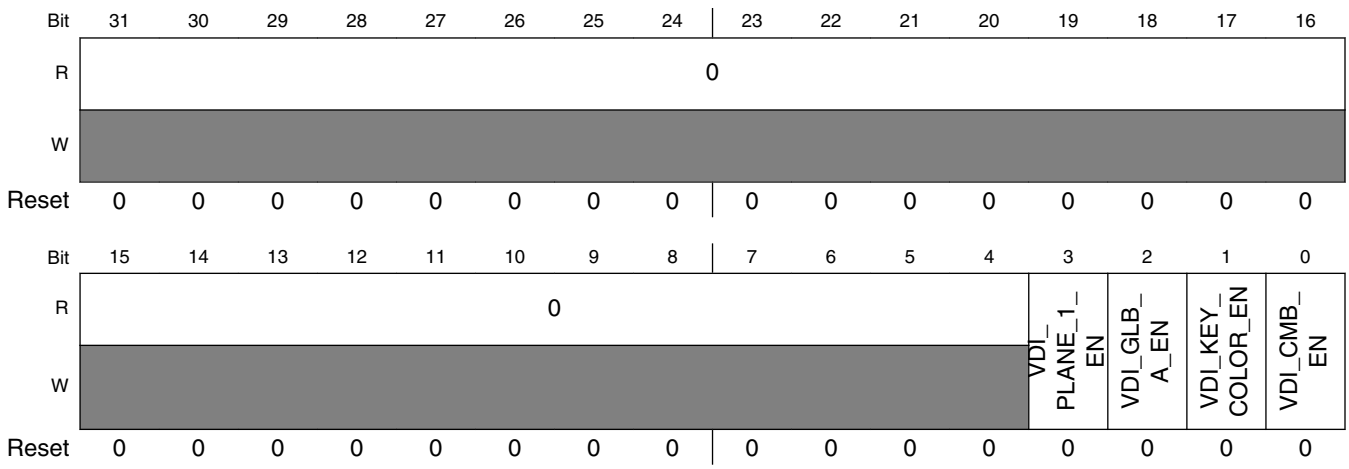
IPU_VDI_C field descriptions (continued)

Field	Description
1 VDI_CH_422	Chroma format at input and output of VDIC. 0 Chroma format is 420. 1 Chroma format is 422.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved

45.51.359 VDI Control Register 2 (IPU_VDI_C2_)

The register used to control modes of operations of VDIC module.

Address: IPU_VDI_C2_ is 1E00_0000h base + 68008h offset = 1E06_8008h



IPU_VDI_C2_ field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3 VDI_PLANE_1_EN	Plane 1 enable 0 plane #1 is disabled 1 plane #1 is enabled
2 VDI_GLB_A_EN	Global alpha enable 0 Alpha is local 1 Alpha is global
1 VDI_KEY_COLOR_EN	Key Color Enable 0 Key Color disabled. 1 Key color enabled

Table continues on the next page...

IPU_VDI_C2_ field descriptions (continued)

Field	Description
0 VDI_CMB_EN	Combining enable 0 Combining disabled. The VDIC works in de-interlacing mode 1 Combining enabled. The de-interlacing mode is not functional

45.51.360 VDI Combining Parameters Register 1 (IPU_VDI_CMDP_1)

The register holds combining paramemters.

Address: IPU_VDI_CMDP_1 is 1E00_0000h base + 6800Ch offset = 1E06_800Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

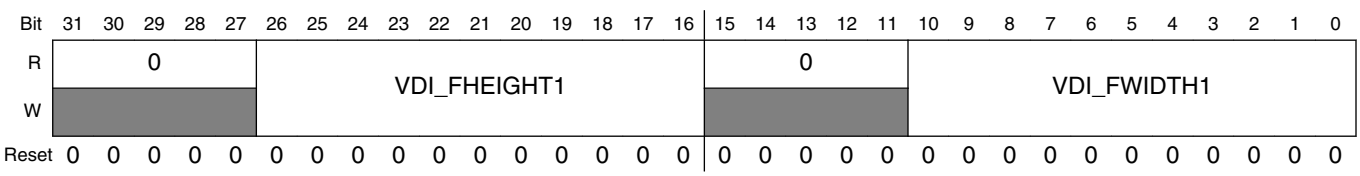
IPU_VDI_CMDP_2 field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value zero. Reserved
23–16 VDI_KEY_ COLOR_R	Red component of background Color
15–8 VDI_KEY_ COLOR_G	Green component of background Color
7–0 VDI_KEY_ COLOR_B	Blue component of background Color

45.51.362 VDI Plane Size Register 1 (IPU_VDI_PS_1)

The register holds the plane size's paramemters.

Address: IPU_VDI_PS_1 is 1E00_0000h base + 68014h offset = 1E06_8014h



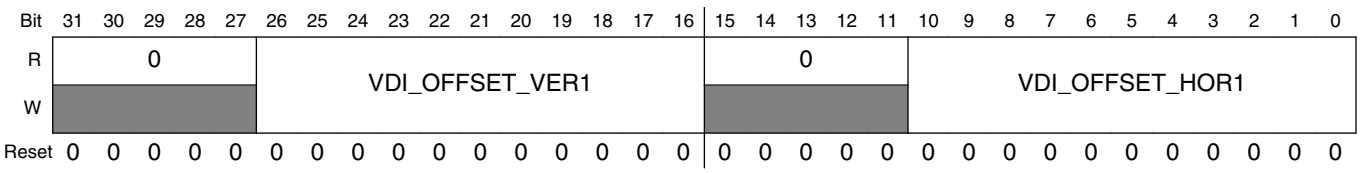
IPU_VDI_PS_1 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26–16 VDI_FHEIGHT1	Plane 1 height The value to be written to this register is the plane's height minus 1. The Plane height should not be smaller than 16. The Plane height should not be greater than 1200. The Plane's height must be even
15–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10–0 VDI_FWIDTH1	Plane 1 width. The value to be written to this register is the plane's width minus 1. The Plane width should not be smaller than 16. The Plane width should not be greater than 1920. The width must be even.

45.51.363 VDI Plane Size Register 2 (IPU_VDI_PS_2)

The register holds the plane's offset paramemters.

Address: IPU_VDI_PS_2 is 1E00_0000h base + 68018h offset = 1E06_8018h



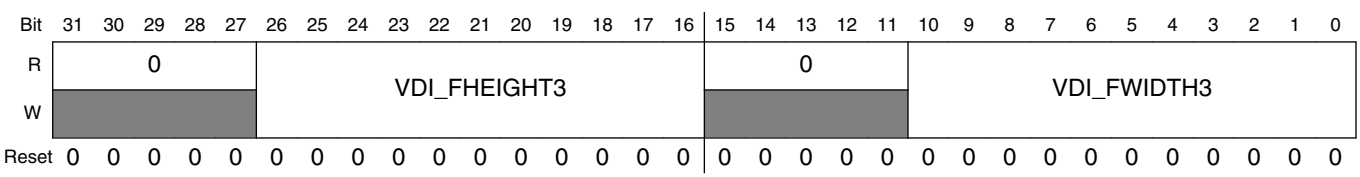
IPU_VDI_PS_2 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26–16 VDI_OFFSET_VER1	Vertical offset of plane 1
15–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10–0 VDI_OFFSET_HOR1	Horizontal offset of plane 1

45.51.364 VDI Plane Size Register 3 (IPU_VDI_PS_3)

The register holds the plane size's paramemters.

Address: IPU_VDI_PS_3 is 1E00_0000h base + 6801Ch offset = 1E06_801Ch



IPU_VDI_PS_3 field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26–16 VDI_FHEIGHT3	Plane 3 height The value to be written to this register is the plane's height minus 1. The Plane height should not be smaller than 16. The Plane height should not be greater than 1200.

Table continues on the next page...

IPU_VDI_PS_3 field descriptions (continued)

Field	Description
	The Plane's height must be even
15–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10–0 VDI_FWIDTH3	Plane 3 width. The value to be written to this register is the plane's width minus 1. The Plane width should not be smaller than 16. The Plane width should not be greater than 1920. The width must be even.

45.51.365 VDI Plane Size Register 4 (IPU_VDI_PS_4)

The register holds the plane's offset paramemters.

Address: IPU_VDI_PS_4 is 1E00_0000h base + 68020h offset = 1E06_8020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

The IDMAC will generate one AXI burst upon the assertion of the DMA request. 01 The IDMAC will generate two AXI bursts upon the assertion of the DMA request. 10 The IDMAC will generate four AXI bursts upon the assertion of the DMA request. 11 The IDMAC will generate eight AXI bursts upon the assertion of the DMA request.

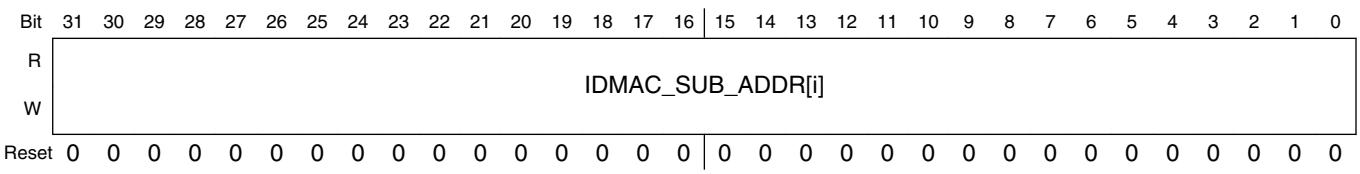
45.51.368 IDMAC Channel Alternate Address 0 Register (IPU_IDMAC_SUB_ADDR_0)

Address: IPU_IDMAC_SUB_ADDR_0 is 1E00_0000h base + 8028Ch offset = 1E08_028Ch

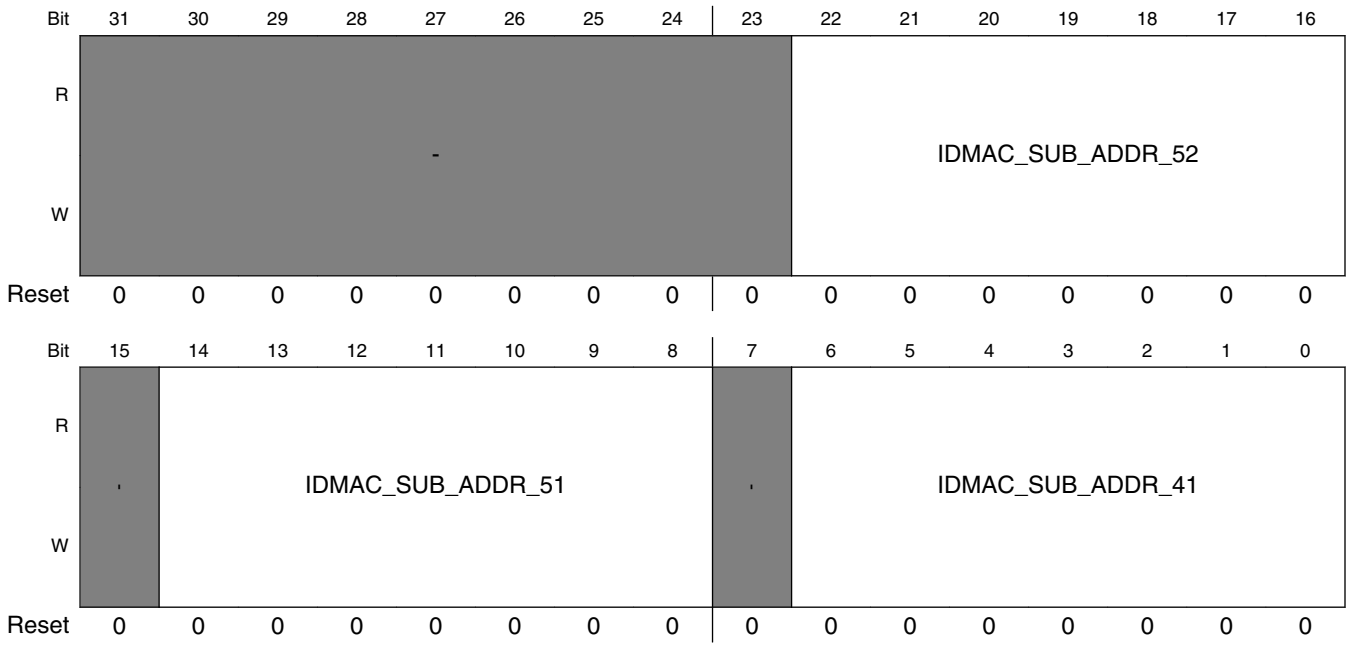


IPU_IDMAC_SUB_ADDR_0 field descriptions

Field	Description
31–0 IDMAC_SUB_ADDR[i]	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.

45.51.369 IDMAC Channel Alternate Address 2 Register (IPU_IDMAC_SUB_ADDR_2)

Address: IPU_IDMAC_SUB_ADDR_2 is 1E00_0000h base + 80304h offset = 1E08_0304h

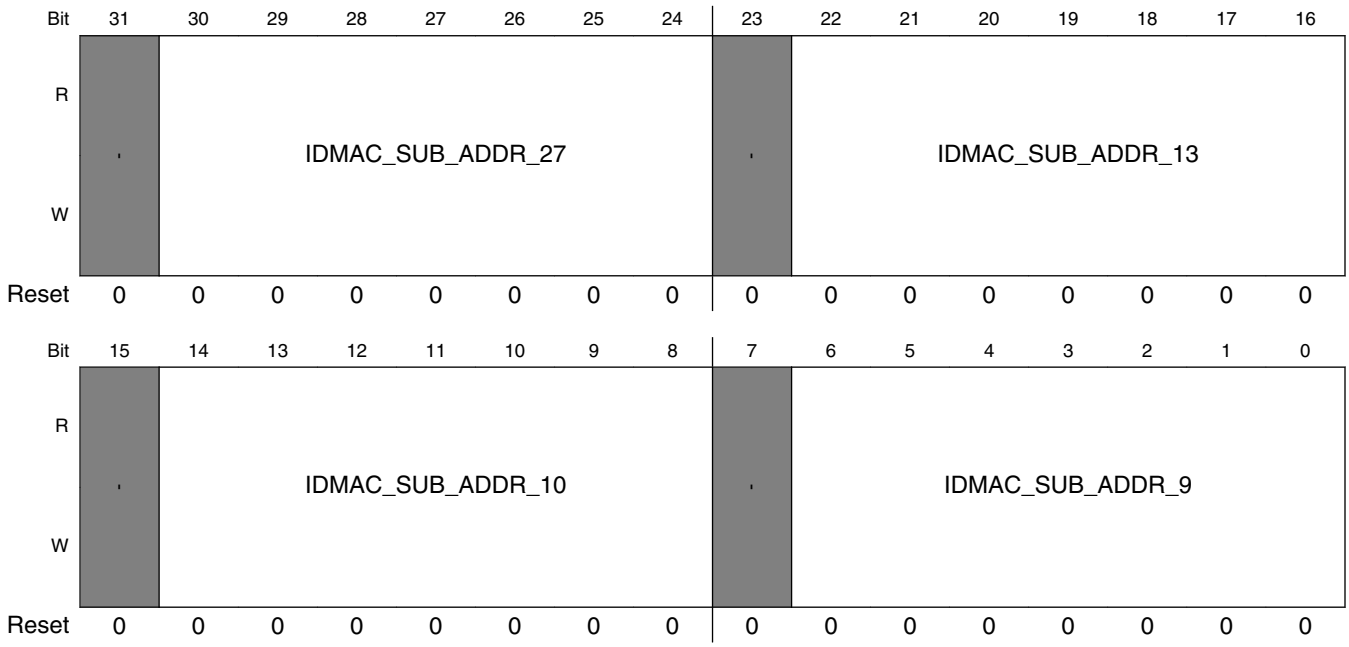


IPU_IDMAC_SUB_ADDR_2 field descriptions

Field	Description
31–23 -	Reserved.
22–16 IDMAC_SUB_ADDR_52	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.
15 -	Reserved.
14–8 IDMAC_SUB_ADDR_51	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.
7 -	Reserved.
6–0 IDMAC_SUB_ADDR_41	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.

45.51.370 IDMAC Channel Alternate Address 3 Register (IPU_IDMAC_SUB_ADDR_3)

Address: IPU_IDMAC_SUB_ADDR_3 is 1E00_0000h base + 80308h offset = 1E08_0308h

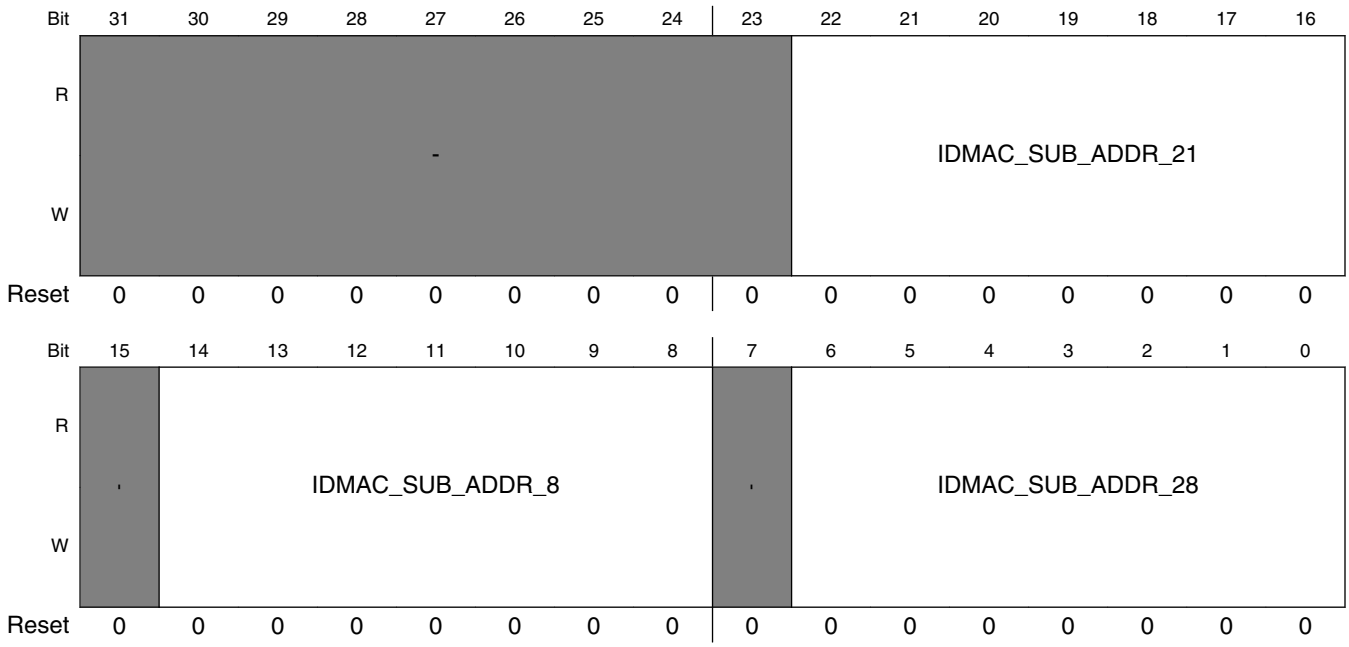


IPU_IDMAC_SUB_ADDR_3 field descriptions

Field	Description
31 -	Reserved.
30–24 IDMAC_SUB_ADDR_27	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.
23 -	Reserved.
22–16 IDMAC_SUB_ADDR_13	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.
15 -	Reserved.
14–8 IDMAC_SUB_ADDR_10	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.
7 -	Reserved.
6–0 IDMAC_SUB_ADDR_9	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.

45.51.371 IDMAC Channel Alternate Address 4 Register (IPU_IDMAC_SUB_ADDR_4)

Address: IPU_IDMAC_SUB_ADDR_4 is 1E00_0000h base + 8030Ch offset = 1E08_030Ch

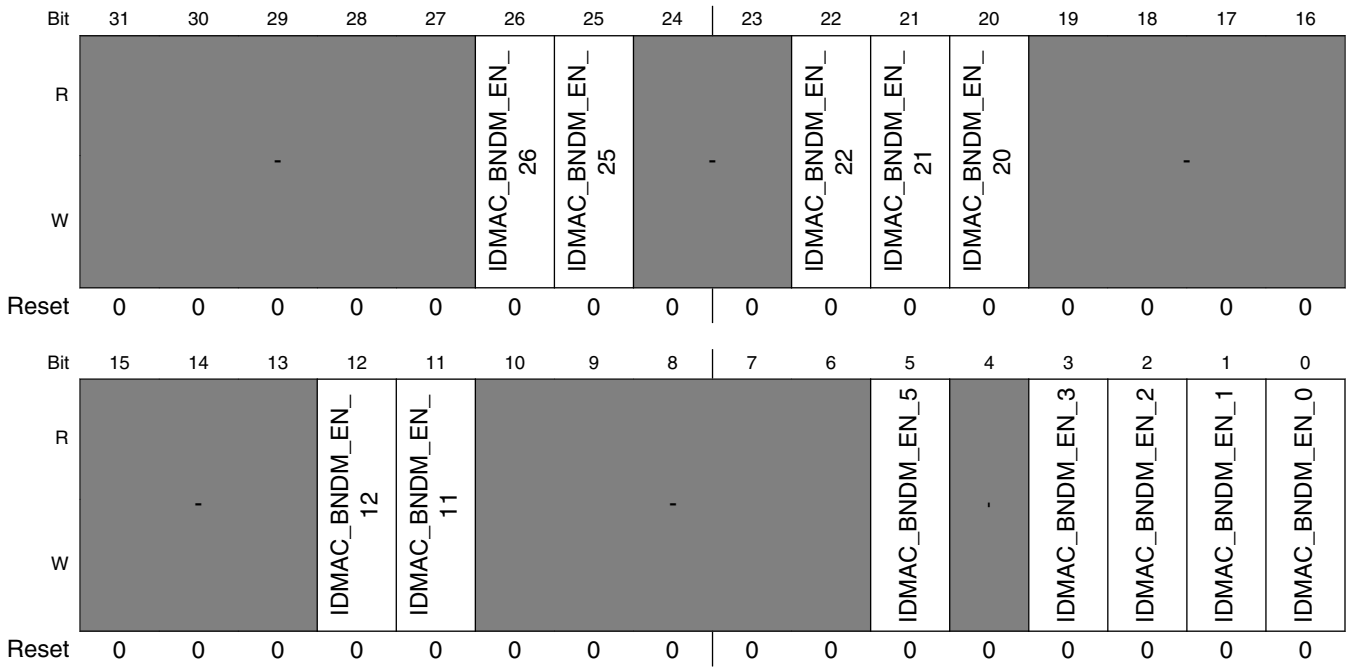


IPU_IDMAC_SUB_ADDR_4 field descriptions

Field	Description
31–23 -	Reserved.
22–16 IDMAC_SUB_ADDR_21	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.
15 -	Reserved.
14–8 IDMAC_SUB_ADDR_8	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.
7 -	Reserved.
6–0 IDMAC_SUB_ADDR_28	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.

45.51.372 IDMAC Band Mode Enable 1 Register (IPU_IDMAC_BNDM_EN_1)

Address: IPU_IDMAC_BNDM_EN_1 is 1E00_0000h base + 80440h offset = 1E08_0440h



IPU_IDMAC_BNDM_EN_1 field descriptions

Field	Description
31–27 -	Reserved.
26 IDMAC_BNDM_EN_26	IDMAC Band Mode Enable bit [i] This bit controls if the channel currently works in band mode. When alternate flow is running via this channel, both the main flow and the alternate flow should have the same band mode configuration. 0 IDMAC channel [i] is not in band mode 1 IDMAC channel [i] is in band mode
25 IDMAC_BNDM_EN_25	IDMAC Band Mode Enable bit [i] This bit controls if the channel currently works in band mode. When alternate flow is running via this channel, both the main flow and the alternate flow should have the same band mode configuration. 0 IDMAC channel [i] is not in band mode 1 IDMAC channel [i] is in band mode
24–23 -	Reserved.

Table continues on the next page...

When alternate flow is running via this channel, both the main flow and the alternate flow should have the same band mode configuration. 0 IDMAC channel [i] is not in band mode 1 IDMAC channel [i] is in band mode
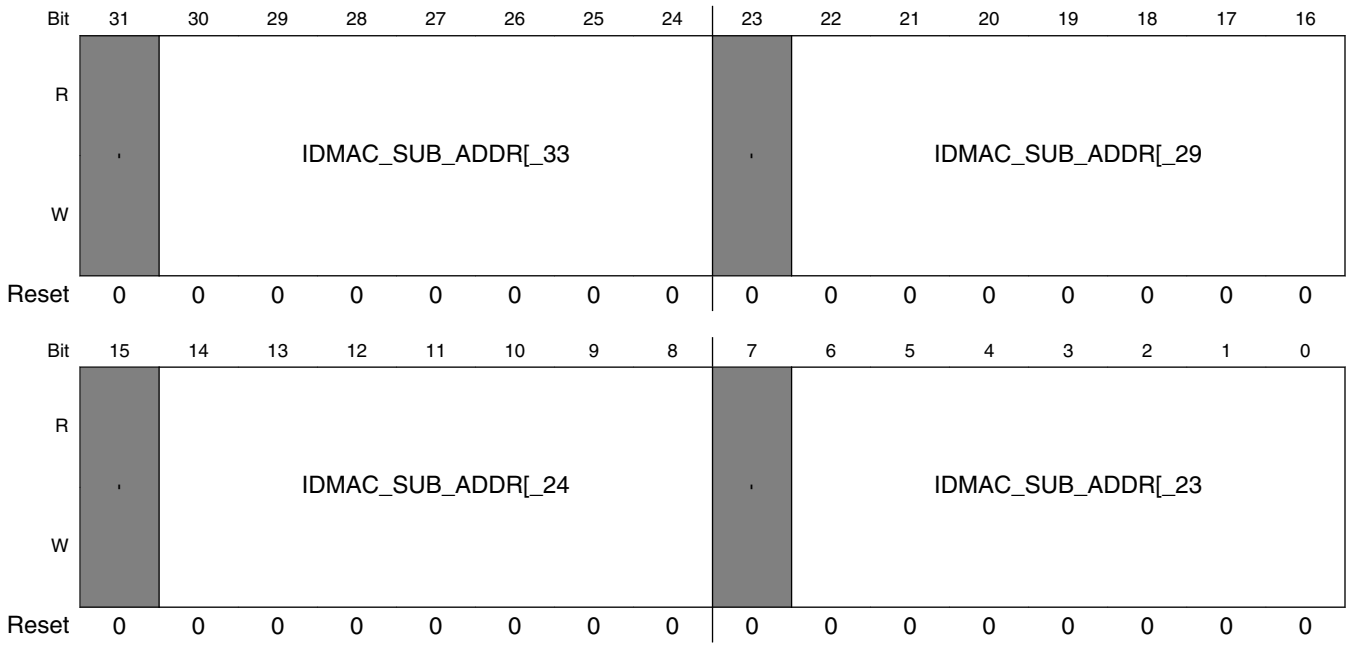
0 IDMAC_BNDM_EN_0	IDMAC Band Mode Enable bit [i] This bit controls if the channel currently works in band mode. When alternate flow is running via this channel, both the main flow and the alternate flow should have the same band mode configuration. 0 IDMAC channel [i] is not in band mode 1 IDMAC channel [i] is in band mode

45.51.373 IDMAC Channel Alternate Address 1 Register (IPU_IDMAC_SUB_ADDR_1)

Address: IPU_IDMAC_SUB_ADDR_1 is 1E00_0000h base + 802C30h offset = 1E80_2C30h



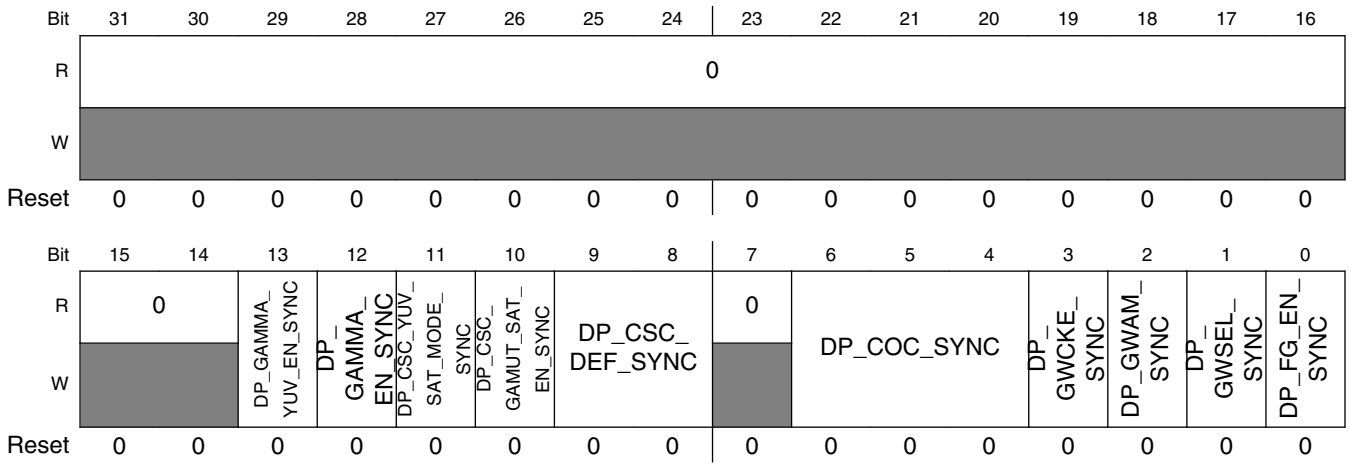
IPU_IDMAC_SUB_ADDR_1 field descriptions

Field	Description
31 -	Reserved.
30–24 IDMAC_SUB_ADDR[_33	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.
23 -	Reserved.
22–16 IDMAC_SUB_ADDR[_29	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.
15 -	Reserved.
14–8 IDMAC_SUB_ADDR[_24	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.
7 -	Reserved.
6–0 IDMAC_SUB_ADDR[_23	The CPMEM alternative entry [i] holds the parameters of the channel that is number appears in IDMAC_SUB_ADDR[i]. The user must set each IDMAC_SUB_ADDR[i] field to a unique channel. Alternative CPMEM entry is relevant only for channels supporting alternate flows.

45.51.374 DP Common Configuration Sync Flow Register (IPU_DP_COM_CONF_SYNC)

This register contains common configuration parameters for the DP.

Address: IPU_DP_COM_CONF_SYNC is 1E00_0000h base + 1040000h offset = 1F04_0000h



IPU_DP_COM_CONF_SYNC field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value zero. Reserved
13 DP_GAMMA_YUV_EN_SYNC	GAMMA's YUV mode enable for sync flow 0 YUV mode is OFF. 1 YUV mode is ON.
12 DP_GAMMA_EN_SYNC	GAMMA_EN - Gamma correction block enable bit 0 disable 1 enable
11 DP_CSC_YUV_SAT_MODE_SYNC	CSC_YUV_SAT_MODE YUV saturation mode for color space conversion 0 Y/U/V range 0 -255 1 Y range 16-235, U/V range 16-240
10 DP_CSC_GAMUT_SAT_EN_SYNC	CSC_GAMUT_SAT_EN Indicate if GAMUT saturation is enabled 0 disable GAMUT mapping 1 enable GAMUT mapping
9–8 DP_CSC_DEF_SYNC	CSC_DEF Enable or disable Color Space Conversion. 00 CSC disable

Table continues on the next page...

IPU_DP_COM_CONF_SYNC field descriptions (continued)

Field	Description
	01 CSC enable after combining 10 CSC enable before combining on BG channel 11 CSC enable before combining on FG channel
7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6–4 DP_COC_SYNC	COC - Cursor Operation Control Controls the format of the cursor and the type of arithmetic operations 000 Transparent, cursor is disabled. 001 Full cursor. 010 Reversed cursor. 011 AND between full plane and cursor. 100 Reserved 101 OR between full plane and cursor. 110 XOR between full plane and cursor. 111 Reserved.
3 DP_GWCKE_ SYNC	GWCKE - Graphic Window Color Keying Enable Enable or disable graphic window color keying. 1 Enable color keying of graphic window 0 Disable color keying of graphic window
2 DP_GWAM_ SYNC	GWAM - Graphic Window Alpha Mode Select the use of Alpha to be global or local. 1 Global Alpha. 0 Local Alpha.
1 DP_GWSEL_ SYNC	GWSEL - Graphic Window Select Select graphic window to be on partial plane or full plane. 1 Graphic window is partial plane. 0 Graphic window is full plane.
0 DP_FG_EN_ SYNC	FG_EN - partial plane Enable. This bit enables the partial plane channel. 1 partial plane channel is enabled. 0 partial plane channel is disabled.

45.51.375 DP Graphic Window Control Sync Flow Register (IPU_DP_Graph_Wind_CTRL_SYNC)

This register contains common configuration parameters for the DP.

Address: IPU_DP_Graph_Wind_CTRL_SYNC is 1E00_0000h base + 1040004h offset = 1F04_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

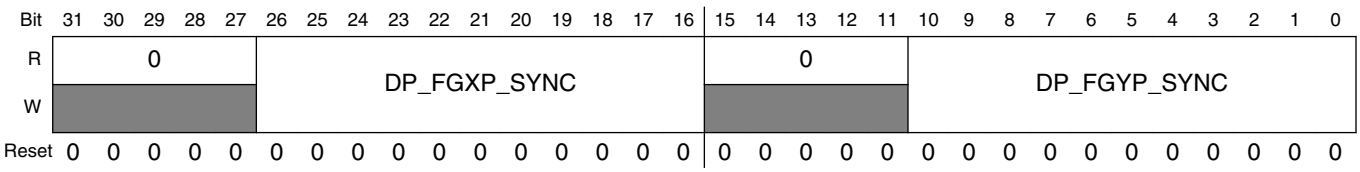
7–0 DP_GWCKB_SYNC	GWCKB - Graphic Window Color Keying Blue Component Defines the blue component of graphic window color keying. 00000000 No blue 11111111 Full blue

45.51.376 DP Partial Plane Window Position Sync Flow Register (IPU_DP_FG_POS_SYNC)

The DP partial plane Window Position Register is used to determine the starting position of the partial plane window relative to BG window position.

This Register is used for the synchronous flow only.

Address: IPU_DP_FG_POS_SYNC is 1E00_0000h base + 1040008h offset = 1F04_0008h



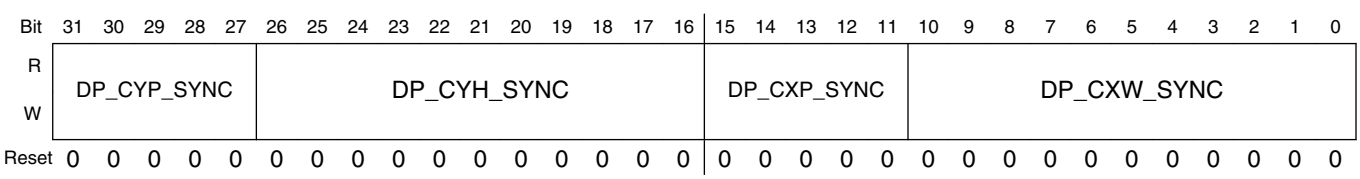
IPU_DP_FG_POS_SYNC field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26–16 DP_FGXP_SYNC	FGXP partial plane Window X Position. partial plane Window X Position - Specifies the number of pixels between the start of full plane window X position and the beginning of the first data of new line.
15–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10–0 DP_FGYP_SYNC	FGYP partial plane window Y position partial plane Window Y Position - Specifies the number of lines between the start of full plane windows Y position and the beginning of the first data.

45.51.377 DP Cursor Position and Size Sync Flow Register (IPU_DP_CUR_POS_SYNC)

The LCD Cursor Position Register is used to determine the starting position of the cursor relative to BG windows position.

Address: IPU_DP_CUR_POS_SYNC is 1E00_0000h base + 104000Ch offset = 1F04_000Ch



IPU_DP_CUR_POS_SYNC field descriptions

Field	Description
31–27 DP_CYP_SYNC	CYP - Cursor Y Position Represents the cursors vertical starting position Y in pixel count (from 0 to CYH).Live View Resolution Mode.
26–16 DP_CYH_SYNC	CYH - Cursor Height Specifies the height of the hardware cursor in pixels.
15–11 DP_CXP_SYNC	CXP - Cursor X Position Represents the cursors horizontal starting position X in pixel count (from 0 to CXW).
10–0 DP_CXW_SYNC	CXW - Cursor Width. Specifies the width of the hardware cursor in pixels.

45.51.378 DP Color Cursor Mapping Sync Flow Register (IPU_DP_CUR_MAP_SYNC)

The LCD Color Cursor Mapping Register defines the color of the cursor in passive or TFT color modes.

Address: IPU_DP_CUR_MAP_SYNC is 1E00_0000h base + 1040010h offset = 1F04_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Chapter 46
Keypad Port (KPP)

46.1 Overview

The Keypad Port (KPP) is a 16-bit peripheral that can be used as a keypad matrix interface or as general purpose input/output (I/O). The figure below shows the KPP block diagram. The KPP provides interface for the keypad matrix with 2-point contact or 3-point contact keys. The KPP is designed to simplify the software task of scanning a keypad matrix. With appropriate software support, the KPP is capable of detecting, debouncing, and decoding one or multiple keys pressed simultaneously on the keypad.

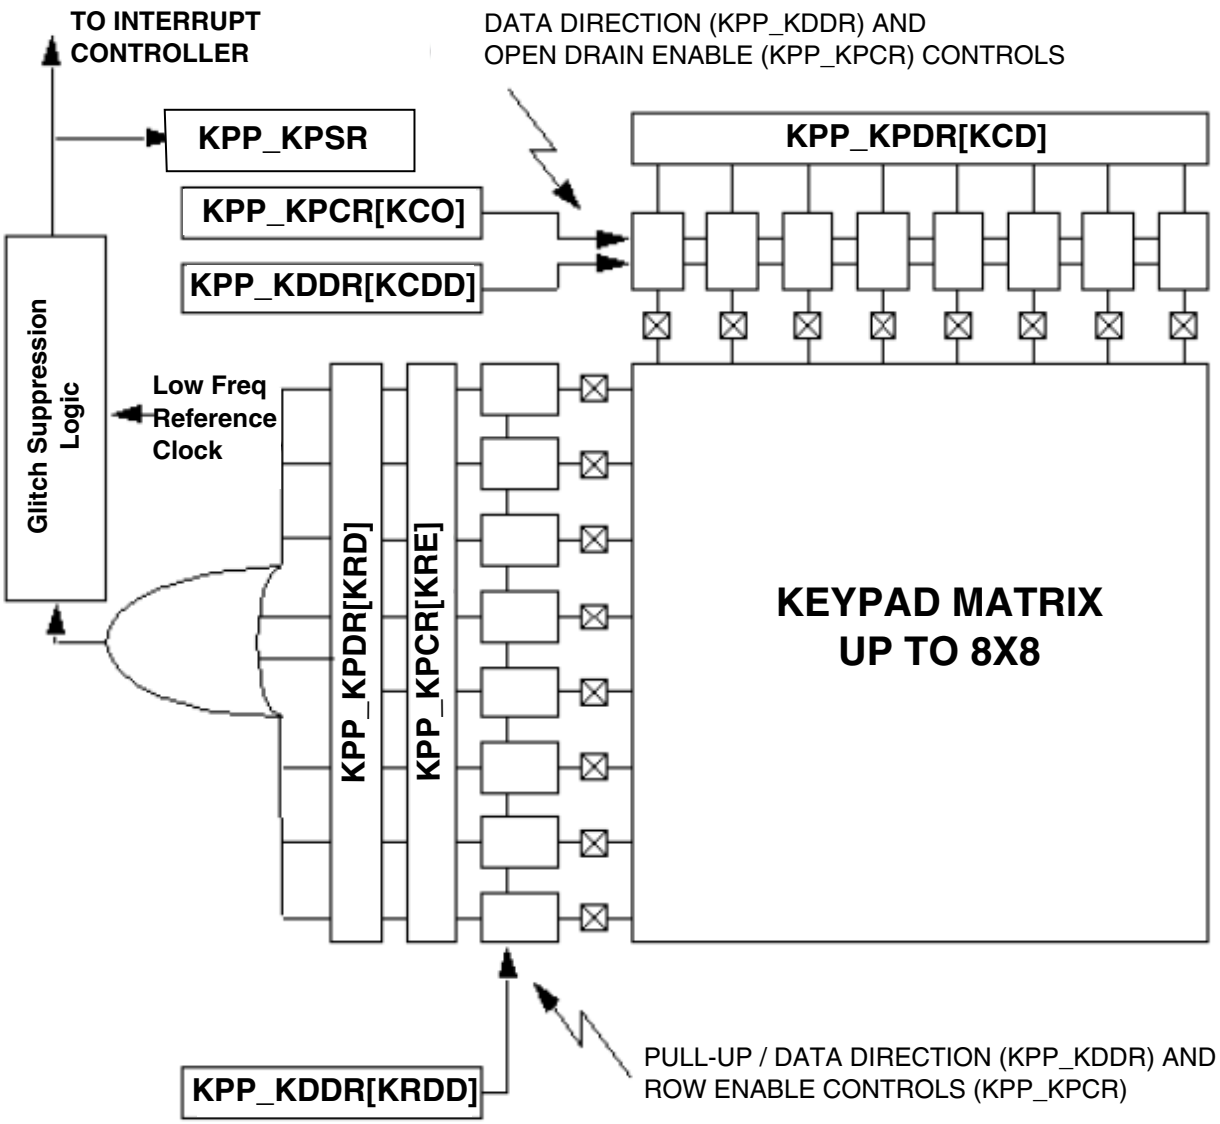

Figure 46-1. KPP Peripheral Block Diagram

46.1.1 Features

The KPP includes these distinctive features:

- Supports up to an 8 x 8 external key pad matrix
- Port pins can be used as general purpose I/O
- Open drain design
- Glitch suppression circuit design
- Multiple-key detection
- Long key-press detection

- Standby key-press detection
- Synchronizer chain clear
- Supports a 2-point and 3-point contact key matrix

46.1.2 Modes and Operations

This block supports the following modes:

- Run Mode-This is the normal functional mode in which the KPP can detect any key press event.
- Low Power Mode-The keypad can detect any key press even in low power modes (when there is no MCU clock).

46.2 External Signals

46.2.1 External Signals Overview

There are 16 pins dedicated to the KPP. Keypads of any configuration up to eight rows and eight columns are supported through the software configuration of the peripheral pins. Any pins not used for the keypad are available as general purpose I/O. The registers are configured such that the pins can be treated as an I/O port up to 16 bits wide.

See the table below for the list of external signals.

Table 46-1. Block Signals

Name	Function	Reset State	Pull up
KPCOL[7:0]	Column input or output pin, from chip	0	Active[1]
KPROW[7:0]	Row input or output pin, from chip	1	Active[2]

1. The corresponding pads are required to be pull-up enabled.
2. The corresponding pads are required to be pull-up enabled.

46.2.1.1 Input Pins

Any of the 16 pins associated with the KPP can be configured as inputs by writing a "0" to the appropriate bits in the KPP_KDDR. Additionally, the least significant 8 bits (ROW inputs) corresponding to KPP_KDDR[KRDD] have internal pull-ups, which are enabled when the pin is used as an input.

46.2.1.2 Output Pins

Any of the 16 pins associated with the KPP can be configured as outputs by writing the appropriate bits in the KPP_KDDR to a "1". Additionally, the 8 most significant bits (15-8) can be designated as open drain outputs by writing a "1" to the appropriate bits in the KPP_KPCR. The lower 8 bits (7-0) are always in "totem pole" style, driven when configured as outputs.

See the table below.

Table 46-2. Keypad Port Column Modes

KPP_KDDR (15:8)	KPP_KPCR (15:8)	Pin Function
0	x	Input
1	0	Totem-Pole Output
1	1	Open-Drain Output

NOTE

Totem pole capability should be provided for column pins. Totem pole configuration helps for a faster discharge of keypad capacitance when all columns need to be quickly brought to a "1" during the scan routine. With this configuration, delay between the scanning of two subsequent columns is reduced.

46.2.1.3 Generation of Transfer Error Signal on Peripheral Bus

If there is an access to an address which is not implemented, then the KPP asserts a transfer error signal on Peripheral Bus.

46.3 Functional Description

The Keypad Port (KPP) is designed to simplify the software task of scanning a keypad matrix. With appropriate software support and matrix organization, the KPP is capable of detecting, debouncing, and decoding one or more keys pressed simultaneously on the keypad.

Logic in the KPP is capable of detecting a key press even while the processor is in one of the low power standby modes provided that a low frequency reference clock is on. The KPP may generate an ARM platform interrupt any time a key press or key release is detected. This interrupt is capable of forcing the processor out of a low power mode.

46.3.1 Keypad Matrix Construction

The KPP is designed to interface to a keypad matrix, which shorts the intersecting row and column lines together whenever a key is depressed. The interface is not optimized for any other switch configuration.

46.3.2 Keypad Port Configuration

The software must initialize the KPP for the size of the keypad matrix. Pins connected to the keypad columns should be configured as open-drain outputs. Pins connected to the keypad rows should be configured as inputs. On-chip, pull-up resistors should be implemented for active keypad rows.

In addition to enabled row inputs in the Keypad Control register, corresponding interrupt (depress or/and release) must also be enabled to generate an interrupt.

Discrete switches that are not part of the matrix may be connected to any unused row inputs. The second terminal of the discrete switch is connected to ground. The hardware detects closures of these switches without the need for software polling.

46.3.3 Keypad Matrix Scanning

Keypad scanning is performed by a software loop that walks a zero across each of the keypad columns, reading the value on the rows at each step. The process is repeated several times in succession, with the results of each pass optionally compared to those

from the previous pass. When several (3 or 4) consecutive scans yield the same key closures, a valid key press has been detected. Software then can decode exactly which switch was depressed and pass the value up to the next higher software layer.

The basic debouncing period, which must be defined in the software routine, may be controlled with an internal timer. The basic period is the period between the scan of two consecutive columns, so the debouncing time between two consecutive scans of the whole matrix shall be the number of columns multiplied by the basic period.

46.3.4 Keypad Standby

There is no need for the ARM platform to continually scan the keypad. Between key presses, the keypad can be left in a state that requires no software intervention until the next key press is detected. To place the keypad in a standby state, software should write all column outputs low. Row inputs are left enabled. At this point, the ARM platform can attend to other tasks or revert to a low power standby mode. The KPP will interrupt the ARM platform if any key is pressed.

Upon receiving a keypad interrupt, the ARM platform should set all the column strobes high, and begin a normal keypad scanning routine to determine which key was pressed. It is important that open-drain drivers be used when scanning to prevent a possible DC path between power and ground through two or more switches.

46.3.5 Glitch Suppression on Keypad Inputs

A glitch suppression circuit qualifies the keypad inputs to prevent noise from inadvertently interrupting the ARM platform. The circuit is a 4-state synchronizer clocked from a low frequency reference clock source.

This clock must continue to run in any low power mode where the keypad is a wake-up source, as the ARM platform interrupt is generated from the synchronized input. An interrupt is not generated until all four synchronizer stages have latched a valid key assertion. This guarantees the filtering out of any noise less than three clock periods in duration of a low frequency reference clock. Noise filtering of the duration between three to four clock periods cannot be guaranteed. The interrupt output is latched in an S-R latch and remains asserted until cleared by the software. The Set input of the latch is rising-edge clocked. See the figure below.

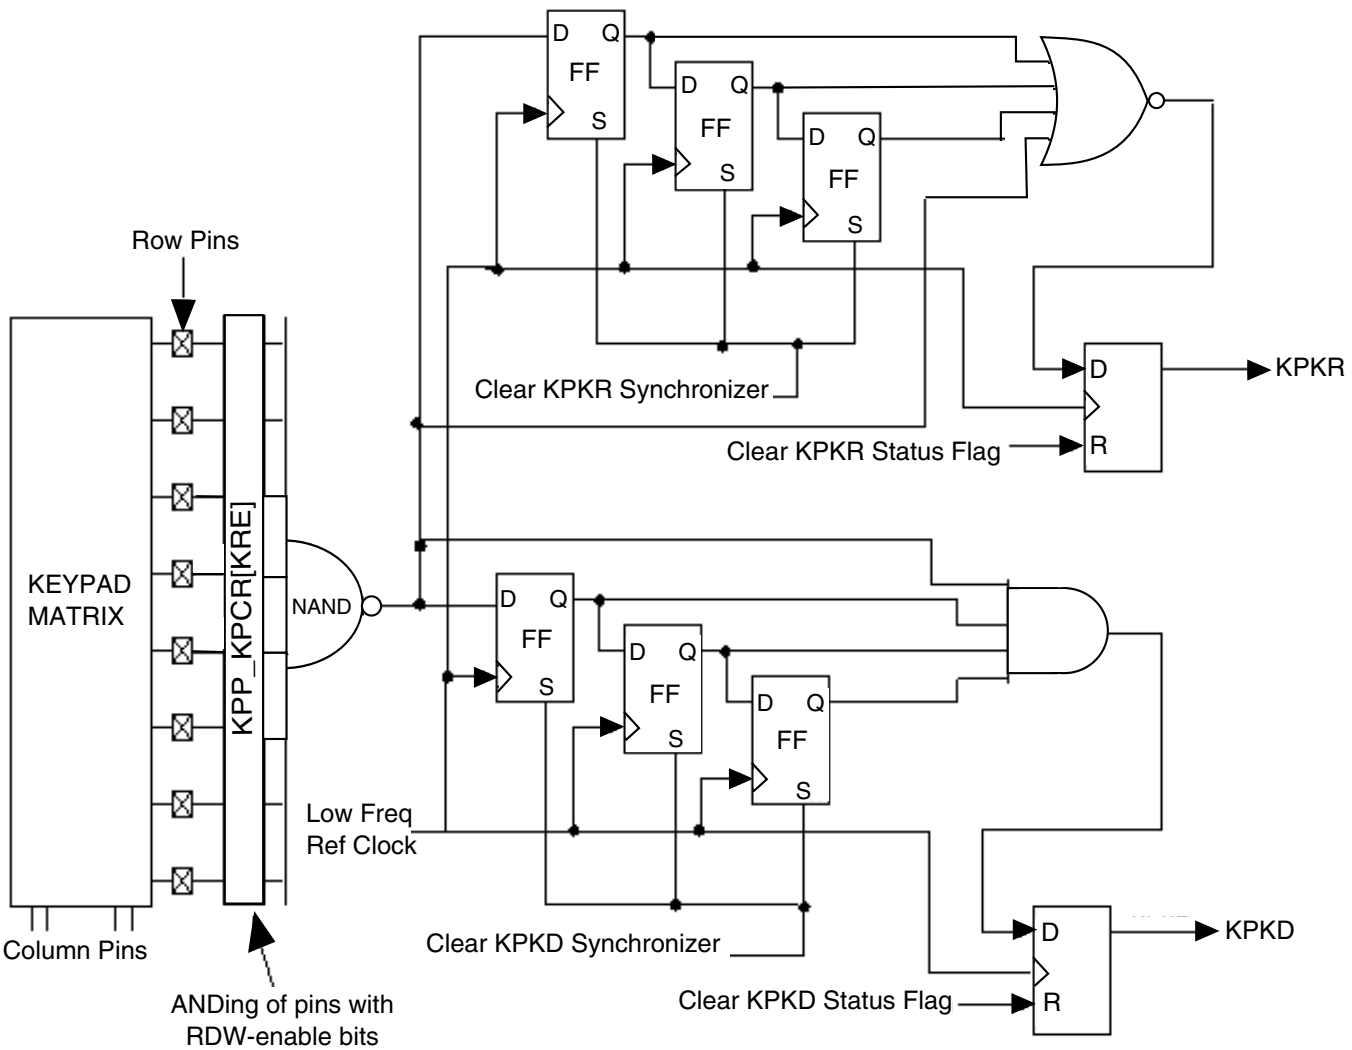

Figure 46-2. Keypad Synchronizer Functional Diagram

46.3.6 Multiple Key Closures

Using the key press and Key release interrupts, the software can detect multiple keys or achieve n key rollover. The key scanning routine can be programmed accordingly.

See the following figures for illustrations of the interfacing of a 2-contact keypad matrix with the KPP controller. With proper enabling of row lines and the performing scan-routine, multiple key presses can be detected. When keys present on the same row are pressed, corresponding row lines (multiple lines) become low when the column is driven low during a scan-routine. By reading the data-register, pressed keys can be detected. Similarly, when keys present on same row line are pressed, the corresponding row line (only one line) becomes low when logic "0" is driven on the column line during a scan-routine.

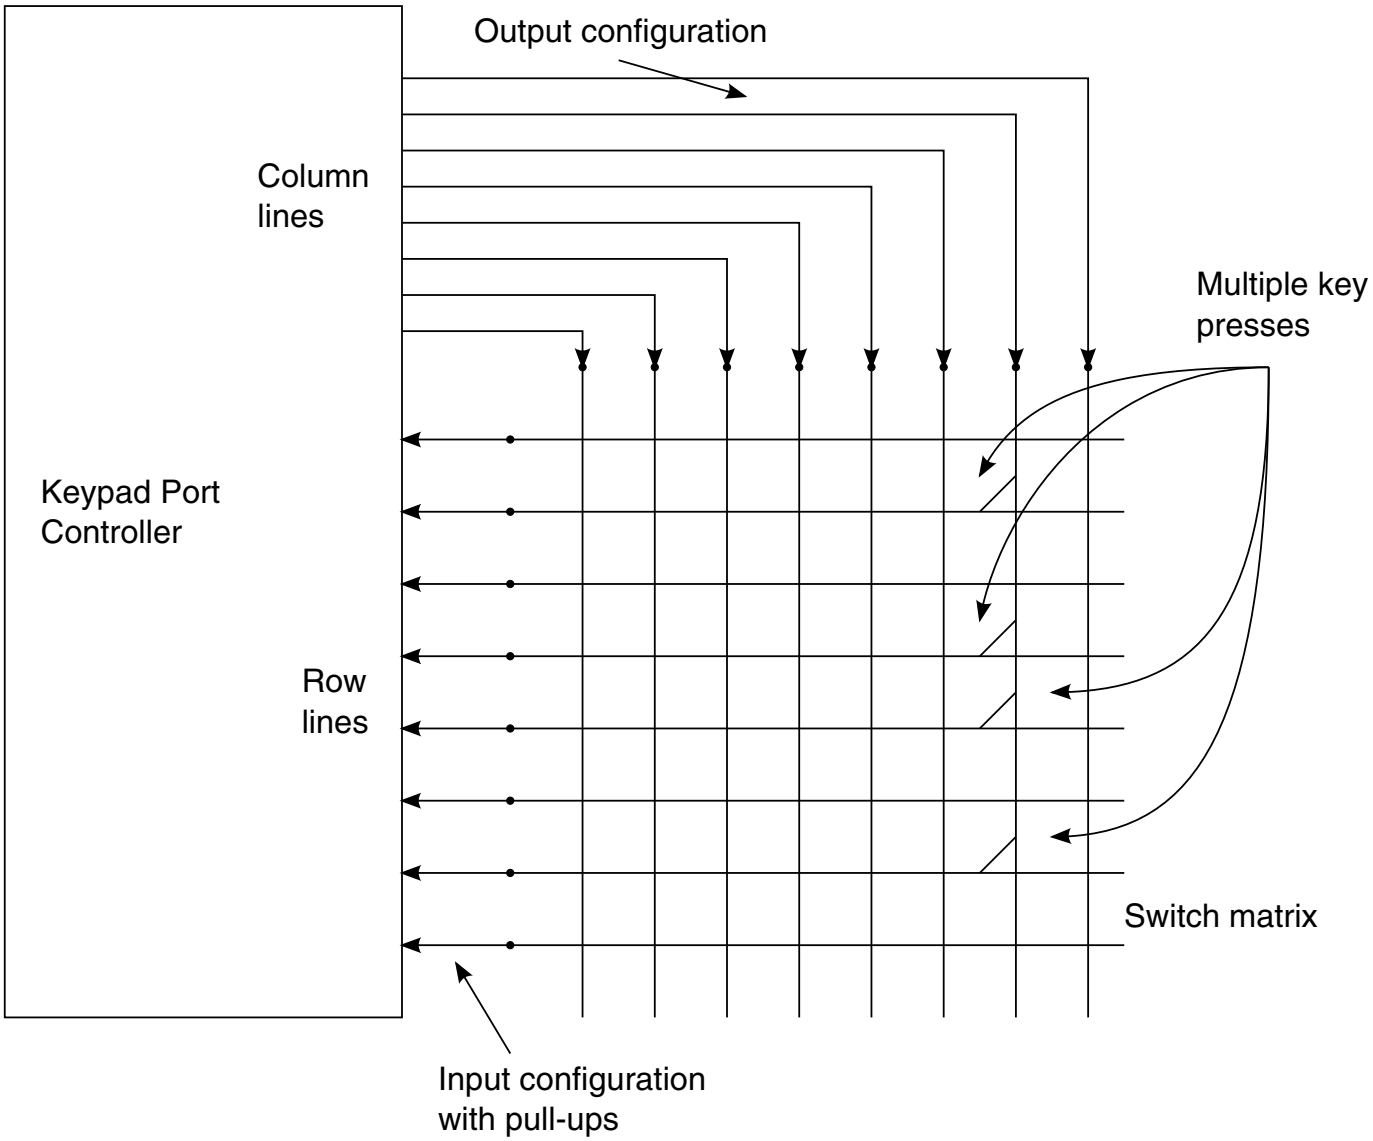

Figure 46-3. Multiple Key Presses on Same Column Line (Simplified View)

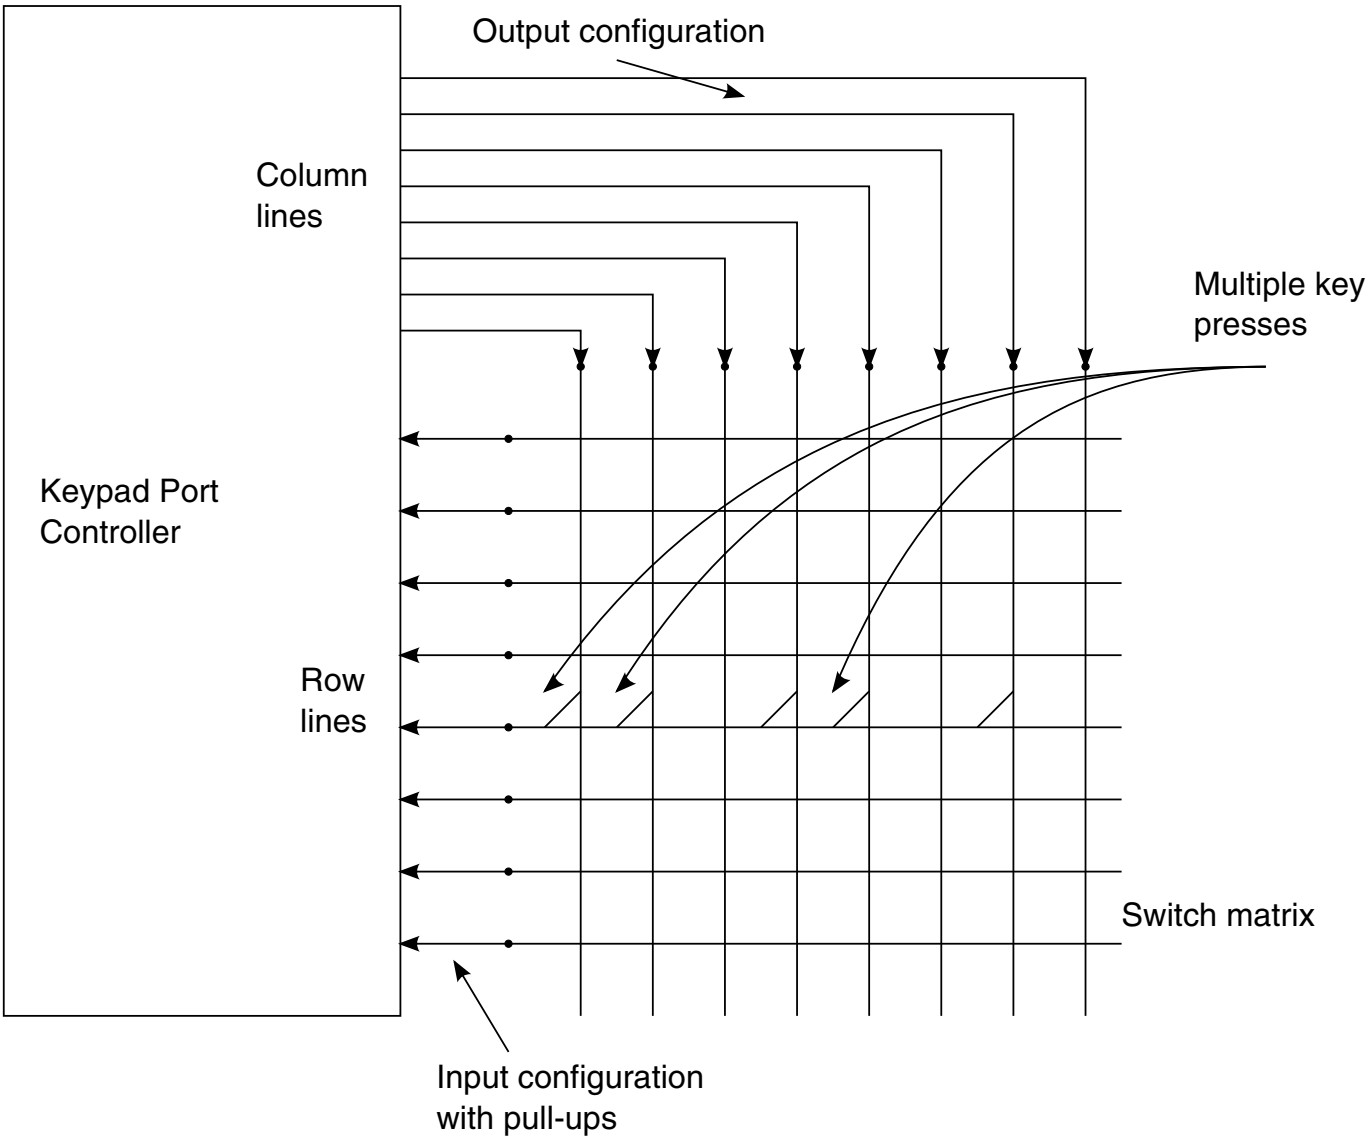

Figure 46-4. Multiple Key Presses on Same Row Line (Simplified View)

NOTE

An n key rollover is a technique with which the system can recognize the order in which keys are pressed.

46.3.6.1 Ghost Key Problem and Correction

The KPP detects if one or multiple keys are pressed or released. In the case where a simple keypad matrix with two-contact switches is used, there is a chance of "ghost" key detection when three or more keys are pressed. This is a limitation imposed by such a keypad matrix.

As can be seen in Figure 46-5, three keys pressed simultaneously can cause a short between the column currently "scanned" by the software and another column. Depending on the location of the third key pressed, a "ghost" key press may be detected.

However, this can be corrected by using a keypad matrix that provides "ghost" key protection. Such a matrix implements a one-way "diode" at all keypad points between rows and columns. This way, the multiple pressing of three keys will not cause a short at a fourth key (see Figure 46-6).

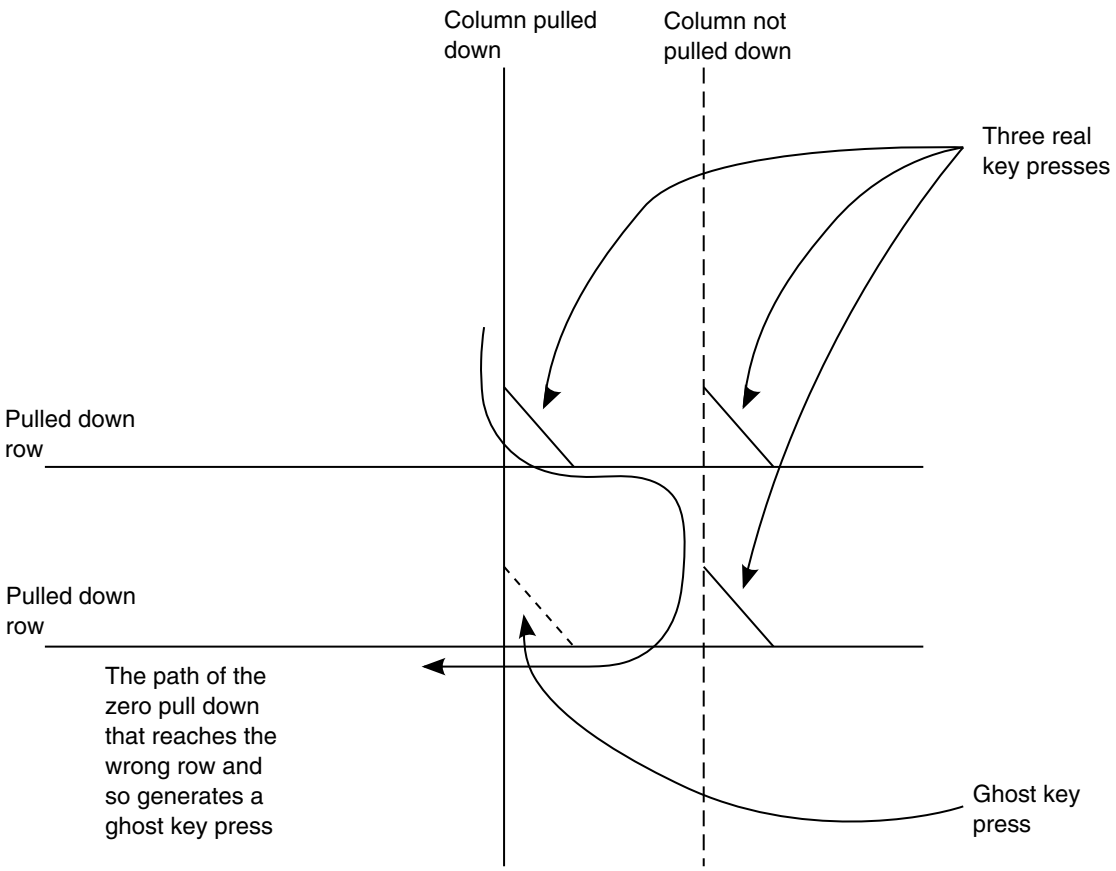

Figure 46-5. Decoding Wrong Three- Key-Presses

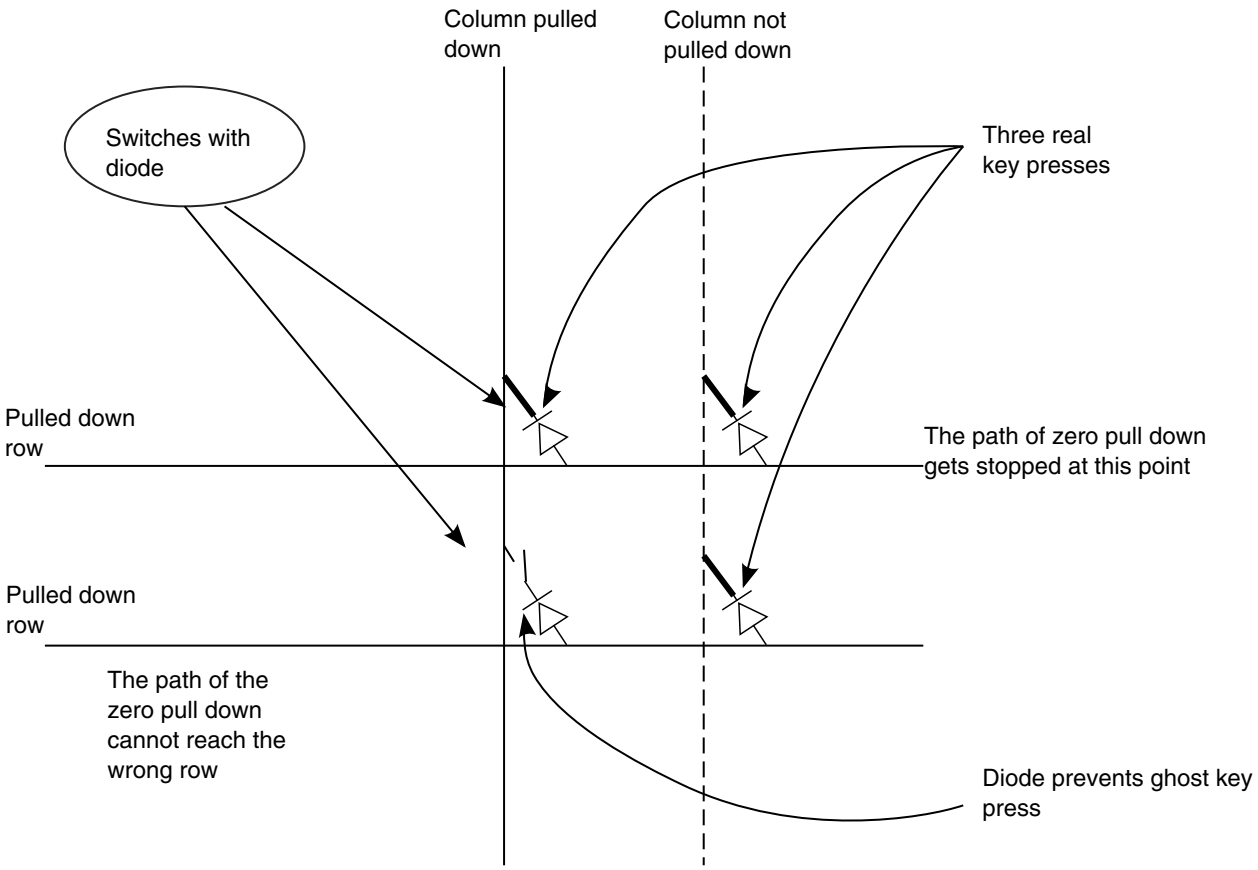

Figure 46-6. Matrix with "Ghost" Key Protections

46.3.7 3-Point Contact Keys Support

The KPP supports interfacing to a matrix consisting of 3-point contact keys. As shown in Figure 46-7, two points of such a key are connected to keypad lines, while a third point is connected to ground (low logic).

The keypad lines should be configured as input and a pull-up should to be present on these lines. When such a key is pressed, corresponding keypad lines go low and an interrupt is generated. There is no need to perform a scanning routine for identification of pressed key as it can be done by reading the keypad data-register. A limitation with such a matrix is that for every key at least one keypad row line should be used.

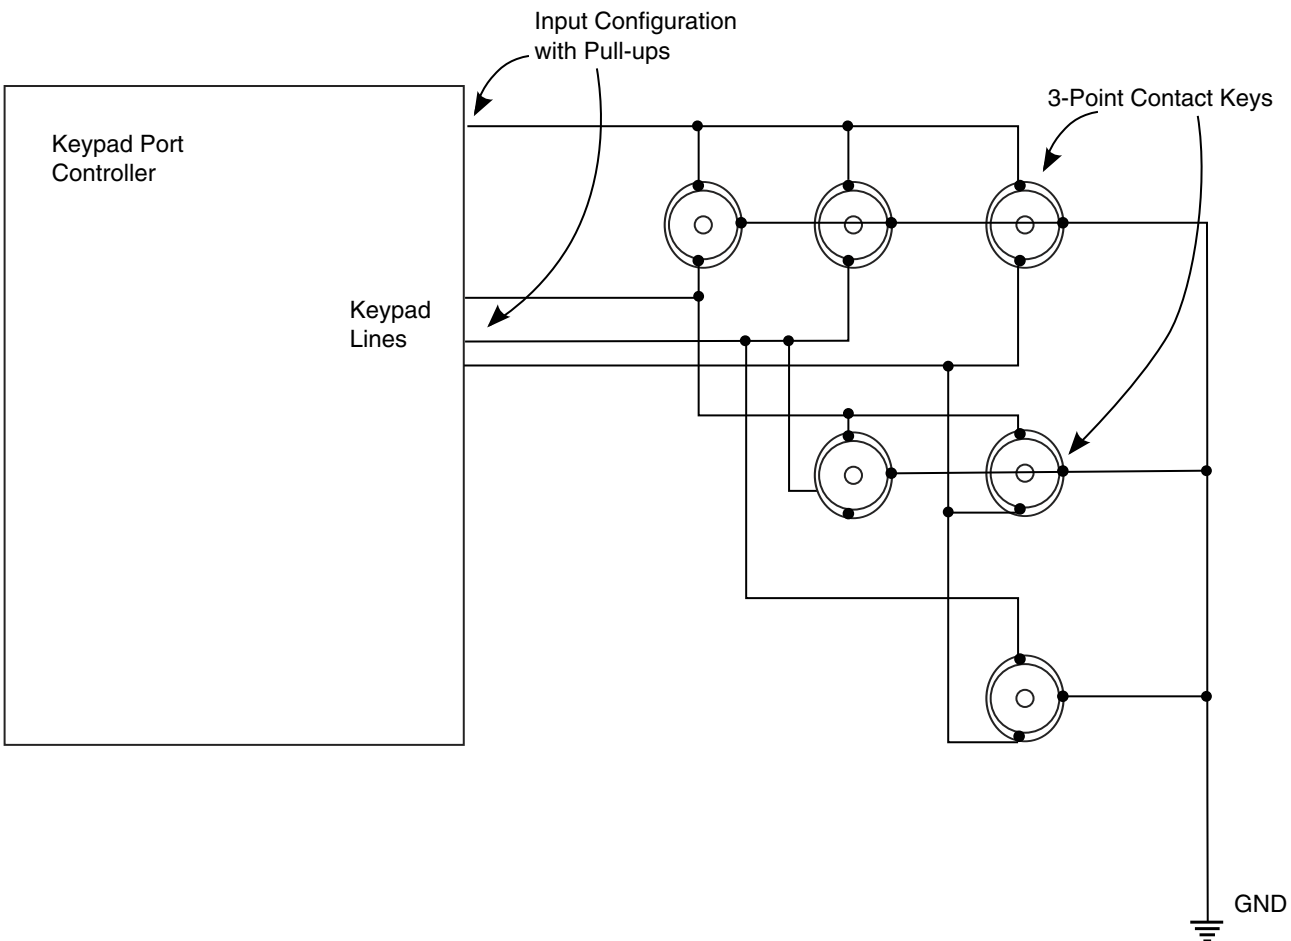

Figure 46-7. KPP Interface with 3-point Contact Key Matrix (Simplified View)

46.4 Initialization/Application Information

46.4.1 Typical Keypad Configuration and Scanning Sequence

Perform the following steps to configure the keypad:

1. Enable the number of rows in the keypad (KPP_KPCR[KRE]).
2. Write 0s to KPP_KPDR[KCD].
3. Configure the keypad columns as open-drain (KPP_KPCR[KCO]).
4. Configure columns as output (KPP_KDDR[KCDD]) and rows as input (KPP_KDDR[KRDD]).
5. Clear the KPKD Status Flag and Synchronizer chain.
6. Set the KDIE control bit, and clear the KRIE control bit (avoid false release events).
7. (The system is now in standby mode, and awaiting a key press.)

46.4.2 Key Press Interrupt Scanning Sequence

Perform the following steps to perform a keypad scanning routine:

1. Disable both (depress and release) keypad interrupts.
2. Write 1s to KPP_KPDR[KCD], setting column data to 1s.
3. Configure columns as totem pole outputs (for quick discharging of keypad capacitance).
4. Configure columns as open-drain.
5. Write a single column to 0, and other columns to 1.
6. Sample row inputs and save data. Multiple key presses can be detected on a single column.
7. Repeat Steps 2-6 for remaining columns.
8. Return all columns to 0 in preparation for standby mode.
9. Clear KPKD and KPKR status bit(s) by writing to a "1"; set the KPKR synchronizer chain by writing a "1" to the KPP_KRSS register; and clear the KPKD synchronizer chain by writing a "1" to the KDSC register.
10. Re-enable the appropriate keypad interrupt(s) so that the KDIE detects a key hold condition, or the KRIE detects a key-release event.

46.4.3 Additional Comments

The order of key press detection can be done in software only. Therefore, the software may need to run the scan routines at very short intervals of time per the application's demands. The reason that such functionality cannot be put in the KPP is that the block is limited by the number of external pins.

For the keys that require a very precise order (such as game keys), individual GPIO pins may be more useful.

46.5 Programmable Registers

The KPP contains four registers.

KPP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53F9_4000	Keypad Control Register (KPP_KPCR)	16	R/W	0000h	46.5.1/ 3427
53F9_4002	Keypad Status Register (KPP_KPSR)	16	R/W	0400h	46.5.2/ 3428
53F9_4004	Keypad Data Direction Register (KPP_KDDR)	16	R/W	0000h	46.5.3/ 3430
53F9_4006	Keypad Data Register (KPP_KPDR)	16	R/W	0000h	46.5.4/ 3430

46.5.1 Keypad Control Register (KPP_KPCR)

The Keypad Control Register determines which of the eight possible column strobes are to be open drain when configured as outputs, and which of the eight row sense lines are considered in generating an interrupt to the core.

It is up to the programmer to ensure that pins being used for functions other than the keypad are properly disabled. The KPP_KPCR register is byte- or half-word-addressable.

Address: KPP_KPCR is 53F9_4000h base + 0h offset = 53F9_4000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read / Write	KCO								KRE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

KPP_KPCR field descriptions

Field	Description
15–8 KCO	Keypad Column Strobe Open-Drain Enable. Setting a column open-drain enable bit (KCO7-KCO0) disables the pull-up driver on that pin. Clearing the bit allows the pin to drive to the high state. This bit has no effect when the pin is configured as an input.

Table continues on the next page...

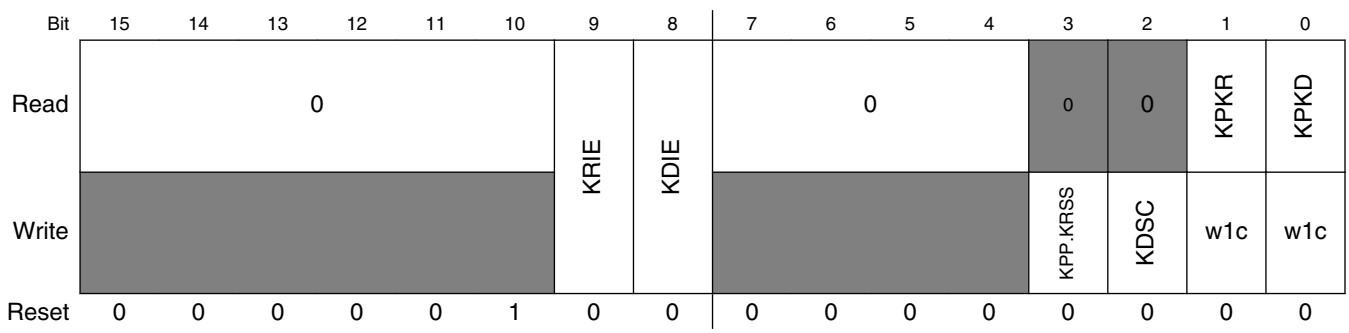
KPP_KPCR field descriptions (continued)

Field	Description
	NOTE: Configuration of external port control logic (for example, IOMUX) should be done properly so that the KPP controls an open-drain enable of the pin. 0 Column strobe output is totem pole drive. 1 Column strobe output is open drain.
7–0 KRE	Keypad Row Enable. Setting a row enable control bit in this register enables the corresponding row line to participate in interrupt generation. Likewise, clearing a bit disables that row from being used to generate an interrupt. This register is cleared by a reset, disabling all rows. The row-enable logic is independent of the programmed direction of the pin. Writing a "0" to the data register of the pins configured as outputs will cause a keypad interrupt to be generated if the row enable associated with that bit is set. 0 Row is not included in the keypad key press detect. 1 Row is included in the keypad key press detect.

46.5.2 Keypad Status Register (KPP_KPSR)

The Keypad Status Register reflects the state of the key press detect circuit. The KPP_KPSR register is byte- or half-word-addressable.

Address: KPP_KPSR is 53F9_4000h base + 2h offset = 53F9_4002h



KPP_KPSR field descriptions

Field	Description
15–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9 KRIE	Keypad Release Interrupt Enable. The software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0 No interrupt request is generated when KPKR is set. 1 An interrupt request is generated when KPKR is set.

Table continues on the next page...

KPP_KPSR field descriptions (continued)

Field	Description
8 KDIE	Keypad Key Depress Interrupt Enable. Software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice-versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0 No interrupt request is generated when KPKD is set. 1 An interrupt request is generated when KPKD is set.
7–4 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared
3 KPP.KRSS	Key Release Synchronizer Set. Self-clear bit. The Key release synchronizer is set by writing a logic one into this bit. Reads return a value of "0". 0 No effect 1 Set bits which sets keypad release synchronizer chain
2 KDSC	Key Depress Synchronizer Clear. Self-clear bit. The Key depress synchronizer is cleared by writing a logic "1" into this bit. Reads return a value of "0". 0 No effect 1 Set bits that clear the keypad depress synchronizer chain
1 KPKR	Keypad Key Release. The keypad key release (KPKR) status bit is set when all enabled rows are detected high after synchronization (the KPKR status bit will be set when cleared by a reset). The KPKR bit may be used to generate a maskable key release interrupt. The key release synchronizer may be set high by software after scanning the keypad to ensure a known state. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by software prior to the system exiting the state it represents. Reset value of register is "0" as long as reset is asserted. However when reset is de-asserted, the value of the register depends upon the external row pins and can become "1". 0 No key release detected 1 All keys have been released
0 KPKD	Keypad Key Depress. The keypad key depress (KPKD) status bit is set when one or more enabled rows are detected low after synchronization. The KPKD status bit remains set until cleared by the software. The KPKD bit may be used to generate a maskable key depress interrupt. If desired, the software may clear the key press synchronizer chain to allow a repeated interrupt to be generated while a key remains pressed. In this case, a new interrupt will be generated after the synchronizer delay (4 cycles of the low frequency reference clock elapses if a key remains pressed. This functionality can be used to detect a long key press. This allows detection of additional key presses of the same key or other keys. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by the software prior to the system exiting the state it represents. 0 No key presses detected 1 A key has been depressed

46.5.3 Keypad Data Direction Register (KPP_KDDR)

The bits in the KPP_KDDR control the direction of the keypad port pins. The upper eight bits in the register affect the pins designated as column strobes, while the lower eight bits affect the row sense pins. Setting any bit in this register configures the corresponding pin as an output. Clearing any bit in this register configures the corresponding port pin as an input. For the Keypad Row DDR, an internal pull-up is enabled if the corresponding bit is clear. This register is cleared by a reset, configuring all pins as inputs. The KPP_KDDR register is byte- or half-word addressable.

NOTE

When a pin is used as row pin for keypad purposes, all corresponding pull-ups should be enabled at the upper level (for example, IOMUX) when the bit in row DDR is cleared.

Address: KPP_KDDR is 53F9_4000h base + 4h offset = 53F9_4004h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read / Write	KCDD								KRDD							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

KPP_KDDR field descriptions

Field	Description
15–8 KCDD	Keypad Column Data Direction Register. Setting a bit configures the corresponding COL*n* pin as an output (where *n* = 7 through 0). 0 COLn pin is configured as an input. 1 COLn pin is configured as an output.
7–0 KRDD	Keypad Row Data Direction. Setting a bit configures the corresponding ROW*n* pin as an output (where *n* = 7 through 0). 0 ROWn pin configured as an input. 1 ROWn pin configured as an output.

46.5.4 Keypad Data Register (KPP_KPDR)

This 16-bit register is used to access the column and row data. Data written to this register is stored in an internal latch, and for each pin configured as an output, the stored data is driven onto the pin. A read of this register returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register.

The KPP_KPDR register is byte- or half-word addressable. This register is not initialized by a reset. Valid data should be written to this register before any bits are configured as outputs.

Address: KPP_KPDR is 53F9_4000h base + 6h offset = 53F9_4006h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	KCD								KRD							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

KPP_KPDR field descriptions

Field	Description
15–8 KCD	Keypad Column Data. A read of these bits returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register. 0 Read/Write "0" from/to column ports 1 Read/Write "1" from/to column ports
7–0 KRD	Keypad Row Data. A read of these bits returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register. 0 Read/Write "0" from/to row ports 1 Read/Write "1" from/to row ports

Chapter 47
LVDS Display Bridge (LDB)

47.1 Introduction

LVDS Display Bridge (LDB) will be used to connect the IPU (Image Processing Unit) to External LVDS Display Interface.

Relevant Standards:

1. ANSI EIA-644-A. Electrical Characteristics of Low Voltage Differential Signaling (LVDS) Interface Circuits.

4. DISM Standard JEIDA-59-1999

Table 47-1. LDB IP Parametric Table

Name	IPU
Function	Connectivity to displays with LVDS interface
External I/O Pins Those are LVDS I/O pads	LVDS Display port: 2 channels. Each channel consists of: • 1 clock pair • 4 data pairs Each pair contains - LVDS special differential pad (PadP, PadM). total of 20 I/O pads.
SoC Buses	None. Only configuration signals.
Interrupts	None
DMA Requests	None
Number of instantiations	1
Clock sources and range	DI0_CLK, DI1_CLK- Display interface clock: 20-150 MHz DI0_SER_CLK, DI1_SER_CLK - Serializer clock: 140-595 MHz

The purpose of the LDB is to support flow of synchronous RGB data from the IPU to external display devices through LVDS interface. This support covers all aspects of these activities:

- Connectivity to relevant devices - Displays with LVDS receivers.
- Arranging the data as required by the external display receiver and by LVDS display standards.
- Synchronization and control capabilities.

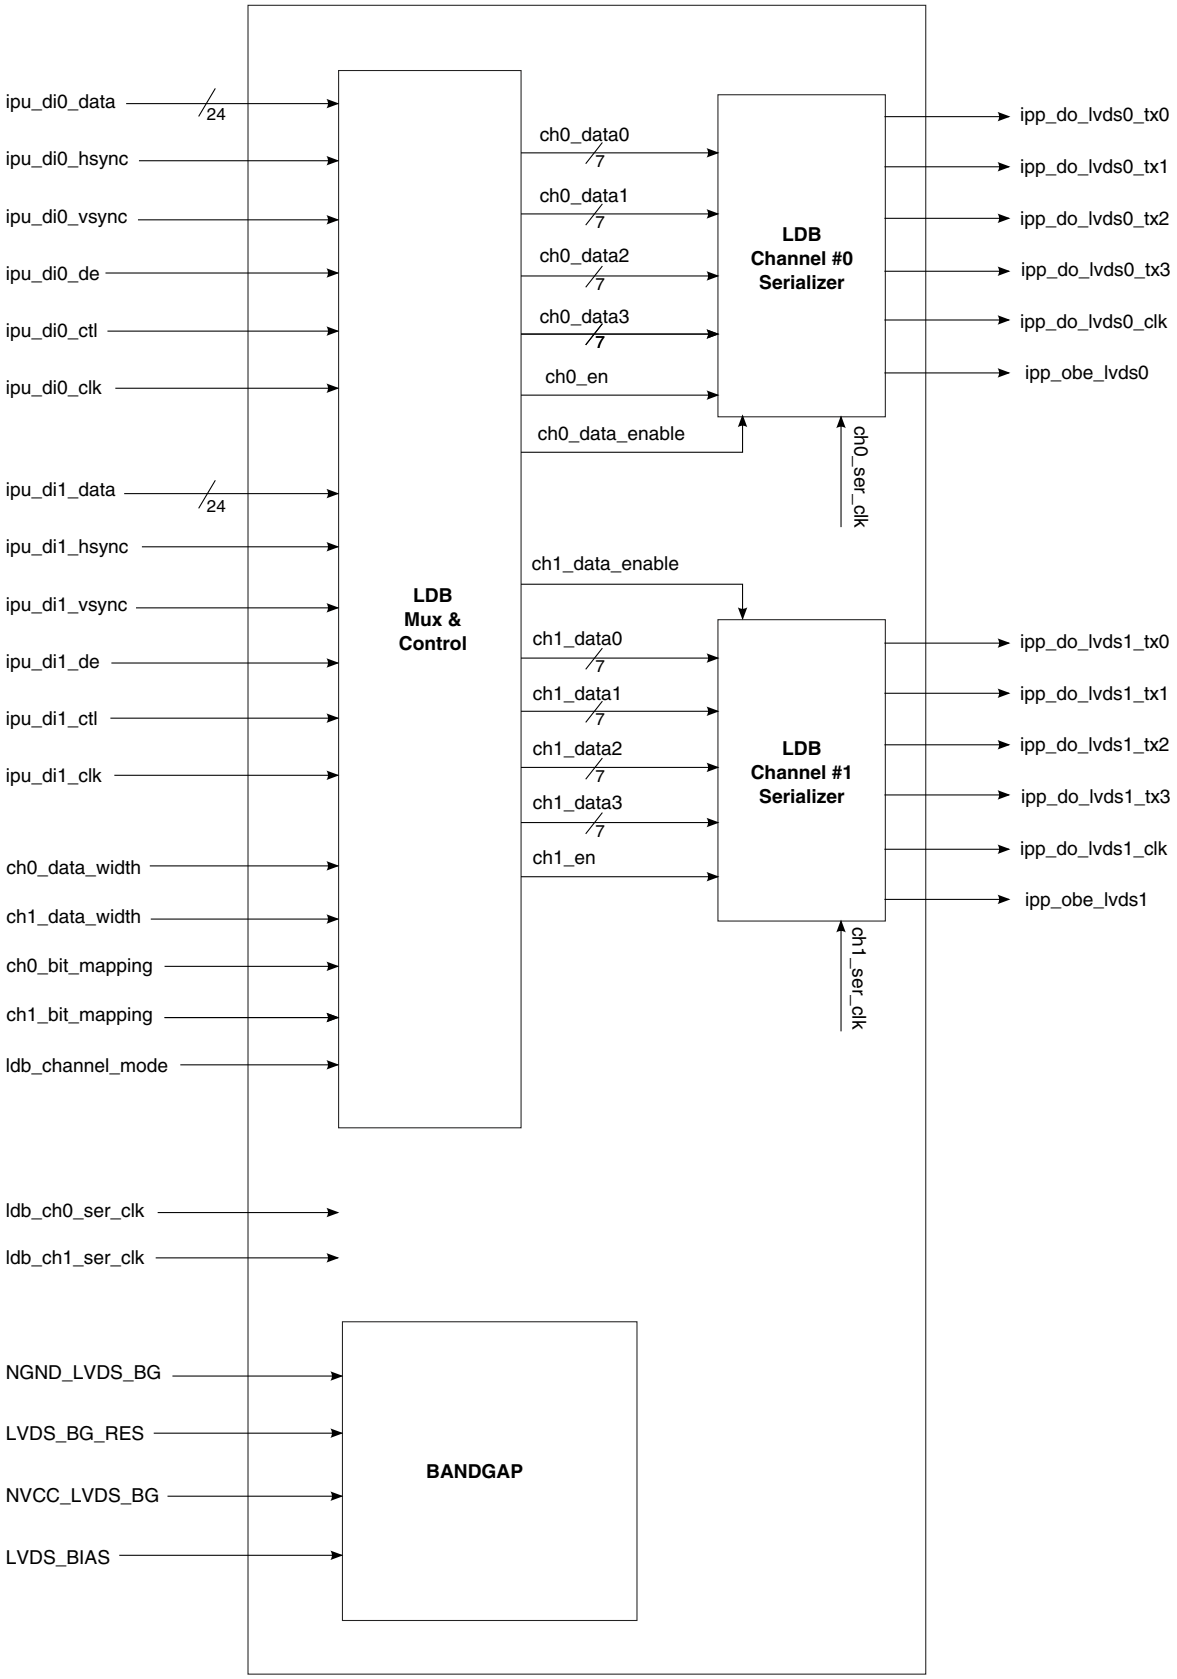

Figure 47-1. LDB - Block Diagram

Table 47-2. LDB - Block Description

Block	Description
LDB mux & control	Gets control signals from SoC and determines parameters of LDB
Channel Serializers	LDB has 2 channel serializers. Each serializer does parallel to serial conversion 7:1 to 3 or 4 data lines
Bandgap	Provides reference current to the LVDS I/O pads.

47.2 External Ports

The LDB has the following ports:

- Two input parallel display ports.
- Two Output LVDS channels - Each channel consisting of 4 data pairs, and 1 clock pair (pair=LVDS pad contains PadP, PadM).
- Control signals - to configure LDB parameters and operations.
- Clocks from SoC DPLLs.

47.2.1 Input Parallel Display Ports

One or Two (DI0, DI1) parallel RGB input ports are supported (configurable). Only synchronous access mode is supported.

Each RGB data interface contains the following:

- RGB Data of 18 or 24 bits
- Pixel clock
- Control signals: HSYNC, VSYNC, DE, and 1 additional optional general purpose control.

Total of up to 28 bits per data interface are transferred per pixel clock cycle.

Rates supported:

- Overall: LDB supports rates needed by WSXGA+ 16:10 aspect ratio (1866 x 1050 @ 60 frames per second, data rate supported up to 150 MHz)
- For single input data intrerface case: Up to 150 MHz pixel clock (WSXGA+ 16:10)
- For dual input data interface case: Up to 85 MHz per interface. (WXGA 1366x768 @ 60 frames per second, 35% blanking).

47.2.2 Output LVDS Ports

There are 2 LVDS channels. These outputs are used to communicate RGB data and controls to external LCD displays.

The LVDS ports may be used as follows:

- Single channel output
- Dual channel output (one input source, two channels outputs for two displays)
- Split channel output (one input source, splitted to 2 channels on output)
- Separate 2 channel output (2 input sources from IPU).

The output LVDS port must comply to 1.

47.3 Clock Sources

Table 47-3. LDB Clock Sources

Name	Symbol	Source	Rate	Comments
IPU DI0 interface pixel clock	DI_0_CLK	Clock control Module	Up to 150 MHz	See note below [1]
IPU DI1 interface pixel clock	DI_1_CLK	Clock control Module	Up to 150 MHz	This input also goes to IPU DI1 as input. See note below
CH0 interface serializer clock	CH0_SERIAL_CLK	Clock control Module	Up to 595 MHz	This is x7 the rate of the DI0 interface pixel clock. See note below.
CH1 interface serializer clock	CH1_SERIAL_CLK	Clock control Module	Up to 595 MHz	This is x7 the rate of the DI1 interface pixel clock. See note below

1. In case of single-channel or separate-channels use-case, the IPU DI_CLK is identical to the LVDS DI_CLK. In case of dual-channel use-case, the IPU DI_CLK has x2 higher frequency than that of the LVDS DI_CLK. Still both need to be synchronized

47.4 Processing

LDB data processing stages are as follows:

- Receive input data from 1 or 2 (configurable) parallel input interfaces. 18/24 RGB data + up to 4 controls and map them to LVDS channels.
  - If needed (dual-channel) split the input bus to two half-rate busses.
- Re-arrange the input data according to channel configuration, and muxing scheme.
- Serialize the 22/28 bit input bus (per channel) on 3-4 output serial data lines (7:1)

47.4.1 Mapping of Input Data Busses

Mapping of Parallel input interfaces (DI0, DI1) to output LVDS channels (Channel 0, Channel 1). See Table 47-2.

Table 47-4. Channel Mapping

Use Case	LVDS Channel 0	LVDS Channel 1
Single Channel DI0	DI0	Disabled
Single Channel DI1 on Channel 1	Disabled	DI1
Separate Channels	DI0	DI1
Dual Channels DI0	DI0	DI0
Dual Channels DI1	DI1	DI1
Split Channel DI0	DI0 (first pixel)	DI0 (second pixel)
Split Channel DI1	DI1 (first pixel)	DI1 (second pixel)

47.4.2 Bit Mapping

LDB supports two mapping standards:

- SPWG mapping
- JEIDA mapping

Table 47-5. SPWG/PSWG/VESA 18/24 bpp Data Mapping

Serializer input	Slot 0	Slot 1	Slot 2	Slot 3	Slot 4	Slot 5	Slot 6
CHx_DATA0	G0	R5	R4	R3	R2	R1	R0
CHx_DATA1	B1	B0	G5	G4	G3	G2	G1
CHx_DATA2	DE	VS	HS	B5	B4	B3	B2
CHx_DATA3 (for 24 bpp only)	CTL	B7	B6	G7	G6	R7	R6

Table 47-6. JEIDA 24bpp Data Mapping

Serializer input	Slot 0	Slot 1	Slot 2	Slot 3	Slot 4	Slot 5	Slot 6
CHx_DATA0	G2	R7	R6	R5	R4	R3	R2
CHx_DATA1	B3	B2	G7	G6	G5	G4	G3
CHx_DATA2	DE	VS	HS	B7	B6	B5	B4
CHx_DATA3	CTL	B1	B0	G1	G0	R1	R0

NOTE

Several options of control usage can be available. some display devices use only DE, some others use all 3 controls, some use only HS, VS. "CTL" is an optional general purpose control which is usually unused by display.

47.5 Programmable Registers

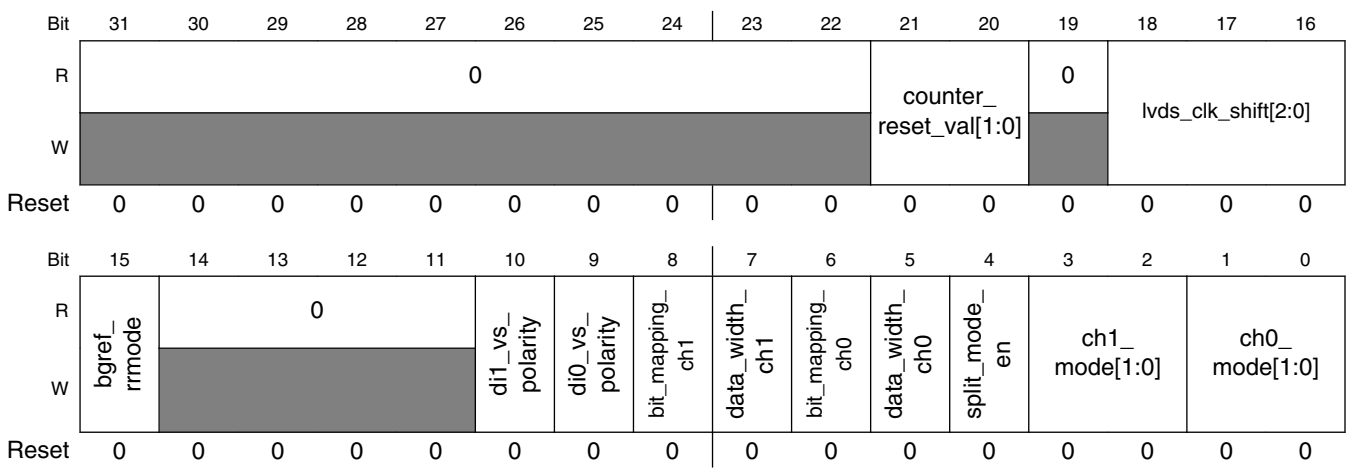
LDB memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53FA_8008	LDB Control Register (LDB_CTRL)	32	R/W	0000_0000h	47.5.1/ 3439

47.5.1 LDB Control Register (LDB_CTRL)

The register is implemented in the IOMUX Controller block (IOMUXC), as the register IOMUXC_GPR2.

Address: LDB_CTRL is 53FA_8008h base + 0h offset = 53FA_8008h



LDB_CTRL field descriptions

Field	Description
31–22 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

LDB_CTRL field descriptions (continued)

Field	Description
21–20 counter_reset_val[1:0]	Reset value for the LDB counter which determines when the shift registers are loaded with data. **NOTE:** Used for debug purposes only. In normal functional operation must be '00' 00 Reset value is 5 01 Reset value is 3 10 Reset value is 4 11 Reset value is 6
19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18–16 lvds_clk_shift[2:0]	Shifts the LVDS output clock in relation to the data. **NOTE:** Used for debug purposes only. In normal functional operation must be '000' 000 Output clock is '1100011' (normal operation) 001 Output clock is '1110001' 010 Output clock is '1111000' 011 Output clock is '1000111' 100 Output clock is '0001111' 101 Output clock is '0011111' 110 Output clock is '0111100' 111 Output clock is '1100011'
15 bgref_rrmode	Select reference resistor for bandgap 0 External resistor of 29kOhm is selected 1 Internal resistor is selected
14–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10 di1_vs_polarity	Vsync polarity for IPU's DI1 interface. 0 ipu_di1_vsync is active high. 1 ipu_di1_vsync is active low.
9 di0_vs_polarity	Vsync polarity for IPU's DI0 interface. 0 ipu_di0_vsync is active high. 1 ipu_di0_vsync is active low.
8 bit_mapping_ch1	Data mapping for LVDS channel 1. 0 Use SPWG standard. 1 Use JEIDA standard.
7 data_width_ch1	Data width for LVDS channel 1. **NOTE:** This bit must be set when using JEIDA standard (bit_mapping_ch1 is set) 0 Data width is 18 bits wide (lvds1_tx3 is not used) 1 Data width is 24 bits wide.
6 bit_mapping_ch0	Data mapping for LVDS channel 0.

Table continues on the next page...

LDB_CTRL field descriptions (continued)

Field	Description
	0 Use SPWG standard. 1 Use JEIDA standard.
5 data_width_ch0	Data width for LVDS channel 0. **NOTE:** This bit must be set when using JEIDA standard (bit_mapping_ch0 is set) 0 Data width is 18 bits wide (lvds0_tx3 is not used) 1 Data width is 24 bits wide.
4 split_mode_en	Enable split mode. **NOTE:** In this mode both channels should be enabled and working with the same DI (ch0_mode and ch1_mode should both be either '01' or '11') 0 Split mode is disabled. 1 Split mode is enabled.
3–2 ch1_mode[1:0]	LVDS channel 1 operation mode 00 Channel disabled. 01 Channel enabled, routed to DI0 10 Channel disabled. 11 Channel enabled, routed to DI1.
1–0 ch0_mode[1:0]	LVDS channel 0 operation mode 00 Channel disabled. 01 Channel enabled, routed to DI0 10 Channel disabled. 11 Channel enabled, routed to DI1.

Chapter 48
Low-Dropout Regulator (LDO)

48.1 Introduction

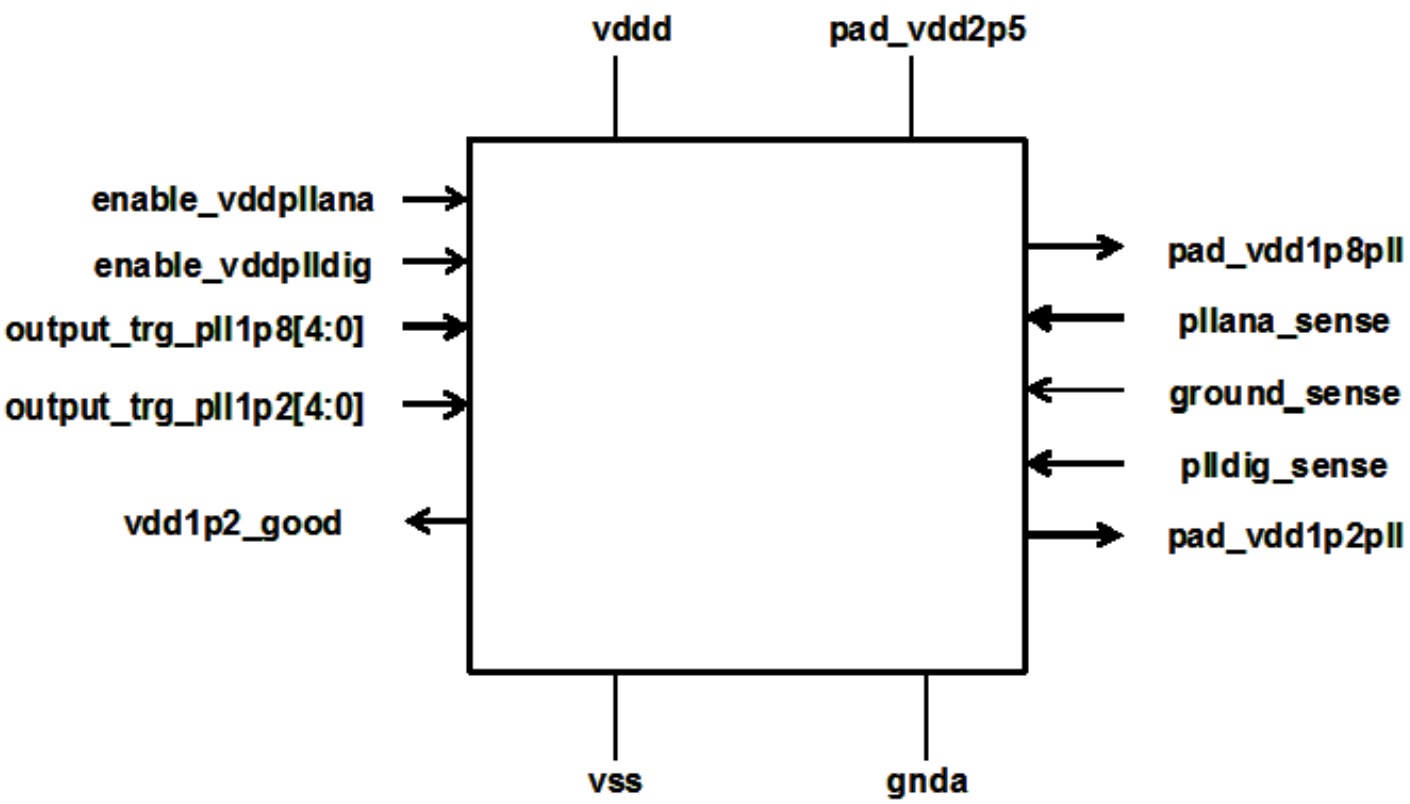


Figure 48-1. LDO Block Diagram

48.1.1 Overview

The LDO is an integrated 1.8 V/1.2 V linear regulator.

48.2 Features

The LDO includes the following list of features:

- Integrated 1.8 V/1.2 V linear regulators with independent controls
- Integrated bandgap reference for stable output voltage over process, temperature and voltage conditions
- Typical quiescent current consumption with everything enabled:
  - Analog 2.5 V Iddq = 0.5 mA
  - Digital 1.2 V Iddq = 0.2 uA
- Power-down current with everything disabled:
  - Analog 2.5 V Iddq = 8 uA
  - Digital 1.2 V Iddq = 0.2 uA

48.3 1.2 V Regulator (plldig) Specifications

- Input supply is 2.5 V±5%.
- 5-bit programmable output voltage in 25 mV steps: nominal output voltage is 1.2 V (0.9 V min 1.4 V max)
- Designed to provide a minimum of 250 mA output current under WCS conditions and nominal output voltage of 1.2 V
- DC output voltage stability is 3% over the ±5% input supply range and -40°C to 125°C junction temperature range.
- Minimum 22 uF external capacitor

48.4 1.8 V Regulator (pllana) Specification

- Input supply is 2.5V±5%
- 5-bit programmable output voltage in 25 mV steps: nominal output voltage is 1.8 V (1.5 V min 2.275 V max)
- Designed to provide a minimum of 75 mA output current under WCS conditions and nominal output voltage of 1.8 V
- DC output voltage stability is 3% over the ±5% input supply range and -40°C to 125°C junction temperature range
- Minimum 22 uF external capacitor

48.5 Register Definition

The 1.2V and 1.8V supply voltage are controllable via software. The 5-bit programming fields are implemented in the IOMUXC in the IOMUXC_GPR1 register.

Table 48-1. Configurable Output Voltage Bits

PLL1P8_VREG[4:0]	Defines the output for voltage regulators. For the 1.8 V regulator: 0x00 = 1.5 V and 0x1F = 2.275 V in 25 mV steps. This puts the reset value for 1.8 V at 0x0C
PLL1P2_VREG[4:0]	Defines the output for voltage regulators. For the 1.2 V regulator: 0x00 = 0.8 V and 0x1F = 1.575 in 25 mV steps. This puts the reset value for 1.2 V at 0x10.

Chapter 49
Multi Master Multi Memory Interface (M4IF)

49.1 Introduction

The Multi-Master Multi Memory Interface (M4IF) controls memory accesses from one or more masters through various port interfaces to external memory controllers (ESDCTL, NFC, and EIM), and to two internal memories in the system. The M4IF block diagram is shown in Figure 49-1.

49.1.1 Overview

M4IF is the external memory controller's (EXTMC) interconnect between system masters and external or internal memory controllers. M4IF is responsible for major functions in EXTMC. It contains the heart of arbitration logic for the memory interfaces. It contains the write and read buffers to support best performance data flow with minimum latency. It contains AXI port gaskets for each master. It manages the AXI access type and transfers it to the arbitration logic. From the arbitration, it moves on to a dedicated memory controller.

M4IF is capable of handling several AXI accesses of different types. In addition, all of EXTMC's handshake protocols with the SoC, such as Low Power Mode entry and DVFS, are handled by M4IF. M4IF interfaces between the SoC's requests and the internal logic, including memory controllers limitations.

M4IF contains the following sub-blocks:

49.1.1.1 AXI Port Gasket

This is the EXTMC interface to AXI masters. M4IF contains 8 AXI port gaskets. This samples the access signals, address and controls into a FIFO and sorts the accesses to their appropriate channels - fast, slow, internal1 memory or internal2 memory channels. The gasket controls the AXI interface and complies with the AXI bus protocol.

49.1.1.2 Dedicated Write Buffers

Each AXI port gasket (master) has a dedicated write buffer. Write data from a master is sampled in the buffer and later transferred to the memory controller upon request. The write buffer size varies from master to master.

49.1.1.3 Read Shared Buffers

The read shared buffer serves all 8 AXI ports. M4IF contains 4 read buffers, one for each channel: slow, fast, internal1 and internal2 memory channel. The data from the memory controller is written to the read buffer. The gasket provides the data back to the master when necessary. Current design configuration supports buffer size of 512Bytes (data only) for fast arbitration, 256Bytes (data only) for slow, and 128Bytes (data only) for internal 1 memory and internal 2 memory arbitration.

For exact buffer sizes please refer to Buffers Size Table.

49.1.1.4 Fast Arbiter

The Fast Arbiter arbitrates master's accesses to the enhanced SDRAM controller (ESDCTL) by using very comprehensive information to optimize accesses to the ESDCTL. It takes into account parameters such as page hit/miss, read/write access etc. If needed, the effect of this additional information can be disabled and the arbitration will function in a fixed priority mode, based on the user defined priority. More details on the dynamic priority arbitration can be found in the functional description section. Fast Arbiter Functional Description - 1st Degree.

49.1.1.5 Slow Arbiter

The Slow Arbiter arbitrates between the masters using a pre-defined bus division. It then sends the accesses to the external interface module (EIM) and NAND Flash Controller (NFC). The division is configurable with high resolution. Further details will be provided in Arbitration Scheme when Masters have Same Priority (Bus Division).

49.1.1.6 Internal 1 Memory Arbiter

The Internal 1 Arbiter arbitrates between the masters using a pre-defined bus division. It then sends the accesses to the internal RAM1 memory controller. The division is configurable with high resolution. Further details will be provided in Arbitration Scheme when Masters have Same Priority (Bus Division).

49.1.1.7 Internal 2 Memory Arbiter

The Internal 2 Arbiter arbitrates between the masters using a pre-defined bus division. It then sends the accesses to the internal RAM2 memory controller. The division is configurable with high resolution. Further details will be provided in Arbitration Scheme when Masters have Same Priority (Bus Division).

49.1.1.8 Debug Unit-Overview

The Debug Unit gives the ability to monitor several internal important EXTMC signals, in order to have better debug capability. It is recommended that these signals be routed out of the chip based on SoC debug definition. In addition, the debug unit would give the option to do a profiling of the arbitration unit of each channel. In that case the user would be able to trace its master bus performance and to fine-tune the arbitration's parameters. The debug unit contains several registers, so that the information can be read from the registers, observed on the pads, or analyzed by the profiling unit data. The debug unit is described in detail in the functional section.

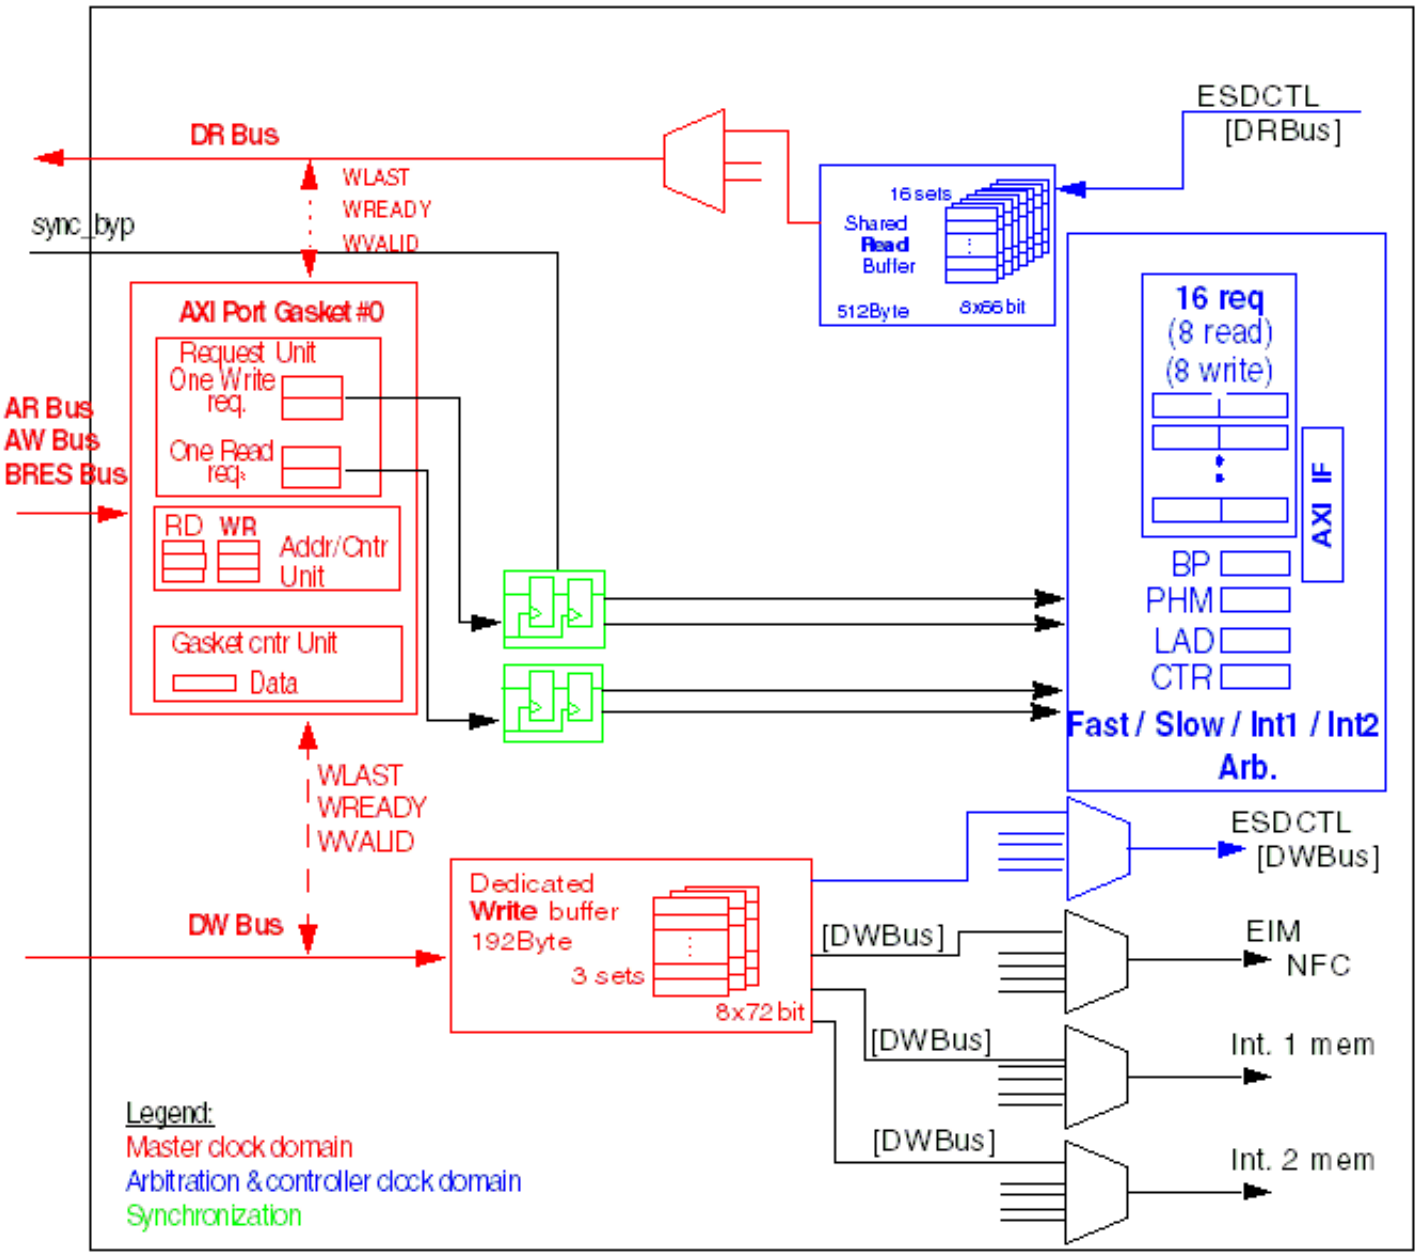

Figure 49-1. M4IF detailed block diagram

49.1.2 Features

The M4IF includes the following features:

- Supports multiple requests from up to 8 masters through different input ports interfaces. Each port can support either of the following two data width options:
  - x32 AXI port.
  - x64 AXI port.

- Arbitrates any master access to 5 main memory controllers, ESDCTL, EIM, NFC, internal 1 salve 0 / slave 1 memory controller and internal 2 memory controller at system level.
- Supports different asynchronous master clock domains for each AXI port, using synchronization system with bypass configuration option in case clocks are aligned and balanced.
- Supports memory watermark protection for up to 2 different chip selects (2 of ESDCTL for preselected masters).
  - Configurable two WM configurations, for two separate masters/domains.
  - Configurable protected memory region (base address with 4 KB resolution) for each one of the watermark memory regions.
  - DDR protected regions must not cross 256MByte boundary.
  - One status bit for each memory region that indicates security violation.
  - Maskable watermark interrupt generation capability in case of security violation for the two WM configurations.
- Separate read and write data buffers for better performance and minimum latency.
- Separate arbitration logic for fast memory interfaces - ESDCTL, slow memory interfaces - EIM & NFC, internal 1 slave 0 / slave 1 memory interfaces and for internal 2 memory interfaces like internal ROM and RAM.
- Separate clocks for each arbiter as mentioned above.
- Enhanced arbitration scheme for fast channel, consider page hit/miss, last access details (read/write), fixed priority configuration, M4IF mechanism and M4IF prediction.
- Support AXI exclusive and lock access per arbitration path, so that locked access of one of the masters to EIM does not lock all EXTMC and access to ESDCTL for example can still be served.
- Bus Division arbitration scheme with programmable resolution for the slow, internal memory and internal 2 memory arbitration logics.
- Supports low power mode techniques. User can put the entire M4IF or partial M4IF (slow arbitration only, etc.) into low power mode.
- Supports auto power saving features for minimum power consumption in idle mode.
- Supports warm reset to allow dynamic reset configuration with minimum system impact.
- Supports several debug capabilities as described in the following section.
- Parametric design capability

49.1.3 Modes of Operation

The following sub-sections describe operation modes supported in M4IF.

49.1.3.1 Normal Operating Modes

In the normal operation mode, M4IF can serve each master access read or write in parallel. All clocks are enabled, and READY signal of the AXI protocol is at high condition. Access from any master can be served. For more details about normal operation mode please refer to Functional Description.

49.1.3.2 Low Power Modes

Low Power mode of operation is supported in M4IF. A low power mode request coming from the SoC will start the low power mode routine. In this mode, no access can be fired through M4IF between any master and memory controller (external or internal). Entering into this mode will cause the whole EXTMC to be in low power mode, meaning DDR external devices will be in self refresh mode and new accesses will not be served. All arbiters will finish serving all pending requests and clean all the buffers. Pending accesses on the memory controller bus will be finished while address READY signals on AXI port gaskets will be LOW. All AXI gaskets will change their address READY signals to be in low state and will not get any new request from any master.

In parallel to this routine, M4IF will pass the LPMD request to memory controllers to initialize its low power mode sequence. At the end of this process each memory controller will send LPMD acknowledge back to M4IF. M4IF would send Low Power Mode Acknowledge signal to the system based on its own process finish flag and on memory controllers acknowledge. This will allow the system clock controller module to disable EXTMC clocks without any risk.

Getting out of low power mode is done by first enabling all EXTMC clocks and then changing low power mode request signal to LOW state. After enabling the internal sub-blocks, gaskets and arbiters, M4IF will change address READY signals in the gaskets to high level to enable new access entry to EXTMC.

In addition to the above, M4IF supports entry to low power mode by SW definition. Please refer to M4IF control register for more details.

M4IF also supports partial low power mode. The system can enter each memory arbitration path into low power mode separately, so that one path can be in idle mode while the other is in low power mode. For example, if DDR is currently working and no accesses to EIM or NFC are needed, the system can set lpmd_slow signal to high so that slow path will be entered into low power mode. Another option is to rely on auto power saving mode to allow M4IF to enter this path into low power mode automatically.

For more details on power saving mode please refer to Power Saving Mode

Please note, in partial low power mode, the READY signals at the AXI gaskets will not be affected. They would remain high as long as one of the arbitration paths are functional. It is the system responsible to stop accesses to an arbitration path, which is in low power mode.

This mode can help the user look in detail, every transaction that crosses each one of the arbiters.

NOTE

In order to get out of SW low-power modes, there has to be an ability to access the IP-registers in M4IF. If access to the M4IF IP-registers is done through M4IF, a dead-lock can occur. Because M4IF is in low-power mode, all AXI accesses through it are blocked and if the IP registers are accessed through the AXI paths, they will not go through. This will leave the system hanging, because it cannot release the SW low-power mode request.

It is the system's responsibility to make sure that this dead-lock will not occur as it is dependant of the M4IF connectivity in the SOC.

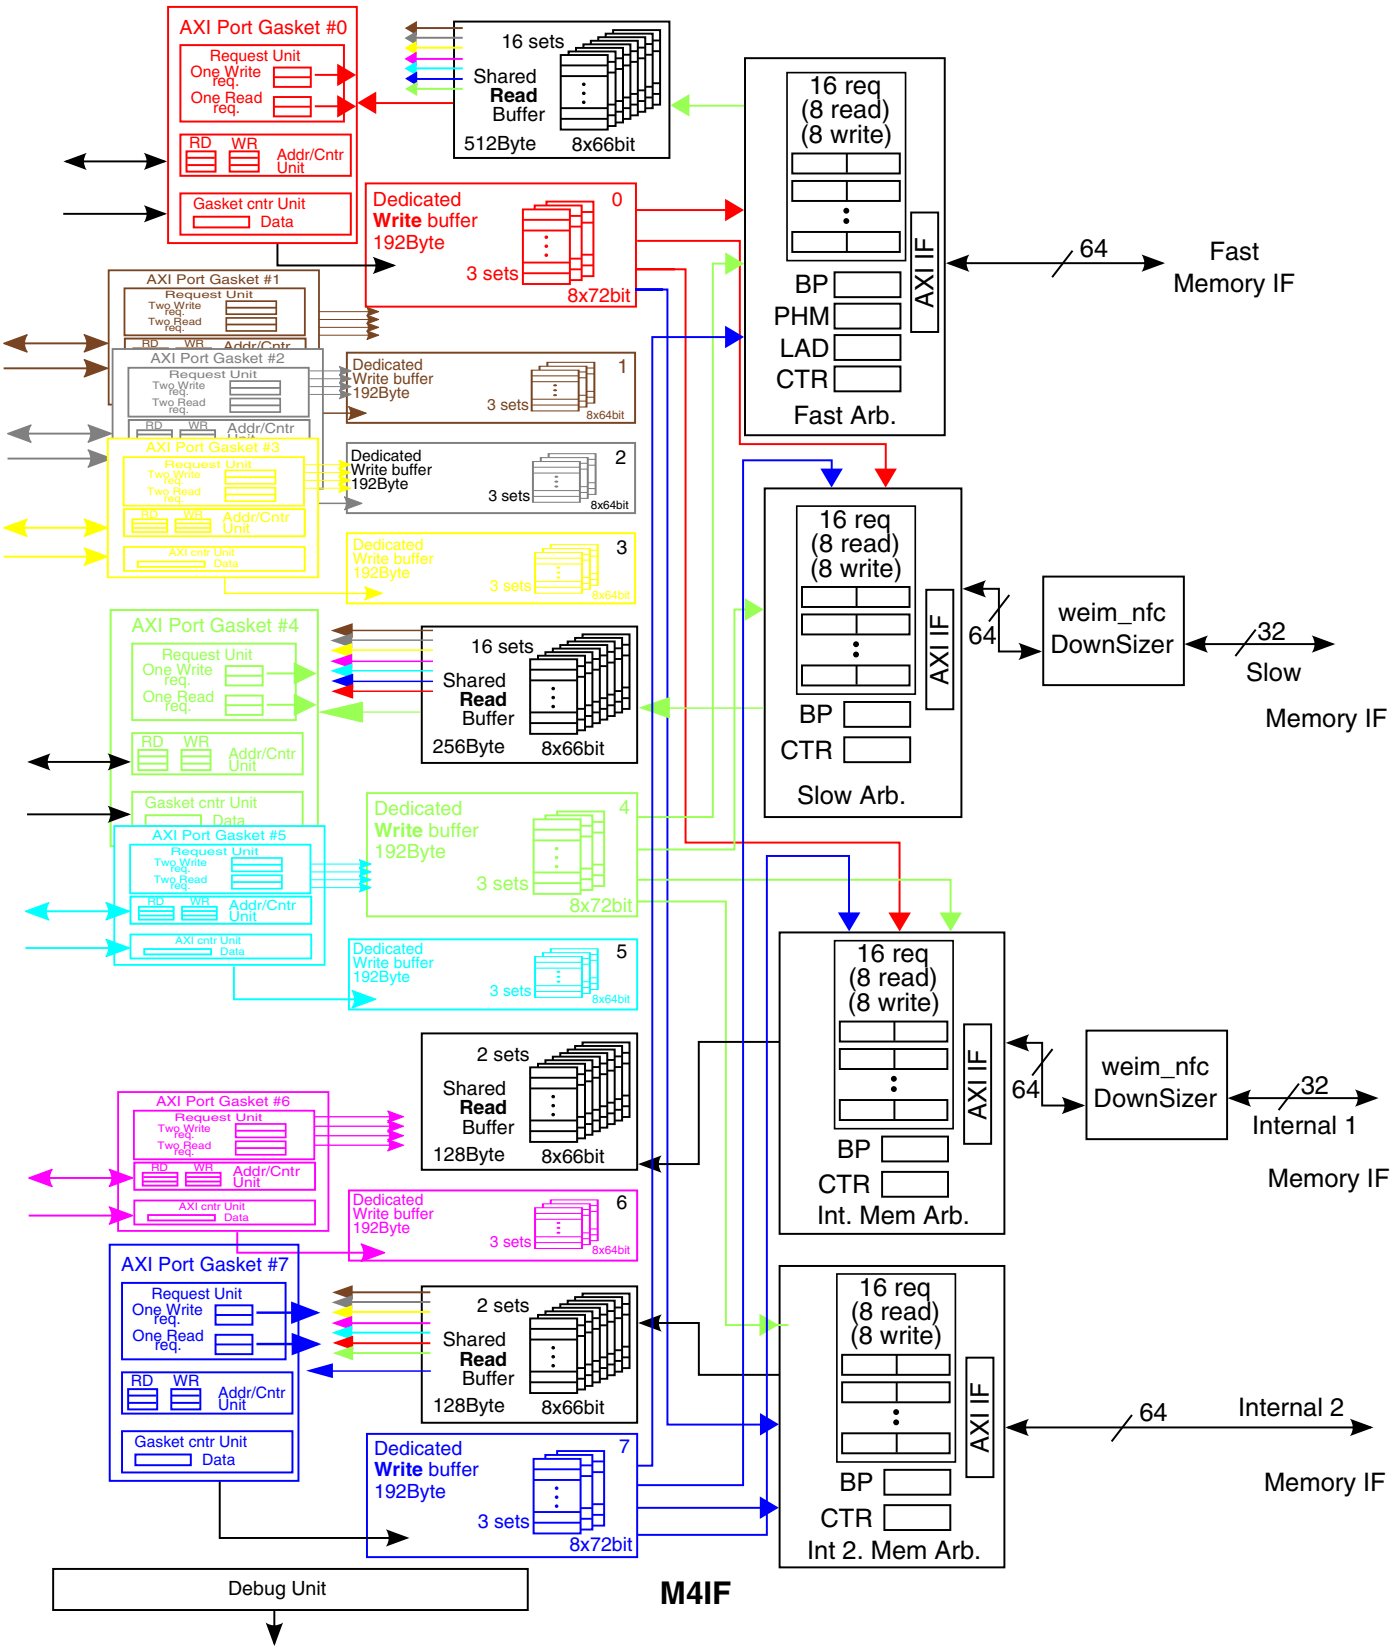

Figure 49-2. M4IF Block Diagram

49.1.3.3 Debug Mode

49.1.3.3.1 Step By Step Mode

This mode allows the user to freeze a specific arbitration after every new transaction that is sent outside the M4IF. The user can then monitor several internal signals of M4IF (while the specific arbitration is on hold) and later write to a register that will release the current transaction and freeze the next one.

Currently, there is no option to enter this mode in the middle of a working system. Entering this mode must be done when there are no transactions in the system, preferably immediately after reset, before any AXI accesses has been issued to M4IF/EXTMC.

Another way to ensure a quiet system is to use the LPMD/LPACK mechanism, either by HW or SW (see Control Register 0 (M4IF_CR0)). By using the LPMD mechanism, M4IF guarantees that all pending accesses have been served.

Once the "step by step" mode is enabled all accesses to the monitored slave (mem. controller) are halted. The properties of the access at the top of the PA fifo can be read via IP registers. (See Step By Step Address (M4IF_SSA).)

In order to release the access at the top of the fifo, the appropriate bit in the M4IF_MDCR (Debug Control Register (M4IF_DCR)) should be set. Either one of the 4 bits: FSBS,SSBS,ISBS or I2SBS depending on which arbitration is being halted.

49.1.3.3.2 Debug Unit - Functional Description

For details about functionality of the Debug Unit in M4IF please refer to Functional Description.

49.1.3.3.3 Debug Signals

The signal list that can be reflected outside is shown in Table 49-1 :

Table 49-1. M4IF Debug Signals

Signal Name	Number of Bits	Description
master_fast	[2:0]	EXTMC Master number of the selected access at fast arbitration bus.
master_slow	[2:0]	EXTMC Master number of the selected access at slow arbitration bus.
master_int1	[2:0]	EXTMC Master number of the selected access at internal 1 memory arbitration bus.

Table continues on the next page...

Table 49-1. M4IF Debug Signals (continued)

Signal Name	Number of Bits	Description
master_int2	[2:0]	EXTMC Master number of the selected access at internal 2 memory arbitration bus.
master_id_fast	[3:0]	Master ID of the selected access at fast arbitration bus.
master_id_slow	[3:0]	Master ID of the selected access at slow arbitration bus.
master_id_int1	[3:0]	Master ID of the selected access at internal 1 memory arbitration bus.
master_id_int2	[3:0]	Master ID of the selected access at internal 2 memory arbitration bus.
id_fast	[3:0]	AXI transaction ID of the selected access at the fast memory arbitration bus.
id_slow	[3:0]	AXI transaction ID of the selected access at the slow memory arbitration bus.
id_int1	[3:0]	AXI transaction ID of the selected access at the internal 1 memory arbitration bus.
id_int2	[3:0]	AXI transaction ID of the selected access at the internal 2 memory arbitration bus.
dyn_pr_fast	[5:0]	Fast Dynamic priority of a certain request. (configured by MDCR[20:16])
dyn_pr_slow	[5:0]	Equal 0, there is no Dynamic Priority mechanism in slow arbitration
dyn_pr_int1	[5:0]	Equal 0, there is no Dynamic Priority mechanism in internal 1 arbitration
dyn_pr_int2	[5:0]	Equal 0, there is no Dynamic Priority mechanism in internal 2 arbitration
acc_type_fast		access type of the selected access at fast arbitration bus.
acc_type_slow		access type of the selected access at slow arbitration bus.
acc_type_int1		access type of the selected access at internal 1 memory arbitration bus.
acc_type_int2		access type of the selected access at internal 2 memory arbitration bus.
addr_fast	[31:0]	AXI ADDRESS of the selected access at fast arbitration bus.
addr_slow	[31:0]	AXI ADDRESS of the selected access at slow arbitration bus.
addr_int1	[31:0]	AXI ADDRESS of the selected access at internal 1 memory arbitration bus.
addr_int2	[31:0]	AXI ADDRESS of the selected access at internal 2 memory arbitration bus.

The selected arbitration's signals are routed outside via a bus called: ipp_do_emi_debug. Only one arbitration can be viewed on the debug bus.

They are ordered on this bus in the following way:

ipp_do_emi_debug[50:0] = {valid_strobe,master,master_id,id,dyn_pr,access_type,addr}

where:

valid_strobe - a signal to indicate that a valid request is selected, this signal will be 3 clocks wide. The clock depends on the arbitration which is selected.

master - EXTMC master port (0:7), 3 bits wide. (Selected between: master_fast, master_slow, master_int1, master_int2)

master_id - system MASTER ID, 4 bits wide.

id - AXI transaction ID, 4 bits wide.

dyn_pr - the updated dynamic priority of a request, 6 bits wide.

access_type - write (0) or read (1), 1 bit.

addr - the address that is accessed (base address), 32 bits wide.

49.1.3.4 Dynamic Voltage and Frequency Scaling (DVFS)

DVFS is supported in M4IF. When DVFS request is high, M4IF sends DVFS request to the memory controllers while stopping all pending requests to the memory controllers. No new access will pass from M4IF to the memory controller but only piped access in the memory controller will be cleaned. At the end, the memory controller pipeline will be cleaned, and a DVFS ack signal will be sent back to M4IF, which will then send a DVFS ACK signal to the system to allow changing of frequency.

In addition to the description above, M4IF supports DVFS request to be enabled by register configuration. Please refer to Control Register 0 (M4IF_CR0) for more details.

49.1.3.5 Power Saving Mode

49.1.3.5.1 Arbitration Power Saving

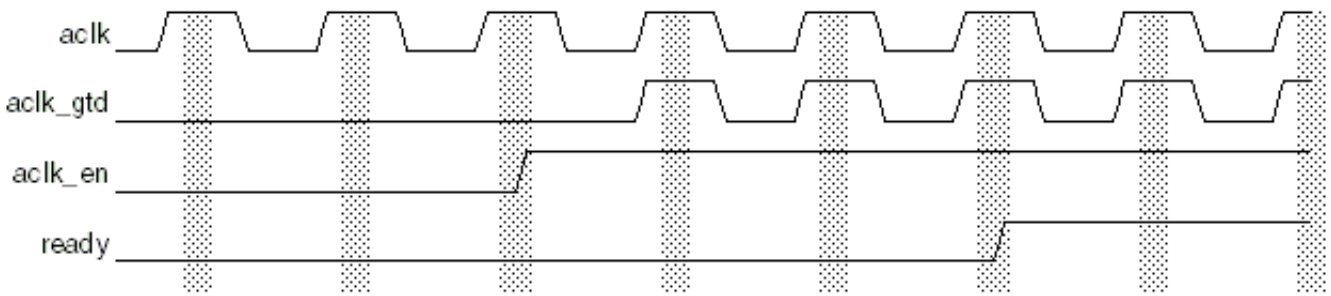
In order to support power saving mode, M4IF should be able to detect whether there is a request pending on any of the arbiters. The power saving register defines the time period that should pass from the last served request in a certain arbitration. If during the specified time period, no request was observed on the arbitration, the arbiter would send low power mode request to its memory controller and would enter itself in low power mode. The power saving mode is defined and functioned separately for each arbitration. In that case fast arbitration can be in normal mode while the slow arbitration can be in power saving mode. Getting out of this mode would be initiated automatically when a new request to a specific arbitration is issued by one of the masters. It is important to mention that it would take few cycles to serve the request since getting out of power saving mode routine takes a few cycles in M4IF as well as in the memory controller.

49.1.3.5.2 Gasket Power Saving

Power saving feature is also supported for each gasket individually. The gasket will detect the number of cycles it was idle. Upon reaching this configurable number of cycles, the gasket will de-assert its clock gating enable, and almost all the FFs inside will stop. There will be a few FFs still running on a free running clock, in order to be able to wake up from this mode. In this mode the 3 ready signals: AWREADY, ARREADY and

WREADY will be de-asserted until an access is issued to this gasket. When detecting a new access (AWVALID, ARVALID or WVALID asserted), the gasket will assert its clock enable signal (in the next cycle). There is a minimum number of cycles that the READY signals have to be de-asserted for, after the clock enable is asserted. Please note these are master clock cycles. For each master the clock period is different. The number of cycles is configurable via a register. The number of idle cycles that will initiate this process is also a configurable number. Refer to Power Saving Masters 0 (M4IF_PSM0) for further details.

The following diagram illustrates the behavior of the clock enable and of the ready signals upon exiting from power saving. In this diagram the "ready off cycles" (ROC) is at its default value - 3



49.1.3.5.3 SW Power Saving

M4IF does not support getting into power saving mode by SW. However, enabling/disabling this mode can be done by SW configuration. Please refer to M4IF control registers for more details. (PSM0-PSM3 for gaskets and MCR0 for arbitration).

Control Register 0 (M4IF_CR0)

Power Saving Masters 0 (M4IF_PSM0)

Power Saving Masters 1 (M4IF_PSM1)

Power Saving Masters 2 (M4IF_PSM2)

Power Saving Masters 3 (M4IF_PSM3)

NOTE

Power saving can only be configured once after reset. Changing the power saving configurations after the system was active (even if now idle) will result in unexpected behavior.

49.1.3.6 Error Handling And Interrupts

49.1.3.6.1 LEN > 8

M4IF does not support AXI accesses longer than 8 beats of data. In the event of an access of this kind arriving to M4IF, it will not be served. The master which sent the response will get an error response (DECERR). For read accesses, the read data will be returned as 0.

In addition to the error response, an interrupt will be issued (LEN interrupt). A status register will indicate which master made the un-supported access. This register will also be used to clear the interrupt. Please refer to Master Len Interrupt (M4IF_MLI).

49.1.3.6.2 Watermark

For detailed description about the watermark feature please refer to WaterMark Functionality Overview.

When a watermark violation occurs, it will be captured at the AXI gasket, and will not be served. The master which sent the request will get an error response (DECERR). For read accesses, the read data will be returned as 0.

In addition to the error response, one of two interrupts will be issued depending on the region which was violated (ARM Platform or Baseband Platform). Status registers will indicate which CS was violated. These registers will also be used to clear the interrupt. Please refer to Watermark Interrupt and Status 0 Register (M4IF_WMIS0).

49.2 Functional Description

This section and the sub-section below provide a functional description of the internal logic of M4IF. This section describes how the M4IF provides access paths between the system and the memory controller. The sub-sections below describe in more detail each part of M4IF and its functionality.

49.2.1 Write Access Description

An AXI access is detected on one or more AXI port gaskets and latched into the addr/ctrl internal buffer. The data buffer is separate from the addr buffer. This enables data to be accepted into the data buffer even before the address arrives on the bus. When WLAST

signal is detected on the bus, an internal logic inside the gasket generates a request to the right arbiter based on the address decoding. Because the request is generated in the master clock domain it is synchronized to the arbitration clock domain. This way it is guaranteed that all the data is stored in the buffer when the request is valid in the arbitration.

The arbiter calculates priority to this new valid request and chooses it according to the arbitration's criterion. See Fast Arbiter Functional Description - 1st Degree for further details. At the moment the access is chosen by the arbitration, it passes to the memory controller. The memory controller gets the data from the write data buffer.

In terms of write response, the gasket sends a bufferable response on the AXI response channel the moment the last data has reached the specific memory controller. In case of a non-bufferable access the response would be sent only after the write access is finished in the memory controller, and the memory controller itself sends a response.

49.2.2 Read Access Description

In a similar way when the access is a read access, the AXI addr and control signals are latched in a read control buffer inside the gasket. They are then transferred to the right arbiter according to the address decoding in the gasket. Based on the arbitration scheme the request is served. The addr and control signals are sent to the memory controller. Data that comes out of the controller is written directly to the read buffer. The read buffer is dedicated to the specific memory controller, and is shared between all 8 AXI masters. The master can pull the data out of the buffer at the moment it gets RVALID signal from the memory controller.

A detailed description of M4IF's functionality is described in the following sub-sections.

49.2.3 AXI Port Gasket Functional Description

The AXI port gasket is an AXI interface to any master in the system. The gasket is a x64 AXI bus interface and can be fitted to a x32 AXI interface. In order to connect a x32 master to the gasket, the wdata and wstrb bus should be duplicated. The rdata bus should connect to the lower 32 bits out of the 64 that come out of the read buffer.

The gasket works with Data Interleaving Depth (DID) of 1. This is a big difference from previous versions of M4IF, where the gasket worked with DID of 2. It can hold as many accesses as its buffer depth (which is parametric) regardless of the AXI ID. This is another noticeable change from the previous M4IF, which was limited to 2 pending IDs.

Each gasket can generate up to two parallel requests to the arbitration logic, one for write and one for read. All requests can be valid in parallel to the same or to different arbiters.

The read addr FIFO and read requests logic is similar to the write logic. The same FIFO exist also for other AXI control signal so it can give the whole information to the arbitration whenever a request is valid at the arbiter.

The write data comes on the bus from the master directly into the write buffer. Because the write buffer is dedicated to each master, that data is latched in the same clock domain of the master and no synchronization is needed.

49.2.4 Read/Write Buffer Functional Description

M4IF includes up to 12 data buffers, eight write data buffers, and four read data buffers. The write buffers are dedicated for each master in the system. If a master is removed from the system, its gasket and its write buffer are removed, saving a lot of area. The read data buffers are dedicated for each arbitration. In the read buffer, data is written by the specific controller and pulled out by any of the eight masters, while in the write buffer the dedicated master writes the data into the buffer and each of the four arbiters can pull out the data.

Therefore, the data in the write buffer is written in the master clock domain, while the data in the read buffer is written in the specific arbitration clock domain.

Both of the read and write buffer types are divided into fixed data slots in which data can be written. The slots are of depth eight (the maximal burst length) and are 64 bits in size. In addition to the data, the buffers store the write strobe (8 bits) for write, and the read response (rresp, 2 bits) for read. Each slot has a pointer_in and a pointer_out to mange the two way data, the way in which it is written into the slot and the way it is pulled out of the slot. It is important to mention that data of a certain access can not be stored in two different slots.

There are two configuration options to pull the data out of the read buffers for the fast arbitration control only, "read through" and "store & forward". In "store & forward" operation mode, the data can be pulled out by the slave only when all the datum of the burst is stored in the buffer, that is, after RVALID, RREADY and RLAST signals are high on the bus. In "read trough" operation mode, the data can be pulled out of the buffer by the slave a few cycles after the first data was written to buffer, due to synchronization reasons. For fast memory controllers it is recommended to use the "read through" (default) and therefore to achieve a minimum latency between the controller and the master.

On the write data buffer it is simpler; there is only one operation mode, the "store & forward" mode. In order to achieve best performance, the arbitration guarantees that when a request is served and moves to the memory controller, all the data is already latched in the write buffer and can be pulled out by the memory controller without any busy or abort cycles in between each data word of the access. This happens because the access request is asserted at the arbitration only after the last data was written to the buffer.

The write buffer gets data from its master. Data can be pulled out of the write buffers by the four memory controllers in the parallel. In the read buffer, only one memory controller can write to the buffer, but several masters can pull the data at the same time, depending on the number of slots in the buffer.

49.2.5 Fast Arbiter Functional Description - 1st Degree

The fast arbiter is responsible for all the accesses that go to ESDCTL memory controller, DDR2/DDR3 memory devices. As was described in the sections before, the addr decoding is done at the AXI port gasket. Any access that is pointed to the ESDCTL memory controller would be sent to the fast arbiter. The fast arbitration arbitrates between all masters request, read and write. The overall number of request is 16, 8 request for read and 8 for write. Each request can be valid on the arbitration logic at any time, it is guaranteed by EXTMC design that whenever a write request is valid on the arbitration logic all the data is already stored in the write buffer. This means that data is ready on the bus between the buffer and the specific memory controller whenever a specific request is chosen by the arbiter. The fast arbitration uses a dynamic priority engine to perform a high performance low latency data path arbitration. The dynamic arbitration uses the following parameters in its engine and calculate the priority of each request accordingly.

49.2.5.1 Page Hit / Miss

DDR memory device is divided into several banks depending on the specific memory configuration detailed by the memory manufacturer. Before any READ or WRITE commands can be issued to a bank in the DDR, a row in that bank must be opened. This is accomplished by the ACTIVE command, by which both the Bank and the Row are selected. More than one bank can be active at any time. Once a row is open, a READ or WRITE command could be issued to that row. A subsequent ACTIVE command to another row in the same bank can only be issued after the previous row has been closed. The minimum time interval between two successive ACTIVE commands on the same bank is defined by tRC timing parameter of the DDR device. A Subsequent ACTIVE

command to another bank can be issued while the first bank is being accessed, which results in a reduction of total row-access overhead. The minimum time interval between two successive ACTIVE commands on the different banks is defined by tRRD timing parameter of the DDR device.

Therefore, selecting access to the same Bank and the same Row one after the other would be issued in a minimum time at the controller. The arbitration would give high score to a page hit access (same Bank and same Row) than any other access in order to get the highest performance from the controller. (The score level can be configured by the user.)

The decoding of the address to bank, row and cs is done in the gasket per each access that arrives from the master. It is later passed on to the "scoring" mechanism in the fast arbitration, in order to calculate the appropriate score for each request. The order of elements on the address is: {cs,bank,row,column}. There is an option to work in "bank interleaving" or "address interleaving" mode. In this mode the order would be: {cs,row,bank,column}. For further details, please refer to the ESDCTL spec.

49.2.5.2 Last Access Details

In order to perform high density on the DDR external bus it is needed to consider last access type when choosing the next request (access) on the arbitration to be served. In addition to Page Hit / Miss parameter in the arbitration, a consecutive READ command (READ after READ) would be issued faster than a WRITE after READ. The same is true for a consecutive WRITE command, (WRITE after WRITE).

The dynamic arbitration logic would prefer a consecutive command access in order to get the highest performance from the controller.

49.2.5.3 Basic Priority Configuration

In continue to the FBP register description, each master in EXTMC will have a basic priority configuration based on the user configuration. This basic priority value will be the base value for each master. The dynamic arbitration, as described below, starts its calculation from the basic priority value per each master.

49.2.5.4 Priority Calculation

The Fast arbiter is designed to arbitrate read and write AXI accesses from a maximum number of 8 masters towards the ESDCTL memory controller.

This arbitration takes into account several parameters in order to decide which access to the controller is the most efficient one of all pending requests.

The arbitration handles a dynamic priority mechanism to allow for improved decision making between the masters. Each master gets a basic priority, which is configurable via a Basic Priority Register, defined below. A dynamic priority as well as page/hit miss score, are added to this basic priority. Thus a total score is formed and according to this score the request is evaluated by the "decision mechanism" of the arbitration.

The dynamic priority is calculated per each request. Each master has 2 possible requests (1 read and 1 write) and therefore a total of 16 dynamic priorities are evaluated per arbitration. If a request is pending on the "decision mechanism" and other requests are chosen at that time, then after a defined amount of selections (configurable by register), the dynamic priority of this request will increase by a defined number of "points" (also configurable via a register). If, however, a request is chosen, then at that cycle the dynamic priority of this request will be decreased by the same number of "points" times the number of data words in the burst (the number of cycles it was taken to served the access).

There is a maximum limit for the dynamic priority. The limit is the same for all masters, and can be configured via a register.

When a master's priority reaches its limit, it cannot surpass that limit. If theoretically, there is a situation in which the limit needs to be exceeded, the priority will remain at its limit value.

Figure 49-3 illustrates the dynamic priority mechanism for a limit offset of 50 "points":

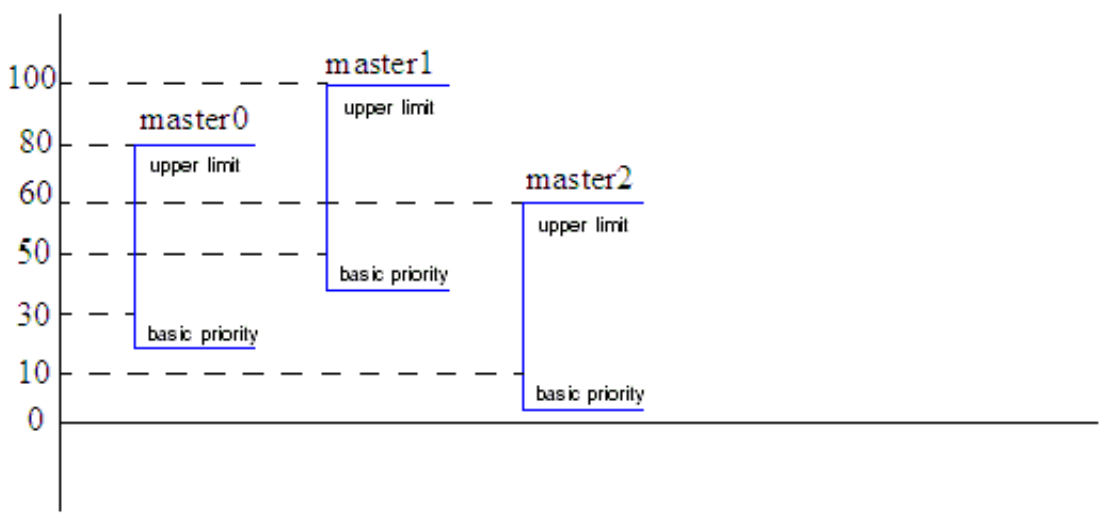


Figure 49-3. Master's Dynamic Priority Scheme

From the above illustration, it is seen that one master can "take control" over the arbitration if its basic priority is too high in comparison to the other masters.

Therefore, the system configuration needs to be such that the odds of such a situation would be as low as possible. The default settings of the fast arbitration and the entire M4IF system must be determined based on intensive modeling simulations. Changes to these values must be made with extreme care.

In case all of the masters have the same score, a simple arbitration logic is used to chose the next request to be served.

49.2.5.5 2nd Degree Arbitration (M4IF)

After choosing the best suited request out of the possible 16, it is latched inside a buffer of size 16 and then it goes through second degree arbitration. The requests which are stored in this buffer are arbitrated in a similar way to the first degree. Here there's a simpler dynamic priority mechanism. Each request gets a single point for each time another request was chosen over it. When a request is chosen its dynamic counter is reset. The page hit and access hit get smaller amount of points. Not 10 and 5 (default values) like in the first degree, but 4 and 2. These parameters are configurable using the M4IF control register. See Control Register (M4IF_CR).

The order of accesses from the same master with the same AXI ID is kept. Even if an access has a high score due to page and access hit, it will not be able to bypass an access from the same master with the same AXI ID that arrived before it.

From the second degree arbitration, the selected request is stored in a FIFO of depth 2. This FIFO handles the AXI accesses between the M4IF and the ESDCTL.

The second degree arbitration also has three more features in its engine:

49.2.5.5.1 M4IF Bypass

It is possible to prioritize a single master over the others in a form of bypass. In the M4IF control register (Control Register (M4IF_CR)) the fields: M4IF_MAS, M4IF_ID,M4IF_IDTOO and M4IF_BYP_EN can be used to do that. Once the M4IF_BYP_EN bit is set to '1', this feature is enabled. There are 2 options for bypass:

1. All accesses from a specific master configured in the M4IF_MAS field will bypass the M4IF arbitration and go directly to the ESDCTL. In this case the M4IF_IDTOO bit should be '0'.

2. Only accesses from M4IF_MAS that have a specific AXI ID, that is configured in the M4IF_ID field, will bypass the M4IF arbitration. For this option to be enabled the M4IF_IDTOO bit must be set to '1'.

Normally, the M4IF bypass feature will be used for IPU's screen refresh channels. Screen refresh channels have a real time nature. It is recommended to have the M4IF bypass feature enabled in any use case where IPU screen refresh is involved.

49.2.5.5.2 Guarding Mechanism

The second degree arbitration is guarded from starvation by using a counter that prevents a specific request from being stuck inside the 2nd degree buffer for more then a predefined number of clock cycles. For more information about this mechanism please refer to the M4IF Scoring register Control Register (M4IF_CR).

49.2.5.5.3 Prediction

The second degree arbitration has the ability to predict the {cs,bank,row} that will be used by the ESDCTL before the transaction is actually sent on the AXI bus. By doing so, we are able to prepare the memory device for future transactions and improve our overall performance. For more information regarding this feature please refer to the ESDCTL spec.

49.2.6 Slow Arbiter Functional Description

The slow arbiter is responsible for all access that goes to EIM and NFC, Nor / PSRAM memory devices or NAND devices. The addr decoding is done at the AXI port gasket. Any access that is pointed to one of these memory controllers would be sent to the slow arbiter. The slow arbiter arbitrates between all masters read and write request. The overall number of requests is 16, 8 requests for read and 8 for write. Each request can be valid on the arbitration logic at any time. EXTMC design guarantees that whenever a request is valid on the arbitration logic all the data is already stored in the write shared buffer. It means that data is ready on the bus whenever a specific request was chosen by the arbiter. The slow arbitration uses the "bus division" mechanism, as described in Arbitration Scheme when Masters have Same Priority (Bus Division).

49.2.7 Internal 1 Memory Arbiter Functional Description

The Internal 1 memory arbiter is responsible for all access that goes to system internal 1 memory controller, like ROM and RAM devices. As described in previous sections, the addr decoding is done at the AXI port gasket. Any access that is pointed to internal 1 memory space is sent to the internal 1 memory arbiter. The internal 1 memory arbiter arbitrates between all master requests, read and write. The overall number of requests is 16, 8 requests for read and 8 for write. Each request can be valid on the arbitration logic at any time. EXTMC design guarantees that whenever a request is valid on the arbitration logic all the data is already stored in the write shared buffer. It means that data is ready on the bus whenever a specific request was chosen by the arbiter. The internal 1 memory arbitration uses the "bus division" mechanism, as described in Arbitration Scheme when Masters have Same Priority (Bus Division).

49.2.8 Internal 2 Memory Arbiter Functional Description

The Internal 2 memory arbiter is responsible for all access that goes to system internal 2 memory controller, like ROM and RAM devices. The addr decoding is done at the AXI port gasket. Any access that is pointed to internal 2 memory space is sent to the internal 2 memory arbiter. The internal 2 memory arbiter arbitrates between all master requests, read and write. The overall number of requests is 16, 8 requests for read and 8 for write. Each request can be valid on the arbitration logic at any time. EXTMC design guarantees that whenever a request is valid on the arbitration logic all the data is already stored in the write shared buffer. It means that data is ready on the bus whenever a specific request was chosen by the arbiter. The internal 2 memory arbitration uses the "bus division" mechanism, as described in Arbitration Scheme when Masters have Same Priority (Bus Division).

49.2.9 Arbitration Scheme when Masters have Same Priority (Bus Division)

The following section describes the arbitration mechanism when the priority of two or more master requests are the same value. It is most likely that this scheme will be dominant in the slow and internal memory arbitration, where the special priority parameters are disabled or even when the dynamic priority is disabled.

The low level arbitration scheme exist in all arbiters. It is built of several levels of the same logic units which are connected in a tree structure. Figure 49-4 describes the general build of the low level arbitration structure.

Each level of arbitration (4 levels total) is built of the same logic unit. Each logic unit can be configured to a different arbitration scheme up on 3 input signals that can be partially configured by the user. It is important to mention that the logic unit follows its configured arbitration scheme only when both inputs (masters or requests) are with the same priority level.

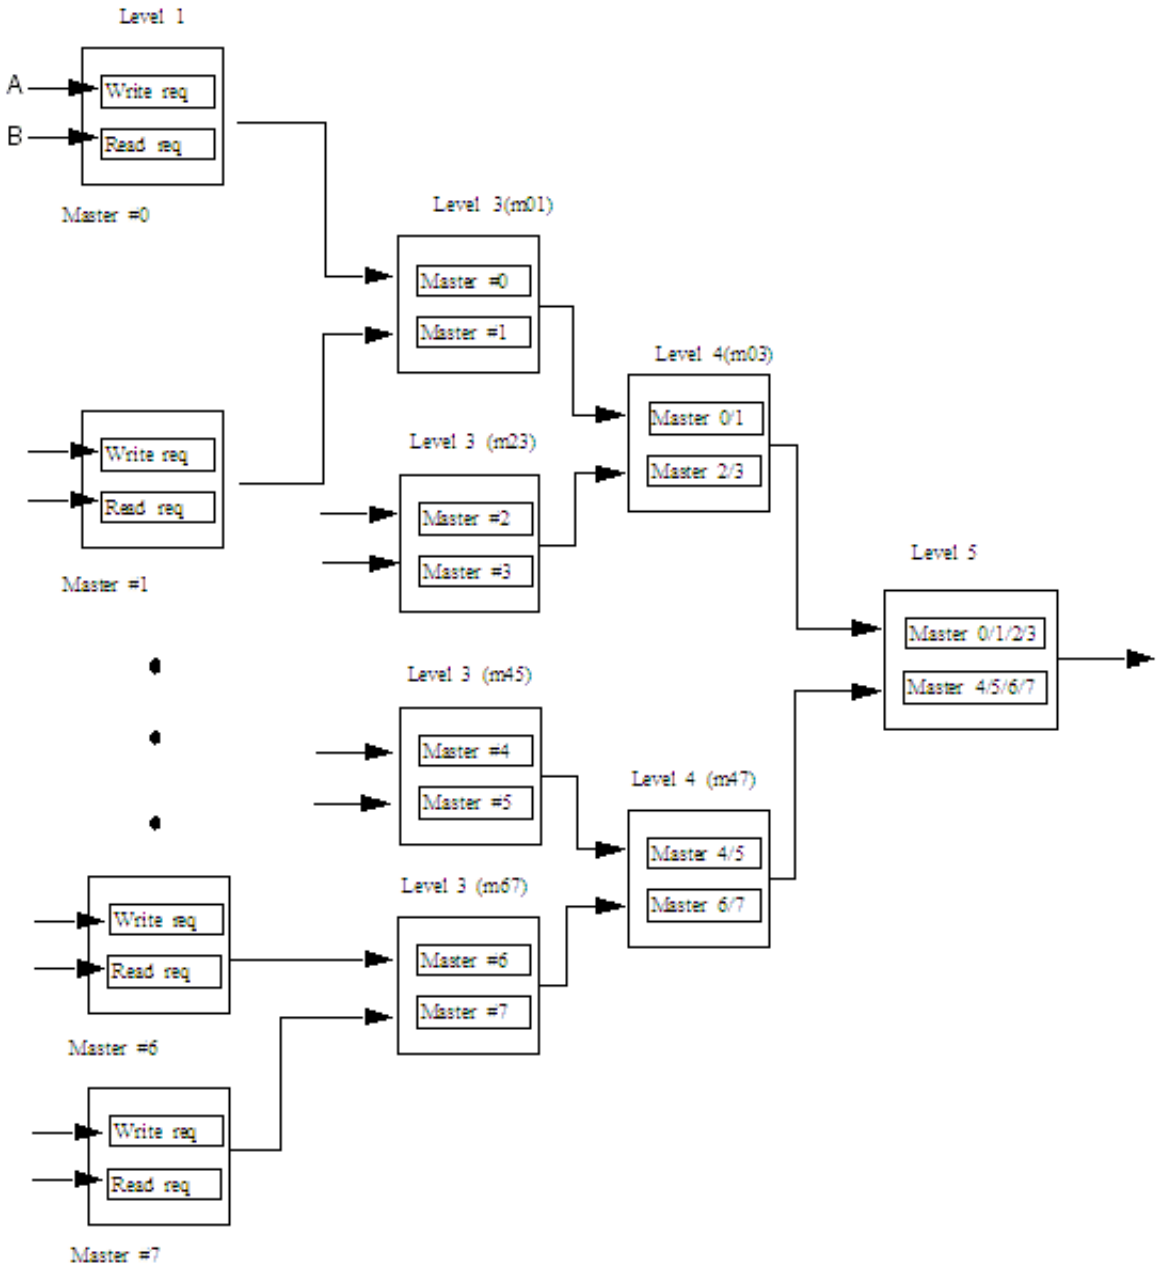

Figure 49-4. Low level arbitration structure

Table 49-2. logic unit fast arbitration configuration

#	bit 2	bit 1	bit0	arbitration scheme
0	0	0	0	100% priority to B.
1	0	0	1	25% priority to A
2	0	1	0	single 50%
3	0	1	1	double 50%
4	1	0	0	75% priority to A
5	1	0	1	100% priority to A
6	1	1	0	Reserved
7	1	1	1	Reserved

The user can configure only part of the logic unit levels. Level 1 has a fixed priority scheme configuration and can not be changed, while levels 3, 4, and 5 can be configured for one of the arbitration configurations as shown in Table 49-2.

Figure 49-5 describes schematically the arbitration scheme of each condition.

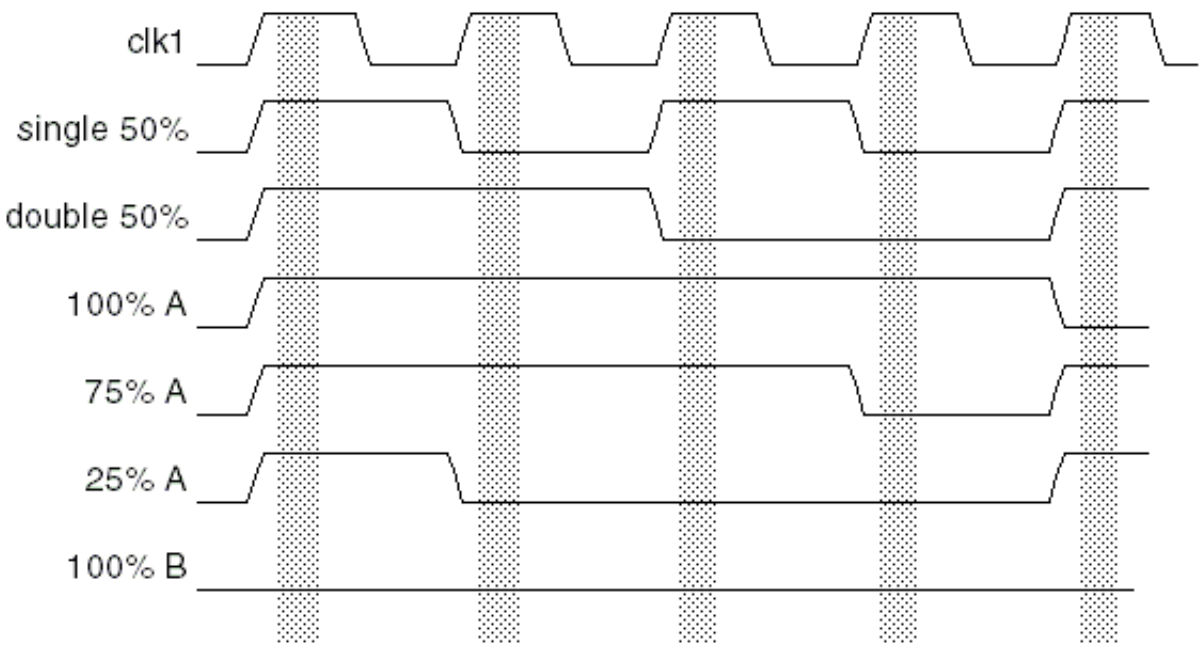

Figure 49-5. Logic units arbitration scheme.

The configuration of the logic units in levels 2, 3 and 4 can be done via the F_Unit_Level_Arbitration_ Register (M4IF_F_ULAR). However, configuration of logic units in level 1 is fixed. Unit level 1 is hard wired to 'double 50%' state.

For 'slow' and 'intr' arbitrations, the scheme has changed from previous versions of M4IF. Now there are more configurations that were added, as described in the table below:

Table 49-3. slow and intr arbitration bus division configuration

#	bit 2	bit 1	bit0	arbitration scheme
0	0	0	0	100% priority to B.
1	0	0	1	12.5% to A.
2	0	1	0	25% to A.
3	0	1	1	37.5% to A.
4	1	0	0	50% - 50%
5	1	0	1	62.5% A.
6	1	1	0	75% to A.
7	1	1	1	100% to A.

49.2.10 EIM-NFC Downsizer

The slow channel of EXTMC ultimately splits into 2 memory controllers, EIM and NFC. These 2 controllers' AXI data bus width is 32 bits. The slow arbitration has an AXI data bus width of 64. Therefore, a 64bit_to_32bit downsizer is required. Such a downsizer is placed inside the M4IF between the slow arbitration and the AXI interfaces to EIM and NFC. The downsizer handles bursts of length up to 8 (awlen/areln <= 7) for 64 (awsize/arsize=3) and 32 (awsize/arsize=2) bits. As for 8 and 16 bit accesses, the downsizer only supports single accesses (awlen/arlen=0). The downsizer is also a splitter and can determine the destination of an accesses, whether EIM or NFC, based on the address of that access.

Single length bursts will always have an output burst type (awburst_weim or awburst_nfc) INCR (2'b01). The awsize field, in case of 64bit accesses, will change from 64bit (2'b11) to 32bit (2'b10).

When sending burst of size 32 bit through the downsizer, wstrb[7:4] must be tied to wstrb[3:0].

49.2.10.1 Endianess In Downsizing (EIM-NFC Downsizer)

The downsizer takes into consideration the endianess of each accesses. If the endianess as LE (0) then the data for addresses with 3 LS bits decoded to: 0, 1, 2 or 3, will be taken from the lower 32 bits out of 64. The data for addresses with 3 LS bits decoded to: 4, 5, 6 or 7 will be taken from the upper 32 bits. If the endianess is BE (1) then for addresses

with 3 LS bits decoded to: 0, 1, 2 or 3 data will be taken from the upper 32 bits, and data corresponding to addresses with 3 LS bits decoded to:4, 5, 6 or 7 will be taken from the lower 32 bits.

NOTE

The information about the destination of an AXI access is not taken into account in the arbiter. The slow arbitration does not select accesses based on the memory controller's condition (busy /idle, etc.).

49.2.11 Internal 1 Downsizer

The internal 1 memory channel of EXTMC ultimately splits to 2 memory controllers, INT1_S0 and INT1_S1. These 2 controllers' AXI data bus width is 32 bits. The internal 1 memory arbitration has an AXI data bus width of 64. Therefore, a 64bit_to_32bit downsizer is required. Such a downsizer is placed inside the M4IF between the internal 1 memory arbitration and the AXI interfaces to INT1_S0 and INT1_S1. The downsizer handles bursts of length up to 8 (awlen/areln <= 7) for 64 (awsize/arsize=3) and 32 (awsize/arsize=2) bits. As for 8 and 16 bit accesses, the downsizer only supports single accesses (awlen/arlen=0). The downsizer is also a splitter and can determine the destination of an accesses, whether INT1_S0 or INT1_S1, based on the address of that access.

Single length bursts will always have an output burst type (awburst_int1_s0 or awburst_int1_s1) INCR (2'b01). The awsize field, in case of 64bit accesses, will change from 64bit (2'b11) to 32bit (2'b10).

Whenever sending burst of size 32 bit through the downsizer, wstrb[7:4] has to be tied to wstrb[3:0].

49.2.11.1 Endianess In Downsizing (Internal 1 Downsizer)

The downsizer takes into consideration the endianess of each accesses. If the endianess as LE (0) then the data for addresses with 3 LS bits decoded to: 0, 1, 2 or 3, will be taken from the lower 32 bits out of 64. The data for addresses with 3 LS bits decoded to: 4, 5, 6 or 7 will be taken from the upper 32 bits. If the endianess is BE (1) then for addresses with 3 LS bits decoded to: 0, 1, 2 or 3 data will be taken from the upper 32 bits, and data corresponding to addresses with 3 LS bits decoded to: 4, 5, 6 or 7 will be taken from the lower 32 bits.

NOTE

The information about the destination of an AXI access is not taken into account in the arbiter. The internal 1 memory arbitration does not select accesses based on the memory controller's condition (busy/idle etc.)

49.2.12 Clocks - i.MX53 Specific

M4IF contains the following clocks:

- ESDCTL main clock (up to 400MHz)
- Slow arbitration clock (up to 133MHz)
- Internal 1 memory arbitration clock (up to 166MHz)
- Internal 2 memory arbitration clock (up to 166MHz)
- 8 x masters clocks, can be asynchronous to EXTMC arbitration clocks (up to 200MHz)
- IP Bus clock (up to 66MHz)

M4IF assumes all of its 4 main clocks: aclk_fast, aclk_slow,aclk_intr and aclk_int2 are on by default (after reset). If the system wishes to turn one of the clocks off, it must do so by going through the specific LPMD sequence. For example, if the system wishes to turn "aclk_fast" off, it should wake up with this clock on, send an "lpmd_fast" request, wait for "lpack_fast" acknowledge, and only then turn "aclk_fast" off. "lpmd_fast" will have to be asserted for the whole duration of "aclk_fast" being off.

Due to synchronization issues, the general "LPMD"/"DVFS" sequences will only be available when "aclk_fast" is on. If "aclk_fast" is turned off, these sequences will not work.

The AXI master clocks, clocks aclk_m0-aclk_m7 are assumed to be "always on". These clocks can only be turned off as a result of proper LPMD sequence. Turning the clocks off without a proper LPMD sequence will result in an unexpected behavior, probably even a dead-lock.

49.2.12.1 Clock Ratios

The IP Bus clock's (ipg_clk_s) frequency should be slower (at least 1/2) than that of aclk_fast, aclk_slow, aclk_int1, aclk_int2 and all the master clocks at all times.

49.2.13 Reset

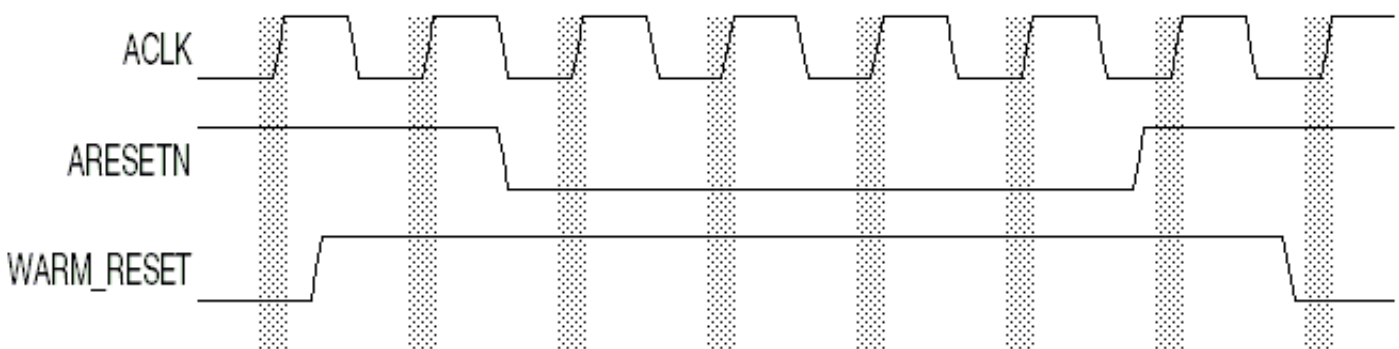
M4IF, as well as the entire EXTMC, supports 3 main reset signals, hard_reset, warm_reset and sw_reset. The reset tree at M4IF as well as in EXTMC is built in a way it provides the maximum flexibility to SoC so it can control the reset scheme according to its needs.

49.2.13.1 Software Reset

The software reset is a reset given to the entire M4IF FFs, except the IP configuration registers. This is done via IP write to bit 31 (SW_RST) in the MCR0 register. Please refer to Control Register 0 (M4IF_CR0).

49.2.13.2 Warm Reset

Warm reset is a reset given to the whole system except the configuration register. The warm reset is issued by asserting the regular reset (aresetn) and by asserting the "warm_reset" signal along with it. The "warm_reset" signal must be asserted before the assertion of the "arestn" signal, and must be deasserted after the deassertion of the "aresetn" signal. As illustrated below:



49.2.13.3 EXTMC Programing Sequence After Warm Reset

This section describes the flow of getting into self-refresh mode before and during warm reset, as well as required configuration to ESDCTL when getting out of warm reset.

Please note that after issuing a precharge all via special command register in the exit warm reset, it is recommended by devices to issue a manual autorefresh command, but not necessary.

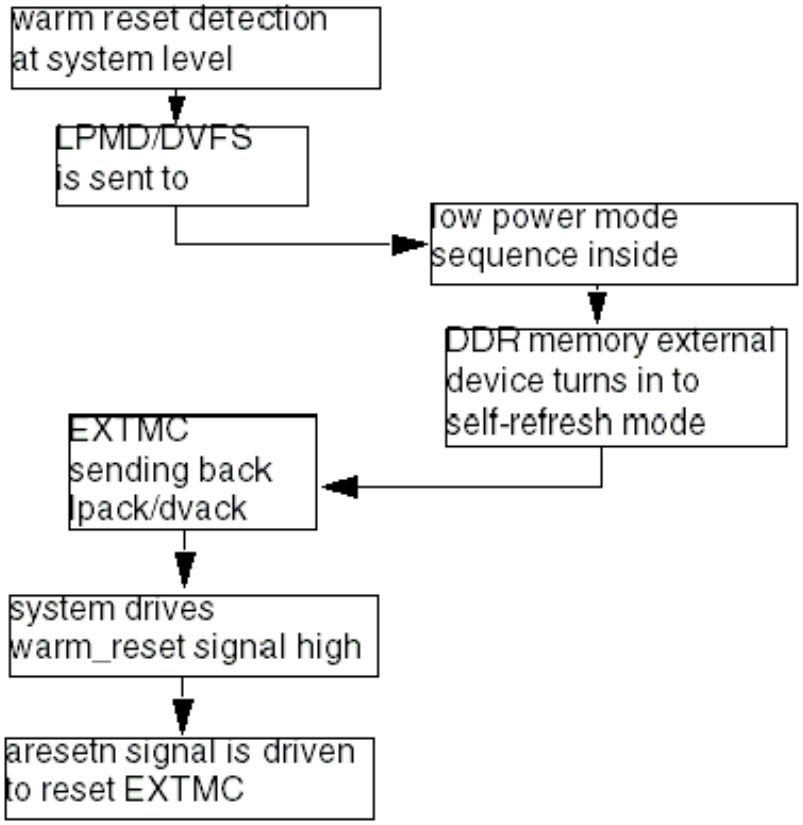


Figure 49-6. Getting into self refresh before warm_reset assertion

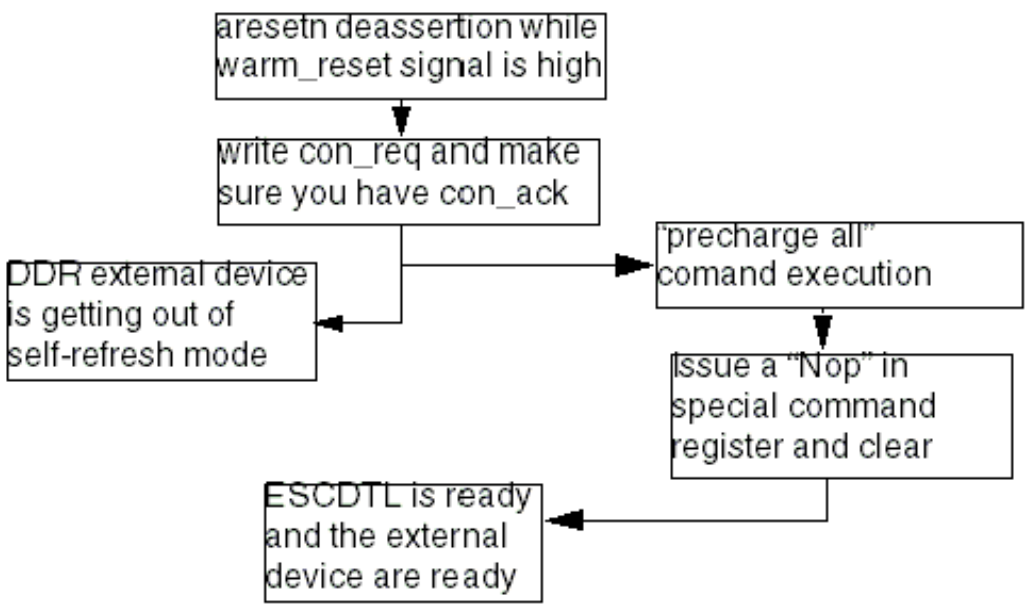

Figure 49-7. Sequence of getting out of self refresh after warm reset

49.2.14 Interrupts

The following interrupts are supported in M4IF.

- Watermark violation interrupt ARM platform.
- Watermark violation interrupt BP domain.
- Master burst length bigger then 8 violation interrupt.

49.2.15 Endianness

Only little endian is supported for i.MX53.

49.2.16 AXI Interface Restrictions

This section describes the built-in limitation in the current M4IF design that lead to some restriction on the EXTMC AXI IF support.

NOTE

Not complying to these restrictions will cause an error at best, and an unknown state (possibly a dead lock) at worst.

49.2.16.1 General Interface Limitations

1. M4IF supports write data interleaved depth of 1 (no interleaving of data is allowed).
2. awcache/arcache - Non-bufferable accesses are supported. In write access there will be a single bit to support bufferable and non-bufferable access types. According to AXI protocol, AWCACHE[0] would reflect the type of the access, AWCACHE[0]=1'b0 means a non-bufferable access and AWCACHE[0]=1'b1 means a bufferable access. The rest of the "cache" signals are not used inside the M4IF. The 'awcache' and 'arcache' output signals (inputs to the memory controller) are set according to the corresponding 'awcache' and 'arcache' inputs from the master.
3. A master must ensure that the written data has reached the destination memory, has to apply non-bufferable access and wait for the response channel.
4. If large block write transfers must be done, it is recommend that the master drive at least one non-bufferable write access for each ID at the end of the write block transfer to ensure transfer complete at the memory device.
5. In order to keep data access coherency between write and read access of the same master, the response signal will be sent as follows:

- bufferable write access - BRESP will be sent when last data of the access has entered the memory controller
- non-bufferable write access - BRESP will be sent when the data is physically written into the external memory device, and valid response was issued by the controller.

6. The AXI ID bus contains four bits total in order to reflect the AXI transaction ID as configured by the master.

NOTE

Inside M4IF an additional three bits will be added for internal use only to reflect master number between 0 and 7.

7. Master ID is supported in EXTMC in a way similar to former versions. Master ID is supported only for address buses and should be considered as ADDR timing. AWMASTER is used for Master ID in write address and ARMASTER for master ID in read address. Each field includes four bits max.

NOTE

The master ID is not an AXI requirement and it is supported for AHB masters option mainly.

8. Burst length up to eight double-words (64 bits), is supported. Access types incr and wrap are supported, fixed access type is not supported. AWSIZE/ARSIZE are two bits wide. AWLEN/ARLEN are three bits wide. When a burst of length greater than eight is issued on the bus, the M4IF will not forward it to the memory controllers, and a "DECERR" will be sent back to the master.
9. The maximum data bus size is 64 bits.
10. Unmapped addresses are not supported. All unmapped addresses will be routed to DDR. It is the SoC's responsibility not to send unmapped addresses to M4IF/EXTMC.

49.2.16.2 Atomic Accesses

M4IF support AXI atomic accesses. The atomic access logic is separate fof each arbiter, so that one CS can be locked or under exclusive monitor while other master can continue accessing another CS on a different arbitration. For example, if one of the masters issued a lock access to DDR's CSD0, the atomic logic will block all accesses to the fast channel (CSD0 & CSD1) from all the other masters. At the same time if a master issues accesses to EIM CS0 these accesses will be served as usual.

49.2.16.2.1 AXI Locked Accesses

The M4IF allows a master to perform lock on a slave region. The lock means that only this master, when using the specific AXI ID of the lock access, can access the locked region.

The master is determined based on the EXTMC master port (0:7) and not based on the MASTER_ID field (AWMASTER/ARMASTER sideband signals).

All other requests from other masters will be masked till the lock access is done. The lock access request will be active only when the request is served by the arbitration. In case there are other pending accesses of the same master that were issues before the lock access, they will be served first by the arbitration. The lock is removed upon selecting request from this master, with the lock ID, and ARLOCK/AWLOCK signals indicates an unlocked access (can be either regular or exclusive access).

49.2.16.2.2 Exclusive Accesses

The M4IF deals with exclusive access for each arbitration path separately. Each arbitration has its own exclusive access monitor and it is not affected by other exclusive accesses to other arbitrations. Thus, once an exclusive read from a certain master with a specific AXI ID has been selected by the arbiter, the specific monitor would be active following this access. If another exclusive access occurs to the same arbitration, the monitor will be updated by the new exclusive access and the old access will be dropped from the monitor. In case a write exclusive access related to the first exclusive read access arrives, it would be treated as a regular access and not as an exclusive one. The data of this write exclusive access would not be written and the response will be sent as OKAY and not EXOKAY.

M4IF supports an exclusive access of a single burst type only. Meaning the exclusive monitor will monitor a single address only. In case an exclusive access of burst length bigger than 1 is done, only the first address of this burst will be monitored.

49.2.16.3 Write Data Interleaving

M4IF has a write data interleaving depth of 1 as opposed to previous version where the depth was 2. This means that write data interleaving is not supported in M4IF.

49.2.17 IPS Interface

All M4IF registers are memory mapped. The registers will be configurable read/write via IPS bus interface only.

The IPS interface unit inside EXTMC will combine all IPS interfaces from EXTMC sub-blocks and M4IF as one of them. The IPS IF unit would route the access to the right sub-block based on ips_module_en signal and address decoding.

M4IF registers uses an accessibility policy as described in the EXTMC spec Chapter.

All M4IF registers are 32bit wide. Only IP accesses of 32bit data width are supported.

M4IF IP accesses should be used in one of the following 2 manners:

1. Check all the status bit are idle. Only if all of them are idle, an IP access could be made.

Status bit list: FPSS, SPPS, IPSS, I2PSS, M#_PSS (#= Master number)

2. Send a LPMD request to a specific arbitration and wait for LPACK before configuring its redigests.

49.2.18 WaterMark Functionality Overview

The WaterMark security feature is used to protect configurable memory regions (WaterMark space) of up to two predefined different CS. Two CS of ESDCT. No watermark capabilities exist for NFC CS and the internal memory interface.

The access (read or write) to the WaterMark space is permitted only if the appropriate control bit of this particular access is high. For read - m#_wtrmrk_ap(bp)_rd, for write - m#_wtrmrk_ap(bp)_wr. The watermark regions are configurable via the watermark registers where watermark space #0 is for AP masters use and watermark space #1 is for BP masters use.

AP masters and BP masters can configure each of its own registers only. An AP master cannot configure BP master registers and vice versa. AP and BP masters are being identified by the predefined via at the EXTMC boundary signals. SoC integration should configure these vias with the right values according to the master ID's in the system. Only a predefined privilege master (AP or BP) can configure the watermark registers.

Access to the WaterMark space when watermark bits are low is considered a WaterMark violation. Even if the accessing master is part of the accessed domain. A WaterMark interrupt will be generated in such a violation. In addition the master who caused the violation will not get access, and an error response (DECERR) will be issued. In case an access was made to watermark space #0 when wtrmrk_ap is in low, an AP watermark interrupt will be generated. The same goes for BP watermarked regions. In both cases the address and the master ID of the first master which made a violated access would be kept in the watermark status registers till the interrupt is cleared. Please refer to Watermark Interrupt and Status 0 Register (M4IF_WMIS0).

If a master violates the same region twice (AP or BP), only the first violation will be captured in the status registers.

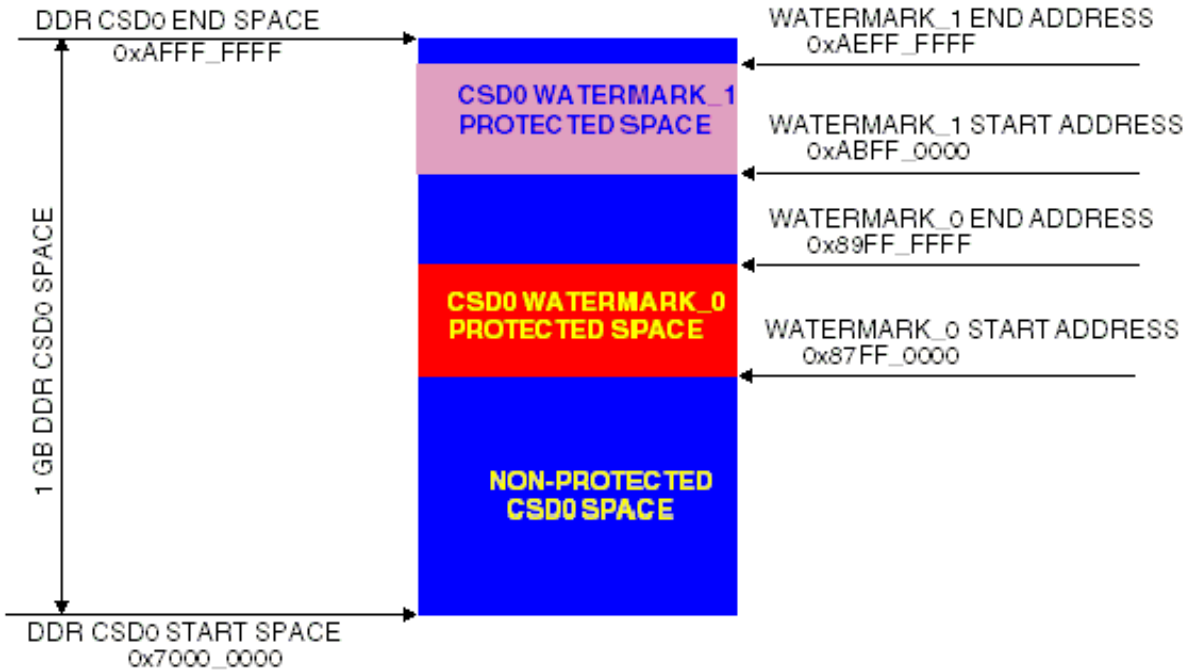
If a "clear" command is issued (by writing to the status register) at the exact same time that a violation occurs, the "clear" will win. Meaning the violation will not be captured in the status register. The access will be treated as a violated access and will not pass through.

Up to two WaterMark spaces can be defined for each predefined CS mapped by the M4IF. The WaterMark space is configurable through a set of configuration registers that contains the WaterMark space start and end address for each chip select. Please refer to Watermark Start ADDR_0 Register n (M4IF_WMSA0_*n*) for specific details.

The watermark address register has a resolution of 4 KByte, meaning:

- The start address can be set at the end of the first 4 KByte.
- The start and end address can be set in steps of 4 KByte.

The figure below illustrates a WaterMark space in DDR CSD0 memory region. The red shaded area in the figure is the WaterMark #0 (AP) space defined in DDR CSD0 memory region while the purple shaded area is the WaterMark #1 (BP) space. These memory regions are accessible only by those masters that have wtrmrk_ap(bp) bits high during the access. Accesses to this region by other masters when wtrmrk_ap(bp) are low generates an interrupt (if enabled through the WaterMark control register) and sets the respective WaterMark space (clear by one) status bit. The blue shaded area is the non protected DDR CSD0 memory region, means that it is accessible by all masters connected to the M4IF.



DDR CSD0 WaterMark Space Diagram

49.2.19 Debug Unit

The M4IF has a debug unit in order to allow for better debug capabilities.

The debug unit is consisted of 2 main parts, visibility unit and profiling units.

49.2.19.1 Visibility Unit

This unit muxes and reflects outside, several crucial signals from within M4IF. These signals are described in detail in Debug Signals. The muxing is done between the 4 channels: fast, slow, internal 1 memory and internal 2 memory. The desired channel is configured via M4IF_MDCR register.

The visibility unit is disabled by default. In order to enable it the user must write to the M4IF_MDCR register's "DBG_EN" bit. Please refer to Debug Control Register (M4IF_DCR) for details.

Note that this unit monitors the signals from within the M4IF, even in a case of fail write exclusive attempt.

49.2.19.2 Profiling Units

There are four profiling units inside the debug unit. Each unit is responsible for profiling a single channel (fast, slow, internal memory and internal 2 memory).

A single profiling unit contains counters which record the number of accesses through the specific channel for each master. The counters are read by the IP bus. The information in the IP register does not contain the lower five bits of the counter, meaning the numbers which are read in the MDSR2-5 registers indicate the number of groups of 32 accesses. For example, if master 5 performed a total of 274 accesses, the number which will be read in the upper 16 bits of MDSR4 will be: trunc(274/32)=8. In order to get the approximate real number of accesses, the user will have to multiply the number in the register by 32. In the above example the outcome will be: 8x32=256. The error will be (274-256)/274=7%. The profiling unit is designed to handle massive use-cases, in which there will be thousands of accesses. In these cases the error will become negligible.

The profiling unit also calculates the maximal dynamic priority of a specific request. The request is selected by M4IF_MDCR configuration register. It also calculates the maximum time the master of that request was pending on the bus without getting a response. These are read by MDSR0 register.

In order to calculate the average time it took a master to get the bus, the profiling unit sums the time (in memory-controller's clock cycles) it took each access to get the bus. This sum can later be read via the M4IF_MDSR8 register. The average can be calculated by reading the counter for the number of accesses that this master performed (via the MDSR2-5 registers), and dividing the 2 numbers.

The two additional registers which contain information about the profiling unit are M4IF_MDSR6 and M4IF_MDSR7. M4IF_MDSR6 contains the total number of accesses a specific request (configured in the MDCR) has accessed the bus. M4IF_MDSR7 contains the sum of "time for bus" for this specific request. An average of "time for bus" for this request can be calculated by dividing the two numbers. There is an option to use these two registers not only for a specific request, but for a type of access (read or write). Each master has two requests for read and two for write. The M4IF_MDSR6-7 registers can be used to accumulate the statistics for a single request or for both. This is configured by the "SPC_REQ" bit of M4IF_MDCR.

There is an option to reset all counters of the profiling unit by setting to "1" the "DBG_RST" bit in the M4IF_MDCR. As long as this bit is asserted, all counters will remain 0.

The debug unit's profiling is disabled by default. In order to enable it the user must write to the M4IF_MDCR register's "DBG_EN" bit. Please refer to Debug Control Register (M4IF_DCR) for details.

49.2.20 Buffers Size Table

Table 49-4. Master Buffers

Master#	Master Port Name	Master Port Write Buffers	Master Port Write Command Buffers	Master Port Read Command Buffers
0	IPU	72bx8x4	65bx4	65bx6
1	VPU	72bx8x6	65bx6	65bx12
2	MAX	36bx8x1 (32bit)	65bx1	65bx1
3	ARM	72bx8x6	65bx6	65bx6
4	SDMA	36bx8x2 (32bit)	65bx2	65bx2
5	GPU	72bx8x8	65bx8	65bx10
6	GPU2D	72bx8x4	65bx4	65bx6
7	USB	36bx8x2 (32bit)	65bx2	65bx2

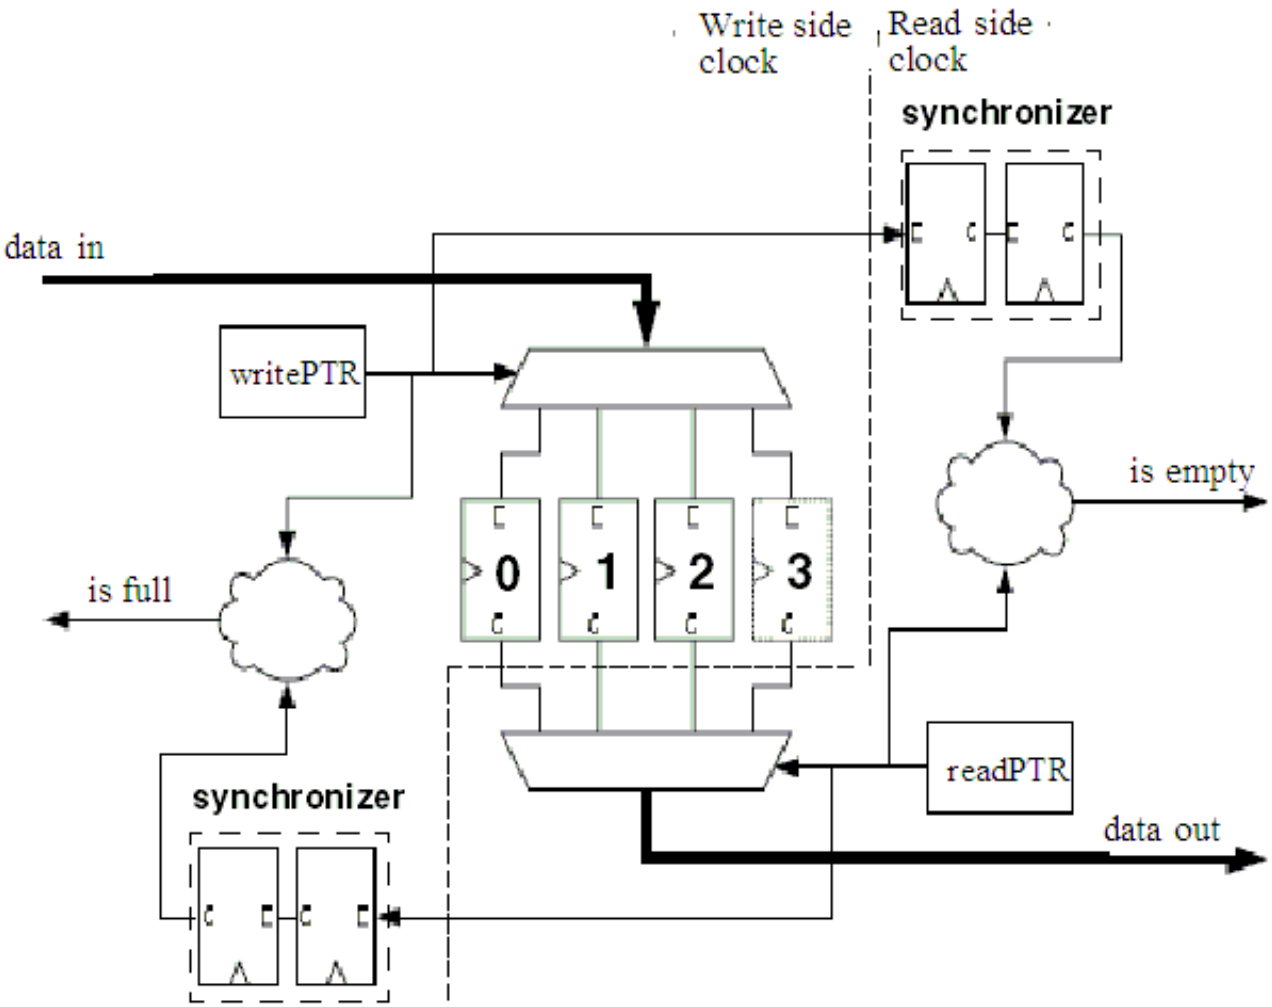
Table 49-5. Slave Buffers

Slave#	Slave Port Name	Slave Port Read Buffers	Slave Pending Address fifo	Slave Last Address Read fifo	Slave Last address Write fifo
0	FAST	66bx16x8	85bx1	13bx16	13bx3
1	SLOW	66bx4x8	67bx2	13bx4	13bx3
2	INT1	66bx2x8	67bx2	13bx2	13bx3
3	INT2	66bx2x8	67bx3	13bx2	13bx4

49.2.21 Synchronization

There are 12 AXI clock domains involved in the M4IF. 8 master clocks and 4 memory-controller clocks. Clock domain crossings are possible only from master clock to arbitration clock and vice versa. There cannot be a clock domain crossing between master clocks.

The controls which cross clock domains are synchronized using the "dual clock FIFO (DCF)".



The DCF allows for synchronization from "fast to slow" clock domains and from "slow to fast", allowing flexibility of the clock ratios between master and arbitration.

49.2.21.1 Synchronization Table

The following table shows the clock-domain relations between all 8 domains of the gaskets/masters, and 4 domains of the arbitrations/slaves.

S - always synchronizer on this path

[] - no synchronizer (domains are synchronized)

NC - No hardware connection at all

Table 49-6. Sync Table

Master#	Master Port Name	FAST	SLOW	INT1	INT2
0	IPU	S	NC	S	S
1	VPU	S	NC	S	S
2	MAX	S	S	[]	[]
3	ARM	S	S	S	S
4	SDMA	S	S	[]	[]
5	GPU	S	NC	S	NC
6	GPU2D	S	NC	S	S
7	USB	S	NC	[]	[]

49.2.22 Supporting 8/16 bit Bursts

M4IF now supports bursts of data size 8/16 bit, and of length up to 8 beat. INCR and WRAP type bursts are supported (according to the AXI protocol spec restrictions).

The M4IF splits the 8/16 bit bursts into a series of single bursts. For instance, an INCR burst of length 6 will be split and issued to the memory-controller/downsizer as a series of 6 single bursts.

4 status bits allow indication whether this kind of burst (8/16 bit) occurred. Please refer to: Master Len Interrupt (M4IF_MLI) for further details.

49.2.23 Dead-Lock Prevention in Read Accesses

M4IF allows flexibility by working in a "parallel routes" scheme. Because it has four separate arbiters, it can allow parallel work of EXTMC against all four slaves. For example, master #0 can send two requests to two different memory controllers (DDR and NFC, for example) and both controllers can handle these requests at the same time without interrupting each other.

This parallel scheme provides enhanced latency hiding when several masters work in parallel against several slaves, or even when a single master works versus multiple slaves.

However, there is a rare theoretical case in which this parallel scheme can cause a dead-lock for read requests. This rare case can only occur if there are two or more masters that work against the two or more slaves in a manner of interleaving the read accesses

between the slaves. That is, a master issues read requests back and forth between two slaves. One request to the first slave and the other to the second slave repeating this over and over. A second master does exactly the same (working with the same slaves).

In order to prevent this case from happening with a 100% certainty, a protection mechanism has been added to the M4IF called "Arbit Stop".

This mechanism limits a master from sending interleaved read requests. If there is an unfinished access in the master's read address buffer, M4IF will accept read accesses that are directed to the same slave as the access that is already inside the buffer. If an access to a different location is issued, it will not be inserted to the buffer. The access will wait on the bus until all accesses in the buffer are served and only then will be accepted.

The limitation is only on the read path. It does affect the write path.

Each master can be configured independently to have this limitation or not. Please refer to Control Register 0 (M4IF_CR0) for specific details.

49.3 Programmable Registers

M4IF memory area is in the IP memory region dedicated for its registers. M4IF registers are located at 0xBASE_0000 - 0xBASE_0FFF. "BASE" address is determined according to the SOC definitions.

The sections below describe the register definition of M4IF. It contains all information on registers definition like watermark and control registers. It contains all user programmable master priority register per arbitration path as well as priority specific definition for fast arbitration.

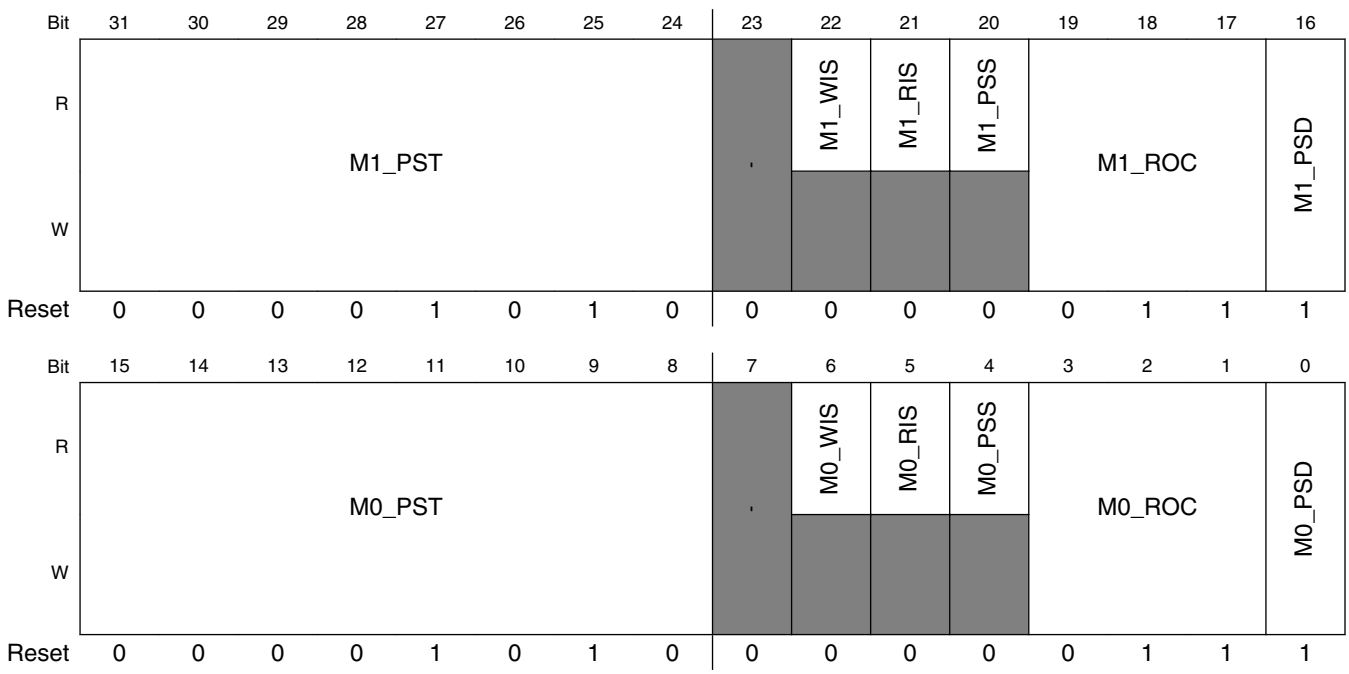
49.3.1 Power Saving Masters 0 (M4IF_PSM0)

The M4IF.PSM0 determines the power saving features for masters #0 and #1.

NOTE

The 'PST' and 'ROC' parameters can only be changed once after reset and before enabling the power saving feature (PSD=0).

Address: M4IF_PSM0 is 63FD_8000h base + 0h offset = 63FD_8000h



M4IF_PSM0 field descriptions

Field	Description
31–24 M1_PST	master #1 Power Saving Timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved this value is forbidden. 00000001 timer is configured to 100 clock cycles.

Table continues on the next page...

M4IF_PSM0 field descriptions (continued)

Field	Description
	00001010 Default value- 1000 clock cycles. 11111111 timer clock is defined to 25500 clock cycles.
23 -	Reserved.
22 M1_WIS	Master #1 Write Idle Status.This read only bit indicates whether master #1 write request buffer is idle (empty) or not. 0 idle 1 not idle
21 M1_RIS	Master #1 Read Idle Status.This read only bit indicates whether master #1 read request buffer is idle (empty) or not. 0 idle 1 not idle
20 M1_PSS	Master #1 Power Saving Status. This read only bit indicates whether master #1 gasket is in power saving mode. 0 not in power saving 1 power saving
19–17 M1_ROC	master #1 Ready Off Cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. 001-111 (000 is a forbidden value)
16 M1_PSD	master #1 Power Saving Disable. 0 power saving enabled 1 power saving disabled (default)
15–8 M0_PST	master #0 power saving timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 timer is configured to 100 clock cycles. 00001010 Default value- 1000 clock cycles. 11111111 timer clock is defined to 25500 clock cycles.
7 -	Reserved.
6 M0_WIS	Master #0 Write Idle Status.This read only bit indicates whether master #0 write request buffer is idle (empty) or not. 0 idle 1 not idle
5 M0_RIS	Master #0 Read Idle Status.This read only bit indicates whether master #0 read request buffer is idle (empty) or not. 0 idle 1 not idle

Table continues on the next page...

M4IF_PSM0 field descriptions (continued)

Field	Description
4 M0_PSS	Masrer #0 Power Saving Status. This read only bit indicates whether master #0 gasket is in power saving mode. 0 not in power saving 1 power saving
3–1 M0_ROC	master #0 Ready Off Cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. Default value is 3 cycles. 001 111 (000 is a forbidden value)
0 M0_PSD	master #0 Power Saving Disable. 0 power saving enabled 1 power saving disabled (default)

49.3.2 Power Saving Masters 1 (M4IF_PSM1)

The M4IF_PSM1 determines the power saving features for masters #2 and #3.

NOTE

The 'PST' and 'ROC' parameters can only be changed once after reset and before enabling the power saving feature (PSD=0).

Address: M4IF_PSM1 is 63FD_8000h base + 4h offset = 63FD_8004h

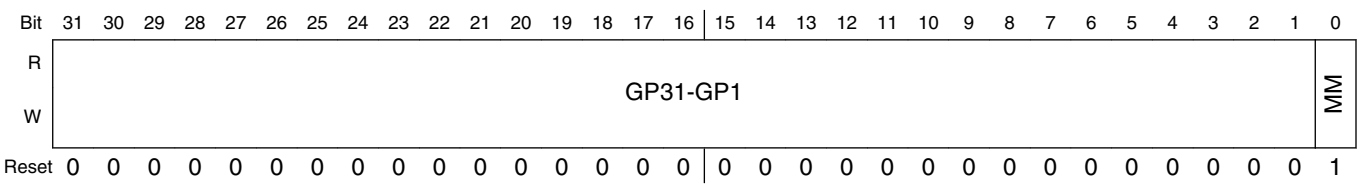
4 M2_PSS	Masrer #2 Power Saving Status. This read only bit indicates whether master #2 gasket is in power saving mode. 0 not in power saving 1 power saving
3–1 M2_ROC	master #2 Ready Off Cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. Default value is 3 cycles. 001-111 (000 is a forbidden value)
0 M2_PSD	master #2 Power Saving Disable. 0 power saving enabled 1 power saving disabled (default)

49.3.3 General Purpose Register (M4IF_GPR)

The M4IF_GENP is a general 32-bit read/write register.

Address: M4IF_GPR is 63FD_8000h base + Ch offset = 63FD_800Ch



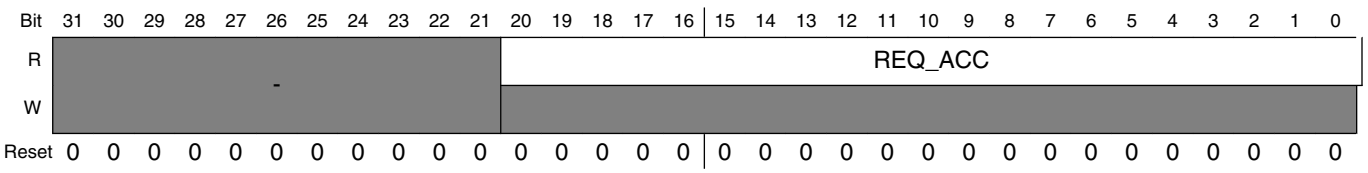
M4IF_GPR field descriptions

Field	Description
31–1 GP31-GP1	General purpose read/write bits. Can be used for anything.
0 MM	MM=1 means that NFC_D is muxed with EIM DATA on NANDF_D (on PATA_DATA[15:0] pins). If MM=0, NFC_D is muxed with EIM A/D on EIM_DA[15:1]. In this case the corresponding CSxGCR2[12] must also be set to notify EIM that its address is muxed with NF data. This MM bit is also selected by boot according to BOOT_CFG1[6] fuse.

49.3.4 Debug Status Register 6 (M4IF_DSR6)

The M4IF_MDSR6 reflects the total number of accesses made by a specific requesting the desired arbitration. The arbitration can be fast, slow, intr1 or intr2. See DCRDebug Control Register.

Address: M4IF_DSR6 is 63FD_8000h base + 18h offset = 63FD_8018h



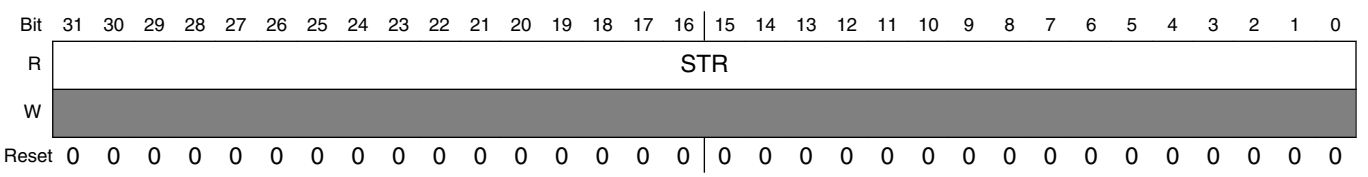
M4IF_DSR6 field descriptions

Field	Description
31–21 -	Reserved.
21–0 REQ_ACC	Number of accesses made by a specific request to a specific arbitration. The request and arbitration are configured in the M4IF_MDCR register.

49.3.5 Debug Status Register 7 (M4IF_DSR7)

The M4IF_MDSR7 reflects the sum of time all the requests of a specific kind were pending in the desired arbitration. The arbitration can be fast, slow, intr1 or intr2 and is configured in the M4IF_MDCR register. See DCRDebug Control Register.

Address: M4IF_DSR7 is 63FD_8000h base + 1Ch offset = 63FD_801Ch



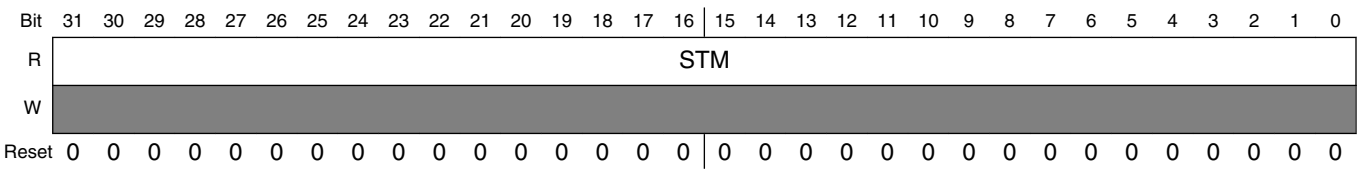
M4IF_DSR7 field descriptions

Field	Description
31–0 STR	Sum Time Request. These bits reflect the sum of time (in arbitration clock cycles) all the requests of a specific kind were pending at a specific arbitration. (The arbitration is configured in the M4IF_MDCR register)

49.3.6 Debug Status Register 8 (M4IF_DSR8)

The M4IF_MDSR8 reflects the sum of time all the requests of a specific master were pending in the desired arbitration. The arbitration can be fast, slow, intr1 or intr2 and is configured in the M4IF_MDCR register. See DCRDebug Control Register.

Address: M4IF_DSR8 is 63FD_8000h base + 20h offset = 63FD_8020h



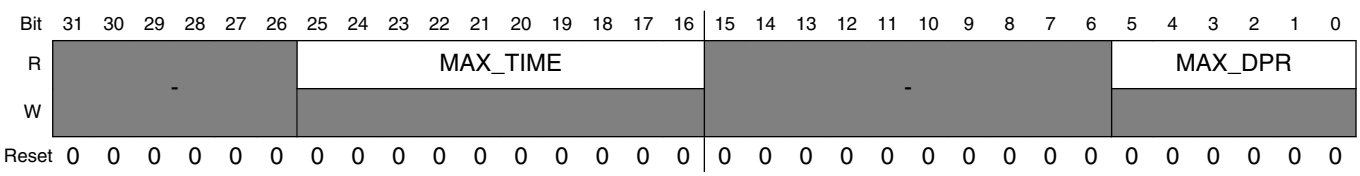
M4IF_DSR8 field descriptions

Field	Description
31–0 STM	Sum Time Master. These bits reflect the sum of time (in arbitration clock cycles) all the requests of a specific master were pending at a specific arbitration. (The arbitration is configured in the M4IF_MDCR register)

49.3.7 Debug Status Register 0 (M4IF_DSR0)

The M4IF_MDSR0 reflects the maximum values of the chosen dynamic priority and the "time for bus" of a master. The desired dynamic priority is configured in the MDCR. Please refer to DCRDebug Control Register.

Address: M4IF_DSR0 is 63FD_8000h base + 24h offset = 63FD_8024h



M4IF_DSR0 field descriptions

Field	Description
31–26 -	Reserved.
25–16 MAX_TIME	Maximum Time for Bus. This field represents the maximum number of cycles the selected master (see DDPM field in MDCR) was pending on the bus.
15–6 -	Reserved.

Table continues on the next page...

M4IF_DSR0 field descriptions (continued)

Field	Description
5–0 MAX_DPR	Maximum Dynamic Priority. These bits reflect the maximum value of the dynamic priority which was selected by the MDCR.

49.3.8 Debug Status Register 1 (M4IF_DSR1)

The M4IF_MDSR1 reflects the total number of accesses that were made through the desired arbitration. The arbitration can be fast, slow or intr, and is configured in the M4IF_MDCR register. Please refer to DCRDebug Control Register.

Address: M4IF_DSR1 is 63FD_8000h base + 28h offset = 63FD_8028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

M4IF_DSR1 field descriptions

Field	Description
31–24 -	Reserved.
23–0 TOT_ACC	Total Accesses. These bits reflect the total number of accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.

49.3.9 Debug Status Register 2 (M4IF_DSR2)

The M4IF_MDSR2 reflects the number of groups of 32 accesses (resolution is of 32 accesses) that master0 and master1 made through the desired arbitration. The arbitration can be fast, slow, int1 or int2 and configured in the M4IF_MDCR register. Please refer to DCRDebug Control Register

Address: M4IF_DSR2 is 63FD_8000h base + 2Ch offset = 63FD_802Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

M4IF_DSR2 field descriptions

Field	Description
31–16 M1_ACC	Master1 Accesses. These bits reflect the total number of master1 accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.
15–0 M0_ACC	Master0 Accesses. These bits reflect the total number of master0 accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.

49.3.10 Debug Status Register 3 (M4IF_DSR3)

The M4IF_MDSR3 register reflects the number of groups of 32 accesses (resolution is of 32 accesses) that master2 and master3 made through the desired arbitration. The arbitration can be fast, slow or internal and is configured in the M4IF_MDCR register. Please refer to DCRDebug Control Register.

Address: M4IF_DSR3 is 63FD_8000h base + 30h offset = 63FD_8030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

M4IF_DSR3 field descriptions

Field	Description
31–16 M3_ACC	Master3 Accesses. These bits reflect the total number of master3 accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.
15–0 M2_ACC	Master2 Accesses. These bits reflect the total number of master2 accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.

49.3.11 Debug Status Register 4 (M4IF_DSR4)

The M4IF_MDSR4 reflects the number of groups of 32 accesses (resolution is of 32 accesses) that master4 and master5 made through the desired arbitration. The arbitration can be fast, slow or intr and is configured in the M4IF_MDCR register.Please refer to DCRDebug Control Register

Address: M4IF_DSR4 is 63FD_8000h base + 34h offset = 63FD_8034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

M4IF_DSR4 field descriptions

Field	Description
31–16 M5_ACC	Master5 Accesses. These bits reflect the total number of master5 accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.
15–0 M4_ACC	Master4 Accesses. These bits reflect the total number of master4 accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.

49.3.12 Debug Status Register 5 (M4IF_DSR5)

The M4IF_MDSR5 reflects the number of groups of 32 accesses (resolution is of 32 accesses) that master6 and master7 made through the desired arbitration. The arbitration can be fast, slow or intr and is configured in the M4IF_MDCR register.Please refer to DCRDebug Control Register.

Address: M4IF_DSR5 is 63FD_8000h base + 38h offset = 63FD_8038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

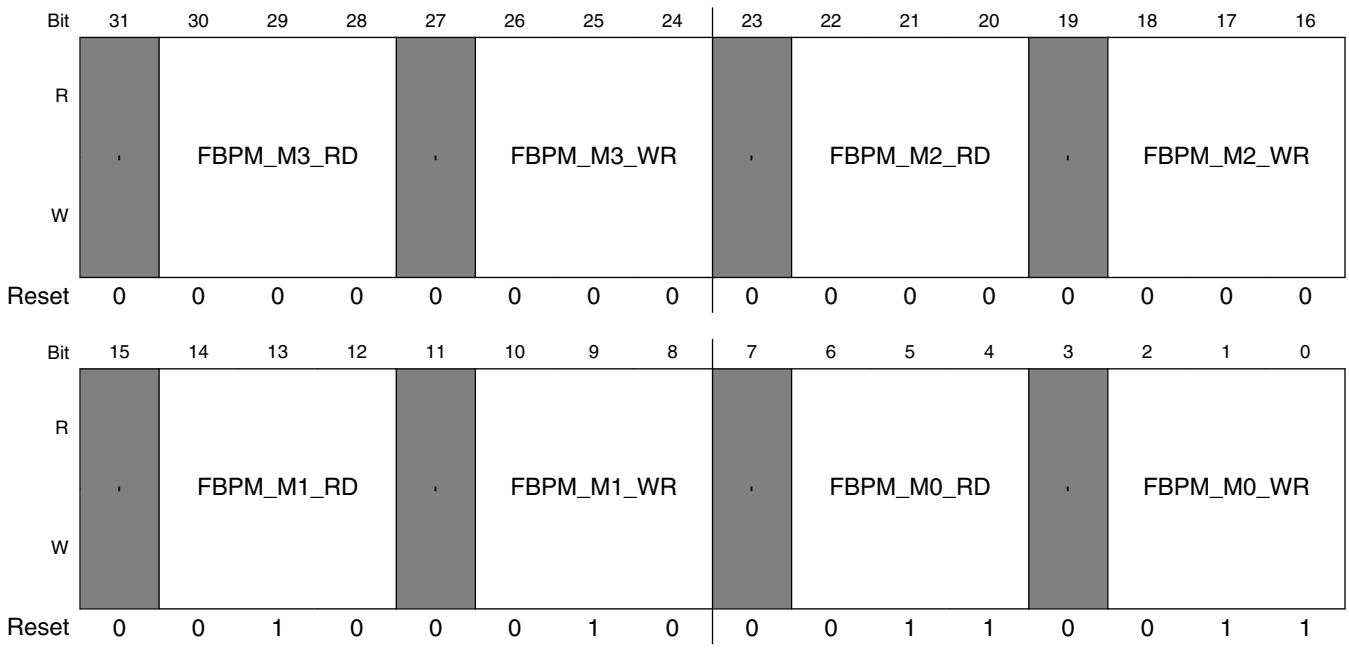
M4IF_DSR5 field descriptions

Field	Description
31–16 M7_ACC	Master7 Accesses. These bits reflect the total number of master7 accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.
15–0 M6_ACC	Master6 Accesses. These bits reflect the total number of master6 accesses that were made to a specific arbitration. The selected arbitration is configured in the MDCR.

49.3.13 F_Basic Priority Reg 0 (M4IF_F_BPR0)

M4IF_FBPM0 register contains the basic priority value for masters 0, 1, 2, and 3 for the fast arbitration logic only. Different registers are used for slow arbitration and internal memory arbitration logic.

Address: M4IF_F_BPR0 is 63FD_8000h base + 40h offset = 63FD_8040h



M4IF_F_BPR0 field descriptions

Field	Description
31 -	Reserved
30–28 FBPM_M3_RD	User defined value. These bits represent the basic priority value for read requests as configured by the user to master 3 000 encoding 0 001 encoding 1 111 encoding 7
27 -	Reserved.
26–24 FBPM_M3_WR	User defined value. These bits represent the basic priority value for write requests as configured by the user to master 3 000 encoding 0 001 encoding 1 111 encoding 7
23 -	Reserved

Table continues on the next page...

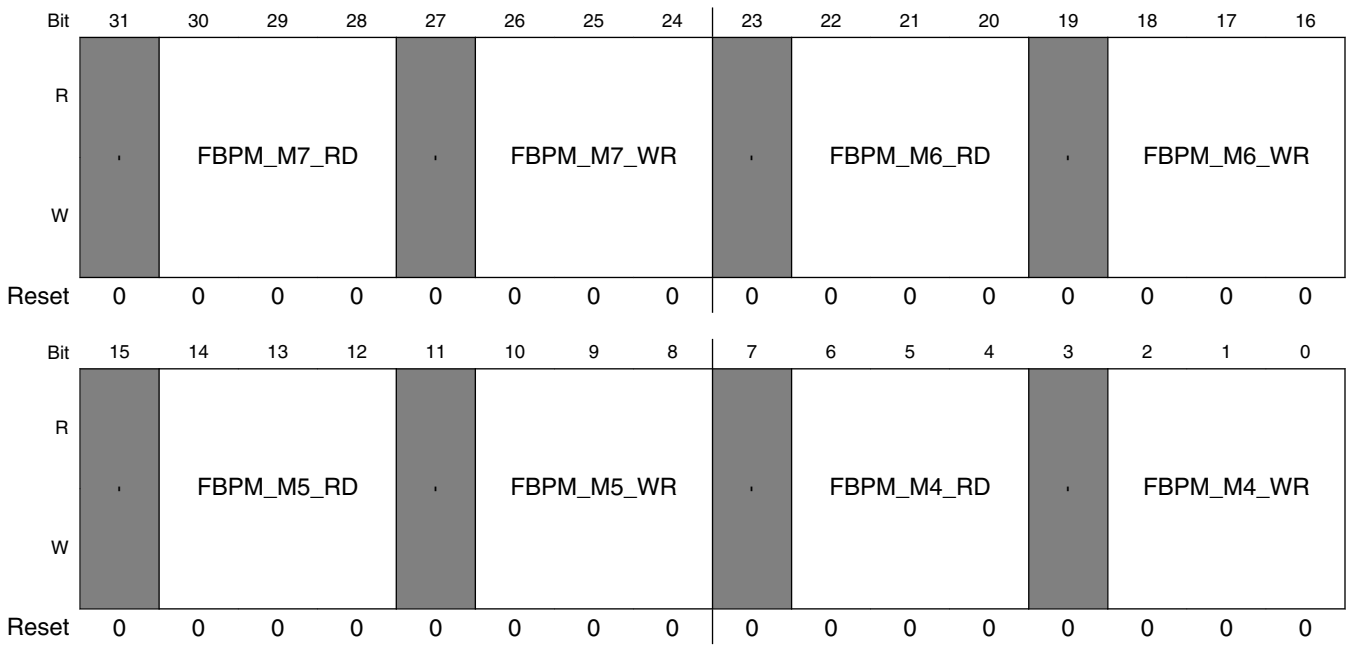
M4IF_F_BPR0 field descriptions (continued)

Field	Description
22–20 FBPM_M2_RD	User defined value. These bits represent the basic priority value for read requests as configured by the user to master 2. 000 encoding 0 001 encoding 1 111 encoding 7
19 -	Reserved
18–16 FBPM_M2_WR	User defined value. These bits represent the basic priority value for write requests as configured by the user to master 2. 000 encoding 0 001 encoding 1 111 encoding 7
15 -	Reserved
14–12 FBPM_M1_RD	User defined value. These bits represent the basic priority value for read requests as configured by the user to master 1. 000 encoding 0 001 encoding 1 111 encoding 7
11 -	Reserved
10–8 FBPM_M1_WR	User defined value. These bits represent the basic priority value for write requests as configured by the user to master 1. 000 encoding 0 001 encoding 1 111 encoding 7
7 -	Reserved
6–4 FBPM_M0_RD	User defined value. These bits represent the basic priority value for read requests as configured by the user to master 0. 000 encoding 0 001 encoding 1 111 encoding 7
3 -	Reserved
2–0 FBPM_M0_WR	User defined value. These bits represent the basic priority value for write requests as configured by the user to master 0. 000 encoding 0 001 encoding 1 111 encoding 7

49.3.14 F_Basic Priority Reg 1 (M4IF_F_BPR1)

M4IF_FBPM1 register contains the basic priority value for masters 4,5,6, and 7 for the fast arbitration logic only. Different registers are used for slow arbitration and internal memory arbitration logic.

Address: M4IF_F_BPR1 is 63FD_8000h base + 44h offset = 63FD_8044h



M4IF_F_BPR1 field descriptions

Field	Description
31 -	Reserved
30–28 FBPM_M7_RD	User defined value. These bits represent the basic priority value for read requests as configured by the user to master 3 000 encoding 0 001 encoding 1 111 encoding 7
27 -	Reserved.
26–24 FBPM_M7_WR	User defined value. These bits represent the basic priority value for write requests as configured by the user to master 7. 000 encoding 0 001 encoding 1 111 encoding 7
23 -	Reserved

Table continues on the next page...

M4IF_F_BPR1 field descriptions (continued)

Field	Description
22–20 FBPM_M6_RD	User defined value. These bits represent the basic priority value for read requests as configured by the user to master 6. 000 encoding 0 001 encoding 1 111 encoding 7
19 -	Reserved
18–16 FBPM_M6_WR	User defined value. These bits represent the basic priority value for write requests as configured by the user to master 6. 000 encoding 0 001 encoding 1 111 encoding 7
15 -	Reserved
14–12 FBPM_M5_RD	User defined value. These bits represent the basic priority value for read requests as configured by the user to master 5. 000 encoding 0 001 encoding 1 111 encoding 7

3 -	Reserved
2–0 FBPM_M4_WR	User defined value. These bits represent the basic priority value for write requests as configured by the user to master 4. 000 encoding 0 001 encoding 1 111 encoding 7

49.3.15 Control Register (M4IF_CR)

This register determines the values of the weights used for the MIF4 arbitration engine. It is also used for configuring the bypass features of the MIF4 (2nd degree) arbitration.

Address: M4IF_CR is 63FD_8000h base + 48h offset = 63FD_8048h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	MIF4_BYP_EN	MIF4_MAS			MIF4_ID				MIF4_IDTOO	-	MIF4_PAG_HIT			MIF4_ACC_HIT		
W																
Reset	1	0	0	0	0	0	0	0	1	0	0	1	1	0	0	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-				MIF4_DYN_JMP				MIF4_DYN_MAX				MIF4_GUARD			
W																
Reset	0	0	0	0	0	0	0	1	1	0	1	0	0	0	1	1

M4IF_CR field descriptions

Field	Description
31 MIF4_BYP_EN	Enable the MIF4 bypass feature. M4IF Bypass 0 - MIF4 bypass is disabled. 1 - MIF4 bypass is enabled. (default)
30–28 MIF4_MAS	This 3 bit field determines which master will be prioritized in the MIF4 arbitration. See M4IF Bypass Default value of MIF4_MAS is 0x000 - master #0.
27–24 MIF4_ID	This 4 bit field determines which AXI ID of the M4IF_MAS will be prioritized provided that the MIF4_IDTOO bit is set to '1'. M4IF Bypass Default value of is MIF4_ID 0x0000 - AXI ID 0.
23 MIF4_IDTOO	This bit defines whether all accesses of the MIF4_MAS master will be prioritized in the MIF4 arbitration, or if only accesses with the specific MIF4_ID will be prioritized. See M4IF Bypass Default value is 1, meaning only a combination of the AXI ID and the master will be prioritized. 0 all access will be prioritized. 1 only accesses with the special AXI ID will be prioritized.
22 -	Reserved

Table continues on the next page...

M4IF_CR field descriptions (continued)

Field	Description
21–19 MIF4_PAG_HIT	MIF4 Page Hit Rate. This value will be added by the MIF4 arbitration logic to any pending request that is considered as page hit. Default value of MIF4_PAG_HIT is 0x00100 - encoding 4.
18–16 MIF4_ACC_HIT	MIF4 Access Hit Rate. Any pending access that is considered as page hit is checked to be a consecutive access type or not. If it is a consecutive access than the weighting value of this request will increase by MIF4_ACC_HIT value. Default value of is MIF4_ACC_HIT 0x0010 - encoding 2.
15–12 -	Reserved
11–8 MIF4_DYN_JMP	MIF4 Dynamic Jump. Each time a request is being popped outside the MIF4 arbitration, the other pending requests will increase there dynamic score value by MIF4_DYN_JMP value. Default MIF4_DYN_JMP value is 0x0001 - encoding 1
7–4 MIF4_DYN_MAX	MIF4 Dynamic Maximum. MIF4_DYN_MAX is the maximum dynamic score value that each request inside the MIF4 mechanism can get. Default MIF4_DYN_MAX value is 0x1000 - encoding 8
3–0 MIF4_GUARD	MIF4 Guard. After a request reached the maximum dynamic score value, it will wait another MIF4_GUARD cycles and then force the request to popped outside the MIF4 arbitration. If MIF4_GUARD equal 0, this guarding mechanism is disabled. See Guarding Mechanism Default MIF4_GUARD value is 0x0000 - encoding 0 (Disabled)

49.3.16 I2_Unit_Level_Arbitration_ Register (M4IF_I2_ULAR)

The M4IF_I2ULA register configures the unit level arbitration configuration bits of each logic unit in levels 3, 4 and 5. Please refer to Arbitration Scheme when Masters have Same Priority (Bus Division) for more details on the arbitration logic units.

Address: M4IF_I2_ULAR is 63FD_8000h base + 74h offset = 63FD_8074h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	-											I2L5			I2L4M47		I2L4M03				I2L3M67				I2L3M45				I2L3M23				I2L3M01			
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	0	0	1	0	0	1	0	0	1	0	0	1	0	0	1	0	0

M4IF_I2_ULAR field descriptions

Field	Description
31–21 -	Reserved.
20–18 I2L5	Int 2 Level 5 - These bits configure the arbitration mode of level 5 arbitration unit in the int2 arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL5 is 0x100 - encoding 4.

Table continues on the next page...

M4IF_I2_ULAR field descriptions (continued)

Field	Description
17–15 I2L4M47	Int 2 Level 4 (m47) - These bits configure the arbitration mode of level 4(m47) arbitration unit in the int2 arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL4M47 is 0x100 - encoding 4.
14–12 I2L4M03	Int 2 Level 4 (m03) - These bits configure the arbitration mode of level 4(m03) arbitration unit in the int2 arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL4M03 is 0x100 - encoding 4.
11–9 I2L3M67	Int 2 Level 3 (m67) - These bits configure the arbitration mode of level 3(m67) arbitration unit in the int2 arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL3M67 is 0x100 - encoding 4.
8–6 I2L3M45	Int 2 Level 3 (m45) - These bits configure the arbitration mode of level 3(m45) arbitration unit in the int2 arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL3M45 is 0x100 - encoding 4.
5–3 I2L3M23	Int 2 Level 3 (m23) - These bits configure the arbitration mode of level 3(m23) arbitration unit in the int2 arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL3M23 is 0x100 - encoding 4.
2–0 I2L3M01	Int 2 Level 3 (m01) - These bits configure the arbitration mode of level 3(m01) arbitration unit in the int2 arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL3M01 is 0x100 - encoding 4.

49.3.17 Int. 2 Memory Arbitration Control Register (M4IF_I2MACR)

Address: M4IF_I2MACR is 63FD_8000h base + 78h offset = 63FD_8078h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	-

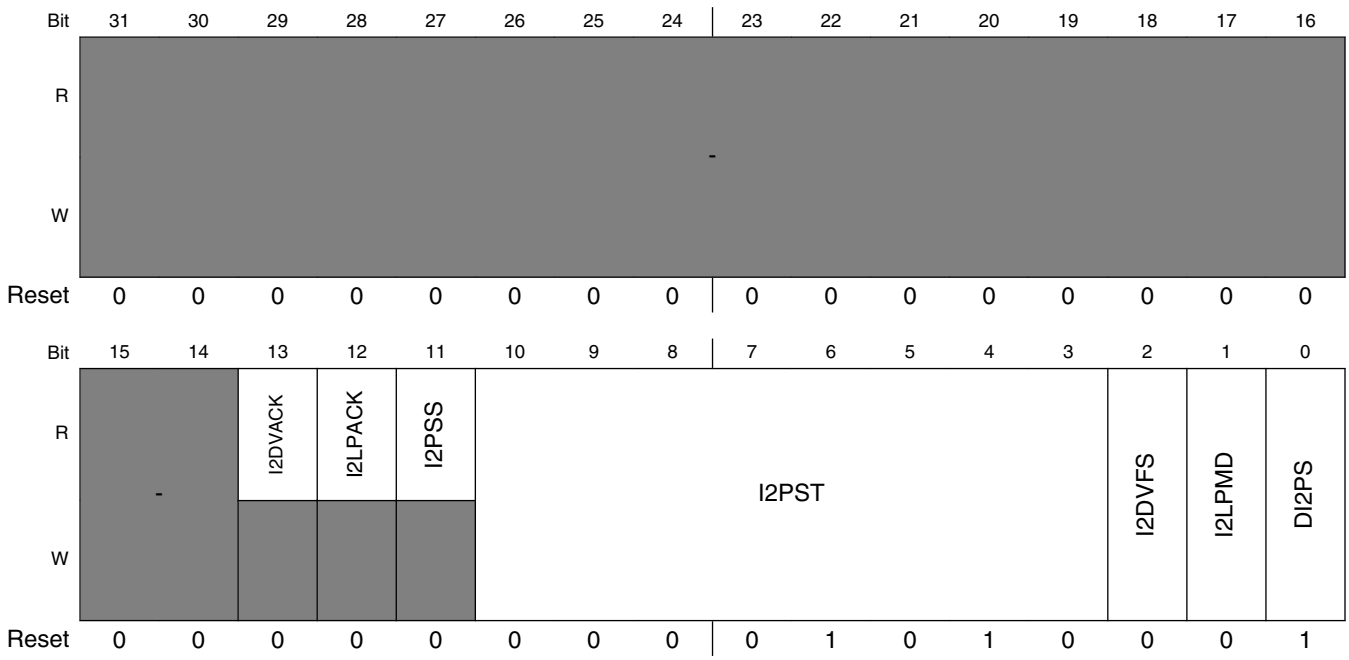
M4IF_I2MACR field descriptions

Field	Description
31–9 -	Reserved
8 -	Reserved must be cleared
7–0 -	Reserved

49.3.18 Internal 2 Control Register (M4IF_I2CR)

The M4IF_RINT2 holds control bits for the int2. memory channel arbitration.

Address: M4IF_I2CR is 63FD_8000h base + 7Ch offset = 63FD_807Ch



M4IF_I2CR field descriptions

Field	Description
31–14 -	Reserved
13 I2DVACK	Intr 2 DVFS acknowledge. This read only bit indicates whether a DVFS acknowledge on the internal 2 memory channel was asserted.
12 I2LPACK	Intr 2 low-power acknowledge. This read only bit indicates whether a low-power acknowledge on the internal 2 memory channel was asserted.

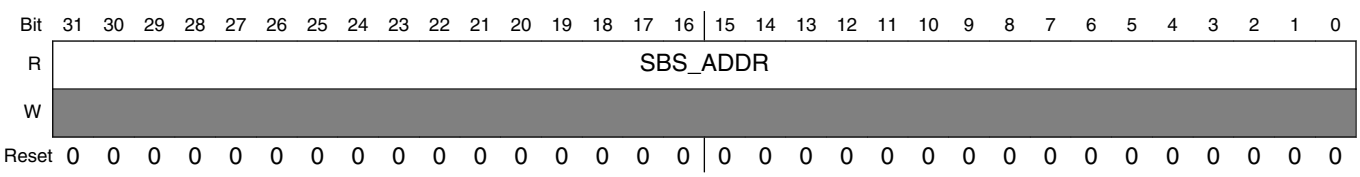
Table continues on the next page...

M4IF_I2CR field descriptions (continued)

Field	Description
11 I2PSS	Intr 2 Power Saving Status. This read only bit indicates whether internal 2 mem. channel is in power saving mode. 0 not in power saving 1 power saving
10–3 I2PST	Internal 2memory arbitration Power Saving Timer - these bits defines the timer value of the power saving mode of the internal 2 memory arbitration. The value in this field represent clock cycles of the internal 2 memory arbitration clock multiplied by 8. Default value is set to 80 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 timer is configured to 8 clock cycles. 00001010 Default value- 80 clock cycles. 11111111 timer clock is defined to 2040 clock cycles.
2 I2DVFS	Internal mem. 2 DVFS request. SW request for DVFS of internal 2 mem. channel. 0 no DVFS request 1 DVFS request
1 I2LPMD	Internal mem. 2 LPMD request. SW request for LPMD of internal 2 mem. channel. 0 no LPMD request 1 LPMD request
0 DI2PS	Disable Internal 2 memory Power Saving mode - this bit when configured can disable auto power saving mode of the internal 2 memory interface. 0 power saving is enabled 1 power saving is disabled (default mode)

49.3.19 Step By Step Address (M4IF_SSA)

Address: M4IF_SSA is 63FD_8000h base + 84h offset = 63FD_8084h



M4IF_SSA field descriptions

Field	Description
31–0 SBS_ADDR	Step By Step Address. These bits reflect the address of a request pending on a specific arbitration/ memory controller, as configured in bits [9:8] (RARB) of the M4IF_MDCR register.

49.3.20 Step By Step Address Controls (M4IF_SSAC)

Address: M4IF_SSAC is 63FD_8000h base + 88h offset = 63FD_8088h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	-		SBS_VLD	SBS_TYPE	SBS_LEN			SBS_SIZE		SBS_BURST		SBS_PROT			SBS_LOCK	
W

R	SBS_CACHE				SBS_AXI_ID				SBS_MASTER_ID				SBS_MASTER_ID			SBS_END
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

M4IF_SSAC field descriptions

Field	Description
31–30 -	Reserved
29 SBS_VLD	Step By Step Valid. This bit reflects whether there is a pending request in the arbitration that is configured in bits [9:8] (RARB) of the M4IF_MDCR register. 0 not valid 1 valid
28 SBS_TYPE	Step By Step Request Type. These bits reflect the pending request type (read/write) as configured in bits [9:8] (RARB) of the M4IF_MDCR register. 0 write 1 read
27–25 SBS_LEN	Step By Step Length. These bits reflect the AXI "LEN" field of the pending request as configured in bits [9:8] (RARB) of the M4IF_MDCR register. 000 burst of length 1 001 burst of length 2 111 burst of length 8
24–23 SBS_SIZE	Step By Step Size. These bits reflect the AXI "SIZE" field of the pending request as configured in bits [9:8] (RARB) of the M4IF_MDCR register. 00 8 bits 01 16 bits 10 32 bits 11 64 bits
22–21 SBS_BURST	Step By Step Burst. These bits reflect the AXI "BURST" field of the pending request as configured in bits [9:8] (RARB) of the M4IF_MDCR register.

Table continues on the next page...

M4IF_SSAC field descriptions (continued)

Field	Description
	00 reserved 01 INCR burst 10 WRAP burst 11 reserved
20–18 SBS_PROT	Step By Step Protection. These bits reflect the AXI "PROT" field of the pending request as configured in bits [9:8] (RARB) of the M4IF_MDCR register.
17–16 SBS_LOCK	Step By Step Lock. These bits reflect the AXI "LOCK" field of the pending request as configured in bits [9:8] (RARB) of the M4IF_MDCR register.
15–12 SBS_CACHE	Step By Step Cache. These bits reflect the AXI "CACHE" field of the pending request as configured in bits [9:8] (RARB) of the M4IF_MDCR register.
11–8 SBS_AXI_ID	Step By Step AXI ID. These bits reflect the AXI "ID" field of the pending request as configured in bits [9:8] (RARB) of the M4IF_MDCR register.
7–4 SBS_MASTER_ID	Step By Step Master ID. These bits reflect the Master ID of the pending request as configured in bits [9:8] (RARB) of the M4IF_MDCR register.
3–1 SBS_MASTER_ID	Step By Step Master ID. These bits reflect the EXTMC Master port of the pending request as configured in bits [9:8] (RARB) of the M4IF_MDCR register.
0 SBS_END	Step By Step Endianess. This bit reflects the endianess of the pending request as configured in bits [9:8] (RARB) of the M4IF_MDCR register.

49.3.21 Control Register 0 (M4IF_CR0)

Address: M4IF_CR0 is 63FD_8000h base + 8Ch offset = 63FD_808Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

M4IF_CR0 field descriptions

Field	Description
31 SW_RST	Software reset. This bit resets all FFs but the configuration registers. 0 reset 1 no reset
30–28 -	Reserved.
27 FDVACK	Fast DVFS acknowledge. This read only bit indicates whether a DVFS acknowledge on the fast channel was asserted.
26 SDVACK	Slow DVFS acknowledge. This read only bit indicates whether a DVFS acknowledge on the slow channel was asserted.
25 IDVACK	Intr DVFS acknowledge. This read only bit indicates whether a DVFS acknowledge on the internal memory channel was asserted.
24 DVACK	General DVFS acknowledge. This read only bit indicates whether a DVFS acknowledge on the whole EXTMC was asserted.
23 FLPACK	Fast low-power acknowledge. This read only bit indicates whether a low-power acknowledge on the fast channel was asserted.
22 SLPACK	Slow low-power acknowledge. This read only bit indicates whether a low-power acknowledge on the slow channel was asserted.
21 ILPACK	Intr low-power acknowledge. This read only bit indicates whether a low-power acknowledge on the internal memory channel was asserted.
20 LPACK	General low-power acknowledge. This read only bit indicates whether a low-power acknowledge on the whole EXTMC was asserted.
19 -	Reserved.
18 FPSS	Fast Power Saving Status. This read only bit indicates whether fast channel is in power saving mode. 0 not in power saving 1 power saving
17 SPSS	Slow Power Saving Status. This read only bit indicates whether slow channel is in power saving mode. 0 not in power saving 1 power saving
16 IPSS	Intr Power Saving Status. This read only bit indicates whether internal mem. channel is in power saving mode. 0 not in power saving 1 power saving
15 EAS3	Enable Arbit Stop M3 - Stop all read accesses to M3 that are not from to the same slave as the ones already inside the gasket. 0 disabled (not stopping) 1 enabled (stopping) - default
14 EAS2	Enable Arbit Stop M2 - Stop all read accesses to M2 that are not from to the same slave as the ones already inside the gasket.

Table continues on the next page...

M4IF_CR0 field descriptions (continued)

Field	Description
	0 disabled (not stopping) - default 1 enabled (stopping)
13 EAS1	Enable Arbit Stop M1 - Stop all read accesses to M1 that are not from to the same slave as the ones already inside the gasket. 0 disabled (not stopping) - default 1 enabled (stopping)
12 EAS0	Enable Arbit Stop M0 - Stop all read accesses to M0 that are not from to the same slave as the ones already inside the gasket. 0 disabled (not stopping) 1 enabled (stopping) - default
11 FDVFS	Fast DVFS request. SW request for DVFS of fast channel. 0 no DVFS request 1 DVFS request
10 SDVFS	Slow DVFS request. SW request for DVFS of slow channel. 0 no DVFS request 1 DVFS request
9 IDVFS	Internal mem. DVFS request. SW request for DVFS of internal mem. channel. 0 no DVFS request 1 DVFS request
8 DVFS	General DVFS request. SW request for DVFS of whole EXTMC. 0 no DVFS request 1 DVFS request
7 FLPMD	Fast LPMD request. SW request for LPMD of fast channel. 0 no LPMD request 1 LPMD request
6 SLPMD	Slow LPMD request. SW request for LPMD of slow channel. 0 no LPMD request 1 LPMD request
5 ILPMD	Internal mem. LPMD request. SW request for LPMD of internal mem. channel. 0 no LPMD request 1 LPMD request
4 LPMD	General LPMD request. SW request for LPMD of whole EXTMC. 0 no LPMD request 1 LPMD request
3 -	Reserved.

Table continues on the next page...

M4IF_CR0 field descriptions (continued)

Field	Description
2 DFPS	Disable Fast arb. Power Saving mode - this bit when configured can disable auto power saving mode of the fast arbitration and its memory controller. 0 power saving is enabled 1 power saving is disabled (default mode)
1 DSPS	Disable Slow arb. Power Saving mode - this bit when configured can disable auto power saving mode of the slow arbitration and its memory controllers. 0 power saving is enabled 1 power saving is disabled (default mode)
0 DIPS	Disable Internal memory Power Saving mode - this bit when configured can disable auto power saving mode of the internal memory interface. 0 power saving is enabled 1 power saving is disabled (default mode)

49.3.22 Control Register 1 (M4IF_CR1)

The M4IF_MCR1 register defines the timer values of each arbitration to be used for auto power saving mode.

Address: M4IF_CR1 is 63FD_8000h base + 90h offset = 63FD_8090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	EAS7	EAS6	EAS5	EAS4	-				IPST						-	SPST [-8:7]

Reset	0	0	0	1	0	1	0	0	0	0	0	0	1	0	1	0

M4IF_CR1 field descriptions

Field	Description
31 EAS7	Enable Arbit Stop M7 - Stop all read accesses to M7 that are not from to the same slave as the ones already inside the gasket. 0 disabled (not stopping) 1 enabled (stopping) - default
30 EAS6	Enable Arbit Stop M6 - Stop all read accesses to M6 that are not from to the same slave as the ones already inside the gasket. 0 disabled (not stopping) - default 1 enabled (stopping)
29 EAS5	Enable Arbit Stop M5 - Stop all read accesses to M5 that are not from to the same slave as the ones already inside the gasket. 0 disabled (not stopping) - default 1 enabled (stopping)
28 EAS4	Enable Arbit Stop M4 - Stop all read accesses to M4 that are not from to the same slave as the ones already inside the gasket. 0 disabled (not stopping) - default 1 enabled (stopping)
27–26 -	Reserved
25–18 IPST	Internal 1 memory arbitration Power Saving Timer - these bits defines the timer value of the power saving mode of the internal 1 memory arbitration. The value in this field represent clock cycles of the internal 1 memory arbitration clock multiplied by 8. Default value is set to 80 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 timer is configured to 8 clock cycles. 00001010 Default value- 80 clock cycles. 11111111 timer clock is defined to 2040 clock cycles.
17 -	Reserved
16–9 SPST	Slow arbitration Power Saving Timer - these bits defines the timer value of the power saving mode of the slow arbitration. The value in this field represent clock cycles of the slow memory arbitration clock multiplied by 8. Default value is set to 80 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 timer is configured to 8 clock cycles. 00001010 Default value- 80 clock cycles. 11111111 timer clock is defined to 2040 clock cycles.
8 -	Reserved

Table continues on the next page...

M4IF_CR1 field descriptions (continued)

Field	Description
7–0 FPST	Fast arbitration Power Saving Timer - these bits defines the timer value of the power saving mode of the fast arbitration. The value in this field represent clock cycles of the fast memory arbitration clock multiplied by 8. Default value is set to 80 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 timer is configured to 8 clock cycles. 00001010 Default value- 80 clock cycles. 11111111 timer clock is defined to 2040 clock cycles.

49.3.23 Debug Control Register (M4IF_DCR)

The M4IF_MDCR controls several functions in the debug unit.

Address: M4IF_DCR is 63FD_8000h base + 94h offset = 63FD_8094h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	FSBS_EN	FSBS	SSBS	I1SBS	I2SBS	-	RARB		-						VARB	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

M4IF_DCR field descriptions

Field	Description
31 DBG_EN	Debug Enable. Enable debug units counters and summing. default is "disable" 0 disable 1 enable

Table continues on the next page...

M4IF_DCR field descriptions (continued)

Field	Description
30–28 -	Reserved.
27 DBG_RST	Debug Reset. Reset all debug unit's counters and summing. 0 no reset 1 reset
26–24 -	Reserved.
23 I2SBS_EN	Step By Step Enable int2. Enable step by step mode for int2 channel. default is "disable" 0 disable 1 enable
22 I1SBS_EN	Step By Step Enable int1. Enable step by step mode for int1 channel. default is "disable" 0 disable 1 enable
21 SSBS_EN	Step By Step Enable slow. Enable step by step mode for slow channel. default is "disable" 0 disable 1 enable
20 DDPT	Debug Dynamic Priority Type. Read or Write request reflect on the debug unit registers. 0 write 1 read
19–17 DDPM	Debug Dynamic Priority Master. Which master to reflect on the debug unit registers.
16 -	Reserved.
15 FSBS_EN	Step By Step Enable fast. Enable step by step mode for fast channel. default is "disable" 0 disable 1 enable
14 FSBS	Fast Step By Step. This bit trigger the fast arbitration in step by step mode. Write '1' to this register in order to initiate a new transaction inside the fast arbitration. This bit goes down to '0' when the new transaction is pending on AXI bus and then waiting for another write '1' in order to initiate the next transaction. 1 Fast arbitration is waiting to a new transaction to go out on the AXI bus. 0 There is a pending transaction on the AXI bus.
13 SSBS	Slow Step By Step. This bit trigger the slow arbitration in step by step mode. Write '1' to this register in order to initiate a new transaction inside the slow arbitration. This bit goes down to '0' when the new

Table continues on the next page...

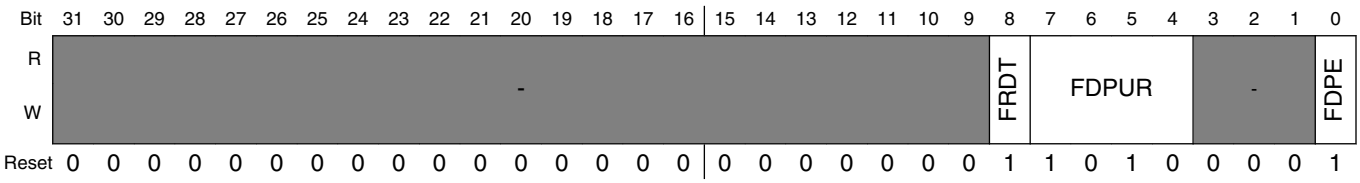
M4IF_DCR field descriptions (continued)

Field	Description
	transaction is pending on AXI bus and then waiting for another write '1' in order to initiate the next transaction. 1 Slow arbitration is waiting to a new transaction to go out on the AXI bus. 0 There is a pending transaction on the AXI bus.
12 I1SBS	Int1 Step By Step. This bit trigger the int1 arbitration in step by step mode. Write '1' to this register in order to initiate a new transaction inside the int1 arbitration. This bit goes down to '0' when the new transaction is pending on AXI bus and then waiting for another write '1' in order to initiate the next transaction. 1 Int1 arbitration is waiting to a new transaction to go out on the AXI bus. 0 There is a pending transaction on the AXI bus.
11 I2SBS	Int2 Step By Step. This bit trigger the int2 arbitration in step by step mode. Write '1' to this register in order to initiate a new transaction inside the int2 arbitration. This bit goes down to '0' when the new transaction is pending on AXI bus and then waiting for another write '1' in order to initiate the next transaction. 1 Int2 arbitration is waiting to a new transaction to go out on the AXI bus. 0 There is a pending transaction on the AXI bus.
10 -	Reserved.
9–8 RARB	Read Arbitration. These 2 bits decide which arbitration will be reflected on the debug status registers when reading them. 00 fast arbitration 01 slow arbitration 10 internal 1 mem. arbitration 11 internal 2 mem. arbitration
7–2 -	Reserved
1–0 VARB	Visibility Arbitration. These 2 bits decide which arbitration to reflect on the EXTMC debug output pins and on the step by step registers. 00 fast arbitration 01 slow arbitration 10 internal 1 mem. arbitration 11 internal 2 mem. arbitration

49.3.24 Fast Arbitration Control Register (M4IF_FACR)

The M4IF_FACR register is the control register of the fast arbitration logic. It contains several configuration field in order to let the user optimize the arbitration.

Address: M4IF_FACR is 63FD_8000h base + 98h offset = 63FD_8098h



M4IF_FACR field descriptions

Field	Description
31–9 -	Reserved
8 FRDT	Read Through bit - this bit indicates the read mode from fast channel 0 store and forward 1 read through (default)
7–4 FDPUR	Dynamic Priority Update Resolution - This field defines the minimum time resolution (in number of arbitration selections) that each priority master would be update by the dynamic priority logic.The minimum value is 2 selections. The value can be changed by the user in order to achieve lower resolution to reduce dynamic priority influence on the arbitration logic. It is recommended not to use higher value than average access time of the memory controller. 0000 reserved 0001 encoding 2 1010 Default value- encoding 11. 1111 Dynamic priority calculation updates will be done once per 15 selections minimum.
3–1 -	Reserved
0 FDPE	Dynamic Priority Enable. This bit defines whether arbitration logic would use dynamic priority logic or not. 0 Dynamic Priority is not used, disabled. 1 Dynamic Priority is used, enabled.

49.3.25 F_Priority Weighting Configuration Register (M4IF_F_PWCR)

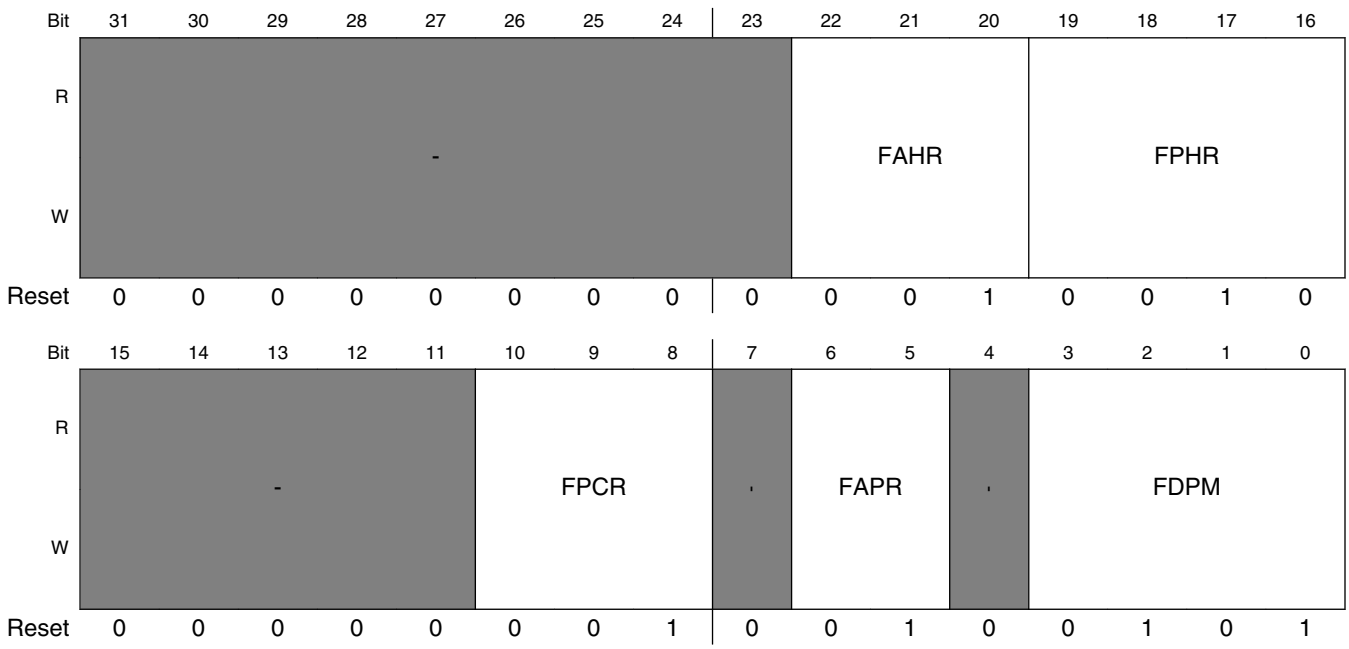
The M4IF_FPWC register configures the weighting values of each field in the arbitration. Each weighting field has a default value based on model simulation. It is highly recommended to use these default values and and to refrain from changing them. Any change to these values should be done with extreme care.

NOTE

At any configuration of these values, the user must make sure that the following restriction is kept:

FPHR+FAHR+FDPM+[highest basic priority of fast channel] < 16

Address: M4IF_F_PWCR is 63FD_8000h base + 9Ch offset = 63FD_809Ch



M4IF_F_PWCR field descriptions

Field	Description
31–23 -	Reserved.
22–20 FAHR	Access Hit Rate. Any pending access that is considered as page hit is checked to be a consecutive access type or not. If it is a consecutive access than the weighting value of this request will increase by FAHR value. Default value of FAHR is 0x001 - encoding 1.
19–16 FPHR	Page Hit Rate. This value will be added by the dynamic arbitration logic to any pending request that is considered as page hit. Default value of FPHR is 0x0010 - encoding 2.
15–11 -	Reserved.
10–8 FPCR	Pending Cycles Rate. Each timing resolution the dynamic arbitration updates a pending request, it will increase its weighting value by FPCR value. Default FPCR value is 0x001 - encoding 1.
7 -	Reserved.
6–5 FAPR	Access Penalty Rate. This value is decreased from any data in a served request. For example, for served access of burst2 type, the weighting value will be decreased by 2xFAPR.

Table continues on the next page...

M4IF_F_PWCR field descriptions (continued)

Field	Description
	Default FAPR value is 0x01 - encoding 1.
4 -	Reserved.
3–0 FDPM	Dynamic Priority Maximum. This field defines the maximum value of the dynamic priority. This value can be changed in order to get larger window for the dynamic arbitration. Default value of FDPM is 0x0101 - encoding 5.

49.3.26 Slow Arbitration Control Register (M4IF_SACR)

Address: M4IF_SACR is 63FD_8000h base + A0h offset = 63FD_80A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
31–9 -	Reserved
8 -	Reserved. Must be cleared
7–0 -	Reserved

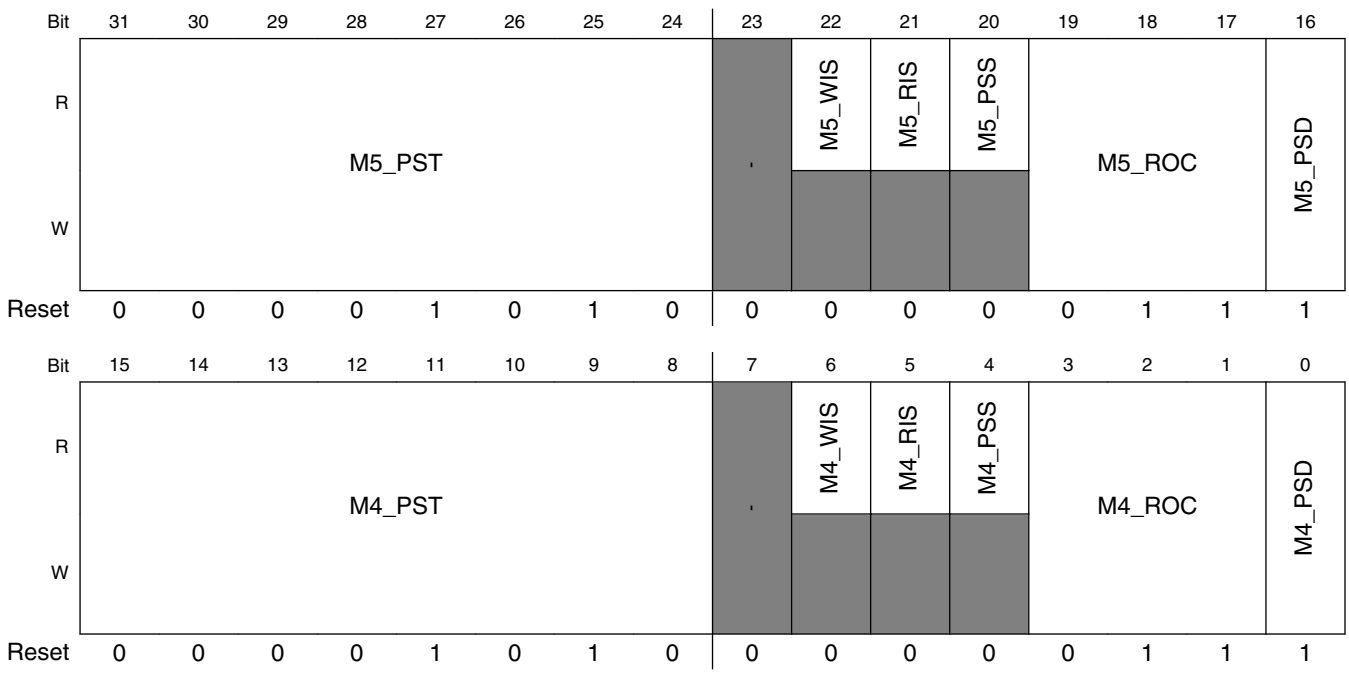
49.3.27 Power Saving Masters 2 (M4IF_PSM2)

The M4IF_PSM2 determines the power saving features for masters #4 and #5.

NOTE

The 'PST' and 'ROC' parameters can only be changed once after reset and before enabling the power saving feature (PSD=0)

Address: M4IF_PSM2 is 63FD_8000h base + A4h offset = 63FD_80A4h



M4IF_PSM2 field descriptions

Field	Description
31–24 M5_PST	master #5 power saving timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 timer is configured to 100 clock cycles. 00001010 Default value- 1000 clock cycles. 11111111 timer clock is defined to 25500 clock cycles.
23 -	Reserved.
22 M5_WIS	Master #5 Write Idle Status.This read only bit indicates whether master #5 write request buffer is idle (empty) or not. 0 idle 1 not idle

Table continues on the next page...

M4IF_PSM2 field descriptions (continued)

Field	Description
21 M5_RIS	Master #5 Read Idle Status.This read only bit indicates whether master #5 read request buffer is idle (empty) or not. 0 idle 1 not idle
20 M5_PSS	Masrer #5 Power Saving Status. This read only bit indicates whether master #5 gasket is in power saving mode. 0 not in power saving 1- power saving
19–17 M5_ROC	master #5 ready off cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. 001-111 (000 is a forbidden value)
16 M5_PSD	master #5 power saving disable. 0 power saving enabled 1 power saving disabled (default)
15–8 M4_PST	master #4 power saving timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 timer is configured to 100 clock cycles. 00001010 Default value- 1000 clock cycles. 11111111 timer clock is defined to 25500 clock cycles.
7 -	Reserved.
6 M4_WIS	Master #4 Write Idle Status.This read only bit indicates whether master #4 write request buffer is idle (empty) or not. 0 idle 1 not idle
5 M4_RIS	Master #4 Read Idle Status.This read only bit indicates whether master #4 read request buffer is idle (empty) or not. 0 idle 1 not idle
4 M4_PSS	Masrer #4 Power Saving Status. This read only bit indicates whether master #4 gasket is in power saving mode. 0 not in power saving 1 power saving
3–1 M4_ROC	master #4 ready off cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. Default value is 3 cycles.

Table continues on the next page...

M4IF_PSM2 field descriptions (continued)

Field	Description
	001-111 (000 is a forbidden value)
0 M4_PSD	master #4 power saving disable. 0 power saving enabled 1 power saving disabled (default)

49.3.28 Int. Memory Arbitration Control Register (M4IF_IMACR)

Address: M4IF_IMACR is 63FD_8000h base + A8h offset = 63FD_80A8h

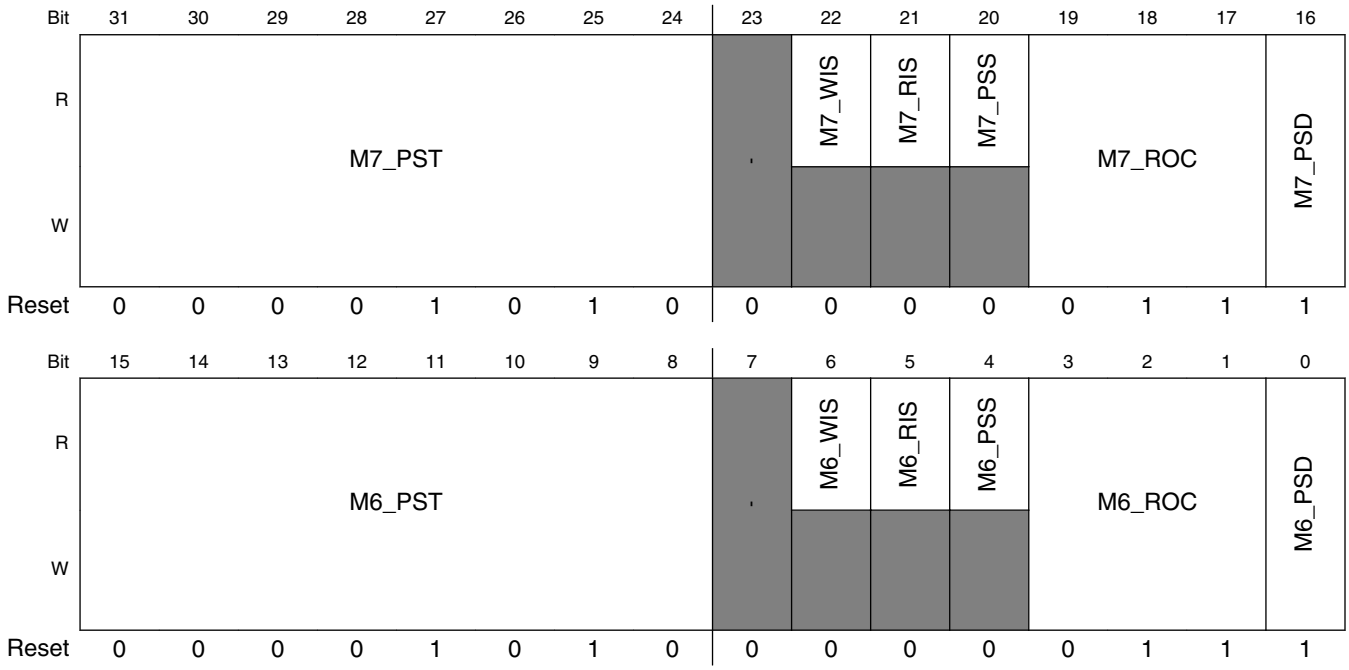
49.3.29 Power Saving Masters 3 (M4IF_PSM3)

The M4IF_PSM3 determines the power saving features for masters #6 and #7.

NOTE

The 'PST' and 'ROC' parameters can only be changed once after reset and before enabling the power saving feature (PSD=0)

Address: M4IF_PSM3 is 63FD_8000h base + ACh offset = 63FD_80ACh



M4IF_PSM3 field descriptions

Field	Description
31–24 M7_PST	master #7 power saving timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 timer is configured to 100 clock cycles. 00001010 Default value- 1000 clock cycles. 11111111 timer clock is defined to 25500 clock cycles.
23 -	Reserved.
22 M7_WIS	Master #7 Write Idle Status.This read only bit indicates whether master #7 write request buffer is idle (empty) or not. 0 idle 1 not idle
21 M7_RIS	Master #7 Read Idle Status.This read only bit indicates whether master #7 read request buffer is idle (empty) or not. 0 idle 1 not idle
20 M7_PSS	Masrer #7 Power Saving Status. This read only bit indicates whether master #7 gasket is in power saving mode.

Table continues on the next page...

M4IF_PSM3 field descriptions (continued)

Field	Description
	0 not in power saving 1 power saving
19–17 M7_ROC	master #7 ready off cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. 001-111 (000 is a forbidden value)
16 M7_PSD	master #7 power saving disable. 0 power saving enabled 1 power saving disabled (default)
15–8 M6_PST	master #6 power saving timer. The real value which is used is register-value multiplied by 100. Default value is set to 1000 clock cycles. 00000000 Reserved - this value is forbidden. 00000001 timer is configured to 100 clock cycles. 00001010 Default value 1000 clock cycles. 11111111 timer clock is defined to 25500 clock cycles.
7 -	Reserved.
6 M6_WIS	Master #6 Write Idle Status.This read only bit indicates whether master #6 write request buffer is idle (empty) or not. 0 idle 1 not idle
5 M6_RIS	Master #6 Read Idle Status.This read only bit indicates whether master #6 read request buffer is idle (empty) or not. 0 idle 1 not idle
4 M6_PSS	Masrer #6 Power Saving Status. This read only bit indicates whether master #6 gasket is in power saving mode. 0 not in power saving 1 power saving
3–1 M6_ROC	master #6 ready off cycles. Number of minimum cycles that the ready signals must be low before they can go back to high. Default value is 3 cycles. 001-111 (000 is a forbidden value)
0 M6_PSD	master #6 power saving disable. 0 power saving enabled 1 power saving disabled (default)

49.3.30 F_Unit_Level_Arbitration_ Register (M4IF_F_ULAR)

The M4IF_FULA register configures the unit level arbitration configuration bits of each logic unit in levels 3, 4 and 5. Please refer to Arbitration Scheme when Masters have Same Priority (Bus Division) for more details on the arbitration logic units.

Address: M4IF_F_ULAR is 63FD_8000h base + B0h offset = 63FD_80B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

M4IF_F_ULAR field descriptions

Field	Description
31–21 -	Reserved.
20–18 FL5	Fast Level 5 - These bits configure the arbitration mode of level 5 arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL5 is 0x000 - encoding 0.
17–15 FL4M47	Fast Level 4 (m47) - These bits configure the arbitration mode of level 4(m47) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL4M47 is 0x000 - encoding 0.
14–12 FL4M03	Fast Level 4 (m03) - These bits configure the arbitration mode of level 4(m03) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL4M03 is 0x000 - encoding 0.
11–9 FL3M67	Fast Level 3 (m67) - These bits configure the arbitration mode of level 3(m67) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL3M67 is 0x000 - encoding 0.
8–6 FL3M45	Fast Level 3 (m45) - These bits configure the arbitration mode of level 3(m45) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL3M45 is 0x000 - encoding 0.
5–3 FL3M23	Fast Level 3 (m23) - These bits configure the arbitration mode of level 3(m23) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL3M23 is 0x000 - encoding 0.
2–0 FL3M01	Fast Level 3 (m01) - These bits configure the arbitration mode of level 3(m01) arbitration unit in the fast arbitration. The arbitration modes configuration options are shown in Table 49-2. Default value of FL3M01 is 0x000 - encoding 0.

49.3.31 S_Unit_Level_Arbitration_ Register (M4IF_S_ULAR)

The M4IF_SULA register configures the unit level arbitration configuration bits of each logic unit in levels 3, 4 and 5. Please refer to Arbitration Scheme when Masters have Same Priority (Bus Division) for more details on the arbitration logic units.

Address: M4IF_S_ULAR is 63FD_8000h base + B4h offset = 63FD_80B4h

31–21 -	Reserved.
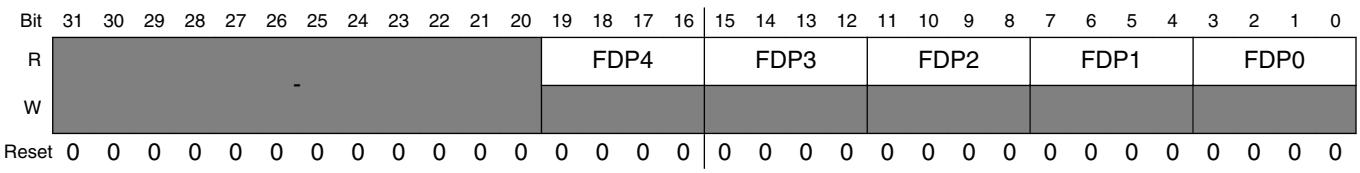
20–18 IL5	int1 arbitration Level 5 - These bits configure the arbitration mode of level 5 arbitration unit in the int1 arbitration. The arbitration modes configuration options are shown in Table 49-3. Default value of IL5 is 0x0100 - encoding 4.
17–15 IL4M47	int1 arbitration Level 4 (m47) - These bits configure the arbitration mode of level 4(m47) arbitration unit in the int1 arbitration. The arbitration modes configuration options are shown in Table 49-3. Default value of IL4M47 is 0x100 - encoding 4.
14–12 IL4M03	int1 arbitration Level 4 (m03) - These bits configure the arbitration mode of level 4(m03) arbitration unit in the int1 arbitration. The arbitration modes configuration options are shown in Table 49-3. Default value of IL4M03 is 0x100 - encoding 4.
11–9 IL3M67	int1 arbitration Level 3 (m67) - These bits configure the arbitration mode of level 3(m67) arbitration unit in the int1 arbitration. The arbitration modes configuration options are shown in Table 49-3. Default value of IL3M67 is 0x100 - encoding 4.
8–6 IL3M45	int1 arbitration Level 3 (m45) - These bits configure the arbitration mode of level 3(m45) arbitration unit in the int1 arbitration. The arbitration modes configuration options are shown in Table 49-3. Default value of IL3M45 is 0x100 - encoding 4.
5–3 IL3M23	int1 arbitration Level 3 (m23) - These bits configure the arbitration mode of level 3(m23) arbitration unit in the int1 arbitration. The arbitration modes configuration options are shown in Table 49-3. Default value of IL3M23 is 0x100 - encoding 4.
2–0 IL3M01	int1 arbitration Level 3 (m01) - These bits configure the arbitration mode of level 3(m01) arbitration unit in the int1 arbitration. The arbitration modes configuration options are shown in Table 49-3. Default value of IL3M01 is 0x100 - encoding 4.

49.3.33 Fast_Dynamic_Priority_Status Register (M4IF_FDPSR)

The M4IF_FDPS register is a read-only register. This register reflects the dynamic priority value of 5 requests in the fast arbitration, as configured in the M4IF_FDPC register.

Address: M4IF_FDPSR is 63FD_8000h base + BCh offset = 63FD_80BCh



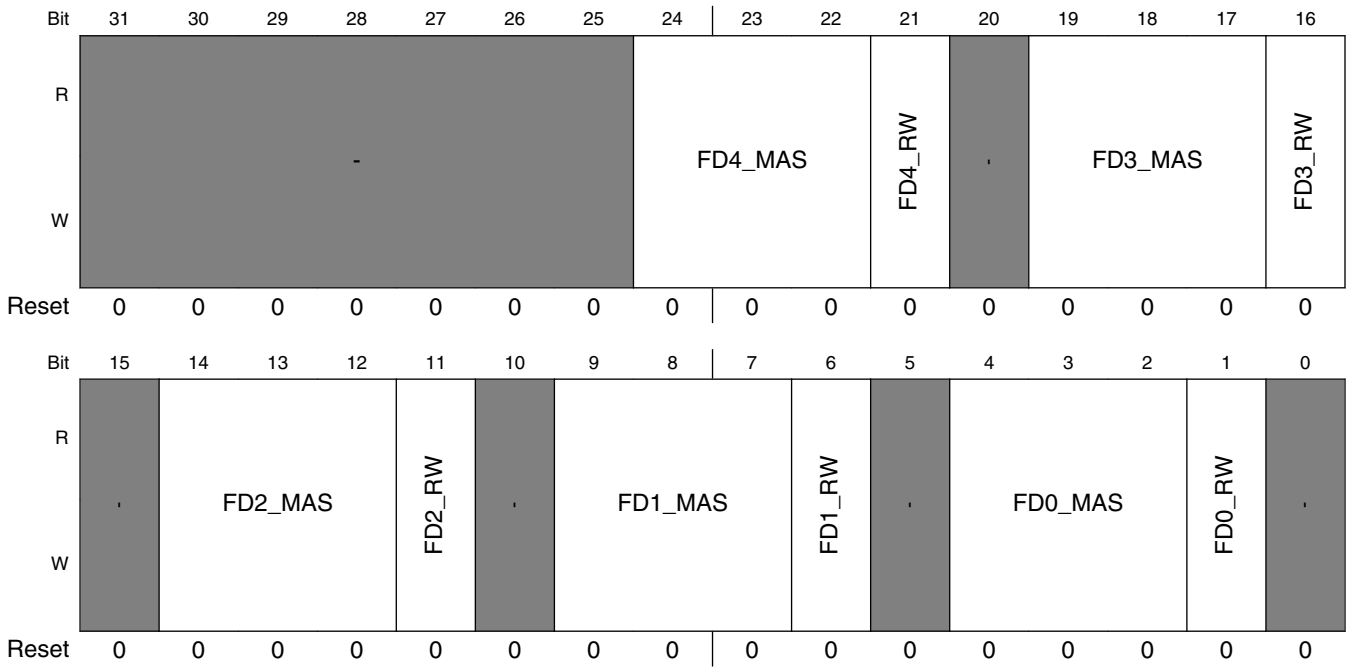
M4IF_FDPSR field descriptions

Field	Description
31–20 -	Reserved.
19–16 FDP4	Fast Dynamic Priority4 - these bits reflect the dynamic priority value of a request as configured in bits [24:20] of the FDPC register.
15–12 FDP3	Fast Dynamic Priority3 - these bits reflect the dynamic priority value of a request as configured in bits [19:15] of the FDPC register.
11–8 FDP2	Fast Dynamic Priority2 - these bits reflect the dynamic priority value of a request as configured in bits [14:10] of the FDPC register.
7–4 FDP1	Fast Dynamic Priority1 - these bits reflect the dynamic priority value of a request as configured in bits [9:5] of the FDPC register.
3–0 FDP0	Fast Dynamic Priority0 - these bits reflect the dynamic priority value of a request as configured in bits [4:0] of the FDPC register.

49.3.34 Fast_Dynamic_Priority_Control Register (M4IF_FDPCR)

The M4IF_FDPC register is a read-write register. This register is used to configure which 5 requests' dynamic priorities will be reflected in the M4IF_FDPS register.

Address: M4IF_FDPCR is 63FD_8000h base + C0h offset = 63FD_80C0h



M4IF_FDPCR field descriptions

Field	Description
31–25 -	Reserved.
24–22 FD4_MAS	Fast Dynamic 4 master - These bits indicate which master is to be reflected in the FDPS register, for dynamic priority 4.
21 FD4_RW	Fast Dynamic 4 read/write - This bit indicates whether a read or a write request is to be reflected in the FDPS register, for dynamic priority 4. 0 write 1 read
20 -	Reserved.
19–17 FD3_MAS	Fast Dynamic 3 master - These bits indicate which master is to be reflected in the FDPS register, for dynamic priority 3.
16 FD3_RW	Fast Dynamic 3 read/write - This bit indicates whether a read or a write request is to be reflected in the M4IF_FDPS register, for dynamic priority 3. 0 write 1 read

Table continues on the next page...

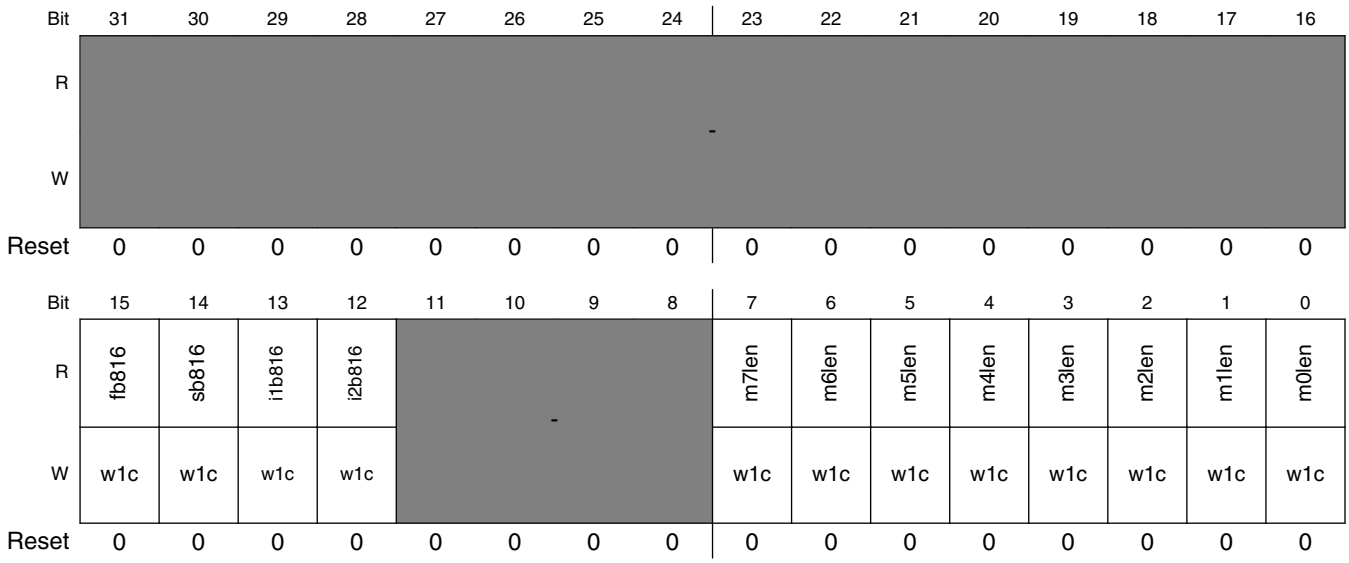
M4IF_FDPCR field descriptions (continued)

Field	Description
15 -	Reserved.
14–12 FD2_MAS	Fast Dynamic 2 master - These bits indicate which master is to be reflected in the M4IF_FDPS register, for dynamic priority 2.
11 FD2_RW	Fast Dynamic 2 read/write - This bit indicates whether a read or a write request is to be reflected in the M4IF_FDPS register, for dynamic priority 2. 0 write 1 read
10 -	Reserved.
9–7 FD1_MAS	Fast Dynamic 1 master - These bits indicate which master is to be reflected in the M4IF_FDPS register, for dynamic priority 1.
6 FD1_RW	Fast Dynamic 1 read/write - This bit indicates whether a read or a write request is to be reflected in the M4IF_FDPS register, for dynamic priority 1. 0 write 1 read
5 -	Reserved.
4–2 FD0_MAS	Fast Dynamic 0 master - These bits indicate which master is to be reflected in the M4IF_FDPS register, for dynamic priority 0.
1 FD0_RW	Fast Dynamic 0 read/write - This bit indicates whether a read or a write request is to be reflected in the M4IF_FDPS register, for dynamic priority 0. 0 write 1 read
0 -	Reserved.

49.3.35 Master Len Interrupt (M4IF_MLI)

Master Len Interrupt is a status register that indicates whether a "LEN>8" interrupt had occurred.

Address: M4IF_MLI is 63FD_8000h base + C4h offset = 63FD_80C4h



M4IF_MLI field descriptions

Field	Description
31–16 -	Reserved
15 fb816	A burst of 16 bit or 8 bit was handled in the fast arbitration. This bit can be cleared by writing 1 to it. 0 no burst occurred 1 burst occurred
14 sb816	A burst of 16 bit or 8 bit was handled in the slow arbitration. This bit can be cleared by writing 1 to it. 0 no burst occurred 1 burst occurred
13 i1b816	A burst of 16 bit or 8 bit was handled in the int1 arbitration. This bit can be cleared by writing 1 to it. 0 no burst occurred 1 burst occurred
12 i2b816	A burst of 16 bit or 8 bit was handled in the int2 arbitration. This bit can be cleared by writing 1 to it. 0 no burst occurred 1 burst occurred
11–8 -	Reserved

Table continues on the next page...

M4IF_MLI field descriptions (continued)

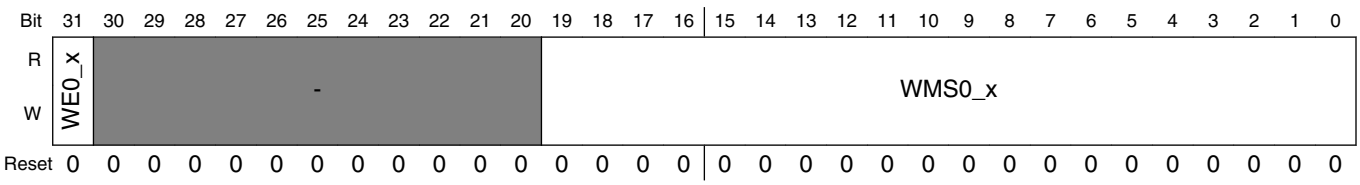
Field	Description
7 m7len	Master 7 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.
6 m6len	Master 6 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.
5 m5len	Master 5 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.
4 m4len	Master 4 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.
3 m3len	Master 3 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.
2 m2len	Master 2 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.
1 m1len	Master 1 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.
0 m0len	Master 0 burst length value bigger then 8 status. This bit indicates if a transaction with a burst length bigger then 8 has been sent. In such case, a violation would occurred. m0len is cleared by writing one to the bit. 0 violation did not occur. 1 violation had occurred.

49.3.36 Watermark Start ADDR_0 Register n (M4IF_WMSA0_*n*)

The M4IF_WMSA0 register defines the watermark start address of space area #0. Watermark space #0 corresponds in general to AP privilege master which is defined by SoC AP via at the EXTMC boundary. AP privilege master is the only master that can configure/read this register.

Addresses: M4IF_WMSA0_6 is 63FD_8000h base + ECh offset = 63FD_80ECh

M4IF_WMSA0_7 is 63FD_8000h base + F0h offset = 63FD_80F0h



M4IF_WMSA0_*n* field descriptions

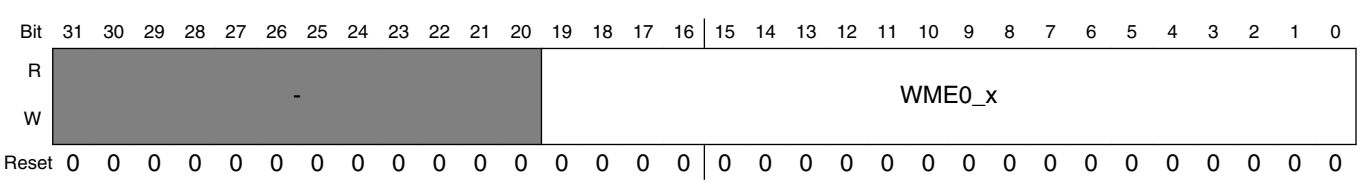
Field	Description
31 WE0_x	WaterMark Region Enable. This bit enables the WaterMark mechanism of space #0 Region X. 0 WaterMark Region X is disabled. 1 WaterMark Region X is enabled.
30–20 -	Reserved.
19–0 WMS0_x	Watermark Start Addr space #0 - As described in the watermark section in this Chapter, the watermark start address can be configured in resolution of 4KByte only. Therefore, WMSA0 register defines the upper 20bits of the start address, bits [31:12]. The lower 12bits that are not configurable via the register are zero always, 12'b0000_0000_0000 (0x000). ESDCTL protected regions must not cross 256MByte boundary.

49.3.37 Watermark End ADDR_0 Register (M4IF_WMEA0_*n*)

The M4IF_WMEA0 register defines the watermark end address of space area #0. Watermark space #0 corresponds in general to AP privilege master which is defined by SoC AP via at the EXTMC boundary. AP privilege master is the only master that can configure/read this register.

Addresses: M4IF_WMEA0_6 is 63FD_8000h base + 10Ch offset = 63FD_810Ch

M4IF_WMEA0_7 is 63FD_8000h base + 110h offset = 63FD_8110h



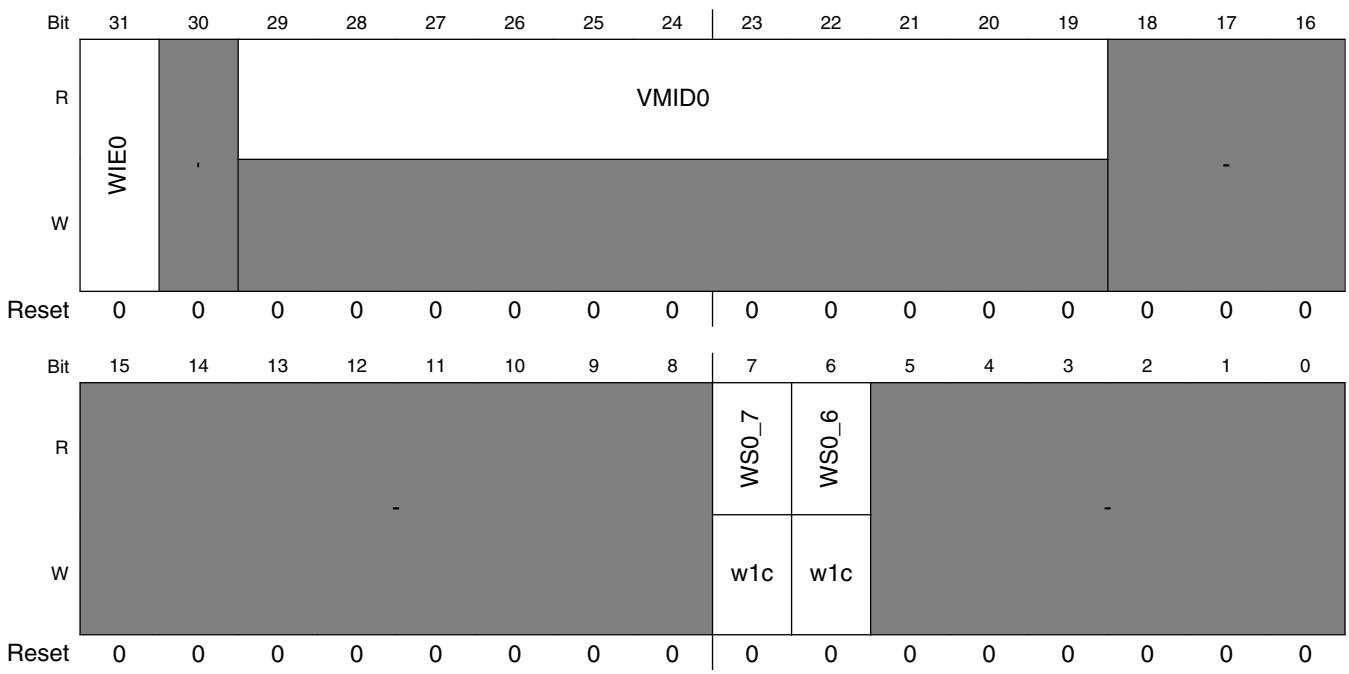
M4IF_WMEA0_*n* field descriptions

Field	Description
31–20 -	Reserved.
19–0 WME0_x	Watermark end Addr space #0 - As described in the watermark section in this Chapter, the watermark end address can be configured in resolution of 4KByte only. Therefore, WMEA0 register defines the upper 20bits of the end address, bits [31:12]. The lower 12bits that are not configurable via the register are one always, 12'b1111_1111_1111 (0xFFF). ESDCTL protected regions must not cross 256MByte boundary.

49.3.38 Watermark Interrupt and Status 0 Register (M4IF_WMIS0)

The M4IF_WMIS0 register defines the watermark interrupt enable of watermark space #0. The register enables the AP interrupt and the clear bits for each watermark space #0 region. AP privilege master is the only master that can configure/read this register.

Address: M4IF_WMIS0 is 63FD_8000h base + 114h offset = 63FD_8114h



M4IF_WMIS0 field descriptions

Field	Description
31 WIE0	WaterMark Enable. This bit enables the WaterMark mechanism of space #0 including the interrupt generation. For example, if WME is set and a WaterMark violation is detected a WaterMark interrupt is generated. 0 WaterMark is disabled. 1 WaterMark is enabled.

Table continues on the next page...

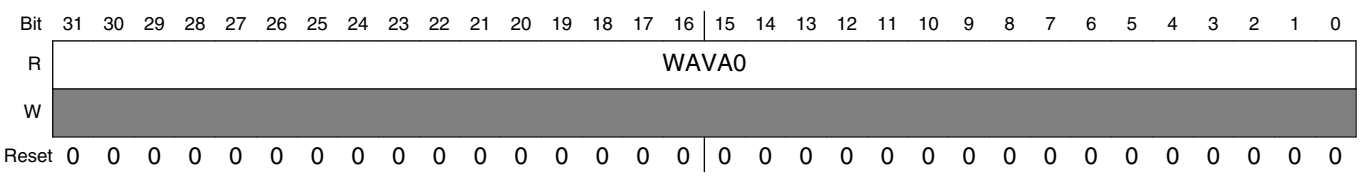
M4IF_WMIS0 field descriptions (continued)

Field	Description
30 -	Reserved.
29–19 VMID0	Violation Master ID - these bits contain the Master [29:27] Master ID [26:23] and AXI ID [22:19] of the master which tried to access a watermark area in the fast channel with WM[0] in low state.
18–8 -	Reserved.
7 WS0_7	WaterMark Status0_7. This bit indicates if WaterMark violation had occurred in the WaterMark space #0 memory region of DDR CS1 as defined in WMSA0_7 and WMEA0_7. WS0_7 is cleared by writing a one to the bit. 0 DDR/MDDR CSD1 WaterMark violation did not occur. 1 DDR CSD1 WaterMark violation had occurred.
6 WS0_6	WaterMark Status0_6. This bit indicates if WaterMark violation had occurred in the WaterMark space #0 memory region of DDR CS0 as defined in WMSA0_6 and WMEA0_6. WS0_6 is cleared by writing a one to the bit. 0 DDR CSD0 WaterMark violation did not occur. 1 DDR CSD0 WaterMark violation had occurred.
5–0 -	Reserved.

49.3.39 Watermark Violation Address 0 Register (M4IF_WMVA0)

The M4IF_WMVA0 register contains the address of the access that violated the AP watermark space. AP privileged master is the only master that can read this register.

Address: M4IF_WMVA0 is 63FD_8000h base + 118h offset = 63FD_8118h



M4IF_WMVA0 field descriptions

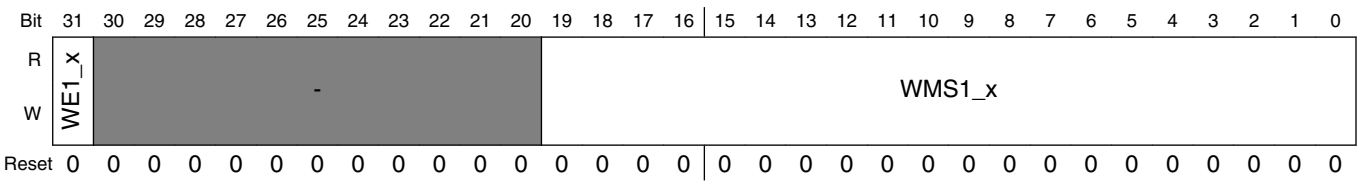
Field	Description
31–0 WAVA0	WaterMark Access violation address - These bits reflect the address of the access that caused the watermark space #0 violation.

49.3.40 Watermark Start ADDR_1 Register n (M4IF_WMSA1_*n*)

The M4IF_WMSA1 register defines the watermark start address of space area #1. Watermark space #1 corresponds in general to BP privilege master which is defined by SoC BP via at the EXTMC boundary. BP privilege master is the only master that can configure/read this register.

Addresses: M4IF_WMSA1_6 is 63FD_8000h base + 138h offset = 63FD_8138h

M4IF_WMSA1_7 is 63FD_8000h base + 13Ch offset = 63FD_813Ch



M4IF_WMSA1_*n* field descriptions

Field	Description
31 WE1_x	WaterMark Region Enable. This bit enables the WaterMark mechanism of space #1 Region X. 0 WaterMark Region X is disabled. 1 WaterMark Region X is enabled.
30–20 -	Reserved.
19–0 WMS1_x	Watermark Start Addr space #1 - As described in the watermark section in this Chapter, the watermark start address can be configured in resolution of 4KByte only. Therefore, M4IF_WMSAO register defines the upper 20bits of the start address, bits [31:12]. The lower 12bits that are not configurable via this register are zero always, 12'b0000_0000_0000 (0x000). ESDCTL protected regions must not cross 256MByte boundary.

49.3.41 Watermark End ADDR_1 Register (M4IF_WEAR1_*n*)

The M4IF_WMEA1 register defines the watermark end address of space area #1. Watermark space #1 corresponds in general to BP privilege master which is defined by SoC BP via at the EXTMC boundary. BP privilege master is the only master that can configure/read this register.

The following table maps watermark registers to their corresponding CS in EXTMC.

Table 49-55. Watermark register mapping

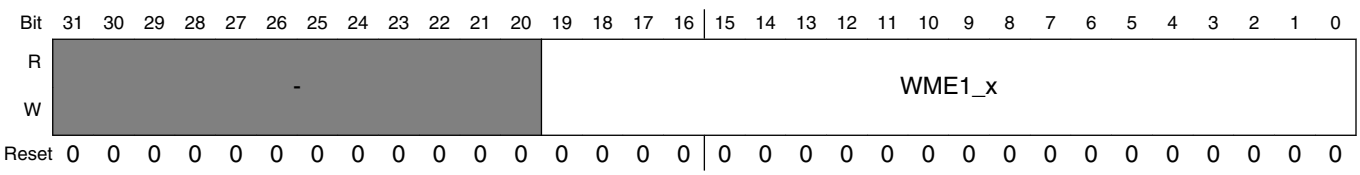
Watermark registers	CS #	Block name
M4IF_WMSA0_6 M4IF_WMEA0_6 M4IF_WMSA1_6 M4IF_WMEA1_6	CSD0	ESDCTL **NOTE:** ESDCTL protected regions must not cross 256MByte boundary.
M4IF_WMSA0_7 M4IF_WMEA0_7 M4IF_WMSA1_7 M4IF_WMEA1_7	CSD1	ESDCTL **NOTE:** ESDCTL protected regions must not cross 256MByte boundary.
Watermark is not supported		NFC
Watermark is not supported		Internal Memory

NOTE

If a watermark register is configured to addresses which are not included in the CS it belongs to, unknown behavior will occur.

Addresses: M4IF_WEAR1_6 is 63FD_8000h base + 158h offset = 63FD_8158h

M4IF_WEAR1_7 is 63FD_8000h base + 15Ch offset = 63FD_815Ch



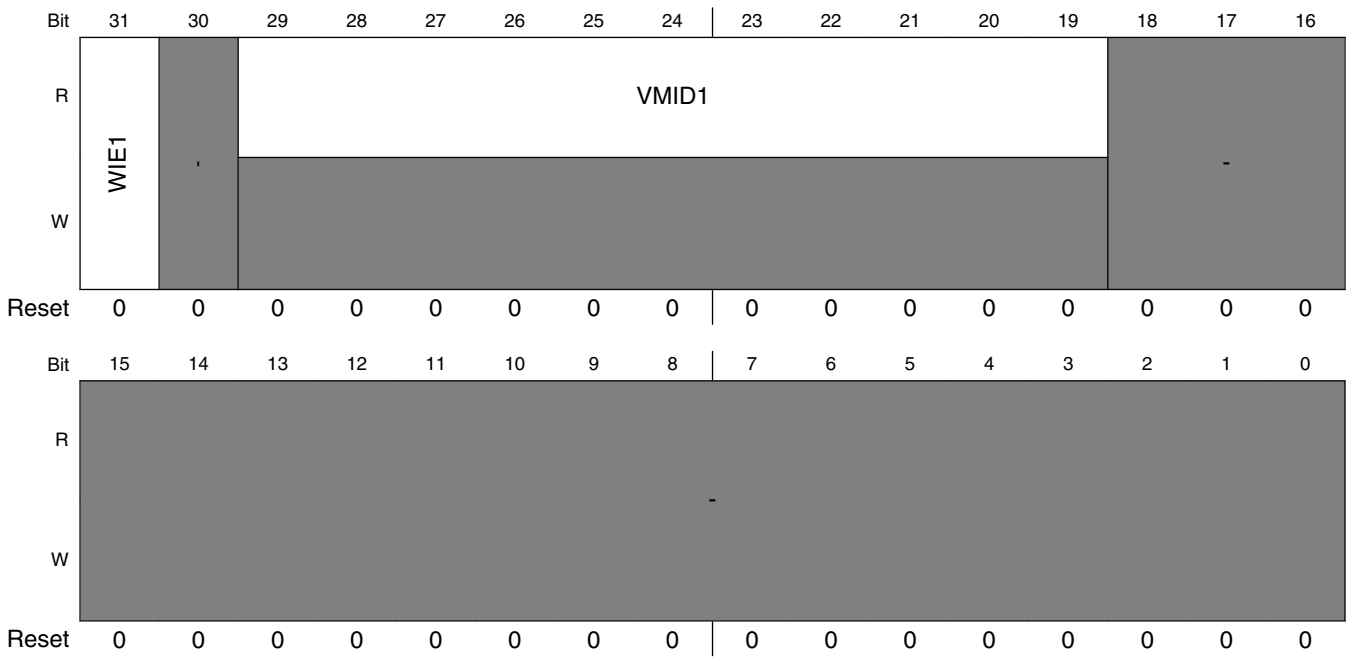
M4IF_WEAR1_*n* field descriptions

Field	Description
31–20 -	Reserved.
19–0 WME1_x	Watermark end Addr space #1 - As described in the watermark section in this Chapter, the watermark end address can be configured in resolution of 4KByte only. Therefore, M4IF_WMEA0 register defines the upper 20bits of the end address, bits [31:12]. The lower 12bits that are not configurable via the register are one always, 12'b1111_1111_1111 (0xFFF). ESDCTL protected regions must not cross 256MByte boundary.

49.3.42 Watermark Interrupt and Status 1 Register (M4IF_WISR1)

The M4IF_WMIS1 register defines the watermark interrupt enable of watermark space #1. The register enables the BP interrupt and the clear bits for each watermark space #1 region. BP privilege master is the only master that can configure/read this register.

Address: M4IF_WISR1 is 63FD_8000h base + 160h offset = 63FD_8160h



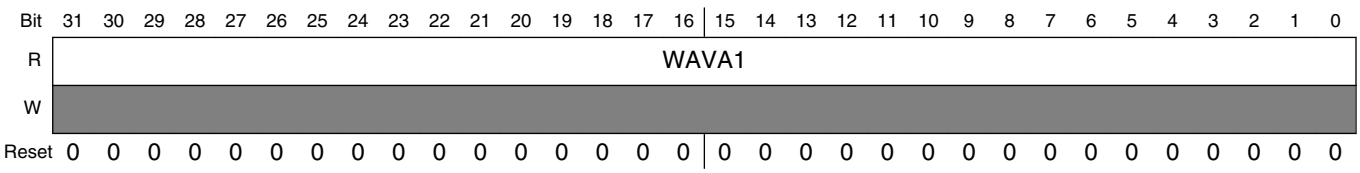
M4IF_WISR1 field descriptions

Field	Description
31 WIE1	WaterMark Enable. This bit enables the WaterMark mechanism of space #1 including the interrupt generation. For example, if WIE is set and a WaterMark violation is detected a WaterMark interrupt is generated. 0 WaterMark is disabled. 1 WaterMark is enabled.
30 -	Reserved.
29–19 VMID1	Violation Master ID - these bits contain the Master [29:27] Master ID [26:23] and AXI ID [22:19] of the master which tried to access a watermark area in the fast channel with WM[1] in low state.
18–0 -	Reserved.

49.3.43 Watermark Violation Address 1 Register (M4IF_WMVA1)

The M4IF_WMVA0 register contains the address of the access that violated the watermark space BP. Corresponding to watermark interrupt and status #1 register. BP privilege master is the only master that can read this register.

Address: M4IF_WMVA1 is 63FD_8000h base + 164h offset = 63FD_8164h



M4IF_WMVA1 field descriptions

Field	Description
31–0 WAVA1	WaterMark Access violation address - These bits reflect the address of the access that caused the watermark space #1 violation.

Chapter 50
Media Local Bus (MediaLB) Block (MLB)

50.1 Introduction

A block diagram of the MLB can be found in Figure 50-1.

50.1.1 Overview

The Media Local Bus (MLB) block implements the Physical Layer and Link Layer of the MediaLB specification, interfacing to an MLB controller. The MLB implements the 3-pin MLB mode and can run at speeds up to 1024Fs. It does not implement MLB controller functionality.

All MLB devices support a set of physical channels for sending data over the MLB. Each physical channel is 4 bytes in length (quadlet) and grouped into logical channels with one or more physical channels allocated to each logical channel. These logical channels can be in any combination of channel type (synchronous, asynchronous, control, or isochronous) and direction (transmit or receive).

The MLB provides support for up to 16 logical channels and up to 31 physical channels with a maximum of 124 bytes of data per frame. Each logical channel is referenced using an unique channel address and represents a unidirectional data path between the MLB device transmitting the data and the MLB device(s) receiving the data.

The MLB controller generates a unique frame sync pattern once per MOST network frame. This pattern defines the frame and channel boundaries of the signal information and data lines.

The MLB Controller initiates all communication over the MLB by sending out the logical channel address on the signal information line for each physical channel. This logical address indicates to the appropriate MLB device that it can transmit data for that logical channel during the next physical channel slot. One quadlet later, the transmitting MLB device sends out a MLB command byte on the signal information line and the

corresponding data on the data line. All other MLB devices (including the controller) have already compared the logical channel address with their internal table of addresses to determine if they are the intended recipient of the data on this logical channel.

The receiving MLB device responds with a receive status response on the signal information line one byte after the transmitting device sends the MLB command byte. Note that synchronous data transmissions (which are the only data formats to support multiple receivers) are not acknowledged, but asynchronous, control and isochronous data transmissions are acknowledged.

For more information about the MediaLB protocol, please refer to the MediaLB Specification.

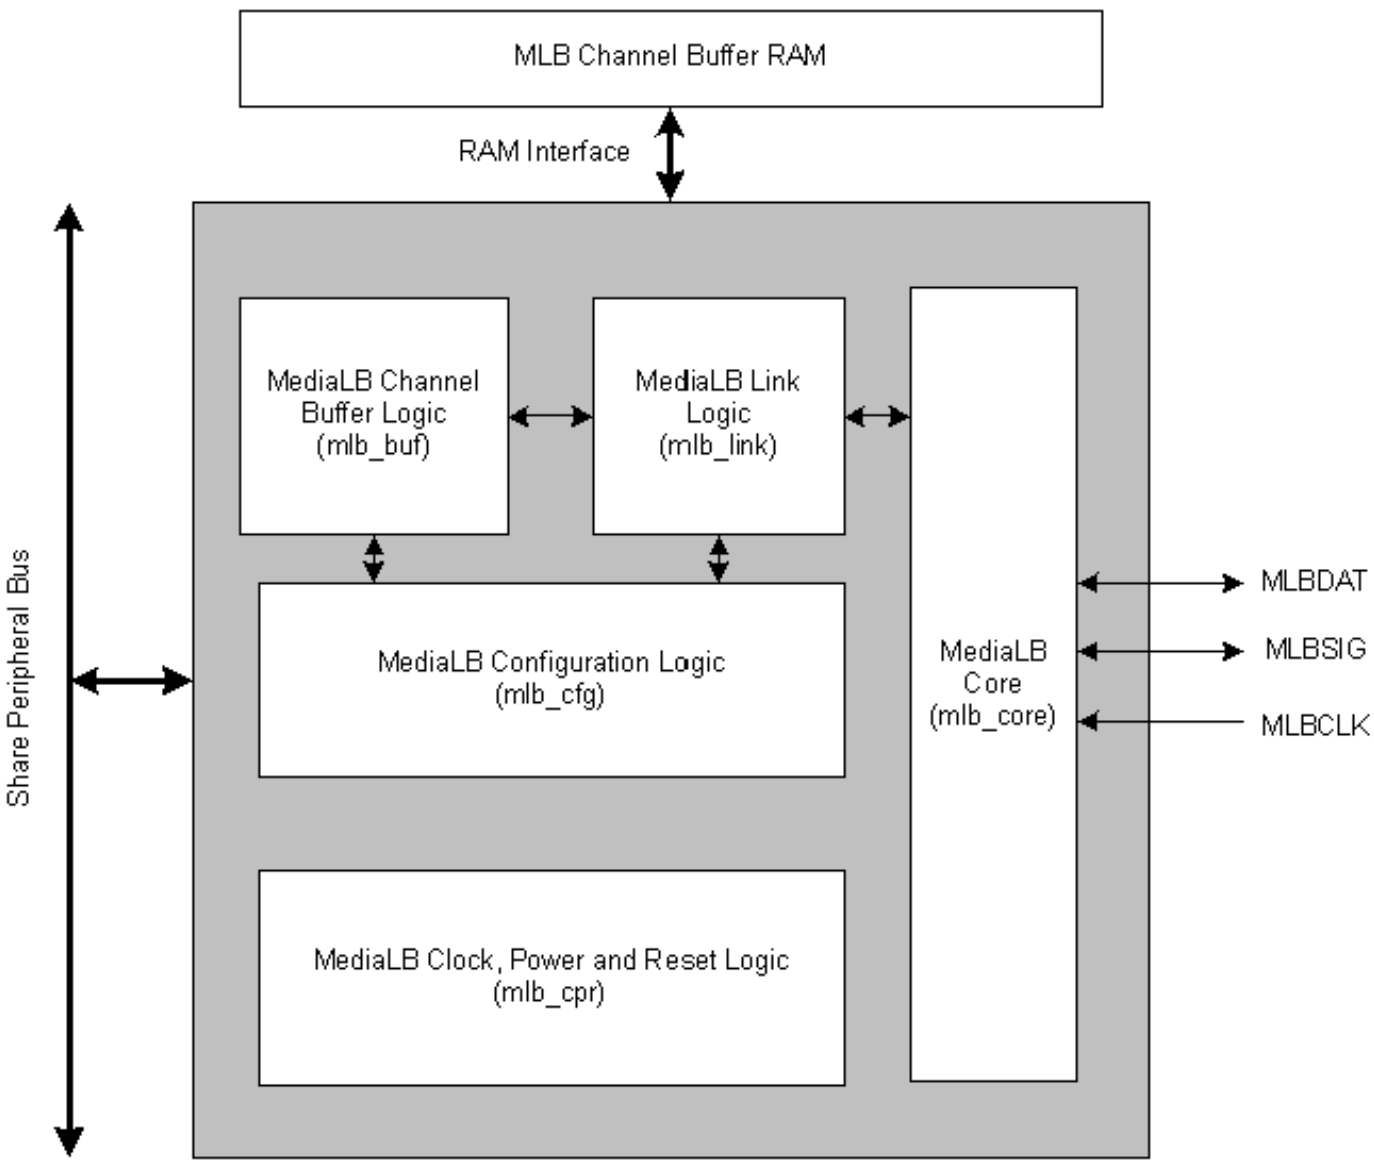


Figure 50-1. Block Diagram

50.1.2 Features

- Support for up to 16 logical channels and 31 physical channels running at a maximum speed of 1024Fs
- Transmission of commands and data, and reception of receive status when functioning as the transmitting device associated with a logical channel address
- Reception of commands and data, and transmission as receive status responses when functioning as the receiving device associated with a logical channel address
- MLB lock detection
- System channel command handling
- Local buffer memory of 2k quadlets shared between all logical channels

50.1.3 Logic Blocks

The MediaLB design is split into five major components:

MediaLB Core- The MediaLB Core implements the physical layer of the MediaLB interface. This physical layer performs serial-to-parallel and parallel-to-serial data transformations and MLB frame synchronization.

MediaLB CPR Logic- The MLB Clocks, Power, and Reset (CPR) Logic implements clock and reset control.

MediaLB Link Logic- The MediaLB Link Logic implements the link layer functionality of the MediaLB interface, including:

- checking of synchronous, asynchronous, control, and isochronous channel protocol,
- handling of both RX and TX initiated breaks,
- generating RX responses to the MediaLB Core,
- generating TX commands for the MediaLB Core,
- processing of and responding to the system channel commands,
- detection of MLB bus lock/unlock, and
- recognition and pipe-lining of logical Channel Addresses.

MediaLB Configuration Logic- The MediaLB Configuration Logic implements the memory space for the Configuration Control Registers and Channel Configuration Registers. These configuration and control registers are used to define various parameters and control the operation of the MediaLB Device.

MediaLB Channel Buffer Logic- The function of the MediaLB Channel Buffer logic block includes:

- buffering of logical channel data for bus latency issues,
- multiplexing of logical channel data in Big- and Little-Endian mode, and
- implementation of hardware loop-back mode between logical channels.

50.1.4 Modes of Operation

The MediaLB uses DMA mode to transfer data between hardware channels and system memory. The byte order in which data is transferred is determined by enabling either Big-Endian or Little-Endian mode through the DCCR.MLE bit.

The MediaLB also provides customers with a single test mode, called Loop-Back Test Mode. This mode provides basic testing capabilities for the MLB pads, physical layer, link layer, channel protocol, and local channel buffer, by enabling a single RX channel and a single TX channel. The RX channel is used to transfer data directly to the enabled TX channel.

50.2 External Signal Description

The MediaLB has three external signals which are summarized in Table 50-1.

Table 50-1. Signal Properties

Name	Function	I/O	Reset	Pull
MLBCLK	MLB Clock	I	In	Down
MLBDAT	MLB Data	I/O	In	Down
$\overline{\text{MLBSIG}}$	MLB Signal	I/O	In	Down

50.2.1 Detailed Signal Descriptions

Table 50-2. MediaLB Interface

Signal	I/O	Description	
MLBCLK	I	MLB Clock	
		State Meaning	Asserted/Negated-Supports a 256Fs, 512Fs or 1024Fs clock input from the MediaLB controller.
		Timing	Assertion/Negation-Supports maximum frequency of 49.2 MHz for a 48 kHz sample rate.

Table continues on the next page...

Table 50-2. MediaLB Interface (continued)

Signal	I/O	Description	
MLBDAT	I/O	MLB Data	
		State Meaning	Asserted/Negated-MediaLB data for serial receive/transmit channel data.
		Timing	Assertion/Negation-Registered on the falling edge of MLBCLK.
MLBSIG	I/O	MLB Signal	
		State Meaning	Asserted/Negated-MediaLB signal information for serial transmit channel commands, serial receive channel responses, and logical channel address information.
		Timing	Assertion/Negation-Registered on the falling edge of MLBCLK.

50.3 Programmable Registers

MLB_DCCR field descriptions

Field	Description
31 MDE	MediaLB Device Enable. When set, enables the MediaLB Interface based on the other bits in the register. 0 MediaLB Device Disabled 1 MediaLB Device Enabled
30 LBM	Loop-Back Mode Enable. When set, enables the loop-back testing of the MediaLB bus between logical channel N (RX) and logical channel N+1 (TX). {N=0, 2, 4, 6,...,14} 0 Loop-Back Mode Disabled Loop-Back Mode Enabled
29–28 MCS	MediaLB Clock Select. These field must be programmed by system software to reflect the MLBCLK_IN speed. 00 256Fs: supports 8 quadlets per frame 01 512Fs: supports 16 quadlets per frame 10 1024Fs: supports 32 quadlets per frame 11 Reserved
27 --	Reserved. Should be written as zero for compatibility.
26 MLK	MLB Lock. When set, indicates that the MLB Port is synchronized to the incoming MLB frame. If MLK is clear (unlocked), MLK is set after FRAMESYNC is detected at the same position for three consecutive frames. If MLK is set (locked), MLK is cleared after not receiving FRAMESYNC at the expected time for two consecutive frames. While MLK is set, FRAMESYNC patterns occurring at locations other than the expected one are ignored.
25 MLE	MLB Little Endian.This field determines how MLB quadlet based data is stored in system memory.

Table continues on the next page...

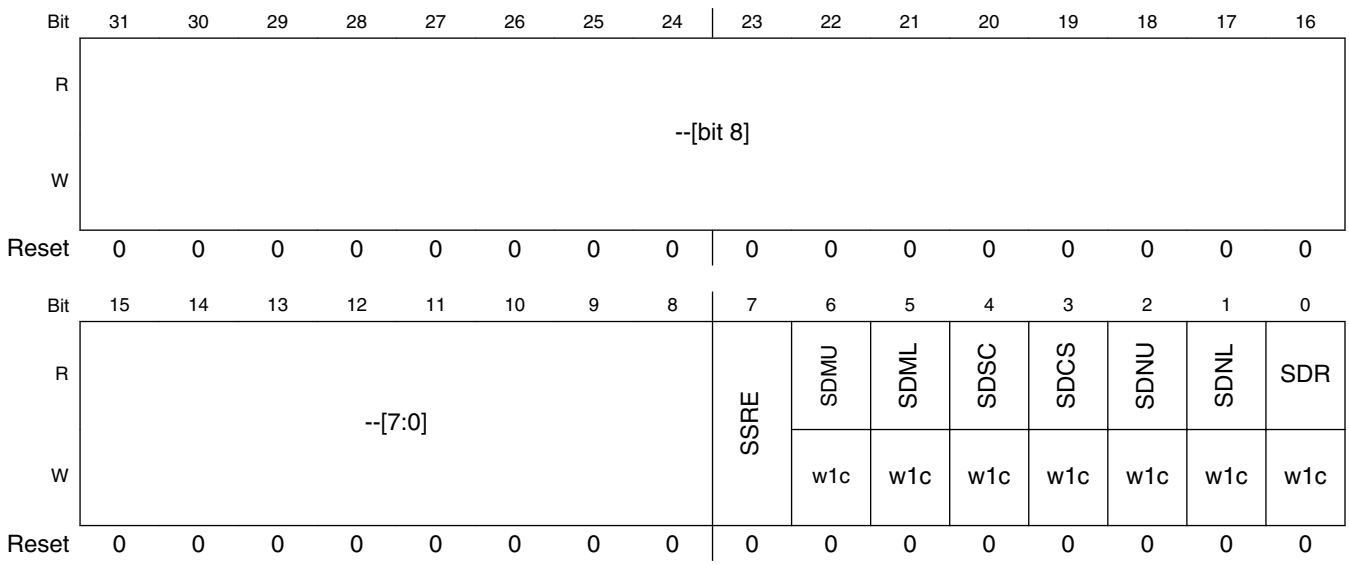
MLB_DCCR field descriptions (continued)

Field	Description
	0 Big Endian mode 1 Little Endian mode
24 MHRE	MLB Hardware Reset Enable. When set, enables hardware to automatically reset the MediaLB physical and link layer logic upon the reception of either a global (SDCR.MDS = 8'h0000) or device specific (SDCR.MDS = DA) MlbReset (FEh) System Command. 0 MediaLB device does not reset on reception of system reset command. 1 MediaLB device is reset on reception of system reset command.
23 MRS	MLB Software Reset. When set, resets the MLB physical and link layer logic. Hardware clears this bit automatically. 0 MediaLB device is not reset by software. 1 MediaLB device is reset by software.
22–8 --	Reserved. Should be written as zero for compatibility.
7–0 MDA	MLB Device Address. Determines the unique DeviceAddress (DA) for the MLB Device. DeviceAddresses are used by the system channel MlbScan command. DA[15:0] = {7'h00, MDA[8:1], 1'b0}

50.3.2 System Status Configuration Register (MLB_SSCR)

The System Status Configuration register (SSCR) allows system software to monitor and control the status of the MLB network. The register is updated once per frame by hardware during the MLB System Channel. Except for the bits associated with MLB lock and unlock (SSCR.SDMU and SSCR.SDML), the bits of the SSCR register are not valid until the MLB is locked to the MLB interface. System software must service status events before the start of the next MLB frame to prevent the current frame status from being lost.

Address: MLB_SSCR is 63FE_4000h base + 4h offset = 63FE_4004h



MLB_SSCR field descriptions

Field	Description
31–8 --	Reserved. Should be written as zero for compatibility.
7 SSRE	System Service Request Enable. System software can set this bit to indicate that this MLB Device is present and needs service. An RxStatus DeviceServiceRequest (82h) will be sent in response to a MlbScan System Command from the MLB Controller. Hardware clears this bit after the RxStatus is sent. 0 MLB device responds to System Scan Command with Device Present (80h). 1 MLB device responds to System Scan Command with Device Service Request (82h).
6 SDMU	System Detects MLB Unlock. This bit is set to indicate that the MLB Device has unlocked from the MLB frame. Detecting a MLB unlock generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software. 0 MLB device has not unlocked from MediaLB frame. 1 MLB device has unlocked from MediaLB frame.

Table continues on the next page...

MLB_SSCR field descriptions (continued)

Field	Description
5 SDML	System Detects MLB Lock. This bit is set to indicate that the MLB Device has locked to the MLB frame. Detecting a MLB lock generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software. 0 MLB device has not locked to MediaLB frame. 1 MLB device has locked to MediaLB frame.
4 SDSC	System Detects SubCommand. This bit is set to indicate that the MLB Device has received the MlbSubCmd (E6h) System Command. The user-defined software command is stored in the SDCR register. The decoding of this command is left up to software. Detecting MlbSubCmd generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software. 0 MLB device has not detected a Sub-command System Command. 1 MLB device has detected a Sub-command System Command.
3 SDCS	System Detects Channel Scan. This bit is set to indicate that the MLB Device has received the MlbScan (E4h) System Command. The target DeviceAddress is stored in the SDCR register. Detecting MlbScan generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software. 0 MLB device has not detected a System Scan Command. 1 MLB device has detected a System Scan Command.
2 SDNU	System Detects Network Unlock. This bit is set to indicate that the MLB Device has received the MOST_Unlock (E2h) System Command. Detecting MOST_Unlock generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software. 0 MLB device has not detected an Unlock Command. 1 MLB device has detected an Unlock Command.
1 SDNL	System Detects Network Lock. This bit is set to indicate that the MLB Device has received the MOST_Lock (E0h) System Command. Detecting MOST_Lock generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software 0 MLB device has not detected a Lock Command. 1 MLB device has detected a Lock Command.
0 SDR	System Detects Reset. This bit is set to indicate that the MLB Device has received the MlbReset (FEh) System Command. The target DeviceAddress is stored in the SDCR register. Detecting MLBReset generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software. 0 MLB device has not detected a Reset Command. 1 MLB device has detected a Reset Command.

50.3.3 System Data Configuration Register (MLB_SDCR)

The System Data Configuration Register (SDCR) allows system software to receive control information from the MLB Controller. The register is updated once per frame by hardware during the MLB System Channel. System software must read SDCR before the start of the next MLB frame to prevent the current frame data from being lost.

Address: MLB_SDCR is 63FE_4000h base + 8h offset = 63FE_4008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MLB_IBCR field descriptions

Field	Description
31–16 IRBA	Isochronous Receive Base Address. This base address is shared by all Isochronous RX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.
15–0 ITBA	Isochronous Transmit Base Address. This base address is shared by all Isochronous TX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.

50.3.10 Channel Interrupt Configuration Register (MLB_CICR)

The Channel Interrupt Configuration Register (CICR) reflects the channel interrupt status of the individual MLB logical channels. These bits are set by hardware when a channel interrupt is generated. The channel interrupt bits are sticky and can only be reset by software.

Address: MLB_CICR is 63FE_4000h base + 30h offset = 63FE_4030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MLB_CICR field descriptions

Field	Description
31–16 --	Reserved. Should be written as zero for compatibility.
15–0 CSU	Channel Status Update for Logical Channels 15 through 0. When set, these bits indicate that hardware has generated an interrupt for the appropriate channel. These bits are sticky and can only be cleared by a software write. Writing to the CICR register has no affect. To clear a particular bit in the CICR, software must clear all of the unmasked status bits in the corresponding CSCRn register. 0 Channel n has not generated an interrupt. 1 Channel n has generated an interrupt.

50.3.11 Channel n Entry Configuration Register (MLB_CECR*n*)

The Channel n Entry Configuration Register (CECRn) defines basic attributes about a given logical channel, such as the channel enable, channel type, channel direction, and channel address. The definition of some of the bit fields in the CECRn register vary dependant on the selected channel type.

Addresses: 63FE_4000h base + 40h offset + (16d × *n*), where *n* = 0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MLB_CECR*n* field descriptions

Field	Description
31 CE	Channel n Enable. 0 Channel n disabled (default) 1 Channel n enabled
30 TR	Channel n Transmit Select. 0 Receive 1 Transmit
29–28 CT	Channel n Type Select. 00 Synchronous 01 Isochronous 10 Asynchronous 11 Control
27 Rsvd/FSE/FCE	The meaning of this bit depends on the type of channel: Rsvd - For Asynchronous and Control Channels

Table continues on the next page...

MLB_CECR*n* field descriptions (continued)

Field	Description
	FSE - For Synchronous Channels - Frame Synchronization Enable. When set, enables Streaming Channel Frame Synchronization for this logical synchronous channel FCE - For Isochronous Channels - Flow Control Enable. When set, allows an isochronous RX channel to generate the ReceiverBusy (10h) response.
26–25 MDS	Channel n Mode Select. 00 ping-pong buffering used 01 circular buffering used 10-11 Reserved
24–23 --	Reserved. Should be written as zero for compatibility.
22 MLFS	Mask Lost Frame Synchronization. When set, masks *Lost Frame Synchronization* channel interrupts for this logical channel. 0 Enable *Lost Frame Synchronization* channel interrupts for this logical channel 1 Disable *Lost Frame Synchronization* channel interrupts for this logical channel
21 --	Reserved. Should be written as zero for compatibility.
20 MBE	Mask Buffer Error. When set,masks *Buffer Error* channel interrupts for this logical channel. 0 Enable *Buffer Error* channel interrupts for this logical channel 1 Disable *Buffer Error* channel interrupts for this logical channel
19 MBS	Mask Buffer Start. When set, masks *Buffer Start* channel interrupts for this logical channel. 0 Enable *Buffer Start* channel interrupts for this logical channel 1 Disable *Buffer Start* channel interrupts for this logical channel
18 MBD	Mask Buffer End. When set, masks *Buffer Done* channel interrupts for this logical channel. 0 Enable *Buffer Done* channel interrupts for this logical channel 1 Disable *Buffer Done* channel interrupts for this logical channel
17 MDB	Mask Detect Break. When set, masks detect break channel interrupts for this logical channel. This bit is valid for asynchronous and control channels only. 0 Enable detect break channel interrupts for this logical channel 1 Disable detect break channel interrupts for this logical channel
16 MPE	Mask Protocol Error. When set, masks Protocol error channel interrupts for this logical channel. This bit is valid for all RX channel types and valid for only asynchronous and control TX channels. 0 Enable protocol error channel interrupts for this logical channel 1 Disable protocol error channel interrupts for this logical channel
15 Rsvd/FSCD/IPL[7]	The meaning of this bit depends on the type of channel: Rsvd: For Asynchronous and Control channels only IPL[7]: For Isochronous channels only - Isochronous Packet Length bit 7 field Isochronous Packet Length. For Isochronous TX channels, defines the number of packet bytes. The smallest isochronous packet size per frame is 5 bytes (IPL[7:0] >= 5). A packet length of 256 bytes can be represented as IPL[7:0]=00h. For Isochronous RX channels, software must program IPL[7:2] to indicate the expected number of bytes per packet, where IPL[1:0] always equals'00'.

Table continues on the next page...

MLB_CECR*n* field descriptions (continued)

Field	Description
	FSCD: For Synchronous channels only - Frame Synchronization Channel Disable. When set, disables this logical channel (set CECRn.CE = 0) when Lost Frame Synchronization occurs. 0 Do not disable this logical channel when frame synchronization is lost 1 Disable this logical channel when frame synchronization is lost
14–13 Rsvd/IPL[6:5]	The meaning of this bit depends on the type of channel: Rsvd: For Asynchronous, control and synchronous channels only IPL[6:5]: For Isochronous channels only - Isochronous Packet Length bit6-bit5 fields
12–8 Rsvd/FSPC/IPL[4:0]	The meaning of this bit depends on the type of channel: Rsvd: For Asynchronous, Control channels only FSPC: For Synchronous channels only - Frame Synchronization Physical Channels Count bit4-bit0 fields. IPL: For Isochronous channels only - Isochronous Packets Length bit4-bit0 fields
7–0 CA	Channel Address. These bits determine the *ChannelAddress* associated with this logical channel. This value is matched against the *ChannelAddress* received each physical channel from the MLB Controller. There is a *ChannelAddress* match if and only if the *ChannelAddress* recovered from the MediaLB input, *MLBSIG*, equals the *ChannelAddress* defined by: CA[15:0] = {7'h00, CA[8:1], 1'b0}.

50.3.12 Channel n Status Configuration Register (MLB_CSCR*n*)

The Channel n Status Configuration Register (CSCRn) reflects the status of the given logical channel. The definition of some of the bit fields in the CSCRn register vary dependant on the selected channel type.

Addresses: 63FE_4000h base + 44h offset + (16d × *n*), where *n* = 0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MLB_CSCR*n* field descriptions

Field	Description
31 BM	Buffer Empty. When set, the local channel buffer (for channel n) is empty. This bit is set and cleared by hardware. At reset, the local channel buffer is empty (BM = 1).
30 BF	Buffer Full. When set, the local channel buffer (for channel n) is full.This bit is set and cleared by hardware.
29–20 --	Reserved. Should be written as zero for compatibility.
19–18 IVB	Isochronous Valid Bytes. These bits are loaded by hardware with the number of valid bytes in the last packet of a broken Isochronous RX channel. Used in conjunction with CCBCRn.BCA, IVB[1:0] can be used by software to determine the final valid byte of the local channel buffer.(Valid for local channel buffers configured for isochronous RX data). 00 Final valid byte = (CCBCRn.BCA - 5) 01 Final valid byte = (CCBCRn.BCA - 4) 10 Final valid byte = (CCBCRn.BCA - 3) 11 Final valid byte = (CCBCRn.BCA - 2)
17 GIRB	GIRB: For isochronous data - Generate Isochronous Receive Break. When set, this bit causes hardware to terminate the current packet, flush the local channel buffer, clear the RDY bit, and load IVB[1:0]. This bit is set by system software and cleared by hardware.

Table continues on the next page...

MLB_CSCR*n* field descriptions (continued)

Field	Description
	GB: For asynchronous and control data - Generate Break. When the local channel buffer is configured for TX data, the setting of this bit causes hardware to send the AsyncBreak (26h) or ControlBreak (36h) command and stop the transfer. When the local channel buffer is configured for RX data, the setting of this bit causes hardware to send the MLB RxStatus ReceiverBreak (70h) and stop the transfer. This bit is set by system software and cleared by hardware.
16 RDY	Next Buffer Ready. System software should set this bit when all the registers, data, and program memory variables are setup and ready to transmit or receive data. For TX data, the system memory buffer should also be filled. For ping-pong buffering mode, hardware clears this bit after the buffer begins to be processed. For circular buffering mode, software should clear this bit only when buffer processing needs to halted. 0 Next buffer is not ready in system memory 1 Next buffer is ready in system memory
15–12 --	Reserved. Should be written as zero for compatibility.
11 PBS	Previous Buffer Start. When set, this bit indicates the first quadlet of the *Previous Buffer* has been successfully transmitted or received. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types. 0 First quadlet of the *Previous Buffer* has not been successfully transmitted or received 1 First quadlet of the *Previous Buffer* has been successfully transmitted or received
10 PBD	Previous Buffer Done. When set, this bit indicates that the last quadlet of the *Previous Buffer* has been successfully transmitted or received. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types. 0 Last quadlet of the *Previous Buffer* has not been successfully transmitted or received 1 Last quadlet of the *Previous Buffer* has been successfully transmitted or received
9 PBDB	Previous Buffer Detect Break. When set, this bit indicates that either a TX channel has detected a receiver break response, *ReceiverBreak* (70h), or an RX channel has detected a transmitter break command, *ControlBreak* (36h) or *AsyncBreak* (26h), while processing the *Previous Buffer*. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types 0 Break response was not detected while processing the Previous Buffer 1 Break response was detected while processing the Previous Buffer
8 PBPE	Previous Buffer Protocol Error. When set, this bit indicates that either a TX channel has detected an RxStatus of *ReceiverProtocolError* (72h), a RX channel has detected an invalid command for this channel type, or an additional *AsyncStart* (20h) or *ControlStart* (30h) command has been received while in the middle of a packet. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all RX channels and valid for only asynchronous and control TX channels. 0 Protocal error was not detected while processing the Previous Buffer 1 Protocal error was detected while processing the Previous Buffer
7 --	Reserved. Should be written as zero for compatibility.
6 LFS	Lost Frame Synchronization. When set, this bit indicates that the logical channel has lost synchronization with the MLB frame. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for synchronous channels only. 0 Frame synchronization not lost 1 Frame synchronization lost

Table continues on the next page...

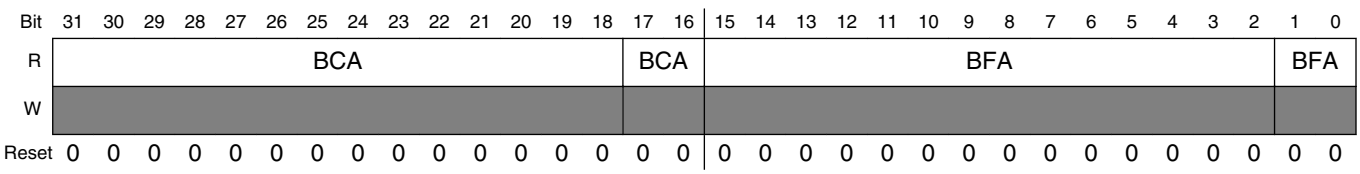
MLB_CSCR*n* field descriptions (continued)

Field	Description
5 ABE	AHB Bus Error. When set, this bit indicates that an AHB bus error has been detected. The setting of this bit generates a non-maskable channel interrupt to system software.
4 BE	Buffer Error. When set, this bit indicates that either a TX channel has detected a buffer underflow (for example, attempt to pop data from an empty buffer), or an RX channel has detected a buffer overflow (for example, attempt to push data onto a full buffer). The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for synchronous RX/TX and isochronous RX (CECRn.FCE = 0) channels only. 0 TX underflow or RX underflow not detected 1 TX underflow or RX underflow detected
3 CBS	Current Buffer Start. When set, this bit indicates that the DMA controller has started processing the *Current Buffer*. This bit is set after the contents of CNBCRn have been loaded into CCBCRn, the CSCRn.RDY bit has been cleared (for ping-pong buffering), and hardware is available to accept the next buffer. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types. 0 First quadlet of the Current Buffer has not been successfully transmitted or received 1 First quadlet of the Current Buffer has been successfully transmitted or received
2 CBD	Current Buffer Done. When set, this bit indicates that the last quadlet from the last packet (in the *Current Buffer*) has been successfully transmitted or received. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types. 0 Last quadlet of the *Current Buffer* has not been successfully transmitted or received 1 Last quadlet of the *Current Buffer* has been successfully transmitted or received
1 CBDB	Current Buffer Detect Break. When set, this bit indicates that either a TX channel has detected a receiver break response, *ReceiverBreak* (70h), or an RX channel has detected a transmitter break command, *ControlBreak* (36h) or *AsyncBreak* (26h), while processing the *Current Buffer*. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for asynchronous and control channels only. 0 Break response was not detected while processing the Current Buffer 1 Break response was detected while processing the Current Buffer
0 CBPE	Current Buffer Protocol Error. This bit indicates that either a TX channel has detected an RxStatus of *ReceiverProtocolError* (72h), an RX channel has detected an invalid command for a given channel type, or an additional *ControlStart* (30h) or *AsyncStart* (20h) command has been received while in the middle of a packet. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all RX channel types and valid for only asynchronous and control TX channels. 0 Protocal error was not detected while processing the Current Buffer 1 Protocal error was detected while processing the Current Buffer

50.3.13 Channel n Current Buffer Configuration Register (MLB_CCBCR*n*)

The Channel n Current Buffer Configuration Register (CCBCRn) allows system software to monitor the address pointer and buffer length of the Current Buffer in system memory for the logical channel.

Addresses: 63FE_4000h base + 48h offset + (16d × *n*), where *n* = 0d to 15d



MLB_CCBCR*n* field descriptions

Field	Description
31–18 BCA	Buffer Current Address. The BCA field defines a 16-bit address pointer, which identifies the lower half of the beginning address of the *Current Buffer* in system memory. The BCA[15:2] bits are loaded from CNBCRn.BSA[15:2] when the Next Buffer is ready for processing. This Current Buffer address pointer should always be quadlet aligned (for example, BCA[1:0] equals 2'b00). During the processing of the *Current Buffer*, the BCA field marks which quadlet of the buffer is currently being processed.
17–16 BCA	For Synchronous, Asynchronous, and Control Channels - Hard-wired to'00' For Isochronous Channels - Buffer Current Address bits 1:0
15–2 BFA	Buffer Final Address. The BFA field defines a 16-bit address pointer, which identifies the lower half of the ending address of the *Current Buffer* in system memory. The BFA[15:2] bits are loaded from CNBCRn.BEA[15:2] when the Next Buffer is read for processing. This Current Buffer address pointer, except when associated with isochronous channels, should always be quadlet aligned (for example, BFA[1:0] equals 2'b00). During the processing of the Current Buffer, the point at which the BCA field becomes equal to (or greater than) the BFA field indicates that the processing of the Current Buffer will end upon successful completion of the current quadlet (for isochronous and synchronous channels) or upon successful completion of the current packet (for asynchronous and control channels). It is the responsibility of system software to ensure the system memory buffers (for RX asynchronous and control channels) can accommodate overflow in the size of the largest packet supported. Additionally, single-packet buffering can be used by simply programming CNBCRn.BSA[15:2] = CNBCRn.BEA[15:2]
1–0 BFA	For Synchronous, Asynchronous, and Control Channels - Hard-wired to'00' For Isochronous Channels - Buffer Final Address bits 1:0

50.3.14 Channel n Next Buffer Configuration Register (MLB_CNBCR*n*)

The Channel n Next Buffer Configuration Register (CNBCRn) allows system software to set the start and end addresses of the Next Buffer in system memory for the logical channel.

Addresses: 63FE_4000h base + 4Ch offset + (16d × *n*), where *n* = 0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BSA																BEA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MLB_CNBCR*n* field descriptions

Field	Description
31–16 BSA	Buffer Start Address. The BSA field defines a 16-bit address pointer, which identifies the lower half of the beginning address of the *Next Buffer* in system memory. Once system software detects CSCRn.RDY has been cleared by hardware (for ping-pong buffering), the beginning address of the *Next Buffer* may be loaded into BSA[15:2]. System software should then set CSCRn.RDY. Once processing of the *Current Buffer* for the logical channel is complete, the BSA[15:2] field is loaded into the CCBCRn.BCA[15:2] field and processing of the next buffer can begin. This *Next Buffer* address pointer must always be quadlet aligned (for example, BSA[1:0] must be written as 2'b00).
15–0 BEA	Buffer End Address. The BEA field defines a 16-bit address pointer, which identifies the lower half of the ending address of the *Next Buffer* in system memory. Once system software detects CSCRn.RDY has been cleared by hardware (for ping-pong buffering), the ending address of the *Next Buffer* may be loaded into BEA[15:2]. System software should then set CSCRn.RDY. Once processing of the *Current Buffer* for the logical channel is complete, the BEA[15:2] field is loaded into the CCBCRn.BFA[15:2] field and processing of the next buffer can begin. The BEA[15:2] bits are loaded into CCBCRn.BFA[15:2] when the *Current Buffer* is finished being processed. This *Next Buffer* address pointer, except when associated with isochronous channels, should always be quadlet aligned (for example, BEA[1:0] defaults to 2'b00).

50.3.15 Local Channel n Buffer Configuration Register (MLB_LCBCR*n*)

The Local Channel n Buffer Configuration Register (LCBCRn) allows software to optimize use of the Local Channel Buffer RAM. This register should only be written by software while the logical channel is disabled (for example, CECR3.CE clear disables Channel 3; therefore software may write LCBCR3). Writing to this register while the corresponding logical channel is enabled may result in unexpected behavior.

Addresses: 63FE_4000h base + 280h offset + (16d × *n*), where *n* = 0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:
- See descriptions for correct reset values.

MLB_LCBCR*n* field descriptions

Field	Description
31–20 --	Reserved
19–13 BD	Buffer Depth. This field defines the depth of the local channel buffer space in the local buffer RAM. 00h Depth = 4 quadlets 01h Depth = 8 quadlets 02h Depth = 12 quadlets 7Fh Depth = 512 quadlets
12–9 --	Reserved
8–0 SA	Buffer Start Address. This field defines the starting address of the channel buffer space in the local buffer RAM. At reset, the LCBCR.SA[9:0] field is loaded with the channel number multiplied by 32 (for channel number multiplied by 128 quadlets). 000h Start Address = 0 quadlets 001h Start Address = 4 quadlets 002h Start Address = 8 quadlets 3FFh Start Address = 2044 quadlets

50.4 Functional Description

50.4.1 Local Channel Buffer RAM

A single-port RAM is used to implement the memory space for local channel buffering. The size of the RAM is 2k x 36-bits (1 quadlet of data; 4-bit tag). The initial start address, depth and threshold values for logical channel buffer RAM are determined by parameters RAM_SADDR and BUF_DEPTH. See Table 50-99 for parameters that indicate the start address, depth and threshold reset values. After reset, the start address, depth for the logical channels buffered in the RAM are controlled through the LCBCRn registers, the initial values can be overwritten by software.

Table 50-99. Local Channel Buffer RAM Parameters

Logical Channel	RAM_SADDR	BUF_DEPTH
0	0	16
1	16	16
2	32	144
3	176	144
4	320	144
5	464	144
6	608	144
7	752	144
8	896	144
9	1040	144
10	1184	144
11	1328	144
12	1472	144
13	1616	144
14	1760	144
15	1904	144

See Figure 50-97 for more information on using the LCBCRn register to configure the local RAM buffer.

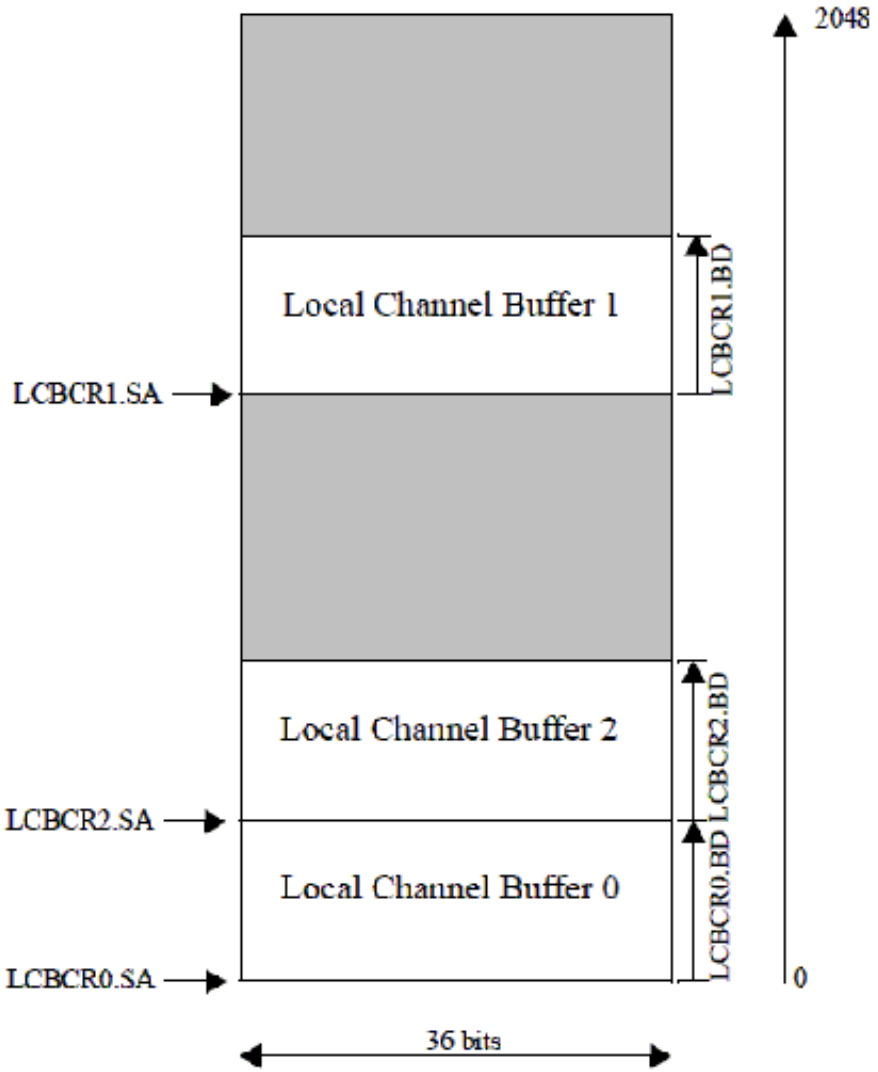

Figure 50-97. Programming Example for LCBCRn

50.4.1.1 Local Buffer Start Address

The initial buffer start address of each local channel buffer is defined by the default (after reset) start address of each local channel buffer (LCBCRn.SA [8:0]). The start address is the location of the beginning of the buffer in the local buffer RAM. Software may change the start address of each local channel buffer after reset by writing to LCBCRn.SA[8:0] directly.

50.4.1.2 Local Channel Buffer Depth

The initial buffer depth of each local channel buffer is configured by the default (after reset) depth of each local channel buffer (LCBCRn.BD[6:3] and LCBCRn.BD[2:0]) in quadlets. The buffer depth should be set based on the worst-case peripheral interface read/write latency. Software may change the depth of each local channel buffer after reset by writing to LCBCRn.BD[6:3] and LCBCRn.BD[2:0] directly.

50.4.2 Streaming Channel Frame Synchronization

Certain types of streaming applications require data to be synchronous with the MediaLB frame, including: stereo, 5.1 audio, and Generic Synchronous Packet Format (GSPF) DTCP. The MediaLB *Streaming Channel Frame Synchronization* feature provides this option.

For example, 24-bit stereo channels require two MLB physical channels (PC) to transmit left (0xLLLLLn) and right (0xRRRRRn) speaker data. Assuming the MLB Controller allocates Physical Channel 1 (PC1) and Physical Channel 2 (PC2) to this stereo channel, the data is synchronized to the MLB frame as shown in Table 50-100.

Table 50-100. Example of 24-bit stereo data synchronous to 256Fs MediaLB frame

Frame	PC=0	PC=1	PC=2	PC=3	PC=4	PC=5	PC=6	PC=7
n=0		0xLLLLLLRR	0xRRRRxxxx					
n=1		0xLLLLLLRR	0xRRRRxxxx					
n=2		0xLLLLLLRR	0xRRRRxxxx					
n=3		0xLLLLLLRR	0xRRRRxxxx					

Without frame synchronization, the MediaLB may begin transmitting or receiving data that is not aligned with the MLB frame. Misalignment, as depicted in Table 50-101, may result in data corruption.

Table 50-101. Example of 24-bit stereo data asynchronous to 256Fs MediaLB frame

Frame	PC=0	PC=1	PC=2	PC=3	PC=4	PC=5	PC=6	PC=7
n=0			0xLLLLLLRR					
n=1		0xRRRRxxxx	0xLLLLLLRR					
n=2		0xRRRRxxxx	0xLLLLLLRR					
n=3		0xRRRRxxxx	0xLLLLLLRR					

The MediaLB supports *Streaming Channel Frame Synchronization* as a programmable option for each logical channel configured for synchronous dataflow. System software can enable the frame synchronization feature for a synchronous logical channel by setting CECRn.FSE. When enabled, the synchronous logical channel begins transmitting and receiving data only at a MediaLB frame boundary.

When the loss of MLB frame synchronization occurs, the MLB detects it and optionally notifies system software through a maskable channel interrupt. In order to use this option, system software must:

- program CECRn.FSPC[4:0] with the expected number of physical channels per frame for the logical channel, and
- unmask the CSCRn.STS[6] bit by setting CECRn.MLFSto 0.

A channel interrupt is generated when the actual number of physical channels detected during a MLB frame does not match the expected value. An additional channel interrupt is generated if the local channel buffer overflows (for RX channels) or underflows (for TX channels).

Additionally, software may instruct the MLB to automatically disable a logical channel when MediaLB frame synchronization is lost. To enable this feature, software must set CSCRn.FSCD, which causes the hardware to automatically clear the Channel Enable bit (CECRn.CE) when synchronization is lost.

Frame synchronization is not supported for asynchronous, control, or isochronous channels.

50.4.3 Loop-Back Test Mode

In order to facilitate silicon debug of the MLB Device, hardware supports the *Loop-Back Test Mode*. This mode allows testing of the MLB pads, physical layer, link layer, channel protocol, and local channel buffer. When the DCCR.LBM bit is set, a data path is enabled which allows RX data from even Channel N to be sent out as TX data on Channel N+1, where N = {0, 2, 4, 6,..., 12, 14}.

Figure 50-98 illustrates the *Loop-Back Test Mode* data path.

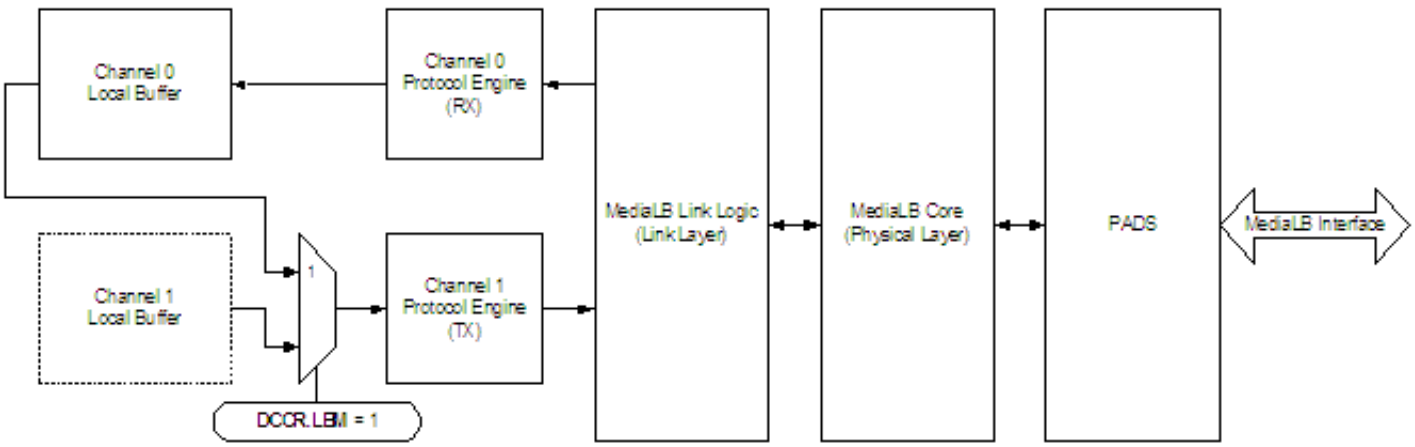

Figure 50-98. Loop-Back Test Mode Data Path

For *Loop-Back Test Mode* operation, software must perform the following steps:

- Set the logical *ChannelAddresses* for Channel N and N+1. (They cannot be the same address.)
- Enable Channel N for receiving synchronous, asynchronous, control, or isochronous data.
- Enable Channel N+1 for transmitting the same channel data type as Channel N.
- Set the Loop-Back Mode bit (DCCR.LBM).

Restrictions on the *Loop-Back Test Mode* are as follows:

- No protocol errors or breaks are allowed on either the RX or TX channel.
- Little-Endian mode must be disabled (DCCR.MLE clear).
- Isochronous packet lengths must be quadlet multiples.

Next Buffer Ready bits for Channels N and N+1 must remain clear (CSCR0.RDY = CSCL1.RDY = 0)

Chapter 51
NAND Flash Controller (NFC)

51.1 Introduction

The Nand Flash Controller (NFC) is composed of various control logic units, a 4.5-Kbyte internal RAM and an internal ECC engine. The NFC can interface standard NAND Flash memory devices. Figure 51-1 shows the block diagram of the NAND Flash controller.

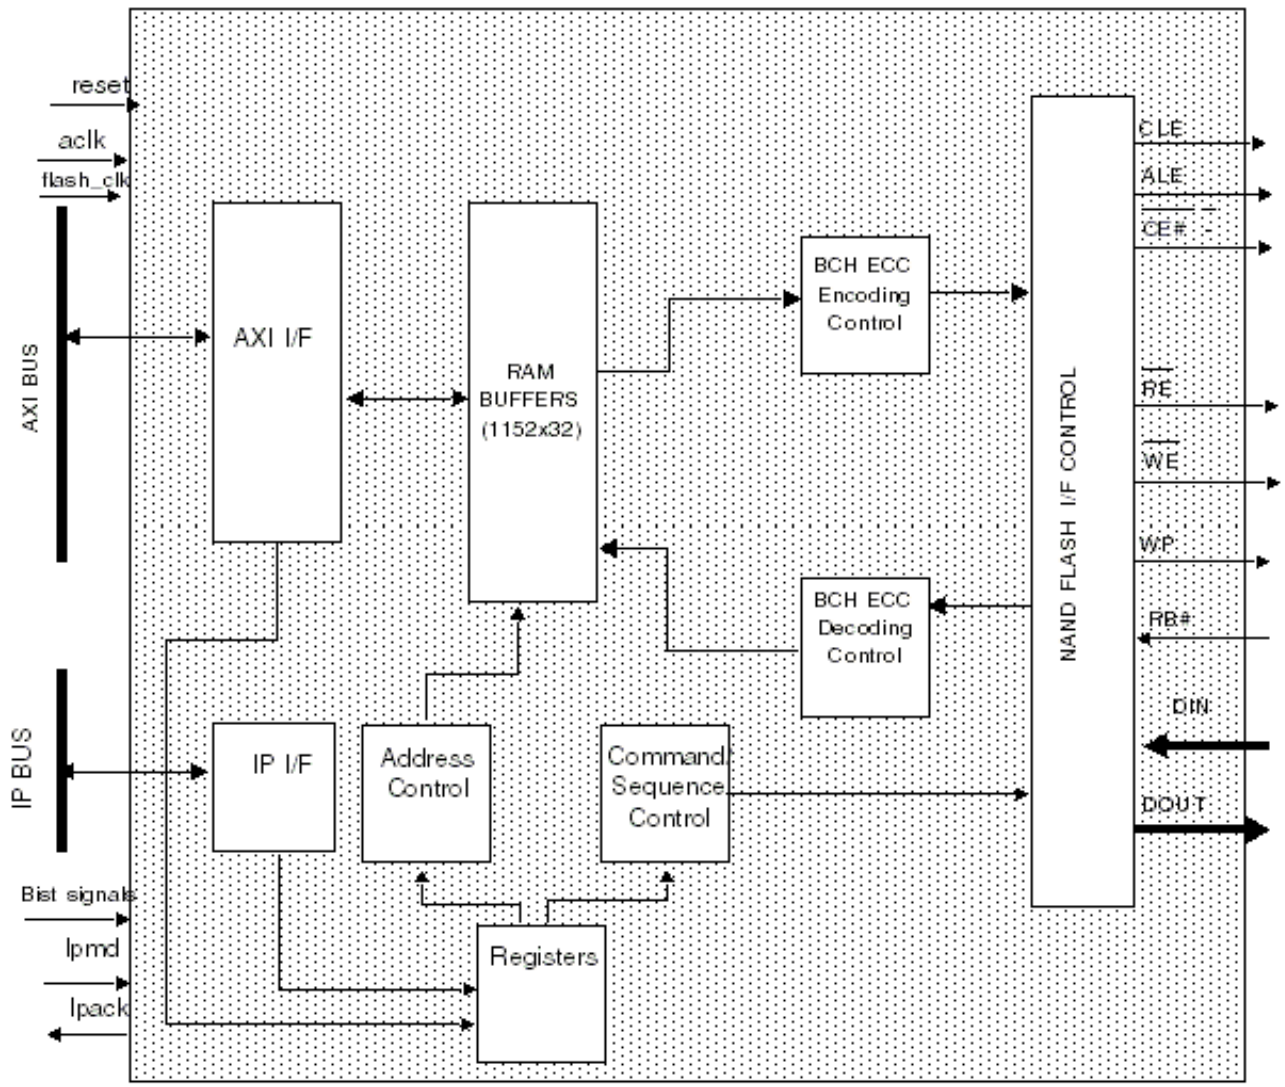

Figure 51-1. NAND Flash Controller Block Diagram

51.2 Overview

The NAND Flash Controller (NFC) can communicate with standard asynchronous NAND Flash devices. It provides a direct interface to both 8-bit and 16-bit NAND Flash devices supporting page sizes of 512B, 2KB, or 4KB.

The NFC is configured by the ARM platform through the AXI and IP Buses. The ARM processor initiates read and write operations (automatic or atomic) towards the NAND flash device. When the operation is finished the NFC issues an interrupt to the host.

The NFC works in two clock domains, aclk (fast clock) for communication with the AXI and ECC calculations and flash_clk (slow clock) for communication with the NAND flash device.

51.3 Features

The NFC includes the following features:

- x8 / x16 NAND Flash bus.
- Page size of 512B, 2KB and 4KB.
- Internal memory mapped RAM of 4KB + spare of up to 512B.
  - Supports page size of 512B + 16B, 2KB + 64B, 4KB + 128B, 4k + 218B, 4KB + 224B (when the spare area is greater than 218B and ECC is enabled then spare area size should be configured to 218B (i.e SPAS = 8'h6D))
- AXI Host interface that can access the internal RAM buffers and several registers. It supports:
  - Read / Write Burst
  - 16-bits / 32-bits bus transfers
- Support atomic (manual) and automatic modes of operation with up to 6 address phases.
- Supports interleaved accesses to up to 4 NAND devices while hiding the busy period of each device
- Supports ECC-BCH(8192) error correction code of 4/8/14/16 error bits in 528/538/548 bytes (512B main data +16B/26B/36B spare).
- Communicates with the system DMA
  - DMA read request after a full page read.
  - DMA write request at the beginning of a full-page programming.
- Multiple Reset
  - AXI reset/Cold Reset/ Warm Reset
- IO pins sharing support
  - Allows sharing of the IO pins with other memory controllers through special arbitration logic.
- Power down handshake mechanism for power saving.

51.4 Restrictions

In case of working with NAND device of x16bits bus then the ratio between aclk and flash clock must be at least 1:3 (i.e the aclk is at least 3 times faster than the flash_clk).

In AUTO_COPY_BACK operation with ADD_OP=01 the NFC can copy data only to the following page.

The address that the NFC drives to the NAND flash device must be aligned to address 0. i.e the columns address must be "0".

51.5 Signals Overview

The following signals shown in Table 51-1 are used to configure and control the NFC and its attached Flash device. Signals ending with _b are active-low signals.

Table 51-1. NFC Signal Properties

Name	Function	I/O	Reset
ipp_nfc_ale_out	Flash Address Latch Enable	O	0
ipp_nfc_ce0_out	Flash #0 Chip Enable	O	1
ipp_nfc_ce1_out	Flash #1 Chip Enable	O	1
ipp_nfc_ce2_out	Flash #2 Chip Enable	O	1
ipp_nfc_ce3_out	Flash #3 Chip Enable	O	1
ipp_nfc_cle_out	Flash Command Latch Enable	O	0
ipp_nfc_rb0_in	Flash #0 Ready/Busy	I	1
ipp_nfc_rb1_in	Flash #1 Ready/Busy	I	1
ipp_nfc_rb2_in	Flash #2 Ready/Busy	I	1
ipp_nfc_rb3_in	Flash #3 Ready/Busy	I	1
ipp_nfc_re_out	Flash Read Enable	O	1
ipp_nfc_read_data_in [15:0]	NFC data input from the NAND Flash	I	
ipp_nfc_we_out	Flash Write Enable	O	1
ipp_nfc_wp_out	Flash Write Protect	O	1
ipp_nfc_write_data_out [15:0]	NFC data output towards the NAND Flash	O	0000

51.6 Detailed Signal Descriptions

The following table gives a detailed description of the NFC signals.

Table 51-2. NFC Detailed Signal Descriptions

Signal	I/O	Description
ipp_nfc_ce0_out	O	Flash #0 Chip Enable. This signal indicates the NAND Flash selection. When the NAND Flash device is accessed, this signal is low. This pin is also called $\overline{\text{CE0\#}}$.
ipp_nfc_ce1_out	O	Flash #1 Chip Enable. This signal indicates the NAND Flash selection. When the NAND Flash device is accessed, this signal is low. This pin is also called $\overline{\text{CE1\#}}$.
ipp_nfc_ce2_out	O	Flash #2 Chip Enable. This signal indicates the NAND Flash selection. When the NAND Flash device is accessed, this signal is low. This pin is also called $\overline{\text{CE2\#}}$.
ipp_nfc_ce3_out	O	Flash #3 Chip Enable. This signal indicates the NAND Flash selection. When the NAND Flash device is accessed, this signal is low. This pin is also called $\overline{\text{CE3\#}}$.
ipp_nfc_re_out	O	Flash Read Enable. This signal controls the read data from the NAND device. The read data is latched on the rising edge of the signal. This pin is also called $\overline{\text{RE\#}}$.
ipp_nfc_we_out	O	Flash Write Enable.This signal controls the write of commands, address and data to the NAND device. The write is latched on the rising edge of the signal. This pin is also called $\overline{\text{WE\#}}$.
ipp_nfc_cle_out	O	Flash Command Latch Enable. The signal controls the command that is being sent to the command register of NAND device. When active high, commands are latched into the command register of NAND device on the rising edge of the $\overline{\text{WE\#}}$ signal. This pin is also called $\overline{\text{CLE\#}}$.
ipp_nfc_ale_out	O	Flash Address Latch Enable. The signal controls address that is being sent to the address register of NAND Flash. When active high, addresses are latched into the NAND device address register of NAND device on the rising edge of the $\overline{\text{WE\#}}$ signal. This pin is also called ALE#.
ipp_nfc_wp_out	O	Flash Write Protect. This signal provides inadvertent program/erase protection. This signal is active (held low) during power-up. This pin is also called WP#.
ipp_nfc_rb0_in	I	Flash #0 Ready/Busy. This signal indicates the status of the NAND Flash operation. When low, it indicates that a program, erase, or read operation of NAND Flash is in process. Upon completion of the process, this signal returns to high state. This pin is also called RB. **NOTE:** This signal is connected to an open drain output, via a 100 KOhm pull-up resister (outside the external NAND Flash memory device).
ipp_nfc_rb1_in	I	Flash #1 Ready/Busy. This signal indicates the status of the NAND Flash operation. When low, it indicates that a program, erase, or read operation of NAND Flash is in process. Upon completion of the process, this signal returns to high state. This pin is also called RB. **NOTE:** This signal is connected to an open drain output, via a 100 KOhm pull-up resister (outside the external NAND Flash memory device).
ipp_nfc_rb2_in	I	Flash #2 Ready/Busy. This signal indicates the status of the NAND Flash operation. When low, it indicates that a program, erase, or read operation of NAND Flash is in process. Upon completion of the process, this signal returns to high state. This pin is also called RB. **NOTE:** This signal is connected to an open drain output, via a 100 KOhm pull-up resister (outside the external NAND Flash memory device).

Table continues on the next page...

Table 51-2. NFC Detailed Signal Descriptions (continued)

Signal	I/O	Description
ipp_nfc_rb3_in	I	Flash #3 Ready/Busy. This signal indicates the status of the NAND Flash operation. When low, it indicates that a program, erase, or read operation of NAND Flash is in process. Upon completion of the process, this signal returns to high state. This pin is also called RB. **NOTE:** This signal is connected to an open drain output, via a 100 KOhm pull-up resister (outside the external NAND Flash memory device).
ipp_nfc_write_data_out[15:0]	O	Flash data output. The NFC uses this bus to drive command/address/data to the NAND device.
ipp_nfc_read_data_in[15:0]	I	Flash data input. The NFC uses this bus to latch data from the NAND device during read operation.

51.7 Memory Map and Register Definition

Table 51-3. Memory Map

Address	Use	Access
0xAXI_BASE_0000–0xAXI_BASE_11FF	Internal RAM	R/W
0xAXI_BASE_1200–0xAXI_BASE_1BFF	AXI Reserved	-
0xAXI_BASE_1E00–0xAXI_BASE_1E43	AXI Reserved	R/W
0xAXI_BASE_1E44–0xAXI_BASE_1FFF	AXI Reserved	-
0xBASE_3000–0xBASE_3003	IP Registers	R/W
0xBASE_3004–0xBASE_3023	IP Registers	-
0xBASE_3024–0xBASE_3037	IP Registers	R/W
0xBASE_3038–0xBASE_3EFC	IP Registers	-

51.7.1 Internal RAM Address Space and Organization

The internal RAM is divided into 4KB of main area and 1/2KB of spare area. The main area is used to hold the data of the NAND device page in read/program operations and is divided into 8 data buffers (also called data sections) of 512B each. The spare area is used to hold user-reserved data as well as the ECC encoding and is divided into 8 buffers of 64B each. Each main area buffer is associated with spare area buffer. For example spare area buffer 0 is associated with main area buffer 0.

Table 51-4 shows the organization of the main and spare area buffers inside the internal RAM. The host can use all of the spare area except for the ECC code areas. For further information of the internal RAM refer to Internal RAM

The NFC automatically generates ECC code for both main and spare area during data programming to NAND Flash. When programming/reading a page, the main and spare area buffer number must be selected using the RAM buffer address (RBA) field at NFC_CONFIGURATION1 Spare Area Buffers

Table 51-4. Internal RAM

Address	Use	Access
0xAXI_BASE_0000-0xAXI_BASE_01FF	Main area Buffer 0	R/W
0xAXI_BASE_0200-0xAXI_BASE_03FF	Main area Buffer 1	R/W
0xAXI_BASE_0400-0xAXI_BASE_05FF	Main area Buffer 2	R/W
0xAXI_BASE_0600-0xAXI_BASE_07FF	Main area Buffer 3	R/W
0xAXI_BASE_0800-0xAXI_BASE_09FF	Main area Buffer 4	R/W
0xAXI_BASE_0A00-0xAXI_BASE_0BFF	Main area Buffer 5	R/W
0xAXI_BASE_0C00-0xAXI_BASE_0DFF	Main area Buffer 6	R/W
0xAXI_BASE_0E00-0xAXI_BASE_0FFF	Main area Buffer 7	R/W
0xAXI_BASE_1000-0xAXI_BASE_103F	Spare area Buffer 0 (SB0)	R/W
0xAXI_BASE_1040-0xAXI_BASE_107F	Spare area Buffer 1 (SB1)	R/W
0xAXI_BASE_1080-0xAXI_BASE_10BF	Spare area Buffer 2 (SB2)	R/W
0xAXI_BASE_10C0-0xAXI_BASE_10FF	Spare area Buffer 3 (SB3)	R/W
0xAXI_BASE_1100-0xAXI_BASE_113F	Spare area Buffer 4 (SB4)	R/W
0xAXI_BASE_1140-0xAXI_BASE_117F	Spare area Buffer 5 (SB5)	R/W
0xAXI_BASE_1180-0xAXI_BASE_11BF	Spare area Buffer 6 (SB6)	R/W
0xAXI_BASE_11C0-0xAXI_BASE_11FF	Spare area Buffer 7 (SB7)	R/W

In case working with a NAND device with spare area of 16B per section of 512B (i.e 512B+spare of 16B, 2KB+ spare of 64B or 4KB + spare of 128B) then only the first 16B of each spare buffer will be used for both user-reserved and ECC code. The number of spare buffers that will be used corresponds the number of main area buffers which are derived from the page size. For example in page size of 4K+ spare of 128B there are 8 main buffers of 512B each and 8 spare buffers of 16B each.

In case working with a NAND device of 4KB + spare of 218B or 4KB + spare of 224B then the size of the first 7 spare buffers (i.e SB0-SB6) will be 26B and the size of the last spare buffer (i.e SB7) will be 36B.

NOTE

In case of working with a NAND device with page size of 4K+ spare of 218B with ECC_MODE of 8/14bits then the last 10B of the last spare buffer (i.e AXI_BASE+0x11DA-AXI_BASE +0x11E3) are not ECC protected. Moreover, in case of 4bits ECC_MODE then the SPAS should be configured to 0x40 (i.e

spare of 128B) and the NFC will use only the first 16B (8B for user-reserved and 8B for ECC) for every section of 512B. That means that the NFC will use only 128B of spare out of the 218B available. In 16 bits ECC_MODE all the bytes of the main and spare buffers are ECC protected.

Table 51-5 shows the sub-organization of the spare area buffers in case of working with NAND device of 4K+218B or 4K+224B (last 6B of the spare area buffer won't be used). Note that the sub-organization of the first 7 buffers (SB0-SB6) are different from the last buffer (SB7).

Table 51-6 shows the sub-organization of the spare area buffers in case of working with NAND devices of 512B+16B, 2K+64B or 4K+128B (i.e 16B per spare buffer)

Table 51-5. Spare Area Buffer for 4K+218B NAND

Address	F	E	D	C	B	A	9	8	7	6	5	4	3	2	1	0

1. When working in 16 bits ECC_MODE, this Byte is an ECC Byte. When working in 4/8/14 bits ECC_MODE, this Byte is user-reserved.
2. When working in 14/16 bits ECC_MODE, this Byte is an ECC Byte. When working in 4/8 bits ECC_MODE, this Byte is user-reserved.
3. When working in 4/14/16 bits ECC_MODE, this Byte is an ECC Byte. When working in 8bits ECC_MODE, this Byte is user-reserved.

4. When working in 8/14/16 bits ECC_MODE, this Byte is an ECC Byte. When working in 4bits ECC_MODE, this Byte is not used.
5. When working in 14 bits ECC_MODE, this Byte is an ECC Byte. When working in 4/8/16 bits ECC_MODE, this Byte is user-reserved
6. When working in 4/14 bits ECC_MODE, this Byte is an ECC Byte. When working in 8/16 bits ECC_MODE, this Byte is user-reserved
7. When working in 16 bits ECC_MODE, this Byte is an ECC Byte. When working in 8/14 bits ECC_MODE, this Byte is unprotected ECC user-reserved. When working in 4 bits ECC_MODE this Byte is not used.

In case of working with NAND devices of 512B+16B, 2K+64B or 4K+128B (i.e 16B of spare buffer) then only ECC_MODE of 4bits is allowed and then the first 8B of the relevant spare buffers are reserved for user and the rest 8B are reserved for ECC. For example in NAND device of 2K+64B only the first 4 spare buffers are in use.

F7FF_1E3C	status sum (NFC_STATUS_SUM)	32	R/W	0000_0000h	51.8.16/ 3595
F7FF_1E40	Initiate an NFC operation (NFC_LAUNCH_NFC)	32	R/W	0000_0000h	51.8.17/ 3595

51.8.1 NAND Flash command (NFC_NAND_CMD)

This register contains the commands to be written during a command phase.

Address: NFC_NAND_CMD is F7FF_0000h base + 1E00h offset = F7FF_1E00h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	NAND_CMD3								NAND_CMD2								NAND_CMD1								NAND_CMD0							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

NFC_NAND_CMD field descriptions

Field	Description
31–24 NAND_CMD3	NAND Flash Command3. second NAND Flash command which will be written to the NAND Flash device during an automatic copy-back operations at the write phase.
23–16 NAND_CMD2	NAND Flash Command2. First NAND Flash command which will be written to the NAND Flash device during an automatic copy-back operations at the write phase.
15–8 NAND_CMD1	NAND Flash Command1. Second NAND Flash command (command confirmation) which will be written to the NAND Flash device during an automatic erase/read/program/copy-back operations. In copy-back operation this command is the second command at the read phase.
7–0 NAND_CMD0	NAND Flash Command0. First NAND Flash command which will be written to the NAND Flash device during an automatic and atomic erase/read/program/copy-back operations. In copy-back operation this command is the second command at the read phase. In atomic (manual) operation only this command will hold the command that will be written to the NAND device.

51.8.2 NAND Flash address0 (NFC_NAND_ADD0)

This register contains the 32 lowest address bits to be written during an address phase to address group0.

- The NFC is always aligned to column 0 therefore the address bits of the column suppose to be zero.
- In case of Erase operation the lsb of the page address should be written to NAND_ADD0[0], In other operations the lsb of the column address should be written to NAND_ADD0[0].

NOTE

For example: Assume 4 devices are connected to the NFC, erasing block 0 of device #0 requires writing 48'h0 to NFC_ADDx register. Erasing block 0 requires writing 48'h1 to NFC_ADDx register. Assuming 2KB devices: Programming page 0 requires writing 48'h10000 to NFC_ADDx register (16 lower bits are column address). For further examples refer to

ADD_OP at NFC Operation Configuration3 (NFC_CONFIGURATION3)

Address: NFC_NAND_ADD0 is F7FF_0000h base + 1E04h offset = F7FF_1E04h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

NFC_NAND_ADD0 field descriptions

Field	Description
31–0 NAND_ADD0	NAND Flash address group 0. This defines the lower 32 bits of address group 0. This will be used as the address of the page/block in an automatic and atomic operations.

51.8.3 NAND address1 (NFC_NAND_ADD1)

This register contains the 32 lowest address bits to be written during an address phase to address group1.

- The NFC is always aligned to column 0 therefore the address bits of the column suppose to be zero.
- In case of Erase operation the lsb of the page address should be written to NAND_ADD1[0], In other operations the lsb of the column address should be written to NAND_ADD1[0].

Address: NFC_NAND_ADD1 is F7FF_0000h base + 1E08h offset = F7FF_1E08h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	NAND_ADD1

NFC_NAND_ADD1 field descriptions

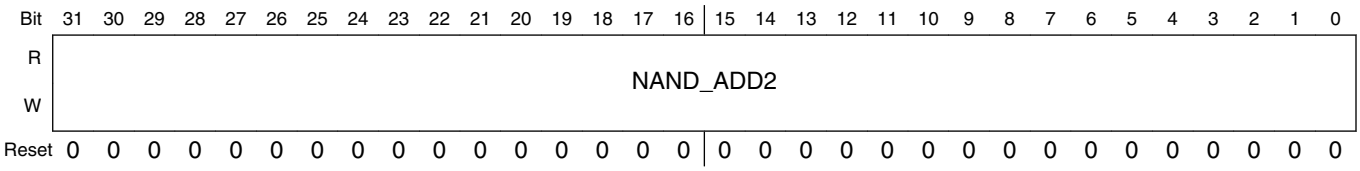
Field	Description
31–0 NAND_ADD1	NAND Flash address group 1. This defines the lower 32 bits of address group 1. This will be used as the address of the page/block in automatic operations depending on ADD_OP.

51.8.4 NAND address2 (NFC_NAND_ADD2)

This register contains the 32 lowest address bits to be written during an address phase to address group2.

- The NFC is always aligned to column 0 therefore the address bits of the column suppose to be zero.
- In case of Erase operation the lsb of the page address should be written to NAND_ADD2[0]. In other operations the lsb of the column address should be written to NAND_ADD2[0].

Address: NFC_NAND_ADD2 is F7FF_0000h base + 1E0Ch offset = F7FF_1E0Ch



NFC_NAND_ADD2 field descriptions

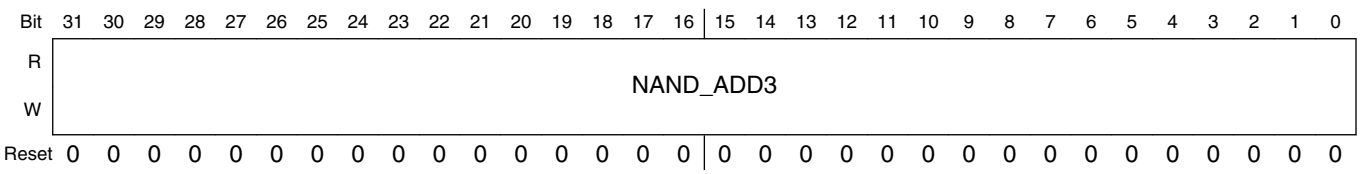
Field	Description
31–0 NAND_ADD2	NAND Flash address group 2. This defines the lower 32 bits of address group 2. This will be used as the address of the page/block in automatic operations depending on ADD_OP.

51.8.5 NAND address3 (NFC_NAND_ADD3)

This register contains the 32 lowest address bits to be written during an address phase to address group3.

- The NFC is always aligned to column 0 therefore the address bits of the column suppose to be zero.
- In case of Erase operation the lsb of the page address should be written to NAND_ADD3[0], In other operations the lsb of the column address should be written to NAND_ADD3[0].

Address: NFC_NAND_ADD3 is F7FF_0000h base + 1E10h offset = F7FF_1E10h



NFC_NAND_ADD3 field descriptions

Field	Description
31–0 NAND_ADD3	NAND Flash address group 3. This defines the lower 32 bits of address group 3. This will be used as the address of the page/block in automatic operations depending on ADD_OP.

51.8.6 NAND address4 (NFC_NAND_ADD4)

This register contains the 32 lowest address bits to be written during an address phase to address group4.

The NFC is always aligned to column 0 therefore the address bits of the column suppose to be zero.

- In case of Erase operation the lsb of the page address should be written to NAND_ADD4[0], In other operations the lsb of the column address should be written to NAND_ADD4[0].

Address: NFC_NAND_ADD4 is F7FF_0000h base + 1E14h offset = F7FF_1E14h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

NFC_NAND_ADD4 field descriptions

Field	Description
31–0 NAND_ADD4	NAND Flash address group 4. This defines the lower 32 bits of address group 4. This will be used as the address of the page/block in automatic operations depending on ADD_OP.

51.8.7 NAND address5 (NFC_NAND_ADD5)

This register contains the 32 lowest address bits to be written during an address phase to address group5.

- The NFC is always aligned to column 0 therefore the address bits of the column suppose to be zero.
- In case of Erase operation the lsb of the page address should be written to NAND_ADD5[0], In other operations the lsb of the column address should be written to NAND_ADD5[0].

Address: NFC_NAND_ADD5 is F7FF_0000h base + 1E18h offset = F7FF_1E18h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

NFC_NAND_ADD5 field descriptions

Field	Description
31–0 NAND_ADD5	NAND Flash address group 5. This defines the lower 32 bits of address group 5. This will be used as the address of the page/block in automatic operations depending on ADD_OP.

51.8.8 NAND address6 (NFC_NAND_ADD6)

This register contains the 32 lowest address bits to be written during an address phase to address group6.

- The NFC is always aligned to column 0 therefore the address bits of the column suppose to be zero.
- In case of Erase operation the lsb of the page address should be written to NAND_ADD6[0], In other operations the lsb of the column address should be written to NAND_ADD6[0].

Address: NFC_NAND_ADD6 is F7FF_0000h base + 1E1Ch offset = F7FF_1E1Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

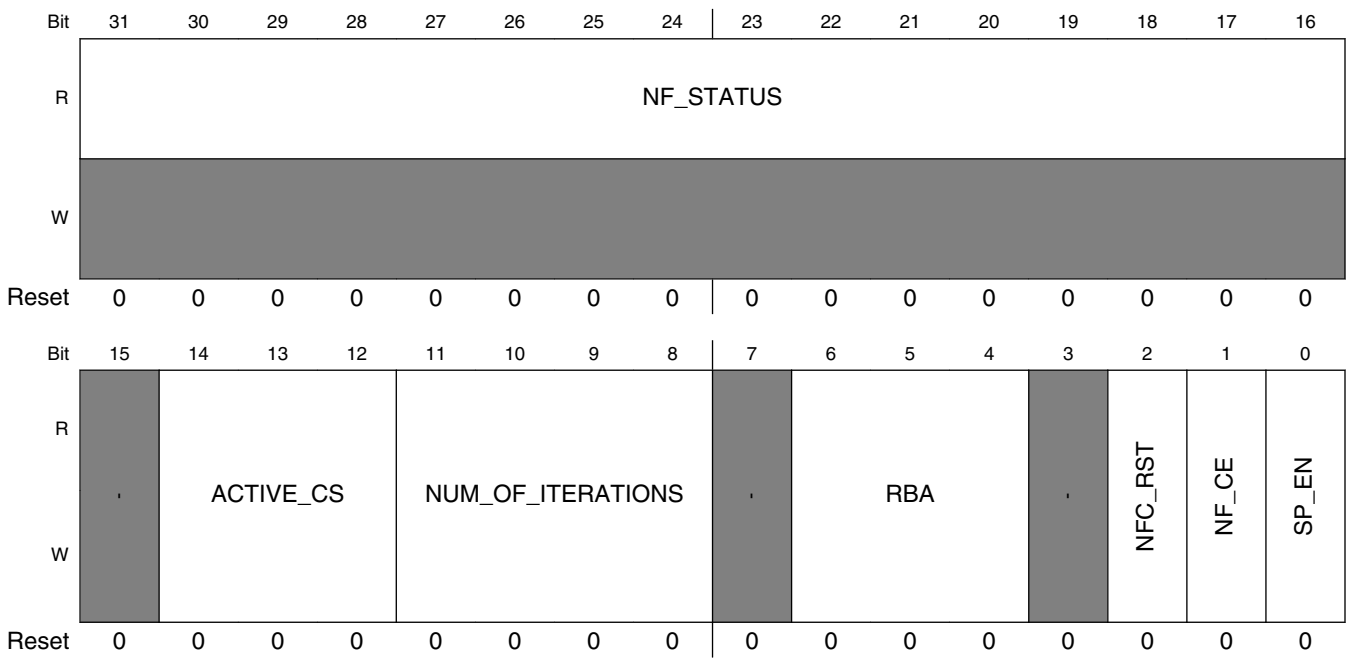
NFC_NAND_ADD11 field descriptions

Field	Description
31–16 NAND_ ADD7[47:32]	NAND Flash address group 7. This defines the upper 16 bits of address group 7. This will be used as the address of the page/block in automatic operations depending on ADD_OP.
15–0 NAND_ ADD6[47:32]	NAND Flash address group 6. This defines the upper 16 bits of address group 6. This will be used as the address of the page/block in automatic operations depending on ADD_OP.

51.8.14 NFC configuration (NFC_CONFIGURATION1)

This register specifies interactive configuration used by the NFC.

Address: NFC_CONFIGURATION1 is F7FF_0000h base + 1E34h offset = F7FF_1E34h



NFC_CONFIGURATION1 field descriptions

Field	Description
31–16 NF_STATUS	NAND Flash Status. This field holds the last NAND device status that was read by the NFC. This register is updated every time that a read status command is executed (AUTO_STAT, atomic read status or when RBB_MODE is set to zero).
15 -	Reserved
14–12 ACTIVE_CS	Active CS. This field indicates the NAND device ID to which the NFC will target its operations. This field is used only during atomic operations (i.e if one of FCMD, FADD, FDI or FDO is set) and during automatic status read operation (AUTO_STAT is set). During other automatic operations the NAND ID is defined based on the ADD_OP register.

Table continues on the next page...

NFC_CONFIGURATION1 field descriptions (continued)

Field	Description
	000 access NAND device connected to CS0 001 access NAND device connected to CS1 010 access NAND device connected to CS2 011 access NAND device connected to CS3 100 access NAND device connected to CS4 101 access NAND device connected to CS5 110 access NAND device connected to CS6 111 access NAND device connected to CS7
11–8 NUM_OF_ ITERATIONS	Number Of Iterations. Defines how many times NFC will execute AUTO_READ/AUTO_PROG/ AUTO_ERASE/AUTO_COPY_BACK without setting an interrupt. When automatic operation bit is set, NFC executes the automatic operation NUM_OF_ITERATIONS+1 times. For example: If NUM_OF_ITERATION is set to 4'h4,and then an AUTO_READ operation is set, then NFC will read 5 pages from the NAND devices. It is the system's responsibility to read the pages content from the NFC's RAM. When NUM_OF_ITERATIONS is greater than 0 and NUM_OF_DEVICES is greater than 0 then an interleaved accesses will be executed and in that case SDMA will be used. if NUM_OF_ITERATION is greater than NUM_OF_DEVICES then after accessing the last device then the NFC will issue another round of accesses to the 1st device and then the 2nd device and etc. until NUM_OF_ITERATIONS is reached. In every round the NFC will increment the address of the page/block. For example if NUM_OF_ITERATIONS=2 (3 iterations) and NUM_OF_DEVICES=1(i.e 2 devices) then the NFC will access 1st device then 2nd device then will increment the address of the page/block and access 1st device and only then issue an interrupt, because 3 iterations were reached. For further examples refer to ADD_OP field at NFC Operation Configuration3 (NFC_CONFIGURATION3) Note: if NUM_OF_ITERATIONS is greater than NUM_OF_DEVICES then this will work only if RBB_MODE is set to "0". 0x0 execute automatic operation 1 time. 0x1 execute automatic operation 2 times. 0xf execute automatic operation 16 times.
7 -	Reserved
6–4 RBA	Ram Buffer Address. Specifies which 1/2K of the internal ram to use when accessing the NAND device. In either Atomic or Automatic operations when NO_SDMA bit is set the value of RBA indicates from which part of the internal RAM to fetch the data in a program operation or to which part of the internal RAM to store the data in a read operation. For example if RBA is set to "100" and the page size is 1/2K (PS is set to "00") and a program operation is configured then the NFC will program the NAND device with the data that is located at the 5th 1/2KB of the internal RAM. In that case it is the user responsibility to store the requested data at the 5th 1/2KB before starting the program operation. Note that in case the page size is 2KB or 4KB then the NFC will fetch/store the data from/to continuos RBA. For example if RBA is set to "000" and page size is 2KB and a program operation is configured then the NFC will program the NAND device with the data that is stored at 1st, 2nd, 3rd, 4th 1/2KB. Note: • In case the page size is 2KB then only RBA of "000" and "100" are allowed and in case the page size is 4KB then only RBA of "000" is allowed. • In case of working with SDMA (NO_SDMA is set to "0") then the NFC will set RBA to "000" in either read or program operations. 000 Use 1st 1/2K of the internal ram.

Table continues on the next page...

NFC_CONFIGURATION1 field descriptions (continued)

Field	Description
	001 Use 2nd 1/2K of the internal ram 010 Use 3rd 1/2K of the internal ram 011 Use 4th 1/2K of the internal ram 100 Use 5th1/2K of the internal ram 101 Use 6th 1/2K of the internal ram 110 Use 7th 1/2K of the internal ram 111 Use 8th 1/2K of the internal ram
3 -	Reserved
2 NFC_RST	NFC Reset. This bit resets the NFC state machines. This bit should be used when issuing a reset command to the NAND Flash device during an operation. When a NAND device received a reset command (0xff) during an operation it aborts its operation and returns to idle. In order to do the same to the NFC, this bit must be set before the reset command is sent. This bit is self cleared. 0 Do not reset the NFC state machine 1 Reset the NFC state machine
1 NF_CE	NAND Flash Force CE. Setting this bit forces the $\overline{\text{CE\#}}$ signal that is driven to the NAND Flash device to 0. There are some NAND devices that require that the CE# will be kept low during the busy period. Therefore when working with such a NAND device with RBB_MODE=0 (in that mode the NFC toggles the CE# while performing a read status during the busy period) NF_CE should set to "1" and then the CE will be forced to "0". This bit is not self cleared. 0 $\overline{\text{CE\#}}$ signal operates normally 1 $\overline{\text{CE}}$ # signal is asserted as long as this bit is set to 1.
0 SP_EN	NAND Flash Spare Enable. This bit determines whether the host will program/read the spare area only or main and spare area together to/from the NAND device. This features is supported only in NAND devices of 1/2K page size. When this bit is enabled then the NFC will program/read 16B of spare area. **NOTE:** There is no ECC when SP_EN=1 0 Program/read main and spare area. 1 Program/read spare area only.

51.8.15 ECC status result (NFC_ECC_STATUS_RESULT)

This register shows the number of bits that were detected/corrected for every page section of 528/538/548 bytes in the main and spare area as a result of the BCH ECC check. For further information of the ECC algorithm refer to 51.12.4/51-77

Address: NFC_ECC_STATUS_RESULT is F7FF_0000h base + 1E38h offset = F7FF_1E38h

NFC_ECC_STATUS_RESULT field descriptions (continued)

Field	Description
11–8 NOBER2	Number Of bit Errors for third528/538/548 bytes section. This field shows the number of bit errors in 512 bytes main area plus 16/26/36 bytes spare (totally 528/538/548 bytes) that were detected/corrected as a result of the BCH ECC check upon read. others > Reserved 0000 No error 0001 >1-3 bit Error (Correctable Error) 0010 > 4-bit Error (Correctable Error) 0011 > 5-7 bit Error (Correctable Error for 8/14/16bit ecc-mode) 0100 > 8-bit Error (Correctable Error for 8/14/16bit ecc-mode) 0101 > 9-13 bit Error (Correctable Error for 14/16bit ecc-mode) 0110 > 14-bit Error (Correctable Error for 14/16bit ecc-mode) 0111 > 15-bit Error (Correctable Error for 16bit ecc-mode) 1000 > 16-bit Error (Correctable Error for 16bit ecc-mode) 1111 > Uncorrectable error.
7–4 NOBER1	Number Of bit Errors for second 528/538/548 bytes section. This field shows the number of bit errors in 512 bytes main area plus 16/26/36 bytes spare (totally 528/538/548 bytes) that were detected/corrected as a result of the BCH ECC check upon read. others > Reserved 0000 No error 0001 >1-3 bit Error (Correctable Error) 0010 > 4-bit Error (Correctable Error) 0011 > 5-7 bit Error (Correctable Error for 8/14/16bit ecc-mode) 0100 > 8-bit Error (Correctable Error for 8/14/16bit ecc-mode) 0101 > 9-13 bit Error (Correctable Error for 14/16bit ecc-mode) 0110 > 14-bit Error (Correctable Error for 14/16bit ecc-mode) 0111 > 15-bit Error (Correctable Error for 16bit ecc-mode) 1000 > 16-bit Error (Correctable Error for 16bit ecc-mode) 1111 > Uncorrectable error.
3–0 NOBER0	Number Of bit Errors for first 528/538/548 bytes section. This field shows the number of bit errors in 512 bytes main area plus 16/26/36 bytes spare (totally 528/538/548 bytes) that were detected/corrected as a result of the BCH ECC check upon read. others > Reserved 0000 No error 0001 >1-3-bit Error (Correctable Error) 0010 > 4-bit Error (Correctable Error) 0011 > 5-7 bit Error (Correctable Error for 8/14/16bit ecc-mode) 0100 > 8-bit Error (Correctable Error for 8/14/16bit ecc-mode) 0101 > 9-13 bit Error (Correctable Error for 14/16bit ecc-mode) 0110 > 14-bit Error (Correctable Error for 14/16bit ecc-mode) 0111 > 15-bit Error (Correctable Error for 16bit ecc-mode) 1000 > 16-bit Error (Correctable Error for 16bit ecc-mode) 1111 > Uncorrectable error.

51.8.16 status sum (NFC_STATUS_SUM)

This register shows a summary status of the NAND device as well as a summary result of the ECC check after a page read.

Address: NFC_STATUS_SUM is F7FF_0000h base + 1E3Ch offset = F7FF_1E3Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	-																ECC_SUM								NAND_STATUS_SUM							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

NFC_STATUS_SUM field descriptions

Field	Description
31–16 -	Reserved
15–8 ECC_SUM	Ecc Summary report. reports correctable/non-correctable ECC result after a page read for each NAND device. Every NAND device has a bit in this field that indicates whether the last page read from this device had any uncorrectable ECC sections. (bit 0 to Nand0, bit 1 to Nand1, and so on). During a page read, NFC checks for error-bits in each section of the page (for further information of the ECC algorithm refer to ECC Normal Operation . If any of the sections had an uncorrectable ECC result, then the corresponding bit will be set. If all sectors of the page had correctable ECC errors or no error at all, then the corresponding bit will not be set. If NFC reports an uncorrectable ECC status, the user must clear this field manually.
7–0 NAND_ STATUS_SUM	NAND Status Summary. Reports the status of all NAND devices. After NFC executes a status-read operation, as part of the automatic operations (Not status-read of atomic operation (FDO)) to any NAND device, it stores the pass/fail indication of the status register in this field. Each NAND device has 1 bit that stores its status. (bit 0 to Nand0, bit 1 to Nand1, etc.). This field is being cleared at any write to LAUNCH_NFC register, thus if an automatic operation was carried more than once to a specific CS, then this field will indicate if any of the operations resulted in an error by the NAND device.

51.8.17 Initiate an NFC operation (NFC_LAUNCH_NFC)

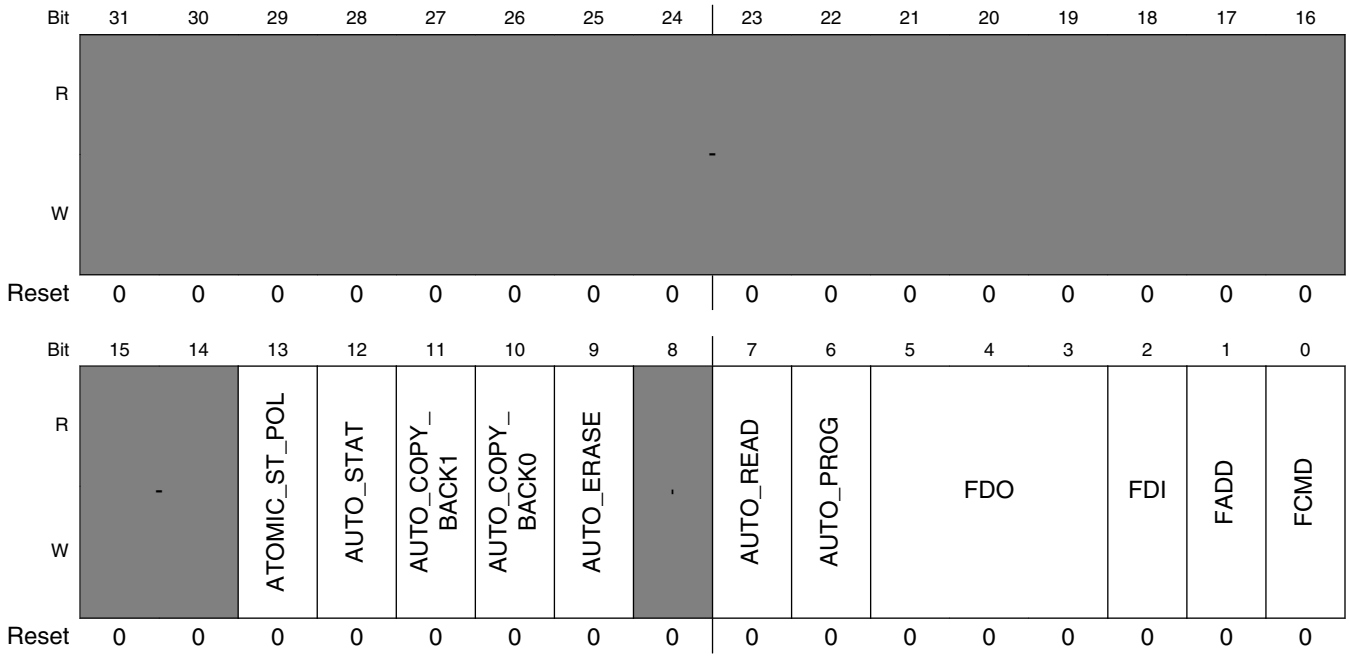
Address of block memory in the NAND Flash that is unlocked in Write Protection mode.

NOTE

When the basic operation is completed, this register is self cleared.

.

Address: NFC_LAUNCH_NFC is F7FF_0000h base + 1E40h offset = F7FF_1E40h



NFC_LAUNCH_NFC field descriptions

Field	Description
31–14 -	Reserved
13 ATOMIC_ST_POL	Atomic Read Status Polling. This bit should be set in Atomic operation when RBB_MODE is set to "0" and when the NAND device is expected to get into busy period. When this bit is set then the NFC will issue a read status command and then issue 1 pulse of RE_B as long as the NAND device is busy (read status polling), When the NAND device will be ready then the NFC will issue an interrupt and clear that bit. For example in read operation from a device that doesn't require a read confirmation command then after the last address cycle the NAND device is expected to get into busy period. Therefore this bit should be set together with the last address cycle and afterwards a read command should be reissued before reading the data in order to read from the data buffer and not from the status buffer of the NAND. So in that example the sequence will be as following: <read command 0x0> <address0>...<addressN + set ATOMIC_ST_POL> <read command 0x0> <read data>. For that example if the device requires a read confirmation then the ATOMIC_ST_POL will have to be set set together with read confirmation command, So in that example the sequence will be as following: <read command 0x0> <address0>...<addressN> <read confirmation command 0x30 + set ATOMIC_ST_POL> <read command 0x0> <read data>. In any automatic operation this bit should be "0" as the whole sequence is executed automatically.ALso when RBB_MODE is set to "1" this bit should be set to "0". For further information refer to Atomic Operations Sequence 0 Do not execute a status read operation. 1 Execute a status read operation.
12 AUTO_STAT	Automatic Status Read operation. When this bit is set, NFC will automatically perform a status read operation: send status read command that is defined in ST_CMD in NFC_CONFIGURATION2, and then issues 1 pulse of RE_B. The status result will be stored in NF_STATUS field. The summary of the status will be recorded in NAND_STATUS_SUM field.

Table continues on the next page...

NFC_LAUNCH_NFC field descriptions (continued)

Field	Description
	The status-read operation will be executed to the NAND device defined by ACTIVE_CS. The status-read operation will be executed only once, and it will be not affected from NUM_OF_ITERATION field. 0 Don't execute a status read operation 1 Execute a status read operation.
11 AUTO_COPY_BACK1	Auto copy back sequence to multiple NAND devices. When this bit is set and interleaved mode is configured (i.e NUM_OF_ITERATION and NUM_OF_DEVICES are greater than 0), NFC will execute a page copy back sequence in interleaved mode as following: <command phase> < address phases> <command phase> <command phase> < address phases> <command phase>. A read status at the end of the sequence is executed only when RBB_MODE is set to "0". For further information refer to AutoMatic Copy-back Operation The commands will be issued from NAND_CMD0, NAND_CMD1, NAND_CMD2 and NAND_CMD3. The source address will be taken from the address group0 and the target address will be taken from address group1 0 Don't execute a page copy back. 1 Execute a page copy back
10 AUTO_COPY_BACK0	Auto copy back sequence. When this bit is set, NFC will execute a page copy back sequence: <command phase> < address phases> <command phase> <command phase> < address phases> <command phase>. A read status at the end of the sequence is executed only when RBB_MODE is set to "0". The first command phase will be taken from NAND_CMD0, the second command phase will be taken from NAND_CMD1 the third command phase will be taken from NAND_CMD2 and the last command phase will be taken from NAND_CMD3. In case of ADD_OP other than 01 then the source address will be taken from the address group0 and the target address will be taken from address group1. In case ADD_OP is set to "01" then the NFC will use only address group0 and copy the page to address group0+1 no matter what is address group1. If the user wish to use a device other than device #0 for this operation, then ADD_OP 2'b01 or 2'b11 must be configured. For further information refer to AutoMatic Copy-back Operation 0 Don't execute a page copy back. 1 Execute a page copy back
9 AUTO_ERASE	Auto erase sequence. When this bit is set, NFC will execute a full block erase sequence: <command phase> < address phases> <command phase>. A read status at the end of the sequence is executed only when RBB_MODE is set to "0". The commands will be issued from NAND_CMD0 and NAND_CMD1. The address will be taken from the active address group. For further information refer to Automatic erase operation 0 Don't execute a full block erase. 1 Execute a full block erase
8 -	Reserved
7 AUTO_READ	Auto read sequence. When this bit is set, NFC will execute a full page-read sequence: <command phase> < address phases> <command phase> <busy polling> <data transfer><read status>. A read status at the end of the sequence is executed when both RBB_MODE is set to "0" or "1".

Table continues on the next page...

NFC_LAUNCH_NFC field descriptions (continued)

Field	Description
	The commands will be issued from NAND_CMD0 and NAND_CMD1. The address will be taken from the active address group. If NUM_OF_ITERATIONS is greater than 0, then NFC will continue reading the next page until NUM_OF_ITERATIONS is reached. NFC will monitor the AXI address in order to decide when next page read should start. For further information refer to FMP and to Automatic Read Operation 0 Don't execute a full page read. 1 Execute a full page read
6 AUTO_PROG	Auto program sequence. When this bit is set, NFC will execute a full page-program sequence: <command phase> < address phases> <data transfer> <command phase>. A read status at the end of the sequence is executed only when RBB_MODE is set to "0". The commands will be issued from NAND_CMD0 and NAND_CMD1. The address will be taken from the active address group. If NUM_OF_ITERATIONS is greater than 0, then NFC will start programming the next page until NUM_OF_ITERATIONS is reached. NFC will monitor the AXI address in order to decide when next page program should start. For further information refer to FPM and to Automatic program operation 0 Do not execute a full page program. 1 Execute a full page program
5–3 FDO	NAND atomic Flash Data Output. This bit enables NAND Flash Data Output. Other options are reserved 001 One page data out. For further information see NAND Flash Atomic Data Output Operation 010 NAND Flash ID data out. Toggles 6 times the read enable signal (re) and store the returned data at the main buffer according to RBA. For further information refer to 51.12.2.6/51-72 100 NAND Flash Status Register data out. This operation toggle once the read enable signal (re) and store the status in NF_STATUS. For further information refer to 51.12.2.7/51-74
2 FDI	NAND Flash atomic Data Input. This field enables NAND Flash Data Input. For further information see NAND Flash Atomic Data Input Operation 0 No NAND Flash data input operation 1 Enable NAND Flash data input operation
1 FADD	NAND Flash atomic Address Input. This field enables NAND Flash Address Input. For further information see NAND Flash Atomic Address Input Operation 0 No NAND Flash Address input operation 1 Enable NAND Flash Address input operation
0 FCMD	NAND Flash atomic Command Input. This field enables the NAND Flash Command Input. For further information see NAND Flash Atomic Command Input Operation 0 No NAND Flash Command input operation 1 Allow NAND Flash Command input operation

51.9 Programmable Registers

NFC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

NFC_CONFIGURATION2 field descriptions

Field	Description
31–24 ST_CMD	Status Command. This is the command NFC will use when executing automatic status-read operations. For most NAND devices this value should be 8'h70
23–16 SPAS	Spare Area Size. This field specifies the size of the spare area of the NAND device.This size is in half words and refers to a full page. For example when working with a NAND device with page of 2KB + 64B then spare area is 64B so the SPAS should be set to 8'h20. Note: In case ECC is enabled then the spare area size must be less or equal 218B.
15 INT_MSK	Mask interrupt Bit. This bit enables the interrupt by masking or not masking the interrupt bit. 0 Mask interrupt is disabled (interrupt enabled) 1 Mask interrupt is enabled (interrupt disabled)

Table continues on the next page...

NFC_CONFIGURATION2 field descriptions (continued)

Field	Description
14 AUTO_PROG_ DONE_MSK	Auto Program Done Mask. This bit enables the auto_prog_done by masking or not masking the AUTO_PROG_DONE bit. 0 Mask AUTO_PROG_DONE is disabled (auto_prog_done enabled) 1 Mask AUTO_PROG_DONE is enabled (auto_prog_done disabled)
13–12 NUM_ADR_ PHASES1	Number Of Address Phases1. he number of address phases need to be executed to the NAND Device during read/program operations. 00 3 phases 01 4 phases 10 5 phases 11 6 phases
11–10 EDC	Extra dead cycles. This field specifies number of dead cycles after a read operation, before nfc will allow any other slave to use the shared IO. NFC will delay its ack_en signal according to this field. This will occur any time the NFC stops reading, whether its during a read (because of EIM request), at the end of a read, or at the end of any read operation. The purpose of this field is to prevent contention on the shared IO when using memories with slow data-to-high-z response (large tRHZ field). 00 EDC disabled 01 2 clocks 10 4 clocks 11 6 clocks.
9–8 PPB	Pages Per Block. Indicates how many pages are in 1 Block of the Nand Flash. PPB is used to: - Calculate the next block to erase in AUTO_ERASE. - Calculate in ADD_OP=1/3 where to start the address of the block after extracting the lsb for CS. 00 32 pages per block 01 64 pages per block 10 128 pages per block (default value) 11 256 pages per block
7–6 ECC_MODE	ECC_MODE. This field selects the error correction capabilities, either 4bits correction, 8bits correction, 14bits correction or 16bits correction. In 4bits ECC_MODE the NFC uses 16B of spare area for every 512B data section of the Nand device. (8B for user specific applications and 8B for ECC). In 8bits ECC_MODE the NFC uses 26B of spare area for every 512B data section of the Nand device (12B for user specific application, 14B for ECC). In 14bits ECC_MODE the NFC uses 26B of spare area for every 512B data section of the Nand device (2B for user specific application, 24B for ECC). In 16bit ECC_MODE the NFC uses either 26B or 36B of spare area for every 512B data section of the Nand device. If the spare area has 36B of spare area available for the current main-data section then NFC will use 10B for user specific application and 26B for ECC. If the spare has less than 36B, then NFC will use 26B for ECC, and no Bytes for user-reserved. Note: - In order to use 8/14/16bits ECC_MODE it is needed to work with a NAND device that has at least 26B of spare area for every 512B data section.

Table continues on the next page...

NFC_CONFIGURATION2 field descriptions (continued)

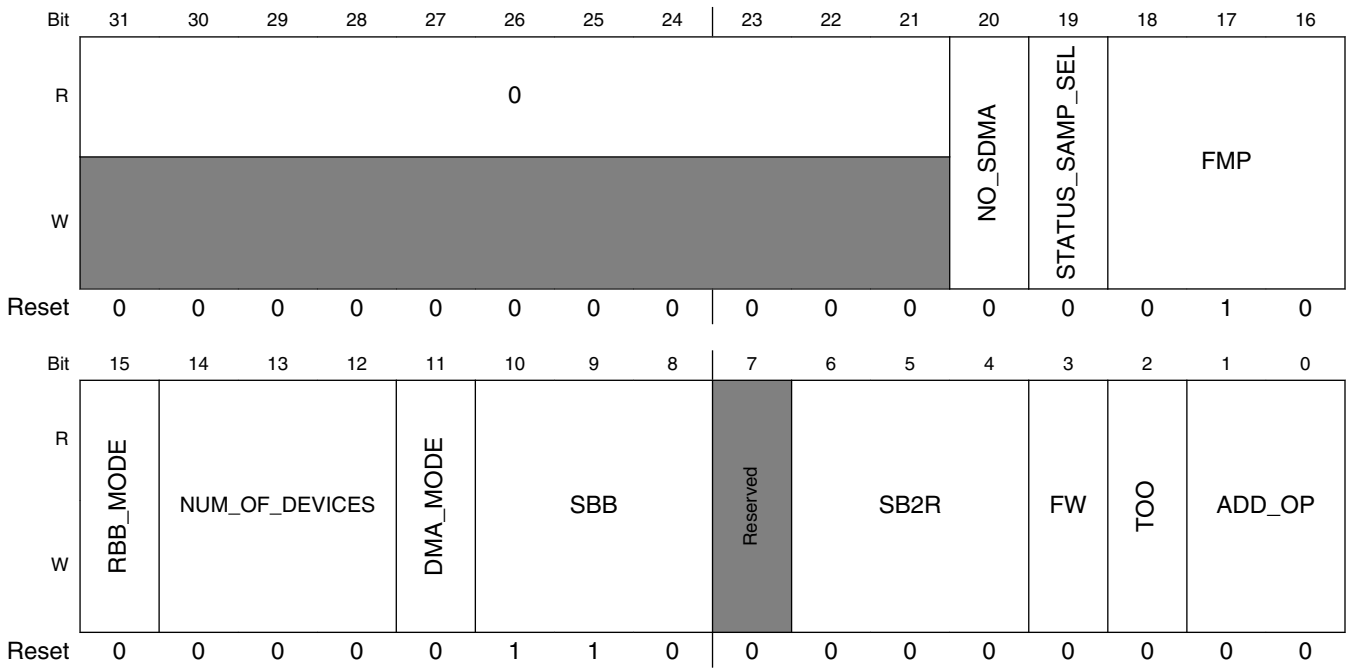
Field	Description
	- In case of working with a NAND device with page size of 4K+ spare of 218B with ECC_MODE of 8/14bits then the last 10B of the last spare buffer (i.e AXI_BASE+0x11DA-AXI_BASE+0x11E3) are not ECC protected. Moreover, in case of 4bits ECC_MODE then the SPAS should be configured to 0x40 (i.e spare of 128B) and the NFC will use only the first 16B (8B for user-reserved and 8B for ECC) for every section of 512B. That means that the NFC will use only 128B of spare out of the 218B available. In 16 bits ECC_MODE all the bytes of the main and spare buffers are ECC protected. For further information of the ECC algorithm refer to ECC Operation. 00 4bit error correction (default value). 01 8bit error correction. 10 14bit error correction 11 16bit error correction.
5 NUM_ADR_PHASES0	Number Of Address Phases0. The number of address phases to be executed to the NAND Device during an AUTO_ERASE operation 0 1 phase less then NUM_ADR_PHASES1 1 2 phases less then NUM_ADR_PHASES1
4 NUM_CMD_PHASES	Number Of Command Phases. The number of command phases to execute to the NAND Device during AUTO_READ operation(i.e, is read-confirm command is needed or not) 0 1 command phase for reading a page 1 2 command phases for reading a page (read command & read-confirm command)
3 ECC_EN	ECC operation Enable. This bit determines whether ECC operation is executed or bypassed. When ECC is bypassed then, in a program operation, the NFC will drive the relevant data sections and the whole data of the associated spare buffers. When ECC is enabled then, in a program operation, the NFC will override the ECC locations in the spare buffers and drive the calculated ECC bytes instead. The default is ECC enable. 0 ECC operation is bypassed. 1 ECC operation is executed.
2 SYM	Symmetric mode. This bit controls the speed of access as well as RE# waveform during read. 0 Two flash clock cycles per access of RE# or WE#, (asymmetric RE waveform). For further information refer to Symmetric/Asymmetric Mode Operation. 1 One flash clock cycle per access of RE# or WE#, (symmetric RE waveform). (default)
1–0 PS	Page Size. Determines the NAND device page size. 00 1/2KB page 01 2KB page 10 4KB page 11 4KB page

51.9.3 NFC Operation Configuration3 (NFC_CONFIGURATION3)

This register is a configuration register for the NAND Flash device to control the way address is extracted, number of nand devices in the system, endianness, and so on.

.

Address: NFC_CONFIGURATION3 is 63FD_B000h base + 28h offset = 63FD_B028h



NFC_CONFIGURATION3 field descriptions

Field	Description
31–21 Reserved	This read-only field is reserved and always has the value zero. Reserved
20 NO_SDMA	NO_SDMA. When this bit is set, then the system is transferring data to/from the RAM by a different master then the SDMA. Furthermore, it means that dma_wr_req and dma_rd_req signals, are not being used. When SDMA is being used to transfer data to/from the RAM, then it starts each transfer upon assertion of dma_wr_req or dma_rd_req. This activates FMP protection mechanism, and prevents RBA from automatically incrementing. When not using SDMA, then the system must first copy data to the RAM (for program), and only then set the AUTO_PROG bit of the NFC. NFC will automatically increment RBA to point to the next section in the RAM, so if the system wants to program more than 1 page (using NUM_OF_ITERATIONS field) it can do it up to a full use of the RAM. During read, NFC will write the page to the RAM, and again will automatically increment RBA, so if NUM_OF_ITERATIONS is not 4'h0, NFC will automatically start another read sequence and will write it to the next slot in the RAM.

Table continues on the next page...

NFC_CONFIGURATION3 field descriptions (continued)

Field	Description
	NFC will not stop after the RAM was fully used. It is the system responsibility to configure NUM_OF_ITERATIONS field to prevent RAM overflow/underflow. NOTE: Setting this bit disables FMP protection mechanism, so the system must fill the RAM with data before setting AUTO_PROG bit. 0 SDMA is responsible for data transfer to/from NFC RAM. 1 SDMA is not in being used for NFC operations.
19 STATUS_ SAMP_SEL	Status Sample Select. This bit determines when to sample the read status. For further explanation refer to Delay Line Operation 0 Read status is sampled at the next posedge after the read data is sampled. 1 Read status is sampled at the same sampling edge as read data.
18–16 FMP	Fifo Mode Protect. In order to prevent underrun/overrun of the RAM data, the NFC uses a protection mechanism in which the NFC monitors the AXI-RAM addresses and the NAND-RAM addresses and maintains a safety buffer in which the AXI must be ahead of the NAND operation. That mode can be operated only when NUM_OF_ITERATIONS is greater than 0 and when SDMA is used (i.e NO_SDMA = 0). When the FMP is smaller than PS then the system part and the NAND part can access simultaneously to the internal RAM in a way that when the difference between the AXI-RAM address and the NAND-RAM address is smaller than FMP then the NFC will pause transferring data to/from the NAND device till the difference will be larger than the FMP. This is the system responsibility to make sure that only 1 master is accessing the NFC during such operations otherwise other masters might "confuse" this protection mechanism. This protection mechanism is protecting only the main area of the RAM, so any system operations must access the spare area prior to the main area. (During program, the system should first copy the spare area data into the RAM and only then copy the main data. During read, the system should first read the spare area, and only then read the main data) Note: In read operation the FMP can be set to one of the options below, but in write operation it must be set to PS (page size). 000 Disable protection buffer. 001 64B 010 128B (default) 011 256B 100 512B 101 1KB (Not to be used with 1/2KB devices) 110 2KB (Not to be used with 1/2KB devices) 111 4KB (To be used only with 4KB devices)
15 RBB_MODE	Ready-Busy mode. This bit determines how NFC monitors the ready-busy signals of the NAND devices during both automatic and atomic operations. If this bit is set, NFC monitors the ipp_nfc_rbbX signals (one signal for each device), that are connected directly from the NAND devices. If this bit is cleared, NFC will perform status-read operations to determine the NAND device status.

Table continues on the next page...

NFC_CONFIGURATION3 field descriptions (continued)

Field	Description
	When RBB_MODE is set to "0" and either atomic or automatic operation is executed then the user must connect all ipp_nfc_rbbx signals to "1" (ready). When RBB_MODE is set to "1" then non active ipp_nfc_rbbx signals must also be connected to "1". Note: In Atomic operation with RBB_MODE=0 it is the user responsibility to set ATOMIC_ST_POL together with the operation (FADD,FCMD,FDO or FDI) that will enter the device into a busy state. This in order to guarantee that an interrupt will be issued only when the device returned to ready. For further information refer to Atomic Operations Sequence. 0 NFC monitors ready-busy status by doing a status-read command (default) 1 NFC monitors ready-busy status by checking ipp_nfc_rbbX signals
14–12 NUM_OF_ DEVICES	Number Of Devices. Defines how many NAND devices are connected to the NFC. 000 1 NAND device 001 2 NAND devices 010 3 NAND devices 011 4 NAND devices 100 5 NAND devices 101 6 NAND devices 110 7 NAND devices 111 8 NAND devices
11 DMA_MODE	Dma Mode. This bit determines the functionality of the dma_req signals (dma_rd_req and dma_wr_req). If this bit is set, then NFC will output only 1 dma request signal on dma_rd_req which is a logical OR of dma_rd_req & dma_wr_req. The system can determine the request type by reading DMA_STATUS register. If this bit is used, then the system must clear DMA_STATUS field after reading it. 0 NFC outputs 2 dma request signals 1 NFC outputs 1 dma signal which is the logical OR of the 2 dma requests.
10–8 SBB	Status Busy Bit. Indicates which bit in the NAND status register is the Ready/Busy indication. For example: In Samsung's K9K8GU0M bit 6 of the status register is the Ready/Busy indication.
7 Reserved	This field is reserved. Reserved
6–4 SB2R	Status bit to Record. Indicates which bit in the NAND status register is the Pass/Fail indication. For example: In Samsung's K9K8GU0M bit 0 of the status register is the Pass/Fail indication.
3 FW	Flash Width. Determines the NAND Flash IO width (x8/x16). 0 x16 1 x8
2 TOO	Two On One. When this bit is set, then NFC assumes there are 2 x8 NAND devices connected to every CS line (One device on the lower byte of ipp_nfc_read_data_in/ipp_nfc_write_data_out, and one device on the upper byte). When using 2 devices on one CS line, then NFC should be configured as if an x16 device is connected to it in order to use all data lines and the page size (PS) equals the page size of a single deice.

Table continues on the next page...

NFC_CONFIGURATION3 field descriptions (continued)

Field	Description
	If 2 devices of 1/2KB page are connected in this manner, then each automatic page-program will transfer 1KB of data from the NFC's RAM to the NAND devices, so RBA field must be 1KB aligned (i.e set to 3'h0, 3'h2, 3'h4 or 3'h6) and PS should be configured to 00. In atomic operations, NFC transfers only 1/2KB data each time REG_FDI is set, so its the user's responsibility to update RBA field and to set FDI again. If 2 devices of 2KB page are connected in this manner, then each automatic page-program will transfer 4KB of data from the NFC's RAM to the NAND devices, so RBA field must be 4KB aligned (i.e set to 3'h0) and PS should be configured to 01. In atomic operations, NFC transfers only 2KB data each time FDI is set, so its the user's responsibility to update RBA field and to set FDI again. **NOTE:** • TOO mode can be activated only when NUM_OF_ITERATIONS is set to "0" (i.e non interleaved mode). • If 2 devices of 4KB page are connected in this manner, then the user must not use automatic operations since the RAM can not hold 8KB data. Only atomic operations are permitted in this mode. 0 Only 1 device is connected to all CS lines. 1 2 NAND devices are connected to each active CS line.
1–0 ADD_OP	Addressing Options. This field defines how NFC handles the addressing of the pages/blocks during an automatic operations. 00 NFC will use only address_group0 (i.e NAND_ADD0,NAND_ADD8) for all the relevant devices. So in interleaved mode (i.e NUM_OF_ITERATIONS and NUM_OF_DEVICES are greater than 0) then the NFC will act as following: First operation will be sent to CS0 and NFC will drive the address from address group 0 Second operation will be sent to CS1 and NFC will drive the address from address group 0 Third operation will be sent to CS2 and NFC will drive the address from address group 0 and so on until NUM_OF_ITERATIONS is reached. If NUM_OF_ITERATIONS is greater than the number of NAND devices (NUM_OF_DEVICES) connected to the NFC then after accessing the last device the NFC will increment address group 0 (For page operations NFC will use the same block address, and will increment the page address. for block operations(erase), NFC will increment the block address) and return in a loop to access CS0, then CS1 and so on until NUM_OF_ITERATIONS is reached. For example in Erase: if 4 devices are connected to NFC and PPB is 10 (128 pages per block) and we wish to erase the 5th block (block number 4) in each device (total of 4 iterations (i.e NUM_OF_ITERATIONS=3)), then address group 0 supposes to be 48'h200 (7 lsb are used for the page and the rest are used for the block). Another example in Erase: if 4 devices are connected to NFC and PPB is 10 (128 pages per block) and we wish to erase the 5th,6th blocks (block number 4,5) in each device (total of 8 iterations (i.e NUM_OF_ITERATIONS=7)), then address group 0 supposes to be 48'h200 (7 lsb are used for the page and the rest are used for the block) for the first loop and in the second loop (5th, 6th, 7th, 8th iterations) the NFC will increment the address to 48'h280. For example in Program/Read: if 4 devices are connected to NFC and PPB is 10 (128 pages per block) and we wish to program/read to/from the 2nd page (page number 1) of the 5th block (block number 4) in each device (total of 4 iterations (i.e NUM_OF_ITERATIONS=3)), then address group 0 supposes to be 48'h2010000 (16 lsb are used for the column, 7 bits are used for the page and the rest are used for the block). 01 NFC will use only address group 0 (i.e NAND_ADD0,NAND_ADD8) and will only use one NAND device as following:

Table continues on the next page...

NFC_CONFIGURATION3 field descriptions

Field	Description
	The NFC will use the lowest bits of the NAND_ADD0 as the CS for the operations according to NUM_OF_DEVICES. In case of 1 or 2 devices then the lsb (of the page) is used for the CS. In case of 4 devices the 2 lsb (of the page) are used for the CS and in case of 8 devices then the 3 lsb (of the page) are used for CS. Those lowest bits will be removed from the address that will be driven to the NAND device. Moreover for CS calculations, NFC ignores the column address and leaves it as it is. For example: Assume 4 devices are connected to the NFC, erasing block 0 of device #0 requires writing 48'h0 to address group 0 register. Erasing block 0 of device #1 requires writing 48'h1 to NFC_ADD0 register. Assume 2KB page devices: Programming page 0 of device #1 requires writing 48'h10000 to NFC_ADD register (16 lower bits are column address and don't take place in CS-Address extraction) If NUM_OF_ITERATIONS is greater than "0" then the NFC will increment the address group 0 every iteration (For page operations NFC will use the same block address, and will increment the page address. for block operations(erase), NFC will increment the block address) and access the same device (according to the extracted CS) until NUM_OF_ITERATIONS is reached. For example in Erase: if 4 devices are connected to NFC and PPB is 10 (128 pages per block) and we wish to make two erase iterations (i.e NUM_OF_ITERATIONS=1) of 4th.5th blocks (block number 3,4) of device3 (CS3) then address group 0 supposes to be 48'h603 (2 lsb are used for the CS then 7 bits are used for the page and the rest are used for the block). In the 2nd iteration the address will be incremented to 48'h803 (increment block by 1). For example in Program/Read: if 4 devices are connected to NFC and PPB is 10 (128 pages per block) and we wish to make 3 program/read iterations (i.e NUM_OF_ITERATIONS=2) to/from 2nd, 3rd,4th page (page number 1,2,3) of the 2nd block (block number 1) of device3 (CS3) then address group 0 supposes to be 48'h2070000 (16 lsb are used for the column, 2 lsb are used for the CS, 7 bits are used for the page and the rest are used for the block). In the 2nd iteration the address will be incremented to 48'h20B0000 (increment page by 1) and In the 3rd iteration the address will be incremented to 48'h20F0000 (increment page by 1). Note: - This option can be used only when using 1,2,4 or 8 NAND device. - Only single device will be accessed (No interleaving) even if both NUM_OF_ITERATIONS and NUM_OF_DEVICES are greater than "0"
	10 NFC will use all the address groups. Each device with the associated address group (device0 with address group 0, device1 with address group 1 and so on). So in interleaved mode (i.e NUM_OF_ITERATIONS and NUM_OF_DEVICES are greater than 0) then the NFC will act as following: First operation will be sent to CS0 and NFC will drive the address from address group 0. Second operation will be sent to CS1 and NFC will drive the address from address group 1. Third operation will be sent to CS2 and NFC will drive the address from NAND_ADD3, and so on. If NUM_OF_ITERATIONS is greater than the number of nand devices (NUM_OF_DEVICES) connected to the NFC then after accessing the last device the NFC will increment the associated NAND_ADDx (For page operations NFC will use the same block address, and will increment the page address. for block operations(erase), NFC will increment the block address) and return in a loop to access CS0, then CS1 and so on until NUM_OF_ITERATIONS is reached.
	11 NFC will use all the address groups and also will use the lowest bits of the NAND_ADDx as the CS for the operations. So in interleaved mode (i.e NUM_OF_ITERATIONS and NUM_OF_DEVICES are greater than 0) then the NFC will act as following: First operation will be sent to CSX based on address group 0 (i.e NAND_ADD0, NAND_ADD8). Second operation will be sent to CSY based on address group 1 (i.e NAND_ADD1, NAND_ADD8).

NFC_CONFIGURATION3 field descriptions (continued)

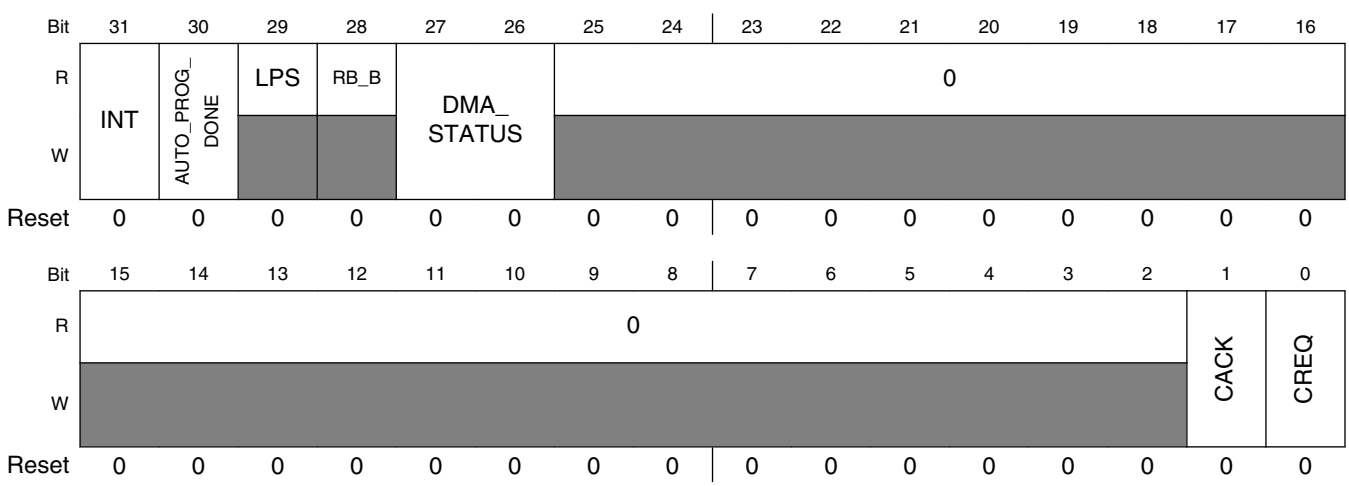
Field	Description
	Third operation will be sent to CSZ based on address group 2 (i.e NAND_ADD2, NAND_ADD9), and so on. In case of 1 or 2 devices then the lsb (of the page) is used for the CS. In case of 4 devices the 2 lsb (of the page) are used for the CS and in case of 8 devices then the 3 lsb (of the page) are used for CS. Those lowest bits will be removed from the address that will be driven to the NAND device. Moreover for CS calculations, NFC ignores the column address and leaves it as it is. For example in Erase: if 4 devices are connected to NFC and PPB is 10 (128 pages per block) and we wish to make 3 erase iterations (i.e NUM_OF_ITERATIONS=2) the first iteration to the 4th block (block number 3) of device3 (CS3), the second iteration to 2nd block (block number 1) of device1(CS1) and the 3rd to the 1st block (block number 0) of device0 (CS0). Then the address for the 1st iteration will be driven from address group 0 that supposes to be 48'h603 (2 lsb will be used for the CS then 7 bits will be used for the page and the rest are used for the block (which is 3)). The address for the second iteration will be driven from address group 1 that supposes to be 48'h201 and the address for the 3rd iteration will be driven from address group 2 that supposes to be 48'h0 Note:This option can be used only when using 1,2,4 or 8 NAND device. In this mode, every address group involved must specify a different CS

51.9.4 NFC IP Control (NFC_IPC)

This register holds the IP write handshake registers as well as the interrupt register.

.

Address: NFC_IPC is 63FD_B000h base + 2Ch offset = 63FD_B02Ch



NFC_IPC field descriptions

Field	Description
31 INT	Interrupt.The output port ipi_int_nfc is a logic AND between this bit and INT_MSK bit. This bit will rise after

Table continues on the next page...

NFC_IPC field descriptions (continued)

Field	Description
	NFC finishes an atomic operation (setting any bit in LAUNCH_NFC[5:0]) or in automatic operation (AUTO_READ/AUTO_PROG/AUTO_ERASE/AUTO_COPY_BACK0/1) it will issue the interrupt only after NUM_OF_ITERATIONS is reached. When interrupt is being set after an automatic operation it means that all status registers from all relevant NAND devices have been read and the status is stored in STATUS_SUM register. This bit is not self cleared, so it must be cleared by the user (by writing "0"). 0 NFC didn't finish its operation. 1 NFC finished its operation and is ready to accept next operation.
30 AUTO_PROG_DONE	Automatic Program Done. Indicates that SDMA finished transferring all NUM_OF_ITERATIONS pages to the NFC. This allows the software to prepare SDMA with the data of next group of pages to be transferred to the NAND devices. This bit is not self cleared, so it must be cleared by the user (by writing "0"). 0 SDMA didn't finish transferring NUM_OF_ITERATIONS pages to NFC. 1 SDMA finished transferring NUM_OF_ITERATIONS pages to NFC.
29 LPS	Low Power Status. This read-only bit reflects the low power mode of the nfc. 0 nfc is not in a low power mode 1 nfc is in a low power mode
28 RB_B	RB_B Status. This read-only bit reflects the RB_B signal of the NAND device. If more than 1 RB_B line are connected to the same port of the RB_Bx of the NFC, then this bit reflects a logical AND of all RB_B signals. 0 NAND device is busy. 1 NAND device is idle.
27–26 DMA_STATUS	Dma Status. This field indicates which dma request signal is asserted. This field is not self cleared, so it must be cleared by the user. 00 All dma request signals are deasserted. 01 dma_wr_req was asserted 10 dma_rd_req was asserted 11 Both dma_rd_req & dma_wr_req were asserted.
25–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 CACK	IP configuration acknowledge. Whenever this bit is set, IP is permitted to configure NFC's IP registers. 0 Configuration of NFC's registers is forbidden. 1 Configuration of NFC's registers is permitted.
0 CREQ	IP request to configure NFC. Whenever IP wants to configure NFC it must set this bit to one, and poll on CACK until it is high. Only then configuration is permitted. After configuration is done, the user must deassert this bit. This feature prevents configuring the NFC during an operation and causing an unexpected behavior. 0 No request to configure NFC. 1 A request to configure NFC is valid.

51.9.5 AXI error address (NFC_AXI_ERR_ADD)

Address of the first erroneous AXI access.

Address: NFC_AXI_ERR_ADD is 63FD_B000h base + 30h offset = 63FD_B030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

NFC_AXI_ERR_ADD field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12–0 AXI_ERR_ADD	AXI Error Address. Whenever NFC returns an error response on the AXI interface, it will sample the address in which the error occurred, and store it in this register for debug purposes. NOTE: Only the first error-address will be stored. If second AXI error response will occur, the second error-address will be lost. Reading from this register, will unlock this register, so, second error-address will be sampled.

51.9.6 Delay line parameters (NFC_DELAY_LINE)

The NFC includes 4 delay line units where each unit can adjust the timepoint in which the NFC latches the read data by 1/2 fast clock cycle (aclk) and therefore the 4 delay line units can adjust that timepoint by up to 2 fast clock cycles (aclk)

NFC_DELAY_LINE register represents a single delay line unit. By default the NFC latches the data after a fixed delay of 1 flash_clk cycle + 1 fast clock cycle (aclk).

Writing to NFC_DELAY_LINE register will adjust the fast clock cycle delay.

For further information refer to Delay Line Operation

Address: NFC_DELAY_LINE is 63FD_B000h base + 34h offset = 63FD_B034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																NFC_OFF_DEL								NFC_ABS_DEL							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

NFC_DELAY_LINE field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–8 NFC_OFF_DEL	NFC Delay-line Offset delay. The field represents positive and negative numbers using twos compliment representation. This allows positive and negative offsets from the quarter cycle measured value. For example, to add 3 delay units to the measured delay, this field should be 00000011, to subtract 3 delay units, it will be set to 11111101.
7–0 NFC_ABS_DEL	NFC Delay-line Absolute delay. This field determines the specific delay line absolute delay in fractions of fast cycle terms. The fraction is process and frequency independent. The delay of single delay line would be (NFC_ABS_DEL / 512) * fast_clock. So for the default value of 128 we get a quarter cycle delay.

51.10 Functional Description

This section provides the functional description for the NAND Flash Controller.

51.10.1 Reset

There are several options to reset the NFC:

axi_reset - asserting axi_reset_b will reset all AXI related functionality, such as AXI state machines and axi registers. axi_reset_b resets block registers as well.

cold reset - asserting of ipp_reset_b will reset all the functionality that is responsible to communicate with the NAND include the ECC engine.

warm_reset - this signal is checked during assertion of axi_reset_b, and if it is high, then all configuration registers will not be reset. This will enable a quick return-to-action reset operation.

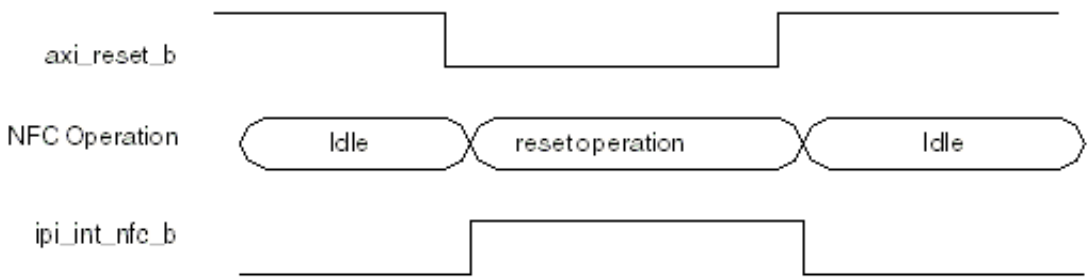

Figure 51-25. Interrupt Functionality During Reset

51.10.2 NAND Flash I/F Control

The NAND Flash I/F Control generates all the following control signals:

CE# (Flash Chip Enable), $\overline{\text{RE\#}}$ (Read Enable for read operations), $\overline{\text{WE\#}}$ (Flash Write Enable), CLE# (Flash Command Latch Enable), ALE (Flash Address Latch Enable). It monitors the RB_B (Flash Ready/Busy indication) or generates read status commands to check if the NAND Flash is in the middle of operation.

Ratio of ipp_flash_clk and aclk should be an integer value and a minimum of 2 (aclk is at least double the frequency of ipp_flash_clk) as long as the clocks are synchronous.

The following will specify the operation of the NFC during program or read:

1/2KB page:

There is a need to configure the address and command sequence before every page of 512B.

Every page is transferred to 1/2KB in the nfc internal RAM buffer so it is important to change RBA register to choose which 1/2KB section of the RAM will be written or read from.

2KB page:

The commands and address cycles occur at the beginning of the program or read sequence. After the command and address sequence, there are four sections of data program/read of 512B each. Every section of 1/2KB is transferred to/from a different 1/2KB in the nfc internal RAM buffer. After command & address cycles are done, upon kicking off a 2K page (writing 16'h4 or 16'h8 to LAUNCH_NFC register), the NFC will transfer the 2K page from/to its internal RAM to/from the NAND device.

Every page is written to 2KB in the nfc internal RAM buffer so it is important to change RBA register to choose which 2KB section of the RAM will be written or read from. Legal values for RBA field are RBA=0 & RBA=4.

4KB page:

The commands and address cycles occur at the beginning of the program or read sequence. After the command and address sequence, there are eight sections of data program/read of 512B each. Every one of the 1/2KB is transferred to/from different 1/2KB in the nfc internal RAM buffer. After command & address cycles are done, upon kicking off a 4KB (writing 16'h4 or 16'h8 to LAUNCH_NFC register), the NFC will transfer the 4KB page from/to its internal RAM from/to the NAND device.

In 4KB page, it is only legal to write 3'b000 to RBA register.

ECC is always calculated for data section of 1/2KB even if the page size is 2KB/4KB.

Figure 51-26, Figure 51-27, and Figure 51-28 show the NAND Flash read, program, and erase timing diagrams.

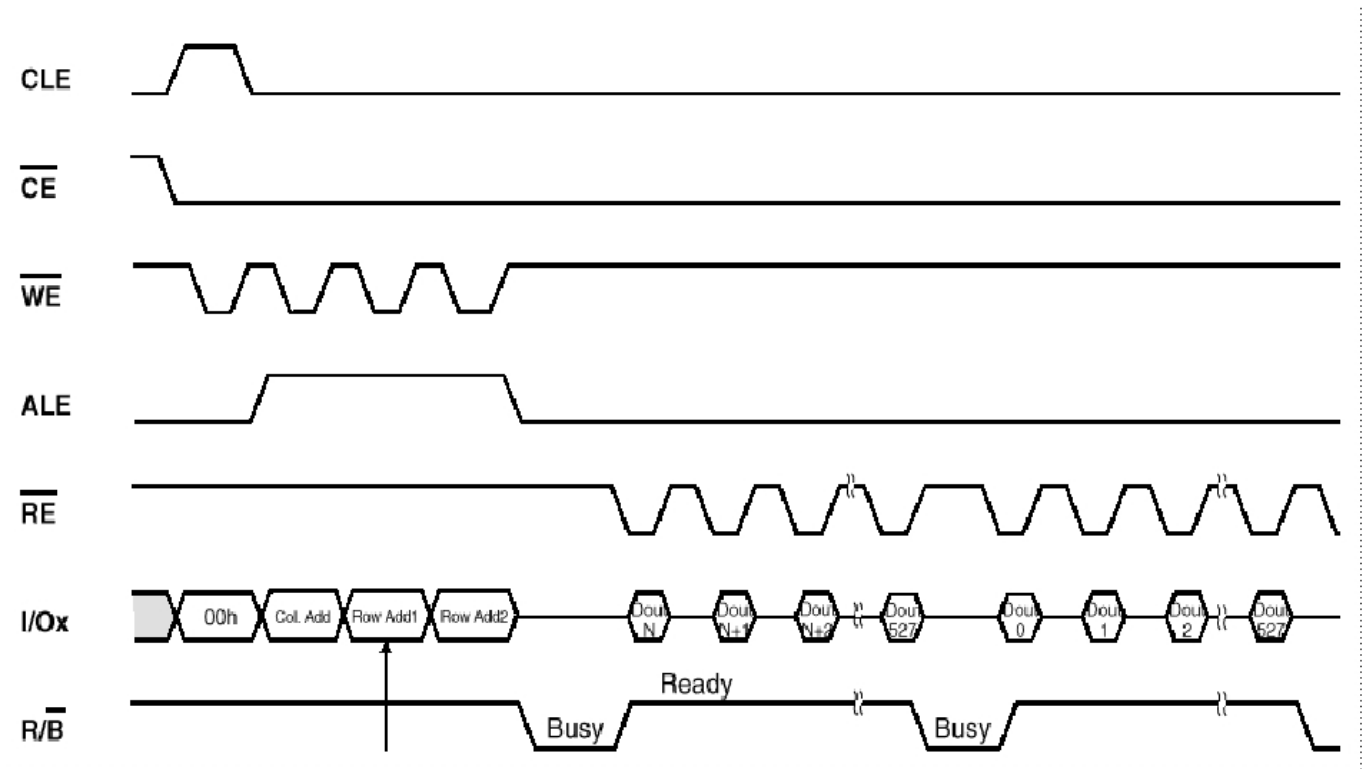

Figure 51-26. Read Operation

ALE can be asserted & deasserted separately for each address phase.

Number of ALE phases is determined by the user.

PAGE PROGRAM OPERATION

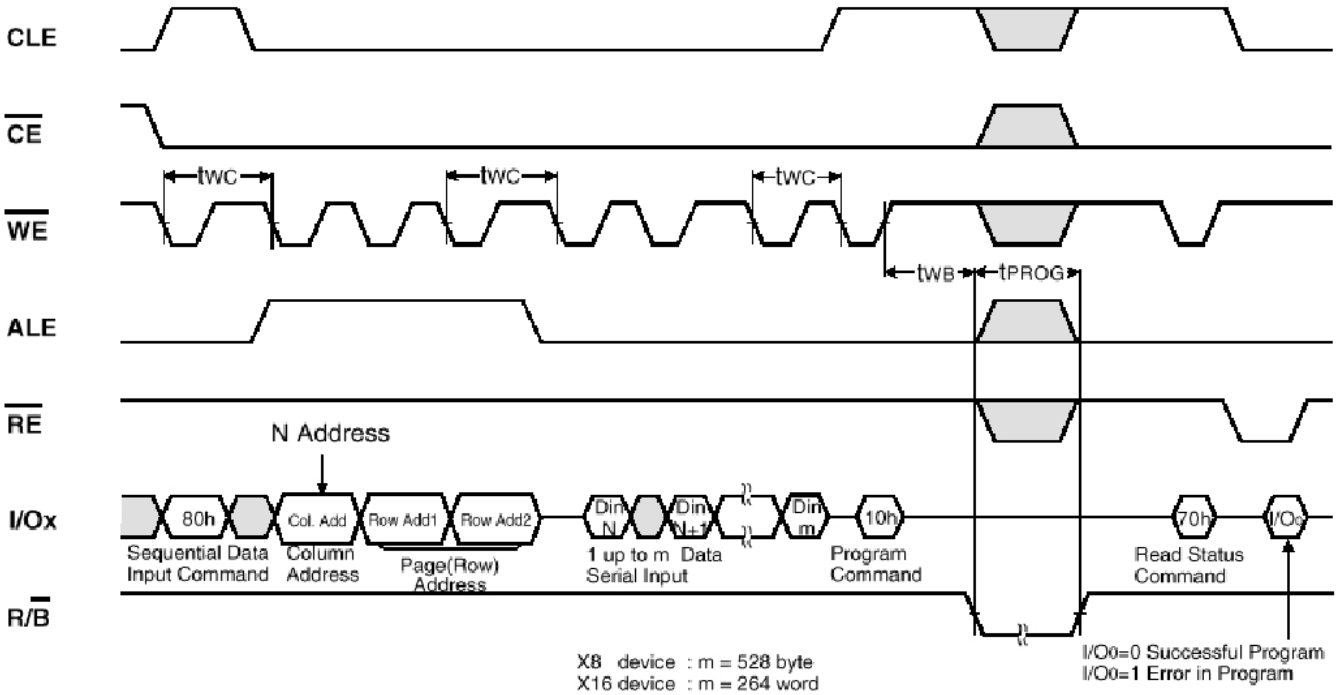

Figure 51-27. Program Operation

BLOCK ERASE OPERATION (ERASE ONE BLOCK)

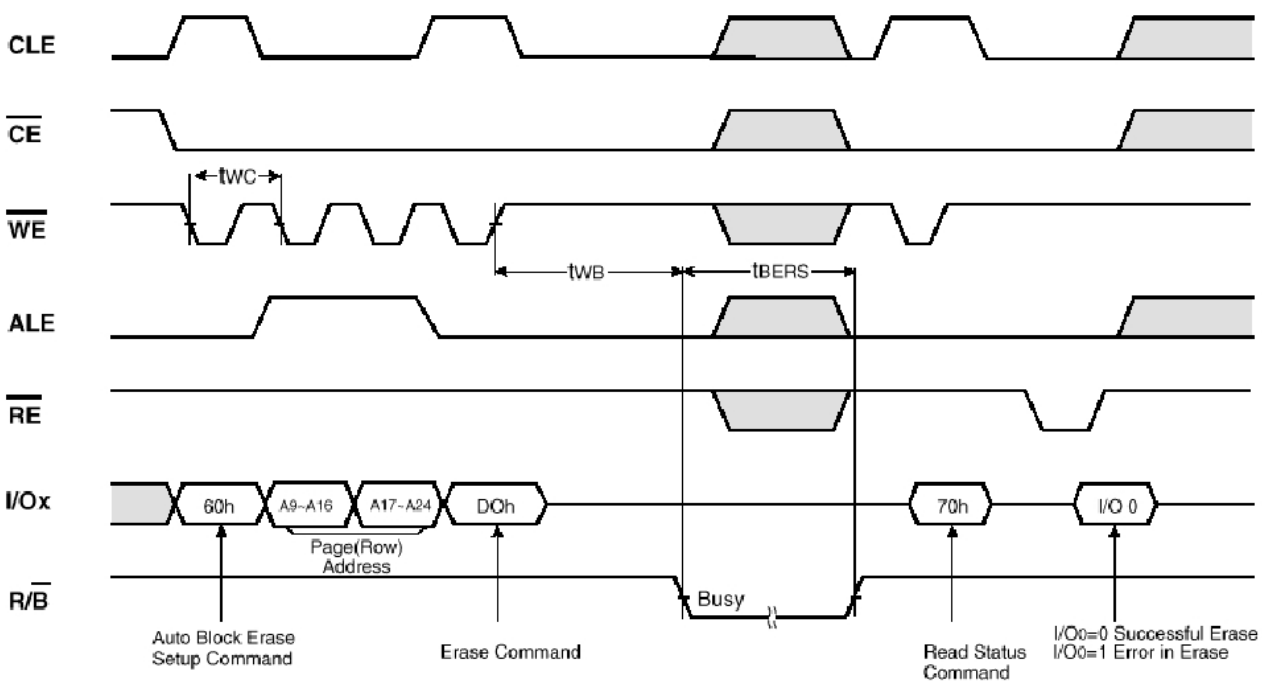

Figure 51-28. Erase Operation

51.10.3 DMA Request Operation

In case NUM_OF_ITERATIONS is greater than "0" then NO_SDMA should be set to "0". In that case the NFC will communicate with the system DMA using two signals as following:

- dma_rd_request-triggers after NFC finished reading a page.
- dma_wr_request-triggers either on write to AUTO_PROG bit, or after NFC finished transferring data from NFC's RAM to the NAND device during an automatic program operation, but only if there are additional pages to program based on NUM_OF_ITERATIONS field.

The configuration bit DMA_MODE selects between a mode of 2 independent dma-request signals, and a combined signal which asserts both on dma_rd_request triggering and on dma_wr_request triggering. This combined dma-request signal is functional on dma_rd_req pin, whereas dma_wr_req pin will be unused in such a mode.

51.10.4 Internal RAM

The internal RAM Buffer is a 4608 Byte single Port RAM buffer. This memory has 1152 words of 32-bits each, where1024 words are used for the main are buffers (data sections) and the remaining 128 words are allotted to spare area buffers, which are used for ECC (Error Correction) and other user-reserved.

Although the RAM is a single port RAM, the NFC holds a mechanism that allows accessing the RAM from two sources at the same time. For example: When NFC reads data from the RAM in order to program it into the NAND device, the host can write to another location in the RAM and prepare the data for the second page program. This mechanism can be achieved since the Flash side is relatively slow, so, there are idle cycles in which the NFC can service the host. Example of a good use for this feature is that the host instead of writing a full page to the NFC, writes only part of the page, and then launches the program operation. Now the host can continue writing the page to the RAM while NFC is reading it out and sends it to the NAND device. Such a use can almost hide the page transfer time from the host to the NFC.

NOTE: There is a limitation for using the dual-port ability of the RAM. The User must not perform AXI read transactions during NFC-program operation, and the user must not perform AXI write transactions during NFC-read operation (If NFC is reading from the RAM - during program, then the user must not read from the RAM also, and while NFC is writing to the RAM, the user must not write to the RAM either.)

When FMP (Fifo Mode Protect field in NFC_CONFIGURATION3 register) is set, the NFC assumes that the host is acting as the example above. NFC will monitor the RAM and makes sure that there is always enough data in the RAM for the NFC to write. i.e if the host is becoming slow when writing the page into the RAM, then the NFC will pause the program operation and waits until the host continues to write the page. Same monitoring is applied in read operations, when the host reads only a part of a read page, and NFC starts reading another page. The NFC may overwrite the previous page before the host can read it - so the NFC monitors the progress of the host and pauses the read operation before an overwrite can occur.

To ensure that this protection mechanism would work properly, the system must make sure that only 1 master is accessing the NFC during the entire operation (for example: SDMA, ARM, etc.).

The NFC logically divides the RAM into 8 sections. Each section contains 512B of main data and 64B of spare area. When reading (or programming) from the NAND device, the NFC writes the main data from the NAND device into the main area, and the spare data from the device is written into the spare section. If the NAND device spare data is less than 64B per 512B main data, then the NFC's spare section in the internal RAM will not be fully used. For example in NAND device that has 2KB main data and 64B spare data, then this device has 16B spare data for every 512B main data, then the spare data in the RAM will be located as following: first 16B of spare data in spare buffer 0,next 16B in spare buffer 1, and so on.

When using a NAND device in which the spare area size is not fully divided by 512B sections, then the remainder will be located at the last spare section. For example in a NAND device with 4KB main data + 218B spare data, then the division will be 27.25B of spare for each 512B of main data. Then the NFC rounds this number down to the nearest even number, which 26B, and that would be the number of Bytes located in each spare buffer. The remaining Bytes will be added to the last section, meaning that the last spare section will contain 26+10=36B.

AXI bus interface

The AXI bus interface is an adapter between ABMA AXI bus and the internal bus.

On the AXI bus side it supports a 16-bit and 32-bit transactions, burst and non burst operations. On the internal bus side it supports 32-bit bus width.

AXI interface supports only INCR accesses (no WRAP nor FIXED), with length of 1-16 data transfers (defined by arlen/awlen of 4 bit).

AXI domain is divided to 2 regions: internal RAM & AXI registers. Any access to AXI registers, must be 32bit wide, with length of 1 data transfer (single access).

In case od reading the reserved area of the AXI address space then the response in unpredictable.

51.10.4.1 LPMD/ DVFS

DVFS is supported using a handshake with the system. The system asserts lpmd signal to request a power down. NFC will respond with assertion of lpack, as soon as it becomes idle from its current operation. lpack assertion signals to the HOST that the NFC is ready for power down.

lpack will be asserted if there is no active axi transaction and there is no active flash accesses.

The NFC holds a register in block domain (LPS) that indicates the status of the lpack signal.

In case the lpmd is asserted during a read operation while NUM_OF_ITERATION is greater than 0 then the NFC will assert the lpack before the assertion of dma_rd_req (DMA read request), Therefore the dma_rd_req will be asserted after returning from DVFS mode.

51.10.4.2 Burst Access Support

Not all AXI burst transactions are supported. Table 51-32 lists NFC supported access burst types.

Table 51-32. NAND Flash Burst Access Support

HBURST	BURST TYPE	SUPPORTED	Description
00	**FIXED**	**No**	**Fixed address burst**
01	**INCR**	**Yes**	**Incrementing-address burst**
10	WRAP	No	Incrementing-address burst that wraps at wrap boundary
11	Reserved	Yes	-

NOTE

NFC supports bursts of 16/32-bit words only. Bursts of byte words (8-bits) are not supported.

51.10.5 Block interface

The block interface is an adapter between block protocol and internal control registers.

NFC's registers are divided between AXI domain & block domain to enable better security and data protection.

Write sequence to block must follow a write handshake protocol:

Whenever the host wants to write to one of the block registers, he must first assert CREQ field. Whenever the NFC will be ready to accept the write, he will assert CACK. Now the write sequence can go on. Upon completion of all write sequences, the host must clear the CREQ field.

The purpose of the handshake mechanism, is to prevent a situation where control registers are being changed during an operation and by that causing an unexpected behavior.

51.10.6 I/O Pins Sharing

The NAND Flash Controller has logic that allows it to share I/O pins with pins of another memory controller.

The arbitration between the NFC and the other memory has hard priority favouring the other memory. Since NFC's accesses are long, when the other memory requests the bus, the NFC will always halt its operation as soon as possible based on its internal state and the other memory will be granted. The only operations that will not halt in the middle are relatively short ones, such as command phase, address phase or spare area read. The host must take into account, that spare area read is the longest operation of the above and can take up to 32 Flash-clock cycles (for 8bit memory in non-symmetric mode).

This hard decision arbitration contains a dead-lock counter in favour of the NFC. The counter counts fast clocks cycles (aclk) in which the NFC requests the bus, but not being granted. If the counter reaches a certain value, it will cause the arbitration to favour the NFC over the other memory. Meaning, that if the other memory will deassert its request it won't get it again until the NFC will be granted at least once. After that grant, arbitration returns to normal mode, meaning, that if the other memory requests the bus, the NFC will pause as soon as possible based on the previous description.

This priority based arbitration mechanism must be taken into account when sharing the I/O bus with another memory.

51.11 NFC Operation

This section describes the operation of the NFC. It is divided to the following sub-sections:

- Automatic operations (Automatic Operations).
- Atomic operations (Atomic Operations).
- Atomic operations sequence (Atomic Operations Sequence).
- ECC operation (ECC Operation).
- Symmetric/Asymmetric operation (Symmetric/Asymmetric Mode Operation).
- Delay line operation(Delay Line Operation).

51.11.1 Automatic Operations

The NFC offers the user a simplification in accessing the NAND device, by automatically performing common NAND sequences. All automatic operations require some kind of preparations from the host, before the automatic operation is performed. NFC informs the host about the completion of the operation.

51.11.1.1 Automatic program operation

Setting AUTO_PROG bit in LAUNCH_NFC register, results in NFC executing a full page program including a status read at the end (The status-read operation will be executed only in case that RBB_MODE=0). NFC will repeat this operation several times as defined in NUM_OF_ITERATIONS field in NFC_CONFIGURATION1 register.

Upon setting AUTO_PROG bit, NFC will immediately set dma_wr_req (in case SDMA is used and NUM_OF_ITERATION is greater than "0"). After setting dma_wr_req the host should start filling the internal RAM while the NFC will start executing the program operation by sending a command defined in NAND_CMD0 register, followed by sending the address from the relevant address group (The address will be divided into several address phases as defined in NUM_ADR_PHASES1 register). After the address phases finished then NFC will start copying the data from the NFC's RAM to the NAND device (If the RAM contains enough data as defined by FMP), and then NFC will issue a program-confirm command defined in NAND_CMD1 register. NFC will monitor the Ready/Busy status of the NAND device, and will read the status of the device as soon as the device returns to ready state.

In case SDMA is not used and NUM_OF_ITERATIONS is set to "0" then it is the user responsibility to fill the RAM with the page data before setting the AUTO_PROG bit.

When NUM_OF_ITERATIONS is greater than 0 and NUM_OF_DEVICES is greater than 0 (meaning interleaved mode. More than 1 page should be programmed to several devices), then NFC will operate a little different:

- NFC will set the next dma_wr_req after the data-transfer phase finished (meaning the RAM can be overwritten)
- NFC will start issuing the next page before the previous device returns to idle (Thus hiding the busy time of the device).

The address that will be sent depends on ADD_OP.

NFC will not set dma_wr_req after the data transfer of the last page (As defined in NUM_OF_ITERATIONS).

Automatic program operation generates 2 types of interrupts:

- INT will be set when all NAND devices that were involved in the operation returned to idle (And their status is recorded inside the NFC).
- AUTO_PROG_DONE will be set when NFC detects that all pages have been copied to its internal RAM (Meaning that the SDMA can be configured with parameters for next set of pages to be programmed).

51.11.1.2 Automatic Read Operation

Setting AUTO_READ bit in LAUNCH_NFC register, results in NFC executing a full page read including a status read at the end (In both RBB_MODE=0 or RBB_MODE=1). NFC will repeat this operation several times as defined in NUM_OF_ITERATIONS field in NFC_CONFIGURATION1 register.

Upon setting AUTO_READ bit, NFC will start executing a page read operation from the NAND device: read-command followed by address phases and a read-confirm-command if needed. Then NFC will monitor the read/busy status of the device, and will start reading the data as soon as the device returns to ready state. NFC will read the status of the operation afterwords.

NFC will set dma_rd_req when it finishes reading a full page from the NAND device and store the data in the internal RAM (After fixing ECC errors if there are any).

If NUM_OF_ITERATIONS is greater than 0, then NFC pauses after reading a page, and waits for the system to read out the data from NFC's RAM. NFC will continue to read the next page as soon as the system reads enough data as defined in FMP register.

INT will be set after NFC has read the status register of all NAND devices that were involved in the operation.

51.11.1.3 Automatic erase operation

Setting AUTO_ERASE bit in LAUNCH_NFC register, results in NFC executing a full block erase including a status read at the end.(The status-read operation will be executed only in case that RBB_MODE=0) NFC will repeat this operation several times as defined in NUM_OF_ITERATIONS field in NFC_CONFIGURATION1 register.

Upon setting AUTO_ERASE bit, NFC will start executing a block erase operation from the NAND device:

Erase-command, followed by erase-address, followed by erase-confirm-command. Then NFC will monitor the read/busy status of the device, and will read the status of the device as soon as the device returns to ready.

INT will be set when all NAND devices that were involved in the operation returned to idle (And their status is recorded inside the NFC).

51.11.1.4 AutoMatic Copy-back Operation

Setting AUTO_COPY_BACK0 bit in LAUNCH_NFC register, results in NFC executing a full copy-back operation including a status read at the end (The status-read operation will be executed only in case that RBB_MODE=0).

NFC will send a command (defined in NAND_CMD0 register), then address phases (defined in the relevant address group), then another command phase (defined in NAND_CMD1 register), then NFC will monitor the ready/busy status of the NAND device, then another command phase (defined in NAND_CMD2 register), then address phases (defined in relevant address group), then last command phase (defined in NAND_CMD3 register), then again NFC will monitor the ready/busy status of the NAND device. Finally NFC will check the status of the operation.

INT will be set when the status of the NAND device is ready.

Setting AUTO_COPY_BACK1 will result in NFC executing AUTO_COPY_BACK0 operation to all NAND devices connected to it (with the same addresses to all the devices).

NFC will perform AUTO_COPY_BACK1 in an interleaved mode (meaning, that if a NAND device is getting busy, NFC will continue to the next device, and will get back to the first device as soon as it becomes ready). So, if the system wants to perform a copy-back operation with the same addresses to all the NAND devices, it is much more efficient to use AUTO_COPY_BACK1 then using AUTO_COPY_BACK0 several times.

51.11.1.5 Automatic Status-read Operation

Setting AUTO_STAT bit in LAUNCH_NFC register, results in NFC executing a full status read operation to the NAND device.

NFC will send status read command (defined in ST_CMD in NFC_CONFIGURATION2 register), then it will read the status of the device and store it in NF_STATUS field in NFC_CONFIGURATION1 register.

51.11.3.3 Atomic Erase Sequence Operation

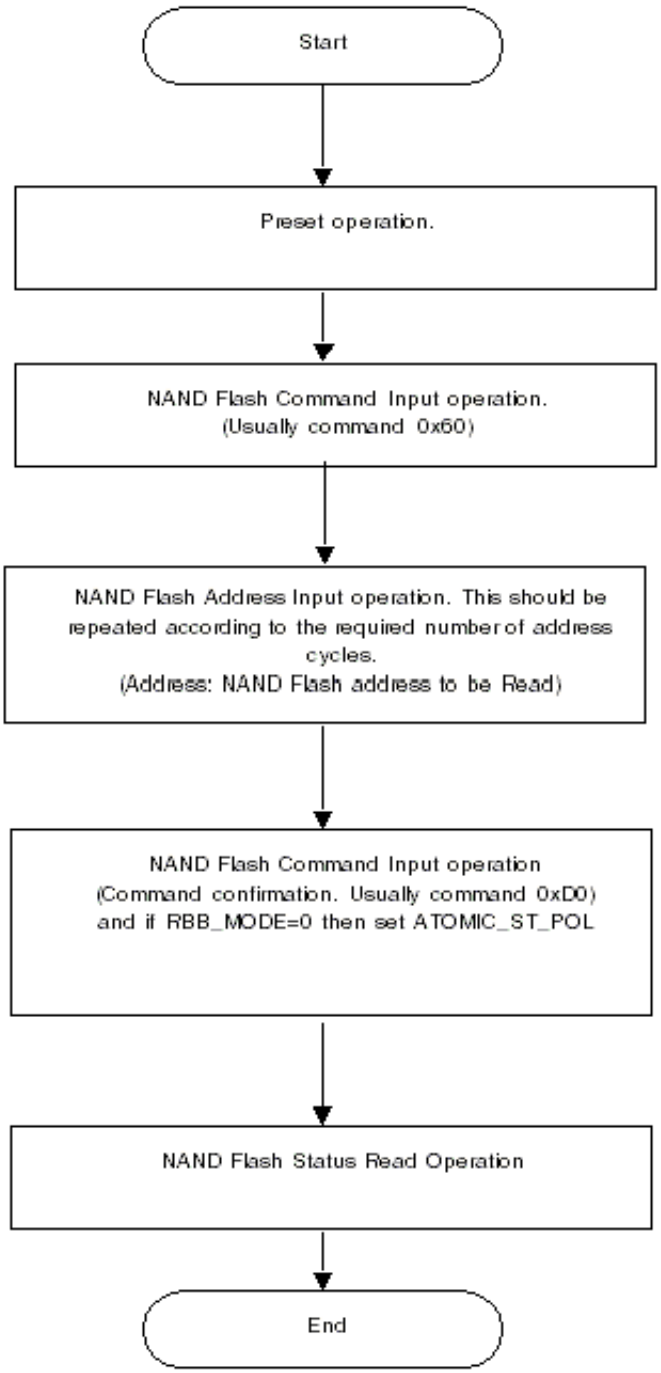

Figure 51-38. Flow Chart of Erase NAND Flash Operation

51.11.4 ECC Operation

51.11.4.1 ECC Normal Operation

The BCH ECC engine is responsible for detection and correction of up to 4/8/14/16 bits in each 528/538/548 byte section.

NFC divides the page into data sections of 1/2KB + spare area buffer. The ECC algorithm protects each data section and the associated spare area buffer.

- 4bits correction mode: In this mode, NFC protects 528B(512B of data section + 16B of spare area buffer). If the data section + spare area buffer are greater than 528B than these Bytes will not be protected by the ECC.
- 8/14bits correction mode: In this mode, NFC protects 538B(512B of data section + 26B of spare area buffer). If the section is greater than 538B than these Bytes will not be protected by the ECC.
- 16bits correction mode: In this mode the ECC will protect the whole data sections and the whole spare area buffers. If working with a page of 4K+218B, then the NFC will protect the first seven sections of 538B(512B of data section and 26B of spare area buffer) and at the last section it will protect 548B(512B of data section and 36B of spare area buffer).

When the NFC accesses the NAND Flash device for Program operation, it generates ECC code of 8/14/24/26 bytes. These bytes will override the corresponding spare area data that is written in the internal RAM refer to Table 51-5. These 8/14/24/26 bytes of ECC code are calculated based on the generator polynomial g(x) = x^13 + x^4 + x^3 + x + 1. When the NFC accesses the NAND Flash device for a Read operation, it performs a BCH decoding algorithm, and indicates how many bit errors were detected and corrected.

After a Read operation, the host can determine how many bit errors were found per 528/538/548 bytes by reading the status register (ECC_STATUS_RESULT). If the indication is uncorrectable error then it means that the number of bit errors that were detected (N) exceed the number of bit errors that can be corrected (T) according to ECC_MODE. Due to an algorithm weakness there might be a decoding error with a very low probability that the NFC will indicate that T number of bits error were detected and corrected instead of uncorrectable errors.

Upon program, the BCH ECC bytes are written directly to the NAND Flash device (and are not written back to the internal RAM). This means that if a user wants to read the ECC that was generated, he must read it from the NAND Flash device spare area.

There will be no error correction when performing a spare-only read from the nand flash device.

ECC is always calculated for 1/2KB+spare and not for 2KB/4KB + spare even if we work with a 2KB/4kB page memory. In case of 2KB/4KB page memory ECC will be calculated 4/8 times (once for every 1/2KB data section + associated spare).

That means that the 2k/4k page in the nandflash should be fill with 1/2k bytes data followed by 16/26 bytes of spare data 4/8 times:

512 main Byte + 16/26 spare byte + 512 main Byte + 16/26 spare byte + 512 main Byte + 16/26 spare byte + 512 main Byte + 16/26 spare byte...

The ECC operation can be bypassed using ECC_EN bit in NFC_CONFIGURATION2 register.

Program sequence:

1. Write a page of data to the internal RAM (main + spare area).
2. Set RBA to point to the section in which the data is in.
3. Configure the command and address sequence for program operation.
4. Program one page (main + spare) by writing "1" to FDI bit in LAUNCH_NFC register (BCH ECC code will override the corresponding spare area bytes)

Read sequence:

1. Set RBA to point to the section in the internal RAM Configure the command and address sequence for read operation.
2. read a page (main + spare) by writing "1" to FDO field in LAUNCH_NFC register (BCH ECC algorithm will automatically fix errors if there are any)

Table 51-35 shows the ECC code assignment of the NAND Flash spare area. This ECC code is updated by NFC automatically.

51.11.4.2 ECC Bypass Operation

In ECC bypass operation, the spare area is copied from NFC internal Ram Buffer to the nandflash device during program operation. During read operation the ECC detection/ correction mechanism will not work and the status register(ECC_STATUS_RESULT) will not be updated as well.

Table 51-35. ECC Code/Result Readability

operation	Read operation		Program operation		
	ECC Code from spare area buffer	ECC status register	ECC Code from spare area buffer	ECC status register	ECC content in NAND Flash device

Table continues on the next page...

Table 51-35. ECC Code/Result Readability (continued)

ECC operation	ECC code copied from nandflash device spare area	Valid	Invalid (old data [1]	-	ECC code generated by the NFC
ECC bypass	ECC code copied from nandflash device spare area	Valid	Invalid (old data)	-	Data from spare area of NFC internal Ram

1. Old data: ECC code is not updated to spare buffer, so ECC code placement of spare buffer remains old data.

51.11.4.3 How to Operate the ECC

In order to generate ECC and carry out the correction by the NFC,

- Program with ECC operation / Read with ECC operation

In order to generate ECC by the NFC and carry out the correction by the host,

- Program with ECC operation / Read without ECC operation

51.11.5 Symmetric/Asymmetric Mode Operation

In the default state of the NFC 1 flash clock cycle is used for toggling RE#/WE#.

In order not to work with lower frequency of flash clock, the SYM bit in NFC_CONFIGURATION2 register should be set to "0" and that will change the WE# and RE# period during read or program to be 2 flash clock cycles instead of 1.

Setting SYM bit also changes the duty cycle of RE# to be ~50% during read operation.

Latching the data during a read operation is done 1 flash_clk cycle + 1 aclk cycle after negedge of RE#.

The user can adjust the capturing timepoint by setting values to NFC_DEL_LINE register.

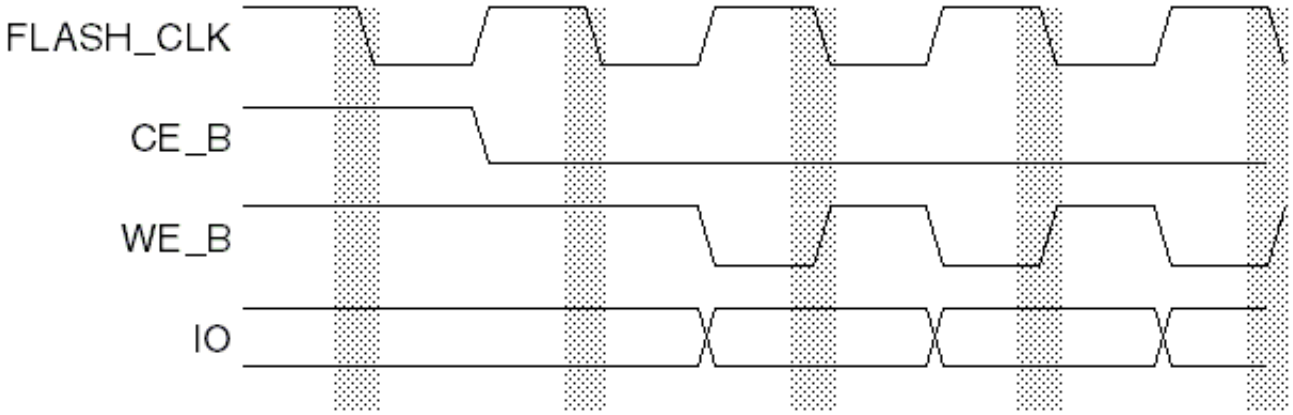

Figure 51-39. One Flash Clock Cycle Per Data Input (SYM bit =1)

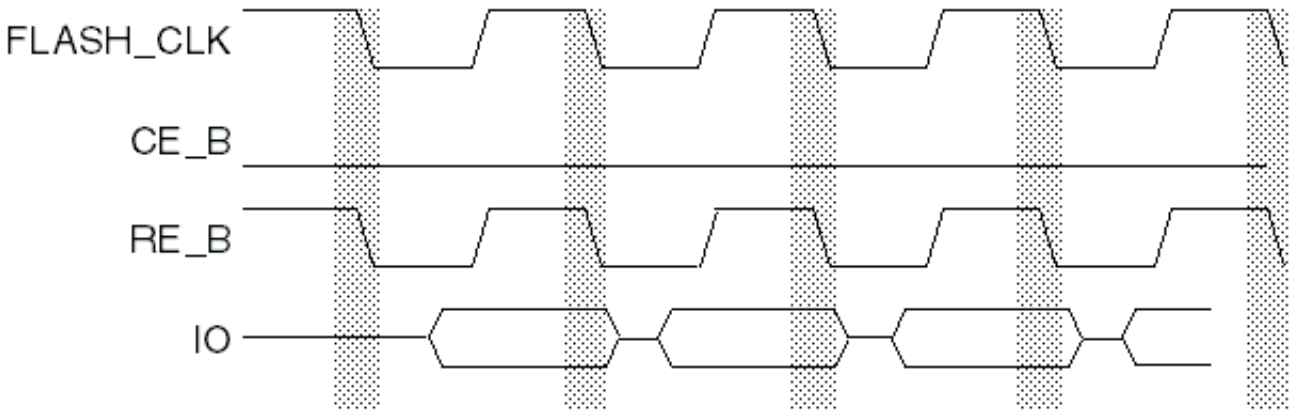

Figure 51-40. One Flash Clock Cycle Per Data Output (SYM bit =1)

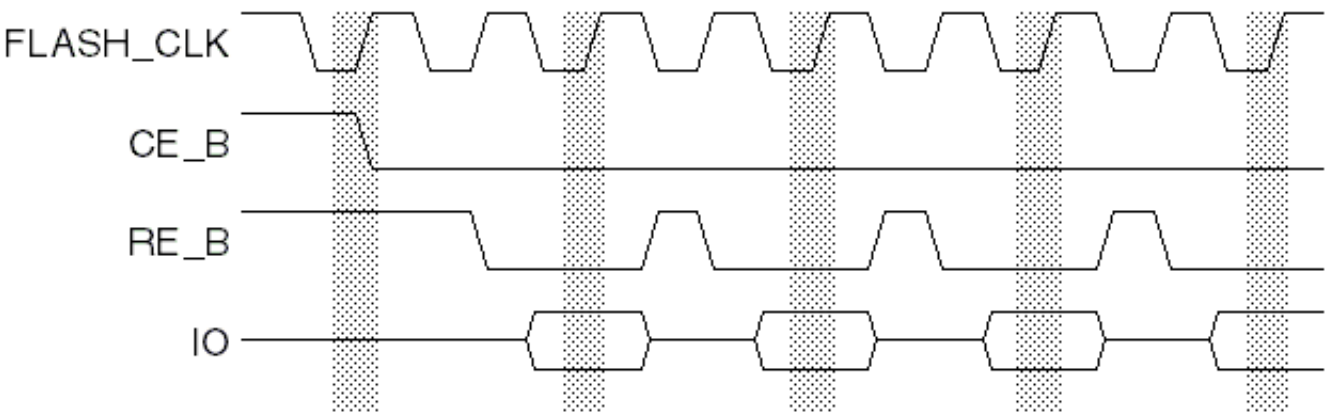

Figure 51-41. Two Flash Clock Cycles Per Data Output (SYM bit =0)

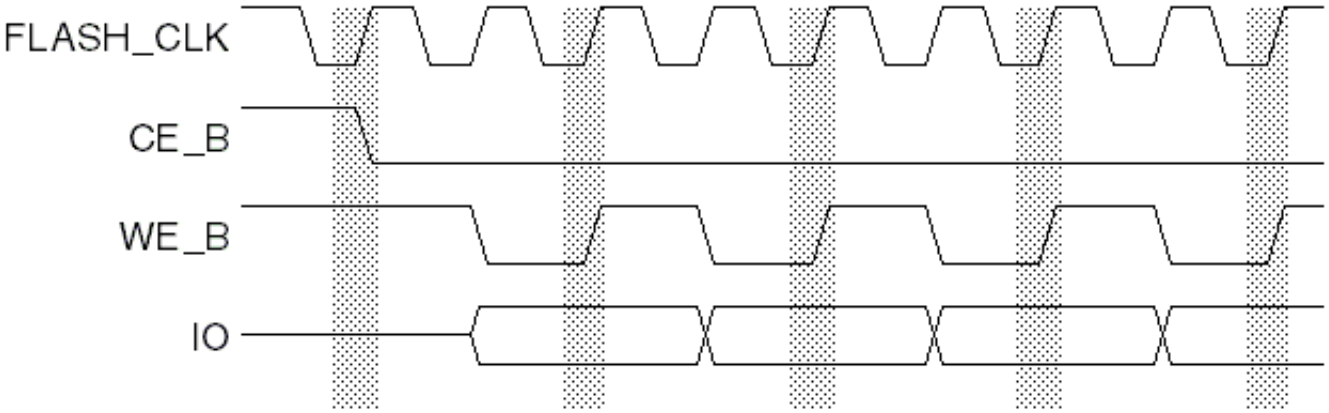

Figure 51-42. Two Flash Clock Cycles Per Data Input (SYM bit =0)

51.11.6 Delay Line Operation

51.11.6.1 Delay line background

When a read access is issued towards the NAND flash device then it takes a relatively long time from the assertion of the RE_B till the read data is latched by the NFC. The read data path starts with the deassertion of the RE_B (read enable) signal through the propagation in the I/O pads and till the RE_B port of the NAND flash device on the board. When the NAND flash device detects the deassertion of the RE_B signal it drives the associated read data back after Trea[ns] through the I/O pads and till being latched by the NFC. The NAND flash device is committed to keep driving the data for Trhoh [ns] after the posedge of RE_B. The delay line is used to compensate the long delay of the read data path and to adjust the sampling edge of the read data without any performance or frequency degradation.

The NFC generates an internal RE_B signal which is delayed by 1 flash clock cycle from the RE_B that is driven to the NAND device. The delayed RE_B passes through a delay line and the output of the delay line is used to latch the read data.

The delay line is composed from 4 delay line units. Each unit can delay the RE_B signal by a configurable time measured by axi slow clock cycle (fast clock of the NFC) fractions and up to 1/2 axi slow clock cycle. So the delay line can shift the RE_B signal by total of 2 axi slow clock cycles. Each fraction is 1/256 part of axi slow clock cycle and is configured in NFC_DELAY_LINE[NFC_ABS_DEL] register. This register is associated with a single delay line unit. By default the NFC latches the data after a fixed delay of 1 flash clock cycle + 1 axi slow clock cycle.

Figure 51-43 shows the read data path and Figure 51-44 shows the associated timing diagram.

51.11.6.2 Delay Line and Flash Clock Settings

The following will show how to set the flash clock cycle (2*Trp) and configure the desired value of the delay line. The calculations are based on parameters which depends on the NAND flash device, Freescale controller and the operating conditions.

- Assume the internal delay of the RE_B + the internal delay of the read data is D1[ns]
- Assume the board delay of the RE_B + board delay of the read data is D2[ns]
- Assume the delay of the RE_B caused by the delay line is Ddel[ns]. Note that the delay line has a minimal delay even if configured to zero delay
- Assume Trea[ns] is RE_B access time
- Assume Trp[ns] is RE_B pulse width
- Assume Trhoh[ns] is read data hold time from RE_B high

Note: The parameter D1 can be obtained from the AC characteristics of the Freescale device.

In order to sample the read data on time it is required that:

- 2Trp +Ddel > Trea + D1 + D2
- Trp + Ddel < Trhoh + D1 + D2
- Trp > Trp min defined by the NAND flash AC characteristics.

For example if:

- D1 = 10ns
- D2 = 2ns
- Delay line is configured to zero delay and its minimal delay is Ddel=3ns
- Trea = 20ns
- Trhoh = 15ns
- Trp min defined by the device is 12ns
- axi slow clock cycle is 7.5ns

In that case the pulse width of flash clock should be 14.5ns < Trp < 24ns or in other words the cycle of flash clock should be 29ns < Trc < 48ns (i.e flash clock frequency is 20.8Mhz < F< 34.4Mhz)

In case it required to work with Trp which is 12ns (i.e the minimal allowed by the NAND device) then it is possible by using the delay line as following. Setting a delay of 14.5 - 12 = 2.5ns means that we should delay the RE_B signal by 2.5/7.5 = 1/3 cycle of slow axi clock, which is approximately 85 parts of 256, So it is needed to configure NFC_DELAY_LINE[NFC_ABS_DEL] = 8'd85.

NOTE

For the above example the allowed ratio between axi slow clock cycle and flash clock cycle are 1:4,1:5 or1:6. If the cycle of the flash clock is set to 37.5ns (i.e ratio 1:4) and the total delay of the delay line is configured to 1 axi slow clock cycle (as the default value) then the latching edge of the read data will be delayed by 1 axi slow clock cycle, which is 7.5ns and it isn't guaranteed that the read data will be latched correctly.

Chapter 52
On-Chip RAM Memory Controller (OCRAM)

52.1 Overview

A couple of options are provided to adding pipeline or wait-state in read/write access, in order to ensures flexible timing control at high/low frequency working conditions.

The internal block are shown in the figure below.

Figure 52-1. On-chip RAM Block Diagram

52.2 Basic Functions

52.2.1 Read/Write Arbitration

The detailed rules used in arbitration are as follows:

- If there is no granted read or write in the last cycle, and there is only read request or write request, the request will be granted.
- If there is no granted read or write in the last cycle, and there are both read or write requests coming in at the same time, the read request will be granted first.
- If a granted read/write transaction has just finished, the write/read request will have the higher priority in the next cycle.
- If the first read/write access request in a transaction is granted, all the data transfer in this burst will be finished before next arbitration begins, that is, the round-robin arbitration mechanism is based on AXI transaction, not data access.

52.2.2 TrustZone

TrustZone is also supported on this block.

When SECURE_ENBL bit in OCRAM.OCRAM_TZSECURE_REGION register is set, the STARTADDR and ENDADDR bit-fields in this register establish the region of OCRAM that can only be accessed (both read and write) according to the execution mode policy described in CSU chapter. If this bit is cleared to zero, the entire OCRAM can be accessed in either secure or non-secure mode.

NOTE

The ENDADDR is not configurable and its value is the last address of the OCRAM space. The STARTADDR granularity is of 4KB.

52.3 Advanced Features

Below are some advanced features designed to avoid timing issues when the on-chip RAM is working at high frequency.

52.3.1 Read Data Wait State

When the wait state is enabled, it will cost 2 cycles for each read access, (each beat of a read burst).

This can avoid the potential timing problem caused by the relatively longer memory access time at higher frequency.

When this feature is disabled, it only costs 1 clock cycle to finish a read transaction, that is, to get read data back in the next cycle of read request becomes valid on the bus.

52.3.2 Read Address Pipeline

When this feature is enabled, the read address from the AXI master is delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issues for the read access on the memory cell at high frequency. Enabling this feature can cost, at most, 1 more clock cycle for each AXI read transaction, that is, at most 1 more clock cycle for each read burst with multiple beats of data.

When this feature is disabled, the read address from the AXI master can be accepted by the on-chip RAM without delay, and data can become ready for master at next clock cycle (if no other access and no read data wait).

52.3.3 Write Data Pipeline

When this feature is enabled, the write data from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enable this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write data from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write address is also ready at this cycle).

52.3.4 Write Address Pipeline

When this feature is enabled, the write address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enable this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write address from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write data is also ready at this cycle).

52.4 Programmable Registers

There are no programmable registers in this block, however the TrustZone bits are implemented in the Software Controllable Signals (IIM.SCS1) register within the IIM No need to configure register SCS1, if TrustZone feature is not used. The bits description are shown below.

Table 52-1. TrustZone Control Register (IIM.SCS1)

0xIIM_BASE+0x030 (IIM.SCS1)					Access: Supervisor read/write			
	7	6	5	4	3	2	1	0
R	LOCK	STARTADDR					SECURE__ ENBL	
W								
RESET	0	0	0	0	0	0	0	0

Table 52-2. TrustZone Control Register (IIM.SCS1)

Field	Description
7 LOCK	Lock this register. 0 The register is not locked, it may be modified 1 The register is locked, all attempts to modify it are ignored
6-2 STARTADDR	STARTADDR - TiustZone Start Address The STARTADDR field holds the TrustZone start address in the OCRAM memory space. The start address affects the OCRAM address bits [16:12], hence the address granularity is 4KB. The ENDADDR is not configurable and is set to the end of OCRAM memory space.
1 SECURE_ENBL	SECURE_ENBL - Secure Enable 0 The TrustZone feature is disabled. Entire OCRAM space is available for all access types (secure/non-secure/user/supervisor). 1 The TrustZone feature is enabled. Access to address in the range specified by [ENDADDR:STARTADDR] follows the execution mode access policy described in CSU chapter.
0	Reserved

Chapter 53
1-Wire Block (OWIRE)

53.1 Overview

The OWIRE provides the communication link to a generic 1-Kbit add-only memory. The block sends or receives one bit at a time with an option for software to manage the data using bytes. The required protocol for accessing the generic OWIRE device is defined by Maxim-Dallas. The generic OWIRE device holds battery characteristics information.

The following figure shows a block diagram of the OWIRE.

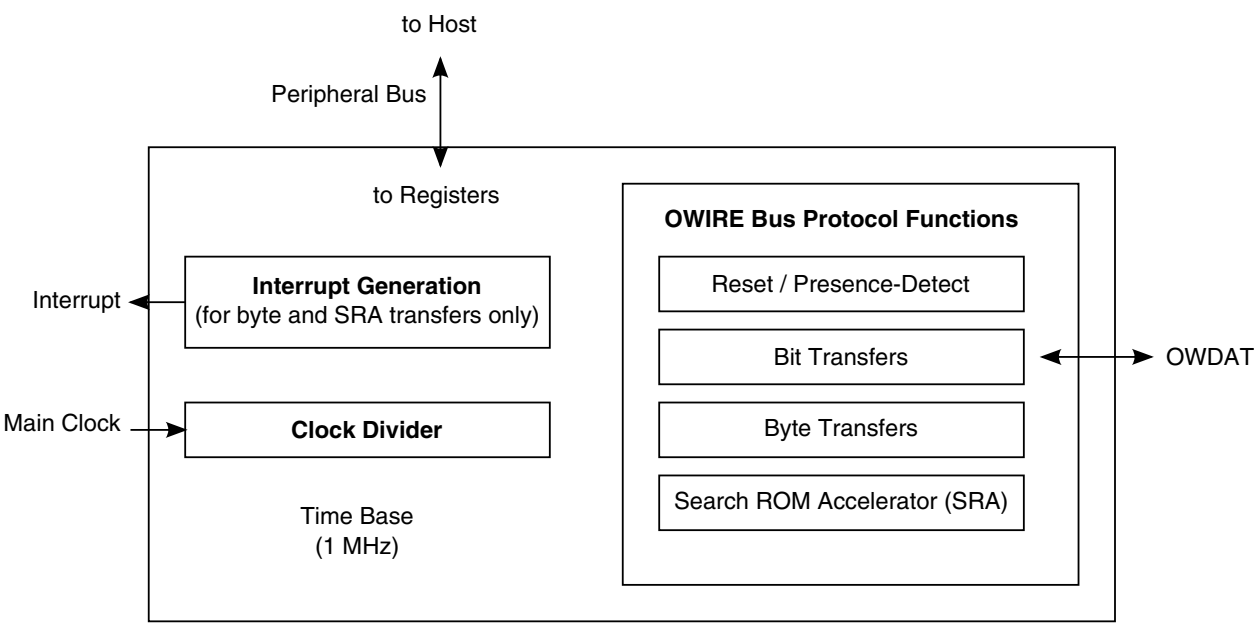

Figure 53-1. OWIRE Block Diagram

53.1.1 Features

The OWIRE includes the following features:

- Performs the OWIRE bus protocol to communicate with an external OWIRE device.
- Provides a clock divider to a generate a OWIRE bus reference clock (derived from the main clock provided internally to the block).
- Supports byte transfers with optional interrupts for more efficient programming.
- Provides a search ROM accelerator mode to speed the search ROM protocol.

53.1.2 Modes of Operation

The OWIRE supports the following operations:

- Normal Operating Modes (See Normal Operating Modes.)
  - Bit or Byte Transfers
  - Reset/Presence-detect Pulse
  - Search ROM Accelerator Mode
- Low Power Mode (See Low Power Mode.)

53.2 External Signals

Table 53-1 shows the signal that interfaces with a generic OWIRE device.

Table 53-1. OWIRE Block Signal

Signal	I/O	Function
OWDAT	I/O	One-Wire bus Requires an external pull-up resistor. The recommended resistor value is specified by the generic OWIRE device used in a given system.

53.3 Functional Description

The OWIRE interfaces with a generic 1-Kbit add-only memory, through a simple 1-bit bus. Software uses the OWIRE bus to program and read the 1-Kbyte memory.

The protocol involves first issuing one of four ROM function commands before the EPROM is accessible:

- Read ROM
- Match ROM
- Search ROM
- Skip ROM

Through the OWIRE bus, the host software interfaces with the generic OWIRE device and allows the required commands to be issued to control the EPROM of a generic OWIRE device. The host (through the OWIRE interface) is the bus master, and the generic OWIRE device(s) are the slave(s)

53.3.1 Normal Operating Modes

The OWIRE supports the following bus protocol functions:

- Reset/Presence-detect Pulse using the Control register (See Reset/Presence-detect Pulse.)
- Bit Transfers using the Control register (See Bit Transfers .)
- Byte Transfers using the TX/RX register (See Byte Transfers.)
- Search ROM Accelerator Mode using the Command register and the TX/RX register (See Search ROM Accelerator Mode.)

53.3.1.1 Reset/Presence-detect Pulse

The OWIRE provides for an automated initialization sequence for the OWIRE bus. Software initiates the initialization sequence by setting OWIRE_CONTROL[RPP]. The automated initialization sequence is as follows:

1. Generate a reset pulse.
2. Listen for a response from an external device by sampling for the OWIRE device presence bit.
3. After an amount of time determined by the OWIRE standard, latch the presence bit (true or false) in OWIRE_CONTROL[PST].

If an external device is detected (PST = 1), software can begin communications on the OWIRE bus.

The presence pulse is used by the OWIRE to determine if at least one generic OWIRE device is connected. Software determines if more than one generic OWIRE device exists.

53.3.1.2 Bit Transfers

After the initialization sequence (see Reset/Presence-detect Pulse), software can write and read one bit at a time using the Control register.

53.3.1.2.1 Write-0 Sequence

The Write-0 sequence writes a zero bit to the generic OWIRE device. Setting the OWIRE_CONTROL[WR0] bit initiates the Write-0 pulse sequence. Once the write is complete, the WR0 bit is automatically cleared.

53.3.1.2.2 Write-1 / Read Sequence

The Write-1 sequence writes a one bit to the generic OWIRE device. Setting the OWIRE_CONTROL[WR1] bit initiates the Write-1 pulse sequence. Once the write is complete, the WR1 bit is automatically cleared.

Because the Write-1 and Read timings are identical, this sequence also reads a bit from the bus. The sampled value is stored in the read status bit OWIRE_CONTROL[RDST] and is valid after the WR1 bit is self-cleared.

53.3.1.3 Byte Transfers

After the initialization sequence (see Reset/Presence-detect Pulse), software can transfer a byte at a time using the TX/RX register. Writing to the register connects to the Transmit buffer; reading to the register connects to the Receive buffer. See Figure 53-2.

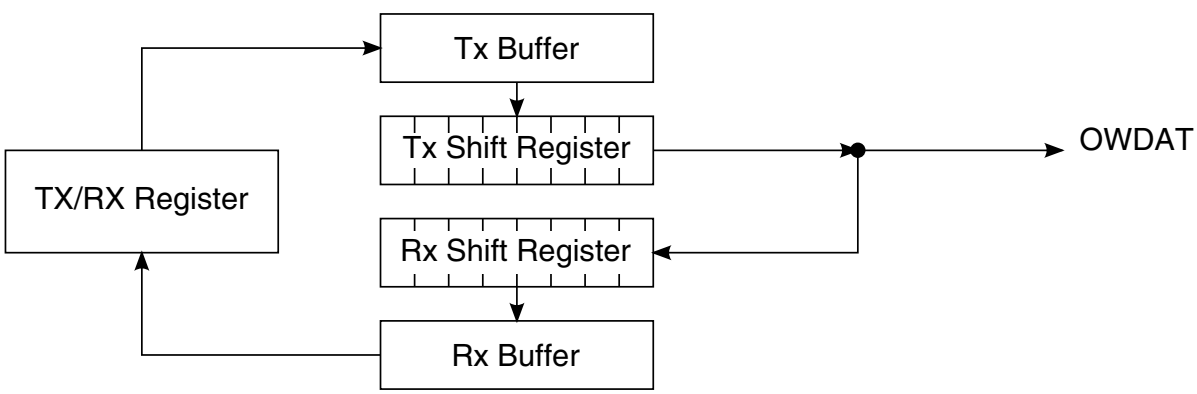

Figure 53-2. Byte Transfers

The Transmit buffer connects to an internal Transmit Shift Register where data is shifted serially onto the bus LSB first. Similarly, the Receive buffer connects to an internal Receive Shift Register where data is sampled serially from the bus.

Software can read a byte from the generic OWIRE device as follows:

1. Write 0xFF to the Transmit/Receive register location (connected to the Transmit buffer).

2. Wait for the receive-buffer-full (OWIRE_INTERRUPT[RBF]) interrupt (or poll the flag bit directly if the interrupt is disabled). During this time, the hardware is writing ones on the bus while sampling the wired-AND of the data from the device. The read data is shifted into the Receive Shift Register. When a byte is collected in the Receive Shift Register, the data is transferred to the Receive buffer, and the RBF flag is set.
3. Read from the Transmit/Receive register location (connected to the Receive buffer) upon receiving the RBF interrupt.

If the Receive buffer is full, new data is not shifted from the Receive Shift Register until the current data is read. To prevent the loss of data, software must read the TX/RX register to clear the receive-buffer-full flag (OWIRE_INTERRUPT[RBF]). This allows the Receive Shift Register to shift new data into the Receive buffer.

53.3.1.4 Search ROM Accelerator Mode

In *search ROM accelerator* mode the OWIRE relieves software from having to perform single-bit operations on the bus and helps determine if more than one generic OWIRE device exists.

The OWIRE enters search ROM accelerator mode when OWIRE_COMMAND[SRA] is set. This protocol specifies that the bus master read two bits (a bit and its complement), then writes a bit to specify which devices should remain on the bus for further processing.

Note that this mode requires that a reset followed by the search ROM command (0xF0) has already been issued on the OWIRE bus.

The OWIRE automatically exits search ROM accelerator mode if the OWIRE bus is re-initialized; see Reset/Presence-detect Pulse.

53.3.2 Low Power Mode

The OWIRE. automatically goes into low power mode whenever it is not communicating with a generic OWIRE device. The main clock is gated off in low power mode.

As soon as software writes to any register, the OWIRE exits low power mode.

53.3.3 Clocks

The OWIRE takes a main clock as a block input and passes it through a clock divider. (See the block diagram in Figure 53-1.) Software must program the divider factor to generate a 1-MHz clock that is used as an internal time base for the block, as given by the following equation:

time_base = main_clock ÷ (TIME_DIVIDER[DVDR] + 1)

For example, if the main clock frequency is 30 MHz, the value to write to the divider register is 29. If the main clock input frequency is not an integer, the programmer must ensure the time base frequency is within the range given by the following equation:

0.98 MHz ≤ time_base ≤ 1.02 MHz

NOTE

A main clock frequency below 10 MHz causes improper function of the block.

53.3.4 Reset

The OWIRE supports two levels of reset: hardware and software.

53.3.4.1 Hardware Reset

Whenever a device reset occurs, a hard reset is performed on the OWIRE, clearing all values written to all registers.

53.3.4.2 Software Reset

Software initiates a software reset by setting the reset bit OWIRE_RESET[RST]. A software reset clears all data written to the registers except for the Command and Interrupt registers (OWIRE_COMMAND, OWIRE_INTERRUPT).

NOTE

The reset register (OWIRE_RESET) itself is not cleared during a software reset. Software must clear the RST bit to release the software reset.

53.3.5 Interrupts

The OWIRE generates interrupts through the programming of the Interrupt Enable register; see Interrupt Enable Register (OWIRE_INTERRUPT_EN). The OWIRE can generate interrupts under the following conditions:

- Receive shift register or buffer full
- Transmit shift register or buffer empty
- Presence detect

Once any of these conditions are met, the Interrupt register (see Interrupt Register (OWIRE_INTERRUPT)) sets the corresponding bit and generates an interrupt if enabled in the Interrupt Enable register. The IAS bit within the Interrupt Enable register determines if the interrupt generated is active low, or active high. By default all interrupts are active high, and software should not modify IAS.

53.4 Programmable Registers

This section provides the block memory map and detailed descriptions of all registers.

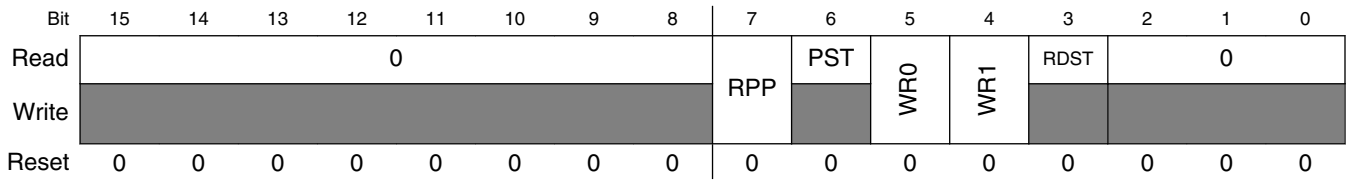
OWIRE memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FA_4000	Control register (OWIRE_CONTROL)	16	R/W	0000h	53.4.1/ 3658
63FA_4002	Time Divider register (OWIRE_TIME_DIVIDER)	16	R/W	0000h	53.4.2/ 3659
63FA_4004	Reset register (OWIRE_RESET)	16	R/W	0000h	53.4.3/ 3659
63FA_4006	Command Register (OWIRE_COMMAND)	16	R/W	0000h	53.4.4/ 3660
63FA_4008	Transmit/Receive Register (OWIRE_TX/RX)	16	R/W	0000h	53.4.5/ 3661
63FA_400A	Interrupt Register (OWIRE_INTERRUPT)	16	R	000Eh	53.4.6/ 3661
63FA_400C	Interrupt Enable Register (OWIRE_INTERRUPT_EN)	16	R/W	0000h	53.4.7/ 3663

53.4.1 Control register (OWIRE_CONTROL)

The control register is used to initiate the reset/presence-detect sequence and bit transfers. The register also provides the presence-detect status and bit-read status.

Address: OWIRE_CONTROL is 63FA_4000h base + 0h offset = 63FA_4000h



OWIRE_CONTROL field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 RPP	Reset/Presence-detect Pulse. This bit is self-clearing and is cleared after the presence is determined. See Reset/Presence-detect Pulse. When writing: 0 Do nothing. 1 Generate Reset Pulse and sample the bus for the presence pulse from the external device. When reading: 0 Reset pulse complete. 1 Sequence not complete.
6 PST	Presence Status. This bit is valid after the RPP bit is self-cleared. 0 Device is not present. 1 Device is present.
5 WR0	Write 0. This bit is self-clearing and is cleared when the write of the bit is complete. See Write-0 Sequence. When writing: 0 Do nothing. 1 Write a 0 bit to the interface. When reading: 0 Write sequence complete. 1 Sequence not complete.
4 WR1	Write-1 / Read. This bit is self-clearing and is cleared when the write sequence is complete. See Write-1 / Read Sequence. When writing: 0 Do nothing 1 Write a 1 bit to the interface and sample the bus. When reading:

3 RDST	Read Status. This bit is valid after the WR1 bit is self cleared. 0 A 0 has been sampled. 1 A 1 has been sampled.
2–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

53.4.2 Time Divider register (OWIRE_TIME_DIVIDER)

The time divider register is used for dividing the main clock input down to 1 MHz.

Address: OWIRE_TIME_DIVIDER is 63FA_4000h base + 2h offset = 63FA_4002h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								DVDR							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OWIRE_TIME_DIVIDER field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–0 DVDR	**Divider Factor.** The internal clock divider uses this field to generate the required time base for the block. See Clocks. 0x00 1 (default) 0x01 2 0xFF 256

53.4.3 Reset register (OWIRE_RESET)

The reset register is used to perform a software reset of the OWIRE.

Address: OWIRE_RESET is 63FA_4000h base + 4h offset = 63FA_4004h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0															RST
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OWIRE_RESET field descriptions

Field	Description
15–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 RST	Software Reset. See Software Reset. 0 Do not perform a software reset. 1 Initiate a software reset and hold the block in the software-reset state.

53.4.4 Command Register (OWIRE_COMMAND)

The OWIRE can be configured to run in Search ROM Accelerator mode using the command register. See Search ROM Accelerator Mode.

Address: OWIRE_COMMAND is 63FA_4000h base + 6h offset = 63FA_4006h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0														SRA	0
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OWIRE_COMMAND field descriptions

Field	Description

1 SRA	**Search ROM Accelerator. This bit is cleared when the reset-presence-pulse bit CONTROL[RPP] is set.** 0 Deactivate the search ROM accelerator. 1 Switch to search ROM accelerator mode.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved

53.4.5 Transmit/Receive Register (OWIRE_TX/RX)

Data sent and received from the OWIRE passes through the Transmit/Receive (TX/RX) register location. The OWIRE is double-buffered with separate transmit and receive buffers connected to the TX/RX register. See Byte Transfers.

Address: OWIRE_TX/RX is 63FA_4000h base + 8h offset = 63FA_4008h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								DATA							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OWIRE_TX/RX field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–0 DATA	Data byte. When writing: The data byte is written to the Transmit buffer. When reading: A data byte is read from the Receive buffer. The data is valid only when INTERRUPT[RBF] is set.

53.4.6 Interrupt Register (OWIRE_INTERRUPT)

Flags for the reset/presence-detect sequence and byte transfer operations are located in the Interrupt Register. These flags can generate an interrupt if the corresponding enable bit is set in the Interrupt Enable Register.

If interrupts are enabled, reading the Interrupt Register deactivates the interrupt even if all current flags are not cleared; therefore, the interrupt service routine should clear all pending flags during each routine call.

NOTE

When a byte is written to the Transmit/Receive Register, software then waits for a Transmit Shift Register Empty (TSRE) interrupt to occur. When the TSRE flag is set, the Receive Buffer Full (RBF) flag is also set. The RBF flag does not trigger an interrupt, assuming it is disabled. However, software should read the Transmit/Receive Register to clear the

RBF flag in order to give a proper status of the pending interrupts.

Address: OWIRE_INTERRUPT is 63FA_4000h base + Ah offset = 63FA_400Ah

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0										RSRF	RBF	TSRE	TBE	PDR	PD
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	0

OWIRE_INTERRUPT field descriptions

Field	Description
15–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 RSRF	Receive Shift Register Full. Hardware automatically clears this flag when data in the Receive Shift Register is transferred to the Receive buffer. 0 The Receive Shift Register is empty or currently receiving data. 1 A byte is waiting in the Receive Shift Register to be transferred to the Receive buffer.
4 RBF	Receive Buffer Full. This flag is cleared when software reads the byte from the TX/RX register. This flag prevents new data from being shifted into the Receive buffer from the Receive Shift Register. 0 No new data 1 A byte is waiting to be read from the TX/RX register.
3 TSRE	Transmit Shift Register Empty. Hardware automatically clears this flag when data in the Transmit buffer is transferred to the Transmit Shift Register. 0 Sending data 1 The Transmit Shift Register is empty and is ready to receive the next byte from the Transmit buffer.
2 TBE	Transmit Buffer Empty. This flag is cleared when software writes a byte to the TX/RX register. 0 The Transmit buffer is currently sending data to the Transmit Shift Register. 1 Nothing to transmit
1 PDR	Presence Detect Result. When a presence-detect (PD) interrupt occurs, this bit reflects the result of the presence-detect sequence. Note that this bit does not generate an interrupt. 0 Device found 1 Device not found
0 PD	Presence Detect. After an OWIRE reset has been issued, this flag is set after the appropriate amount of time for a presence detect pulse to have occurred. This flag is cleared when software reads the Interrupt Register. 0 A reset/presence-detect sequence has not been issued. 1 Reset/presence-detect sequence has completed. The result is provided in the PDR bit.

53.4.7 Interrupt Enable Register (OWIRE_INTERRUPT_EN)

The Interrupt Enable Register allows the system programmer to specify the source of interrupts. During a reset (hardware or software), all bits in this register are cleared, disabling all interrupt sources.

Address: OWIRE_INTERRUPT_EN is 63FA_4000h base + Ch offset = 63FA_400Ch

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0										ERSF	ERBF	ETSE	ETBE	IAS	EPD
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OWIRE_INTERRUPT_EN field descriptions

Field	Description
15–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 ERSF	Enable Receive Shift Register Full Interrupt. 0 Disable interrupt. 1 Enable interrupt.
4 ERBF	Enable Receive Buffer Full Interrupt. 0 Disable interrupt. 1 Enable interrupt.
3 ETSE	Enable Transmit Shift Register Empty Interrupt. 0 Disable interrupt. 1 Enable interrupt.
2 ETBE	Enable Transmit Buffer Empty Interrupt. 0 Disable interrupt. 1 Enable interrupt.
1 IAS	Interrupt Trigger Active State. This bit determines the polarity for all interrupts. Note that this bit is not an interrupt-enable bit. 0 Active high 1 Active low
0 EPD	Enable Presence Detect. 0 Disable interrupt. 1 Enable interrupt.

Chapter 54
Parallel Advanced Technology Attachment (PATA)

54.1 Overview

The Parallel Advanced Technology Attachment (PATA) block is an AT Attachment host interface, that is compliant with the ATA-5 standard. Its main use is to interface with IDE hard disc drives and ATAPI optical disc drives. It interfaces with the PATA device over a number of PATA signals.

See Figure 54-1 for the block diagram of the PATA interface.

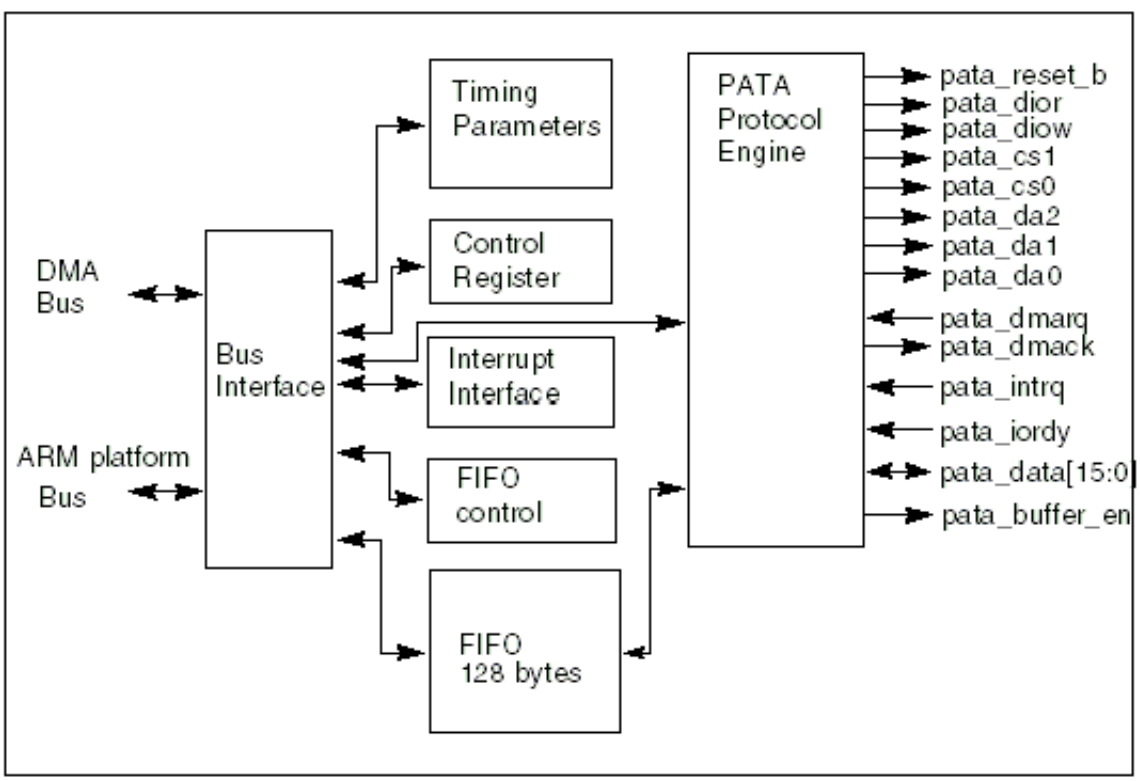

Figure 54-1. PATA Interface Block Diagram.

In Figure 54-1, the ARM platform and DMA buses communicate with the host processor and host DMA unit, respectively. All internal registers are visible from both the ARM and DMA buses, allowing smart DMA access to program the interface.

Two access modes are possible over the PATA bus: PIO mode and DMA mode. There are also two types of DMA mode: DMA slave mode (controlled by the host DMA) and DMA master mode (controlled by the internal DMA master). See Modes of Operation, for more information about these access modes.

54.1.1 Features

The PATA interface includes the following features:

- Programmable timing on the PATA bus. Works with a wide range of bus frequencies.
- Compliant with ATA-5 specification
  - Supports PIO modes 0-4
  - Supports multi-word DMA (MDMA) modes 0, 1, and 2
  - Supports ultra DMA (UDMA) modes 0-4 with a bus clock of at least 50 MHz, and the actual maximum supported speed is 66MHz
  - Supports ultra DMA (UDMA) mode 5 with a bus clock of maximum supported speed 66MHz
- 128-byte FIFO included within the interface
- FIFO receive, transmit, and end-of-transmission alarms to DMA unit
- Zero-wait cycles transfer between DMA bus and FIFO (enables fast FIFO reads/ writes)

54.1.2 Modes of Operation

The interface offers two alternative modes of operation, PIO mode and DMA mode. These modes are described in the following subsections.

54.1.2.1 PIO Mode

An access to the PATA bus in PIO mode occurs whenever an PATA PIO register is read or written by the host ARM platform or the host (smart) DMA unit. During a PIO transfer, the incoming IP Bus cycle is translated to an PATA PIO bus cycle by the PATA protocol engine. No buffering of data occurs, so the host ARM or host DMA cycle is stalled until the PATA bus read data is available on read, or is stalled until the IP Bus data can be put on the PATA bus during a write.

PIO accesses can be made at any time, even during a running PATA DMA transfer. In this case, the DMA transfer is paused, the PIO cycle is completed, and the DMA transfer is resumed.

54.1.2.2 DMA Mode

In DMA mode, data is transferred between the PATA bus and the FIFO. Two different DMA protocols are supported on the PATA bus: ultra DMA (UDMA) mode and multi-word DMA (MDMA) mode. These are described in more detail in the sections indicated below.

In DMA mode transfers, data is transferred between the PATA bus and the FIFO. Normally it is the task of the host smart DMA unit to write and read data to and from the FIFO to keep the transfer going.

The transfer pauses to avoid FIFO overflow and FIFO underflow. For this purpose, the fifo_rcv_alarm and fifo_tx_alarm signals are sent to the host DMA unit. An additional alarm signal (fifo_txfer_end_alarm) signals the end of the transfer to the smart DMA, which then completes the transfer and informs the ARM platform. Further details on these alarm signals are given in FIFO ALARM register (PATA_FIFO_ALARM).

The typical packet size is 32 bytes (8 32-bit words), but other packet sizes can also be handled.

Further details on DMA mode may be found in the following sections:

- Receiving Data from PATA Bus in DMA Mode
- Transmitting Data to PATA Bus in DMA Mode

54.2 External Signal Description

Table 54-1 lists the signals between this block and peripherals within the Tortola chip.

Table 54-1. Signal Properties

Name	Port	Function	Reset State	Type
pata_reset_b		PATA bus reset signal. Active low. If active, The PATA device is reset[1]	0	out
pata_dior		PATA bus read strobe	1	out
pata_diow		PATA bus write strobe	1	out
pata_cs1		PATA bus chip select 1	1	out
pata_cs0		PATA bus chip select 0	1	out

Table continues on the next page...

Table 54-1. Signal Properties (continued)

Name	Port	Function	Reset State	Type
pata_da2		PATA bus address line 2	0	out
pata_da1		PATA bus address line 1	0	out
pata_da0		PATA bus address line 0	0	out
pata_dmarq		PATA bus DMA request	-	in
pata_dmack		PATA bus DMA acknowledge	1	out
pata_intrq		PATA bus interrupt request	-	in
pata_iordy		PPATA bus iordy	-	out
pata_data[15:0]		PATA data bus (little-endian)	Hi-z	tristate in-out

1. This signal is a standard PATA bus signal. It conforms with the PATA specification.

The signals in Table 54-1 are described in Signal Descriptions.

54.2.1 Signal Descriptions

For a detailed description of the PATA bus signals, refer to the ATA-5 specification.

54.2.1.1 pata_reset_b (out)

When negated, the PATA reset signal indicates the PATA bus is in reset state. The PATA bus is in reset whenever the appropriate bit in the control register is cleared. After system reset, the PATA bus is reset.

54.2.1.2 pata_dior (out)

During PIO and MDMA transfers, the DIOR PATA signal functions as a read strobe. During UDMA data in bursts, it functions as HDMARDY. During UDMA data out burst mode, it functions as host strobe.

54.2.1.3 pata_diow (out)

During PIO and MDMA transfers, the DIOW PATA signal functions as a write strobe. During UDMA burst mode, it is used by the host terminate running UDMA transfers.

54.2.1.4 pata_cs0, pata_cs1, pata_da2, pata_da1, pata_da0 (out)

The address group of the PATA bus consists of the chip selects ata_cs0 and ata_cs1, and the address lines ata_da2, ata_da1, and ata_da0. All five lines follow the same timing.

54.2.1.5 pata_dmarq (in)

The PATA bus device DMA request is pulled high by the device if it wants to transfer data using MDMA or UDMA mode.

54.2.1.6 pata_dmack (out)

The PATA bus host DMA acknowledge is pulled low by the host when it grants the DMA request.

54.2.1.7 pata_intrq (in)

The PATA bus interrupt request is pulled high by the device whenever it wants to interrupt the host ARM platform.

54.2.1.8 pata_iordy (in)

The PATA bus IORDY line has three functions:

- IORDY-Active low, wait during PIO cycles
- DDMARDY-Active low, device ready during UDMA out-transfers
- DSTROBE-Device strobe during UDMA in-transfers

54.2.1.9 pata_data[15:0] (in/out-tristate)

The PATA data bus signal carries data to/from the PATA device.

54.2.1.10 pata_buffer_en

When the buffer direction control signal is asserted, data is driven outward to the device; when negated, data is driven inward to the host.

54.2.2 PATA Bus Timing

This section describes the PATA bus timing, and explains how to ensure that the PATA interface meets timing requirements. Timing diagrams and timing relation equations are provided.

54.2.2.1 Timing Parameters

Table 54-2 shows the PATA timing parameters, and their determining factors.Determining factors include the system design, the bus buffer used, the cable delay and the cable skew.

Table 54-2. Timing Parameters

Name	Meaning	Controlled by
T	Bus clock period	Tortola clock generator
ti_ds	Set-up time ata_data to ata_iordy edge (UDMA-in only)	top level design
ti_dh	hold time ata_iordy edge to ata_data (UDMA-in only)	top level design
tco	propagation delay bus clock L-to-H to ata_cs0, ata_cs1, ata_da2, ata_da1, ata_da0, ata_dior, ata_diow, ata_dmack, ata_data, ata_buffer_en	top level design
tsu	set-up time ata_data to bus clock L-to-H	top level design
tsui	set-up time ata_iordy to bus clock H-to-L	top level design
thi	hold time ata_iordy to bus clock H to L	top level design
tskew1	Max difference in propagation delay bus clock L-to-H to any of following signals ata_cs0, ata_cs1, ata_da2, ata_da1, ata_da0, ata_dior, ata_diow, ata_dmack, ata_data (write), ata_buffer_en	top level design
tskew2	Max difference in buffer propagation delay for any of following signals ata_cs0, ata_cs1, ata_da2, ata_da1, ata_da0, ata_dior, ata_diow, ata_dmack, ata_data (write), ata_buffer_en	transceiver
tskew3	Max difference in buffer propagation delay for any of following signals ata_iordy, ata_data (read)	transceiver
tbuf	Max buffer propagation delay	transceiver
tcable1	cable propagation delay for ata_data	cable
tcable2	cable propagation delay for control signals ata_dior, ata_diow, ata_iordy, ata_dmack	cable
tskew4	Max difference in cable propagation delay between ata_iordy and ata_data (read)	cable
tskew5	Max difference in cable propagation delay between (pata_dior, pata_diow, pata_dmack) and pata_cs0, pata_cs1, pata_da2, pata_da1, pata_da0, pata_data (write)	cable
tskew6	Max difference in cable propagation delay without accounting for ground bounce	cable

54.2.2.2 PIO Mode Timing

54.2.2.2.1 PIO Read Mode Timing

A timing diagram for PIO read mode is given in Figure 54-2.

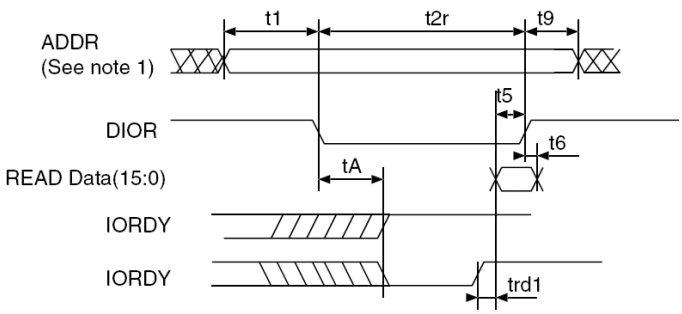

Figure 54-2. PIO Read Mode Timing

To meet timing requirements, a number of timing parameters must be controlled. Table 54-3 shows relations between different timing parameters, and identifies parameters in the PATA timing registers which may be programmed by the user to satisfy timing constraints (see Time Off register (PATA_TIME_OFF).

In Table 54-3 (and Table 54-4 below), the first column lists parameters from the PATA specification; the second column refers to timing parameters shown in Figure 54-2; the third column shows the relation between these timing parameters and programmable values; and the fourth column identifies the registers which may be programmed to meet the timing relations.

Table 54-3. Timing Parameter Relations for PIO Read

PATA parameter	PIO Read Mode Timing Parameter [1]	Relation	Programmable Register
t1	t1	t1(min) = time_1 * T - (tskew1 + tskew2 + tskew5)	time_1
t2 (read)	t2r	t2(min) = time_2r * T - (tskew1 + tskew2 + tskew5)	time_2r
t9	t9	t9(min) = time_9 * T - (tskew1 + tskew2 + tskew6)	time_9
t5	t5	t5(min) = tco + tsu + tbuf + tbuf+ tcable1 + tcable2	time_2 (affects tsu and tco)
tA	tA	tA(min) = (1.5 + time_ax) * T - (tco + tsui + tcable2 + tcable2 + 2*tbuf)	time_ax
trd	trd1	trd1(max) = (-trd)+ (tskew3 + tskew4) trd1(min) = (time_pio_rdx - 0.5)*T - (tsu + thi) (time_pio_rdx - 0.5) * T > tsu + thi + tskew3 + tskew4	time_pio_rdx
t0	-	t0(min) = (time_1 + time_2r+ time_9) * T	time_1, time_2r, time_9

1. See Figure 54-2 .

54.2.2.2.2 PIO Write Mode Timing

A timing diagram for PIO write mode is given in Figure 54-3.

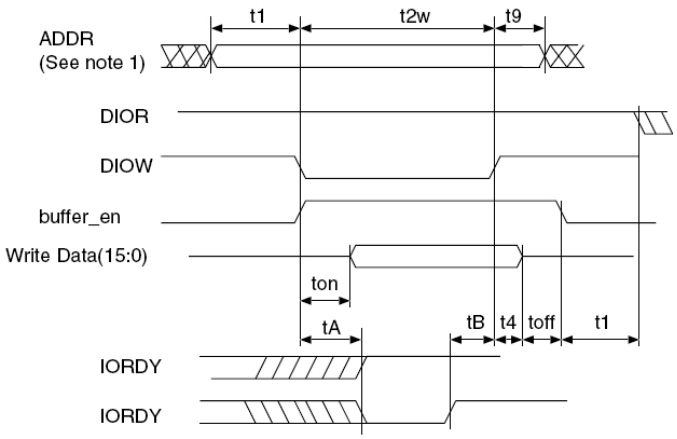

Figure 54-3. PIO Write Mode Timing

Table 54-4 shows relations between timing parameters, and identifies parameters in the PATA timing registers which may be programmed by the user to meet timing constraints (see Time Off register (PATA_TIME_OFF)).

Table 54-4. Timing Parameters Relations for PIO Write

PATA Parameter	PIO Write Mode Timing Parameter[1]	Relation	Programmable Value
t1	t1	t1(min) = time_1 * T - (tskew1 + tskew2 + tskew5)	time_1
t2 (write)	t2w	t2(min) = time_2w * T - (tskew1 + tskew2 + tskew5)	time_2w
t9	t9	t9(min) = time_9 * T - (tskew1 + tskew2 + tskew6)	time_9
t3	-	t3(min) = (time_2w - time_on)* T - (tskew1 + tskew2 +tskew5)	if not met, increase time_2w
t4	t4	t4(min) = time_4 * T - tskew1	time_4
tA	tA	tA = (1.5 + time_ax) * T - (tco + tsui + tcable2 + tcable2 + 2*tbuf)	time_ax
t0	-	t0(min) = (time_1 + time_2 + time_9) * T	time_1, time_2r, time_9
-	-	Avoid bus contention when switching buffer on by making ton long enough	-
-	-	Avoid bus contention when switching buffer off by making toff long enough	-

1. See Figure 54-3 .

54.2.2.3 Timing in Multi-word DMA (MDMA) Mode

Figure 54-4 and Figure 54-5 show read and write timings respectively for MDMA mode.

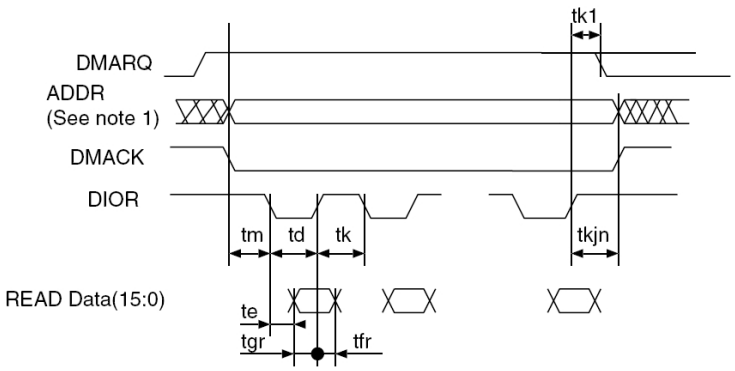

Figure 54-4. MDMA Read Timing

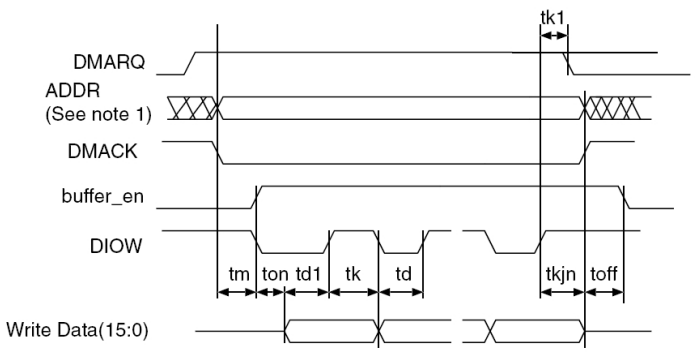

Figure 54-5. MDMA Write Timing

To meet timing requirements for MDMA mode, a number of timing parameters must be controlled. Table 54-5 shows the relations between different timing parameters, and identifies parameters in the PATA timing registers which may be programmed by the user to satisfy timing constraints (see Time Off register (PATA_TIME_OFF)).

In Table 54-5, the first column lists parameters from the PATA specification; the second column refers to timing parameters shown in Figure 54-2; the third column shows the relation between these timing parameters and programmable values; and the fourth column identifies the registers which may be programmed to meet timing constraints.

Table 54-5. Timing Parameter Relations for MDMA Read and Write

PATA Parameter	MDMA Read TIming[1] and MDMA Write TIming[2]	Relation	Programmable Value
tm, ti	tm	tm(min) = ti(min) = time_m * T - (tskew1 + tskew2 + tskew5)	time_m
td	td, td1	td1(min) = td(min) = time_d * T - (tskew1 + tskew2 + tskew6)	time_d
tk	tk[3]	tk(min) = time_k * T - (tskew1 + tskew2 + tskew6)	time_k
t0	-	t0(min) = (time_d + time_k) * T	time_d, time_k
tg (read)	tgr	tgr(min-read) = tco + tsu + tbuf + tbuf + tcable1 + tcable2 tgr(min-drive) = td - te(drive)	time_d
tf (read)	tfr	tfr(min) = 5 ns	(met by design)
tg(write)	-	tg(min-write) = time_d * T -(tskew1 + tskew2 + tskew5)	time_d
tf(write)	-	tf(min-write) = time_k * T - (tskew1 + tskew2 + tskew6)	time_k
tL	-	tL(max) = (time_d + time_k-2)*T - (tsu + tco + 2*tbuf + 2*tcable2)	time_d, time_k[4]
tn, tj	tkjn	tn= tj= tkjn = time_jn * T - (tskew1 + tskew2 + tskew6)	time_jn
-	ton toff	ton = time_on * T - tskew1 toff = time_off * T - tskew1	-

1. See Figure 54-4.
2. See Figure 54-5.
3. tk1 in the MDMA figures (Figure 54-4 and Figure 54-5) equals (tk -2*T)
4. tk1 in the MDMA figures equals (tk -2*T)

54.2.2.4 Timing for Ultra DMA (UDMA) Data In-Transfers

Figure 54-6 shows timing for the start of a UDMA data in-transfer.

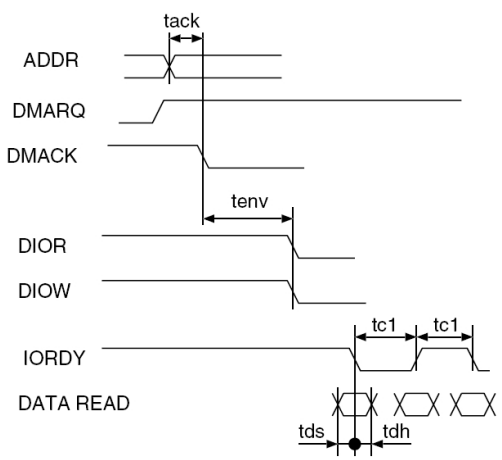

Figure 54-6. Timing for Start of UDMA Data In-transfer

Figure 54-7 shows timing for host termination of a UDMA data in-transfer.

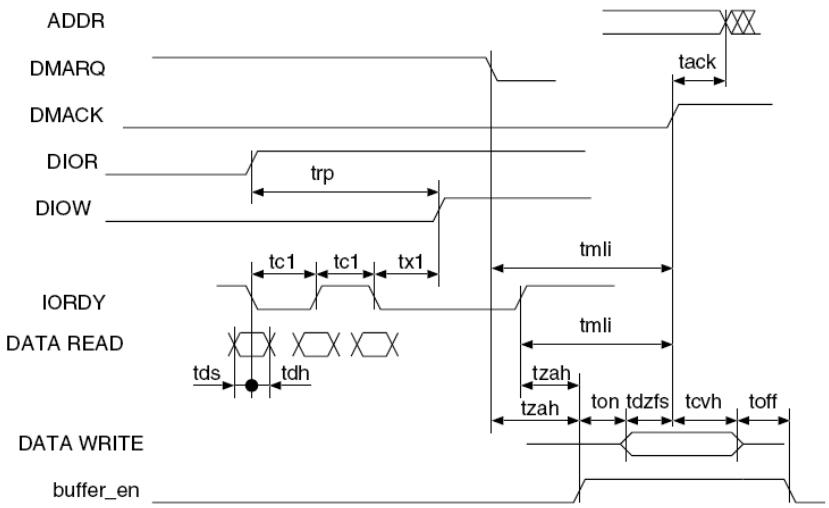

Figure 54-7. Timing for Host Termination of UDMA Transfer

Figure 54-8 shows timing for device termination of a UDMA data in-transfer.

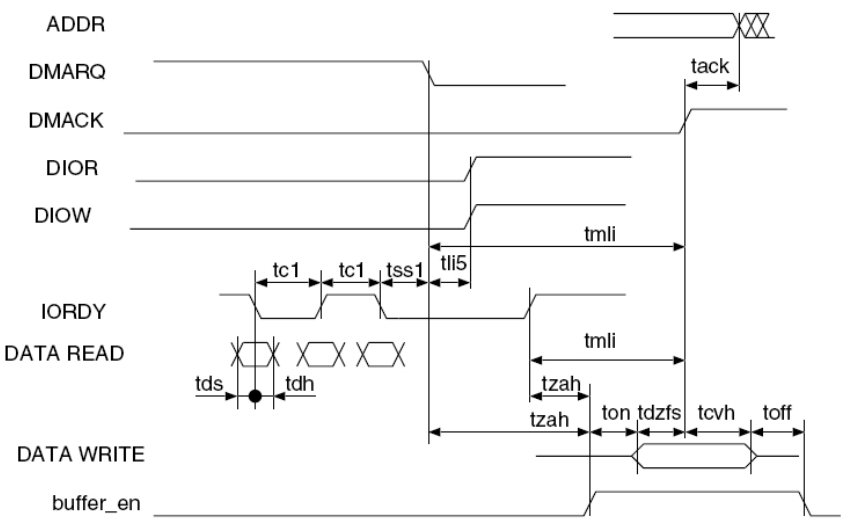

Figure 54-8. Timing for Device Termination of a UDMA Transfer

Timing parameters for UDMA data in-bursts are listed in Table 54-6. The UDMA in-burst timing parameters listed in the second column refer to Figure 54-6 through Figure 54-8.

Table 54-6. Timing Parameter Relations for UDMA Data In-bursts

PATA Parameter	UDMA In-burst Timing Parameter	Relation	Programmable Value
tack	tack	tack(min) = (time_ack * T) - (tskew1 + tskew2)	time_ack

Table continues on the next page...

Table 54-6. Timing Parameter Relations for UDMA Data In-bursts (continued)

PATA Parameter	UDMA In-burst Timing Parameter	Relation	Programmable Value
tenv	tenv	tenv(min) = (time_env * T) - (tskew1 + tskew2) tenv(max) = (time_env * T) + (tskew1 + tskew2)	time_env
trp	trp	trp(min) = time_rp * T - (tskew1 + tskew2 + tskew6)	time_rp
-	tx1[1]	(time_rp * T) - (tco + tsu + 3T + 2 *tbuf + 2*tcable2) > trfs (drive)	time_rp
tmli	tmli1	tmli1(min) = (time_mlix + 0.4) * T	time_mlix
tzah	tzah	tzah(min) = (time_zah + 0.4) * T	time_zah
tdzfs	tdzfs	tdzfs = (time_dzfs * T) - (tskew1 + tskew2)	time_dzfs
tcvh	tcvh	tcvh = (time_cvh *T) - (tskew1 + tskew2)	time_cvh
-	ton toff[2]	ton = time_on * T - tskew1 toff = time_off * T - tskew1	-

1. There is a special timing requirement in the PATA host that requires the internal DIOW to go only high three clocks after the last active edge on the DSTROBE signal. The equation given on this line tries to capture this constraint.
2. Make ton and toff big enough to avoid bus contention.

54.2.2.5 Timing for UDMA Data Out-transfers

Figure 54-9 shows the timing for the start of a UDMA data out-transfer.

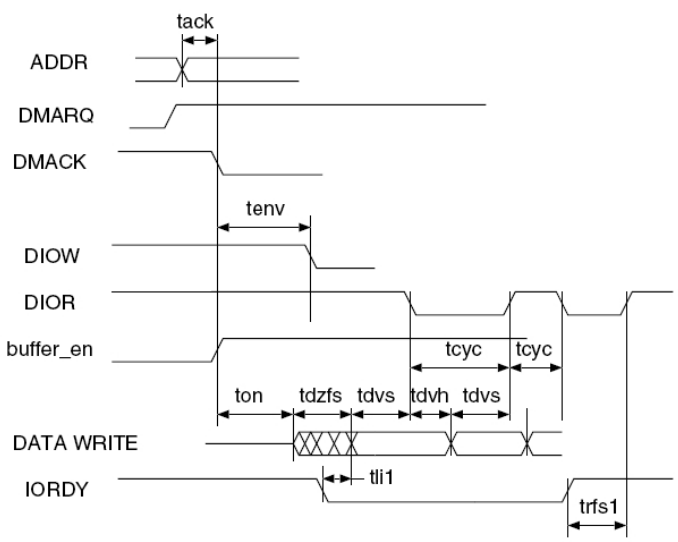

Figure 54-9. Timing of Start of UDMA Data Out-transfer

Figure 54-10 shows the timing for host termination of a UDMA data out-transfer.

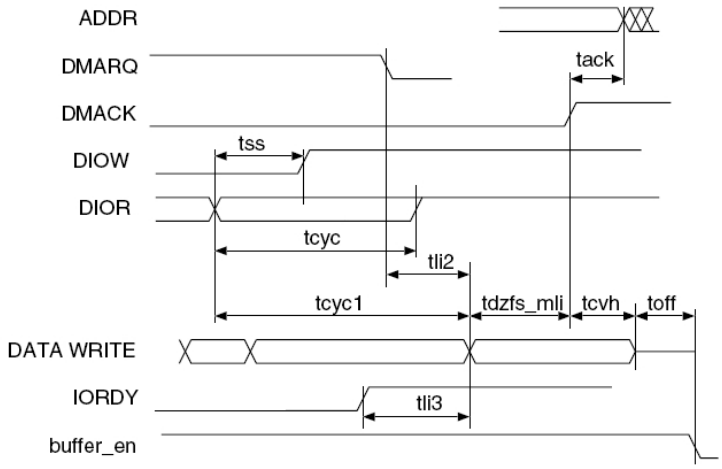

Figure 54-10. Timing of Host Termination of UDMA Data Out-transfer

Figure 54-11 shows timing for device termination of a UDMA data out-transfer.

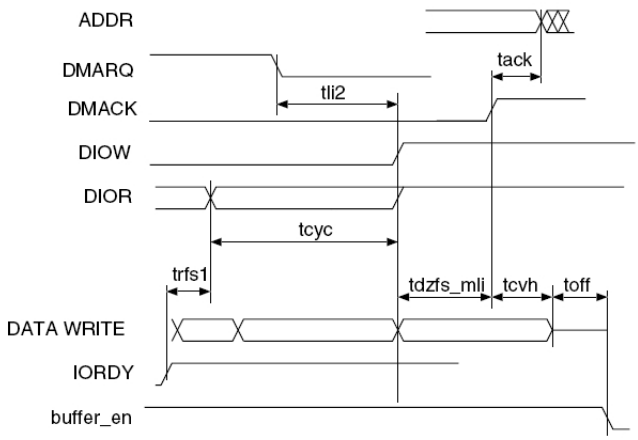

Figure 54-11. Timing for Device Termination of UDMA Data Out-transfer

Timing parameters and relations for UDMA data out-bursts are listed in Table 54-7. The UDMA out-burst timing parameters listed in the second column refer to Figure 54-9 through Figure 54-11.

Table 54-7. Timing Parameters and Relations for UDMA Out Burst

PATA parameter	UDMA Out-burst Timing Parameter	Timing Relation	Programmable Value
tack	tack	tack(min) = (time_ack * T) - (tskew1 + tskew2)	time_ack
tenv	tenv	tenv(min) = (time_env * T) - (tskew1 + tskew2) tenv(max) = (time_env * T) + (tskew1 + tskew2)	time_env
tdvs	tdvs	tdvs = (time_dvs * T) - (tskew1 + tskew2)	time_dvs

Table continues on the next page...

Table 54-7. Timing Parameters and Relations for UDMA Out Burst (continued)

PATA parameter	UDMA Out-burst Timing Parameter	Timing Relation	Programmable Value
tdvh	tdvh	tdvs = (time_dvh * T) - (tskew1 + tskew2)	time_dvh
tcyc	tcyc	tcyc = time_cyc * T - (tskew1 + tskew2)	time_cyc
t2cyc	-	t2cyc = time_cyc * 2 * T	time_cyc
trfs1	trfs	trfs = 1.6 * T + tsui + tco + tbuf + tbuf	-
-	tdzfs	tdzfs = time_dzfs * T - (tskew1)	time_dzfs
tss	tss	tss = time_ss * T - (tskew1 + tskew2)	time_ss
tmli	tdzfs_mli	tdzfs_mli =max(time_dzfs, time_mli) * T - (tskew1 + tskew2)	-
tli	tli1	tli1 > 0	-
tli	tli2	tli2 > 0	-
tli	tli3	tli3 > 0	-
tcvh	tcvh	tcvh = (time_cvh *T) - (tskew1 + tskew2)	time_cvh
-	ton toff	ton = time_on * T - tskew1 toff = time_off * T - tskew1	-

54.3 Functional Description

The PATA interface provides two alternative modes for communication with the PATA peripherals connected to the PATA bus:

- PIO mode read/write operations through the PATA bus
- DMA transfers through the PATA bus

The operation of the peripheral under these two modes is described in detail in subsequent sections.

54.3.1 Resetting the PATA Bus

The PATA bus reset ata_reset_b is asserted whenever bit 'ata_rst_b' (bit #6) of the PATA control register is cleared (see PATA interface control register (PATA_CONTROL)). Clearing the bit also resets the PATA protocol engine. When the bit is set, the reset is released.

54.3.2 Programming PATA Bus Timing and iordy_en

The timing of the PATA interface is programmable, using the 24 timing registers described in the Programmable Registers section. Programming the registers requires that the PATA bus be idle, so before reprogramming the user should make sure that:

- The dma_pending bit in the PATA control register is cleared (see PATA interface control register (PATA_CONTROL)).
- The controller_idle bit in the interrupt pending register is set (see Interrupt pending register (PATA_INTERRUPT_PENDING)).

These two conditions can be met by first clearing dma_pending, and then waiting until controller_idle is set before reprogramming the timing parameters. If dma_pending was set before the reprogramming started, it should be set again after the new timing is in effect to allow the drive to finish the current DMA transfer.

The bus timing should only be reprogrammed during an ongoing DMA transfer when the operating system requires a change in the bus clock (for example, in dynamic voltage frequency scaling).

The controller_idle bit must be set before reprogramming the bus timing: otherwise, the new timing values may affect a bus cycle that is still running and cause a error. PIO reads or writes to the PATA bus terminate after the bus cycle with the ARM platform has been terminated.

The iordy_en bit in the PATA control register determines whether the PATA interface responds to the drive's IORDY signal. Just as with timing registers, it should only be reprogrammed when dma_pending is cleared, and controller_idle is set.

54.3.3 Access to PATA Bus in PIO Mode

Before accessing the PATA bus in PIO mode, the user must:

1. Set the ata_rst_b bit in the PATA control register
2. Program the timing parameters

The drive is accessed in PIO mode simply by reading or writing to the correct drive register. The bus cycle is translated to an PATA cycle, and the drive is accessed.

Reads and writes to the drive are not possible while the PATA bus is in reset; the attempted operation fails, and is discarded.

54.3.4 Receiving Data from PATA Bus in DMA Mode

In DMA receive mode, the protocol engine transfers data from the drive to the FIFO using the multi-word DMA (MDMA) or ultra DMA (UMDMA) protocol. The transfer pauses when any of the following conditions occurs:

- The FIFO is full.
- The drive negates its DMA request signal ata_dmarq.
- The dma_pending bit in the ata_control register is cleared.

When the condition is removed, the transfer restarts. At the end of the transfer, the drive signals the host by asserting the ata_intrq signal. Alternatively the host can read the device status register, which also indicates when the transfer has ended.

The transfer of data from FIFO to memory is handled by the host system DMA. DMA data transfers from device to host are set up as follows:

1. Make sure the PATA bus is not in reset, and all timing registers are programmed.
2. Make sure the FIFO is empty by reading it until empty or by resetting it.
3. Initialize the DMA channel connected to fifo_rcv_alarm. Every time the fifo_rcv_alarm is high, the DMA should read <packetsize> 32-bit words from the FIFO, and store them in main memory (here 'packetsize' is defined as the number of 32-bit words in a packet: typically packetsize=8). This keeps the transfer going while avoiding FIFO overrun.
4. Write 2*<packetsize> to the FIFO alarm register (note that this setting corresponds to one packet of data, since the alarm threshold is specified in units of 16-bit halfwords). In this way, the FIFO notifies the DMA whenever there is at least one packet ready for transfer.
5. Ensure the FIFO is out of reset by setting the fifo_rst_b bit in the PATA control register (see PATA interface control register (PATA_CONTROL)).
6. Set the fifo_rcv_en bit in the PATA control register. This enables the DMA to empty the FIFO.
7. Set the dma_pending bit, and clear the dma_write bit. Also, program ultra_mode_selected=0 (for MDMA) or ultra_mode_selected=1 (for UDMA).

   Steps (1-7) have prepared the host side of the DMA.

8. Send commands to the drive in PIO mode that cause it to request DMA transfer on the PATA bus (consult the PATA specification for the specifics of this operation).
9. At this point, when the drive requests a DMA transfer by pulling ata_dmarq high, the PATA interface acknowledges with ata_dmack, and the transfer starts. Data is transferred automatically to the FIFO, and from there to the host memory.
10. During the transfer, the host can monitor for end of transfer by reading some device PATA registers. These reads cause the running DMA to pause; after the read is

completed, the DMA resumes. Alternatively, the host can wait unit the drive asserts ata_intrq, which also indicates end of transfer.

11. When the transfer ends, the host or host DMA should wait until the controller_idle bit is set in the PATA control register, then read the remaining halfwords from the FIFO and transfer these to memory. Note that there may be less than <packetsize> remaining 32-bit words, in which case the transfer is not be performed automatically by the DMA.

54.3.5 Transmitting Data to PATA Bus in DMA Mode

In DMA transmit mode, the protocol engine transfers data from the FIFO to the drive using the multi-word DMA (MDMA) or ultra DMA (UDMA) protocol. The transfer pauses when one of following conditions occurs:

- The FIFO is empty
- The drive negates its DMA request signal ata_dmarq
- The dma_pending bit in the ata_control register is cleared

When the condition is removed, the transfer restarts. At the end of the transfer, the drive signals the host by asserting the ata_intrq signal. Alternatively the host can read the device status register, which also indicates when the transfer has ended.

The transfer of data from FIFO to memory is handled by the host system DMA. DMA data transfers from host to device are set up as follows:

1. Make sure the PATA bus is not in reset, and all timing registers are programmed.
2. Make sure the FIFO is empty by reading it until empty, or by resetting it.
3. Initialize the DMA channel connected to fifo_tx_alarm. Every time the fifo_tx_alarm signal is high, the DMA should read <packetsize> 32-bit words from the main memory, and write them to the FIFO (typical packetsize is 8 32-bit words). Program the DMA such that it does not transfer more than <sectorsize> 32-bit words in total.
4. Write FIFO_SIZE - 2*<packetsize> to the FIFO alarm register. In this way, FIFO notifies the DMA when there is room for at least one additional packet. FIFO_SIZE is given in 16-bit halfwords: the typical value is 64 halfwords, or 128 bytes.
5. Prepare the PATA for a DMA transfer from host to device as follows:
   - Make sure the FIFO is out of reset by setting bit fifo_rst_b in the ata control register (see PATA interface control register (PATA_CONTROL)).
   - Program fifo_tx_en=1 in the PATA control register. This enables the FIFO to be filled by DMA.
   - Program dma_pending =1 and dma_write=1. Also, program ultra_mode_selected =0 (for MDMA) or ultra_mode_selected=1 (for UDMA).

Steps (1-5) have prepared the host side of the DMA.

6. Send commands to the drive in PIO mode that cause it to request DMA transfer on the PATA bus (consult the PATA specification for the specifics of this operation).
7. At this point, when the drive requests a DMA transfer by pulling ata_dmarq high, the PATA interface acknowledges with ata_dmack, and the transfer starts. Data is transferred automatically from the FIFO, and also from host memory to FIFO.
8. During the transfer, the host can monitor for end of transfer by reading some device PATA registers. These reads cause the running DMA to pause; after the read is completed, the DMA resumes. Alternatively, the host can wait unit the drive asserts ata_intrq, which also indicates end of transfer.

When the transfer ends, no additional FIFO manipulations are needed.

54.4 Initialization and Application of PATA

If the host asserts RESET the PATA device executes the hardware reset protocol, regardless of power management mode. For more details about the power-on and hardware reset protocol, refer to the PATA specification).

The host issues an IDENTIFY DEVICE command after the power-on reset or hardware reset protocol has been completed, in order to determine the current status of features implemented by the device.

54.5 Programmable Registers

This section contains the detailed register descriptions for the PATA registers.

The PATA interface works both in little-endian or big-endian mode. The addresses of all registers are the same in either mode. The 16-bit and 32-bit registers represent strings of 2 or 4 bytes. The byte order in the 16-bit or 32-bit register is dependent on the mode selection.

- Little-endian mode, 16- or 32-bit register:
  - bits [7:0]: byte 0
  - bits [15:8]: byte 1
  - bits [23:8]: byte 2
  - bits [31:24]: byte 3
- Big-endian mode, 32-bit register
  - bits [31:24]: byte 0

    - bits [23:16]: byte 1
    - bits [15:8]: byte 2
    - bits [7:0]: byte 3
- Big-endian, 16-bit register
    - bits [15:8]: byte 0
    - bits [7:0]: byte 1

The registers at offsets 0x00 through 0x17 contain timing parameters. These timing parameters control the timing on the PATA bus.

Every timing parameter is 8 bits wide and can assume valid values between 0x01 and 0xFF. The reset value for all registers is 0x01.

The three interrupt registers control the interrupt interface between the PATA block and the ARM platform/DMA. Two interrupts (ipbus_int and fifo_txfe_end_alarm) are controlled by these registers, as follows:

- The ipbus_int interrupt is controlled by bits 3,4,5 and 6 of the interrupt registers. It is asserted if one of the 4 bits is set in the interrupt_pending register, while the same bit is set in the interrupt_enable register. This interrupt goes to the ARM platform.
- The fifo_txfer_end_alarm interrupt is controlled by bit 7 of the interrupt registers. If ata_intrq1 is set in both the interrupt enable and interrupt pending register, then fifo_txfer_end_alarm is asserted. The purpose of this interrupt is to inform the DMA that the running data transfer has ended. This interrupt goes to the smart DMA.

PATA memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
5003_0000	Time Off register (PATA_TIME_OFF)	8	R/W	01h	54.5.1/ 3685

54.5.1 Time Off register (PATA_TIME_OFF)

Address: PATA_TIME_OFF is 5003_0000h base + 0h offset = 5003_0000h

Bit	7	6	5	4	3	2	1	0
Read / Write	TIME_OFF							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_OFF field descriptions

Field	Description
7–0 TIME_OFF	transceiver timing parameter. Controls toff

54.5.2 Time On register (PATA_TIME_ON)

Address: PATA_TIME_ON is 5003_0000h base + 1h offset = 5003_0001h

Bit	7	6	5	4	3	2	1	0
Read / Write	TIME_ON							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_ON field descriptions

Field	Description
7–0 TIME_ON	transceiver timing parameter. Controls ton

54.5.3 Time 1register (PATA_TIME_1)

Address: PATA_TIME_1 is 5003_0000h base + 2h offset = 5003_0002h

Bit	7	6	5	4	3	2	1	0
Read Write	TIME_1							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_1 field descriptions

Field	Description
7–0 TIME_1	PIO timing parameter. Controls t1

54.5.4 Time 2W register (PATA_TIME_2W)

Address: PATA_TIME_2W is 5003_0000h base + 3h offset = 5003_0003h

Bit	7	6	5	4	3	2	1	0
Read Write	TIME_2W							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_2W field descriptions

Field	Description
7–0 TIME_2W	PIO timing parameter. Controls t2 during write cycles

54.5.5 Time 2R register (PATA_TIME_2R)

Address: PATA_TIME_2R is 5003_0000h base + 4h offset = 5003_0004h

Bit	7	6	5	4	3	2	1	0
Read Write	TIME_2R							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_2R field descriptions

Field	Description
7–0 TIME_2R	PIO timing parameter. Controls t2 during read cycles

54.5.6 Time AX register (PATA_TIME_AX)

Address: PATA_TIME_AX is 5003_0000h base + 5h offset = 5003_0005h

Bit	7	6	5	4	3	2	1	0
Read Write	TIME_AX							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_AX field descriptions

Field	Description
7–0 TIME_AX	PIO timing parameter. Controls tA

54.5.7 Time PIO RDX register (PATA_TIME_PIO_RDX)

Address: PATA_TIME_PIO_RDX is 5003_0000h base + 6h offset = 5003_0006h

Bit	7	6	5	4	3	2	1	0
Read Write	TIME_RDX							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_PIO_RDX field descriptions

Field	Description
7–0 TIME_RDX	PIO timing parameter. Controls trd

54.5.8 Time 4 register (PATA_TIME_4)

Address: PATA_TIME_4 is 5003_0000h base + 7h offset = 5003_0007h

Bit	7	6	5	4	3	2	1	0
Read / Write	TIME_4							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_4 field descriptions

Field	Description
7–0 TIME_4	PIO timing parameter. Controls t4

54.5.9 Time 9 register (PATA_TIME_9)

Address: PATA_TIME_9 is 5003_0000h base + 8h offset = 5003_0008h

Bit	7	6	5	4	3	2	1	0
Read / Write	TIME_9							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_9 field descriptions

Field	Description
7–0 TIME_9	PIO timing parameter. Controls t9

54.5.10 Time M register (PATA_TIME_M)

Address: PATA_TIME_M is 5003_0000h base + 9h offset = 5003_0009h

Bit	7	6	5	4	3	2	1	0
Read / Write	TIME_M							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_M field descriptions

Field	Description
7–0 TIME_M	MDMA timing parameter. Controls tm

54.5.11 Time JN register (PATA_TIME_JN)

Address: PATA_TIME_JN is 5003_0000h base + Ah offset = 5003_000Ah

Bit	7	6	5	4	3	2	1	0
Read Write	TIME_JN							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_JN field descriptions

Field	Description
7–0 TIME_JN	MDMA timing parameter. Controls tn and tj

54.5.12 Time D register (PATA_TIME_D)

Address: PATA_TIME_D is 5003_0000h base + Bh offset = 5003_000Bh

Bit	7	6	5	4	3	2	1	0
Read Write	TIME_D							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_D field descriptions

Field	Description
7–0 TIME_D	MDMA timing parameter. Controls td

54.5.13 Time K register (PATA_TIME_K)

Address: PATA_TIME_K is 5003_0000h base + Ch offset = 5003_000Ch

Bit	7	6	5	4	3	2	1	0
Read / Write	TIME_K							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_K field descriptions

Field	Description
7–0 TIME_K	MDMA timing parameter. Controls tk

54.5.14 Time ACK register (PATA_TIME_ACK)

Address: PATA_TIME_ACK is 5003_0000h base + Dh offset = 5003_000Dh

Bit	7	6	5	4	3	2	1	0
Read / Write	TIME_ACK							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_ACK field descriptions

Field	Description
7–0 TIME_ACK	UDMA timing parameter. Controls tack

54.5.15 Time ENV register (PATA_TIME_ENV)

Address: PATA_TIME_ENV is 5003_0000h base + Eh offset = 5003_000Eh

Bit	7	6	5	4	3	2	1	0
Read / Write	TIME_ENV							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_ENV field descriptions

Field	Description
7–0 TIME_ENV	UDMA timing parameter. Controls tenv

54.5.16 Time RPX register (PATA_TIME_RPX)

Address: PATA_TIME_RPX is 5003_0000h base + Fh offset = 5003_000Fh

Bit	7	6	5	4	3	2	1	0
Read Write	TIME_RPX							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_RPX field descriptions

Field	Description
7–0 TIME_RPX	UDMA timing parameter. Controls trp

54.5.17 Time ZAH register (PATA_TIME_ZAH)

Address: PATA_TIME_ZAH is 5003_0000h base + 10h offset = 5003_0010h

Bit	7	6	5	4	3	2	1	0
Read Write	TIME_ZAH							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_ZAH field descriptions

Field	Description
7–0 TIME_ZAH	UDMA timing parameter. Controls tzah

54.5.18 Time MLIX register (PATA_TIME_MLIX)

Address: PATA_TIME_MLIX is 5003_0000h base + 11h offset = 5003_0011h

Bit	7	6	5	4	3	2	1	0
Read / Write	TIME_MLIX							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_MLIX field descriptions

Field	Description
7–0 TIME_MLIX	UDMA timing parameter. Controls tmli

54.5.19 Time DVH register (PATA_TIME_DVH)

Address: PATA_TIME_DVH is 5003_0000h base + 12h offset = 5003_0012h

Bit	7	6	5	4	3	2	1	0
Read / Write	TIME_DVH							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_DVH field descriptions

Field	Description
7–0 TIME_DVH	UDMA timing parameter. Controls tdvh

54.5.20 Time DZFS register (PATA_TIME_DZFS)

Address: PATA_TIME_DZFS is 5003_0000h base + 13h offset = 5003_0013h

Bit	7	6	5	4	3	2	1	0
Read / Write	TIME_DZFS							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_DZFS field descriptions

Field	Description
7–0 TIME_DZFS	UDMA timing parameter. Controls tdzfs

54.5.21 Time DVS register (PATA_TIME_DVS)

Address: PATA_TIME_DVS is 5003_0000h base + 14h offset = 5003_0014h

Bit	7	6	5	4	3	2	1	0
Read Write	TIME_DVS							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_DVS field descriptions

Field	Description
7–0 TIME_DVS	UDMA timing parameter. Controls tdvs

54.5.22 Time CVH register (PATA_TIME_CVH)

Address: PATA_TIME_CVH is 5003_0000h base + 15h offset = 5003_0015h

Bit	7	6	5	4	3	2	1	0
Read Write	TIME_CVH							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_CVH field descriptions

Field	Description
7–0 TIME_CVH	UDMA timing parameter. Controls tcvh

54.5.23 Time SS register (PATA_TIME_SS)

Address: PATA_TIME_SS is 5003_0000h base + 16h offset = 5003_0016h

Bit	7	6	5	4	3	2	1	0
Read / Write	TIME_SS							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_SS field descriptions

Field	Description
7–0 TIME_SS	UDMA timing parameter. Controls tss

54.5.24 Time CYC register (PATA_TIME_CYC)

Address: PATA_TIME_CYC is 5003_0000h base + 17h offset = 5003_0017h

Bit	7	6	5	4	3	2	1	0
Read / Write	TIME_CYC							
Reset	0	0	0	0	0	0	0	1

PATA_TIME_CYC field descriptions

Field	Description
7–0 TIME_CYC	UDMA timing parameter. Controls tcyc and t2cyc

54.5.25 FIFO Data register 32-bit (PATA_FIFO_DATA_32)

The FIFO_DATA register is used to read or write data to' the internal FIFO. It can be accessed as a 16-bit register or as a 32-bit register. Word writes (respectively long writes) put two bytes (respectively four bytes) into the FIFO. Word reads (respectively long reads) read two bytes (respectively four bytes) from the FIFO.

Address: PATA_FIFO_DATA_32 is 5003_0000h base + 18h offset = 5003_0018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R / W	FIFO_DATA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PATA_FIFO_DATA_32 field descriptions

Field	Description
31–0 FIFO_DATA	32 bit wide data port to/from FIFO

54.5.26 FIFO Data register 16-bit (PATA_FIFO_DATA_16)

The FIFO_DATA register is used to read or write data to the internal FIFO. It can be accessed as a 16-bit register or as a 32-bit register. Word writes (respectively long writes) put two bytes (respectively four bytes) into the FIFO. Word reads (respectively long reads) read two bytes (respectively four bytes) from the FIFO.

Address: PATA_FIFO_DATA_16 is 5003_0000h base + 1Ch offset = 5003_001Ch

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	FIFO_DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PATA_FIFO_DATA_16 field descriptions

Field	Description
15–0 FIFO_DATA	16 bit wide data port to/from FIFO

54.5.27 FIFO FILL register (PATA_FIFO_FILL)

FIFO_FILL is a read-only register. Any read returns the current number of halfwords present in the FIFO.

Address: PATA_FIFO_FILL is 5003_0000h base + 20h offset = 5003_0020h

Bit	7	6	5	4	3	2	1	0
Read	FIFO_FILL							
Write								
Reset	0	0	0	0	0	0	0	0

PATA_FIFO_FILL field descriptions

Field	Description
7–0 FIFO_FILL	FIFO filling in halfwords

54.5.28 PATA interface control register (PATA_CONTROL)

Address: PATA_CONTROL is 5003_0000h base + 24h offset = 5003_0024h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	-								fifo_rst_b	ata_rst_b	fifo_tx_en	fifo_rcv_en	dma_pending	dma_ultra_selected	dma_write	iordy_en
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PATA_CONTROL field descriptions

Field	Description
15–8 -	Reserved.
7 fifo_rst_b	This field controls the internal FIFO reset 0 FIFO reset 1 FIFO normal operation
6 ata_rst_b	This bit controls the level on the ata_reset_b pin, which controls the reset of the internal PATA protocol engine. 0 ata_reset_b = 0, PATA drive is reset, and internal protocol engine reset. 1 ata_reset_b = 1, PATA drive is not reset; internal protocol engine normal operation.
5 fifo_tx_en	FIFO transmit enable. This bit controls whether the FIFO makes transmit data requests to the DMA. If enabled, the FIFO requests the DMA to refill it whenever the FIFO level drops below the alarm threshold. 0 FIFO refill by DMA disabled 1 FIFO refill by DMA enabled
4 fifo_rcv_en	FIFO receive enable. This bit controls whether the FIFO makes receive data requests to the DMA. If enabled, the FIFO requests the DMA to empty it whenever the FIFO level meets or exceeds the alarm threshold. 0 FIFO empty by DMA disabled 1 FIFO empty by DMA enabled
3 dma_pending	DMA pending bit. This bit controls whether the PATA interface responds to a DMA request originating in the drive. If this bit is set, the PATA interface starts a MDMA or UDMA burst whenever the drive asserts the ata_dmarq signal. 0 PATA interface does not start DMA burst 1 PATA interface starts MDMA or UDMA burst whenever drive asserts dmarq
2 dma_ultra_selected	This bit determines the protocol (UDMA or MDMA) for any new DMA burst 1 UDMA protocol is used 0 MDMA protocol is used
1 dma_write	This bit determines the data direction on any new DMA burst

Table continues on the next page...

PATA_CONTROL field descriptions (continued)

Field	Description
	1 DMA out burst, PATA interface writes to drive 0 DMA in burst, PATA interface reads from drive
0 iordy_en	This bit determines whether ata_iordy handshake is used during PIO mode 1 IORDY handshake is used 0 IORDY is disregarded

54.5.29 Interrupt pending register (PATA_INTERRUPT_PENDING)

Address: PATA_INTERRUPT_PENDING is 5003_0000h base + 28h offset = 5003_0028h

Bit	7	6	5	4	3	2	1	0
Read	ata_intrq1	fifo_ underflow	fifo_overflow	controller_idle	ata_intrq2	Reserved		
Write								
Reset	0	0	0	1	0	0	0	0

PATA_INTERRUPT_PENDING field descriptions

Field	Description
7 ata_intrq1	PATA interrupt request 1. This bit reflects the value of the ata_intrq interrupt input. It is set in the when the drive interrupt is pending, and cleared otherwise. The interrupt clear register has no influence on this bit.
6 fifo_underflow	FIFO underflow. This bit reports FIFO underflow. Sticky bit. It is set when there is a FIFO underflow condition. It is cleared by writing a '1' to this bit in the interrupt clear register.
5 fifo_overflow	FIFO overflow. This bit reports FIFO overflow. Sticky bit. It is set when there is a FIFO overflow condition. It is cleared by writing a '1' to this bit in the interrupt clear register.
4 controller_idle	Controller Idle. This bit reports controller idle. It is set when the PATA protocol engine is idle, there is no activity on the PATA bus. It is cleared when there is activity on the PATA bus. The interrupt clear register has no influence on this bit.
3 ata_intrq2	PATA interrupt request 2. This bit reflects the value of the ata_intrq interrupt input. It is set when the drive interrupt is pending, and cleared otherwise. It has exactly same functioning as ata_intrq1, but this bit affects ipbus_int, while the other affects interrupt to the DMA.
2–0 Reserved	This field is reserved. -

54.5.30 Interrupt enable register (PATA_INTERRUPT_ENABLE)

Address: PATA_INTERRUPT_ENABLE is 5003_0000h base + 2Ch offset = 5003_002Ch

Bit	7	6	5	4	3	2	1	0
Read	ata_intrq1	fifo_ underflow	fifo_overflow	controller_idle	ata_intrq2	Reserved		
Write								
Reset	0	0	0	0	0	0	0	0

PATA_INTERRUPT_ENABLE field descriptions

Field	Description
7 ata_intrq1	PATA interrupt request 1. If this bit is set, then fifo_txfer_end_alarm is driven to the DMA when the corresponding bit is set in the interrupt enable register. This informs the DMA that the current transfer is finished. The interrupt clear register has no influence on this bit.
6 fifo_underflow	FIFO underflow. If this bit is set, then ipbus_int is driven to the ARM platform when the corresponding bit is set in the interrupt enable register.
5 fifo_overflow	FIFO overflow. If this bit is set, then ipbus_int is driven to the ARM platform when the same bit is set in the interrupt enable register.
4 controller_idle	Controller Idle. If this bit is set, then ipbus_int is driven to the ARM platform when the same bit is set in the interrupt enable register. The interrupt clear register has no influence on this bit.
3 ata_intrq2	PATA interrupt request 2. This bit reflects the value of the ata_intrq interrupt input. If this bit is set, then ipbus_int is driven to the ARM platform when the same bit is set in the interrupt enable register. This informs the ARM platform that the drive is requesting attention. The interrupt clear register has no influence on this bit.
2–0 Reserved	This field is reserved. -

54.5.31 Interrupt clear register (PATA_INTERRUPT_CLEAR)

Address: PATA_INTERRUPT_CLEAR is 5003_0000h base + 30h offset = 5003_0030h

Bit	7	6	5	4	3	2	1	0
Read	Reserved			Reserved				
Write		fifo_ underflow	fifo_overflow					
Reset	0	0	0	0	0	0	0	0

PATA_INTERRUPT_CLEAR field descriptions

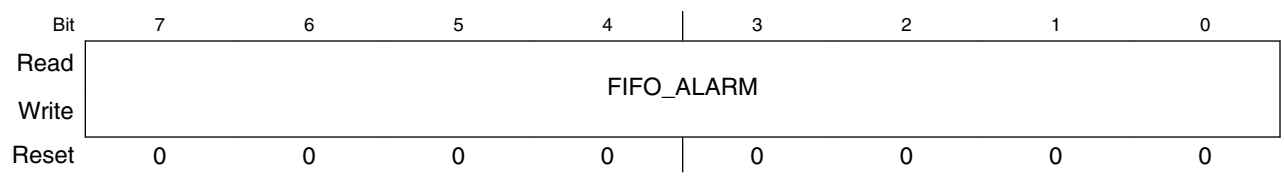
Field	Description
7 Reserved	This field is reserved. -
6 fifo_underflow	FIFO underflow. Writing '1' to this bit clears the corresponding bit in the interrupt pending register.
5 fifo_overflow	FIFO overflow. Writing '1' to this bit clears the corresponding bit in the interrupt pending register.
4–0 Reserved	This field is reserved. -

54.5.32 FIFO ALARM register (PATA_FIFO_ALARM)

This register contains the threshold (in 16-bit halfword units) which triggers fifo_rcv_alarm or fifo_tx_alarm signals to the DMA interface.

- If the fifo_rcv_en bit is set in the PATA control register and fifo_fill ≥ fifo_alarm, then the fifo_rcv_alarm signal is asserted to request the DMA to empty the FIFO.
- If the fifo_tx_en bit is set in the PATA control register and fifo_fill < fifo_alarm), then the fifo_tx_alarm signal is asserted to request the DMA to refill the FIFO.

Address: PATA_FIFO_ALARM is 5003_0000h base + 34h offset = 5003_0034h



PATA_FIFO_ALARM field descriptions

Field	Description
7–0 FIFO_ALARM	FIFO alarm threshold

54.5.33 Drive Registers Connected to PATA Bus

Some drive registers are addressable, but are not present in the PATA interface block. These are listed in Table 54-41. If a read or write access is made to one of these registers, the read or write is mapped to a PIO read or write cycle on the PATA bus, and the corresponding register in the device attached to the PATA bus is accessed. No description of these registers is given here-consult the PATA specification for information on these registers.

If the drive_dataregister is accessed while the PATA interface operates in big-endian mode, the bytes to/from the PATA bus are swapped. No swaps occur in little-endian mode, or for the other registers.

Table 54-41. Drive Registers connected to PATA Bus

Address	Name	Description	Access
Offset: A0 (DRIVE_DATA)	drive_data	Drive data register	R/W
Offset: A4 (DRIVE_FEATURES)	drive_features	Drive features register	R/W
Offset: A8 (DRIVE_SECTOR_ COUNT)	drive_sector_coun t	Drive sector count register	R/W
Offset: AC (DRIVE_SECTOR_ NUM)	drive_sector_num	Drive sector number register	R/W
Offset: B0 (DRIVE_CYL_LOW)	drive_cyl_low	Drive cylinder low register	R/W
Offset: B4 (DRIVE_CYL_HIGH)	drive_cyl_high	Drive cylinder high register	R/W
Offset: B8 (DRIVE_DEV_HEAD)	drive_dev_head	Drive device head register	R/W
Offset: BC (DRIVE_COMMAND)	drive_command	Drive command register	W
Offset: BC (DRIVE_STATUS)	drive_status	Drive status register	R
Offset: D8 (DRIVE_ALT_STATUS)	drive_alt_status	Drive alternate status register	R
Offset: D8 (DRIVE_CONTROL)	drive_control	Drive control register	W

Chapter 55
Power Fail Detector (PFD)

55.1 Introduction

Figure 55-1 shows the block diagram of PFD.

55.1.1 Overview

The PFD is a sub-block of the Secure Real Time Clock (SRTC). PFD circuit generates a reset signal till its supply vdd reaches a predetermined voltage level.The PFD circuit works only when the chip is in the Non-DSM mode. This means that when DSM is asserted high then there is no activity on the Power_Fail line and it is pulled high by the logic in the circuit. The back bone of the circuit is the resistance ladder and an inverter (shown as detector in Figure 55-1). The input to the inverter comes from one of the tap points in the resistance ladder.

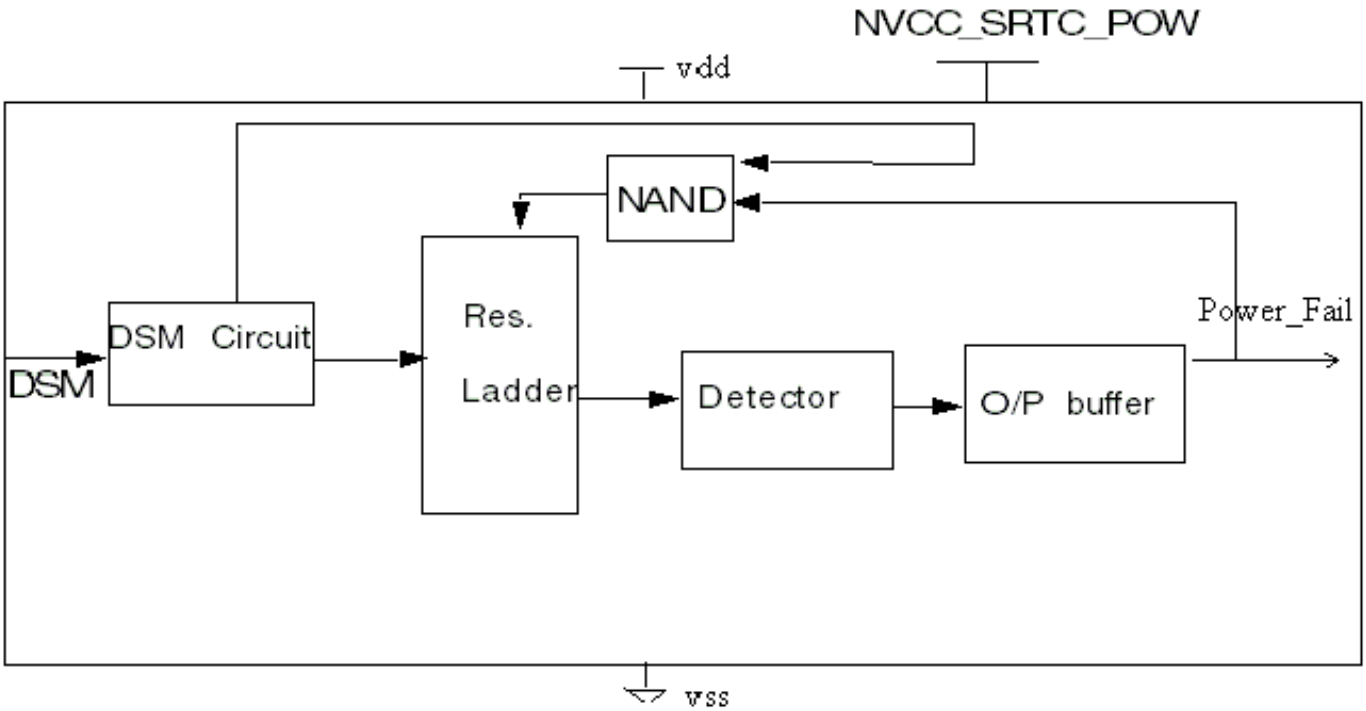


Figure 55-1. PFD Block Diagram

55.1.1.1 Assumptions

The NVCC_SRTC_POW voltage supply is nominally 1.2V. However, the PFD circuit has been simulated taking into account a 50mV variation in the NVCC_SRTC_POW voltage. With a 50mV variation on this supply, the threshold voltage levels at the same PVT corner exhibit a 35mV variation.

55.1.2 Features

The PFD has the following features:

- De-assertion voltage independent of vdd ramp-up rate
- Very Low current consumption
- Brown Out (BO) voltage independent of vdd ramp-down rate
- Negligible variation in threshold over Process, Voltage and Temperature (PVT) variations

55.1.3 Modes of Operation

There are three basic modes of operation: LPM, HPM and DSM. In the DSM mode, the PFD circuit does not function and the logic in the circuit ensures that the Power_Fail output is pulled high.

In the LPM and the HPM mode the PFD circuit functions as follows:

The PFD generates a Power_Fail active low pulse when the chip is powering up. When vdd ramps up and reaches a pre-determined threshold then the output signal Power_Fail goes low (meaning that there is no Power Failure at this time)

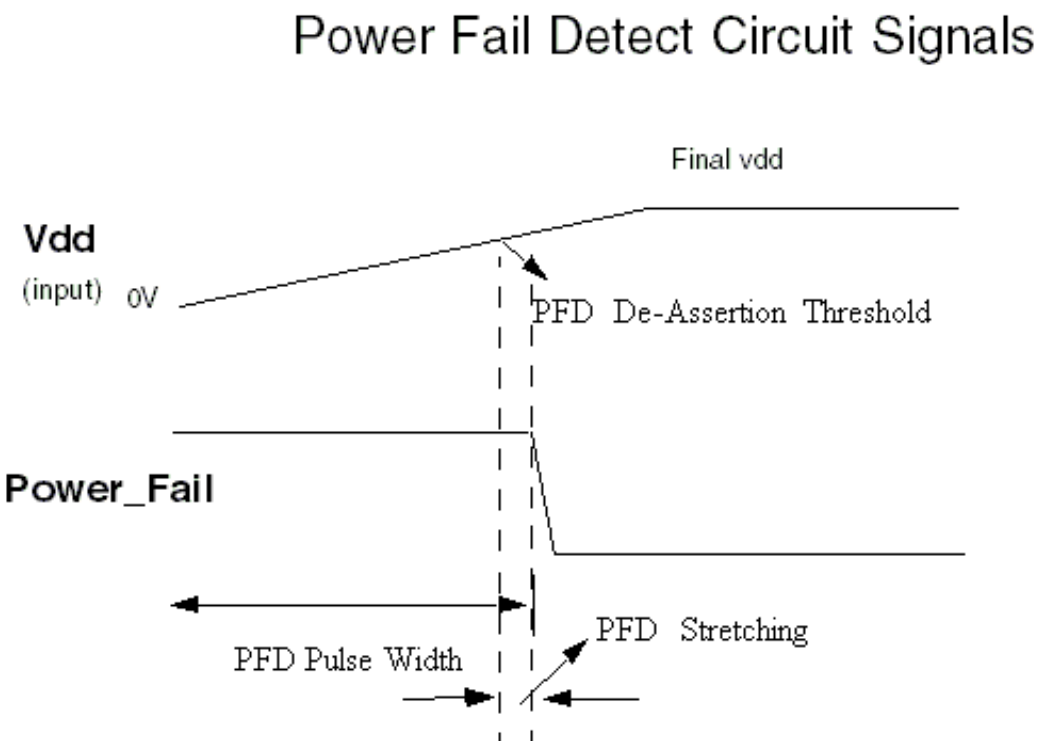

Figure 55-2. Power_Fail De-Assert Detection

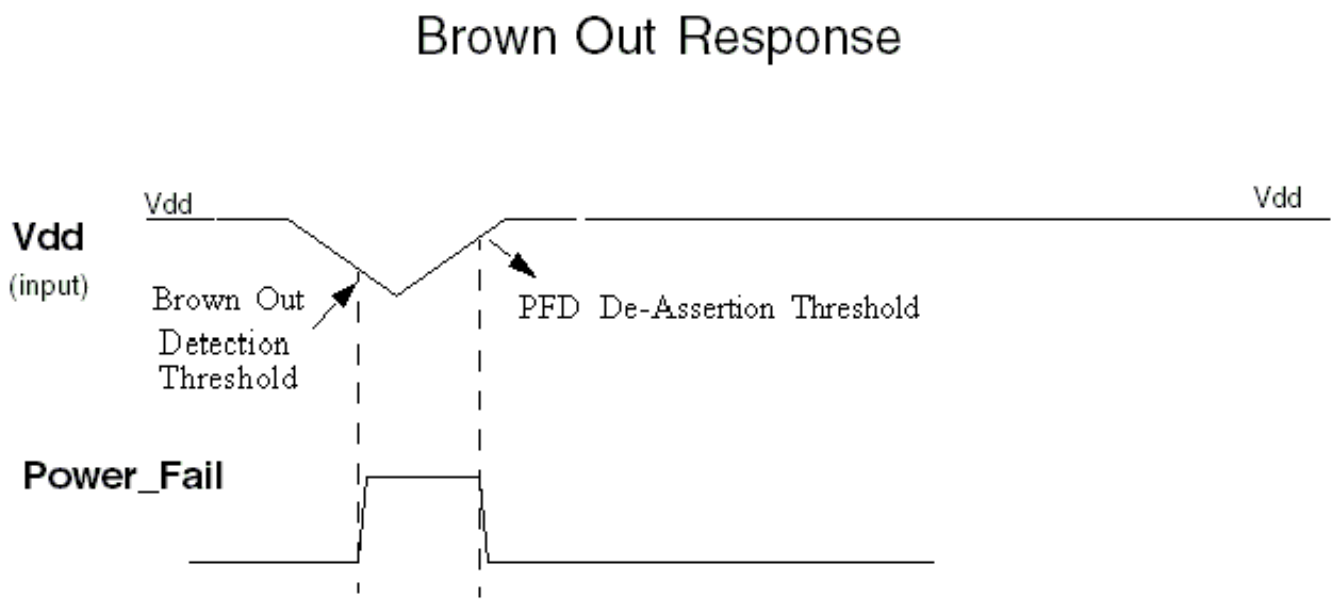

Figure 55-3. Power_Fail Brown-Out Detection

When a glitch appears in vdd and the supply goes below the Brown-Out (BO) voltage, then the output signal Power_Fail goes high.

The following table shows the various modes of operation of PFD and the behavior of Power_Fail output in these modes.

Table 55-1. Modes of Operation of PFD

DSM	LPM/HPM	vdd	Power_Fail
1	0	X	1
0	1	>0.8V	0
0	1	<0.8V	1

The PFD circuit design has been centred around the typical process corner, where the De-Assert threshold is 824mV and the BO threshold is 798mV. The De-Assert threshold at best process corner and worst process corners are 814mV and 835mVrespectively. Similarly the BO threshold at best process corner and worst process corners are 788mVand 809mVrespectively. Hence, the total variation in the De-Assert threshold around the mean value is 21mV, and that in the BO threshold is 21mV.

55.2 Functional Description

The PFD circuit will provide a LOW Power_Fail output upon power up. The Power Fail Detect Circuit has two power supplies namely, vdd and NVCC_SRTC_POW. The inverters and the buffers that are operational in the non-DSM mode work on the NVCC_SRTC_POW supply which is the always-ON supply for the chip. The 'vdd' supply has to be detected.

This circuit can be divided into the following parts:

- Resistance ladder
- A Detection inverter
- Brown-out detection
- Pulse Stretcher
- DSM circuitry

55.2.1 Resistance Ladder

The Resistance ladder is connected to vdd through two pmos switches and to vss directly. One of the two pmos switches is always kept on and hence there is a direct path current flowing from vdd to vss in all states of operation. During vdd ramping up, the voltages at the tapping points of the resistance ladder also start ramping up.

55.2.2 Detection Inverter

The detection inverter detects the voltage at one of the tapping points and changes its state when the vdd voltage has risen high enough to cause the tripping of this inverter. The sizing of this inverter and the inputs are selected so as to meet the "de-assert" threshold spec at all corners. Once the detection inverter trips, the output Power_fail is pulled low ensuring that we have reached a NO power failure state.

55.2.3 Brown-Out Detection

The Brown-Out is also detected through the same inverter that detects "de-assertion". Only difference is that now the second switch that connects to the resistance ladder also turns on, thus lowering the threshold for Brown-Out. This ensures that De-assert and Brown-Out have a minimum hysteresis between them.

55.2.4 Pulse Stretcher/Output Buffer

The buffer in the circuit ensures that the Power_Fail meets the specification for minimum pulse width at all corners.

55.2.5 DSM Circuitry

The NAND gate and the inverters that use vdd as their supply constitute the DSM circuitry. When DSM=High then the resistance ladder is OFF and input to the detection inverter is LOW and its output is HIGH. This ensures that Power_Fail is also HIGH and there is no current consumption through the PFD circuit.

55.3 Initialization/Application Information

The PFD does not contain nor access any memory map data or registers.

Chapter 56
PL301 4x1 AXI Arbiter (PLARB1)

56.1 Overview

This section provides an overview of the PL301_4x1 AXI Arbiter (PLARB1). The PL301 HPM (High Performance Matrix - by ARM Ltd.) is a configurable AXI arbiter between several interconnected masters and slaves, and is based on a standard configurable PrimeCell. The PLARB1 is designed such that many configuration options are selected at the HW design stage, determined by SoC characteristics and needs, while several other configuration options are SW controlled. This chapter covers the specific features enabled for this PLARB1 instance.

The top level diagram of PLARB1 is shown in the following block diagram.

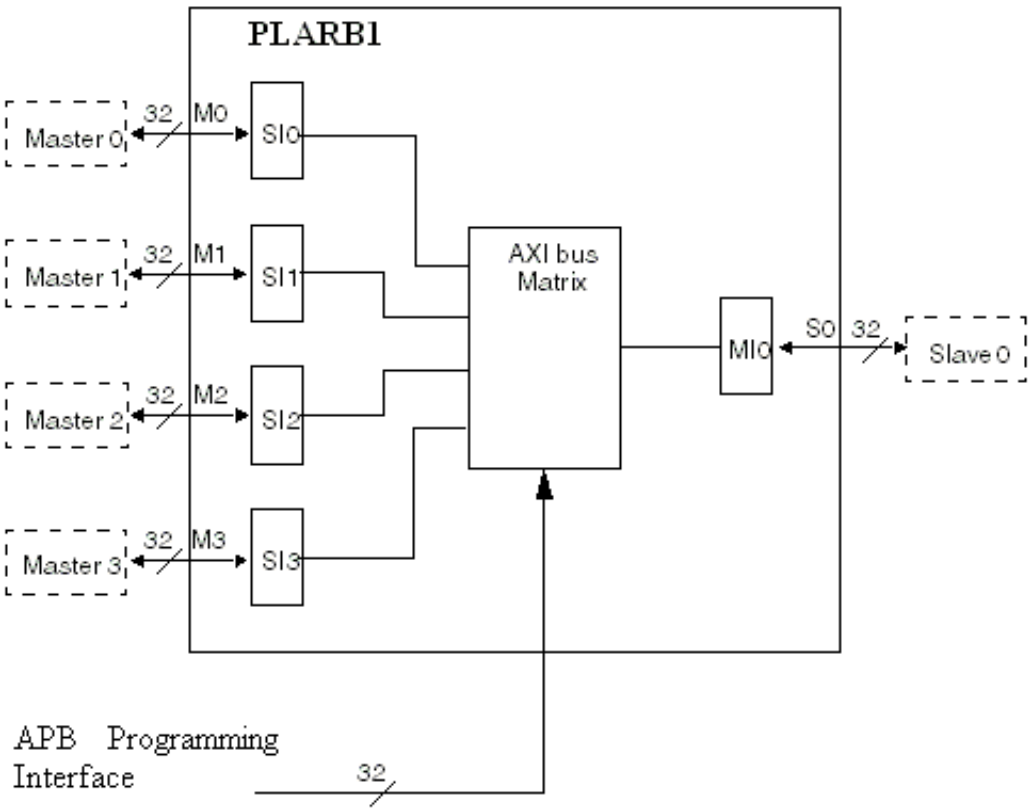

Figure 56-1. i.MX53 PLARB1 Block Diagram

56.1.1 System Connectivity

Masters and slaves of PLARB1:

- M0 - Coming from Burst-DMA port of SDMA
- M1 - FEC
- M2 - SATA
- M3 - MLB
- The S0 slave port of the PLARB is connected to M4 input of EMI (M4IF)

56.1.2 Features

Key features of the PLARB1 include:

- Support programmable Round Robin (Prog_RR) arbitration scheme with 16 slots on MI0 port
- All interfaces are 'Synchronous' with the core AXI arbiter

- "Single Slave" Cyclic Avoidance scheme
- APB interface for programming configuration / control registers
- Not supporting access interleaving
- Provide one buffer for Read and one for Write accesses on all slave interfaces, and a four (4) registers on the MI0 master interface. (The FIFO depth is one on all slave ports. Because the PLARB1 is designed for AHB masters arbitration, which could only have one active transaction at a time).

56.1.3 Modes and Operations

The PLARB1 supports a normal functional mode, as described in Normal Mode.

56.2 External Signals

There are no external I/O interfaces.

56.3 Programmable Registers

PLARB1 memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FE_0408	PLARB1 AR Programmable RR Arbitration Configuration for MI0 (PLARB1_RAC_MI0)	32	R/W	0000_0000h	56.3.1/ 3710

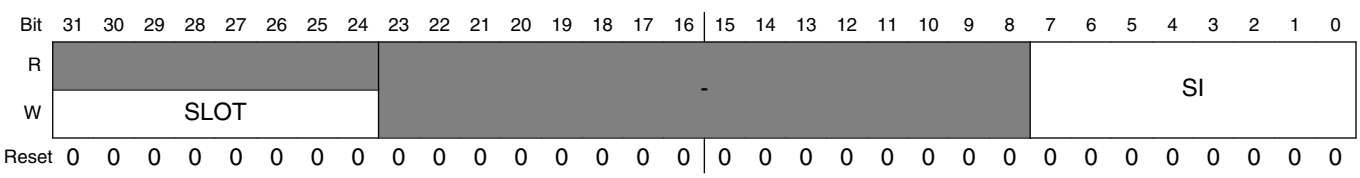
56.3.1 PLARB1 AR Programmable RR Arbitration Configuration for MI0 (PLARB1_RAC_MI0)

This register configures the slots that implement the Programmable Round Robin (prog_rr) scheme. See Programmable Round Robin (Prog_RR) Scheme for detailed algorithmic descriptions. The arbitration schemes are configured, programmed, and interrogated on a per-master-interface basis. The per-master-interface address space is at offset 0x400. The interfaces are spaced at 0x20 intervals from this base. The arbitration register address within the individual interface's space is further partitioned as:

a) the read channel, located at offset 0x8.

b) the write channel, at offset 0xC.

Address: PLARB1_RAC_MI0 is 63FE_0000h base + 408h offset = 63FE_0408h



PLARB1_RAC_MI0 field descriptions

Field	Description
31–24 SLOT	Contains the slot where data is to be written. For preliminary read operations, these bits are 0xFF. For rest of the read operations, their value is 0x00.

Table continues on the next page...

PLARB1_RAC_MI0 field descriptions (continued)

Field	Description
	NOTE: A write operation must be followed by a read operation to the same address. The write transfer sets the slot number to be read for that master interface. A read operation with 31:24 bits set to 0xFF returns the slave interface that is associated with that slot number.
23–8 -	Reserved.
7–0 SI	These bits set the slot number for the following read operation. It holds the encoded slave interface number associated with the addressed slot number. **NOTE:** The format of the read data returned has the slave interface number associated with the addressed slot in bits [7:0]. All other bits are set to zero. — — — 3 SATA

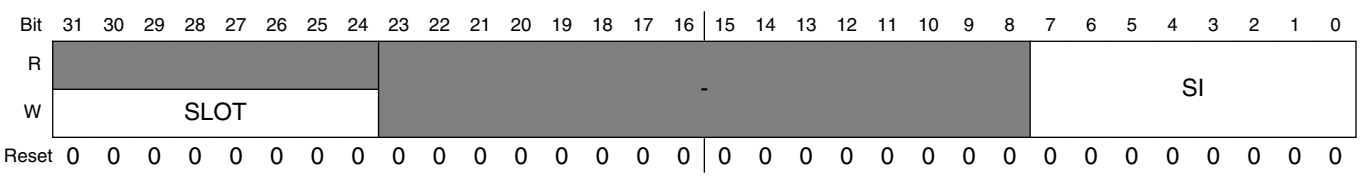
56.3.2 PLARB1 AW Programmable RR Arbitration Configuration for MI0 (PLARB1_WAC_MI0)

This register configures the slots that implement the Programmable Round Robin (prog_rr) scheme. See Programmable Round Robin (Prog_RR) Scheme for detailed algorithmic descriptions. The arbitration schemes are configured, programmed, and interrogated on a per-master-interface basis. The per-master-interface address space is at offset 0x400. The interfaces are spaced at 0x20 intervals from this base. The arbitration register address within the individual interface's space is further partitioned as:

a) the read channel, located at offset 0x8.

b) the write channel, at offset 0xC.

Address: PLARB1_WAC_MI0 is 63FE_0000h base + 40Ch offset = 63FE_040Ch



PLARB1_WAC_MI0 field descriptions

Field	Description
31–24 SLOT	The bits define the slot for which the data is to be written. There must be at least one slot per connected slave interface.When the programmable RR scheme is selected for a master interface, then, each of its arbitration slots can have the slave interface associated with it changed. For PLARB1 the slot configuration is as follow: • MI0 - 16 slots exists, default order of: 0, 1, 2, 3, 0, 1, 2, 3, 0, 1, 2, 3, 0, 1, 2, 3.

Table continues on the next page...

PLARB1_WAC_MI0 field descriptions (continued)

Field	Description
	NOTE: If these bits contain the master interface slot number, (while assigning the bits for writing Master Interface Channel Arbitration Values) then bits 7:0 contains the corresponding Slave Interface Number.
23–8 -	Reserved
7–0 SI	The encoded slave interface number. **NOTE:** No protection is imposed when you program the slots in the programmable RR arbitration scheme. So it is possible for you to remove a slave interface from all the slots which would make that slave interface inaccessible. — — — 3 SATA

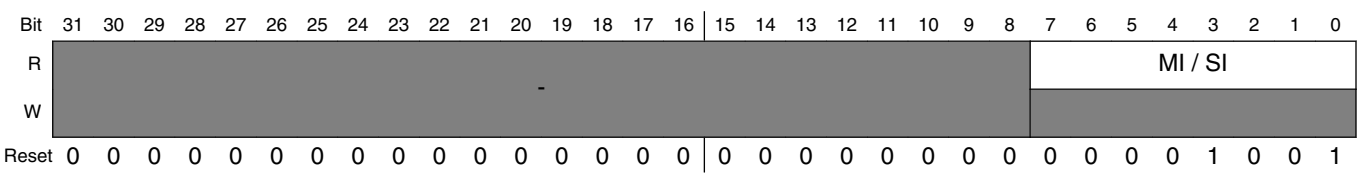
56.3.3 PLARB1 Configuration Register 0 (PLARB1_CR)

These are four 32-bit read-only registers at address 0xFC0-0xFCC. The register at:

- 0xFC0 is hard-coded and identifies how many SI's are configured in the PLARB1.
- 0xFC4 is hard-coded and identifies how many MI's are configured in the PLARB1.

The registers at 0xFC8 and 0xFCC read as zeros.

Address: PLARB1_CR is 63FE_0000h base + FC0h offset = 63FE_0FC0h



PLARB1_CR field descriptions

Field	Description
31–8 -	Reserved.
7–0 MI / SI	The total number of master/slave interfaces configured for the PLARB1. 0x0 Reserved 0x1 One MI / SI 0x2 Two MI's / SI's 0x3 Three MI's / SI's 0x20 32 MI's / SI's 0x21 0xFF Reserved

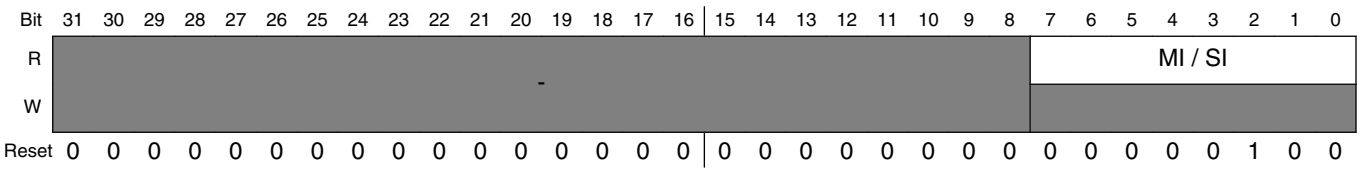
56.3.4 PLARB1 Configuration Register 1 (PLARB1_CR)

These are four 32-bit read-only registers at address 0xFC0-0xFCC. The register at:

- 0xFC0 is hard-coded and identifies how many SI's are configured in the PLARB1.
- 0xFC4 is hard-coded and identifies how many MI's are configured in the PLARB1.

The registers at 0xFC8 and 0xFCC read as zeros.

Address: PLARB1_CR is 63FE_0000h base + FC4h offset = 63FE_0FC4h



PLARB1_CR field descriptions

Field	Description
31–8 -	Reserved.
7–0 MI / SI	The total number of master/slave interfaces configured for the PLARB1. 0x0 Reserved 0x1 One MI / SI 0x2 Two MI's / SI's 0x3 Three MI's / SI's 0x20 32 MI's / SI's 0x21 0xFF Reserved

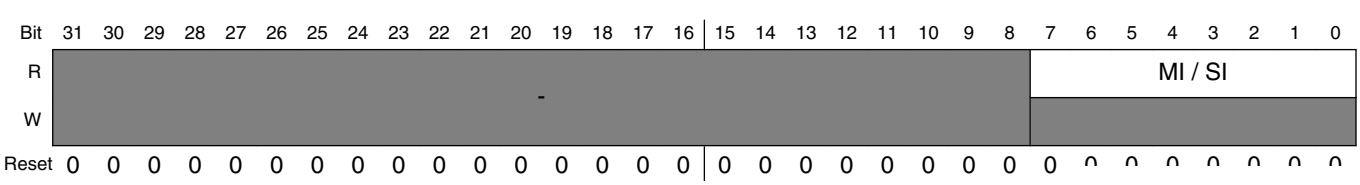
56.3.5 PLARB1 Configuration Register n (PLARB1_CR*n*)

These are four 32-bit read-only registers at address 0xFC0-0xFCC. The register at:

- 0xFC0 is hard-coded and identifies how many SI's are configured in the PLARB1.
- 0xFC4 is hard-coded and identifies how many MI's are configured in the PLARB1.

The registers at 0xFC8 and 0xFCC read as zeros.

Addresses: PLARB1_CR2 is 63FE_0000h base + FC8h offset = 63FE_0FC8h
PLARB1_CR3 is 63FE_0000h base + FCCh offset = 63FE_0FCCh



PLARB1_CR*n* field descriptions

Field	Description
31–8 -	Reserved.
7–0 MI / SI	The total number of master/slave interfaces configured for the PLARB1. 0x0 Reserved 0x1 One MI / SI 0x2 Two MI's / SI's 0x3 Three MI's / SI's 0x20 32 MI's / SI's 0x21 0xFF Reserved

56.3.6 PLARB1 Peripheral ID Register 0 (PLARB1_PID0)

The register is hard-coded.

Address: PLARB1_PID0 is 63FE_0000h base + FE0h offset = 63FE_0FE0h

Bit	7	6	5	4	3	2	1	0
Read	PART0							
Write								
Reset	0	0	0	0	0	0	0	0

PLARB1_PID0 field descriptions

Field	Description
7–0 PART0	These bits read back as 0x01.

56.3.7 PLARB1 Peripheral ID Register 1 (PLARB1_PID1)

The register is hard-coded.

Address: PLARB1_PID1 is 63FE_0000h base + FE4h offset = 63FE_0FE4h

Bit	7	6	5	4	3	2	1	0
Read	DES0				PART1			
Write								
Reset	0	0	0	1	0	1	0	0

PLARB1_PID1 field descriptions

Field	Description
7–4 DES0	These bits read back as 0x1.
3–0 PART1	These bits read back as 0x3.

56.3.8 PLARB1 Peripheral ID Register 2 (PLARB1_PID2)

The register is hard-coded.

Address: PLARB1_PID2 is 63FE_0000h base + FE8h offset = 63FE_0FE8h

Bit	7	6	5	4	3	2	1	0
Read	REV				PART1			
Write								
Reset	0	0	0	1	0	0	1	1

PLARB1_PID2 field descriptions

Field	Description
7–4 REV	These bits read back as the revision number. This can be between 0 and 15: 0x3 r1p2
3–0 PART1	These bits read back as 0x04.

56.3.9 PLARB1 Peripheral ID Register 3 (PLARB1_PID3)

The register is hard-coded.

Address: PLARB1_PID3 is 63FE_0000h base + FECh offset = 63FE_0FECh

Bit	7	6	5	4	3	2	1	0
Read	-				-			
Write								
Reset	0	0	0	0	0	0	0	1

PLARB1_PID3 field descriptions

Field	Description
7–4 -	Reserved
3–0 -	Reserved, read as 0x0

56.3.10 PLARB1 ID Register 0 (PLARB1_ID0)

The register is hard-coded.

Address: PLARB1_ID0 is 63FE_0000h base + FF0h offset = 63FE_0FF0h

Bit	7	6	5	4	3	2	1	0
Read	ID							
Write								
Reset	0	0	0	0	1	1	0	1

PLARB1_ID0 field descriptions

Field	Description
7–0 ID	These bits read back 0x0D

56.3.11 PLARB1 ID Register 1 (PLARB1_ID1)

The register is hard-coded.

Address: PLARB1_ID1 is 63FE_0000h base + FF4h offset = 63FE_0FF4h

Bit	7	6	5	4	3	2	1	0
Read	ID							
Write								
Reset	1	1	1	1	0	0	0	0

PLARB1_ID1 field descriptions

Field	Description
7–0 ID	These bits read back 0xF0

56.3.12 PLARB1 ID Register 2 (PLARB1_ID2)

The register is hard-coded.

Address: PLARB1_ID2 is 63FE_0000h base + FF8h offset = 63FE_0FF8h

Bit	7	6	5	4	3	2	1	0
Read	ID							
Write								
Reset	0	0	0	0	0	1	0	1

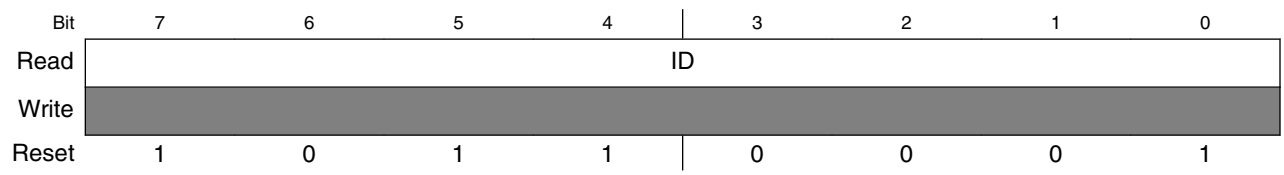
PLARB1_ID2 field descriptions

Field	Description
7–0 ID	These bits read back 0x05

56.3.13 PLARB1 ID Register 3 (PLARB1_ID3)

The register is hard-coded.

Address: PLARB1_ID3 is 63FE_0000h base + FFCh offset = 63FE_0FFCh



PLARB1_ID3 field descriptions

Field	Description
7–0 ID	These bits read back 0xB1

56.4 Functional Description

The PLARB1 is an interconnect consists of a high-performance AXI cross-bar switch and related auxiliary components that supports 4 external masters to a single slaves arbitration logic.

56.4.1 Normal Mode

The PLARB1 is an interconnect that provides the means for master transactions initiated by a master to reach the intended slave in a multi-master and multi-slave AXI environment.

56.4.2 Operations

The PLARB1 supports the "Single Slave" cyclic schemes to avoid possible deadlock. The scheme is determined at the hardware level, per PLARB1 salve interfaces (SI's) and cannot be changed by the software.

Please refer to Cyclic Dependency Avoidance Scheme (CDAS) below for details.

56.4.2.1 Sparse Connect

The PL301 HPM, provide means to specify "Sparse Connects", to specify just the needed connects between SI's to MI's.

Using Sparse Connects, reduces the overall gate count of the interconnect and can improve timing.

A sample sparse connection scheme is shown in Figure 56-17.

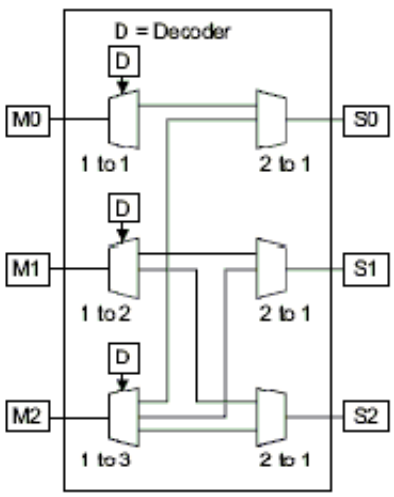


Figure 56-17. Sparse Connection Example

The PLARB1 specific "Sparse Connection" scheme is provided in Table 56-17. A "YES" denotes an existing path between masters and a "NO", a non-existing path between (SI's interfaces) to slaves (MI's interfaces).

NOTE

Because the PLARB1 has just one MI interface, there are no sparse connections.

Table 56-17. Sparse Connections

	MI0
SI0	YES
SI1	YES
SI2	YES
SI3	YES

56.4.2.2 Memory region mapping

Table 56-18 lists the memory map for each of the SIs in this example, based on the global memory map for the entire system. (Missing connections are marked by "-" in the table).

Table 56-18. PLARB1 Memory Regions

From Master	To Slave	Start Address	End Address
M0	S0	0x00000000	0xFFFFFFFF
M1	S0	0x00000000	0xFFFFFFFF
M2	S0	0x00000000	0xFFFFFFFF
M3	S0	0x00000000	0xFFFFFFFF

56.4.2.3 Cyclic Dependency Avoidance Scheme (CDAS)

In any AXI system, the interconnect must ensure that deadlock cannot occur when routing transactions concurrently to multiple slaves (because it is possible that any of the connected slaves would re-order the returning read /write data response). To remove any potential for deadlock, the HPM supports a variety of cyclic dependency avoidance schemes.

The PL301 HPM, supports various cyclic schemes, which are HW configurable, at SoC design time, and are not configurable by software. The schemes offer varying degrees of cyclic restriction and you can trade this off against timing performance.

The PLARB1 slave ports are configured to "Single Slave" scheme. See Single Slave Scheme section below for details.

56.4.2.3.1 Single Slave Scheme

This scheme enforces the rule that a master can have active transactions to only a single slave at any time. It is the simplest scheme, and has the lowest timing overhead, but it is also the most restrictive. Figure 56-18 shows the Single Slave scheme rules.

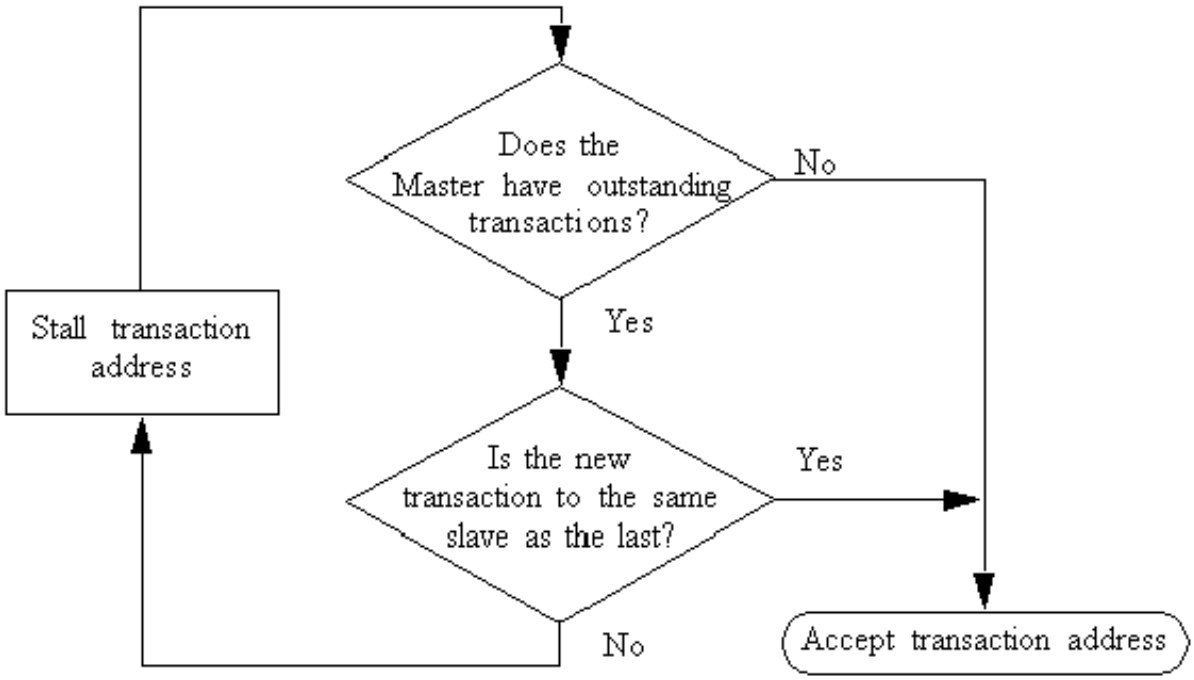

Figure 56-18. Single Slave Scheme Behavior

56.4.2.4 Arbitration Scheme

General arbitration scheme details of PL301 HPM:

Each MI can be configured separately to have an arbitration scheme that is either:

- A programmable or fixed Round-robin (RR) scheme
- A programmable Least Recently Granted (LRG) scheme

The AW and AR channels have separate arbiters and can be programmed, if applicable, and interrogated separately through the APB programming interface, but both AW and AR channels are configured identically. Because the AW and AR channels are arbitrated separately, an MI can permit simultaneous read and write transactions from different SIs.

The arbitration mechanism registers the arbitration decision for use in the subsequent cycle. An arbitration decision taken in the current cycle does not affect the current cycle. If no SIs are active, the arbiter adopts default arbitration, that is, the highest priority SI. If this occurs, and the highest priority interface becomes active in the same cycle as (or before) any other SI, then this does not constitute a grant to an active SI and the arbitration scheme does not change its state as a result of that transfer.

56.4.2.5 Arbitration Options Specific to the PLARB1 Arbiter

The Programmable RR arbitration scheme (Prog_RR) is used for MI0, with 16 slots, who's HW default slots is set to 0, 1, 2, 3, 0, 1, 2, 3, 0, 1, 2, 3, 0, 1, 2, 3 (25% for each master).

56.4.2.5.1 Programmable Round Robin (Prog_RR) Scheme

There must be at least one slot per connected SI and there can be up to 32 slots. By allocating multiple slots for a SI, you can allocate access to the slave, on average, in proportion to the number of slots. If the slots are appropriately ordered, this can also reduce the maximum time before a grant is guaranteed. The SI associated with a slot can be interrogated from the APB programming interface, but it cannot be changed.

Whenever arbitration is granted to an active SI, the slots are rotated so that the slot currently in the highest priority position becomes the lowest, and all other slots move to a higher priority but maintain their relative order, as shown in Figure 56-19. This means that if an SI is the highest priority active SI, but is not the highest priority interface, then it continues to win the arbitration until it becomes the highest priority interface, and then the lowest priority interface subsequently.

Because the arbitration value is registered, the arbitration decision made in this cycle is used in the next cycle. This means that if the SI that currently holds the arbitration is still the highest priority active SI in this cycle, then it wins the arbitration again regardless of whether or not it is active in the next cycle, as shown by the status of M3 in stages A, B, and C of Figure 56-19.

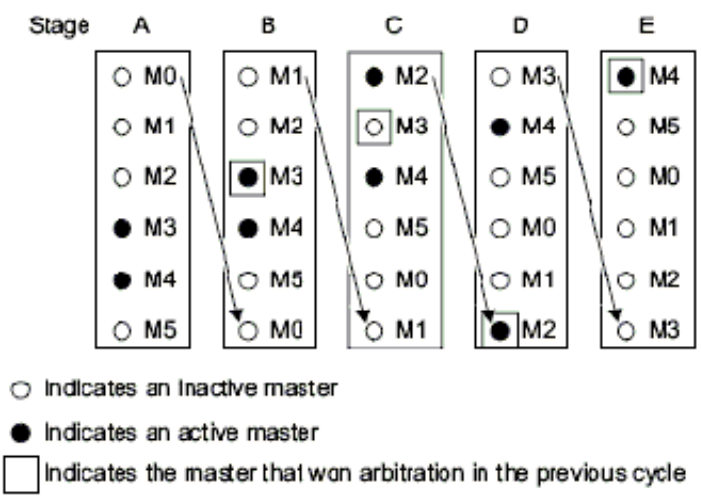

Figure 56-19. Operation of RR Arbitration Scheme

56.4.3 Various Configuration Options

The following options were selected at instantiation of PLARB1 during the design phase, and are hard-coded in the PLARB1 instance and therefore cannot be changed by SW.

For more details on the configuration parameters functionality, refer to *"PrimeCell High-Performance Matrix (PL301) Technical Reference Manual"* document by ARM.

56.4.3.1 SI Configuration

SI's ports settings:

- "read_acceptance_capability" = "1"
- "write_acceptance_capability" = "1"
- No registered I/O used. ("registered_io" = "0")
- "single_active_write" = "false".

56.4.3.2 MI Configuration

MI0 port settings:

- "write_interleave_capability" = "1"
- "write_issuing_capability" = "4"

56.4.4 Clocks

The PLARB1 supports multiple clock domains for several masters and slaves, as follows:

Table 56-19. PLARB1 Clock Domains

Port	Synchronization Type	Max Frequency[1]
PL301 Core	N/A	133 MHz
SI0	Synchronous to PL301 Core	133 MHz
SI1	Synchronous to PL301 Core	133 MHz
SI2	Synchronous to PL301 Core	133 MHz
SI3	Synchronous to PL301 Core	133 MHz
MI0	Synchronous to PL301 Core	133 MHz

1. As used in i.MX53.

56.4.5 Interrupts

This block does not generate interrupts.

Chapter 57
PL301 2x2 Arbiter (PLARB2)

57.1 Overview

This section provides an overview of the PL301 2x2 Arbiter (PLARB2). The PLARB2 HPM (High Performance Matrix - by ARM Ltd.) is a configurable AXI arbiter between several interconnected masters and slaves, and is based on a standard configurable PrimeCell. The PLARB2 is designed such that many configuration options are selected at the HW design stage, determined by SoC characteristics and needs, while several other configuration options are SW controlled. This chapter focuses largely on the features enabled for this PLARB2 instance.

The top level diagram of PLARB2 is shown in Figure 57-1.

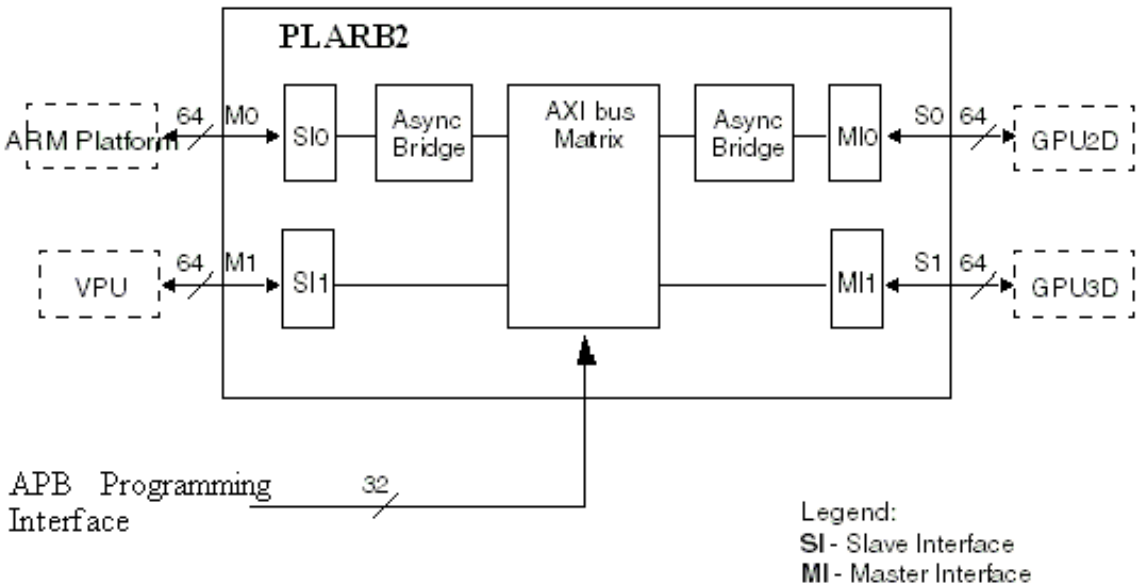

Figure 57-1. MX53 PLARB2 Block Diagram

57.1.1 Features

Key features of the PLARB2:

- Supports programmable Round Robin (Prog_RR) arbitration scheme on MI1 port (4x slots)
- Implements sparse connection, where path from SI0 to MI0 is omitted
- Supports cross-clocks domain synchronization on Master 0 and Slave 0 ports
- "Single Slave" Cyclic Avoidance scheme
- APB interface for programming configuration / control registers
- Provides FIFOs for both Read Write accesses on slave interfaces, and a single register on the MI0 master interface

57.1.2 Modes and Operations

The PLARB2 supports a normal functional mode, as described in Normal Mode.

57.2 External Signals

There are no external I/O interfaces.

57.3 Programmable Registers

PLARB2 memory map

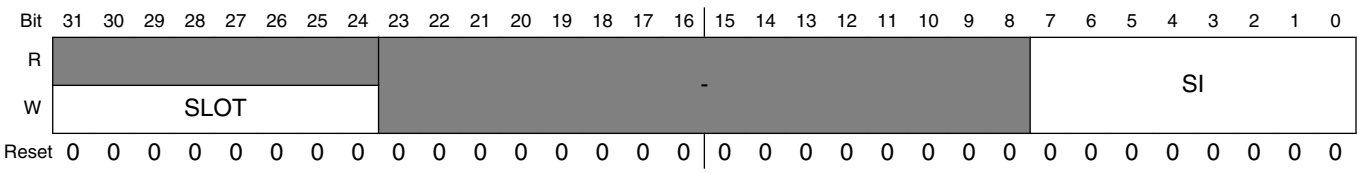
57.3.1 PLARB2 AR Programmable RR Arbitration Configuration for MI0 (PLARB2_RAC_MI0)

This register configures the slots that implement the Programmable Round Robin (prog_rr) scheme. See Programmable Round Robin (Prog_RR) Scheme for detailed algorithmic descriptions. The arbitration schemes are configured, programmed, and interrogated on a per-master-interface basis. The per-master-interface address space is at offset 0x400. The interfaces are spaced at 0x20 intervals from this base. The arbitration register address within the individual interface's space is further partitioned as:

a) the read channel, located at offset 0x8.

b) the write channel, at offset 0xC.

Address: PLARB2_RAC_MI0 is 0h base + 408h offset = 0000_0408h



PLARB2_RAC_MI0 field descriptions

Field	Description
31–24 SLOT	Contains the slot where data is to be written. For preliminary read operations, these bits are 0xFF. For rest of the read operations, their value is 0x00. **Note:** A write operation must be followed by a read operation to the same address. The write transfer sets the slot number to be read for that master interface. A read operation with 31:24 bits set to 0xFF returns the slave interface that is associated with that slot number.
23–8 -	Reserved.
7–0 SI	These bits set the slot number for the following read operation. It holds the encoded slave interface number associated with the addressed slot number. **Note:** The format of the read data returned has the slave interface number associated with the addressed slot in bits [7:0]. All other bits are set to zero. 2 - 7 - Not Used 0 256KB GPU 3D memory (GMEM). 1 On Chip 128KB RAM (via OCRAM controller)

57.3.2 PLARB2 AW Programmable RR Arbitration Configuration for MIn (PLARB2_WAC_MI*n*)

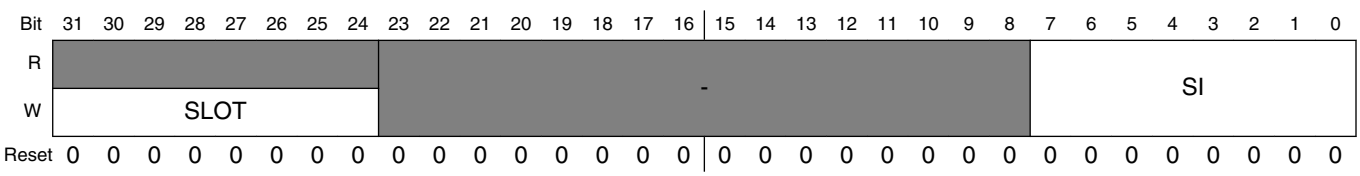
This register configures the slots that implement the Programmable Round Robin (prog_rr) scheme. See "Programmable Round Robin (Prog_RR) Scheme" for detailed algorithmic descriptions. The arbitration schemes are configured, programmed, and interrogated on a per-master-interface basis. The per-master-interface address space is at offset 0x400. The interfaces are spaced at 0x20 intervals from this base. The arbitration register address within the individual interface's space is further partitioned as:

a) the read channel, located at offset 0x8.

b) the write channel, at offset 0xC.

Addresses: PLARB2_WAC_MI0 is 0h base + 40Ch offset = 0000_040Ch

PLARB2_WAC_MI1 is 0h base + 42Ch offset = 0000_042Ch



PLARB2_WAC_MI*n* field descriptions

Field	Description
31–24 SLOT	The bits define the slot for which the data is to be written. There must be at least one slot per connected slave interface.When the programmable RR scheme is selected for a master interface, then, each of its arbitration slots can have the slave interface associated with it changed. For PLARB2, the slot configuration is as follow: • MI0 - One slot, fixed for SI1 (SI0 is sparse connection of MI0) MI1 - 4 slots exists, in order of: SI0, SI1, SI1, SI0. Note: If these bits contain the master interface slot number, (while assigning the bits for writing Master Interface Channel Arbitration Values) then bits 7:0 contains the corresponding Slave Interface Number.
23–8 -	Reserved.
7–0 SI	The encoded slave interface number. **NOTE:** No protection is imposed when you program the slots in the programmable RR arbitration scheme. So it is possible for you to remove a slave interface from all the slots which would make that slave interface inaccessible. 2 - 7 - Not Used 0 256KB GPU 3D memory (GMEM). 1 On Chip 128KB RAM (via OCRAM controller)

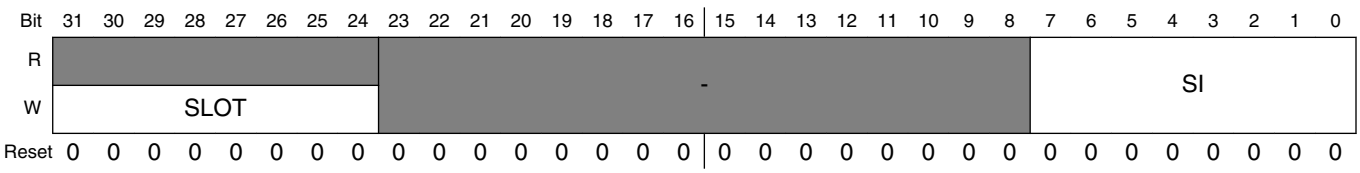
57.3.3 PLARB2 AR Programmable RR Arbitration Configuration for MI1 (PLARB2_RAC_MI1)

This register configures the slots that implement the Programmable Round Robin (prog_rr) scheme. See Programmable Round Robin (Prog_RR) Scheme for detailed algorithmic descriptions. The arbitration schemes are configured, programmed, and interrogated on a per-master-interface basis. The per-master-interface address space is at offset 0x400. The interfaces are spaced at 0x20 intervals from this base. The arbitration register address within the individual interface's space is further partitioned as:

a) the read channel, located at offset 0x8.

b) the write channel, at offset 0xC.

Address: PLARB2_RAC_MI1 is 0h base + 428h offset = 0000_0428h



PLARB2_RAC_MI1 field descriptions

Field	Description
31–24 SLOT	Contains the slot where data is to be written. For preliminary read operations, these bits are 0xFF. For rest of the read operations, their value is 0x00. **Note:** A write operation must be followed by a read operation to the same address. The write transfer sets the slot number to be read for that master interface. A read operation with 31:24 bits set to 0xFF returns the slave interface that is associated with that slot number.
23–8 -	Reserved.
7–0 SI	These bits set the slot number for the following read operation. It holds the encoded slave interface number associated with the addressed slot number. **Note:** The format of the read data returned has the slave interface number associated with the addressed slot in bits [7:0]. All other bits are set to zero. 2 - 7 - Not Used 0 256KB GPU 3D memory (GMEM). 1 On Chip 128KB RAM (via OCRAM controller)

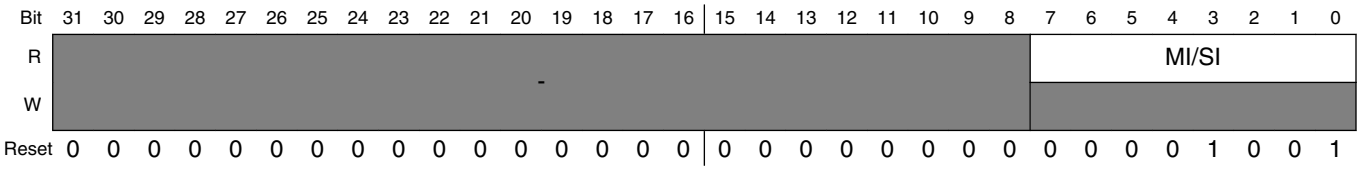
57.3.4 PLARB2 Configuration Register 0 (PLARB2_CR0)

These are four 32-bit read-only registers at address 0xFC0-0xFCC. The register at:

- 0xFC0 is hard-coded and identifies how many SI's are configured in the PLARB2.
- 0xFC4 is hard-coded and identifies how many MI's are configured in the PLARB2.

The registers at 0xFC8 and 0xFCC read as zeros.

Address: PLARB2_CR0 is 0h base + FC0h offset = 0000_0FC0h



PLARB2_CR0 field descriptions

Field	Description
31–8 -	Reserved
7–0 MI/SI	The total number of master/slave interfaces configured for the PLARB2. 0x0 Reserved 0x1 One MI / SI 0x2 Two MI's / SI's 0x3 Three MI's / SI's 0x20 32 MI's / SI's 0x21 0xFF Reserved

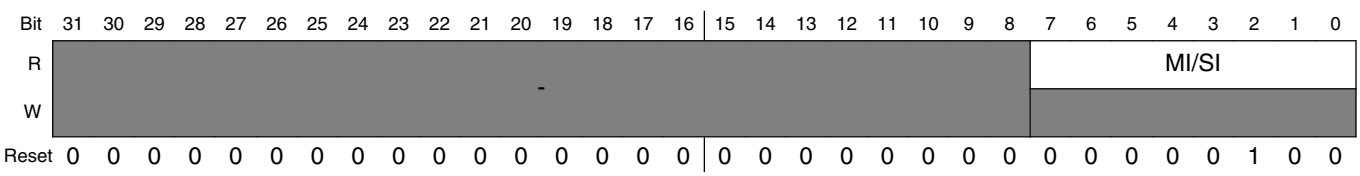
57.3.5 PLARB2 Configuration Register 1 (PLARB2_CR0)

These are four 32-bit read-only registers at address 0xFC0-0xFCC. The register at:

- 0xFC0 is hard-coded and identifies how many SI's are configured in the PLARB2.
- 0xFC4 is hard-coded and identifies how many MI's are configured in the PLARB2.

The registers at 0xFC8 and 0xFCC read as zeros.

Address: PLARB2_CR0 is 0h base + FC4h offset = 0000_0FC4h



PLARB2_CR0 field descriptions

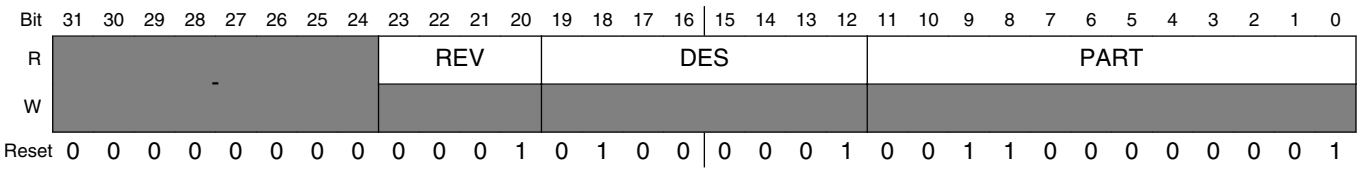
57.3.7 PLARB2 Peripheral ID Register 0-3 (PLARB2_PID0-3)

The registers are four eight-bit read-only registers and span address locations 0xFE0-0xFEC. The registers can be treated conceptually as a single register holding a 32-bit peripheral ID value. An external master reads them to determine the PLARB2 version of the device.

Address: PLARB2_PID0-3 is 0h base + FE0h offset = 0000_0FE0h



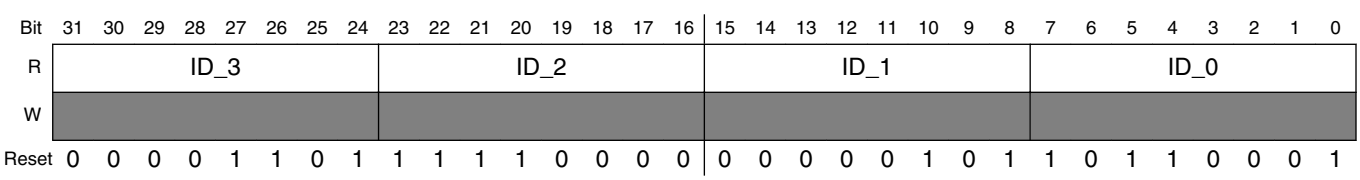
PLARB2_PID0-3 field descriptions

Field	Description
31–24 -	Reserved.
23–20 REV	The peripheral revision number is revision-dependent.
19–12 DES	Designer's ID number. This is 0x41 for ARM.
11–0 PART	The Identifies the peripheral. The part number for PLARB2 is 0x301.

57.3.8 PLARB2 ID Registers 0-3 (PLARB2_ID0-3)

The PrimeCell ID value is a 32-bit value. However, to ensure that it is accessible in all systems, the 32 bits are implemented as four 8-bit registers that can be accessed separately as the least significant eight bits of addresses 0xFF0, 0xFF4, 0xFF8, and 0xFFC.

Address: PLARB2_ID0-3 is 0h base + FF0h offset = 0000_0FF0h



PLARB2_ID0-3 field descriptions

Field	Description
31–24 ID_3	pcell_id_3 [7:0] - 0xB1
23–16 ID_2	pcell_id_2 [7:0] - 0x05
15–8 ID_1	pcell_id_1 [7:0] - 0xF0
7–0 ID_0	pcell_id_0 [7:0] - 0xD

57.4 Functional Description

The PLARB2 is an interconnect consists of a high-performance AXI cross-bar switch and related auxiliary components that supports 2 external masters and 2 external slaves.

57.4.1 Normal Mode

The PLARB2 is an interconnect that provides the means for master transactions initiated by a master to reach the intended slave in a multi-master and multi-slave AXI environment.

57.4.2 Low Power Modes

There is no special Low-Power mode for the PLARB2.

57.4.3 Operations

The PLARB2 supports the "Single Slave" cyclic schemes to avoid possible deadlock. The scheme is determined at the hardware level, per PLARB2 salve interfaces (SIs) and cannot be changed by the software.

Please refer to Cyclic Dependency Avoidance Scheme (CDAS) below for details.

57.4.3.1 Sparse Connect

The PLARB2 HPM provides means to specify "Sparse Connects", to specify just the needed connects between SIs to MIs.

Using Sparse Connects, reduces the overall gate count of the interconnect and can improve timing.

A sample sparse connection scheme is shown in Figure 57-14.

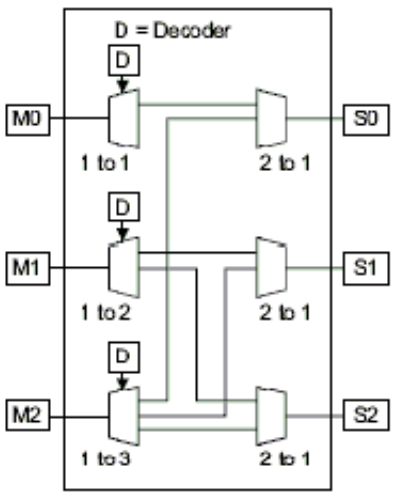


Figure 57-14. Sparse Connection Example

The PLARB2 specific "Sparse Connection" scheme is provided in Table 57-14. A "Yes", denotes an existing path between masters and a "NO" marks a non-existing path between (SI's interfaces) to slaves (MI's interfaces).

Table 57-14. Sparse Connections

	MI0	MI1
SI0	No	Yes
SI1	Yes	Yes

57.4.3.2 Memory Region Mapping

Table 57-15 lists the memory map for each of the SIs in this example, based on the global memory map for the entire system. (Missing connections are marked by "-" in the table).

Table 57-15. PLARB2 Memory Regions

From Master	To Slave	Start Address	End Address
M0	S0	-	-
M0	S1	0xF8000000	0xF801FFFF
M1	S0	0xF8020000	0xF805FFFF
M1	S1	0xF8000000	0xF801FFFF

57.4.3.3 Cyclic Dependency Avoidance Scheme (CDAS)

In any AXI system, the interconnect must ensure that deadlock cannot occur when routing transactions concurrently to multiple slaves (because it is possible that any of the connected slaves would re-order the returning read /write data response). To remove any potential for deadlock, the HPM supports a variety of cyclic dependency avoidance schemes.

The PLARB2 HPM, supports various cyclic schemes, which are HW configurable, at SoC design time, and are not configurable by software. The schemes offer varying degrees of cyclic restriction and you can trade this off against timing performance.

The PLARB2 slave ports are configured to "Single Slave" scheme. See Single Slave Scheme section below for details.

57.4.3.3.1 Single Slave Scheme

This scheme enforces the rule that a master can have active transactions to only a single slave at any time. It is the simplest scheme, and has the lowest timing overhead, but it is also the most restrictive. Figure 57-15 shows the Single Slave scheme rules.

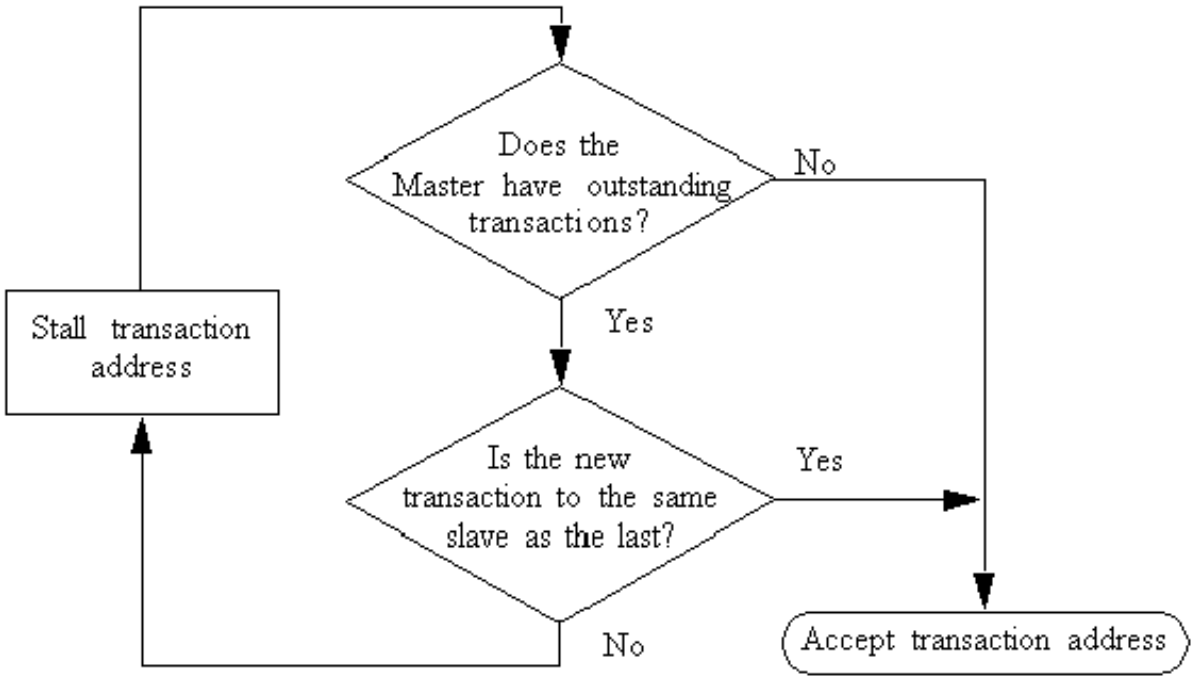

Figure 57-15. Single Slave Scheme Behavior

57.4.3.4 Arbitration Scheme

General arbitration scheme details of PLARB2 HPM:

Each MI can be configured separately to have an arbitration scheme that is either:

- A programmable or fixed Round-robin (RR) scheme
- A programmable Least Recently Granted (LRG) scheme.

The AW and AR channels have separate arbiters and can be programmed, if applicable, and interrogated separately through the APB programming interface, but both AW and AR channels are configured identically. Because the AW and AR channels are arbitrated separately, an MI can permit simultaneous read and write transactions from different SIs.

The arbitration mechanism registers the arbitration decision for use in the subsequent cycle. An arbitration decision taken in the current cycle does not affect the current cycle. If no SIs are active, the arbiter adopts default arbitration, that is, the highest priority SI. If this occurs and then the highest priority interface becomes active in the same cycle as, or before any other SI, then this does not constitute a grant to an active SI and the arbitration scheme does not change its state as a result of that transfer.

57.4.3.5 Arbitration Options Specific to the PLARB2 Arbiter

Because MI0 passes just SI1 traffic there is no need for any arbitration. A fixed RR arbitration is used with a single slot assigned to S1.

The Programmable RR arbitration scheme is used for MI1 with 4 slots. HW default SI slots is set to 0, 1, 1, 0. (50%/50%).

57.4.3.5.1 Programmable Round Robin (Prog_RR) Scheme

There must be at least one slot per connected SI and there can be up to 32 slots. By allocating multiple slots for a SI, you can allocate access to the slave, on average, in proportion to the number of slots. If the slots are appropriately ordered, this can also reduce the maximum time before a grant is guaranteed. The SI associated with a slot can be interrogated from the APB programming interface, but it cannot be changed.

Whenever arbitration is granted to an active SI, the slots are rotated so that the slot currently in the highest priority position becomes the lowest, and all other slots move to a higher priority but maintain their relative order, as Figure 57-16 shows. This means that if an SI is the highest priority active SI, but is not the highest priority interface, then it continues to win the arbitration until it becomes the highest priority interface, and then the lowest priority interface subsequently.

Because the arbitration value is registered, the arbitration decision made in this cycle is used in the next cycle. This means that if the SI that currently holds the arbitration is still the highest priority active SI in this cycle, wins the arbitration again regardless of whether or not it is active in the next cycle as shown by the status of M3 in stages A, B, and C of Figure 57-16.

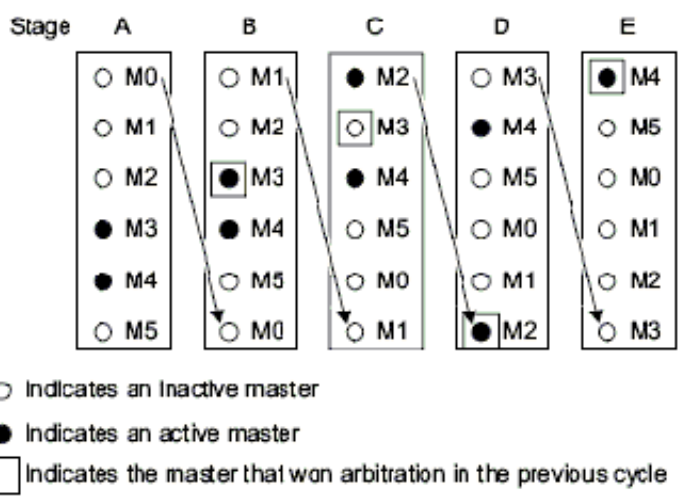

Figure 57-16. Operation of RR Arbitration Scheme

57.4.4 Various Configuration Options

The following options were selected at instanciation of the PLARB2, during the design phase, and are hard-coded in the PLARB2 instance. They cannot be changed by SW.

For more details on the configuration parameters functionality, refer to *"PrimeCell High-Performance Matrix (PL301) Technical Reference Manual"* document by ARM.

57.4.4.1 SI Configuration

SI's ports settings:

- "read_acceptance_capability" = 4
- "write_acceptance_capability" = "16" / "4" for SI0 and SI1 respectively.
- No registered IO used. ("registered_io" = "0")
- "single_active_write" = "false"

57.4.4.2 MI Configuration

MI's ports settings:

- "write_interleave_capability" = "1"
- "write_issuing_capability" = "1"

57.4.5 Clocks

The PLARB2 supports multiple clock domains for several masters and slaves, as follow:

Table 57-16. PLARB2 clock domains

Port	Synchronization Type	Max Frequency[1]
PLARB2 Core	N/A	133 MHz
SI0	Synchronous to PLARB2 Core	133 MHz
SI1	Asynchronous	200 MHz
MI0	Synchronous to PLARB2 Core	133 MHz
MI1	Asynchronous	200 MHz

1. As designed for i.MX53.

57.4.6 Interrupts

This block does not generate interrupts.

Chapter 58
Power On Reset (POR)

58.1 Overview

The POR is part of the Secure Real Time Clock (SRTC). It is designed for use in SoC applications which require low voltage, low power consumption. POR circuit generates a reset signal till its supply VDD reaches a predetermined voltage level.The POR circuit has five main sub-circuits: Recognition circuit, Pulse Latch, Brown-Out Detection Circuit, POR Stretcher and Output Buffer. The Recognition circuit detects and generates a signal till VDD crosses a predetermined voltage level called de-assertion voltage. The POR Pulse Stretcher widens the POR pulse. BO Detector detects brown out condition in VDD. Pulse Latch latches the POR output. Buffer is used to drive the on-chip load.

Figure 58-1 shows the block diagram of POR.

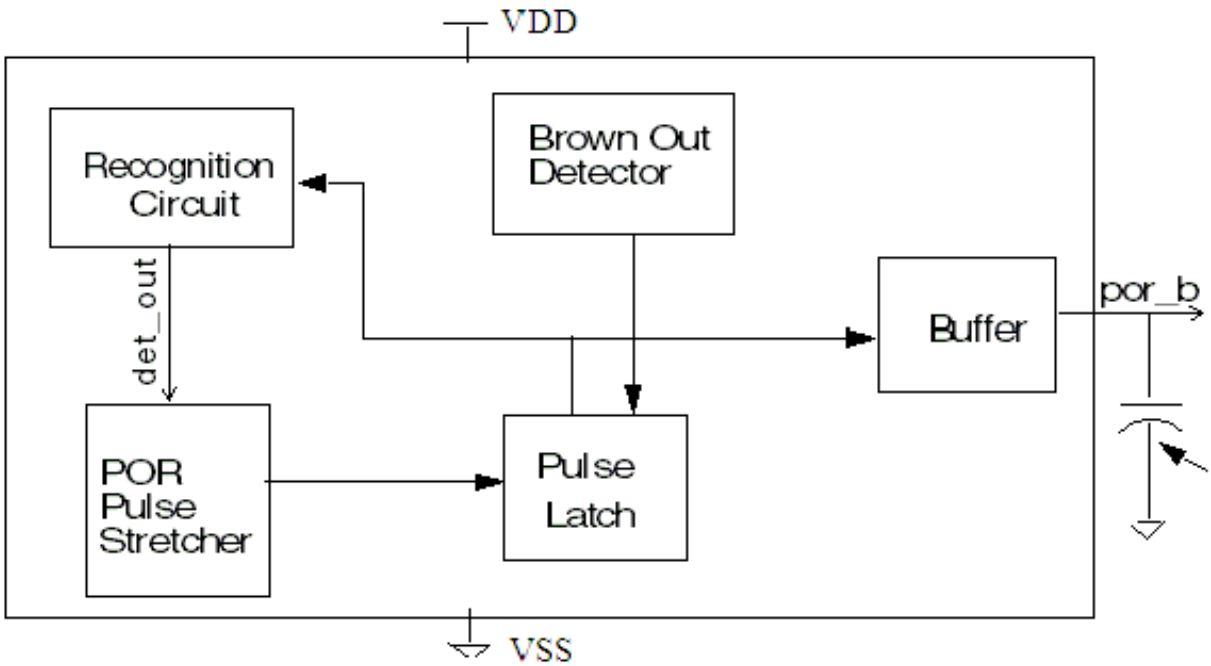

Figure 58-1. POR Block Diagram

58.2 Features

The POR has the following features:

- De-assertion voltage Independent of VDD ramp rate
- Almost zero steady state power consumption
- Brown Out Detection
- Voltage dependent Brown Out thresholds

58.3 Mode of Operation

The POR generates a por_b active low pulse when the chip is powering up.When the POR output gets de-asserted, the POR goes to low power state (POR circuit shuts off and output signals are latched). When a glitch appears in VDD and the supply goes below the Brown-Out (BO) detection threshold, the BO detection circuit pulls down the por_b signal and a reset is generated to indicate a BO condition. The por_b signal de-asserts only when VDD passes POR recognition threshold.

58.4 External Signal Description

58.4.1 Detailed Signal Descriptions

Table 58-1 lists all the pins in the POR.

Table 58-1. POR pins list

Name	Port	Function
por_b	Output	Power on Reset signal
vdd	Power	Power supply
vss	Power	Power ground

58.4.2 por_b - Power On Reset Signal

This signal is generated from the POR. This is the reset (active low) signal for the chip.

58.4.3 VDD - Power Supply

This signal is the power supply for the POR circuit.

58.4.4 VSS - Power Ground

This signal is the ground supply for the POR circuit.

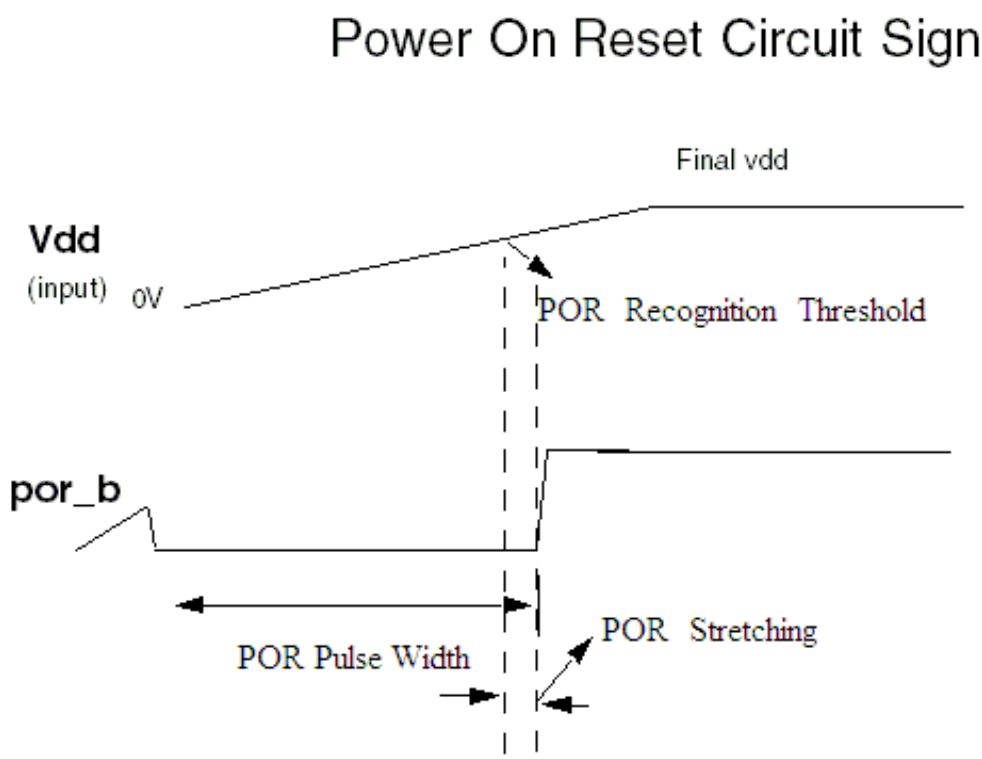

Figure 58-2. Power on sequence and RESET pulse generation

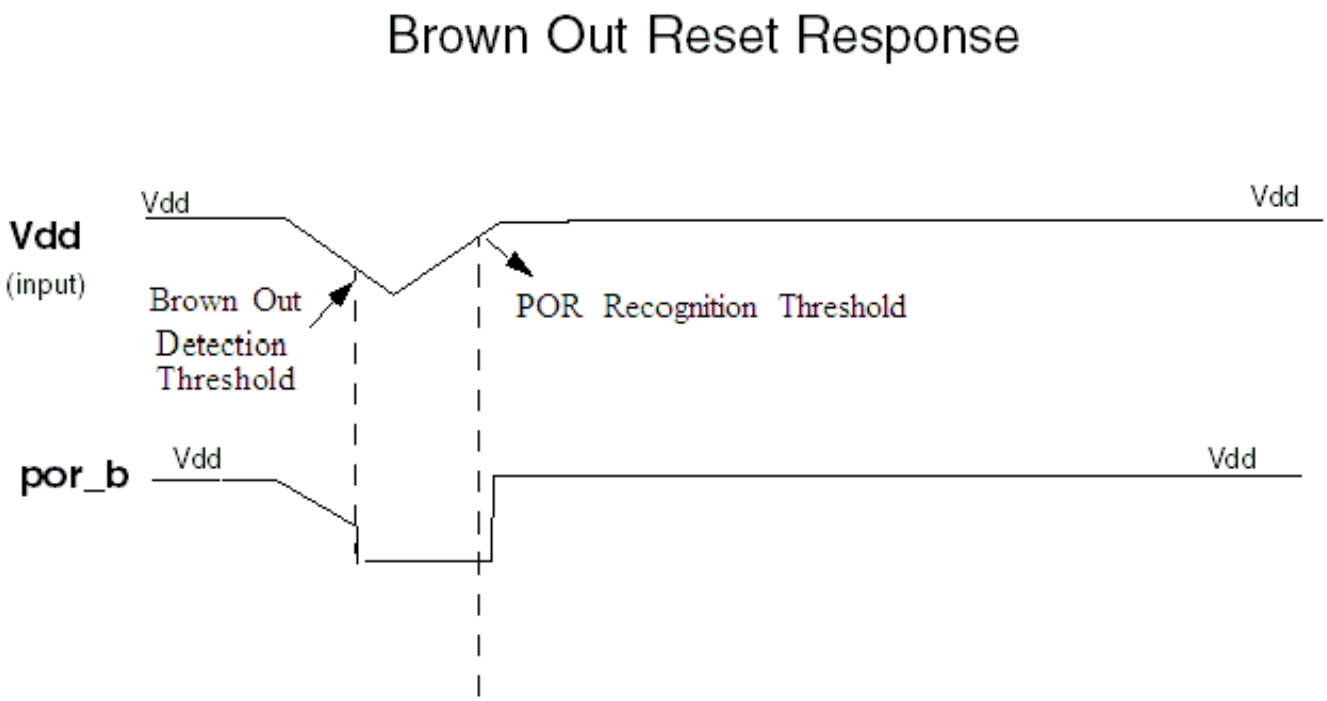

Figure 58-3. Brown-Out Detection

58.5 Functional Description

The POR does not contain nor access any memory map data or registers,

The POR circuit will provide a reset upon power up. The Power On Reset Circuit is connected to the on-chip core supply.

This circuit has five main elements:

- POR Recognition circuit
- A Pulse Latch circuit
- A Brown-Out detection Circuit
- POR Stretcher
- Output Buffer

58.5.1 Recognition Circuit

The Recognition circuit output is low when the supply is below a certain predetermined value. Below this value, known as the POR deassertion voltage, the POR output is asserted and causes the chip to reset as the supply continues to rise. On detecting this threshold, the recognition circuit output toggles, and subsequently the POR output is deasserted and the chip comes out of reset. This denotes the end of the POR operation. The recognition circuit output signal is stretched to ensure minimum assertion-width of POR reset signal. The delayed POR is used to disable the recognition circuit once its deasserted.

Thus the POR circuit goes into low-power state.

58.5.2 Pulse Latch

The Pulse Latch is used to latch the low-to high transition of the recognition circuit output, so that the recognition circuit can be powered down once the detection is over. It also ensures that POR output goes low initially during power-up.

58.5.3 Brown-Out Detector

The Brown-Out detection circuit detects conditions in supply when VDD dips below Brown-Out Detection threshold and begins to rise again. This threshold is supply dependent, meaning that they vary with the supply level from which VDD begins to drop in case of a Brown-Out event.

58.5.4 POR Pulse Stretcher

This comprises of a cascade of inverters to provide delay. It is used to stretch the POR pulse.

58.5.5 Output Buffer

These buffers are used to drive the on-chip capacitive load at the output of the signal por_b.

58.6 Initialization/Application Information

The POR does not contain nor access any memory map data or registers.

Chapter 59
Pulse Width Modulation (PWM)

59.1 Overview

The Pulse Width Modulation (PWM) has a 16-bit counter, and is optimized to generate sound from stored sample audio images and it can also generate tones. It uses 16-bit resolution and a 4 x 16 data FIFO.

This section presents an overview of the PWM. The figure below illustrates the PWM diagram.

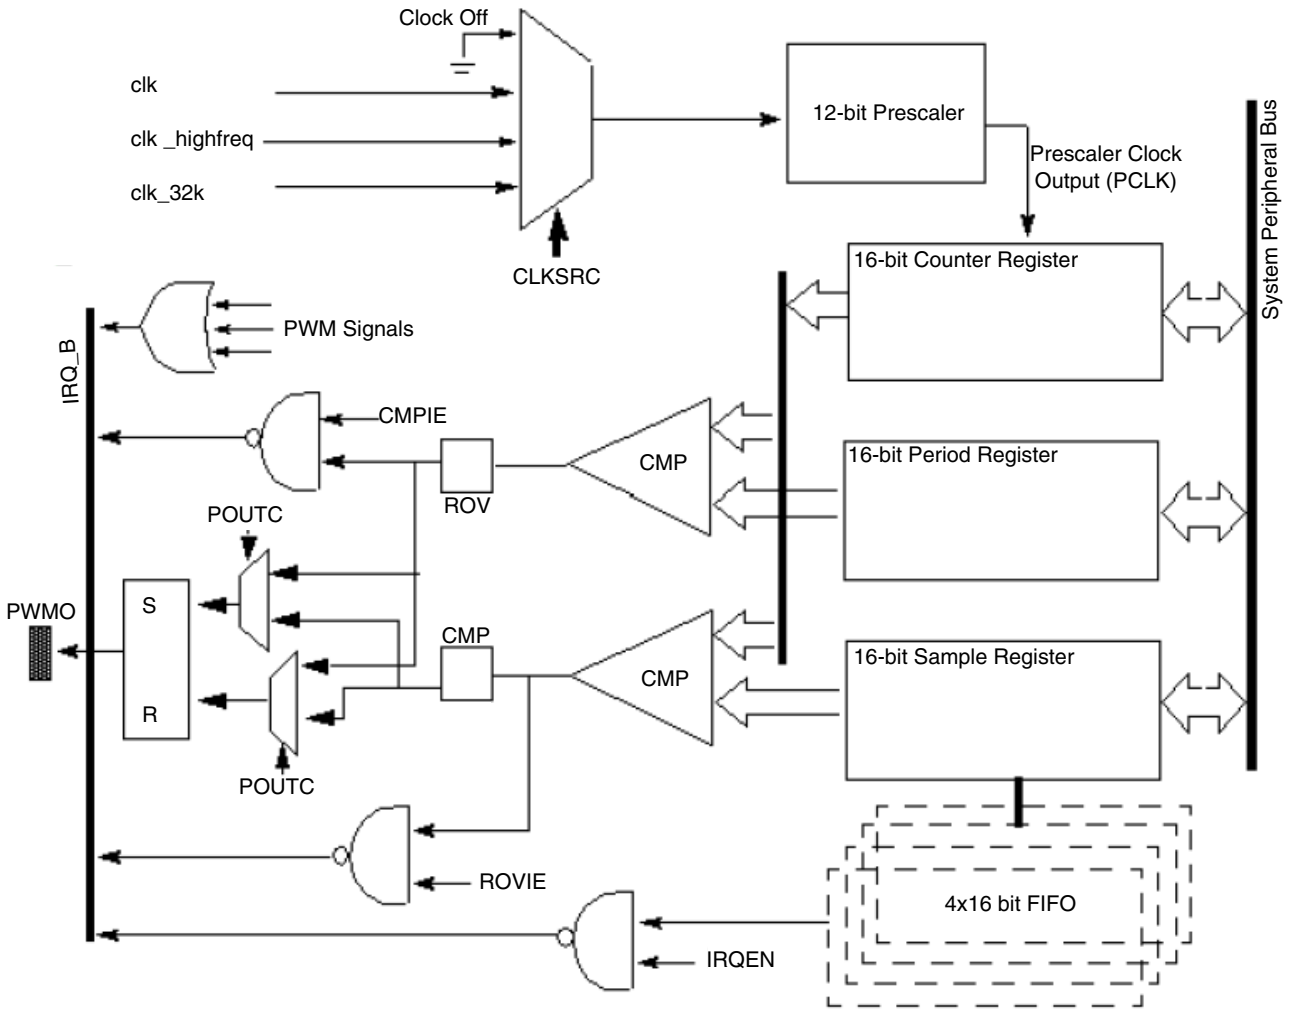

Figure 59-1. Pulse-Width Modulator Block Diagram

The following features characterize the PWM:

- 16-bit up-counter with clock source selection
- 4 x 16 FIFO to minimize interrupt overhead
- 12-bit prescaler for division of clock
- Sound and melody generation
- Active high or active low configured output
- Can be programmed to be active in low-power mode
- Can be programmed to be active in debug mode
- Interrupts at compare and rollover

59.2 Signal Description

The PWM follows IP Bus protocol when interfacing with the processor core. It does not have any interface signals with any other block inside the chip except for clock and reset inputs from the Clock Control Module (CCM), System Reset Controller (SRC), and interrupt signals to the processor interrupt handler. There is a single output signal going outside the chip boundary.

59.2.1 External Signals

PWM has a single output signal to the chip boundary named ipp_do_pwmo.

The following table outlines the external signals.

Table 59-1. External Signals

Name	Direction	Function	Reset State	Pull up
PWMxO	Output	This is the functional output of the PWM. The modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the PWM. The smallest period can be two ipg_clk clock periods with duty cycle of 50%.	0	-

59.3 Functional Description

The following sections detail the PWM operation and function.

59.3.1 Operation

The output of the PWM is a toggling signal whose frequency and duty cycle can be modulated by programming the appropriate registers. It has a 16-bit up counter which counts from 0x0000 until the counter value equals the [Value in Period register] + 1. After this match occurs the Counter is reset to 0x0000.

At the beginning of a count period cycle, the PWMO pin is set to one (default) and the counter begins counting up from 0x0000. The sample value in the sample FIFO is compared on each count of prescaler clock. When the sample and count values match, the PWMO signal is cleared to zero (default). The counter continues counting until the period match occurs and subsequently another period cycle begins.

When the PWM is enabled the counter starts running and generates an output with the reset values in the period and sample registers. It is recommended that the programming of these registers be done before PWM is enabled.

A hardware reset results in all the PWM count and sample registers begin cleared and the FIFO being flushed. The control register shows that FIFO is empty and it can be written into, and the PWM is disabled. A software reset has the same results, however the state of the STOPEN, DOZEN, WAITEN, and DBGEN bits in the control register are not affected. Software reset can be asserted even when the PWM is in disabled state.

59.3.1.1 Clocks

The clock that feeds the prescaler can be selected from:

- High frequency Clock (ipg_clk_highfreq) pat_ref or CKIH

  This is a high frequency clock, provided by the Clock Control Module (CCM). This clock should be in the low power mode when the ipg_clk is turned off. Thus, the PWM can be run on this clock in the low power mode.

- Low Reference Clock (ipg_clk_32k) CKIL

  This is the 32 KHz low reference clock which is provided by the CCM. This clock should be on in the low power mode when ipg_clk is turned off. Thus, PWM can be run on this clock in the low power mode.

- Global Functional Clock (ipg_clk)

  This clock should be on in normal operations. In low power modes it can be switched off.

The clock input source is determined by the CLKSRC field of the PWM control register. The CLKSRC value should only be changed when the PWM is disabled.

A change in the value of the PRESCALER field of the control register is immediately reflected on its output clock frequency.

59.3.1.2 FIFO

Digital sample values can be loaded into the pulse-width modulator as 16-bit words. The endianess can be changed using the BCTR and HCTR bits of the control register. A 4-word (16-bit) FIFO minimizes interrupt overhead. A maskable interrupt is generated when the number of data words fall below the water level set by the FWM field in the control register.

A write in the sample register results in the value being stored into the FIFO if it is not full. A write when the FIFO is full sets FWE (FIFO write error) bit in the status register and the FIFO contents remain unchanged. The FIFO can be written at any time, but can be read only when the PWM is enabled. The FIFOAV field shows how many data words are currently contained in the FIFO and whether or not it can be written into.

A read on the sample register yields the current FIFO value that is being used, or will be used, by the PWM for generation on the output signal. Therefore, a write and a subsequent read on the sample register may result in different values being obtained.

59.3.1.3 Rollover and Compare Event

The counter is reset to 0x0000 after its value equals the PERIOD + 1 and resumes counting thereafter. This event is referred to as a rollover. When PERIOD = 0x0000, the counter is reset after count reaches 0x0001. Therefore PERIOD = 0xffff or 0xfffe results in the counter value being reset after count till 0xffff. During a rollover event the output is either set (default), reset or has no effect according to the programming of the POUTC field in the control register. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

When the counter value reaches the sample value, the output of the PWM is reset (default), set or has no effect according to the programming of the POUTC field of control register. This event is referred to as a compare event. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

If the rollover event sets the PWM output signal, the compare event will reset it and vice versa for a particular programming configuration of POUTC field.

59.3.1.4 Low Power Mode Behavior

In low power modes, if the clock from the selected clock source is available, the PWM counter continues to run and an output is produced, depending on whether the control bit for that mode is set or not. In the absence of the clock itself, or if the corresponding low power bit in the control register is 0, the counter is reset and resumes counting when it exits the low power mode.

59.3.1.5 Debug Mode Behavior

In debug mode, PWM has the option of continuing to run or be halted. If the DBGEN bit is not set in the PWM_PWMCR, the PWM is halted. If the DBGEN bit is set, then the PWM will continue to run in the debug mode.

59.4 Programmable Registers

The PWM includes six user-accessible 32-bit registers.

PWM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53FB_4000	PWM Control Register (PWM-1_PWMCR)	32	R/W	0000_0000h	59.4.1/ 3753

PWMx_PWMCR field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved. These reserved bits are always read as zero.
27–26 FWM	FIFO Water Mark. These bits are used to set the data level at which the FIFO empty flag will be set and the corresponding interrupt generated 00 FIFO empty flag is set when there are more than or equal to 1 empty slots in FIFO 01 FIFO empty flag is set when there are more than or equal to 2 empty slots in FIFO 10 FIFO empty flag is set when there are more than or equal to 3 empty slots in FIFO 11 FIFO empty flag is set when there are more than or equal to 4 empty slots in FIFO
25 STOPEN	Stop Mode Enable. This bit keeps the PWM functional while in stop mode. When this bit is cleared, the input clock is gated off in stop mode. This bit is not affected by software reset. It is cleared by hardware reset.

Table continues on the next page...

PWMx_PWMCR field descriptions (continued)

Field	Description
	0 Inactive in stop mode 1 Active in stop mode
24 DOZEN	Doze Mode Enable. This bit keeps the PWM functional in doze mode. When this bit is cleared, the input clock is gated off in doze mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in doze mode 1 Active in doze mode
23 WAITEN	Wait Mode Enable. This bit keeps the PWM functional in wait mode. When this bit is cleared, the input clock is gated off in wait mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in wait mode 1 Active in wait mode
22 DBGEN	Debug Mode Enable. This bit keeps the PWM functional in debug mode. When this bit is cleared, the input clock is gated off in debug mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in debug mode 1 Active in debug mode
21 BCTR	Byte Data Swap Control. This bit determines the byte ordering of the 16-bit data when it goes into the FIFO from the sample register. 0 byte ordering remains the same 1 byte ordering is reversed
20 HCTR	Half-word Data Swap Control. This bit determines which half word data from the 32-bit IP Bus interface is written into the lower 16 bits of the sample register. 0 Half word swapping does not take place 1 Half words from write data bus are swapped
19–18 POUTC	PWM Output Configuration. This bit field determines the mode of PWM output on the output pin. 00 Output pin is set at rollover and cleared at comparison 01 Output pin is cleared at rollover and set at comparison 10 PWM output is disconnected 11 PWM output is disconnected
17–16 CLKSRC	Select Clock Source. These bits determine which clock input will be selected for running the counter. After reset the system functional clock is selected. The input clock can also be turned off if these bits are set to 00. This field value should only be changed when the PWM is disabled 00 Clock is off 01 ipg_clk 10 ipg_clk_highfreq 11 ipg_clk_32k
15–4 PRESCALER	Counter Clock Prescaler Value. This bit field determines the value by which the clock will be divided before it goes to the counter. 0x000 Divide by 1 0x001 Divide by 2 0xfff Divide by 4096

Table continues on the next page...

PWMx_PWMCR field descriptions (continued)

Field	Description
3 SWR	Software Reset. PWM is reset when this bit is set to 1. It is a self clearing bit. A write 1 to this bit is a single wait state write cycle. When the block is in reset state this bit is set and is cleared when the reset procedure is over. Setting this bit resets all the registers to their reset values except for the STOPEN, DOZEN, WAITEN, and DBGEN bits in this control register. 0 PWM is out of reset 1 PWM is undergoing reset
2–1 REPEAT	Sample Repeat. This bit field determines the number of times each sample from the FIFO is to be used. 00 Use each sample once 01 Use each sample twice 10 Use each sample four times 11 Use each sample eight times
0 EN	PWM Enable. This bit enables the PWM. If this bit is not enabled, the clock prescaler and the counter is reset. When the PWM is enabled, it begins a new period, the output pin is set to start a new period while the prescaler and counter are released and counting begins. 0 PWM disabled 1 PWM enabled

59.4.2 PWM Status Register (PWMx_PWMSR)

The PWM status register (PWM_PWMSR) contains seven bits which display the state of the FIFO and the occurrence of rollover and compare events. The FIFOAV bit is read-only but the other four bits can be cleared by writing 1 to them. The FE, ROV, and CMP bits are associated with FIFO-Empty, Roll-over, and Compare interrupts, respectively.

Addresses: PWM-1_PWMSR is 53FB_4000h base + 4h offset = 53FB_4004h

PWM-2_PWMSR is 53FB_8000h base + 4h offset = 53FB_8004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0

PWMx_PWMSR field descriptions

Field	Description
31–7 Reserved	This read-only field is reserved and always has the value zero. Reserved. These reserved bits are always read as zero.

Table continues on the next page...

PWMx_PWMSR field descriptions (continued)

Field	Description
6 FWE	FIFO Write Error Status. This bit shows that an attempt has been made to write FIFO when it is full. 0 FIFO write error not occurred 1 FIFO write error occurred
5 CMP	Compare Status. This bit shows that a compare event has occurred. 0 Compare event not occurred 1 Compare event occurred
4 ROV	Roll-over Status. This bit shows that a roll-over event has occurred. 0 Roll-over event not occurred 1 Roll-over event occurred
3 FE	FIFO Empty Status Bit. This bit indicates the FIFO data level in comparison to the water level set by FWM field in the control register. 0 Data level is above water mark 1 When the data level falls below the mark set by FWM field
2–0 FIFOAV	FIFO Available. These read-only bits indicate the data level remaining in the FIFO. An attempted write to these bits will not affect their value and no transfer error is generated. 000 No data available 001 1 word of data in FIFO 010 2 words of data in FIFO 011 3 words of data in FIFO 100 4 words of data in FIFO 101 unused 110 unused 111 unused

59.4.3 PWM Interrupt Register (PWMx_PWMIR)

The PWM Interrupt register (PWM_PWMIR) contains three bits which control the generation of the compare, rollover and FIFO empty interrupts.

Addresses: PWM-1_PWMIR is 53FB_4000h base + 8h offset = 53FB_4008h

PWM-2_PWMIR is 53FB_8000h base + 8h offset = 53FB_8008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PWMx_PWMIR field descriptions

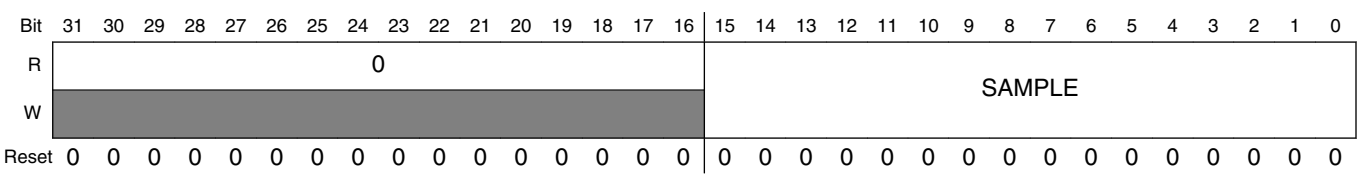
Field	Description
31–3 Reserved	This read-only field is reserved and always has the value zero. Reserved. These reserved bits are always read as zero.
2 CIE	Compare Interrupt Enable. This bit controls the generation of the Compare interrupt. 0 Compare Interrupt not enabled 1 Compare Interrupt enabled
1 RIE	Roll-over Interrupt Enable. This bit controls the generation of the Rollover interrupt. 0 Roll-over interrupt not enabled 1 Roll-over Interrupt enabled
0 FIE	FIFO Empty Interrupt Enable. This bit controls the generation of the FIFO Empty interrupt. 0 FIFO Empty interrupt disabled 1 FIFO Empty interrupt enabled

59.4.4 PWM Sample Register (PWMx_PWMSAR)

The PWM sample register (PWM_PWMSAR) is the input to the FIFO. 16-bit words are loaded into the FIFO. The FIFO can be written at any time, but can be read only when the PWM is enabled. The PWM will run at the last set duty-cycle setting if all the values of the FIFO has been utilized, until the FIFO is reloaded or the PWM is disabled. When a new value is written, the duty cycle changes after the current period is over.

A value of zero in the sample register will result in the ipp_pwm_pwmo output signal always being low/high (POUTC = 00 it will be low and POUTC = 01 it will be high), and no output waveform will be produced. If the value in this register is higher than the PERIOD + 1, the output will never be set/reset depending on POUTC value.

Addresses: PWM-1_PWMSAR is 53FB_4000h base + Ch offset = 53FB_400Ch
PWM-2_PWMSAR is 53FB_8000h base + Ch offset = 53FB_800Ch



PWMx_PWMSAR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. These are reserved bits and writing a value will not affect the functionality of PWM and are always read as zero.
15–0 SAMPLE	Sample Value. This is the input to the 4x16 FIFO. The value in this register denotes the value of the sample being currently used.

59.4.5 PWM Period Register (PWMx_PWMPR)

The PWM period register (PWM_PWMPR) determines the period of the PWM output signal. After the counter value matches PERIOD + 1, the counter is reset to start another period.

PWMO (Hz) = PCLK(Hz) / (period +2)

A value of zero in the PWM_PWMPR will result in a period of two clock cycles for the output signal. Writing 0xFFFF to this register will achieve the same result as writing 0xFFFE.

A change in the period value due to a write in PWM_PWMPR results in the counter being reset to zero and the start of a new count period.

Addresses: PWM-1_PWMPR is 53FB_4000h base + 10h offset = 53FB_4010h

PWM-2_PWMPR is 53FB_8000h base + 10h offset = 53FB_8010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PWMx_PWMPR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. These are reserved bits and writing a value will not affect the functionality of PWM and are always read as zero.
15–0 PERIOD	Period Value. These bits determine the Period of the count cycle. The counter counts up to [Period Value] +1 and is then reset to 0x0000.

59.4.6 PWM Counter Register (PWMx_PWMCNR)

The read-only pulse-width modulator counter register (PWM_PWMCNR) contains the current count value and can be read at any time without disturbing the counter.

Addresses: PWM-1_PWMCNR is 53FB_4000h base + 14h offset = 53FB_4014h

PWM-2_PWMCNR is 53FB_8000h base + 14h offset = 53FB_8014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PWMx_PWMCNR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. These are reserved bits and writing a value will not affect the functionality of PWM and are always read as zero.
15–0 COUNT	Counter Value. These bits are the counter register value and denotes the current count state the counter register is in.

Chapter 60
ROM Controller with Patch (ROMC)

60.1 Introduction

60.1.1 Overview

The Read Only Memory Controller with ROM Patch (ROMC) acts as an interface between the ARM advanced high-performance bus (AHB - Lite) and the Read Only Memory. The ROMC consists of a ROM Controller and a ROM Patch. The ROM Patch is used to either patch code routines or fix data tables in the ROM area. There is an IP Bus interface to access the ROM Patch Registers and. The figure below depicts the main functional sub-blocks of the ROMC.

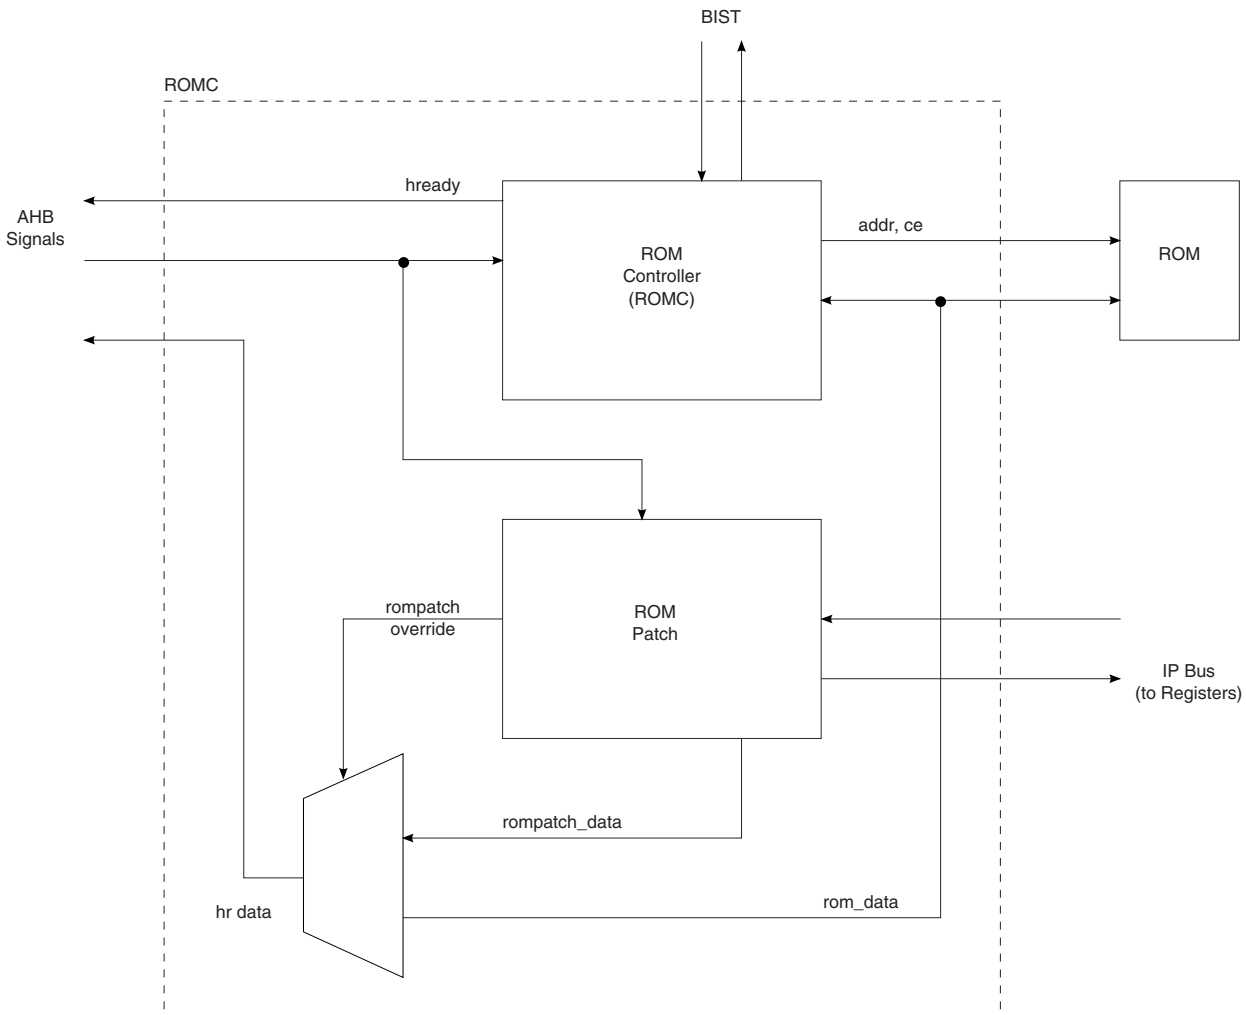

Figure 60-1. ROMC Block Diagram

60.1.2 Features

- Supports ROM size ranges from 16 Kbyte up to 4 Mbyte with increments of 1 Kbyte
- Supports opcode patching for a maximum of 16 different addresses in 4 Mbytes of ROM space
- Supports one-word data fixes for a max of 8 memory locations in 4 Mbytes of ROM space
- Supports patching of the Reset Vector (at 0x0000_0000) to allow external booting

60.1.3 Modes of Operation

There are two modes of operation: normal mode and BIST mode.

In normal mode (ipt_bist_en = 0), the ROMC ensures correct reads from the ROM, assuming the memory complies with the characteristics and requirements for which the ROMC was designed. The ROMC also performs hole decoding, aborting accesses into memory holes and converting the non-continuous ROM memory map into a continuous one for physical memory accesses.

60.1.3.1 Low Power Modes

There are two clock enables that are used to switch off parts of the ROMC logic when inactive. The first clock enable is used to disable the ROM Controller when the master connected to the AHB interface is not initiating a read to the ROM. The second clock enable is used to disable the registers used to program the ROM patch feature when the registers are not being accessed.

60.2 Memory Map

The figure below shows a sample memory map.

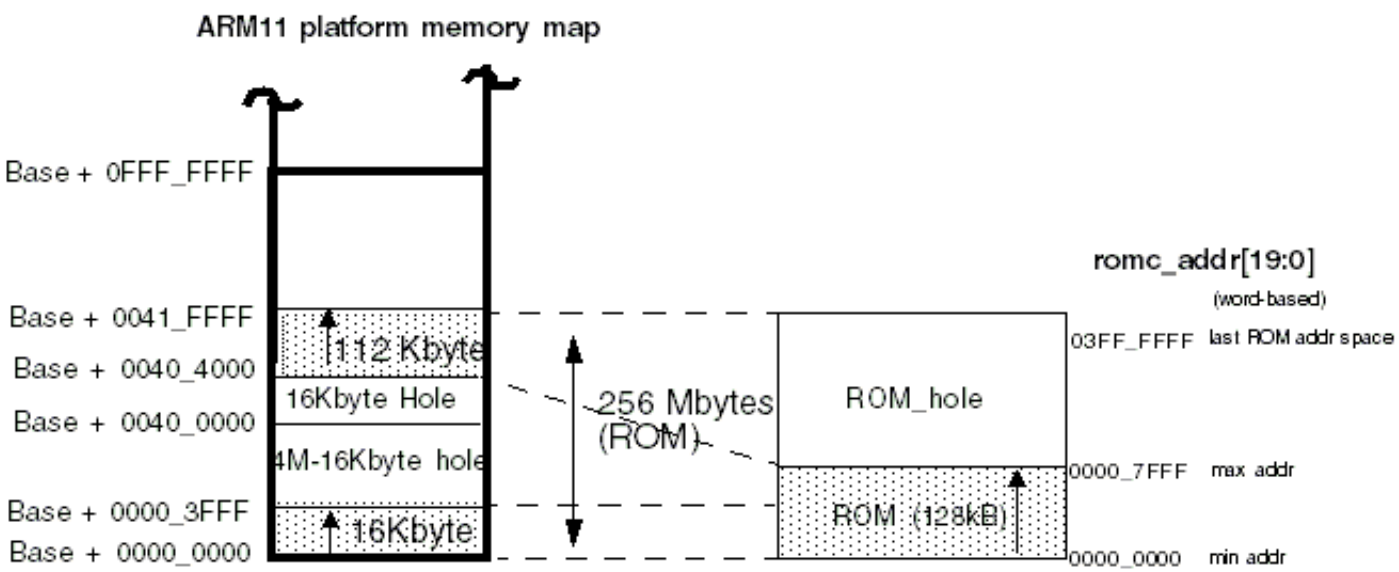

Figure 60-2. Memory Map-Example 128K ROM Connected

60.2.1 ROM Memory Map in detail

The ROMC supports ROM sizes with a range of 16 Kbyte to 4 Mbyte with an increment of 1 Kbyte. The 16 Kbyte lower limit was chosen because the minimum size of security code on an ARM platform is approximately 16 Kbyte of code, which is only accessible in supervisor mode. Note that it is the MMU that controls whether any region of memory is secure.

The exception vectors must be secured as well, and must be put in the same area as the security code. Since they must reside at address 0x0000_0000, the entire 16 Kbyte of ROM which can only be accessible in supervisor mode is located at the very beginning of the platform memory map.

If the user chooses not to use the security code, a memory size smaller than 16 Kbyte can be connected to the platform (minimum of 1 Kbyte). The MMU can be programmed to allow any kind of access into this memory. However, if the ROM size is less than 16 Kbyte, memory aliasing will occur for all invalid addresses greater than the memory size but within the 16 Kbyte of space.

For ROM sizes bigger than 16 Kbyte, the rest of its physical size resides at the address starting at 0x0040_4000 (4 M+16 Kbyte) going up to [0x0040_4000 + (mem. size - 16Kbyte)]. For examples on power-of-two memories please see Figure 60-3.

The reason for the big memory hole is because the ROMC is designed to be as flexible as possible to comply with demands of different operating systems. For example, the requirement of Windows CE OS is to be able to manage memory regions through the MMU page tables (to control accesses to privileged, cacheable, or bufferable areas) which requires regions to be separated into 1 Mbyte page tables. Since it is preferable to offer the flexibility of having the first 16 Kbyte as a secure region with vectors and security code, but allowing the rest of the ROM to be user-mode accessible, two separate 1Mbyte page tables are used.

To start a potentially insecure region directly on a 1 Mbyte boundary (starting on address 0010_0000) requires additional address translation within the ROMC. That causes an extra delay in the address path through the complicated shifting logic in an already critical design timing path. To prevent the extra delay, the first bit above the maximum address of the maximum ROM size that can be connected to the platform is used to select the region. After entering the ROMC this bit is only used in the ROM hole decode, and is not passed to the ROM on the address bus. Therefore, no translation is necessary and the address timing path is unaffected by the mapping scheme.

The maximum size of ROM connectable to the ROMC is 4 Mbyte. To address it the address bits haddr[21:2] are needed - as a consequence haddr[22] is the bit selecting between the upper or lower ROM in cases where the ROM is bigger than 16 Kbyte. That creates a 4 Mbyte hole between the two regions, which is greater than the required 1 Mbyte boundary, but acceptable. The branch instruction of the ARM code is capable of jumping between these two separate regions. It also implies that the second (potentially unprotected) region always starts at address 0x0040_4000 (4 M-16 Kbyte) and goes up to the maximum size of the memory connected to the platform (- 16 Kbyte). If an address outside the given regions is accessed, the ROMC will respond with an AHB-lite two-cycle error response.

60.3 Functional Description

This section is divided up into the ROM Controller Functional Description and the ROMC functional description.

60.3.1 ROM Controller (ROMC) Functional Description

60.3.1.1 Functionality overview

The ROMC serves two main functions. First, as an interface between the AHB-Lite bus on an ARM platform and the ROM. Second, it drives and receives several signals for the BIST engine. In normal mode of operation, the ROMC monitors the AHB-Lite for memory access requests and performs the memory operation to the ROM.

The ROMC includes the option to wait state all accesses from either the ARM or non-ARM masters to ROM in the event that timing requirements will not allow single hclk clock cycle reads. If a wait state is required, the static inputs rom_wait_arm or rom_wait_alt_mstr can be set to 1 and accesses will take two hclk clock cycles. If wait states are not required, rom_wait_arm or rom_wait_alt_mstr can be set to 0 and accesses will take one hclk clock cycle to complete.

60.3.1.2 ROMC Architecture Diagram

A simple block diagram illustrating the internal architecture of the ROMC is shown in the figure below. The basic logic sub-blocks of the ROMC include an AHB-Lite interface, a ROM memory interface, a BIST sub-block and a sub-block for muxing between BIST mode and normal mode.

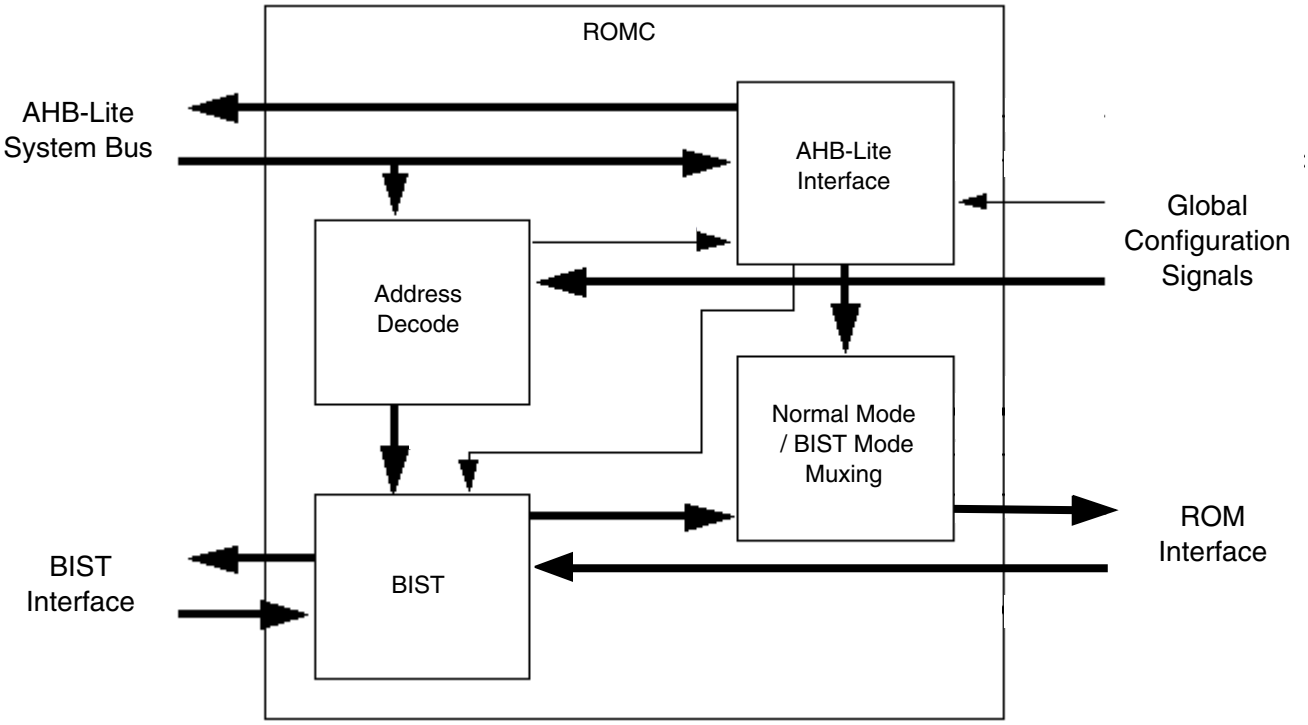

Figure 60-3. ROMC Internal Architecture

60.3.2 ROMC Functional Description

60.3.2.1 ROMC Disabling

All the bits in the ROMC_ROMPATCHENL register are cleared on Reset, disabling all the address comparators. Once the comparators have been enabled, the ROMC functions of data fixing and opcode patching can be quickly disabled by setting the DIS bit in the ROMC_ROMPATCHCNTL register. This bit is used to enable secure operations in which patching functions need to be disabled. This bit is cleared on Reset.

60.3.2.2 ROMC Event Priority

The ROMC has a total of 16 address comparators. The first 8 (0 through 7) comparators can be programmed for the data fixing function (through the 8 data fix enable bits in the ROMC_ROMPATCHCNTL register) while the rest are for opcode patching by default. This allows for potential multiple matching events involving both data fixing and opcode patch types. In these cases the ROMC assigns the highest priority to a data fixing event.

For example, if the ROMC is set up to data fix a certain address with comparator 4 and also opcode patch the same address with comparator 7, it will let comparator 4 have higher priority in indicating a match, and data from ROMC_ROMPATCHD4 will be put on the rompatch_romc_hrdata bus as the override value.

If multiple address matches of the same type level occur concurrently, then the ROMC will choose the source number based on the one with the highest source number. For example, the ROMC is setup to data fix the same location with address comparators 4 and 7, then address comparator 7 will have higher priority in indicating a match, and the value from ROMC_ROMPATCHD7 will be put on the rompatch_romc_hrdata bus as the orverride value. The same priority applies for an opcode patch event, except the override data is in the form of an SWI instruction with the comment field set to the source number with the highest priority.

60.3.2.3 Data Fixing

The data fixing feature allows ROM data to be updated by direct replacement when it is being read. This data usually originates from data tables, but can include ARM instructions. To enable data fixing on a certain address, this address value is written in to one of the first eight (0 through 7) of ROMC_ROMPATCHAxx registers and the same numbered bit set in the ROMC_ROMPATCHENL and ROMC_ROMPATCHCNTL registers. The data to be used for replacement is placed in the corresponding ROMC_ROMPATCHDxx.

The ROMC looks for a read access to ROM (either code fetch or data load) by snooping the AHB interface for read transactions. The address is compared with the values stored in the ROMC_ROMPATCHAxx[22:2] registers. If a match occurs from one of the comparators, the ROMC places the value in the corresponding ROMC_ROMPATCHDxx register on the read data bus by overriding the read data coming from the actual ROM (see the mux in Figure 60-1). The value on the read data bus is maintained until hready is asserted to terminate the access. In data fixing, the entire word is replaced so if a byte or half-word access occurs on a "data fix" location, the entire data word is replaced. The word being replaced is word aligned. (The two LSBs of the matching ROMC_ROMPATCHAxx are ignored in the data fix operation.)

60.3.2.4 Opcode Patching

The opcode patch feature provides the ARM core a mechanism to fetch updated versions of code routines that were originally programmed in ROM. This patching mechanism makes use of the SWI (software interrupt instruction) and a table of function pointers residing in writable memory. The opcode being patched is replaced with a SWI

instruction by the ROMC. Subsequent processing of the SWI reads from a function pointers table to obtain the address of the replacement code. Execution resumes with this code patch.

To enable opcode patching of a certain address, this address value is written into one of the ROMPATCHAxx registers and the corresponding bit set in the ROMPATCHENL to enable the associated comparator. The register's LSB (ROMC_ROMPATCHxx[0]) should be set if THUMB mode patching is in effect for this address. The ROMC identifies a ROM read access by snooping the AHB interface. The address is compared with the values stored in the ROMC_ROMPATCHAxx[22:2] registers. If a match occurs from one of the comparators, the ROMC generates the opcode of a software interrupt (SWI) instruction with the comment field containing the number of the matching address comparator. This opcode and comment is placed on the read data bus until hready is asserted by the ROM controller to terminate the read access.

The type of SWI generated, (that is, either ARM or THUMB), is determined by the LSB of the ROMC_ROMPATCHAxx register associated with the opcode patch. This bit is cleared for ARM mode (32 bits). The ROMC generates a 32-bit SWI (opcode field is 0xEF, occupying bits [31:24] of the word), with the least significant 5 bits of the 24-bit comment field (bits [23:0]) containing the number of the matching address comparator. The rest of the comment field is filled with zeros. This means that the ROMC will use 16 of the 16777216 possible software interrupts. The ROMC overrides the read data from the ROM.

If the LSB of the matching ROMC_ROMPATCHAxx register is set, the opcode patch is in THUMB mode (16 bits or half word). The ROMC generates a 16-bit SWI instruction (opcode field is 0xDF, occupying bits [15:8] of the half word) with the least significant 5 bits of the 8-bit comment field containing with the source number of the address comparator. The rest of the comments field is filled with zeros. This means that the ROMC will use 16 of the 256 possible software interrupts. The ROMC puts this 16 bit SWI instruction value on the proper half of the rompatch_romc_hrdata bus. The other half is zeroed out. Which half of the bus contains the SWI opcode and comment depends on the mode (Big Endian or Little Endian) and the bit 1 of the matching ROMC_ROMPATCHAxx register. In Little Endian mode, the lower half is bits {15:0] and the upper half is bits {31:16]. The order is reversed in Big Endian mode.

In Little Endian mode (bigend signal negated), if bit 1 of the matching ROMC_ROMPATCHAxx is cleared (lower half word selected) then the SWI instruction is put on the lower 16 bits of the read data bus and the upper 16 bits are zeroed out. Only the lower 16 bits of the read data bus is overwritten by the ROMC data. If ROMC_ROMPATCHAxx[1] is set (upper half word selected), the SWI instruction is put on the upper 16 bits of the read data bus and the lower 16 bits are zeroed out. Only the upper 16 bits of the read data bus is overwritten.

In Big Endian mode (bigend asserted), if bit 1 of the matching ROMC_ROMPATCHAxx is cleared (lower half word selected) then the SWI instruction is put on the upper 16 bits of the read data bus while the lower 16 bits are zeroed out. Only the upper 16 bits of the read data bus is overwritten. If ROMC_ROMPATCHAxx[1] is set (upper word selected), the SWI instruction is put on the lower 16 bits and the upper 16 bits are zeroed out. Only the lower 16 bits of the read data bus is overwritten.

The eventual execution of the SWI causes the ARM to save the CPSR in SPSR_SVC, the address of the next instruction after the SWI in R14_SVC, enter Supervisor mode, and fetch the SWI vector at 0x8, which then takes it to a handler for further processing as described in the next section.

60.3.2.4.1 Typical Software Response to Opcode Patch

When the SWI handler executes it needs to determine whether the SWI was generated by the ROMC. This is done by loading the SWI instruction and extracting its comment field. The state of the ARM core (ARM or THUMB) when the SWI was executed dictates whether to load the instruction word (ARM) or half word (THUMB). This state information can be determined by testing the T bit (bit 5) of the SPSR. If it's set, the execution was in THUMB mode.

By convention, if the comment field of the SWI is greater than 16, the software interrupt was initiated by software (i.e. an operating system call), and a branch is taken to the appropriate handler routine for further processing. If the comment field is less than 16, the SWI was generated by the ROMC performing a code patch operation. In this case, the software then reads from a table of function pointers, using the value in the SWI comment field as the index into the table. The value that is read is the address of the code patch. This value is loaded into the PC to begin the execution of the code patch. The following code segment illustrates a typical handling of the SWI.

```
stmfd        sp!, {r0-r1,lr}       @ push register onto SWI stack
mrs         r0, spsr        @ get saved status register
tst          r0, #0x20     @ check if call was in THUMB mode
ldrneh      r0, [lr,#-2]        @ yes: load opcode half-word and
bicne       r0, r0, #0xff00   @ yes: extract THUMB comment
ldreq       r0, [lr,#-4]        @ no: load opcode word and
biceq       r0, r0, #0xff000000 @ no: extract ARM comment
                    @ now r0 has comment field
cmp         r0, #16      @ compare to 16 (maximum for ROMC)
ldrlt          lr, =rompatch_tbl_ptr @ < 16: get top of current ROMC
                    @ table; global variable which is
                    @ changeable per context
ldrlt          r1, [lr, r0, lsl #2]   @ < 16: read function pointer from
                    @ table assumed an array of pointers
                    @ patch functions
strlt           r1, [sp, #8]     @ < 16: store function pointer onto
                    @ stack in position of link register
ldmltfd        sp!, {r0-r1,pc}^      @ < 16: "fake" return from SWI, will
                    @ vector core to appropriate patch
                    @ function and set core back to previous
                    @ mode of operating
ldr          r1, =swi_hdler   @ >= 16: pointer to standard SWI
```

```
                        @ handler
mov         lr, pc          @ >= 16: set link register
bx          r1            @ >= 16: jump to standard SWI
                        @ handler
ldmfd        sp!, {r0-r1,pc}^      @ >= 16: pop registers from stack
```

60.3.2.5 External Boot Feature

Following a Reset event, the ARM issues an instruction fetch of the Reset Vector from address 0x0. This instruction, normally residing in ROM is usually a branch to a Reset handler or boot code which also normally resides in ROM. The ROMC external boot feature allows the bypassing of this code, using a different boot code residing perhaps in external memory.

This feature uses the data fix mechanism and works as follows: if the boot_int signal is negated when a Reset event occurred, the ROMC will perform a data fix of the Reset Vector at 0x0 with the following instruction (opcode 0xE59FF00C):

```
ldr         pc,[pc,#12]      @ read 0x0000_0014 for reset_vector
```

The value of PC when this instruction is executed is 8 so that a PC relative offset of 12 makes the source address 20 or 0x14. When this instruction executes, the ARM core reads from address 0x0000_0014, triggering a ROMC data fix operation which places the value taken from the external boot address on the read data bus, with the two LSBs zeroed out. This value is returned to the ARM to be placed in the PC causing code fetch and execution to start from that address.

60.3.2.6 Alternate Masters and ROMC

The ROMC sits on the AHB bus of the internal ROM (ROMC). This means that the ROMC can modify values on the read data bus going to the master. Therefore, any master which reads an opcode patched or data patched location will read patched data.

60.4 Programmable Registers

All registers are accessible through an IP Bus and can only be accessed in privileged mode. These registers can only be written with 32-bits stores and are clocked by hclk_reg.

The ROMC register placement was originated from the AWPT design used in the ARM7 platform of Neptune

ROMC memory map

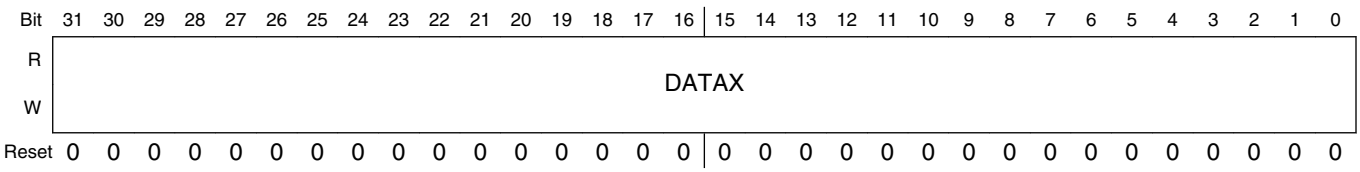
60.4.1 ROMC Data Registers (ROMC_ROMPATCHD)

The ROMC data registers (ROMC_ROMPATCHD7 through ROMC_ROMPATCHD0) store the data to use for the 8 1-word data fix events. Each register is associated with an address comparator (7 through 0). When a data fixing event occurs, the value in the data register corresponding to the comparator that has the address match is put on the romc_hrdata[31:0] bus until romc_hready is asserted by the ROM controller to terminate the access. A MUX external to the ROMC will select this data over that of romc_hrdata[31:0] in returning read data to the ARM core. The selection is done with the control bus rompatch_romc_hrdata_ovr[1:0] with both bits asserted by the ROMC.

If more than one address comparators match, the highest-numbered one takes precedence, and the value in corresponding data register is used for the patching event.

Addresses: ROMC_ROMPATCH0D is 63FB_8000h base + D4h offset = 63FB_80D4h
ROMC_ROMPATCH1D is 63FB_8000h base + D8h offset = 63FB_80D8h
ROMC_ROMPATCH2D is 63FB_8000h base + DCh offset = 63FB_80DCh
ROMC_ROMPATCH3D is 63FB_8000h base + E0h offset = 63FB_80E0h
ROMC_ROMPATCH4D is 63FB_8000h base + E4h offset = 63FB_80E4h
ROMC_ROMPATCH5D is 63FB_8000h base + E8h offset = 63FB_80E8h
ROMC_ROMPATCH6D is 63FB_8000h base + ECh offset = 63FB_80ECh
ROMC_ROMPATCH7D is 63FB_8000h base + F0h offset = 63FB_80F0h



ROMC_ROMPATCH*n*D field descriptions

Field	Description
31–0 DATAX	Data Fix Registers - Stores the data used for 1-word data fix operations. The values stored within these registers do not affect the writes to the memory system. They are selected over the read data from ROM when a data fix event occurs. If any part of the 1-word data fix is read, then the entire word is replaced. Therefore, a byte or half-word read will cause the ROMC to replace the entire word. The word is word address aligned.

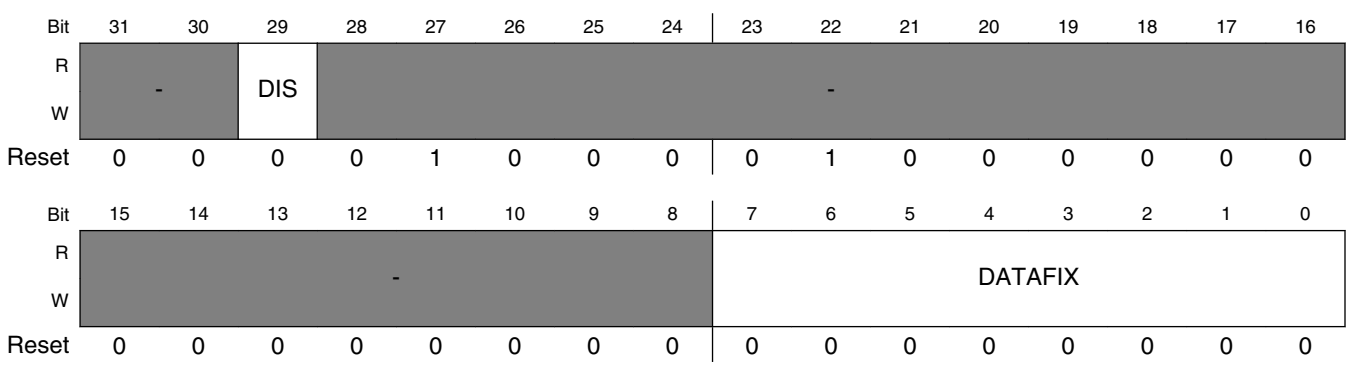
60.4.2 ROMC Control Register (ROMC_ROMPATCHCNTL)

The ROMC control register (ROMC_ROMPATCHCNTL) contains the block disable bit and the data fix enable bits. The block disable bit provides a means to disable the ROMC data fix and opcode patching functions, even when the address comparators are enabled. The External Boot feature is not affected by this bit. The eight data fix enable bits (0 through 7), when set, assign the associated address comparators to data fix operations

NOTE

Bits 27 and 22 always read as 1s.

Address: ROMC_ROMPATCHCNTL is 63FB_8000h base + F4h offset = 63FB_80F4h



ROMC_ROMPATCHCNTL field descriptions

Field	Description
31–30 -	Reserved
29 DIS	ROMC Disable -- This bit, when set, disables all ROMC operations. This bit is used to enable secure operations. 0 Does not affect any ROMC functions (default) 1 Disable all ROMC functions: data fixing, and opcode patching
28–8 -	Reserved
7–0 DATAFIX	**Data Fix Enable - Controls the use of the first 8 address comparators for 1-word data fix or for code patch routine.** 0 Address comparator triggers a opcode patch 1 Address comparator triggers a data fix

60.4.3 ROMC Enable Register High (ROMC_ROMPATCHENH)

The ROMC enable register high (ROMC_ROMPATCHENH) and ROMC enable register low (ROMC_ROMPATCHENL) control whether or not the associated address comparator can trigger a opcode patch or data fix event. This implementation of the ROMC only has 16 comparators, therefore ROMC_ROMPATCHENH and the upper half of ROMC_OMPATCHENL are read-only. ROMC_ROMPATCHENL[15:0] are associated with comparators 15 through 0. ROMC_ROMPATCHENLH[31:0] would have been associated with comparators 63 through 32.

Address: ROMC_ROMPATCHENH is 63FB_8000h base + F8h offset = 63FB_80F8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ROMC_ROMPATCHENH field descriptions

Field	Description
31–0 -	Reserved

60.4.4 ROMC Enable Register Low (ROMC_ROMPATCHENL)

The ROMC enable register high (ROMC_ROMPATCHENH) and ROMC enable register low (ROMC_ROMPATCHENL) control whether or not the associated address comparator can trigger a opcode patch or data fix event. This implementation of the ROMC only has 16 comparators, therefore ROMC_ROMPATCHENH and the upper half of ROMC_ROMPATCHENL are read-only. ROMC_ROMPATCHENL[15:0] are associated with comparators 15 through 0. ROMC_ROMPATCHENLH[31:0] would have been associated with comparators 63 through 32.

Address: ROMC_ROMPATCHENL is 63FB_8000h base + FCh offset = 63FB_80FCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																ENABLE																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

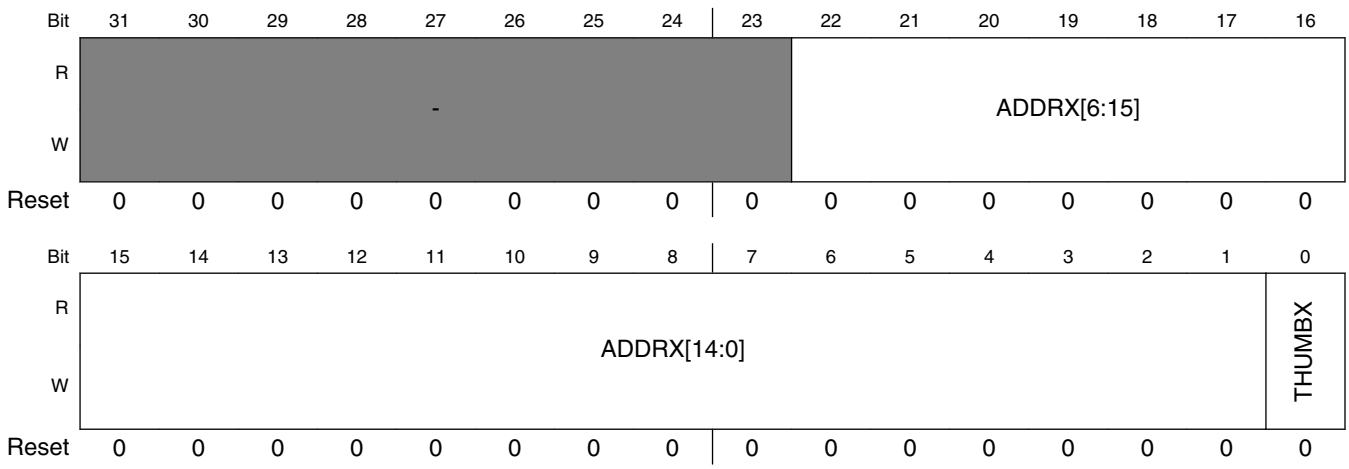
ROMC_ROMPATCHENL field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved 0 Address comparator disabled 1 Address comparator enabled, ROMC will trigger a opcode patch or data fix event upon matching of the associated address
15–0 ENABLE	**Enable** Address **Comparator -** This bit enables the corresponding address comparator to trigger an event. 0 Address comparator disabled 1 Address comparator enabled, ROMC will trigger a opcode patch or data fix event upon matching of the associated address

60.4.5 ROMC Address Registers (ROMC_ROMPATCHA)

The ROMC address registers (ROMC_ROMPATCHA0 through ROMC_ROMPATCHA15) store the memory addresses where opcode patching begins and data fixing occurs. The address registers ROMC_ROMPATCHA0 through ROMC_ROMPATCHA15 are each 21 bits wide and dedicated to one 4 Mbyte memory space. Bits 21 through 2 are address bits, to be compared with romc_haddr[21:2] for a match; bit 1 is also an address bit used for half word selection. Bit 0 is the mode bit (set to 1 for THUMB mode). 1-word data fixing can only be used on the first 8 of the address comparators. ROMC_ROMPATCHA0 through ROMC_ROMPATCHA15 are associated each with address comparators 0 through 15.

Addresses: 63FB_8000h base + 100h offset + (4d × *n*), where *n* = 0d to 15d



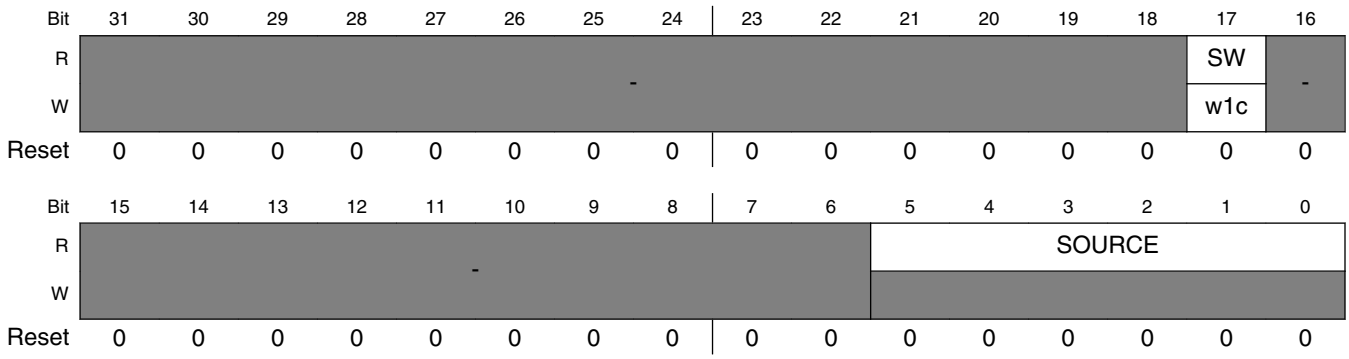
ROMC_ROMPATCH*n*A field descriptions

Field	Description
31–23 -	Reserved
22–1 ADDRX	Address Comparator Registers - Indicates the memory address to be watched. All 16 registers can be used for code patch address comparison. Only the first 8 registers can be used for a 1-word data fix address comparison. Bit 1 is ignored if data fix. Only used in code patch
0 THUMBX	THUMB Comparator Select - Indicates that this address will trigger a THUMB opcode patch or an ARM opcode patch. If this watchpoint is selected to be a data fix, then this bit is ignored as all data fixes are 1-word data fixes. 0 ARM patch 1 THUMB patch (ignore if data fix)

60.4.6 ROMC Status Register (ROMC_ROMPATCHSR)

The ROMC status register (ROMC_ROMPATCHSR) indicates the current state of the ROMC and the source number of the most recent address comparator event.

Address: ROMC_ROMPATCHSR is 63FB_8000h base + 208h offset = 63FB_8208h



ROMC_ROMPATCHSR field descriptions

Field	Description
31–18 -	Reserved
17 SW	ROMC AHB Multiple Address Comparator matches Indicator - Indicates that multiple address comparator matches occurred. Writing a 1 to this bit will clear this it. 0 no event or comparator collisions 1 a collision has occurred
16–6 -	Reserved
5–0 SOURCE	ROMC Source Number - Binary encoding of the number of the address comparator which has an address match in the most recent patch event on ROMC AHB. If multiple matches occurred, the highest priority source number is used. 0 Address Comparator 0 matched 1 Address Comparator 1 matched 15 Address Comparator 15 matched

Chapter 61
Run-Time Integrity Checker (RTIC)

61.1 Overview

The Run-Time Integrity Checker (RTIC) is part of the Platform Independent Security Architecture (PISA) family of platform security components. Its function is to ensure the integrity of the peripheral memory contents and assist with boot authentication. The RTIC has the ability to verify the memory contents during system boot and during run-time execution. If the memory contents at runtime fail to match the hash signature, an error in the security monitor is triggered.

61.2 Features

The RTIC offers the following features:

- SHA-1 and SHA-256 message authentication
- Input DMA (AMBA-AHB Lite bus master) interface
- Segmented data gathering to support non-contiguous data blocks in memory (up to 2 segments per)
- Works with High Assurance Boot process
- Secure-scan DFT security
- Programmable DMA bus duty cycle timer
- Power-saving clock gating logic
- Full word memory reads (word-aligned addresses, multiple of 32-bit lengths)

61.2.1 Modes of Operation

The RTIC operates in two primary modes:

- One time hash mode

- Used during high assurance boot for code authentication or one time integrity checking
- Stores hash result internally and signals interrupt to host

- Continuous hash mode
  - Used at run time to continuously verify integrity of memory contents
  - Checks re-generated hash against internally stored values and interrupts host only if error occurs

Chapter 62
SAHARA Security Accelerator (SAHARA)

62.1 Overview

The Symmetric/Asymmetric Hashing and Random Accelerator (SAHARA) is a security coprocessor.

SAHARA implements block encryption algorithms, (AES, DES, and 3DES), hashing algorithms (MD5, SHA-1, SHA-224, and SHA-256), a stream cipher algorithm (ARC4), and a hardware random number generator. It has a slave IP bus interface for the host to write configuration and command information, and to read status information. SAHARA also has a DMA controller with an AHB bus interface to reduce the burden on the host to move the required data to and from memory.

See the figure below for the block diagram of SAHARA.

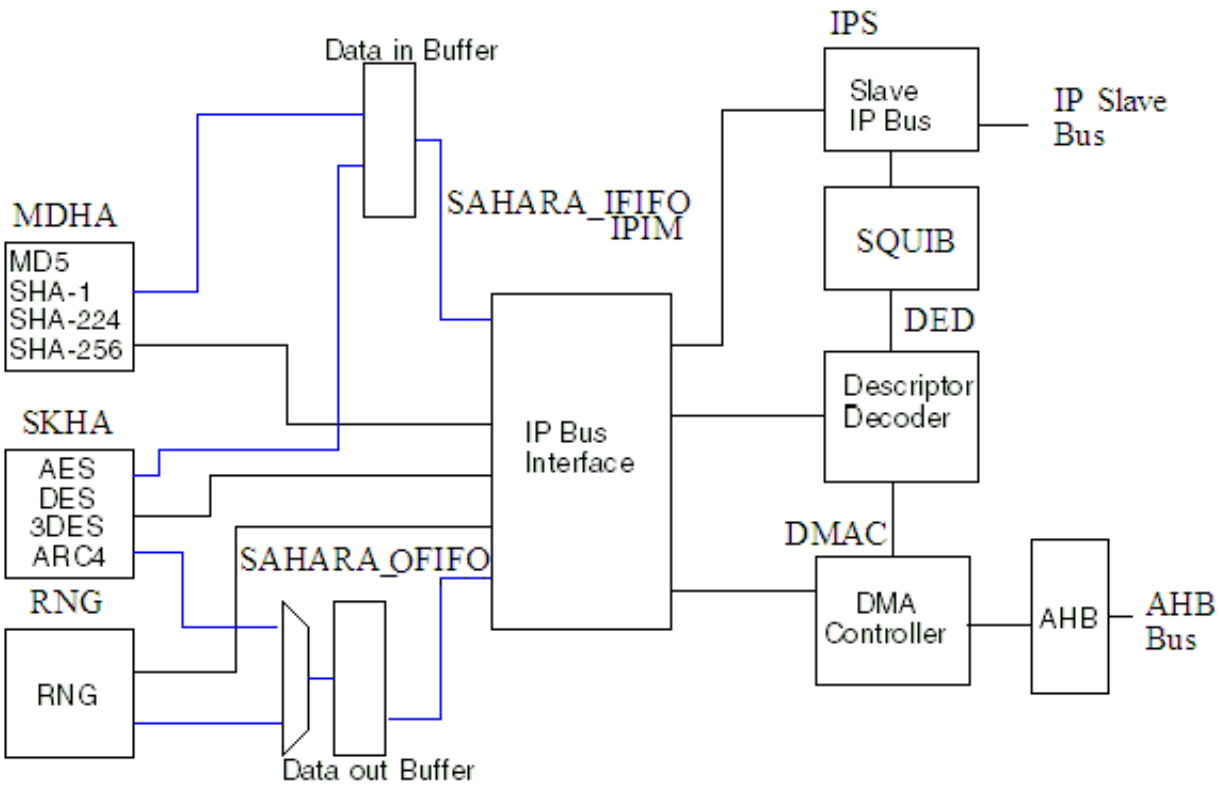


Figure 62-1. Block Diagram of SAHARA

62.2 Features

SAHARA accelerates the following security functions:

- AES encryption/decryption
  - ECB, CBC, CTR, and CCM modes
  - 128-bit key
- DES/3DES
  - ECB, CBC and CTR modes
  - 56-bit key with or without parity (DES)
  - 112-bit or 168-bit key with parity (3DES)
- ARC4 (RC4-compatible cipher)
  - 5-16 byte key
  - Host accessible S-box
- MD5, SHA-1, SHA-224 and SHA-256 hashing algorithms.
  - Messages lengths that are multiples of bytes (with auto padding).
  - Auto padding supported.

    - HMAC (support for IPAD and OPAD via Descriptors).
    - Up to 2^{32} byte message length (with auto padding).
- Pseudo-Random number generator
    - Entropy is generated via independent free running ring oscillators.

SAHARA also provides the following features:

- Descriptor based processing to reduce communication between host processor and SAHARA
- Multiple Master Interface (SQUIB), allows two masters to share SAHARA transparently.
- ARM TrustZone support via additional AHB and IPBus signalling
- Low power design
    - Automatic power down of individual blocks when not in use
    - Clock gating on registers
    - RNG sleep mode
- Restricted access to potentially sensitive information
    - Internal registers are cleared after a Descriptor chain has completed processing in BATCH mode.
    - SCC Security Monitor can cause data to be cleared.
    - Scan reset and scan exit signals prevent data being scanned out.
- Optimization for Maximum of 8-word AHB Burst.

62.2.1 Modes of Operation

SAHARA can be used in three modes. The mode bits can be changed only when SAHARA is idle. Otherwise, the mode bits are not written and no other indication is given.

62.2.1.1 BATCH Mode-Overview

The BATCH mode is the default operating mode. After a chain of Descriptors has been processed, the internal functional blocks are initialized, and an interrupt is generated. Initializing SAHARA prevents a task from being able to access the left over data from a Descriptor chain of a different task.

62.2.1.2 DEDICATED Mode-Overview

The DEDICATED mode is used when SAHARA is dedicated to a single task. In the DEDICATED mode, SAHARA does not reset the internal state information at the end of a Descriptor chain. This allows a task to improve performance by not having to save and restore its context information between each set of Descriptor chains. This is useful when a task does not have access to all of the data at one time, and must therefore present its Descriptors at different times.

62.2.1.3 DEBUG Mode-Overview

In direct access DEBUG mode, the host writes directly to the address space of the internal hardware blocks. SAHARA single-steps Descriptors only when in DEBUG mode. This is intended only for interactive debugging, and is disabled when the SCC Security Monitor is in the Secure state .

In the DEBUG mode, the host processor can read and write the internal encryption engine's registers. No interrupts are generated while SAHARA is in DEBUG mode.

NOTE

Detailed information about SAHARA is provided in the Securety Reference Manual. Contact your Freescale representative for information about obtaining this document.

Chapter 63
Serial Advanced Technology Attachment Controller (SATA)

63.1 Introduction

The chip includes an integrated Serial Advanced Technology Attachment (SATA) Controller that is compatible with the Advanced Host Controller Interface (AHCI) specification.

The SATA Controller block (SATA) along with integrated physical link hardware (SATA PHY) provide one SATA port for the attachment of external SATA compliant storage devices.

The following section introduces the block features and architecture.

63.1.1 Features

The SATA block supports the following features:

- Compliant with the following specifications:
  - Serial ATA 2.6
  - AHCI Revision 1.3 (except FIS-based switching)
  - AMBA 2.0 from ARM
- SATA 1.5 Gb/s speed.
- eSATA (external analog logic also needs to support eSATA)
- RX data buffer for recovered clock systems
- Data alignment circuitry when RX data buffer is also included
- OOB signaling detection and generation
- 8b/10b encoding/decoding
- Asynchronous signal recovery, including retry polling
- Power management features including automatic partial-to-slumber transition
- BIST loopback modes

- Supports one SATA device(port0)
- Configurable AMBA AHB interface (one master and one slave for each interface)
- Internal DMA engine
- Hardware-assisted Native Command Queuing for up to 32 entries
- Port Multiplier with command-based switching
- Disabling RX and TX Data clocks during power down modes

63.1.2 System Overview

SATA is an AHCI-compliant Host Bus Adapter (HBA). Together with the corresponding physical layer (PHY), it forms a complete AHCI HBA interface.

Note that only Port 0, PHY0, and bus interface are implemented in this product.

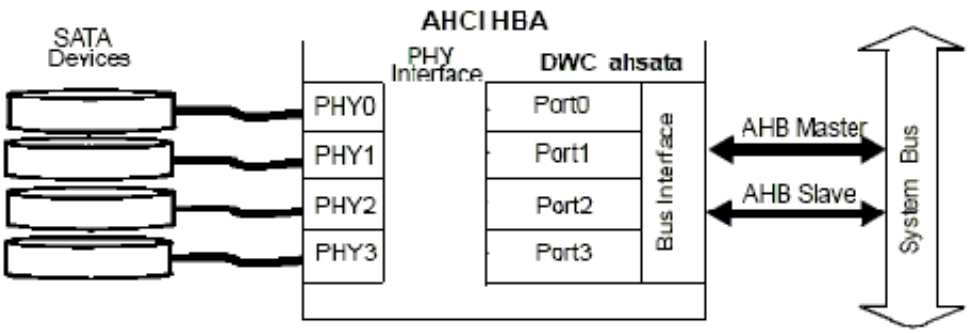

Figure 63-1. SATA AHCI System Block Diagram (Shown with Four Ports)

63.2 Block Overview

This section describes the functional sub-blocks of the SATA block

63.2.1 Block Diagram

The following figure provides a high-level view of the SATA architecture, followed by a brief description. The diagram shows additional ports and PHY interfaces not implemented in this product.

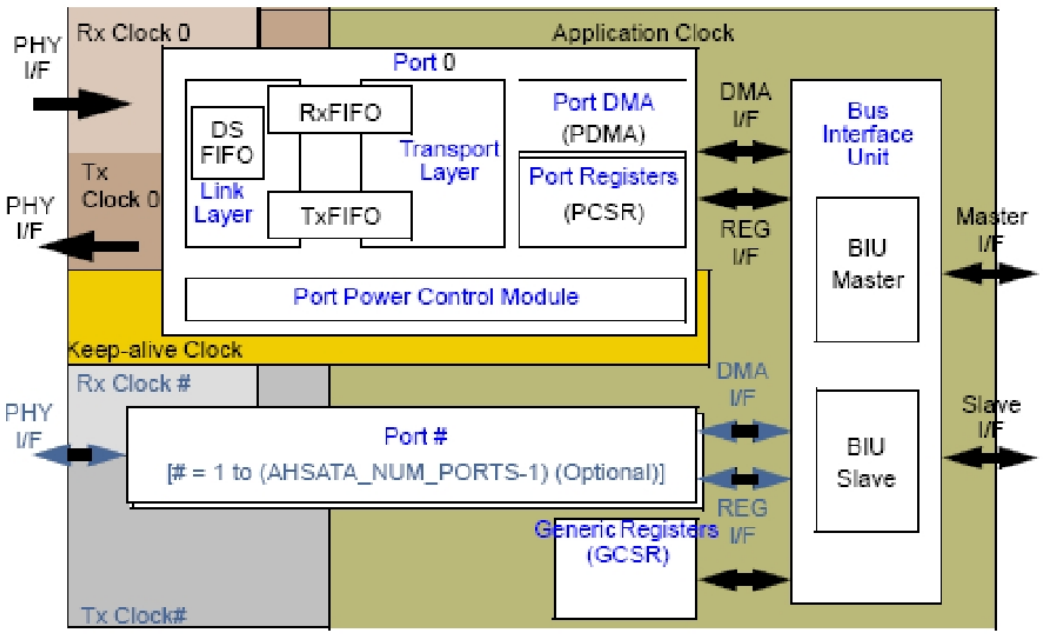

Figure 63-2. SATA Block Diagram

The SATA block consists of three main sub-blocks:

- Bus Interface Unit (BIU)
- Generic Registers (GCSR) (GCSR)
- Port

The system bus provides the application clock (hclk). BIU, GCSR and part of the Port operate in the application clock domain. Rx (when present), and Tx clocks are generated in the PHY and depend on the interface speed and PHY data width, as shown in the table below. The Rx OOB clock frequency is 50 or 60 MHz depending on PHY's reference clock (external or internal respectively).

Table 63-1. PHY-Supplied Clock Frequencies (clk rbc and clk asic)

Interface Speed (GB/s)	8/10 bits (Mhz)	16/20 bits (Mhz)	32/40 bits (Mhz)
1.5	150	75	37.5

Port logic contains its own DMA engine that implements AHCI functionality and initiates all of the data transfers between the external SATA device and system memory.

The Port PHY interface operates in three or four clock domains: RxOOB clock (clk_rxoob), Rx clock (clk_rbc) when present, keep-alive clock (clk_pmalive) and Tx clock (clk_asic). Most of the Link Layer (both receive and transmit data paths), and part of the Transport Layer always operate in the Tx clock domain. The Rx clock is a clock

recovered from the PHY, and is used for clocking data into the SATA block. The Port contains a Power Control Module operating in the always-alive pmalive clock domain. This Power Control Module facilitates disabling Rx and Tx clocks in power down modes.

All SATA block clocks are asynchronous to each other in general. The BIU connects the Port to the system bus. AHB master interface is used to transfer data between the Port and the system memory, while the AHB slave interface is used by the software (driver) to access SATA block registers. All the SATA global registers are implemented in the Generic Register module.

63.2.2 SATA Block Transfer Hierarchy

The following figure shows the SATA block transfer hierarchy from the system bus point of view.

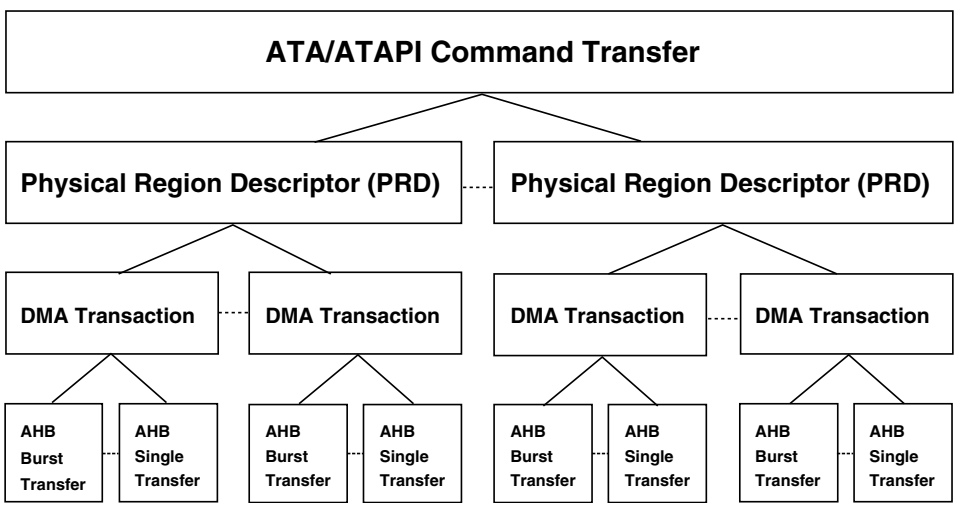

Figure 63-3. SATA Block Transfer Hierarchy

Data for an ATA/ATAPI command resides in the system memory in the form of one or more Physical Region Descriptors (PRD). PRD entries describe the physical location and length of data to be transferred.

Each PRD entry is read by the SATA Port DMA from the system memory before transferring the block of data associated with this entry.

The Port DMA transfers the PRD data block between the system memory and its FIFOs using one or more DMA transactions. DMA transaction size can be set by software.

Finally, the BIU Master generates one or more AHB burst or single bus transfers based on the DMA transaction request from the PDMA. The BIU Master tries to generate a burst equal to the DMA transaction size, but it might break it into several burst/single transfers due to various bus conditions (for example, early burst termination, 1-KB address boundary crossing, etc.).

63.2.3 Standards Compliance

1. The Serial ATA specifications can be found at the following website:

   http://sata-io.org

2. The AMBA Specification can be found at the following website:

   http://www.arm.com/products/solutions/AMBA_Spec.html

3. The AHCI specification can be found at the following website:

   http://www.intel.com/technology/serialata/ahci.htm

In the event of any conflict between the information in this chapter and the AHCI specification, the AHCI specification prevails.

63.3 Architecture

This section describes the SATA block interfaces, protocols, functionality, and implementation.

63.3.1 Architecture Overview

The SATA block diagram is shown in the following figure. While this diagram shows multiple ports, note that only one port is implemented.

The functional blocks that make up SATA are described in the following sub-sections.

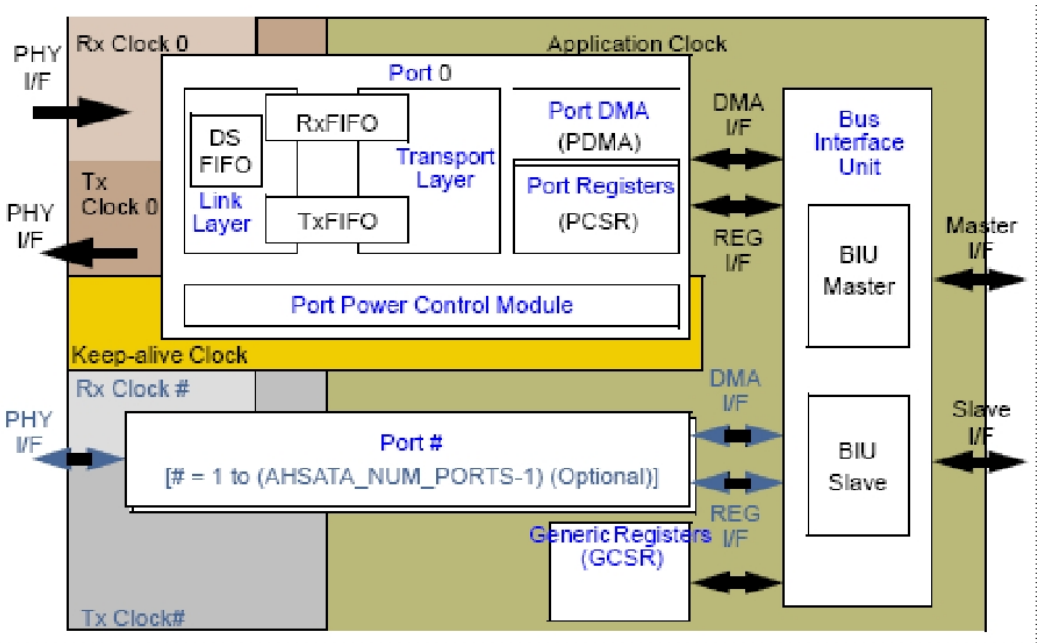

Figure 63-4. SATA Block Functional Diagram

63.3.2 Bus Interface Unit

The Bus Interface Unit (BIU) connects the AHB Master to the internal Port DMA controllers, and connects the AHB Slave to the internal Port registers.

The BIU is comprised of the following:

- AHB Slave Bus/GIF Interface (AHB Slave) and mapping logic.
- Register Read MUX, mapped to the AHB Slave read-response channel.
- AHB Master Bus/GIF Interface (AHB Master) and mapping logic.
- DMA Arbiter, mapped to the AHB Master.

The following figure displays a block diagram of the Bus Interface Unit.

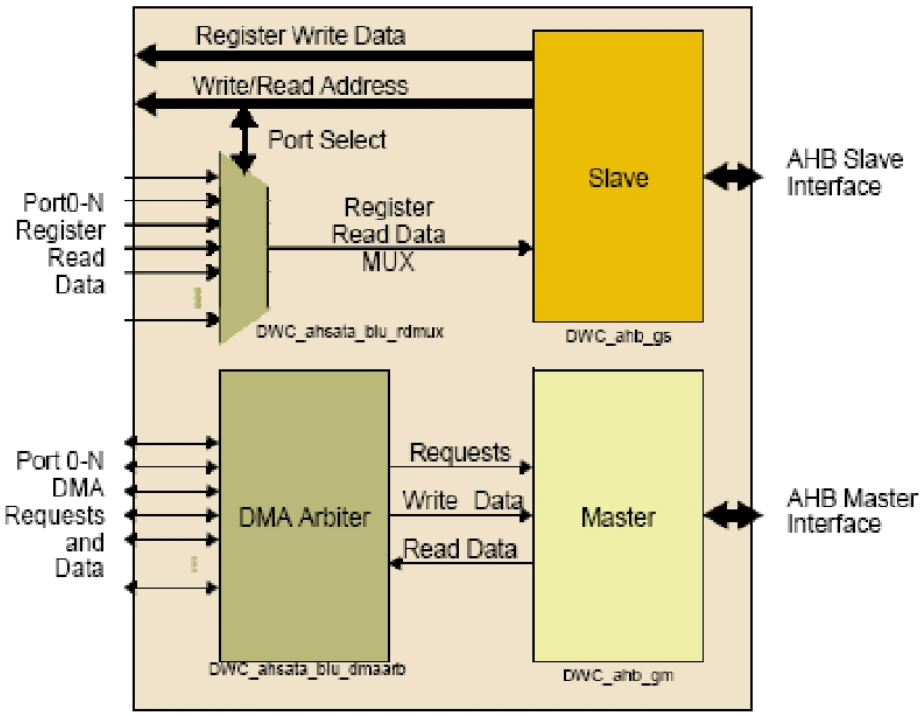

Figure 63-5. SATA Block Bus Interface Unit Block Diagram

63.3.2.1 AHB Slave Bus GIF Interface

The AHB Slave Bus GIF Interface (AHB Slave) converts AHB bus cycles to internal read/write request and response channel signals, which are mapped to Generic and Port control registers (GCSR and PCSR).

Characteristics of this unit include the following:

- Fully AMBA 2.0-Compliant AHB slave interface
- Supports single transfer type
- Supports INCR burst type
- Configured for little-endian byte ordering
- Supports 32-bit data bus width and 32-bit address width
- Master supports 32-bit (burst/single) and 16-bit (single only) transfer sizes, slave supports 8, 16, and 32-bit transfer sizes using SINGLE, INCR4, INCR8, and INCR16 burst types.
- Supports master BUSY and early burst termination
- Generates OKAY or ERROR response (SPLIT and RETRY are not supported).

The wait state for different accesses are:

- 0 wait state for any NSEQ or SEQ write access, 1 wait state for any NSEQread access.
- 1 wait state for any read after write decode to the same address.

AHB Slave generates ERROR response on s_hresp output when it detects any of the following illegal accesses:

- Transfer size is not 8, 16, or 32-bit.
- Address is not 32-bit or greater aligned.

Each Port decodes the csr_waddr address to select the required register when AHB Slave external mapping asserts corresponding p0_csr_sel signal during register write access. When a Port is not configured, then its register locations should be treated as reserved: read accesses return zeros, write accesses have no effect.

Figure 3-3 shows various AHB Slave accesses.

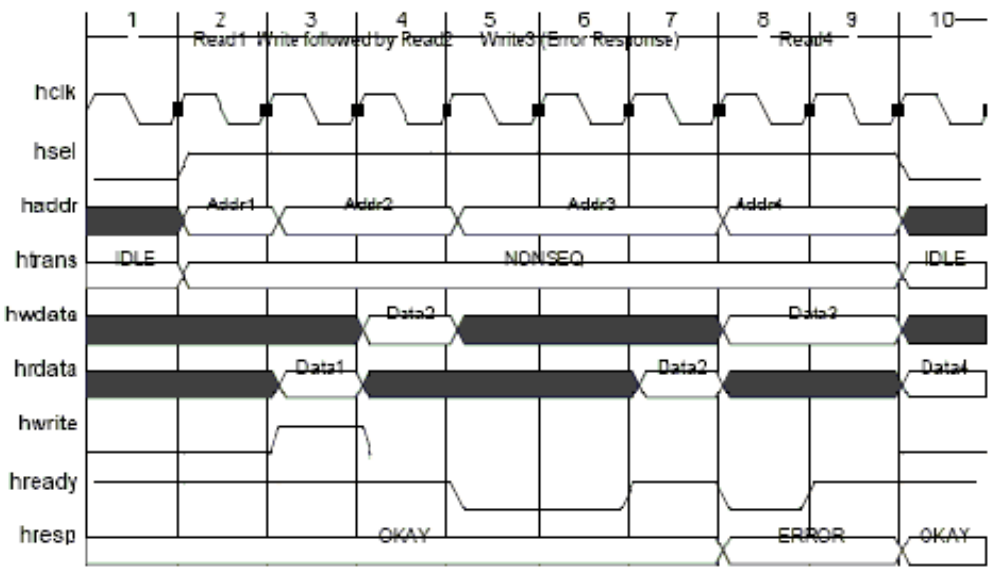

Figure 63-6. AHB Single Transfer

63.3.2.2 Register Read Multiplexer

The Register Read Multiplexer simply multiplexes all of the Port registers to the AHB Slave read response channel.

The AHB Slave read address selects which registers to read.

63.3.2.3 AHB Master Bus/GIF Interface

The AHB Master Bus/GIF Interface (AHB Master) converts Port DMA requests, from the DMA Arbiter, into AHB Master requests.

The AHB Master implements the following function:

- Converts Port DMA requests into AHB cycles

Characteristics of this unit include the following:

- Fully AMBA 2.0-compliant AHB master
- SINGLE, INCR4, INCR8 & INCR16 burst types supported on the Port DMA request:
- Handles AHB SPLIT, RETRY, ERROR conditions
- Supports early burst termination via requesting remainder of burst
- Configured for little-endian byte ordering
- Handles AHB 1-KB boundary breaking
- All AHB transfers are 16- or 32-bit aligned
- Does not support locked transfers (m_hlock=0) and wrapped burst transfer (WRAP type).

The following sequence of events describes basic AHB Master operation:

1. When a Port becomes active, that is has data in the RxFIFO to transfer to system memory, or needs data to transfer to the Device, it asserts dma_req signal to the AHB Master to request DMA transaction in the direction indicated by the dma_read signal (0 - Port to AHB, 1- AHB to Port). Transaction size is indicated by the dma_count signal. Since all configured Ports operate independently, several Ports may assert dma_req at the same time.
2. The DMA Arbiter arbitrates between multiple active Ports using round-robin equal-priority scheme, selects a Port, and provides the request to the AHB Master. The AHB Master then latches starting address and transaction size. Arbitration is done on a per-transaction basis, that is, the Port "owns" the bus until all data of the given transaction size has been transferred or the transfer is terminated due to error.
3. AHB Master asserts either dma_rxpop signal to request data from the Port during AHB bus write transfer, or dma_txpush signal along with valid data to the Port during AHB bus read transfer.
4. AHB Master generates AHB transfer and tries to complete the data transfer either in one AHB burst (ideally), or it may break the transaction into multiple burst transfers, for example, due to the 1-KB address boundary crossing, or early burst termination condition.
5. AHB Master completes the AHB transfers when all the data of the requested transaction size has been successfully transferred, which allows the DMA Arbiter to

switch to the next active Port. The following figure shows various BIU Master accesses.

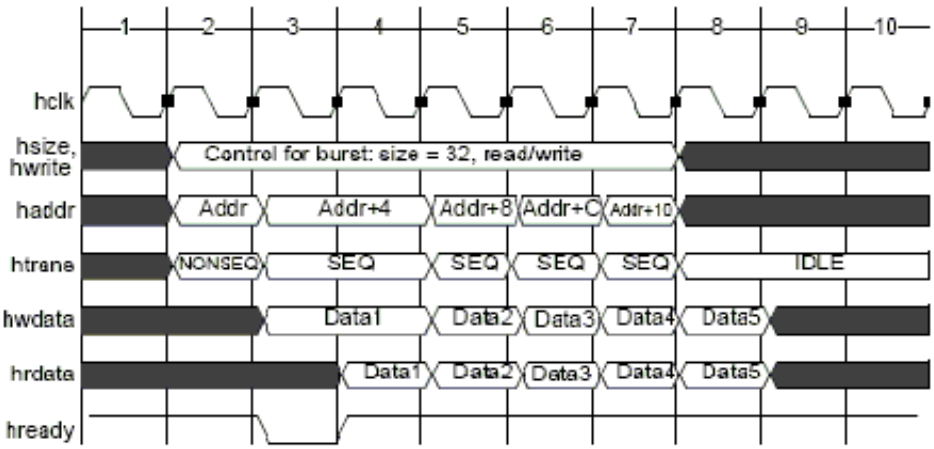

Figure 63-7. AHB Burst Transfer

63.3.2.4 DMA Arbiter

The DMA Arbiter simply monitors individual Port DMA requests and presents them to the AHB Master based on a round robin priority scheme.

Requests of larger burst length inherently gain more AHB bus priority than requests of shorter burst length. Software can use this approach to give Ports different priority.

63.3.3 Generic Registers (GCSR)

This module implements all SATA global registers and provides the following functions:

- Generic configuration and control;
- Global interrupt support;
- BIST operation (implementation-specific registers).

Refer to "Register Descriptions" for details on register operation.

63.3.4 Port

The Port instantiates the following modules:

- Port DMA

- Port Registers
- Transport Layer
- Link Layer
- Port Power Control Module

63.3.4.1 Port DMA

The Port DMA (PDMA) module implements the following functions:

- Monitors commands posted by system software using SATA_P 0CI register. When any of the command slots becomes active, PDMA downloads the corresponding Register FIS from the Command List structure and passes it to the Transport Layer TxFIFO for transmission to the Device.
- Controls data transfer between the Transport Layer FIFOs and system memory using Physical Region Descriptor Tables (PRDT).
  - During Data FIS reception, PDMA requests AHB write transfer of SATA_P 0DMACR[RXTS] size from the BIU Master when RxFIFO contains data of at least this size.
  - During Data FIS transmission, PDMA requests AHB read transfer of SATA_P 0DMACR[TXTS] size from the BIU Master when TxFIFO contains space of at least this size.
- Transfers non-Data FISes received from the device to system memory using Received FIS Structure.

Most of the communication between the PDMA and software is done using two system memory descriptors that are constructed by software prior to initiating the transfer: FIS descriptor, which contains FISes received from the device, and the other is the Command List, which contains a list of 1 to 32 commands available for the Port to execute and the pointers for data transfers.

Some additional communication is done via registers located in the GCSR and PCSR modules.

System memory structures are described in the SATA AHCI specification and are not repeated in this document for the sake of brevity.

The PDMA module operates in the application clock (hclk) domain and has 32-bit-wide data path. It supports 32-bit addressing.

The following figure shows a high-level state diagram of the Port DMA operation. Refer to the SATA AHCI specification for a more detailed Port state diagram.

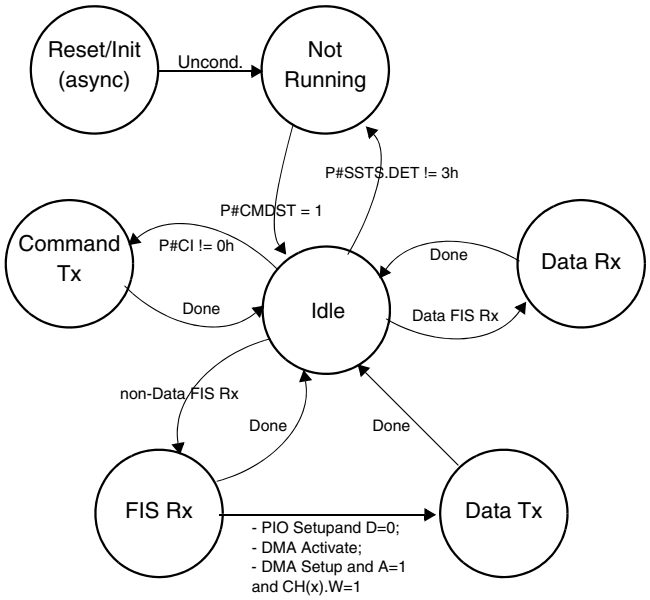

Figure 63-8. Port DMA State Diagram

63.3.4.2 Port Registers

The Port registers (PCSR) module implements all Port-specific registers:

- Command List and FIS Base address
- Interrupt Status/ Enable
- Port Command/ Status
- Task File Data/ Signature/ Serial ATA
- DMA status/control (implementation-specific)
- PHY status/control (implementation-specific)

Refer to "Register Descriptions" for details on register operation.

63.3.4.3 Transport Layer

The Transport Layer constructs Frame Information Structures (FIS) for transmission and decomposes received FISes.

The following list describes how an FIS is constructed:

- Receives FIS content from the Port DMA or Port Register modules;
- Notifies the Link Layer of required frame transmission and passes FIS to Link;
- Manages TxFIFO flow, notifies Link of required flow control via TxFIFO flags;

- Receives frame receipt acknowledge from Link;
- Reports good transmission or errors to requesting higher layer.

The following list describes how an FIS is decomposed:

- Receives the FIS from the Link Layer;
- Determines FIS type and checks for PHY/Link/Transport errors;
- Provides good/bad FIS acknowledge to the Link Layer;
- Distributes the FIS content to the locations indicated by the FIS type;
- Reports good reception or errors to the Port DMA/Registers.

The Transport Layer functional block diagram is shown in the figure below. The Transport Layer consists of the following five main modules:

- Receive FIFO (RxFIFO)
- Transmit FIFO (TxFIFO)
- Transport Check module (TCHK)
- Transport State Machine module (TSM)
- Synchronization module (APP_ASIC)

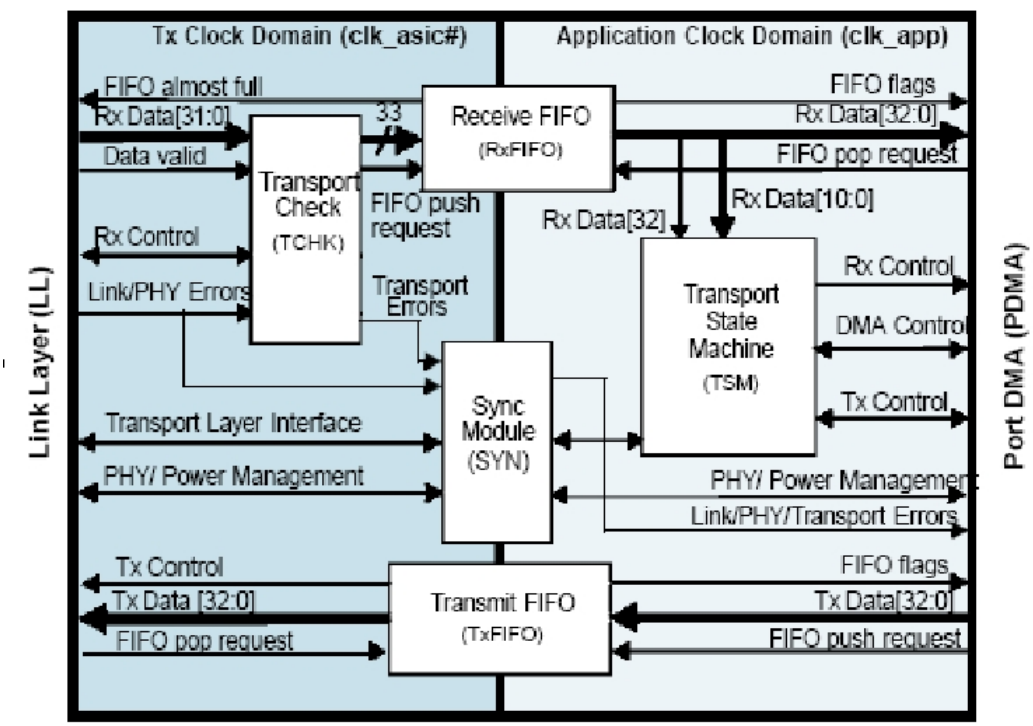

Figure 63-9. Transport Layer Functional Block Diagram

The Transport Layer operates in two clock domains: transmit and application. Transmit clock is generated in the PHY and depends on the Link Layer data path width (valid frequency values are: 37.5 MHz, 75 MHz,150 MHz, and 300 MHz). The application clock is sourced from the system bus and depends on the software. Both transmit and receive data paths are 32-bits wide.

The Transport Layer block provides FIS reception and transmission functions of the SATA Transport Layer. During reception the Transport Layer receives a new FIS from the Link Layer through the RxFIFO, decodes the FIS type, and instructs the PDMA to route the FIS payload data to the appropriate location in system memory. During transmission the Transport Layer instructs the PDMA to construct the appropriate FIS, and then passes it to the Link Layer through the TxFIFO. The Transport Layer block receives all the PHY/Link errors from the Link Layer, detects Transport errors, and passes them to the PCSR for setting the corresponding error bits.

The Transport Layer processes one FIS at time on the transmit side, meaning only one FIS is allowed in the TxFIFO at a time. On the receive side, RxFIFO can potentially contain more than one FIS at a time. For example, when the device transmits several DMA Data FISs back-to-back with minimal delay, RxFIFO might still have the previous Data FIS while the next FIS is being received.

63.3.4.3.1 Transport Layer FIS Reception

The FIS reception process is described as follows:

- The Link Layer starts frame reception and passes FIS content to the Transport Layer THCK. RxFIFO "almost full" flag notifies the Link Layer to send HOLDp to the device to prevent RxFIFO overflow. Upon detecting EOFp, the Link Layer asserts an "End status" signal to indicate the end of the FIS. All Link Layer/PHY errors are valid at this time.
- THCK module checks for Transport Layer protocol errors, passes FIS data to the RxFIFO, then appends "End Status" DWORD at the end with all the Link/PHY and Transport errors.
- TSM module receives the FIS from the RxFIFO and passes it to the PDMA/PCSR. When any of the Link/PHY/Transport errors is detected, then the FIS is either ignored (when non-Data FIS) or the transfer is aborted (when Data FIS) and the corresponding bits are set in the SATA_P 0SERR register.

63.3.4.3.2 Transport Layer FIS Transmission

The FIS transmission process is described as follows:

- The PDMA detects a request from the system software and notifies the TSM to enter a transmit state. The DMA data transmission is activated by the TSM after it receives DMA Activate FIS from the device.
- The PDMA receives the appropriate FIS from BIU Master and pushes it into the TxFIFO. The following FIS types are supported:
  - Register FIS - Control or Command type.
  - Data FIS - PIO or DMA type.
  - BIST Activate FIS
- The Link Layer uses negation of the TxFIFO "empty" flag to generate SOFp and begin frame transmission. Bit 32 of the TxFIFO is used to indicate the FIS "last DWORD" to the Link Layer. When the Link Layer sees this bit valid, it closes the frame with CRC and EOFp.
- The TSM waits for either positive or negative frame transmission acknowledgement from the Link Layer (Link Layer "handshake" error). Both of these conditions are passed from Link to TSM in the "End Status" DWORD. Negative acknowledgement is generated when the device detects an error during the frame reception and signals it to the host Link Layer. In this case any non-data FIS is resent to the device using Transport Layer retry logic. When the error is detected during Data FIS transmission, then this transfer is aborted and the FIS is not resent.

NOTE

When neither positive nor negative acknowledgement is received from the Link Layer following frame transmission, host s/w times-out and resets the interface.

63.3.4.3.3 Error Handling

All SATA errors are summarized in SATA_POSERRPort0 Serial ATA Error Register. The Link Layer accumulates all Link Layer/PHY errors during frame reception and presents them to the Transport Layer TCHK module with "End Status" signal asserted when it detects EOFp. "PHY Not READY" and "Link Illegal Transition/Sequence" errors terminate the current frame reception/transmission in progress and cause PHY/Link Layer reset and "End Status" assertion. During frame transmission, Link Layer detects R_ERRp/R_OKp from the device and passes this condition in the "End Status" DWORD.

The TCHK module checks for Transport Layer errors in the received FIS when no PHY/Link Layer errors were detected. All errors from the PHY, Link Layer, and Transport Layer TCHK module are passed to the Transport Layer TSM module by way of RxFIFO in the "End status" DWORD (with bit 32 set).

Some errors such as "Non-recovered/Recovered Data Integrity" are detected in the Transport Layer TSM module. "Internal Host Adapter" error is detected in the BIU.

All PHY, link, and transport errors are also passed to the PCSR module through the APP_ASIC module directly for setting the appropriate bits in the SATA_P 0SERR register. This is done to insure that error bits are reliably set in various error conditions. For example, when Data FIS is corrupted, this may result in potential DMA lock-up unless error that caused this condition is passed to the PCSR module and software can act on it.

PHY internal errors are filtered out outside the FIS. Errors related only to the current receive FIS cause SATA_P 0SERR[DIAG_I] bit to be set. To enable errors inside the FIS or outside the FIS to be reflected in the SATA_P 0SERR register, software must set SATA_BISTCR[ERREN] bit for the corresponding Port selected by the SATA_TESTR[PSEL] field.

63.3.4.3.4 Receive/Transmit FIFO (Rx/TxFIFO)

Both receive and transmit FIFOs are used as temporary FIS buffers and for clock domain crossing.

The RxFIFO width is 33 bits: 32 bits are used to transfer data and the 33rd bit is used to indicate the "End- Status" DWORD so the Transport Layer can detect the end of the previous FIS and the start of the next FIS in the situation when more than one FIS is in the RxFIFO.

The TxFIFO is 33-bits wide: 32 bits are used to transfer data and 33rd bit is used to indicate the "last" FIS DWORD to the Link Layer. Both FIFOs are reset on power-up either by the system bus reset signal, by software setting SControl register (P 0SCTL) DET field bit 0 (which results in the SATA block performing an interface initialization sequence COMRESET), or by the COMINIT condition.

NOTE

Both RX and TX FIFO RAM width is (M_HDATA_WIDTH + M_HDATA_WIDTH/32 + 1) bits.

You can select FIFO capacity in DWORDS for each Port separately, based on the system bus software requirements, such as number of masters, burst size, utilization, and so on.

The RX FIFO “almost full” level is set to the value indicated in the following table, to prevent an RX FIFO overflow regardless of the total Host and Device HOLD-HOLDA latency. When the RX FIFO “almost full” flag is asserted, the Link layer starts sending a HOLD status to the Device.

NOTE

Both RX and TX FIFO RAM width is (M_HDATA_WIDTH + M_HDATA_WIDTH/32 + 1) bits.

Table 63-2. RX FIFO "Almost Full" Level

RX FIFO Capacity (DWORDS)	M_HDATA_WIDTH (Bits)	"Almost Full" Level (DWORDs)
64	32 64 128	54 52 52
128	32 64 128 256	62 60 56 64
256	32 64 128 256	64
512	32 64 128 256	64
1024	32 64 128 256	64
2048	32 64 128 256	64

NOTE

It is very important that the total HOLDp/HOLDAp latency for both host and device does not exceed the number of RX FIFO almost full-level DWORDs as indicated in Table 63-2, otherwise, RX FIFO overflow (fatal error) occurs.

NOTE

Host latency must be calculated by adding the Link layer latency to the Host PHY latency. Some SATA configurations are close to 20 DWORDs leaving no margin for the PHY. It is recommended that such configurations be used only for FPGA validation/testing and not for actual product because exceeding 20 DWORD latency requirement may result in Device RX FIFO overflow.

63.3.4.4 Transport Check (TCHK)

The TCHK module provides the following functions:

- Detects new FIS reception by the Link Layer based on the received control signals.
- Decodes the FIS type located in the least-significant byte of the first DWORD and checks its validity. The following FIS types are supported:
  - Register FIS
  - Set Device Bits FIS
  - PIO Setup FIS
  - DMA Activate FIS
  - DMA Setup FIS
  - Data FIS
  - BIST Activate FIS
  - Unknown FIS (length is less than or equal to 64 bytes)

- Checks for all the Transport Layer errors (for example, unrecognized FIS, protocol, or transition).
- Detects an "End Status" signal assertion indicating the end of the current FIS from the Link Layer and passes all Link Layer/PHY/Transport Layer errors to the RxFIFO and to the PCSR module.
- The TCHK provides "Good FIS/Bad FIS" status acknowledgement to the Link Layer at the end of the received FIS.

The TCHK module receives 32-bit FIS DWORD data from the Link Layer and adds one bit (bit 32) before writing it to the RxFIFO. This bit indicates either FIS data, when cleared, or "End Status" DWORD, when set. The following Transport Layer errors are checked in the TCHK (assuming no errors were detected in the Link/PHY):

1. FIS length:
   - Non-data FIS according to the FIS type
   - Data FIS should be between 2 and 2049 DWORDs
   - Unknown FIS should be between 1 and 16 DWORDs
2. PIO Setup FIS transfer count - should be non-zero and even byte count and not exceed 8192 bytes
3. PIO Data FIS following the PIO Setup FIS with D=1 (PIO read) DWORD count - should match the transfer count
4. PIO read protocol FIS sequence - only Data FIS or end status when error are expected after the PIO Setup FIS with D=1, any other FIS would be negatively acknowledged to the Link Layer
5. DMA Setup FIS buffer offset - bits 0 and 1 should be cleared and transfer count should be an even (not zero) number
6. First Party DMA read protocol - DMA Setup FIS with D=1 is followed either by Data FIS or Set Device Bits FIS or end status when error
7. First Party DMA write protocol - DMA Setup FIS with D=0 is followed by DMA Activate FIS (when A=0) or Set Device Bits FIS or end status (when A=1)
8. BIST Activate FIS is supported type only (see BIST Operation for details)
9. RxFIFO push error for Data FIS - detected when Link has valid data and RxFIFO is "full" (for example, device violates HOLD latency requirement)

The Transport Transition Error SATA_P 0SERR[DIAG_T] bit is set when errors 1-8 are detected. The Unknown FIS SATA_P 0SERR[DIAG_F] bit is set when the Unknown FIS length does not exceed 64 bytes. The Protocol Error SATA_P 0SERR[ERR_P] bit is set on detection of error 9.

63.3.4.4.1 Transport State Machine (TSM)

The TSM module provides the following functions:

- Implements the host Transport Layer state machine according to the SATA spec with the exception of the FIS checking and error handling functions.
- Decodes the FIS type by reading the least-significant-byte of the first DWORD of the FIS.
- Detects the "End status" DWORD and checks for any Link Layer/PHY/Transport Layer errors. When any of the errors is detected:
  - On a non-data FIS, the received FIS is discarded, the transmitted FIS is retried indefinitely, and the corresponding SATA_P 0SERR register ERR_I bit is set.
  - On a data FIS, it can be passed to the system memory before the final status is reflected in the SATA_P 0SERR register ERR_T bit.
- Generates/receives the appropriate control signals to/from the PDMA based on the received FIS and its state.
- Handles transfer termination requests originated from the Link Layer or PDMA module.

63.3.4.4.2 Sync Module (APP_ASIC)

This module is used to synchronize several control signals between the Link Layer and the Transport Layer clock domains.

63.3.4.5 Link Layer

The Link Layer performs the following functions:

- Controls initialization between the Link Layer, PHY, and a connected device
- Generates and detects OOB signaling
- Transmits and receives frames
- Transmits primitives based on control signals from the Transport Layer and PHY
- Receives primitives from the PHY layer that are used to control the Transport and Link Layers
- Controls power management via the Port Power Control Module

Hot-plugging a device is digitally supported in the Link Layer when Tx OOB sequences are generated by the Link Layer via normal initialization polling. When Tx OOB sequences are generated in the PHY, it is up to the PHY to digitally support hot-plugging a device.

The Link Layer functional block diagram is shown in the following figure.

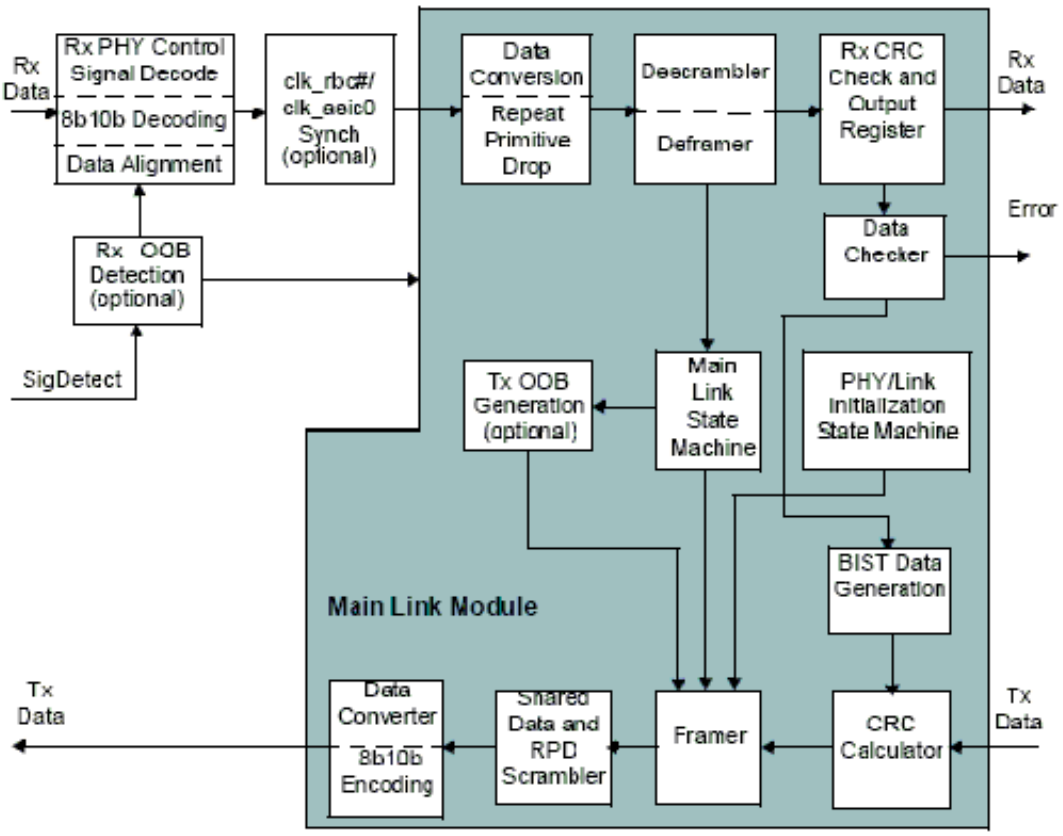

Figure 63-10. Link Layer Functional Block Diagram

On power-up, system reset or device hot-plug, the following sequence occurs:

1. The Link Layer transmits sequences of control data and ALIGN Primitives to the PHY. .
2. They are then forwarded to a device PHY as OOB signaling.
3. In addition, the Link Layer detects OOB sequences.

These OOB sequences bring the host controller, PHY, and device to an initialized condition. Once this occurs:

1. The Link Layer passes a PHY Ready status to the Transport Layer and normal communication begins.
2. The Link Layer receives requests from the Transport Layer to transmit data, in the form of a Frame Information Structure (FIS) comprised of DWORDs, to a device via the local PHY.
3. The Link Layer in turn transmits the FIS by inserting Primitives, scrambling and optionally encoding the data, sending it to the PHY and waiting for status.

4. When a status FIS is received, the Link Layer optionally decodes, aligns and descrambles the data, removes Primitives and forwards the data to the Transport Layer.
5. The Link Layer then notifies the Transport Layer of the ending transfer status. The Link Layer has no notion of the FIS content, other than its beginning and end points and CRC.
6. Data alignment is performed on received FIS data via ALIGN Primitives. Flow control is also achieved on FIS going in either direction via HOLD Primitives.
7. In addition, the Link Layer receives requests from the Transport and PHY Layers to go into and out of power management modes.

Power management is achieved by notifying the PHY of a partial or slumber condition and then disabling normal data transmission on PHY Rx and Tx interfaces until a wake-up request from Transport Layer or remote device via the PHY is seen from the Power Control Module. Power management is controlled via Partial and Slumber requests as described in the SATA specifications.

The Initialization State Machine controls the Link Layer, PHY and device system initialization. The main Link Layer State Machine controls FIS traffic, flow control, and error detection and status reporting. FIS traffic is generated and disassembled via Framer and Deframer modules. The Link Layer also performs CRC calculations on FIS, as well as scrambling and optionally encoding the data.

- Decoding of received FIS is performed in the clk_rbc0 clock domain due to the fact that the incoming FIS is on an asynchronous, but frequency locked clock of the same rate as the clk_asic0 clock domain.
- 8b/10b encoding and decoding are performed in the Link Layer.

The Link Layer receives data on either clk_rbc0, recovered from the incoming data stream by the PHY, or on clk_asic0. This single receive clock is then used in this module to decode data and control signals from the PHY and pass it to the rest of the Link Layer. Data is passed through a synchronizing Datastream FIFO. ALIGN Primitives are also detected and dropped in the front end of the receiver as a means of guaranteeing no Datastream FIFO overruns, when a Datastream FIFO is included. ALIGN Primitives are also used to synchronize to the data stream in the PHY by triggering data realignment where necessary.

Finally, ALIGNs are required by the Tx OOB initialization state machine to complete initialization, following the SATA specifications. For this reason, the PHY must indicate the presence of at least two ALIGNs after the Link Layer detects the release of COMWAKE. Otherwise the Link Layer is not able to complete initialization and begin normal operation. This is required regardless whether the PHY drops ALIGNs at any other time.

NOTE

Even if the PHY drops ALIGNs, data indicating the comma character must be present on phy_rx_data, in the corresponding phy_comma_det slot. This is required to invalidate comma characters before they are stable.

This Databook attempts to avoid redundancy with the *High Speed Serialized ATA* specification. Please refer to the latter for standard specifications and descriptions. This discussion pertains to specific implementation-related operation and details.

63.3.4.5.1 Link Layer Features

The SATA block Link Layer features are as follows:

- Rx Data Buffer for recovered clock systems
- OOB signaling and system Initialization
- Frame negotiation and arbitration
- Envelope framing/deframing
- CRC calculating, insertion and checking
- 8b/10b encoding/decoding
- Flow control
- Frame acknowledgement and status reporting
- Data width conversions
- Data scrambling/descrambling for EMI reduction
- Repeat Primitive data transmission and reception handling
- ALIGN Primitive detection, dropping and data alignment
- Power management support

63.3.4.5.2 User-Defined Status and Control

There are up to 32 bits each of optional user-defined status and control Ports available in the SATA block. These are used to obtain information from the PHY, and control PHY functions that might differ across particular PHYs and which are not defined in the SATA specifications.

Each of these variable bit width, user defined Ports map to a register that can be read and/or written by the system via the Bus Interface. When no user-defined Ports are included in the design, they are absent from the netlist, along with the registers that would have been allocated for their use. See Figure 63-8 for the top-level I/O diagram.

NOTE

There are clock crossing restrictions on these Ports. Refer to "Signal Descriptions".

63.3.4.5.3 PHY Initialization Details

Please refer to the "Out of band signaling" section of the SATA specifications for the following descriptions.

The PHY/device signaling from SATA block is dependent on whether the Link Layer generates and detects the proper OOB sequences or whether the PHY generates and detects them.

NOTE

For PHY Initialization and general operation related to the Link Layer, all SATA block inputs and outputs are sampled and generated, respectively, in the following clock domains. Note that the arrangement of signals facilitates there being no clk_rbc present until the clock is recovered from incoming data.

- Rx Data Inputs
  - clk_asic
  - clk_rbc
    - phy_rx_err
    - phy_comma_det
    - phy_rx_data_vld
    - phy_rx_data
    - phy_rx_kch_det
    - phy_rx_dec_err
    - phy_rx_disp_err
- Tx Data Outputs
  - clk_asic
  - phy_tx_data_vld
  - phy_tx_data
- Control Outputs
  - clk_asic
    - phy_rx_enable
    - phy_tx_enable
    - phy_spdsel
    - phy_nearafelb
    - phy_farafelb
    - phy_reset
- Control Outputs
  - clk_pmalive
    - phy_partial
    - phy_slumber

- Control Inputs - Fixed, multiple and/or configuration-dependent clock domains
  - phy_sig_det - Sampled in all of these clock domains
    - clk_rbc

- phy_spdmode
  - clk_asic

NOTE

phy_rx_data_vld should not be delayed after OOB initialization (held inactive LOW), while phy_comma_det is indicating COMMA characters are being received, or normal operation may not begin. Either phy_comma_det must be ANDed with phy_rx_data_vld, or all phy_rx_data_vld bits must be tied permanently HIGH.

However, in order to tie phy_rx_data_vld permanently HIGH, a phy_sig_det must be present and indicate valid signal detection. For example, phy_sig_det cannot be tied HIGH when phy_rx_data_vld is also tied HIGH. Normal operation can fail due to missing the first non-ALIGN Primitives when they are in the form of Repeat Primitive Data, before phy_rx_data_vld becomes active. A PHY that always drops all ALIGN data cannot delay phy_rx_data_vld at all after initialization. Finally, phy_rx_data_vld and phy_comm_det should not become high until the PHY has completely locked onto ALIGNs and data is error free, to avoid problems transitioning between OOB and normal operation.

63.3.4.5.3.1 Link Layer Tx OOB Initialization Sequence Details

NOTE

In order for the Link Layer to generate the Tx OOB initialization sequences, at least two ALIGN Primitives must be indicated and flagged to the Link Layer by the PHY via the phy_comma_det signal. This must occur after the release of COMWAKE, per the SATA initialization specifications. Otherwise the Link layer is not able to complete initialization

and begin normal operation. This is required regardless of whether the PHY drops ALIGNs at any other time. In addition, if data can ever become misaligned from the PHY, ALIGN Primitives are required in order for the Link Layer to realign the data. Finally, ALIGNs must be returned to the SATA block for all BIST modes to function properly.

The Link Layer Tx OOB initialization sequence is depicted in the figure below. Not all details are shown, but the following sequence summarizes the flow:

1. PHY Reset state is entered during a system asynchronous-reset or if a Port reset (COMRESET) has been detected. This causes the phy_reset output signal to become active and can be used to synchronously clear the PHY of any errors, when the PHY has that capability. The PHY reset is active for 12 1.5 Gb/s rate DWORDs of time, or 320 ns.

NOTE

clk_asic0 cannot be removed while phy_reset is asserted, because clk_asic0 is required to negate phy_reset.

Signal phy_reset is intended only to clear non SATA errors in this configuration, and must not be used to asynchronously reset the PHY.

2. Upon exiting PHY Reset state, the PHY speed is always set to 1.5 Gb/s speed, regardless of the speed being negotiated for.
3. After a PHY reset, and anytime an unsolicited COMINIT has been detected, the PHY Wait state is entered in order to check and wait for PHY calibration.
4. After the PHY Wait state, communication with a device is attempted by transmitting a COMRESET sequence, followed by waiting for a COMINIT sequence from the device. This takes place in a polling routine. During the Wait Cominit state, when a COMINIT has not been detected in 14ms, the state machine loops back and restarts from the PHY Wait state indefinitely.
5. Once a COMINIT has been detected, normal OOB sequences then take place, interrupted only by an unsolicited COMINIT; a COMINIT that was not expected.
6. After completion of the OOB sequence, when 6.0 Gb/s or 3.0 Gb/s are enabled and have not already been attempted and failed, phy_spd_sel is asserted to the PHY to change clk_asic0 rate to the highest supported speed. The host then begins waiting for ALIGNs.
7. At the beginning of awaiting ALIGNs, the speed is changed back to the highest speed to be negotiated. Otherwise the speed stays at Gen1. During the Await ALIGN state, when an ALIGN has not been detected by the time 32K 1.5 Gb/s rate DWORDS of D10.2 characters have been transmitted, the Link Layer moves to the

PHY Wait state. In addition, when a higher speed fails negotiation, an internal flag is set to force the host to stay at the current speed after the next OOB sequence has completed, unless one of the following occurs:

- Asynchronous system reset
- Port reset
- An unsolicited COMINIT has been detected from the device
- 6.0 and 3.0 speed disabled and re-enabled (programmed to 1.5 Gb/s speed, then back to 3.0 Gb/s or 6.0 Gb/s, followed by a host COMRESET)

8. When an ALIGN has been detected before 32K 1.5 Gb/s rate DWORDS of D10.2 have been transmitted, the Link Layer moves to the Send ALIGN state, followed by the Init Complete state, once three non-ALIGN Primitives have been detected. Note that while the Link Layer is generating D10.2 characters at 3.0 Gb/s or 6.0 Gb/s, 1.5 Gb/s rate D10.2 characters are emulated by doubling or quadrupling the transmitted data, i.e., 1100110011, as opposed to 1010101010.
9. Once initialization is complete, the Ready state is entered and the Main Link state machine takes control.
10. Finally, the Partial and Slumber states are only entered after a Power Mode has been set. This disables the Tx interface until either the host or device requests a wake-up. For further information, refer to Power Management Operations.

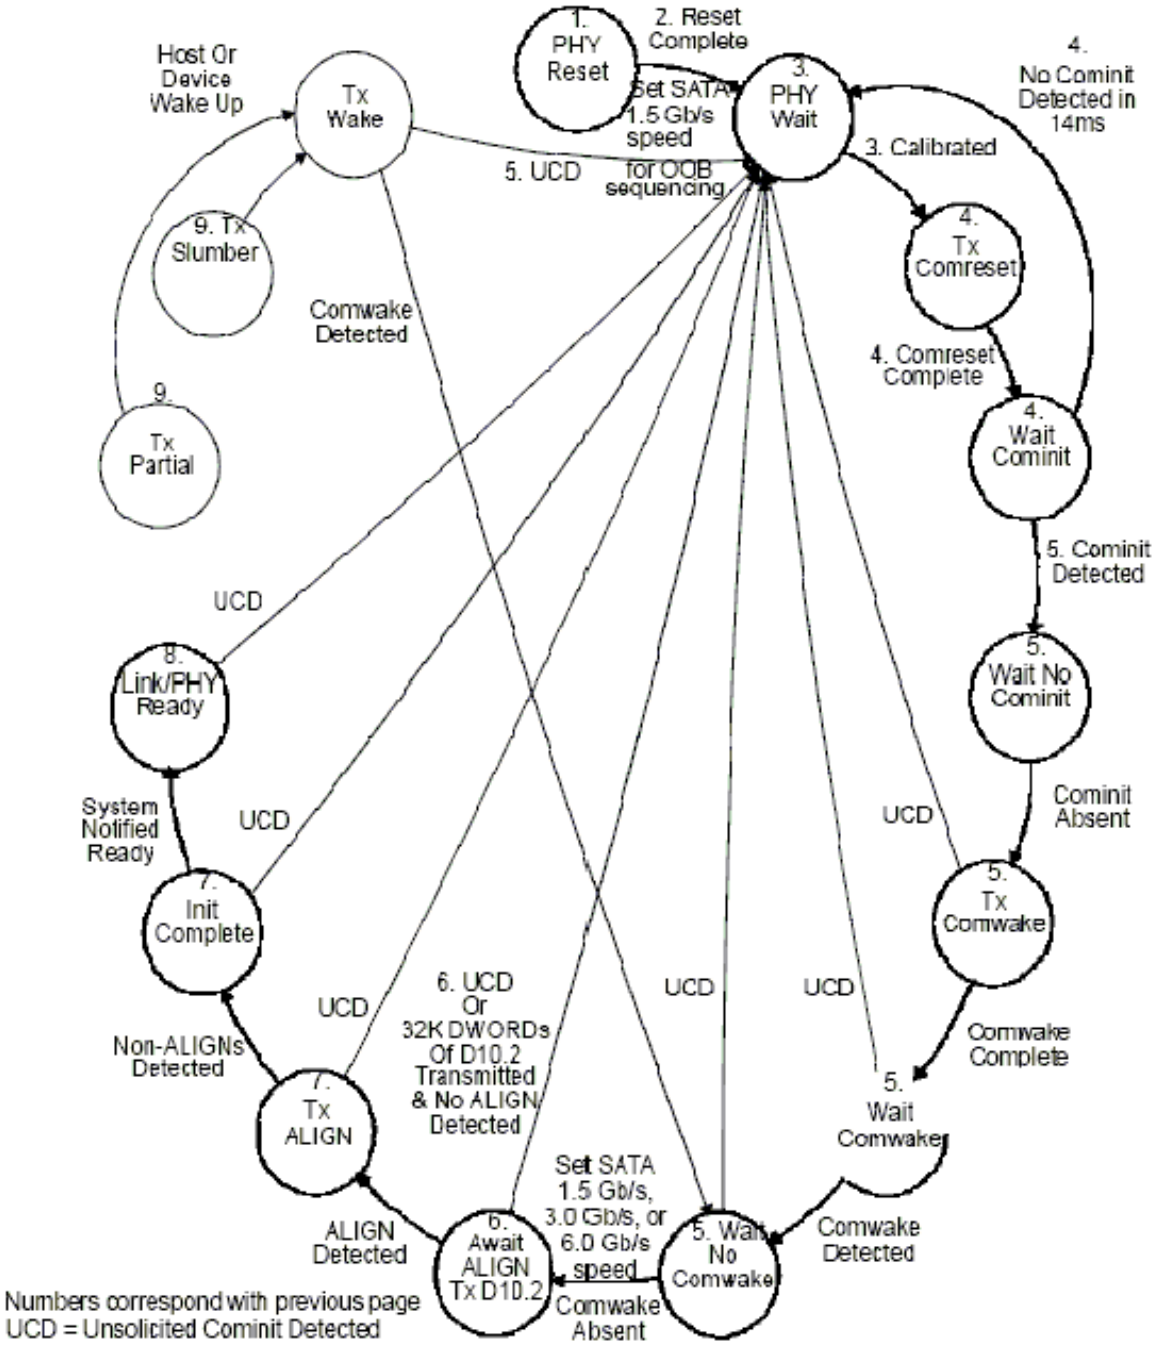

Figure 63-11. Tx OOB Initialization Sequence

63.3.4.5.3.2 Link Layer Tx OOB Sequence Generation

When the Link Layer generates the Tx OOB sequences , the Tx interface connections are different than when the PHY generates them.

Figure 63-11 depicts a small portion of an initialization phase, which includes the first part of a COMRESET condition, followed by a portion of a COMWAKE. The actual OOB sequences are created by sending ALIGN Primitives in conjunction with de-assertion of the phy_tx_enable signal. This causes the Tx OOB data and NULL sequences required by the SATA PHY specifications. Note that this diagram is not the complete initialization sequence. In a complete initialization sequence, there are multiple bursts of COMRESTs and COMWAKEs, followed by a d10.2 stream, followed by an ALIGN stream and then finally normal data. The phy_tx_data_vld is only used for qualifying data in systems that require it, but is unrelated to the OOB sequencing itself.

NOTE

Even when TX OOB signaling is generated in the PHY, the Link Layer still needs to see two ALIGNs, followed by three non-ALIGN primitives to transition from initialization to normal operation.

This feature allows the Link Layer to transition to normal operation without requiring the two ALIGNs. However, this also requires all data from the PHY to be properly aligned and to stay that way. The Link layer does still require three non-ALIGN Primitives, so they must be passed to the core before the incoming data turns into CONT 'Repeat Primitive Data'. This feature does not work when ALIGN_MODE = Misaligned. For more details, see BISTCR.QPHYINIT (bit 14) on page 162.

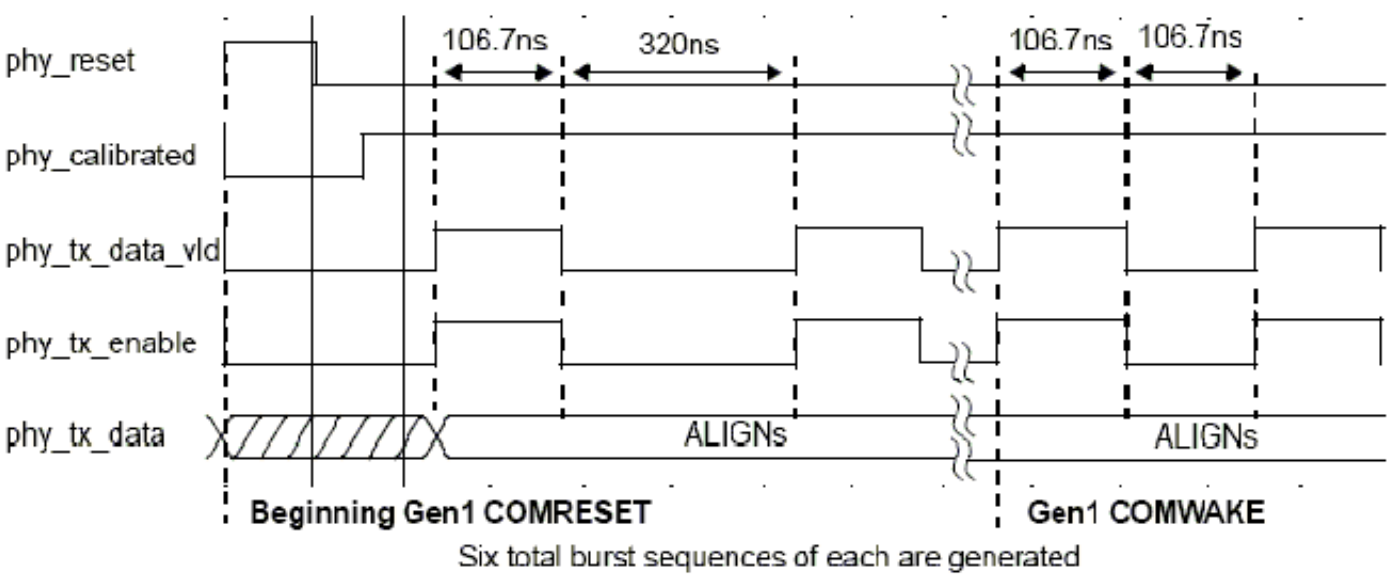

Figure 63-12. Link Layer Generated Tx OOB Signaling

63.3.4.5.3.3 Link Layer Rx OOB Sequence Detection

When the Link Layer detects the Rx OOB sequences, the Rx interface connections are different than when the PHY detects them.

Figure 63-12 depicts a small portion of an initialization phase, which includes the first part of a COMINIT condition, followed by a portion of a COMWAKE.

The actual OOB sequences are comprised of specifically timed ALIGN Primitives in combination with negation of the phy_sig_det signal (indicating NULL on the differential pair). However, only the phy_sig_det signal is used for qualifying Rx OOB sequences by the Link Layer.

NOTE

The PHY must “condition” (filter and delay) phy_sig_det so that the OOB detector accurately detects SATA sequences and prevents the Link Layer from accidentally misreading the Device as disconnected, thus avoiding reset. A filter is required to prevent phy_sig_det from detecting transient ‘loss of signal’ due to bits on the Rxp/Rxn wires crossing the zero voltage level.

To ensure that power modes function properly, phy_sig_det should be timed to the data delay through the PHY so that it does not go low until at least four PMACKs are passed completely to the core. This delay must also account for the existence of an ‘elasticity buffer’ located in the PHY. Both the filtering and the delay must be ‘symmetric’ (phy_sig_det rise filter/delay equal to the fall filter/delay) so that errors are not introduced in OOB signal detection or impact OOB compliance.

Figure 63-12 does not show the complete initialization sequence. In a complete initialization sequence, the host receives multiple bursts of COMINITs and COMWAKEs, followed by an ALIGN stream, and then finally normal data.

The Link Layer qualifies valid COMINIT and COMWAKE sequences according to the SATA specifications, using calculated comparator values that always fall within specification-compliant ranges. The SATA- specified valid ranges of sequence spacing are shown in Figure 63-12. The actual COMINIT and COMWAKE sequences are calculated and qualified by the Link Layer as described in the following subsections. See the application note and "Example Calculated COMWAKE, COMINIT and Data Burst Lengths" for important information.

To accurately qualify OOB spacing inside the compliant range required by the SATA specifications, the OOB sampling clock, clk_rxoob, must be no lower than 60 MHz.

The phy_rx_data_vld input is used only to qualify data in systems that require it, but is unrelated to the OOB sequencing itself. Systems with this configuration that do not use phy_rx_data_vld (data valid every clock cycle), should tie the bits HIGH. This does not affect OOB detection, because data is qualified with phy_sig_det for this purpose.

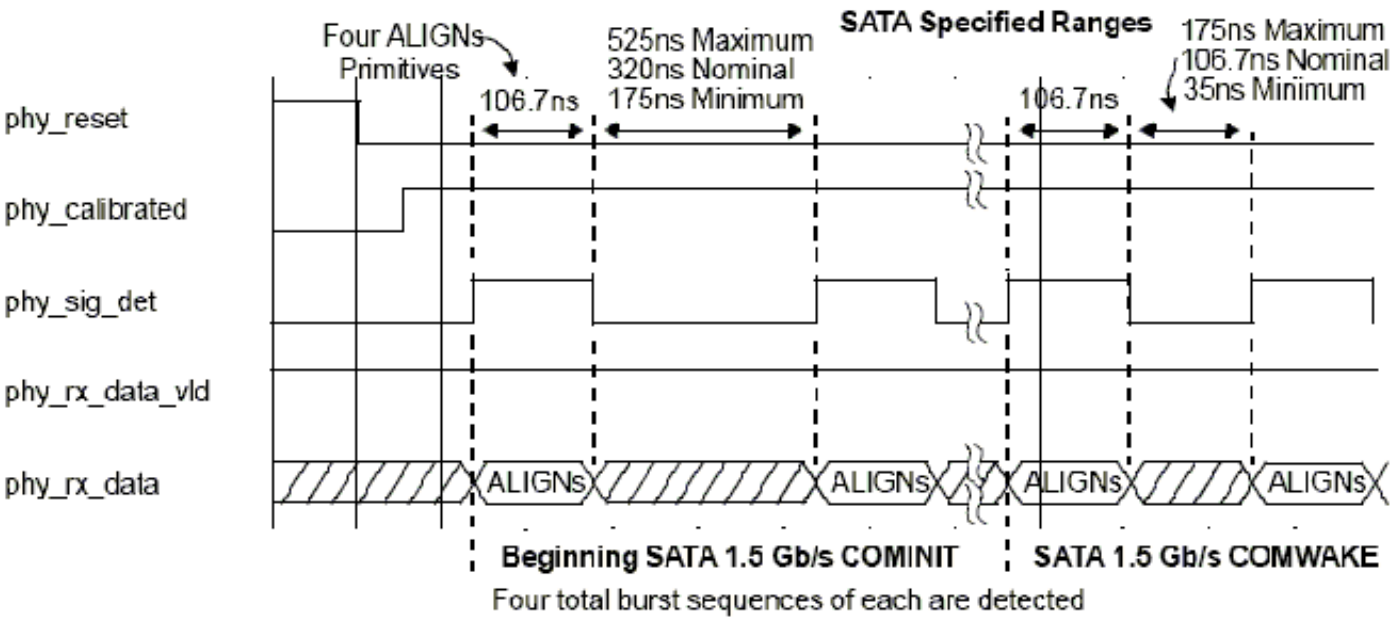

Figure 63-13. Link Layer Rx OOB Detection

63.3.4.5.4 Link Layer Power Management Details

Power management OOB detection and generation sequences occur in the same signaling format as described in PHY Initialization Details. However, they follow the required sequencing specified in the SATA Power management specifications.

In the SATA block, all data on the Tx channel is disabled until the host or device requests a wake-up condition. In addition, Rx data is not allowed to propagate in the SATA block Rx data path until one of these conditions has been detected and the PHY and device have been fully initialized per requirements.

A power down and wake up is depicted in Figure 63-14 and Figure 63-15, excluding actual OOB signaling, which are dependent on OOB Modes. Note that 'OOB' on Tx and Rx Data indicates that OOB sequences are present.

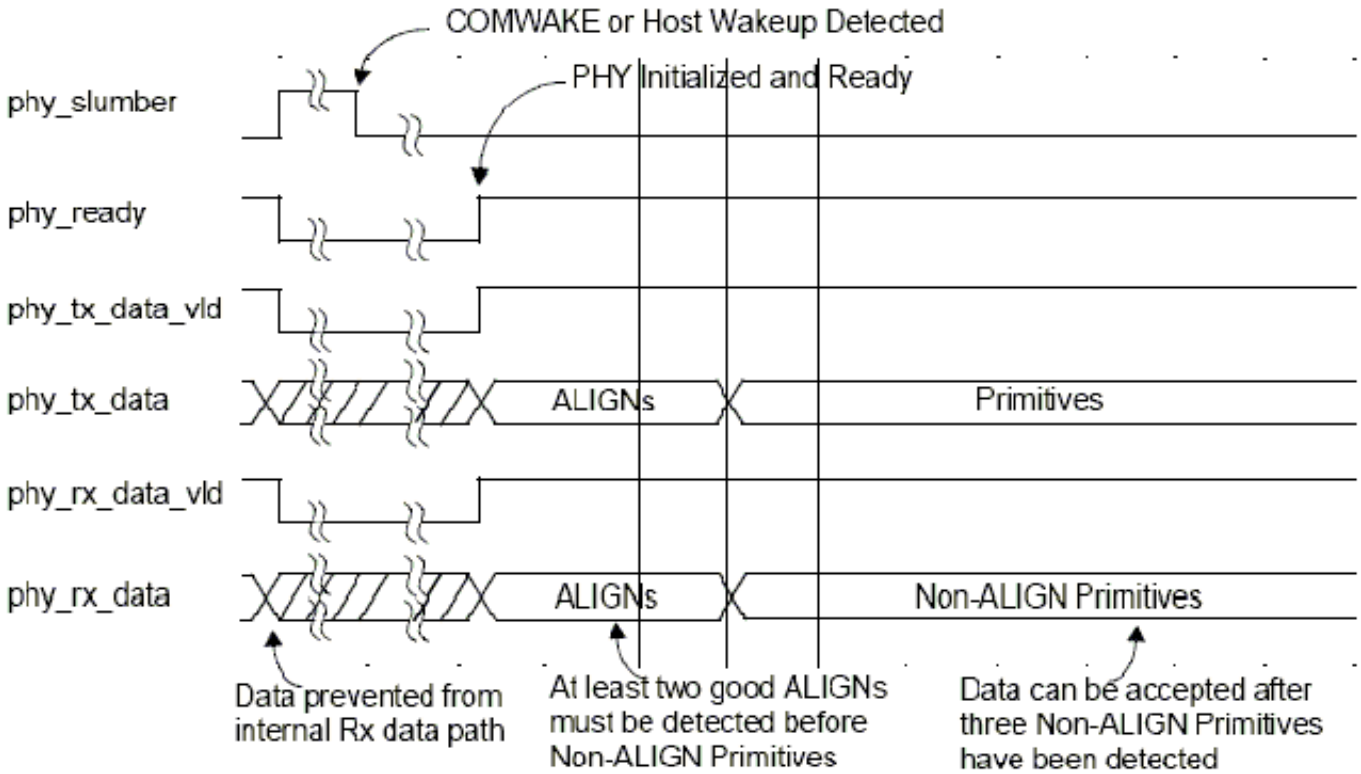

Figure 63-14. Power Mode Example: Rx and Tx OOB In PHY

Seperator Text

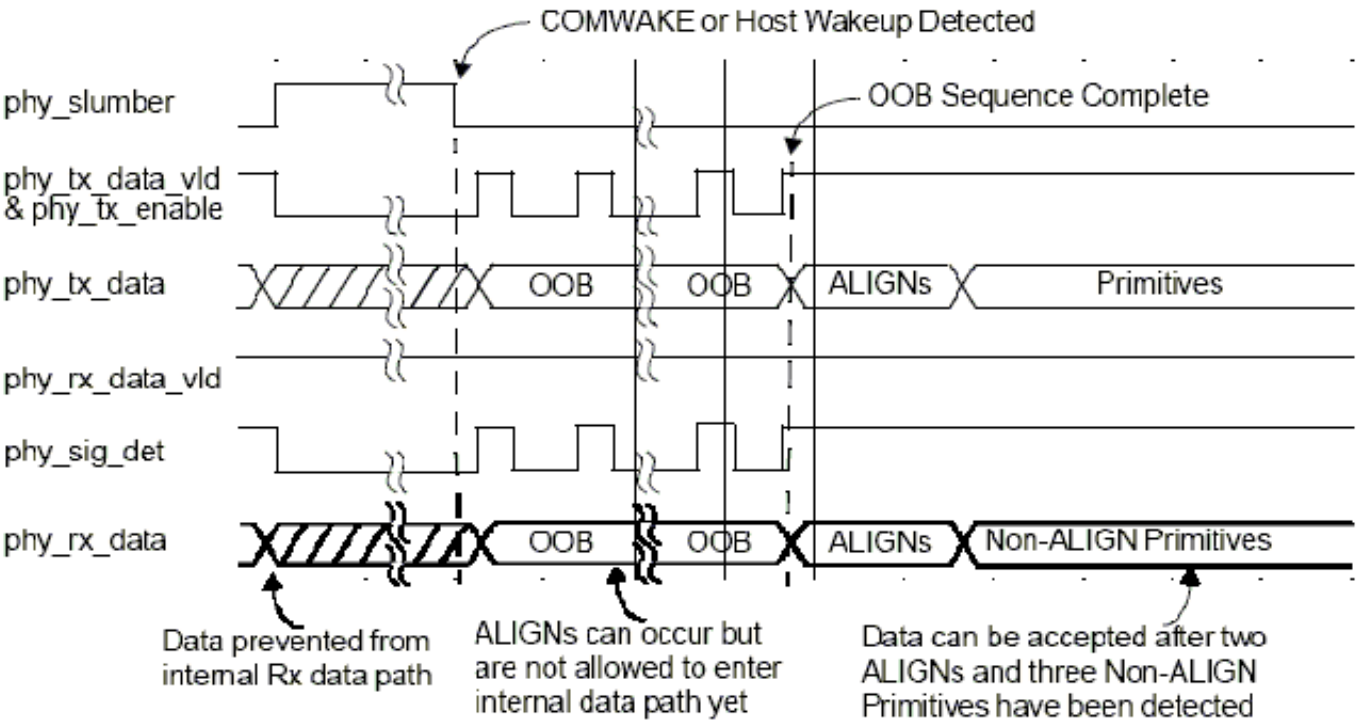

Figure 63-15. Power Mode Example: Rx and Tx In Link

63.3.4.6 Port Power Control Module

The Port Power Control Module (PCM) implements the following functions:

- Monitors Transport, Link and PHY ready/not ready conditions, as well as Device and Host power requests.
- Systematically controls the Link and Transport Layer transitions into and out of offline conditions (system reset, COMRESET and power modes).
- Allows clk_asic0 and clk_rbc0 to be stopped during Slumber and Partial power modes.

The PCM main function is to allow disabling clk_asic0 and clk_rbc0 in SATA power down modes.

CAUTION

Clocks supplied to the core should never glitch at any time, including before, during, and after initialization and power modes. Clock glitch protection should be performed outside the core for any clocks that might glitch.

In addition, inputs to the core should remain static during the time external logic is removing external clock glitches.

For more information, refer to the SATA specifications related to power mode exit time requirements, or contact Synopsys support.

NOTE

If clk_asic0 or clk_rbc0 are stopped, Near End Analog Loopback mode is not supported when a device is connected to the system. Therefore, it is recommended to only stop clocks in Slumber mode, in order to support Near End Analog Loopback mode when a device is connected.

NOTE

In order to support Host-initiated power modes where clk_rbc and clk_asic are removed, the PMACK received from the Device must be able to make it through the clk_rbc clock domain, synchronization, and the Link Layer clk_asic domain Rx Data path to the Link state machine, before the clocks can be removed. The SATA specifications allow a Device to transmit 4 to 16 PMACKs before going into power down. While 16 PMACKs are enough to guarantee receipt by the Link state machine, 4 are not. In the cases where a Device does not send enough PMACKs, the clocks will need to be kept running long enough for the Link state machine to detect the PMACK, or the Host will not go completely into power down mode and a Host COMRESET would be required to exit the failed power mode.

Figure 63-16 shows a high-level state diagram of the Power Control Module. Some signals are omitted for clarity.

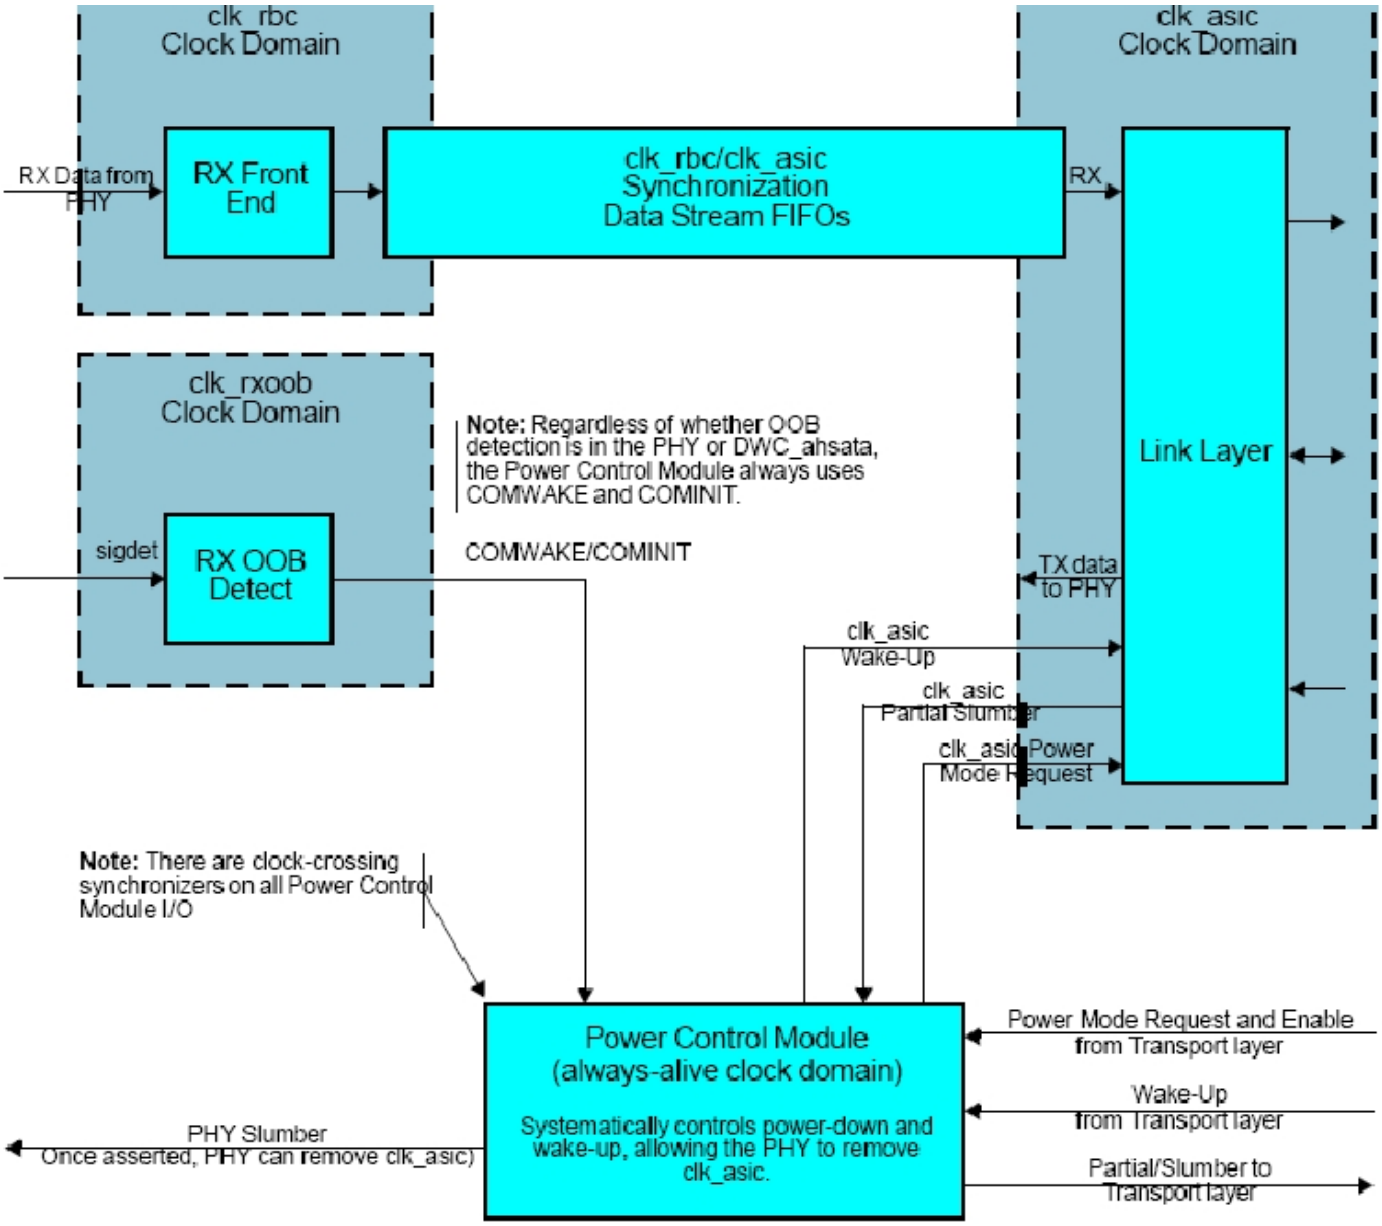

Figure 63-16. Port Power Control Module Diagram

The Power Control Module exists in the 'always alive' clk_pmalive clock domain. The clk_pmalive must always be present and must never change frequency. All signals into and out of the PCM are synchronized between the clk_pmalive, clk_asic0, clk_rbc0, and hclk clock domains with one or more of the synchronizers described in "Cross Clock Synchronization". The Power Control Module serves to assure all SATA block Layers and the PHY move correctly between inactive and active states in unison.

NOTE

Within the core there is no difference between going into and out of Partial and Slumber power modes, even if a system

disables clk_asic0 and clk_rbc0 in one mode, but not the other. Clocks do not have to be removed in either mode.

An example Slumber Power Mode Control with clocks stopped follows:

Example 1: Host Initiated Slumber Power Mode 1

1. System host requests Slumber Power Mode and asserts a Slumber request to the Power Control Module, which then forwards the request to the Link Layer.
2. If the Link Layer was in an IDLE state, then the Link Layer sends PMREQ_Sp primitives to the device. If the device responds with PMACKp primitives, the Link Layer asserts a Slumber signal back to the Power Control Module. If the Link Layer was not IDLE (or already in a power state), or the device denies the Slumber request, the Link Layer sends a power mode abort signal to the Power Control Module, which forwards it to the Transport Layer, and normal operation continues.
3. Provided the Link did not abort the Slumber request, and once the power control module receives sees the Slumber signal from the Link Layer, phy_slumber is asserted to the PHY and clk_asic and clk_rbc can be stopped.
4. At the same time, a slumber signal is sent to the Transport Layer; if no activity or wake up has been detected since the original request was made, the Transport Layer asserts an acknowledge signal back to the power control module. If activity has been detected in the Transport Layer, it responds with a wake up signal back to the power control module and the power mode is cancelled to the PHY. If the Transport Layer allowed the power mode to take place, it records the power down status in register SATA_P 0SSTS[IPM]. Note that the power mode to the PHY must be asserted if the Link Layer had accepted it, given the Tx Data will have been stopped at that point. Therefore, to avoid a power mode assertion to the PHY that is too short, the phy_slumber will be asserted for a minimum of 16 clk_pmalive clock cycles before the signal is asserted to the Transport Layer. This guarantees the power mode is not cancelled before a minimum of 16 cycles of assertion.
5. Once the PHY sees the Slumber signal, p0_phy_slumber, then clk_asic0 and clk_rbc0 can be stopped.

Example 2: Wake Up From Slumber Power Mode

1. The Slumber power mode is stopped by either detection of a COMRESET/ COMWAKE from the device, or software cancelling the power mode. When software has cancelled the power mode, an internal wake up signal is sent from the Transport Layer to the Power Control Module. Whenever the PCM detects the a host "wake up", or a COMRESET or COMWAKE, the Slumber signal to the PHY p0_phy_slumber, is immediately negated, which should result in the PHY restarting clk_asic0 and clk_rbc.

2. At the same time the Slumber is negated to the PHY, Slumber is negated to the Transport Layer and all power requests to the Link Layer are cancelled and normal operation resumes. Because the Link

Layer uses rising edge detection on power requests, and the Transport Layer uses rising edge detects on power mode assertion, unwanted power modes do not occur.

63.3.5 Operation Details

63.3.5.1 Data Transfer

The DMA engine for PORT0 is implemented in the PDMA module. Its operation is based on the AHCI specification Port State Machine.

The following sections outline examples of the ATA DMA read and write transfers.

NOTE

Optional prefetching of ATAPI commands, PRD entries or data, as indicated by the 'P'-bit in the Command Header, is not supported in the current release.

63.3.5.1.1 ATA DMA Read

This is the DMA read sequence:

1. Software finds a free command slot by reading the SATA_P 0CI register, then builds a DMA read command in the Command List for the Port to execute, and sets the bit corresponding to this command slot in the SATA_P 0CI register.
2. The PDMA fetches the Command Header from system memory.
3. The PDMA fetches the command Register FIS from system memory and transfers it to the device.
4. Since this was a DMA read command, the device responds with a number of Data FISes. When they arrive, PDMA performs the following operations:
   - Fetches the first PRD from system memory.
   - Transfers data from the RxFIFO to system memory until the byte count for this PRD is satisfied.
   - Continues to fetch PRDs and transfer data until the byte count for the command is satisfied.
5. Device sends D2H Register FIS with the command ending status and when the I-bit is set, interrupt is generated. D2H Register FIS is posted to the Received FIS memory structure.

6. When this is the last command, and the SATA block was enabled for aggressive power management, the PDMA requests the Link Layer to enter either Partial or Slumber state.

63.3.5.1.2 ATA DMA Write

This is the DMA write sequence:

1. Software finds a free command slot by reading the SATA_P 0CI register, then builds a DMA write command in the Command List for the Port to execute and sets the bit corresponding to this command slot in the SATA_P 0CI register.
2. The PDMA fetches the Command Header from system memory.
3. The PDMA fetches the command Register FIS from system memory and transfers it to the device.
4. Device responds with DMA Activate FIS. When it arrives, PDMA performs the following operations:
   - Fetches the first PRD from system memory;
   - Transfers data from system memory to TxFIFO until the PRD byte count is satisfied or 8-KB FIS boundary is reached. The Link layer sends Data FIS to the device. If more than one FIS is needed, device sends DMA Activate FIS for each Data FIS;
   - Continues to fetch PRDs and transfer data until the byte count for the command is satisfied.
5. Device sends D2H Register FIS with the command ending status and when the I-bit is set, interrupt is generated. D2H Register FIS is posted to the Received FIS memory structure.
6. When this is the last command, and the SATA block was enabled for aggressive power management, the PDMA requests the Link Layer to enter either Partial or Slumber state.

63.3.5.1.3 Native Queued Command (NCQ) Transfers

The SATA block supports NCQ feature (READ/WRITE FPDMA QUEUED commands). Data transfers are activated via the DMA Setup FIS, and command completion is performed via the Set Device Bits FIS.

NOTE

- Device must also support NCQ, otherwise it aborts READ/ WRITE FPDMA QUEUED commands. The non-zero buffer offset feature should be disabled in the device.
- ATA/ATAPI-7 queued feature set (legacy queueing) is not supported by the AHCI spec.

63.3.5.1.4 PIO Transfer

The SATA block supports multiple DRQ block PIO operation (SATA_CAP[PMD]=1).

From the SATA block point of view, PIO transfer looks like a DMA transfer: a command table is set up, and the data is transferred from or to system memory by the PDMA module.

63.3.5.1.5 Transfer Size

Normally, all SATA block AHB master transfers are done with 32-bit transfer size (m_hsize==3'b010) and 32-bit-aligned addresses.

When the transfer count for a command has odd number of 16-bit words (for example, 257 words, or 514 bytes), then on device reads the device would pad bits [31:16] of the last Data FIS dword with zeroes, and on device writes, SATA block would clear bits [31:16] of the last Data FIS dword sent to the device.

Odd-word transfer count implies creating a PRD with odd-word byte count and possibly 16-bit-aligned data address.

Setting PRD Data Base Address (DBA) or Byte Count (DBC) to a 16-bit-aligned value (for example, 2, 6, 10, etc.) results in 16-bit single transfers on AHB master interface (m_hsize==3'b001) regardless of the SATA_P 0DMACR[RXTS] or SATA_P 0DMACR[TXTS] values. This is due to the fact that SATA block operation is optimized for 32-bit operation when both DBA and DBC are 32-bit-aligned (for example, 4, 8, and so forth).

NOTE

To achieve maximum performance with odd-word transfer, it is recommended that the PRD with the odd-word byte count is the last and the smallest PRD of all the PRDs for the command, and the rest of the PRDs are all 32-bit-aligned. This assumes that the starting address of the data is 32-bit- aligned

63.3.5.2 Power Management Operations

The SATA block Port power management states (PARTIAL or SLUMBER) can be initiated by the software, the Port itself, or by the device.

The power state machine is implemented in the Link Layer power management module (refer to Link Layer Power Management Details for details). It asserts corresponding signal (p0_phy_partial or p0_phy_slumber) to the PHY to enter the power management state.

Software requests transition to either PARTIAL or SLUMBER state using the SATA_P 0CMD[ICC] field, however, the Port acts on it when the Link Layer is currently in the L_IDLE state, otherwise this request is ignored.

The device requests power management state by transmitting PMREQ_Pp or PMREQ_Sp primitives to the Port. Software can disable transition to power management states using the SATA_P 0SCTL[IPM field].

The SATA block supports aggressive power management states that allow the Port to initiate an interface power management state as soon as there are no commands outstanding to the device. The SATA_P 0CMD[ALPE] bit defines whether the feature is enabled and the SATA_P 0CMD[ASP] field controls whether PARTIAL or SLUMBER state is initiated by the Port when enabled. When SATA_P 0CMD[ALPE] is set, if the Port recognizes that there are no commands to process, the Port transitions to PARTIAL or SLUMBER state based upon the SATA_P 0CMD[ASP] field setting.

The Port recognizes no commands to transmit as either:

- SATA_P 0SACT is cleared to 0h, and the SATA_P 0CI is updated from a non-zero value to 0h.
- SATA_P 0CI is cleared to 0h, and a Set Device Bits FIS is received that updates SATA_P 0SACT from a non-zero value to 0h.

SATA block supports automatic PARTIAL to SLUMBER power state transition feature. This is enabled by the software setting the bit SATA_P 0CMD[APSTE]. When SATA_P 0CMD[APSTE] is set and the SATA block Link is in PARTIAL state, the core automatically transitions to SLUMBER state regardless whether it was host software-, Port (aggressive)-, or device-initiated.

The power management state is terminated when either one of the following conditions becomes true:

- Software requests transition to active state by writing SATA_P 0CMD[ICC] = 1h
- Device requests interface wakeup by transmitting COMWAKE OOB sequence

The state of the interface (active, PARTIAL, or SLUMBER power management) is reflected in the SATA_P 0SSTS[IPM] field.

63.3.5.3 Hot Plug

This topic covers the following descriptions:

- Native Hot Plug

63.3.5.3.1 Native Hot Plug

The SATA block supports native SATA hot-plug through the use of the SATA_P#0SERR[DIAG_X] and SATA_P#0IS[PCS] bits. It is set every time the Link detects a COMINIT sequence, indicating hot plug insertion event or system power-up.

Hot plug removal is detected by a change in the state of the Port internal "PHY READY" signal. This event is reflected in the SATA_P#0SERR[DIAG_N] and SATA_P#0IS[PRCS] bits.

63.3.5.4 Port Multiplier Support

The SATA block supports Port Multiplier functionality with command-based switching. When a Port is connected to a Port Multiplier, software must first enumerate it by issuing software reset to Port 0Fh (control Port) on the Port Multiplier.

When the signature returned corresponds to a Port Multiplier, then a Port Multiplier is attached. When the signature returned corresponds to another device type, then a Port Multiplier is not attached.

The SATA block provides command list override feature (as indicated by the SATA_CAP[SCLO] = 1) via SATA_P 0CMD[CLO] to help software reliably enumerate the Port Multiplier:

1. Software ensures that SATA_P 0CMD[ST] bit is '0';
2. Software constructs the two Register FISes required for a software reset in the command list, where the PM Port field value in the Register FIS is cleared to 0Fh;
3. Software sets SATA_P 0CMD[CLO] to '1' to force the BSY and DRQ bits in the SATA_P 0TFD register to be cleared;
4. Software sets SATA_P 0CMD[ST] bit to '1' and set appropriate SATA_P 0CI bits in order to begin execution of the software reset command.

63.3.5.5 Interrupts

The SATA block uses a two-tiered interrupt structure defined in the AHCI specification.

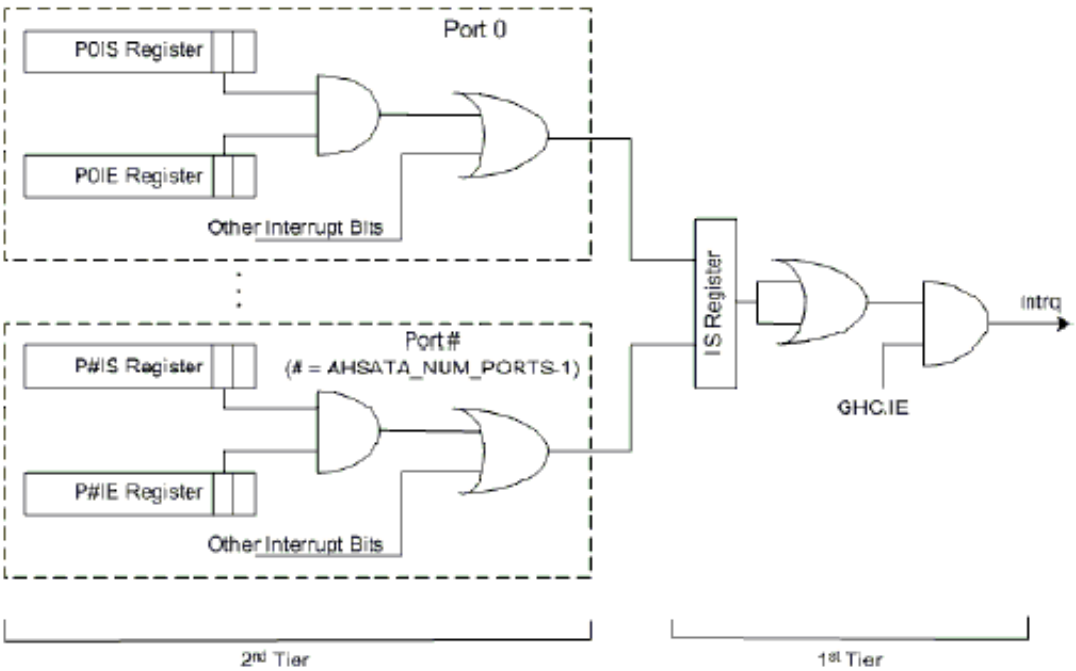

Figure 63-17. SATA block Interrupt Tiers

63.3.5.5.1 First Tier (SATA_IS Register)

The first tier is identified by the IS and SATA_GHC registers. SATA_GHC[IE] bit enables interrupts for the entire SATA block: when it is cleared, intrq output is not asserted regardless of any bits set in the SATA_IS register.

SATA_GHC[IE] bit acts as a mask and does not affect the setting of any interrupt status bits.

The 32-bit SATA_IS register reports the SATA Port has an interrupt pending.

Command Completion Coalescing (CCC) logic generates interrupt (if enabled by software) by setting the IS.IPS[INT] bit, where INT= AHSATA_NUM_PORTS. For example, if DWC_ahsata is configured with eight ports (AHSATA_NUM_PORTS = 8), then the ports use IS bits [7:0], while the CCC interrupt uses IS bit 8.

63.3.5.5.2 Second Tier (SATA_P 0IS Registers)

The second tier is identified in each Port through the SATA_P 0IS (status) and SATA_P 0IE (interrupt enable) register. The SATA_P 0IS register has various interrupt bits that can be individually enabled or disabled by setting the corresponding bit in the SATA_P0IE.

The status bit in the SATA_P 0IS is always set regardless of the setting of the corresponding SATA_P 0IE bit.

63.3.5.6 PHY and Link Control

The SATA block provides two registers - SATA_P0PHYCR and SATA_P0PHYSR for PHY control and status respectively (both are located in the Port PCSR module).

SATA_P0PHYCR register is mapped to the corresponding bits of the p0_phy_ctrl output bus and the SATA_P0PHYSR register to the phy_status input bus.

The Port Link Layer features (scrambler, descrambler, repeat drop) are controlled by the SATA_BISTCR[LLC] field (SATA_BISTCR is located in the GCSR module) and can be disabled in normal operation, such as for testing purposes, by clearing the corresponding bits. The required Port is selected using SATA_TESTR[PSEL] register.

SATA_BISTCR[LLC] bits are set on power up enabling scrambler, descrambler, RPD functions by default. To disable these functions, software must:

1. set SATA_P0SCTL[DET]
2. clear the required SATA_BISTCR[LLC] bits
3. clear SATA_P0SCTL[DET]

63.3.5.7 Reset Conditions

63.3.5.7.1 System Reset

System bus resets SATA block by asserting hresetn=0 (asynchronous bus reset). It is usually initiated on power-up or during system bus failure. All components of the SATA block are initialized, including Ports, Generic registers, BIU.

63.3.5.8 Global Reset

Software may globally reset SATA block by setting SATA_GHC[HR]. When software sets the SATA_GHC[HR] bit, the SATA block performs an internal reset action, then clears this bit when the reset is complete.

Writing 0 to SATA_GHC[HR] has no effect.

NOTE

This reset clears the field SATA_P 0SCTL[SPD]. All Port communication is restarted with the maximum allowable speed, as set by the p0_phy_spdmode input.

To perform the Global reset, software sets SATA_GHC[HR] to '1' and may poll until this bit is read to be '0', indicating the reset completion. The SATA block is initialized as follows:

- SATA_GHC[AE], SATA_GHC[IE], the SATA_IS register, and all Port register fields (except SATA_P 0FB and SATA_P 0CLB) that are not HwInit in the register memory space are reset;
- All other global registers/bits and any HwInit bits in the Port-specific registers are not affected by setting SATA_GHC[HR] to '1';
- The Port-specific registers SATA_P 0FB, and SATA_P 0CLB are not affected by setting SATA_GHC[HR] to '1';
- SATA_P 0CMD[SUD] bit is reset to '0'; software is responsible for setting the SATA_P 0CMD[SUD] and SATA_P 0SCTL[DET] fields appropriately such that communication can be established on the SATA link.

63.3.5.8.1 Port Reset (COMRESET)

Software causes a Port reset by writing 1h to the SATA_P 0SCTL[DET] field to invoke COMRESET on the interface and start a re-establishment of the PHY Layer communication.

Software should wait at least 1ms before clearing SATA_P 0SCTL[DET] to 0h; this ensures that at least one COMRESET signal is sent over the interface. After clearing SATA_P 0SCTL[DET] to 0h, software should wait for communication to be re-established as indicated by bit 0 of SATA_P 0SSTS[DET] being set to '1'. Then software should write all ones to the SATA_P 0SERR register to clear any bits that were set as part of the Port reset.

NOTE

SATA asserts the corresponding p 0_phy_reset(_n) output when P 0SCTL.DET=0x1. It negates p 0_phy_reset(_n) and sends a COMRESET OOB sequence when P 0SCTL.DET=0x0

63.3.5.8.2 Software Reset

Software builds two H2D Register FISes in the command list.

The first Register FIS has the SRST bit set to '1' in the Control field of the Register FIS, the 'C' bit is cleared to '0' in the Register FIS, and the command table has the CH[R] (reset) and CH[C] (clear BSY on R_OK) bits set to '1'. The CH[R] (reset) bit causes the Port to perform a SYNC escape when necessary to put the device into an idle condition before sending the software reset. The CH[C] (clear BSY on R_OK) bit needs to be set for the first Register FIS to clear the BSY bit and proceed to issue the next Register FIS since the device does not send a response to the first Register FIS in a software reset sequence. The second Register FIS has SRST='0' in the Control field of the Register FIS, the 'C' bit is cleared to '0'in the Register FIS, and the command table has the CH[R] (reset) and CH[C] (clear BSY on R_OK) bits cleared to '0'. When issuing a software reset sequence, there should not be other commands in the command list. Before issuing the software reset, software must clear SATA_P 0CMD[ST], wait for the Port to be idle (SATA_P 0CMD[CR]='0'), and then set SATA_P 0CMD[ST] bit again. SATA_P 0TFD[STS] BSY bit and SATA_P 0TFD[STS] DRQ bit must be cleared prior to issuing the reset. When SATA_P 0TFD[STS] BSY bit or the SATA_P 0TFD[STS] DRQ bit is still set based on the failed command, then a Port reset should be attempted or command list override (SATA_P 0CMD[CLO]) should be used.

NOTE

A Port reset (COMRESET) is the preferred mechanism for error recovery and should be used in place of software reset.

63.3.5.9 Interface Speed Support

The SATA block supports 1.5 Gb/s and 3 Gb/s interface speeds as indicated by the SATA_CAP[ISS]=2h. Software can limit a Port's speed to 1.5 Gb/s by setting SATA_P 0SCTL[SPD] field to 1h.

63.3.5.10 Staggered Spin-up

The SATA block supports staggered spin-up operation when SATA_CAP[SSS]='1'. This feature is used to individually spin-up attached devices, thus reducing power supply requirements for multiple devices power-up.

NOTE

In order for a system to support staggered spin-up, the devices and BIOS/driver software must also support staggered spin-up

The SATA_P 0CMD[SUD] bit is used to manipulate the PHY behavior. SATA_P 0SCTL[DET] and SATA_P 0CMD[SUD] must be set correctly in order to avoid illegal combinations of the two values.

The following table describes interaction between the SATA_P 0CMD[SUD] and SATA_P 0SCTL[DET] bits.

Table 63-3. SATA_P 0CMD[SUD] and SATA_P 0SCTL[DET] Interaction

SATA_P0SCTL[DET]	SATA_P0CMD[SUD]	Mode	Behavior
0h	0	Listen	Interface is in a reduced power state. When COMINIT is received then SATA_P 0SERR[DIAG_X] is set and no response (OOB signal) is sent to the device COMWAKE is ignored. The applcation must place the Port into this state only when no device is detected as connected to this Port. In this mode, the Port forces the PHY into a low power state without requesting a SLUMBER transition on the link.
0h	0 -> 1	Spin-Up	Port sends COMRESET, begins initialization sequence.
0h	1	Normal	Normal operating state when the Port is performing data transfers.
1h	0	(not allowed)	This combination is prohibited in hardware. SATA_P 0CMD[SUD] can not be cleared when SATA_P0 SCTL[DET]=1h, and SATA_P0 SCTL[DET] can not be set to 1h when SATA_P0 CMD[SUD}=0.
1h	1	Reset	Port continuously transmits COMRESET and does not listen for COMINIT. When COMINIT is received in this state, the SATA_P0 SERR[DIAG_X] bit is set.
1h-> 0h	1	Initialize	Port stops sending COMRESET, begins initialization sequence.
4h	N/A	Off	Port PHY is off.

Software must only clear SATA_P 0CMD[SUD] when it believes that no device is attached. In Listen Mode (SATA_P 0SCTL[DET]=0h and SATA_P 0CMD[SUD]=0), the Port PHY enters a reduced power state, equivalent to the SLUMBER power management state. The Port PHY enters this state without negotiating a transition to SLUMBER on the link, as asking for a transition to SLUMBER when no device is attached fails, and therefore the PHY remains in a high power state. To avoid this software should ensure that SATA_P 0SSTS[DET]=0h indicating that no device is present before clearing SATA_P 0CMD[SUD].

In order to spin up the devices attached to the SATA block Ports, software should perform the procedure outlined in Firmware Specific Initialization.

63.3.5.11 Asynchronous Notification

The SATA block supports asynchronous notification feature as indicated by the SATA_CAP[SSNT]=1. This feature allows an ATAPI device to send a signal to the host when media is inserted or removed and avoids polling the device for media changes.

The signal sent to the host is a Set Device Bits FIS with the 'I' (interrupt) and'N' (notification) bits set to '1'.

To use asynchronous notification, software should set the SATA_P 0IS[SDBS] bit to enable interrupt notification on a Set Device Bits FIS. When accesses to the ATAPI device are idle, software should place the device in a low power state. When the device has a media change, it signals this to the block's SATA Port with a Set Device Bits FIS. In response to receiving a P 0IS[SDBS] interrupt on an idle Port, software should interrogate the device to determine the cause of the interrupt.

The first DWORD of any FIS received by the host contains a 4-bit Port Multiplier Port (PM Port) field. The second DWORD of the BIST Activate FIS least significant byte (bits [7:0]) is stored in the SATA_BISTAFR[NCP] field. The PM Port field indicates which Port/target behind the Port Multiplier issued the FIS to the block's SATA Port. When a Set Device Bits FIS is received by the block's SATA Port and the 'N' (notification) bit is set, the bit position in the SATA_P 0SNTF register corresponding to the PM Port field is set. The block's SATA Port sets the SATA_P 0IS[SDBS] field when the 'I' (interrupt) bit is set in the Set Device Bits FIS. This causes an interrupt to be generated when that interrupt is enabled.

NOTE

When a Port Multiplier is not present, the PM Port field in the Set Device Bits FIS is 0h, causing bit 0 of the SATA_P 0SNTF register to be set.

63.3.5.12 BIST Operation

The SATA Port can be put into one of the BIST loopback modes described in the following subsections.

NOTE

Scrambler and Descrambler are bypassed (disabled) in the Port Link layer in all BIST modes by default. When needed, Scrambler and Descrambler can be enabled through software, by clearing the bits SATA_BISTCR[SCRAM] and SATA_BISTCR[DESCRAM] (SCRAM and DESCRAM are

bits within the SATA_BISTCR[LLC] field) prior to entering BIST mode.

63.3.5.13 Loopback Responder

Software must ensure that the Port is in idle state and there are no outstanding commands by checking SATA_P 0CI

and SATA_P 0SACT registers are both cleared, SATA_P 0TFD[STS] register BSY, DRQ and ERR bits are all cleared.

The block's SATA Port enters one of the BIST loopback responder modes when a corresponding BIST Activate FIS is successfully received from the device and is supported by the SATA block. SATA_P 0SSTS[DET] field returns 4h when read. Since BIST registers' locations are shared between all the active Ports, software must first select the Port for BIST operation by writing the Port number to the SATA_TESTR[PSEL] field before accessing SATA_BISTAFR (Port0 is selected in the SATA_TESTR[PSEL] on power-on (system) or global SATA block reset).

NOTE

When the device sends a BIST Activate FIS with a request to enter a non-supported loopback mode, SATA block responds with R_ERRp response upon reception of the FIS.

The following loopback responder modes are supported by the SATA block:

- Far-end retimed
  - The Port receives BIST Activate FIS with Pattern Definition field (bits [23:16] of the first DWORD) = 0x10 from the RxFIFO and stores it in the SATA_BISTAFR[PD] field
  - All the data received from the device in the form of a SATA-compliant pattern is retimed in the Link Layer and transmitted back to the device.
  - Alternately, this mode can be initiated with device disconnected from the Port PHY (Link is in NOCOMM state) when software writes SATA_BISTCR[FERLB]=1. After the device is connected to the SATA block, the device must transmit the number of ALIGNs required for the PHY to sync.
- Far-end analog (Port PHY must support this mode)

- The Port receives BIST Activate FIS with Pattern Definition field (bits [23:16] of the first DWORD) = 0x08 from the RxFIFO and stores it in the SATA_BISTAFR[PD] field
- The Port asserts p0_phy_farafelb signal to the PHY to put it to the Far-end analog loopback mode. The PHY receives and retransmits the raw data without retiming

- Far-end transmit only
  - The Port receives BIST Activate FIS with Pattern Definition field (bits [23:16] of the first DWORD) = 0x80 (scrambling is enabled) or 0xA0 (scrambling is bypassed) from the RxFIFO The Port stores it in the SATA_BISTAFR[PD]. The second DWORD of the BIST Activate FIS least significant byte (bits [7:0]) is stored in the SATA_BISTAFR[NCP] field.
  - The Port transmits corresponding a SATA non-compliant test pattern to the device based on the SATA_BISTAFR[NCP] value:
    - 0xF1: Low transition density pattern (LTDP)
    - 0xB5: High transition density pattern (HTDP)
    - 0xAB: Low frequency spectral component pattern (LFSCP)
    - 0x7F: Simultaneous switching outputs pattern (SSOP)
    - 0x8B: Lone bit pattern (LBP)
    - 0x78: Mid frequency test pattern (MFTP)
    - 0x4A: High frequency test pattern (HFTP)
    - 0x7E: Low frequency test pattern (LFTP)
  - Alternately, this mode can be initiated with device disconnected from the Port PHY (Link NOCOMM state) when software writes a one to the SATA_BISTCR[TXO] bit. SATA block transmits non-compliant BIST pattern defined by the value in the SATA_BISTCR[PATTERN] field.

Loopback responder BIST modes can be exited either when the device signals COMINIT OOB condition, or when the software initiates Port reset (COMRESET).

63.3.5.13.1 Loopback Initiator

The software first selects the Port for BIST operation by writing the Port number to the SATA_TESTR[PSEL] field, then the required pattern by writing to the SATA_BISTCR[PATTERN] field.

The software builds a BIST FIS with the required mode in the commands list and sets CTBAz[B]. Once a BIST command is placed into the list, software is not allowed to build any more commands until it clears SATA_P 0CMD[ST]. After the Port successfully transmits this FIS, it enters this mode and generates/receives the compliant test pattern selected by the SATA_BISTCR[PATTERN] field.

SATA_P 0SSTS[DET] returns 4h when read. SATA_BISTSR and SATA_BISTFCTR registers are updated with error/FIS count information for each received BIST FIS.

NOTE

The device must support either PARTIAL or SLUMBER power modes for near-end analog loopback mode, otherwise it should be initiated with the device disconnected from the Port PHY. It is not clear how the device responds when it does not support the requested BIST mode - with R_OKp and ignoring the request or with R_ERRp. In the former case, the host assumes the device has entered the BIST mode and starts the test that fails.

The following BIST initiator modes can be requested by the software:

- "Far-end retimed"
- "Far-end analog"
- "Near-end analog"
- "Far-end transmit only"

63.3.5.13.1.1 Far-end retimed

The host software writes the SATA_BISTCR[PATTERN] field to select one of the SATA-defined compliant patterns:

- 0000b: Simultaneous switching outputs pattern (SSOP)
- 0001b: High transition density pattern (HTDP)
- 0010b: Low transition density pattern (LTDP)
- 0011b: Low frequency spectral component pattern (LFSCP)
- 0100b: Composite pattern (COMP)
- 0101b: Lone bit pattern (LBP)
- 0110b: Mid frequency test pattern (MFTP)
- 0111b: High frequency test pattern (HFTP)
- 1000b: Low frequency test pattern (LFTP)

The software prepares BIST Activate FIS with bits [23:16]=10h of the first DWORD (Pattern Definition field) in the command list. The Port sends this BIST Activate FIS to the device.

After successful transmission of the BIST Activate FIS (device acknowledges the FIS with R_OKp) the Port generates the requested compliant pattern in the form of BIST frames continuously and checks for errors on the receive side.

SATA_BISTFCTR register is updated with the received BIST frame count and SATA_BISTSR with frame/burst error count. . SATA_P 0SERR register is updated with CRC, disparity, and 10B8B errors for each frame. SATA_BISTFCTR, and SATA_BISTSR registers can be cleared by writing '1' to the SATA_BISTCR[CNTCLR] bit.

To change the pattern, the software issues a Port Reset (COMRESET), writes to the SATA_BISTCR[PATTERN] field to select a new pattern and re-issues the command by setting the SATA_P 0CI bit.

63.3.5.13.1.2 Far-end analog

The software prepares BIST Activate FIS with bits [23:16]=08h of the first DWORD (Pattern Definition field) in the command list. The Port sends this BIST Activate FIS to the device.

The operation proceeds as described in the far-end retimed test above.

63.3.5.13.1.3 Near-end analog

NOTE

Port PHY must support this mode, plus both clk_asic0 and clk_rbc0 must be running in the selected power management states or when the device is disconnected. When this is not true, this loopback mode is not supported by the SATA block.

This mode can be initiated either in one of the power management modes (PARTIAL or SLUMBER) or with the device disconnected from the Port PHY (Link NOCOMM state). The software issues a PARTIAL or SLUMBER power state request to the device via SATA_P 0CMD[ICC] field and sets the SATA_BISTCR[NEALB] bit. The SATA_BISTCR[PATTERN] field selects the required BIST pattern.

The Port asserts p 0_phy_nearafelb to the PHY. The PHY loops the data from its transmitter to its receiver and ignores any data coming from the device.

The operation proceeds as described in the far-end retimed test above, except BIST Activate FIS is not sent to the device.

63.3.5.13.1.4 Far-end transmit only

The software prepares BIST Activate FIS in the command list with the second and third DWORDs containing the required pattern, and the first DWORD - with the Pattern Definition (bits [23:16]) value corresponding to the required mode - Bit 23 (T) is set, bits 20 (L), 19 (F), 17 (R) cleared and bits 22, 21 and 18 are used to enable the following options:

- Bit 22 (A) is set - Bypass ALIGN
- Bit 21 (S) is set - Bypass scrambling
- Bit 18 (P) is set - Primitive bit (refer to the SATA specification for more details)

The Port sends this BIST Activate FIS to the device. After the device acknowledges the reception of this FIS with R_OKp, the Port disables the PHY receiver and transmitter (any received data is ignored by the Link Layer, transmitter is idle and maintains common mode bias per SATA specification).

Loopback initiator BIST modes can be terminated either by the device when it signals COMINIT OOB condition (except the near-end analog mode), or when the software initiates Port reset (COMRESET).

63.3.5.14 Command Completion Coalescing

A Command Completion Coalescing (CCC) feature is used to reduce the interrupt and command completion overhead in a heavily-loaded system.

The SATA block core generates an interrupt to allow software to process completed commands when either of these conditions is true:

- A software-specified number of commands have completed
- A software-specified time-out has expired

This feature applies to all Ports selected to be in the CCC set by software via the SATA_CCC_PORTS register.

CCC logic uses SATA block-specific register SATA_TIMER1MS to generate 1ms interval based on the AHB clock frequency. Software must load this register with the required value before enabling the CCC feature:

- Fhclk * 1000, where Fhclk = AHB clock frequency, in MHz

Additional Command Completion Coalescing details and examples can be found in the AHCI specification.

NOTE

CCC logic can be removed from the SATA core if it is not needed by setting the CCC_SUPPORT configuration parameter to “Exclude” (0). In this case, all CCC-related registers become “reserved” (returns 0 on read).

63.4 Programming

The SATA block software initialization consists of two independent phases: a firmware phase (platform BIOS) and a system software phase.

This section contains the following sub-sections:

- Firmware Specific Initialization
- System software Specific Initialization

63.4.1 Firmware Specific Initialization

The firmware initialization is done on power-up.

The following registers should be initialized to values that reflect the capabilities supported by the platform:

- SATA_CAP[SSS] - support for staggered spin-up
- SATA_CAP[SMPS] - support for mechanical presence switches
- SATA_PI - Ports implemented
- SATA_P 0CMD[HPCP] - whether the Port is hot plug capable. The SATA_P 0CMD[HPCP] should be set to 1 when SATA_P 0CMD[MPSP] or SATA_P 0CMD[CPD] is set to 1 for the Port.
- SATA_P 0CMD[MPSP] - whether mechanical presence switch is attached to the Port.
- SATA_P 0CMD[CPD] - whether cold presence detect logic is attached to the Port.

NOTE

Firmware should initialize the HPCP, MPSP, and CPD bits for each Port implemented on the platform as defined by the SATA_PI register.

After firmware has initialized the above mentioned registers, it should then perform the following steps to complete the staggered spin-up process (when applicable to the platform) on each Port implemented (as indicated by the SATA_PI register):

1. Ensure that SATA_P 0CMD[ST]=0, SATA_P 0CMD[CR]=0, SATA_P 0CMD[FRE]=0, SATA_P 0CMD[FR]=0, and SATA_P 0SCTL[DET]=0.
2. Allocate memory for the command list and the FIS receive area. Set SATA_P 0CLB 0 to the physical address of the allocated command list. Set SATA_P 0FB to the physical address of the allocated FIS receive area. Then set P 0CMD[FRE] to 1.
3. Initiate a spin-up of the SATA drive attached to the Port by setting P 0CMD[SUD] to 1
4. Wait for a positive indication that a device is attached to the Port (the maximum time to wait for presence indication is specified in the Serial ATA specification). This is done by polling SATA_P 0SSTS[DET]. When SATA_P 0SSTS[DET] returns a value of 1h or 3h when read, then the firmware should continue to the next step, otherwise when polling process times out, it moves to the next implemented Port and returns to Step 1.
5. Clear the SATA_P 0SERR register by writing ones to each implemented bit location.
6. Wait for indication that SATA drive is ready. This is determined through examination of SATA_P 0TFD[STS]. When SATA_P 0TFD[STS] BSY bit, SATA_P 0TFD[STS] DRQ bit, and SATA_P 0TFD[STS] ERR bit are all 0, prior to the maximum allowed time as specified in the ATA/ATAPI-7 specification, the device is ready.

63.4.2 System software Specific Initialization

Software may perform the SATA block global reset prior to initializing by setting SATA_GHC[HR] to 1 when desired.

When firmware (BIOS) already allocated memory and initialized the appropriate registers for the command list and FIS receive area, the software may skip this step in the process.

Following is the list of steps for system software to place the SATA block into a minimally initialized state:

1. Determine which Ports are implemented by the SATA block, by reading the PI register. This bit map value aids the software to determine how many Ports are available and which Port registers need to be initialized.
2. Ensure that the SATA block is not in the running state by reading and examining each implemented Port's SATA_P 0CMD register. When SATA_P 0CMD[ST], SATA_P 0CMD[CR], SATA_P 0CMD[FRE] and SATA_P 0CMD[FR] are all cleared, the Port is in an idle state. Otherwise, the Port is not idle and should be placed in the idle state prior to manipulating the SATA block global and Port specific register. System software places a Port into the idle state by clearing SATA_P 0CMD[ST] and waiting for SATA_P 0CMD[CR] to return 0 when read. Software should wait at least 500ms for this to occur. When SATA_P 0CMD[FRE] is set to 1

software should clear it to 0 and wait at least 500ms for SATA_P 0CMD[FR] to return 0 when read. When SATA_P 0CMD[CR] or SATA_P 0CMD[FR] do not clear to 0 correctly, then software may attempt a Port reset or a global reset to recover.

3. Determine how many command slots the HBA supports, by reading SATA_CAP[NCS].
4. For each implemented Port, system software should allocate memory for and program:
   - SATA_P 0CLB
   - SATA_P 0FB

NOTE

It is good practice for system software to zero-out the memory allocated and referenced by SATA_P 0CLB and SATA_P 0FB. After setting SATA_P 0FB to the physical address of the FIS receive area, system software should set SATA_P 0CMD[FRE] to 1.

5. For each implemented Port, clear the SATA_P 0SERR register, by writing ones to each implemented bit location.
6. Determine which events should cause an interrupt and set the appropriate enable bits of the SATA_P 0IE register. To enable the SATA block to generate interrupts, system software must also set SATA_GHC[IE] to 1.

NOTE

Due to the multi-tiered nature of the SATA block interrupt architecture, system software must always ensure that the SATA_P 0IS (clear this first) and SATA_IS[IPS] (clear this second) register are cleared to '0' before programming the SATA_P 0IE and SATA_GHC[IE] registers. This prevents any residual bits set in these registers from causing an interrupt to be asserted.

Software should not set SATA_P 0CMD[ST] to 1 until it is determined that a functional device is present on the Port as determined by SATA_P 0TFD[STS] BSY bit, SATA_P 0TFD[STS] DRQ bit, and SATA_P 0TFD[STS] ERR bit all cleared, and SATA_P 0SSTS[DET]=3h. To enable the SATA_P 0TFD register to be updated with the initial Register FIS for a Port, the SATA_P 0SERR[DIAG_X] bit must be cleared to 0.

63.5 Software Manipulation of Port DMA

This section contains the following topics:

- Start (SATA_P 0CMD[ST])
- FIS Receive Enable (SATA_P 0CMD[FRE])

63.5.1 Start (SATA_P 0CMD[ST])

When SATA_P 0CMD[ST] is set to 1, software is not allowed to perform the following actions:

- Manipulate SATA_P 0CMD[POD] to power on or off a device through cold presence detect logic (when supported by the platform and enabled in the SATA block);
- Manipulate SATA_P 0SCTL[DET] to change the PHY state;
- Manipulate SATA_P 0CMD[SUD] to spin-up the device (when supported by the platform)

The above actions are only allowed while the Port is in the Not Running state, indicated by both SATA_P 0CMD[ST] and SATA_P 0CMD[CR] being 0.

Software should set SATA_P 0CMD[ST] only after the following conditions become true:

- SATA_P 0CMD[CR] is verified to be cleared to '0' and SATA_P 0CMD[FRE] has been set to 1;
- A functional device is present on the Port (as determined by SATA_P 0TFD[STS] BSY bit=0, SATA_P 0TFD[STS] DRQ bit=0, and SATA_P 0SSTS[DET]=3h) and the registers SATA_P 0CLB are programmed to valid values.

63.5.2 FIS Receive Enable (SATA_P 0CMD[FRE])

When SATA_P 0CMD[FRE] is set (causing SATA_P 0CMD[FR] to be set to 1), the Port receives FISes from the devices and copies them into system memory. When SATA_P 0CMD[FRE] is cleared (causing SATA_P 0CMD[FR] to be cleared to 0), received FISes are held in the RxFIFO, and when it is full, further FIS reception is blocked.

Software is allowed to manipulate SATA_P 0CMD[FRE] so that it may move the FIS receive area to a new location. When this bit is cleared to 0, software must first wait for SATA_P 0CMD[FR] to clear to 0, indicating that the Port DMA engine for FIS reception is in an idle condition. When SATA_P 0CMD[FR] and SATA_P 0CMD[FRE] are both cleared to 0, software may update the values of SATA_P 0FB. Prior to setting SATA_P 0CMD[FRE] to 1, software should ensure that SATA_P 0FB are set to valid values. Software should not write SATA_P 0FB while SATA_P 0CMD[FRE] is set to 1.

Software should set SATA_P 0CMD[FRE] to 1 prior to setting SATA_P 0CMD[ST] to 1. Software should not clear SATA_P 0CMD[FRE] while SATA_P 0CMD[ST] or SATA_P 0CMD[CR] is set to 1.

Upon global or Port reset, the SATA_P 0CMD[FRE] bit is cleared. The D2H Register FIS containing the device signature is accepted by the Port, and the signature field is updated.

NOTE

When the SATA block Port stops running due to an error (e.g., SATA_P 0IS[IFS] is set to 1), FISes may not be posted until the SATA_P 0CMD[ST] bit is cleared to 0 to recover from the error.

63.6 Register Descriptions

This section contains register memory maps, register groups, and bit-field descriptions.

63.6.1 Register Overview

The SATA block registers occupy 328 bytes of the 8-KB address space assigned to the SATA block and are divided into two parts: Generic control, and Port control.

Register space above the offset of 0x14F is reserved.

63.6.1.1 Register Basics:

All registers are 32-bits wide and can be accessed using 8, 16, or 32-bit wide transfers, except when noted otherwise in the register descriptions.

All registers that start below the offset 0x100 are global and apply to the entire SATA block.

63.6.1.2 Reserved Locations

When a register, field, or bit is reserved:

- Reads return zero.
- Writes have no effect.

63.7 Programmable Registers

This section provides high-level summaries of the Generic and Port control regsier maps.

The register names in SATA Memory Map are cross-referenced to the detailed register descriptions in the following section (double-click on the register name to link to the detailed description).

SATA memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

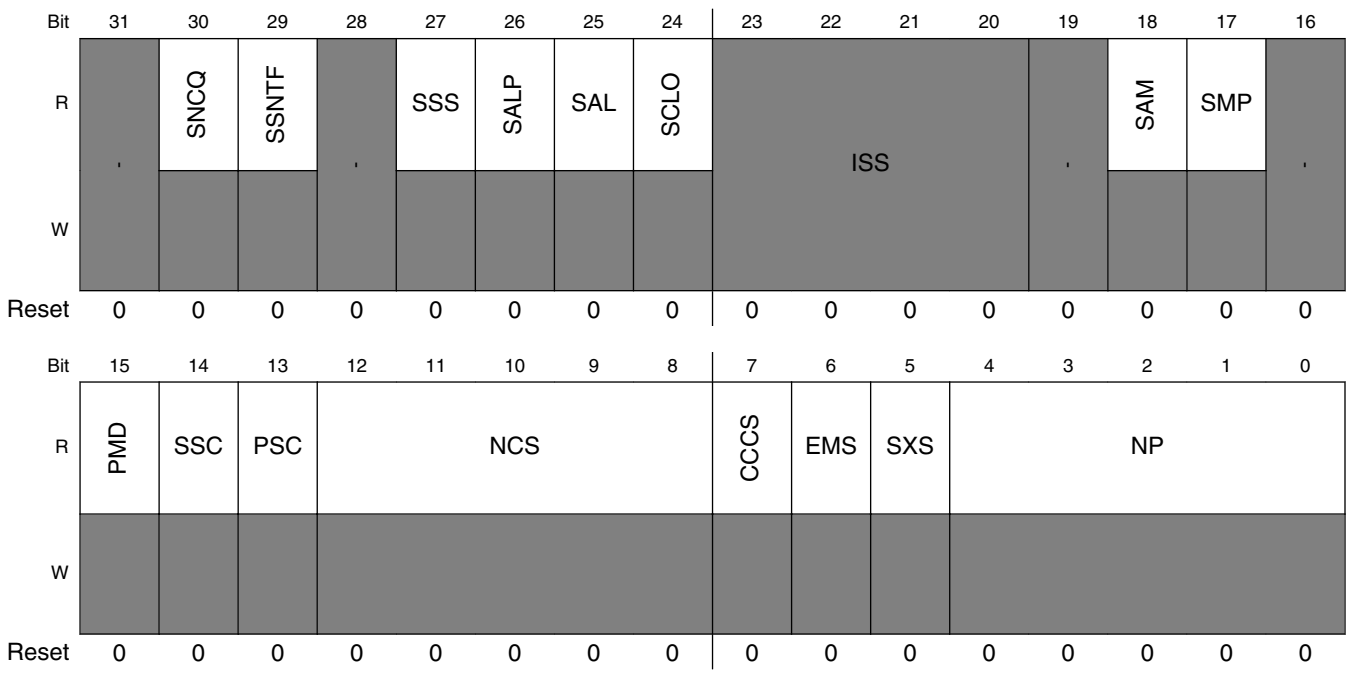
63.7.1 HBA Capabilites Register (SATA_CAP)

This register indicates basic capabilities of the SATA block to the software.

Address: SATA_CAP is 1000_0000h base + 0h offset = 1000_0000h



SATA_CAP field descriptions

Field	Description
31 -	Reserved. Returns 0 on read.
30 SNCQ	Supports Native Command Queuing. SATA block supports SATA native command queueing by handling DMA Setup FIS natively.
29 SSNTF	Supports SNotification Register. SATA block supports SATA_P 0 SNTF (SNotification) register and its associated functionality.
28 -	Reserved. Returns 1 on read.

Table continues on the next page...

SATA_CAP field descriptions (continued)

Field	Description
27 SSS	Supports Staggered Spin-up. This bit is set by the system firmware/BIOS to indicate platform support for staggered devices' spin-up. SATA block supports this feature through the SATA_P 0 CMD[SUD] bit functionality.
26 SALP	Supports Aggressive Link Power Management. SATA block supports auto-generating (Port-initiated) Link Layer requests to the PARTIAL or SLUMBER power management states when there are no commands to process.
25 SAL	Supports Activity LED. SATA block supports activity indication using signal p 0 _act_led.
24 SCLO	Supports Command List Override. SATA block supports the SATA_P 0 CMD[CLO] bit functionality for Port Multiplier devices' enumeration.
23–20 ISS	Interface Speed Support. Reserved. Returns 0x2 on read.
19 -	Reserved. Returns 0 on read.
18 SAM	Supports AHCI Mode Only. SATA block supports AHCI mode only and does not support legacy, task-file based register interface.
17 SMP	Supports Port Multiplier. SATA block supports command-based switching Port Multiplier on any of its Ports.
16 -	Reserved.
15 PMD	PIO Multiple DRQ Block. SATA block supports multiple DRQ block data transfers for the PIO command protocol.
14 SSC	Slumber State Capable. SATA block supports transitions to the interface SLUMBER power management state.
13 PSC	Partial State Capable. SATA block supports transitions to the interface PARTIAL power management state.
12–8 NCS	Number of Command Slots. SATA block supports 32 command slots per Port.
7 CCCS	Command Completion Coalescing Support. SATA block supports command completion coalescing.
6 EMS	Enclosure Management Support. SATA block does not support enclosure management.
5 SXS	Supports External SATA. The options for this field are:

Table continues on the next page...

SATA_CAP field descriptions (continued)

Field	Description
	1 Indicates that the SATA block has one or more Ports that has a signal only connector (power is not part of that connector) that is externally accessible. When this bit is set to 1, the software can refer to the SATA_P 0 CMD[ESP] bit to determine whether a specific Port has its signal connector externally accessible. 0 Indicates that the SATA block has no Ports that have a signal only connector externally accessible. Reset Value: Configurable 1 when any of the SATA_P 0 CMD[ESP]=1 0 when all of the SATA_P 0 CMD[ESP]=0
4–0 NP	Number of Ports. 0's based value indicating the number of Ports supported by the SATA block: The options for this field are: • 0x00: 1 Port • 0x01: 2 Ports • 0x02: 3 Ports Reset Value: 0x00

63.7.2 Global HBA Control Register (SATA_GHC)

This register controls various global actions of the SATA block.

Address: SATA_GHC is 1000_0000h base + 4h offset = 1000_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	AE	-																													IE	HR
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SATA_GHC field descriptions

Field	Description
31 AE	AHCI Enable. This bit is always set since SATA block supports only AHCI mode as indicated by the SATA_CAP[SAM]=1.
30–2 -	Reserved
1 IE	Interrupt Enable. This global bit enables interrupts from the SATA block. When cleared, all interrupt sources from all the Ports are disabled (masked). When set, interrupts are enabled and any SATA block interrupt event causes intrq output assertion. This field is reset on Global reset (SATA_GHC[HR]=1).

Table continues on the next page...

SATA_GHC field descriptions (continued)

Field	Description
0 HR	HBA Reset. When set by the software, this bit causes an internal Global reset of the SATA block. All state machines that relate to data transfers and queueing return to an idle state, and all the Ports are re-initialized by sending COMRESET When staggered spin-up is not supported. When staggered spin-up is supported, then the software must spin-up each Port after this reset has completed. See Global Reset for details. The SATA block clears this bit when the reset action is done. A software write of 0 has no effect.

63.7.3 Interrupt Status Register (SATA_IS)

This register indicates which of the Ports within the SATA block have an interrupt pending and require service. This register is reset on Global reset (SATA_GHC[HR]=1).

- Size: 32 bits
- Address offset: 0x08
- Read/write access: Read/Write One to Clear
- Reset: 0x0000_00000

Address: SATA_IS is 1000_0000h base + 8h offset = 1000_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATA_IS field descriptions

Field	Description
31–2 -	Reserved.
1–0 IPS	Interrupt Pending Status. When bit 1is set, this indicates that Port 0 has an interrupt pending. This bit is set when the Port has an interrupt event pending and the interrupt source is enabled (see the definition of the SATA_P 0 IE register). Bit 0 of the IPS field is not used.

63.7.4 Ports Implemented Register (SATA_PI)

This register indicates which Ports are exposed by the SATA block and are available for the software to use. It is loaded by the BIOS. For example, when the SATA block supports 8 Ports as indicated in the SATA_CAP[NP], only Ports 1, 3, 5, and 7 could be available, while Ports 0, 2, 4, and 6 being unavailable.

NOTE

The contents of this register are relevant to the SATA_CCC_PORTS (Command Completion Coalescing Ports) register.

Address: SATA_PI is 1000_0000h base + Ch offset = 1000_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:
- See descriptions for reset values.

SATA_PI field descriptions

Field	Description
31–1 -	Reserved.
0 PI	Ports Implemented. BIOS must set this bit to 1

63.7.5 AHCI Version Register (SATA_VS)

This register indicates the major and minor version of the AHCI specification that the SATA block implementation supports. The SATA block supports version 1.20.

NOTE

The SATA block core currently complies fully with AHCI version 1.10 , and complies with AHCI version 1.2, except with respect to FIS-based switching. FIS-based switching is not currently supported.

BIST register locations (SATA_BISTAFR, SATA_BISTCR, SATA_BISTFCTR, and SATA_BISTSR) are shared between the SATA block Ports. Before accessing any of the BIST registers, the software must first select the required Port by writing the Port number to the SATA_TESTR[PSEL] field.

Address: SATA_VS is 1000_0000h base + 10h offset = 1000_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATA_VS field descriptions

Field	Description
31–16 MJR	Major Version Number. Indicates that the major AHCI version is 1.
15–0 MNR	Minor Version Number. Indicates that the minor AHCI version is 20.

63.7.6 Command Completion Coalescing Control (SATA_CCC_CTL)

This register is used to configure the command completion coalescing (CCC) feature for the SATA block core. It is reset on Global reset.

Address: SATA_CCC_CTL is 1000_0000h base + 14h offset = 1000_0014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

* Notes:
- See descriptions for reset values.

SATA_CCC_CTL field descriptions

Field	Description
31–16 TV	Time-out Value. This field specifies the CCC time-out value in 1ms intervals. The software loads this value prior to enabling CCC. The options for this field are: • RW when SATA_CCC_CTL[EN]==0. • RO when SATA_CCC_CTL[EN]==1. A time-out value of 0x0000 is reserved and should not be used.
15–8 CC	Command Completions. This field specifies the number of command completions that are necessary to cause a CCC interrupt. The value 0x00 for this field disables CCC interrupts being generated based on the number of commands completed. In this case, CCC interrupts are only generated based on the timer. Software loads this value prior to enabling CCC: Field access is:

Table continues on the next page...

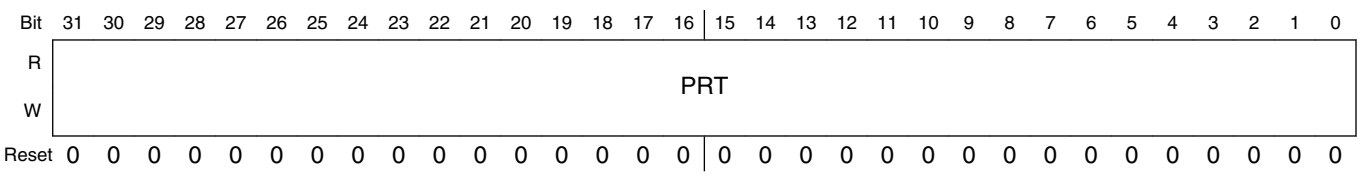
SATA_CCC_CTL field descriptions (continued)

Field	Description
	• RW when SATA_CCC_CTL[EN]==0 • RO when SATA_CCC_CTL[EN]==1
7–3 INT	Interrupt. Set this field to 0x01.
2–1 -	Reserved.
0 EN	Enable. **NOTE:** When field SATA_CCC_CTL[EN]==1, the software can not change the fields SATA_CCC_CTL[TV] and SATA_CCC_CTL[CC]. The options for this field are: 0 CCC feature is disabled and no CCC interrupts are generated. 1 CCC feature is enabled and CCC interrupts may be generated based on the time-out or command completion conditions.

63.7.7 Command Completion Coalescing Ports (SATA_CCC_PORTS)

This register specifies the Ports that are coalesced as part of the command completion coalescing (CCC) feature when SATA_CCC_CTL[EN]==1. It is reset on Global reset.

Address: SATA_CCC_PORTS is 1000_0000h base + 18h offset = 1000_0018h



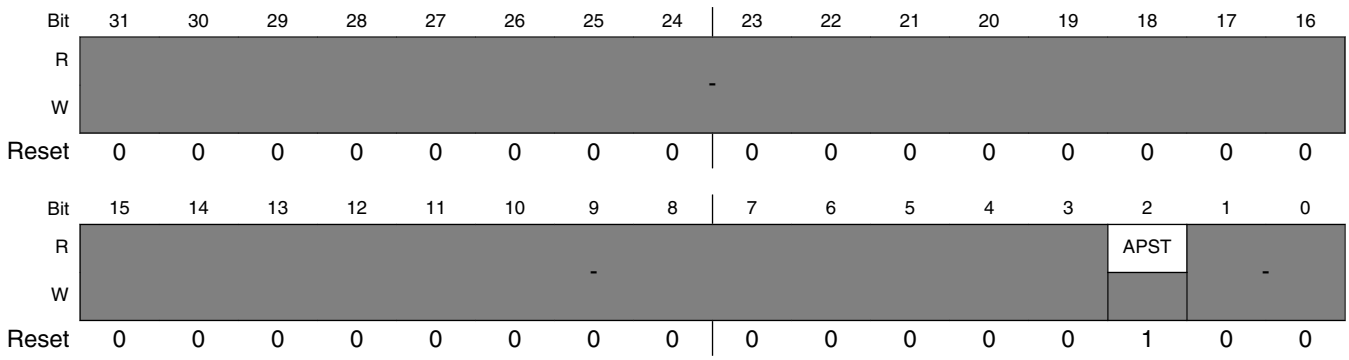
SATA_CCC_PORTS field descriptions

Field	Description
31–0 PRT	Ports. This field is bit significant. Each bit corresponds to a particular Port, where bit 0 corresponds to Port0. Bits set in this register must have the corresponding bit set in the SATA_PI (Ports Implemented Register). The options for this field are: 1 the corresponding Port is part of the CCC feature. 0 the corresponding Port is not part of the CCC feature.

63.7.8 HBA Capabilities Extended Register (SATA_CAP2)

This register indicates capabilites of the SATA block core to the software.

Address: SATA_CAP2 is 1000_0000h base + 24h offset = 1000_0024h



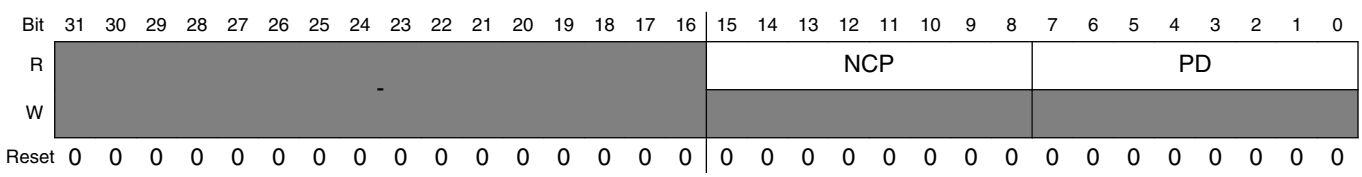
SATA_CAP2 field descriptions

Field	Description
31–3 -	Reserved
2 APST	Automatic Partial to Slumber Transitions. SATA block supports automatic Partial to Slumber transitions.
1–0 -	Reserved.

63.7.9 BIST Activate FIS Register (SATA_BISTAFR)

This register contains the pattern definition (bits [23:16] of the first DWORD) and data pattern (bits [7:0] of the second DWORD) fields of the received BIST Activate FIS. These fields define the SATA block loopback responder mode requested by the device. It is updated every time a new BIST Activate FIS is received from the device. Reset on Global or Port reset.

Address: SATA_BISTAFR is 1000_0000h base + A0h offset = 1000_00A0h



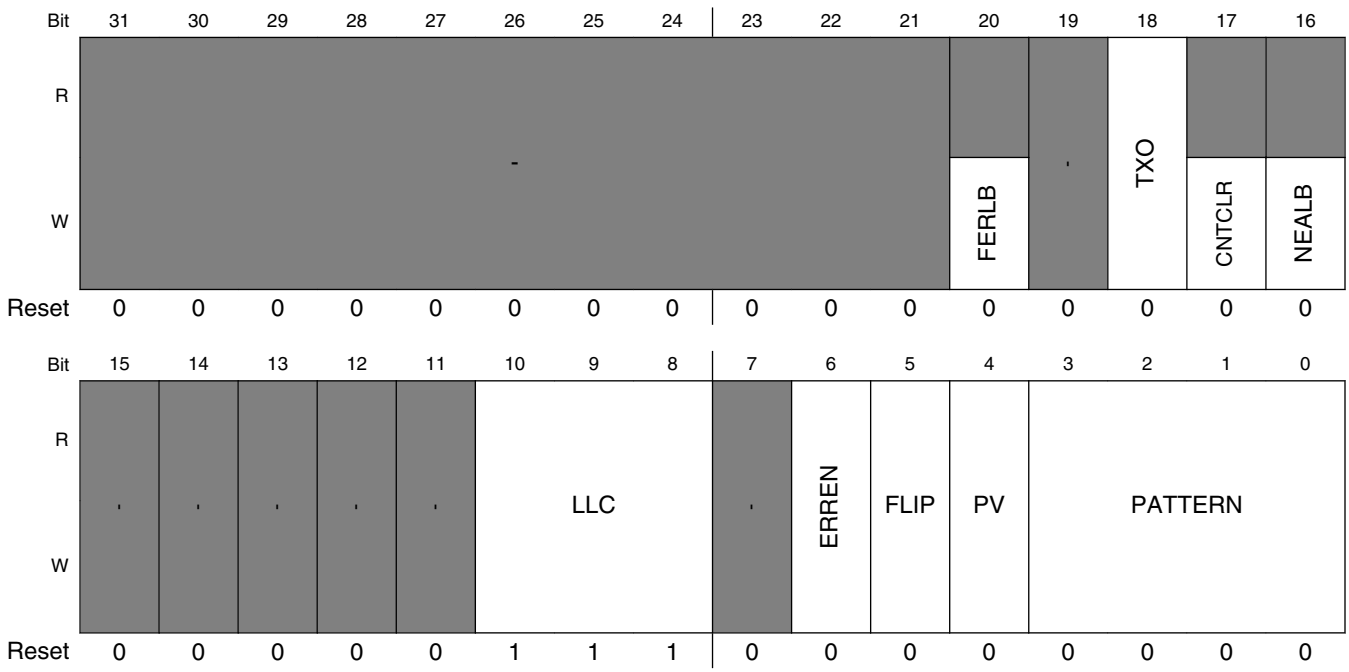
SATA_BISTAFR field descriptions

Field	Description
31–16 -	Reserved.
15–8 NCP	Least significant byte of the received BIST Activate FIS second DWORD (bits [7:0]). This value defines the required pattern for far-end transmit only mode (SATA_BISTAFR[PD]=0x80 or 0xA0): When none of these values is decoded, the simultaneous switching pattern is transmitted by default. 0xF1 Low transition density pattern (LTDP) 0xB5 High transition density pattern (HTDP) 0xAB Low frequency spectral component pattern (LFSCP) 0x7F Simultaneous switching outputs pattern (SSOP) 0x8B Lone Bit pattern (LBP) 0x78 Mid frequency test pattern (MFTP) 0x4A High frequency test pattern (HFTP) 0x7E Low frequency test pattern (LFTP)
7–0 PD	Pattern Definition Indicates the pattern definition field of the received BIST Activate FIS - bits [23:16] of the first DWORD. It is used to put the SATA block in one of the following BIST modes: For far-end transmit only modes SATA_BISTAFR[NCP] field contains the required data pattern. 0x10 Far-end retimed 0x08 Far-end analog (when PHY supports this mode) 0x80 Far-end transmit only 0xA0 Far-end transmit only with scrambler bypassed All other values should not be used by the device, otherwise, the FIS is negatively acknowledged with R_ERRp.

63.7.10 BIST Control Register (SATA_BISTCR)

This register is used in BIST initiator modes. It is loaded by the host software prior to sending BIST Activate FIS to the device (via TXBISTPD write). It is reset on a Global or Port reset.

Address: SATA_BISTCR is 1000_0000h base + A4h offset = 1000_00A4h



SATA_BISTCR field descriptions

Field	Description
31–21 -	Reserved.
20 FERLB	Far-end Retimed Loopback. When set, this bit is used to put the SATA block Link into Far-end Retimed mode, without the BIST Activate FIS, regardless whether the device is connected or disconnected (Link in NOCOMM state). This field is one-shot type and reads returns 0.
19 -	Reserved.
18 TXO	Transmit Only. This bit is used to initiate transmission of one of the non-compliant patterns defined by the SATA_BISTCR[PATTERN] value when the device is disconnected.
17 CNTCLR	Counter Clear This bit clears BIST error count registers. This field is one-shot type and reads returns 0. 1 Clear SATA_BISTFCTR, and SATA_BISTSR registers.

Table continues on the next page...

SATA_BISTCR field descriptions (continued)

Field	Description
16 NEALB	Near-End Analog Loopback This mode should be initiated either in the PARTIAL or SLUMBER power mode, or with the device disconnected from the Port PHY (Link NOCOMM state). BIST Activate FIS is not sent to the device in this mode. This bit places the Port PHY into near-end analog loopback mode. This field is one-shot type and reads returns 0: 1 Near-end analog loopback request. SATA_BISTCR[PATTERN] field contains the appropriate pattern.
15 -	Reserved.
14 -	Reserved.
13 -	Reserved.
12 -	Reserved.
11 -	Reserved.
10–8 LLC	Link Layer Control This field controls the Port Link Layer functions: scrambler, descrambler, and repeat primitive drop. Note the different meanings for normal and BIST modes of operation: • Bit8-SCRAM The options for this field are: 0 Scrambler disabled in normal mode, enabled in BIST mode 1 Scrambler enabled in normal mode, disabled in BIST mode • Bit9-DESCRAM The options for this field are: 0 Descrambler disabled in normal mode, enabled in BIST mode 1 Descrambler enabled in normal mode, disabled in BIST mode • Bit10-RPD The options for this field are: 0 Repeat primitive drop function disabled in normal mode, NA in BIST mode. 1 Repeat primitive drop function enabled in normal mode, NA in BIST mode. The SCRAM bit is cleared (enabled) by the Port when the Port enters a responder far-end transmit BIST mode with scrambling enabled (SATA_BISTAFR[PD]=0x80). In normal mode, the functions scrambler, descrambler, or RPD can be changed only during Port reset (SATA_P 0 SCTL[DET]=0x1)
7 -	Reserved.

Table continues on the next page...

SATA_BISTCR field descriptions (continued)

Field	Description
6 ERREN	Error Enable. This bit is used to allow or filter (disable) [internal errors outside the FIS boundary to set corresponding SATA_P 0 SERR bits. The options for this field are: 0 Filter errors outside the FIS, allow errors inside the FIS; 1 Allow errors outside or inside the FIS.
5 FLIP	Flip Disparity This bit is used to change disparity of the current test pattern to the opposite every time its state is changed by the software.
4 PV	Pattern Version This bit is used to select either short or long version of the SSOP, HTDP, LTDP, LFSCP, COMP patterns. The options for this field are: 0 Short pattern version 1 Long pattern version
3–0 PATTERN	This field defines one of the following SATA compliant patterns for far-end retimed/ far-end analog/ near-end analog initiator modes, or non-compliant patterns for transmit-only responder mode when initiated by the software writing to the SATA_BISTCR[TXO] bit. If the value is none of the listed below, Composite pattern (COMP) is transmitted by default. 0000b Simultaneous switching outputs pattern (SSOP) 0001b High transition density pattern (HTDP) 0010b Low transition density pattern (LTDP) 0011b Low frequency spectral component pattern (LFSCP) 0100b Composite pattern (COMP) 0101b Lone bit pattern (LBP) 0110b Mid frequency test pattern (MFTP) 0111b High frequency test pattern (HFTP) 1000b Low frequency test pattern (LFTP) All other values Reserved and should not be used.

63.7.11 BIST FIS Count Register (SATA_BISTFCTR)

This register contains the received BIST FIS count in the loopback initiator far-end retimed, far-end analog and near-end analog modes. It is updated each time a new BIST FIS is received. It is reset by Global reset, Port reset (COMRESET) or by setting the SATA_BISTCR[CNTCLR] bit. This register does not roll over and freezes when the FFFF_FFFFh value is reached. It takes approximately 65 hours of continuous BIST operation to reach this value.

Address: SATA_BISTFCTR is 1000_0000h base + A8h offset = 1000_00A8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATA_BISTFCTR field descriptions

Field	Description
31–0 -	Received BIST FIS Count

63.7.12 BIST Status Register (SATA_BISTSR)

This register contains errors detected in the received BIST FIS in the loopback initiator far-end retimed, far- end analog and near-end analog modes. It is updated each time a new BIST FIS is received. It is reset by Global reset, Port reset (COMRESET) or by setting the SATA_BISTCR[CNTCLR] bit.

Address: SATA_BISTSR is 1000_0000h base + ACh offset = 1000_00ACh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

23–16 -	Reserved.

Table continues on the next page...

SATA_BISTSR field descriptions (continued)

Field	Description
15–0 FRAMERR	Frame Error. This field contains the frame error count. It is accumulated (new value is added to the old value) each time a new BIST frame with a CRC error is received. The FRAMERR value does not roll over and freezes at FFFFh.

63.7.13 OOB Register (SATA_OOBR)

This register controls the Link layer OOB detection counters. The default values, MIN_COMWAKE, MAX_COMWAKE, MIN_COMINIT and MAX_COMINIT are calculated based on the RXOOB_CLK parameter and loaded on power-up or asynchronous SATA block reset.

Address: SATA_OOBR is 1000_0000h base + BCh offset = 1000_00BCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATA_OOBR field descriptions

Field	Description
31 WE	Write Enable This bit is cleared when COMRESET is detected. The options for this field are: 1 SATA_OOBR bits [30:0] can be written 0 SATA_OOBR bits [30:0] are read-only
30–24 cwMin	COMWAKE Minimum Value This field is RW when WE=1 and RO when WE=0.
23–16 cwMax	COMWAKE Maximum Value This field is RW when WE=1 and RO when WE=0.
15–8 ciMin	COMINIT Minimum Value This field is RW when WE=1 and RO when WE=0.
7–0 ciMax	COMINIT Maximum Value This field is RW when WE=1 and RO when WE=0.

63.7.14 General Purpose Control Register (SATA_GPCR)

This 32-bit register is used for general purpose control. This register only exists when GP_CTRL parameter is set to “Include” otherwise this location is reserved.

The bits of this register are connected to the corresponding bits of the gp_ctrl output. Resets on power-up (system reset) only to the GP_CTRL_DEF value.

Address: SATA_GPCR is 1000_0000h base + D0h offset = 1000_00D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATA_GPCR field descriptions

Field	Description
31–0 GP_CONTROL	General Purpose Control. Present only when GP_CTRL=Include(1). Reset Value: Configurable parameter GP_CTRL_DEF

63.7.15 General Purpose Status Register (SATA_GPSR)

This 32-bit register is used to monitor the general purpose status. This register only exists when GP_STAT parameter is set to “Include”, otherwise, this location is reserved.

The bits of this register reflect the state of the corresponding bits of the gp_status input. Signals connected to the gp_status input can be asynchronous to any of the DWC_ahsata clocks, however they must not change faster than five hclk/aclk periods, otherwise the GPSR register may never be updated with the intermediate changing values.

Address: SATA_GPSR is 1000_0000h base + D4h offset = 1000_00D4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

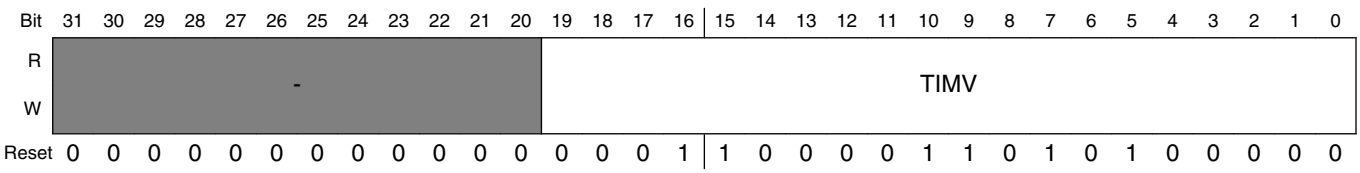
SATA_GPSR field descriptions

Field	Description
31–0 GP_STATUS	General Purpose Status. Present only when GP_STAT=Include(1)

63.7.16 Timer 1-ms Register (SATA_TIMER1MS)

This register is used to generate a 1-ms tick for the command completion coalescing (CCC) logic, based on the AHB bus clock frequency. The Software must initialize this register with the required value after power up before using the CCC feature. This register is reset to 100,000 (TIMV value for 100-MHz hclk) on power up and is not affected by Global reset.

Address: SATA_TIMER1MS is 1000_0000h base + E0h offset = 1000_00E0h



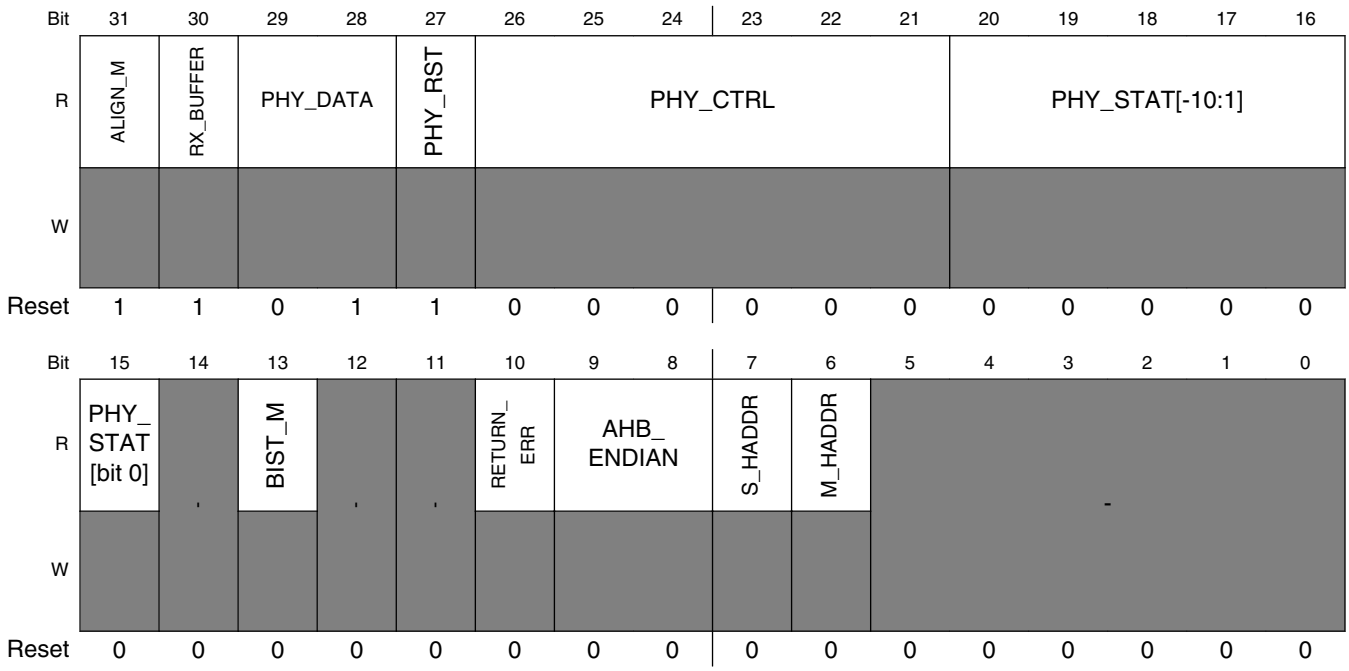
SATA_TIMER1MS field descriptions

Field	Description
31–20 -	Reserved.
19–0 TIMV	1ms Timer Value This field contains the following value for the internal timer to generate 1-ms tick: Fhclk*1000 where Fhclk = AHB clock frequency in MHz The options for this field are: • RW when SATA_CCC_CTL[EN]==0 • RO when SATA_CCC_CTL[EN]==1.

63.7.17 Global Parameter 1 Register (SATA_GPARAM1R)

This read-only register contains encoded information about the SATA block global configuration parameters' settings.

Address: SATA_GPARAM1R is 1000_0000h base + E8h offset = 1000_00E8h



SATA_GPARAM1R field descriptions

Field	Description
31 ALIGN_M	Rx Data Alignment 0 Misaligned —
30 RX_BUFFER	Rx Data Buffer — 1 Include
29–28 PHY_DATA	PHY Data Width 0x1: PHY DATA WIDTH = 2
27 PHY_RST	PHY Reset Mode 0 Low —
26–21 PHY_CTRL	PHY Control Width 0x20 (32) PHY Control Width is 32 bits.

Table continues on the next page...

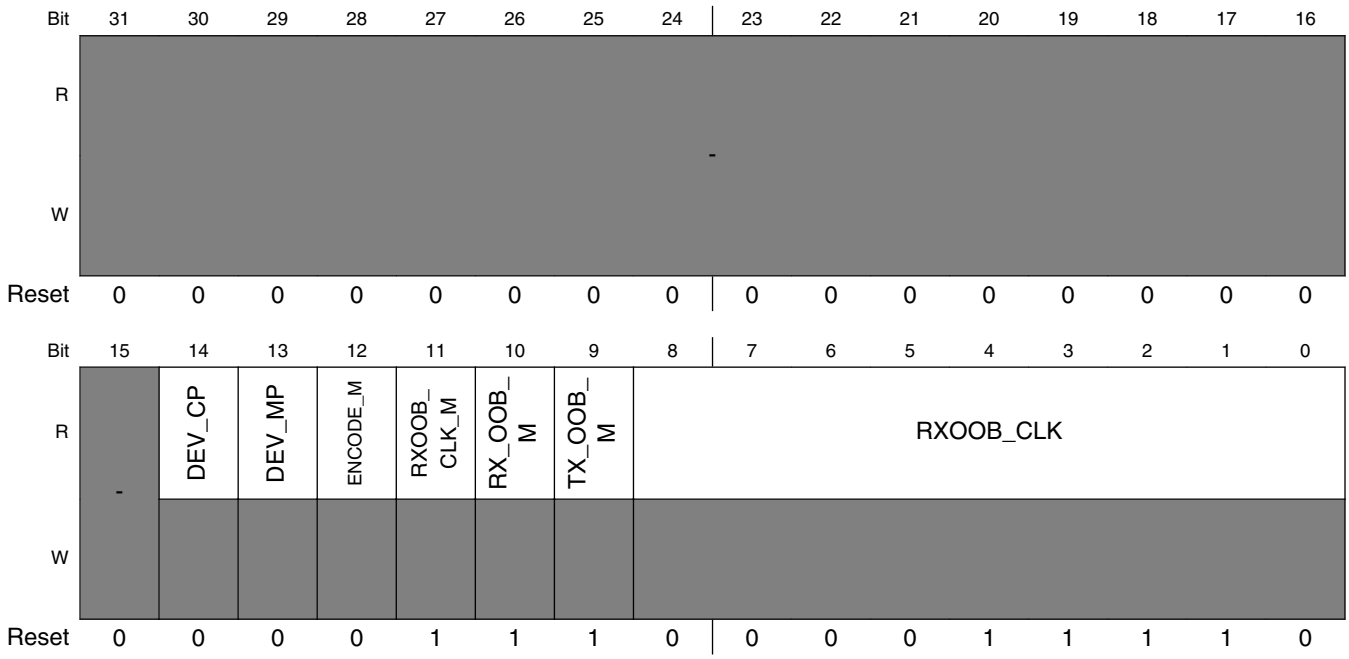
SATA_GPARAM1R field descriptions (continued)

Field	Description
20–15 PHY_STAT	PHY Status Width 0x20 (32) PHY Status Width is 32 bits.
14 -	Reserved. Returns 0.
13 BIST_M	BIST Loopback Checking Depth 0 FIS —
12 -	Reserved. Returns 1.
11 -	Reserved
10 RETURN_ERR	AHB Error Response — 1 True
9–8 AHB_ENDIAN	AHB Bus Endianness 0 Little Endian — —
7 S_HADDR	AHB Slave Address Bus Width 0 32 bits —
6 M_HADDR	AHB Master Address Bus Width 0 32 bits —
5–0 -	Reserved.

63.7.18 Global Parameter 1 Register (SATA_GPARAM2R)

This read-only register contains encoded information about the SATA block global configuration parameters' settings.

Address: SATA_GPARAM2R is 1000_0000h base + ECh offset = 1000_00ECh



SATA_GPARAM2R field descriptions

Field	Description
31–15 -	Reserved
14 DEV_CP	Cold Presence Detect — — 0 cold presence detect is not supported
13 DEV_MP	Mechanical Presence Switch — — 0 Mechanical presence switch is not supported
12 ENCODE_M	8b/10b Encoding/Decoding — — 1 8b/10b encoding/decoding is supported
11 RXOOB_CLK_M	Rx OOB Clock Mode

Table continues on the next page...

SATA_GPARAM2R field descriptions (continued)

Field	Description
	— — 1 separate clock
10 RX_OOB_M	Rx OOB Mode — — 1 Rx OOB signalling is supported
9 TX_OOB_M	Tx OOB Mode — — 1 Tx OOB signalling is supported
8–0 RXOOB_CLK	Rx OOB Clock Frequency This field returns 0x32 (50 decimal) The Rx OOB clock frequency is 50 MHz. .

63.7.19 Port Parameter Register (SATA_PPARAMR)

This read-only register contains encoded information about the selected Port configuration parameters' settings. The Port is selected by the SATA_TESTR[PSEL] field.

Address: SATA_PPARAMR is 1000_0000h base + F0h offset = 1000_00F0h

SATA_TESTR field descriptions

Field	Description
31–19 -	Reserved
18–16 PSEL	Port Select This field is used to select a Port for BIST operation: The options for this field are: 0x0 Port0 is selected 0x0 Port1 is selected 0x0 Port2 is selected 0x0 Port3 is selected 0x0 Port4 is selected 0x0 Port5 is selected 0x0 Port6 is selected 0x0 Port7 is selected
15–1 -	Reserved
0 TEST_IF	TEST_IF: Test Interface Normal operation is disabled. The following registers can be accessed in this mode: - SATA_GHC register IE bit - SATA_BISTAFR register NCP and PD bits become read-write - SATA_BISTCR register LLC, ERREN, FLIP, PV, PATTERN - SATA_BISTFCTR, SATA_BISTSR become read-write - SATA_P 0 CLB , SATA_P 0 FB registers - SATA_P 0 IS register RW1C and UFS bits become read-write - SATA_P 0 IE register - SATA_P 0 CMD register ASP, ALPE, DLAE, ATAPI, PMA bits - SATA_P 0 TFD, SATA_P 0 SIG registers become read-write - SATA_P 0 SCTL register - SATA_P 0 SERR register RW1C bits become read-write bits - SATA_P 0 SACT, SATA_P 0 CI, SATA_P 0 SNTF registers become read-write - SATA_P 0 DMACR register - SATA_P 0 PHYCR register - SATA_P 0 PHYSR register becomes read-write Notes: • Interrupt is asserted when any of the SATA_IS register bits is set after setting the corresponding SATA_P 0 IS and SATA_P 0 IE registers and SATA_GHC[IE]=1. • SATA_CAP[SMPS], SATA_CAP[SSS], SATA_PI, SATA_P 0 CMD[ESP], SATA_P 0 CMD[CPD], SATA_P 0 CMD[MPSP], and SATA_P 0 CMD[HPCP] register bits are HwInit type and can not be used in Test mode. They are written once after power-on reset and become read-only. • Global SATA block reset must be issued (SATA_GHC[HR]=1) after TEST_WHEN bit is cleared following the Test mode operation.

Table continues on the next page...

SATA_TESTR field descriptions (continued)

Field	Description
	This bit is used to put the SATA block slave interface into the test mode: The options for this field are: 0 Normal mode: the read back value of some registers is a function of the SATA block state and does not match the value written. 1 Test mode: the read back value of the registers matches the value written.

63.7.21 Version Register (SATA_VERSIONR)

This 32-bit read-only register contains a hard-coded ASCII string that represents the version level of the SATA block.For the i.MX53, this register contains the ASCII string "140*" (hexadecimal 0x3134302A).

Address: SATA_VERSIONR is 1000_0000h base + F8h offset = 1000_00F8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

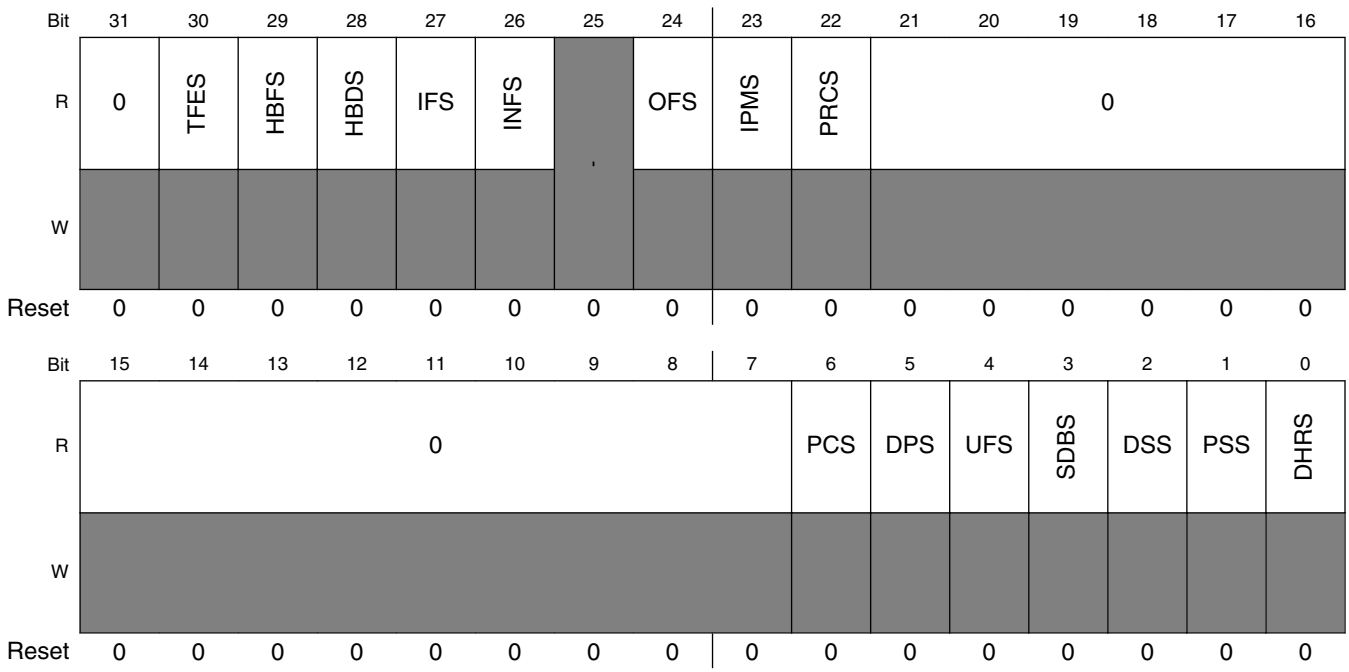
SATA_P0FB field descriptions

Field	Description
31–8 FB	FIS Base Address. Indicates the 32-bit base physical address for received FISes. The structure pointed to by this address range is 256 bytes in length. This address must be 256byte-aligned as indicated by bits [7:0] being read only. Reset: 0x000000
7–0 -	Reserved.

63.7.24 Port0 Interrupt Status Register (SATA_P0IS)

This register is used to generate SATA block interrupt when any of the bits are set. Bits in this register are set by some internal conditions, and cleared by the software writing ones in the positions it wants to clear. This register is reset on Global SATA block reset.

Address: SATA_P0IS is 1000_0000h base + 110h offset = 1000_0110h



SATA_P0IS field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value zero. Reserved. Returns 0 on read.
30 TFES	Task File Error Status. This bit is set whenever the SATA_P 0 TFD[STS] register is updated by the device and the error bit (bit 0) is set.
29 HBFS	Host Bus Fatal Error Status. This bit is set when SATA block AHB Master detects an ERROR response from the slave.
28 HBDS	Host Bus Data Error Status. This bit is always cleared to 0.
27 IFS	Interface Fatal Error Status This bit is set when any of the following conditions is detected: • SYNC escape is received from the device during H2D Register or Data FIS transmission; • One or more of the following errors are detected during Data FIS transfer:

Table continues on the next page...

SATA_P0IS field descriptions (continued)

Field	Description
	- 10B to 8B Decode Error (SATA_P 0 SERR[DIAG_B]) - Protocol (SATA_P 0 SERR[ERR_P]) - CRC (SATA_P 0 SERR[DIAG_C]) - Handshake (SATA_P 0 SERR[DIAG_H]) - PHY Not Ready (SATA_P 0 SERR[ERR_C]) • Unknown FIS is received with good CRC, but the length exceeds 64 bytes; • PRD table byte count is zero. Port DMA transitions to a fatal state until the software clears SATA_P 0 CMD[ST] bit or resets the interface by way of Port or Global reset.
26 INFS	Interface Non-fatal Error Status This bit is set when any of the following conditions is detected: • One or more of the following errors are detected during non-data FIS transfer - 10B to 8B Decode Error (SATA_P 0 SERR[DIAG_B]) - Protocol (SATA_P 0 SERR[ERR_P]) - CRC (SATA_P 0 SERR[DIAG_C]), - Handshake (SATA_P 0 SERR[DIAG_H]) - PHY Not Ready (SATA_P 0 SERR[ERR_C]); • Command list underflow during read operation (i.e. DMA read) when the software builds command table that has more total bytes than the transaction given to the device.
25 -	Reserved
24 OFS	Overflow Status This bit is set when command list overflow is detected during read or write operation when the software builds command table that has fever total bytes than the transaction given to the device. Port DMA transitions to a fatal state until the software clears SATA_P 0 CMD[ST] bit or resets the interface by way of Port or Global reset.
23 IPMS	Incorrect Port Multiplier Status. Indicates that the HBA received a FIS from a device whose Port Multiplier field did not match what was expected. This bit may be set during enumeration of devices on a Port Multiplier due to the normal Port Multiplier enumeration process. The software must use the IPMS bit only after enumeration is complete on the Port Multiplier.
22 PRCS	PHY Ready Change Status This bit reflects the state of the SATA_P 0 SERR[DIAG_N] bit. When set to 1, indicates the internal p 0 _phy_ready signal changed state. To clear this bit, the software must clear the SATA_P 0 SERR[DIAG_N] bit to 0.

Table continues on the next page...

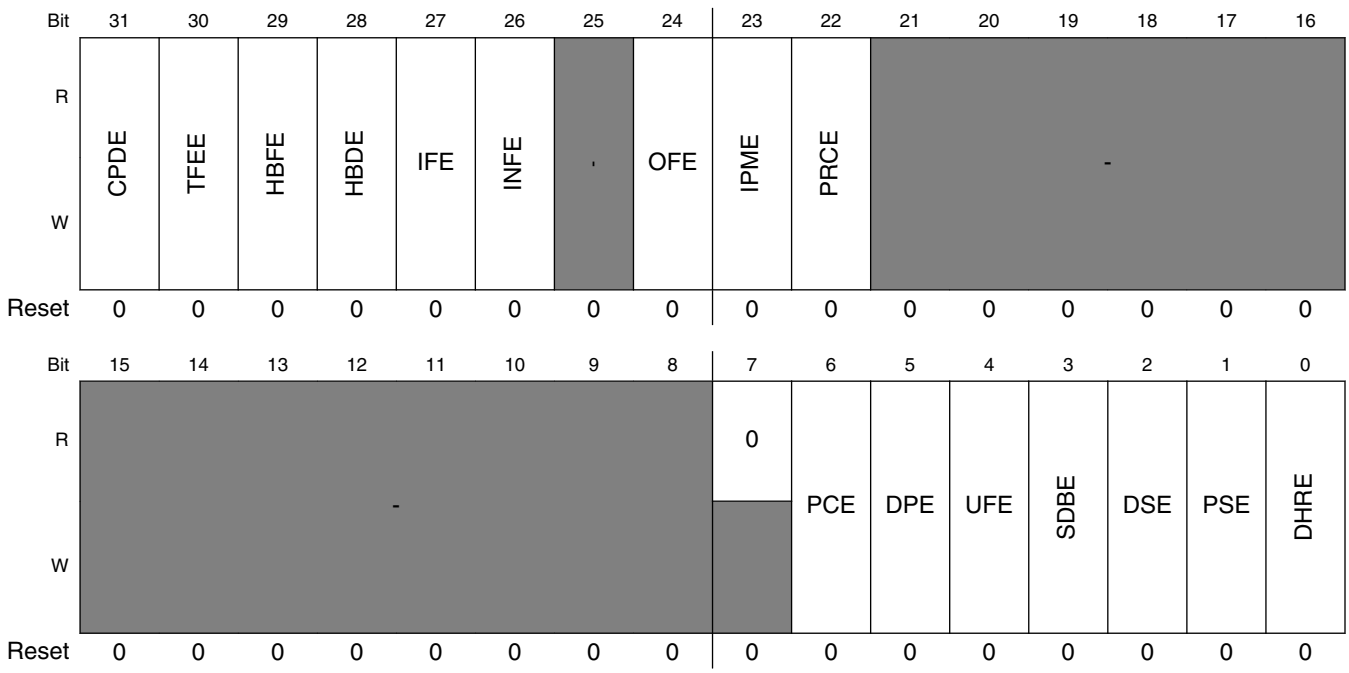
SATA_P0IS field descriptions (continued)

Field	Description
21–7 Reserved	This read-only field is reserved and always has the value zero. Reserved. Returns 0 on read.
6 PCS	Port Connect Change Status This bit is cleared only when SATA_P 0 SERR[DIAG_X] is cleared. This bit reflects the state of the SATA_P 0 SERR[DIAG_X] bit: 1 Change in Current Connect Status; 0 No change in Current Connect Status.
5 DPS	Descriptor Processed A PRD with the I bit set has transferred all of its data. **NOTE:** This is an opportunistic interrupt and must not be used to definitively indicate the end of a transfer. Two PRD interrupts could happen close in time together such that the second interrupt is missed when the first PRD interrupt is being cleared.
4 UFS	Unknown FIS Interrupt. When set to 1, indicates that an unknown FIS was received and has been copied into system memory. This bit is cleared to 0 by the software clearing the SATA_P 0 SERR[DIAG_F] bit to 0. **NOTE:** The UFS bit does not directly reflect the SATA_P 0 SERR[DIAG_F] bit. SATA_P 0 SERR[DIAG_F] bit is set immediately when an unknown FIS is detected, whereas the UFS bit is set when that FIS is posted to memory. The software should wait to act on an unknown FIS until the UFS bit is set to 1 or the two bits may become out of sync.
3 SDBS	Set Device Bits Interrupt. A Set Device Bits FIS has been received with the 'I' bit set and has been copied into system memory.
2 DSS	DMA Setup FIS Interrupt A DMA Setup FIS has been received with the 'I' bit set and has been copied into system memory.
1 PSS	PIO Setup FIS Interrupt. A PIO Setup FIS has been received with the 'I' bit set, it has been copied into system memory, and the data related to that FIS has been transferred. **NOTE:** This bit is set even when the data transfer resulted in an error.
0 DHRS	Device to Host Register FIS Interrupt A D2H Register FIS has been received with the 'I' bit set, and has been copied into system memory.

63.7.25 Port0 Interrupt Enable Register (SATA_P0IE)

This register enables and disables the reporting of the corresponding interrupt to the software. When a bit is set (1), and the corresponding interrupt condition is active, then the SATA block intrq output is asserted. Interrupt sources that are disabled (0) are still reflected in the status registers. This register is symmetrical with the SATA_P 0 IS register. This register is reset on Global SATA block reset.

Address: SATA_P0IE is 1000_0000h base + 114h offset = 1000_0114h



SATA_P0IE field descriptions

Field	Description
31 CPDE	Cold Port Detect Enable Read-only. Returns 0.
30 TFEE	Task File Error Enable Dependencies: when the following conditions are true, the intrq output signal is asserted: • This bit=1 • SATA_GHC[IE]=1 • SATA_P 0 IS[TFES]=1
29 HBFE	Host Bus Fatal Error Enable Dependencies: when the following conditions are true, the intrq output signal is asserted: • This bit=1 • SATA_GHC[IE]=1

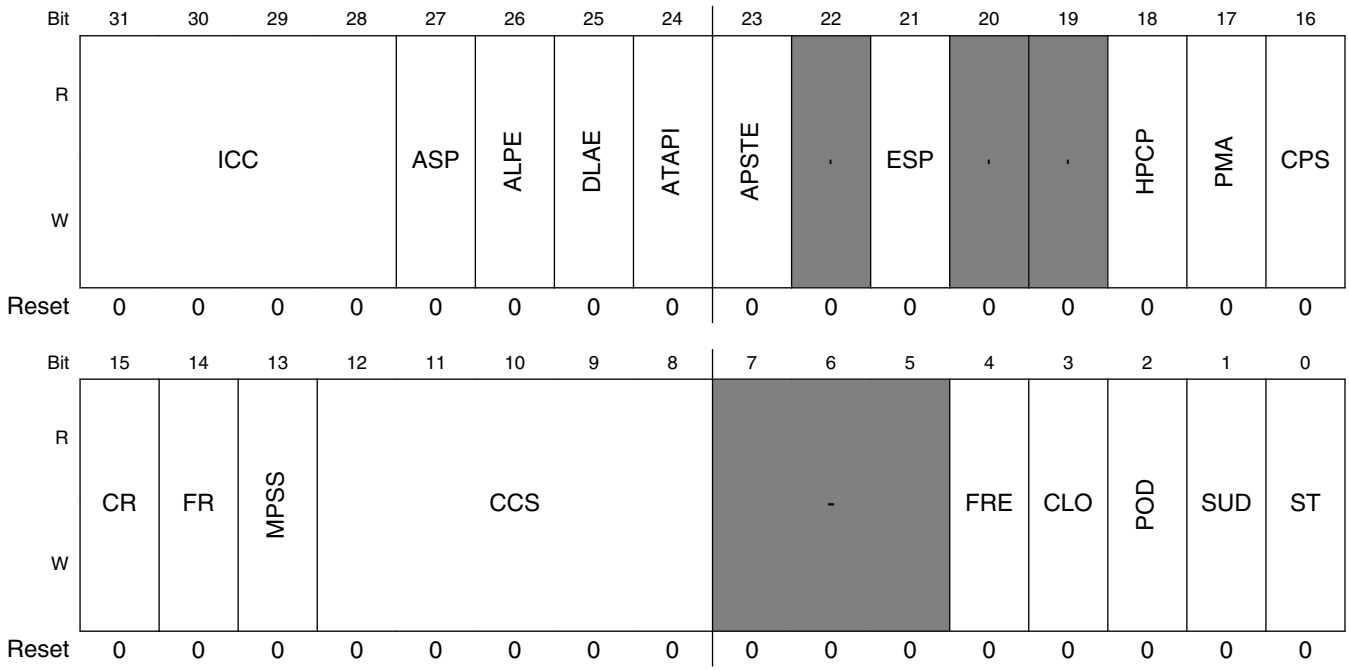
63.7.26 Port0 Command Register (SATA_P0CMD)

This register contains bits controlling various Port functions. All RW bits are reset on Global reset.

Address: SATA_P0CMD is 1000_0000h base + 118h offset = 1000_0118h



SATA_P0CMD field descriptions

Field	Description
31–28 ICC	Interface Communication Control This field is used to control power management states of the interface. When the Link layer is currently in the L_IDLE state, writes to this field cause the Port to initiate a transition to the interface power management state requested. When the Link layer is not currently in the L_IDLE state, writes to this field have no effect. • 0xF-0x7: Reserved • 0x6: Slumber. This causes the Port to request a transition of the interface to the Slumber state. The SATA device can reject the request and the interface remains in its current state. • 0x5-0x3: Reserved • 0x2: Partial. This causes the Port to request a transition of the interface to the Partial state. The SATA device can reject the request and the interface remains in its current state. • 0x1: Active. This causes the Port to request a transition of the interface into the active state. • 0x0: No-Op/ Idle. This value indicates to the software that the Port 0 is ready to accept a new interface control command, although the transition to the previously selected state may not yet have occurred. When the software writes a non-reserved value other than No-Op (0x0), the Port performs the action and update this field back to Idle (0x0).

Table continues on the next page...

SATA_P0CMD field descriptions (continued)

Field	Description
	When the software writes to this field to change the state to a state the link is already in (i.e., interface is in the active state and a request is made to go to the active state), the Port takes no action and returns this field to Idle. When the interface is in a low power state and the software wants to transition to a different low power state, the software must first bring the link to active and then initiate the transition to the desired low power state.
27 ASP	Aggressive Slumber/ Partial The options for this field are: • When set to 1, and SATA_P 0 CMD[ALPE]=1, the Port aggressively enters the SLUMBER state when one of the following conditions is true: - The Port clears the SATA_P 0 CI and the SATA_P 0 SACT register is cleared. - The Port clears the SATA_P 0 SACT register and SATA_P 0 CI is cleared. • When cleared to 0, and SATA_P 0 CMD[ALPE]=1, the Port aggressively enters the PARTIAL state when one of the following conditions is true: - The Port clears the SATA_P 0 CI register and the SATA_P 0 SACT register is cleared. - The Port clears the SATA_P 0 SACT register and SATA_P 0 CI is cleared.
26 ALPE	Aggressive Link Power Management Enable When set to 1, the Port aggressively enters a lower link power state (PARTIAL or SLUMBER) based on the setting of the SATA_P 0 CMD[ASP] bit. When cleared to 0, aggressive power management state transition is disabled.
25 DLAE	Drive LED on ATAPI Enable When set to 1, SATA_P 0 CMD[ATAPI]=1, and commands are active, the Port asserts p 0 _act_led output.
24 ATAPI	ATAPI Device is ATAPI This bit is used by the Port to control whether to assert p 0 _act_led output when commands are active. The options for this field are: 0 non-ATAPI device 1 ATAPI device
23 APSTE	Device is ATAPI This bit is used by the Port to control whether to assert p 0 _act_led output when commands are active. The options for this field are: 0 non-ATAPI device 1 ATAPI device
22 -	Reserved
21 ESP	External SATA Port When set to 1, indicates that this Port's signal only connector is externally accessible. When set to 1, SATA_CAP[SXS] is also set to 1. When cleared to 0, indicates that this Port's signal only connector is not externally accessible. Note: The ESP bit is mutually exclusive with SATA_P 0 CMD[HPCP]

Table continues on the next page...

SATA_P0CMD field descriptions (continued)

Field	Description
20 -	Reserved. Returns 0 on read.
19 -	Reserved. Returns 0 on read.
18 HPCP	Hot Plug Capable Port **NOTE:** The HPCP bit is mutually exclusive with SATA_P 0 CMD[ESP]. The options for this field are: 1 Indicates that this Port's signal and power connectors are externally accessible via a joint signal-power connector for blindmate device hot plug. 0 Indicates that this Port's signal and power connectors are not externally accessible.
17 PMA	Port Multiplier Attached The software is responsible for detecting whether a Port Multiplier is present; the SATA block Port does not auto-detect the presence of a Port Multiplier. The options for this field are: 1 A Port Multiplier is attached to this Port. 0 A Port Multiplier is not attached to this Port.
16 CPS	Cold Presence State This bit reports whether a device is currently detected on this Port as indicated by the p 0 _cp_det input state (assuming SATA_P 0 CMD[CPD]=1). The options for this field are: 1 device is attached to this Port 0 no device attached to this Port
15 CR	Command List Running When this bit is set to '1', the command list DMA engine for this Port is running. See AHCI state machine in AHCI specification section 5.3.2 for details on when this bit is set and cleared by the Port.
14 FR	FIS Receive Running When set to '1', the FIS Receive DMA engine for the Port is running. See AHCI specification section 10.3.2 for details on when this bit is set and cleared by the Port.
13 MPSS	Mechanical Presence Switch State The software must use this bit only when both SATA_CAP[SMPS] and SATA_P 0 CMD[MPSP] are set. This bit reports the state of a mechanical presence switch attached to this Port as indicated by the p 0 _mp_switch input state (assuming SATA_CAP[SMPS]=1 and SATA_P 0 CMD[MPSP]=1). The options for this field are: When SATA_CAP[SMPS]=0 then this bit is cleared to 0. 0 Switch is closed 1 Switch is open
12–8 CCS	Current Command Slot This field is set to the command slot value value of the command that is currently being issued by the Port.

Table continues on the next page...

SATA_P0CMD field descriptions (continued)

Field	Description
	• When SATA_P 0 CMD[ST] transitions from 1 to 0, this field is recleared to 0x00. • After SATA_P 0 CMD[ST] transitions from 0 to 1, the highest priority slot to issue from next is command slot 0. After the first command has been issued, the highest priority slot to issue from next is SATA_P 0 CMD[CCS]+1.For example, after the Port has issued its first command, when CCS=0x00 and SATA_P 0 CI is cleared to 0x3, the next command issued is from command slot 1. This field is valid only when SATA_P 0 CMD[ST] is set to 1.
7–5 -	Reserved.
4 FRE	FIS Receive Enable When set to 1, the Port may post received FISes into the FIS receive area pointed to by SATA_P 0 FB . When cleared, received FISes are not accepted by the Port, except for the first D2H register FIS after the initialization sequence, and no FISes are posted to the FIS receive area. The software must not set this bit until SATA_P 0 FB has been programmed with a valid pointer to the FIS receive area When the software wishes to move the base, this bit must first be cleared, and the software must wait for the SATA_P 0 CMD[FR] bit to be cleared.
3 CLO	Command List Override Setting this bit to 1 causes the SATA_P 0 TFD[STS] field BSY bit and the SATA_P 0 TFD[STS] field DRQ bit to be cleared. This allows a software reset to be transmitted to the device regardless of whether the BSY and DRQ bits are still set in the SATA_P 0 TFD[STS] field. This bit is cleared to 0 when SATA_P 0 TFD[STS] BSY bit and SATA_P 0 TFD[STS] DRQ bit have been cleared. A write to this register with a value of '0' has no effect. This bit should only be set to 1 immediately prior to setting SATA_P 0 CMD[ST] bit to 1 from a previous value of 0. Setting this bit to 1 at any other time is not supported and results in indeterminate behavior.
2 POD	Power On Device This bit is read/write when cold presence detection is supported on this Port as indicated by SATA_P 0 CMD[CPD]=1. This bit is read-only 1 when cold presence detection is not supported and SATA_P 0 CMD[CPD]=0. When set, the Port asserts the p 0 _cp_pod output pin so that it may be used to provide power to a cold-presence detectable Port.
1 SUD	Spin-Up Device This bit is read/write when staggered spin-up is supported as indicated by the SATA_CAP[SSS]=1. This bit is read-only 1 when staggered spin-up is not supported and SATA_CAP[SSS]=0. On an edge detect from 0 to 1, the Port starts a COMRESET initialization sequence to the device. Clearing this bit causes no action on the interface. Note: The SUD bit is read-only 0 on power-up until SATA_CAP[SSS] bit is written with the required value.
0 ST	Start When set to 1, the Port processes the command list. When cleared, the Port does not process the command list. Whenever this bit is changed from a 0 to a 1, the Port starts processing the command list at entry'0. Whenever this bit is changed from a 1 to a 0, the SATA_P 0 CI register is cleared by the Port upon transition into an idle state. Refer to AHCI specification, section 10.3.1, for important restrictions on when this bit can be set to 1. Note: SATA_P 0 SERR register must be cleared prior to setting ST bit to 1.

63.7.27 Port0 Task File Data Register (SATA_P0TFD)

This register contains Error and Status registers updated every time a new Register FIS, PIO Setup FIS, or Set Device Bits FIS is received from the device. Reset on Global or Port reset (COMRESET).

Address: SATA_P0TFD is 1000_0000h base + 120h offset = 1000_0120h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATA_P0SIG field descriptions

Field	Description
31–0 SIG	Signature This field contains the signature received from a device on the first D2H Register FIS. The bit order as follows: • Bits [31:24] - LBA High (Cylinder High) Register • Bits [23:16] - LBA Mid (Cylinder Low) Register • Bits [15:8] - LBA Low (Sector Number) Register • Bits [7:0] - Sector Count Register This field is updated once after a reset sequence. Reset on Global or Port reset.

63.7.29 Port0 Serial ATA Status Register (SATA_P0SSTS)

This 32-bit register conveys the current state of the interface and host. The Port updates it continuously and asynchronously. When the Port transmits a COMRESET to the device, this register is updated to its reset values (i.e., Global reset, Port reset, or COMINIT from the device

Address: SATA_P0SSTS is 1000_0000h base + 128h offset = 1000_0128h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATA_P0SSTS field descriptions

Field	Description
31–12 -	Reserved
11–8 IPM	Interface Power Management Indicates the current interface state. The options for this field are: 0x0 Device not present or communication not established 0x1 Interface in active state 0x2 Interface in Partial power management state 0x6 Interface in Slumber power management state All other values Reserved
7–4 SPD	Current Interface Speed Indicates the negotiated interface communication speed. The options for this field are: 0x0 Device not present or communication not established 0x1 1.5 Gb/s communication rate negotiated All other values Reserved and should not be used

Table continues on the next page...

SATA_P0SSTS field descriptions (continued)

Field	Description
3–0 -	Reserved

63.7.30 Port0 Serial ATA Control {SControl} Register (SATA_P0SCTL)

This 32-bit read-write register is used by the software to control SATA interface capabilities. Writes to this register result in an action being taken by the Port PHY interface. Reads from the register return the last value written to it. Reset on Global reset.

These bits are static and should not be changed frequently due to the clock crossing between the Transport and Link Layers. The software must wait for at least seven periods of the slower clock (clk_asic 0 or hclk) before changing this register

Address: SATA_P0SCTL is 1000_0000h base + 12Ch offset = 1000_012Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATA_P0SCTL field descriptions

Field	Description
31–12 -	Reserved
11–8 IPM	Interface Power Management Transitions Allowed This field indicates which power states the Port PHY interface is allowed to transition to. When an interface power management state is disabled, the Port does not initiate that state and any request from the device to enter that state is rejected via PMNAKp The options for this field are: 0x0 No interface power management state restrictions 0x1 Transitions to the Partial state disabled 0x2 Transitions to the Slumber state disabled 0x3 Transitions to both Partial and Slumber states disabled All other values. Reserved and should not be used
7–4 SPD	Speed Allowed This field indicates the highest allowable speed of the Port PHY interface. The options for this field are: **NOTE:** When the host software must change this field value, the host must also reset the Port (SATA_P 0 SCTL[DET] = 0x1) at the same time to ensure proper speed negotiation. 0x0 No speed negotiation restrictions

Table continues on the next page...

SATA_P0SCTL field descriptions (continued)

Field	Description
	0x1 Limit speed negotiation to SATA 1.5 Gb/s communication rate All other values Reserved and should not be used.
3–0 DET	Device Detection Initialization Controls the Port's device detection and interface initialization. The options for this field are: **NOTE:** This field may only be modified when SATA_P 0 CMD[ST] is 0. Changing this field while the SATA_P 0 CMD[ST]=1 results in undefined behavior. When SATA_P 0 CMD[ST] is set to 1, this field should have a value of 0x0. 0x0 No device detection or initialization action requested 0x1 Perform interface initialization sequence to establish communication. This results in the interface being reset and communication re initialized. 0x4 Disable the Serial ATA interface and put the Port PHY in offline mode. All other values reserved.

63.7.31 Port0 Serial ATA Error Register (SATA_P0SERR)

This 32-bit register represents all the detected interface errors accumulated since the last time it was cleared. The set bits in the SError register indicate that the corresponding error condition became true one or more times since the last time the bit was cleared. The set bits in this register are explicitly cleared by a write operation to the register, Global reset, or Port reset (COMRESET). The value written to clear the set error bits should have ones encoded in the bit positions corresponding to the bits that are to be cleared. All bits in the following table have a reset value of 0.

Address: SATA_P0SERR is 1000_0000h base + 130h offset = 1000_0130h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-				ERR_E	ERR_P	ERR_C	ERR_T	-						ERR_M	ERR_I
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SATA_P0SERR field descriptions

Field	Description
31–27 -	Reserved
26 DIAG_X	Exchanged This bit is set to 1 when PHY COMINIT signal is detected. This bit is reflected in the SATA_P 0 IS[PCS] bit.
25 DIAG_F	Unknown FIS Type This bit indicates that one or more FISes were received by the Transport layer with good CRC, but had a type field that was not recognized/known and the length was less than or equal to 64bytes. **NOTE:** When the Unknown FIS length exceeds 64 bytes, the DIAG_F bit is not set and the DIAG_T bit is set instead.
24 DIAG_T	Transport State Transition Error This bit indicates that a Transport Layer protocol violation was detected since the last time this bit was cleared. See Transport Check (TCHK) for details.
23 DIAG_S	Link Sequence Error This bit indicates that one or more Link state machine error conditions was encountered. One of the conditions that cause this bit to be set is device doing SYNC escape during FIS transmission.
22 DIAG_H	Handshake Error This bit indicates that one or more R_ERRp was received in response to frame transmission. Such errors may be the result of a CRC error detected by the device, a disparity or 8b/10b decoding error, or other error condition leading to a negative handshake on a transmitted frame.
21 DIAG_C	CRC Error
20 DIAG_D	Disparity Error This bit is always cleared to 0 since it is not used by the AHCI specification.
19 DIAG_B	10B to 8B Decode Error This bit indicates errors were detected by 10b8b decoder. This bit indicates that one or more CRC errors were detected by the Link layer during FIS reception. **NOTE:** This bit is set only when an error is detected on the received FIS data dword. This bit is not set when an error is detected on the primitive, regardless whether it is inside or outside the FIS.
18 DIAG_W	Comm Wake This bit is set when PHY COMWAKE signal is detected.
17 DIAG_I	PHY Internal Error This bit is set when the PHY detects some internal error as indicated by the assertion of the p 0 _phy_rx_err input. **NOTE:** The setting of this bit is controlled by the SATA_BISTCR[ERREN] bit: when ERREN==0 (default), only errors occurring inside the received FIS cause DIAG_I bit to be set; when ERREN==1, any error inside or outside the FIS causes the DIAG_I bit to be set.
16 DIAG_N	PHY Ready Change This bit indicates that the PHY Ready signal changed state. This bit is reflected in the SATA_P 0 IS[PRCS] bit.

Table continues on the next page...

SATA_P0SERR field descriptions (continued)

Field	Description
15–12 -	Reserved
11 ERR_E	Internal Error This bit is set to 1 when one or more AHB bus ERROR responses are detected on the master interface.
10 ERR_P	Protocol Error This bit is set to 1 when any of the following conditions are detected. • Transport state transition error (DIAG_T) • Link sequence error (DIAG_S) • RxFIFO overflow • Link bad end error (WTRM instead of EOF is received).
9 ERR_C	Non-Recovered Persistent Communication Error This bit is set to 1 when PHY Ready signal is negated due to the loss of communication with the device or problems with interface, but not after transition from active to Partial or Slumber power management state.
8 ERR_T	Non-Recovered Transient Data Integrity Error This bit is set when any of the following SATA_P 0 SERR register bits is set during Data FIS transfer: ERR_P (Protocol) • DIAG_C (CRC) • DIAG_H (Handshake) • ERR_C ("PHY Ready" negation)
7–2 -	Reserved
1 ERR_M	Recovered Communication Error This bit is set to 1 when PHY Ready condition is detected after interface initialization, but not after transition from Partial or Slumber power management state to active state.
0 ERR_I	This bit is set when any of the following SATA_P 0 SERR register bits is set during non- Data FIS transfer: • DIAG_C (CRC) • DIAG_H (Handshake) • ERR_C ("PHY Ready" negation)

63.7.32 Port0 Serial ATA Active Register (SATA_P0SACT)

Address: SATA_P0SACT is 1000_0000h base + 134h offset = 1000_0134h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATA_P0SACT field descriptions

Field	Description
31–0 DS	Device Status This field is bit significant. Each bit corresponds to the TAG and command slot of a native queued command, where bit 0 corresponds to TAG 0 and command slot 0. Software sets this field prior to issuing a native queued command for a particular command slot. Prior to writing SATA_P 0 CI[TAG] to 1, the software sets DS[TAG] to 1 to indicate that a command with that TAG is outstanding. This field is cleared to 0 when: • The software writes SATA_P 0 CMD[ST from a 1 to a 0 . • The device sends a Set Device Bits FIS to the Port. The Port clears bits in this field that are set in the SActive field of the Set Device Bits FIS. The Port clears only bits that correspond to native queued commands that have completed successfully. This field is not cleared by the following: • Port reset (COMRESET). • Software reset. **NOTE:** Software must write this field only when SATA_P 0 CMD[ST] bit is set to 1.

63.7.33 Port0 Command Issue Register (SATA_P0CI)

Address: SATA_P0CI is 1000_0000h base + 138h offset = 1000_0138h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CI																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SATA_P0CI field descriptions

Field	Description
31–0 CI	Command Issued This field is bit significant. Each bit corresponds to a command slot, where bit 0 corresponds to command slot 0. This field is set by the software to indicate to the Port that a command has been built in system memory for a command slot and may be sent to the device. When the Port receives a FIS which clears the BSY, DRQ, and ERR bits for the command, it clears the corresponding bit in this register for that command slot. Bits in this field can only be set to 1 by the software when SATA_P 0 CMD[ST] is set to 1. **NOTE:** This field is reset when SATA_P 0 CMD[ST] is written from a 1 to a 0 by the software.

63.7.34 Port0 Serial ATA Notification Register (SATA_P0SNTF)

This register is used to determine when asynchronous notification events have occurred for directly connected devices and devices connected to a Port Multiplier.

Address: SATA_P0SNTF is 1000_0000h base + 13Ch offset = 1000_013Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATA_P0SNTF field descriptions

Field	Description
31–16 -	Reserved
15–0 PMN	PM Notify This field indicates whether a particular device with the corresponding PM Port number issued a Set Device Bits FIS to the SATA block Port with the Notification bit set: • PM Port 0h sets bit 0, • PM Port 1h sets bit 1, ... • PM Port Fh sets bit 15. Individual bits are cleared by the software writing 1s to the corresponding bit positions. This field is reset on Global reset, but it is not reset by Port reset (COMRESET) or software reset.

63.7.35 Port0 DMA Control Register (SATA_P0DMACR)

This register contains bits for controlling the Port DMA engine. The software can change the fields of this register only when SATA_P 0 CMD[ST]=0. Power-up (system reset), Global reset, or Port reset (COMRESET) reset this register to the default value.

Address: SATA_P0DMACR is 1000_0000h base + 170h offset = 1000_0170h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATA_P0DMACR field descriptions

Field	Description
31–16 -	Reserved
15–12 RXABL	Receive AHB Burst Limit This field allows the software to limit the AHB master write burst size. The options for this field are: **NOTE:** SATA block AHB master breaks the burst at 1-KB address boundary regardless of the RXABL value. **NOTE:** This field is read-write when SATA_P 0 CMD[ST]=0 and read-only when SATA_P 0 CMD[ST]=1. 0x0, 0x9-0xF Limit AHB burst size to 256 DWORDs 0x1 Limit AHB burst size to 1 DWORD 0x2 Limit AHB burst size to 2 DWORDs 0x3 Limit AHB burst size to 4 DWORDs 0x4 Limit AHB burst size to 8 DWORDs 0x5 Limit AHB burst size to 16 DWORDs 0x6 Limit AHB burst size to 32 DWORDs 0x7 Limit AHB burst size to 64 DWORDs 0x8 Limit AHB burst size to 128 DWORDs
11–8 TXABL	Transmit AHB Burst Limit This field allows the software to limit the AHB master read burst size. The options for this field are: **NOTE:** SATA block AHB master breaks the burst at 1-KB address boundary regardless of the TXABL value. **NOTE:** This field is read-write when SATA_P 0 CMD[ST]=0 and read-only when SATA_P 0 CMD[ST]=1. 0x0, 0x9-0xF Limit AHB burst size to 256 DWORDs 0x1 Limit AHB burst size to 1 DWORD 0x2 Limit AHB burst size to 2 DWORDs 0x3 Limit AHB burst size to 4 DWORDs 0x4 Limit AHB burst size to 8 DWORDs 0x5 Limit AHB burst size to 16 DWORDs 0x6 Limit AHB burst size to 32 DWORDs 0x7 Limit AHB burst size to 64 DWORDs 0x8 Limit AHB burst size to 128 DWORDs
7–4 RXTS	Receive Transaction Size This field defines the Port DMA transaction size in DWORDs for receive (system bus write, device read) operation. This field is read-write when SATA_P 0 CMD[ST]=0 and read-only when SATA_P 0 CMD[ST]=1. The maximum value of this field is determined by the RxFIFO depth parameter. When the software attempts to write a value exceeding this value, the maximum value would be set instead. 0x0 1 DWORD 0x1 2 DWORD 0x2 4 DWORD 0x3 8 DWORD 0x4 16 DWORDs (maximum value when RXFIFO_DEPTH=64)

Table continues on the next page...

SATA_P0DMACR field descriptions (continued)

Field	Description
	0x5 32 DWORD 0x6 64 DWORDs (maximum value when RXFIFO_DEPTH=128) 0x7 128 DWORDs (maximum value when RXFIFO_DEPTH=256) 0x8 256 DWORDs (maximum value when RXFIFO_DEPTH=512) 0x9 12 DWORDs (maximum value when RXFIFO_DEPTH=1024) 0xA 1024 DWORDs (maximum value when RXFIFO_DEPTH=2048) All other values are reserved and should not be used.
3–0 TXTS	Transmit Transaction Size This field defines the DMA transaction size in DWORDs for transmit (system bus read, device write) operation. The options for this field are: This field is read-write when SATA_P 0 CMD[ST]=0 and read-only when SATA_P 0 CMD[ST]=1. The maximum value of this field is determined by the TxFIFO depth parameter. When the software attempts to write a value exceeding this value, the maximum value would be set instead. 0x0 1 DWORD 0x1 2 DWORD 0x2 4 DWORD 0x3 8 DWORD 0x4 16 DWORDs (maximum value when TXFIFO_DEPTH=32) 0x5 32 DWORDs (maximum value when TXFIFO_DEPTH=64) 0x6 64 DWORDs (maximum value when TXFIFO_DEPTH=128) 0x7 128 DWORDs (maximum value when TXFIFO_DEPTH=256) 0x8 256 DWORDs (maximum value when TXFIFO_DEPTH=512) 0x9 512 DWORDs (maximum value when TXFIFO_DEPTH=1024) 0xA 1024 DWORDs (maximum value when TXFIFO_DEPTH=2048) All other values are reserved and should not be used.

63.7.36 Port0 PHY Control Register (SATA_P0PHYCR)

This register is used for Port PHY control.

Bits of this register are connected to the corresponding bits of the p 0 _phy_ctrl output Port.

NOTE

The SATA_P 0 PHYCR register supports only 32-bit write access

Address: SATA_P0PHYCR is 1000_0000h base + 178h offset = 1000_0178h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SATA_P0PHYCR field descriptions

Field	Description
31–21 -	Reserved
20 TEST_PDDQ	Test IDDQ
19 CR_READ	CR Read. Reads from the referenced Address register.
18 CR_WRITE	CR Write. Writes the Write Data register to the referenced Address register.
17 CR_CAP_DATA	CR Capture Data. Captures phy_cr_data_in[15:0] into the Write Data register.
16 CR_CAP_ADDR	CR Capture Address. Captures phy_cr_data_in[15:0] into the Address register.
15–0 CR_DATA_IN	CR Address and Write Data Input Bus. Supplies and captures address and write data.

63.7.37 Port0 PHY Status Register (SATA_P0PHYSR)

This register is used to monitor PHY status.

The bits of this register reflect the state of the corresponding bits of the p 0 _phy_status input.

Signals connected to the p 0 _phy_status input can be asynchronous to any of the SATA block clocks, however they must not change faster than five hclk periods, otherwise the SATA_P 0 PHYSR register may never be updated with the intermediate changing values.

Address: SATA_P0PHYSR is 1000_0000h base + 17Ch offset = 1000_017Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SATA_P0PHYSR field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value zero.
18 CR_ACK	CR Acknowledgement. Acknowledgement for the phy_cr_cap_addr, phy_cr_cap_data, phy_cr_write, and phy_cr_read control signals.
17–16 Reserved	This read-only field is reserved and always has the value zero.
15–0 CR_DATA_OUT	CR Data Output Bus. Always presents last read data.

Chapter 64
Serial Advanced Technology Attachment PHY (SATA PHY)

64.1 Overview

The Serial-ATA PHY is an ultra low-power SATA physical layer that complies with *Serial ATA*, Revision 2.5.

64.1.1 General Product Description

The SATA2 PHY is a complete mixed-signal IP solution designed to implement SATA connectivity in a System-on-Chip (SoC) design targeted to a specific fabrication process.

The SATA2 PHY provides a unique combination of:

- Small area
- Low power
- High performance
- Testability and characterization (diagnostic) features

64.1.1.1 System Overview

Each SATA2 PHY lane takes a 10- or 20-bit input and produces a serial output at 10 or 20 times the input word rate, respectively.

The transmitted data is synchronous to the local refclk. The receiver is clock- forwarded (source-synchronous) and the received data and its accompanying clock are synchronous to refclk at the far end of the link. Synchronicity with refclk depends on the system application.

64.1.2 Features

The SATA2 PHY provides the following features:

- Data rates of 1.5/3.0 Gbps, selectable per transceiver
- Clock module:
- Pin-programmable MPLL bandwidth from 2.5-10 MHz in 1.25-MHz increments
- Selectable use of an alternative reference clock delivered from the ASIC
- Flexible, glitchless clock outputs to ASIC: word rate, 1/2 word rate, and keep-alive clock options buffered from RefClk
- Power on or off and suspension of RefClk
- Flexible baud rate: RefClk ratio. Includes all integers greater than 3 (excluding 6, 7, and 11) and less than 67, and all even integers up to and including 130.
- RefClk frequencies of 25 MHz or 50-156.25 MHz. Common RefClk frequencies of 100 MHz, 125 MHz, and 156.25 MHz are supported.
- Generation of low jitter spread-spectrum clock (0.5% downspread at 31.5 KHz)
- Transmit path:
- Multiple power-down modes
- Differential Tx amplitude with less than ± 10% variation across temperature, voltage, and process
- Pin-programmable transmit level
- Pin-programmable attenuation of {8, 9, 10, 12, 14, 16} / 16 of full scale
- Pin-programmable Tx boost of 0-5.75 dB in increments of ~ .37 dB
- 10- or 20-bit wide ASIC interface
- Per-lane word clock (in addition to word clock from MPLL) for maximum flexibility
- Out of Band (OOB) signaling
- Latency of 22-24 bit times from when the 10-bit data is sampled to when the first bit of the word is transmitted serially
- Receive path:
- Pin-programmable equalization of .5-4 dB in .5-dB increments
- Programmable Rx clock data recovery (CDR) based on a digital PLL (DPLL) for robust operation despite independently spread-spectrum references
- Rx CDR that can tolerate run lengths of thousands of bits
- Pin-programmable loss of signal (LOS) threshold
- Pin-programmable ACJTAG hysteresis level
- Multiple power-down modes
- Rx bandwidth of 2.5 GHz
- 10- or 20-bit wide ASIC interface
- Clock forwarding
- OOB signaling

- Latency of 22-31 bit times from when the last bit of a 10-bit word is received to when the 10-bit word is available on the ASIC interface
- Tx and Rx termination impedances that are automatically calibrated to match the external reference resistance

Test Features

The SATA2 PHY provides the following test features.

- Integrated test features:
- Combinatorial loopback for full testing of the ASIC/IP interface with the ASIC's native testing methodology
- Burn-in mode to toggle most internal modes without using clocks or controls
- IDDQ test mode
- Loopback:
- Tx-to-Rx serial analog loopback for wafer probe only
- Tx-to-Rx serial digital loopback
- Byte Error Rate Testing (BERT) independent per lane:
- 7th- and 15th-order polynomial pattern generation and recognition
- Generation of simple test patterns
- Byte error counting from polynomial patterns or simple test patterns
- Voltage margining with 10-bit resolution, synchronous or asynchronous operation
- Phase margining with UI/512 resolution, synchronous or asynchronous (when number of lanes is greater than one) operation
- Combined 2D margining
- High resolution scope per Rx signal pair:
- Acquisition of eye from patterns of known periodicity
- Acquisition and analysis of signals of modest periodicities (< 1,024 bytes)
- Analog DC testing:
- 10-bit A/D converter
- Selection and measurement of any individual Rx and Tx termination resistor
- Limit testing that enables vector-only tests, which pass results in a non-trivial limit range:
- High/low limits
- Whether register read is within limits
- Whether difference between register readback values is within limits

64.2 Architecture

64.2.1 Block Diagram

The figure below shows a high-level SATA2 PHY block diagram.

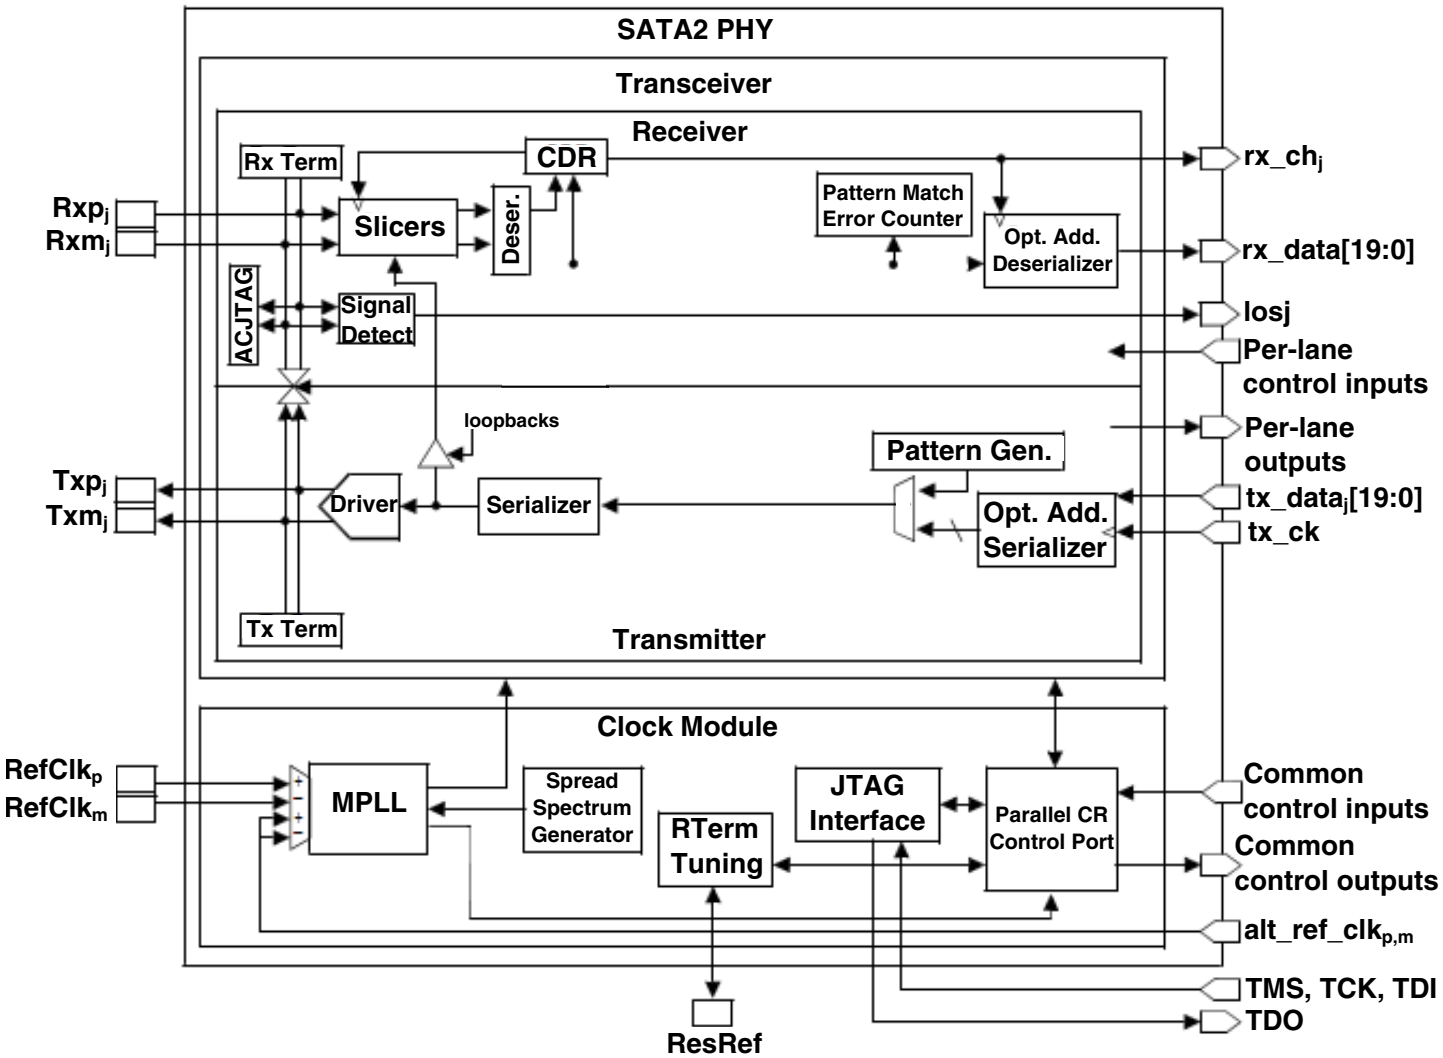

Figure 64-1. SATA2 PHY Block Diagram

64.2.2 Block Descriptions

This section describes blocks in the SATA2 PHY.

Transceiver Block - The Transceiver block is replicated per lane. This section describes blocks in the transceiver.

Receiver Block - This block converts the incoming, high-speed differential serial link to 10- or 20-bit parallel data and recovers the clock.

- **Rx Termination Block** - This block produces single-ended termination impedances of ~50 ohms to ground, differential ~ 100 ohms.

- **Rx Signal Detect** - This block detects the presence of a signal on the Rx signal pair. In a SATA implementation, this block detects OOB signals.

- **ACJTAG (Boundary Scan) Interface** - This block contains the logic for doing industry-standard (1149.1-2001 and 1149.6-2003) connectivity testing.

- **Rx Slicers** - This block converts the receive signal from a high-bandwidth analog signal to a sequence of 1s and 0s sampled when directed by the Clock and Data Recovery (CDR) block.

- **Deserializer** - The deserializer converts the output of the slicers to a 10-bit wide (1 coded byte) format. The deserializer uses COMMA characters to select the correct word alignment.

- **Clock and Data Recovery** - The CDR block comprises both a digital PLL (DPLL) and an analog PLL (APLL). The DPLL comprises phase detectors and a digital loop filter, which combine to produce a selected output phase. The APLL generates and filters the clock phase selected by the DPLL. The generated output clock feeds the slicers with multiple phases, while another output is divided down to become the word rate (baud rate / 10) recovered clock.

- **Rx Pattern Match and Error Count** - To identify errors during characterization of the channel quality, this block determines whether each byte of the received data sequence matches one of a few pseudo-random sequences. Detected byte errors are counted and available in the Pattern Matcher Control register (see lanej Memory Map/Register Definition).

- **Optional Additional Deserializer** - When enabled by the assertion of the wide_xface control, this block doubles the Rx datapath width (from 10 bits to 20 bits) and reduces the Rx_Ck rate to baud_rate/ 20. When wide_xface is deasserted, only bits [9:0] of the RxData bus are used; Rx_Ck runs at baud_rate / 10. When the half_rate signal is asserted, clock frequencies are halved, but still based on the true baud rate as previously described.

Transmitter Block - This block converts outgoing, parallel 10- or 20-bit data to a high-speed, differential serial link.

- **Tx Termination Block** - This block produces single-ended termination impedances of ~ 50 ohms to the I/O supply or ground.

- **Tx-to-Rx Analog Serial Loopback Switch** - This switch establishes a serial loopback connection between Tx and Rx differential signals for wafer test only. This analog loopback encompasses the complete analog signal path.

- **Tx-to-Rx Digital Serial Loopback Switch** - This switch establishes a serial loopback connection between the Tx and Rx circuits. This digital loopback encompasses most of the signal path, skipping the actual transmit driver and the first stage of the receiver.

- **Optional Additional Tx Serializer** - When enabled in Wide (20-bit) mode by assertion of the wide_xface control, this block reduces the width of the Tx datapath from two words to one word. In Wide mode, the Tx_Ck rate is expected to be 1/20th the baud rate. When the wide_xface control is deasserted (10-bit mode), only bits [9:0] of the TxData[] bus are used. In either 10- or 20-bit mode, this block converts Tx data from the Tx_Ck domain to the internal "baud / 10" domain. Tx_Ck is derived by buffering the cko_word or tx_cko_word clock. When half_rate is asserted, the clock frequencies are halved, but still based on the true baud rate as previously described.

- **Tx Pattern Generator** - This block produces one of a few pseudo-random sequences that can be easily matched in a receiver as part of the built-in Byte Error Rate Testing (BERT) function.

- **Tx Serializer** - This block serializes data, converting 10 bits at the word rate to 1 bit at the baud rate.

- **Tx Driver** -When fully enabled, this block drives a serialized signal with the programmed signal level and de- emphasis.

Clock Module - This section describes blocks in the Clock module.

- **Multiplying PLL** - The Multiplying PLL (MPLL) block converts the provided reference clock into the "baud / 2" rate required. This high-speed differential clock is buffered internally through an array of transceivers. The cko_word clock is produced at 1/10th or 1/20th the MPLL baud rate.

- **Spread Spectrum Generator** - This block generates the appropriate clock offsets for SATA spread spectrum support.

- **RTerm Tuning** -This block uses an external resistor (ResRef) as reference to determine the proper calibration setting for centering the Rx and Tx termination resistances at 50 ohms.

- **JTAG Interface** - This block enables test mode programming of internal test features.

NOTE

To use the SATA2 PHY in product applications, JTAG transactions are not required. To use the provided automatic test equipment (ATE) vectors and diagnostic capabilities, the JTAG interface is required.

64.3 Functional Description

This section describes SATA2 PHY functions.

64.3.1 Power Controls

This section describes power-down controls available to the ASIC.

64.3.1.1 Tx Power Controls

The table below provides the recommended Tx power state mappings.

Table 64-1. Recommended SATA Tx Power State Mappings

tx_en[2:0]	SATA
000 (OFF)	Disabled
001 (CM)	Slumber
010 (CM_CLK)	Partial
011 (ON)	Enabled/OOB

For tx_en[2:0] settings, see Per-Transceiver Control and Status Signals.

The table below lists all possible state changes. The SATA2 PHY supports only changes that are indicated as valid.

Most changes are immediate (only logic and signal delay times). Changes that are not immediate are complete when tx_done toggles, as noted in the table below. The tx_done signal also toggles due to the assertion of tx_clk_align.

If the tx_ck input changes in phase or frequency, the internal transmit clock must be resynchronized to the tx_ck input before driving data. This resynchronization occurs automatically during state transitions. If this resynchronization is required outside these transitions, resynchronization can be requested by asserting the tx_clk_align input.

Table 64-2. Transmitter State Transitions

From State	To State	Valid Change	tx_done Toggle	Clock Resync
OFF	CM	Yes	No	No
OFF	CM_CLK	Yes	Yes	Yes
OFF	ON	Yes	Yes	Yes
CM	OFF	Yes	No	No
CM	CM_CLK	Yes	Yes	Yes
CM	ON	Yes	Yes	Yes
CM_CLK	OFF	Yes	No	No
CM_CLK	CM	Yes	No	No
CM_CLK	ON	Yes	No	No
ON	OFF	Yes	No	No
ON	CM	Yes	No	No
ON	CM_CLK	Yes	No	No

64.3.1.2 Rx Power Controls

The receiver function is controlled through the rx_en, rx_pll_pwr_on, and rx_term_en pins. The successful change of the PLL power state (due to change in rx_pll_pwr_on) is signaled back to the ASIC by transitioning the rx_pll_state signal.

The LOS function continues to operate unless explicitly disabled. The table below provides the recommended Rx power state mappings.

Table 64-3. Recommended SATA Rx Power State Mappings

SATA	rx_en	rx_pll_pwr_on	rx_term_en
Disabled	0	0	0
Slumber	0	0	1

Table continues on the next page...

Table 64-3. Recommended SATA Rx Power State Mappings (continued)

SATA	rx_en	rx_pll_pwr_on	rx_term_en
Partial	0	0/1	1
Enabled/OOB	1	1	1

or fastest exit from partial, set rx_pll_pwr_on to 1'b1. For lower power, set rx_pll_pwr_on to 1'b0.

When rx_en is set to 1'b0, rx_ck is disabled; therefore, either asynchronous logic or another clock source must be used to move between states during this period.

64.3.1.3 Clock Module Power Controls

The table below provides the MPLL power state settings.

Table 64-4. Recommended SATA Power State Mappings

SATA	mpll_pwron (PCLK State)
Disabled	0
Slumber	1
Partial	1
Enabled/OOB	1

The Clock module contains the MPLL and is the entry point for the SATA2 PHY reference clock. The MPLL can be powered down using this module, and the reference clock coming into the PHY can be suspended.

NOTE

Suspending the reference clock requires the ASIC to be able to unsuspend the reference clock without a clock from the SATA2 PHY.

Before disabling the reference clock externally or suspending the clock via the mpll_ck_off pin, always power down the MPLL. The mpll_ck_off pin gates the reference clock on and off at the entry point to the SATA2 PHY. Before disabling the external reference clock, always set mpll_ck_off to prevent needless power consumption in the block that converts the reference clock to full logic levels. Setting mpll_ck_off disables all clocks (even cko_alive). When powering down the MPLL, consider whether you want cko_word to be suspended or switched to the reference clock and if you want the cko_alive clock to be available.

64.3.1.4 Power-Up Sequences

This section describes various power-up sequences.

64.3.1.4.1 Powering Up the Chip (Initial Power-Up)

To perform initial chip power-up:

1. Power up the power supplies.

NOTE

If you use the power_good indicator to determine when the power supplies have all reached 80% of their respective nominal values, ensure that you power up the lowest supply first.

2. Without using a clock from the SATA2 PHY, enable the external reference clock and wait for it to become stable.

3. To propagate refclk to the MPLL, set mpll_ck_off to 1'b0.

NOTE

Before setting mpll_ck_off to 1'b0, set the mpll_ncy, mpll_ncy5, and mpll_prescale signals to the appropriate values.

4. Perform a PHY reset by either toggling reset_n or writing a 1 to the Reset register (see Reset Register Reset Register) through the JTAG interface or Parallel CR Control port.

Upon writing the PHY reset bit in the reset register, the internal PHY reset is active immediately. Since the reset also affects the control register state machine, there will not be an acknowledgement of the write; that is, cr_ack will not be asserted.

NOTE

Diagnostic code should treat the *lack* of an acknowledgment of the write as a *successful* write; alternatively, it should treat the PHY *acknowledging* a write of the reset as a write *failure*. This is the opposite expectation of all other registers, where the lack is a failure and the *acknowledge* is successful. It is sufficient to wait 20 ref_clock cycles in order to determine that the acknowledgement has *not* occurred.

For information about the JTAG interface and the Parallel CR Control port, see Block Descriptions.

64.3.1.4.2 Powering Up the Clock Module

The following procedure assumes the chip is powered up and all blocks are in their power-down state. To power up the Clock module:

1. To start the MPLL, set the mpll_pwron signal to 1'b1.
2. Wait for op_done to transition.

The Tx and Rx can now be powered up as appropriate.

64.3.1.4.3 Powering Up the Tx

Assuming that the Clock module is powered up, tx_en[2:0] can be changed to any mode. Some transitions might require waiting for tx_done to transition before the transmitter is in the intended state.

64.3.1.4.4 Powering Up the Rx

The following procedure assumes that the Clock module is powered up.

To power up the Rx:

1. Turn on receiver terminations by setting rx_term_en to 1'b1.
2. Power up the Rx PLL by setting rx_pll_pwron to 1'b1.
3. Wait for rx_pll_state to go high.
4. Enable rx_ck and drive data out on the rx_data pins by setting rx_en to 1'b1.
5. Wait for rx_valid to indicate that the data is valid.

64.3.1.5 Power-Down Sequences

This section describes various power-down sequences.

64.3.1.5.1 Powering Down the Rx

To power down the Rx:

1. To disable the rx_ck and rx_data pins, set rx_en to 1'b0.
2. To power down the Rx PLL, set rx_pll_pwron to 1'b0.
3. Wait for rx_pll_state to go low.

64.3.1.5.2 Powering Down the Tx

To disable the transmitter, set tx_en[2:0] to the OFF or CM setting.

64.3.1.5.3 Powering Down the Clock Module

This procedure assumes the Tx and Rx are powered down.

To power down the Clock module:

1. If you want refclk to be output on cko_word while the MPLL is powered down, change cko_word_con to the refclk setting (3'b000).
2. To power down the MPLL, set mpll_pwron to 1'b0.
3. Wait for op_done to transition.
4. If refclk is to be suspended, or if mpll_ncy, mpll_ncy5, or mpll_prescale must be changed, first set mpll_ck_off to 1'b1.

64.3.2 Clock Module Operations

Figure 64-2 below shows the input and output clocks for one receiver/transmitter pair and the Clock module.

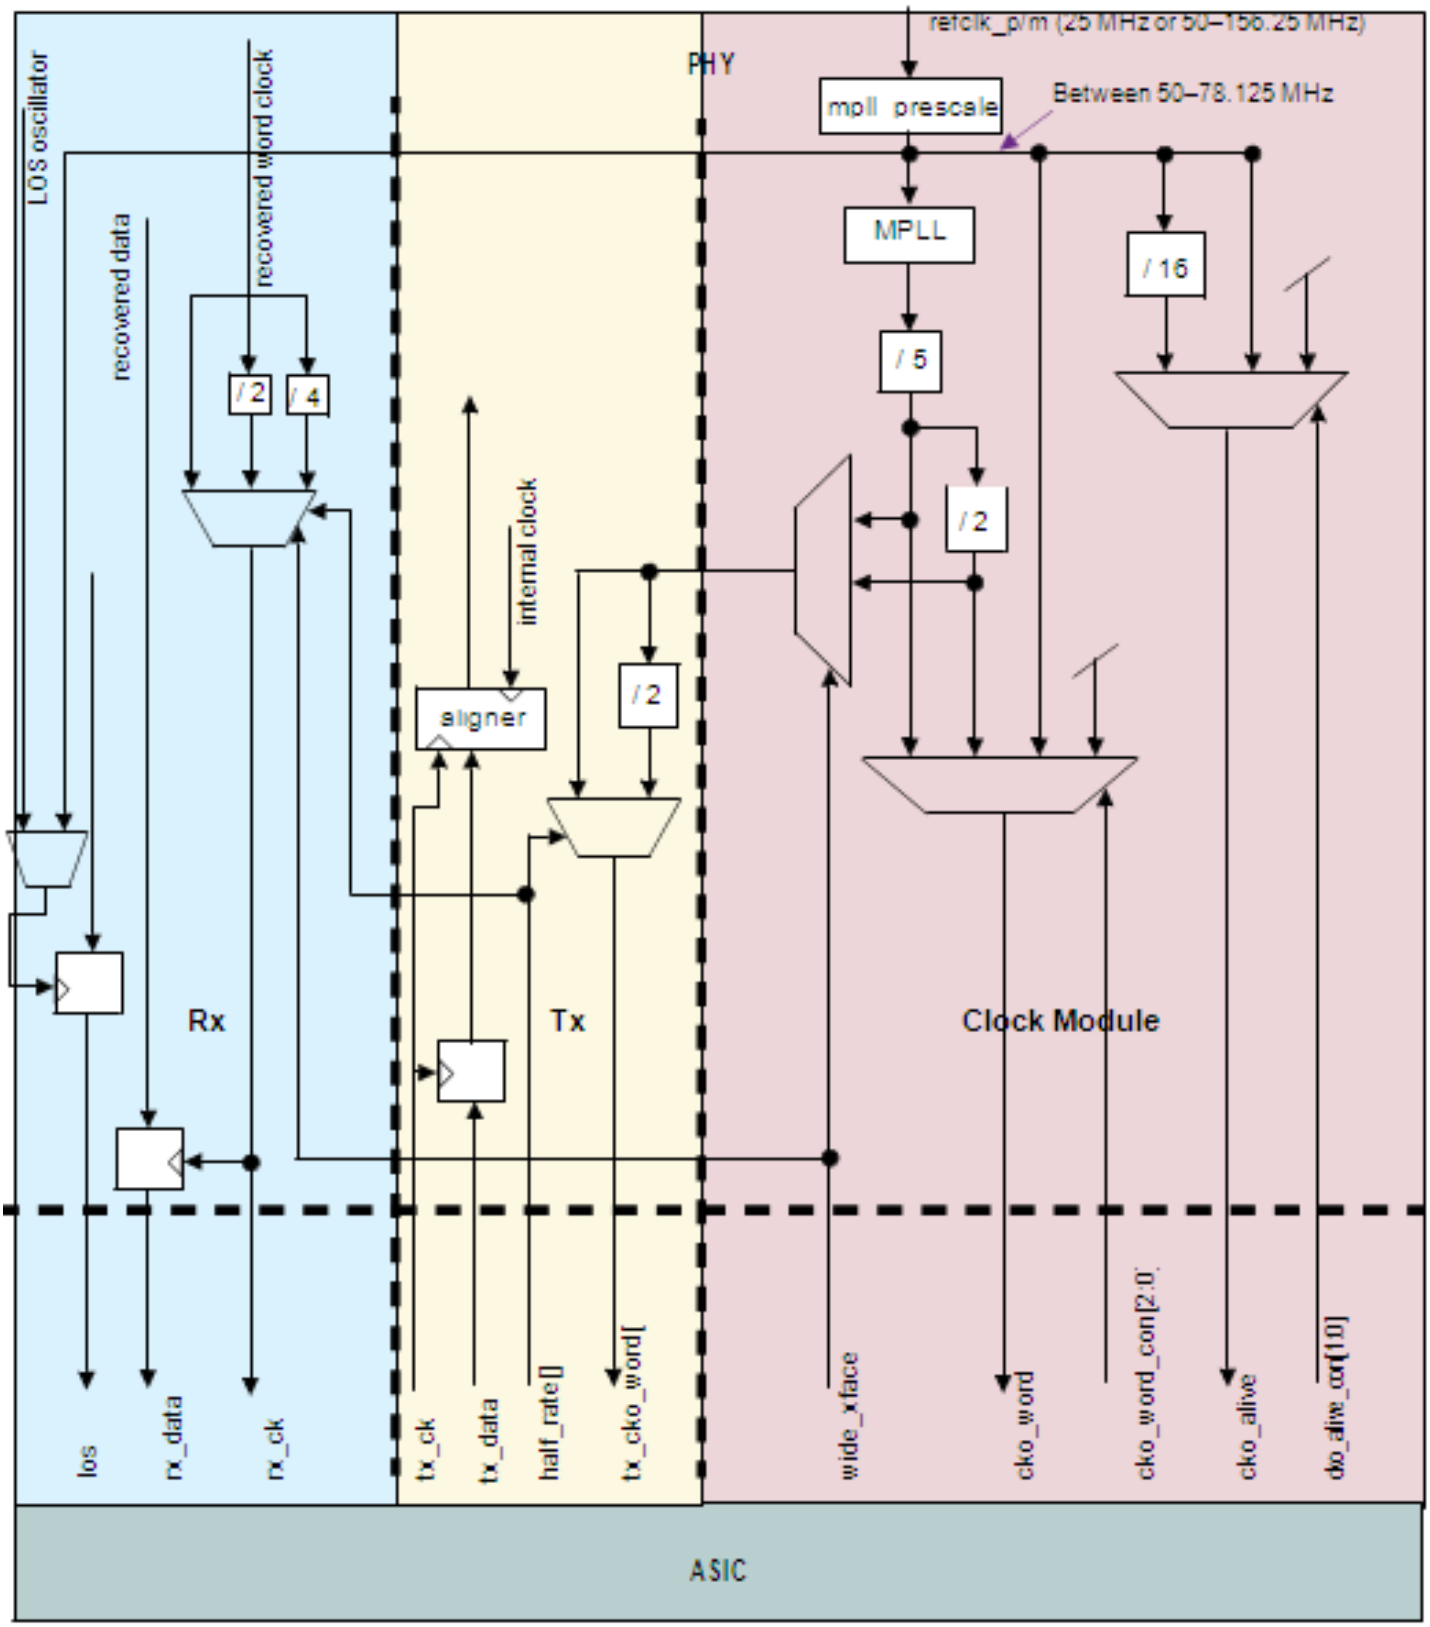

Figure 64-2. Clock interface

Note: tx_ck must be derived from tx_cko_word or cko_word.

64.3.3 Clock Inputs to the SATA2 PHY

The SATA2 PHY reference clock can be sourced from the ref_clk_p/m pads or the alt_ref_clk_p/m pins. The SATA2 PHY reference clock input has a frequency range of 25 MHz or 50-156.25 MHz.

Although the MPLL has a wide frequency range, there is a subset of specific input frequences that achieves the desired data rate. The reference clock is not used by the MPLL directly; instead, the clock passes through a prescaler that can pass the ref_clk through or divide/multiply the ref_clk frequency by 2. To guarantee that the MPLL input is in the range of 50-78.125 MHz, the prescaler must be set properly.

64.3.3.1 mpll_prescale[1:0]

The prescaler is a block that inputs the reference clock and outputs the clock used as input to the MPLL and the cko_word and cko_alive multiplexers.

The MPLL expects input clock (output from the prescaler) frequencies of 50-78.125 MHz. The table below provides some common settings. Set up the MPLL to operate at half the baud rate (except for SATA I where the MPLL operates at baud rate).

Valid refclk Range and Formulaic MPLL Settings provides a general formulaic approach for determining settings for less common scenarios. In the table below, the MPLL Divider column can be decoded into the appropriate mpll_ncy[4:0] and mpll_ncy5[1:0] settings using Table 64-7.

Table 64-5. mpll_prescale[1:0]: Sample Reference Clock Configurations

Reference Clock Frequency (MHz)	pll_prescale[1:0]	mpll_prescale Effect on ref clk	Input to MPLL (MHz)	MPLL Divider	Resultant Baud Rate (Gbps)
25	01	x 2	50	30	3
50	00	As is	50	30	3
60	00	As is	60	25	3
62.5	00	As is	62.5	24	3
75	00	As is	75	20	3
100	10	/ 2	50	30	3
120	10	/ 2	60	25	3
125	10	/ 2	62.5	24	3
150	10	/ 2	75	20	3

64.3.3.2 Valid refclk Range and Formulaic MPLL Settings

This section presents a formulaic approach for setting the MPLL values.

As mentioned in mpll_prescale[1:0], the MPLL input must be in the range of 50-78.125 MHz. Frequency doubling and halving is available at the refclk input. The following table lists all valid refclk ranges and the appropriate mpll_prescale[1:0] settings to place refclk in the proper range. This list includes valid refclk frequencies, but there is no guarantee that a particular refclk frequency can be used to create the intended baud rate.

Table 64-6. Valid refclk Frequencies

refclk Frequency Range (MHz)	mpll_prescale[1:0]	Effect on refclk Frequency	Clock Input to MPLL (MHz)
25	01	Doubled	50
50-78.125	00	No effect	50-78.125
100-156.25	10	Halved	50-78.125

To create the intended baud rate, the clock input to the MPLL (as determined from Table 2-5 on page 31) must evenly divide half the intended baud rate (or the baud rate in Half-Rate mode). The formula for Full- Rate mode is:

MPLL Divider = 0.5 x (baud rate) / (clock input to MPLL)

The formula for Half-Rate mode is:

MPLL Divider = (baud rate) / (clock input to MPLL)

The MPLL Divider value can then be used to determine the values for the mpll_ncy5 and mpll_ncy buses, as listed in the following table.

NOTE

The preceding formulae must yield a valid integer. If the result is not an integer, a refclk frequency that produces a valid integer must be used. The table below lists valid divider values.

Table 64-7. MPLL Divider Settings

MPLL Divider	mpll_ncy[4:0]	mpll_ncy5[1:0]
4	00000	00
5	00000	01
8	00001	00
9	00001	01

64.3.3.3 Clock Module Power Control

For information about the Clock module power controls, see Clock Module Power Control.

64.3.3.4 Presence of refclk Signal

The reference clock must be present during all operational modes, except when the MPLL is powered down and mpll_ck_off has been set to 1'b1.

For more information, see Power-Up Sequences and Power-Down Sequences.

64.3.3.5 Power-On Reset

The SATA2 PHY asserts its internal power-on reset (POR) whenever the voltage level of the high supply has not yet reached the initial "power valid" trip point at ~70-75% of the rated supply voltage.

After a POR is asserted, to prevent accidental reactivation of the POR, the trip point is reduced to ~65-70% of the rated supply voltage. Reactivation of a POR causes the SATA2 PHY to go into a reset state again.

Note that deassertion of a POR causes a normal transition out of reset. During power-up, constraints on the state of the control inputs must be maintained-meaning that the POR mechanism in the SoC must ensure that control inputs are set to the intended states.

64.3.3.6 Resistor Calibration

During a reset or at the request of the ASIC via the rtune_do_tune pin, a resistor calibration occurs. When the operation is complete, the op_done pin is transitioned.

Resistor calibration consists of learning which state of the internal Resistor Calibration register causes an internal, digitally trimmed calibration resistor to best match the impedance applied to the ResRef pin. The calibration register value is then supplied to all Tx and Rx termination resistors.

During the calibration process (for a few tens of microseconds), up to 0.3 mW can be dissipated in the external ResRef resistor. At other times, no power is dissipated by the ResRef resistor.

64.3.4 Tx Operations

This section describes transmitter settings and operations.

64.3.4.1 Recommended Tx Settings

The following table outlines the recommended transmitter settings, and the sections that follow describe each setting in detail.

Table 64-8. Recommended Tx Settings

Application	tx_atten[2:0] (Short/ Medium/Long)[1, 1]	tx_boost[3:0] (Short/ Medium/Long)[1]	tx_lvl[4:0] (Short/Medium/ Long)[1]	x_edgerate[1:0]
SATA 1i	011	N/A	00110	01
SATA 1m	011	N/A	00110	01
SATA 1x	N/A	1001	00110	01
SATA 2i	100	N/A	10001	00
SATA 2m	100	N/A	10001	00
SATA 2x	000	1001	10001	00

1. Short/medium/long are typical values based on 5-cm, 23-cm, and 48-cm trace lengths on FR4 material. These values are provided as guidelines. It is recommended that the final setting be based on the characteristics of the actual serial channel.

64.3.4.2 Tx Amplitude Control

The transmitter has a programmable boost, level, and attenuation. The transmitter's full-scale amplitude is a function of the selected level (tx_lvl), attenuation (tx_atten), and boost (tx_boost).

The actual peak-to-peak differential amplitude is the Tx amplitude multiplied by the attenuation multiplier:

$$\text{Tx amp}_{\text{(p-p differential near-end)}} = \text{attenuation multiplier} \bullet \frac{1.24}{63.5} \left[(48 + 0.5 (\text{tx\_lvl[4:0]}) - V \right]_{\text{, p-p differential near-end}}$$

Using a larger transmit amplitude provides a larger eye to a far-end receiver (at the expense of a slight increase in power).

For tx_lvl[4:0] settings, see Common Signals.

64.3.4.3 Tx Boost Control

The transmitter can be programmed to provide boost (pre-emphasis/de-emphasis). Boost is achieved by reducing the drive level of a non-transition bit with respect to a transition bit.

The amount of boost the transmitter supplies is programmed through the tx_boost[3:0] pins as follows:

$$\text{boost} = - 20\log\left(1 - \frac{\text{txboost[3:0]} + 0.5}{32}\right) \text{ db}$$

except that setting tx_boost[3:0] to 4'b0000 actually produces 0 db of boost. This boost control produces results up to 5.75 dB in increments of ~0.37 dB. These pins can be transitioned asynchronously. The best boost setting is channel dependent. For lossy channels, the maximum boost setting is appropriate; for low- loss channels, lower settings provide a better eye. Table 64-8 provides the recommended boost settings for short, medium, and long trace lengths. If lossy channels are expected in the application, setting

the boost to its maximum value is appropriate. If more information is known about the channel, a good rule is to take the loss at Nyquist, subtract 3 dB, and find the tx_boost setting that most closely achieves this value. For example, if the worst-case loss at Nyquist is 6.5 dB, a good setting for tx_boost is one that achieves 3.5 dB of boost. From the preceding equation, the tx_boost setting is 4'b1010.

64.3.4.4 Tx Far-End Amplitude

The transmitter far-end amplitude is a function of boost, level, and attenuation.

The actual far-end differential amplitude can be defined as the most commonly transmitted level:

$$\left(-\frac{\text{boost}_{db}}{\text{attenuation factor}}\right) = \text{atten}_{multiplier} \cdot 10^{20}$$

$$\text{Tx amp}_{\text{(differential far-end)}} = \text{attenuation factor} \cdot \frac{1.24}{63.5}\left[\left(48 + 0.5\left(\text{tx\_lvl[4:0]}\right) - V\right]_{\text{, differential far-end}}\right.$$

With proper boost settings, the actual far-end differential amplitude is approximately equal to the far-end peak-to-peak differential amplitude.

64.3.4.5 Tx Edge Rate Control

The following table describes the edge rate control settings, which enable the SATA2 PHY to meet the edge rate requirements of all SATA variants.

Table 64-9. tx_edgerate Settings

tx_edgerate[1:0]	Value
00	Fast edge rate
01	Medium edge rate
10	Slow edge rate
11	Reserved

64.3.5 Rx Operations

This section describes receiver operations.

64.3.5.1 Recommended Rx Settings

The table below describes the recommended Rx settings.

Table 64-10. Recommended Rx Settings

Application	rx_eq_val[2:0]	los_lvl[4:0]	rx_dpll_mode[2:0]
SATA1i	101	10000	011 with SS 001 without SS
SATA1m	101	10000	011 with SS 001 without SS
SATA1x	101	11010	011 with SS 001 without SS
SATA2i	101	10010	011 with SS 001 without SS
SATA2m	101	10010	011 with SS 001 without SS
SATA2x	101	11010	011 with SS 001 without SS

64.3.5.2 Loss of Signal Detection

Flexible LOS detection is provided on a per-lane basis. The per-lane output of the LOS detection is provided through the LOS pins. LOS detection is controlled by filtering the raw LOS signal using the los_ctl pins and setting the LOS threshold.

Table 64-11 describes the los_ctl settings.

Table 64-11. los_ctl Settings

los_ctl[1:0]	Description
00	Disabled
01	Reserved
10	Filtering for SATA to enable OOB processing. The LOS signal is synchronous to the output of the prescaler (available on cko_alive or cko_word).
11	Heavy filtering. The LOS signal is synchronous to the prescaler's output (available on cko_alive or cko_word). Heavy filtering needs longer periods of inactivity or activity before indicating an LOS event because of slower response time to chatter on the receiver lines.

As defined in the SATA specification, OOB signaling is accomplished by measuring the gaps between bursts of energy. An energy burst is defined to be 160 UI long (107 ns long) at SATA I rates. The burst consists of repeating ALIGN primitives (k28.5, d10.2, d10.2, d27.3).

Table 64-12. Words Used in ALIGN Primitive

ALIGN words	+ Disparity	- Disparity
k28.5 (COMMA)	1 1 0 0 0 0 0 1 0 1	0 0 1 1 1 1 1 0 1 0
d10.2 (NYQUIST)	0 1 0 1 0 1 0 1 0 1	0 1 0 1 0 1 0 1 0 1
d27.3	1 1 0 1 1 0 0 0 1 1	0 0 1 0 0 1 1 1 0 0

The ALIGNs during OOB signaling are always sent at SATA I rates. The communication is realized by the length of the gap between bursts. The following three tables describe the OOB gap-sensing limits for COMWAKE, COMSET/COMINIT, and COMSAS, respectively.

Table 64-13. OOB Gap-Sensing Limits for COMWAKE

Gap Length	Decision
< 55 ns	Must not indicate a gap
55-101 ns	Can indicate COMWAKE
101-112ns	Must indicate COMWAKE
112-175ns	Can indicate COMWAKE
> 175 ns	Must not indicate there was a gap

Table 64-14. OOB Gap-Sensing Limits for COMRESET/COMINIT

Gap Length	Decision
< 175 ns	Must not indicate a gap
175-304 ns	Can indicate COMRESET/COMINIT
304-336 ns	Must indicate COMRESET/COMINIT
336-525 ns	Can indicate COMRESET/COMINIT
> 525 ns	Must not indicate there was a gap

Table 64-15. OOB Gap-Sensing Limits for COMSAS

Gap Length	Decision
< 525 ns	Must not indicate a gap
525-911.7 ns	Can indicate COMSAS
911.7-1,008 ns	Must indicate COMSAS
1,008-1,575 ns	Can indicate COMSAS
> 1,575 ns	Must not indicate there was a gap

For OOB detection/transmission, to synchronously transfer the LOS signal to the ASIC, the SATA2 PHY relies on a clock that is proportional to the reference clock. If the reference clock frequency is 25 MHz, it is multiplied by 2-50 MHz; if the reference clock frequency is 100 MHz, it is divided by 2-50 MHz. In addition, the LOS signal is preprocessed. Therefore, based on the results, it is recommended that the decision points indicated in Table 2-16 be used for detecting OOB signals.

Table 64-16. Recommended Decision Points (Assumes 25-MHz, 50-MHz or 100-MHz Reference Clock)

LOS Length (20-ns Periods)	Decision	True Limits (ns)
0-2	Invalid gap length	< 80
3-6	COMWAKE	70-150
7-10	Invalid gap length	140-230
11-22	COMINIT/COMRESET	220-470
22-28	Invalid gap length	460-590
29-75	COMSAS	580-1,530
>=76	Invalid gap length	>=1,520

NOTE

Recommended decision points assume a reference clock of 25 MHz, 50-MHZ, or 100 MHz.

To measure/count the LOS length, it is recommended that you use cko_alive with cko_alive_con[1:0] set to 2'b01. With this setting, the cko_alive frequency will be 50 MHz .

64.3.5.3 rx_dpll_mode[2:0]

The table below describes the rx_dpll_mode[2:0] settings. At each point in time, the actual gain setting is the larger of the gains indicated by the fast startup (if in use) and rx_dpll_mode[1:0]. The values of Phase

Update Gain (PHUG) and Frequency Update Gain (FRUG) correspond to the proportional and integral gains of the DPLL. Higher gains in the PHUG and FRUG settings cause an increase in jitter.

Table 64-17. rx_dpll_mode Settings

rx_dpll_mode[2:0]	PHUG	FRUG	fast_startup	Frequency Tolerance (ppm)
000	1	1	None	780

Table continues on the next page...

Table 64-17. rx_dpll_mode Settings (continued)

rx_dpll_mode[2:0]	PHUG	FRUG	fast_startup	Frequency Tolerance (ppm)
001[1, 1]	2	2	None	780
101	1	4	None	6,250
011[2, 2]	2	4	None	6,250
100	Reserved			
101				
110				
111				

1. Recommended setting (without Spread Sectrum (SS))
2. Recommended setting (with Spread Sectrum (SS))

64.3.5.4 Rx Equalizer Settings

The SATA2 PHY provides an Rx equalizer that can be programmed using the rx_eq_val[2:0] bits. The table below lists the approximate boost that each setting provides.

Table 64-18. Rx Equalizer Settings

rx_eq_val[2:0]	Boost (dB)
000	0.5
001	1.0
010	1.5
011	2.0
100	2.5
101	3.0
110	3.5
111	4.0

These pins can be transitioned asynchronously, but a dynamic change to these pins during data transmission might result in bit errors. Typically, these settings do not change during operation. Although the specification does not define receive equalization, a more robust link can be achieved by providing some equalization. A good general setting is to set the equalizer to approximately 3 dB of boost-suitable for many applications.

64.4 Control Registers

SATA2 PHY test features are controlled by registers that are accessible through the JTAG interface. Each register is a maximum of 16 bits wide.

Because some registers contain different fields, when changing a single field in a register, use a read-modify-write approach.

64.4.1 Register Fields

Some fields are single bits while other fields encompass the entire contents of the containment register. Some registers have Xs as reset values.

These registers are categorized as follows.

Registers That Reflect Inputs From the ASIC Interface

The values of these inputs are unknown on reset; therefore, the register's reset value is indeterminate.

These registers include:

- lane0.tx_stat
- lane0.rx_stat
- clock.freq_stat
- clock.ctl_stat
- clock.lvl_stat
- clock.creg_stat

Registers That Reflect Results of Operations Not Initialized on Reset

These registers might have actual Xs on part reset. However, those bits have no meaning until the associated function is enabled or initialized; until then, discard the read results of these register bits.

These registers include:

- lane0.out_stat
- lane0.pm_err
- clock.crcmp_stat
- clock.scope_count
- clock.adc_out

When reading a register, mask the result to view only the bits with which you are concerned. Correct masking disables the Xs from propagating through your logic.

64.4.1.1 Field Properties

The property string associated with each field is a concatenation of the applicable attributes listed in the table below. For example, the most common field property is RWCr, which denotes readable, writable, and subject to a reset.

Table 64-19. Register Attributes

Property	Description
R	Readable. A register read returns the current value of the register itself (if it is also writable) or the state to which the register is attached.
R2	Read operation on this register is pipelined. Two reads are required to get "current" value.
W	Writable
V	Volatile (that is, the value can change at any time)
I	Value is in signed integer format (2's complement).
Cr	Register is subject to being returned to its reset value on a reset.

In addition, each field requires two numeric parameters to specify the field's location in the register: a width (in bits) and an offset (in bits) from the register's least-significant bit (LSB).

64.4.1.2 Field Names

Fully specified field names consist of the concatenation of a register name and a field name, as in *register.field*.

Fields in registers comprising a single field (for example, clock.crcmp_lo_range.crcmp_lo_range) are typically named without the concatenation (for example, clock.crcmp_lo_range). In these cases, the single field name always matches the last portion of the register name.

64.4.1.3 Read/Modify/Write Operations

To modify one field in a register containing multiple fields, it is generally necessary to read the register, modify the target field, then write the entire result.

One approach to writing control registers is to monitor the contents of each field; this approach does not require read-modify-write operations. The read is not necessary if the current register value is known (reset value at the time of the reset updated with any subsequent modifications to values of other fields in the register). Therefore, volatile control fields such as DPLL PHASE are never combined in the same register with other control fields.

Methods that do not maintain this information must work by reading a register, modifying only the field being changed, then writing the register.

64.5 Signal Descriptions

64.5.1 Signal Descriptions Overview

The SATA2 PHY top-level signals are grouped as follows:

- Power supply signals
- Package I/O signals
- Per-transceiver control and status signals
- Per-transceiver datapath signals
- Common signals
- JTAG interface signals
- Parallel CR Control port signals

Per-transceiver pins are replicated for each lane in the SATA2 PHY. In the signal descriptions, this replication is denoted by "lane" in the signal name.

For example, a x2 PHY half_rate[lane] denotes two signals: half_rate[0] and half_rate[1]. tx_data_{lane}[19:0] denotes two buses: tx_data_0[19:0] and tx_data_1[19:0].

For information about actual pin layers and pin locations, refer to the LEF file provided in the database deliverables. All ASIC-side pins are at CMOS logic.

The figure below shows the SATA2 PHY top-level signals.

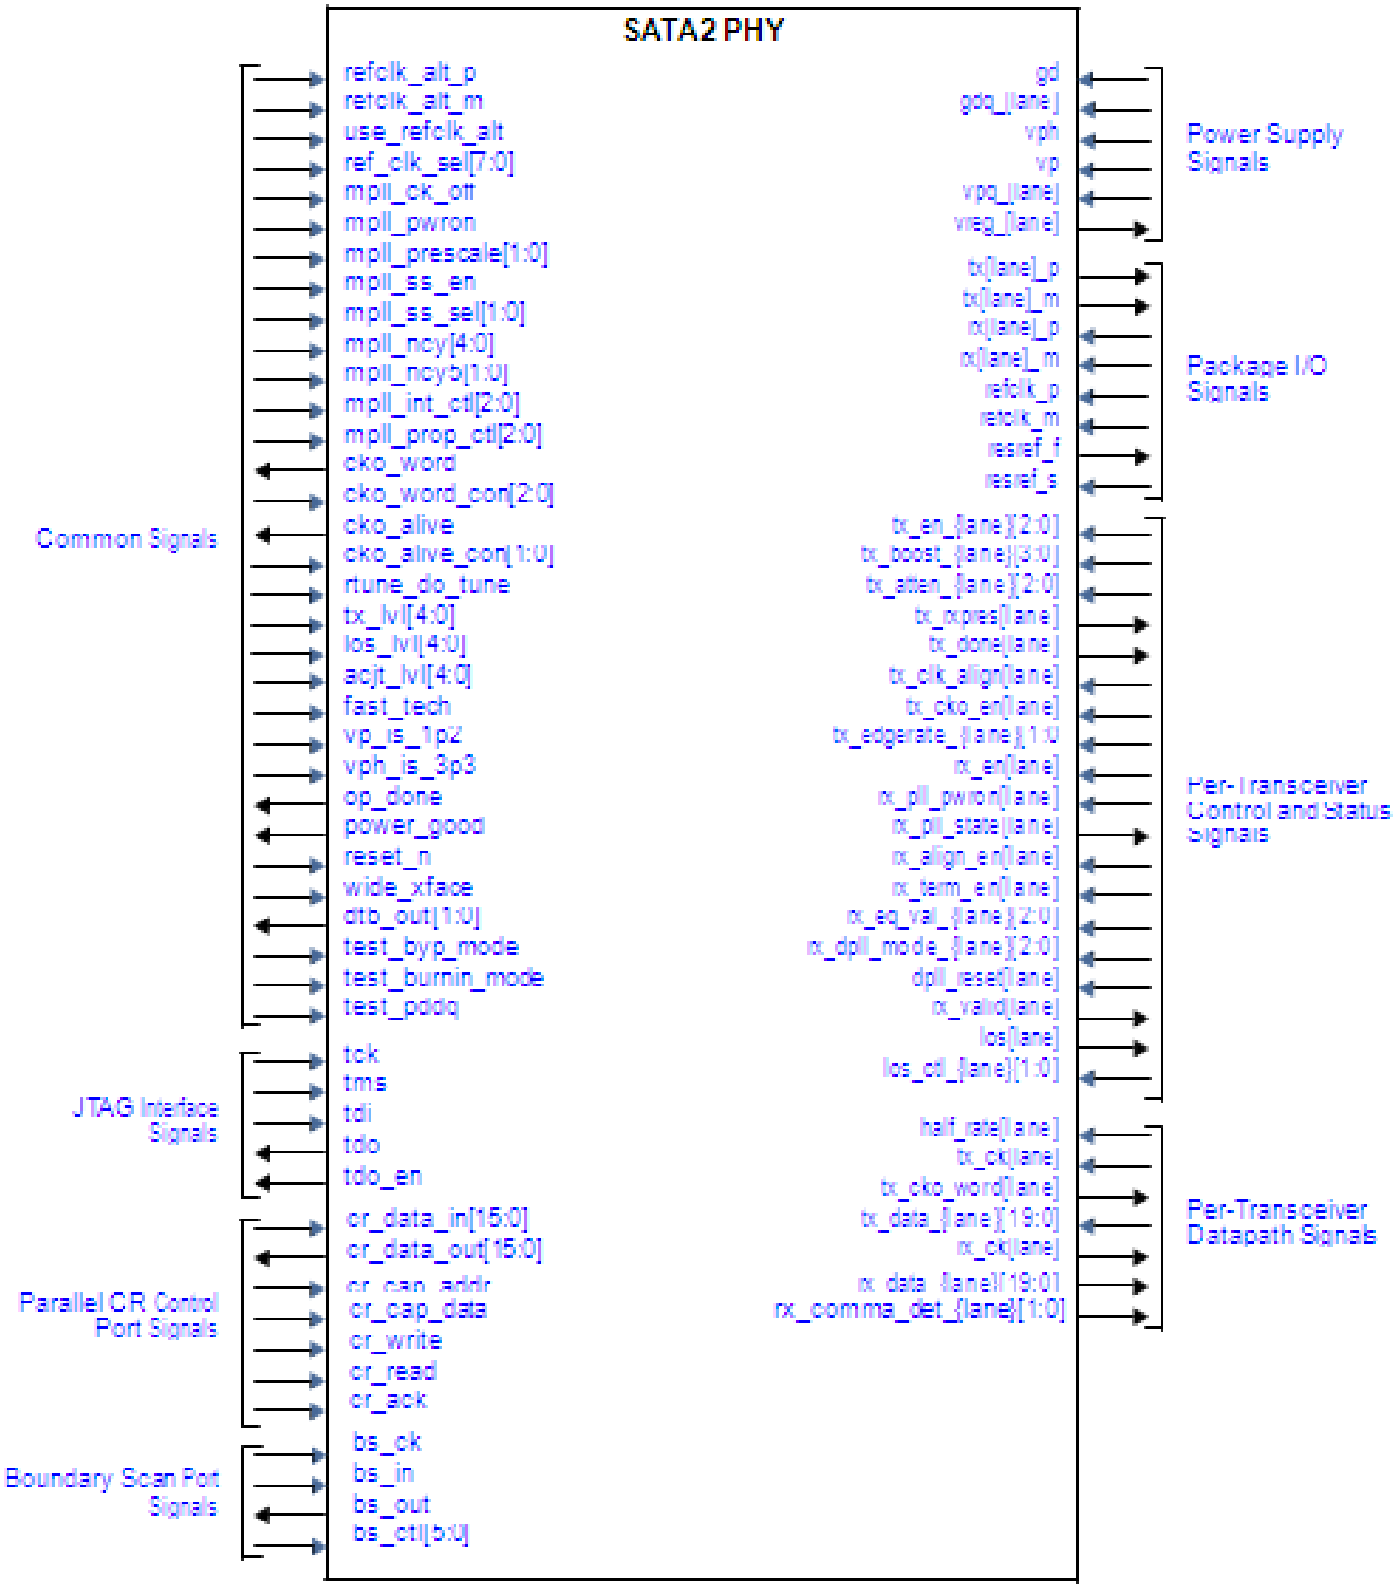

Figure 64-3. Top-Level IO Diagram

64.5.2 Signal Descriptions Information

In addition to describing the function of each signal, the signal descriptions include the following information:

- **Voltage Range:** Describes the voltage range expected on the pin.
- **Synchronous:** Indicates that the signal is asserted or deasserted with respect to a clock edge. (For synchronous-signal timing requirements.
- **Asynchronous:** Indicates that the signal is not asserted or deasserted with respect to a clock edge.

64.5.2.1 Power Supply Signals

The SATA2 PHY core requires two power supply voltages and a ground. Power connections abut directly between the Active and Pad sections; no routing of these power connections is required nor permitted.

Table 64-20. Power Supply Signals

Signal	IO	Description	Pad Section Connection
gd	I	Ground **Function:** Ground **Voltage Range:** 0 V **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** none - power/ground signal	gd
gdq_[lane]	I	Filtered Ground **Function:** Isolated version of gd for transmit jitter-sensitive devices. **Voltage Range:** 0 V **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** none - power/ground signal	gd
vph	I	High-Voltage Supply **Function:** Core Power **Voltage Range:** Varies (internal use only) **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** none - power/ground signal	vp25

Table continues on the next page...

Table 64-20. Power Supply Signals (continued)

Signal	IO	Description	Pad Section Connection
vp	I	Low-Voltage Supply **Function:** Core Power **Voltage Range:** Varies (internal use only) **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** none - power/ground signal	vp
vpq_[lane]	I	Filtered Low-Voltage Supply **Function:** Core Power **Voltage Range:**Varies (internal use only) **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** none - power/ground signal	vpq[lane] **Note:** For an x1 configuration, this pin is vpq.
vreg_[lane]	O	Regulated Voltage Supply for Transmitter **Function:** Regulated voltage supply for transmitter that is output from the PHY for attachment to an ESD clamp in the Pad section. **Voltage Range:** Varies (internal use only) **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** don't care	vreg[lane] **Note:** For an x1 configuration, this pin is vreg.

64.5.2.2 Package I/O Signals

The SATA2 PHY includes pins that must connect to package pins.

The table below describes these pins, which include the Tx, Rx, and reference clock differential pairs, and connections to an external resistor. These package I/O signals abut directly between the Active and Pad sections and connect to the Pad ports as described in the "Pad Section Connection" column. No additional routing of these signal connections is required nor permitted.

Table 64-21. Package I/O Signals

Signal	IO	Description	Pad Section Connection
• tx[0]_p • tx[0]_m	O	High-Speed Differential Transmit Pair **Function:** High-speed differential transmit outputs **Voltage Range:** 0 V-I/O voltage **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** don't care	• txp[0] • txm[0] Attach the same wire to the pad, macro, and chip interfaces.
• rx[0]_p • rx[0]_m	I	High-Speed Differential Receive Pair **Function:** High-speed differential receiver inputs **Voltage Range:** 0 V-I/O voltage **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** • rx[0]_p: none - loopback from tx0_p • rx[0]_p: none - loopback from tx0_m	• rxp[0] • rxm[0] Attach the same wire to the pad, macro, and chip interfaces.
• refclk_p • refclk_m	I	Differential Reference Clock Input **Function:** Input reference clock. If the sample pads are not used, but the refclk_alt_{p,m} signals are used instead, refclk_{p,m} can remain disconnected (not bonded or bumped). **Voltage Range:** 0 V-I/O voltage **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** • refclk_p: none - application-specific • refclk_m: none - application-specific	• refclkp_int • refclkm_int These wires are internal-only. Connect the chip interface to the refclkp and refclkm pins in the Pad section.

Table continues on the next page...

Table 64-21. Package I/O Signals (continued)

Signal	IO	Description	Pad Section Connection
• resref_f • resref_s	• O • I	Reference Resistor Connection **Function:** 191 ohms 1% precision resistor to ground. During resistor tuning, current is forced through the external resistor using resref_f while the induced voltage is sensed on resref_s. In the Pad section, the resref_f and resref_s pins are combined into a single external pad. **Voltage Range:** N/A **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** • resref_f: don't care • resref_s: none - connect to resistor on silicon	• rext • rext_s Connect one package pin to both resref_f on the IP and rext in the Pad section. Using a second wire, connect resref_s on the IP and rext_s in the Pad section.

64.5.2.3 Per-Transceiver Control and Status Signals

The table below describes the per-transceiver control/status and miscellaneous signals.

Table 64-22. Per-Transceiver Control and Status Signals

Signal	I/O	Description
Related to Transmitter		

Table continues on the next page...

Table 64-22. Per-Transceiver Control and Status Signals (continued)

Signal	I/O	Description
tx_en_{lane}[2:0]	I	Transmitter Enable **Function:** Enables transmitter. Transitions between 010 and 011 are staged to match the tx_data latency, so that all data on the parallel interface when tx_en is 011 is guaranteed to be output from the serial transmitter. • 000 (OFF): Tx off, no internal clocks running • 001 (CM): Hold common mode, no internal clocks running • 010 (CM_CLK): Hold common mode, transmitter clock divider running • 011 (ON): Transmitter fully enabled, all internal clocks running • 100: Reserved • 101: Reserved • 110: Reserved • 111: Reserved For information about the recommended Tx power state mappings, see Tx Power Controls. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** tx_ck **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
tx_boost_{lane}[3:0]	I	Transmit Boost Control **Function:** Programmed boost value (ratio of drive level of transition bit to non- transition bit) is: boost-20log[(tx_boost[3:0] + 0.5)/32] = db except that setting tx_boost[3:0] to 0000 actually produces 0 db of boost. This control produces results up to 5.75 dB in increments of ~ 0.37 dB. For more information about tx_boost_{lane}[3:0] and the recommended settings, see Tx Operations. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous; changes while the transmitter is on might briefly cause unwanted transmit waveforms **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction

Table continues on the next page...

Table 64-22. Per-Transceiver Control and Status Signals (continued)

Signal	I/O	Description
tx_atten_{lane}[2:0]	I	Transmit Attenuation Control **Function:** Provides discrete driver attenuation factors of either 16-, 14-, 12-, 10-, 9-, or 8-sixteenths of full drive level. • 000: 16/16 • 001: 14/16 • 010: 12/16 • 011: 10/16 • 100: 9/16 • 101: 8/16 • 11x: Reserved Attenuating the drive level in this way does not use less power than using the non-attenuated (16/16) drive level. Attenuation factor is dependent on boost level and $atten_{multiplier}$ (for more information about these calculations, see Tx Boost Control and Tx Far-End Amplitude, respectively). **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous; changes while the transmitter is on might briefly cause unwanted transmit waveforms **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
tx_rxpres[lane]	O	Receiver Detection **Function:** Reserved Leave these pins floating. **Voltage Range:** 0 V-core voltageOverride Ablility: 18-bit CREG_OVRD register
tx_done[lane]	O	Transmitter Operation Complete **Function:** Transitions (in either direction) when the transmitter has completed a requested power state transition or operation requested via the tx_en_{lane}[2:0] pins when a tx_clk_align operation is complete. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to**: tx_ck, but can be sampled asynchronously if necessary **Override Ablility:** 18-bit CREG_OVRD register

Table continues on the next page...

Table 64-22. Per-Transceiver Control and Status Signals (continued)

Signal	I/O	Description
tx_clk_align[lane]	I	Transmit Clock Align **Function:** Rising edge is a request to realign the internal Tx word clock to the applied tx_ck signal. Required only if the tx_ck path is interrupted or changed after the automatic alignments. Automatic alignments are triggered by tx_en_{lane}[2:0] transitions, which enable the transmit clocks. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous, but should be kept high for at least two tx_ck cycles **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
tx_cko_en[lane]	I	tx_cko_word Clock Enable **Function:** Enables tx_cko_word clock on a per-lane basis. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous, but transitions might take several cycles to be reflected in the clock output **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
tx_edgerate_{lane}[1:0]	I	Tx Edge Rate Control **Function:** Controls the edge rate of the serial output. • 00: Fastest edge rate • 01: Medium edge rate • 10: Slowest edge rate • 11: Reserved For more information about tx_edgerate_{lane}[1:0] and the recommended settings, see Tx Operations. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
Related to Receiver		
rx_en[lane]	I	Receive Clock and Data Outputs Enable **Function:** Enables receive clock and data outputs. The rx_en signal must be set to 1 only when both the rx_pll_pwron and rx_pll_state signals are set to 1'b1. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction

Table continues on the next page...

Table 64-22. Per-Transceiver Control and Status Signals (continued)

Signal	I/O	Description
rx_pll_pwron[lane]	I	Receive PLL Power-Up and Reset **Function:** Powers up and resets the receive PLL. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous, but must not be changed until the rx_pll_state signal matches rx_pll_pwron. **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
rx_pll_state[lane]	O	Receive PLL State **Function:** Indicates the current state of the receive PLL. This signal will match rx_pll_pwron when the PLL reaches the requested state. The PLL changes states as long as the MPLL is powered up, regardless of the state of incoming data lines. This signal does not indicate that the link is ready. After rx_en is asserted (set to 1'b1), rx_valid must be used to indicate that the link is ready. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register
rx_align_en[lane]	I	Word Alignment Enable **Function:** Assertion of this level-sensitive signal enables word alignment. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
rx_term_en[lane]	I	Rx Termination Enable **Function:** Assertion of this level-sensitive signal enables Rx termination. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
rx_eq_val_{lane}[2:0]	I	Receiver Equalization Control **Function:** Internal linear equalizer boost is ~ (rx_eq_val + 1) x 0.5 dB. For the recommended setting, see Recommended Rx Settings. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous, but transitions might cause bit errors while the boost level changes **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction

Table continues on the next page...

Table 64-22. Per-Transceiver Control and Status Signals (continued)

Signal	I/O	Description
rx_dpll_mode_{lane} [2:0]	I	DPLL Mode **Function:** Sets phase and frequency gain of receiver DPLL. rx_dpll_mode[1:0] define the steady state gains. For more information about this bus, see rx_dpll_mode[2:0]. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous while rx_en is deasserted; otherwise, must reset DPLL after change via the dpll_reset signal **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
dpll_reset[lane]	I	DPLL Frequency Register Reset **Function:** Rising edge of this signal triggers the reset of the DPLL's frequency and phase register. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous, but must be kept high for at least two rx_ck cycles **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
rx_valid[lane]	O	Receive Data Valid **Function:** Indicates that the receive DPLL is bit-locked and that the rx_data and rx_comma_det signals are valid for the corresponding lane. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** rx_ck **Override Ablility:** 18-bit CREG_OVRD register
los[lane]	O	Loss of Signal Output **Function:** Determines if a signal is present at the receiver based on the filtering selected by the los_ctl values. This signal enables higher layers to receive OOB signaling. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Output of the refclk prescaler. This same clock can be routed to the cko_alive clock output for synchronous sampling of the LOS signal. **Override Ablility:** 18-bit CREG_OVRD register

Table continues on the next page...

Table 64-22. Per-Transceiver Control and Status Signals (continued)

Signal	I/O	Description
los_ctl_{lane}[1:0]	I	LOS Detector and/or Filter Raw LOS Output Enable **Function:** Enables LOS detector and/or filtering of raw LOS output. • 00: Off • 01: Reserved • 10: Optimized for OOB signaling • 11: Heavy filtering For information about using this signal, see Loss of Signal Detection. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous; however, LOS output will be briefly unreliable during transition of the los_ctl signal **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction

64.5.2.4 Per-Transceiver Datapath Signals

Table 64-23. Per-Transceiver Datapath Signals

Signal	I/O	Description
Common to Tx and Rx		
half_rate[lane]	I	Half-Rate Mode Control **Function:** Halves the baud rate with respect to normal operation. This signal is asserted in SATA I operation and deasserted in SATA II operation. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** The transition of half_rate between the two modes of operation can be asynchronous to all clocks. **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
Related to Transmitter		
tx_ck[lane]	I	Transmit Clock **Function:** This clock must pulse at the word rate when the wide_xface signal is set to 1'b0 and at half the word rate when wide_xface is set to 1'b1. This clock must be a buffered version of the cko_word clock or tx_cko_word clock. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** none - must be buffered copy of cko_word

Table continues on the next page...

Table 64-23. Per-Transceiver Datapath Signals (continued)

Signal	I/O	Description
tx_cko_word[lane]	O	Per-Lane Word Clock **Function:** This clock runs whenever the MPLL is powered up. Clock frequency is the MPLL frequency / 10 or 5 if half_rate is set to 1'b1 or 1'b0, respectively. This clock can be used instead of cko_word if a per-lane word clock is required (that is, the Clock module can use this clock instead of cko_word.) **Note:** tx_cko_word is derived from either a divide-by-5 or divide-by-10 version of the MPLL clock based on wide_xface. If the lane is in Half-Rate mode, the tx_cko_word clock frequency is further divided by 2. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** don't care - must be connected to tx_ck for ATE testing
O tx_data_{lane} [19:0]	I	Transmit Data **Function:** Serial transmit data. Most-significant bit (MSB) is transmitted first. If wide_xface is set to 1'b0, only bits [9:0] are used. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** tx_ck **Override Ablility:** none - overriden by internal pattern generator
Related to Receiver		
rx_ck[lane]	O	Received Clock **Function:** This clock is the recovered per-lane clock. The rx_ck output runs when rx_en is set to 1'b1, but turns off in other modes. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** rx_data[19:0] (or rx_data[9:0] if wide_xface is set to 1'b0) **Override Ablility:** don't care
rx_data_{lane}[19:0]	O	Received Data **Function:** Serial received data. MSB is received first. If wide_xface is set to 1'b0, only bits [9:0] are used. This bus must be qualified with rx_valid. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** rx_ck **Override Ablility:** don't care

Table continues on the next page...

Table 64-23. Per-Transceiver Datapath Signals (continued)

Signal	I/O	Description
rx_comma_det_{lane}[1:0]	O	Comma Detect **Function:** Asserted when the associated word on rx_data is detected to be a comma (K28.5). This bus must be qualified with rx_valid. If wide_xface is set to 1'b1 (20-bit mode), bit 1 corresponds to the first word, and bit 0 corresponds to the second word. If wide_xface is set to 1'b0 (10-bit mode), only bit 0 is used. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** rx_ck **Override Ablility:** don't care

64.5.2.5 Common Signals

This section describes signals that are not replicated per transceiver. Common signals not included in this section are grouped into one of the following sections:

- JTAG Interface Signals
- Parallel CR Control Port Signals

Table 64-24. Common Signal Pins

Signal	I/O	Description
Related to MPLL or clocks		
• refclk_alt_p • refclk_alt_m	I	Alternate Reference Clock **Function:** Alternate reference clock inputs. If sample pads nor refclk_alt are not used, these pins can be left floating (they are pulled down internally). Delivery of a low-jitter reference clock (via refclk_alt_{p,m}) from the ASIC core is critical for meeting transmitter jitter specifications. If you are using the sample pads, connect these pins to refclk_alt_p and refclk_alt_m, respectively, in the Pad section. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** N/A **Override Ability:** none - application-specific; float or ground if unused

Table continues on the next page...

Table 64-24. Common Signal Pins (continued)

Signal	I/O	Description
use_refclk_alt	I	Alternate Reference Clock Control **Function:** Selects the MPLL inputs as an alternate reference clock. This signal must be static while mpll_ck_off is set to 1'b0. **Voltage Range:** 0 V-core voltage **Active State:** HIgh **Synchronous to:** N/A **Override Ablility:** 17-bit ATEOVRD JTAG register, and 18-bit CREG_OVRD register; JTAG override takes precedence
ref_clk_sel[7:0]	I	Reference Clock Frequency Select **Function:** Sets a fixed ppm offset to the MPLL output clock. • 8'd0 : No offset (Default) • 8'd1 to 8'd255 : Reserved. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
mpll_ck_off	I	Reference Clock Stop Enable **Function:** Disables the reference clock to the IP at the PHY's entry point. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ablility:** 17-bit ATEOVRD JTAG register, and 18-bit CREG_OVRD register; JTAG override takes precedence
mpll_pwron	I	MPLL Power-Up **Function:** Enables power to the MPLL. When this signal is set to 0, the cko_word clock is glitchlessly stopped low, unless refclk production at cko_word has been selected. When this signal is set to 1, the internal MPLL reset and locking is timed based on refclk, then the cko_word clock is restarted. Before turning off the MPLL, tx_en must be in the OFF or CM state, and rx_en and rx_pll_pwron must be set to 1'b0. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous; must not be transitioned again before the op_done signal indicates that the previous operation is complete **Override Ablility:** 17-bit ATEOVRD JTAG register, and 18-bit CREG_OVRD register; JTAG override takes precedence

Table continues on the next page...

Table 64-24. Common Signal Pins (continued)

Signal	I/O	Description
mpll_prescale[1:0]	I	MPLL refclk Prescaler Control **Function:** Controls the MPLL's refclk prescaler. • 00: ref_clk is used as is. • 01: ref_clk doubler is enabled. • 10: ref_clk is divided by 2. • 11: Reserved Transitions must occur only while mpll_ck_off is set to 1'b1. For information about using this signal, see mpll_prescale[1:0] and Valid refclk Range and Formulaic MPLL Settings. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** 17-bit ATEOVRD JTAG register, and 18-bit CREG_OVRD register; JTAG override takes precedence
mpll_ss_en	I	Spread Spectrum Enable **Function:** Enables spread spectrum clock production (0.5% downspread at ~ 31.5 kHz) in the SATA2 PHY. If the applied RefClk is already spread spectrum, mpll_ss_en must be deasserted. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
mpll_ss_sel[1:0]	I	Spread Spectrum Select **Function:** Selects frequency spread for the spread spectrum clock. • 00: 5,000 ppm • 01: 4,500 ppm • 10: 4,000 ppm • 11: 3,000 ppm **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction

Table continues on the next page...

Table 64-24. Common Signal Pins (continued)

Signal	I/O	Description
mpll_ncy[4:0]	I	MPLL x4 Multiplier **Function:** MPLL x4 multiplier. Valid refclk Range and Formulaic MPLL Settings provides a formulaic approach for setting the MPLL values. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous; must not be changed while MPLL is running **Override Ablility:** 17-bit ATEOVRD JTAG register, and 18-bit CREG_OVRD register; JTAG override takes precedence
mpll_ncy5[1:0]	I	MPLL x1 Multiplier **Function:** MPLL x1 multiplier. "Valid refclk Range and Formulaic MPLL Settings" on page 31 provides a formulaic approach for setting the MPLL values. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous; must not be changed while MPLL is running **Override Ablility:** 17-bit ATEOVRD JTAG register, and 18-bit CREG_OVRD register; JTAG override takes precedence
mpll_int_ctl[2:0]	I	MPLL Integral Bandwidth Control **Function:** Integral charge pump control. Must be set to 3'b000. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
mpll_prop_ctl[2:0]	I	MPLL Proportional Bandwidth Control **Function:** Proportional charge pump control. Must be set to 3'b111. Must be static except during a reset or when the MPLL is disabled. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
Related to generation of output clocks		

Table continues on the next page...

Table 64-24. Common Signal Pins (continued)

Signal	I/O	Description
cko_word	O	Output Clock Based on Reference Clock or MPLL Output **Function:** Output clock based on the reference clock or the MPLL output. The cko_word_con bus selects the clock output. This clock is held low when cko_word_con is set to 3'b1xx. The tx_ck signal that is provided to the SATA2 PHY must be a buffered version of this clock. While switching between the reference clock and the MPLL, word clock is performed glitchlessly. • 000: Buffered version of mpll_prescaler output • 001: Word-rate clock is produced (baud rate / 10 in Full-Rate mode or baud rate / 5 in Half-Rate mode) • 010: Two-word-rate clock is produced (baud rate / 20 in Full-Rate mode or baud rate / 10 in Half-Rate mode) • 1xx: Disabled. Zero output produced. **Voltage Range**: 0 V-core voltage **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** don't care
cko_word_con[2:0]	I	cko_word Output Select **Function:** Selects the clock to be driven on the cko_word output. Changing settings causes cko_word to transition from one clock to another glitchlessly. • 000: Buffered version of prescaler output clock • 001: MPLL frequency / 5 clock • 010: MPLL frequency / 10 clock • 1xx: Disabled **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
cko_alive	O	Keep-Alive Clock **Function:** Keep-alive clock based on the ref_clk prescaler output. This clock can be half or twice the reference clock's frequency based on the mpll_prescaler control. This low-rate clock can be set to always be available for circuitry that the ASIC needs to run continuously provided ref_clk is enabled. This signal is controlled by cko_alive_con[1:0]. **Note:** The cko_alive clock is not suitable as a reference clock for other cores. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** don't care

Table continues on the next page...

Table 64-24. Common Signal Pins (continued)

Signal	I/O	Description
cko_alive_con[1:0]	I	cko_alive Output Select **Function:** Selects the clock to be driven on the cko_alive output. Changing settings causes cko_alive to transition from one clock to another glitchlessly. • 00: Output is disabled • 01: Prescaler output • 10: Prescaler output / 16 (very-low-speed clock) • 11: Reserved **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
Related to resistor tuning		
rtune_do_tune	I	Do Resistor Tune **Function:** Rising edge triggers a resistor calibration. When the operation is complete, the op_done pin is transitioned. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous; must be held high for at least two cko_word cycles. **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
Analog controls		

Table continues on the next page...

Table 64-24. Common Signal Pins (continued)

Signal	I/O	Description
tx_lvl[4:0]	I	Transmit Level **Function:** Fine resolution setting of transmit signal level, common to all lanes connected to one Clock module. • 00000: 0.937 V • 00001: 0.947 V • 00010: 0.957 V • 00011: 0.966 V • 00100: 0.976 V • 00101: 0.986 V • 00110: 0.996 V • 00111: 1.005 V • 01000: 1.015 V • 01001: 1.025 V • 01010: 1.035 V • 01011: 1.045 V • 01100: 1.054 V • 01101: 1.064 V • 01110: 1.074 V • 01111: 1.084 V • 10000: 1.094 V • 10001: 1.104 V • 10010: 1.113 V • 10011: 1.123 V • 10100: 1.133 V • 10101: 1.143 V • 10110: 1.152 V • 10111: 1.162 V • 11000: 1.172 V • 11001: 1.182 V • 11010: 1.191 V • 11011: 1.201 V • 11100: 1.211 V • 11101: 1.221 V • 11110: 1.230 V • 11111: 1.240 V Peak-peak output level (without attenuation) is: 1.24 x (48 + tx_lvl / 2) / 63.5 V. Setting the maximum Tx amplitude to greater than 1 V peak-to-peak differential results in overdrive (applying 1.2 V) to the thin-gate output transistors. For the recommended setting, see Recommended Tx Settings.

Table continues on the next page...

Table 64-24. Common Signal Pins (continued)

Signal	I/O	Description
		Voltage Range: 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
os_lvl[4:0]	I	LOS Detection Threshold Control **Function:** Controls LOS detection threshold. For the recommended los_lvl setting, see Recommended Rx Settings. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
acjt_lvl[4:0]	I	ACJTAG Receiver Comparator Level Control **Function:** Controls the ACJTAG receiver comparator level. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
fast_tech	I	Fast Technology Flag **Function:** IP is processed in one of the faster process variants. This signal must be set to 1'b0. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** N/A **Override Ablility:** 17-bit ATEOVRD JTAG register, and 18-bit CREG_OVRD register; JTAG override takes precedence
vp_is_1p2	I	Low-Voltage Supply Setting **Function:** Specifies the voltage level of the low-voltage supply. This signal must be set to 1'b0. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** N/A **Override Ablility:** 17-bit ATEOVRD JTAG register, and 18-bit CREG_OVRD register; JTAG override takes precedence

Table continues on the next page...

Table 64-24. Common Signal Pins (continued)

Signal	I/O	Description
vph_is_3p3	I	High-Voltage Supply Setting **Function:** Specifies the voltage level of the high-voltage supply. This signal must be set to 1'b0. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** N/A **Override Ablility:** 17-bit ATEOVRD JTAG register, and 18-bit CREG_OVRD register; JTAG override takes precedence
Digital controls		
op_done	O	Operation Complete Indicator **Function:** Indicates that the requested operation is complete by transitioning in either direction. Operations that generate a transition of op_done include: • mpll_pwron assertion: Transitions after the MPLL is operating and is at the correct frequency. If enabled and based on the MPLL, cko_word starts toggling before op_done transitions. • mpll_pwron deassertion: Asynchronously transitions after cko_word is suspended. • rtune_do_tune assertion: Transitions when resistor tuning is complete. • reset deassertion: Transitions when resistor tuning and MPLL power-up is complete. If one of these operations is in progress, the next operation must not be triggered until op_done transitions. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register; JTAG override takes precedence
power_good	O	Power Supply Valid Indicator **Function:** Indicates that the analog, digital, and I/O power supplies have all reached 80% of their respective nominal values, provided the low supply is powered up first. If the high supply is powered up first, do not use this pin as an indicator. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register; JTAG override takes precedence
reset_n	I	Reset **Function:** Reset signal. Resets all registers in the SATA2 PHY to their default value. Holding reset_n low holds the SATA2 PHY in a reset state. **Voltage Range:** 0 V-core voltage **Active State:** Low **Synchronous to:** Asynchronous; must be held low for a minimum of 5 ns **Override Ablility:** 17-bit ATEOVRD JTAG register

Table continues on the next page...

Table 64-24. Common Signal Pins (continued)

Signal	I/O	Description
wide_xface	I	Wide Interface Enable **Function:** When this signal is asserted, the Tx and Rx data interfaces are 20 bits wide and rx_ck is (and tx_ck must be) periodic in 20-bit intervals. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
dtb_out[1:0]	O	Debug Test Bus Output **Function:** Routes internal signals to external pins. This bus can be ignored or to aid characterization-multiplexed to high-speed output drivers. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** don't care
Test controls		
test_byp_mode	I	Test Bypass Mode **Function:** This signal sets up the ASIC interface so that all inputs are connected to outputs through a purely combinatorial path. Use this signal to enhance test coverage of the SATA2 PHY/ASIC interface. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ability:** none - hold at 0 for test
test_burnin_mode	I	Test Burn-In Mode **Function:** Enables the SATA2 PHY to toggle as much circuitry as possible and to bias unused circuitry so that devices do not degrade asymmetrically. Use this signal in burn-in testing in conjunction with the test_byp_mode signal. When this pin is asserted, no other clocks are necessary, the external signal pins may be floated, and the ASIC-side signal pins do not matter. However, it is recommended to externally loop the transmitter back to the receiver through the appropriate DC blocking capacitors. This ensures that the receiver circuitry also toggles. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ability:** none - hold at 0 for test

Table continues on the next page...

Table 64-24. Common Signal Pins (continued)

Signal	I/O	Description
test_pddq	I	Test IDDQ **Function:** Powers down all circuitry for IDDQ testing. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ability:** none - hold at 0 for test

64.5.2.6 JTAG Interface Signals

The SATA2 PHY provides a JTAG interface that is compliant with *IEEE Std 1149.1*.

The table below describes the interface signals.

ATE and bench characterization features are accessed through internal registers using either the JTAG interface or Parallel CR Control port. Normal PHY startup and operation do not require using the JTAG interface.

Table 64-25. JTAG Signals

Signal	I/O	Description
tck	I	JTAG Clock **Function:** JTAG interface clock. Maximum frequency is 35 MHz. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** N/A **Override Ablility:** none; used for ATE testing
tms	I	JTAG State Machine Control **Function:** JTAG test mode select pin **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** tck **Override Ablility:** none; used for ATE testing
tdi	I	JTAG Data Input Port **Function:** JTAG test data input pin **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** tck **Override Ablility:** none; used for ATE testing

Table continues on the next page...

Table 64-25. JTAG Signals (continued)

Signal	I/O	Description
tdo	O	JTAG Output Port Data Value **Function:** JTAG test data output pin **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** tck **Override Ablility:** don't care
tdo_en	O	JTAG Output Enable **Function:** JTAG test data output enable pin. For compliance with the JTAG specification, the ASIC's test data out (TDO) output must be tri-stated when tdo_en is low. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** tck **Override Ablility:** don't care

64.5.2.7 Parallel CR Control Port Signals

ATE and bench characterization features are accessed through internal registers using either the JTAG interface or Parallel CR Control port. Normal PHY startup and operation do not require using the Parallel CR Control port.

Table 64-26. Parallel CR Control Port

Signal	I/O	Description
cr_data_in[15:0]	I	CR Address and Write Data Input **Function:** Supplies and captures address and write data. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous **Override Ablility:** none - don't care when not performing CR operation
cr_data_out[15:0]	O	CR Data Output **Function:** Always presents last read data. **Voltage Range:** 0 V-core voltage **Active State:** N/A **Synchronous to:** Asynchronous **Override Ablility:** don't care

Table continues on the next page...

Table 64-26. Parallel CR Control Port (continued)

Signal	I/O	Description
cr_cap_addr	I	CR Capture Address **Function:** Captures cr_data_in into the Address register. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
cr_cap_data	I	CR Capture Data **Function:** Captures cr_data_in into the wrdata register. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
cr_write	I	CR Write **Function:** Writes the wrdata register to the referenced Address register. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
cr_read	I	CR Read **Function:** Reads from the referenced Address register. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ablility:** 18-bit CREG_OVRD register accessed using crsel instruction
cr_ack	O	CR Acknowledgement **Function:** Acknowledgement for the cr_cap_addr, cr_cap_data, cr_write, and cr_read control signals. **Voltage Range:** 0 V-core voltage **Active State:** High **Synchronous to:** Asynchronous **Override Ablility:** don't care

64.6 Timing and Specifications

64.6.1 SATA2 PHY Implementation-Specific Timing

The table below describes the timings for a standalone SATA2 PHY.

Table 64-27. SATA2 PHY Implementation-Specific Timing

Name	Description	Value
Transmit latency	Measured from when the 10-bit data is sampled to when the first word bit is serially transmitted.	22-24 bit times
Transmit latency	Measured from when the 10-bit data is sampled to when the last word bit is serially transmitted.	• 10-bit wide interface: 31-33 bit times • 20-bit wide interface: 41-43 bit-times
Receive latency	Measured from when the first bit of a 10-bit word is received to when the 10-bit word is available to be sampled at the ASIC interface. Alignment can be turned off.	• 10-bit wide interface: 31-40 bit times • 20-bit wide interface: 41-50 bit times
Receive latency	Measured from when the last bit of a 10-bit word is received to when the 10-bit word is available to be sampled at the ASIC interface. Alignment can be turned off.	22-31 bit times
refclk spin-up latency	Time from deassertion of a reset (assuming mpll_ck_off is deasserted) or deassertion of mpll_ck_off to when the reference clock is available for the MPLL and cko_alive.	< 1.65 µs (or 31 µs if refclk doubler is used)
MPLL lock latency	Time from assertion of mpll_pwron (assuming refclk is on and stable) to when the MPLL is ready and cko_word begins toggling.	< 41 µs
Resistor tuning	Time to perform a resistor tune	2 µs
Receive PLL lock latency	Time from assertion of rx_pll_pwron (assuming the MPLL is ready) to when rx_pll_state is asserted. Does not require incoming data transmission.	9 µs
Receive CDR lock time	Time from end of loss of signal or assertion of rx_en to assertion of rx_valid. These are worst- case values; nominal lock times might be shorter. Assuming 30 kHz minimum frequency spread spectrum clocking. Non-spread spectrum receiver lock will be significantly shorter.	37 µs
Transmit enable latency	Time from tx_en change to serial lines leaving common mode.	• CM to ON: 300 ns • CM_CLK to ON: Same as transmit latency
LOS detection latency	For information about loss of signal detection, see Loss of Signal Detection.	20 ns

64.6.1.1 Synchronous Tx Inputs

The Tx input, tx_data, is clocked into the Tx block at the rate of either baud / 10 or baud / 20 (based on the wide_xface setting) with a source-synchronous clock, tx_ck (that must be derived from either tx_cko_word or cko_word).

The figure below shows timing for the Tx inputs.

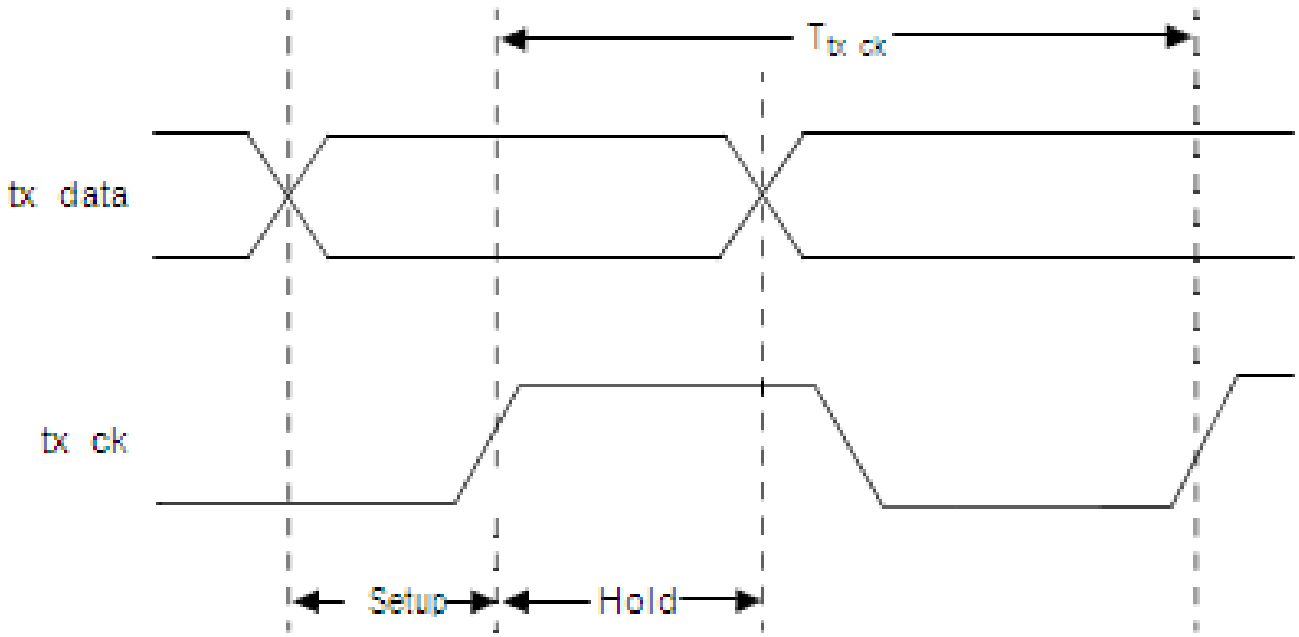

Figure 64-4. Parallel Input Tx Timing

64.6.1.2 Synchronous Rx Outputs

The Rx output data, rx_data, is generated with the rising edge of rx_ck (that has a Trx_ck of either 10 or 20 baud based on wide_xface). The data is stable based on the rising edge of this clock.

The figure below shows timing for the Rx outputs.

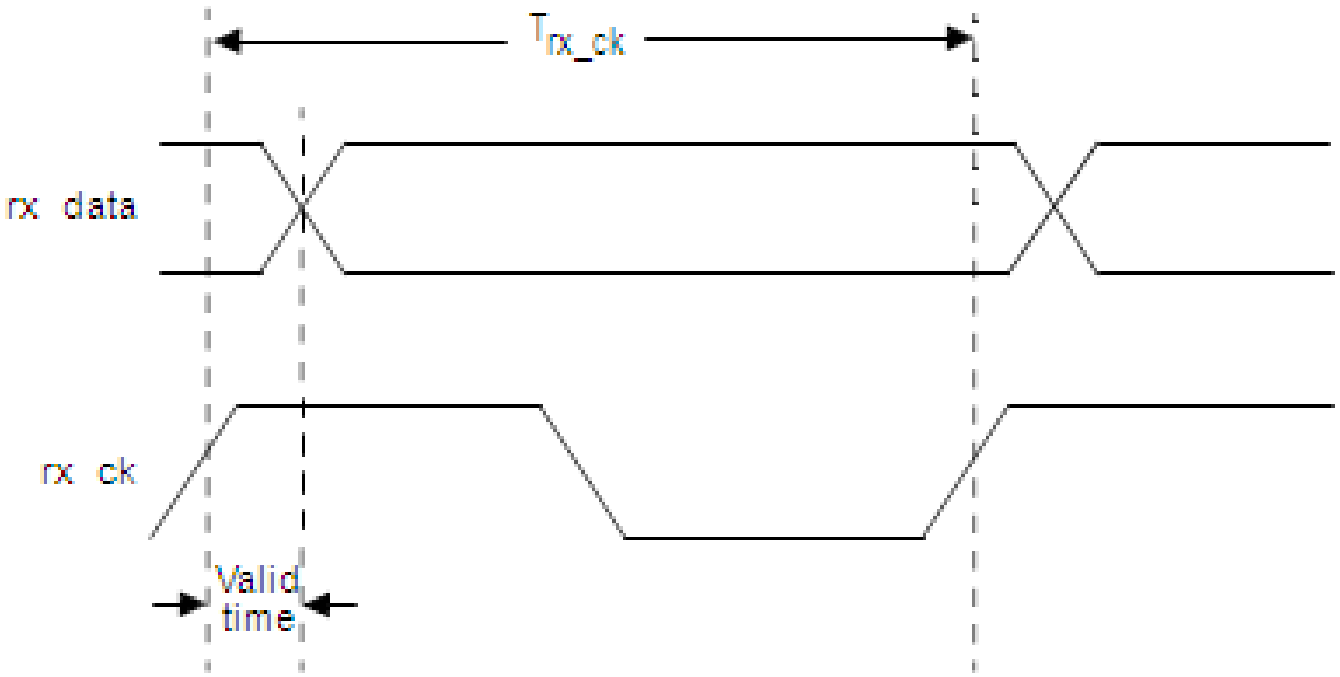

Figure 64-5. Parallel Output Rx Timing

64.6.1.3 Asynchronous Tx and Rx I/O

There are no static timing requirements for inputs or outputs noted as asynchronous in Table 64-23. The inputs take a short time to propagate to the associated circuitry that they control. Signals that do not have restrictions specified in Table 64-23 have no high or low pulse-width requirements. All outputs must be either synchronized before using or sampled appropriately for the pin's function.

64.6.1.4 Control Register Bus Interface

Timing of the Parallel Control Register bus is accomplished with a standard four-phase asynchronous handshake using the four CR request lines and the cr_ack signal.

For information about using this interface, see Parallel CR Control Port Testing.

Because the interface is asynchronous, it does not need to be timed with a static timing tool. There is zero setup time from cr_data_in[15:0] to the rising edge of cr_cap_{addr, data}. There is zero hold time from the rising edge of cr_ack to cr_data_in[15:0].

64.6.1.5 JTAG Interface Timing

The JTAG interface complies with interface pin timings as defined in the JTAG specification; therefore, you should not have timing issues interfacing this port with other internal or external JTAG implementations.

The tck clock signal has a maximum frequency of 35 MHz, but no minimum frequency. This clock can be stopped at any point without loss of state. The figure below shows timing for the JTAG interface.

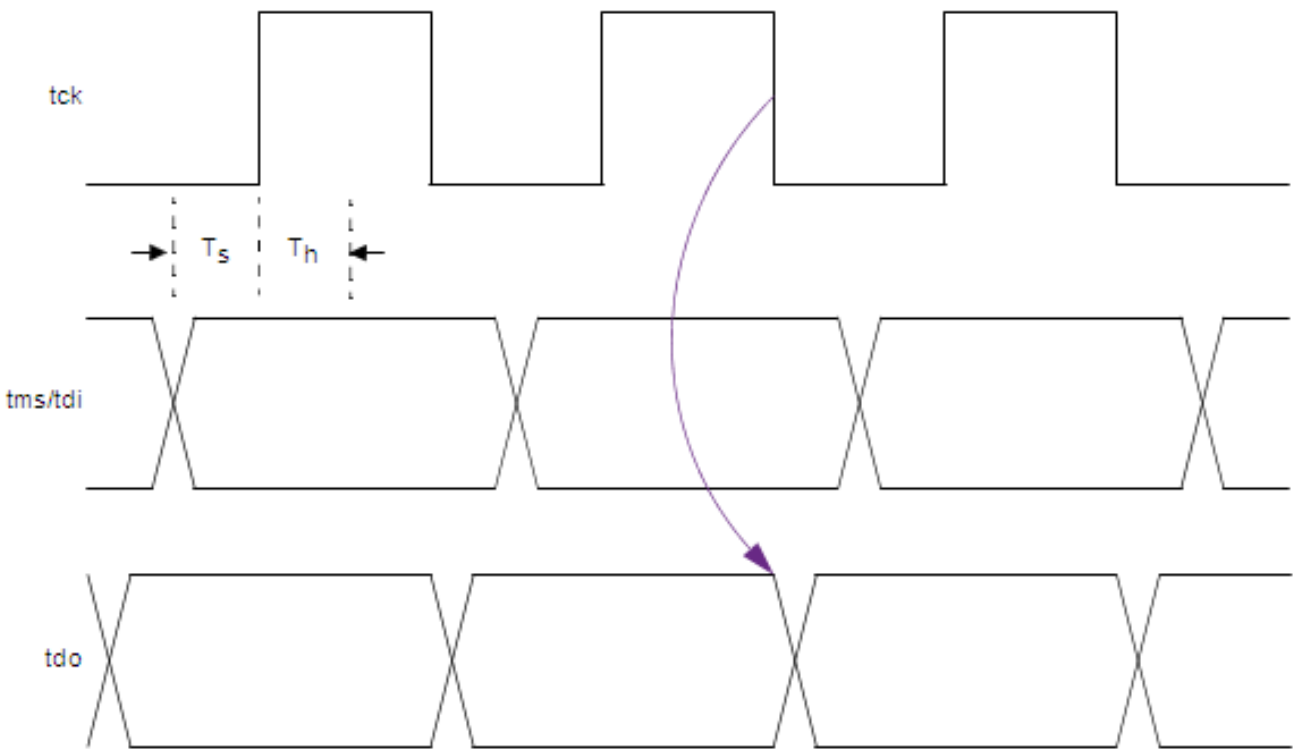

Figure 64-6. JTAG Interface Timing

NOTE

Setup (Ts) and hold (Th) times for tms and tdi are defined in the .lib files. The tdo signal transitions on the falling edge of tck.

The maximum frequency of operation for the JTAG port is 35 MHz. For detailed timing information, refer to the .lib files in the database deliverables.

If you are using the JTAG interface for off-chip connections, you must instantiate appropriate Low Voltage Transistor-Transistor Logic (LVTTL) input buffers in the ASIC for the JTAG inputs. To drive the tdo pin in compliance with the JTAG specification, you must also instantiate a tri-state output buffer.

64.6.2 Silicon Testing

This section describes SATA2 PHY interfaces and features that can be used in silicon testing.

64.6.2.1 Boundary Scan Port

The Boundary Scan port on the SATA2 PHY enables any ASIC using the macro to be fully compliant with the 1149.1-2001 and 1149.6-2003 standards.

The SATA2 PHY contains scannable, sequential elements to support ACJTAG and boundary scan. These elements are connected in a scan chain and made available on the ASIC interface. Concatenate this scan chain with any other scan chains on the ASIC.

64.6.2.1.1 Per-Lane Block Diagram

The figure below shows the Boundary Scan circuitry included in each lane. The signals to control the Boundary Scan circuitry are derived from the Scan Port interface pins. There are no boundary scan cells in the Clock module.

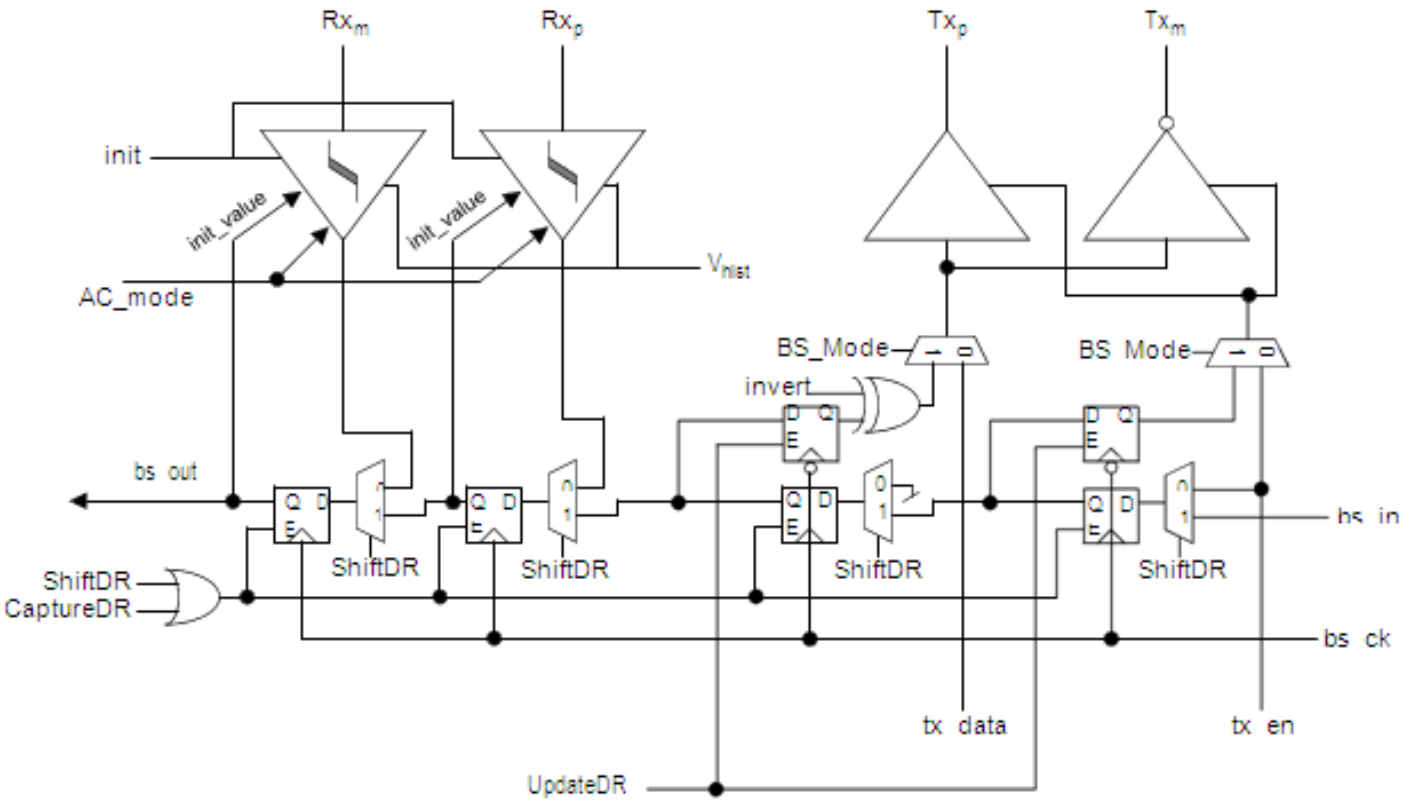

Figure 64-7. Per-Lane ACJTAG Details

The following figures show the function of the comparator associated with the receive pins shown in the previous figure.

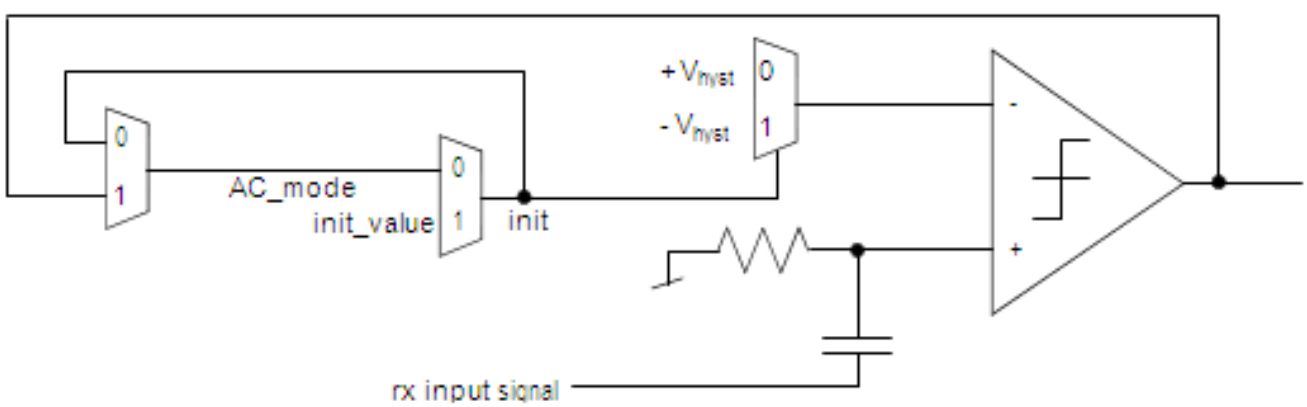

Figure 64-8. Comparator in AC mode

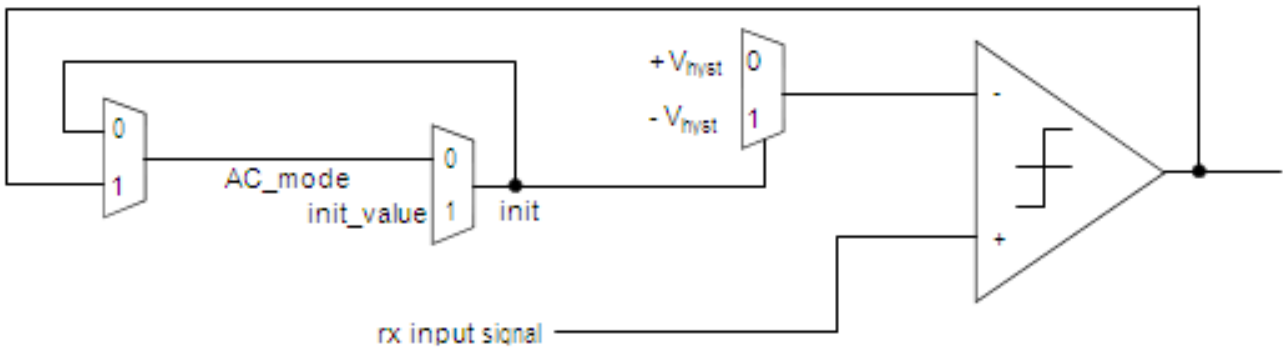

Figure 64-9. Comparator in DC mode

64.6.2.2 JTAG Interface Silicon Testing

The SATA2 PHY's JTAG interface provides access to an internal TAP controller implementing 1149.6-2003- compliant IDCODE and USERCODE instructions.

In addition, the CRSEL instruction is available for writing and reading registers in the SATA2 PHY. This instruction provides access to features available for bench characterization and ATE (manufacture) testing. Read and/or write register access for normal operations is neither necessary nor recommended.

64.6.2.2.1 Interface Options

The SATA2 PHY's JTAG interface excludes the optional TRSTb reset pin as defined in the 1149.6-2003 specification.

64.6.2.2.2 Resets

Entry into the TEST-LOGIC-RESET state clears the IR register and DR-shift register; no other registers are affected.

Note that due to the JTAG state machine's topology, TEST-LOGIC-RESET is entered regardless of the JTAG machine's current state-by clocking in at least five consecutive 1s on TMS.

After a power-on reset, TEST-LOGIC-RESET is the default state for the JTAG state machine.

64.6.2.2.3 IR Codes

The table below lists the supported JTAG instructions. The least-significant bit (LSB) of the IR and DR registers is the first bit shifted into TDI.

Table 64-28. Supported JTAG Instructions

Instruction	IR	DR	Operation
BYPASS	All others	1 bit	TDI to TDO bypass (bit is preloaded to 1)
IDCODE	8'h01	32 bits	Shift out ID Code
USERCODE	8'h0d	32 bits	Shift out USER Code
CRSEL	8'h31	18 bits	Control register access (see Control Register Operations)
DSCAN	8'h51	TBD bits	MUX-D scan testing
ATEOVRD	8'h5d	17 bits	Override reset, MPLL settings, and technology-specific parameters

64.6.2.2.4 ID Code

The table below provides the 32-bit JTAG ID code for the SATA2 PHY.

Table 64-29. JTAG ID for the SATA2 PHY

Bit Range	Signal	Value
31:16	ID_VAL_HI	1017
15:0	ID_VAL_LO	74CD

64.6.2.2.5 USER Code

The 32-bit JTAG USER code reflects the hard-wired programming of the SATA2 PHY in an ASIC. Various bits reflect the status of ASIC interface pins defined in Per-Transceiver Control and Status Signals. The table below provides the register mapping for the USER code.

Table 64-30. JTAG USERCODE

Bit Range	Signal
31:0	000, use_refclk_alt, mpll_prescale[1:0], mpll_ncy[4:0], mpll_ncy5[1:0], wide_xface, fast_tech, vp_is_1p2, vph_is_3p3, tx_lvl[4:0], los_lvl[4:0], acjt_lvl[4:0]

64.6.2.2.6 Control Register Operations

Internal registers can be accessed through the JTAG interface when operating with the CRSEL instruction (for a list of supported JTAG instructions, see Table 64-28).

The JTAG controller implements two shadow registers that access the macro's register space: an address register (Addr_reg) and data register (Data_reg).

Addr_reg is loaded with the address of the register to be accessed. Data_reg holds data to be written to or data that has been read from the addressed register. Four operations involving Addr_reg and Data_reg and the reading and writing of registers are performed with the shifting of 18 bits (16 bits of data or address and 2 bits of opcode) through the DR scan path of the JTAG state machine. The first 16 bits that are shifted out when in Shift-DR are the current contents of the Data_reg register for any operation (before the register read occurs).

Data_reg is also updated with the 16 bits of address or data shifted in as part of one of the following operations.

- Address (op = 2'b00): Addr_reg and Data_reg are loaded with the 16 bits of address shifted in.
- Write (op = 2'b01): Data_reg is loaded with the 16 bits of data shifted in. The register addressed by the contents of Addr_reg is written with this value.
- Read (op = 2'b11): Addr_reg is loaded with the 16 bits of address shifted in. A read of the register addressed by the contents of Addr_reg is initiated. The read data is latched into Data_reg with the passing through of the Capture-DR state. Therefore, a subsequent operation is required to shift out the read data.
- Data (op = 2'b10): This No Operation (NOP) operation can be used to shift out the current contents of Data_reg (for example, after a read operation). Data_reg is consequently loaded with the 16 bits shifted in.

NOTE

A standalone register read requires two passes down the DR scan path to actually do the read and retrieve the data. However, the second pass can be overlapped or effectively pipelined with a subsequent operation.

64.6.2.2.7 JTAG Override Register (jtag_ovrd)

Reset, MPLL controls, and technology-specific parameters can be overridden using the JTAG interface.

The Instruction register (ATEOVRD)-at JTAG IR address 8'h5d-enables the JTAG Override register to be written to

Reset Value: 17'b0 0000 0000 0000 0000

Table 64-31. JTAG Override Register (jtag_ovrd)

Field Name	Bits	Description
jtag_ovrd	0	JTAG override. Enables control of this register. Active high.
reset	1	Reset override. Active high.
mpll_ck_off	2	Reference clock stop enable override. Active high.
mpll_pwron	3	MPLL power-on override. Active high.
use_refclk_alt	4	Alternate reference clock control override. Active high.
mpll_prescale	6:5	Reference clock prescaler control override. For more information, see the mpll_prescale[1:0] signal description in Table 64-24.
mpll_ncy	11:7	MPLL x4 multiplier override. For more information, see the mpll_ncy[4:0] signal description on Table 64-24.
mpll_ncy5	13:12	MPLL x1 multiplier override. For more information, see the mpll_ncy5[1:0] signal description on Table 64-24.
fast_tech	14	Fast technology flag override. For more information, see the fast_tech signal description on Table 64-24.
vp_is_1p2	15	Low-voltage supply is 1.2-V override. For more information, see the vp_is_1p2 signal description on Table 64-24.
vph_is_3p3	16	High-voltage supply is 3.3-V override. For more information, see the vph_is_3p3 signal description on Table 64-24.

64.6.2.3 Parallel CR Control Port Testing

ATE and bench characterization features are accessed through internal registers via the JTAG interface or Parallel CR Control port. Normal SATA2 PHY startup and operation do not require the use of neither the JTAG interface nor the Parallel CR Control port.

The Parallel CR Control port comprises two internal registers (Address and Data) as well as control signals to manipulate these registers and to use them to perform control register reads and writes. The cr_data_in signal can be used to write to either the Address or Data register (depending on the control signals). The cr_data_out signal is always the Data register's output.

Communicating with the control port itself is accomplished with a standard four-phase asynchronous handshake using the four CR request lines and the cr_ack signal.

This protocol can be summarized by the following sequence.

1. The ASIC waits until the cr_ack signal is deasserted from a previous operation. At this point, all request signals are deasserted.

2. The ASIC sets up data on cr_data_in (if necessary) and asserts the target request signal.

3. After capturing the data and completing the requested operation, the SATA2 PHY sets up data on cr_data_out (if necessary) and asserts the cr_ack signal.

4. After capturing data from cr_data_out (if necessary), the ASIC deasserts the request signal.

5. The SATA2 PHY deasserts the cr_ack signal to indicate that the SATA2 PHY is ready for the next request.

64.6.2.3.1 Addressing

Before reading or writing a register, an address must be supplied and latched into the port's Address register.

This transaction requires the following steps.

1. Supply the address on cr_data_in[].

2. Assert the cr_cap_addr signal.

3. Wait for the cr_ack signal to be asserted.

4. Deassert cr_cap_addr.

5. Wait for cr_ack to be deasserted.

The following figure shows timing for this transaction.

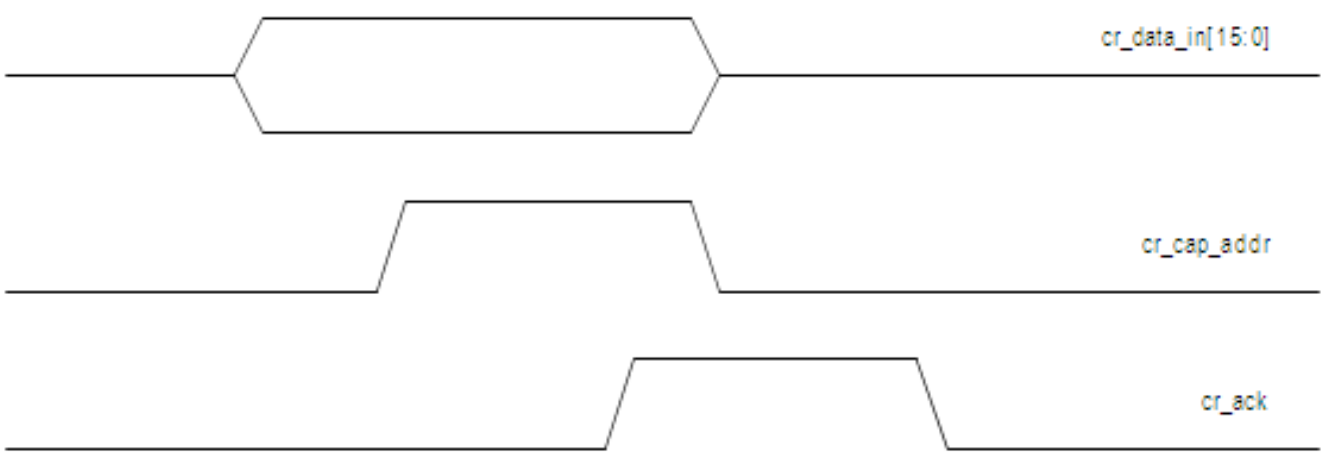

Figure 64-10. Capture Address Transaction (Precedes Read or Write)

64.6.2.3.2 Register Write

Writing to an internal register requires providing the write data and latching it into the port's Data register, then executing the write itself.

This transaction requires the following steps.

1. Supply the data on cr_data_in[].
2. Assert the cr_cap_data signal.
3. Wait for the cr_ack signal to be asserted.
4. Deassert cr_cap_data.
5. Wait for cr_ack to be deasserted.
6. Assert the cr_write signal.
7. Wait for cr_ack to be asserted.
8. Deassert cr_write.
9. Wait for cr_ack to be deasserted.

The following figure shows timing for this transaction.

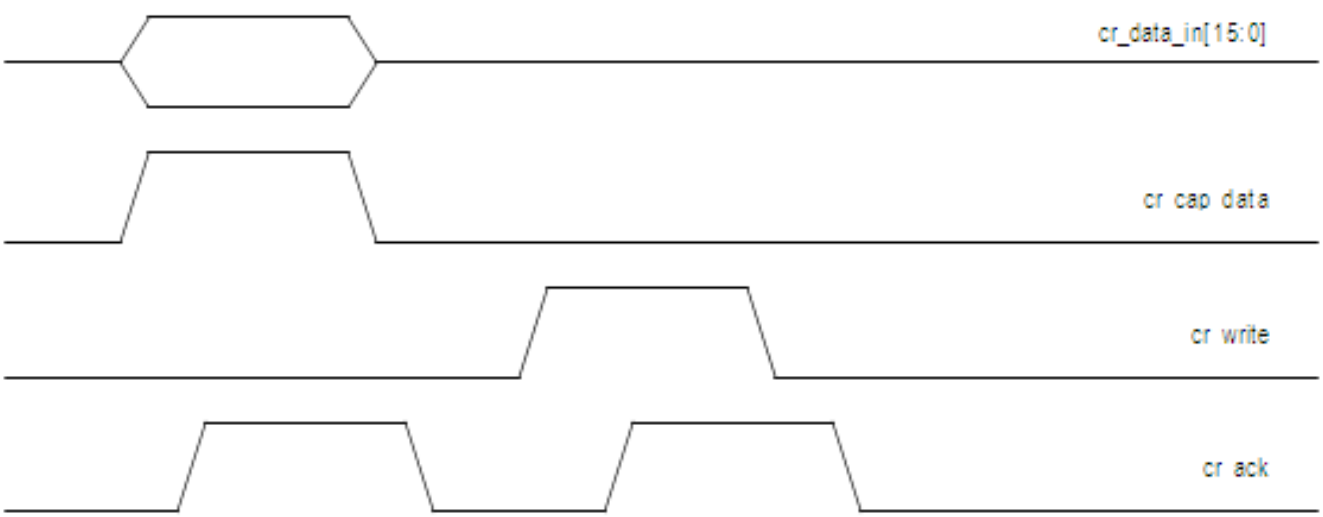

Figure 64-11. Write Transaction

64.6.2.3.3 Register Read

Reading from an internal register requires the following steps (to latch the read value into the port's Data register).

1. Assert the cr_read signal.
2. Wait for the cr_ack signal to be asserted.
3. Capture the data from cr_data_out[].
4. Deassert cr_read.
5. Wait for cr_ack to be deasserted.

The figure below shows timing for this transaction.

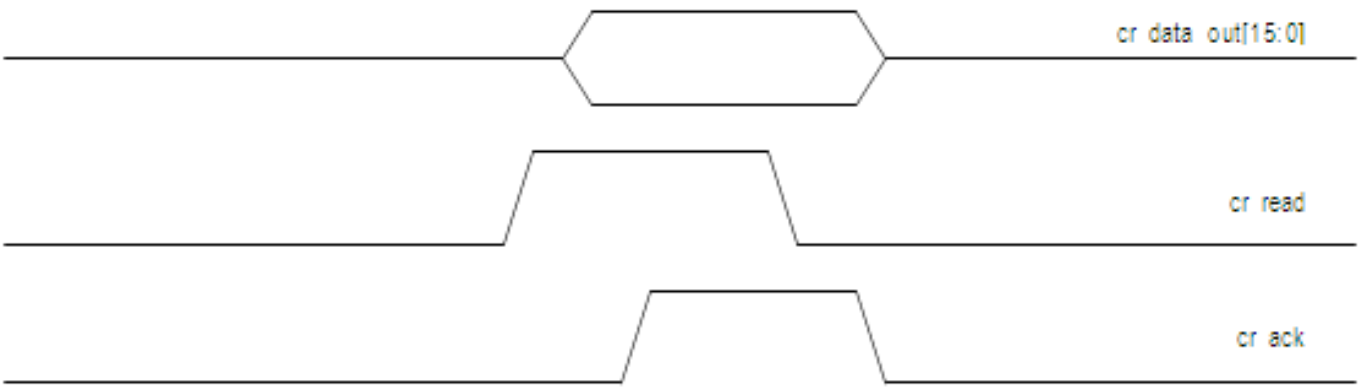

Figure 64-12. Read Transaction

64.6.2.4 Diagnostic Features

The SATA2 PHY provides the following diagnostic features to enhance bench characterization and ATE testing.

- Loopback functions:
- Digital serial loopback
- Serial loopback for wafer probe only
- For information about the loopback functions, see Loopback Functions.
- Asynchronous operation in a synchronous test environment for enhanced coverage of functional tests: For information about asynchronous operation, see Asynchronous Operation.
- BERT independent per lane:
- 7th- and 15th-order polynomial pattern generation and recognition
- Generation of simple test patterns
- Byte error counting from polynomial pattern
- For information about the BERT, see Byte Error Rate Tester.
- Margining:

- Voltage margining with 10-bit resolution, synchronous or asynchronous operation
- Phase margining with sub-ps resolution, synchronous or asynchronous (when number of lanes is greater than one)
- For information about margining, see Margining.
- High-resolution scope per Rx signal pair:
- Acquisition of eye or signal from 7th- or 15th-order polynomial patterns
- For information about scope function, see Scope Function.
- Analog DC test:
- Signal selection matrix embedded in the SATA2 PHY
- 10-bit A/D converter
- Selection and measurement of any individual Rx and Tx termination resistors
- For information about the SATA2 PHY's analog DC test capabilities, see Analog DC Test Capabilities.
- Limit testing:
- Specification of high/low limits
- Determination of whether register read was within limits
- Determination of whether difference between register read values was within limits
- For information about limit testing, see Limit Testing.
- Integrated test modes:
- Bypass test mode
- Burn-in test mode
- IDDQ test mode
- For information about the SATA2 PHY's integrated test modes, see Integrated Test Modes.
- Temperature monitor:
- Real-time die temperature
- No extra pins required, access is through JTAG interface or Parallel CR Control port.
- For information about the temperature sensor, see Temperature Sensor.

64.6.2.4.1 Loopback Functions

The figure below depicts the SATA2 PHY's loopback functions.

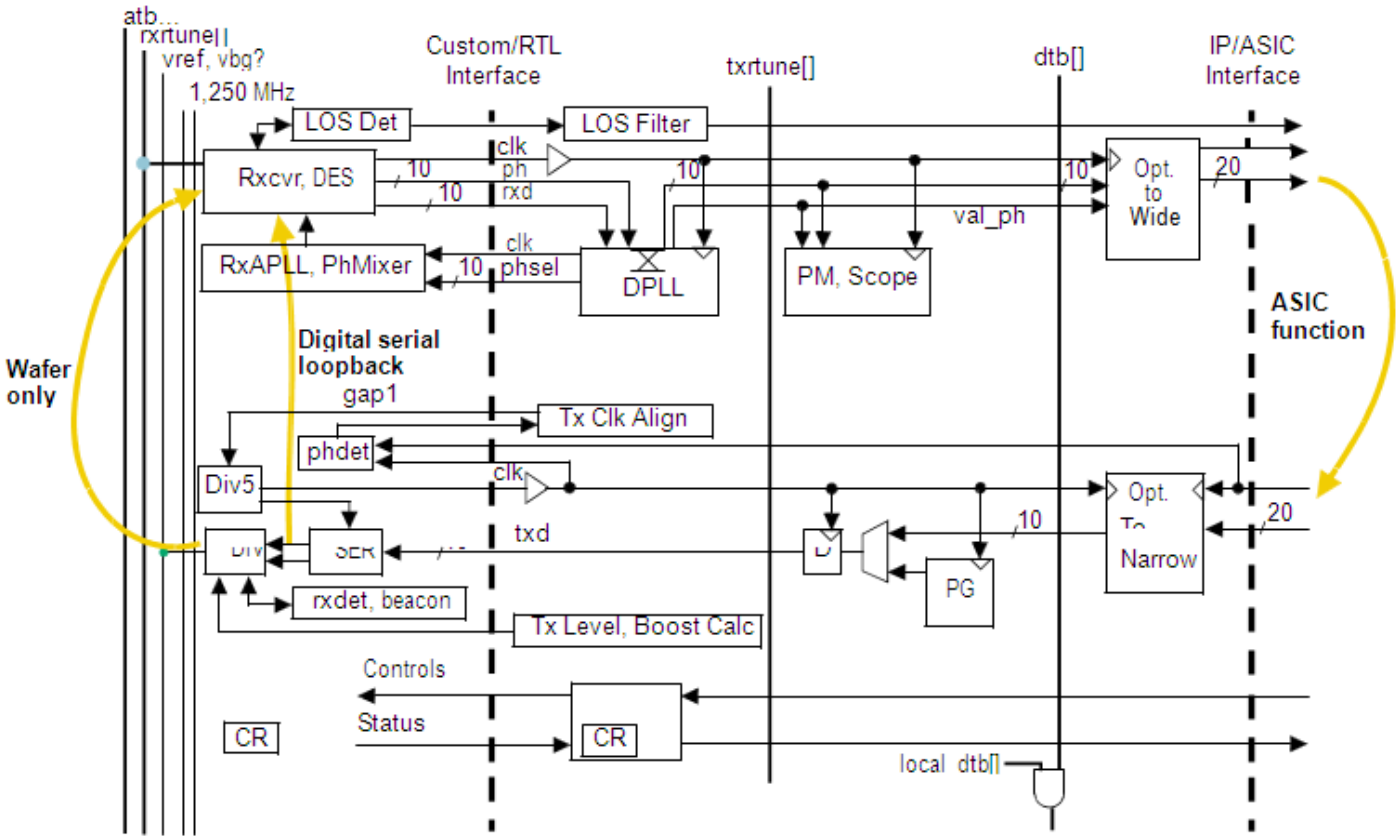

Figure 64-13. Loopback Functional Diagram

64.6.2.4.1.1 Rx-to-Tx Parallel Data Loopback

This loopback function must be provided by the ASIC.

64.6.2.4.1.2 Tx-to-Rx Digital Serial Data Loopback

This loopback function selects serial data located just before the Tx driver and inserts the data into the Rx just after the first stage of the receiver.

This function enables verification of the entire datapath, except for actual output drivers and the Rx's first stage. This loopback function is useful for testing the ASIC and is activated by asserting the rxlbi_en field in the Receive Analog Control register (lanej.rx_ana.ctrl), as indicated in Receive Analog Control Register (lane0_RX_ANA_CONTROL).

64.6.2.4.1.3 Tx-to-Rx Serial Analog Loopback

This loopback function is intended to be used only in manufacturing test at wafer probe. Without wafer probes landing on the Tx or Rx serial differential pads, this loopback function tests the entire transceiver at wafer test, where providing loopback traces with sufficient signal integrity through a probe card is typically impossible.

This loopback function is activated by asserting the rxlbe_en field in the Receive Analog Control register (lanej.rx_ana.ctrl.rxlbe_en), as indicated in Receive Analog Control Register (lane0_RX_ANA_CONTROL).

Using this loopback function with typical packaged parts (even without connections to the Tx and Rx serial differential pins) would provide too much parasitic capacitance loading to enable operation at speed.

64.6.2.4.1.4 Full Analog Loopback for In-Package ATE Test

This loopback function requires the use of loopback traces in the ATE load board.

64.6.2.4.2 Asynchronous Operation

ATE test environments are typically synchronous, where only a single reference clock is available.

In addition, when loopbacks (internal to the PHY or wired into a package load board) are used in production test, only a single Clock module is typically part of the test setup; therefore, only synchronous operation is possible. However, a variety of circuit defects can exist that might have little or no effect on CDR operation when operating synchronously.

The SATA2 PHY addresses this coverage gap for multi-lane PHYs. Each pair of lanes is interconnected with the ability to use the recovered clock of the other member of a pair as reference for receive CDR.

One member (master) of the pair of lanes is programmed to ignore the received signal and produce a specified frequency offset by a specified number of ppm from the actual reference clock. The other member (slave) of the pair uses the synthesized offset clock as reference.

While receiving data synchronous to the actual reference clock, the slave's CDR must constantly slew to maintain a fixed recovered clock phase despite the offset frequency of the slave's reference. This task exercises the slave's DPLL and phase mixer in the same way they would operate during normal, asynchronous operation. Margining tests performed under this condition reveal any defects in the slave's CDR.

64.6.2.4.3 Byte Error Rate Tester

The Byte Error Rate Tester (BERT) comprises two independently programmed modules: a pattern generator and a pattern matcher/error counter.

64.6.2.4.3.1 BERT Pattern Generator

The following table provides a list of patterns that can be generated with the built-in pattern generator.

Table 64-32. Pattern Generator mode[2:0] Control

mode[2:0]	Description
000	Pattern generator is disabled.
001	15th order polynomial: $X^{15} + X^{14} + 1$
010	7th order polynomial: $X^7 + X^6 + 1$
100	Fixed 8- or 10-bit pattern from bottom of PAT0 field
101	2-byte DC balanced pattern constructed as {PAT0, ~PAT0}
111	4-byte DC balanced pattern constructed as {0x000, PAT0, 0x3FF, ~PAT0}

64.6.2.4.3.2 BERT Pattern Matcher and Error Counter

The pattern matcher is capable of synchronizing to and detecting errored bytes in multiple types of patterns. Errored bytes are counted in the error counter.

Note that there is no dependence on the pattern generator in the same lane. That pattern generator does not need to be enabled nor programmed for the same pattern.

The following table describes the mode[2:0] field, which selects the expected pattern and operating mode.

Table 64-33. mode[2:0] Control of the Pattern Matcher

mode[1:0]	Description
000	Disabled
001	lfsr15
010	lfsr7
011	d[n] = d[n-10]
100	d[n] = !d[n-10]
101	Reserved
110	Reserved
111	Reserved

NOTE

When using either the LFSR7 or LFSR15 pattern, the rx_align_en needs to be de-asserted at the pin or through the register override.

For modes 1 and 2, the pattern matcher operates by generating the expected pattern and synchronizing the generated pattern to the incoming pattern. Synchronization and error counting are initiated by asserting and deasserting the sync bit. Therefore, during synchronization in high-error-rate conditions, synchronization can fail if an error occurs during the last 15 bits prior to clearing of the sync bit.

The error counter is 22 bits wide.

The contents are presented according to these rules:

- When the contents are less than 2^{15}, the bottom 15 bits are presented in the count field and the ov14 field is cleared.
- When the contents are greater than 2^{22} but less than or equal to 2^{15}, the top 15 bits are presented in the count field and the ov14 field is set. This result effectively scales the contents down by a factor of 2^{7}.
- When the 22-bit counter overflows, the count field is set to 0x7FFF, and the ov14 field is set.

The error counter is typically used in a "clear after read" mode. The error registers are reset on a read-only when the pattern matcher is enabled. If the pattern matcher is disabled, the registers return the error count that was indicated when the pattern matcher was disabled and never reset the error counter.

64.6.2.4.4 Margining

Margining is the process of learning about the quality of a communications system by studying how its BER is changed when known impairments are introduced to the system.

Typical BER targets for systems are extremely low (for example, 1e-18; at 2.5 Gbps; that is, one error every 12.7 years). Margining makes it possible to extrapolate from a short set of measurements to project bounds on the actual error rate, assuming there are no additional sources of low-rate errors (for example, metastability), which do not occur during the measurement, but would dominate the BER over large periods.

One common margining technique-phase margining-is referred to as a "bathtub curve." The figure below shows an example of this technique, where the extrapolated phase margin is a measurement of margin between the extrapolated system performance and the performance target.

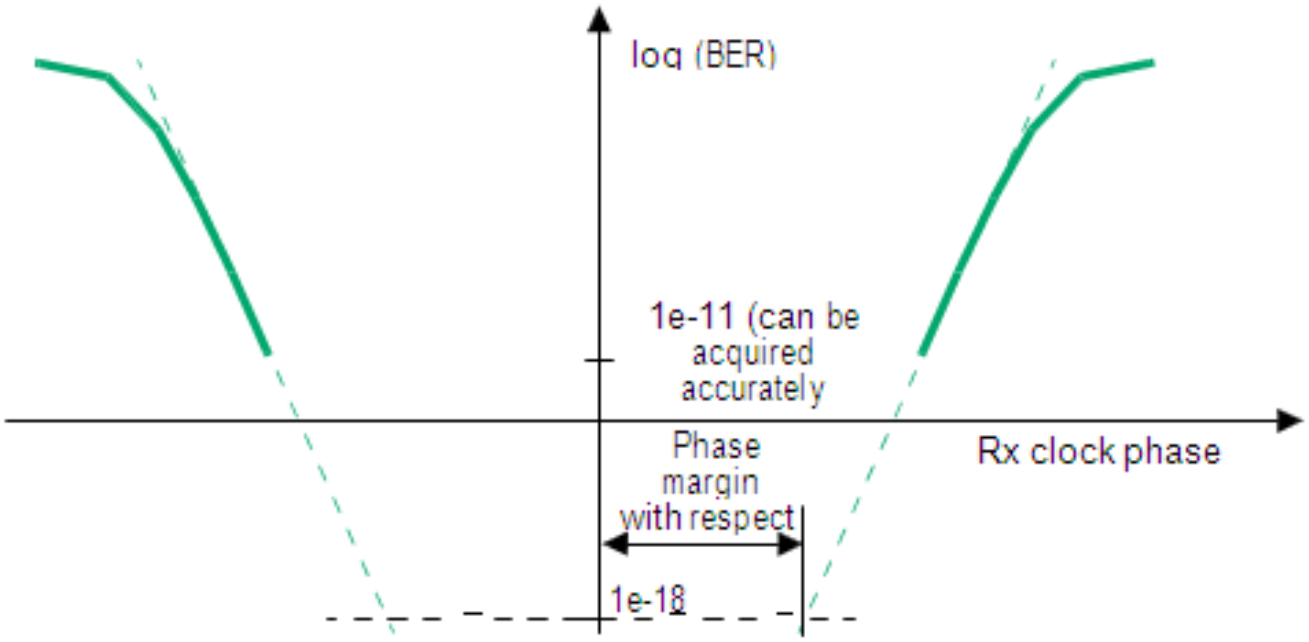

Figure 64-14. Example of Phase Margining Technique

Margining can be used on the testbench to study the effects of other changes (for example, crosstalk, trace lengths, power supply noise, temperature, power supply voltage) on system performance.

In ATE testing, during test time intervals in the order of 100 ms, simple error counting can pass defective parts that might produce BER results in the order of 1e-8. However, during that same period, margining can be used to provide a better bound on the performance of shipped parts.

64.6.2.4.4.1 Phase Margining

Phase margining is more common than voltage margining, but phase margining requires you to turn off (or freeze) the receiver's clock recovery-an important receiver function. Generally, to perform phase margining, you must ensure that the transmitter and receiver are operating from a common clock.

Synchronous phase margining requires the following steps.

1. 1. Provide a common clock to the transmitting and receiving devices.

   2. Determine the mean selected phase of the receiver's CDR by reading the DPLL Phase register (lanej.phase)-of the lane to be margined-a number of times and averaging the values.

3. Enable the pattern generator in the relevant transmitter. For information about the BERT pattern generator, see BERT Pattern Generator.

4. Enable the pattern matcher and error counter in the receiver under test. For information about the BERT pattern matcher and error counter, seeBERT Pattern Matcher and Error Counter.

5. Freeze the receiver's CDR.

In lanej.rx_ctl, set the phug_value field to 1'b1, the ovrd_dpll_gain field to 1'b1, and the frug_value field to 2'b00 (default).

Set lanej.freq to 13'b0_0000_0000_0000.

In lanej.rx_ctl, set the phug_value field to 2'b00.

6. Force a selected phase offset from the mean phase identified in step 2 by adding a value to the value measured in step 2 and writing the sum to lanej.phase.

7. Measure the BER at this phase offset.

8. Repeat steps 6 and 7 to get the BER versus programmed phase offset.

5.2.5.4.2 Voltage Margining

Voltage margining can be performed in an asynchronous environment without shutting down the CDR, because the receiver is clock-forwarded. Voltage margining is performed by adding an offset voltage to the received signal.

Note that when the applied offset voltage is large relative to the peak-to-peak received signal, the Rx CDR's phase detector develops a dead zone that adds to the sampling jitter, causing additional loss in margin.

Voltage margining requires the following steps.

1. Enable the pattern generator in the relevant transmitter. For information about the BERT pattern generator, see BERT Pattern Generator.

2. Enable the pattern matcher and error counter in the receiver under test. For information about the BERT pattern matcher and error counter, see BERT Pattern Matcher and Error Counter.

3. Enable the margining DAC in the Clock module.

4. Set the DAC to its midrange by setting clock.dac_ctl.dac_val to 10'b01_1111_1111 (511). The DAC is 10 bits wide and the DAC's midrange corresponds to a zero offset.

5. Enable the DAC by setting clock.dac_ctl.dac_mode to 2'b11.

6. Program an additive offset voltage by changing the value of clock.dac_ctl.dac_val from 511. The resolution (1 LSB) of the DAC is VP25 x 279e-6 volts.

7. Measure the BER at this voltage offset.

8. Repeat steps 4 and 5 to get the BER versus programmed voltage offset.

64.6.2.4.5 Scope Function

Scope function (capturing and viewing the signals received at each input) can be achieved by combining the SATA2 PHY's signal acquisition capabilities with software running on an external host and utilizing external graphics display capabilities.

Note that scope function differs from the function of expensive lab equipment in some important ways; for example:

- Scope: The actual signal delivered to the receiver's slicers is measured. When a lab hardware scope is used, different reflections are present. In some cases, an alternative board-not the board with the receiver-is plugged in, enabling use of an external connector. Consequently, the reflection environment is changed entirely. In other cases, an active probe is used to pick up the signal near the receiver. This technique picks up reflections from the receiver that are not actually present at the receiver (at least 11-20 mm from the closest possible pickup point).
- Scope: The signal is acquired with the actual bandwidth limitations of the slicers in the receivers. This situation might not suit your measurement goals.
- A limitation of the on-die scope is that only periodic signals of known periodicity can be acquired, though the periodicity can be as long as 2^16 bytes.
- Scope: Jitter of the receiving device's Rx Analog Phase-Locked Loop (APLL) and MPLL is present in the measurement. This jitter is generally larger than the sampling jitter of a quality piece of bench equipment. In a loopback situation (same MPLL for both Tx and Rx), much of this jitter is cancelled, yielding the appearance of Tx jitter that is lower than is actually present.
- Scope function is analogous to an undersampling scope, not a real-time, oversampling scope.
- Bench hardware typically has voltage and time accuracy that are carefully specified and directly traceable to external standards. Tracing voltage, offset, and phase accuracy to external standards is more indirect.

The scope's greatest strength is its ease of use in debugging and understanding a system in situ. The scope is not intended to replace traditional lab equipment for the purpose of compliance testing, but the scope provides a nondestructive view of incoming data.

64.6.2.4.6 Analog DC Test Capabilities

This section describes the SATA2 PHY's analog DC test capabilities.

64.6.2.4.6.1 Analog Test Bus

The analog test bus (ATB) comprises four signals routed throughout the Active section, through the Clock module and each lane.

Some of these signals can be brought to the internal ADC while others can be brought to any Tx or Rx pin. The table below describes the ATB signals.

Table 64-34. Analog Test Bus Signals

Signal	Description	Can be Brought to:
atb_s_p	Zero current "sense" connections	ADC, Txp, Rxp
atb_s_m	Zero current "sense" connections	ADC, Txm, Rxm
atb_f_p	Large current (up to about 3 mA) "force" connection	Txp, Txm, Rxp, Rxm

Many internal circuits have connections that can be enabled to these buses. Note that these connections are intended to be used in a very-low-frequency (near DC) situation. Series resistance between connections on the bus are typically > 30 ohms, while bus parasitic capacitance can be multiple picoFarads, yielding bandwidths below 2 MHz. When connections are made to nodes carrying high-frequency signals such as Tx or Rx serial pins, explicit 10-k ohm resistors are used so that connecting the ATB bus does not impair the lane's operation.

The figure below shows a high-level map of the ATB.

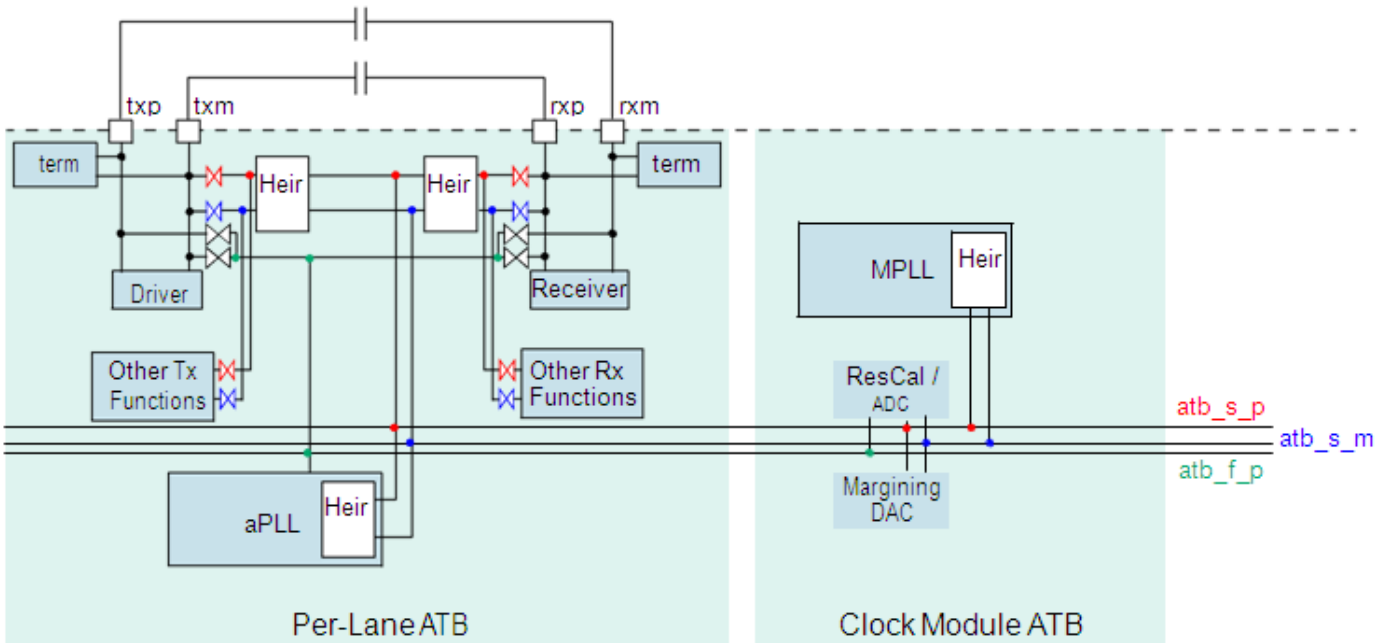

Figure 64-15. High-Level Map of ATB

Bringing a selected internal signal to either a package pin or the internal ADC is a matter of activating the correct combination of hierarchical switches and leaf-level switches. Control of these switches is distributed across several registers, as described in the table below.

Table 64-35. Location of ATB Switch Controls

Circuit Area	Control Register
Transmit	Hierarchical switch: "atb_en" in Receive Analog Control Register (lane0_RX_ANA_CONTROL) Leaf-level switches: Transmit ATB 1 Control Register (lane0_TX_ANA_ATBSEL1) and Transmit ATB 2 Control Register (lane0_TX_ANA_ATBSEL2)
Receive	Hierarchical switch: "atb_en" in Receive Analog Control Register (lane0_RX_ANA_CONTROL) Leaf-level switches: Receive ATB Register (lane0_RX_ANA_ATB)
CDR aPLL	Hierarchical switch: "atb_sense_sel" in Rx PLL Programming 2 Register (lane0_PLL_PRG2) Leaf-level switches: Rx PLL Measurement Register (lane0_PLL_PRG3)
MPLL	Hierarchical switch: "atb_sense_sel" in Rx PLL Programming 2 Register (lane0_PLL_PRG2) Leaf-level switches: MPLL Test Register (clock_MPLL_TEST)

Disabling Rx Termination

To bring ATB signals out on the Rx pins, it is recommended that you disable the resistive terminations that are otherwise present at these pins.

When using the Rx pins connected to an external measuring device, disable the receive termination resistors by deasserting the rx_term_en bit. In addition, disable the LOS by setting the los_ctl bits to 2'b00.

The Tx pins must not be used for this purpose, because the driver contains some impedances and leakage that cannot be completely eliminated.

64.6.2.4.6.2 10-Bit DAC

The 10-bit DAC is required for voltage margining and is used as part of the 10-bit AD converter (see 10-Bit ADC).

In addition, the DAC can be connected to the DC test bus for other purposes and is generally controlled by the DAC Control register (clock.dac_ctl). (For information about this register, see "DAC Control Register (clock.dac_ctl)" on page 47.)

To use the 10-bit DAC:

1. Place the DAC in one of the DAC operating modes by setting clock.dac_ctl.dac_mode to a value of 4-7 (see DAC Control Register (clock_DAC_CTL)).
2. Connect the DAC output to the global atb_s_p bus by setting clock.rtune_ctl.dac_chop (see Resistor Tuning Control Register (clock_RTUNE_CTL)).
3. To produce the intended output voltage, write a value to clock.dac_ctl.dac_val (see DAC Control Register (clock_DAC_CTL)).

64.6.2.4.6.3 10-Bit ADC

The 10-bit ADC uses circuit components that are present in the Clock module, because the 10-bit DAC is required for voltage margining, and the offset calibrated comparator is present for resistor calibration.

64.6.2.4.7 Limit Testing

In most ASIC production test environments, the tests simply run a vector (drive controls into the DUT and verify that the correct output is produced) due to either limitations of the tester itself or time constraints in the development of more sophisticated tests. Therefore, tasks that would otherwise seem simple (for example, reading a register and verifying that the result is < 20) become effectively impossible.

The limit testing feature can be used to place upper and lower bounds on a masked version of a register read or to place bounds on a masked version of the difference between two masked register reads.

The figure below shows the hardware functions involved in limit testing.

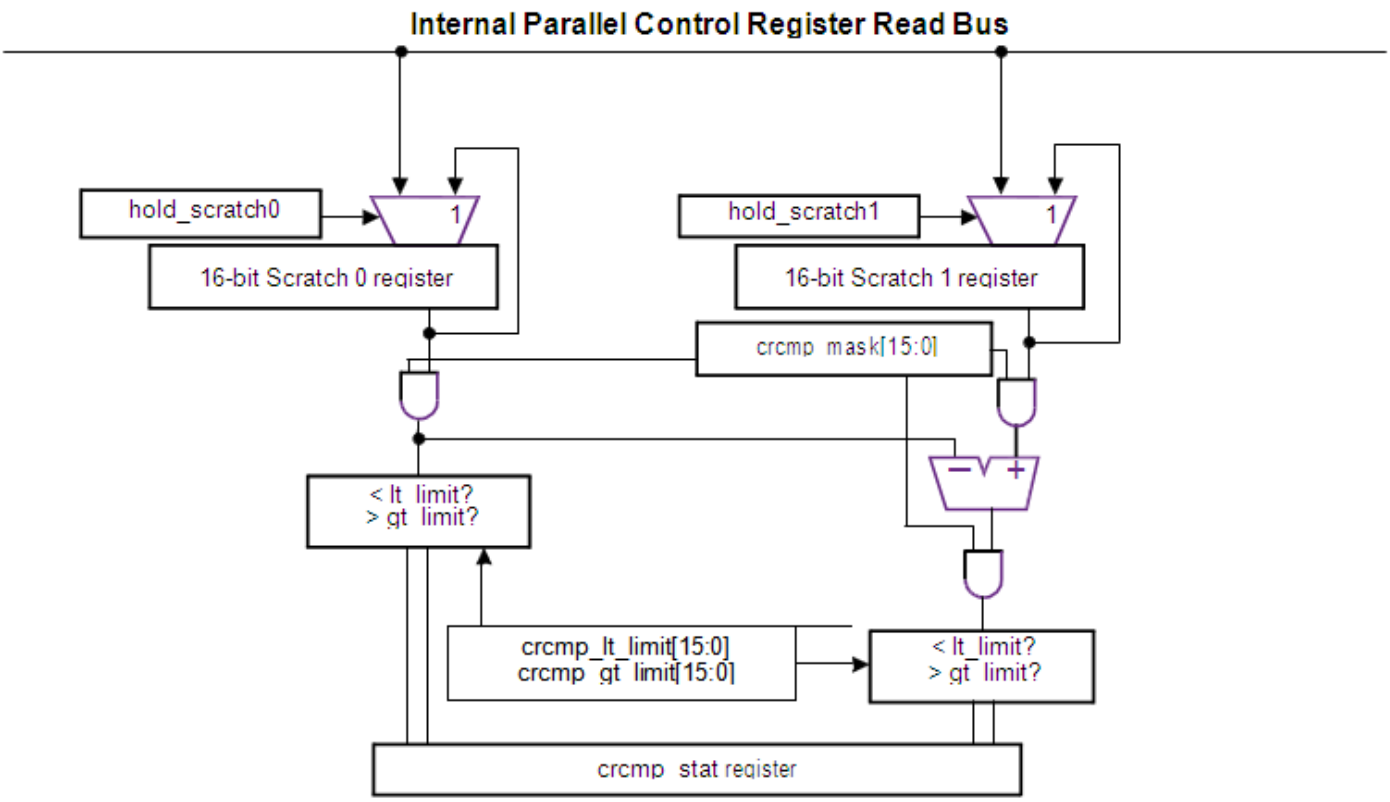

Figure 64-16. Hardware for Limit Testing

Each internal scratch register is updated each time a register read occurs through the JTAG interface, unless the associated hold_scratch1 or hold_scratch0 bit is set.

Note that the values written to the crcmp_lt_limit and crmp_gt_limit registers are also masked with the crcmp_mask field before being used.

64.6.2.4.8 Integrated Test Modes

The SATA2 PHY integrates the following test modes, which can be used to enhance characterization and ATE testing.

64.6.2.4.8.1 IDDQ Test Mode

To enable IDDQ test mode, set the pddq_h signal to 1'b1 (I/0 voltage level). This setting powers down circuitry that cannot be powered down as described in Power-Down Sequences.

All preconditioning of the SATA2 PHY must be done before asserting pddq_h, because the device becomes non-functional when pddq_h is set to 1'b1.

64.6.2.4.8.2 Bypass Test Mode

Setting the test_byp_mode signal to 1'b1 connects the parallel data inputs to the parallel data outputs through a purely combinatorial path. This mode enables testing of the ASIC/SATA2 PHY interface; the passthru.v Verilog model represents this mode.

This interface is designed to be orders of magnitude slower than the operational frequency, so no timing information is provided. However, if necessary, using 1ns for a hold time would be a very conservative number.

64.6.2.4.8.3 Burn-In Test Mode

Setting the test_burnin_mode signal to 1'b1 enables the SATA2 PHY for burn-in testing. An on-board oscillator is activated and multiplexed to the prescaler inputs to be used as the reference clock.

This oscillator removes the requirement for an external reference. As much circuitry as possible is toggled, and unused circuitry is biased so that devices do not degrade asymmetrically.

64.6.2.4.9 Burn-In Test Requirements

For burn-in testing, the IP must be placed in a mode so that the IP's circuitry is stressed in its intended mode of operation.

This requirement involves providing the IP a reference clock, applying power, powering up the device as described in Power-Up Sequences, and sending parallel data to the transmitter. Externally, the transmitter pins must be AC-coupled through a capacitor (typically 0.1 µF) to the receiver, and the rbias resistor must be connected. Burn-in test mode satisfies this requirement-power must be applied to the IP and Burn-in test mode must be activated. Externally, the rbias resistor must be connected.

64.6.2.4.10 Temperature Sensor

The die's temperature is derived using measured voltages from the internal analog circuitry. These voltages are first converted to a digital value through an ADC, and in turn these values are simply read from standard register reads.

To determine the die temperature, you must then apply the two measurements in an equation.

The figure below shows the flow for measuring and calculating the temperature.

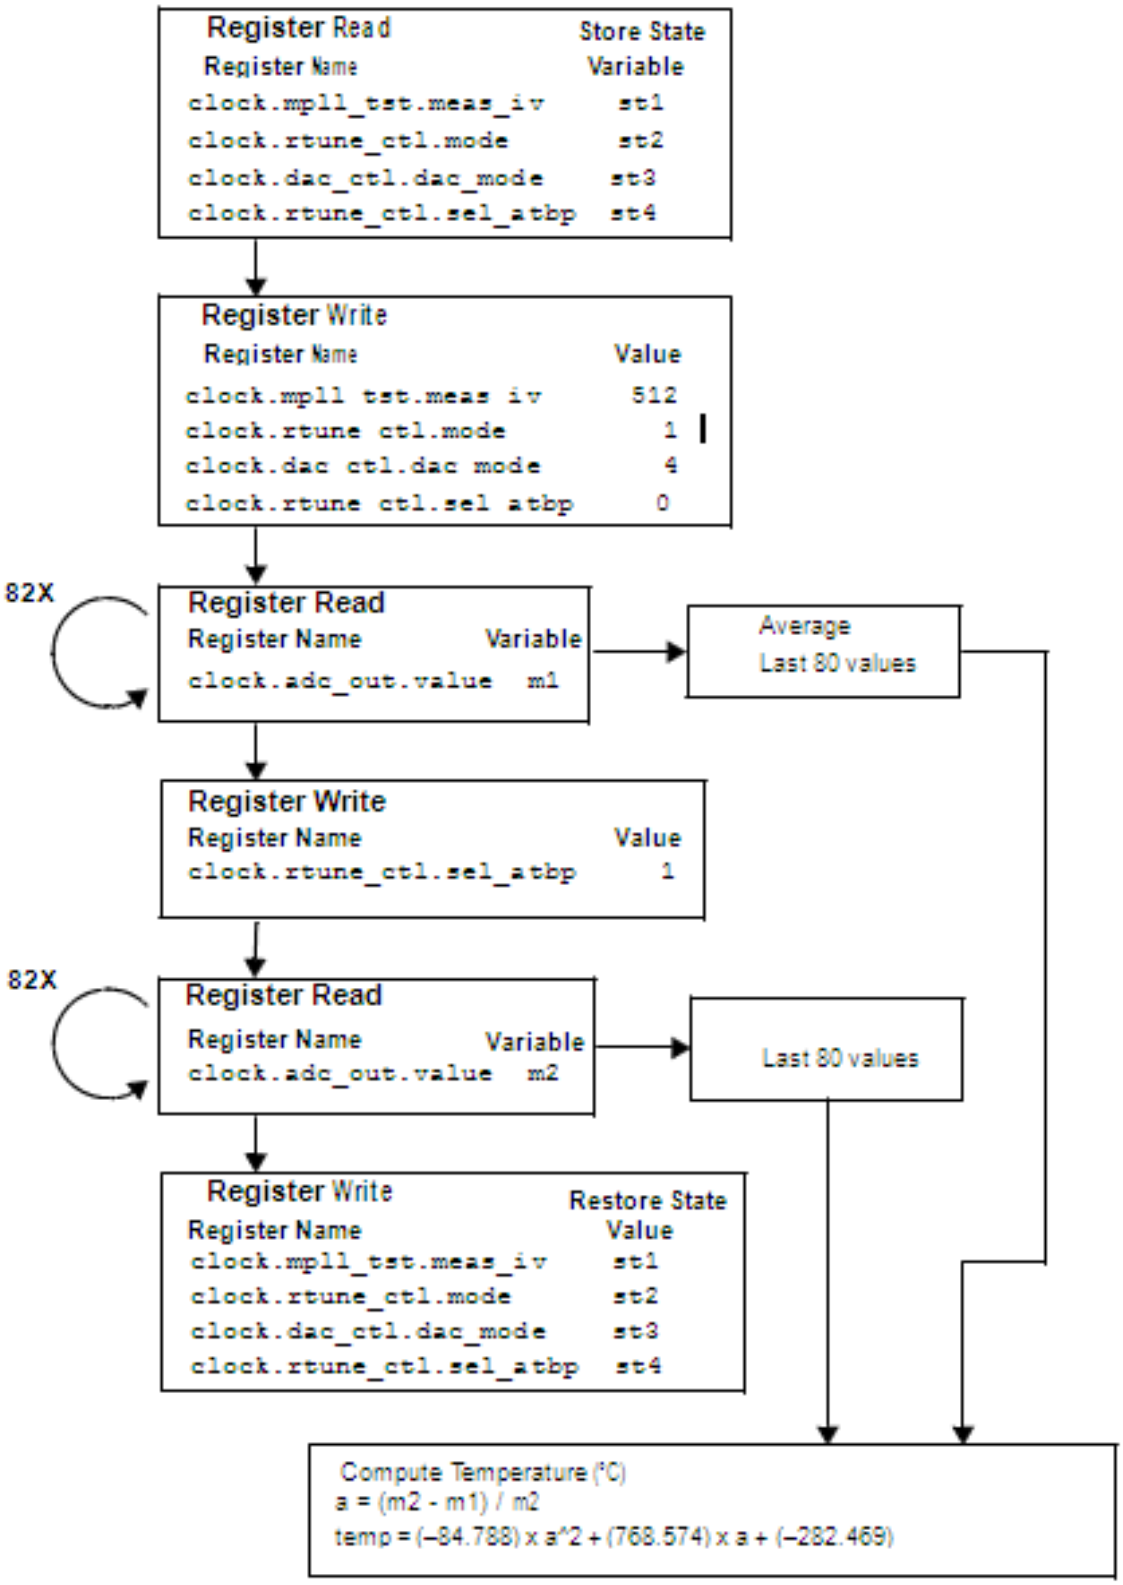

Figure 64-17. Temperature Measurement Flow

Synopsys has verified the temperature sensor's function in the lab environment using temperature control equipment and an additional high-precision temperature sensor fabricated with the IP on a test chip. The equation for the temperature calculation is a quadratic curve fit to simulation and experimental data. The temperature measurement has proven to be supply-independent, with an absolute error of less than 5° C across process. The temperature measurement can be made without disturbing data traffic.

NOTE

Refer to the SATA Temperature Sensor application note (AN4380) for more details regarding programming and its usage.

64.6.2.5 ATE Testing

The features described in Diagnostic Features were used to develop an analog, production-ready test program. This test suite tests the analog functions of the IP using simple pass/fail vectors that can be used on a low-cost digital tester.

Test vectors are entered into the core through the JTAG interface. By request, a program for generating digital test patterns as well as documentation that provides implementation guidelines will be provided .

64.7 clock Memory Map/Register Definition

This section describes registers in the Clock module. Only one instance of each register exists in the Clock module, regardless of the number of lanes.

Registers in the Clock module have 16-bit addresses. These addresses are noted in the register map and in the section for the applicable register.

NOTE

SATA PHY registers are only accessible by the corresponding controller (SATA_P0_PCSR_PHYCR and SATA_P0_PCSR_PHYSR) or in debug through the JTAG port. SATA PHY is not memory mapped to processor address space, so the absolute addresses shown is the relative address and is not valid. See SATA Memory Map for more information.

clock memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0001	Creg Compare Upper Limit Register (clock_CRCMP_LT_LIMIT)	16	R/W	0000h	64.7.1/ 3970

64.7.1 Creg Compare Upper Limit Register (clock_CRCMP_LT_LIMIT)

Address: 0x0001

Reset value: 16'b 0000 0000 0000 0000

This register contains the less-than-limit compare point.

Address: clock_CRCMP_LT_LIMIT is 0h base + 1h offset = 0001h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read / Write	crcmp_lt_limit															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

clock_CRCMP_LT_LIMIT field descriptions

Field	Description
15–0 crcmp_lt_limit	Less-than-limit compare point

64.7.2 Creg Compare Lower Limit Register (clock_CRCMP_GT_LIMIT)

Address: 0x0002

Reset value: 16'b 1111 1111 1111 1111

This register contains the greater-than-limit compare point.

Address: clock_CRCMP_GT_LIMIT is 0h base + 2h offset = 0002h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read / Write	crcmp_gt_limit															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

clock_CRCMP_GT_LIMIT field descriptions

Field	Description
15–0 crcmp_gt_limit	Greater-than-limit compare point

64.7.3 Creg Compare Mask Register (clock_CRCMP_MASK)

Address: 0x0003

Reset value: 16'b 1111 1111 1111 1111

This register contains the compare/scratch value mask.

Address: clock_CRCMP_MASK is 0h base + 3h offset = 0003h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read / Write	crcmp_mask															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

clock_CRCMP_MASK field descriptions

Field	Description
15–0 crcmp_mask	Mask for comparisons

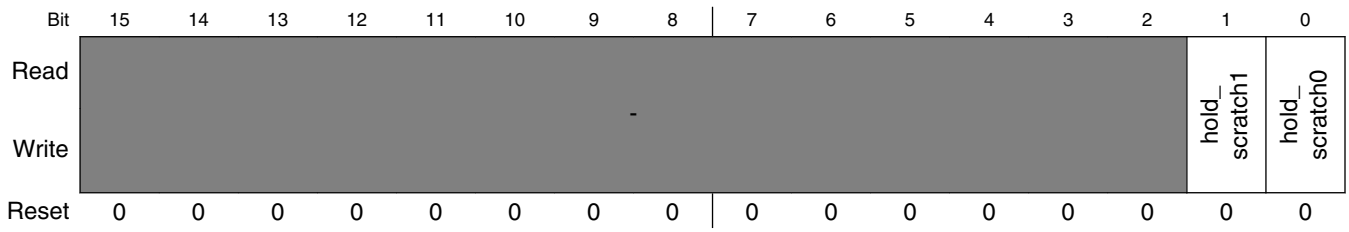
64.7.4 Creg Compare Control Register (clock_CRCMP_CTL)

Address: 0x0004

Reset value: 16'b 0000 0000 0000 0000

This register contains the scratch space control bits.

Address: clock_CRCMP_CTL is 0h base + 4h offset = 0004h



clock_CRCMP_CTL field descriptions

Field	Description
15–2 -	Reserved
1 hold_scratch1	Scratch1 is not updated on register reads.
0 hold_scratch0	Scratch0 is not updated on register reads.

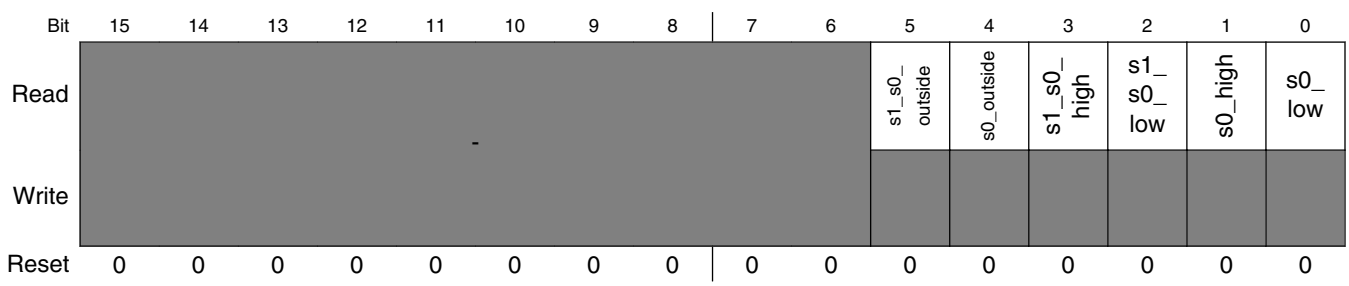
64.7.5 Creg Compare Status Register (clock_CRCMP_STAT)

Address: 0x0005

Reset value: 16'b xxxx xxxx xxxx xxxx

This register contains the results of scratch register comparisons to various limits.

Address: clock_CRCMP_STAT is 0h base + 5h offset = 0005h



clock_CRCMP_STAT field descriptions

Field	Description
15–6 -	Reserved
5 s1_s0_outside	Logical OR of S1_S0_LOW and S1_S0_HIGH Useful for determining if the difference is near signed zero.
4 s0_outside	Logical OR of S0_LOW and S0_HIGH Useful for determining if the value is near signed zero.

Table continues on the next page...

clock_CRCMP_STAT field descriptions (continued)

Field	Description
3 s1_s0_high	Masked (Scratch1 - Scratch0) is higher than CRCMP_HT_LIMIT.
2 s1_s0_low	Masked (Scratch1 - Scratch0) is lower than CRCMP_LT_LIMIT.
1 s0_high	Masked Scratch0 is higher than CRCMP_HT_LIMIT.
0 s0_low	Masked Scratch0 is lower than CRCMP_LT_LIMIT

64.7.6 Scope Sample Count Register (clock_SCOPE_SAMPLES)

Address: 0x0006

Reset value: 16'b 0000 0001 0000 0000

This register specifies the number of samples to count.

Address: clock_SCOPE_SAMPLES is 0h base + 6h offset = 0006h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	scope_samples															
Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

clock_SCOPE_SAMPLES field descriptions

Field	Description
15–0 scope_samples	The number of samples to count

64.7.7 Scope Count Result Register (clock_SCOPE_COUNT)

Address: 0x0007

Reset value: 16'b xxxx xxxx xxxx xxxx

This register provides the results of scope counting. A write to this register starts the counting process. A value of FFFF indicates that the count is still in progress.

Address: clock_SCOPE_COUNT is 0h base + 7h offset = 0007h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	scope_count															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

clock_SCOPE_COUNT field descriptions

Field	Description
15–0 scope_count	Results of scope counting

64.7.8 DAC Control Register (clock_DAC_CTL)

Reset value: 16'b x000 0001 1111 1111

This register supports DAC values and controls.

Address: clock_DAC_CTL is 0h base + 8h offset = 0008h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	-	dac_mode			ovrd_rtune_rx	ovrd_rtune_tx	dac_val									
Write																
Reset	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1

clock_DAC_CTL field descriptions

Field	Description
15 -	Reserved
14–12 dac_mode	DAC output mode: 000 Powers down DAC 001 Reserved 010 High-range margining (VP25 x 418e-6 res) 011 Low-range margining (VP25 x 279e-6 res) 100 100% range DAC, 0% offset 101 36% range DAC, 0% offset 110 36% range DAC, 33% offset 111 36% range DAC, 66% offset
11 ovrd_rtune_rx	Writes DAC_VAL[5:0] to the Rx rtune bus

Table continues on the next page...

clock_DAC_CTL field descriptions (continued)

Field	Description
10 ovrd_rtune_tx	Writes DAC_VAL[5:0] to the Tx rtune bus
9–0 dac_val	Digital value to be used for DAC

64.7.9 Resistor Tuning Control Register (clock_RTUNE_CTL)

Reset value: 16'b xxxx x000 0010 0000

This register contains resistor tuning controls.

Address: clock_RTUNE_CTL is 0h base + 9h offset = 0009h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	-					adc_trig	rtune_trig	rtune_dis	cmp_invert	dac_chop	rsc_x4	sel_atbp	pwron_lcl	frc_pwron	mode	
Reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0

clock_RTUNE_CTL field descriptions

Field	Description
15–11 -	Reserved
10 adc_trig	Triggers ADC conversion
9 rtune_trig	Triggers manual resistor calibration
8 rtune_dis	Disables automatic resistor recalibrations
7 cmp_invert	Inverts output of comparator (to reverse successive approximation register (SAR) feedback loop)
6 dac_chop	Polarity of chop control for DAC
5 rsc_x4	Sets x4 in rescal circuitry
4 sel_atbp	Selects atb_s_p for A/D measurement
3 pwron_lcl	Value of power-on to force
2 frc_pwron	Overrides internal power-on

Table continues on the next page...

clock_RTUNE_CTL field descriptions (continued)

Field	Description
1–0 mode	Resistor tune SAR mode: 00 Normal restune 01 ADC 10 Rx Resistor test 11 Tx Resistor test

64.7.10 ADC Output Register (clock_ADC_OUT)

Address: 0x000A

Reset value: 16'b xxxx xxxx xxxx xxxx

This register contains the results of the ADC process. A read from this register starts a new A/D conversion.

Address: clock_ADC_OUT is 0h base + Ah offset = 000Ah

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	-					fresh	value									
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

clock_ADC_OUT field descriptions

Field	Description
15–11 -	Reserved
10 fresh	Flag indicates that a new A/D conversion result is present.
9–0 value	A/D conversion result Based on RTUNE_CTL.MODE, this value is the result of either the last conversion (MODES 0 or 1) or the current Tx/Rx cal value (MODES 3/2).

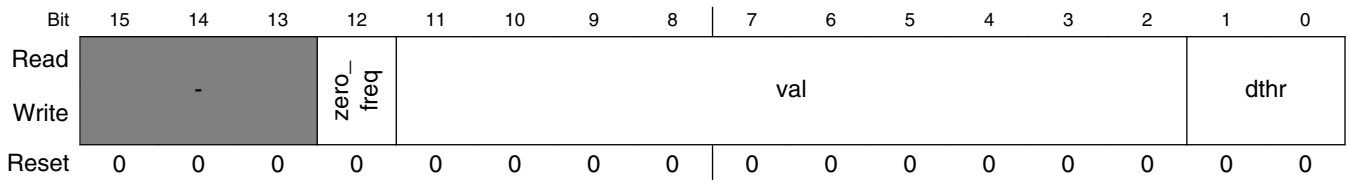
64.7.11 Spread Spectrum Phase Register (clock_SS_PHASE)

Address: 0x000B

Reset value: 16'b xxx0 0000 0000 0000

This register contains the current MPLL phase selector value.

Address: clock_SS_PHASE is 0h base + Bh offset = 000Bh



clock_SS_PHASE field descriptions

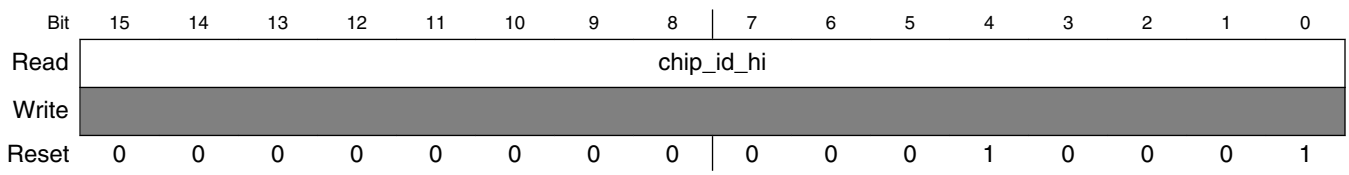
Field	Description
15–13 -	Reserved
12 zero_freq	Zero frequency register Must be set for PHASE writes to not be immediately overwritten.
11–2 val	Phase value from zero reference
1–0 dthr	Bits below the useful resolution

64.7.12 JTAG Chip ID (High Bits) Register (clock_CHIP_ID_HI)

Address: 0x000C

This register contains the internal chip ID (high 16 bits) of the JTAG interface.

Address: clock_CHIP_ID_HI is 0h base + Ch offset = 000Ch



clock_CHIP_ID_HI field descriptions

Field	Description
15–0 chip_id_hi	Internal chip ID (high 16 bits)

64.7.13 JTAG Chip ID (Low Bits) Register (clock_CHIP_ID_LOW)

Address: 0x000D

This register contains the internal chip ID (low 16 bits) of the JTAG interface.

Address: clock_CHIP_ID_LOW is 0h base + Dh offset = 000Dh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	chip_id_lo															
Write																
Reset	0	1	1	1	0	1	0	0	1	1	0	0	1	1	0	1

clock_CHIP_ID_LOW field descriptions

Field	Description
15–0 chip_id_lo	Internal chip ID (low 16 bits)

64.7.14 Frequency Status Register (clock_FREQ_STAT)

Address: 0x000E

Reset value: 16'b xxxx xxxx xxxx xxxx (depends on inputs)

This register indicates the status of frequency control inputs.

Address: clock_FREQ_STAT is 0h base + Eh offset = 000Eh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	reserved	prescale		ncy					ncy5		int_ctl			prop_ctl		
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

clock_FREQ_STAT field descriptions

Field	Description
15 Reserved	This field is reserved. Always reads as 1
14–13 prescale	Prescaler control
12–8 ncy	Divide-by-4 cycle control
7–6 ncy5	Divide-by-5 control
5–3 int_ctl	Integral charge pump control
2–0 prop_ctl	Proportional charge pump control

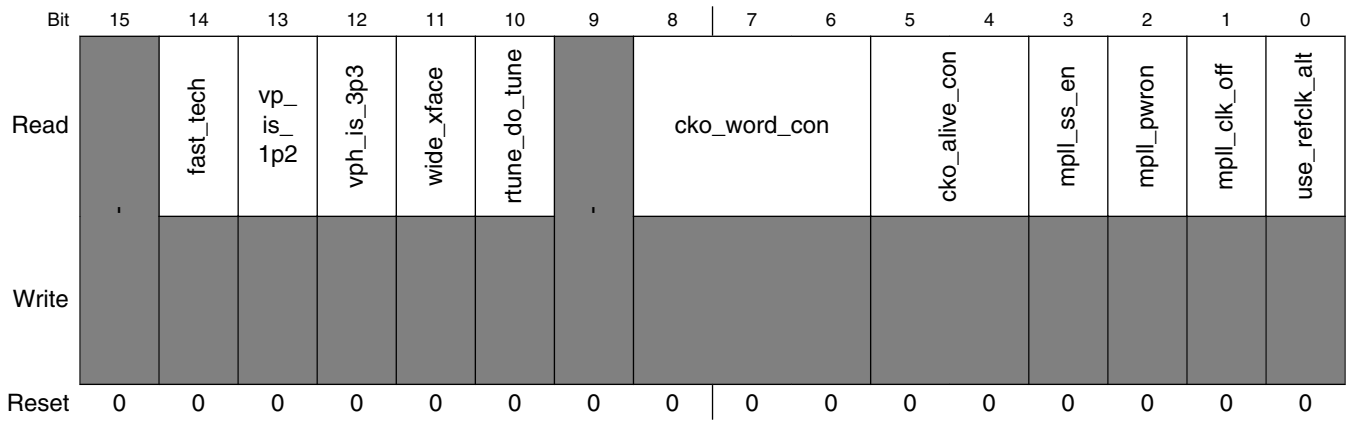
64.7.15 Control Status Register (clock_CTL_STAT)

Address: 0x000F

Reset value: 16'b xxxx xxxx xxxx xxxx (depends on inputs)

This register indicates the status of various control inputs.

Address: clock_CTL_STAT is 0h base + Fh offset = 000Fh



clock_CTL_STAT field descriptions

Field	Description
15 -	Reserved
14 fast_tech	Technology is fast
13 vp_is_1p2	Low voltage supply is 1.2 V
12 vph_is_3p3	High voltage supply is 3.3 V
11 wide_xface	Wide interface control
10 rtune_do_tune	Manual resistor tune control
9 -	Reserved
8–6 cko_word_con	cko_word MUX control
5–4 cko_alive_con	cko_alive MUX control
3 mpll_ss_en	Spread spectrum enable

Table continues on the next page...

clock_CTL_STAT field descriptions (continued)

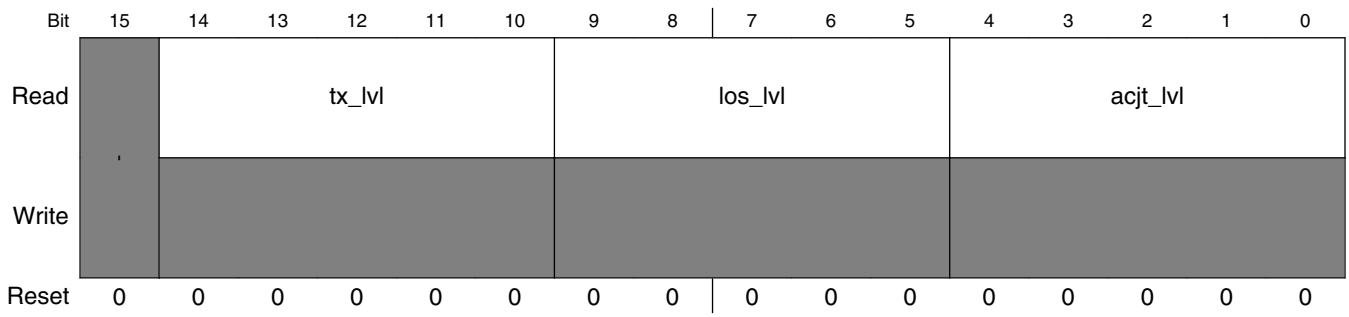
Field	Description
2 mpll_pwron	MPLL power-on control
1 mpll_clk_off	Reference clock is off
0 use_refclk_alt	Alternate refclk is used

64.7.16 Level Status Register (clock_LVL-STAT)

Reset value: 16'b xxxx xxxx xxxx xxxx (depends on inputs)

This register indicates the status of level control inputs.

Address: clock_LVL-STAT is 0h base + 10h offset = 0010h



clock_LVL-STAT field descriptions

Field	Description
15 -	Reserved
14–10 tx_lvl	Transmit level
9–5 los_lvl	Loss of Signal Detector level
4–0 acjt_lvl	ACJTAG comparator level

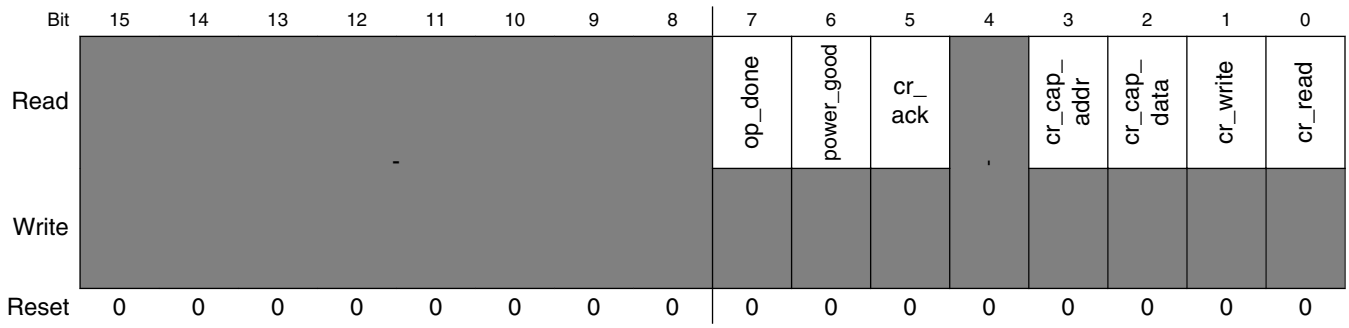
64.7.17 Creg Status Register (clock_CREG_STAT)

Address: 0x0011

Reset value: 16'b xxxx xxxx xxxx xxxx (depends on inputs)

This register indicates the status of creg control I/O.

Address: clock_CREG_STAT is 0h base + 11h offset = 0011h



clock_CREG_STAT field descriptions

Field	Description
15–8 -	Reserved
7 op_done	Operation is complete output
6 power_good	Power good output
5 cr_ack	Creg request acknowledgement
4 -	Reserved
3 cr_cap_addr	Captures address request
2 cr_cap_data	Captures data request
1 cr_write	Write request
0 cr_read	Read request

64.7.18 Frequency Override Register (clock_FREW_OVRD)

Reset value: 16'b 0100 0101 0100 0111

This register contains the override of frequency control inputs.

Address: clock_FREW_OVRD is 0h base + 12h offset = 0012h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	ovrd	prescale		ncy					ncy5		int_ctl			prop_ctl		
Write																
Reset	0	1	0	0	0	1	0	1	0	1	0	0	0	1	1	1

clock_FREW_OVRD field descriptions

Field	Description
15 ovrd	Enables override of all bits in this register
14–13 prescale	Prescaler control: 00 No scaling 01 Doubles refclk frequency 10 Halves refclk frequency 11 Reserved
12–8 ncy	Divide-by-4 cycle control MPLL Divider period = 4 x (NCY + 1) + NCY5. Valid only when NCY5 <=NCY.
7–6 ncy5	Divide-by-5 control MPLL Divider period = 4 x (NCY + 1) + NCY5. Valid only when NCY5 <=NCY
5–3 int_ctl	Integral charge pump control Integral current = (n + 1) / 8 x full_scale
2–0 prop_ctl	Proportional charge pump control Proportional current = (n + 1) / 8 x full_scale

64.7.19 Control Override Register (clock_CTL_OVRD)

Reset value: 16'b 0000 1000 0101 0100

This register contains the override of various control inputs.

Address: clock_CTL_OVRD is 0h base + 13h offset = 0013h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	ovrd_static	fast_tech	vp_is_1p2	vph_is_3p3	wide_xface	rtune_do_tune	ovrd_clk	cko_word_con			cko_alive_con		mpll_ss_en	mpll_pwron	mpll_clk_off	use_refclk_alt
Write																
Reset	0	0	0	0	1	0	0	0	0	1	0	1	0	1	0	0

clock_CTL_OVRD field descriptions

Field	Description
15 ovrd_static	Overrides static controls (bits [14:10])
14 fast_tech	Technology is fast
13 vp_is_1p2	Low-voltage supply is 1.2 V
12 vph_is_3p3	High-voltage supply is 3.3 V
11 wide_xface	Wide interface control
10 rtune_do_tune	Manual resistor tune control
9 ovrd_clk	Overrides clock controls (bits [8:0])
8–6 cko_word_con	cko_word mux control
5–4 cko_alive_con	cko_alive mux control
3 mpll_ss_en	Spread spectrum enable
2 mpll_pwron	MPLL power-on control
1 mpll_clk_off	Reference clock is off
0 use_refclk_alt	Uses alternate refclk

64.7.20 Level Override Register (clock_LVL_OVRD)

Address: 0x0014

Reset value: 16'b 0100 0010 0001 0000

This register contains the override of level control inputs.

Address: clock_LVL_OVRD is 0h base + 14h offset = 0014h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	ovrd	level tx_lvl					los_lvl					acjt_lvl				
Reset	0	1	0	0	0	0	1	0	0	0	0	1	0	0	0	0

clock_LVL_OVRD field descriptions

Field	Description
15 ovrd	Overrides all level controls
14–10 level tx_lvl	Transmit level
9–5 los_lvl	Loss of Signal Detector
4–0 acjt_lvl	ACJTAG comparator level

64.7.21 Creg Override Register (clock_CREG_OVRD)

Address: 0x0015 Reset value: 16'b xxxx xxx0 0100 0000 This register contains the override of creg control I/O.

Address: clock_CREG_OVRD is 0h base + 15h offset = 0015h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	-							ovrd_out	op_done	power_good	cr_ack	ovrd_in	cr_cap_addr	cr_cap_data	cr_write	cr_read
Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

clock_CREG_OVRD field descriptions

Field	Description
15–9 -	Reserved
8 ovrd_out	Overrides outputs (bits [7:5])
7 op_done	Operation is complete output
6 power_good	Power good output
5 cr_ack	Creg request acknowledgement
4 ovrd_in	Overrides inputs (bits [3:0])
3 cr_cap_addr	Captures address request
2 cr_cap_data	Captures data request
1 cr_write	Writes request

Table continues on the next page...

clock_CREG_OVRD field descriptions (continued)

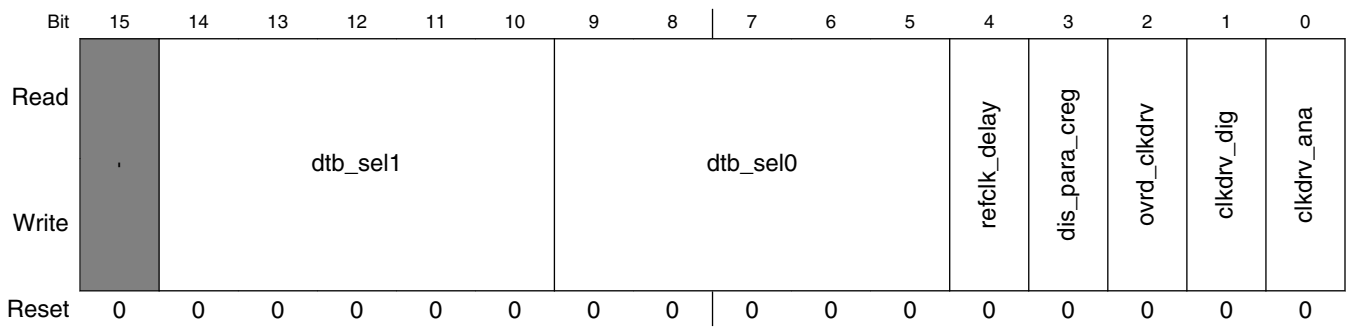
Field	Description
0 cr_read	Reads request

64.7.22 MPLL Control Register (clock_MPLL_CTL)

Reset value: 16'b xxxx xx00 0000 0000

This register contains MPLL controls.

Address: clock_MPLL_CTL is 0h base + 16h offset = 0016h



clock_MPLL_CTL field descriptions

Field	Description
15 -	Reserved
14–10 dtb_sel1	Selects wire to drive onto DTB bit 1: All other bits: Disabled 00000 Disabled 00001 mpll_gear_shift 00010 mpll_reset 00011 mpll_pwron (at analog boundary) 00100 reset_n 00101 cr_ack 00110 power_good 00111 op_done 01000 cr_read 01001 cr_write 01010 cr_cap_data 01011 cr_cap_addr 01100 rtune_do_tune 01101 cko_alive_con[0] 01110 cko_alive_con[1] 01111 cko_word_con[0]

clock_MPLL_CTL field descriptions (continued)

Field	Description
	10000 cko_word_con[1] 10001 cko_word_con[2] 10010 mpll_pwron (ASIC control) 10011 mpll_ck_off
9–5 dtb_sel0	Selects wire to drive onto DTB bit 0: All other bits: Disabled 00000 Disabled 00001 mpll_gear_shift 00010 mpll_reset 00011 mpll_pwron (at analog boundary) 00100 reset_n 00101 cr_ack 00110 power_good 00111 op_done 01000 cr_read 01001 cr_write 01010 cr_cap_data 01011 cr_cap_addr 01100 rtune_do_tune 01101 cko_alive_con[0] 01110 cko_alive_con[1] 01111 cko_word_con[0] 10000 cko_word_con[1] 10001 cko_word_con[2] 10010 mpll_pwron (ASIC control) 10011 mpll_ck_off
4 refclk_delay	Delays refclk output of prescaler
3 dis_para_creg	Disables parallel creg interface
2 ovrd_clkdrv	Overrides clock driver controls
1 clkdrv_dig	Value for digital clock drivers
0 clkdrv_ana	Value for analog clock drivers

64.7.23 MPLL Test Register (clock_MPLL_TEST)

Address: 0x0017

Reset value: 16'b 0000 0000 0000 0000

This register contains MPLL test controls.

Address: clock_MPLL_TEST is 0h base + 17h offset = 0017h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	ovrd_ctl	gearshift_val	reset_val	meas_iv											meas_gd	atb_sense
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

clock_MPLL_TEST field descriptions

Field	Description
15 ovrd_ctl	Overrides MPLL reset and gearshift controls
14 gearshift_val	Value to override for mpll_gearshift
13 reset_val	Value to override for mpll_reset
12–2 meas_iv	Measures various MPLL controls: • Bit 2: Measures dcc_vcntrl_p on atb_sense_p • Bit 3: Measures dcc_vcntrl_m on atb_sense_m • Bit 4: Measures 1-V supply voltage on atb_sense_m • Bit 5: Measures vp_cp voltage on atb_sense_p; gd on atb_sense_m • Bit 6: Measures VCO supply voltage on atb_sense_p; gd on atb_sense_m • Bit 7: Measures clock tree supply voltage on atb_sense_p; gd on atb_sense_m • Bit 8: Measures vp16 on atb_sense_p; gd on atb_sense_m • Bit 9: Measures vref on atb_sense_p; gd on atb_sense_m • Bit 10: Measures vcntrl on atb_sense_m • Bit 11: Measures copy of bias current in oscillator on atb_force_m • Bit 12: Enables phase linearity testing of phase interpolator and VCO
1 meas_gd	Measures Ground For correct measurements, this field must be set when various meas_iv bits are set.
0 atb_sense	Hooks up ATB sense lines

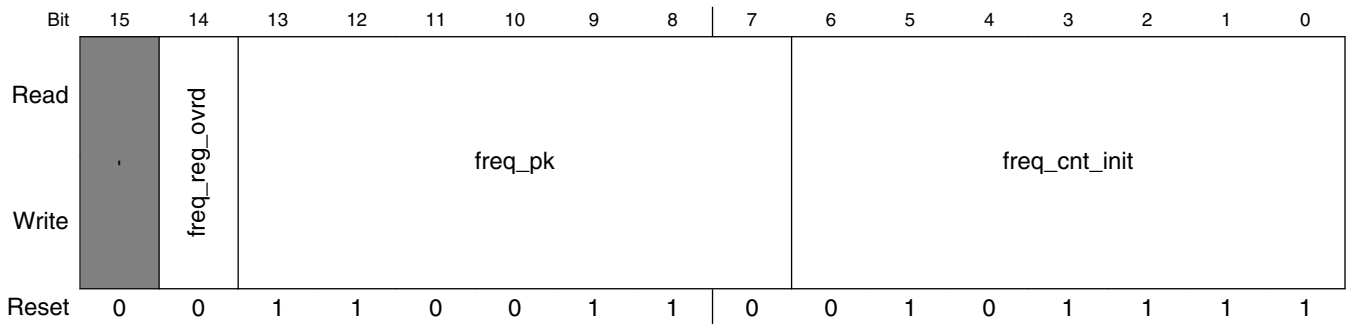
64.7.24 Spread Spectrum Frequency Register (clock_SS_FREQ)

Address: 0x0018

Reset value: 16'b x011 0011 0010 1111

This register contains the frequency register override, peak frequency value, and frequency counter step values.

Address: clock_SS_FREQ is 0h base + 18h offset = 0018h



clock_SS_FREQ field descriptions

Field	Description
15 -	Reserved
14 freq_reg_ovrd	Override control, indicating that overridden value is active
13–7 freq_pk	Peak frequency value
6–0 freq_cnt_init	Frequency counter step value. **Note:** This value is independent of the freq_pk value.

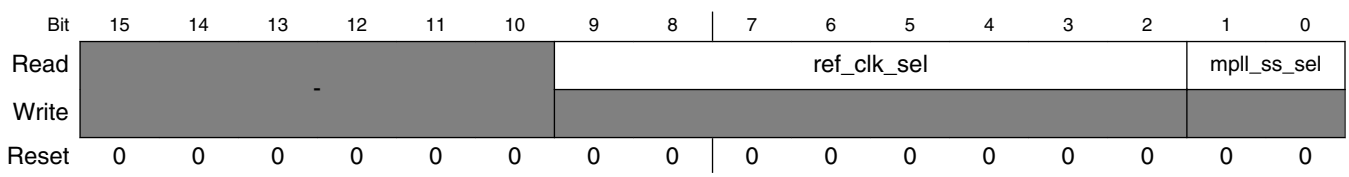
64.7.25 Clock Select Status Register (clock_SEL_STAT)

Address: 0x0019

Reset value: 16'bxxxx xxxx xxxx xxxx (depends on inputs)

This register indicates the status of the ref_clk_sel and mpll_ss_sel inputs.

Address: clock_SEL_STAT is 0h base + 19h offset = 0019h



clock_SEL_STAT field descriptions

Field	Description
15–10 -	Reserved
9–2 ref_clk_sel	Reference clock select input
1–0 mpll_ss_sel	MPLL spread spectrum select input

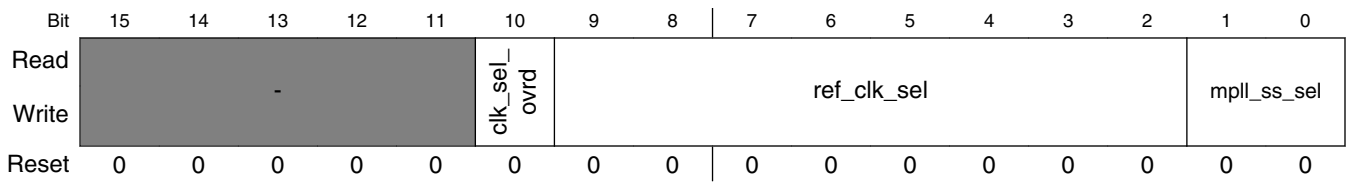
64.7.26 Clock Select Override Register (clock_SEL_OVRD)

Address: 0x001A

Reset value: 16'b0000 0000 0000 0000

This register contains the clock select override, the ref_clk_sel override value, and the mpll_ss_sel override value.

Address: clock_SEL_OVRD is 0h base + 1Ah offset = 001Ah



clock_SEL_OVRD field descriptions

Field	Description
15–11 -	Reserved
10 clk_sel_ovrd	Override control, indicating that the overridden value is active
9–2 ref_clk_sel	Reference clock select
1–0 mpll_ss_sel	MPLL spread spectrum select

64.7.27 Reset Register (clock_RESET)

Address: 0x7F3F

Reset value: 16'b xxxx xxxx xxxx xxx0

This register is a write-only register (not a real register) that resets the SATA2 PHY.

Upon writing the PHY reset bit in the reset register, the internal PHY reset is active immediately. Since the reset also affects the control register state machine, there will not be an acknowledgement of the write; that is, cr_ack will not be asserted.

NOTE

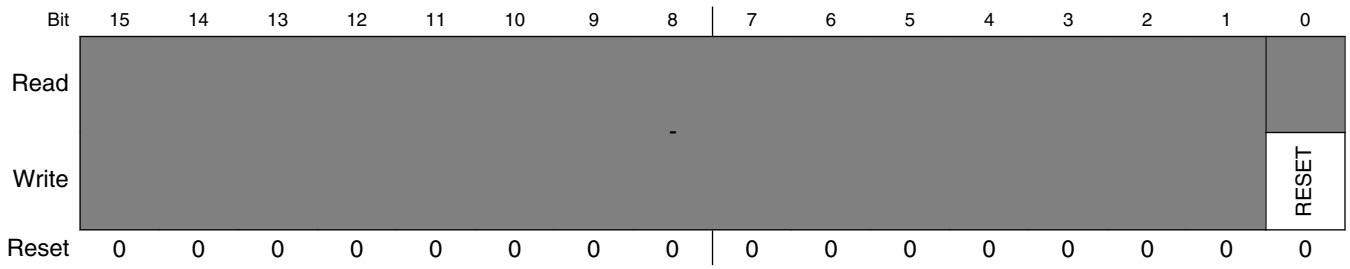
Diagnostic code should treat the *lack* of an acknowledgment of the write as a *successful* write; alternatively, it should treat the PHY *acknowledging* a write of the reset as a write *failure*. This

is the opposite expectation of all other registers, where the lack is a failure and the *acknowledge* is successful.

NOTE

It is sufficient to wait 20 ref_clock cycles in order to determine that the acknowledgement has not occurred.

Address: clock_RESET is 0h base + 7F3Fh offset = 7F3Fh



clock_RESET field descriptions

Field	Description
15–1 -	Reserved
0 RESET	Writing a 1 to this field resets the SATA2 PHY.

64.8 lanej Memory Map/Register Definition

Register Addresses

The SATA2 PHY comprises two parts, the Clock module and one or more lane modules. Only one Clock module exists in each assembly, but there can be multiple lanes.

NOTE

SATA PHY registers are only accessible by the corresponding controller (SATA_P0_PCSR_PHYCR and SATA_P0_PCSR_PHYSR) or in debug through the JTAG port. SATA PHY is not memory mapped to processor address space, so the absolute addresses shown is the relative address and is not valid. See SATA Memory Map for more information.

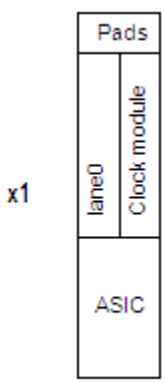
Broadcast Addressing

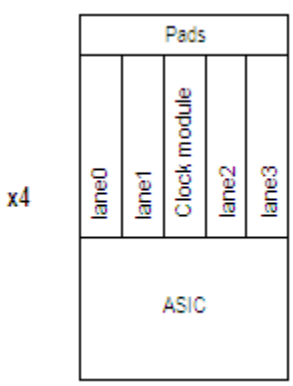
In addition to supporting writes to a single register, the register controller in the SATA2 PHY also supports broadcast writes. Broadcast writes make it easy (a single register write operation) to write the same value into N instantiations of the same register that exist in N lanes. To do a broadcast write to all lanes, simply replace the upper byte of the address with 0xA3. Note that broadcast reading of registers is not possible.

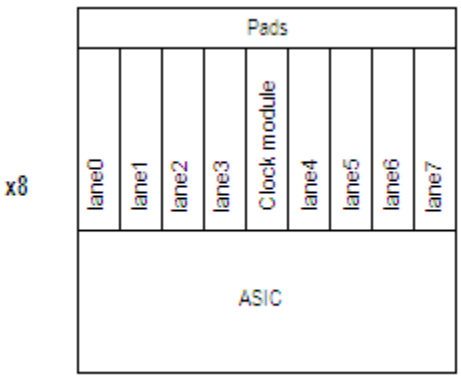
Per-Lane Register Numbering

NOTE

In an N lane SATA2 PHY, there are a total of N instantiations of each register. Each register name begins with "lane0." When referring to a particular lane, the "0" is replaced with the lane number, as in lane3.dpll.freq. The upper byte in the 16-bit address for all registers in the lane is 0x2{lane#}, where lane# is 0x0 for an x1 configuration, between 0x0 and 0x7 for an x8 configuration, and between 0x0 and 0x3 for an x4 configuration. Lane numbering always starts from 0 at the far-left side, as shown in the following three figures:







In the tables in this section, the lower byte in the 16-bit address is noted as the base address.

lane0 memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
2001	Transmit Input Status Register (lane0_TX_STAT)	16	R	0000h	64.8.1/ 3993

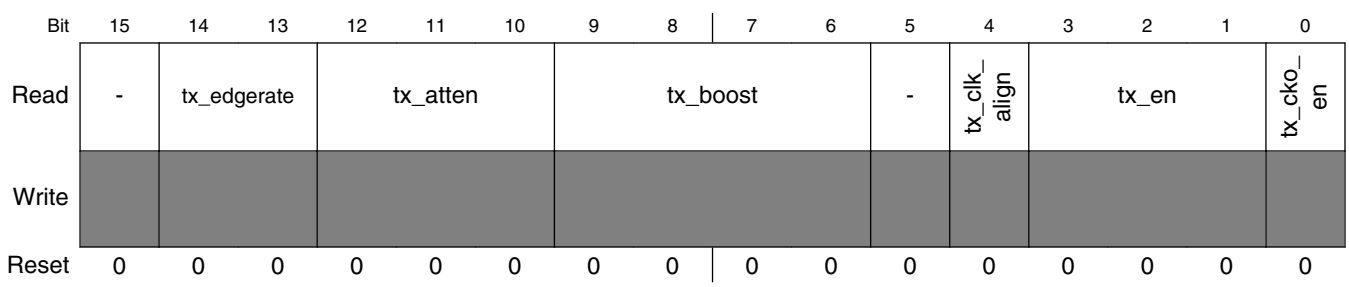
64.8.1 Transmit Input Status Register (lane0_TX_STAT)

Address: 0x2001

Reset value: 16'b xxxx xxxx xxxx xxxx (depends on inputs)

This register indicates the status of transmit control inputs.

Address: lane0_TX_STAT is 0h base + 2001h offset = 2001h



lane0_TX_STAT field descriptions

Field	Description
15 -	Always reads as 1
14–13 tx_edgerate	Edge rate control
12–10 tx_atten	Attenuation amount control
9–6 tx_boost	Boost amount control
5 -	Always reads as 0
4 tx_clk_align	Command to align clocks
3–1 tx_en	Transmit enable control
0 tx_cko_en	tx_cko clock enable

64.8.2 Receiver Input Status Register (lane0_RX_STAT)

Address: 0x2002

Reset value: 16'b xxxx xxxx xxxx xxxx (depends on inputs)

This register indicates the status of receiver control inputs.

Address: lane0_RX_STAT is 0h base + 2002h offset = 2002h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	-		los_ctl		dpll_reset	rx_dpll_mode			rx_eq_val			rx_term_en	rx_align_en	rx_en	rx_pll_pwron	half_rate
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

lane0_RX_STAT field descriptions

Field	Description
15–14 -	Always reads as 1
13–12 los_ctl	LOS filtering mode control

Table continues on the next page...

lane0_RX_STAT field descriptions (continued)

Field	Description
11 dpll_reset	DPLL reset control
10–8 rx_dpll_mode	DPLL mode control
7–5 rx_eq_val	Equalization amount control
4 rx_term_en	Receiver termination enable
3 rx_align_en	Receiver alignment enable
2 rx_en	Receiver enable control
1 rx_pll_pwron	PLL power state control
0 half_rate	Digital half-rate data control

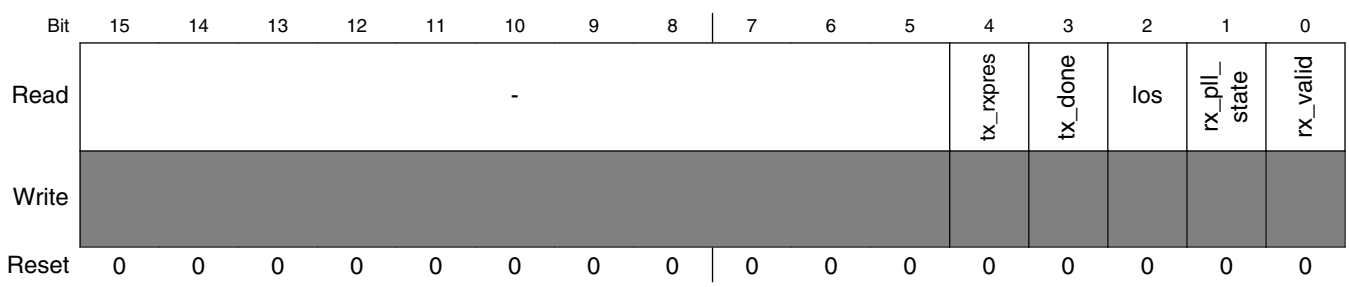
64.8.3 Output Status Register (lane0_OUT_STAT)

Address: 0x2003

Reset value: 16'b xxxx xxxx xxxx xxxx (depends on inputs)

This register indicates the status of output signals.

Address: lane0_OUT_STAT is 0h base + 2003h offset = 2003h



lane0_OUT_STAT field descriptions

Field	Description
15–5 -	Always reads as 1
4 tx_rxpres	Transmit receiver detection result

Table continues on the next page...

lane0_OUT_STAT field descriptions (continued)

Field	Description
3 tx_done	Transmit operation is complete output
2 los	Loss of signal output
1 rx_pll_state	Current state of Rx PLL
0 rx_valid	Receiver valid output

64.8.4 Transmit Input Override Register (lane0_TX_OVRD)

Address: 0x2004

Reset value: 16'b 0000 0000 0000 0111

This register contains the override transmitter control inputs.

Address: lane0_TX_OVRD is 0h base + 2004h offset = 2004h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	ovrd	tx_edgerate		tx_atten			tx_boost				tx_dis_align	tx_clk_align	tx_en			tx_cko_en
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

lane0_TX_OVRD field descriptions

Field	Description
15 ovrd	Enables override of all bits in this register
14–13 tx_edgerate	Edge rate control
12–10 tx_atten	Attenuation amount control
9–6 tx_boost	Boost amount control
5 tx_dis_align	Disables clock alignment FSM
4 tx_clk_align	Command to align clocks
3–1 tx_en	Transmit enable control
0 tx_cko_en	tx_cko clock enable

64.8.5 Receive Input Override Register (lane0_RX_OVRD)

Address: 0x2005

Reset value: 16'b x001 0100 0001 1110

This register contains the override of receiver control inputs.

Address: lane0_RX_OVRD is 0h base + 2005h offset = 2005h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	-	ovrd	los_ctl		dpll_reset	rx_dpll_mode			rx_eq_val			rx_term_en	rx_align_en	rx_en	rx_pll_pwron	half_rate
Reset	0	0	0	1	0	1	0	0	0	0	0	1	0	1	1	0

lane0_RX_OVRD field descriptions

Field	Description
15 -	Reserved
14 ovrd	Enables override of all bits in this register
13–12 los_ctl	LOS filtering mode control
11 dpll_reset	DPLL reset control
10–8 rx_dpll_mode	DPLL mode control
7–5 rx_eq_val	Equalization amount control
4 rx_term_en	Receiver termination enable
3 rx_align_en	Receiver alignment enable
2 rx_en	Receiver enable control
1 rx_pll_pwron	PLL power state control
0 half_rate	Digital half-rate data control

64.8.6 Output Override Register (lane0_OUT_OVRD)

Address: 0x2006

Reset value: 16'b xxxx xxxx xx01 0001

This register contains the override of output signals.

Address: lane0_OUT_OVRD is 0h base + 2006h offset = 2006h

lane0_OUT_OVRD field descriptions

Field	Description
15–6 -	Reserved
5 ovrd	Enables override of all bits in this register
4 tx_rxpres	Transmit receiver detection result
3 tx_done	Transmit operation is complete output
2 los	Loss of signal output
1 rx_pll_state	Current state of Rx PLL
0 rx_valid	Receiver valid output

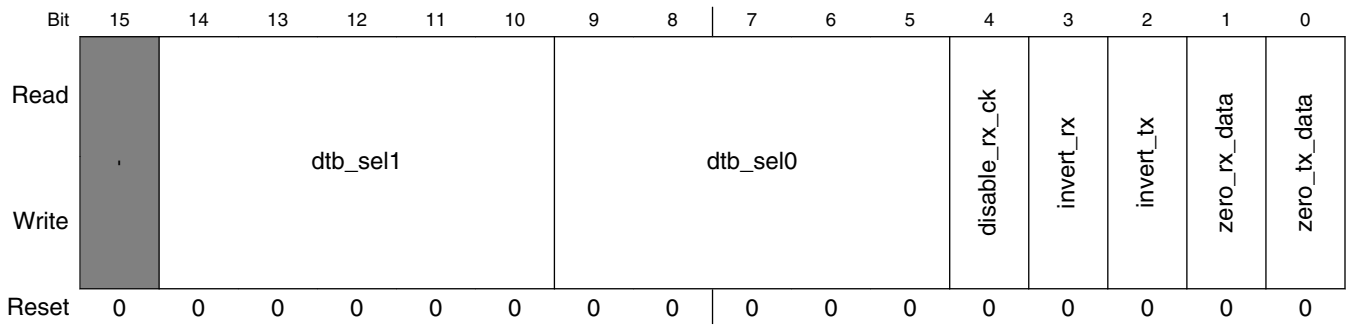
64.8.7 Debug Control Register (lane0_DBG_CTL)

Address: 0x2007

Reset value: 16'b x000 0000 0000 0000

This register contains debug controls.

Address: lane0_DBG_CTL is 0h base + 2007h offset = 2007h



lane0_DBG_CTL field descriptions

Field	Description
15 -	Reserved
14–10 dtb_sel1	All other bits: Disabled Selects wire to drive onto DTB bit 1: 00000 Disabled 00001 half_rate 00010 tx_en[0] 00011 tx_en[1] 00100 tx_en[2] 00101 tx_clk_align 00110 n/a 00111 rx_pll_pwron 01000 rx_en 01001 dpll_reset 01010 rx_valid 01011 rx_pll_state 01100 los 01101 tx_done 01110 rx_ck (output to ASIC) 01111 ck_rx (PLL output) 10000 ck_los 10001 tx_ck (ASIC input) 10010 ck_tx_out (serializer output) 10011 pll_pwron (analog input) 10100 pll_reset 10101 ser_clk_kill 10110 LBERT pg strobe 10111 rx_present_p (sampled) 11000 rx_present_m (sampled) 11001 acjt receiver o/p from rx_p 11010 acjt receiver o/p from rx_m

3 invert_rx	Inverts receive data (pre-LBERT)
2 invert_tx	Inverts transmit data (post-LBERT)
1 zero_rx_data	Overrides all receive data to zeros
0 zero_tx_data	Overrides all transmit data to zeros

64.8.8 Pattern Generator Control Register (lane0_PG_CTL)

Address: 0x2010

Reset value: 16'b xx00 0000 0000 0000 0000

This register contains pattern generator controls.

Address: lane0_PG_CTL is 0h base + 2010h offset = 2010h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	-		pat0										trigger_err	mode		
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

lane0_PG_CTL field descriptions

Field	Description
15–14 -	Reserved
13–4 pat0	Pattern for modes 3-5
3 trigger_err	Inserts a single error into the LSB
2–0 mode	Selects a pattern to generate: 000 Disabled 001 lfsr15. X^15 + X^14 + 1 010 lfsr7. X^7 + X^6 + 1 011 Fixed word (PAT0)3'b 100 DC balanced word (PAT0, ~PAT0) 101 Fixed pattern: (000, PAT0, 3ff, ~PAT0) 110 Reserved 111 Reserved

64.8.9 Pattern Matcher Control Register (lane0_PM_CTL)

Address: 0x2018

Reset value: 16'b xxxx xxxx xxxx 0000

This register contains pattern matcher controls.

Address: lane0_PM_CTL is 0h base + 2018h offset = 2018h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	-												sync	mode		
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

lane0_PM_CTL field descriptions

Field	Description
15–4 -	Reserved
3 sync	To enable checking, "Synchronize pattern matcher LFSR with incoming data" must be turned on, then turned off.
2–0 mode	All other bits: Reserved Pattern to match: 000 Disabled 001 lfsr15 010 lfsr7 011 d[n] = d[n-10] 100 d[n] = !d[n-10]

64.8.10 Pattern Matcher Error Register (lane0_PM_ERR)

Address: 0x2019

Reset value: 16'b xxxx xxxx xxxx xxxx (a read resets the register)

This register is the pattern match error counter. When the clock to the error counter is turned off, reads and writes to the register are queued until the clock is turned back on.

Address: lane0_PM_ERR is 0h base + 2019h offset = 2019h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	ov14	count														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

lane0_PM_ERR field descriptions

Field	Description
15 ov14	If this field is active, the count is multiplied by 128. If ov14 is set to 1 and count = 2^15 - 1, indicates overflow of counter.
14–0 count	Current error count If the ov14 field is active, the count is multiplied by 128.

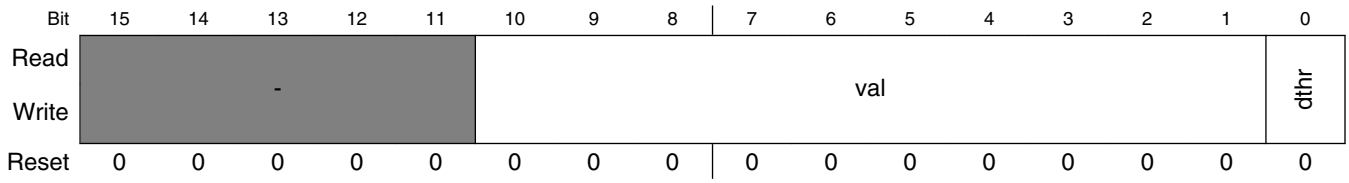
64.8.11 DPLL Phase Register (lane0_DPLL_PHASE)

Address: 0x201A

Reset value: 16'b xxxx x000 0000 0000

This register contains the current phase selector value.

Address: lane0_DPLL_PHASE is 0h base + 201Ah offset = 201Ah



lane0_DPLL_PHASE field descriptions

Field	Description
15–11 -	Reserved
10–1 val	Phase is .UI/512 x VAL ps from zero reference
0 dthr	Bits below the useful resolution

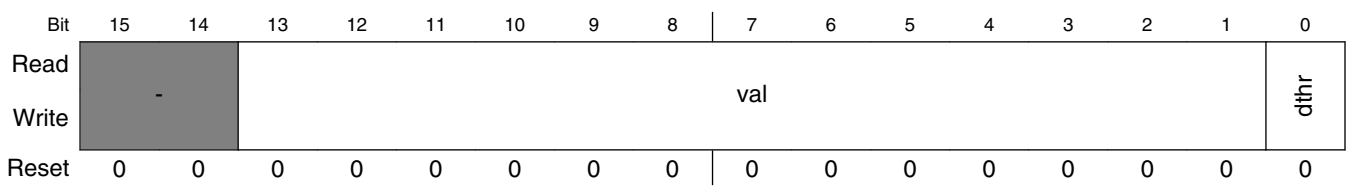
64.8.12 DPLL Frequency Register (lane0_DPLL_FREQ)

Address: 0x201B

Reset value: 16'b xx00 0000 0000 0000

This register contains the current frequency integrator value.

Address: lane0_DPLL_FREQ is 0h base + 201Bh offset = 201Bh



lane0_DPLL_FREQ field descriptions

Field	Description
15–14 -	Reserved
13–1 val	Frequency is 1.526 x VAL ppm from the reference
0 dthr	Bits below the useful resolution

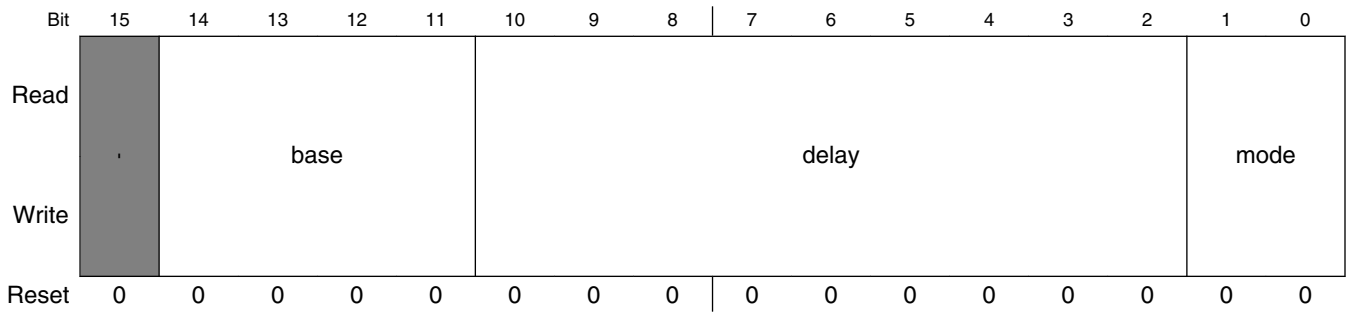
64.8.13 Scope Control Register (lane0_SCOPE_CTL)

Address: 0x201C

Reset value: 16'b x000 0000 0000 0000

This register contains control bits for the per-transceiver scope portion.

Address: lane0_SCOPE_CTL is 0h base + 201Ch offset = 201Ch



lane0_SCOPE_CTL field descriptions

Field	Description
15 -	Reserved
14–11 base	The bit to be sampled when mode = 2'b01
10–2 delay	Number of symbols to skip between samples
1–0 mode	Mode of counters: 00 Off 01 Sample every 10 bits (see base) 10 Sample every 11 + 10 x delay bits 11 Sample every 12 + 10 x delay bits

64.8.14 Receiver Control Register (lane0_RX_CTL)

Address: 0x201D

Reset value: 16'b x000 0000 0000 1111

This register contains control bits for the receiver in the recovered domain.

Address: lane0_RX_CTL is 0h base + 201Dh offset = 201Dh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15–8 -	Reserved
7 frc_pwrst	Locally forces power state When this field is set to 1, the tx_en[1:0] input is overridden by en_lcl.
6–5 en_lcl	Locally forces tx_en[1:0]: 00 Power off 01 Tx idle (slow) 10 Transmit data 11 Tx idle (fast)
4 frc_do	Forces dataovrd locally When set to 1, this field overrides the input data_ovrd value.
3 dataovrd_lcl	RWCr Local dataovrd control value To validate this field, set lane0.tx_ana.control.frc_do.
2 frc_beacon	Forces beacon to local value (bcn_lcl) When this field is set to 1, BCN_LVL overrides input value.
1 bcn_lcl	Local beacon on/off control value To validate this field, set lane0.tx_ana.control.frc_beacon.
0 -	Reserved

Chapter 65
Security Controller (SCC)

65.1 Introduction

Information security within a data processing platform is dependent upon the platform's ability to provide mandatory and optional information protection services. A secure platform is intended to protect sensitive data such as encryption keys, software and premium data content from unauthorized access in the form of inspection (read), modification (write), or execution (use). Security assurance refers to the degree of confidence that security claims are actually met and is therefore associated with the correctness of the security design and the integrity of the resources upon which it depends. The Freescale Platform Independent Security Architecture (PISA) incorporates the hardware and software resources necessary to provide high assurance for the security claims of a given embedded platform. PISA provides a secure foundation upon which platform architects can construct application-specific security mechanisms. The Security Controller (SCC) is an integral part of that PISA security foundation. A block diagram of the SCC is shown in Figure 65-1.

65.1.1 Overview

The SCC-AES is the second generation of the Security Controller. It implements secure RAM that can be used either as general-purpose memory for storing data and software, or as special confidentiality-preserving memory that protects disclosure-sensitive data such as cryptographic keys, passwords, code, or PIN numbers. The RAM within the SCC-AES is divided into 4 partitions, each of which contains 4 Kbytes, and is byte accessible. A partition can be allocated to either the TrustZone or non-TrustZone domains of the ARM, which can then determine how this partition can be accessed by the other domain and other bus masters. The SCC-AES aborts accesses to a partition that are not in accordance with the access permissions set by the partition's current owner.

The SCC-AES also incorporates cryptographic logic and a DMA engine that can be used to safely export the data stored within a partition to external RAM or non-volatile memory. As the data is exported it is encrypted with AES using a secret non-volatile 256-bit key (different in each SCC-AES). This secret key cannot be read or changed by software, or other bus masters, or by JTAG/scan logic. Before this 256-bit key is used to encrypt or decrypt data for a partition, the key value is modified by the SCC-AES hardware based upon the ID of the partition owner and the access permissions that the owner has set. Software can optionally supply additional key modification data that is also mixed with the basic secret key value. These key modifications ensure that data owned and exported by one domain cannot be decrypted and placed within a partition owned by the other domain, or in a partition with less restricted access permissions.

The SCC-AES also maintains the security state of the SoC. Upon reset, the SCC-AES hardware performs a number of security checks, and the High Assurance Boot (HAB) software on the SoC performs additional checks. If all checks pass, the SCC-AES's security state is set to Secure, otherwise the state is set to Non-secure. In Secure state, the Secret Key is available for cryptographic operations. In the Non-secure state, a known default key is used in place of the Secret Key. This allows the SCC-AES to be tested without compromising the confidentiality of data that has been encrypted using keys derived from the Secret Key. If RTIC and/or SAHARA are present on the SoC, the SCC-AES monitors their security status outputs. The SCC-AES also monitors indications of failures or potential security intrusions that are output by other components on the SoC. If security failures are detected, the SCC-AES's security state transitions to Fail state. In Fail state the SCC-AES shuts off access to, and begins erasing, the SCC-AES partitions that contain confidential data. Cryptographic operations are disabled in Fail state.

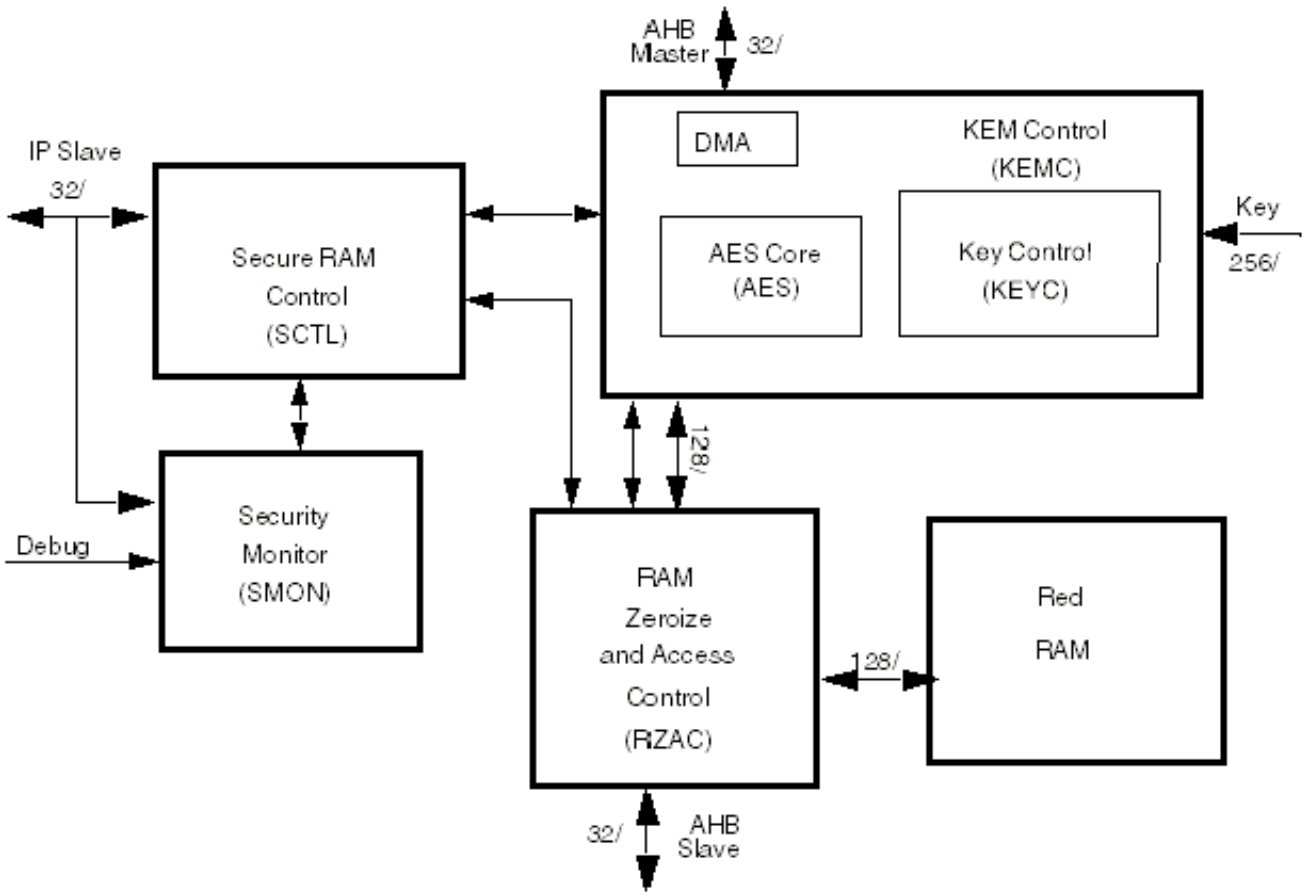

Figure 65-1. Block Diagram of SCC-AES

65.1.2 Features

The SCC-AES provides the following features:

- An autonomous hardware security state controller with security violation inputs, which are tied to all platform security violation signals to trigger a security shutdown when a violation is detected.
- Access Control to ensure supervisor-mode and user-mode access separation.
- Controls to ensure high assurance internal boot is the only procedure that can put the SCC-AES into the Secure state after Reset.
- A dedicated AES cryptographic engine to encrypt plaintext (RED) data or decrypt ciphertext (BLACK) data.
- A port to accept an OTP 256-bit statistically unique secret key, referred to as the Security Key, for use by the AES engine only when it is in the Secure state and which is provided/programmed at manufacture and unavailable for external test or inspection.

- Clearing of certain security sensitive registers upon scan entry.
- Special scan interface logic to detect whether scan test has been active since the last reset and consequently whether the current hardware security state can be trusted.
- A self-clearing (zeroizing) Red RAM, which clears itself upon reset, command, or failure and can therefore be used to store security-sensitive Red data (that is, disclosure-sensitive plaintext) such as cryptographic keys.
- A Security Timer, which is an independent security watchdog timer whose time-out triggers a security violation. Its use is mandatory in the Initialization state and optional in other SCC states.
- Bus Master access controls to prevent unauthorized access to Red Memory.
- An Algorithm Sequence Checker (ASC), which can be used by software to force software synchronization to the ASC's internal linear feedback shift register (LFSR) as a software assurance check. Its use is mandatory in the Initialization state and optional in other SCC states.
- A Bit Bank counter that can be used with the ASC to ensure that a cryptographic function uses the same number of algorithm bits as traffic bits to ensure that no traffic data is accidentally left in the clear.
- A Plaintext/Ciphertext comparator that may be used to ensure that a cryptographic algorithm has not been replaced with a function that XORs the data with a simple fixed pattern.
- Instruction storage and execution capability.

NOTE

Detailed information about the SCC is provided in the Security Manual. Contact your Freescale representative for information about obtaining this document.

Chapter 66
Smart Direct Memory Access Controller (SDMA)

66.1 Introduction

The Smart Direct Memory Access (SDMA) controller offers highly-competitive DMA features combined with software-based virtual-DMA flexibility. It enables data transfers between peripheral I/O devices and internal/external memories.

The SDMA controller helps maximize system performance by off-loading the ARM core in dynamic data routing.

66.1.1 Overview

The figure below shows a block diagram of the SDMA controller. It includes the custom RISC core along with its RAM, ROM, DMA units, the CRC unit, and the scheduler.

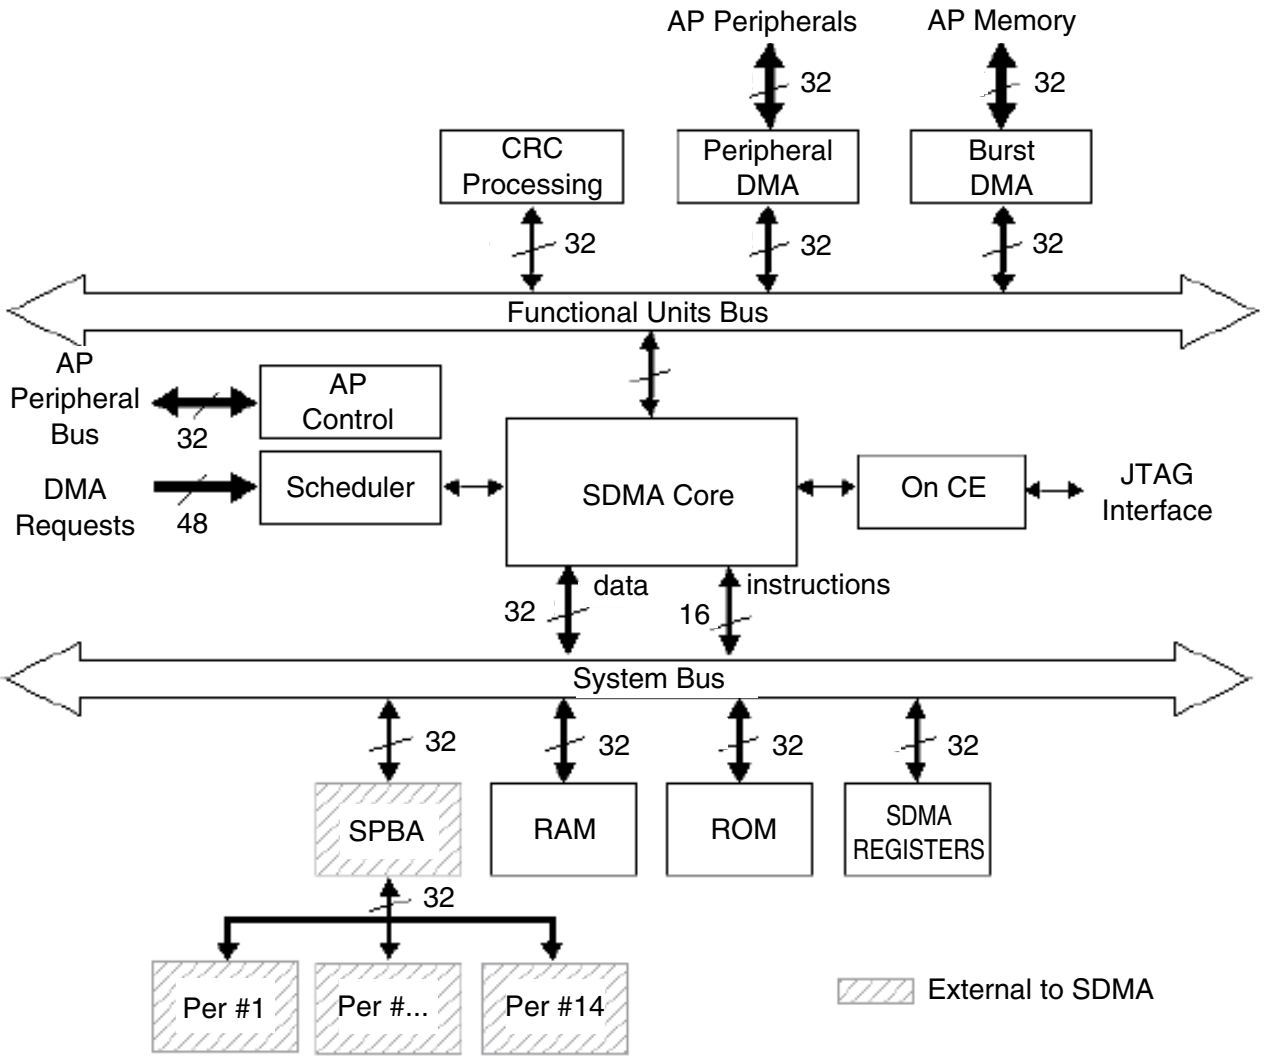

Figure 66-1. SDMA Block Diagram

The SDMA core executes short routines that perform DMA transfers; these routines are called *scripts*. The SDMA core interfaces to its own memory via the SDMA system bus. The SDMA system bus supports a 32-bit data path and a 16-bit address bus. The system bus datapath is used for both 16-bit instruction (program) memory access and 32-bit data access. DMA units interface to the core via the Functional Unit Bus and use dedicated registers to perform DMA transfers.

The SDMA memory contains a ROM and a RAM. The ROM contains startup scripts (for example, boot code) and other common utilities, which are referenced by the scripts that reside in the RAM. The internal RAM is divided into a context area and a script area (more details about this mapping are available in Instruction Memory Map and Data Memory Map).

Every transfer channel requires one context area to keep the contents of all the core and unit registers while inactive. Channel scripts are downloaded into the internal RAM by the SDMA using a dedicated channel that is started during the boot sequence. Downloads are invoked using commands and pointers provided by the ARM platform. Every channel contains a corresponding channel script located in RAM and/or ROM that can be reconfigured independently as-needed. Channel scripts can be stored in an external memory and downloaded when needed. The SDMA can be configured with any mixture of scripts to enable an endless combination of supported services.

The scheduler monitors and detects DMA requests, mapping them to channels, and mapping individual channels to a pre-configured priority. At any given point, the scheduler presents the highest priority channel that requires service to the SDMA core. A special SDMA core instruction is used to "conditionally yield" the current channel being executed to an eligible channel that requires service. If (and only if) there is an eligible channel pending, will the current channel execution be preempted.

There are two yield instructions that differently determine the eligible channels: In the first version, eligible channels are pending channels with a strictly higher priority than the current channel priority. In the second version (yieldge), eligible channels are pending channels with a priority that is greater or equal to the current channel priority. The scheduler detects devices that need service through its 48 DMA request inputs. After a request is detected, the scheduler determines the channel(s) that is (are) triggered by this request and marks it (them) as pending in the "Channel Pending (EP)" register. The priorities of all the pending channels are continuously evaluated in order to update the highest pending priority. The channel pending flag is cleared by the channel script when the transfer has completed.

The ARM platform control block contains the control registers used to configure the 32 individual channels. There are 48 Channel Enable registers, and every register maps one DMA request to any desired combination of channels. The 32 Priority registers are used to assign a programmable 1-of-7 level priority to every possible channel. This block also contains all other control registers that the ARM platform can access.

The 48 DMA requests that are connected to the scheduler come from a variety of sources. The "receive register full" and "transmit register empty" signals found in the UART and USB ports are typical examples of DMA requests that can be connected to the SDMA. These requests can be used to trigger a specific SDMA channel, or several channels.

There is an OnCE compatible debug port for product development. The OnCE includes support for setting breakpoints, single-step and trace, and register dump capability. In addition, all memory locations are accessible from the debug port.

66.1.2 Features

The following are the SDMA features:

- Multi-channel DMA supporting up to 32 time-division multiplexed DMA channels
- Hardware or software driven triggers for each channel
- 48 hardware driven triggers that can be mapped to any channel.
- Memory accesses including linear addressing, FIFO addressing and 2D addressing
- Fast context-switching with two-level, priority-based preemptive multi-tasking
- 16-bit instruction-set micro-RISC engine (the SDMA core)
- Two DMA units with some or all the following features:
  - Auto-flush and prefetch capability
  - Flexible address management (increment, decrement, and no address changes on source and destination address)
  - Misaligned data-transfer support
  - Uni-directional and bi-directional flows (copy mode)
  - Up to eight-word buffers for configurable burst transfers
- Support of byte-swapping and CRC calculations
- An available API and library of scripts
- Little-Endian and Big-Endian modes
- Hardware handshakes for low-power entry sequence
- Security support to lock contents of the SDMA script RAM.
- 4-Kbyte ROM containing startup scripts (for example, boot code) and other common utilities that can be referenced by RAM-located scripts
- 8-Kbyte RAM area is divided into a processor context area and a code space area used to store channel scripts that are downloaded from the system memory
- Debug support, including a OnCE port, real-time monitors, and embedded cross-trigger events
- Supported clock frequencies in process:
  - Configurable clock options for the SDMA core and the ARM platform DMA units
    - 1:2 ratio with maximum of SDMA core running at ARM platform Peripheral Bus speed and DMA running at max DMA frequency.
    - 1:1 ratio when both SDMA core and ARM platform DMA clocks are set to the ARM platform Peripheral Bus speed.
- Peripheral bus interface for configuration register programming by the ARM platform
- The SDMA RISC engine (arithmetic and logic operations, plus CRC acceleration), which is referred to as the "SDMA core."
- An internal peripheral bus connected to the Shared Peripherals Bus Interface (SPBA) that enables access to up to 14 shared peripherals. SDMA supports 32-bit accesses to word peripherals and 16-bit accesses to half-word peripherals.

- The peripheral DMA unit that is hooked-up to the ARM platform Crossbar Switch to service ARM peripherals
- The burst DMA unit is able to perform burst accesses to the external memory
- All the DMA units are 32-bit AHB masters. They are connected to different buses, thus allowing concurrent accesses.

66.2 Functional Description

Figure 66-2 shows the SDMA topology, and is composed of the following components:

- SDMA Core (SDMA Core)
- SDMA Scheduler (Scheduler)
- Functional Units:
  - CRC (CRC Calculation Unit)
  - Burst DMA (Burst DMA Unit)
  - Peripheral DMA (Peripheral DMA Unit)
- ARM platform Control for ARM control register access.
- Internal RAM and ROM Memory (SDMA Programming Model)
- OnCE debug Port (The OnCE Controller)

The functional unit bus provides access by the SDMA core to the CRC hardware accelerator and the DMA units. The system bus provides access to SDMA internal memory and also supports up to 14 peripherals.

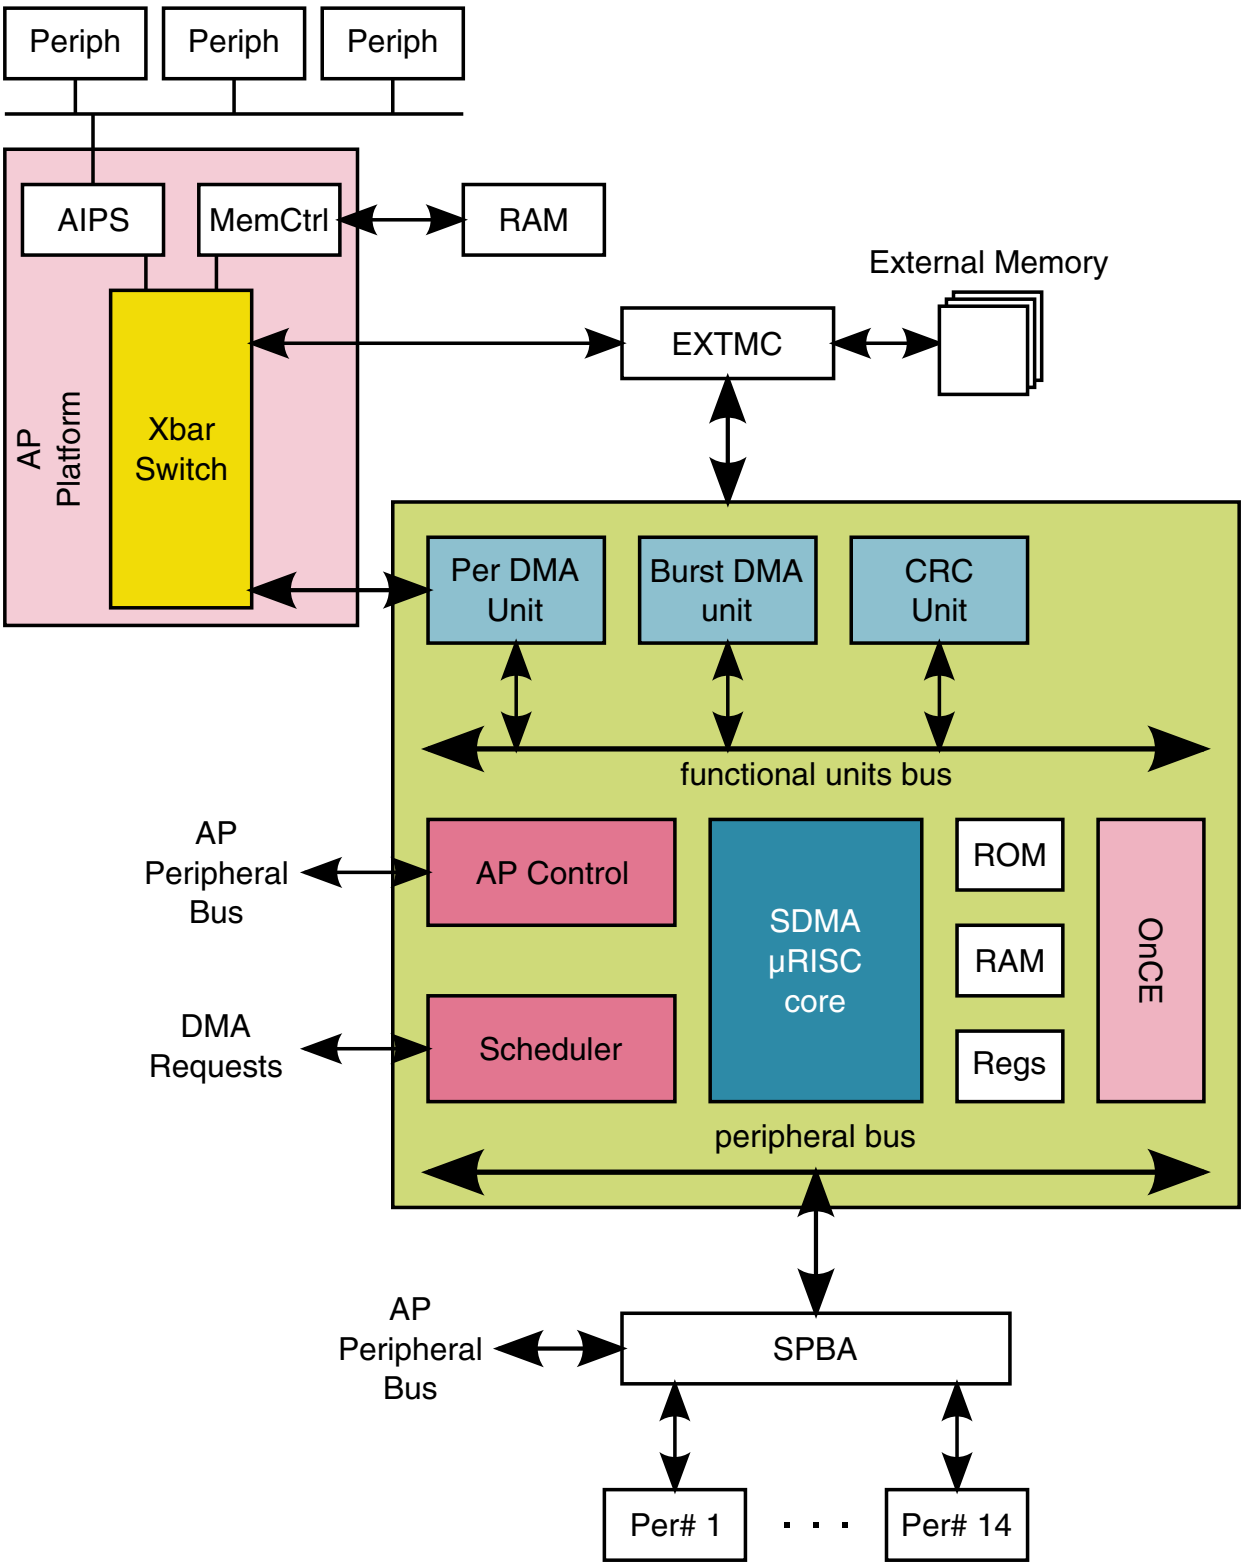

Figure 66-2. SDMA Connections

NOTE

EDITOR NOTE: This copy of the figure is for the case where the BP interfaces are NOT connected. Unconnected interfaces are removed from this diagram since not visible at all to the user.

66.3 SDMA Core

The SDMA core is a customized RISC-like processor that is specifically developed to control DMA units and perform L1 tasks like byte-stuffing or framing.

The SDMA core incorporates on-chip debug capability using the OnCE.

The SDMA core is based on a 32-bit register architecture with 16-bit instructions. There are eight general purpose 32-bit registers, four flags (T, LM, SF, and DF), and four PCU registers (PC, RPC, SPC, and EPC) that can address 16,384 16-bit instructions.

66.3.1 SDMA Core Structure

The following figure shows the structure of the SDMA core. It also shows the different registers, calculation resources, and possible data movements.

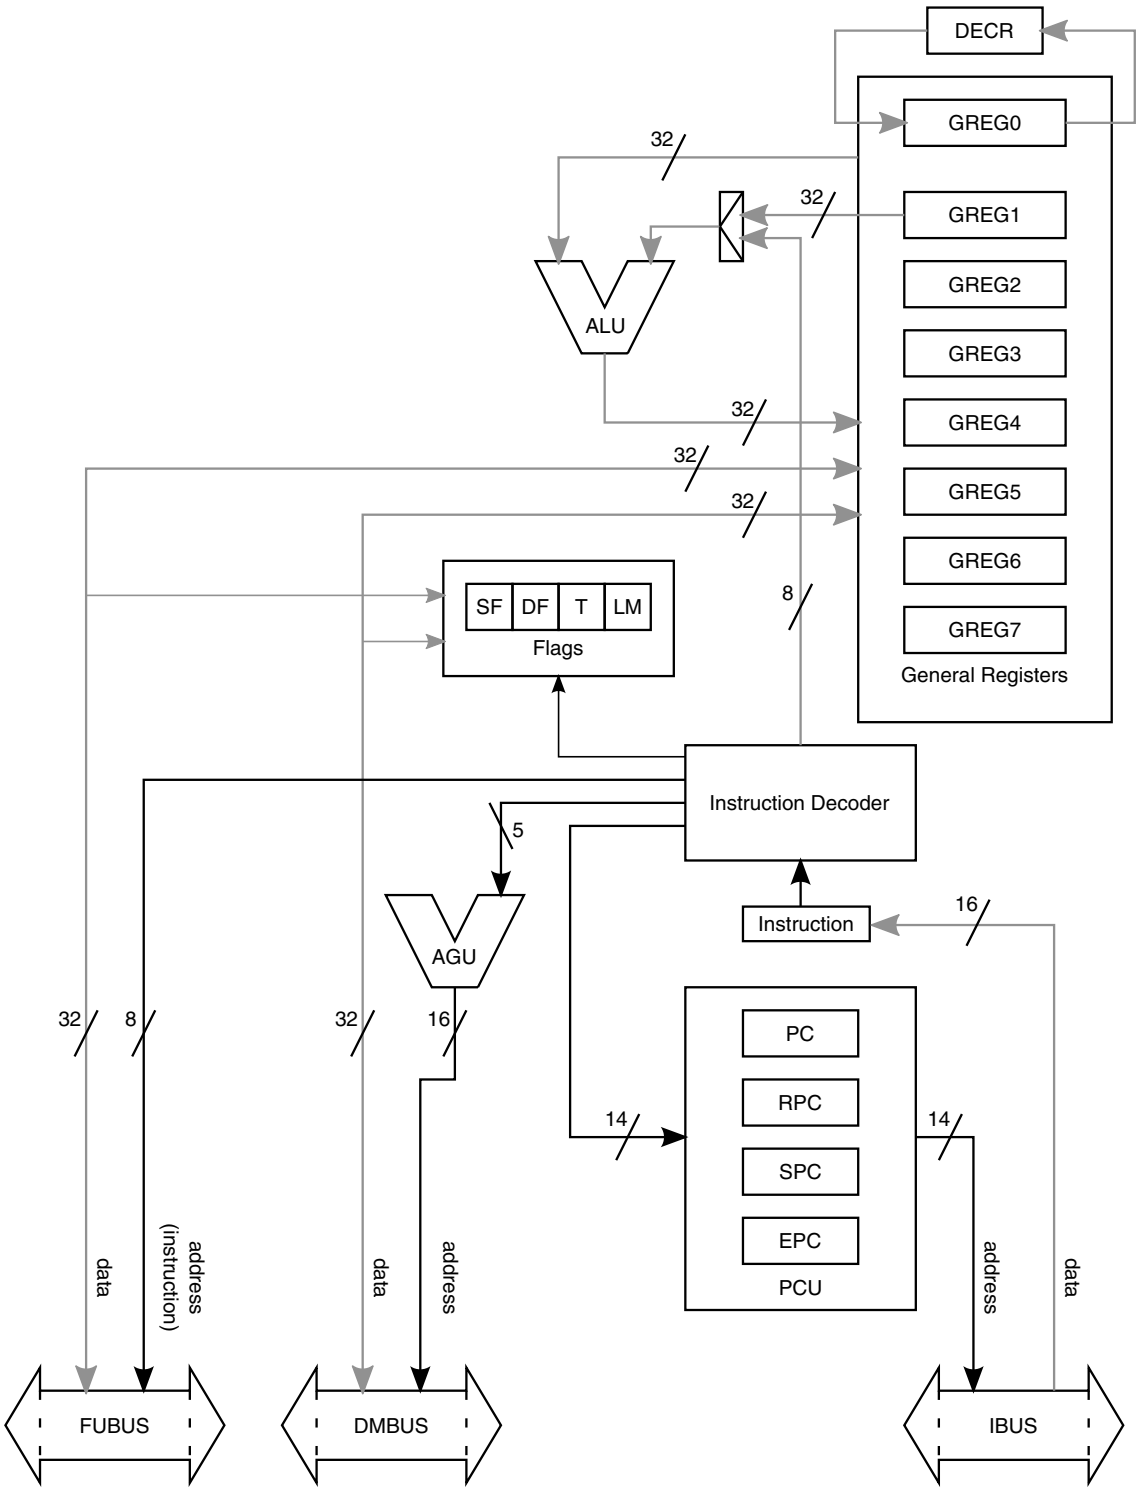

Figure 66-3. SDMA Core

- The Program Control Unit (PCU) is described in Program Control Unit (PCU). It handles the state of the core and generates the instruction fetch addresses. Instructions are retrieved from the Instruction Bus (IBUS) and stored in the SDMA

core instruction register prior to their decoding. The PCU contains the following registers:

- The Program Counter (PC) contains the address of the current instruction.
- The Return Program Counter (RPC) contains the address of the instruction that follows a jump to the subroutine.
- The Start Program Counter (SPC) contains the address of the first instruction of the current hardware loop.
- End Program Counter (EPC) contains the address of the last instruction of the current hardware loop.

- The other core registers are the general purpose registers (GREGn) and the flags.
  - The general purpose registers can be used to hold data and addresses. They can be loaded with immediate values (for example, 8-bit data that are encoded in the instruction), results of calculations that were performed with the ALU, 32-bit data that comes from the memory or peripherals via the Data Memory Bus (DMBUS), 32-bit data that comes from the DMAs or CRC via the Functional Units Bus (FUBUS) or another general purpose register. Their content can be the operands of the ALU, the data to send on either bus (DMBUS or FUBUS), or a pointer to memory (DMBUS address).
  - The general register 0 (GREG0) is also the hardware loop counter. In hardware loops, it cannot be used for any other purpose. This register uses a dedicated decrement unit (DECR) shown in Figure 66-3.
  - The flags reflect the status of operations:
    - SF and DF are set when the last load or store on either bus (FUBUS or DMBUS) received an error response.
    - LM is set when the core is executing instructions inside a hardware loop.
    - T is set when the ALU operation result was 0 or the loop counter reaches 0 (the latter is preponderant when an ALU operation is the last instruction of a hardware loop).
- The ALU has two operands: any general register and either a second general register or an immediate value. The result is always stored into the first general register. A NOP function can be utilized by moving a register's contents into itself (For example, the instruction: mov R0,R0).
- The 16-bit instructions are fetched via the instruction bus (IBUS) whose address is driven by the PC. The SDMA RAM and ROM are visible to the core as 16-bit devices through this interface.
- The memory (RAM and ROM), memory mapped registers, and external peripherals are accessed via the DMBUS. The address is always taken from a general register whose content is added to a 5-bit immediate value. This is the only available addressing mode. The DMBUS is a 32-bit data bus. Except for the peripherals that

are external to the SDMA, the address accuracy is the 32-bit word (for example, adding 1 to an address points to the next word, not the next byte).
- The functional units are accessed via the FUBUS connection. The data is exchanged with any general register, but the address (which in fact is the instruction and the selector of the functional unit) comes from an 8-bit field of the corresponding load or store.

66.3.2 Program Control Unit (PCU)

This part of the SDMA core is dedicated to the control of the RISC engine, as implied by the instructions that are executed. Its behavior is determined by the instruction type and the inputs of the SDMA.

It contains the PC, RPC, SPC, and EPC registers that are described in SDMA Core Structure.

66.3.2.1 Instruction Types

The state sequence and the delay of execution vary according to the type of the instruction. There are six possible categories of instructions, as follows:

1. Standard: Most of the instructions belong to this category, and always last 1 cycle.
2. ldf/stf: These are respectively the load and store instructions that access the functional units. They last 1+n cycles where n is the number of wait-states of the targeted functional unit.
3. ld/st: These are the load and store instructions that access the memory and peripherals. They last 1+n cycles where n is the number of wait-states of the targeted device (1 for the ROM, RAM, and memory mapped registers, 1 + the external peripheral wait-states). These instructions always last at least two cycles, but the core is able to handle them in one cycle. The first wait-state is inserted outside the core.
4. Branch: These are all the instructions that cause the Program Counter to point to another instruction other than the following one (for example, one that breaks the sequential flow). There are the absolute jumps, the conditional branches, the jump to the sub-routines, and the return from the sub-routine.
5. Loop,Modified Load or Store: The hardware loop instruction modifies the potential behavior of any load or store inside the loop (for example, when the LM flag is set). A jump may be implied after any such load or store if it received an error. The error causes an early exit of the loop, which means a jump to the instruction that follows the one that is pointed to by EPC. An additional cycle is required by the PCU to perform the jump (+1 to the ld/st/ldf/stf original execution delay). Although there is

usually an implicit jump after the last instruction of the loop when the PC goes back to SPC, this is performed at no cycle cost.

6. Done: The done, yield, or yieldge instructions are used to control channel switching. When no channel switching is performed, these instructions last a single cycle. When there is a change of channel or context switch, the delay is variable and depends on many factors (as detailed in Context Switching).

66.3.2.2 PCU States

The PCU state is visible through outputs of the SDMA (see Real-Time Debug Outputs) or the OnCE status register(see OnCE Status Register (OSTAT)).

The PCU state is a four-bit field that can take the values shown in the following table. Figure 66-4 shows the possible state transitions and the corresponding conditions.

Table 66-1. PCU States

Value	State	Description
0	Program	The is the usual instruction cycle.
1	Data	This state is inserted when there are wait-states during a load or a store on the data bus (ld/st type).
2	Change of Flow	This is the second cycle of any instruction that breaks the sequence of instructions (branch and done types). This state lasts only a single cycle; it is always followed by the Program state.
3	Error in Loop	This state is used when an error causes a hardware loop exit (loop-modified load or store type). This state only lasts a single cycle; it is always followed by the Program state.
4	Debug	he SDMA is stopped in debug mode.
5	Functional Unit	This state is inserted when there are wait-states during a load or a store on the functional units bus (ldf/stf type).
6	Sleep	No script is running: The core is idle after saving the last channel context.
7	Save	The context switch FSM is saving the current channel.
8	Program in Sleep	Same as Program except there is no associated channel, this state is used when instructions are executed after entering debug mode, whereas the core was in either Sleep mode.
9	Data in Sleep	This is the same as Data except there is no associated channel.
10	Change of Flow in Sleep	This is the same as Change of Flow except there is no associated channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
11	Error in Loop in Sleep	This is the same as Error in Loop except there is no associated. channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
12	Debug in Sleep	This is the same as Debug except the core was put in debug mode when no channel was active.

Table continues on the next page...

Table 66-1. PCU States (continued)

Value	State	Description
13	Functional Unit in Sleep	This is the same as Functional Unit except there is no associated channel.
14	Sleep after Reset	This shows that no script is running, and the core is idle after a reset. When a channel becomes active, no context is restored but the core starts its boot program located at address 0 (or the address available in register in Channel 0 Boot Address (SDMAARM_CHN0ADDR)).
15	Restore	The context switch FSM is restoring the next channel context.

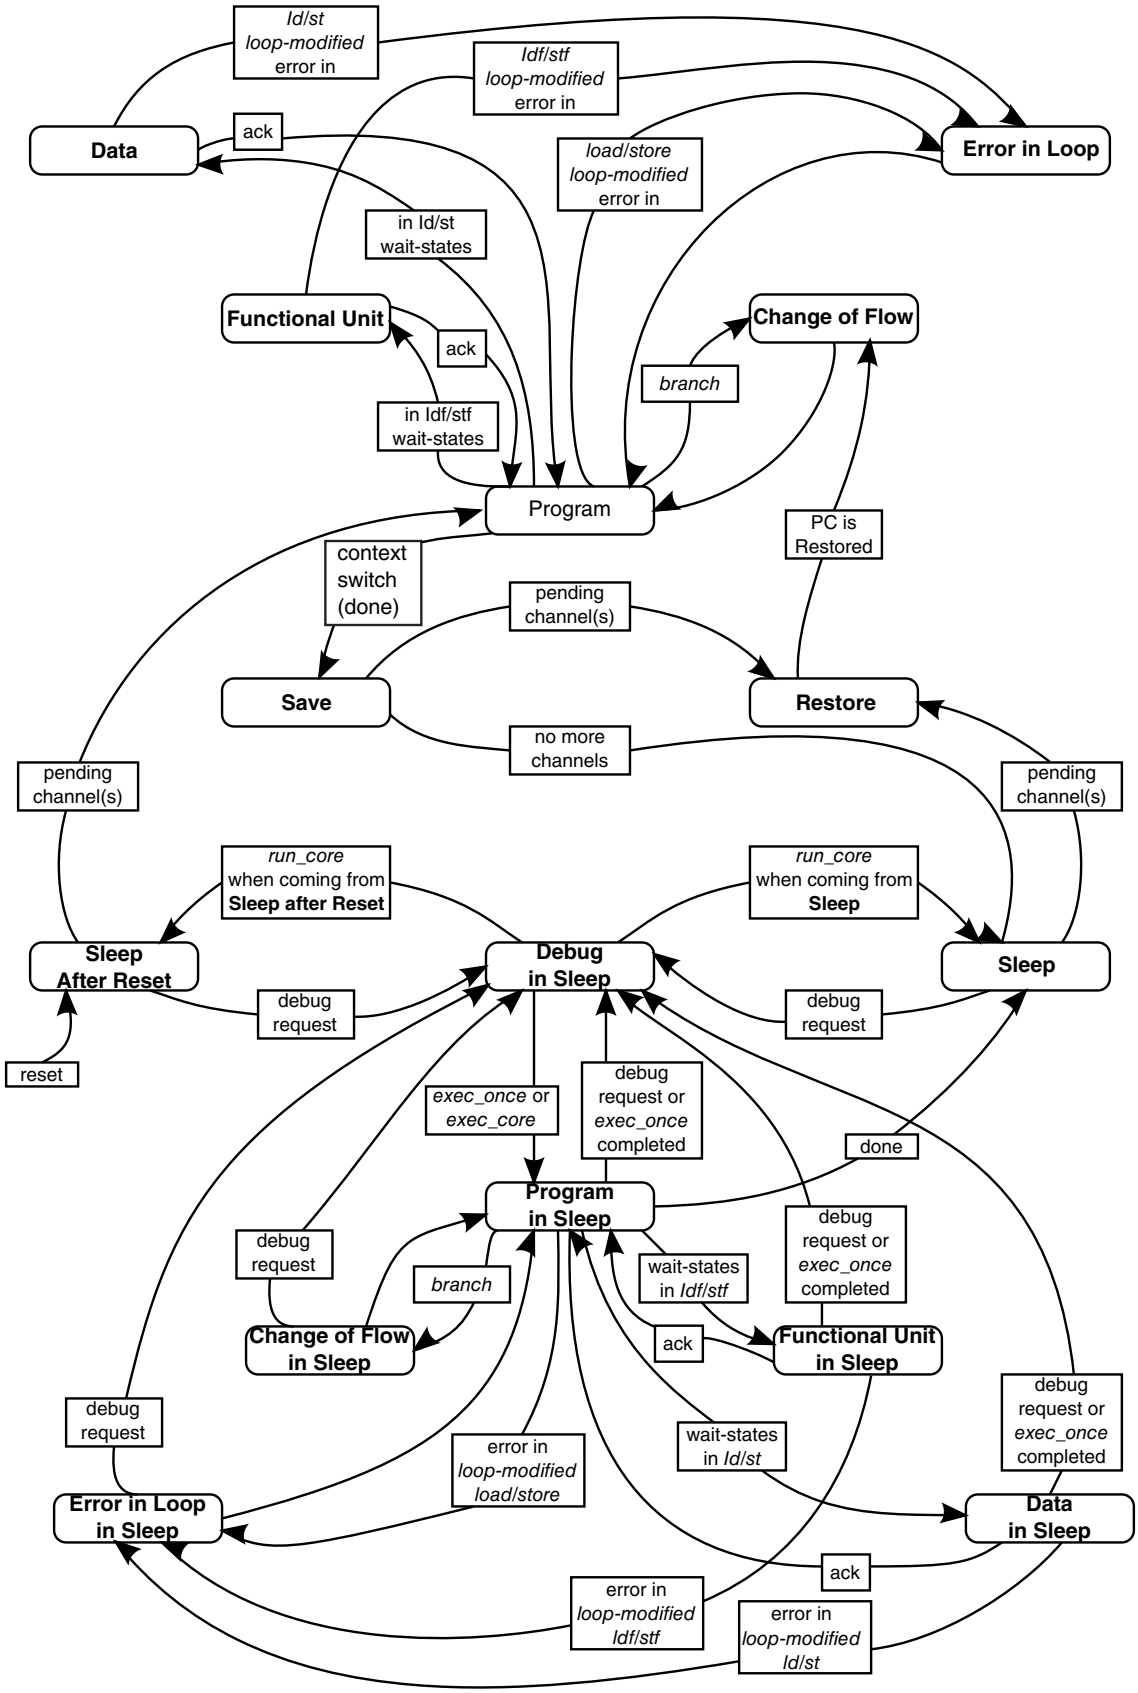

Figure 66-4. PCU State Diagram

66.3.3 SDMA Core Memory

The SDMA has two memory spaces: one for the instructions and one for the data. As both spaces share the same resources (ROM and RAM devices), the system bus manages possible conflicts when the core accesses the same resource for both an instruction read and a data read or write.

Program and data memory is further described in Address Space.

Instructions of 16-bit width are stored in 32-bit wide devices and can be accessed as data. The mapping is Big Endian: an even instruction address (terminated by 0) accesses the most significant part of the 32-bit data (bits [31:16]), and an odd instruction address (terminated by 1) accesses the least significant part of the 32-bit data (bits [15:0]). Instructions can be fetched out of internal ROM or RAM.

Data can be read from ROM, RAM, memory mapped registers, and external peripherals, and written to the same devices (except the ROM).

The ROM contains bootload scripts, channel scripts, and common subroutines which may be referenced by channel scripts elsewhere in the ROM or RAM.

The RAM is divided into a context area and a code space area which may be used to store channel scripts. The RAM contains undefined values after a hardware reset. Channel scripts and initial context values are downloaded into RAM using channel 0 which is reserved for bootload functions.

66.4 Scheduler

All channel scheduling hardware is included in the Scheduler.

66.4.1 Primary Functions

The scheduler is a hardware-based design used to coordinate the timely execution of 32 virtual DMA channels by the SDMA core on the basis of channel status and priority.

The scheduler performs the following functions:

- Monitors, detects, and registers the occurrence of any one of the 48 DMA requests
- Links a specific request to a channel or group of channels (channel mapping)
- Ignores requests that are not mapped to a previously configured channel
- Maintains a list of all the channels that are requesting service

- Assigns a pre-programmed priority level (1 of 7) to every channel requesting service
- Detects and flags overrun/underrun conditions

66.4.2 Channels and DMA Requests

66.4.2.1 Channels

A Virtual Channel (hereafter simply called a channel) manages a flow of data through the SDMA. Flows are typically unidirectional.

The SDMA can have up to 32 simultaneously operating channels, numbered from 0 to 31. Channel 0 is usually dedicated to control the SDMA script downloading. All the channels can be assigned by the ARM platform software.

66.4.2.2 DMA Requests

A DMA request is caused by externally (for example, external to the SDMA) controlled conditions (for example, UART receive FIFO reaches a threshold). The SDMA currently supports up to 48 DMA requests.

66.4.2.3 Mapping from DMA Requests to Channels and Priorities

A channel can stall waiting on a single DMA request. A single DMA request can awake more than one channel (in fact, any request can awake any combination of channels).

The mapping between DMA requests and channels is program-controlled. There is a storage element assigned for each of the 48 requests that contains a bitmap table of the channels that are awakened by the event.

Every channel also has a three-bit register that indicates its priority.

66.4.3 Scheduler Functional Description

Scheduler Overview describes the behavior of the SDMA scheduler-from the channel enabling conditions to the highest priority pending channel selection.

66.4.3.1 Scheduler Overview

The scheduler algorithm is built in hardware. It is provided with possibilities for the ARM platform to control its behavior.

The scheduler processes incoming DMA requests, maps detected requests to 0, one, or several channels, maintains a list of channels that are requesting service (pending channels), identifies the top priority and its associated channel, and selects the next active channel when the current channel yields.

The following figure shows a functional overview.

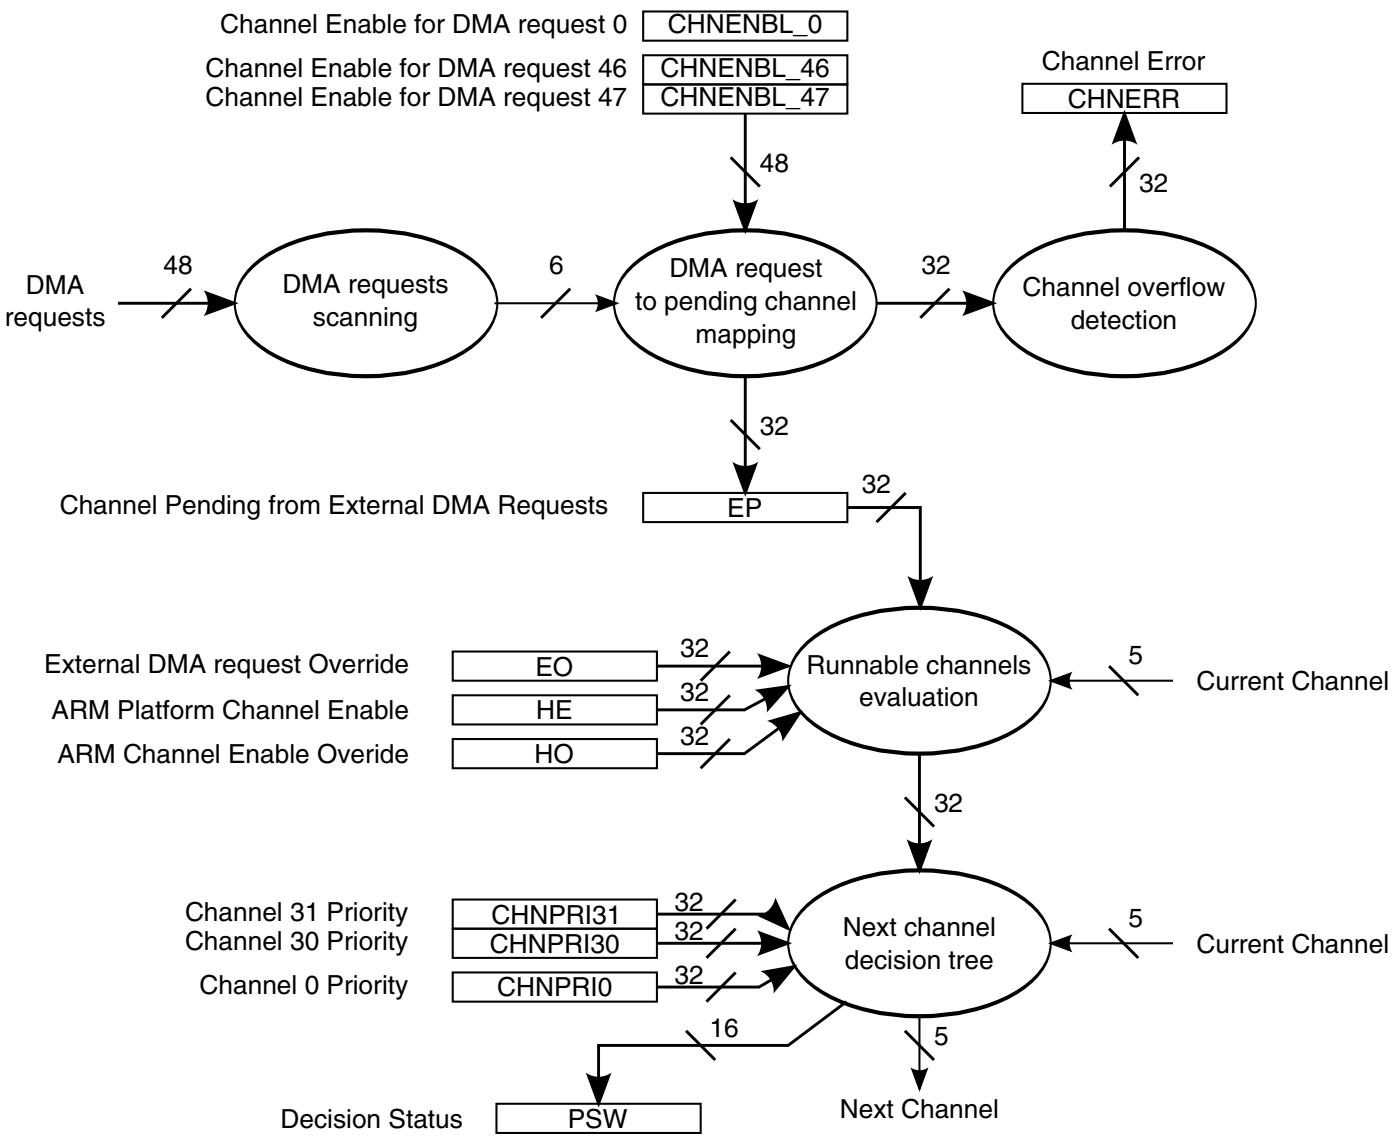

Figure 66-5. SDMA Hardware Scheduler

66.4.3.2 DMA Requests Scanning

The scheduler contains a 48-bit edge detection device that detects the rising edge of every DMA request and transmits the request number to the next stage.

The DMA requests are assumed to be generated on the same reference clock as the SDMA core clock; they are detected as soon as the signal goes from a 1-to-n-cycles low state to a 1-to-m-cycles high state.

This system is able to detect single-cycle pulses as well as level-based DMA requests such as a FIFO threshold crossing. In this case, the SDMA provides a memory mapped register that can be used by the channel script to monitor the DMA requests lines, and thus determines whether the data transfer is done or not done, and then continues with the transfer or closes the channel.

When several DMA requests are detected at the same time, they are forwarded to the next scheduler stage at the rate of one request per cycle. No request is lost.

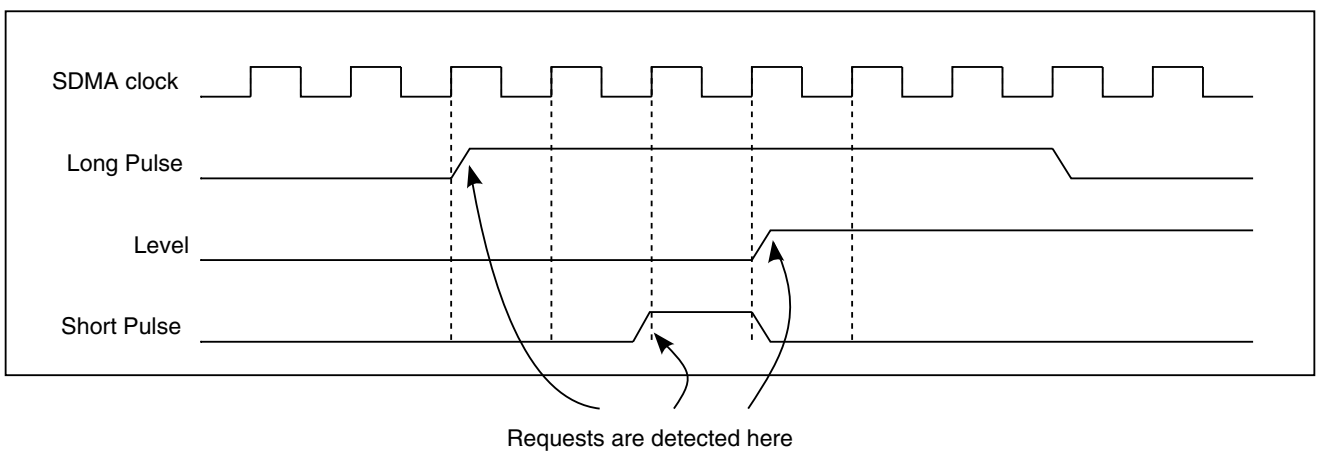

Figure 66-6. Examples of Valid DMA Requests

The DMA request inputs are connected to various sources that depend on the SoC. The exact list of DMA request inputs and their associated number is available in each respective project-specific chapter.

66.4.3.3 Mapping DMA Requests to Pending Channels

Whenever a DMA request is detected by the first stage, its number is used in the second stage to determine the channels that have to be activated.

This is performed with an array of 48 registers that are 32 bits wide: There are 48 Channel Enable Registers (CHNENBLn), one register per DMA request. The DMA request number selects the Channel Enable Registers, and every bit of this 32-bit register indicates that the corresponding channel must be activated when it is a 1.

This information is passed on the EP register. For every bit of the Channel Enable Register that is set, the corresponding bit of the EP register is also set, and the remaining bits of EP are left unchanged. The transformation of EP is summarized by the following equation:

EP = EP or CHNENBLn

The EP register is used to know which channels require service because they received a DMA request.

Typical contents of the CHNENBLn registers are all 0s, except for a single bit set. For example, a DMA request triggers one channel, but all 0s or several 1s are possible. One DMA request could activate several channels, and the channel execution sequence can be controlled by the channel priorities and numbers, as explained in the next sections. The following table illustrates an example configuration.

NOTE

From the table, the DMA request 0 is programmed to simultaneously trigger channels 0, 1, and 31. Also, DMA requests 30-47 are not used in this example. The remaining channels 2 to 30, are configured to be triggered by DMA requests 29 to 1, respectively.

Table 66-2. Channel Enable RAM Programming Example

66.4.3.4 Channel Overflow

A channel overflow occurs when a DMA request requires service from channel *n* by setting bit *n* of the register EP, but this bit is already set, meaning channel *n* is already pending. This can come from an overrun/underrun condition.

This detection is possible only when the DMA requests are pulses, because a level-based DMA request stays high until it is serviced, even though an underrun or overrun condition occurs, thus preventing another edge detection of the DMA request.

The channel overflow information is saved in the 32-bit CHNERR register (1 bit per channel). You can configure the SDMA to trigger an interrupt to the ARM platform when there are 1s in CHNERR. Every bit of CHNERR is masked with the corresponding bit of INTRMASK and if it gives a 1, the corresponding bit of INTR is set, triggering the interrupt.

66.4.3.5 Runnable Channels Evaluation

The EP register is used in conjunction with several other 32-bit registers to determine the channels that are runnable.

Registers EO, DO, HO and HE, are controlled by the ARM platform. EP is controlled by the DMA requests and their mapping to channels.

Several channels may be runnable at any given time. The i^{th} channel is runnable if (and only if) the condition below is true:

(HE[i] or HO[i]) and (DO[i]) and (EP[i] or EO[i])

After reset, the HE[i], HO[i], EP[i], and EO[i] bits are all cleared whereas the DO[i] bits are all set. The functions associated with DO are not available for this device. When DO[i] is set, the scheduler condition becomes:

(HE[i] or HO[i]) and (EP[i] or EO[i])

The registers in these equations are controlled as follows:

- ARM platform (host) channel enable flag HE[i] may be set or cleared by the ARM platform with the HSTART and STOP_STAT registers. It can also be cleared by the i^{th} channel script.

  Typical usage is for the ARM platform to set this flag to activate the channel. The flag is cleared by the SDMA core when the transfer is done.

- Externally triggered channel pending flag EP[i] is set by the scheduler when the channel was activated by a DMA request. It can be cleared by the i^{th} channel script.
- The ARM platform channel override flag HO[i] may be set or cleared by the ARM platform. When set, it enables the i^{th} channel to run without the involvement of the ARM platform.

  Typical usage is for the ARM platform to set this flag for channels that do not need ARM platform supervision such as channels that are controlled by DMA request events (EP).

- DO should always be set to 1 so that the runnable channel evaluation considers only HO, HE, EP, and EO.
- Externally triggered channel override flag EO[i] may be set or cleared by the ARM platform. When set, it prevents the i^{th} channel from stopping and stalling on incoming peripheral DMA requests. This is the case when the channel is not handling data transfers with peripherals (for example, a memory to memory transfer).

The SDMA can clear the HE[i], and EP[i] bits by means of adone or notify instruction. The done instruction causes a reschedule; thus, enabling another channel to preempt the current one, while the notify instruction does not. The done and notify instructions can clear either HE[i] or EP[i] (never more than one at a time).

Table 66-3. Runnable Channel Selection Control

Register	Set by	Cleared By
HO	Write to HOSTOVR register	Write to HOSTOVR register
HE	Write to HSTART register	Write to STOP_STAT register or by the channel script with the done or notify instructions.
DO	Write to DSPOVR register	Write to DSPOVR register
EO	Write to EVTOVER register	Write to EVTOVER register
EP	Set by external DMA request event input.	By the channel script with the done or notify instructions

66.4.3.6 Next Channel Decision Tree

The next channel number is computed from the runnable channels list, the current channel number, and their respective priorities.

It is re-evaluated every cycle, but is only used when the current channel yields or terminates by executing a yield, yieldge, or done instruction.

The decision tree is based on the selection of the runnable channel that has the highest priority.

The highest priority channel is selected according to the following rules:

- Runnable channels are sorted by priority.
- If one of the channels with the highest priority had been preempted by a channel with a higher priority, but did not want to yield to a channel of the same priority (for example, it executed a yield, not a yieldge), it is elected as the next channel.
- The channels that belong to the highest priority group are sorted by their number and the channel that has the highest number in this group becomes the next channel. For example, if priorities are the same, channel 31 will be selected before channel 30.

When the current channel requires a reschedule with a yield(ge) or a done instruction, the context switch decision is based on the instruction parameter, the current channel number and priority, and the next channel number and priority. The possible cases are all listed in the following table. The grayed cells correspond to unusual cases that should not occur with a typical usage of the SDMA.

Table 66-4. Channel Switching Decision with a yield, yield(ge), or done

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
yield (done 0)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Current
			Current < Next	Next[1]
	Not runnable	Not runnable	none	none[2] (occurs when the channel was disabled by the ARM platform)
	Not runnable	Runnable	none	Next[1] (occurs when the channel was disabled by the ARM platform)
yieldge (done 1)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Next[1]
			Current < Next	Next[1]
	Not runnable	Not runnable	none	none[2] (occurs when the channel was disabled by the ARM platform)
	Not runnable	Runnable	none	Next[1] (occurs when the channel was disabled by the ARM platform)
done (done>1)	Not runnable	Not runnable	none	none[2]
	Runnable	Not runnable	none	Current[3] (occurs when the done instruction does not disable the channel runnable condition)
	Not runnable	Runnable	none	Next[1]
	Runnable	Runnable	none	Current[3] (occurs when the done instruction does not disable the channel runnable condition)

1. Current channel script execution is stopped, its context is saved; the next channel context is restored and its script execution resumes
2. Current channel context is saved and SDMA enters IDLE mode
3. Current channel context is saved, then restored, and the current channel script resumes execution

Finally, when the SDMA is in IDLE mode and a runnable channel is elected as the next channel, its context is immediately restored and the script execution resumes.

The *combinatorial-decision* tree supports dynamic modifications of the EP, EO, HE, HO, and DO flags as well as dynamic modifications of the channel priorities. The propagation times are detailed in Scheduler Pipeline Timing Diagram.

The decision tree status is available in the PSW register, which is continuously updated. It contains the next channel priority, the next channel number, the current channel priority, and the current channel number. When a priority is read as 0, it means the channel is not runnable.

A few examples of decisions are presented below:

- Channel 31 is running with priority 5, channels 13 and 24 are pending with the same priority 5; channel 24 is eligible as the next channel since 24 > 13.
- Channel 31 is running with priority 7, channels 13 and 24 are pending with priority 5; channel 31 is the next channel because its priority is greater than the other pending channels.
- Channels 7, 23, and 29 are pending with the same priority. Channel 7 is active and runs a yieldge; it is preempted by channel 29. After a period of time, channel 29 runs a yieldge, it is then preempted by channel 23 that is the selected channel since channel 29 is the current channel. Later, channel 23 runs a yieldge and is preempted by channel 29. Channels 23 and 29 will go on switching after every yieldge until one of them terminates. It is only at that point that channel 7 becomes eligible again.
- Channel 11 is running with priority 3, and channel 15 is pending with priority 4. When the channel 31 script executes a yield instruction, it gets preempted by channel 15; then channels 6 and 18 with priority 3 become pending. Because channel 11 was preempted after executing a yield and there is no pending channel with a strictly greater priority, it is eligible as the next channel (although its number 11 < 18).

66.4.3.7 Scheduler State Diagram

The Figure 66-7 summarizes the behavior of the SDMA scheduler with details about the exact mechanism of the priority decision tree. It is important to understand the scheduler is a hardwired pipeline, which means all the stages are performed simultaneously every cycle, but a change on any given stage is reflected on the next stage after the delays presented in Scheduler Pipeline Timing Diagram.

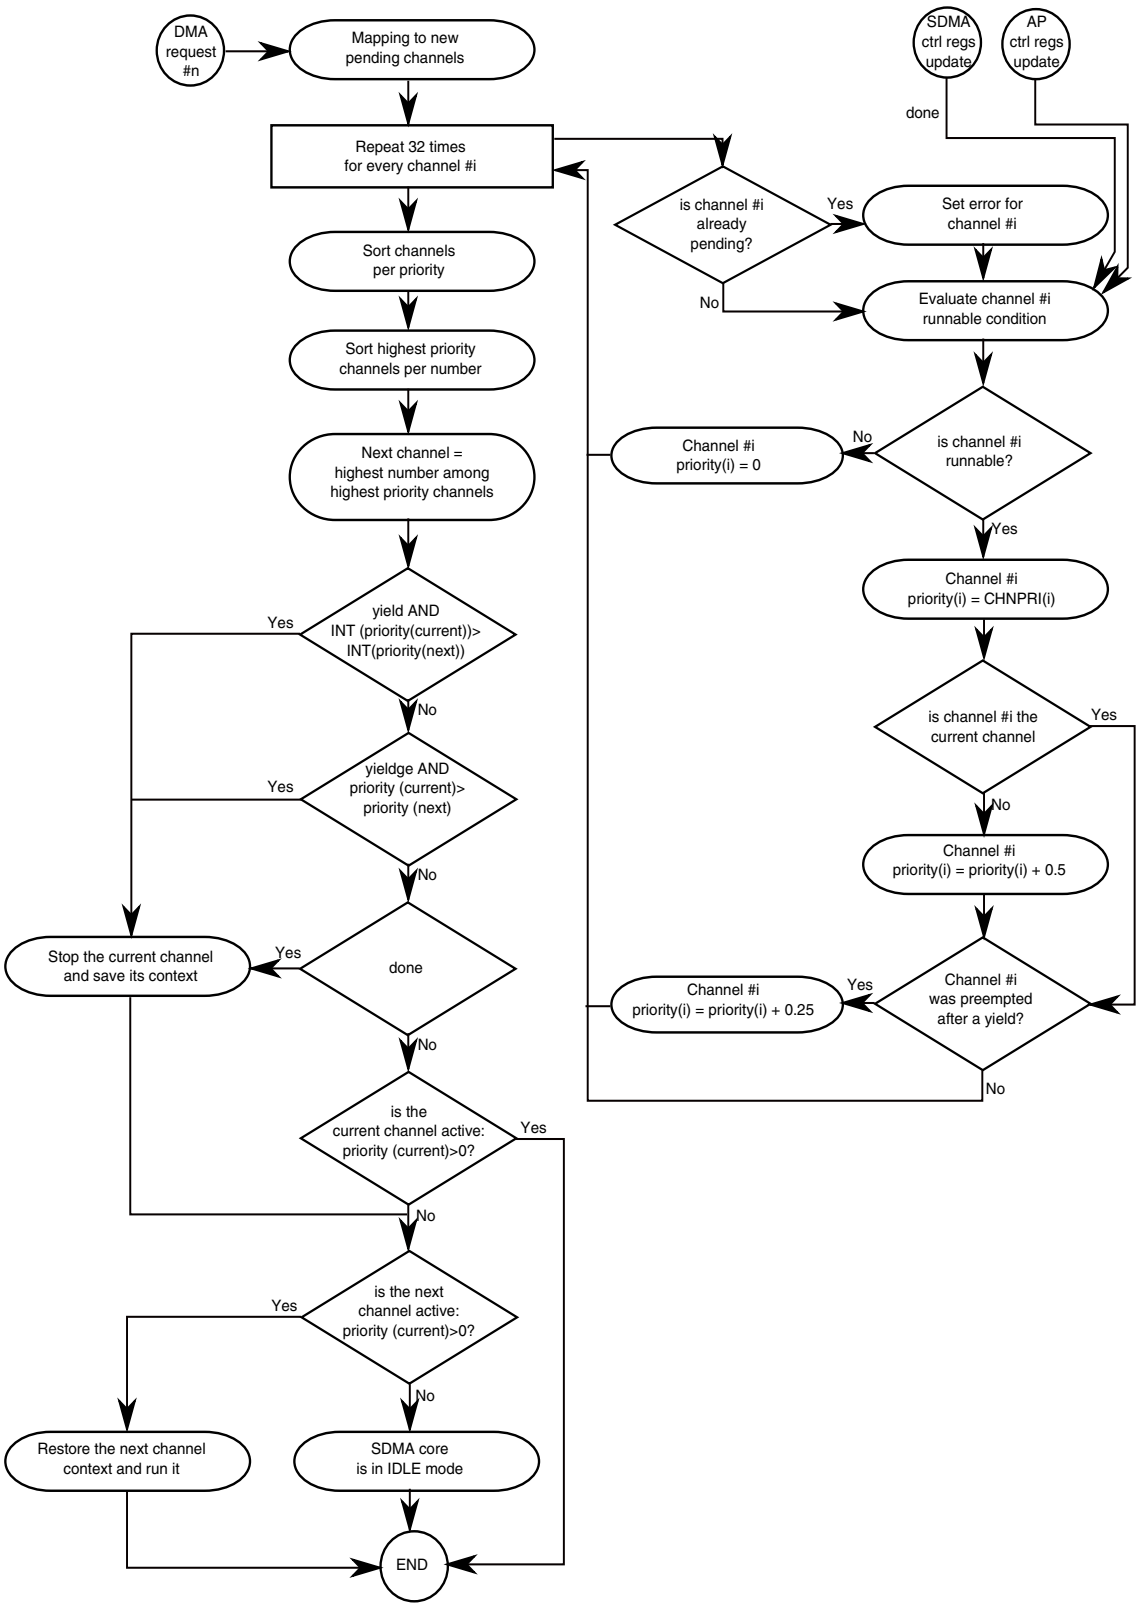

Figure 66-7. Scheduler State Diagram

66.4.3.8 Scheduler Pipeline Timing Diagram

The SDMA scheduler process of DMA-request and control-register modifications is not immediate.

The figure below shows the exact delays of all the tasks. The reference clock is the SDMA core clock.

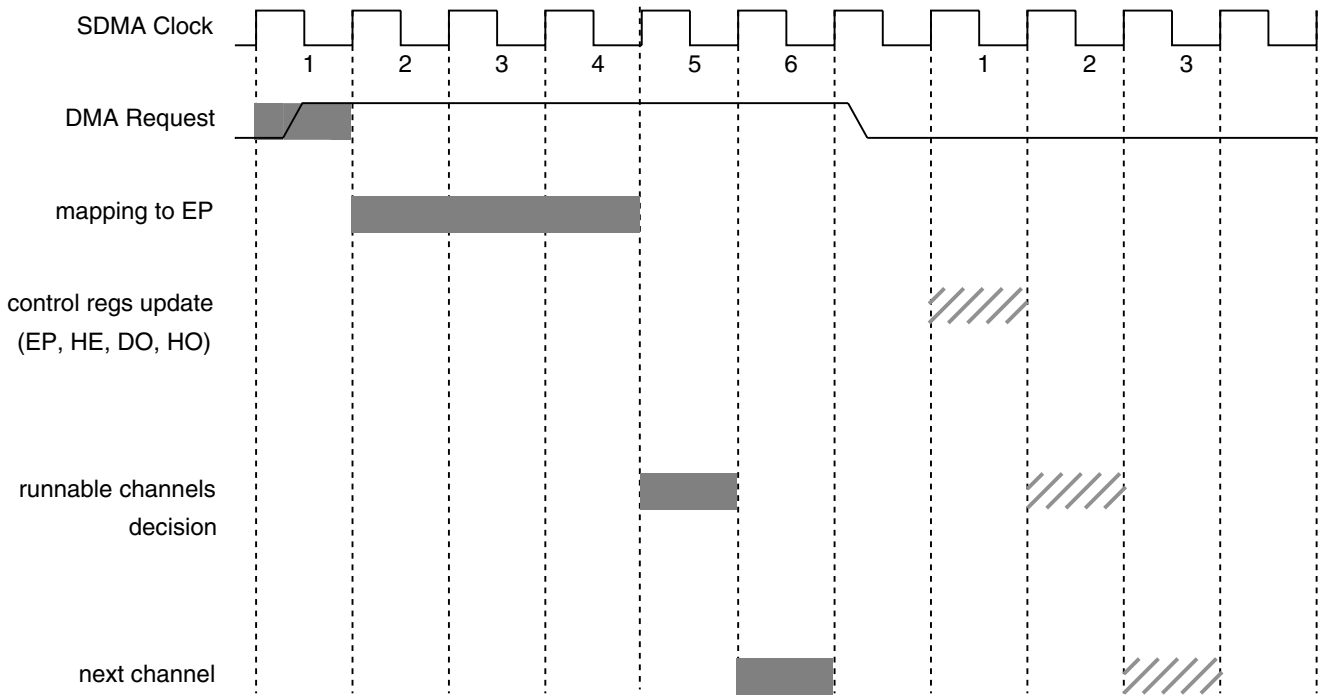

Figure 66-8. Scheduler Timing Diagram

Two numbers can be inferred from this timing diagram. First, it takes six SDMA core clock cycles to update the next channel from a DMA request. Second, it takes three SDMA core clock cycles to update the next channel from a direct modification of the condition registers (EP, DO, HE, or HO) by any processor. The processors that can modify these bits include SDMA with a done instruction or the ARM platform with a write access through the corresponding control port on their respective peripheral bus).

66.4.3.9 Channel-DMA Request Mapping

The 48 DMA request inputs to the SDMA scheduler are listed in project-specific chapters. Refer to the respective chapters for this information.

66.4.3.10 Examples: How to Start a Channel

A channel can be started when the following equation is true for channel *i*:

(HE[i] or HO[i]) and (DO[i]) and (EP[i] or EO[i])

Once this equation is true, the scheduler can start this channel according to the priority of all pending channels. Several examples of configuration are listed below:

1. To start a channel triggered by ARM platform software:
   - Initially, configure HO[i]=0, DO[i]=1, and EO[i]=1 using registers indicated in Table 66-3.
   - ARM platform software triggers the channel by writing to the HSTART register to set HE[i]=1, thereby setting the above equation true.
2. To start a channel triggered by DMA request event.
   - Initially, configure HO[i]=1, DO[i]=1, and EO[i]=0 using registers indicated in Table 66-3.
   - The DMA request is asserted to trigger the channel by setting EP[i]=1, which makes the above equation true.

66.4.4 Context Switching

On execution of a done or yield(ge) instruction, the current channel may be changed either because it has finished (which necessarily happens when the done instruction is executed), or it was preempted by a higher priority channel (which is possible but not systematic when the yield(ge) is executed).

Upon a channel change the SDMA goes through a context switch procedure. When the current channel yields or ends, the context for that channel is saved into the context RAM locations for that channel. When the next channel starts running, its context is first restored from RAM.

Since context RAM is not yet initialized by reset, there will be no context restore at the beginning of the first channel (bootload channel) run after reset. It is expected that the bootload channel will be used to initialize the context for all other channels. When the bootload channel finishes running or yields, SDMA will enter its SAVE state and save that channel's context into RAM. Then, if the bootload channel is called again later, the context will be restored from RAM when the channel starts again.

The context structure for each channel is defined in Context Switching-Programming andTable 66-10. There will be one context area reserved for each channel. When a channel ends or yields, the SDMA core registers are automatically saved into the context RAM and later restored from the context RAM when the channel is next run. The total

RAM space reserved for 32-channel contexts is either 3K or 4K depending on whether the SMSZ bit is set in the CHN0ADDR register, which enables an additional 8 words of scratch RAM for each context.

66.4.4.1 Context Switch Modes

The exact procedure to save the context of the old channel, and to restore the context of the new channel depends on the context switch mode selected by the ARM platform in the CONFIG control register.

The following are the context switch modes:

- By default, the "dynamic" context switch is set. This mode provides the most efficient context switch for an average of eight cycles to stop the current channel, save its context, restore the next channel context, and resume its execution. It consists of saving modified registers of the current channel in the background (for example, during the channel execution)-which leaves very few registers to save when the switch is decided-resuming execution of the next channel as soon as possible (for example, when the minimal set of registers is restored), and continuing the restore phase during this execution.
- In "dynamic with no loop" mode, the same principle is followed except the modified registers are only saved in the background when the loop flag is not set. This mode offers almost the same effectiveness as the previous one, but it prevents the system from accessing the RAM during loops to save power. This is the recommended mode for an efficient context-switch when the loop bodies are short.
- In "dynamic power" mode, no background saving is performed, which reduces power consumption to the minimum. The modified registers are only saved when the context switch starts. The restore phase is the same as before. This is the mode that achieves the optimal power consumption at the cost of a slower context-switch.
- In a "static" context switch, all the registers are saved when a context switch is decided, and all the registers are restored before starting the execution of the new channel. This mode enables a predictable behavior of the context switch since all the registers are restored prior to the channel start and all registers are saved after the channel termination.

NOTE

Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized during the context SAVE phase when the channel is done or yields. Subsequent calls to the same channel or different channels may use any of the dynamic context modes. This will ensure that all context locations for the bootload

channel are initialized, and prevent undefined values in context RAM from being loaded during the context restore if the channel is re-started later.

66.4.4.2 Context Switch Procedure

The Program Control Unit goes into the *save* state, the current context is spilled into memory, and the next channel context is restored according to the context-switch mode that was selected by the ARM platform.

The context switch procedure is as follows:

1. Load the current context's spill base address.
2. Spill the modified registers of the current channel to memory according to the selected context switch mode while the channel is running.

   On a done or yield(ge) that causes the channel preemption, the PCU goes into the *save* state. In *static* mode, all the registers are saved; whereas, in either *dynamic* mode, the registers that were modified but not yet saved are then saved, and the PCU registers and flags are finally saved.

3. Put the SDMA core into *sleep* and wait for new channels to be serviced. This step is skipped if there are pending channels when the current channel is saved.

   As soon as there is at least one pending channel, the PCU goes into its *restore* state to restore the context of the channel that was elected by the scheduler.

   Once a channel is elected, it remains the current channel until its script requests a rescheduling operation with a done or yield(ge) instruction. That means the current channel cannot be modified by the ARM platform, even if it is no more runnable or if its priority is modified.

   The ARM platform can however force a reschedule by writing the corresponding bit in the CONFIG register, which has the same effect as if the script had executed a done instruction. That feature should only be used to stop the SDMA in emergency cases.

4. Load the context base-address of the new channel.

   In "static" mode, all the registers are restored. In either "dynamic" modes, only the PCU registers are restored.

   The new channel is running. In "static" mode, no more activity regarding context restoring or saving is performed. In either "dynamic" modes, the registers are restored in the background every time an access to the context RAM is possible, and

priority is given to restoring the registers that are required by the next instruction to be executed. When a register has not been restored and the next instruction needs it, this instruction gets stalled until the register was restored.

In "dynamic" and "dynamic with no loop" modes, background saving of dirty registers is performed every time an access to the context RAM is possible and allowed by the context switch mode.

NOTE

The contents of a channel context space in the context RAM depends on the selected context switch mode. In "dynamic" and "dynamic with no loop" modes, the contents of the context RAM tend to match the contents of the SDMA registers (except for the PCU registers and flags that are never saved in the background). In "dynamic power" and "static" modes, the contents of the context RAM remain unchanged until the channel terminates with a done or gets preempted.

66.4.4.3 Context Map in Memory

Refer to Context Switching-Programming.

66.5 Functional Units

The functional units are small systems that are used by the SDMA core to perform complex calculations like the CRC unit, or to handle data transfers between the core and a bus domain external to the SDMA.

The SDMA core is able to control and exchange data with these systems by sending instructions and reading or writing data from/to the functional units' registers via the FUBUS. This is done with the ldf and stf instructions.

The following sections provide introductions to the available functional units. Functional Units Programming Model provides descriptions the functional units' behaviors.

66.5.1 CRC Calculation Unit

The Cyclic Redundancy Check (CRC) unit can perform CRC calculation. A single byte of data can be processed every cycle, but up to four bytes can be simultaneously loaded

The CRC unit supports the following set of polynomials:

CRC32: $X^{32}+X^{26}+X^{23}+X^{22}+X^{16}+X^{12}+X^{11}+X^{10}+X^8+X^7+X^5+X^4+X^2+X+1$

CRC16: $X^{16}+X^{15}+X^2+1$

CCITT16: $X^{16}+X^{12}+X^5+1$

IS136: $X^{12}+X^{10}+X^8+X^5+X^4+X^3+1$

CRC10: $X^{10}+X^9+X^5+X^4+X+1$

CRC8: X^8+X^2+X+1

parity: X^8+1

66.5.1.1 CRC Structure

The following figure describes the overall structure of the CRC unit and introduces its registers that are accessible by the SDMA core via the FUBUS.

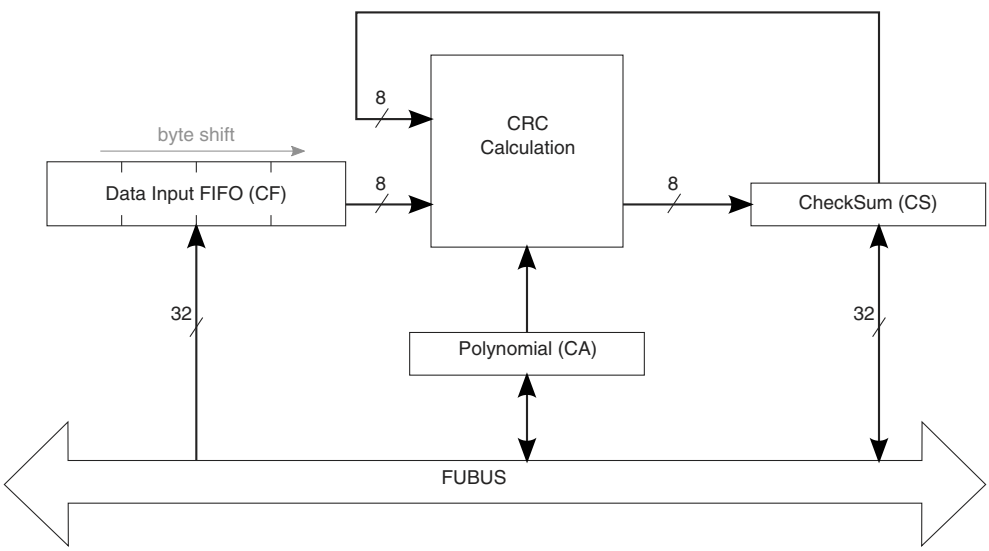

Figure 66-9. CRC Structure

66.5.1.2 CRC Data Processing

CRC processing requires the following three stages:

1. The preliminary initialization stage consists of selecting the desired polynomial, and storing the initialization pattern into the checksum register.
2. Data processing itself, which comes to feeding incoming bytes to the CRC input FIFO - bytes can be written one at a time (8-bit write access from the SDMA core), by pairs (16-bit write), or groups of four (32-bit write). One byte is processed every

cycle: Any subsequent access may stall the SDMA core until completion of the previous calculation.

3. The CRC result (or checksum) can be retrieved at any time, but all data must be processed before it is made available.

66.5.1.3 CRC Registers

The CRC enables reading and writing to three register addresses, which trigger the operations described in CRC Data Processing. The following are the three registers:

- *CA (CRC algorithm)*-The CA selects the desired polynomial. Reading and writing this register correspond to retrieving and changing the polynomial.
- *CS (CRC checksum)*-Writing to this register initializes the checksum accumulator, and reading this register yields the result from the CRC calculation (the result width depends on the polynomial size).
- *CF (CRC FIFO)*-Writing to this register loads the data into the input FIFO and triggers the CRC calculation process. It is not possible to read this register.

66.5.1.4 CRC Summary

Every operation mentioned in CRC Registers takes time to be executed by the CRC unit.

When the CRC receives a command, it immediately acknowledges the SDMA core provided it is not busy completing a previous operation. Therefore, wait-states are inserted by the CRC when a command succeeds another command that is not yet competed.

The following table lists the number of cycles that the CRC takes to execute every possible command. When an operation lasts one cycle, it means the CRC is able to process another command in the next clock cycle (for example, no wait-state is inserted by the CRC because of the former operation that is processing).

Table 66-5. CRC Processing Summary

Operation	Command	Delay	Comments
Set the polynomial	Write CA	1	
Retrieve the polynomial	Read CA	1	
Initialize the checksum	Write CS	1	
Retrieve the checksum	Read CS	1	
Store 1 byte to process	Write CF	1	
Store 2 bytes to process	Write CF	2	CRC is busy for 1 cycle

Table continues on the next page...

Table 66-5. CRC Processing Summary (continued)

Operation	Command	Delay	Comments
Store 4 bytes to process	Write CF	4	CRC is busy for 3 cycles

66.5.2 Burst DMA Unit

The burst DMA unit enables the SDMA core to perform data transfers to and from the ARM platform memory.

It is optimized for accessing SDRAM-like devices. It does not provide control to assign a privilege level to the DMA access. The burst DMA unit provides the SDMA with means to do the following:

- Perform up to 8-beat read and write bursts to the ARM platform memory, which optimizes throughput when accessing SDRAM-type devices because of an internal, 36-byte FIFO
- Access the ARM platform memory at once or twice the SDMA core frequency
- Copy data from one ARM platform memory location to another ARM platform memory location at the ARM platform bus speed, which provides a very high throughput
- Control the method for addressing the ARM platform memory (automatic increment of addresses or frozen addresses-the former aimed at accessing RAM-like memory and the latter aimed at accessing single-address FIFOs)
- Enable or disable automatic prefetch when reading data from the ARM platform memory. When the prefetch mode is selected, the burst DMA automatically triggers external bursts to fill its FIFO without waiting for the SDMA core to request the corresponding data, greatly improving throughput.
- Rely on the DMA to automatically flush its FIFO content when there is enough data to generate an 8-beat burst to the ARM platform memory. Or, it forces a flush when a data transfer must terminate.
- In the former case, the SDMA core may only be stalled when it tries writing data and there is not enough room left in the FIFO. In the latter case, the core is stalled until the data is effectively written to the ARM platform memory.

In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the ARM platform memory. This error status is retrieved by a later access to the burst DMA. Terminating a write data transfer with a forced flush command guarantees that any bus error to the ARM platform memory is caught.

- Handle address alignment issues between the ARM platform memory map and the SDMA core data. This enables the core to read or write 32-bit data from the burst DMA, whereas the corresponding ARM platform address is not 32-bit aligned. This drastically improves the SDMA scripts' efficiency since the same loop that transfers 32 bits at a time can be used regardless of the start and end addresses in the ARM platform memory space.

This unit structure and registers are described in Burst DMA Structure and Burst DMA Registers.

66.5.2.1 Burst DMA Structure

The burst DMA is essentially made up of a 36-byte FIFO, address registers, and a controlling state-machine. The 36-byte FIFO enables eight-word buffering with address alignment, and the state-machine manages clock adaptation when required.

The burst DMA is depicted in the figure below.

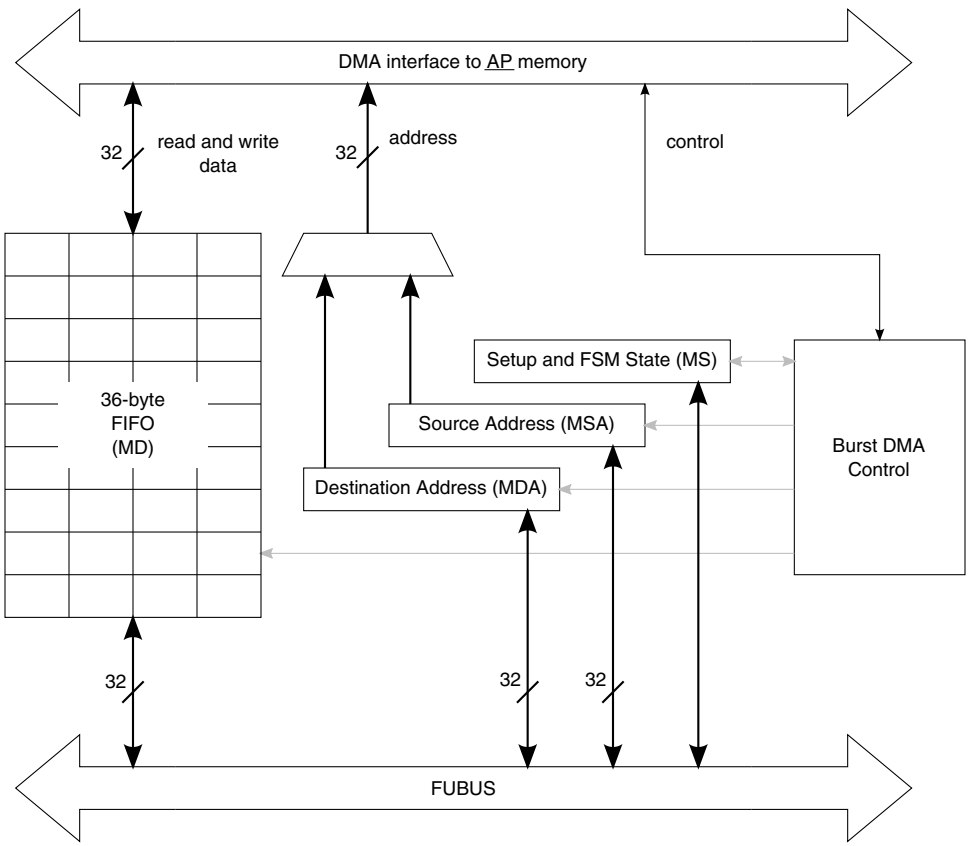

Figure 66-10. Burst DMA Structure

66.5.2.2 Burst DMA Registers

There are four registers, as follows, that may be accessed from the SDMA core:

- MSA (Memory Source Address) - Holds the source byte address in the ARM platform memory map for reading data from this location. This register is automatically modified every time the core reads new data from the FIFO.
- MDA (Memory Destination Address) - Holds the destination byte address in the ARM platform memory map for writing data to this location. This register is automatically modified every time the core writes new data into the FIFO.

- MD (Memory Data) - Labels the 36-byte FIFO access point: Reading a byte, halfword, or word from MD respectively retrieves the first 1, 2, or 4 bytes of the FIFO (for example, the bytes that were stored first by the DMA state-machine when transferring data from the ARM platform memory).
- When the FIFO does not hold as many bytes as required by the SDMA core, the core is stalled until the missing bytes are read from the ARM platform memory. In the case of prefetch mode, the DMA controller decides when it should start a burst to ARM platform memory in order to reduce the risk to not have the required data for the future accesses of the core. When there is no prefetching, a burst is triggered when the required data is not available in the FIFO.

  Writing a byte, halfword, or word to MD stores 1, 2, or 4 bytes, respectively, at the end of the FIFO (for example, these bytes are transmitted to the ARM platform memory after all the other bytes that were previously stored in the FIFO). When the FIFO does not have enough room left to hold the written data, the SDMA core is stalled until a sufficient amount of FIFO contents are flushed out to the ARM platform memory. Flushing is decided by the DMA controller when there are enough bytes in the FIFO to perform the largest allowed burst to ARM platform memory (the exact size depends on the burst start address and the AHB 1 Kbyte boundary rule). However, the SDMA core has the ability to force the flushing operation at any time, for example, when at the end of the data transfer, prior to channel closure.

- MS (Memory Setup) - Contains the state of the burst DMA control, the two flags that define whether each address register is incremented after every access to the external memory, and another flag that is set when a bus error occurred.

66.5.2.3 Burst DMA Data Transfers

Three typical usages have been identified that involve the burst DMA: the data transfer startpoint, the endpoint, or both.

Every case requires a different procedure, as listed in the following sections:

66.5.2.3.1 Data Retrieval from the ARM platform Memory

The following steps retrieve data from ARM platform memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the source address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the source address register itself (MSA).
- Read data from the FIFO using the *ldf MD* instruction as many times as needed. If an error occurred during the fetch from ARM platform memory, the DMA control tags

the error status on the data and the SDMA core SF flag is set when reading this data from the FIFO.

66.5.2.3.2 Storing Data Into the ARM platform Memory

The following steps store data from ARM platform memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the destination address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the destination address register itself (MDA).
- Store data into the FIFO using the *stf MD* instruction as many times as needed.
- When the transfer is finished and if the DMA worked in automatic flush mode, force the flush of the FIFO. This instruction is stalled until all the FIFO data is effectively sent to the ARM platform memory and the error status of the transfer is available in the DF flag.

66.5.2.3.3 Transferring Data Between Two ARM platform Memory Locations-Burst DMA Unit

The following steps copy data between two ARM platform memory locations using the burst DMA unit:

- Set up the MS flags to reflect the modes for the source and destination addresses (all the combinations are possible), then initialize the source address register (MSA) and the destination address register (MDA). Both addresses must be word-aligned.
- Use as many *stf MD* instructions with the *COPY* flag as needed. Every instruction triggers a burst read of a given number of words from the source address (this number is provided to the burst DMA via the SDMA core general purpose register, which is referenced in the *stf* instruction). Once all the data is loaded into the FIFO, the DMA empties it with a write burst of the same count to the destination address. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the burst DMA to check the error status.

66.5.3 Peripheral DMA Unit

The peripheral DMA unit is the second functional unit that connects the SDMA to the ARM platform memory.

Unlike the burst DMA, it does not support burst transfers and is optimized for accessing peripherals. It does not provide control to assign a privilege level to the DMA access. Its feature list comprises the following:

- Access to the ARM platform peripherals or memory at once or twice the SDMA core frequency
- Data copy from one ARM platform memory location to another ARM platform memory location at memory bus speed, improving throughput
- Control of the method for addressing the ARM platform memory (automatic increment or decrement of addresses or frozen addresses, the first ones aimed at accessing RAM-like memory and the last one aimed at accessing single-address FIFOs)
- Selectable automatic prefetch when reading data from the ARM platform memory. In prefetch mode, the peripheral DMA automatically fetches another data-without waiting for the SDMA core to request it-when its data register is empty, which improves the throughput
- Selectable automatic flush. In this mode, the SDMA core may only be stalled when it tries writing data and the previous write operation is not finished yet; whereas, in forced flush mode, the core is stalled until the data is effectively written to the ARM platform memory.
- In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the ARM platform memory or the peripheral. This error status is retrieved by a later access to the peripheral DMA. Terminating a write data transfer with a forced flush command guarantees that any bus error to the ARM platform memory has been caught.

  This unit structure and registers are described in Peripheral DMA Structure and Peripheral DMA Registers.

66.5.3.1 Peripheral DMA Structure

The peripheral DMA is made up of a 32-bit data register, two address registers, and a controlling state-machine. The state-machine manages clock adaptation, when required.

It is shown in the following figure.

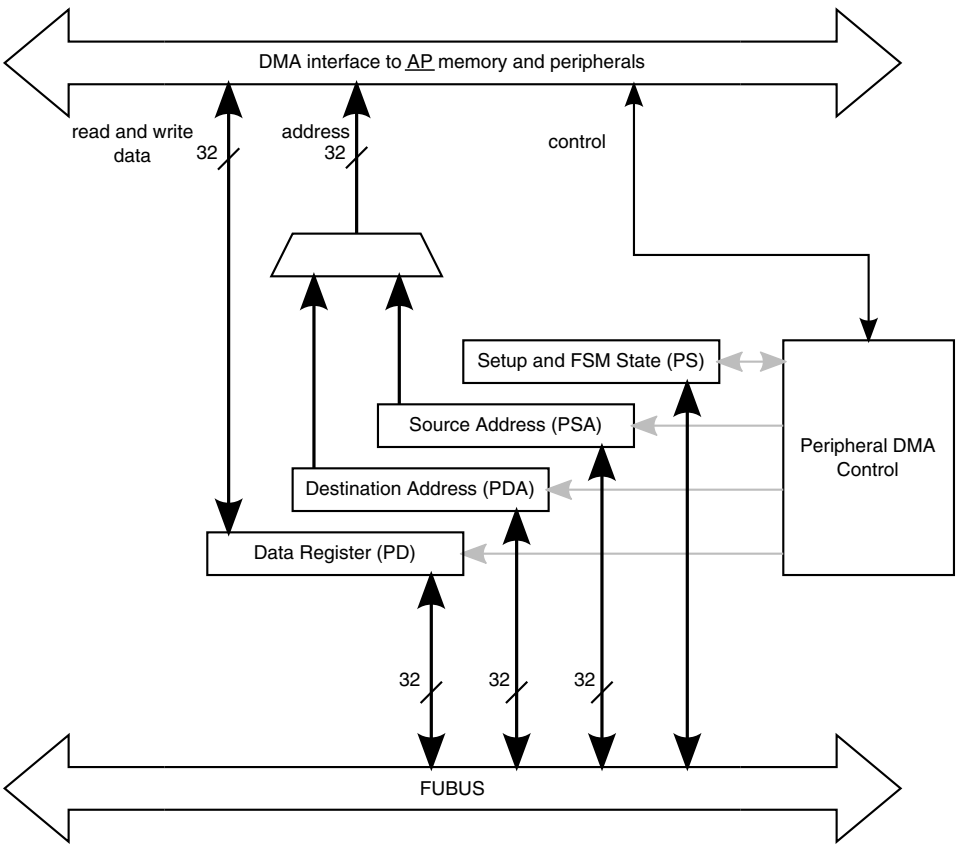

Figure 66-11. Peripheral DMA structure

66.5.3.2 Peripheral DMA Registers

According to Figure 66-11, the peripheral DMA has four registers that may be read or written by the SDMA core:

- *PD (Peripheral Data)* is the DMA 32-bit data register.
- *PSA (Peripheral Source Address)* holds the source byte address in the ARM platform memory map for reading data from this location. This register is automatically modified every time the core reads a new data from PD.

- *PDA (Peripheral Destination Address)* holds the destination byte address in the ARM platform memory map for writing data to this location. This register is automatically modified every time the core writes a new data into PD.
- *PS (Peripheral Setup)* contains the state of the peripheral DMA control, two configuration fields that define the way address registers are modified after every data access, two additional configuration fields that define the data size to access the source and destination devices, and another field that contains the latest transfer error status.

66.5.3.3 Peripheral DMA Data Transfers

There are three typical usages that involve the peripheral DMA, whether it is the data transfer start-point, endpoint, or both.

Every case requires a different procedure, as described in Data Retrieval from the ARM platform Memory or Peripheral, Storing Data into the ARM platform Memory or Peripheral, and Transferring Data Between Two ARM platform Memory Locations-Peripheral DMA Unit.

66.5.3.3.1 Data Retrieval from the ARM platform Memory or Peripheral

The following steps retrieve data from ARM platform memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the source (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the source address register itself (PSA) with an address that is aligned to the programmed data size.
- Read data from PD using the ldf PD instruction as many times as needed. If an error occurs during the fetch from the ARM platform memory or peripheral, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from PD.

66.5.3.3.2 Storing Data into the ARM platform Memory or Peripheral

The following steps store data to ARM platform memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the destination (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the destination address register itself (PDA) with an address that is aligned to the programmed data size.

- Store data into PD using the *stf PD* instruction as many times as needed.
- When the transfer is finished and if the peripheral DMA worked in automatic flush mode, force the flush of PD. This instruction is stalled until PD contents are effectively sent to the ARM platform memory or peripheral, and the error status of the transfer is available in the DF flag.

66.5.3.3.3 Transferring Data Between Two ARM platform Memory Locations-Peripheral DMA Unit

The following steps copy data between two ARM platform memory locations using the peripheral DMA unit:

- Set up the PS fields to reflect the modes and data size for the source and destination addresses (all the combinations of addressing modes are possible, but both data sizes must be identical), then initialize the source address register (PSA) and the destination address register (PDA). Both addresses must be aligned with the programmed data size.
- Use as many *stf PD* instructions with the *COPY* flag as needed. Every instruction triggers a single read from the source address; a single write of the received data immediately follows. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the peripheral DMA to check the error status.

66.6 SDMA Security Support

The SDMA provides support to SDMA software to block unauthorized updates to the scripts in RAM.

SDMA supports the following Security modes:

- Open Mode: has full control to load scripts and context into SDMA RAM. This is the default mode.
- Locked Mode: The ARM platform loads scripts and channel contexts at startup when it is still executing known safe software. When finished, it locks the SDMA to prevent further updates to RAM and selected registers. More details described in Locked Mode.

66.6.1 Locked Mode

The LOCK bit in the SDMA_LOCK register provides support for SDMA scripts to freeze RAM contents after the initial bootload routine to prevent future unauthorized updates to SDMA RAM.

After initial RAM contents are uploaded, ARM platform software can set the LOCK bit to secure the RAM contents to prevent future updates by an unauthorized. After the LOCK bit is written with a '1', the SDMA is "locked" until reset.

The LOCK bit can be read in the SDMA's internal memory map in the LOCK register (see Section SDMA LOCK (SDMAARM_SDMA_LOCK)). SDMA scripts which load information into RAM can check the value of the LOCK bit to determine if an upload to RAM is allowed. If not allowed, the script can refuse to allow the request to copy data into the RAM to continue. The exact use of the LOCK bit in SDMA scripts for security control will be described in SDMA software documentation (see SDMA Scripts).

While SDMA is locked, attempts to write to the SDMA_LOCK, CHN0ADR, ILLINSTADDR, and ONCE_ENB registers will be ignored. All registers remain readable. Writes to other registers are still allowed.

Once the SDMA is locked, the LOCK bit can only be cleared by a reset. A hardware reset will always clear the LOCK bit. A software reset initiated by writing to the RESET register will only clear the LOCK bit if the SRESET_LOCK_CLR bit in the SDMA_LOCK register is set. Since SDMA_LOCK register cannot be updated if SDMA is locked, the SRESET_LOCK_CLR bit must be configured before setting the LOCK bit. The SREST_LOCK_CLR bit will also be cleared by resets that clear the LOCK bit.

The SDMA RISC core uses the ILLINST and CHN0ADDR registers as pointers to determine where to jump to after an illegal instruction or upon boot after a reset. The LOCK bit prevents updates to these registers to protect against unauthorized changes to these pointers.

While SDMA is locked, the ONCE_ENB register cannot be written to prevent the OnCE under ARM platform control from being used to gain access to SDMA internal memory. If ARM platform control of the OnCE is enabled before setting the LOCK bit, the ARM platform can use the ONCE for debug purpose after LOCK is set.

66.7 OnCE and PCU Debug States

The SDMA has two different debug modes in which the OnCE performs debug instructions.

Refer to Figure 66-4 for an example of the PCU states in debug. The following are the two debug states:

- When a channel is running (that is, when CCR and CCPRI are different from 0, which can be read in the PSW register), SDMA can execute a SoftBkpt instruction from the channel script or receive a debug request. When either happens, the SDMA enters its "Classical" *Debug* state, which is described in OnCE and Real-Time Debug.
- When a channel is not running, the SDMA can be in *Sleep* state or in *Sleep after Reset* state. If a debug request is sent to the core, it enters its *Debug in Sleep* state. This debug mode works similarly to the "Classical" *Debug* state, except it returns to the original state (*Sleep* or *Sleep after Reset*) when the debug mode is left via the exec_core instruction of the OnCE. From this *Debug in Sleep* state, the SDMA can execute a program whereas no channel is running. If a new debug request is sent to the core or if a SoftBkpt is executed, it comes back to this *Debug in Sleep* state.

The OnCE is provided with several instructions that can be executed when the core is in either debug state. The following table summarizes the behavior of these OnCE debug instructions. There exists other secondary OnCE instructions that are described in OnCE and Real-Time Debug.

Table 66-6. SDMA in Debug Mode

Instruction	Debug	Debug in Sleep
exec_once	exec_once <instruction> SDMA executes the <instruction> and returns to the *Debug* state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.	exec_once <instruction> SDMA executes the <instruction> and returns to the *Debug in Sleep* state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.
run_core	run_core <instruction> SDMA executes the <instruction>, leaves the *Debug* state and continues executing the channel script from the position where it stopped. This command must not be used with an instruction that modifies the PC value.	run_core <instruction> SDMA executes the <instruction> and returns to its *Sleep* or *Sleep after Reset* initial state. This command must not be used with an instruction that modifies the PC value.
exec_core	exec_core <instruction> It is similar to run_core except it requires an instruction that changes the PC value (jump, branch...): the SDMA jumps to the new PC value, leaves the *Debug* state and starts executing instructions from this new PC value.	exec_core <instruction> If the previous state was *Sleep after Reset*, the SDMA returns to this state, and Chn0Addr value overrides the PC value. Otherwise, the SDMA jumps to the new PC value and starts executing instructions from this new PC.

NOTE

The feature exec_core in *Debug in Sleep* after *Sleep after Reset* was added for the Channel boot (channel 0) to allow the debugger to return to *Sleep after Reset* state with a new PC

value. The SDMA will be ready to boot at the Chn0Addr address.

66.8 SDMA Clocks and Low Power Modes

The SDMA receives several root clocks from the SoC clock controller block and performs adaptive clock gating to optimize its power consumption. From a user standpoint, clock gating and power mode selection are fully automatized inside the SDMA.

Root clock control is available from the SoC clock controller block.

There are numerous clock sources that are used in the SDMA. They belong to one of two possible clock domains listed in the following table, and have frequency constraints within each domain. Clocks are considered asynchronous between domains.

Within the ARM platform/SDMA clock domain, all clocks must come from the same DPLL. The ARM platform DMA interfaces (peripheral DMA and burst DMA) receive their clock from the ARM platform DMA clock source whose frequency can be once or twice the frequency of the SDMA core clock. The DMA interfaces are designed to work at the ARM platform DMA frequency, but the SDMA core is physically limited to a maximum 104 MHz frequency. Since this is lower than the maximum ARM platform DMA frequency, the SDMA core clock is tied to the ARM platform peripheral clock frequency.

The ARM platform Peripheral Bus Clock source must be an exact sub-frequency of the SDMA Core clock source (any integer value greater or equal to 1).

Table 66-7. Clocking Scheme

Clock Domain	Source Clock	Comments
ARM platform	SDMA core (SDMA main core)	Source clock for the core and all its operations; this clock is thus used by most of the SDMA sub-blocks.
	ARM platform DMA	DMA interface for the peripheral DMA and the burst DMA. It is balanced with the main clock source, and its frequency is either once or twice the main clock frequency.
	ARM platform peripheral	Connection to the ARM platform peripheral bus. It is a sub-frequency of the main clock frequency.
JTAG	TCK	Clock for JTAG access, limited to maximum of 1/8 of the SDMA core clock frequency.

The JTAG clock is sampled by the SDMA main clock to determine its rising edge. This simplifies design and clock management, but it also adds a ratio constraint between those two clocks. It is guaranteed the JTAG interface works properly when the frequency of TCK is lower than 1/8th of the frequency of the SDMA main clock (which is about 8 MHz when the SDMA core clock frequency is 66 MHz).

66.8.1 Clock Gating and Low Power Modes

The SDMA automatically performs power saving without requiring user involvement. It implements two levels of automatic clock gating.

66.8.1.1 Coarse Clock Gating

Every sub-block clock comes from one of the five available sources, and is gated with the sub-block specific enabling condition.

The following table displays the sub-block clocks and their source. It also indicates the relationships that may exist between different sub-blocks clock enables.

Table 66-8. Sub-blocks Clocks

Sub-block	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
Core	SDMA Main Core	The core sub-block clock is running when the core is not in one of its sleep states (Sleep or Sleep after Reset) or there is a pending channel. Typically, the core sub-block clock is stopped once all the channels are processed and the core enters its sleep state. A new pending channel awakes the core sub-block clock.	None
Memories	SDMA Main Core	The clock activation only occurs during a core access.	Disabled when Core sub-block clock is disabled or no memory access in progress
Scheduler	SDMA Main Core	Its clock only runs when scheduling is needed: for example, when there are pending channels, upon reception of a DMA request, and anytime the ARM platform modifies the channel running conditions.	None
ARM platform Control	SDMA Main Core & ARM platform peripheral	The ARM platform peripheral clock is solely used to determine the frequency ratio with the SDMA main clock. The control registers' clock is based on *SDMA main clock*; it is active when the ARM platform or the SDMA modifies the contents of one of these registers.	None
CRC	SDMA Main Core	The CRC clock is based on *SDMA main clock* and is only active during data processing.	Disabled when Core sub-block clock is disabled

Table continues on the next page...

Table 66-8. Sub-blocks Clocks (continued)

Sub-block	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
Burst DMA	SDMA Main Core & ARM platform DMA	The burst DMA has two clocks: The first clock is derived from the SDMA main core clock and drives registers that are connected to the FUBUS. The second clock is derived from the ARM platform DMA clock and drives registers that are connected to the ARM platform DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the burst DMA is not used by the running channel script).	Disabled when Core sub-block clock is disabled
Peripheral DMA	SDMA Main Core & ARM platform DMA	The peripheral DMA has two clocks: The first clock is derived from SDMA main clock and drives registers that are connected to the FUBUS. The second clock is derived from the ARM platform DMA clock and drives registers that are connected to the ARM platform DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the peripheral DMA is not used by the running channel script).	Disabled when Core sub-block clock is disabled
OnCE	SDMA Main Core	The OnCE clock is derived from main source clock. It is disabled by default. In order to use the OnCE, its clock must be explicitly turned on, either by enabling the OnCE access from the ARM platform peripheral bus (register ONCE_ENB), or by driving the clk_gating_off input pin high. This is a SDMA input whose driver depends on the SoC implementation (typically a JTAG controller). The OnCE also receives the TCK input, which is the JTAG clock. It does not use it as a functional clock; the TCK input is sampled instead. Refer to Synchronization Implementation.	When enabled, all other clocks are systematically on (clock gating is off)

66.8.1.2 Refined Clock Gating

The SDMA implements a second level of clock gating on a register-per-register basis.

Unlike the first level that covers all the SDMA flip-flops, except the synchronizers (only five flip-flops are always running), the second level is only available for eligible registers, which amounts to about 90% of the SDMA flip-flops.

These gated registers are only clocked when the hardware logic detects a new data loading. This additional gating further reduces dynamic power consumption.

66.8.1.3 Low Power Modes and User Control

Power savings are automatically managed by the SDMA hardware without any user involvement; however, one can distinguish three different power modes: SLEEP, RUN, and DEBUG.

The following table describes these modes, and shows how to switch from one mode to another.

Table 66-9. Power Modes

Power Mode	Sub-blocks								Comments
	Core	Memories	Scheduler	ARM platform Control	CRC	Burst DMA	Peripheral DMA	OnCE	
SLEEP	off[1]	off	wait[2]	wait	off	off	off	off	Set when the PCU state is either *Sleep* or *Sleep after Reset* and the SDMA is not in DEBUG mode. This is the default mode after reset.
RUN	on[3]	wait	wait	wait	wait	wait	wait	off	Set for the other PCU states that are reachable out of debug: *Program*, *Data*, *Change of Flow*, *Error in Loop*, *Debug*, *Functional Unit*, *Save,* or *Restore*.
DEBUG	on	on	on	on	on	on	on	on	Set regardless of the PCU state when clock gating is turned off to use the OnCE features (either *clk_gating_off* pin high or ONCE_ENB[0] set).

1. *off*: no clock
2. *wait*: only clocked when accessed or stimulated
3. *on*: clock is always running

It is possible to control the SDMA power mode. The procedures to force the SDMA into either mode are described in SLEEP Mode.

66.8.1.3.1 SLEEP Mode

This is the default mode after reset; therefore, resetting the SDMA forces this mode.

However, the common procedure is as follows:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Disable all channels (via the STOP_STAT control register, and the HO, DO, EO if necessary).
- Wait for the active channels to complete or force a reschedule via the reschedule bit in the RESET register.
- The SDMA is in SLEEP mode making it possible to completely shut off its clock from the chip level clock controller using the procedure described in Stop Mode Response.

66.8.1.3.2 RUN Mode

This is the default mode when a channel is running:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Activate at least one channel (via the HSTART control registers, a DMA request, and/or the HO, DO, EO register bits).

66.8.1.3.3 DEBUG Mode

The DEBUG mode must be set when one needs to use the debugging facilities of the SDMA.

- Ensure the SDMA clocks are running from the CCM.
- Set the *clk_gating_off* pin high or use the SDMA to set ONCE_ENB[0].

66.8.1.4 Stop Mode Response

The SDMA receives a stop request from the chip level clock controller. This request may be asserted when the chip enters the stop low power mode.

If the SDMA is running when the request is received, then the SDMA will complete all pending channels before returning to the SLEEP state. The SDMA sends an acknowledgement to the clock controller when the SLEEP state is entered indicating that the SDMAs clocks can be turned off.

66.8.2 Reset

After reset (either received from the reset block or a software reset required by the ARM platform), the SDMA is in IDLE mode. It will start its boot code located at address 0 once a channel is activated.

Activating a channel can be done by the ARM platform after programming a positive priority and setting the channel bit in the EVTPEND register.

There will not be a context RESTORE for the first channel (bootload channel) called after a reset because the context data in RAM has not been initialized. Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized. Subsequent calls to the same channel or different channels may use any of the dynamic context modes

66.9 Software Interface

Appendix A fully describes the SDMA Application Programming Interface (API).

66.10 Initialization Information

This section discusses the following:

66.10.1 Hardware Reset

After reset, the program RAM, context RAM, data RAM, and RAM containing the channel enable registers (CHNENBLn) have unpredictable contents.

The active register set is assigned to channel 0 and the PC is initialized to all zeros. However, since the channel enable register is all zeros, there are no active channels and the SDMA is halted waiting for the boot channel to start.

The ARM platform will have to setup the SDMA in order to boot it. The CONFIG register must be initialized to determine the DMA/core clock ratio (1 or 2). Channel Enable Registers must also be initialized.

To start up the SDMA, the ARM platform first creates some channel control blocks (CCB) and buffer descriptors (BD) in ARM platform memory for the boot channel (channel 0) and then initializes the channel 0 pointer register (SDMA_MC0PTR) to the address of the first control block. Data Structures for Boot Code and Channel Scripts provides an overview of the data structure for the CCB and BD's. The SDMA_HSTART, SDMA_HOSTOVR and SDMA_EVTOVR registers are then configured according to Runnable Channels Evaluation to allow channel 0 to run.

Upon being enabled, the SDMA begins executing the script located at the address indicated by the Channel 0 Boot Address register (SDMA_CHN0ADDR) in the program memory. The reset value of SDMA_CHN0ADDR points to the default bootload script in ROM. This ROM script will read the channel 0 pointer register (SDMA_MC0PTR) to determine the location of the Channel Control Block (SDMA_CCB) in ARM platform memory. The script will then begin fetching by DMA the first channel control block which contains a pointer to the location channel 0 Buffer Descriptor chain which is also fetched via DMA. If the buffer descriptor contains a valid command, the script interprets the command in each buffer descriptor and proceeds to implement the command and move on to the next buffer descriptor control block. The buffer descriptor commands for channel zero are typically set up to load SDMA's program RAM, Data RAM, and initial values for the channel contexts. Some channel scripts expect particular parameters to be passed

There are two ways to make the SDMA boot on a user-defined script. The OnCE (either via its JTAG interface or its ARM platform Control interface) can be used to download any code in the SDMA RAM and force the SDMA to boot on that code. Also, the SDMA_CHN0ADDR register in the ARM platform programming model can be modified to point to user code in RAM which would need to either have been loaded via the ONCE or default bootload routine (ex before a S/W reset).

66.10.2 Channel Script Execution

The execution of an SDMA script depends on both the instructions that make up the script, the data context upon which it operates, and commands or parameters passed in the buffer descriptor or. All these items must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate context, but may share scripts and locations in data RAM.

Channels are initialized by the ARM platform by using channel 0 to download any required scripts and data values and the channels initial context. The context contains all the initial values of the SDMA core registers. This includes the Program Counter (PC) which is set to the start of the desired script in SDMA program memory.

The ARM platform selects which trigger conditions that must occur for the channel to start by configuring the SDMA_CHNENBL, SDMA_HOSTOVR and SDMA_EVTOVR registers. The trigger events include ARM platform setting HE (SDMA_HSTART) or a hardware DMA request asserts an event input to SDMA. The channel can become active according to its priority compared with other runnable channels when the selected trigger(s) cause the condition described in Runnable Channels Evaluation to evaluate as true.

The specific parameters to be passed to each script in the buffer descriptor or context are documented in the software documentation for each script. Please refer to SDMA Scripts for complete script documentation. Buffer Descriptor Format provides an overview of the buffer descriptor format.

66.10.3 Initialization and Script Execution Setup Sequence

To summarize, the following steps are minimally required to setup SDMA and run channel scripts.

- Perform Hardware Reset. The program RAM, context RAM, data RAM and SDMA_CHNENBLn registers have unpredictable contents after this reset

- Initialize SDMA_CHNENBLn registers to map DMA request events to desired channels.
- Configure SDMA_CHNPRIn registers to select priority for runnable channels, A non-zero priority is required for the channel to run.
- Configure the SDMA_CONFIG register to select DMA to SDMA core clock ratio .
- Set up channel control blocks and buffer descriptors in ARM platform to specify the loading of SDMA program RAM and channel contexts for each SDMA channel to be used. Reference Data Structures for Boot Code and Channel Scripts.
- Configure SDMA_MC0PTR register with base address of ARM platform Channel Control Block base address.
- Initialize SDMA_CHNENBLn registers to map DMA request events to associated channel. Reference Mapping DMA Requests to Pending Channels.
- Configure SDMA_CHNPRIn registers to set priority for each channel to be run.
- For each channel to be run, configure SDMA_HOSTOVR (HO) and SDMA_EVTOVR (EO) registers to select which events (hardware and/or software trigger events) must occur for the channel to be runnable. Reference Runnable Channels Evaluation.
- Set bit 0 of the SDMA_HSTART register to set HE[0] and allow Channel 0 to run (assumes EO[0] andDO[0] were both set in previous step). This will cause SDMA to load the program RAM and channel contexts configured previously.
- Wait for Channel 0 to finish running. This is indicated by HI[0]=1 in the SDMA_SDMA_INTR register, or by optional interrupt to the ARM platform.
- Set the LOCK bit in the SDMA_SDMA_LOCK register to prevent un-authorized uploads of data to SDMA RAM.
- Additional channel scripts can now be run by enabling the selected software or hardware trigger event according to Runnable Channels Evaluation.

66.11 SDMA Programming Model

The following section describes the programming model for the SDMA RISC engine, including its processor, memory, and internal control registers.

All addresses are related to the internal SDMA memory map, which is completely different from the ARM platform memory maps. The ARM platform processor has no access to any hardware resource described, except when those resources are described in ARM Platform Memory Map and Control Register Summary. .

66.11.1 State and Registers Per Channel

The SDMA can be seen as a set of 32 identical devices that are able to perform one data transfer channel each. Only one channel can work at a time, but every channel state is available at any time.

This chapter lists the components of every channel state.

66.11.2 General Purpose Registers

Each channel has eight general purpose registers of 32 bits for use by scripts. General register 0 has a dedicated function for the loop instruction, but otherwise can be used for any purpose.

66.11.3 Functional Unit State

Each channel context has some state that is part of the functional units.

The specific allocation of this state is part of the functional unit definition that is described in Burst DMA Unit Programming, Peripheral DMA Unit Programming .

This state must be saved/restored on context switches.

66.11.3.1 Program Counter Register (PC)

The PC is 14 bits. Since instructions are 16 bits in width and all memory in the SDMA is 32 bits in width, the low order bit of the PC selects which half of the 32-bit word contains the current instruction.

A low order bit of zero selects the most significant half of the word.[1]

66.11.3.2 Flags

Each channel has the following four flags:

- The T bit reflects the status of some arithmetic and test instructions. It is set when the result of an addition or a subtraction is zero and cleared otherwise. It is also the copy of the tested bits. Finally, it can also be set when the loop counter (GReg0) reaches

1. For example, big-Endian.

zero. When the last instruction of the hardware loop is an operation that can modify the T flag, its effect on T is discarded and replaced by the GReg0 status.

- Two additional bits, SF and DF, are used to indicate error conditions resulting from loading data sources and storing to destinations, respectively. Access errors set these bits, and successful transactions clear them. They can also be cleared by specific instructions (CLRF and loop). The source fault (SF) is updated by the loads LD and LDF; the destination fault (DF) is updated by the stores ST and STF.
- Access errors are caused by several conditions including writing to the ROM, writing to a read-only memory mapped register, accessing an unmapped address, or any transfer error received by a peripheral when it is accessed.

  The SF and DF flags have a major impact on the behavior of the hardware loop: If SF or DF is set when starting a hardware loop and it is not masked by the loop instruction, the loop body will not be executed. Inside the loop body, if a load or store sets the corresponding SF or DF flag, the loop exits immediately. Testing the status of the T flag at the end of the loop (as well as testing both SF and DF) tells if the loop exited abnormally as any anticipated exit prevents GReg0 from reaching the zero value and thus setting the T flag. This is also valid if the fault occurs at the last instruction of the last loop.

- The last flag is the loop mode flag, LM, which is composed of two bits. The most significant bit indicates when the processor is currently operating in loop mode. It is set by the loop instruction and is cleared after execution of the last instruction of the last loop. The least significant bit is set when the program counter points to the last instruction of a loop on the last path. It is used for a channel that is restored with this configuration to know that the next program counter is EPC. As with the dynamic context switch Greg0, which indicates when the program must get out of the loop, it can be restored only on the last instruction of the loop. This, however, is too late to fetch the next instruction after the loop.

66.11.3.3 Return Program Counter (RPC)

The RPC is 14 bits. It is set by the jump to the subroutine instructions and used by the return from the subroutine instructions.

Instructions are available to transfer its contents to and from a general register.

66.11.3.4 Loop Mode Start Program Counter (SPC)

The SPC is 14 bits. It is set by the loop instruction to the location immediately following it.

66.11.3.5 Loop Mode End Program Counter (EPC)

The EPC is 14 bits. It is set by the loop instruction to the location of the next instruction after the loop.

66.11.4 Context Switching-Programming

Each channel has a separate context consisting of the eight general purpose registers and additional registers representing the state of the functional units.

The active registers and functional units contain the context of the active channel. The context of inactive channels is stored in SDMA RAM, which is part of the SDMA address space.

In a function of the selected context switching mode (Context Switching), modified registers by the program can be saved in the channel RAM space while the program is going on. In every cycle, a write access to the RAM is possible.

On a done or yield(ge) instruction, SDMA goes into "real" context switching. In one of the dynamic modes, modified registers not previously saved, as well as the PC-Loop registers, are stored into the context area of the channel that will be closed. The new PC-Loop registers are loaded from the context area of the new channel. All other registers are restored while the program is executed, giving priority to registers used by the decoded instruction. Therefore, in the best case, only the PC and Loop registers should be saved and restored during this context-switching phase, which only requires five SDMA cycles.

In static mode, the context switch stores all registers in the old channel RAM space, and restores all registers from the new channel RAM space. It requires 26 SDMA cycles.

The address of the context memory for channel *i* is *CONTEXT_BASE* + 24**i* or *CONTEXT_BASE* + *32*i w*here CONTEXT_BASE equals 0x0800. The table below presents the layout of a channel context in memory:

Table 66-10. Layout of a Channel Context in Memory for SDMA

66.11.5 Address Space

The SDMA has four internal buses, as follows:

- The Instruction bus reads instructions from the memory. Its address map is described in Instruction Memory Map.
- The Data bus (DMBUS) accesses the same memories as those visible on the Instruction bus, some memory-mapped registers (scheduler status and OnCE

registers), and up to 14 peripherals. Its address map is described in Data Memory Map.

- The Functional Units bus (FUBUS) accesses the burst DMA, peripheral DMA, and CRC internal registers. The addressing mechanism is further detailed in Functional Units Programming Model.
- The Context Switch bus reads/writes registers into context-switch RAM space. It is a 64-bit bus dedicated for accessing this RAM space for updating the context of the running channel. While the program is going on, this bus has the lowest priority compared to the Instruction and Data buses, except for restoring a register needed for the decoded instruction to be executed. On the save part of a context switch (when the PCU is in its slave state), this is the only one used. On the restore part, the Instruction bus has the priority to read the next instruction at the restored PC and otherwise the Context Switch bus is used. It is not possible to control the actual data transfers that occur on this bus.

66.11.5.1 Instruction Memory Map

The instruction memory map is based on a 14-bit address bus and a 16-bit data (instruction) bus. Each address corresponds to a 16-bit data location.

Instructions are fetched from either program ROM or program RAM. An SDMA script is able to change the contents of the program RAM, which is also visible from the data bus.

The first two instruction locations (at 0 and 1) are special. Location 0 is where the PC is set on reset. Location 1 is where the PC is set upon the execution of an illegal instruction. It is expected that both of these locations will contain a jmp to handle routines.

Table 66-11. SDMA Instruction Memory Space

Device	SDMA Address (Hex)	Base Address Label	Block Name	WS	Description
ROM	0x0000 ↓ 0x07FF	SDMA_IBUS_ROM_ADDR	-	0	4 Kbyte internal ROM with boot code and standard routines.
RAM	0x1000 ↓ 0x1FFF	SDMA_IBUS_RAM_ADDR	-	0	8 Kbyte internal RAM with channels context and user data/routines.

66.11.5.2 Data Memory Map

All of the data accessible to SDMA scripts make up the data memory space of the SDMA.

This address space has several components:

- ROM (also visible on the Instruction bus)
- RAM (also visible on the Instruction bus)
- Shared Peripherals Registers
- SDMA Internal Registers (scheduler, OnCE, and registers that are also accessible by the ARM platform)

SDMA scripts can read and write to the context RAM, data RAM, shared peripheral registers, and internal registers.

The address range is 16 bits and the data width is 32 bits. Each address corresponds to a 32-bit data word. When accessing peripheral registers (USB and so on), the data width may be different. The exact address map for the peripherals depends on the project (as presented in each respective chapter).

The SDMA can perform only 32-bit access to shared peripheral registers. For this device, shared peripherals registers are aliased as if byte addressed. This is a consequence of connections through the SPBA shared peripheral bus outside of the SDMA. The result is that although address space 4 Kwords (16Kbyte) is allocated for each peripheral, only the first 4 Kbyte of the peripheral's register space can accessed. For example, the shared peripheral register at address 0x3000 is mapped also to addresses 0x3001, 0x3002, 0x3003. A read or write access to any of any of these 4 addresses will respond as if the access was to address 0x3000.

Data access is performed with *ld* and *st* instructions that take the address from a general purpose register in the core (GReg*n*). The mapping between the general purpose register contents and the address bus is given in the following table:

Table 66-12. GReg*n* to DMBUS Address Mapping

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sz	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
address															

Grayed bits are simply discarded but they must be cleared to ensure forward-script compatibility.

- sz (bit 31) indicates the peripheral data width: 0 is used for a 32-bit peripheral and 1 is used for a 16-bit peripheral.
- address (bits 15 down to 0) is the address of the accessed resource (internal memory, internal register, or shared peripheral).

Table 66-13. SDMA Data Memory Space

Device	SDMA Address (Hex)	Size	Description
ROM	0x0000 → 0x03FF	4 Kbyte	4 Kbyte internal ROM with boot code and standard routines
Reserved	0x0400 → 0x07FF	4 Kbyte	4 Kbyte Reserved
RAM	0x0800 → 0x0FFF	8 Kbyte	8 Kbyte internal RAM with channels contexts and user data/routines
per1	0x1000 → 0x1FFF	16 Kbyte	*peripheral 1* memory space (4 Kbyte peripheral's address space)
per2	0x2000 → 0x2FFF	16 Kbyte	*peripheral 2* memory space (4 Kbyte peripheral's address space)
per3	0x3000 → 0x3FFF	16 Kbyte	*peripheral 3* memory space (4 Kbyte peripheral's address space)
per4	0x4000 → 0x4FFF	16 Kbyte	*peripheral 4* memory space (4 Kbyte peripheral's address space)
per5	0x5000 → 0x5FFF	16 Kbyte	*peripheral 5* memory space (4 Kbyte peripheral's address space)
per6	0x6000 → 0x6FFF	16 Kbyte	*peripheral 6* memory space (4 Kbyte peripheral's address space)
Registers	0x7000 → 0x7FFF	16 Kbyte	Memory mapped registers
per7	0x8000 → 0x8FFF	16 Kbyte	*peripheral 7* memory space (4 Kbyte peripheral's address space)
per8	0x9000 → 0x9FFF	16 Kbyte	*peripheral 8* memory space (4 Kbyte peripheral's address space)
per9	0xA000 → 0xAFFF	16 Kbyte	*peripheral 9* memory space (4 Kbyte peripheral's address space)
per10	0xB000 → 0xBFFF	16 Kbyte	*peripheral 10* memory space (4 Kbyte peripheral's address space)
per11	0xC000 → 0xCFFF	16 Kbyte	*peripheral 11* memory space (4 Kbyte peripheral's address space)
per12	0xD000 → 0xDFFF	16 Kbyte	*peripheral 12* memory space (4 Kbyte peripheral's address space)
per13	0xE000 → 0xEFFF	16 Kbyte	*peripheral 13* memory space (4 Kbyte peripheral's address space)
per14	0xF000 → 0xFFFF	16 Kbyte	*peripheral 14* memory space (4 Kbyte peripheral's address space)

66.12 SDMA Initialization

Appendix A describes the setup of the SDMA . This section provides a quick description of several initialization procedures.

NOTE

There may be differences with the actual implementation in the API.

66.12.1 Hardware Reset-SDMA

After reset, the RAM that holds contexts, data, scripts, and the DMA request-channels matrix has unpredictable content.

The core registers are all reset to 0, including the PC; the PCU state is *Sleep after Reset*. No channel can be activated because all of the priorities are also reset to 0.

66.12.2 Standard Boot Sequence

The following is the standard boot sequence:

1. Initialize the CONFIG register-detailed in Configuration Register (SDMAARM_CONFIG)-to determine the ARM platform DMA/core clock ratio (1 or 2)
2. Initialize the DMA request-channels matrix (seeChannel Enable RAM (SDMAARM_SDMA.CHNENBL*n*)).
3. Program the channel control registers-Channel Event Override (SDMAARM_EVTOVR), Channel BP Override (SDMAARM_DSPOVR), Channel BP Override (SDMA_HOSTOVR), and Channel Event Pending (SDMAARM_EVTPEND)-according to the channel allocation.
4. Perform any necessary setup as required by the standard boot script in ROM (this is described in Appendix A).
5. Trigger channel 0 with the Channel Start (SDMAARM_HSTART) register, which starts the execution of the ROM script starting at address 0. This boot downloads channel scripts and contexts in RAM.

66.12.3 User-Defined Boot Sequence

The following is a user-defined boot sequence:

1. Initialize the Configuration Register (SDMAARM_CONFIG)Channel Enable RAM (SDMAARM_SDMA.CHNENBL*n*), Channel Event Override (SDMAARM_EVTOVR), Channel BP Override (SDMAARM_DSPOVR), Channel ARM platform Override (SDMAARM_HOSTOVR), and Channel Event Pending (SDMAARM_EVTPEND).
2. Use the OnCE (either via its JTAG interface or its ARM platform control registers) to download any code in the SDMA RAM. Accessing the Memory describes how to write data to the RAM via the OnCE.
3. Use the OnCE instructions to make the PC default value point to the new boot script start address, or rely on the ROM startup script, which first jumps to the address in Channel 0 Boot Address (SDMAARM_CHN0ADDR). (This register default address points to the standard boot script.)

66.12.4 Script Loading and Context Initialization

The execution of an SDMA script depends on both the instructions that make up the script and the data context upon which it operates. Both must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate data context, but may share scripts and locations in the data RAM.

The ARM platform manages the space in program RAM and data RAM. It also manages the assignment of SDMA channels to the device drivers that need them. Channels are initialized by the ARM platform via the channel 0 boot script. The boot channel downloads any required scripts with their data and the channels' initial contexts. Every context contains all the initial values of the registers, including the PC. Then the ARM platform can enable any channel that becomes active and begins fetching and executing instructions from its script.

66.13 Instruction Description

The following sections introduce the instruction of the SDMA. Instruction set details are available in Instruction Set.

66.13.1 Scheduling Instructions

The following are scheduling instructions:

- done-The instruction causes certain scheduling or interrupt bits to be set or cleared, which may cause a change in the schedule-ability of the running channel. Then the instruction causes the SDMA to evaluate the current scheduling priorities and to choose the highest priority ready channel. If this channel is not the current channel, a context switch will take place. If there are no runnable channels, the SDMA will enter the stopped mode. The done 5 has a special usage reserved for debug, as explained in Debug Instructions.
- yield-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater than the current channel priority.
- yieldge-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to

preempt the current channel if the pending channel priority is strictly greater or equal to the current channel priority.
- notify-The notify instruction affects the scheduling bits, but does not cause rescheduling.

66.13.2 Conditional Branch Instructions

The conditional branch instructions of an 8-bit displacement, which is sign-extended and added to the current PC (which points to the next instruction) if the condition is satisfied.

Otherwise, control passes to the next sequential instruction.

- BF-Branch if False. The branch is taken if the T bit in the processor status is zero (false).
- BT-Branch if True. The branch is taken if the T bit in the processor status is one (true).
- BSF-Branch if Source Fault. The branch is taken if the SF bit in the processor status is one.
- BDF-Branch if Destination Fault. The branch is taken if the DF bit in the processor status is one.

66.13.3 Unconditional Jump Instructions

There are two varieties of unconditional control transfers: an absolute transfer and a through-register transfer.

Absolute transfers have a 14-bit address field that replaces the current PC.

- JMP-Jump. Causes the processor to jump to an absolute address encoded in the instruction itself.
- JSR-Jump to Subroutine. Causes the processor to jump to a subroutine, the address of which is encoded in the instruction itself.
- JMPR-Jump through Register. Causes the processor to jump to an absolute address contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.
- JSRR-Jump to Subroutine through Register. Causes the processor to jump to a subroutine, the address of which is contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.

66.13.4 Subroutine Return Instructions

The following are subroutine return instructions:

- RET-Return from Subroutine. The RET restores the contents of RPC to PC.
- LDRPC-Load from RPC to Register. THe LDRPC instruction is meant to be used when more than one level of subroutines are required. It stores the contents of RPC in any General register.

66.13.5 Loop Instruction

The following is a loop instruction:

LOOP-Enters Loop Mode. Before entering loop mode, the loop instruction can optionally clear the fault flags (SF and/or DF) based on a 2-bit field in the instruction. This feature is linked to the fact that setting SF or DF in loop mode will cause an immediate exit of the loop.

66.13.6 Miscellaneous Instructions

The following are miscellaneous instructions:

- CLRF-Clear Fault Flags. This instruction clears any combination of SF and DF.
- MOV r,s-This moves data from GReg[s] to GReg[r].
- LDI r,immediate-This loads GReg[r] with a zero-extended immediate value.

66.13.7 Logic Instructions

The following are logic instructions:

- XORr,s-This performs an exclusive or between GReg[r] and GReg[s], and stores the result in GReg[r].
- XORIr,immediate-This performs an exclusive or between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- ORr,s-This performs an or between GReg[r] and GReg[s], and stores the result in GReg[r].
- ORIr,immediate-This performs an or between GReg[r] and a zero-extended immediate value and, stores the result in GReg[r].
- ANDNr,s-This performs an and between GReg[r] and the negated GReg[s], and stores the result in GReg[r].

- ANDNIr,immediate-This performs an and between GReg[r] and the negated zero-extended immediate value, and stores the result in GReg[r].
- ANDr,s-This performs an and between GReg[r] and GReg[s], and stores the result in GReg[r].
- ANDIr,immediate-This performs an and between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].

66.13.8 Arithmetic Instructions

Arithmetic instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the result is zero, otherwise it is cleared.

- ADD r,s-This performs the addition of GReg[r] and GReg[s], and stores the result in GReg[r].
- ADDI r,immediate-This performs the addition of GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- SUB r,s-This performs the subtraction of GReg[s] from GReg[r], and stores the result in GReg[r].
- SUBIr,immediate-This performs the subtraction of a zero-extended immediate value from GReg[r], and stores the result in GReg[r].

66.13.9 Compare Instructions

Compare instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the comparison is true, otherwise it is cleared.

NOTE

Only one version of the immediate form is implemented. Non-equality comparisons to immediate values will require two instructions.

- CMPEQ r,s-This sets T when registers GReg[r] and GReg[s] are equal.
- CMPEQIr,immediate-This sets T when register GReg[r] and the zero-extended immediate value are equal.
- CMPLTr,s-This sets T when register GReg[r] is less than and not equal to GReg[s]. The comparison is signed.
- CMPHS r,s-This sets T when register GReg[r] is greater than or equal to GReg[s]. The comparison is signed.

66.13.10 Test Instructions

Test instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if any bit in the result is one, otherwise it is cleared.

- TSTr,s-This performs an and between GReg[r] and GReg[s], and sets T if the result is not zero.
- TSTIr,immediate-This performs an and between GReg[r] and a zero-extended immediate value, and sets T if the result is not zero.

66.13.11 Byte Permutation Instructions

These instructions shuffle the bytes in a register. For the purpose of describing these instructions, have the bytes in a register be numbered from the most significant as b_3, b_2, b_1, b_0.

- RORBr-The rotate right byte. The result is b_0, b_3, b_2, b_1.
- REVBr-The reverse bytes in word. The result is b_0, b_1, b_2, b_3.
- REVBLOr-The reverse, two low-order bytes. The result is b_3, b_2, b_0, b_1.

66.13.12 Bit Shift Instructions

The following are bit shift instructions:

- ROR1r-The rotate right 1 bit. This instruction does a circular right shift of 1 bit.
- LSR1r-The logical shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by a 0.
- ASR1r-The arithmetic shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by itself.
- LSL1r-The logical shift left 1 bit. This instruction shifts all bits to the left by 1. The low order bit is replaced by zero.

66.13.13 Bit Manipulation Instructions

- BCLRIr,n-The bit clear is immediate; clears bit number *i* in register *r*.
- BSETIr,n-The bit set is immediate; sets bit number *i* in register *r*.
- BTSTIr,n-The bit test is immediate; tests bit number *i* in register *r* (T becomes equal to the selected register bit).

66.13.14 SDMA Memory Access Instructions

All memory accesses are 32 bits.

Any memory location that is implemented with less than 32 bits (for example, peripheral registers) causes unimplemented bits to be read as 0s.

All memory accesses will cause either the SF or DF flags in the processor status to be set if they cause a fault.

What constitutes a fault, especially when accessing peripheral registers, is a property of the memory location.

- LDr,(b,d)-The load instruction creates an address by adding the displacement field (d) to the contents of the base register (b). The SDMA location at the resulting address is read and placed in the destination register (r).
- STr,(b,d)-The store instruction creates an address in the same manner as the load instruction. The register (r) is stored in the SDMA location at the resulting address.

66.13.15 Functional Unit Instructions

The functional unit instructions have an 8-bit field that is placed on the functional unit bus.

Some of these bits are used to select which functional unit should be involved in the transfer. The remaining bits are decoded by the selected functional unit so their specific use depends on the functional unit. See Functional Units Programming Model.

There are two functional unit instructions, as follows:

- LDFr,fub-The 8-bit field is placed on the functional unit bus and a read is issued to the selected functional unit. As a result of this instruction, the SF may be set in the processor status.
- STFr,fub-The 8-bit field is placed on the functional unit bus and a write is issued to the selected functional unit. As a result of this instruction, the DF may be set in the processor status.

66.13.16 Illegal Instructions

All instruction encodings that are illegal cause the following actions:

- The current PC (which points to one beyond the offending instruction) is put in the EPC register.

- The loop mode bit is cleared.
- The PC is set to the value stored in the Illegal Instruction Trap Address (SDMAARM_ILLINSTADDR) register (the default value is 0x0001).

ILLEGAL-Although any instruction other than those indicated in the SDMA specification will trigger the illegal instruction mechanism, the ILLEGAL instruction code is preferred as it will always be kept as *illegal* in the possible future versions of the SDMA core.

66.13.17 Debug Instructions

The following are debug instructions:

- SOFTBKPT-The software breakpoint instruction causes the core to stop and enter debug mode. The core can then be accessed and started by the OnCE debug block only.
- done 5-This instruction is used for debugging, as it copies the contents of the PCU registers and flags to the context memory. Information on this instruction is described in Saving the Context.
- CpShReg-This instruction copies the context memory into the PCU registers and flags. Modifying the corresponding memory location before executing this instruction enables you to have the channel continue from a new instruction address. This instruction is described in Restoring the Context.

66.14 Functional Units Programming Model

The functional unit instructions cause an 8-bit code, found in the low eight bits of the instruction, to be asserted on the functional unit control bus.

Some of these bits are used to select one of several functional units. Functional units which can be selected include SDMA registers such as MSA and MSD which are not mapped in the SDMA memory map, and are accessible only through the functional unit bus. These Functional Unit Registers are listed in the following table. In order to establish

a programming convention, assume the selection bits are some number of the most significant bits of the 8-bit code. Furthermore, some number of the least significant bits is decoded by a given functional unit to establish the type of operation to perform.

Table 66-14. Functional Unit Registers

Functional Unit	Register	Register Name	Section/Page
Burst DMA Unit Programming	SDMSA	Memory Source Address Register	Memory Source Address Register (MSA)
	MDA	Memory Source Address Register	Memory Destination Address Register (MDA)
	MD	Memory Data Buffer Register	Memory Data Buffer Register (MD) (Write) Burst DMA Write (stf) (Read) Burst DMA Read (ldf)
	MS	Memory State Register	State Register (MS)
Peripheral DMA Unit Programming	PSA	Peripheral Source Address Register	Peripheral Source Address Register (PSA)
	PDA	Peripheral Source Address Register	Peripheral Destination Address Register (PDA)
	PD	Peripheral Data Buffer Register	Peripheral Data Register (PD) (Write) Peripheral DMA Write (stf)-Write Mode (Read) Peripheral DMA Read (ldf)-Read Mode
	PS	Peripheral State Register	Peripheral State Register (PS)
CRC Unit	CA	Polynomial Register	Polynomial Register (CA)
	CS	Accumulator Register	Accumulator Register (CS)

More information regarding the functional units can be found in CRC Calculation Unit,Peripheral DMA Unit, and Burst DMA Unit.

66.14.1 Burst DMA Unit Programming

The DMA instructions control the DMA state machine and may cause a DMA cycle on the associated memory bus.

There are four registers associated with the burst DMA unit: a Memory Source Address register (MSA), a Memory Destination Address register (MDA), a Memory Data buffer (MD), and a state register (MS). The burst DMA has two different uses:

- A data transfer between External Memory Interface and SDMA general register
- A data transfer in copy mode where blocks of data are transferred from the source address to the destination address

66.14.1.1 Memory Source Address Register (MSA)

The source address register contains the pointer into EXTMC memory associated with the next read data transfer. It has byte granularity.

Reading the register with the ldf instruction has no side effects, and gives the address value in the EXTMC memory of the next data that is read by the SDMA during an ldf MD instruction.

Writing the source address register has two side effects: If the prefetch bit is set, a DMA read cycle (8-word read access) is issued with the new address. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MSA to guarantee all the data is effectively written to memory.

The MSA register has two modes of programming:

- Frozen-In frozen mode, the MSA register is not modified after DMA accesses.
- Incremented (default mode)-In incremental mode, MSA is incremented by the number of bytes transferred during read cycles.

66.14.1.2 Memory Destination Address Register (MDA)

The destination address register contains the pointer into EXTMC memory associated with the next write data transfer. It has byte granularity.

Reading the MDA register with the ldf instruction has no side effects. It gives the address value in the EXTMC memory where the next SDMA data (stf r,MD instruction) is stored when MD FIFO is flushed.

Writing the destination address register has one side effect. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MDA to guarantee all the data is effectively written to memory.

The MDA register has two modes of programming:

- Frozen-In frozen mode, the MDA register is not modified after DMA accesses.
- Incremented (default mode)-The MDA register is incremented by the number of bytes transferred during write cycles.

66.14.1.3 Memory Data Buffer Register (MD)

The data buffer register consists of a bank of 36 bytes that behave like FIFO.

This FIFO stores the eight words received when a read burst is triggered by the DMA (DMA is in read mode).

The MD register is in write mode after a writing in MDA or after an stf MD instruction.

In that case, a burst write access is automatically triggered when there are more than eight words in MD. For bandwidth optimization, any transfers between DMA and the EXTMC controller are based on burst accesses.

An ldf r,MD|SIZE instruction that reads the data buffer may cause a DMA cycle, as follows:

- If there are less bytes in the FIFO than the size parameter of the instruction. For instance, if only two bytes are available in MD and a 4-byte read is requested, a burst read access is executed to complete the two bytes.
- If the prefetch bit is set, and after reading there is enough space in the FIFO to store a full burst, a burst read access is triggered.

An stf r,MD|SIZE instruction that writes to the data buffer may cause a DMA cycle if the number of written bytes in MD is higher than 32 (eight words) or if the flush bit is set.

When DMA is used for data transfer between SDMA and EXTMC (reading or writing), no immediate error is possible because the block manages a data misalignment issue; therefore, it is allowed to read/write a word to/from a half-word address. However, the addresses (source or destination) must belong to the EXTMC memory mapping. The only potential error, in this mode, would be the error sent back by the EXTMC controller when an access to a super-user page is detected. The whole transfer on the DMA associated bus will be considered successful when there are no errors seen on the bus during the transfer. In copy mode, an immediate error could be returned to SDMA as described in Burst DMA Unit Error Management.

66.14.1.4 State Register (MS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer. MS is also accessed to set-up the conditional yielding feature.

The initialization value of this register is 0 and it consists of the following:

Table 66-15. SDMA_MS Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0	0	0	0	0	0	0	0	0	0	spriv	stype	0	0	dpriv	dtype
W																
R	0	0	0	0	y	d	e		0	0	n					
W																

Table 66-16. SDMA_MS Field Descriptions

Field	Description
31-22	Reserved
21 spriv	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
20 stype	Source Mode. Indicates if MSA has to be incremented (or not) during accesses. 0 Frozen-MSA is not modified. 1 Incremented-MSA is incremented by the number of transferred bytes during read access.
19-18	Reserved
17 dpriv	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved
16 dtype	Destination Mode. Indicates if MDA has to be incremented (or not) during accesses. 0 Frozen-MDA is not modified. 1 Incremented-MDA is incremented by the number of transferred bytes during write access.
15-12	Reserved
11 y	Conditional Yielding selector. When selected, theyield/yieldge instructions will not switch channels if the Burst DMA is in Write Mode, and it has less than four bytes in its FIFO. This is aimed at reducing the number of inefficient FIFO flushes due to context switches. 0 Always yields 1 Yields conditionally (when there are less than four bytes in the FIFO in write mode)

Table continues on the next page...

Table 66-16. SDMA_MS Field Descriptions (continued)

Field	Description
10 d	Access Direction or DMA Mode. DMA is in write mode when data was written into MD by stf MD instructions, or if a previous DMA cycle on the external bus was a write access. Writing MDA or MSA changes the DMA mode to the respective value. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by SDMA with an ldf MD instruction. Reading MDA or MSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 *reserved* 10 Error mode 11 error read burst
7-6	Reserved
5-0 n	Number of bytes in the MD FIFO.

66.14.1.5 Burst DMA Write (stf)

When received from a stf instruction, the function code bits are interpreted as follows, depending on the addressed register:

Table 66-17. STF Code Bits

Register	7	6	5	4	3	2	1	0
MSA	s		p	freeze	r			spriv
MDA								dpriv
MD			f	cpy			sz	
MS								

Table 66-18. STF Code Bit Field Descriptions

Field	Description
7-6 s	Functional Unit selector 00 for Burst DMA
5 p (MSA)	Prefetch Flag 0 No prefetch 1 Prefetch required from new MSA

Table continues on the next page...

Table 66-18. STF Code Bit Field Descriptions (continued)

Field	Description
5 f (MD)	Forced Flush Flag 0 Automatic flush 1 FIFO contents are flushed (including the new written data).
4 freeze (MSA/MDA)	Address Freeze Mode 0 Address is normally incremented. 1 Address is frozen.
4 cpy (MD)	Copy Mode selection 0 Write Mode 1 Copy Mode
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD/MS)	Transfer Size 00 size 0 (no data stored in the FIFO) 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
0 spriv (MSA)	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
0 dpriv (MDA)	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved

The possible write instructions are listed in the table below (unused bits should always be cleared).

Table 66-19. Burst DMA STF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	stf r,MSA	Writes content of the SDMA general register (r) to the source address register. MSA is in incremented mode.
00_0_1_00_00	stf r,MSA|FR	Writes content of the SDMA general register (r) to the source address register. MSA is in frozen mode.
00_1_0_00_00	stf r,MSA|PF	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access. MSA is in incremented mode.

Table continues on the next page...

Table 66-19. Burst DMA STF Instruction List (continued)

Binary	Assembly	Comments
00_1_1_00_00	stf r,MSA|PF|FR	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access.
00_0_0_01_00	stf r,MDA	Writes content of the SDMA general register (r) to the destination address register. MDA is in incremented mode.
00_0_1_01_00	stf r,MDA|FR	Writes content of the SDMA general register (r) to the destination address register. MDA is in frozen mode.
00_1_0_10_00	stf r,MD|SZ0|FL	No data transfers between the SDMA and MD, but all valid written data of the MD is flushed to the memory. An acknowledge or error is sent back to the SDMA core on transfer completion.
00_0_0_10_01	stf r,MD|SZ8	8-bit (byte) transfer to write buffer MD
00_1_0_10_01	stf r,MD|SZ8|FL	8-bit (byte) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_10	stf r,MD|SZ16	16-bit (half-word) transfer to write buffer MD
00_1_0_10_10	stf r,MD|SZ16|FL	16-bit (half-word) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_11	stf r,MD|SZ32	32-bit (word) transfer to write buffer MD
00_1_0_10_11	stf r,MD|SZ32|FL	32-bit (word) transfer to write buffer MD and flush after transfer. All valid written data of MD is flushed to memory.
00_0_1_10_00	stf r,MD|CPY	No data transfer between SDMA and MD but starts a copy transfer whose length is given by the 4 LSB of *r* register. (Maximum burst length is eight words.)
00_0_0_11_11	stf r,MS	32-bit (word) transfer to status register MS
00_0_0_11_00	stf r,MS|SZ0	Clears the error flag (if set). Other MS bits are unchanged; this instruction is also known as clref MS.

NOTE

When a flush bit is set, the SDMA flushes the FIFO including the newly written data. An acknowledge is sent to the core before the flush completes (except if size 0 is used). The goal of this flush bit is to force a flush, but it is recommended to use it only when needed (for example, when finishing a row of pixels during 2D data transfers). Indeed, if this bit is omitted and if there are more than 32 bytes in the FIFO, a burst write access is automatically triggered.

Since all the stf r,MD instructions (including the copy mode) acknowledge the SDMA core before the store is effective (except if size 0 is used), it is recommended to perform an ldf from MS before terminating a channel in order to check the final error status. (The ldf from MS will stall the core until all the data was flushed out and the transfer status is known.)

After every stf MD instruction, the MDA is incremented by the number of bytes that are written in MD, except when it is programmed in frozen mode.

66.14.1.6 Burst DMA Read (ldf)

When received from an ldf instruction, the function code bits are interpreted as follows, depending on the addressed register:

Table 66-20. LDF Code Bits

Register	7	6	5	4	3	2	1	0
MSA	s				r			
MDA								
MD			p				sz	
MS								

Table 66-21. LDF Code Bit Field Descriptions

Field	Description
7-6 s	Functional Unit selector 00 for Burst DMA
5 p (MD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD)	Transfer Size 00 reserved 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

The table below lists the possible write instructions (unused bits should always be cleared).

Table 66-22. Burst DMA LDF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	ldf r,MSA	Copies the source address register value into an SDMA general register. It gives the memory address of the next data that will be read with an ldf MD instruction.
00_0_0_01_00	ldf r,MDA	Copies the destination address register value into an SDMA general register. It gives the memory address where the next incoming data will be flushed.
00_0_0_10_01	ldf r,MD|SZ8	8-bit (byte) read
00_1_0_10_01	ldf r,MD|SZ8|PF	8-bit (byte) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_10	ldf r,MD|SZ16	16-bit (half-word) read
00_1_0_10_10	ldf r,MD|SZ16|PF	16-bit (half-word) read. If after this reading, and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_11	ldf r,MD|SZ32	32-bit (word) read
00_1_0_10_11	ldf r,MD|SZ32|PF	32-bit (word) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_11_00	ldf r,MS	Copy the status register value into an SDMA general register.

NOTE

Read data is 0-extended before writing in the SDMA general registers. When reading the MD register, the DMA takes data from the FIFO if it is available. If part or whole data is not in the FIFO, an external burst read access is performed to provide the missing data. The SDMA is stalled as long as the required read data is not complete.

After every reading, MSA is incremented by the number of read bytes from MD FIFO, except when MSA is programmed in frozen mode.

66.14.1.7 Prefetch/Flush and Auto-Flush Management-Burst DMA Unit

The prefetch and auto-flush management enables the SDMA RISC machine to go on while a DMA access is performed.

When the RISC core requires a prefetch (p = 1) to the Burst DMA, it will receive an immediate transfer acknowledge before the DMA has finished the external access. This enables the RISC core to do other things like accessing another DMA machine.

The basic principle in prefetch mode is for the DMA to anticipate data reads from the SDMA RISC engine by fetching external bursts of data as soon as there is enough space in the DMA FIFO to store it. If ever the RISC engine required data that is not available in the FIFO, the read acknowledge is delayed until the data is available, but it does not have to wait until the burst completes.

The auto-flush basic principle is similar: An automatic flush is triggered every time there are eight words to be written in the FIFO. If the FIFO is full and the RISC engine requires another write, it is stalled until the burst has started and enough space was freed in the FIFO to store that new data. This means the SDMA RISC engine does not have to wait for the completion of a burst to receive its acknowledge and continue its processing.

In particular, an auto-flush is executed when DMA is in write mode and if the following is true:

- If the FIFO is empty and the first write is to a word-aligned address of any size (ex: the 2 LSB of MDA[1:0]= 0x0), the auto-flush is triggered immediately after the write of the 32'nd byte.
- If the FIFO is empty, and if MDA is an odd byte address (1, 3, 5, 7,...) and an stf MD|SZ8 is executed, the byte is flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is a half-word address (2, 6, 0xA,...) and an stf MD|SZ16 is executed, the two bytes of the incoming data are flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is not a word-aligned address (ex 1, 2, 3, 5, 6, 7, 9,...), and an stf MD|SZ32 is executed, the first 1 to 3 bytes will be flushed up to the next word aligned address. Afterwards, an auto-flush will be triggered each time the FIFO receives 32-bytes.
- Therefore, if an stf MD|SZ32 is executed with MDA equal to 0x1 and with an empty MD FIFO, the bytes located at addresses 1, 2, and 3 are flushed, and the byte located at address 4 remains in MD FIFO. This solves the misalignment issue. Additionally, the next write instructions (stf) complete the FIFO until it contains eight words; then a burst write is executed by the DMA to empty the FIFO. Protocol on the external bus does not support bursts of different data types (byte, half-word, or word).

  For example, consider the case where data is written using a byte access, stf MD|SZ8. The value of MDA during the very first byte write determines when the auto-flush will occur as follows:

- If MDA=0x0, the flush occurs following the write of byte 32
- If MDA=0x1, the flush occurs following the write of byte 1, byte 3 and byte 35.
- If MDA=0x2, the flush occurs following the write of byte 2 and byte 34.

- If MDA=0x3, the flush occurs following the write of byte 1 and byte 33.
- If MDA=0x4, the flush occurs following the write of byte 32

The flush command forces the DMA to flush all MD valid bytes to the EXTMC controller. An acknowledge is sent immediately to the SDMA, and any potential error is reported on a future access. It is thus essential to conclude a transfer with a last read from MS, which will stall the core until all data was flushed out and returned to the transfer status (acknowledge or error).

NOTE

During this kind of auto-flush (which occurs only at the beginning of a misaligned write transfer) no acknowledge is sent back to the SDMA, which is stalled until a flush is completed.

66.14.1.8 Data Alignment and Endianness-Burst DMA Unit

66.14.1.8.1 Burst DMA in Read Mode

For every read access to MD, the data returned to the SDMA core and the new FIFO state depends on the MSA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is fetched externally on a 32-bit bus, but the valid bytes only are stored in the FIFO and left-aligned (for a transfer of consecutive words, it is only the first word that may be truncated). The following table shows the FIFO byte alignment strategy and the corresponding MSA, the returned data, and the new FIFO state for any access size of an internal read from MD.

Table 66-23. FIFO Read Configuration

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
00	x0 x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 and so on...	sz8	00 00 00 x0	01	x1 x2 x3 y0 y1 y2 y3 z0
		sz16	00 00 x0 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz32	x0 x1 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3

Table continues on the next page...

Table 66-23. FIFO Read Configuration (continued)

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
01	x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 and so on...	sz8	00 00 00 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz16	00 00 x1 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz32	x1 x2 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
10	x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 and so on...	sz8	00 00 00 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz16	00 00 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz32	x2 x3 y0 y1	10	y2 y3 z0 z1 z2 z3 t0 t1
11	x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 t2 and so on...	sz8	00 00 00 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz16	00 00 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
		sz32	x3 y0 y1 y2	11	y3 z0 z1 z2 z3 t0 t1 t2

66.14.1.8.2 Burst DMA in Write Mode

For every write access to the MD, the new FIFO state depends on the MDA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is stored in the FIFO according to the internal access size and the former MDA value. The following table shows the FIFO byte alignment strategy corresponding to MDA, as well as the new FIFO state for any access size of an internal write to MD.

Table 66-24. FIFO Write Configuration

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
00	tt uu vv ww ?? ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	01	tt uu vv ww x0 ?? ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	10	tt uu vv ww x0 x1 ?? ?? ?? ?? ?? ??
		sz32	x0 x1 x2 x3	00	tt uu vv ww x0 x1 x2 x3 ?? ?? ?? ??
01	tt uu vv ww xx ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	10	tt uu vv ww xx x0 ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	11	tt uu vv ww xx x0 x1 ?? ?? ?? ?? ??
		sz32	x0 x1 x2 x3	01	tt uu vv ww xx x0 x1 x2 x3 ?? ?? ??
10	tt uu vv ww xx yy ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	11	tt uu vv ww xx yy x0 ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	00	tt uu vv ww xx yy x0 x1 ?? ?? ?? ??
		sz32	x0 x1 x2 x3	10	tt uu vv ww xx yy x0 x1 x2 x3 ?? ??

Table continues on the next page...

Table 66-24. FIFO Write Configuration (continued)

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
11	tt uu vv ww xx yy zz ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	00	tt uu vv ww xx yy zz x0 ?? ?? ?? ??
		sz16	?? ?? x0 x1	01	tt uu vv ww xx yy zz x0 x1 ?? ?? ??
		sz32	x0 x1 x2 x3	11	tt uu vv ww xx yy zz x0 x1 x2 x3 ??

NOTE

If the FIFO mode changes from a write to a read mode, all remaining written bytes in MD are lost but no error is returned. Typically, this happens if an ldf MD is executed after stf MD instructions. Before a mode change, it is recommended to force the flush of a potential remaining byte by a stfMD|SZ0|FL instruction. In the same way, if a FIFO mode changes from a read to a write mode, all prefetched data present in the FIFO is lost and no error is returned.

66.14.1.8.3 Endianness-Burst DMA Unit

Big and Little Endian are supported by the Burst DMA, but data is always stored in MD in Big Endian.

Byte manipulation is performed when data is exchanged with an Burst controller (for example, during read or write burst accesses).

66.14.1.9 Burst DMA Unit Copy Mode

A mechanism is available to perform fast ARM-to-ARM transfers.

Data does not flow through the SDMA core: It is kept in the DMA FIFO. This mechanism is selected when writing MD with a special option in the instruction code (copy flag).

It is possible to transfer up to eight words in one SDMA instruction (this does not mean in one cycle). In this mode, every time an stf MD|CPY is executed, a read burst is executed and directly followed by a write burst transfer. Burst transfers are limited to eight words. The size of the transfer (in words)-given by the SDMA general register (4 LSB)-is also limited to eight. The following SDMA code shows how 100 bytes could be copied from the MSA address to the MDA address. This is sample code only.

Burst DMA copy mode example

```
          ldi r0,@src
          stf r0,MSA                          // Source address setup
          ldi r1,@dst
          stf r1,MSA                          // Destination address setup
          ldi r0,0x64                         // data transfer counter
          ldi r1,0x8
MAIN_XFER:
          cmphs r0,r1                         // Is r0 >= 0x8
          bf LAST_XFER                      // If not, jump to last transfer label
          stf r1,MD|CPY                        // Copy 8 words from MSA to MDA address.
          subi r0,0x8                         // Decrement counter
          jmp MAIN_XFER                     // return to main transfer loop
LAST_XFER:
          stf r0,MD|CPY
```

The main transfer loop is executed 12 times; then r0 equals 4 and the last transfer loop is run.

In this mode, an acknowledge is transmitted to the core as soon as the read burst can start; thus, a first copy instruction returns an immediate acknowledge and subsequent copy instructions will be acknowledged as soon as the previous copy has finished.

66.14.1.10 Burst DMA Unit Error Management

Another point to consider is the management of errors.

Because the DMA immediately sends an acknowledge to the RISC core (except for the stf MS|SZ0|FLS instruction), it assumes no error will occur. If an error occurs, it is flagged (transfer error acknowledge) for the following DMA access.

This should not be a problem if the DMA is used properly. The MD accesses are meant to stall the SDMA as little as possible to optimize throughput and hide calculation time. Therefore, final access to MS should be performed before closing a channel. This access waits until any pending operation is finished in the burst DMA and gather any remaining error.

In copy mode, an error could be immediately returned to the SDMA on execution of the ldf copy or stf copy instruction. It happens when MSA or MDA are not word addresses (for example, 0[4]). This is because copy mode must only be used for transferring a large packet of aligned data.

When an error is received during a *read* transfer to the external bus, which may occur during the burst accesses, the MD FIFO contains the valid beats of the burst, and the error flag of MS is set to 2'b11 (error read burst). It is possible to read MS ("n" field) to know how much valid data remains in MD and when MD is empty (after ldf instructions). The next read MD instruction sets the MS error flag to 2'b10 (error mode), and an error is sent back to the SDMA core. In error mode, it is possible to read MSA, which gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, gives rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

In "error read burst" mode, writing MDA, MSA, or MD, or starting a copy transfer by a stf MD|COPY instruction will cancel the error mode. The following table shows when an immediate error is sent back according to the executed instruction.

Table 66-25. Possibilities in ERROR READ BURST Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA (|U |PF) stf rn, MDA stf rn,MD|COPY	NO	Error mode is reset. MSA, MDA, or MD are updated and a DMA cycle may start. For the stf MD|COPY, a copy loop is executed.
stf rn, MS	NO	MS is updated.
ldf rn, MS ldf rn, MSA ldf rn, MDA	NO	MS, MSA, and MDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	YES/NO	Immediate error if there is no more data available for read in the FIFO.

When an error is received during a *write* transfer, the error is reported to the next DMA access. In this case, an error is sent to the SDMA core and the DMA goes to its error mode. Reading MS gives the number of bytes that remain in MD; reading MDA gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, give rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

Table 66-26. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA stf rn, MDA	Yes	Any attempt to modify MD, MSA, MDA will raise an immediate error and burst DMA remains in error mode. When address registers are write-accessed, an error is returned.
stf rn, MS	No	This is the only way to exit error mode. MS[9:8] must be reset by an stf MS|SZ0 instruction.
ldf rn, MS ldf rn, MSA ldf rn, MDA	No	MS, MSA, and MDA could be read in error mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	Yes	Whatever the DMA direction (read or write), an ldf rn triggers an immediate error.

66.14.1.11 Conditional Yielding-Burst DMA Unit

The standard SDMA transfer is based upon a hardware loop that has the following structure:

Hardware Loop

```
loop
load Rn,source            // can be ldf or ld
<computation>            // can be done through functional units
store Rn,dest              // can be st or stf
done 0               // yield
```

This structure needs to be kept independent of the functional units' particularities regarding the context switch. However, there can be variations in the context switch's efficiency, which can depend on the number of data received up to that point, and on the data itself.

The DMA, with its 8-word burst capability, has a preferable context switch period when its address register is 8-word aligned: It is the only moment that occurs once every eight loops when the succession of bursts is not broken by the context switch. When this is not the case, a context switch requires the storing (or loading) of less than eight words, which requires separate accesses and is far less efficient. The rest of the 8-word packet is stored (or loaded) after the context restore, and this is done as separate accesses.

The proposed solution is a conditional yielding, which occurs only when the DMA is in an optimum state. It does not require any modification to the scripts. The condition is decided at the DMA level.

The DMA can be programmed in two modes-conditional or always-true-for every channel, which provides complete flexibility. By default, the DMA is not in conditional mode.

The DMA condition is computed from the FIFO fill level and the various modes, as follows:

- When copy mode is selected, regardless of the transfer direction ('read' or 'write'), the condition is always true.
- In read mode, the condition is always true.
- In write mode, the condition is true when there are four bytes or less in the FIFO; it is false when there are more than four bytes. The 4-byte limit comes from the possibility of saving those bytes as MD with absolutely no impact on the bus accesses.

The aim at conditional yielding is to avoid splitting bus accesses (especially bursts).

66.14.2 Peripheral DMA Unit Programming

The peripheral DMA unit is connected to the Multi-Layer DMA Crossbar Switch of the ARM platform. Its goal is to perform data transfers between any blocks connected to the DMA bus of this platform.

These blocks are either peripherals or memories. The peripheral DMA could be seen as the ARM platform DMA controller.

The DMA performs data transfers in three modes:

- Read mode, where data is read from peripherals or from memory connected to the ARM platform and copied in a SDMA general register.
- Write mode, where data of a general register has to be written in a peripheral or a memory.
- Copy mode, where data is read from a peripheral (or memory) at a source address (PSA) and automatically written to a peripheral (or memory) at a destination address (PDA).

In copy mode, no SDMA general register is involved as transferred data only goes through the data register of the DMA.

The peripheral DMA has three addressing modes: frozen, incremented, and decremented, as follows:

- Frozen mode-When source or destination addresses are frozen, their value is not modified after a transfer. This mode is typically used for addressing peripheral FIFOs located at a fixed address.

- Incremented mode-When source or destination addresses are in incremented mode, after every transfer they are incremented by the number of bytes transferred.
- Decremented mode-In decremented mode, addresses are decremented by the number of bytes transferred.

The peripheral DMA registers are as follows:

- Two, 32-bit address registers (PSA and PDA) that respectively contain the source address for a read access and the destination address for a write access
- A 32-bit status register (PS) that contains information on the peripheral DMA configuration, such as the number of valid bytes in the data register, the error flag, the source and destination address mode, and so on.
- A 32-bit data register (PD) that stores data involved in a data transfer

66.14.2.1 Peripheral Source Address Register (PSA)

The source address register contains a pointer to a source peripheral or a memory associated with the next read data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (PSA) to store the address value
- A 2-bit register (stype) to store the source address mode (frozen, incremented, or decremented)
- A 2-bit register (ssize) to store the source target data path size (byte, half-word, or word)

Reading the register with the ldf instruction has no side effects and gives the address value of the next data that will be read by the SDMA during an ldf MD instruction. Writing the source address register may have side effects. If there is valid write data in the data register and the source address is changed, the write data is discarded. If the prefetch bit is set, a DMA read cycle is issued with the new address.

When PSA is to be written, you must specify the source target address mode, providing its size (byte, half-word, or word). This enables omission of the size field in all ldf MD instructions. When DMA performs a read cycle, its size is given by the value of the PSA source size register (ssize). If source is a memory in incremented mode, first programmed in word mode (stf PSA|SZ32|I), and if an SDMA script needs to read bytes from this memory, the size of the source target must be updated before executing new accesses. The source address mode and its size are given by labels added to the stf PSA instruction as described in the write section. The ssize and stype registers are part of the DMA status register (PS).

Writing to PSA may issue an immediate error if the source size is not compatible with the value to be written into the PSA register. For instance, writing a 2 in PSA and specifying that it is memory-accessed in word mode creates an immediate error.

66.14.2.2 Peripheral Destination Address Register (PDA)

The destination address register contains a pointer to a source peripheral or a memory associated with the next write data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (PDA) to store the address value
- A 2-bit register (dtype) to store the destination address mode (frozen, incremented, or decremented)
- A 2-bit register (dsize) to store the destination target data path size (byte, half-word, or word)

Reading the register with the ldf instruction has no side effects, and gives the address value of the next data that will be written by SDMA during an stfMD instruction. Writing the destination register has no side effect. Similar to the PSA register, the destination address mode and source are specified in the stf PDA instruction and may also generate an error in case of incorrect programming.

66.14.2.3 Peripheral Data Register (PD)

The data register of the peripheral DMA is a 32-bit register. When the destination address is correctly set up, any writing to PD will automatically flush the new input data.

The number of SDMA bytes that will be transferred is given by the PDA size register. Unlike other SDMA DMAs, PD is not a FIFO: It is not used to accumulate bytes that from the SDMA and must be packed before being sent to external memories. In read mode, and if the source address is correctly set up, an ldf instruction will empty PD. If a prefetch is required along with the instruction, the DMA will initiate a new read transfer.

Reading PD in prefetch mode only stalls the SDMA when the prefetched data is not yet available. Writing PD only stalls the SDMA if the previous write operation was not completed. As soon as the previous operation is over, the acknowledge is sent back to the SDMA RISC engine.

An error flag-part of PS-is set when an external access fails. The error is thus reported to the next SDMA instruction that involves the peripheral DMA.

66.14.2.4 Peripheral State Register (PS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer.

Although all PS fields can be written by an stf instruction, it is recommended to access only the error bit (to reset it). Modifying other PS fields will provide an un-guaranteed DMA behavior.

The initialization value of PS is 0, and it consists of the following structure:

Table 66-27. PS Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	ssize		stype		dsize		dtype

R	0	0	0	0	0	d	e		0	0	0	0	0	n		
W																

Table 66-28. PS Field Descriptions

Field	Description
31-24	Reserved
23-22 ssize	Source Target Size. Determines the size of the read transfers on the external bus. It should match the accessed device characteristics. 00 *reserved* 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
21-20 stype	Source address Mode. Determines whether PSA is incremented, decremented, or kept unmodified after every read from the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decremented Mode 11 *reserved*
19-18 dsize	Destination Target Size. Determines the size of the write transfers on the external bus. It should match the accessed device characteristics. 00 *reserved* 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

Table continues on the next page...

Table 66-28. PS Field Descriptions (continued)

Field	Description
17-16 dtype	Destination address Mode. Determines whether PDA is incremented, decremented, or kept unmodified after every write on the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decremented Mode 11 *reserved*
15-11	Reserved
10 d	Direction Flag or DMA Mode. DMA is in write mode when data was written into PD by stf PD instructions, or if a previous DMA cycle on the external bus was a write access. Writing PDA or PSA does not change the DMA mode. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by the SDMA with an ldf PD instruction. Reading PDA or PSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 *reserved* 10 Error mode 11 Error read
7-3	Reserved
2-0 n	number of bytes in PD

NOTE

dtype, dsize, stype, and ssize are updated when PSA and PDA are written.

66.14.2.5 Peripheral DMA Write (stf)-Write Mode

When written by an stf instruction, the function code bits are interpreted as follows:

Table 66-29. STF Code Bits

Register	7	6	5	4	3	2	1	0
PSA	s		p	ar	am		sz	
PDA								
PD			pdsel					
PS			pssel					

Table 66-30. STF Code Bits Field Descriptions

Field	Description
7-6 s	Functional Unit selector 11 for Peripheral DMA
5 p (PSA)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
3-2 am (PSA/PDA)	Address Mode. Determines how PSA or PDA is modified after every read or write access to the PD. 00 Frozen-Address registers are not modified after the transfer. 01 Incremented-Address registers are incremented by the number of transferred bytes. 10 Decremented-Address registers are decremented by the number of transferred bytes. 11 Updated-PSA and PDA are not modified. Either address mode is not modified, but the width of the data path is updated by the sz field.
1-0 sz	Transfer Size 00 *reserved* 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
5-0 pdsel	PD access selector 001000 is the only valid option
5-0 pssel	PS access selector 111111 writes to PS 001100 only clears the error flag in PS

Due to the large number of possible stf instructions, the following table provides only a short list of all the possible write instructions:

Table 66-31. Peripheral DMA STF Instruction List

Binary	Assembly	Comments

11_00_01_01 11_00_01_10 11_00_01_11	stf Rn, PSA|SZ8 |I stf Rn, PSA|SZ16|I stf Rn, PSA|SZ32|I	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA + 1,2 or 4 after read PD.
11_10_01_01 11_10_01_10 11_10_01_11	stf Rn, PSA|SZ8 |I|PF stf Rn, PSA|SZ16|I|PF stf Rn, PSA|SZ32|I|PF	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA + 1, 2, or 4 after read PD. • 1, 2, or 4 bytes are *fetched* from the peripheral source.
11_00_10_01 11_00_10_10 11_00_10_11	stf Rn, PSA|SZ8 |D stf Rn, PSA|SZ16|D stf Rn, PSA|SZ32|D	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA-1,2, or 4 after read PD.
11_10_10_01 11_10_10_10 11_10_10_11	stf Rn, PSA|SZ8 |D|PF stf Rn, PSA|SZ16|D|PF stf Rn, PSA|SZ32|D|PF	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA-1,2, or 4 after read PD. • 1, 2, or 4 bytes are *fetched* from the peripheral source.
11_00_11_01 11_00_11_10 11_00_11_11	stf Rn, PSA|SZ8 |U stf Rn, PSA|SZ16 |U stf Rn, PSA|SZ32 |U	• *Update* source pointer to memory, which becomes a pointer to a memory accessed in byte, half-word, or word. • PSA value is not modified by Rn. • Bytes present in PD are lost.
11_10_11_01 11_10_11_10 11_10_11_11	stf Rn, PSA|SZ8 |PF|U stf Rn, PSA|SZ16 |PF|U stf Rn, PSA|SZ32 |PF|U	• *Update* source pointer, which becomes a pointer to a target accessed in byte, half-word, or word. • PSA value is not modified by Rn. • Bytes present in PD are lost. • 1, 2, or 4 bytes are *fetched* from the memory source.
11_01_00_01 11_01_00_10 11_01_00_11	stf Rn, PDA|SZ8 |F stf Rn, PDA|SZ16|F stf Rn, PDA|SZ32|F	• Destination is a byte, half-word, or word target at the Rn address, and any further PD write instructions will trigger byte, half-word, or word access to the destination. • Destination address is frozen.
11_01_01_01 11_01_01_10 11_01_01_11	stf Rn, PDA|SZ8 |I stf Rn, PDA|SZ16|I stf Rn, PDA|SZ32|I	• Destination is a byte, half-word, or word target at the Rn address, and any further PD write instructions will trigger byte, half-word, or word access to the destination. • Destination address is in incremented mode: PDA = PDA + 1, 2, or 4 after write PD.
11_01_10_01 11_01_10_10 11_01_10_11	stf Rn, PDA|SZ8 |D stf Rn, PDA|SZ16|D stf Rn, PDA|SZ32|D	• Destination is a byte, half-word, or word target at the Rn address, and any further PD write instructions will trigger byte, half-word, or word access to the destination. • Destination address is in incremented mode: PDA = PDA-1, 2, or 4 after write PD.
11_01_11_01 11_01_11_10 11_01_11_11	stf Rn, PDA|SZ8 |U stf Rn, PDA|SZ16 |U stf Rn, PDA|SZ32 |U	• *Update* destination pointer to memory, which becomes a pointer to a memory accessed in byte, half-word, or word. • PDA value is not modified by Rn • bytes present in PD are lost

Table continues on the next page...

Table 66-31. Peripheral DMA STF Instruction List (continued)

Binary	Assembly	Comments
11_00_10_00	stf Rn, PD	• Write "dsize" bytes of Rn in PD and automatically flush to destination target
11_11_11_11	stf Rn, PS	• Write status register
11_00_11_00	stf Rn,clrefPS	• Clear error flag if set

NOTE

When writing PD, size information is not important: It is embedded in the dsize field of PDA register. If dsize is 1, 2, or 4, then one, two, or four bytes from Rn is written to the PD register, and automatically flushed out to the destination target.

66.14.2.6 Peripheral DMA Read (ldf)-Read Mode

When received from an ldf instruction, the function code bits are interpreted as follows.

Table 66-32. LDF Code Bits

Register	7	6	5	4	3	2	1	0
PSA	s			ar	a			
PDA								
PD			p	cpy				
PS			pssel					

Table 66-33. LDF Code Bits Descriptions

Field	Description
7-6 s	Functional Unit selector 11 for Peripheral DMA
5 p (PD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
4 cpy (PD)	Copy Mode 0 standard access 1 copy mode access

Table continues on the next page...

Table 66-33. LDF Code Bits Descriptions (continued)

Field	Description
3 a	Register Set selection 0 PSA or PDA 1 PD or PS
5-0 pssel	PS access selector 111111 is the only valid option to read PS

Table 66-34. Peripheral DMA LDF Instruction List

Binary	Assembly	Comments
11_0_0_0_000	ldf Rn, PSA	Reads 32-bit of PSA value
11_0_1_0_000	ldf Rn, PDA	Reads 32-bit of PDA value
11_0_0_1_000	ldf Rn, PD	Reads programmed source size bytes of PD (0-extended)
11_1_0_1_000	ldf Rn, PD|PF	Reads programmed source size bytes of PD (0-extended), and starts a prefetch at PSA address.
11_0_1_1_000	ldf Rn, PD|COPY	Starts a copy transfer from the source target at the PSA address to the destination target at the PDA address. No data transmits through Rn, but Rn contents are lost (Rn is loaded with PD temporary contents that are *not* the copied data).
11_111111	ldf Rn, PS	Reads 32-bit of PS value

NOTE

When reading PD, size information is not important: It is embedded in the ssize field of the PSA register. If ssize is 1, 2, or 4, the one, two, or four bytes is transferred from PD to Rn. Read data is 0-extended.

66.14.2.7 Peripheral DMA Unit Copy Mode

Like burst DMA, the peripheral DMA unit has a copy mode that is used when data transfers do not involve SDMA general registers.

Data is read from the source target at a PSA address, stored in PD, and then automatically flushed to the destination target at the PDA address. Copy mode is only available for transfers that involve two targets of the same data path width.

Since copy mode is invoked with an ldf instruction, the *loaded* general purpose register loses its previous contents. (However, the new contents are unpredictable as they depend on temporary values that are seen on the external DMA bus.)

66.14.2.8 Error Management

Peripheral DMA generates two kinds of errors: the immediate error that sanctioned incorrect register programming; and the error triggered by the previous access and stored in the error flag of PS until a DMA instruction is executed.

66.14.2.8.1 Immediate Errors

The following table lists all incorrect DMA register setups.

Table 66-35. Immediate Errors with Peripheral DMA

Rn[1:0] values	DMA instruction	Comments
0x01 0x11	stf Rn, PSA|SZ16|F stf Rn, PSA|SZ16|I stf Rn, PDA|SZ16|F stf Rn, PDA|SZ16|I	If PSA points to a half-word peripheral or to a half-word address in memory, its value must be 0 modulo 2.
0x01 0x10 0x11	stf Rn, PSA|SZ32|F stf Rn, PSA|SZ32|I stf Rn, PDA|SZ32|F stf Rn, PDA|SZ32|I	If PSA points to a word peripheral or to a word address in memory, its value must be 0 modulo 4.
PSA[1:0]-PDA[1:0]	DMA instruction	Comments
0x01 0x10 0x11	stf Rn, PSA|SZ32|U stf Rn, PDA|SZ32|U	When PDA or PSA is updated and becomes a pointer to a word address in memory, its content must be 0 modulo 4.
0x01 0x11	stf Rn, PSA|SZ16|U stf Rn, PDA|SZ16|U	When PDA or PSA is updated and becomes a pointer to a half-word address in memory, its content must be 0 modulo 2.
Read/Write PD instruction	Comments	
stf Rn,PD ldf Rn,PD	If PDA size (dsize) has never been set up before an stf PD instruction (dsize=0) If PSA size (ssize) has never been set up before an ldf PD instruction (ssize=0)	
ldf Rn,PD|CPY	Copy mode is possible only between two targets whose data path width is identical. It is P8↔P8, P16↔P16, or P32↔P32 regardless of the way the address registers are incremented.	

66.14.2.8.2 Data Transfer Errors

When PSA and PDA are correctly set up, the only error that may arise for an ldf PD or stf PD instruction would be the error of the previous DMA cycle.

Error handling is driven by a single consideration: When an error occurred during a data read on the DMA interface, this error should appear as a transfer error to the core when the core attempts to retrieve the data that was not successfully read from the accessed device (memory or peripheral).

When an error occurred during a write access to the DMA interface, the data is still available in PD and should not be destroyed by subsequent core accesses: The core must be warned about the error issue.

There are three error handling mechanisms for each case: Read Error (First Phase), Write Error and Read Error (Second Phase), and Copy Mode Errors handling.

66.14.2.8.3 Read Error (First Phase)

If an error occurred during a prefetch command, the peripheral DMA enters its ERROR READ mode (PS[9:8]=11). In this mode, the error is reported on the next ldf PD instruction and writing PSA, PDA, or PD will cancel the error flag.

The block returns no error mode and instructions are normally executed (a DMA cycle may be triggered). Similarly, initiating a copy transfer will reset the error flag and start a copy transfer. The following table details which instructions can be executed in this mode.

Table 66-36. Possibilities in ERROR READ Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA (IU IPF) stf rn, PDA ldf rn,PD|COPY	NO	Error mode is reset, PSA or PDA are updated, or a write cycle is started. For the ldf PD|COPY, a copy loop is executed.
stf rn, PS	NO	PS is updated.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Error of the previous read access is reported here and the peripheral DMA enters its ERROR mode.

66.14.2.8.4 Write Error and Read Error (Second Phase)

The peripheral DMA enters its ERROR mode (PS[9:8]=10) when the previous DMA write cycle failed, or, as explained in Read Error (First Phase), when an ldf PD is executed while the block is in ERROR READ mode. When a DMA cycle failed, address registers (PSA, PDA) are not modified and continue to point to the problematic address. In ERROR mode, stf instructions may raise an immediate error, and ldf instructions will not (as detailed in the table below).

Table 66-37. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA stf rn, PDA	YES	Any attempt to modify PD, PSA, or PDA will raise an immediate error, and the peripheral DMA stays in ERROR mode. When address registers are write accessed, an error is returned.
stf rn, PS	NO	This is the only way to exit the ERROR mode. PS[3] must be reset by an stf PS instruction.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Whatever the DMA direction (read or write), an ldf rn, PD instruction will show an immediate error.

66.14.2.8.5 Copy Mode Errors

Because copy mode is a write access that follows a read access, there are two possible cases of bus error.

When the read access incurs a bus error, the peripheral DMA behaves exactly as described in Read Error (First Phase) and Write Error and Read Error (Second Phase) : It enters its ERROR READ mode, and so on.

When the error occurred during the write access of the copy transfer, the DMA enables the core to retrieve the data that was read because it is assumed the read from the peripheral removed the data from its source device. Therefore, the data to be flushed is still in PD. Any subsequent access to PD triggers an error to the core, which should execute its error handling procedure.

Once the ERROR mode is left (after writing to PS), it is possible for the core to retrieve the data in PD with an ldf instruction or try to flush PD contents once again (for example, when the error was due to a full FIFO and the script waited for the FIFO to be emptied) with another ldf instruction in copy mode. This latter instruction detects that there is valid data in PD, tries to flush it, and thus skips the read phase of the copy instruction. This is a different behavior from the usual stf PD instruction that overwrites PD with the selected General Purpose register contents. The same mechanism can be used any time PD holds data that is not written because of a bus error on the DMA interface; when the data was written via a copy instruction, or via the usual stf PD instruction.

66.14.2.8.6 Error Check Example

The following code illustrates an example checking for both immediate and data transfer errors on a store to the PD register. The first bdf instruction checks for an immediate error, but if a data transfer error occurred it is reported until the next instruction to access the Peripheral DMA. A second check of the error flags is done after the ldf PS

instruction. The value of PS here can be ignored. The act of reading any register in Peripheral DMA while it is in an error mode that returns the error to the core to set either the SF or DF flag. Any error returned on an ldf command sets the SF flag and any error returned on an stf instruction sets the DF flag. This can create a situation as shown in the example where a bus error during a DMA write which would normally be considered as a destination fault is reported as a source fault because the error was reported to the SDMA core during an ldf instruction.

Peripheral DMA Error Check

```
    clrf    0            // Clear SF and DF flags
 stf    R4, PD        // Write data to memory
bdf    error_routine    // Check for immediate error from write to PD.
ldf    r3, PS        // Read PS (PS value in R3 can be ignored)
    bsf    error_routine    // Check for bus error from "stf R4,PD"
            // SF is set because it is a ldf instruction, even though
            // the original error was a destination fault
```

66.14.2.9 Peripheral DMA Unit Prefetch/Flush Management

There is no flush bit because every time data is stored in PD by a stf PD instruction-assuming PDA is correctly programmed-it is automatically flushed to the destination.

An acknowledge is returned in the cycle of the DMA instruction, and the SDMA is only stalled by an instruction that addresses the peripheral DMA when the previous DMA access is not over.

66.14.3 CRC Unit

The Cyclic Redundancy Check (CRC) unit is connected to the SDMA core via the FUBUS. This unit can perform a CRC calculation for a set of given polynomials from degree 8 to 32.

When all CRC unit registers are loaded, the unit can process one byte of data every clock cycle. When loading new data to compute the CRC, the SDMA can perform 32-bit, 16-bit, or 8-bit accesses.

Two 32-bit registers comprise the unit:

- The CRC algorithm CA that describes the polynomial
- The CRC checksum CS to accumulate the data after each processing

66.14.3.1 Polynomial Register (CA)

This register defines the CRC algorithm currently used in the calculation, and the management of data ordering to/from the data register CS.

Before starting any CRC calculation, it must be loaded with the chosen polynomial reference number and data ordering mode as indicated in the following figure and table.

Table 66-38. CA Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
R	0	0	0	0	0	0	0	0	0	0	0	ri	ro	p		
W																

Table 66-39. CA Descriptions

Field	Description
31-5	Reserved
4 ri	Reverse bit order of data in 0 Must be used when the peripheral receives bytes as bit streams in LSB-first order (UART case). 1 Selects the reverse mode, which must be used when the peripheral receives bytes as bit streams in MSB-first order (MMC case).
3 ro	Reverse bit order of data out 0 Must be used when the peripheral transmits bytes as bit streams in LSB-first order (UART case). 1 Selects the reverse mode, which must be used when the peripheral transmits bytes as bit streams in MSB-first order (MMC case).
2-0 p	Polynomial selection 000 CRC32 ($X^{32}+X^{26}+X^{23}+X^{22}+X^{16}+X^{12}+X^{11}+X^{10}+X^8+X^7+X^5+X^4+X^2+X+1$) 001 CRC16 ($X^{16}+X^{15}+X^2+1$) 010 CCITT16 ($X^{16}+X^{12}+X^5+1$) 011 IS136 ($X^{12}+X^{10}+X^8+X^5+X^4+X^3+1$) 100 CRC10 ($X^{10}+X^9+X^5+X^4+X+1$) 101 CRC8 ($X^8+X^2+X+1$) 110 Parity ($X^8+1$) 111 Reserved

66.14.3.2 Accumulator Register (CS)

The accumulator register accumulates the division remainder during the CRC processing.

When writing the accumulator register (process bit is not set) if the *ro* bit is set, the write data has its order reversed whatever the data length (the length is specified by the selected polynomial).

When computing new CRC (writing CS and process bit set) if the *ri* bit is set in CA, any byte of write data will have its bit order reversed before storage and calculation. In the first byte, bit 7 is replaced by bit 0, bit 6 is replaced by bit 1, and so on. In the second byte, bit 7 is replaced by bit 0, bit 6 is replaced by bit 1, and so on, which means in the write data, bit 15 is replaced by bit 8, bit 14 will replaced by bit 9, and so on.

If the *ro* bit is set in CA, any read data will have its bit order reversed whatever the data length. If the valid data length is 16 bits, bit 15 is replaced by bit 0, bit 14 is replaced by bit 1, and so on.

When loading new data to compute the CRC, the SDMA can perform 32-bit, 16-bit, or 8-bit accesses. The CRC is computed in four clock cycles when performing a 32-bit access, in two clock cycles when performing a 16-bit access, and in one clock cycle when performing an 8-bit access. In all cases, an immediate acknowledge is sent back to the SDMA. A wait state is inserted if the SDMA tries to perform a new access before the end of the computation.

When performing a multi-bit access, the first byte used to compute the CRC is the most significant byte of the valid data.

66.14.3.3 Write Instruction (stf)

The following table shows the stf instructions.

Table 66-40. Stf Instructions for CRC

Byte Command								Description
1	0	0	0	0	0	0	0	Write polynomial encoded in the General Register (CA)
1	0	0	0	0	1	0	0	Write accumulator register (right-aligned)
1	0	0	1	0	1	0	0	Compute the CRC with the new incoming byte (b0)
1	0	0	1	0	1	0	1	Compute the CRC with the new incoming byte (b0)
1	0	0	1	0	1	1	0	Compute the CRC with the new incoming halfword (b1 b2) The bytes are used in the following order: b1 and b0.
1	0	0	1	0	1	1	1	Compute the CRC with the new incoming word (b3 b2 b1 b0) The bytes are used in the following order: b3, b2, b1, and b0.

66.14.3.4 Read Instruction (ldf)

The following table shows the ldf instructions.

Table 66-41. Ldf Instructions for CRC

Byte Command								Description
1	0	0	0	0	0	0	0	read the polynomial register encoded
1	0	0	0	0	1	0	0	read the accumulator register, right aligned

66.14.3.5 Operating Mode

The following is the operating mode example:

- Load the polynomial register to select the algorithm and preset the accumulator, if required.
- Data is right-aligned in the general register.
- Input data is fed byte-by-byte into the accumulator through stf instructions.
- When all data is fed into the CRC unit, the CRC checksum is read with ldf ca, sz.

16-bit CCITT CRC with $P(X) = X^{16}+X^{12}+X^{5}+1$

```
          .equ rL,0 // GReg[0] = rL; loop count register
.equ rA,1 // GReg[1] = rA; CCITT16 polynomial
.equ rP,2 // GReg[2] = rP; initial CRC value
.equ rT,3 // GReg[3] = rT; transferred byte register
.equ aT,4 // GReg[4] = aT; transferred byte address
// (MMC DAT_RX - 0xA003)
.equ CA,8 // CRC unit CA register
.equ CS,9 // CRC unit CS register
ldi rA,2 // init register with CCITT16 polynomial
stf rA,CA // updates the selected polynomial
ldi rP,0xff // initializes register with 0x000000ff
stf rP,CS,0 // presets the accumulator with 0x000000ff
ldi aT,0xA0 // initializes aT with 0xA003: aT = 0x000000A0
revblo aT // initializes aT with 0xA003: aT = 0x0000A000
ori aT,0x03 // initializes aT with 0xA003: aT = 0x0000A003
ldi rL,200 // expects to read 200 bytes from MMC DAT_RX
loop 2 // executes 200 times the next 2 instructions
```

```
ld rT,(aT,0) // loads next byte from MMC DAT_RX

stf rT,CS,1 // process checksum with new incoming byte

ldf rT,CS // read the final checksum at the end
```

66.14.4 OnCE and Real-Time Debug

The On-Chip Emulation block (OnCE) is the debug interface to the SDMA. It supports the access to all core internal devices (registers, memory, and so on), and provides a set of mechanisms that control the core.

The OnCE is accessed by JTAG ports at the chip's board level, or by the host via its peripheral bus.

To reduce the size of the hardware material involved, all tasks supported by the OnCE are performed on the SDMA core. The architecture of the SDMA OnCE is relatively simple and very flexible.

The commands supported by the SDMA OnCE are listed in the following sections.

66.14.4.1 Memory and Register Access

A set of mechanisms is provided to access SDMA memory and register locations. Both reading and writing are allowed. The access is supported if the processor is in debug mode.

Those registers can also be accessed through the ARM platform Control interface when the OnCE is controlled by the ARM platform, as described in the "Using BP" section.

66.14.4.2 Hardware Breakpoints

An event detection unit is implemented to support memory breakpoints. The unit watches the data exchanged between the SDMA memory bus and the core.

A debug request is sent to the core when matching conditions occur. The unit supports mixed conditions based on address range, access type, and data value. Event detection unit configuration registers are memory mapped in the SDMA space (see ARM platform Channel 0 Pointer (SDMAARM_MC0PTR)): You can modify them through a regular memory access or the ARM platform control interface.

66.14.4.3 Watchpoints

One output pin is provided to monitor matching trigger conditions that are defined in the event detection unit.

66.14.4.4 Software Breakpoints

The SDMA instruction set contains a software breakpoint. Upon executing a software breakpoint instruction, the core suspends normal execution and enters debug mode.

No hardware step execution mode is implemented in the OnCE, but this feature may be implemented at the software level with this instruction.

66.14.4.5 Core Control

Commands are provided to monitor and control processor activity. You can halt the core, rerun the core from another address location, and get processor status.

Any hardware breakpoint on the instruction bus is not supported, but this feature may be implemented by inserting a software breakpoints program.

66.15 The OnCE Controller

The OnCE controller receives commands from the ARM platform or from the JTAG controller. Each command is interpreted before being sent to the core.

66.15.1 OnCE Commands

A small set of commands supports the communication between the OnCE and the external world. This command set enables you to perform any of the following tasks: control processor activity, save core context, and execute an SDMA instruction from the OnCE.

Combined together, these tasks perform more complex commands.

A full OnCE command contains a 4-bit instruction (the OnCE command opcode) and a variable length data field (the OnCE data). During command execution, the OnCE data is transferred in a OnCE internal register before being exchanged with the SDMA. Some

data values are also exported. This mechanism creates a link between the processor and the external world. Nine commands are defined: The following table presents their formats.

Table 66-42. OnCE Command Opcode Values

Instruction Opcode	Name	Action	Register	Data Field Size	Mode
0000	rstatus	Reads the OnCE status register	STATUS	16-bit	normal/debug
0001	dmov	Updates general register GReg1	GREG1	32-bit	debug
0010	exec_once	Runs the instruction from the SDMA instruction register	INSTRUCTION	16-bit	debug
0011	run_core	Returns to normal execution	BYPASS	1-bit	debug
0100	exec_core	Returns to normal execution via a jump instruction that specifies the new address	INSTRUCTION	16-bit	debug
0101	debug_rqst	Stops the core after execution of current instruction	BYPASS	1-bit	normal
0110	rbuffer	Reads the real time buffer	RTB	32-bit	normal/debug
0111-1110	reserved	Reserved	BYPASS	1-bit	normal/debug
1111	bypass	Bypasses TARM platform controller	BYPASS	1-bit	normal/debug

Each instruction corresponds to a specific action performed on the OnCE. The nature of the associated data field is clearly identified. The dmov command is followed by a 32-bit data value (which is a data value for the SDMA); the exec_once and the exec_core commands are followed by a 16-bit data value (which is an instruction for the SDMA); the rstatus command is followed by a 16-bit control value (which is the content of the OnCE status register); the rbuffer command is followed by a 32-bit data value. The debug_rqst and the run_core commands are followed by a single bit data field (this is a bypass value). Finally, the bypass instruction enables the SDMA JTAG TAP controller to be daisy-chained with another JTAG TAP controller. This is a JTAG-only feature. The set of commands is simple, but enables you to perform any possible task on the SDMA during a debug process.

66.15.2 Sending Commands to the OnCE Controller

The JTAG access is the standard access to the OnCE, but sometimes the JTAG is not available to fix some bugs (if the chip is in production for instance), an additional access is then required. Therefore, one ARM platform access to the OnCE is provided.

66.15.2.1 Using the JTAG Interface

A serial access is performed through the five JTAG pins TCK, TRST, TMS, TDI, and TDO. A Test Access Port controller is provided to decode the TMS control signal.

It produces shift-enable signals (shift_ir and shift_dr), and updates enable signals (update_ir and update_dr). It is fully compliant with the IEEE 1149.1 testability (JTAG) standard.

During the shift_ir state, the command opcode is shifted into the OnCE controller (for example, the signal from the TDI pin is shifted into the command register and the TDO pin receives the signal shifted out). After transferring the four bits of the command, an update_ir signal is asserted and the command is decoded. The target data register is now clearly identified and the corresponding control signal is produced, as follows: bypass enable signal (bp_en), instruction enable signal (inst_en), data enable (data_en), and status enable signal (stat_en).

During the shift_dr state, the TDI signal is shifted into one of the following target registers: bypass register (1 bit), SDMA instruction register (16 bits), SDMA data register (32 bits), or OnCE status register (16 bits). The TDO pin is connected to the output of the selected register to receive the signals shifted out.

The JTAG access is disabled when the ARM platform access is enabled.

66.15.2.2 Using the ARM platform

The ARM platform access to the OnCE is not the standard access, but it is required if the JTAG is not available.

For example, if the SDMA ROM is out of use on a chip in production, and the ARM platform needs to download new code and restart the SDMA, the OnCE can easily perform this operation. This type of debug operation justifies the use of an ARM platform access to the OnCE.

To drive the OnCE, the ARM platform uses some registers contained in the ARM platform Control block of the SDMA. These registers are accessed through the ARM platform peripheral bus. Most of these registers are connected to another register in the OnCE controller. Thus, accessing one of these registers is equivalent to accessing the associated register in the OnCE controller.

The set of registers in the ARM platform Control block is listed below:

- ONCE_ENB register (1 bit, read/write)-This 1-bit register enables the ARM platform access to the OnCE. When this bit is set, the signals from the JTAG are ignored.

When it is cleared, all writing operations to the following registers through the Host Control interface are ignored. This register is reset on a JTAG reset.

- ONCE_CMD register (4 bits, read/write)-This 4-bit register receives the command opcode. It is connected to the command register in the controller. A write access to this register causes the associated command to be executed on the OnCE. For example, after writing "0001" in this register, a dmov command is executed.

NOTE

On the ARM platform side, the rstatus and bypass commands are not supported. This register is reset on a JTAG reset.

- ONCE_DATA register (32 bits, read/write)-This 32-bit register is connected to the SDMA data register. This register is used when executing a dmov or rbuffer command.

NOTE

Before requesting a dmov command, the 32-bit data to transfer must be written in the ONCE_DATA register. At the end of the execution, the register is updated with GReg1 former value. This register is reset on a JTAG reset.

- ONCE_INSTR register (16 bits, read/write)-This 16-bit register is connected to the SDMA instruction register. This register is used when executing an exec_core or an exec_once command.

NOTE

Before requesting an exec_core or an exec_once command, the appropriate instruction must be written in the ONCE_INSTR register. This register is reset on a JTAG reset.

- ONCE_STAT register (16 bits, read only)-A read access to the ONCE_STAT register returns the content of the OnCE status register (OSTAT). This register is read only.
- The bypass register is not useful when the ARM platform controls the OnCE, therefore no register is defined in the ARM platform Control block to access the bypass register.

66.15.2.3 Conflicts Between the JTAG and the ARM platform Accesses

When ARM platform access to the SDMA OnCE is enabled (that is, when the bit in the ONCE_ENB register is set), the JTAG access is disabled. This guarantees that the block is not accessed at the same time on both sides.

It is possible to check whether the JTAG access to the SDMA OnCE is enabled from the JTAG port. When the JTAG access is disabled, the SDMA TDO always returns 1. The check requires the following steps:

- Execute a dmov command from debug mode (with neither 0xffffffff nor 0x0 as dmov value: 0x5a5a5a5a is good).
- Execute another dmov command (the value here is not important).
- The returned value from the latter dmov command should be the original one if the JTAG access is enabled; if it is 0xffffffff instead of the original input value, this means the JTAG access is disabled.

66.15.3 Executing a Command from the OnCE

All the commands defined in OnCE Commands can be accessed through the JTAG. The ARM platform can access all these commands except the rstatus command.

On the ARM platform side, the OnCE status is directly accessed by reading the ONCE_STAT register.

66.15.3.1 Nature of the Commands

Two types of commands may be distinguished. First, there are two commands that do not interact with the core: rstatus and rbuffer. Those commands may be requested at any time: They do not depend on the core status.

NOTE

Each of these commands exports a data value or a status value from the SDMA.

There are also commands that interact with the core: dmov, run_core, exec_core, exec_once, and debug_rqst. These commands are core status dependent, as follows:

- During user mode only the debug_rqst is taken into account.
- During debug mode, all these commands are taken into account except the debug_rqst. For example, an exec_once command requested while not in debug mode has no effect.

66.15.3.2 Execution Request

The SDMA starts executing a task in debug mode when requested by the OnCE controller. The execution starting time depends on the type of access used to communicate with the OnCE.

If the JTAG is used, the request is send after decoding the update_dr state in the TAP controller. Therefore, always cross this state when sending a command through the JTAG. If the OnCE is driven from the ARM platform side, the request is sent after detecting a write access to the ONCE_CMD register. All the registers involved in this operation must be loaded first.

The following is an example of an exec_core command execution from the ARM platform side: After writing '010' in the ONCE_CMD register, the OnCE controller asks the SDMA to execute the instruction contained in the ONCE_INSTR register. The instruction involved should be available in the ONCE_INSTR register before the beginning of the execution.

66.15.3.3 Command Execution

The following list shows the commands and details how each command is executed:

- rstatus command execution-The rstatus command exports the content of the OnCE status register (OSR). If the JTAG is used, the status information is captured in the OnCE status register during the capture_dr state, and shifted out after 16 TCK clock cycles in the shift_dr state. The rstatus command is not supported on the ARM platform side, but a status register is provided instead. The rstatus may be performed in both debug and user modes.
- dmov command execution-The dmov command accesses SDMA internal registers. Executing a dmov instruction exchanges the 32-bit data values between the SDMA data register and the general register GReg[1].
- If the JTAG is used, the content of GReg1 is captured in the SDMA data register during the capture_dr state, then it is shifted out after 32 TCK clock cycles in the shift_dr state. During the update_dr state, GReg1 is updated with the new, shifted-in 32-bit data value. If the OnCE is driven from the ARM platform side, the data values contained in GReg1 and the SDMA data register are exchanged after detecting a write access to the ONCE_CMD register. The ONCE_DATA register must therefore be loaded first.
- exec_once command execution-The exec_once command executes the instruction loaded in the SDMA instruction register. The command may only be requested from debug mode. The SDMA returns to debug mode at the end of the execution.

- Change of flow instructions as well as instructions that may cause a context switch are not supported: The comprehensive list comprises done/yield/yiedge (except done 5), BF, BT, BSF, BDF, JMP, JSR, JMPR, JSRR, RET, and LOOP, as well as all the illegal instructions.

  No other command should be requested before the SDMA returns to debug mode. The SDMA status (for example, whether it is in debug mode or not) can be detected by polling with the rstatus OnCE command, monitoring the debug_mode pin, or checking the OnCE Status Register (SDMAARM_ONCE_STAT) register via the ARM platform control interface.

  NOTE

  Most of the instructions are single-cycle, which omits the step of polling the status. Loads and stores to DMA units are typical instructions that might require this polling.

  If the JTAG is used, the 16-bit instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift_dr state. A request is sent to the core when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the request is sent to the SDMA when detecting a write access to the ONCE_CMD register. The ONCE_INSTR register must be therefore be loaded first.

- run_core command execution-The run_core command leaves debug mode and resume normal program execution. The next instruction executed is the last instruction decoded before entering debug mode. Be sure to restore core context before re-running the core. This procedure is detailed in Restoring the Context.
- If the JTAG is used, a 1-bit bypass value is shifted in the bypass register in the shift_dr state. The SDMA is rerun when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the core is rerun when detecting a write access to the ONCE_CMD register.

- exec_core command execution-The exec_core command resumes program execution from any address. The 16-bit instruction provided with the exec_core overwrites the last instruction decoded before entering debug mode. This command is designed to support change of flow instructions, so that a program execution can be restarted from any address. After executing an exec_core command, the SDMA leaves debug mode. The exec_core command is usually used with a jmp instruction.
- If the JTAG is used, the 16-bit branch instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift_dr state. The SDMA is rerun when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the SDMA reruns when detecting a write access to the

ONCE_CMD register. The ONCE_INSTR register must therefore be loaded first. For example, to restart the SDMA from the program address 0x100, the instruction loaded should be a jump to address 0x100 instruction.

- debug_rqst command execution-The debug_rqst command puts the SDMA in debug mode. If the JTAG is used, a 1-bit bypass value is shifted in the bypass register during the shift_dr state. A debug request is sent to the SDMA when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the debug request is sent when detecting a write access to the ONCE_CMD register. When the SDMA is already in debug mode, this command is simply ignored.
- rbuffer command execution-The rbuffer command exports the content of the real time buffer (RTB). If the JTAG is used, the content of the real time buffer (RTB) is captured in the SDMA data register during the capture_dr state. The register is completely shifted out after maintaining the shift_dr state during 32 TCK clock cycles. If the OnCE is driven from the ARM platform side, the content of the RTB is captured in the ONCE_DATA register after detecting a write access to the ONCE_CMD register.
- bypass command execution-This command is only available from the JTAG interface. It enables daisy-chaining of the SDMA JTAG TAP controller with other JTAG TAP controllers. This command does not change the SDMA state and can be executed in any mode (run, debug, or sleep). It selects the bypass register of the TAP controller.

66.15.4 Registers Descriptions

See SDMACORE, and SDMAARM, for detailed information on each register.

66.15.4.1 Event Cell Counter Register (ECOUNT)

The event cell counter register is a 16-bit register that contains the number of times minus one that an event detection occurs before generating a debug request.

This register should be written before attempting to use the event detection counter during an event detection process. The event cell counter register is cleared on a JTAG reset.

66.15.4.2 Event Cell Address Registers (EAA or EAB)

The event cell contains two address registers-the event cell address register (a), called EAA, and the event cell address register (b), called EAB. Every address register is a 16-bit register that stores a user-defined address value. This value computes one of the following address conditions: addra_cond or addrb_cond. Every address register is cleared on a JTAG reset.

66.15.4.3 Event Cell Address Mask Register (EAM)

The event cell address mask register is a 16-bit register that contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before comparing addresses.

NOTE

There is a common address mask value for the two address comparators. If bit *i* of this register is set, then bit *i* of the address value latched from the memory bus does not influence the result of the address comparison. The event cell address mask register is cleared on a JTAG reset.

66.15.4.4 Event Cell Data Register (ED)

The event cell data register is a 32-bit register that contains a user-defined data value. This data value is an input for the data comparator, which generates the data_cond condition.

The event cell data register is cleared on a JTAG reset.

66.15.4.5 Event Cell Data Mask Register (EDM)

The event cell data mask register is a 32-bit register that contains a user-defined data mask value. This mask is applied to the data value latched from the memory bus before comparing data.

Setting bit *i* of the event cell data mask register means that bit *i* of the data value latched from the address bus does not influence the result of the data comparison. The event cell data mask register is cleared on a JTAG reset.

66.15.4.6 Real Time Buffer Register (RTB)

The real Time Buffer register is a 32-bit register that stores and retrieves run-time information without putting the SDMA in debug mode.

Refer to Real Time Buffer for more details.

66.15.4.7 Event Control Register (ECTL)

The event cell control register is a 16-bit register that defines cell event occurrence conditions.

The event cell control register is cleared on a JTAG reset. See also OnCE Event Detection Unit for more details.

66.15.4.8 Trace Buffer (TB)

The Trace Buffer register retrieves the information in the Trace Buffer.

See Trace Buffer for more details.

66.15.4.9 OnCE Status Register (OSTAT)

The OnCE status register is a 16-bit register that contains processor and event detection unit status. The OSTAT is a read-only register.

Refer to OnCE Status Register (SDMAARM_ONCE_STAT) for detailed description of the individual fields in the OSTAT register.

The following figure shows the OSTAT structure.

Table 66-43. OnCE Status Register (OnCE)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PST[3:0]				RCV	EDR	ODR	SWB	MST					ECDR[2:0]		

Where PST[3:0] is the SDMA core state, RCV is set when the real-time buffer (RTB) is modified. EDR, ODR, and SWB are set, respectively, when the SDMA has entered debug mode because of an external debug request, a OnCE debug_rqst command, or a software breakpoint. MST is set when the OnCE is controlled from the ARM platform control interface, and when ECDR is a three-flag set that shows the event cell condition(s) that put the core in debug mode. The OSTAT never provides more than one reason for entering debug mode.

There are two ways of accessing OSTAT content, as follows:

1. Send an rstatus command to the OnCE controller through the JTAG, or read the ONCE_STAT register through the ARM platform access. Executing the rstatus command through the JTAG can be performed in both user and debug modes.
2. Perform an SDMA read access to the location in the SDMA core memory map (OSTAT register) debug mode using the exec_once command. With this method of access, the SDMA state reflected by the PST (processor status bit) is always DATA.

The register may also be accessed by a running application.

66.15.5 JTAG Interface Requirements

Because the signals received from the JTAG (running on TCK) are transferred to the OnCE controller (running on the SDMA clock), a synchronization mechanism is required.

66.15.5.1 TCK Speed Limitation

In the JTAG top-level layer, the TDO signal is always captured on a TCK falling edge. To guarantee a stable TDO signal from the SDMA during this operation, a falling edge detection is performed on TCK.

Before being latched in the *I* flip-flop (see Figure 66-12) on TCK falling edge, the TDO signal must be stable at the input of the flip-flop. This condition is verified if the TCK period is superior to the following delay:

worst-case edge detection delay + negative-edge signal propagation delay + JTAG top-level logic propagation delay

The frequency relationship, TCK < CLK/8, limitation guarantees that all operations are performed as expected.

66.15.5.2 Synchronization Implementation

The following figure shows the synchronization mechanism. Flip-flops tck0, tck1, and tck2 perform falling- and rising-edge detections on TCK. They generate the posedge_detected and negedge_detected nets that are used to sample the TDI and TMS inputs into the respective tdi and tms flip-flops, and update the tdo flip-flop to yield the

TDO output. In the design, the only signal that might go metastable is the output of the tck0 flip-flop. This signal is captured in the tck1 flip-flop and no logical operation is performed on it to minimize a metastability propagation risk.

The TDI and TMS flip-flops also cannot go metastable: The propagation time of the rising-edge detection signal through tck0, tck1, and tck2 guarantees that the TDI and TMS inputs are stable when captured in the TDI and TMS flip-flops.

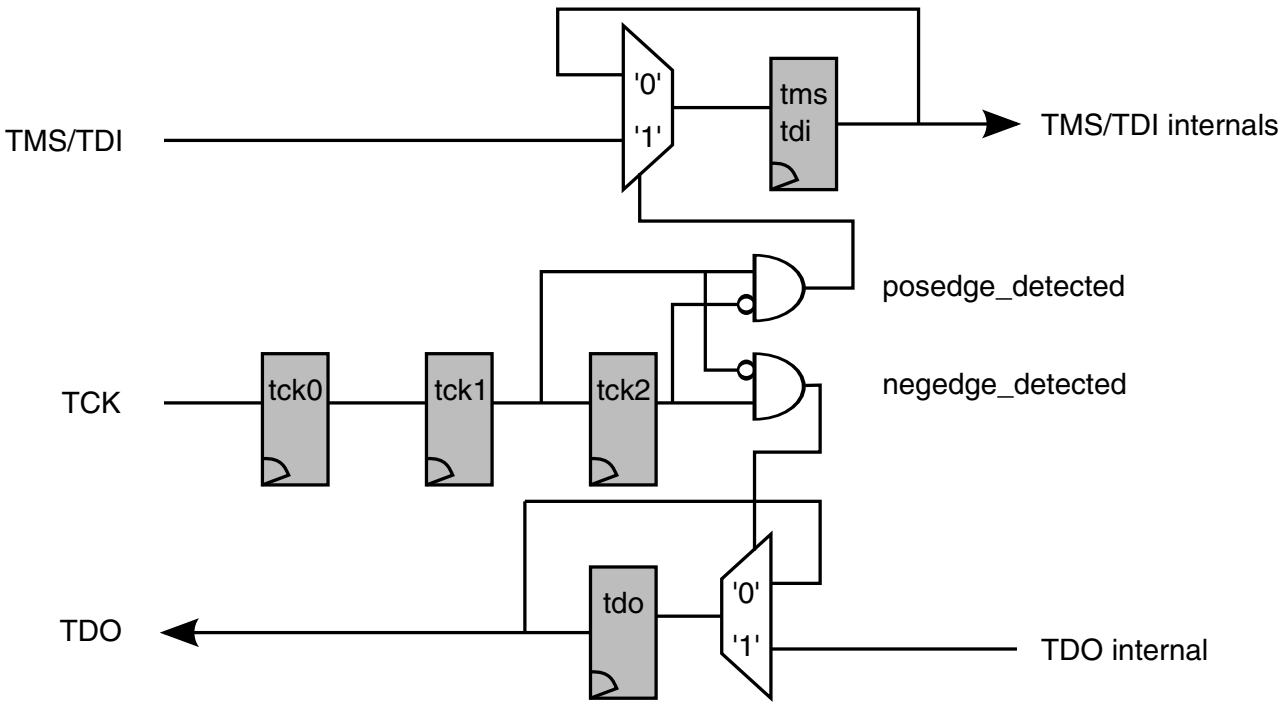

Figure 66-12. OnCE Synchronization Layer

The following figure shows synchronization timings. It takes three CLK clock cycles to synchronize TDI on the SDMA clock.

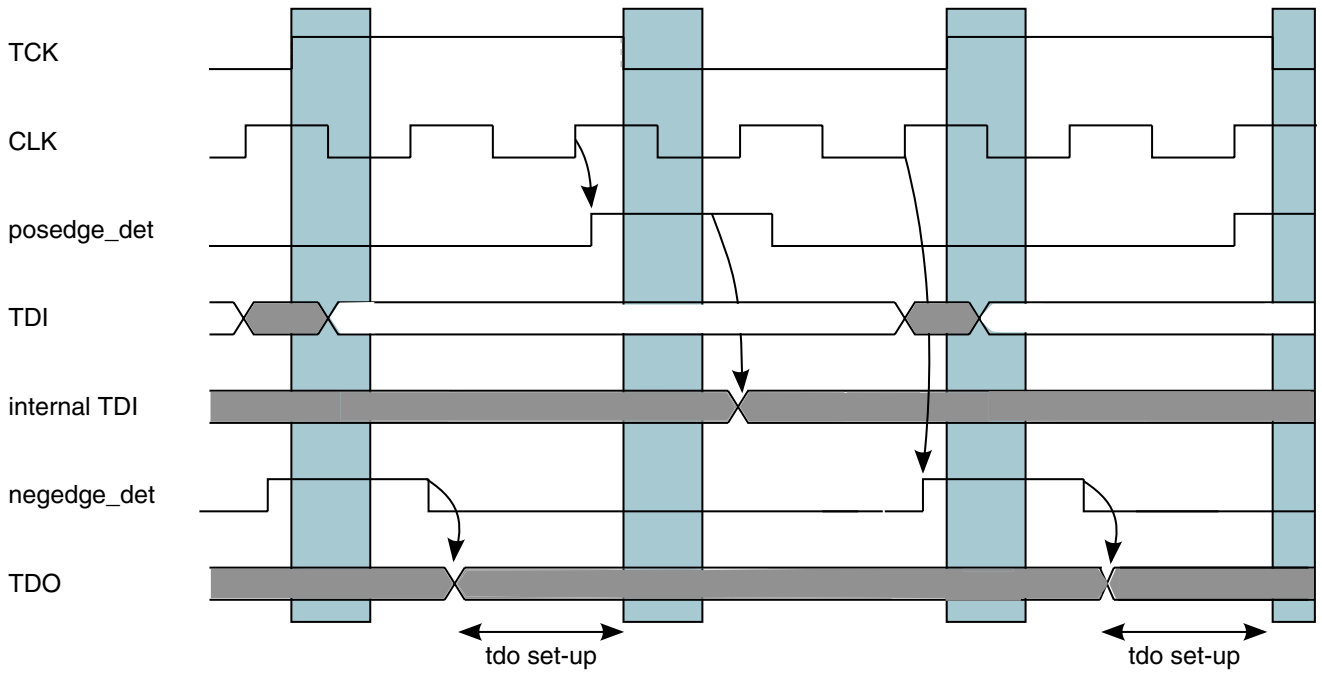

Figure 66-13. Synchronization Timings

66.15.5.3 JTAG Controller Start-Up Recommended Procedure

To ensure correct TAP controller initialization, it is recommended to use the following procedure:

1. Assert JTAG reset TRSTB (for example, set low).
2. Set TMS low.
3. Wait for 1 TCK clock.
4. Release JTAG reset TRSTB (for example, set high).
5. Wait for a minimum of five TCK cycles.

66.16 Using the OnCE

This section provides the elements necessary to run the OnCE during a debug process. In addition to the basic set of commands described in OnCE Commands, more complex commands can be built to meet users' requirements.

66.16.1 Activating Clocks in Debug Mode

For power consumption issues, some clocks in the SDMA are disabled when not needed. This is the case for instances when the SDMA is in sleep mode. Clock gating management depends on the interface used to control the OnCE.

- For the JTAG access, the SDMA clock gating must be turned off via the clk_gating_off input.
- For the ARM platform access, the SDMA clock gating is automatically turned off when the ARM platform access is enabled (see OnCE Enable (SDMAARM_ONCE_ENB)).

66.16.2 Getting the Current Status

Most of the commands the OnCE supports have an impact on the status of the SDMA.

It is not permissible to request the execution of an instruction on the SDMA from the OnCE while the SDMA is not in debug mode. Such a violation may cause unpredictable behavior, and it might be necessary to reset the SDMA.

Therefore, the value of the PST bits provided in the OnCE status register should always be checked before sending any request to the SDMA.

66.16.3 Methods of Entering Debug Mode

A debug request may be asserted at any time, but it is not always taken into account immediately. Debug mode cannot be entered in the middle of an instruction, or during the save or restore states of a context switch.

The request is ignored when the core is already in debug mode. Refer to Figure 66-4, which shows all possible transitions to the debug state, as there are several ways to enter debug mode.

66.16.3.1 External Debug Request During Reset

To enter debug mode after exiting reset, the external debug line has to be maintained high. This line is handled by the JTAG top-level block.

NOTE

The SDMA detects the debug requests only if the SDMA clock is running (see Activating Clocks in Debug Mode). The debug

request line should be not be maintained high when the SDMA is in debug mode.

NOTE

The debug_rqst command (from the OnCE command set) is not supported during system reset.

66.16.3.2 Debug Request During Normal Activity

During normal activity, the SDMA enters debug mode when the following is true:

1. If the debug request line from the JTAG top-level is asserted, or
2. If the OnCE controller receives a debug_rqst command.

   The debug_rqst command can be sent by the JTAG access or by an access on the ARM platform side (if the ARM platform access is enabled).

66.16.3.3 Software Breakpoint Instruction

The SDMA enters debug mode at the end of the execution of a software breakpoint instruction. This instruction must be inserted in program flow executed by the core.

66.16.3.4 Event Detection Unit Matching Condition

If the event detection is enabled, a debug request is sent to the core after detecting a matching condition on the SDMA memory bus.

See OnCE Event Detection Unit for more details.

66.16.4 Executing Instructions in Debug Mode

The OnCE supports a mechanism to execute instructions in debug mode. If the SDMA is in debug mode, then the exec_once command can be used to execute an SDMA instruction from the OnCE controller. The SDMA returns to debug mode at the end of each execution.

Some instructions are not supported by the exec_once command: done/yield/yiedge (except done 5), BF, BT, BSF, BDF, JMP, JSR, JMPR, JSRR, RET, and LOOP, as well as all the illegal instructions are not supported.

NOTE

While instructions are executed in debug mode from the OnCE, the program counter of the SDMA is not incremented.

66.16.5 Command Sequences Examples

This section provides examples of command sequences that run the SDMA in debug mode. These sequences are available for both the ARM platform and JTAG accesses.

The following presents the syntax used in this section. The data field provided with each command is put in parenthesis with the command name. A '-' is used if the data field provided is a *don't care* value.

```
my_command(data_field);                 // executing my_command with a data field
my_command(-);                        // executing my_command with a don't care data field
```

The value returned by the command (if there is one) is referred by an assignment. In case the value returned by the command is not used, the assignment is omitted. For an ARM platform access, the value returned (it is always a data value) is obtained by reading back into the SDMA data register.

```
data_out = my_command(data_in); // returning a data value
```

To clarify the syntax, the instructions' opcodes are referred to by their names. In practice, use the corresponding 16-bit encoding.

66.16.5.1 Getting the SDMA Status

NOTE

Before executing any command that affects the SDMA (like dmov or exec_once), check that the SDMA is in debug mode.

Use the following snippet:

```
rstatus();        // read SDMA status until the SDMA is in debug mode
...
rstatus();
```

If the SDMA is not in debug mode, then a debug request must be generated. In this case, the SDMA enters debug mode at the end of the execution of the current instruction. Use this snippet:

```
debug_rqst(-);   // debug request
```

In the following sections, it is assumed that the SDMA was successfully put into debug mode.

66.16.5.2 Saving the Context

The first debug task is to save the SDMA context, which is the content of the eight general-purpose registers, the loop and PC-related registers, and the flags. Use the general register GReg[1] as an intermediate register to export the entire context of the SDMA.

The following example shows how to save GReg[0], GReg[1], GReg[2] and GReg[3]. The sequence of commands used to export additional general registers is very similar to this.

Save GReg[0], GReg[1], GReg[2], and GReg[3]

```
GReg1_data = dmov(-);                          // the value exported is the content of
GReg[1]
exec_once("mov GReg1,GReg0");                      // puts the content of GReg[0] into
GReg[1]
GReg0_data = dmov(-);                          // the value exported is the content of
GReg[0]
exec_once("mov GReg1, GReg2");                     // puts the content of GReg[2] into
GReg[1]
GReg2_data = dmov(-);                          // the value exported is the content of
GReg[2]
exec_once("mov GReg1, GReg3");                     // puts the content of GReg[3] into
GReg[1]
GReg3_data = dmov(-);                          // the value exported is the content of
GReg[3]
```
